KIDNEYWEEK 2012
San Diego, CA | Oct 30 - Nov 4

JASN Abstract Supplement

Abstract Publication
More than 4,600 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date*, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined. For the poster sessions, the publication numbers and poster board numbers are the same.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 23, 2012: Page(s).

For example: Sussman CR, Ward CJ, Leightner AC, Harris PC, Torres VE: Regulation of Renal Cyst Formation by Phophodiesterase 1A in Zebrafish [Abstract]. J Am Soc Nephrol 23, 2012: 1A.

Abstract Experts
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The *Onsite Program* lists all abstract experts.

Abstract Disclaimer and Copyright
The Abstract Issue of JASN® contains proprietary information belonging to the American Society of Nephrology (ASN). It is published as a service for the personal, noncommercial, and informational use only of its members and Kidney Week participants. Any commercial use is strictly prohibited. ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such material within Kidney Week and other ASN publications, or online postings does not constitute an endorsement by ASN.

ASN General Information

Kidney Week Program and Presentations
The Kidney Week 2012 program, which can be found in the *Onsite Program*, includes:

- Early Programs' content
- Plenary Sessions
- Basic and Clinical Science Symposia
- Clinical Nephrology Conferences
- Special Sessions
- Educational Symposia
- High-Profile Oral Abstract Sessions
- Oral Abstract Sessions
- Poster Sessions

Disclosure Statement
ASN requires all individuals in a position to control content for Kidney Week 2012 to complete a disclosure form. Responses are listed in the Kidney Week 2012 *Disclosure Digest*, which is available to each meeting participant.

Program Builder
All abstracts and the complete Kidney Week 2012 program are viewable online through the Program Builder at www.asn-online.org/KidneyWeek with features including keyword search and PDA download.

Support provided by Mitsubishi Tanabe Pharma.

Posters On-Demand™
Fully paid participants can access electronic versions of the Kidney Week 2012 posters at no additional cost. Search and locate posters easily by authors, categories, or keywords during and after the meeting. Posters can be accessed online at www.asn-online.org/KidneyWeek/PostersOnDemand.

Support provided by Amgen and Mitsubishi Tanabe Pharma.

TH-OR002

Regulation of Renal Cyst Formation by Phosphodiesterase 1A in Zebrafish

Caroline R. Sussman,[1] Christopher James Ward,[2] Amanda Christine Leightner,[3] Peter C. Harris,[2] Vicente E. Torres.[2] *[1]Physiology & BME, Mayo Clinic, Rochester, MN; [2]Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [3]Biochemistry & Molecular Biology, Mayo Clinic, Rochester, MN.*

Background: A large body of evidence indicates the importance of elevated cAMP in Polycystic Kidney Disease (PKD). Accumulation of cAMP in cystic tissues may in part be due to enhanced adenylyl cyclase activity, but inhibition of cAMP degradation by phosphodiesterases (PDE) likely plays an important role, as cAMP is inactivated faster than it is synthesized. PDE1 is the only PDE family activated by calcium, which is reduced in PKD cells.

Methods: To assess the contribution of the PDE1A subfamily to renal cyst formation, we examined the expression and function of PDE1A in zebrafish using RT-PCR and antisense morpholinos (MO), and effects of the PDE1 inhibitor, vinpocetine.

Results: We identified two splice isoforms with alternative starts corresponding to human PDE1A1 and PDE1A5. Each has 77% amino acid identity to its human ortholog overall, and 89% in the hydrolase domain. Two splice-blocking (SB) MO caused deletion of exon 7, at the beginning of the hydrolase domain, and increased the percent of embryos with renal cysts and/or tubule dilation (32%±12 (n=4) or 12%±5 (n=3) vs 1%±1, p≤0.002, t-test). One SB MO also caused phenotypes similar to PKD2 mutant zebrafish including hydrocephalus (79%±14 vs. 3%±2, p=3e-6, t-test, n=4) and curvature (44%±12 vs. 10%±5, p=0.004, t-test, n=4). A third MO targeting the start of the PDE1A1 isoform also increased the percent of embryos with renal cysts (42%±13 vs 3±2, p=0.01, t-test, n=4) and hydrocephalus (85%±8 vs 3%±3, p=0.001, t-test, n=4). Vinpocetine caused defects in glomerulus development visualized in a transgenic reporter fish, Tg(*wt1b*:EGFP). Vinpocetine additionally caused edema, dorsal curvature, and inhibited clearance of 10K MW rhodamine-dextran. Differences between vinpocetine and PDE1A MO may be due to inhibition of PDE1B and PDE1C, in addition to PDE1A, by vinpocetine.

Conclusions: Overall, data indicate that PDE1A has potent effects on kidney development and cyst formation, and are consistent with PDE1A function downstream of Polycystin 1/Polycystin 2.

Defective Glucose Metabolism in Polycystic Kidney Disease Identifies a Novel Therapeutic Paradigm

Isaline Rowe,[1] Marco Chiaravalli,[1] Valeria Manella,[1] Valeria Ulisse,[1] Monika Pema,[1] Xuewen Song,[2] Silvia Mari,[1] Giacomo Quilici,[1] York P. Pei,[2] Giovanna Musco,[1] Alessandra Boletta.[1] *[1]DTI-DIBIT San Raffaele, Milan, Italy; [2]University Health Network and University of Toronto, Toronto, Canada.*

Background: ADPKD is a common genetic disorder characterized by bilateral renal cyst formation. Identification of de-regulated cascades has led to the initiation of several clinical trials, but an effective therapy is still lacking. Using *Pkd1* knock-out cells we identified metabolic alterations in ADPKD that could be targeted for therapy.

Methods: We performed a metabolomic screening using NMR analysis followed by biochemical studies, microarrays and real-time analysis of the expression levels of the enzymes involved using cells as well as cystic tissues derived from either a PKD mouse model or human ADPKD kidneys.

Results: Metabolomic profiling of the extracellular medium of $Pkd1^{-/-}$ and $Pkd1^{+/+}$ MEFs indicated an increase in glucose uptake and lactate production in the mutant cells, suggesting an increased aerobic glycolysis.

Consistent with this, intracellular ATP concentration and glycolytic enzymes gene expression was enhanced in the mutant compared to the wt cells whereas the mitochondrial potential was unchanged. Notably, glucose deprivation reduced proliferation and sensitized *PKD1* mutant cells to apoptosis.

Next, we analysed glycolytic enzymes gene expression using microarray databases derived from *PKD1* human renal cysts and found that several genes encoding glycolytic enzymes were up-regulated. A similar upregulation of glycolytic enzymes and ATP content was found in the cystic kidneys of *a* $Pkd1^{flox/-}$*:Ksp-Cre* mouse model.

Notably, treatment of this mouse model with 2DG, an inhibitor of glycolysis, greatly reduced kidney weight and proliferation rates in the cystic epithelia. Importantly, 2DG also increases the number of non-cystic tubules. Finally, we show that these metabolic alterations depend on the ERK pathway acting by inhibiting the LKB1-AMPK axis and activating the mTORC1-glycolytic cascade.

Conclusions: Our data show that defective glucose metabolism is involved in ADPKD and provide the rationale for a novel therapeutic approach.

A BET Bromodomains Inhibitor Decreases Cystic Epithelial Cell Proliferation through Targeting c-Myc

Xia Zhou, Lucy X. Fan, Wei Liu, Xiaogang Li. *Department of Pediatrics and Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Overexpression of c-Myc is proposed to play an important role in the pathogenesis of polycystic kidney disease (PKD). The increased expression of c-Myc has been reported in all rodent models of PKD and human ADPKD, which makes c-Myc as a potential therapeutic target in ADPKD. JQ1, a selective small-molecular inhibitor of BET bromodomains (BRD), down-regulates c-Myc transcription through inhibition of BRD proteins. We hypothesized that targeting c-Myc with JQ1 might prevent/delay cyst formation.

Methods: To determine whether overexpression of c-Myc in renal cystic epithelial cells is induced by BRD proteins and test whether JQ1 prevents/delays renal cyst formation in ADPKD mouse model, we treated renal cystic epithelial cells and *Pkd1* conditional knockout mice with JQ1.

Results: We found that c-Myc mRNA and protein expression were upregulated in Pkd1 mutant mouse embryonic kidney epithelial (MEK) cells, postnatal *Pkd1* homozygous PN24 cells and kidney tissues from $Pkd1^{flox/flox}$:Ksp-cre mice compared to that in *Pkd1* wild type MEK cells, postnatal *Pkd1* heterozygous PH2 cells and *Pkd1* wild type kidneys respectively. We also found that BRD4 mRNA was increased in *Pkd1* postnatal homozygous PN24 cells compared to that in *Pkd1* postnatal heterozygous PH2 cells. Treatment with JQ1 1) decreased the levels of c-Myc mRNA and protein in a time-dependent manner in *Pkd1* mutant MEK cells and PN24 cells; 2) increased the expression of p21 mRNA and protein, which is transcriptionally down-regulated by the c-Myc; 3) decreased the phosphorylation of Rb in *Pkd1* mutant MEK cells; 4) decrease cystic epithelial cell proliferation indicated by inhibition of S phase entry with FACS analysis. These results suggested that JQ1 might inhibit renal cystic epithelia proliferation through BRD4-c-Myc- p21 pathway. Further, we found that JQ1 strikingly delayed cyst development in the kidneys from $Pkd1^{flox/flox}$:Ksp-cre mice.

Conclusions: In sum, JQ1 produces a potent antiproliferative effect through targeting c-Myc in renal cystic epithelia and delays renal cyst formation, which may function as a therapeutic strategy in ADPKD.

Novel Insights into the Development of Renal Fibrosis in ADPKD

Kandai Nozu,[1,2] William E. Sweeney,[1,2] Dorien J.M. Peters,[4] Ellis D. Avner.[1,2,3] *[1]Children's Research Institute, Children's Hospital of Wisconsin, Milwaukee, WI; [2]Pediatrics, Medical College of Wisconsin, Milwaukee, WI; [3]Physiology, Medical College of Wisconsin, Milwaukee, WI; [4]Human and Clinical Genetics, Leiden Medical Center, Leiden, Netherlands.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by two phases: 1) bilateral kidney enlargement; and 2) diffuse intraparenchymal fibrosis. The C57BL6/J-$Pkd1^{nl/nl}$ (Pkd1-W) is a novel orthologous mouse model of ADPKD which demonstrates both characteristic phases with cyst formation beginning in late gestation and fibrosis beginning at PN28. This model is ideal for studying the pathogenesis and potential therapeutic intervention of both phases. KD019, is a novel multi-kinase inhibitor effective in reducing cyst formation (In Press JASN 2012).

Methods: In this study we tested the hypothesis that KD019 retards ADPKD specific fibrosis. Cystic and control Pkd1-W mice received KD019 (30mg/kg;IP) or vehicle daily from PN-8 to PN 28. Evaluation included target analysis and changes in molecular and standard pathologic markers of fibrosis.

Results: KD019 decreased phosphorylation (activity) of all KD019 targets including ErbB1, ErbB2, c-Src and VEGFR2 (KDR). However, expression of TGF-β, TNF-α, and macrophage recruitment to interstitial areas showed no difference compared to controls. Despite decreasing cystic changes, KD019 therapy did not eliminate early stages of interstitial fibrosis.

Conclusions: These data suggest that in genetically-determined ADPKD, the fibrosis which leads to renal failure may be independent of the pathways that lead to cyst formation. The identification of a RTK-independent pathway of renal interstitial fibrosis in ADPKD may provide new insight into the development of interstitial fibrosis in a number of progressive renal diseases in which fibrosis and disease progression follow an acute insult despite elimination of the initial injury. In conclusion, we speculate that in ADPKD, the two phases of: 1) cyst formation and growth; and 2) renal fibrosis may be independent. If confirmed, treatment of human ADPKD in the future may require anti-fibrotic therapies in addition to therapies which reduce cyst formation.

A Novel PPARγ Agonist DJ5 Retards Cyst Growth and Preserves Kidney Function in a PKD1 Conditional Knock Out Mouse Model

Xueqi Wang,[1,2] Yang Liu,[2] Rudolf P. Wuthrich,[2] Andreas L. Serra,[2] Changlin Mei.[2] *[1]Kidney Institute of PLA, Department of Nephrology, Shanghai Changzheng Hospital, Second Military Medical University, Shanghai, China; [2]Institute of Physiology, University Zurich, Division of Nephrology, University Hospital Zurich, Zurich, Switzerland.*

Background: Several studies have shown that the TZD class of PPARγ agonists could reduce renal cystogenesis, retard the progression of kidney failure and prolong survival in animal models of ADPKD. However, treatment with TZDs was associated with fluid retention and heart failure. To overcome these side effects, we developed a novel non-TZD PPARγ agonist termed DJ5 which did not cause cardiac side effects in the Han:SPRD rat model of PKD, yet it significantly inhibited cyst epithelial cell proliferation and retarded cyst development in these rats.The purpose of the present study was to investigate the therapeutic effect of DJ5 in a mouse model which is orthologous to human ADPKD.

Methods: Tamoxifen (150 mg/kg/d) was given to nursing mothers of *Pkd1* knockout mice from P10 to P12. From P7-P21, DJ5 (100 mg/kg/day) was administered to the nursing mothers by gavage. After weaning, from P22-P35, DJ5 (100 mg/kg/day) was administered to the mice directly through gavage. At P36, 24-hr urine samples were collected and the kidneys were harvested.

Results: Compared with vehicle treated *Pkd1*$^{-/-}$mice, DJ5 treatment reduced the BUN for 80.5% (P=0.002), the the two-kidney/total body weight ratio for 43.8% (P=0.014) without causing body weight loss. cyst volume density for 30.5% (P=0.001). Ki-67 staining was decreased while TUNEL staining was increased in dilated tubular and cyst epithelial cells in DJ5 treated *Pkd1*$^{-/-}$ mice compared with the vehicle group.

Conclusions: The new PPARγ agonist DJ5 markedly delays the loss of renal function, retards cyst development, inhibits the dilated tubular epithelial cell proliferation, and increases apoptosis in cyst lining epithelial cells in *Pkd1*$^{-/-}$ mice. DJ5 might become a potential drug candidate to retard progressive renal failure in patients with ADPKD in the future. The mechanisms of the pathways which are influenced by DJ5 will be further investigated.

TH-OR007

Glucosidase II Activity Represents a Novel Urine Biomarker in the Detection Autosomal Dominant Polycystic Liver Disease (ADPLD) due to Mutations in *PRKCSH* Sorin V. Fedeles,[1] Xin Tian,[1] Rachel Gallagher,[1] Sohan Lal,[1] Ming Ma,[1] Vicente E. Torres,[2] Stefan Somlo.[1] *[1]Internal Medicine/Nephrology, Yale School of Medicine, New Haven, CT; [2]Internal Medicine/Nephrology, Mayo Clinic, Rochester, MN.*

Background: *PRKCSH* is one of the genes mutated in Autosomal Dominant Polycystic Liver Disease (ADPLD) and it encodes the non-catalytic β-subunit of the ER glucose-trimming enzyme glucosidase II (GII), involved in transmembrane/secreted glycoprotein processing. The GIIβ subunit contains an HDEL motif through which it retains the catalytic GIIα subunit in the ER. In the current study we set forth to test the effect of *Prkcsh* deletion on the activity of GIIα in the context of murine and human ADPLD.

Methods: We performed GII substrate cleavage assays using cell media from GIIβ knockout cells and urine samples from both mice with conditional inactivation of *Prkcsh* and ADPLD patients with heterozygous truncating mutations in *PRKCSH*.

Results: Removal of the HDEL motif in *GIIβ* resulted in increased GIIα activity in the media of transfected Cos7 cells (p<0.001). Additionally, media from GIIβ knockout cells displayed a 2-fold increase in GIIα activity (p=0.0021). Conditional inactivation of *Prkcsh* in the kidney resulted in a gene dosage dependent increase in urine GIIα activity in *Prkcsh*$^{fl/+}$*;KspCre* mice (*p<0.05) compared to control which was further exacerbated in homozygous mutant *Prkcsh*$^{fl/fl}$*;KspCre mice (***p<0.001)*. Between the two experimental groups, urine activity was higher in the *Prkcsh* homozygous vs. heterozygous mice (*p<0.05). As a control, *Sec63*$^{fl/+}$*;KspCre* and *Sec63*$^{fl/fl}$*;KspCre* mice (*Sec63* is the other known ADPLD gene acting in the same pathway with *Prkcsh*) did not differ in urine GIIα activity. Finally, GIIα activity was examined in the urine of 4 ADPLD patients with truncating *PRKCSH* mutations and found to be ~3 fold higher than control (p<0.001).

Conclusions: These data suggest that *in vivo,* GIIα is secreted in the urine in a dose dependent manner with reduction or absence of the ER retention motif present on the *PRKCSH* gene product, GIIβ. These findings suggest the utility of the GII urine assay as a diagnostic tool for ADPLD patients with mutations in *PRKCSH.*

TH-OR008

Immune Cell Derived C3a AND C5a Mediate Human Alloreactive T Cell Immunity Paolo Cravedi, Jeremy S. Leventhal, Parth R. Lakhani, Peter S. Heeger. *Department of Medicine, Mount Sinai School of Medicine, New York, NY.*

Background: Mouse studies previously showed immune cell derived C3a/C5a are costimulatory intermediaries required for T cell activation. Herein we tested whether these concepts apply to human alloreactive T cells.

Methods: Human DCs were matured from monocytes and naïve human CD45RA+CD45RO-CD4+ T cells were isolated from peripheral blood by magnetic beads/sorting. Experimental strategies included RT-PCR, flow cytometry with CFSE dilution, ELISA (C3a, C5a, IL-12), and siRNA transfection.

Results: Human DCs produced C3, factor B (fB), and C5 RNA. LPS upregulated C3 and fB (135.8±17.8 and 166.1±14.4 fold, respectively, p<0.05). No C3, fB or C5 RNA was detected in resting or anti-CD3/CD28 stimulated T cells. DCs and naïve CD4 T cells expressed C3aR and C5aR on their surfaces. CD4 cells proliferated in response allogeneic DCs, yielding C3a and C5a in culture supernatants (p<0.05 vs control), indicating alloreactions cause complement production/activation. C3aR- and/or C5aR-blockade (specific antagonists) reduced T cell proliferation (C3aR block: -28.2±25.8%, C5aR block: -60.1±41.5%; p<0.05). We tested effects of increasing local C3a/C5a by downregulating (siRNA) DC expression of decay accelerating factor (DAF), a surface protein that restrains complement activation. In MLRs, DAF deficient DCs produced more C3a/C5a (1.9±0.4/1.4±0.4 fold, respectively; p<0.05) and enhanced T cell proliferation (26.0±2.0% increase, p<0.05). The augmented responses were abrogated by C3aR- and/or C5aR blockade (p<0.05). When we stimulated naïve CD4+ T cells with anti-CD3±C3a we observed a 3.4±0.2 fold increase in proliferation (p<0.05) along with increased p-AKT, the latter biochemically linking C3aR/C5aR to known T cell signaling pathways. C3a/C5a also augmented IL-12p70 production by DCs without altering costimulatory molecule or class II HLA levels.

Conclusions: Our findings that DC-derived and locally produced C3a/C5a mediate human alloreactive T cell responses provide new mechanistic insight, and support the need for testing whether C3aR/C5aR can be exploited as targets for treating T cell mediated allograft rejection in humans.

TH-OR009

Critical Role of Notch Receptors in Alloimmunity Ciara N. Magee, Tetsunosuke Shimizu, Nader Najafian, Leonardo V. Riella. *Brigham & Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Notch receptor signaling is known to be crucial in cell development. More recently, Notch signaling has been found to play a key role in T cell activation and differentiation. Using both a genetic and antibody approach, we sought to investigate the role of Notch-1 and Notch-2 in transplantation.

Results: Using flox-cre technology, we first generated Notch1/2$^{flox/flox}$ CD4-Cre mice. We observed that N1N2DKO CD4$^+$ T cells proliferated 10-fold less than control CD4$^+$ T cells upon stimulation with irradiated allo-splenocytes *in vitro* (811±35 *vs* 9185±2360 cpm;p=0.0002), and, furthermore, produced significantly less inflammatory cytokines, as detected by Luminex (e.g. IL1β 3±0.07 *vs* 209±16;p<0.01).

We then investigated the effect of a novel, selective antibody against either Notch-1 (aNotch-1) or Notch-2 (aNotch-2) on allograft survival in a fully MHC mismatched (Balb/c→B6) transplant model. Mice treated with either aNotch-1 or aNotch-2 for 5 days had significantly prolonged graft survival compared to IgG-treated controls (MST 13 and 10 *vs* 7 days;p=0.0019 & 0.0023, respectively). Furthermore, the addition of aNotch-1 to a single dose of CTLA4-Ig synergistically prolonged graft survival from 30 to 66 days (p=0.002).

Using this model, we determined that use of aNotch-1 significantly inhibited CD4$^+$ and CD8$^+$ effector memory T cells, but not splenic CD4$^+$FoxP3$^+$ regulatory T cells (20.4±0.47 *vs* 19.8±1.2% controls;p=0.66). Further characterization of the thymus of aNotch-1 treated mice revealed interruption of the maturation of CD4$^-$CD8$^-$ double negative (DN) to double positive thymocytes at DN stage I (CD44$^+$CD25$^-$). Blockade of Notch1 also significantly affected lymphocyte function with a decrease in the frequency of cells secreting IFN-γ (250±40 *vs* 1014±7.9;p<0.0001) and Granzyme B (114±22 *vs* 390±10;p<0.0001), as well as a decrease in alloantibody production (IgG2>IgG1).

Conclusions: These data reveal an important role of Notch in T cell development and differentiation in alloimmunity. Selective targeting of Notch receptors may have the potential to modify the balance between effector and regulatory T cell subsets, a promising novel approach for immune modulation in transplantation.

TH-OR011

Different Effects of Calcineurin Inhibitor versus mTOR Inhibitor on the Proliferation, Activation and Differentiation of Human B Cells Giovanna La Monica,[1] Luting Xu,[1] Geetha Chalasani,[2] Lorenzo G. Gallon.[1] *[1]Nephrology/Medicine, Northwestern University Feinburg School of Medicine, Chicago, IL; [2]Renal-Electrolyte/Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: In organ transplantation, humoral immunity is increasingly recognized as an important factor in promoting transplant rejection. However, the direct effect of immunosuppressive drugs calcineurin inhibitor (Tacrolimus, TAC) and mTOR inhibitor (Sirolimus, SRL) on B cell proliferation, activation and differentiation is not well documented.

Methods: Purified human B cells from healthy volunteers were stimulated with two different protocols (BCR/CD40 and polyclonal TLR9/CpG) for 6 days. A variety of parameters of B cell activity including proliferation, activation, differentiation, and cytokine productions were monitored by flow cytometry.

Results: SRL at clinically relevant concentrations (e.g. 6 ng/ml) profoundly inhibited CD19+ B cell proliferation (up to ~2 folds) compared to controls whereas TAC at 6-10ng/ml had a minimal effect. SRL decreased total CD27+ memory B cells by 2-3 folds; however, this inhibition was on newly expressed CD27+ B cells but not from CD27+ memory B cells. SRL effectively blocked plasma cell differentiation (% of CD19+CD138+) even at low dose (e.g. 2ng/ml), and totally eliminated this cell population at over 6ng/ml (% of CD19+CD138+ and % of Blimp1+/Pax5(low) transcriptional factors). SRL-treated group decreased absolute B cell accounts, but maintained an activated phenotype (CD25+/CD69+) and increased expression of HLA-DR. Both SRL and TAC decreased % of CD24hiCD38hi Breg subset without affecting CD21hiCD23hi Breg subset. Finally, TAC was more effective than SRL in inhibiting inflammatory cytokine TNFalpha expression in B cells; however, both drugs had no effects on other cytokines tested, which include anti-inflammatory cytokines IL-10 and IL-35.

Conclusions: SRL strongly inhibits B cell responses when compared to TAC. These data can help to guide the use of SRL in humoral alloimmune responses in transplantation.

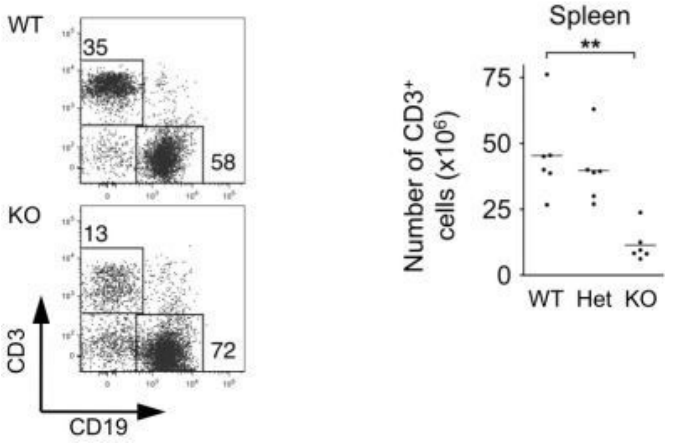
TH-OR012

Identification of microRNAs with Critical Roles in the Differentiation and Function of CD4+ T Helper Cells Kerem Atalar, Graham M. Lord. *MRC Centre for Transplantation, King's College London, London, United Kingdom.*

Background: CD4$^+$ T cells play a central role in allograft rejection. These cells may differentiate to multiple subtypes including T helper type 1 (Th1), Th2, Th17 and regulatory T cells, but the mechanisms that control differentiation are incompletely understood. It has also recently been recognised that interconversion between subsets is possible, but the pathways that regulate lineage stability and plasticity are poorly defined. microRNAs (miRNAs) are short non-coding RNAs that post-transcriptionally regulate gene expression, and T cells that are globally deficient in all miRNAs have been shown to exhibit abnormal development, survival and differentiation. However, current understanding of the specific miRNAs that are responsible for these defects is limited.

Methods: In order to identify candidate miRNAs of importance in CD4+ T helper cell differentiation and function we performed microarray profiling of miRNA expression in T cell subsets. These data have been analysed in combination with genome-wide master regulatory transcription factor binding data to select candidate miRNAs for functional investigation.

Results: We identified a single candidate miRNA for further study from microarray and binding data, and generated a mouse line that is deficient in this miRNA (KO). Analysis of these animals revealed dramatic defects in T cell homeostasis and survival *in vivo* compared with wild-type (WT). In addition, KO T cells exhibit default adoption of the Th1 phenotype following T cell receptor-mediated activation and impaired lineage stability.



Conclusions: The combination of miRNA microarray and ChIP data enabled the identification of a miRNA that is critically important for normal T cell function and homeostasis. We believe that these data have important implications for our understanding of T helper cell biology, and are therefore of relevance to clinical transplantation.

TH-OR013

Overexpression of MiR-126 in the Hematopoietic Compartment Protects against Renal Ischemia Reperfusion Injury Roel Bijkerk,[1,2] Coen van Solingen,[1,2] Pieter van der Pol,[1] Ellen Lievers,[1] Nicole Schlagwein,[1] Danielle Van Gijlswijk,[1] Annemarie Van Oeveren-rietdijk,[1,2] Hetty C. de Boer,[1,2] Antoine A.F. De Vries,[3] Cees van Kooten,[1] Frank Staal,[4] Ton J. Rabelink,[1,2] Anton Jan Van Zonneveld.[1,2] *[1]Nephrology, LUMC; [2]Einthoven Laboratory for Experimental Vascular Medicine, LUMC; [3]Cardiology, LUMC; [4]Immunohematology and Blood Transfusion, LUMC.*

Background: Hematopoietic stem/progenitor cells (HSPC) are known to promote kidney repair after ischemia/reperfusion injury (IRI). Stromal cell-derived factor-1 (SDF-1) has been described to provide protection against IRI and is thought to be an important mediator of mobilization of these HSPC to the site of injury. However, the exact mechanism of how SDF-1 protects against renal IRI remains under debate. We previously identified microRNA-126 (miR-126) to be able to modulate SDF-1 expression and subsequent mobilization of HSPC. Here we investigated the effect of overexpression of miR-126 in the hematopoietic compartment on IRI in the kidney.

Methods: Using a lentiviral construct we overexpressed miR-126 in lineage depleted bone marrow cells. Subsequently these cells were intravenously injected into lethally irradiated mice. Eight weeks after reconstitution of the bone marrow the mice underwent renal bilateral IRI. Mice were sacrificed 3 days after surgery.

Results: Blood urea levels were 40% reduced in mice that overexpressed miR-126 when compared with mice that were transplanted with mock-transduced cells. In addition, we found decreased levels of damage markers KIM-1 and NGAL. Q-PCR analyses of inflammatory cytokines showed a shift in the expression profile towards a protected state. We observed a 40% decrease in neutrophil influx as determined by Gr-1 staining. Surprisingly, we did not find a reduction in the number of CD45 positive cells or F4/80 positive cells. SDF-1 mRNA and protein levels were elevated and HSPC number was increased, suggesting a protective effect of miR-126 through SDF-1 in mobilization of HSPC.

Conclusions: Overexpression of miR-126 in the hematopoietic compartment protects against renal ischemia/reperfusion injury through a mechanism in which SDF-1 may play a central role.

TH-OR014

Multi-Photon Microscopy Based Kidney Live Imaging Identifies a Series of Micro-Circulation Changes in a Rat Acute Kidney Rejection Model Jun-Ya Kaimori,[1] Yoichi Kakuta,[4] Hidetoshi Tsuda,[1] Masaki Hatanaka,[2] Yoshitsugu Obi,[2] Hiromi Rakugi,[2] Masaru Ishii,[3] Shiro Takahara,[1] Yoshitaka Isaka.[2] *[1]ATT, Osaka Univ, Japan; [2]Geront & Neph, Osaka Univ; [3]Osaka Univ iFrec; [4]Urology, Osaka Univ.*

Background: Multi-photon microscopy based kidney live imaging enables us to see on-going phenomena in a living kidney, including microcirculation, and cell dynamics in the deep kidney tissue.

Methods: We constructed kidney live imaging system using an inverted multi-photon microscopy and special attachments for kidney live imaging, whose images were not affected by breathing or heart beating. We employed rat kidney syngeneic and allogeneic transplantation models, using GFP-expressing LEW rats as recipients and wild type LEW rats and wild type DA rats as donors, respectively, with contra-lateral native kidney spared. After 1-4 days post transplantation, graft kidneys were observed by this system and fluorescent dextrans.

Results: We observed more severe endothelial damages, vascular leakages and microcirculation defects in allogeneic kidneys than syngeneic. Administration of serum of allogeneic rat induced similar microcirculation defects in normal rat, suggesting that humoral factors in allogeneic animal serum were implicated in compromised microcirculation. Next we examined GFP-positive cells behavior in syngeneic or allogeneic transplanted kidneys, using GFP-expressing LEW rats as recipients. The time laps video images in allogeneic kidneys revealed that GFP-positive cells attached to and infiltrated between tubular cells. Surprisingly, almost GFP-positive infiltrating cells stayed in the same focal plane when they went across the lumen of tubules. In concordance with these images, cell tracking analysis using IMARIS software identified the decrease in mean velocity [50.4μm/min (syn) vs 22.2μm/min (allo), p<0.001] and confinement ratio [0.81 (syn) vs 0.73 (allo), p<0.001] of allogeneic kidneys, compared with syngeneic kidneys.

Conclusions: The multi photon microscopy based kidney live imaging system enables us to see the series of cortical microcirculation changes in an allograft kidney and will become one of powerful tools for renal transplantation researches.

Immunomodulation with a Selective Cytopheretic Device (SCD) Improves Myocardial Contractility and Renal Sodium Excretion in a Canine Model of Congestive Heart Failure David Humes,[1,2,3] D. Buffington,[1] Angela J. Westover,[1] Hani N. Sabbah.[4] *[1]Innovative BioTherapies, Inc.; [2]University of Michigan; [3]CytoPherx, Inc.; [4]Henry Ford Hospital.*

Background: Cardiorenal syndrome (CRS), the most severe subset of patients with CHF, is characterized by diuretic resistance in volume overload. Current therapy is limited and new innovative approaches are needed. CHF is characterized by a proinflammatory state. The cytokines, TNF-a and IL-6, inhibit mitochondrial respiration and depress cardiac contractility (CC). Monocytes and tissue macrophages are sources of systemic inflammation in CHF. Systemic monocyte levels correlate with poor outcome in CHF. The SCD, a novel biomimetic device, when placed in an extracorporeal circuit with regional citrate (c) anticoagulation has been shown to be an effective immunomodulatory device in acute multiorgan organ failure.

Methods: To evaluate the acute effects of the SCD in a canine model of CHF, three groups of animals were evaluated during 4 hours of treatment: SCD-C, SCD-Heparin (H), and a sham control (S-C), n=2-5 in each group.

Results: Left ventricle (LV) ejection fraction (EF) increased substantially in the SCD-C group from 34 ± 2.3 to 48 ± 3.7% while SCD-H and S-C (n= 2-5) did not change. This effect was not due to a decline in systemic vascular resistance (SVR) which was similar in all groups. Ventriculograms demonstrated the SCD-C to convert viable but non-contracting myocardium to better contracting myocardium. The renal effects were also substantive. The fractional excretion (FE) Na nearly doubled in the SCD-C compared to SCD-H increasing from 2.2 ± to 0.8 to 5.3 ± 0.8% and FE_{urea}went from 59 ± 3.1 to 81 ± 11.3%. No adverse events of arrhythmia or hypotension were observed during treatment. Isolated peripheral blood monocytes showed a decline in IL-6 and TNF-a secretion at end of treatment compared to baseline demonstrating a change in proinflammatory phenotype.

Conclusions: These results demonstrate that immunomodulation with the SCD improves left ventricular function and improves natriuresis. Removal of the cardio depressant effects of the chronic inflammatory state of CHF may be a new innovative approach to the management of CRS.

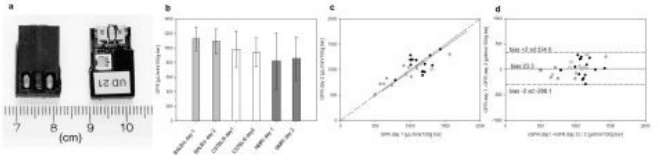
Reproducibility of Transcutaneous Measurement of Glomerular Filtration Rate in Conscious Mice Daniel Schock-kusch,[1] Esther Ermeling,[2] Yury Shulhevich,[1] Stefania Geraci,[1] Jürgen Werner Hesser,[1] Dzmitry Stsepankou,[1] Sabine Neudecker,[1] Stefan Koenig,[3] Tobias Michael Hoerr,[4] Johannes Pill,[5] Roland Schmitt,[2] Anette Melk.[2] *[1]Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany; [2]Hannover Medical School, Hannover, Germany; [3]Freudenberg Forschungsdienste KG, Weinheim, Germany; [4]Mektec Europe GmbH, Weinheim, Germany; [5]Mannheim Pharma & Diagnostics GmbH, Germany.*

Background: Recently developed approaches for the transcutaneous (TC) measurement of glomerular filtration rate (GFR) in lab animals allow GFR assessment without blood and/or urine sampling. Reproducability of measurements in the same animal is missing so far. Therefore, we investigated the reproducibility using our TC GFR assessment method in conscious mice.

Methods: Two TC GFR measurements were performed within three days in three mouse strains. In total 31 mice were examined (Balb/c n=15 (open circles); C57BL/6 n=10 (black circles); NMRI n=6 (grey diamonds). A miniaturized fluorescence detector (Fig.1a) allows the TC measurement of the elimination kinetics of the fluorescent GFR marker FITC-sinistrin. The device was fixed on the depilated back of the mice using an adhesive patch, before FITC-sinistrin (7.5 mg/100g) was injected.

Results: Results are depicted in fig.1.



Mean values of the two measurements show modest day to day variability in all three strains (b). Standard deviations do not reflect imprecision of the measurement but individual variations of GFR (c). Good agreement between both measurements is also reflected in the Bland Altman plot (d) with negligible bias and narrow 95% confidence interval. In total 100% of GFR values measured on day two are within the 30% range of day one, 80.6% are within 20% and 50.6% within 10%.

Conclusions: The data given let expect the TC method appropriate for GFR monitoring in conscious mice over a longer period of time.

TH-OR017

Hypertonicity Maintains a Differentiated Renal Epithelial Monolayer: A Promising Approach for Bioartificial Kidney Sa'ad Al-lahham, Ruud A. Bank. *Department of Pathology & Medical Biology, University Medical Centre Groningen, Groningen, Netherlands.*

Background: The development of a successful bioartificial kidney faces some challenges such as overgrowth and dedifferentiation of epithelia on synthetic membranes. It is known that renal medullary epithelial cells are exposed to hypertonic environment in vivo and it modulates the synthesis of the extracellular matrix proteins, therefore we aim to investigate the effect of hypertonicity treatment on the performance of epithelial cells.

Methods: Human epithelial cells were treated with regular (300 mOsm) and hypertonic media (400 and 500 mOsm). Hypertonic media was made by adding NaCl.

Results: We found that hypertonic media suppressed the mitochondrial activity, suggesting the suppression of the overgrowth of cells. Morphological evaluation revealed that hypertonic media maintained an intact epithelial monolayer, while isotonic medium treatment resulted in a disrupted layer of cells, where some cells looked like mesenchymal cells. On mRNA level, hypertonic media treatment significantly induced certain epithelial markers (e.g. E-cadherin, EPCAM and ZO-1) and renal transporters (e.g. OATP4C1 and MRP4), while it induced slightly N-cadherin and had no effect on α-SMA (mesenchymal markers). Hypertonic media treatment had no effect on the mRNA expression of COL4A1, LAMA1, LAMA5 and FN. Suggesting that hypertonic effect was not due to modulation of extracellular matrix genes.

Conclusions: Our results are promising for bioartificial kidney, since they suggest that hypertonicity inhibits the overgrowth of the cells and maintains an intact differentiated monolayer, which are some of the major obstacles that counteract the development of bioartificial kidney. In the future we will investigate the effect of hypertonicity on certain epithelial functions and the mechanism(s) behind that.

A Computational Drug Prediction Approach Identifies an Additive Renal-Protective Effect between an ACEI and a Histone Deacetylase Inhibitor Yifei Zhong,[1] Ruijie Liu,[2] Peter Y. Chuang,[2] John C. He.[2] *[1]Department of Nephrology, Longhua Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China; [2]Division of Nephrology, Department of Medicine, Mount Sinai School of Medicine, New York City, NY.*

Background: Because of the complexity of the kidney disease, investigators have attempted to develop the combination therapy with two drugs such as ACEI and ARBs. However, these combination therapies that target on one system (RAS) are not very successful.

Methods: The Connectivity Map (CMAP) dataset was created from over 6000 gene expression microarrays testing the effects of approximately 1300 individual drugs in several human cancer cell-lines. The CMAP web-site provides a querying tool for matching drug induced gene expression signatures with differentially expressed gene lists provided by users. Based on this, we have implemented a Java program called Drug Pair Seeker(DPS) that allows us to predict and prioritize pairs of drugs which are likely reverse or aggravate the gene expression state in a disease condition. We used this approach to analyze the microarray data obtained from the kidney of HIV-1 transgenic mice (Tg26), a model for HIV-associated nephropathy, compared to WT.

Results: We predicted that, among these 1300 drugs, the combination of an ACEI and a histone deacetylase inhibitor (HDACI) was able to reverse the maximal number of genes altered in the diseased kidney while causing the minimal number of genes to be further altered. Then, we experimentally validated in Tg26 mice that the combined therapy with both ACEI and HDACI provided an additive renal protection as suggested by reduction of proteinuria, improvement of renal function, and attenuation of kidney injury. We also validated experimentally the expression of selected genes, which are predicted to be reversed by the therapy, in kidneys of these mice. Finally, we explored potential signaling pathways affected by either ACEI or HDACI or both using combined computational and experimental approach.

Conclusions: In conclusion, our studies suggest that DPS tool could be used to predict the drug combination. ACEI combined with HDACI could be a potential new therapy for kidney disease.

Engineering of Vascularized Nephrons from Simple Suspensions of Single Embryonic Cells Christodoulos Xinaris,[1] Valentina Benedetti,[1] Paola Rizzo,[1] Mauro Abbate,[1] Daniela Corna,[1] Nadia Azzollini,[1] Mathieu Unbekandt,[2] Jamie Davies,[2] Marina Morigi,[1] Ariela Benigni,[1] Giuseppe Remuzzi.[1,3] *[1]Mario Negri Institute for Pharmacological Research, Bergamo, Italy; [2]University of Edinburgh, Scotland, United Kingdom; [3]Azienda Ospedaliera Ospedali Riuniti di Bergamo, Italy.*

Background: Paucity of organs for transplantation and cost of dialysis render the development of alternative therapeutics a vital task for regenerative nephrology. An engineering method of producing organoids similar to immature kidney from embryonic mouse cells has major potential applications (Unbekandt, Davies KI, 2010), but the avascular *in vitro* environment precluded efficient formation of glomeruli. Here, we combined this method with an *in vivo* approach to obtain vascularized glomeruli, key step toward functional tissue.

Methods: We dissociated enzymatically E11.5 embryonic mouse kidneys into single precursor cells, centrifuged the cell suspensions, and then cultured pellets (5 days) to yield cell-aggregates. We characterized the resulting organoids *in vitro*by IF analysis of renal markers and transplanted them beneath renal capsule of athymic rats to examine morphology and function.

Results: *In vitro* organoids showed typical phenotypes of developing nephrons. Pax-2 and NCAM were transiently expressed in a spatiotemporally specific manner. Podocytes were identified as cells devoid of Pax-2 and expressing WT-1 and synaptopodin. To examine whether the self-organising tissue sustained development *in vivo*, we first tested organoids by varying cell numbers and chose large cell-aggregation cultures (LCA, $4x10^5$ cells). Implanted LCA organoids showed imperfect glomerulogenesis. To stimulate vessel formation and glomerulogenesis, we applied combined pretreatment of LCA and local/systemic administration of VEGF. This protocol greatly improved vascularization of grafted LCA resulting in formation of filtering glomeruli, proximal tubules capable of protein reuptake, and EPO-producing cells.

Conclusions: These results provide a proof of principle that tissue-engineering protocols can be successfully applied to single embryonic kidney cells, to grow vascularized grafts for possible use in basic and translational studies.

Evaluation of Bioartificial Renal Epithelial Cell System (BRECS) Therapy in a Porcine Septic Shock-Associated Acute Kidney Injury (SSAKI) Model Angela J. Westover,[1] D. Buffington,[1] P. Smith,[1] K. Johnston,[1] C. Pino,[1] Charu Dewitt,[1] David Humes.[1,2,3] *[1]Innovative BioTherapies, Inc.; [2]University of Michigan Medical School; [3]Cytopherx, Inc.*

Background: Renal cell therapy incorporated into a CRRT circuit has shown therapeutic efficacy in renal failure in preclinical and clinical studies. To improve upon previously used hollow fiber based delivery platforms, and accommodate projected clinical need, an injection molded (IM), freezable BRECS has been developed. BRECS contain approximately 10^8 human renal epithelial cells, obtained from donor discards and grown using an established enhanced propagation (EP) method. EP cells are seeded onto trabeculated carbon disks and maintained within BRECS by continuous perfusion.

Methods: Hemofiltration, established in a SSAKI model, incorporates the BRECS into an ultrafiltrate (UF) loop, with processed UF returned to the animal allowing for maintenance of cell viability and communication between BRECS and host. Hemodynamic parameters including cardiac output (CO), hematocrit (HCT) and renal blood flow (RBF) were monitored through death, as assessed by a mean arterial pressure of less than 10, or up to 16 hours. Systemic inflammation was evaluated by neutrophil (NE) expression of CD11b and evaluation of NE extravasation into lung tissue. Cell viability was verified via in-line O_2 consumption.

Results: 6 IM-EP BRECS and 6 acellular sham treated SSAKI pigs were evaluated. A significant difference in survival time was seen between SSAKI pigs treated with IM-EP BRECS (13.7±1.1 hrs) vs. acellular sham (6.8±0.4 hrs). Of note, 3 of the 6 IM-EP BRECS treated SSAKI pigs survived the entire 16 hour study. Improvements in CO, HCT and RBF were observed with IM-EP BRECS vs. acellular sham treatment. Although significant differences in systemic cytokine levels were not observed, CD11b expression and NE extravasation into lung tissue decreased in the IM-EP BRECS vs. acellular sham group. O_2 consumption indicated cells in the BRECS remained viable for the entire study.

Conclusions: In this SSAKI model, IM-EP BRECS therapy was shown to improve hemodynamic parameters and decrease systemic inflammation, contributing to the increased survival time of the animal.

Development of Sequential Techniques to Correlate Hemodynamics with Subsequent Lumen Geometry Changes in Arteriovenous Fistula Christi M. Terry,[1] Yong He,[4] Yan-Ting E. Shiu,[1] Rupak Banerjee,[3] Prabir Roy-Chaudhury,[3] Scott A. Berceli,[4] Alfred K. Cheung.[1,2] *[1]Medicine, Univ of UT, Salt Lake City, UT; [2]Medicine, VASLCHCS, Salt Lake City, UT; [3]Medicine, U Cinci, Cincinatti, OH; [4]Surgery, Univ of FL, Gainesville, FL.*

Background: Arteriovenous fistulas (AVF) often fail to mature. To assess the influence of hemodynamics on AVF maturation, a sequence of techniques was developed that allows for the serial assessment of blood flow characteristics with later coincident changes in lumen geometry in human AVF.

Methods: Contrast-free black-blood MRI at 1 day, 6 weeks and 6 months after AVF creation yielded lumen geometry. Cine phase-contrast MRI provided volumetric blood flow rates at the inflow and outflow regions. Lumen geometry and flow rates were input for computational fluid dynamic modeling of the pulsatile velocity flow fields to calculate wall shear stress (WSS), WSS gradient, and oscillatory shear index. The hemodynamic parameters and later coincident lumen geometries were co-registered at 1-mm intervals using the anastomosis as an anatomical landmark.

Results: MRI scans required up to 1 hr and were well tolerated but patient body size was sometimes a limiting factor on scan acquisition. Oscillatory and disturbed blood flow within the AVF was typical and often persisted between the first and last scans. Outward lumen expansion was observed but was frequently of limited extent at the anastomoses. This suggests impaired wall distensibility perhaps due to factors unique to the anastomosis such as suture constriction and low-compliance scar formation due to surgical manipulation. Regions in proximity to vein valves also may be associated with restricted wall expansion.

Conclusions: Early findings suggest that AVF regions with unique vein wall characteristics such as the anastomosis and vein valves, have divergent biomechanical characteristics that may need to be considered in correlation analyses separate from other regions. This novel MRI-to-CFD pipeline sets the stage for in-depth serial assessment of AVF hemodynamics and lumen geometry over time. It will be used in a multicenter prospective study to identify critical hemodynamic factors that contribute to AVF maturation failure.

TH-OR022

24-h Intraocular Pressure Monitoring in Patients Undergoing Chronic Hemodialysis Vassilios Liakopoulos,[2] Evangelia S. Panagiotou,[1] Dimitrios Mikropoulos,[1] Theodoros Giannopoulos,[1] Paraskevi Demirtzi,[2] Eirini C. Voudouragkaki,[1] Eleni Paschalinou,[1] Vasileios Konidaris,[1] Olga Nikitidou,[2] Pavlos Nikolaidis,[2] Anastasios G.P. Konstas.[1] *[1]Glaucoma Unit, 1st University Department of Opthalmology, AHEPA Hospital, Thessaloniki, Greece; [2]Renal Unit, 1st University Department of Internal Medicine, AHEPA Hospital, Thessaloniki, Greece.*

Background: The effect of hemodialysis (HD) upon 24-hour IOP of subjects with normal intraocular pressure (IOP) has not been previously documented. The aim of this study was to document 24-hour IOP changes caused by HD and compare them with 24-hour IOP profile of the same subjects on a day without HD.

Methods: This was a prospective, observational, before-after 24-hour trial performed on consecutive subjects with normal IOP undergoing maintenance HD 3 days a week between 13:00-17:00 hours in an academic unit. Following a comprehensive ocular assessment those with conditions that may have influenced IOP were excluded. One eye was randomly selected and two 24-hour IOP curves were performed (HD day first). The IOP was measured at 10:00, 13:00, 15:00, 17:00, 22:00, 02:00 and 06:00 hours employing Goldmann and Perkins tonometry on habitual position. During the course of one year 23 HD patients were enrolled out of whom 18 patients completed the study.

Results: IOP monitoring on a HD day demonstrated a significantly higher mean 24-hour IOP (15.4±2.7 vs. 14.1±2.2 mm Hg; p=0.025), higher mean peak 24-hour IOP (18.5±3.5 vs. 15.8±2.5 mm Hg; p=0.003) and significantly wider 24-hour fluctuation of IOP (6.2±2.3 vs. 4.0±1.9 mm Hg; p=0.001). When individual timepoints were compared after a Bonferroni correction, IOP was significantly higher only at 17:00 on HD day reflecting gradual IOP elevation during HD (p=0.021). Further, the mean IOP curve evaluated during the HD procedure (13:00, 15:00 and 17:00) was significantly higher on a HD day (16.4±3.0 vs. 14.7±2.4 mm Hg; p=0.004).

Conclusions: This prospective, before-after trial suggests that HD significantly worsens 24-hour IOP characteristics in normotensive eyes. The long-term significance of these findings requires further elucidation with larger, long-term studies in normal and particularly in glaucoma patients undergoing HD.

TH-OR023

Microcirculatory Impairment during Haemodialysis Jean-christophe Szelag, Myriam Pastural, Carlos Cardozo, Alejandra Lenz, Ignace Mpio, Nouredine Boumendjel, Elias Abdullah, Walid Arkouche, Denis Fouque, Maurice Laville. *AURAL.*

Background: The incidence of peripheral arterial occlusive disease (PAOD) is higher in chronic haemodialysis (HD) patients and little is known about the specific effect of the dialysis session. We studied the impact of one single HD session on the microcirculatory function.

Methods: Fifty stable patients were enrolled in the study (mean age 67,4+/-14,6 years, diabetes 45%). Lower limbs were classified according Ankle Brachial Index (ABI) and Toe Brachial Index (TBI) (PAOD <0,9 and < 0,65, respectively). Microcirculation function was assessed using laser Doppler flowmetry (Toe pressure) and transcutaneous oxygen pressure (TcPO2) at the dorsum of the foot. Measurements were started after 20 minutes of rest in supine position, in the first thirty minutes and in the second part (mean: 165 minutes) of the HD session.

Results: PAOD could be suspected in 30 lower limbs using ABI, 69 legs using TBI. TcPO2 was significantly reduced along the dialysis session. The largest drop was observed in the PAOD population (34% reduction, 31,6 +/-15,6 to 20,8+/-15,8 mmHg, p=0,0001*)*. One third of PAOD legs reached the threshold of critical ischemia (<10 mmHg) in the second part of HD session*.* The reduction was either observed in non PAOD patients but remained above the threshold usually defining ischemia (>30mmHg) (16,9% reduction, 36+/-13 to 30+/-13,5 mmHg, p=0,04). The same fall pattern was observed by classifying the lower limbs with TBI (21% reduction) Toe pressure was significantly decreased in PAOD population (30 legs, 53,15+/-20,1 to 38,3+/-24 mmHg, p<0,0001) whereas no change was detected in patient with ABI>0,9 (76,4+/-34 to 71,6+/-34,18 mmHg, p=0,12, 65 legs). The only factors retained in multivariate analysis were: systemic blood pressure variation (TcPO2 and Toe pressure), diabetes (TcPO2 only) and PAOD (Toe pressure only).

Conclusions: Haemodialysis is associated with a significant impairment of lower limbs microcirculation. This phenomenon exacerbates the ischemia of PAOD patients but seems to exist despite the absence of severe macrocirculatory lesions. It is poorly explained by the classical haemodialysis associated factors, patient condition or drugs.

TH-OR024

Cardioprotective Profile of Intradialytic Changes in Arterial Stiffness with Hemodiafiltration Compared to Hemodialysis Albert J. Power,[1] Evangelia E.M. Charitaki,[2] Andrew Davenport.[2] *[1]Imperial Renal & Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom; [2]UCL Centre for Nephrology, Royal Free Hampstead NHS Trust, London, United Kingdom.*

Background: Intradialytic myocardial ischemia has been associated with adverse outcomes in hemodialysis [HD]. Although hemodiafiltration [HDF] confers better blood pressure stability compared to HD during treatment it is unclear whether these modalities affect vascular tone and cardiac perfusion differently and independently of ultrafiltration.

Methods: 231 maintenance dialysis patients [HD=121; HDF=110, 92% postdilution] were studied [mean age 62.1±16.6yrs, 48% diabetic]. There were no significant differences in age, gender, comorbidities, treatment time between groups. Pulse wave velocity [PWV], aortic augmentation index [AAix], central aortic systolic blood pressure [SBPAo] were measured just before dialysis, at 20 minutes and at the end of treatment [T2] using the Arteriograph device. The diastolic reflection area [DRA], a measure of coronary perfusion was derived from available data.

Results: There were no significant changes in PWV at all time points in both groups. Compared to baseline there were significant reductions in AAix at 20 mins in the HDF group alone [median -5.3%, p<0.001] associated with greater reductions in SBPAo compared to HD [13±2 vs 7±2mmHg, p=0.02]. Significant increases in DRA occurred in both groups at 20 mins [p<0.01] without significant differences in magnitude by modality [p=0.09]. By the end of dialysis and despite similar ultrafiltration [UF] volumes [2.1±0.8 vs 2.0±0.9, p=0.5] the HDF group manifested greater reductions in SBPAo [12±3 vs 23±3mmHg, p=0.007] but had 90% greater increase in DRA compared to HD [p=0.03].

Conclusions: These findings suggest that despite more pronounced early reductions in central aortic systolic blood pressure, HDF facilitates progressive increases in coronary perfusion that may be cardioprotective in the long term.

TH-OR025

Changes in Vascular Tone Occur Early in Hemodialysis Independently of Volume Reduction Albert J. Power,[1] Evangelia E.M. Charitaki,[2] Andrew Davenport.[2] *[1]Imperial Renal & Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom; [2]UCL Centre for Nephrology, Royal Free Hampstead NHS Trust, London, United Kingdom.*

Background: Cardiovascular disease is the leading cause of death in hemodialysis [HD] patients in the US. Ultrafiltration [UF] leading to intradialytic myocardial ischemia ("stunning") has been proposed as a significant treatment-related mechanism. Whether this is due to intravascular volume depletion or changes in vascular tone during HD remains unclear. We investigated changes in arterial tone shortly after the start of dialysis.

Methods: Arterial stiffness was measured using a brachial oscillometric device [Arteriograph] just prior to HD [T0], 20 minutes in [T1] and at the end of treatment [T2] in 121 stable maintenance HD patients [mean age 60.7±17.5yrs, 59% male, 50% diabetic, 31% with diagnosed ischemic heart disease] over one dialysis session. Variables of interest were aortic pulse wave velocity [PWV] & augmentation index [Aix], aortic systolic blood pressure [SBPAo] and diastolic reflection area [DRA], a measure of coronary perfusion. HD was performed using high-flux polysulfone membranes [Elisio] with mean session length 3.9±0.4hrs, UF volume 2.1±0.8 liters, predialysis BP 145±26/77±15mm.

Results: HD led to early significant reductions in SBPAo [p<0.001] with reciprocal increases in DRA [p=0.009] but no significant change in PWV [p=0.1]. This was associated with significant changes in brachial but not aortic Aix [p=0.02 & 0.2 respectively].

	T0	T1	T2
PWV [m/sec]	9.5±2.1	9.3±1.9	9.7±2.3
Aortic Aix [%]	37.7±17.6	35.1±17.3	30.7±19.1
Brachial Aix [%]	0.68±34.5	-4.94±34.1	-33.3±37.6
SBPAo [mmHg]	152±31	145±31	140±36
DRA	40.9±16.6	45.2±18.8	45.9±19.8

Overall HD reduced SBPAo [p<0.001] and Aix [p=0.001] but no significant change in PWV compared to baseline [p=0.2]. Significant changes to the DRA were restricted to the first 20 minutes of HD.

Conclusions: This suggests that early reductions in vascular tone in HD occur before clinically significant UF. A sustained increase in DRA does not match progressive reductions in SBPAo that are seen and which could lead to relative coronary hypoperfusion mediating cardiac dysfunction during HD.

TH-OR026

The Effects of Limiting Maximum Ultrafiltration Rate in an In-Center Hemodialysis Population James L. Pirkle,[1] Amret T. Hawfield,[1] Gregory B. Russell,[2] John M. Burkart.[1] *[1]Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; [2]Department of Biostatistics, Wake Forest School of Medicine.*

Background: Both intradialytic hypotension and high ultrafiltration (UF) rates are independently associated with cardiac morbidity and mortality. An analysis of the HEMO study showed that UF rates higher than 13 ml/kg/h were associated with an increased risk of all-cause and CV mortality. The effects of limiting maximum UF rates are unknown.

Methods: We compared treatment patterns, BPs, and weights in 123 patients in one urban based ICHD unit during the 8 week periods before (pre-policy) and after (post-policy) implementation of a policy limiting UF rates to a maximum of 13 ml/kg/h. Treatment times were extended and/or extra treatments were offered when necessary to achieve target weights (TW).

Results: Pre-policy, 57 patients (46.3%) had >3 treatments with high UF rates (>13 ml/kg/h). The highest quartile of weight gainers (n=31) had an average interdialytic weight gain (IDWG) ≥ 4% of TW. Post-policy implementation, patients who had signed off treatments early (n=21, 17.0%) increased time on dialysis by 8 minutes per treatment (+/-16, p=0.03); treatment times were extended in 62 (2.2%) of 2779 treatments; and 13 patients (10.5%) returned for a total of 28 extra treatments. Post-policy, TWs and pre-dialysis weights for the entire cohort did not change and IDWG decreased -0.3 kg (+/-1.1, p=0.001). Pre-dialysis BPs decreased: systolic -13.9 mmHg (+/-15.0, p<0.0001), diastolic -6.6 mmHg (+/-8.3, p<0.0001); as did post-dialysis BPs. Lowest BPs during dialysis were higher: systolic +1.3 mmHg (+/-8.5 p=0.096), diastolic +1.8 mmHg (+/-5.5, p=0.0006). For the highest quartile of IDWG, the decrease in IDWG was the most pronounced: -1.1 kg (+/-1.7, p=0.0007) as was the increase in lowest dialysis BP: systolic +4.0 mmHg (+/-8.2, p=0.011), diastolic +2.5 mmHg (+/-6.1, p=0.027).

Conclusions: A policy limiting maximum UF rates in an urban ICHD unit resulted in minimal changes in treatment patterns of extended dialysis times and extra treatments. Instead, patients responded to the policy with behavioral changes by reducing IDWG. All BP parameters improved with the policy.

TH-OR027

Consequences of Changing Trends in Buffer Content of Acid Concentrate B. Horowitz, O. Myers, S. Paine, A. Harford, A. Gul, P. Zager. *UNM.*

Background: Many dialysis providers have begun using acid concentrates with increased alkaline buffer. Manufacturers and FDA have cautioned providers about potential increases in serum bicarbonate and related health risks. K/DOQI guidelines recommend pre-dialysis serum bicarbonate 22 mmol/L with no upper limit. This study explores the hypothesis that pre-dialysis serum bicarbonate levels have increased over time and are associated with increased all-casue mortality.

Methods: We conducted a cross-sectional study of pre-dialysis serum bicarbonate in hemodialysis (HD) patients (n=33912) treated in facilities operated by DCI from 2007 to 2012. We computed the percentage of serum bicarbonate values that fell into a given range.

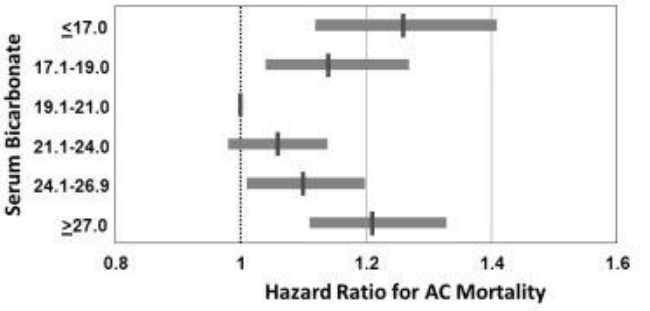
We constructed a Cox model to compute the hazard ratios (HR) for all-cause mortality associated with each category of pre-dialysis serum bicarbonate. We studied incident patients (n=15,774), age >18 years, who began HD between Jan 2004 and June 2011. Median follow-up was 18 months. We adjusted for baseline demographics (race/ethnicity, sex, age, cause ESRD, vintage, and vascular access) and standard time-dependent covariates (albumin, creatinine, potassium (K), hemoglobin, Kt/V, and clinic SMR.

Results: The distributions of serum bicarbonate in 2007 and 2012 are shown. Values >27 mEq/L increased from 10% to 16.7% and the percentage ≤17 decreased from 8% to 4%.

Serum Bicarbonate in 2007 & 2012.

Year	≤17	17.1-19	19-21	21-24	24-27	>27
2007	8	13	21	34	19	10
2012	4	8	16	36	26	17

A Forest plot depicting the hazard ratios for each serum bicarbonate category is shown. There was not a significant K x bicarbonate interaction (P=0.81) and the results were not significantly altered by removing K from the model.



Conclusions: Since 2007, the serum bicarbonate have increased. Serum bicarbonate >27 mEq/L and ≤17 mEq/L were associated with increased mortality. This association was not modified by serum K.

TH-OR028

The Effect of Using Ultrapure Water for Hemodialysis on the Circulating Bacterial Fragment and Vascular Stiffness Chi-bon Leung, Cheuk-Chun Szeto, Bonnie Kwan, Kai Ming Chow, Philip K.T. Li. *Department of Medicine and Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.*

Background: Cardiovascular disease (CVD) is the major cause of mortality and morbidity in dialysis patients. Recently, circulating endotoxin is found to associate with the systemic inflammatory state and CVD of dialysis patients. Previous studies showed that the use of ultrapure dialysate for hemodialysis could reduce the exposure to exogenous endotoxin. We studied the effect of using ultrapure water for hemodialysis on circulating endotoxin and bacterial DNA fragment levels and vascular stiffness.

Methods: This is an open-labelled prospective study of 25 patients (14 male). Circulating endotoxin and bacterial DNA level, vascular stiffness as represented by arterial pulse wave velocity (PWV), nutrition and hydration status were monitored before and repeatedly with 12 months after the use of ultrapure dialysate for hemodialysis.

Results: The average age was 58.9 ± 10.2 years; 21 patients completed the study. Within 4 weeks of conversion to ultrapure water for hemodialysis, plasma endotoxin level fell from 0.302 ± 0.083 to 0.209 ± 0.044 EU/ml ($p < 0.0001$) and then remained static, while serum bacterial DNA level remained similar. Furthermore, the time-averaged plasma endotoxin level during the study period significantly correlated with the carotid-femoral PWV ($r = 0.455$, $p = 0.033$), malnutrition inflammation score (MIS) ($r = 0.461$, $p = 0.031$), and inversely with lean tissue mass ($r = -0.571$, $p = 0.006$). The time-averaged serum bacterial DNA level significantly correlated with the subjective global assessment score ($r = -0.543$, $p = 0.009$), and inversely with MIS ($r = 0.550$, $p = 0.008$), but not with PWV.

Conclusions: Using ultrapure water for hemodialysis effectively reduces circulating endotoxin in hemodialysis patients, which is associated with less severe vascular stiffness and systemic inflammation. The causal relationship of this change and the long term benefit of using ultrapure water require further study.

Recurrent Acute Kidney Injury: Prevalence and Outcomes Areef Ishani,[1,2] Bipin R. Bista,[3] Craig Solid.[1] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Minneapolis VAMC, Minneapolis, MN; [3]University of MN, Minneapolis, MN.*

Background: Outcomes after an acute kidney injury (AKI) episode are poor. It is unknown what percentage of patients with an AKI episode are re-hospitalized within one year for a recurrent AKI, and if the rate of recurrence varies by race or age.

Methods: Using the General Medicare 5% Random Sample, we identified patients aged 65+ who had an inpatient (IP) hospitalization for AKI during 2009, and then followed them for 1 year to look for recurrent AKI. The percent with a recurrence was calculated by age and race group. Outcomes following the recurrent-AKI were identified using Medicare claims.

Results: We identified 28,389 patients with an index AKI event in 2009, 648 of whom required dialysis during the AKI hospitalization. A total of 28% of all AKI patients and 33% of AKI-dialysis patient experienced a recurrent AKI within 1 year. While rates were consistent across age groups, African-Americans experienced recurrent AKI at a higher rate (34% of all, 49% of AKI-dialysis), compared to Whites (27% of all, 30% of AKI-dialysis).

Percent with a Recurrent AKI

	Original AKI: All (N=28,389)		Original AKI: with dialysis (N=648)	
	N	%	N	%
Recurrent AKI				
All	7990	28.1	216	33.3
Age 66-69	980	28.1	127	33.1
Age 70-74	1398	28.9	152	31.6
Age 75-79	1595	28.0	151	36.4
Age 80-84	1757	28.7	128	32.8
Age 85+	2260	27.4	90	32.2
White	6370	27.0	156	29.7
African American	1188	34.3	43	49.4
Other/Unk	432	32.1	17	48.6

Conclusions: Recurrent AKI within one year of an initial AKI hospitalization is common, occurring in about 30% of patients. Patients requiring dialysis during their index AKI have higher recurrence rates. African Americans appear to have a greater risk of AKI recurrence compared to white patients.

Electronic Alerting for Acute Kidney Injury Edward Stern,[1] Rebecca Edwards,[1] Mark Harber,[1] Chris Laing,[2] Anne B. Dawnay.[2] *[1]Departments of Nephrology and Clinical Biochemistry, Whittington Health, London, United Kingdom; [2]Departments of Nephrology and Clinical Biochemistry, University College London Hospital, London, United Kingdom.*

Background: Acute kidney Injury (AKI) is associated with greatly increased risk of in-hospital death. Avoidable delay in identification contributes to mortality in a large proportion of these deaths (43% in a UK survey). We piloted electronic alerting for AKI in two hospitals in North Central London as an aid to early identification and response.

Methods: We designed an automated rule for the hospitals' electronic pathology systems to identify patients whose creatinine rose by ≥50% within 90 days. In response, an electronic alert was posted on the pathology report for clinicians, identifying the patient as having AKI and providing a link to the London AKI Network website, which gives relevant clinical guidelines. The biochemistry team used their discretion to subsequently telephone requesting clinicians.

Results: We collected data in Whittington Health for the first 100 adult patients identified by alert (86 inpatients, 7 hospital outpatients and 7 community general practitioner patients). Mean delta creatinine was 1.27 mg/dL (130%). Mean time from baseline to alert creatinine was 27 days. Divided by KDIGO stage: 56 patients had AKI 1, 29 had AKI 2, 15 had AKI 3. 15 patients died within the six-week period (five AKI 1, eight AKI 2, two AKI 3) compared with 1.7% overall mortality for Whittington inpatients.

Conclusions: This automated rule identifies a heterogeneous group: alert creatinines ranged from 0.49 to 11.02 mg/dL. Nevertheless, 24-hour electronic alerting was simple to implement and facilitated early identification of patients with unmet clinical need. In particular, post-op AKI was identified and managed early and we identified a number of unexpected AKI cases among samples sent by community GPs. Our data helped to raise awareness of the high mortality associated with even moderate rises in creatinine. Despite some limitations, this has proved to be a powerful tool in mobilising a response to AKI. We are now introducing the alerting system across five hospitals in North Central London as part of a standardised regional approach to the management of AKI.

TH-OR031

Association of Kidney Biomarkers with Progression of Acute Kidney Injury and Mortality in Patients with Cirrhosis Justin Miles Belcher,[1] Guadalupe Garcia-Tsao,[2] Arun Sanyal,[3] Chirag R. Parikh.[1] *[1]Section of Nephrology, Yale University School of Medicine, New Haven, CT; [2]Section of Digestive Diseases, Yale University School of Medicine, New Haven, CT; [3]Division of Gastroenterology, Virginia Commonwealth University School of Medicine, Richmond, VA.*

Background: Acute kidney injury (AKI) is common in patients with cirrhosis and is independently associated with mortality. We have conducted the first prospective study evaluating the utility of urinary biomarkers of kidney injury and tubular function for the prediction of AKI progression and mortality in patients with cirrhosis.

Methods: Patients with cirrhosis and AKI were identified via hospital-wide screening at four academic centers. AKI was defined via AKIN criteria based on documented outpatient baseline creatinine values. Structural; urinary NGAL, IL-18, KIM-1, L-FABP and albumin, and functional; urinary sodium and FENa, biomarkers were evaluated for association with a composite outcome of AKI progression or mortality. Patients were stratified via IAC criteria into non-HRS (n=159) and HRS (n=26) for analysis.

Results: For non-HRS patients, median injury biomarker values were significantly higher and sodium lower in those who had progressive AKI or death. NGAL, IL-18, L-FABP, and albumin were independently associated with the primary outcome. Remarkably, in patients with HRS, median NGAL, urinary sodium and FENa were lower in patients with the primary outcome.

Figure 1. Association of Biomarkers with the Primary Outcome in non-HRS Patients

Urine Biomarker* (Log transformed)	AKIN Progression or Death	
	Unadjusted RR (95% CI)	Adjusted RR (95% CI)**
Tubular injury markers		
NGAL (ng/ml)	1.71 (1.42-2.07)	1.34 (1.05-1.71)
IL-18 (pg/ml)	1.63 (1.30-2.04)	1.29 (1.01-1.64)
KIM-1 (ng/ml)	1.39 (1.07-1.80)	1.18 (0.93-1.48)
L-FABP (ng/ml)	1.51 (1.27-1.79)	1.33 (1.11-1.60)
Tubular function markers		
Sodium (mmol/L)	0.67 (0.48-0.93)	0.79 (0.56-1.13)
FENa (%)	1.02 (0.77-1.34)	0.98 (0.73-1.31)
Glomerular injury marker		
Albumin (mg/dL)	1.48 (1.21-1.81)	1.41 (1.14-1.74)

*Variables are $\log_{10}$ transformed and RR are per log-unit change
**Adjusted for CKD stage + demographics (race, age, and sex) + MELD score + Serum Sodium

Conclusions: Both structural and functional biomarkers of kidney injury are independently associated with progression of AKI and mortality in patients with cirrhosis. In patients without HRS, an elevation in injury markers was seen in those with worse outcomes. In patients meeting criteria for HRS, this typical association was inverted and those with less tubular injury and evidence of more intact tubular function actually fared worse.

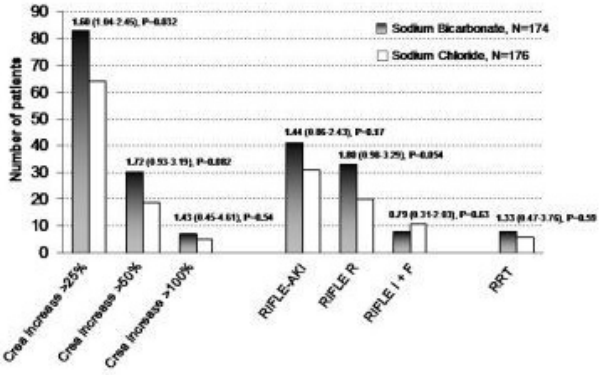
Sodium Bicarbonate and Renal Function after Cardiac Surgery: Results of a Multicenter Double-Blind Randomized Controlled Trial Michael Haase,[1] Anja Haase-Fielitz,[1] Michael Plass,[2] Patrick T. Murray,[3] Michael J. Bailey,[4] Rinaldo Bellomo,[5] Sean M. Bagshaw.[6] *[1]Nephrology, Otto von-Guericke-University, Magdeburg, Germany; [2]Anesthesiology, German Heart Center, Berlin, Germany; [3]Mater Misericordiae Hospital, University College, Dublin, Ireland; [4]ANZIC, Monash University, Melbourne, Australia; [5]Intensive Care, Austin Health, Melbourne, Australia; [6]Intensive Care, University of Alberta, Canada.*

Background: Preliminary evidence suggests a potentially beneficial reno-protective effect of urinary alkalinization in patients at risk of acute kidney injury (AKI). We tested whether perioperative sodium bicarbonate infusion can prevent postoperative AKI.

Methods: In a multicenter, double-blind, randomized controlled trial we enrolled 350 cardiac surgical patients to receive either 24hrs of iv. infusion of sodium bicarbonate (5mmol/kg) or sodium chloride (5mmol/kg). The primary endpoint was the proportion of patients developing AKI defined as creatinine increase >25% or >0.5 mg/dL of baseline within the first 5 postop. days. Secondary renal outcomes included RIFLE-AKI and renal replacement therapy (RRT).

Results: Patient groups were similar in demographics, comorbidities and cardiac procedures performed. Sodium bicarbonate increased plasma bicarbonate concentration (P<0.001) and urine pH (P<0.001) compared to control. More patients in the bicarbonate group (47.7%, 83/174) developed the primary endpoint compared to control (36.4%, 64/176) (OR 1.60 [95%CI, 1.04-2.45]; unadjusted P=0.032). Multivariate adjustment, adjustment of peak creatinine to corresp. fluid-balance, testing for RIFLE-AKI or RRT revealed no significant group differences. There were no significant side effects.



Conclusions: Sodium bicarbonate, although safe, was not associated with a lower incidence of AKI in cardiac surgical patients. The findings of this study do not justify further investigation. (NCT00672334).

TH-OR033

Usefulness of Renal Ultrasound in the Evaluation of Hospitalized Patients with Acute Kidney Injury Dipal Patel, Kavitha Ganta, Vidyasagar Reddy Cirra, Andres Serrano. *Mount Sinai Hospital, Chicago, IL.*

Background: Renal Ultrasound (RUS) is routinely ordered in the evaluation of hospitalized patients with Acute Kidney Injury (AKI). The main purpose of the test is to identify obstructive uropathy (UO). We evaluated the usefulness of RUS as a routine test.

Methods: We conducted a retrospective review of all hospitalized patients who underwent renal ultrasound at our institution from January 2005 to June 2011. Among the patients who underwent this test, we selected patients who had AKI (AKIN definition). Patients younger than 18 years-old, pregnant women, and patients with history of kidney transplantation were excluded. Clinical history at the time of presentation, patient demographics (age, sex, and race), serum creatinine, and prostatic specific antigen (PSA) - if available, were collected. Adittionally, the presence of the following medical problems, which are known to cause OU, were identified from the patients past medical history: benign prostatic hypertrophy, abdominal or pelvic surgery, pelvic malignancy, and nephrolithiasis. Patients who had a positive RUS, defined by the presence of bilateral hydronephrosis, were compared against patients who had a negative RUS, trying to find parameters, which will help identify patients with a higher likelihood of having a positive RUS.

Results: 5010 patients underwent RUS during the defined period. Of these, 1121 met inclusion criteria. In this group, the mean age was 62 year-old, 53.8% were male, and the majority of patients were AA (73.5%). 62 (5.5%) patients had a positive RUS. Among the patients with a positive RUS, 43 (69%) were male, and mean age was 65 year-old.

Interestingly, only 28 of the 62 (45%) patients presented with symptoms of urinary retention. The majority of patients, 47 or 76%, had risk factors known to cause OU. Elevated PSA, male gender, and having one or more of the defined medical problems in their history, were significantly associated with a positive RUS.

Conclusions: The incidence of OU is very low to justify the routine use of RUS in the evaluation of hospitalized patients with AKI. We suggest that RUS should be performed in patients who have, based on history, a higher likelihood of OU.

TH-OR034

The Relationship between Intraoperative Mean Arterial Pressure and Acute Kidney Injury after Noncardiac Surgery Michael Walsh,[1] Amit X. Garg,[2] Philip J. Devereaux,[1] Daniel Sessler.[3] *[1]McMaster University; [2]Western University; [3]Cleveland Clinic.*

Background: Worldwide over 200 million patients undergo noncardiac surgery annually and are at risk of acute kidney injury (AKI). Intraoperative hypotension may contribute to AKI however, there is little empiric data to inform anesthetists safe intraoperative blood pressures targets. We studied the relationship between intraoperative mean arterial pressure (MAP) and the risk of acute kidney injury.

Methods: We obtained preoperative characteristics, perioperative variables and postoperative laboratory data for 33,330 noncardiac surgeries that occcurred between January 2005 and September 2010 at the Cleveland Clinic in Ohio, USA. We first evaluated whether there was an association between the time spent at a MAP of <55, 55 to 59, 60 to 64, 65 to 69, and 70 to 74 mmHg and the outcomes of AKI (defined as at least a 1.5-fold rise in serum creatinine within 7 days of surgery) to determine at which MAP risk is increased. We then evaluated the independent risk associated with 1 to 5, 6 to 10, 11 to 20 and >20 minutes below the MAP at which risk increased for AKI and myocardial injury by adjusting for potential confounding variables.

Results: AKI developed in 2478 (7.4%) surgeries. The risk of AKI increased only at MAPs below 55 mmHg and was increased at even 1 to 5 minutes with a MAP <55 mmHg. Compared to never developing a MAP <55 mmHg, those with a MAP < 55 mmHg for 1 to 5, 6 to 10, 11 to 20 and >20 minutes the risk of AKI was 1.18 (95% confidence interval [CI] 1.06 to 1.31), 1.19 (95% CI 1.03 to 1.39), 1.32 (95% CI 1.11 to 1.56) and 1.51 (95% CI 1.24 to 1.84).

Conclusions: A MAP below 55 mmHg is associated with AKI even at very short durations. Further research is required to determine if interventions to keep the MAP >55 mmHg during surgery will improve clinical outcomes.

TH-OR035

Statin Toxicity from Macrolide Antibiotic Co-Prescription: A Population Based Study of Older Adults Amit Patel, Salimah Z. Shariff, David G. Bailey, Sonja Gandhi, David N. Juurlink, Jamie L. Fleet, Tara Gomes, Y. Joseph Hwang, Amit X. Garg. *Institute for Clinical Evaluative Sciences, ON, Canada.*

Background: HMG-CoA reductase inhibitors ("statins") are among the most commonly prescribed medications. Clarithromycin and erythromycin inhibit cytochrome P450 (CYP) 3A4, increasing blood levels of statins metabolized by CYP3A4. The clinical consequences of this drug-drug interaction at the population level are unknown.

Methods: We studied a population-based cohort of older atorvastatin, simvastatin, or lovastatin users in Ontario, Canada who were co-prescribed either clarithromycin or erythromycin between 2003 and 2010. The mean age was 74 years. All outcomes were assessed in the 30 days following a new prescription for these macrolide antibiotics. The primary outcome was hospital admission with rhabdomyolysis. Secondary outcomes included hospital admission with acute kidney injury and all-cause mortality. The comparison group was statin users co-prescribed azithromycin, a related antibiotic that does not inhibit CYP3A4 and does not increase statin blood levels. Risks were expressed in both relative and absolute terms.

Results: Co-prescribing clarithromycin or erythromycin (75,858 patients), or azithromycin (68,479 patients) with a CYP3A4 metabolized statin was common. A co-prescription for clarithromycin or erythromycin was associated with a higher risk of hospital admission with rhabdomyolysis (relative risk (RR) 2.17 (95% confidence interval (CI) 1.04 to 4.53)), acute kidney injury (RR 1.78 (95% CI 1.49 to 2.14)), and a higher risk of all-cause mortality (RR 1.56 (95% CI 1.36 to 1.80)). Results were consistent in adjusted analyses and in a subpopulation with laboratory measurements. When risk was expressed in absolute terms, a co-prescription for clarithromycin or erythromycin was associated with a 1.26% (95% CI 0.58 to 1.95) higher incidence of hospital admission with acute kidney injury and a 0.25% (95% CI 0.17 to 0.33%) higher incidence of all-cause mortality.

Conclusions: In older adults co-prescription of clarithromycin or erythromycin with a CYP3A4 metabolized statin increases the risk of serious statin toxicity and the combination should be avoided.

Muscle Damage, Heat and Exercise: Effects on Acute Kidney Injury Biomarkers and Renal Function Naushad Ali Junglee, Umberto Di Felice, Alberto Dolci, Matthew B. Fortes, Andrew B. Lemmey, Neil Peter Walsh, Jamie Hugo Macdonald. *Extremes Group, College of Health and Behavioural Sciences, Bangor University, Bangor, Gwynedd, United Kingdom.*

Background: Physical activity in the heat can result in acute kidney injury (AKI). This study examined whether muscle-damaging and inflammatory-inducing exercise, as typically induced in military, occupational and sports settings, would result in upregulation of the AKI biomarker neutrophil-gelatinase associated lipocalin (NGAL) and alter kidney function following physical activity in the heat.

Methods: Ten males (mean age±SD, 20±2 years) completed two randomized and counter-balanced treadmill running trials separated by 14 days. The first trial involved running for 60 minutes at 64% of maximal aerobic capacity in 68°F, on a +1% gradient (CON). The second trial was identical but on a -10% gradient to induce muscle damage (MD). Following each trial, subjects performed an exercise heat-stress test that involved running for 40 minutes at 65% of maximal aerobic capacity on a +1% gradient in 91°F. Urine and plasma NGAL, urine flow rate and specific gravity, plasma creatine kinase (CK) and plasma inflammatory cytokine interleukin-6 (IL-6) were measured at baseline, pre- and post-heat stress. Data were analyzed using repeated measures ANOVA and Pearson's correlations. Statistical significance was set at $P \leq 0.05$.

Results: By design the MD trial induced significant muscle damage and inflammation compared to CON, as measured by a greater concentration in plasma CK ($P<0.01$) and IL-6 ($P<0.01$). During heat-stress, MD induced a greater increase in urine NGAL compared to CON (+2291% vs. +113%; $P<0.01$) and similarly with plasma NGAL ($P=0.04$). MD also decreased urine flow rate to a greater degree than CON (-50% vs. -13%; $P=0.05$); consequently specific gravity was elevated in MD ($P=0.04$). Finally, plasma NGAL was positively correlated to plasma IL-6 ($R=0.65$; $P=0.04$) but negatively correlated with urine flow rate in MD ($R=-0.62$; $P=0.05$).

Conclusions: Muscle damaging exercise and its inflammatory effects elevated NGAL and altered kidney function following exercise-heat stress. Muscle injury is thus a novel risk factor for AKI when performing physical activity in the heat.

TH-OR037

Urinary α-Glutathione S-Transferase (GST) May Identify Patients at Highest Risk for Renal Injury (AKI) during Cisplatin Chemotherapy Peter H. O'Donnell,[1] Alicia J. Wyche,[1] Claudia Wing,[1] Jay L. Koyner,[1] Walter M. Stadler,[1] Patrick T. Murray.[2] *[1]University of Chicago; [2]University College Dublin.*

Background: AKI limits use of cisplatin in treating cancers. There are no reliable predictive biomarkers to identify patients (pts) at greatest risk for cisplatin-induced AKI.

Methods: We prospectively enrolled adult cancer pts newly-starting cisplatin at our institution. Urine samples were collected 2 hrs before first cisplatin administration and analyzed for α- and π-GST. Serum creatinine (SCr) was measured at baseline and throughout therapy. Comparison of baseline (pre-cisplatin) GSTs in pts with ≥50% SCr rise (RIFLE "Risk") during cisplatin vs controls (≤25% and ≤0.2mg/dL SCr rise) was the primary endpoint.

Results: From Nov'09—May'12, 87 pts (74% male; 77% White/16% Black) enrolled. Of these, 13 (15%) exhibited RIFLE "Risk" AKI during cisplatin. Using the broader AKIN definition (SCr rise ≥0.3mg/dL or ≥50%), an additional 15 pts (28 total=32%) had AKI. There was no difference in average baseline SCr between cases/controls (1.0 vs 0.9mg/dL, P=NS) however control pts were younger (61 vs 54 yrs, P=0.003). Urinary GSTs were available for 57/87 pts, including 27/28 pts with AKI. Baseline α-GSTs were significantly higher in pts developing subsequent RIFLE "Risk" AKI compared to controls (median=11.8 vs 4.4μg/L, P=0.04). This remained significant when using AKIN. Age did not correlate with higher baseline α-GST. Significant differences in π-GSTs between cases/controls were not observed. Five pts with the highest baseline α-GST (133, 87, 80, 70, 28μg/L) all showed dramatic SCr rises during cisplatin (44%, 131%, 82%, 174%, 214%, respectively). Area under the receiver-operator characteristic curve was 0.81 (P=0.003). A cutpoint of 10μg/L for baseline α-GST provided PPV=75%, NPV=85%, and a likelihood ratio for AKI of 7.7.

Conclusions: Urinary α-GST measured before receipt of cisplatin can identify pts at higher risk of developing cisplatin-related AKI. Since nephrotoxic effects of cisplatin likely involve direct proximal tubule (PT) injury, our results for α-GST (a PT marker) provide clinical evidence that baseline PT dysfunction is detectable and predicts for cisplatin AKI.

TH-OR038

Timing of Renal Replacement Therapy and Outcomes in Critically Ill Patients with Acute Kidney Injury in the Randomized Evaluation of Normal versus Augmented Level of Replacement Therapy Trial Min Jun,[1] Rinaldo Bellomo,[2] Alan Cass,[1] Martin P. Gallagher,[1] Serigne N. Lo.[1] *[1]Renal and Metabolic Division, The George Institute for Global Health, Camperdown, NSW, Australia; [2]U of Melbourne, Australian and New Zealand Intensive Care Society Clinical Trials Group (ANZICS CTG), Austin, VIC, Australia.*

Background: The effect of timing of RRT initiation upon patient outcomes in AKI has not been well defined. We assessed the relationship between the timing of commencement of renal replacement therapy (RRT) in patients with acute kidney injury (AKI) and death at 28 and 90 days.

Methods: As a planned sub-study of the Randomized Evaluation of Normal vs. Augmented Level Replacement Therapy (RENAL) Study, we collected data on timing of onset of AKI using the RIFLE criteria in a nested cohort of patients. The timing of RRT commencement was determined using the time from AKI diagnosis to randomization (proxy to RRT commencement). Cox and logistic regression models were constructed using baseline demographic, disease-severity measures, and biochemical information.

Results: RIFLE criteria were obtained in 439 patients with a median time between renal failure diagnosis and RRT commencement of 17.6hrs. Patients were grouped into 4 categories of increasing time from renal failure to RRT commencement (based on quartiles: <7.1 [reference group], ≥7.1 to <17.6, ≥17.6 to <46.0, ≥46.0hrs). Earlier commencement of RRT was not associated with a lower risk of death at 28 days (HR for ≥7.1 to <17.6: 1.06, 95% CI: 0.62 to 1.81; p=0.83; HR for ≥17.6 to <46.0: 1.23, 95% CI: 0.71 to 2.12; p=0.46; HR for ≥46.0: 1.33, 95% CI: 0.77 to 2.31; p=0.31). Similar findings were observed for death at 90 days. Whilst not statistically significant, multivariate Cox and logistic regression models suggested a step-wise increase in mortality with increasing delay in RRT commencement.

Conclusions: In the RENAL Study, earlier commencement of RRT was not significantly associated with improved mortality rates. A step-wise increase in mortality may suggest progressive harm with delayed RRT and this needs to be tested in sufficiently powered randomized trials.

TH-OR039

Fgfr/Frs2α Signaling Is Required in Nephron Progenitors

Valeria E. Di Giovanni, Sunder Sims-Lucas, Caitlin M. Schaefer, Carlton M. Bates. *Div of Nephro, Dept of Peds, University of Pittsburgh, Pittsburgh, PA.*

Background: Fibroblast growth factor receptors (Fgfrs) signal intracellularly via adapters including fibroblast growth factor substrate 2α (Frs2α). We have shown critical roles for Fgfr/Frs2α signaling in the early metanephric mesenchyme (MM) in compound mice with Pax3cre deletion of *Fgfr1* and global point mutations in the Frs2α binding site of Fgfr2 (PFLR mice). PFLR mice develop ureteric bud (UB) branching defects and ureteric and mesenchyme-derived cysts with ciliary defects.

Methods: To understand the role of Fgfr/Frs2α signaling axis in more restricted populations of the MM, we generated SFLR mice using Six2cre, which delete *Fgfr1* slightly later than in PFLR mice, and specifically in nephron progenitors (NPs).

Results: Unlike PFLR mice, SFLR mice have normal ureteric development. However, SFLR mice have progressively worsening mesenchyme-derived cysts associated with abnormally long cilia. Strikingly, SFLR mice had abnormalities in the NP population. Embryonic day (E) 13.5 SFLR kidneys had normal-appearing NP cells by histology, Six2 and Sall1 antibody staining; however, they lost expression of Cited1, a marker of the "stem-cell like" renewing NP subpopulation, and demonstrated excessive apoptosis. By E14.5, SFLR NP cells were severely depleted and continued to demonstrate excessive apoptosis. Analysis of PFLR mice showed a similar loss of NPs. Despite the loss of NPs, those that survived were able to differentiate into nephrons as noted by H&E and Ncam staining in both SFLR and PFLR mice. Preliminary RNA-Seq analysis in FACS sorted E13.5 SFLR NP cells confirm a loss of expression of early NP markers in SFLR mutants, including Meox1 and Osr1. Also, Egf receptor pathways appeared down regulated and Notch activity appeared to be up regulated in SFLR NP cells, suggesting candidate molecules downstream of Fgfr/Frs2α signaling.

Conclusions: In conclusion, Fgfr/Frs2α signaling in NPs is critical for controlling early NP survival and in preventing mesenchyme-derived cystogenesis, possibly by regulating cilia length. Furthermore, the PFLR and SFLR allelic series reveals temporal and spatial roles of Fgfr/Frs2α signaling in regulating ureteric and MM development.

Hematopoietic Progenitor Cells and Vascular Development in the Kidney

Yan Hu,[1,2] Minghong Li,[1] Roberto Ariel Gomez,[1,2] Maria Luisa S. Sequeira Lopez.[1] *[1]Department of Pediatrics, University of Virginia, Charlottesville, VA; [2]Department of Biology, University of Virginia, Charlottesville, VA.*

Background: There is currently very limited information regarding the crucial events that govern the morphogenesis of the renal arterial tree, including the origin, lineage relationship and mechanisms involved in the formation of the renal vasculature. It is now accepted that hematopoietic stem cells (HSCs) and endothelial cells (ECs) originate from a common progenitor, the hemangioblast. The following studies were performed to define the presence and contribution of the renal hemangioblast to the formation of the kidney vasulature.

Methods: Fate-tracing studies using transgenic mice (EC-SCL-CRE-ER^T and HSC-SCL-CRE-ER^T) that specifically express inducible cre upon tamoxifen administration in EC progenitors and HSCs, respectively. Histological methods, including X-gal staining and immunohistochemistry. Identification of hematopoietic progenitors using methylcellulose based colony-forming-cell assays using embryonic kidney cells from HSC-SCL-Cre-ER^T; mTmG mice, which express GFP in the cells from the HSC lineage upon tamoxifen induction. Crosstransplantation of embryonic kidneys from EC-SCL-Cre-ER^T;R26R mice under the kidney capsule of adult WT mice.

Results: 1. Cells from the endothelial and HSC lineage contribute to both erythroblasts and ECs in renal arteries, capillaries in between developing tubules and inside the glomeruli in the early embryonic kidney.

2. Renal hemangioblasts only give rise to ECs and blood.

3. The embryonic kidney possesses early hematopoietic progenitors.

4. Blood cells derived from the transplanted embryonic kidneys suggest that the embryonic kidney possesses HSCs that originate *in situ.*

Conclusions: The embryonic kidney possesses hemangioblasts that develop *in situ* and are progenitors of kidney vascular ECs and blood cells, which are distinct from the progenitor of mural cells.

Renal Stroma Derived Endothelial Precursors Are Critical for Renal Development

Sunder Sims-Lucas, Caitlin M. Schaefer, Edward Prochownik, George K. Gittes, Carlton M. Bates. *Pediatrics, Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: Kidney structural abnormalities are amongst the leading causes of pediatric chronic kidney disease, producing significant morbidity and mortality. Understanding how different kidney lineages develop and interact is critical for making an impact on structural kidney disease. While most of the field has focused on ureteric, nephrogenic and stromal lineages, few have interrogated the role of the vasculature in the process of kidney development, except as it relates to the glomerulus. Moreover, the origin of the kidney vasculature has been debated to come from either the nephrogenic mesenchyme (within the kidney) or invading vessels.

Methods: Utilizing a combination of flow sorting and immunostaining both in wildtype and linage tagged renal cortical stroma we have shown a portion of the renal endothelium is derived from the cortical stroma.

Results: Immunofluorescence revealed that the lineage tagged stromal-derived endothelial cells gave rise to a significant portion of the peritubular capillary network, but not glomerular capillaries. In vitro, cultured embryonic stromal cells differentiated into tubular networks that expressed endothelial markers such as Flk1. To determine roles of stroma derived endothelium in vivo, we conditionally deleted Flk1 in the renal stroma with Foxd1cre lines (Flk1$^{ST-/-}$ mice). Flk1$^{ST-/-}$ mice had dilated peritubular capillaries with normal-appearing glomerular capillaries. Flk1$^{ST-/-}$ mice also had renal papillary hypoplasia/fibrosis and urinary concentrating defects. Microarray analysis of Flk1$^{ST-/-}$ kidneys revealed perturbations in key renal developmental pathways including, Vegf, Tgfβ and Notch.

Conclusions: These studies provide new insights into the origins of renal endothelium and their contribution to renal development including the renal medulla. Manipulation of this novel progenitor pool may impact therapeutically on vascular related kidney abnormalities and congenital kidney diseases.

Targeted Inactivation of the Prorenin Receptor (*PRR*) in the Ureteric Bud (UB) Inhibits UB Branching Morphogenesis and Collecting Duct Development

Renfang Song,[1] Graeme James Preston,[1] Atsuhiro Ichihara,[2] Ihor V. Yosypiv.[1] *[1]Pediatrics, Tulane University School of Medicine, New Orleans, LA; [2]Nephrology, Keio University School of Medicine, Tokyo, Japan.*

Background: The PRR is the cell-surface receptor for renin and prorenin, and an accessory subunit of the vacuolar proton pump H$^+$-ATPase. In this study, we tested the hypothesis that targeted inactivation of the *PRR* (*Atp6ap2*) in the UB is essential for normal kidney development.

Methods: *PRR*$^{flox+}$ mice were bred with mice that express the Cre recombinase under the control of the UB-specific promoter (*Hoxb7*$^{Cre+}$). The resulting *Hoxb7*$^{Cre+}$/*PRR*$^{flox/flox}$ mice represent UB-specific *PRR*-knockout mice.

Results: RT-PCR demonstrated that isolated intact embryonic (E) day E11.5 UBs and cultured UB cells express PRR mRNA. The number of UB tips was reduced as early as on E12.5 in mutant *Hoxb7*$^{Cre+}$/*PRR*$^{flox/flox}$ (n=4 mice) compared to control *Hoxb7*$^{Cre-}$/*PRR*$^{flox/flox}$, n=4 mice) kidneys (5.2±0.5 vs. 13±0.6, p<0.01). The number of caspase 3-positive apoptotic cells in the UB was higher in mutant compared to control kidneys (7.6±1.2 vs. 0.6±0.1, p<0.01). qRT-PCR showed that Ret, Wnt11, Etv4 and Etv5 mRNA levels were decreased in mutant compared to control kidneys (p<0.001-0.01). Immunohistochemistry demonstrated reduced Erk1/2 phosphorylation in the UB of mutant kidneys. On E17.5, marked kidney hypoplasia, widespread apoptosis of the collecting duct cells, decreased expression of Foxi1, AE1, pendrin, Nos1, and H$^+$-ATPase mRNA levels (p<0.001-0.01), determined by qRT-PCR, were observed in mutant compared to control kidneys. On P1, kidney length (471±15 vs. 711±38 μm, p<0.01) and surface area (50117±3000 vs. 93000±2650 pixels, p<0.001) were reduced in mutant compared to control mice. Histological examination of P1 kidney sections demonstrated moderate dilation and occasional cysts in medullary collecting ducts.

Conclusions: PRR present in the UB epithelia performs essential functions during normal UB branching morphogenesis and collecting duct development *via* control of Ret/Wnt11 gene expression, UB/collecting duct cell survival, activation of Erk1/2 signaling and differentiation of collecting duct cells involved in acid-base homeostasis.

Transcription Factor Tcfcp2l1 Is Necessary and Sufficient for Distal Nephron Differentiation

Max Werth,[1] Andong Qiu,[1] Jonathan M. Barasch.[1] *[1]Columbia University.*

Background: Transcription factor Tcfcp2l1 belongs to the Grainyhead family and plays important roles in epithelial development in the kidney and other organs (e.g. Max Werth and Kai Schmidt-Ott, *Development* 2010).

Methods: We generated a conditional knockout of Tcfcp2l1 and deleted the gene from metanephric mesenchyme using Pax3ProCre and the whole kidney using EIIA-Cre. We overexpressed Tcfcp2l1 in the metanephric mesenchyme using adenoviral mediated gene transfer and we developed specific ChIP protocols.

Results: The expression pattern of Tcfcp2l1 during kidney development was very dynamic and covered mesonephros, ureteric bud stalk and the distal part of S-shaped bodies. In the adult kidney highest expression level of the Tcfcp2l1 was observed in the distal convoluted tubule, connecting segment and lower expression in the cortical collecting duct. To study the function of Tcfcp2l1 we generated the conditional knockout in the distal tubule. We observed downregulation of major markers of alpha- and beta-intercalated cells in the knockouts such as V-ATPase, Pendrin and AE-1. Gene array analysis confirmed the loss of expression of these major intercalated genes. Using chromatin immunoprecipitation assay we were able to show that Tcfcp2l1 binds to the promoter region of several subunits of V-type ATPase implicating Tcfcp2l1 is a direct regulator. By lentiviral expression, Tcfcp2l1 induced epithelial tubules in metanephric mesenchyme.

Conclusions: Taken together these data demonstrate that Tcfcp2l1 is sufficient and necessary for epithelial development and terminal differentiation particularly in the intercalated cell lineage.

Role of the PCP Pathway Gene Fuzzy in Ciliary Formation and Signalling: Implications for Kidney Development

Elena Torban, Sima Babayeva. *Department of Medicine, McGill University, Montreal, QC, Canada.*

Background: In humans, congenital anomalies of the kidneys and urinary tract (1-3 cases per 500 births) are the leading cause of the end stage renal failure in the pediatric population. Normal kidney development depends on timely activation of key intracellular signaling pathways including the canonical and non-canonical WNT. Currently, it is believed that these pathways are influenced by signals from the primary cilium in response to onset of tubular flow. We recently found that homozygous inactivation of the Fuzzy gene, encoding a protein in the non-canonical WNT planar cell polarity (PCP) pathway, causes profound renal hypoplasia and loss of cilia in kidney cells. We hypothesize that Fuzzy is crucial for normal ciliogenesis and regulation of intracellular signaling during kidney development.

Methods: A gene-trap Fuzzy mouse was generated in our lab; kidneys from E14.5 wildtype and mutant embryos were analyzed by histological and immunological methods with various antibodies. Wildtype and mutant mouse embryonic fibroblasts were established to study ciliogenesis and both WNT/β-catenin and WNT/PCP signaling by immunofluorescent microscopy and reporter assays.

Results: We established that Fuzzy is expressed in developing renal epithelial structures (ureteric buds, comma and S-shaped bodies). In MEFs and renal epithelial cells, native and exogenous Fuzzy protein was detected in the basal body, ciliary membrane and TGN/late endosomal vesicular compartment. We show that loss of Fuzzy leads to the loss of Rab8 small GTPase at the basal body suggesting that Fuzzy regulates recruitment of Rab8 to the primary cilium. We identified an interaction between Fuzzy and the modular PCP protein, Dishevelled. The latter is critically involved in both canonical and PCP pathways. Loss of Fuzzy results in loss of cilium with concomitant hyperactivation of the canonical WNT pathway and loss of PCP signaling.

Conclusions: We propose that Fuzzy is a crucial regulator of early renal development and that loss of Fuzzy causes renal hypoplasia by disrupting normal ciliogenesis and disturbing WNT and PCP signaling.

Ret Docking Tyrosines Y1015 and Y1062 Regulate Ureterovesicular Junction Development through Different Mechanisms by Modulating MAPK Activity

Masato Hoshi, Sanjay Jain. *Renal, Medicine, Washington University School of Medicine, St. Louis, MO.*

Background: Connection of the upper and lower urinary tract at the ureterovesicular junction (UVJ) requires precise spatio-temporal regulation of molecular signals in the Wolffian duct (WD) and the surrounding structures that are not well defined. Delayed or defective insertion of WD or abnormalities in ureter remodeling can cause congenital anomalies of kidneys or urinary tract (CAKUT) including hydronephrosis, ureterocele, vesicoureteral reflux and megaureter. Mutations in the receptor tyrosine kinase *RET* are associated with CAKUT. RET signaling is mediated by docking tyrosines that regulate downstream signaling pathways. We previously showed that abrogation of the docking sites for PLCγ (Y1015) or SHC (Y1062) causes markedly different CAKUT.

Methods: We performed ontogenic and molecular analyses of early events in the formation of UVJ in RetY1015F and Y1062F mutant mice.

Results: We found abnormal ureter-bladder fusion in both Y1015F and Y1062F mutant mice, however through quite distinct developmental and cellular mechanisms. The common nephric ducts (CND), the caudal-most WD segment, of Y1015F mutants failed to degenerate normally, had increased MAPK activity and reduced apoptosis at E12.5 compared to controls. In contrast, WDs in RetY1062F mutant mice show failure to reach the cloaca at E10.5, asymmetric caudal growth at E11.5. At later developmental time points the ureters continued to show insertion/fusion defects into the primitive bladder. Both Ret-null and RetY1062F mutants show reduced MAPK activity throughout the entire WD at E10.5. These results show that the mechanism of WD to reach cloaca in Ret-null mice is reduction in the RetY1062-mediated MAPK activity. Inhibiting MAPK activity in half-genitourinary organ cultures in conjunction with time-lapse microscopy and whole mount immunohistochemistry analyses at E10 in wild-type mice revealed a major effect of MAPK pathway in the formation of UVJ.

Conclusions: Our study demonstrates how the same gene *RET* can modulate lower tract development through different mechanisms and provides a possible explanation for the broad range of phenotypes observed in the CAKUT affected individuals.

Absence of MicroRNA-21 Aggravates Glomerular Damage in Experimental Diabetic Nephropathy

Markus Bitzer, Jinghui Luo, Yingbao Yang, Christopher Lund O'Connor, Jennifer Yi-Chun Lai. *Internal Medicine, University of Michigan, Ann Arbor, MI.*

Background: Diabetic nephropathy (DN) is associated with mesangial expansion, loss of podocytes, and increased extracellular matrix (ECM) deposition in glomeruli and tubulo-interstitium. TGF-beta/Smad signaling is an important mediator of these changes in DN and regulates microRNAs (miRs) expression. The functional role of miRs in DN is not well understood. We had previously reported that miR-21 expression levels strongly correlate with proteinuria in patients with DN and that loss of miR-21 is associated with increased loss of podocytes and accelerated glomerular disease in TGF-beta1 transgenic mice. Now we present our findings on the role of miR-21 in a murine model of DN.

Methods: Experimental DN was induced in 10 weeks old miR-21 mutant DBA mice by administration of 50 mg/kg streptozotocin (STZ) intraperitoneally for 5 consecutive days. Functional and histological analyses were carried out at 10, 16 and 20 weeks after the completion of STZ injection. Furthermore, primary renal tubular epithelial cells (RTECs), fibroblasts and mesangial cells (MCs) were isolated from miR-21 mutant mouse kidneys, and the impact of high-glucose (HG) on the proliferation of the culture cells was detected using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) method. ECM deposition in the kidney was quantified using Sirius red staining.

Results: MiR-21 knockout (KO) mice developed increased albuminuria, higher blood urea nitrogen (BUN) levels and increased ECM deposition in glomeruli but not in tubule-interstitium compared with wild-type (WT) littermates 16 weeks after STZ-treatment. Whereas proliferation of miR-21 KO MCs and renal fibroblasts was increased, miR-21 KO RTECs proliferated less compared with WT cells. HG further decreased proliferation in miR-21 KO RETCs but increased it miR-21 KO fibroblast and MCs.

Conclusions: Consistent with our previous findings in TGF-beta1 transgenic mice, miR-21 provides protection from glomerular damage in a murine model of DN. Candidate cellular mechanisms includes increased podocyte loss and MC proliferation. Studies exploring the underlying molecular mechanisms are ongoing.

Cross-Talk between TGF-β1 and 12/15-Lipoxygenase in the Epigenetic Regulation of Pro-Fibrotic Genes Related to Diabetic Nephropathy

Hang Yuan, Marpadga A. Reddy, Linda L. Lanting, Mei Wang, Jung Tak Park, Wen Jin, Mitsuo Kato, Rama Natarajan. *Department of Diabetes, Beckman Research Institute of City of Hope, Duarte, CA.*

Background: Epigenetic chromatin histone modifications such as H3-lysine methylation (H3KMe) and acetylation (H3KAc) at gene promoters have profound effects on gene expression. Increased expression/activity of TGF-β1 (TGFB) and 12/15-Lipoxygenase (LO) and cross-talk between them play key roles in the upregulation of profibrotic genes (Collagen1a1, PAI-1 and CTGF) in Diabetic Nephropathy. We recently demonstrated the role of H3KMe in high glucose and TGFB induced profibrotic gene expression in mesangial cells (MC). Here, we evaluated the role of LO-TGFB cross-talk in the regulation of histone modifications and expression of a key H3K4-methytransferase (HMT) Set7/9 in MC and renal cortex from diabetic mice.

Methods: Gene expression was determined by QRT-PCR and histone modifications by Chromatin immunoprecipitation (ChIP) assays in rat MC treated with 12(S)-HETE (a LO- product) as well as in MC derived from wild type (WT) or LO-knockout (LOKO) mice after TGFB stimulation. In vivo relevance was tested using renal cortex from STZ injected diabetic LOKO mice, and WT diabetic mice treated with LO siRNAs.

Results: 12(S)-HETE increased the expression of profibrotic genes and SET7/9, and also altered H3K9Ac/H3K4Me1/H3K4Me3 levels at profibrotic gene promoters in rat MC. Interestingly, TGFB induced Set7/9 and profibrotic gene expression as well as H3K9Ac at their promoters was significantly ameliorated in MC from LOKO mice. Further, SET7/9 and profibrotic gene expression were increased in diabetic WT mice and these were significantly attenuated in diabetic LOKO mice, and in diabetic WT mice treated in vivo with LO siRNAs.

Conclusions: These new results demonstrate that oxidized lipids of the LO pathway can regulate key HMTs and histone modifications under diabetic conditions and also modulate TGFB induced epigenetic mechanisms involved in profibrotic gene expression. This can augment extracellular matrix deposition and fibrosis linked to diabetic nephropathy.

TH-OR048

Renal Protection by Knockout of the Atypical Chemokine Receptor D6 in Diabetic OVE Mice

Shirong Zheng,[1] Haribabu Bodduluri,[2] Paul N. Epstein.[1] [1]*Pediatric, University of Louisville, Louisville, KY;* [2]*Microbiology, University of Louisville, Louisville, KY.*

Background: Monocyte/macrophage recruitment correlates strongly with the progression of renal impairment in diabetic nephropathy. Chemokines and their receptors play a major role in leukocyte recruitment into inflammatory sites. The chemokine receptor D6 is a chemokine scavenging receptor that binds and sequesters many inflammatory CC

chemokines but does not transduce an apparent intracellular signal. It may play an important role in modulating the inflammatory response by scavenging CC chemokines in inflamed tissue. But its function in the diabetic kidney disease has not been tested.

Methods: In this study, we utilized the D6 knockout mice to test whether elimination of D6 will aggravate renal damage in diabetic nephropathy. D6KO mice were back crossed onto FVB background for 10 generations and then mated with OVE26 (OVE) mice to eliminate the D6 gene in this diabetic model. Control mice, OVE mice and OVE-D6$^{-/-}$ mice were tested for albuminuria, renal fibrosis, leukocyte infiltration and gene expression.

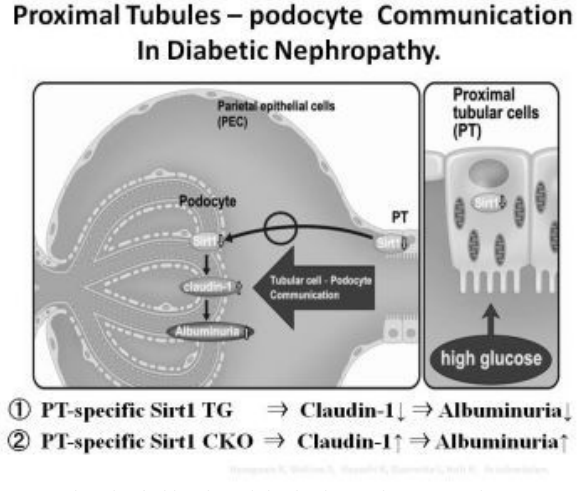
Results: D6 deficiency did not alter the diabetic blood glucose levels. Surprisingly, deletion of the D6 gene drastically reduced all features of diabetic nephropathy. Compared to OVE mice OVE-D6$^{-/-}$ mice had a 5 fold reduction in albuminuria. Renal fibrosis and leukocyte infiltration, which were greatly increased by OVE diabetes, declined to almost non-diabetic levels in OVE-D6$^{-/-}$ mice. Consistent with the changes in phenotype, gene expression in pathways of renal damage, inflammation and fibrosis were more normal in OVE-D6$^{-/-}$ mice. Renal protection by D6 knockout was unexpected but very effective.

Conclusions: The mechanisms by which the loss of inflammatory chemokine scavenging function in the diabetic kidney resulted in reduced leukocyte infiltration and inflammation remains to be investigated but our results reinforce the importance of inflammatory chemokines in modulating the progression of diabetic nephropathy.

TH-OR049

In-Vivo Claudin-1 Ectopic Overexpression in Podocytes Worsens Diabetic Albuminuria Kazuhiro Hasegawa, Shu Wakino, Koichi Hayashi, Hiroshi Itoh. *Internal Medicine, Keio University, Shinjuku-ku Shinanomachi-35, Tokyo, Japan.*

Background: We created proximal tubule (PT)-specific Sirt1 TG (JBC 2010) and conditional knockout (CKO) mice (oral presentation in 2010, 2011 ASN). After streptozotocin (STZ) treatment, wild-type (WT) mice had diabetic nephropathy (DN) with prominent albuminuria (Alb), combined with decreased Sirt1 and increased tight-junction protein claudin-1 (Cldn-1) in podocytes (Pods) as compared to saline-treated (Sal) control mice. These changes were prevented in TG and were aggravated in CKO.



However, the role of Cldn-1 in Pods in vivo has not been reported.

Methods: We delivered the gene of NPHS2-Cldn-1 cDNA vector, Cldn-1 siRNA, and control (Cont) plasmid using HVJE vector by tail-vein injection in Sal-treated or STZ-treated mice. The efficiency was tested by Cldn-1 staining and immunoelectron microscopy.

Results: In Cont+Sal, endogenous Cldn-1 was detected in PECs. In Cont+STZ, Cldn-1 was detected in PECs and Pods. Gold particles in Cont+STZ were characteristically located on the bottom side of foot processes (FP), not along with the lateral side. FP might be dragged from the bottom side by the tension power formed by newly emerged Cldn-1, which seems likely as FP become flattened and effaced. In Cldn-1+Sal, Cldn-1 upregulation was detectable in a Pods-specific way, which was concordant with the usage of NPHS2 promoter. In Cldn-1+STZ, further intense staining was seen in Pods. Cont+STZ or Cldn-1+Sal revealed significantly enhanced Alb and FP effacement, which was further enhanced in Cldn-1+STZ. When mice were rendered Cldn-1 siRNA, Cldn-1 was successfully silenced in the kidney. Cldn-1 in Pods and Alb after STZ was dramatically abolished by Cldn-1 siRNA.

Conclusions: Pods-specific Cldn-1 significantly worsened FP effacement and Alb. Cldn-1 siRNA therefore seems to be beneficial for the maintenance of Pods function and is a novel therapeutic approach for DN.

TH-OR050

Overexpression of Heterogeneous Nuclear Ribonucleoprotein F Up-Regulates Angiotensin-Converting Enzyme-2 Expression and Attenuates Systemic Hypertension in Diabetic Akita Transgenic Mouse Kidney Chao-Sheng Lo,[1] Shiao-ying Chang,[1] Yixuan Shi,[1] Isabelle Chenier,[1] Shao-Ling Zhang,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] John S.D. Chan.[1] *[1]Res. Ctr., CHUM-Hotel Dieu Hospital, Montreal, Canada; [2]Res. Ctr., Maisonneuve-Rosemont Hosp., Montreal, QC, Canada; [3]Pediatr Nephrol Unit, Mass Gen Hosp, Boston, MA.*

Background: We investigated whether overexpression of heterogeneous nuclear ribonucleoprotein F (hnRNP F) modulates renal angiotensin-converting enzyme-2 (Ace-2) and angiotensin-converting enzyme (ACE) expression and subsequently attenuates hypertension in type 1 diabetic Akita mice.

Methods: Akita transgenic (Tg) mice specifically overexpressing hnRNP F in their renal proximal tubular cells (RPTCs) were studied. Plasma glucose, systolic blood pressure (SBP) and albuminuria were monitored bi-weekly in adult male non-Akita littermates, Akita and Akita hnRNP F-Tg mice from 10 to 20 weeks of age. Kidneys were processed for immunostaining of Ace-2 and ACE. Renal proximal tubular (RPT) Ace2 and ACE mRNA and protein expression were evaluated by respective real time-qPCR and Western blotting. Urinary angiotensin 1-7 (Ang 1-7) and angiotensin II (Ang II) levels were quantified by ELISA.

Results: Akita mice developed hypertension (SBP: 136.8 ±2.60 mm Hg) with increased glomerular filtration rate (GFR: 520.1 ± 44.08 µl/min), and displayed renal hypertrophy as compared to non-Akita controls (SBP: 107.7 ±1.11 mm Hg and GFR: 229.3 ±13.69 µl/min). HnRNP F overexpression normalized SBP, and decreased GFR (408.7 ±17.91 µl/min), renal hypertrophy and the urinary albumin/creatinine ratio without affecting plasma glucose levels in Akita hnRNP-F Tg mice. RPT Ace-2 mRNA and protein expression, and urinary Ang 1-7 levels were significantly decreased in Akita mice but normalized in Akita hnRNP F-Tg mice. In contrast, RPT ACE mRNA and protein expression were similar in Akita and Akita hnRNP F-Tg mice, whereas urinary Ang II levels were significantly increased in Akita mice and normalized in Akita hnRNP F-Tg mice.

Conclusions: Our data suggest that hnRNP F plays a protective role by attenuating SBP and preventing RPTC injury in diabetes,predominantly through increasing intrarenal Ace-2 gene expression.

TH-OR051

Inhibition of the MAPK p38 Decreases Nephrin Endocytosis and Protects Mice against Hyperglycemia-Induced Proteinuria Magdalena Woznowski, Sebastian Alexander Potthoff, Eva Koenigshausen, Johannes Stegbauer, Lars C. Rump, Lorenz Sellin, Ivo Quack. *Nephrology, Heinrich Heine University, Duesseldorf, Germany.*

Background: We could recently demonstrate that hyperglycemia leads to PKC? mediated endocytosis of nephrin. It has also been shown that p38 activation leads to loss of nephrin. However, the underlying pathomechanism remains unclear. Thus we were interested whether p38 is involved in nephrin endocytosis.

Methods: GST-fusion proteins of nephrin were used in kinase assay with recombinant p38. HEK293T cells were transfected with nephrin and β-arrestin2 as well as PKCα and PICK1. Co-IP with subsequent western blotting was performed. C57BL/6 mice were treated i.p with streptozotocin to induce hyperglycemia. As p38 inhibitor, SB202190 (i.p.) or BIRB0796 (p.o.) were used. Albuminuria was quantified as albumin/creatinin ratio. Isolated glomeruli were analyzed via western blot for activation of p38 and the interaction of nephrin with β-arrestin2 and nephrin endocytosis.

Results: Treatment of podocytes with high glucose (30 mmol) induced activation of the MAPK p38. Under high glucose conditions p38 phosphorylated nephrin at Ser1146 strenghtening the binding of PICK1 to nephrin. PICK1 facilitated the interaction of PKCα with nephrin promoting the phosphorylation of nephrin Thr 1120/1125 by PKCα. This step enabled the binding of β-arrestin2 to nephrin, initiating nephrin endocytosis. In mice hyperglycemia also led to p38 activation, nephrin endocytosis and proteinuria, which could be nearly completely prevented by p38 inhibition.

Conclusions: Here we propose a model for the role of p38 in nephrin endocytosis: high glucose levels lead to activation of MAPK p38 acting as an upstream mediator of PKCα. Active p38 phosphorylates nephrin at Ser1146 and faciliates the binding of PICK1 and PKCα to nephrin. The phosphorylation of Thr1120/1125 by PKCα is the prerequisite for β-arrestin2 binding and nephrin endocytosis, leading to a leaky filter. Noteworthy,in vivo the inhibition of p38 attenuates high glucose mediated nephrin endocytosis and proteinuria nearly completely. These findings suggest p38 and PKCα as promising targets for prevention and therapy of hyperglycemia induced proteinuria.

The Coagulation Protease Activated Protein C Ameliorates Diabetic Nephropathy by Regulating the Endoplasmic Reticulum Stress Response

Berend Heinrich Isermann,[1] Hongjie Wang,[1] Vedat Schwenger,[2] Hermann-Josef Groene,[3] Madhusudhan Thati.[1] *[1]Clinical Pathology and Pathobiochemistry, OvG University, Magdeburg, Germany; [2]University of Heidelberg, Heidelberg, Germany; [3]DKFZ, Heidelberg, Germany.*

Background: Diabetic nephropathy (DN) is associated with endothelial dysfunction and impaired function of the endothelial derived, cytoprotective thrombomodulin (TM) protein C (PC) system. Impaired PC activation causes glomerular cell dysfunction and DN. The intracellular mechanism through which PC activation modulates DN is not known. Here we show that activated PC (aPC), a central mediator of haemostatic system, regulates cellular homeostasis by inhibiting endoplasmic reticulum (ER)-stress in DN., the cellular components of the glomerular barrier.

Methods: Wild-type (Wt) mice or mice with altered activity of the TM-PC system (loss of function with impaired protein C activation ($TM^{Pro/Pro}$) or gain of function with high aPC plasma levels (APC^{high})) were maintained diabetic for 26 weeks. Subsets of diabetic mice were treated with a chemical ER-chaperone (TUDCA). After 26 weeks markers of DN were determined and tissue samples were isolated for *ex vivo* analysis. *In vitro* assays were performed in podocytes and endothelial cells.

Results: Compared to Wt mice, impaired PC activation in $TM^{Pro/Pro}$ mice increased markers of ER-stress (CHOP/ATF6) in DN, while nuclear translocation of the transcription factor X-box binding protein-1 (XBP1) was impaired. Restoring aPC levels in $TM^{Pro/Pro}$ mice or inhibition of ER-stress with TUDCA normalized nuclear levels of XBP1, inhibited CHOP/ATF6 expression and protected against DN. In addition deletion of CHOP in $TM^{Pro/Pro}$ mice protected against DN. Consistent with these *in vivo* results, aPC promotes the nuclear translocation of XBP1 in endothelial cells and podocytes and inhibits hyperglycaemia induced ER-stress (reduced CHOP/ATF6expression). Podocyte or endothelial specific deletion of XBP1 abolished the cytoprotective effect of aPC.

Conclusions: These studies demonstrate that impaired PC activation is causally linked to ER-stress, establishing a novel link between haemostatic system and endoplasmic reticulum function in regulating cellular homeostasis in kidney disease.

TH-OR053

Distal Renal Tubular Acidosis in Sjögren's Syndrome Is Associated with Loss of Differentiated Intercalated Cells

Nilufar Mohebbi,[1,2] Stephen B. Walsh,[3] Antje Furstenberg,[3] Chris Laing,[3] Hanna Debiec,[4] Olivier Devuyst,[1] Pierre M. Ronco,[4] Robert J. Unwin,[3] Carsten A. Wagner.[1] *[1]Inst. of Physiology, Univ. of Zurich, Zurich, Switzerland; [2]Div. of Nephrology, Univ. Hospital Zurich, Zurich, Switzerland; [3]UCL Center for Nephrology, UCL, London, United Kingdom; [4]INSERM UMR_S702, Hopital Tenon, Paris, France.*

Background: Sjögren's syndrome is associated with renal manifestations such as distal renal tubular acidosis (dRTA). Few studies have suggested a pathophysiological role for autoantibodies against carbonic anhydrase type II or subunits of the vacuolar H^+-ATPase in the acid secretory type A intercalated cells.

Methods: We aimed to investigate if dRTA in Sjögren's disease is caused by altered expression of acid-base transport proteins and abnormal acid-secretory cells in kidney biopsies of patients with clinically defined dRTA. Immunohistochemistry was performed for anion exchanger AE1, the Cl^-/HCO_3^- exchanger pendrin, the a4 and B1 subunits of the vacuolar H^+-ATPase, and carbonic anhydrase II. Principal cells were identified with AQP2. 15 patients with various types of nephritis served as controls and were compared to 15 Sjögren patients with dRTA.

Results: While control patients showed basolateral staining for AE1, no AE1 staining was detected in Sjögren patients with dRTA. Notably, AE1 was still detectable in red blood cells. Similar findings were made for pendrin. The a4-subunit was detected only in intercalated cells from control patients. In contrast, staining for B1-subunit was still detectable in some Sjögren patients but with lower intensity. The number of cells positive for any intercalated cell specific markers was dramatically reduced in Sjögren patients with dRTA. Next, IgG fractions from patients with Sjögren's disease and dRTA stained intercalated cells in normal kidney tissues and showed reactive bands in human kidney protein lysates that were absent when control IgG fractions were used.

Conclusions: In conclusion, patients with Sjögren's disease and dRTA show autoantibodies against intercalated cells with loss of differentiation markers and reduced numbers of intercalated cell which may contribute to the development of dRTA and serve as a new diagnostic hallmark.

Stimulatory Effect of Insulin on Renal Proximal Na Transport Is Preserved in Insulin Resistance

Motonobu Nakamura,[1] Ayumi Shirai,[1] Osamu Yamazaki,[1] Hideomi Yamada,[1] Masashi Suzuki,[1] Shoko Horita,[1] Yukio Homma,[2] George Seki.[1] *[1]Internal Medicine, Tokyo University, Tokyo, Japan; [2]Urology, Tokyo University, Tokyo, Japan.*

Background: To clarify the pathogenesis of hypertension associated with insulin resistance, we examined whether the stimulatory effect of insulin on proximal tubule (PT) transport is preserved in insulin resistance.

Methods: Normal human kidney cortex tissues were obtained during the nephrectomy for renal carcinoma. Cell pH measurement with BCECF was performed to determine the Na-HCO_3 cotransporter NBCe1 activity in freshly isolated human or rat PTs. NBCe1 activity was also determined after isolated PTs were incubated for 24 h in DMEM containing FBS and siRNA at 37 °C. Glucose uptake into adipocytes prepared from perirenal (human) or periepididymal (rat) fat tissues was measured to estimate the degree of insulin resistance.

Results: In isolated PTs from human and Wistar rats, the stimulatory effect of insulin on NBCe1 activity was completely suppressed by a PI3-kinase inhibitor wortmannin. The siRNA treatment against IRS2 but not IRS1 largely (~85%) suppressed the stimulatory effect of insulin in rat PTs. In hyperphagic OLETF rats with obesity and hyperinsulinemia, the stimulated glucose uptake into adipocytes by 10^{-8} M insulin was severely reduced to 21% of that in control LETO rats. By sharp contrast, the stimulation of NBCe1 activity by 10^{-8} M insulin was comparable in OLETF and LETO rats (70 ± 11 vs 74 ± 15%). In insulin resistant human with elevated HOMA-IR (> 3.5), the stimulated glucose uptake into adipocytes by 10^{-8} M insulin was severely reduced to 19% of that in human with normal HOMA-IR. However, the stimulation of NBCe1 activity by 10^{-8} M insulin was comparable in human with or without insulin resistance (93 ± 7 vs 85 ± 13%).

Conclusions: These results indicate that the stimulatory effect of insulin on PT transport, dependent on IRS2/PI3-kinase pathway, was completely preserved in insulin resistance. Because insulin-induced vasodilation is known to be impaired in insulin resistance, hyperinsulinemia associated with obesity may contribute to the occurrence of hypertension by facilitating renal Na absorption.

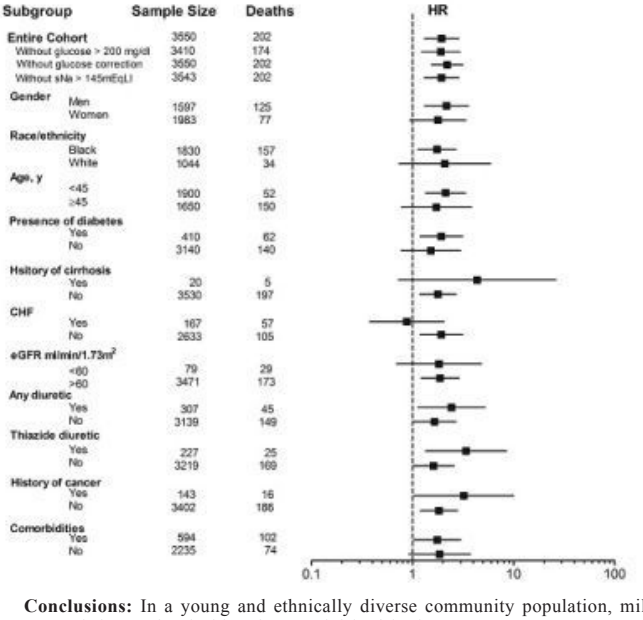
Hyponatremia and Mortality in an Ambulatory Setting: Results from the Dallas Heart Study

Fabrice Gankam Kengne, Colby Ayers, Amit Khera, James Delemos, Naim M. Maalouf. *Internal Medicine - Division of Cardiology, UTSW, Dallas, TX.*

Background: Hyponatremia is a common disorder associated with higher mortality in hospitalized patients, but its impact in an ambulatory setting remains unclear. We sought to determine the prevalence and determinants of hyponatremia and its impact on mortality in a general ambulatory population from a diverse ethnic background.

Methods: Serum sodium was measured in individuals aged 30 to 65 years enrolled in the Dallas Heart Study. Individuals were categorized based on baseline serum sodium levels, with hyponatremia defined as serum sodium below 135 mEq/L. The main outcomes were the prevalence, determinants and all-cause mortality associated with hyponatremia.

Results: 3,551 individuals were included in this analysis. The median age was 43 years (interquartile range 36-52 years) and median follow-up was 8.4 years (interquartile range 8.0-8.9 years). The sample weight-adjusted prevalence of hyponatremia in Dallas County was 6.9%, and age, black ethnicity, presence of cirrhosis or congestive heart failure (CHF) and use of selective serotonin reuptake inhibitors (SSRIs) were significantly associated with hyponatremia. By the end of the follow up period, 202 deaths occurred, including 29 in hyponatremic individuals. The unadjusted HR for hyponatremia and death was 1.94 (95% CI 1.31-2.87, p=0.001). Hyponatremia remained significantly associated with mortality after adjustment for age, gender, ethnicity, diabetes, hypertension, dyslipidemia, smoking, alcohol use, renal function, plasma CRP, use of antiepileptic drugs and SSRIs, and history of CHF, cirrhosis, and cancer (HR: 1.75; 95% CI: 1.08-2.81, p=0.02).



Conclusions: In a young and ethnically diverse community population, mild hyponatremia is associated with an increased risk of death.

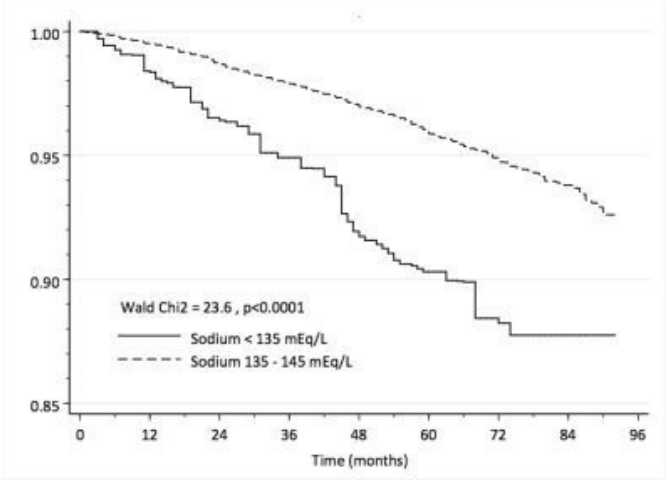
TH-OR056

Prevalence of Hyponatremia in NHANES 1999-2004 and Association with Mortality Sue Gu, Sumit Mohan, Amay Parikh, Jai Radhakrishnan. *Department of Medicine, Division of Nephrology, Columbia University Medical Center, New York, NY.*

Background: Hyponatremia is the most frequently observed electrolyte abnormality in the US, with prevalence reported to be from 2.5% up to 42.6% in the acute care setting, where it is associated with increased mortality, morbidity, and longer hospital stays. Hyponatremia in the ambulatory setting is poorly studied and is likely underdiagnosed due to its often subtle symptomatology. We seek to establish the prevalence of hyponatremia in the general US population and its association with mortality.

Methods: Data from NHANES 1999-2004 was analyzed for the presence of hyponatremia, defined as serum Na < 135 mEq/L, in the US population aged ≥ 18. Survival analysis was performed using linked mortality data through December 31, 2006.

Results: The overall prevalence of hyponatremia in the adult US population was 3.38%, with significantly higher prevalence of hyponatremia among women (4.32% vs 2.37% $p<0.0001$). For subjects aged 18-44, 45-64, and >65, we noted a significant increase in the overall prevalence with increasing age (2.82%, 3,32%, 5.31%, $p<0.0001$) among both men (1.75% 2.63%, 4.13%, $p<0.0001$), and women (3.89%, 3.97%, 6.19%, $p<0.0013$), respectively. Hyponatremia was associated with significantly lower survival rates on univariate analysis (hazard ratio 2.35, $p<0.0001$).



Conclusions: Hyponatremia is common in the US adult population, with significantly higher prevalence rates among women and older adults, and appears to be associated with significantly higher mortality in the general population.

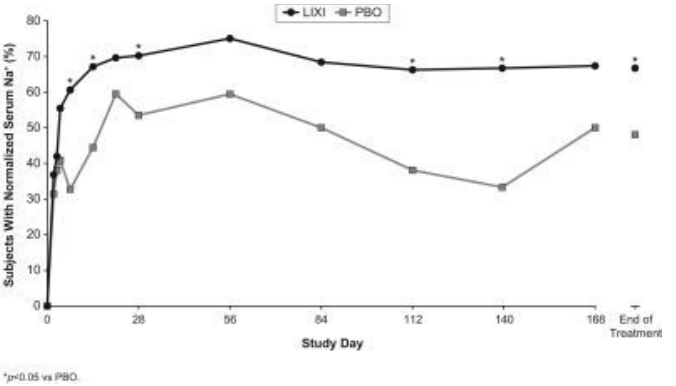
24-Week Treatment with Lixivaptan for Euvolemic Hyponatremia: Effect on Serum Sodium Levels and Safety in an Outpatient Setting William Abraham,[1] Guy Decaux,[2] Richard Josiassen,[3] Yoram Yagil,[4] Nelson P. Kopyt,[5] Hemant Thacker,[6] Massimo Mannelli,[7] Daniel G. Bichet,[8] Cesare Orlandi.[9] *[1]The Ohio State Univ; [2]Erasme Univ Hosp; [3]Drexel Univ Col of Med; [4]Ben-Gurion Univ; [5]Lehigh Valley Hosp; [6]Bhatia Hosp; [7]Univ of Florence; [8]Université de Montréal; [9]Cardiokine Biopharma, Inc.*

Background: Treatment with lixivaptan (LIXI) for 24 wks was previously shown to increase serum Na^+ levels in subjects with euvolemic hyponatremia (EH) (ASN 2011). We further assessed the rapidity, degree, predictability, and safety of this increase in outpatients with EH.

Methods: In this multicenter, randomized, double-blind study (HARMONY), non-hospitalized subjects received (3:1) oral LIXI 25mg (n=154) or placebo (PBO; n=52) once daily, with subsequent dose titration (25–100mg) based on serum Na^+ levels. Fluid restriction was implemented at the investigator's discretion. The treatment period lasted 24 wks.

Results: Mean baseline serum Na^+ was 131.5mmol/L (LIXI) and 131.6mmol/L (PBO). Least-square mean±SE changes from baseline to Day 7 (primary endpoint) were 3.2±0.5 and 0.8±0.6mmol/L, respectively (p<0.001). The benefit of LIXI was consistent across gender/age groups; the magnitude of change in serum Na^+ increased with increasing baseline severity of hyponatremia. Normalization rates (serum Na^+ levels 135–145mmol/L) were greater with LIXI than PBO (60.6% vs 32.7% on Day 7, p<0.05; Figure). Kaplan-Meier analysis of time to first serum Na^+ level ≥135mmol/L favored LIXI (p=0.051). Few subjects experienced a rapid rise in serum Na^+ levels during titration (2.0% LIXI, 1.9% PBO). LIXI was well tolerated; no subject had signs/symptoms of osmotic demyelination syndrome.



*p<0.05 vs PBO.

Conclusions: Our findings suggest that LIXI effectively increases serum Na^+ levels in non-hospitalized subjects with EH and can be initiated and titrated in an outpatient setting.

Acyclovir Induced Hypokalemia Paul E. Drawz,[1,2,3] Federico Perez,[1,3] Robert Bonomo.[1,3] *[1]Louis Stokes Cleveland VAMC; [2]MetroHealth Medical Center; [3]Case Western Reserve University, Cleveland, OH.*

Background: Intravenous (IV) acyclovir, a mainstay antiviral for herpesviruses, may cause crystalluria and lead to acute kidney injury. A patient with hypokalemia following treatment with IV acyclovir prompted us to evaluate whether acyclovir also poses an increased risk of hypokalemia.

Methods: We evaluated the rate of hypokalemia (potassium < 3.5 mEq/L) in the four days after receipt of IV acyclovir for all patients treated between Jan 1, 2002 and Jan 1, 2012. As a comparison, we evaluated the rate of hypokalemia in the 14 days after admission for all subjects not treated with acyclovir and admitted to the same ward within 30 days of a patient who received IV acyclovir.

Results: 423 patients received IV acyclovir; 29,634 patients were admitted to the same ward within 30 days of a patient who received IV acyclovir. Hypokalemia developed in 46% of patients treated with IV acyclovir. The rate of significant hypokalemia was more than threefold greater among acyclovir recipients than in the control group, even after excluding subjects with previous hypokalemia, reduced kidney function, and diuretic use.

Rate of hypokalemia in patients treated with IV acyclovir and in untreated patients (%)

	All patients					
			Excluding subjects with K < 3.6mEq/L in week prior to first acyclovir dose (or week prior to admission) or eGFR <60 within one week of acyclovir dose (or one week prior to or two weeks after admission)			
					Excluding subjects who received diuretics	
	Acyclovir	No acyclovir	Acyclovir	No acyclovir	Acyclovir	No acyclovir
	(N=423)	(N=29,634)	(N=154)	(N=16,157)	(N=124)	(N=11,147)
<3.5mEq/L	45.6	21.3	29.2	8.6	26.6	6.9
<3.4mEq/L	38.5	15.9	23.4	5.8	19.4	4.5
<3.3mEq/L	30.0	11.5	16.2	3.7	12.9	2.8
<3.2mEq/L	25.1	8.2	13.6	2.4	10.5	1.6
<3.1mEq/L	19.4	5.7	9.1	1.5	6.5	1.0
<3.0mEq/L	12.1	4.1	5.8	1.0	4.8	0.7
<2.9mEq/L	8.9	2.7	3.2	0.6	2.4	0.4

Potassium levels within 4 days after IV acyclovir (or within 14 days after admission, if untreated)

Conclusions: Our data demonstrates, for the first time, that hypokalemia is common in patients treated with IV acyclovir. Reduced renal plasma flow and crystal induced distal tubular damage may be two mechanisms by which acyclovir induces hypokalemia.

Hereditary Nephrogenic Diabetes Insipidus in Japanese Patients: Analysis of 73 Families Sei Sasaki, Motoko Chiga, Eriko Kikuchi, Shinichi Uchida. *Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Familial form of nephrogenic diabetes insipidus (NDI) is a rare hereditary disease caused by the AVPR2 and AQP2 gene mutations. It is speculated that about 90% of NDI are due to the AVPR2 gene mutations and the remaining 10% are due to AQP2, but rigid data supporting this relative frequency are lacking. It is also unknown whether this frequency is the same in different ethnic backgrounds.

Methods: Since 1994, gene mutation analyses were performed for 73 Japanese NDI families in our department. All exons and intron-exon boundaries of AVPR2 and AQP2 genes were directly sequenced. Some cases that were reported previously were included in the present analysis (16 families).

Results: Disease-causing mutations were identified in the AVPR2 gene in 60 families (82%), and in the AQP2 gene in 8 families (11%). In the remaining 5 families (7%) no mutation could be detected. This relative frequency of causative genes matches the general speculation. A total of 21 novel disease-causing mutations were newly identified in this study (17 in AVPR2 and 4 in AQP2). Regarding AVPR2, 52 disease-causing mutations were identified in 60 families. Among them, missense mutations were most popular accounting for a half of the mutations, followed by deletion mutations > nonsense mutations > insertions

and splicing mutations. These relativities are comparable with those of a global summary (Spankis 2008). In 49 female subjects who had heterozygous disease-causing AVPR2 mutations, 16 subjects (26%) had polyuria and 4 showed a complete NDI, demonstrating a quarter of female carriers are symptomatic. For AQP2, 8 disease-causing mutations were identified in 8 families (of these, 3 mutations in 3 families were previously reported). Two missense mutations showed a recessive inheritance, while one missense mutation (R254Q) and five deletion mutations (1~10nt) in the C-terminus of AQP2 showed a dominant inheritance, confirming its importance in AQP2 pathophysiology.

Conclusions: In Japanese NDI, most families (82%) are related to AVPR2 and 11% are to AQP2. A small portion of the families (7%) without any obvious mutations may imply the presence of unknown NDI-causing genes.

Prominent Neointima Formation Is Common in Veins Utilized for AV Fistula Creation: The Hemodialysis Fistula Maturation (HFM) Study

Charles E. Alpers,[1] The HFM Study Group.[2] *[1]Pathology, Univ. of Washington, Seattle, WA; [2]Cleveland Clinic.*

Background: A major cause of native arteriovenous fistula (AVF) failure is stenosis as a result of venous neointimal hyperplasia (VNH). Little is known about the morphology of veins at the time of AVF creation that may contribute to future AVF stenosis and failure.

Methods: Segments of vein used for anastomosis creation were harvested at the time of AVF creation from 303 HFM Study participants with advanced CKD or ESRD and analyzed histologically. Intimal and medial wall thickness and length of the internal and external elastic lamina were quantified by morphometry. Intimal cells were assessed by immunohistochemistry and extracellular matrices (ECM) were analyzed with Movat's stain.

Results: A major finding was a neointima (N) that was present in 87.8% of the samples in which a full circumferential vein structure was present in histologic sections (n=204). The neointima was usually irregularly thickened (Fig. A), sometimes concentric (Fig. B), and all contained α-smooth muscle actin expressing cells of smooth muscle or myofibroblast origin. Proteoglycans (P) constituted the predominant matrix in the neointima. A novel finding was large aggregates of collagen (C), present in 82% of vein samples within the media (M) of vessel walls, in addition to collagen which also was present in the neointima. Figures A and B show abnormalities typical of a large majority of vein samples analyzed; Figure C shows one of the veins without neointima formation.

Conclusions: Among HFM Study participants, we observed pre-existing abnormalities, with neointimas and prominent accumulation of ECM, in the great majority of veins used for AVF creation. Outcome studies to determine the importance of these common abnormalities on fistula maturation and use are underway.

Notch Signaling Regulates CKD-Induced Endothelial-Mesenchymal Transition and Neointima Formation in a Mouse Model of Arteriovenous Fistula

Yun Wang,[1,2] Anlin Liang,[1] William E. Mitch,[1] Jizhong Cheng.[1] *[1]Division of Nephrology, Baylor College of Medicine, Houston, TX; [2]Department of Cell Biology, Third Military Medical University, Chongqing, China.*

Background: A functional arteriovenous fistula (AVF) is the Achilles heel of dialysis patient. An intact endothelium can prevent neointima formation in AVF because endothelial cells (ECs) dysfunction causes vascular remodeling. Indeed, CKD patients with failed AVFs have biomarkers of endothelial dysfunction in the nonfunctioning AVF.

Methods: To study mechanisms of CKD-induced AVF failure, we created a mouse model of AVF by anastomosing common carotid artery and internal jugular vein. At different times, the molecular events in the AVFs were explored.

Results: The endothelium in AVFs from humans or CKD mice had positive staining of mesenchymal markers (SMA-α and FSP-1), indicating there was endothelial cell to mesenchymal transition (EnMT). ECs treated with serum from CKD mice had increased Jagged 1 and Notch activation VS results in ECs exposed to serum from control mice. With CKD, Notch and its downstream transcription factor, RBP-Jk, were significantly activated in AVF VS controls ($P < 0.05$). Overexpression of Jagged 1 or expose to TGF-β1 decreased VE-cadherin expression in ECs, while the expression of SMA-α and FSP-1 were increased. Pretreatment with the Notch inhibitor, DAPT, blocked these markers of EnMT. Notably, RBP-Jk KO preserved the endothelial barrier function and ameliorated the increased permeability associated with Jagged 1 overexpression or TGF-β1 treatment in ECs. Similarly, RBP-Jk KO suppressed Notch activation- or TGF-β1- induced transmigration of bone marrow inflammatory cells. We also found that EnMT in AVF was suppressed in endothelial-specific RBP-Jk knockdown mice (RBP-Jk$^{+/-}$/VE-cadherin-Cre). Thus, the neointima in AVFs created in RBP-Jk knockdown mice was ~ 40% less VS results in WT mice despite CKD ($P < 0.05$).

Conclusions: We conclude that CKD induces Notch activation as well as EnMT that results in accelerated AVF failure. Blocking Notch in the endothelium suppresses CKD-mediated neointima formation. Notch might be a target for suppressing neointima formation in AVFs.

Development of Novel Bioengineered Grafts for Hemodialysis Vascular Access

Yan-Ting E. Shiu,[1] Huan Li,[1] Ilya S. Zhuplatov,[1] Christi M. Terry,[1] Alfred K. Cheung,[1] Wei Tan.[2] *[1]Medicine, Univ of UT, Salt Lake City, UT; [2]Mechanical Engineering, Univ of CO, CO.*

Background: Arteriovenous (AV) dialysis grafts made of polytetrafluoroethylene are susceptible to stenosis. Tissue-engineered dialysis grafts using autologous vascular cells and biomaterials have shown success in clinical trials, but their potential is tempered by the shortage of autologous cell sources, long lead time, high costs and storage complications. We thus aimed to design a degradable graft that readily allows grafting of allogeneic mesenchymal stem cells (MSCs) for vessel generation in vivo.

Methods: We have developed an inexpensive biodegradable graft, consisting of a bilayered scaffold composed of a nanofibrous heparin-impregnated polycaprolactone inner layer and a porous collagen-based outer layer. The graft lumen can be seeded with allogeneic MSCs from bone marrow, and the graft possesses compliance (4.5% / mmHg $X10^2$) comparable to native blood vessels, and burst strength (680-800 mm Hg) and permeability (500-600 ml/cm^2.min) values suitable for implantation. Grafts were implanted as carotid artery interposition grafts in sheep. In the pig, a seeded graft was placed as a jugular vein interposition graft and an acellular graft was placed as a carotid-jugular AV graft.

Results: The interposition grafts in sheep remained patent for one month, the latest time point tested. Acellular grafts (n=4) had significant outward remodeling mainly by proliferation and migration of adventitial fibroblasts, and had no PECAM+ cells on the lumen. MSC-seeded grafts (n=2) showed significant reduction in the fibrotic process, and PECAM+ cells were found on the lumen, suggesting the possibility of MSCs transforming into endothelial-like cells. The MSC-seeded interposition graft in pig remained patent for at least 3 weeks after implantation. The acellular AV graft in pig withstood arterial hemodynamic forces and was patent for 2 weeks.

Conclusions: Allogeneic MSCs on the polymeric vascular graft appeared to be non-immunogenic and have anti-fibrotic and pro-regenerative potential in sheep. Preliminary graft results in the pig model are promising warranting further exploration.

TH-OR063

True Benefit or Selection Bias?: Vascular Access and Mortality in the Elderly

Vanessa Grubbs,[1] Monnie Wasse,[2] Barbara A. Grimes,[1] Kirsten L. Johansen.[3] *[1]UCSF; [2]Emory; [3]UCSF-VAMC.*

Background: Prior studies suggest a survival benefit from the "fistula (AVF) first" initiative among the elderly, but the extent to which this benefit is driven by selection of healthier patients for AVF has not been fully explored. We hypothesized that functional status and hospital days prior to dialysis initiation partially explain the increased mortality associated with catheter use.

Methods: From the U.S. Renal Data System 2005-2007, we included 117,277 incident hemodialysis patients aged 67-90 years. Using proportional hazards models, we examined the association between initial vascular access and mortality through 2010 after accounting for functional status at dialysis initiation (institutionalized, need assistance with activities of daily living, or inability to ambulate or transfer) and number of hospital days in the two years prior to dialysis initiation. We defined access as AVF, graft (AVG), catheter with maturing AVF, catheter with maturing AVG, or catheter only.

Results: Of those with catheter, 25.5% had limited functional status vs. 10.8% of those with AVF. Those with catheter had 3-fold more prior hospital days (mean 18.0 vs. 5.4) than those with AVF. Median survival was shortest among those with catheter (Table). After adjusting for demographics, co-morbid conditions, and nephrology care prior to dialysis initiation (Model 1), all access types compared to AVF were associated with higher mortality. This finding was modestly attenuated after additionally adjusting for functional status and prior hospital days (Model 2).

Mortality by access type

Access type	Time to death in days, median (IQR)	unadjusted, HR (95% CI)	Model 1, HR (95% CI)	Model 2, HR (95% CI)
AVF	1,070 (456, 1548)	1.0	1.0	1.0
AVG	905 (337, 1533)	1.21 (1.16-1.25)	1.20 (1.15-1.26)	1.17 (1.12-1.22)
catheter with AVF	778 (263, 1447)	1.34 (1.31-1.38)	1.22 (1.19-1.26)	1.17 (1.14-1.21)
catheter with AVG	716 (214, 1437)	1.46 (1.40-1.53)	1.32 (1.26-1.39)	1.23 (1.17-1.29)
catheter only	374 (101, 1078)	1.94 (1.90-1.99)	1.60 (1.55-1.64)	1.48 (1.44-1.53)

Conclusions: Mortality risk among elderly with non-AVF access is attenuated, but not eliminated, after accounting for functional status and prior hospitalization.

TH-OR064

First Year Hospitalization in Incident Hemodialysis versus Peritoneal Dialysis Patients

Eduardo K. Lacson,[1] Nien-chen Li,[1] Raymond M. Hakim,[2] J. Michael Lazarus,[3] Franklin W. Maddux,[1] Joseph P. Pulliam.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Vanderbilt University, Nashville, TN; [3]University of North Carolina, Chapel Hill, NC.*

Background: Recent modality analyses attributed the survival advantage observed in Canadian peritoneal dialysis (PD) patients largely to hemodialysis (HD) catheter use. We sought to compare hospitalization from all causes during the first year between incident PD and HD patients, then evaluating hospitalization risk for patients by access type: HD catheter vs. arteriovenous access.

Methods: Incident patients who started dialysis in Fresenius Medical Care North America facilities in 2009 were compared with regards to time to first hospitalization during their first year using an intention to treat methodology. Cox models were adjusted for case-mix and the first available admission quality indicator labs (albumin, hemoglobin, & phosphorus). HD patients were also stratified by catheter vs. non-catheter access.

Results: 58% of 1,677 PD and 69% of 24,516 HD patients were hospitalized during follow-up. Hospitalization rates were 0.92 (PD) and 1.48 (HD) per patient-year, with HD catheter patients at 1.69 vs 1.03 (no catheter) per patient-year (all p<0.001). PD patients were younger (57 vs. 64 years), admitted later (admission vintage 22 vs. 11 days), had fewer black patients (21% vs. 31%), larger BMI (32 vs. 31 kg/m^2) and had fewer comorbidities (DM: 53% vs. 62%, CHF: 3% vs. 4%, PVD: 6% vs. 10%, & Amputations: 3% vs. 5%) than HD patients all p<0.001), although both cohorts had 56% males. The adjusted hazard ratio for hospitalization was 0.65 (0.61-0.70) favoring PD. The corresponding adjusted hazard ratios were 1.22 (1.13-1.32) for non-catheter and 1.64 (1.53-1.75) for HD catheter patients, compared to PD (all p<0.001).

Conclusions: In this national US cohort, incident PD patients had lower hospitalization risk than HD patients during the first year, despite adjusting for favorable case-mix. Stratifying by access type did not abrogate the difference in hospitalization risk in non-catheter access patients but the associated risk in HD catheter patients was much higher.

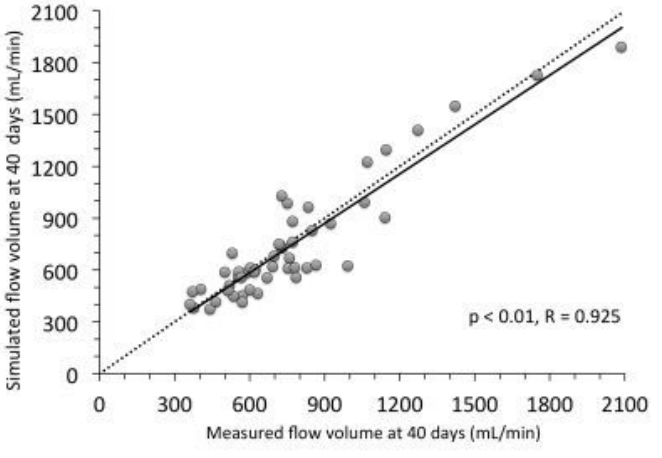
TH-OR065

Validation of a Patient-Specific Hemodynamic Computational Model for Planning Vascular Access Surgery in Hemodialysis Patients Simone Manini,[1] Anna Caroli,[1] Luca Antiga,[1,3] Stefano Rota,[4] Giuseppe Remuzzi,[1,4] Andrea Remuzzi.[1,2] *[1]Biomedical Engineering Department, Mario Negri Institute, Ranica, Bergamo, Italy; [2]Industrial Engineering Department, Bergamo University, Bergamo, Italy; [3]Orobix S.r.l, Bergamo, Italy; [4]Unit of Nephrology and Dialysis, Ospedali Riuniti, Bergamo, Italy.*

Background: Short- and long-term vascular access (VA) dysfunctions, including non-maturation and thrombotic complications, are the major cause of morbidity and hospitalization in hemodialysis (HD) patients. The extent of this major clinical problem points out the need of prediction and prevention of VA dysfunctions.

Methods: We developed specific 1D computational vascular network modelling tools (archTk) to simulate pre- and post-surgery blood flow, including vascular adaptation due to vessel wall remodeling up to 40 days after surgery. The advantage of this computational modeling is the ability to quantitatively estimate hemodynamic results with low computational cost. For model validation, a multicenter longitudinal clinical prospective observational study was performed in patients with end stage renal disease awaiting VA creation for HD treatment, in order to collect longitudinal data on arm vasculature and VA function by ultrasounds.

Results: Sixty-five patients with newly created arteriovenous fistula (AVF) were included in the simulation dataset and divided in 4 groups, based on AVF configuration. Predicted blood flow showed good agreement with measured values 40 days after surgery, regardless of AVF configuration.



Conclusions: These computational tools allowed to reliably predict patient-specific blood flow increase resulting from VA creation and vascular adaptation. This innovative approach may help the surgeon to choose the most appropriate AVF location and configuration, to reduce AVF primary non-function and to obtain a lower incidence of short- and long-term VA dysfunctions.

TH-OR066

Vitamin D Therapy and Arteriovenous Fistula (AVF) Maturation in End Stage Renal Disease (ESRD) Patients M. Salman Singapuri, Monnie Wasse. *Renal Division, Emory University School of Medicine, Atlanta, GA.*

Background: Vitamin D therapy reduces development of neointimal hyperplasia in animal models and attenuates markers of vessel remodeling in vitro. We tested the effect of vitamin D3 on AVF maturation in a double-blinded, placebo-controlled pilot study.

Methods: Fifty-two ESRD patients preparing to undergo AVF creation were randomly assigned to receive either 200,000 IU of oral cholecalciferol once weekly for 3 weeks (total 600,000 IU), or placebo. Blood was collected at study enrollment and 3 weeks after study drug completion, followed by surgical AVF creation within 3 weeks. The outcome was AVF maturation, defined as the ability to cannulate the AVF with two large bore needles at ≥ 6 consecutive dialysis sessions, and achievement of an AVF Qb >300 ml/min, assessed at six months.

Results: At baseline 94% of all subjects were 25(OH) D insufficient (< 30 ng/mL); mean 25 (OH) D was 16 ± 7 ng/mL, and mean 1,25 (OH) D was 17 ± 9 pg/mL. Other baseline characteristics were similar between the study groups, except for hemoglobin levels (p<0.04). Post-treatment, 25(OH) D sufficiency (≥ 30 ng/mL) was achieved in 91% of cholecalciferol-treated patients (mean 25(OH) D= 52 ± 18 ng/mL) and only 14% of the placebo-treated, while 1,25(OH) D significantly increased in cholecalciferol-treated patients (p<0.001). There was no significant change in serum calcium, phosphorus or iPTH. At follow-up, among patients with an AVF outcome (n=44), 41% of cholecalciferol-treated and 50% of placebo-treated patients achieved AVF maturation (p=0.74). Following adjustment, there was no association between AVF maturation and baseline, post-treatment or change in 25 (OH) D levels (p=0.9, 0.5, 0.5, respectively), or 1,25 (OH)D levels (p=0.5, 0.6, 0.4, respectively).

Conclusions: Although high-dose, short-term vitamin D3 supplementation is safe and effective, peri-operative 25(OH) D sufficiency did not improve AVF maturation. Longer-term studies may be valuable in assessing the role of correction and maintenance of vitamin D on AVF outcome.

Whole Exome Resequencing and Homozygosity Mapping Identify Mutation of ADCK4 as a Novel Single-Gene Cause of Steroid Resistant Nephrotic Syndrome Shazia Ashraf,[1] Heon Yung Gee,[1] Virginia Vega-Warner,[1] Humphrey Fang,[1] Jameela Abdulaziz Kari,[2] Detlef Bockenhauer,[3] Robert Kleta,[3] Letian Xie,[4] Catherine F. Clarke,[4] Friedhelm Hildebrandt.[1,5] *[1]Departments of Pediatrics and of Human Genetics, University of Michigan; [2]Department of Pediatrics, King Abdulaziz University, Saudi Arabia; [3]Pediatric Nephrology, Great Ormond Street Hospital and UCL Institute of Child Health, United Kingdom; [4]Department of Chemistry and Biochemistry, University of California; [5]Howard Hughes Medical Institute, University of Michigan.*

Background: Identification of single-gene causes of steroid resistant nephrotic syndrome (SRNS) has furthered the understanding of its pathogenesis. However, additional genes and disease mechanisms remain obscure. To identify a new causative gene for SRNS, we combined homozygosity mapping and whole exome resequencing (WER).

Methods: In two consanguineous siblings with SRNS, homozygosity mapping yielded 5 segments of homozygosity by descent (~115 Mb). We performed WER in one sibling to identify the underlying disease-causing mutation.

Results: We detected a homozygous missense mutation (p.R178W) in the *ADCK4* (*aarF domain containing kinase 4*) gene in an amino acid residue conserved to prokaryotes and the mutation segregated in this family. ADCK4 participates in the biosynthesis of coenzyme Q_{10} (CoQ_{10}) and has a high sequence similarity to ADCK3, the ortholog of yeast Coq8. Primary CoQ_{10} deficiencies due to mutations in ubiquinone biosynthesis genes have previously been identified in patients with NS. We identified recessive mutations in *COQ6* as a novel cause of SRNS that can be treated with the innocuous food supplement CoQ_{10}. By coimmunoprecipitation, we show that ADCK4 interacts with COQ6 and COQ7 in human cultured podocytes. Knockdown of ADCK4 in cultured podocytes results in the decrease of their migratory phenotype. ADCK4 is strongly expressed in human glomerular podocytes and localizes to mitochondria.

Conclusions: We, thus, identified mutation of *ADCK4* as a novel single-gene cause of SRNS. Better understanding of genes involved in CoQ_{10} biosynthesis will provide a therapeutic basis for the use of CoQ_{10} in nephrotic syndrome.

Rhophilin-1 Is a Key Regulator of the Podocyte Actin Cytoskeleton and Is Required for Glomerular Filtration Mark Lal, Ann-charlotte M. Andersson, Karl Tryggvason. *Matrix Division, Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden.*

Background: The podocyte is a critical cellular component of the glomerular filtration barrier and dysfunction of this cell type is implicated in most glomerulopathies. Here, we identify and describe the functional role of a novel podocyte–specific protein, Rhophilin-1.

Results: Immunohistochemical analysis indicates that Rhophilin-1 is uniquely expressed in podocytes of both mouse and human glomeruli. *Rhpn1* knockout mice were phenotypically normal at birth but developed progressive albuminuria from about two weeks of age. Histological examination of kidneys from severely albuminuric mice revealed tubular protein casts and FSGS-like lesions as well as glomerular hypertrophy. Immunochemical analysis of a host of podocyte-marker proteins indicated that glomerular dysfunction in *Rhpn1*$^{-/-}$ was not likely a result of any overt alterations in the pattern of their expression. Widespread podocyte foot process effacement as well as thickening of the glomerular basement membrane were readily detected upon electron microscopy and are indicative of a principal podocyte insult likely involving impaired cytoskeleton dynamics. In vitro culture of primary glomerular explants indicates that Rhophilin-1 is enriched at the plasma membrane leading edge of podocytes where it elicits reorganization of the actin network from the cell body towards lamellipodia. This effect of Rhophilin-1 is mediated by inhibition of RhoA-dependent phosphorylation of myosin light chain and actin stress

fiber formation. Conversely, a lack of Rhophilin-1 in *Rhpn1*$^{-/-}$ mice glomeruli was correlated with increased RhoA signaling and myosin light chain hyper phosphorylation in podocyte foot processes. Interestingly, conditional deletion of RhoA in podocytes in vivo did not result in glomerular damage, but when bred onto a Rhophilin-1 null background, double deletion mutants presented with nephrotic syndrome and death.

Conclusions: Taken together, our results indicate that Rhophilin-1 is essential for the integrity of the glomerular filtration barrier and that this protein is a master regulator of Rho-dependent signaling and cytoskeleton architecture in podocytes.

Loss of Robo2 Alleviates Podocyte Structural Defects in Nephrin Null Mice

Anna Pisarek-Horowitz,[1] Hila Milo Rasouly,[1] Xueping Fan,[1] David J. Salant,[2] Weining Lu.[2] *[1]Boston University, Boston, MA; [2]Boston University Medical Center, Boston, MA.*

Background: Robo2 is the cell surface receptor for the repulsive guidance cue Slit and is involved in axon guidance and neuronal migration. Nephrin is a podocyte slit-diaphragm protein that functions in the kidney glomerular filtration barrier. Previous research has shown that engagement of nephrin ectodomain can induce localized actin polymerization. Nephrin homozygous knockout mice develop characteristic phenotypes including dilation of the Bowman's space, abnormally broad foot processes, and absence of glomerular slit-diaphragms. Our recent in vitro studies show that Robo2 is expressed in podocytes where it forms a complex with nephrin through the adaptor protein Nck and opposes nephrin-induced actin polymerization. However, it is not clear if loss of Robo2 would modify the podocyte phenotype in nephrin null mice in vivo.

Methods: To test the hypothesis of a genetic interaction between Robo2 and nephrin, we generated Robo2-nephrin double knockout mice and analyzed their survival and the glomerular phenotype by light and electron microscopy.

Results: Like nephrinsingle homozygotes, all Robo2-nephrindouble knockout mice died within 10 hours after birth. By histological analysis, we found that the morphology of glomeruli in the Robo2-nephrin double homozygous knockout mice appeared relatively normal compared with the severe phenotype in nephrin single homozygousmice. Detailed analysis of podocyte ultrastructure by scanning electron microscopy revealed that over 90% glomeruli in nephrin single homozygous knockouts lost the interdigitating podocyte foot process structure. Remarkably, the interdigitating pattern of the podocyte foot processes was restored in 75% glomeruli from Robo2-nephrin double homozygous knockout newborn mouse kidneys.

Conclusions: These results suggest that a concomitant loss of Robo2 and nephrin alleviates the podocyte foot process structural defect in mice. Our findings indicate that the Robo2-Nck-nephrin physical interactions have a substantial effect on podocyte foot process morphology in vivo when the levels of expression of Robo2 and nephrin are genetically altered.

Homozygosity Mapping and Whole Exome Resequencing Identify Mutation of *MED28* as a Novel Single-Gene Cause of Nephrotic Syndrome

Humphrey Fang,[1] Heon Yung Gee,[1] Andrew Cluckey,[1] Shazia Ashraf,[1] Svjetlana Lovric,[1] Virginia Vega-Warner,[1] Abdul M.D. Majid,[2] Richard S. Trompeter,[3] Friedhelm Hildebrandt.[1,4] *[1]Department of Pediatrics and Communicable Diseases, University of Michigan, Ann Arbor, MI; [2]Pediatric Nephrology, Dubai Health Authority, Dubai, United Arab Emirates; [3]Pediatric Nephrology, Great Ormond Street Hospital, London, United Kingdom; [4]Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI.*

Background: A large proportion of single-gene causes of nephrotic syndrome (NS) remains genetically unsolved, and the discovery of novel NS genes may shed light on its pathogenesis.

Methods: In order to identify new genes for NS, we performed homozygosity mapping with whole exome resequencing in a cohort of 63 sibling cases of NS. The expression and function of MED28 were examined in podocytes and rat kidney tissues using biochemical and molecular approaches.

Results: In one affected sibling pair, a homozygous truncating mutation (p.Y163X) was found in the *MED28* gene (*mediator complex subunit 28*). This mutation segregated with the affected status of each sibling and was confirmed by Sanger sequencing. MED28 has been previously characterized as a direct interaction partner of the neurofibromatosis 2 tumor supressor protein (NF2/Merlin), Grb2, and Src-family kinases, e.g. FYN, LCK. In addition, MED28 has been shown to localize not only to the nucleus where it regulates transcription, but also to the cytoplasm where it associates with the actin cytoskeleton. By immunofluorescence of MED28 in rat glomeruli, we showed that MED28 localized to both the nucleus and the cytoplasm of podocytes. MED28 also colocalized with PLCE1, which is mutated in NS in humans, and RHOA, which has been implicated in a mouse model of NS. We also show that overexpression of mutant MED28 (p.Y163X) significantly decreased RhoA activation, but had no effect on the activation of Rac1 and CDC42.

Conclusions: We propose that MED28 has a role in RhoA-mediated cellular signaling, and that mutation of MED28 may be a novel single-gene cause of NS.

GLEPP1 Enforces the Integrity of the Glomerular Silt Diaphragm by Activation of Src Kinases and Modulation of Focal Adhesions

Eva Koenigshausen, Laura Gerbaulet, Sarah Grabowski, Paul Probst, Magdalena Woznowski, Ivo Quack, Lars C. Rump, Lorenz Sellin. *Nephrology, Heinrich Heine University, Duesseldorf, Germany.*

Background: Proteinuria is one of the symptoms of inherited and acquired glomerular kidney diseases. Proteinuria evolves out of the damage of the glomerular filter. One major components of the glomerular slit diaphram is nephrin, which is phosphorylated by src kinases. A loss of nephrin out of the glomerular silt, for example by endocytosis, results in proteinuria. GLEPP1 is a receptor tyrosine phosphatase in the podocyte foot process. Recently, mutations in the GLEPP1 gene were shown to be associated with FSGS in childhhood. The precise function of GLEPP1 is not fully understood.

Methods: Cells expressing nephrin, GLEPP1, β-arrestin2 and src-kinasen were used. After lysis Co-immunoprecipitations were done and the binding partners deteced by western blot. To visualize the activation of src-kinases phosphospecific antibodies for Y527 and Y416 were used. Cos7 cells were retrovirally transduces with GLEPP1 or a control. In a wound scratch assay cell migration was documented after 12h and 24h. For immunofluorescence Glepp1 expressing cos7 cells were used. After fixation the cells were stained for phosphorylated tyrosine, FAK and GLEPP1. Proteinuria in GLEPP1 -/- deficient mice on a 129P3/J background with an age of 6 months was analysed by a commassie.

Results: GLEPP1 interacts with podocin, src, fyn and paxillin. GLEPP1 ameliorates the nephrin interaction with β-arrestin2 and inhibits thereby the nephrin endocytosis. GLEPP1 activates src and fyn by dephosphorylation at their Y527. The activation of src and fyn is confirmed by their autophosphorylation at Y416. Cells stabely transduced with GLEPP1 present an increased migration. GLEPP1 expressing cells present more focal adhesions in the immunoflurescence compared to controls. GLEPP1 -/- mice are proteinuric at the age of 6 months.

Conclusions: Glepp1 stabelizes the glomerular slit diaphram by activation of src-kinases and an increased tunrover of focal adhesions. Patients with a GLEPP1 mutation are lacking the GLEPP1 enabled dynamic regulation of the podocyte foot processes and suffer from FSGS.

TH-OR073

A Chemical Chaperone Improves Defective Secretion of a Mutant Laminin Associated with Human Congenital Nephrotic Syndrome

Ying M. Chen,[1] Yamato Kikkawa,[2] Joseph T. Marmerstein,[1] Jeffrey H. Miner.[1] *[1]Renal Division, Washington University, St. Louis, MO; [2]Laboratory of Clinical Biochemistry, Tokyo University of Pharmacy and Life Sciences, Tokyo, Japan.*

Background: Laminin beta 2 (LAMB2) is a component of Laminin-521, the major laminin of the glomerular basement membrane (GBM). Null mutations in *LAMB2* cause Pierson syndrome (congenital nephrotic syndrome with severe extrarenal defects). In contrast, patients with missense *LAMB2* mutations, such as C321R, display congenital nephrotic syndrome with much milder extrarenal symptoms. Here we investigated how the C321R mutation causes proteinuria.

Methods: We generated 3 independent lines of C321R-LAMB2 transgenic mice, each with differing podocyte expression levels (Tg^{Lo}, Tg^{Med}, and Tg^{Hi}) and bred them onto the *Lamb2* null background.

Results: In the 1st postnatal month, *Lamb2*$^{-/-}$ mice exhibited proteinuria that was attenuated in a dose-dependent fashion by deposition of C321R-LAMB2 into the GBM. However, proteinuria increased in all 3 lines, leading to renal failure. Analysis of transgene-derived mRNA and protein levels suggested that ample levels of mRNA were associated with unexpectedly low levels of C321R-LAMB2 in the GBM, suggesting a defect in secretion. *In vitro* studies demonstrated an inhibition of secretion of C321R-LAMB2 that was associated with intracellular retention; similarly, significant podocyte endoplasmic reticulum (ER) distension in Tg^{Med} or Tg^{Hi} mutants was observed, presumably due to accumulation of the mutant protein. Additionally, C321R-LAMB2 expression upregulated the ER chaperones Bip and protein disulfide isomerase, suggesting a protein folding defect. Chemical chaperones such as taurodeoxycholic acid (TUDCA) can assist protein folding in the ER and facilitate the trafficking of mutant proteins. TUDCA treatment of cells expressing C321R-LAMB2 greatly increased its secretion into the medium.

Conclusions: These results may have significant therapeutic implications for the treatment of proteinuria in patients carrying the C321R and perhaps other missense LAMB2 mutations.

TH-OR074

The Role of Ubiquitin C-Terminal Hydrolase L1 (UCH-L1) in ACTN4-Associated Focal Segmental Glomerulosclerosis (FSGS)

Naomi C. Read,[1,2] Josee Coulombe,[2] Doug A. Gray,[2] Chris R. Kennedy.[1,2] *[1]Cellular and Molecular Medicine, University of Ottawa, Ottawa, ON, Canada; [2]Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: Podocyte UCH-L1 is upregulated in ACTN4-associated FSGS and may promote ubiquitin proteasome system (UPS) and macroautophagy (MA) impairment. Loss of UCH-L1 should improve podocyte injury in ACTN4-associated FSGS.

Methods: UCH-L1+/- and K256E-ACTN4^{pod+} mice were crossed to generate K256E-ACTN4^{pod+}/UCH-L1-/- mice. Glomeruli were scored for sclerosis using PAS stained kidney sections. Albuminuria (albumin/creatinine) was determined by ELISA. Conditionally

immortalized podocytes were infected with adenovirus containing GFP, WT or K256E α-actinin-4 (αA4) for 3 days and treated with LDN57444 (UCH-L1 inhibitor; 50μM; 24h), or mechanically stretched (24h). Protein expression and localization were assessed by western blot and IF.

Results: K256E-ACTN4^{pod+} mice show segmental and global (35.5% and 31.3% of glomeruli) glomerulosclerosis, with 2519μg/mg albuminuria by 10 weeks of age. K256E-ACTN4^{pod+}/UCH-L1-/- mice exhibit reduced segmental (14.2%) and global (16.6%) glomerulosclerosis at 10 weeks with 569μg/mg albuminuria. Renal ubiquitin (Ub) is elevated in K256E-ACTN4^{pod+} mice while levels are normalized in K256E-ACTN4^{pod+}/UCH-L1-/- mice. K256E αA4 levels were not reduced by UCH-L1 inhibition nor was peripheral localization ameliorated. Similar to WT αA4 expressing cells, UCH-L1 inhibition increased poly-Ub proteins and cleaved caspase-3 in K256E αA4 expressing cells. LC3II levels were also elevated, suggesting MA activation. Interestingly, UCH-L1 inhibition led to loss of UCH-L1 expression in podocytes expressing GFP or WT αA4 but not K256E αA4. Preserved UCH-L1 expression may be due to an impaired UPS or MA pathway. Similar reductions of mono-Ub correlated with UCH-L1 expression. Finally, mechanical stretch decreased LC3II levels in K256E αA4 expressing podocytes, suggesting MA impairment.

Conclusions: Our data suggest that K256E αA4 is associated with UPS/ MA dysfunction and that loss of UCH-L1 may relieve these pathways in a mouse model of FSGS, reducing poly-Ub K256E αA4 aggregates.

TH-OR075

Role of p120 Catenin in Glomerular Function Denise K. Marciano,[1] Bing Liu,[1] Chao-zong Lee,[2] Louis Reichardt.[2] *[1]Medicine, Division of Nephrology, University of Texas Southwestern Medical Center, Dallas, TX; [2]Physiology, University of California, San Francisco, San Francisco, CA.*

Background: Diseases of the glomerulus account for more than 50% of all cases of end stage renal disease, yet few targeted therapies exist to date. This is due in part to our limited understanding of the molecules and signaling pathways that develop and maintain glomerular function. Cell-cell adhesive junctions between glomerular podocytes act as a selective barrier for passage of filtrate into Bowman's space. Similarly, adhesive junctions between parietal epithelial cells have been proposed to act as a selective barrier to retain glomerular filtrate within Bowman's space. While there is considerable knowledge of some of the adhesive proteins involved in podocyte cell-cell junctions, little is known about the role of the adherens junction proteins, namely cadherins and p120 catenin (p120ctn) in glomerular function.

Methods: We used a mouse model to conditionally delete p120ctn from developing nephrons.

Results: We found that p120ctn is produced in developing podocytes as well as parietal epithelial cells. Our data showed that mice lacking p120ctn from developing nephrons acquire proteinuria, inflammation, and focal segmental glomerulosclerosis, a common glomerular pathology in humans. Inflammation was a prominent aspect of this phenotype and was associated with cell-autonomous, as well as non-cell autonomous, upregulation of NF-kB and NF-kB targets. We examined this further by performing gene expression analysis in control and p120ctn-depleted renal epithelial cells and found upregulation of NF-kB targets, as well as several additional genes.

Conclusions: Together these results implicate a role for p120ctn in developing podocytes and/or parietal epithelial cells and suggest that dysregulation of NF-kB signaling may play a critical role in the glomerular function.

TH-OR076

The Effects of Rac1 Deletion on Short and Long-Term Injury to the Podocyte Stephanie Wylie,[1] Masashi Nishio,[2] Kevin B. Atkins,[2] Matthias Kretzler,[2] Jeffrey B. Hodgin.[1] *[1]Pathology, University of Michigan, Ann Arbor, MI; [2]Internal Medicine - Nephrology, University of Michigan, Ann Arbor, MI.*

Background: Podocyte function relies on maintenance of a complex cytoarchitecture through precise regulation of the actin cytoskeleton. The Rho GTPases are a family of 20+ intracellular signaling molecules with multiple cellular effects, but are best known for cytoskeleton assembly and organization. Pharmacologic evidence indicates that inhibition of the RhoGTPase Rac1 imparts a protective podocyte phenotype, in part by abrogating foot process effacement and proteinuria. We hypothesized that podocyte-specific deletion of Rac1 would be protective in mouse models of podocyte and glomerular injury.

Methods: Podocyte-specific Rac1 deletion in the mouse (podo-Rac1-/-), using Cre-lox technology, showed normal podocyte structure and function. In addition, podo-Rac1-/- mice displayed no podocyte foot process effacement with protamine sulfate infusion, a short-term podocyte injury model. To investigate the effect of podocyte Rac1 deletion in the setting of chronic glomerular damage, we employed a hypertensive model using deoxycorticosterone acetate (DOCA) implants after uninephrectomy (UNX) in mice given high-salt drinking water (UNX/DOCA-salt model).

Results: After 4 weeks, both podo-Rac1-/- and control mice showed similar elevations in blood pressure, kidney and left ventricular weight compared to sham groups. As expected, uninephrectomy and DOCA-salt elicited proteinuria and glomerulosclerosis in control mice. However, UNX/DOCA-salt podo-Rac1-/- mice were not protected, but instead had exacerbated albumin to creatinine ratios at 2 (46.3±6.5 vs. 26.4±4.2 mg/g, $P<0.05$) and 4 weeks (54.3±11.7 vs. 32.7±4.5 mg/g, $P=0.19$) after UNX/DOCA, and twice the glomerulosclerosis by 4 weeks (5.8±0.9 vs 2.7±0.0 glomeruli per 100). Podocyte foot process effacement was focal, but evident in both control and podo-Rac1-/- treated mice, suggesting Rac1-independent pathways may mediate podocyte cytoskeleton rearrangement after injury.

Conclusions: Thus the loss of Rac1 appears to impair immediate cytoskeletal responses in acute injury, but this may predispose to chronic progression of disease.

Conditioned Nanofibers with Embryonic Stem Cells Improve Nephrotoxicity and Survival in Cisplatin-Induced Renal Failure Yin Wang, Farhad R. Danesh. *Medicine/Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Cisplatin and other platinum derivatives are the most commonly used chemotherapeutic agents to treat solid tumors. Several strategies have been proposed with the potential to improve the nephrotoxicity and improve cancer patient survival without impairing the chemotherapeutic effect of cisplatin. We have previously reported that conditioned nanofibers with embryonic stem cells (ESCs) can protect against kidney injury in several models of AKI (Wang et al, JASN 2011). In this study, we investigated the protective effects of conditioned nanofibers with ESCs on cisplatin-induced nephrotoxicity.

Methods: Conditioning of nanofibers was performed by exposing nanofibers (100μl) to ESCs for 24 hours as previously described (Wang et al, JASN 2011). Secretome from ESCs was concentrated using centrifugal filters with a 3-kD molecular weight cut-off (Amicon Ultra-PL3). Mice were allocated to receive an IP injection of: 1) conditioned nanofibers (100μl/day), 2) concentrated secretome from ESCs (100μl/day) or 3) non-conditioned nanofibers (100μl/day) for 3 consecutive days. At the 4th day, mice received a single IP injection of cisplatin (20mg/kg). Mice were sacrificed at day6 after cisplatin injection.

Results: We found that conditioned nanofibers with ESCs significantly improved the survival rate of cisplatin-treated mice compared with all other groups (91% vs. 57% and 0% respectively, $P<0.001$). Serum levels of BUN and creatinine were also significantly lower in mice treated with conditioned nanofibers. PAS staining and TUNEL assays indicated that tubular damage score and tubular apoptosis were improved by using conditioned nanofibers. We also examined expression levels of BAX and ROCK1 activity in the kidney. Cisplatin increased the levels of BAX protein and ROCK1 activity, whereas these changes were prevented in mice treated with conditioned nanofibers.

Conclusions: This study demonstrates the first evidence for the renoprotective effect of conditioned nanofibers with ESCs on cisplatin-induced AKI. These findings provide a novel therapeutic strategy in preventing cisplatin-induced AKI.

TH-OR078

The Effect of Nrf2 Activation by CDDO-Im on Progression of Chronic Kidney Disease after Acute Kidney Injury in Mice Elizabeth M. Higbee,[1] Sanjeev Noel,[1] Thomas W. Kensler,[2] Sekhar P. Reddy,[3] Hamid Rabb.[1] *[1]Johns Hopkins Medical Institutions; [2]University of Pittsburgh; [3]University of Illinois.*

Background: The progression of acute kidney injury (AKI) to chronic kidney disease (CKD) is an important problem, involving unresolved oxidative stress and inflammation. Transcription factor Nrf2 is a crucial regulator of antioxidant gene expression that is known to confer protection against AKI (KI, 76:277, 2009). Recently, increased Nrf2 activation by prolonged treatment with CDDO-Me (bardoxolone) delayed the progression of CKD in humans (NEJM, 365:327, 2011). We tested the hypothesis that long term Nrf2 activation using CDDO-Im would prevent CKD progression after AKI.

Methods: Male C57BL/6 mice (6-8 weeks) underwent 45 min unilateral kidney ischemia. CDDO-Im (30 μmol/kg) or vehicle was administered 3 times per week for 6 weeks, beginning 24 h after injury.

Results: Real-time PCR analysis showed that Nrf2 target gene expression (NQO1, HO1, GCLM, GCLC, and GPX3, $p<0.05$, n=5) was significantly impaired in AKI-induced CKD kidneys. NQO1 was significantly upregulated in all CDDO-Im kidneys as compared to vehicle-treated counterparts (fold change CDDO-Im/vehicle, CKD: 3.8, contralateral: 4.1, n=5); however, CDDO-Im failed to broadly upregulate other Nrf2 target genes at six weeks, which contrasts with short-term CDDO-Im treatment. CKD led to a significant reduction in kidney mass both in vehicle-treated (0.16g±0.02 contralateral vs. 0.08g±0.03 CKD) and CDDO-Im-treated mice (0.18g±0.02 contralateral vs. 0.06g±0.02 CKD, n=5); however, this decrease was not improved by CDDO-Im. Cytokine analysis showed a significant increase in proinflammatory mediators (TGF-β1, TGF-β2, IL-1β, IL-10, IFN-γ, TNF-α, MCP-1) in all CKD kidneys. This increase was significantly higher in CDDO-Im mice compared to vehicle-treated mice (TGF-β2, IL-1β, TNF-α, MCP-1, $p\leq0.01$, n=4).

Conclusions: These data suggest that long-term CDDO-Im treatment, as used in our experimental conditions, is insufficient to prevent established AKI from progressing to CKD. Furthermore, prolonged Nrf2 activation could increase proinflammatory cytokines during CKD.

Delivery of Adipose-Derived Stem Cells Demonstrates Greater Efficacy than Expanded Bone Marrow-Derived Mesenchymal Stem Cells in Prevention and Treatment of AKI, with Potential for Point-of-Care Treatment and Significant Cost Advantage Anna Gooch,[1] Ping Zhang,[1] Zhuma Hu,[1] Dmitry O. Traktuev,[3] Stephanie Merfeld-clauss,[3] Keith L. March,[3] Christof Westenfelder.[1,2] *[1]Medicine, University of Utah and VA Medical Centers, Salt Lake City, UT; [2]Physiology, University of Utah, Salt Lake City, UT; [3]Vascular and Cardiac Center for Adult Stem Cell Therapy, IU SOM, VAMC, Indianapolis, IN.*

Background: Our pre-clinical studies (AJP 2005) and a Phase I Clinical Trial (Nat Rev Neph 2010) showed that administration of expanded allogeneic bone marrow-derived stromal cells (MSCs) is effective in prevention of and recovery from experimental acute kidney injury (AKI), and is safe and apparently renoprotective in on-pump cardiac surgery patients at risk for post-op AKI. However, MSC expansion and banking are expensive and time-consuming. To address these issues, we compared the therapeutic efficacy of MSCs to those of 1. freshly prepared adipose derived Stromal Vascular Fraction (SVF, composed of adipose derived stem cells [ASCs], endothelial cells, and leukocytes), or 2. minimally processed adipose derived stem cells (ASCs) in rats with AKI. ASCs share therapeutic activities with MSCs but are available in sufficient quantities without need for expansion. SVF can be readily prepared at point of care.

Methods: ASCs and SVF were isolated from abdominal fat from Fisher344 (F344) rats. IRI AKI was induced (40' bilateral renal pedicle clamp) in 5 groups of adult F344 rats (n=7 each). Post reflow, rats were infused via suprarenal aorta with $1x10^6$ (a) autologous SVF,(b) ASCs, (c) syngeneic, cultured MSCs, or vehicle (controls and shams).

Results: Renal function (serum Creatinine) was significantly better protected in ASC and SVF treated animals, and recovery was achieved more rapidly vs. vehicle or MSC treated rats.

Conclusions: Our data suggest that treatment of AKI patients with autologous SVF or ASCs, obtained by minimally invasive lipoaspiration and bedside processing, can provide a safe, efficient, inexpensive point-of-care therapy to prevent or treat AKI. Safety and feasibility of freshly isolated SVF and minimally-expanded ASC will be tested in a Phase I Clinical Trial.

Renal Proximal Tubular Epithelial Cell Survivin Deletion Delays Functional and Structural Recovery from Acute Kidney Injury Jianchun Chen,[1] Jian-Kang Chen,[1] Edward M. Conway,[2] Raymond C. Harris.[1] *[1]Nephrology/Medicine, Vanderbilt University, Nashville, TN; [2]Univ. Centre for Blood Research, British Columbia, Vancouver, BC, Canada.*

Background: Renal proximal tubule cells have a remarkable capacity for regeneration. Survivin is an important component of the mitotic apparatus involved in cell proliferation, but its role in response to AKI is incompletely understood.

Methods: We generated renal proximal tubule cell-specific Survivin knockout mice ($Survivin^{ptKO}$) by crossing $Survivin^{flox/flox}$ mice with gGT-Cre mice and these mice and their wild type littermates (*WT*) were subjected to ischemia reperfusion injury (IR).

Results: Balb/c mice were subjected to bilateral renal pedicles clamping for 35 min followed by reperfusion. Survivin protein expression was markedly increased 48h after IR injury and remained elevated at 6 days after IR. *WT* and $Survivin^{ptKO}$ mice were subjected to IR injury and developed similar initial functional and structural impairment estimated by BUN (24h after I/R: *WT* vs $Survivin^{ptKO}$: 114 ± 15.2 mg/dl vs 115 ± 16.4 mg/dl). 7 days after IR, the BUN recovered (22.4 ± 1.2 mg/dl) in *WT* mice, but remained elevated (50 ± 5.3 mg/dl) in $Survivin^{ptKO}$ mice. Histologic data showed more severe proximal tubule dilation and epithelial simplification and cast formation in $Survivin^{ptKO}$ mice than that in *WT* mice at day 14 after IR injury. Phosphorylation of a Signal Transducers and Activators of Transcription 3 (STAT3) was markedly increased in response to IR within 48h, and inhibition of STAT3 phosphorylation by a specific inhibitor S3I-201 inhibited survivin up-regulation and delayed renal functional and structural recovery in response to IR. To simulate the IR model *in vitro*, we treated mouse cortical tubule epithelial cells (MCT) with antimycin and found that both survivin expression and STAT3 Kphosphorylation were up-regulated within 48h. knocking down the expression of STAT3 by specific siRNAs inhibited antimycin treatment-induced survivin expression in MCT cells.

Conclusions: This study demonstrates that STAT3 phosphorylation-mediated survivin expression is an important molecular mechanism underlying renal functional and structural recovery in response to acute kidney injury.

TH-OR081

CSF-1-Mediated Proliferation and Polarization of Renal Macrophages/ Dendritic Cells Is Essential for Recovery from Acute Kidney Injury Ming-Zhi Zhang, Bing Yao, Shilin Yang, Raymond C. Harris. *Medicine, Vanderbilt University School of Medicine, Nashville, TN.*

Background: We have previously reported an important role for macrophages in the recovery process following acute kidney injury induced by ischemia/reperfusion (I/R) injury or selective apoptotic proximal tubule injury in transgenic mice expressing the human diphtheria toxin (DTR) receptor and exposed to DT.

Methods: For I/R injury, wild type (WT), CSF-1 -/- mice or WT mice treated with GW2580, a CSF-1 receptor inhibitor, were subjected to 30 min of ischemia and contralateral nephrectomy. CSF-1 -/- mice were also crossed with DTR transgenic mice.

Results: Following I/R-induced AKI, there were early increases in renal macrophages derived from circulating monocytes that expressed "M1" (inflammatory) markers, followed by accumulation of renal macrophages/dendritic cells with an "M2" (wound healing) phenotype. In contrast, in renal injury induced by DT, only M2 macrophages/dendritic cells increased. Depletion of M2 macrophages/dendritic cells with clodronate delayed recovery in both models. We used flow cytometry to double label renal F4/80+ cells with the proliferation marker, Ki67. The increases in M2 macrophages/dendritic cells resulted largely from *in situ* proliferation in the kidney in both models. In both CSF-1-/- mice and mice treated with GW2580, there was markedly delayed recovery in both models of AKI. Genetic or pharmacologic inhibition of CSF-1 signaling inhibited renal macrophage/ dendritic cell proliferation and prevented polarization of these cells to an M2 phenotype.

Conclusions: These studies demonstrate that CSF-1-mediated expansion and polarization of resident renal macrophages/dendritic cells is a novel and important mechanism mediating renal tubule epithelial regeneration following acute kidney injury.

Selective Proximal Tubular Mitofusin 2 Deficiency Prevents Oxidant Stress and Promotes Cell Proliferation Following Ischemia Reperfusion (I/R) Injury Jonathan M. Gall,[1] Andrea Havasi,[1] Marc Liesa,[2] John H. Schwartz,[1] Steven C. Borkan,[1] Ramon G. Bonegio.[1] *[1]Renal Section, Boston Medical Center, Boston, MA; [2]Obesity Center, Boston Medical Center, Boston, MA.*

Background: Renal ischemia causes dramatic changes in mitochondrial morphology. Mitochondria regulate cell survival after stress. We hypothesized that MFN2, required for mitochondrial fusion, contributes to organ function by altering mitochondrial injury and/or accelerating organ recovery. To test this hypothesis, mice with structure-specific, conditional MFN2-deficiency (MFN2cKO) were subjected to I/R injury and mitochondrial morphology, histologic injury score, oxidant stress, cell proliferation and renal function were quantified.

Methods: To delete MFN2 in renal proximal tubule cells, MFN2f/f mice were crossed to Kap2-Cre mice that express Cre-recombinase exclusively in renal proximal tubular (PT) epithelial cells. Acute kidney injury was induced in Cre-positive males (MFN2cKOs) and Cre-negative littermates (control) by renal pedicle occlusion. Blood urea nitrogen (BUN), renal histology, oxidant stress (anti-nitrotyrosine staining), and proliferation (BrdU uptake) were assessed within 48 hours after transient ischemia/reperfusion.

Results: MFN2cKO caused fragmentation in proximal tubular epithelial cell mitochondria. Despite similar tubular injury scores, levels of apoptosis and necrosis, post-ischemic survival (86% vs. 28%, $P<0.05$) and renal function were significantly improved in MFN2cKO mice compared to control. Cortical nitrotyrosine staining was reduced by 40% ($P< 0.05$) and BrDU positive cortical epithelial cells were increased 3.5-fold ($P< 0.05$) in MFN2cKO mice.

Conclusions: MFN2 deficiency in proximal tubule epithelial cells promotes proximal tubule survival, decreases local oxidant stress and promotes proximal tubular cell proliferation, key determinants of organ injury and recovery after renal I/R. We propose that modulators of mitochondrial dynamics and/or MFN2 function represent rational targets for treating ischemic acute kidney injury that involve critical injury pathways.

Toll-Like Receptor-4 Activation Induces Interleukin-22 Secretion in Renal Mononuclear Phagocytes Which Stimulates Tubular Epithelial Cell Regeneration upon Kidney Injury Onkar Kulkarni, Ingo Hartter, Shrikant R. Mulay, Murthy Darisipudi, Dana Thomasova, Hans J. Anders. *Nephrology Center, Medizinische Klinik and Poliklinik IV, Munich, Germany.*

Background: Inflammation involves leukocyte activation at sites of injury which contributes to tissue damage and remodelling. For example, the activation of leukocyte Toll-like receptors (TLR) drives kidney inflammation and injury. Here we address the speculative hypothesis that TLR-mediated leukocyte activation also contributes to repair during the healing phase of acute kidney injury (AKI).

Results: We used the isolation of primary tubular epithelial cells (TECs) as an in-vitro assay to evaluate the potential of various cytokines to enhance tubular cell survival as well as regenerative TEC outgrowth from surviving cells. IL22 showed significant improvement in TEC survival and regeneration. Supernatant from necrotic TECs (NS) induced IL22 release in bone marrow-derived mononuclear phagocytes (BMDC). TLR4 inhibition significantly reduced NS-induced IL22 production in these cells. Only TLR4 but not TLR2/9 stimulation of BMDCs produced significant amounts of IL22. To evaluate the physiological significance of TLR4 activation in renal repair, we blocked TLR4 signaling with anti-TLR4 or control IgG from day 2-4 after unilateral renal pedicle clamping for 45 min. Kidneys were analyzed at day 5. TLR4 blockade significantly reduced IL22 expression in the ischemic kidney (IHC) and reduced the numbers of $CD11b^+CD103^-IL22^+$ and $CD11b^+CD103^+IL22^+$ cells (FACS). TLR4 inhibition was associated with more necrotic tubules (PAS stain) and less intact distal tubules (THP stain) or proximal tubules (lectin stain) and increased expression of injury markers such as πGTP, Kim-1, TGF-β, MCP-1 and TNF-α.

Conclusions: We conclude that necrotic tubuli release endogenous agonists for TLR4 on intrarenal CD11b/CD103+ or CD11b/CD103- mononuclear phagocytes, to release IL22. IL22 promotes TEC survival and enhances tubular regeneration. The role of intrarenal mononuclear phagocytes is not redundant because direct TLR activation of surviving TECs cannot affect survival or repair. These data first document a role of TLR signalling in renal regeneration.

Thiazide-Sensitive Na^+-Cl^- Cotransporter Gene Inactivation Enhances Bone Ca^{2+} Content and Osteoblast Differentiation In Vitro and In Vivo Yu-Juei Hsu, Sung-Sen Yang, Shih-Hua P. Lin. *Tri-Service General Hospital, Neihu, Taiwan.*

Background: Gitelman's syndrome (GS) is caused by inactivating thiazide-sensitive Na^+-Cl^- cotransporter (*NCC*). GS typically manifests with hypocalciuria and increased bone mineral density (BMD), resembling the effects of long-term treatment with thiazide diuretics.

Methods: To elucidate the molecular mechanisms underlying the effects of NCC inhibition and thiazides on bone we have investigated bone metabolism in nonsense Ncc Ser707X (S707X) homozygous knockin mice ($Ncc^{S707X/S707X}$ mice), analyzing bone Ca^{2+} content, bone architecture, expression of osteoblast differentiation markers and osteoblast-specific transcription factors in vitro and in vivo.

Results: The bone Ca^{2+} content in femurs of $Ncc^{S707X/S707X}$ mice was significantly increased compared to wild-type and heterozygous littermates. Bone structure parameters obtained by mCT revealed significantly increased trabecular bone volume, cortical bone thickness and BMD with a slightly increased polar moment of inertia in Ncc S707X homozygous knockin mice. The expression of bone alkaline phosphatase, procollagen I, osteocalcin and osterix were significantly increased in femoral bones of $Ncc^{S707X/S707X}$ mice as determined by real time quantitative PCR and immunohistochemistry. In vitro, osteoblastic differentiation was enhanced and associated with increased phosphorylation of focal adhesion kinase (FAK) and extracellular signal-regulated kinase 1/2 (ERK 1/2) in cells from mutant mice or from wild type mice treated with thiazides.

Conclusions: NCC inhibition stimulates osteoblast differentiation, and enhances bone Ca^{2+} content, possibly through a FAK / ERK dependent mechanism.

Ankyrin-3 Binds and Potently Inhibits the Shaker-Like Potassium Channel (Kv1.1): Implications for Renal Mg^{2+} Handling Pedro San-Cristobal, Sergio Lainez Vicente, Henrik Dimke, Joost G. Hoenderop, René J. Bindels. *Department of Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: The kidney is the principal organ responsible in regulation of body Mg^{2+} balance. After being identified as a causative factor in isolated dominant hypomagnesemia, Kv1.1 has emerged as a novel key player in the maintenance of systemic Mg^{2+} balance. Kv1.1 is situated in the distal convoluted tubule (DCT) where it generates a favourable electrochemical gradient, which drives Mg^{2+} into the cell via the Transient Receptor Potential Melastatin 6. Little is, however, known about the molecular mechanisms governing Kv1.1 regulation in the kidney.

Methods: Pull-down experiments using total mouse kidney lysates, coupled with mass-spectrometry were performed. Co-immunoprecipitation assays confirmed interaction of Ankyrin-3 (ANK3) with Kv1.1. Furthermore, electrophysiology studies elucidating the functional properties of those candidates were performed. Finally, RT-PCR (mRNA) of magnesiotropic candidates was quantified from C57BL/6 mice that were fed diets with low (0.005 %w/w), normal (0.19 %w/w), or high dietary Mg^{2+} Content (0.48 %w/w) for 10 days.

Results: ANK3 was identified as a novel binding partner of Kv1.1. ANK3 was predominantly expressed in DCT. Co-expression of ANK3 with Kv1.1 had a significant inhibitory effect on currents generated by Kv1.1. The decrease in channel activity was a consequence of a reduction in the conductance of the potassium channel. This effect occurred independently of changes in the membrane abundance of the channel. Finally, to evaluate a potential role of ANK3 in Mg^{2+} handling, we investigated whether changes in dietary Mg^{2+} content could affect the renal abundance of ANK3. Mice exposed to a high Mg^{2+}diet showed an appropriate elevation in their fractional urinary excretion of Mg^{2+}. Moreover, these mice had an increased renal expression of ANK3 compared to mice on a normal or low Mg^{2+} diet.

Conclusions: Our observations demonstrate a novel functional role for the Kv1.1-ANK3 complexin renal Mg^{2+} handling, which is achieved by modifying the biophysical properties of Kv1.1.

The Membrane Cytoskeletal Crosslinker Ezrin Is Essential for the Regulation of Phosphate Homeostasis in the Kidney Ryo Hatano,[1] Hiroko Segawa,[2] Atsushi Tamura,[3] Ken-ichi Miyamoto,[2] Sachiko Tsukita,[3] Shinji Asano.[1] *[1]Department of Molecular Physiology, College of Pharmaceutical Sciences, Ritsumeikan University, Kusatsu, Shiga, Japan; [2]Department of Molecular Nutrition, Institute of Health Biosciences, University of Tokushima Graduate School, Tokushima, Japan; [3]Laboratory of Biological Science, Graduate School of Frontier Biosciences/Graduate School of Medicine, Osaka University, Suita, Osaka, Japan.*

Background: Ezrin is a cross-linker between the plasma membrane proteins and actin cytoskeleton. In the kidney, ezrin mainly localizes at the brush border membrane of proximal tubules with the scaffolding protein, Na^+/H^+ exchanger regulatory factor (NHERF) 1. NHERF1 interacts with the Na^+/phosphate (P_i) cotransporter, Npt2a. Defects in NHERF1 or Npt2a in mice cause hypophosphatemia. Therefore, in the present study, we investigated the physiological role of ezrin in renal P_i reabsorption by using ezrin knockdown mice (*Vil2$^{kd/kd}$*).

Methods: We used *Vil2$^{kd/kd}$* mice and MDCK cells to investigate roles of ezrin in the regulation of phosphate reabsorption *in vivo* and *in vitro*, respectively.

Results: We found that *Vil2$^{kd/kd}$* mice exhibited hypophosphatemia, hypocalcemia, and osteomalacia. The reduced plasma concentrations of P_i were attributable to defects in urinary P_i reabsorption. Immunofluorescence staining and immunoblotting revealed a marked reduction in renal Npt2a and NHERF1 expression at the apical membrane of proximal tubules in *Vil2$^{kd/kd}$* mice whereas total expression levels of these proteins were not different between WT and *Vil2$^{kd/kd}$* mice kidneys. In *Vil2$^{kd/kd}$* mice, Npt2a localizes mainly in the subapical and other vesicular compartments. In MDCK cells, stable expression of dominant negative ezrin also revealed abnormal membrane expression of Npt2a.

Conclusions: These results suggest that ezrin is required for the regulation of systemic P_i homeostasis by the regulation of membrane localization of Npt2a.

TH-OR087

Klotho Upregulates the Calcium Channel TRPV5 by Intra- and Extracellular N-Glycosylation Dependent Mechanisms Matthias Tilmann Florian Wolf,[1] Chou-Long Huang.[2] *[1]Pediatrics, UTSW Medical Center, Dallas, TX; [2]Internal Medicine, UTSW Medical Center, Dallas, TX.*

Background: Klotho (KL) is an anti-aging molecule synthesized in the distal convoluted tubule (DCT) as a type-1 transmembrane protein; the extracellular domain is secreted into urine to regulate ion homeostasis. Secreted KL functions as sialidase by removing terminal sialic acids from N-glycans of TRPV5. This enables TRPV5 to bind extracellular galectin-1 and to avoid endocytosis. Because Klotho and TRPV5 are both expressed in DCT, we examined if Klotho also regulates TRPV5 acting from intracellular.

Methods: HEK293 cells were cotransfected with TRPV5 and secreted or transmembrane KL. Whole-cell current was analyzed by patch-clamp recording.

Results: We distinguished between extracellular and intracellular actions of KL by using secreted KL (lacks transmembrane domain and is easily detected in supernatant of transfected cells) and transmembrane KL (which was not detected in supernatant). Secreted and transmembrane KL upregulated wild-type TRPV5 but not N-glycosylation-defective mutant TRPV5, supporting that KL increases TRPV5 acting at extracellular and intracellular sites. The role as a sialidase for intracellular KL was supported by mutations of crucial residues for sialidase activity. These mutations abolished TRPV5 regulation by secreted and transmembrane KL. Intracellular action of transmembrane KL was supported by the finding that extracellular application of sialidase inhibitor DANA abolished the effect of secreted but not of transmembrane KL. Secreted and transmembrane KL upregulate TRPV5 by different mechanisms; one involves inhibition of endocytosis and the other increases forward trafficking. While dominant-negative dynamin II abrogated the effect of secreted KL, it did not prevent the effect of transmembrane KL. Blocking forward trafficking by brefeldin A prevented the upregulation of TRPV5 by transmembrane KL, but not by secreted KL.

Conclusions: KL upregulates TRPV5 current acting from intracellular and extracellular sites. Both actions require N-glycosylation of TRPV5 and KL sialidase activity. While extracellular KL inhibits endocytosis of the channel, intracellular KL enhances forward trafficking.

Urinary Plasmin Inhibits Transient Receptor Potential Cation Channel V5 in Nephrotic-Range Proteinuria Joost G. Hoenderop,[1] Kukiat Tudpor,[1] Sergio Lainez Vicente,[1] Gerjan Navis,[2] René J. Bindels.[1] *[1]Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Internal Medicine, Division of Nephrology, University Medical Center Groningen, Groningen, Netherlands.*

Background: In patients with nephrotic syndrome serum plasminogen levels are elevated. After leakage into the urine, plasminogen is converted into active plasmin by tubular urokinase-type plasminogen activator (uPA). Disturbances in Ca^{2+} homeostasis are frequently reported in patients with nephrotic syndrome including hypocalcemia. This study aims to investigate the effect of urinary plasmin on TRPV5-mediated Ca^{2+} reabsorption.

Methods: TRPV5 activity was determined by patch clamp analysis and $^{45}Ca^{2+}$-influx measurements. Immunoblotting was used to detect the expression level of TRPV5 under the various conditions. Urinary calcium and plasmin was measured by a colometric assay and immunoblotting, respectively. The binding of CaM with TRPV5 was studied by NMR spectroscopy.

Results: We showed that purified plasmin from the urine of patients with nephrotic-range proteinuria inhibits Ca^{2+} uptake in HEK293 expressing TRPV5 via activation of protease-activated receptor-1 (PAR-1). PAR-1 was expressed in HEK293 cells and colocalized with TRPV5 in the mouse distal convoluted tubule. Pre-incubation with plasmin inhibitor, PAR-1 antagonist, or PKC inhibitor abolished the effect of plasmin. The S144A-TRPV5 PKC phosphorylation mutant was resistant to plasmin action. The plasmin-mediated reduction in Ca^{2+} uptake was accompanied by decreased TRPV5 pore size and open probability (NPo) as shown by patch-clamp analysis. Because CaM has been found to interact with residues 133-154 in the N-terminus of TRPV5 (N_{ter}), the effect of S144 phosphorylation on CaM-N_{ter} binding affinity was investigated. High-resolution NMR spectroscopy indicated a tighter binding between CaM-N_{ter} when S144 was phosphorylated.

Conclusions: PAR-1 activation by plasmin induced PKC phosphorylation of TRPV5, enhancing the binding affinity of CaM for TRPV5 and decreasing the channel pore size and NPo. These results demonstrate that urinary plasmin can be involved in the downstream effects of proteinuria on the tubulo-interstitium by the negative modulation of TRPV5.

Constitutively Active LXRα Transgenic Mice Demonstrates Inhibition of Intestinal Phosphate Transporter NaPi-2b Hector Giral-Arnal, Yupanqui A. Caldas, Moshe Levi. *Medicine, University of Colorado, Aurora, CO.*

Background: Pi homeostasis is maintained through the activity of synchronized mechanisms involving intestinal absorption, bone retention-release, and kidney reabsorption. Renal Pi reabsorption has been considered the main mechanism controlling Pi homeostasis. Recently, small intestine Pi absorption has strongly emerged as a new putative pharmacological target for the control of hyperphosphatemia. We have recently reported that activation of Liver X Receptor (LXR) with LXR agonists leads to the decreased expression of renal and intestinal NaPi co-transporters which induced an increase in urinary Pi excretion and a decrease in serum Pi concentration. In order to prove that these effects are associated to specific activation of LXR and to unravel the mechanisms behind this regulation we decided to study a transgenic model, VP16-LXRα Tg mouse.

Methods: VP16-LXRα Tg mouse expresses an active form of the LXRα isoform fused with the activation domain of VP16 under the control of the endogenous LXRα promoter.

Results: VP16-LXRα Tg mice showed reduced expression of NaPi-2b protein in the apical membrane of enterocytes compared to wild type animals. This was paralleled by reduced NaPi uptake in BBM. Moreover, a significant reduction of NaPi-2b mRNA expression was found in the VP16-LXRα Tg animals. Additionally, we characterized the CaCo-2_{BBE} cell line as a model to study the regulation of intestinal Pi transport. LXR activation induced a decrease in the expression of the endogenous NaPi-2b, and reduced the transport activity in our intestinal cell model.

Conclusions: These results point to a direct effect of LXR nuclear receptors in the enterocyte to downregulate the expression of NaPi-2b protein and NaPi transport activity in the apical membrane.

TH-OR090

Gas6 Protein and It's Role in Vascular Calcification Nadine Kaesler, Svenja Immendorf, Chun Ouyang, Thilo Krueger, Peter Carmeliet, Jürgen Floege, Georg Schlieper. *Nephrology, University Hospital of the RWTH Aachen, Aachen, Germany.*

Background: Vascular calcification is reduced by vitamin K and accelerated by warfarin, i.e. a direct inhibitor of the vitamin K regenerating cycle. These vascular effects are believed to largely involve the vitamin K dependent matrix gla protein. Another vitamin K dependent protein, Gas6, is also expressed in vascular smooth muscle cells (VSMC). Recent data indicated that gas6 mediates protective effects in vascular calcification by inhibition of VSMC apoptosis.

Methods: Here we investigated the role of Gas 6 in *in vivo* and *in vitro* calcification models (*in vitro* cell culture; *in vivo* Warfarin diet for 8 weeks, uninephrectomy (UniNx) combined with high phosphate diet, aging mice at the age of 36 weeks). At the end of the feeding period, echocardiography was performed. After sacrifice, the extent of soft tissue calcification, serum and urine biochemistries were measured.

Results: *In vitro* VSMC exposed to warfarin calcified and this was not different between VSMC generated from wildtype (WT) and $Gas6^{-/-}$ mice. *In vivo*, serum phosphate was higher in UniNx $Gas6^{-/-}$ compared to UniNx WT mice but no significant difference in aortic calcium content was observed between these groups. After 8 weeks of warfarin, total protein and phosphate in serum were significantly higher in $Gas6^{-/-}$ than in WT mice. This was accompanied by a higher aortic calcium content in $Gas6^{-/-}$ mice, however von Kossa staining revealed only a weakly positive vascular staining in $Gas6^{-/-}$ mice. In aging, non-manipulated mice, no significant differences in vascular calcification could be identified between $Gas6^{-/-}$ and WTmice. No differences were found in LV mass, stroke volume or pulse wave velocity in all groups.

Conclusions: Our data do not support a major role of gas 6 in the pathogenesis of vascular calcification.

TH-OR091

Chondrocyte-Specific Calcium-Sensing Receptor (Casr) Deficient Mice Display Severe Growth Retardation, Hypercalcemia, Hyperparathyroidism and Early Death Hakan R. Toka,[1,2] Salvatore Dibartolo,[2] David B. Mount,[1] Gary C. Curhan,[1] Edward M. Brown,[3] Martin R. Pollak.[2] *[1]Nephrology, Brigham and Women's Hospital, Boston, MA; [2]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [3]Endocrinology, Brigham and Women's Hospital, Boston, MA.*

Background: The calcium-sensing receptor (Casr) has an important role in regulating calcium homeostasis within several tissues including cartilage. Previous *in vivo* studies suggest that chondrocyte-specific Casr-deficient mice driven by the Collagen 2alpha1 (Col2a1) promoter, in which exon 7 of the Casr was deleted, display a very severe phenotype with embryonic lethality.

Methods: We generated a conditional Casr-deficient mouse model targeting exon 3 using the Cre/Lox system. We obtained Cre transgenic mice driven by the chondrocyte-specific Col2a1 promoter and developed chondrocyte Casr-deficient mice (Ch $Casr^{-/-}$).

Results: Ch $Casr^{-/-}$ mice are viable and born at the expected Mendelian ratio displaying growth retardation beginning at 3 to 4 days of age. Most Ch $Casr^{-/-}$ show significant growth retardation by the age of 3 to 4 weeks with decreased life expectancy. The cause of death is unclear. Studies at ages 3 days and 3 weeks show hypercalcemia (12.4mg/dl ±0.7 vs. 9.2 ±0.4, p=0.02, and 15.2 ±5.5 vs. 11.6 ±0.3, p=0.4, respectively) and hypophosphatemia (3.1 mg/dl ±0.4 vs. 4.0 ±0.6, p=0.06, and 1.8 ±0.4 vs. 3.0 ±0.7, p=0.03, respectively) with significantly elevated PTH levels at age 3 weeks (510 pg/ml ±373 vs. 128 ±18, p=0.01). Ch $Casr^{-/-}$ animals surviving 5 weeks or longer display dwarfism with thick bones.

Conclusions: Chondrocyte-specific Casr-deficient mice driven by the Col2a1 promoter are viable, exhibiting a less severe phenotype than that observed previously by others using conditional deletion of exon 7 in chondrocytes. However, they display significant growth retardation, hypercalcemia, hyperparathyroidism and early death. The cause of the unexpected hypercalcemic hyperparathyroidism is currently unclear. *In vivo* and *in vitro* studies addressing parathyroid function, chondrocyte differentiation and proliferation, and endochondrial ossification in our model are being pursued.

Membrane Topology and Intracellular Processing of Cyclin M2 (CNNM2) Jeroen H.F. De Baaij,[1] Marchel Stuiver,[2] Iwan Meij,[3] Sergio Lainez Vicente,[1] Dominik Müller,[2] René J. Bindels,[1] Joost G. Hoenderop.[1] *[1]Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Department of Pediatric Nephrology, Charité Universitätsmedizin Berlin, Berlin, Germany; [3]Molecular Medicine, Max Delbrück Centre for Molecular Medicine, Berlin, Germany.*

Background: Recently, mutations in the Cyclin M2 (CNNM2) gene were identified to be causative for severe hypomagnesemia. In kidney, CNNM2 is a basolaterally expressed protein with highest expression in the distal convoluted tubule (DCT). Transcellular magnesium (Mg^{2+}) reabsorption in DCT represents the final step before Mg^{2+} is excreted into the urine. The present study aims to get insight in the structure of CNNM2 and to characterize its post-translational modifications.

Methods: The topology of CNNM2 was evaluated by immunocytochemistry using intramolecular epitopes. In addition, CNNM2 was expressed in HEK293 cells after which expression and modifications of the protein were measured by immunoblot analysis.

Results: Extensive expression profiling shows that CNNM2 is mainly expressed in the DCT. Furthermore, immunocytological membrane topology studies showed that CNNM2 has an extracellular amino-terminus and an intracellular carboxy-terminus. This suggests that one of the predicted transmembrane regions is reentrant. By homology modeling we demonstrated that the loss-of-function mutation as found in patients disturbs potential ATP binding by the intracellular cysthationine β-synthase domains. In addition, the cellular processing pathway of CNNM2 was exposed in detail. In the endoplasmic reticulum, the signal peptidase complex cleaves off a large amino-terminal signal peptide of about 64 amino acids. Mutagenesis screening showed that CNNM2 is glycosylated at N112 stabilizing CNNM2 on the plasma membrane. Interestingly, co-immunoprecipitation studies evidenced that CNNM2a forms heterodimers with the smaller isoform CNNM2b.

Conclusions: In conclusion, we propose a protein topology of CNNM2 consisting of three membrane-spanning domains and a reentrant loop. CNNM2 is post-translationally modified by signal peptide cleavage and glycosylation. Rather than transporting Mg^{2+} itself, we hypothesize CNNM2 indirectly regulates other Mg^{2+} transporters.

TH-OR093

New Regulatory Mechanism Explaining the Molecular Basis of Constitutively Active Variants of the Calcium-Sensing Receptor (CaSR) Marianna Ranieri,[1] Grazia Tamma,[1] Annarita Di Mise,[1] Giuseppe Vezzoli,[2] Laura Soldati,[3] Maria Svelto,[1] Giovanna Valenti.[1] *[1]Department of Biosciences, Biotechnologies and Pharmacological Sciences, University of Bari, Bari, Italy; [2]Division of Nephrology and Dialysis (IRCCS), San Raffaele Hospital, Milan, Italy; [3]Department of Health Sciences, University of Milan, Milan, Italy.*

Background: To evaluate some aspects of renal CaSR physiopathology, we analyzed the signaling underling two constitutively active variants of the CaSR.

Methods: Constructs encoding human wild-type CaSR (hCaSR-wt) and its constitutively active (hCaSR-R990G; hCaSR-N124K) and inactive variants (hCaSR-del121) were transiently transfected in HEK cells.

Results: Immunofluorescence studies revealed that both hCaSR-wt and its activating variants were expressed at the plasma membrane, whereas the inactive form localized intracellularly. The physiological agonist, calcium (Ca^{++} 5mM), and the calcimimetic NPS-R568 (5μM) induced a significant increase in cytosolic calcium in cells expressing hCaSR-wt and its active variants, compared to mock. We also found that the basal intracellular calcium was significantly lower in cells expressing hCaSR-wt and its activating variants compared to mock and hCaSR-del121 transfected cells. Low calcium levels are expected to make cells more sensitive to intracellular calcium changes in response to CaSR agonists. In line, FRET studies using D1ER probe, which detects $[Ca^{++}]_{ER}$ directly demonstrated a significant higher calcium accumulation in cells expressing the activating CaSR variants. Since the storage of calcium in the ER is mainly regulated by SERCA, the activity and the expression of this pump were evaluated. Compared to hCaSR-wt expressing cells SERCA expression and activity were found significantly increased in cells expressing activating CaSR variants. An inverse correlation with PMCA was also found.

Conclusions: Together, these findings indicate that for the efficiency of calcium signaling system, cells monitor cytosolic and ER calcium levels regulating the expression of the SERCA and PMCA. To our knowledge this is the first demonstration that a complex parallel adaptive feedback can explain the molecular basis of constitutively active variants of the CaSR.

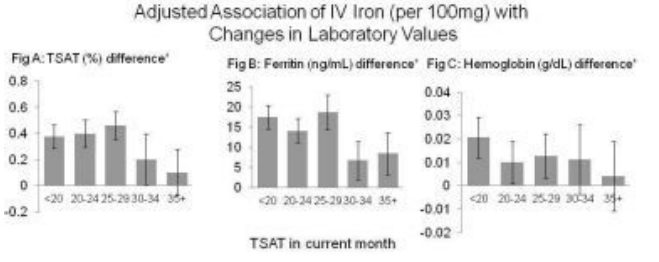
IV Iron Dosing and Changes in Serum TSAT, Ferritin, and Hemoglobin Levels: Implications of Increasing IV Iron Dosing in the US

Bruce M. Robinson,[1,2] Maria Larkina,[1] Yun Li,[1,2] David A. Goodkin,[1] Alfred K. Cheung,[3] Hal Morgenstern,[1,2] Ananda Sen,[2] Panduranga S. Rao,[2] Francesco Locatelli,[4] Ronald L. Pisoni,[1] Masaaki Inaba,[5] Werner Kleophas.[6] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]U of Michigan, Ann Arbor, MI; [3]U of Utah; [4]Ospedale A Manzoni, Lecco, Italy; [5]Osaka City Univ, Japan; [6]Dialysezentrum Karlstrasse, Germany.*

Background: Dialysis Outcomes and Practice Patterns Study (DOPPS) data (8/2010 to 12/2011) indicate that, since the new US bundled payment system in 1/2011, the 1mo period prevalence of IV iron (Fe) use rose in the US by 20% (to 77%) and the median serum ferritin level rose by 25% (to 697ng/mL), but the median TSAT rose by only 3% (to 29%). We evaluated the hypothesis that iron dosing at higher TSAT levels raises ferritin but has little effect on subsequent TSAT.

Methods: Monthly data were from 15,183 HD patients in 12 DOPPS 4 countries (2009-11). Among patients prescribed IV Fe, the effects of Fe dose within strata of current TSAT on the next month's TSAT(N=28,000), ferritin(N=18,818), and hemoglobin(hgb, N=37,677) were estimated using GEE models.

Results: Fe dose was positively associated with next month's TSAT, ferritin, and hgb, but associations were weaker for current TSAT≥30%. Every 100mg of Fe raised next month's TSAT by 0.43%(for TSAT<30%) vs 0.10%(for TSAT≥30%; p<.001 for interaction); ferritin by 17 vs 7ng/mL(p<.001); and hgb by 0.017 vs 0.004g/dL (p<.001).Findings by 5% TSAT increments follow.



*Y axis shows next-month minus current-month values, for the effect of IV iron dose in current month.
Adjusted for: age, gender, black race, vintage, catheter use, BMI, region (Japan, Europe/ANZ, US/Canada), 14 comorbid conditions including GI bleed; current month: ESA dose, hemoglobin, white blood cell count, and serum albumin, creatinine, TSAT, and ferritin; one month prior: IV iron dose, ESA dose, hemoglobin, TSAT and ferritin.
For results presented in the text, 'TSAT in current month' was dichotomized at 30%.

Conclusions: Though targeting TSAT 30-50% is now common in the US, Fe dosing has little effect on TSAT when TSAT is already ≥30%. The effect of Fe on ferritin and hgb levels is also modest at TSAT≥30%. Ongoing Fe dosing when TSAT is ≥30% provides little erythropoietic support and may deleteriously increase parenchymal iron deposition. Studies evaluating this possibility are needed.

Comparative Safety of Intravenous Iron Supplementation Practices in Hemodialysis Patients

M. Alan Brookhart,[1] Janet K. Freburger,[1] Alan R. Ellis,[1] Lily Wang,[1] Wolfgang C. Winkelmayer,[2] Abhijit V. Kshirsagar.[1] *[1]University of North Carolina at Chapel Hill; [2]Stanford University School of Medicine.*

Background: Intravenous (IV) iron is in widespread use in hemodialysis patients, but the comparative safety of different approaches to dosing is unknown. We sought to compare different IV iron supplementation practices with respect to risk of various adverse outcomes in hemodialysis patients.

Methods: We conducted a retrospective cohort study of hemodialysis patients using clinical data from a large dialysis organization merged with hospitalization data from the United States Renal Data System, 2004-2008. We compared the effects of bolus dosing (providing a large amount of iron over a short period of time) vs maintenance dosing (smaller administrations designed to maintain iron repletion) and high vs low dose. Semiparametric additive risk models were used to assess the relation between measures of iron exposure and mortality, infection- and cardiovascular-related hospitalizations, and hypersensitivity reactions occurring during a 3-month (mo) follow-up. The models included a range of clinical and laboratory variables assessed prior to exposure.

Results: Of 117,050 patients who met our study entry requirements, 9,033 (16.3%) received a bolus administration, 55,457 (47.4%) received maintenance therapy, and 42,560 (36.4%) received no iron during the 1-mo exposure assessment period. Compared with maintenance iron, those receiving bolus iron were at increased risk of infection-related hospitalization (4.3 additional events/100 patient years(PY), 95% CI 2.0-6.5) during follow-up. Patients receiving over 200mg/mo of iron were at slightly increased risk of infection (2.0 events/100 PY, 95%CI 0.2-3.8). We observed no association between bolus dosing and the other outcomes considered. Compared to no iron, maintenance dosing was not associated with an increased risk of adverse outcomes. The results were robust to changes to the length of the exposure, follow-up period, and the inclusion of additional covariates.

Conclusions: Sequences of large doses of IV iron are associated with an increased risk of infection; smaller, less frequent doses aimed at maintenance of iron reserves appear to be safe.

FG-4592, an Oral Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitor, Corrects Anemia without Iron Supplementation in Incident Dialysis Patients

Anatole Besarab,[1] Elena Na Chernyavskaya,[2] Igor Motylev,[3] Shutov Evgeny,[4] Anatoly F. Yampolskiy,[5] Lalathaksha Murthy Kumbar,[1] Konstantin Gurevich,[6] Daniel Tak Mao Chan,[7] Robert Leong,[8] Ming Zhong,[8] Marietta Franco,[8] Kin-Hung Peony Yu,[8] Thomas B. Neff.[8] *[1]Henry Ford Hosp, Detroit, MI; [2]City Clin Hosp, Omsk, RU; [3]City Hosp, N. Novgorod, RU; [4]City Clin Hosp, Moscow, RU; [5]Regional Nephrology Center, Krasnodar, RU; [6]City Hosp of St Venerable Martyr Elizabeth, St Petersburg, RU; [7]Queen Mary Hosp, HK; [8]FibroGen, Inc., San Francisco, CA.*

Background: Optimal iron management strategy in treating anemia is controversial. We evaluated whether FG-4592, with or without iron supplementation, can correct hemoglobin (Hb) levels in incident dialysis patients.

Methods: In an ongoing, open-label, phase 2 study, erythropoiesis-stimulating-agent-naïve patients on hemodialysis (HD) for 2 wks to 4 mos, with baseline (BL) Hb ≤ 10.0 g/dL, were randomized to 3 arms (N=12/arm) to receive FG-4592 thrice weekly for 12 wks without iron, with oral iron, or with intravenous (IV) iron. Another arm evaluated FG-4592 with oral iron in peritoneal dialysis patients (N=12). A confirmatory arm further assessed FG-4592 without iron in HD patients (N=12). Initial FG-4592 doses were tiered by weight; dose adjustments were allowed every 4 wks.

Results: Results are reported for 36 HD patients completing ≥8 weeks of treatment (Table); a majority were not iron replete at BL. Mean Hb changes from BL at Wk 8 were similar across arms. FG-4592 was well tolerated, with an adverse event profile consistent with the patient population.

FG-4592 Arm (N=12/Arm)	N (%) Not Iron Replete at Baseline (BL)	Mean±SE Ferritin (ng/mL), BL	Mean±SE TSAT (%), BL	Mean±SE Hb (g/dL), BL	Mean±SE Change in Hb (g/dL), Wk 8	Mean±SE Max Change in Hb (g/dL)
No Iron	9 (75)	150±19	20±2	7.8±0.3	2.1±0.4	2.8±1.0
Oral Iron	6 (50)	184±63	21±2	8.5±0.3	2.2±0.4	3.3±1.9
IV Iron	9 (75)	158±25	23±5	8.3±0.3	2.3±0.7	3.2±1.7

Conclusions: Preliminary data indicated that treatment with oral FG-4592 TIW increased mean Hb in incident dialysis patients, regardless of BL iron status or iron supplementation. FG-4592 may prevent iron-deficient erythropoiesis, thus avoiding potential risks associated with parenteral iron.

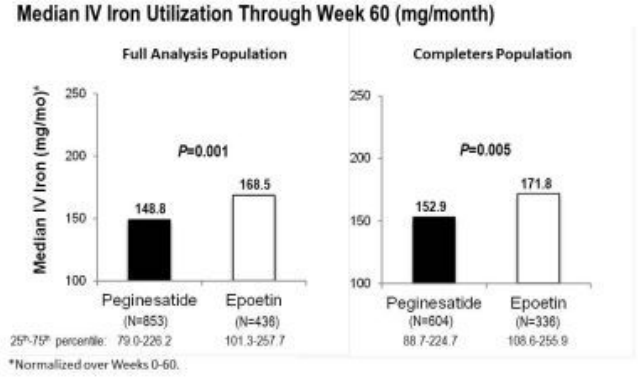
TH-OR097

Intravenous (IV) Iron Use in US Hemodialysis (HD) Patients (Pts) Receiving Peginesatide for Anemia due to Chronic Kidney Disease Robert Provenzano,[1] Bruce S. Spinowitz,[1] Anatole Besarab,[1] Steven Fishbane,[1] Whedy Wang,[2] Alex Yang,[2] Martha Mayo,[2] Iain C. Macdougall.[1] *[1]AFX01-12 & -14 Peginesatide Study Groups; [2]Affymax, Inc, Palo Alto, CA.*

Background: Two randomized open-label, active-controlled trials (EMERALD 1, 2) provide a large (N~1600) database on long-term (median follow-up >60 wk) anemia treatment with peginesatide or epoetin in HD pts. In these trials, peginesatide was noninferior to epoetin in maintaining hemoglobin (Hb) levels, with similar cardiovascular safety. Given the interdependence of iron and ESAs on red cell production, we conducted post-hoc analyses of iron use and status in US EMERALD pts.

Methods: Data were pooled from EMERALD 1 and 2, assessing peginesatide Q4W vs epoetin 1-3X weekly (randomized 2:1) in US HD pts on stable epoetin doses ≥4 wk. IV iron dose, serum ferritin, and TSAT in full analysis population (FAS, randomized pts receiving ≥1 study drug dose; N=853 peginesatide, N=436 epoetin) and in completers (≥60 wks' drug exposure; ferritin, TSAT measured at same visit; N=604 peginesatide; N=336 epoetin) were summarized in 12-wk intervals through week 60.

Results: In both populations, peginesatide pts received less IV iron than epoetin pts (Figure).



TSAT (FAS) was similar at baseline in both arms (30.2% peginesatide; 29.4% epoetin) and increased to 37.9% with peginesatide compared to 30.7% with epoetin by week 12, with similar results in completers *(P*<0.01 wk 12-60, both populations). In both arms, ferritin was similar at baseline and through week 60, and Hb levels were similar for the duration of the study (FAS and completers).

Conclusions: In two post-hoc analyses in US pts, peginesatide pts received less IV iron, had higher TSAT, and had similar ferritin levels over 60 weeks, while maintaining similar Hb levels, vs epoetin pts. The observed difference in iron availability between these agents merits further scientific evaluation.

Sickle Cell Trait in African-American (AA) Hemodialysis Patients Associates with Higher Doses of Erythropoiesis-Stimulating Agents Vimal K. Derebail,[1] Eduardo K. Lacson,[2] Abhijit V. Kshirsagar,[1] Nigel S. Key,[1] Susan L. Hogan,[1] Raymond M. Hakim,[3] Ann Mooney,[2] Chinu M. Jani,[2,4] James Zazra,[4] Yichun Hu,[1] Ronald J. Falk,[1] J. Michael Lazarus.[1,2] *[1]University of North Carolina; [2]Fresenius Medical Care, NA; [3]Vanderbilt University; [4]Spectra Laboratories.*

Background: Based upon initial small studies, we evaluated whether variant hemoglobin (Hb) - sickle cell trait (HbAS) and hemoglobin C trait (HbAC)- associated with higher dose erythropoiesis-stimulating agents (ESAs) in a large, targeted national sample of AA in-center hemodialysis (HD) patients.

Methods: 5,319 AA adult prevalent HD patients were screened by hemoglobin (Hb) electrophoresis. Laboratory data and ESA dose were collected over seven months. Data were evaluated by Hb type (HbAA, HbAS, HbAC). Multivariate linear regression models (adjusted for case-mix and labs) were constructed with log-transformation of ESA dose/ treatment.

Results: Variant Hb was common and present in 671 (12.6%) patients – HbAS in 542 (10.2%) and HbAC in 129 (2.4%). Except ESA dose, variables were similar even when stratified by Hb variant, including vascular access type. Achieved Hb and hospitalization days were also similar among groups. In univariate analysis, median ESA dose was ~8.6% (p=0.02) greater in those with variant Hb and consistent between HbAS and HbAC.(Table) In multivariate models, variant Hb was associated with 13.2% (p=0.001) higher ESA dose, primarily driven by HbAS at 13.2% (p=0.003) with HbAC at 12.9% (p=0.1).

ESA dosing by Hb phenotype.

	HbAA	Variant Hb*	HbAS	HbAC
	N=4,648	N=671	N=542	N=129
Unadjusted				
ESA dose (u/tx)†	4364.1 (2237.4, 7903.4)	4737.4 (2566.0, 8645.5)	4701.1 (2611.9, 8489.2)	5449.2 (2550.5, 9832.4)
Multivariate model				
% Diff. in ESA dose (95% CI)‡	ref	13.2 (5.1, 21.9)	13.2 (4.3, 22.9)	12.9 (-3.1, 31.6)

*HbAS&HbAC, †Median(IQR), ‡Adj for age, sex, vintage, iPTH, albumin, Kt/V, ferritin, Tsat, vascular access, iron dose, missed treatments, hospitalizations

Conclusions: In a large cohort of AA HD patients, variant Hb, particularly HbAS, is common and associated with 13% higher ESA dose. Besides the potential financial impact, the clinical implications of higher ESA dose in these patients require further study.

TH-OR099

Protein Carbamylation Is due to Urea-Amino Acid Imbalance and Predicts Kidney Failure Mortality Anders H. Berg,[1] Christiane Drechsler,[2] Julia Beth Wenger,[3] Christoph Wanner,[2] Ravi I. Thadhani,[3] S. Ananth Karumanchi.[1] *[1]Beth Israel Deaconess Medical Center; [2]University of Wuerzburg, Wuerzburg, Germany; [3]Massachusetts General Hospital.*

Background: Urea carbamylates proteins and amino acids, and carbamylated proteins contribute to atherosclerosis. We hypothesized that serum levels of carbamylated albumin represent a time-averaged index of uremia and risk in hemodialysis patients, and that deficiencies of free amino acid scavengers promote protein carbamylation.

Methods: Serum from 187 participants of the Accelerated Mortality on Renal Replacement study and 1,131 subjects of Die Deutsche Diabetes Dialyze Studie were analyzed. Specimens were collected at the beginning of the 12-month study and analyzed for % carbamylated albumin and free amino acids using LC-MS/MS.

Results: Serum carbamylated albumin (%C-Alb) correlated with average blood urea and was doubled in ESRD patients compared to controls (*P*< 0.0001). %C-Alb was associated with 1-year mortality. In the 4D study cohort, %C-Alb was a similarly strong predictor of mortality. Negative correlations between subjects' %C-Alb and most amino acids suggested that free amino acids inhibit protein carbamylation. Glycylglycine, taurine, and cysteine efficiently inhibited albumin carbamlyation in vitro. Serum myeloperoxidase, thiocyanate, and smoking history were not associated with %C-Alb levels.

ArMORR Study Hazard Ratio Estimates for Mortality by Level of % Carbamylated Albumin.

	Univariate		Multivariable	
Variables	HR (95% CI)	p-value	HR (95% CI)	p-value
% Carbamylated Albumin	3.76 (2.20 - 6.43)	<0.0001*	3.04 (1.70 - 5.42)	0.0002*
Albumin	0.43 (0.26 - 0.71)	0.001*	0.58 (0.34 - 0.99)	0.04*
Hemoglobin	0.79 (0.69 - 0.91)	0.001*	0.95 (0.81 - 1.10)	0.46
History of Hypertension	0.42 (0.25 - 0.71)	0.001*	0.44 (0.26 - 0.74)	0.002*
Systolic Blood Pressure	0.98 (0.97 - 0.99)	<0.0001*	0.99 (0.98 - 1.00)	0.007*

*Students' t-test for significance at p<0.05. Data collected on days 15 - 90 after initiation of dialysis. HR represents risk of death over 12 month period.

Conclusions: Serum %C-Alb represents a novel biomarker associated with mortality in hemodialysis patients. Chronic uremia combined with amino acid deficiencies contributes to protein carbamylation, and may be modifiable by amino acid therapy.

Funding: Private Foundation Support

TH-OR100

Hemodialysis-Induced Regional Left Ventricular Systolic Dysfunction Is Associated with Inflammation Solmaz Assa,[1] Yoran M. Hummel,[2] Adriaan A. Voors,[1] Johanna J. Kuipers,[3] Paul E. de Jong,[1] Ralf Westerhuis,[3] Casper F. Franssen.[1] *[1]Nephrology; [2]Cardiology, University Medical Center Groningen; [3]Dialysis Center Groningen, Netherlands.*

Background: Hemodialysis (HD) may acutely induce regional left ventricular (LV) systolic dysfunction ('cardiac stunning'), which is associated with increased mortality and progressive heart failure. We hypothesize that patients with HD-induced regional LV systolic dysfunction have elevated markers of inflammation, which might affect cardiac function. We, therefore, studied the relation between HD-induced regional LV systolic dysfunction and plasma markers of inflammation.

Methods: In 105 patients with a mean (±SD) age of 62.5±15.6 and median (IQR) dialysis vintage of 21.4 (7.8-48.5) months, echocardiography was performed pre-HD, 60 and 180 min intra-HD, and 30 min post-HD. HD-induced regional LV systolic dysfunction was defined as an increase in wall motion score index in ≥2 segments compared with pre-HD. Plasma levels of hsCRP, IL-6 and IL-10 were measured pre-HD.

Results: Twenty-nine (27%) patients developed HD-induced regional LV systolic dysfunction. These patients had significantly higher CRP and IL-6 levels and higher lL-6/ IL-10 ratio.

Pre-dialysis, median (IQR)	No HD-induced regional LV systolic dysfunction (n=76)	HD-induced regional LV systolic dysfunction (n=29)	P value
hsCRP, mg/l	4.7 (1.6-8.8)	8.8 (6.7-12.7)	0.011
IL-6, pg/ml	4.7 (3.0-7.6)	7.1 (5.2-9.3)	0.021
IL-10, pg/ml	0.40 (0.29-0.57)	0.33 (0.22-0.59)	0.149
IL-6/ IL-10 ratio	10.7 (6.2-21.1)	20.1 (12.4-30.6)	0.002

In multivariate analysis correcting for age, sex and dialysis vintage, higher log-hsCRP (p=0.028), lower log-IL-10 (p=0.038) and higher log-IL-6/IL-10 ratio (p=0.005) were significantly associated with HD-induced regional LV systolic dysfunction. hsCRP increased with an increasing number of abnormal LV segments developing during or after HD: 0-1 abnormal segments: 4.7 (1.6-8.8); 2-3 abnormal segments: 7.8 (6.9-9.1); ≥4 abnormal segments: 9.8 mg/l (3.2-14.5); p=0.035.

Conclusions: Patients with HD-induced regional LV systolic dysfunction have a pro-inflammatory cytokine profile. These findings suggest that inflammation is involved in the pathogenesis of HD-induced regional LV systolic dysfunction.

Funding: Government Support - Non-U.S.

TH-OR101

Myostatin and Atrogin-1 mRNA Are Upregulated with TNF-α/IL-6 Elevated in Skeletal Muscle of Patients Hemodialysis Huiling Wang. *Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: The accelerated muscle wasting is common in advancedchronic kidney disease (CKD). A chronic inflammatory cytokine condition including elevated levels of the proinflammatory cytokine such as tumor necrosis factor alpha (TNF-α) and interleukin-6 (IL-6), play a pivotal role in muscle wasting in CKD. This study investigates the relationship of inflammation cytokines and muscle wasting in patients with hemodialysis (HD), and the expression of genes involved in the regulation of muscle massin musclebiopsies.

Methods: 40 HD patients were selected(HD)and 30 healthy adults with gender and age matched as control(Ctl). The biochemical, inflammatory cytokine were measured with their serum samples, the muscle mass was measured by magnetic resonance imagin(MRI). Then we analyzed the expression of Myostatin and Atrogin-1in muscle biopsies from 8HD patients and 6 non-kidney patients.

Results: The HD patients had asignificantly lower body mass index (BMI 23.44±2.50 kg/m²Ctl vs 21.36±4.47kg/m² HD, p<0.05), though the plasma albumin showed no difference in HD and Ctl.(44.02±2.33g/L Ctlvs 42.23±3.50g/L HD, p=0.329), the serum inflammation markers such as high sensitive C-protein, TNF-α and IL-6 showed elevated (hs-CRP(2.08±2.14 mg/L Ctl vs 23.95±46.46 mg/L HD, p<0.001),TNF-α(50.03±9.19 pg/mLCtl vs 65.10±12.05pg/mL HD, p<0.05), IL-6(7.29±6.91 pg/mL Ctl vs 38.53±108.99 pg/mL HD, p<0.001) in HD compared with Ctl. The HD patients tend to have a less muscle mass when analyses the cross-sectional area (CSA) of low limb by MRI. The muscle composition: total CSA ratio for all layers of MRI images was significantly decrease (p<0.01). Interestingly, the muscle TNF-α, IL-6, mostatin and Atrogin-1 mRNA levels was elevated 3-6 fold measured by RT-PCR.

Conclusions: Advanced CKD patients present a high level of TNF-α and IL-6 in serum and muscle sample. The loss of muscle mass accompanies the expression of myostatin and Atrogin-1 upregulated. So ameliorate chronic inflammatory disorders might be a reasonable strategy to improve muscle wasting in CKD.

Hypoglycemia-Related Hospitalization in Diabetic Hemodialysis Patients: Risk Factors Mark E. Williams,[1] Weiling Wang,[2] Eduardo K. Lacson.[2] *[1]Renal Division, Joslin Diabetes Center, Boston, MA; [2]Fresenius Medical Care, NA, Waltham, MA.*

Background: The benefit of tight glycemic control on outcomes in diabetic ESRD appears to be weak. Hypoglycemia is associated with increased risk of adverse clinical outcomes in the general diabetic population. We previously reported that the risk of hypoglycemia-related hospitalization was associated with higher, not lower, hemoglobin A1c (HbA1c) values.

Methods: We further analyzed 24,751 diabetic chronic in-center HD patients in Fresenius-North America facilities active on January 1, 2003 with at least one HgA1c in Q4-2002. Baseline patient characteristics (age, gender, race, body surface area or BSA, diabetes type, vascular access), insulin use, and labs (HbA1c, eKt/V, albumin, hemoglobin, calcium, phosphorus, creatinine, and white blood cell count) were recorded. Over the next three years, hospitalization ICD-9 diagnosis codes that specified hypoglycemia were found in 1,017, or 4.1% of patients (cases). Stepwise logistic regression models were used to determine significant associates of hypoglycemia-related hospitalizations. Time-dependent Cox models were used to relate HbA1c and glucose results to the same outcome.

Results: High HbA1c was associated with increased risk of hypoglycemia in the same quarter for Type 1 and, to a lesser extent in Type 2, patients. Glucose variability was strongly associated with hospitalization and mortality by standard Cox model. HbA1c levels drawn one quarter earlier confirmed the greater risk of hypoglycemia-hospitalization for high HbA1c levels. Over 12 quarters, distribution of HbA1c values in the population remained constant, except for a decrease in the lowest HbA1c categories. Use of insulin rose steadily in incident patients throughout the 12 quarters. High-A1c patients were more likely to be on insulin. Greater glucose variability was associated with higher mean glucose levels by trend analysis.

Conclusions: High HbA1c values and glucose variability increase the hazard risk for hypoglycemia requiring hospitalization in diabetic ESRD. Risk of hypoglycemia must be considered when attempts are made to improve high A1c levels with aggressive use of medications such as insulin.

TH-OR103

Effect of Ultrapure Dialysate on Markers of Inflammation, Oxidative Stress, and Nutrition, and Anemia Parameters: A Meta-Analysis Paweena Susantitaphong,[1,2] Cristian Riella,[1] Bertrand L. Jaber.[1] *[1]Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Medicine, Chulalongkorn University, Bangkok, Thailand.*

Background: Markers of inflammation have been linked to malnutrition and confer an increased mortality risk in hemodialysis patients. Ultrapure dialysate has been hypothesized to have a beneficial effect on markers of inflammation. To systematically review the evidence, we conducted a meta-analysis of all the studies of patients on hemodialysis that examined the effect of ultrapure vs. standard dialysate on markers of inflammation, oxidative stress and nutrition, and anemia parameters, and explored sources of heterogeneity.

Methods: We performed a literature search using MEDLINE, Cochrane Central Register of Controlled Trials, ClinicalTrials.gov, scientific abstracts, and bibliographies of retrieved articles. Single-arm cohort studies (pre-/post-study evaluations), non-randomized and randomized controlled trials were included. We conducted random-effects model meta-analyses to assess changes in outcomes of interest.

Results: We identified 16 single-arm or cohort studies, 2 crossover and 3 parallel-arm non-randomized controlled trials, and 5 crossover and 5 parallel-arm randomized controlled trials. In an analysis of 23 study arms or cohorts that assessed CRP (n=2,221), use of ultrapure dialysate resulted in a significant decrease in the CRP level (-0.32 mg/dL; 95% CI -0.46,-0.18; P<0.001). Other inflammatory markers displayed similar significant improvements. There were also a significant increase in the serum albumin (0.11 g/dL; 95% CI 0.02, 0.19; P=0.011) and hemoglobin level (0.40 g/dL; 95% CI 0.06, 0.75; P=0.022), and a decrease in the weekly erythropoietin dose (-273 units; 95% CI -420, -126; P<0.001). The results remained significant when the analyses were restricted to the controlled trials.

Conclusions: Use of ultrapure dialysate in hemodialysis patients results in a decrease in several markers of inflammation and oxidative stress, an increase in serum albumin and hemoglobin, and a decrease in erythropoietin requirement. Although, the improvement in these surrogaste endpoints might confer a cardiovascular benefit, a large trial with hard clinical endpoints is required.

β2 Integrin-Mediated Cell-Cell Contact Transfers Myeloperoxidase from Neutrophils to Endothelial Cells Uwe Jerke,[1] Susanne Rolle,[1] Bettina Purfürst,[2] Friedrich C. Luft,[1] William Michael Nauseef,[3] Ralph Kettritz.[1,4] *[1]Experimental and Clinical Research Center, a Joint Cooperation between the Charité and the Max-Delbrück Center for Molecular Medicine (MDC); [2]MDC, Berlin; [3]Iowa Inflammation Program and Department of Medicine, Roy and Lucille A. Carver College of Medicine, University of Iowa and VA Medical Center, IA; [4]Nephrology and Intensive Care Medicine, Charité Campus Virchow, Berlin.*

Background: ANCA vasculitis and atherosclerosis both feature inflammation mediated by neutrophil-endothelial-cell (EC) contact. The heme protein myeloperoxidase (MPO) provides an ANCA antigen, but also disrupts normal EC function. MPO has the unique capacity to oxidize chloride and to generate hypochlorous acid, a potent microbicide that contributes to host defense, but also promotes cardiovascular disease. The mechanism by which MPO is transferred to EC are unknown. It is assumed that EC capture MPO that is released into the blood by activated neutrophils. We tested the hypothesis that close, β2-integrin-dependent neutrophil-EC contact also mediates MPO transfer from neutrophils to EC.

Methods: We used sensitive MPO assays, flow cytometry and confocal microscopy to detect MPO in EC. Human and wild-type and CD11b knock-out mouse neutrophils as well as different EC lines were employed.

Results: We demonstrate that EC acquired MPO when direct neutrophil contact was allowed, but not when EC and neutrophils were separated in transwells. The transfer was dependent on neutrophil number, incubation temperature and time. Transfer occurred in several EC types, increased with endotoxin, was not accompanied by MPO release into the medium and was not abrogated by inhibiting degranulation to secretogogues. Confocal microscopy showed MPO internalization by EC. Neutrophils and EC formed intimate contact sites by electron microscopy. Blocking CD11b or CD18 β2-integrin chains, or using neutrophils from CD11b gene-deleted mice, reduced MPO transfer.

Conclusions: The data suggest an alternative to EC uptake of soluble MPO, namely the cell contact-dependent, β2-integrin-mediated transfer from neutrophils. The findings could be of therapeutic relevance in atherosclerosis and vasculitis.

Biomechanical Strain-Mediated Mesangial Filopodial Invasion of Capillary Tuft as the Source of GBM Laminin 211 in Alport Mice: Early Mechanism for Alport Glomerular Pathology Dominic E. Cosgrove, Brianna Johnson, Daniel T. Meehan, Duane C. Delimont, Marisa Zallocchi. *Genetics, Boys Town National Research Hospital, Omaha, NE.*

Background: Alport syndrome results from mutations in type IV collagen COL4A3, COL4A4, or COL4A5 genes. Mutations in any of these genes results in the absence of all 3 in the GBM type IV collagen network. The result is a thinner and less crosslinked GBM collagen network resulting in delayed onset progressive glomerulonephritis. The molecular trigger for disease onset is unknown.

Methods: Alport mice, CD151 knockout mice, laminin α2-deficient Alport mice, Rac1 inhibition in Alport mice, and L-NAME-induced hypertension. Glomeruli analyzed by fluorescence immunohistochemistry and real time qRT-PCR. Mesangial cell migration and mesangial cell stretching assays.

Results: A comparative analysis of glomerular disease progression in Alport mice and CD151 knockout mice revealed a progressive irregular deposition of mesangial laminin 211 in the GBM. Co-localization studies showed that integrin α8β1 also progressively accumulates in the capillary loops of both models, reflecting an invasion of the capillary loops by mesangial cell processes. L-NAME salt-induced hypertension accelerated mesangial filopodial invasion, suggesting biomechanical strain plays a role in this mechanism. Mesangial cells showed reduced migratory potential when treated with either integrin linked kinase inhibitor, focal adhesion kinase inhibitor, or Rac1 inhibitors. Biomechanical stretching of cultured mesangial cells induced promigratory cytokines TGF-β1 and CTGF. Treatment of Alport mice with Rac1 inhibitors reduced mesangial filopodial invasion of the glomerular capillary tuft. Laminin α2-deficient Alport mice show reduced GBM damage and triple the lifespan of Alport mice, indicating a central role for mesangial laminins in progression of Alport glomerular pathogenesis.

Conclusions: Collectively, these findings predict a role for biomechanical insult in the induction of mesangial filopodial invasion of the glomerular capillary tuft leading to the irregular deposition of mesangial laminin 211 as an initiation mechanism of Alport glomerular pathology.

Model for Idiopathic FSGS: Proteinuria after Injection or Overexpression of Cardiotrophin-Like Cytokine 1 in Mice Virginia J. Savin,[1] Mukut Sharma,[1] Changli Wei,[3] Jochen Reiser,[3] Ellen T. McCarthy,[2] Jean-francois Gauchat,[4] Ram Sharma.[1] *[1]Research Service, Kansas City VAMC, Kansas City, MO; [2]Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [3]Nephrology, University of Miami School of Medicine, Miami, FL.*

Background: Idiopathic focal segmental glomerulosclerosis (FSGS) is associated with recurrence after transplantation due to circulating permeability factor(s) (NEJM, 334:878-883, 1996, Nat Med, 17:952-60, 2011). We have shown the effects of FSGS plasma and its fractions on glomerular permeability *in vitro* and *in vivo* and have used state-of-the-art proteomics to identify cardiotrophin-like cytokine-1 (CLCF1), a member of the IL-6 family, as a candidate for the active substance. We propose to develop a unique model of FSGS based on the effects of CLCF1 in mice.

Methods: rCLCF1 (R&D Systems) was injected intraperitoneally (IP), one dose, 10 μg/kg, or infused by minipump for 28 days, 200 ng/day. A construct containing *CLCF1* was administered by electroporation. Studies were done in C57BL6 mice. Urinary albumin/creatinine, pJAK1, pSTAT3, pATK, and pERK in peripheral blood cells (PBC) and in kidney homogenate were measured and glomerular histology was assessed.

Results: Albuminuria of up to 5 times baseline occurred after injection or electroporation. Albuminuria was maximal 6 days after electroporation of *CLCF1* construct. pJAK2 and pSTAT3 of PBC were increased within 15 min. of injection and kidney pJAK1 and pSTAT3 remained upregulated for at least 72 hours after injection. Kidney homogenate pJAK2, pSTAT3, pERK/12 and pAKT were each increased after 28 days of infusion. Glomeruli at 28 days showed increased mesangial matrix.

Conclusions: We conclude that CLCF1 mimics renal effects of the active fraction of plasma from patients with idiopathic FSGS and may play an important role in FSGS in native kidneys and transplant recurrence. Its relationship to other candidates such as circulating urokinase receptor (suPAR) requires further investigation. A murine model based on administration or overexpression of *CLCF1* may permit us to define mechanisms of injury and to test potential therapeutic agents prior to clinical trials.

A Transcriptional Network Underlies Susceptibility to Kidney Disease Progression Denise Laouari,[1] Martine Burtin,[1] Frank Bienaime,[1] Christophe M. Legendre,[1] Gerard Friedlander,[1] Marco Pontoglio,[2] Fabiola Terzi.[1] *[1]INSERM U845 - Universite Paris Descartes - APHP, Paris, France; [2]INSERM U1016 - CNRS UMR 8104 - Universite Paris Descartes, Paris, France.*

Background: The molecular networks that control the progression of chronic kidney diseases (CKD) are poorly defined. EGFR stimulates CKD progression, but the molecular networks that activate this signaling pathway remain unknown. We have recently shown that the susceptibility to development of renal lesions after nephron reduction is controlled by a locus (*Ckdp1*) on mouse chromosome 6 and requires EGFR activation through TGF-α. The aim of the present study was to identify the modifier gene(s) encoded by the *Ckdp1* locus.

Methods: For this purpose, we used *in silico, in vivo* and *in vitro* approaches. *In vivo*, we combined an experimental model of nephron reduction to mice from different genetic backgrounds and genetically modified animals. *In vitro*, molecular and cellular studies were conducted to determine the functional consequence of the genetic variant. In addition, human biopsies from renal transplant recipients with different scores of renal lesions were studied.

Results: We identified *Mitfa*, a gene encoding for a bHLH transcription factor, as a candidate modifier of CKD progression. Sequencing revealed a strain-specific hypomorphic variant in the 5' UTR of *Mitfa* that decreased the efficiency of MITF-A translation in FVB/N mice. *In vitro*, we observed that MITF-A acts in a complex genetic network in which it interacts with histone deacetylases to repress the transcription of TGF-α and antagonizes transactivation by its related partner, TFE3. Consistent with the key role of this network in CKD, TFE3 significantly increased after nephron reduction. More importantly, *Tgfa* gene inactivation protected hypomorphic *Mitfa* FVB/N mice from renal deterioration after nephron reduction. These data are relevant to human CKD, as we found that TFE3/MITF-A ratio markedly increased in patients with progressive renal damage.

Conclusions: In conclusion, our study uncovers a novel transcriptional network and unveils novel potential prognostic and therapeutic targets for preventing progression of human CKD.

Downregulation of miR-205 Modulates Cell Susceptibility to Oxidative and Endoplasmic Reticulum Stresses in Renal Tubular Cells Shiyo Muratsu, Masaomi Nangaku, Yoichiro Ikeda, Tetsuhiro Tanaka, Takehiko Wada, Reiko Inagi. *Division of Nephrology and Endocrinology, University of Tokyo Hospital, Tokyo, Japan.*

Background: Oxidative stress and endoplasmic reticulum (ER) stress play a crucial role in tubular damage. While the pathophysiological contribution of microRNAs (miR) to renal damage has been highlighted, the effect of miR on renal damage under oxidative and ER stresses remains elusive.

Methods: We assessed the effect of miR expression in cultured human tubular cells (HK-2) exposed to hypoxia-reoxygenation or ER stress by miR microarray analysis. The pathophysiological effect of miR was evaluated by cell survival rate, intracellular reactive oxygen species (ROS) level, and anti-oxidant enzyme expression in miR-modulated HK-2 under these stress conditions. The target gene of miR was identified by 3'UTR-luciferase assay.

Results: In 799 miRs we tested, we identified one miR, miR-205, whose expression was markedly decreased under both stress conditions. Functional analysis revealed that decreased miR-205 enhanced cell susceptibility to both stresses, which was associated with the induction of intracellular ROS. While increased miR-205 by itself made no change in phenotypes of HK-2, cell viability under both stresses was partially restored. Further, miR-205 bound to the 3'UTR of the prolyl hydroxylase 1 (PHD1) and suppressed the transcription level of PHD1. The upregulation of PHD1 by inhibiting miR-205 decreased nuclear amount of HIF, resulting in the reduction of HIF-regulated anti-oxidant enzymes (SOD1, SOD2, and catalase). Moreover, the inhibition of miR-205 decreased nuclear activating transcription factor 4 (ATF4), which was a crucial regulator of ER stress. Targets of ATF4 include genes for redox balance, such as hemoxygenase 1 (HO-1), which mediates an adaptive response to oxidative stress and was indeed decreased by miR-205 inhibition.

Conclusions: PHD1 is one of the novel direct targets of miR-205, and its upregulation by inhibiting miR-205 leads to subsequent downregulation of HIF and ATF4, then finally increases the intracellular ROS via suppression of HIF/ATF4-regulated anti-oxidant enzymes, and renders the cells more vulnerable to these stresses.

TH-OR109

Tubular β-Catenin Signaling Controls Interstitial Fibroblast Fate via Epithelial-Mesenchymal Communication Dong Zhou, Youhua Liu. *Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Activation of β-catenin, the principal mediator of canonical Wnt signaling, is a common finding in a wide variety of chronic kidney diseases (CKD). Inhibition of hyperactive β-catenin in CKD is known to be reno-protective, leading to amelioration of renal fibrotic lesions. β-Catenin is predominantly induced in renal tubular epithelium; however, the role of tubule-specific β-catenin activation in renal fibrogenesis remains elusive.

Methods: We investigated this issue by utilizing mice with tubule-specific ablation of endogenous β-catenin (Ksp-β-cat-/-). These mice are phenotypically normal under normal physiologic conditions.

Results: Surprisingly, we found that loss of tubular β-catenin resulted in little alterations in renal fibrosis after obstructive injury. Both Ksp-β-cat-/- mice and their control littermates displayed similar fibrotic lesions at different time points after unilateral ureteral obstruction (UUO), as shown by the same levels of collagen, fibronectin and PAI-1 expression. No difference was found in renal α-SMA levels in the obstructed kidneys of Ksp-β-cat-/- and control mice, suggesting a similar size of myofibroblast population, despite epithelial-mesenchymal transition was largely inhibited in Ksp-β-cat-/- kidneys. Interestingly, more apoptosis was detected selectively in renal interstitial fibroblasts of control mice, compared to Ksp-β-cat-/- mice, which was accompanied by an increased renal expression of Bax and Fas ligand (FasL). Tubule-specific knockout of β-catenin abolished the induction of MMP-7 in the obstructed kidneys. In vitro, recombinant MMP-7 induced FasL expression in renal interstitial fibroblasts and promoted fibroblast apoptosis.

Conclusions: These results demonstrate that loss of tubular β-catenin resulted in an enhanced interstitial fibroblast survival. Our studies also illustrate a novel role of MMP-7 in mediating epithelial-mesenchymal communication in renal fibrogenesis.

Nuclear Hormone Receptor Farnesoid X Receptor and G Protein Coupled Receptor TGR5 Exhibit Calorie Restriction Mimetic Effects in Aging Mice Xiaoxin Wang, Hannah Danielle Santamaria, Liru Qiu, Moshe Levi. *Medicine, University of Colorado, Aurora, CO.*

Background: Lifelong calorie restriction (CR) has been shown to have beneficial effects on life and health span in aging rodents and mammals and to prevent age-related decline is renal function. We have found that renal expression of FXR and TGR5 are decreased in ad lib fed aging mice. In contrast in mice with lifelong CR FXR and TGR5 expression are markedly increased. The purpose of the present study was to determine if activation of FXR and TGR5 in the kidneys of ad lib fed aging mice have similar effects to CR.

Methods: We studied 5 month old ad lib fed, 24 month old ad lib fed, 22 months old ad lib fed mice treated with the dual FXR/TGR5 agonist INT-767 for 2 months, and compared them to lifelong 24 month old CR mice.

Results: We found that treatment of 22 month old ad lib fed aging mice with INT-767 decreased urinary albumin excretion, markers of fibrosis, and oxidative stress. INT-767 also prevented age-related decreases in eNOS protein and mRNA. In addition INT-767 treatment augmented energy metabolism and mitochondrial biogenesis in the aging kidney, including increases in Nampt, SIRT1, PGC-1α, ERRα, SIRT3, Nrf1, mitochondrial DNA content, and mitochondrial fatty acid oxidizing enzymes MCAD and PDK4, when compared to ad lib fed 24 month old mice. The changes induced by INT-767 treatment of 22 month old ad lib fed aging mice over a 2 month period were remarkably similar to those induced by lifelong CR in 24 month old mice and also the long-lived Ames Dwarf mice.

Conclusions: Our results therefore indicate that activation of FXR and TGR5 in the aging kidney reverses most of the age-related changes and the effects of FXR and TGR5 are similar to beneficial effects achieved by lifelong calorie restriction.

Internalization and Retromer Binding Regulate Vasopressin V2-Receptor Desensitization: Differential Effects of Vasopressin and Oxytocin on cAMP Signaling Richard Bouley,[1] Timothy N. Feinstein,[2] Naofumi Yui,[3] Dennis Brown,[1] Jean-Pierre Vilardaga.[2] *[1]CSB, Program in Membrane Biology and Nephrology Division, Massachusetts General Hospital, Boston, MA; [2]Department of Pharmacology and Chemical Biology, University of Pittsburgh, Pittsburgh, PA; [3]Nephrology Division, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: The peptide hormones vasopressin (VP) and oxytocin (OT) both bind a single G protein-coupled receptor, the vasopressin type 2 receptor (V2R), in renal epithelial cells. The antidiuretic effect of VP, however, is much greater than OT.

Methods: Here we used a combination of pharmacological, biochemical and optical techniques, including FRET-based approaches, to determine the molecular and cellular mechanisms that differentiate for the biological differences between VP and OT acting at the V2R.

Results: We find that VP induced rapid translocation of β-arrestins, V2R internalization and cAMP generation that persisted for 20-30 min after VP washout. In kidney epithelial cells expressing transgenic V2R (MDCK-V2R), VP induced persistent apical localization of the water channel protein aquaporin 2 (AQP2) and phosphorylation at S269. OT induced neither arrestin binding nor V2R internalization. cAMP generation ended quickly after OT washout, and phosphorylation and apical localization of AQP2 did not persist after OT washout. Expression of a dominant-active mutant of β-arrestin 1 further enhanced cAMP generation and cAMP generation was shorter when either V2R or the cAMP biosensor was restricted to the plasma membrane, supporting a model in which arrestin and V2R internalization enhance rather than inhibit cAMP generation by V2R. Desensitization was mediated instead by the endosomal sorting complex retromer. Internalized V2R colocalized and formed a complex with retromer, which in turn inhibited cAMP generation triggered by VP.

Conclusions: We conclude that V2R can signal from early endosomes after challenge with VP but not OT, and that endosomal signaling is terminated by the retromer sorting complex. This ligand-biased signaling could explain distinct physiological effects during the therapeutic use of ligands that target the V2R.

Absence of PKC-alpha Attenuates Lithium-Induced Nephrogenic Diabetes Insipidus Jae H. Sim, Sara K. Redd, Seongun M. Hong, Tobias N. von Bergen, Mitsi A. Blount. *Department of Medicine - Renal Division, Emory University, Atlanta, GA.*

Background: Lithium, the most effective treatment for bipolar disorder, induces nephrogenic diabetes insipidus (NDI) in ~ 60% of patients. We and others have shown that the decreased capacity to concentrate urine is likely due to lithium acutely disrupting the cAMP pathway and chronically reducing the urea transporter (UT-A1) and water channel (AQP2) expression in the kidney inner medulla. Targeting an alternative signaling pathway, such as PKC signaling may be an effective method of treating lithium-induced polyuria.

Methods: PKC-alpha KO mice and strain-matched wild type (WT) controls were first treated with 40 mmol/kg of lithium for 0, 3, or 5 days. In separate experiments, animals were treated with lithium for 6 wk.

Results: WT mice had increased 24 h urine output and lowered urine osmolality after 3 and 5 days of treatment whereas PKC-alpha KO mice had no change in basal urine output or concentration at either time point. Western blot analysis revealed that AQP2 expression was lowered 53% after 3 days and 86% after 5 days; however, APQ2 was unchanged in PKC-alpha KO mice. Similar results were observed with UT-A1 expression. Animals were next treated with lithium for 6 wk. Lithium-treated WT mice had 19-fold increased urine output which was significantly different from treated PKC-alpha KO animals which had a 4-fold increase in urine output. Western blot analysis revealed that AQP2 and UT-A1 expression were barely detectable in 6 wk lithium-treated WT animals whereas in treated PKC-alpha KO mice, APQ2 and UT-A1 expression was only reduced by 2-fold.

Conclusions: Our data shows that ablation of PKC-alpha preserved urine concentrating transporter expression in lithium-induced NDI and this likely prevents the development of the severe polyuria associated with therapy.

Vasopressin V2R-Targeting Peptide Carrier Mediates siRNA Delivery Into Collecting Duct Cells Hyun Jun Jung, Jung-suk Lim, Hyo-jung Choi, Tae-Hwan Kwon. *Department of Biochemistry and Cell Biology, School of Medicine, Kyungpook National University, Taegu, Korea.*

Background: Internalization of receptor proteins after interacting with specific ligands has been proposed to facilitate siRNA delivery into the target cells via receptor-mediated siRNA transduction. In this study, we demonstrated a novel method of vasopressin V2 receptor (V2R)-mediated siRNA delivery against AQP2 in primary cultured inner medullary collecting duct (IMCD) cells of rat kidney.

Methods: The dDAVP conjugated with nine D-arginines (dDAVP-9r) as a peptide carrier for siRNA delivery was synthesized. We examined 1) formation and stability of the polyplexes by Electrophoretic mobility shift assay; 2) Cellular uptake of the polyplexes in V2R-expressing cells by flow cytometry analysis and confocal microscopy; 3) Particle size and surface charge of the polyplexes; 4) Phsphorylation of AQP2 (S256) in rat IMCD cells by interaction of V2R and the polyplexes; 5) Protein knockdown of AQP2 via siRNA delivery using AQP2-siRNA/dDAVP-9r polyplexes by semiquantitative immunoblotting.

Results: The results revealed that 1) synthesized dDAVP-9r peptides formed a stable polyplex with siRNA; 2) siRNA/dDAVP-9r polyplex could bind to the V2R of IMCD cells and induced AQP2 phosphorylation (Ser 256); 3) siRNA/dDAVP-9r polyplex was stable in response to the wide range of different osmolalities, pH levels, or to the RNases; 4) fluorescein-labeled siRNA was delivered into V2R-expressing MDCK and LLC-PK1 cells by siRNA/dDAVP-9r polyplex, but not into the V2R-negative Cos-7 cells; and 5) AQP2-siRNA/dDAVP-9r polyplex effectively delivered siRNA into the IMCD cells, resulting in the significant decrease of protein abundance of AQP2, but not AQP4.

Conclusions: We introduced a novel method of V2R-mediated siRNA delivery in the kidney collecting duct cells using a specific peptide ligand to V2R. siRNA/dDAVP-9r polyplex effectively delivered siRNA into the IMCD cells in vitro, resulting in the significant decrease of protein abundance of AQPs. This method could be exploited to deliver siRNAs to regulate abnormal expression of specific target proteins in vivo, potentially associated with disease conditions in the kidney tubule cells expressing V2R.

Identification of Proteins Involved in the Trafficking of Aquaporin-2 via Genome-Wide siRNA Screening Doerte Faust,[1] Martin Neuenschwander,[2] Katina Lazarow,[2] Simone M. Graeber,[2] Jens Peter von Kries,[2] Walter Rosenthal,[1] Enno Klussmann.[1] *[1]Max-Delbrück-Center for Molecular Medicine, Berlin, Germany; [2]Leibniz-Institut für Molekulare Pharamakologie (FMP), Berlin, Germany.*

Background: Arginine-vasopressin (AVP) controls water reabsorption in renal collecting duct principal cells and thereby fine tunes body water homeostasis. AVP stimulates V2R receptors on the basolateral surface of the cells, which increases cAMP and leads to activation of protein kinase A (PKA). PKA phosphorylates the water channel aquaporin-2 (AQP2), inducing its redistribution from intracellular vesicles into the plasma membrane. This facilitates water reabsorption from primary urine. Aberrations of AVP secretion or AVP-activated signaling cause nephrogenic diabetes insipidus (NDI). An elevated blood plasma AVP level is associated with chronic heart failure and the syndrome of inappropriate antidiuretic hormone secretion (SIADH).

Methods: We are establishing a genome-wide siRNA screening using mouse collecting duct cells stably expressing human AQP2 (MCD4). The cells are transfected with siRNA in 384 well format to down regulate the expression of 17,000 genes. The localisation of AQP2 is analyzed by automated immunofluorescence microscopy.

Results: By using CellProfiler analysis software detailed image information was extracted. To classify the different complex phenotypes ranging from exclusive intracellular to exclusive plasma membrane localization of AQP2, machine learning was used, combining advanced statistical and computational techniques in learning generative models. The efficiency of reverse siRNA transfection was optimized to minimize adverse effects on cell viability and maximize down regulation of protein expression. Up to 80% reduction of gene expression was achieved. Using this system we aim to identify components of the AQP2 trafficking machinery.

Conclusions: Our approach contributes to understanding the molecular mechanisms underlying the control of AQP2 and to identify potential therapeutic targets for the treatment of diseases that are associated with disturbances of AVP-mediated water reabsorption.

Funding: Government Support - Non-U.S.

TH-OR115

A Novel PKA-Independent Signaling Pathway Controlling AQP2 Trafficking as a Possible Cause for the Syndrome of Inappropriate Antidiuresis Grazia Tamma,[1] Christiane Trimpert,[2] Marianna Ranieri,[1] Annarita Di Mise,[1] Maria Grazia Mola,[1] Olivier Devuyst,[3] Maria Svelto,[1] Peter M.T. Deen,[2] Giovanna Valenti.[1] *[1]Dept. Bioscience Biotechnologies and Pharmacological Sciences I, University of Bari, Bari, Italy; [2]Dept. of Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [3]Inst. of Physiology, University of Zurich, Zurich, Switzerland.*

Background: Renal water reabsorption is controlled by vasopressin (AVP) which activates phosphorylation of AQP2 at serine 256 (pS256) and translocation to the plasma membrane. Besides S256, AVP causes dephosphoryation of S261. Recent studies showed that cyclin-dependent kinases can phosphorylate S261 AQP2 peptides in vitro. In an attempt to investigate the possible role of cdk_s on AQP2 phosphorylation, we identified a PKA-independent pathway regulating AQP2 trafficking.

Methods: MDCK cells or kidney slices were left untreated or forskolin stimulated with or without roscovitine (10μM), a specific cdk_s inhibitor.

Results: In *ex-vivo* kidney slices and MDCK cells roscovitine increased pS256 and decreased pS261.The changes in AQP2 phosphorylation were paralleled by an increase in cell surface AQP2 expression and osmotic water permeability in the absence of forskolin stimulation. Of note, roscovitine did alter neither cAMP intracellular level nor PKA activity. Because phosphorylation results from the balance between kinase and phosphatase activity we evaluated the possible contribution of protein phosphatases PP1, PP2A and PP2B. Of these, roscovitine treatment specifically reduced PP2A activity in MDCK cells. Interestingly, in $PKD1^{+/-}$ mice displaying a syndrome of inappropriate antidiuresis with high level of pS256 despite unchanged AVP and cAMP (Alharabi et. al 2007) we found a reduced PP2A expression and activity. Indeed similarly to what previously found in $PKD1^{+/-}$ mice, roscovitine significantly decreased intracellular calcium in MDCK.

Conclusions: Our data indicate that a reduced activity of PP2A, secondary to reduced intracellular Ca2+ levels, promotes AQP2 trafficking independently from the AVP-PKA axis. This pathway may be relevant for explaining pathological states characterized by inappropriate AVP secretion and positive water balance.

TH-OR116

Small Molecule Library Screening to Identify Components of the Machinery Controlling Aquaporin-2 in Renal Principal Cells Enno Klussmann,[1] Jana Bogum,[2] Doerte Faust,[1] Jens Furkert,[2] Martin Neuenschwander,[2] Jens Peter von Kries,[2] Burkhard Wiesner,[2] Giovanna Valenti,[3] Walter Rosenthal.[1] *[1]Max Delbrueck Center Berlin-Buch (MDC), Berlin, Germany; [2]Leibniz-Institut für Molekulare Pharmakologie (FMP), Berlin, Germany; [3]Department of General and Environmental Physiology, University of Bari, Bari, Italy.*

Background: Arginine-vasopressin (AVP) regulates water reabsorption of renal collecting duct principal cells. It binds to V2 receptors on the surface of the cells, leading to elevation of cAMP and subsequent activation of protein kinase A (PKA). PKA phosphorylates the water channel aquaporin-2 (AQP2) at serine 256 (S256), which elicits the translocation from intracellular vesicles to the plasma membrane and facilitates water reabsorption from primary urine. Our study aims at the identification of novel players controlling AQP2.

Methods: MCD4 cells stably expressing AQP2 were incubated with each of 17,700 small molecules (ChemBioNet library), stimulated with the cAMP-elevating agent forskolin and AQP2 was detected by automated immunofluorescence microscopy.

Results: One of the small molecules identified by this approach was 4-acetyldiphyllin (4AD), a specific blocker of vacuolar (V)-ATPase. It inhibits the cAMP-dependent increase of AQP2 phosphorylation at S256 and its translocation to the plasma membrane of principal cells. 4AD does not affect cAMP levels or PKA activity; it increases pH levels of intracellular vesicles and causes an accumulation of AQP2 in the Golgi.

Conclusions: The acidification of intracellular vesicles by V-ATPase is not only essential for the exit of AQP2-bearing vesicles from the Golgi but also facilitates the PKA-catalyzed phosphorylation of AQP2 at S256, a prerequisite for its AVP-induced translocation to the plasma membrane of renal collecting duct cells.

In general, the identification of the target proteins of candidate molecules will contribute to understanding the molecular mechanisms underlying AQP2 trafficking and may lead to the development of new therapeutic approaches for the treatment of diseases that are associated with disturbances of AVP-mediated water reabsorption such as chronic heart failure or SIADH.

Deep Sequencing of the Cortical Thick Ascending Limb Transcriptome Jae Wook Lee, Chung Lin Chou, R. Lance Miller, Mark A. Knepper. *Epithelial Systems Biology Laboratory, Systems Biology Center, National Heart, Lung and Blood Institutes, National Institutes of Health, Bethesda, MD.*

Background: Renal tubule microdisseection has been an important tool in the discovery of renal mechanisms for the past 50 years. Here, we extend the use of microdissected renal tubules to transcriptomic analysis using the RNA-seq method with small sample amplification.

Methods: Samples containing 5-25 mm of cortical thick ascending limbs (cTAL) were isolated by hand dissection from collagenase-incubated rat renal cortex. After lysis of cells, poly(A)-targeted reverse transcription and library preparation were performed. Paired-end sequencing of the cDNA library was done using an Illumina HiSeq 2000 sequencer. The generated 50-bp reads were aligned to the UCSC rat reference genome. Reads per kilobase exon model normalized by million mapped reads (RPKM) were calculated.

Results: In an initial sample of 5 mm cTALs, 451,694,588 total reads were obtained of which 235,735,784 reads (52%) were mapped and properly paired. In this experiment, 5410 RefSeq genes were identified. To assess accuracy, we surveyed G-protein coupled receptors (GPCRs) and transport proteins that were identified. Among the GPCRs known to be expressed in cTAL (*Avpr2, Pth1r, Gcgr, Calcr, Casr, and Ptger3*) only the calcitonin receptor was not found. Among the transporter proteins generally accepted to be expressed in cTAL (*Slc12a1, Kcnj1, Clcnkb, Cldn16, Slc9a3, Slc2a4 and Atp1a1*) only *Slc9a3* was not found. In contrast, transporter proteins characteristic of neighboring tubule segments were not detected. Gene-set analysis also showed overrepresentation of mitochondrial genes among transcripts of high RPKM. When longer lengths of cTAL were used, the number of mapped transcripts increased, but not linearly (15 mm, 8455 genes; 25 mm, 12,110 genes). Experiments with a second segment, medullary TALs, gave a profile very similar to that of the cTAL.

Conclusions: These studies establish the feasibility of RNA-seq-based transcriptomic profiling in microdissected renal tubule segments and 'open the door' for profiling of gene expression along the entire renal tubule.

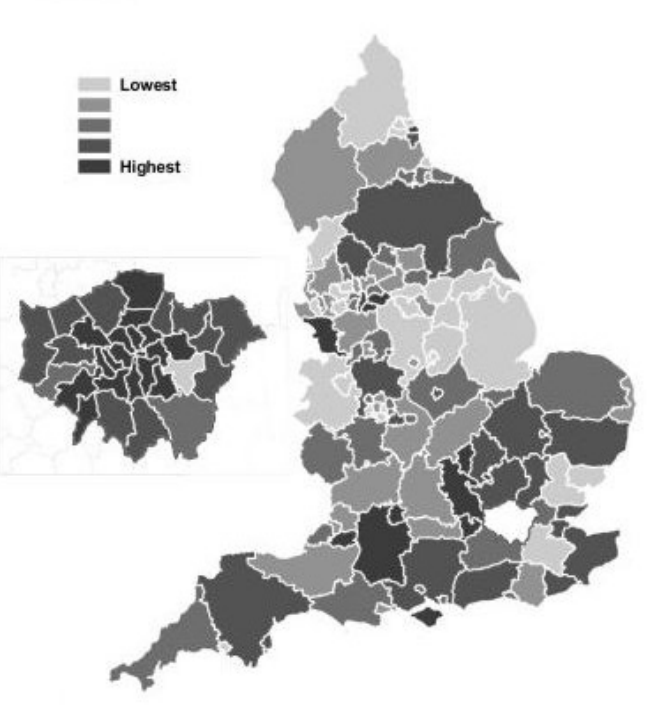
Mapping Healthcare in England: The Atlas of Variation for People with Kidney Disease Partha Das,[1] Ben Bray,[1] Donal O'Donoghue,[2] Beverley Matthews.[1] *[1]NHS Kidney Care, London, United Kingdom; [2]National Clinical Director for Kidney Care, Department of Health, London, United Kingdom.*

Background: Geographical variations in healthcare will always occur but some variations are unwarranted. The study of unwarranted variation has been revolutionised since the publication of the Dartmouth Atlas of Healthcare in 1996 by John Wennberg. The NHS in England has replicated this with the Atlas of Variation in 2010 and 2011. Nephrology has had no such analysis by regional until now. The service improvement organisations NHS Kidney Care and Right Care present the first Atlas of Variation for People with Kidney Disease.

Methods: 18 indicators have been selected encompassing CKD in primary care, secondary care treatments and patient reported outcome measures. Data have been extracted from a variety of sources including UK Renal Registry data and visualised as maps by geographical region, NHS primary care trust (PCT) or renal service provider.

Results: Significant variations exist across England. Examples include the observed:expected prevalence of CKD which varies from 0.3 to 1.4 (4.5-fold variation.)



The standardised acceptance ratio for incidence of RRT ranges from 0.4 to 2.6 (7-fold variation) and those presenting late (<90 days) range from 11.5% to 35.2% (3.1-fold variation). The percentage of incident patients with definitive dialysis access ranges from 42.5% to 62.3% (1.5-fold variation by network). The rate of kidney transplants from living donors ranges from 11.6 to 22.3 per million population (1.9-fold variation).

Conclusions: This atlas is the first to highlight geographical variations in kidney care in a nation. The causes are many but the fact that unwarranted variation exists in the delivery of renal services should prompt improvements in the organisation of care. The atlas provides a unique opportunity to understand and eliminate unwarranted variation in kidney care.

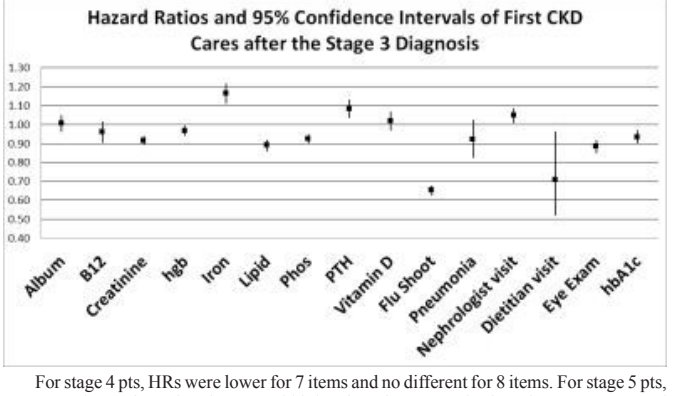
Racial Disparity in CKD Care among Medicare CKD Patients

Jiannong Liu,[1] Robert N. Foley,[1,2] David T. Gilbertson,[1] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Mpls, MN; [2]Medicine, Univ of MN, Mpls, MN.*

Background: Studies have shown racial disparities in provision of health care in various populations, including CKD patients (pts). However, racial disparities in CKD care among Medicare CKD pts have not been assessed.

Methods: Using the 5% Medicare data, this study compared CKD care among race groups in the Medicare CKD population by stage. Included pts were diagnosed with CKD stage 3, 4, or 5 between January 1, 2007, and December 31, 2009; were not on dialysis; and had not undergone kidney transplant. Pts were followed from the first diagnosis date to the earliest of death, CKD stage change, loss to follow-up, loss of Medicare coverage, or 1 year. CKD care after diagnosis was derived from Medicare claims. Care items included specialist visits (nephrologist, dietitian), lab tests (hgb, PTH, phosphorus, albumin, creatinine, iron, lipids, vitamin D, B12), diabetes care (diabetic patients only: hbA1c tests, diabetic eye exams), and vaccinations (flu, pneumonia). Time to first care event was compared between race groups for each care item using a Cox model adjusted for patient age, sex, socioeconomic status, Medicare/Medicaid dual eligibility, rural/urban residence, and comorbid conditions.

Results: In all, 102,856 pts were included; 67.2%, 22.0%, and 10.8% were in stages 3, 4, and 5, respectively; 84.1% were white, 11% black, and 4.9% other race. Among the 15 CKD care items listed above, compared with whites, HRs were lower for blacks for 8 items, no different for 4 items, and higher for 3 items among stage 3 pts.



For stage 4 pts, HRs were lower for 7 items and no different for 8 items. For stage 5 pts, HRs were lower for only 4 items, and higher for 1 item. Results for other race compared with whites were similar.

Conclusions: Among CKD patients, racial disparity was found in CKD care. The differences were small among stage 5 pts than that among pts in stages 3 and 4.

Effect of the Implementation of Clinical Practice Guidelines for the Prevention, Diagnosis and Treatment of CKD in Patients with Type2 Diabetes Mellitus at the Primary Health-Care

Petra Martínez, Héctor R. Martínez Ramírez, Laura Cortes-sanabria, Alfonso M. Cueto-Manzano. *U. Investigación Médica en Enfermedades Renales, IMSS, Guadalajara, Jalisco, Mexico.*

Background: The Application of Clinical Practice Guidelines (CPG) could help to improve clinical attitude of family physicians (FP) and renal function of patients with type 2 diabetes mellitus (DM2). This has never been demonstrated in the CKD area.

Methods: Objective. To evaluate the effect of an educative intervention to FP based on CPG published on-line on renal function of patients with DM2 and CKD. Prospective cohort in which an educative-participative intervention based on the CPG for Prevention, Diagnosis and Treatment of Chronic Kidney Disease (CKD) was applied to FP of 3 Family Medicine Units (Mexican Institute of Social Security). Once the educative intervention was concluded, DM2 patients attended by participant FP were evaluated for CKD. Patients with confirmed CKD (K/DOQI classification) were evaluated every six months. Glomerular filtration rate was estimated (simplified MDRD/formula), and albuminuria (nephelometry). Patients were integrally managed by FP.

Results: Two-hundred sixty patients had CKD; they were divided in 2 groups: Early CKD (58 with stage 1 and 55 with stage 2) and Late CKD (23 with stage 3 and 5 with stage 4). In both groups, median follow-up was 12 (9-15) months. Main results are shown.

Variable	Early/CKD n=113		Late/CKD n=28	
	Baseline	Final	Baseline	Final
Age(yrs)	63±11		71±9	
Duration of DM2(yrs)	13(8-18)		16(11-20)	
Presence of hypertension, n(%)	74(66)		27(93)	
Systolic blood pressure (mmHg)	136±23	121±14*	138±24	127±18*

*p<0.05 vs baseline/same group

Conclusions: CPG for Prevention, Diagnosis and Treatment of CKD to FP, implemented by means of an educative intervention, positively influences on the improvement of renal function and other variables of DM2 patients with CKD.

TH-OR121

Preservation of Renal Function by Thyroid Hormone Replacement Therapy in Chronic Kidney Disease Patients with Subclinical Hypothyroidism

Shin-Wook Kang,[1,2] Dong Ho Shin,[1] Mi Jung Lee,[1] Dae-Suk Han,[1] Seung Hyeok Han.[1] *[1]Department of Internal Medicine, College of Medicine; [2]Brain Korea 21, Yonsei University, Seoul, Republic of Korea.*

Background: Subclinical hypothyroidism is not a rare condition, but the replacement of thyroid hormone to treat subclinical hypothyroidism is an issue of debate. This study was undertaken to investigate the impact of thyroid hormone therapy on the changes in estimated glomerular filtration rate (eGFR) in subclinical hypothyroidism patients with chronic kidney disease (CKD).

Methods: A total of 309 CKD patients with subclinical hypothyroidism were included in this study. The changes in eGFR over time were compared between patients with and without thyroid hormone replacement therapy using a linear mixed model. Kaplan-Meier curves were constructed to determine the effect of thyroid hormone on renal outcome; a reduction of eGFR by 50% or end-stage renal disease. The independent prognostic values of subclinical hypothyroidism treatment for renal outcome were also ascertained by multivariate Cox regression analysis.

Results: One hundred and eighty patients (58.3%) took thyroid hormone (treatment group), while 129 (41.7%) did not (non-treatment group). Serum cholesterol and triglyceride concentrations were significantly higher in the treatment group than in the non-treatment group (P<0.01). During the mean follow-up duration of 34.8±24.3 months, the overall rates of decline in eGFR were significantly greater in the non-treatment group compared to the treatment group (-5.93±1.65 vs. -2.11±1.12 mL/min/year/1.73 m^2, P=0.04). In addition, a linear mixed model revealed that there was a significant difference in the rates of eGFR decline over time between the two groups (P<0.01). Kaplan-Meier analysis also showed that renal event-free survival was significantly higher in the treatment group (P<0.01). In multivariate Cox regression analysis, thyroid hormone replacement therapy was found to be an independent predictor of renal outcome (Hazard ratio, 0.28; 95% confidence interval, 0.12-0.68; P=0.01).

Conclusions: Thyroid hormone replacement therapy preserved renal function and was an independent predictor of renal outcome in CKD patients with subclinical hypothyroidism.

TH-OR122

Improved Physical Function in Patients with Chronic Kidney Disease Stage (CKD) 3 and 4 through a Renal Rehabilitation Exercise (RRE) Program

Ana Paula Rossi, Debra D. Morgan, F.L. Lucas, Gail A. Crocker, James C. Wasserman. *Maine Medical Center, Portland, ME.*

Background: Patients with CKD have a high prevalence of cardiovascular disease (CVD) associated with or exacerbated by inactivity. Cardiac rehabilitation is proven to have beneficial effects on cardiovascular risk factors and exercise capacity in patients with CVD. The goal of this study was to determine whether a RRE program for patients with stage 3 or 4 CKD would improve their physical function.

Methods: Patients with CKD stage 3 and 4 were randomized to the RRE intervention or usual care (UC). The RRE intervention consisted of guided exercise at a cardiac rehabilitation facility, 3 times per week for 12 weeks. Physical function at baseline and after the intervention period was determined by 3 well-established performance-based physical function tests: 6-minute walk test (6MWT), sit-to-stand test (STST) and gait speed test (GST).

Results: There were 48 patients (mean age 69±12 yr, 69% males) in the UC group and 59 patients (mean age 68±12 yr, 39% males) in the RRE group. At baseline there were no differences in self-reported level of activity, BMI, or 6MWT and STST scores, but the RRE group had a higher GST score than the UC group (173±143 vs. 119±106 cm/sec; p=0.03). After the intervention period, the UC group did not experience improvements in the 3 main outcomes. The RRE group demonstrated significant improvement in the 6MWT (19%, from 1117±320 to 1327±373 ft/6 min; p=<0.0001) and STST (29%, from 1.64±0.85 to 1.16±0.48 % of age predicted; p=0.0004). No improvement in the GST was observed (183±160 vs 171±145 cm/sec; p=0.6). The improvements observed were significant for both CKD stages, males and females, and patients >70 and <70 years of age. The number of exercise sessions attended were positively correlated with improvements in the 6MWT (r=0.38, p=0.009) and STST (r=0.49, p=0.006). Six patients in the RRE group withdrew early; time conflict was the main reason. Overall RRE was well tolerated.

Conclusions: A 12-week RRE program improved the physical capacity of patients with CKD stage 3 and 4. Longer follow-up is needed to determine if this will translate into decrease mortality rates.

TH-OR123

Fluid Intake, Mortality and Kidney Function: A Cohort Study

Suetonia Palmer,[1] Germaine Wong,[2] Jonathan C. Craig,[2] Giovanni F.M. Strippoli.[3] *[1]Univ. of Otago; [2]Univ of Sydney; [3]Mario Negri Sud Consortium and Diaverum AB.*

Background: Drinking eight glasses of water each day to improve health is a widely-held belief. Observational data exploring the association between fluid intake and mortality or kidney disease are sparse and conflicting. We examined these associations.

Methods: We examined adults ≥49 years in a census population in Sydney, Australia. Daily fluid intake was measured using a self-administered food frequency questionnaire and death obtained from the National Death Index. Cox proportional hazard models were used to assess the relationship between all-cause and cardiovascular mortality and daily fluid consumption controlling for age, gender, smoking, prior myocardial infarction, cancer or cerebrovascular disease, employment, glucose, HDL, cholesterol, triglyceride, platelet, white cell count and fibrinogen. We evaluated the association between fluid intake and change in estimated glomerular filtration rate (eGFR) during follow up. Adjusted Hazard ratios (AHRs) and 95% confidence intervals (CI) with higher water intake (>2.0 l/day, in quartiles) were then compared with those drinking <2.0 l/day.

Results: We had follow-up data for 2897 of 3654 individuals (age 66.2 ± 9.8 years; eGFR 66.9 [17.6] ml/min/1.73 m^2) over 13.1 (11.1-13.9) years. eGFR was available for 1209 individuals. Compared with the lowest fluid intake, the AHR for total mortality did not differ significantly for each quartile of fluid intake (aHR 0.85 (95% CI 0.70-1.03), 1.03 (0.85-1.25), and 0.94 (0.78-1.15) for fluid intakes of 2.0-2.4, 2.5-3.0 and >3.0 l/day when compared to <2.0 l/day, respectively). There was no association between cardiovascular mortality and fluid intake. There was no dose-response relationship between increasing daily fluid consumption (per deciliter) and all-cause (1.01 (95% CI 0.99 to 1.02) or cardiovascular mortality (1.05 [0.89 to 1.12]) compared to less than 2 l/day. Change in eGFR was not associated with fluid intake (p=0.15).

Conclusions: Daily fluid intake is not associated with survival or change in kidney function in this opportunistic analysis from an existing database. An ad hoc designed cohort study and a randomized trial are needed to confirm the findings.

Efficacy and Safety of Combined versus Single Renin Angiotensin Aldosterone System Blockade in Chronic Kidney Disease: A Meta-Analysis

Paweena Susantitaphong,[1,2] Kamal Sewaralthahab,[1] Ethan M. Balk,[3] Somchai Eiam-Ong,[2] Nicolaos E. Madias,[1] Bertrand L. Jaber.[1] *[1]Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Medicine, Chulalongkorn University, Bangkok, Thailand; [3]Tufts Clinical and Translational Science Institute, Tufts University, Boston, MA.*

Background: Although dual blockade of the renin-angiotensin-aldosterone system (RAAS) has gained popularity for the treatment of kidney disease, its benefits and potential risks have not been fully elucidated.We conducted a meta-analysis of all randomized controlled trials comparing the efficacy and safety of combined vs. single RAAS blockade therapy in patients with CKD.

Methods: We performed a literature search using MEDLINE, Cochrane Central Register of Controlled Trials, ClinicalTrials.gov, scientific abstracts from meetings, and bibliographies of retrieved articles. Data were extracted independently by 2 authors; random-effects models were used to compute absolute and standardized net changes, and rate differences.

Results: Fifty-nine (25 crossover and 34 parallel-arm) were identified (4,975 patients). Combined RAAS blockade therapy was associated with a significant net decrease in GFR (-1.8 mL/min or mL/min/1.73 m2; 95%CI -3.1,-0.5; P=0.005), albuminuria (-62 mg/day; 95%CI -97,-28; P<0.001), and proteinuria (-339 mg/day; 95%CI -434, -243; P<0.001). Similar results were observed using standardized net changes. Combined RAAS blockade therapy was associated with 9.4% higher rate of regression to normoalbuminuria and 5% higher rate of achieving blood pressure goal. However, combined RAAS blockade therapy was associated with a significant net increase in serum potassium level (0.13 mEq/L; 95% CI 0.09, 0.18; P<0.001), a 3.4% higher rate of hyperkalemia, and a 4.6% higher rate of hypotension. There was no effect on doubling of serum creatinine, hospitalization or mortality.

Conclusions: Although combined RAAS blockade therapy in CKD is associated with a decrease in albuminuria and proteinuria, there is a decrease in GFR, and a higher incidence of hyperkalemia and hypotension relative to single therapy. The potential long-term kidney benefits of this treatment strategy require further study.

The Relationship of ADHD Symptoms with Literacy, Depression, Quality of Life and Transition/Self-Management among Adolescents and Emerging Adults with Chronic Kidney Disease

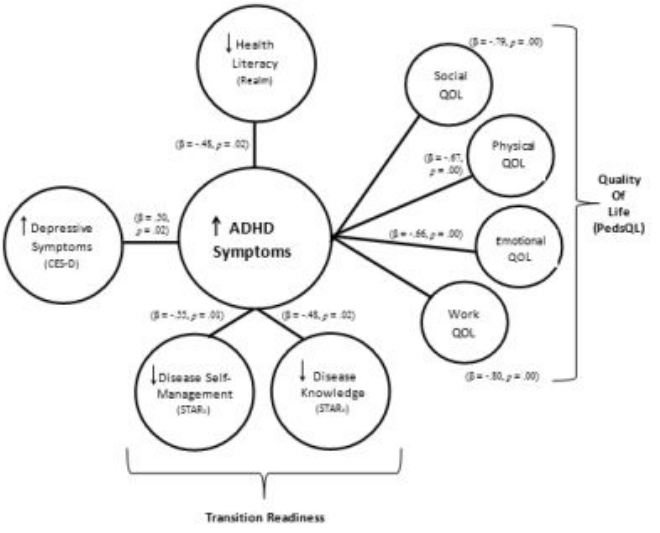
Maria E. Ferris,[1] Nicole M. Fenton,[1] Edward Iglesia,[1] Karina Javalkar,[1] Marley E. Burns,[1] Keisha L. Gibson,[1] Heather D. Stewart,[1] Karin A. True,[1] Kenneth A. Andreoni,[2] Randal K. Detwiler.[1] *[1]Kidney Center, UNC Chapel Hill; [2]Ohio State University.*

Background: ADHD is an often undiagnosed co-morbidity of CKD that may impact the ability to successfully self-manage CKD. We determined the relationship of ADHD symptoms with transition readiness/self-management, literacy, health-related quality of life (QoL) & depression among adolescents/young adults in pediatric and internal medicine nephrology practices.

Methods: Youth with CKD ages 12-29 completed 5 scales: (1)REALM- literacy (2) Depression (CES-D) scale (3)PedsQL- physical, social, emotional, work (4)PedsQL-ADHD/cognitive (5)STARx- transition readiness. Depression or ADHD were determined by chart review.

Results: 25 patients with CKD stage ≥4 had these characteristics: Females 60%; μ age 21.56(±4.7); μ age at diagnosis 9.47(±8.46); Whites 44%; Blacks 32%; Hispanic 16%. 9 participants were managed by pediatric & 16 by adult nephrology. Three participants self-reported depression (4 on anti-depressants) & 2 participants reported ADHD (1 on stimulants).

Higher prevalence of ADHD symptoms was related to lower transition readiness/self-management (ß=-.55, p=.01), disease knowledge (ß=.48, p=.02), health literacy (ß=-.48, p=0.02), and QoL - social (ß=-0.79, p=.00), physical (ß=-.67, p=.00), emotional (ß=-.66, p=.00) & work-related (ß=-.80, p=.00). In addition, higher ADHD symptoms were related to higher depressive symptoms (ß=.50, p=.02).



Conclusions: Among youth with CKD, self-reported ADHD symptoms were significantly correlated with lower transition/self-management, QoL & health literacy and higher depressive symptoms. Addressing these modifiable factors may improve patient outcomes. Further validation is underway.

Effects of Multidisciplinary Care on Outcomes in Chronic Kidney Disease: A Systematic Review and Meta-Analysis

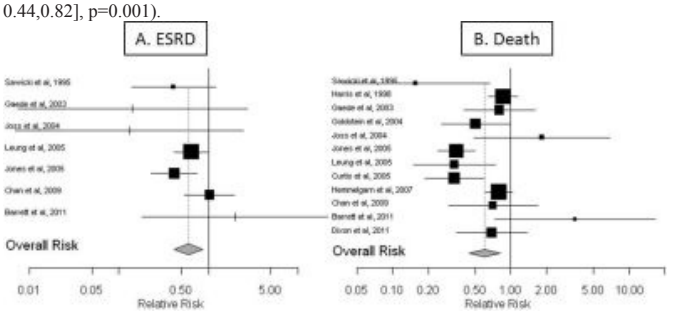
Romita Mukerjee,[1] Remy R. Coeytaux,[1] Rasheeda K. Hall,[1] Diane Reams,[2] Jane O. Schell,[1] Crystal C. Tyson,[1] Virginia Wang,[1] Hayden Bosworth,[1] Laura P. Svetkey,[1] Uptal D. Patel.[1] *[1]Duke U.; [2]UNC.*

Background: Chronic kidney disease (CKD) is common and often suboptimally managed. Multidisciplinary care (MDC) may improve important clinical outcomes and reduce the public health burden of kidney disease: this study synthesizes the evidence on effects of MDC among patients with CKD.

Methods: We performed a systematic review of available literature in MEDLINE, CINAHL, and the Cochrane trials databases through 2011. Summary effects of MDC interventions in patients with pre-dialysis CKD were obtained using random effects models.

Results: From 8686 search results, 28 studies evaluated MDC in 11143 patients (median 200 [IQR 147,437]) from 12 countries. Two studies used shared-care models to enhance collaboration between primary care and nephrology, while 26 used MDC teams of physicians, nurses, pharmacists, dietitians, and/or social workers. MDC was generally associated with favorable results for many outcomes, such as control of CKD-related risk factors and complications, and planning for dialysis. Only 1 study included a formal cost analysis. In studies with a mean follow-up of 4.2 years, annual change in estimated glomerular filtration rate was -1.79 ml/min/1.73m^2 for MDC vs. -4.70 for usual care (difference -2.91 [95%CI -4.42,-1.39], p<0.001). Compared to usual care, MDC was also

associated with significantly lower cumulative risks of incident ESRD (7 studies [Fig.A]; RR 0.60 [95%CI 0.41,0.87], p=0.008) and death (12 studies [Fig.B]; RR 0.60 [95%CI 0.44,0.82], p=0.001).



Conclusions: MDC may reduce progression of kidney disease, ESRD, and death among patients with CKD. Future studies should evaluate the cost effectiveness and public health impact of broader implementation of MDC, which could significantly improve morbidity and mortality among patients with CKD.

TH-OR127

Early Dialysis Starts Experience Greater Improvements in Survival than Late Starts Despite Higher Comorbidity Burden at Dialysis Initiation

Austin G. Stack,[1,2] Liam F. Casserly,[1] Ahad Abdalla,[1] Cornelius John Cronin,[1] Ailish Hannigan.[2] *[1]Nephrology, Mid-Western Regional Hospitals, Limerick, Ireland; [2]Internal Medicine, Graduate Entry Medical School, University of Limerick, Limerick, Ireland.*

Background: Recent studies have shown that early dialysis initiation compared with late is associated with poorer survival among patients receiving haemodialysis in the US. This finding has led to skepticism in promoting early start programs. We explored patterns in survival between "early and late dialysis initiation" in a representative sample of US dialysis patients.

Methods: Mortality trends among 'early start' (estimated glomerular filtration rates (eGFR): 10-15, 15-20 and > 20 ml/min/1.73 m²) and 'late start' patients (eGFR: 5-10 and < 5ml/min) were compared from 1995-2005 in 570, 903 incident patients and followed until Oct 2006 using data from the US Renal Data System. Crude mortality rates and adjusted 2-year mortality risks were compared across 3 time periods (1995-98, 1999-01 and 2002-04) within each eGFR category using Cox regression.

Results: Although comorbidity profiles and crude mortality rates were significantly higher for early than late starts, the multivariate analysis found significantly greater improvements in survival over 10 years for early compared with late start patients. No significant improvement was found for patients with eGFR < 5 ml/min.

Crude Mortality Rate (deaths/1000 person yrs)	1995-98	1999-01	2002-04
< 5 ml/min	186	189	186
5-10 ml/min	255	254	250
10-15 ml/min	361	333	305
15-20 ml/min	453	400	369
> 20 ml/min	407	328	308
Relative Risk Death[1],[2]			
< 5 ml/min	1.00	1.02	0.99
5-10 ml/min	1.00	0.98*	0.96**
10-15 ml/min	1.00	0.95**	0.90**
15-20 ml/min	1.00	0.93*	0.90**
>20 ml/min	1.00	0.87*	0.87*

[1]Each eGFR category modeled separately.[2]Adjusted for 17 demographic, clinical and laboratory variables, *P<0.001 **P<0.0001

Conclusions: Although mortality risks are significantly higher for early start compared to late starts, this study found that relative improvements in survival over time were unequal across GFR categories and were far superior for early start patients. The improved survival experience for these "high risk early starts" suggests potential benefits of early start programmes in selected populations.

TH-OR128

Angiotensin II Receptor Blocker Improves the Stenotic Kidney Microvasculature in Swine Unilateral Renal Artery Stenosis

Xin Zhang,[1] Zi-lun Li,[1] Alfonso Eirin,[1] John A. Crane,[1] Aditya S. Pawar,[1] Hui Tang,[1] Amir Lerman,[2] Stephen C. Textor,[1] Lilach O. Lerman.[1,2] *[1]Division of Nephrology and Hypertension, Mayo Clinic; [2]Division of Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

Background: Renal artery stenosis (RAS) is associated with intra-renal microvascular loss and remodeling. Angiotensin II receptor blockers (ARB) may decrease stenotic kidney (STK) function acutely, but their long-term effect on the STK is incompletely understood.

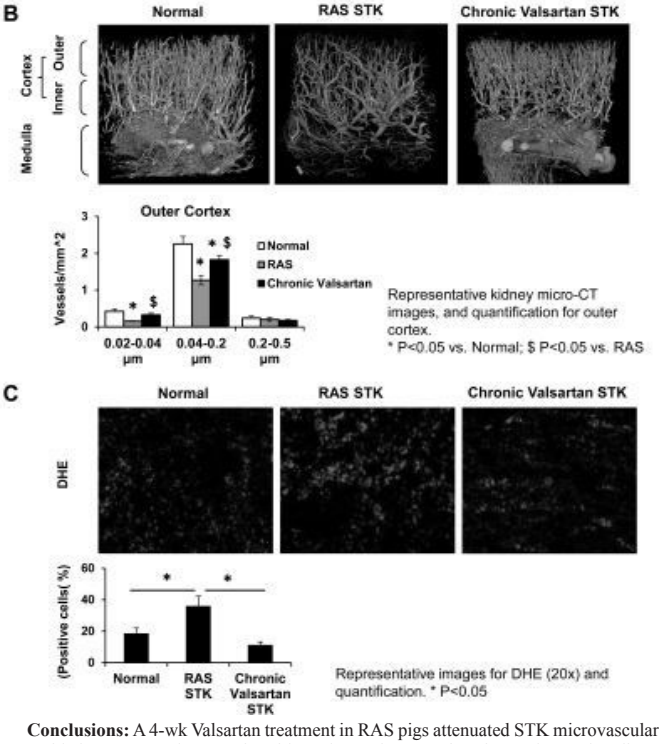
Methods: Domestic pigs were randomized as Normal, RAS, and RAS+Valsartan (n=6 each). The ARB Valsartan (320mg/d PO) was administered for 4 wks starting at 6 wks of unilateral RAS. After 10 wks of RAS, STK GFR was assessed by CT. STK tissue oxidative stress was then evaluated by DHE, apoptosis by TUNEL, and fibrogenic activity by plasminogen activator inhibitor-1 (PAI-1) expression. Density of STK microvessels (diameter <500 μm) in cortex was determined by micro-CT. In 6 additional RAS pigs the acute effects of intra-renal Valsartan infusion (320 mg IV) on GFR was assessed.

Results: RAS and RAS+Valsartan had comparable stenosis. At 10 wks MAP was unchanged in RAS but decreased in chronic Valsartan (from 151.5±12.7 to 128.1±6.2 mmHg, P<0.05). Valsartan infusion caused an acute 14.6% decrease of STK GFR, but not MAP (P=0.23), while chronic treatment did not affect GFR (Figure A). Conversely, chronic valsartan improved density of small microvessels (<200 μm) in the STK in outer cortex (Figure B), attenuated oxidative stress (Figure, C), and TUNEL positive cells (P<0.05 vs. RAS). Valsartan also normalized elevated PAI-1 expression in RAS (P<0.01 vs. Normal and RAS).

A

	Normal	RAS	Chronic Valsartan
Serum creatinine (mg/dl)	1.2±0.1	1.6±0.2*	1.6±0.2*
Single kidney (STK) GFR (ml/min)	81.8±6.5	57.5±9.4*	62.4±5.2*
Degree of stenosis (%)	/	78±7	76±5

STK: stenotic kidney; GFR: glomerular filtration rate. * P<0.05 vs. Normal



Conclusions: A 4-wk Valsartan treatment in RAS pigs attenuated STK microvascular loss, oxidative stress, and apoptosis, without decreasing STK function. Valsartan has direct renoprotective effects that preserve the STK in experimental RAS.

TH-OR129

Indoxyl Sulfate, a Uremic Toxin, Counteracts Endothelial Effects of Erythropoietin through Suppression of Akt Phosphorylation

Adelibieke Yelixiati, Toshimitsu Niwa, Hidehisa Shimizu. *Department of Advanced Medicine for Uremia, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Erythropoietin (EPO) is used to treat anemia in patients with chronic kidney disease (CKD). However, a wide variation in individual response to EPO is often observed, causing EPO resistance. EPO exhibits not only hematopoietic but also extra-hematopoietic functions such as endothelial effects. Indoxyl sulfate, a uremic toxin, is involved in endothelial dysfunction, and consequently the pathogenesis of CKD-associated cardiovascular disease (CVD). Hemodialysis patients with increased serum level of indoxyl sulfate require a higher dosage of EPO. The present study aimed to determine the effect of indoxyl sulfate on the extra-hematopoietic functions of EPO in human umbilical vein endothelial cells (HUVECs).

Methods: HUVECs were incubated with EPO in the presence or absence of IS. HUVEC proliferation was examined using MTS cell proliferation assay. Cellular apoptosis was examined by caspase 3/7 assay. Expression of Akt, phosphorylated-Akt (p-Akt), extracellular signal-regulated kinases (ERK), p-ERK, endothelial nitric oxide synthase (eNOS), p-eNOS, thrombospondin-1 (TSP-1), EPO receptor (EPOR), and p-EPOR was detected by western blotting. A specific Akt inhibitor was used to determine the role of Akt.

Results: Indoxyl sulfate suppressed EPO-induced survival/proliferation, anti-apoptosis function, phosphorylation of eNOS, and the expression of TSP-1, an erythroid-stimulating factor, in HUVECs. Although EPO induced phosphorylation of both Akt and ERK, indoxyl sulfate suppressed phosphorylation of Akt but not ERK. An Akt kinase inhibitor suppressed all the EPO-induced cellular effects in HUVECs. As a site of action of indoxyl sulfate on EPO signaling, indoxyl sulfate attenuated EPO-induced tyrosine phosphoryaltion of EPOR.

Conclusions: Indoxyl sulfate negatively regulates EPOR-Akt pathway that is crucial for the pathogenesis of endothelial dysfunction and anemia, and might be involved in EPO resistance in patients with CKD.

TH-OR130

Differential Actions of Angiotensin II on Proximal Tubule Transport Carolina Panico,[1] Earl H. Rudolph,[1] Roland C. Blantz,[3] Giovambattista Capasso,[2] Christopher S. Wilcox,[1] William J. Welch.[1] *[1]Nephrology, Georgetown University; [2]Second University of Naples; [3]University of California.*

Background: Studies in proximal tubule (PT)-specific AT_1R deficient-mice showed that the PT contributes to Ang II-induced hypertension. Ang II levels in PT fluid are 100- to 1000-fold higher than in plasma, yet the function of AT_1-Rs on the luminal side of the PT is unclear. Moreover, the hemodynamic effect of Ang II, which increases filtration fraction and peritubular forces, also increases fluid reabsorption.

Methods: We tested the effects of Ang II and AT_1-Rs on PT fluid uptake in rats.

Results: In Sprague Dawley (SD) rats, Ang II (200 ng/kg/min) delivered for 2 weeks increased MAP (Veh: 95±9 vs Ang II: 140±5 mmHg, p<0.001), single nephron GFR (SNGFR)(Veh: 36±3 vs Ang II: 43±3, p<0.05) and absolute proximal reabsorption (APR) (Veh: 20±3 vs Ang II: 34.5±6.5 nl/min, p<0.01), measured by free-flow collections in the S2 segment. These effects were normalized by acute reduction of MAP via a supra-renal aortic clamp. In Munich Wistar Frömter (MWF) rats, whose kineys allow access to the S1 segment, Ang II increased SNGFR and APR in the S1 segment (Veh: 19±4 vs Ang II: 44±5 nl/min, p<0.01; +125±9%) substantially more than in the S2 segment (Veh: 25±6 vs Ang II 37±7 nl/min, p<0.01; +48±6%). In SD rats, microperfusion *in situ* experiments, which allow for control of SNGFR, Ang II delivered into the lumen of the S2 segment reduced PT fluid reabsorption (Jv) in a dose-dependent manner. Ang II (10^{-9} M) at physiological levels reduced Jv by 60±7%; this effect was blocked by co-perfusion of an AT_1R blocker. Ang II (10^{-9} M), microperfused into the S2 segment reduced Jv in MWF rats by 44±5%. Ang II in cultured PT cells at high concentrations (10^{-7} to 10^{-9} M) also reduced $^{22}Na^+$ uptake by 20-35%.

Conclusions: In conclusion, Ang II acting on luminal AT_1-Rs reduces PT fluid reabsorption in the S2 segment. This effect could be overcome by the ability of systemic Ang II to increase absolute proximal reabsorption via hemodynamic enhancement of peritubular forces, especially in the S1 segment.

TH-OR131

Intra-Renal Over-Expression of Heat Shock Protein 90 alfa or beta (Hsp90α or Hsp90β) Protects against Ischemia/Reperfusion Injury Jonatan Barrera-Chimal,[1,2] Rosalba Pérez-villalva,[1,2] Juan-antonio Ortega,[1,2] Norma Bobadilla.[1,2] *[1]Molecular Physiology Unit, Instituto de Investigaciones Biomédicas, UNAM, Mexico; [2]Instituto Nacional de Ciencias Médicas y Nutrición SZ, Mexico.*

Background: We previously reported that Hsp90α and Hsp90β are equally and abundantly expressed in all the nephron segments. Moreover, we have also shown that radicicol (Hsp90 inhibitor) induced a reduction in the renal blood flow (RBF) and GFR, in part due to a reduction in urinary NO2/NO3 excretion, suggesting that Hsp90 regulates RBF in physiological conditions. However, the specific role of Hsp90α or Hsp90β on RBF regulation remains unclear. This study evaluated the effect of Hsp90α or Hsp90β over-expression in normal and ischemic settings.

Methods: Fifty Wistar rats were divided in sham, bilateral renal ischemia (B-I/R), unilateral ischemia (U-I/R) and nephrectomy plus I/R (Nx+I/R) groups. Rat Hsp90α and Hsp90β were cloned into pcDNA3.1(+). Gene identity was corroborated by clone sequencing. Intra-renal transfection was carried out by left renal artery injection of either pcHsp90α, pcHsp90β or empty vector (EV), 48-h before inducing ischemia (30 min). At the end of the experiment, RBF, serum creatinine (SCr) and urinary protein excretion (Uprot) were measured.

Results: I/R injury was characterized by renal dysfunction. In contrast, Hsp90α or Hsp90β over-expression (corroborated by Western Blot) prevented RBF reduction and reduced or prevented Uprot, however, this renoprotective effect was more evident in Nx+I/R transfected rats, because the lack of contra-lateral non-transfected kidney contribution.

	Groups n=5	**RBF** (mL/min)	**Uprot** (mg/24 h)	**SCr** (mg/dL)
Sham		9.5±0.4	14.9±3.3	0.5±0.1
	EV	6.3±0.8	70.4±20.1	2.8±0.3
B-I/R	Hsp90α	9.2±0.5a	39.6±7.4a	2.9±0.2
	Hsp90β	9.3±1a	40.3±13.9a	2.9±0.5
	EV	5.9±0.6	38.7±8.7	0.6±0.1
U-I/R	Hsp90α	8.2±0.3b	21.3±3.1b	0.5±0.1
	Hsp90β	8.1±0.1b	13.8±1.8b	0.6±0.1
	EV	5.8±0.3	33.4±3.4	2.9±0.6
Nx+I/R	Hsp90α	9.2±0.2c	15.5±1.6c	0.7±0.1c
	Hsp90β	9.9±0.7c	13±3.4c	0.9±.0.1c

a p<0.05 vs. B-I/R, b p<0.05 vs. U-I/R, c p<0.05 vs. Nx+I/R

Conclusions: This is the first study to demonstrate that intra-renal transfection of Hsp90α or Hsp90β before ischemia protects against renal injury induced by I/R.

This study was supported by CONACYT and PAPPIT.

Functional Consequences of Calcium-Sensing Receptor (CaSR) Gene-Knockdown in Renin-Secreting Cells in Mice Jan Czogalla,[1] Takahiro Masuda,[1] Maria Gerasimova,[1] Michael A. Rose,[1] Roberto Ariel Gomez,[2] Wenhan Chang,[3] Volker Vallon.[1] *[1]Dept of Medicine, UC San Diego and VA San Diego Healthcare System, San Diego, CA; [2]Dept of Biology, University of Virginia, Charlottesville, VA; [3]Dept of Medicine, UC San Francisco and Veteran Affairs Medical Center, San Francisco, CA.*

Background: Renin-secreting cells express the CaSR, but its function is unclear.

Methods: Utilizing the cre/lox system, we generated a CaSR mutant mouse model with knockdown of the CaSR in cells expressing renin ($renin^{Cre/+}/CaSR^{lox/lox}$), and compared with control mice ($CaSR^{lox/lox}$).

Results: On normal diet (0.8% NaCl) or after 6 days of low-salt diet (0.01% NaCl), systolic blood pressure (SBP, tailcuff in awake mice), heart rate (HR) and plasma renin concentration (PRC) were not different between genotypes. In contrast, 6 days of high-salt diet (4.0% NaCl) increased SBP in CaSR mutants relative to the change observed in controls (Δ mmHg: 3±2 vs -7±2, n=6-9, P<0.05). HR was reduced over the first 48h (-45±2 bpm) only in CaSR mutants, potentially due to a compensatory baroreceptor response. PRC was similar in both genotypes despite lower renal renin mRNA expression in CaSR mutants vs controls (low-salt: 0.95±0.04 vs 1.46±0.19; high-salt: 0.31±0.05 vs 0.60±0.10; P<0.05 each). Considering the strong correlation between renal mRNA and protein expression of renin, this may indicate a "fractional" increase in renin secretion in CaSR mutants. Acute i.p. injections of isoproterenol or furosemide increased PRC to a similar extent in both genotypes, but the effect of the ACE inhibitor, enalapril, on PRC was greater in CaSR mutants (Δ ng angiotensin I/ml per hr: 4471±474 vs 3056±118 in controls, n=5-6, P<0.05).

Conclusions: We propose that enalapril unmasked an enhanced angiotensin II tone in CaSR mutants that feeds back to lower PRC (by reducing renin expression and/or secretion) when the inhibitory influence of the CaSR on renin secretion is reduced. The efficiency of this feedback may make it difficult to detect differences in PRC in the steady state. An inhibitory influence of the CaSR on renin secretion may facilitate NaCl homeostasis and maintain blood pressure in response to a high NaCl diet.

TH-OR133

Constrictor Mechanism of the Afferent Arteriole Initiated by Na/H Exchanger in the Nephron Hong Wang, Martin A. D'Ambrosio, Yilin Ren, Jeffrey L. Garvin, Oscar A. Carretero. *Hypertension & Vascular Research Division. Department of Internal Medicine, Henry Ford Hospital, Detroit, MI.*

Background: The afferent arteriole (Af-Art) accounts for most of renal vasculature resistance, thus controlling glomerular filtration rate and renal function. Two mechanisms have been described in which nephron helps control Af-Art resistance, namely tubuloglomerular feedback (TGF), and connecting tubule glomerular feedback (CTGF). TGF is a constrictor mechanism initiated at the macula densa by the Na/K/2Clcotransporter (NKCC2), while CTGF is a dilator mechanism initiated at the connecting tubule by the epithelial Na channel (ENaC). However, when NKCC2 is blocked by furosemide, CTGF-induced Af-Art dilation is not evident, thus we hypothesize that there is a constrictor mechanism that is furosemide-insensitive and counters CTGF.

Methods: To test this, we used *in vivo* micropuncture of single nephrons. Stop-flow pressure (P_{SF}) was measured as an index of glomerular capillary pressure (which decreases when the Af-Art constricts). Two consecutive P_{SF} curves were generated by raising nephron perfusion from 0 to 40 nL/min while adding drugs to the tubular perfusate.

Results: The decrease in P_{SF} induced by increasing nephron perfusion was blocked by furosemide 10^{-4}M (control: 7.9±0.2 mmHg, furosemide: 0.4±0.2 mmHg, P<0.001, n=6), but was partially restored when blocking CTGF with the ENaC inhibitor benzamil 10^{-6}M (furosemide: 0.2±0.1 mmHg, furosemide+benzamil: 4.3±0.3 mmHg, P<0.001, n=6). A possible explanation for these observations is that TGF may be activated to some degree by Na/H exchanger (NHE)-mediated Na entry at the macula densa when NKCC2 is blocked. When we added the NHE blocker dimethylamiloride (DMA, 10^{-4}M) in the presence of furosemide and benzamil, the decrease in P_{SF} was significantly prevented (furosemide+benzamil: 4.6±0.3 mmHg, furosemide+benzamil+DMA: 1.1±0.2 mmHg, P<0.001, n=6).

Conclusions: Therefore, we conclude that a constrictor mechanism of the Af-Art is initiated by NHE in the nephron and is observable when NKCC2-mediated TGF and ENaC-mediated CTGF have been blocked.

Activation of mTOR Pathway Induced by Inflammation Accelerates the Progression of Atherosclerosis in Apolipoprotein E Knockout Mice Kun Ling Ma, Jing Liu, Jie Ni, Yang Zhang, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiang Su Province, China.*

Background: Our previous studies demonstrated that Rapamycin overrode the dysregulation of low lipoprotein receptor (LDLR) pathway induced by inflammation. This study was to investigate whether the activation of mammalian target of Rapamycin (mTOR) pathway was involved in the progression of atherosclerosis in apolipoprotein E knockout (apoE KO) mice.

Methods: The apoE KO mice fed with Western diet were divided into four groups for eight weeks (n=8): distilled water injection (Control), 8 mg/kg/q.o.d Sirolimus injection, 10% casein injection, Sirolimus plus casein injection. Plasma cytokine production was measured by ELISA. Foam cell formation and lipid accumulation were checked by hematoxylin-eosin (HE) staining and Oil red O (ORO) staining. The associated protein expressions of mTOR pathway and LDLR pathway were examined by immunohistochemical staining and immunofluorescent staining.

Results: Increased serum amyloid A (SAA) in casein injected mice suggested a successful induction of inflammatory stress. Interestingly, Serum total cholesterol, triglyceride, LDL, and HDL were significantly decreased in casein injected mice, while these were no difference in Rapamycin treated group compared to the controls. Inflammatory stress exacerbated foam cell formation and atherosclerotic plaque, which was correlated with the increased protein expressions of LDLR, sterol regulatory element binding protein-2 (SREBP-2), and SREBP cleavage-activating protein (SCAP). Furthermore, inflammation enhanced the translocation of SCAP escorting SREBP-2 from the endoplasmic reticulum to the Golgi, thereby activating LDLR gene transcription. Further analysis showed that inflammation increased protein expressions of mTOR, phosphated-mTOR, eukaryotic translation initation factor 4E binding protein 1(4EBP1), p-4EBP1, ribosomal protein S6 kinase 1(S6K1), p-S6K1, which were closely associated with the dysregulation of LDLR pathway.

Conclusions: Inflammation accelerated the progression of atherosclerosis in apoE KO mice via dysregulation of LDLR pathway, which could be mediated by the activation of mTOR pathway.

Missense Mutation S427L Impairs NBCe1-A Transport Function by Altering the Orientation of Transmembrane Segment 1

Quansheng Zhu, Rustam Azimov, Liyo Kao, Weixin Liu, Debra Newman, Natalia Abuladze, Ira Kurtz. *Medicine, UCLA, Los Angeles, CA.*

Background: NBCe1-A plays a critical role in renal proximal tubule bicarbonate transport where it is responsible for reabsorption of 80% of the filtered bicarbonate load. Eight missense mutations in NBCe1-A have been identified that cause proximal renal tubular acidosis including S427L that resides in the transmembrane segment 1 (TM1). Recently, three residues in NBCe1-A-TM1 have been shown to line the NBCe1-A ion translocation pathway implying the structural importance of TM1 in NBCe1-A mediated transport.

Methods: In this study, we examined the topology of NBCe1-A-TM1 in detail and determined the structural effect of S427L on the orientation of TM1 in NBCe1-A protein complex, by using the substituted cysteine accessibility method combined with chemical stripping, in situ chemical probing, and functional transport assays.

Results: Our data show that: 1) NBCe1-A-TM1 contains 31 residues starting from amino acid Phe412 to Thr442, which is considerately longer than what was thought previously; 2) the region prior to Phe412 till Arg394 is inaccessible to aqueous except Lys404 and Arg408, suggesting it is in a folded conformation potentially in close contact with the cytoplasmic domain; 3) none of the cysteine substitutions in the region of Cys389-Gln424 is sensitive to MTS inhibition, indicating this region is not involved in forming the ion translocation pathway; 4) aqueous accessibility of T442C is completely blocked in the presence of S427L, and not in the presence of S427A which retains over 50% transport function.

Conclusions: Our findings demonstrate that NBCe1-A-TM1 contains 31 amino acids with its N-terminus in close interaction with the cytoplasmic domain. Missense mutation S427L alters the orientation of NBCe1-A-TM1 significantly changing the configuration of the ion permeation pathway resulting in impaired transport function.

Extracellular Loop 3 Forms a Domain-Like Structure on the Surface of NBCe1-A

Quansheng Zhu, Liyo Kao, Weixin Liu, Debra Newman, Rustam Azimov, Ira Kurtz. *Medicine, UCLA, Los Angeles, CA.*

Background: All sodium-driven bicarbonate transporters within the SLC4 family share a common feature: the presence of four cysteines (Cys) in the glycosylated extracellular loop 3 (EC-loop 3). Topological studies have determined that EC-loop 3 is the largest highly exposed surface loop in NBCe1-A which contains 82 amino acids. More surprisingly, EC-loop 3 from each of the NBCe1-A monomers resides at the dimer interface.

Methods: In the present study, we analyzed the potential pattern of disulfide bonding among the four Cys in the NBCe1-A EC-loop 3, and the role of glycosylation in assisting the precise bond formation. NBCe1-A constructs carrying one to four Cys residues in various combinations in EC-loop 3 were expressed in HEK-293 cells and subjected to an SDS-PAGE gel shift assay, chemical stripping, DTT treatment, chemical probing and proteolytic analysis. The function of each construct was analyzed in HEK-293 cells.

Results: Our study revealed: 1) the four Cys in EC-loop 3 are in a folded conformation and intra-disulfided; 2) Cys 1, 2 and Cys 3, 4 form two intramonomeric disulfide bonds; 3) the first disulfide bond determines the number of glycosylation sites in the loop, and glycosylation guides the disulfide bond formation between Cys 3 and 4; 4) in the absence of the four Cys residues, NBCe1-A traffics normally to the plasma membrane, however, each monomer becomes triply glycosylated and most of the introduced Cys in loop 3 become self cross-linked; 5) when the four Cys are absent, EC-loop 3 adopts an extended conformation and becomes accessible to proteolytic cleavage.

Conclusions: Our findings indicate that EC-loop 3 in NBCe1-A is highly structured via two disulfide bonds. This unique structure on the extracellular surface of NBCe1-A is reminiscent of G-protein coupled receptors and may interact with specific ligand(s).

An Atp6v0a4 Knockout Mouse Is a Model of Distal Renal Tubular Acidosis with Hearing Loss, with Additional Extra-Renal Phenotype

Elizabeth Norgett,[1] Zoe J. Golder,[1] Beatriz Lorente-canovas,[2] Neil Ingham,[2] Karen P. Steel,[2] Fiona E. Karet.[1] *[1]Medical Genetics, University of Cambridge, Cambridge, United Kingdom; [2]Wellcome Trust Sanger Institute, Cambridge, United Kingdom.*

Background: Recessive distal Renal Tubular Acidosis (dRTA) is a severe childhood disorder of acid base homeostasis. It is characterised by hyperchloremic acidosis, hypokalemia, alkaline urine, hypercalciuria, hypocitraturia, nephrocalcinosis and rickets if untreated. Sensorineural deafness is often associated. Mutations in *ATP6V0A4,* which encodes the tissue restricted a4 subunit of the H^+-ATPase, can underlie dRTA. H^+-ATPases are multisubunit pumps found in organellar membranes, and in specialized cells of the distal nephron, inner ear and male reproductive tract, additional plasma membrane pumps contain tissue restricted subunits which replace generic ones.

Methods: An *Atp6v0a4*-null mouse line was created and using β-galactosidase as a reporter, embryonic a4 expression was investigated. Postnatally, biochemical and histological assessments were undertaken before and after dietary manipulation. Auditory brainstem response thresholds (ABRs), endocochlear potential (EP), olfactory behavior and bone mineral density (BMD) were assessed.

Results: a4 expression was detected in developing kidney, ear, bone, nose, eye and skin. At 21 days, *Atp6v0a4*$^{-/-}$ pups were smaller than their littermates, with hyperchloremic acidosis and hypokalemia. Most -/- pups died at weaning unless treated with alkali from birth, which facilitated survival into adulthood. Alkali supplementation could later be withdrawn, but -/- animals remained acidotic with alkaline urine. Null mice were hypocitraturic and nephrocalcinotic, but hypercalciuria was absent. They were severely hearing-impaired by 14 days, with elevated ABR thresholds and absent EPs. They were also hypo-osmic. +/- animals were biochemically normal until acid-loaded, when they became acidotic with reduced BMD.

Conclusions: This is the first faithful mouse model of dRTA. It illustrates the vital role of a4 in both renal and extra-renal acid-base homeostasis and reveals new avenues for clinical investigation of bone physiology and olfaction in patients and mutation carriers.

Effect of Collecting Duct-Specific Deletion of Both Rh B Glycoprotein (Rhbg) and Rh C Glycoprotein (Rhcg) on Renal Response to Metabolic Acidosis

Hyun-Wook Lee,[1] Jill W. Verlander,[1] Jesse M. Bishop,[1] Mary E. Handlogten,[1] I. David Weiner.[1,2] *[1]Renal Division, University of Florida, Gainesville, FL; [2]Nephrology Section, NF/SGVHS, Gainesville, FL.*

Background: Rhbg and Rhcg are ammonia transporters in distal nephron and collecting duct believed important in net acid excretion. Our purpose was to determine the effect of their combined deletion on the renal response to metabolic acidosis.

Methods: Mice with collecting duct-specific deletion of both Rhbg and Rhcg (CD-KO) were generated using Cre-loxP techniques and the Ksp-cadherin promoter for Cre-recombinase. Control mice (C) did not express Cre-recombinase. Acid-loading was performed by pair-feeding chow mixed with HCl, 0.4 M, for 7 days. N=6/group.

Results: We confirmed kidney-specific deletion with genomic PCR analysis and collecting duct-specific deletion with immunohistochemistry. On regular diet, without HCl, urine ammonia excretion, urine pH, and serum HCO_3^- and K^+ were similar in C and CD-KO. On diet with HCl, CD-KO developed more severe metabolic acidosis than did C (serum HCO_3^-: 4.3 ± 2.5 vs 15.9 ± 2.7 mmol/L, respectively, $P<0.01$), and developed hypokalemia, whereas C did not (serum K^+: 3.9 ± 0.1 vs 4.5 ± 0.2 mmol/L, respectively, $P<0.01$). Acid-loading increased ammonia excretion, but it increased more slowly in CD-KO and was significantly less than in C on days 1-5. Urine pH was lower in CD-KO than in C on days 1 and 3 of acid-loading. Without acid-loading, PEPCK, PDG, NHE-3 and glutamine synthetase (GS) expression were similar in CD-KO and C. Metabolic acidosis increased PEPCK and NHE-3 expression and decreased GS expression, and the changes were significantly greater in CD-KO than in C.

Conclusions: 1) Rhbg and Rhcg are critically important in the renal response to metabolic acidosis; 2) the significantly greater changes in PEPCK, NHE-3 and GS expression in acid-loaded CD-KO compared to C mice indicates the role of Rhbg and Rhcg is underestimated due to exaggerated changes in other proteins involved in renal ammonia metabolism; and 3) in mice with intact Rhbg and Rhcg expression, acidosis-induced changes in PEPCK, NHE-3 and GS expression are submaximal, despite the presence of persistent metabolic acidosis.

FR-OR005

Phosphotyrosine Signaling during Acid-Base Sensing in the Mouse Proximal Tubule Antonios Charokopos, Lara A. Skelton, Walter F. Boron. *Physiology and Biophysics, Case Western Reserve, Cleveland, OH.*

Background: The renal proximal tubule (PT) is a major site for maintenance of blood pH homeostasis. During acidosis, the PT increases HCO_3- reabsorption and also generates "new HCO_3-", thus neutralizing excess blood protons. The question of how does the PT sense blood pH has been a puzzling one in renal physiology. Previously, we found that the PT modulates its HCO_3- reabsorption in response to blood [CO_2] and [HCO_3-], paradoxically not pH. We also found that this modulation is prevented: i) by inhibiting the ErbB tyrosine kinase family and ii) by knocking out tyrosine phosphatase RPTPγ. We sought to understand the interaction between RPTPγ and ErbB1 and 2 in response to varying [CO_2]. We also looked at the Src tyrosine kinase family, known to synergize with ErbB receptors and also to be activated by acidosis.

Methods: We generated PT suspensions from WT and RPTPγ-KO mice and then subjected the PTs to respiratory alkalosis and acidosis (2.5% or 5% or 10% CO_2, constant HCO_3-) for an acute timeframe (20 min).

Results: By Western Blot, we were able to detect total ErbB1 and its phosphorylation (p) at Y845, Y992, Y1068 and Y1173; total ErbB2 and its phosphorylation at Y1221/2; specific Src family members (Src Fyn Lyn Lck and Yes); Src-family phosphorylation at the Y416 (stimulatory) and Y527 (inhibitory) sites; and the M-calpain protease and its inhibitor calpastatin. As [CO_2] increases we observe, in both genotypes: i) a modest increase in ErbB1 phosphorylation, ii) an increase (as detected with a C-terminal antibody) in total ErbB2 levels, and iii) an increase in calpastatin levels. Compared to the WT, the RPTPγ-KO exhibits: i) increased activation of the Src family (based on increased pY416 and/or decreased pY527), and ii) low levels of total p60Src, but not p55Src. The changes in total protein levels of ErbB2 and p60Src may reflect involvement of the calpain-calpastatin proteolytic system.

Conclusions: In summary, respiratory acidosis/alkalosis in the PT seems to produce changes in total protein or pY levels of ErbB1/2 and the Src family, and these changes appear to be modulated by the presence/absence of RPTPγ.

FR-OR006

Lipopolysaccharide (LPS) Activates Different TLR4 Signaling Mechanisms in Apical and Basolateral Membranes to Inhibit HCO_3- Absorption in Medullary Thick Ascending Limb (MTAL) Bruns A. Watts, Andrew Badalamenti, David W. Good. *U TX Med Branch, Galveston, TX.*

Background: Previously we demonstrated that bacterial LPS inhibits HCO_3- absorption in the MTAL through activation of its cell-surface receptor TLR4, and that LPS inhibits HCO_3- absorption through different TLR4 signaling pathways in the basolateral and apical membranes. Basolateral LPS inhibits HCO_3- absorption through TLR4-dependent ERK activation. Here we examined signaling mechanisms involved in inhibition by luminal LPS and factors that may contribute to different basolateral and apical TLR4 signaling.

Results: Adding LPS to the lumen decreased HCO_3- absorption by 28% in perfused mouse and rat MTALs. Inhibitors of ERK activation, which eliminate inhibition of HCO_3- absorption by bath LPS, had no effect on inhibition by lumen LPS. Conversely, inhibitors of phosphatidylinositol 3-kinase (PI3K) or its downstream target Akt eliminated inhibition of HCO_3- absorption by lumen LPS but not by bath LPS. Inhibition by lumen LPS also was eliminated by inhibiting mTOR, a downstream effector of PI3K/Akt signaling. Exposure to LPS for 15 min increased Akt and mTOR phosphorylation; these effects were blocked by wortmannin, confirming that Akt and mTOR are activated downstream of PI3K. TLR2 is expressed along with TLR4 in the basolateral membrane, but not in the apical membrane, of MTAL cells. Basolateral LPS failed to activate ERK or inhibit HCO_3- absorption in MTALs from $TLR2^{-/-}$ mice despite normal TLR4 expression. Inhibition of HCO_3- absorption by lumen LPS via PI3K was preserved in $TLR2^{-/-}$ MTALs. Co-immunoprecipitation studies showed that TLR4 and TLR2 are physically associated in inner stripe of outer medulla.

Conclusions: We conclude: 1) lumen LPS inhibits HCO_3- absorption in the MTAL through a TLR4-mediated PI3K/Akt/mTOR pathway; 2)TLR2 is required for LPS-induced TLR4 signaling at the basolateral but not the apical membrane. The ability of LPS to induce different intracellular signals at the two membranes may involve a novel interaction between TLR4 and TLR2 in the basolateral membrane and could provide new mechanisms for control and selective targeting of TLR4-mediated responses that impair renal tubule function.

Glutamine Synthetase: Expression in Proximal Tubule and Intercalated Cells and Differential Cellular Regulation in Hypokalemia Jill W. Verlander,[1] Hyun-Wook Lee,[1] Diana Chu,[1] Sharon W. Matthews,[1] Mary E. Handlogten,[1] Jesse M. Bishop,[1] I. David Weiner.[1,2] *[1]Renal Division, University of Florida, Gainesville, FL; [2]NF/SGVHS, Gainesville, FL.*

Background: Renal glutamine synthetase (GS) is regulated by acid-base disturbances, hypokalemia, and genetic deletion of renal ammonia transporters, suggesting GS is important in ammonia metabolism. Thus we re-examined GS expression in mice and identified cell-specific changes in expression induced by hypokalemia.

Methods: We examined renal GS expression by immunoblot, RT-PCR and immunohistochemisty (IHC). Hypokalemia was induced by feeding zero-K vs normal K diet X 12 days (n=4/group). 24-hr urines and blood were analyzed for ammonia and potassium. We measured cell-specific GS expression using IHC with quantitative analysis.

Results: Immunoblots showed GS protein in cortex and outer and inner stripe of outer medulla (OMo and OMi). By IHC, GS label intensity was similar in cortical and OMo proximal tubules; GS was also in collecting duct, connecting segment (CNT) and DCT intercalated cells. Double immunolabel for GS with AE-1, H^+ATPase, and NCC showed GS in type A intercalated cells in CNT through IMCD and in nonAB intercalated cells in CNT and DCT. Type B intercalated cells were GS-negative. RT-PCR showed GS mRNA in OMi, which has no proximal tubules. Zero-K diet decreased serum and urine K and increased urine ammonia excretion. By IHC, proximal tubule GS was greatly reduced in cortex and OMo. Conversely, quantitative IHC showed significantly increased GS expression in type A intercalated cells in CCD and OMCD.

Conclusions: 1) We show for the first time that type A intercalated cells from CNT through IMCD and nonAB intercalated cells in CNT and DCT express GS. 2) GS expression is similar in proximal convoluted and straight tubules in mouse kidney. 3) In hypokalemia GS regulation differs in proximal tubule and intercalated cells. Decreased GS in proximal tubules would enhance renal ammonia excretion and promote alkalosis; increased GS in type A intercalated cells may counter the proximal tubule effect on acid-base balance. Thus, intercalated cells not only transport ammonia, but may contribute to regulated ammonia metabolism.

Detection of PLA_2R in Glomerular Deposits in Membranous Nephropathy Cases Seronegative for Anti-PLA_2R A. Bernard Collins,[1] Evan A. Farkash,[1] Laurence H. Beck,[2] Rex Neal Smith,[1] Robert B. Colvin.[1] *[1]Pathology, Massachusetts General Hospital, Boston, MA; [2]Medicine, Boston University School of Medicine, Boston, MA.*

Background: Approximately 70% of patients with primary membranous nephropathy (MN) have autoantibodies to the phospholipase A_2 receptor (PLA_2R). In contrast, PLA_2R antibodies are rarely detected in secondary forms of MN (e.g., lupus and de novo transplant MN). The nature of the autoantibody in the 30% of primary MN patients seronegative for anti-PLA_2R is unknown. We hypothesize that some are anti-PLA_2R-associated disease that might be detected by the presence of PLA_2R in immune deposits.

Methods: Double immunofluorescence (IF) studies for IgG4/PLA_2R and IgG/PLA_2R colocalization were performed on frozen tissue sections from the renal biopsies of 11 MN patients seronegative for anti-PLA_2R by Western blot and 4 comparison patients who were seropositive for anti-PLA_2R. IgG4 and IgG were directly labeled with FITC and PLA_2R was detected using a 3 step Cy3 amplified IF technique. Colocalization was assessed morphometrically as % of Cy3 pixels with FITC signal using Image J Software.

Results: All of the patients seropositive for anti-PLA_2R had colocalization (70±15%) by IF (4/4) and were clinically felt to have primary MN. A subset of the patients seronegative for anti-PLA_2R (4/11) also had widespread colocalization (81±34%) by IF. One of these 4 patients had SLE and one had HCV; the other two had no clear etiology of the MN and were considered idiopathic. Seven patients had no colocalization by IF (1.3±1.2%) and a negative Western blot assay. Most of these patients (57%) had morphological evidence of secondary MN (mesangial deposits, TBM deposits and/or penetrating deposits). While morphometric techniques were used in this study, visual inspection alone clearly distinguished cases with or without colocalization.

Conclusions: Dual staining of renal biopsies by IF can detect most or all cases of anti-PLA_2R-associated MN, including a hitherto undetectable subgroup of patients (~35%) who are seronegative for anti-PLA_2R probably due to immunological remission. Such IF techniques will also be useful to distinguish primary from secondary MN.

FR-OR009

Phospholipase A2 Receptor (PLA2R) Staining in the Deposits of Membranous Glomerulopathy Christopher Patrick Larsen,[1,2] Nidia Cordeiro Messias,[1] Patrick D. Walker.[1,2] *[1]Nephropath, Little Rock, AR; [2]Dept of Path, Univ of Ark for Med Sci, Little Rock, AR.*

Background: Anti-PLA2R antibodies are the underlying etiology in most cases of primary membranous glomerulopathy (MG). The data on PLA2R staining in renal biopsies is limited and all reports thus far have utilized confocal microscopy, a technique not readily available in many renal pathology laboratories. The aim of this study was to determine the sensitivity and specificity of PLA2R staining in renal biopsies for detecting primary MG.

Methods: The database at our institution was searched for cases of known primary and secondary MG. 162 cases met inclusion criteria including 83 primary and 79 secondary. Standard renal biopsy processing techniques were used including light, immunofluorescence (IF), and electron microscopy. PLA2R was detected with standard IF.

Results: PLA2R was positive in 63/83 cases of primary MG and 14/79 of secondary MG. The sensitivity and specificity of PLA2R for detection of primary MG was 76% and 82%, respectively. Hepatitis C virus was the most common secondary etiology with PLA2R staining (7/11, 64%) followed by sarcoidosis (3/4, 75%) and neoplasia (3/12, 25%). Autoimmune etiologies showed the least PLA2R staining (1/45, 2%). The morphologic findings examined in all cases included the pattern of deposition, IF staining pattern, and evaluation for subendothelial and mesangial deposits. 8 segmental MG cases were present including 2 idiopathic and 6 secondary and all were negative for PLA2R. 5 cases showed light chain restriction and only one was PLA2R positive. Subendothelial deposits were seen in 17 secondary and no primary biopsies, all were negative for PLA2R. Mesangial deposits were found in 84 cases including 24 primary and 60 secondary. 24 cases with mesangial deposits were positive for PLA2R. 10 cases had 'full house' staining, none of which were positive for PLA2R.

Conclusions: We present the largest series to date detailing the sensitivity and specificity of PLA2R in MG, utilizing a technique that could be immediately adopted by most renal pathology laboratories. PLA2R staining in kidney biopsies is a useful marker of primary MG with a sensitivity of 76% and specificity of 82%.

FR-OR010

Genetical and Clinical Aspects of X-Linked Alport Syndrome in Males with Positive Staining of the α5(IV) Chain Yuya Hashimura,[1] Kandai Nozu,[2] Hiroshi Kaito,[2] Hiromi Ohtsubo,[2] Fusako Hashimoto,[2] Shingo Ishimori,[2] Takeshi Ninchoji,[2] Naoya Morisada,[2] Koichi Nakanishi,[3] Norishige Yoshikawa,[3] Kazumoto Iijima.[2] *[1]Pediatrics, Hyogo Prefectural Kobe Children's Hospital, Japan; [2]Pediatrics, Kobe University Graduate School of Medicine, Japan; [3]Pediatrics, Wakayama Medical University, Japan.*

Background: X-linked Alport syndrome (XLAS) is caused by mutations in *COL4A5* that encodes the type IV collagen α5 chain. In male patients, complete negativity for α5 staining in the renal basal membrane is considered a pathological characteristic; however, it has been demonstrated α5 staining is positive in >20% of patients. Further, the genetic and clinical backgrounds of male XLAS patients presenting with such atypical immunohistological findings have not yet been elucidated.

Methods: We retrospectively studied 52 male patients diagnosed with XLAS on the basis of *COL4A5* analysis, in whom α5 expression had been examined. Patients showing complete negativity for α5 staining were classified as the negative group (NG); all other patients were classified as the positive group (PG). The genetic and clinical backgrounds of patients in both groups were examined using the Kaplan–Meier method and receiver operating characteristic (ROC) analysis.

Results: PG included 15 of the 52 patients (28%). All 15 patients had non-truncating mutations. The renal survival curve for the patients and their affected family members showed that renal failure occurred at a significantly later age in PG than in NG ($p = 0.03$). Further, ROC analysis of patients with missense mutations showed that the cutoff value was exon 25 in both groups and that mutations in PG showed a significant bias to be located before exon 25.

Conclusions: This is the first report on the genetic and clinical backgrounds of male XLAS patients with atypical immunohistological findings. Male XLAS patients who showed α5 chain expression had relatively mild clinical manifestations, and their genotypes matched with those of reported cases presenting with a mild form of the disease. Further, we also showed for the first time that differences in α5 expression among patients with missense mutations resulted from differences in the location of the mutation.

FR-OR011

Decreased Circulating C3 Levels and Mesangial C3 Deposition Predict Renal Outcome in Patients with IgA Nephropathy Seung Hyeok Han,[2] Hye-young Kang,[1] Dae-Suk Han,[2] Dong Ho Shin,[2] Mi Jung Lee,[2] Seong Hun Kim,[1] Shin-Wook Kang.[1,2] *[1]Severance Biomedical Science Institute, Brain Korea 21, College of Medicine, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea.*

Background: Mesangial C3 deposition is frequently observed in patients with IgA nephropathy (IgAN). However, the role of complement in the pathogenesis or progression of IgAN is uncertain. In this observational cohort study, we aimed to identify the clinical implication of circulating C3 levels and mesangial C3 deposition and to investigate their potentialities as predictors of renal outcomes in patients with IgAN.

Methods: A total of 343 patients with biopsy-proven IgAN were enrolled between January 2000 and December 2008. Decreased serum C3 levels (hypoC3) was defined as C3<90 mg/dl. The study endpoint was end-stage renal disease (ESRD) or a doubling of the baseline serum creatinine concentrations (D-SCr).

Results: Of the patients, there were 66 patients (19.2%) with hypoC3. During a mean follow-up of 53.7 months, ESRD occurred in 5 patients (7.6%) with hypoC3 compared to 9 patients (3.2%) with normal C3 levels (P=0.11). However, 12 patients (18.2%) with hypoC3 reached D-SCr compared to 17 patients (6.1%) with normal C3 levels [Hazard ratio (HR), 3.59; 95% confidence interval (CI), 1.33-10.36; P=0.018]. In a multivariable model in which serum C3 levels were treated as a continuous variable, hypoC3 significantly predicted the development of D-SCr (per 1 mg/dl increase of C3; HR, 0.95; 95% CI, 0.92-0.99; P=0.011). The risk of reaching renal endpoint was significantly higher in patients with mesangial C3 deposition 2+ to 3+ than in patients without deposition (HR, 9.37; 95% CI, 1.10-80.26; P=0.04).

Conclusions: HypoC3 and mesangial C3 deposition were independent risk factors for progression, suggesting that complement activation may play an unfavorable pathogenic role in patients with IgAN.

FR-OR012

Interobserver Agreement amongst 77 Nephropathologists Using the New Classification System for Diabetic Nephropathy Elisabeth J. Valk,[1] Eloise Magnenat,[2] Ron Wolterbeek,[3] Emile De Heer,[1] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, LUMC, Leiden, Netherlands; [2]University of Geneva, Switzerland; [3]Medical Statistics, LUMC, Netherlands.*

Background: In 2010, the new classification system for Diabetic Nephropathy was launched (JASN 2010). In this paper, a pilot study on the interobserver agreement amongst 5 pathologists who participated in the design of the classification system, showed a good correlation for scoring the separate classes (ICC: 0.84). The purpose of the present study was to assess the interobserver agreement of an international group of nephropathologists who were still fairly unfamiliar with the classification system.

Methods: 13 biopsies with Diabetic Nephropathy were selected and sent round on a DVD to all members of the Renal Pathology Society and also, an announcement was made to the members of the ISN to join in this survey. The 2010 publication served as a guideline. Participants had to classify the 13 cases and also had to score: IFTA, interstitial inflammation, amount of hyalinosis and arteriosclerosis. They also had to evaluate their own level of expertise.

Results: 77 nephropathologists from 28 countries participated in the study. The ICC for the classification score was 0.74 amongst all pathologists and 0.76 amongst experienced pathologists. The ICC for IFTA, interstitial inflammation, hyalinosis and arteriosclerosis was 0.72; 0.47; 0.41; 0.53 for all pathologists and 0.73; 0.57; 0.43; 0.42 for experienced pathologists. Comments made by the nephropathologists who joined in the study concerned confusion over the definitions for clasess IIa and IIb (mild versus severe mesangial expansion), scoring inflammation inside or outside areas with IFTA, the assessment of arterial hyalinosis, and definition of vessel size in which arteriosclerosis had to be scored.

Conclusions: The classification system for Diabetic Nephropathy shows good interobserver agreement among nephropathologists worldwide, with experienced pathologists performing similar to less experienced ones. Rephrasing of some of the definitions would be useful, and might ameliorate the interobserver agreement.

FR-OR013

β2-Microglobulin Asearly Predictors of Glucocorticoid Treatment Failure in Adult Patients with Nephrotic Syndrome Jingyuan Xie, Qiongxiu Zhou, Hong Ren, Jing Xu, Xu Hao, Wen Xue, Nan Chen. *Nephrology, Ruijin Hospital, Shanghai Jiaotong University, Shanghai, China.*

Background: Urinary α1-microglobulin(uα1-MG) and β2-microglobulin (uβ2-MG) which were reported have predictable value of Steroid-resistant nephrotic syndrome(SRNS) in children. The aim of this study is to examine whether they can predict steroid responses in adult-onset primary nephrotic syndrome(PNS).

Methods: We retrospectively enrolled 113 cases with PNS [78 had focal segmental glomerulosclerosis (FSGS), 35 had minimal-change disease(MCD)], patients with BMI≥30kg/m^2 were excluded. They were divided to SRNS and SSNS based on their response to steroid treatment of 12-16 weeks. We recorded demographic and clinical data from all patients at the time of renal biopsy and during follow up. These included gender, sex, body mass index (BMI), serum creatinine (Scr), albumin, urine protein, uα1-MG and uβ2-MG et al. The association of baseline variables with the primary outcome (response to steroid therapy) was tested using Logistic regression models. Areas under receiver operator characteristics (ROC) curves were also assessed for evaluating predictable valuable of baseline variables include uα1-MG and uβ2-MG.

Results: Of all the 113 participants, 43 were SRNS and 70 were SSNS. There were 79 men and 34 women with a median age of 27 years old in this study. Baseline uα1-MG (9.92vs 2.97 mg/dl, P<0.001) and uβ2-MG(623.85 vs 131.45 ug/l, P<0.001) were significantly increased in SRNS group when compared to the SSNS group. In univariate analysis, elder age [OR=1.03, 1.00-1.06, P=0.049], lower hemoglobulin[OR=0.98, 0.96-0.99, P=0.028], lower albumin [OR=0.94, 0.90-0.99, P=0.01], higher Scr [OR=1.02, 1.01-1.03, P=0.003],higher ln(uα1-MG) [OR=2.12, 1.42-3.15, P=$2.21*10^{-4}$]and ln(uβ2-MG) [OR=3.10, 1.46-6.58, P=$3*10^{-3}$] were associated with increased risk for SRNS. In the multivariate stepwise Logistic regression models, only ln(β2-MG)(OR=3.16, 95%CI=1.24-8.07, P=0.02) had a significant, independent effect on the risk of SRNS. The area under the ROCcurves was estimated at 0.83(95%CI=0.70-0.96) for ln(β2 –MG).

Conclusions: Urine β2-MG can be considered as early and reliable prognostic predictors of adult-onset SRNS.

FR-OR014

Plasma Cell Rich Infiltrate Is an Independent Risk Factor for Allograft Failure in Late Acute Rejection Sharad Sathyan, Thangamani Muthukumar, Choli Hartono, Darshana Dadhania, Manikkam Suthanthiran, Surya Seshan. *Nephrology and Pathology, Weill Medical College of Cornell University.*

Background: Late acute rejection (AR) portends a poor prognosis. AR with plasma cell rich (>20%) infiltrates (Plasma cell-rich AR) tend to occur late after transplant. The clinico-pathological features of late AR and risk factors of allograft failure has not been well characterized.

Methods: We reviewed the records of all kidney recipients who had for-cause biopsies done >1 year after transplant (1999-2010). AR was defined as per the Banff classification. We obtained relevant demography, clinical, laboratory, hisopathological and follow up information. Primary outcome was graft loss (persistent decline of eGFR to <15 ml) or return to dialysis or re-transplant. Patients who did not reach the outcome were censored at

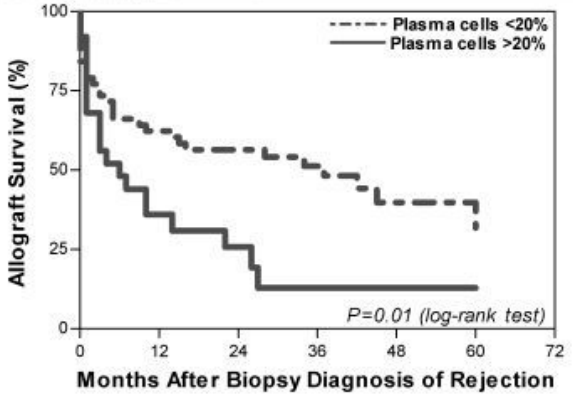
their last follow up. We generated Kaplan-Meier curves and performed Cox-proportional hazard regression to determine the independent risk factors for allograft failure.

Results: There were 82 patients with late AR; 23 (28%) acute T-cell mediated rejection; 23 (28%) C4d+ acute antibody mediated rejection and 11 (13%) mixed. The remaining 25 (30%) had plasma cell-rich AR. Among them 9 (36%) were C4d+.

The salient characteristics are shown in the table.

Patients with plasma cell-rich AR had an inferior allograft outcome compared to those who did not have plasma cell-rich AR.

Category	Acute Rejection >1 year After Transplant		
	Rich in Plasma Cells (>20%) [N=25]	Not Rich in Plasma Cells (<20%) [N=57]	P
Age, years, *median*	40	46	NS
Gender, M:F	10:15	32:25	NS
African American, n	12	17	NS
Deceased donor, n (%)	11 (44%)	39(68%)	0.035
Cold Ischemia time, hours, *median*	16h30min	23h55m	NS
Delayed graft function, n (%)	0 (0%)	11(19%)	0.02
Antithymocyte globulin induction, n (%)	12 (48%)	29(51%)	NS
Steroid based immunosuppression, n (%)	14 (56%)	31(54%)	NS
Time to biopsy, months, *median (IQR)*	38 (46)	28 (24)	NS
Prior rejection, n (%)	9 (36%)	11(19.2%)	NS
Serum Creatinine at biopsy, mg/dl, *median*	4.3	3	NS
Tacrolimus trough at biopsy, ng/ml, *median*	3.35	4.1	NS
3 months prior	4.6	5	NS
6 months prior	5.2	5.9	NS
IF/TA, moderate/severe (>25%), n (%)	9 (36%)	15(26%)	NS
Follow up, months, *median*	49	38	NS
Allograft survival 1-year post biopsy	31%	60%	0.01
Median allograft survival, months	6	37	



By Cox regression, plasma cell-rich AR was a significant risk factor for allograft failure independent of receiving a transplant from a deceased donor, history of delayed graft function, time from transplant to biopsy or interstitial fibrosis/tubular atrophy.

Conclusions: In our single center study of 82 late AR, plasma cell rich AR has an inferior allograft survival as compared to other late AR, independent of the time to biopsy or severity of interstitial fibrosis/tubular atrophy.

FR-OR015

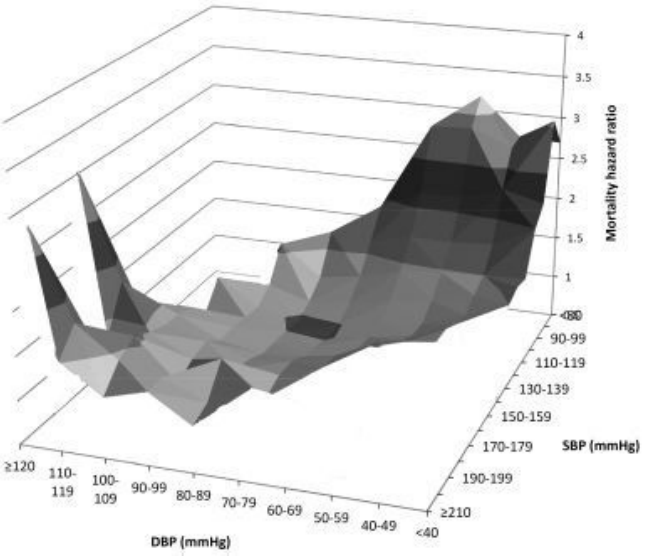
Association of Blood Pressure Levels with Mortality in a Nationally Representative Cohort of US Veterans with Non-Dialysis Dependent CKD

Csaba P. Kovesdy,[1,2] Anthony J. Bleyer,[3] Miklos Zsolt Molnar,[4] Jennie Z. Ma,[5] Leigh Darryl Quarles,[2] Kamyar Kalantar-Zadeh.[4] *[1]Memphis VA Medical Center, Memphis, TN; [2]University of Tennessee Health Science Center, Memphis, TN; [3]Wake Forest University, Winston Salem, NC; [4]Harold Simmons Center at Harbor-UCLA, Torrance, CA; [5]University of Virginia, Charlottesville, VA.*

Background: SBP and DBP display U-shaped associations with mortality in CKD, but the concomitant presence of an ideal SBP and DBP is rare. It is unclear if elevated SBP combined with ideal DBP, or ideal SBP combined with low DBP is better.

Methods: We evaluated the association of BP with all-cause mortality in a national cohort of 650,243 US veterans with CKD stages 1-5. SBP and DBP were examined both separately, and as all possible combinations of each other in 96 categories (from <80/<40 to >210/>120 mmHg, in increments of 10 mmHg). Associations with mortality were examined in time-dependent Cox models, with adjustment for age, sex, race, comorbidities, eGFR, serum K and antihypertensive use.

Results: Over a median follow-up of 4.6 years 185,502 patients died. Both SBP and DBP had U-shaped associations with mortality individually. When considering combinations of SBP and DBP, patients with BP of 130-139/80-89 had the lowest adjusted mortality, and those in whom both SBP and DBP were concomitantly very high or very low had the highest mortality (Figure). Patients with elevated SBP of 140-179 mmHg combined with ideal DBP experienced lower mortality compared to those with ideal SBP of 130-139 mmHg combined with low DBP.



Conclusions: Both low and high SBP and DBP are associated with increased mortality in patients with CKD. The optimal BP appears to be 130-139/80-89 mmHg. It may not be advantageous to lower SBP to ideal levels in patients whose DBP would decrease below ideal as a result.

FR-OR016

Analysis of Renal Histological Findings Associated with Blood Pressure in Ambulatory Blood Pressure Monitoring of CKD Patients

Kotaro Haruhara, Nobuo Tsuboi, Akira Fukui, Takashi Yokoo, Yoichi Miyazaki, Yasunori Utsunomiya, Tatsuo Hosoya. *Division of Kidney and Hypertension, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Recent studies have demonstrated that ambulatory blood pressure monitoring (ABPM) is useful in the prediction of long-term renal prognosis and cardiovascular events in CKD patients. Currently, however, information is limited regarding the relationship between individual renal pathological findings and blood pressure (BP) in the analyses of ABPM. We therefore aimed to determine renal pathological parameters associated with the findings of ABPM in CKD patients.

Methods: This study included a total of 93 CKD patients in whom both renal biopsy and ABPM were performed. Renal pathological parameters, including global glomerular sclerosis (GS), interstitial fibrosis/tubular atrophy (IF/TA), arterial lesion (AA) and arteriole lesion (AO) were scored (grade 0-2) and analyzed in relation to the findings of BP in ABPM.

Results: The IF/TA grade was significantly associated with the daytime systolic ($p<0.001$) and diastolic ($p=0.002$) BP and nighttime systolic ($p<0.001$) and diastolic ($p=0.002$) BP in ABPM. The AO grade was significantly associated with the daytime systolic ($p=0.011$) and diastolic ($p=0.013$) BP and nighttime diastolic BP ($p=0.039$), but did not associate with systolic BP. In contrast, the grades for GS and AA did not show statistically significant relationships with these ABPM findings. In the analysis of the patients without anti-hypertensive medications, IF/TA was the only pathological parameter significantly associated with the daytime systolic ($p=0.006$) and diastolic ($p=0.004$) BP and nighttime systolic ($p=0.017$) and diastolic ($p=0.033$) BP in ABPM. In the further multivariate analysis, IF/TA (≥25%) showed significant associations with both daytime and nighttime hypertension, which was independent of age, kidney function or use of anti-hypertensive medications. The IF/TA grade was not associated with daytime and nighttime BP ratio of ABPM in these CKD patients.

Conclusions: These results suggest that the severity of IF/TA is a renal pathological parameter that has close relationships to daytime and nighttime hypertension in CKD patients.

FR-OR017

Association of Central Blood Pressure with Kidney Histology in Living Kidney Donors

Yasushi Ohashi, George Thomas, Martin J. Schreiber, Emilio D. Poggio. *Nephrology and Hypertension, Glickman Urological and Kidney Institute, Cleveland Clinic, Cleveland, OH.*

Background: Most kidney transplant centers exclude prospective living kidney donors with hypertension from donation because of concerns that nephrectomy may increase any medical risks of hypertension after donation. It is unclear however, whether blood pressure (BP) is independently associated with kidney histology and function in living kidney donors. Markers of central BP, such as aortic stiffness and central wave reflection characteristics, may be better to assess target organ damage. Our objective was to assess association of central BP with kidney histology in living kidney donors.

Methods: 51 donors who donated a kidney between 2009 to 2011 had in-office brachial (peripheral) BP assessed by an automated sphygmomanometer, and central (aortic) BP assessed by the Sphygmocor device, in addition to implant kidney biopsy.

Histological abnormalities were defined as any one or more of the following: a) >5% global glomerulosclerosis, b) >5% interstitial fibrosis with any tubular atrophy, or c) any arteriosclerosis.

Results: Histological abnormalities were present in 19 (37.3%) donors, who were more likely to be men (94.7% vs. 37.5%, $p<0.01$) and older (47.9 ± 8.6 vs. 38.0 ± 10.1 years, $p<0.01$) with lower unadjusted iothalamate GFR (100.5 ± 14.2 vs. 112.6 ± 20.1 ml/min, $p<0.05$) than donors with normal histology. There was no difference in brachial systolic BP (SBP) between these 2 groups (118.1 ± 16.9 vs. 114.9 ± 11.0 mmHg, $p=0.43$). Donors with histological abnormalities had significantly higher aortic SBP (106.2 ± 13.1 vs. 96.7 ± 11.0 mmHg, $p<0.05$), aortic pulse pressure (30.3 ± 7.6 vs. 26.2 ± 5.6 mmHg, $p<0.05$) and augmentation pressure (6.5 ± 4.3 vs. 3.0 ± 4.0 mmHg, $p<0.01$) than donors with normal histology. After adjusting for age and gender, augmentation pressure was an independent risk factor for histological abnormalities (OR, 1.20; 95%CI, 1.03-1.38).

Conclusions: Aortic stiffness and abnormalities in central BP can be associated with histological abnormalities in the kidney. Central augmentation pressure is a parameter of target organ damage in living kidney donors.

FR-OR018

Progressive Renal Injury after Subtotal Nephrectomy (NX) Exhibits Stronger Correlation with BP Fluctuation Patterns during Sleep than Awake Periods

Anil K. Bidani,[1] Aaron Polichnowski,[1] Maria M. Picken,[1**] Hector Licea-vargas,[1] Jianrui Long,[2] Geoffrey A. Williamson,[2] Karen A. Griffin.[1]
*[1]Medicine (Pathology**), Loyola University Chicago and Hines VA Hospital, Maywood, IL; [2]Electrical and Computer Engineering, Illinois Institute of Tehcnology, Chicago, IL.*

Background: Clinical data suggest that nocturnal hypertension confers significant independent risk for CKD progression. The responsible mechanisms remain poorly defined. The hypothesis was tested that BP elevations during sleep may be more pathogenic than during active periods.

Methods: The relationship of radiotelemetrically monitored BP parameters during sleep (6AM – 6PM) vs. active (6PM – 6AM) periods with progressive glomerulosclerosis (GS) was examined in the rat 3/4 surgical excision nephrectomy (NX model) which exhibits impaired renal autoregulation and enhanced glomerular BP transmission. Two wks after NX, graded hypertension was superimposed by either substituting diets with 2 and 4% instead of standard 1% salt or by SQ phenylephrine (PE, 50 mg/kg/d, Alzet pumps) and blinded assessment of % GS was done after 4 more wks. Results: Mean±SE.

Results: Linear regression analysis (table) showed strong and significant correlations between BP parameters and % GS in both salt groups ($p < 0.025$) but not in the PE group indicating reduced glomerular BP transmission in PE rats. For most BP parameters and in each of the groups, better correlations and steeper slopes were observed during sleep vs. active periods.

	2% SALT DIET (n=19)		4% SALT DIET (n=11)		PE (n=17)	
% GS	7±2		18±4		7±2	
	Awake	Sleep	Awake	Sleep	Awake	Sleep
Average Systolic BP	151±3.3	144±3.1*	169±3.9	161±3.8*	157±3.5	154±3.5
Correlation with GS (r^2)	0.39	0.47	0.43	0.45	0.15	0.21
BP values > 175 mmHg (%)	14.7±3.5	9.3*±4.5	38.2±6.9	27.8*±6.1	27.5±4.2	25.1±3.9
Correlaton with GS (r^2)	0.47	0.56	0.35	0.43	0.06	0.07

*P < .001 compared to awake BP parameters

Conclusions: These results are consistent with the dependence of progressive GS after NX on glomerular transmission of BP fluctuations, which appears to occur to a greater extent during sleep than active periods and is likely reduced by α1 adrenoreceptor activation as would be expected during activity/exercise.

Funding: NIDDK Support, Veterans Administration Support

FR-OR019

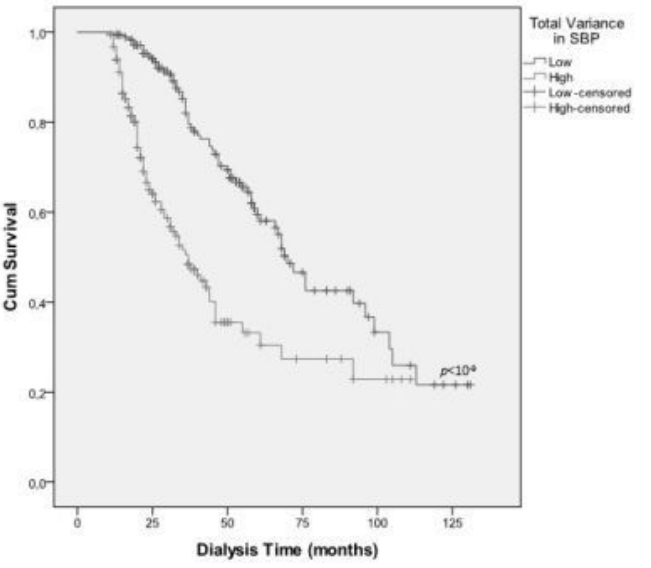
Longterm Variability in Blood Pressure Predicts Outcome in Chronic Hemodialysis Patients

Gretchen Norine De Graav,[1] Charlotte van Noord,[2] Marinus A. Van Den Dorpel.[2] *[1]Internal Medicine, Erasmus MC, Rotterdam, Zuid-Holland, Netherlands; [2]Internal Medicine, Maasstad Hospital, Rotterdam, Zuid-Holland, Netherlands.*

Background: Cardiovascular morbidity and mortality are significantly higher in hemodialysis patients than in the general population. Previous studies have shown that a high short-term variability in blood pressure is an adverse prognostic factor for survival in hemodialysis patients. We studied whether a high variation in long-term, i.e. monthly, systolic blood pressure leads to a higher mortality rate.

Methods: Blood pressure was recorded in every individual patient before and after each dialysis session. Mean values of all recordings of each month of the year were calculated and used for analysis. The differences in survival between 417 patients with either a low or high monthly variability in systolic blood pressure was compared with multivariate Cox survival analysis. Patient characteristics between the groups were compared with either the unpaired t-test or the Chi square-test.

Results: Patients with a high monthly variability for systolic blood pressure (SBP) showed a significantly higher all-cause mortality. Unadjusted hazard ratio for total mortality high vs. low variability in systolic blood pressure was 2.61 (95% CI 1.88-3.64), $p<10^{-9}$. Hazard ratio adjusted for confounders was 2.89 (95% CI 1.96-4.26), $p< 10^{-8}$. Survival in months in the groups low vs. high variability in systolic blood pressure were 78 (±4) vs. 52(±4) months, $p<10^{-9}$.



Kaplain Meier Curve of Survival: Low or High Variability in Systolic Blood Pressure

Conclusions: A high monthly variability in systolic blood pressure is an independent adverse prognostic factor in patients on maintenance hemodialysis. Further study is needed to elucidate the role of contributing factors such as seasonal variation in vascular tone or physical activity.

FR-OR020

Impaired Exercise-Induced Production of Nitric Oxide in Patients with Early Autosomal Dominant Polycystic Kidney Disease

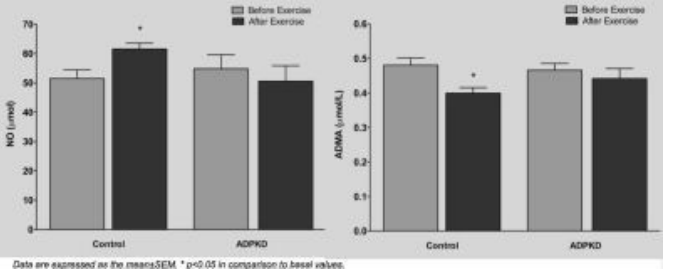
Natália Lopes Reinecke,[1] Thulio Marquez Cunha,[2] Elisa M.S. Higa,[1] Ita Pfeferman Heilberg,[1] Waldemar S. Almeida,[1] Nestor Schor.[1] *[1]Nephrology, UNIFESP, Sao Paulo, Brazil; [2]Pneumology, UNIFESP, Sao Paulo, Brazil.*

Background: It has been suggested that early Autosomal Dominant Polycystic Kidney Disease(ADPKD) patients may exhibit lower Nitric Oxide(NO) and higher Asymmetric Dimethylarginine(ADMA) levels in comparison to healthy subjects, what could lead to endothelial dysfunction and hypertension. It is known that physical exercise increases shear stress and NO. However,the effect of exercise in ADPKD remains unknown. We aimed to evaluate the influence of acute exercise on Blood Pressure(BP),production of NO and ADMA in early ADPKD.

Methods: Sedentary normotensive ADPKD patients (n=26;M/F=8/18; 29.8±7.7yr; CrCl=99.6±16.8ml/min) and healthy subjects(n=30;M/F=9/21;28.7±6.5yr) performed a maximum incremental cardiopulmonary test to determine the peak oxygen uptake(VO2peak). After, the subjects underwent to a 20min of moderate aerobic exercise, with BP measures and blood samples collected before and after for NO and ADMA measurements.

Results: ADPKD patients presented lower VO2peak and maximal workload, and higher mean exercise Systolic BP. Basal NO and ADMA did not differ between groups. However, NO did not increase and ADMA did not decrease after exercise in ADPKD, as observed in controls. Serum NO after exercise correlated with VO2peak (r=0.4,p<0.05).

Variable	Control	ADPKD	p
BMI	23.5±4.4	23.4±3.0	NS
VO2peak	28.8±6.2	22.5±3.5	<0.05
Maximal Workload	156.5±50.8	117.6±32.8	<0.05
Basal SBP	108.9±12	119.5±13.2	NS
Basal DBP	70.4±9	76.9±11.8	NS
Exercise SBP	143.5±12.2	160.6±19.4	<0.05
Exercise DBP	64.9±8.5	72.9±11	NS



Data are expressed as the mean±SEM. * p<0.05 in comparison to basal values.

Conclusions: This study suggests that patients with early ADPKD have an impaired regulation of exercise-related vasodilator system showed by a limited generation of NO and lack of ADMA decrease after exercise.

FR-OR021

Impact of Losartan and Hydrochlorothiazide Combination on Proteinuria in Patients with Chronic Kidney Disease and Hypertension: ILOHA Study Kiichiro Fujisaki,[1] Kazuhiko Tsuruya,[1] Hideki N. Hirakata,[2] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Division of Nephrology, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan.*

Background: It remains unknown whether use of diuretics is more optimal than the other antihypertensive agents in CKD patients whose BP is still uncontrolled despite treatment with RAS inhibitors, because hydrochlorothiazide (HCTZ) showed more effective in reducing albuminuria than calcium channel blocker (CCB), while CCB reduced progression of CKD more effectively than HCTZ in such patients. In the present study, we assessed an additive effect of HCTZ in reducing proteinuria in CKD patients under treatment with losartan (LS).

Methods: We performed a multicenter, open-label randomized trial. One hundred and two CKD patients with hypertension and proteinuria were recruited from nine centers and randomly assigned to either treatment with LS (50 mg, n=51) or combination of LS and HCTZ (12.5 mg) (LS/HCTZ, n=51). The primary outcome was a decrease in the urinary protein to creatinine ratio (Up/Ucr). The target blood pressure (BP) was less than 130/80 mmHg, and antihypertensive agents (other than RAS inhibitors and diuretics) were added if target BP was not attained in the both groups. The primary population was the intent-to-treat population, defined as all randomly assigned patients.

Results: The baseline data of the two groups were similar. After a year of the treatment, the decrease in Up/Ucr was significantly lower in LS/HCTZ group than in LS group (-578±106 vs. -25±133 mg g^{-1}, P <0.05); however, there were no significant differences in BP and estimate GFR between the two groups through the observation period.

Conclusions: The combination therapy with LS/HCTZ showed a greater reduction in proteinuria compared to the treatment with LS even though BP in LS was similar to that in LS/HCTZ using additive antihypertensive agents through the observation period. This finding suggests that addition of diuretics is optimal treatment in CKD patients under treatment with RAS inhibitors and with LS/HCTZ exhibits renoprotective effects through a mechanism independent of BP reduction.

FR-OR023

Atrial Fibrillation and Stroke in the U.S. Hemodialysis Population: 1992-2009 Charles A. Herzog,[1] Craig Solid,[1] Wolfgang C. Winkelmayer.[2] *[1]CVSSC, USRDS, MMRF, Minneapolis, MN; [2]Stanford Univ, Palo Alto, CA.*

Background: Non-valvular atrial fibrillation (AF) is a major cause of stroke in the elderly, in whom anticoagulation (AC) is of proven benefit. It is unclear if hemodialysis (HD) pts with AF should receive AC, as these pts were excluded from clinical trials. Observational studies suggest harm in HD AF pts receiving warfarin. In this study we analyze temporal trends in warfarin use and stroke rates in HD pts with AF over two decades.

Methods: We searched the USRDS database to identify prevalent HD pts in 1992-2009 with non-valvular AF. We used Medicare claims to count ischemic and hemorrhagic strokes after the AF diagnosis. We searched for Prothrombin-Time/INR claims (≥ 3 as a previously validated surrogate for warfarin use) to identify warfarin-treated pts. For each year's cohort, we calculated the rate of stroke events (per time at risk) and warfarin use within the cohort.

Results: The prevalence of non-valvular AF in the U.S. HD population grew from 5% in 1992 (n= 3,130; 53% male, 68% white, 30% black, mean age 67.6 yrs, primary cause of renal failure: 26% Diabetes, 39% HTN) to 11% in 2009 (n= 13,730; 58% male, 66% white, 30% black, mean age 68.6 yrs, primary cause of renal failure: 45% DM, 31% HTN). Ischemic stroke rates declined from 45.4 (per 1,000 pt-yrs) in 1992 to 22.7 in 2009, while hemorrhagic stroke rates remained stable (3.32 per 1,000 pt-yrs in 1992 vs. 3.37 in 2009). Warfarin use progressively increased from 12% to 43%.

Conclusions: Despite uncertainty regarding AC in HD pts with AF, progressively more HD AF pts have received warfarin therapy from 1992 to 2009 (mirroring trends in non-ESRD pts, but with lower utilization rates). The decline in ischemic stroke (with no change in hemorrhagic stroke) is temporally co-incident with increasing warfarin use. Clinical trials testing the safety and efficacy of AC for prevention of stroke in HD pts with AF are warranted.

Anticoagulation, Anti-Platelet Therapy or No Treatment for Hemodialysis Patients with Atrial Fibrillation: A Decision Analysis Melanie Wyld,[1] Philip A. Clayton,[1,2] Rachael L. Morton,[1] Steven J. Chadban.[1,2] *[1]Sydney Medical School, University of Sydney, Sydney, NSW, Australia; [2]Department of Transplantation, Royal Prince Alfred Hospital, Sydney, NSW, Australia.*

Background: Optimal treatment of AF in the hemodialysis population is uncertain due to the exclusion of this group from randomized trials. The risk-benefit profile for anticoagulation and anti-platelet therapy in hemodialysis differs from the general population due to platelet dysfunction from uremia, altered pharmacokinetics and increased falls risk. We sought to determine whether anticoagulation or anti-platelet therapy is associated with improved outcomes for hemodialysis patients with atrial fibrillation (AF).

Methods: We developed a Markov model with a five-year time horizon to determine the preferred treatment (warfarin, aspirin, clopidogrel, no treatment) for hemodialysis patients with AF. Treatments were assessed by their expected utility (quality of life weight) and life years gained after factoring in the probability of stroke and bleeding events. Probability of events and utility data were obtained from published estimates. Outcomes were discounted at 5% per annum.

Results: In the base case (70 year-old-male on hemodialysis), the total health outcomes in life years and quality adjusted life years (QALYs) were 2.30 and 1.41 respectively for warfarin, 2.37 and 1.60 respectively for aspirin, 2.38 and 1.61 respectively for clopidogrel and 2.39 and 1.62 respectively for no treatment. The finding that warfarin had the lowest expected utility was robust to multiple one-way sensitivity analyses including the probability of bleeding, probability of stroke and relative risks of bleeding and stroke.

Conclusions: Our results suggest that hemodialysis patients should not be anticoagulated for AF as the risk of bleeding outweighs the potential benefit of stroke reduction. Further research is required to delineate the role, if any, of anticoagulation and anti-platelet agents in this patient population.

Spironolactone Reduces Cardio- and Cerebrovascular Morbidity and Mortality in Hemodialysis Patients Yoshihiro Matsumoto,[1] Shinji Kageyama,[2] Yasuo Mori,[3] Toru Yakushigawa,[3] Kazuo Arihara.[4] *[1]Shizuoka City Hospital; [2]Kageyama Clinic; [3]Shibukawa Clinic; [4]Ohtemachi Clinic.*

Background: Aldosterone receptor blockers reduce cardiac-related morbidity and mortality. Recently, we demonstrated that long-term low-dose spironolactone is clinically safe in many hemodialysis (HD) patients. In the present study, we assessed whether low-dose spironolactone treatment reduces the high incidence of cardio- and cerebrovascular (CCV) morbidity and mortality in HD patients.

Methods: A 3-year randomized trial involving 5 Japanese clinics was performed. Oligoanuric HD patients (n=309) were enrolled and 157 patients were randomly assigned to receive 25 mg of spironolactone daily without any restriction in dietary potassium intake. The primary end point was CCV events, and secondary end point was death from all causes. CCV events included stroke, myocardial infarction, angina pectoris, exacerbation of heart failure, cardiovascular surgery, dissecting aneurysm of the aorta, and sudden death.

Results: At 3 years, spironolactone significantly reduced CCV events (7.1% vs. 17.8%; P=0.0105) and all-cause mortality (7.9% vs. 22.9%; P=0.0011). With Cox proportional hazards analysis, spironolactone was an independent determinant of CCV events (hazard ratio [HR]: 0.33; 95% confidence interval [CI]: 0.14 to 0.71; P=0.0038) and all-cause mortality (HR: 0.33; 95% CI: 014 to 0.71; P=0.0015). Gynecomastia or breast pain was reported in 15 patients (9.6%) in the spironolactone group. Serious hyperkalemia led to discontinuation of treatment in 3 patients (1.9%).

Conclusions: Aldosterone receptor blockade by spironolactone substantially reduces the risk of both CCV morbidity and death among HD patients.

Extracellular Volume Control in Dialysis Patients to Reduce Hospitalizations Thomas F. Parker,[1] Raymond M. Hakim,[2] Allen R. Nissenson,[3] Mahesh Krishnan,[4] Franklin W. Maddux,[5] Kevin Chan.[5] *[1]Renal Ventures Management; [2]Vanderbilt University School of Medicine; [3]DaVita, Inc; [4]DaVita Clinical Research; [5]Fresenius Medical Care.*

Background: Extracellular volume (ECV) overload is a leading cause of hospitalizations in chronic hemodialysis (HD) patients. Congestive heart failure, pulmonary edema and left ventricular failure hospitalizations far exceed other causes; yet objective measurement of ECV is not standard in HD care. Renal Ventures Management, DaVita, Inc and Fresenius Medical Care combined resources in a self funded quality initiative (QI) to determine if objective measurement of ECV removal and attainment of normalized ECV could reduce all cause and ECV related hospitalizations.

Methods: 14 facilities were randomly selected for either Education (E) or education + ECV monitoring (EM). In the EM facilities, ultrafiltration monitoring and assessment of normalized ECV - "dry weight" - was accomplished with a monitoring device (Critline). In the E group, clinical assessment used ultrafiltration algorithm to achieve "dry weight".

Results:
Hospitalization in facilities with Fluid Management Education or ECV monitoring devices

	Before ECV monitoring device	After ECV monitoring device	Before education	After education
N (patients)	571	587	625	644
hospital admits (per patient year)	2.03	1.55	1.83	1.60
hospital days (per patient year)	11.18	9.38	10.18	9.94
Fluid admits (per patient year)	0.18	0.09	0.14	0.31
Fluid days (per patient year)	0.75	0.16	0.68	0.82

before intervention: 9/4/10-9/4/11; after intervention: 9/4/11-3/4/12

Table 1 summarizes outcomes. Before E and EM implementation, all-cause and ECV related hospital rates were similar between the two groups. After E implementation, there was an actual increase in ECV hospitalizations and days, whereas, after EM implementation, there was a 50% decrease in ECV hospitalizations and and 78% decrease in ECV hospital days.

Conclusions: In this QI, among 3 major providers, objective measurement of ECV during dialysis is associated with significant decrease in ECV related hospitalizations, substantially more than education alone. Such processes hold promise for patient and provider outcomes.

The Impact of a Low Glucose Peritoneal Dialysis Solution Regimen on Serum Lipids and Lipoproteins in Diabetic Patients: The IMPENDIA and EDEN Randomized, Controlled Clinical Trials

Joanne M. Bargman,[1] Bruce F. Culleton,[2] Jun-Young Do,[3] Rafael Alberto Gomez, Alex W. Yu,[4] Sarah S. Prichard,[2] Kenneth Story,[2] Philip K.T. Li.[5] *[1]Toronto General Hospital, Toronto, Canada; [2]Baxter Healthcare Corporation, Deerfield, IL; [3]Yeungnam University Hospital, Daegu, Korea; [4]Alice Ho Miu Ling Nethersole Hospital, Hong Kong; [5]Prince of Wales Hospital, Hong Kong.*

Background: The use of glucose-containing peritoneal dialysis (PD) solutions may exacerbate lipid and lipoprotein abnormalities in diabetic PD patients. We hypothesized that a low glucose PD regimen incorporating icodextrin and amino acids would lead to improvements in serum lipids and lipoproteins.

Methods: Two randomized controlled clinical trials were completed in 11 countries across 4 continents. In both studies, prevalent diabetic PD patients were randomized in a 1:1 manner to the intervention group (a low glucose PD regimen consisting of either the combination of Physioneal, Extraneal, and Nutrineal in the IMPENDIA trial, or Dianeal, Extraneal, and Nutrineal in the EDEN trial) or the control group (Dianeal only) and followed for up to 6 months after randomization. We previously reported the results of the primary efficacy and safety analyses. We now report the comparison of change from baseline between groups for serum lipids and lipoproteins (secondary endpoints).

Results: 251 PD patients were allocated to the intervention (n=124) or control groups (n=127). The difference between the intervention and control groups for change from baseline for the measured lipids and lipoproteins is shown in the table.

	Difference Between Groups (Change in Control - Change in Intervention)			
Parameter	Estimate	Lower 95% CI	Upper 95% CI	P-Value
Total cholesterol, mmol/L	0.3	0.0	0.7	0.07
LDL cholesterol, mmol/L	0.1	-0.2	0.4	0.59
HDL cholesterol, mmol/L	0.0	-0.1	0.0	0.30
VLDL cholesterol, mmol/L	0.3	0.1	0.5	0.003
Serum triglycerides, mmol/L	0.7	0.3	1.1	0.002
Apolipoprotein B, mg/dl	8.4	0.8	15.9	0.03
Lipoprotein (a), mg/dl	-1.9	-8.2	4.4	0.56
Apolipoprotein A1, mg/dl	5.0	-1.5	11.5	0.13

Conclusions: In diabetic PD patients, a low glucose PD solution regimen significantly improves serum triglycerides, VLDL-cholesterol, and apolipoprotein B.

A Randomized, Controlled Trial of Colestilan versus Simvastatin for Treatment of Dyslipidemia in Hemodialysis Patients

Christoph Wanner,[1] Andrei Varushchanka,[2] Natallia Apanasovich,[3] Shigekazu Nakajima,[4] Koji Takei,[4] Francesco Locatelli.[5] *[1]University Clinic, Wuerzburg, Germany; [2]Gomel Regional Clinical Specialized Hospital, Gomel, Belarus; [3]Brest Regional Hospital, Brest, Belarus; [4]Mitsubishi Tanabe Pharmaceutical Corporation, Tokyo, Japan; [5]Ospedale Manzoni, Lecco, Italy.*

Background: To demonstrate superiority of the new phosphate binder, colestilan (COL) over placebo and non-inferiority with simvastatin (SIM) in reducing serum LDL-cholesterol (LDL-C) in CKD 5D subjects.

Methods: Global, multi-centre, double-blind, double-dummy, randomised, flexible-dose, comparative study. Comprising: 2 to 6-week wash-out from lipid-modifying agents; subjects with LDL-C ≥100 mg/dL randomised 1:1 to COL (3, 6, 9 or 12g/day) or SIM (10, 20, 30 or 40 mg/day) with double-dummy design and matching placebos; titrated up (if LDL-C ≥70mg/dL) or down (if tolerability was an issue) as needed to control LDL-C, every 4 weeks for 16 weeks, followed by re-randomisation to active (COL or SIM) or placebo and a 4-week placebo-withdrawal phase.

Results: 260 subjects were randomised (127 to COL and 133 to SIM). At end of double-blind, double-dummy titration phase both COL and SIM reduced LDL-C by similar amounts (-29.5 and -28.9% respectively). There was no real change in HDL-C levels. At end of the placebo-withdrawal phase, COL and SIM both reduced LDL-C significantly versus placebo by 30.7 mg/dL and 36.1 mg/dL, respectively (percentage reductions versus placebo of 37.4 and 45.8% respectively; P<0.001 for both groups) whilst HDL-C was not essentially altered. Triglyceride levels were not significantly changed by COL but lowered by SIM (P<0.001). Both SIM and COL similarly reduced serum TC, oxidised LDL and apoprotein B levels. Also, COL reduced serum phosphate levels during the 16-week titration period, whilst SIM did not (P<0.01 between groups). The safety profile of COL was comparable to SIM, with discontinuations due to AEs mainly due to GI-related issues.

Conclusions: In subjects with CKD Stage 5D, COL effectively reduces LDL-C levels versus placebo and was non-inferior to SIM in reducing LDL-C during the active comparison phase thus achieving co-primary endpoints of the study.

Systolic Blood Pressure (SBP), Mortality and Cardiovascular Disease (CVD) Outcomes in Incident Hemodialysis (HD) Patients: Role of Troponin I and NT-proBNP

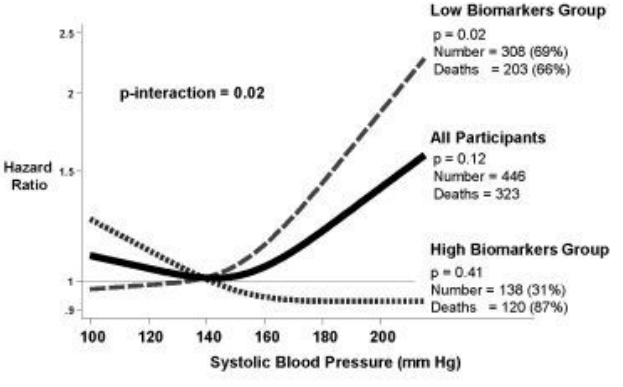
Tariq Shafi,[1] P. Zager,[2] Stephen M. Sozio,[1] Neil R. Powe,[3] L. Ebony Boulware,[1] Josef Coresh.[1] *[1]Johns Hopkins University; [2]University of New Mexico; [3]University of California San Francisco.*

Background: There is uncertainty regarding treatment of hypertension in HD patients due to the observed "U" shaped association between blood pressure (BP) and death. This association likely reflects confounding due to CVD and its associated short-term mortality. We hypothesized that elevated levels of serum troponin I (TNI) and NT-proBNP may identify HD patients with higher risk of death and therefore less long-term benefit from BP reduction.

Methods: We measured TNI and NT-proBNP in baseline samples from 446 incident HD participants of the CHOICE Study, a national prospective cohort study. Presence of elevated cardiac biomarkers was defined as TNI ≥ 0.1 ng/mL or NT-proBNP ≥ 9,252 pg/mL, based on published cutoffs. Primary exposure was baseline predialysis SBP. Outcomes were mortality (overall and CVD) and first CVD event analyzed using Cox regression adjusted for age, sex, race and serum albumin.

Results: Mean age was 58 years; 64% white; 55% male; and mean SBP was 153±25 mmHg. Of the 446 participants, 138 (31%) were in the high biomarker group. There were 323 deaths during follow-up (median 3.6 yrs). High biomarker levels were independently associated with risk of death (HR, 1.84; p<0.001). Overall, SBP had a "U" shaped association with death. There was no association between SBP and death in the high biomarker group (p=0.41), but in the low biomarker group, SBP ≥160 mmHg was associated with an increased risk of death (HR per 10 mmHg increase, 1.15; p=0.03). Similar trends were seen with CVD deaths and events.

Figure: Adjusted Association between Predialysis Systolic Blood Pressure and All-Cause Mortality Stratified by Biomarker Levels



Conclusions: A stratification approach based on TNI and NT-proBNP has the potential to inform BP treatment in HD patients, distinguishing which patients are at increased risk of outcomes with uncontrolled SBP.

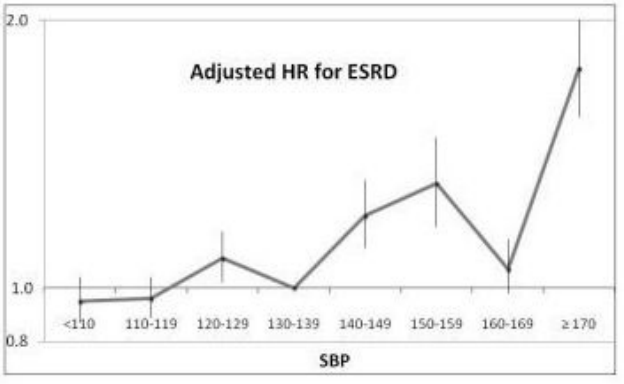
FR-OR030

Evaluating Ranges of Blood Pressure (BP) and Risk of End Stage Renal Disease (ESRD) in a Large Ethnically Diverse Hypertensive (HTN) Population Simran K. Bhandari,[1] Jiaxiao Shi,[1] Kristi Reynolds,[1] Dean A. Kujubu,[1] Kamyar Kalantar-Zadeh,[2] John J. Sim.[1] *[1]Nephrology & Hypertension, Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [2]Nephrology & Hypertension, Harbor UCLA Medical Center, Torrance, CA.*

Background: HTN is a risk for ESRD particularly in those with CKD. The differential impact of blood pressure (BP) and ESRD risk are not well known. We sought to evaluate the association of BP ranges and ESRD incidence in a large HTN population.

Methods: Kaiser Permanente Southern California members age≥18 yrs (1/1/06-12/31/07) with HTN and min 4 months continuous follow-up evaluated. Demographics, medications, comorbidities, and outcomes data were retrieved from electronic medical records. Primary outcome was incident ESRD defined as need for dialysis or renal transplant. Cox proportional regression models used to calculate hazard ratios (HR) for different BP indexes in 10mmHg increments (SBP reference 130-139 and DBP 80-89) adjusted for age, gender, race, eGFR, diabetes, and cardiovascular disease.

Results: 470,988 subjects were identified (mean age, 65 yrs; mean BP, 133/75; 54% female; 21% Hispanic, 12% black). Mean eGFR was 71 ml/min and 8% had eGFR < 60. Over follow-up of 3.0 yrs, 13,034 (2.8%) progressed to ESRD. The lowest rates occurred in SBP 130-139 and DBP 90-100. Compared to SBP 130-139 multivariable HR (95% CI) for ESRD were 0.95 (0.87-1.04), 0.96 (0.89-1.04), 1.11 (1.02-1.21), 1.27 (1.15-1.40), 1.39 (1.23-1.56), 1.07 (0.98-1.18), and 1.82 (1.64-2.02) for SBP ranges <110, 110-119, 120-129, 140-149, 150-159, 160-169, and ≥170 respectively. DBP was not associated with ESRD risk.



Conclusions: In a large ethnically diverse HTN population primarily without CKD, we found a strong, graded linear association between SBP>140 and risk for ESRD. Whether aggressive BP treatment similarly protects against ESRD outcomes is yet to be determined.

FR-OR031

Impact of Cardiac Valvular Calcification at Beginning Hemodialysis Therapy on Cardiovascular Outcome in Patients with End-Stage Renal Disease Hirotake Kasuga,[1] Ryo Takahashi,[1] Chieko Matsubara,[1] Keiko Kimura,[1] Kyoko Kikuchi,[1] Yasuhiko Ito.[2] *[1]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; [2]Nephrology, Nagoya University Graduated School of Medicine, Nagoya, Japan.*

Background: Cardiac valvular calcification is highly prevalent in patients with end-stage renal disease (ESRD), and its presence may be potentially linked with the increasing risk of systemic atherosclerotic events. We investigated whether the presence of calcified valve at just beginning of hemodialysis (HD) therapy could predict individual cardiovascular (CV) events in ESRD patients.

Methods: A total of 1785 consecutive ESRD patients were screened by echocardiography at beginning of HD therapy. Calcification was defined as bright echoes >1mm on one or more cusps of the cardiac valve. They were divided into three groups; those without valve calcification (group 0, n=783), those with calcification in a single (aortic or mitral) valve (group 1, n=651) and those with calcification in both valves (group 2, n=351), and were followed up for up to 10 years.

Results: During follow-up period (median 55months),687 CV events [358 cardiac events (20.1%), 153 cerebrovascular events (8.6%) and 176 peripheral arterial events (9.9%)] occurred, and 536 patients (30.0%) died including 234 CV death (13.1%). In the group 0, 1 and 2, 10-year event-free rates were 67.6%, 58.6% and 40.9% for cardiac events (p<0.0001), 85.0%, 84.9% and 72.4% for cerebrovascular events (p=0.0008), 83.4%, 82.9% and 70.5% for peripheral arterial events (p<0.0001), and 56.6%, 48.0% and 29.1% for composite endpoint of CV events (p<0.0001), respectively. Similarly, survival rates were 82.8%, 77.1% and 62.6% for CV mortality, and 66.3%, 54.5% and 39.8% for all-cause mortality, respectively (p<0.0001 in both). Even after adjustment, valvular calcification was an independent predictor for all endpoints.

Conclusions: The presence of calcified valves at beginning of HD therapy could predict not only cardiac events but also cerebrovascular and peripheral artery events, and might be associated with systemic atherosclerotic events in ESRD patients.

FR-OR032

Increased Nox5 Activity Induces Podocyte Damage and Filtration Barrier Dysfunction Chet E. Holterman,[3] Chelsea Towaij,[3] Mark E. Cooper,[1] Rhian Touyz,[2] Chris R. Kennedy.[3] *[1]Baker IDI Heart & Diabetes Institute, Australia; [2]University of Glasgow, United Kingdom; [3]Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, Canada.*

Background: Reactive oxygen species (ROS) play a key role in glomerular filtration barrier damage. As part of this barrier podocytes are particularly sensitive to ROS. NADPH oxidase (Nox) enzymes are a major source of ROS and their role in the kidney has been well studied. However a paucity of information regarding the role of Nox5 in the kidney remains partly due to its absence from mouse and rat genomes. Here we establish a previously unappreciated role for Nox5 in podocyte damage and diabetic kidney diease in both humans and transgenic mouse models.

Methods: Human diabetic and control kidney biopsies were examined for Nox5 by immunofluorescence. Immortalized human podocytes (hPOD) were stimulated with TGFb, AngII, stretch, or high glucose and Nox5 expression and activity were examined. The effect of Nox5 knockdown via siRNA was also studied. Similar experiments were performed on mouse podocytes (mPOD) infected with Nox5 adenovirus. Transgenic mice ($Nox5^{Pod+}$) expressing Nox5 specifically in podocytes were generated and characterized.

Results: Biopsies from diabetic individuals had higher immunodetectable Nox5 expression in glomerular structures. Stimulation of podocytes with TGFb or AngII induced Nox5 expression and activity. Inhibition of Nox5 via siRNA blunted ROS production in response to these stimuli. Increased Nox5 ROS production altered podocyte actin cytoskeleton, resulted in a more motile phenotype, and increased expression of markers of epithelial to mesenchymal transition. $Nox5^{Pod+}$ mice displayed increased albumin to creatinine ratios as early as 4 weeks following birth. Kidney weight to body weight was increased in $Nox5^{Pod+}$ compared to non-transgenic littermates indicative of kidney hypertrophy. QPCR on mRNA from kidney cortex demonstrated elevated Cox2 expression and decreased nephrin expression in $Nox5^{Pod+}$ compared to non-transgenic littermates.

Conclusions: Upregulation of Nox5 in diabetic kidney occurs in response to classic diabetic stimuli and contributes to ROS–induced podocyte damage and filtration barrier dysfunction.

FR-OR033

Heat Shock Protein 70/CHIP/Nox4 NAD(P)H Oxidase Interaction in the Antioxidative Effect of Losartan on Proximal Tubule Cells from Spontaneously Hypertensive Rats (SHR) Patricia G. Vallés,[1] Andrea Gil Lorenzo,[2] Victoria Bocanegra.[2] *[1]Notti Pediatric Hospital; [2]CONICET.*

Background: Full expression of Angiotensin II signaling is dependent on the reactive oxygen species derived from NAD(P)H oxidase and the dynamic association of the Angiotensin II Type I receptor (AT_1R) with caveolae/lipid rafts.The chaperone Hsp70 regulates a diverse set of signaling pathways.CHIP (Carboxyl terminus of the Hsc70-Interacting Protein) is a E3 ubiquitin ligase that targets proteins for polyubiquitination and degradation.

We investigated Hsp70/CHIP contribution to the regulation of Nox4 after AT_1R receptor blockade,in primary culture of proximal tubule epithelial cells (PTCs) from SHR.

Methods: PTCs from 8 week SHR and WKY rats were stimulated with Angiotensin II (100 nmol/L) for15 min (AII),pretreated with Losartan (100 μmol/L) 90 min (L) and with Losartan75 min plus Angiotensin15 min(L+AII). Interaction and localization of Nox4, Hsp70 and CHIP were determined by immunoprecipitation and immunofluorescence confocal microscopy. PTCs transfection with p-SIREN RetroQ shHsp72 plasmid vector to knockdown Hsp72 or control empty vector was performed.

Results: Whereas SHR PTCs exposure to Angiotensin II downregulated membrane Caveolin-1 expression and overexpressed Nox4 NAD(P)H-oxidase,Losartan increased Caveolin-1expression, increased Hsp70 and decreased Nox4 protein levels in SHR (L) PTC membranes. Decreased Hsp70 in SHR(L) vs SHR(AII) in cytosolic fraction confirm Hsp70 translocation to PTC membranes.No differences were shown in Nox4 gene expression among groups. Increased levels ofHsp7/CHIP contrasts with the decreased immunoprecipitation of Nox4 in membrane from PTCs SHR(L)vs SHR(AII).To validate these results, knockdown of Hsp72 in PTCs was associated with higher Nox4 expression and increased NAD(P)H oxidase activity in SHR (L+AII) related to SHR (L+AII) without transfection.After Hsp72 silencing of PTCs from SHR (AII), Losartan could not prevent Angiotensin II-enhanced Nox 4 expression and NAD(P)H oxidase activity.

Conclusions: Membrane interaction of Hsp70/CHIP may induce Nox4 protein degradation, which could be involved in the cytoprotective effect of Losartan in PCTs from SHR.

FR-OR034

Unique Role of NADPH Oxidase 5 in Oxidative Stress in Renal Proximal Tubule Cells from Humans with Essential Hypertension Peiying Yu,[1] Van Anthony M. Villar,[2] Yu Yang,[3] Robin Allen Felder,[4] Pedro A. Jose.[5] *[1]Department of Medicine, University of Maryland School of Medicine, Baltimore, MD; [2]Clinical Chemistry, University of Virginia, Charlottesville, VA.*

Background: NADPH oxidases (Nox) are the major sources of reactive oxygen species in the kidney. Nox1, Nox2, and Nox4, but not Nox3, are expressed in renal proximal tubule (RPT) cells from rodents and human kidneys. However, NADPH oxidase 5 (*NOX5)* gene is present in humans but not rodents. We tested the hypothesis that *NOX5* is expressed in human RPT cells but the expression is different between normotensive (NT) and hypertensive subjects (HT).

Methods: In addition to cell culture, cell treatment, Biotinylation, immunoprecipitation and immunoblotting, we have used four methods to measure NADPH oxidase activity and/or ROS production in RPT cells.

Results: *NOX5* mRNA expression (quantitative real-time RT-PCR) is 4.2±0.68-fold greater in HT than NT ($P<0.01$, n=4). Total protein expression of Nox5, but not Nox1, Nox2, or Nox4, quantified by immunoblotting, is 5.2 ± 0.65-fold greater in HT than NT. Apical membrane Nox5 is also 2.75 ± 0.46-fold greater in HT than NT. Basal total Nox activity is 4.13±0.26-fold greater in HT (n=4) than NT (n=3). Basal Nox5 activity is also 2.23±0.079-fold greater in HT than NT ($P<0.05$, n=6). Silencing of *NOX5* using *NOX5*-specific siRNA decreases Nox activity (54.87±3.21%, vs. control-siRNA, n=6-8) in HT but not NT. D_1 receptor stimulation with fenoldopam decreases Nox activity to a greater extent in NT (-32.4±1.6) than HT (-14.7±2.1). We demonstrate for the first time that of NOX5 is expressed to a greater extent in RPT cells from HT than NT and may be responsible for the increased oxidative stress in RPT cells from HT.

Conclusions: In conclusion, we report for the first time that Nox5 is the predominant Nox isoform expressed in human RPT cells and its expression and activity are increased in humans with essential hypertension. Thus, increased Nox5 expression and activity may contribute to the increased oxidative stress in human essential hypertension.

Essential Roles of Ghrelin in the Maintenance of Oxidative Stress Levels in the Renal Tubular Tissues by Mitochondria-Dependent Mechanisms

Keiko Fujimura, Shu Wakino, Koichi Hayashi, Hiroshi Itoh. *Department of Internal Medicine, Keio University, 35 Shinanomachi Shinjyuku, Tokyo, Japan.*

Background: Recent study revealed that growth hormone secretagogue Ghrelin(Ghr) exerts renal protective effects. In this study we explored its renal protective effetcs by mitochondria(Mit)-related mechanism.

Methods: Renal tissue damages were induced by infusion of AngII in mice with osmotic mini-pump. Ghr was administered by the daily intraperitoneal injection. 8 weeks after the treatment, mice were sacrificed. In *in vitro* experiment, renal tubular HK-2 cells expressing the receptors for both Ghr and AngII, were used. Growth hormone secretagogue receptor(GHSR) null mice were utilized for the evaluation of the role of endogenous Ghr.

Results: AngII infusion raised blood pressure, which was lowered by Ghr. AngII infusion also induced renal damages as assayed by the urinary excretion of renal tubular marker, which were ameliorated by Ghr but not by blood pressure lowering by hydraladine. AngII also increased urinary protein excretion, which was attenuated both by Ghr and by hydraladine. AngII induces tissue oxidative stress, senescence,and interstitial fibrosis. These changes were attenuated by Ghr independently by its blood pressure-lowering effects. In the kidney of Ghr-treated mice, the expressions of Mit uncoupling protein UCP2 and PPAR-γ coactivator(PGC-1α) increased and Mit number increased. In HK-2 cells, Ghr increased UCP2 expression, reduced Mit membrane potential and Mit-derived ROS and increased Mit number.Transfectionn of siRNA for UCP2 negated the anti-oxidative effects by Ghr. Finally, GHSR null mice were presented with higher serum creatinine levels, renal protein excretion,more severe renal tubular damage, renal ROS levels, SA β-Gal staining levels as compared with those of wild-type littermates. Mit in proximal tubulus of GHSR null mice were elongated and less in number as compared with those of WT mice.

Conclusions: Our data indicated that Ghr suppressed AngII-induced renal damages by reducing the Mit-derived ROS production and Mit number through UCP2-dependent mechanisms. Endogenous Ghr/GHSR systems were essential for the maintenance ROS levels of renal tubular cells and these functions.

HVCN1 Is Required for Superoxide Production in Medullary Thick Ascending Limb in Response to H^+ Efflux

Paul O'Connor, Jingping Sun. *Experimental Medicine, Georgia Health Sciences University, Augusta, GA.*

Background: We have previously reported that H^+ efflux stimulates superoxide (O_2^-) production in the medullary thick ascending limb of the loop of Henle (mTAL) in rats by activation of an as yet unidentified H^+ transport pathway. As HVCN1, a voltage gated H^+ channel associated with NADPH oxidase in immune cells, is also expressed in mTAL, we hypothesized that HVCN1 is responsible for H^+ efflux induced production of O_2^- in mTAL.

Methods: In order to test this hypothesis we utilized HVCN1$^{-/-}$ mice and wild type litter mates obtained from KOMP. To confirm that HVCN1 was functionally knocked out in HVCN1$^{-/-}$ mice we stimulated the respiratory burst using PMA (100mM) in peritoneal macrophages extracted from HVCN1$^{-/-}$ and WT mice and determined maximal O_2^- production using L-012 luminescence. mTAL were isolated from the inner stripe of the outer-medulla by micro-dissection and loaded for 60 min with the O_2^- sensitive dye dihydroethidium (DHE). Live mTAL were then imaged on a heated chamber attached to a fluorescent microscope and the ratio of ethidium (Eth) to DHE quantified using metafluor imaging software as an index of O_2^- production. O_2^- producing H^+ currents were isolated in 0 Na^+, 100mM $BaCl_2$ media and cellular H^+ efflux stimulated using an NH_4Cl (20mM) prepulse.

Results: Maximal O_2^- production during the respiratory burst was significantly lower in macrophages from HVCN1$^{-/-}$ mice (23±4AU; n=6) compared to WT mice (92±3AU; n=5; $p<0.05$), confirming loss of HVCN1 function. Following removal of NH_4Cl from the bath there was a significant increase in O_2^- production in mTAL from WT mice (Delta slope Eth/DHE 15.9±3.6 AU/sec; $p<0.02$ (n=5)) but not HVCN1$^{-/-}$ mice (Delta slope4.7±9.6; P=0.64 (n=6)). The response of WT mice was significantly greater than that of HVCN1$^{-/-}$ mice ($P<0.001$).

Conclusions: We conclude that HVCN1 is required for maximal O_2^- production in mTAL in response to H^+ efflux. These data suggest that HVCN1 may be a novel target to prevent renal oxidative stress.

High Glucose Induces eNOS Internalization and Dysfunction in Glomerular Endothelial Cells

Huifang Cheng, Xiaofeng Fan, Raymond C. Harris. *Medicine, Vanderbilt University Medical School, Nashville, TN.*

Background: Glomerular endothelial cells (GEnCs) play a crucial role in the pathogenesis of diabetic nephropathy, and endothelial nitric oxide synthase (eNOS) is an important modulator of their function. We have previously shown that high glucose impairs eNOS activity, but the underlying molecular mechanisms have not been completely elucidated.

Methods: To mimic the *in vivo* environment, we utilized conditionally immortalized GEnCs cultured in either normal or high glucose (HG) medium.

Results: HG (30mM) medium progressively increased GEnC permeability to BSA and induced apoptosis (0.7±0.2% in normal medium vs. 5.1±0.7% in HG, n=4, $P<0.05$ at 48 hrs) as well as stimulating GEnC proliferation at early stages(24-48 hrs). HG significantly decreased eNOS dimerization (measured by the ratio of dimer/monomer) and decreased phosphorylation at Ser 1179 (an essential step in eNOS activation), while the levels of eNOS monomers and phosphorylation at Thr 497 remained unchanged. In normal growth medium, eNOS was predominantly localized to the membrane of GEnCs, and caveolin-1 (Cav-1) was also abundant at the cell surface. Immunofluorescence indicated that HG induced eNOS translocation to the cytoplasm, with co-localization with Cav-1. Immunoblotting confirmed decreased plasma membrane and increased cytosolic eNOS. In addition, co-immunoprecipitation studies indicated decreases in eNOS associated with Cav-1 at the plasma membrane and increases in cytosol. Taking together, these results suggested that HG stimulates eNOS translocation into the cytoplasm without significant dissociation from Cav-1. HG markedly reduced eNOS activity in GEnCs, measured by nitrate/nitrite production (0.53±0.07 fold control, n=4, $P<0.05$) and also reduced production of the downstream second messenger, cGMP (from 4.5±0.6 to 0.5±0.2 pmol/mg pro., n=4, $p<0.05$).

Conclusions: HG induced eNOS dysfunction in GEnCs via multiple mechanisms: eNOS uncoupling, defective phosphorylation of at Ser 1179 and promoting its translocation from plasma membrane to cytoplasm.

Renal Tubular-Specific LKB1 Deletion Results in Severe Kidney Damage

Laura Malaga-Dieguez,[1] Jianling Tao,[2] Kimberly J. Reidy,[1] Katalin Susztak.[2] *[1]Pediatric Nephrology, Children's Hospital at Montefiore, Albert Einstein College of Medicine, Bronx, NY; [2]Renal Electrolyte and Hypertension, University of Pennsylvania, Philadelphia, PA.*

Background: The Lkb1 (Stk11) gene encodes a serine/threonine kinase. Mice with targeted Lkb1 mutations have shown the in vivo role of Lkb1 in the regulation of metabolism, cell growth, polarity and the cytoskeleton. The kidney contains highly differentiated and polarized cells, and we hypothesize that LKB1 must play a role in the development and maintenance of the structure of these different cell types as well as the regulation of cellular metabolism via undetermined downstream pathways. The aim of our study is to describe the effect of LKB1 deletion in renal tubular cells and the signaling pathways involved in the development of the LKB1 deficient phenotype.

Methods: Tubule-specific LKB1 knock out mice were developed using the Cre/LoxP system of gene splicing. The $Ksp^{Cre}/Stk^{Flox/Flox}$ mice (using the Cadherin 16 cre/Ksp cre mice) lack the Lkb1 gene in the collecting ducts and thick ascending limbs of Henle's loops. The $Pax8^{rtTA}/TRE^{Cre}/Stk^{Flox/Flox}$ mice are inducible transgenic mice that exhibit deletion of Lkb1 in the entire renal tubular system when exposed to doxycycline. We have assessed the renal phenotype of these mice at 5, 14 and 27 weeks and compared it to age-matched controls, using microscopy, RT-PCR, WB and immunohistochemistry.

Results: Kidneys from mice with tubule-specific LKB1 deletion show a strong phenotype at 27 weeks of age. They are grossly enlarged. On light microscopy, the normal renal architecture is lost and the kidney had a fibrotic appearance. The renal tubules in the medulla and inner cortex are largely dilated, while the glomeruli remain intact. Earlier lesions, at 14 weeks of age were consistent with unusual cuboidal appearance of the renal epithelial cells. These changes are not observed in the 5 week-old mice, and are very subtle in the 14 week-old mice, indicating that the damage occurs over time.

Conclusions: Renal tubular-specific LKB1 deletion results in severe damage. Experiments are ongoing to determine the mechanism underlying this damage and pathways involved in LKB1 signaling in the mice kidney.

FR-OR040

A Signal Relay from Transforming Growth Factor beta (TGFb): Stimulated Smad 3 to mTOR Involves Deptor Suppression to Force Mesangial Cell (MC) Hypertrophy Falguni Das,[1] Nandini Ghosh-choudhury,[2] Nirmalya Dey,[1] Hanna E. Abboud,[1] Balakuntalam S. Kasinath,[1] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA, San Antonio, TX.*

Background: The ominous features of TGFb action in kidney consist of altered glomerular hemodynamics, whole kidney hypertrophy including glomerular hypertrophy and matrix synthesis. TGFb receptor activates Smad 3 and mTOR to force these effects. mTOR forms two kinase complexes, mTORC1 and mTORC2 that contain common and distinct proteins. One such common protein, deptor, is an endogenous inhibitor of both kinases. The role of deptor in TGFb-induced signal transduction is not known.

Methods: Human glomerular MCs were used.

Results: Incubation of MCs with TGFb rapidly increased mTORC1 and mTORC2 activities. However, extended incubation of MCs with TGFb significantly reduced the levels of deptor, resulting in increased activity of both kinase complexes. Prolonged incubation with TGFb was necessary for dissociation of deptor from mTOR. Using ATP competitive mTOR inhibitor PP242, we showed that both rapid and sustained activation of mTORC1/2 were required for deptor downregulation and 4EBP-1 translation repressor phosphorylation. Furthermore, PP242-induced reversal of deptor expression was associated with significant inhibition of TGFb-induced MC protein synthesis and hypertrophy. Interestingly, expression of Smad 7, an endogenous inhibitor of Smad 3 signaling, blocked TGFb-induced suppression of deptor and mTORC1/2 activities. Moreover, over-expression of Smad 3 was sufficient to reduce deptor expression and increase in mTORC1/2 activities, similar to TGFb stimulation. Finally, shRNA-mediated knockdown of deptor significantly reversed Smad 7-induced suppression of TGFb-stimulated protein synthesis and hypertrophy of MC.

Conclusions: Together our data provide the first evidence for the requirement of both early and late activation of mTOR complexes for TGFb-induced protein synthesis. These data reveal the presence of a Smad 3-dependent feed forward loop between deptor suppression and mTORC1/2 activation to drive MC hypertrophy.

FR-OR042

Podocyte Structural Parameters Do Not Predict Progression to Diabetic Nephropathy (DN) in Normoalbuminuric (NA) Type 1 Diabetic (T1D) Patients (pts) Tasma Harindhanavudhi,[1] Alicia Parks,[1] Michael Mauer,[2] Maria Luiza A. Caramori.[1] *[1]Medicine, University of Minnesota, Minneapolis, MN; [2]Pediatrics, University of Minnesota, Mineapolis, MN.*

Background: Although microalbuminuria has been used as a predictor of DN, it is well clear that substantial glomerular structural changes can occur before clinical DN is present. Podocyte injury has been implicated in DN pathogenesis. Increased foot processes (FP) width was reported in NA T1D pts. This study aimed to determine whether podocyte/endothelial structural parameters predict progression to proteinuria and/or ESRD (progressors;P) in initially NA T1D pts.

Methods: We performed kidney biopsies in 94 NA T1D pts with≥8 yrs T1D duration, and followed for≥5 yrs (11±7yrs). At follow-up,12 pts were P and 59 were non-progressors (NP). In a nested case-control study,podocyte parameters were studied in each P, in sex and T1D duration matched NP, and in sex and age-matched non-diabetic controls (C). Two P with inadequate tissue for studies were excluded. Glomerular, podocyte parameters and %endothelial fenestration (EF) were estimated by electron microscopy. Glomerular volume was measured on light microscopy.

Results: $HbA1_c$(11±2*vs*.8±1%;p=0.001) and DBP(74±8*vs*.67±7mmHg;p=0.04) were higher in P *vs*.NP. Podocyte number per glomerulus, numerical density of podocyte per glomerulus, FP width, %EF, and the fraction of peripheral glomerular basement membrane (PGBM) and mesangial GBM (MGBM) covered by intact FP were not different among groups. However, the fraction of PGBM(3.2±3.3*vs*.0.5±1.0%) and MGBM(3.5±4.0*vs*.0.5±1.0%) with FP detachment was greater in NP *vs*.C(p=0.014 and p=0.016,respectively),but not different from P. Mirroring the larger cohort, GBM width was greater in P(522.8±89.2nm) *vs*.NP(448.1±85.2nm;p<0.041) or C (361.6±43.1;p<0.001), and greater in NP than C(p=0.027). Mesangial fractional volume was greater in P(0.23±0.06;p=0.006) or NP(0.26±0.07;p=0.001) *vs*.C(0.15±0.04),with no differences between P and NP.

Conclusions: This study does not support the hypothesis that podocyte structural changes are a necessary precondition for DN progression in NA T1D pts. However, this does not preclude an important role for podocytes at later DN stages.

Funding: NIDDK Support, Private Foundation Support

FR-OR043

Renal Prognosis of Patients Diagnosed with Diabetic Nephropathy 10 Years after Renal Biopsy Koki Mise, Yoshifumi Ubara, Junichi Hoshino, Keiichi Sumida, Masayuki Yamanouchi, Tatsuya Suwabe, Kenmei Takaichi. *Nephrology, Toranomon Hospital, Japan.*

Background: Recently, a classification of diabetic nephropathy was reported by Tervaert et al., but the association between pathological findings and the clinical outcome is unknown.

Methods: Among 250 patients with diabetes mellitus who underwent renal biopsy from 1985 to 2002 and were confirmed to have diabetic nephropathy according to the classification of Tervaert et al., 150 patients (followed for longer than 10 years) were enrolled in this study. Cox proportional hazard regression analysis was used to calculate the hazard ratio (HR) and 95% confidence interval (CI) for death-censored renal death. In each regression analysis, two levels of multivariate adjustment were examined.

Results: The hazard ratio (HR) for death-censored renal death of each pathological category is shown below.

		model 1			model 2		
	n	HR	95%CI	p-value	HR	95%CI	p-value
glomerular-class I	12	0.23	0.03-1.79	0.16	0.27	0.03-2.18	0.22
IIA	48	reference			reference		
IIB	34	2.60	1.21-5.59	0.01	2.72	1.12-6.60	0.03
III	26	5.11	2.30-11.36	0.00	5.17	2.03-13.16	0.00
IV	30	2.69	1.23-5.89	0.01	2.78	1.07-7.23	0.04
IFTA 0	16	0.22	0.03-1.74	0.15	0.24	0.03-1.92	0.18
1	52	reference			reference		
2	35	4.25	1.99-9.10	0.00	3.80	1.67-8.63	0.00
3	47	5.79	2.51-13.37	0.00	4.76	1.90-11.88	0.00
Interstitial inflammation 0	19	0.19	0.04-0.80	0.02	0.22	0.05-0.96	0.04
1	119	reference			reference		
2	12	1.02	0.48-2.16	0.96	1.04	0.48-2.25	0.92
Arteriolar hyalinosis 0	15	0.26	0.08-0.86	0.03	0.33	0.10-1.13	0.08
1	24	0.36	0.15-0.86	0.02	0.43	0.17-1.06	0.07
2	111	reference			reference		
Arteriosclerosis 0	13	0.29	0.07-1.28	0.10	0.31	0.07-1.38	0.12
1	69	reference			reference		
2	54	1.32	0.75-2.33	0.34	1.09	0.62-1.94	0.76

In model 1, compared with glomerular class IIA, the HRs for classes IIB, III, and IV were respectively 2.60 (95% CI: 1.21-5.58), 5.11 (2.30-11.36), and 2.69 (1.23-5.89). Also, compared with an IFTA score of 1, HRs for scores of 2 and 3 were 4.25 (1.99-9.10) and 5.79 (2.51-13.37), respectively.

Conclusions: The progression of glomerular, interstitial, and vascular lesions was associated with higher HRs for renal death. These results suggest the clinical utility of Tervaert's pathological classification.

FR-OR044

Urinary MCP-1 and Progression to ESRD in Subjects withType 1 Diabetes Monika A. Niewczas, Jan Skupien, Jung Eun Lee, Tomohito Gohda, William Walker, Adam Smiles, Rita R. Holak, Kevin Patrick Mcdonnell, Jackson Jeong, James Warram, Andrzej S. Krolewski. *Genetics and Epidemiology, Joslin Diabetes Center, Boston, MA.*

Background: Macrophage accumulation is a hallmark of diabetic nephropathy and MCP1 is one of the most potent chemoattractant for those cells. MCP1-based interventions are under investigation; nevertheless the predictive value of MCP-1 as a marker for diabetic nephropathy progression in subjects with proteinuria has not been studied in depth.

Methods: Our cohort included 140 Joslin Kidney Study subjects with type 1 diabetes, proteinuria, and eGFR between 30-60 ml/min/173m^2 (chronic kidney disease stage 3) at baseline. Patients were followed for up to 12 years and incidence of end-stage renal disease (ESRD) and deaths were ascertained. At the study entry, serum Tumor Necrosis Factor receptor 1 (TNFR1) and urinary markers of filtration barrier damage (albuminuria, ACR, proteinuria, PCR, and IgG excretion) and of local inflammation (monocyte chemoattractant protein – 1, MCP-1) were measured.

Results: 56% (n=76) developed ESRD during the follow-up. Serum TNFR1 and urinary excretion of albumin, total protein, IgG and of MCP-1 were higher at baseline in subjects who subsequently developed ESRD. After adjustment for the relevant clinical covariates sTNFR1, ACR and MCP1 emerged as independent significant predictors for the progression to ESRD, whereas the effect of urinary excretion of total protein and IgG was weak. Effect of ACR was confounded by MCP1 (HR for ACR: 2.45, p<0.0001; HR for ACR adjusted by MCP1 1.69, p<0.0001).

Conclusions: In subjects with type 1 diabetes and proteinuria, circulating sTNFR1 and urinary excretion of albumin and MCP1, but not of IgG or total protein, are important predictors of progression to ESRD. Our data suggest also that mechanisms behind albuminuria-driven injury of diabetic kidney are partially mediated via MCP1-involved inflammation.

Funding: NIDDK Support

FR-OR045

Osteoprotegerin (OPG) Is Increased in Patients with Type 1 Diabetes and Diabetic Nephropathy and Predicts Mortality Aino Soro-Paavonen,[1] Daniel Gordin,[1] Carol Forsblom,[1] Niina Sandholm,[1] Merlin C. Thomas,[2] Per-Henrik Groop.[1] *[1]Department of Nephrology, Helsinki University Central Hospital, Helsinki, Finland; [2]Diabetic Complications, Baker IDI Heart and Diabetes Institute, Melbourne, Victoria, Australia.*

Background: The bone-related peptide osteoprotegerin (OPG) is produced by vascular cells and is involved in vascular calcification. We investigated the predictive effect of serum OPG on the progression of diabetic nephropathy (DN), cardiovascular disease (CVD) events, and all-cause mortality in patients with type 1 diabetes (T1D).

Methods: Serum OPG was measured by a Time-Resolved Immunofluorometric Assay in 2,116 patients with T1D and in 212 healthy control subjects in the Finnish Diabetic Nephropathy (FinnDiane) study. The patients were followed for 11.1 (0.1-15.9) years (mean +/- range) and data was collected on DN, incidence of CVD and mortality.

Results: At baseline, serum OPG was increased in the patients with DN [in patients with macroalbuminuria; 2.07±0.08 ng/l or end-stage renal disease (ESRD); 2.70±0.14 ng/l] than in patients without DN (1.61±0.04 ng/l) or healthy controls (1.63±0.06 ng/l). During the follow-up, 130 (6%) patients progressed to a higher level of albuminuria or to ESRD; 31 to microalbuminuria, 46 to macroalbuminuria, and 53 to ESRD. OPG was increased in patients who progressed to ESRD as compared to those who did not. In the Cox-regression model, the highest (fourth) OPG quartile was a significant risk factor for an incident CVD event independently of clinical CVD risk factors [HR 1.02 (1.00-1.02); *P*=0.007]. OPG predicted progression to ESRD [1.20 (1.03-1.39); *P*=0.03 with adjustment with age, gender, SBP, total cholesterol, HbA_{1c}, smoking, and previous CVD], but this association was borderline after the inclusion of eGFR in the model [1.19 (0.82-1.73); *P*=0.36]. OPG independently predicted all-cause mortality in patients with T1D (covariate-adjusted HR 1.01 [1.01-1.01]; *P*<0.001).

Conclusions: In a large cohort of individuals with T1D, OPG was not only predictive of CVD events and progression to ESRD but also of all-cause mortality.

A Urinary Proteomic Set of Biomarkers Predicts Albuminuria Progression in Type 2 Diabetes

Sara S. Roscioni,[1] Dick de Zeeuw,[1] Merel E. Hellemons,[1] Harald Mischak,[2,3] Petra Zürbig,[2] Stephan J.L. Bakker,[4] Ron T. Gansevoort,[4] Henrik Reinhard,[5] Maria Lajer,[5] Peter Rossing,[5,6] Hiddo Jan Lambers Heerspink.[1] *[1]Clinical Pharmacology, University of Groningen, UMC Groningen, Netherlands; [2]BHF Glasgow Cardiovascular Research Centre, University of Glasgow, United Kingdom; [3]Mosaiques Diagnostics GmbH, Germany; [4]Nephrology, UMC Groningen, Netherlands; [5]Steno Diabetes Centre, Gentofte, Denmark; [6]Health, University of Aarhus, Denmark.*

Background: In patients with diabetes, development of microalbuminuria is the first clinical sign of diabetic nephropathy and is associated with adverse renal outcomes. Detection of patients at risk to develop micro- and macroalbuminuria may allow "early" therapeutic intervention. We assessed the value of a urinary proteomic risk score (classifier) in predicting development of micro- or macroalbuminuria.

Methods: We conducted a prospective case-control study by using data from the PREVEND study and the Steno Diabetes Centre. Cases (n=44) represented patients with diabetes who progressed one albuminuria stage (from normo- to micro- or from micro- to macroalbuminuria). Controls (n=44) with diabetes but no albuminuria transitions were matched for age, gender, and albuminuria status. A model for the progression of albuminuria was built using a previously defined classifier based on the abundance of 273 urinary peptides.

Results: Conditional logistic regression revealed that the proteomic classifier was independently associated with albuminuria transition (OR=1.32, 95%CI=1.06-1.64, P=0.014). The classifier predicted onset of micro- and macroalbuminuria on top of baseline albuminuria and eGFR.

Area Under the Receiver Operating Characteristic curve and Integrated Discrimination Index (IDI) for albuminuria progression by using the proteomic classifier

	AUC	95% CI	P	IDI	95% CI	P
Control model*	0.91	[0.85-0.98]	-	-	-	-
+ Classifier	0.94	[0.89-0.99]	0.002	0.105	[0.038-0.172]	0.002

*Includes baseline albuminuria and eGFR

Among the biomarkers, fragments of collagens, glycoproteins, and uromodulin showed statistically significantly different levels between cases and controls.

Conclusions: Our findings suggest the use of urinary proteomics in renal risk assessment in diabetic patients.

FR-OR047

Metabolite Profiles and the Risk of Worsening of Albuminuria in Type 2 Diabetes

Michelle J. Pena,[1] Sara S. Roscioni,[1] Torben Friedrich,[2] Guido Dallmann,[2] Maria Lajer,[3] Stephan J.L. Bakker,[4] Ron T. Gansevoort,[4] Peter Rossing,[3] Dick de Zeeuw,[1] Hiddo Jan Lambers Heerspink.[1] *[1]Dept Clinical Pharmacology, UMC Groningen, Netherlands; [2]Biocrates Life Sciences AG, Innsbruck, Austria; [3]Steno Diabetes Center, Gentofte, Denmark; [4]Division Nephrology, UMC Groningen, Netherlands.*

Background: Microalbuminuria is an early sign of diabetic nephropathy and is associated with adverse renal outcomes. Early detection of patients with type 2 diabetes (T2D) at risk for micro- or macroalbuminuria may be a key strategy for early intervention. We assessed the predictive value of metabolomic biomarkers for development of micro- and macroalbuminuria in T2D.

Methods: T2D patients were selected from a general population cohort (the PREVEND study) and the Steno Diabetes Center. Cases (n=45) represented subjects who transitioned to a higher albuminuria stage (i.e. from normo- to micro- or from micro- to macroalbuminuria), whereas controls (n=45) had stable albuminuria during follow-up. Cases and controls were matched for age, gender, and baseline albuminuria status. Metabolite profiles were measured with flow injection analysis (FIA) and LC-MS/MS. The predictive performance of plasma and urine metabolites for albuminuria progression was assessed by the area under the ROC-curve (AUC) and integrated discrimination index (IDI).

Results: In plasma, histidine was decreased and acylcarnitine was increased, and in urine, tyrosine and glutamine were decreased, in cases compared to controls (fold change 0.30, p=0.03; fold change 0.32, p<0.01; fold change 0.87, p<0.01; and fold change 1.17, p=0.03, respectively). In plasma and urine, the metabolites improved risk prediction for albuminuria progression irrespective of other renal risk markers including blood pressure, glucose, albuminuria and eGFR.

Conclusions: Plasma and urine metabolites can predict albuminuria progression in T2D patients on top of traditional markers.

AUC-ROC and IDI for predicting albuminuria transition

Urinary Proteomics Predict Onset of Microalbminuria in a Cohort of Normoalbuminuric Type 1 Diabetic Patients in the DIRECT 1 Study

Morten Lindhardt,[1] Frederik I. Persson,[1] Petra Zürbig,[3] Angelique Stalmach,[4] Harald Mischak,[3,4] Dick de Zeeuw,[5] Hiddo Jan Lambers Heerspink,[5] Anne Katrin Sjoelie,[6] Ron Klein,[6] Trevor Orchard,[6] Massimo Porta,[6] John Fuller,[6] Rudolf W. Bilous,[6] Nish Charturvedi,[6] Hans-Henrik Parving,[6] Peter Rossing.[1,2] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]University of Aahus, Denmark; [3]Mosaiques Diagnostics GmbH, Hannover, Germany; [4]University of Glasgow, United Kingdom; [5]University Medical Centre, Groningen, Netherlands; [6]The DIRECT Steering Group.*

Background: Early prevention of diabetic nephropathy is not successful as early interventions have shown diverging results. Urinary proteomics has shown promise as an early indicator of future development of diabetic nephropathy.

Methods: In a post-hoc study of the DIRECT-Protect 1 study, a randomized, controlled clinical trial of candesartan for slowing the progression of diabetic retinopathy, we studied patients with type 1 diabetes and normoalbuminuria (n=782), followed for a mean of 4.7 years. We determined a previously defined CKD risk score based on proteomic measurement of 273 urinary peptides (CE-MS), selected from previous cross sectional case-control studies. A Cox regression model for progression of albuminuria was built. The primary endpoint was development of persistent microalbuminuria (MA) (3 out of 4 samples).

Results: Persistent MA developed in 45 patients (5,7%). At baseline the CKD risk score was able to predict development of MA during follow-up, independent of treatment (candesartan/placebo), age, gender, baseline systolic BP, baseline UAER, baseline eGFR, baseline HbA_{1c} and diabetes duration (HR 3.7 (95% CI 1.4-9.3), p=0.006). In the placebo treated group the HR was 7.7 (2.1 to 29.1) compared to 1.8 (0.4 to 7.0) in the candesartan group.

Conclusions: In this cohort of patients with type 1 diabetes and normoalbuminuria from a large intervention study, the urinary proteome-based CKD classifier was an independent predictor of MA. This may provide a better opportunity to select normoalbuminuric patients for early prevention of diabetic nephropathy as treatment with candesartan seems to mitigate this risk.

***APOL1* Variant-Associated FSGS Is More Aggressive but Manifests Similar Response to Cyclosporine and Mycophenolate Compared to Other Forms of Primary FSGS**

Jeffrey B. Kopp,[1] Xiongce Zhao,[1] Cheryl Ann Winkler,[1] Robert Woroniecki,[7] Milena Radeva,[2] Jennifer J. Gassman,[2] Debbie S. Gipson,[3] Howard Trachtman,[4] Marva M. Moxey-Mims,[1] Aaron L. Friedman,[5] Frederick J. Kaskel.[6] *[1]NIDDK, NIH; [2]Cleveland Clinic; [3]Univ Michigan; [4]New York Univ; [5]Univ Minnesota; [6]Albert Einstein Coll Med, Bronx, NY; [7]Columbia University.*

Background: *APOL1* kidney risk variants, which are present in some individuals of recent African descent, are strongly associated with primary focal segmental glomerulosclerosis (FSGS), HIV-associated nephropathy, and hypertensive nephrosclerosis. Prior work has shown that individuals with and without *APOL1*-associated FSGS respond at similar rates to glucocorticoids.

Methods: The FSGS Controlled Trial randomized children and young adults with glucocorticoid-resistant FSGS to one year of therapy with cyclosporine and low dose daily prednisone (CSA, N=72) versus mycophenolate, pulse oral dexamethasone, and low dose daily prednisone (MMF/DEX, N=66). DNA was available from 94 subjects, including 32 African Americans, 59 European Americans, and 3 others. Subjects were genotyped for *APOL1* risk variants (G1, G2). Primary outcome was complete or partial remission by week 52 (treatment end).

Results: Two *APOL1* risk alleles were present in 23/32 African Americans (72%) and in 4/59 (7%) European Americans, of whom 2 homozygous risk subjects were of Hispanic ancestry. Baseline eGFR was lower among 2 risk-allele subjects, 96±39 vs 143±70 ml/min/1.73m2, p<0.001, but proteinuria levels were similar. Collapsing FSGS was more common among 2 risk-allele subjects (8/27 vs 3/67, p<0.002), and cortical atrophy/ fibrosis (p<0.001) and arteriosclerosis (p<0.05) were more severe among 2 risk-allele subjects. Remission rates were similar (p=0.22) and the test for interaction between genotype and intervention (CSA vs MMF/DEX) was non-significant (p=0.45). The risk for progression to ESKD during follow-up was three-fold higher among 2 risk-allele subjects, 10/27 vs 8/67, p<0.01.

Conclusions: Racial self-identification is not a reliable means to exclude the presence of *APOL1* risk alleles. FSGS patients with 2 *APOL1* risk-alleles have more aggressive kidney disease but comparable response to CSA and MMF/DEX compared to other individuals.

Funding: NIDDK Support

Genetic Locus on Chromosome 2q31.1 Associated with End Stage Renal Disease in Women with Type 1 Diabetes Per-Henrik Groop,[1] Niina Sandholm,[2] A.J. McKnight,[3] Rany M. Salem,[4] Eoin P. Brennan,[5] On Behalf of the GENIE Consortium.[6] *[1]Division of Nephrology, Helsinki University Central Hospital, Finland; [2]Folkhälsan Research Center, Helsinki, Finland; [3]Queen's University of Belfast, United Kingdom; [4]Broad Institute, Cambridge; [5]University College Dublin, Ireland; [6]GENIE Consortium.*

Background: Diabetes is the leading cause of end stage renal disease (ESRD). Notably, male gender is a major risk factor for diabetic nephropathy and ESRD. As men are more likely to develop ESRD, we performed a genome-wide association study on Finnish subjects with type 1 diabetes (T1D) to elucidate if genetic variants explain this discrepancy between men and women.

Methods: We genotyped 3652 subjects with T1D from the FinnDiane study on the Illumina 610 Quad array, and used HapMap II CEU as the reference panel to impute 2.4 million single nucleotide polymorphisms (SNPs). After quality control, cases included 258 women and 387 men with ESRD, and controls consisted of 936 women and 655 men with T1D but no evidence of kidney disease. Association was evaluated separately in men and woman using logistic regression adjusted for T1D duration, age and ten first principal components. Supporting replication evidence was gained from additional T1D cohorts from the GENIE collaboration: 1830 UK-ROI, 1792 GoKinD US and 397 Italian T1D subjects.

Results: We identified a common variant on chromosome 2q31.1 associated with ESRD at genome-wide level of statistical significance in women (odds ratio (OR) 2.4, $P=3\times10^{-8}$) but not in men (P=0.77). This signal was replicated ($P=0.02$) and the combined meta-analysis resulted in a P-value of 3.8×10^{-8} and OR 1.8 in women. This intergenic variant is located between the *SP3* and *CDCA7* genes. SP3 encodes a transcription factor that regulates expression of *CD2AP*, a protein essential for the glomerular filtration barrier. *CDCA7* encodes a DNA-dependent transcription factor that participates in the regulation of cell proliferation.

Conclusions: This signal represents the first genetic factor robustly associated with diabetic ESRD in women, but not in men, and points to a plausible biological pathway that may contribute to observed gender differences in risk of ESRD.

FR-OR052

Common Variant in Uromodulin Promoter: Pleiotropic Consequences for Uric Acid, Diastolic Blood Pressure and Renal Function Decline in Community Based Population Yu-qing Chen,[1] Jia Han,[1] Ying Liu,[1] Xingyu Wang,[2] Yu Liang,[1] Fang Wang,[1] Luxia Zhang,[1] Hong Zhang,[1] Haiyan Wang.[1] *[1]Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China; [2]Beijing Hypertension League Institute China, Beijing, China.*

Background: Uromodulin (UMOD) is the most abundant protein in human urine. Here we asked whether UMOD genetic variants influence plasma uric acid, blood pressure and CKD progression in a community based population.

Methods: We took advantage of a community based population from Beijing, including 1000 individuals, 48% males and 52% females, mean age 63.7±9.0 years. 7 UMOD SNPs across the gene were genotyped in this population. Urinary uric acid, sodium, uromodulin and creatinine were measured in 898 cases. Transcriptional activity of promoter variants was estimated in luciferase reporter plasmids transfected into human kidney cells.

Results: The most common haplotype ATTGGCA (5'-3') was associated with a higher urinary uromodulin levels (p=0.016). UMOD promoter variants (rs13333226, rs6497476 and rs4293393] were associated with plasma uric acid, diastolic blood pressure and GFR decline as well. Rs13333226G allele carriers (n=133) have higher diastolic blood pressure, higher plasma uric acid level compared with A homozygotes (n=777) (p=0.035, p=0.009). Rs6497476 C carriers (n=112) have higher diastolic blood pressure and plasma uric acid level compared with T homozygotes (n=767) (p=0.025, p=0.005). At the same time variants rs13333226 (OR 1.687, p=0.036) and rs6497476 (OR 1.875, p=0.016) were associated with renal function decline in the cohort during 4 years follow up. rs4293393 C/T associated with plasma uric acid level only, and C carriers have higher uric acid level than T homozygotes (p=0.032). Site-directed mutagenesis at two trait-associated UMOD promoter variants, rs13333226 (A to G) and rs6497476 (C to T) altered promoter activity in transfected luciferase reporter plasmids.

Conclusions: Our study indicated that uromodulin gene variant predicted plasma uric acid, diastolic blood pressure and renal function decline in a community based population, suggested important roles of UMOD in the regulation of renal function.

Prevalence of Combined Complement Gene Mutations in aHUS and Their Impact on Clinical Phenotype Marina Noris,[1] Elena Bresin,[1] Erica Rurali,[1] Jessica Caprioli,[1] Pilar Sánchez-corral,[2,3] Veronique Fremeaux-bacchi,[4] Santiago Rodriguez de Cordoba,[5,3] Sheila Pinto,[5,3] Tim Goodship,[6] Marta Alberti,[1] David Ribes,[7] Elisabetta Valoti,[1] Giuseppe Remuzzi.[1,8] *[1]IRFMN, Bergamo; [2]IdiPAZ, Madrid; [3]CIBERER, Madrid; [4]HEGP, Paris; [5]CSIC, Madrid; [6]IGM, Newcastle upon Tyne; [7]CHU, Toulouse; [8]OORR, Bergamo.*

Background: aHUS is characterized by hemolytic anemia, thrombocytopenia, renal impairment and is associated with complement gene mutations (mut). Multiple genetic factors have been proposed to contribute to full-blown disease.

Methods: By screening 795 aHUS patients from 4 European cohorts (I, S, F, UK) we evaluated the prevalence of combined complement gene mut and their impact on clinical phenotype.

Results: 27 out of 795 aHUS patients (3.4%) carried combined mut in at least two complement genes, while 323 patients (40.6%) had single mut. Combined mut were more frequently found in patients with CFI mut (27% of patients), followed by MCP (23%), CFB (10%), CFH (9%) and C3 (8%), indicating that CFI and MCP mut more frequently need a second mut to manifest aHUS. Extending genetic screening to available relatives of combined mutated patients, we found that 29, 26 and 5 subjects carried 1, 2 or 3 mut. HUS penetrance increased across subjects with 1 (10% affected), 2 (50%) or 3 (100%) complement gene mut. Concomitant presence of CFH (c.1-332T, c.2808T) and MCP*ggaac* risk haplotypes significantly increased penetrance in affected carriers of 2 mut (71% vs 25%, P<0.05). Long-term prognosis in patients with combined CFH, CFI or C3 mut (ESRF at 3yrs: 36%, 40%, 50%) was similar to that in patients with single CFH, CFI or C3 mut (ESRF at 3yrs: 23%, 40%, 33%). Graft outcome at 3yrs was similar in the combined and single mutated subgroups (50% of graft lost). At variance, 50% of patients with MCP-combined mut developed ESRF at 3yrs from onset vs 6% of patients with single MCP mut (P<0.05). Moreover, patients with MCP combined mut had worse kidney transplant outcome than patients with single MCP mut (50% vs 7% graft lost at 3yrs).

Conclusions: We recommend screening of all known disease-associated genes in aHUS patients, particularly before taking a decision about transplantation.

FR-OR054

DNA Methylation Profile Associated with Rapid Progression of Kidney Disease: Findings from the CRIC Study Maria R. Wing,[1] Joseph M. Devaney,[2] Marshall M. Joffe,[3] Dawei Xie,[3] Harold I. Feldman,[3] Kevin A. Sterling,[1] Katalin Susztak,[4] Nicolas Jose Guzman,[1] James G. Herman,[5] Leslie Cope,[5] Brennan Harmon,[2] Alan S. Go,[6] Jiang He,[7] James P. Lash,[8] Eric Hoffman,[2] John W. Kusek,[9] Dominic S. Raj.[1] *[1]Division of Renal Disease and Hypertension, George Washington University; [2]Children's National Medical Center; [3]Clinical Epidemiology Unit, University of Pennsylvania School of Medicine; [4]Division of Nephrology, Albert Einstein College of Medicine, Bronx, NY; [5]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine; [6]Division of Research, Kaiser Permanente Northern California; [7]Tulane University School of Public Health and Tropical Medicine; [8]Division of Nephrology, University of Illinois; [9]DKUHD, NIDDK.*

Background: Recent evidence indicates that epigenetic mechanisms may be important in progression of chronic kidney disease (CKD).

Methods: The genome-wide DNA methylation pattern associated with rapid loss of kidney function was studied using the Infinium Human Methylation 450K BeadChip in 40 Chronic Renal Insufficiency Cohort (CRIC) Study participants (n=3,939) with the highest and lowest rates of decline in eGFR. The data was analyzed using an ANOVA with response (rapid loss of kidney function vs. stable kidney function), sex, race, and diabetes status.

Results: The mean eGFR slope was 3.6(1.4) and -3.7(1.2) ml/min/1.73 m^2 in the stable kidney function group and rapid progression group respectively. The *TPBG*, *ZFYVE21*, and *FKBP5* genes were hypomethylated in subjects with rapid decline in eGFR (P-values: 9.6E-06 to 5.7E-05). A CpG island within the *NOS3* gene was hypermethylated (P-value 1.6E-03) in diabetics. Other CKD-related genes with differential methylation included *NFKBIA*, *NFKBIZ*, *TGFRB3*, *TGFRB2*, *SOD1*, and *SOD2* (P-values: 3.8E-04 to 8.8E-03). Gene set enrichment analysis identified *CLU*, *TGFB2*, *NFkB* family genes, and DNMT3A to be differentially methylated. Pathway analysis showed that gene networks related to gene expression, cellular growth and cellular proliferation were epigenetically regulated.

Conclusions: These results indicate that epigenetic modifications could be important in determining the rate of loss of kidney function.

Genome-Wide Association Study (GWAS) of Renal Function Decline: The CKDGen Consortium Carsten A. Böger. *Nephrology, on Behalf of the CKDGen Progression Writing Group, University Hospital Regensburg, Regensburg, Germany.*

Background: Multiple loci associated with cross-sectional eGFR in population-based cohorts have recently been identified by GWAS, but a systematic genetic analysis of longitudinal kidney traits is outstanding. We thus performed GWAS meta-analysis of several definitions of kidney function decline.

Methods: 45409 participants from 16 CKDGen studies with follow-up data (AGES, AMISH, ARIC, ASPS, CHS, CoLaus, FHS, GENOA, HABC, JUPITER, KORA S3, KORA S4, MESA, Rotterdam Study, SHIP, 3C) participated. GFR was estimated from serum creatinine calibrated to NHANES standards. Median follow-up was 5.7 years. We derived four traits from serial eGFR: annual eGFR decline (eGFR-decline, in ml/min/1.73m^2 per year), incident CKD (new eGFR<60ml/min/1.73m^2,n=3187 cases), incident CKD with a 25% eGFR decline (CKDi25, n=1685 cases), rapid eGFR-decline (annual eGFR-decline^{3}3ml/min/1.73m^2, n=7748 cases). Study-specific GWAS for each trait was adjusted for age, sex, and baseline eGFR, and additionally for study site, principal components and family relatedness where applicable. Analyses stratified by presence of baseline CKD for rapid eGFR-decline and eGFR-decline were also performed. Meta-analysis was performed using an inverse-variance weighted fixed effects model.

Results: Seven loci were associated with at least one of the analyzed traits at p<1.0 x 10^{-6}. The previously identified *UMOD* locus showed genome-wide association with eGFR-decline (p=2.6x10^{-14}). The next highest ranking SNPs, both associated with rapid eGFR-decline, were located in the *MEOX2* (p=6.8x10^{-8}) and the *PRKAG2* loci (p= 3.0x10^{-7}). In those without CKD, one SNP was associated with rapid eGFR-decline in the *IL1RAP* region (p=4.1x10^{-7}). Other loci identified were the *MTHFR*/*NPPA/NPPB* and *CDH23* (in eGFR-decline in those with CKD), and *C2orf48* (in the CKDi25 analysis) regions.

Conclusions: Several novel loci and the previously identified *UMOD* locus were associated with clinically relevant kidney function decline traits. If confirmed, these findings suggest an additional genetic component to kidney function deterioration when compared to cross-sectional eGFR. Validation in independent cohorts and by functional studies is ongoing.

Sat1 Anion Transporter (SLC26A1) Is Linked to Calcium Oxalate Urolithiasis Daniel Markovich, Sarah C. Mcleay, Soohyun Lee. *School of Biomedical Sciences, University of Queensland, St Lucia, QLD, Australia.*

Background: Urolithiasis is a common disorder leading to significant health care costs. The most prevalent form of kidney stones in humans is calcium oxalate urolithiasis, which is linked to perturbations in oxalate homeostasis. Sat1 (Slc26a1) is an anion transporter that mediates oxalate transport across epithelial cells of the kidney, liver and intestine. In this study, we aimed to determine the role of Sat1 in oxalate homeostasis and calcium oxalate urolithiasis.

Methods: Blood and urine profiling, X-ray spectrometry, membrane transport assays and histological analysis was used to characterise abnormal physiological features in Sat1 (Slc26a1) null (Sat1$^{-/-}$) mice (generated in our laboratory) and compared to age- and gender-matched wild-type littermates.

Results: Sat1$^{-/-}$ mice have calcium oxalate urolithiasis, hyperoxaluria with hyperoxalemia, elevated urine oxalate/creatinine ratios and reduced oxalate transport in intestinal basolateral membrane vescicles (BLMVs). Sat1$^{-/-}$ mice also exhibit leukocyte infiltration around renal cortical vessels, suggestive of ureteral obstruction or obstructive uropathy.

Conclusions: Our data demonstrates that Sat1 is crucial for oxalate homeostasis and is linked to the development of calcium oxalate kidney stones. This animal model provides the foundation for studying the roles of SAT1 (SLC26A1) in human kidney stone formation.

FR-OR057

Activation of the Ca^{2+}-Sensing Receptor Increases Renal Claudin-14 Expression and Urinary Ca^{2+} Excretion Henrik Dimke, Prajakta Desai, Wanling Pan, Jelena Borovac, R. Todd Alexander. *Pediatrics & Physiology, University of Alberta, Edmonton, AB, Canada.*

Background: Kidney stones are a prevalent clinical condition imposing a large economic burden to the healthcare system. Hypercalciuria remains the major risk factor for development of a Ca^{2+}-containing stone. The kidneys ability to alter Ca^{2+} excretion in response to changes in serum Ca^{2+} is in part mediated by the Ca^{2+}-sensing receptor (CaSR). A recent GWAS study linked claudin-14 (Cldn14) to kidneys stones. Moreover, recent expression studies have localized cldn14 to the thick ascending limb (TAL) and revealed that expression is regulated by the CaSR.

Methods: To interrogate the role of claudin-14 expression in calcium homeostasis we manipulated Ca^{2+}homeostasis *in vivo* by placing mice on altered calcium diets, administering 1,25-dihydroxyvitamin D_3 or the calcimimetic, Cinacalcet. We also over expressed Cldn14 in a renal epithelial cell culture model.

Results: We find that Cldn14 expression is increased by high dietary Ca^{2+} intake and by elevated serum Ca^{2+} levels induced by prolonged 1,25-dihydroxyvitamin D_3 administration. Consistent with this, activation of the CaSR *in vivo* via administration of the calcimimetic Cinacalcet, led to a 40-fold increase in Cldn14 mRNA abundance. Moreover, overexpression of Cldn14 in a cell culture model decreased paracellular Ca^{2+} flux by preferentially decreasing cation permeability and consequently increasing transepithelial resistance.

Conclusions: These data support the existence of a mechanism whereby activation of the CaSR in the TAL increases Cldn14 expression, thus blocking the paracellular reabsorption of Ca^{2+}. This molecular mechanism likely facilitates renal Ca^{2+} losses in response to elevated serum Ca^{2+}. Moreover, dysregulation of the newly described CaSR-Cldn14 axis likely contributes to the development of hypercalciuria and kidney stones.

FR-OR058

Genetic Hypercalciuric Stone-Forming Rats Have a Decrese in Paracellular Permeability to Calcium in the Cortical Thick Ascending Limb Suresh K. Ramakrishnan,[1] Alexandre Loupy,[2] Aurelie Edwards,[1] David A. Bushinsky,[3] Pascal Houillier.[2] *[1]CNRS, P. et . Curie Univ., Paris, France; [2]INSERM, Paris Descartes Univ., Paris, France; [3]University of Rochester Medical Center, Rochester, NY.*

Background: Idiopathic hypercalciuria (IH) is the principal risk factor for calcium (Ca) nephrolithiasis. Patients with IH generally have increased intestinal Ca absorption, increased bone resorption and a decreased renal tubular Ca reabsorption. The Genetic Hypercalciuric Stone-forming (GHS) rats have been shown to have each of these pathophysiologic abnormalities resulting in hypercalciuria and stone formation. Previous clearance studies in GHS rats suggested deficient Ca transport in the thick ascending limb (TAL).

Methods: To test this hypothesis, we measured net transepithelial Ca transport (J_{Ca}) in in vitro microperfused cortical TAL from male GHS and control Sprague-Dawley (SD) rats.

Results: Under baseline conditions, J_{Ca} was significantly lower in cTAL from GHS than from SD rats (1.7±0.7 vs 4.9±1.2 pmol.min^{-1}.mm^{-1} (m±sd), p <0.001). In contrast, J_{Na}, J_{Cl} and the transepithelial voltage were similar in GHS and SD rats. The passive transepithelial permeability to Ca (P_{Ca}) was measured under conditions of transepithelial voltage clamp obtained by imposing a dilution potential. P_{Ca} was significantly lower in GHS than in SD rats (4.7±0.4 vs 8.4±0.6 x 10^{-5} cm.s^{-1}, p=0.0006). We then determined whether the defect in Ca absorption in the cTAL could be reversed by inhibition of the calcium-sensing receptor CaSR. When added in the bath, the calcilytic NPS2143 (1 μM) increased Ca absorption by 2.2±0.6 pmol.min^{-1}.mm^{-1} in the SD rats and by 1.8±0.6 pmol.min^{-1}.mm^{-1} in the GHS rats. J_{Ca} remained lower in GHS than in SD rats. Similarly, peritubular PTH (300 pM) increased J_{Ca} both in SD (by 2.1±0.7 pmol.min^{-1}.mm^{-1}) and GHS rats (by 2.3±0.6 pmol.min^{-1}.mm^{-1}) but J_{Ca} remained lower in GHS than in SD rats.

Conclusions: Thus GHS rats display a severe decrease in Ca absorption in the cTAL due to a decrease in paracellular pathway permeability, which cannot be reversed by inhibiting the CaSR or activating the PTH receptor. The molecular basis of the cTAL defect in Ca permeability remains to be determined.

FR-OR059

Defective SLC26A6-Mediated Oxalate Secretion in *CFTR*-Null Mice Felix Knauf,[1] Robert Brent Thomson,[1] Marie E. Egan,[2] John R. Asplin,[3] Peter S. Aronson.[1] *[1]Medicine/Nephrology, Yale School of Medicine, New Haven, CT; [2]Pediatrics/Pulmonology, Yale School of Medicine, New Haven, CT; [3]Litholink Corporation, Chicago, IL.*

Background: Patients with cystic fibrosis have an increased incidence of hyperoxaluria and calcium-oxalate nephrolithiasis. Net intestinal absorption of dietary oxalate results from passive paracellular oxalate absorption as modified by SLC26A6-mediated back-secretion of oxalate. It has been postulated that fat malabsorption observed in patients with cystic fibrosis leads to an increased oxalate absorption by reducing precipitation of oxalate with calcium in the lumen of the intestine, thereby increasing soluble oxalate available for absorption. We used *CFTR*-null mice to test the additional hypothesis that SLC26A6-mediated oxalate secretion is defective in cystic fibrosis.

Methods: We mounted isolated intestinal tissue from wild-type and *CFTR*-null mice in Ussing chambers and measured active secretion of [14C]-oxalate. To determine the specificity of any observed defect in active oxalate secretion, we also assayed active [14C]-glucose absorption. Duodenum was harvested and probed for SLC26A6 protein expression normalized to actin by Western blot analysis. Plasma and urine oxalate levels were measured.

Results: Active oxalate secretion was completely abolished in intestinal tissue isolated from *CFTR*-null mice as compared to wild-type mice. Glucose absorption was not changed between wild-type and *CFTR*-null mice, indicating that the effect of CFTR deletion to reduce oxalate secretion is not the result of a general downregulation of intestinal transport processes. Intestinal SLC26A6 protein abundance was reduced by 50% in *CFTR*-null mice compared with wild-type mice. Serum and urine oxalate levels were 3-fold increased in *CFTR*-null mice compared to wild-type mice.

Conclusions: We demonstrate that SLC26A6-mediated oxalate secretion in the intestine is impaired in a mouse model of cystic fibrosis. Downregulation of SLC26A6 may contribute to the increased net absorption of dietary oxalate contributing to hyperoxalemia, hyperoxaluria and increased risk for calcium-oxalate stone formation observed in patients with cystic fibrosis.

FR-OR060

Calcium-Induced Acid Secretion in the Cortical Collecting Duct Involves GPRC6A Marie-lucile Figuères,[1] Alexandre Loupy,[1] Suresh K. Ramakrishnan,[2] Patrick Bruneval,[1] Chantal Mandet,[1] Sanela Smajilovic,[3] Hans Bräuner-osborne,[3] Pascal Houillier.[1] *[1]INSERM, ParisDescartes Univ., Paris, France; [2]CNRS, P.&M. Curie Univ., Paris, France; [3]Copenhagen Univ., Copenhagen, Denmark.*

Background: Hypercalciuria stimulates urinary acidification that might protect against the formation of calcium(Ca) stones. However, the mechanism of Ca-sensing in the collecting duct (CD) remains elusive. We hypothesized that GPRC6A, a G protein-coupled receptor related to CaSR, may be involved in the urinary acidification elicited by hypercalciuria. This study aimed at localizing GPRC6A in the kidney and at assessing its role in the Ca-dependent urine acidification.

Methods: GPRC6A and CaSR proteins were localized by immunohistochemistry (IHC) on serial sections of mouse kidney, using anti-GPRC6A and anti-CaSR antibodies (from MBL and ABR, respectively). The activity of H^+ transporters was assessed by measuring the initial rate of alkalinisation of type A intercalated cells after intracellular acidification by the NH_3/NH_4^+ prepulse method in *in vitro* microperfused cortical CD.

Results: IHC experiments with the anti-GPRC6A antibody revealed a predominant staining of intercalated cells of cortical and medullary CD. No staining was present in $Gprc6a^{-/-}$ mice. No staining of CD was observed with the anti-CaSR antibody. In $Gprc6a^{+/+}$ mice, the initial rate of cell alkalinisation was 0.17±0.02 and 0.38±0.05 UpH/min in the presence of 1 and 3 mM luminal Ca, respectively ($p = 0.002$). In $Gprc6a^{-/-}$ littermate mice, the initial rate of cell alkalinisation was 0.29±0.07 and 0.23±0.06 UpH/min in the presence of 1 and 3 mM Ca, respectively ($p = 0.5$).

Conclusions: In the mouse CD, GPRC6A is expressed in intercalated cells of CD. Increasing luminal Ca concentration stimulates H^+ secretion by intercalated cells, an effect involving GPRC6A.

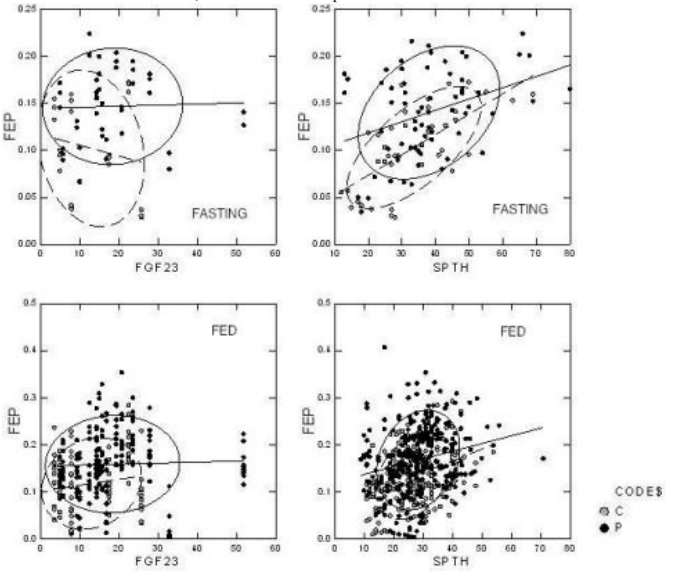
Effect of Parathyroid Hormone and FGF23 on Fractional Excretion of Phosphorus in Stone Formers and Controls

Anna L. Zisman,[1] Kristin J. Bergsland,[1] Kenneth E. White,[2] Fredric L. Coe,[1] Elaine M. Worcester.[1] *[1]Section of Nephrology, University of Chicago, Chicago, IL; [2]Department of Medical and Molecular Genetics, Indiana University, Indianapolis, IN.*

Background: The average serum phosphorus (P) of calcium stone formers (SF) with idiopathic hypercalciuria (IH) is lower than among normal people; their hypophosphatemia is associated with an increase in overall fractional excretion of filtered P (FEP).

Methods: We have measured FGF23 (using the Kainos assay), PTH, P, and FEP in 18 SF with IH and 7 controls (C) studied on standard diets in the CRC. Fasting and fed time periods were analyzed separately. To determine the independent correlation with FEP we used stepwise multivariate analysis with FEP as the dependent variable.

Results: FGF23 correlated directly with P in SF but not C. PTH correlated with FEP in SF and C. In the stepwise multivariate analysis with FEP in the fasting state as the dependent variable, PTH and subject group (Code, SF vs. C) entered the model with significant F values (PTH F=26, Code F=6, $p<0.01$ for both), $R^2 = 0.3$. In model of FEP in the fed state, PTH and Code (F=33 and 26, respectively; $R^2 = 0.11$) entered the model. FGF did not enter either model, nor did the cross product of Code with either PTH or FGF23.



Conclusions: Although FGF23 was strongly related to P in SF the relationship was a direct one, whereas it must be inverse if FGF23 is lowering P via increase of FEP. On the other hand PTH was strongly correlated with FEP as one expects if it is the cause of reduced P. FGF23 did not enter as an independent term in the multivariable model indicating a lack of effect. Analysis of TmP/GFR gave similar results (not shown). We conclude that the increased FEP of SF is not due to FGF23.

WNK Signaling Can Control Renal Oxalate Transport and Calcium Oxalate Crystal Formation in Drosophila

Taku Hirata,[1,2] Anna Czapar,[1,2] Consuelo Plata,[3] David B. Mount,[6] Gerardo Gamba,[3] Pablo Cabrero,[4] Erik L. Ritman,[1] Julian A.T. Dow,[4,5] Michael F. Romero.[1,2] *[1]Physiol & BME, Mayo Clinic, Rochester, MN; [2]Mayo O'Brien Urol Res Ctr, Mayo Clinic, Rochester, MN; [3]Molec Physiol Unit, Nephrol, INNSZ & IIB, UNAM, Mexico City, Mexico; [4]Molec, Cell and Sys Biol, U Glasgow, Glasgow, United Kingdom; [5]Clin Lab Sciences, Coll Appl Med Sci, King Saud U, Riyadh, Saudi Arabia; [6]Renal Div, Brigham & Women's Hospital, Boston, MA.*

Background: Kidney stones (nephrolithiasis) are a painful and expensive health care issue with complex etiology. More than 70% of stones are calcium oxalate (CaOx). Some Slc26 genes encode proteins that transport oxalate in the gut and kidney. Slc26a6 knockout mice have hyperoxaluria and CaOx stones. Yet, the details of ox^{2-} transport in the gut and kidney, e.g., regulation or signaling factors, are poorly understood or not investigated. To overcome this issue, our group established *Drosophila* kidney stone model using dSlc26a5/6 (dPrestin), *Drosophila* orthologue of Slc26a6, for a simple, fast and straight forward analysis. Additionally, we and others found that WNK signaling controls Slc26 transporter activities.

Methods: (*in vitro*) Using *Xenopus* oocytes, the effect of WNK signaling kinases (WNK or SPAK/OSR1) on mSlc26a6 and dPrestin transport activities were examined. (*in vivo*) To evaluate *in vivo* effect on stone formation in fly, we dissected Malpighian tubules (MT) from SPAK/OSR1 mutant (*frayed*) and wild-type and observed stone formation by soaking them in a Na-oxalate solution.

Results: mSlc26a6 and dPrestin transport activities are increased in the presence of active mWNK3 and dSPAK/OSR1, respectively and suppressed by dominant-negative clones of these kinases. OSR1 fly mutants showed decreased CaOx crystal formation in MT when compared to wild-type flies.

Conclusions: Our observations indicate that WNK/OSR1 signaling controls CaOx crystal formation by regulating oxalate secretion via dPrestin at MT, thus, we hypothesize that a similar regulation system exists in humans. This is the first report to examine *in vivo* function and intercellular signaling relating oxalate absorption and secretion by renal tubules.

Increased Intestinal Barrier Permeability Contributes to Hyperoxaluria in Obese Mice

Hatim A. Hassan,[1] Ruhul Amin,[1] Sireesha Ratakonda,[1] Sapna Sharma,[1] Ignacio Granja,[2] John R. Asplin.[2] *[1]Medicine, University of Chicago, Chicago, IL; [2]Litholink Corporation, Chicago, IL.*

Background: The majority of kidney stones are composed of calcium oxalate, and minor changes in urine oxalate affect stone risk. Obesity is a risk factor for kidney stones and obese patients often have mild hyperoxaluria. A positive correlation between increased body size and elevated urine oxalate excretion was reported. However, the mechanism(s) underlying this positive correlation remain(s) unknown. To explore the pathogenesis of obesity-associated hyperoxaluria, urine oxalate levels were measured in Ob (an animal model of obesity) mice and their lean controls (C). Ob mice were found to have significantly higher urine oxalate (adjusted for Cr) compared with C (μM: C=19.43±1.43; Ob=48.27±5.09). Significant hyperoxaluria was also seen in Db (another obesity model) mice compared with C (> 2-fold). Since the Ob mice are hyperphagic, the mice were pair-fed (4 g/mouse/day, based on our finding a control and an Ob mouse consume 4.03±0.22 and 7.58±0.59 g/day, respectively) and significant hyperoxaluria was still observed in Ob mice (μM: C=13.84±1.08; Ob=30.94±5.43), indicating that it is not due to overeating. Ob mice have increased intestinal paracellular permeability and intestinal oxalate absorption was shown to be passive through the paracellualr pathway. We thus used the mouse ex vivo intestinal loop model to assess intestinal paracellular permeability, and observed significantly higher jejunal (> 46%) and ileal (> 30%) ^{14}C-oxalate and ^{3}H-mannitol (a paracellular marker) fluxes (from lumen to outside medium bathing the loops) in Ob mice compared with C. Obesity is characterized by increased systemic inflammation (e.g. IFN-γ {I}, TNF-α {T}) and oxidative stress (e.g. H_2O_2). H_2O_2 and cytokines (I+T), which are known to disrupt intestinal barrier function, caused > 5 - and 2-fold increase in apical to basolateral ^{14}C-oxalate and ^{3}H-mannitol fluxes in human intestinal Caco2 cells compared with controls, respectively. We conclude that increased intestinal barrier permeability contributes to hyperoxaluria in obese mice by increasing passive oxalate absorptive flux.

Should Pediatric Idiopathic Hypercalciuria Be Treated with Hypocalciuric Agents?

Maria Goretti Penido,[1] Marcelo S. Tavares,[1] Lucas Lage Marinho,[1] Igor Leao Araujo,[1] Uri S. Alon.[2] *[1]Pediatric Nephrology Unit, School of Medicine, Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil; [2]Bone and Mineral Disorders Clinic, Pediatric Nephrology, Children's Mercy Hospital, University of Missouri, Kansas City, MO.*

Background: The issues related to the need for hypocalciuric therapy, its nature and duration, in children with Idiopathic Hypercalciuria (IH) remains to be determined. This treatment may be required not only to protect against stone formation but also against low bone density, documented in many of these patients. The aim of this study was to examine whether thiazides have a beneficial effect on bone mass in children with IH.

Methods: We have followed 40 children with IH (62.5% male) aged 10.5±3.5 yr, for median time of 6.0 yr (4.5–8.3). Initial approach consisted of dietary modifications for 4 months. In case of no normalization of calcium excretion with dietary measures, potassium citrate was added (0.5–1.0 mEq/kg/day), to the dietary measures for 2 months. Treatment with thiazide was initiated (0.5–1.0 mg/kg/day) in association with K-citrate if there was no improvement of calciuria levels after 2 months on alkali treatment. Patients took K-citrate alone or combined with thiazides for at least 1 year. Initial bone densitometry (BMD) was performed before patients started treatment with K-citrate, and the final BMD was conducted at the end of follow-up. Nine patients took K-citrate alone (Group G1) and 31 received K-citrate and thiazides (Group G2).

Results: There were no differences in age, BMI Z-scores, biochemical and mineral parameters between G1 and G2 before and after treatment. BMD Z-score of the lumbar spine (L1–L4) increased significantly with treatment in G2 from -1.7 to -1.4 (p=0.04; U-Test Mann-Whitney) but there was no improvement in G1 (from -1.3 to -1.6; p=0.16).

Conclusions: Our results point to a beneficial effect of thiazides on BMD in children with IH. We speculate that thiazide may have a role in acheivement of positive calcium balance and consequently optimal peak bone mass, and suggest further prospective randomized studies on the effect of thiazide therapy in children with IH.

FR-OR065

Molecular Genetic Characterization of Primary Hyperoxaluria Pedigrees: Update of the International Primary Hyperoxaluria Registry

Sandro Rossetti, Andrea G. Cogal, Carla G. Monico, Barbara M. Seide, Julie B. Olson, Alicia Meek, Dawn S. Milliner. *Mayo Clinic, Rochester, MN.*

Background: Primary Hyperoxaluria (PH) is an autosomal recessive condition characterized by the development of kidney stones and end stage renal failure. PH is caused by mutations at the *AGXT* (PH1), *GRHPR* (PH2) and *HOGA1* (PH3) genes.

Methods: The International PH Registry collected a cohort of 280 unrelated pedigrees with a clinical diagnosis compatible with primary hyperoxaluria where DNA from at least one proband was available for genetic analysis. We sequenced the 3 PH disease genes in this PH cohort by bidirectional sequencing of all the coding exons using M13-tailed primers. Mutations were segregated in all available family members.

Results: Of the 280 pedigrees, 219 (78%) provided sufficient mutation data for disease classification as PH1 (167, 76%), PH2 (22, 10%) or PH3 (30, 14%) disease, while 61 (22%) remained mutation negative. Of these 219 pedigrees, 208 (95%) were fully resolved with 2 recessively inherited mutations (160 *AGXT* pedigrees-77%, 20 *GRHPR*-10% and 28 *HOGA1*-13%); in 11 pedigrees (5%) only one mutation was identified (7 *AGXT* pedigrees, 2 *GRHPR* pedigrees and 2 *HOGA1* pedigrees). In total, we identified 327 *AGXT* disease alleles (110 missense-33%, 87 truncating-27%, 3 in frame indels-1%, and 127 mis-targeting-39%); 44 *GRHPR* disease alleles (17 missense-39%, 27 truncating-61%); and 60 *HOGA1* disease allele (16 missense-27%, 1 truncating-1%, 43 in-frame indels-72%). While the largest group of *AGXT* disease alleles is missense, truncating and in-frame indels are the largest group for *GRHPR* and *HOGA1*.

Conclusions: We characterized the genetics of a large PH population, ideal for genotype-phenotype correlations and disease natural history analysis. PH3 represents a considerable proportion of cases in this cohort, second only to PH1. Atypical mutations may be present in the 11 partially resolved PH pedigrees, suitable to further analysis by deep sequencing the entire genomic structure of the PH genes. The presence of a sizable group of mutation-negative PH pedigrees, suitable to whole exome analysis, suggests the involvement of additional, yet to be identified disease genes.

Endogenous Klotho Regulates Proliferative Effects of FGF23 in Human Endothelial Cells, In Vitro

Chih-ping Chung,[1,2] Tzong-Shi Lu,[1] Kenneth Lim,[1,3] Christina Lee,[1] Daniel Zehnder,[3] Li-Li Hsiao.[1] *[1]Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Department of Neurology, Taipei Veterans General Hospital, Taipei, Taiwan; [3]Clinical Sciences Research Institute, Warwick Medical School, United Kingdom.*

Background: Rising FGF-23 levels have been associated with cardiovascular disease and mortality in CKD. We previously showed that this may in part, be due to progressive resistance to FGF-23 caused by Klotho deficiency in cells of the arterial wall. Here, we hypothesize site-specific differential expression of Klotho in human endothelial cells and that FGF-23 effects are dependent on this expression pattern.

Methods: *In vitro* models: Human aorta endothelial cells (HAECs) +/- Klotho siRNA; brain microvascular endothelial cells (HBMECs) +/- 0.2 nM recombinant human Klotho. Assessment of cell proliferation: XTT assay.

Results: We show for the first time Klotho is expressed in HAECs at both the mRNA and protein level. In addition, FGFR1 is also expressed in HAECs. Previous studies showed that Klotho-FGFR1 is the principal receptor-site for FGF-23 signaling, here we show that FGF-23 stimulated significant proliferation of HAECs at 50ng/ml and 100ng/ml in our dose dependent studies, however these effects were mitigated by Klotho knockdown. In contrast, we found that HBMECs expresses FGFR1 but not Klotho. And FGF-23 did not stimulate HBMEC proliferation in dose dependent studies (0 – 100 ng/ml). We next investigated whether circulating Klotho could render HBMECs responsive to FGF-23. Our results showed that treatment with FGF-23 in the presence of recombinant soluble human Klotho did not stimulate HBMEC proliferation.

Conclusions: Our study shows for the first time, site-specific Klotho expression within the human vascular endothelium where its expression confers FGF-23 responsive properties. Specifically, expression of Klotho in HAEC confers this cell-type responsive to FGF-23 proliferative effects whilst its absence in HBMECs renders these cells resistant to this FGF-23-related effect.

FR-OR067

Increased Plasma Fibroblast Growth Factor 23 Is Associated with an Impaired Response to Intensified Antiproteinuric Therapy

Jelmer Kor Humalda,[1] Arjan J. Kwakernaak,[1] Marc G. Vervloet,[2] Pieter M. Ter Wee,[2] Gerjan Navis,[1] Martin H. De Borst.[1] *[1]Nephrology, University Medical Center Groningen; [2]Nephrology, Free University Medical Center Amsterdam, the Netherlands, for NiGrAm.*

Background: Fibroblast growth factor 23 (FGF23) is an independent risk factor for chronic kidney disease (CKD) progression and cardiovascular disease. High serum phosphate has been associated with impaired efficacy of RAAS-blockade, but the role of FGF23 is unknown. We hypothesized that high FGF23 levels impair the response to intensification of antiproteinuric therapy.

Methods: Post-hoc analysis of a 2x2 crossover RCT aimed at maximizing the effect of RAAS-blockade. Non-diabetic CKD patients (n=51) on background ACEi (lisinopril 40 mg/day) underwent four 6-week periods with add-on valsartan 320 mg/day (ACEi+ARB) or placebo, with either regular (RS, 186[150-216] mmol/d) or low (LS, 97[68-130] mmol/d) sodium diet. Plasma C-terminal FGF23 levels were measured by ELISA.

Results: At baseline (ACEi+RS) median UP was 1.9[IQR 0.9-3.4] g/d, creatinine clearance (CrCl) 69[50-108] ml/min and FGF23 146[119-244] U/mL. During maximal therapy (ACEi+ARB+LS) UP decreased to 0.7[0.4-1.4] g/d ($p<0.001$) and CrCl to 59[42-77] mL/min ($p<0.001$). At baseline, UP was similar in tertiles of FGF23. Patients in the lowest baseline FGF23 tertile responded stronger to therapy intensification (72%[46%-90%] UP reduction (UPR) by ACEi+ARB+LS vs baseline) compared to those in the highest tertile (40%[25%-65%] UPR, $p<0.05$). In multivariate analysis, baseline FGF23 predicted UPR (st. β -0.65, $p<0.05$) independent of CrCl (St. β 0.16, NS), BMI (St. β 0.46, $p<0.05$), UP (St. β 0.29, NS), serum phosphate (St. β 0.19, NS), phosphate excretion (St. β -0.10, NS), age and gender. FGF23 was also the only determinant (St. β 0.79, $p<0.05$) for UPR during ACEi+LS (47%[30%-66%]) but not during ACEi+ARB+RS (20%[-12%-41%]). Neither FGF23 nor other variables predicted SBP reduction.

Conclusions: Higher baseline FGF23 levels are independently associated with an impaired response to intensification of antiproteinuric therapy by add-on salt restriction with or without ARB. Future studies should confirm whether reduction of FGF23 could enhance RAAS-blockade efficacy.

FR-OR068

Effects of Dietary Phosphate Restriction and Lanthanum Carbonate on Fibroblast Growth Factor 23 in Chronic Kidney Disease

Tamara Isakova,[1] Allison Barchi-Chung,[1] Gwen Enfield,[1] Kelsey T. Smith,[1] Gabriela S. Vargas,[1] Jessica Houston,[1] Huiliang Xie,[1] Patricia R. Wahl Pristau,[1] Eva Schiavenato,[1] Austin Dosch,[1] Jorge Diego,[1] Oliver Lenz,[1] Gabriel Contreras,[1] Armando Mendez,[1] Rory Weiner,[2] Myles S. Wolf.[1] *[1]University of Miami Miller School of Medicine, Miami, FL; [2]Massachusetts General Hospital, Boston, MA.*

Background: FGF23 excess is the earliest and most common mineral metabolism abnormality in CKD patients, in whom it is associated with left ventricular hypertrophy and with increased risks of death and end stage renal disease. Though prior studies suggested that interventions targeting dietary phosphate intake or absorption may decrease FGF23, it remains unknown if combining phosphate binders with dietary counseling based phosphate restriction will have synergistic effects.

Methods: In this single-blinded, placebo-controlled 3-month study, we randomly assigned 39 patients with CKD stage 3–4 and normal serum phosphate levels to four groups: double placebo (ad lib diet plus lanthanum carbonate placebo, 10 patients), diet alone (900-mg phosphate diet plus lanthanum carbonate placebo, 10), lanthanum carbonate alone (ad lib diet plus lanthanum carbonate, 11), and diet-lanthanum carbonate (900-mg phosphate diet plus lanthanum carbonate, 8). The dose of lanthanum carbonate was 1000 mg three times daily with meals. Dietary restriction was accomplished with dietary counseling.

Results: At baseline, mean eGFR was 38±11 ml/min/1.73 m^2, mean serum phosphate was 3.6±0.7 mg/dl, and median FGF23 was 128 (interquartile range 89 – 155) RU/ml. Diet and lanthanum carbonate alone each significantly lowered FGF23: 22% and 19% decline, respectively ($P=0.01$ for both). However, the diet-lanthanum carbonate group resulted in a 35% decrease in FGF23 (P for interaction 0.009), suggesting synergy between diet and lanthanum carbonate.

Conclusions: Over the course of three months, lanthanum carbonate and dietary phosphate restriction synergistically decrease FGF23 levels in normophosphatemic CKD patients.

Vitamin D-Induced Antibacterial Activity in Cells from Peritoneal Dialysate Effluent Justine Bacchetta, Rene Chun, Barbara Gales, Joshua Zaritsky, Sandrine Leroy, Katherine Wesseling-Perry, Isidro B. Salusky, Martin Hewison. *UCLA, Los Angeles, CA.*

Background: Vitamin D has potent immunomodulatory properties, notably the induction of antibacterial innate immunity. The aim of this study was to assess potential antibacterial benefits of vitamin D in patients undergoing peritoneal dialysis (PD), hypothesizing that peritoneal monocytes may be targets for vitamin D.

Methods: PD cells were isolated from 24 hr PD effluent in 27 non-infected patients and studied by FACS (common leukocyte marker CD45 and monocyte marker CD14), and RT-PCR to assess expression of vitamin D-related genes (VDR, CYP27B1, CYP24A1, LL37 encoding antibacterial cathelicidin) at baseline and after in vitro exposure to vitamin D. We also performed a clinical prospective trial in 12 PD patients (median age 20.8 yrs) to study the impact of an oral supplementation with vitasmin D2 (100,000 IU/wk for 4 wks).

Results: In the 27 samples obtained at baseline, PD cells were mainly monocytic (38±18% CD14/CD45 double positive), while 25±15% were only CD45 positive and 32±20% were double negative. There was a strong association between expression of CYP27B1 and LL37 ($r= 0.637$, $p<0.001$). In vitro treatment with 25D (100 nM, 6hrs) or 1,25D (5 nM) induced expression of LL37 in PD cells, demonstrating the ability of these cells to utilize different forms of vitamin D for antibacterial responses. After one month of vitamin D2 supplementation, patient serum concentrations of 25D rose from 19±8 ng/ml to 40±15 ($p=0.002$) but this had no effect on: 1) associated circulating markers such as PTH; 2) expression of CD14/CD45 by PD cells; 3) concentrations of LL37 in dialysis effluent. However, after adjustment for the proportion of CD14 negative/CD45 positive cells, PD cells showed significantly higher levels of LL37 expression following vitamin D supplementation (1.85-fold, $p=0.01$).

Conclusions: These data show for the first time that PD cells have a functional intracrine system for vitamin D-induced innate immunity. This response is enhanced following vitamin D supplementation in vivo, highlighting an important new function for vitamin D in preventing infectious related complications in PD patients.

FR-OR070

Furosemide-Induced Increase of Plasma Parathyroid Hormone Is Mediated by the Calcium-Sensing Receptor in Humans Valentina Forni, Marie-Eve Muller, Carole Zweiacker, Marc P. Maillard, Michel Burnier, Olivier Bonny. *Néphrologie/Hypertension, Centre Hospitalier Universitaire Vaudois, Lausanne, Vaud, Switzerland.*

Background: Chronic oral furosemide administration has been reported to increase intact plasma parathormone (iPTH) levels in humans, alike acute furosemide injections in the rat, but the mechanisms of this interaction are still unknown. Experiments on rats suggested that acute administration of a calcimimetic could blunt this effect. We designed a prospective randomized placebo-controlled crossover study addressing the role of the calcium sensing receptor in the iPTH response to furosemide.

Methods: 12 Caucasian, non-smoker healthy males were enrolled. After 3 days of a fixed salt diet, they received either a single dose of 60 mg cinacalcet or placebo with at least one week interval. Three hours after cinacalcet, 20 mg furosemide were given iv. Plasma levels of iPTH and plasma and urinary levels of calcium, sodium and potassium were measured at baseline (before cinacalcet), before the furosemide injection and at regular time intervals (every 15 minutes for the first hour, then each hour for the next ten hours) after the administration of furosemide.

Results: Plasma iPTH levels were suppressed (38.0±12.0 ng/l vs 2.4±1.7 ng/l, $p<0.05$), and calciuria was increased 3 h after administration of cinacalcet and before furosemide injection. Under placebo, a sharp increase in plasma iPTH levels was observed as soon as15 min after furosemide injection (from 20.9±6.6ng/l before to 33.2±10.7 ng/l), while subjects under cinacalcet showed only blunted iPTH response (from 2.4± 1.7 ng/l to 3.2±2.9 ng/ml). Furosemide induced a significant decrease in plasma ionized calcium in cinacalcet-treated subjects, an effect which was absent in subjects under placebo. The changes in plasma sodium and potassium after furosemide were comparable in both cinacalcet and placebo groups.

Conclusions: These data show in humans that furosemide acutely stimulates iPTH an effect which is blunted by the administration of a calcimimetic despite a decrease in plasma ionized calcium. Changes in sodium and potassium levels do probably not play any role in the iPTH response to furosemide.

FR-OR071

microRNAs Are Essential to the Response of the Parathyroids to Hypocalcemia but Not to a Calcimimetic or Experimental Uremia in Mice Vitali Shilo, Chofit Chai, Justin Silver, Tally Naveh-Many. *Nephrology, Hadassah Hebrew University Medical Center, Jerusalem, Israel.*

Background: microRNAs (miRNAs) are short non-coding RNA molecules that affect protein levels by sequence-specific repression of translation and mRNA degradation.The final step in miRNA maturation is mediated by Dicer, a RNase III-like enzyme expressed in all cell types that is essential for life.

Methods: To study the role of miRNAs in the parathyroid we have generated parathyroid specific *dicer* knock-out (PT-*Dicer*$^{-/-}$) mice.

Results: Remarkably, the PT-*Dicer*$^{-/-}$ mice failed to increase serum PTH after a short-term decrease in serum Ca^{2+} by EGTA as compared to the 3-fold increase in serum PTH in the control mice. Furthermore, the PT-*Dicer*$^{-/-}$ mice failed to develop secondary hyperparathyroidism (SHPT) due to a prolonged calcium depleted diet as compared to the 10-fold increase in serum PTH levels in the control mice. Chronic hypocalcemia not only failed to increase serum in the PT-*Dicer*$^{-/-}$ mice but also PTH mRNA levels. These results show that parathyroid miRNAs are necessary for the response of the parathyroid to both acute and chronic hypocalcemia. In contrast, activation of the calcium receptor (CaR) by a calcimimetic decreased serum PTH in both PT-*Dicer*$^{-/-}$ and control mice, suggesting that activation of the CaR acts through a different pathway from hypocalcemia that does not involve miRNAs. Our results imply that the increased PTH secretion of hypocalcemia is not just due to relaxation of the parathyroid CaR but is an active process dependent upon miRNAs. Experimental uremia was induced in control and PT-*Dicer*$^{-/-}$ mice by aristolochic acid and a high phosphorus diet. Surprisingly, both PT-*Dicer*$^{-/-}$ and control mice developed SHPT indicating a different mechanism for the SHPT of CKD from that of chronic hypocalcemia.

Conclusions: Therefore, the PT-*Dicer*$^{-/-}$ mice demonstrate that miRNAs in the parathyroid are essential for the response of the parathyroids to acute and chronic hypocalemia but not for the SHPT of CKD and activation of the CaR by a calcimimetic.

FR-OR072

The HNF1β Transcription Factor Regulates Human PTH Gene Transcription Silvia Ferrè,[2] Ernie M.H.F. Bongers,[3] Elisabeth Cornelissen,[4] Kazushige Sakaguchi,[5] Yasumasa Iwasaki,[6] Gerben A. Boekel Van,[1] Jack F. Wetzels,[1] Joost G. Hoenderop,[2] René J. Bindels,[2] Tom Nijenhuis.[1] *[1]Nephrology, Radboud University Nijmegen Medical Centre (RUNMC), Netherlands; [2]Physiology, RUNMC, Netherlands; [3]Genetics, RUNMC, Netherlands; [4]Pediatrics, RUNMC, Netherlands; [5]Molecular Cell Biology, Wakayama University, Japan; [6]Endocrinology, Kochi Medical School, Japan.*

Background: Parathyroid hormone (PTH) plays a key role in Ca^{2+} and PO_4^{3-} homeostasis. Heterozygous mutations or deletions of the transcription factor HNF1β result in a heterogeneous syndrome characterized by renal cysts and diabetes (RCAD), together with a variety of other extra-renal and renal manifestations. Since we observed hyperparathyroidism in several of these patients, we tested the hypothesis of a direct role of HNF1β in the transcriptional regulation of the human PTH gene in the parathyroid gland.

Methods: We assessed 11 patients, 9 with heterozygous HNF1β whole gene deletions and 2 with frameshift mutations (c.18delG and c.883C>T). HNF1β expression in human parathyroid tissue and in a rat parathyroid cell line (PT-r) was evaluated. The HNF1β-responsiveness of the human PTH promoter and localization of putative HNF1β-responsive elements were investigated by luciferase-reporter assays and serially deleted promoter analyses.

Results: Eight out of 11 patients showed hyperparathyroidism. In one of these, the hyperparathyroidism was clearly appropriate for the level of renal function, in the others it could be discrepant. We demonstrated HNF1β expression in nuclei of Ca^{2+}-sensing receptor-positive chief cells in human parathyroid gland, and in the PT-r cell line. Co-transfection of a PTH promoter-luciferase construct with a wild-type HNF1β construct resulted in a maximal reduction of 30% of PTH promoter activity, while HNF1β mutants lacked this inhibitory property. Serial deletions in the PTH promoter construct revealed that the inhibitory effect of HNF1β resides -200/-70 bp from the transcription initiation site.

Conclusions: Our data demonstrate that HNF1β is a novel repressor of human PTH gene transcription, which could explain the apparent early development of hyperparathyroidism in patients with HNF1β mutations or deletions.

FR-OR074

FGF23 Regulates Renal Sodium Handling and Blood Pressure Olena Andrukhova,[1] Svetlana Slavic,[1] Ute Zeitz,[1] Victoria Shalhoub,[2] Beate Lanske,[3] Reinhold Erben.[1] *[1]University of Veterinary Medicine, Vienna, Austria; [2]Amgen Inc, Thousand Oaks, CA; [3]Harvard School of Dental Medicine, Boston, MA.*

Background: Fibroblast growth factor-23 (FGF23) is a bone-derived endocrine signal regulating renal phosphate reabsorption and vitamin D synthesis. In patients with chronic kidney disease (CKD), FGF23 serum levels are associated with cardiovascular risk and mortality for unknown reasons. In earlier studies, we found that FGF23 signaling in distal renal tubules involves serum/glucocorticoid-regulated kinase 1 (SGK1) and with-no lysine kinase-4 (WNK4) which are both involved in renal sodium (Na) handling.

Methods: Here, we examined the role of FGF23 in the regulation of renal Na reabsorption in gain- and loss-of-function models.

Results: Nine-month-old compound mutant mice deficient in both *Fgf23* and vitamin D receptor (VDR) function revealed increased urinary loss of Na, relative to wild-type (WT) and VDR mutant mice. Serum aldosterone was elevated in compound mutants. Compound mutants showed reduced membrane expression of the Na-chloride cotransporter NCC, but upregulated expression of the epithelial Na channel ENaC, as measured by immunoblotting of renal membrane preparations. Treatment of WT mice with recombinant FGF23 (rFGF23) profoundly upregulated NCC membrane expression, and decreased ENaC membrane abundance as well as serum aldosterone, 8 hours post-injection. After 5 days of treatment, urinary Na excretion and urine volume was decreased, whereas systolic and diastolic blood pressure, and heart-to-body weight ratio was increased in rFGF23-treated animals. *In vitro* experiments with isolated distal tubular segments showed that rFGF23 increased NCC and decreased ENaC protein expression in an ERK1/2-SGK1 dependent fashion.

Conclusions: Taken together, our data have uncovered a previously unknown function of FGF23 in distal renal tubular Na reabsorption. Gain of FGF23 function results in renal Na retention and volume overload due to increased NCC membrane abundance, leading to hypertension and heart hypertrophy. Our data may explain why serum FGF23 is associated with cardiovascular risk and mortality in patients with CKD.

FR-OR075

FGF23 Is More Strongly Associated with Death and Recurrent Cardiovascular Events in Patients with Low Urine Phosphorus Excretion: The Heart and Soul Study Julie R. Dominguez,[1] Michael Shlipak,[2] Kenneth J. Mukamal,[3] Mary Whooley,[4] Joachim H. Ix.[1] *[1]UCSD, San Diego, CA; [2]UCSF, San Francisco, CA; [3]Beth Israel Deaconess Medical Center, Boston, MA; [4]UCSF, San Francisco, CA.*

Background: Higher fibroblast growth factor-23 (FGF23) levels are associated with cardiovascular disease (CVD) events. We explored whether this association differed in persons with more or less phosphaturia in response to FGF23.

Methods: In 896 outpatients with stable CVD, we measured serum FGF23 and 24-hour urine fractional excretion of phosphorus (FePi). Cox regression evaluated associations between FGF23, FePi, and their interaction with CVD events (MI, stroke, CVD death) and death.

Results: Mean age was 67±11 years and 82% were men. Mean baseline eGFR was 71±22 mL/min/1.73m^2. There were 183 CVD events and 295 deaths during 6.7 years (mean) follow-up. The association of FGF23 with each outcome was modified by urinary FePi (P-interactions with either outcome <0.008). In models adjusted for CVD risk factors, kidney function, and PTH, those with high FGF23 but low FePi had the highest risk of recurrent CVD events and death.

Association of FGF23 and Urine FePi Above or Below the Median with CVD Events and All-Cause Mortality

	# Events	# at Risk	HR (95% CI)
CVD Events (MI, stroke, CVD death)			
Low FGF23/Low FePi	33	249	1.00 (ref)
Low FGF23/High FePi	36	199	1.16 (0.72-1.88)
High FGF23/High FePi	61	249	1.26 (0.79-2.02)
High FGF23/Low FePi	53	199	2.09 (1.33-3.29)
All-Cause Mortality			
Low FGF23/Low FePi	56	249	1.00 (ref)
Low FGF23/High FePi	55	199	1.07 (0.73-1.57)
High FGF23/High FePi	106	249	1.54 (1.07-2.20)
High FGF23/Low FePi	78	199	2.19 (1.52-3.15)

Adjusted for age, sex, HRT use (women), diabetes, SBP, BMI, smoking, total cholesterol, HDL cholesterol, CRP, eGFR, urine ACR, PTH

Conclusions: The association of high FGF23 with CVD events and death is stronger in persons who also have low urine phosphorus excretion, independent of PTH. In such individuals, the renal tubular response to FGF23 may not be optimal. Future studies should determine whether integrated evaluation of FGF23 and urine FePi could serve as an indicator of renal tubular dysfunction.

FR-OR076

Intβ1 Is Required for Cystogenesis in Autosomal Dominant Polycystic Kidney Disease Kim Lee,[1] Sylvia Boctor,[1] Laura M.C. Barisoni,[2] G. Luca Gusella.[1] *[1]Medicine/Div of Nephrology, Mount Sinai School of Medicine, New York, NY; [2]Pathology, University of Miami, Miami, FL.*

Background: Dysregulation of *PKD1* leads to ADPKD, a disorder characterized by the formation and expansion of multiple bilateral cysts that ultimately result in ESRD. Increased accumulation of extracellular matrix (ECM) and the development of tubulointerstitial fibrosis parallel the progression of ADPKD. Correspondingly, cystic epithelia express higher levels of integrins, a class of heterodimeric ECM receptors. Signal transduction *via* integrins mediates various cellular responses including proliferation, migration and survival. Since these cellular processes are also altered in cystic cells, we asked whether integrins are involved in the cystic development in ADPKD.

Methods: In the kidney, integrin β1 is the major β subunit that participates in most of the integrin heterodimers. We therefore targeted *Itgb1* to ascertain the role of integrins in the context of ADPKD. A double conditional knockout mouse model was generated in which both *Pkd1* and *Itgb1* are specifically ablated in collecting ducts expressing Aqp2-Cre transgene.

Results: The single *Pkd1* knockout (KO) animals present kidneys with multiple microcysts that become overtly polycystic by week 3, leading to renal failure and death between several weeks to one year. In contrast, cystic development in the double knockout (DKO) animals is dramatically reduced with significantly fewer and smaller renal cysts present at any tested time. Cell proliferation, as measured by BrdU incorporation, is readily detectable in the *Pkd1* KO kidneys, but rarely observed in the kidneys of DKO and control wild type animals. Concomitantly, the accumulation of ECM and interstitial fibrosis apparent in the *Pkd1* KO kidneys are undetectable in the DKO kidneys. Importantly, in accordance with the phenotypic data, the renal function of the DKO animals is maintained at normal levels, allowing them to reach a longer life span as control animals.

Conclusions: Overall, these data indicate that integrin β1 is a required component of renal cystogenic process in ADPKD and that targeting the integrin signaling pathway may be an effective approach against the progression of the disease.

Role of NEDD9 as a Regulator of Cystogenesis in Pkd1-Conditional Knockout Model Anna Nikonova,[1] Olga Plotnikova,[1] Gregory G. Germino,[2] Erica A. Golemis.[1] *[1]Fox Chase Cancer Center, Philadelphia, PA; [2]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive cyst formation and ultimate loss of renal function, caused by mutational inactivation of polycystins 1 and 2 (PC1 and PC2, encoded by *PKD1* and *PKD2*). PC1 and PC2 function at cilia; a growing number of mutations in genes regulating ciliary function are now known to impact cystogenesis. We have recently shown that the oncogenes NEDD9/HEF1 and Aurora-A (AURKA) have unexpected actions relevant to PKD. NEDD9 activation of AURKA at the ciliary basal body controls ciliary disassembly. NEDD9 and AURKA also bind and regulate the activity of the PC2 calcium channel, influencing cytoplasmic Ca^{2+}. NEDD9 and AURKA are abundant and periodically active in normal kidneys, with AURKA expression and activity elevated in early PKD-associated renal cysts.

Methods: We have now used a tamoxifen-Cre, Pkd1-floxed mouse model (>*Piontek et al, J Am Soc Nephrol 2004, 15:3035-43*) crossed to *Nedd9*$^{-/-}$ mice to investigate the effect of eliminating NEDD9 expression on renal cyst formation.

Results: Analysis of the progression in cyst development using a combination of immunohistochemical analysis and magnetic resonance imaging (MRI) revealed that cystic burden and kidney volume increased more rapidly, and kidneys attained a greater ratio to body weight, in *Pkd1*$^{-/-}$*Nedd9*$^{-/-}$ mice in comparison with *Pkd1*$^{-/-}$ mice, although *Nedd9* ablation per se had no impact on cyst formation. Analysis of proliferation in primary kidney cells obtained from P10 mice revealed accelerated rate of growth associated with a *Nedd9*$^{-/-}$ genotype. Cilia in primary kidney and kidney cells from *Pkd1*$^{-/-}$*Nedd9*$^{-/-}$ mice were lengthened and deformed, and centrosomal defects were observed. Interestingly, endogenous Nedd9 protein levels are upregulated in kidney lysates from *Pkd1*$^{-/-}$ mice in comparison to wild type kidneys; analysis of related signaling is in progress.

Conclusions: These and other findings newly identify NEDD9 as a physiological regulator of cystogenesis, and suggest use of NEDD9 as a biomarker for prognosis.

BBSome Regulates Ciliary Trafficking of Polycystin-1 Xuefeng Su, Kaitlin Driscoll, Gang Yao, Jing Zhou. *Harvard Center for Polycystic Kidney Disease Research, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

Background: The Bardet-Biedl Syndrome (BBS) is a pleiotropic disorder characterized by six primary features including renal dysfunction and cysts. Although sixteen genes have been identified, the mechanism by which mutation in these genes causes BBS remains largely unknown, particularly for the renal phenotype. Polycystin-1 (PC1) is an atypical G-protein coupled receptor whose deficiency causes autosomal dominant polycystic kidney disease (ADPKD).

Methods: Yeast two-hybrid screening was performed to identify potential interacting partners of PC1. GST pull-down studies were used to identify interaction of PC1 with different BBSome subunits. N-terminal YFP-tagged full-length PC1 construct (YFP-PC1) and a set of related constructs were generated to examine whether PC1 trafficking to the primary cilia is controlled by the BBSome. YFP-PC1 trafficking in kidney epithelial cells was evaluated by immunostaining. To evaluate the role of individual BBSome components in the ciliary trafficking of PC1, stable BBS components depleted kidney epithelial cell lines were developed by expressing respective small hairpin RNAs in lentiviral vectors.

Results: Through a yeast two-hybrid screening, we identified BBS8, a component of the BBSome, as an interacting partner of polycystin-1. GST pull-down studies revealed that PC1 interacts with four out of seven components of the BBSome. Lack of one but not other BBSome components inhibits ciliary trafficking of PC1. Further experiments using a dominant-negative ADP ribosylation factor-like small GTPase suggests a role of holo-BBSome complex in this process. Deletion analyses of PC1 defined a critical motif in the C–terminal cytoplasmic tail for the ciliary but not the plasma membrane targeting of PC1. Notably, deletion of the most distal part of PC1 C-tail containing the VxPx motif, a previously reported ciliary targeting sequence, had no detectable effect.

Conclusions: Taken together, we provide the first evidence of a biochemical association between critical players of BBS and ADPKD. We propose that distinct components of BB. Some are required for the ciliary trafficking of PC1.

Polycystin-2 Ciliary Targeting Requires Polycystin-1 in a GPS-Cleavage Dependent Manner in Distal Nephrons of Developing Kidneys Hyunho Kim, Hangxue Xu, Qiong Huang, Valeriu Cebotaru, Feng Qian. *Nephrology, Johns Hopkins University SOM, Baltimore, MD.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by the formation of renal cysts that arise from dysfunction of the primary cilium. It is caused by mutation in *PKD1* or *PKD2*, which encode polycystin-1 (PC1) or polycystin-2 (PC2) respectively. PC1 is regulated in part by post-transcriptional modifications *via* cleavage at the GPS domain that results in heterodimer consisting of the N-terminal fragment (NTF) and C-terminal fragment (CTF). PC1 interacts physically with PC2, a calcium-permeable cation channel. They both have been found in renal cilia and are thought to function as a ciliary mechano-sensor that is important for maintaining proper renal tubular diameter. We have previously shown that GPS cleavage of PC1 is essential

for its full biological function and is frequently disrupted in ADPKD patients.Significantly, $Pkd1^{V/V}$ knockin mice with expression of a non-cleavable PC1 (PC1V) develop distal tubular cystic kidneys postnatally and die by ~1month of age.

Results: In this study, we found that PC2 is localized at the ER and cilia in Pkd1 WT MEF cells, whereas it is present only at the ER and is absent in the cilia of $Pkd1^{V/V}$ and Pkd1 KO MEF cells. Importantly, PC2 is not stained in the cilia of precystic and cystic distal tubules of $Pkd1^{V/V}$ and $Pkd1^{cko/cko}$ postnatal kidneys, while it is detectable in the cilia of the matching WT controls. This result indicates that PC2 ciliary targeting requires PC1 in a GPS cleavage dependent manner in the distal tubules of developing kidneys. Using an inducible expression system in MDCK cells, we showed that endogenous PC2 is targeted to cilia upon expression of WT PC1, while expression of PC1V or a mutant PC1 lacking the C-terminal PC2 interaction domain does not result in PC2 ciliary targeting. Biochemically, Endo H resistant form of NTF and PC2 were found in the cilia of MDCK cells expressing WT PC1, but were absent in the cilia of cells expressing the mutant PC1.

Conclusions: We conclude PC2 ciliary trafficking requires interaction with PC1. the PC1/2 complex traffics to cilia *via* trans-Golgi in a GPS cleavage dependent manner.

Polycystin-1 Regulates Polycystin-2 Dephosphorylation at a Critical Residue Important during Development and Disease Andrew J. Streets,[1] Oliver Wessely,[3] Dorien J.M. Peters,[2] Albert C. Ong.[1] *[1]Kidney Genetics Group, Academic Unit of Nephrology, Sheffield Kidney Institute, University of Sheffield, Sheffield, United Kingdom; [2]Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands; [3]Department of Cell Biology, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Mutations in *PKD1* (85%) or *PKD2* (15%) account for almost all cases of autosomal dominant polycystic kidney disease (ADPKD). The ADPKD proteins, termed polycystin-1 (PC1) and polycystin-2 (PC2), interact via their C-termini to form a receptor-ion channel complex which regulates kidney tubulogenesis. PC2 is a member of the TRP superfamily of channel proteins whose function is regulated by phosphorylation. The study aimed to determine whether PC2 phosphorylation is regulated by PC1, which if pathologically increased might represent a therapeutic target in PKD1 patients.

Methods: LC MS/MS Mass Spec, phosphoserine antibody mapping, calcium imaging and Xenopus rescue experiments.

Results: LC MS/MS Mass Spec identified a PC2-Ser^{829} phosphorylation site. A new phosphospecific antibody to this site demonstrated that Ser^{829} is phosphorylated by two different protein kinases, Protein kinase A (PKA) or Aurora A (AurA), and dephosphorylated by Protein phosphatase 1 (PP1). Ser^{829} phosphorylation by PKA or AurA showed distinct cell cycle and subcellular organisation, however it was constitutively phosphorylated in cells and tissues lacking PC1. We show that Ser^{829} dephosphorylation is regulated by PC1 binding and the the recruitment of PP1. Ser^{829} phosphorylation was essential for Xenopus pronephric development but when constitutively overexpressed, was associated with enhanced ATP-dependent ER Ca^{2+} release.

Conclusions: These results reveal a new functional dynamic link between PC1 and PC2 which is critically dependent on their interaction. Targeting PC2 phosphorylation could represent a promising new therapeutic approach in the treatment of PKD1 patients.

miR-17~92 miRNA Cluster Promotes Kidney Cyst Growth through Repression of Cystic Kidney Disease Genes Vishal Patel, Darren Williams, Sachin S. Hajarnis, Peter Igarashi. *Internal Medicine, UT Southwestern, Dallas, TX.*

Background: microRNAs (miRNAs) are short, non-coding RNAs that negatively regulate post-transcriptional gene expression. Dysregulation of miRNA expression has been observed in animal models of PKD, but the roles of miRNAs in the pathogenesis of PKD remain unclear.

Methods: miRNA microarrays and qRT-PCR analysis were performed on kidneys from Ksp/Cre;$Kif3a^{F/F}$ (*Kif3a*-KO) mice, an animal model of PKD. Transgenic mice that either overexpress miR-17~92 or lack miR-17~92 in renal tubules were produced by Cre/loxP recombination. TargetScan was used to identify candidate miR-17~92 targets, which were validated by mRNA microarrays, qRT-PCR, and luciferase reporter assays.

Results: Microarray analysis showed increased expression of the miR-17~92 miRNA cluster in cystic kidneys from *Kif3a*-KO mice. Upregulation of miR-17~92 was also observed in three other mouse models of PKD. Transgenic overexpression of miR-17~92 in the kidney promotes proliferation of tubular epithelial cells, reduces the abundance of mRNAs encoded by *Pkd1*, *Pkd2*, and *Hnf-1*β, and produces kidney cysts. Conversely, deletion of miR-17~92 in the renal tubules of *Kif3a*-KO mice decreases proliferation, retards kidney cyst growth, improves renal function, and prolongs survival. Members of the miR-17~92 cluster bind to the 3'UTRs of mRNA transcripts encoded by *Pkd1*, *Pkd2*, and *Hnf-1*β and inhibit the expression of a linked reporter gene. Genome-wide expression profiling combined with bioinformatics analysis identified 258 additional miR-17~92 targets that may have relevance to PKD pathogenesis.

Conclusions: The miR-17~92 miRNA cluster is overexpressed in PKD. Overexpression of miR-17~92 is sufficient to produce kidney cysts, whereas inhibition of miR-17~92 retards cyst growth. miR-17~92 mediates these effects through repression of cystic disease genes. These findings demonstrate that miR-17~92 plays a key role in the progression of PKD in vivo and provide a strong rationale for the development of inhibitors of miR-17~92 as therapeutic agents in PKD.

FR-OR082

Crosstalk between Bicaudal-C and miRNAs in the Formation of Polycystic Kidney Disease Oliver Wessely, Debora M. Cerqueira, Uyen Tran. *Lerner Research Institute/Cell Biology, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Polycystic Kidney Diseases are the leading cause of end-stage renal failure and require extensive treatments, such as dialysis and kidney transplantation. Among the many animal models to study the pathogenesis of these diseases mice carrying mutations in the RNA-binding molecule Bicaudal-C (Bicc1) have been very valuable to understand multiple aspects of the disease. Indeed, Bicc1 has turned out to be an evolutionary conserved key player in polycystic kidney disease as loss-of-function causes cyst formation in humans, mice and even the amphibian *Xenopus*. In the kidney, Bicc1 modulates the expression of Polycystin-2 (Pkd2). Bicc1 acts as a post-transcriptional and regulates the stability of *Pkd2* mRNA. Moreover, molecular analyses demonstrate that the *miR-17* microRNA family represses Pkd2 and that Bicc1 antagonizes this activity.

Results: Here we provide additional data on the *in vivo* importance of this antagonism. Assaying the expression levels of the *miR-17* miRNA family members by small RNA sequencing demonstrated that only the miRNAs encoded in the *miR-17-92* and the *miR-106b-25* cluster were expressed in the kidney. Moreover, their levels were not altered in Bicc1 mutant mice. This implied that the antagonism between Bicc1 and the *miR-17* family was at the target gene level. It also suggested that lowering miRNA levels rescues the effects of loosing Bicc1. This hypothesis was addressed using mouse compound mutants. We initially focused on reducing the *miR-17* miRNA dose by analyzing *Bicc1*/*miR-17-92* compound mutant mice. Interestingly, removing only one copy of *miR-17-92* was already sufficient to dramatically reduce cystogenesis. The overall kidney volumes were reduced to almost wild type levels at E18.5. Transcriptional profiling by mRNA sequencing validated this effect. The kidney expression levels of several of the mRNAs altered in Bicc1 mutant mice were restored to wild-type levels in the compound mutant mice.

Conclusions: Together these data suggest miRNAs are a crucial component of the epithelial cell program disturbed in Polycystic Kidney Disease and that this program is disrupted in Bicc1 mutant mice.

FR-OR083

MCP-1 Is the Primary Macrophage Recruitment Factor Produced by Human and Mouse Polycystic Kidney Cells and Promotes Disease Progression in *cpk* Mice Katherine Swenson-Fields, Carolyn J. Vivian, Darren P. Wallace, Timothy A. Fields. *The Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

Background: High concentrations of infiltrating macrophages (MΦs) are present within the kidneys of patients with autosomal dominant polycystic kidney disease (ADPKD) and mice with PKD. Studies using PKD mouse models have suggested that these MΦs, which in the context of kidney injury are known to promote tissue repair, act in the cystic kidney to promote cyst expansion and disease progression. Monocyte chemotactic protein 1 (MCP-1) has been found in high concentrations in the cyst fluids and urine of ADPKD patients, but it is not clear what role this factor plays in PKD pathophysiology. In this study, we assessed the contribution of MCP-1 to human ADPKD cyst cell- and mouse congenital polycystic kidney *(cpk)* cell-stimulated macrophage migration. We also used knockout mice to assess the contribution of MCP-1 to disease progression in the *cpk* mouse model.

Methods: Conditioned media (CM) from primary ADPKD cyst and *cpk* mouse kidney cells was collected and tested for monocyte chemoattractive activity (MCA) using a transwell migration assay of THP-1 cells in the presence or absence of neutralizing antibody against MCP-1. Heterozygous +/*cpk* mice were bred with MCP-1(*Ccl2*)$^{-/-}$ mice to generate +/*cpk*:*Ccl2*$^{-/-}$ mice. These were interbred to generate *cpk*/*cpk*:*Ccl2*$^{-/-}$ mice. Blood urea nitrogen (BUN) was measured on P10.

Results: Both primary ADPKD cyst cells and *cpk* kidney cells produced robust MCA. The majority of this MCA was blocked by the presence of maximally effective concentrations of neutralizing antibody to MCP-1 but not by equivalent concentrations of control Ig. To determine the contribution of MCP-1 to disease progression in *cpk* mice, homozygous *cpk* strains also deficient for MCP-1 were generated. MCP-1 knockout significantly improved both renal function (BUN of 51 ± 6 mg/dL vs 69 ± 4 mg/dL; p=0.038) and survival (21 ± 0.9 d vs 18 ± 0.3 d; p=0.04). for *cpk*/*cpk*:*Ccl2*$^{-/-}$ vs *cpk*/*cpk*:*Ccl2*$^{+/+}$ mice.

Conclusions: Therapeutic treatments that block MCP-1 production or neutralize its activity may be viable strategies to block disease progression in PKD.

A Single Amino Acid Deletion in the Polycystin-1 (PC1) C-Tail Affects G-Protein Signaling and Causes PKD in Mice Stephen C. Parnell,[1] Brenda S. Magenheimer,[1] Robin L. Maser,[1] Mallory A. Havens,[2] Lynn Magenheimer,[1] Michelle Hastings,[2] James P. Calvet.[1] *[1]Kidney Inst, Univ of Kansas Med Ctr, Kansas City, KS; [2]Dept of Cell Biol and Anatomy, Rosalind Franklin Univ, Chicago, IL.*

Background: An ADPKD-associated mutation causing deletion of a single leucine residue within the PKD1 gene has been reported (L4131Δ, Afzal et al Hum Genet 1999 105:648), but is not known to be pathogenic. L4131 is located within a highly conserved region in the C-tail of PC1 adjacent to the G-protein activation sequence (Parnell et al J Biol Chem 2002 277:19566). To determine if L4131Δ is pathogenic, a knock-in mouse was made.

Methods: The corresponding mouse mutation (L4122Δ) was introduced by targeted insertion of a construct containing a floxed NEO cassette in Pkd1 intron 45 (Pkd1NEO). Mice carrying Pkd1NEO were bred with the EIIA-Cre mouse to generate the Pkd1ΔL allele. Matings with Pkd1NEO/+, Pkd1m1Bei/+ and Pkd1ΔL/+ mice were examined for cystic offspring and were used for metanephric organ culture to assay cAMP-mediated cyst formation. Splicing of intron 45 was analyzed by RT-PCR.

Results: While Pkd1NEO/+ and Pkd1ΔL/+ mice were normal, no Pkd1NEO/NEO, Pkd1NEO/m1Bei or Pkd1ΔL/ΔL pups were born, suggesting that the Pkd1NEO and ΔL alleles were embryonic lethal. RT-PCR demonstrated that the floxed NEO cassette prevented splicing of intron 45, consistent with the generation of a functionally null allele. However, RT-PCR showed that the ΔL allele was properly spliced. E15.5 embryos from Pkd1ΔL/+ crosses were generated for metanephric organ culture. Pkd1ΔL/ΔL embryos were edematous and had pancreatic cysts. Kidneys from ΔL/ΔL embryos showed massive cyst-like dilations with cAMP treatment as previously shown for Pkd1m1Bei/m1Bei kidneys. PC1ΔL protein expression was detected by immunofluorescence. Transient transfection assays showed that a membrane-anchored PC1 L4122Δ C-tail construct was significantly impaired in PC1-induced signaling to AP1 and NFAT promoter-reporter constructs, but retained the ability to interact with co-immunoprecipitated polycystin-2.

Conclusions: These results demonstrate that the human L4131Δ mutation is pathogenic, and suggest that disruption of G-protein signaling is sufficient to cause PKD.

Funding: NIDDK Support

FR-OR085

PKD1 Mutation Type, but Not the Mutation Location, Influences Renal Outcome in Autosomal Dominant Polycystic Kidney Disease

Emilie Cornec-Le Gall,[1] Marie-Pierre Audrezet,[2] Maryvonne Hourmant,[3] Marie-pascale Morin,[4] Anne Grall-jezequel,[1] Eric Renaudineau,[5] Claude Ferec,[2] Yannick Le Meur.[1] *[1]Nephrology, University Hospital, Brest, France; [2]Molecular Genetics, INSERM 1078, University Hospital, Brest, France; [3]Nephrology, University Hospital, Nantes, France; [4]Nephrology, University Hospital, Rennes, France; [5]Nephrology, Hospital, Saint Malo, France.*

Background: Age of end stage renal disease (ESRD) is highly variable in Autosomal Dominant Polycystic Kidney Disease (ADPKD). The aim of this work was to study the influence of the identified mutations on the renal outcome.

Methods: Genkyst is a registry including ADPKD patients from Brittany in France. Clinical and genetic data were collected in a population of 609 patients from 436 pedigrees. Mutation analysis was performed by direct sequencing of *PKD1* and *PKD2* coding sequences, and Quantitative Fluorescent Multiplex PCR and Array-CGH were performed to detect large rearrangements. Renal survival and median age at ESRD were studied for each mutational group, using Kaplan-Meier method. The influence of the position of the mutation in *PKD1* gene was also studied.

Results: A mutation was identified in 90.4% of the pedigrees, which is the highest mutation detection rate ever reported. 248 of the 609 patients of our cohort had reached ESRD, at the median age of 60.6 yrs. No gender effect was observed. Median age of ESRD was 57.5 yrs [55.7-59.2] when a *PKD1* mutation was implied vs 78.0 yrs [65.9-90.0] for *PKD2* mutations (p<0.0001). Among *PKD1* mutations, truncating ones (65.5%) were associated with poor renal survival, with a median age of ESRD at 55.4 yrs [53.2-57.6]. Conversely, mutations with no truncating effect (33.5%) led to ESRD 10 years later (median age 65.5 yrs [56.7-74.3], p<0.0001). The location of the mutation, in relation to the median nucleotide position, was not associated with the age at onset of ESRD (p=0.87).

Conclusions: We report here one of the largest cohorts of ADPKD patients with genetic data, and for the first time, a high influence of *PKD1* mutation type on the severity of the renal disease. This is an important finding, as targeted therapies are on the way, and make the identification of such prognostic factors crucial.

Ablation of Healthy Adult Kidney Pericytes and Fibroblasts In Vivo Leads to Acute Kidney Injury with Features of Early Acute Tubular Necrosis

Gabriela Campanholle,[1] Takahisa Kawakami,[1] Takahide Aburatani,[1] Akio Kobayashi,[2] Jeremy Stuart Duffield.[1] *[1]Renal Division, University of Washington, Seattle, WA; [2]Harvard Medical School, Boston, MA.*

Background: Kidney pericytes and perivascular (PV) fibroblasts (Foxd1-derived, PDGFRb+, CD73+ Col1a1+ cells) are progenitors of scar-forming myofibroblasts. Pericytes are attached to endothelial cells & play important roles in vascular stabilization. After kidney injury, pericytes detach, migrate & differentiate into myofibroblasts, leaving an unstable endothelium, prone to rarefaction. Pericytes are derived from embryonic metanephric mesenchyme that activates a lineage restricted Fork-head transcription factor Foxd1.

Methods: We used a Cre-LoxP system to activate permanent diphtheria toxin receptor (DTR) expression in cells (& their daughters) which had expressed Foxd1 in nephrogenesis. Healthy adult mice expressing the transgene or controls were treated with IP injections of Diphtheria Toxin (DT). Tissues, blood, urine harvested at timepoints after injection. Mice with kidney injury and fibrosis were also subjected to ablation with DT at timepoints after injury.

Results: In healthy adult kidney, DT ablated >95% PDGFRb+ cells without effect on podocyte number at 48h & 72h in mice with the DTR. Controls unaffected. 60% of mice with ablation died at 72h, the remainder recovered. At 48h there was an increase in plasma Creatinine from 0.15 to 0.6mg/dL and a small decrease in BP in mice with ablation. Histologically, proximal tubules exhibited loss of polarization & severe vacuolization particularly basolaterally. Kidney microvasculature remained largely intact. In mice with kidney injury & fibrosis (UUO or unilateral IRI models), ablation of myofibroblasts DT on d8 resulted in 80% loss of aSMA myofibroblasts & >85% reduction in interstitial fibrosis on d10.

Conclusions: Acute ablation of Foxd1 derived pericytes & (PV) fibroblasts leads to loss of nephron function & acute proximal tubule injury. However, ablation of pericyte/fibroblast-derived myofibroblasts is potently anti-fibrotic.

TRPM2 Channels Activate Rac1 and Contribute to Ischemic AKI

Guofeng Gao,[1] William Brian Reeves,[1] Weiwei Wang,[1] Wenyi Zhang,[2] Barbara A. Miller.[2] *[1]Dept of Medicine, Penn State College of Medicine, Hershey, PA; [2]Dept of Pediatrics, Penn State College of Medicine, Hershey, PA.*

Background: TRPM2 (Transient receptor potential melastatin 2) is a non-selective cation channel activated by oxidative stress. Using TRPM2 deficient mice and TRPM2 inhibitors, we recently demonstrated a role for TRPM2 in mediating renal ischemic AKI. The present studies examined possible mechanisms whereby TRPM2 contributes to AKI. Oxidant stress plays a role in ischemia/reperfusion injury. Rac1, a small GTP-binding protein, is a subunit of the NADPH oxidase complex and is involved in its activation. The possible role of Rac1 in ischemic AKI and the interactions between Rac1 and TRPM2 are unknown.

Methods: For *in vitro* studies, primary cultures of proximal tubule epithelial cells (PTC) were prepared from wild type WT) and TRPM2 deficient (KO) mice. Cells were stressed with either H_2O_2 or hypoxia-reoxygenation. Cell viability was determined using the MTS assay and Rac1 activity using a pull-down assay. For *in vivo* studies, mice were subjected to 28 minutes of bilateral renal ischemia. BUN and creatinine were determined 24 hrs later.

Results: Rac1 was strongly activated by H_2O_2 in WT PTCs but not in TRPM2 KO PTCs. In addition, KO cells were resistant to hypoxic and oxidant-induced cell death. Likewise, WT kidneys subjected to IRI *in vivo* demonstrated greater activation of Rac1 than kidneys of KO mice. To investigate the role of Rac1 in IRI-induced AKI, we treated mice with a Rac1 inhibitor, NSC23766, prior to IRI. Mice treated with NSC23766 had better preservation of kidney function than vehicle-treated mice (BUN=53±13 vs 147±23 mg/dl, p<0.02; cr=0.37±0.08 vs 1.49±0.16 mg/dl, p<0.002).

Conclusions: These results indicate that Rac1 is activated during ischemic and oxidant stress to renal epithelial cells and that the TRPM2 channel modulates the activation of Rac1. These results also provide the first evidence for a role of Rac1 in mediating ischemic AKI *in vivo*. We also show that activation of Rac1 may account for some of the pathogenic actions of TRPM2 in ischemic AKI. Inhibition of TRPM2 or Rac1 may have an important impact in reducing kidney injury and preserving kidney function in AKI.

FR-OR088

Regulation of Autophagy in Renal Ischemia-Reperfusion Injury: Orchestration of Multiple Signaling Pathways

Man Jiang, Zheng Dong. *Department of Cellular Biology and Anatomy, Georgia Health Science University and Charlie Norwood VA Medical Center.*

Background: Autophagy is induced during acute kidney injury (AKI), but its role in AKI remains debated and the regulatory signaling pathways are poorly understood.

Methods: We determined the role of autophagy in AKI using a conditional knockout mouse model, in which Atg7 was specifically deleted from proximal tubules. We further investigated the signaling mechanisms that regulate autophagy during ischemic AKI in vivo and hypoxia-reoxygenation in vitro in cultured renal tubular cells.

Results: Conditional knockout of Atg7 resulted in impaired autophagy and aggravated AKI following renal ischemia-reperfusion or cisplatin treatment, supporting a renoprotective role of tubular cell autophagy. In cultured rat proximal tubular cells (RPTC) during hypoxia-reoxygenation. Hypoxia-reoxygenation induced autophagy as indicated by LC3-II accumulation and GFP-LC3 puncta formation. AMPK, JNK, p38 and ULK1 were activated during hypoxia, whereas mTOR was inactivated, as shown by their phosphorylation status. Blockade of ULK1, JNK or AMPK by shRNA or pharmacological inhibitors partially suppressed LC3-II accumulation during hypoxia, while inhibition of p38 was not effective. After reoxygenation, hypoxia-induced changes of AMPK, mTOR and ULK1 were mostly abolished, but JNK and p38 remained active and ERK became activated. Under this condition, inhibition of either p38 or JNK, but not ERK, attenuated autophagy. The changes of these signaling pathways were further observed in kidney tissues after renal ischemia-reperfusion in mice.

Conclusions: Together, these results suggest that AMPK, mTOR, JNK and ULK1 may initiate autophagy during ischemia/hypoxia, while the induction and maintenance of autophagy following reperfusion/reoxygenation may depend on JNK and p38.

FR-OR089

Loss of Acid Sphingomyelinase Causes Defective Autophagy-Induction *In Vivo* and Sensitizes for Renal Ischemia/Reperfusion Injury Andreas Linkermann,[1] Signe Diness Vindelov,[2] Elisabeth Corcelle-Termeau,[2] Jan H. Bräsen,[3] Ulrich Kunzendorf,[1] Stefan Krautwald,[1] Marja Jaattela.[2] *[1]Clinic for Nephrology and Hypertension, Christian-Albrechts University, Kiel, Germany; [2]Unit of Cell Death and Metabolism and Centre for Genotoxic Stress Research, Danish Cancer Society Research Center, Copenhagen, Denmark; [3]Department of Pathology, Christian-Albrechts University, Kiel.*

Background: Niemann-Pick disease (NPD) is characterized by reduced activity of acid sphingomyelinase (ASMase). Autophagy is a renoprotective mechanism in acute kidney injury (AKI). In this study, we define ASMase as a critical component for the induction of autophagy. ASMase is inhibited by diverse commonly used drugs, but nothing is known about ASMase-inhibition in AKI.

Methods: *In vitro*, we investigated cells from NPD patients and from cancer cell lines for their capacity to initiate autophagy using electron microscopy and monitored autophagic flux by p62 and LC3 western blots. *In vivo*, we analysed basal levels of autophagy in ASMase-deficient mice by IHC and western blotting and challanged these mice in a model of renal ischemia/reperfusion injury (IRI). IRI was also performed in wt mice that were pre-treated with the ASMase-inhibitor trimipramin (Stangyl®).

Results: We identified inhibitors of ASMase activity as indirect inhibitors of autophagy and demonstrate ASMase activity to be prerequisite for the closure of the autophagophore. In ASMasedeficient mice, we detected markedly reduced basal levels of autophagy in all organs examined, resulting in severe sensitivity for IRI in both AKI and survival readouts. Similar effects were seen in wt mice that were pretreated with timipramine.

Conclusions: We identified ASMase as a component that is required for the progression of autophagic flux on the level of autophagophore closure. Desipramine and trimipramine inhibited ASMase activity in vitro and in vivo, respectively, the latter of which sensitises mice to AKI comparable to the sensitization of ASMase-ko mice. The autophagy inhibitory capacity of tricyclic antidepressants opens new possibilities for cancer treatment but opposes the use of these drugs in patients at risk for cardiovascular events.

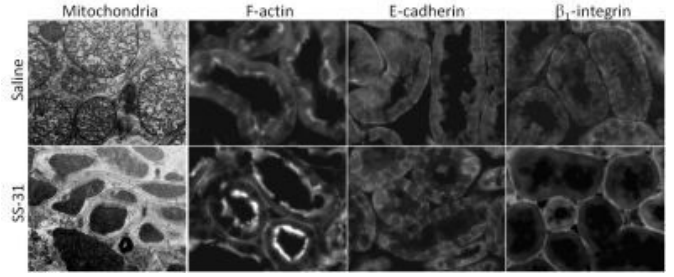
Mitochondria-Targeting Peptide (SS-31) Promotes Rapid Repair of Actin Cytoskeleton Following Ischemia and Protects Tubular Epithelial Cell Architecture Hazel H. Szeto,[1] Shaoyi Liu,[1] Yi Soong,[1] Surya V. Seshan.[2] *[1]Pharmacology, Weill Cornell Medical College, New York, NY; [2]Pathology, Weill Cornell Medical College, New York, NY.*

Background: Actin cytoskeletal disruption is a hallmark of ischemic injury. Rapid restoration of ATP is essential for the maintenance of the tubular epithelial cell structure after ischemic insult. SS-31 is a mitochondria-targeting tetrapeptide that has been shown to accelerate ATP recovery, reduce oxidative stress, and minimize ischemic kidney injury (Szeto et al., JASN 22:1041-1052, 2011). Here we show that SS-31 preserves mitochondrial cristae during ischemia and protects epithelial cell architecture upon early reperfusion.

Methods: Sprague-Dawley ratswere assigned to sham, IR+saline and IR+SS-31 (n=4). Rats were subjected to bilateral renal ischemia for 30 min followed by 0, 5, 20 or 60 min reperfusion. SS-31 (2.0 mg/kg, sc) was administered 30 min before ischemia and immediately before reperfusion. Kidneys were harvested for histopathology.

Results: 30 min ischemia caused mitochondrial swelling with loss of cristae in the saline group, while SS-31-treated kidneys showed preservation of mitochondrial cristae. F-actin, E-cadherin and b_1-integrin were internalized into the cytosol in both saline and SS-31 groups after 30 min ischemia. However, rapid redistribution of F-actin, E-cadherin and b_1-integrin were observed in the SS-31 group as early as 5 min after reperfusion while they remained internalized in the saline group. Electron microscopy also revealed significant protection of the capillary endothelium in the SS-31 group.



Conclusions: SS-31 protects mitochondrial cristae during ischemia and accelerates recovery of ATP for maintenance of cell structure and viability.

Identification of Proton Pump Inhibitors as Novel Therapy for the Prevention of Acute Kidney Injury Almut Grenz, Eunyoung Tak, Douglas Ridyard, Holger Eltzschig. *Anesthesiology, UC Denver, Denver, CO.*

Background: During renal ischemia, shifts in the metabolic supply to demand ratio – particularly for oxygen – result in severe tissue hypoxia. Cellular responses to hypoxia are regulated by enzymes that sense cellular oxygen levels and coordinate transcriptional responses to hypoxia or ischemia. Central among these enzymes are three oxygen-sensing prolyl hydroxylases (PHD1-3). Limited oxygen availability results in inhibition of PHDs with subsequent stabilization of hypoxia-inducible factors (HIFs). Activation of HIF results in a transcriptionally regulated response that re-programs cellular metabolism towards hypoxia adaptation. Systematic studies in mice with genetic deletion of PHD's pointed us towards a very surprising role of the renal proton pump ATP4A.

Methods: Gene targeted mice for PHD1, 2 and 3 ($PHD1^{-/-}$, $PHD2^{+/-}$, $PHD3^{-/-}$) were studied in an ischemic model of acute kidney inury (AKI) by utilizing a hanging weight system. Renal function was determined by FITC-labeled inulin clearance, serum creatinine, renal cytokine levels, renal myeloperoxidase (MPO ELISA) and histology.

Results: Here, we exposed gene-targeted mice for *Phd1*, *Phd2* or *Phd3* to AKI and assessed renal function by measuring glomerular filtration rate (GFR), or renal histology. Indeed, we found a selective phenotype in *Phd1-/-* mice with remarkable protection from ischemic AKI. To gain mechanistic insight into how *Phd1* deletion protects the kidneys from ischemia, we performed microarray studies. The most profound difference in gene expression was an over 10 fold repression of Atp4a, when comparing ischemic kidneys from *Phd1-/-* mice with controls. Subsequent studies with pharmacologic ATP4A inhibitors (esomeprazole, SCH28080) mimicked the kidney protection from ischemia seen in *Phd1-/-* mice. Moreover, *Atp4a-/-* mice were remarkably protected from renal ischemia.

Conclusions: Based on these findings we hypothesize that proton pump inhibitors can be used to prevent or treat ischemic AKI as occurs in perioperative patients.

FR-OR092

TRAPing Cell Type-Specific Signatures in Acute Kidney Injury A. Michaela Krautzberger,[1,2] Jing Liu,[1,2] Shannan J. Ho Sui,[3] Oliver Hofmann,[3] Winston Hide,[3] Andrew P. McMahon.[1,2] *[1]Dept. of Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA; [2]Broad CIRM Center, University of Southern California, Los Angeles, CA; [3]Dept. of Biostatistics, Harvard School of Public Health, Boston, MA.*

Background: Acute kidney injury (AKI) can be triggered by multiple insults including hypoxia, sepsis and nephrotoxic drugs. Identifying novel biomarkers and therapeutic targets requires a better understanding of the complex molecular and cellular interactions underlying the pathogenesis of AKI.

Methods: We have generated a new mouse strain enabling Cre-dependent expression of an eGFP-tagged ribosomal protein (eGFP-L10a) that allows extraction of mRNA by *t*ranslating *r*ibosome *a*ffinity *p*urification (TRAP) for subsequent profiling by microarray or RNA-seq. To determine cell type-specific signatures during early damage and later regenerative phases of AKI, we combine the TRAP methodology with an ischemia-reperfusion injury (IRI)-generated AKI model in mice.

Results: Six2-, Foxd1-, Cdh5-, and Lyz2-Cre driver strains were used to activate eGFP-L10a expression in nephron epithelial, interstitial, endothelial, and macrophages/dendritic cells, respectively. Immunofluorescent analysis confirmed transgene expression in the expected cell population, and an initial proof-of-principle experiment using TRAP-extracted RNA from untreated kidneys demonstrated significant population-specific GO term enrichment. We next examined cell type-specific signatures 24 hours after bilateral IRI. Bioinformatic analysis revealed a large number of genes deregulated in specific target cell populations. In addition, responses shared in two or more cell compartments were identified. Expression changes of top candidates were confirmed by real-time qPCR and section *in situ* hybridization at the RNA level, and by immunostaining at the protein level.

Conclusions: We have generated and validated a novel system for defining cell type-specific translational profiles during AKI. This approach will help to elucidate the complex mechanisms involved in AKI, and thus facilitate the discovery of new biomarkers and potential therapeutic strategies.

MicroRNA-668 Is Induced during Renal Ischemia-Reperfusion to Protect against Acute Kidney Injury Qingqing Wei, Zheng Dong. *Department of Cellular Biology and Anatomy, Georgia Health Science University and Charlie Norwood VA Medical Center.*

Background: MicroRNAs are important regulators of gene expression in a variety of physiological as well as pathological conditions.

Methods: Here we investigated the role of specific microRNAs in ischemic acute kidney injury (AKI) using both in vivo animal and in vitro proximal tubular cell models.

Results: We showed that conditional knockout of Dicer (a microRNA biogenesis enzyme) from proximal tubular cells resulted in microRNA depletion and protected mice from ischemic AKI, supporting a critical pathogenic role of microRNAs. Further microarray analysis identified a dozen of microRNAs that were significantly changed during ischemic AKI in mice. mir-668 was one of the microRNAs that were significantly up-regulated in ischemic AKI. The induction of mir-668 in ischemically injured kidney tissues was further confirmed by real-time PCR mir-668 was also induced by hypoxia in cultured rat renal proximal tubular cells (RPTCs). Hypoxic induction of mir-668 was diminished in

HIF-1-deficient cells, suggesting a role of HIF-1 in the inductive response. Functionally, transfection of anti-mir-668 in RPTC cells induced apoptosis. In vivo in C57BL/6 mice, anti-mir-668 treatment increased AKI after ischemia-reperfusion as indicated by renal function and histological examination.

Conclusions: Together, the results suggest that mir-668 may be induced via HIF-1 to protect against ischemic AKI.

FR-OR094

MMP-2 Activation Perpetuates Injury in AKI Timothy A. Sutton, Henry Mang, Nicci Knipe. *Department of Medicine/Division of Nephrology, Indiana University School of Medicine, Indianapolis, IN.*

Background: Ischemic acute kidney injury (AKI) is characterized by a complex interplay of tubular injury, inflammation and microvascular alterations. We have previously shown that in a rodent model of ischemic AKI, gelatinases {matrix metalloproteinases (MMP)-2 and -9} are activated and this activation is associated with increased microvascular permeability. However, genetic deletion of MMP-9 alone did not confer protection of renal function as determined by serum creatinine.

Methods: To further investigate the selective role of MMP-2 in ischemic AKI we utilized a 19 minute bilateral artery clamp model of AKI (RAC) to examine the effect of pharmacologic MMP-2/9 inhibition in the MMP-9 knockout (KO) mouse on kidney and microvascular function.

Results: MMP-9 KO mice administered the inhibitor had a significantly lower mean creatinine (0.74 mg/dL) as compared to the MMP-9 KO mice (2.1 mg/dL, p=0.02) 24 hours following injury. In addition, altered microvascular permeability was significantly improved in the MMP-9 KO mice administered the inhibitor compared to the MMP-9 KO mice as determined by an Evans blue dye assay (314 vs. 448 mcg EBD/g dried tissue, p=0.04). Similar protection was observed in FVB-NJ background (WT) mice administered the inhibitor in the RAC model. These findings support the importance of MMP-2 activation in the early phase of ischemic AKI. To further delineate the cellular source of gelatinase activity in ischemic AKI, we utilized bone marrow transplantation to generate chimeric mice. Surprisingly, we found that chimeric mice generated by transplanting MMP-9 null bone marrow into irradiated WT mice (MMP-9 KO into WT) demonstrated functional protection following acute ischemic injury (serum creatinine 1.37 mg/dL, $p<0.05$) as compared to WT into WT (2.15 mg/dL) and WT into KO (2.13 mg/dL) chimeric mice. Furthermore, altered microvascular permeability was improved in the KO into WT as compared to the WT into WT (268 vs. 488 mcg EBD/g dried tissue, $p> 0.1$).

Conclusions: Together these data suggest that MMP-2 activation is an important pathophysiologic mechanism in ischemic AKI that can be partially mitigated by selective MMP-9 inhibition in radiosensitive bone marrow cells.

Tubular Kidney Injury Molecule-1 Mediated Phagocytosis Downregulates the Kidney's Innate Immune Response after Injury Li Yang,[1,2] Craig R. Brooks,[1] Sheng Xiao,[3] Venkata Sabbisetti,[1] Takaharu Ichimura,[1] Vijay K. Kuchroo,[3] Joseph V. Bonventre.[1] *[1]Renal Division, Brigham and Women's Hospital and Harvard Medical School; [2]Renal Division, Peking University First Hospital, Beijing, China; [3]Center for Neurologic Disease, Brigham and Women's Hospital, Harvard Medical School.*

Background: Kidney Injury Molecule-1 (Kim-1) is upregulated more than any other protein in the renal proximal tubule in acute kidney injury (AKI), and is a phosphatidylserine receptor, which mediates phagocytosis of apoptotic cells. This study aimed to investigate whether Kim-1 facilitated phagocytosis of apoptotic cells is protective against AKI.

Methods: Wild-type (WT) and Kim-1$^{\Delta mucin}$ mice were exposed to bilateral ischemia/reperfusion(IRI) or cisplatin injection. The Kim-1$^{\Delta mucin}$ mouse expresses a mutant protein lacking the mucin domain. Serum creatinine and tubular necrosis were analyzed after injury. Bone marrow (BM) transplantation was performed to determine the relative importance of tubular vs BM-derived Kim-1 in the pathogenesis of kidney IRI. Proximal tubular cells derived from the WT and Kim-1$^{\Delta mucin}$ mice were exposed to LPS or TNF-α with or without apoptotic cells pre-feeding. Inflammatory cytokines, toll-like receptors (TLR), anti-inflammatory growth factors were evaluated.

Results: Proximal tubular cells expressing Kim-1$^{\Delta mucin}$ had markedly decreased ability to phagocytose apoptotic cells compared to WT Kim-1 expressing cells. Kim-1$^{\Delta mucin}$ mice had greater functional impairment, inflammation and mortality in response to IRI and cisplatin. The differential susceptibility to IRI between WT and Kim-1$^{\Delta mucin}$ mice was attributed to the kidney parenchymal cells as determined with BM chimeric mice. In cell culture, Kim-1-mediated phagocytosis of apoptotic cells resulted in decreased proximal tubular cell inflammatory cytokines and TLR4 production, and increased anti-inflammatory growth factor secretion which together decrease the inflammatory activity of macrophages. By contrast the Kim-1$^{\Delta mucin}$ cells had markedly impaired anti-inflammatory function.

Conclusions: Kim-1-mediated epithelial cell phagocytosis protects the kidney from acute injury by downregulating innate immunity.

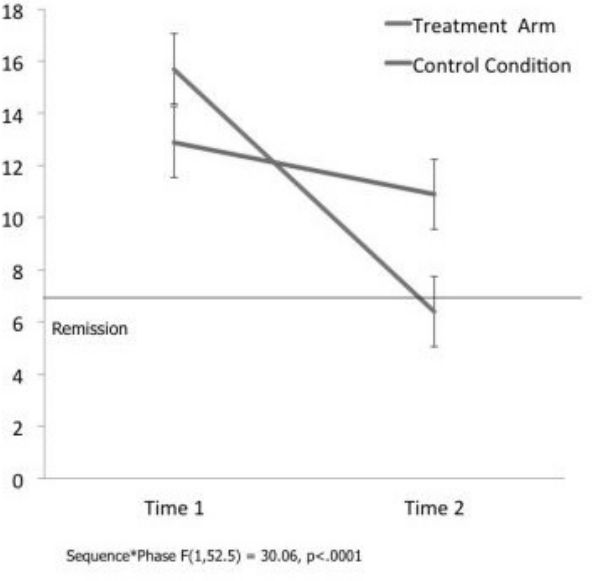
Depression, Quality of Life and Fluid Adherence Are Improved by Psychosocial Intervention: Results of an RCT in Two Urban Hemodialysis Centers Daniel Cukor,[1] Nisha Ver Halen,[1] Subodh J. Saggi,[2] Paul L. Kimmel.[3] *[1]Psychiatry, SUNY Downstate Medical Center, Brooklyn, NY; [2]Medicine, SUNY Downstate Medical Center, Brooklyn, NY; [3]Medicine, George Washington Uninversity, Washington, DC.*

Background: Depression is the primary mental health concern of ESRD patients, and is associated with lower QOL, decreased adherence, and decreased survival. Antidepressants have not been well tested in ESRD patients.

Methods: A 10 session individual cognitive behavioral intervention (CBT) aimed at reducing depression was compared to a wait-list control. Secondary goals were to determine if the CBT had positive effects on quality of life (KDQOL) and fluid compliance (IDWG).

Results: 63 depressed subjects on HD for at least 6 months enrolled. 59 completed all assessments. The sample was 94% Black, 72% female, 30% diabetic and been on dialysis 4.1 ± 2.8 years. Baseline depression was 15.2 ± 8.9 (moderate) on a clinician-administered measure (Hamilton Depression). There was a significant effect for the intervention on depression (62% reduction) with the mean dropping to 6.2 ± 3.7, below clinical cut-off. There was no significant change in the untreated group. The difference between groups was highly significant ($p<0.001$).

Hamilton-D ratings pre and post treatment for the treatment (n=30) and control (n=29) groups



Sequence*Phase F(1,52.5) = 30.06, p<.0001

There was significant improvement in QOL (18%) and fluid adherence (30%) compared to controls. Assessments were done blind to condition.

Conclusions: Depression is associated with negative health outcomes in HD samples. These results highlight a powerful effect of a behavioral intervention, especially, given the (1) ease of administration (2) acceptability of the intervention (no side effects), and (3) complex population studied. The intervention was also successful at improving the secondary outcomes of quality of life and fluid adherence. This intervention has the promise of reducing morbidity associated with depression in ESRD patients.

Physicians' Communication during Decision-Making to Start Dialysis: Patients' Perspectives Mi-Kyung Song,[1] Robert M. Arnold,[3] Constance Gilet.[2] *[1]School of Nursing, University of North Carolina-Chapel Hill; [2]UNC Kidney Center, University of North Carolina-Chapel Hill; [3]Internal Medicine, Univ. of Pittsburgh, Pittsburgh, PA.*

Background: Because of significant burdens associated with dialysis and its limited survival benefits, clinicians have a moral obligation to fully explain the need for dialysis and its impact on the patient's quality of life and survival. However, there are few data on how decisions to start dialysis are made in practice and how patients perceive the decision-making process.

Methods: We report preliminary results of a qualitative interview study to explore patients' perspectives of how decisions to start dialysis were made. Thirty patients on in-center hemodialysis (HD) completed a semi-structured interview (age, M±SD=60.2±11.4). Years on dialysis were 4.4 (M).

Results: Although 70% (n=21) of the patients knew what conditions led to their kidney failure at that time, 60% (n=18) said that the need for dialysis was unexpected. Sixteen patients were told about the imminent need for dialysis during an acute hospitalization. Mortality without dialysis was presented clearly, but no patient recalled any information about prognosis with dialysis, given by their nephrologists. While 90% said that the life-long need of dialysis was presented, only 19 patients said dialysis options other than HD were presented (even when the decision was made during an office visit). Only one patient reported that information about side effects of dialysis or complications was given. Twenty-three (76.7%) recalled that their doctors were trying to make sure the patient understood information, but only 5 perceived that the doctor tried to understand their values and what's important in their life. Eighteen felt that they had no choice about dialysis. The most difficult part of decision making was accepting their life would be confined and not knowing what to expect once the decision to start dialysis is made.

Conclusions: Patients perceived that the decision to start dialysis was made with little information. Although preliminary, our data suggest that there is a significant room for improvement in decision-making process surrounding dialysis initiation.

FR-OR098

Relationship between Prognostic Expectations of Hemodialysis Patients and Their Nephrologists Melissa Wachterman,[1] Edward Marcantonio,[1] Roger B. Davis,[1] Robert A. Cohen,[1] Sushrut S. Waikar,[2] Russell Phillips,[1] Ellen P. McCarthy.[1] *[1]Beth Israel Deaconess Medical Center; [2]Brigham & Women's Hospital.*

Background: The average 1-year mortality rate for hemodialysis (HD) patients is >20%. Perceptions of prognosis and expectations for transplant may influence goals of care (GOC). We compared HD patients' and their nephrologists' perceptions of prognosis and transplant candidacy, and explored the relationship between patients' expectations and GOC.

Methods: We conducted interviews with seriously-ill HD patients and their nephrologists. 2 prognostic models were used to identify patients with a ≥20% chance of dying in the next year. Of 207 patients treated at 2 HD units, 151 (73%) had a ≥20% mortality risk. 81 patients were eligible after exclusions including cognitive impairment, with 63 participating (78% response). We assessed prognostic expectations by asking patients and their nephrologists what they thought the chances were of 1-year survival (≥90%, 61-89%, 40-60%, 11-39%, ≤10%) and whether they thought kidney transplant was a possibility. Patients were also asked about their GOC (prefer mainly life-extending or symptom-directed care). McNemar's test was used to examine whether patients' and nephrologists' beliefs differed; Fisher's exact tests explored the association between GOC and expectations.

Results: Patients (mean age 68±10 yrs; 57% female; 51% African American) were significantly more likely than their nephrologists to report a ≥90% chance of being alive at 1 year (81% vs. 25%, P<.0001). In 60% of patient-nephrologist pairs, patients were more optimistic than their doctor, whereas doctors were more optimistic in 10% of pairs. Patients were also significantly more likely than their doctor to report they were transplant candidates (66% vs. 39%, P<.01). Of patients reporting a ≥90% chance of being alive at 1 year, 44% preferred care focused on extending life, compared to 9% of patients reporting a lower chance of survival (P=0.045).

Conclusions: HD patients appear more optimistic about prognosis and transplant than their nephrologists. Patients' potentially unrealistic expectations may influence their treatment choices. This suggests a need for improved prognostic communication.

FR-OR099

How Robust Is the Surprise Question in Identifying Increased Mortality Risk in Haemodialysis Patients Maria Da Silva-gane,[1] David Wellsted,[2] Ken Farrington.[1] *[1]Renal, Lister Hospital, Stevenage, Hertfordshire, United Kingdom; [2]Centre for Lifespan & Chronic Illness Research, University of Hertfordshire, Hatfield, Hertfordshire, United Kingdom.*

Background: Mortality on haemodialysis (HD) is high. Many patients are elderly and frail. Their end-of-life care needs are often unrecognised. The Surprise Question (SQ) "would I be surprised if this patient were to die in the next 12 months" may aid timely identification of patients with such needs. In a cohort of HD patients, we assessed the prognostic value of SQ and the variability of responses among individual clinicians.

Methods: In a private interview undertaken by a Research Fellow, clinicians in each of our 3 HD units were asked to answer the SQ about all patients dialysing in their unit. There were 29 nurses of varying seniority and 6 nephrologists. There were 344 patients, 116 in Unit-1, 132 in Unit-2 and 96 in Unit-3. Patients were subsequently followed-up for 12 months.

Results: A negative SQ response – "I would not be surprised if this patient were to die in the next 12 months", was reported for between 6 and 43% of patients (mean 24 ± 9%). Doctors responded negatively for significantly more patients, than nurses. 52 patients (15%) died during 12 months follow-up. There were wide variations between clinicians in the predictive power of SQ responses. Sensitivity and Relative Risk Ratio (RR) were significantly higher for doctors than for nurses. SQ responses of 67% of doctors and senior nurses, 50% of nurses of intermediate seniority, and 36% of less senior nurses, significantly improved baseline models of 12 month mortality. SQ responses of nurses in Unit-3 had significantly lower Positive Predictive Value (PPV) and RR than those in other units. Agreements between clinicians on SQ responses improved PPV.

Conclusions: The SQ provides a unique contribution to prediction of short term prognosis in HD patients. The predictive power of the SQ responses of individual clinicians varied with clinical discipline, seniority and clinical setting.

FR-OR100

Outcomes, Prognostication, and Clinician Comfort with In-Patient Dialysis Initiation Jennifer S. Scherer, Vaughn W. Folkert. *Division of Nephrology, Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY.*

Background: Acute kidney injury (AKI) requiring hemodialysis (HD) increases patient mortality, yet there is no prognostic model for these patients. This prognostic ambiguity often leads to discordance between caregivers concerning the appropriate level of care. The objectives of this study were to obtain demographic and outcome data on patients who initiated HD in an urban medical center, to determine the degree of clinician agreement concerning this decision, and to estimate caregivers' prognostic abilities.

Methods: An observational study of 45 patients that initiated HD during hospitalization. Outcomes measured: survival, disposition, and renal function at discharge. Objective data was coupled with data from a survey, completed at the time of HD initiation that asked clinicians if they believed HD would change patient mortality, if they were comfortable with HD initiation, and if they thought HD was prolonging death. Clinicians were also asked to prognosticate patient survival.

Results: Survival was 64%. 52% of survivors were discharged home, 17% to nursing homes, and 31% to rehabilitation facilities; 48% were HD dependent. 98 surveys for 32 patients were obtained from clinicians representing seven hospital departments. There was 80% concordance between the nephrology fellows' and their attendings' prognostic opinions that HD would change the patient's mortality. The nephrology team had an 82% correct prognostication rate of survival. There was 44% prognostic discordance between nephrologists and non-nephrologists, with the nephrology team being correct 75% of the time. 24% of responders felt that HD was prolonging the patient's death. In 22% of cases there was at least one clinician who was uncomfortable with HD initiation.

Conclusions: AKI requiring HD has a high mortality rate. Overall, the nephrology team had good agreement concerning the initiation of HD, as well as good prognostic abilities. In comparison, there was high prognostic discordance between nephrologists and non-nephrologists, with the nephrology team often predicting the correct prognosis. In many cases there was at least one caregiver who was uncomfortable with HD initiation.

FR-OR101

Use of the Distress Thermometer in Low Clearance Populations Helen Alston, Aine Burns. *Centre for Nephrology, University College London, London, United Kingdom.*

Background: Patients with advanced CKD and multiple comorbidities have high symptom and depression burdens. Quality of life is comparable with advanced cancer patients. Commonly-used depression and symptom scores are not practical for routine clinic use, being long and unwieldy. We found the distress thermometer (DT), a self-scoring visual analogue scale for recording distress, easy to use in our multi-ethnic CKD population. We piloted its use to enhance communication and ensure a patient-centred approach at outpatient visits.

Methods: We reviewed 45 DTs completed by patients immediately prior to outpatient consultation. We compared distress scores with the clinical assessment. The distribution of scores was compared with standardised distributions from other UK patient populations. We characterised our sample using information from the electronic patient record (age, gender, eGFR, haemoglobin, Charlson comorbidity index), and looked for correlation between these factors and DT scores.

Results: 100% of patients with DT scores 8-10 were assessed as requiring clinical intervention during subsequent consultation, compared with 36% of those scoring 4-7 and 10% of those scoring 0-3. Patients ≥70yrs had higher DT scores than younger patients (fig 1). These distributions are significantly higher than standardised distributions for other UK populations such as cancer patients. Charlson score correlated with DT score, and patients ≥70yrs also had higher mean Charlson scores than those <70. There was no correlation between eGFR and DT score, neither was there a gender difference.

Conclusions: DT scores correlate with Charlson scores and age but not with eGFR, suggesting distress in CKD patients is due to factors other than renal function. The distribution of DT scores was higher in renal patients than in other populations. This may represent higher incident levels of distress within our population (renal patients have high levels of psychological morbidity), or may indicate that the DT requires recalibration before it can be used as a screening tool in nephrology. We suggest formal validation of this tool in renal populations to clarify this. The DT can continue to be used to stimulate communication in the clinical consultation.

FR-OR102

Clinical Outcomes of Suboptimal and Crash Starts to Dialysis Kenrry Chiu, Sameena Z. Iqbal, Ahsan Alam. *Division of Nephrology, McGill University Health Centre, Montreal, QC, Canada.*

Background: Many patients start dialysis suboptimally with a catheter despite having prior nephrology care, while others "crash" onto dialysis never having seen a nephrologist before. The aim of this study was to examine the impact of suboptimal and crash dialysis starts on mortality and kidney transplantation.

Methods: We retrospectively reviewed 377 incident dialysis patients from January 2006-April 2011 at two adult tertiary care hospitals with dedicated pre-dialysis clinics. Dialysis start type was categorized as: 1) optimal, 2) suboptimal with permanent access attempted, 3) suboptimal without permanent access attempt, and 4) crash start. Cox proportional hazard models were used to examine the association of start type with all-cause mortality or kidney transplantation, adjusting for age, gender, eGFR, serum phosphate, and Charlson comorbidity index.

Results: There were 377 patients (mean age 66 years, 57% male, 63% Caucasian, 56% diabetic, mean eGFR at start 8 ml/min/1.73 m^2) consisting of 27% optimal, 59% suboptimal, of which 45% had a permanent access attempt, and 14% crash starts. During a median follow up of 1.6 yrs, there were 104 deaths and 44 kidney transplants. As compared to an optimal start, adjusted mortality was increased for those with crash starts (HR 2.28; 95% CI 1.14-4.53) or suboptimal starts (HR 2.09; 95% CI, 1.21-3.60). However, suboptimal starts with a permanent access attempt had outcomes not significantly different than optimal starts. Compared to optimal starts, crash starts were less likely to have a kidney transplant (HR 0.08; 95% CI 0.01-0.61). Suboptimal starts did exhibit a decreased risk for kidney transplant (HR 0.57; 95% CI 0.30-1.07), but this was non-significant and not modified by prior permanent access attempt.

Conclusions: In our study, non-optimal starts represent the largest proportion of those starting dialysis. Suboptimal starts are a heterogeneous risk group, with a prior permanent access attempt conferring a favourable risk profile. Crash starts exhibit the highest risk for mortality and are less likely to receive a kidney transplant. Strategies to improve the rates of optimal dialysis starts should be identified, as this may improve patient outcomes on dialysis.

Impact of End Stage Renal Disease in Children on Their Parents

Min Hyun Cho,[1] Ki-Soo Park,[2] Youngju Hwang,[1] IL-Soo Ha,[3] Hee Gyung Kang,[3] Hae Il Cheong,[3] Young Seo Park,[4] Heeyeon Cho.[5] *[1]Pediatrics, Kyungpook National University Hospital; [2]Preventive Medicine, Gyeongsang National University Hospital; [3]Pediatrics, Seoul National University Children's Hospital; [4]Pediatrics, Asan Medical Center; [5]Pediatrics, Samsung Medical Center.*

Background: End stage renal disease (ESRD) in children is very problematic condition to their families as well as patients themselves. We performed the cross-sectional investigation of impact of ESRD on their families, especially parents with children undergoing renal replacement therapies.

Methods: We used the Korean version of PedsQL Family Impact Module (FIM) and compared the results of Health-related Quality of Life (HRQOL) estimated from PedsQL 4.0 Generic Core Scales and PedsQL 3.0 ESRD module after adjustment for child age, child gender, treatment method, cause of disease, co-morbidity, parent's age, education level, parent's marital status, Hemoglobin, and Kt/V. Ninety two pediatric patients with ESRD aged 2-18 year old were enrolled in four Korean university hospitals. PedsQL Family Impact Module was completed by their parents.

Results: Male: Female ratio was 44:48 and most common cause of ESRD was chronic glomerulonephritis. Fifth five children have been treated by dialysis and thirty seven children received renal transplantation. Treatment modality and co-morbidity were significant variables to the impact of ESRD on their parents. Hemodialysis produced worse impact on their parents than other modalities including peritoneal dialysis and transplantation, especially in the three domains and total score: Emotional function, Social functioning and Cognitive functioning. Co-morbidity also produced worse impact on their parents in the five domains and total score: Social functioning, Cognitive functioning, Communication, Daily activities and Family relationship. Moreover, HRQOL of patients and family impact score showed significant positive correlation.

Conclusions: Treatment modality, co-morbidity and HRQOL of patients are very important factors to decide the impact of ESRD on their parents with children undergoing dialysis or renal transplantation. Larger, longitudinal prospective study is needed.

FR-OR104

The Impact of Real-Time Dosage Guidance for CKD: A Cluster Randomized Controlled Trial

Linda Awdishu,[1,2] Kim T. Tran,[2] Carrie R. Coates,[3] Adam Lyddane,[3] Robert El-kareh.[4] *[1]Pharmacy, UCSD School of Pharmacy, San Diego, CA; [2]Medicine, Division of Nephrology, UCSD School of Medicine, San Diego, CA; [3]Pharmacy, UCSD Health System, San Diego, CA; [4]Medicine, Division of Biomedical Informatics, UCSD School of Medicine, San Diego, CA.*

Background: Patients with CKD are at risk for frequent adverse medical events due to improper medication dosing. We aimed to design and implement computerized decision support tool to improve the rate of appropriate drug prescriptions in CKD.

Methods: A decision support tool was developed using best practice alert (BPA) functionality within the EPIC electronic health record. Alerts on 30 study medications for CKD patients (stage 3-5) were displayed in inpatient and outpatient settings during the process for ordering new medications and prior to the provider signing. Additionally, our tool featured "look backs" which provided alerts on existing medications when kidney function changed. We randomized all physicians at our institution to receive either standard of care (pharmacist review after order signing) or alerts in addition to standard of care. In both groups, we prospectively reviewed these opportunities for potential prescription adjustment to determine the proportion of study prescriptions that were appropriately adjusted for kidney function prior to pharmacist review. We created a multivariate logistic regression model that adjusted for GFR, gender, age, weight, hospitalized status and clustering within the prescribing provider.

Results: During the first 16 days of this study, a total of 346 opportunities for potential drug dosage adjustment or discontinuation occurred in 144 unique patients; 154 in the intervention arm and 192 in the control arm. Patient demographics were well matched with respect to age, gender, kidney function and length of stay. The primary outcome, drug discontinuation or dosage adjustment was 23.4% vs. 5.2% in the intervention and control arm, respectively (OR 3.9 [95%CI 1.8-8.8], p <0.001).

Conclusions: The rate of appropriate drug prescribing in CKD is low and remains a patient safety concern. Preliminary results suggest that our decision support tool improves drug prescribing in CKD.

FR-OR105

Improving In-Patient Detection of Acute Kidney Injury Stage 3 (AKI-3)

Daniel Mcnaughton,[1] Gayathri K. Rajakaruna,[1] Aditi Sharma,[1] Arunraj Navaratnarajah,[1] Peter Simon West,[1] Chris Laing,[2] Shyama Dakshina Jayasena.[1] *[1]North Middlesex Hospital, London, United Kingdom; [2]Royal Free Hospital, London.*

Background: AKI affects 20% of hospital admissions. Retrospective studies have demonstrated a linear relationship between mortality and AKI grade. AKI-3 represents a powerful predictor of inpatient mortality and is a risk factor for chronic kidney disease.

In 2009 the UK National Confidential Enquiry into Patient Outcome and Death report 'Adding Insult to Injury' showed serious deficiencies in AKI care in UK hospitals. As a result in North Central London an AKI network has been set up to try and improve care.

In 2010, a retrospective audit of 40 patients with AKI-3 admitted in 2009/10, identified through coding and the pathology services, showed significant shortcomings in our own practice.

In 2011 we introduced a creatinine alert system and re-audited to identify impact of earlier intervention in AKI-3 care.

Methods: Nephrologists were e-mailed daily the Identifiers of in-patients with a Creatinine >300μmol/l who were unknown to their team. We studied management and outcome of patients generated by this method who fulfilled criteria for AKI-3 for each day in 2011.

Results: 123/282 patients generated by the alert system, fulfilled criteria for AKI-3 (see table).

Mortality of 35.8% in this study shows no improvement compared to 2010 audit figure of 33%. However, compared to our previous audit, we have shown 50.4% made a full renal recovery compared to 35% previously.

Patient demographics and Outcome

1. Patient Demographics		
	n=	% of total
Total Alerts	282	
AKI-3	123	43.6
Male	80	65.0
Female	43	35.0
Average Age	70.2	
Age Range	21-98	
2. Patient outcomes		
No recovery	31	25.2
Partial recovery	30	24.4
Full recovery	62	50.4
Died	44	35.8

Conclusions: A creatinine alert system identifies more patients with AKI-3 at an earlier stage and improves chances of full renal recovery. Abnormal renal function may represent end stage of an underlying disease process, rather than reversible renal causes per se (accounting for unchanged mortality). Other measures which may improve detection of an at risk population may include structured clerking pro-formas at point of care or a lower threshold for alerts (i.e. >200μmol/l).

FR-OR106

Peritoneal Dialysis Reduces the Number of Hospitalization Days in Heart Failure Patients without End-Stage Renal Disease

Amir Kazory,[1] Cécile Courivaud,[2] Thomas Crépin,[2] Raymond Azar,[3] Catherine Bresson-Vautrin,[2] Jean Marc Chalopin,[2] Didier Ducloux.[2] *[1]University of Florida; [2]University of Franche-Comté, France; [3]Dunkerque Medical Center, France.*

Background: Heart failure is the most common reason for hospitalization in patients older than 65, and represents a significant burden on healthcare expenditure. Previous small-sized studies have reported favorable results for peritoneal dialysis (PD) in the setting of chronic refractory heart failure (CRHF). This study was designed to evaluate the impact of PD in a larger cohort of patients who did not have end-stage renal disease (ESRD).

Methods: All non-ESRD patients who received PD therapy for CRHF between January 1995 and December 2010 in two medical centers in France were included. Baseline characteristics were compared with a number of clinical parameters over the first year after initiation of PD (e.g. left ventricular ejection fraction [LVEF]). Safety and sustainability of PD, as well as mortality rate were analyzed.

Results: A total of 126 patients were included, with a mean age of 72 ± 11 years and an estimated glomerular filtration rate of 33.5 ± 15.1 ml/min/1.73m^2. Mean time on PD therapy was 16 ± 16.6 months. There was a significant reduction in the number of days of hospitalization for acute decompensated heart failure compared to the year preceding PD therapy (3.3 ± 2.6 vs. 0.3 ± 0.5 days/patient/month; $p < 0.0001$). Patients with LVEF ≤ 30% experienced improvement in cardiac function during the first year (30% ± 10 vs. 20% ± 6, $p< 0.0001$). There was a reduction in body weight at 3 months (74 ± 15 vs. 72 ± 15 kg, p=0.04). One-year mortality was 42% and cardiovascular events were the most common cause of death.

Conclusions: This study, the largest in this field, shows that PD can significantly reduce the number of days that patients with CRHF are hospitalized for heart failure-related complications. PD is also associated with significant improvement in LVEF, especially in patients with more compromised cardiac function. Whether these beneficial effects will translate into a beneficial impact on mortality and financial aspects of heart failure needs to be tested in future randomized studies.

FR-OR107

Stimulation of Soluble Guanylate Cyclase Attenuates Epithelial-Mesenchymal Transition of the Peritoneal Membrane and Prevent the Development of Peritoneal Fibrosis Hiroyuki Kadoya, Minoru Satoh, Hajime Nagasu, Kengo Kidokoro, Yuko Nishi, Chieko Ihoriya, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: The decrease in ultrafiltration capacity after prolonged peritoneal dialysis (PD) is the major reason for its discontinuation. The peritoneal membrane is continuously exposed to the high glucose, leading to peritoneal fibrosis and functional deterioration of the peritoneum. However, the mechanisms underlying this process have not yet been elucidated. The epithelial-mesenchymal transition (EMT) of peritoneal mesothelial cells has been regarded as an important mechanism of peritoneal fibrosis. Recently, nitric oxide (NO) has been reported to attenuate EMT in tissue fibrosis of various organs. We hypothesized that NO signaling inhibits EMT and thereby prevents the development of peritoneal fibrosis. The aims of this study are to evaluate the role of eNOS-NO signaling pathway and to elucidate the mechanisms of peritoneal fibrosis.

Methods: We used eNOS-deficient (eNOSKO) and wild type (WT) mice. A peritoneal fibrosis model was created by mechanical scraping. Some eNOSKO were treated with the soluble sGC stimulator Bay41-2272 (10 mg/kg/day, i.p). The mice were divided into the following groups: WT-sham, WT-peritoneal fibrosis(PF), eNOSKO-sham, eNOSKO-PF, and eNOSKO-PF-Bay. Two weeks after the operation, the mice were sacrificed. Peritoneal fibrosis was evaluated by Masson's trichrome staining. EMT was evaluated with α-smooth muscle actin (SMA) and vimentin expressions.

Results: Peritoneal fibrosis in eNOSKO-PF was more aggravated than in WT-PF. The expressions of α-SMA and vimentin were increased in eNOSKO-PF compared to WT-PF. The fibrosis and EMT of the peritoneal membrane were significantly attenuated in eNOSKO-PF-Bay. Furthermore, peritoneal function, assessed by a peritoneal equilibration test, was significantly improved in eNOSKO-PF-Bay.

Conclusions: The eNOS-NO-sGC signaling pathway was identified as potential therapeutic target to prevent peritoneal fibrosis. Thus the drugs that activate sGC possess therapeutic efficacy for protection of peritoneum in PD therapy.

FR-OR108

First Year Mortality in Incident Hemodialysis versus Peritoneal Dialysis Patients Joseph P. Pulliam,[1] Nien-chen Li,[1] Raymond M. Hakim,[2] J. Michael Lazarus,[3] Franklin W. Maddux,[1] Eduardo K. Lacson.[1] *[1]Fresenius Medical Care, North America, Waltham, MA; [2]Vanderbilt University, Nashville, TN; [3]University of North Carolina, Chapel Hill, NC.*

Background: The survival advantage observed in Canadian incident peritoneal dialysis (PD) patients was attributed largely to high incident hemodialysis (HD) catheter use. We sought to confirm these findings in a US cohort of incident patients.

Methods: Survival of incident patients starting dialysis in Fresenius Medical Care North America facilities in 2009 were compared by modality for one year using an intention to treat methodology. Cox models were adjusted for case-mix and the first available results for albumin, hemoglobin, & phosphorus. HD patients were also stratified by catheter vs. non-catheter (fistula/graft) access.

Results: PD patients were younger (57 vs. 64 years), admitted later (admission vintage 22 vs. 11 days), had fewer black patients (21% vs. 31%), larger BMI (32 vs. 31 kg/m^2) and had fewer comorbidities (DM: 53% vs. 62%, CHF: 3% vs. 4%, PVD: 6% vs. 10%, & Amputations: 3% vs. 5%) than HD patients (all p<0.001), although both cohorts had 56% males. Mortality rates were 0.10 and 0.25 per patient-year for PD and HD patients, respectively (p<0.0001). Among HD patients initiated with fistula/graft and catheter, mortality rates were 0.13 vs. 0.30 per patient-year (p < 0.0001). Kaplan-Meier 1st year mortality rates were 9.3% for PD vs. 21.5% for HD patients. The adjusted hazard ratio for death was 0.47 (0.40-0.56) favoring PD. The corresponding adjusted hazard ratios for non-catheter patients was 1.40 (95% CI 1.16-1.68) and for catheter patients was 2.31 (1.95-2.75), all p<0.0001.

Conclusions: In this national US cohort, incident PD patients had lower death risk than HD patients in the first year, despite adjusting for favorable case-mix. Unlike in the Canadian study, access type did not abrogate the difference in death risk for non-catheter access patients, although the associated risk in HD catheter patients was much higher. Further study is needed to determine if predialysis management practices and modality selection processes differ between cohorts (and countries) that may explain these findings.

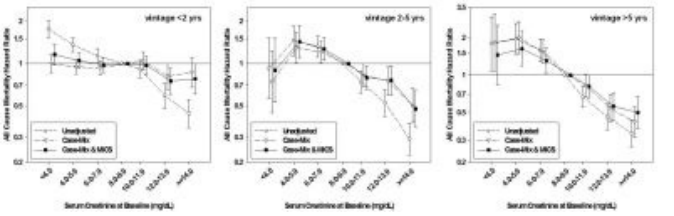
FR-OR109

Serum Creatinine and Mortality in Peritoneal Dialysis: Impact of Dialysis Vintage Jongha Park,[1,2] Rajnish Mehrotra,[3] Miklos Zsolt Molnar,[1] Lilia R. Lukowsky,[1,4] Sapna Singh Patel,[3] Joel D. Kopple,[3,4] Csaba P. Kovesdy,[5] Kamyar Kalantar-Zadeh.[1,3,4] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, LA BioMed at Harbor-UCLA, Torrance, CA; [2]Ulsan University Hospital, Ulsan, Republic of Korea; [3]Harbor-UCLA Medical Center, Torrance, CA; [4]David Geffen School of Medicine and Fielding School of Public Health at UCLA, Los Angeles, CA; [5]University of Tennessee, Memphis, TN.*

Background: Serum creatinine (Cr) levels are affected by body muscle mass and protein (meat) intake, both of which are associated with mortality in end-stage renal disease. However, serum Cr may be influenced dialysis vintage due to the effects of residual renal function.

Methods: Association of baseline serum Cr with all-cause mortality was explored in three different PD vintage groups (<2 yrs, 2-5 yrs, >5yrs) in 10,840 patients treated from July 2001 to June 2006 in 580 units owned by a large dialysis organization in the US.

Results: The patients were 55±15 yrs old and included 52% women, 24% Blacks and 48% diabetics. In patients with vintage <2yrs (n=7,175), there was an inverse association between serum Cr and mortality in the unadjusted model, but the association was no longer significant after adjustment for confounders. However, in patients with vintage 2-5 yrs (n=1,995), the relationship remained significant even after full adjustment except in patients with serum Cr <4.0 mg/dl. Patients with vintage >5 yrs (n=1,670) showed a robust association. Compared to patients with serum Cr range of 8.0-9.9 mg/ml as reference, hazard ratios were 1.63, 1.31, 0.81 and 0.60 in patients with serum Cr of 4.0-5.9, 6.0-7.9, 10.0-11.9 and 12.0-13.9 mg/dl, respectively (all p < 0.05).



Conclusions: The longer the PD vintage, the more closely serum Cr was associated with mortality as the confounding influence of residual renal function is mitigated.

FR-OR110

Standardising Data Definitions for Peritoneal Dialysis(PD): Progress towards P-DOPPS Mark Lambie,[1] Simon J. Davies,[1] Jeffrey Perl,[4] David W. Johnson,[2] Martin E. Wilkie,[5] Ronald L. Pisoni,[3] Friedrich K. Port,[3] Bruce M. Robinson.[3] *[1]U. Hosp. of North Staffordshire; [2]Princess Alexandra Hosp.; [3]Arbor Research; [4]U. of Toronto; [5]Sheffield Teaching Hosp.*

Background: Standardizing definitions across data sources is vital to understanding differences in PD care and outcomes and to identify barriers to PD utilization. Within and between national renal registries, the study of fundamental issues (e.g. rates and causes of PD technique failure [TF]) is challenged by variability in the population covered, data completeness, definitions of PD start/end dates, and definitions of causes of TF. This project seeks to identify variation across registries in the definition, reporting, and documentation of PD TF and its causes.

Methods: We surveyed 11 national and international registries. Available information regarding data collection procedures, data completeness, comorbidities and definitions, definitions of PD start/end dates, and reasons for PD TF were systematically evaluated. Selected preliminary results are shown for national registries in Australia/New Zealand (ANZDATA), the United Kingdom (UKRR), Canada(CORR) and the United States(USRDS).

Results: See table.

Table: National and International PD Registry Characteristics

Registry	Data Collection Technique	Calculating Rate of Technique Failure: Specific Definition of PD Start Date	Calculating Rate of Technique Failure: Specific Definition of PD End Date (Duration off PD)	Causes of Technique Failure: # of Available Causes of TF	Causes of Technique Failure: > 1 cause permitted	Other Complications: Peritonitis Episodes Recorded	Other Complications: Exit Site Infections Recorded
ANZDATA	Form (paper or web-based) completed by physician	No	Yes	31	No	Yes	No
CORR	Form (paper) completed by nurse	No	No	12	No	No	No
UKRR	Electronic transfer and ad hoc audits	No	No	14, not routinely collected	No	No	No
USRDS	Principally administrative data	No	No	No PD TF specific causes recorded	No	No	No

Conclusions: We identified differences in data collection methods and the scope of data, as well as weaknesses across registries. As a result, comparisons of rates and causes of PD TF remain limited, both across facilities and between countries. The Peritoneal Dialysis Outcomes and Practice Patterns Study(P-DOPPS), led by Arbor Research Collaborative for Health along with the International Society of PD(ISPD), will address these limitations by development of a set of consensus data definitions to allow for valid comparisons of differences in PD practice and outcomes across facilities and between countries. These definitions will be published by ISPD as a resource for the PD community.

FR-OR111

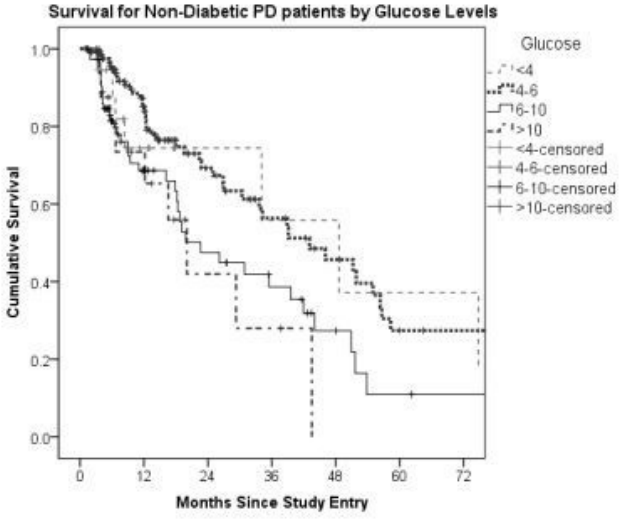
A Random Glucose in Non-Diabetic Prevalent Peritoneal Dialysis Patients Is Strongly Predictive of Death: Results from the GLOBAL Fluid Study

Mark Lambie,[1] James A. Chess,[2] Paul F. Williams,[3] Andrew J. Williams,[2] Yong-Lim Kim,[4] Sara N. Davison,[5] Nicholas Topley,[6] Simon J. Davies.[1] *[1]Renal Department, University Hospital of North Staffordshire, Stoke on Trent, United Kingdom; [2]Renal Department, Morriston Hospital, Swansea, United Kingdom; [3]Renal Department, Ipswich Hospital, Ipswich, United Kingdom; [4]Nephrology, Kyung-pook University Hospital, Daegu, Korea; [5]Nephrology, University of Alberta Hospital, Edmonton, Canada; [6]School of Medicine, Cardiff University, Cardiff, United Kingdom.*

Background: Glucose control is a significant predictor of death in diabetic patients. In peritoneal dialysis (PD), the local toxic effects of peritoneal glucose are well recognized, but despite large amounts being absorbed, the systemic effects are not clear.

Methods: We analysed the Global Fluid Study, an observational cohort study of over 1,200 PD patients from 16 centres in 6 countries. 10 centres from 3 countries with high data quality were selected, with survival analysis by forward selection of a stratified Cox regression model after multiple imputation. Multivariate multilevel analysis was used for log transformed random glucose levels.

Results: By multivariate Cox models, random glucose levels were highly significant predictors of death in non-diabetic prevalent PD patients, (HR 1.05 per 1mmol/l increase, p=0.002), but not in incident patients. A Kaplan-Meier plot is shown.



On multivariate analysis random glucose levels were significantly associated with only daily dialysate glucose (0.018mmol/l increase per 1 litre 1.5% equivalent, p=0.001) and serum albumin levels (0.014mmol/l decrease for 1g/l increase, p<0.0001). Peritoneal Solute transport was positively associated until albumin was included.

Conclusions: Random glucose levels are strongly predictive of survival in non-diabetic prevalent PD patients, and these levels are partly determined by dialysate glucose.

Characterization of Mesothelial Cell VEGF Release during Peritonitis: The Role of c-Fos-Mediated Stimulation by TGF-β1 and TNFα

Achim Joerres,[1] Rusan Catar,[1] Philine Wagner,[1] Duska Dragun,[1] Janusz Witowski.[1,2] *[1]Department of Nephrology and Medical Intensive Care, Charite-Universitaetsmedizin Berlin Campus Virchow-Klinikum, Berlin, Germany; [2]Department of Pathophysiology, Poznan University of Medical Sciences, Poznan, Poland.*

Background: TGF-β1 is thought to contribute to adverse peritoneal vasculopathy that develops during peritoneal dialysis (PD) by inducing VEGF expression. The mesothelium has been identified as a major source of VEGF in the peritoneum. Mechanism of VEGF induction is strictly cell type- and context-dependent and the regulatory circuits dependent on other pathophysiology relevant cytokines remain to be clarified. We have hypothesized direct involvement of TGF-β1 and TNFα in regulation of VEGF expression in human peritoneal mesothelial cells (HPMC).

Methods: HPMC were isolated from normal omentum obtained during elective surgery. Dialysate effluent was obtained from stable PD patients and during peritonitis. VEGF mRNA and protein levels were measured by RT-qPCR and ELISA respectively. The involvement of transcriptional factors was assessed by EMSA and transient HPMC transfection with VEGF promoter constructs.

Results: Quiescent HPMC secreted only trace amounts of VEGF. Stimulation with TGF-β1 resulted in a time- and dose-dependent increase in VEGF mRNA expression and protein release. These effects were further synergistically amplified by TNFα, which alone exerted only minimal effect. Stimulation of HPMC with TGF-β1 ± TNFα led to the induction of the transcription factor c-Fos and activation of the VEGF promoter region that contained high affinity binding sites for c-Fos. Exposure of HPMC to dialysate effluent obtained during acute peritonitis and containing increased levels of TGF-β1 and TNFα resulted in a dose-dependent VEGF induction. This effect was significantly attenuated in cells treated simultaneously with an inhibitor of the activator protein-1 that is formed by c-Fos subunits.

Conclusions: Dialysate TGF-β1 and TNFα act through c-Fos to synergistically up-regulate VEGF production in the peritoneal mesothelium, thus pointing at an important link between inflammation, fibrosis and angiogenesis in the peritoneal membrane.

FR-OR113

Ceramides, Cardiac Structure and Function in Children with Chronic Kidney Disease

Matthew J. O'Rourke,[1] Bradley A. Warady,[2] Susan L. Furth,[2] Philipp Scherer,[2] Mark Mitsnefes.[1,2] *[1]Cincinnati Childrens Hospital Medical Center; [2]CKiD Study.*

Background: Chronic kidney disease (CKD) is associated with an increased incidence of cardiac dysfunction, even in subjects with an early decline of kidney function. The mechanism of accelerated cardiomyopathy is not well-understood. Recent animal studies determined that elevated sphingolipid, ceramide, causes dilated cardiomyopathy. Ceramide has not been studied in patients with CKD. We hypothesized that ceramide levels are elevated in children with CKD and that ceramide is associated with known cardiovascular risks and abnormal cardiac structure and function.

Methods: Multiple species of ceramide (C16, C18, C20, C22, C24) were determined as a part of sphingolipid analysis by LC/ESI/MS/MS using a TSQ Quantum Ultra-triple quadrupole mass spectrometer. Pilot data from 64 children aged 1-16 years enrolled in the CKiD study, median (IQR) iohexol GFR 49 (38, 64) ml/min/1.73m^2, with complete demographic, clinical and laboratory information and sphingolipid measures were analyzed cross-sectionally. Echocardiography was performed to determine LVM index, systolic (shortening fraction, SF) and diastolic (E/A) function. Ceramide levels were compared to 24 age-matched healthy controls.

Results: Serum ceramides were significantly higher in the CKD children, with especially pronounced difference in C24:0 lactosyl (L) ceramide (p<0.0001). In univariate analysis, logC24:0L was inversely associated with SF, (%) (r=-0.28, p=0.01) and E/A ratio (r=-0.24, p=0.04). In multivariate analysis adjusted for age, BMI Z score, LVM index, SBP Z score, DBP Z score, GFR and hemoglobin, higher logC24:0L was the only independent predictor of lower SF (β= - 20.480, p=0.01). Similar analysis for diastolic function determined that higher LVM index (β= -0.26, p=0.04) and C24:0L (β= -0.31, p=0.01) were only independent predictors of lower E/A ratio.

Conclusions: We concluded that ceramide levels are increased in children with CKD. The study identified C24:0L as independent predictor of lower diastolic and systolic function in these children. Larger confirmatory studies are needed to evaluate ceramide as a possible biomarker or a cause of abnormal cardiac function in CKD.

Funding: NIDDK Support

FR-OR114

Protective Role of Latent TGF-β1 in Diabetic Kidney Disease

Hui Y. Lan,[1,2] Haiyong Chen,[1] Xiao Ru Huang,[1,2] Xiaoming Meng.[1] *[1]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, China; [2]Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Hong Kong, China.*

Background: Transforming growth factor-β1 (TGF-β1) has diverse roles in renal fibrosis and inflammation. While activation of TGF-β1 induces renal fibrosis in diabetes, the role of latency-associated peptide-TGF-β1 (LAP-TGF-β1) in diabetic kidney disease (DKD) remains unexplored.

Methods: A type-1 diabetic model was induced by strepotozotocin in TGF-β1 transgenic (Tg) mice that overexpress a human LAP-TGF-β1 in skin. Diabetic kidney injury including fibrosis and inflammation pathways were examined after 16 weeks.

Results: While wild type mice developed progressive DKD as demonstrated by a significant increase in microalbuminuria, renal fibrosis, and inflammation (all p<0.05), unexpectedly, LAP-TGF-β1 Tg mice were protected against DKD as evidenced by the findings that LAP-TGF-β1 Tg mice were able to prevent the development of microalbuminuria (60%↓, p<0.05), renal fibrosis including collagen I, and IV expression, and renal inflammation such as T cell and macrophage accumulation (50-60%↓, p<0.01) and upregulation of TNF-α, IL-1β and ICAM-1 (all p<0.01). Further studies revealed that these inhibitory effects in Tg mice were associated with elevated levels of LAP-TGF-β1, but not active TGF-β1 in the plasma and diseased kidneys (p<0.01), which was associated with upregulation of renal Smad7 (p<0.01), thereby blocking both TGF-β/Smad3 and NF-κB/p65 signaling pathways (all p<0.01). Moreover, we also found that blockade of Th-17-mediated renal injury by inhibiting expression of renal IL-6, Stat3, and IL-17A was another mechanism by which LAP-TGF-β1 Tg mice were protected from diabetic renal injury. Interestingly, all these protective effects of LAP-TGF-β1 on DKD were reversed by blocking LAP-TGF-β with a neutralizing antibody, validating a protective role of LAP-TGF-β1 in DKD.

Conclusions: Mice overexpressing LAP-TGF-β1 in skin are able to protect against DKD. Upregulation of renal Smad7, thereby inhibiting TGF-β/Smad3-mediated renal fibrosis and NF-κB-dependent renal inflammation, and blockade of Th-17 immune response, may be mechanisms whereby LAP-TGF-β1 protects DKD.

Prospective Randomized Trial of Effect of Direct Renin Inhibition in Non-Diabetic Chronic Kidney Disease (DRINK): An Interim Analysis
Sydney C.W. Tang, Desmond Y.H. Yap, Maggie Kam Man Ma, Maggie Ming Yee Mok, Kar Neng Lai. *Department of Medicine, University of Hong Kong, Queen Mary Hospital, Hong Kong, China.*

Background: Aliskiren reduces proteinuria among type 2 diabetics in the AVOID study. However, the ALTITUDE trial has been prematurely terminated on account of increased adverse events at 18-24 months in the aliskiren arm. We report the interim results of the DRINK study initiated in 2009 to investigate the renoprotective potential and safety of aliskiren added to maximum-dose angiotensin receptor blocker (ARB) in non-diabetic CKD stage 3-4 (eGFR 15-59ml/min/1.73 m^2) patients, with a planned follow-up time of 3 years.

Methods: Eligible patients receiving an ARB were randomly assigned aliskiren (150 mg titrated up to 300 mg daily) or conventional antihypertensive treatment to achieve blood pressure under 130/80 mmHg. The primary outcome was the composite of a doubling of baseline serum creatinine (sCr), ESRD or death. Analysis was by intention to treat.

Results: Seventy-six patients were randomized: 37 to aliskiren (27 male, mean age 55.0±11.1 y), and 39 to control (27 male, mean age 55.1±9.4 y). There was no difference in baseline demographics, sCr (194±61 *vs.* 214±65 mmol/l, P=0.15), eGFR (31.9±9.0 *vs.* 28.0±9.0 ml/min/1.73m^2, P=0.06), serum K^+ (4.3±0.5 *vs.* 4.4±0.6 mmol/l, P=0.23) and urine protein-to-creatinine ratio (98.8±19.0 *vs.* 74.4±10.9 mg/mmol, P=0.26) between the treatment *vs*. control group. After a median follow-up of 96 weeks (IQR: 64-112), two patients in each group reached the composite endpoint of doubling of sCr or ESRD (5.4% *vs.* 5.1%, P=0.769). The number of cardiovascular events was 4 (10.8%) *vs.* 1 (2.5%), P=0.217. Hyperkalemia (serum K^+ >5.5 mmol/l) was encountered in 7 (18.9%) *vs.* 2 (5.1%) patients (P=0.045), which was controlled with resin therapy without withdrawing the study medications. There was no difference in the change in proteinuria between the 2 groups.

Conclusions: Our interim results demonstrated no significant increase in adverse events except for more hyperkalemia in aliskiren-treated non-diabetic CKD stage 3-4 patients. The DRINK study will continue as planned. Funding: partially from the Yu Professorship in Nephrology Endowment Fund.

AKB-6548, a New Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitor, Increases Hemoglobin in Chronic Kidney Disease Patients without Increasing Basal Erythropoietin Levels
Robert Shalwitz,[1] Charlotte Hartman,[1] Cindy Flinn,[1] Isaiah Shalwitz,[1] Kevin G. Peters,[1] Anatole Besarab,[2] Volker H. Haase.[3] *[1]Akebia Therapeutics, Inc.; [2]Henry Ford Hospital; [3]Vanderbilt University Medical Center.*

Background: Treatment of anemia associated with chronic kidney disease (CKD) using currently available erythropoiesis-stimulating agents often results in prolonged, supraphysiologic circulating erythropoietin (EPO) levels, which have been implicated in increased thromboembolic events. Therefore, a drug that increases hemoglobin (HGB), while only moderately increasing EPO levels, is highly desirable. AKB-6548, a new, short-acting hypoxia-inducible factor prolyl hydroxylase inhibitor, has been shown to induce such daily rises in EPO levels in patients with CKD in a manner that mimics the physiologic diurnal response in healthy individuals.

Methods: In a double-blind, placebo-controlled Phase 2a trial, 93 patients with CKD stage 3, 4, or 5, not on dialysis, were randomized to receive either placebo or AKB-6548 240 mg, 370 mg, 500 mg, or 630 mg once daily for 6 weeks.

Results: By Week 6, AKB-6548 significantly increased HGB (Figure 1) compared to baseline in all dose groups and compared to placebo (ANOVA, p <0.0001). The increase in HGB occurred without increasing basal (pre-dose measurement) EPO levels. Results at Week 6 also revealed a significant dose-related increase in total iron binding capacity and a decrease in hepcidin, suggesting improved iron mobilization. No drug-related serious adverse events were reported, and dosing was generally well-tolerated.

Conclusions: Thus, AKB-6548 significantly increases HGB in anemic CKD patients by inducing only moderate daily increases in EPO levels in a manner similar to the physiologic diurnal response and by enhancing iron mobilization. Figure 1: HGB: Change from Baseline to Week 6 in the Intent-to-Treat Population.

Fruits and Vegetables or Oral $NaHCO_3$ Preserve GFR and Reduce Urine Angiotensinogen, a Marker of Kidney Angiotensin II Activity, in Stage 3 CKD
Nimrit Goraya,[1,2] Chanhee Jo,[3] Jan Simoni,[4] Donald E. Wesson.[1,2] *[1]Internal Medicine, Texas A&M College of Medicine, Temple, TX; [2]Internal Medicine, Scott & White Healthcare, Temple, TX; [3]Biostatistics, Scott & White Healthcare, Temple, TX; [4]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: KDOQI directs Na^+-based alkali therapy of metabolic acidosis (MA) in CKD patients with plasma total CO_2 ($PTCO_2$) <22 mM and such treatment preserves eGFR. Because MA increases kidney angiotensin II (AII) activity, dietary alkali might preserve eGFR through reduced kidney AII and so treating less severe MA in CKD might also preserve eGFR. Fruits and vegetables (F+V) are also dietary alkali so we explored if added F+V or $NaHCO_3$ reduce kidney AII activity and preserve eGFR in CKD patients with MA and $PTCO_2$ 22-24 mM.

Methods: We randomized 108 subjects with CKD stage 3 eGFR (30-59 ml/min) and $PTCO_2$ >22 but <24 mM as follows: F+V (n=36) added to reduce dietary potential renal acid load (PRAL) 50%, oral $NaHCO_3$ (HCO_3, n=36) to reduce PRAL 50%, or no alkali (Control, n=36). All were treated toward systolic blood pressure (SBP) <130 mmHg with regimens including ACE inhibition and followed 3 years with yearly cystatin C calculated eGFR, $PTCO_2$, and urine angiotensinogen, factored by g creatinine (AGT/cr).

Results: Entry SBP (p=0.12), PRAL (p=0.60), $PTCO_2$ (p=0.62), eFGR (p=0.99), and AGT/cr (p=0.99) were not different among groups. At 3 years, $PTCO_2$ decreased in Control (23.0 to 22.4 mM, p<0.0001) but increased in F+V (23.0 to 23.9 mM, p<0.0001) and HCO_3 (23.1 to 24.0, p<0.0001). At 3 years, AGT/cr increased in Control but decreased in F+V and HCO_3 (all p<0.0001), was lower (p<0.0001) in F+V (32.1 ug/cr) and HCO_3 (32.0 ug/cr) than Control (38.8 ug/cr), but not different between F+V and HCO_3 (p=0.92). At 3 years, Control eGFR (26.6 ml/min) was lower (p<0.0001) than F+V (34.3 ml/min) and HCO_3 (32.7 ml/min) but was not different between F+V and HCO_3 (p=0.34).

Conclusions: F+V or $NaHCO_3$ each reduced a marker of kidney AII activity and preserved eGFR in stage 3 CKD patients with entry $PTCO_2$ 22-24 mM, supporting alkali therapy for CKD patients with MA less severe than that for which KDOQI directs therapy.

FR-OR118

A Crossover Trial of Lowering Dietary Sodium (Na) in Chronic Kidney Disease (CKD)
Rajiv Saran,[1] Robin L. Sands,[1] Brenda W. Gillespie,[1] Michael Heung,[1] Scott L. Hummel,[1] Vimal K. Derebail,[4] Bertram Pitt,[1] Nathan W. Levin,[2] Fansan Zhu,[2] Peter Kotanko,[2] Philip J. Klemmer.[4] *[1]Univ. of MI; [2]RRI; [3]Univ. of NC.*

Background: CKD patients are often volume expanded and hypertensive (HTN). Despite guideline recommendations, few prior controlled studies have assessed the effects of dietary Na restriction on these two factors. We conducted a randomized crossover trial of dietary Na restriction in CKD to assess hydration status measured by bioelectrical impedance spectroscopy (BIS) and 24-hr ambulatory blood pressure (ABP).

Methods: Stable adults with Stage 3-4 CKD were randomized to low Na diet (<2g Na/day) or 'usual diet' for 4 weeks, followed by a 2-week wash-out before the second 4-week phase. Weekly dietary advice using a motivational interviewing technique (MIT) was provided by study dieticians. Dietary Na intake was measured by 24-hour urine Na. BIS measurements included calf, whole body (WB) and segmental readings using a Hydra 4200. T-tests for crossover studies analyzed treatment and period effects.

Results: 58 subjects were enrolled (mean age 61±13, 60% male, 71% white, 43% diabetic, 93% HTN, mean BMI 32kg/m^2, eGFR 39ml/min/1.73m^2, 24-hr urine Na 171mmol/d and 24-hr systolic ABP 138mmHg). Baseline BIS measurements were not significantly different across CKD stage suggesting equivalent fluid status. WB extracellular volume decreased significantly on average by 0.9L in the low Na phase and calf normalized resistivity increased by 0.01 Ω m^3/kg, both implying lowered water content ($p<0.01$). On average, there were significant reductions in 24-hr urinary Na (52mmol/d), weight (2.2kg), and 24-hr systolic ABP (11.3mmHg) during the low Na diet phase (all $p<0.005$). Albuminuria was not statistically lower in the low Na group (mean change=0.07mmol). Mean serum creatinine rose by 0.13mg/dL ($p=0.04$) in the low Na group. No period effects were observed.

Conclusions: Low Na dietary intervention with MIT significantly reduced ABP and measures of volume expansion in CKD Stage 3-4 patients in this short-term crossover trial. This simple intervention may be similar in effect to a single antihypertensive agent and merits more formal study on a larger scale to assess its effect on outcomes.

FR-OR119

Specialised Renal Care in Patients with CKD Stage IIIb-IV: Does It Impact on Mortality and Emergency Hospitalisation? Patrick Saudan, Nicola Marangon, Sophie M. De Seigneux, Belen Ponte, Pierre-Yves F. Martin. *Nephrology, Geneva University Hospitals, Geneva, Switzerland.*

Background: Long-term prognosis of patients with CKD is poor and there is a need for the development and implementation of new strategies through collaboration between primary care physicians (PCP) and nephrologists. We undertook a prospective randomised trial to determine the impact of regular renal care compared to guidelines-directed management by primary care physicians (PCP) on prognosis, planning of RRT and patient satisfaction in CKD patients.

Methods: Single center prospective randomised study. Inclusion criteria: CKD patients with an eGFR< 45 ml/min and > 15 ml/mn, aged 18-80 years old and enrolled during a hospitalization. Exclusion criteria: AKI or ESRD, estimated life expectancy < 2 yrs, refusal or inability to sign writing consent and patients previously known by nephrologists. The primary composite endpoint is death and/or hospitalisation during the 24 months after inclusion. The secondary endpoints are urgent RRT, decline of renal function and quality of life. Study design: Patients are randomised in two arms: -Combined management PCP and nephrologists (4 nephrology visits/year) -Management by PCPs with the help of written instructions and consultations being provided by our unit if requested by PCPs.

Results: The study began in November 2009. At the end of April 2012, 194 patients have been randomised, of whom 68% are male and 40% diabetics type II. Mean age is 69 ± 9 yrs, mean baseline eGFR is 33 ± 9 ml/min, mean 24-hr proteinuria is 1.24 ±1.9 g/24h. At the end of April 2012 (mean follow-up is 18 ± 9 months), 60% of the patients in the combined management group have reached the primary endpoint vs 55% in the PCP management group. Mean follow-up is 18 ± 9 months. Mortality rose to 11 % in the combined management group vs 15 % in the PCP management group. Free time interval until next hospitalisation is 313 ±280 days in the combined management group vs 304 ±256 in the PCP management group.

Conclusions: These short-term preliminary results do not demonstrate a benefit of regular renal care in terms of survival or rehospitalisation rate in patients with CKD stage IIIb-IV.ClinicalTrials.gov**:** NCT00929760.

FR-OR120

Is Time-Updated Blood Pressure Related to End-Stage Renal Disease in the Setting of Chronic Kidney Disease after Accounting for Kidney Function over Time? Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study Amanda Hyre Anderson,[1,2] Wei (Peter) Yang,[1,2] Raymond R. Townsend,[1,2] Glenn M. Chertow,[1] Jiang He,[1] Radhakrishna Reddy Kallem,[1,2] John W. Kusek,[1] James P. Lash,[1] Edgar R. Miller,[1] Mahboob Rahman,[1] Susan P. Steigerwalt,[1] Matthew R. Weir,[1] Jackson T. Wright,[1] Harold I. Feldman.[1,2] *[1]Chronic Renal Insufficiency Cohort (CRIC) Study; [2]University of Pennsylvania Perelman School of Medicine.*

Background: Blood pressure (BP) is frequently inadequately controlled in chronic kidney disease (CKD) patients. Previous reports of the longitudinal relationship between BP and end-stage renal disease (ESRD) often relied solely on baseline measures of BP and kidney function, and those with updated information may have inadvertently adjusted for pathway effects.

Methods: Data from CRIC Study participants (N=3,817, follow-up: 4 yrs) were used in a marginal structural model to assess time-updated BP exposure on the risk of ESRD with proper adjustment for time-dependent confounding. The time-updated BP exposure was characterized as mean systolic BP (SBP), % time with BP uncontrolled (≥130 and ≥120 mmHg), and mean SBP variability (SBPVar).

Results: In separate models, mean SBP, % time with BP ≥130 or ≥120 mmHg, and mean SBPVar each significantly increased risk for ESRD after adjustment for demographics, co-morbidities, and time-updated kidney function and antihypertensive medication use. In a model including both SBP and SBPVar, mean SBP retained significance (HR, 95% CI: 1.40, 1.27-1.55) but SBPVar did not (1.12, 0.97-1.30). The interaction between mean SBP and urine protein excretion was of borderline significance (P=0.07) with the BP association attenuated among those with higher levels of proteinuria.

	Adjusted HR (95% CI)
Mean SBP, per 10mmHg increase	1.38 (1.28-1.49)
% time SBP ≥130 mmHg, per 10% increase	1.11 (1.06-1.16)
% time SBP ≥120 mmHg, per 10% increase	1.12 (1.06-1.19)
Mean SBPVar, per 10 mmHg change	1.33 (1.21-1.47)

Conclusions: After accounting for time-updated kidney function and antihypertensive medication use, the relationship between BP and ESRD was robust and consistent with prior studies. Modification of this relationship by proteinuria requires further study.

Risk of Hypoglycemic Episodes among Diabetic Patients with Chronic Kidney Disease (CKD) Bessie A. Young,[1,2,3] Luis A. Bent-Shaw,[2,3] Margaret K. Yu.[2,3] *[1]Veterans Affairs Puget Sound Health Care System, Seattle Epidemiology Research and Information Center, Seattle, WA; [2]Kidney Research Institute, University of Washington, Seattle, WA; [3]Division of Nephrology, University of Washington, Seattle, WA.*

Background: Intense glycemic control is one of the cornerstones of diabetes care and has been shown to improve both microvascular and macrovascular events. Hypoglycemia is a known complication of more intensive glycemic control in patients and has been associated with increased risk of mortality Less is known regarding risk of severe hypoglycemic reactions requiring hospitalizations. We hypothesize that patients with diabetes and CKD will haveincreased risk of severe hypoglycemic episodes requiring hospitalization over time, which will increase depending on stage of kidney function.

Methods: We analyzed the incidence of severe hypoglycemic reactions requiring hospitalization among a primary care cohort with diabetes followed longitudinally as part of the Pathways to Health Study. All patients who completed baseline surveys and had laboratory tests available to assess eGFR were analyzed. The primary outcomes of interest was severe hypoglycemic reactions requiring emergency room visit or hospitalization identified by ICD-9 code over 5 years of follow up.

Results: 3943 subjects were identified at baseline with stage 0-5 CKD, of whom 1227 were found to have an eGFR<60ml/min/1.73m^2. The mean age was 70.7, 83.8% were white, 7.2% African American and 6.5% Asian. Over a 5 year period, 240 episodes of severe hypoglycemia were identified. Cox proportional hazards models found that CKD stages 3 (Hr=2.2, 95% CI1.22-4.10), stage 4 (HR=3.45, 95% CI=1.65-7.23), and stage 5 (HR=4.34, 95% CI=2.07-9.00)were associated with greater risk of severe hypoglycemic reaction compared to stage 0 CKD after adjusting for age, gender, race, type of diabetes, insulin use, oral hypoglycemic agent, and ace-inhibitor. Other risk factors included depression, insulin use, and type 1 diabetes.

Conclusions: Patients with diabetes are at greatly increased risk of severe hypoglycemic episodes. Patients with latter stage CKD and diabetes should be closely managed to avoid severe hypoglycemic reactions.

FR-OR122

Do the Associations of eGFR and Albuminuria with Mortality and Renal Failure Differ by Gender? A Meta-Analysis from a Global Consortium (for the CKD-PC Collaborators) Dorothea Nitsch, M. Grams, Yingying Sang, Corri Black, Massimo Cirillo, Ognjenka Djurdjev, Kunitoshi Iseki, Simerjot K. Jassal, Heejin Kimm, Florian Kronenberg, Cecilia Montgomery Øien, Andrew S. Levey, Adeera Levin, Mark Woodward, Brenda Hemmelgarn. *CKD Prognosis Consortium.*

Background: There is substantial clinical uncertainty whether the associations of chronic kidney disease (CKD) with mortality and end-stage renal disease (ESRD) differ between men and women.

Methods: We assessed the presence of a gender interaction in the associations of estimated glomerular filtration rate (eGFR) and albuminuria with all-cause mortality, cardiovascular mortality and ESRD in 2,051,158 participants (54% women) from general population (n=1,861,052), cardiovascular high-risk (n=151,494), and CKD (n=38,612) cohorts. We used random-effects meta-analysis using pooled individual participant data.

Results: All-cause and cardiovascular mortality risk was higher in men at all levels of eGFR and ACR. While higher risk was associated with lower eGFR and higher ACR in both genders, the risk relationship for all-cause and cardiovascular mortality was steeper in women than in men. Compared with eGFR 95, the adjusted hazard ratio (HR) for all-cause mortality at eGFR 45 was 1.32 (95% CI, 1.08 to 1.61) in women and 1.22 (CI, 1.00 to 1.48) in men (p for interaction<0.001). Compared with ACR 5, the HR for all-cause mortality at ACR 30 was 1.69 (CI, 1.54 to 1.84) in women and 1.43 (CI, 1.31 to 1.57) in men (p for interaction=0.005). Conversely, there was no evidence of a gender difference in associations of eGFR and ACR with ESRD risk.

Conclusions: While both genders face increased risk of all-cause and cardiovascular mortality and ESRD with lower eGFR and higher albuminuria, the relative mortality risk in women increases more steeply with diminished kidney function. These findings were robust across a large global consortium.

VALIGA: Preliminary Clinical Results from the European Collaborative Database of 1178 IgA Patients Designed to Validate the Oxford Classification

Rosanna Coppo, Stephan Troyanov, Daniel C. Cattran, John Feehally, H. Terence Cook, Ian Roberts, Laura Morando, Shubha Bellur, Roberta Camilla. *Immunonephrology Working Group, ERA-EDTA, Italy.*

Background: The independent prognostic value of renal biopsy features in patients with IgA Nephropathy (IgAN) was established by the Oxford Classification from 265 patients and deserves validation.

Methods: The ERA-EDTA Immunonephrology Working Group sponsored in 2009 the European Validation Study (VALIGA), which enrolled 1178 IgAN patients from 55 centers of 13 countries. The clinical data collection at renal biopsy and during follow-up has been completed and dual review of biopsies according to the Oxford criteria will be available by August 2012. We report here the VALIGA clinical risk factors for progression.

Results: 1178 IgAN patients aged 36±16 years, 73% M, eGFR 75±34ml/min, proteinuria (UP) 1.27 (IQ 0.57-2.6) g/day, mean BP (MAP) 98±13mmHg. Mean follow-up 5.8 years ± 4.5, loss of e-GFR (slope) of -2.0±8.1 ml/min/year. ESRD developed in 141 cases (12%), 50% loss of e-GFR in 171 (15%) and combined end point in 195 (16.5%). Initial UP, e-GFR and MAP and follow-up UP and MAP were strongly correlated by multivariate analysis with 50% loss of eGFR or combined end points, and slope of e-GFR (all P<0.0001). The predictive value of follow-up proteinuria was the strongest predictor. Assuming the end point of 50% reduction in eGFR, ROC analysis indicated the best cut-off value for UP was 0.96 g/day (sensitivity 91%, specificity 64%, AUC 0.85) versus for follow-up BP the best MAP was 98 mmHg (sensibility 67%, sensitivity 67%, AUC 0.74).

Conclusions: The clinical data from the 1178 IgAN European cohort (VALIGA) has validated the relevance of the definition of partial remission (persistent proteinuria < 1 g/day) as the major risk factor for preventing progression.

FR-OR124

Impacts of Tonsillectomy Plus Steroid Pulse Therapy on IgA Nephropathy Depending on Histological Classification: A Multicenter Cohort Study

Tetsu Miyamoto,[1] Tomoya Nishino,[2] Takeshi Nakata,[3] Yuji Sato,[4] Hideyuki Arai,[2] Kaede Ishida,[3] Nana Ishimatsu,[1] Hiroyuki Komatsu,[4] Masanobu Miyazaki,[5] Tadashi Tomo,[3] Masahito Tamura,[1] Shouichi Fujimoto.[4] *[1]University of Occupational and Environmental Health; [2]Nagasaki University School of Medicine; [3]Oita University School of Medicine; [4]Miyazaki University School of Medicine; [5]Miyazaki Naika Clinic.*

Background: Besides corticosteroids and RAS inhibitors, tonsillectomy may have a beneficial impact on the clinical course of IgA nephropathy (IgAN). However, much uncertainty remains about the indications for and protocols of therapeutic options for IgAN.

Methods: We enrolled 334 patients with biopsy-proven IgAN diagnosed between 2000 and 2010 at four centers. Baseline characteristics at biopsy were analyzed in relation to clinical remission. The impact of treatment was evaluated after a median follow up of 4.1(1.5-8.6) years according to histological grade of the lesions and in line with the guidelines of the Study Group on Progressive Glomerular Disease in Japan. Clinical remission was defined as disappearance of both proteinuria and hematuria.

Results: During the follow-up period, 151 patients(46%) achieved clinical remission with a median time-to-remission of 382 days. Patients reaching remission had younger age(p=0.008), lower incidence of hypertension(p=0.01), higher levels of albumin(p=0.04) and eGFR(p=0.003), and lower levels of triglyceride(p=0.002). Multivariate logistic regression analysis found that tonsillectomy plus steroid pulse therapy independently contributed to achieving remission only in the histological grade 3 group with glomerulosclerosis, crescent formation or adhesion to Bowman's capsule in 10–30% of all biopsied glomeruli, or mild cellular infiltration in the interstitium(OR 2.4, 95%CI 1.2–5.0, p=0.02). In patients reaching remission, the patients with tonsillectomy had shorter time-to-remission compared to patients without tonsillectomy[365(62–1447) days vs 579(22–2304) days, p=0.03].

Conclusions: The combination therapy of tonsillectomy and steroid pulse for IgAN may have a beneficial impact on the clinical course for patients with mild to moderate glomerular and interstitial lesions.

FR-OR125

A Pilot Study to Determine Dose, Effectiveness and Depletion of Anti-PLA2R Antibodies of Adrenocorticotrophic Hormone (ACTH Acthar® Gel) in Subjects with Nephrotic Syndrome and Idiopathic Membranous Nephropathy (iMN)

Michelle A. Hladunewich,[1] Fernando C. Fervenza,[2] Laurence H. Beck,[3] Heather N. Reich,[1] Sanjeev Sethi,[2] Maria V. Irazabal,[2] Alfonso Eirin,[2] Rivka Ayalon,[3] Daniel C. Cattran.[1] *[1]University of Toronto, Toronto, ON, Canada; [2]Mayo Clinic, Rochester, MN; [3]Boston University School of Medicine, Boston, MA.*

Background: H.P. Acthar® Gel is obtained from porcine pituitary. Active ingredients include structurally related peptides such as ACTH and the melanocyte stimulating hormones, which bind to melanocortin receptors (MCRs) expressed in glomerular podocytes reducing oxidative stress, diminishing podocyte apoptosis, and podocyte loss in kidney injury models. We hypothesized that H.P. Acthar® Gel would induce remission of proteinuria in patients with iMN.

Methods: Twenty patients were randomized to receive either 40 or 80 IU SQ twice weekly for 120 day with a total follow-up period of one year (final follow-up still pending in 2 patients). Proteinuria, albumin, cholesterol profile, changes in eGFR and anti-PLA2R antibodies along with tolerance and safety were assessed.

Results: Baseline characteristics were median proteinuria of 7802 (5665-10092) mg/24h, albumin of 2.7±8 g/dL, total cholesterol of 7.9±3.5 mmol/L and eGFR of 81±25 ml/min. The use of Acthar® Gel resulted in a significant reduction in median proteinuria to 2025(951-5140) mg/24h (p<0.001) along with improvements in both albumin and total cholesterol levels. At last follow-up, 60% of the patients had > 50% decrease in proteinuria. The majority of the patients did not respond to the 40 IU dose. No significant change in eGFR was noted over the period of follow-up nor were then any significant adverse side effects. Anti-APLA2R antibodies were present in 15/20 patients at baseline with decreased or increased levels noted prior to improvements or worsening of proteinuria, respectively.

Conclusions: H.P. Acthar® Gel is a safe and well-tolerated potential therapy to induce remission of proteinuria in patients with iMN. A dose of at least 80 IU units SQ twice weekly appears necessary for maximal effect. Anti-APLA2R levels may assist with prediction of response to therapy.

FR-OR126

Long Term Outcomes of a Restrictive Treatment Regimen in Idiopathic Membranous Nephropathy

Jan A.J.G. van den Brand,[1] Peter R. Van Dijk,[2] Julia M. Hofstra,[1] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Medical Centre, Nijmegen, Netherlands; [2]Diabetes Centre, Isala Clinics, Zwolle, Netherlands.*

Background: We present the long term disease course and outcomes of patients with biopsy proven membranous nephropathy (MN) who were treated according to a restrictive treatment regimen that was initiated in 1995.

Methods: We prospectively evaluated 269 patients. Progression risk was estimated using low-molecular weight protein excretion. Subsequently, intensive ACEi/ARB and statin treatment was advised for low risk patients with well preserved kidney function, whereas immunosuppressive therapy, mostly with alkylating agents, was given to patients at high risk for disease progression as soon as kidney function deteriorated. We gathered follow-up data on treatment, outcomes and adverse events from medical records, and used Kaplan-Meier estimates to calculate five and ten year cumulative incidence rates of outcomes.

Results: The table shows characteristics and disease course for the cohort, which was followed for a median 6.1 (IQR 3.3 to 10.3) years.

Biopsy variables	**total cohort**
n (% male)	269 (70%)
age	52 (14.9)
year of biopsy	2000 (7.0)
eGFR	68 (24)
proteinuria	7.0 (4.6)
Therapies	
none	142 (53%)
cyclophophamide	116 (43%)
other	11 (4%)
Outcomes	
remission of proteinuria	147 / 203 (72%)
relapse of proteinuria	47 / 147 (32%)
doubling of serum creatinine	37 / 235 (16%)
end stage renal disease	12 (4%)
Adverse events	
death	9 (3%)
malignancy	20 (7%)
cardiovascular and thrombotic events	27 (10%)
leucopenia	48 (18%)
infection	53 (20%)

data are presented as mean (SD) or percentages

The restrictive treatment strategy resulted in 127 (46%) patients receiving immunosuppressive therapy. Five year cumulative incidence rates of remission, end stage renal disease and death were 68%, 3.2% and 1.8%, respectively. In addition, respective ten year incidence rates were 75%, 4.5% and 3.6%.

Conclusions: A restrictive therapeutic regimen leads to favorable long term outcomes in iMN, whilst limiting exposure to potentially hazardous immunosuppressive drugs. The high incidence of adverse events such as cardiovascular complications and infections necessitates a search for less harmfull therapies.

Prophylactic Anticoagulation in Membranous Nephropathy: A Decision Analysis

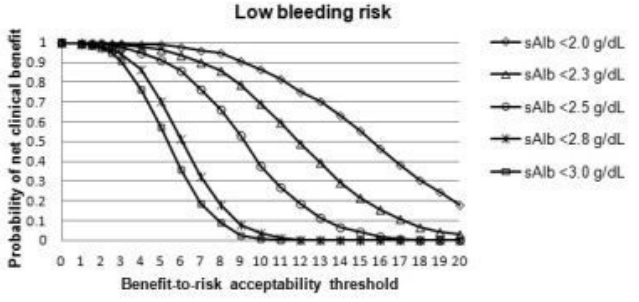
Taewoo Lee,[1] Andrea K. Biddle,[3] Sean Barbour,[2] Sophia Lionaki,[1] Yichun Hu,[1] Vimal K. Derebail,[1] Michelle A. Hladunewich,[2] Caroline Jennette Poulton,[1] Shannon L. Mahoney,[1] Susan L. Hogan,[1] Shannon L. Mahoney,[1] Ronald J. Falk,[1] Daniel C. Cattran,[2] Heather N. Reich,[2] Patrick H. Nachman.[1] *[1]UNC Kidney Center, University of North Carolina, Chapel Hill, NC; [2]Division of Nephrology, University of Toronto, Toronto, ON, Canada; [3]Health Policy and Management, School of Public Health, University of North Carolina, Chapel Hill, NC.*

Background: In membranous nephropathy, the risk of venous thromboembolic events (VTE) is inversely correlated to serum albumin level (sAlb). This study estimates the benefit of prophylactic anticoagulation (VTEs prevented) relative to the risk (bleeds incurred) by sAlb level.

Methods: A hybrid Markov-decision tree model was constructed to compare anticoagulation to observation. The risk of VTE was obtained from a cohort of 539 patients. The categorized (low, intermediate, high) risk estimates of bleeding were obtained from the ATRIA study (J Am Col Cardiol 58:395). The benefit-to-risk ratios were calculated by bleeding risk category. We used probabilistic sensitivity analyses to estimate effects of parameter uncertainty.

Results: For patients at low bleeding risk, the base-case model predicts a benefit-to-risk ratio of 4.5:1 and 13:1 for sAlb <3.0 g/dL and <2.0 g/dL respectively. With intermediate or high bleeding risk, the ratios are 3.9:1 and 1.8:1 for sAlb < 2.0 g/dL. In probabilistic sensitivity analysis, patients at intermediate or high risk are unlikely to benefit from anticoagulation whereas those at low risk are likely to benefit with a benefit-to-risk ratio of 5:1 and 10:1 for sAlb <2.5 g/dL and <2.0g/dL.

Conclusions: The decision for anticoagulation should begin with assessing a patient's bleeding risk. We provide a tool to estimate the likelihood of benefit based on sAlb level and acceptable benefit-to-risk ratio.



FR-OR128

An Effective Regime for Prevention of Venous Thromboembolism in Nephrotic Syndrome Nicholas R. Medjeral-Thomas, Stela Ziaj, Jack Galliford, Jeremy B. Levy, Tom Cairns, Megan Griffith. *West London Renal and Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Venous thromboembolism (VTE) occurs in 7-40% of nephrotic patients. The severity and underlying cause of nephrotic syndrome (NS) influence the VTE risk. This study investigates the use of low dose prophylactic anticoagulation to prevent VTE in patients (pts) with NS caused by primary glomerulonephritis (GN).

Methods: Pts presenting with NS secondary to primary membranous GN (MGN), minimal change GN (MinGN) and focal segmental glomerulosclerosis (FSGS) from September 2006 to September 2011 were considered for the study. Pts already taking anticoagulation for a pre-existing condition were excluded. Pts with serum albumin <20g/L received prophylactic dose low molecular weight heparin or low dose coumarin; pts with albumins 20–30g/L received aspirin or clopidogrel 75mg once daily. All thrombotic events and bleeding complications were recorded.

Results: 162 pts were identified (65 MGN, 49 Min GN, 48 FSGS). Mean follow-up was 168 weeks (range 38-307). Initial mean serum albumin was 14.5 g/L (range 5-29) and UPCR was 1365 units (range 255-14000). 11/162 pts were diagnosed with VTE at presentation and were treated following local VTE guidelines. 151 pts received prophylactic anticoagulation. 4/151 pts subsequently developed VTE. Only 1/4 was taking the prophylaxis at the time of VTE (6 days after diagnosis and commencement of prophylaxis). 1 pt had VTE when the prophylaxis was stopped pending biopsy. 2 pts had stopped prophylaxis as their NS was in remission; 1 relapsed with NS and presented with VTE prior to anticoagulation being restarted; 1 developed VTE when not nephrotic, but had a prior history of DVT 3 years before. 3/151 pts on prophylactic anticoagulation were admitted with a gastrointestinal bleed requiring transfusion. 1/3 was also taking steroids for the underlying GN at the time of the bleed.

Conclusions: This regime of prophylactic anticoagulation appears relatively safe and effective in preventing VTE in NS. Care must be taken when stopping the anticoagulation peri-procedure, and in patients in remission likely to relapse or with a history of DVT.

FR-OR129

Role for miR-30 in Podocytes and Its Clinical Relevance Junnan Wu, Chun-xia Zheng, Wanfen Zhang, Changming Zhang, Zhao-hong Chen, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu, China.*

Background: miRNAs are essential for glomerular podocyte homeostasis as shown by selective Dicer deletion in mouse podocytes, and miR-30 family has been suggested to be a player as evidenced by its anti-apoptotic effect in podocytes in vitro. Here, we explored the clinical relevance of miR-30, and further define its actions in podocytes.

Methods: Glomeruli were microdissected from renal biopsies, and subjected to RNA preparation and qRT-PCR of miR-30. miR-30 levels were correlated with proteinuria remission of the patients. Conditionally-immortalized human podocyte cell line was used for in vitro studies. Podocyte injury was evaluated by apoptosis, cytoskeletal alteration and injury markers. The expressions of miR-30 targets were examined by western blotting.

Results: miR-30 members were abundantly expressed in podocytes of glomeruli, but all downregulated in patients of FSGS and MN. Glomerular miR-30 levels of FSGS patients positively correlated with proteinuria remission. In vitro, human podocytes were treated with TGF-β, LPS and PAN, and miR-30 members were found all downregulated. When exogenous miR-30 was expressed to sustain miR-30 level of the podocytes in the treatment, both apoptosis and cytoskeletal damage were significantly ameliorated. We further show that miR-30 exerted its protective role, at least partly, through inhibition of its targets, Notch1 and p53. Lastly, we show glucocorticosteroid prevented TGF-β and LPS-induced miR-30 downregulation in podocytes, accompanied with prevention of upregulation of proapoptotic p53, Bax and Notch1, and restoration of anti-apoptotic Bcl2 and CD2AP expression.

Conclusions: miR-30 protects podocytes, at least partly, through inhibiting its targets, Notch1 and p53, two known culprits in podocyte injury. Downregulation of miR-30 causes podocytes vunerable to injury. miR-30 expression appears to have a signficant clinical relevance as shown by its downregulation in podocytes of patients, its correlation with proteinuria, its restoration by glucocorticosteroid in vitro. Thus, miR-30 family is a promising therapeutic target for glomerular disease.

Plasma Soluble Urokinase Receptor Levels Were Elevated in Patients with Primary Focal Segmental Glomerulosclerosis and Were Associated with Renal Damage Gang Liu, Jing Huang, Ming Hui Zhao. *Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China.*

Background: To detect the plasma soluble urokinase receptor (suPAR) levels of patients with primary focal segmental glomerulosclerosis (FSGS) and investigate their associations with clinical and pathological data.

Methods: Sixty-eightpatients with primary FSGS, diagnosed between Jan 2006 and Aug 2011, with complete clinical and pathologic data were enrolled. Healthy donors and patients with minimal change disease (MCD), membranous nephropathy (MN), secondary FSGS (s-FSGS) were used as controls. Plasma suPAR was measured using commercial ELISA kits.

Results: The plasma suPAR levels of patients with primary FSGS (3676.4± 2241.3 pg/ml) were significantly higher than that of patients with MCD (2024.7± 378.4 pg/ml, $P<0.001$), MN (2092.5± 874.7 pg/ml, $P<0.001$), and normal subjects (1787.2± 455.9 pg/ml, $P<0.001$) respectively. The plasma suPAR levels were also higher than that of patients with s-FSGS (2597.9± 695.4 pg/ml, $P=0.181$), though it did not have statistical differences. The mean plasma suPAR levels increased in the order of tip variant to not otherwise specified variant to cellular variant (2925.5± 1704.4 pg/ml, 3838.7± 2099.8 pg/ml, and 4179.9± 2475.2 pg/ml, respectively).The plasma suPAR level was negatively correlated with creatinine clearance at presentation (r=-0.454, $P=0.001$) and positively correlated with the percentage of glomerular crescents (r=0.303, $P=0.012$). During follow-up, we collected plasma samples of 16 patients with therapeutic responses. The plasma suPAR level of 7 patients with complete remission decreased substantially (4778.9± 3326.7 pg/ml vs. 2845.3± 935.4 pg/ml, $P=0.128$), for 4 patients with partial remission, it was comparable (2340.3± 239.3 pg/ml vs. 2055.2± 385.9 pg/ml, $P=0.273$), however, for 5 patients with treatment failure, it was even increased (3180.9± 757.4 pg/ml vs. 4360.6± 1573.2 pg/ml, $P=0.080$).

Conclusions: Plasma suPAR levels were specifically elevated in patients with primary FSGS and might be associated with severe renal damage. The plasma suPAR might be helpful to differentiate primary FSGS from MCD and certain s-FSGS.

Urinary Excretion of Vitamin D Binding Protein Is Markedly Increased in Focal Segmental Glomerulosclerosis versus Minimal Change Nephrotic Syndrome Michael R. Bennett, Hermine Brunner, Prasad Devarajan. *Cincinnati Children's.*

Background: Idiopathic nephrotic syndrome (NS) is the most common glomerular disorder of childhood. Pathology on invasive biopsy, including minimal change disease and focal segmental glomerulosclerosis (FSGS), remains the diagnostic method of choice for NS. Vitamin D deficiency is a common complication of chronic kidney disease. This is thought to occur due to loss of functioning 25-OH-D-1a-hydroxylase in the proximal tubules as well as through urinary loss of vitamin D binding protein (VDBP), the main carrier of vitamin D in the blood. Due to the prolonged and persistent proteinuria in FSGS, it is likely that vitamin D binding protein is excreted to a greater degree than in MCD. If VDBP is higher in FSGS, this could serve both as a non-invasive biomarker for diagnosis of NS as well as a possible therapeutic target. We set out to determine if urinary VDBP levels were elevated in FSGS vs MCD.

Methods: Urine and clinical data were collected from patients at Cincinnati Children's Hospital recently diagnosed with active nephrotic syndrome as well as healthy controls. Patients with a history of gross hematuria, active/recurrent UTI or nephrotic syndrome secondary to systemic disease were excluded from the study. Urinary VDBP measurements were performed with a commercially available ELISA kit and normalized to urine creatinine.

Results: This study included subjects in three groups: biopsy-proven FSGS (n=15), presumed MCD (n=12), and normal controls (n=5). Median VDBP levels were calculated and subjected to Mann-Whitney Rank Sum analysis. VDBP was significantly higher ($p<0.001$) in FSGS (14526 ng/ml, IQR 976-45541) than both MCD (85 ng/ml, IQR 15-274) and healthy controls (23 ng/ml, IQR 22-99, $p=0.002$). Results did not change with NGAL corrected for urine creatinine.

Conclusions: Urinary excretion of VDBP was markedly elevated in FSGS vs. both MCD and healthy controls. The massive loss of VDBP in FSGS could potentially result in greater vitamin D deficiency in patients with FSGS vs MCD. VDBP could serve as both

a target for therapy in FSGS as well as a non-invasive biomarker that could distinguish FSGS, which is associated with poor prognosis, from the more benign MCD.

Clinicopathological Features and Predictors of Outcome in C3 Glomerulopathy Michelle M. O'Shaughnessy,[1] John O'Regan,[1] Limy Wong,[1] Carol A. Traynor,[1] Michael James Flanagan,[1] Anthony M. Dorman,[1] Chia Wei Teoh,[2] Nicholas R. Medjeral-Thomas,[3] Matthew C. Pickering,[3] H. Terence Cook,[3] Peter J. Conlon.[1] *[1]Nephrology, Beaumont Hospital, Dublin, Ireland; [2]Nephrology, Children's University Hospital, Temple Street, Dublin, Ireland; [3]Centre for Complement and Inflammation Research, Imperial College London, London, United Kingdom.*

Background: Dysregulation of the alternative complement pathway can result in a variety of forms of glomerular injury, collectively termed C3 glomerulopathy (C3G). Light microscopic (LM) and electron microscopic (EM) appearances are heterogeneous. Diagnosis relies upon identification of isolated deposits of C3 without immunoglobulin on immunofluorescence (IF). Differences in pathophysiology, clinical phenotype and renal outcomes between patients with dense deposit disease (DDD) and other forms of C3G are largely unknown.

Methods: All native renal biopsies (n=4,554) referred to a single pathology service from 1995 to 2011 were retrospectively reviewed. Cases satisfying pathological criteria for a diagnosis of C3G, as determined by two independent renal pathologists, were included. Demographic, clinical and laboratory data were obtained. Patients with and without DDD were compared.

Results: Sixty-five patients were identified (13 DDD, 52 non-DDD): 36 male, 29 children. At presentation, 46% had a creatinine >1.5mg/dL, 44% had nephrotic syndrome, 93% had hematuria. Membranoproliferative glomerulonephritis (GN) (n=26) and diffuse proliferative GN (n=22) were prevalent on LM. DDD and non-DDD groups had similar baseline clinical characteristics. Low serum C3 was more common in the DDD group (100% vs. 55%, p=0.017). At last follow-up, 67% of DDD and 24% of non-DDD patients had reached end-stage kidney disease (ESKD). By multivariate Cox regression analysis, DDD was the only independent predictor of ESKD (HR 8.34, 95% CI 1.98 to 35.20, p=0.004).

Conclusions: We have described the clinical phenotype and renal outcomes of 65 patients with C3G. We have demonstrated that DDD on EM may portend a particularly poor prognosis in this population cohort. We plan to investigate these patients for acquired and genetic defects in alternative complement pathway regulation.

FR-OR133

SYK Inhibition Reduces Autoantibody Production and Abrogates Crescentic Glomerulonephritis (cGN) and Lung Haemorrhage (LH) in Experimental Autoimmune Glomerulonephritis (EAG) Stephen Paul McAdoo,[1] John Reynolds,[1] Jennifer Smith,[1] Gurjeet Bhangal,[1] Esteban S. Masuda,[2] H. Terence Cook,[1] Charles D. Pusey,[1] Frederick W.K. Tam.[1] *[1]Imperial College London, United Kingdom; [2]Rigel Pharmaceuticals.*

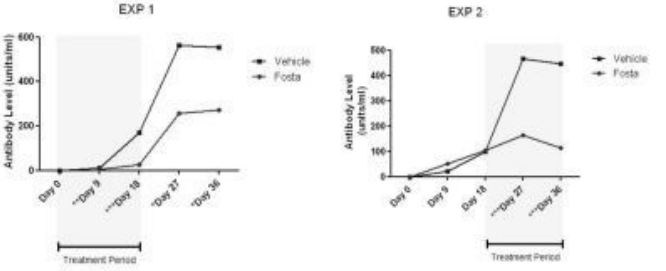
Background: SYK is a critical component of FcR and BCR signaling pathways. SYK inhibition with Fostamatinib (Fosta) prevents immune-mediated injury in several animal models, including rat nephrotoxic nephritis. The effect of SYK inhibition on other models of GN is not known, nor is the effect of SYK inhibition on autoantibody (autoAb) production in any experimental model clearly defined. This study aimed to address these questions in EAG.

Methods: In EAG, rats immunized with rat GBM antigen (α3) at day 0 develop autoAb to α3 and cGN with proteinuria by day 18, and have LH at day 36. In study 1, animals (n=8/group) received either Fosta 40mg/kg or Vehicle (Veh) by twice daily gavage from day 0-18, in order to examine the effects of SYK inhibition on induction of autoimmunity. In study 2, animals received Fosta or Veh from day 18-36, to study the effects of treatment on established disease. In both studies, animals were monitored until Day 36.

Results: Expressed as mean/group at Day 36:

	EXP 1			EXP 2		
	Veh	Fosta	Reduction	Veh	Fosta	Reduction
Proteinuria (mg/day)	172	96	41%*	118	2	98%†
Haematuria (cell/ul)	139	34	75%*	200	0	100%†
Crescentic Glom (%)	74	41	45%†	70.5	1.5	98%†
Macrophage/ Glom (Score)	10.5	12.6	NS	9.8	0.2	99%†
LH Score	2	0.85	58%*	1.75	0	100%†

*=p<0.05;† =p<0.01; NS=not significant



Conclusions: SYK inhibition reverses cGN and prevents LH in EAG. This effect appears to be mediated by inhibiting both the induction of humoral autoimmunity and the effector phase of the immune response. We believe this is the first report that SYK inhibition reduces autoAb production in a genuine model of autoimmunity. The results augur well for use of SYK inhibition in human renal disease.

MicroRNA-155 Drives Th17 Immune Response and Tissue Injury in Experimental Crescentic Glomerulonephritis Christian Krebs, Sonja Kapffer, Hans-Joachim Paust, Tilman Schmidt, Sabrina Bianca Bennstein, Anett Peters, Gesa Stege, Silke R. Brix, Oliver M. Steinmetz, Rolf A. Stahl, Ulf Panzer. *Nephrology, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: IL-17-producing $CD4^+$ Th17 cells play a pivotal role in the pathogenesis of autoimmune diseases, including human crescentic glomerulonephritis and its murine model, nephrotoxic nephritis. MicroRNAs (miRNAs) have emerged as important regulators of immune cell function, however, the impact of miRNAs in the regulation of Th17 immunity remains to be fully elucidated.

Methods: MicroRNA expression was quantified in the course of NTN by qRT-PCR in mice. NTN was induced in Mir-155-deficient and in wildtype mice. Th17 responses were quantified by intracellular cytokine staining and FACS analysis as well as by renal IL-17 expression and IL-17 ELISA of splenocyte cultures. Mir-155-deficient and wildtype $CD4^+$ cells were transferred into Rag1-deficient mice. MiRNA expression was quantified in renal tissue of patients with crescentic GN by array analysis (Affimetix) and by qPCR.

Results: Here we report that upregulation of microRNA-155 (miR-155) in the spleen preceded renal Th17 cell infiltration and that Th17 immune response in the kidney and secondary lymphoid organs was markedly reduced in nephritic Mir-$155^{-/-}$ mice. Moreover, Mir-155-deficient mice developed less severe nephritis, with reduced histologic and functional injury. To examine the function of miR-155 specifically in $CD4^+$ T cells we transferred wild-type and Mir-$155^{-/-}$ $CD4^+$ T cells into nephritic Rag$1^{-/-}$ mice. Recipients of Mir-$155^{-/-}$ cells had reduced Th17 immune response and developed less severe GN than wild-type recipients. Finally we show that miR-155 expression is selectively up-regulated in the kidneys of patients with crescentic GN.

Conclusions: These findings indicate that the ameliorated glomerulonephritis in Mir-155-deficient mice is due to impaired renal and systemic Th17 immune response and identify miR-155 as a potential therapeutic target in Th17-mediated human crescentic glomerulonephritis.

FR-OR135

ANCA Epitope Specificity Determines Pathogenicity Aleeza J. Roth,[1] Jacob Hess,[1] Mirjan M. Van Timmeren,[2] Elisabeth Berg,[1] Caroline Jennette Poulton,[1] Madelyn Burkart,[1] Susan L. Hogan,[1] Yichun Hu,[1] Patrick H. Nachman,[1] Coen A. Stegeman,[2] Peter Heeringa,[2] J. Charles Jennette,[1] Gloria A. Preston,[1] Ronald J. Falk.[1] *[1]UNC Kidney Center, Department of Medicine, Univeristy of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Pathology and Medical Biology, University Medical Center Groningen, Groningen, Netherlands.*

Background: Anti-neutrophil cytoplasmic autoantibodies (ANCA) specific for myeloperoxidase (MPO) or proteinase 3 (PR3) are detectable in >90% of patients with ANCA-associated vasculitis (AAV). ANCA titers do not correlate well with disease activity. *In vivo* and *in vitro* studies demonstrate that ANCA are pathogenic. Herein we report an analysis of MPO-ANCA epitopes that elucidates the poor correlation between disease activity and ANCA titer, and failure to detect ANCA by conventional assays in some AAV patients.

Methods: Epitope mapping entailed binding MPO-ANCA to MPO, which protects epitopes from enzymatic digestion. Epitope peptides were eluted and identified by matrix-assisted laser desorption mass spectrometry (MALDI-MS). ^{16}O-to-^{18}O exchange was used to detect peptide targets of low level autoantibodies. Samples were from 52 active or 35 remission AAV patients, and 10 healthy controls. Reactivity with epitope peptide was assayed by ELISA. Pathogenic potential of ANCA was tested using *in vitro* neutrophil action.

Results: 25 unique anti-MPO epitopes were detected. Pathogenic epitopes (12/25) reacted only with ANCA from patients with active disease. Nonpathogenic epitopes (6/25) reacted with ANCA from patients in remission. Natural epitopes (7/25) reacted at very low levels with immunoglobulin from healthy controls. Antibodies to one pathogenic epitope were detectable when an epitope-masking fragment of ceruloplasmin was removed in 8/10 AAV patients who were negative by conventional assays.

Conclusions: ANCA titers in clinical assays reflect a combination of both pathogenic and nonpathogenic ANCA. Pathogenic ANCA alone correlate better with disease activity. IgG from patients with ANCA-negative AAV reacts with a restricted pathogenic anti-MPO ANCA whose target epitope is masked in serum by ceruloplasmin.

Increased Recruitment of Dendritic Cells Is Associated with Tubular Atrophy in Human Kidney Disease

Helen G. Healy,[1] Andrew J. Kassianos,[1] Kimberly A. Muczynski,[2] Xiangju Wang,[1] Sandeep Sampangi,[1] Ray Wilkinson.[1] *[1]Conjoint Kidney Research Laboratory, Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia; [2]Division of Nephrology, University of Washington, Seattle, WA.*

Background: Dendritic cells (DC) have been defined as key players in immune-mediated kidney diseases. However, the identification and enumeration of human DC subsets in diseased kidney tissue has been restricted to limited pathologies and performed using only immunohistochemistry, demonstrating that DC are primarily localised to the tubulointerstitium.

Methods: We developed novel protocols for obtaining single cell suspensions from biopsies from a wide range of human kidney diseases to allow the detection and quantitation of DC subsets via flow cytometry. DC were defined as $CD45^+$ $lineage^-$ $HLA\text{-}DR^+$ cells and were classified into $CD11c^-CD123^+$ plasmacytoid DC (pDC) and $CD11c^+$ myeloid DC (mDC), which were subdivided into $CD1c^+$, $CD141^+$ and $CD16^+$ subsets, and enumerated with Flow-Count Fluorospheres.

Results: We observed significantly elevated numbers of total DC, $CD1c^+$ and $CD141^+$ mDC subsets in diseased kidney biopsies with interstitial fibrosis/tubular atrophy (IF/TA) compared to both diseased biopsies without IF/TA and healthy kidney tissue. Numbers of $CD16^+$ mDC were similar between groups, whilst pDC numbers were significantly higher in the IF/TA cohort compared to healthy tissue only. The expression of HLA-DR on DC in diseased biopsies with IF/TA was significantly reduced compared to healthy kidney tissue, suggestive of an altered DC phenotype. The majority of $CD1c^+$ mDC lacked expression of both CD1a and DC-SIGN, confirming these cells as infiltrating blood DC and not resident or monocyte-derived DC. Notably, higher levels of chemokine IL-8, inflammatory cytokine IL-1β and Th1-inducing IL-12p70 were detected in the dissociation supernatants of diseased kidney biopsies than healthy kidney tissue.

Conclusions: This study provides novel tools for the phenotyping and enumeration of renal DC that will allow us to better understand their functional roles in the kidney. Our data suggest that DC may play a critical role in the development of IF/TA and thus, progression to chronic kidney disease.

FR-OR137

Reduced CD5+ B Cells in Active Anti-Neutrophil Cytoplasmic Autoantibody Vasculitis and Relapse after Rituximab

Donna O. Bunch,[1] JulieAnne G. McGregor,[1] Lydia Aybar,[1,2] Kerry R. Colby,[1] Yichun Hu,[1] Susan L. Hogan,[1] Caroline Jennette Poulton,[1] Elisabeth Berg,[1] John Schmitz,[2] Ronald J. Falk,[1] Patrick H. Nachman.[1] *[1]UNC Kidney Center, UNC, Chapel Hill, NC; [2]Microbiology and Immunology, UNC, Chapel Hill, NC.*

Background: B cell significance in ANCA disease pathogenesis is underscored by the effectiveness of rituximab as therapy in ANCA-small vessel vasculitis (ANCA-SVV). To avoid infections and adverse events from therapy, clinicians require improved markers of disease activity and impending relapse to guide immunosuppression strategies post-rituximab. We hypothesize that CD5, a surrogate marker of B regulatory cells, may serve this purpose.

Methods: We investigated B cell phenotype in patients with active ANCA-SVV and in remission by flow cytometry. 54 patients were followed longitudinally for 4 to 99 m and compared to 68 healthy controls (HC). Whole blood or PBMCs were stained with antibodies to CD19, CD20, CD24, CD38, CD45, and CD5. We examined B cell phenotype in 19 patients after rituximab. Additional $CD5^+$ B cell data was acquired from clinical Rituxan panels for 29 patients.

Results: Patients with active ANCA-SVV had lower $\%CD5^+$ B cells (21±13; p=0.003) than those in remission and were similar to HC (30±14 and 30±13 respectively). After rituximab, median time to relapse was 31 months in patients maintaining normalized $\%CD5^+$ B cells, with or without maintenance immunosuppression (IS). Patients whose B cells repopulated with low $\%CD5^+$ B cells and were on low or no maintenance IS had a shorter time to relapse (17m) than patients who repopulated with low $\%CD5^+$ B cells maintained on high levels of oral maintenance IS (29m, p= 0.002). Preliminary analysis of Rituxan panel data indicates patients who had ≤30% CD5+ B cells at the time of B cell repopulation (≥1% B cells) relapsed sooner (16m) than patients who repopulated with >30% CD5+ B cells (22m; p=0.05).

Conclusions: The $\%CD5^+$ B cells, as a component of the human B regulatory cell phenotype, is a useful indicator of disease activity, remission and future relapse, and therefore, may guide remission maintenance therapy following rituximab.

FR-OR138

A Novel Murine Model of B Cell-Mediated Proteinuria Suggests Cytokines Mediate Podocyte Injury

Alfred Hyoungju Kim,[1] Andrey S. Shaw.[2] *[1]Rheumatology, Washington University School of Medicine, Saint Louis, MO; [2]Immunobiology, Washington University School of Medicine, Saint Louis, MO.*

Background: B cell depletion therapies have been efficacious in several glomerulopathies. The contributions of B cells to proteinuria and foot process effacement remain unknown. The development of a murine model of B-cell induced proteinuria would enhance our understanding of immune-based glomerular diseases.

Methods: The B cell model antigen model hen egg lysozyme (HEL) was biotinylated and complexed to avidin. Following intravenous (IV) injection in mice, purified naïve HEL-specific B cells were adoptively transferred and proteinuria assessed using PAGE. Kidneys were processed for immunofluorescence (IF), H&E and PAS staining, and scanning electron microscopy (SEM). Cultured podocyte membrane ruffling was assessed with DIC videomicroscopy.

Results: HEL embedded within the glomerular basement membrane (GBM) following IV injection. Proteinuria occurred after the transfer of HEL-specific B cells and was associated with foot process effacement. No antibody or complement deposition was observed in the GBM. 2-photon microscopy of live mice demonstrated that HEL-specific B cells arrested trafficking within glomeruli in the presence of HEL. The rapid kinetics of proteinuria induction suggested cytokines secreted by activated intraglomerular B cells may be responsible. We hypothesize that activation of the small Rho GTPase Rac is important in podocyte injury by virtue of its ability to regulate the actin cytoskeleton. Using murine cultured podocytes, we measured membrane ruffling in the presence of cytokines as a surrogate for Rac activation. IL-4 significantly increased cultured podocyte membrane ruffling and induced foot process retractions on ex vivo fragments of renal cortex. Hydrodynamic DNA immunization of wild-type 129 mice with plasmid encoding IL-4 lead to proteinuria.

Conclusions: We have developed a novel model of B cell-induced proteinuria with foot process effacement. Furthermore, these data demonstrate that cytokines can induce alterations in foot process morphology, leading to proteinuria. This has important implications in therapies preserving podocyte function in glomerular disease.

FR-OR139

CD25+CD45RA+CD4+ T-Cell Subset as a Predictive Marker of Responsiveness in Pediatric Nephrotic Patients Treated with Rituximab

Wee Song Yeo,[1] Chang Yien Chan,[1] Henry He Yang,[1] Kong Peng Lam,[2] Hui Kim Yap.[1] *[1]Pediatrics, National University of Singapore, Singapore, Singapore; [2]Bioprocessing Technology Institute, A*STAR, Singapore, Singapore.*

Background: Rituximab, an anti-CD20 chimeric monoclonal antibody, is an increasingly popular modality of therapy in steroid-resistant nephrotic syndrome (SRsNS) patients who have failed therapy with conventional immunosuppressants. This study aimed to identify markers predicting responsiveness in pediatric nephrotic patients treated with rituximab.

Methods: Ten patients with SRsNS or cyclosporine-dependent nephrotic syndrome were given 2-weekly doses of rituximab (375 mg/m^2) for 4 doses. Both urinary and blood biochemical parameters were monitored throughout the study. Quantitation of B cells (CD19) and T cells (including CD4+CD25+CD45RA+ (naïve regulatory T-cells), CD4+CD25+CD45RO+ (memory regulatory T-cells), CD4+CD45RA+ (naïve CD4+ cells), CD4+CD45RO+ (memory CD4+ cells), CD4+CD25+ (activated CD4+ cells), CD4+ICOS+ (stimulated ICOS+CD4+ cells), CD8+ICOS+ (stimulated ICOS+ CD8+ cells), CD8+CD25+ (activated CD8+ cells), CD8+CD45RO+ (memory CD8+ cells), CD8+CD45RA+ (naïve CD8+ cells), CD8+CD25+CD45RA+ (activated naïve CD8+ cells), CD8+CD25+CD45RO+ (activated memory CD8+ cells)) was performed using multi-color flow cytometry.

Results: Six (60%) patients achieved complete remission defined as urine protein:creatinine (PCR) ratio of <0.02 g/mmol, while the rest only had partial remission (urine PCR 0.02-0.2 g/mmol). Analysis of the cellular subsets revealed a statistically significant decrease in percentage of CD19+ cells in all patients post-rituximab infusion (14.53±6.23% (pre) vs 0.46±0.58% (post), p<0.001) as anticipated. Of the various immunological subsets analyzed, CD25+CD45RA+CD4+ cells was a potential marker for complete responsiveness towards rituximab therapy (8.40±2.06 (partial responders) vs 3.11±0.69 (complete responders), p= 0.021). Using ROC curve analysis for CD25+CD45RA+CD4+, the area under the curve is 0.917 (95% CI: 0.73-1.00).

Conclusions: Our study illustrated the potential utilization of CD25+CD45RA+CD4+ cellular subset as a marker of complete responsiveness. Further studies are, however, required to affirm the above findings.

Alternative Complement Pathway Is Essential for Glomerular C3 Deposition and Progressive Proteinuria in Murine Membranous Nephropathy

Wentian Luo,[1] Florina Olaru,[1] Linna Ge,[1] Angelique Rops,[3] Johan Van der Vlag,[3] V. Michael Holers,[2] Joshua M. Thurman,[2] Dorin-Bogdan Borza.[1] *[1]Vanderbilt University School of Medicine, Nashville, TN; [2]University of Colorado, Denver, CO; [3]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: Membranous nephropathy (MN) is a major cause of nephrotic syndrome in adults. Pathology is driven by subepithelial immune complexes activating complement, leading to C5b-9-mediated podocyte injury and proteinuria. Which complement pathways are implicated is not known. The alternative pathway may be involved because human IgG4 autoAbs, which are prevalent in idiopathic MN, do not activate complement via the classic pathway.

Methods: We evaluated how genetic and pharmacologic targeting of factor B (a key component of the alternative pathway) alters disease course in an active mouse model of MN that faithfully recapitulates human disease, including the prevalence of non-complement fixing IgG subclasses.

Results: Glomerular deposition of C3 and development of proteinuria after the induction of experimental MN in C57Bl/6 mice were completely abolished in congenic factor B-/- mice. After inducing experimental MN in more susceptible DBA/1 mice, treatment with a blocking anti-factor B mAb was initiated when ACR increased over 10-fold over normal values. Inhibition of factor B prevented the glomerular C3 deposition and blunted further exacerbation of albuminuria by >80%, compared to untreated control mice. Ablation of factor B activity did not affect serum titers of autoAbs or glomerular deposition of IgG and antigen.

Conclusions: Our results show that the amplification of complement activation by the alternative pathway is necessary for glomerular C3 deposition and progression of proteinuria in experimental MN. Thus, the alternative pathway has a pivotal role in the MN pathomechanism. Inhibiting factor B uncouples subepithelial immune complexes from pathogenic complement activation, providing proof-of-concept about the feasibility of this novel therapeutic strategy for treating MN.

Autoimmunity to the Alpha 3 Chain of Type IV Collagen Is Triggered by 'Autoantigen Complementarity'

John Reynolds,[1,4] Gloria A. Preston,[2] Barrak M. Pressler,[3] Peter Hewins,[2] Michael C. Brown,[2] Aleeza J. Roth,[2] Elizabeth A. Alderman,[2] Donna O. Bunch,[2] J. Charles Jennette,[2] H. Terence Cook,[1] Ronald J. Falk,[2] Charles D. Pusey.[1] *[1]Renal Section, Department of Medicine, Imperial College, London, United Kingdom; [2]UNC Kidney Center, Department of Medicine, University of Noth Carolina, Chapel Hill, NC; [3]Department of Pathology, University of North Carolina, Chapel Hill, NC; [4]Institute of Biomedical and Environmental Science and Technologies, University of Bedfordshire, Luton, United Kingdom.*

Background: 'Autoantigen complementarity' is a theory proposing that the initiator of an autoimmune response is not necessarily the autoantigen or its molecular mimic, but may instead be a peptide that is 'antisense/complementary' to the autoantigen. We investigated whether such complementary proteins play a role in the immunopathogenesis of autoimmune glomerulonephritis. Experimental autoimmune glomerulonephritis, a model of anti-glomerular basement membrane (GBM) disease, can be induced in Wistar Kyoto (WKY) rats by immunization with the α3 chain of type IV collagen.

Methods: In this study, WKY rats were immunized with a complementary α3 peptide (c-α3-Gly) comprised of amino acids that 'complement' the well characterized epitope on α3(IV)NC1, pCol(24-38).

Results: Within 8 weeks post-immunization, these animals developed cresentic glomerulonephritis, similar to pCol(24-38)-immunized rats, while animals immunized with scrambled peptide were normal. Anti-idiotypic antibodies to epitopes from c-α3-Gly-immunized animals were shown to be specific for α3 protein, binding in a region containing sense pCol(24-38) sequence. Interestingly, anti-complementary α3 antibodies were identified in sera from patients with anti-GBM disease, suggesting a role for 'autoantigen complementarity' in immunopathogenesis of the human disease.

Conclusions: This work supports the idea that autoimmune glomerulonephritis can be initiated through an immune response against a peptide that is anti-sense or complementary to the autoantigen. The implications of this discovery may be far reaching, and other autoimmune diseases could be due to responses to these once unsuspected 'complementary' antigens.

Funding: Government Support - Non-U.S.

FR-OR142

Costimulation Blockade with Systemic SiRNA Anti CD40 Ameliorates Experimental Lupus Nephritis in a Dose Dependent Manner

Elia Ripoll,[1] Laura De Ramon,[1] Montse Goma,[2] Nuria Bolanos,[1] Immaculada Herrero_ Fresneda,[1] J. Grinyo,[1] Joan Torras.[1] *[1]Experimental Nefrology, IDIBELL-HUB, Hospitalet de Llobregat, Barcelona, Spain; [2]Patology Service, Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Barcelona, Spain.*

Background: In a murine model of lupus nephritis we assayed the potential therapeutic benefit of mice-specific-siRNA-CD40 with different doses, taking into the pathogenic role of CD40-CD40L pathway in this autoimmune nephritis.

Methods: Six month old NZB/NZWF1 mice were divided into the following groups:Cyclophosphamide CYPgroup:mice were treated with intraperitoneal Cyclophosphamide,50mg/kg/10d;CTLA4 group:mice were treated with 50µg of intraperitoneal CTLA4 three times/week;si1w group:mice were treated with 50µg of intraperitoneal siRNA once/week, si2w group:mice were treated with 50µg of intraperitoneal siRNA twice/week, and LES (Control-group):without therapy.Mice were treated for 12 weeks.

Results: Mice from CYP and siRNA-CD40 groups had lower proteinuria and albuminuria versus control group.CYP was able to interrupt the progression of the antibody production, a dose dependent scale effects with the treatment of siRNA-anti-CD40 was seen. All treatments prolonged cumulative survival. Costimulatory blockade clearly reduced both the mean score and elementary lesions of lupus nephritis.It was more effective in reducing the deposition of IgG in the kidney than CYP treatment.siRNA treatment induced down regulation of renal mRNA for CD40, modulated innate immunity gene expression, chemokine and cytokines, and the expression of inflammasome components.CYP treatment reduced B cell population and did not affect the activation process; of note, the main feature of costimulation blockade with siRNA was a reduction in early B/T cell activation.Plasma cell presence in kidney was reduced in all treatment groups, those groups with costimulatory blockade treatment, shows less plasma cell presence than CYPgroup.

Conclusions: From our results we can conclude that our specific siRNA anti CD40 is highly effective to slow down the course of experimental lupus nephritis. Thus, the blockade of costimulatory signal CD40 becomes as a potential therapeutic tool in this renal autoimmune disease.

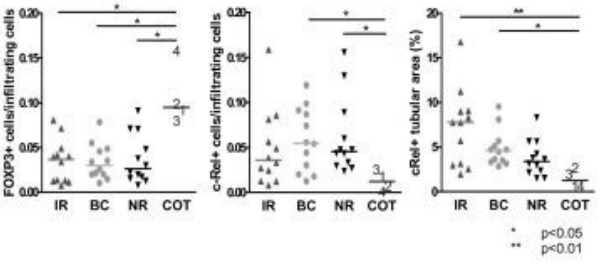
Cellular Infiltrates and NFKB Subunit c-Rel Signaling in Kidney Allografts of Patients with Clinical Operational Tolerance

Luis Eduardo Becker,[1] Sebastian Schäfer,[1] Matthias Schaier,[1] Lars Kihm,[1] Ruediger Waldherr,[2] Martin G. Zeier,[1] Christian Morath.[1] *[1]Nephrology, University of Heidelberg, Germany; [2]Pathology, University of Heidelberg, Germany.*

Background: NFKB plays a potential role in tolerance by orchestrating onset and resolution of inflammation and T-reg differentiation through subunit c-Rel. We characterized cellular infiltrates and expression of NFKB1, c-Rel and its upstream regulators phosphatidylinositol 3-kinase (PI3K)/RAC-alpha serine-threonine kinase (Akt1) in allograft biopsies from patients with spontaneous clinical operational tolerance (COT).

Methods: Paraffin-fixed kidney allograft biopsies from 40 patients with COT (n=4), interstitial rejection (IR; n=12), borderline changes (BC; n=12) and long-term allograft function without rejection (NR; n=12) were studied. Cellular infiltrates and immunohistochemical expression of key proteins of the NFKB pathway were evaluated in the cortical tubulointerstitium using digital image analysis. Results were given as mean±SEM.

Results: Biopsies from patients with COT exhibited a comparable amount of cellular infiltrate to IR, BC and NR (COT: 191±81; IR: 291±62; BC: 178±45; NR: 210±42 cells/mm^2), but a significantly higher proportion of FOXP3 positive cells (COT: 11±1.7%; IR: 3.5±0.70%; BC: 3.4±0.57%, NR: 3.7±0.78% of infiltrating cells, p=0.02). C-Rel expression in cellular infiltrates was significantly elevated in IR, BC, and NR when analyzing the number of positive cells/mm^2 (p=0.02) and positive cells/infiltrating cells (p=0.04). In contrast, tubular PI3K and c-Rel expression were significantly higher in IR and BC, but not in NR compared to COT (p=0.03 and p=0.006, respectively). With Akt1, similar tendencies were seen.



Conclusions: Allografts from COT patients show significant cellular infiltrates but a distinct expression of proteins involved in the NFKB pathway and a higher proportion of FOXP3 positve cells.

FR-OR144

Increased Cellular Immune Response Related Gene Expresion in Both DSA+ and DSA- Transplant Glomerulopathy

Nicole A. Hayde,[1] James M. Pullman,[2] Enver Akalin.[3] *[1]Pediatric Nephrology; [2]Department of Pathology; [3]Adult Nephrology, Transplant Center, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY.*

Background: Transplant Glomerulopathy (TGP) with donor-specific anti-HLA antibodies (DSA) and positive C4d staining is a criterion of chronic antibody-mediated rejection (AMR). The etiology of DSA-/C4d-TGP is unclear. We investigated the mechanisms of DSA-/C4d- TGP using microarray analysis of allografts.

Methods: We studied 255 clinically indicated kidney transplant biopsies. The biopsy gene expression profiles were studied by Affymetrix HuGene 1.0 ST expression arrays.

Results: There were 15 (6%) DSA+ and 24 (9%) DSA– TGP patients. 48 (19%) patients with non-specific interstitial fibrosis/tubular atrophy (IFTA) without DSA were used as controls. DSA+ TGP patients had higher peritubular capillary C4d+ staining (20% vs. 0% vs. 2%), microcirculation inflammation scores as seen by higher glomerulitis (0.7 vs. 0.4 vs. 0.1; p=0.02) and peritubular capillaritis (1, 0.3, 0.2; p=0.02) compared to DSA- TGP and IFTA. Microarray analyses were performed in 10 DSA+, 8 DSA-/C4d- TGP, 10 IF/TA, and 9 pre-implantation living donor biopsies. Both DSA+ and DSA- TGP biopsies showed upregulation of genes related to activation of the cellular immune response including T cells, mast cells, T cell receptor, interferon gamma and transforming growth factor beta receptor signaling pathways, T cell co-stimulation, innate immunity, and chemotaxis. Using Pathogenesis Based Transcripts, upregulation of Endothelial Cell Associated Transcripts (ENDAT) was seen in all transplant kidney biopsies. There was a trend towards significant upregulation of interferon gamma and rejection induced and cytotoxic T cell associated transcripts in both DSA+ (p=0.06) and DSA– TGP (p=0.07). The only significant difference between DSA+ and DSA- TGP was upregulation of transcripts differentially expressed between rejection-classified biopsies from DSA+ patients.

Conclusions: Microarray analysis revealed significant activation of cellular immune-response related genes in both DSA+ and DSA- TGP biopsies. The upregulation of ENDAT in all transplant biopsies questions its promise as a molecular biomarker for AMR.

FR-OR145

Reproducibility for C4d and BK Immunohistochemistry in Renal Allografts: Results from the Banff Initiative for Quality Assurance in Transplantation (BIFQUIT) Michael Mengel,[1] Robert B. Colvin,[2] Heinz Regele,[3] Parmjeet S. Randhawa.[4] *[1]Laboratory Medicine and Pathology, Univeristy of Alberta; [2]MGH; [3]University of Insbruck; [4]University of Pittsburg.*

Background: Detection of C4d and BK related proteins is crucial for diagnosing antibody mediated rejection and polyoma virus nephropathy (PVN), respectively. Yet formal reproducibility studies are limited.

Methods: We conducted an international multi-center trial (78 participants at 60 institutions) to assess the reproducibility for C4d and BK immunohistochemistry on paraffin-sections. Tissue microarrays (TMA) were constructed comprising kidney allograft specimens representing the whole analytical spectrum for C4d and PVN, respectively. Participants stained the TMA slides using local protocols, evaluated their stains following the current Banff grading schemas and entered their scores online. Stained slides were returned for centralized panel scoring. Weighted kappa statistics were used to determine reproducibility.

Results: Inter-observer reproducibility (comparing local participant scoring to panel scores) was fair (kappa 0.45) for C4d and substantial for BK (kappa 0.64). Inter-laboratory reproducibility was moderate (kappa 0.46) for C4d but was inacceptable for BK (kappa -0.22). Inter-observer reproducibility for C4d could be significantly improved by omitting the Banff C4d grading schema and only considering +/- calls (kappa 0.60). Scoring only C4d+/- inter-laboratory reproducibility also improved considerably (kappa 0.78). Collapsing the proposed BK scoring schema into a simple positive/negative call improved the BK inter-laboratory reproducibility to 0.77.

Conclusions: These results indicated that C4d and BK (SV40 large-T antigen) results reported from paraffin section are highly variable between institutions. For C4d this is mainly due to complexity of the current Banff grading schema. But also for BK, the proposed grading schema combining staining intensity and % stained cells was the major source of variability between laboratories. Respective simplification of the grading schemas would significantly improve reproducibility for C4d and BK immunohistochemistry on paraffin sections.

FR-OR146

Interstitial Fibrosis and Tubular Atrophy on Biopsy for Cause in Recipients of Kidney Transplants Is Not Always due to Calcineurin Inhibitor Exposure Venkata R. Reddivari,[1] Ravinder K. Wali,[2] Matthew R. Weir.[1] *[1]UMMC; [2]Inova Transplant Center.*

Background: Intersitial fibrosis and tubular atrophy(IF-TA) is often attributed to cumulative exposure to calcineurin inhibitor.Can replacement of CNI with m-TOR inhibitors prevent progression in IF-TA and graft failure?

Methods: Patients with IF-TA on for cause biopsy and on maintenance CNI and MMF without steroids were treated with sirolimus (SRL) as the exposure group and continuation of CNI as the comparator group between Jan 2003 to Apr 2006,prospectively followed for 3 yrs.The primary outcome was a composite of graft loss and death with functioning graft (DWF).Secondary out comes included e-GFR and Cr at 1,2,and 3yrs.

Results: A total of 497 recipients of kidney transplants with index biopsy had IF-TA. As routine care CNI was discontinued in 221(45%) patients.There were no differences in the baseline characteristics between the two groups (table 1). There was a difference in the primary and secondary outcomes in the two groups.

TAB1			
Recipient data	Sirolimus (N=221)	Tacrolimus (N=276)	P-value
Age ,years (Mean±SD)	46.2 ±18.4	48.6 ±18.4	0.152
Gender, female	83 (38%)	99 (36%)	0.324
Race, blacks	108 (47%)	125 (53%)	0.324
Type of transplant,Deceased	147 (67%)	182 (55%)	0.782
Time to index biopsy (months), Mean ±SD (95% CI)	10.1 ±15.4 (8.14-12.24)	10.2 ±16.6 (8.19-12.3)	0.96
Serum Cr at index biopsy, Mean ± SD (95% CI)	3.1 ±1.9 (2.3-3.3)	3.3 ± 2.5 (3.0-3.6)	0.282
e-GFR at index biopsy, Mean ± SD (95% CI)	31.2± 22.6 (28.18-34.33)	32.0 ±19.8 (29.52-34.49)	0.245
TAB 2			
Primary out come,n (%) a	76 (35%)	53 (19%)	0.001
Graft loss,n (%)	28 (12.6%)	31 (11.2%)	0.08
Death with functioning graft, n (%) b	54 (25%)	22 (8%)	0.001

Unless otherwise noted, data are represented as numbers (percentage) of patient, Primary outcome(graft loss and DFW,Tab 2 a and b Kaplan-Meier log-rank p value is <0.05

After adjusting for baseline variables,none of these had a impact on primary outcome and graft function on Cox analysis.

Conclusions: Discontinuation of CNI does not abrogate IF-TA. SRL use increased the risk of graft loss, DWF, and death after graft failure. Routine practice of changing CNI to SRL in patients with IF-TA needs to be studied.

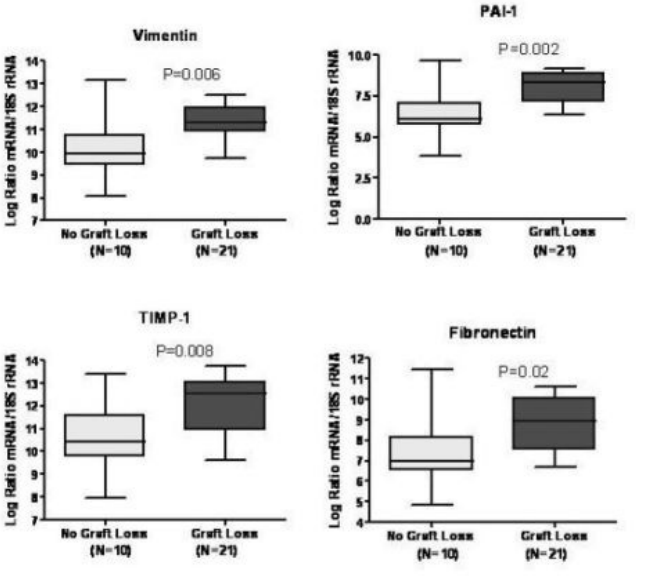
FR-OR147

Prediction of Graft Loss Following BKV Nephropathy (BKVN) Non-Invasively Darshana Dadhania, Catherine Snopkowski, Ruchuang Ding, Thangamani Muthukumar, Jun B. Lee, Vijay K. Sharma, Surya Seshan, Manikkam Suthanthiran. *Nephrology, Weill Cornell Med. Center, NY, NY.*

Background: BKVN associated graft loss is common among renal allograft recipients. Development of prognostic biomarkers may aide in the management & development of novel treatment strategies. We studied whether biomarkers associated with fibrosis measured in urinary cells at the time of initial BKVN diagnosis would predict subsequent graft loss.

Methods: We isolated total RNA from urinary cells from 31 kidney recipients with BKVN (10 with & 21 with out graft loss) and measured mRNA levels associated with inflammation (granzyme-B, perforin, CD25, FoxP-3, CTLA4, CD103), tubular cells (E-cadherin, NKCC2, USAG), fibrosis (TGFb1, Vimentin, BMP, FGF, HGF, PAI-1, TIMP-1, FIbronectin, a-smooth muscle actin, collagen 1A1), BKV VP1 and house keeping gene 18S rRNA using pre-amplification enhanced real-time quantitative PCR assays. We compared log transformed 18S-normalized mRNA levels to identify any differences between the two groups & then performed multivariate logistic regression analysis using backward stepwise elimination method to indentify independent biomarkers for graft loss.

Results: Univariate analysis of mRNA levels demonstrated that vimentin, PAI-1, TIMP-1, and fibronectin at the time of initial BKVN diagnosis were elevated in individuals with graft loss compared to those without (Figure). Serum creatinine at time of biopsy in those with graft loss was 2.9±1.3 vs. and 2±0.7 (P=0.01). Multivariate logistic regression analysis identified PAI-1 as an independent predictor of graft loss (P=0.007).



P-value was calculated by comparing the two groups using Mann Whitney Test.

Conclusions: We identified PAI-1 as an independent predictor of graft loss following BKVN diagnosis. Measurement of PAI-1 at the time of BKVN diagnosis will allow identification of high-risk patients and personalization of therapy.

FR-OR148

Transcriptomic Profile of Peripheral Blood Mononuclear Cells (PBMC) in Renal Chronic Antibody-Mediated Rejection (CAMR) Paola Pontrelli,[1] F. Rascio,[1] Matteo Accetturo,[1] Margherita Gigante,[2] Giovanni Stallone,[2] Anna Zito,[1] Maddalena Gigante,[2] G. Castellano,[1] Loreto Gesualdo,[1] Giuseppe Grandaliano.[2] *[1]Dept. of Emergency and Organ Transplantation, University of Bari, Italy; [2]Dept. of Medical and Surgical Sciences, University of Foggia, Italy.*

Background: CAMR represents one of the main causes of chronic graft injury, but the molecular mechanisms underlying it are still unclear. Aim of the study was to define a transcriptomic profile of CAMR using genome-wide expression analysis.

Methods: We enrolled 10 patients with biopsy-proven CAMR and 10 stable transplant recipients with normal graft function (control group). mRNA expression profile of PBMC isolated from both groups was assessed by Agilent microarray.

Results: The statistical analysis (unpaired t tests, Benjamini-Hochberg correction) revealed 67 probe sets (53 genes) differentially expressed in the two groups ($p<.05$; $FC\geq2$). In 97% of the cases (65/67) gene expression was increased in CAMR. PCA showed the ability of these genes to distinguish the two groups. The biological functions concerned immune ($p<.01$) and inflammatory response ($p<.01$).The main canonical pathways were complement system ($p=8.49*10^{-7}$) and IFNα ($p=6.0*10^{-5}$). The functional networks, generated by Ingenuity Pathway Analysis, showed that more than 41% of the differentially-expressed genes (22/53) regulate or are regulated by IFNα (IPA score=52, $p\leq.05$). Real time PCR confirmed an increase of two genes included in IFNα a network, GBP1 and CXCL9, in CAMR when compared to control group (GBP1: FC=4.8, p=.0001; CXCL9: FC=1.6, p=.0004) and patients with chronic cell-mediate rejection (GBP1: FC=2.9, p=.001; CXCL9: FC=1.3, p=.04). Moreover, we observed by flow cytometry an increase of circulating $BDCA1^+$ myeloid dendritic cells (DC) (p=.03) and a reduction of circulating $BDCA2^+$plasmacytoid DC (p=.03), the main producers of IFNα, in CAMR group compared to the other two groups. The $BDCA2^+$DC were increased in the kidney graft biopsies of CAMR (p=.04) patients along with MXA, a protein induced by IFNα (p=.02), as shown by confocal microscopy.

Conclusions: Our data suggest a key role of IFNα during CAMR and open new perspectives for identification of therapeutic targets.

FR-OR149

Non-C1q-Fixing Antibodies Predominate in C4d-Negative Chronic Antibody Mediated Rejection Evan A. Farkash, Peng Zhang, Zeeshan Khawaja, Susan Saidman, Rex Neal Smith, Winfred W. Williams, A. Bernard Collins, Alessandro Alessandrini, Robert B. Colvin. *Massachusetts General Hospital, Boston, MA.*

Background: Chronic active antibody mediated rejection (CAMR) is a major cause of late kidney allograft dysfunction and loss. CAMR diagnosis requires circulating donor specific antibody (DSA), C4d deposition in peritubular capillaries (PTC), and histologic evidence of chronic injury. However, molecular and longitudinal studies suggest that some cases of CAMR lack C4d staining. Either the C4d stain is insensitive, or some alloantibodies act via a complement-independent pathway. We hypothesize that some cases of CAMR are caused by antibodies unable to fix complement.

Methods: All for-cause biopsies on transplants of >1 year duration from 2006 to 2011 with saved serum from within 3 weeks of the biopsy were identified. PTC C4d staining was evaluated by indirect immunofluorescence. Serum samples were tested for HLA class I and II DSA using single lot Luminex single antigen beads (LabScreen, OneLambda). To determine whether DSA fixed complement, positive sera were heat-treated, incubated with C1q, and evaluated using beads and an anti-C1q reporter (C1qScreen, OneLambda).

Results: Of 129 specimens, 56 were DSA+C4d+, 40 were DSA-C4d-, 28 were DSA+C4d-, and 5 were DSA-C4d+. DSA in the absence of tissue C4d portended a rapid progression to graft failure. 19/28 cases of C4d-negative CAMR (DSA+C4d-) lacked detectible C1q-fixing antibody. In contrast, 48/56 cases of C4d-positive CAMR (DSA+C4d+) had detectible C1q-fixing antibody ($p<5x10-6$, Fisher's exact test). Tissue C4d positivity and C1q-fixation both show a strong correlation with increasing DSA MFI. Interestingly, several patients have stronger or weaker C1q fixation than predicted by their DSA MFI.

Conclusions: We successfully identify cases of C4d-negative late antibody mediated rejection. These cases have poor 2 and 5 year graft survival. Direct endothelial injury or leukocyte-recruitment via Fc receptor ligation may predominate in cases of C4d-negative CAMR. Chronic rejection via these pathways may cause rapid progression to graft failure. Future studies will also evaluate whether DSA C1q-fixation correlates with antibody subclass.

Antigen Specific ELISA to Improve Anti-PLA2R1 Antibody Monitoring after Renal Transplantation for Membranous Nephropathy Barbara Seitz-Polski,[1] Christine Payre,[2] Laetitia Albano,[1] Elisabeth Cassuto,[1] Sylvia Benzaken,[3] Ghislaine Bernard,[3] Vincent L.M. Esnault,[1] Gerard J. Lambeau.[2] *[1]Nephrology, Nice University Hospital, Nice, France; [2]Institute of Molecular and Cellular Pharmacology, CNRS and University of Nice, Valbonne, France; [3]Immunology, Nice University Hospital, Nice, France.*

Background: Membranous Nephropathy (MN) recur after renal transplantation (RT) in 30 to 42% of cases, decreasing graft survival. Autoantibodies (Anti-PLA2R1 Ab) directed to phospholipase A2 receptor type 1 (PLA2R1) are found in 65 to 82% of patients with MN. The pathogenic role and the interest of anti-PLA2R1 Ab to predict recurrence of MN in kidney recipiens remain controversial.

Methods: An antigen specific ELISA measuring levels of anti-PLA2R1 Ab in patients'sera was established and validated in a cohort of 120 MN patients, and compared with Western blot (WB) and Indirect ImmunoFluorescence (IIF) on HEK cells transfected with PLA2R1.

Results: ELISA had higher sensibility and accuracy than WB and IIF. Twelve kidney recipiens with MN had serial sera available for follow-up studies. Out of 8 patients with anti-PLA2R1 Ab at the time of RT, 1 patient relapsed with persistent high anti-PLA2R1 Ab titers and was successfully treated with rituximab, 1 patient had a histological relapse with persistently high anti-PLA2R1 Ab titers but no proteinuria under maximal renin angiotensin system blockadge, and 6 patients with a decrease in their anti-PLA2R1 Ab titers after RT did not relapse, including 1 with an increase of proteinuria induced by a BK virus nephropathy. One out of 4 patients relapsed with no anti-PLA2R1 Ab at the time of RT, suggesting the presence of another antigen target.

Conclusions: The established ELISA appeared to be a suitable assay to accurately monitor anti-PLA2R1 Ab and predict MN recurrence after RT.

Funding: Government Support - Non-U.S.

FR-OR151

Do Anti-Phospholipase A2 Receptor Antibodies Predict Recurrence of Membranous Nephropathy after Transplantation? Rivka Ayalon,[1] Laurence H. Beck,[1] Fernando C. Fervenza,[2] Fernando G. Cosio,[2] Daniel C. Brennan,[3] David J. Salant.[1] *[1]Boston University Medical Center; [2]Mayo Clinic; [3]Washington University.*

Background: Primary Membranous Nephropathy (MN) recurs in 10-45% of cases after transplantation. Early diagnosis of recurrent MN should prompt treatment as graft loss occurs in a high proportion of cases. Previous studies have not disclosed any pre-transplant variables that differentiate patients that will recur from those that will not. We analyzed if the presence of circulating Anti-Phospholipase A2 Receptor Antibodies (anti-PLA2R) at the time of transplantation predicts recurrence and assessed the prevalence of anti-PLA2R soon after recurrence.

Methods: We conducted a retrospective analysis of anti-PLA2R by western blotting of sera obtained at or before transplantation (pre-TP), when available, and within 4 months of recurrence or non-recurrence as diagnosed by protocol biopsy or proteinuria. Anti-PLA2R level was semi-quantitated by band intensity.

Results: Pre-TP sera were available from 34 patients. MN has recurred in 17 of the 23 patients that were anti-PLA2R positive (74%); however 8 (32%) of the patients that recurred were negative for pre-TP anti-PLA2R. Of 16 patients in which serum was available at the time of recurrence, anti-PLA2R was detected in 11 (69%) and was negative in 5 (31%). The median time for recurrence in 9 patients that were strongly positive for anti-PLA2R pre-TP was significantly shorter than in 7 patients with undetected pre-TP anti-PLA2R [11 (1- 45) vs 51 (12 – 270) weeks, p=0.0127].

Conclusions: We found that positive anti-PLA2R pre-TP predicts a high risk for recurrence but not all seropositive cases have recurred to date. The absence of pre-TP anti-PLA2R does not rule out future recurrence, which might be explained by post-TP reappearance of anti-PLA2R or other as yet unidentified antibodies. The prevalence of anti-PLA2R at the time of recurrence is similar to that seen in primary MN. Our results also suggest that high pre-TP anti-PLA2R levels predict early recurrence. Thus we propose that the presence of anti-PLA2R before or after transplantation merits close monitoring for recurrent MN.

FR-OR152

Soluble Urokinase Receptor (suPAR) in the Serum and Urine of Patients with Focal Segmental Glomerulosclerosis (FSGS) and IgA Nephropathy Carlos R. Franco-Palacios,[1] John C. Lieske,[1] Hani Wadei,[2] Andrew D. Rule,[1] Nick Voskoboev,[1] Mark D. Stegall,[1] Fernando G. Cosio,[1] Hatem Amer.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic, Jacksonville, FL.*

Background: Elevated serum suPAR levels have recently been identified in a subset of patients with FSGS.

Methods: Serum and urine suPAR were measured in bio-banked pre-kidney transplant (KTx) samples using a commercial ELISA kit. Four groups were studied (n=10 each): FSGS with recurrence in the first year post (R-FSGS); FSGS patients without recurrence post KTx (NR-FSGS); IgA nephropathy (IgA) and healthy kidney donors (Do).

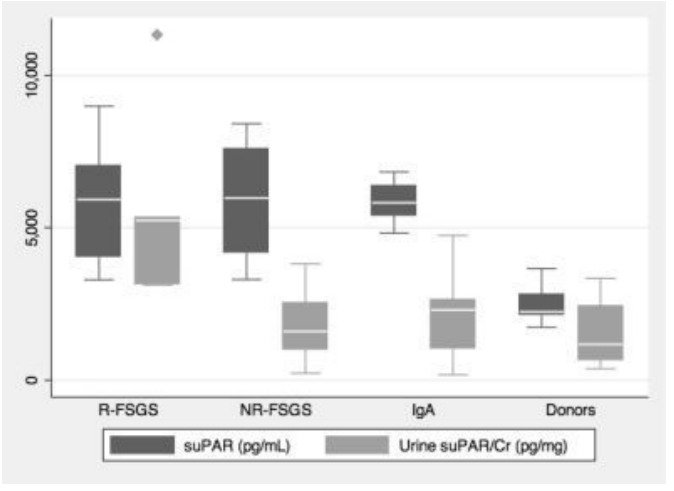
Urine samples were not available for 2 NR-FSGS and 5 R-FSGS patients. Samples were collected before any plasmapheresis or anti CD20 therapy.

Results: Results are summarized in Table 1 and Figure 1.

Table 1

	R-FSGS	NR-FSGS	IgA	Do	P
Age at KTx, yrs*	47.1 (17.4)	53.1 (14.1)	42.7 (10.8)	42.4 (9.3)	>0.05
Male**	6 (60)	8 (80)	7 (70)	4 (40)	>0.05
Cystatin C eGFR (ml/min/1.73m2)*	9 (3)	12 (6)	8 (4)	100 (15)	<0.001 vs Do
Urinary albumin mg/g creat***	7576 [4120, 9896]	1752 [820, 2894]	1237 [726, 3889]	6 [2, 11]	<0.001
Serum suPAR pg/ml ***	5922 [4027, 7313]	5974 [4061, 7706]	5819 [5297, 6362]	2246 [2048, 2879]	<0.001 vs Do
Urinary suPAR pg/mg***	5239 [3131, 8321]	1598 [754, 2815]	2304 [964, 2889]	1175 [662, 2492]	0.01

* mean (SD), ** N (%), *** median [25, 75th percentile]



In KTx patients, serum suPAR did not correlate with pretransplant albuminuria or proteinuria, Spearman's rho=0.26 and 0.16, P>0.05. Urinary suPAR did correlate with albuminuria and proteinuria, Spearman's rho=0.69 (both), P=<0.001.

Conclusions: Serum suPAR was elevated in both recurrent and non-recurrent FSGS, as well as IgA nephropathy. Urinary suPAR appears to be elevated in R-FSGS. Further studies regarding the use of serum and urine suPAR to predict renal histology and risk of disease recurrence after KTx are needed.

Circulating Klotho Levels Are Independently Associated with eGFR in Patients with Chronic Kidney Disease

Seung Hyeok Han,[1] Seong Hun Kim,[2] Dae-Suk Han,[1] Dong Ho Shin,[1] Mi Jung Lee,[1] Shin-Wook Kang,[1,2] Hye-young Kang.[2] *[1]Severance Biomedical Science Institute, Brain Korea 21, College of Medicine, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea.*

Background: Klotho is expressed in the renal distal tubules and exerts coreceptor function for FGF-23. It can also be released into the circulation by proteinase-induced cleavage or alternative splicing, and acts like an anti-oxidant. However, it is unknown whether circulating klotho levels are associated with estimated glomerular filtration rate (eGFR) in patients with chronic kidney disease (CKD).

Methods: We analyzed 243subjects who were diagnosed as CKD between January 2006 and December 2011. Demographic and clinical data were reviewed based on medical records. We measured serum concentrations of klotho, FGF-23, high-sensitivity C-reactive protein (hsCRP), and intact parathyroid hormone (iPTH).

Results: The mean age of the subjects was 45.7 years. The median klotho and FGF-23 levels were 396.3 (306.3-558.4) and 68.2 (52.2-99.1) pg/ml, respectively. When the subjects were categorized into 5 groups according to eGFR, circulating klotho levels gradually decreased as the stages of CKD increased (P for trend <0.01). Log-transformed klotho (log α-klotho) was positively correlated with eGFR (γ=0.503, P<0.001), serum albumin (γ=0.274, P<0.001) and calcium concentrations (γ=0.257, P <0.001), whereas it was negatively correlated with age (γ=-0.395, P<0.001), mean arterial pressure (γ=-0.161, P<0.001), phosphorus levels (γ=-0.169, P = 0.009), log FGF-23 (γ=-0.245, P<0.001), log iPTH (γ=-0.196, P=0.003), log hsCRP (γ=-0.285, P<0.001), and log proteinuria (γ=-0.377, P<0.001). In a multivariate linear regression, log α-klotho was independently associated with eGFR (β=0.179, P<0.001).

Conclusions: Circulating klotho levels decreased as renal function declined and were independently associated eGFR in CKD patients, suggesting that klotho may play a protective role in disease progression.

SA-OR002

Dietary Habits, Poverty, and Chronic Kidney Disease in an Urban Population

Deidra C. Crews,[1] Marie Kuczmarski,[2] Edgar R. Miller,[1] Alan B. Zonderman,[3] Michele Kim Evans,[3] Neil R. Powe.[4] *[1]Johns Hopkins U.; [2]U. of Delaware; [3]National Institute on Aging, NIH; [4]San Francisco General Hospital.*

Background: Poverty is associated with chronic kidney disease (CKD) in the US and worldwide. Poor dietary habits may contribute to this disparity.

Methods: We examined the relationship between adherence to the Dietary Approaches to Stop Hypertension (DASH) diet and CKD, by poverty status in the Healthy Aging in Neighborhoods of Diversity across the LifeSpan (HANDLS) study (Baltimore, MD). DASH scoring was based on 9 target nutrients (total fat, saturated fat, protein, fiber, cholesterol, calcium, magnesium, sodium, and potassium), with adherence defined as a score ≥4.5. CKD was defined as eGFR <60 ml/min/1.73m² (CKD-EPI). Multivariable logistic regression assessed the relationship of DASH score tertile and CKD, stratified by poverty status (income below or above 125% of poverty guideline).

Results: Among 2,058 participants (mean age 48 years; 57% black; 44% male; 42% with poverty), median DASH score was 1.5 (IQR, 1-2.5). Only 5.4% were adherent. Evaluation of DASH score tertiles revealed male sex, black race, poverty and smoking to be more prevalent among the lower tertiles, while higher education and regular health care were prevalent among the highest tertile (P<0.05 for all). Nutrient analysis by poverty status revealed fiber, calcium, magnesium and potassium intake to be lower, and cholesterol higher, among the poverty as compared to non-poverty group (P<0.05 for all), with no difference in sodium intake. CKD was present among 5.6% of the poverty, and 3.8% of the non-poverty group (P=0.05). DASH tertile was associated with CKD only among the poverty group (final model P interaction 0.02).

Logistic Regression Models of DASH Score Tertiles and CKD, by Poverty Status

		Poverty (N=869)			Non Poverty (N=1189)		
Model	Variables Included	DASH Tertile	OR (95%CI)	p-value for trend	DASH Tertile	OR (95%CI)	p-value for trend
1	DASH tertile only	Lowest	3.32 (1.26-8.73)	0.02	Lowest	0.77 (0.38-1.56)	0.5
		Middle	2.93 (1.06-8.13)		Middle	0.81 (0.38-1.71)	
		Highest	reference		Highest	reference	
2	+age, sex, race	Lowest	3.20 (1.19-8.62)	0.03	Lowest	0.91 (0.44-1.89)	0.8
		Middle	2.85 (1.00-8.10)		Middle	0.98 (0.45-2.10)	
		Highest	reference		Highest	reference	
3	+ years of education, regular health care	Lowest	3.12 (1.16-8.41)	0.03	Lowest	0.90 (0.43-1.88)	0.8
		Middle	2.73 (0.96-7.76)		Middle	0.91 (0.42-1.97)	
		Highest	reference		Highest	reference	
4	+ diabetes, hypertension, smoking status	Lowest	2.91 (1.06-7.96)	0.06	Lowest	0.77 (0.36-1.67)	0.5
		Middle	2.71 (0.94-7.82)		Middle	0.95 (0.44-2.07)	
		Highest	reference		Highest	reference	

Conclusions: Poor dietary habits are strongly associated with CKD among the urban poor and may represent a target for interventions aimed at reducing disparities in CKD.

Educational Attainment or Income Inequality, Which Is the Stronger Determinant of Chronic Kidney Disease in a Western European and a US Population?

Priya Vart,[1] Ron T. Gansevoort,[2] Ute Bültmann,[1] Sijmen A. Reijneveld.[1] *[1]Health Sciences, UMCG; [2]Nephrology, UMCG the Netherlands.*

Background: Higher income inequalities and income dependent access to health care are potential explanations for more consistent associations of CKD with income-based measures of socio-economic status (SES) than educational level in US populations. In Western Europe access to health care is mostly income independent, and education as SES measure might therefore be a stronger determinant of CKD. Therefore, we investigated the relative strengths of the associations of educational and income levels with CKD in a Western European and a US population.

Methods: Baseline data were used from PREVEND (N=7,367) and NHANES 1999-2002 (N=4,563), general population-based cohort studies in the Netherlands and USA, respectively. Education and income were divided in five levels of nearly equal size. CKD was defined as eGFR <60 mL/min/1.73m2 (using creatinine and cystatin C) and/or albuminuria ≥30 mg/24h or ACR≥30mg/g.

Results: In logistic regression models, including age, gender, race, education (for income) and income (for education), only educational level in PREVEND showed a significant association with CKD [OR=1.43, 95% CI (1.02–1.99), p=0.037 and 1.36, 95% CI (0.95–1.97), p=0.096 for lowest vs. highest category of education and income, resp.] and only income level in NHANES [OR = 2.89, 95% CI (1.56–5.85), p=0.001 and 0.78, 95% CI 0.43–1.40), p=0.392 for lowest vs. highest category of income and education, resp.]. For PREVEND, adding education to the model with income improved fit of the model significantly (p=0.002), while for NHANES adding income to the model with education did so (p<0.001). Sensitivity analyses with other CKD defining variables (eGFR CKD-EPI <60 and/or albumin: creatinine ratio>30 mg/g) and other acknowledged SES associated outcomes like smoking and obesity resulted in similar findings.

Conclusions: Educational level is a stronger determinant of CKD in a Western European population, while income inequality is in the US population. Preventive strategies addressing social inequalities in CKD prevalence should therefore employ a region based approach.

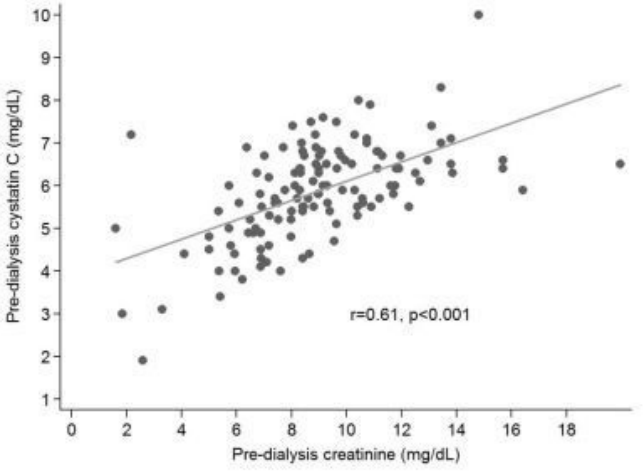
SA-OR004

Body Composition Affects Serum Creatinine but Not Serum Cystatin C Levels Nestor E. Almeida,[1] T. Alp Ikizler,[3] Y. Zhang,[1] R. Filipowicz,[1] G. Morrell,[1] G. Wei,[1] J. Abraham,[1] A. N. Habib,[1] T. S. Bjordahl,[1] Tom Greene,[1] Alfred K. Cheung,[1,2] S. Beddhu.[1,2] *[1]Univ of Utah, SLC, UT; [2]VA, SLC, UT; [3]Vanderbilt Univ, Nashville, TN.*

Background: Muscle mass is known to affect serum creatinine (SCr), it is unclear whether body composition (BC) affects serum cystatin C (SCy). Non-renal factors affecting SCy could be better studied when the kidney function is known. Therefore, in hemodialysis (HD) pts with measured residual urine volume, we examined the associations of BC with SCy and SCr.

Methods: 93 pts in the ongoing Protein Intake, Cardiovascular disease and Nutrition in CKD stage V (PICNIC) study with MRI data on mid-thigh muscle area (MTMA) and intra-abdominal fat area (IAFA) and preHD SCy and SCr were included. Cross-sectional multiple linear regression analyses were used to relate preHD SCy and SCr to MTMA and IAFA.

Results: Mean age was 52±16 yrs, 59% men, 84% Caucasians and 46% had DM. PreHD mean SCr was 8.8±2.8 mg/dL and mean SCy was 5.8±1.2 mg/dL. PreHD SCr and SCy were correlated (Figure 1)



The associations of SCy and SCr with BC measures are presented in Table 1.

Multiple Linear Regression Model of SCr and SCy

	SCr (mg/dL), β, (95%, CI), p value	SCy (mg/dL), β, (95%,CI), p value
For each 10 yrs ↑ in age	-0.63 (-0.94 to -0.33), <0.001*	-0.18 (-0.33 to -0.03), 0.02*
Male	0.19 (-0.98 to 1.36), 0.7	0.023 (-0.55 to 0.59), 0.9
Black	1.75 (0.47 to 3.04), 0.008*	0.58 (-0.04 to 1.21), 0.09
Smoking	-0.14 (-1.04 to 0.77), 0.8	-0.42 (-0.86 to 0.02), 0.06
For each 10 cm² ↑ in MTMA	0.34 (0.11 to 0.58), 0.004*	-0.02 (-0.14 to 0.09), 0.7
For each 10 cm² ↑ in IAFA	0.008 (-0.063 to 0.08), 0.82	0.008 (-0.025 to 0.043), 0.62
For each doubling of CRP	0.01 (-0.23 to 0.26), 0.92	-0.08 (-0.2 to 0.04), 0.18

Adjusted by URR and residual urine volume

Conclusions: Muscle mass is strongly associated with pre-dialysis SCr. Neither muscle nor fat mass appear to substantially affect SCy. In people in extremes of nutritional status SCy may be better than SCr in estimating kidney function.

SA-OR005

Prediction of Renal Function Trajectories in Early Autosomal Dominant Polycystic Kidney Disease Michal Mrug,[1] Sylvie Mrug,[1] Lisa M. Guay-Woodford,[2] Vicente E. Torres,[3] Kyong Tae Bae,[4] Peter C. Harris,[3] Doug Landsittel,[4] Michael F. Flessner,[5] William M. Bennett,[6] Jared J. Grantham,[7] Arlene B. Chapman.[8] *[1]U Alabama Birmingham; [2]George Washington U; [3]Mayo Clinic; [4]U Pittsburgh; [5]NIDDK; [6]Legacy Good Samaritan Medical Center; [7]U Kansas; [8]Emory U.*

Background: There are no reliable formulas for predicting renal function in early autosomal dominant polycystic kidney disease (ADPKD).

Methods: We have developed longitudinal mixed statistical models of GFR trajectories in ADPKD and tested their utility to predict GFR decline over time using data collected by the Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP), a prospective, observational, longitudinal, multicenter study of 241 ADPKD adults with preserved renal function.

Results: After a mean follow-up of 8.7 years, mean iothalamate clearance (GFR) decreased from 97.8 to 74.0 ml/min/1.73m². Baseline GFR alone was a poor predictor of true GFR trajectories over time; the correlation of predicted vs. true individual GFR slopes was 0.01 (p=0.86). Addition of thirteen demographic and routine laboratory data improved this correlation to 0.49 (p<0.0001). However, addition of MR based height adjusted total kidney volume (htTKV), cyst number and renal blood flow (RBF) data further improved this correlation to 0.76 (p<0.0001; both htTKV and RBF were significant predictors of slope of GFR decline). Predicting the development of CKD within 8 yrs using ROC analyses demonstrated an area under the curve (AUC) of 0.83 for a simplified model utilizing baseline GFR, age, hypertension, and 24 hr urinary excretion of albumin, calcium and sodium for CKD stage 3b. Addition of the MR based imaging data (htTKV, cyst number and RBF) improved the AUC to 0.93. Similar AUCs were obtained using 10-fold cross-validation. The GFR based modeling was repeated with MDRD-GFR and obtained similar outcomes.

Conclusions: Longitudinal mixed models using routine clinical data predicted GFR decline in patients with early ADPKD. Improvement in their accuracy by adding MR based data (htTKV, cyst number and RBF) points to critical role of imaging in predicting the development of CKD in these patients.

The Urea to Creatinine Ratio Is Highly Predictive of the Onset and Progression of the Cardiorenal Syndrome in Ambulatory Heart Failure Patients Manish M. Sood,[1] Mahwash Fatima Saeed,[2] Leigh Anne Shafer,[1] Navdeep Tangri,[1] Claudio Rigatto,[1] Paul Komenda,[1] Shelley Zieroth.[2] *[1]Medicine, Section of Nephrology, University of Manitoba, Winnipeg, MB, Canada; [2]Medicine, Section of Cardiology, University of Manitoba, Winnipeg, MB, Canada.*

Background: Development and progression of the cardiorenal syndrome often follow changes in renal perfusion and solute clearance. We investigated the prognostic value of serial measures of the fractional excretion of urea(FEur), the fractional excretion of sodium (FEna) and the urea to creatinine ratio (UCr) in determining subsequent declines in renal function in an ambulatory cohort of heart failure patients.

Methods: A total of 140 patients (83% male, mean EF 24.8±7.0%) were prospectively followed for up to 24 months (median 333 days (IQR 192-457). Laboratory values and clinical outcomes were assessed every 3 months. Renal function was determined by the eGFR as calculated by the MDRD equation. Mixed and ordinary linear regression models with a sandwich estimator were employed to determine the relationship between changes in FEur, FEna and UCr and subsequent changes in renal function. Models were adjusted for renal function, NYHA class, age, sex, diabetes, and proteinuria.

Results: The mean baseline eGFR was 69.6±24.2 ml/min/m² with a mean decline of 0.3 per month over the course of follow up.Mean values for the UCr (N=805), FEur (N=758 measurements), and FEna (N=768) were 0.09 ± 0.03, 35.5 ± 13.0% and 1.44 ± 2.1%, respectively. An increase in the UCr was highly predictive of a subsequent monthly decline in renal function (adjusted eGFR decline 3.2 (95% CI 1.9-4.6)ml/min/m², p=0.001 per 0.1 unit increase in UCr) whereas FEur and FEna were not (FEurea p=0.6, FEna p=0.8).

Conclusions: The UCr is a simple and cheap biomarker that is strongly predictive of the onset or progression of the cardiorenal syndrome in ambulatory heart failure patients and may be useful in guiding therapeutic decision making.

SA-OR007

Selected Biomarkers Have Differential Prognostic Value in Specific Primary Kidney Diseases Adeera Levin,[1] Ognjenka Djurdjev,[2] Claudio Rigatto,[3] Francois Madore,[4] Brendan J. Barrett,[5] Norman Muirhead.[6] *[1]UBC; [2]BC PRA; [3]UofM; [4]UdeM; [5]MUN; [6]UWO.*

Background: Patients with chronic kidney disease (CKD) experience variable progression of kidney disease (KD) and heart disease. Better prediction models are needed.

Objective: To determine if inclusion of selected novel biomarkers (NBM) improves prediction of renal replacement therapy (RRT) at one year in specific primary KD.

Methods: Pan-Canadian prospective cohort study of 2546 referred CKD patients, from 25 rural, urban, academic and non-academic nephrology centres. NBM tests at baseline included asymmetric dimethylarginine (ADMA), high sensitivity C-reactive protein (CRP), interleukin 6 (IL6), pro-brain natriuretic peptide (proBNP), troponin I, transforming growth factor beta-1 (TGβ1) and cystatin C .

Main Outcome: Dialysis or transplantation (RRT) within one year. We used proportional hazards modeling to evaluate impact of NBM to base models for specific KD.

Results: Mean age of the cohort is 68yrs; median eGFR was 28 ml/min/1.73m² (20% < 20ml/min, 38% 20-29ml/min and 41% 30-45mil/min); 62% were male. Base models for each KD included age, sex, eGFR and uACR. Base models, extended (base + NBM) models and improvement in prediction with the extended models are presented in the following table.

	Diabetic Nephropathy	Hypertensive Nephropathy	Glomerular Nephritis	Other
	HR (95% CI)	HR (95% CI)	HR (95% CI)	HR (95% CI)
Age (5 years)	0.91 (0.80-1.03)	0.99 (0.86-1.14)	0.99 (0.86-1.15)	0.94 (0.77-1.15)
Sex (Male vs. Female)	2.75 (1.39-5.43)	2.06 (0.89-4.77)	2.53 (0.85-7.52)	0.78 (0.22-2.73)
GFR mL/min	0.88 (0.83-0.93)	0.85 (0.79-0.91)	0.78 (0.70-0.88)	0.88 (0.79-0.98)
Log uACR	1.33 (1.10-1.62)	1.34 (1.07-1.69)	1.56 (1.07-2.29)	1.48 (1.07-2.06)
Log ProBNP	1.43 (1.14-1.78)	1.37 (1.02-1.85)	n.s.	n.s.
Log IL6	n.s.	0.65 (0.45-0.94)	n.s.	n.s.
Log CRP	n.s.	n.s.	n.s.	1.67 (1.03-1.70)
C Statistic Difference	0.01 (-0.00-0.03)	0.02 (0.01-0.05)	-0.00 (-0.00-0.02)	0.02 (-0.00-0.08)
NRI	0.4% (-8.4%-19.5%)	3.0% (0.8%-33.2%)		-4.0% (-12.1%-27.6%)

Conclusions: Different NBMs are independently associated with RRT progression in specific KDs after adjustment for age, sex and kidney markers (eGFR and uACR). Addition of NBMs to base models results in differential and modest improvement of RRT risk prediction.

Long Term Outcomes of Severe AKI: Results of the Post-Renal Study Martin P. Gallagher,[1] Rinaldo Bellomo,[2] Alan Cass,[1] David Gattas,[3] Joanne Y. Lee,[1] Serigne N. Lo,[1] Shay Mcguinness,[4] John A. Myburgh,[1] Rachael L. Parke.[4] *[1]The George Institute for Global Health, Australia; [2]The Austin Hospital, Australia; [3]Royal Prince Alfed Hospital, Australia; [4]Auckland City Hospital, New Zealand.*

Background: The literature on long term outcomes from AKI is derived from retrospective cohorts that often use administrative data and exclude early patient death from the analyses. Recent literature has emphasised the increased risk of end stage kidney disease in survivors of an episode of AKI with few prospectively derived reports of the markers of chronic kidney disease in such survivors. We report the 3.5 year outcomes of a large prospective cohort of patients with acute kidney injury (AKI) enrolled in the Randomised Evaluation of Normal vs Augmented Level of Renal Replacement (RENAL) Study.

Methods: The RENAL Study randomised patients with AKI in intensive care to standard dose (25 ml/kg/hr) or higher dose (40 ml/kg/hr) continuous renal replacement, with no mortality difference at 90 days. Ethics approval was granted at 35 centres to ascertain mortality, dialysis and clinical outcomes on all patients surviving beyond day 90. Extended follow up was derived by using a combination of data linkage to mortality registers and the ANZDATA Registry, along with clinical visits in consenting survivors.

Results: Outcomes were ascertained on 98% (1464/1508) of the randomised RENAL Study participants at a median of 43.9 months following randomisation. During follow up 258 patients (32% of those alive at day 90) died, giving an overall mortality from randomisation of 62%. Survival was not different between the two study interventions. A total of 44 patients (5.4% of patients alive at day 90) entered a maintenance dialysis program during follow up. Albuminuria was present in 42% of survivors and mean eGFR was 58 ml/min/1.73m^2.

Conclusions: Mortality risk over the 3.5 years following an episode of severe AKI in ICU is greater than the requirement for maintenance dialysis. Dialysis dose intensity does not influence mortality nor requirement for long term dialysis. Survivors have a high prevalence of risk factors for chronic kidney disease and mortality, most notably albuminuria.

Polymorphisms in the Myeloperoxidase Gene Locus and Acute Kidney Injury: A Two-Step Genetic Association Study Mary Celine R. Perianayagam,[1] Hocine Tighiouart,[2] Orfeas Liangos,[3] Diana Kouznetsov,[4] Ron Wald,[5] Fangwen Rao,[6] Daniel T. O'Connor,[6] Bertrand L. Jaber.[1] *[1]Department of Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Biostatistics Research Center, Tufts Medical Center, Boston, MA; [3]III. Medizinische Klinik, Klinikum Coburg, Coburg, Germany; [4]University of Massachusetts Memorial Medical Center, Worcester, MA; [5]Division of Nephrology, St. Michael's Hospital and University of Toronto, Toronto, Canada; [6]Department of Medicine, Center for Human Genetics and Genomics, La Jolla, CA.*

Background: Myeloperoxidase (MPO) is a lysosomal enzyme that may be involved in oxidative stress-mediated kidney injury.

Methods: Using a 2-step approach, we examined the association of 4 polymorphisms (rs2243828, rs7208693, rs2071409, and rs2759) acrossthe MPO gene locus with systemic markers of oxidative stress and adverse outcomes in 262 hospitalized adults with AKI *primary cohort*), and 277 patients undergoing cardiac surgery with cardiopulmonary bypass at-risk for post-operative AKI *secondary cohort*). Dominant and haplotype multivariable logistic regression analyses were performed.

Results: In the primary cohort, a genotype-phenotype association was observed between all 4 MPO polymorphisms and 2 markers of oxidative stress, plasma MPO and urinary 15-F_{2t}-isoprostane levels. In adjusted analyses, all 4 polymorphic allele groups had 2-3-fold higher odds for the composite of dialysis requirement or in-hospital death, as well as the composite of dialysis requirement, assisted mechanical ventilation or in-hospital death. The MPO T-G-A-T haplotype copy-number was associated with lower plasma MPO levels and lower adjusted odds for the composite outcomes. Significant but less consistent associations were observed in the *secondary cohort*.

Conclusions: This 2-step genetic association study identifies several polymorphisms spanning the entire MPO gene locus and a common haplotype as risk markers for artificial organ support or in-hospital death in patients with or at-risk for AKI. Additional studies are needed to replicate these findings, and establish the mechanisms underlying the influence of genotypes on disease traits.

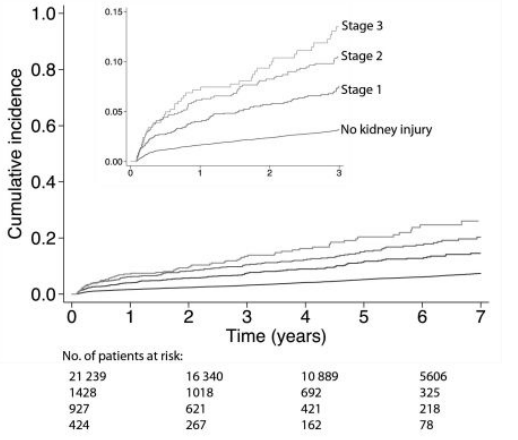
SA-OR010

Acute Kidney Injury Following Coronary Artery Bypass Surgery and Long-Term Risk of Incident Heart Failure Daniel Olsson, Ulrik Sartipy, Martin Holzmann. *Karolinska Institute, Stockholm, Sweden.*

Background: Acute kidney injury (AKI) after coronary artery bypass grafting (CABG) is common and increases the risk of post-operative complications and mortality. There is little information on the association between AKI after CABG and long-term risk of incident heart failure.

Methods: All patients (n=24 018) undergoing primary, isolated CABG between 2000 and 2008 with complete information on pre- and post-operative serum creatinine values and no prior hospitalization for heart failure were included. Acute kidney injury was divided into three stages based on absolute increase in post-operative serum creatinine; Stage 1. 0.3-0.5 mg/dL; Stage 2. 0.5-1 mg/dL; Stage 3. >1 mg/dL. Hazard ratios with 95% confidence intervals for first hospitalization for heart failure were calculated for different stages of AKI using Cox proportional hazards regression.

Results: Mean age was 67 years, 21% were women, 23% had diabetes mellitus and 19% chronic kidney disease. Twelve percent of the study population developed AKI and during a mean follow-up of 4.1 years there were 1325 (5.5%) cases of new-onset heart failure. Among patients with AKI 12% developed heart failure during follow-up compared to 5% among patients without AKI. Hazard ratios for heart failure in AKI stage 1, 2 and 3 were 1.60 (1.34-1.92), 1.87 (1.54-2.27), 1.98 (1.53-2.57) respectively, after adjustment for age, sex, diabetes mellitus, estimated glomerular filtration rate, left ventricular ejection fraction, myocardial infarction before or during follow-up. The cumulative incidence of first hospitalization for heart failure according to AKI is shown in Figure 1.



Conclusions: Acute kidney injury is associated with increased long-term risk of developing heart failure after CABG. Patients undergoing CABG should be assessed for development of post-operative AKI and followed more closely in order to detect early changes in cardiac function.

SA-OR011

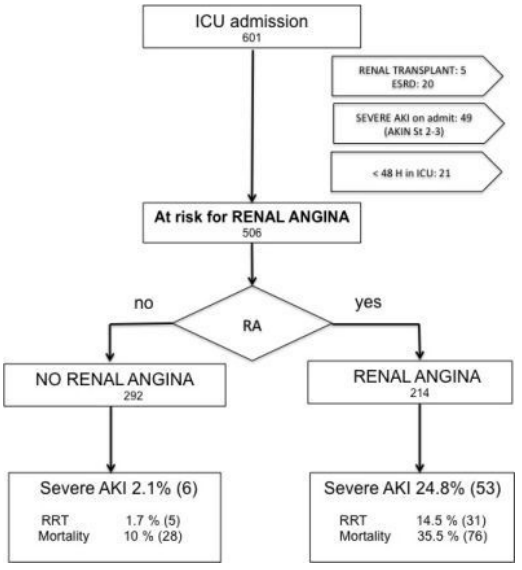
Renal Angina Syndrome (RA) Predicts Severe Acute Kidney Injury (AKI) in Critically Ill Patients Asunción Ferrer-Nadal,[1] Silvia Gramaticopolo,[2] Pasquale Piccinni,[2] Nicola Brienza,[3] Claudio Ronco,[1] Dinna N. Cruz.[1] *[1]IRRIV, Dept. of Nephrology, Dialysis and Transplantation, S. Bortolo Hospital, Vicenza, Italy; [2]Dept. of Intensive Care and Anesthesiology, S. Bortolo Hospital, Vicenza, Italy; [3]Univ. Bari.*

Background: Identifying patients at risk for AKI in ICUs could allow physicians to start earlier preventitive strategies. This could also serve as an "enriched" population for AKI biomarker testing. Recently, a definition for a renal anginal syndrome equivalent has been proposed. Our aim was to evaluate if RA is a good predictor of severe AKI in the ICU.

Methods: We performed a secondary analysis of data from a prospective multicenter ICU cohort (NEFROINT study). We excluded ESRD, severe AKI (defined as AKIN St 2-3) on ICU admission, and ICU stay<48h, leaving 506 patients at risk for developing RA. We classified patients as very high, high and low risk (VHR, HR, LR) for RA based on published acute, major and minor risk factors (Chawla 2005). RA was defined as ↑sCr 0.1, 0.3 and 0.4mg/dL over baseline in VHR, HR and LR patients, respectively. These were then labeled as RA1, RA2 and RA3. Main outcome was development of severe AKI after RA.

Results: Of 506 patients (mean age 62 yrs, 60% M), 214 (42%) had RA. Among them, RA1 occurred in 90 (42%), RA2 in 80 (37%) and RA3 in 44 (21%) patients. RA subjects were older, had more CVD, CKD and sepsis, and higher APACHE II (p<0.001 for all). Severe AKI (AKIN St 2-3) developed in 53 (25%) subjects in the RA group vs 6 (2%) in patients without RA (Fig 1). They also had higher need for RRT, mortality (Fig 1) and longer ICU stay (13±15 vs 8±9 days [no RA], p<0.001).

Conclusions: The proposed definition for RA syndrome can identify patients at high risk to develop AKI and adverse outcomes in the ICU. This may be useful for informing clinical decision making and trial design. RA patients can be a target population for AKI biomarker testing.



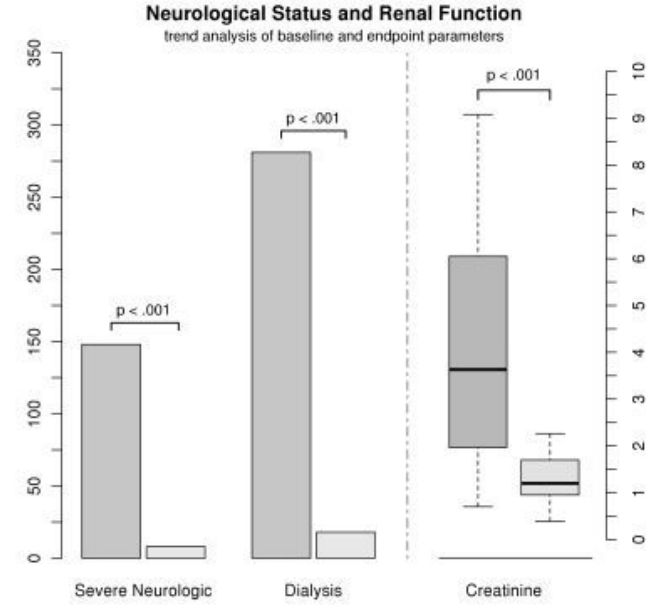
SA-OR012

Comparison of Therapeutic Plasma Exchange Alone or in Combination with Eculizumab for the Treatment of Shiga-Toxin-Producing E. Coli O104:H4 Induced Hemolytic Uremic Syndrome: An Analysis of the German STEC-HUS Registry Jan T. Kielstein, Gernot Beutel, Tobias N. Meyer, Andreas Kribben, Sylvia Stracke, Eiske Dorresteijn, Ola G. Samuelsson, reinhard Brunkhorst Richard Brunkhorst. *STEC-HUS Registry of the German Society of Nephrology.*

Background: In 2011 an outbreak of Shiga-toxin-producing E. coli (STEC) O104:H4 in Northern Germany claimed 52 deaths in 2,987 STEC and 855 HUS cases.

Methods: Using a web-based registry, established 5 days after the start of the outbreak, we aimed to describe short term effectiveness of best supportive care (BSC), therapeutic plasma exchange (TPE), and TPE with eculizumab (TPE-Ecu) using propensity score analysis.

Results: Of 621 entries from 84 hospitals (Germany, Sweden, Netherlands) 491 fulfilled the definition of HUS (median age 46 years; 71% females). Median [IQR] hospital stay was 22 [14-31] d. 281 (57%) patients underwent dialysis, 114 (23%) mechanical ventilation. 57 patients received BSC, 241 TPE and 193 TPE-Ecu. Disease severity (hemolysis, need for dialysis, frequency of seizures) were lower in BSC than in TPE and TPE-Ecu patients. At study endpoint (hospital discharge or death), median creatinine was lower in BSC (1.1 mg/dL [0.9-1.3]) than in TPE (1.2 mg/dL [1.0-1.5], p<0.05) and TPE-Ecu (1.4 mg/dl [1.0-2.2], p<0.001). Need for dialysis was not different between BSC (0.0%, n=0), TPE (3.7 %; n=9) and TPE-Ecu (4.7%, n=9). Severe neurolgical symptoms were markedly reduced at endpoiunt.



Total hospital mortality in HUS patients was 4.1% (n=20) and did not differ between TPE and TPE-Ecu.

Conclusions: Despite frequent renal impairment, advanced neurological disorders, and severe respiratory failure short term outcome was better than expected as compared to previous reports. Within the limitations of a retrospective registry analysis, our data do not prove marked differences in treatment efficiency between the groups.

SA-OR013

Quality of Communication about Acute Kidney Injury (AKI) at Hospital Discharge to Patients and Their Outpatient Providers Raquel Greer, Deidra C. Crews, Hamid Rabb, Bernard G. Jaar, L. Ebony Boulware. *Medicine, Johns Hopkins Medical Institutions, Baltimore, MD.*

Background: Given the long-term consequences associated with AKI (i.e. chronic kidney disease, cardiovascular disease, and death), communication between hospital-based and outpatient health care providers about the occurrence and care plan for patients hospitalized with AKI is important to ensure patients' adequate follow-up care.

Methods: We characterized the prevalence and quality of written discharge communications about the occurrence of AKI during hospitalizations for 284 adult patients in Baltimore, MD during 2009. We reviewed inpatients' medical records, discharge summaries, and documentation of patient's discharge instructions. Using a standardized data collection form, we assessed hospital-based providers' documentation of AKI in patients' discharge summaries, including their documentation of the cause of AKI, peak and discharge creatinine and instructions for follow-up appointments. We also assessed mention of AKI in discharge instructions provided to patients.

Results: Of 284 patients with AKI (stages 1-3 defined by AKIN criteria) during their hospitalization, only 168 (59%) discharge summaries documented the occurrence of AKI. While the discharge summaries mentioned the cause of AKI in all documented cases, many did not include a discharge creatinine (61%) or peak creatinine (41%). Most (77%) included instructions for patients to follow-up with an outpatient provider (12% with a nephrologist and 76% with a primary care or other provider). However, follow-up medical plans for treatment or observation of patients were not provided in 20% of summaries. Of the patients whose creatinine did not return to baseline prior to discharge (n=177), only 27% included clear plans for follow-up assessment. Among 88 patients whose patient discharge instructions were available, few received information about the diagnosis (31%) or cause (12%) of AKI.

Conclusions: Communication of the occurrence of AKI and follow up care plans after hospital discharge to outpatient providers and patients is suboptimal. Interventions to improve transitions of care in hospitalized patients with AKI are needed.

SA-OR014

Association of Kallikrein-1 Gene Polymorphisms and Acute Kidney Injury: A Case-Control and Cohort Study Paweena Susantitaphong,[1,2] Mary Celine R. Perianayagam,[1] Sunwoo Kang,[3] Wenyi Zhang,[3] Fangwen Rao,[3] Daniel T. O'Connor,[3] Bertrand L. Jaber.[1] *[1]Medicine, St.Elizabeth's Medical Center, Boston, MA; [2]Medicine, Chulalongkorn University, Bangkok, Thailand; [3]Medicine, University of California, La Jolla, CA.*

Background: Kallikrein-1 (KLK1) is a highly conserved serine protease that is expressed in the kidney, and involved in blood pressure regulation. The activity of this enzyme is diminished in experimental and human AKI. We evaluated the potential role of functional multiallelic *KLK1* promoter gene polymorphisms in human AKI.

Methods: We first performed a case-control study of 481 subjects (214 patients with AKI and 267 healthy controls). The complex, multiallelic G/C-rich repeat region of the proximal *KLK1* promoter was determined in each subject by direct Sanger/capillary re-sequencing. Association between *KLK1* promoter polymorphisms and development of AKI, and the composite of doubling of serum creatinine, oliguria, or dialysis requirement were explored by logistic regression analyses.

Results: Sixteen alleles were identified in a complex, polymorphic G/C-rich region of the *KLK1* proximal promoter; frequencies for 5 of these alleles (F, G, H, I, and K) were associated with development of AKI. Alleles I and G were classified as risk-alleles (unadjusted OR 1.86; 95% CI 1.23, 2.81; P=0.003), whereas alleles F, H, and K were classified as protective-alleles (unadjusted OR 0.32; 95% CI 0.22, 0.46; P<0.001), according to their directional association with development of AKI. After adjustment for sex, race, or APACHE II score, the *KLK1* risk-allele carrier state was associated with the composite of doubling of serum creatinine, oliguria, or dialysis requirement (adjusted odds ratio 2.62; 95% CI 1.11, 6.20, P=0.03). The *KLK1* risk-allele carrier state was also marginally associated with the composite of doubling of serum creatinine, oliguria, dialysis requirement, or in-hospital death (adjusted OR 2.26; 95% CI 0.96, 5.33; P=0.06).

Conclusions: *KLK1* promoter polymorphisms are associated with development of AKI, and adverse kidney-related outcomes. Further studies are needed to validate these findings.

Nutritional Supplement Use and Mortality in Hemodialysis

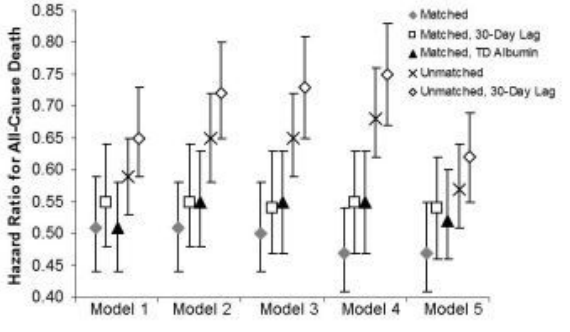
Daniel E. Weiner,[1] Hocine Tighiouart,[1] Klemens B. Meyer,[1] P. Zager,[2] Doug Johnson.[2] *[1]Tufts Medical Center, Boston, MA; [2]Dialysis Clinic, Inc, Nashville, TN.*

Background: Hemodialysis patients have high mortality rates, and malnutrition may be an important factor contributing to poor outcomes. DCI widely implemented a nutritional supplement protocol (NSP), such that, when serum albumin was ≤3.5 g/dl (BCG), patients would receive 15g of oral protein at each dialysis session until albumin reached 4 g/dl. We evaluated the impact of this program on mortality.

Methods: Patients in facilities that largely adopted the NSP in 9-10/2010 were paired with patients from facilities that did not adopt the NSP using a greedy matching algorithm based on a propensity score for physician ordering of the NSP. The propensity score was built using extensive data on individual patient and facility characteristics. We then used Cox models to assess the patient-level association between the NSP and mortality through March 2012, with secondary analyses incorporating time dependent albumin measures, evaluating a 30-day lag, and looking at unmatched data with multivariable adjustment.

Results: Of 7568 eligible patients, 2702 were ordered the NSP and 1571 of these were matched to controls; only blood pressure had standardized difference >10% between groups. In the matched cohort, there were 331 deaths in the NSP group vs 504 in controls. Albumin increased over time only in the NSP group, and, in all analyses, the NSP was associated with significantly lower mortality (figure). This effect was most prominent at lower baseline albumin levels.

Conclusions: NSP protocol use is associated with a significant reduction in mortality for in-center hemodialysis patients.



Model 1: Univariate +/- time-dependent albumin
Model 2: Model 1 + age, sex, race
Model 3: Model 2 + ESRD cause, access, vintage
Model 4: Model 3 + patient clinical characteristics and labs
Model 5: Model 4 + facility characteristics, including prior SMR

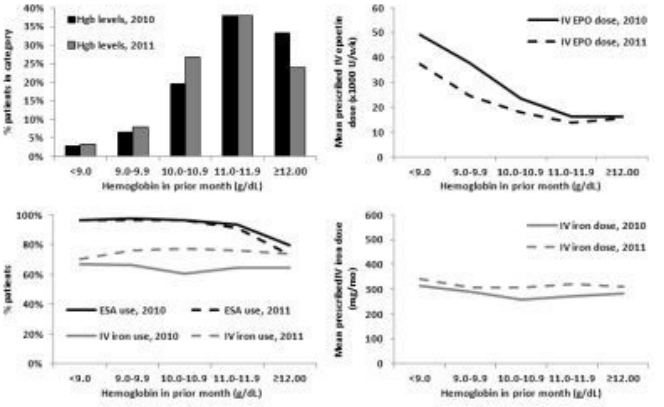
The DOPPS Practice Monitor: Patient Hemoglobin (Hgb) Levels and Changes in Anemia Management Practice in US Hemodialysis Patients from 2010 to 2011

Douglas S. Fuller,[1] Ronald L. Pisoni,[1] Brenda W. Gillespie,[2] Bruce M. Robinson.[1,2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]U of Michigan, Ann Arbor, MI.*

Background: In response to changes in erythropoietin-stimulating agent (ESA) labeling, reimbursement policy, and quality incentive payment (QIP) targets for US dialysis patients (pts), it has been reported that Hgb levels declined from 2010 to 2011 and rates of red blood cell transfusions increased. Here we identify changes in anemia management practices (AMPs) over this time period.

Methods: Using cross-sectional samples from the US Dialysis Outcomes and Practice Patterns Study (DOPPS) Practice Monitor (DPM), we describe Hgb levels in Sep 2010 and Sep 2011 (n=6,958), as well as anemia management practices (AMPs) in response to these Hgb levels (in Oct 2010 and Oct 2011; n=6,899).

Results: From 2010 to 2011, Hgb ≥12 g/dL declined by 9% and Hgb 11-11.9 declined by 5%, while Hgb 10-10.9 rose by 9% and Hgb <10g/dL rose by 5%.



% ESA use was stable in most Hgb groups but declined in pts with Hgb ≥12 g/dL. Mean prescribed IV Epo dose declined 31% for Hgb <10 g/dL, 24% for Hgb 10-11 g/dL, and 12% for Hgb ≥11 g/dL. However, the decline in mean delivered IV Epo dose was similar for all Hgb groups (28%) because of an increase in Epo dose holds at high Hgb levels (not shown). % IV iron use rose modestly for all Hgb levels except Hgb <9. Prescribed IV iron dose increased 7-10% for Hgb <10 g/dL, and 18% for Hgb 10-12 g/dL.

Conclusions: There was a large shift toward lower Hgb levels from 2010 to 2011. Although the largest change in distribution was from ≥12 to 10-10.9 g/dL, 14% of patients had Hgb <10g/dL in Sep 2011. Pts with Hgb <10 g/dL had the largest decline in subsequent prescribed EPO doses, but similar IV iron prescription patterns as other pts. To limit transfusions, consideration to raising EPO dose and IV iron use in pts with Hgb <10 g/dL is warranted.

Variation in Observed Infection Control Practices in the NOTICE Project

Joseph M. Messana,[1] Stephen C. Hines,[2] Rajiv Saran,[1] John Kalbfleisch,[1] Teri Spencer,[3] Kelly M. Frank,[4] Diane Carlson,[5] Jan Deane,[5] Erik Roys,[1] Natalie Scholz,[1] Casey Parrotte,[1] Carol Chenoweth.[1] *[1]Uni. of MI, Ann Arbor, MI; [2]HRET, Chicago, IL; [3]TB Spencer Consulting LLC, Fallbrook, CA; [4]CMS, Waterloo, IA; [5]Renal Network of the Upper Midwest, Inc., St. Paul, MN.*

Background: The National Opportunity to Improve Infection Control in ESRD (NOTICE) project is designed to assess recommended infection control (IC) practices at US dialysis facilities with the aim of identifying potential areas for quality improvement.

Methods: Trained IC Evaluators observed 73 distinct IC practices at 34 randomly selected hemodialysis facilities. Facility selection was stratified on large dialysis organization (LDO) affiliation, size, socioeconomic status, and urban/rural status from 4 ESRD Networks. Observations were made using an IC Worksheet (ICWS) developed under contract with AHRQ in collaboration with CMS and the CDC.

Results: There was considerable variation in IC practices across enrolled facilities. Overall adherence was 68% (range=53% to 92%). Overall adherence to expected hand hygiene (HH) practice was 72% (range=30% to 95%). Use of chlorhexidine was 19% overall but varied from 35% in independent facilities to 0% in LDO facilities. Overall HH and medication preparation procedures (cleaning the injection port, proper needle insertion, and proper assembly of supplies) were significant predictors of ICD-9 based infection rate (p=0.02).

Mean % Adherence to ICWS items selected for low adherence

Selected ICWS Items	Mean %
Overall Adherance	68
Adherance to Hand Hygiene Items	72
Use Antimicrobial Ointment	17
Transfer of Non-Disposable Items to Common Areas	18
Use Chlorhexidine	19
Vacate Dialysis Chair Prior to Disinfecting	26
Scrub External CVC Hub at Termination	29
Disinfect Non-Disposable Items	31
Scrub Internal CVC Hub at Initiation	34
Scrub Internal CVC Hub at Termination	36
Disinfect Surfaces per Manufacturer DFU	41
Scrub External CVC Hub at Initiation	45
Wash Skin Over CVC Access	53

Conclusions: Our findings suggest that there is room for improvement in HH and other IC practices. These NOTICE project findings will help to inform the development of a larger quality improvement initiative at dialysis facilities.

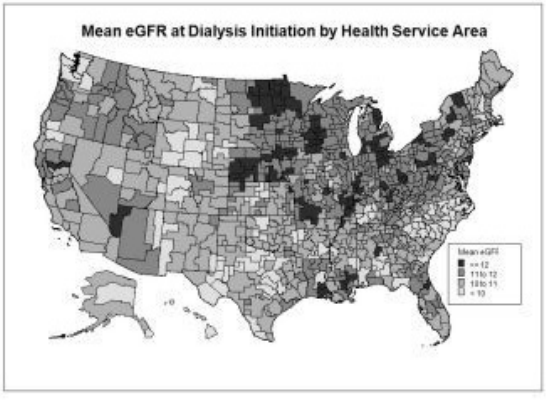
Geographic Variation in the Timing of Dialysis Initiation in the US
Julia J. Scialla,[1,2] Deidra C. Crews,[1,3] Jiannong Liu,[1,4] Haifeng Guo,[1,4] Karen J. Bandeen-roche,[1,3] L. Ebony Boulware.[1,3] *[1]For the DEcIDE Network Patient Outcomes in End Stage Renal Disease Study Investigators; [2]University of Miami; [3]Johns Hopkins University; [4]Chronic Disease Research Group.*

Background: There is an ongoing trend of earlier dialysis initiation worldwide despite no evidence of clinical benefit. Regional differences in the timing of dialysis initiation in the US have not been examined.

Methods: Using the US Renal Data System ESRD database, we identified 310,962 adult patients initiating dialysis between 2006-2008 within the 805 health service areas (HSAs) in the US. We obtained demographics, comorbidity and serum creatinine from CMS Form 2728 for each participant and estimated GFR at initiation using the 4-variable MDRD equation. We plotted the HSA-level mean eGFR at dialysis initiation using a Bayesian hierarchical model to smooth the eGFR means and delineate patterns. A random effects model was used to calculate adjusted and unadjusted mean eGFR for each HSA and assess geographic variation based on those estimates.

Results: Mean eGFR at dialysis initiation showed a regional pattern.



The mean HSA-level eGFR at dialysis initiation was 10.92 (SD 0.92) ml/min/1.73m^2. The variability in mean eGFR at dialysis initiation across HSAs was decreased by 11% after adjusting for age, sex, race, ethnicity and income (mean eGFR 10.92; SD 0.82 ml/min/1.73m^2). Variability did not decrease any further after adjustment for comorbidity index, diabetes and congestive heart failure (mean eGFR 10.92; SD 0.85 ml/min/1.73m^2). With full adjustment, 92% of the variation across HSAs was not accounted for by patient-level characteristics.

Conclusions: The timing of dialysis initiation varies across the US. Differences in patient characteristics only account for a small portion of the variability, suggesting that patient/provider preferences and/or health system factors may account for this variation.

Early Referral to Nephrologist Improves Risk Stratification of Mortality in Patients at Dialysis Initiation but Exerts Limited Survival Advantage
Terumasa Hayashi, Kodo Tomida, Tatsuya Shoji, Noriyuki Okada, Yoshiharu Tsubakihara. *Kidney Disease and Hypertension, Osaka General Medical Center, Osaka, Japan.*

Background: Impact of early referral (ER) on predialysis risk stratification of mortality and on long-term survival are closely interacted, however they have been assessed separately. Thus, the present study was aimed to examine whether ER improves risk stratification of mortality at dialysis initiation and exerts long-term survival advantage.

Methods: Using Cox proportional hazards models, the effect of referral timing on long-term survival stratified by eGFR at dialysis initiation was analyzed in 603 consecutive patients between 2001 and 2008 in Senshu district in Osaka prefecture, Japan.

Results: The median eGFR at dialysis initiation was 5.26 ml/min/1.73m^2 and the 5-year-mortality rate was 56%. In ER group (referred to nephrologist ≥ 6 months before dialysis initiation), unadjusted analysis revealed that the hazard ratio (HR) of mortality was increased with increased eGFR at dialysis initiation, but after adjustment for age, gender, diabetes, and other clinical characteristics at dialysis initiation, HR was identical among the eGFR categories. Contrary, in late referral (LR) group, mortality risk was independent on the eGFR categories.

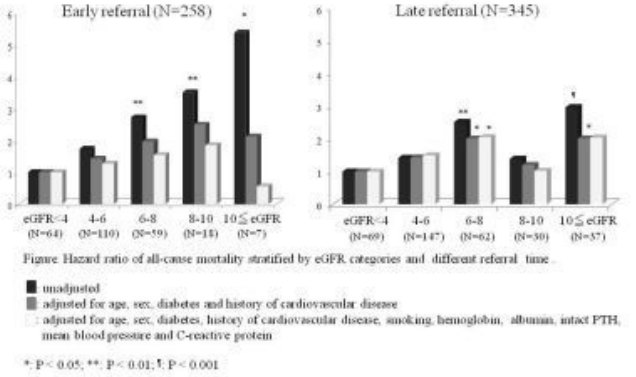

Figure Hazard ratio of all-cause mortality stratified by eGFR categories and different referral time.

unadjusted
adjusted for age, sex, diabetes and history of cardiovascular disease
adjusted for age, sex, diabetes, history of cardiovascular disease, smoking, hemoglobin, albumin, intact PTH, mean blood pressure and C-reactive protein

*: P < 0.05; **: P < 0.01; ¶: P < 0.001

Furthermore, the detrimental effect of ER on survival was limited to the first 6 months. The effect of referral timing on survival was not significant (HR 1.124, 95%CI 0.828-1.527). Of note, HR of LR for early death was 2.615 (95%CI 1.440-4.750) and after extensive adjustment, the HR became marginal (HR 1.878, 95%CI 0.968-3.644).

Conclusions: Although our results suggest that predialysis care improve patients survival by stratifying the mortality risk at dialysis initiation, the effect is limited to the first few month. The strategy to prevent early death on dialysis for LR patients needs to be established.

SA-OR020

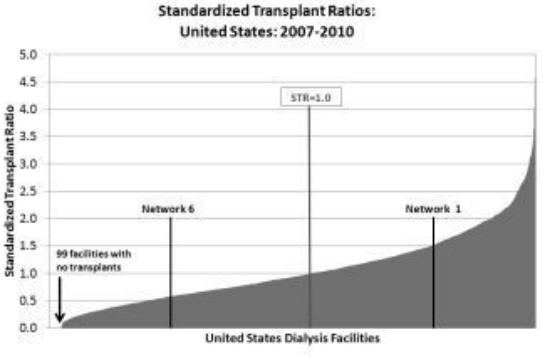
Factors Associated with Low Kidney Transplant Rates among United States Dialysis Facilities
Rachel E. Patzer,[1] Carlos F. Zayas,[2] Laura L. Mulloy,[3] Stephen O. Pastan.[1] *[1]Emory Transplant Center, Atlanta, GA; [2]Piedmont Transplant Center, Atlanta, GA; [3]Georgia Health Sciences, Augusta, GA.*

Background: Variability in transplant rates between different dialysis units has been noted, yet little is known about facility-level factors associated with low standardized transplant ratios (STRs) across facilities in the 18 End Stage Renal Disease (ESRD) Networks within the United States (US).

Methods: We analyzed Centers for Medicare and Medicaid Services Dialysis Facility Report data for facilities open from 2007 to 2010. Multivariable-adjusted linear regression models were used to identify the facility characteristics associated with low four-year average STR and to examine regional differences across ESRD Networks.

Results: Among 4,098 dialysis facilities treating 243,038 patients, there was variability in facility-level STRs across the 18 ESRD networks. Median 4-year facility-level STRs ranged from 0.61 [Interquartile Range (IQR): 0.36, 0.94] in Network 6 (Southeastern Kidney Council) to 1.52 (IQR: 0.95, 2.18) in Network 1 (New England). 99 (2.4%) of dialysis facilities reported an STR of zero for all four years. The majority of dialysis facilities reporting STRs of zero were in Network 6 (34.3%), followed by ESRD Network 13 (11.1%). In multivariable analyses, factors significantly associated with a lower STR (p<0.0001) included a higher percentage of African Americans, older patient age, diabetes, cardiovascular disease, a higher proportion of patients on ESRD therapy for > five years, lower number of facility staff, lack of pre-ESRD nephrology care, for-profit facility status, and ESRD network region.

Conclusions: There is significant variability in dialysis facility-level STRs in the US. Understanding the modifiable factors associated with low transplant rates can be used to develop interventions to improve access to kidney transplantation among low-performing dialysis facilities.



SA-OR021

Segregation, Income Disparity and Survival in US HD Patients

Paul L. Kimmel,[1] Chyng-Wen Fwu,[2] Paul W. Eggers.[1] *[1]Division of Kidney, Urologic and Hematologic Diseases, NIDDK, NIH, Bethesda, MD; [2]Social & Scientific Systems, Inc., Silver Spring, MD.*

Background: Social determinants of health and ecologic analyses have become increasingly important in analyses of population health. Residential segregation has been highlighted as an important correlate of health in the US. Socioeconomic status (SES) is associated with improved survival in diverse conditions. US states with greater income maldistribution have increased mortality. Black US end-stage renal disease (ESRD) HD patient survival, however, is improved compared to Whites, with higher income. The underlying mechanisms are unknown. We examined associations of income inequality and residence as social determinants of health with Black and White ESRD patients' survival.

Methods: US Renal Data System information, 2000-2008, regarding patients starting HD for ESRD was merged with Census Bureau Black and White race-specific median household income to assess SES, and Gini coefficients to assess income inequality. Residential segregation was determined by the Dissimilarity Index (DI). Survival was compared using Cox proportional hazard models, controlling for known risk factors.

Results: 589,036 patients were included. Mean median area household income for Black and White patients was $26,742 and $41,922 ($p<0.001$). Residence in areas with higher median household income was associated with improved survival. In White patients only, income inequality was associated with mortality (hazard ratio (HR) for the highest relative to lowest quartile of Gini coefficient was 1.06, $p<0.001$). In Black patients exclusively, residence in highly segregated areas was associated with increased mortality (HR for the highest relative to lowest quartile of DI was 1.13, $p<0.001$).

Conclusions: Black US ESRD HD patients are particularly susceptible to gradients in income and residential segregation. Unknown biological, psychosocial or cultural factors associated with SES and neighborhood characteristics may mediate differential survival for Black ESRD patients. Interventions will be challenging, involving multiple organizations at varying levels, but those directed at highly segregated Black neighborhoods might favorably affect HD patient outcomes.

Generation and Characterization of a Novel Pericyte-Specific Conditional Cre Mouse Line

Ivica Grgic,[1,2] Andreas Hofmeister,[1,2] Benjamin D. Humphreys.[2] *[1]Dept. of Internal Medicine and Nephrology, Philipps-University Marburg, Marburg, Germany; [2]Renal Division, Brigham and Women's Hospital, Boston, MA.*

Background: Cre drivers are now indispensable tools for studying the biology of specific cell populations *in vivo*. The ability to control the time point and frequency of Cre mediated recombination is desirable in many situations, and there is a lack of such conditional Cre driver lines to study pericytes - a main source of myofibroblast recruitment in renal fibrosis.

Methods: We utilized the collagen 1α1 promoter/enhancer to drive expression of a triple fusion protein consisting of GFP, Cre recombinase and the mutated estrogen receptor ERT2 and created a novel conditional Cre mouse line with tamoxifen-inducible *cre* activity in pericytes.

Results: We validated this Coll1α1GCE mouse by crossing it to three different reporter lines (R26LacZ, mT/mG and R26Tomato) and treating bigenic offspring with tamoxifen. Genetically labeled cells were found in kidney tubulointerstitium of all three bigenic lines. These cells stained positive for pericyte marker PDGFRβ but not for CD31, F4/80, CD3, αSMA or S100A4 in healthy kidneys thus verifying their pericyte identity. Morphological analysis revealed a typically spindle- or triangle-like cell shape with prominent projections and a close association with endothelial cells. Some pericyte processes projected within the capillary basement membrane. One submaximal dose of tamoxifen at P7 labeled 1.5 ± 0.4% and three consecutive tamoxifen pulses (P7-P9) labeled 25.8 ± 5.1% of all PDGFRβ+ pericytes. During UUO, fate labeled pericytes acquired αSMA positivity reflecting their transformation into myofibroblasts. Morphometrical analysis of single fate-labeled pericytes showed that while there was no significant difference in cell size between kidney pericytes of P9 pups (92.5 ± 3.4μm^2) and adult mice (101.8 ± 4.3 μm^2), there was a notable increase in size (128.8 ± 3.3μm^2; $P<0.0001$) and complexity after myofibroblast differentiation in UUO kidneys.

Conclusions: In conclusion, we have developed a new pericyte-specific conditional Cre driver mouse as a versatile new tool to study the biology of pericytes in health and disease.

Funding: NIDDK Support

Dysfunction of Fibroblasts of Extra-Renal Origin Underlies Renal Fibrosis and Renal Anemia

Masayuki Takase,[1] Nariaki Asada,[1] Jin Nakamura,[1] Akiko Oguchi,[1] Misako Asada,[1] Norio Suzuki,[2] Narihito Nagoshi,[3] Shinsuke Shibata,[3] Nageswara Rao Tata,[4] Hans Jörg Fehling,[4] Atsushi Fukatsu,[5] Naoko Minegishi,[2] Hideyuki Okano,[3] Masayuki Yamamoto,[2] Motoko Yanagita.[1] *[1]Kyoto University, Japan; [2]Tohoku University, Japan; [3]Keio University, Japan; [4]University of Clinics Ulm, Germany; [5]Yachiyo Hospital, Japan.*

Background: Renal anemia and renal fibrosis are common complications during chronic kidney disease (CKD), which is caused by the dysfunction of renal fibroblasts. Renal fibrosis is mediated by the accumulation of myofibroblasts, whereas renal anemia is mediated by the reduced production of erythropoietin (EPO) in some fibroblasts. Despite of the essential role of fibroblasts in the kidney, their characteristics and developmental origin remain unknown.

Methods: To explore the origin of the fibroblast, we trace the fate of neural crest-derived cells, utilizing transgenic mice expressing *cre* recombinase under the control of myelin protein zero (*P0-Cre* mice), a marker of migrating neural crest cells. In *P0-Cre:indicator* mice, the cells arising from *P0-Cre*–expressing precursors were tagged with the expression of indicator genes.

Results: We demonstrated that most of the fibroblasts in the kidney cortex and outer medulla are *P0-Cre* lineage-labeled cells (P0 cells), and that some of them are EPO producing cells. P0 cells migrate into the embryonic kidney at E13.5 and differentiate into fibroblasts. In the diseased kidney, P0 cells transdifferentiate into myofibroblasts and predominantly contribute to fibrosis, with concomitant loss of EPO production. We further demonstrated that attenuated EPO production in transdifferentiated myofibroblasts is recovered by the administration of neuroprotective agents. Moreover, the in vivo administration of tamoxifen, a selective estrogen receptor modulator, restores reduced production of EPO and attenuates renal fibrosis.

Conclusions: These findings clarify the direct link between renal fibrosis and renal anemia. Therapeutic trials targeting *P0-Cre* lineage-labeled fibroblasts might be effective for both renal fibrosis and renal anemia.

SA-OR024

Exploring the Function of Renal Fibroblasts of Extra-Renal Origin

Jin Nakamura, Akiko Oguchi, Motoko Yanagita. *Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: We previously reported that most of the fibroblasts in the kidney cortex and outer medulla are myelin protein zero-Cre (*P0-Cre*) lineage-labeled cells, and that some of them are EPO producing cells in the healthy kidney. In the diseased kidney, *P0-Cre* lineage-labeled cells transdifferentiate into myofibroblasts and predominantly contribute to fibrosis, with concomitant loss of EPO production. In the present study, we further investigated the pathophysiological function of *P0-Cre* linage-labeled fibroblasts (P0 cells) and the crosstalk between these cells and tubuloepithelial cells.

Methods: To analyze the function of P0 cells in the kidney, we utilized *P0-Cre* inducible simian diphtheria toxin receptor (DTR) transgenic mice (*P0-Cre:iDTR* mice) in which Cre-mediated excision of a STOP cassette renders P0 cells sensitive to diphtheria toxin (DT). The binding of DT to DTR halts protein synthesis within the cells.

Results: First we confirmed that DTR is expressed in almost all fibroblasts in the cortex and outer medulla in the kidney of *P0-Cre:iDTR* mice. After the administration of DT to *P0-Cre:iDTR* mice, the expression of DTR and fibroblast markers in the kidney was significantly decreased, indicating the effective cessation of protein synthesis in P0 cells. Simultaneously, the expression of EPO was also significantly reduced, and did not increase even after the induction of severe anemia. The administration of DT to *P0-Cre:iDTR* mice with unilateral ureteral obstruction (UUO) decreased the expression of PDGFRb, collagen1a1, and aSMA. Futhermore, we demonstrated that the administration of DT to *P0-Cre:iDTR* mice causes the expression of proximal tubule injury marker Kim1, and the proliferation of proximal tubule cells in the cortical-medullary junction.

Conclusions: Cessation of protein synthesis in P0 cells reduced the expression of EPO in healthy kidney and the fibrosis markers in UUO-operated kidney, supporting our previous findings. Cessation of protein synthesis in P0 cells also induced proliferation and injury of proximal tubule cells, suggesting the possible interactions between P0 cells and tubular epithelial cells. We are currently searching for the molecules responsible for the interactions.

SA-OR025

Lineage Tracing Reveals an Endothelial Origin for the Crim1$^{KST264/KST264}$ Renal Interstitial Fibrosis but Not Periglomerular Fibrosis

Yu Leng Phua, Nick Martel, Lorine J. Wilkinson, Melissa H. Little. *University of Queensland, Institute for Molecular Bioscience, Brisbane, Queensland, Australia.*

Background: Tubulointerstitial fibrosis is a detrimental pathological feature which exists in virtually all cases of progressive renal disease. The main characteristics include *de novo* appearance of myofibroblasts and collagen deposition within the interstitial space. The Crim1$^{KST264/KST264}$ hypomorphic mice develop progressive renal disease, identified by a series of renal abnormalities such as glomerular cysts, leaky peritubular capillaries and compromised endothelial integrity, eventually progressing to the development of peritubular interstitial and periglomerular fibrosis.

Methods: To delineate whether the endothelium may in part contribute to the fibrogenic process, endothelial gene expression profiling, transmission electron microscopy imaging of the endothelium as well as Tie2Cre-DsRed endothelial lineage tracing was undertaken in the Crim1$^{KST264/KST264}$ mice.

Results: In-depth ultrastructural analysis of the Crim1$^{KST264/KST264}$ renal endothelium revealed several endothelium abnormalities which include cellular detachment and abnormal collagen accumulation within the basement membrane. To further investigate this endothelium dysfunction, gene expression profiling of CD31$^+$ endothelial cell was performed which showed differentially expressed transcripts associated with renal fibrosis (*Col3a1, Loxl1, Serpina10*), endothelial dysfunction (*Abp1, Dcn, Lcn2*), biomarkers of renal damage (*Lcn2, Havcr1*) as well as evidence for a TGFβ1/TNF associated inflammatory process. Our lineage tracing of the Crim1$^{KST264/KST264}$ mice showed that approximately 31% of αSMA$^+$ myofibroblasts present within the interstitium were derived from the endothelium via Endothelial to Mesenchymal Transition. Conversely, a majority (88%) of αSMA$^+$ myofibroblasts surrounding glomerular cysts were not of an endothelial origin.

Conclusions: These results confirm the contribution of Endothelial to Mesenchymal Transition towards interstitial fibrosis, but also indicate differences in the origin of fibrosis within the same kidney in this model of renal damage.

Adiponectin Promotes Macrophage Polarization and Monocyte-to-Fibroblast Transition in Renal Fibrosis

Jun Yang,[1] Gang Chen,[2] Liqun He,[2] Zhaoyong Hu,[1] William E. Mitch,[1] Yanlin Wang.[1] *[1]Medicine-Nephrology, Baylor College of Medicine, Houston, TX; [2]Medicine-Nephrology, Shuguang Hospital, Shanghai, China.*

Background: Progressive renal fibrosis is the final common manifestation of chronic kidney disease resulting in irreversible loss of kidney parenchyma and renal function. We have recently demonstrated that bone marrow-derived fibroblasts contribute significantly to the pathogenesis of renal fibrosis. However, the signaling mechanisms underlying the recruitment and maturation of bone marrow-derived fibroblast precursors into the kidney in response to injury are incompletely understood. We found that adiponectin was upregulated in the kidney in a murine model of renal fibrosis. Therefore, we examined if adiponectin can regulate the maturation of bone marrow-derived fibroblasts in the kidney and development of renal fibrosis.

Methods: We performed unilateral ureteral obstruction to induce renal fibrosis in wild-type and adiponectin-knockout mice and utilized mouse splenocytes to examine the effect of adiponectin on monocyte to fibroblast transition.

Results: Compared with wild-type mice, adiponectin-knockout mice displayed significantly fewer bone marrow-derived fibroblasts in obstructed kidneys. Furthermore, we demonstrated that $CD206^+$ M2 macrophages produced procollagen I, which is associated with induction of Th2 cytokines - IL-4 and IL-13. Adiponectin knockout mice exhibited a significant reduction CD206 and procollagen I dual positive fibroblasts in obstructed kidneys, which was associated with a reduction of Th2 cytokines - IL-4 and IL-13. Consistent with these findings, targeted deletion of adiponectin inhibited myofibroblast activation, reduced total collagen deposition, and suppressed expression of collagen I and fibronectin. In vitro studies showed that adiponectin promoted macrophage polarization and monocyte to fibroblast transition and increased extracellular matrix protein expression.

Conclusions: Our study identifies adiponectin as a critical regulator of macrophage polarization and monocyte-to-fibroblast transition. Therefore, inhibition of adiponectin signaling may represent a novel therapeutic target for fibrotic kidney disease.

Increased Proximal Tubule PPARα Reduces Renal Interstitial Fibrosis by Reducing miR21 Expression and by Increasing Autophagy

Shenyang Li,[1,2] Judit Megyesi,[1,2] Alexandrea Holmes,[2] Sue Theus,[2] Peter M. Price,[1,2] Gur P. Kaushal,[1,2] Didier Portilla.[1,2] *[1]Division of Nephrology, UAMS, Little Rock, AR; [2]CAVHS, Little Rock, AR.*

Background: MicroRNA21(miR-21) expression is significantly increased in mice subjected to unilateral ischemia and unilateral ureteral obstruction (UUO). Reducing miR21 expression in kidney tissue by using oligos or miR21 knockout mice results in increased expression of PPARα in kidney tissue and amelioration of renal fibrosis (Sci Transl Med 2012 Feb). In the present study we examined mechanisms by which increased expression of proximal tubule PPARα reduces kidney fibrosis.

Methods: C57BL wild type mice and proximal tubule PPARα transgenic mice were subjected to 5 days of UUO. We compared the development of interstitial fibrosis detected by Sirius red staining of the kidneys, and mRNA expression of pathological matrix proteins Col1a1, Col3a1. We also measured expression of miR21, PPARα and fatty acid oxidation(FAO) genes MCAD and CPT1. In *in vitro* studies we examined the fibrotic response of proximal tubular epithelial cells in culture (TKPTS) to aristolochic acid (AA), a compound that induces progressive interstitial fibrosis. AA-mediated fibrosis was measured by changes in mRNA levels of Col1a1, TGFβ and miR21. Proximal tubular cell autophagy was measured by western blot as increased expression of LC3-II protein.

Results: Interstitial fibrosis induced by UUO was significantly reduced in PPARα Tg mice when compared to wild type mice. UUO-mediated reduction of FAO in wild type mice was recovered to normal levels in PPARα Tg mice. miR 21 expression was increased in wild type mice but significantly attenuated in PPARα Tg mice. Exposure of TKPTS cells to 10 uM AA for 18 hrs resulted in increased expression of TGFβ, Coll1a1 and miR21 mRNA levels. Increased expresion of PPARα by adenovirus infection attenuated AA-mediated increased expression of fibrotic genes and increased the expression of LC3II protein levels.

Conclusions: Increased expression of proximal tubule PPARα reduces UUO-mediated interstitial fibrosis by increasing FAO via reduced expression of miR21. PPARα reduces AA-mediated fibrotic response in TKPTS cells by increasing intracellular autophagy.

Renal Fibrosis Is Attenuated by Targeted Disruption of miR-22

Shawn Samson Badal, Jianyin Long, Yin Wang, Farhad R. Danesh. *Medicine-Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Progressive renal fibrosis is the final common manifestation of various chronic kidney diseases resulting in irreversible loss of kidney parenchyma. MicroRNAs are small noncoding RNAs that negatively regulate gene expression by base pairing to partially complementary sites in the 3'-untranslated regions of specific target mRNAs. An emerging body of evidence suggests that microRNAs serve as important therapeutic targets in a wide range of complex human diseases, including kidney diseases. miR-22 is a microRNA with predicted involvement in several pathways central to the development and progression of fibrosis.

Methods: We generated a miR-22 null mouse using a targeted strategy to replace and delete the genomic region containing the primary miR-22 sequence. A targeting vector with homology arms flanking this genomic locus was used to replace the pre-miR-22 hairpin. Renal fibrosis was induced by unilateral ureteral obstruction (UUO) in mice. Changes in mRNA and miRNA expression were assessed by SYBR Green qPCR (Bio-Rad, Hercules, CA) on RNA extracted from total kidney lysates.

Results: We used a classical knockout approach using miR-22 deficient mice that were recently generated in our laboratory. Age and sex-matched knock out ($miR\text{-}22^{-/-}$) and wild type ($miR\text{-}22^{+/+}$) mice were subjected to UUO maneuver and killed after 10 days. We found that kidney gene expression levels of established fibrotic markers were considerably lower in UUO kidneys from $miR\text{-}22^{-/-}$ mice compared with $miR\text{-}22^{+/+}$ mice. Specifically, we identified ~20% decrease in mRNA expression levels in Type I and III collagens and a reduction (~25%) in a-Smooth Muscle Actin (a-SMA). Of note, no appreciable differences in fibronectin and Type IV collagen mRNA expression levels were observed between the two groups. Histopathological analyses of UUO kidneys revealed a significant attenuation of chronic tubulointerestitial damage and reduced collagen deposition in miR-22 deficient mice.

Conclusions: Our data suggest that miR-22 serves as an important regulator of renal fibrosis. Targeted disruption of miR-22 may provide a therapeutic rationale for combating progressive renal fibrosis.

Blockade of miR-433 Inhibits Renal Fibrosis In Vitro and In Vivo

Rong Li,[1,2,5] Arthur Chi-kong Chung,[1,4] Yuan Dong,[1] Qin Wei Yang,[3] Xiang Zhong,[1,2] Hui Y. Lan.[1,3,4] *[1]Li Ka Shing Institute of Health Sciences, CUHK, Hong Kong, China; [2]Department of Chemical Pathology, CUHK, Hong Kong, China; [3]Department of Medicine and Therapeutics, CUHK, Hong Kong, China; [4]CUHK Shenzhen Research Institute, CUHK, Shenzhen, China; [5]Department of Nephrology, First People's Hospital of Yunnan Province, Yunnan, China.*

Background: We have previously shown that TGF-β/Smad3-dependent microRNAs are key mediators in renal fibrosis. Here we report that miR-433 is a new fibrogenic miRNA regulated by TGF-b/Smad3 and is a therapeutic target for renal fibrosis in vitro and in vivo.

Methods: Expression of miR-433 was examined in tubular epithelial cells (TECs) after TGF-b treatment and in unilateral ureteral obstructive nephropathy (UUO). The functional role and therapeutic potential of miR-433 in fibrosis were examined in vitro in a rat NRK52E tubular epithelial cell (TEC) line by overexpressing or down-regulating of miR-433 and in vivo a mouse model of UUO by an ultrasound- microbubble- mediated anti-miR-433 gene transfer.

Results: Renal miR-433 was significantly increased in NRK52E cells after TGF-b1 stimulation and in the UUO kidney. Upregulation of miR-433 was associated with activation of Smad3 signaling. Findings that knockdown of miR-433 suppressed, but overexpression of miR-433 enhanced, TGF-β1-induced collagen I and fibronectin expression revealed a functional importance of miR-433 in renal fibrosis. More importantly, ultrasound-microbubble- mediated gene transfer of miR-433 knockdown plasmid into the mouse kidney before or after UUO (an established UUO) was capable of preventing or blocking renal fibrosis, particularly in the established obstructive nephropathy ($p<0.01$), demonstrating a therapeutic potential for renal fibrosis by targeting miR-433. Furthermore, we also found that antizyme inhibitor 1 (Azin1) was a potential target of miR-433. Overexpression of miR-433 suppressed Azin1 expression, whereas Azin1 overexpression blocked the fibrotic effect of TGF-β1.

Conclusions: MiR-433 is a key mediator of TGF-β/Smad3-induced renal fibrosis and is a therapeutic target for chronic kidney disease associated with progressive fibrosis.

Recombinant Fusion Protein of Albumin-Retinol Binding Protein Attenuates Renal Fibrosis in Unilateral Obstructive Nephropathy

Jin Joo Cha,[1] Young Sun Kang,[1] Jung Eun Kim,[1] Mihwa Lee,[1] Hye Kyung Song,[1] Mi Jin Lee,[1] Young Youl Hyun,[2] Ji Eun Lee,[3] Hyunwook Kim,[3] Kum Hyun Han,[4] Jee Young Han,[5] Jun Seo Oh,[1] Dae R. Cha.[1] *[1]Nephrology, Korea Univ., Korea; [2]Kangbuk Samsung Hosp.; [3]Wonkwang Univ.; [4]Inje Univ.; [5]Inha Univ.*

Background: In previous study, Oh et al introduced a novel recombinant fusion protein of albumin-retinol binding protein (albumin domain I/III coupled to RBP, R-III), which induced phenotypic reversal of pancreatic stellate cells from the myofibroblast to the fat storing cells. Considering that the importance of pathologic changes into myofibroblasts in renal fibrosis and the increased uptake of R-III in the kidney.

Methods: We investigated the potential of R-III to reduce fibrogenic and inflammatory responses in an established interstitial fibrosis model-unilateral ureteric obstruction (UUO). After inducing UUO, R-III was injected every day for 7days through a tail vein.

Results: Compared to UUO group, R-III treated group showed decreased urinary protein excretion ($p<0.05$) and lower level of urinary 8-isoprostane ($p<0.05$). R-III treatment also suppressed the increase of renal levels of MCP-1, TGF-β1, CTGF, type I collagen ($p<0.05$) and phosphorylation of Smad3. It also attenuated NF-kB activation in kidney. Sirius red staining also showed decreased renal fibrosis by fusion protein treatment.

Myofibroblast cells were increased in the tubulointerstitial tissues in UUO kidney confirmed by aSMA staining, and RBP-peptide was co-localized in the aSMA positive myofibroblast cells. Interestingly, most fusion protein was localized in the tubule and myofibroblast cells of the obstructed kidney by IHC. Additionally, macrophage infiltration measured by F4/80 staining was markedly decreased in fusion protein treatment. In cultured cell lines, the uptake of fusion protein was increased in podocyte, HK2 proximal tubule cells and mouse mesangial cells (MMC). The expression of STRA6, RBP specific receptor, was increased in podocytes and MMC.

Conclusions: Our results suggest that the recombinant fusion protein (albumin-RBP) has anti-fibrotic effects in the experimental UUO murine model, probably via RBP receptor (STRA6) mediated uptake to the kidney.

SA-OR032

Intra-Abdominal Pressure and Bioimpedance-Based Volume Estimation in Septic Shock Patients Treated by Continuous Veno-Venous Hemofiltration

Daniel Schneditz,[1] Wojciech Dabrowski,[2] Wojciech T. Zaluska,[2] Ziemowit Rzecki,[2] Edyta Kotlinska,[2] Jacek Pilat.[2] *[1]Medical University of Graz, Austria; [2]Medical University of Lublin, Poland.*

Background: Intra-abdominal pressure (IAP) is an important risk-factor for the outcome of septic shock and acute kidney injury (AKI). It was the aim to analyze to which degree continuous veno-venous hemomofiltration (CVVH) affected IAP as well as abdominal perfusion pressure (APP), and how these variables were related to fluid volume as measured by bioimpedance analysis and to patient outcome.

Methods: Adult septic shock patients were studied before, 6, 12, 24, 48, 72 and 96 h after the beginning of CVVH because of AKI. The Kron method was used to measure IAP (in mm Hg). APP was determined as mean arterial pressure (MAP) minus IAP. Fluid volume excess (VE), total body water (TBW), extracellular body water (ECW), and intracellular body water (ICW) were derived from whole-body bioimpedance measurements (BCM, Fresenius Medical Care, Germany). Based on clinical outcome, the data were analyzed for survivors (S) and non-survivors (nS).

Results: 30 patients were studied. 24 patients survived CVVH and 6 died during CVVH but after the observational period. VE, TBW, ECW, ICW, and IAP were successfully decreased in S whereas these variables remained essentially unchanged in nS. APP slowly increased in S during CVVH but remained unchanged in nS. IAP strongly correlated with VE in S.

Tab. 1

	APP baseline (mmHg)	APP 96h (mmHg)	ECW baseline (L)	ECW 96h (L)
S	54 [49.75-69]	73 [69.25-79.83]***	26.2 [26.2-32.7]	20.1 [14.9-20.5]***
nS	52 [49-63.25]	60.5 [57.5-67.5]	26.6 [20.7-3-.25]	21.6 [18.1-24.86]
ID	P=0.69	P<0.05	P=0.55	P<0.01

Median [quartile 1 and 3]; S – survivors; nS – non-survivors; ID – intergroup difference; *** P<0.001 – significant difference relative to baseline (Wilcoxon test)

Conclusions: 1. CVVH successfully reduced IAP and TBW in critically ill patients who survived, 2. APP increased during CVVH in survivors, 3. Failure to increase APP predicted fatal outcome, 4. IAP was a sensitive indicator of fluid volume excess measured by whole-body bioimpedance analysis, and 5.) Bioimpedance analysis was useful to monitor fluid volume indicating positive patient outcome.

Inflammatory Cytokines and Markers of Volume Excess Assessed by Bioimpedance Analysis in Patients with Acute Kidney Failure

Wojciech T. Zaluska,[1] Wojciech Dabrowski,[1] Daniel Schneditz,[2] Edyta Kotlinska,[1] Ziemowit Rzecki,[1] Manu Malbrain.[3] *[1]Medical University of Lublin, Poland; [2]Medical University of Graz, Austria; [3]ZNA Campus Stuivenberg, Antwerp, Belgium.*

Background: Increased microvascular permeability mediated by cytokines such as vascular endothelial growth factor (VEGF), tumour necrosis factor α (TNFα), E-selectine, and histamine leads to an expansion of extracellular volume (ECV) and to an increase in intra-abdominal pressure (IAP). It was the aim to analyze the relationship between IAP and fluid volumes using bioimpedance analysis and cytokines in critically ill patients treated by continuous veno-venous haemofiltration (CVVH) or furosemide infusion.

Methods: Adult critically ill patients with acute kidney failure (AKF) of different origin were studied. Variables were analyzed at the time of ICU admission (t=1) as well as 24 (t=2) and 48 h (t=3) after ICU admission. Patients were divided into CVVH and furosemide treatment groups. IAP was measured using the Kron technique. Whole-body bioimpedance (BCM, Fresenius Medical Care, Germany) was used for the measurement of intra- and extracellular volumes (ICV, ECV). Cytokines were measured by immunochemistry.

Results: 40 patients aged 53±15 years were enrolled, 17 were treated using CVVH, and 23 using furosemide, respectively. In all patients ECV and VEGF were highly and positively correlated with IAP (Tab. 1). IAP, VEGF, and ECV were higher in CVVH compared to furosemide treated patients.

Tab. 1

Groups	Time	IAP (mmHg)	VEGF (pg/mL)	ECV (L)
CVVH	t=1	13 [10-15]**	64.4 [25.8-247.9]**	26.0 [25-32.4]***
	t=2	11.5 [10-12]*	35.3 [15.2-94.5]**	25.4 [25.1-32.4]**
	t=3	12 [11-12]***	32.3 [20.7-60.4]**	25.2 [24.7-32.4]*
IAP correlation			P<0.0000; r=0.81	P<0.0001; r=0.51
Furosemide	t=1	7 [6-12]	14.3 [12.6-34.3]	21.3 [17.9-23.7]
	t=2	9 [6.5-11.5]	17.9 [14.0-25.7]	21.2 [19.1-25.2]
	t=3	7 [6.5-10]	15.2 [14.0-25.4]	20.5 [19.2-26.75]
IAP correlation			P<0.0000; r=0.51	P<0.0000; r=0.78

Median [quartile 1 and 3]; * P<0.05, ** P<0.01, *** P<0.001 – significant difference relative to Furosemide group

Conclusions: 1. IAP strongly depends on plasma VEGF concentration. 2. ECV depends on plasma VEGF and TNFα concentrations. 3. IAP is a sensitive marker of ECV expansion.

SA-OR034

Urine Output as a Determinant to Initiate Continuous Renal Replacement Therapy for Acute Kidney Injury

Mi Jung Lee,[1] Dong Ho Shin,[1] Dae-Suk Han,[1] Seung Hyeok Han,[1] Hye-young Kang,[2] Seong Hun Kim,[2] Shin-Wook Kang.[1,2] *[1]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea; [2]Severance Biomedical Science Institute, Brain Korea 21, College of Medicine, Yonsei University, Seoul, Republic of Korea.*

Background: Although some studies have found that early initiation of continuous renal replacement therapy (CRRT) is associated with better prognosis, no consensus exists on the best timing to start CRRT. We investigated whether the timing of CRRT initiation was relevant to overall mortality and explored which factors at the time of CRRT initiation were associated with better outcomes in critically ill patients with acute kidney injury (AKI).

Methods: A total of 361 patients, who received CRRT for AKI between 2009 and 2011, were collected and divided into two groups based on the median BUN levels or 6-hour urine output immediately before CRRT start. The impact of the timing of CRRT initiation stratified by BUN concentration or urine output on 28-day all-cause mortality was compared between the groups. Cox proportional hazards analysis was also performed to determine whether early CRRT initiation was an independent prognostic factor.

Results: When the timing of CRRT initiation was stratified by 6-hour urine output, 28-day all-cause mortality rates were significantly lower in the early CRRT group compared to the late CRRT group (P = 0.02). In contrast, clinical outcomes were not different between early and late CRRT groups classified by BUN levels (P = 0.30). Cox regression analysis revealed that 28-day all-cause mortality risk was significantly lower in the early CRRT group stratified by 6-hour urine output, even after adjusting for age, gender, mean arterial pressure, serum biomarkers, and APACHE II and SOFA scores (Hazards ratio: 0.85, 95% confidence interval: 0.65-0.99, P = 0.04).

Conclusions: Urine output might be more useful than BUN concentrations in making decision to initiate CRRT in critically ill patients with AKI.

SA-OR035

Survival with Self-Care Conventional versus In-Centre Nocturnal Hemodialysis: A Prospective Cohort Study

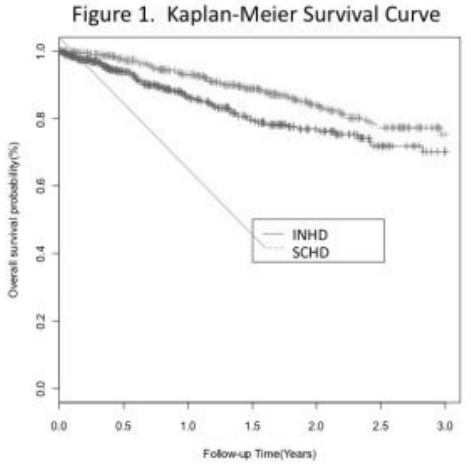
Gihad E. Nesrallah,[1] Lihua Li,[1] Weiling Wang,[2] Ronald L. Pisoni,[3] Brian Bieber,[3] Bruce M. Robinson,[3] Rita Suri,[1] Eduardo K. Lacson.[2] *[1]Western University, Canada; [2]Fresenius Medical Care, USA; [3]Arbor Research, USA.*

Background: In-centre nocturnal HD (INHD) associates with better survival than conventional full-care in-centre HD. However, unmeasured confounders including motivation, health literacy, functional and cognitive ability may account for this finding. We used self-care status as a proxy variable for these factors to test the hypothesis that INHD and self-care conventional HD (SCHD) have similar survival.

Methods: Adults on INHD (>6 hrs, 3/wk) were identified in the Fresenius US database (Jan2006-Jun2010), and matched (1:1) by age, vintage, and propensity score (PS) to US patients on SCHD (<6 hrs, 3/wk) in DOPPS(Feb2002-Apr2009). PS included:age, sex, race, vintage, dry weight, albumin, Hb, phos, DM, cancer, CVA, HTN, PVD, and psychiatric illness. We used Cox regression, attributing deaths within 90 days of a modality switch to baseline exposure.

Results: We matched 691 pairs from eligible pools of 1244 (INHD) and 1524 (SCHD) patients. Prognostic variables were balanced with std. difference <10%. 174 deaths occurred in 1688 patient-yrs; 240 (35%) of INHD patients switched to conventional HD. Median follow-up (SD) was 0.6(0.98)vs.1.42(0.87) yr, mean HD time 466(37) vs. 232(34) minutes and transplant rates 3.8(2.5-5.7) vs. 5.3(4.1-6.9)/100pt-yr in INHD and SCHD (p=0.13). In the primary as-treated model, the HR for death was 1.63 (1.20-2.20;p=0.002), favoring SCHD. Sensitivity analyses with an intent-to-treat model, 60-day attribution rule, and analysis of the entire sample with PS adjustment yielded similar results.

Conclusions: Results were unexpected and require further study. Self-care ability may be a more potent prognostic factor than length of HD session and warrants consideration for adjustment in future observational modality comparisons.



SA-OR036

The Feasibility of Caregiver Assisted Home Nocturnal Hemodialysis Karthik K. Tennankore, Joseph Kim, Christopher T. Chan. *Medicine, Division of Nephrology, Toronto General Hospital, Toronto, ON, Canada.*

Background: Home nocturnal hemodialysis (NHD) has several clinical advantages. However, NHD patients that require caregiver-assistance for dialysis may be at-risk for poor outcomes. In an effort to see if NHD can be extended to this patient subgroup, an analysis of their comparative outcomes is important.

Methods: We examined a single center cohort of all patients that started and completed NHD training between 01 Jan 2003 to 31 Dec 2010 (last follow up 01 Jul 2011). Patients were classified as "dependent" if they relied on a caregiver to perform some or all of their NHD therapy. The primary outcome of this study was to compare time to first hospitalization, technique failure or death for dependent versus independent patients, censored at transplantation. Secondary outcomes included hospitalization rate and hospital days.

Results: 47 (31%) and 105 (69%) dependent and independent NHD patients were included in this study. Dependent patients were older (51 vs. 42 years), were more likely to have diabetic ESRD (26% vs. 8%) and had higher Charlson Comorbidity Index Scores (4 vs. 3) compared to independent patients. Unadjusted, there was a significant difference in the time to first event for dependent versus independent patients (HR 1.71 [95% CI, 1.10 to 2.66]). Adjusting for comorbidity, age, dialysis catheter access, diabetic ESRD, race, gender and renal replacement therapy vintage, this difference was no longer statistically significant (HR 1.25 [95% CI, 0.76 to 2.04], figure 1). Incidence rate ratios for hospitalizations (IRR 1.58 [95% CI, 0.95 to 2.65]) and hospital days (1.84 [95% CI, 0.78 to 4.34]) were not significantly different for dependent versus independent patients.

Conclusions: The outcomes of caregiver-assisted versus independent NHD patients are driven by comparative differences in case-mix. The need for caregiver assistance alone should not be a deterrent to NHD.

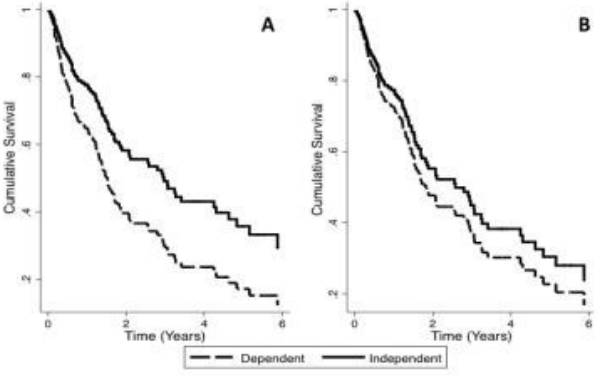


Figure 1. Unadjusted (A) and adjusted (B) Cox survival curves for time to first hospitalization, technique failure or death

SA-OR037

Effect of Frequent Dialysis on Residual Kidney Function in the Frequent Hemodialysis Network (FHN) Nocturnal and Daily Trials John T. Daugirdas,[1] Tom Greene,[2] Michael V. Rocco,[3] George A. Kaysen,[4] Thomas A. Depner,[4] Nathan W. Levin,[5] Glenn M. Chertow,[6] Daniel B. Ornt,[7] Jochen G. Raimann,[5] Brett Larive,[8] Alan S. Kliger,[9] The FHN Trial Group.[10] *[1]Univ of IL at Chicago; [2]Univ of Utah; [3]Wake Forest Univ; [4]Univ CA Davis; [5]Renal Research Institute; [6]Stanford Univ; [7]Rochester Inst Technol; [8]Cleveland Clinic; [9]Yale Univ; [10]NIDDK, NIH.*

Background: Frequent hemodialysis can alter levels of extracellular fluid volume and blood pressure and the concentration of osmotically active solutes, each of which might have an effect on residual kidney function (RKF).

Methods: In the Frequent Hemodialysis Network (FHN) Nocturnal and Daily Trials, we examined the effects of 6 versus 3 times per week hemodialysis on follow-up levels of RKF as measured by daily urine volume (UVol), and kidney urea (Kru) and creatinine (Krcreat) clearances. RKF inclusion criteria were Kru <10 mL/min/35L body water for the Nocturnal Trial, and Kru <3.0 for the Daily Trial.

Results: In both trials, baseline RKF was inversely correlated with years since onset of ESRD. In the Nocturnal Trial, 63/87 participants had nonzero RKF at baseline (mean urine volume 0.76 L/d, Kru 2.3 mL/min, Krcreat 4.7, mL/min). At months 4 and 12, UVol, Kru, and Krcreat were all lower in the group assigned to 6 times per week hemodialysis compared to the group assigned to 3 times per week. Of those with nonzero RKF at baseline, at month 12, 70% in the 6/week group had lost all RKF compared to 40% of controls. In the Daily Trial, 83/245 subjects had nonzero RKF at baseline (mean urine volume 0.43 L/d, Kru 1.2 mL/min, Krcreat 2.7 mL/min). Treatment assignment did not significantly influence level of RKF (as Uvol, Kru or Krcreat) at 4 or 12 months. Of those with nonzero RKF at baseline, at month 12, 48% in the 6/week group had lost all RKF compared to 53% of controls.

Conclusions: Frequent nocturnal hemodialysis is associated with more rapid loss of RKF, the mechanism of which remains to be determined. Whether this also occurs with frequent daily treatments could not be determined from the FHN Daily Trial design, which excluded subjects with higher levels of RKF.

SA-OR038

Effects of Daily Hemodialysis on Heart Rate Variability: Results from the Frequent Hemodialysis Network (FHN) Daily Trial Christopher T. Chan,[1] Glenn M. Chertow,[2] John T. Daugirdas,[3] Tom Greene,[4] Peter Kotanko,[5] Brett Larive,[6] Andreas Pierratos,[1] John B. Stokes,[7] The FHN Trial Group.[8] *[1]U of Toronto; [2]Stanford Univ; [3]Univ of IL; [4]Univ of Utah; [5]Renal Research Institute; [6]Cleveland Clinic Foundation; [7]Univ of Iowa; [8]NIDDK.*

Background: End-stage renal disease is associated with reduced heart rate variability (HRV), components of which generally are associated with increased age, diabetes, and left ventricular mass (LVM). We reported previously, that daily in-center hemodialysis (DHD) resulted in reductions in LVM. We hypothesized that DHD would increase HRV globally and that changes in those components of HRV linked to LVM might be associated with changes in LVM.

Methods: The FHN Daily Trial randomized 245 patients to receive 12 months of 6 versus 3 times per week in-center hemodialysis (conventional HD). In 131 patients, HRV measures were calculated from 24-hour Holter monitoring. HRV measures included low frequency power (LF, a measure of sympathetic modulation), high frequency power (HF, a measure of parasympathetic modulation), and standard deviation of the R-R interval (SDRR, a measure of beat to beat variation). We tested for an effect of frequent dialysis on components of HRV, and for associations between change in LVM and changes in HRV components.

Results: Baseline to month 12 change in LF was 49% greater (95% CI 7.3%, 107%), p=0.018) and LF+HF was augmented by 38% (4.2%, 84.0%) in patients assigned to DHD compared to conventional HD. In contrast to LF, changes in HF and SDRR were similar between the DHD and conventional HD groups. Older age and diabetes (predefined subgroups) each were associated with weaker effects of DHD on LF. Changes in LVM were inversely associated with changes in HF (r = -0.20, p =0.02) and SDRR (r = -0.18, p = 0.04).

Conclusions: DHD increased the LF component of heart rate variability. Reduction of LVM by DHD was associated with increased vagal modulation of heart rate (HF) and with increased beat to beat heart rate variation (SDRR), suggesting an important functional correlate to the structural effects of DHD on the heart in uremia.

FGF9 and FGF20 Maintain the Stemness of Nephron Progenitors in Mice and Man In Vivo and In Vitro Raphael Kopan,[1] Hila Barak,[1] Sung-ho Huh,[1] Shuang Chen,[1] Cecile Jeanpierre,[2] Mélanie Parisot,[3] Christine Bole-feysot,[4] Patrick Nitschke,[5] Remi Salomon,[2] Corinne Antignac,[2] David M. Ornitz.[1] *[1]Developmental Biology, Washington University, St. Louis, MO; [2]Universite´ Paris Descartes, Sorbonne, Paris, France; [3]Institut Imagine, Paris, France; [4]Genomic Plateform, Fondation Imagine, Paris, France; [5]6 Bioinformatic Plateform, Universite´ Paris Descartes, Sorbonne, Paris, France.*

Background: The identity of niche signals necessary to maintain embryonic nephron progenitors is unclear. FGF ligands are candidates for such signal because inactivation of FGF receptors in the progenitors results in arrested kidney development (Poladia et

al., 2006; Sims-Lucas et al., 2011) and because supplementing isolated metanephric mesenchyme (MM) *in vitro* with FGF2 (which is not present in the niche and its removal does not have a delaterious effect) and Bmp7 (which is in the niche, is required *in vivo* but is not sufficient *in vitro*) can maintain MM competent to differentiate for 48 hours in culture (Dudley et al., 1999).

Methods: We investigated the role of the *Fgf9* sub-family in renal development using mouse genetics, tissue culture, and human genetics.

Results: We discovered that Fgf9 acts redundantly with Fgf20 to promote the proliferation, survival and stemness of mouse MM progenitors *in vivo*. Moreover, we identified a human missense mutation in *FGF20* that results in bilateral renal agenesis. We show that Fgf9 or Fgf20 are sufficient to maintain MM with nephron progenitors *in vitro* for 5 days, whereas sorted Six2+ cells retained competence to form epithelia for at least 48h in culture when grown in serum-free media containing Fgf9 or Fgf9+BMP7. Differentiation-competent Six2+ cells slowly disappear over 7 days *in vitro,* and optimizing conditions for Six2+ self-renewal seems incompatible with maintaining competence to differentiate.

Conclusions: Our studies identify Fgf20/9 as integral parts of the MM niche where they act in autocrine and paracrine loop to maintain a self-renewing progenitor population competent to respond to Wnt signals. Though this lays the foundation for creating an artificial niche, much remains to be done to substentailly extend progenitor life *in vitro*.

Development of Efficient Induction Methods from Human iPSCs/ESCs into Intermediate Mesoderm by Using Low-Molecular Weight Compounds

Toshikazu Araoka, Takafumi Toyohara, Fumihiko Shiota, Shin-ichi Mae, Yuko Kurose, Kenji Osafune. *Center for iPS Cell Research and Application (CiRA), Kyoto University, Kyoto, Japan.*

Background: The increased prevalence of chronic kidney disease has caused a rise in the number of dialysis patients, and is associated with elevated morbidity and mortality. Development of kidney regeneration therapy is required because most patients with chronic kidney disease never recover renal function. Kidney is derived from one of early embryonic germ layers, intermediate mesoderm (IM), and directing pluripotent stem cells, such as induced pluripotent stem cells (iPSCs) and embryonic stem cells (ESCs), into IM lineage is a crucial step for kidney regeneration.

Methods: To identify small molecules that can efficiently induce the differentiation from human iPSCs/ESCs into IM lineage cells, we screened a chemical library of about 1,800 low-molecular weight compounds using human iPSC lines that contain an allele of an IM-specific marker gene OSR1 into which a green fluorescence protein (GFP) gene was knocked-in by homologous recombination.

Results: We identified two chemical compounds with the inducing ability and established a differentiation protocol using the combinational treatment of these compounds that direct differentiation of human iPSCs/ESCs into IM lineage cells. The combinational treatment with these compounds induces nearly 90% of OSR1(+) cells from human iPSCs, in the same way as that achieved by our combinational treatment of growth factors. Moreover, the generated OSR1(+) cells produced the substantial expression of other IM markers, and had the ability to differentiate into the cells expressing the specific markers for renal cells constituting the adult kidney *in vitro* and *in vivo*. We also elucidated a part of the mechanisms involved in the differentiation of human iPSCs/ESCs into IM lineage cells.

Conclusions: Our differentiation methods using chemicals alone can produce more consistent and lower-cost generation of IM cells than growth factor-based protocols, which may contribute to understanding the mechanisms of kidney development and supplying the cell sources for the regenerative medicine strategies for chronic kidney disease.

Parietal Podocytes: Transdifferentiation from Parietal Epithelial Cells or Migration of Podocytes?

Kevin Schulte,[1] Katja Berger,[1] Eva Maria Sicking,[1] Peter Boor,[2] Peggy Jirak,[1] Larissa Thevissen,[1] Astrid Fuß,[1] Wilhelm Kriz,[3] Jürgen Floege,[1] Bart Smeets,[1] Marcus J. Moeller.[1] *[1]Nephrology and Immunology, RWTH University of Aachen, Aachen, NRW, Germany; [2]Pathology, RWTH University of Aachen, Aachen, NRW, Germany; [3]Div. of Anatomy, Medical Faculty Mannheim / University of Heidelberg, Mannheim, Ba-Wue, Germany.*

Background: In adults, it is still unresolved whether parietal epithelial cells (PECs) can potentially act as progenitor cells by differentiating into podocytes. "Parietal podocytes", i.e. fully differentiated podocytes residing on the inner aspect of Bowman's capsule, are an interesting model in this context. Parietal podocytes have been observed in multiple human kidney diseases, in particular in atubular glomeruli.

Methods: First, a mouse model to generate atubular glomeruli by electrocoagulation was established and characterized in different genetic backgrounds.

Results: Parietal podocytes were observed exclusively in atubular glomeruli. In addition, glomerular cysts were formed particularly in young mice of the Sv129 genetic background. Next, PECs or podocytes were traced in the above-described model for detubularization by irreversible genetic tagging in triple transgenic mice (PEC- or Pod-rtTA/LC1/R26R). Our results showed conclusively that PECs undergo apoptosis after detubularisation and that visceral podocytes migrate onto Bowman's capsule. No direct transdifferentiation from PECs towards podocytes was observed. This finding was confirmed in the unilateral ureter obstruction (UUO) model. Immunohistochemical stainings of human kidney biopsies always showed a sharp-edged border between PECs and podocytes on Bowman's capsule of atubular glomeruli. No gradual differentiation of PECs into podocytes could be observed, supporting that no transdifferentiation of PECs into parietal podocytes occurrs also in humans.

Conclusions: In summary, there are two surprising findings of this study: 1. Detubularisation leads to acute ablation of PECs and 2. visceral podocytes migrate onto Bowman's capsule in atubular glomeruli. Transdifferentiation from PECs to parietal podocytes did not occur in this model.

The Directed Differentiation of Podocyte Progenitors Following Kidney Reprogramming

Sharon D. Ricardo,[1] Bi Song,[1] Alexandra Smink,[4] Christina V. Jones,[1] Andrew L. Laslett,[3] Peter G. Kerr.[2] *[1]Monash Immunology and Stem Cell Laboratories, Monash University, Clayton, Victoria, Australia; [2]Medicine, Nephrology, Monash Medical Center, Clayton, Victoria, Australia; [3]CSIRO Materials Science and Engineering, Melbourne, Victoria, Australia; [4]Pathology and Medical Biology, University of Groningen, Groningen, Netherlands.*

Background: The loss of podocytes is a key event in the progression of chronic kidney disease. Therefore, the reprogramming of adult cells to generate induced pluripotent stem (iPS) cells with a high proliferative ability and progenitor potential represents a major advance in the field. We have previously generated iPS cells from human kidney cells (JASN 2011), and now provide the first report of directed differentiation of iPS cells to podocyte progenitors.

Methods: iPS cells were differentiated into podocytes with the addition of BMP-7, retinoic acid and activin A. Morphology was assessed by phase contrast and scanning electron microscopy (SEM). Immunofluorescence microscopy and qPCR determined protein and mRNA expression of podocyte markers compared to primary human podocytes. iPS podocytes were transduced with RFP-talin/actin and visualized with confocal and live cell imaging providing functional assays of the contractile response to angiotensin II (AII), and uptake of albumin and integration into developing glomeruli.

Results: The iPS-derived podocytes shared a cell morphology similar to human podocytes including tertiary cytoplasmic processes by SEM. Using immunofluorescence microscopy the iPS podocytes showed protein localisation of and podocyte markers. qPCR confirmed that iPS podocytes had an upregulated expression of Wilm's tumor protein (WT1), nephrin, podocin and synaptopodin and down-regulation of the pluripotency gene OCT3/4. Using a kidney reaggregation explant assay the iPS-derived podocytes integrated into WT1+ developing glomeruli and had functional characteristics of podocytes in their contractile response of RFP-talin to AII and endocytosis of albumin.

Conclusions: This study establishes the derivation of iPS-derived podocytes that will be useful for screening new treatments, understanding podocyte pathogenesis, and offering possibilities for regenerative medicine.

Incorporation of the Endogenous Renal Mesenchymal Stem Cells into the Elongating Collecting Ducts

Melissa H. Little,[1] Joan Li,[1] Norseha Suhaimi,[1] Usukhbayar Ariunbold,[1] Nana Sunn.[2] *[1]Institute for Molecular Bioscience, University of Queensland, Brisbane, Queensland, Australia; [2]University of Queensland Diamantina Institute, University of Queensland, Brisbane, Queensland, Australia.*

Background: Endogenous mesenchymal stem cells (MSC) have been identified in many solid organs where their specific role and phenotype is unclear. Previously we described endogenous renal MSCs (ER-MSCs) present in the adult mouse kidney[1].

Methods: Colony forming efficiency and clonogenicity showed that ER-MSCs were enriched in the papilla region of the kidney when isolated based on regional dissection. While the immunophenotype and differentiation capacity of these cells was similar to bone marrow MSCs (Bm-MSCs), gene expression profiling revealed differential expression of >2400 genes, including the collecting duct gene *Hoxb7*. To investigate the renal epithelial capacity of these cells we microinjected GFP^+ ER-MSC into the neonatal kidney (P1) under ultrasound guidance.

Results: The ER-MSCs integrated into $Aqp2^+$ collecting duct within the medulla and papilla region 3 days after injection. There was no integration into any other tubular structures. Epithelial integration was never observed from Bm-MSCs. Given the differential *Hoxb7* expression of ER-MSCs, we isolated the GFP^+ fraction from adult Hoxb7GFP kidneys. This fraction also gave rise to MSCs culture with classical MSC immunophenotype. When cultured in 3-D culture, these ER-MSCs showed a capacity to convert to an epithelial phenotype *in vitro.* Temporal analysis of the location of *Hoxb7* showed evidence for an initial neonatal $GFP^{+/lo}$ interstitial population that was absent in the adult kidney.

Conclusions: We have identified an endogenous MSC population in the adult kidney capable of selective integration into the neonatal collecting duct. This population may initially exist in the interstitium and epithelializes shortly after birth. This challenges our understanding of the origin of the collecting duct and the presence of stem/progenitor cells within this compartment. Further *in vivo* experiments will examine whether these cells play a role in normal tissue turnover as well as in renal damage or disease.

Infusion of Autologous Bone Marrow Mononuclear Cells Leads to Transient Reduction in Proteinuria in Treatment Refractory Patients with Idiopathic Membranous Nephropathy Upal Sengupta, Vinod Sharma, Ashok Kumar Yadav, Harbir Singh Kohli, Neelam Marwaha, Vinay Sakhuja, Vivekanand Jha. *Nephrology, Postgraduate Medical Institute, Chandigarh, India.*

Background: The current treatment options for idiopathic membranous nephropathy (IMN) carry significant toxicity. Stem cells have been used for immunomodulation in many diseases. In this open label, prospective, observational pilot study, we used one-time infusion of autologous bone marrow derived mononuclear cells (MNCs) in adults with treatment refractory IMN.

Methods: Twelve patients of biopsy proven IMN who had failed a cyclical 6-month regimen of steroid and cyclophosphamide were enrolled. Four had also been unresponsive to tacrolimus. Bone-marrow was harvested from the iliac crest and MNCs isolated. Cells were counted and subjected to viability testing before being infused in a dose of 2-4x10^6/kg through a peripheral vein. Subjects were followed up monthly for the next six months. Supportive treatment including angiotensin antagonists and stains was continued throughout the study period.

Results: All the 12 subjects exhibited full-blown nephrotic syndrome despite being on on ACE inhibitors, statins and diuretics. The proteinuria, protein-creatinine ratio (PCR), serum albumin and creatinine values at entry were 3.27± 0.41 gm/d, 3.37±0.6 g/g, 2.38 ± 0.6 gm/l and 0.9 ± 0.2 mg/dl respectively. The average number of MNCs injected was 293.58±96.14 X 10^6. There was a reduction in proteinuria ($p<0.001$) and PCR ($p=.0024$) and increase in serum albumin ($p=0.026$) at 1 month, with 64% of the subjects showing > 50% reduction in proteinuria. However, the proteinuria again increased to almost or more than the baseline value in majority of the cases. At 6 months, only 2 patients had >50% reduction. No infusion related side effects were noted. Serum creatinine was stable during the study period.

Conclusions: Autologous MNC infusion in peripheral vein appears can lead to transitory reduction in proteinuria and improvement in serum albumin in treatment refractory IMN patients. This effect, however, is transient. Whether this can be overcome by infusion of cultured MSCs or directed delivery to the kidneys needs to be investigated.

The Renal Ciliopathy Gene Product Regulates DNA-Damage Induced Cell Cycle Progression Amiya K. Ghosh,[1] Rannar Airik,[1] Moumita Chaki,[1] Rachel H. Giles,[2] Gisela G. Slaats,[2] Edgar Otto,[1] Friedhelm Hildebrandt.[1,3] [1]*Department of Pediatrics, University of Michigan, Ann Arbor, MI;* [2]*Department of Nephrology and Hypertension, University Medical Center, Utrecht, Netherlands;* [3]*Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI.*

Background: Nephronophthisis-related ciliopathies (NPHP-RC) are recessive disorders featuring dysplasia or degeneration of retina, kidney and cerebellum. By virtue of localization to the cilia/centrosome complex, diseases associated with NPHP gene products are termed as 'ciliopathies', although the disease mechanism remains elusive. We have recently identified recessive loss-of-function mutations of centrosomal protein CEP164 as a novel cause of NPHP-RC (Chaki & Airik, *Cell, in press*).

Methods: To assess the effects of Cep164 loss of function on cell cycle, we generated inducible-gfp-hCEP164 IMCD3 cells for both wild type and disease associated mutant constructs. Stable knockdown of Cep164 in IMCD3 cells were also generated using retroviral transduction system. To address the role of Cep164 in NPHP-RC, cell lines were studied as described below.

Results: We observe:

a. Wild type but not its disease-associated mutant Cep164 localizes to the mother centriole in an inducible N-gfp-cep164 expression system in IMCD3 cells.

b. Lack of endogenous *Cep164* leads to reduced cell proliferation and cilia formation, which was rescued by expression of Human wild type *CEP164* but not by disease-associated mutant in cell culture models.

c. Endogenous *Cep164* knockdown leads to cell cycle block in S-phase under thymidine induced replication stress. This is rescued wild type h*CEP164* but not by disease-associated mutants.

d. Under replicative stress Cep164 additionally localizes to TIP60 positive nuclear foci. (TIP60 is known to activate the DNA damage response protein ATM at sites of DNA damage).

e. Upon irradiation, stable knockdown of *Cep164* in IMCD3 cells resulted in elevated g-H2AX levels, a marker of increased DDR.

Conclusions: Our observations point towards a novel disease mechanism that implicates DNA damage response (DDR) signaling and retarded cell cycle progression in the pathogenesis of NPHP-RC.

SA-OR047

***Gli2* Dosage Modulates Renal Cystogenesis in the *Thm1* Mouse Model of Ciliopathy** Pamela Vivian Tran,[1] George Talbott,[2] Michael P. Schonfeld,[1] David Beier.[2] [1]*Anatomy and Cell Biology, Kidney Institute, University of Kansas Medical Center, Kansas City, KS;* [2]*Genetics Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Cystic kidney disease (CKD) is a leading cause of renal failure. Mutations associated with CKD affect genes encoding proteins that localize to primary cilia, though the precise molecular mechanisms connecting ciliogenesis to renal cystogenesis remain unclear. The ciliary gene *Thm1* (also *Ttc21b*) negatively regulates the Hedgehog (Hh) pathway (Tran et al. 2008) and has been identified as the most commonly mutated gene in ciliopathies (Davis et al, 2011), which manifest renal cysts as a major clinical feature.

Methods: We examined the role of *Thm1* in renal cystogenesis in the mouse using *Thm1*-null and *Thm1* conditional knock-out (cko) alleles. To explore a causative role for enhanced Hh activity in *Thm1* renal cystogenesis, we utilized a *Gli2*-null and a *Gli2* cko allele to create different *Gli2* doses on the *Thm1* cko background.

Results: We report that loss of murine *Thm1* indeed leads to renal cysts, both in the perinatal lethal *alien* (*aln*; $Thm1^{aln/aln}$) mouse mutant and postnatally in *Thm1* cko mice following *Thm1* ablation at E17.5. In *Thm1* cko mice, renal cysts are present at P20 and progress to severe CKD at 6 weeks of age. Although Hh signaling has not been commonly explored as a causal factor for CKD, we hypothesize that *Thm1* renal cystogenesis is mediated by increased Hh signaling. In support of our hypothesis, $Thm1^{aln/aln}$ embryonic renal cysts were prevented by genetically reducing *Gli2*, which encodes the main transcriptional activator of the Hh pathway. Further, preliminary results indicate that the reduction of *Gli2* expression by 50% in $Thm1^{fl/aln}$, $Gli2^{+/-}$ mutants markedly ameliorated the *Thm1* cko renal cystic disease, suggesting Hh signaling also mediates *Thm1* renal cystogenesis postnatally. We have generated $Thm1^{fl/aln}$, $Gli2^{fl/-}$ mutant mice in which *Gli2* expression can be completely ablated in postnatal development; the analysis of these mice is in progress.

Conclusions: Our results establish a role for *Thm1* in renal cystogenesis and suggest that GLI2 activity may present a valuable target in the treatment of CKD.

A Transition Zone Complex of Ciliopathy Proteins Regulates Ciliary Composition Jeremy Reiter. *Biochemistry and Biophysics, University of California, San Francisco, CA.*

Background: Pkd1, Pkd2, and Fibrocystin, the products of genes mutated in polycystic kidney disease localize to the primary cilia of kidney epithelial cells. Defects in ciliary function can result in polycystic kidney disease, suggesting that these proteins regulate epithelial proliferation at the cilium.

Methods: Through a combination of mass spectrometry, biochemistry, and mouse genetics, we have identified a complex of proteins that form part of the transition zone, a region at the base of the cilium.

Results: This transition zone complex includes the three members of the Tectonic family (Tctn1, Tctn2 and Tctn3), extracytosolic proteins that interact with transmembrane components of the transition zone such as Tmem67. These transmembrane proteins connect to a intracellular transition zone complex comprised of many known Joubert- and Meckel-associated proteins including Cc2d2a and Mks1. Joubert syndrome is a defect in cerebellar vermis formation resulting in ataxia, and can be associated with kidney cysts. Meckel syndrome is a postnatal lethal disorder characterized by heterotaxia, polydactyly and cystic kidneys.

Loss of components of this transition zone complex in mice compromises ciliogenesis in some tissues, and deregulates ciliary protein composition in others. In particular, the ciliary localization of Smoothened (Smo), a central component of the Hedgehog pathway, and Pkd2, mutated in autosomal dominant PKD, depends on this complex. As Smo functions at the cilium, many mouse transition zone mutants show deregulation of Hh signaling. Mouse transition zone mutations also develop kidney cysts, consistent with a critical ciliary function for Pkd2.

Defining the components of the transition zone has led to the identification of additional genes underlying Joubert and Meckel syndromes including Tctn1, Tctn2 and B9d2. We hypothesize that Joubert and Meckel syndromes are caused by transition zone dysfunction that disrupts intercellular signaling, leading to developmental defects including kidney cysts.

Conclusions: The signaling functions of kidney cilia require regulation of ciliary composition, which depends on the control of protein traffic into and out of cilia by the transition zone.

TRPV4 Functional Status Is Impaired in the Collecting Duct-Derived Cysts of ARPKD Mykola Mamenko, Oleg L. Zaika, Roger G. O'Neil, Oleh Pochynyuk. *Integrative Biology and Pharmacology, University of Texas Health Science Center at Houston, Houston, TX.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is a rapidly progressing congenital pathology, characterized by the development of fluid-filled cysts in the collecting ducts (CD). At the cellular level, ARPKD is associated with loss of mechano-sensitivity and compromised Ca^{2+} homeostasis. Ca^{2+}-permeable TRPV4 channel was recently shown to have a pivotal role in flow-sensitivity of CD cells.

Methods: To investigate TRPV4 functional status during in ARPKD progression, we used Fura-2 Ca^{2+} imaging with IHC in freshly isolated split-opened CDs of S/D rats, non-dilated CDs and monolayer cyst fragments from PCK453 rats (rat model of ARPKD).

Results: We found that elevated flow induces comparable TRPV4-mediated elevations of $[Ca^{2+}]_i$ in individual cells of the CDs from S/D rats and non-dilated CDs from PCK453 rats. However, Ca2+ responses to flow were abolished in cyst cells from PCK453 rats. Consistently, TRPV4 function and basal $[Ca^{2+}]_i$ levels were drastically diminished in ARPKD cyst cells, but not in non-dilated CDs. ATP-mediated activation of TRPV4 channel was also virtually absent in freshly isolated cyst segments from PCK453 rats. Surprisingly, TRPV4 expression was preserved during ARPKD progression, while TRPV4 subcellular localization was markedly shifted towards the luminal plasma membrane. Potentiation of TRPV4 activity with a selective activator GSK1016790A, rescues Ca^{2+} homeostasis by restoring flow-mediated Ca^{2+} responses, increasing basal $[Ca^{2+}]_i$ levels and recovering purinergic signaling. At the systemic level, GSK1016790A attenuates renal ARPKD progression by decreasing cyst area and numbers.

Conclusions: Overall, during development of ARPKD, functional activity of TRPV4 channels is significantly impaired, contributing to reduced $[Ca^{2+}]_i$ levels and disrupted mechano-sensitivity in the CD-derived cysts. Treatment with a TRPV4 activator significantly attenuates morbific manifestations of ARPKD on both systemic and cellular levels.

Characterization of a New ARPKD Mouse Model: An "in Vivo" Model to Study the Function of the C-Terminal Region of Fibrocystin/Polyductin

Patricia Outeda Garcia,[1] Xianjun Zhu,[2] Luis F. Menezes,[2] Erum A. Hartung,[1] Terry J. Watnick,[1] Gregory G. Germino.[2] *[1]Johns Hopkins University, Baltimore, MD; [2]NIDDK, Bethesda, MD.*

Background: Autosomal Recessive Polycystic Kidney Disease affects 1/20,000 and results from mutations of PKHD1. The gene exhibits a complex splicing pattern and its longest mRNA encodes a >400kDa polypeptide (FPC) that undergoes Notch-like post-translational processing. Its C-terminus is thought to translocate to the nucleus in response to cleavage. In humans, renal disease is associated with mutations scattered along the length of the gene, but in rodent models renal disease is mild, if it develops at all. Hepatobiliary disease is a universal feature in both humans and rodents. All of the reported rodent mutations are 5' of exon 49, raising the possibility that an intact C-terminus expressed by alternative splicing modulates severity.

Methods: To test this hypothesis, we generated a novel floxed allele of *Pkhd1* in the C57Bl6 strain with lox P sites flanking its last coding exon and a triple-HA epitope tag inserted in-frame to the carboxyl terminus of FPC.

Results: We find that homozygotes for the floxed allele are healthy and that anti-HA antibodies can be used to detect full length FPC in lysates and to affinity purify native protein. The predominant species appears to be full-length protein, though a minor cleaved product is detected as well. Using anti-HA sera, we can detect endogenous tagged FPC by IF in collecting ducts and in epithelial cells of the biliary tract. At a subcellular level, HA-tagged FPC was found in ciliated cholangiocytes and cells lining pancreatic ducts. After deleting the LoxP cassette, homozygous Pkhd1Δ67/67 mice were born at the expected frequency. Remarkably, mutant mice lacked typical hepatobiliary abnormalities at up to 4m of age.

Conclusions: In conclusion, we have developed a novel, HA-tagged Pkhd1 allele that can be used to track the endogenous protein by standard methods. This will be a useful tool complementary to prior 5'tagged models. We show that the C-terminus, which was hypothesized to be an essential domain, is not necessary for normal hepatobiliary development. Our findings challenge the current model of FPC function.

SA-OR051

Missense Mutation of the Transcriptional Regulator *FSGS8* Is a Cause of Autosomal Dominant FSGS

Gentzon Hall,[1] Rasheed A. Gbadegesin,[1] Peter J. Lavin,[1] Guanghong Wu,[1] Andrey S. Shaw,[2] Nicholas Katsanis,[1] Yangfan Liu,[1] Kevin Shianna,[1] Michelle P. Winn.[1] *[1]Duke University; [2]Washington University.*

Background: FSGS is a clinical disorder characterized by focal scarring of the glomerular capillary tuft, podocyte injury and loss, and nephrosis. While idiopathic forms of this heterogeneous disorder constitute the majority of cases, recent insights into the molecular and genetic causes of inherited forms of FSGS have greatly enhanced our understanding of the pathogenic mechanisms of FSGS. Here we report the discovery of a novel mutation of the transcriptional regulator *FSGS8* which caused an early-onset form of autosomal dominant (AD) FSGS in a 88 family member kindred (Family 6524) from Lumberton, North Carolina.

Methods: In this study, we performed genome-wide linkage analysis using the Illumina Infinum II HumanLinkage-24 beadchip genotyping assay and whole-exome sequencing. All identified novel variants were confirmed by Sanger sequencing. Complimentary molecular genetic analyses in HEK 293 cells and zebrafish were also peformed.

Results: We identified a missense mutation R458Q within a c-terminal zinc finger domain of *FSGS8* as a new cause of AD FSGS. The mutation segregates with the disease in each of the seven affected family members within our study cohort and the mutation was not found in 1600 control chromosomes. The change is evolutionarily conserved and is considered damaging by *in silico* simulation. In complimentary *in vitro* studies in HEK 293 cells, overexpression of FSGS8 significantly downregulated nephrin and synaptopodocin mRNA expression, increased apoptosis, and altered the subcellular distribution of nephrin protein expression. Additionally, zebrafish morphants lacking *FSGS8* exhibited marked cardiac and yolk sac edema as well as retinovascular and trunk vascular network dextran leak consistent with nephrosis.

Conclusions: In summary, we report the identification of a novel mutation of the transcriptional regulator *FSGS8* which causes a particularly aggressive form of AD FSGS in a large US kindred. The FSGS8 R458Q mutation adversely affects the transcriptional regulation of key slit diaphragm proteins, causes mislocalization of nephrin, and promotes cellular apoptosis.

APOL1 Genotype and Kidney Microanatomy: Insights into the Predisposition of African Americans to Kidney Disease

Wendy E. Hoy,[1] Michael D. Hughson,[2] Cheryl Ann Winkler,[3] George W. Nelson,[3] Rebecca N. Douglas-Denton,[4] Susan A. Mott,[1] John F. Bertram,[4] Jeffrey B. Kopp.[5] *[1]SOM, The Uni of Queensland, QLD, Australia; [2]Uni of Mississippi MC, MS; [3]NCI-Frederick, NIH, MD; [4]DADB, Monash University, VIC, Australia; [5]NIDDK, NIH, MD.*

Background: APOL1 variants associate with excess kidney disease in African Americans (AA). We investigate their association with kidney parameters in autopsies.

Methods: 149 adult AA and 111 Whites from Mississippi were studied at autopsy. People with clinical histories, anatomic kidney abnormalities or histologic findings of renal disease were excluded. Glomerular number (N_{glom}) and mean glomerular volume (V_{glom}) were estimated using the disector/fractionator method. DNA from kidney blocks was typed for APOL1 renal risk alleles.

Results: Leading causes of death were misadventure and cardiovascular (CV) disease (29% each). 64% of AA (vs 2% of whites) were APOL1 risk allele positive: 44% and 20% had one and two alleles respectively. In aggregate, there were no differences in BMI, kidney weight, N_{glom} or V_{glom} in AA by APOL1 status, but APOL1 positive subjects, unlike APOL1 negative subjects, showed striking increases in V_{glom} ($p=0.02$) and kidney weight ($p\leq0.001$) with increasing BMI, tending to smaller values below, and higher values above the BMI median of 29 kg/m^2. On this cross-sectional study, APOL1 positive AA had 9480 fewer glomeruli per kidney per yr between ages 18 and 65 yr ($p=0.004$), vs 1724 per yr in APOL1 negative AA ($p=0.66$). All these phenomena were more marked in AA with two than with one APOL1 risk allele. In APOL1 positive AA, the adjusted OR (95%CI) for hypertension was 2.9 (1.1-7.3), and for CV death was 2.8 (1.6-6.8) compared with APOL1 negative AA.

Conclusions: APOL1 risk alleles were dominantly associated with excessive glomerular and kidney hypertrophy in relation to increasing body size, and accelerated nephron loss with age, all with a gene dose effect, and with hypertension and CVD. We speculate that the more extreme forms of APOL1-associated glomerular hypertrophy and nephron loss predispose to glomerulosclerosis, subclinical and clinical kidney disease and associated hypertension.

Negative Selection of Deleterious Variants in Genes Associated with Mendelian Forms of Nephrotic Syndrome

Matthew G. Sampson,[1] Matthias Kretzler,[2] Hyun Min Kang.[3] *[1]Pediatric Nephrology, University of Michigan, Ann Arbor, MI; [2]Internal Medicine-Nephrology, University of Michigan, Ann Arbor, MI; [3]Biostatistics, University of Michigan, Ann Arbor, MI.*

Background: Genes associated with Mendelian diseases tend to undergo negative selection of deleterious single nucleotide variants (SNV). Annotating known and/or candidate nephrotic syndrome (NS) genes with measures of purifying selection may help to identify disease-associated loci. Leveraging genome-wide SNV data from the 1000 Genomes Project (1000G) coupled with functional prediction software, we developed and implemented both novel and known methods to quantify the degree of negative selection in twelve genes of known association with NS and compared these results with 17,494 other genes.

Methods: Using 1000G data, we measured the frequency of non-synonymous SNV present in coding regions across the genome and used functional prediction software to stratify them as deleterious or benign. We then created two metrics of selection: 1) number of SNV/kilobase ("Suppressed Mutation") & 2) percentage of SNV that are private ("Enriched Rare Variants"). Using a Wilcoxon rank sum test, we contrasted the difference of frequency spectrum between benign and silent mutations for 17,506 genes across the genome and established the quantile in which the 12 NS-associated genes were located.

Results: *APOL1* (.008 quantile of all genes tested), *LAMB2* (.016 quantile), and *TRPC6* (.036 quantile) demonstrated the most enrichment of rare deleterious variants. The NS genes with the strongest suppression of deleterious SNV were *INF2* (.008 quantile), *MYH9* (.011 quantile), and *ACTN4* (.045 quantile). *INF2* had a 66x lower rate of deleterious vs benign SNV.

Conclusions: Multiple NS genes exhibit strong negative selection, suggesting that, when present, deleterious SNV in these genes are likely functional and could have large effects. The prevalence of these rare, deleterious SNV can be further investigated by sequencing these genes in large NS cohorts. Additionally, utilizing these metrics of negative selection to functionally annotate genes may help in prioritizing particular NS candidate genes for further study.

FAN1 Mutations Cause Karyomegalic Interstitial Nephritis, Linking DNA Damage Response Signaling to Renal Fibrosis Friedhelm Hildebrandt,[1,2] Weibin Zhou,[1] Edgar Otto,[1] Andrew Cluckey,[1] Katrina A. Diaz,[1] Heon Yung Gee,[1] Rannar Airik,[1] Moumita Chaki,[1] Toby W. Hurd,[1] Amiya K. Ghosh,[1] Jaap A. Joles,[3] Rachel H. Giles,[3] Agata Smogorzewska.[4] *[1]Pediatrics, University of Michigan, Ann Arbor, MI; [2]Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI; [3]Nephrology and Hypertension, University Medical Center, Utrecht, Netherlands; [4]Laboratory of Genome Maintenance, Rockefeller University, New York, NY.*

Background: Chronic kidney disease (CKD) remains one of the largest health problems in developed countries. Its prevalence increases for unknown reasons, and its central phenotypic feature, renal fibrosis, is not well understood.

Methods: In order to identify single-gene causes of renal fibrosis/CKD we performed homozygosity mapping and whole exome resequencing in a model disorder for renal fibrosis known as 'karyomegalic interstitial nephritis (KIN)' (Mihatsch et al. *Clin Nephrol 12:54, 1979).*

Results: We identified recessive mutations of Fanconi anemia-associated nuclease 1 (FAN1) as causing karyomegalic interstitial nephritis (KIN) in 9 of 10 families ascertained. KIN causes CKD with renal histology indistinguishable from NPHP, except for the presence of karyomegaly. FAN1 has nuclease activity and acts in DNA interstrand crosslinking (ICL) repair within the Fanconi anemia (FA) pathway of DNA damage response (DDR). Interestingly, ICL-causing genotoxins generate a KIN-like phenotype. We demonstrate that cells from individuals with FAN1 mutations exhibit sensitivity to the ICL agent mitomycin C. However, they do not exhibit chromosome breakage or cell cycle arrest after diepoxybutane treatment, unlike cells from patients with Fanconi anemia. We complement ICL sensitivity with wild type FAN1 but not mutant cDNA from individuals with KIN. The FAN1 defect was not epistatic with the Fanconi anemia pathway. By depletion of fan1 in zebrafish we recapitulated increased DDR, apoptosis, and kidney cysts akin to NPHP.

Conclusions: Our findings implicate susceptibility to environmental genotoxins and inadequate DNA repair as novel mechanisms of renal fibrosis and CKD.

Identification of Homozygous Mutations in Two alpha Integrin Encoding Genes in Fetuses with Severe Kidney Development Defects Cecile Jeanpierre,[1,2] Mélanie Parisot,[1,3] Flora Silbermann,[1,2] Stephanie Reichen,[1] Christine Bole-feysot,[3] Patrick Nitschke,[2] Laurence Heidet,[4,5] Patricia Blanchet,[6] Remi Salomon,[1,2,5] Corinne Antignac,[1,2] Sophie Saunier.[1,2] *[1]Inserm U983, Paris, France; [2]Université Paris Descartes, Paris, France; [3]Institut Imagine, Paris, France; [4]MARHEA Reference Center, AP-HP, Necker Hospital, Paris, France; [5]Pediatric Nephrology Department, AP-HP, Necker Hospital, Paris, France; [6]Genetic Department, Hôpital Arnaud de Villeneuve, Montpellier, France.*

Background: Renal hypodysplasia (RHD) is an heterogeneous condition encompassing a spectrum of kidney development defects responsible for pediatric end-stage renal failure and mortality. Dominant mutations in *PAX2*, *EYA1*, *SIX1* and *HNF1B* have been identified in syndromic forms of RHD. However, other genes involved in isolated and syndromic RHD remain to be identified. Moreover, examination of families highly suggests that not only dominant but also recessive forms of RHD exist.

Methods: In order to identify genes involved in recessive RHD, we analysed fetuses belonging to independent consanguineous families by whole exome sequencing [50 Mb SureSelect assay (Agilent) and SOLiD4 (Life Technologies)].

Results: We identified homozygous mutations in two genes encoding alpha integrin subunits. A splicing mutation in *ITGA8*, leading to skipping of exon 28, was identified in two fetuses from a family with bilateral renal agenesis. This mutation was absent from dbSNP, 1000genome and our in-house databases. A missense variation in *ITGA3* was detected in two fetuses with multicystic renal dysplasia from a family originating from Turkey. This mutation, L518P, was predicted as damaging by Polyphen2 and Sift softwares. It was absent from databases as well as from 30 Turkish DNA controls.

Conclusions: Integrins play a crucial role during development of epithelial tissues, notably in the kidney. Integrin a8- and integrin a3-deficient mice display abnormal kidney development, with renal agenesis and cystic formation respectively. This is the first report of human mutations in these genes associated with RHD. Functional studies based on 3D-cultures and adhesion assays are in progress to formally demonstrate the causative effect of these mutations.

SA-OR056

Regulation of Sclerostin Expression and Bone Volume by Phosphate in a Model of Adynamic Bone Disease Juliana C. Ferreira,[1] Guaraciaba O. Ferrari,[1] Raquel T. Cavallari,[1] Katia R. Neves,[1] Wagner V. Dominguez,[1] Luciene M. dos Reis,[1] Fabiana G. Graciolli,[1] Elizabeth M. Oliveira,[1] Shiguang Liu,[2] Yves Sabbagh,[2] Vanda Jorgetti,[1] Susan Schiavi,[2] Rosa M.A. Moyses.[1] *[1]Nephrology Division, Universidade de São Paulo, Brazil; [2]Genzyme, A Sanofi Company.*

Background: Recent studies have linked the protein Sclerostin (SOST), a Wnt pathway inhibitor, to the pathogenesis of CKD-MBD, where a negative association between PTH and SOST was found. In this study, we investigated the role of phosphate (P) in SOST regulation by testing it in a experimental model of CKD adynamic bone disease mantained on diets with different P contents.

Methods: Rats were divided into 3 groups and subjected to nephrectomy (Nx) and parathyroidectomy (PTx) with different P content in the diet: CKD 1.2% (P = 1.2%), CKD 0.6% or Control (sham NX/PTX + 0.6%). After 8 wks, biochemical, histomorphometric and bone gene expression (TLDA) analyses were performed.

Results: CKD rats showed higher Creat and P, but lower iCa and FGF-23 than Controls. Comparing uremic rats, P overload was associated with higher FeP, lower bone volume (BV/TV), as well as higher serum SOST, elevated bone expression of SOST and RANK, and apoptotic rate of osteoblasts (1.3 vs 0.4%) and osteocytes (0.4 vs. 0.2%; $p<0.05$ for all), when compared to 0.6% P rats.

	CKD 1.2%	CKD 0.6%	Control
Creat(mg/dl)	1.3±0.2	1.4±0.9	0.6±0.1[a]
P(mg/dl)	11.7±1.9	12.2±1.9	5.5±0.6[a]
iCa(mmol/L)	0.5±0.1	0.5±0.1	1.2±0.1[a]
FeP(%)	42(32-54)[a]	1.0(0.3-9.8)	7.6(3.7-10)
PTH(pg/ml)	16(5-224)	26(19-117)	124(88-199)
FGF-23(pg/ml)	138±118	192±42	286±92[a]
serum SOST(ng/ml)	1.10(0.51-0.70)	0.15(0.07-0.43)[a]	1.71(0.71-3.35)
BV/TV(%)	26.8±5.5	33.6±4.4[a]	24.2±5.0
SOST(fold change)	4.1±0.3[a]	0.5±0.2	1.2±0.4
RANK(fold change)	1.1±0.04	0.6±0.2[a]	1.0±0.2

a = $p< 0.05$ vs. all

Therapy with sevelamer, but not with calcium, decreased bone expression of SOST in animals fed with 1.2%P.

Conclusions: We demonstrate that in CKD, P can regulate bone SOST mRNA expression and serum protein levels independent of PTH. P was also shown to increase the expression of RANK and the apoptosis of osteoblasts, leading to a lower bone volume. Our findings underscore the role of P in CKD-MBD, emphasizing the value of its control in this disease.

SA-OR057

Secreted Klotho Protects against Stress-Induced Cardiac Hypertrophy by Down-Regulating TRPC6 Channel Jian Xie, Sung Wan An, Makoto Kuroo, Chou-Long Huang. *UT Southwestern Medical Center, Dallas, TX.*

Background: Klotho is an anti-aging membrane protein predominantly produced in the kidney, which sheds its extracellular N-terminus into the systemic circulation. It was recently reported that increased serum FGF23 contributes to cardiac hypertrophy of CKD via a Klotho-independent mechanism. Klotho expression is decreased in CKD and aging, two conditions associated with increased risk for heart failure. Whether Klotho is cardioprotective is unknown.

Methods: Mice overexpressing Klotho (KL-Tg) and wild-type littermates were studied at baseline and in response to isoproterenol (ISO) overstimulation (sc x 10 days). Hypertrophy was assessed by measuring heart size, heart weight/body weight (HW/BW) ratio, and expression of cardiac fetal genes (*BNP*, *ANP*, and β-*MHC*). Serum phosphate and FGF23 levels were measured.

Results: Heart size and HW/BW ratio were not different between WT and KL-Tg mice at baseline. ISO treatment induced cardiac hypertrophy, and Klotho overexpression blunted the ISO-induced cardiac hypertrophy. Consistently, Klotho overexpression did not alter cardiac fetal gene expression at baseline, but attenuated ISO-induced increases in expression. Klotho overexpression in mice did not alter serum phosphate or FGF23 levels. It was reported that increased TRPC6 induces cardiac hypertrophy. Indeed, mice with heart-specific overexpression of TRPC6 (C6-Tg) developed spontaneous cardiac hypertrophy and had increased fetal gene expression and decreased long-term survival relative to WT. Transgenic Klotho overexpression ameliorated hypertrophic responses and improved long-term survival of C6-Tg mice. Direct addition of secreted Klotho inhibits TRPC6 currents recorded by patch-clamp in isolated cardiomyocytes.

Conclusions: Klotho has no effect on hearts at baseline, but protects against stress-induced pathological cardiac hypertrophy. Cardioprotection by Klotho is mediated by down regulation of cardiac TRPC6. As FGF23 appears to induce cardiac hypertrophy independently of stress factors, increased FGF23 and Klotho deficiency may synergistically contribute to cardiac hypertrophy in CKD by participating at different stages of pathogenesis.

SA-OR058

Inhibition of Systemic Factors Produced by Kidney Injury Decreases Cardiovascular Risk in the CKD-MBD Charles Ginsberg, Yifu Fang, Toshifumi Sugatani, Keith A. Hruska. *Pediatric Nephrology, Washington University School of Medicine, St. Louis, MO.*

Background: Kidney injury causes recapitulation of developmental programs in attempted repair leading to increased production of factors that circulate, some of which are inhibitory to skeletal remodeling. The early CKD-MBD begins in stage 2 CKD and is characterized by the inhibitors of skeletal remodeling, stimulation of VC, increased secretion of FGF23 and normal mineral metabolism. In CKD, osteoblastic differentiation of cells in the neointima causes calcification of atherosclerotic plaques and stimulates medial vascular calcification (VC). VC is an important cause of CV morbidity in CKD and is a CV risk factor associated with CKD. Here we tested the hypothesis and examined the mechanisms that neutralization of the inhibitors of skeletal remodeling would decrease CV risk in CKD.

Methods: We used neutralizing monoclonal antibodies to specific circulating skeletal inhibitory factors produced by renal injury in early CKD. *Ldlr-/-* mice fed high fat diets

were subjected to renal cortical electrocautery and contralateral nephrectomy at 12-14 weeks of age to produce the early CKD–MBD, euthanasia was at 22 or 28 weeks. Treatment with vehicle, DKK1 mab (30 mg/Kg tiw IP), or CaAc (3% w/w mixed in diet) was begun at 14 or 22 wks.

Results: Dickkopf-1 (Dkk1) levels were increased from normal wt 1868±772 or sham 1650±882 to 3132±1590 (pg/ml, p<0.01). Glomerular filtration rate was reduced to 76% of normal (stage 2 CKD). BUN, Ca, Pi and PTH levels were normal. CKD stimulated and DKK1 mab inhibited accumulation of aortic Ca levels (0.52±0.19 (CKD) vs. 0.26±0.14 (wt), 0.32±0.23 (sham) and 0.4±0.1 (DKK1 mab) mg/g dry weight, p<0.05). CaAc did not improve CKD stimulated VC. Serum levels and aortic expression of FGF-23 were also increased in CKD, but were not decreased by the DKK1 mab (554±263 (CKD) vs. 242±56 (wt), 309±64 (sham) and 590±185 (DDK1 mab).

Conclusions: Factors, such as Dkk1, produced by kidney injury and inhibitory to the skeleton stimulate VC without evidence of direct action on the vasculature suggesting that inhibition of bone formation may be a contributory mechanism of VC early CKD.

SA-OR059

FTI-277 Inhibits Calcification by Promoting Akt Signalling and Regulating Osteogenic Differentiation of VSMC Arvind Ponnusamy,[1] Smeeta Sinha,[1,2] Gareth D. Hyde,[2] Heather Jane Eyre,[2] Nick Ashton,[2] Andrew Gilmore,[1] Philip A. Kalra,[1] Ann E. Canfield.[2] *[1]Renal Department, Salford Royal Hospital, Salford, United Kingdom; [2]University of Manchester, United Kingdom.*

Background: Patients with chronic kidney disease have poor cardiovascular outcomes due to increased vascular calcification and atherosclerosis. Vascular calcification is a highly-regulated process involving the osteogenic differentiation of vascular smooth muscle cells (VSMC) and VSMC apoptosis. This study aims to indentify new therapeutic agents for vascular calcification.

Methods: Bovine and human VSMC, FTI-277 (farnesyl transferase inhibitor), wortmannin (PI3K inhibitor) and SH6 (Akt inhibitor) were used in mineralisation and apoptosis experiments. Rat aortic rings from 5/6 nephrectomy models were used in *ex vivo* experiments.

Results: FTI-277 significantly inhibits calcification of VSMC (p<0.001). Pre-incubation of VSMCs with FTI-277 (10 μM) inhibits Ras activation and markedly enhances serum-induced Akt phosphorylation. Calcification of VSMC is associated with decreased Akt phosphorylation. Mineralisation was detected in cells incubated with FTI-277 and wortmannin (100 nM) or FTI-277 and SH6 (10μM), demonstrating that the effects of FTI-277 can be partially negated by preventing PI3K/Akt signalling. FTI-277 significantly inhibits phosphate-induced VSMC apoptosis (p<0.05) and this effect is negated by SH6 (p<0.05). FTI-277 also inhibits Runx2, Msx 2 and alkaline phosphatase mRNA expression (p<0.05), promotes matrix Gla protein mRNA expression (P<0.05), and maintains α-smooth muscle actin mRNA expression. These effects are negated by co-incubation of VSMC with FTI-277 with SH6.Rat aortic rings from short-term (CKD stage1-3) and long-term (CKD stage 4-5) 5/6 nephrectomy models were induced to undergo mineralisation with elevated phosphate +/- FTI-277. Calcium assays and histology demonstrate that FTI-277 inhibits mineralisation in rat aortic rings from both short-term and long-term 5/6 nephrectomy models.

Conclusions: These studies demonstrate that FTI-277 inhibits VSMC osteogenic differentiation, apoptosis and mineralisation by increasing Akt signalling. FTI-277 also inhibits mineralisation in CKD rat aortic rings *ex vivo*.

SA-OR060

Deletion of the Proton Receptor OGR1 in Mice Leads to Increased Bone Density Nancy Krieger,[1] Zhenqiang Yao,[2] Kelly Kyker-snowman,[1] Brendan F. Boyce,[2] David A. Bushinsky.[1] *[1]Medicine, Univ. of Rochester, Rochester, NY; [2]Pathology, Univ. of Rochester, Rochester, NY.*

Background: Chronic metabolic acidosis (MET) stimulates net calcium (Ca) efflux from bone mediated primarily by increased prostaglandin E_2-induced stimulation of RANKL and increased osteoclastic bone resorption. Osteoblasts express the H^+-sensing G-protein coupled receptor, OGR1, which signals through IP_3-mediated intracellular Ca release. We found that H^+-induced Ca_i signaling in osteoblasts requires OGR1, which suggests OGR1 is the H^+ sensor activated by MET to initiate bone resorption. Mice with a genetic null mutation in OGR1 (KO, provided by K. Seuwen, Novartis) were utilized to test the hypothesis that lack of OGR1 would lead to increased bone mass in actively growing mice, a time when large amounts of metabolic acid are generated.

Methods: Bones from 8 wk old KO and wild type C57/Bl6 mice (WT) were dissected, fixed and decalcified as necessary and analyzed by μCt and histomorphometry. All indicated comparisons are p<0.05.

Results: Although the KO mice have no gross phenotype when compared to WT, there are μCT and histologic abnormalities in KO bones. By μCT, KO vertebrae have increased bone volume (BV/TV=0.38±0.02 vs 0.28±0.01), trabecular number (7.3±0.2 vs 6.2±0.1) and trabecular thickness (0.054±0.001 vs 0.047±0.001) and decreased trabecular spacing (0.127±0.003 vs 0.151±0.004) compared to WT. Tibiae from KO mice also have increased trabecular bone volume (0.23±0.01 vs 0.15±0.01) and trabecular number (7.2±0.1 vs 5.2±0.1) and decreased trabecular spacing (0.128±0.003 vs 0.185±0.005) compared to WT. Histomorphometric analysis of tibial metaphysis sections demonstrates increased bone volume (11.2±1.0% vs 7.5±0.7%) and decreased trabecular spacing (45.0±2.6 vs 67.0±4.9/mm^2) in KO vs WT. However, there was an increase in tibial trabecular osteoclast numbers/mm bone surface (17.8±3.2 vs 13.5±2.8) and increased osteoclast surface/bone surface (28.1±4.5% vs19.7±6.7%) in KO vs WT.

Conclusions: These data demonstrate that in rapidly growing mice which generate large amounts of H^+, lack of the H^+ receptor OGR1 leads to increased trabecular bone mass and an increased number of osteoclasts.

Bone Biopsy Findings, Biochemical Markers and Aortic Calcification in Waitlisted Dialysis Patients Satu Keronen,[1] Leena Martola,[1] Patrik Finne,[1] Inari S. Tamminen,[4] Leena Kauppila,[2] Heikki Kroger,[3] Eero Honkanen.[1] *[1]Helsinki University Central Hospital; [2]Terveystalo Healthcare; [3]Kuopio University Hospital; [4]University of Eastern Finland.*

Background: It has been shown that histomorphometric parameters of bone volume and turnover are correlated with arterial calcifications and arterial stiffness in CKD patients. The aim with this prospective, observational trial was to study whether the bone histomorphometric findings have correlations with aortic calcification score or parameters of calcium homeostasis and bone turnover in CKD5d patients. The present study is an interim cross sectional analysis of baseline data.

Methods: After double tetracycline labelling transiliac bone biopsy was performed and analyzed using the TVM (turnover -volume- mineralization) classification on 50 consecutive dialysis patients as routine procedure. 72% were men and HD/PD ratio was 52%/48%. All patients were waitlisted for the kidney transplantation. Blood samples were obtained for parameters of calcium homeostasis and bone turnover. Also the lateral lumbar radiography of the abdominal aorta was taken to determine the abdominal aortic calcification score (AAC).

Results: TVM was classified high in 31 (62%) pts., low in 14 (28%) pts. and 5 (10%) pts.had normal turnover. Demographic and biochemical data in high, normal and low bone turnover states are shown in Table 1. Only 3 pts. (6%) had entirely normal bone histology according to TMV classification.

Table 1

	TVM		
	Low	**Normal**	**High**
	n=14	n=5	n=31
Age (years±SD)	54±11	49±9	49±13
M:F	11:3	3:2	22:9
Dial duration (mo)	32±35	18±5	30±32
AAC score(0-24)	8±9	3±3	8±8
PTH (ng/l)	344±230	181±155	438±239
Bone ALP (ug/l)	15±11	10±2	17±13

Conclusions: In this cross sectional analysis almost all patients had abnormal bone histology. Low turnover bone was less common than previously reported. Both high and low turnovers states were associated with elevated bone ALP. Repeated analyses (including bone biopsy) in the ongoing study will probably elucidate relationships between dynamic changes in bone histology and aortic calcification.

MicroRNA Expression Is Altered in Chronic Kidney Disease Neal X. Chen,[1] Kraiwiporn Kiattisunthorn,[2] Kalisha O'Neill,[1] Xianming Chen,[1] Vincent H. Gattone,[3] Sharon M. Moe.[1,4] *[1]Medicine, Indiana University School of Medicine; [2]Faculty of Siriraj Medical School, Mahidol University, Bangkok, Thailand; [3]Anatomy and Cell Biology, Indiana University School of Medicine; [4]Roudebush Veterans Affairs Medical Center, Indianapolis, IN.*

Background: Several studies have shown that specific microRNA (miRNA) may lead to altered gene expression resulting in downstream signaling pathways that contribute to vascular disease. Specifically, miRNA 145 is decreased in patients with cardiovascular disease and diabetes, miRNA 155 is associated with inflammation, and miRNA125b is involved in calcification of vascular smooth muscle cells (VSMC) and osteoblast differentiation. The purpose of the present study was to determine if these miRNA are altered in CKD.

Methods: Sera were collected from 10 stage 3-4 CKD, 10 hemodialysis patients and 8 healthy volunteers. VSMC were isolated from aorta from the Cy/+ rat, a model of progressive CKD, and normal littermates. Total RNA were isolated from serum or VSMC and miRNA concentration determined by Agilent Bioanalyzer. The expression of miRNAs, miRNAs processing enzymes and target genes was determined by real-time PCR.

Results: The results demonstrated that circulating levels of miR125b, miR145, miR155 were all significantly decreased with declining eGFR. These same miRNA were lower in CKD and hemodialysis patients compared to healthy volunteers despite a greater percentage of miRNA in the RNA samples. VSMC from CKD rats also showed decreased expression of miR-125b, miR-145 and miR-155 compared to VSMC from normal rats. Downstream target genes of miR145 (myocardin) and miR125b (RUNX2) were decreased and increased, respectively, coinciding with the known effects of these miRNA. There was no difference in the expression of the miRNA processing proteins DROSHA and DICER.

Conclusions: Circulating levels of vascular miRNA 125b, 145, 155, are decreased in CKD. The observed decrease in miRNAs is specific, results in downstream gene changes, and not due to altered cellular processing or degradation in sera. Thus, decreased miRNA expression in VSMC and/or sera of patients with CKD may contribute to cardiovascular disease and vascular calcification.

SA-OR063

Decreased Serum Soluble αKlotho Levels Are Significantly Associated with Cardiovascular Dysfunction in Patients with Chronic Kidney Disease
Masashi Kitagawa, Hitoshi Sugiyama, Hiroshi Morinaga, Keiichi Takiue, Ayu Ogawa, Toshio Yamanari, Yoko Kikumoto, Tatsuyuki Inoue, Shinji Kitamura, Yohei Maeshima, Hirofumi Makino. *Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Klotho was originally identified in a mutant mouse strain that was unable to express the gene and consequently showed shortened life spans. In humans, low serum αKlotho levels are related to a prevalence of cardiovascular (CV) diseases in community-dwelling adults; however, it is unclear whether the serum αKlotho levels are associated with CV dysfunction in patients with chronic kidney disease (CKD).

Methods: We assessed the relationships between the serum soluble αKlotho levels measured by ELISA and parameters of CV dysfunction, including flow-mediated dilatation (FMD), intima-media thickness (IMT), ankle-brachial pulse wave velocity (baPWV) and aortic calcification index (ACI), in 114 CKD patients. Early peak diastolic annular velocity (E') and left ventricular mass index (LVMI) were evaluated using echocardiography to detect left ventricular diastolic dysfunction (LVDD).

Results: The serum αKlotho levels positively correlated with FMD values ($r = 0.3174$; $p = 0.0016$) and inversely correlated with both baPWV and mean IMT values; however, no correlation was observed with ACI values. We also found a significant correlation between the serum αKlotho levels and LVDD assessed by LVMI and E'. Comparing patients with fibroblast growth factor 23 (FGF23) levels < 44.4 pg/mL (median), FMD values in patients with serum αKlotho ≥ 616.3 pg/mL (median) were higher than those in patients with the serum αKlotho < 616.3 pg/mL, thus suggesting that, even at low FGF23 levels, the lower serum αKlotho levels correlate with endothelial dysfunction.

Conclusions: Decreases in the serum αKlotho levels are significantly associated with CV dysfunction in CKD patients. Moreover, the combined use of the serum αKlotho levels and FGF23 levels delineates the degree of CV dysfunction. Serum αKlotho measurements may be sensitive and early biomarkers of CV dysfunction, and endothelial dysfunction in particular, in CKD patients.

SA-OR064

Effects of Calcimimetics on Bone in a Rodent Parathyroidectomy Model
Mariano Rodriguez,[3] Ignacio Lopez,[1] Victor Lorenzo,[2] Escolastico Aguilera-tejero,[1] Eduardo C. Salido,[2] Fatima Guerrero,[1] Addy Rosa Montes de Oca Gonzalez,[1] Carmen Pineda.[1] *[1]Medicina y Cirugia Animal, Universidad de Cordoba, Spain; [2]Hospital Universitario, Servicio Canario de Salud, Tenerife, Spain; [3]Servicio Nefrologia, Hospital Reina Sofia, Córdoba, Spain.*

Background: We have shown that calcimimetics (CM) prevent vascular calcification (VC) and accelerate regression of extraosseous calcification and we have proposed the increase in urinary Ca excretion induced by CM as a potential factor in the protective effect on VC. CM have been reported to have a deleterious effect on bone which may be related to changes in PTH. In the present study we evaluate the impact of CM on bone independently of PTH.

Methods: Wistar rats were parathyroidectomized (PTX) and randomly allocated to 4 groups of 5 rats each. Sham: underwent a sham surgery; PTX: received constant infusion of vehicle using miniosmotic Alzet Pump; PTX+PTH: received a physiological dose of PTH, and PTX+PTH+CM also received PTH through the pump and 1.5 mg/kg/48 h of CM AMG 641 sc. Rats were sacrificed on day 28 and the ileum was dissected and processed to study bone histomorphometry.

	Sham	PTX	PTX+PTH	PTX+PTH+CM
TBV (%)	12.3±1.7	9.8±1.4	12.4±1.8	11.6±2.1
OV (%)	0.53±0.24	0.23±0.07	0.51±0.16	0.80±0.18b
BS (%)	5.4±2.3	2.5±0.6	4.5±1.2	7.2±1.3b
BSO (%)	9.5±0.9	2.1±0.5a	7.1±1.4b	10.3±2.1b
RS (%)	1.98±0.43	2.17±0.62	2.19±0.55	3.65±1.03
RSOcl (%)	2.68±0.49	0.65±0.24a	1.31±0.42	1.58±0.52

TBV: trabecular bone volume; OV: osteoid volume, BS: bone surface; BSO: bone surface cover by osteblasts, RS: resorptive surface and RSOcl: resorptive surface cover by osteoclasts. Values are means ± SE, n=5. ap<0.05 vs Sham, bp<0.05 vs PTX

Results: PTX rats showed a decrease in bone turnover, bone formation and bone resorption. The addition of PTH increased bone turnover to normal values. The addition of CM to this model induced minimal changes in bone. In contrast to previous published data, we have not found detrimental effects on bone by CM, in fact AMG 641 improved bone turnover.

Conclusions: These data suggest that in a rodent PTX model, inclusion of CM in the therapeutic regimen do not induce important changes in bone turnover, and the changes observed show a tendency to increased bone formation.

SA-OR065

Pit-1 and BMP-2 Expression in the Radial Arteries from Uremic Patients and Their Relationship with Histological Changes
Yi Yu. *Department of Hemodialysis, Dongfang Hospital of Fujian Province, Fuzhou, Fujian, China.*

Background: To investigate sodium-phosphate cotransporter (Pit-1) and bone morphogenetic protein-2 (BMP-2) expressions in the radial arteries from uremic patients.

Methods: Pieces of radial arteries were removed from 45 uremic patients during arterial venous fistula operation. Ten patients with subtotal gastrectomy and normal renal function were chosen as controls. Segments of radial arteries were evaluated by HE, Masson and von Kossa staining. The expressions of Pit-1 and BMP-2 were detected by immunohistochemistry.

Results: Non-calcified radial arteries presented uniformly normal media. Calcified radial arteries presented thickened media and intima, in which most calcification occurred in medial layer and most of smooth muscle cells were in disorder. The thickened media decreased in elastin, increased in collagen fibers and matrix. 24/45 (53.33%) had no evidence of vessel calcification, 11/45 (24.44%) had mild/moderate calcification and 10/45 (22.22%) had severe calcification, while calcification was not found in controls. Staining for Pit-1 was marked in the media from uremic patients and controls. The expression of Pit-1 in the calcified arteries was more marked compared with non-calcified arteries and controls ($P<0.01$). Staining for BMP-2 was more intense in calcified versus non-calcified arteries and controls ($P<0.01$). And there were 12 specimens of the non-calcified arteries that presented positive staining of BMP-2, while not in controls. Staining for Pit-1 and BMP-2 was more marked in severe calcified arteries compared with from mild/moderate calcified arteries ($P<0.05$). The calcification score was positively correlated with serum phosphorus and C-reactive protein (CRP) levels ($P<0.05$). The staining for Pit-1 and BMP-2 significantly correlated with serum phosphorus and CRP ($P<0.01$), and also the staining for Pit-1 correlated with the staining for BMP-2 ($P<0.01$).

Conclusions: Uremic radial artery calcification is mainly located in medial 1ayer and positively correlates with serum phosphorus and CRP. The increased expression of Pit-1 and BMP closely correlates with vascular calcification. The expression of BMP-2 is upregulated before marked vascular calcification.

Mitochondrial Permeability Transition Pore Inhibitor Improves Renal Outcomes after Revascularization in Experimental Atherosclerotic Renal Artery Stenosis
Alfonso Eirin, Zilun Li, Xin Zhang, James Krier, John R. Woollard, Xiang-Yang Zhu, Sandra Herrmann, Amir Lerman, Stephen C. Textor, Lilach O. Lerman. *Mayo Clinic, MN.*

Background: Percutaneous transluminal renal angioplasty (PTRA) fails to improve renal function for most patients with atherosclerotic renal artery stenosis (ARAS), possibly due to injury incurred during reperfusion. Bendavia is a novel tetrapeptide that prevents mitochondrial permeability transition pore (mPTP) opening and ischemia reperfusion injury, but its potential for improving renal response to PTRA is unknown. We hypothesized that adjunct Bendavia would improve renal structure and function during PTRA.

Methods: Pigs with 6 wks of ARAS or control were treated with PTRA (or sham), with adjunct systemic 4-hr infusion of Bendavia (0.05 mg/kg IV) or Vehicle during PTRA (n=7 each). Single-kidney hemodynamics and function were studied in vivo 4 wks later and renal mitochondrial biogenesis, microvascular architecture, and injurious pathways ex-vivo.

Results: Monocyte chemoattractant protein (MCP-1) levels rose over 3 hours after PTRA, consistent with inflammatory injury in all PTRA-treated pigs. Bendavia infusion did not affect MCP-1 levels, yet 4 weeks later, stenotic-kidney GFR and RBF that remained decreased in PTRA+Vehicle were restored in PTRA+Bendavia pigs. Renal mitochondrial biogenesis and microvascular density were restored after PTRA+Bendavia, and fibrosis and apoptosis decreased only in Bendavia-treated pigs.

Conclusions: Infusion of Bendavia during PTRA preserved mitochondrial biogenesis, restored renal function, and attenuated tissue injury in swine ARAS. Functional mitochondrial injury during renal reperfusion sustains inflammatory injury and limits recovery after PTRA. Inhibition of mPTP opening with Bendavia may provide a novel therapeutic potential for improving kidney function and outcomes following PTRA in ARAS.

	NORMAL	ARAS	ARAS+PTRA +Vehicle	ARAS+PTRA +Bendavia

Deletion of NOS1 in the Macula Densa Induces Salt-Sensitive Hypertension

Yan Lu,[1] David E. Stec,[1] Liang Cheng,[1] Ying Ge,[1] Yiling Fu,[1] Paul L. Huang,[2] Jin Wei,[1] Jennifer S. Pollock,[3] Luis A. Juncos,[1] Ruisheng Liu.[1] *[1]Physiology, U of Mississippi Medical Center, Jackson, MS; [2]Harvard Medical School; [3]Georgia Health Sciences University.*

Background: Nitric oxide (NO) released from NO synthase 1 (NOS1), which is highly expressed in the macula densa (MD), blunts tubuloglomerular feedback (TGF). However, the role of MD NOS1 and TGF in regulation of salt-water balance and blood pressure is unknown.We developed a tissue specific NOS1 knockout strain to examine the significance of NOS1 in the MD.

Methods: We developed a strain of MD Cre mice using the sodium, potassium, 2 chloride cotransporter (NKCC2) promoter. To characterize this new Cre strain, we crossed the NKCC2-Cre mice with an EGFP reporter strain (Rosa). Cre activity as measured by EGFP fluorescence was found in MD and was further confirmed *via immunofluorescent staining in isolated perfused MD and found to be limited to the MD* and not in the distal tubule.

Results: Next, we generated tissue specific NOS1 knockout mice by crossing NKCC2-Cre mice with $NOS1^{flox/flox}$, which targets at exon-6 of NOS1 and deletes all splice variants of NOS1. We confirmed NOS1 KO by immunohistochemistry and found no staining of NOS1 in the MD in KO mice. To measure NO generation in the MD, we perfused isolated MD and loaded with fluorescent dye DAF-2. When we switch tubular NaCl from 10 to 80 mM, NO generation in the MD was from 114±12 to 165±11 units/min in WT mice, while in KO mice NO production were absent at both 10 and 80 mM NaCl. We measured maximal change of stop flow pressure as an indicator of TGF using micropuncture. In WT mice, TGF was 4.5±0.3 mmHg; while in KO mice, TGF enhanced to 8.4±0.7 mmHg. (n=5; p<0.01)

To determine the effect of MD NOS1 deletion on the blood pressure response to changes in sodium intake, we measured mean arterial pressure (MAP) by telemetry in mice fed a low salt diet (0.01% NaCl) for 10 days, followed by a high salt diet (8%NaCl) for 14 days. MAP of KO mice increased by 10.5±2.4 *versus* 3.1±2.7 mmHg in WT mice (p <0.01, n=5).

Conclusions: These results indicate that NOS1 in the MD and TGF play important roles in the regulation of blood pressure in response to changes in sodium intake.

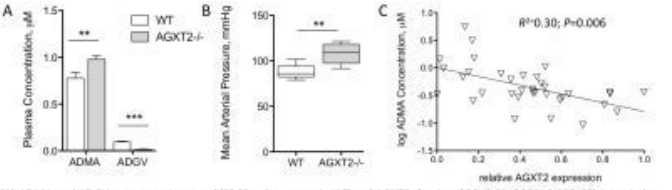
Alaninie-Glyoxylate Aminotransferase-2 Metabolises Endogenous Methylarginines and Controls Blood Pressure in Mice and Humans

Ben Caplin,[1,2] James Alexander Tomlinson,[2] Alan D. Salama,[1] The International Consortium for BP Genome-Wide Studies, James M. Leiper,[2] David C. Wheeler.[1] *[1]UCL Medical School; [2]MRC Clinical Sciences Centre, United Kingdom.*

Background: Asymmetric dimethylarginine (ADMA) is an endogenous inhibitor of nitric oxide synthesis that may mediate cardiovascular disease. Alanine-glyoxylate aminotransferase-2 (AGXT2) has been reported to degrade ADMA. We investigated the significance of AGXT2 in ADMA metabolism *in vivo* and examined the impact of this enzyme on blood pressure (BP).

Methods: We measured ADMA and asymmetric dimethylguanidino valeric acid (ADGV; the product of AGXT2 metabolism of ADMA) and invasive terminal BP in AGXT2 knockout (AGXT2-/-) mice. To investigate the effects of AGXT2 in humans we quantified the association between renal allograft protocol biopsy gene expression and both ADMA and ADGV. Finally, taking a hypothesis-driven approach, we examined the association between the intermediate-frequency AGXT2 coding variant rs37369 (which leads to a valine to isolecucine substitution and increased substrate levels) and BP in data from subjects of European origin in a meta-analysis of genome-wide studies.

Results: AGXT2-/- mice demonstrate reduced ADGV, high ADMA and hypertension (Fig. A and B). In transplant patients allograft AGXT2 expression was correlated with urinary ADGV and strongly inversely associated with plasma ADMA (Fig. C). The association between AGXT2 and ADMA remained after adjustment for potential confounders including renal function and DDAH1 expression (partial R^2=0.20; P=0.009). In data from the meta-analysis (n=69,000) each T allele at rs37369 was associated with a 0.31±0.11mmHg increase in diastolic BP (P=0.0052).



(A) ADMA and ADGV concentrations, and (B) Blood pressure in WT and AGXT2-/- mice; **P<0.01; ***P<0.005. (C) Association between plasma ADMA and allograft AGXT2 gene expression in transplant patients.

Conclusions: Although the impact of variation at rs37369 needs further study these findings imply AGXT2 is an important regulator of ADMA and represents a novel mechanism through which the kidney influences BP.

An Orally Active Epoxyeicosatrienoic Acid (EET) Analog Decreases Renal Injury in the Dahl Salt-Sensitive Hypertensive Rat

John D. Imig,[1] Abdul Hye Khan,[1] John Falck.[2] *[1]Pharmacology, Medical College of Wisconsin; [2]Biochemistry, University of Texas Southwestern Medical Center.*

Background: Renal injury is associated with salt-sensitive hypertension. The Dahl salt-sensitive hypertensive rat (Dahl SS) is a model of salt-sensitive hypertension and the related kidney injury. The kidney injury in Dahl SS hypertension is associated with oxidative stress, inflammation and ER stress. We have recently developed orally active EET analogs that provide organ protection in hypertension and other pathologies through multiple signaling pathways. We hypothesized that these EET analogs with their anti-inflammatory, anti-oxidant and anti-ER stress effects will protect the kidney in Dahl SS hypertension.

Methods: Dahl SS rats received high salt diet and treated either with an EET analog (10 mg/kg/d) or vehicle in drinking water for 14 days. Systolic blood pressure (SBP) was measured and urine, plasma and tissue samples were collected at the end of the treatment protocol. Urinary creatinine, albumin, nephrin, monocyte chemoattractant protein-1 (MCP-1) and renal TBARS content were measured using ELISA or colorimetric assays. Renal expression of oxidative, inflammatory and ER stress marker genes were examined using RT-PCR. Histological analysis was done to assess renal injury.

Results: In Dahl SS rats, EET analog treatment did not affect the SBP compared to vehicle (183±6 vs. 185±12 mmHg). Interestingly, the EET analog treatment in Dahl SS reduced albumin-creatinine ratio (49±17 vs. 12±3) and nephrinuria (11±1 vs. 4±1 mg/d). EET analog treatment also reduced glomerular injury, intra-tubular cast formation and kidney fibrosis in Dahl SS rats compared to vehicle. In Dahl SS rats, EET analog treatment caused a 40% reduction in kidney TBARS content compared to vehicle. Moreover, the EET analog treatment In Dahl SS resulted 2-10 fold attenuation in the renal expression of oxidative (*p47PHOX*), inflammation (*IL-6, TGF*-β), and ER stress (*CHOP, GADD34*) genes.

Conclusions: These data, demonstrate that a novel orally active EET analog provides kidney protection in Dahl SS hypertension by reducing oxidative stress, inflammation and ER stress, and this kidney protection was independent of blood pressure reduction.

Intercalated Cell Nedd4-2 Modulates Blood Pressure and Cl^- Absorption in the Mouse Cortical Collecting Duct Masayoshi Nanami,[1] Vladimir Pech,[1] Diana Agazatian,[1] Yoskaly Lazo Fernandez,[1] John B. Stokes,[2] Baoli Yang,[2] R. Lance Miller,[3] Jill W. Verlander,[4] Susan M. Wall.[1] *[1]Department of Medicine, Emory University School of Medicine, Atlanta, GA; [2]Department of Medicine, University of Iowa School of Medicine, Iowa City, IA; [3]Department of Pediatrics, University of Utah School of Medicine, Salt Lake City, UT; [4]Department of Medicine, University of Florida School of Medicine, Gainesville, FL.*

Background: The expression and subcellular localization of many renal Na^+ and Cl^- transporters, such as ENaC and NCC, are highly regulated by the ubiquitin ligase, NEDD4-2. NEDD4-2 binds to proteins, such as ENaC, which results in ubiquitination, and then internalization and degradation. With global NEDD4-2 gene ablation, salt-sensitive hypertension is observed, in part, from the increased renal NaCl transporter expression. While principal cell NEDD4-2 function has been studied, virtually nothing is known about NEDD4-2 within intercalated cells (ICs). Thus, the purpose of this study was to determine the effect of IC Nedd4-2 ablation on blood pressure and on Cl^- absorption in the cortical collecting duct (CCD).

Methods: IC-specific NEDD4-2 null mice were generated using Cre-loxP technology and fed a high NaCl diet for 1 week (1.4 meq NaCl/day). Mean arterial pressure was measured by telemetry. Transepitherial net Cl^- transport and voltage were measured in CCDs perfused in vitro.

Results: Mean arterial pressure was ~10 mM Hg higher in the IC NEDD4-2 null than in wild type mice ($P < 0.05$). Moreover, CCDs from wild type mice secreted Cl^- (-9.0 ± 3.3 pmol/mm/min, n=8) whereas CCDs from IC-specific NEDD4-2 null mice absorbed Cl^- (+9.3 ± 1.7 pmol/mm/min, n=6, $P < 0.001$). However, there was no significant difference in transepithelial voltage and no difference in either the benzamil-sensitive or the thiazide-sensitive components of Cl^- absorption.

Conclusions: IC Nedd4-2 gene ablation contributes to the pathophysiology of salt-sensitive hypertension, at least in part, by increasing Cl^- absorption by ICs through a mechanism independent of the benzamil- or thiazide-sensitive components of Cl^- absorption.

SA-OR071

Regulation of Renal Sodium Chloride Cotransporter by D_3 Dopamine Receptor Xiaoyan Wang, Laureano D. Asico, Crisanto Escano, Ines Armando, John Edward Jones, Pedro A. Jose. *Medicine, Unversity of Maryland, Baltimore, MD.*

Background: The regulation of salt and water reabsorption by renal D_3R may be involved in the pathogenesis of hypertension since disruption of the D_3R gene (*Drd3*) in mice is associated with a decreased ability to excrete an acute salt load and chronic dietary salt load.

Methods: The role of the D_3 dopamine receptor (D_3R) on renal function and blood pressure was studied by measuring renal protein abundance of sodium chloride cotransporter (NCC), sodium excretion, and salt sensitivity in D_3 knockout (D_3-/-, D_3+/-) mice and wild-type (D_3+/+) littermates.

Results: D_3R was found in proximal and distal convoluted tubules, macula densa, and thick ascending limb and co-stained with NCC in distal convoluted tubule in D_3+/+ mice. NCC abundance (immunoblotting) was increased in D_3-/-(whole kidney homogenates, 596±43 vs 100±23%, n=5/group) and D_3+/-(17k and 200k membrane fractions, 161±8 vs 100±8% and 140±6 vs 100±4% respectively, n=5-6/group) relative to D_3+/+ mice. Its mRNA (real-time PCR) was similar in D_3+/+ and D_3-/- mice. The NCC inhibitor, hydrocholorothiazide (IP, 30 mg/kg, qd), increased sodium excretion (6 hrs) to a greater extent in D_3+/- than D_3+/+ mice and diminished the difference in blood pressures (3 days) between the two strains. High NaCl diet increased blood pressure (telemetry) of D_3-/- mice which was associated with a reduced ability to excrete the sodium load relative to D_3+/+ mice (n=4/group). Membranous NCC abundance was decreased by high NaCl diet in both strains, but remained higher in D_3-/- than D_3+/+ mice (183±19 vs 100±15%, n=4/group). NCC co-immunoprecipitated and co-localized with D_3R in mouse distal convoluted tubule cells and its activity inhibited by a D_3R agonist (PD128907, 1µm, 1hr).

Conclusions: D_3R directly regulates NCC expression and function and increased NCC abundance and function are associated with salt sensitivity and hypertension in D_3 deficient mice.

MYH9 E1841K Mutation Enhances Susceptibility to Angiotensin-II Induced Proteinuria and Podocyte Injury that Are Ameliorated by AT_1 Receptor Inhibition Thu H. Le,[1] Michael Kelly,[2] Sylvia Cechova.[1] *[1]Medicine, University of Virginia, Charlottesville, VA; [2]Medicine, Duke University Medical Center.*

Background: The *MYH9* gene encodes the nonmuscle myosin heavy chain IIA. Recent GWAS suggested that intronic variants of *MYH9* are associated with non-diabetic kidney disease and hypertension-attributed ESRD in African-Americans. However, this has been challenged by the discovery of stronger kidney disease associations of the functional variants of the *APOL1* gene that are in linkage disequilibrium with the *MYH9* risk variants. Rare autosomal-dominant missense mutations in *MYH9* cause macrothrombocytopenia, and are occasionally associated with nephropathy. The E1841K mutation is the most common *MYH9* missense mutation and is associated with nephropathy in some carriers.

Methods: To determine the role of the *MYH9* E1841K mutation in the development of kidney disease, we studied a mouse line carrying the E1841K mutation.

Results: On a mixed genetic background (129S6 and C57BL/6), there was no difference in systolic blood pressure (SBP) nor albumin/creatinine ratio (A/C) between wild-type (WT) and mice with the E1841K mutation (E1841K (+): +/- and/or +/+) at baseline or after high salt diet (HSD,6 % NaCl). We assessed the effects of the E1841K mutation in response to angiotensin II (Ang II) infusion @1000 ng/kg/min for 28 days by mini-osmotic pump. Despite similar increases in SBP (WT 197 ± 4 mm Hg, n=15; E1841K +/- 197 ± 3 mm Hg, n=9; E1841K +/+ 199 ± 5 mm Hg; n=6), E1841K(+) mice displayed severe proteinuria (A/C (ug/mg): WT 806±94, E1841K +/- 1341±293, E1841K +/+ 2209± 366, p=0.001, ANOVA). WT mice displayed mild mesangial expansion and intact podocytes, whereas E1841K +/+ mice displayed focal segmental glomerulosclerosis and severe podocyte foot process effacement/fusion. Treatment of E1841K (+) mice with candesartan, an angiotensin type 1 receptor (AT_1R) inhibitor, significantly prevented Ang II-induced hypertension and proteinuria (E1841K (+) (+/- (n=4) and +/+ (n=2)): SBP = 138 ± 4 mm Hg, A/C ratio = 111 ± 47 ug/mg; $p \leq 0.0001$ vs. untreated), and ameliorated podocyte foot process effacement in E1841K +/+ mice.

Conclusions: The *MYH9* E1841K mutation predisposes to AT_1R mediated podocyte injury.

Uncovering the Surprising and Complex Roles of Collecting Duct Adenylyl Cyclases Donald E. Kohan,[1] Vladislav V. Bugay,[2] Elena V. Mironova,[2] James D. Stockand,[2] Nirupama Ramkumar,[1] Karl P. Roos.[1] *[1]Division of Nephrology, University of Utah, Salt Lake City, UT; [2]Department of Physiology, University of Texas San Antonio, San Antonio, TX.*

Background: Hormone-stimulated cAMP is a fundamental mechanism for regulating collecting duct (CD) biology. Since the CD expresses several adenylyl cyclase (AC) isoforms, we initiated studies to delineate AC isoform-specific actions.

Methods: Mice were generated with CD-specific knockout (KO) of AC3 or AC6 using loxP-flanked *Adcy3* or *Adcy6* genes and a mouse transgenic for the aquaporin-2 promoter diving Cre recombinase expression.

Results: CD-specific KO of AC6 causes a mild urinary concentrating defect, characterized by reduced urine osmolarity (Uosm) and decreased AVP-stimulated cAMP accumulation in acutely isolated IMCD. In contrast, CD AC3 KO surprisingly caused increased Uosm and enhanced AVP-induced cAMP levels in acutely isolated IMCD. CD AC6 KO did not detectably alter BP (as assessed by telemetry) or urinary Na excretion (UNaV) regardless of Na intake. However, plasma renin concentration was increased in these animals, suggesting a compensatory response. CD AC6 KO mice had decreased renal mRNA content of all three ENaC isoforms as well as reduced ENaC-alpha and -gamma protein expression. Patch clamp analysis of split-open cortical CD revealed that CD AC6 KO mice had abolished AVP-stimulated ENaC Po and N. In contrast, CD AC3 KO mice had a 30-35% decrease in UNaV as compared to control mice that was evident on a low, normal or high Na diet.

Conclusions: In summary, these studies have uncovered previously unsuspected and potentially opposing roles for AC3 and AC6 in the CD. AC6 mediates, at least in part, AVP stimulation of CD water reabsorption and may fully account for AVP stimulation of ENaC activity. In contrast, AC3 activation may actually oppose the effects of AC6, exerting a net inhibitory effect on CD Na and water transport. These findings point to previously unsuspected and complex roles for individual AC isoforms in the CD.

Phosphorylation in Ligand Binding Domain of Mineralocorticoid Receptor Regulates Ligand Binding and Activation of Electrolyte Flux Shigeru Shibata,[1] Jesse Rinehart,[1] Gilbert W. Moeckel,[2] Richard P. Lifton.[1] *[1]Department of Genetics, Yale University, New Haven, CT; [2]Department of Pathology, Yale University.*

Background: Mineralocorticoid receptor (MR) is a ligand-activated nuclear receptor that regulates fluid and electrolyte homeostasis. Aldosterone is produced in two distinct physiological states, hypovolemia and hyperkalemia; the mechanisms by which the kidney responds differently to these states are poorly understood.

Methods: Phosphorylation sites in purified MR were identified by TiO_2 - affinity coupled to tandem mass spectrometry. The consequence of specific phosphorylation sites was evaluated by assay of transcriptional activation of luciferase reporters in mammalian cells and in vitro binding assays. The in vivo significance of phosphorylation was analyzed using antibodies specific for phospho-sites in MR and assaying the effect of MR signaling on target proteins by Western blotting.

Results: We identified 16 phosphorylation sites in MR in COS-7 cells. One phosphorylation site at serine 843 in the ligand binding domain (S843-P), prevented aldosterone and cortisol binding to MR, inhibiting transcriptional activation. S843-P occurs exclusively in α and β intercalated cells in vivo in mice and humans. S843-P was reduced by NaCl restriction or in mice lacking NCC (*Slc12a3*$^{-/-}$) ($P<0.01$), whereas it was increased by a high-K^+ diet ($P<0.002$). NaCl restriction did not alter S843-P in mice lacking AT1a receptor. Angiotensin II (AII) infusion on high salt diet reduced S843-P in wild-type mice, confirming the role of AII. Intercalated cell proteins pendrin and B1 H^+ ATPase were increased in *Slc12a3*$^{-/-}$ and this was reversed by spironolactone, identifying downstream MR-dependent effectors. The intercalaeted cell sodium-dependent Cl/HCO3 exchanger was also upregulated by AII.

Conclusions: Our data provide the first example in which ligand binding to a nuclear receptor is regulated by phosphorylation. This modification contributes to the distinct effects of MR in hypovolemia and hyperkalemia by promoting the intercalated electroneutral salt reabsorption pathway in volume depletion, maximizing Na-Cl reabsorption and minimizing K^+ loss.

SA-OR075

sgk1 Regulation by miR-466g Paru P. Kathpalia,[1] Sheela V. Thomas,[1] Emily J. Noonan,[1] Alan C. Pao.[1,2] *[1]Department of Medicine, Stanford University School of Medicine, Palo Alto, CA; [2]Veterans Affairs Palo Alto Health Care System, Palo Alto, CA.*

Background: In the cortical collecting duct (CCD), aldosterone stimulates the expression of genes that increase activity of the epithelial sodium channel (ENaC); in the early phase of aldosterone induction, one such gene is serum and glucocorticoid regulated kinase 1 (sgk1). MicroRNAs (miRNAs) are a class of small non-coding RNAs that bind target mRNA transcripts and silence gene expression. We hypothesized that aldosterone regulates the expression of miRNAs in the early phase of induction to control expression of target genes that stimulate ENaC activity.

Methods: We treated $mpkCCD_{c14}$ cells with aldosterone or vehicle for 1 hour and used a miRNA microarray to analyze differential miRNA expression. We identified 4 miRNAs to be downregulated, including miR-466g. We fed C57/Bl6 mice either high (8%) or low (0.01%) sodium chloride (NaCl) diet for 1 week to suppress or stimulate endogenous aldosterone and found that renal expression of miR-466g was decreased in mice fed a low NaCl diet. Next, we identified a putative miR-466g binding site in the 3'UTR of sgk1. To test functional interaction between miR-466g and sgk1, we constructed an sgk1 3'-UTR luciferase reporter and found that co-transfected miR-466g suppressed luciferase activity in HEK293 cells in a dose dependent manner. Deletion or introduction of point mutations that disrupt the miR-466g binding site in the sgk1 3'-UTR reporter resulted in attenuation of miR-466g directed suppression of luciferase activity. To determine whether miR-466g regulates sgk1 and/or ENaC activity, we heterologously expressed miR-466g in $mpkCCD_{c14}$ cells and found that both sgk1 mRNA and equivalent current were decreased compared to cells expressing scrambled miRNAs.

Results: See above.

Conclusions: Our findings implicate miR-466g as an aldosterone responsive miRNA that regulates sgk1 and equivalent current in CCD cells. We propose that, at baseline, miR-466g suppresses sgk1 expression and ENaC activity in CCD cells; with aldosterone stimulation, expression of miR-466g is decreased, relieving inhibition of sgk1 expression and leading to increased ENaC activity.

SA-OR076

Pore-Forming Sites within the Epithelial Sodium Channel γ Subunit Contribute to Channel Gating and Amiloride Block Shujie Shi,[1] Thomas R. Kleyman.[1,2] *[1]Medicine, University of Pittsburgh, Pittsburgh, PA; [2]Cell Biology and Physiology, University of Pittsburgh, Pittsburgh, PA.*

Background: The epithelial sodium channel (ENaC) is a key regulator of extracellular fluid volume and blood pressure, and channel's activity is tightly regulated a variety of endogenous and external factors. Functional channels are comprised of three homologous subunits, namely α, β, and γ. Previous studies suggested that the transmembrane (TM2) pore-forming regions have critical roles in channel gating, ion selectivity and amiloride binding. Channels composed solely of α and β subunits (αβ channels) exhibit a very high open probability (Po) and a reduced efficacy of amiloride block, in contrast to channels that include all three subunits (αβγ channels). These observations suggest that site(s) within the γ subunit dampen channel activity and enhance amiloride efficacy.

Methods: In order to identify these sites, we generated a chimeric γ subunit construct (γ-βTM2) where the region immediately preceding (β12 and wrist) and encompassing TM2 (γI522-γF564) was replaced with the corresponding region of the β subunit (βI505-βI546).

Results: We observed that αβγ-βTM2 channels displayed characteristics reminiscent of αβ channels, a reduced efficacy of amiloride block (IC_{50} of ~ 7 μM) as well as a loss of Na^+ self-inhibition (reflecting a high Po). Additional mutations identified a key residue (γE531) in γTM2 that dampened channel activity. Na^+ self-inhibition response was largely reduced in αβγE531V channels, whereas the high Po phenotype of γ-βTM2 could be partially rescued by the swapping back the γ residues in the γ-βTM2 construct (γ-βTM2-VW531/2EM). Analyses of a panel of γ subunit mutants suggested that multiple sites within γTM2 were required to confer the high amiloride efficacy of αβγ channels.

Conclusions: Our data suggest that the pore-lining residues of the γ subunit are important for maintaining proper channel gating and its interaction with amiloride.

Acute Renal Homeostatic Effect of a Single Potassium Load Involves Rapid Dephosphorylation of the NCC Transporter Mads V. Sorensen,[1] Solveig Grossmann,[1] Marian Andreas Roesinger,[1] Dominique Loffing-Cueni,[1] Gery Barmettler,[2] Urs Ziegler,[2] Alex Odermatt,[3] Johannes Loffing.[1] *[1]Institute of Anatomy, University of Zürich, Zürich, Switzerland; [2]Center for Microscopy and Image Analysis, University of Zürich, Zürich, Switzerland; [3]Department of Pharmaceutical Sciences, University of Basel, Basel, Switzerland.*

Background: A dietary K^+ load induces a rapid kaliuretic and natriuretic response, which may occur even before plasma K^+ and aldosterone (aldo) levels increase.

Methods: To get insights into underlying molecular mechanisms, we analyzed in mice the time course (15', 30', 2h, and 6h) of the effect of a gastric K^+ load on plasma ion concentrations, aldo levels, urinary ion excretion, and expression and/or phosphorylation of renal ion transport proteins.

Results: Following a gastric gavage of 2% KCl, plasma K^+ concentrations rose rapidly (at 15'), followed by a significant rise of plasma aldo (at 30'). Enhanced urinary K^+ and Na^+ excretion was detectable as early as spot urines could be collected (~30'). The functional changes were accompanied by a rapid and sustained dephosphorylation of the NaCl cotransporter (NCC) (15'-6h) and a later up-regulation of proteolytic activated epithelial sodium channels (ENaC) (6h). The rapid effect on NCC and the late effects on ENaC were independent from the co-administered anion (same effect with $KHCO_3$; no effect with NaCl). In contrast to the proteolytic ENaC regulation, NCC dephosphorylation was independent of plasma aldo as indicated by experiments in aldo-deficient mice. The observed urinary Na^+ loss was likely related to NCC, as it was not seen in NCC-deficient mice.

Conclusions: Thus, rapid aldo-independent down-regulation of NCC is a part of the acute homeostatic adaptation of the kidney to an increased K^+ intake. The increased Na^+ delivery to the ENaC-positive renal collecting system (CS) likely improves the electrochemical gradient for K^+ secretion in the CS.

SPAK Is Critical for Sodium Reabsorption in Thick Ascending Limb Chih-Jen Cheng, Joonho Yoon, Michel G. Baum, Chou-Long Huang. *Medicine, University of Texas Southwestern Medical Center, Dallas, TX.*

Background: SPAK and OSR1 are Ste20-related protein kinases that activate SLC12 transporters, NCC and NKCCs. In vitro studies have provided ample support for activation of NCC and NKCCs by SPAK and OSR1. While regulation of NCC by SPAK in DCT is well accepted, the role of SPAK in regulating NKCC2 in TAL is controversial. Also, it is recently reported that kinase-deficient kidney-specific (KS-) SPAK is the predominant isoform in renal medulla and functions as an antagonist of full-length (FL-) SPAK. Here, we examined the role of SPAK in TAL using in vitro microperfusion .

Methods: mTAL and cTAL dissected from 4-month old SPAK-KO and age-and gender-matched WT mice were microperfused in vitro under no transepithelial osmotic gradients. $[Na^+]$ in perfusate and collected fluids were analyzed using ion selective electrodes. Transepithelial potential difference (PD_{TE}) was measured. mRNA levels of FL- and KS-SPAK in mTAL and cTAL dissected from 8-week old WT mice were determined using real-time PCR (qRT-PCR).

Results: Compared to WT, Na^+ reabsorption ($pmol.min^{-1}.mm^{-1}$) in both mTAL and cTAL of SPAK- KO mice were much reduced (mTAL: 176 ± 15 & 22 ± 2, WT vs KO, $p < 0.01$; cTAL: 162 ± 18 & 48 ± 5, WT vs KO, $p < 0.01$). Lumen-positive PD_{TE} (+mV) was similarly decreased in KO mice (mTAL: 9.5 ± 1.1 & 4.9 ± 0.8, WT vs KO, $p < 0.05$; cTAL: 6.5 ± 1.2 & 2.6 ± 1.0, WT vs KO, $p < 0.05$). Vasopressin (DDAVP, 100 pM in bath) stimulated Na^+ reabsorption in mTAL and cTAL of WT as well as KO mice (after 30-min incubation, mTAL: 297 ± 21 & 88 ± 7 for WT & KO, respectively; cTAL: 296 ± 19 & 137 ± 16 for WT & KO, respectively; $p < 0.05$ vs before DDAVP for each). qRT-PCR showed that FL-SPAK mRNA was most abundant in mTAL, followed by cTAL and DCT. mRNA for KS-SPAK in TAL and DCT were higher than for FL-SPAK.

Conclusions: SPAK is abundantly expressed in TAL and regulates NKCC2-mediated Na^+ reabsorption. While mRNA of KS- SPAK is more abundant than FL-SPAK, the net effect of FL-SPAK + KS-SPAK on Na^+ reabsorption in TAL is stimulatory. SPAK is not essential for vasopressin stimulation of NKCC2-mediated Na^+ reabsorption.

SPAK Deficiency Corrects WNK4 Mutation-Causing Pseudohypoaldosteronism II Pei-yi Chu,[1] Sung-Sen Yang,[1,2] Shinichi Uchida,[3] Sei Sasaki,[3] Shih-Hua P. Lin.[1,2] *[1]National Defense Medical Center, Graduate Institute of Medical Sciences, Taipei, Taiwan; [2]Department of Medicine, Tri-Service General Hospital, Division of Nephrology, Taipei, Taiwan; [3]Graduate School of Medicine, Tokyo Medical and Dental University, Department of Nephrology, Tokyo, Japan.*

Background: An enhanced Osr1 (Oxidative stress-responsive kinase-1)/Spak [STE20 (sterile 20)/SPS1-related proline/alanine-rich kinase]-Ncc (Na^+-Cl^- cotransproter) phosphorylation signaling plays a major role in Wnk [With-No-Lysine (K)] kinase 4 D561A knock-in (KI) mice as a model of pseudohypoaldosteronism type II (PHA II) with salt-sensitive hypertension and hyperkalemia. The aim of this study was to investigate the respective role of OSR1 and SPAKin the pathogenesis of PHA II.

Methods: Wnk4 D561A KI mice were crossed with kidney tubule-specific (KSP-) Osr1 knockout (KO) and Spak KO mice. Blood pressure, blood and urine electrolytes and biochemistries, and relevant protein expression in the kidneys were examined.

Results: Compared with wild-type (WT), Wnk4 KI, Spak KO, and KSP-Osr1 KO mice recapitulated the phenotype of PHA II, Bartter-like syndrome (BS) and Gitelman syndrome (GS), respectively. Wnk4$^{D561A/+}$KSP->Osr1$^{-/-}$ still exhibited PHA II phenotype but Wnk4$^{D561A/+}$Spak$^{-/-}$mice became normotensive without serum and urine electrolytes abnormalities. The abundance of p-Spak and p-Ncc was significantly increased in Wnk4$^{D561A/+}$KSP-Osr1$^{-/-}$mice but p-Ncc expression was relatively normal despite the increased OSR1 expression in Wnk4$^{D561A/+}$Spak$^{-/-}$ mice. The immunofluorescence results of Ncc, p-Ncc, Nkcc2, and p-Nkcc2 expression in the kidney tissue of WT, Wnk4$^{D561A/+}$KSP-Osr1$^{-/-}$,and Wnk4$^{D561A/+}$Spak$^{-/-}$ mice were consistent with those observed by immunoblotting. Furthermore, Wnk4$^{D561A/+}$KSP-Osr1$^{-/-}$mice had anexaggerated salt excretionbut Wnk4$^{D561A/+}$Spak$^{-/-}$ mice exhibited normal in response to thiazide.

Conclusions: An activation of SPAK-NCC might play a more dominant role than OSR1-NCC in the pathogenesis of PAH II. Inhibition of SPAK may be a promising target for the disorders with salt-sensitive hypertension related to WNK4 activation.

An Eye-Catching View of the Glomerulus: Non-Invasive Imaging of Glomeruli Transplanted into the Anterior Chamber of the Mouse Eye

Andreas D. Kistler,[1] Dontscho Kerjaschki,[2] Susan E. Quaggin,[3] Per-Olof Berggren,[4] Jochen Reiser,[1] Alessia Fornoni.[1] *[1]University of Miami; [2]Medical University of Vienna, Austria; [3]The Samuel Lunefeld Research Institute, Toronto, Canada; [4]Karolinska Institutet, Stockholm, Sweden.*

Background: Advanced in vivo imaging technologies allow to study complex physiological and pathological processes. Here, we utilized the anterior chamber of the mouse eye as a natural body window to image transplanted glomeruli engrafted on top of the highly vascularized iris.

Methods: Mouse glomeruli were isolated by sequential sieving, handpicked and microinjected into the anterior chamber of recipient mice. For allogeneic transplantation, immune deficient recipient mice were used.

Results: Within 3 weeks after transplantation 10% of transplanted glomeruli gained access to the iris vasculature, and became perfused as demonstrated by intravenous injection of fluorescently labeled dextrans. Laser-scanning confocal microscopy allowed repetitive visualization of transplanted glomeruli. Survival of podocytes could be demonstrated for more than 5 months in transplanted glomeruli isolated from transgenic mice expressing CFP under control of the nephrin promoter. Use of recipient mice expressing GFP under an endothelial-specific promoter revealed the contribution of recipient endothelial cells to the glomerular filtration barrier (GFB). While 10kD dextran was filtered across the GFB of transplanted glomeruli, 70kD dextran did only leak through the GFB after induction of glomerular disease. Filtration of 10kD dextran revealed the presence of a presumed subpodocyte space between CFP-expressing podocytes and GFP-labeled endothelium that restricted further passage of the dye-labeled dextran. Electron microscopical analysis confirmed preservation of interdigitating podocyte foot processes in transplanted glomeruli.

Conclusions: We established a novel technique that allows repetitive non-invasive *in vivo* imaging to study glomerular physiology in the absence of parietal epithelial cells. In addition to convenient high resolution visualization, this novel technique allows for easy delivery of pharmacological compounds as well as local injection of intravital dyes.

Evidence for the Presence of Mesangial Cells within the Zebrafish Glomerulus

Arindam Majumdar,[1] Lwaki Ebarasi,[2] Konstantin Gaengel,[2] Christer Betsholtz.[2] *[1]Immunology, Genetics, and Pathology, Uppsala University, Uppsala, Sweden; [2]Vascular Biology/MBB, Karolinska Institute, Stockholm, Sweden.*

Background: Pericytes are specialized vascular smooth muscle cells that are associated with microvessels and, through cell-cell interactions with neighboring endothelia, perform important functions in blood vessel formation, stabilization and permeability. In the kidney glomerulus, the mesangial pericytes are responsible for the organization of endothelial capillary loops and the regulation of glomerular filtration rate. While the zebrafish has served as an excellent genetic and bio-imaging system for studying hematopoiesis, vasculogenesis, and sprouting angiogenesis, the presence and function of a pericyte cell population is unknown.

Results: We report a descriptive, ultrastructural, and functional study of pericytes in zebrafish with a special focus on glomerular pericytes, the mesangial cells. Using pdgfrb mRNA and protein expression as molecular markers of pericytes, we have documented for the first time the presence of a vascular associated pericyte population within the zebrafish. We identify vascular associated pdgfrb positive cells within the eye, brain, and kidney glomerulus. Confocal microscopy reveals how individual pericytes associate with micro-vessels and capillaries. By electron microscopy, we identify the glomerular mesangial cells and pericytes associated with brain microcapillaries.

Functional inactivation of pdgfrb using antisense morpholinos results in loss of capillary loop structure phenocopying those results seen in Pdgf-b -/- and Pdgfrb -/- knock out mice. The phenotypes are reproducible with additional morpholinos and can be rescued by co-injection of human Pdgfrb mRNA. We have analyzed the glomerular structure by electron microscopy. In addition, brain vasculature in pdgfrb morphants sprouts normally but displays increased leakiness as evidenced by dextran dye filtrations studies suggesting a role for pericytes in regulating permeability.

Conclusions: We conclude that pericytes exist in zebrafish and that they have a conserved function within the vasculature and kidney glomerulus. The results advance the zebrafish as a system for studying mesangial cell biology in vivo.

Cell Fate Tracking with Serial Multiphoton Imaging of a New Podocyte Confetti Mouse In Vivo Reveals Podocyte Proliferation and Migration

Matthias Hackl,[1,2] Lisa Lam,[1] James L. Burford,[1] Janos Peti-Peterdi.[1] *[1]Physiology & Biophysics, University of Southern California, Los Angeles, CA; [2]Renal Division, Department of Medicine and Centre for Molecular Medicine, University of Cologne, Cologne, Germany.*

Background: Podocytes are critical in the maintenance of a healthy glomerular filter and in the development of glomerular disease. However, their ability to proliferate, migrate and regenerate is highly debated. We aimed to develop a direct visual approach to track single podocytes over time in vivo.

Methods: Podocyte confetti mice featuring cell-specific expression of 4 different fluorescent proteins (membrane-bound CFP, nuclear GFP, cytosolic YFP and RFP) were developed using podocin-Cre and floxed confetti reporter mice. C57BL6 mice (3 to 5 weeks of age) were subjected to unilateral ureteral ligation (UUO, a model of tubulointerstitial fibrosis) since podocytes seem to be protected from injury in this condition. Between 2-4 weeks after UUO mice were anaesthetized, the left kidney was exteriorized and the kidney was imaged *in vivo* on a multiphoton microscope. Multiple surviving surgeries were performed every 24 hours to exteriorize the same region of the left kidney and to image the same glomeruli.

Results: In heterozygous podocyte confetti mice only a few podocytes per glomerulus were labeled in one of the 4 different colors. This allowed an unobstructed view of the podocyte primary, secondary and foot processes. The number of FP expressing cells was increasing continuously over time migrating from the visceral to the parietal layer of the Bowman's capsule. These multi-cellular podocyte projections developed in the same color suggesting that the newly formed cells were daughter cells of the same parent podocyte. Podocyte proliferation was confirmed using BrdU labeling. The serial *in vivo* imaging revealed a dynamic regulation of these projections.

Conclusions: In summary, the robust proliferation/migration of podocytes after UUO suggests that under specific conditions podocytes are able to proliferate and migrate to other glomerular regions. This function may be consistent with glomerulus and nephron regeneration, particularly in disease conditions.

Tracing Podocyte Injury in Confetti Mice with a Stochastic Multicolor Cre-Reporter

Jianling Tao,[1] Christina Polumbo,[2] Leslie Gunther Cummins,[2] Katalin Susztak.[1] *[1]Renal Electrolyte and Hypertension Division, Department of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Analytical Imaging Facility, Albert Einstein College of Medicine, Yeshiva University, Bronx, NY.*

Background: Podocyte injury is a critical step in the pathogenesis of proteinuria. However, we have limited tools to examine podocyte injury in vivo, mostly still limited to fixed tissue and electron microscopy. The purpose of this study is to utilize a stochastic multicolor Cre-reporter, encoding four fluorescent proteins, to label and image individual podocytes and foot processes.

Methods: A new double-transgenic mouse was developed (NPHS2^{Cre} /R26R-Confetti$^{TG/TG}$ or NPHS2^{Cre} /R26R-Confetti$^{TG/WT}$) in C57/B6 mice. Adriamycin nephropathy was induced by a one-time injection of (25mg/kg) adriamycin. Seven days later, animals were sacrificed and kidneys were imaged without any fixation using a Leica SP5 AOBS Laser Scanning Confocal microscope.

Results: In the normal glomerulus, podocytes were randomly labeled as red (cytoplasmic), yellow (cytoplasmic), blue (cell membrane) and green (nucleus). Individual podocytes and their foot processes can be easily identified. In control saline injected mice, there was no change in the urinuria and the foot process interaction between neighboring podocytes can be clearly demonstrated and images were comparable to SEM images. In mice injected by ADR, urine albumin increased 500-fold and remarkable protein casts in the proximal tubule were identified. The foot processes (secondary and tertiary) were significantly widened, consistent with the foot process effacement also observed on SEM. There was a significant decrease in labeled podocyte number in this model also. Podocyte cell body measurements based on confocal Z-stack series, showed an increase in podocyte size from 727±344μm^3 in normal saline injected mice to 1108±336μm^3 in ADR injected mice, indicating that cell hypertrophy is early feature of podocyte injury.

Conclusions: By the virtue of confetti, a multicolor Cre-reporter, podocyte/injury can be viewed in real time by confocal microscopy, at almost similar resolution as with the SEM. It will serve as a useful and practical method in podocyte research.

Live In Vivo Imaging of Zebrafish Podocytes: An Approach to Understanding Podocyte Biology and Disease Ritu Tomar, Aleksandr Vasilyev, Iain A. Drummond. *Nephrology Division, Massachusetts General Hospital, Charlestown, MA.*

Background: Glomerular disease is caused by podocyte foot process effacement and disruption of filtration slits, resulting in proteinuria and nephrotic syndrome. Using electron microscopy to visualize podocyte foot process effacement in pathological conditions is labor-intensive and does not provide information on cellular dynamics that occurs in vivo. The transparency of zebrafish larva offers the possibility to study organ development and function by *in vivo* imaging using transgenic zebrafish expressing fluorescent reporters. The zebrafish pronephric glomerulus consists of cell types common to all vertebrates, making it a relevant model to understand podocyte biology and glomerular diseases.

Methods: We have employed a bipartite Gal4-UAS technology to image podocytes in living zebrafish larve. We generated a zebrafish podocin:Gal4 transgenic line and crossed it to UAS:fluorescent protein lines to image live podocytes by confocal microscopy.

Results: Live podocytes in three day old larvae imaged at high resolution clearly showed dynamic primary processes enveloping glomerular blood vessels. Time-lapse imaging of podocytes under normal and nephrotoxic conditions will shed light on foot process development and dynamics after injury.

Conclusions: The versatility of the Gal4-UAS system will enable us to express constitutively active and dominant-negative forms of signaling proteins that regulate formation of filtration apparatus. This approach will be useful to model glomerular diseases in zebrafish and enable generation of a high-throughput screening platform for therapies for nephrotic syndrome.

Podocyte Calcium Waves Visualized In Vivo in Podocin: GCaMP3 Mice Using Multiphoton Microscopy James L. Burford, Lisa Lam, Matthias Hackl, Janos Peti-Peterdi. *Dept. of Physiology & Biophysics, University of Southern California.*

Background: Mutations in calcium channels (including TRPC6) highlight the role of podocyte cytosolic calcium [$(Ca^{2+})_i$] in the regulation of glomerular filtration rate, development of albuminuria and glomerulosclerosis. However, due to technical constraints, the physiological dynamics and role of podocyte $(Ca^{2+})_i$ is incompletely understood. We aimed to directly visualize podocyte $(Ca^{2+})_i$ in the intact kidney and study its temporal correlations with changes in cell shape and glomerular capillary diameter.

Methods: Podocin:GCaMP3 mice featuring cell-specific expression of the fluorescent calcium indicator protein GCaMP3 were developed using podocin-Cre and floxed GCaMP3 mice. Mice were anaesthetized, the left kidney was exteriorized and the kidney was imaged *in vivo* on a multiphoton microscope. Alexa594-albumin was injected to label the plasma.

Results: Podocytes showed two-component regular $(Ca^{2+})_i$ oscillations with a faster (0.12 Hz, cycle time about 10 seconds) and a slower (0.023 Hz, cycle time about 45 seconds) frequencies, suggesting that podocyte $(Ca^{2+})_i$ is controlled by the afferent arteriole myogenic and tubuloglomerular feedback (TGF) mechanisms. Laser-induced focal podocyte injury triggered a robust podocyte $(Ca^{2+})_i$ wave propagating to the entire glomerulus with a speed of 5μm/s. Increased podocyte $(Ca^{2+})_i$ correlated with cell flattening and reductions in glomerular capillary diameter. In addition, Munich-Wistar-Fromter rats, a model of FSGS were anesthetized and surgically prepared for renal micropuncture and microperfusion delivery of the calcium fluorophore Rhod-2AM (10 μM) directly into the Bowman's space for 15 min. High podocyte $(Ca^{2+})_i$ was observed in focal adhesions and heterogeneously throughout the glomerulus. Flufenamic acid (FFA, 10mg/kg iv) increased while the ACE inhibitor ramipril (5mg/kg iv) decreased $(Ca^{2+})_i$ suggesting that TRPC6 and angiotensin II regulate podocyte $(Ca^{2+})_i$.

Conclusions: This study visually demonstrated in vivo for the first time the high functional integration of the intraglomerular podocyte network (syntitium) and the importance of podocyte $(Ca^{2+})_i$ in the control of glomerular functions in health and disease.

Podocyte-Specific NFAT Activation in Mice Results in Foot Process Effacement and Profound Proteinuria, but Does Not Cause Progressive Glomerular Injury Alexis J. Sloan,[1] Britta Sylvia Walter,[2] Ansel P. Amaral,[1] Saurav Singh,[1] Alessia Fornoni,[2] Christian Faul.[2] *[1]Department of Cell Biology & Anatomy, University of Miami Miller School of Medicine, Miami, FL; [2]Department of Medicine, Division of Nephrology & Hypertension, University of Miami Miller School of Medicine, Miami, FL.*

Background: Gain-of-function mutations in the TRCP6 calcium channel can cause alterations in proper podocyte morphology and glomerular filter function leading to proteinuria. The protein phosphatase calcineurin is activated when cytoplasmic calcium levels rise, and our group has shown that constitutive activation of calcineurin in podocytes *in vivo* leads to proteinuria. The role of calcineurin's canonical downstream target, the transcription factor nuclear factor of activated T-cells (NFAT), in the kidney and podocytes in particular has not been well characterized.

Methods: We have generated a transgenic mouse model where NFAT is constitutively activated in podocytes (NFATc1nuc) in the presence of doxycycline (Dox).

Results: These mice develop profound proteinuria within 4 days of Dox exposure and display partial podocyte foot process (FP) effacement. Prolonged NFATc1nuc expression for up to 12 months leads to an increase in FP effacement, but does not result in histological changes in the glomerulus or tubular system and does not cause renal failure. The level of FP effacement accompanied by chronic proteinuria is reminiscent of the pathology of Minimal Change Disease and challenges the concept that proteinuria alone is sufficient to induce tubular damage and to drive progressive kidney disease. Our preliminary data show that mice expressing NFATc1nuc for 2 months are unable to revert to normal podocyte morphology and glomerular filter function once Dox is removed and normal chow is re-introduced, indicating the induction of epigenetic changes that are non-reversible, but also non-progressive.

Conclusions: Future studies aim to identify direct NFAT target genes in podocytes that are involved in the development of FP effacement and epigenetic changes that occur as a result of persistent NFAT activation and force the podocyte to remain in an effaced state.

The Pharmacokinetics and Safety of a Single Dose of Sotatercept (ACE-011), in Subjects on Hemodialysis and the Effects of Its Murine Analog (RAP-011) on Anemia and in Preventing Bone Loss in C57BL/6 Mice with 5/6 Nephrectomy Thomas D. Wooldridge,[1] Mark Kaplan,[2] Harry W. Alcorn,[2] Aaron W. Mulivor,[3] William T. Smith.[4] *[1]Nephrology & Hypertension Associates, Tupelo, MS; [2]DaVita Clinical Research, Minneapolis, MN; [3]Acceleron Pharma, Cambridge, MA; [4]Celgene Corporation, Summit, NJ.*

Background: Sotatercept is a recombinant protein composed of the extracellular domain of ActRIIA linked to the Fc domain of human IgG1 that acts as a soluble TGF-β superfamily ligand trap, primarily for activins, BMPs, and GDF-11 but not for TGF-β. Animal models using ACE-011, and its murine analog (RAP-011), showed dual anabolic-antiresorptive effects on bone and increased RBC parameters. Phase 1 studies in healthy postmenopausal women dose-dependently increased hemoglobin, biomarkers of osteoblast activity, and bone mineral density (BMD). Some subjects also had blood pressure increases.

Methods: A double-blind, placebo-controlled, single-dose study (ACE-011-REN-001) evaluating pharmacokinetics (PK) and safety enrolled hemodialysis subjects with proven responsiveness to epogen. Subjects were washed out of epogen to hemoglobin <10 g/dL and randomized to a single dose of ACE-011 0.1 mg/kg or placebo. Studies in female C57BL/6 mice undergoing 5/6 nephrectomy surgery or corresponding sham surgery were also conducted. Mice received vehicle control or RAP-011 continuously starting at 4 weeks postsurgery in a preventive model and 8 weeks postsurgery in a treatment model. Mice were DEXA scanned and cheek bled monthly, and bones and blood were analyzed at study end.

Results: Seven hemodialysis subjects enrolled (ACE-011=6, placebo=1). PK parameters were similar to phase 1 results (slow absorption/elimination) but with higher variability. ACE-011 was not dialyzed. ACE-011 was safe and well tolerated and did not induce blood pressure response. RAP-011 prevented anemia and bone loss in both mouse models and significantly increased cortical bone thickness (femur), trabecular bone volume and thickness, BMD, and RBC parameters.

Conclusions: ACE-011 was safe and well tolerated in hemodialysis subjects. RAP-011 prevented anemia and bone loss in mice.

Potential of Therapeutic Drug Monitoring of Ertapenem (E) and Daptomycin (D) Using Effluent in Continuous Renal Replacement Therapy (CRRT) Bruce A. Mueller,[1] Rachel F. Eyler,[2] A. Mary Vilay,[3] Michael Heung,[1] Kevin M. Sowinski.[4] *[1]Univ. Michigan, Ann Arbor, MI; [2]College of Pharmacy, Univ. Connecticut, Storrs, CT; [3]College of Pharmacy, Univ. New Mexico, Albuquerque, NM; [4]College of Pharmacy, Purdue Univ, Indianapolis, IN.*

Background: Use of spent effluent in therapeutic drug monitoring of piperacillin/tazobactam has recently been proposed as an alternative to plasma concentration monitoring in an effort to minimize blood sampling. Measurement of effluent simplifies the analytical procedures required for quantitating drug concentrations. The purpose of this study was to evaluate the ability of effluent concentrations of E & D in predicting free drug concentrations of these agents.

Methods: Sixteen subjects receiving CRRT were enrolled in this study, 8 received D and 8 received E. E study subjects received a single 1000 mg dose and serial blood and effluent samples were collected over the next 24 hours. D study subjects received a single 8 mg/Kg dose and serial blood and effluent samples were collected over the next 48 hours. D & E total plasma, free plasma and effluent concs were determined using HPLC. The CV% for all assays was <10%. Predictive performance analysis using the method of Altman and Bland was utilized to assess the relationship between the free and effluent concs.

Results: A total of 55 (E arm) and 14(D arm) free & effluent concentrations were collected. The free and effluent concentrations were collected simultaneously. The mean ± SD effluent flow rates were 38±10 ml/Kg/hr in the E arm & 33±5 ml/Kg/hr in the D arm.

Comparison of Ertapenem/Daptomycin Effluent & Free Concentrations

	Concentration Range (mg/dL)		Mean difference ± SD of the difference (SDd) (mg/dL)	Limits of Agreement (mg/dL)
	Free	Effluent	Free-Effluent	Free-Effluent
Ertapenem (n=55 pairs)	0.68-58.5	0.66-46.4	-1.23±3.38	-7.99 to 5.53
Daptomycin (n=14 pairs)	0.72-21.85	0.40-12.64	-3.31±8.19	-19.67 to 13.06

Conclusions: Effluent concentrations were lower than free plasma concentrations for both D & E. Further, substantial variability was observed for both D & E. These data suggest that neither effluent concentrations of D nor E are useful for therapeutic drug monitoring.

Gradual versus Rapid Vitamin D Repletion in Stage 3 & 4 CKD Joel Z. Melnick,[1] Martin P. Petkovich,[1,2] Jay A. White,[1] Charles W. Bishop,[1] Eric Messner,[1] Samir P. Tabash.[1] *[1]Cytochroma Inc., Markham, ON, Canada; [2]Department of Biomedical and Molecular Sciences, Queen's University, Kingston, ON, Canada.*

Background: CYP24, the vitamin D-specific catabolic enzyme, is upregulated in CKD patients and contributes to vitamin D insufficiency. Rapidly administered vitamin D therapies such as intravenous (IV) or Immediate-release (IR) forms, further upregulate CYP24 and, thereby, limit the effectiveness of such repletion strategies. CTAP101 Capsules is a modified-release (MR) formulation of calcifediol ($25D_3$) that raises serum $25D_3$ levels gradually and which in animal models has been shown to minimize CYP24 induction. The present study in patients with stage 3 & 4 CKD examined the effectiveness of gradual vs. rapid $25D_3$ in reducing elevated plasma iPTH.

Methods: Data from two similar studies in patients with stage 3 and 4 CKD, secondary hyperparathyroidism (SHPT) and vitamin D insufficiency were combined to compare $25D_3$ exposures and resultant reductions in iPTH following MR or IV $25D_3$ administration. Study CL-2008 examined the iPTH lowering effects of 3 daily doses (30, 60 or 90 μg) of MR $25D_3$ after 6 weeks. Study CL-2004 compared the iPTH effects of a single dose (450 or 900 μg) of MR vs. 450 μg IV $25D_3$.

Results: Mean exposures (AUC in ng*d/mL) over 6 weeks were 58, 188, 817, 1531 and 2134 for the 450, 900, 30, 60 and 90 μg MR groups, respectively, with mean % iPTH changes (from pre-treatment baseline) of 3.4, -16.8, -20.2, -32.0 and -37.9. Exposure for the 450 μg IV group was 709 with a mean % iPTH change of -2.1.

Conclusions: Rapid administration of $25D_3$ to correct vitamin D insufficiency in stage 3 and 4 CKD can limit or prevent the effective treatment of the associated SHPT, possibly by inducing CYP24. CTAP101 Capsules provides a means to gradually raise serum total 25D and effectively lower elevated plasma iPTH in CKD patients.

Experimental Kidney Failure Leads to Increased Exposure to Warfarin Metabolites Thomas D. Nolin,[1] Emilie Robidoux,[2] François A. Leblond,[2] Josée Michaud,[2] Judith Naud,[2] Desiree Kosmisky,[1] Vincent Pichette.[2] *[1]Pharmacy and Therapeutics, University of Pittsburgh School of Pharmacy, Pittsburgh, PA; [2]Centre de Recherche Guy-Bernier, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: The anticoagulant warfarin undergoes hepatic elimination via CYP2C9. Use in end-stage renal disease patients is associated with lower required doses independent of CYP2C9 genotype, poorer anticoagulation control, a doubled risk of major hemorrhage, and a 27% increase in mortality. We hypothesized that uremia leads to altered pharmacokinetics (PK) of warfarin, thereby leading to increased pharmacologic effects. Therefore, the aim of this project was to explore the effect of experimental kidney failure (KF) on the PK of warfarin and its hydroxy-metabolites.

Methods: KF was induced in Sprague–Dawley rats by performing two-staged, five-sixths nephrectomies. Concentrations of warfarin and its metabolites were determined using a validated LC-MS/MS method. KF rats and control rats were administered a single-dose of warfarin 2 mg/kg IV bolus, and serial plasma samples were collected up to 144 hours after administration. PK analysis was performed by standard non-compartmental methods.

Results: The PK of warfarin was not affected by KF. However, systemic exposure (area under the plasma concentration-time curves, AUC) to 6-, 7-, and 8-OH warfarin was increased by 112% (p=0.09), 198% (p=0.01), and 352% (p=0.16), respectively, in KF vs control rats. The AUC of 10-OH warfarin was reduced by 83% (p=0.12) in KF vs control.

Conclusions: These findings suggest that the PK of warfarin metabolites, but not warfarin itself, are significantly altered in the presence of KF. Possible mechanisms include decreased renal clearance of 6-, 7-, and 8-OH warfarin, and decreased metabolic formation of 10-OH warfarin. Further study is warranted to investigate the pharmacological effects of individual hydroxywarfarin metabolites.

Funding: Government Support - Non-U.S.

Systemic Evaluation of Treatment with Vitamine B6 in Patients with Primary Hyperoxaluria Type I: A Pilot Trial Bernd Hoppe,[1] Heike Katharina Hoyer-Kuhn,[1] Bodo B. Beck.[2] *[1]University Hospital, Department of Pediatrics and Adolescents Medicine, Division of Pediatric Nephrology, University of Cologne; [2]Institute of Human Genetics, University of Cologne.*

Background: Primary hyperoxaluria type I (PH I) as an hereditary autosomal recessive disease is caused by a deficiency of liver specific peroxisomal enzyme alanine-glyoxylate:aminotransferase that requires vitamine B6 as a cofactor. Treatment with vitamine B6 is based on an agreement of experts due to retrospective analyses and case reports. It should, however, be administered in all patients with PH I to evaluate its effect on the reduction of urinary oxalate (UOX) excretion. Primary objective of this pilot trial was to investigate the relative reduction of UOX excretion under increasing dosages of vitamine B6 at week 24 compared to baseline in a prospective setting.

Methods: 12 patients (7 males; age 13.5 ± 3.3 years; eGFR 139 ± 37 ml/1.73m^2/min) were included with confirmed PH I by mutation analyses: c.508G>A homozygous (n=3), c.508G>A heterozygous (n=5), c.508G>A negative (n=4). Medication was interrupted for 4 weeks or until serum levels were normal in the 8/12 patients treated with vitamine B6 at study entry. Vitamine B6 dosage at baseline was 5 mg/kg/day for 6 weeks and increased by 5 mg/kg steps to a final dosage of 20 mg/kg/day every six weeks until week 24. Two 24 h urines were sampled at baseline and each step of dosage adjustment.

Results: Preliminary data of an intention-to-treat analysis showed a mean relative reduction of UOX excretion of 25.0%. UOX excretion declined from 2.14 ± 0.54 mmol/1.73m^2/day at baseline to 1.57 ± 0.58 mmol/1.73m^2/day ($p<0.02$) at week 24 and vitamine B6 levels increased from 24 ± 10 ng/ml to 1228 ± 813 ng/ml ($p<0.001$), respectively. Five patients showed a relative reduction of UOX ≥ 30%.

Conclusions: UOX excretion could be reduced by vitamine B6 treatment in a prospective setting comparable to retrospective data. These preliminary data underline the need for further evaluation in a multicenter trial to analyze a genotype/phenotype related response to vitamine B6 treatment.

Personalised Azathioprine Therapy in Renal Transplantation: Are We Missing a Trick? Jennifer R. Joslin, Paul A. Blaker, Anthony Marinaki, Jeremy D. Sanderson, David Goldsmith. *Guy's & St Thomas' Hospital, London.*

Background: Immunosuppression for renal transplantation (RTx) has shifted from azathioprine- (AZA) to mycophenolate mofetil (MMF)-containing regimens with improved five-year patient and graft survival rates. However, data to support this strategy did not include AZA optimisation by measurement of thiopurine-*S*-methyltransferase (TPMT) activity, or AZA metabolites, thioguanine nucleotides (TGN) and methyl-mercaptopurine (MMP). In other disciplines these are used to optimise the dose of AZA, suggesting that AZA use in RTx may be sub-optimal. We hypothesized that these biomarkers would identify patients at risk of AZA toxicity, under-dosing and non-adherence.

Methods: EDTA blood samples were collected from 71 AZA long-term RTx patients and tested for TPMT activity and AZA metabolite profiles. TPMT activity, TGN and MMP levels were correlated with mean white cell counts (WBC), lymphocyte counts, alanine transaminase (ALT) and haemoglobin (Hb) concentrations.

Results: One of 4 patients with intermediate TPMT activity was prescribed a higher than recommended dose of AZA (1.5mg/kg). Of patients with normal TPMT activity (n=67, mean 36.9pmol/gHb/hr, range 27-59), the mean AZA dose was 1.06mg/kg. Mean TGN and MMP levels were 239pmol/8x10^{8}RBC (range 0-831) and 743pmol/8x10^{8}RBC (range 0-8787) respectively. 43/71 patients had TGN levels ≤ 240pmol/8x10^{8}RBC. 1 of 2 patients with TGN and MMP levels of zero, suggesting non-adherence, showed chronic rejection. The dose of AZA correlated with both TGN ($p=0.001$) and MMP ($p=0.007$) levels. There was no correlation between TGN or MMP levels and the mean WBC, lymphocyte count, ALT or Hb.

Conclusions: Pre-treatment TPMT phenotyping identifies patients with low or intermediate activities at risk of AZA toxicity. In our cohort the mean AZA dose was at the lower limit of the recommended dose, and more than 50% of patients had a TGN level less than the range considered therapeutic in a number of chronic inflammatory conditions (240-400pmol/8x10^8 RBC). Prospective studies are needed to determine the ideal therapeutic range of AZA metabolites in RTx, since switching AZA to MMF without optimising the dose of AZA is potentially a missed opportunity.

SA-OR093

An Inosine 5'-Monophosphate Dehydrogenase Gene Variant in Mycophenolic Acid Efficacy Wolfgang Winnicki, Gerald Cohen, Florina Regele, Michael Baier, Gurkan Sengoelge. *Department of Medicine III, Division of Nephrology and Dialysis, Medical University of Vienna.*

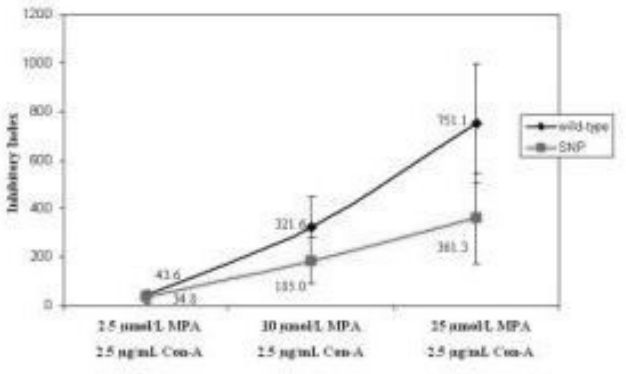
Background: Mycophenolic acid (MPA) is a selective inhibitor of inosine 5'-monophosphate dehydrogenase (IMPDH), the rate-limiting enzyme of purine metabolism. The isoenzyme IMPDH2 predominates in activated lymphocytes, and its inhibition by MPA is part of standard immunosuppressive regimens.

Significant unexplained differences in MPA efficacy and tolerability among patients are known, whether variants in the IMPDH2 gene lead to changes in IMPDH activity and to differences in responsiveness to MPA therapy is tested.

Methods: All 14 exons and intron–exon boundary regions of IMPDH2 are sequenced from genomic DNA probes from 100 healthy individuals by bi-directional PCR-based dideoxy chain termination sequencing.

After lymphocyte isolation and incubation at different MPA concentrations a 3H-thymidine proliferation assay is performed and lymphocytic IMPDH activity is determined by means of high-performance liquid chromatography.

Results: One intronic polymorphism (rs11706052) is identified in 19% of the study population. Lymphocyte IMPDH activity and proliferation under three therapeutic relevant MPA concentrations are compared in rs11706052 carriers and wild-type individuals. The presence of the rs11706052 polymorphism reduces the antiproliferative effect of MPA on lymphocytes by approximately 50% compared with the IMPDH2 wild-type form.



Conclusions: Renal transplant recipients with the rs11706052 polymorphism may suffer from higher rejection rates due to poorer response to MPA therapy.

To confirm these findings a prospective clinical study is underway at our center that combines MPA pharmacokinetic, IMPDH pharmacodynamic and rs11706052 pharmacogenetic approaches in 150 renal transplant recipients with a follow-up of 1 year. Preliminary data will be shown.

Long Term Effects of Migalastat HCl on Fabry Nephropathy

Dominique P. Germain,[1] Roberto Giugliani,[2] Gregory Pastores,[3] Kathleen M. Nicholls,[4] Suma P. Shankar,[5] Raphael Schiffmann,[6] Atul B. Mehta,[7] Derralynn A. Hughes,[7] Stephen Waldek,[8] Ana Jovanovic,[9] Pol Boudes,[10] Sheela Sitaraman,[10] Vilma Sniukiene,[10] Robert Eduard Winkler,[10] Alexander C. Bragat.[10] *[1]U. of Versailles, France; [2]HCPA, UFRGS, Porto Alegre, RS, Brazil; [3]NYU, NY, NY; [4]Royal Melbourne Hospital, Parkville, Australia; [5]Emory U., Decatur, GA; [6]Baylor RI, Dallas, TX; [7]Royal Free Hospital, London, United Kingdom; [8]Independent, Manchester, United Kingdom; [9]Salford Royal Hospital, Manchester, United Kingdom; [10]Amicus Thx, Cranbury, NJ.*

Background: Fabry disease (FD) is caused by mutations affecting α-galactosidase A. Accumulation of globotriaosylceramide (GL-3) leads to multiorgan dysfunction, including progressive kidney disease.

Methods: This analysis is on the effects of oral migalastat (AT1001/GR181413A) on kidney histology and function in FD, as evaluated in ongoing FAB-CL-205/NCT00526071 (cut-off April 2012). This open-label study was in 23 patients who completed a preceding phase 2 study. Kidney biopsy was performed and the average number of GL-3 inclusions per peritubular capillary (PTC) is compared with results from the baseline (B) biopsy. eGFR was calculated and 24-hour urine protein was measured.

Results: Median treatment duration, including the preceding study, was 5.0 years (range: 1.9/6.2 years). By an in-vitro assay, 11/14 males and 5/9 females had mutations considered amenable to migalastat. Eight patients had paired biopsies: 5 amenable (2 males) and 3 non-amenable (3 females). Median treatment duration in FAB-CL-205 at the time of biopsy was 60 weeks (44 weeks on a 500 mg 3 days on 4 days off regimen). Median GL-3 in PTCs decreased by 78% in patients with amenable mutations and increased by 114% in patients with non-amenable mutations. Mean decline in eGFR was 0.48 ml/min/1.73m^2/year in all patients (0.87 in amenable and +0.41 in non-amenable; 0.99 in males and +0.3 in females). 24-hour urine protein decreased in patients with amenable mutations, and was associated with use of renal protective therapies.

Conclusions: All patients with amenable mutations had a reduction of GL-3 in kidney PTCs. Mean decline in eGFR was similar to the decline seen in the normal population.

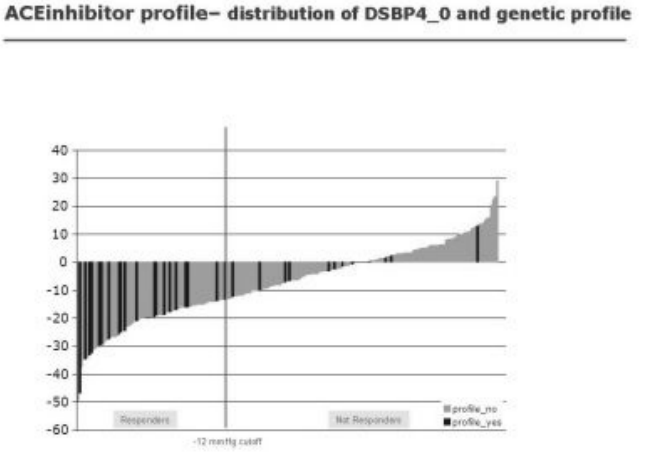
Genetic Profile of ACE-Inhibitor Responder Patients in Essential Hypertension

Simona Pozzoli, Chiara Lanzani, Lorena Citterio, Simona Delli Carpini, Stefano Tentori, Marco Simonini, Marie Jancarikova, Paolo Manunta. *San Raffaele Scientific Institute, Italy.*

Background: Less than 25% (about 1 million) of patients currently under antihypertensive agents have target blood pressure values, despite numerous antihypertensive drugs available. The enormous variation in the individual response to antihypertensive treatment could be solved by pharmacogenomic studies. ACE-inhibitor (ACEi) therapy is recommended by guidelines, however BP variability is under unknown genetic control. Our aim was to built the genetic profile of hypertensive patients responder to ACEi mono-therapy.

Methods: 175 essential hypertensive patients (114 naïve) from the hypertension clinic of our hospital were treated for 4 weeks with Perindopril 4 mg. The outcome was the variation in systolic and diastolic BP (ΔSBP and ΔBP at 1st month).We performed genetic study using both candidate gene and Genome Wide Analysis.

Results: As expected a great variability of blood pressure response is present, with approximately one third of ACEi responders (ΔSBP 1st month <-12.6 mmHg, ΔDBP 1st month <-9 mmHg). Patients carrying specific combination of NKAIN2 and APBA2 or MYO16 and PRKG1 or NKAIN2 + PRKG1 genes (15% of sample) showed a greater decrease of SBP compared to not carrying (-15,8 mmHg vs -6 mmHg; GLM p<0.00001 adjusted for sex, age, BMI, basal SBP and Plasma renin activity). The OR to be responder was 4.0 (IC 95% 1.69-9.60 p-model <0.001) in the patients carrying the genetic profile. The specificity of ACEi genetic profile was 92%, whereas positive predictive value was 70% and negative predictive values was 62%.



Conclusions: Our results identified, for the first time, a genetic combination able to predict the response to ACEi therapy in essential hypertension. The same approach could be applied in kidney disease to personalize treatment and select those patients that will reverse renal function decay.

Genetic and Epigenetic Variants Important in Susceptibility to Clofarabine Cytotoxicity: Implications for Application to Renal Cell Death

Michael T. Eadon,[1] Heather E. Wheeler,[1] Xu Zhang,[2] Hae Kyung Im,[1] Amy Stark,[1] Yujia Wen,[1] Wei Zhang,[2] Patrick Cunningham,[1] M. Eileen Dolan.[1] *[1]University of Chicago; [2]University of Illinois Chicago.*

Background: Clofarabine, a purine nucleoside analog, was associated with acute kidney injury (AKI) in up to 50% of cases in clinical trials. The use of clofarabine is increasing as indications now include stem cell transplant induction and treatment of adult leukemias. The etiology of AKI is often multifactorial in these patients and it is presently unclear the extent of nephrotoxicity due to clofarabine. This novel investigation aims to determine whether genetic variation mediates changes in susceptibility to clofarabine cytotoxicity in lymphoblastoid cell lines (LCLs) and whether genes identified in our genome wide association study (GWAS) impact susceptibility to clofarabine in renal cells.

Methods: Dose-response clofarabine cytotoxicity curves were generated for HEK293 cells and LCLs. Genetic factors were identified using an unbiased whole-genome approach using LCLs derived from persons of European (CEU) or African (YRI) ancestry. Over 2 million single nucleotide polymorphisms (SNPs) were interrogated for association with susceptibility to clofarabine. Epigenetic modification due to DNA methylation was interrogated for association with cytotoxicity. Strength of association between cytotoxicity and expression of 450 transcription factors and 13,000 target genes guided prioritization for validation by siRNA knockdown.

Results: HEK293 cells and LCLs demonstrate dose related cytotoxicity to clofarabine at similar drug concentrations. Associations between cytotoxicity and expression of 230 genes as well as methylation status of 157 CpG sites reached genome wide significance. From GWAS, 11 SNPs were associated at p <5x10^{-6}. Seven of the 11 SNPs were expression quantitative trait loci with target genes correlating with one or more of the 230 genes identified above.

Conclusions: Genetic and epigenetic variation are important determinants in susceptibility to clofarabine. The LCL model is appropriate to generate hypotheses for future functional studies and mechanistic inquiry in renal cell lines.

Multi-Target Therapy of Lupus Nephritis: A Prospective Randomized Control Multi-Center Trial Zhi-Hong Liu, Hai-tao Zhang, Wei-Xin Hu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu, China.*

Background: To evaluate the efficacy and safety of multi-target regimen in the induction therapy of lupus nephritis (LN).

Methods: A 24-week randomized, open-label, superiority trial was conducted to compare multi-target therapy (MT group, oral mycophenolate mofetil 1.0 g/d, tacrolimus 4 mg/d and corticosteroids) with monthly intravenous cyclophosphamide (IVCY group, CTX, 0.5-1.0 g/m2 BSA and corticosteroids) as induction therapy for active LN. The study protocol specified adjunctive care and the use of corticosteroids (intravenous methylprednisolone, 0.5 g/d for 3 days followed by oral prednisolone 0.6 mg/kg/d and tapering). The primary end point was complete remission (CR) at 24 weeks. The secondary end point was partial remission (PR) and adverse effects.

Results: 362 patients (329 females and 33 males, average age 32.7±10.2 years) were enrolled in 26 Chinese centers. The renal pathology was classed according to ISN/RPA 2003 classification, including class III (n=20), IV (n=150), V (n=68), V+III (n=26) and V+IV(n=98).These patients were randomly assigned to MT group (n=181) and IVCY group (n=181). 310 patients completed the 24 weeks treatment. The accumulative rate of CR at 24-week in MT group (43.65%) was significantly higher than that in IVCY group (23.2%) (P<0.01). This difference was statistically significant in class V+IV(42.22% vs 20.75%, P<0.05)and class V (37.5% vs 5.56%, P<0.01). The PR rate was 49.03% and 41.18% respectively in two groups. There was no significant difference of adverse events between two groups (51.11% vs 54.29%). However, MT group had markedly lower incidences of gastrointestinal symptoms, GPT/GOT elevation and leucopenia, but higher incidences of tremor and new onset hypertension comparing IVCY group. No significant difference was found in infection and hyperglycemia.

Conclusions: The multi-target regimen was more effective than intravenous CTX in inducing remission of LN and had a more favorable safety profile.

Myeloperoxidase Antibodies Associate with the Future Diagnosis of Proliferative Lupus Nephritis Mark D. Poirier, Christina M. Yuan, Kevin C. Abbott, Stephen W. Olson. *Nephrology, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Systemic Lupus Erythematosus (SLE) is a systemic disease with significant morbidity to include Lupus Nephritis (LN). In addition to anti-double stranded DNA antibodies, anti-neutrophil cytoplasmic antibodies (ANCA) have been shown to associate with LN at the time of diagnosis. There have been no previous studies to evaluate ANCA levels prior to the diagnosis of LN and specifically proliferative lupus nephritis (PLN), which carries the worst renal prognosis.

Methods: We utilized the Department of Defense Serum Repository (DoDSR) to compare longitudinal pre-diagnostic ANCA levels in 23 biopsy confirmed proliferative lupus nephritis cases to 23 age, race, gender, and age of serum matched SLE without LN disease controls identified by the DoDSR.

Results: A greater percent of PLN cases versus disease controls had a single elevated myeloperoxidase (MPO) antibody level (>5 U/mL) at any time prior to diagnosis (57% vs. 5%, p<0.001). An MPO antibody rate of rise greater than 0.5 U/mL was 100% specific for future disease (45% vs. 0%, p=0.001). A greater percent of PLN cases versus disease controls had an absolute rise (> 0 U/mL) in MPO antibody over time (70% vs. 16%, p=0.001).

Conclusions: An elevated and rising MPO antibody level is associated with the future diagnosis of PLN. Our data set better defines the role of MPO antibody in the pathogenesis of PLN. MPO antibody could contribute to a future autoantibody profile that better describes the risk for future PLN in patients with SLE.

SA-OR099

The Efficacy of Rituximab versus Cyclophosphamide for Treatment of Renal Disease in ANCA-Associated Vasculitis: The RAVE TRIAL Duvuru Geetha, Fernando C. Fervenza. *RAVE-ITN Group.*

Background: Rituximab (RTX) is non-inferior to cyclophosphamide (CYC) followed by azathioprine (AZA) for remission-induction in severe ANCA associated vasculitis (AAV) but details of outcomes among patients with renal involvement have not been reported. We present the long-term outcomes of patients who had renal involvement at baseline in the RAVE trial.

Methods: Patients with renal involvement defined by a Birmingham Vasculitis Activity Score/Wegener's Granulomatosis (BVAS/WG) renal item score ≥ 3 at baseline were included. Glomerular filtration rate was estimated (e-GFR) by Cockcroft-Gault formula. Complete remission (CR) was defined by BVAS/WG = 0, off prednisone; Renal flare by renal BVAS/WG ≥ 3. Remission rates, slopes of eGFR and renal flares were compared between treatment groups.

Results: 102 of the 197 (52%) patients had renal involvement at entry (GPA: 68; MPA: 34; PR3-ANCA: 58; MPO-ANCA: 44; new diagnosis: 58; relapsing disease: 44). The mean age was 55 years, 52% were males. 51 patients each received RTX or CYC/AZA. Except for lower mean baseline e-GFR in the RTX group (53 ml/min vs 69ml/min p=0.01), there were no clinical differences between the treatment groups. 60.8 % patients treated with RTX and 62.7 % patients treated with CYC/AZA achieved CR by 6 months, and 74.5 % and 76.5% at any time on the originally assigned treatment, respectively. Median times to CR were similar in both groups. The mean e-GFR increased in parallel in the two groups during the 18 months. The number of renal flares did not differ between the two groups at 6, 12, or 18 months. When stratified by ANCA or AAV type or new vs relapsing disease, there were no differences in remission rates or slopes of e-GFR increase at 18 months. Four MPA patients treated with RTX without maintenance therapy had a total of 5 renal flares by month 18 vs none treated with CYC/AZA (p=0.04).

Conclusions: A single course of RTX is as effective as 18 months of therapy with CYC/AZA for induction and maintenance of remission in patients with AAV with renal disease. MPA patients treated with RTX and no maintenance therapy may be more likely to experience a renal flare following B cell reconstitution.

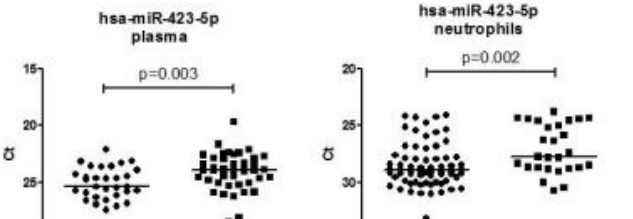
Neutrophil and Plasma microRNA Expression during Remission in Patients with Systemic Vasculitis Marten Segelmark,[1] Camilla Skoglund,[1] Tino Kurz,[1] Anting Liu Carlsen,[2] Thomas Hellmark,[3] Per Eriksson,[1] Niels H. Heegaard.[2] *[1]Medical and Health Sciences, Linköping University, Linköping, Sweden; [2]Autoimmunity, Statens Serum Institut, Copenhagen, Denmark; [3]Clinical Sciences, Lund University, Lund, Sweden.*

Background: Patients with ANCA-associated vasculitis (AVV) in remission live under a constant threat of relapse. Levels of ANCA in plasma have limited capacity to predict relapses, new biomarkers are needed. MicroRNAs (miRNA) are small non-coding oligonucleotides present in cells as well as in microparticles in plasma. Microparticle miRNA has been proven to be stable during storage.

Methods: Candidate miRNAs were chosen using a PCR based mini-array on plasma samples (39 patients and 106 controls) and an Affymetrix 2.0 miRNA microarray Chip on neutrophil RNA (4 patients and 4 controls). All candidate miRNA were tested on a cohort consisting of 68 patients with AAV in remission and 28 controls using quantitative real-time PCR (qPCR) and specific Taqman probes.

Results: Out of about 1000 human miRNAs present on the chip 500 could be detected in neutrophils, and out of 45 miRNAs present on the mini-array 26 could be detected in all plasma samples. All miR detected in neutrophils could also be detected in plasma, indicating that a proportion of plasma miRNA is of neutrophil origin. After a selection process 20 miRNA were subjected to qPCR on neutrophil RNA. Significant differences between AAV patients and controls were detected for 4 miRNAs. MiR-20a*, miR-339-5p and miR-423-5p were found to down-regulated while miR-638 was up-regulated. MiR-423-5p was also down-regulated in AAV plasma.



Conclusions: Patients with vasculitis in remission exhibit significant differences in their miRNA expression, compared to healthy controls, both intracellulary in neutrophil and extracellulary in plasma microvesicles. These differences have a potential to be exploited as biomarkers.

Eculizumab (ECU) in Atypical Hemolytic Uremic Syndrome (aHUS) Patients (pts) with Progressing TMA: Continued Improvements at 2-Year Follow-Up Christophe M. Legendre,[1] Laurence A. Greenbaum,[2] Sunil Babu,[3] Richard Furman,[4] Neil Sheerin,[5] David J. Cohen,[6] A. Osama Gaber,[7] Frank Eitner,[8] Yahsou Delmas,[9] Camille Bedrosian,[10] Chantal Loirat.[11] *[1]Hôpital Necker, France; [2]Emory Univ, GA; [3]Fort Wayne Med, IN; [4]Weill Cornell Med Coll, NY; [5]Newcastle Univ, United Kingdom; [6]Columbia Univ Med Center, NY; [7]Methodist Hosp, TX; [8]Univ Aachen, Germany; [9]CHU Pellegrin, Bordeaux, France; [10]Alexion Pharmaceuticals Inc.; [11]Hôpital Robert Debré, Paris, France.*

Background: aHUS is a genetic disease of chronic uncontrolled complement activation and systemic thrombotic microangiopathy (TMA). Despite plasma exchange/infusion (PE/PI), 33-40% of aHUS pts progress to ESRD/die during the first clinical manifestation[1,2]. We report longer follow-up with ECU, a terminal complement inhibitor, in aHUS pts with progressing TMA.

Methods: aHUS pts ≥12 yrs with progressing TMA (platelets <150x10^9/L at screening) despite ≥4 PE/PI sessions 1 wk before were enrolled in an phase II trial and continued in a long-term extension. Primary endpt: platelet count change. We report data for median 100 wks (range, 2-145) duration.

Results: 17 pts enrolled (2 discontinued at 1 and 6 wks; protocol violation, an adverse event (AE) unrelated to ECU, respectively). Median time from diagnosis to screening=10 mo (0.3-236). 13 pts continued in the extension study.

Chronic ECU continued to increase platelets and more pts achieved key renal endpoints with time (Table). ECU was generally well tolerated (1 serious AE [severe hypertension] possibly drug related).

Conclusions: Long-term ECU therapy inhibited complement-mediated TMA and resulted in significant and continuous improvements in renal function. At a median duration of almost 2 yrs, all pts receiving chronic ECU therapy remain alive.

Key Outcomes	Week 26 ECU (N =17)*	Median duration of 100 wks ECU (N=17)†
Mean change in platelet count, $x10^9$/L (95% CI) (primary endpoint)	73 (40, 105) P=0.0001	88 (63, 112) P<0.0001 (wk 96)
TMA-event-free status, n (%)	15 (88)	15 (88)
eGFR increase of ≥15 mL/min/1.73m^2, n (%)	8 (47)	10 (59)
CKD improvement of ≥1 stage, n (%)	10 (59)	12 (71)
Serum creatinine decrease of ≥25%, n (%)	11 (65)	13 (76)
Mean change in eGFR‡, mL/min/1.73m^2 (95% CI)	31 (17, 45) P=0.0001	32 (15, 49) P<0.0008 (wk 96)
Decrease in proteinuria ≥1 grade, n/N (evaluable patients)	12/15	7/9 (wk 96)
Mean change in health-related quality of life§, EQ-5D score (95% CI)	0.32 (0.27, 0.38) P<0.0001	0.33 (0.30, 0.36) P=0.0001 (wk 96)

ECU dosage: 900mg/wk for 4 wks, 1200mg at wk 5, 1200mg q2 wks thereafter.
Significance was tested with a repeated measures model.
*Two pts discontinued at wks 1 and 6.
†Two pts discontinued at wks 1 and 6, two pts discontinued at week 26 and two during the extension phase (one pt discontinued at wk 68 and another at wk 83).
‡ECU eliminated the need for dialysis in 4/5 pts receiving dialysis at baseline. An additional pt (eGFR, 19 mL/min/1.73m^2 at screening) initiated dialysis at wk 64.
§Clinically meaningful threshold ≥0.6.

SA-OR102

Open-Label, Multi-Center Trial of Eculizumab in Patients with Shiga-Toxin-Producing *E. coli* Hemolytic Uremic Syndrome (STEC-HUS)

Rolf A. Stahl, The STEC-HUS Study Group.

Background: Patients (pts) with Shiga-toxin–producing *E.coli* infection can develop hemolytic uremic syndrome (STEC-HUS), a rare, systemic, life-threatening disease in which shiga-toxin–mediated uncontrolled complement activation leads to systemic inflammation and thrombotic microangiopathy (TMA), resulting in immediate, severe organ damage and also severe, long-term and/or delayed-onset sequelae. While protracted, the exact duration of excessive complement activation is unknown. Supportive pt management, including plasmapheresis, is generally considered ineffective. Use of eculizumab (ecu), a humanized monoclonal anti-C5 antibody that inhibits terminal complement activation, is associated with positive STEC-HUS clinical outcomes in case reports. From May-July 2011, Germany experienced one of the largest STEC outbreaks and 855 STEC-HUS cases. In response to physician requests, an ecu compassionate access program was initiated and controlled trial started to ensure pt monitoring and to assess safety/efficacy of ecu treatment for STEC-HUS.

Methods: This 28wk, open-label trial enrolled STEC-HUS pts with TMA/systemic organ complications. In adults, IV ecu 900mg was administered on Days 0,7,14,21, then 1200mg on Days 28,42,56; pediatric pts received weight-based dosing. Ecu was permitted for an additional 8wks (1200mg every 2wks). Follow-up continued to a total of 28wks. Pts received meningococcal vaccination per protocol before ecu and antibiotic prophylaxis for ≥14d post-vaccination. Primary/key secondary study endpoints are listed (Table). The study was approved by the Paul-Ehrlich-Institute and each site's Independent Ethics Committee.

Results: 198 pts were enrolled; baseline characteristics are summarized (Table). Previously presented interim (8wk) results showed that ecu treatment substantially improved TMA/systemic organ complications in STEC-HUS. Final (28wk) results will be presented.

Primary and Key Secondary Study Endpoints

Eculizumab (ECU) Is Effective in Atypical Hemolytic Uremic Syndrome (aHUS) Patients (Pts) with a Long Disease Duration and CKD: 2-Year Data

Christoph Licht,[1] Petra Muus,[2] Christophe M. Legendre,[3] Kenneth Douglas,[4] Maryvonne Hourmant,[5] Yahsou Delmas,[6] Maria Herthelius,[7] Antonella Trivelli,[8] Timothy Goodship,[9] Camille Bedrosian,[10] Chantal Loirat.[11] *[1]Hospital for Sick Children, Toronto, Canada; [2]Radboud Univ Nijmegen Med Centre, Netherlands; [3]Hôpital Necker, France; [4]Beatson W. Scotland Cancer Centre, United Kingdom; [5]CHU Hotel Dieu Nantes, France; [6]CHU Pellegrin, Bordeaux, France; [7]Karolinska Univ Hosp, Sweden; [8]Istituto G Gaslini, Italy; [9]Newcastle Univ, United Kingdom; [10]Alexion Inc; [11]Hopital Robert Debré, Paris, France.*

Background: Chronic uncontrolled complement activation causes systemic thrombotic microangiopathy (TMA) in aHUS. We report longer follow-up from the 26-wk, phase II trial with the complement inhibitor ECU in aHUS pts with a long disease duration and CKD previously undergoing plasma exchange/infusion (PE/PI).

Methods: aHUS pts ≥12 yrs receiving chronic PE/PI (unchanged regimen) were enrolled in a phase II trial. After 8 wks observation, pts stopped PE/PI and initiated ECU. Primary endpt: TMA event-free status (≥12 wks: no platelet change >25% + no PE/PI + no new dialysis). Median ECU duration at data cut-off=114 wks (26-129).

Results: 20 pts received ECU through wk 26; 19 continued ECU. Median time from diagnosis to screening=48 months (0.66-286). Chronic ECU therapy (>2 yrs) resulted in 19 pts achieving TMA event-free status. As compared to chronic PE/PI before ECU, 8 pts achieved eGFR increase ≥15 mL/min/1.73m^2(Table). No pt required PE/PI or progressed to ESRD/dialysis. ECU was well tolerated; 3 SAEs related to ECU (severe, all resolved). No meningococcal infection. 1 death (GI bleed unrelated to drug). 18 pts treated >2 yrs are alive.

Conclusions: Long-term ECU sustained suppression of TMA, was associated with no new ESRD, continued to markedly improve renal function and was well-tolerated.

Parameter	ECU Treatment 26 wks (N=20)	Median Duration of ECU Treatment 114 wks* (N=20)
TMA event-free status, n (%)	16 (80)	19 (95)
eGFR increase of ≥15 mL/min/1.73m^2, n (%)	1 (5)	8 (40)
Improvement in ≥1 CKD, n (%)	7 (35)	12 (60)
≥25% reduction in serum creatinine, n (%)	3 (15)	11 (55)
Mean change in eGFR, mL/min/1.73m^2, (95% CI)	6.1 (3.3, 8.7) P<0.0001	7.1 (-0.03, 14)[†] P=0.05 (wk 96)
Decrease in proteinuria ≥1 grade, n/N	8/16[‡]	12/15[‡] (wk 96)
Mean change in health-related quality of life (EQ-5D score) (95% CI) (clinically meaningful threshold ≥0.06)	0.12 (0.07, 0.17) P<0.0001	0.14 (0.10, 0.18) P<0.0001 (wk 96)

ECU dosage: 900mg/week for 4 wks, 1200mg at wk 5, then 1200mg q2 wks thereafter.
Significance was tested with a repeated measures model.
*Median duration of 114 weeks unless otherwise indicated.
[†]One pt on dialysis received a transplant on day 217, renal data from this pt were censored on day 217 and during continued ECU treatment.

A 4 Plus 2 Infusion Protocol of Rituximab Provides Long-Term Beneficial Effects in Patients with HCV-Associated Mixed Cryoglobulinemia with Diffuse Membranoproliferative Glomerulonephritis and Severe Polyneuropathy

Dario Roccatello. *Centro Ricerche di Immunopatologia-Documentazione su Malattie Rare, Ospedale S. G. Bosco.*

Background: B cells expansion triggered by HCV infection plays a central role in the pathogenesis of Mixed cryoglobulinemia syndrome (MCs).The long term effects of B-cells depletion in MCs are still on debate.

Methods: 27patients,(mean age 60.2[range35-78]years,HCV infection in96%of cases) with symptomatic type-II MCs with systemic manifestations,including renal involvement(diffuse membranoproliferative glomerulonephritis in 15cases),peripheral neuropathy (26cases)and large skin ulcers (9 case,in7necrotizing)were considered eligible for Rituximab(RTX)therapy.RTX (375mg/m^2) was administered on days1,8,15and22.Two more doses were administered 1 and 2 months later.No other immunosuppressive drugs were added.Response was evaluated by assessing the changes in clinical signs, symptoms, laboratory parameters and electromyographic indices for a very long term follow-up(mean 54.3months[12-96]).

Results: Complete remission of pre-treatment active manifestations was observed in all the cases of skin purpuric lesions and non-healing vasculitic leg ulcers, and in80% of the peripheral neuropathy. A significant improvement($p>0.02$) in the clinical neuropathy disability score was observed. Electromyography examination revealed that the amplitude of compound motor action potential had increased($p<0.04$).Improvement of glomerulonephritis in 15affected patients, starting from the second month after RTX, was documented by the decrease of serum creatinine from 2.2±1.9SD to1.6±1.2SD mg/dl, $p<0.05$; 24-hour proteinuria levels from 2.3±2.1SDto0.9±1.9SD g/24h,$p<0.05$.Improvement of cryoglobulinemic serological hallmarks, such as cryocrit and low complement C4, was also observed($p<0.05$).The safety of RTX was confirmed by the absence of severe side effects recorded during the mean 54-month follow-up. Re-induction was performed in 9 relapsed cases (after a mean of 31.1 months, range 12-54) with definitely beneficial effects.

Conclusions: In this open prospective study, RTX appeared to be effective and safe in the treatment of patients with MCs-associated neuropathy and membranoproliferative glomerulonephritis.

SA-OR105

Renal Involvement in Non-Infectious Mixed Cryoglobulinemia

Mohamad Zaidan,[1] Benjamin Terrier,[2] Isabelle Brochériou,[1] Agnieszka Anna Pozdzik,[3] Patrice Cacoub,[4] Emmanuelle M. Plaisier.[1] *[1]Tenon Hospital, Paris, France; [2]Cochin Hospital, Paris, France; [3]Hospital Erasme, Brussels, Belgium; [4]Pitié-Salpêtrière Hospital, Paris, France.*

Background: Mixed cryoglobulinemia (MC) has been primarily characterized in patients with hepatitis C virus infection while non infectious MC has been poorly investigated. Our aim was to study the spectrum of renal disease in non-infectious MC.

Methods: Retrospective analysis of patients with non infectious MC and biopsy-proven renal involvement, identified from a collaborative French multicentric survey (the "CryoVas" study).

Results: 80 patients were included (50F/30M, mean age 63±14 years). MC was related to Sjögren syndrome (pSS) alone (18 patients, 22%), lymphoproliferative disorders (23 patients, 29%), 7 of whom had a history of pSS, or finally classified as essential (39 patients, 49%). Renal features included hematuria, proteinuria >1g/day, hypertension and renal failure (mean eGFR 40±20 ml/min/1.73m²) in 97%, 85%, 85% and 82% of cases, respectively. Extrarenal manifestations included skin (71%), neurological (43%) and joint (35%) involvement. 73 patients (91%) had type 1 membranoproliferative glomerulonephritis while 7 had mesangioproliferative glomerulonephritis. Renal interstitium was infiltrated by CD3+ and CD20+ lymphocytes in >50% of cases with a nodular organization in 40% of cases. Mild to severe fibrosis was observed in 20% of cases. Vascular lesions included arteriosclerosis and more rarely necrotizing arteritis. First line treatment consisted of steroids (88%) and/or immunosuppressive agents including cyclophosphamide (40%) and/or rituximab (30%). 18 patients had plasma exchanges. Initial renal remission was observed in 86% of cases. However, relapses occurred in half of patients. At last follow-up, mean eGFR was 49±26 ml/min/1,73m² including 5% of ESRD. Severe infections and new onset of B-cell lymphoma occurred in 30% and 8% of cases. 19 (25%) patients died, 9 of whom within the 6 months after biopsy.

Conclusions: Non infectious MC is characterized by a high rate of pSS and B-cell lymphoma at diagnosis and during disease course. 25% of patients died underscoring the importance to identify prognostic factors of renal non infectious MC.

SA-OR106

Abundant APRIL-Producing Macrophages in IgG4-Related Kidney Disease

Takahiro Kawakami,[1] Kazunori Yamada,[1] Ichiro Mizushima,[1] Hiroshi Fujii,[1] Kiyoaki Ito,[2] Shozo Izui,[2] Bertrand Huard,[2] Mitsuhiro Kawano.[1] *[1]Division of Rheumatology, Kanazawa University Hospital, Kanazawa, Japan; [2]Department of Pathology and Immunology, University of Geneva, Geneva, Switzerland.*

Background: IgG4-related disease (IgG4-RD) is a systemic disease characterized by histopathologic features of marked infiltration of IgG4-positive plasma cells in association with fibrosis. Kidney is one of the representative organs affected by this disease, and plasma cell-rich tubulointerstitial nephritis (TIN) is a typical manifestation. However, cellular and molecular mechanisms responsible for plasma cell accumulation in IgG4-related TIN is unknown.

Methods: We performed immunohistochemical staining for a proliferation inducing ligand (APRIL), a member of the TNF superfamily implicated in plasma-cell survival, in IgG4-related TIN with two different antibodies specifically recognizing APRIL-producing cells (Stalk-1) and secreted APRIL (Aprily-8). We also analyzed lacrimal and submandibular glands of patients with IgG4-RD and Sjögren's syndrome, and compared the staining pattern between these organs.

Results: Numerous Stalk-1-positive APRIL-producing cells were detectable in lesions of IgG4-related TIN. Using double immunofluorescence staining method, CD68-positive macrophages were proved to be the major cell type for APRIL production. The secreted form of APRIL, stained with Aprily-8, was distributed close to infiltrating plasma cells. Essentially identical results were obtained in lacrimal or submandibular glands of IgG4-RD. In contrast, APRIL-producing cells were rarely detectable in salivary glands with Sjögren's syndrome. After successful corticosteroid treatment, infiltration of APRIL-producing cells and plasma cells markedly decreased in IgG4-RD.

Conclusions: Abundant infiltration of APRIL-producing macrophages and localization of secreted APRIL close to plasma cells in IgG4-related TIN suggest a role of APRIL in the pathogenesis of plasma cell-rich TIN in IgG4 RD.

SA-OR107

C5 Inhibition in Mice Prevents Fatal C3 Glomerulopathy

Allison Lesher, Takashi Miwa, Sayaka Sato, Wenchao Song. *Pharmacology and Institute for Translational Medicine and Therapeutics, University of Pennsylvania, Philadelphia, PA.*

Background: Improper control of the alternative pathway (AP) of complement has been implicated in the pathogenesis of several kidney diseases including C3 glomerulopathy and atypical hemolytic uremic syndrome (aHUS). Although Eculizumab, a humanized anti-C5 mAb, has been approved for the successful treatment of aHUS, current therapy for C3 glomerulopathy remains nonspecific and ineffective, and many patients eventually progress to end-stage renal failure. We developed a murine model of fatal C3 glomerulopathy and performed experimental therapeutics of C5 inhibition in this study.

Methods: We used gene targeting to create a mouse model of lethal C3 glomerulopathy resembling human dense deposit disease. The mutant mice ($fH^{m/m}/fP^{-/-}$) carried a C-terminal mutation in the negative AP complement regulator factor H (fH) and were also deficient in the positive complement regulator properdin (fP). We treated $fH^{m/m}/fP^{-/-}$ mice with an anti-mouse C5 mAb (BB5.1) at 4 or 6 weeks of age and monitored mouse survival, proteinuria and renal pathology.

Results: $fH^{m/m}/fP^{-/-}$ mice developed severe C3 glomerulonephritis (GN) characterized by heavy proteinuria by 6-8 weeks and all died from rapidly progressive, crescentic GN by 14 weeks. Treatment with anti-C5 mAb starting at 4 weeks of age rescued them from death and prevented proteinuria with marked improvement in renal pathology. Mice appeared healthy throughout a 4-month treatment period, but proteinuria and lethal GN rapidly returned once anti-C5 therapy stopped. When anti-C5 mAb was given to 6-week old $fH^{m/m}/fP^{-/-}$ mice which had already developed high levels of proteinuria, 6 of 10 treated mice also survived with diminished proteinuria and significant improvement in renal pathology.

Conclusions: These results suggest that C5 activation plays a key role in the pathogenesis of C3 glomerulopathy and treatment of human patients with Eculizumab may be effective and should be investigated in clinical studies. This conclusion is in agreement with recent case reports describing anecdotal successes of Eculizumab use in human C3 glomerulopathy patients (see NEJM, 366(12): 1161-1166, 2012).

Recombinant Murine Proteinase 3 Induces Crescentic Glomerulonephritisin NOD Mice Peiqi Hu, Hong Xiao, Ronald J. Falk, J. Charles Jennette. *Pathology and Laboratory Medicine, University of North Carolina, Chapel Hill, NC.*

Background: Proteinase 3 (PR3) is a major target antigen of antineutrophil cytoplasmic autoantibody (PR3-ANCA) that are closely associated with pauci-immune crescentic glomerulonephritis (CGN) and small vessel vasculitis (SVV). However, a direct pathogenic role for PR3-ANCA remains unclear. Here we report the induction of immune-complex CGN in autoimmune-prone NOD mice by immunization with recombinant mouse PR3 (rPR3).

Methods: 8-12 wk-old NOD/LtJ mice were immunized i.p. with 100ug of affinity-purified enzymatically inactive rPR3 (n=11) or BSA (n=5)as control in CFA and boosted i.p. 4 times at 10-20 day intervals with the same doses of antigens in IFA. Autoimmune responses were confirmed by measurement of circulating anti-mouse PR3 by ELISA. Mice were sacrificed at day 75 post-immunization.

Results: NOD mice immunized with rPR3 developed high levels of anti-PR3 antibodies. No anti-PR3 was detected in BSA immunized control mice. The rPR3 recipient mice also developed urine abnormalities with average scores (0-4+) of proteinuria (4.0), leukocytes (3.0) and hematuria (0.36), whereas none of BSA control mice had urine abnormalities. All rPR3-immunized mice had crescentic glomerulonephritis (average 25.6% glomerular crescents and 3.7% glomerular necrosis). Glomeruli had well defined, diffuse, global, finely granular capillary wall staining by immunofluorescence microscopy for IgG, C3 and PR3. There were no glomerular lesions and no immune deposits in control animals.

Conclusions: Immunization of NOD mice with rPR3 can break tolerance toward self-PR3 and result in a high level of circulating anti-PR3. The development of CGN in all rPR3-immunized mice suggests that anti-PR3 antibodies are pathogenic. The presence of well-defined granular capillary wall immunostainging for IgG and PR3 is not typically present in pauci-immune ANCA CGN in patients. Thus, injection of rPR3 induces CGN in NOD mice, but it is not pauci-immune. This phenotypic complexity in NOD mice requires further investigation to understand the role of anti-PR3 in pathogenesis.

All ANCA Are Not Equally Pathogenic Hong Xiao, Peiqi Hu, Donna O. Bunch, Ronald J. Falk, J. Charles Jennette. *Pathology and Laboratory Medicine, University of North Carolina, Chapel Hill, NC.*

Background: Immunizing MPO-/- mice with murine MPO produces anti-MPO IgG and anti-MPO splenocytes that cause necrotizing and crescentic glomerulonephritis (NCGN). Despite 85% identity between human MPO (hMPO) and mouse MPO (mMPO), immunizing MPO-/- mice with hMPO does not produce pathogenic anti-MPO. Thus, regions of heterogeneity between mMPO and hMPO apparently contain pathogenic epitopes. To test this, we immunized MPO-/- mice with chimeric m/hMPO to identify mMPO regions responsible for inducing pathogenic antibodies.

Methods: MPO was divided into four heavy chain segments (a, b, c, d for mMPO; and A, B, C, D for hMPO) in addition to the light chain (l or L). Recombinant full-length mMPO (labcd) and hMPO (LABCD), and 2 chimeric m/h MPO (LAbcd and LABcD) were expressed in HEK293 cells, affinity purified, and used to immunize MPO-/- mice. 1x10^8 anti-MPO splenocytes from these mice (and control anti-BSA splenocytes) were transferred into Rag2-/- mice. Mice were sacrificed on day 13 and blood and tissues collected for analysis.

Results: All Rag2-/- mice that received splenocytes developed similar levels of antibodies to the corresponding antigens. Rag2-/- mice receiving splenocytes against full-length hMPO or BAS did not develop NCGN. Rag2-/- mice receiving splenocytes against MPO containing murine segments b, c, and d developed severe NCGN (avg. 89.5% crescents) similar to the Rag2-/- mice that received splenocytes against full-length mMPO (avg. 90.7% crescents). Rag2-/- mice that received splenocytes against MPO molecules only containing murine segments c developed mild NCGN (avg. 16.3% crescents).

Conclusions: Not all anti-MPO antibodies are equally pathogenic. Anti-MPO to epitopes on full-length hMPO are not pathogenic in mice. Anti-MPO to epitopes on mMPO segments b and/or d induced robust nephrotogenic antibodies. Epitopes on murine segment c induced weakly nephrotogenic antibodies. These data indicate that all anti-MPO antibodies are not equally pathogenic. These observations agree with recent observations that all MPO-ANCA are not equally pathogenic in patients with ANCA-associated vasculitis (Roth et al, ASN 2012 abstract).

The Protective Role of NADPH Oxidase in ANCA-Induced Vasculitis Adrian Schreiber,[1,2] Sylvia Krueger,[1] Friedrich C. Luft,[1] Ralph Kettritz.[1,2] *[1]Experimental and Clinical Research Center (ECRC) at the Max-Delbrueck Center for Molecular Medicine at the Charité, Berlin, Germany; [2]Department of Nephrology, Campus Virchow Clinic, Medical Faculty of the Charité, Berlin, Germany.*

Background: ANCA-activated neutrophils and monocytes cause necrotizing crescentic glomerulonephritis (NCGN) and vasculitis. *In vitro* studies suggest that both reactive oxygen species (ROS) and serine proteases mediate the disease, but their *in vivo* role is unclear. Generation of ROS involves activation of the NADPH oxidase in myeloid cells. We tested the hypothesis that ROS generation is essential to induce NCGN in ANCA disease.

Methods: To induce NCGN, we immunized MPO-deficient mice with murine MPO followed by bone marrow (BM) transplantation from either wild-type (WT) or gp91^{phox}-deficient (gp91$^{phox-/-}$) mice.

Results: WT BM-transplanted mice developed NCGN, whereas the gp91$^{phox-/-}$ BM-transplanted mice developed a significant stronger renal phenotype (13.3±2.5% vs. 60.7±8.9% glomerular crescents). The aggravated NCGN was confirmed in a second independent set of experiments using a different NADPH-knock out (p47$^{phox-/-}$). In addition to necrosis and crescents, gp91$^{phox-/-}$ mice showed markedly stronger glomerular inflammatory cell influx and higher kidney levels of IL-1β (757±120 vs. 1708±360 pg/mg). We hypothesized that superoxide generated by ANCA-stimulated NADPH oxidase down-regulates IL-1β generation by inhibition of the NLRP3-inflammasome and caspase-1, the classical pathway of IL-1β generation. Stimulation of WT murine monocytes with murine anti-MPO IgG resulted in IL-1β generation that was significantly accelerated in both gp91$^{phox-/-}$ und p47$^{phox-/-}$ monocytes. This increase was reduced by pretreatment with a specific caspase-1 inhibitor. Finally, we treated p47$^{phox-/-}$BM transplanted mice with the specific IL-1-receptor antagonist Anakinra. Untreated mice developed NCGN with 45.5±10.1% crescents, whereas Anakinra-treated mice were rescued from the aggravated renal phenotype (14.8±6.3% crescents).

Conclusions: Our data strongly suggest that ROS generated by ANCA-stimulated NADPH oxidase are important for down-regulating the inflammatory cascade by blocking caspase-1- and NLRP3-dependent IL-1β generation.

Mineralocorticoid Receptor Activation in Macrophages Promotes Renal Injury in Experimental Glomerulonephritis David J. Nikolic-Paterson,[1] Louis L. Huang,[1] Yingjie Han,[1] Morag Young,[2] Gregory H. Tesch.[1] *[1]Nephrology and Medicine, Monash University and Monash Medical Centre, Clayton, Victoria, Australia; [2]Prince Henry's Institute of Medical Research, Clayton, Victoria, Australia.*

Background: Clinical and experimental studies have identified that MR antagonists substantially reduce kidney injury; however, the side effect of hyperkalemia, particularly in the context of renal impairment, is a major barrier to the use of this therapy. Thus, it would be beneficial to determine the specific cellular targets and mechanisms by which MR antagonists protect against kidney injury. This studied aimed to establish the contribution of macrophage mineralocorticoid receptor (MR) signaling to kidney inflammation and injury in experimental glomerulonephritis.

Methods: A 15 day model of accelerated anti-GBM glomerulonephritis was examined in groups (n=8) of: (i) wild type (WT) mice; (ii) MR$^{flox/flox}$/LysM^{Cre} mice lacking MR signaling in macrophages; and (iii) WT mice receiving the MR antagonist eplerenone (100mg/kg/bid).

Results: WT mice with anti-GBM glomerulonephritis developed glomerular crescents (37±5%), severe proteinuria and a 6-fold increase in serum cystatin-C. In comparison to these disease controls, MR$^{flox/flox}$/LysM^{Cre} mice and eplerenone-treated WT mice with anti-GBM glomerulonephritis displayed similar proteinuria; however, both groups had a 35% reduction in serum cystatin-C levels ($p<0.05$ vs WT) and had reduced crescent numbers (MR$^{flox/flox}$/LysM^{Cre} = 26±4%, eplerenone-treated = 11±5%, both $p<0.001$ vs WT). The protection seen in MR$^{flox/flox}$/LysM^{Cre} mice was associated with a 50% reduction in macrophages and a marked reduction in gene expression of M1 proinflammatory markers (TNF-α, iNOS, MMP-12). In contrast, the gene expression of profibrotic molecules (TGF-β1, PAI-1, collagen IV) was not affected.

Conclusions: MR signaling in macrophages contributes to the proinflammatory response, glomerular damage and loss of renal function in mouse anti-GBM nephritis. Our comparison with eplerenone treatment shows that MR signaling in macrophages accounts for a substantial degree of the protection achieved with systemic MR blockade in this disease model.

Mineralocorticoid Receptor Depletion in Macrophage Protects against Lipopolysaccharide-Induced Acute Kidney Injury and Inflammation Kenichi Ishizawa,[1] Shigetaka Yoshida,[1] Nobuhiro Ayuzawa,[1] Kohei Ueda,[1] Morag Young,[2] Toshiro Fujita,[1] Masaomi Nangaku,[1] Miki Nagase.[1] *[1]Nephrology and Endocrinology, University of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]Prince Henry's Institute, Clayton, Australia.*

Background: Mineralocorticoid receptor (MR) overactivation is known to promote renal damage via induction of inflammation and fibrosis. In the present study, we examined the role of macrophage MR in acute kidney injury and inflammation, and mechanisms of MR activation in macrophage.

Methods: MR was selectively deleted in macrophage using Cre/loxP system (MΦMRKO). Acute kidney injury model was created by intraperitoneal injection of lipopolysaccharide (LPS) in flox control and MΦMRKO mice. Macrophage M1 or M2 phenotype was evaluated by qPCR and flow cytometric analysis.

Results: LPS provoked acute kidney injury, as revealed by increased serum creatinine and BUN, in control mice. Serum creatinine and BUN was markedly suppressed in LPS-injected MΦMRKO mice. LPS promoted renal infiltration of F4/80-positive macrophages both in control and MΦMRKO mice. However, induction of M1 cytokine by LPS, including TNFα and IL-6, was reduced, whereas expression of M2 markers, such as Arg1 and Fizz1, was enhanced in the kidney of MΦMRKO. Consistently, flow cytometric analysis showed that macrophages in LPS-treated MΦMRKO kidney were polarized to M2 phenotype compared with those in LPS-injected control kidney. LPS-induced M1 cytokine

production was diminished by MR blocker spironolactone or MR knockdown in primary cultured peritoneal macrophages. As for mechanisms of MR activation, LPS augmented MR-dependent luciferase activity, and Rac inhibitor EHT1864 suppressed this activity, suggesting the involvement of Rac1. Indeed, LPS increased active Rac1 in macrophage, and EHT1864 diminished LPS-induced M1 cytokine production. EHT1864 as well as MR blocker eplerenone ameliorated LPS-evoked renal inflammation.

Conclusions: We demonstrate that MR in macrophage plays a pivotal role in the pathophysiology of acute kidney injury, possibly by controlling macrophage M1/M2 polarization. Our data also suggest that Rac1 mediates LPS-induced MR activation and M1 cytokine production in macrophage.

SA-OR113

Increases in Glomerular Permeability due to Free Fetal Hemoglobin (HbF), Released in Early Preeclampsia (PE): Reversal with Scavengers of Reactive Oxygen Species (ROS) Kristinn Sverrisson,[1] Josefin Axelsson,[1] Anna Rippe,[1] Magnus Olsson,[2] Bo Akerstrom,[2] Stefan R. Hansson,[3] Bengt Rippe.[1] *[1]Department of Nephrology, Lund University, Lund, Sweden; [2]Division of Infection Medicine, Lund University, Lund, Sweden; [3]Division of Obstetrics and Gynecology, Lund University, Lund, Sweden.*

Background: The pathogenesis of PE is not fully understood, but increased plasma levels of free HbF have been reported to occur early in PE. Free HbF, as well as adult Hb (HbA), are pro-inflammatory and will release ROS. Alpha-1-microglobulin (A1M) is a heme- and ROS scavenger that counteracts vascular permeability increases induced by HbA in perfused placenta. This study was performed to investigate whether HbF and HbA will increase glomerular permeability and to test whether the ROS scavengers, A1M and Tempol, can prevent their effects.

Methods: In anaesthetized Wistar rats blood access was achieved and the left ureter was cannulated for urine collection. Rats were continuously infused i.v. with either HbA, HbF or cyano-inactivated (CN)-HbF, together with polydisperse fluorescein isothiocyanate (FITC)-Ficoll-70/400, Inulin and ^{51}Cr-EDTA for 2h. Plasma and urine samples were taken simultaneously at different time points and analyzed by high performance size exclusion chromatography (HPSEC) for determination of glomerular sieving coefficients (θ) for Ficoll. Glomerular filtration rate was assessed with ^{51}Cr-EDTA. In separate experiments A1M or Tempol was given before and together with the HbF infusion.

Results: Free HbF caused rapid, partly reversible increases in glomerular permeability to large Ficoll molecules ($Ficoll_{50\text{-}80A}$), contrary to the effects of HbA and CN-HbF. For HbF $\theta\text{-}Ficoll_{70A}$ thus increased from $3.69 \times 10^{-5} \pm 1.11 \times 10^{-5}$ to $2.41 \times 10^{-4} \pm 9.57 \times 10^{-5}$ at 15 min. Treatment with A1M or Tempol reduced the increase in glomerular permeability caused by free HbF.

Conclusions: Free HbF causes marked, rapid and partly reversible increases in glomerular permeability, which is reduced by rescue treatment with ROS scavengers, such as endogenous A1M or by Tempol. Our data strongly suggest that free HbF contributes to the increases in glomerular permeability and proteinuria occurring in PE.

Funding: Government Support - Non-U.S.

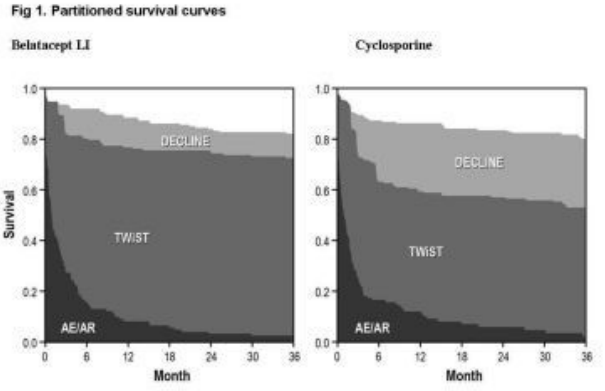
A Q-TWiST Analysis of Belatacept Compared with Cyclosporine in Kidney Transplant Recipients Beth Sherrill,[1] Jianmin Wang,[1] Diana Hall,[1] Anupama Kalsekar.[2] *[1]RTI Health Solutions, Research Triangle Park, NC; [2]Bristol-Myers Squibb, Princeton, NJ.*

Background: The objective of this analysis is to compare quality adjusted survival in patients treated with belatacept (approved regimen) vs cyclosporine (CsA) in BENEFIT-EXT clinical trial using a novel methodology: quality-adjusted time without symptoms or toxicity (Q-TWiST).

Methods: The time period from transplant until graft loss or death or end of the trial was partitioned into 3 health states. AE/AR (toxicity) included time spent with adverse events or acute rejection prior to renal function decline, which was defined as the earliest date at which the calculated GFR decreased to ≤ 30 mL/min/1.73m^2 after excluding the first 56 days post-transplant. DECLINE included time post-renal function decline until death/graft loss/end of trial and TWiST was the remaining time in trial. Kaplan-Meier analyses were run to determine time spent in AE/AR, TWiST and DECLINE. Q-TWiST was defined as a weighted average of the 3 health state durations, weights accounting for quality of differences between the health states.

Results: Overall time to all-cause graft loss and time with adverse events/acute rejection were comparable between the belatacept (N=175) and CsA (N=184) groups.



Survival analyses of time to renal function decline, demonstrated separation of groups beginning at month 3 and increasing over time (p =0.0002). Mean time spent without toxicity or renal function decline (TWiST) in belatacept group was 6 months longer than cyclosporine group (p=0.0001). Q-TWiST differences between groups favored the belatacept group across an entire matrix of weights and were statistically significant for most plausible values.

Conclusions: The renal-sparing effects of Belatacept may allow patients more quality-adjusted survival time than cyclosporine.

SA-OR115

Likelihood of Improving or Sustaining Renal Function over Four Years with Belatacept or CSA: Insights from the BENEFIT-EXT Long-Term Extension Study J. Grinyo,[1] B. Charpentier,[2] R. Zhang,[3] M. Abouljoud,[4] F. Lehner,[5] M. Rial,[6] J. Morales,[7] M.B. Harler,[8] J. Medina-Pestana.[9] *[1]Univ Hosp Bellvitge; [2]Bicêtre Hosp; [3]Tulane Univ; [4]Henry Ford Hosp; [5]Medizinische Hochschule Hannover; [6]Instituto de Nefrologia; [7]Hosp Universitario 12 de Octubre; [8]Bristol-Myers Squibb; [9]Hosp do Rim e Hipertensão.*

Background: Sustained renal function improvement and a consistent safety profile were observed at 4 yrs in belatacept-treated recipients of extended criteria donor (ECD) kidneys in the long-term extension (LTE) of BENEFIT-EXT. Changes in cGFR stage of pts in the LTE cohort are reported.

Methods: In BENEFIT-EXT, recipients of ECD kidneys were randomized to a more or less intensive (LI) belatacept regimen, or CsA. Pts remaining on assigned therapy through Yr 3 were eligible to enter the LTE. This posthoc analysis used cGFR (MDRD) and assessed shifts in cGFR staging between Months (Mos) 3 and 48 in LTE pts. cGFR stages were defined per the KDOQI classification of CKD stages. cGFR was imputed as 0 for death or graft loss. Only pts who had a GFR value at Mo 3 and Mo 48 are included in the analysis (99/113 LI and 74/87 CsA pts had data available at both Mos 3 and 48).

Results: GFR stage at Mo 3 and 48 in LI and CsA pts of the LTE are shown in the Figure. Among Stage 2 pts at Mo 3, GFR stage was sustained or improved through Mo 48 in 17 (68%) LI and 3 (18%) CsA pts. In Stage 3 pts, GFR stage from Mo 3–48 was sustained or improved in 59 (94%) LI and 33 (67%) CsA pts. At Mo 3, 11 LI and 6 CsA pts were in Stage 4; 10 (91%) LI and 5 (83%) CsA pts sustained or improved their GFR stage through Mo 48. Trends from Mo 12–48 were similar to those reported above.

Conclusions: Belatacept LI-treated pts receiving ECD kidneys were more likely than CsA pts to experience sustained or improved renal function over 4 yrs in BENEFIT-EXT LTE cohort.

Pre-Transplant Polyoma BK-Virus Replication in Urine or Blood of Donor or Recipient Is a Risk Factor for Post-Transplant BK Virus Infection of the Recipient Anke Schwarz,[1] Sylvia Linnenweber,[1] Hermann G. Haller,[1] Albert Heim,[2] Lubna Raggub,[2] Corinna Schmitt.[2] *[1]Nephrology, Hannover Medical School, Hannover, Germany; [2]Virology, Hannover Medical School, Hannover, Germany.*

Background: Spontaneous polyoma BKV replication in donor and/ or recipient urine or blood before renal transplantation (tx) may be a risk factor for post-tx recipient infection. This was tested in donor-recipient pairs before and after living transplantation.

Methods: Since 2008, we test blood and urine of donor-recipient pairs before living kidney tx by quantitative PCR (qPCR) (Cepheid-Affigene); the recipient then is followed by post-tx qPCR controls. In post-tx viremic and/ or viruric patients, the pre-tx and post-tx blood and/ or urine specimens are compared by sequencing of the BK VP1 typing region and additionally of the complete VP1 gene.

Results: 203 donor-recipient pairs had blood and urine tests before and recipient tests after tx; 57 of them showed pre-tx donor (n=54) or recipient (n=38) urine or blood viral replication. 68/180 recipients (37%) with a post-tx follow-up of at least 3 mos developed either BKV nephropathy (n=19, 11%) or BKV replication in blood or urine (n=49, 27%) after tx; in 32 of these 68 recipients (47%) donor or recipient had pre-tx viral replication in blood or urine compared to 25 out of 112 patients (22%) without post-tx BKV-infection (p=0.001). In 28/50 donors (56%) and 15/35 recipients (43%) with pre-tx BKV replication in urine genotyping of the VP1 region was possible. In 14/14 donor-recipient pairs with positive pre-tx donor replication and later recipient BKV-infection, the BKV VP1-sequence was identical (100%); however, in only 3/6 pairs with pre-tx recipient replication the VP1-sequence was identical (50%, p=0.001), while in 2 other pairs (17%), it was not identical. In 1 pair with positive pre-tx donor as well as positive recipient urine replication (different subtypes), later BKV-infection of the recipient showed the subtype of the donor.

Conclusions: Pre-tx BKV replication in donor or recipient urine or blood is a risk for later BKV-infection of the recipient. According to genotyping of the BK VP1 typing region, the donor seems to carry the higher risk.

SA-OR117

Outcomes of Simultaneous Liver and Kidney Transplantation Using Donation after Brain Death Compared to Donation after Cardiac Death Donors Umar Farooq, Christin M. Spatz, Erik Lehman, Tarek Alhamad, Nasrollah Ghahramani, Tadahiro Uemura. *Penn State University Hershey Medical Center, Hershey, PA.*

Background: The demand for organs for transplantation exceeds the supply of available donation after brain death (DBD) donors. In order to expand the donor pool, use of donation after cardiac death (DCD) donors has become more common. In renal and liver single organ transplant, DCD organs are frequently utilized and have similar outcomes to DBD organs. Outcomes for recipients of DCD organs for simultaneous liver and kidney transplant (SLKT) are not well established.

Methods: We used the UNOS (United Network for Organ Sharing) database to compare recipient outcomes of DBD and DCD donation for SLKT in regard to graft survival. Multivariate survival analysis was performed using a Cox proportional hazards model to evaluate graft survival controlling recipient and donor factors.

Results: A total of 4132 SLK recipients were identified from which 4028 (97.5%) received DBD organs and 104 (2.5%) received DCD organs. The DBD recipients had a higher MELD score (29.3 vs. 26.8) and older donors (35.4 vs. 32 years) compared to DCD. The mean graft survival in years (y) was lower for DCD liver (6.8y vs. 10y p=0.015) and kidney (6.6y vs. 9.3y p=0.027) compared to DBD recipients. There was improved graft survival in DBD compared to DCD with the unadjusted hazard ratio (HR) for liver and kidney graft survival 0.68 (p =0.015) and 0.71 (p = 0.027), respectively. When the model was adjusted for recipient age, donor age, sex, dialysis status, MELD score, and UNOS region the allograft survival benefit of DBD over DCD remained positive with respective HRs of 0.56 and 0.58.

Conclusions: In SLKT, DBD recipients have a statistically significant improved graft survival when compared to DCD recipients even after adjustment for common co-variables. Although outcomes with DCD recipients were inferior to DBD, use of these organs has previously been shown to offer a survival advantage compared to no transplant. Further studies are needed to determine which patients may benefit most from DCD donation.

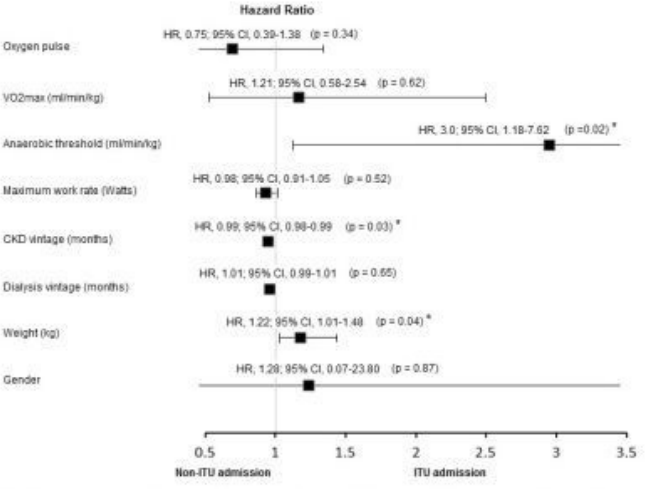
Reduced Functional Measure of Cardiovascular Reserve Predicts Admission to Intensive Care Unit for Patients Undergoing Kidney Transplantation Stephen M. Ting,[1] Hasan Iqbal,[1] Prithwish Banerjee,[1] Robert Higgins,[1] Chris H.E. Imray,[1] Nicolas Aldridge,[1] Rosemary Bland,[2] Daniel Zehnder.[2] *[1]University Hospitals Coventry & Warwickshire NHS Trust, UK; [2]Warwick Medical School, University of Warwick.*

Background: There is no effective preoperative risk stratification assessment for patients undergoing kidney transplantation that is able to identify those at risk of cardiopulmonary complication needing intensive care (ICU) support. We sought to determine if objective measures of cardiovascular reserve could identify these high risk patients.

Methods: 68 kidney transplant recipients were prospectively assessed between 2010 and 2012. Cardiopulmonary exercise testing (CPX), TD echo and aortic pulse wave velocity were performed within 4 weeks prior to surgery.

Results: 13 patients (19%) required admission to ICU. There were no deaths. In univariate analysis, significant findings in the ITU vs non-ITU attendees – female (69.2 vs 30.8%, p=0.01), weight [60.6 (56.5-75.2) vs 72.7 (65.6-78.5) kg, p=0.02], CKD vintage (p=0.04), dialysis vintage (p=0.001), VO2max [18.1 (15.3-19.5) vs 21.3 (17.7-25.7) ml/min/kg, p=0.02], anaerobic threshold (AT) [10.7 (9.2-11.2) vs 12.4 (10.4-13.3) ml/min/kg, p=0.002], oxygen pulse (p=0.02), maximal work rate (p=0.001). Echo and aortic compliance measures were not significant. In multivariate logistic regression analysis, reduced AT is the most significant independent predictor of ICU admission (p= 0.02). Shorter duration of CKD is associated with a lower risk (p= 0.03) and lower body weight is associated with a higher risk of ICU admission (p= 0.04).



Independent predictors of ITU admission following kidney transplantation

Conclusions: Measures of cardiovascular reserve, especially the AT, strongly predict post-operative morbidity in kidney transplant recipients. This is the first prospective study to demonstrate the usefulness of CPX testing as a preoperative risk stratification tool for kidney transplantation.

Racial Variation in Medical Outcomes among Older Living Kidney Donors: (From the WHOLE-DONOR Disparities Collaborative) Krista L. Lentine,[1] Dorry L. Segev,[2] David Axelrod,[3] Daniel C. Brennan,[4] Amit X. Garg,[5] Connie L. Davis,[6] Thomas E. Burroughs,[1] Janet E. Tuttle-newhall,[1] Mark Schnitzler.[1] *[1]Saint Louis Univ; [2]Johns Hopkins; [3]Dartmouth; [4]Washington Univ; [5]Univ Western Ontario; [6]Univ Washington.*

Background: We constructed a novel database that links Organ Procurement and Transplant Network (OPTN) identifiers of living kidney donors (LKDs) to Medicare billing claims to examine correlates of post-nephrectomy (NTX) medical diagnoses in a sample of generally older prior LKDs.

Methods: Eligible persons had OPTN records of serving as a LKD in 1987-2008 and post-NTX billing claims within the available claims data (2004-2008). Post-NTX medical diagnoses of hypertension (HTN), chronic kidney disease (CKD), and diabetes mellitus (DM) were ascertained by ICD-9-CM diagnosis codes on claims. We examined relative risks (adjusted hazard ratio, aHR) of post-donation diagnoses by race using multivariate Cox regression with left-censoring for time from NTX to start of captured Medicare. Diagnosis rates within observed Medicare data were also examined as rates per 100-person years (PY).

Results: We identified 4007 prior LKDs, of whom 40% were men. Median ages at NTX and at the start of captured Medicare claims were 57 & 65 yrs, respectively. Racial composition included: 8.1% black, 83.4% white, and 5.7% Hispanic. After adjustment for age and gender, black LKDs, as compared with white LKDs, had an increased risk of HTN (aHR 1.41, P=0.0003), DM (aHR 1.50, P=0.009) and CKD (aHR 1.85, P<0.0001) diagnoses. Diagnosis rates per 100 PY enrollment were higher in black versus white LKDs (Table).

ADJUSTED RELATIVE RISKS FOR POST-DONATION MEDICAL DIAGNOSES AMONG MEDICARE-INSURED PRIOR LIVING KIDNEY DONORS

	Hypertension Diagnosis aHR (95% CI)	Diabetes Diagnosis aHR (95% CI)	CKD Diagnosis aHR (95% CI)
Age (per yr)	**1.02 (1.01–1.02)†**	1.00 (1.00–1.01)	**1.03 (1.02–1.04)†**
Male	**1.12 (1.041–1.23)***	**1.38 (1.16–1.65)†**	**2.33 (1.95–2.78)†**
Race			
Black	**1.41 (1.17–1.70)***	**1.50 (1.11–2.04)†**	**1.85 (1.34–2.46)†**
White	Reference	Reference	Reference
Hispanic	1.17 (0.95–1.45)	**2.11 (1.53–2.89)†**	1.23 (0.75–1.69)
Other	1.03 (0.76–1.39)	1.6 (1.00–2.57)	1.18 (0.71–1.98)

aHR, adjusted hazards ratio * P<0.04-0.0001; † P <0.0001

POST-DONATION MEDICAL DIAGNOSES RATES DURING CAPTURED MEDICARE BENEFITS PERIOD

	Rates per 100 Person-Years of Medicare Enrollment		
	Hypertension Diagnosis	Diabetes Diagnosis	CKD Diagnosis
Black	**9.12**	**3.30**	**3.08**
White	**7.41**	**2.20**	**2.14**
Hispanic	**7.56**	**3.56**	**2.19**

Conclusions: Among older prior LKDs enrolled in Medicare, black LKDs experience higher relative risks of HTN, DM and CKD compared with white LKDs. These data support a need for increased monitoring and evaluation of health outcomes among African American living kidney donors.

SA-OR120

Systolic Blood Pressure and Risk of Cardiovascular-Related Death in the FAVORIT Trial Daniel E. Weiner,[2] Myra A. Carpenter,[1] John W. Kusek,[3] Lawrence G. Hunsicker,[4] Andrew S. Levey.[2] *[1]Biostatistics, University of North Carolina, Chapel Hill, NC; [2]Tufts Medical Center, Boston, MA; [3]NIDDK, NIH, Bethesda, MD; [4]University of Iowa, Iowa City, IA.*

Background: The 2009 Kidney Disease: Improving Global Outcomes (KDIGO) clinical practice guidelines recommend a systolic blood pressure (SBP) target of 130 mm Hg or lower in kidney transplant recipients (KTRs). Some studies have shown increased risks of cardiovascular events and deaths in patients with diabetes when targeting low SBP levels (i.e., a J-shaped survival curve). The impact of specific SBP targets has not been studied in KTRs.

Methods: FAVORIT was a randomized controlled trial to evaluate homocysteine-lowering therapy on CVD and kidney outcomes in 4,110 KTRs in the US (n=3,000), Brazil (n=612) and Canada (n=498) with elevated homocysteine levels and stable graft function.

Results: Among 3,673 participants with complete baseline data, mean ± SD age was 52 ± 9.4 years; 37% were women, 41% had a history of diabetes, and 64% had eGFR between 30 and 60 ml/min/1.73m^2. Mean follow-up time was 4.1 ± 1.5 years. Most participants (89%) were being treated for HTN. The mean SBP at baseline was 136 ± 20 (interquartile range, 122 – 147.5) mm Hg. CV-related death occurred in 172 (5%) of KTRs. After adjusting for age, sex, race, randomized group, country, diastolic blood pressure, use of antihypertensive medications, history of CVD, diabetes, smoking, lipids, BMI, eGFR, graft vintage and donor type, each 20 mm Hg increase in SBP was associated with a 44% increase in risk of CV-related death (HR: 1.44, 95% CI: 1.22 – 1.70), with no suggestion of a 'J'-shape. In the subgroup of 1,695 KTRs with eGFR ≤45 ml/min/1.73m^2, there were 104 CV-related deaths (HR: 1.31, 95% CI: 1.06 – 1.61). In this subgroup, those with SBP <120 mmHg had the lowest risk of CVD-death (HR: 0.84, 95% CI: 0.39 – 1.84, vs reference of 120-129 mm Hg).

Conclusions: These results suggest that among KTRs lower systolic blood pressure is associated with lower risk of CV-related death throughout the entire range measured. Subgroup analysis of the risk of CV-related death among KTRs with lower eGFR is consistent with this finding.

Associations between Metabolic Syndrome, Renal Function, and Histology in Living Kidney Donors Yasushi Ohashi, George Thomas, Sankar D. Navaneethan, Emilio D. Poggio. *Nephrology and Hypertension, Glickman Urological and Kidney Institute, Cleveland Clinic, Cleveland, OH.*

Background: Prospective living kidney donors are now older and have higher BMI along with other co-morbidities that are known risk factors for chronic kidney disease. We evaluated the association of metabolic syndrome (MetS) with renal function and histology in living kidney donors.

Methods: We identified 376 donors between 2005 to 2011 in whom we assessed metabolic risk factors, kidney size, function, and histology of implant biopsy at donation, 158 of whom had post-donation follow-up [median (10–90th percentile) of 13 months (6–26 months)]. MetS was defined using modified NCEP-ATP III criteria, and histological abnormalities were defined as any one or more of: a) >5% global glomerulosclerosis, b) >5% interstitial fibrosis with any tubular atrophy, or c) any arteriosclerosis.

Results: MetS was present in 47 (12.5%) donors, who were more likely to be male (53.2% vs. 38.9%, p<0.05), older (45.3 ± 9.9 vs. 40.7 ± 10.6 years, p<0.01) and Caucasian (97.9% vs. 89.4%, p<0.05). There was no difference in kidney volumes by CT scan between MetS and non-MetS, but donors with MetS were more likely to have abnormal histology (65.7% vs. 42.7%, p<0.01) and a significantly lower iothalamate GFR (iGFR) (90.6 ± 14.3 vs. 99.3 ± 20.2 ml/min/1.73m^2, p<0.01). Rise of serum Creatinine (SCr) post-nephrectomy was significantly associated with male gender, African-American (AA) race, and higher kidney volume; whereas recovery of SCr was associated with younger age and AA race, but not with MetS nor with abnormal histology. Donors with lower HDL and elevated uric acid were more likely to develop MetS after donation, manifesting with a significantly higher BMI, diastolic blood pressure, and elevated triglyceride post-nephrectomy.

Conclusions: MetS is associated with histological abnormalities and lower iGFR in living kidney donors, but nephrectomy in these donors was not associated with subsequent changes in kidney function. There is a predisposition for development of MetS in donors who had lower HDL and elevated uric acid levels pre-donation. These findings emphasize the importance of life style modification in living kidney donors.

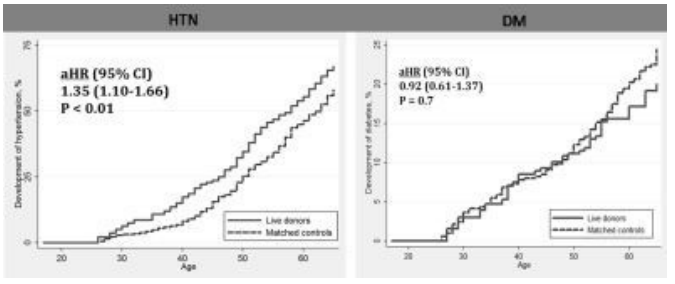
SA-OR123

Hypertension and Diabetes after Living Kidney Donation: Racial Differences and Comparison to Healthy Matched Controls Brian Boyarsky, Mara Mcadams, Allan Massie, Kyle Van Arendonk, M. Grams, Po-han Chen, Dorry L. Segev. *Johns Hopkins.*

Background: Though living donation is generally considered safe, long-term morbidity is not well characterized. Recent studies suggest a higher rate of hypertension (HTN) and diabetes in black versus white donors, but no comparisons have been made to healthy non-donors, so the risk attributable to donation remains unknown.

Methods: We surveyed 1,046 donors between 1970-2011. Participants reported new onset HTN and diabetes since donation, as well as all current medications; interviews were augmented by detailed review of medical records since donation. Healthy non-donors were drawn from a large cohort study where contraindications to donation were captured, and matched controls who would have been eligible for donation at the time of matching were selected.

Results:



19% of donors (26% black, 18% non-black) developed HTN. Compared to healthy non-donors, donors had an increased risk of post-donation hypertension (aHR 1.35 95%CI 1.10-1.66, p <0.01); this risk was seen in non-black donors (aHR 1.44 95%CI 1.15-1.83, p <0.01) but not in black donors (aHR 1.01 95%CI 0.62-1.63, P=0.9). 4% of donors (8% black, 3% non-black) developed diabetes. Compared to healthy non-donors, donors had a similar rate of developing diabetes (aHR 0.92 95%CI 0.61-1.37, P=0.7), with no differences by race.

Conclusions: Living donors are at a greater risk for developing HTN than healthy controls. Interestingly, while black donors had a higher rate of HTN compared with non-black donors, a risk attributable to donation was only seen in non-black donors. Donors did not have an increased risk of developing diabetes compared to healthy controls, contrary to some recent reports. It is critical to compare donors to healthy non-donors in studies of post-donation morbidity, so that risks attributable to the actual donation can be understood.

TH-PO001

Angiopoietin-2 Contributes to the Pathophysiology of Septic Acute Kidney Injury Sascha David,[1] Chandra C. Ghosh,[2] Aditi Mukherjee,[2] Eliyahu V. Khankin,[2] S. Ananth Karumanchi,[2] Samir M. Parikh.[2] *[1]Nephrology and Hypertension, Medical School Hannover, Germany; [2]Medicine, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA.*

Background: Intensive basic research into sepsis and associated multi organ dysfunction has yielded numerous putative molecular targets, but many have not translated into successful therapies. We hypothesized that Angiopoietin-2 (Angpt-2), a partial antagonist of the endothelium-stabilizing receptor Tie-2 secreted by endothelium, contributes to acute kidney injury (AKI) and adverse outcomes in this disease. We determined its mechanistic effects (i.e. vascular permeability and inflammation) by depletion experiments in murine and cellular models.

Methods: Murine sepsis was induced by endotoxin (LPS) and cecal ligation and puncture (CLP) in Angpt-2 heterozygotes (+/-) or wildtype littermates (+/+). Vascular leakage was assessed by bronchoalveolar lavage and consecutive protein measurements. Fluorescent immunohistochemistry (IF) from snap frozen kidneys and lungs was used to visualize changes in adhesion molecule expression (ICAM-1, VCAM-1) and tissue inflammation (Cd11b). Immunofluorescence for cytoskeletal (F-actin) and junctional (VE-cadherin) components from human micro-vascular endothelial cells (HMVEC) challenged with septic serum +/- Angpt-2 Antibody was performed.

Results: Angpt-2 +/- mice compared to their wildtype littermates had less adhesion molecule expression (VCAM-1) in different organ beds that consequently led to less tissue inflammation (Cd11b), and less vascular leakage. As a result heterozygotes developed milder AKI (crea: WT 0.6 mg/dl vs. het 0.2 mg/dl, p=0.02). Moreover, Angpt-2 +/- mice experienced over 40% survival advantage in both models (p = 0.004 and 0.018) without treating sepsis per se. Next, we studied the effect of human septic serum on endothelial cell architecture. Compared to control serum, septic serum disrupted the barrier function of HMVECs, an effect fully neutralized by a monoclonal Angpt-2 antibody.

Conclusions: We conclude that sepsis induced Angpt-2 release contributes to AKI and adverse outcomes in sepsis, opening a new avenue for therapeutic investigation.

TH-PO002

Hypoxic Preconditioning Enhances the Benefit of Bone Marrow Mesenchymal Stem Cell Therapy for Treatment of Acute Kidney Injure by Improving Cell Homing Xiaofang Yu,[1] Chunlai Lu,[2] Hong Liu,[1] Yi Fang,[1] Xiaoqiang Ding.[1] *[1]Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China; [2]Thoracic Surgery, Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: Hypoxic preconditioning (HP) of bone marrow mesenchymal stem cell (MSC) has been tested for enhancing the benefit of cell therapy for cardiovascular disease after transplantation. The present study was to test whether hypoxic preconditioned MSC transplantation could enhance the efficacy of cell therapy on AKI by stimulating MSC homing to the injured kidney using magnetic resonance imaging (MRI).

Methods: Passage 3 MSC was subjected to HP by culture for 24 h in 200μmol/L cobalt.

Results: Compared with normoxia preconditioning (NP), HP significantly increased the mRNA and protein expressions of HIF-1α and CXCR4 in MSC. HP enhanced the migration of MSC in vitro, as assessed by scratch wound healing assay and Transwell assay, and this effect was removed by siRNA HIF-1α or AMD3100 incubation. Intracarotid administration of SPIO labeled HP-MSC (3×10^6/animal) immediately to anesthetized rats with ischemia-reperfusion-induced AKI (40-min bilateral renal pedicle clamping) resulted in more cells homing to the ischemia kidney and longer retaining time than NP-MSC, as demonstrated by MR imaging. Histologically, HP increased the number of MSC located in glomerular capillaries than NP, as evidenced by Prussion bun staining. Importantly, occasional tubules showed iron labeling in HP group, while no tubules had iron labeling in NP group, indicating the possibility of tubular transdifferentiation after HP. Furthermore, the increased recruitment of HP-MSC was associated with reduced kidney injure and enhancedfunctional recovery.

Conclusions: HP could improved the migration of MSC in vitro through the activation of HIF-1α and up-regulation of CXCR4, and HP could be a useful method of enhancing the homing and prolonging the retaining of MSC for AKI cell therapy.

Redox-Sensitive Glycogen Synthase Kinase 3β Directed Control of Mitochondrial Permeability Transition: Rheostatic Regulation of Acute Kidney Injury Zhen Wang,[1,2] Yan Ge,[1] Rujun Gong.[1] *[1]Nephrology, Brown Medical School, Providence, RI; [2]Department of Nephrology, Tongji University School of Medicine, Shanghai, China.*

Background: Mitochondria dysfunction plays a pivotal role in the development of acute kidney injury (AKI) and necroapoptotic death of tubular epithelial cells. Evidence suggests that glycogen synthase kinase (GSK) 3β is a novel modulator of AKI.

Methods: The regulatory effect of GSK3β on mitochondrial permeability transition (MPT) was examined in cultured tubular epithelial cells and in a murine model of AKI induced by the pro-oxidant herbicide praquat.

Results: In tubular epithelial cells, a specific subcellular distribution of GSK3β was detected in mitochondria. Co-immunoprecipitation studies confirmed that GSK3β physically interacts with cyclophilin F, a key component of the MPT pore complex that possesses multiple GSK3β phosphorylation consensus motifs as demonstrated by *in silico* analysis, suggesting that GSK3β have a direct control of MPT pore activity. Upon a strong burst of reactive oxygen species elicited by praquat, the activity of the redox-sensitive GSK3β was drastically enhanced. This was accompanied with elevated phosphorylation of cyclophilin F and associated with MPT and cell death. TDZD-8, a highly selective small molecule inhibitor of GSK3β abrogated praquat-induced phosphorylation of cyclophilin F, markedly improved cellular viability and prevented MPT and cell death. Conversely, ectopic expression of a constitutively active GSK3β amplified the effect of praquat on cyclophilin F phosphorylation and sensitized cells to praquat induced MPT and death. *In vivo*, praquat injection elicited marked oxidant injury in the kidney and resulted in acute kidney dysfunction and massive tubular apoptosis and necrosis. Consistent with *in vitro* findings, the activity of GSK3β was enhanced in the injured kidney, associated with increased phosphorylation of cyclophilin F and MPT. Concomitant treatment with TDZD-8 blocked GSK3β activity in the kidney, blunted cyclophilin F phosphorylation, prevented MPT, attenuated tubular damage and improved praquat-induced AKI.

Conclusions: Our data suggest that redox-sensitive GSK3β regulates AKI via controlling the activity of MPT pore.

TH-PO004

Tamm-Horsfall Protein (Uromodulin) Is Uniquely Trafficked during Acute Kidney Injury and Its Presence Promotes Faster Recovery Tarek M. El-Achkar,[1] Monique R. Heitmeier,[1] Yan Liu,[2] Ruth A. Mccracken,[1] Xue-Ru Wu.[2] *[1]Nephrology, St. Louis University and St. Louis VA Medical Center; [2]Urology, New York University and Manhattan VAMC.*

Background: Tamm-Horsfall protein (THP) is a glycoprotein uniquely expressed in the thick ascending loops (TAL) of Henle. We recently showed that THP has a protective role in acute kidney injury (AKI). We also showed that its expression is increased during kidney recovery without an increase in urinary excretion. The significance of this expression pattern and its relationship to kidney recovery is unclear.

Methods: Using a murine model of ischemia–reperfusion (IRI), we studied the changes in THP expression using immunogold electron microscopy. We also measured changes in THP serum levels and its effect on tubular inflammatory signaling and renal recovery.

Results: THP was predominantly expressed at the apical domain of the TAL in sham sections. 48 hours after IRI, THP gold labeling was increased in the cellular and basolateral aspect of TAL, along with a marked increase in the interstitium. Occasionally, THP was also identified in the basolateral aspect of S3 segments. To investigate if THP is retained within the kidney or released systemically, we measured its serum levels by ELISA. During recovery from AKI, the serum level of THP in mice subjected to IRI was significantly higher compared to sham, supporting a significant uptake of THP by the peritubular vascular network. This trafficking pattern is unique to THP, because the expression of NKCC2 was unaltered by ischemia. THP also inhibited the expression of the macrophage chemo-attractant MCP-1 in HK-2 proximal cells subjected to ischemia. In addition, THP deficiency was associated with delayed recovery from AKI In THP-/- mice compared to wild type mice subjected to an equivalent degree of injury.

Conclusions: Our findings suggest that THP is specifically directed towards the interstitial and intravascular space in the recovery phase of AKI, where it down-regulates tubular inflammation and possibly promotes repair. Because of its increased systemic levels, we propose that serum THP could serve as a biomarker predicting renal recovery and possibly mediating a protective distant effect after kidney injury.

TH-PO005

Transcriptomic Analysis of Proximal Straight Tubules (PST) and Medullary Thick Ascending Limbs (mTAL) during Cisplatin (CP) Acute Kidney Injury (AKI) Jonathan Michael Starkey,[2] Wen Liu,[1] Beth Zavilowitz,[1] Bruce A. Luxon,[2] Lisa M. Satlin,[1] Robert L. Safirstein.[3] *[1]Pediatrics, Mount Sinai School of Medicine, New York, NY; [2]Biochemistry & Molecular Biology, UTMB Health, Galveston, TX; [3]Internal Medicine, UAMS, Little Rock, AR.*

Background: CP AKI is characterized by PST necrosis while the mTAL remain intact. Regenerating cells reline the PST accompanied by a robust transcriptional response.

Methods: We performed microarrays of PST and TAL during CP (20mg/kg or saline) AKI in mice to reveal the cell source of these changes. At 24 and 72 h after injection (encompassing early and peak events in CP AKI), PST and mTAL were individually micro-dissected and total RNA prepared from pooled samples of each segment. Affymetrix 3' IVT Mouse Expression Set 430 v 2.0 microarrays were used and results analyzed using Bioconductor packages in the R programming environment. Differentially expressed mRNA transcripts were analyzed by IPA.

Results: In the PST at 24 h expression of oxidative response genes, most notably those induced by CEBPA (Regulation z-score 2.5, p = 0.01), was observed. In the PST at 72 h, expression of genes relevant to lipid metabolism and molecular transport were reduced indicative of mitochondrial dysfunction. Pathway analysis supports a key role of mitochondrial dysfunction and network analysis reveals an NFE2L2-driven signaling hub. By contrast in the TAL at 72 h, gene ontology analysis reveals prominent changes in genes regulating cellular movement, immune cell trafficking (z-score 2.175, p = 0.003) and genes developmentally regulated, including the Hedgehog induced GLI1 transcription factor (Regulation z-score -2.5, p=0.002) recently connected to fibrotic reactions in the kidney. Network analysis reveals hubs of CEBPB, NFkB, p53 and ERK in the TAL at 72 h.

Conclusions: The data suggest that the response to CP AKI includes an increase in oxidative stress and early inflammation in the PST and an inhibition of cell cycle events in the TAL along with delayed inflammatory activity. The results reveal a distinct pattern of gene expression in the two segments in response to CP and suggest an interaction among the segments to direct repair of the injury.

Downregulation of Matrix Metalloproteinase-8 Is Associated with Worsened Effects of Ischemic Acute Kidney Injury

Rajit K. Basu,[1] Emily Donaworth,[1] Prasad Devarajan,[2] Hector R. Wong.[1] *[1]Pediatric Critical Care, Cincinnati Childrens Hospital Medical Center, Cincinnati, OH; [2]Pediatric Nephrology, Cincinnati Childrens Hospital Medical Center, Cincinnati, OH.*

Background: After ischemic acute kidney injury (AKI), the role of the matrix metalloproteinase family of proteases (MMPs) is poorly understood. While knock-out models of the gelatinases MMP-2 and MMP-9 offer protection from ischemic AKI, little is known about the role of neutrophil collagenase (MMP-8), presumed to be anti-fibrotic. We recently reported the derivation and validation of serum MMP-8, using microarray technology, as a putative biomarker of severe sepsis associated AKI (SSAKI) in critically ill children.

Methods: Here we report an association between MMP-8 and ischemic AKI using a mouse model of ischemic AKI (bilateral renal pedicle clamping for 30 minutes) in wild type and MMP-8 null mice.

Results: Mice subjected to ischemia-reperfusion had significantly higher serum MMP-8 levels than sham operated controls after 24 hours (61 [50-100] vs. 50 [40-52], p=0.03). However, tissue MMP-8 expression and activity were significantly decreased in ischemic AKI mice at 6, 12, 24, and 48 hours (6h, etc.) after ischemia. (Decrease in activity: 6h – 52%, 12h – 37%, 24h – 25%, 48h – 52%; decrease in expression: 6h – 78%, 12h – 27%; $p < 0.05$ for all experiments). Use of an MMP-8 inhibitor resulted in higher serum creatinine after ischemia versus untreated mice (23% increase, $p = 0.05$). Additionally, the fold increase in serum creatinine after ischemia versus sham was higher in MMP-8 null mice than wild type controls (9.6 vs. 2.5). Finally, immunofluorescent staining 24 hours after ischemia demonstrates decreased tubular epithelial MMP-8 staining in mice after AKI versus sham controls.

Conclusions: Taken together, our data suggest that while serum MMP-8 levels may increase in response to ischemia, mirroring a neutrophilic inflammatory response, MMP-8 is down-regulated at the level of kidney. This may reflect suppression of the homeostatic role of MMP-8 after AKI – required to balance the potential deleterious effects of other MMPs (2 and 9). Further work is required to understand the precise role of MMP-8 after ischemic AKI.

TH-PO007

Exposure of Cultured Proximal Tubular and Mesenchymal Stem Cells to Serum from Rats with Acute Kidney Injury Induces Oxidative and Mitochondrial Stress

Jon D. Ahlstrom,[1] Florian Toegel,[2] Zhuma Hu,[1] Ping Zhang,[1] Christof Westenfelder.[1,3] *[1]Medicine, University of Utah and VA Medical Centers, Salt Lake City, UT; [2]Medicine, Brigham and Women's Hospital, Boston, MA; [3]Physiology, University of Utah, Salt Lake City, UT.*

Background: Acute kidney injury (AKI) is a common and largely treatment-resistant syndrome in which complex mechanisms mediate injury and repair. "Uremic" changes in the internal milieu caused by Ischemia/Reperfusion (I/R)-induced AKI result in pathological manifestations in virtually all major organs.

Methods: To further investigate the distant organ effects of of acute azotemia, either induced in rats by bilateral IR-AKI or bilateral nephrectomy (NPHX), we exposed cultured normal rat kidney cells (NRK, proximal tubular) and rat mesenchymal stem cells (MSC), highly renoprotective in AKI (AJP Renal 2005), to 10% serum obtained from rats 24 hrs post 50 min IR-AKI, NPHX or from shams.

Results: Both AKI and NPHX resulted at 24 hrs in similar increases in serum creatinine levels (AKI: 4.9, NPHX: 4.8 mg/dL). Exposure of both cell types to 10% AKI serum for 48 hours caused, compared to incubation with NPHX or sham animal sera, up regulation of anti-oxidant genes (catalase, HO-1), increased reactive oxygen species activity (CM-H_2DCFDA**),** higher mitochondrial membrane potential, increased mitochondrial complex I activity, and reduced mitochondrial reserve capacity (XF Cell Mito Stress Test). Summary: At comparable levels of azotemia (AKI vs. NPHX), AKI induced distinct changes in the internal milieu that adversely and similarly affected NRK and MSC functions.

Conclusions: These data identify yet inadequately defined pathogenic signals that are generated by the injured kidney and that likely target renal tissue, distant organs, and administered MSCs. identification of the exact nature of these noxious signals is expected to further advance our understanding of the acutely uremic state and how it affects renal and systemic organ functions. In addition, these initial observations provide the impetus for the development of therapeutic interventions that are both renoprotective in AKI and protective for therapeutic MSCs.

Proximal Tubule H-Ferritin Mediates Renal Iron Trafficking and Confers Protection in Acute Kidney Injury

Abolfazl Zarjou,[1] Subhashini Bolisetty,[1] Reny Joseph,[1] Amie Traylor,[1] Jozsef Balla,[2] Anupam Agarwal.[1] *[1]Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Medicine, University of Debrecen, Debrecen, Hungary.*

Background: Ferritin plays a central role in iron metabolism and is made of 24 subunits of two types (heavy [H] and light [L] chain). The H-chain has ferroxidase activity that is important not only for iron incorporation but also in controlling toxicity of iron. The purpose of this study was to investigate the role of H-ferritin in acute kidney injury (AKI) and renal iron handling. Proximal tubule specific H-ferritin knockout mice (H-ferritin$^{PT-/-}$) were generated by breeding floxed H-ferritin mice with PEPCK-Cre mice to test the hypothesis that H-ferritin expression in the proximal tubules is essential for protection in AKI.

Methods: Proximal tubule specific H-ferritin knockout mice (H-ferritin$^{PT-/-}$) were generated by breeding floxed H-ferritin mice with PEPCK-Cre mice to test the hypothesis that H-ferritin expression in the proximal tubules is essential for protection in AKI after rhabdomyolysis and cisplatin nephrotoxicity.

Results: Deletion of H-ferritin in the proximal tubules of H-ferritin$^{PT-/-}$ mice was confirmed by standard and real time-PCR, western blot and immunohistochemistry. In wild-type mice, H-ferritin was markedly upregulated in proximal tubules following AKI and was not detectable in the H-ferritin$^{PT-/-}$ mice. H-ferritin$^{PT-/-}$ mice demonstrated significantly higher mortality, worse structural and functional evidence of renal injury and higher levels of cleaved caspase-3 expression in glycerol-induced rhabdomyolysis and cisplatin-induced AKI, despite significantly higher expression of heme oxygenase-1 (HO-1), an anti-oxidant enzyme. Expression of divalent metal transporter-1 (required for normal export of iron from phagosomes) was not affected by deletion of H-ferritin. However, ferroportin expression was significantly lower under both basal and rhabdomyolysis induced-AKI in H-ferritin$^{PT-/-}$ mice.

Conclusions: These studies demonstrate a protective role of H-ferritin in AKI and reveal that proximal tubule H-ferritin is actively involved in regulation of iron trafficking that may have important consequences in AKI and subsequent outcomes.

Serum microRNAs Are Predictive Biomarkers of Acute Kidney Injury after Cardiac Surgery

Elia Aguado Fraile,[1] Edurne Ramos,[1] Elisa Conde,[1] Esperanza Macarena Rodriguez Serrano,[1] Fernando Liano,[2] Elena Elías-marín,[3] Angel M. Candela-Toha,[3] Laura Garcia-Bermejo.[1] *[1]Pathology Dpt., Hospital Ramon y Cajal, IRYCIS, Madrid, Spain; [2]Nephrology Dpt., Hospital Ramon y Cajal, IRYCIS, Madrid, Spain; [3]Anesthesiology Dpt., Hospital Ramon y Cajal, IRYCIS, Madrid, Spain.*

Background: Acute Kidney Injury is one of the most frequent complications after cardiac surgery (CS) and its severity is determinant for patient outcome. miRNAs are small non-coding RNAs which regulate gene expression. Recently, it has been demonstrated that miRNAs are present in body fluids, including serum. Moreover, serum microRNAs have been unveiled as biomarkers for diagnosis and monitoring of several pathologies.

Our aim is to identify and validate serum miRNAs as early biomarkers for AKI development after CS.

Methods: Total RNA was extracted from serum samples. Firstly, a screening experiment was performed and a panel of 10 miRNAs modulated in patients with ischemic AKI was selected. Next, we studied if these miRNAs could predict AKI development in a cohort of patients which underwent CS with cardiopulmonary bypass. We analyzed 50 patients organized in the following groups: IA, adults with 0-2 points in Thakar5 system; IB: Paediatric patients firstly operated; II: adults with altered basal renal function and > 5 points in Thakar5 system; III: adults with normal renal function and > 5 points in Thakar5 system. For each patient, we have analyzed serum samples at different time-points: Basal (before surgery), Immediate post-surgery, 24, 48, 72 hours and 7 days of evolution.

Results: Our results demonstrate that miR-26b, miR-27a and miR-127-3p shows different levels in basal samples between patients which develop ARF and those which do not develop ARF after surgery. Moreover, ROC analysis demonstrates that these miRNAs present AUC values higher than 0.8. Similar results were found at immediate post-surgery time.

Conclusions: In summary, serum levels of miR-26b, miR-27a and miR-127-3p could be early biomarkers of AKI development after CS with predictive value. These new biomarkers could improve patient management and outcome after cardiac surgery by allowing the application of early therapeutic strategies.

Protein SUMOylation in Experimental Models of Acute Kidney Injury

Zheng Dong, Chunyuan Guo. *Cellular Biology and Anatomy, Georgia Health Science University and Charlie Norwood VA Medical Center.*

Background: SUMOylation is a central regulatory post-translational modification whereby Small Ubiquitin-like Modifier proteins (SUMO) are covalently attached to target proteins to regulate their function. SUMOylation has been demonstrated during hypoxia, oxidative, genotoxic and metabolic stresses, suggesting an important role of this modification in cellular stress response. However, it is largely unclear if SUMOylation contributes to the pathogenesis of kidney diseases, such as acute kidney injury (AKI).

Methods: Here we examined protein SUMOylation in two experimental models of AKI: cisplatin nephrotoxicity and renal ischemia-reperfusion. We further examined the regulation of SUMOylation during cisplatin treatment of cultured rat kidney proximal tubular cells.

Results: It was shown that N-acetylcysteine and dimethyurea (two ROS scavengers) could attenuate cisplatin induced SUMOylation. In addition, SUMOylation by SUMO-2/3, but not SUMO-1, was partially suppressed by pifithrin-alpha, a pharmacological inhibitor of p53.

Conclusions: Together, the results demonstrate the first evidence of SUMOylation in AKI, which may regulate tubular cell response to injury. SUMOylation in AKI may result from oxidative stress and p53 signaling.

Tubular Cell Necroptosis Is Specifically Triggered by Fas Ligand through a Receptor-Interacting Protein Kinase 1 and 3-Dependent Pathway

Andreas Linkermann,[1] Joel M. Weinberg,[4] Jan O. Heller,[1] Jan H. Bräsen,[2] Ricardo Weinlich,[3] Douglas Green,[3] Ulrich Kunzendorf,[1] Stefan Krautwald.[1] *[1]Christian-Albrechts-University Kiel, Clinic for Nephrology and Hypertension, Kiel, Schleswig-Holstein, Germany; [2]Christian-Albrechts-University Kiel, Department for Pathology, Kiel, Schleswig-Holstein, Germany; [3]Department for Immunology, St. Jude Medical Research Hospital, Memphis, TN; [4]Division of Nephrology, Department of Internal Medicine, Veterans Affairs Ann Arbor Healthcare System, University of Michigan, Ann Arbor, MI.*

Background: Receptor-interacting protein kinase 1 (RIP1)-mediated programmed necrosis (necroptosis) was demonstrated to significantly contribute to acute tubular necrosis and AKI in an ischemia/reperfusion model. The renal necroptosis signaling pathway downstream of RIP1 and the activating stimulus of necroptosis in vivo have not been identified.

Methods: *Ex vivo*, we freshly isolated primary tubules from RIP3-deficient mice and cell death was analyzed in various readout systems after cisplatin-incubation and hypoxia/reoxygenation. RIP3-deficient mice and caspase-8/RIP3-double deficient mice were investigated in cisplatin-induced acute renal failure and a renal ischemia/reperfusion model in the presence and absence of Nec-1 and the Fas Ligand-inactivating monoclonal antibody MFL3 and inhibitors of other TNFR-family members.

Results: RIP3-deficient Renal tubules were protected from hypoxia/reoxygenation and cisplatin-induced cell death. In vivo, application of MFL3 was similarly effective in protecting mice from renal IRI as was genetic deficiency for RIP3. No further protection was achieved by application of MFL3 in RIP3-deficient mice or in combined extrinsic apoptosis/necroptosis-deficient caspase-8/RIP3-dko mice.

Conclusions: We demonstrate that AKI-induced necroptosis in the kidney depends on a RIPK1 - RIPK3 -dependent pathway. In the first renal caspase-8-deficient *in vivo* model we further demonstrate that blockade of extrinsic apoptosis did not provide any further protection from AKI. Finally, we identified Fas Ligand as the specific activating receptor of this pathway that can be clinically interfered with by either MFL3 or a Fas-Fc fusion protein.

Hydrogen Sulfide Donor GYY4137 Prevents Acute Renal Failure

Yang Zhou, Junwei Yang. *Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Ischemia/reperfusion (I/R) and medicine toxicity are the most common causes of acute renal failure (ARF) in hospitalized patients. Recent pharmacologic intervention strategies seem to be incapable of reducing the mortality and morbidity. Hydrogen sulfide (H_2S), recently identified as an endogenous gaseous messenger, was protective for ischemia/reperfusion injury of various organs. However, most commonly used H_2S-releasing "drug" releases H_2S instantaneously, which is different from its biological production. Here, the therapeutic potential of GYY4137, an ideal molecule releasing H_2S over a long period both in vivo and in vitro, was examined in acute renal failure mice.

Methods: In this study, acute renal failure was induced by I/R injury and cisplatin treatment, respectively. GYY4137 was daily administered intraperitoneally. Renal function and morphology were evaluated.

Results: In both ARF mice models, treatment with GYY4137 reduced renal function impairment measured by blood urine nitrogen and serum creatinine. Renal lipid oxidative stress was also decreased in GYY4137-treated groups. Moreover, GYY4137 treatment improved ATP recovery after I/R. Pro-inflammatory NF-κB signaling, as well as chemokines and cytokines was all markedly reduced after GYY4137 treatment. The tubular morphologic changes, including brush boarder loss, tubule dilation, tubular cells necrosisand detachment was greatly attenuated by GYY4137. TUNEL staining also revealed a minimized tubular cell apoptosis in GYY4137-treated groups. Furthermore, the reduced tubular cells apoptosis and necrosis were probably attributed to the preservation of pro-survival Akt and Erk signaling induced by GYY4137.

Conclusions: These results supported GYY4137 as a pharmacologic maneuver to prevent tubule apoptosis and necrosis, recover mitochondrial function, reduce oxidative stress and limit inflammation. GYY4137 might be a novel therapeutic strategy for treatment of ARF.

Overexpression of Protein Kinase G Protects Proximal Tubular Cells from Hypoxia/Reoxygenation Induced Apoptosis

Shuxia Wang, Hasiyeti Maimaitiyiming. *Graduate Center for Nutritional Sciences, University of Kentucky, Lexington, KY.*

Background: Inflammation and cell apoptosis are two major pathological responses of acute kidney injury. Our previously published studies demonstrated that overexpression of cGMP dependent protein kinase G-I (PKG-I) attenuates ischemia/reperfusion induced kidney injury (IRI) through inhibiting inflammatory cells infiltrating into the kidney and inhibiting tubular cell apoptosis. In the current studies, we further investigated the role of PKG-I in regulating apoptosis of mouse and human proximal tubular cells in an in vitro IRI model.

Methods: Mouse primary proximal tubular cells were isolated from wild type (WT) mice or transgenic mice (Tg) with overexpression of the constitutively active PKG-I in the kidney. Mouse primary proximal tubular cells were cultured and exposed to hypoxia (1% oxygen) for 24 hours and then returned to normal oxygen condition (21 % Oxygen) for additional 24 hours.

Results: We found that this hypoxia/reoxygenation model induced wild type PTC apoptosis with increased caspase 3 activity, increased TUNEL positive cells, and increased cytochrome C levels in the cell lysates. However, proximal tubular cells from transgenic mice exhibited reduced hypoxia/reoxygenation (H/R) induced apoptosis. To determine the effect of PKG-I on H/R induced apoptosis in human proximal tubular cells, HK-2 cells (purchased from ATCC) were used. HK-2 cells were undergone apoptosis after H/R exposure, associated with reduced PKG-I levels in these cells. Overexpression of the constitutively active PKG-I protected HK-2 cells from H/R induced apoptosis; while knockdown of PKG-I by siRNA promoted HK-2 cells to undergo apoptosis.

Conclusions: Taken together, these data indicate that overexpression of PKG-I protects both mouse and human proximal tubular cells from hypoxia/reoxygenation induced apoptosis.

Autophagy Protects against Necrotic Renal Epithelial Cells-Induced Death of Renal Interstitial Fibroblasts

Shougang Zhuang.[1,2] *[1]Department of Medicine, Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [2]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China.*

Background: Necrotic renal proximal tubular cells (RPTC) can induce the death of renal interstitial fibroblasts, the underlying mechanism remains unclear.

Methods: Since autophagy plays either cytoprotective or cytodestructive roles depending on the experimental condition, the present study was carried out to investigate whether necrotic RPTC would induce autophagy of renal interstitial fibroblasts and if so, whether autophagy would contribute to cell death or exerts a protective effect.

Results: Exposure of necrotic RPTC supernatant (RPTC-Sup) induced autophagy in renal interstitial fibroblast cells (NRK-49F) in a time and dose dependent manner, and its induction was earlier than caspase 3 activation. Inhibition of autophagy with 3-methyladenine (3-MA) or knockdown of Beclin 1, a molecule involved in the initiation of autophagosome formation, with siRNA significantly enhanced necrotic RPTC-Sup induced cell death. Necrotic RPTC-Sup induced phosphorylation of extracellular signal-regulated kinases (ERK1/2), p38, c-Jun N-terminal kinases (JNKs) and AKT. Treatment with an ERK1/2 pathway inhibitor, but not by specific inhibitors for p38, JNKs or AKT pathways, blocked NRK-49F autophagy and cell death upon exposure to necrotic RPTC-Sup. Further, knockdown of MEK1 with siRNA also reduced autophagy along with cell death in NRK-49F exposed to necrotic RPTC-Sup. In contrast, overexpression of MEK1/2 increased RPTC-Sup induced fibroblast cell death without enhancing autophagy.

Conclusions: Collectively, this study demonstrates that necrotic RPTC induces both autophagy and cell death and that autophagy plays a cytoprotective or prosurvival role in renal fibroblasts. Further, necrotic RPTC induced autophagy and cell death in renal fibroblasts is mediated by the activation of the MEK1-ERK1/2 signaling pathway.

AMPK/Autophagy Axis in the Kidney Ischemia Reperfusion Model of AKI

Joseph Satriano, Volker Vallon, Roland C. Blantz, Kumar Sharma. *Medicine / Nephrology, UCSD & VASDHS, San Diego, CA.*

Background: Kidney ischemia-reperfusion injury (IRI) leads to cellular damage and organ dysfunction. 5'AMP-activated protein kinase (AMPK) activity induces protective cell survival mechanisms, including autophagy. We have shown previously that renoprotective AMPK decreases during IR.

Methods: We examined the molecular effects of AMPK agonists AICAR (0.1g/kg) or metformin (0.3g/kg) applied i.p. 24 hrs prior to kidney ischemia in rats. Plasma creatinine and protein expressions were evaluated after 24 hrs of reperfusion. N=4-5 animals per group.

Results: In IR, accumulation of the linker protein p62, and increase in p70S6k, reflecting mTOR activity, indicate low autophagy (C, IR, AICAR, IR+AICAR for all data sets; p62: 5716±747, 10956±923, 8199±1029, 6445±757; p70S6K: 4623±816, 11281±1018, 4945±670, 4560±232, relative densitometric units for all immunoblots). Autophagy marker LC3-II is increased in IR+AICAR vs IR (LC3-II: 469±137, 1205±169, 885±172, 3276±474), accompanied by normalization of p62 and p70S6K. Caspase-3-dependent cleavage of beclin-1 inactivates beclin-1 induced autophagy and promotes apoptosis. We

observe an increase in caspase-3 and beclin-1 fragments with IR, responses attenuated in IR+AICAR (casp3: 2591±232, 5699±307, 3421±169, 4352±390; beclin1 frag: 774±51, 1541±146, 512±67, 1101±47). The increase in hemoxygenase-1 in IR is attenuated in IR+AICAR, implying less stressor stimulation (HO-1: 240±30, 5000±1135, 669±207, 3397±651). TGF-beta induces Wnt/beta-catenin to increase PAI-1 expression, which enhances fibrosis. Up regulation of beta-catenin and PAI-1 expressions in IR are reduced in IR+AICAR (b-cat: 2190±378, 5465±481, 2636±207, 3204±167; PAI-1: 515±40, 1107±81, 586±40, 771±54). IR+AICAR increases plasma creatinine beyond IR alone (0.061±0.006, 0.116±0.027, 0.052±0.002, 0.221±0.035, in mmol/l). The AICAR effect might reflect a stronger decrease in GFR due to AMPK-induced transport inhibition and tubuloglomerular feedback activation, which could be protective during this early phase of tubular injury. Results with metformin mirrored those for AICAR.

Conclusions: Our data indicate that pharmacological activation of AMPK offers a viable strategy for reducing cellular IRI.

TH-PO016

Programmed Cell Death 1 Ligands Promote Resistance to Renal Ischemia Reperfusion Injury Gilbert R. Kinsey, Katarzyna Jaworska, Liping Huang, Mark D. Okusa. *Medicine - Division of Nephrology, Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia.*

Background: Ischemia reperfusion injury (IRI) is a major contributor to acute kidney injury. The inflammatory response to ischemic injury, involving innate immune cells such as neutrophils, compounds the renal cell death and loss of function induced by IRI. Recent studies have demonstrated that regulatory T cells (Tregs) suppress the immune response to kidney IRI and preserve renal function. Blockade of the co-inhibitory receptor programmed cell death 1 (PD-1) on the surface of Tregs negates their ability to protect from ischemic kidney injury. We hypothesized that one or both of the known PD-1 ligands must interact with PD-1 on Tregs and possibly other PD-1 expressing cells to mediate resistance to kidney IRI.

Methods: Naïve C57Bl/6 mice were treated with a B7-H1 (PD-L1) blocking antibody, B7-DC (PD-L2) blocking antibody or an isotype control antibody 18 hr prior to mild bilateral renal ischemia. Kidneys were allowed to reperfuse for 18 hr then renal function and histology were assessed and accumulation of leukocytes was measured by flow cytometry.

Results: Compared to isotype control antibody treated mice after IRI (plasma creatinine (PCr) level: 0.5±0.1, n=5; sham PCr: 0.3±0.1, n=3) blockade of either PD-L1 (PCr: 1.3±0.3, n=5) or PD-L2 (PCr: 1.4±0.2, n=5) significantly enhanced renal functional impairment. Likewise, acute tubular necrosis, assessed by H&E staining, was markedly increased in the PD-1 ligand blocking antibody treated mice. Flow cytometric analysis of kidney infiltrating leukocytes revealed that blockade of either PD-1 ligand significantly enhanced accumulation of neutrophils (CD45+Live/Dead cell stain-negativeCD11b+GR-1high) after ischemia and reperfusion.

Conclusions: These studies suggest that both PD-1 ligands participate in the natural defense against kidney IRI and that the PD-1 ligand interactions regulate innate immune responses to renal injury.

TH-PO017

Endothelial Sphingosine 1-Phosphate Receptor 1 Signaling Protects Kidneys from Acute Kidney Injury Amandeep Bajwa, Sangju Lee, Hong Ye, Liping Huang, Mark D. Okusa. *Medicine, CIIR, University of Virginia, Charlottesville, VA.*

Background: Sphingosine 1-phosphate (S1P), a sphingolipid that is the natural ligand for five G-protein coupled receptors (S1P1-5Rs) and S1PR agonists reduced kidney ischemia-reperfusion injury (IRI) in mice. S1P maintains endothelial cell barrier integrity (primarily via S1P1) and functions in the development of a stable and mature vascular system. We sought to determine the role of endothelial S1P1 in mediating tissue protection from IRI *in-vivo* and whether endothelial S1P1 are necessary and sufficient to mediate the protection of S1P1 agonists.

Methods: We used conditional endothelial $S1P1^{-/-}$ ($Tie2CreER^{T2}S1pr1^{fl/fl}$) and control ($Tie2CreER^{T2}$) mice to determine the role of endothelial S1P1, because germline S1P1 deficiency is embryonically lethal. Tamoxifen was given daily (1 mg/mouse; i.p., 5d) prior to mild kidney IRI. Renal injury was assessed by plasma creatinine (PCr; mg/dl), FACS, Evans blue dye to measure changes in vascular permeability and real time RT-PCR.

Results: Under normal conditions, there was no difference in vascular permeability in control and $S1P1^{-/-}$ mice after 5 days of tamoxifen treatment. Compared to control mice (PCr:0.34±0.02) IRI induced more injury in endothelial $S1P1^{-/-}$ mice (0.98±0.10, $p<0.01$). Pretreatment with the S1P agonist FTY720 partially protected $S1P1^{-/-}$ mice, and there were no differences in circulating lymphocyte in control and $S1P1^{-/-}$ mice after IRI with FTY720. Compared to control mice, $S1P1^{-/-}$ mice had higher levels of pro-inflammatory cytokines (CXCL1, MCP-1 and TNF-α) and infiltrating inflammatory cells in the kidney. FTY720-treated $S1P1^{-/-}$ mice had reduced infiltration of pro-inflammatory cytokines and infiltration of inflammatory leukocytes after IRI, similar to control mice.

Conclusions: In summary, endothelial S1P1 activation attenuates kidney IRI and S1P1 on endothelial cells serve as a target for FTY720. We conclude that activation of endothelial S1P1 is vital for kidney tissue protection in addition to known protective effects to induce lymphopenia and proximal tubule survival. This study and our prior studies demonstrate multiple targets of S1P1 activation leading to tissue protection.

TH-PO018

ABCG2 Protects Kidney Side Population Cells from Hypoxic/Ischemic Injurythroughactivating MEK/ERK Pathway Hongbao Liu. *Nephrology, Xijing Hospital, Xi'an, Shaanxi, China.*

Background: Breast cancer resistance protein 1 (BCRP1/ABCG2) is used to identify the side population (SP) within a population of cells, which is enriched for stem and progenitor cells in different tissues. Here, we investigated the role of extracellular-regulated kinase (ERK) 1/2 in the signaling mechanisms underlying ischemic/hypoxic conditions in kidney SP cells.

Methods: The kidney SP cells were isolated using Hoechst 33342 dye-mediated fluorescein-activated cell sorting and then incubated under hypoxia/reoxygenation (H/R) with or without verapamil, a selective BCRP1/ABCG2 inhibitor.ABCG2 expression, ERK activity, cell viability, metabolic activity and membrane damage were tested after H/R treatment. To evaluate the role of ERK 1/2 on the expression and function of ABCG2, the expression of mitogen-activated protein kinase/ERK kinase (MEK), which preferentially activates ERK, was upregulated bytransfection with the recombinant sense expression vector pcDNA3.1-MEK and downregulated by pretreatment with U0126, a specific MEK inhibitor.

Results: We found that hypoxia activated ERK activity in the kidney SP cells but not in non-SP cells both *in vitro* and *in vivo*. Overexpression of MEK mimicked hypoxia-induced ABCG2 expression. Contrarily, U0126 inhibited hypoxia- and MEK-upregulated ABCG2 expression. Furthermore, H/R induced significant increases in nuclear, metabolic and membrane damage in both SP cells and non-SP cells; however, this H/R-induced cytotoxicity was much more severe in non-SP cells than in SP cells. Importantly, the viability of kidney SP cells was enhanced by MEK overexpression and inhibited by U0126. Verapamil treatment reversed MEK-induced viability of kidney SP cells. When administered systemically into animals with renal ischemia/reperfusion injury, the SP cells significantly improved renal function, accelerated mitogenic response, and reduced cell apoptosis. However, this improved therapeutic potential of SP cells was significantly reduced by pretreatment with verapamil.

Conclusions: Collectively, these findings provide evidence for a crucial role for the MEK/ERK-ABCG2 pathway in protecting kidney SP cells from ischemic/hypoxic injury.

Monitoring Live Actin Cytoskeleton Alterations in the Setting of Ischemia-Reperfusion Injuries Peter R. Corridon,[1] George Rhodes,[1] Robert L. Bacallao,[1,2] Simon J. Atkinson.[1,3] *[1]Department of Medicine, Division of Nephrology, Indiana University School of Medicine, Indianapolis, IN; [2]Richard, L. Roudebush VA Medical Center, Indianapolis, IN; [3]Department of Biology, School of Science, Indiana University - Purdue University Indianapolis (IUPUI), Indianapolis, IN.*

Background: Our present understanding of the kidney in various disease settings is limited. As a result, renal dysfunction is both a common and progressive problem threatening the lives of millions worldwide. Ischemia-reperfuson injury is a major cause of such dysfunction. Gene delivery has been proposed as a novel approach to investigate underlying causes of this complex disorder. Recent work conducted in our laboratory has developed hydrodynamic gene delivery as a robust method of providing significant transgene expression in all nephron segments.

Our present understanding of the kidney in various disease settings is limited. As a result, renal dysfunction is both a common and progressive problem threatening the lives of millions worldwide. Ischemia-reperfuson injury is a major cause of such dysfunction.

Gene delivery has been proposed as a novel approach to investigate the underlying causes of this complex disorder. Recent work conducted in our laboratory has developed hydrodynamic gene delivery as a viable and robust method of gene delivery by providing efficient transgene expression.

Methods: Utilizing this technique, we introduced fluorescent actin plasmid expression vectors in rat kidneys, subjected to ischemia-reperfusion injury. We then tracked subsequent structural and functional changes in actin cytoskeleton renal injury initiated by renal pedicle cross clamp using intravital multiphoton microscopy.

Results: We were able to monitor the loss and remodeling of actin components in live proximal tubule epithelial cells, which is the major site of ischemia-reperfusion injury.

Conclusions: These results provide a novel approach to study in detail cellular and subcellular events associated with renal ischemic injury. This work paves the way for evaluating protective interventions in ischemia reperfusion and extends the use of reporter constructs for use in intravital imaging studies.

Novel Mouse Models for Studying the Role of Renal Cytochrome P450 Enzymes in Chemically Induced Kidney Injury Senyan Liu,[1,2] Yunyi Yao,[2] Shijun Lu,[2] Xinxin Ding,[2] Changlin Mei,[1] Jun Gu.[2] *[1]Division of Nephrology, Changzheng Hospital, Shanghai, China; [2]Wadsworth Center, New York State Department of Health, Albany, NY.*

Background: The kidney is a primary target for numerous toxic compounds. Cytochrome P450 enzymes (P450s), responsible for metabolic activation of chemical compounds, are predominantly expressed in proximal tubules in the kidney. The in vivo role of renal P450s in chemically induced renal injury is not clear due to lack of appropriate animal models.In this study, we have developed one mouse model having proximal tubule-specific deletion of cytochrome P450 reductase (Cpr) gene (the enzyme required for all microsomal P450 activities), and another mouse model with proximal tubule-specific rescue of CPR activity (extra-renal Cpr-low) bred from an existing mouse with global suppression

of CPR activity (Cpr-low). Kidney injury induced by chloroform was studied in the two new mouse models along with Cpr-low and wild-type (WT) mice.

Methods: The mice were treated with a single oral dose of chloroform at 200 mg/kg. The tissue samples were collected at 24 h after the treatment. The kidney injury was examined by serum BUN and creatinine and pathology, and the levels of chloroform in the blood and tissues were analyzed by gas chromatography.

Results: The Cpr gene deletion was observed in 84% of the proximal tubules in kidney-Cpr-null mouse, and the CPR activity rescue was achieved in 76% of the proximal tubules in extrarenal-Cpr low mouse. Chloroform induced tubular lesions were less severe in kidney-Cpr-null mice and Cpr-low mice, compared to WT and extra-renal-Cpr low mice, respectively, which is in agreement with BUN and creatinine levels in the four strains. There is no significant difference in chloroform levels in the blood, liver, and kidney between kidney-Cpr-null and WT mice, and between extra-renal-Cpr low and Cpr-low mice.

Conclusions: The novel mouse models are useful for studying the in vivo roles of proximal tubule P450 enzymes in renal function and injury and local P450 dependent metabolic activation plays an important role in kidney injury induced by chemical compounds such as chloroform.

Outcome of Acute Renal Injury in Diabetic Mice with Experimental Endotoxemia: Role of Hypoxia Inducible Factor-1α

Ricardo J. Bosch,[1] Arantxa Ortega,[1] Ana Belen Fernandez,[1] Nuria Olea,[1] Carmen Muñoz,[1] Pilar Lopez-Luna,[1] María I. Arenas,[1] Ignacio Arribas,[2] Laura Garcia-Bermejo,[3] Javier Lucio.[1] *[1]Physiology, University of Alcalá, Alcalá de Henares, Spain; [2]Bioquímica, Hospital Príncipe de Asturias, Alcalá de Henares, Spain; [3]Pathology, Hospital Ramón y Cajal, Madrid, Spain.*

Background: The role of diabetes in the outcome of acute renal injury (AKI) is not well defined. Herein we evaluate the outcome of lipopolysacharide (LPS)-induced AKI in experimental diabetes, as well as the potential role of Hypoxia inducible factor (HIF-1α) in this condition.

Methods: Diabetes was induced by streptozotocin (65mg/Kg) 6 weeks before LPS (10mg/Kg) injection (n=104). Renal HIF-1α expression was assessed by Western blot and immunohistochemistry. The effect of glycated albumin (GA) and LPS on HIF-1α expression as well as the production of the vascular endothelium growth factor (VEGF) in proximal tubular HK-2 cells was also analyzed by Western blot and ELISA respectively.

Results: Although 6h after LPS injection diabetic and non-diabetic mice developed a similar decrease in renal function as assessed by endogenous creatinine clearance, the diabetic animal showed a better recovery of renal function throughout the study (72h). HIF-1α was found to be upregulated in diabetic mice. After LPS injection, all animals showed an upregulation of HIF-1α, although it was statistically higher in the diabetic group. GA was found to upregulate HIF-1α in HK-2 cells, which resulted in increased production of the putative renal protector VEGF. Interestingly, LPS cooperated with AG to induce an over-increase in the expression of HIF-1a.

Conclusions: Diabetic mice display a better recovery of renal function after experimental endotoxemia. Interestingly, diabetic animals showed an increased expression of HIF-1α that was reproduced by incubating renal cells with GA. Since GA determined an HIF-1a-dependent increase in VEGF, a survival factor for tubular cells, our findings suggest that the diabetic condition displays renal upregulation of HIF-1α that might function as a "precondition state" offering protection from endotoxic AKI.

Role of Megalin in Cisplatin Induced Acute Kidney Injury

Ravikiran Mahadevappa,[1] Rikke Nielsen,[1] Bente Gammelgaard,[2] Erik I. Christensen,[1] Henrik Birn.[1] *[1]Dept. of Biomedicine, Aarhus Univ., Aarhus, Denmark; [2]Dept. of Pharmaceutics and Analytical Chemistry, Univ. of Copenhagen, Copenhagen, Denmark.*

Background: Megalin, a proximal tubule, multiligand, endocytic receptor, is involved in the nephrotoxic effect of a number of substances mediating the tubular uptake of these. Cisplatin, a nephrotoxic chemotherapy drug, affects proximal tubule endocytic function and megalin gene polymorphisms are associated with increased sensitivity to cisplatin ototoxicity suggesting involvement of megalin in cisplatin toxicity. We examined the role of megalin in cisplatin induced acute kidney injury.

Methods: Megalin knockout (MKO) and wild type (WT) mice were injected with 15mg/kg of cisplatin i.p. Blood, urine, and renal tissue were collected after 4 days. Cisplatin uptake was quantified by ICP-MS. Renal tissue damage was examined histologically. We further analysed plasma creatinine (HPLC), renal expression of damage markers (Q-PCR), and urinary excretion of KIM1 and NGAL (ELISA).

Results: Following cisplatin treatment a significant increase in plasma creatinine and histological evidence of tubular necrosis was observed, but there was no difference between MKO and WT and no difference in renal uptake of cisplatin. Urinary KIM1 was higher at baseline in MKO compared to WT. After cisplatin treatment urinary NGAL and KIM1 were increased in both groups and the excretion of both markers was higher in MKO (Figure 1A). Furthermore, KIM1 expression after cisplatin was higher in WT than MKO (Figure 1B).

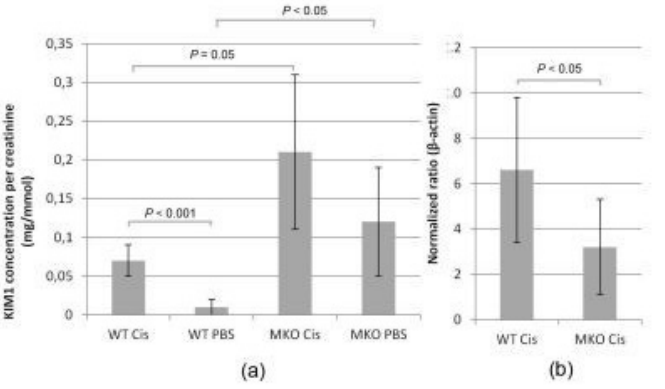

Figure 1: (a) KIM1 Excretion in urine. (b) Renal expression of KIM1 mRNA

Conclusions: Megalin knock out does not protect against cisplatin induced acute kidney injury nor does it affect renal cisplatin-uptake; however, a differential expression and urinary excretion of the renal damage markers NGAL and KIM1 were observed. Urinary KIM1 was higher in MKO despite lower renal expression suggesting a role of megalin for the expression and clearance of KIM1.

A Potential Acute Renal Failure Marker, microRNA494, Modulates Expression of the Inducible Transcription Factor ATF3 and Affects Kidney Function

Yifan Lan,[1] Pei-fang Lai,[1] Hsin Tzu Liu,[1] Hsiao-Fen Li,[3] Heng Lin.[2] *[1]Pharmacology and Toxicology, Tzu Chi University, Hualien, Taiwan; [2]Physiology, Taipei Medical University, Taipei, Taiwan; [3]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan.*

Background: Previous reports have shown ATF3 plays a protective role in acute renal failure, ischemia/reperfusion (I/R) injury. The aim of this study was to analyze the potential regulation of ATF3 expression by microRNAs.

Methods: Lenti-miRNA overexpression, mouse renal ischemia reperfusion.

Results: In this study, we demonstrated that miR-494 target 3' untranslated region of ATF3 reporter and decreased ATF3 mRNA expression by reporter assay and molecular analysis. Overexpression miR-494 in mice kidney was significantly attenuate ATF3 mRNA and protein, accompany with I/R induced inflammatory related factor include IL-6, MCP-1, P-selectin resulting cells apoptosis and renal function decreased. Importantly, the mice urinary miR-494 was increased significantly earlier than serum creatinine after renal I/R. In clinical, the urinary miR-494 expression was higher in acute kidney injury (AKI) patients than patients with no AKI and normal.

Conclusions: These data suggest that up-regulation of miR-494 contributes to inflammatory factor or adhesion molecule induced kidney injury after I/R via inhibition ATF3 expression and miR-494 may act as an early specific and non-invasive biomarker in AKI.

TH-PO024

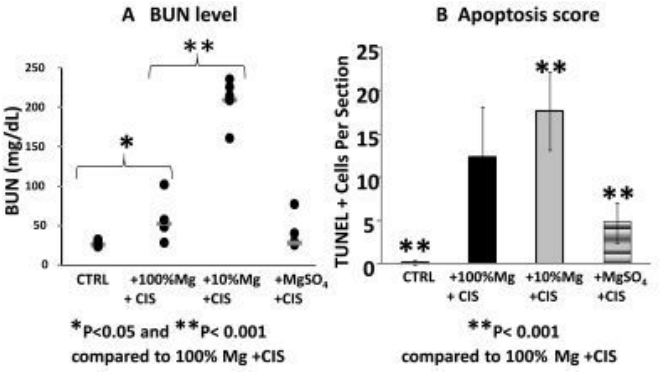
Magnesium Controls Cisplatin-Induced Acute Kidney Injury

Malvika Solanki, Madhu Gupta, Prodyot K. Chatterjee, Xiangying Xue, Christine N. Metz. *Laboratory of Medicinal Biochemistry, Feinstein Institute for Medical Research, Manhasset, NY.*

Background: Cisplatin-induced acute kidney injury (AKI) limits the use of this chemotherapeutic agent. Renal handling of magnesium (Mg) is severely impaired by cisplatin. Because Mg deficiency is associated with enhanced inflammation, we examined the effects of Mg deficiency and Mg supplementation on cisplatin-induced renal epithelial cell death and cisplatin-induced AKI.

Methods: ***In vitro:*** Renal epithelial (HK-2) cells were grown in 0%, 100% and 200% Mg ($MgSO_4$) media and treated with cisplatin; cell death was measured 48hrs later. ***In vivo:*** C57BL/6 mice (n=4-5 per group, males) were maintained on normal (100% Mg) or 10% Mg deficient diets for 2wks; cisplatin (20mg/kg, ip) was injected on day 14. One group of mice received $MgSO_4$ (200mg/kg, ip daily) on days 14-16. Mice were euthanized 48hrs post cisplatin. Kidney function was measured by blood urea nitrogen (BUN) levels; renal cell apoptosis was analyzed by TUNEL and inflammatory and apoptotic markers were measured by Q-PCR.

Results: ***In vitro*****:** Mg deficiency significantly increased cisplatin-induced HK-2 cell death; $MgSO_4$ significantly reduced cisplatin-cell death. ***In vivo*****:** Mg deficiency significantly elevated BUN levels and $MgSO_4$ decreased BUN levels in cisplatin-mice treated compared to cisplatin controls (Fig.1A). Mg-deficient mice had significantly more cisplatin-induced renal apoptosis compared to cisplatin controls; $MgSO_4$ significantly reduced cisplatin-renal apoptosis (Fig. 1B).



Renal markers of inflammation (CCL2, CXCL2, CXCL10) and apoptosis (BAK) were increased in Mg-deficient mice and decreased in $MgSO_4$ mice compared to cisplatin controls.

Conclusions: Mg deficiency worsens cisplatin-AKI (as determined by BUN levels) and promotes renal inflammation and apoptosis. $MgSO_4$ improves cisplatin-induced AKI as evidenced by lower BUN levels, apoptosis, and inflammation.

Deletion of Ace2 Gene Exacerbates Kidney Injury in Mice after Renal Ischemia Reperfusion Fei Fang,[1] James W. Scholey,[1] George Chu Liu,[1] Xiaohua Zhou,[1] Amanda Hu,[1] Vanessa R. Williams,[1] Gavin Oudit,[2] Rohan John.[1] *[1]Institute of Medical Sciences, University of Toronto, Toronto, ON, Canada; [2]Department of Medicine, University of Alberta, Edmonton, AB, Canada.*

Background: Activation of the renin-angiotensin system has been implicated in several forms of kidney injury, including ischemia/reperfusion (I/R). ACE2 is a homologue of ACE and functions to counterbalance the effect of ACE by metabolizing angiotensin II (AngII) to angiotensin-(1-7) (Ang-(1-7)). Previous reports suggest that ACE2 is beneficial to kidney in models of chronic kidney disease and diabetic nephropathy. However the role of ACE2 in I/R-induced kidney damage has not been fully elucidated. We hypothesized that ACE2 is protective against acute kidney I/R injury, and we tested this hypothesis by studying I/R in wild-type control mice and mice with a deletion in the gene for *Ace2*.

Methods: 8-week old male control and ACE2 knock-out (ACE2 KO) mice were subjected to sham operation or left kidney ischemia for 45 min. Kidneys were harvested after 48 hours of reperfusion for measurement of AngII levels, histologic kidney injury, inflammatory gene expression (IL-1β, IL-6 and TNFα) and immunohistochemical analysis of infiltrating cells, oxidative stress, and apoptosis.

Results: I/R increased wet kidney weight and resulted in severe histologic kidney injury compared to kidneys subjected to sham operation. Deletion of the *Ace2* gene did not significantly affect the injury score. AngII levels were higher in kidneys of ACE2 KO mice than in wild type mice following I/R. ACE2 KO mice had higher IL-1β, IL-6 and TNFα mRNA levels compared to wild-type mice after IR, though the differences were significant only for IL-1β. T cell and neutrophil infiltration was increased in kidneys of both ACE2 KO and wild-type mice after I/R. Deletion of the *Ace2* gene further increased T cell and neutrophil infiltration in association with enhanced oxidative stress (nitrotyrosine staining) and apoptosis (activation of caspase-3).

Conclusions: Deletion of the *Ace2* gene increases AngII levels and oxidative stress in kidneys subjected to I/R and promotes I/R-induced inflammation and apoptosis.

TH-PO026

BNIP3 Mediates Mitophagy (Mitochondrial Autophagy) of Renal Tubular Cells in Acute Kidney Injury Masayuki Ishihara,[1] Madoka Urushido,[1] Nazuki Okada,[1] Yoshiko Shimamura,[1] Koji Ogata,[1] Kosuke Inoue,[1] Toru Kagawa,[1] Toshihiro Takao,[2] Yoshio Terada.[1] *[1]Department of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Nankoku, Kochi, Japan; [2]Division of Community Medicine, Department of Community Nursing, Kochi Medical School, Kochi University, Nankoku, Kochi, Japan.*

Background: Autophagy is one of the systems, which protects renal tubular cells from acute kidney injury (AKI). Mitophagy is one of the forms of autophagy, and may play damaged mitochondria recycling system. However, little is known about mechanism and roles of mitophagy in AKI. Bcl-2/adenovirus E1B 19kDa-interacting protein 3 (BNIP3) is one of the target proteins of hypoxia inducible factor -1a (HIF-1a). We also report that autophagy in renal tubules in AKI is induced by at least two independent pathways, p53-sestrin2 pathway and HIF-1a-BNIP3 pathway The aim of this study is to reveal the roles of BNIP3 in mitophagic pathway in AKI.

Methods: We used rat ischemia/reperfusion (I/R) AKI model in vivo and cultured renal tubular cells as an in vitro AKI model. We established NRK cells which stably transfected with a fusion protein of green fluorescent protein and light chain 3 (LC3-GFP) as a marker of autophagy. Overexpression of BNIP3 induced autophagy in NRK-LC3-GFP cells and induced LC3 protein expression. We used Mitochondria-red plasmid to detect mitochondria in confocal microscopy and also used electron-microscope for detection of mitophagy.

Results: The expression of BNIP3 is up-regulated after I/R in proximal tubules in immunostaining and immunoblotting. BNIP3 is up-regulated in cytoplasm under hypoxia condition in NRK cells. Mitophagy detected as LC3 and Mitochondria-Red double positive particles are significantly increasing under hypoxia condition. Overexpression of BNIP3 induced mitophagy in NRK cells even in normal oxygen condition. We also confirm mitophagy in electron microscope in hypoxia and BNIP3 overexpression.

Conclusions: Although there will be several pathway of mitophagy, in this study, we revealed BNIP3 induce mitophagy in renal tubular cells. We firstly demonstrate that mitophagy are observed in proximal tubules in hypoxic condition and BNIP3 regulates mitophagy in renal cells.

TH-PO027

Meprin Metalloproteases Cleave OS-9 In Vitro and In Vivo Elimelda Moige Ongeri. *Biology, North Carolina A&T State University, Greensboro, NC.*

Background: Meprins are metalloproteinases that are abundantly expressed in the brush border membranes (BBM) of proximal kidney tubules, and have been implicated in the pathology of ischemia-reperfusion (IR) induced renal injury. Osteosarcoma-9 (OS-9), a cytoplasmic protein, has been shown to interact with the carboxyl-terminal tail of meprin β. However, it has not been determined if OS-9 is a meprin substrate, and whether OS-9 interaction with meprin β is significant *in vivo.* More importantly, OS-9 has been shown to interact with the hypoxia-inducible factor 1α (HIF-1α) and prolyl hydroxylase, a protein which mediates the cell's response to changes in oxygen concentration. The interaction of OS-9 with HIF1α promotes oxygen-dependent degradation/hydroxylation of HIF1α, Von Hippel–Lindau tumor suppressor(VHL) binding, and inhibition of HIF-1-mediated transcription. OS-9 is associated with the endoplasmic reticulum (ER) and is present in both nuclear and cytoplasmic protein extracts, suggesting that it could traffic HIF proteins between the nucleus and the ER during the hypoxic response.

Methods: To determine whether meprin β cleaves OS-9, kidney proteins from meprin αβ double knockout (KO) mice were incubated with the activated form of purified recombinant meprin β. Control reactions were incubated with (i) tris buffer, and (ii) latent meprin β. Products were electrophoretically separated, and Western blot analysis used to detect OS-9 protein bands. To determine whether meprin β cleaves OS-9 *in vivo*, wild-type (WT) and meprin KO mice were subjected to renal IR, and kidney tissue harvested at 3h- and 6h-post renal artery clamping. Western blot analysis was used to evaluate OS-9 fragments in kidney proteins.

Results: Degradation of OS-9 was observed in proteins from meprin αβ KO kidneys incubated with activated meprin β, but not in control reactions. Fragmentation of OS-9 was observed in kidney proteins from WT mice subjected to IR, with a unique 60 KDa OS-9 fragment being detected. This fragmentation was not observed in proteins from meprin β KO kidneys subjected to IR, or sham operated WT controls.

Conclusions: These data suggest that meprin β plays a role in the hydrolysis of OS-9 during hypoxia/ATP-depletion *in vivo.*

TH-PO028

Cdk2-Dependent Bax Activation Is Necessary for Cisplatin-Induced Renal Cell Death *In Vitro* and *In Vivo* Peter M. Price,[1,2] Adel Tarcsafalvi,[1] Rawad Hodeify,[1] Nang San Hti Lar Seng,[1] Judit Megyesi.[1] *[1]UAMS; [2]VA Med Ctr.*

Background: Expression of p21 *in vitro* and *in vivo* protected kidney cells from cisplatin cytotoxicity. The protective effect of p21 *in vitro* was by its inhibition of Cdk2 activity, and Cdk2 inhibitory drugs also protected from cisplatin cytotoxicity *in vitro* and *in vivo*. Similarly, induction of DN-Cdk2 in kidney proximal tubules protected from cisplatin-induced AKI. We now show that the mechanism of this protection is by prevention of Bax activation. This structural change in Bax is required for Bax oligomerization in the mitochondrial membrane and subsequent permeabilization of the outer mitochondrial membrane (MOMP), release of intermembrane proteins, caspase activation, and cell death.

Methods: Cultured mouse proximal tubule cells were used as an *in vitro* model; cells were exposed to cisplatin at 25 μM. Mice were administered cisplatin at 20 mg/kg body weight. Bax activation was assessed by a conformation-specific antibody; cell fractionation into cytoplasmic, nuclear and mitochondrial fractions was by differential centrifugation. Proteins were detected by Western blot after PAGE.

Results: Bax was reported to shuttle between the cytoplasm and the mitochondrial membrane, where it interacts with anti-apoptotic proteins, such as Bcl-xL, and is retrotranslocated back to the cytoplasm. Accumulation of Bax on mitochondrial membrane causes auto-activation. Previous studies by other investigators showed that Bcl-xL phosphorylation caused dissociation of Bax/Bcl-xL heterodimers, in which Bax release was responsible for induction of apoptosis. We provide preliminary evidence that Bcl-xL is phosphorylated by Cdk2 *in vitro* and *in vivo* after cisplatin exposure. Also, we show that cytoplasmic Bax accumulated on mitochondrial membranes after cisplatin exposure, supporting the idea that Bax/Bcl-xL interactions were affected.

Conclusions: We propose the following hypothesis for the mechanism of Cdk2-dependence of cisplatin induced cytotoxicity in vitro and nephrotoxicity in vivo. Cdk2 phosphorylation of Bcl-xL interferes with Bax retrotranslocation back into the cytoplasm, resulting in Bax accumulation on mitochondrial membranes, Bax activation, MOMP, and subsequent cell death.

TH-PO029

Pathomechanistic Relevance of the Extracellular (ec) Superoxid-Dismutase SOD in Ischemic Acute Kidney Injury (iAKI) Boris Betz,[1] Kerstin Möller-Ehrlich,[2] Christoph Wanner,[1] Reinhard Schneider.[1] *[1]Dept. Nephrology, University Hospital Wuerzburg; [2]Center of Experimental Moleculare Medicine (ZEMM), Wuerzburg.*

Background: Generation of reactive oxygen species is an important pathomechanism in iAKI. Here, superoxide radicals (O2-*) are responsible for e.g. inactivation of nitric oxide (NO) and generation of further oxygen derived radicals with detrimental effects on cellular or protein levels. Superoxide dismutase (SOD) initiates the first step of O2-*-radical detoxification. Here, we analyzed the influence of the extracellular SOD (ecSOD) in iAKI with regard to renal function, inflammation and tubular epithelial transport in an ecSOD deficient mouse model.

Methods: iAKI was induced in ecSOD -/- and ecSOD +/+ mice (c57bl6) by ligation of renal arteries for 45 min followed by reperfusion. 24h and 72h after ischemic injury the clearance of inulin (CIN, resp. GFR) and para-aminohippuric acid (CPAH, resp. RPF) were measured. PAH net secretion (NSPAH) was determined to elucidate tubular epithelial transporter capacities and respective expressions (OAT1/OAT3). In parallel, markers of inflammation which include COX1/COX2, HO1/HO2, HSP70, MCP1, IL1b, CX3CL1/CX3CR1 and NO-synthases (iNOS/eNOS) were characterized in homogenate of renal cortex by qPCR and western blot.

Results: Nonischemic ecSOD -/- and ecSOD +/+ demonstrated neither difference regarding CIN, CPAH and NSPAH nor expression of OATs, but eNOS and markers of inflammation were already induced (e.g. COX1, HO1, HSP70). In iAKI, ecSOD deficiency caused pronounced functional deterioration of CIN, CPAH and NSPAH but no additional down regulation of OATs. Following I/R injury, ecSOD deficient mice exhibit a differential regulted inflammatory pattern (COX1/COX2, HO1/HO2, HSP70, MCP1, IL1b, CX3CL1/CX3CR1), whereas and iNOS induction was delayed.

Conclusions: These results emphasize the detrimental pathophysiologic impact of the extracellular O2-* radical in iAKI with regard to renal function in an ecSOD deficient mouse modell. Tubular epithelial transport might be additionally regulated by primary or secondary O2-* depenent mechanisms in iAKI.

Funding: Government Support - Non-U.S.

TH-PO030

Small Heat Shock Protein beta-1 (HSPB1 or HSP27) Is Up-Regulated and Regulates Autophagy and Apoptosis of Renal Tubular Cells in the Acute Kidney Injury In Vitro and In Vivo Kosuke Inoue,[1] Koji Ogata,[1] Masayuki Ishihara,[1] Madoka Urushido,[1] Nazuki Okada,[1] Yoshiko Shimamura,[1] Kazu Hamada,[1] Toru Kagawa,[1] Toshihiro Takao,[2] Yoshio Terada.[1] *[1]Department of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Oko-cho, Nankoku, Kochi, Japan; [2]Department of Community Nursing, Kochi Medical School, Kochi University, Oko-cho, Nankoku, Kochi, Japan.*

Background: HSPB1 is a member of small heat shock proteins and participates in several processes in cells. HSPB1 was reported to protect cells against oxidative stress. Autophagy is one of the systems which protects life from many kinds of stresses. Autophagy is thought to play an important role for preventing AKI from stresses. However, little is known about the role of HSPB1 in autophagy and apoptosis of AKI pathogenesis.

Methods: We used a rat ischemia/reperfusion AKI model in vivo and cultured renal tubular cells as an in vitro model. We observed up-regulation of HSPB1 mRNA and protein expression in 6-24 h and 12-72 h after ischemia/reperfusion by RT-PCR and western blot analysis. In immunohistological examination, HSPB1 expressed in the proximal tubule cells and co-localized with light chain 3 (LC3). To elucidate the regulation of HSPB1, we evaluated the promoter activity and expression of HSPB1 in NRK-52E cells in the presence of H_2O_2.

Results: HSPB1 promoter activity, mRNA, and protein expression were induced by H_2O_2 dose-dependently. To examine HSPB1 regulates autophagy or not, we established NRK cells which stably transfected with a fusion protein between GFP and LC3 as a marker of autophagy. Overexpression of HSPB1 induced autophagy in NRK cells in normal oxygen condition by confirmed LC3 positive granules in confocal microscopy and electron microscope. Furthermore autophagy induced by H_2O_2 (400μM) was inhibited by transfection of siRNA for HSBP1. Overexpression of HSPB1 reduced H_2O_2 (600μM) induced-apoptosis measuring by caspase3 activity.

Conclusions: We showed that HSPB1 expression increased in oxidative stress in the AKI. Increments of HSPB1 expression caused autophagy and inhibited apoptosis in renal tubular cells. These results indicate the up-regulated HSPB1 play a role in the pathophysiology of AKI.

TH-PO031

Deletion of NOS1 in the Macula Densa Exacerbates Ischemia-Induced Acute Kidney Injury Yan Lu, Kiran B. Chandrashekar, Ying Ge, Yiling Fu, Robert Kampen, Istvan Arany, Luis A. Juncos, Richard J. Roman, Ruisheng Liu. *University of Mississippi Medical Center.*

Background: Nitric oxide synthase 1 (NOS1) is highly expressed in the macula densa (MD) and generates NO that dilates the afferent arteriole (Af-Art) by blunting tubuloglomerular feedback (TGF). Increased tone of the Af-Art contributes to the fall in GFR following acute kidney injury (AKI), but the role of MD NOS1 and alterations in TGF in this process is unknown.

Methods: In the present study we generated a new MD specific NOS1 knockout mouse strain to study the role of MD derived NO in ischemia/reperfusion (I/R) injury. The MD specific NOS-1 KO mice were generated by crossing NKCC2 Cre mice with $NOS1^{flox/flox}$ mice in which exon-6 of NOS1 is targeted to inactivate all splice variants of NOS1. We confirmed that NOS1 is expressed in the MD in wild type (WT) mice and verified the deletion of NOS1 in the MD in the KO mice by immunohistochemistry. NO generation in the MD of KO and WT mice was measured in isolated perfused MD preparation using DAF-2.

Results: When we switch tubular NaCl from 10 to 80 mM, NO generation in the MD increased from 114±12 to 165±11 units/min in WT mice, NO generation in the MD was absent in the KO mice (n=5; $p<0.01$). TGF was measured *in vivo* using micropuncture when flow to the MD was increased from 0-40 nl/min. TGF was 4.5±0.3 mmHg in WT and enhanced to 8.4±0.7 mmHg in the KO animals (n=5; $p<0.01$). The effect of MD NOS1 deletion on AKI was compared in WT and KO animals subjected to bilateral renal ischemia for 18 min at 37°C. Twenty four hours post I/R injury, serum creatinine concentration (mg/dl) rose to 0.89±0.03 in KO mice *versus* 0.56±0.02 in WT animals and 0.35±0.02 in the sham controls. NGAL excretion (pg/ml) increased from 349±18 to 2975±42 after I/R in KO mice, while it increased from 283±21 to 2327±37 in WT controls. Concentration of nitrotyrosine in kidney homogenates (μmol/L) was 2.4±0.4 in KO mice and 1.5±0.5 in WT controls ($p<0.05$).

Conclusions: These data indicated that KO of NOS1 in the MD which augments TGF response worsens ischemia-induced AKI. Maintaining NO levels in the kidney to attenuate TGF may provide a new therapeutic strategy for the treatment for AKI.

TH-PO032

Roles of Endoplasmic Reticulum Stress in the Radiocontrast-Induced Nephropathy: Emphasize in Caspase 12 Activation Zong-yu Li,[2] Cheng-tien Wu,[3] Kuan-Yu Hung,[2] Chih-Kang Chiang,[123] Shing-Hwa Liu.[3] *[1]Department of Integrated Diagnostics & Therapeutics, National Taiwan University Hospital, Taipei, Taiwan; [2]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; [3]Institute of Toxicology, College of Medicine; National Taiwan University, Taipei, Taiwan.*

Background: Contrast medium (CM)-induced nephropathy played a significant role in acute kidney Injury. We previously demonstrated activation of GRP78 /EIF2α-phosphorylation played a protective role in urografin-induced tubular injury. In this study, we comprehensively examined endoplasmic reticulum (ER)-related proapoptotic activators in urografin-induced tubular cells injury.

Methods: Male Wistart rats were intravenously injected with indomethacin and L-NAME, and followed by Urografin (10 ml/kg) administration to ensure the induction of CM-induced nephropathy. Rats were sacrificed for pathology and cellular signals studies 24 and 48 hours later. Urografin-treated normal rat kidney epithelial cells (NRK-52E) were pretreated with specific ER-stress inhibitors or siRNA, and then analyzed the tubular apoptosis.

Results: Treatment with urografin significantly induced CM-induced nephropathy, which presented as tubular dilation, tubular cells detachment and increasing in serum creatinine level in rats' sample. Tubular apoptosis, ER stress-related proapoptotic activators, and kidney injury molecule-1 were induced in CM-treated kidney. We found urografin activated ER stress-related signals, including ATF6/CHOP, Bax/caspase 12 and IRE/caspase 12 pathways. The findings suggested ER stress implicated in the urografin-induced tubular apoptosis. We further explored the roles of ER signals by administered specific blockers or siRNA of ER pathways in NRK-52E cells. We found that ATF6 inhibitor (AEBSF), JNK phosphorylaed inhibitor (SP600125), and CHOP siRNA failed to reverse the CM-induced tubular apoptosis, but Caspase 12 inhibitor (zATAD), at least partially, attenuated Urografin-induced renal tubular apoptosis.

Conclusions: In addition to GRP78 /EIF2α-phosphorylation, ER stress-dependent caspase12 pathway might be a novel therapeutic target in the CM-induced kidney injury.

Funding: Government Support - Non-U.S.

ERK ½ Activity Mediates Hydrogen Peroxide-Induced Renal Epithelial Cell Injury that Is Inversely Affected by Occludin Protein Content Danielle Janosevic, Victoria V. Rohring, Josephine Axis, Kurt Amsler. *Biomedical Sciences, New York College of Osteopathic Medicine of NYIT, Old Westbury, NY.*

Background: Oxidative stress has been implicated in the disruption of renal epithelial tight junctions and consequent increased paracellular permeability in several pathologic processes including ischemia/reperfusion injury, radiocontrast-induced nephropathy, and exposure to calcium oxalate.

Methods: In order to study this process in more detail, we examined the effect of H_2O_2 treatment, as a model of oxidative stress, on paracellular permeability of two renal epithelial cell lines, LLC-PK_1/Cl4 (proximal tubule-like) and MDCK II (distal tubule-like). Permeability of the two components of paracellular permeability, the pore pathway (small solutes and ions) and the leak pathway (large solutes), was monitored by TransEpithelial Resistance (TER) and calcein flux, respectively. Cell damage was monitored with Trypan Blue staining.

Results: At sublethal concentrations, H_2O_2 produced a concentration-dependent increase in calcein flux in both renal cell lines. In contrast, TER only decreased at H_2O_2 concentrations that also increased the number of Trypan Blue-staining cells. ERK ½ inhibitors blocked both the increased calcein flux produced at sublethal H_2O_2 concentrations and the increased calcein flux, TER, and cell damage produced at higher H_2O_2 concentrations. H_2O_2 produced

a decrease in basal F-actin stress fibers and a modest change in occludin protein localization. Occludin knockdown in MDCK cells produced an enhanced responsiveness to sublethal H_2O_2 treatment, whereas, occludin overexpressing MDCK cells were resistant to H_2O_2 at similar concentrations. ERK ½ inhibition attenuated the H_2O_2-induced increase in calcein flux in both occludin knockdown and occludin overexpressing cells.

Conclusions: Our results indicate that ERK ½ mediates both the H_2O_2-induced increase in leak pathway at sublethal concentrations and increased cell damage at lethal concentrations. Occludin protein protects against both the sublethal and lethal effects of H_2O_2.

A Model of Chronic Cisplatin-Induced Kidney Injury in Mice with Cancer

Hyun-Jung Kim, Raphael A. Nemenoff, Zhibin He, Danica Ljubanovic, Charles L. Edelstein. *Univ. of Col. Denver.*

Background: Patients with cancer may require chronic administration of cisplatin (Cis). However, most previous in vivo studies of Cis-induced AKI (CIA) have been in models of acute (3 days), high dose (25mg/kg) Cis administration in normal mice. Aim of study was to develop a model of 4 week, low dose (5 mg/kg) Cis administration in mice with cancer, that resembles the Cis dosing regimen for 4 cycles that is used in humans with cancer.

Methods: Mice were injected with 10^5 lung cancer cells into the flank at day 0. The first dose of Cis 5 mg/kg or vehicle (Veh) was given at day 9. Cis 5 mg/kg or Veh was then given on days 16, 20, 23 and 27 for a total of 5 doses. Mice were sacrificed on day 29. Tumors were measured on day 16, 20 and 29. IL-33 and CXCL1 (IL-8) are pro-inflammatory cytokines. IL-33 signals via the ST2 receptor on CD4 T cells. We have previously described the role of the IL-33/ST2/CD4 T cell/CXCL1 axis in a 3 day model of CIA.

Results: AKI model: BUN (mg/dL) was 23 in Veh and 114 in Cis (P<0.001). SCr (mg/dL) was 0.2 in Veh and 0.5 in Cis (P<0.001). ATN score was 0 in Veh and 3.5 in Cis (P<0.001). Apoptosis in tubular cells (/HPF) was 0 in Veh and 1.2 in Cis (P<0.001). Cancer model: Tumor volume (mm^3) in Veh was 308 on day 16 and 1791 on day 29 (P<0.001). Tumor volume in Cis was 604 on day 16 and 702 on day 29 (NS). At the end of the study, tumor weight (g) was 1.23 in Veh and 0.46 in Cis (P<0.001). IL-33/ST2/CD4 T cell/CXCL1 signaling: IL-33 (pg/mg) was 70 in Veh and 198 in Cis (P<0.001). CXCL1 (pg/mg) was 1.9 in Veh and 58 in Cis (P<0.001). CD4 T cell subset (% of live cells) on flow cytometry was 13 in Veh and 35 in Cis (P<0.001). In time course experiments, the increase in IL-33, CD4 T cells and CXCL1 at week 1 preceded the increase in BUN and SCr at week 2 after Cis administration.

Conclusions: We have developed a model of chronic Cis-administration that resembles the human condition in mice with cancer. There are increases in BUN, SCr, ATN, apoptosis, IL-33, CD4 T cells and CXCL1 and also a significant chemotherapeutic effect of Cis on the tumor. The effect of IL-33, ST2 or CXCL1 inhibition on the CIA and the chemotherapeutic effect of Cis will be interesting in future experiments.

TH-PO035

Shiga Toxin Triggered Renal Apoptosis Is Caused by Imbalance between Bax and Bcl-xl Expression and Rescued by Ouabain/Na,K-ATPase Signaling

Ievgeniia Burlaka,[1] Johan Rebetz,[2] Ida Arvidsson,[2] Diana Karpman,[2] Xiao Liu,[1] Anita Aperia.[1] *[1]Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden; [2]Pediatrics, Lund University, Lund, Sweden.*

Background: Hemolytic uremic syndrome (HUS), a life threatening disease with renal failure as a prominent symptom, generally occurs after gastrointestinal infection with Shiga toxin2 (Stx2) producing *E coli*. Stx2 binds to Gb3 receptors and triggers apoptosis by activating the apoptotic factor Bax. Since we recently found that signaling via the ouabain/Na,K-ATPase/IP3R complex increases expression of Bcl-xL, an inhibitor of Bax, we have tested if ouabain can protect from Stx2 triggered apoptosis.

Methods: In vitro studies were performed on primary cultures of rat proximal tubule cells (RPTC) expressing Gb3 receptors. Other methods include TUNEL staining and FACS analysis, using early and late markers of apoptosis; Western blot; immunostaining; p65 DNA binding assays; In vivo studies were performed on mice given ip injection of Stx2 285 ng/kg and receiving either ouabain 15µg/kg/d or saline via subcutaneous pumps. Mice were sacrificed after 4 days. Kidneys were serially sectioned and TUNEL stained for quantitative analysis of tubule cell apoptosis.

Results: Exposure of RPTC to Stx2 resulted in massive apoptosis. Co-incubation of Stx2 with 10nM ouabain almost completely rescued from apoptosis. Stx2 caused 40% up-regulation of Bax, 50% increase in cleaved caspase (downstream effect of Bax) and 20% down-regulation of Bcl-xL. All effects are significant. Ouabain co-incubation significantly attenuated Bax up-regulation, reduced caspase cleavage and increased Bcl-xL expression. Bcl-xL up-regulation was mediated via transcription factor p65, member of the NF-kB family. Ouabain translocated p65 to nucleus. Inhibition of p65 DNA binding abolished anti-apoptotic effect of ouabain. Preliminary results from in vivo studies provide proof of principle that ouabain protects from apoptotic effects of Stx2.

Conclusions: Non-toxic concentrations of the cardiotonic steroid ouabain can rescue from Stx2 triggered renal apoptosis, a main cause of permanent renal damage following *E coli*-associated HUS.

The Role of Mannose Receptor in Folate Nephropathy

Hsu-han Wang,[1] Sally Hamour,[2] Ruth J. Pepper,[1] H. Terence Cook,[2] Alan D. Salama.[1] *[1]Centre for Nephrology, University College London, London, United Kingdom; [2]Renal Medicine, Imperial College London, London, United Kingdom.*

Background: Folic acid (FA) administration induces dose-dependent acute and chronic tubular injury which is associated with heavy macrophage infiltration. FA nephritis is therefore a good model of acute and progressive renal failure secondary to tubular damage. We have previously demonstrated deficiency of mannose receptor (MR) protects mice from glomerulonephritis via altered cytokine production and FcR mediated signalling, and we have now evaluated the role of MR deficiency in FA mediated acute kidney injury.

Methods: MR -/- homozygote and heterozygote mice and control WT C57BL6 mice were used at 8-12 weeks age. FA 240mg/kg was injected intraperitoneally with 0.2ml sodium bicarbonate as vehicle. Mice were sacrificed at 7 or 14 days after injection. We assessed renal function, histological damage using an acute tubular injury (ATI) score and immunohisto-chemistry staining. Real-time quantitative polymerase chain reaction (qPCR) was used to evaluate gene regulation in our model.

Results: At day 7 following injury, serum urea and creatinine were similar between WT and MR-/- mice; however, the ATI score was higher in WT and MR+/- than MR -/- mice (60.20±16.56, 42.60±10.56, & 10.67±1.78 respectively) with decreased CD68 staining in MR-/- mice. Two weeks following injury, the ATI score showed significant reduction according to MR genotype (WT:40.67±4.30, MR+/-:25.33±2.00, MR-/-:12.09±3.56; p<0.01). Using qPCR analysis at day 14, we found Arg1 (WT 241.24±161.11 vs MR-/- 5.91±3.04, p=0.020), Ym1(WT 10.24±4.23 vs MR-/- 4.23±2.17, p=0.039), and Mrs1 (WT 19.84±12.77 vs MR-/- 2.07±0.79, p=0.025) were significantly down-regulated in the MR-/- mice, whilst the expression of IL1b and iNOS were also reduced but to a lesser extent (8.98±5.96 vs 3.99±2.05 & 4.72±2.38 vs 3.57±1.28 respectively).

Conclusions: Mannose receptor deficient mice are protected from acute FA-induced macrophage mediated kidney damage, with evidence of reduced infiltration and attenuated alternative macrophage activation. MR antagonism may be a novel therapeutic strategy for various forms of acute kidney injury mediating an important effect on macrophage activation.

TH-PO037

Genetic Deficiency of Adiponectin Protects against Acute Kidney Injury

Xiaogao Jin, Jiyuan Chen, Zhaoyong Hu, Yanlin Wang. *Medicine-Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Acute kidney injury (AKI) is a common clinical condition that is associated with high morbidity and mortality. Ischemia-reperfusion injury (IRI) is a common cause of AKI. There is no effective therapy for this devastating clinical condition except renal replacement. Therefore, a better understanding of the pathogenic mechanisms underlying IRI is essential for ultimately developing effective therapy. Inflammation plays a critical role in the pathogenesis of acute kidney injury. Adiponectin is a cytokine that regulates inflammation, but its role in acute kidney injury is not known.

Methods: To determine if adiponectin contributes to acute kidney injury, we subjected wild-type and adiponectin knockout mice to 30 minutes of ischemia followed by 24 hours of reperfusion.

Results: Compared with wild-type mice, adiponectin knockout mice demonstrated lower serum creatinine and less tubular damage. Tubular cell apoptosis induced by ischemia-reperfusion injury was decreased in the kidney of adiponectin knockout mice, which was associated with a decrease in Bax, a proapoptotic protein, and reduced activation of p53 and caspase-3. Furthermore, targeted disruption of adiponectin inhibited the infiltration of neutrophils, macrophages, and T cells into the injured kidneys, which was associated with a decrease in the expression of the proinflammatory molecules – IL-6, TNF-α, MCP-1, and MIP-2. Moreover, targeted disruption of adiponectin inhibited NF-κB activation in the kidney after ischemia-reperfusion injury.

Conclusions: Our results demonstrate that adiponectin plays a pivotal role in the pathogenesis of acute renal ischemia-reperfusion injury, suggesting that inhibition of adiponectin may be a potential therapeutic strategy in acute kidney injury.

Preconditioning Mouse Proximal Tubular Cells with A-769662, a Pharmacologic Activator of AMP-Activated Protein Kinase (AMPK), Ameliorates Apoptosis Induced by Subsequent Metabolic Stress

Wilfred Lieberthal,[1] Vimal Patel,[2] Jerrold S. Levine.[2] *[1]Nephrology, Stony Brook Medical Center, Stony Brook, NY; [2]Nephrology, University of Chicago at Illinois, Chicago, IL.*

Background: We have previously demonstrated that acute metabolic stress activates AMPK in mouse proximal tubular cells (MPTs) and that, once activated, AMPK ameliorates the stress-induced apoptosis (Lieberthal et. al.: AJP, 301:F1177, 2011). We now test the hypothesis that preconditioning of MPT cells with A-769662, a pharmacologic activator of AMPK, can reduce apoptosis induced by a subsequent period of metabolic stress.

Methods: MPT cells were preconditioned with the AMPK activator A-769662, or its vehicle, and then subjected to metabolic stress using a mitochondrial inhibitor (antimycin A) in the presence of reduced concentrations of dextrose. Control cells were incubated in medium containing 5 mM dextrose without antimycin A.

Results: Apoptosis during metabolic stress was substantially reduced when MPT cells were subjected to "long-term" (24 hr) preconditioning with A-769662. Long-term preconditioning also significantly ameliorated the decrease in ATP induced by metabolic stress. These effects of long-term preconditioning were associated with increases in expression of the Glut1 transporter, in glucose influx, and in the rate of glycolysis (assessed by lactic acid production). By contrast, "short-term" (2 hrs) preconditioning with A-679662 had no effects on apoptosis, ATP levels, or glucose metabolism.

Conclusions: Long term preconditioning with A-769662 substantially reduces apoptosis of MPT cells subjected to metabolic stress, an effect likely due to amelioration of ATP depletion. Preservation of energy stores is probably mediated, in part, by preconditioning-induced increases of glucose uptake and glycolytic activity. The difference in the effects of long- vs. short-term preconditioning suggests a requirement for AMPK-regulated new gene expression.

Role of beta-Actin in DNase I-Mediated Death of Tubular Epithelial Cells during Kidney Ischemia-Reperfusion Injury Tariq Fahmi,[1] Xiaoying Wang,[1] Eugene Apostolov,[1] Alena Savenka,[1] Intisar Islam,[1] Sudhir V. Shah,[1,2] Alexei G. Basnakian.[1,2] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Background: DNase I is the most active endonuclease in the kidney which is responsible for DNA fragmentation leading to tubular epithelial cell death. The only known endogenous inhibitor of DNase I is monomeric (beta) actin. However relationship between DNase I and beta-actin are not understood. This study was aimed to determine mechanistic relationships between the two proteins during ischemia-reperfusion (IR) in rat kidney.

Methods: Real-time RT-PCR and immunocytochemistry (IHC) was used to assess expression of DNase I and beta-actin, and TUNEL assay was applied to measure DNA fragmentation.

Results: We showed that kidney IR injury in rats is associated with DNA fragmentation located mainly in cortico-medullary junction of the kidney and peaking at 16 hrs of reperfusion. According to IHC, both DNase I and beta-actin were elevated and partially colocalized at the same time point. At low levels of TUNEL, DNase I was linearly and positively associated with TUNEL and beta-actin, but later beta-actin induction decreased, which created an excess of DNase I. To study the mechanism of beta-actin induction by DNase I, two DNase I mutants were produced: one with inactive DNA binding/cleavage site and another with defective actin-binding site. Transfection of rat kidney tubular epithelial NRK-52E cells with wild-type (WT) DNase I gene or the mutants followed by real-time RT-PCR and IHC showed that beta-actin is induced by DNase I, but not by the mutants, suggesting that DNase I induces beta-actin through DNA breaks and actin binding. Transfection of the cells with the actin-binding mutant resulted in more cytotoxicity than with WT DNase I as determined by LDH assay suggesting that beta-actin is important regulator of DNase I cytotoxicity.

Conclusions: Overall our results show that during IR, DNase I induces beta-actin through DNA breaks and actin-binding, but induced beta-actin cannot inhibit DNase I completely, which continues raising, inducing DNA breaks and causing cytotoxicity.

Positive and Negative Regulation of Endonucleases by EndoG in Kidney Tubular Epithelial Cells Alexei G. Basnakian,[1,2] Dmitry D. Zhdanov,[1] Tariq Fahmi,[1] Xiaoying Wang,[1] Alena Savenka.[1] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Background: Cisplatin toxicity to kidney was shown to be mediated by cytotoxic/apoptotic endonucleases, of which deoxyribonuclease I (DNase I) is the most active, and endonuclease G (EndoG) is the second active. We have previously obtained evidence of an endonuclease network, in which EndoG and other endonucleases are induced by DNase I through its DNA-degrading activity. Because DNA breaks can be produced by any endonuclease, our next question was whether another endonuclease could have the same effect.

Methods: we transfected rat kidney tubular epithelial NRK-52E cells with EndoG gene cloned in pECFP vector. The expression of EndoG-CFP fusion protein was monitored for up to 24 hours by using quantitative fluorescent microscopy, while CFP expression was used as control. At 24 hours post-transfection, mRNA expressions of eight other endonucleases, including DNase I, DNase X, DNase gamma, DNase 1L2, DNase IIalpha, DNase IIbeta, L-DNase II and caspase-activated DNase (CAD) were measured using real-time RT-PCR.

Results: Our data showed that within first several hours, EndoG overexpression induced only DNase I-like endonucleases (DNase I, DNase X, DNase gamma, DNase 1L2). Unexpectedly, we observed that DNase I was downregulated to almost zero level by 20 hours post-transfection. Agarose electrophoresis of DNase I gene amplification product showed that DNase I pre-mRNA is alternatively spliced lacking 84 bases directly corresponding to exon 4. The alternatively-spliced DNase I without exon 4 was dominant-negative against wild-type DNase I.

Conclusions: This is the first evidence that EndoG can activate DNase I-like endonucleases and downregulate DNase I by inducing alternative splicing of its pre-mRNA.

A Modified Ultrasound Regimen Reduces Kidney Ischemia Reperfusion Injury in Mice via Splenic Cholinergic Modulation Joseph C. Gigliotti,[1] Kryt Chattrabhuti,[1] Liping Huang,[1] Amandeep Bajwa,[1] Hong Ye,[1] Sangju Lee,[1] Diane L. Rosin,[2] Alexander L. Klibanov,[3] Kambiz Kalantari,[1] Mark D. Okusa.[1] *[1]Med, CIIR, Univ of Virginia, Charlottesville, VA; [2]Pharmacology, CIIR, Univ of Virginia, Charlottesville, VA; [3]Med, Cardiology, Univ of Virginia, Charlottesville, VA.*

Background: Activation of innate immunity is key in the pathogenesis of ischemia reperfusion injury (IRI). Previous research suggests that ultrasound (US) exposure modulates the immune response. Our hypothesis is that prior exposure to US will reduce the severity of kidney injury in a mouse model of IRI.

Methods: Anesthetized male C57BL/6 mice were exposed to US (frequency: 7MHz; MI: 1.2). Mice underwent bilateral renal IRI 24 hr after US exposure. After reperfusion, tissue samples were collected for plasma creatinine (PCr), renal tissue histology, and flow cytometry. In subsequent studies, TNFα was quantified in LPS treated splenocytes isolated 24 hr after US exposure. In others, mice underwent splenectomy 7 d prior to US and IRI. To determine the role of cholinergic signaling in US prevention of IRI, the α-7 nicotinic antagonist α-bungarotoxin (BT) was administered i.v. 30 min prior to US.

Results: Following IRI, US treated mice had reduced PCR ($P<0.001$), tubular damage ($P<0.001$), and kidney leukocyte infiltration ($P=0.003$) compared to mice receiving IRI alone. Protection from IRI ($P<0.005$; PCr) lasted up to 2-3 d following US exposure. Splenocytes from US treated mice produce 75% less TNFα in response to ex vivo LPS stimulation compared to non-US treated animals. Furthermore, prior splenectomy ($P=0.01$) removed the protective effect of US. BT administration also abolished US protection from IRI.

Conclusions: Our data is consistent with the hypothesis that US mediated kidney tissue protection occurs via activation of the splenic cholinergic anti-inflammatory pathway. We believe that this finding could have an important impact in attenuating human acute kidney injury given the routine noninvasive nature of US, which is a safe, portable and an inexpensive method of immune modulation.

ER Stress-Induced Autophagy Provides Cytoprotection from Chemical Hypoxia and Oxidant Injury and *Ameliorates Ischemia-Reperfusion-Induced AKI* Bhavya Balan Chandrika,[1] Cheng Yang,[1] Alexandrea Holmes,[2] Sue Theus,[2] Sarika Deshmukh,[1] Didier Portilla,[1,2] Gur P. Kaushal.[1,2] *[1]Division of Nephrology, UAMS, Little Rock, AR; [2]Division of Nephrology, CAVHS, Little Rock, AR.*

Background: The role of ER stress and accompanied UPR is not completely understood in renal pathophysiology. ER stress afforded protection in Renal Tubular Epithelial cells (RTEC) *in vitro* against oxidants as well as against renal ischemia-reperfusion (IR) injury *in vivo*. However, the mechanism of protection by ER stress-induced UPR in acute kidney injury (AKI) is not known.

Methods: The study encompassed different techniques for assaying apoptotic and necrotic cell death such as activity assays for caspase3/7, PI staining by FACS, LDH release and western blot analysis. Autophagy was scored by LC3 puncta formation by imaging and by western blot for major autophagy proteins. Implemented Transfection and siRNA mediated silencing of specific genes for the study. AKI was induced in mouse models via Ischemia Reperfusion surgery.

Results: We demonstrated that the ER stress inducer Tunicamycin activated autophagy via AMPK-mTOR pathway in RTEC as a survival mechanism without impairing autophagic flux. ER stress-induced autophagy markedly provided cyto-protection in renal cells from the oxidants H_2O_2 and tert-Butyl hydro peroxide as well as chemical hypoxia induced by antimycin A. Inhibition of ER stress-induced autophagy both by pharmacological and genetic approaches, significantly enhanced cell death in response to oxidative and chemical hypoxic stress. ER stress-induced autophagy attenuated renal IR injury as evident from significant improvement in renal function and histology. Inhibition of ER stress-induced autophagy worsened renal function in IR injury and supported a protective role of ER stress-induced autophagy in IR-induced AKI.

Conclusions: ER stress mediated cyto-protection for renal cells *in vitro* and *in vivo* from oxidative/hypoxic stress is conferred by the activation of autophagy mechanism suggesting that ER stress initiated autophagy as a pro survival mechanism and further insights may offer new avenues for devising therapeutic strategies against AKI.

TH-PO043

Natural IgM Can Induce Tolerance in Bone Marrow Dendritic Cells Kailo H. Schlegel, Li Li, Amandeep Bajwa, Mark D. Okusa, Peter I. Lobo. *Medicine/CIIR, University of Virginia, Charlottesville, VA.*

Background: Prior clinical observations have shown an association between high levels of natural IgM autoantibodies in transplantation recipients, especially IgM with anti-leucocyte reactivity (IgM-ALA), and protection from rejection of renal and cardiac allografts. We have shown that natural IgM inhibits inflammation in mouse kidneys induced by ischemia- reperfusion injury (IRI) and by rejection in cardiac allografts. The current studies were aimed at determining if natural IgM mediates these anti-inflammatory effects by inducing tolerance in dendritic cells (DCs), which normally activate effector natural

killer cells and T cells by presenting antigen, providing cytokines (IL-12, TNF-α) and co-stimulatory signals via receptors (CD86 and CD40).

Methods: Bone marrow DCs (BMDCs), obtained from femurs of C57BL/6 mice and cultured with GMCSF, were activated for 18 hr in-vitro with LPS and vehicle, IgM (50 μg/ml), IgG or isotype IgM lacking IgM-ALA activity, and cells were analyzed for expression of CD40, and TNF-α. Secondly, 18 hr pretreated BMDCs were washed and added to a 1-way mixed lymphocyte reaction (MLR) with CFSE-labeled splenic responders from C57BL/6 mice and Balb/c irradiated splenic stimulators. Lastly, BMDC were pulsed with glycolipid (α-GalCer) to determine if IgM inhibits DC glycolipid presentation via the CD1d receptor. We used an antibody that detects the glycolipid/CD1d complex by flow cytometry.

Results: Pretreatment with IgM, but not IgG or isotype IgM, inhibited LPS-induced up-regulation of CD40 (MFI: 6200 (IgG) vs 3000 (IgM)) and enhancement of TNF-α production (pg/ml: 6300 (IgG) vs 3900 (IgM) by BMDCs. Additionally, IgM pre-treated BMDCs significantly inhibited alloantigen activated T cells from proliferating (CFSE (%): 61.7% (IgG) vs 19.5% (IgM), and differentiating into Th-1 cells. Finally, we show that IgM pretreated (18 hr) DCs blocked cell surface expression of the glycolipid/CD1d complex.

Conclusions: The mechanism by which natural IgM attenuates inflammation may in part be mediated by the effects of IgM directly on DCs, through induction of DC tolerance. These in-vitro findings, prompted by clinical observations, may have therapeutic relevance.

TH-PO044

The Purified Micronized Flavonoid Fraction Effect in the Sepsis-Associated Acute Kidney Injury (AKI) Maria De Fatima Vattimo, Carolina Ferreira Pinto, Mirian Watanabe, Cassiane Dezoti Fonseca. *School of Nursing, University of Sao Paulo, Sao Paulo, SP, Brazil.*

Background: The concept of renal vasoconstriction and kidney ischemia as a key pathogenic factor is still valid for sepsis-associated AKI. This may result from global renal hypoperfusion, mediated by the upregulation of pro-inflammatory cytokines (TNF-α and IL-6), with tubular cell apoptosis. Ischemia and reoxygenation in the reperfusion cause oxygen cell damage and capillary stoppage, leading to the renal injury mainly in inflammatory enviromnent as sepsis. The aim of this study was to evaluate the effect of the purified micronized flavonoid fraction (Diosmin), that reduces microvascular permeability and leukocyte adhesion, with antioxidant role, on the creatinine clearance, urinary peroxides and the kidney histology in sepsis associated AKI .

Methods: Adult male Wistar rats (250–300g) were used. Renal function (RF) (creatinine clearance, crCl), urinary peroxides (UP, FOX-2), kidney, lung and intestinal tract levels of TNFα and IL-6 (ELISA) and kidney histology were evaluated. Sepsis was induced by cecal ligature and puncture (CLP). Groups: Sham (without CLP); Sepsis (CLP); Sepsis+Diosmin (Diosmin 3mg/Kg 30 minutes before CLP).

Results:

Physiological paramethers, creatinine clearance and UP

Groups	MAP (mmHg)	BT (°C)	crCl (ml/min)	UP (mmmol/mg creat)
SHAM (n=6)	77 ±5	36.4±0.3	0.60±0.11	3.4±0.6
Sepsis (n=5)	53±6♣	35.7±0.2♣	0.27±0.06♣	13.9±5.1♣
Sepsis+Diosmin (n=5)	72±13♦	36.6±0.6♦	0.34±0.03♣♦	7.4±3.1♦

♣ p<0.05 vs SHAM; ♦ vs Sepsis. Being MAP: mean arterial pressure and BT: body temperature

A similar quantitative inflammatory response (TNFα and IL-6) in distant organs and in the kidneys was observed in CLP animals. CLP induced a decrease in mean arterial pressure, body temperature and creatinine clearance, accompanied by a prominent increase in UP. These paramethers were significantly changed in the pretreated Diosmin group. In the kidney histology, loss of brush border was evident as was a severe dilation of the tubular lumen after CLP.

Conclusions: Remote organs can mediate sepsis-associated AKI. These data provide a new insight about Diosmin attenuating the Sepsis-associated AKI action by decreasing oxidant damage and endothelial swelling.

Ectodomain Shedding by TACE/ADAM17 Regulates Kidney Injury Molecule-1 (KIM-1) Mediated Phagocytosis of Apoptotic Cells Rushi Gandhi,[1,3] James Yi,[1,3] Hang Shi,[1,3] Sahra Nathoo,[1,3] Ola Ismail,[1,3] Xizhong Zhang,[2,3] Lakshman Gunaratnam.[1,2,3] *[1]Dept of Microbiology and Immunology, Western Univ., London, ON, Canada; [2]Division of Nephrology, Schulich School of Medicine and Dentistry, London, Canada; [3]Matthew Mailing Centre for Translational Transplant Studies, Lawson Health Research Institute, London, Canada.*

Background: Apoptosis of tubular epithelial cells is a hallmark of ischemic and toxic acute kidney injury. Phagocytic clearance of apoptotic cells protects multicellular organisms from chronic inflammation and autoimmunity. KIM-1 is a receptor that enables proximal tubule epithelial cells (PTECs) to engulf and clear apoptotic cells. KIM-1 is rapidly upregulated on PTECs following cellular injury. It undergoes constitutive membrane-proximal cleavage resulting in release of a soluble (90 kDa) protein into the urine, or into culture medium of KIM-1-expressing cells. Although KIM-1 is a biomarker of acute kidney injury, the enzyme responsible for KIM-1 shedding and the biological significance of this phenomenon are unknown.

Methods: In addition to studying constitutive shedding, we used phorbol-12-myristate-13-acetate to accelerate KIM-1 shedding. TACE activity was repressed with an inhibitor (TAPI-O) and by shRNA knockdown. We used Western blot to detect KIM-1 cleavage products. Conditioned medium containing shed KIM-1 was used to competitively inhibit the phagocytic uptake of apoptotic cells by PTECs.

Results: We report for the first time that TACE/ADAM17 regulates both constitutive and accelerated shedding of KIM-1.

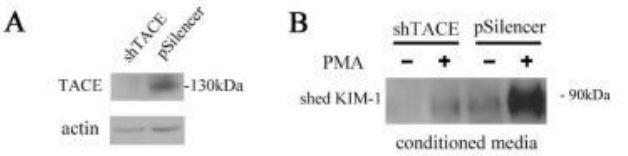

Figure 1. (A) shRNA was used to stably knockdown TACE (shTACE) in 786-O cells expressing endogenous KIM-1. (B) Constitutive and accelerated KIM-1 shedding was studied in the above cells.

The accelerated shedding of KIM-1 inhibited its phagocytic function while silencing TACE expression had the opposite effect.

Conclusions: We conclude that KIM-1-dependent phagocytosis of apoptotic cells is regulated by TACE-mediated shedding. We postulate that the biological significance of this regulation may have significant implications to acute kidney injury.

TH-PO046

mTORC1 Influences Tubular Transport and Ischemic Stress Response by Regulating Autophagy and Mitochondrial Energy Provision Florian Grahammer, Tobias B. Huber. *Renal Division, Department of Medicine, University Hospital, Freiburg, Germany.*

Background: mTORC1 is a known master regulator of mitochondrial biogenesis and autophagy. Despite widespread use of mTOR inhibitors in clinical practice hardly anything is known on its physiological und pathophysiological role within renal tubules.

Methods: Cell specific deletion of conditional mTORC 1 (*Raptor*) allels was achieved by using *Ksp* or inducible *Pax8* Promotor driven Cre lines. These mice were analyzed further using functional assays, light and electron microscopy, immunofluorescence, western blotting and MRI.

Results: Both *Raptor fl/fl*Ksp*Cre and induced *Raptor fl/fl*Pax8*TetOCre* mice were viable. *Raptor fl/fl*Ksp*Cre mice presented with a urinary concentration defect due to reduced transport capacity in the TAL. Kidney morphology of these mice was altered macroscopically with MRI showing an enlarged medulla. Histologically an increased interstitial proliferation, increased fibrous tissue and loss of tubular cells were evident. Ultrastructurally prominent, fragmented mitochondria could be detected, biochemically markers of mitochondrial biogenesis were reduced as were TAL specific transport proteins.

*Raptor fl/fl*Pax8*TetOCre* mice did not show any gross macroscopic nor histologic phenotype. Ultrastructurally aberrant formation of multi-layered autophagosomes were present in proximal tubular cells. When exposed to ischemia – reperfusion these mice showed an increased proximal tubular damage, increased apoptosis and reduced recovery as evidenced by diminished proliferation after injury.

Conclusions: Lack of mTORC1 alters renal function and stress response depending on the tubular segment.

Funding: Government Support - Non-U.S.

TH-PO047

Testosterone (TST) Augments Renal Heme Oxygenase-1 (HO-1) Expression Independent of Androgen Receptor (AR) or Estrogen Conversion and Improves Ischemia Reperfusion Induced Acute Kidney Injury (IR-AKI) Andrea P. Soljancic,[1] Arnaldo F. Lopez-Ruiz,[1] Kiran B. Chandrashekar,[1] Istvan Arany,[2] Ruisheng Liu,[3] Luis A. Juncos.[1,3] *[1]Medicine/Nephrology, University of Mississippi Medical Center, Jackson, MS; [2]Pediatrics, University of Mississippi Medical Center, Jackson, MS; [3]Physiology and Biophysics, University of Mississippi Medical Center, Jackson, MS.*

Background: Sex hormones modulate renal function during IR-AKI. We reported that AKI reduces plasma TST, and that TST replacement improves AKI. However, the mechanism involved is unclear. We tested if TST-induced renal cytoprotection is via AR activation or conversion to estradiol.

Methods: Male Sprague-Dawley rats treated with TST and/or either flutamide (Flut; AR antagonist), anastrazole (AN; an aromatase inhibitor) or both, were subjected to I/R-AKI (40 mins of bilateral renal pedicle clamping). At 48 hours, we determined renal outer medullary RBF (OM-RBF), function (Pl Creat), injury (KIM-1), inflammation (TNFα), and HO-1 levels. We also examined the *in vitro* effect of TST on proximal tubular cells (LLC-PK1) exposed to oxidative stress.

Results:

TST ameliorated I/R-AKI and increased renal HO-1. independenlyof the androgen receptor or of conversion of TST to estradiol by aromatase. In fact, blocking endogenous estrogen generation with AN ameliorated IR-AKI and potentiated the effect of TST on I/R-AKI and HO-1. TST blunted LDH release in LLC-PK1 cells exposed to H2O2 by inducing HO-1 and antioxidant

response element (ARE) in an ERK1/2-dependent manner.

Conclusions: TST-mediated protection against I/R-AKI is associated with ERK1/2-dependent induction of HO-1 and ARE. This effect is independent of the androgen receptor and does not due to the conversion of TST to estrogen.

TH-PO048

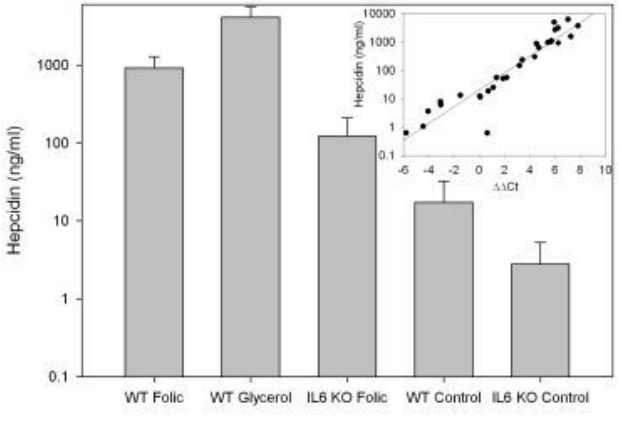
Increased Hepcidin May Contribute to the Anemia of AKI Joshua Zaritsky,[1] Erika Valore,[2] Victoria Rivka Gabayan,[2] Elizabeta Nemeth,[2] Tomas Ganz,[2] Isidro B. Salusky.[1] *[1]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Anemia is a frequent complication in patients with acute kidney injury (AKI) however disordered iron regulation as a potential cause remains unexplored. Therefore we sought to examine the expression of hepcidin, the key regulator of iron homeostasis, in two well described mouse models of AKI.

Methods: AKI was produced by either 1) IP injection of folic acid (200mg/kg) or 2) IM injection of 50% glycerol (7.5ml/kg) in 12 week old male wild-type (WT) BL6 or IL6 KO mice. Mouse serum hepcidin was measured by ELISA. Hepcidin, liver serum amyloid A1 (SAA1), and NGAL mRNAs were measured by real-time PCR amplification and reported as ΔΔCt.

Results: AKI at 48 hours was confirmed by elevated serum BUN and increased kidney NGAL mRNA ($p<0.01$ vs. control) (table). Serum hepcidin levels were highly elevated in AKI models ($p<0.01$ vs. control) (figure) which highly correlated with increased liver hepcidin mRNA ($r= 0.958$; $p<0.01$) (figure inset). SAA1 mRNA, a marker of inflammation, was also very elevated in AKI animals ($p<0.01$ vs. control). Although the absolute levels of serum hepcidin and liver hepcidin and SAA1 mRNA were lower in IL6 KO animals their relative increase in AKI versus control were similar to WT. There were no differences seen in kidney hepcidin mRNA.

	n	BUN	Liver Transcript (ΔΔCt)		Kidney Transcript (ΔΔCt)	
		(mg/dl)	Hepcidin	SAA1	NGAL	Hepcidin
WT Folic	16	93±4	5.5±1	10±1	8.2±1.2	0.6±1.5
WT Glycerol	6	88±9	6.6±0.8	8.5±0.5	7.2±0.9	0.7±3
IL6 KO Folic	6	89±12	2.5±0.9	6.4±0.5	-	-
WT Control	16	16±2	0±1.5	0±1.3	0±2	0±1.1
IL6 KO Control	6	26±5	-4.3±1	-1.4±1	-	-



Conclusions: In both mouse models, AKI results in very high serum hepcidin levels which appear to be mediated by increased liver mRNA via an IL6-independent inflammatory pathway. Future studies are needed to determine if these inflammatory driven acute elevations in hepcidin contribute to disordered iron regulation and anemia in the setting of AKI.

Production of Mitochondrial Reactive Oxygen Species in Proximal Tubules after Hypoxia/Reoxygenation Anja H. Bienholz,[1,2] Ahmad Al-Taweel,[1] Thorsten Feldkamp,[2] Joel M. Weinberg.[1] *[1]Department of Internal Medicine, Division of Nephrology, University of Ann Arbor, Ann Arbor, MI; [2]Nephrology, University of Duisburg-Essen, Essen, Germany.*

Background: Reactive oxygen species (ROS) figure prominently in both acute and chronic kidney injury and mitochondria are major intracellular sources. We have investigated approaches to best assess mitochondrial ROS (mtROS) production in isolated mouse and rabbit proximal tubules (PT) and the effects of hypoxia/reoxygenation (H/R) on the process.

Methods: Among widely used methods, dichlorofluorescein was unsuitable because of active secretion of the probe by the tubules and the signal from MitoSOX had strong nuclear localization and was increased in the absence of tubules by nonesterified fatty acids (NEFA), precluding its use to test effects of H/R-induced NEFA increases in PT. Measurement of H2O2 by Amplex Red was not subject to artifact and detected appropriate responses based on known mtROS biology.

Results: Oxygen consumption from succinate was 2.9x higher in mouse than in rabbit and concomitant mtROS production was 9.5x higher (238 ± 15 vs. 25 ± 3 nmol H2O2/mg protein/min, $P<0.001$). In both species, supraphysiological succinate (4 mM) produced high rates of mtROS production by reverse electron transport in complex I that were sensitive to decreases of proton motive force (PMF) by NEFA, chemical uncouplers, and H/R. Antimycin-induced mtROS production in complex III by both species was increased 3x by lowering succinate concentrations to 0.03-0.125 mM, and was not inhibited by uncoupling or H/R. mtROS production from complex I-dependent substrates was increased 3.3x by rotenone in mouse PT, but was not affected in the rabbit and was not altered by H/R in either species.

Conclusions: High rates of mtROS production in mice are not necessarily shared with other species and could impact generalizability of data obtained with them. Under conditions in which mitochondria develop a NEFA-mediated energetic deficit that strongly impacts on cellular recovery, H/R has a relatively small effect on mtROS production except for mtROS produced by reverse electron transport from succinate, which is inhibited by the PMF-lowering effect of accumulated NEFA.

Paricalcitol Supresses Renal Inflammation during Ischemia, Reperfusion Induced Acute Kidney Injury Jae-Won Lee, Eunjung Cho, Sang-Kyung Jo, Won-Yong Cho. *Division of Nephrology, Department of Internal Medicine, Korea University Anam Hospital, Seongbuk-Gu, Seoul, Republic of Korea.*

Background: The pathophysiologic mechanisms of ischemic acute kidney injury (AKI) are thought to include a complex interplay among vascular endothelial cell dysfunction, inflammation and tubular cell damage. In this study, we investigated the effect of the synthetic vitamin D analogue paricalcitol on renal inflammation in a mouse model of ischemia/reperfusion (I/R)-induced AKI.

Methods: Paricalcitol(500ng) or vehicle was administered via intraperitoneal injection 24 hour before ischemia, and then mice underwent ischemia through bilateral clamping of renal pedicles. At 24hour after I/R injury, mice were sacrificed for measurement of several parameters. To examine the direct effect of paricalcitol in tubular cellls, we also performed *in vitro* study using tubular epithelial cell line, HK-2 cells.

Results: Pretreatment with paricalcitol attenuated I/R induced AKI and reduced neutrophil and macrophage infiltration in kidney. It also reduced pro-inflammatory cytokine, interleukin (IL)-6, and chemokine, monocytechemotactic protein (MCP)-1 in kidney tissue. Tubular cell apotosis, determined by the number of terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL)-positive nuclei, was decreased by paricalcitol pretreatment. Bcl-2–associated X protein (Bax) in kidney tissue was also decreased by paricalcitol. Increased expression of toll-like receptor (TLR) 4 in tubular cells after I/R injury was attenuated by paricalcitol pretreatment. Paricalcitol pretreatment suppressed I/R-induced nuclear translocation of P65, suggesting that it blocked the activation of nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB) mediated inflammatory pathway following I/R. In *in vitro* experiment, paricalcitol pretreatment also suppressed the depletion of cytosolic inhibitor of κB (IκB) induced by tumor necrosis factor (TNF)-α in HK-2 cells.

Conclusions: These results suggest that beneficial effect of paricalcitol might be mediated by suppressing the innate immune response or inflammation including the activation of TLR4 and NF-kB pathway following I/R injury.

Neutophil Fate in Ischemia/Reperfusion Induced Acute Kidney Injury Sang-Kyung Jo,[1] Eunjung Cho,[1] So-young Lee,[2] Won-Yong Cho,[1] Hyoung-kyu Kim.[1] *[1]Internal Medicine, Korea University Medical College, Seoul, Korea; [2]Eulji Medical School.*

Background: Neutrophils rapidly infiltrate kidney and play an important role in I/R injury. For injured kidneys to repair and restore normal function, effective removal of neutrophils and other inflammatory cells seems to be prerequisite and inappropriate delay in neutrophil clearance might lead to chronic inflammation. Here we show an in-vivo evidence that neutrophil apoptosis is a critical step in resolution of inflammation in I/R induced AKI.

Methods: Annexin V positive apoptotic neutrophils were identified during the recovery phase and the role of neutrophil apoptosis on repair process was assessed in chimeric mice in which bone marrow was ablated by sublethal irradiation and then reconstituted with bone marrow from apoptosis resistant Bax KO mice (Bax KO->WT). WT bone marrow transplanted to WT mice (WT->WT) served as control.

Results: Initial neutrophil influx and kidney injury were comparable between the two groups. However, compared to control, neutrophils persisted in Bax KO-> WT chimeric mice throughout the recovery phase and this impaired neutrophil clearance due to resistance to apoptosis was associated with delayed recovery of kidney function and histologic kidney injury, persistently higher tissue proinflammatory cytokine level and also impaired regeneration (decreased PCNA positive cells). In addition to neutrophil apoptosis, we also identified other possible mechanisms involved in resolution of neutrophilic inflammation; reverse transendothelial migration and urinary expulsion. Following I/R injury, ICAM-1^{high}, $CXCR1^{low}$ long-lived neutrophils that are phenotypically distinct from circulating

ICAM- neutrophils that have been demonstrated in a model of reverse transendothelial migration appeared in peripheral blood during the recovery phase. In addition, Gr-1 positive neutrophils were also identified by flow cytometric analysis of urine obtained in recovery phase.

Conclusions: We suggest that neutrophil apoptosis, reverse transendothelial migration and urinary expulsion are involved in resolution mechanisms of neutrophilic inflammation and kidney repair in I/R induced AKI and might serve as new targets for facilitating recovery.

TH-PO052

Pituitary Adenylate Cyclase-Activating Polypeptide38 Ameliorates Renal Ischemia/Reperfusion Injury in Mice through TLR Mediated NF-κB Pathways Altaf-M. Khan,[1] Min Li,[1] Kristine E. Gullo,[1] Anna Wei Cai,[1] Solange Abdulnour-Nakhoul,[2] Jerome L. Maderdrut,[3] Eric E. Simon,[1,4] Vecihi Batuman.[1,4] *[1]Medicine, Nephrology & Hypertension, Tulane Medical University; [2]Gastroenterology, Tulane Medical University; [3]Peptide Research Laboratory, Tulane Medical University; [4]Department of Veterans Affairs, SLVHCS, New Orleans, LA.*

Background: We investigated whether pituitary adenylate cyclase-activating polypeptide38 (PACAP38) ameliorates kidney injury after ischemia/reperfusion (IR) through modulation of TLR-associated signaling pathways.

Methods: Male C57BL/6 mice (6-8 weeks-old, n = 4) were subjected to bilateral renal ischemia for 45 min followed by 3 d of reperfusion. PACAP38, 20 µg in 100 µl saline, was administered i.p. either 1 hr before IR with two additional doses at 24 and 48 hr or only at 24 and 48 hr after IR, and mice were euthanized at 72 hr. Sham-operated mice received the same amount of saline i.p. on the same schedule.

Results: In IR mice, PACAP38 maintained serum creatinine near control levels, (0.81 ± 0.08 vs. 0.69 ± 0.17 mg/dl in controls, p = NS, vs. 1.8 ± 0.03 in saline-treated IR mice, $p <$ 0.01) and significantly reduced expressions of kidney injury biomarkers KIM-1, Nogo-B1 and netrin-1. PACAP38 significantly reduced levels of apoptosis and neutrophil infiltration, demonstrated by immunohistology and by RT-PCR (Aifm-1 and CD11b) and protected against tubular damage assessed histologically. In PCR array, 59 of 83 TLR-related genes significantly changed their expression after IR. TLR2 increased 162-fold, followed by Fadd (37-fold) and TLR6 (24-fold), while Ube2v1 decreased 55-fold. PACAP38 given 24 hr after IR injury significantly reversed these changes in 56 genes, including TLR2, TLR4 and TLR6 with the largest effect on TLR6 (62-fold decrease) and also genes in the NF-κB pathways. The alterations in TLR2, TLR3, TLR6, and Ube2v1 were confirmed by RT-PCR. After IR, PACAP38 also suppressed protein levels of TLR-associated cytokines (TNF-α, MCP-1, IL2, IL6, IL1-β, and IFN-γ).

Conclusions: Acute kidney injury due to IR stimulates TLRs and associated NF-κB signaling pathways. PACAP38 reversed these IR-activated signaling pathways even when treatment was started 24 hr after IR.

TH-PO053

Pituitary Adenylate Cyclase-Activating Polypeptide38 Is a Potential Therapeutic Agent for Contrast-Induced Nephropathy in Human Kidney Cells and eNOS-Deficient Mice Altaf-M. Khan,[1] Min Li,[1] Herman L. Toliver,[1] Kristine E. Gullo,[1] Anna Wei Cai,[1] Jerome L. Maderdrut,[2] David H. Coy,[2] Eric E. Simon,[1,3] Vecihi Batuman.[1,3] *[1]Department of Medicine, Section of Nephrology & Hypertension, Tulane Medical University; [2]Department of Medicine, Peptide Research Laboratory, Tulane Medical University; [3]Department of Veterans Affairs, SLVHCS, New Orleans, LA.*

Background: We investigated whether pituitary adenylate cyclase-activating polypeptide38 (PACAP38) ameliorates contrast–induced nephropathy (CIN) in human renal proximal tubule epithelial (HK-2) cells and in a novel model of CIN using homozygous endothelial nitric oxide synthase-deficient ($eNOS^{-/-}$) mice.

Methods: Cultured HK-2 cells, pretreated with 10^{-9}-10^{-6} M PACAP or vasoactive intestinal peptide (VIP) for 1 hr, were exposed to ionic (Urografin) or non-ionic (iohexol) contrast media at 50 mg iodine/ml for 24 hr. Male $eNOS^{-/-}$ mice (22-26 g, n = 5-8) received Urografin iv (1.85 g iodine/kg) after 24-hr water deprivation, and PACAP38 (10 µg) i.p. 1 to 2 hr before and 12 hr after Urografin injection; control mice received an equal volume of saline. All mice were euthanized at 72 hr.

Results: Urografin and iohexol increased the release of LDH and KIM-1 into culture medium, induced apoptosis and inhibited cell proliferation in HK-2 cells ($p < 0.01$). PACAP38 and VIP reversed these changes in a dose-dependent manner. PACAP38 was more potent than VIP. In $eNOS^{-/-}$ mice, Urografin raised serum creatinine and cystatin C levels, caused renal tubule damage, apoptosis (Aifm-1 and Fas-1), neutrophil influx (CD11b), and increased protein levels of TNF-α, TGF-β1, MCP-1 and IFN-γ,and mRNA levels of kidney injury biomarkers KIM-1, Nogo-B1, and netrin-1 as well as Nox-4, Nox-2 and iNOS. PACAP38 significantly reversed these changes and restored towards baseline the mRNA levels of selected immune modulatory genes.

Conclusions: Both contrast media are toxic to HK-2 cells but Urografin was more toxic than iohexol. Urografin caused acute kidney injury in $eNOS^{-/-}$ mice. PACAP38 protected HK-2 cells and mouse kidney from CIN and is a potential therapeutic agent for CIN.

TH-PO054

Crucial Role of Calcium-Binding Protein S100A8/A9 in Controlling Macrophage-Mediated Renal Repair Following Ischemia/Reperfusion Mark Dessing, Gwendoline J.D. Teske, Loes Butter, Nike Claessen, Sandrine Florquin. *Department of Pathology, Academic Medical Center, Amsterdam, Netherlands.*

Background: Upon ischemia/reperfusion (I/R)-induced injury, several damage associated molecular patterns (DAMPs) are released including calcium-binding protein S100A8/A9. S100A8/A9 can be recognized by Toll-like receptor (TLR)-4 and activation of this TLR is known to deleteriously contribute to renal I/R induced injury. We hypothesized that S100A8/A9 contributes to renal I/R-induced injury.

Methods: Wild-type (WT) and S100A9 knockout (KO) mice (deficient for S100A8/A9 complex) were subjected to renal I/R and sacrificed after 1, 5 or 10 days.

Results: Although S100A8/A9 expression was significantly increased, 1 day after I/R, S100A9 KO mice displayed similar renal dysfunction, damage and neutrophil-influx compared to WT mice. Interestingly, S100A9 KO mice showed an impaired repair mechanism 5 days post I/R as reflected by increased renal damage, sustained inflammation, induction of fibrosis and increased expression of collagen. This coincided with enhanced expression of alternatively-activated macrophage (M2) markers while the expression of classically-activated macrophage (M1) markers was comparable. Similar, S100A8/A9 deficiency favored M2-macrophage activation *in vitro*, whereas M1-polarization was similar between the two strains.

Conclusions: We showed for the first time that S100A8/A9 inhibits M2-polarization of macrophages, thereby preventing the induction of renal fibrosis and damage after acute kidney injury. We conclude that S100A8/A9 plays a crucial part in controlling macrophage-mediated renal repair following I/R.

TH-PO055

Lcn-2 Over-Expressing Bone Marrow-Derived Macrophages Promote Renal Regeneration Anna Sola,[1] Marina Ventayol,[2] Georgina Hotter.[2] *[1]CIBER-BBN; [2]IIBB-CSIC.*

Background: Recent studies revealed a reparative role of macrophage therapy against different types of human pathologies. Specifically, re-injection of macrophages ex vivo genetically modified towards an anti-inflammatory phenotype has been described to protect against nephrotoxic nephritis.

Methods: Lipocalin-2 (Lcn-2) is a 25 kDa protein of the lipocalin superfamily that is synthesized from macrophages and that exerts a positive modulation of acute inflammation. In the kidney, it is known that Lcn-2 is produced at sites of injury and may modulate renal repair. In this study, we found that ex vivo genetically modified bone marrow derived macrophages towards lipocalin- 2 (Lcn-2) over-expression were capable of modulating injury and inflammation outcome in ischemic kidneys, promoting kidney repair and tissue regeneration.

Results: Renal function markers BUN and creatinine were decreased upon adoptive transfer of these macrophages and the expression of pro-inflammatory mediators was attenuated. Results indicated that macrophage-derived Lcn-2 promotes the proliferation of tubular epithelial cells. Immunostaining for the regeneration markers stathmin and PCNA showed markedly positive expression in the kidney sections with Lcn-2-macrophage treatment. Real-Time RT-PCR of the proliferation markers Ki-67 and PCNA further confirmed these effects.

Conclusions: In conclusion, we provide a novel role for macrophage-derived Lcn-2 on kidney regeneration and protection from experimental renal ischemia/reperfusion injury. Our results indicate a possible target for further therapeutic use in disease, since Lcn-2 not only modulates the macrophage phenotype, but also its pro-repair properties.

TH-PO056

Blockade of TNFa Prevents Kidneys from Atrophy after Ischemia-Reperfusion Injury Takaomi Adachi,[1,2] Noriyuki Sugiyama,[2] Yasukiyo Mori,[1] Takahiko Yokoyama.[2] *[1]Department of Nephrology, Kyoto Prefecture University of Medicine, Kyoto, Japan; [2]Department of Anatomy and Developmental Biology, Kyoto Prefecture University of Medicine, Kyoto, Japan.*

Background: Recent studies have reported that a significant population of patients with AKI develops a predisposition toward chronic kidney disease (CKD). However, the mechanism of AKI progression is not known well, and the available therapies are not found yet. We aim to reveal the mechanism of AKI progression and propose a new therapeutic approach for AKI.

Methods: We made two ischemia-reperfusion injury (IRI) mice models (repaired kidney model and atrophic kidney model) and compared them about phenotype and cellular response. In addition, we compared IRI kidneys treated with TNFa neutralizing antibodies with IRI kidneys treated with isotype IgG.

Results: Kidneys exposed to 45min IRI repaired completely, but kidneys exposed to 60 min IRI fell into atrophy at 28 days after IRI. We regarded kidneys exposed to 45 min IRI as repaired model, whereas we regarded kidneys exposed to 60 min IRI as atrophic model.

Kidney weight and nephron number were significantly decreased in atrophic model in comparison with repaired model. To find difference in cellular response that may cause different outcomes between two models, we examined cell proliferation and apoptosis after IRI. Interestingly, there was a high peak of apoptosis at 14 days after IRI only in atrophic model. From these results, we thought that renal atrophy on IRI kidney was due to apoptosis on later phase after IRI.

We found that TNFa was upregulated at 1 and 14 days after IRI only in atrophic model. To elucidate if suppression of TNFa prevent renal atrophy in atrophic model, we performed a blockade of TNFa before IRI using neutralizing antibody. As a result, blockade of TNFa before IRI repressed apoptosis at 14 days and prevented kidney from atrophy after IRI. Next, we performed a blockade of TNFa after IRI. As a result, blockade of TNFa after IRI also repressed apoptosis at 14 days and prevented kidney from atrophy after IRI.

Conclusions: We propose that TNFa-associated apoptosis might play a major role in AKI progression and blockade of TNFa might be a new therapeutic approach for AKI.

TH-PO057

Systematic Screening Identifies Interleukin-22, Produced by Intrarenal Mononuclear Phagocytes, to Drive Kidney Regeneration In-Vitro and In-Vivo Onkar Kulkarni, Shrikant R. Mulay, Jan H. Hagemann, Murthy Darisipudi, Ingo Hartter, Mi Ryu, Santhosh Kumar V, Dana Thomasova, Hans J. Anders. *Nephrology Center, Medizinische Klinik and Poliklinik IV, Munich, Bavaria, Germany.*

Background: Growth factors are essential for wound healing or tissue repair. Here we speculate that the intrarenal mononuclear phagocytes (rMoPh), besides mediating kidney inflammation, secrete interleukins that have a selected capacity to drive kidney regeneration upon acute kidney injury (AKI).

Results: We used the isolation of primary tubular epithelial cells (TECs) as an in-vitro assay to evaluate the potential of 25 interleukins (IL) to enhance tubular cell survival as well as regenerative outgrowth from surviving TECs. Only IL22 showed significant improvement in TEC survival and regeneration. Pharmacological blockade of JAK/STAT & ERK pathway of IL22 signalling abrogates the regeneration potential of IL22. Supernatant from necrotic TECs (NS), Ahr ligand-, and ROS-induced IL22 release in bone marrow-derived mononuclear cells.

IL22 was expressed in the ischemic kidney and in the serum upon murine unilateral ischemia with unilateral renal pedicle clamping for 45 min. To understand its functional role, we injected anti-IL22 or control IgG on day 2-4 and analysed kidneys on day 5. IL22 blockade aggravated tubular injury, defined by more necrotic tubules (PAS stain), reduced living distal and proximal tubules (THP-1 and Lectin stain) and increased expression of injury markers such as πGTP, Kim-1, TGF-β, MCP-1 and TNF-α. We observed similar aggravation of tubular injury with depletion of rMoPh by clodronate liposome injection which reduced intra-renal $CD11b^{+}CD103^{-}IL22^{+}$, $CD11b^{+}CD103^{+}IL\text{-}22^{+}$, $CD11c^{+}IL\text{-}22^{+}$ cells (FACS) and reduced IL22 expression in ischemic kidneys (IHC). Reconstitution of IL22 by injection of rm-IL22 (20µg) on day 3 in clodronate injected mice reverted the tubular injury and improved the percentage of repaired THP-1+ or lectin+ tubules and reduced tubular necrosis (PAS stain).

Conclusions: We conclude that the tubular injury induced resident renal rMoPh to secrete IL22 which induces proliferation of TECs through STAT3/ERK signaling and thereby promotes the kidney regeneration during AKI.

TH-PO058

CD26/DPP4 Deficiency Impairs Kidney Function in the Ischemia/Reperfusion Model in the Rat Christoph Daniel,[1] Christina Grigo,[1] Stephan Von Hoersten,[2] Kerstin U. Amann.[1] *[1]Nephropathology, University Erlangen-Nuremberg, Erlangen, Germany; [2]Experimental Biomedicine, University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: Dipeptidyl peptidase 4 (DPP4) is an exopeptidase inactivating incretins that promote insulin secretion and were therefore used in the treatment of type II diabetes. Beside its ability to cleave incretins, several chemokines and neuropeptide Y were also regulated by DPP4. In lung ischemia/reperfusion injury (IRI) treatment with DPP-4 inhibitors were protective, but the effect of DPP-4 inhibition in renal IRI is unknown.

Methods: Wildtype Dark Agouti (DA) rats (n=8) and congenic rats who did not express CD26/DPP4 (DPP4-/-) (n=8) were used for induction of renal IRI. For analysis of renal function blood was collected 24h and 3 days after reperfusion. Rats were sacrificed on day 3 after IRI and kidney was collected for analysis of morphologic changes, capillary rarefaction, proliferation and inflammation.

Results: Twenty four hours after induction of IRI DPP4-/- rats showed significantly reduced kidney function compared to similar treated DA rats, as assessed by serum creatinine (3.1±0.5 mg/dl vs. 1.7±0.3 mg/dl) and serum urea (237±29.7 mg/dl vs. 173±29.6 mg/dl). In addition, the high serum creatinine and urea levels persisted in DPP4-/- while these parameters declined in DA rats from day 1 to 3. Impairment of kidney function in DPP4-/- rats was accompanied by increased renal morphologic damage, as reflected by tubular injury and a higher proliferative activity. Furthermore, capillary rarefaction, as detected by CD31 positive capillaries, was significantly increased in DPP4-/- rats after IRI (29.8±2,7% vs. 21.2±5.2%). At the inner stripe, ED-1 positive macrophages were significantly increased in DPP4-/- compared to DA rats. In contrast, CD161a positive NK-cells could be detected in significantly fewer numbers in DPP4-/- rat compared to DA IRI controls (23.2±9.3 vs. 64.9±10.3 CD161a pos. cells/mm^2).

Conclusions: CD26/DPP4 deficiency impairs IRI as shown by decreased renal function and capillary density as well as increased tubular damage and macrophage infiltration. Further studies are needed to determine the complete mechanism of this CD26/DPP4 dependent impairment.

Role of Spleen in B Cell Trafficking during Repair from Ischemic Acute Kidney Injury in Mice Hye Ryoun Jang,[1] Minsu Kim,[1] Jung Eun Lee,[1] Wooseong Huh,[1] Yoon-Goo Kim,[1] Dae Joong Kim,[1] Ha Young Oh,[1] Hamid Rabb.[2] *[1]Medicine, Sunkyunkwan University School of Medicine, Samsung Medical Center, Seoul, Korea; [2]Medicine, Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: B cells are a newly identified mediator of kidney repair after ischemia reperfusion injury (IRI), and trafficking of B cells into kidneys underlies this response. *The spleen contains B cells and splenectomy can modify systemic B cell function. We therefore hypothesized that B cell changes during repair from kidney IRI are, in part, mediated by the spleen.*

Methods: C57BL/6 mice were randomly allocated into IRI group and IRI-splenectomy (SPX) group. IRI surgery was performed on the left renal pedicle and splenectomy was performed prior to reperfusion. Splenic B cells were analyzed in the kidney IRI group. B cells were compared in the post-ischemic kidneys of IRI and IRI-splenectomy groups on day 1, 3, and 10 after IRI with flow cytometry.

Results: Total B cells expressing CD 19 increased in the spleen after kidney IRI [Day 0: 29.2±4.33, Day 1: 36.8±2.54, Day 3: 52.1±2.33, Day 10: 47.7±3.3%]. Activated mature B cells expressing CD 69 and CD21/35, and plasma cells expressing CD126 and CD138 also increased in the spleen after IRI. The total number of mononuclear cells decreased in the post-ischemic kidney on day 3 after splenectomy, but was comparable on day 10 [IRI vs. IRI-SPX,Day 3: 10.1±0.51 vs. 2.0±0.21, Day10: 4.7±0.38 vs. 3.3±0.9 ($X10^5$)]. Total B cells decreased in the post-ischemic kidney on day 3 after splenectomy, but were similar on day 10 [IRI vs. IRI-SPX, Day 3: 33.4±1.54 vs. 27.9±2.31, Day 10: 15.1±0.98 vs. 14.1±6.91%]. Activated mature B cells were comparable between IRI and IRI-SPX groups [IRI vs. IRI-SPX, Day 3: 8.1±1.11 vs. 10.1±1.66, Day 10: 15.7±2.84 vs. 18.1±2.09%]. Plasma cells were decreased in the post-ischemic kidney by splenectomy [IRI vs. IRI-SPX, Day 3: 9.1±1.20 vs. 4.5±1.33, Day 10: 5.5±0.65 vs. 3.6±1.35%].

Conclusions: B cells in spleen became activated and differentiated after ischemic AKI. Splenectomy decreased B cell infiltration into the post-ischemic kidney and suppressed the final differentiation of B cells to plasma cells during the early repair phase of AKI.

Renoprotective Effect of Human Umbilical Cord-Derived Mesenchymal Stem Cells in Immunodeficient MiceSuffering from Acute Kidney Injury Te-Chao Fang,[1,2,3] Cheng-yoong Pang.[3] *[1]Department of Internal Medicine, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]Department of Medicine, Medical College, Tzu Chi University, Hualien, Taiwan; [3]Institute of Medical Sciences, Medical College, Tzu Chi University, Hualien, Taiwan.*

Background: It is unknown whether human umbilical cord-derived mesenchymal stem cells (hUC-MSCs) can improve the renal function of patients suffering from acute kidney injury (AKI). Moreover, before beginning clinical trials, it is necessary to investigate this renoprotective effect of hUC-MSCs in a xenogeneic model of AKI.However, no previous studies have examined the application of hUC-MSCs to immunodeficient mice suffering from AKI. The objectives of this study were to examine whether hUC-MSCs could improve renal function in nonobese diabetic-severe combined immune deficiency (NOD-SCID) mice suffering from AKI, and to investigate the mechanism(s) for hUC-MSCs to improve renal function in this xenogeneic model.

Methods: Administration of hUC-MSCs (10^6 cells) was performed via the external jugular vein into NOD-SCID mice treated with either vehicle only or folic acid (FA) (250 mg/kg body weight) for resulting inAKI.

Results: hUC-MSCs improved renal function of mice suffering from FA-induced AKI, as evidenced by decreased serum urea nitrogen and serum creatinine levels, as well as a reduced tubular injury score. The beneficial effects of hUC-MSCs were through promoting proliferation of renal tubular cells, reducing caspase -3 and -9, and the rise of Akt phosphorylation.However, these benefits were independent of inflammatory cytokine effects and transdifferentiation.

Conclusions: hUC-MSCs improved renal function in NOD-SCID mice suffering from FA-induced AKI. The beneficial effects of hUC-MSCs in this xenogeneic model were through reducing apoptosis and promoting proliferation of renal tubular cells, and these benefits were independent of inflammatory cytokine effects and transdifferentiation.

Effective Treatment of IRI AKI in Rats with Human Alkaline Phosphatase Transgenic Rat Marrow Stromal Cells, Human Marrow Stromal Cells or Human Adipose-Derived Stem Cells Elicits an Immune Response Anna Gooch,[1] Ping Zhang,[1] Zhuma Hu,[1] Elizabeth Phillips,[1] Dmitry O. Traktuev,[3] Stephanie Merfeld-clauss,[3] Keith L. March,[3] Christof Westenfelder.[2] *[1]Medicine, U. of Utah and VAMC., Salt Lake City, UT; [2]Physiology, U. of Utah, Salt Lake City, UT; [3]Vascular and Cardiac Center for Adult Stem Cell Therapy, IU SOM and VAMC, Indianapolis, IN.*

Background: We showed that allogeneic rat and human Marrow Stromal Cells (MSCs) effectively protect renal function post experimental IRI AKI (AJP 2005), and appear to be renoprotective in on-pump cardiac surgery patients at risk for post-op AKI (Nat Rev Neph 2010). Such paracrine effects in allogeneic settings are obtained without the elicitation of an antibody response, confirming MSCs' immune privileged properties.

Methods: The present study tested whether (1) the expression of human antigens by MSCs from Fischer344 rats transgenic for human Alkaline Phosphatase (hPAP-MSC; a gift of Dr. Eric Sandgren, U. of WI), by human MSCs (hMSC) or human Adipose-derived Stem Cells (hASC) alters the ability of these cells to protect renal function in female Fischer344 rats (F344; 150-200 g) with IRI-induced AKI (40' bilateral pedicle clamp), and (2) the administration of these cells elicits an antibody response in the recipients. IRI AKI was induced in 4 groups of F344s (n=6 each). Post reflow, groups were infused (suprarenal aorta) with $1x10^6$ hPAPMSC or hASCs /animal, or $0.5x10^6$ hMSC/kg bw, or vehicle.

Results: Compared to controls, all three cell therapies significantly protected renal function and accelerated recovery from AKI, as assessed by serum Cr levels and tissue injury scores. Although robust organ-protective and repair-stimulating actions were observed by d 1-3, within 14 days, each of these cell treatments elicited a significant IgG antibody response (57-99%) directed at the infused cell type.

Conclusions: Although the long-term significance of this immune response is unknown, it essentially rules out the single and particularly the repeated use of transgenic and xenogeneic MSCs or ASCs. The impact these cell-specific antibodies have on the treatment of AKI in rats with these sensitizing cell types is under investigation.

ECFC Represent the Major Subtype of Endothelial Progenitor Cells Recruited to the Kidney after Endothelial Injury in Mice Jan Sradnick, Bernd Hohenstein, Christian Hugo. *Division of Nephrology, Department of Internal Medicine III, University Hospital CGC, Technical University Dresden, Dresden, Germany.*

Background: We have previously shown that CD34+/Flk-1+ EPCs were recruited to the kidney after selective endothelial injury in mice (Am J Physiol Renal Physiol 298:1504-1514, 2010). Two types of endothelial progenitor cells (EPCs), the (early) colony forming units (CFU-EC) and (late) endothelial outgrowth (EOC, ECFC) were described in vitro recently. However, whether and to what extent these types might contribute to the cells recruited to the kidney is unclear. Therefore, the present study investigated these EPC subtypes after selective endothelial injury in the mouse kidney.

Methods: Selective endothelial injury was induced in left kidneys of 25 C57/Bl6 mice. Kidneys and spleens were harvested at days 1, 3, 5 and 7. Five mice served as healthy controls (ctrl). After digestion, non-viable cells were excluded and CD34+/Flk-1+/CD133-/CD45- ECFC, CD34+/Flk-1+/CD133+ CFU and also CD150+/CD117+ HSC were measured using multicolour FACS analysis.

Results: CD34+/Flk-1+ cells were increased in kidney on days 3-7 after endothelial injury as demonstrated before (ctrl=0.2%, d1=0.19%; d3=0.58%; d5=0.59%; d7=0.69%all $P<0.01$). Among these cells, ECFC represented the major subtype at d1-d7 (d1=73%; d3=94%; d5=93%; d=93%) and in controls (98%). CFU represented a minor population in diseased kidneys at any time point. Hematopoietic stem cells increased significantly on d5 (0.8% vs. 0,3% ;$p<0.01$). In contrast to our former study, neither ECFCs nor CFUs were found in significant amount in the spleen, while HSC were increased at d7 ($p<0.05$).

Conclusions: The present study verified that CD34+/Flk-1+ cells are recruited to kidneys subsequent to endothelial injury. We now demonstrate that ECFC represent the major EPC subtype recruited to the kidney and could not detect these cells in the spleen, while HSC were found in the kidney and the spleen.

TH-PO063

Magnification Effect for CXCR4 Gene Transfection on Repairing Acute Kidney Injury for Mice by Bone Marrow Mesenchymal Stem Cells Transplantation Huiling Wang. *Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: To construct CXCR4 gene transinfected bone marrow mesenchymal stem cells(BM-MSCs), take cell transplantation for acute kidney injury(AKI) mice via tail vein, observe whether there is magnification effect on AKI repairing.

Methods: Lentivirus that carry CXCR4 target gene had been constructed, then transinfecting BM-MSCs; Transinfection efficiency,CXCR4 expression, differentiation and multiplication capacity were all tested. 100 C57BL/6 mice were divided into normal group, model group (AKI group), BM-MSCs transplantation group, null-BM-MSCs transplantation group and CXCR4-BM-MSCs transplantation group; the transplanted BM-MSCs were marked by BrdU for every group. Some mice were sacrificed after the model been constructed 1d, 3d, 7d, and 14d; testing BUN and Scr level; pathological changes for nephridial tissue were observed and the injury degree for renal tubular had been scored; BM-MSCs distributed were observed with IHC and stromal cell derived factor-1 (SDF-1) level in injured nephridial tissue was tested by Western Blot.

Results: Target lentivirus carrying CXCR4 gene together with null lentivirus both successfully transinfected BM-MSCs. Alizarin red staining, alkaline phosphatase staining and oil red staining results for the transinfected BM-MSCs all reflected positive; Cell multiplication capacity was not changed by MTT. CXCR4 expression in CXCR4-BM-MSCs group was enhanced for mRNA and protein level. Contrasted with BM-MSCs transplantation group and null-BM-MSCs transplantation group, BUN, Scr and ATN scores in CXCR4-BM-MSCs transplantation group were declined sharply. SDF-1 level for nephridial tissue after AKI model constructed were rising. IHC showed that $BrdU^+$ cell distribution could be tested in mouse kidney in BM-MSCs transplantation group, positive cell proportion for null-BM-MSCs transplantation group was similar. While in CXCR4-BM-MSCs transplantation group, the $BrdU^+$ positive cells were increased significantly.

Conclusions: CXCR4 gene transinfection could increase the number of BM-MSCs homing to injured kidney after BM-MSCs transplantation for AKI mice, so that, the AKI repairing effect for transplanted stem cells was distinctly enhanced.

Lineage-Negative Cord Blood (CB) Cells Protect against Ischemia/Reperfusion-Acute Kidney Injury (IR-AKI) in Rats Camila Eleuterio Rodrigues,[1] Ana C. de Bragança,[1] Mauro Shigueharu Oide Junior,[1] Enio Jose Bassi,[2] Niels O.S. Camara,[2] Antonio C. Seguro,[1] Lucia Andrade.[1] *[1]Nephrology, University of Sao Paulo Medical School, Sao Paulo, SP, Brazil; [2]Immunology, University of Sao Paulo Biomedical Institute, Sao Paulo, SP, Brazil.*

Background: IR-AKI induces cell-cycle inhibitors, including the cyclin-dependent kinase inhibitor p21(WAF1/CIP1), which is protective against AKI. However, it is known that critically short telomeres cause increased p21 expression, which increases the number of apoptotic renal cells. In telomerase-deficient mice, IR-AKI-induced impairment of renal function is more severe than in normal mice. Young stem cells can alleviate renal aging in mice and have less effect on p21 expression than do aged stem cells. The telomeres of CB stem cells are longer than are those of other stem cells. Although many stem cell types show potential as therapies for kidney diseases, uncultured lineage-negative CB cells (CBLin-) cells have never been tested in IR-AKI.

Methods: Blood was collected from healthy women and babies, and the mononuclear fraction was used for depletion of lineage-committed cells. Cell fluorescence was evaluated using a flow cytometer. Male Wistar rats were induced to IR by 45-min clamping of both renal arteries, and some rats received 10^6 CBLin- cells (via tail vein) 6h after surgery. We studied three groups: control (C, n=8); IR (n=9); and IRLin- (n=6). After 48h of IR, we measured inulin clearance (Cin) and urinary volume. Immunoblotting for p21, eNOS and Klotho was performed in renal tissue. Data are mean±SEM.

Results: Selected cells were negative for CD2, CD3, CD14, CD16, CD19, CD24, CD34, CD56, CD66b, CD73, CD90, CD 105, HLA-DR and glycophorin A.

Group	Cin (ml/min/100 g BW)	Urinary output (ml/h)	p21 expression (%)	eNOS expression (%)
C	0.94±0.05	0.56±0,13	97±7	87±8
IR	0.40±0.04[a,b]	1.04±0.22	179±16[a,b]	69±6[b]
IRLin-	0.63±0.08[a]	0.67±0.11	99±1	101±4

[a]$p<0.05$ vs. C; [b]$p<0.05$ vs. IRLin-

Renal blood flow and mean arterial pressure did not differ among the groups. Klotho expression was dramatically decreased in IR rats and restored in IRLin- rats.

Conclusions: CBLin- cells could be used in treating IR-AKI. Further studies could identify the exact mechanism of their action.

Human Renal Stem/Progenitor Cells Repair Tubular Epithelial Cell Injury through TLR2-Driven Inhibin-A and Microvesicle-Shuttled Decorin Fabio Sallustio, Vincenzo Costantino, Sharon N. Cox, C. Divella, Francesco Paolo Schena. *Department of Emergency and Organ Transplantation, University of Bari, Bari, Italy.*

Background: Acute renal failure (ARF) is emerging as a public health problem worldwide and many studies recently focused their attention on the possibility of using human adult renal stem/progenitor cells (ARPCs) to improve regeneration in ARF. We studied the influence of ARPCs on the regenerative process of cisplatin-injured renal proximal tubular epithelial cells (RPTECs) and the mechanisms underlying the ARPC regenerative processes. Moreover, we investigated the nature of the regenerative factors secreted by ARPCs.

Methods: We set up an in vitro model of cisplatin-induced toxicity, in which RPTECs were co-coltured with ARPCs. We studied apoptosis and proliferation by immunofluorescence experiments. By bioinformatic analyses on microarray data and by multiplex cytokine assays, we identified some specific cytokines and growth factors secreted specifically by ARPCs following the damage perception.

Results: We found that tubular ARPCs (tARPCs), but not glomerular ARPCs, provided a protective effect by promoting tubular cell proliferation of survived cells and inhibiting cisplatin-induced apoptosis. The regenerative effect was specific of tARPCs, occurred only following the sensing of the damage and was completely cancelled blocking the TLR2, present on tARPCs. Moreover, we found that tARPCs, but not gARPCs, were resistant to the apoptotic effect of the drug. We showed that tARPCs operated mainly through the TLR2 engagement and the secretion of inhibin-A protein and of microvesicle-shuttled decorin, inhibin-A and cyclin D1 mRNA. These factors worked synergistically and were essential in the regenerative process. The involvement of tARPC-secreted inhibin-A and decorin mRNA in the pathological process of ARF was confirmed also *in vivo* on transplant patients affected by delayed graft function.

Conclusions: We demonstrated that TARPCs could have a regenerative effect on damaged RPTECs by both preventing apoptosis and enhancing proliferation of surviving cells through the TLR2 engagement, and identified factors that were indispensable for the regenerative processes.

Proximal Tubuli Contain a Phenotypically Distinct, Scattered Cell Population Involved in Tubular Regeneration Bart Smeets,[1,4] Peter Boor,[2] Henry Dijkman,[3] Katja Berger,[1] Shagun V. Sharma,[4] Jürgen Floege,[1] Johan Van der Vlag,[4] Jack F. Wetzels,[4] Marcus J. Moeller.[1] *[1]Nephrology, University Hospital Aachen, RWTH, Aachen, Germany; [2]Pathology, University Hospital Aachen, RWTH, Aachen, Germany; [3]Pathology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [4]Nephrology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.*

Background: Regeneration of injured tubular cells occurs after acute tubular necrosis primarily from intrinsic renal cells. This may occur from a fixed intratubular stem/progenitor cell population or from any surviving proximal tubular cell.

Methods: In this study, we characterize a CD24, CD133, and vimentin positive subpopulation of cells scattered throughout the proximal tubule in normal human kidney.

Results: Compared to adjacent "normal" proximal tubular cells, these CD24+ cells contained less cytoplasm, less mitochondria and no brush border. In addition, 49 marker proteins are described that also identify this distinct cell population. In human biopsies of patients with acute tubular necrosis (ATN), the number of CD24+ tubular cells was increased. In both normal human kidneys and in the ATN biopsies, around 85% of proliferating cells were CD24 positive – indicating that this cell population participates in tubular regeneration. In healthy rat kidneys, the novel cell subpopulation was absent. However, upon unilateral ureteral obstruction (UUO), the novel cell population was detected in significant amounts in the injured kidney.

Conclusions: In summary, in human renal biopsies, the CD24+ cells represent tubular cells with a deviant phenotype, characterized by a distinct morphology and marker expression. After acute tubular injury, these cells become more numerous. In healthy rat kidneys, these cells are not detectable, whereas after UUO, they appeared *de novo* – arguing against the notion that these cells represent a fixed progenitor cell population. Our data indicate rather that these cells represent transiently dedifferentiated tubular cells involved in regeneration.

Kidney Stem Cell Responses in Acute Kidney Injury Repair Gilbert W. Moeckel, Dong Chen. *Pathology, Yale University School of Medicine, New Haven, CT.*

Background: The renal medulla is a proposed stem cell niche in the kidney. This study focuses on isolating and characterizing an endogenous kidney stem cell population from primary mouse medullary interstitial cells and assessing their role in the repair of tubular cell injury.

Methods: Mouse medullary interstitial cell primary cultures were grown in Knockout Serum Replacement (KSR) buffer. Some cells were also cultured in Dulbecco's modified Eagle Medium/F12 (DMEM/F12) with N-2(1x) Supplement. Cells were grown under both hyperosmotic and hypoxic conditions. Selectively grown kidney progenitor cells were stained with fluorescence labeled antibodies against CXCR4, CXCR7, CD24, CD34, Rat-CD44, Rabbit CD-44, Nestin and Pax-7. Cell survival and proliferation was evaluated using MTT assay and PCNA western blot. In wound healing experiments different tubular epithelial cell lines were grown on fibronectin coated plates, and the repair of a wound following treatment with progenitor cell supernatant recorded after 6 and 26 hours.

Results: We saw an enrichment of stem cell marker positive cells by up to 865%, compared to cell cultures without selective growth conditions. Immunofluorescent staining revealed, that the enriched cells stain positive for CXCR4 (95%), positive for CXCR7 (56%), positive for CD24 (68%), positive for Nestin (43%), positive for Pax 7 (77%) and positive for several other kidney stem cell markers. Wound healing assays showed significant differences between the control and the supernatant treated cells regarding number of cells migrating into the wound area.

Conclusions: We have developed a new method to enrich potential stem cells from the kidney medulla. After enrichment, these cells were characterized and expressed positivity for stem cell markers: CD24, CXCR4, CXCR7, Nestin, CD44 and Pax7. Furthermore, these stem cells exhibit phenotypic traits of renal stem cells and have biological effects that benefit kidney injury repair as demonstrated with PCNA proliferation assay, MTT cell viability assay and wound healing assay. Our studies confirm the hypothesis that the renal medulla is indeed a reservoir for endogenous kidney stem cells.

TH-PO068

Human Endothelial Colony Forming Cells Attenuate Ischemic Acute Kidney Injury in Mice Dylan Burger, David Allan, Yuan Chung, Alex Gutsol, Anthony Carter, Rhian Touyz, Kevin D. Burns. *Kidney Research Centre, Dept. of Medicine, Ottawa Hospital Research Centre, University of Ottawa, Ottawa, ON, Canada.*

Background: Microvascular injury is a key feature of ischemic acute kidney injury (AKI), suggesting that strategies targeting endothelial health could promote recovery of renal function. While the administration of certain progenitor cell populations improves renal recovery following AKI, we recently reported that a population of human cord blood-derived $CD133^+$ progenitor cells exacerbated ischemic AKI in mice, associated with enhanced inflammation and apoptosis (Burger D. et al. Nephrol Dial Transplant 2012). Accordingly, the choice of progenitor cell populations may be important in cell-based therapy in human AKI.

Methods: The purpose of this study was to examine the effects of human endothelial colony forming cells (ECFCs) in a mouse model of AKI, induced by bilateral ischemia-reperfusion (I/R). ECFCs were isolated from human umbilical cord blood, expanded in culture, and injected (10^6/mouse) via the jugular vein into non-obese diabetic severe combined immunodeficient (NOD-SCID) mice (male, 8 weeks) at the time of reperfusion. Renal functional and structural outcomes were evaluated.

Results: Analysis of human ECFCs by flow cytometry revealed expression of CD31 but not CD14, CD45, or CD133, consistent with an endothelial, but not a hematopoietic phenotype. Administration of ECFCs attenuated I/R-induced renal injury at 24 hours as revealed by reductions in plasma urea (control: 78±2 mM vs. ECFCs: 65±5 mM, $P<0.05$, n=5-6) and creatinine (control: 174±6 μM vs. ECFCs: 106±22 μM, $P<0.05$, n=5-6) and reduced hyperphosphatemia ($P<0.05$, n=5-6). At 24 hours post I/R, mice receiving ECFCs also displayed significantly less tubular injury (anuclear tubules: control: 64±1% vs. ECFCs: 57±2%, $P<0.001$, n=5-6).

Conclusions: These data indicate that human ECFCs attenuate renal injury in a mouse model of ischemic AKI. The results suggest that these effects may be achieved by improvement in post-ischemic endothelial function, and imply a potential therapeutic role for ECFCs in human AKI.

Mesenchymal Stem Cells Promote Renal Regeneration via Alteration of Macrophage Phenotype Andrea F. Wise,[1] Timothy M. Williams,[1] Junli Zhuang,[1] Chrishan S. Samuel,[2] Sharon D. Ricardo.[1] *[1]Monash Immunology and Stem Cell Laboratories, Monash University, Melbourne, Victoria, Australia; [2]Department of Pharmocology, Monash University, Melbourne, Victoria, Australia.*

Background: Mesenchymal stem cells (MSCs) have cytoprotective and immunomodulatory properties that aid in tissue regeneration. This study investigated the ability of human mesenchymal stems (hMSCs) to alter macrophage phenotype and provide renoprotection following acute tubulointersitial injury.

Methods: C57BL6/J mice (20-25g; n=5/group) with unilateral IR injury were injected with $1x10^6$ hMSCs or PBS (i.v.). At 7 days post-hMSC treatment, kidney histology was examined, total collagen concentration quantified by hydroxyproline assay and macrophage phenotype analyzed via FACS and qPCR. In addition, hMSCs and bone marrow-derived macrophages were co-cultured directly/indirectly for 48 hours and macrophage phenotype assessed using qPCR.

Results: hMSC treatment promoted structural repair with increased tissue matirx remodeling and decreased collagen accumulation at 7 days post-treament compared to vehicle treatment. *In vitro,* hMSCs further increased the gene expression of the anti-inflammatory M2 marcophage markers *Ccl2* (unstimulated and M2 stimulated macrophages), *Arg1* (unstimulated, M1 and M2 stimulated macrophages), *Chi313* (M2 stimulated macrophages) and *Fizz1* (M2 stimulated macrophages). This alteration in macrophage phenoytpe is translatable to an *in vivo* hMSC promotion of tissue repair.

Conclusions: The administration of hMSCs to mice with IR injury promoted renal regeneration and repair 7 days post-treatment. The promotion of this structural repair may be due to the ability of the hMSCs to alter macrophage phenotype to an M2 polarization state resulting in downstream tissue remodeling and accelerated wound healing within the damaged kidney.

TH-PO070

Activation of DNA Injury-Associated Histone H2AX-ATM Complex and Expression of Development-Associated Regulator β-Catenin in Pro-Fibrotic Kidney Injury Models Yumin Liu, Takaharu Ichimura, Li Yang, Joseph V. Bonventre. *Renal Division, Brigham & Women's Hospital/Harvard Med. School, Boston, MA.*

Background: We have proposed that renal epithelial cell cycle arrest after acute kidney injury (AKI) contributes to chronic kidney disease. Cell cycle arrest results in a secretory profibrotic phenotype in part via DNA damage response regulator ATM (ataxia telangiectasia mutated). β-catenin has previously been proposed to play an important role in renal fibrosis. We now report an association between β-catenin and ATM activation in kidney epithelial cells.

Methods: We evaluated the temporal and spatial patterns of the aristolochic acid (AA)-induced activation of phosphorylated-ATM (pATM) and phospho-Histone (pH2AX), which is a substrate of ATM and together form a DNA damage complex. AA induces AKI with accelerated chronic kidney disease in humans and rodents. We also characterized the acivation of β-catenin in proximal tubular epithelial cells after AA.

Results: AA resulted in activation of ATM and was associated with formation of DNA damage complexes. On days 11-14 after AA exposure p-ATM co-localized with pH2AX, often in BrdU positive, TUNEL-negative nuclei of epithelial cells. Nuclear pH2AX-positive cells were often positive for Kidney injury molecule-1 (Kim-1). At these stages of injury, upregulated β-catenin was commonly detected in the p-ATM positive proximal tubule epithelial cells. This upregulated β-catenin was also found at later stages after renal ischemia/reperfusion in mouse kidneys (days 5-7), a model also associated with fibrosis. AA-treatment induced β-catenin translocation to the nucleus in primary epithelial cells isolated from the mouse kidney. In AA-treated LLC-PK1 renal epithelial cells, the p-ATM-H2AX complex was co-activated and transcription of pro-fibrotic TGF-β and CTGF genes was upregulated.

Conclusions: These data suggest that activation of ATM and H2AX with co-activation of β-catenin may be important regulatory steps in Kim-1 positive injured tubular epithelial cells to cause a maladaptive fibrotic response resulting in tubulo-interstitial fibrosis. This activation pathway may be a potential therapeutic target in chronic kidney disease.

Trps1 Plays a Critical Role in Mesenchymal-Epithelial Transition of Epithelial Cells Response to Acute Ischemic Kidney Injury Kun Huang, Jurong Yang, Yani He. *Department of Nephrology, DaPing Hospital, Third Military Medical University, ChongQing, China.*

Background: Incomplete kidney repair, induced by acute ischemic reperfusion injury, is a major cause of chronic kidney disease(CKD). The process of AKI repair has been considered to be the reappearance of embryonic metanephron development. Trps1 has been shown to activate mesenchymal-epithelial transition (MET) in kidney development.This study explored the role of Trps1 in reparation of acute ischemic reperfusion kidney injury.

Methods: Rat renal I/R injury (45 and 60 minutes)model was established. The serum creatinine, BUN, changes of histology, Na^+-K^+-ATPase were tested. The expression of Trps1, α-Catenin and vimentin was detected by immunohistochemistry and western blotting. The over-expression of Trps1 was used to investigate the effect of Trps1 by transfecting GFP-Trps1 adenovirus into kidney.

Results: Compared with I/R 45min group, the renal function of serious ischemic-reperfusion kidney injury (I/R 60min group) was delayed recovery. Pathological examination showed the repair of renal tissues in serious I/R injury group was delayed and incomplete. Trps1 expression decreased during the phase of injury, then elevated during the phase of repair. The Trps1 expression in serious kidney injury group was lower than I/R 45min group. In the serious injury group, the Trps1 expression was decreased in impaired areas of tissues, while the Trps1 expressed high in well repaired areas. The increased expression of Trps1 correlated with epithelial re-differentiation rather than de-differentiation, leading to increased expression of epithelial marker(α-catenin) and decreased expression of mesenchymal marker(vimentin). Compared with serious injury group, Trps1 over-expression group showed an earlier decrease of serum creatinine and BUN, alleviated chronic lesions, especially about tubular atrophy and tubulointerstitial fibrosis.

Conclusions: Trps1 promotes the repair of acute ischemic reperfusion kidney injury by mediating the MET of injured renal tubular epithelial cells.

The SIRT1 Activator SRT1720 Improves Renal Cortical Mitochondrial and Tubular Function Following Ischemia-Reperfusion Injury Jason A. Funk, Rick G. Schnellmann. *Drug Discovery and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Background: Ischemia-reperfusion (IR) injury in the kidney initiates lethal and sub-lethal injury in the proximal tubule. Mitochondrial dysfunction is a pathological consequence of I/R injury, and promoting mitochondrial biogenesis (MB) as a repair mechanism after injury may offer unique benefits to restore mitochondrial and organ function. Since we previously showed that the SIRT1 activator SRT1720 stimulates MB in renal cells, we examined its efficacy in IR injury.

Methods: Rats were subjected to bilateral renal pedicle ligation for 22m or sham surgery and then treated once daily with SRT1720 (5 mg/kg, i.p.) or vehicle starting 24h after reperfusion until 72h or 144h. Mitochondrial proteins, as well as Kim-1, Na^+,K^+-ATPase, and vimentin were examined after injury. State 2 and uncoupled respiration of isolated mitochondria was determined using a Clark-type oxygen electrode.

Results: Mitochondrial proteins ATP synthase β, COX I, and NDUFB8 were diminished at 24h, 72h and 144h in rats subjected to IR. Rats treated with SRT1720 after IR (IR+SRT1720) had improved mitochondrial protein expression by 144h and restoration of state 2 and uncoupled mitochondrial respiration. PGC-1α was elevated at 72h and 144h in both IR and IR+SRT1720 rats; however, SRT1720 treatment increased de-acetylated PGC-1α, the more active form. Renal Kim-1, a sensitive marker of tubular injury, was persistently expressed in the renal cortex of IR rats but was attenuated in IR+SRT1720 rats. Additionally, sustained loss of Na^+,K^+-ATPase expression and elevated vimentin in IR rats was normalized in IR+SRT1720 rats, suggesting SRT1720 treatment was associated with restoration of a differentiated, polarized proximal tubule epithelium.

Conclusions: Overall, these results reveal that treatment with SRT1720 increased de-acetylated PGC1a and stimulated MB, enhancing recovery of mitochondrial protein expression and function. Rescue of mitochondrial function was associated with faster recovery of proximal tubule integrity. Targeting mitochondrial biogenesis may offer unique therapeutic benefits as a strategy to improve tubule repair following ischemic injury.

Phenylthio Butanoate Class HDAC Inhibitors Enhance Recovery from Acute Kidney Injury (AKI) Nataliya Skrypnyk,[1] Tatiana Novitskaya,[1] Neil A. Hukriede,[2] Mark P. De Caestecker.[1] *[1]Division of Nephrology, Vanderbilt University, Nashville, TN; [2]Department of Developmental Biology, University of Pittsburgh, Pittsburgh, PA.*

Background: We previously identified a new class of HDAC inhibitors (HDACi), phenylthio butanoates (PTBA), which promote renal progenitor cell expansion in zebrafish embryos. Due to conservation of signaling pathways in kidney organogenesis and regeneration, we hypothesized these compounds would also enhance renal regenerative responses in mouse models of AKI.

Methods: PTBA analogues given in 20% cyclodextrin (vehicle control) IP. Renal histone H4 acetylation (H4Ac) evaluated by fluorescence immunoblot; EC50 by CNT assay with Tg (*Cdh17:GFP*) zebrafish larvae; serum creatinine by enzymatic assay after moderate IR-induced AKI (BALB/c, 26 mins ischemia), or severe IR-induced AKI (BALB/c, 30 mins unilateral ischemia, contra-lateral nephrectomy day 8).

Results: We first evaluated effect of 8 PTBA analogues on renal H4Ac (marker of HDACi activity) after IP injection in mice: 5 increase H4Ac: 4 with carboxylic acid (CA) and 1 with hydroxamic acid (HA) "warheads". 3 analogues with highest biologic activity in zebrafish (EC50s 500-900nM) were tested in IR-induced AKI: #29 (HA derivative) and #22 (CA derivative) induce 1.5X increases in renal histone acetylation 12 hours after IP injection; #25 (CA derivative) induces 2-3X increase after 2 hours, and also has the lowest EC50 (470nM). Daily treatment with #22 or #29 started 24 hours after injury reduce serum creatinine at 2 and 3 days post injury, respectively, but effects are not sustained. In contrast, daily treatment with #25 gives a sustained decrease in serum creatinine from day 3-7 post injury. Daily treatment with #25 for 7 days in severe IR-induced AKI also reduces serum creatinine 1-7 days post nephrectomy.

Conclusions: PTBA analogues ameliorate IR-induced AKI if administered 24 hours after injury; the PTBA analogue #25 is shortest acting, has greatest effect on H4Ac and has highest biological activity in zebrafish assays, also most effectively ameliorates AKI. These studies are the first evidence that compounds identified from renal progenitor cell expansion screen in zebrafish also ameliorate AKI in mice.

Phenylthio Butanoate Class HDAC Inhibitors Ameliorate Chronic Kidney Injury by Improving Functional Recovery after Different Forms of Acute Kidney Injury in Mice Nataliya Skrypnyk,[1] Tatiana Novitskaya,[1] Neil A. Hukriede,[2] Mark P. De Caestecker.[1] *[1]Division of Nephrology, Vanderbilt University, Nashville, TN; [2]Department of Developmental Biology, University of Pittsburgh, Pittsburgh, PA.*

Background: We previously identified a new class of HDAC inhibitors (HDACi), phenylthio butanoates (PTBA), which promote expansion of renal progenitor cells in zebrafish embryos. We hypothesized that PTBA analogues would also enhance renal regenerative responses in mouse models of kidney injury, and have shown that the PTBA analogue, #25, accelerates recovery after ischemia reperfusion (IR)-AKI in mice when given daily starting 24 hours after injury. Since impaired recovery following AKI is associated with development of CKI, we now hypothesize that #25 would reduce CKI post AKI.

Methods: The PTBA analogue #25 was administered IP at different time points following: a) severe IR-induced renal fibrosis (BALB/c, 30 mins unilateral ischemia and contra-lateral nephrectomy at day 8); b) aristolochic acid (AA) induced CKI (BALB/c, 4.7mg/kg); and c) unilateral ureteric obstruction (UUO, C57Bl/6). Serum creatinine, renal fibrosis and QRT-PCR were performed using standard techniques.

Results: In severe IR, daily treatment with #25 for 7 days starting 24 hours after injury reduces serum creatinine 1-7 days post nephrectomy and reduces renal fibrosis at day 28. Daily treatment with #25 starting 5 days after AA decreases serum creatinine from day 7-42 after injury. Short term treatment with #25 from days 5-10 and from days 5-7 after AA also reduce serum creatinine, but there is no reduction in renal fibrosis in #25 treated vs. controls. In UUO #25 was administered as a single dose 3 days after surgery. There is reduced renal *Kim1* (injury marker) and *Collagen1* mRNA in #25 treated mice, but no reduction in renal fibrosis at 5 days post surgery.

Conclusions: The PTBA analogue #25 ameliorates CKI by accelerating recovery after different forms of renal injury. Decreased fibrosis after severe IR-induced AKI suggests PTBA analogues ameliorate AKI induced CKI but do not reverse progressive renal fibrosis.

Tubule-Specific Hepatocyte Growth Factor Signaling Is Essential in Renal Repair and Regeneration after Acute Kidney Injury Dong Zhou,[1] Roderick J. Tan,[2] Youhua Liu.[1] *[1]Department of Pathology, University of Pittsburgh, Pittsburgh, PA; [2]Department of Medicine, University of Pittsburgh, Pittsburgh, PA.*

Background: Hepatocyte growth factor (HGF) is a pleiotrophic factor that plays an essential role in promoting injury repair and regeneration in multiple organs. After acute kidney injury (AKI), HGF receptor, c-met, was induced predominantly in renal tubular epithelium; but the potential role of tubule-specific induction of c-met in injury repair after AKI was elusive.

Methods: To address this issue, we generated conditional knockout mice, designated as Ksp-met-/-, in which the c-met gene was specifically disrupted in renal tubules.

Results: The Ksp-met-/- mice were phenotypically normal and displayed no appreciable defect in kidney morphology and function. However, in AKI induced by either cisplatin or ischemia/reperfusion injury (IRI), loss of tubular c-met substantially aggravated renal dysfunction and lesions. Compared with controls, Ksp-met-/- mice displayed higher serum creatinine and more severe morphologic injury. More apoptosis was detected in Ksp-met-/- kidneys, accompanied by an increased expression of Bax and Fas ligand and decreased phosphorylation/activation of Akt. In addition, tubule-specific ablation of c-met also augmented pro-inflammatory cytokine expression and promoted renal infiltration of inflammatory cells after AKI. Consistently, ectopic expression of exogenous HGF in vivo inhibited tubular cell apoptosis, decreased renal inflammation and repressed TNF-α and Bax expression after AKI.

Conclusions: Collectively, these results suggest that tubule-specific HGF/c-met signaling is crucial in conferring renal protection after AKI, primarily via its anti-apoptotic and anti-inflammatory mechanisms.

Characterization of Kidney Injury Molecule (Kim) Family of Proteins in Zebrafish Wenqing Yin, Said Movahedi Naini, Dirk M. Hentschel, Joseph V. Bonventre. *Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: The Kim/Tim (T-cell immunoglobulin mucin) family of genes encodes an IgV-like and a mucin-like domain, with three members in human and eight members in mice. (Kim-1/Tim-1), was the first identified member of this family and shown to be an important marker of proximal tubule injury in all mammalian species analyzed to date. KIM-1 also serves as a highly sensitive and specific urinary biomarker, and is markedly upregulated on dedifferentiated proximal tubular epithelium after ischemic or toxic kidney injury. Use of a kidney injury model and a wide array of genetic methods in zebrafish would facilitate an understanding of the role of Kim proteins in the development and recovery from acute kidney injury.

Methods: Kim family members were identified in zebrafish and their expression pattern determined in different stages of development and in adult TU/AB zebrafish, by performing PCR, western blotting, in situ hybridization (ISH) and immunostaining, We also used Tol2-mediated transgenesis to identify zkim-1 tissue specific regulatory elements.

Results: We identified Kim1, Kim3 and Kim4 in zebrafish, on chromosome 21. We cloned the zebrafish orthologs of Kim-1 with three splice forms, which we called long zKim-1, short zKim-1 and immunoglobulin zKim-1. zKim-1 encoded a type-1 cell transmembrane glycoprotein, including a six-cysteine immunoglobulin-like domain and threonine-serine-proline (T/SP) rich domain in the extracellular domain, and a relatively short intracellular domain. zKim3 and zKim4 are expressed in zebrafish larvae during development as detected by PCR and ISH. zKim-1 is markedly up-regulated on the brush borders of the injured tubular cells after injury in a model of gentamicin toxicity in the pronephros as well as mesonephros. We identified 25 conserved regions as potentialregulatory elements and created stable transgenic zebrafish lines harboring each conserved region to elucidate zkim-1 regulatory elements.

Conclusions: Zebrafish express Kim1, Kim3 and Kim4. zKim-1 expression recapitulates post-injury expression of mammalian Kim1. Highly structural and functional similarities exist between human KIM-1 and zebrafish. The structural similarities also allow for identification of tissue specific regulatory elements for human Kim-1 expression.

HIF-1α Promotes Renal Tissue Repair after Ischemic Damage Controlling Proximal Tubule Cell Proliferation, Cell Death and Inflammatory Response Elisa Conde, Edurne Ramos, Ignacio Blanco Sanchez, Elia Aguado Fraile, Esperanza Macarena Rodriguez Serrano, Laura Garcia-Bermejo. *Anatomia Patologica, Instituto Ramón y Cajal de Investigación Sanitaria (IRYCIS), Madrid, Spain.*

Background: Acute tubular necrosis (ATN) caused by ischemia/reperfusion (I/R) during renal transplantation delays allograft function. Identification of factors and mechanisms that mediate epithelium recovery could help to improve graft outcome. We previously reported an induction of Hypoxia Inducible Factor (HIF-1α)during reperfusion which is critical for tissue regeneration after renal I/R in a rat model. Here, we unveil several mechanisms triggered by HIF-1αinvolved in this regeneration.

Methods: For that purpose we have silenced HIF-1α in the rat I/R model by specific siRNAs. We estimate cell proliferation by BrdU staining, cell death by TUNEL, protein expression by western blot, proinflammatory mediators expression by qRT-PCR and cell infiltration by H&E staining.

Results: *In vivo* interference of HIF-1αexacerbated proximal tubule cell proliferation but not cell death, leading to an abnormal tissue repair. Moreover, HIF-1α inhibition altered p21 and p27 expression as well as bcl2/bax ratio.We also demonstrate that HIF-1α regulates the inflammatory response associated to ischemic renal damage. Its inhibition leads to an increase of proinflammatory mediators expression such as MCP-1, IL-1β e INFγ an increase of VCAM-1 expression and, consequently, an increase in inflammatory cells infiltration. Altered renal inflammatory response resolution will lead also to abnormal tissue repair.

Conclusions: In summary, we have identified several mechanisms triggered by HIF-1α, including the control of cell proliferation vs cell death and the inflammatory response, involved in the renal tissue repair after I/R, pointing out the critical role of HIF-1α in the kidney response to I/R. Modulation of this transcription factor could be considered a therapeutic option to reduce ATN and improve allograft outcome after renal transplantation.

MG53 Attenuates Ischemia Reperfusion (I/R) Caused Acute Kidney Injury Pu Duann,[1] Ling-Mei Chiang,[2] Shing Li.[1] *[1]Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Paediatric, Chang Gung Memorial Medical Center, Keelung, Taiwan.*

Background: Ischemia is a central pathophysiological factor in developing acute kidney injury (AKI). In rat models of AKI. The tubular ischemic necrosis involving the proximal tubule and the thick ascending limb of Henle's loop. Reactive oxygen species was generally consided as the core factor in AKI pathophysiology. But several other factors like acute membrane damage of tubule epithelial cells was also suggested. Dysferin plays an importasnt role in maintenance of sacrolemmal membrane integrity. It was proposed that dysferin can function as a fusogen to allow vesicles to form a membrane repair patch. Immunostaining observed that dysferin concentrated at injury site at patch. However, dyferin itself can not translocate vesicles associated with acute membrane damage. Mitsuguimin 53 (MG53), a muscle-specific TRIM-family protein, acts as a sensor of oxidation to nucleate recruitment of intracellular vesicles to the injured plasma membrane. MG53 interact with dysferin form a repair machinery and repair membrane in acute injury. In this study we investigated the protective effect of MG53 in ischemia AKI.

Methods: Ischemic AKI was induced by clamping unilateral renal artery for 35 min with 2 days of reperfusion afterwards. Recombinant MG53 (6 mg/Kg BW) was intravanously given 5 min before or 35 minutes after ischemia induction. Kidney tissues and serum samples were collected 48 hours after I/R from three groups rats: sham treated group, I/R groups with or without MG53 treatment.

Results: Renal morphology and functional parameters confirmed clamping of the renal pedicles led to profound ischemic injury in the outer medulla. Compared to wildtype rat, MG53 treatment functionally (creatinine: AKI with MG53 treated, n=6, 0.48±0.17 vs. AKI no treatment, n=6, 1.42±0.42 mg/dl, p=0.007; p= 0.006; Ualb/Uc AKI with MG53 treated, 0.026±0.011, AKI no treatment, 0.057±0.032, p=0.002) and morphologically protected rat from ischemic AKI.

Conclusions: Our findings underscore the role of the acute membrane injury, most likely tubule epithelialcells, in the pathophysiology of AKI. The MG53 point to new therapeutic options for AKI.

Association with Active Protein Kinase C-α Is Required for Recovery of F_0F_1-ATPase Activity Following Injury in Renal Proximal Tubules Grazyna Nowak, Diana Bakajsova. *Pharmaceutical Sciences, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: We have shown that F_0F_1-ATPase activity and ATP content are decreased by oxidant exposure in primary cultures of renal proximal tubular cells (RPTC) and that these changes are preceded by reduction of protein levels of phosphorylated (active) PKC-α in mitochondria of oxidant-injured RPTC. Recovery of active PKC-α levels in mitochondria precedes the recovery of F_0F_1-ATPase activity and ATP content. The goal of this study was to determine whether PKC-α interacts with F_0F_1-ATPase and if this association plays a role in the recovery of F_0F_1-ATPase activity following oxidant injury.

Methods: Wild-type PKC-α (wtPKC-α) and inactive PKC-α (dnPKC-α) were overexpressed in primary cultures of RPTC to increase mitochondrial levels of active and inactive PKC-α. PKC-α was immunoprecipitated from mitochondria after RPTC injury induced by the model oxidant, *tert*-butylhydroperoxide (TBHP), and proteins associated with mitochondrial PKC-α were identified. In addition, F_0F_1-ATPase activity and ATP content were assessed following injury.

Results: Overexpressing wtPKC-α prevented TBHP-induced decreases in active PKC-α levels and F_0F_1-ATPase activity in RPTC mitochondria. Overexpressing dnPKC-α blocked recovery of F_0F_1-ATPase activity and ATP content after oxidant injury. Protein levels of the catalytic (F_1) subunit in isolated mitochondria decreased at 24 h but not at 4 h after TBHP injury demonstrating that the activity of F_0F_1-ATPase declines prior to decreases in its protein levels. Proteomic analysis demonstrated association of both subunits (F_0 and F_1) of F_0F_1-ATPase with PKC-α in non-injured and oxidant-injured RPTC. The association of these subunits was predominantly with the active PKC-α. Overexpressing dnPKC-α markedly decreased the association of F_0 and F_1 subunits with PKC-α at 4 h following TBHP injury. Protein levels of both subunits associated with PKC-α were greater in injured RPTC overexpressing wtPKC-α than RPTC overexpressing dnPKC-α.

Conclusions: We conclude that F_0F_1-ATPase associates with active PKC-α and that this association promotes recovery of F_0F_1-ATPase activity and ATP content following oxidant injury in RPTC.

BMP-7 Serves as a Prognostic Biomarker for Evaluating the Regenerative Capacity of the Kidney after Renal Injury Scott R. Manson, Paul F. Austin. *Department of Surgery, Washington University School of Medicine, St. Louis, MO.*

Background: Although obstructive uropathies are correctable through surgery, these conditions remain a leading cause of renal insufficiency because reliable prognostic indicators for surgical intervention are critically lacking. This study examines the mechanisms that contribute to the repair of obstruction-induced renal injuries and their clinical utility in the evaluation of obstructive uropathies.

Methods: A reversible murine model of unilateral ureteral obstruction (UUO) was used to characterize kidney repair following the correction of short-term obstructions (2d) that lead to reversible renal injury and prolonged obstructions (7d) that lead to irreversible renal injury. The role of BMP-7 was examined by treatment with BMP-7-neutralizing antibodies or recombinant BMP-7. The clinical relevance of our findings was assessed by examining BMP-7 levels in renal biopsies and urine samples from patients with obstructive uropathies.

Results: While renal injuries resulting from short-term UUO are effectively repaired following the correction of obstruction, treatment with BMP-7-neutralizing antibodies results in a 74.1 decrease* in collagen remodeling and a 84.9 % decrease* in tubular restoration in the kidney. In contrast, prolonged UUO results in irreversible renal injury and a 67.6% decrease* in BMP-7 levels. The restoration of BMP-7 activity with recombinant BMP-7 enhances kidney repair following prolonged UUO by promoting a 4.0-fold increase in collagen remodeling and a 3.8-fold increase* in tubular restoration in the kidney. Finally, injured kidneys from patients with obstructive uropathies exhibit a 64.1% decrease* in BMP-7 levels, a change mirrored by urinary BMP-7 levels.

* $p<0.01$.

Conclusions: These findings demonstrate that, while BMP-7 plays a critical role in the repair of renal injuries, the potential for renal recovery following chronic injury is diminished due to the loss of BMP-7. Together, these findings suggest that assessing the regenerative capacity of the kidney by measuring BMP-7 levels is an effective diagnostic approach to evaluate the likelihood of renal dysfunction and the necessity for surgery in patients with obstructive uropathies.

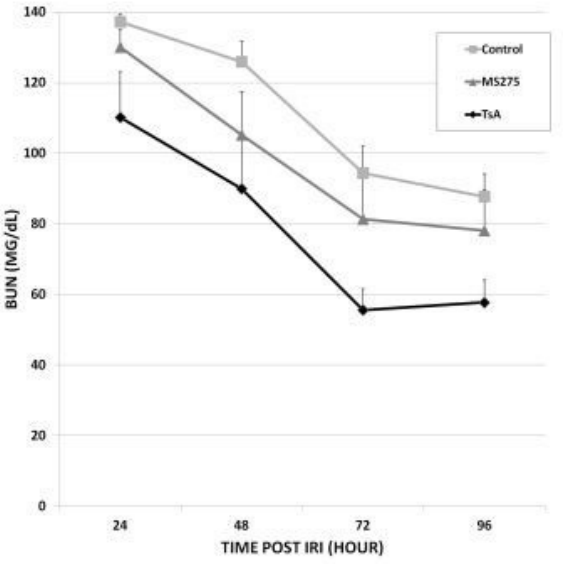
Pan Histone-Protein Deacetylase Inhibition Protects Early Renal Function and Inhibits Fibrosis in Renal Ischemia Reperfusion Injury Matthew H. Levine,[1] Tricia Bhatti,[2] Yanfeng Wang,[1] Zhonglin Wang,[1] Wayne W. Hancock.[2] *[1]Surgery, University of Pennsylvania, Philadelphia, PA; [2]Pathology, Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Histone Protein Deacetylases (HDACs) remove acetyl groups from histone and non-histone proteins. Class I HDACs alter histone acetylation and gene accessibility. Class II HDACs deacteylate a variety of non-histone proteins and regulate heat shock factor 1 (HSF1) trafficking and downstream heat shock protein (HSP) expression. We wished to determine if HDAC inhibitors (HDACi) could improve renal ischemia reperfusion injury (IRI) tolerance and determine HDAC class-specificity.

Methods: Mice were treated with pan-HDACi Trichostatin (TSA), class-I specific HDACi (MS-275), or DMSO contol and then subjected to unilateral renal IRI with contralateral nephrectomy. Class II member HDAC6-/- mice were similarly tested. Early renal function after IRI was assessed by BUN daily for the first 4 days after IRI and computerized Sirius Red scoring for renal fibrosis was done at 28 days after IRI.

Results: Mice treated with TSA had improved tolerance of IRI compared to control mice over all early time points by BUN ($p = 0.001$). This correlated with diminished fibrosis (8 vs 16%) at 28 days by Sirius Red percentage ($p = 0.002$). MS-275 treated mice had a trend toward improved BUN but this did not reach significance ($p = 0.18$). HDAC-6-/- mice had no improvement in BUN relative to wildtype controls. HSP70 expression was lower in HDACi treated mice.



Conclusions: Pan-HDAC inhibition improved tolerance to renal IRI with less peak renal injury, more rapid recovery, and diminished fibrosis. Class I HDAC partially reproduced these effects. HDAC6-/- mice did not have altered IRI tolerance compared to control and HSP70 expression was lower in HDACi treated mice, demonstrating that HSP70 induction was not responsible for renal protection.

Modeling Acute Kidney Injury in Zebrafish Larvae Lauren Brilli,[1,2] Chiara Cianciolo Cosentino,[1] Neil A. Hukriede.[1] *[1]Developmental Biology, University of Pittsburgh, Pittsburgh, PA; [2]Medical Scientist Training Program, University of Pittsburgh, Pittsburgh, PA.*

Background: Acute kidney injury (AKI) is associated with significant morbidity and mortality. Currently, there are no therapies available that can enhance human kidney repair. Several vertebrate species, including zebrafish, have maintained a robust ability to regenerate the kidney following injury; therefore, elucidating the mechanisms of organ regeneration in zebrafish may help us improve human kidney regeneration. Our lab has developed a model of AKI in zebrafish larvae that enables us not only to study the regeneration process but also to screen compounds that have the potential to enhance regeneration. Using this method, we have identified methyl 4-(phenylthio)butanoate (m4PTB), a novel histone deacetylase inhibitor (HDACi) that expands the population of renal progenitor cells during organogenesis. HDACis are known to improve renal injury in rodents; therefore, we hypothesized that m4PTB might enhance renal recovery following nephrotoxic damage in zebrafish larvae.

Methods: To induce AKI, we injected gentamicin into the circulatory system of zebrafish larvae. We performed H&E to evaluate tubular damage and TUNEL assay to visualize apoptotic cells. We examined effects on epithelial polarity by staining for Na^+/K^+ ATPase. To visualize proliferating cells in the proximal tubule, we performed double immunofluorescence using anti-EdU and anti-3G8. For drug treatment studies, we treated AKI-induced larvae with m4PTB and determined survival rate.

Results: Following gentamicin injection, larvae developed edema in a dose-dependent manner, reflecting loss of kidney water balance function. In AKI-induced larvae, we observed tubular cell apoptosis, cell sloughing, and loss of epithelial polarity. Treatment with m4PTB resulted in enhanced proliferation in the proximal tubular epithelium and improved survival.

Conclusions: These results suggest that the zebrafish larval pronephric kidney provides a suitable model for the study of kidney regeneration and point to the potential value of HDACi for improving post-AKI recovery. Whether m4PTB is a promising therapeutic agent to promote renal regeneration requires further study.

TH-PO083

Renal Functional Decline and Glomerulotubular Injury Are Arrested but Not Restored by Release of Unilateral Ureteral Obstruction (UUO) Françoise Praddaude,[1] Wassim Chaabane,[1] Marie Buleon,[1] Acil Jaafar,[1] Marion Vallet,[1] Carolina I. Galarreta,[2] Robert L. Chevalier,[2] Ivan A. Tack.[1] *[1]INSERM U1048, CHU Toulouse, Toulouse, France; [2]Dpt of Pediatric, University of Virginia, Charlottesville, VA.*

Background: Murine UUO is a classical model of progressive chronic kidney disease. Release of UUO permits the study of recovery even if most models do not permit measurement of renal function. Loss of proximal tubular mass and injury to the glomerulotubular junction (formation of atubular glomeruli) are major pathways for progression in this model.

Methods: Adult C57BL/6 mice underwent sham-operation or reversible UUO. In one group, kidneys were harvested after 7 days. In a second group, the obstruction was released after 7 days and animals allowed to recover. Physiologic study of left and right kidneys was performed 30 days after. Renal blood flow (RBF, PAH clearance), glomerular filtration rate (GFR, inulin clearance), urine protein and albumin excretion were measured after ligation of either the left or right ureter. Glomerular volume (PAS), glomerulotubular integrity and fractional proximal tubular mass (*Lotus tetragonolobus lectin) and interstitial collagen (Sirius red) were measured.*

Results: Obstructed kidney weight was reduced by 15% at 7d, but was not different from sham after 30d. Glomerular volume and fractional proximal tubular area of the obstructed kidney were reduced by 55% at 7d, but normalized after 30d. Interstitial collagen deposition increased 2.4-fold after 7 days of UUO, and normalized after release. However, GFR and RBF were reduced by 40% and urine albumin/protein ratio was increased 2.8-fold after 30d ($p<0.05$ for all data). This was associated with ~50% reduction in glomerulotubular integrity following UUO release, which was not improved compared to the value after 7d of UUO.

Conclusions: We conclude that release of 7 days UUO can arrest, but does not restore, normal function of the postobstructed kidney. Although remaining intact nephrons have hypertrophied, glomerular injury is revealed by albuminuria. These results suggest that glomerulotubular injury, rather than interstitial fibrosis, should become the primary target of slowing progressive kidney disease.

TH-PO084

Effect of Carbonic Anhidrase II (CAII) on Cell Regeneration and Damage in the Renal Lesion Induced by Ischemia-Reperfusion Marina Ventayol,[1] Anna Sola,[2] Georgina Hotter.[1] *[1]IIBB-CSIC; [2]CIBER-BBN.*

Background: Carbonic anhydrase is a metalloenzyme that is widely distributed throughout the entire body (renal cortex, glial tissues, the eye, erythrocytes, etc.) and reversibly catalyses the conversion of carbonic anhydride and water into carbonic acid. This enzyme presents four isoforms. Amongst them, carbonic anhydrase II (CAII) is the most active isoenzyme. The aim of this work is to demonstrate the capacity of CAII to induce regeneration and inhibit apoptosis in an in vivo experimental model of renal ischemia-reperfusion in rats.

Methods: The following groups were performed: I/R.- Animals subjected to 45 minutes of ischemia and 24 hours of reperfusion; I/R + CAII.- Animals subjected to I/R, but with injection of CAII i.v., CONTROL.- Control animals; CONTROL + CAII.-control group, but with intravenous injection of CAII ; I/R + Act: I/R, but with intraperitoneal injection of the CAII inhibitor, Acetazolamide.

Results: Regeneration, evaluated by the overexpression of the regenerative genes stathmine and PCNA, and erythropoietin synthesis evaluated by Western blot, were increased after administration of CAII to ischemic rats. Administration of the CAII inhibitor acetazolamide reversed the increases, indicating that CAII is a regenerative promoter and an inductor of EPO synthesis.

On the other hand, CAII showed a regenerative effect only on the damaged tissue, since the administration thereof to controls (control + CAII) did not induce regeneration.

Apoptosis, evaluated by the activity of caspase 3 was drastically reduced following treatment with CAII. The administration of CAII to control animals shows that CAII does not affect the apoptosis that is naturally present in healthy tissue (control group + CAII).

Conclusions: CAII promotes regeneration and prevents apoptosis after renal ischemia/reperfusion.

Funding: Government Support - Non-U.S.

TH-PO085

p66ShcA Deficiency Restores Redox-Sensitive Stress Response Program in Cisplatin-Induced Acute Kidney Injury Rungwasee Rattanavich,[1] Andrei Plagov,[1] Partab Rai,[1] Dileep Kumar,[1] Himanshu Vashistha,[2] Mohammad Husain,[1] Ashwani Malhotra,[1] Leonard G. Meggs,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Ochsner Clinic, New Orleans, LA.*

Background: Overwhelming oxidative stress and compromised tubular cell antioxidant response have been incriminated for cisplatin (Cis) -induced acute kidney injury (AKI). We hypothesized that Cis-induced AKI was the outcome of the deactivated redox-sensitive stress response program (RSSRP).

Methods: Wild (WT) and p66ShcA$^{+/-}$ mice (n=6) were administered either saline (WT) or Cis (12.5 mg/kg, intraperitoneal, Cis/WT). Renal biomarkers were collected and kidneys were harvested for renal histology. Severity of tubular injury was scored on coded samples. In addition, renal cortical sections were stained for TUNEL positive cells. Renal tissue lysates were immunoelectrophoresed and probed for the expression of phospho-p66ShcA, phospho-Foxo3A, MnSOD, and catalase. The same blots were stripped and reprobed for total p66, total Foxo3A and actin. In *in vitro* studies, mouse proximal tubular cells (MPTC) were treated with either vehicle or Cis. Immunoblots were probed for phospho-p66, phospho-p53, Bax, and MnSOD. Control and p66-silenced MPTCs were treated with Cis and evaluated for apoptosis.

Results: Cis/WT showed increased ($P<0.01$) BUN levels and enhanced tubular cell apoptosis and necrosis when compared to Cis/p66$^{+/-}$. Cis/p66$^{+/-}$ developed a clinically occult AKI (normal BUN and only microscopic alterations). Immunoblots from the lysates of renal tissues of Cis/WT displayed enhanced expression of phospho-p66ShcA, and phospho-Foxo3A but attenuated expression of MnSOD and catalase; conversely, p66 deficit prevented these alterations in Cis milieu. In *in vitro* studies, Cis treated mouse proximal tubular cells (MPTCs) displayed enhanced phosphorylation of p66ShcA and no increase in MnSOD expression. Renal tissues of Cis/WT and Cis-treated MPTCs also displayed enhanced phosphorylation of p53 and Bax expression.

Conclusions: Cis-induced AKI was caused by the deactivated RSSRP (attenuated anti-oxidant response) and activation of pro-apoptotic (p53-induced Bax expression) pathway.

NADPH Oxidase Activation in Renal Ischemia-Reperfusion (I/R) Injury: The Role of Complement System Activation S. Simone,[1] F. Rascio,[1] G. Castellano,[1] P. Ditonno,[1] M. Battaglia,[1] Antonio Crovace,[1] F. Staffieri,[1] Beatrijs D. Oortwijn,[3] Francesco Paolo Schena,[1] Loreto Gesualdo,[1] Giovanni Pertosa,[1] Giuseppe Grandaliano.[2] *[1]Dept. of Emergency and Organ Transplantation, Univ of Bari, Bari, Italy; [2]Dept. of Medical and Surgical Sciences, Univ of Foggia, Foggia, Italy; [3]Pharming BV, Leiden, Netherlands.*

Background: Renal I/R plays a key role in the pathogenesis of delayed graft function after renal transplantation and is characterized by increased ROS generation. We demonstrated the activation of complement (C) system in a swine model of renal I/R damage. Aim of this study was to investigate the activation of NADPH oxidase in a swine model of renal I/R injury.

Methods: Renal I/R was induced in 10 pigs by arterial clamping; 5 of them were treated with a recombinant form of human recombinant C1-inhibitor (C1-INH). We collected biopsies before ischemia (T0), after 30' (T30') and 60' of reperfusion (T60').

Results: I/R injury was able to induce protein expression of NADPH oxidase subunits, gp91phox/NOX-2 and p22phox, with a peak at T60' ($p=.04$) in infiltrating monocytes-macrophages (CD163^{+}) and myeloid dendritic cells (SWC3a^{+}). A colocalization of gp91phox/NOX-2 and RAC was already observed in these cells at T30', supporting an early activation of the enzyme. NADPH oxidase renal isoform, NOX-4, was also studied by immunohistochemistry. We observed an increase in tubular NOX-4 expression with a peak at T60' ($p=.03$) that was completely inhibited by C1INH infusion. The NADPH oxidase activity was assessed (chemiluminescence) on renal tissue taken from both control and treated animals at T0, T30' and T60'. Enzyme activity significantly increased at 60' (220.2±18.8 vs baseline 91.6±12.0 ΔURL/Dt, $p=.01$) and was drastically reduced in C1INH-treated animals at the same time point (128.4±33 ΔURL/Dt, $p=.02$). In cultured tubular epithelial cells C3a induced NOX-4 expression in a time-dependent manner with a peak at T15'($p=.03$).

Conclusions: Data suggest that NOX-2 and NOX-4 are activated during I/R in a C-dependent manner and play a key role in ROS generation in renal I/R. Therefore, NADPH oxidases and C system may represent pharmacological targets to prevent oxidative damage during I/R injury.

TH-PO087

Surgically Injured Collecting Ducts in the Adult Rat Kidney Exhibit Capacity for *De Novo* Tubulogenesis Natalia O. Litbarg,[1,2] Snezana Vujicic,[1,2] Suman Setty,[1] Jose A.L. Arruda.[1] *[1]Medicine, UIC, Chicago, IL; [2]Medicine, JBVA Medical Center, Chicago, IL.*

Background: We have previously described a novel model of surgical wound regeneration, in which the polectomized kidney of adult rats was wrapped in an inert plastic pouch to prevent extrarenal tissue adhesions. During healing, we observed formation of branching tubular epithelial outgrowths (TEOs) that extended from the wounded edge of the kidney into the surrounding granulation tissue. Here, we sought to determine the nephronic origin of these TEOs.

Methods: Adult male rats were subjected to right nephrectomy and left renal polectomy followed by plastic pouch enclosure. Tissues were obtained between 1 and 12 wks after injury and subjected to serial sectioning and immunohistological profiling.

Results: Branching TEOs were anatomically connected to tubules at the kidney's wound edge. They were not involuting tubular remnants, since they showed increased expression of several proliferative and mitotic markers (pHH3, Ki67, and PCNA). TEOs and their tubules of origin expressed the following markers characteristic of collecting ducts and ureteric buds: *Dolichos biflorus* agglutinin, E-cadherin, pancytokeratin, Pax2, HoxB7, and calbindin. TEOs, however, lacked Aquaporin 2 (a marker of terminal differentiation first expressed by ureteric buds at embryonic day 18), suggestive of a dedifferentiated state. As the granulation tissue surrounding TEOs fails to express a number of markers of metanephric mesenchyme (Cited1, Pax2, Six2), the mechanism of tubulogenesis in our adult kidney injury model differs from embryonic tubulogenesis.

Conclusions: Together, our results suggest that surgically disrupted adult collecting ducts are capable of dedifferentiation and propagation into adjacent granulation tissue in the form of branching tubular epithelial outgrowths (TEOs). Our model offers evidence of a novel and previously unrecognized potential for regeneration by the adult mammalian kidney.

Gβγ Signaling Plays a Critical Role in Recovery from Renal Ischemia-Reperfusion Injury in Rats Emily C. Haines, Sarah M. White, Frank Park, Kevin R. Regner. *Nephrology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Renal tubular epithelial cell (RTEC) proliferation is vital to tubular regeneration following ischemia-reperfusion injury (IRI). The mechanisms that regulate RTEC proliferation following kidney injury remain poorly understood. Heterotrimeric G proteins are pivotal molecular switches that can regulate epithelial cell function. We previously demonstrated that pharmacologic and genetic inhibition of Gβγ subunit activity

decreased renal epithelial cell proliferation in vitro. We therefore hypothesized that inhibition of Gβγ subunit activity would impair recovery from renal IRI in vivo.

Methods: Male Sprague-Dawley rats underwent 30 min bilateral renal ischemia (or sham) and reperfusion for 24, 72, or 168 hours. Rats were treated with a small molecule inhibitor of Gβγ (gallein, 100 mg/kg s.c.) or an equivalent volume of vehicle (phosphate buffer saline) daily for 4 days beginning one hour after reperfusion.

Results: At 24 hours, plasma creatinine (measured by LC-MS/MS) was 3.8 ± 0.6 mg/dl in vehicle treated rats and 3.6 ± 0.3 mg/dl in gallein treated rats (p=0.8). By 72 hours, plasma creatinine was significantly higher in gallein treated rats in comparison to vehicle treated rats (3.1 ± 2.3 mg/dl vs 0.90 ± 0.5 mg/dl, p=0.03) This was associated with a significant increase in the degree of tubular injury (tubular cell necrosis, tubular cast formation, and dilated tubules) in the outer stripe of the outer medulla and persistent expression of neutrophil gelatinase-associated lipocalin in gallein treated kidneys in comparison to vehicle treated kidneys. Gβγ subunit inhibition significantly increased mortality following IRI in a 7 day survival study. Median survival in gallein treated rats was 3 days in comparison to 100% survival in vehicle treated rats (p=0.03).

Conclusions: Taken together, these data suggest that Gβγ subunit signaling modulates kidney repair following IRI.

α-Ketoglutarate-Related Inhibitors of HIF Prolyl Hydroxylases Are Substrates of the Renal Organic Anion Transporter 1 (OAT1) Birgitta C. Burckhardt,[1] Yohannes Hagos,[1] Gunnar Schley,[2] Johannes Schoedel,[2] Carsten Willam,[2] Gerhard Burckhardt.[1] *[1]Department of Systemic Physiology and Pathophysiology, University Medical Center Göttingen, Göttingen, Germany; [2]Department of Nephrology and Hypertension, University Medical Center Erlangen, Erlangen, Germany.*

Background: α-Ketoglutarate (αKG) is a substrate of HIF prolyl hydroxylases 1-3 that decrease cellular levels of the hypoxia inducible factor 1α (HIF-1α) in the presence of oxygen. αKG analogues are applied to stabilize HIF-1α even in the presence of oxygen and thus provide a novel therapeutic option in treating kidney diseases. In the kidneys, the organic anion transporters 1 and 3 (OAT1, OAT3) in cooperation with the sodium-dependent dicarboxylate transporter 3 (NaDC3) might be responsible for the uptake of αKG analogues across the basolateral membrane into proximal tubular cells.

Methods: Using the radiolabelled substrates p-aminohippurate (PAH; OAT1), estrone-3-sulfate (ES; OAT3), and succinate (NaDC3), N-oxalylglycine (NOG), dimethyloxalyl glycine (DMOG), 2,4-diethylpyridine dicarboxylate (2,4-DPD), and pyridine-2,4-dicarboxylic acid (PDCA) were tested in cis-inhibition and trans-stimulation experiments on HEK293 cells stably transfected with either human NaDC3, OAT1 or OAT3.

Results: None of the αKG analogues interacted with hNaDC3. At a concentration of 0.1 mM, 2,4-DPD and PDCA inhibited ES uptake in HEK293 cells stably transfected with OAT3 by 31.3 ± 8.3 and 29.7 ± 5.7%, respectively. NOG, 2,4-DPD and PDCA, but not DMOG, inhibited PAH uptake by OAT1 exhibiting IC50 values <0.1 mM. In trans-stimulation experiments, uptake of PAH increased upon pre-incubation of OAT1-transfected HEK293 cells for 2 h with NOG and PDCA. NOG and PDCA are substrates of OAT1, because of OAT1-mediated stabilization of HIF-1α by NOG and PDCA. Stabilization of HIF-1α was prevented by application of probenecid, an inhibitor of OAT1.

Conclusions: Therefore, OAT1 can be used for targeting αKG-related PHD inhibitors to proximal tubule cells to avoid hypoxic kidney injury.

IRAK-M Prevents Chronic Injury after Acute Kidney Injury through Suppression of Renal Inflammation Maciej Lech, Regina Groebmayr, Mi Ryu, Hans J. Anders. *Nephrologisches Zentrum, Klinische Biochemie, Medizinische Klinik und Poliklinik IV der LMU, Munich, Germany.*

Background: Acute kidney injury (AKI) is defined as a rapid decrease in the glomerular filtration rate with an accumulation of serum urea and creatinine. If functional parameters of kidneys return to normal levels within 30 days of dialysis the AKI is considered as reversible. Nevertheless, patients that recovered from AKI often develop chronic kidney disease (CKD), probably due to incomplete regeneration and persistent renal inflammation. IRAK-M is an inhibitor of TLR- and IL-1R-signaling, that prevents dissociation of IRAK-1 and IRAK-4 from MyD88 and inhibits proinflammatory signals in macrophages. As macrophages are important regulators of renal inflammation and tubular healing, we hypothesize, that genetic factors which influence the activation state of these cells have influence on inflammatory processes and regeneration after AKI.

Methods: Kidneys from wild type and IRAK-M-/- mice were investigated 3, 5 and 10 weeks after ischemia/reperfusion injury.

Results: Post-ischemic wild type kidneys regenerate successfully after 5 weeks and show no significant changes in size and structure compared to sham operated kidney. In contrast, IRAK-M-/- kidneys shrank to 1/3 of their original size due to loss of proximal tubules and formation of atubular glomeruli. Remarkably, macrophages infiltrates were massively increased in IRAK-M-/- mice. Lack of IRAK-M aggravated post-ischemic chronic renal failure evidenced by increased fibrosis and loss of tubular compartment as well as increased mRNA expression of TNF-a and the kidney damage markers. Finally, the TNF-a signaling pathway inhibitor Etanercept prevented loss of renal tissue in post-ischemic kidneys of IRAK-M -/- mice and reduced chronic inflammation.

Conclusions: Thus IRAK-M suppresses the persistent activation of renal macrophages and renal chronic inflammation upon transient renal ischemia by blocking expression of the proinflammatory and proapoptotic cytokine TNF. This process promotes tubular repair and recovery from post-ischemic tubular injury. IRAK-M loss-of-function mutations may predispose to chronic kidney injuries caused by acute triggers.

TH-PO091

Changes in Notch Signaling Contribute to Defective Regeneration and Increased Senescence in the Aging Kidney Inga Soerensen, Song Rong, Nathan D. Susnik, Hermann G. Haller, Roland Schmitt. *Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

Background: Notch signaling is involvedin determining cell fate during development, tissue maintenance,and repair. The aging kidney has a diminished regenerative potential and an increased tendency to develop fibrosis. In this study, we wanted to test the impact of Notch signaling on the aging kidney in the context of acute damage and repair.

Methods: Notch activation in young (10 weeks) and old (18 months) mice was compared after renal ischemia/reperfusion (IR). Mice with conditional overexpression of constitutively active Notch1 in proximal tubules were created by mating GGT::Cre-ERT2 mice with floxed RosaNICD mice (NICD mice). Post-ischemic kidneys were analyzed by quantifying damage, apoptosis, inflammation, cell proliferation and senescence markers. In vitro, tubular epithelial cells were analyzed after overexpression of Notch signaling components.

Results: After IR injury, we observed a rapid activation of Notch1 in renal tubular cells in both young and old mice. This Notch activation and the expression of the downstream targets, Hes1 and Hey1, decreased quickly in young kidneys but old kidneys showed significantly prolonged activation. To analyse the consequences of sustained Notch activation, NICD mice were observed after IR. NICD overexpression was associated with higher expression of tubular damage markers Kim1 and NGAL and increased signs of fibrosis. In parallel, NICD kidneys showed higher expression of the cellular senescence marker $p16^{INK4A}$, but no differences were found in proliferation of tubular cells or inflammation. In cell culture, we used primary tubular epithelial cells of NICD mice or stimulated tubular epithelial cells with Notch ligand, Dll4, and observed a pro-senescent effect of Notch signaling.

Conclusions: Our data indicate that Notch activation is sustained in old versus young kidneys after IR. This mechanism might contribute to the overall worse outcome of old kidneys since transgenic activation of Notch is associated with defective regeneration, enhanced fibrosis and with a higher risk of developing cellular senescence.

TH-PO092

Kidney Proximal Tubular Epithelial Cell-Specific Overexpression of Netrin-1 Suppresses Acute Kidney Injury Induced Interstitial Fibrosis and Glomerular Sclerosis Punithavathi Vilapakkam Ranganathan, Calpurnia Jayakumar, Ganesan Ramesh. *Medicine/Vascular Biology Center, Georgia Health Sciences University, Augusta, GA.*

Background: Acute kidney injury (AKI) is recognized as a major risk factor for the development chronic kidney disease (CKD), which remains one of the leading causes of death in the developed world. Fibrosis is responsible for chronic progressive kidney failure. However, knowledge on molecules that may suppress fibrogenic response after injury is lacking. In ischemic models of AKI, we demonstrate a new function of netrin-1 in regulating interstitial fibrosis.

Methods: Acute kidney injury was induced by clamping renal pedicle for a period of 26 minutes and then reperfused for a period of 1, 2 and 3 weeks. Kidney function was determined by measuring serum creatinine. Fibrosis, macrophage infiltration and vascular density were quantified by Western blot analysis, immunostaining and RT-PCR.

Results: Acute injury was promptly followed by rise in serum creatinine in both wild type and netrin-1 transgenic animals (1.2± 0.1 mg/dl vs. 1.1±0.1mg/dl). However, wild type showed a slow recovery of the kidney function as compared to netrin-1 transgenic animals (0.65±0.1 mg/dl vs. 0.37±0.1 mg/dl on day 7) and reached baseline by three weeks. Histological examination showed increased infiltration of interstitial macrophages, extensive fibrosis, reduction of capillary density and glomerular sclerosis. Collagen IV and α-smooth muscle actin expression was absent in sham operated kidney, however, expression was significantly increased at 2 weeks and peaked at 3 weeks after reperfusion. These changes were minimal in transgenic mice kidney which overexpresses netrin-1 in the proximal tubular epithelial cells.

Conclusions: Our data suggests that proximal tubular epithelial cells may play an important role in interstitial fibrosis and netrin-1 could be a useful therapeutic agent for treating kidney fibrosis.

COMT LL Genotype Predisposes to Postoperative Acute Kidney Injury in Australian and German Cardiac Surgery Cohorts Annemarie Dittrich,[1] Johanna Kube,[1] Anja Haase-Fielitz,[1] Michael Plass,[2] Martin Zenker,[3] Denny Schanze,[3] Rinaldo Bellomo,[4] Peter R. Mertens,[1] Michael Haase.[1] *[1]Nephrology, Otto von Guericke University, Magdeburg, Germany; [2]Anaesthesiology, German Heart Center, Berlin, Germany; [3]Human Genetics, Otto von Guericke University, Magdeburg, Germany; [4]Intensive Care, Austin Health, Melbourne, Australia.*

Background: Cardiocirculatory shock and acute kidney injury (AKI) are severe complications after cardiac surgery. Catecholamin-O-methyltransferase (COMT) is a ubiquitous enzyme, involved in systemic and renal degradation of catecholamines. In

a pilot study enrolling 260 cardiac surgical patients in Melbourne, Australia, 24.6% of patients were homozygous for the COMT "L"-allele, coding for thermolabile COMT variant Val158Met with low enzyme activity. COMT LL carriers more frequently developed AKI with or without acute dialysis compared to patients with HL (intermediate) or HH (high) enzyme activity [JASN 2009;20:1393-03].

Methods: In the present study, we wished to validate the results of the Australian study in an independent cohort prospectively enrolling 200 patients at the German Heart Center, Berlin. AKI was defined according to the RIFLE criteria.

Results: COMT genotype distribution (LL 23.1%; HL 55.9% HH 21.0%) was similar to the Australian cohort. There was no difference in age, comorbidities and operation. In the Berlin cohort, 17.8% of patients with LL, 9.2% with HL and 9.7% with HH developed AKI. *(Fig. 1)*. In 9.1% of LL, 5.6% of HL and 7.3% of HH patients acute dialysis was initiated. After pooling of both cohorts, COMT LL carriers showed higher AKI and dialysis rates (P=0.002, P=0.027) compared to HL and HH carriers.

Conclusions: Patients with COMT LL genotype are predisposed to worse renal outcomes after cardiac surgery. For preoperative risk stratification, COMT genotyping appears to be useful in patients who present with classical renal risk factors.

Risk of Acute Kidney Injury from Oral Acyclovir: A Population-Based Study Ngan Lam,[1] Matthew A. Weir,[1] Zhan Yao,[2] Peter G. Blake,[1] Michael Matthew Beyea,[1,3] Tara Gomes,[2] Sonja Gandhi,[1] Muhammad Mamdani,[2,3] Ron Wald,[3] Chirag R. Parikh,[4] Daniel G. Hackam,[1] Amit X. Garg.[1,3] *[1]Nephrology, University of Western Ontario, London, ON, Canada; [2]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; [3]Nephrology, University of Toronto, Toronto, ON, Canada; [4]Nephrology, Yale University School of Medicine, New Haven, CT.*

Background: Intravenous acyclovir-induced acute kidney injury (AKI) from drug crystallization in the renal tubules is described in case reports, review articles and drug prescribing manuals. Similarly, AKI from oral acyclovir is described in case reports but the risk in routine practice is unknown.

Methods: We studied a large cohort of older patients in Ontario, Canada receiving new outpatient prescriptions between 1997 and 2011 for oral acyclovir or valacyclovir (which is metabolized to acyclovir). The primary outcome was hospital admission with AKI in the 30 days following the initial prescription. The comparison group was older patients receiving new prescriptions for famciclovir, an antiviral used for similar indications as acyclovir but with no known renal toxicity.

Results: A total of 76,269 patients received acyclovir or valacyclovir and 84,646 received famciclovir. On average, patients were 76 years old (interquartile range 71 to 81 years) and the prescription duration was 7 days. Acyclovir or valacyclovir use was not associated with a higher risk of hospital admission with AKI (209 [0.27%] events with acyclovir or valacyclovir versus 238 [0.28%] events with famciclovir, relative risk 0.97, 95% confidence interval 0.81 to 1.17). Results were consistent in adjusted analyses, in all subgroups and in the subpopulation with laboratory measurements.

Conclusions: In this population-based study, it is reassuring that routine use of oral acyclovir in older adults was not associated with serious AKI.

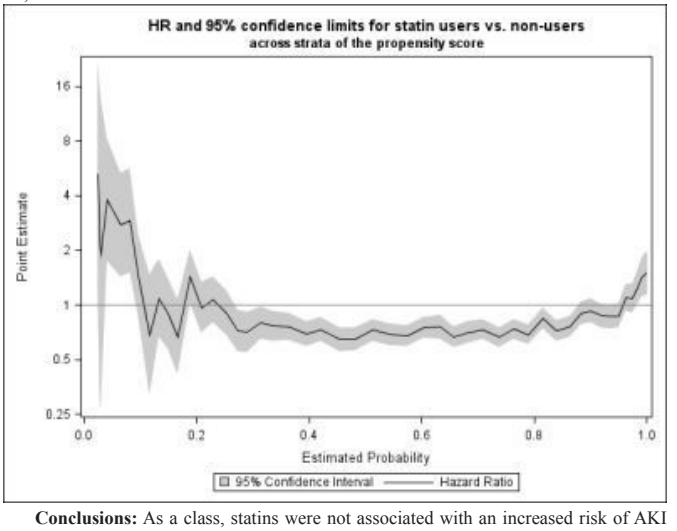
The Risk of Acute Kidney Injury among Statin Initiators J. Bradley Layton,[1,2] M. Alan Brookhart,[1] Michele Jonsson Funk,[1] Ross J. Simpson,[2] Virginia Pate,[1] Til Stürmer,[1] Abhijit V. Kshirsagar.[2] *[1]Epidemiology, Univeristy of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Statins are widely used medications for preventing acute cardiovascular events, but recent reports have suggested they may increase risk of renal injury. We investigated the risk of acute kidney injury (AKI) in a large, claims-based observational cohort based in the United States during 2000-2010.

Methods: We identified individuals with new statin use following a six month washout period among employer-insured individualxs in a large, US, administrative claims database. A comparison group of non-users were identified at outpatient physician visits. Individuals were followed for one-year, and diagnosis codes in claims were searched for evidence of AKI or renal failure. Rates of AKI were compared in statin users vs. non-users with Cox-proportional hazard models to calculate hazard ratios (HR) and 95% confidence intervals (CI). We employed standard adjustment and propensity score (PS) methods.

Results: We identified 4,146,506 eligible statin users and 4,033, 800 non-users. Users had a 1-year AKI incidence of 0.9%, and non-users' was 0.3%. Adjusted models for statin users vs. non-users yielded HR=0.97 (95% CI: 0.94-0.99), while PS matching yielded HR=0.79 (95% CI: 0.76-0.81). Heterogeneity was observed over the distribution of the PS, with elevated risks observed at the tails of the PS distribution.



Conclusions: As a class, statins were not associated with an increased risk of AKI in the majority of users. Yet, substantial heterogeneity was observed in the baseline characteristics of statin initiators.

TH-PO096

Renal Tubular Injury Biomarkers in Non-Critically Ill Children Treated with Aminoglycosides Michael Zappitelli,[1] Melissa Piccioni,[1] Michael Pizzi,[1] Ang Gao,[3] Zubaida Al-Ismaili,[1] Michael R. Bennett,[2] Prasad Devarajan,[2] Julie Ho.[3] *[1]Pediatrics, McGill, Montreal, QC, Canada; [2]Pediatrics, Cin Child Hosp Med Cent, Cincinnati, OH; [3]Nephrology, U Manitoba, Winnipeg, MB, Canada.*

Background: Amionoglycosides (AG) are nephrotoxins commonly used in children. Little data exist on acute kidney injury (AKI) biomarkers in nephrotoxicity other than contrast-AKI. We evaluated previously studied urine biomarkers alpha-glutathione S-transferase (a-GST, µg/L) and pi-GST (µg/L) for reflecting AG-related tubular injury and performed a pilot study of hepcidin-25 (HEP-25, ng/ml) and liver-type fatty acid-binding protein (L-FABP, ng/ml) for AG-AKI diagnosis.

Methods: We prospectively studied 103 children receiving AG treatment [Rx](no renal disease, Rx≥3 days, available baseline serum creatinine[SCr]) on non-critical care units. Daily SCr and urine were collected for biomarker measurement. AKI was:SCr rise ≥50% from baseline (≤3 days pre-Rx). We calculated biomarker area under the curve (AUC) from a)2 days pre to 1 day post-AKI diagnosis and b) the 1st 2 Rx days to diagnose AKI.

Results: Mean[SD] age was 8.4[4.6] yrs (19% AKI;52% boys;73% tobramycin[Tobra]). All AUC's are shown in the table. Pi-GST performed better at AKI diagnosis when only Tobra patients were studied (max AUC 0.72 at 2 days after 1st AKI evidence). Pre-AKI a- nor pi-GST predicted AKI. Early Rx a- and pi-GST: only pi-GST predicted AKI development (AUC 0.77), especially on Tobra. Early Rx L-FABP was also diagnostic of AKI; HEP-25 was diagnostic of NON-AKI status. We confirmed higher early Rx HEP-25 levels in non-AKI patients ($p<0.05$).

Conclusions: Pi-GST is more discriminatory than a-GST for AG-AKI and more so with Tobra. We confirmed the HEP-25 association with non-AKI status. Together, these biomarkers may help identify early on the presence of AG-renal injury and ultimately lead to fewer AG renal complications.

AUC's (95% CI) for various biomarkers to diagnose AKI when obtained at different timepoints.

Post-Operative Proteinuria as a Biomarker of Acute Kidney Injury in Pediatric Cardiac Surgery: A TRIBE-AKI Consortium Study
Michael Zappitelli,[1] Catherine D. Krawczeski,[2] Simon Li,[4] Steven G. Coca,[3] Chirag R. Parikh,[3] Prasad Devarajan.[2] *[1]Pediatrics, McGill, Montreal, QC, Canada; [2]Nephrology & Hypertension, Cincin Child Hosp Med Cent, Cincinnati, OH; [3]Medicine, Yale University, New Haven, CT; [4]Pediatrics, New York Med Coll, Valhalla, NY.*

Background: We determined if early post-operative (post-op) cardiac surgery (CS) urine albumin to creatinine ratio (ACR) predicts post-op AKI in children.

Methods: We performed a 3-center (Montreal, Cincinnati, Yale-New Haven), prospective study of 294 children having CS (excluded:end stage renal disease;<1 month old). Post-op ACR was measured 0-6 hrs post-intensive care unit (ICU) entry. AKI definition: Stage 1(≥50% or 0.3 mg/dl rise from baseline); Stage 2 (≥SCr doubling or dialysis) AKI. We calculated adjusted relative risk (aRR) of post-op ACR to predict AKI. We used the C-statistic (AUC) and continuous net reclassification improvement (NRI) to determine if post-op ACR enhanced a clinical+biomarker (serum Cystatin C, urine neutrophil gelatinase-associated lipocalin, interleukin-18) AKI prediction model. We used multiple regression to determine if post-op ACR predicted longer hospital and ICU stay (LOS). We conducted analyses in children < *vs.* ≥2 years old (y.o.).

Results: 145/294 (49.3%) were <2 y.o. 78/145(54%) and 43/149(29%) of <2 *vs.* ≥2 y.o. developed AKI. In the ≥2 y.o. group, children in the highest tertile post-op ACR had an aRR=2.1 (95% CI 1.1-4.1) for AKI. Only in the ≥2 y.o. group, post-op ACR improved AKI prediction when added to a clinical-biomarker model (Table, NRI p≤0.03). Higher post-op ACR predicted longer hospital and ICU LOS (adjusted p = 0.02 and 0.01, respectively) in the ≥2 y.o. group but only hospital LOS (adjusted p = 0.02) in the <2 y.o. group.

Conclusions: Post-op ACR is a readily available early test for AKI development after CS in children ≥2 y.o.

Table. Performance of early post-operative albumin to creatinine ratio (ACR) to predict post-operative AKI (≥50% serum creatinine rise or receipt of dialysis). All Area under the curve (AUC) values with associated standard errors. All net reclassification improvement (NRI) values with associated upper and lower 95% CI.

	AUC for AKI: ACR only	**AUC for AKI:** Clinical factors + other biomarkers	**AUC for AKI:** Clinical factors + other biomarkers + **ACR** (p-value: difference with previous AUC)	NRI after adding ACR to Clinical+biomarker model (p-value)
1 month-2 y.o.	0.57 (0.05)	0.79 (0.04)	0.80 (0.04) p=0.46	0.22 (0.17) p=0.21
≥2 y.o.	0.63 (0.05)	0.86 (0.03)	0.88 (0.03) p=0.46	0.39 (0.13) p=0.03

Clinical factors: age, gender, site, cardiopulmonary bypass time, surgical severity score, pre-operative renal function.
Other early post-op biomarkers: urine neutrophil gelatinase- associated lipocalin and interleukin-18; serum cystatin C.

TH-PO098

Vancomycin-Induced Acute Kidney Injury (Van-AKI): An Underreconized Issue on the Rise with Incomplete Recovery but Preventable by Mandatory Drug & Serum Creatinine Monitoring
Talla A. Rousan,[1] Omar S. Abu-Romeh,[1] Ahmad Bilal,[1] Muhammad Ali Chaudhry,[1] Jimmy A. Thomas,[1] Kai Lau.[1,2] *[1]Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Medicine, OKC VA Medical Center, Oklahoma City, OK.*

Background: Although the literature suggests Van-AKI, conclusive evidence has been elusive. Recently the incidence seems to rise due to MRSA & MRSE epidemics, escalating use for health care associated pneumonia & osteomyelitis, & organisms sensitive only to levels >15-20 mg/L. We here present evidence from 17 cases to argue for Van-AKI, analyze risk factors & forewarning signs, provide a functional profile & guidelines for prevention.

Methods: These cases were seen in 3-mon renal consults & diagnosed by toxic levels & vigorously excluding all other known causes.

Results: The mean therapy duration was 21 d & mean dose was 2.3 g /d. On day 16, 3 d before the highest vancomycin level, drug level was already elevated at 27 mg/L. On this day, serum creatinine (Screat) was 1.6 mg% & estimated creatinine clearance (eCrCl) fell by 33 % vs baseline 110 ml/min. Maximal vancomycin level (66 ± 5 mg/L) was noted 18 d after the 1st dose & 8.4 h after the last dose. On this day, Screat had risen to 4.1 vs baseline 0.97 mg% & CrCl fell by 79 %. Screat peaked at 5.8 mg%, ~5.4 d after maximal level or 57 h after the last dose. At this point, eCrCl fell to a nadir of 22 ml/min, an 80 % drop. After stopping vancomycin, Screat fell to a nadir of 1.34 mg%, ~ 36 d after the last & 57 d after the first dose. Recovery was incomplete even 36 d after the last dose since the best eCrCl of 61± 7 ml/min indicated 45% loss. 4.6 d before maximal level, elevated level of 27.3 +/-5.3 mg/L already existed, which should be a warning signal for toxicity. 8.4 h before the last dose, toxic level (66 mg/L) was already reported, which should prompt omission of the last dose, given the markedly increased Screat of 4.1mg/dl.

Conclusions: Van-AKI is a real & costly financially & clinically since significant irreversible loss ensues. Prescribers must document the last trough level & creatinine before orders. We suggest dose reduction if level ≥ 20-25 mg/L &/or Screat doubles the baseline.

Peritoneal Dialysis for Acute Kidney Injury in Developing Counties: Decreasing Maternal and Childhood Mortality Rates
Mary Carter,[1,2] Fredric O. Finkelstein,[3] Karen E. Yeates,[4] Peter Kotanko,[1,2] Nathan W. Levin,[1,2] John Callegari.[1,2] *[1]Renal Research Institute, NY, NY; [2]Sustainable Kidney Care Foundation, NY, NY; [3]Hospital of St Raphael, Yale Univ., New Haven, CT; [4]Queens Univ., Kingston, ON, Canada.*

Background: There is an increasing need for treatment of AKI in developing countries. Sustainable Kidney Care Foundation (SKCF), working with industry and professional societies starts PD programs for AKI with a focus on the UN Millennium Goals, namely saving the lives of children and women of childbearing age. An shortage of clinicians with nephrology training exists.

Methods: SKCF model focuses on sustainability and capacity building. The hospitals need to have a reliable medical laboratory and trained clinical staff who can perform PD catheter placement. PD consumables are donated for 2 years during which payment from insurance and/or patients is collected, when possible, and then saved and used for acquisition of supplies for subsequent years. PD was selected as the modality of choice as it can be provided in low technology settings vs. HD, which requires major capital expenditures and technical sophistication. Training has been provided by ISN, ISPD and IPNA.

Results: Successful programs are ongoing in Tanzania and Ghana, with new programs starting in Benin, Cameroon, Ethiopia and Uganda. 85% of treated AKI patients have had a full recovery of their kidney function after an average of 10 days of PD. One of the challenges continues to be educating healthcare workers in remote areas to recognize AKI for early referral.

Conclusions: PD for AKI programs can be organized in developing countries. In addition to saving lives, they can become important catalysts for starting a national discussion about kidney disease, prevention and treatment; result in the inclusion of nephrology in the medical school curriculum and outreach to rural communities. While kidney disease was not specifically mentioned in the WHO September 2011 meeting calling for the reduction of 4 major non-communicable diseases (heart attacks, strokes, cancer and respiratory disease), a rising number of renal patients can be expected and saving lives with adequate dialysis is feasible.

Hypophosphatemia during Continuous Veno-Venous Hemofiltration Associated with Mortality in Critically Ill Patients with Acute Kidney Injury
Yi Yang, Yiwen Li, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

Background: To determine whether continuous veno-venous hemofiltration (CVVH) associated hypophosphatemia is conferring effect on the global outcome of critically ill patients with acute kidney injury (AKI).

Methods: We studied 622 patients who were diagnosed as AKI, receiving CVVH therapy more than 72 hours. The primary outcome was death during the 28-day period or survival at 28 days after initiation of CVVH. Demographic and clinical data including serum phosphorus levels were recorded along with clinical outcome.

Results: The multivariate analysis indicated that the incidence of CVVH associated hypophosphatemia was an independent risk factor of outcome, conferring a 1.513-fold (95% CI 1.160–1.972, p = 0.002) increased mortality rate at 28 days compared with those without developing hypophosphatemia. Analysis with the subcohort of patients who hadhypophosphatemia episodes during the CVVH therapy period indicated that the frequency of hypophosphatemia (which defined as the hypophosphatemia days in the ratio of total CVVH therapy time) but not the incidence of severe hypophosphatemia (p = 0.138) was an independent risk factor of outcome. Compared with the patients having low hypophosphatemia frequency (< 0.49), those with high hypophosphatemia frequency (≥ 0.49) conferring a 2.302-fold increased mortality rate (95% CI 1.617–3.275, p<0.001).

Conclusions: CVVH associated hypophosphatemia was an independent risk factor of the global clinical outcome of critically ill patents with AKI. During the CVVH therapy period, the frequency of hypophosphatemia but not the incidence of severe hypophosphatemia served as an independent risk factor of outcome, and high hypophosphatemia frequency suggested increased mortality rate.

Acute Kidney Injury Requiring Renal Replacement Therapy in Patients without Pre-Existing Disease
Gijs Fortrie,[1] Adrianus L.H.J. Aarnoudse,[1] Hilde R. De Geus,[2] Robert Zietse,[1] Johan Groeneveld,[2] Michiel G.H. Betjes.[1] *[1]Nephrology, Erasmus Medical Center, Rotterdam, Netherlands; [2]Intensive Care, Erasmus Medical Center, Rotterdam, Netherlands.*

Background: Acute kidney injury (AKI) necessitating renal replacement therapy (RRT) in the critically ill is associated with an excessively high mortality. After hospital discharge, these patients have an increased risk for progression towards end stage renal disease (ESRD) and increased mortality. However, critically ill patients are often known with pre-existing diseases which may significantly confound the association of AKI with in-hospital mortality and its long-term consequences.

Methods: We performed a retrospective cohort study in a large academic hospital, selecting for critically ill patients with AKI necessitating RRT without pre-existing disease. The associations with mortality and ESRD requiring dialysis in the short and long term were evaluated.

Results: Of the 1221 critically ill patients recruited, only 94 (7.7%) had no pre-existing disease. In-hospital mortality was 43.6%, which was equally high as in a group of patients matched for age and sex with pre-existing disease. Those who survived hospital admission had a mean follow-up of 8.6 years (range = 0 - 17) and 49.1% left the hospital with an estimated glomerular filtration rate (eGFR) <90 ml/min/1.73m² of which two were dialysis dependent. The 1-year, 5-year and 10-year cumulative survival rates for patients that survived hospital admission were, 96.2%, 91.4% and 85.6%, respectively. Cumulative survival rates for the matched patients with pre-existing disease were 89.8%, 65.7% and 57.0%, respectively. Compared to the predictive survival rate in the average Dutch population, the 10-year survival rate in this study was 7% lower. Besides the two survivors that progressed towards ESRD during hospital admission, one additional patient reached ESRD during follow-up after 7.5 years, which constituted a 10-year renal survival of 93%.

Conclusions: Critically ill patients with RRT-requiring AKI have an excessively high in-hospital mortality risk, even in the absence of pre-existing disease. However, those without pre-existing disease have a good long-term prognosis.

TH-PO102

Acute Renal Failure in the Pediatric Intensive Care Unit: Etiology and Outcome Rainer Büscher, Janet Atinga, Anja K. Büscher, Peter F. Hoyer. *University of Duisburg-Essen, Pediatrics 2, Pediatric Nephrology, Essen, Germany.*

Background: Acute renal failure (ARF) is common in critically ill children and characterized by a sudden but reversible increase of serum creatinine, nitrogenous waste products and disturbances of the electrolyte and fluid balance. The etiology of ARF has shifted from primary renal disease to multifactorial causes. Therapeutic strategies and prognosis depend on the underlying disease. The aim of this retrospective study was to define etiology and clinical features of ARF in 147 children and to evaluate prognostic factors and the outcome after renal replacement therapy.

Methods: Between 2001 and 2011, 147 pediatric patients (66 females, 81 males), were admitted to our hospital for ARF. Out of those, 26 (17.6 %) were newborns (median age 4 days, range 1-22 days) and 121 patients (82.4%) were children older than 1 month (median 3.21 years, range 1 month–18 years). Causes of ARF, accompanying medical conditions, pediatric-modified RIFLE criteria, treatment, indications and mode of dialysis as well as patient outcome were retrospectively analyzed.

Results: While haemolytic uremic syndrome (n=42; 35%), sepsis (n=36; 30%) and dehydration (n=34; 28%) were the most common causes of ARF in children older than 1 month, renal vein thrombosis (n=11; 42%) as well as shock and asphyxia (n=10; 38%) were predominant reasons in newborns. Dialysis was performed in 12.5% (n=3, all CVVHD) of newborns and 55% (n=66, 37 CVVHD, 29 CVVHF) of children older than 1 month. Overall mortality was 23% (n=34) and was predominantly observed in the group of septic children following bone marrow transplantation (BMT; n=30, 88%). All BMT patients underwent dialysis treatment. Out of 66 dialysed patients restitution could not be achieved in 15 cases (22.7%) and chronic dialysis treatment became necessary.

Conclusions: Our overall results suggest a favourable outcome of ARF in children regardless the necessity of dialysis. In contrast, ARF in children following BMT and sepsis is associated with a 100% mortality rate. Improved understanding of the pathophysiology, early biomarkers of AKI, and better classification are required to optimize successful therapeutic efforts.

TH-PO103

Hyperglycemia and Acute Kidney Injury in Critically Ill Children Roberto Gordillo,[1] Robert Woroniecki.[2] *[1]Pediatric Nephrology, University of Illinois Medical College at Peoria, Peoria, IL; [2]Pediatric Nephrology, Columbia University College of Physicians and Surgeons, New York, NY.*

Background: Hyperglycemia has been associated with increased mortality and morbidity in critically ill adults and children. However, it is still not clear if hyperglycemia is associated with acute kidney injury (AKI) in critically ill children.

Methods: We conducted a retrospective review of charts of children admitted to the pediatric intensive care unit (PICU) of the University of South Alabama Children's and Women's Hospital (n= 37) followed by ongoing prospective subject enrollment (n=6)at the Children's Hospital of Illinois. Critically ill subjects were defined as subjects on mechanical ventilation within 36 hours of admission.

We excluded infants and children with known kidney disease. Pediatric RIFLE criteria and the revised Schwartz formula were used to determine degree of AKI. Peak glycemia was correlated with the degree of AKI and with the length (days) of PICU stay.

Results: Out of 43 subjects 19 had AKI.

	No-AKI (n=24)	AKI (n=19)	p
Age (years)	5.98 ± 1.18	6.2 ± 1.07	0.3
Female (%)	45	42	0.99
Caucasian (%)	38	42	0.52
Peak glucose mg/dl	194.54 ± 13.12	240.52± 18.15	0.03
Length of hospital stay (days	24.29± 3.84	29.42± 4.74	0.4
Length of PICU stay (days	14.79± 1.94	19.1± 3.81	0.57

± standard error of the mean

We found a statistical difference in peak glycemia between the no-AKI group and the AKI group and a significant positive correlation between length of hospital ($p<0.05$) and intensive care unit stay ($p<0.05$) and peak glycemia. No difference in serum glycemia was found between the Risk and the Injury/Failure groups ($p=0.72$). 1 subject died in the in the AKI group, none died in the no-AKI group.

Conclusions: Serum glucose was significantly higher in the AKI group. A positive correlation between length of hospital and intensive care unit and serum glucose was found. The intensity of AKI did not correlate with serum glucose.

TH-PO104

Predictors of Dialysis and Death in Hospitalized Patients with Severe Acute Kidney Injury Francis P. Wilson, Wei (Peter) Yang, Harold I. Feldman. *Medicine, Perelman School of Medicine at University of Pennsylvania, Philadelphia, PA.*

Background: Acute kidney injury (AKI) carries a substantial risk of mortality, even after adjustment for comorbidities. Effective risk stratification may lead to more effective therapeutic interventions for high risk subgroups.

Methods: We identified adults who suffered severe in-hospital AKI from 1/1/2004 – 8/31/2010 at three hospitals in the University of Pennsylvania Health System. Patients were included if baseline creatinine was ≤1.4mg/dl for men or ≤1.2 mg/dl for women, and serum creatinine doubled during the hospital admission. Cox proportional hazards models predicting death, dialysis, or both were fit using data from patients admitted to the Hospital of the University of Pennsylvania (n=4,263), and validated at the two other UPHS facilities (n=758, n=1098). Models were evaluated with C-statistics.

Results: 6119 patients were included; 602 (9.8%) received dialysis therapy. 14-day mortality was 44% in the RRT group and 19% in the non-RRT group ($p<0.001$). In adjusted analyses, strong predictors of the combined endpoint included ICU location (vs. floor), medical service, liver disease, higher creatinine, greater rate of change in creatinine, and greater number of pressor medications. Higher absolute creatinine concentration was associated with greater use of dialysis, but lower overall mortality in adjusted analyses. Harrell's C-index for the model predicting the combined endpoint was 0.85 (0.84-0.86) in the derivation cohort, and 0.83 (0.80 – 0.86) and 0.84 (0.82 – 0.86) in the validation cohorts. Early predictors (measured on day 1 of AKI) of the combined endpoint included medical service, lower admission eGFR, lower bicarbonate, ICU location, and liver disease. C-index for the prediction of death or dialysis using only day 1 metrics was 0.78 (0.77 – 0.79) in the derivation cohort and 0.77 (0.72 – 0.81) and 0.75 (0.72 – 0.78) in the validation cohorts.

Conclusions: A small group of easily measured clinical factors has good ability to predict mortality and dialysis in severe AKI. The predictive power increases as AKI progresses, but early prediction of death or dialysis is feasible.

Funding: NIDDK Support

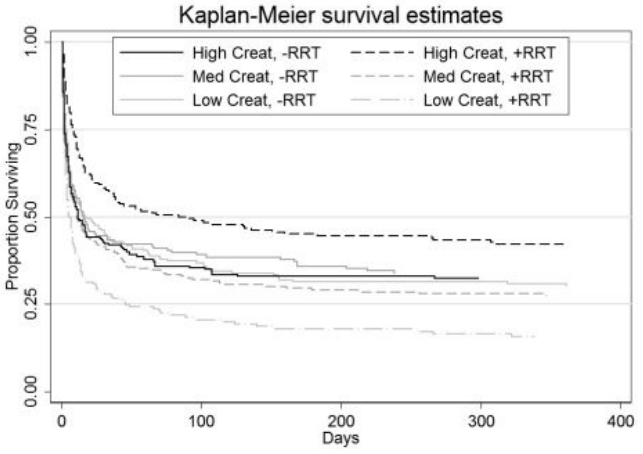
TH-PO105

Dialysis at a Higher Creatinine Is Protective in Acute Kidney Injury: A Propensity-Matched Cohort Study Francis P. Wilson, Wei (Peter) Yang, Harold I. Feldman. *Medicine, Perelman School of Medicine at University of Pennsylvania, Philadelphia, PA.*

Background: Currently, no guidelines regarding the provision of dialysis based upon the severity of acute kidney injury exist. We designed a propensity-matched cohort study to assess the benefit of dialytic therapy for the treatment of AKI.

Methods: We identified adults who suffered severe in-hospital AKI from 1/1/2004 – 8/31/2010 at three hospitals in the University of Pennsylvania Health System. Patients were included if baseline creatinine was ≤1.4mg/dl for men or ≤1.2 mg/dl for women, and serum creatinine doubled during the hospital admission. Logistic regression relating a variety of demographic, clinical, and laboratory variables to the initiation of dialysis was used to generate a daily propensity score to receive dialytic therapy for each of the 14 days following the onset of AKI (defined by AKIN 1 criteria). AKI patients who received dialysis were then matched to non-dialyzed patients based on the propensity score for dialysis and days since AKI onset. The primary analysis was implemented to define laboratory parameters that would identify patients in whom dialysis was most beneficial.

Results: 6119 patient hospitalizations met entry criteria, representing 143,891 patient-days of follow-up. 602 patients received dialytic therapy. Compared to patients who were not dialyzed, those receiving dialysis were younger, more often male, more often on a surgical service and less often black, (all $p<0.001$). After propensity score matching, covariates were well-balanced between the groups, and the overall hazard ratio for death in dialyzed vs. non-dialyzed patients was not significantly different than 1.0. Serum creatinine concentration strongly modified the association between dialysis and survival, with a 16% greater benefit from dialysis on survival for each mg/dL increase in serum creatinine concentration ($p<0.001$), with net benefit occurring at a creatinine greater than 3.9 mg/dL.



Conclusions: Our results suggest that dialysis may be particularly beneficial for AKI patients with higher serum creatinine concentration. This may reflect benefit due to AKI severity, but could be due to a protective effect of increased muscle mass.

TTP in Australia: Initial Data from a New National Registry Shlomo J. Cohney,[1] Simon Wilkins,[1] James Sloane,[1] Louise E. Phillips,[1] Paul K. Cannell,[3] Sunelle Engelbrecht,[2] Danny Hsu,[4] Zoe Mcquilten,[1] Stephen Opat,[1] David J. Roxby,[5] Erica M. Wood.[1] *[1]Department of Epidemiology, Monash University, Victoria, Australia; [2]ARCBS, Victoria, Australia; [3]Hematology, Royal Perth Hospital, Western Australia, Australia; [4]Liverpool Hospital, NSW, Australia; [5]Flinders Medical Centre, South Australia, Australia.*

Background: Thrombotic Thrombocytopenic Purpura (TTP) and other TMA are rare, but cause significant morbidity & mortality with uncertainty around incidence, diagnosis and optimal management. Recent insights into pathophysiology, new diagnostic tests and therapies, have made the need for clinical data collection increasingly important to determine optimal therapy.

Methods: A registry was established to determine the incidence, clinical characteristics, & natural history of patients with TTP, & recently expanded to encompass atypical hemolytic syndrome (aHUS) & other thrombotic microangiopathies (TMA).

Results: Data have been received from 14 hospitals on 67 episodes in 60 patients (16-83y, 59% female). Presenting features included neurological (55%), gastrointestinal or genitourinary (51%), hemorrhagic (35%), fever (30%) & thrombotic (17%). Precipitants included infection (31%), autoimmune (21%), malignancy (16%), medication (15%), allograft (1%) or postpartum (1%). ADAMTS13 levels were requested in 70%; 40% had <10% levels, 43% had >10% & in 16% results were unknown. 70% of patients with <10% ADAMTS13 were in complete remission (CR) without impairment compared with only 38% of those >10%. Most patients initially received plasma exchange (PEx), at least daily. 42% had PEx tapered. 65% received additional therapy, including corticosteroids (73%) or rituximab (30%), to augment PEx (41%), because of suboptimal response (11%) or other (26%). 21% are receiving ongoing therapy, 41% patients are in CR without impairment, 8% in CR with persisting impairment and 16% died.

Conclusions: TTP continues to cause significant morbidity and mortality, with continued variation in management. Increased understanding of pathophysiology and new therapies makes collection and analysis of patient data critical to direct future treatment appropriately.

Pathognomonic Constellation of Ultrasound Findings in EHEC-Associated Hemolytic-Uremic Syndrome and Their Clinical Relevance Ansgar Reising,[1] Gunilla Einecke,[1] Marcus Hiss,[1] Jan T. Kielstein,[1] Carsten Hafer.[2] *[1]Nephrology, Medical School Hannover, Hannover, Germany; [2]Nephrology, Nephrologisches Zentrum Niedersachsen, Hann. Münden, Germany.*

Background: During the 2011 German epidemic of hemolytic-uremic syndrome caused by EHEC O104:H4 we performed abdominal ultrasound at time of hospital admission in 44 patients and repeatet it after recovery (6 ± 2 weeks later).

Methods: We screened the patients for pleural effusion, ascites, kidney size and morphology, renal resistance indices (RI) and size of the liver and spleen. For quantification of parenchymal density we performed a computer-based image analysis of the kidney parenchyma and the liver parenchyma grey intensity values in 16 patients. For each patient we obtained 10 measurements each from two separate ultrasound images. For standardization we calculated the ratio between average kidney and liver intensity values for each image.

Results: Upon initial presentation, we observed moderate hepatomegaly in 43% of patients, splenomegaly in 16 patients, ascites and pleural effusions in 87% of patients. There was no significant relationship between the presence of pleural effusion and the necessity for dialysis treatment (p = 0.246). The kidneys appeared swollen, with an average intrarenal RI of 0.79 ± 0.09. RI-values were higher in patients with dialysis-dependent renal failure (0.82 ± 0.07) than in patients who did not require dialysis (0.75 ± 0.10, p = 0,006). The kidney/liver intensity ratio was 1.49 ± 0.39 at the time of diagnosis but was significantly reduced after recovery (0.99 ± 0.31 (p < 0.001). The kidney/liver intensity ratio at time of diagnosis correlated with the number of dialysis treatments before recovery (r = 0.44). Patients who required dialysis treatment had higher values than those who did not (1.58 ± 0.41 vs 1.23 ± 0.20).

Conclusions: Patients with EHEC-HUS had a characteristic constellation of morphologic abnormalities on ultrasound examination. Surprisingly, the majority of patients had pleural effusions, ascites, and striking changes in kidney morphology. The parameters reflecting renal perfusion correlated with the necessity for renal replacement therapy and thus may have prognostic value in future patient evaluation.

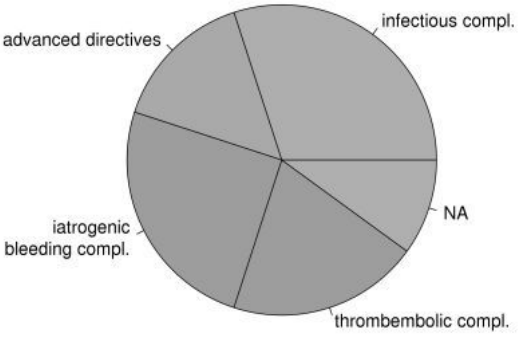
TH-PO108

Detailed Analysis of Causes of Death from HUS during the 2011 STEC-HUS Outbreak in Germany Gernot Beutel,[1] Jan T. Kielstein,[1] Tobias N. Meyer,[3] Reinhard Brunkhorst Richard Brunkhorst.[2] *[1]Department of Internal Medicine, Medical School Hannover, Hannover, Germany; [2]Krankenhaus Region Hannover, Department of Nephrology and Hypertension, Hannover, Germany; [3]Department of Nephrology, Asklepios Klinik Barmbeck, Hamburg, Germany.*

Background: The 2011 Shiga-toxin-producing E. coli (STEC) O104:H4 outbreak in Germany claimed 52 deaths among 2,987 STEC and 855 confirmed HUS cases. Survival data in adult patients with STEC- HUS are limited. We aimed to provide an in depth analysis of causes of death of the 621 HUS patients in the STEC-HUS registry, established by the Germany Society of Nephrology in response to the outbreak.

Methods: To identify main risk factors for death 100 parameters including demographic data, clinical symptoms, time course illness, microbiological information and laboratory parameters were collected. Firther, analysis by treatment options best supportive care (BSC), therapeutic plasma exchange (TPE), and TPE with eculizumab (TPE-Ecu) was performed.

Results: Age was the main risk factor for predicting death rate. While survivors had a median age of 45 years (IQR 31-60) non-survivors were 70 years old (IQR 61-76, p<0.001). Mortality rate was higher in patients receiving BSC (10.6%, p<0.05) than in TPE (3.7%) or TPE-Ecu (2.6%) patients. However deaths were frequently found not HUS related: Six (30%) patients suffered from infectious complications, five (25%) from iatrogenic bleedings, and four (20%) from thrombembolic complications. Three (15%) patients had advanced directives.



Those patients increased mortality rate for an intend-to-treat analysis from 4 to 6 patients in the BSC group.

Conclusions: Mortality rate in adult patients during the 2011 outbreak of O104:H4 in 2011 was lower than during previous outbreaks with O157:H7. More than half of the patients died due to limitation of care and iatrogenic bleeding complications. Age was the main risk factor for death.

TH-PO109

Epidemiology of Acute Kidney Injury from the O'Brien Center Registry Josee Bouchard,[1] Anjali Acharya,[2] Jorge Cerda,[3] Elizabeth R. Maccariello,[4] Rajasekara Chakravarthi Madarasu,[5] Ashita J. Tolwani,[6] Xinling Liang,[7] Ping Fu,[8] Zhi-Hong Liu,[9] Ravindra L. Mehta.[10] *[1]U de Montreal; [2]Jacobi Medical Center; [3]Albany Medical College, Albany, NY; [4]Rede d'Or; [5]CARE Hospitals; [6]UAB; [7]Guangdong General Hospital; [8]Sichuan Univ; [9]Nanjing Univ; [10]UCSD.*

Background: AKI is frequent and is associated with poor outcomes. However, there is lack of multicenter large databases on the epidemiology of mild to severe AKI throughout the world.

Methods: We conducted a prospective observational study in ICU patients in 14 centers to determine the incidence of AKI (AKIN criteria) and to characterize clinical factors and processes of care associated with patient outcomes. Patients were screened at ICU admission, and daily for 7 days.

Results: Over the last 4 years, 1275 of 6647 patients had AKI (19%) and 1007 (79%) were enrolled in our Registry. Data was available for 745 patients. Mean age was 61±18

years, 62% were male, 57% non-Caucasian, 52% had CKD. At ICU admission, 37% were on ventilator, 24% on pressors, 39% on diuretics, 30% were oliguric and 44% had sepsis. Mean APACHE 3 scores were 56±27. 24% required renal replacement therapy (RRT): CRRT, IHD, SLED and PD in 76%, 30%, 34% and 2% of patients, respectively. Hospital mortality was 22% (32% in RRT vs. 19% in non-RRT patients; p<0.001) and 15% were dialysis-dependent at hospital discharge. Among AKI patients, independent risk factors associated with hospital mortality included age (OR 1.02; 95%CI 1.01-1.04;p=0.006), use of pressors (OR 2.53; 95%CI 1.44-4.47;p=0.001), APACHE 3 score (OR 1.03; 95%CI 1.01-1.04;p<0.001) and cumulative fluid balance (L) (OR 1.05; 95%CI 1.02-1.09;p=0.003). After controlling for fluid balance, diuretic use had no protective effect on mortality. Mortality was higher as AKIN stage progressed (stage 1 18%; 2 31%; 3 32%;p<0.001) and in the absence of renal function recovery (30% vs. 14%;p<0.001).

Conclusions: This multinational registry provides a contemporary view of clinical factors, management and outcomes of AKI in the ICU with an incidence of 19% and mortality of 22%. These data highlight the changing characteristics of AKI and can inform the design and conduct of future trials.

TH-PO110

Acute Kidney Injury Is a Major Determinant of Mortality in Burn Patients

Meryem Tuncel-Kara,[1] Sharmila Dissanaike,[2] Melvin E. Laski.[1] *[1]Internal Medicine, Texas Tech University Health Sciences Center, Lubbock, TX; [2]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: The data available regarding renal injury in patients with burns are not extensive. Established predictors of burn survival are % burn, patient age, and concomittent respiratory injury. We investigated the impact of AKI on survival and AKI interactions with established risk factors.

Methods: Data were abstracted from EMRs of 1,142 burn patients admitted to University Medical Center, Lubbock between 1/1/2000 and 6/31/2007. Age, gender, race, % burn, initial, highest, lowest, and final serum creatinine, length of stay, survival/non-survival, co-morbidities includiing DM, CAD, COPD, cancer, CHF, CKD with stage, use of antibiotics, and use of pressor agents were recorded. Since admissions of less than two days represent small burn areas or non-survivable injuries, we limited analysis to patients who stayed over two days (n = 728). A model was established and odds ratios were generated by multivariant analysis.

Results: Data from 728 patients were analyzed; 77 died and 651 survived. Most (83.7%) had an initial creatinine consistent with an eGFR (by MDRD) over 60 ml/min/1.73M^2. Using the difference between low and high serum creatinine we found that 21.8% had modified RIFLE scores (precise urine output could not be determined) of R, I, or F, and 28.6% had AKIN scores of one or higher. In the final model, the odds ratio for mortality for AKIN score was 5.88 for AKIN 1, 12.49 for AKIN 2, and 10.43 for AKIN 3 as compared to AKIN 0 (all p= or < 0.001). For RIFLE scores, the OR was 3.0 (p = 0.25) for R, 7.51 (p<0.001) for I, and 8.13 for F (p=0.001). The OR was 1.29 per 10 years (0.03) for age, and 1.42 per 10% burn area (<0.001) when controlled for RIFLE score, and 1.26 (0.05) per 10 years, and 1.44 (0<0.001) per 10% burn when controlled for AKIN score.

Conclusions: AKI as defined by either RIFLE or AKIN classification had a major effect on burn mortality. Increased creatinine during the burn hospitalization was associated with greater mortality independent of age and burn extent.

TH-PO111

Risk of Mortality and Re-Hospitalization among Patients with Acute Myocardial Infarction and Acute Kidney Injury

Kenn B. Daratha,[1,3] Katherine R. Tuttle,[1] Jonathan Himmelfarb.[2] *[1]Providence Medical Research Center, Spokane, WA; [2]Kidney Research Institute, University of Washington, Seattle, WA; [3]Washington State University, Spokane, WA.*

Background: The primary objective of this study was to determine risks of death and re-hospitalization in patients with acute myocardial infarction (AMI) with and without acute kidney injury (AKI).

Methods: This longitudinal cohort study included persons hospitalized in Washington State 2004-2008 followed through 2009 (WA-CHARS). Patients with a primary diagnosis code of AMI (N=28,050) were classified into an AKI cohort (n=1,651) based on co-occurring diagnosis code for AKI during the index hospitalization and a reference cohort (n=26,399) for patients without AKI during index hospitalization. Fully-adjusted statistical models controlling for demographic and clinical and procedural characteristics were used to examine increased risks of in-hospital death and subsequent hospitalization by cohort.

Results: Compared to the reference cohort, patients in the AKI cohort were older and more likely to be female, Medicare insured, and hospitalized for longer lengths of stay. They were also more likely to have coronary artery bypass graft surgery, cardiogenic shock and acute respiratory failure. The AKI cohort was less likely to have a percutaneous coronary intervention or cardiac catheterization. Fully-adjusted risks for in-hospital death were significantly increased among patients in the AKI cohort (HR=2.70; 95%CI=2.29-3.18; p<0.001). Unadjusted increased risks were also observed for all-cause re-hospitalization, re-hospitalization for AKI and fatal re-hospitalization. Fully-adjusted risks for re-hospitalization for AKI were significantly increased among patients in the AKI cohort (HR=1.67; 95%CI=1.32-2.05; p<0.001). Patients were followed an average of 43 months in which 9.5% of the reference cohort and 37.4% of the AKI cohort died.

Conclusions: Patients admitted with AMI who experience AKI are at substantially higher risk for death and subsequent re-hospitalization for AKI. Measures to minimize AKI in AMI patients as well as closely monitoring of those who experience AKI should be a major focus to improve patient outcomes.

TH-PO112

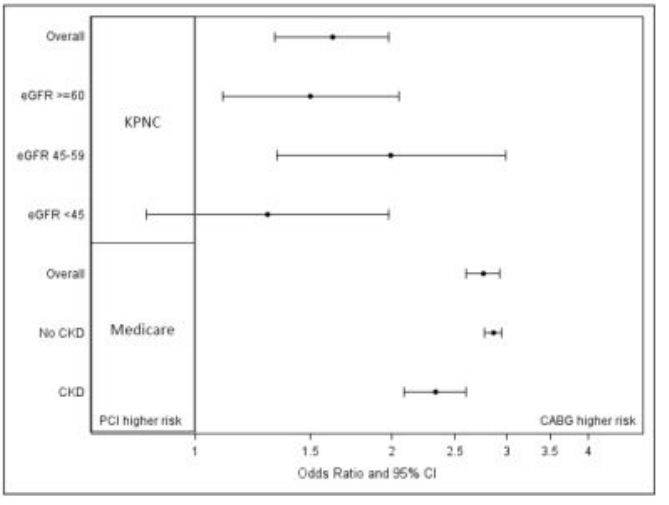
Risk of Acute Kidney Injury after Coronary Artery Bypass Surgery versus Percutaneous Coronary Intervention for Multivessel Coronary Disease

Tara I. Chang,[1] Thomas Leong,[2] Derek Boothroyd,[1] Mark Hlatky,[1] Alan S. Go.[2] *[1]Stanford; [2]Kaiser Permanente Northern California.*

Background: Relatively little is known about the risk of acute kidney injury (AKI) after coronary artery bypass grafting (CABG) compared with percutaneous coronary intervention (PCI).

Methods: We examined patients receiving incident CABG or PCI for multivessel coronary disease in two complementary cohorts. First, we used data from Kaiser Permanente Northern California (KPNC), which has detailed laboratory data, defining AKI as an increase in serum creatinine ≥0.3 mg/dL and/or ≥150% above baseline during the index hospitalization (1996-2008). Second, we used data from Medicare beneficiaries (1992-2008), defining AKI as an ICD-9 584.x primary or secondary discharge code during the index hospitalization and AKI requiring dialysis (AKI-D) as an 584.x code plus a dialysis procedure code. In both cohorts, patients on dialysis pre-revascularization were excluded. We used logistic regression to determine the odds ratio of AKI with CABG versus PCI.

Results: In 7295 patients in the KPNC cohort, 20% of CABG patients and 15% of PCI patients had AKI. The incidence of AKI increased as baseline kidney function decreased. In 105,216 Medicare patients, 9% of CABG patients and 4% of PCI patients had AKI. In both cohorts, CABG was associated with higher odds of AKI compared to PCI. Only 0.3% and 0.1% of Medicare patients undergoing CABG or PCI had AKI-D, respectively.



Conclusions: In two separate cohorts, we found that AKI is common after coronary revascularization, and that the incidence of AKI is higher in patients with lower kidney function. CABG was associated with higher odds of AKI compared with PCI across levels of kidney function. When weighing revascularization options, the risk of AKI should be considered and minimized where possible, particularly in patients with underlying kidney disease.

TH-PO113

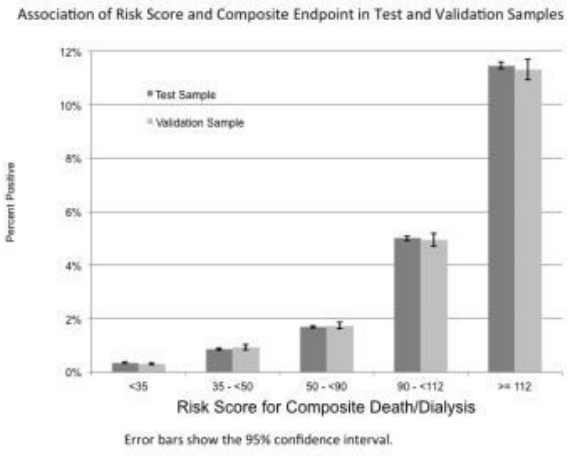
Incidence and Risk Factors for the Development of Acute Kidney Injury in Trauma Patients: Development of a Risk Prediction Score

Lakhmir S. Chawla, Richard Amdur, Babak Sarani, Michael Seneff. *Department of Anesthesiology and Critical Care Medicine, Geore Washington University, Washington, DC.*

Background: Trauma related injuries are the leading cause of death for persons < 44 years of age. Incidence of AKI in this population is not well characterized. We sought to determine the incidence and risk factors for AKI in subjects with a trauma related injury.

Methods: We analyzed the National Trauma Data Bank, a nationally representative dataset of over 400 US trauma centers. We assessed demographic and relevant clinical variables for hospital admissions from 2002-2008. Patients under the age of 18 years, those with burns, and baseline CKD were excluded. AKI was defined as the need for dialysis during the index hospitalization. The primary outcome variable was the composite of inpatient death/dialysis.

Results: 2,014,803 admissions were examined, of which 1,205,307 had complete data. The incidence of death was 2.5%, and the incidence of AKI was 0.32%. We conducted a multivariable analysis that included age, gender, race, ISS, trauma type, comorbidities, and insurance type. All predictors were independently associated with the composite outcome variable except for baseline DM and chronic lung disease. Using a 90% data sample, we developed a risk score to predict the composite of death/dialysis. We then validated the score in the remaining 10%. The test and validation model were significant (p<.0001 for both) and good prediction accuracy (ROC AUC = .85, and .83, respectively).



Conclusions: Trauma is an important cause of AKI. By comparison, there are @ 300K cardiac surgeries/year with a severe AKI incidence of @ 1-2%. There are over 2.5 million trauma admissions per year, and we found an incidence of AKI of 0.32%, which suggests that trauma contributes more annual cases of AKI than cardiac surgery. We also developed and validated a risk prediction score.

TH-PO114

Stroke Volume Variation (SVV) and Oxigenation Index(OI) Are Risk Factors for Acute Kidney Injury (AKI) in Abdominal Aortic Aneurysm (AAA) Surgery Paolo Lentini,[1] Luca Zanoli,[2] Valentina Pellanda,[1] Andrea Contestabile,[1] Anna Basso,[1] Massimo de Cal,[3] Claudio Ronco,[3] Graziella Berlingò,[1] Antonio Granata,[4] Roberto Dell'Aquila.[1] *[1]Nephrology, San Bassiano Hospital, Bassano del Grappa, Italy; [2]University of Catania, Catania, Italy; [3]Nephrology, S.Bortolo Hospital, Vicenza, Italy; [4]Nephrology, S. G. Di Dio Hospital, Agrigento, Italy.*

Background: AAA surgery patients are at high risk for AKI. Hemodynamic instability, hypovolemia, haemorrhage and reduced cardiac output may play a key role in AKI. SVV predicts volume responsiveness in mechanically ventilated patients; elevated levels of Oxigenation Index (OI) are linked to fluid overload and associate to poor outcome in critical ill patients but little is known about their role in AKI. We aimed to assess if patients with wide changes of SVV or OI at clamping and declamping time of the aorta are associated with high risk of AKI development.

Methods: We enrolled 21 consecutive hypertensive patients undergoing elective AAA surgery with supra-renal clamping. Patients were all on volume-control mechanical ventilation (8 ml/kg) and positive end expiratory pressure of 4 cmH_2O. Patients with arrhythmias, spontaneous ventilations, and those extubated before 12h post-operative were excluded. SVV was measured with the FlowTrack/Vigileo (Edwards Lifesciences®) device every 3 minutes during the procedure and for 24h after surgery. OI was calculated as =mean airway pressure/(PaO2/FiO2)x100. Patients received 70ml/kg/h of crystalloids; fluid boluses and transfusions were given if needed. Data were compared with ANOVA.

Results: 9 patients(43%) developed AKI, defined as RIFLE Risk category. SVV and OI were significantly higher at aortic clamping ($p<0.0001$) and declamping time ($p< 0.0001$ and $p< 0.01$ respectively).

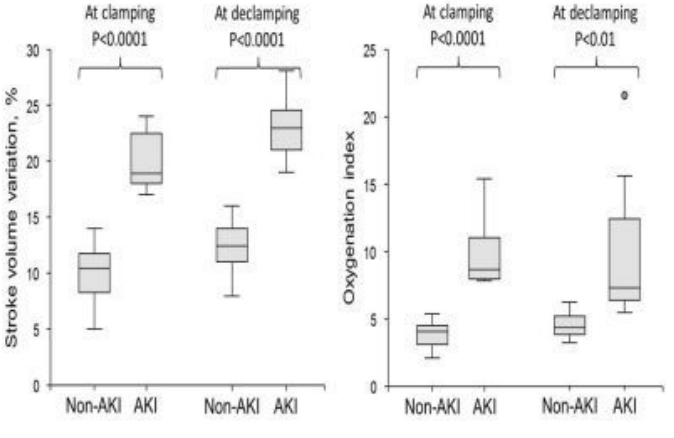


Fig.1 SVV and OI at Clamping and Declamping of the aorta

Conclusions: High SVV and OI during and after suprarenal AAA surgery are associated with high risk of AKI.

TH-PO115

Urinary Basigin/CD147 as a Biomarker of Acute Kidney Injury Hiroshi Kojima, Tomoki Kosugi, Waichi Sato, Hibiki Shinjo, Yuka Sato, Kayaho Maeda, Hiroshi Nagaya, Mayuko Maeda, Seiichi Matsuo, Shoichi Maruyama. *Department of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan.*

Background: Acute kidney injury (AKI) develops due to complex interactions between acute insults, including ischemia and infection, and subsequent activation of the immune system such as inflammation and coagulation. The mortality and morbidity associated with AKI remains high, despite advances in interventions. Basigin (Bsg)/CD147 is a transmembrane glycoprotein, and contributes to cell survival, invasion and metastasis. Recently, we documented that Bsg is involved in the pathogenesis of renal inflammation caused by ischemia and renal fibrosis. We therefore investigated whether urinary Bsg could serve as an early and sensitive biomarker of AKI.

Methods: 397 patients, who entered the surgical intensive care units (SICU) in Nagoya university hospital, were enrolled. Spot urine samples were collected three times at the baseline before surgery, immediately after SICU admission, and 12 hours after SICU admission. Urinary Bsg and neutrophil gelatinase-associated lipocalin (NGAL) values were measured by ELISA method and normalized to those of urinary creatinine. AKI was defined by the Acute Kidney Injury Network criteria.

Results: While no obvious differences in both groups were found in urinary Bsg values and serum creatinine before operation, mean Bsg level in patients with AKI was significantly higher than those with non-AKI immediately after SICU admission. Regardless of the involvement of carcinoma metastasis, these were not affected in the presence or absence of aging and malignant diseases. Interestingly, the time course of Bsg was similar to that of NGAL, one of reliable biomarkers for AKI after cardiac surgery, during the experimental periods. In addition, Bsg is mainly distributed in tubular epithelial cells of healthy kidneys and its expression was extremely lower in injured and atrophic tubules. Indeed, there was the strong relationship between urinary Bsg and serum creatinine in patients with AKI.

Conclusions: Urinary Bsg may be a prime candidate for developing a new procedure for the evaluation of AKI.

TH-PO116

Does Sitagliptin Modifies Risk and Outcome of Acute Kidney Injury in Diabetes Patients with Septic Shock? Kadapalakere Reddy, Lori M. Rose, Arash Rashidi. *Internal Medicine, Fairview Hospital A Cleveland Clinic Hospital, Cleveland, OH.*

Background: Sitagliptin, a DPP4 inhibitor, used for treatment of type 2 diabetes mellitus has been shown to be protective against renal injury in rats. It was suggested that the anti-inflamatory effect and increased levels of various antioxidants, as well as decreased necrosis and apoptosis might mediate this effect. We therefore hypothesized that sitagliptin could be protective against acute kidney injury (AKI) in humans.

Methods: We conducted a retrospective cohort study of diabetes patients admitted to our institution between January 2010 and September 2011 with the diagnosis of sepsis and/or septic shock. Of 257 patients studied, 29 were taking sitagliptin and 228 were not. Baseline variables including demographics, co-morbidities, severity of illness with respect to vasopressors and lowest blood pressure, medications at the time of admission, exposure to aminoglycosides and contrast agents and levels of serum creatinine, blood urea nitrogen and glomerular filtration rate were collected. We then determined the incidence and severity of AKI, need for renal replacement therapy (RRT), length of stay and time to return to a stable creatinine. Twenty three patients who had end stage renal disease or did not have a baseline serum creatinine level were excluded. Both univariate and multivariate analyses were conducted.

Results: There was no difference in regard to baseline characteristics between patients who were and were not on sitagliptin in univariate analysis. In the multivariate regression analysis no difference was found between the two groups in regard to the incidence or severity of AKI (Peak creatinine 3.0 vs 2.10 mg/dl, p=0.2), RRT (17/1 vs 80/7 p=0.99), LOS (12.1 vs 11.9 days, p=0.91), and days to return to a stable creatinine (14.6 vs 9.70 p=0.21).

Conclusions: In contrast to experimental models in rats, in our study on patients, pre-exposure to sitagliptin did not appear to be protective against acute kidney injury in patients with T2DM admitted to an intensive care setting with multiple complex medical issues.

TH-PO117

Urinary Levels of Prostanoid Metabolites Predict for Acute Kidney Injury in Adult Japanese Heterogenous ICU Patients Haruyo Ujike,[1] Yohei Maeshima,[1] Masaru Kinomura,[1] Daisuke Saito,[1] Hiroko Yamasaki,[1] Hiroyuki Watatani,[1] Norikazu Hinamoto,[1] Hitoshi Sugiyama,[1] Hiroshi Morimatsu,[2] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama University, Okayama, Japan; [2]Anesthesiology, Okayama University, Okayama, Japan.*

Background: Acute kidney injury (AKI) is associated with increased risk of morbidity and mortality in critically ill patients. Prostanoids regulate numerous biological functions including hemodynamics and tubular transport process. Here, we investigated the ability of urinary prostanoid metabolites to predict the onset of AKI in adult ICU patients.

Methods: We prospectively collected data of patients admitted to the ICU in the Okayama University Hospital (Nov. 2010-July 2011). Patients already in end-stage renal disease and receiving renal replacement therapy (RRT) were excluded. Urine was collected within 24 h of ICU admission (Day 1). Urinary levels of prostaglandin E_2 (PGE_2), PGI_2 metabolite (2,3-dinor-6-OXO-$PGF_{1\alpha}$) and thromboxane A_2 metabolite (11-dehydro-TXB_2), NAG and albumin were determined and were normalized to creatinine levels.

Results: Of the 93 patients, 24 developed AKI (AKIN criteria). The mean age (66, 60; non-AKI, AKI, respectively) and the mean baseline eGFR (72, 73) were equivalent. Surgical operation (93%, 75%) was the leading cause of ICU admission. In the AKI group, 2 patients (8.3%) required RRT and a patient died. Overall, the ratio of serum Cr at Day1 after admission to ICU to baseline positively correlated with urinary 2,3-dinor-6-OXO-$PGF_{1\alpha}$/Cr ratio (R=0.57, P<0.0001) or 11-dehydro-TXB_2/Cr ratio (R=0.47, P<0.0001). The levels of urinary prostanoid metabolites except for PGE_2, also positively correlated with urinary NAG/Cr level. In 16 cases developing de novo AKI, the levels of urinary 2,3-dinor-6-OXO-$PGF_{1\alpha}$/Cr and 11-dehydro-TXB_2/Cr were significantly elevated compared with non-AKI group (18477 vs. 8277 ng/gCr, P=0.002; 18637 vs. 7926 ng/gCr, P<0.002), but urinary levels of PGE_2/Cr were not.Urinary 2,3-dinor-6-OXO-$PGF_{1\alpha}$/Cr showed the most excellent diagnostic and predictive performance among them in the ROC analysis (ROC-AUC 0.75).

Conclusions: Urinary 2,3-dinor-6-OXO-$PGF_{1\alpha}$/Cr and 11-dehydro-TXB_2/Cr associate with subsequent onset of AKI.

TH-PO118

Serial Measurement of Urinary L-FABP and NAG Can Predict Progression of Acute Kidney Injury in ICU Population Maki Tsukamoto,[1] Kent Doi,[1,2] Daisuke Katagiri,[1] Yoshifumi Hamasaki,[1] Masaomi Nangaku,[1] Takehiro Matsubara,[2] Naoki Yahagi,[2] Eisei Noiri.[1] *[1]Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan; [2]Emergency and Critical Care Medicine, University of Tokyo, Tokyo, Japan.*

Background: Reportedly, combination of urinary L-type fatty acid-binding protein (L-FABP) and N-acethyl-β-D-glucosaminidase (NAG) can detect acute kidney injury (AKI) before serum creatinine elevation in adult post-cardiac surgery AKI [Ann Thorac Surg. 2012;93:577-83]. However, critically ill patients treated in ICU frequently suffer from multiple and transient/persistent insults. This study was aimed to evaluate whether serial measurement of urinary L-FABP and NAG enables us to predict AKI progression in these patients.

Methods: We prospectively studied 274 adult critically ill patients who were treated in mixed ICU of the University of Tokyo Hospital. Urinary L-FABP and NAG were measured at ICU admission (day 1) and 24 hr after (day 2). Patients who showed anuria or died within 24 hr were excluded. Diagnosis and severity of AKI was determined by the RIFLE criteria with one exception; the patients who needed RRT were categorized as Failure, as suggested by the AKIN criteria (i.e. stage 3).

Results: Of 159 AKI patients, 64 (40%) patients showed worsening kidney function. Urinary L-FABP and NAG of day 1, day 2, their average, maximum and minimum values were all significantly associated with worsening kidney function. Neither absolute change nor increase/reduction rate contributed to prediction of worsening kidney function. Among these factors, the highest area under the curve of receiver operating curve (AUC-ROC) was observed with minimum L-FABP [0.76, 95%CI (0.69–0.83)] and NAG at day 2 [0.71, 95%CI (0.63–0.78)]. Combination of minimum values of L-FABP and NAG, and serum creatinine at day 1 significantly increased AUC-ROC [0.85, 95%CI (0.79–0.90)] compared with any single measurement of these three markers.

Conclusions: In a heterogeneous cohort of adult mixed ICU, serial measurement of urinary L-FABP and NAG could contribute to prediction of worsening AKI by combining their minimal values during 24 hours after ICU admission.

Predictor of Snakebite Mediated Acute Kidney Injury: A Prospective Study Pinaki Mukhopadhyay, Raghwendra Mishra, Debarati Mukherjee, Monoj Kar, Gautam Mukherjee, Piyali Banerjee. *[1]Dept of Neph, NRSMC, Kol, WB, India; [2]Dept of Biochem, NRSMC, Kol, WB, India; [3]Dept of Gynaec, NBMC, Siliguri, WB, India; [4]Dept of Gynaec, BRH, Howrah, WB, India.*

Background: To determine the prognostic predictors of snakebite induced AKI (SAKI) required renal replacement therapy. To measure the oxidative and carbonyl stress level in SAKI patient and correlate with adverse outcome.

Methods: All SAKI patients admitted from Apr-10 to Dec-11 and received HD were included. Demographical, clinical & biochemical data were analyzed and they are followed from hospitalization to discharge or death. Oxidative & carbonyl stress markers [Advanced oxidation protein product (AOPP), Advanced Glycation End product (AGE), Pentosidine, Dityrosine, Thioberbituric acid reactive substance (TBARS) and Methyl glyoxal (MG)] were measured consecutively in 60 SAKI patient according to standard protocol. All data were analyzed with appropriate statistical methods.

Results: Among 205 SAKI patients received HD. Male: Female was 2.5:1. The mean age was 37.2 years (4-75 years). Commonest site of bite was lower limb (89.5%).About 76.2% received primary treatment. Oliguria & bleeding manifestation were the common presentation. Hypotension was found in 35.5% cases, cellulites & inflammation was found in about 66% patients. About 27.8 % had disseminated intravascular coagulation (DIC). Antisnake venom (ASV) was used 22.5±1.85 vial. Median HD was required 3 session .Mean hospital stay was 12 days (2-34 days). Bite to HD initiation time was 3.3 days. Out of 28.5%) patients died 34.48% were <18 years. About 78.2% had cellulites, 52.5% had shock/hypotension at initial presentation (p<0.05), bleeding manifestation was found in 80.4% & 46.8% had DIC (p<0.05).DIC & shock/hypotension at initial presentation was came out as independent predictor of death at multivariate level. Among the biochemical markers measured for oxidative and carbonyl stress (n=60) AOPP and MG came out as independent predictor (p<0.05) of adverse outcome.

Conclusions: Shock/hypotension, DIC, advanced oxidation protein product (AOPP) and methyl glyoxal (MG) was surrogate prognostic marker in SAKI patients requiring dialysis leading to death.

TH-PO120

NGAL, KIM-1 Do Not Predict Recovery from Rise in Serum Creatinine in Heart Failure Exacerbation Meyeon Park, Eric Vittinghoff, Kathleen D. Liu, Michael Shlipak, Chi-yuan Hsu. *University of California, San Francisco, CA.*

Background: Patients with acute heart failure (HF) exacerbation commonly have deterioration in renal function (i.e. serum creatinine rise), often ascribed to prerenal azotemia. We evaluated whether subtle ischemic tubular injury is detectable using sensitive biomarkers neutrophil gelatinase-associated lipocalin (NGAL) and kidney injury molecule-1 (KIM-1), and whether elevations of these markers are associated with recovery of kidney function.

Methods: We recruited consecutive patients admitted for HF exacerbation from March 2-May 31, 2011 at one medical center, regardless of renal function. We collected daily urine samples (up to 5 days) and measured urine NGAL (AntibodyShop) and KIM-1 (R&D Systems). Acute kidney injury (AKI) was defined by AKIN criteria. Outcome was recovery from AKI, defined as return to within 10% of the original creatinine (cr). We also assessed recovery in patients whose cr rise had occurred prior to admission, i.e. those admitted above baseline cr (ABL). We defined baseline cr as the most recent to the index hospitalization (excluding values within 7 days or older than 1 year).

Results: 53 eligible patients were recruited. 20 experienced AKI (9 recovered). Mean age was 65; 30 were men; mean baseline cr was 1.2 mg/dl. Mean NGAL and KIM-1 were similar in those with and without AKI (Table). 9 patients presented ABL (6 recovered) and 24 had no change in renal function; mean biomarkers were not significantly different between ABL and at baseline groups. In pooled logistic regression models, NGAL and KIM-1 were not associated with recovery from serum cr rise. In contrast to NGAL, KIM-1 levels rose over the first 5 days of hospitalization in individuals with no AKI and stayed static in those who experienced AKI.

Mean (SD) Biomarkers

	AKI (n=20)	No AKI (n=33)	p
NGAL/cr (ng/mg)	70.0 (27.4)	65.9 (11.7)	0.56
KIM-1/cr (ng/mg)	1.41 (0.21)	1.61 (0.13)	0.26

Conclusions: In this pilot study, levels of urine NGAL and KIM-1 were not associated with recovery from serum cr rise in patients with HF exacerbation. Patterns of NGAL and KIM-1 may differ in this clinical setting.

TH-PO121

Acute Renal Tubular Injury Biomarkers in Non-Cardiac Critically Ill Children Ana Palijan,[1] Prasad Devarajan,[2] Qing Ma,[2] Michael R. Bennett,[2] Michael Zappitelli.[1] *[1]Nephrology, McGill University Health Centre, Montreal, QC, Canada; [2]Nephrology and Hypertension, Cincinnati Children's Hospital Medical Centre, Cincinnati, OH.*

Background: Acute kidney injury (AKI) in non-cardiac pediatric intensive care unit (ICU) patients (pts) is common, associated with poor outcome and earlier AKI diagnosis is needed. Little AKI biomarker research exists in this population. We evaluated alpha-glutathione S-transferase (a-GST; proximal), pi-glutathione S-transferase (pi-GST; distal) and liver fatty-acid-binding protein (LFABP- proximal) for AKI diagnosis in an attempt to validate findings in other study populations.

Methods: We prospectively followed 74 ICU children admitted ≥2days and collected SCr, clinical data and urine daily. AKI was defined as ≥50% rise from pre-ICU baseline; severe AKI was doubling of SCr. In all pts, we measured urine a-GST and pi-GST (EIA; Argutus Medical Ltd); in a subset we measured LFABP (ELISA). We compared AKI *vs.* non-AKI peak ICU biomarker levels (Mann-Whitney test). We calculated area under the curve [AUC] to evaluate the biomarkers for discriminating presence of AKI and severe AKI.

Results: Mean (±SD) age and ICU length of stay were 5.2(±5.9) yrs and 9.9(±9.6) days, respectively; 66% male, 78% ventilated, 46% vasopressors, 74% ≥ mild AKI, 36% ≥ severe AKI.**1st 3 ICU days urine:** early ICU pi-GST (not a-GST) was higher in AKI *vs.* non-AKI pts (p<0.05); AUC for AKI diagnosis was 0.69 (95%CI 0.51-0.86). **2 pre-AKI days urine**: pre-AKI a-GST (not pi-GST) was higher in AKI *vs.* non-AKI pts (p=0.01, AKI diagnostic AUC=0.72 95%CI=0.51-0.93). **Day of AKI event urine:** pi-GST was higher in pts with *vs.* without AKI (p=0.05) and those with severe *vs.* non-severe AKI (p<0.003) (diagnostic AUC=0.69, 95%CI 0.51-0.87; AUC=0.85, 95%CI of 0.70-1.00, respectively). LFABP, but not a-GST or pi-GST, was higher in AKI *vs.* non-AKI pts (p<0.04) on the day after AKI diagnosis.

Conclusions: We confirmed an association between a-GST, pi-GST and LFABP and AKI in non-cardiac ICU children for the first time to our knowledge. a-GST appeared to rise before AKI while pi-GST and LFABP were later AKI biomarkers. Future larger studies will further determine their clinical and research utilities.

TH-PO122

Prognosis after Acute Kidney Injury in the Pediatric Intensive Care Unit Marina Ferreira,[1] Isac De Castro,[2] Emmanuel A. Burdmann,[2] Emerson Quintino Lima.[1] *[1]Nephrology Division, FAMERP, Sao Jose Rio Preto, Sao Paulo, Brazil; [2]Nephrology Division, University of Sao Paulo, Sao Paulo, Brazil.*

Background: Acute kidney injury (AKI) is associated with increased morbidity in critically ill children. We identified hospital and long term mortality risk factors after admission to pediatric intensive care unit (PICU).

Methods: Data from children admitted to PICU between 2004 to 2008 was retrospectively collected. AKI was identified according to pediatric RIFLE. Long term

survival (up to 7 years) after PICU admission was evaluated by phone call or hospital data bank verification. Bivariate and logistic regression analyses were used to identify hospital and long term mortality risk factors.

Results: 434 children (49 ± 47 months, 246 (57%) boys) were admitted to PICU. AKI occurred in 279 (64%) children (Risk 106 [24%], Injury 113 [26%], Failure 60 [14%]) during their PICU stay and pRIFLE was associated with hospital mortality (no AKI 4%, R 33%, I 26%, F 38%; p=0,001). Long term survival was not affected by AKI occurrence (no AKI 10% vs AKI 16%; p=0,14). After logistic regression, the identified hospital mortality risk factors were: AKI (OR 3.3; 1.09-13.43), mechanical ventilation (OR 19.1; 2.14-17.05), dopamine (OR 4.85; 1.59-14.77), volume overload (OR 2.3; 1.2-3.01) and weight (OR 1.2; 1.02-2.1). Long term death risk factors were: mechanical ventilation (OR 4.61; 2.36-9.02), diuresis (OR 1.2; 1.2-4.07), PRISM score (OR 1.11; 1.04-1.18) and systolic blood pressure (OR 1.09, 1.04-1. 14).

Conclusions: AKI was highly prevalent and associated with increased hospital mortality after PICU admission. Unlike what occurs in adults, AKI in pediatric patients was not related to long term survival. Studies are needed to evaluate the consequences of AKI in adulthood.

Biomarkers of Acute Kidney Injury in Urine Exosomes from Care Units Patients Carlos E. Irarrazabal,[1] Guillermo Eugenio Villamizar,[2] Sergio Alvarez,[2] Antonio Vukusich,[2] Margarita Hurtado,[2] Sandra Villanueva,[1] Guilio Innocenti,[2] David Carvajal,[2] Rogelio Altuzarra,[1] Andres Boltansky.[2] *[1]Universidad de Los Andes, Santiago, Chile; [2]Clinica Davila, Santiago, Chile.*

Background: The acute kidney injury (AKI) is an important marker of morbidity and mortality in Intensive Care Unit (ICU). Despite of experience in the use of hemodialysis and other renal replacement therapies in the management of AKI, the mortality remains high and many problems remain unresolved. Recently, it was showed that AKI incidence in patients admitted in the Critical Units (tertiary health center in Santiago-Chile) was 27.69%. The severe AKI (AKIN criteria) increased the hospital length of stay and the mortality. There are now several molecules with potential for diagnosis of AKI in its early stages. However, more clinical evidence is required to validate the sensitivity and specificity in both plasma and urine. Exosomes are vesicles released into urine from the renal epithelium and have been proposed as a source of exploration of biomarkers of renal injury.

Methods: Urine were collected at ICU admission. Protease inhibitor was added to the urine and the cell fraction was discarded by centrifugation (4000g x 10 minutes, 4 ° C). The supernatant was ultracentrifuged (38000g x 1hr, 4 ° C), resulting in the supernatant (S) and pellet rich en exosome (E). The NGAL, KIM-1 and HIF-1α was determined in 100 micrograms of total protein by Western blot and the results were expressed as E/S ratio.

Results: We prospectively analyzed 52 patients from ICU. The average age was 57 years (21-95) and 58% were male. The average cretininemia on the day of ICU admissions was 1.47 ± 1.5 mg/dl, and 37% were classified as AKI using AKIN criteria. The E/S NGAL expression in AKI (4,41±2,239) was higher than without AKI (0,80 ± 0,46) patients. The E/S KIM-1 expression in AKI (6,18 ± 3,814) was also higher than without AKI (0,80 ± 0,559) patients. The E/S HIF-1α expression in AKI (0,888 ± 0,520) was equally to no AKI (0.988±0,764) patients.

Conclusions: Our data establish that NGAL and KIM-1 in the exosomal fraction are better associated with AKI, but not HIF-1α.

Funding: Other NIH Support - FONDECYT 1100885-Chile, Government Support - Non-U.S.

TH-PO124

Biomarker Performance at the Time of ICU Admission Jay L. Koyner,[1] Dana Hoffmann,[2] Eoin J. Cotter,[3] Patrick T. Murray,[3] Vishal S. Vaidya.[2] *[1]University of Chicago; [2]Brigham and Women's Hospital; [3]University College Dublin.*

Background: Internationally accepted diagnostic criteria for acute kidney injury (AKI) are well validated and define AKI via changes in either serum creatinine (SCr) or urine output (UOP). The majority of AKI biomarker studies report AKI based on changes in SCr and little has been published about biomarker's ability to predict UOP based AKI.

Methods: We prospectively collected urine samples on ICU admission from patients in a Medical ICU (Chicago) and compared the ability of biomarkers to detect AKI Network (AKIN) Stage 1 via SCr and UOP. Additionally we assessed the ability to detect severe AKI defined as the future need for renal replacement therapy (RRT).

Results: We enrolled 59 patients, 40 (68%) of whom developed AKIN Stage 1 or higher AKI during the first 5 days of their ICU stay. 38 subjects developed SCr based AKI while 21 developed AKI based on UOP. 8 subjects (13.6%) required RRT. Table 1 demonstrates the area under the curve (AUC) and p values for SCr and blood urea nitrogen (BUN) and several urinary biomarkers to predict AKIN Stage 1 (SCr and UOP) and RRT at the time of ICU admission.

Biomarker Performance at ICU Admission

	AKIN-Stage 1 SCr -(n=38) AUC (p value)	AKIN Stage 1 UOP (n=21) - AUC (p value)	RRT AUC (n=8) (p value)
Serum Creatinine mg/dl	0.79 (0.0001)*	0.69 (0.02) *	0.67 (0.13)
BUN mg/dl	0.82 (0.0001)*	0.63 (0.11)	0.57 (0.52)
Urine Albumin mg/L	0.68 (0.03) *	0.66 (0.04) *	0.63 (0.26)
Urine NGAL ng/ml	0.81 (0.0002) *	0.75 (0.003) *	0.77 (0.02) *
Urine Cystatin C ng/ml	0.67 (0.04) *	0.61 (0.20)	0.77 (0.02)*
Clusterin ng/ml	0.63 (0.11)	0.74 (0.003)*	0.68 (0.11)
KIM-1 pg/ml	0.60 (0.23)	0.80 (0.0003)*	0.59 (0.42)
Fibrinogen ng/ml	0.56 (0.49)	0.46 (0.59)	0.48 (0.89)
α-Glutathione-S-transferase μg/L	0.42 (0.33)	0.53 (0.67)	0.44 (0.62)
π Glutathione-S-transferase μg/L	0.60 (0.22)	0.68 (0.04) *	0.79 (0.01) *

* p value < 0.05

Conclusions: Biomarkers can detect AKIN Stage 1 (SCr and UOP) and the need for RRT at the time of ICU admission. Each biomarker has its own specific prognostic fingerprint and the ability to detect SCr based AKI does not necessarily equate to UOP-based AKI. Future studies are needed to better understand which biomarkers can detect AKIN stage 1 and the need for RRT early on in the setting of critical illness.

Urine Cystatin C and Acute Kidney Injury after Cardiac Surgery Jay L. Koyner, Amit X. Garg, Michael Shlipak, Uptal D. Patel, Kyaw Sint, Prasad Devarajan, Charles L. Edelstein, Michael Zappitelli, Chirag R. Parikh. *TRIBE AKI Consortium.*

Background: Acute Kidney Injury (AKI) is common following cardiac surgery and is associated with adverse patient outcomes. Urine Cystatin C (UCysC), is a biomarker of proximal tubule function and may rise earlier in settings of injury than serum creatinine.

Methods: We conducted the prospective multicenter Translational Research Investigating Biomarker Endpoints in AKI (TRIBE AKI) study, a cohort involving 1219 adults and 311 children. We evaluated the performance of UCysC in the peri-operative period and defined AKI as a doubling of serum creatinine from baseline or need for acute renal replacement therapy (RRT). The cohort was divided into quintiles using the first post-op value of UCysC (0-6 hour timepoint).

Results: AKI occurred in 73 (4.9%) adults and 53 (17%) of children after surgery; with 18 adults (1.5%) receiving RRT. There was no statistical difference between the pre-operative UCysC values for those with and without AKI in the adult (p=0.76) or pediatric (p=0.92) cohorts. UCysC measured in at the 0-6 hour timepoint did not correlate with the future development of AKI in either the adult or pediatric cohort. The area under the curve (AUC) for the receiver operator characteristics (ROC) curve for the first post-operative UCysC to predict AKI was (AUC(SE)) 0.60 (0.04) in adults and 0.62 (0.04) in children (p=NS for both). Further, when defining AKI as AKIN Stage 1 (0.3 mg/dl or 50% increase), UCysC did not improve risk stratification in adults or children. However in adults, the highest quintile of the first post-operative UCysC was associated with a 7-fold increased odds for the receipt of RRT compared to the lowest two quintiles.

Risk of RRT Startified by UCysC (mg/L) in Adults in the Early Post-op Period

Quintile (cutpoints)	N(%)	Unadjusted OR (95%CI)
Q1&Q2 (<0.12) n=485	2(0.8)	1 (referent)
Q3 (0.13,0.20) n=242	4(1.6)	4.0 (0.7-22)
Q4 (0.21, 0.28) n=231	3 (1.3)	3.2 (0.5, 19)
Q5 (>0.28) n=245	7 (2.9)	7.1 (1.4, 34)

Conclusions: UCysC values do not associate with the development of AKI following cardiac surgery. However, there may potentially be a role in predicting the most severe forms of AKI treated with RRT.

Urinary NGAL, KIM-1, Hsp-72 and Interleukin 18: Prognostic Biomarkers of Acute Graft Dysfunction in Kidney Transplant Recipients Juan Carlos Ramirez-Sandoval,[1] Jonatan Barrera-Chimal,[2] Alejandro Rojas Montaño,[1] Perla E. Simancas,[1] Ricardo Correa-Rotter,[1] Norma Bobadilla,[2] Luis E. Morales-Buenrostro.[1] *[1]Nephrology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico DF, Mexico; [2]Instituto de Investigaciones Biomedicas, Universidad Nacional Autonoma de Mexico, Mexico DF, Mexico.*

Background: Neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule (KIM-1), interleukin 18 (IL-18) and heat shock protein 72 (Hsp72) are novel biomarkers of renal tubular damage which have been used as prognostic markers in acute kidney injury (AKI). However these biomarkers have not been tested in kidney transplant recipients (KTR) with AKI. The aim of this study was to establish the prognostic value of NGAL, KIM-1, IL-18 and Hsp-72 in KTR.

Methods: We included 71 KTR from out-patient and hospital scenarios presenting AKI (according to AKIN criteria) with baseline glomerular rate function (GRF) >30 mL/min/1.73m2. NGAL, KIM-1, IL-18 and HSP-72 were measured at AKI diagnosis with ELISA, in a single urinary specimen. Patients were followed for one year. Three groups were identified related to kidney function evolution: return to baseline kidney function and GRF >30 mL/min/1.73m2 (group A n=47, 66%), persistent GRF between 15 and 30 mL/min/1.73m2 (Group B n=16, 22%) and GRF <15 mL/min/1.73m2 or graft loss during follow-up related to AKI episode (Group C n=5, 7%). Three patients did not complete the follow up. All measurements were blinded to the investigators.

Results: Median NGAL urinary biomarkers levels were 92, 89 and 244 mcg/dL for groups A, B and C respectively (P: 0.001). KIM-1, levels were 99.2, 108.4 and 244 ng/dL for groups A, B and C respectively (P: 0.004). There were no statistical differences between groups for IL-18 and Hsp-72. A NGAL level of 217 mcg/dL had a sensitivity of 100% and a specificity of 86% (ROC AUC: 0.89, 95% IC: 0.81-0.97, P: 0.004) for graft failure during one year follow up.

Conclusions: NGAL and KIM-1 may be useful for prognostic markers in KTR with AKI.

Novel Biomarkers for the Prediction of Acute Renal Replacement Therapy: A Systematic Review

Manish Kaushik,[1] Hilde R. De Geus,[2] Claudio Ronco,[1] Dinna N. Cruz.[1] *[1]IRRIV, St Bortolo Hospital, Italy; [2]Erasmus Univ Med Center, Netherlands.*

Background: Novel biomarkers (BM) have been reported to aid in early diagnosis of acute kidney injury (AKI) and its severity. BM may have potential to identify AKI patients who will need renal replacement therapy (RRT). Our aim was to evaluate the performance of BM for prediction of RRT.

Methods: We performed a systematic review to identify studies which reported on novel BM and RRT as an outcome, whether separate or part of a composite. Studies which reported area under the receiver operating curve and/or sensitivity/specificity for any outcome which included RRT were eligible. We excluded studies in transplant patients. Two authors independently extracted data on study characteristics and measures of diagnostic accuracy.

Results: 34 studies were identified (31 prospective, 2 retrospective, 1 RCT), representing total 10431 patients. 782/3897 AKI patients needed RRT. Clinical settings included cardiac surgery (CS, n=8), critical illness (ICU, n=9), CS&ICU (n=2), hospital AKI (n=9) and others (n=6). Both urine and blood BM were studied (Fig1). The BM most frequently studied were Neutrophil Gelatinase Associated Lipocalin (n=22), CystatinC (n=12), Kidney Injury Molecule-1 (n=6) and Interleukin-18 (n=7). Various assays were used. The reported cut-off values for selected urine BM were: NGAL 16-680 ng/ml and 41 ng/ml/mmol/l Cr and 130 mcg/g Cr; KIM-1, 2.8 ng/ml and 210 pg/ml/mmol/l Cr and >15 ng/mg Cr; IL-18, 17-69.8 pg/ml and 36 pg/ml/mmol/l Cr. Fig 2 shows the corresponding sensitivity and specificity.

Conclusions: There was a wide range of cut-off values; most had fairly low sensitivity/specificty (i.e <0.85). Additional research must clarify the optimal BM values for categorizing high PPV/NPV for specific clinical management decisions. This will be in part also be determined by platform standardization and inter-laboratory calibration.

Fig 1: Study distribution by specimen type, BM number and evaluation time-points

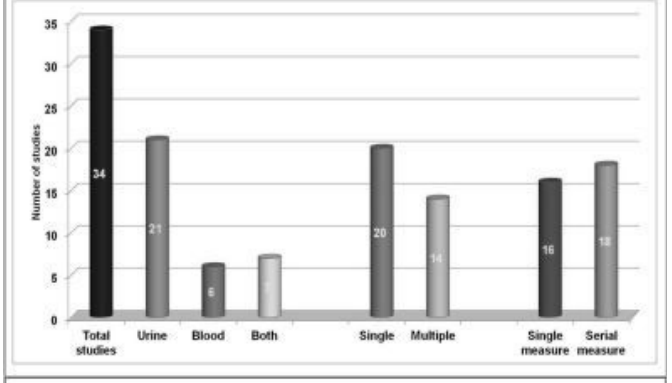

Fig 2: Sensitivity/Specificity of selected urinary BM for RRT prediction

Determination of Biomarker Cut-Offs in Acute Kidney Injury

John W. Pickering,[1] Zoltan H. Endre.[1,2] *[1]Christchurch Kidney Research Group, Department of Medicine, University of Otago, Christchurch, New Zealand; [2]Department of Nephrology, Prince of Wales Hospital, Sydney, New South Wales, Australia.*

Background: Current definitions of acute kidney injury (AKI) utilise arbitrary cut-offs for defining change in serum or plasma creatinine and urine output. Biomarkers of renal injury have been validated against these definitions. There is an urgent need for an independent outcome against which to judge both functional change and structural markers of injury. We propose using sensitivity for the combined outcome of mortality and need for dialysis as a better alternative for both parameters of change in renal status.

Methods: We retrospectively analysed data in 507 intensive care patients in whom urinary neutrophil-gelatinase associated lipocalin (NGAL) was measured on admission, at 12 and 24h, and plasma creatinine was measured daily for 7 days. The sensitivity of AKI (defined using KDIGO definition; Functional-AKI: plasma creatinine increase ≥0.3mg/dl in 48h or ≥50% in 7d) for dialysis or death within 30 days (the outcome) was determined in a randomly selected cohort of 254 patients (development cohort). Structural-AKI was subsequently defined using as >NGAL cut-off concentration with the same sensitivity as that of Functional-AKI for the same outcome. The relative risk (RR) of the outcome was then assessed in a validation cohort of 253 patients using the same Functional-AKI and Structural-AKI cut-offs.

Results: In the development cohort the sensitivity of Functional-AKI for the outcome was 62%. The threshold for urinary NGAL with a 62% sensitivity for this outcome was 140ng/ml. Sixty-five (25.6%) patients had both Functional-AKI and Structural-AKI, 38 (15%) Structural-AKI only, and 45 (17.7%) only Functional-AKI. Compared to the referent group (no-AKI) the RR of Functional-AKI and Structural-AKI was 3.62, of Structural-AKI only was 2.48 and of Functional-AKI only 2.09. The validation cohort was not different from the development cohort (p=0.87).

Conclusions: Sensitivity to need for dialysis and death can be used to link and give equal weight to functional or biomarker-based definitions of AKI. This hypothesis awaits validation in large multicentre datasets.

Urinary Angiotensinogen: A Novel Prognostic Biomarker of Acute Kidney Injury

Joseph Alge,[1,2] Nithin Karakala,[1,2] Benjamin Neely,[1] Michael G. Janech,[1,2] James A. Tumlin,[3] Lakhmir S. Chawla,[4] Andrew Shaw,[5,6] John M. Arthur.[1,2] *[1]Medical University of South Carolina; [2]Ralph H. Johnson VAMC; [3]University of Tennessee College of Medicine in Chattanooga; [4]George Washington University; [5]Duke University; [6]Durham VAMC.*

Background: Prognostic biomarkers that discriminate between patients who will develop severe acute kidney injury (AKI) and those who will not at the time of diagnosis with mild AKI could facilitate timely intervention in populations at risk of adverse outcomes.

Methods: Liquid chromatography-tandem mass spectrometry was used to discover potential prognostic biomarkers of severe AKI in the urine of 12 patients with AKI after cardiac surgery. Angiotensinogen was the best candidate biomarker. Subsequently, urinary angiotensinogen was measured by ELISA in patients who developed AKI after cardiac surgery (n=97) and evaluated for its prognostic potential using the area under the ROC curve (AUC).

Results: There were no differences among outcome groups with respect to demographics, type of surgery, bypass time, or pre-op serum creatinine. The urine angiotensinogen-to-creatinine ratio (uAnCR) was discriminative of the following outcomes: worsening of AKI (AUC=0.7), AKIN stage 3 AKI (AUC=0.71), the need for renal replacement therapy (RRT) (AUC=0.71), discharge ≤7 days after sample collection (AUC=0.74), as well as the composite outcomes AKIN stage 2 or 3 (AUC=0.64), AKIN stage 3 or death (AUC=0.75), and RRT or death (AUC=0.71). Furthermore, its prognostic predictive power was improved when only patients who were classified as AKIN stage 1 at the time of sample collection (n=79) were analyzed, having an AUC=0.81 for AKIN stage 3 or death. The predictive power of uAnCR was also augmented in patients who developed AKI after off-pump cardiac surgery (n=24), among whom it was an excellent predictor of AKIN stage 3 AKI and RRT (AUC=0.93 and 0.86, respectively).

Conclusions: Urinary angiotensinogen is a useful prognostic biomarker of AKI after cardiac surgery and can potentially be used alone or in combination with other biomarkers to predict adverse outcomes early in the course of the disease.

Urinary π-Glutathione-s-Transferase Predicts Developing (Septic) Acute Kidney Injury at Least as Well as Urinary Neutrophil Gelatinase Associated Lipocalin

Hilde R. De Geus,[1] Gijs Fortrie,[2] Michiel G.H. Betjes,[2] Johan Groeneveld.[1] *[1]Intensive Care, Erasmus University Medical Center, Rotterdam, Netherlands; [2]Nephrology, Erasmus University Medical Center, Rotterdam, Netherlands.*

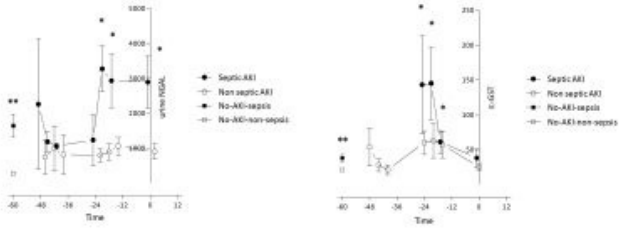
Background: Urinary Neutrophil gelatinase associated lipocalin (NGAL) is a biomarker for acute kidney injury (AKI) and considered as a reference marker for other candidates such as urinary π-Glutathione-s-transferase (π-GST). The aim of this study was

to assess the ability of π-GST to predict for AKI in adult critically ill patients with and without sepsis and to compare its performance with urinary NGAL.

Methods: 700 adult ICU patients were prospectively included for urine measurements at four time-points (T=0, 4, 8 and 24 h) straight after entry. Samples were analysed after study completion for biomarker expression. Patients were stratified according to the presence of sepsis at entry. Receiver operating characteristic (ROC) curves were generated using peak biomarker values and the area under the curve (AUC) was calculated. The primary study endpoint was the development of AKI (stage 1, 2 or 3 according to AKIN classification).

Results: Individual data of 508 patients entered the final analysis. Of these 57 developed the primary outcome. Thirty patients had sepsis at ICU entry (19 without AKI [4%] and 11 with AKI [19%]). The predictive value for any AKI of NGAL and π-GST was 0.75 and 0.70 (P=0.33). In the subgroup of septic patients both NGAL and π-GST concentrations were higher at all time points preceding AKI compared to non-septic patients (P≤0.05) (Figure 1). Sepsis did not affect the predictive properties of the biomarkers for AKI, except for π-GST; the AUC for the latter increased to 0.91 (P=0.005).

Conclusions: Peak urinary NGAL and π-GST concentrations preceding AKI after ICU admission express a comparable predictive power. In septic AKI, the prediction of π-GST further improves.



TH-PO131

Urine NGAL, L-FABP, and Cystatin C for the Early Detection of AKI and Prognosis of Critically Ill Adults with Preserved Kidney Function

Edward D. Siew,[1] Lorraine B. Ware,[2] Aihua Bian,[3] Ayumi Shintani,[3] Svetlana Eden,[3] Nancy Wickersham,[2] T. Alp Ikizler.[1] *[1]Medicine/Nephrology and Hypertension, Vanderbilt University, Nashville, TN; [2]Medicine/Allergy, Pulmonary, and Critical Care Medicine, Vanderbilt University, Nashville, TN; [3]Biostatistics, Vanderbilt University, Nashville, TN.*

Background: Early detection of acute kidney injury(AKI) in the critically ill with urinary biomarkers is hindered by the confounding effects of pre-existing injury and injury diversity.

Methods: We examined the utility of urine NGAL, L-FABP, and Cystatin C for the early detection of AKI and predicting dialysis/death in a nested case-control study of 380 critically ill adults (127 cases:245 controls) with eGFR≥60 ml/min/1.73 m^2 at measurement.

Results: The AUC-ROCs for AKI discrimination over 48-hours for uNGAL, uL-FABP, and uCyst were 0.58(95%CI:0.52-0.64), 0.59(95%CI:0.52-0.65), and 0.51(95%CI:0.48-0.57), respectively. Combining uNGAL and uL-FABP resulted in an AUC of 0.59(95%CI:0.56-0.69). Discrimination for AKIN stages II and III improved to 0.69(95%CI:0.59-0.77), 0.65(95%CI:0.55-0.74) and 0.69(95%:0.65-0.82) for uNGAL,uL-FABP, and the combination, respectively. Neither uNGAL nor uL-FABP independently associated with the composite outcome of death or dialysis [uNGAL HR 1.35 (95%CI:0.93-1.96), uL-FABP HR 1.15 (95%CI:0.82-1.62)] though both independently predicted dialysis after adjusting for APACHE II [uNGAL HR 3.17 (95%CI:1.58-6.34), uL-FABP HR 2.12(95%CI:1.18-3.84)].

Cox Model for Clinical Outcomes

Outcome	uNGAL HR	95% CI	uL-FABP HR	95% CI
Dialysis (N=10)[a]	3.17	1.58-6.34	2.12	1.18-3.84
Mortality 28d (N=38)[b]	1.11	0.73-1.68	0.95	0.65-1.40
Dialysis or Mortality(n=48)[c]	1.35	0.93-1.96	1.15	0.82-1.62

Biomarkers were log10 transformed. Separate cox proportional hazards regression models for uNGAL, and uL-FABP were adjusted for: a: APACHE II b: APACHE II, sepsis c: modified APACHE II, sepsis, creatinine

Conclusions: Urine NGAL and L-FABP performed modestly, alone or combined, for the early detection of AKI in critically ill adults with preserved kidney function. Both markers provide useful prognostic information but require further study in early established injury.

Prognostic Value of Urine Neutrophil Gelatinase Associated Lipocain in Critical Patients at the Admission to an Intensive Care Unit

Carmen Bernis,[1] Ian Carrasco,[2] Alicia Garcia Rodriguez,[3] Marta Chicot,[2] Laura Salanova,[1] Rosario Madero,[4] Jose-Antonio Sanchez-Tomero.[1] *[1]Nephrology, H.U la Princesa, Madrid, Spain; [2]ICU, H.U. la Princesa, Madrid, Spain; [3]Biochemistry, HU Princesa; [4]Biostatistics, HU la Paz, Madrid, Spain.*

Background: NGAL is a promising biomarker for early AKI detection. However the performance of Urine NGAL (uNGAL) at admission to ICU has not been studied. Our objective is to estimate the diagnostic accuracy of uNGAL at the admission to an adult general ICU for early detection of AKI, need for Renal Replacement Therapy (RRT) and prediction of thirty days mortality.

Methods: A prospective observational study of 415 consecutive adult patients admitted to a general ICU was approved by the institutional review board. AKI was defined by AKIN criteria. Patients (APACHE, SAPS index, RRT) were follow up 30 days until their discharge from Hospital or their death. Samples: uNGAL at the admission in the ICU, Creatinine daily till 96 h, weekly and discharge creatinine. NGAL was done by Standardized Clinical Platform ARCHITECT assay, provided by Abbott Diagnostics. Diagnostic characteristic of uNGAL were evaluated with receiver –operating characteristic (ROC) curves for AKI diagnosis, need of RRT and thirty days mortality. Yeuden test was used to find best sensitivity, specificity, predictive positive value (PPV) and predictive negative value (PNV). SPSS17 was used.

Results: 99 patients (23, 3%) developed AKI, 46 (11%) need RRT and 71 (17, 1%) died. The ROC curve for uNGAL at admission and the occurrence of AKI was 0.845 (IC 0.80 a 0.89) p<0.001. We found for NGAL values >60ng/ml 78% sensitivity, 78%specificity, 53% PPV and 92% PNV. (Yeuden test) The ROC curve for uNGAL at admission and the need of RRT was 0.80 (IC 0.74 a 0.87) p<0.001. Yeuden test found for values >156 of u NGAL 71% sensitivity, 81% specificity, 32% PPV and 96% PNV. The ROC curve for uNGAL at admission and 30 days mortality was 0.66 (IC 0.59 a 0.74) p<0.001. Yeuden test found for values >100 of uNGAL 57% sensitivity, 73% specificity, 30% PPV and 89 % predictive negative value PNV.

Conclusions: Urine NGAL at admission in ICU predicts AKI, need for RRT and 30 days survival.

TH-PO133

Tubular Damage Biomarkers Linked to Inflammation or Iron Metabolism Predict Acute Kidney Injury

Anja Haase-Fielitz,[1] Sabine Westphal,[2] Rinaldo Bellomo,[3] Prasad Devarajan,[4] Mark E. Westerman,[5] Peter R. Mertens,[1] Michael Haase.[1] *[1]Nephrology, Otto-von-Guericke University Magdeburg, Germany; [2]Clinical Chemistry, Otto-von-Guericke University Magdeburg, Germany; [3]Intensive Care, Austin Health, Melbourne, Australia; [4]Pediatrics and Developmental Biology, Children's Hospital, Cincinnati, OH; [5]Intrinsic LifeSciences, La Jolla.*

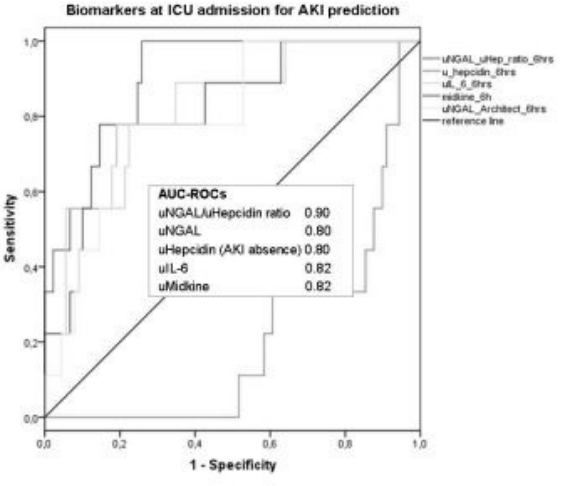
Background: Novel tubular damage biomarkers have been suggested to be included in acute kidney injury (AKI) definition to complement excretory renal functional criteria.

We compared the value of tubular damage markers measured early after cardiac surgery for prediction of postoperative AKI compared to conventional renal risk markers.

Methods: 100 adult patients undergoing cardiac surgery were analyzed. Preoperatively and at ICU admission, we quantified *in urine*: NGAL (ARCHITECT), hepcidin, midkine, IL-6, alpha1-microglobulin (all ELISA); *in plasma*: hepcidin, haptoglobin, CK, CKMB, CRP, leukocytes, lactate, urea, creatinine. Endpoint was RIFLE-AKI.

Results: Preoperatively, no biomarker predicted AKI (N=9). At ICU arrival, four urinary biomarkers showed good discriminatory ability for subsequent development of or absence of AKI (Fig 1). An excellent predictive value was found for uNGAL/uhepcidin ratio (Fig 1). Contrary, at ICU admission, none of the plasma biomarkers, including creatinine, was an early AKI predictor.

Conclusions: Several urinary markers of tubular damage predict AKI after cardiac surgery and the combination of NGAL and hepcidin provides excellent AKI prediction. This ratio combines an AKI prediction marker (NGAL) and a marker of AKI absence (hepcidin), potentiating their individual discriminatory values. Both markers may have unique roles in AKI pathophysiology, thereby multiple functions within inflammatory processes and in iron metabolism may be assessed. Validation in larger studies is desirable.



TH-PO134

Retooling the Creatinine Clearance Equation to Estimate Kidney Function when the Serum Creatinine Is Changing Acutely: Kinetic eGFR Formula

Sheldon C. Chen. *Medicine, Northwestern University, Chicago, IL.*

Background: It is desirable to estimate the GFR at the bedside to better assess acute kidney injury (AKI) or renal recovery. Current eGFR formulas can estimate a kidney function when the serum creatinine is stable but do not work if the creatinine is changing rapidly. To analyze renal function outside of the steady-state, a novel formula is proposed.

Methods: The formula is $CrCl_{between2creats.}$=SteadyStateP_{Cr}×CorrespondCrCl×{Time(h)/24–[P_{Cr}(2)–P_{Cr}(1)]/nadirP_{Cr}}×mean$P_{Cr}$$^{-1}$×Time(h)$^{-1}$×24. It builds upon the creatinine clearance equation. Urinary creatinine excretion, U_{Cr}×V, is solved indirectly as the P_{Cr}×CrCl. CrCl is available from any eGFR formula. The {Time(h)/24–deltaP$_{Cr}$/nadirP_{Cr}}×Time(h)$^{-1}$×24 takes on one of three values: =1 in steady-state, <1 when the serum creatinine is rising, and >1 when the creatinine is declining. This adjusted urinary creatinine excretion gets divided by the serum creatinine, really the mean of two consecutive creatinines, to yield the eGFR a patient must have in order to transition from one creatinine to the next.

Results: The power of the kinetic eGFR formula is best seen in an example of AKI. A 40-year-old man with a baseline and nadir creatinine of 1.0 develops AKI and in the next 24 hours increases his creatinine to 1.9 mg/dl. If his P_{Cr} of 1.0 corresponds to an eGFR of 100 ml/min, the formula gives an answer of 1.0×100×{24/24-[1.9-1.0]/1.0}×1.45^{-1}×24^{-1}×24=6.90 ml/min. Consistent with our sense of severe AKI, the GFR has plummeted to <10 ml/min. This is immediately and quantitatively revealed by the kinetic formula, whereas a misapplied clearance equation wrongly informs that the GFR at a P_{Cr} of 1.9 is 1.0×100/1.9=52.6 ml/min. The clearance equation and other eGFR formulas will not be applicable until the serum creatinine stabilizes. But the kinetic formula works at all times and in fact reduces to the clearance equation in steady-state, attesting to its intrinsic validity.

Conclusions: Deduced from first principles of creatinine balance and mathematically proved for all cases, the kinetic eGFR formula upgrades the clearance equation with the ability to ascertain kidney function in AKI or renal recovery, which is of clinical and educational value.

TH-PO135

Kidney Injury Molecule-1 Staining Is a Specific Marker of Acute Tubular Injury in Pediatric Renal Biopsies

Xu Zeng,[1] Joseph V. Bonventre,[2] Ping L. Zhang.[3] *[1]Pathology, Detroit, MI; [2]Renal Division, Boston, MA; [3]Anatomic Pathology, Royal Oak, MI.*

Background: Kidney injury molecule-1 (KIM-1) has proven very useful in identifying acute tubular injury (ATI) present in proximal tubules of adult renal biopsies, but its role in pediatric biopsies has not been fully characterized. In this study we compared the KIM-1 staining patterns in children and adults and correlated these findings with clinical indices.

Methods: 77 adults (mean age of 52 years, ranging from 21 to 81 years old) and 60 children (mean age of 12 years, ranging from 2 to 20 years old) were included in the study. Their renal biopsies showed a large range of glomerular, tubulointerstitial and renal vascular diseases, and were all stained for KIM-1 (AKG monoclonal antibody). KIM-1 staining scores in proximal tubules were graded from 0 to 3+ in all biopsies and correlated with serum creatinine levels (sCr).

Results: In adults, positive KIM-1 staining was seen in 73 % (56/77) of adult biopsies. Nine (9) of 21 KIM-1 negative cases had elevated sCr ranging from 1.4 to 3 mg/dl and included 2 "acute kidney injury", 2 minimal change disease, 1 membranoproliferative glomerulonephritis, 2 focal segmental glomerulosclerosis, 1 IgM nephropathy and 1 IgA nephropathy. In pediatric biopsies, 82% (49/60) had positive staining for KIM-1. Only one pediatric KIM-1 negative case (IgA nephropathy) had elevated sCr (2.8 mg/dl). By linear regression analysis, in both adults and children there were significant correlations between respective KIM-1 staining scores and sCr (adult: r = 0.353, p = 0.0013; pediatric r = 0.483 and p = 0.0001). In adults, plotting sCr vs KIM-1 score showed a slope of 1.019 with intercept of 1.831. In pediatric slope was 0.760 with intercept of 0.310.

Conclusions: KIM-1 staining is a specific measure of ATI in both adult and pediatric groups with similar linear regression slopes. A lower intercept in the pediatric group would be expected from the lower baseline sCr values in children. Few negative KIM-1 staining cases with elevated sCr may result from a prerenal cause for the creatinine accumulation or stable chronic kidney disease with low levels of ongoing injury.

TH-PO136

Urinary α-Glutathione S-Transferase (GST) and π-GST for Prediction of Severe Acute Kidney Injury (AKI) Following Cardiopulmonary Bypass (CPB)

Paweena Susantitaphong,[1,2] Mary Celine R. Perianayagam,[1] Hocine Tighiouart,[3] Diana Kouznetsov,[4] Orfeas Liangos,[5] Bertrand L. Jaber.[1] *[1]Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Medicine, Chulalongkorn University, Bangkok, Thailand; [3]Biostatistics Research Center, Tufts Medical Center, Boston, MA; [4]Umass Memorial Med Center, Worcester, MA; [5]III. Medizinische Klinik, Klinikum Coburg, Coburg, Germany.*

Background: Urinary α-GST and π-GST are proximal and distal tubular leakage markers that have been proposed for early detection of AKI. We examined the performance characteristics of these 2 markers for detection of post-CPB AKI (>50% or >0.3 mg/dl ↑sCr), including severe AKI (>2-fold ↑ sCr or dialysis) and the composite of severe AKI or in-hospital death.

Methods: These hypotheses were tested in a prospective cohort of 252 adults undergoing CPB at 3 hospitals. Pre-CPB and 2-hr post-CPB urinary samples were obtained and treated with protease inhibitors. α-GST and π-GST were measured by ELISA. Receiver-operating- characteristic (ROC) curves were generated to explore the diagnostic performance of urinary α-GST and π-GST (modeled in tertiles).

Results: AKI developed in 72 (28.6%) patients. The area under-the-ROC curves (AUCs, with 95%CI) examining the performance of α-GST and π-GST are summarized in the Table. Overall, urinary π-GST measured 2-hr post-CPB performed better than α-GST for predicting severe AKI. Urinary α-GST alone performed poorly. However, combining urinary α-GST and π-GST 2-hr post-CPB improved discrimination for predicting severe AKI.

Conclusions: In adults undergoing CPB, urinary π-GST, measured 2-hr post-CPB, performed better than α-GST for predicting severe AKI, but neither marker displayed good discrimination.

Urinary marker	>0.3 mg/dl or >50% ↑sCr (n=72)	>2-fold ↑sCr or dialysis (n=9)	>2-fold ↑sCr, dialysis, or in-hospital death (n=16)
α-GST			
Pre-CPB	0.53 (0.46, 0.61)	0.57 (0.39, 0.76)	0.58 (0.44, 0.73)

Biomarkers for Adult Cardiac Surgery Related Acute Kidney Injury:a Systematic Review and Meta Analysis

Claudio Rigatto, Julie Ho, Paul Komenda, Manish M. Sood, Rakesh C. Arora, Navdeep Tangri. *University of Manitoba, Canada.*

Background: Cardiac Surgery related AKI (CSA-AKI) represents an important complication of heart surgery. Although several new biomarkers of CSA-AKI have been proposed, the clinical utility of these new tests in intraoperative or early postoperative diagnosis remains unclear. We conducted a systematic review and meta-analysis of the diagnostic performance of early biomarkers of CSA-AKI.

Methods: We searched EMBASE, CINAHL, Cochrane, SCOPUS and PUBMED using MeSH terms for AKI, cardiac surgery, and biomarkers. We reviewed all cohort studies in adult cardiac surgery patients having an N of at least 100 and an event rate of at least 30. All studies had to have a clearly defined AKI outcome (AKIN/RIFLE), and report the timing of the biomarker assessment (intraoperative or postoperative (≤24 h)). We excluded studies in whom the timing of biomarker assessment was unknown or more than 24 hours after surgery. We extracted and summarized the AUROC for each biomarker.

Results: Of the 2745 studies identified in the initial search, 17 studies examining 2 plasma and 7 urine biomarkers met the search criteria after full text review. Table 1

Table 1

Postoperative Biomarkers of CSA-AKI	Summary AUROC [*95 CI*]	N Studies
Urinary NGAL	0.73 [*0.69, 0.76*]	10
Plasma NGAL	0.69 [*0.65, 0.73*]	6
Plasma Cystatin C	0.71 [*0.65, 0.77*]	5
Urinary Cystatin C	0.67 [*0.60, 0.74*]	4
Urinary NAG	0.70 [*0.63, 0.76*]	4
Urinary KIM-1	0.79 [*0.75, 0.84*]	4
Urinary IL-18	0.68 [*0.63, 0.73*]	5
Intraoperative biomarkers of CSA-AKI		
Urinary NGAL	0.62 [*0.55, 0.69*]	3

14 studies reported diagnostic performance in the early postoperative period, whereas 3 studies reported intraoperative data. All biomarkers studied post operatively, including NGAL, showed at best moderate discrimination (summary AUROC for each biomarker ranging from 0.68-0.79,. Only urinary NGAL was studied in the intraoperative period, and showed poor diagnostic performance (summary AUROC 0.6, Table 1).

Conclusions: Current biomarkers exhibit modest discrimination for CSA-AKI in the early postoperative period. Intraoperatively, only NGAL has been studied to any extent, and its performance is poor. Efforts on development of new biomarkers for CSA-AKI are still needed.

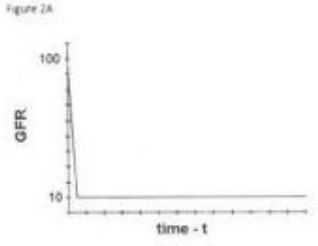
TH-PO138

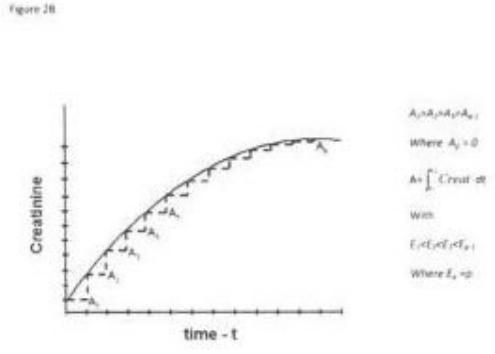
The Description of a New and Unique Method for Measuring Glomerular Filtration Rate in Acute Kidney Injury John Mellas. *Nephrology, St. Mary's Health Center, St. Louis, MO.*

Background: Acute kidney injury is defined by severity according to the AKIN and RIFLE criteria. KDIGO guidelines for AKI suggest that GFR should be measured when possible. The AKIN and RIFLE criteria do not measure GFR directly nor is there a method generally availble to measure GFR in AKI.

Methods: Herein is descibed a method to measure GFR in AKI using the following variables; Urine creatinine excretion (E); measured as urine volume times urine creatinine concentration, creatinine production rate (P); equal to [29-(.203xage)]x weight in kg, and basleine GFR which is the estimated creatinine clearance at time t1. By this method actual GFR=estimated GFR(at time t1)x E divided by P (E/P).

Results: In a patient with AKI the baseline GFR (at time t)x E/P is a constant number and thus measures actual GFR at any time course of AKI in a particular patient.





Patient with ARF. Baseline C creat is 100 ml/min and drops to 10 ml/min abruptly.
Assume P= 1440 mg/day (production)
At C creat 100 = U x V/P = 1440/p x 1440 x 100, p=1 (Creatinine)
At C creat 10 = U xV/P = 1440/p x 1440 x 100, p=10

S creat	GFR by MDRD	Actual C creat	U x V = E	E/P	MDRD X E/P
1	100	10	144	0.1	100x.1=10
2	50	10	288	0.2	50x.2=10
3	33.3	10	432	0.3	33.3x.3=10
4	25	10	576	0.4	25x.4=10
5	20	10	720	0.5	20x.5=10
6	16.7	10	864	0.6	16.7x.6=10
7	14.3	10	1008	0.7	14.3x.7=10
8	12.5	10	1152	0.8	12.5x8=10
9	11.1	10	1296	0.9	11.1x.9=10
10	10	10	1440	1	10x1=10

Conclusions: In AKI actual GFR = GFR estimated at time t1 x E/P measured over time intervals t1 to t2. This method provides the most accurate estimate of GFR in AKI thus far described.This method avoids the pitfalls of serum creatinine concentration where the distribution volume of creatinine would be required to measure serum creatinine accumulation and hence GFR, with the serum volume of distribution of creatinine diiffcult if not impossible to measure with accuracy.

TH-PO139

Novel Urinary Biomarkers Remain Elevated Following AKI in Children Donna J. Claes, Michael R. Bennett, Lori Brunner, Qing Ma, Stuart Goldstein. *Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Novel urinary biomarkers have been studied to diagnose AKI & CKD. There are no human studies that have longitudinally followed novel urinary biomarkers post-AKI.

Methods: We prospectively enrolled 18 pediatric pts (mean age 14.6 +/- 4.8 y) who developed either pRIFLE-I (n=6) or -F (n=12) any-cause AKI ≥ 48 h during admission. Serum creatinine (SCr) and novel urinary biomarkers were studied at AKI onset, then 2 wk, 1 mo, & 3 mo post-AKI.

Results: 44% (10/18) of pts had no underlying medical history; other PMHx included cardiac disease (16.7%), ESLD (11%), s/p liver Tx (5.6%), and cerebral palsy (5.6%). Baseline SCr was known in 58%. Mean pre-AKI Schwartz eGFR was 131 ml/min/1.73 m2 (SD 37). No pts had underlying hypertension; 3 pts (20%) were on anti-HTN meds for non-HTN causes. Pts had more than one etiology for AKI; causes ranged from nephrotoxic meds (67%), pre-renal (44%), sepsis/shock (39%), acute GN (22%), tumor lysis (5.6%), & rhabdomyolysis (5.6%). Median AKI duration was 14 d (IQR 10-22). 67% were admitted to the ICU for 6.5 d (IQR 3, 16.5). 6 pt required RRT (n=3 CRRT & IHD, n=3 IHD only) for 8 d (IQR 6-17).

18 pts represent 31 encounters. Markers of renal function/injury (eGFR and urinary biomarkers) from onset of AKI over time show the following (median, IQR provided):

Time post-AKI	Days from AKI	n	Schwartz eGFR (ml/min/1.73 m2)	NGAL (ng/ml)	IL-18 (pg/ml)	KIM-1 (pg/ml)	L-FABP (ng/ml)
Baseline	5 (4, 7)	9	25.8 (15, 40.6); n=18	164 (67, 679)	71 (20, 131)	1912.2 (1589, 2815)	17.4 (12, 49)
2 wk	20 (17, 24)	7	55.2 (33, 95)	25 (21, 58)	27.3 (18, 113)	1980 (1032, 2297)	6.7 (6, 63)
1 mo	33 (32, 37)	6	104 (81, 115)	19 (7, 143)	52 (18, 215)	1206 (616, 3469)	11.4 (4, 48)
3 mo	64.5 (56, 80)	9	116 (85, 119)	21 (3, 55)	30 (8, 93)	439 (376, 2221)	6 (4, 8)

Conclusions: In this small pediatric cohort, urinary KIM-1 appears to remain elevated up to 3 months post-AKI while other urinary biomarkers decrease to normal reference levels. We suggest that screening for future CKD risk at 3 months using urinary KIM-1 may identify pts at greater CKD risk.

TH-PO140

Renal Angina Prediction of Acute Kidney Injury Improves with Inclusion of Serum Biomarkers in Critically Ill Children Rajit K. Basu,[1] Lori Brunner,[1] Derek Wheeler,[1] Hector R. Wong,[2] Stuart Goldstein.[1] [1]*Center for Acute Care Nephrology, Cincinnati Childrens Hospital Medical Center, Cincinnati, OH;* [2]*Critical Care, Cincinnati Childrens Hospital Medical Center, Cincinnati, OH.*

Background: Earlier detection of acute kidney injury (AKI) with biomarkers may expedite treatment and improve outcomes. Our empiric concept of *Renal Angina* (ANG) identifies children (pts) at-risk for AKI in the pediatric intensive care unit (PICU) by combining known AKI risk factors with graded thresholds of early clinical AKI signs creating an ANG index (RAI). We suggest only pts who fulfill ANG should undergo biomarker assessment.

Methods: We studied 215 PICU pts with sepsis to determine if day of admission 1) ANG predicts severe sepsis AKI (SSAKI; (50% reduction in creatinine clearance)) on PICU day 7 and 2) serum biomarkers (matrix metalloproteinase-8 (MMP-8) and neutrophil elastase-2 (Ela-2)) improved upon ANG prediction of SSAKI. Based on derivation methodology, RAI ≥8 (range: 1-40) fulfilled ANG. We previously derived and validated MMP-8 and Ela-2 cutoffs for the prediction of SSAKI (≥11 ng/ml and ≥235 ng/ml, respectively).

Results: The area under the curve – receiver operating characteristic (AUC-ROC) for ANG was greater than the AUCs for both MMP-8 and Ela-2. Biomarker incorporation improved the AUC for ANG. Notably, the combination of the biomarkers with ANG increased the **specificity** of Day 0 ANG for Day 7 SSAKI (Table). Finally, while negative predictive value (NPV) remained high, positive predictive value (PPV) of ANG increased when combined with either biomarker.

	Sensitivity	Specificity	PPV	NPV	AUC-ROC
RAI ≥ 8	93 (76-99)	36 (33-37)	18 (15-19)	97 (90-99)	0.846
Ela-2 ≥ 235	89 (73-97)	45 (42-46)	19 (16-21)	97 (91-99)	0.725
MMP-8 ≥ 11	86 (69-95)	33 (30-34)	16 (13-18)	94 (87-98)	0.693
RAI-8 ≥ 8, Ela-2 ≥ 235	83 (65-93)	65 (62-67)	27 (21-30)	96 (92-99)	0.862
RAI ≥ 8, MMP-8 ≥ 11	89 (72-97)	57 (54-58)	24 (19-26)	97 (93-99)	0.841

Conclusions: In summary, we suggest that stratification using the renal angina prodrome allows a practitioner identify pts at-risk vs. not at-risk for AKI, focusing subsequent biomarker measurement to "rule out" AKI only in pts with ANG to increase predictive precision.

TH-PO141

Fluid Balance in ICU Setting: The More May Not Always Be the Better: Relationship with Mortality and Acute Renal Failure Pedro V.A. Aguiar,[1] Pedro Francisco Azevedo,[1] Hugo Mário Silva,[1] Anibal Marinho.[1] *[1]Centro Hospitalar do Porto - Hospital Santo Antonio, Porto, Portugal.*

Background: Fluid resuscitation from the Early Goal Directed Therapy led to an increased incidence of fluid overload in intensive care units (ICU). Though, recent observational studies revealed an increased 60-day mortality in the overhydrated patients, particularly if associated to acute renal failure (ARF) and the need to renal replacement therapy.

Methods: We conducted a prospective observational study in an ICU from a single center. All patients over 18 years old were included. Demographic data, fluid balance, SOFA score, serum creatinine, and diuretic therapy from day 1 to day 7 were recorded.

Results: A total of 47 patients (66% male, age 68,2±16,3, mean time on ICU 9,3 ± 6,3 days) were included. Most were admitted due to medical complications (62%). Six (13%) patients died. Positive fluid balances were found from day 1-3 (712,6 vs 362,3 vs 538,6mL) followed by negative tendency (-29,9 vs -248 vs -301,1mL). Patients with renal failure (serum creatinine > 2,5mg/mL) presented higher fluid balances (389,5 vs 1189,9mL), as opposed to those on furosemide therapy (249,9 vs 3536,1mL). Deceased patients presented higher fluid balances from day 3 onwards (day 3 4181,8 vs 1238,3mL; day 5 4363 vs 940ml, day 6 1563,8 vs -135,2mL), higher catecholamine doses, and higher SOFA score (8,5 vs 6,4%). Overall, patients with need for vasopressor support presented higher fluid balances (min: 183,1-max:1354,2mL vs min:-559,0- max: 379,0mL). No fluid balance differences were found between deceased patients under catecholamine therapy and the rest from days 1-4.

Conclusions: Increased hydration was found in patients presenting acute renal failure. In non-oliguric patients furosemide may prevent fluid overload. More, positive fluid balance was increased in deceased patients in the ICU setting.

TH-PO142

The Accuracy of Acute Kidney Injury Diagnosis Depends on Fluid Balance in ICU Patients Pedro Fidalgo,[1] Silvia Coelho,[1] Bruno Rodrigues,[1] Luis Inchaustegui,[1] Ana Luisa Papoila,[3] Fernando Liano,[2] Karina Soto.[1] *[1]Nephrology, Hospital Fernando Fonseca, Portugal; [2]Nephrology, Hospital Ramon y Cajal, Portugal; [3]Biostatistic, Faculty of Medical Sciences of Lisbon, Portugal.*

Background: Fluid management is an integral element of the care of critically ill patients. However, fluid overload may modify the volume distribution of serum creatinine (SCr). The aim of this study was to determine whether fluid balance changes the accuracy of Acute Kidney Injury (AKI) diagnosis and staging.

Methods: In a prospective study of 128 consecutive ICU patients AKI was classified by RIFLE criteria. SCr and serum Cystatin C (SCysC) were measured daily. Fluid balance (FB) was calculated with daily input-output fluids. Sum of daily FB was defined as Cumulative fluid balance (CFB). The Percentage of CFB (PCFB) was calculated according to the formula:[∑ daily FB/admission body weight (kg)]*100. SCr and SCysC were adjusted with the formula: biomarker x ((admission body weight x 0.6) + (Σ daily FB))/(admission weight x 0.6). A new adjusted RIFLE was calculated with adjusted SCr and were distributed into: maintaining RIFLE stage (Eq); worsening (Wr) and improved (Ip). Mann-Whitney test was used. Generalized linear models and linear mixed-effects models were applied. p value <0.05 was considered significant.

Results: AKI was diagnosed in 35.2 % of patients. A significant difference was detected between measured and adjusted SCr and SCysC, incrementing with the length of stay in ICU and increasing with CFB. Comparison between RIFLEs showed that, 79.8% were Eq most of them corresponding to the RISK class; 12.5% were Wr and had a significantly higher median of PCFB, 22.9% (12-33) compared to the other groups. Additionally, 7.8% were Ip, corresponding to lower CFB.The worst performance of unadjusted SCr was in "Failure" stage of RIFLE, diagnosing only 53.7% of cases correctly. Finally, the threshold of PCFB above which the unadjusted RIFLE classification was inaccurate, was determined to be 6.7% (2.3-13.0).

Conclusions: Unadjusted SCr influences the RIFLE classification, particularly in patients with higher volume overload. Patients in "Failure" stage have a higher probability of being misclassified.

TH-PO143

The Role of Depletion of Renal Progenitors in the Development of Renal Fibrosis in a Rat Remnant Kidney Model Xinzhou Zhang,[1] Liu Junmin.[2] *[1]Department of Nephrology, The Second Clinical College of Jinan University, Shenzhen, Guangdong, China; [2]Department of Nephrology, The Second Clinical College of Jinan University, Shenzhen, Guangdong, China.*

Background: Recent studies demonstrate renal stem/progenitor cells exist in mature mammalian kidney and participate in regeneration of podocytes and tubular epithelia after kidney injury. Subtotal nephrectomy cause development of renal fibrosis, involving glomerulosclerosis and tubulointersticial fibrosis, which were characterized by podocyte damage and tubule atrophy respectively. This study hypothesized that depletion of renal progenitor exist during renal fibrosis in the remnant kidney model.

Methods: Kidney specimens were obtained from the rats underwent 5/6nephrectomy. Morphologic analysis was based on HE-staining. The analysis of CD133,Pax-2,Podocin and Ki67 expression on/in renal cortex cells was performed by flow cytometry. The level of TGF-β1,VEGF and AngiotensinII(AngII) in renal cortex were measured by western blotting and enzyme linked immunosorbent assay (ELISA) respectively. The expression of AngII type1 receptor (AT1R), AT2R and Pax-2 mRNA on/in $CD133^+$cells was evaluated by RT-PCR.

Results: The level of AngII and TGF-β1 were upregulated in cortex of remnant kidneys compared with normal kidneys, as well as increased sign of AT1R mRNA expression on $CD133^+$cells. Going with gradual downregulation of Pax-2 gene expression in $CD133^+$ cells, the proportions of $CD133^+Pax\text{-}2^+$cells and $Podocin^+Ki67^+$cells in cortex cells of remnant kidneys underwent progressive decrease with development of glomerulosclerosis.

Conclusions: Subtotal nephrectomy induces nephrogenous AT1R-mediated activation of RAS and upregulation of TGF-β1 level, which cause downregulation of Pax-2 gene expression, thus lead to reduction of renal progenitors and deficiency of podocyte regeneration, suggesting that depletion of renal progenitors exist in the procession of remnant kidney and maybe play a pivotal role in the pathogenesis of renal fibrosis.

TH-PO144

TIMAP Is Critical for Glomerular Endothelial Cell (EC) Angiogenesis Marya Obeidat, Barbara J. Ballermann. *Dept. of Medicine, University of Alberta, Edmonton, AB, Canada.*

Background: Glomerular capillaries develop through vasculogenesis and angiogenesis. Angiogenesis involves migration of tip EC towards the angiogenic stimulus, proliferation of stalk EC to elongate the sprout, and controlled apoptosis to remove superfluous cells. We showed that TGFβ1 regulates glomerular capillary formation *in vitro* and *in vivo,* in part by enhancing EC apoptosis. TIMAP is an EC- predominant inhibitory protein phosphatase 1 (PP1c) regulatory subunit strongly repressed by TGFβ1. This study sought to define the role of TIMAP in glomerular EC angiogenesis.

Methods: Human glomerular EC were transfected with TIMAP-specific siRNAs or control siRNA (siRNAScr). The rate of change of electrical impedance by non-confluent EC was used to monitor EC proliferation. DNA synthesis was quantified by flow-cytometric analysis of EdU incorporation. To quantify 3D-angiogenesis, collagen-coated beads containing confluent glomerular EC were suspended in fibrin gels and for each transfection, sprouts per bead were counted for 40 consecutive beads. Protein phosphorylation was assessed by Western blot analysis. Caspase 3 activity was quantified as a measure of apoptosis. All experiments, except Caspase 3 activity, were repeated at least 3 times and are presented as the mean ± SEM.

Results: After 72 hours of transfection with siRNA, TIMAP protein was reduced by 76 ± 8% compared to siRNAScr. TIMAP knockdown reduced the rate of electrical impedance development by 93 ± 2% compared to siRNAScr ($p<0.05$). TIMAP siRNA reduced EdU incorporation by 38 ± 2% vs. siRNAScr ($p<0.05$). Angiogenic sprouts decreased by 43 ± 1% in EC transfected with TIMAP siRNA compared to siRNAScr ($p<0.05$). TIMAP siRNA reduced phosphorylation of AKT on Ser473 by 83 ± 1% ($p<0.01$), without effect on total AKT. ERK1/2 MAPK phosphorylation was unaffected. In two experiments so far, TIMAP knockdown augmented staurosporine-induced Caspase 3 activity, 1.6 and 2.1 fold, compared to siRNAScr.

Conclusions: AKT phosphorylation on Ser473 is critical for EC survival and proliferation. Our data indicate that TIMAP promotes the Ser473 phosphorylation of AKT, potentially by inhibiting its dephosphorylation. In turn, TIMAP enhances EC proliferation and protects EC from apoptosis.

MMP-9 Contributes to TGF-β-Induced Endothelial-Mesenchymal Transition through Notch Signalling in Human Renal Glomerular Endothelial Cells Ye Zhao,[1] Thian Kui Tan,[1] Jianlin Zhang,[2] Changqi Wang,[1] Yiping Wang,[1] Ya Wang,[1] Yuan Min Wang,[3] Vincent W.S. Lee,[1] Stephen Alexander,[3] Tania Tsatralis,[1] Guoping Zheng,[1] David C. Harris.[1] *[1]Centre for Transplant and Renal Research, Westmead Millennium Institute, Sydney, NSW, Australia; [2]Dept. of Biochemistry and Molecular Biology, Shanxi Medical University, Taiyuan, Shanxi, China; [3]Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia.*

Background: Endothelial-mesenchymal transition (EndoMT) has been shown to be a major source of myofibroblast formation in kidney fibrosis. Our previous study showed a profibrotic role for MMP-9 in kidney fibrosis by inducing epithelial-mesenchymal transition (EMT). Inhibition of MMP-9 activity reduced kidney fibrosis in murine unilateral ureteral obstruction. This study investigated whether MMP-9 also plays a role in EndoMT.

Methods: Human renal glomerular endothelial cells (HRGEC) were treated with TGF-β1 to induce EndoMT. EndoMT was assessed by morphological changes, immunofluorescence staining (IF) and western blot (WB) of endothelial (CD31 and VE-cadherin) and mesenchymal markers (α-SMA, vimentin and N-cadherin). Snail expression and Notch signaling were examined by RT-PCR and WB. MMP-9 and MMP-2 expression were examined by zymography.

Results: TGF-β1 (10 or 20 ng/ml) induced EndoMT in HRGEC as evidenced by morphological changes, and by significant downregulation of VE-cadherin & CD31 and upregulation of α-SMA, vimentin and N-cadherin. RT-PCR showed an upregulation of Snail, a known inducer of EMT. The TGF-β1-induced EndoMT was abrogated by MMP inhibitor GM6001. Zymography showed that MMP-9 was unregulated in the TGF-β1 treated HRGECs.Recombinant MMP-9(2 μg/ml) also induced EndoMT in HRGECs with an upregulation of Notch signaling evidenced by an increase of Notch intracellular domain (NICD) accompanied by a decrease of Notch 1. Inhibition of MMP-9 activity by its inhibitor demonstrated a dose-dependent response in preventing TGF-β1-induced α-SMA and NICD in HRGECs.

Conclusions: MMP-9 has an important role in TGF-β1-induced EndoMT in HRGECs, potentially through upregulation of Notch signaling.

TH-PO146

MicroRNA-155 Functions as a Negative Regulator of RhoA Signaling in TGF-β-Induced Endothelial to Mesenchymal Transition Ruben de Bruin,[1] Roel Bijkerk,[1] Coen van Solingen,[1] Jacques Duijs,[1] Eric P. Van der Veer,[1] Peter Dijke,[2] Ton J. Rabelink,[1] Marie-jose Goumans,[2] Anton Jan Van Zonneveld.[1] *[1]Department of Nephrology, Leiden University Medical Center, Leiden, Netherlands; [2]Department of Molecular Cell Biology and Centre for Biomedical Genetics, Leiden University Medical Center, Leiden, Netherlands.*

Background: Endothelial to mesenchymal transition (EndoMT) has been proposed to be involved in the loss of microvascular capillaries in the pathophysiology of renal fibrosis and renal failure. In EndoMT, endothelial cells (ECs) undergo a mesenchymal transition associated with the loss of cell-cell contacts and the acquisition of a synthetic phenotype that can contribute to organ fibrosis.

Methods: Here, we sought to identify microRNAs (miRNAs) that could play a central role in regulating EndoMT. In a TGF-β dependent *in vitro* model for EndoMT, we identified miRNAs that were differentially expressed in normoxic and hypoxic conditions. Furthermore, cellular characteristics such as morphological transition, stress fiber formation, endothelial cell markers (e.g. CD31) and fibrotic markers (e.g. a-SMA, collagen) were investigated.

Results: This study identifies a variety of miRNAs to be differentially expressed in endoMT. Especially miR-155 is significantly upregulated upon TGF-betainduced EndoMT. Silencing of miR-155 directly increased RhoA expression and activity in endothelial cells and affected phosphorylation of downstream LIMK. In contrast, overexpression of miR-155 counteracted RhoA function. Using a selective Rho kinase inhibitor, we could partly suppress EndoMT, strengthening the notion that RhoA plays a central role in EndoMT. Moreover, forced overexpression of miR-155 completely suppressed EndoMT, as evidenced by the maintenance of EC characteristics and blocking the acquisition of a mesenchymal phenotype.

Conclusions: Our data demonstrate that several miRNAs and in particular miR-155, are differentially expressed upon TGF-β induced EndoMT. We show that miR-155 functions as a negative regulator of RhoA signaling and hereby modulates the capability of endothelial cells to aquire a synthetic phenotype.

TH-PO147

Dapper1, a Wnt-Pathway Inhibitor, Mediates Human Mesangial Cell, TGF-β1-Induced, Apoptosis Daniele Pereira Jardim,[1,2] Alexandre Holthausen Campos.[1] *[1]Experimental Research Center, Albert Einstein Hospital, Sao Paulo, SP, Brazil; [2]Medicine - Nephrology Division, UNIFESP, Sao Paulo, SP, Brazil.*

Background: TGF-β1 promotes extracellular matrix deposition, cell hypertrophy and death, main components of glomerular damage in chronic nephropathies. We detected the upregulation of Dapper1 (Dpr1) in human immortalized mesangial cells (hiMC) in response to TGF-β1.It is already known that Dpr1 negatively modulates the pro-survival Wnt pathway. In addition, Wnt reduces apoptosis of mesangial cells cultured in high ambient glucose. This study aims to investigate the role of Dpr1 in mesangial cell apoptosis promoted by TGF-β1.

Methods: hiMC were treated with TGF-β1 (0.2-2ng/ml) or vehicle for various periods of time (1-24h). Dpr1 overexpression was achieved by means of adenoviral infection. Dpr1 constitutive expression was blocked by siRNA transfection. Apoptosis was evaluated through chromatin morphology (Hoeschst 33342 staining) and caspase-3 activity analysis. For *in vivo* experiments, male Wistar rats (150-200g) underwent subtotal nephrectomy (Nx 5/6), according to methods largely described. After four weeks, remaining renal mass was used for TGF-β1 and Dpr1mRNA expression level analysis by qPCR.

Results: TGF-β1 increases Dpr1 expression in a time- and concentration-dependent manner (peak response at 3h: 3.7x; p=0.00007). Similar TGF-β1 concentrations lead to marked hiMC apoptosis (+2.4x, N=4, $p<0.01$ in the absence of serum). Dpr1 forced expression potentiated serum withdrawal-induced apoptosis (+2.1x, N=6, $p<0.01$). In fact, Dpr1 caused hiMC death even in the presence of 10% serum (+1.5x N=6, $p<0.01$). Dpr1 knock-down significantly decreased apoptosis induced by TGF-β1 (- 1.9x, N=4, $p<0.01$). Dpr1 expression was shown to be increased in samples from Nx5/6 animals (2.7x, N=12, $p<0.02$) and Dpr1 mRNA levels positively correlated to TGF-β1 expression in diseased kidneys ($r^2=0.88$, $p<0.01$).

Conclusions: The collective analysis of our data indicates that Dpr1 is an essential mediator of TGF-β1-induced apoptosis in mesangial cells. Additional studies are underway to better define the influence of Wnt pathway inhibition by TGF- β1 in the pathophysiology of chronic renal diseases.

Gene Expression Profiling of Wild-Type and Progeroid Mice Reveals Pathways Involved in Glomerular Aging Valerie Bartels,[1] Bernhard Schermer,[1] Peter Frommolt,[1] Bianca H. Habermann,[1] Marianne Roodbergen,[2] Jan H.j. Hoeijmakers,[3] Peter Nuernberg,[1] Martijn E. Dollé,[2] Thomas Benzing,[1] Roman-ulrich Mueller,[1] Christine E. Kurschat.[1] *[1]Cologne University, Germany; [2]RIVM Bilthoven, Netherlands; [3]Rotterdam University, Netherlands.*

Background: Due to the worldwide increase in the elderly population prevention and therapy of aging-related diseases such as chronic kidney disease have become important medical issues. One of the factors contributing to renal aging is DNA damage. The Ercc1 protein is a major component of nucleotide excision repair which detects and repairs DNA damage. $Ercc1^{-/\Delta 7}$ mice carry one hypomorphic variant of Ercc1 leading to a progeroid phenotype. To elucidate molecular mechanisms involved in glomerular aging we analyzed gene expression levels of glomeruli from young and old wild-type (wt) and $Ercc1^{-/\Delta 7}$ mice.

Methods: Wt mice were sacrificed at 14 and 96 wks, $Ercc1^{-/\Delta 7}$ mice at 4 and 14 wks. Glomeruli were isolated by a magnetic particle concentrator after kidney perfusion with magnetic beads. Glomerular RNA was reverse transcribed and cDNA was hybridized to Affymetrix microarrays. Statistical, GO enrichment and network analyses were conducted using R/ Bioconductor, DAVID server and NetBox software.

Results: Hierarchical clustering of 521 genes differentially regulated between young and old wt and $Ercc1^{-/\Delta 7}$ mice showed cluster formation between young wt and $Ercc1^{-/\Delta 7}$ and old wt and $Ercc1^{-/\Delta 7}$ samples. There was a significant overlap of 77 genes differentially regulated between both young and old wt and young and old $Ercc1^{-/\Delta 7}$ mice ($p<0.0001$). GO enrichment revealed these genes to be involved in biological functions such as immune and inflammatory response, cell death, and chemotaxis. A network analysis showed that these genes were part of insulin signalling, chemokine and cytokine signalling, and extracellular matrix pathways.

Conclusions: Our findings demonstrate that beyond insulin signalling immune and inflammatory signalling as well as extracellular matrix pathways play major roles in the aging glomerulus. These molecular components can also be found in the progeroid $Ercc1^{-/\Delta 7}$ mouse model which might be a helpful tool for exploring glomerular aging in the future.

TH-PO149

Notch2 Pathway Reactivation Ameliorates Urinary Protein and Glomerular Sclerosis in Adriamycin Nephropathy Mice Eriko Tanaka,[1,2] Katsuhiko Asanuma,[1] Kanae Nonaka,[1] Juan Alejandro Oliva Trejo,[1] Takuto Seki,[1] Rin Asao,[1] Yoshiko Hosoe,[1] Eun-hee Kim,[1] Miyuki Takagi,[1] Hideo Yagita,[3] Yasuhiko Tomino.[1] *[1]Division of Nephrology, Juntendo University, Tokyo, Japan; [2]Department of Pediatrics and Developmental Biology, Graduate School of Medicine, Tokyo Medical and Dental University, Tokyo, Japan; [3]Department of Immunology, Juntendo University, Tokyo, Japan.*

Background: Notch signaling pathway is an evolutionarily conserved intracellular signaling pathway that regulates cell fate. Recently, it has been reported that Notch1 and Notch2 pathways are reactivated in glomerular disease and that Notch1 pathway reactivation correlates with glomerulosclerosis. However, the role of Notch2 pathway reactivation remains unclear.

Methods: We used adriamycin (ADR) nephropathy mice as nephrotic syndrome and focal segmental glomerulosclerosis model. Anti-Jagged1 antagonistic antibody, anti-Notch1 receptor agonistic antibody or anti-Notch2 receptor agonistic antibody was injected intraperitoneally in ADR nephropathy mice simultaneously with ADR. The levels of urinary protein and the ratio of sclerotic glomeruli were evaluated in each group. Next, to elucidate the Notch2 signaling pathway in podocytes, we treated cultured podocytes injured by ADR with anti-Notch2 agonistic antibody. The effect for cytotoxic reduction and the pathways induced by anti-Notch2 agonistic antibody were examined.

Results: Injection of anti-Notch2 agonistic antibody reduced the levels of urinary protein. The ratio of sclerotic glomeruli in ADR nephropathy mice treated with anti-Notch2 agonistic antibody was dramatically decreased. Anti-Notch2 agonistic antibody reduced cell toxicity in cultured podocytes injured by ADR. Phosphorylated Akt was significantly increased by anti-Notch2 agonistic antibody in cultured podocytes injured by ADR.

Conclusions: This is the first report demonstrating that Notch2 reactivation has a role for podocyte recovery and that Notch2 acceleration by Notch2 agonistic antibody ameliorates urinary protein and glomerular sclerosis in focal segmental glomerulosclerosis mouse model, possibly through the Akt pathway. The Notch2 signaling pathway could be a new target for the treatment of glomerular diseases.

TH-PO150

hVps34 Deficiency Reveals the Importance of Endosomal Pathways for Podocyte Homoeostasis Wibke Bechtel,[1] Martin Helmstädter,[1] Bjorn Hartleben,[1] Shuya Liu,[1] Jan Balica,[1] Fatima Hrnjic,[1] Dontscho Kerjaschki,[2] Tobias B. Huber.[1] *[1]Renal Division, University Medical Center Freiburg, Freiburg, Germany; [2]Department of Pathology, Medical University of Vienna, Vienna, Austria.*

Background: Podocytes are critical components of the glomerular filtration barrier and their injury often leads to progressive glomerulosclerosis and proteinuria. Recent functional genetic studies identified the pathological relevance of cytoskeletal-, metabolic- and receptor signalling pathways for the integrity of podocytes. However, the role of endosomal pathways for podocyte function and maintenance remained largely unknown.

Methods: We generated podocyte-specific hVps34-deficient mice to functionally analyse the importance of endosomal pathways for podocytes homeostasis using a Nphs2-cre line. Further analysis on primary podocyte cell cultures was performed after isolation and FACS sorting of GFP-labelled primary podocytes. D. melanogaster virgins of UAS-VPS34RNAi were crossed to prospero-Gal4 for further analysis of a Garland Cell Nephrocyte (the podocytelike cells of Drosophila) specific knockdown of Vps34.

Results: Here we demonstrate that the class III phosphoinositide 3-kinase hVps34 plays a critical role in regulating endocytic pathways maintaining podocyte homeostasis. Podocyte-specific hVps34-conditional knockout mice develop early proteinuria and die within 3 to 9 weeks of age. hVps34 deficient podocytes develop substantial vacuolization and foot process effacement progressing to glomerular scarring and severe proteinuria. Rab5-positive endosomal compartments and autophagosome formation are disrupted at early stages. In addition, endo-lysosomal fusion is inhibited in conditional hVps34 knockout mice. Strikingly, these hVps34 dependent pathways are highly conserved in nephrocytes, the podocyte-like cells of Drosophila.

Conclusions: In summary, these data identify hVps34 as a major regulator of enodolysosomal pathways in podocytes and underline the fundamental role of endosomal trafficking for the maintenance of the glomerular filtration barrier.

PGC-1α Activation Protects against Aldosterone-Induced Podocytes Damage via Regulating Mitochondrial Antioxidant Genes Aihua Zhang, Yanggang Yuan, Songming Huang, Guixia Ding, Min Su. *Nephrology, Nanjing Children's Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: Podocytes are specialized visceral epithelial cells that reside on the glomerular basement membrane (GBM) outside of the glomerular capillaries. It therefore forms the final barrier to protein loss, which explains why podocyte damage is typically associated with marked proteinuria. Previous study has showed that reactive oxygen species (ROS) play a crucial role in the pathogenesis of proteinuria and podocyte damage. This study investigated whether the transcriptional coactivator, peroxisome proliferator activated receptor-g coactivator 1α (PGC-1α), a major regulator of oxidative metabolism and mitochondrial function, prevented podocyte damage by regulating mitochondrial antioxidant genes.

Methods: Podocyte cell line MPC-5 was infected with PGC-1α adenoviral vector and cultured in the presence or absence of Aldo. The expression of mitochondrial antioxidant genes, including superoxide dismutase 2 (SOD2), peroxiredoxin 3 (Prx3) and peroxiredoxin 5 (Prx5) were detected by real time RT-PCR and immunoblotting. Mitochondrial ROS production was examined by mitochondrial specific probe MitoSOX staining.

Results: Aldosterone (Aldo) induced mitochondrial ROS production and decreased PGC-1α expression in a dose dependent manner. Increased PGC-1α levels in podocytes by infection with PGC-1α adenoviral vector prevented Aldo-induced mitochondrial ROS production and podocyte damage. Meanwhile, PGC-1α overexpression increased the levels of mitochondrial antioxidant genes SOD2, Prx3, and Prx5. Finally, suppression of endogenous PGC-1α expression results in the down-regulation of the mitochondrial detoxification machinery.

Conclusions: These results unveiled that PGC-1α was important in regulating mitochondrial antioxidant genes. PGC-1α activation enhanced the expression of mitochondrial antioxidant genes, which then inhibited Aldo-induced mitochondrial ROS production and finally protected against Aldo-induced podocyte damage.

Mitochondrial Dysfunction Is an Early Event in Aldosterone-Induced Podocyte Injury Aihua Zhang, Songming Huang, Yanggang Yuan, Guixia Ding. *Nephrology, Nanjing Children's Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: We previously showed that mitochondrial dysfunction is involved in an aldosterone (Aldo)-induced podocyte injury. Here, the potential role of mitochondrial dysfunction in the initiation of podocyte damage was investigated.

Methods: The dynamic changes of urinary protein, urinary F_2-isoprostane and renal malondialdehyde levels, kidney ultrastructure morphology, mitochondrial DNA (mtDNA) copy number, mitochondrial membrane potential ($\Delta\Psi_m$), mitochondrial complex I activity, and nephrin and podocin expression were detected in Aldo-infused mice and Aldo-stimulated podocyte. Mitochondrial transcription factor A (TFAM) shRNA or adenoviral vectors (Ad-TFAM) was transfected into podocyte to suppression or overexpression of TFAM, respectively.

Results: Aldosterone-infusion first induced renal oxidative stress, as evidenced by increased levels of urinary F_2-isoprostane and renal malondialdehyde, and mitochondrial dysfunction, as demonstrated by reduced mtDNA, $\Delta\Psi_m$, ATP production, and complex I activity. Later, at 5 days after aldosterone-infusion, proteinuria and the decreases of nephrin and podocin began to appear. In cultured podocytes, Aldosterone induced mitochondrial dysfunction after 2–8 h of treatment, whereas the decreased nephrin and podocin expression occurred later after 12 h of treatment. Thus, Aldo treatment both in vitro and in vivo indicated that mitochondrial dysfunction occurred prior to the decreases of nephrin and podocin. Additionally, MtDNA depletion by mitochondrial transcription factor A (TFAM) RNAi induced mitochondrial dysfunction, further promoting podocyte damage. TFAM expression was found to be reduced in aldosterone-infused mice and aldosterone-treated podocytes. Adenoviral vector-mediated overexpression of TFAM prevented aldosterone-induced mitochondrial dysfunction and protected against podocyte injury.

Conclusions: These findings support mitochondrial dysfunction as an early event in podocyte injury, and manipulation of TFAMmay be a novel strategy for treatment of glomerular diseases such as podocytopathy.

TH-PO153

All-Trans Retinoic Acid Inhibits the Fibrotic Effect of TGF-β1 on Renal Tubular Epithelial Cells by Activating Pea3/BMP-7 Signaling Aihua Zhang, Songming Huang, Min Su, Yanggang Yuan. *Nephrology, Nanjing Children's Hospital, Nanjing, Jiangsu, China.*

Background: Renal interstitial fibrosis is the final common pathway that determines the long-term prognosis of chronic kidney diseases. Phenotypic changes in the proximal tubular epithelial cells driven by maladaptive transforming growth factor-β1 (TGF-β1) signaling are crucial to this process. Based on current evidence, all-trans retinoic acid (ATRA),which are natural derivatives of vitamin A, play an important role in renal diseases. Retinoic acids act mainly through nuclear receptors such as retinoic acid receptors (RARs) and rexinoid receptors (RXRs). In this study, we investigated the molecular mechanism of ATRA in the phenotypic changes induced by TGF-β1 in renal tubular epithelial cells.

Methods: Human renal proximal tubular epithelial cell line HK-2 was cultured in the presence or absence of ATRA. **TGF-β1-induced** fibrogenic responses were assessed by the expression of α-SMA, collagen I, CTGF, E-cadherin, and ZO-1. Chromatin immunoprecipitation assays were conducted to detect the interaction of PEA3, RARs, and RXRs with BMP-7 promoter.

Results: ATRA suppressed TGF-β1-induced α-SMA, collagen I, and CTGF expression and blocked TGF-β1-reduced E-cadherin and ZO-1 expression. Interestingly, ATRA regulated and activated the BMP-7 signaling pathway through RARα and RXRα. BMP-7 knockdown abrogated the ATRA-induced inhibition of TGF-β1. Moreover, as with RARα and RXRα, Pea3 mediated ATRA-induced BMP-7 activation, and Pea3 knockdown increased the TGF-β1-induced fibrogenic responses. Conversely, overexpression of Pea3 blocked the effects of TGF-β1 by targeting the BMP-7/Smad1/5/8 signaling pathway. BMP-7 knockdown in Pea3-overexpressing cells also abrogated Pea3-induced inhibition of TGF-β1. Finally, we demonstrated the interaction of RARα and Pea3 with the BMP-7 promoter.

Conclusions: These results suggest that ATRA may directly inhibit TGF-β1-induced fibrogenic responses in HK-2 cells by affecting the RARα/RXRα/Pea3/BMP-7 signaling pathway, which may represent a novel therapeutic target for the treatment of renal tubulointerstitial fibrosis.

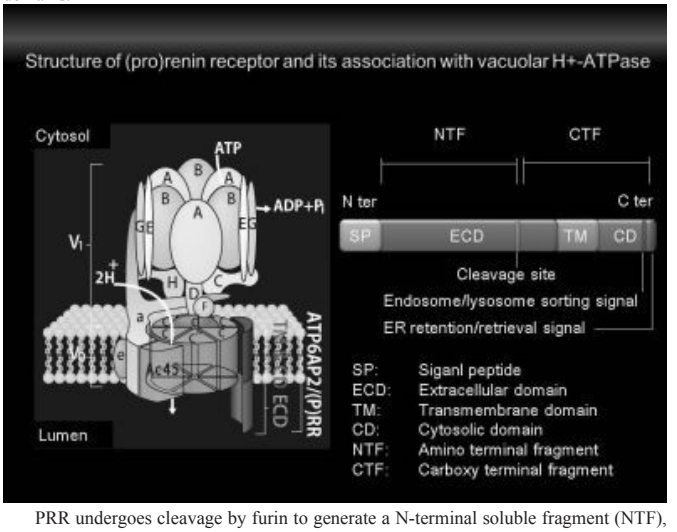
TH-PO154

Structure of (Pro)renin Receptor and Its Association with Vacuolar H^+-ATPase Kenichiro Kinouchi,[1] Atsuhiro Ichihara,[2] Kanako Bokuda,[1] Hideaki Kurosawa,[1] Hiroshi Itoh.[1] *[1]Division of Endocrinology, Metabolism, and Nephrology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan; [2]Department of Endocrinology and Hypertension, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Podocyte specific ablation of (pro)renin receptor (PRR) results in nephrotic syndrome and renal failure due to dysfunction of vacuolar H^+-ATPase (V-ATPase) which maintains intracellular vesicular acidification. The PRR contains four different domains.



PRR undergoes cleavage by furin to generate a N-terminal soluble fragment (NTF), along with a C-terminal residue (CTF). While PRR is essential for assembly of V-ATPase, exact domains that need for V-ATPase assembly remain determined.

Methods: We performed rescue experiments, where several different constructs of PRR were overexpressed in PRR-null mouse embryonic fibroblasts (MEF). Protein expressions of V-ATPase subunits were analyzed in Western Blot analysis. Acidification of intracellular compartments was evaluated by LysoTracker staining.

Results: While PRR-null MEF demonstrated reduced expression of membrane-bound Vo subunits of V-ATPase and decreased staining of LysoTracker, full-length PRR overexpression in PRR-null MEF completely rescued expressions of V-ATPase subunits and LysoTracker staining. Extracellular domain (ECD) and transmembrane domain (TM) overexpression similarly abrogated the reduction of V-ATPase subunits expression and LysoTracker staining, while CTF overexpression failed to cancel these effects. Interestingly, mutant PRR that cannot be cleaved by furin also successfully recovered expressions of V-ATPase subunits and LysoTracker staining.

Conclusions: ECD and TM of PRR are essential for assembly of V-ATPase. Since prorenin binds to ECD of PRR, ECD is not only an important domain as a receptor, but also as an accessory protein of V-ATPase.

TH-PO155

IQGAP1 Mediates Angiotensin II-Induced Apoptosis of Podocyte via ERK1/2 MAPK Signaling Pathway Yipeng Liu,[1] Wei Liang,[1] Qian Yang,[1] Xinghua Chen,[1] Pravin C. Singhal,[2] Guohua Ding.[1] *[1]Division of Nephrology, Renmin Hospital of Wuhan University, Wuhan, China; [2]Medicine, North Shore LIJ Hofstra Medical School.*

Background: Podocyte is an important component of glomerular filtration barrier and plays a pivotal role in proteinuria onset and progression of glomerular diseases. Our previous studies have demonstrated that Ang II is capable to directly promote podocyte apoptosis. However the precise mechanisms of Ang II- induced apoptosis of podocyte deserve further investigation. IQGAP1, as a scaffold protein of the mitogen activated protein kinase signaling pathway, plays a significant role in the process of apoptosis. In the present study, we evaluated the role of IQGAP1 in Ang II-induced podocyte apoptosis.

Methods: Thirty-six male Wistar rats were randomly assigned to receive either normal saline or AngII by osmotic mini-pump, or be used as normal control. The podocyte apoptosis was detected by TUNEL assay at day 14, 28 respectively. In vitro, differentiated mouse podocytes were exposed to AngII at different concentrations for 6h or at 10-8M for variable incubation times. Podocyte apoptosis was assessed by nucleus staining with Hochest-33258 and flow cytometry. The expression of IQGAP1 and phosphorylation of ERK1/2 were analyzed by western blotting. Co-immunoprecipitation was used to evaluate the interaction between ERK1/2 and IQGAP1. IQGAP1 siRNA and U0126 (inhibitor of ERK1/2) were further introduced to investigate the role of IQGAP1 in the process.

Results: Ang II promoted podocyte apoptosis in vivo and in vitro. Under control conditions, IQGAP1 was distributed linearly along the capillary loops in glomeruli, and was located in celluar membrane and cytoplasm in cultured podocyte. Exposure to Ang II stimulated the expression of IQGAP1 and elevated phosphorylation of ERK1/2 in vivo and in vitro. Furthermore, knockdown of IQGAP1 with siRNA obviously prevented Ang II-induced apoptosis of podocyte in vitro and reduced Ang II-induced phosphorylation of ERK1/2, which was accompanied with a lower interaction between ERK1/2 and IQGAP1.

Conclusions: IQGAP1, as an adaptor protein, contributes to AngII-induced apoptosis of podocyte via ERK1/2 signaling pathway.

Block of Par1 Signaling Induces Podocyte Apoptosis In Vitro Mary Gomez,[1] Karen Jorge,[1] Zhongfang Du,[1] Anne Muesch,[2] David Cohen,[2] Katalin Susztak,[3] Kimberly J. Reidy.[1] *[1]Pediatrics/ Nephrology, Albert Einstein College of Medicine, Bronx, NY; [2]Developmental and Molecular Biology, Albert Einstein College of Medicine, Bronx, NY; [3]Internal Medicine/ Nephrology, University of Pennsylvania, Philadelphia, PA.*

Background: Partioning defective (Par1) is a serine threonine kinase that interacts with the complex of Par3/Par6/aPKC to specify cell membrane domains and estabish cell polarity. It has been shown that the apical polarity protein Par3 co-localizes with nephrin at podocyte slit diaphrams and that conditional deletion of aPKC in podocytes resulted in foot process effacement, proteinuria, and focal glomerulosclerosis (FSGS) lesions in mice, suggesting there is a polarity proteins are required to maintain podocyte structure. We have previously identified altered expression of Par1 homologues Par1a and 1b in glomeruli of patients with minimal change disease and focal glomerulosclerosis. We hypothesized the Par1a/b contribute to maintenance of podocytes, and sought to examine their effect on podocytes in vitro.

Methods: Western blot was used to examine for Par1a/1b expression in immortalized murine podocytes. To examine Par1a/1b function in podocytes, differentiated murine podocytes were infected with adenoviral constructs to block Par1 function with a adenovirus expressing a GFP tagged dominant negative Par1 virus. Controls were infected with Adenovirus expressing GFP.

Results: Expression of both Par1a and 1b was identified in immortalized murine podocyes. Block of Par1 by Adeno-DNPar1 led to decreased cell number. Cell quantification at 24 hours revealed a 40% decreased of DNPar 1 cell counts vs. GFP-only infected cells. Increased cleaved caspase 3 was identified in Adeno-DNPar1 infected podocytes as compared to Adeno-GFP controls, suggesting apoptosis contributed to decreased cell survival.

Conclusions: Our results suggest Par1 signaling may contribute to podocyte cell survival.

Inhibition of a Novel p66ShcA Signaling Pathway in Podocytes Prevents Hyperglycemia-Induced Danger Signals and Apoptosis Himanshu Vashistha,[1,3] Pravin C. Singhal,[2] Ashwani Malhotra,[2] Krzysztof Reiss,[3] Leonard G. Meggs.[1,3] *[1]Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [2]Nephrology, Feinstein Research Institute, New York, NY; [3]Neurological Cancer Research, SSSCC, LSUHSC, New Orleans, LA.*

Background: Podocytes are terminally differentiated epithelial cells, that are key target cells in the pathobiology of diabetic glomerulosclerosis (DG), the leading cause of ESRD. A major limitation in the development of innovative strategies to arrest or prevent DG, is the absence of podocyte regeneration, following podocyte loss or apoptosis. Here, we demonstrate cell based gene interventions, targeting the p66 longevity gene, confer a survival advantage in podocytes maintained under hyperglycemic conditions, by preventing the generation of danger signals that trigger apoptosis.

Methods: To inhibit p66, conditionally immortalized differentiated human podocytes (CIDHP) were transfected with p66shRNA or dominant negative p66 expression vector. To simulate hyperglycemia, CIDHP were maintained in serum free media at 40 mM glucose (HG) for 48 h.

Results: In contrast with CIDHP/p66shRNA at HG, empty vector (EV)-CIDHP exhibit a striking increase in apoptosis, in association with robust generation of reactive oxygen species (ROS) and increased levels of angiotensin II (ANG II) in conditioned media. Moreover, signals for p66 and ROS were increased in mitochondria, as was the % of EV-CIDHP undergoing mitochondrial depolarization and cytochrome c release, indicative of the intrinsic apoptosis program. A key role for the prolyl isomerase Pin1, in both HG-induced p66 translocation and p66 redox function in mitochondria, was identified by Pin1 siRNA experiments. Finally, we show p66 is indispensable for the generation of ANG II by podocytes maintained under hyperglycemic conditions, where HG-induced p66 redox signals, activate transcription of p53 dependent genes, including the renin substrate, angiotensinogen.

Conclusions: The activated p66 redox enzyme targets the mitochondrial compartment via Pin1, to increase ROS production and destabilize mitochondria and the nuclear compartment via p53, leading to ANG II generation and podocyte apoptosis.

Funding: NIDDK Support

TH-PO158

Upregulation of Autophagy and Autophagy-Related Proteins in Podocytes in Patients with Minimal Change Nephrotic Syndrome Ayu Ogawa, Hitoshi Sugiyama, Keiichi Takiue, Toshio Yamanari, Masashi Kitagawa, Hiroshi Morinaga, Yoko Kikumoto, Tatsuyuki Inoue, Shinji Kitamura, Yohei Maeshima, Hirofumi Makino. *Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan.*

Background: Autophagy is a cellular process for the bulk degradation of proteins and organelle turnover. The autophagy-related genes (ATG) encode various proteins that are important for the initiation and maturation in autophagosomes. Recent studies have shown the significance of autophagy of tubular epithelium in several renal tubulointerstitial disorders by using transgenic or knockout mice models. However, the role of autophagy in regulating human glomerular diseases is undetermined. This study aimed to elucidate the morphological evidence of autophagy, the expression of autophagy-related proteins, and their association with the clinical parameters in human glomerular diseases.

Methods: The total study population included 41 patients with human glomerular diseases (minimal change nephritic syndrome 12, IgA nephropathy 13, others 16), who underwent renal biopsy. The study investigated autophagy by electron microscopy and the expression of LC3, a mammalian homologue of ATG8, by immunohistochemistry. The relationship between the expression of ATG8 and the clinical parameters was also determined.

Results: The number of autophagosomes and autophagic vacuoles in glomerular cells, especially, in podocytes, was significantly correlated with the degree of proteinuria ($r = 0.35$, $p = 0.03$), and tended to increase along with the decrease in serum albumin levels. The LC3-positive cells colocalized with WT1, a podocyte marker and their number significantly increased in glomeruli in patients with minimal change nephritic syndrome in comparison to those in IgA nephropathy ($p = 0.03$).

Conclusions: The data indicated that autophagy of podocytes may be associated with proteinuria in patients with glomerular diseases. Activation of the mechanism of autophagy, as detected by LC3, may underlie the pathophysiology of minimal change nephrotic syndrome.

Deletion of Scavenger Receptor A Enhances the Autophagy-Specific Lipids Degradation in Podocytes and Renal Tubular Cells via Rho Kinase Pathway Wenjian Wang, Wei Shi, Xinling Liang, Shuangxin Liu, Jianchao Ma, Zhiming Ye. *Division of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Science, Guanzhou, Guangdong, China.*

Background: Autophagy has been identified as a major pathway that delivers damaged proteins, and organelles to lysosomes in order to maintain cellular homeostasis. Our previous study found that scavenger recepor A (SR-A) accelerated progressive nephropathy in high fat diet (HDF) mice by increasing the lipid vacuole formation and decreasing autophagy. However, the role and the mechanism of SR-A involved in the autophagy in the lipid-induced

nephropathy remains unclear. In this study, we hypothesized that SR-A plays a critical role in the progressive nephropathy induced by HFD via its involvement in ROCK-modulating autophagy and autophagy-specific lipid decomposition.

Methods: In vitro, signaling proteins involved in the lipid vacuolar formation and the autophagy in lipid-stimulated HK-2 cells and podocytes were analyzed in the condition of forced-expression or knock-down of SR-A-ROCK. In vivo, SR-A diffiency mice treated with fasudil were used to evaluated the the effects of SR-A/ROCK1 double-blocking on the progression of nephropathy induced by HFD.

Results: Here we demonstrated for the first time that SR-A modulated ROCK activity in oxidative low-density-lipoprotein(ox-LDL)-treated HK-2 cells and podocytes. Furthermore, our data showed that at the cellular level, SR-A-ROCK signal pathway modulateds the lipid vacuolar formation and the autophagy in lipid-stimulated HK-2 cells and podocytes via regulating the phosphorylation of dynamic protein (MLC, Arp-2 and CRMP-2), activation of PIK3/Akt signaling pathway, and the expression of autophgy molecules. Importantly, with a experimental model of lipid-induced kidney disease, we found that double block of SR-A/ROCK markedly meliorates the progression of nephropathy by inhibiting ROCK-mediated lipid vacuolar degeneration and increased autophagy-specific lipid decomposition.

Conclusions: Our data provides a new insight into the pathogenesis of the lipid-induced nephropathy. It hleps to development of novel therapeutic strategies in the prevention of progression of chronic kidney disease.

MiR-21 Upregulation Promotes Podocyte and Tubular Cell Injuries in IgA Nephropathy Hao Bao, Shaolin Shi, Changming Zhang, Yaojun Liang, Weisong Qin, Cai-hong Zeng, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing.*

Background: IgA nephropathy (IgAN) is a common cause of end-stage renal disease with a molecular pathogenesis largely unknown. We found miR-21 is one of the miRNAs that are significantly upregulated in kidney of IgAN patients. We explored the clinical significance of miR-21 upregulation and the role for miR-21 in renal cell injury.

Methods: Glomerular and tubular fractions of renal biopsies were isolated and subjected to qRT-PCR for miR-21. In situ hybridization was employed for miR-21 localization. Conditioned media from mesangial cells stimulated with IgA of IgAN patients and controls were used to treat immortalized human podocyte and HK2 tubular cells. qRT-PCR and western blot were used to for gene expression quantification.

Results: Twenty patients and ten normal controls were enrolled, and miR-21 level was found to be higher in both glomeruli and tubuli of IgAN patients than that of controls, and positively correlated with the levels of urinary protein and serum creatinine, as well as the degrees of glomerulosclerosis and tubulointerstitial fibrosis. Enhanced expression of miR-21 occurred mainly in podocytes and tubular cells. IgAN conditioned media (but not the healthy control) upregulated miR-21 and downregulated nephrin, CD2AP and synaptopodin of the podocytes. IgAN conditioned media also upregulated miR-21 in HK2 cells, accompanied with upregulation of collagen I and fibronectin, and reduced expression of E-cadherin. Overexpression of miR-21 in podocytes and HK2 cells exacerbated the damage of the cells in the treatment of IgAN conditioned media as shown by loss of epithelial morphology, decreased expression of podocyte specific proteins and fibrogenic activation of HK2 cells. While inhibition of miR-21 prevented the decrease of nephrin, CD2AP and synaptopodin in podocytes, attenuated the synthesis of collagen I and fibronectin and preserved E-cadherin in HK2 cells.

Conclusions: miR-21 upregulation may promote both podocyte and tubular cell injuries in IgAN. Inhibition of miR-21 may represent a therapeutic approach for IgAN.

Identification and Characterization of a Novel HIF-1 Target that Regulates Cytokinesis as a Defensive Mechanism against Polyploidy Kumi Shoji,[1] Imari Mimura,[1] Takashi Murayama,[2] Takehiko Wada,[1] Tetsuhiro Tanaka,[1] Takamoto Ohse,[1] Reiko Inagi,[1] Hiroyuki Aburatani,[3] Tatsuhiko Kodama,[3] Masaomi Nangaku.[1] *[1]Division of Nephrology and Endocrinology, University of Tokyo School of Medicine, Tokyo, Japan; [2]Department of Pharmacology, Juntendo University School of Medicine, Tokyo, Japan; [3]Research Center for Advanced Science and Technology, University of Tokyo, Tokyo, Japan.*

Background: Hypoxia plays a crucial role in many physiological and pathophysiological phenomena such as chronic kidney disease, acute kidney injury and cancer biology. Hypoxia inducible factor-1 (HIF-1) is a key transcription factor that regulates adaptive responses against hypoxia.

Methods: We performed genome-wide analysis of HIF-1 targets utilizing microarray analysis in combination with chromatin immunoprecipitation with deep sequencing. We focused one of the new targets, sperm associated antigen 4 (SPAG4). We performed cell biological studies utilizing live cell imaging, flow cytometry, immunocytochemistry, siRNA technique and deletion mutants to investigate SPAG4 function.

Results: We identified 37 new targets of HIF-1, and SPAG4 was selected for a further analysis, of which function remains unknown. We demonstrated that SPAG4 was up-regulated under hypoxia via the hypoxia response element motif in its enhancer. We generated stable transfectants of HeLa cells expressing SPAG4-EGFP, and live cell imaging showed that SPAG4 was localized in nuclear envelop and ER in interphase, and also at the intercellular bridge during telophase. We also examined the localization of truncated forms of SPAG4. The localization suggested SPAG4 involvement in cytokinesis. Flow cytometric analysis showed that hypoxia increased the number of tetraploid cells, and furthermore, knockdown of SPAG4 by siRNA increased the number of tetraploid cells. Microarray analysis using SPAG4 siRNA confirmed the significant involvement of SPAG4-regulated genes in cytokinesis.

Conclusions: In conclusion, we identified SPAG4 as a novel HIF-1 target that plays a crucial role in cytokinesis. It is likely that SPAG4 serves a defensive role against hypoxia-induced polyploidy via regulation of cytokinesis.

New Autophagy Reporter Mice Reveal a Dynamic Autophagy Process in Post-Ischemic Renal Tubules Ling Li,[1] Megan G. Carmody,[1] Zhao Wang,[2] Joseph A. Hill,[2] Fangming Lin.[1] *[1]Pediatrics, Columbia University College of Physicians and Surgeons, New York, NY; [2]Internal Medicine (Cardiology), University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Autophagy is induced in post-ischemic kidneys.

Methods: To study autophagy flux and examine the cell fate of autophagic cells, we used our new CAG-RFP-GFP-LC3 mice, in which RFP and a pH-sensitive GFP were expressed ubiquitously in cells undergoing autophagy. The quench of GFP but persistence of RFP signals in low pH after fusion of autophagosome with lysosome would allow visualization of newly formed autophagic vesicles and identification of autophagic cells.

Results: In control kidneys, no GFP and few RFP signals were detected in the nephron. At 1 day post ischemia-reperfusion injury (IRI), 21% of proximal tubular cells showed both GFP and RFP puncta. However, at 3 days, GFP puncta were detected in 0.9% while RFP puncta were visualized in 18% of proximal tubular cells, suggesting little new autophagosome formation and/or increased fusion of autophagosome with lysosome. Injection with hydroxychloroquine to raise the lysosomal pH led to an increase in GFP puncta that were co-localized with a lysosomal marker LAMP-1, supporting the pH sensitivity of GFP. At 14 days, fluorescent signals in the kidneys were similar to that of controls and were in an agreement with LC3II levels. Furthermore, the presence of RFP correlated with the expression of Atg5, validating the mice as autophagy reporters. Our results also suggest that the persistence of RFP could be used to track cells that had recent autophagy. In proximal tubules, Ki67 expression was significantly lower in RFP^+ cells compared to RFP^- cells (13% vs. 38%, $p<0.05$) at 3 days post IRI, suggesting reduced proliferation in autophagic cells. To understand molecular events that lead to proliferation, we examined mTOR pathways and found increased levels of p-Akt, p-S6 and p-4E-BP1 proteins. Immunostaining showed increased p-S6 expression in proliferating RFP^+ cells.

Conclusions: Our studies indicate that autophagy may render cell cycle arrest and renal repair is accompanied by mTOR activation and resolution of autophagy.

Autophagy Protects Kidney from Metabolic Stress through the Maintenance of Metabolism in Mitochondria Tomonori Kimura,[1] Yoshitsugu Takabatake,[1] Atsushi Takahashi,[1] Tomoko Namba,[1] Takeshi Yamamoto,[1] Jun-Ya Kaimori,[2] Isao Matsui,[1] Harumi Kitamura,[1] Fumio Niimura,[3] Taiji Matsusaka,[4] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Advanced Technology for Transplantation, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [3]Pediatrics, Tokai University, Isehara, Kanagawa, Japan; [4]Institute of Medical Science, Tokai University, Isehara, Kanagawa, Japan.*

Background: Mitochondria are master of energy metabolism, and generate ATP through TCA cycle. Damaged mitochondria are linked to pathogenesis. On the other hand, autophagy degrades damaged mitochondria (this process is specifically called 'Mitophagy'), which involves the sequestrationof mitochondria in a double-membraned autophagosome, followed by fusion with lysosome. We aimed to analyze the role of autophagy in the quality control of mitochondria from the metabolic points of view.

Methods: Metabolic stress was induced in proximal tubule-specific autophagy-deficient mice by treating with cyclosporine A, and histological changes and biological profiles were examined. We also constructed cell lines of immortalized autophagy-deficient proximal tubular cells and their revertants, and examined the effect of autophagy against metabolic stress.

Results: Autophagy-deficiency exaggerates cyclosporine A-induced kidney injury with significant increase in apoptotic cells. Metabolome analysis demonstrated that cyclosporine A induced metabolic stress with abnormal metabolism of TCA cycle in proximal tubular cells, and this stress is further enhanced in autophagy-deficient proximal tubular cells when compared with autophagy-retrieved control cells.

Conclusions: These observations proved our hypothesis that autophagy protects kidney tubular cells against metabolic stress through the maintenance of TCA cycle in mitochondria. Further understanding of autophagy will provide a novel therapeutic approach for kidney diseases.

Albumin Endocytosis Leads to Dysfunctional Autophagy Raymond Yan, Jonathan M. Gall, Steven C. Borkan, John H. Schwartz, Andrea Havasi. *Renal Department, Boston University Medical Center, Boston, MA.*

Background: Proteinuria is a risk factor for chronic kidney disease progression. In addition, exposure of proximal tubular epithelial (PTEC) cells to excess albumin promotes tubular atrophy and fibrosis, key predictors of progressive organ dysfunction. We hypothesize that exposing PTEC to albumin inhibits autophagy, a function responsible for effective turnover of cellular macromolecules and organelles, including dysfunctional mitochondria.

Methods: Autophagy was measured both in suspension of intact tubules and cultured mouse tubular cells exposed to albumin at baseline and during starvation, an autophagy stimulus. To assess autophagy, steady state LC3-II, an autophagy marker was quantified by immunoblot and autophagosomes (AP) were visualized in cells that expressed an LC3-GFP fusion protein. Autophagic flux (accumulation of LC3-II) was measured in the presence of bafilomycin, an H^+-ATPase inhibitor that prevents lysosomal LC3-II degradation.

Results: We show that albumin overload, designed to mimic nephrotic glomerular filtrate, is associated with autophagic and lysosomal dysfunction. Exposure to either recombinant human albumin or fatty acid free bovine albumin decreased LC3-I to LC3-II conversion in a concentration-dependent manner. In the presence of bafilomycin, increased albumin exposure caused a progressive decrease in autophagic flux. Albumin treatment decreased the number of GFP positive AP both in normal media (*basal* autophagy) as well as in starved cells (*induced* autophagy). During 48hr exposure to albumin, large GFP positive structures were observed. In contrast, prolonged albumin exposure (3-5 days) markedly reduced the number of APs. Albumin exposure increased lysosomal pH and decreased lysosomal enzyme activity in PTEC.

Conclusions: These data show that at shorter time points albumin inhibits fusion between AP and lysosomes without impairing the maturation of small autophagosomes into larger structures. Prolonged albumin exposure blocks AP formation and causes lysosomal dysfunction. This inhibition of autophagy and lysosomal function might be a major contributor to renal epithelial cell toxicity caused by albumin overload.

Autophagy Protects Kidney from Diseases through the Reduction of Mitochondrial Reactive Oxygen Species Yoshitsugu Takabatake,[1] Tomonori Kimura,[1] Atsushi Takahashi,[1] Tomoko Namba,[1] Takeshi Yamamoto,[1] Jun-Ya Kaimori,[2] Isao Matsui,[1] Harumi Kitamura,[1] Fumio Niimura,[3] Taiji Matsusaka,[4] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Department of Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Department of Advanced Technology for Transplantation, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [3]Department of Pediatrics, Tokai University School of Medicine, Isehara, Kanagawa, Japan; [4]Institute of Medical Science, Tokai University School of Medicine, Isehara, Kanagawa, Japan.*

Background: Mitochondria can produce intracellular reactive oxygen species (ROS), which sometimes lead to an oxidative damage. Thus, damaged mitochondria are supposed to be degraded by autophagy (or specifically called 'Mitophagy'), which involves the sequestrationof cytoplasmic contents in a double-membraned autophagosome, followed by fusion with lysosome. We aimed to analyze the role of autophagy in the clearance of damaged mitochondria using mitochondria-related kidney disease models.

Methods: Proximal tubule-specific autophagy-deficient mice were treated with mitochondria-damaging drugs (cisplatin and cyclosporine A), and histological changes and biological profiles were examined. We also constructed cell lines of immortalized autophagy-deficient proximal tubular cells and their revertants, and examined the effect of autophagy against damaged mitochondria by assessing mitochondrial ROS.

Results: Autophagy-deficiency exaggerates cisplatin-induced kidney injury with significant increase in apoptosis and DNA damage. This damage is associated with increase in mitochondria ROS in immortalized autophagy-deficient proximal tubular cells when compared with autophagy-retrieved control cells. Cyclosporine A treatment also increased ROS-producing damaged mitochondria in proximal tubule-specific autophagy-deficient mice, and this damage is associated with increase in mitochondria ballooning *in vivo*.

Conclusions: These observations proved our hypothesis that autophagy protects kidney tubular cells from kidney diseases through quality control of mitochondria. Further understanding of autophagy may provide a novel therapeutic approach for kidney diseases.

Funding: Government Support - Non-U.S.

Autophagy Upregulation Reduces Progressive Renal Fibrosis during Unilateral Ureteral Obstruction Cheng Yang,[1] Alexandrea Holmes,[2] Christian Herzog,[1] Sue Theus,[1,2] Judit Megyesi,[1,2] Gur P. Kaushal.[1,2] *[1]Internal Medicine/Nephrology, University of Arkansas for Medical Sciences, Little Rock, AR; [2]Internal Medicine/Nephrology, Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Background: Autophagy is an evolutionarily-conserved and dynamic process of degradation of intracellular organelles and long-lived proteins by lysosomes. The specific role of autophagy in the development of progressive renal fibrosis during chronic kidney disease (CKD) is poorly understood. We used both genetic and pharmacologic approaches to upregulate autophagy and examined the effect of autophagy in accumulation of fibrosis in a unilateral ureteral obstruction (UUO) model.

Methods: We produced proximal tubule-specific beclin-1 transgenic (beclin-I Tg) mice under control of the androgen-inducible KAP2 (kidney androgen-regulated protein) promoter and obtained overexpression of beclin-1 in the proximal tubules.

Results: In wild-type mice, during the progression of UUO injury at 1d, 3d, 5d, 7d, and 9d, a significant increase in the conversion of LC3-I to LC3-II and expression of beclin-1, Atg5, Atg7, and Atg12 as well as production of matrix proteins including collagen type-1, fibronectin, and α-SMA was observed. In beclin-1 Tg mice, there was a corresponding marked reduction in matrix accumulation in the UUO model, indicating beclin-1 overexpression promoted a reduction in matrix proteins. The autophagic-enhancing drug Torin 1, a selective and better inducer of autophagy than rapamycin, was quite effective in reducing renal fibrosis. Inhibition of autophagic flux by chloroquine was unable to reduce UUO-induced accumulation of matrix proteins. Moreover, we observed that autophagic substrates p62 and LC3-II were accumulated during the progression of UUO injury, indicating impaired autophagic flux.

Conclusions: In conclusion, our studies demonstrated that overexpression of the key autophagic protein beclin-1 in the proximal tubule and upregulation of the autophagic pathway markedly reduced renal fibrosis in the UUO model. In contrast, inhibition of the autophagic pathway enhanced matrix protein accumulation. These findings suggest that autophagy is an important therapeutic target in CKD.

Gene Targeting in Renal Collecting Duct Cells Reveals mVPS34 as a Key Determinant of Nephron Number Bo Hu, Jianchun Chen, Jian-Kang Chen. *Nephrology/Medicine, Vanderbilt University, Nashville, TN.*

Background: Nephron number plays an important role in regulation of blood pressure and kidney function. mVPS34 (the mammalian homologue of yeast vacuolar protein sorting defective 34) is indispensable in glomerular podocytes, but its role in renal collecting duct system has not previously been reported.

Methods: We generated an mVPS34-floxed mouse ($mVPS34^{flox/flox}$) and crossed with Hoxb7-Cre mice to produce renal collecting duct cell-specific mVPS34 knockout mice ($mVPS34^{cdKO}$) and compared them with their $mVPS34^{flox/flox}$;Hoxb7-$Cre^{(-)}$ wild type littermates (*WT*).

Results: $mVPS34^{cdKO}$ mice exhibited decreased kidney-to-body weight ratios (0.39±0.17% vs. *WT*: 0.66±0.10%, N=4; P<0.001), without difference in body weight or glomerular size at birth. By 4 weeks of age when nephrogenesis is complete, $mVPS34^{cdKO}$ mice had a strikingly lower number of glomeruli: 24±2 vs. *WT*: 53±5, N=6, P<0.0001 (the totalnumber of glomeruli in 5 randomly chosen fields/kidney section), with drastically thinner renal medulla, and developed glomerular and tubular hypertrophy, proteinuria (Alb/Cr in μg/mg: $mVPS34^{cdKO}$: 278.20±67.27 vs. *WT*: 20.49±2.36, N=6, P<0.01), and elevated BUN (mg/dl: 53.33±8.43 vs. *WT*: 23.75±7.60, N=6; P<0.001). Dilated renal tubules and protein casts were also seen. Immunofluorescence staining with nephron segment-specific markers indicated that tubular enlargement and dilation occurred in the proximal tubule, thick ascending limb, distal tubule as well as collecting duct. Masson's trichrome staining revealed glomerulosclerosis and interstitial fibrosis. Immunohistochemistry confirmed increases in fibronectin and fibroblast-specific protein-1 (FSP1). TUNEL-positive tubular epithelial cells were markedly increased in the collecting ducts, suggesting a potential mechanism underlying the phenotype of low nephron number, defective renal medulla, dilated upstream renal tubules and the subsequent glomerulosclerosis and tubulointerstitial fibrosis, leading to impaired renal function.

Conclusions: This study indicates an essential role for mVPS34 in dictating nephron number and maintaining normal renal structure and function through a mechanism of antagonizing programmed cell death.

TH-PO168

Bif-1 Interacts with PHB2 to Regulate OPA-1 Processing and Mitochondrial Fragmentation during Apoptosis Sunggyu Cho, Zheng Dong. *Department of Cellular Biology and Anatomy, Georgia Health Science University and Charlie Norwood VA Medical Center.*

Background: Mitochondria are highly dynamic, constantly undergoing fission and fusion. During cell stress, mitochondrial dynamics is shifted to fission, resulting in mitochondrial fragmentation that contributes to mitochondrial membrane permeabilization and subsequent cell death. Mitochondrial fragmentation involves the cleavage of both outer and inner membranes. While the outer membrane cleavage involves Drp-1, Fis-1 and mitofusins, cleavage of the inner membrane may involve the regulation of OPA-1. However, the regulation of OPA-1 during mitochondrial fragmentation and apoptotic cell death is largely unknown.

Methods: Here we show that Bif-1 regulates OPA-1 processing via the binding of PHB2 at mitochondria.

Results: Bif-1, originally identified as a Bax-interacting protein, translocated to mitochondria during apoptosis. By yeast-two hybrid and immunoprecipitation pull-down assays, we detected the interaction of Bif-1 with PHB2, a mitochondrial protein implicated in OPA-1 regulation. Functionally, Bif-1-deficient cells were resistant to mitochondrial fragmentation, release of cytochrome c and apoptosis. Interestingly, Bif-1 deficiency did not affect Bax translocation to mitochondria, but inhibited Bax insertion and oligomerization in mitochondrial membrane. Moreover, the proteolytic processing of OPA1 was prevented in Bif-1-deficient cells.

Conclusions: It is suggested that upon cell stress, Bif-1 translocates to mitochondria to interact with PHB2 to induce OPA-1 processing, resulting in inner membrane cleavage, mitochondrial fragmentation, sensitization to Bax insertion and apoptosis.

Mechanical Deformation Induces Apoptotic Induction in Response to Na^+/H^+ Exchanger NHE1 Isoform Downregulation Following ERK Activation and p38 Inhibition Victoria Bocanegra,[1] Andrea Gil Lorenzo,[1] Patricia G. Vallés.[2] *[1]CONICET; [2]Notti Pediatric Hospital-School of Medicine.*

Background: Mechanical deformation following congenital ureteral obstruction is traduced into biochemical signals that represent a key step in the understanding of the mechanisms that leads to the tubular atrophy during obstructive nephropathy.The study included the analysis of Na^+/H^+ isoform 1 exchanger, NHE1, on apoptosis regulation and the signaling pathways associated with NHE1 regulation.

Methods: For cell mechanical deformation,HK-2 (Human Kidney-2) cells were subjected to mechanical stretch which included 15, 60, 90 and 180 minutes of cyclic exposure. Apoptosis was examined with flow cytometry (Annexin V) and protein expression with western blot that included Caspase 3,Bcl2,NHE1,RhoA,ERK 1/2 and p38.NHE1 expression inhibition was assessed with NHE1-siRNA.

Results: when mechanical stretch was applied to HK-2 cells, we observed an apoptosis induction in a time dependent manner with an increase in Annexin V^+ cells, a decrease in Bcl2 and an increase in caspase 3 expression.Apoptotic response to mechanical stretch was associated with a progressive decrease of NHE1.NHE1 expression inhibition with siRNA lead to a subsequent decreased Bcl2 expression and increased Caspase 3 activation. HK-2 cells subjected to mechanical stretch showed progressive RhoA activation,with early activation of ERK 1/2 associated to an opposite p38 expression effect.Treatment with specific MAPKinasas signaling pathway inhibitors increased NHE1 expression by inhibiting p38 pathway with absence of caspase 3 expression,whereas persistent lower NHE1 protein levels and increased Caspase 3 expression were shown after ERK 1/2 inhibition.

Conclusions: Renal tubular apoptosis following mechanical deformation is associated with decreased NHE1 protein expression. Different signaling pathways participate in NHE1 regulation including both RhoA GTPase activation and the opposing actions of the ERK and -p38 MAP kinase signaling pathways as events involved in tubular cell apoptosis induction in response to mechanical injury.

Metformin Inhibits mTOR Pathway Independent of AMPK in HIV-Infected Tubular Cells Partab Rai, Tejinder Singh, Gautam Kishore Valecha, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Patients with HIV infection are living an almost normal life and are increasingly prone to develop obesity and diabetes. Mammalian target of rapamycin (mTOR) pathway has been reported to play an important role in the development of renal lesions in patients with diabetes as well HIV infection. Since metformin is known to alter glucose metabolism as well as known to inhibit mTOR pathway, we hypothesized that metfomin may be an ideal therapeutic agent in HIVAN patients with diabetes mellitus (DM). In the present study, we evaluated the effect of metformin on HIV-induced activation of mTOR pathway in mouse tubular cells.

Methods: Mouse proximal tubular epithelial cells (MPTECs) were transduced with either gag/pol-deleted NL4-3 (HIV/MPTEC) or empty vector (EV/MPTEC). EV/MPTEC and HIV/MPTECs were incubated in media for 48 hours. Immunoblots were probed for phospho-AMPK, phospho-mTOR, S70S6 kinase, phospho-eEF2, eIF4B, and 4EBP-1. To evaluate the effect of metformin on AMPK and mTOR pathway, EV/MPTECs and HIV/MPTECs were incubated in media containing either buffer or metformin (0.5 mM) for 24 hours. Subsequently, cellular lysates were immunoelectrophoresed and probed for phospho-AMPK, phospho-mTOR, S70S6 kinase, phosphor-eEF2, eIF4B, and 4EBP-1. The same blots were stripped and reprobed for actin.

Results: Analysis of mTOR revealed two-fold increase in phospho-mTOR expression in HIV/MPTECs when compared to vector/MPTECs. Further downstream analysis of mTOR pathway revealed enhanced (2.5-fold) phosphorylation of p70S6 kinase and associated diminished phosphorylation of eEF2 in HIV/MPTECs; moreover, HIV/MPTECs displayed enhanced (two-fold) phosphorylation of eIF4B and 4EBP-1. However, HIV/MPTEC did not show any alteration in phospho-AMPK expression. Metformin inhibited HIV-induced mTOR phosphorylation and associated down stream signaling. However, metforimin did not alter phosphorylaion of AMPK in HIV/MPTECs.

Conclusions: Metformin attenuates HIV-induced activation of mTOR pathway independent of AMPK. These observations provide a basis to confirm these findings in experimental animal and human studies.

Epithelial-Mesenchymal Transition of Aging Kidney Were Alleviated by Short-Term Caloric Restriction and Caloric Restriction Mimetics via AMPK/mTOR Signaling Guangyan Cai, Dan Dong, Yichun Ning, Yang Lu, Quan Hong, Shaoyuan Cui, Bo Fu, Xiang-Mei Chen. *Department of Nephrology, State Key Laboratory of Kidney Diseases, Chinese PLA General Hospital, Beijing, China.*

Background: Epithelial-mesenchymal transition (EMT) in aging kidney plays an import role during renal fibrosis, which contributes to declining renal function in the elderly. This study is to investigate whether 8-week short-term caloric restriction (CR) and caloric restriction mimetics (CRMs) alleviates EMT process during kidney aging.

Methods: 25-month-old male Sprague-Dawley rats were divided as control group (fed ad libitum, OAL), AL group (40% food intake restriction, OCR) and metformin treatment group (metformin 300mg/kg/d, OMET). 3-month-old rats were fed ad libitum as young age control (YAL). High glucose (HG) was used to induce premature senescence and EMT in human primary proximal tubular cells (PTC). The effects of CRMs, including resverotrol or metformin, were explored. siRNA technology was used to deplete AMPK to test the role of AMPK-mTOR signaling. Senescence-associated markers were analyzed. P16, P21, E-cadherin, alpha-SMA, ZEB1, AMPK, P-AMPK, mTOR and P-mTOR were detected by western blot or immunofluorescence.

Results: Expression of E-cadherin was decreased, while expression of alpha-SMA and ZEB1 were increased significantly in old kidneys. After treatment for 8 weeks, age related EMT in old kidney was alleviated in aged rats which were subjected to OCR and OMET. Alleviation of EMT in old kidney was associated with up regulation of AMPK and down regulation of mTOR. In vitro study demonstrated high glucose induced both premature senescence and EMT in cultured PTC. CRMs including both resverotrol and metformin decreased the EMT process accompanying with activation of AMPK-mTOR signaling. Silenced AMPK was associated with mTOR over-expression and promoted EMT of senescent PTC. However, protective effect of CRMs on EMT in senescent PTC diminished significantly when AMPK was silenced.

Conclusions: Short-term CR and CRMs alleviated age-related EMT of PTC via AMPK-mTOR signaling, which serves as potential interventions for protecion of renal fibrosis during kidney aging.

TH-PO172

Mannan-Binding Lectin Mediates Mitochondrial Injury, Endoplasmic Reticulum Stress, and Autophagy in Tubular Epithelial Cells Pieter van der Pol,[1] Nicole Schlagwein,[1] Danielle Van Gijlswijk,[1] Hetty C. de Boer,[1] Ingeborg M. Bajema,[2] Cees van Kooten.[1] *[1]Nephrology, Leiden University Medical Center, Leiden, Netherlands; [2]Pathology, Leiden University Medical Center, Leiden, Netherlands.*

Background: Ischemia/reperfusion (I/R) injury is a key event in kidney transplantation. Recently, we demonstrated a crucial role for Mannan-binding lectin (MBL), the initiator of the lectin pathway of complement, in the pathophysiology of renal I/R (*Van der Pol et al. AJT 2012*). In the present study we explored the underlying mechanism of this MBL-mediated tubular injury.

Methods: *In vivo*, rats were subjected to 45 min of unilateral renal ischemia. After 2, 5 or 24h of reperfusion, renal tissue was collected and analyzed for histology, deposition of MBL and expression of ER-stress genes sXBP-1 and CHOP. *In vitro*, human tubular epithelial cells (TEC) were incubated with purified human MBL for 24h and analyzed for sXBP-1 and CHOP expression and conversion of LC-II using Western blot.

Results: Exposure of human TEC to purified MBL *in vitro* resulted in binding and internalization of MBL followed by epithelial cell death. Internalized MBL partially co-localized with mitochondria and affected the mitochondrial membrane potential. Moreover, co-localization of MBL and GRP78, a molecular chaperone involved in the unfolded protein response following endoplasmic reticulum (ER) stress was observed. Therefore, sXBP-1 and CHOP, markers for ER-stress were assessed, demonstrating a twenty- and tenfold induction within two hours of MBL exposure. ER stress is known to induce autophagy, an intracellular self-degradation system, characterized by conversion of LC3-II from LC3-I. Using Western blot, we demonstrated an extensive LC-II conversion within six hours of MBL exposure.

Assessment of rat sXBP-1 and CHOP following I/R *in vivo* revealed an induction of ER-stress within 2 hours following reperfusion, which was accompanied by intra-epithelial presence of MBL, formation of autophagic membrane structures followed by tubular cell death within 24 hours following reperfusion.

Conclusions: These findings demonstrated that MBL affects mitochondrial homeostasis in tubular cells, induces ER-stress and autophagy leading to tubular injury.

TH-PO173

Vitamin D Receptor Plays a Critical Role in p53-Induced Tubular Cell Epithelial Mesenchymal Transition Gautam Kishore Valecha, Nirupama Chandel, Tejinder Singh, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Both p53 and vitamin D receptor (VDR) play important roles in cellular proliferation and apoptosis. We hypothesize that p53 may be modulating tubular cellular epithelial mesenchymal transition (EMT) by modulating VDR expression, renin angiotensin system (RAS) and generation of reactive oxygen species (ROS).

Methods: Human renal proximal tubular cells (HRPTC) were treated with normal glucose (5 mM, NG) or high glucose (30 mM, HG) for 48 hours. Similarly, HRPTC were

transduced with empty vector (EV/HRPTC) or HIV (NL4-3, HIV/HRPTC) constructs. In parallel experiments, HRPTCs were silenced for p53 and VDR by transfecting with respective siRNAs and scrambled (Scr) siRNA. Subsequently, immunoblots were probed for VDR, phospho-p53, markers of epithelial mesenchymal transition (Snail, proliferating nuclear antigen [PCNA], α-SMA, vimentin, fibroblsast specific factor [FSP]-1), and renin. The same blots were reprobed for actin. To confirm the role of p53 and VDR in cross talk, stable colonies of HRPTCs over-expressing p53 and activated VDR were evaluated for above mentioned molecular markers. Tubular cell ROS generation was determined in all the above mentioned conditions.

Results: Both HG/HRPTC and HIV/HRPTC demonstrated enhanced expression of phospho-p53 and down regulation of VDR. Silencing of p53 stimulated tubular cell VDR expression under basal as well as HG/HIV stimulated states. On the other hand, silencing of VDR enhanced expression of phospho-p53 both under basal and HG/HIV stimulated states. HRPTC silenced for p53 displayed normal renin expression but diminished ROS generation; whereas, HRPTC silenced for VDR displayed enhanced renin expression as well as ROS generation. Nonetheless, HRPTC silenced for either p53 or VDR displayed enhanced expression of EMT markers.

Conclusions: These findings suggest that down regulation of p53 and upregulation of VDR contribute to down regulation of ROS generation and enhanced expression of EMT markers; whereas, down regulation of VDR enhanced ROS generation and might have initiated EMT as compensatory feed back to ROS-induced tubular cell injury.

Nek1 Regulates G1: S Transition and DNA Replication in Cell Cycle Mallikarjun Patil, Zheng Dong. *Department of Cellular Biology and Anatomy, Georgia Health Science University and Charlie Norwood VA Medical Center.*

Background: Never in Mitosis Gene A (NIMA) was originally identified in *A Nidulans*. Fungal NIMA regulates G2M phase progression, spindle organization and cytokinesis in cell division. In mammals, there is a family of NIMA-related kinases (NEK1 to Nek11). While several Neks (Nek6, Nek7 and Nek9) regulate mitosis in mammalian cells; Nek1 has been suggested to regulate DNA damage response, centrosome duplication and primary cilium formation. The role of Nek1 in cell cycle regulation is unknown. Nek1 mutant mice develop polycystic kidney disease (PKD) similar to human autosomal dominant PKD, although the underlying molecular mechanism is unclear.

Methods: Here we report that Nek1 is required in G1 phase to S phase transition and DNA replication in cell cycle.

Results: Knockdown of Nek 1 inhibited cell proliferation. Cell cycle analysis revealed more Nek1 knock down cells in S phase. Nek1 knock down cells failed to progress into the S and G2M phase following cell cycle synchronization with thymidine block and release. Renal proximal epithelial cells derived from Kat2J (Nek1 mutant) mice also showed defective S phase. Moreover, chromatin localization of DNA replication factors was compromised in these cells resulting in replication stress. Interestingly, in Nek1 knock down cells the centrosome was organized but failed to duplicate.

Conclusions: These results reveal a new role of Nek1 in G1-S transition and DNA replication in cell cycle.

Atg5-Dependent Autophagy Activation Promotes Aristolochic Acid-Induced Renal Apotposis Ching-chin Yang,[1] Cheng-tien Wu,[1] Chih-Kang Chiang,[1,2] Shing-Hwa Liu.[1] *[1]Institute of Toxicology, College of Medicine, National Taiwan University, Taipei, Taiwan; [2]Department of Internal Medicine, University Hospital and College of Medicine, National Taiwan University, Taipei, Taiwan.*

Background: Autophagy involves a bulk degradation pathway to maintain cellular homeostasis, and is highly conserved during the evolution. Ingestion of aristolochic acid (AA) causes AA nephropathy by inducing apoptosis. AA-induced aristolactam-DNA adducts lead to tubular epithelial cells death via activation of cell cycle arrest. However, the roles of autophagy in the acute phase of AA nephropathy are still unclear. Here we provided evidences that Atg5-dependent autophagy activation is involved in the AA nephropathy both *in vivo* and *in vitro*.

Methods: Male Wistart rats were subcutaneously injected with aristolochic sodium (AANa, 10 mg/kg body weight) or with the solvent (H_2O) for 7 days to ensure the induction of AANa-induced kidney injury. Normal rat kidney epithelial cells (NRK-52E) were pretreated with AANa, and then evaluate the effect of autophagy in AANa-induced tubular apoptosis by western blotting and immunofluorescence (IF).

Results: Renal cell autophagy was proven by the induction of Atg5 and LC3-II expression in the AANa-treated kidney. Punctuated LC3-GFP dots were detected by IF staining, and autophagosome formation was demonstrated by transmission electron. Treatment of AANa (100uM) suppressed the viability of NRK52E. It accompanied by the cleavage of PARP and the condensation and fragmentation of nuclei. In addition, AANa also induced the Atg5 and LC3-II expression, and punctuated LC3-GFP dots IF staining in the NRK52E cells. Pretreated 3-methyl adenine (3-MA), an autophagy inhibitor, attenuated AANa-induced apoptosis as shown by lower expression levels of cleavaged PARP, fewer condensation of nuclei, and lesser negative acridine orange/ethidium bromide staining cells. Furthermore, knockdown of Atg5 by using the short hairpin RNA attenuated the expression LC3-II and PARP cleavage in the NRK52E cells.

Conclusions: In conclusion, we demonstrated autophagy involved in the acute phase of AAN *in vivo*, and Atg5-dependent autophagy activation prompted renal tubular apoptosis.

A Novel In-Vivo Model Displaying Accelerated Senescence in the Mutant AS/AGU Rat Kidney Marc Gingell-littlejohn, Paul G. Shiels, Marc J. Clancy. *University of Glasgow.*

Background: The mutant rat sub-strain (AS/AGU) arose spontaneously as a result of a specific single gene mutation (PKCγ) in a colony of Albino Swiss (AS) rats. PKCγ is a member of an important family of cell signalling molecules with a wide range of functions in various cell types. This knowledge enhances the importance of this strain, as it provides a defined molecular change from which all subsequent physiological and pathological changes derive. The strain was demonstrated to display accelerated bio-ageing in the kidney (Wright et al: unpublished data) and we have subsequently performed glomerular filtration (GFR) and biochemical studies to phenotypically characterise this model.

Methods: 0.2% w/v FITC-Inulin was used for GFR experiments by constant infusion under general anaesthesia. Measurements of fluorescence in the urine of each kidney and plasma at equilibrium provided quantitative data on the filtration process across the glomerulus, which was then calculated according to the equation: *GFR = Urine FITC fluorescence x urine flow rate / Plasma FITC fluorescence* and standardised to 100 grams body weight. Biochemical analysis was performed on separated plasma and urinary samples.

Results: A significant difference was observed in both sodium and urea concentrations between the strains (n=61), with mutant AS/AGU having higher mean urea concentrations (8.67mmol/L vs 7.23mmol/L, p=0.009) and lower mean sodium concentrations (144.7mmol/L vs 146.9mmol/L, P=0.023). There was a proportional increase in GFR with increasing weight of the animal (n=24, p=<0.001) and a significant difference in GFR/100gr body weight between AS and AS/AGU rats in female rats (n=11, p=0.028). The GFR difference between AS and AS/AGU in the total experimental cohort approached significance (n=24, p=0.065).

Conclusions: It is postulated that the PKCγ mutation impairs the sodium-urea counter transporter in the rat inner-medullary collecting duct and in conjunction with the difference in GFR between both strains, confirms the premature senescent genotype of the mutant AS/AGU strain. This strain is a unique and useful model of human diseases of ageing and organ dysfunction in particular, for renal dysfunction and transplant related pathologies.

microRNA:21:dependent Positive Feedback Loop Involving NFkappaB (NFkB) Regulates Renal Cancer Cell Proliferation Amit Bera,[1] Nirmalya Dey,[1] Falguni Das,[1] Balakuntalam S. Kasinath,[1] Hanna E. Abboud,[1] Nandini Ghosh-choudhury,[2] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA, San Antonio, TX.*

Background: Renal cell carcinoma is often resistant to chemotherapy due to upregulation of kinase cascades that promote proliferation and survival of tumor cells. MicroRNAs (miRs) are well suited for regulation of tumor growth because of their capacity to repress mRNA translation. miR-21 is upregulated in renal cancer. Neither the underlying mechanism nor the identification of its downstream targets that force proliferation are known.

Methods: ACHN human renal carcinoma cells were used.

Results: Here we report that the transcription factor NFkB increases the expression of miR-21 in ACHN renal cancer cells (RCCs). Expression of phosphorylation-deficient mutant of p65 NFkB subunit (p65 S536A) inhibited transcription of miR-21. Expression of miR-21 Sponge (Sponge), which quenches endogenous miR-21 level, abrogated phosphorylation of p65, IkB kinase (IKK) and IkB concomitant with attenuation of Akt phosphorylation. Sponge inhibited expression of NFkB target cyclin D1 mRNA and protein. We have previously shown that miR-21 targets and downregulates the tumor suppressor PTEN in renal proximal tubular epithelial cells. siRNA-directed downregulation of PTEN (siPTEN) reversed Sponge-induced inhibition of phosphorylation of these proteins and suppression of cyclin D1, suggesting miR-21 utilizes PTEN for its action. Expression of constitutively active (CA) Akt along with Sponge reversed the Sponge-induced inhibition of phosphorylation of p65, IKK and IkB. Additionally, Sponge increased cyclin kinase inhibitor p27 phosphorylation/inactivation, which was blocked by expression of siPTEN or CA Akt. Moreover, p65 S536A, dominant negative IKK, mutant IkBA3 and Sponge inhibited RCC DNA synthesis. Expression of wild type p65, IKK or CDK4 reversed the Sponge-induced inhibition of DNA synthesis in RCC.

Conclusions: We uncover a positive feed back loop involving miR-21-PTEN-Akt-NFkB, which act in concert with miR-21-PTEN-Akt-p27 to regulate cyclin D1-CDK4 axis driving RCC proliferation.

Anthracycline Inhibits Recruitment of Hypoxia-Inducible Transcription Factors, Blunts the Induction of Lysyl Oxidase and Suppresses Migration of Renal Cell Carcinoma Tetsuhiro Tanaka,[1] Junna Yamaguchi,[2] Kumi Shoji,[2] Masaomi Nangaku.[2] *[1]Division for Health Service Promotion, University of Tokyo, Tokyo, Japan; [2]Division of Nephrology and Endocrinology, University of Tokyo School of Medicine, Tokyo, Japan.*

Background: Anthracycline chemotherapeutic agents of the topoisomerase inhibitor family are widely used for the treatment of various tumors. While targeted tumor tissues are generally situated in a hypoxic environment, the connection between efficacy of anthracycline agents and cellular hypoxia response has not been investigated in depth.

Here, we report that doxorubicin (DXR) impairs the transcriptional response of the hypoxia-inducible factor-1 (HIF-1) in human proximal tubular cells and renal cell carcinoma (RCC) cell lines.

Methods: The hypoxic induction by HIF was measured by luciferase reporter assays. The expression of HIF-1α, HIF-target gene mRNA and protein was quantified by real-time PCR and immunoblotting. Recruitment of HIF-1α to the enhancer was evaluated by chromatin immunoprecipitation (ChIP). Migration of RCC was evaluated by scratch assays.

Results: DXR treatment significantly suppressed the hypoxic induction of HIF-1-target genes, such as glucose transporter 1 and vascular-endothelial growth factor. While there was no quantitative difference in HIF-1α protein between the DXR(-) and DXR(+) groups, ChIP assays revealed inhibition of HIF-1-recruitment by DXR. Notably, this pleiotropic effect was also observed in the HIF-2-mediated hypoxia response and retarded migration of von Hippel-Lindau (VHL)-defective RCC and that of VHL-competent RCC in hypoxia, which was accompanied by a co-ordinated downregulation of HIF target lysyl-oxidase (LOX) family members, such as LOX and LOX-like2. The functional involvement of LOX in RCC migration was confirmed by inhibiting LOX catalytic activity using β-aminopropionitrile.

Conclusions: These findings highlight the impaired hypoxia response by anthracycline agents which counteract the invasive phenotype of RCC, and offer a promising opportunity to develop HIF-inhibitors using DXR as a chemical template.

bcl-7, Caenorhabditis elegans Homologue of Human *BCL7B* Gene, Located at Williams-Beuren Syndrome Locus, Regulates Both Somatic and Germ Cell Division

Tomoko Uehara, Eriko Kage-nakadai, Shohei Mitani. *Physiology, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan.*

Background: *BCL7B* gene is expressed in kidney and located on chromosome 7q11.23, which is the microdeletion region in Williams-Beuren syndrome (WBS). Approximately 50% of patients with WBS have kidney or urinary tract dysfunction including developmental anomaly. It is unclear how loss of function of *BCL7B* causes these anomalies. We found that *bcl-7* (*Caenorhabditis elegans BCL7* gene homologue) deletion mutants had sterile (Ste) and protruding vulva (Pvl) phenotypes. Here, we show *bcl-7* is a regulator of cell division in both somatic and germ cells.

Methods: Firstly, we monitored cell cycle of gonads by immunostaining with an anti-PH3 antibody as a mitotic marker. Secondly, we examined patterns of cell division of somatic stem-like cells, seam cells, with the integrant transgenic worms that expressed green fluorescent protein (GFP) in seam cell nuclei. Thirdly, we searched for suppressor genes of somatic phenotypes of mutants with RNA interference (RNAi) screening.

Results: In germ cells, the mitotic region was maintained about distal 10~15 cell diameters in the adult hermaphrodite gonad of wild type *C. elegans*. In contrast, *bcl-7* deletion mutants have expanded mitotic region in gonads as shown by the anti-PH3 immunoreactivity. As somatic stem-like cells, seam cells divide asymmetrically during each larval stage and have self-renewal property. This characteristic pattern of cell division in seam cells was also seriously damaged in mutants. RNAi screening showed that *bcl-7* as a regulator of somatic cell division has genetic interactions with genes in the Wnt pathway.

Conclusions: We analyzed the functions of *BCL7B* gene homologue, *bcl-7*, and found that it works as the regulator of cell division in both somatic and germ cell line. In addition, as a regulator of somatic cell division, *bcl-7* works possibly through the Wnt pathway. One of the next issues to be solved is whether *BCL7B* gene has the same function and works in the same pathway in human.

TH-PO180

Candidate Action Mechanisms of Peginesatide-Induced Erythropoiesis

Rakesh Verma,[1] Jennifer M. Green,[2] Karen Leu,[2] Peter J. Schatz,[2] Don Wojchowski.[1] *[1]Maine Medical Center Research Institute, Scarborough, ME; [2]Affymax, Inc., Palo Alto, CA.*

Background: Peginesatide is a pegylated, peptide-based erythropoiesis stimulating agent that stimulates the erythropoietin receptor (EPOR) that has recently been approved for the treatment of anemia due to chronic kidney disease in adult patients on dialysis. Peginesatide has been shown to stimulate sustained erythropoiesis in vivo, allowing for once monthly dosing. As a dimeric peptide compound conjugated to a 40 kDa PEG moiety, peginesatide exhibits an increased in vivo half-life (47.9 h) compared to recombinant human erythropoietin (rHuEPO, 7 h). Beyond the extended in vivo persistence, additional unique properties may contribute to peginesatide's durable erythropoietic action.

Methods: To investigate these candidate properties, multi-parametric flow cytometry and Western blotting were utilized to evaluate the effects of peginesatide vs. rHuEPO treatment on erythroid precursor cells.

Results: First, it was found that peginesatide up-modulates cell surface EPOR expression. Specifically, when UT-7/EPO erythroid progenitor cells were cultured in peginesatide vs. rHuEPO, EPOR levels among cells expanded in peginesatide were discovered to be elevated approximately 6 fold. This was observed at varied, functionally matched-doses with ligand replacement. Possible mechanisms for increased EPOR expression include extended peginesatide residence time on the EPOR (1300 min vs. 77 min for rHuEPO), and/or diminished peginesatide-EPOR complex turnover. A second unexpected property was revealed in studies of primary murine bone marrow erythroid progenitor development ex vivo. When used to support erythroid cell expansion, peginesatide promoted an increased expansion of early $cKIT^{pos}CD71^{low}$ erythroid progenitors when compared to rHuEPO. Via multi-parametric flow cytometry, this unique population was identified as $cKIT^{pos}CD71^{low}CD36^{pos}CD13^{pos}$ progenitors.

Conclusions: Peginesatide therefore appears to more effectively recruit early $cKIT^{pos}CD71^{low}$ erythroid progenitors from a myeloerythroid compartment than rHuEPO, possibly due to peginesatide's effect on increased EPOR expression.

Modulation of Epigenetic Factors by HIV-1 in Podocytes Causes Downregulation of P-Cadherin and Nephrin through Upregulation of Snail

Nirupama Chandel, Tejinder Singh, Xiqian Lan, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hoftra North Shore LIJ Medical School, Great Neck, NY.*

Background: Podocytes in HIV-associated nephropathy have been demonstrated to display enhanced expression of Snail, down regulation of p-cadherin, and nephrin. However, the involved mechanism needs to be clearly definced. We hypothesized that HIV-induced epigenetic factors might be contributing to upregulation of Snail and downregulation of p-cadherin and nephrin.

Methods: Immortalized and differentiated human podocytes (IDHPs) were transduced with either empty vector (EV) or HIV (NL4-3) constructs. Both EV/IDHPs and HIV/CIDHPs were de-differentiated (at 33°C). Proteins and RNAs were extracted and probed for Snail, p-cadherin, and nephrin. To determine the role of epigenetic factors, EV/IDHPs and HIV/IDHPs were incubated in media containing buffer, 5-azacytidine (AZAC, a demethylating agent, 5 μM), or suberoylanilide hydroxamic acid (SAHA, a HDAC blocker, 20 μM) for 48 hours. Immunoblots were probed for Snail, p-cadherin, and nephrin. To determine the role of Snail in downregulation of p-cadherin and nephrin, HIV/IDHPs were silenced for Snail as well as stable colonies of IDHPs over-expressing Snail were developed. Renal tissues of four weeks old, control and Tg26 (HIV transgenic mice) in groups of six were evaluated for expression (both protein and mRNA) of Snail, p-cadherin, and nephrin. Renal cortical sections of control and Tg26 mice were labeled for Snail, p-cadherin, and nephrin and examined under an immunofluorescence microscope.

Results: HIV/IDHPs displayed 3-fold enhanced expression of Snail, and 2-3-folds attenuated expression of p-cadherin, and nephrin. HIV/IHDPs silenced for Snail displayed normalization of p-cadherin and nehrin expression. HIV/IDHPs displayed 3-fold increase in DNA methyl transferase (Dnmt)-3 expression; whereas, AZAC inhibited HIV-induced podocyte up regulation of Snail and down regulation of p-cadherin and nephrin. Renal sections of Tg26 mice also revealed upregulation of Snail and downregulation of p-cadherin and nephrin by podocytes.

Conclusions: These findings suggest that HIV-induced epigenetic factors contributie to podocyte damage in HIVAN.

Susceptibility of Podocytes to Palmitic Acid Is Regulated by LXR-Dependent Stearoyl-CoA Desaturases 1 and 2

Jonas Sieber,[1,2] Kapil Dev Kampe,[1] Maja Lindenmeyer,[3,4] Clemens D. Cohen,[3,4] Peter H. Mundel,[2] Andreas Werner Jehle.[1,5,6] *[1]Department of Biomedicine, University Hospital, Basel, Switzerland; [2]Department of Medicine, Massachusetts General Hospital, Boston, MA; [3]Institute of Physiology, University of Zurich, Zurich, Switzerland; [4]Division of Nephrology, University Hospital, Zurich, Switzerland; [5]Department of Internal Medicine, Transplantation Immunology & Nephrology, University Hospital, Basel, Switzerland; [6]Department of Internal Medicine, Kantonsspital Bruderholz, Basel, Switzerland.*

Background: Type 2 diabetes mellitus is associated with elevated free fatty acid (FFA) levels. We reported the antagonistic effects of saturated FFAs (SFAs) and monounsaturated FFAs (MUFAs) for podocyte survival, with SFAs being deleterious and MUFAs protective. Here, we elucidate whether fatty acid metabolism is altered in diabetic nephropathy and whether induction of stearoyl-CoA desaturases (SCDs) can prevent palmitic acid-induced podocyte death.

Methods: Human glomerular gene expression was studied by microarray analysis in patients with diabetic nephropathy and healthy controls. Murine podocytes were used. mRNA levels were quantified by RT-PCR and apoptosis and necrosis by staining with annexin V and PI. Incorporation studies were performed using [^{3}H]palmitic acid and TLC.

Results: Gene expression analysis revealed a significant induction of SCD-1 in diabetic nephropathy. Similarly, palmitic acid upregulated Scd-1 and Scd-2 mRNA in podocytes. The effect of SCDs was investigated by the LXR-agonist TO901317 (TO), a known SCD-inducer. TO induced Scd-1 (2.5x) and Scd-2 (5.0x) mRNA and reduced palmitic acid-induced apoptosis and necrosis by 40% and 30%. Only combined gene silencing of Scd-1 and Scd-2 reverted the TO-effect, indicating a causative role for both SCD-isoforms. In addition, Scd-1-overexpression ameliorated survival of palmitic acid-treated podocytes. Finally, TO shifted palmitic acid-derived FFAs into biologically inactive triglycerides.

Conclusions: These results indicate a protective effect of SCDs on palmitic acid-induced podocyte death. The observed induction of SCD-1 in glomerular extracts of patients with diabetic nephropathy may be part of a protective mechanism against SFAs.

TH-PO183

PDK1 Regulates Apoptosis in Podocytes Pauliina H. Saurus,[1] Mervi Ristola,[1] Moin Saleem,[2] Harry B. Holthofer,[1] Sanna H. Lehtonen.[1] *[1]Haartman Institute, University of Helsinki, Helsinki, Finland; [2]University of Bristol, Southmead Hospital, Bristol, United Kingdom.*

Background: Podocyte injury or loss caused e.g. by cell detachment or apoptosis leads to proteinuria, a hallmark of most glomerular diseases, including diabetic nephropathy. 3-phosphoinositide-dependent kinase-1 (PDK1) activates protein kinase B (PKB)/Akt and many other soluble guanylyl cyclase kinases. Since Akt is known to inhibit apoptosis in other cell types by phosphorylating the Bcl-2 family member Bad or by activating IKKα, PDK1 might promote also podocyte survival by increasing the phosphorylation level of Akt.

Methods: To study the role of PDK1 in podocyte apoptosis, PDK1 was knocked down in cultured human podocytes using lentiviral small hairpin RNA (shRNA) constructs. The apoptotic rate of podocytes was measured by Annexin V staining and flow cytometry. The involvement of phosphatidylinositol 3-kinase/Akt (P13-K/Akt) and p38 mitogen-activated protein kinase (p38MAPK) signaling cascades and the expression levels of proapoptotic BAX and antiapoptotic BCL-2 after knockdown of PDK1 were analyzed by quantitative Western blotting. Further, the expression level of PDK1 in glomeruli of lean and obese Zucker rats was studied.

Results: PDK1 is expressed in rat glomeruli and tubules and in cultured human podocytes. Knockdown of PDK1 increased apoptosis in cultured human podocytes, and inhibited the PI3-K/Akt and activated the p38MAPK pathways. BCL-2 level was decreased and BAX increased in PKD1 knockdown cells. Further, the level of PDK1 was lower in glomeruli of obese Zucker rats compared to lean littermates.

Conclusions: Our data show that PDK1 may protect podocytes against apoptosis. Downregulation of PDK1 in Zucker rat glomeruli might suggest a protective role for PDK1 in the development of podocyte injury.

TH-PO184

Apoptotic Cells Inhibit Proximal Tubular Cell Growth via Activation of AMP-Activated Protein Kinase (AMPK) Vimal Patel,[1] Donald Massenburg,[1] Lanfei Feng,[1] Angelika Antoni,[4] Natalia O. Litbarg,[1] Snezana Vujicic,[1] Joyce Rauch,[2] Wilfred Lieberthal,[3] Jerrold S. Levine.[1] *[1]Medicine, University of Illinois at Chicago, Chicago, IL; [2]Medicine, McGill University, Montreal, QC, Canada; [3]Medicine, SUNY at Stony Brook, Stony Brook, NY; [4]Medicine, Kutztown University, Kutztown, PA.*

Background: Cells undergoing apoptosis acquire new activities that modulate the fate and function of adjacent live cells. We have shown that apoptotic (Apo) target cells inhibit the viability and proliferation of kidney proximal tubular cell (PTC) responders. Here, we examine the effect of Apo targets on PTC responder cell growth (cell size during G1 of cell cycle).

Methods: We used BU.MPT cells, a conditionally immortalized PTC line, as responder cells. BU.MPT cells, induced to undergo apoptosis in several ways, were used as Apo targets.

Results: Apo targets induced dose-dependent inhibition of mTOR (assessed by inhibition of phosphorylation of p70S6K, a direct target of mTOR), as well as concomitant inhibition of cell growth (~30% reduction of cell volume during G1) in BU.MPT responders. Apo targets also activated AMPK in responders, whether in the presence or absence of EGF stimulation. In contrast, necrotic targets had no effect on responder cell growth. Compound C, a pharmacologic inhibitor of AMPK, prevented both inhibition of p70S6K phosphorylation and reduction in cell volume, indicating that Apo target modulation of mTOR and cell growth occurs via AMPK. Notably, AMPK activation occurred via an energy-independent mechanism, as responder cell ATP levels were unchanged. Infection of BU.MPT responders with a constitutively active construct of Akt, which lies upstream of mTOR and is itself inhibited by Apo targets, did not prevent inhibition of cell growth, implying that inhibition of BU.MPT growth is largely AMPK-dependent and induced via a novel signaling pathway, independent of changes in ATP.

Conclusions: These data reveal that Apo targets inhibit cell growth in nearby PTC responders. By acting as sentinels of environmental change, Apo targets may allow nearby viable cells, especially non-migratory epithelial cells, to monitor and adapt to local stresses.

TH-PO185

Dose-Dependent Expression of ApoL1 Protein Sensitizes Cell Death Pathways Zhonghai Chen,[1] Barry I. Freedman,[1] Wayne D. Graham,[1] Nicole A. Ross,[1] Martin R. Pollak,[2] Michael D. Ross,[2] Mariana Murea,[1] Lijun Ma,[1] Peter A. Antinozzi.[1] *[1]Wake Forest School of Medicine, Winston-Salem, NC; [2]Beth Israel Deaconess Med Ctr, Boston, MA.*

Background: Two apolipoprotein L1 gene (*APOL1*) variants associate with non-diabetic kidney disease in African Americans. These non-synonymous variants confer resistance to trypanosomiasis. Whereas ApoL1 has a known role as the trypanolytic factor of human serum, the cellular function of ApoL1 and how specific variants contribute to kidney disease are unknown. Dose-dependent expression of ApoL1 was evaluated to better understand its cellular role.

Methods: Four eukaryotic expression vectors were constructed for the transfection of HEK293, HepaC1C7, and HepG2 cells: (1) control vector (no ApoL1); (2) ApoL1 (reference sequence); (3) ApoL1 G1 (S342G/I384M); and (4) ApoL1 G2 (DN388/Y389). Cell-by-cell analysis of ApoL1 expressing cells was enabled by the co-expression of GFP and an automated high-content cell imaging system. Cell fates were scored by tracking GFP positive cells, propidium iodide (PI) staining and localization of autophagy markers.

Results: Dose-dependent expression of each ApoL1 variant was verified by western blot and immunofluorescence. Time-lapse microscopy was initiated 24h post-transfection and monitored for an additional 24h. Cell survival was assessed by semi-automated scoring of loss of GFP and gain of PI staining. Consistent with ApoL1 alteration of lipid membrane permeability, cell death was increased in a dose-dependent manner with ApoL1 expression (reference sequence). To directly compare the potency of G1 and G2 vs the reference variant, matched levels of protein expression were attained. G1 was the most potent cell death sensitizer (61%), followed by G2 and the reference variant, 52% and 34%, respectively. Confirmation of this order of potencies was re-demonstrated with the fluorescent autophagy marker LC3-RFP.

Conclusions: These data suggest that ApoL1 sensitizes cell death pathways and this may underlie its functional role in kidney disease. G1 and G2 *APOL1* variants have co-evolved with the parasite to protect against human trypanosomal infection. These variants also sensitize cell death pathways and may contribute to kidney disease.

Endothelial-to-Mesenchymal Transition (EndMT) Is a Source for Cancer-Associated Fibroblasts in Renal Cell Carcinoma (RCC) Margherita Gigante,[1] G. Castellano,[2] Paola Pontrelli,[2] Alessandra Stasi,[2] C. Divella,[2] Matteo Accetturo,[2] Giuseppe Grandaliano,[1] Loreto Gesualdo,[2] E. Ranieri.[1] *[1]University of Foggia; [2]University of Bari.*

Background: The progression of tumors towards a malignant phenotype does not depend exclusively on the cell-autonomous properties of cancer cells themselves but it is also deeply influenced by tumor stroma reactivity. In tumors, EndMT is an important source of cancer-associated fibroblasts (CAFs), which are known to facilitate tumor progression. The aim of our study was to investigate whether tumor-derived endothelial cells (TECs) isolated from RCC may be assimilated to CAF phenotype with enhanced migratory capacity and invasiveness.

Methods: We evaluated differences between TEC andendothelial cells (HUVEC)in genome wide gene expression by using a microarray approach. Genes with an FDR≤5% and a fold-change≥2 were considered to be differently expressed. Furthermore, we evaluated the changes of TECs phenotype *in vitro* by using confocal microscopy and flow cytometry. Finally, we analyzed tissue specimens from RCC patients.

Results: The comparison between TEC vs HUVEC, revealed that differently regulated genes were involved in EndMT in TEC. Among these genes, we found FSP1 significantly up-regulatedand CD31 and cadherin-associated proteins significantly down-regulated. Various genes belonging to the TGF-b pathway were modulated (BMP2, NFAT, Wnt/b-catenin). The surface phenotypic analyses confirmed a statistically significant ($p<0.01$) down-regulation of endothelial markers CD31(10%vs98%),VE-cadherin(3.1%vs40,4%), CD105(41%vs96%), CD146(60%vs98%) and up-regulation of mesenchymal markers such as N-cadherin (80%vs18%). We also found a slight but significant ($p<0.03$) increase of CD34(2,1%vs0,3%) and CD133(1,8%vs0,2%) in TEC vs HUVEC. Interestingly, we identified a substantial proportion of CAF in RCC tissue, as a unique population of cells that co-express CD31 along with FSP1 and a-SMA, indicating the occurrence of EndMT in vivo.

Conclusions: These data suggest that EndMT is a relevant mechanism for CAF recruitment to the tumor stroma, probably mediated by TGF-β. These CAFs may have a unique role in RCC progression and invasiveness.

TH-PO187

Sphingosine 1-Phosphate/Sphingosine 1-Phosphate Receptor-3, Potential Mediators of Renal Fibrosis, Are Assessed by siRNA and Scratch Assay Shunji Shiohira, Takumi Yoshida, Junko Kohei, Hidekazu Sugiura, Kosaku Nitta, Ken Tsuchiya. *Department of Medicine Four, Tokyo Women's Medical University, Shinjuku, Tokyo, Japan.*

Background: Sphingosine 1-phosphate (S1P), a bioactive lipid mediator, has been suggested to be involved in the mechanism of renal fibrosis. Previously, we have shown the direct effects of S1P on the fibrotic process in the UUO model using nude mice which were characterized by deficit of immune response. To get more insight into roles for S1P and receptor subtype effects *in vivo*, we performed siRNA knockdown of receptor subtype and wound healing scratch assay.

Methods: NRK-49F (normal rat kidney interstitial fibroblast cells) were stimulated with exogenous S1P and the expressions (mRNA/Western blotting) of a-SMA, E-cadherin, collagen type 1 (COL1), collagen type 4 (COL4), TIMP1 and PAI1 were examined. To specify the kidney specific signal pathway, siRNAs targeted to S1P receptor subtype were generated. Then, the morphological changes of the NRK-49F after stimulation by S1P were examined (3 days, 7 days). The growth and migration of cultured cells was quantified by using CL-Quant software to analyze time-lapse images in a Nikon BioStation CT. The real-time images of cell migration were monitored for 2 days.

Results: S1P stimulated fibrosis of NRK-49F in a dose- and time-dependent manner as previously observed, and induced morphological changes (elongation of the cell shape with spindle-like extension, increased migration) of the NRK-49F. Migration of NRK49F was accelerated and increase in a-SMA, COL1, COL4, TIMP1 and PAI1 expressions and decrease in E-cadherin expression were observed by addition of S1P. In preliminary data, S1PR3(S1Precptor-3) siRNA transfection to NRK-49F attenuated cell growth and migration, in addition, the expression of fibrotic markers was also diminished by S1P stimulation.

Conclusions: These results suggest that activation of S1P signaling mediated by S1PR3 results in chronic pathological fibrosis, such as in chronic kidney disease (CKD).

TH-PO188

Podocyte Derived Expression of Fibronectin Tarunkumar H. Madne,[1] Rachel Lennon,[2] Mysore Keshavmurthy Phanish,[1] Mark Edward Dockrell.[1] *[1]SWT Institute for Renal Research, London, United Kingdom; [2]University of Manchester, Manchester, United Kingdom.*

Background: Cell phenotype and survival are regulated by extracellular matrix proteins (ECM), particularly those of basement membranes. In disease there are changes to the quantity and quality of matrix and basement membrane proteins contributing to the progression of disease. The glomerular basement membrane (GBM) is dynamic structure made up of protein secreted by endothelial cells (EC) and podocytes (Pod); fibronectin (Fn) is an ECM protein in fibrosis but its expression in the GBM and its potential to regulate Pod function is unknown. The interaction of Pod with GBM specifically with Fn could be critical in regulating Pod phenotype & survival. We are investigating the potential of human Pod to produce Fn and regulate its alternative splicing and how, subsequently Fn may alter Pod responses and survival.

Methods: LC –MS/MS was performed on glomerular matrix enriched fraction derived from normal human kidney. Experiments were conducted on conditionally immortalised human Pod incubated with TGFβ1 (2.5ng/ml) for 24-72 h. Fn expression was assessed by RT-PCR, Western blotting (WB) and Immunofluorescence (IF).Cells were also grown on different matrices; including collagen IV (Col IV) and Fn with and without the EDA Exon (EDA+ Fn, EDA –Fn).

Results: Analysis of glomerular ECM by MS shows the presence of Fn potentially derived from both EC and Pod. In culture Pod express Fn and TGFβ1 further induced expression as determined by IF. To quantify the expression, cell lysates were subjected to WB and an increase in both EDA+Fn and EDA-Fn was observed. TGFβ1 regulated the alternative splicing of Fn as evinced by increase in the ratio EDA+Fn to EDA-Fn. On investigating signalling Fn expression was shown to be P38 MAPK dependent. TGFβ1 also induced PI3K activity. Cell grown on Fn had altered morphology and TGFβ1 responsiveness compared to cells grown on plastic or col IV.

Conclusions: Our evidence suggests that human Pod in vivo and in vitro can express Fn and TGFβ1 can induce alternative splicing to produce the pathological isoform EDA+. Pod phenotype appears to be altered by the presence of Fn in culture.

TH-PO189

Phosphorylation of Nephrin Regulates Adhesion of Podocyte by PINCH-1-ILK-Parvin Complex Dongqing Zha,[1] Cheng Chen,[1] Wei Liang,[1] Xinhua Shu,[1] Tean Ma,[1] Pravin C. Singhal,[2] Guohua Ding.[1] *[1]Division of Nephrology, Renmin Hospital of Wuhan University, Wuhan, Hubei, China; [2]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY.*

Background: Nephrin is a signal molecule which transduces signal with its phosphorylation. The downregulation of phosphorylation of nephrin has been demonstrated to correlate with podocyte injury. PINCH-1-ILK-a-parvin (PIP) complex, as an important molecule of focal adhesion, play a crucial role in cell adhesion and cytoskeleton. In this study, we evaluated whether phosphorylation of nephrin influence cytoskeleton and cell adhesion in podocyte via regulation of PIP complex.

Methods: Wistar rats were received either puromycin aminonucleoside (15 mg/100 g) or normal saline via one-time intraperitoneal injection. 24-hour urinary albumin and serum biochemical profile were measured on 0, 1, 4, 7, 14, 28 days after injection. The glomerular morphology and podocyte ultrastructure were observed under the light and transmission election microscopies respectively. In vitro, cultured murine podocytes were exposed to puromycin aminonucleoside pretreated with or without PINCH-1 siRNA or nephrin siRNA or protamin for variable concentrations and time periods. Nephrin and phosphorylation of nephrin expression were analyzed by Western-blotting and immunofluorescence. PIP complex.

Results: Rats injected with puromycin aminonucleoside displayed diminished phosphorylation of nephrin, PIP complex, F-actin gradually, then increased in consistent with glomerular/podocyte injury and proteinuria when compared to control rats. Knockdown of PIP complex protein(using siRNA) resulted in reorganization of cytoskeleton and decreasing of cell adhesion and spreading, but nephrin and phosphorylation of nephrin kept no change. Furthermore, knockdown or overexpression of phosphorylation of nephrin protein(using siRNA or protamin) inhibited or enhanced PIP complex expression, disorganized cytoskeleton of podocyte and decreased cell adhesion and spreading.

Conclusions: These findings indicate that alteration of nephrin phosphorylation disorganized cytoskeleton of podocyte and discreased cell adhesion through a PIP complex-dependent mechanism.

TH-PO190

Elucidating the Role of a Renal Proximal Tubule-Specific Olfactory Receptor Blythe D. Shepard,[1] Lydie Cheval,[2] Alain Doucet,[2] Jennifer L. Pluznick.[1] *[1]Department of Physiology, Johns Hopkins University School of Medicine, Baltimore, MD; [2]Centre de Recherche des Cordeliers, Paris, France.*

Background: Olfactory receptors (ORs) are seven transmembrane domain G protein-coupled chemosensors that detect odorants in the nose. Recently, studies have found that ORs are also expressed and play important functions outside of their native tissue. We previously reported that OR signaling plays a role in the kidney, and that 9 ORs, including Olfr1393, are present in the kidney (PNAS 2009).

Methods: In order to elucidate the role that Olfr1393 plays in the kidney, we examined its localization and ligand profile. To determine its localization, we performed RT-PCR from microdissected renal segments. We determined potential ligands for Olfr1393 using a luciferase reporter assay, as well as a calcium signaling assay.

Results: In microdissected renal segments, we found that Olfr1393 is exclusively expressed in all three proximal tubule segments (S1, S2 and S3, n=3). The majority of ORs, including Olfr1393, are "orphan receptors" with no known ligand. To screen for ligands, Olfr1393 must be expressed on the plasma membrane (PM). However, most ORs are retained in the ER when expressed heterologously. We cloned Olfr1393 and found that it can traffic to the PM in HEK293T when coexpressed with Receptor Transporting Protein (RTP). Using a comprehensive screening approach, we found that Olfr1393 detects cyclic molecules containing either carbonyl or alcohol groups. These ligands were confirmed by Fura-2 calcium imaging. We also found that coexpression of Olfr1393 with RTP allows Olfr1393 to traffic to the surface in in MDCK cells, where it localizes to the apical, *not the basolateral, PM.*

Conclusions: These data suggest that Olfr1393 is expressed on the apical membrane of the proximal tubule where it comes in contact with the newly forming urine to detect molecules containing cyclic carbonyls and/or alcohols. There are a vast array of physiological chemicals that are derived from this basic structure including bile acids, vitamins and steroid hormones. We are currently focusing on defining the full complement of ligands for Olfr1393, and understanding the physiological role that this OR plays in the kidney.

Protein Kinase G and Calcineurin Antagonistically Regulate TRPC6 Activity in Podocytes Gentzon Hall,[1] Janelle Rowell,[2] Rasheed A. Gbadegesin,[1] Peter J. Lavin,[1] Guanghong Wu,[1] David A. Kass,[2] Michelle P. Winn.[1] *[1]Duke University; [2]Johns Hopkins University.*

Background: The emerging role of TRPC6 as a central contributor to various pathologic processes affecting podocytes has generated considerable interest in the development of therapeutic strategies to modulate its function. The development of selective pharmacologic inhibitors of TRPC6 has been hindered by the high degree of sequence homology between TRPC family members. Protein Kinase G (PKG) is now recognized as a potent negative modulator of TRPC6 activity via phosphorylation of 2 highly conserved amino acid residues, threonine 69 (Thr 69) and serine 321 (Ser321). In an effort to characterize the role of PKG in the modulation of TRPC6 activity in podocytes, we evaluated the regulation of Thr69 phosphorylation and dephosphorylation in conditionally immortalized podocytes.

Methods: We examined the role of PKG-mediated TRPC6 phosphorylation at Thr69 using a combination of immunoblotting, immunofluorescence, adenoviral gene expression, and scratch wound healing assays in immortalized mouse podocytes.

Results: In unstimulated podocytes, TRPC6 is heavily phosphorylated at Thr69. This basal phosphorylation is reduced by Ang II, overexpression of a constitutively active calcineurin (Cn), and pharmacologic inhibitors of PKG. Pretreatment of podocytes with the PKG signaling agonists SNAP, 8br-cGMP, Bay 41-2772, and a selective phosphodiesterase 5 inhibitor (PDE5*i*) attenuate Ang II-induced decrease in Thr69 phosphorylation and inhibits TRPC6-dependent podocyte motility by 30-70%. In Ang II-stimulated podocytes overexpressing a phosphomimetic mutant TRPC6, TRPC6-dependent podocyte migration was inhibited by greater than 30%. Finally, the increased basal and Ang II-induced podocyte motility observed in $TRPC6_{P112Q}$ overexpressing podocytes was significantly inhibited by 25% and 55% respectively after pretreatment with 8br-cGMP and PDE5*i*.

Conclusions: In conclusion, PKG and Cn antagonize one another in the regulation of TRPC6 activity in podocytes. These findings further elucidate the complex regulation of TRPC6 activity and highlight the potential value of phosphodiestrase inhibition in the modulation of aberrant TRPC6 activity in podocytes.

p66ScA Deficiency Retards Development of HIV-Associated Nephropathy Andrei Plagov,[1] Partab Rai,[1] Rivka Lederman,[1] Himanshu Vashistha,[1] Mohammad Husain,[2] Ashwani Malhotra,[1] Leonard G. Meggs,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Ochsner Clinic, New Orleans, LA.*

Background: p66ShcA is considered an atypical signal transducer that converts redox reaction into pro-apoptotic signals. On that account, intracellular levels of ROS are decreased in p66ShcAdeficient cells. Therefore, p66ShcA deficient mice have diminished levels of both systemic and intracellular oxidative stress. Recently we demonstrated that tubular cells and podocytes silenced for p66ShcA displayed resistance to HIV-induced injury. We hypothesized that p66ShcA deficit status will provide protection against the development of overt renal lesions in HIVAN mice. in the present study, we evaluated the development of renal lesions in genetically engineered p66ShcA deficient HIV transgenic mice.

Methods: HIV transgenic mice (Tg26) were bred with $p66ShcA^{+/-}$ mice to develop colonies of Tg26 with partial deficit status of p66ShcA. Three groups of animals: FVB/N mice (serving as negative controls of HIVAN), Tg26 mice (serving as positive controls of HIVAN), and $Tg26;p66^{+/-}$ mice (n=4) were studied. Mice were sacrificed at 8 weeks. Blood pressure was measured. Renal biomarkers (blood and urine) were collected; kidneys were harvested for renal histology, immunohistochemistry, immunoblotting and real time PCR studies. Severity of renal lesions was scored on the coded slides.

Results: Tg26 mice displayed elevated BUN levels (FVBN, 38 mg/dl; Tg26, 100 mg/dl, and $p66^{+/-}$;Tg26, 37 mg/dl) and increased proteinuria (albumin: creatinine ratio, FVBN, 51 mg/g creatinine; Tg26, 807.4 mg/g creatinine; and $Tg26;p66^{+/-}$, 109 mg/g creatinine). FVB/N mice did not display any sclerosed glomeruli; Tg26 mice displayed focal segmental sclerosis (FSGS) in 33% of glomeruli and collapsing glomerulopathy in

29% of glomeruli; whereas, Tg26;p66$^{+/-}$ mice showed FSGS in only in 1% of glomeruli and collapsing glomerulopathy only in 6% of glomeruli. These findings indicated that p66 deficient Tg26 mice were resistant to HIV-induced injury.

Conclusions: p66 deficient Tg26 mice displayed resistant to develop overt HIVAN.

Dickkopf Related Protein-1 Inhibits Fibrogenesis by Blocking Multiple LRP-6-Regulated Signaling Pathways in Pericytes and Myofibroblasts

Shuyu Ren, Jeremy Stuart Duffield. *Division of Nephrology, University of Washington, Seattle, WA.*

Background: Fibrosis of vital organs is a major public health problem with limited therapeutic options. Recent studies indicate that mesenchyme-derived pericytes and fibroblasts are the progenitors of scar-forming cells in kidney and other organs.

Methods: - Col1a1-GFP mice
- TCF/LEF:H2B-GFP WNT reporter mice
- Axin2+/lacz WNT reporter mice
- UUO (unilateral ureteric obstruction)
- Unilateral IRI (ischemia reperfusion injury)

Purification of pericyte/myofibroblast from kidneys and study the signaling in vitro.

Results: We observed canonical WNT signaling responses in normal kidney pericytes which were markedly upregulated following kidney injury, during pericyte transition to myofibroblasts. Here we show Dickkopf related protein-1 (DKK-1), a ligand for canonical WNT receptors, Low Density Lipoprotein Receptor-related proteins-5 and -6 (LRP-5, LRP-6), effectively inhibits pericyte activation, detachment and transition to myofibroblasts *in vivo* in response to kidney injury. The consequence is attenuated fibrogenesis, capillary rarefaction and inflammation. DKK-1 also reverses evolving fibrogenesis. DKK-1 blocks activation and proliferation of established myofibroblasts *in vitro*, triggering G1 cell-cycle arrest. DKK-1 blocks pericyte proliferation to platelet-derived growth factor (PDGF), and pericyte migration, gene activation, and cytoskeletal reorganization in response to transforming growth factor-b (TGF-b) or connective tissue growth factor (CTGF). Although DKK-1 affects these responses partly by canonical WNT signaling, it acts dominantly by inhibiting PDGF-, TGFb-, and CTGF-activated MAPK and JNK signaling cascades. LRP-6 is necessary for these responses independently of the canonical WNT pathway, suggesting LRP-6 is a co-receptor for pathways other than WNT. DKK-1 therefore blocks all of the changes in pericytes required for myofibroblast transition, attenuates established myofibroblast proliferation/activation by novel mechanisms dependent on LRP-6, but not the WNT signaling cascade.

Conclusions: DKK-1 is a candidate therapy for evolving fibrogenesis in kidney, and potentially elsewhere.

Transforming Growth Factor-β (TGF-β)-Activated Kinase 1 (TAK1) Plays a Crucial Role in Podocytes

Sung Il Kim,[1] Zhibo Wang,[1] So-young Lee,[1,2] Yan Ding,[1] Mary E. Choi.[1] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Internal Medicine, CHA Medical Center, Seoungnam, Kyunggido, Korea.*

Background: Transforming growth factor-β (TGF-β)-activated kinase 1 (TAK1) is a serine/threonine kinase belonging to the mitogen-activated kinase (MAPK) kinase kinase family. TAK1 is a key intermediate in signal transduction induced by TGF-β or inflammatory cytokines such as tumor necrosis factor-α (TNF-α) and interleukin 1 (IL-1). Although it is well known that these cytokines mediate podocyte injury responses that lead to proteinuria and glomerulosclerosis, the role of TAK1 in podocyte is not yet known. We show that the inhibition of TAK1 in human podocyte abrogated the activation of p38 and JNK MAPK induced by TGF-β1 or lipopolysaccharide, indicating that TAK1 mediates the signal transduction induced by TGF-β as well as by inflammatory cytokines in podocytes.

Methods: To examine the *in vivo role of TAK1, we generated podocyte-specific Tak1 knockout mice (Nphs2-Cre^{+}:Tak1$^{fx/fx}$ herein referred to as Tak1$^{\Delta/\Delta}$).* Effect of *Tak1* deletion in podocytes was analyzed by immunohistochemical and immunofluorescence staining of kidney tissues.

Results: Targeted deletion of *Tak1* in podocytes resulted in approximately 50% perinatal lethality of new born *Tak1*$^{\Delta/\Delta}$ mice and 90% of them died within one week after birth. *Tak1*$^{\Delta/\Delta}$ mice developed proteinuria from postnatal day 1 (P1), and exhibited delayed glomerulogenesis and reduced expression of Wilms' tumor 1 (WT1) and nephrin in podocytes. In addition, nephrin was abnormally distributed in podocytes of *Tak1*$^{\Delta/\Delta}$ mice, compared to *Tak1*$^{fx/fx}$ mice. Intriguingly, *Tak1*$^{\Delta/\Delta}$ mice showed increased expression of vascular endothelial cell growth factor (VEGF) in podocytes and abnormal glomerular microvasculature. Furthermore, 4-week and 7-week old *Tak1*$^{\Delta/\Delta}$ mice also developed increased proteinuria and renal fibrosis as evidenced by enhanced collagen deposition in the mesangium and tubular interstitial area.

Conclusions: Taken together, our data demonstrate that TAK1 plays a crucial role in podocyte differentiation and glomerular microvasculature during kidney development and kidney function through the regulation of the expression of WT1, nephrin and VEGF.

Akt Mediates Albumin Endocytosis via Phosphorylation of Dab2

Elif Erkan,[1] Kenneth R. Hallows.[2] *[1]Pediatrics, University of Pittsburgh; [2]Medicine, University of Pittsburgh.*

Background: Protein kinase B (Akt) is involved in proliferation, cell survival and insulin signaling. We demonstrated that Akt mediates albumin endocytosis in the proximal tubule through its interaction with disabled-2 (Dab2), an endocytic adaptor that binds to megalin. We hypothesized that Dab2 may be a novel substrate of Akt. Our aims were to evaluate phosphorylation of Dab2 by Akt and to examine the physiological relevance of this event by functional studies. Furthermore we aimed to identify the isoform and domain of Akt involved in albumin endocytosis.

Methods: We utilized human kidney proximal tubule cells (HKC-8) to study albumin endocytosis by fluorometry and confocal microscopy. Phosphorylation of Dab2 was examined by in-vitro phosphorylation assays. Dab2 phosphorylation sites Akt were identified and mutated by site-directed mutagenesis. The Akt isoform that is involved in albumin endocytosis was examined by silencing RNA technique. The interacting domains of Akt and Dab2 were investigated by yeast two hybrid (Y2H) method and GST pull-down experiments.

Results: Both Akt1 and 2 were expressed in the proximal tubule where as Akt3 expression was negligible. Silencing experiments revealed redundancy between Akt 1 and Akt2 in albumin endocytosis. Our results showed a diversity in the interaction and phosphorylation sites of Dab2 and Akt. Akt phosphorylated Dab2 at Ser-448-449 residues in the M15 portion (335-610). Dab2 Ser to Ala mutants at these phosphorylation sites reduced albumin endocytosis ($p<0.001$). Y2H and GST-PD experiments revealed that pleckstrin homology (PH) domain of Akt interacts with proline rich domain (PRD) of Dab2 and the minimally sufficient region in Dab2 for interaction with Akt is Dab2-PRD(600-619).

Conclusions: Akt is an important regulator of albumin endocytosis in the proximal tubule. Disabled-2 is a novel substrate of Akt and phosphorylation of Dab2 by Akt is physiologically relevant in Akt mediated albumin endocytosis. We showed a functional redundancy between Akt 1 and Akt2 in albumin endocytosis. We postulate that PH domain of Akt serves as a hub in albumin endocytosis connecting membrane lipids, Dab2 and megalin.

Resveratrol Has Anti-Fibrotic Effect on the Kidney of CKD Rodent via Deacetylating Smad3

Min Zhang, Xinzhong Huang, Chuan-Ming Hao. *Nephrology, Huashan Hospital, Fudan University, China.*

Background: TGF-β/Smad3 signaling plays an important role in the pathogenesis of chronic kidney disease (CKD). Sirt1, an NAD^{+} deacetylase, has been shown to deacetylase transcriptional factors or co-factors. The present study examines the effect of SIRT1 on Samd3 signaling and its role in the progression of CKD.

Methods: Immortalized murine glomerular mesangial cells were used to examine the effect of SIRT1 on TGFß/Smad signaling. 5/6 nephrectomy was used to generate an animal model of CKD. The binding of SIRT1 with Smad3 was assessed with co-immunoprecipitation.

Results: In cultured mesangial cells, TGF-β increased fibronectin and type I collagen expression. Resveratrol (RSV) dose-dependently attenuated TGF-β induced fibronectin and type I collagen expression. Knocking-down Sirt1 using a RNAi attenuated these effects of RSV. Further studies showed that TGF-β increased acetylation levels of Smad3, and RSV significantly down-regulated TGF-β induced acetylation of Smad3. Down-regulation of Sirt1 increased TGF-β-induced Smad3 acetylation, consistent with the deacetylation effect of Sirt1 on Smad3. RSV failed to reduce TGF-β induced phosphorylation of Smad3. Co-immunoprecipitation showed the binding of SIRT1 with Smad3 and this binging was associated with reduced Smad3 acetylation. To examine whether SIRT1 alters Smad3's transcription activity, cells were transfected with a Smad3 transcription reporter construct. TGF-β significantly increased Smad3 transcriptional reporter activity. Sirt1 deletion substantially enhanced TGF-β induced-Smad3 reporter activity (330%). Sirt1 deletion also attenuated the effect of RSV on Smad3 reporter activity. In subtotal nephrectomized rats, RSV significantly reduced urinary protein (79.87±34.27 vs 152.14±30.48 mg/day) and serum creatinine (83±14.69 vs 111.6±21.5 µmol/L) at 12 weeks after the surgery. RSV reduced the acetylation levels of Smad3 in the remnant kidney. Finally, loss of one allele of Sirt1 (Sirt1$^{+/-}$) in mice caused higher proteinuira and higher BUN levels compared with wild type mice following 5/6 nephrectomy.

Conclusions: These results suggest that Sirt1 deacetylases Smad3 and attenuates TGF- β signaling, protecting the kidney from damage in CKD.

Renally-Targeted Activation of Epac1 Reduces Oxidative Stress in Ischemia-Reperfusion Injury

Geurt Stokman,[1] Yu Qin,[1] Sandrine Florquin,[2] Ingeborg M. Bajema,[3] Emile De Heer,[3] Robbert J. Kok,[4] Marie Lacombe,[5] Bob Water,[1] Leo Price.[1] *[1]Toxicology, LACDR, Leiden, Netherlands; [2]Pathology, Academic Medical Center, Amsterdam, Netherlands; [3]Pathology, LUMC, Leiden, Netherlands; [4]Pharmaceutics, Utrecht University, Utrecht, Netherlands; [5]Kreatech Diagnostics, Amsterdam, Netherlands.*

Background: Activation of Epac1, a cAMP-dependent exchange factor for Rap1, by the cAMP analogue 8-pCPT-2'-O-Me-cAMP (8-pCPT) reduced cell detachment during renal ischemia-reperfusion (IR) injury and promoted survival of proximal tubular epithelial cells (PTEC) during exposure to cisplatin. Here we studied whether activation of Epac by 8-pCPT protects against ROS-mediated oxidative stress during renal IR injury.

Methods: Effects of forskolin and 8-pCPT on ROS levels were measured using 5,6-carboxy-DCF-DA conversion and MitoSOX Red labeling. Morphology changes were studied in a 3D cell culture model during diethyl maleate (DEM) exposure. Lysozyme-conjugated 8-pCPT (LZM-8-pCPT) or vehicle was injected intravenously in mice. Renal Rap1 activity was determined by pull down assay. Bilateral renal IR injury was induced for 35 minutes and animals were sacrificed after 1, 24 or 72 hours. Plasma urea and creatinine levels were measured and sections were stained for clusterin-α, active caspase-3, Nrf2, Keap1, heme oxygenase-1 and neutrophils.

Results: Epac activation by 8-pCPT or forskolin decreased ROS production in conditionally immortalized PTEC during in vitro IR injury. Epac activation prevented tubular network disruption caused by DEM in 3D culture. Renal targeting of 8-pCPT by LZM conjugation led to prolonged activation of Rap1 compared to non-conjugated 8-pCPT. LZM-8-pCPT was specifically taken up by proximal tubules and reduced renal failure during IR injury. Epac activation reduced tubular injury, apoptosis, oxidative stress and inflammation during IR injury.

Conclusions: Pharmacological activation of Epac1 reduced oxidative stress in proximal tubules during IR injury. Our data suggest that Epac1 decreases ROS production by preventing mitochondrial dysfunction during IR injury.

Dynamic Change of the Chromatin Conformation in Response to Hypoxia Enhances the Expression of *GLUT3* (SLC2A3) by Cooperative Interaction of HIF1 and KDM3A Imari Mimura,[1,2] Tsuyoshi Inoue,[1,2] Yasuharu Kanki,[2] Hiroyuki Aburatani,[2] Youichiro Wada,[2] Tatsuhiko Kodama,[2] Masaomi Nangaku.[1] *[1]Division of Nephrology and Endocrinology, Univ. of Tokyo, Japan; [2]Laboratory for Systems Biology and Medicine, Research Center for Advanced Science and Technology, Univ. of Tokyo, Japan.*

Background: Hypoxia has a crucial role in chronic kidney disease. We aimed at clarifying a new epigenetic regulation induced by hypoxia.

Methods: Chromatin immunoprecipitation with deep sequencing (ChIP-Seq) is one of the powerful tools to identify the genome-wide binding sites of hypoxia inducible factor (HIF) 1. We performed ChIP-seq and clarified the histone modifications in human umbilical vein endothelial cells. In order to identify downstream targets of HIF1 and KDM (lysine-specific demethylase)3A, a well-known histone demethylase, we performed DNA microarrays using siRNA. Additionally, we performed chromatin conformation capture assay to identify the chromatin structural change under hypoxia.

Results: HIF1 ChIP-seq clarified that HIF1 mainly binds to the intergenic regions distal from transcriptional starting sites under both normoxia and hypoxia. The temporal profiles of gene expression under hypoxia demonstrated that early hypoxia responsive genes are functionally associated with glycolysis including *GLUT3* (glucose transporter 3). HIF1 binds to the promoter and distal enhancers of *GLUT3* and we clarified that the distal HIF1 binding region enhances *GLUT3* expression by changing chromatin conformational structure via HIF1. *GLUT3* expression is reduced under hypoxia when HIF1 or KDM3A is knocked down, suggesting that *GLUT3* is regulated by both HIF1 and KDM3A. We performed ChIP using KDM3A antibody and confirmed that KDM3A is recruited to the enhancer regions of *GLUT3* in a HIF1-dependent manner. On the loci of *GLUT3* enhancers KDM3A demethylates dimethyl-H3K9, repressive mark of histone modifications, in order to up-regulate the expression of *GLUT3* under hypoxia. We also confirmed the endogenous interaction of HIF1 and KDM3A under hypoxia.

Conclusions: These findings provide novel insights into the epigenetic regulation of HIF1 via chromatin conformational change and interaction with KDM3A.

Silencing of the Insulin Receptor Attenuates Cellular Accumulation of Fibronectin in Renal Mesangial Cells Naohiro Yano,[1] Daisuke Suzuki,[2] Masayuki Endoh.[2] *[1]Pediatrics, Women & Infants Hospital, Providence, RI; [2]Nephrology and Metabolism, Tokai University School of Medicine, Isehara, Kanagawa, Japan.*

Background: Inslin receptor and insulin signaling proteins are widely distributed throughout the kidney cortex. The insulin signaling can act in the kidney in multiple ways, some of which may be totally independent of its primary role of the maintenance of whole-body glucose homeostasis. However, descriptions of the insulin signaling in the mesangial cells (MCs) are quite limited and the roles of insulin signaling in MC functions have not been sufficiently elucidated.

Methods: Stable trasfection of gene specific single hairpin (sh)-RNA was used to silence InsR expression in MCs. Activities of kinases and expression of related proteins were evaluated by western blotting, in vitro PI3K assay, Ras pull-down assay, immunoprecipitation and RT-PCR. Genetic and pharmacological manipulations were employed to modify signaling pathways.

Results: InsR silencing induced a unique phenotype of reduced fibronectin (FN) accumulation in renal glomerular MCs. Transcription level of FN showed no significant changes in the InsR silenced cells, suggesting the phenotype switching was caused by post-transcriptional modification. The decreased expression of InsR was associated with enhanced activity of insulin-like growth factor-1 receptor (IGF-1R)/PI3K/Akt signaling pathway which contributed in part to the attenuation of the cellular FN accumulation. Formation of IGF-1R homodimer was increased in InsR silenced cells. InsR silenced cells also showed increased sensitivity to exogenous IGF-1, and increased PI3K activity was reversed significantly by incubating cells with IGF-1R specific antagonist, AG538. PI3K/Akt dependent activation of cAMP response element-binding protein (CREB)-1 induced expression of matrix metalloproteinase (MMP)-9 and suppressing MMP activity by doxycycline partially reversed FN accumulation in InsR silenced cells.

Conclusions: Effects of InsR silencing on cellular FN accumulation are, at least partially, mediated by increased degradation of FN by MMPs which is induced by enhanced signaling sequence of IGF-1R/PI3K/Akt/CREB-1.

TonEBP Stimulates NF-κB via Direct Interaction and Promotes Inflammatory Action of TLR2 and 4 Satoru Sanada, H. Moo Kwon. *Division of Nephrology, University of Maryland, Baltimore, MD.*

Background: TonEBP (Tonicity-responsive enhancer binding protein) enables cellular adaptation to hypertonic stress by stimulating transcription of its target genes. Under isotonic conditions, however, TonEBP is involved in the pro-inflammatory gene expression following TLR2 and 4 (Toll-like receptors 2 and 4) ligation. We hypothesize that TonEBP stimulates nuclear factor-κB (NF-κB) by direct interaction and recruitment of its powerful transactivation domains. Stimulation of NF-κB contributes to the pro-inflammatory action of TonEBP.

Methods: Protein interaction was analyzed by co-immunoprecipitation assays. NF-κB activity was assessed by reporter assays and quantitative PCR analyses of its target gene mRNAs.

Results: TonEBP and p65 co-immunoprecipitated in both directions demonstrating their interaction, which was maintained when they were expressed from cDNA constructs. Analyses of various recombinant constructs revealed that the interaction was between RHDs (Rel-homology domain = DNA binding domain) of TonEBP and p65. TonEBP lacking RHD (TonEBPdRHD) did not stimulate NF-κB. On the other hand, TonEBP lacking C-terminal quarter of RHD (TonEBPdIPT) retained the ability to stimulate NF-κB along with its ability to interact with p65, even though it lost TonEBP activity. Fusion of the TonEBP transactivation domains to p65 resulted in a dramatically higher transcriptional activity suggesting that recruitment of the TonEBP transcriptional domains led to stimulation of NF-κB. MEF cells established from mice homozygous for a deletion mutant in which C-terminal third of TonEBP was deleted in-frame displayed dramatically reduced NF-κB activity in association with reduced interaction between the mutant TonEBP and p65. Taken together, the data provide a strong support that TonEBP directly stimulates NF-κB by bringing its powerful transactivation domains.

Conclusions: TonEBP stimulates the transcriptional activity of NF-κB through direct interaction. Since TonEBP is a critical regulator in inflammatory diseases such as rheumatoid arthritis and atherosclerosis, we propose that TonEBP is a central regulator in inflammation due to its action on NF-κB.

In Vivo Knockdown of TRPV4 Decreases Flow-Induced NO Production in the Thick Ascending Limb Pablo D. Cabral, Jeffrey L. Garvin. *Internal Medicine-Hypertension and Vascular Research Division, Henry Ford Hospital, Detroit, MI.*

Background: Nitric oxide (NO) is a potent regulator of blood pressure and renal function. In the thick ascending limb it inhibits sodium chloride transport. Transient receptor potential vanilloid 4 (TRPV4), a member of the TRPV family of cation channels, is activated by luminal flow in different types of cells. We have previously shown that luminal flow stimulates NO production in this nephron segment. Thus, we hypothesized that TRPV4 mediates flow-induced NO production in the thick ascending limb.

Methods: To test this hypothesis we examined the effect of reducing and enhancing TRPV4 activity by using: 1) the selective TRPV4 antagonist RN 1734; 2) an adenovirus-delivered TRPV4 small hairpin (sh) RNA; and 3) the selective TRPV4 agonist GSK1016790A on NO production in the absence and/or presence of luminal flow. The NO-sensitive dye DAF FM was used to measured NO production in isolated and perfused thick ascending limbs from Sprague Dawley rats.

Results: Increasing luminal flow from 0 to 20 nL/min stimulated NO production from 8 ± 3 to 45 ± 12 arbitrary units (AU)/min ($p<0.05$, $n=5$). In the presence of the TRPV4 selective antagonist RN 1734 (10 μM) flow did not increase NO production (from 11 ± 7 to 9 ± 2 AU/min, $n=4$). In the absence of luminal flow, activating TRPV4 using the TRPV4 selective agonist GSK1016790A (10 ηM) increased NO production 118 ± 52 % ($n=5$). We next tested whether decreasing TRPV4 expression blocks flow-induced NO production. Three days after in *vivo* delivery of an adenovirus expressing TRPV4 shRNA to the outer medulla, TRPV4 protein expression was decreased by 50 ± 5 % in thick ascending limbs lysates as measured by Western blot. Flow did not increase NO production in thick ascending limbs from TRPV4 shRNA transduced kidneys (26 ± 29 %, $n=5$).

Conclusions: From these data we conclude that TRPV4 activation mediates flow-induced NO production in the thick ascending limb.

ANGPTL4, a Mediator of Nephrotic Syndrome, Is Induced through a HIF1 alpha-PPAR beta/delta Axis under Hypoxia Tsuyoshi Inoue,[1,2] Imari Mimura,[1] Takahide Kohro,[2] Hiroyuki Aburatani,[2] Tatsuhiko Kodama,[2] Youichiro Wada,[2] Masaomi Nangaku.[1] *[1]Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan; [2]Laboratory for Systems Biology and Medicine, University of Tokyo, Tokyo, Japan.*

Background: Angiopoietin-[zwj]like 4 (*ANGPTL4)* has drawn attention as a cause of minimal change nephrotic syndrome recently, but the mechanism of this gene induction has not been elucidated yet. ANGPTL4 regulates vascular permeability, lipid metabolism, and glucose metabolism.

Methods: We used epigenetic methods including Chromatin Immunoprecipitation (ChIP) assay with deep sequencing (ChIP-seq) analysis of HIF1α, PPARβ/δ, PolII and H3K27ac, and Chromosome Conformation Capture (3C)-PCR assay to dissect the molecular mechanism of HIF1α dependent gene expression.

Results: *ANGPTL4* is the most markedly induced gene extracted by microarray analysis (20.1-fold change) of human umbilical vein endothelial cells (HUVEC) under hypoxia (1%O_2 for 24h) vs normoxia. As *ANGPTL4* is also known to be induced by peroxisome proliferator-activated receptors (PPARs), we investigated the presence of crosstalk between PPARβ/δ and HIF signaling axes. Synergistic activation of *ANGPTL4* by PPARβ/δ ligand (GW501516) plus hypoxia was observed with HUVEC by quantitative RT-PCR (124 % higher than the additive) and this was also confirmed by reporter assay. The combination of ChIP-seq and reporter assay identified the functional hypoxia responsive element (HRE) and PPAR responsive element (PPRE) in the promoter and intron regions of *ANGPTL4*. In addition, 3C-PCR assay showed that spatial proximity of two responsive elements induced by two stimuli could be the molecular background of additive transcriptional induction, supported by temporal profile of acetylation of H3K27, the active enhancer marker in *ANGPTL4.*

Conclusions: These results imply that hypoxic and PPARβ/δ stimulations are important for activation of *ANGPTL4* transcription, and the synergistic activation is achieved by spatial proximity formation in *ANGPTL4 loci.*

Endoplasmic Reticulum Stress Induces Fibrogenesis by Activating C/EBP Homologous Protein (CHOP) Gang Li, Yordanka Ivanova, Meghan Clements, Steven R. Ledbetter, Anna Zuk. *Tissue Protection and Repair, Genzyme-Sanofi R&D, Framingham, MA.*

Background: Tubulo-interstitial fibrosis is a prominent feature of chronic kidney disease and is closely associated with progression to end-stage renal disease. Recent studies implicate tubular injury in facilitating fibrogenesis, yet the cellular mechanisms are incompletely understood. Using ischemic and nephrotoxic mouse models of acute kidney injury, we first show that the unfolded protein response (UPR), including IRE1α, ATF6 and CHOP, are markedly induced with tubular damage and renal dysfunction. However, CHOP induction, but not the other two UPR branches, correlates with progression of kidney fibrosis. Therefore, we examined how epithelial injury contributes to fibrogenesis and the effect of ER stress in mediating this process. Using in-vitro ATP depletion-repletion and toxin epithelial models to recapitulate tubular injury in vivo, we observed that epithelial injury induces ER stress, which causally leads to a fibrogenic response. Induction of pro-fibrotic and pro-inflammatory cytokines is significantly suppressed when CHOP expression is inhibited by siRNA, providing direct causal evidence that CHOP is a mediator of this response. Moreover, these cytokines are induced in a calcium- and IP3R-dependent manner in injured epithelial cells, indicating the role of CHOP-mediated ER calcium release in fibrogenesis. In support of the role of ER stress in mediating fibrosis, we also show that conditioned medium from the stressed epithelial cell promotes fibroblast activation, and this effect is markedly inhibited when epithelial CHOP expression is suppressed by siRNA. These data provide new insight into how ER stress in general, and the CHOP branch in particular, contributes to fibrogenesis. These findings suggest that interventions targeting CHOP and its subsequent downstream signaling may provide new opportunities to prevent kidney fibrosis.

A Protective Role for Extracellular Superoxide Dismutase in Adriamycin Nephropathy Roderick J. Tan,[1] Ying Li,[2] Li Li Zhou,[2] Tim D. Oury,[2] Youhua Liu.[2] *[1]Dept of Medicine, University of Pittsburgh, Pittsburgh, PA; [2]Dept of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Development of an effective therapy for chronic kidney disease (CKD) remains elusive, emphasizing the need for a greater understanding of its molecular pathogenesis. Current evidence suggests a role for oxidative stress (the imbalance between reactive oxygen species and antioxidants) in the progression of CKD. Extracellular superoxide dismutase (EC-SOD) is an antioxidant enzyme abundant in normal kidney whose role is to scavenge the superoxide free radical. Based on its unique extracellular localization, we hypothesized that EC-SOD plays a protective role against CKD and that EC-SOD is depleted from the kidney in disease states, ultimately leading to increased oxidative stress and renal damage.

Methods: To study CKD, we utilized a mouse model of adriamycin nephropathy, which recapitulates focal segmental glomerulosclerosis. After exposure to adriamycin via a single tail vein injection, mice were euthanized at various timepoints and kidneys recovered for RNA, protein, and histologic analysis. Serum and urine were collected for creatinine and albuminuria analysis, respectively. Homozygous EC-SOD null mice were similarly exposed to adriamycin and samples recovered for disease severity analysis.

Results: During the development of adriamycin nephropathy, we found that levels of EC-SOD were significantly decreased as early as one week after exposure to adriamycin. Depletion of this antioxidant was associated with development of disease as well as with increases in oxidative stress markers. To definitively assess EC-SOD's role in adriamycin nephropathy, we exposed homozygous EC-SOD null mice to injury. Null mice had significantly greater levels of albuminuria, serum creatinine, and histologic injury compared to wild type controls.

Conclusions: Depletion of EC-SOD from the kidney appears to be a pathologic mechanism underlying adriamycin nephropathy. Loss of EC-SOD is associated with progression of disease and measurable increases in oxidative stress. Complete absence of EC-SOD leads to increased disease severity, indicating that it plays a critical role in the pathogenesis of adriamycin nephropathy.

Involvement of NADPH-Derived Reactive Oxygen Species in the Down-Regulation of Na/K-ATPase in Chronic Kidney Disease Yu Wang, Liqiang Meng, Lei Qu, Jiawei Tang, Xiaomei Li. *Renal Division, Dept. of Medicine, Institute of Nephrology, Beijing, China.*

Background: The Na/K-ATPase contributes to sodium reabsorption of kidneys by regulating transcellular Na transport. The purpose of this study was to observe the changes of Na/K-ATPase expression under CKD status and the possible involvement of NADPH-derived ROS in this particular regulation.

Methods: Renal biopsy specimens of CGN patients were studied. UUO model was made in male Wistar rats and apocynin 100ug/kg was administered by oral gavage once daily. The expression of NOX2, NOX4, p22-phox and a1 Na/K-ATPase in obstructed kidneys were detected by Western blot. LLC-PK1 cells were treated with glucose oxidase.

Results: 28 CGN patients with different eGFRs were studied. Compared to normal kidneys, the tubular expression of a1 Na/K-ATPase (percentage of positive area) in CKD patients was significantly decreased [2.1% (0.5%-6.2%) vs. 5.6% (3.5%~10.8%), P=0.003]. Consecutive staining and double immunofluorescence staining of both a1 Na/K-ATPase and aquaporin 1 suggested that the decrease of a1 Na/K-ATPase was mostly derived from proximal tubules. Furthermore, semi-quantification of a1 Na/K-ATPase staining was positively correlated with the urinary sodium excretion of those patients (r=0.551, p=0.002). There was also decreased staining of a1 Na/K-ATPase in UUO rats. Western blot confirmed the early down-regulation of a1 Na/K-ATPase at 24 hours after surgery ($p<0.01$). Meanwhile, there was increased expression of NOX2 (1.00±0.20 vs 1.45±0.42, $p<0.05$), NOX4 (1.00±0.31 vs 1.99±0.54, $p<0.01$) and p22-phox (1.00±0.17 vs 1.29±0.11, $p<0.05$), which was inhibited by 33%, 40% and 30%, separately, with the treatment of apocynin. Simultaneously, the decrease of the Na/K-ATPase expression was significantly prevented, as compared to UUO group (0.96±0.07 vs 0.69±0.05,$p<0.01$). Glucose oxidase treatment induced endocytosis of cell surface Na/K-ATPase and down regulated the Na/K-ATPase protein levels in cultured LLC-PK1 cells (1.00±0.00 vs 0.85±0.06,$p<0.01$).

Conclusions: Na/K-ATPase is down-regulated in CKD. ROS, at least partly derived from NADPH, may participate this regulation.

Renal GABA Prduction, Release and Locally-Functional GABA Signaling in Rodents Junichi Yatabe,[1] Midori Sasaki Yatabe,[1] Kozue Takano,[1] Tsuyoshi Watanabe,[1] Robin Allen Felder,[2] Pedro A. Jose,[3] Hironobu Sanada,[4] Junko Kimura.[1] *[1]Fukushima Med. Univ., Japan; [2]Univ. of Virginia; [3]Univ. of Maryland; [4]Fukushima Welfare Federation of Agricultural Cooperatives, Japan.*

Background: Gamma-aminobutyric acid (GABA) administration induces natriuresis and lowers blood pressure. However, the mechanism has not been fully elucidated. Therefore, the GABAergic system and a possible local GABA signaling in the kidney were examined.

Methods: Distribution of GABA-producing enzyme (GAD67) was observed using GAD67-EGFP hetero knock-in mice. Urinary and plasma GABA was measured by HPLC. GABA release from kidney slices were assayed using immobilized enzyme-linked photoanalysis. GABA receptor expressions were detected by RT-PCR, immunoblotting and immunostaining. GABA(B) signaling was assayed by phospho-MAPK detection.

Results: GAD67-EGFP fluorescence was observed in the kidney cortex, with stronger signal in young (4-days old) compared to old (6-months old) mice. GABA concentration in rat urine was approximately 100 times that of plasma. Real-time GABA imaging revealed GABA release from kidney slices in responses to Ang II and dopamine. These suggest GABA production and regulated secretion in the kidney. As for GABA receptors, GABA(A) α1, β3 and π subunits, GABA(B) R1, R2 subtypes and GABA(C) ρ1, ρ2 subunits were found in rat renal cortex. In cultured rat mesangial and proximal tubule cells, GABA(A) α1 expression was approximately 1000 times higher in proximal tubule cells, and GABA(A) α3 expression was approximately 16 times higher in mesangial cells. Both types of cells also expressed GABA(B) R1 and R2. Response downstream of GABA(B) receptor was confirmed in proximal tubule cells, as baclofen, a GABA(B) receptor agonist, phosphorylated p42/44 MAPK in a time- and dose-dependent manner.

Conclusions: The results show the existence of a unique set of GABAergic system components in the kidney with characteristic expression patterns in different renal cell types. Locally-produced GABA may regulate ion transport or renal hemodynamics to modulate blood pressure in a paracrine/autocrine fashion.

TH-PO207

Alterations of Oxygen Metabolism in Pathophysiology Prabhleen Singh,[1,2] Hai Pham,[2] Susanna Petrosyan,[1] Guy Perkins,[1] Weylin Wagnon,[1] Joseph Satriano,[1,2] Joseph Cameron Finley,[1,2] Sameh Ali.[1,2] *[1]UCSD; [2]VASDHS.*

Background: The kidney exhibits a high rate of oxygen consumption (QO2) and oxidative metabolism. Early in remnant kidneys, compensatory adaptations like hyperfiltration and hypertrophy can increase QO2. We examined the the alterations in QO2 and mitochondrial function in early subtotal nephrectomy (STN) and the impact of hypoxia inducible factor (HIF-1α) activation in STN.

Methods: In 1-week STN rats, renal blood flow (RBF), GFR, whole kidney QO2 along with mitochondrial QO2, reactive oxygen species (ROS) generation by electron paramagnetic resonance (EPR) and morphology by electron microscopy was examined. AMPK activation in the STN kidney and markers of cellular hypertrophy, autophagy and apoptosis were also examined. Finally, effects of HIF-1 α induction by dimethyloxaloylglycine (DMOG) treatment was examined. Data presented as mean±sem.

Results: Whole kidney QO2 factored for GFR was elevated in STN (0.08±0 vs. 0.05±0 ml/min, p=0.03), despite lower RBF and GFR. Mitochondrial QO2 in STN showed elevated State3ADP, State4oligomycin, and State3u rates (p<0.01). EPR revealed high ROS production in STN in state 3 (212±10 vs. 148±4 a.u., p=0.001) and state 4 (232±12 vs. 173±4, a.u., p=0.003). Morphological analyses revealed no differences in mitochondrial lengths, but fewer mitochondria (0.34±01. vs. 0.72±0.1 sq.microns, p=0.001) and mitochondrial volume density (7.4±1.1 vs. 18±2 %, p<0.001) in STN. However, cristae were more abundant in STN (1.4±0.1 vs. 1±0.1, p=0.008). In STN, high total AMPK, but low phosphorylated AMPK (pAMPK) levels were observed. Markers for hypertophy (p70S6k) and apoptosis (cleaved caspase-3) were elevated, while autophagy marker (LC3-II/LC3-1 ratio) was lower in STN. HIF induction with significantly improved several parameters including GFR, RBF, QO2/GFR, pAMPK levels and reduced markers for hypertrophy and apoptosis.

Conclusions: In the STN kidney, significant increases in QO2 were observed at the whole kidney and mitochondrial levels. ROS production was elevated and significant morphological changes in mitochondria were observed even in the very early stages. Several of these abnormalities were corrected by HIF induction.

Plasma Membrane (PM) Is a Biomechanical Sensor for Fluid Shear Stress (FSS) Mediated Signaling in Collecting Duct (CD) Cells Daniel Armando Flores,[1,2] Yu Liu,[2] Rajeev Rohatgi.[1,2] *[1]Medicine, James J. Peters VAMC, Bronx, NY; [2]Medicine and Pediatrics, Mount Sinai School of Medicine, New York, NY.*

Background: The PM is an inhomogenous mixture of phospholipids, glycolipids, and steroids with distinct regions of high viscosity/low fluidity (e.g., lipid rafts). Whereas cholesterol (chol) raises PM viscosity in localized regions to form lipid rafts, FSS reduces PM viscosity and stimulates signaling complexes embedded locally in the PM. We hypothesize that chol, through changes in spatial PM viscosity, differentially regulates FSS-induced signaling in CD cells.

Methods: Immortalized inner medullary CD3 (IMCD3) cells were exposed to a physiologic level of FSS. ATP and prostaglandin E2 (PGE2) were measured in the media bathing the cells before and after treatments that decreased (methyl-β-cyclodextrin[MβC], filipin) or increased (chol) PM viscosity.

Results: Compared to static controls (n=4), FSS (n=6-8) activates a robust increase in PGE2 (3.9±1.9 vs. 34.1±1.4 pg/mL/ug protein; p<0.05) and ATP(0.14±0.02 vs. 1.5±0.1 nM/ug protein; p<0.05) concentration in the media bathing IMCD3 cells. Pre-treatment of cells with MβC, a compound that chelates chol and decreases PM viscosity, increased the FSS-mediated PGE2 concentration (101.1±26.9 pg/mL/ug protein; n=4) compared to shear untreated cells in a concentration- and time-dependent manner. In contrast, MβC reduced medium ATP concentrations (0.47±0.01 nM/ug protein; n=3) in shear exposed IMCD3 cells. Incubation of cells with chol, to increase PM chol and viscosity, stimulated FSS-mediated ATP release by 86±3% (n=3) vs. that detected in untreated sheared cells, but did not alter FSS-mediated PGE2 secretion. The effect of filipin, which binds and disrupts chol, inhibited FSS-mediated ATP release, but did not affect FSS-induced PGE2 secretion. DCVJ, a viscosity sensitive flourophore, revealed that FSS decreased PM viscosity .

Conclusions: Specificity of FSS-activated signaling may be due to local variations in PM viscosity, which is related to PM chol content, and the signaling complexes embedded within the PM. We speculate that PM chol may regulate flow-induced PGE2 and ATP in the CD and, in turn, regulate Na excretion.

Endoplasmic Reticulum (ER) Stress Signal Impairs Erythropoietin Production: A Role for ATF4 Chih-Kang Chiang,[1,2] Masaomi Nangaku,[1] Tetsuhiro Tanaka,[1] Reiko Inagi.[1] *[1]Div of Nephrol and Endocrinol, Univ of Tokyo Sch of Med, Tokyo, Japan; [2]National Taiwan University Hospital, Taipei, Taiwan.*

Background: Hypoxia induces hypoxia inducible factor (HIF) pathway and ER stress signal, unfolded protein response (UPR). The crosstalk of both signals orchestrates the cellular responses to hypoxia, suggesting the alteration of HIF target gene expression by UPR.

Methods: To assess the effect of UPR in transcription of erythropoietin (EPO), a representative HIF target gene, HepG2 were treated with ER stress inducers (tunicamycin or thapsigargin) and/or an ER stress modulator (salubrinal) under hypoxic conditions ($CoCl_2$ or 0.1% O_2). UPR state was estimated by expression of UPR regulator GRP78. EPO transcriptional level of HepG2 overexpressing the wild or mutated (loss of function) UPR transcription factor ATF4 was also assessed. The effect of ATF4 on EPO 3' enhancer activity, which is mainly regulated by HIF, was evaluated by the reporter and ChIP analyses.

Results: UPR activation by ER stress inhibitors suppressed hypoxia-induced EPO transcription in HepG2 and it was restored by normalization of the UPR state. Importantly, the decreased EPO expression was also observed in HepG2 overexpressing ATF4. Overexpression of mutated ATF4, which lacks transcriptional activity, did not alter EPO transcriptional regulation. Transcriptional activity of EPO 3' enhancer region was abolished by both ER stress inhibitors and ATF4 overexpression, while nuclear HIF accumulation or expression of other HIF target genes was not suppressed by ER stress. ChIP analysis identified a novel ATF4 binding site (TGACCTCT) within the EPO 3' enhancer region, suggesting a distinct role for ATF4 in UPR-dependent suppression of the enhancer. Induction of ER stress in rat liver and kidney by tunicamycin decreased the hepatic and renal mRNA, respectively, and plasma level of EPO.

Conclusions: ER stress, namely pathogenic UPR activation, selectively impaired the transcriptional activity of EPO but not of other HIF target genes. This effect was mediated by suppression of EPO 3' enhancer activity via ATF4 without any direct effect on HIF, indicating that UPR contributes to oxygen-sensing regulation of EPO.

Complement-Mediated Activation of Calcium-Independent Phospholipase $A_2\gamma$: Role of Protein Kinases and Phosphorylation Hanan Elimam, Tomoko Takano, Joan Papillon, Andrey V. Cybulsky. *Medicine, McGill University, Montreal, QC, Canada.*

Background: In experimental membranous nephropathy, complement C5b-9-induces glomerular epithelial cell (GEC) injury and proteinuria. The effects of C5b-9 are mediated via signaling pathways, including calcium-independent phospholipase $A_2\gamma$ (iPLA$_2\gamma$), and mitogen-activated protein kinases (MAPKs), that is extracellular signal-regulated kinase (ERK), c-Jun N-terminal kinase (JNK) and p38. The iPLA$_2\gamma$ pathway is cytoprotective. We address the mechanisms of iPLA$_2\gamma$ activation.

Methods: Cultured GEC were stably transfected with iPLA$_2\gamma$ cDNA. GEC were incubated with antibody and normal serum (to assemble C5b-9) or heat-inactivated serum (control). To study MAPKs in iPLA$_2\gamma$ activation, COS-1 cells were transfected with iPLA$_2\gamma$ and cyclooxygenase-1 (COX-1). PLA$_2\gamma$ activity was monitored by quantifying prostaglandin E_2 (PGE_2) release.

Results: In GEC, GFP-iPLA$_2\gamma$ localized at the endoplasmic reticulum and mitochondria. Complement-mediated production of PGE_2 was amplified in GEC that overexpress iPLA$_2\gamma$, compared with control cells, and stimulated iPLA$_2\gamma$ activity was blocked by the iPLA$_2\gamma$ inhibitor, bromoenol lactone (BEL) in both control and iPLA$_2\gamma$-overexpressing GEC. In GEC that overexpress iPLA$_2\gamma$, complement-mediated PGE_2 production was reduced significantly by chemical inhibitors of MAPK/ERK kinase-1 (MEK1) and p38, but not JNK. In COS-1 cells that overexpress iPLA$_2\gamma$, PGE_2 production and ERK activation were induced by expression of constitutively active MEK1 or by stimulation with epidermal growth factor (EGF)+ionomycin, and the effect of EGF+ionomycin was inhibited by BEL. Stimulated iPLA$_2\gamma$ activity was not affected by mutations in iPLA$_2\gamma$ putative ERK phosphorylation sites (S168A, S271A and S168A/S271A), but was markedly attenuated by the S511A/S515A double mutation. Moreover, EGF+ionomycin induced S511 phosphorylation.

Conclusions: Complement-mediated activation of iPLA$_2\gamma$ is mediated via ERK and p38 pathways. Activation is dependent on phosphorylation of S511 and/or S515 by a kinase that remains to be identified. Defining the mechanisms by which complement stimulates iPLA$_2\gamma$ provides opportunities for development of novel therapeutic approaches to GEC injury and proteinuria.

HIV-Induced Epigenetic Factors Down Regulate Vitamin D Receptor (VDR) and Promote Tubular Cell DNA Damage Divya Salhan, Nirupama Chandel, Tejinder Singh, Gautam Kishore Valecha, Ashaan Subrati, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Epigenetic factors have been demonstrated to play a key role in the alteration of gene expression. We hypothesize that HIV-induced epigenetic factors will cause down regulation of tubular cell VDR and associated DNA damage in HIV-associated nephropathy (HIVAN).

Methods: To have a model of tubular cell HIV infection, primary human renal proximal tubular cells (HRPTC) were transduced with either empty vector (EV) or HIV (NL4-3) constructs. Measurement of VDR methylation status, cytosine phosphate guanosine (CpG) DNA methylation qPCR (Epitect Restriction) and methylation qPCR assay with VDR specific primers was carried out in EV/HRPTCs and HIV/HRPTCs. Immunoblotting and real time PCR studies were conducted for protein and mRNA expression for VDR and renin. Ang II ELISA was carried out on cells prepared under similar conditions. To determine DNA damage and repair EV/HRPTCs an d HIV/HRPTCs were co-labeled for H2AX and KU80. To confirm relationship between DNA methylation, VDR and DNA and tubular cell DNA damage EV/HRPTCs and HIV/HRPTCs were treated with either vehicle, a vitamin D receptor agonist (VDA, EB1089, 10 nM), or a demethylating agent (DMA; azacytidine, AZAC, 5 μM) for 24 hours and evaluated for DNA damage and repair.

Results: HIV/HRPTCs displayed two fold enhanced CpG methylation of VDR, 2.5-fold increase in DNA methyl transferase (Dmnt)-1 expression, 3-fold down regulation of VDR and activation of the RAS. Similarly, siRNA-VDR/HRPTCs displayed activation of the RAS. Both DMA as well as VDA inhibited the effect of HIV on tubular cell VDR expression. HIV/HRPTC not only displayed enhanced double strand breaks but also showed diminished DNA repair when compared to EV/HRPTCs. On the other hand, Both DMA and VDA not only enhanced DNA repair but also attenuated DNA damage in HIV/HRPTECs.

Conclusions: These findings indicated HIV-induced VDR downregulation was mediated by HIV-induced DNA methylation. HIV-induced DNA damage was mediated through down regulation VDR. Both DMA and VDA provided protection against HIV-induced tubular cell DNA damage.

Hyperglycemia Accelerates HIV-Associated Nephropathy through Downregulation of Vitamin D Receptor Partab Rai, Dileep Kumar, Andrei Plagov, Rivka Lederman, Guohua Ding, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Patients with HIV infection are living almost a normal life and are thus prone to develop diabetes mellitus (DM) and its associated complications. We hypothesized that development of hyperglycemia in HIVAN (HIV-associated nephropathy) mice would exacerbate the progression of HIVAN through down regulation of renal cell vitamin D receptors (VDR) and associated activation of the renin-angiotensin system (RAS).

Methods: Four weeks old control (C) and Tg26 (HIV) mice (n=4) were either administered vehicle or streptozotocin (STZ, 150 mg/Kg, intraperitoneal, single dose). At the end of two weeks, mice were sacrificed. Blood and urine were collected and kidneys were harvested for renal histology, imunohistochemical, and immunoblotting studies for VDR, renin and angiotensinogen (Agt) expression. In addition, renal tissue Ang II content was measured by ELISA. In *in vitro* studies, podocytes and tubular cells were incubated in media containing either 5 mM or 30 mM glucose for 24 hours. Immunoblots were probed VDR, renin, Agt and reprobed for actin. Renal tissues and cells were also probed for occurrence of oxidative stress.

Results: STZ-treated mice (C-STZ) developed higher proteinuria vs. control (C) mice (C, 0.3 ± 0.08 vs. C-STZ, 3.1 ± 1.0 mg/g creatinine; P<0.01); STZ-treated Tg26 mice (HIV-STZ) displayed greater proteinuria vs. vehicle-treated Tg26 mice (C-HIV) (HIV-STZ, 24.0 ± 0.8 vs. C-HIV, 15.7 ± 1.1 mg/g creatinine; P<0.01). HIV-STZ displayed higher BUN levels when compared to C-HIV (C-HIV, 48 ± 2 vs. HIV-STZ, 59 ± 5 mg/dl; P<0.05). Renal tissues of C-HIV displayed down regulation of VDR, activation of the RAS (including higher renal tissue Ang II levels) and increased oxidative DNA damage vs control mice; however HIV-STZ displayed increased (two-fold) downregulation of VDR and higher activation of the RAS (including renal tissue Ang II levels) when compared to C-HIV mice.

Conclusions: Development of hyperglycemia in HIVAN mice accelerated the progression of HIVAN by renal tissue down regulation of VDR and enhanced activation of the RAS.

Funding: NIDDK Support

p66ShcA Deficiency State Downregulates HIV-Induced Tubular Cell Activated mTOR Pathway Partab Rai,[1] Andrei Plagov,[1] Mohammad Husain,[1] Ashwani Malhotra,[1] Praveen N. Chander,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Pathology, New York Medical College, Valhalla, NY.*

Background: Both mammalian target of rapamycin (mTOR) and p66ShcA pathways have been demonstrated to play an important role in the developmen of HIVAN. We asked whether there was any relationship between mTOR and p66ShcA pathways.

Methods: Four weeks old control and Tg26 mice were bred with $p66^{+/-}$ mice and a colony heterozygous p66; Tg26 mice was developed. Renal function and histology was evaluated in 8 weeks old control, Tg26, $p66^{+/-}$ and Tg26;$p66^{+/-}$. Immunoblots of protein lysates from renal tissues of control, Tg26, $p66^{+/-}$ and Tg26;$p66^{+/-}$ were probed for phospho-mTOR, S706 Kinase, phospho-eEF2, phospho- eIF4B, and phospho-4EBP-1. The same blots were stripped and reprobed for total mTOR and actin. Renal cortical sections of all mice were labeled for 8-Oxo-dG. Immortalized differentiated human podocytes (IDHPS) were transduced with either empty vector or HIV (NL4-3) constructs. Subsequently, EV/IDHPs and HIV/IHDPs were transfected with siRNA- p66 the role of reaactive oxygen species (ROS), HIV/IHDPs were incubated in media containing either buffer or superxoxide dismutase (SOD, 500 U) for 48 hours. Immunoblots were probed for mTOR pathway.

Results: Renal tissues of Tg26 mice displayed activation of mTOR pathway and associated down stream signaling when compared to control mice; on the other hand Tg26;$p66^{+/-}$mice as well as $p66^{+/-}$ mice displayed attenuated expression of phoshpho-mTOR and associated down stream molecules. Renal cortical sections of Tg26 mice displayed enhanced number of 8-Oxo-dG +ve nuclei when compared to Tg26;$p66^{+/-}$ mice as well as $p66^{+/-}$ mice. siRNA-p66/IDHP and siRNA-p66-HIV/IDHPs displayed attenuated expression of phospho-mTOR and associated down stream molecules. SOD also attenuated the activation of mTOR pathway in HIV/IDHPs.

Conclusions: These findings indicate that p66ShcA-induced ROS generation contributed to HIV- induced mTOR pathway activation in HIVAN. Conversely, deficit of p66ShcA-induced not only attenuated oxidative stress but also inhibited activation of mTOR pathway.

Caspase-3 Acts Downstream of Wnt11 and Stimulates Branching Morphogenesis by Activating Rho-Associated Protein Kinase 1 and Inhibiting β Catenin Signaling Midori Awazu,[1] Yoshifumi Yamaguchi,[2] Michio Nagata,[3] Masayuki Miura,[2] Mariko Hida.[1] *[1]Department of Pediatrics, School of Medicine, Keio University, Tokyo, Japan; [2]Department of Genetics, Graduate School of Pharmaceutical Sciences, University of Tokyo, Tokyo, Japan; [3]Renal and Vascular Pathology, University of Tsukuba, Tsukuba, Japan.*

Background: Inhibition of caspase-3 leads to reduced ureteric bud branching and kidney size in organ culture. Caspase-3 is known to activate Rho-associated protein kinase 1 (ROCK-1) and inactivate ß catenin, critical molecules in ureteric branching, by cleavage. The metanephroi cultured with caspase-3 inhibitors closely resemble those of mice deficient in Wnt11, a noncanonical Wnt ligand. We thus investigated the role of caspase-3 in Wnt11 signaling and in branching morphogenesis.

Methods: Phosphorylation of myosin phosphatase targeting subunit 1 (P-MYPT1), a regulator of actin cytoskeleton organization, at threonine 696 by ROCK1 and ß catenin were detected by immunoblot. Cell migration was assessed by wound healing assay. Caspase-3 activity was detected by carboxyfluorescein caspase-3 detection kit. Glomerular number of caspase-3 knockout mice (Casp3-/-) was determined by acid maceration at 3 weeks.

Results: Activation of caspase-3 was observed at the wound-edge UB cells at 4 h after scratching, which disappeared by 24 h when the wound was almost closed. A caspase-3 inhibitor Ac-DNLD-CHO (DNLD) inhibited wound healing dose-dependently. Recombinant Wnt11 increased caspase-3 activity in UB cells with no signs of apoptosis. P-MYPT1 was increased and stabilized ß catenin was decreased by Wnt11. These changes were completely reversed by DNLD. Wnt11 enhanced UB cell wound healing, which was inhibited by DNLD, lithium chloride, and a ROCK inhibitor. Casp3-/- had 30% fewer glomeruli than heterozygotes (Casp3+/-). At embryonic day 13, ureteric bud tip numbers (10±3 vs 36±6) and kidney surface area (60%) were reduced in Casp3-/- compared with Casp3+/-. In kidney lysates from embryonic day 15 Casp3-/-, P-MYPT1 was markedly reduced and ß catenin was increased compared with Casp3+/-.

Conclusions: Caspase-3 acts downstream of Wnt11 and mediates ureteric branching *via* modulation of ROCK1 and ß catenin.

Hypoxia and Aldosterone Stimulate Erythropoietin Production in Intercalated Cells of the Collecting Ducts Takanori Nagai,[1] Kahori Hori,[1] Yuichiro Izumi,[2] Yushi Nakayama,[3] Yukiko Hasuike,[1] Takahiro Kuragano,[1] Masayoshi Nanami,[4] Akito Tanoue,[5] Katsumasa Kawahara,[6] Kimio Tomita,[3] Takeshi Nakanishi,[1] Hiroshi Nonoguchi.[7] *[1]Kidney and Dialysis, Hyogo Col Med, Japan; [2]Systems Biology Center, NHLBI, NIH; [3]Nephrol, Kumamoto Univ, Japan; [4]Renal Div, Emory Univ; [5]Pharmacol, Nat Res Inst for Child Health, Japan; [6]Physiol, Kitasato Univ, Japan; [7]Int Med, Kitasato Univ Kitasato Inst Med Cent Hosp, Japan.*

Background: Erythropoeietin (Epo) production has been suggested to occur in the peritubular interstitial cells and/or in the nephron. The role of vasopressin and aldosterone for Epo production is not known. The purpose of our study is to examine the effect of vasopressin and aldosterone on Epo production and to identify the Epo production in intercalated cells of the collecting ducts.

Methods: Vasopressin V1a receptor knockout (V1aR-KO), wild type (WT) mice, and rat intercalated cell line (IN-IC cells) were used for Western blot, ELISA, real time PCR and immunohistochmistry of Epo after stimulation by hypoxia or aldosterone. HepG2 cells were also examined as a positive control to confirm the effect of hypoxia on Epo production. Rat kidney slices were also used for immunohistochemistry of Epo.

Results: Plasma hemoglobin levels were not different between WT and V1aR-KO mice. However, the administration of fludrocortisone increased plasma Epo (ELISA) in WT by 3 folds but slightly in V1aR-KO mice. Epo and Epo-receptor mRNAs were detected in rat kidney and IN-IC cells. Hypoxia (1% O2) increased Epo production (ELISA) by 50-60% and Epo abundance in cytoplasm (immunostaining) in IN-IC cells. Western blot showd a band at 42kDa and it was increased by hypoxia. Aldosterone dose-dependently increased Epo mRNA and protein in IN-IC cells. Aldosterone increased Epo abundance (immunostaining) in IN-IC cells. Knockdown of V1aR gene abolished aldosterone-induced Epo production. Immunohistochemistry of Epo showed a staining of the collecting ducts, especially in the deeper portion, as well as peritubular interstitial cells in rat.

Conclusions: Epo production is regulated by aldosterone and vasopressin in intercalated cells of the collecting duct.

Endothelin Converting Enzyme (ECE)-1: A Plausible Target Gene for Hypoxia Inducible Factor (HIF) Mogher Khamaisi,[6] Imari Mimura,[2] Hala Toukan,[6] Christian Rosenberger,[3] Jonathan H. Axelrod,[1] Ahuva Shina,[1] Galia Skarzinsky,[1] Robert Koesters,[7] Gail Walkinshaw,[4] Seymour Rosen,[5] Masaomi Nangaku,[2] Samuel N. Heyman.[1] *[1]Hadassah Hebrew University Hospitals, Jerusalem, Israel; [2]University of Tokyo School of Medicine, Japan; [3]Carite, Berlin, Germany; [4]FibroGen, CA; [5]BIDMC Harvard, Boston, MA; [6]Rambam Medical Center - Technion, Haifa, Israel; [7]Tenon Hospital, University of Paris 6, France.*

Background: Renal endothelin converting enzyme (ECE)-1, a key regulator of endothelin synthesis, is induced in experimental diabetes and following radiocontrast administration (Khamaisi, KI 2008), conditions characterized by renal hypoxia, HIF stabilization and enhanced endothelin synthesis. We have also reported cross-stimulation of HIF and p-STAT3 in vivo (ASN 2009). We now explored the possibility that ECE-1 might be a HIF/STAT3-target gene by their selective induction.

Methods: HIF stimulation was induced in rats subjected to the HIF prolyl-hydroxylase inhibitors mimosine or FG-4497, or in conditional Von Hippel Lindau knock-out (VHL KO) mice. Renal tubular p-STAT3 was induced in mice transfected by or injected with a chimeric IL-6/IL6-receptor protein (HIL-6, Nechemia-Arbely, JASN 2008). ChIP seqencing was performed in normoxic and hypoxic cultured human umbilical vascular endothelial cells (HUVEC).

Results: Mimosine and FG-4498, as well as HIL-6 in rats and mice, respectively, led to renal HIF-1α and p-STAT3 co-expression, principally in distal nephron segments. HIF-1α and p-STAT3 co-stimulation was associated with markedly enhanced ECE-1 protein expression, predominantly in the inner and outer medulla. Immunostaining confirmed enhanced ECE-1 expression principally in distal nephron segments following mimosine and in conditional VHL KO mice, which develop intense HIF-1α and p-STAT3 expression over time. Finally, ChIP-seq of HIF-1 binding sites, performed in cultured HUVEC subjected to hypoxia, revealed HIF attachment to the promoter and intron regions of the ECE-1 gene, supporting the possibility that it triggers ECE-1 under hypoxia.

Conclusions: Collectively, these findings suggest that ECE-1 expression might be induced by HIF and p-STAT3 co-stimulation.

TGF-β/Smad3 Activates Mammalian Target of Rapamycin Complexes to Promote Kidney Fibrogenesis Benaya Rozen-zvi, H. William Schnaper. *Pediatrics, Northwestern Univ. Feinberg School of Medicine, Chicago, IL.*

Background: The transforming growth factor (TGF)-β pathway activates mammalian target of Rapamycin (mTOR) in human mesangial cells (HMC) and fibroblasts. mTOR inhibition is antifibrotic in some animal models of kidney disease. We investigated the pathways by which TGF-β activates mTOR and the role of mTOR activity in TGF-β-induced fibrogenesis.

Methods: mTOR activity was evaluated in TGF-β-treated HMC by Western blot for phosphorylated S6 kinase-1 and S6 ribosomal protein. Collagen expression was evaluated by reporter assay and western blot.

Results: TGF-β stimulated HMC mTOR activity within 10 minutes. The PI3K inhibitor wortmannin blocked both basal and TGF-β-induced mTOR activation, whereas blockade of TGFβ signaling by TβRI kinase inhibition abolished the TGF-β induced mTOR activation but did not reduce basal activity. Surprisingly, in Smad3-null mouse embryonic fibroblasts (MEF) basal mTOR activity was increased compared to wild type (WT) MEF but, unlike the WT MEF, there was no increase after stimulation with TGF-β. In human embryonic kidney cells (HEK), overexpressing WT Smad3 decreased basal mTOR activity but increased TGF-β-stimulated activity. On the other hand, overexpressing the dominant-negative Smad3A reduced both basal and TGF-β-stimulated mTOR activity. Rapamycin, a relatively selective mTOR complex 1 (TORC1) inhibitor, or shRNA for the TORC1 protein RAPTOR, reduced collagen-1 promoter activity and protein expression in HMC. This inhibition was fully reversible by expressing non-degradable (ND) hypoxia-inducible factor (HIF1)-1α or the hypoxia mimetic, desferoxamine mesylate (DFO). However, ND HIF-1α or DFO did not overcome the reduction in collagen1 promoter activity caused by either the non-selective mTOR kinase inhibitor, PP242, or shRNA for the TORC2 protein RICTOR .

Conclusions: mTOR signaling contributes to TGF-β-stimulated collagen expression. Inactive Smad3 may reduce basal mTOR activity, whereas active Smad3 appears essential for TGF-β-stimulated TORC1 and TORC2 actions. Activation of TORC1 promotes kidney fibrogenesis, probably by facilitating normoxic HIF activity, while TORC2 stimulates fibrogenesis in a separate pathway.

TH-PO218

Dual RAS Blockade Normalizes Renal Tubular Atrial Natriuretic Peptide and Angiotensin-Converting Enzyme-2 Expression in Angiotensinogen-Transgenic Mice Chao-Sheng Lo,[1] Shyi-jang Shin,[2] Shiao-ying Chang,[1] Isabelle Chenier,[1] Shao-Ling Zhang,[1] Janos G. Filep,[3] Julie R. Ingelfinger,[4] John S.D. Chan.[1] *[1]Res. Ctr., CHUM-Hotel Dieu Hospital, Montreal, QC, Canada; [2]Endorinol & Metab, Kaohsiung Med Univ Hosp, Kaohsiung, Taiwan; [3]Res. Ctr., Maisonneuve-Rosemont Hosp, Montreal, QC, Canada; [4]Pediatr Nephrol Unit, Mass Gen Hosp, Boston, MA.*

Background: Atrial natriuretic peptide (ANP) is an endogenous angiotensin II (Ang II) antagonist that acts both systemically and locally. In the present study, we investigated the interaction of Ang II, ANP and angiotensin-converting enzyme-2 (Ace-2) in renal proximal tubular cells (RPTCs), and the effect of dual RAS blockade on renal ANP and Ace-2 expression in transgenic (Tg) mice with specific overexpression of angiotensinogen (Agt) in their RPTCs.

Methods: Adult male Agt-Tg mice (age 13 weeks) were treated ± RAS blockers (losartan, 30 $mg.Kg^{-1}.day^{-1}$ and perindopril, 4 $mg.Kg^{-1}.day^{-1}$ in drinking water). Untreated non-Tg littermates served as controls. Systolic blood pressure (SBP) and albuminuria were monitored bi-weekly up to age 20 weeks. Kidneys were processed for immunostaining of Agt, ANP and Ace-2. Renal proximal tubular (RPT) Agt, ANP and Ace-2 mRNA were evaluated by real-time quantitative polymerase chain reaction (RT-qPCR). Urinary Ang II and Ang 1-7 levels were quantified by ELISA. We also examined ANP and Ace-2 mRNA expression in immortalized rat cultured RPTCs that were stably transfected with the control plasmid pRC/RSV or the plasmid containing the rat Agt cDNA (pRSV/Agt).

Results: SBP was significantly higher at 20 weeks in male Agt-Tg as compared to non-Tg and was normalized with RAS blockade. Furthermore, both ANP and Ace-2 mRNA and protein expression were decreased in RPTs of Agt-Tg and normalized by dual RAS blockade. Urinary Ang II and Ang 1-7 levels were respectively increased and decreased in Agt-Tg mice, and were normalized with RAS blockade. *In vitro*, ANP and ACE2 mRNA expression was reduced in RPTCs stably transfected with pRSV/Agt as compared to control RPTCs.

Conclusions: These data demonstrate that overexpression of Agt inhibits renal ANP expression via Ang II-induced down-regulation of Ace-2 and Ang 1-7 expression.

GPR40 Serves as a Functional Receptor for EETs Seong Kwon Ma,[1,2] Jianchun Chen,[1] Raymond C. Harris,[1] Jian-Kang Chen.[1] *[1]Department of Medicine, Vanderbilt University School of Medicine, Nashville, TN; [2]Department of Internal Medicine, Chonnam National University Medical School, Gwangju, Korea.*

Background: The cytochrome P450 epoxygenase-dependent arachidonic acid metabolites, epoxyeicosatrienoic acids (EETs), are potent mitogens for renal tubular epithelial cells, but the potential functional receptor(s) mediating the biological effect of EETs has remained elusive.

Methods: siRNA was used to knock down GPR40 expression and assess its effect on EET-induced phosphorylation of extracellular signal-regulated kinase (ERK) in the renal proximal tubular epithelial-like cell line, LLCPKcl4. A human GPR40 cDNA construct was stably transfected into the human embryonic kidney cell line, HEK293.

Results: Knocking down GPR40 with siRNA inhibited EET-induced ERK phosphorylation in LLCPKcl4 cells. GPR40 overexpression in HEK293 cells significantly enhanced EET-induced cell proliferation and markedly augmented epidermal growth factor receptor (EGFR) phosphorylation and ERK activation, which were inhibited by either the EGFR tyrosine kinase inhibitor, AG1478, or the HB-EGF inhibitor, CRM197. In hGPR40-transfected HEK293 cells, EETs significantly enhanced HB-EGF release into the culture medium. RT-PCR indicated GPR40 mRNA expression in murine kidney. Immunoblotting revealed that GPR40 is primarily expressed in the renal cortex and outer stripe of outer medulla (OSOM), with minimal expression in the inner medulla and papilla. Immunohistochemistry indicated high expression in the OSOM and a subset of cortical tubules, and immunofluorescence staining with nephron segment specific markers confirmed that GPR40 is highly expressed in S2 and S3 segments of the renal proximal tubules, with moderate expression in cortical collecting ducts.

Conclusions: This study provides the first demonstration that GPR40 serves as a functional receptor to mediate the mitogenic signaling of EETs. GPR40 is highly expressed in S2 and S3 segments of the renal proximal tubule, the nephron segments previously reported to express the highest level of EET synthase (cytochrome P450 epoxygenase) in the kidney and in cortical collecting duct, which has previously been shown to be a target for EET regulation of sodium reabsorption.

Imbalance of CCN2/CCN3: A Novel Mechanism for Glomerular Matrix Accumulation in Experimental Glomerulonephritis Long Chen, Dan Liu, Linli Lv, Haifeng Ni, Bi-Cheng Liu, Jiandong Zhang. *Institute of Nephrology, Southeast University, Nanjing, China.*

Background: Members of CCN family proteins such as CCN2 and CCN3 play important but controversial role in remodeling extracellular matrix. Our recent work suggested that divergent alteration in glomerular expression of CCN2/CCN3 associated with rapid expansion of mesangial matrix in experimental models. Furthermore, the imbalance

of CCN2/CCN3 correlated with glomerular histological changes in patients with chronic kidney diseases. Therefore, we hypothesize that imbalance of CCN2/CCN3 contributes to the glomerular matrix accumulation in experimental glomerulonephritis.

Methods: To test this, we first administered maximal dose of Enalapril (100mg/L) to nephritic rats between day 4 and day 6 after injection of OX-7 Ab.

Results: Enalapril treatment substantially normalized the imbalance of CCN2/CCN3 in experimental glomerulonephritis(reducing CCN2(by 37.7% in mRNA, by 63.8% in protein); increasing CCN3(by 165.6% in mRNA, by 191.9% in protein), accompanying with the repression of glomerular matrix expansion (43.2±3.12 %vs. 65.2±3.12%, p<0.05), and proteinuria by 54.5% (66.0±8.1 vs. 30±8.3 mg, p<0.05). Next, we decided to directly test the individual contribution of CCN2/3 in matrix accumulation by using cultured glomeruli. Depressing CCN2 expression in glomeruli by specific siRNA by 85% in cultured nephritic glomeruli reduced mRNA expression of fibrotic markers PAI-1(49.2%), TGFß1 (23.6%),FN(24.5%), comparably to recombinant CCN3 protein(10ng/ml). Additionally, combination therapy led to a further reduction in disease markers such as production of TGFß1 protein by additional 40.3% to CCN2 siRNA alone (217.7±14.8 vs. 128.9±6.2 pg TGFß1/5000 glomeruli, p<0.05). Furthermore, recombinant CCN3,but not CCN2 siRNA gained "add-on" effects to maximal dose of enalapril treatment in cultured glomeruli(273.3±6.9 vs. 185.6±2.2 pg TGFß1/5000 glomeruli, p<0.05).

Conclusions: Collectively, these results demonstrate that imbalance of CCN2/CCN3 plays critical role in the accumulation of glomerular matrix in experimental glomerulonephritis, and posit CCN3 as a novel therapeutic means at least supplementing to Ang II inhibitor.

A Pro-Inflammatory Role of C5L2 in C5a-Primed Neutrophils for ANCA-Induced Activation Min Chen, Jian Hao, Ming Hui Zhao. *Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China.*

Background: The complement system is crucial for the development of ANCA-associated vasculitis (AAV). In particular, C5a and its receptor on neutrophils, CD88, play a central role. The function role of the second receptor of C5a, C5L2, remains unclear. In the current study, we investigated the role of C5L2 in C5a-primed neutrophils for ANCA-induced activation.

Methods: The effect of blocking C5L2 were tested on respiratory burst and degranulation of C5a-primed neutrophils activated with ANCA, as well as on membrane-bound proteinase 3 (PR3) and concentration of myeloperoxidase (MPO) in supernatant of C5a-primed neutrophils.

Results: Blocking C5L2 resulted in a decreased MPO concentration in C5a-primed neutrophils supernatant.mPR3 expression increased from 223.0±36.1 in untreated cells to 423±40.7 after C5a treatment (P<0.001) and decreased to 348.0±52.0, 323.4±57.9 and 313.8±49.7 by pre-incubating blocking C5L2 antibody at 2.5μg/ml, 5μg/ml or 10μg/ml (compared with that C5a-priming group, P<0.001, P<0.001, and P<0.001), respectively. In C5a-primed neutrophils, subsequently activating with MPO-ANCA-positive IgG, the MFI value was 348.1±198.2, which decreased to 306.7±193.7, 297.7±163.4 and 291.5±163.3 upon pre-incubation with mouse anti-human C5L2 blocking antibody at 2.5μg/ml, 5μg/ml or 10μg/ml (compared with that C5a-primed neutrophils, for MPO-ANCA-positive IgG induced activation, P<0.05, P<0.05, and P<0.05), respectively. Blocking C5L2 also resulted in a decreased C5a-primed neutrophils for PR3-ANCA-positive IgG induced activation. Moreover, the lactoferrin concentration decreased in pre-incubation with anti-human C5L2 blocking antibody, compared with that C5a-primed neutrophils induced by PR3- or MPO ANCA-positive IgG supernatant.

Conclusions: C5L2 may implicate in the pro-inflammatory role in C5a-primed neutrophils for ANCA-induced activation.

Transforming Growth Factor β1-Induced Vascular Endothelial Cell Growth Factor-D from Renal Proximal Tubule Cells and Macrophages Is Associated with Lymphangiogenesis in a Unilateral Ureteral Obstruction Won Kim, Aesin Lee, Dal Kim, Yujin Jung, Young Min Hong, Kyung Pyo Kang, Sik Lee, Sung Kwang Park, Jung Eun Lee. *Department of Internal Medicine, Chonbuk National University Medical School, Jeonju, Jeonbuk, Korea.*

Background: Lymphatic endothelial proliferation has been detected in tubulointerstitial fibrotic regions in rat remnant kidney and human kidney transplant. Vascular endothelial cell growth factor (VEGF)-D is a lymphangiogenic factor. However, there is few data about the role of VEGF-D in lymphangiogenesis in renal fibrosis.

Methods: We performed quantitative real-time RT-PCR and ELISA of VEGF-D, immunohistochemistry in a unilateral ureteral obstruction (UUO) model. We also evaluated role of VEGF-D in inhibitory effect of transforming growth factor β1 on VEGF-C-induced in vitro lymphangiogenesis.

Results: The number of LYVE-1-positive lymphatic vessels was increased after ureteral obstruction. VEGF-D mRNA and protein expression in the UUO kidney was significantly increased to sham-operated mice. VEGF-D mRNA expression was increased in macrophages (Raw 264.7 cells) or renal proximal tubule cells (HK-2 cells) by stimulation with TGF-β1. Treatment of Raw 264.7 cells or proximal tubule cells with TGF type 1 receptor inhibitors (SD208) and an inhibitor of TGF-β superfamily type I activin receptor-like kinase (ALK) receptors ALK4, 5, and 7 (SB431542) decreased TGF-β1-induced VEGF-D mRNA expression. Depletion of macrophages with clodronate decreased lymphangiogenesis in UUO kidney. Blockade of VEGF-D signaling after direct injection into the kidney with adenovirus encoding the soluble extracellular domain of VEGFR-3 (Ad-sVEGFR3) decreased the UUO-induced lymphangiogenesis. As TGF-β1 is a negative regulator in VEGF-C-induced lymphangiogenesis and migration, capillary-like tube formation and proliferation are important component in *in vitro* lymphangiogenesis, we evaluated the effect of VEGF-D. VEGF-D reversed the inhibitory effect of TGF-β1 on VEGF-C-induced migration, capillary-like tube formation and proliferation of human lymphatic endothelial cells.

Conclusions: These results indicate that VEGF-D is associated with lymphangiogenesis in fibrotic kidney in UUO mouse model.

Colony Stimulating Factors Regulates the Expressions of Interleukin 6, Tumor Necrosis Factor-alfa and Plasminogen Activator Inhibitor-1 Induced by Thrombin in Human Proximal Tubular Epithelial Cells in Culture Michiko Shimada, Yoshiko Shutto, Ikuyo Narita, Yuko Shimaya, Takeshi Fujita, Reiichi Murakami, Norio Nakamura, Hideaki Yamabe, Ken Okumura. *Nephrology, Hirosaki University, Hirosaki, Japan.*

Background: In the tubulointerstitial injury, fibrin deposition is commonly seen, therefore, the local activation of thrombin is suggested. Colony-stimulating factors (CSFs) are well-known hematopoietic growth factors. However, recent studies revealed that CSFs are involved in many inflammatory conditions. In the experimental anti-glomerular membrane glomerulonephritis, both glomerular lesions and tublointerstitial lesions were attenuated in the granulocyte-macrophage CSF (GM-CSF) knockout mice. We have recently reported that thrombin increased the production of M-CSF, GM-CSF and G-CSF in human proximal tubular epithelial cells (PTEC). In this study, we examined the role of CSFs in the pathorogic effects of thrombin in PTEC utilizing siRNA.

Methods: Primary human PTEC were purchased and used between passages 4-6. The cells were transfected with M-CSF, GM-CSF and G-CSF siRNA or non-coding control siRNA for the transient knockdown of the gene expression. 48hours later, cells were incubated with or without thrombin (5U/ml) for 6 hours and total RNA was harvested. The expressions of CSFs,Interleukin-6 (IL-6) and Tumor Necrosis Factor-alfa (TNF-alfa), Plasminogen Activator Inhibitor-1 (PAI-1) and Metalloproteinase-9 (MMP-9) were examined by quantitative RT-PCR.

Results: In PTEC, 6-hour incubation with thrombin (5U/ml) significantly increased mRNA expression of IL-6, (4.1±0.1fold, P<0.0001), TNF-alfa (3.3±0.3fold, P<0.001), PAI-1(2.74±0.2fold, P<0.001) and MMP-9 (3.3±0.9 fold, P<0.05) when transfected with non-coding siRNA. The augumented expression of IL-6, TNF-alfa, PAI-1 was significantly reduced by the knockdown of CSFs, whereas MMP-9 expression was not affected.

Conclusions: Locally increased CSFs play a significant role in regulating IL-6, TNF-alfa and PAI-1 which are all important factors for the tissue remodeling in the tubulointerstitium in the kidney.

TH-PO224

Inducible CTGF (CCN2) Knockout Mice Attenuates Anti-Glomerular Basement Membrane Nephritis Naohiro Toda, Hideki Yokoi, Masato Kasahara, Kiyoshi Mori, Takashige Kuwabara, Hirotaka Imamaki, Kenichi Koga, Akira Ishii, Yukiko Kato, Keita P. Mori, Shoko Ohno, Akira Sugawara, Masashi Mukoyama, Kazuwa Nakao. *Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Connective tissue growth factor (CTGF/CCN2) is a matricellular protein that regulates signaling of other growth factors and promotes fibrosis. We previously showed that CTGF overexpression in podocytes aggravates diabetic nephropathy in mice and that CTGF is upregulated in glomeruli in anti-glomerular basement membrane (GBM) nephritis in rats. It is interesting to examine the phenotypes of CTGF knockout mice with renal diseases, however, perinatal death of the mice hampers invesitgation of CTGF in adult mice.

Methods: To address this problem, we generated inducible CTGF knockout mice. CTGF floxed mice were crossed with RosaCreER^{T2} mice, which ubiquitously express a tamoxifen-inducible Cre recombinase. We administered 4-hydroxytamoxifen (4-OHT) to 3-week old mice and then examined CTGF mRNA expression and histological changes in the kidney at 8 weeks of age. Next, we evoked anti-GBM nephritis in inducible CTGF knockout mice and investigated the progression of renal injury for 28 days.

Results: CTGF mRNA expression in the kidney was decreased by 77% with the treatment of 4-OHT. Inducible CTGF knockout mice showed normal renal appearance. After induction of anti-GBM nephritis, severe proteinuria and renal injury including mesangial expansion and crescents, were developed in fl/fl mice. In contrast, inducible CTGF knockout mice exhibited reduced proteinuria by 47% at day 7 with ameliorated histological changes at day 28. Analyses on glomerular expression revealed that upregulated expressions of TGF-β1, fibronectin, col1a1 and col4a3 in fl/fl mice were significantly reduced in inducible CTGF knockout mice.

Conclusions: These results indicate that the deficiency of CTGF can reduce proteinuria and ameliorate glomerular injuries in anti-GBM nephritis, suggesting that CTGF/CCN2 plays an important role in the progression of anti-GBM nephritis.

CCR2 Inhibition Ameliorates Renal Damage in Mice with 2-Kidney, 1-Clip Hypertension Stella Hartono, Bruce Knudsen, Joseph P. Grande. *Mayo Clinic, Rochester, MN.*

Background: Renal artery stenosis (RAS) affects 7% of individuals over 65 and up to 40% of individuals previously diagnosed with coronary or peripheral vascular disease. We have previously shown that induction of CCL2 precedes arrival of inflammatory cells in 129SV mice subjected to RAS. In this study, we further examined the contribution of CCL2/CCR2 signaling to the pathogenesis of renal artery stenosis in C57/BLKS mice. We hypothesize that abrogation of CCL2/CCR2 signaling prevents chronic renal damage in the stenotic kidney of mice with RAS.

Methods: RAS was established by placing a 0.2mm (internal diameter) polytetrafluoroethylene cuff on the right renal artery of C57/BLKS mice. Mice were either given a CCR2 antagonist or vehicle orally. After 2 weeks, kidneys were harvested and processed for histology or PCR.

Results: RAS induced the expression of CCL2 mRNA and protein in stenotic kidneys, which was followed by infiltration of macrophages and CD3+ T cells. Inhibition of CCR2 was associated with significant reduction of renal atrophy in the stenotic kidney. The expression of CCL2 was increased in mice treated with the CCR2 antagonist compared with vehicle treated mice. However, the number of infiltrating macrophages was markedly decreased in the RAS mice treated with CCR2 antagonist (0.4 vs. 1.4 cells/10HPF, $p<0.05$). CCR2-antagonist treatment did not affect the number of CD3+ T cells, and did not significantly reduce blood pressure (systolic BP 151±8 vs. 152±3mmHg, p = ns).

Conclusions: We conclude that CCL2/CCR2 signaling plays a key role in the pathogenesis of renal artery stenosis by inducing infiltration and activation of macrophages, and offers a potential therapeutic target for treatment of renal artery stenosis.

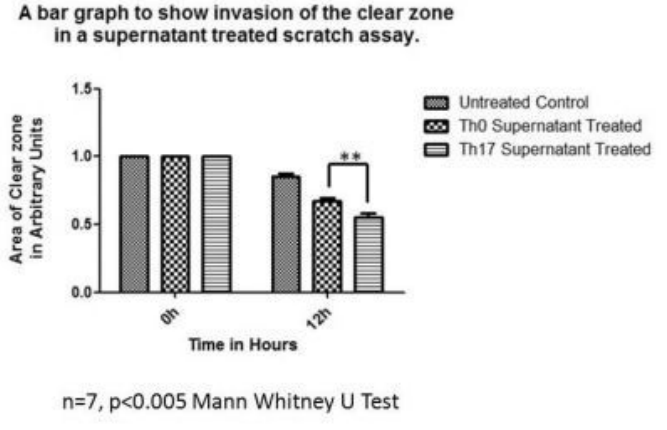
Effect of Th17 Supernatant on the Motility of the Podocyte Carl James May,[1] Gavin Iain Welsh,[1] Richard Lee,[2] Moin Saleem.[1] *[1]Academic Renal Unit, University of Bristol, Bristol, United Kingdom; [2]Academic Unit of Ophthalmology, University of Bristol, Bristol, United Kingdom.*

Background: Steroid Resistant Nephrotic Syndrome (SRNS) is a common renal disease whose pathophysiology is poorly understood. The 'circulating factor hypothesis' in the pathogenesis of the disease suggests that an abnormality of T-cell function leads to the secretion of a toxic 'SRNS factor' that has deleterious effects on the podocyte. Schewitz *et al* (IOVS 2009) showed that there is a discrete population of CD4+ cells that survive steroid treatment in steroid resistant patients. Due to a lower IL-10/IL-17 ratio in the steroid resistant patients this CD4+ population is thought to be of the Th17 subtype. We tested the hypothesis that these cells release soluble factors causing podocyte effacement.

Methods: Th17 cell culture supernatants were collected and applied to differentiated podocytes in vitro. Th0 cell culture supernatants were also collected and used as control. A scratch assay system was used to measure the motility of the podocyte. Podocytes also had their protein extracted after treatment with supernatant for use in Western blot experiments.

Results:



Th0 and TH17 supernatant was applied to wild type podocytes. Th17 supernatant significantly increased their motility compared to those treated with Th0 supernatant. Th17 supernatant treatment also stimulated p38MAPK and Jnk signalling in the podocyte while Th0 supernatant did not.

Conclusions: Treatment of the podocytes with Th17 supernatant significantly increased their motility. The effector of this is specifically released by the Th17 cells. *In vivo* this could lead to increased foot process effacement and concomitant nephrotic syndrome. This work provides evidence for a link between T-cell function and nephrotic syndrome.

TH-PO227

Gremlin via VEGFR2 Increases Profibrotic Evens in Renal Cells Sergio A. Mezzano,[1] Raquel Rodrigues-Diez,[2] Carolina Lavoz,[2] Alberto Ortiz,[3] Jesus Egido,[3] Marta Ruiz-Ortega.[2] *[1]Nephrology, Universidad Austral, Valdivia, Chile; [2]Cellular Biology in Renal Diseases Laboratory, Universidad Autónoma, Madrid, Spain; [3]Nephrology, Instituto de Investigacion Sanitaria Fundacion Jimenez Diaz, Madrid, Spain.*

Background: Gremlin is a developmental gene upregulated in chronic renal diseases associated to extracellular matrix (ECM) accumulation but its direct role in the regulation of renal fibrosis is still unclear. In endothelial cells gremlin induces angiogenesis via vascular endothelial growth factor receptor-2 (VEGFR2) pathway. Our aim was to investigate the receptor and mechanisms involved in gremlin-mediated fibrogenic events in renal cells.

Methods: Human tubular epithelial cells (HK2) and renal fibroblasts were studied. The effect of renal fibrosis was determined by evaluation of key profibrotic factors, ECM and EMT markers, by western blot/confocal microscopy or Real-time PCR.

Results: In tubular epithelial cells and fibroblasts gremlin binds and phosphorylates VEGFR2. As gremlin is a BMP antagonist, we evaluated the involvement of BMPs in the activation of VEGFR2. In the presence of BMPs (BMP-2, 4 or 7) gremlin-induced VEGFR2 activation was not modify, showing BMPs-independent effect. In renal fibroblasts Gremlin increases gene expression of profibrotic factors and matrix proteins (including collagens), which were markedly downregulated by VEGFR2 inhibition. Similar results were found in tubular epithelial cells. Moreover, in these cells gremlin induced phenotypic changes to myofibroblast-like morphology, including loss of epithelial markers and induction of mesenchymal markers. Among the intracellular signaling systems involved in renal fibrosis Smad pathway is one of the most relevant. Gremlin increases Smad2/3 phosphorylation and nuclear translocation after 20 min. This early Smad activation was TGF-β-independent. Smad7 overexpression, which blocks Smad2/3 activation, diminished Smad-dependent gene transcription and epithelial mesenchymal changes in gremlin-transfected tubuloepithelial cells.

Conclusions: We propose that gremlin, by VEGFR2 and activation of Smad signaling, increased profibrotic events and therefore could contribute to renal fibrosis.

Deacetylase Inhibition Attenuates Renal Fibrosis by Downregulation of Multiple Profibrotic Growth Factor Receptors Shougang Zhuang.[1,2] *[1]Department of Medicine, Rhode Island Hospital and Alpert Medical School of Brown University, Providence, RI; [2]Department of Nephrology, Shanghai East Hospital, Tongji University, Shanghai.*

Background: Inhibition of histone/protein deacetylases (HDACs) has been shown to attenuate the development and progression of renal fibrosis, however, the underlying mechanism remains poorly understood.

Methods: In this study, we studied the effect of class I HDAC inhibition on the expression of mutiple profibrotic growth factor receptors in the kidney after unilateral ureteral obstruction and in the cultured renal interstitial fibroblasts.

Results: We demonstrated that development of renal fibrosisafter unilateral ureteral obstruction (UUO) is concurrent with a sustained increase in the expression of three profibrotic receptors: transforming growth factor-beta (TGF-beta) receptor I, platelet-derived growth factor receptor (PDGFR) and epidermal growth factor receptor (EGFR). Inhibition of HDACs by MS-275 blocked expression of all those receptors and attenuated activation of renal fibroblasts and deposition of extracellular matrix proteins in the obstructed kidney. MS-275 treatment also abrogated UUO-induced PDGFR and EGFR phosphorylation, as well as activation of Smad-3, STAT3 (signal transducer and activator of transcription 3) and ERK½ (extracellular signal-regulated kinase½)pathways. Furthermore, MS-275 suppressed TGF-beta1 and serum-induced activation and proliferation of renal interstitial fibroblasts. However, MS-275 treatment did not affect expression/phosphorylation of c-MET, a receptor that antagonizes renal fibrosis.

Conclusions: Taken together, these findings provide a novel mechanism by which HDAC inhibition attenuates renal fibrogenesis through selective downregulation of multiple profibrotic growth factor receptors.

Expression of Gas6 and Axl in Human IgA Nephropathy: A Possible Involvement of Gas6 in Podocyte Damage Masashi Miyoshi,[1] Kojiro Nagai,[1] Takei Kake,[2] Naoshi Fukushima,[2] Motokazu Matsuura,[1] Eriko Shibata,[1] Satoshi Yamada,[1] Kazuhiro Yoshikawa,[1] Akira Mima,[1] Fumi Kishi,[1] Seiji Kishi,[1] Tatsuya Tominaga,[1] Hideharu Abe,[1] Toshio Doi.[1] *[1]Department of Nephrology, University of Tokushima, Tokushima, Japan; [2]Chugai Research Institute for Medical Science Inc., Gotenba, Shizuoka, Japan.*

Background: Gas6 is a growth factor which causes proliferation of mesangial cells in the development of glomerulonephritis. The purpose of this study is to clarify Gas6 involvement in the progression of human IgA nephropathy (hIgAN).

Methods: Thirty-one biopsy proven primary hIgAN cases were enrolled. They were aged 16 to 63 years (mean ± SD, 35.9 ± 14.6 years). There were 16 women (51.6%). Immunohistochemistry of Gas6/Axl was performed and stained area in glomeruli was measured. We compared the expression level with histological severity, clinical data, or p27

that is expressed in podocytes in normal glomeruli and decrease in proliferating glomeruli, which was inversely correlated with mesangial proliferation in hIgAN in the previous report.

Results: In 28 of 31 cases, Gas6 was upregulated mainly in podocytes. In the other 3 cases, Gas6 expression was induced in endothelial and mesangial cells, which was similar as that in rat nephritis model. Among three kinds of Gas6 receptors named Axl, Dtk, and Mer, Axl was mainly expressed in endothelial cells. Among 28 podocyte pattern cases, the expression level of Gas6 was correlated with mesangial hypercellularity score of hIgAN Oxford classification and urine protein excretion. It was also inversely correlated with p27 expression in glomeruli. In vitro, cultured podocytes express Dtk and Mer. TGFβ could increase Gas6 mRNA and decrease p27 in podocytes. Gas6 itself could reduce the expression of p27. Moreover, Gas6 urine excretion increased in IgA nephropathy patients compared as normal subjects.

Conclusions: Gas6 upregulation in hIgAN was observed in either endothelial/mesangial cells or podocytes. The expression pattern can be a marker to classify hIgAN. Gas6 has a possibility to be involved in podocyte damage via Dtk or Mer in hIgAN.

Prostaglandin E2 Modulates Cell Cycle Regulatory Genes in Restoring Function and Pathology in Nephrotoxic Nephritis Nino Kvirkvelia, Maggie McMenamin, Michael P. Madaio. *Medicine, Georgia Health Sciences University, Augusta, GA.*

Background: Though PGE_2 has been studied for its regulatory properties in: maintaining tissue homeostasis, controlling inflammation and fibrosis, and reshaping immunity, its role in tissue regeneration has been less evident. We observed that PGE_2 promoted recovery from NTN, and enhanced cellular regeneration contributed to the improvement. The present aim was to define the pathways involved in recovery.

Methods: Microarray gene expression and pathway analysis was carried out. Total RNA (trizol extraction) was isolated from kidneys of NTS, NTS/PGE_2 treated, and control mice, and processed. Affymetrix Gene Chip: Mouse gene 1.0 array was used for gene expression profiling. Further pathway and statistical analysis were generated through the use of iReport (Ingenuiy Systems).

Results: "Proliferation of cells", "tissue development" and "growth of the cells" were ranked highest based on p_value enrichment score and the number of differentially expressed genes (DEG: 272, 232, 195 respectively). In particular, genes specific for cell cycle/growth promoting pathways were identified as responsive to PGE_2 treatment and upregulated in PGE_2 treated kidneys. Among them: CDK1 (5.568 fold), FOXM1 (3.882fold), S100A6 (8.484 fold), CCN2 (2.003 fold), CCNF (2.014 fold), ANLN (8.698 fold) were of particular relevance.

Conclusions: Beneficial effects of PGE_2 in acute nephritis was mediated at least in part, by eliciting in growth promoting genes, regulating cell cycle progression and recovery processes within the kidney. Further definition of functional relevance of identified genes /pathways are under investigation.

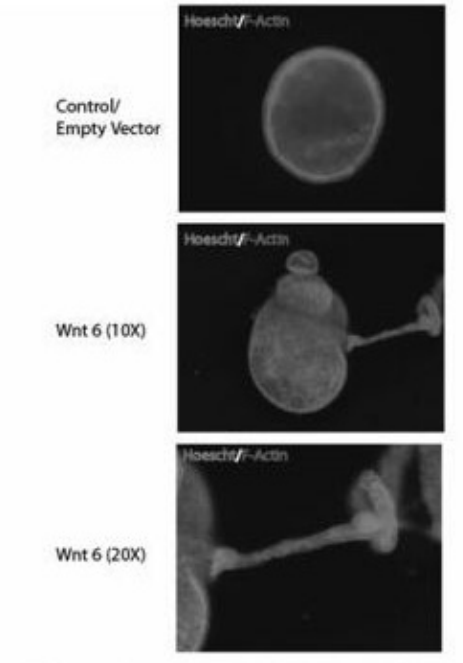
Wnt 6 Is Increased in Diabetic Nephropathy and Modulates De Novo Tubulogenesis and Opposes TGFβ1 Mediated Epithelial Cell Differentiation In Vitro John Crean, Andrew Gaffney, Noel Faherty, Catherine Godson, Debra F. Higgins. *UCD Conway Institute of Biomolecular and Biomedical Science, University College Dublin, Dublin, Co. Dublin, Ireland.*

Background: Studies from our group and others have identified a role for Wnt signalling in the pathogenesis of diabetic nephropathy. In this context, Wnt pathways are increasingly seen as targets for therapeutic intervention.

Methods: Microarray analyses of renal biopsis from patients with diabetic nephropathy were performed identifying genes whose expression was significantly increased. One of these genes, Wnt6, was cloned and expressed in renal epithelial cells. Tubulogenesis was analysed in MDCK cells. The effect of Wnt 6 on signaling and proliferation were analysed in HKC8 cells. Fluorescent microscopy was used to assess the effect of Wnt6 on TGFβ1 mediated epithelial to mesenchymal differentiation.

Results: Wnt6 expression is significantly increased in nephropathy correlating with disease severity. *In vitro* Wnt6 expression leads to de novo tubulogenesis(Figure 1) associated with enhanced cell proliferation, phosphorylation and activation of the EGF receptor.



Wnt 6 induces tubulogenesis in MDCK 3-dimensional culture. MDCK Cells were grown in 3D culture in Matrigel for 10 days. Cells were then transfected with a expression vector encoding Wnt 6 or a control/empty vector. Cultures were grown for a further 72 hours, fixed and stained with Alexa 488 Phalloidin and Hoescht 33342. Control cells maintained a cyst-like spherical structure while cells expressing Wnt 6 underwent cellular proliferation and differentiation resulting in the production of *de novo* tubular process, analagous to tubulogenesis

The canonical Wnt pathway was activated in cells treated with Wnt6 conditioned media as evidenced by increased phosphorylation of GSK3β (Ser9), nuclear accumulation of β-catenin and TCF/LEF activity. Overexpression of Wnt6 increased e-cadherin, suggesting a role in maintenance of epithelial phenotype. Importantly, overexpression of Wnt6 rescued epithelial to mesenchymal cell transdifferentiation in response to TGFβ.

Conclusions: We propose that Wnt 6 is involved in determining cell fate specification and as such its increased expression activates transcriptional programmes that determine phenotypic transition. These studies provide a valuable insight into the pathogenesis of diabetic nephropathy and raise the possibility that manipulation of Wnt6 may be of therapeutic benefit.

Angiotensin II Regulated Proteome of Human Kidney Cells Uncovers Nrf2 Target Proteins Ana Konvalinka,[1] Eleftherios P. Diamandis,[2] James W. Scholey.[1] [1]*Medicine, Division of Nephrology, University of Toronto, Toronto, ON, Canada;* [2]*Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada.*

Background: Angiotensin II (ANGII), an effector of the renin angiotensin system leads to kidney disease progression, but there are no measures of renal ANGII activity. Accordingly, we sought to define an ANGII-stimulated proteome in primary human proximal tubular cells (PTEC) in order to identify potential markers of ANGII activity in the kidney.

Methods: We utilized stable isotope labeling with amino acids (SILAC) in PTECs to compare proteomes of ANGII treated to Control cells. PTECs treated with ANGII were also compared to ANGII + Angiotensin-type1 receptor (AT-1R) blocker stimulated PTECs. Experimental PTEC pairs of lysates were processed together. Desalted peptide fractions were analyzed using LTQ-Orbitrap. Peptide/Protein identification and calculation of ANGII:Control ratios was performed by MaxQuant on the human IPI database. Ingenuity Pathway Analysis (IPA) and Cytoscape identified protein networks and enriched Gene Ontology (GO) terms.

Results: Of 5010 identified proteins, 4968 were quantified in 5 replicates. Eighty four proteins were differentially regulated in more than one replicate with $p<0.01$. IPA uncovered differential regulation of proteins in antioxidant response (Nrf2) pathway by ANGII. The most consistently upregulated protein in response to ANGII, heme oxygenase-1 (HO-1), is downstream of Nrf2. HO-1 protects from oxidative stress and limits fibrosis. Enriched GO term network of differentially expressed proteins was overlaid with gene expression set from an analogous study in mice. "Response to stress" was an enriched GO term in both sets and contained five proteins from Nrf2 network, including HO-1. In the presence of AT-1R blocker, HO-1 was upregulated 2.3 fold, compared to 1.6 fold with ANGII alone. The same pattern of HO-1 gene expression was identified by RT-PCR.

Conclusions: SILAC and bioinformatic analyses have identified Nrf2 related proteins, which may serve as markers of ANGII activity in the kidney, and represent potential therapeutic targets. Pattern of HO-1 upregulation suggests novel mechanism of action of AT-1R blockers.

TH-PO233

Impact of Prophylactic Antibiotic Lock on Healthcare Utilization and Costs
Carol Moore, Anatole Besarab, Vivek Soi, Edward Peterson, Beth Adams, Jerry Yee, Lois Lamerato. *Henry Ford Health System, Detroit, MI.*

Background: Catheter-related bacteremia (CRB) is associated with significant morbidity and healthcare utilization in hemodialysis patients. Prophylactic antibiotic lock (ABL) can reduce CRB, its impact on healthcare utilization has not been described.

Methods: We conducted a prospective, multicenter, observational cohort study comparing heparin (HEP) and prophylactic ABL containing gentamicin 0.32mg/ml with trisodium citrate (4%) over 33 months in pts dialyzing with tunneled caths. Primary outcome compared infection-related hospitalization (IR-HOSP) rates between grps. Other outcomes were CRB, overall HOSP and vascular access procedures (VASC). Charges from billing records were available for 83% of pts and used as a proxy for cost. Since patients could have CRB, HOSP, VASC and charge accrual in both time periods we adjusted for correlation between measurements using a ratio estimator from sampling theory to test the various rates.

Results: The population (n=555) had a median age of 62, 50% male and 71% black. 427 subjects were followed for 90,627 days in HEP period compared to 304 and 73,169 during ABL period.

Demographics and Outcomes Comparisons

	HEP (n=427)	ABL (n=304)	P
Age	62 +/- 15	62 +/- 15	0.752
Sex	213 (50%)	157 (52%)	0.523
Black	299 (70%)	227 (75%)	0.090
CRB/1000 days	1.6	0.4	0.001
IR-HOSP/pt yr	1.3	0.9	0.004
Overall HOSP/pt yr	3.6	3.0	0.146
VASC/pt yr	2.8	2.5	0.274
HOSP Charges ($)/pt yr	128,050	91,120	0.015
VASC Charges ($)/pt yr	18,555	16,134	0.194
Total Charges ($)/pt yr	146,605	107,253	0.015

CRB declined 75% from 1.6 to 0.4/1000 days, p=0.001. 328 IR-HOSP occurred in HEP period and 176 in ABL period (1.3 vs 0.9/pt yr, p=0.004). Extrapolating this reduction, we estimate 85 IR-HOSP were averted due to use of ABL. Overall HOSP and VASC were similar. HOSP costs were significantly lower by $36,930/pt yr, p=0.015, in ABL period and VASC costs were similar. Overall healthcare costs were significantly lower by $39,352/pt yr, p=0.015, in ABL period. Extrapolating this reduction, we estimate $7,903,275 in costs averted due to use of ABL over study period.

Conclusions: The use of prophylactic ABL was associated with a significant reduction in CRB, healthcare utilization and costs.

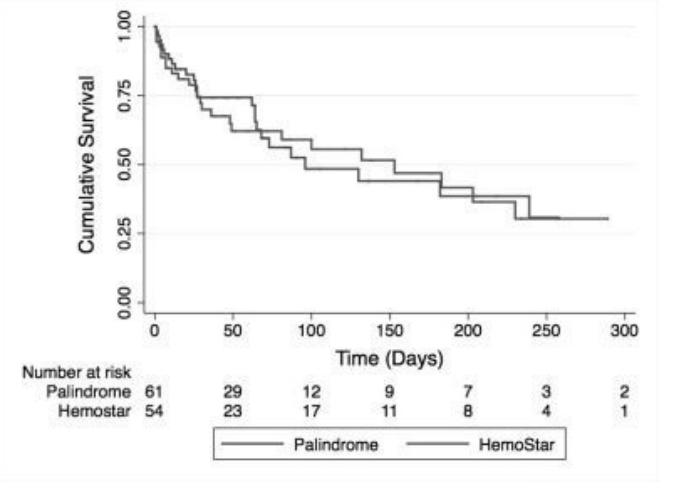
TH-PO234

Comparison of Heparin and Silver Coated and Standard Central Venous Catheters: Randomized Controlled Trial
Meteb M. AlBugami, Karthik K. Tennankore, Paula Mossop, Bryce A. Kiberd, Steven D. Soroka. *Department of Medicine, Division of Nephrology, Dalhousie University, Halifax, NS, Canada.*

Background: The use of central venous catheters (CVC) in hemodialysis has been growing, thereby more infections and thromboses are encountered on daily basis. Certain enhancements have been applied to the CVCs to minimize these complications, however, these come at a cost. Using Enhanced CVCs would be cost effective if they require less fibrinolysis and have longer patency.

Methods: A randomized controlled trial comparing the Enhanced, heparin and silver coated (*Sapphire Palindrome*) to Standard CVCs (*Hemostar*), with the hypothesis that using Enhanced CVCs will result in decreased tPA use and prolonged catheter patency. Those with new CVC incretion or replacement, using 19 or 23 cm placed over the right or left IJ were included. The primary outcome was the difference in tPA use. The secondary outcomes were the time to the first tPA use, and the times to CVC replacement for poor flow or bacteremia.

Results: 61 Enhanced and 58 Standard CVCs in 92 patients were included in the final analysis. Patients characteristics were the same. The mean tPA doses were 15.6 mg and 17.1 mg for the Enhanced and Standard groups, respectively (*P*=0.59). The cumulative time to first tPA use was 162 (95% CI 116 to 209) and 156 (95% CI 113 to 200) days for both groups respectively (*P*=0.54).



12 Enhanced and 8 Standard CVCs were changed due to poor flow, respectively (*P*=0.47), also 7 and 11 were changed due bacteremia, respectively (*P*=0.31). There were no differences on cumulative time to CVC removal due to poor flow or bacteremia. More cuff migrations were seen in the Enhanced group.

Conclusions: Using heparin and silver coated CVCs does not seem to be cost effective, as there was no difference in catheter survival. Given the small numbers of bacteremia, significant difference might have been missed.

TH-PO235

A Comparison of Costs of Using Once Weekly rt-PA or Heparin as a Locking Solution for Hemodialysis Catheters: Findings from the Prevention of Catheter Lumen Occlusion with rt-PA versus Heparin(Pre-CLOT) Randomized Trial
Braden J. Manns,[1] Nairne William Scott-Douglas,[1] Scott Klarenbach,[2] Louise M. Moist,[3] Marcello Tonelli,[2] Pietro Ravani,[1] Flora Au,[1] Marc Dorval,[5] Charmaine E. Lok,[4] Betty K. Chui,[2] Natasha Wiebe,[2] Brenda Hemmelgarn.[1] *[1]Univ Calgary, Calgary, AB, Canada; [2]Univ Alberta, Edmonton, AB, Canada; [3]Univ W ON, London, ON, Canada; [4]Univ Toronto, Toronto, ON, Canada; [5]Moncton Univ, Moncton, NB, Canada.*

Background: In a recent RCT, weekly rt-PA, 1 mg per lumen, once per week and twice weekly heparin as a locking solution, resulted in lower risks of hemodialysis catheter malfunction and catheter-related bacteremia compared to thrice weekly heparin. We conducted an extensive costing study using data collected alongside the RCT to determine how using rt-PA, rather than heparin, would affect overall health care costs.

Methods: The primary objective was to determine the cost associated with using rt-PA rather than heparin, considering the cost of locking solutions and all other relevant medical costs (including the cost of managing catheter dysfunction, and catheter-related bacteremia) during the 6 month trial. As the data for costs from the trial were skewed, non-parametric bootstrap estimates were used to derive 95% CIs and mean cost differences.

Results: The cost of the locking solution was higher in patients receiving rt-PA, but this was offset by lower costs for managing complications. Overall, the difference in unadjusted mean cost for managing patients with rt-PA vs heparin was CAN -$118 (95% CI -$1,480 to $1,244; p = 0.865).

	rt-PA (n=110)	Heparin (n=115)
Mean rt-PA and heparin costs for locking solution (SD)	$1206 (598)	$130 (85)
Mean cost of managing patients with catheter malfunction (SD)	$47 (249)	$149 (499)
Mean cost managing patients with catheter-related bacteremia (SD)	$466 (2785)	$1550 (7038)
Total mean cost (SD)	$1718 (2724)	$1830 (7013)
Mean cost difference (rt-PA minus heparin) (95% CI; p-value)	-$118 (-1,480 to +1,244; p=0.865))	

Conclusions: Using patient-specific data on all relevant health care costs collected alongside a RCT, we observed no significant difference in the mean cost of using once-weekly rt-PA as a locking solution for catheters, compared to heparin.

Crossing Infections in Patients Undergoing Hemodialysis through a Temporary Dual Lumen Catheter: A Prospective Study with Bacterial Genotyping Methods
Jose A.C. Costa, Miguel Moyses-Neto, Viviane Ferreira, Juliana P. Falcão, Roberto Martinez. *Faculty of Medicine-USP, Ribeirao Preto, SP, Brazil.*

Background: Patients undergoing hemodialysis (HD), through a temporary dual lumen catheter (TC), have a high incidence of infection. The aim of this study was to compare isolated bacteria, by genotyping methods, collected at different sites in the same patient as well as strains isolated in the same sites, but in different patients.

Methods: Patients with acute kidney injury at an Intensive Care Unit (ICU) were studied with microbiological analysis of samples collected at different sites: TC insertion site, blood cultures (BC) of TC lumen, peripheral vein BC, and BC of other central venous accesses before the first session of HD; at TC removal, we analyzed the cultures of TC catheter tip and all BC previously mentioned. The bacterial isolation was carried out in conventional culture media. Genotyping diversity was performed by Pulsed-Field Gel Electrophoresis with enzyme XbaI for *Klebsiella pneumoniae* and speI for *Pseudomonas aeruginosa*. Data were analyzed by Bionumerics 5.1 program (Applied Maths) and the similarity of fragment length patterns between two strains was scored by the Dice coefficient.

Results: Although 96 patients were evaluated, our results are related to 6 patients who presented 14 strains of *P.aeruginosa* and 6 patients who presented 14 strains of *K.pneumoniae* at different sites. From 6 patients infected with *P.aeruginosa*, 3 of them were infected by similar strains in at least 3 different sites at TC removal (BC of TC lumen, culture of catheter tips, BC of a peripheral vein, and BC of any other central venous accesses), and at least at one site of other 3 patients. From 6 patients infected with *K.pneumoniae* 5 of them were infected by similar strain in at least 3 sites, and at least at one site of other patient at TC removal.

Conclusions: The same strain of *P.aeruginosa* and *K.pneumoniae* has infected the same patient at different sites suggesting that these patients should have better assistance to avoid spreading of the bacteria. Also, the isolation of the same strain with high genotypical similarity in different patients suggest that crossing infections are occurring in the ICU.

Microbiological Screening for Detection of Central Venous Catheter Related Bloodstream Infections in Patients Undergoing Hemodialysis

Jasmin Wagner,[1] Thomas Valentin,[1] Martin Hoenigl,[1] Gernot Schilcher,[2] Werner Ribitsch,[2] Joerg H. Horina,[2] Alexander R. Rosenkranz,[2] Robert Krause.[1] *[1]Section of Infectious Diseases, Medical University of Graz, Austria; [2]Division of Nephrology, Medical University of Graz, Austria.*

Background: Catheter colonization with a cut off level of 1000 organisms/ml catheter blood is considered to be a forerunner of central venous catheter related bloodstream infections (CRBSI). This prospective trial was undertaken to evaluate whether the PNA FISH test could serve as a screening tool to detect CRBSI in a subclinical stage in hemodialysis patients with central venous catheters (CVCs) used with non antimicrobial locking anticoagulants (heparin, citrat 4%).

Methods: Fiftyfive hemodialysis patients with 60 catheter episodes were prospectively investigated. Screening for CRBSI was performed by PNA FISH test with universal hybridisation probes (for detection of all relevant bacteria and fungi) three times a week using EDTA blood from both lumina of CVCs obtained prior to hemodialysis. In addition blood samples were quantitatively cultured on chocolate agar. If CRBSI was clinically suspected, routine investigation was performed by the Gram stain/acridine orange leucocyte cytospin (AOLC) test, differential time to positivity (DTP) and Brun Buisson method.

Results: 2972 blood samples were investigated. With routinely performed investigations 2 CRBSIs were detected in 3691 catheter days resulting in a CRBSI rate of 0,5/1000 catheter days. Both of these 2 CRBSIs were detected by PNA FISH screening before the diagnosis was established by routine measures. In 58 catheter episodes no CRBSI could be detected by routinely performed tests. In 3 of these catheter episodes PNA FISH screening was false positive. The sensitivity and specificity of PNA FISH screening were 100% and 95%, the PPV and NPV were 40% and 100%.

Conclusions: Screening of blood drawn from CVCs prior to hemodialysis by PNA FISH helps to detect patients at risk for clinically evident CRBSI. Thus, patients with positive screening should be thoroughly observed with regard to development of clinically evident CRBSI. Patients with negative PNA FISH screening tests are unlikely to develop CRBSI.

TH-PO238

Impact of Enhanced Infection Control Practices on Access Infections in an Acute Dialysis Unit

Deeba N. Ali,[1] Elizabeth Kuo,[1] Henry Quinones,[1] Annette Palm,[3] Valsala Jacob,[3] James P. Luby,[2] Daniel Spiegel,[4] Pranavi Sreeramoju.[2] *[1]Nephrology, UT Southwestern Medical Center, Dallas, TX; [2]Infectious Disease, UT Southwestern Medical Center, Dallas, TX; [3]Parkland Health and Hospital System, Dallas, TX; [4]UT Southwestern Medical Center, Dallas, TX.*

Background: Infections are a major contributor to mortality and morbidity. Parkland Health and Hospital System (PHHS), a large public academic health system in Dallas, TX, provides emergent dialysis to numerous unfunded individuals. We performed this quality improvement study to determine if changes in the acute dialysis unit's (ADU) infection control policies improved rates of access-related infections in this population.

Methods: We conducted a retrospective review of all patients who underwent dialysis treatments in the ADU during a 3 month period before (period 1) and after (period 2) infection control policy changes were implemented in August 2011, including increased hand hygeine, use of personal protective equipment with gowns/gloves by all hospital staff and no food/drinks in the unit. We assessed catheter-related bloodstream infection (CRBSI) and complication (death, ICU transfer, endocarditis, bone/joint or other) rates per 100 patient-weeks of hemodialysis.

Results: Overall, 264 patients underwent 1379 patient-weeks of dialysis in period 1, and 256 patients underwent 1340 patient-weeks of dialysis in period 2. Forty percent were unfunded. There was no significant difference in rates of CRBSI (1.54 v 1.53) or complications (0.87 v 0.57) among the unfunded patients. The unfunded patients were significantly more likely to have a tunneled catheter for access and to have CRBSI of gram-negative or polymicrobial etiology when compared to funded patients.

Comparison by funding status

	Unfunded	Funded	*P-value*
Tunneled catheter (%)			
Period 1	82	46	*<0.000*
Period 2	80	44	*<0.000*
Gram-negative or polymicrobial infections (%)			
Period 1	69	18	*0.026*
Period 2	56	10	*0.021*

Conclusions: CRBSI rates did not change after implementation of enhanced infection control practices. Unfunded patients who receive emergent dialysis differed from the overall dialysis population, with a greater susceptibility to CRBSI of gram-negative or polymicrobial etiology.

TH-PO239

Cost Analysis of the Hemodialysis Infection Prevention with Polysporin Ointment Study

Sarah Daisy Kosa,[1] Amiram Gafni,[2] Charmaine E. Lok.[1] *[1]Nephrology, Toronto General Hospital, Toronto, ON, Canada; [2]Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, ON, Canada.*

Background: In a multicenter RCT, application of polysporin triple ointment (PTO) at the catheter (CVC) entry site significantly decreased hemodialysis (HD) CVC-related bacteremia, hospitalizations and mortality (Lok, 2003). We performed an economic analysis of the use of PTO over standard HD catheter care without PTO (SOC) in Ontario, Canada.

Methods: Health care utilization data comparing PTO to SOC was calculated from a third party payer perspective, including opportunity costs of dialysis nurses. Resource use associated with CVC-related bacteremia, all visit data for all HD patients with CVC from April 1, 2008 to March 31, 2011 was extracted from the University Health Network's Case Costing Database.

Results: The cost of PTO was $240.36 (per patient) and $1,449,615.36 (all HD patients in Ontario with CVC) for one year from a third party payer perspective. The cost reduction with PTO over SOC due to the treatment of CVC-related bacteremia in Ontario is $22,893,676.84. The total savings from PTO use after accounting for the cost of PTO implementation in Ontario and considering the infection related costs of PTO instead of SOC is approximately $21,444,061.48 (Table 1).

Table 1

Type of Cost	**Unit Cost**	**Total Cost per Year**
Polysporin Triple Ointment	$43.20/pt year	$259,891.20
Hemodialysis Nurse Application of PTO	$197.76/pt year	$1,189,724.16
Cost of PTO Program for Hemodialysis Patients in Ontario		**$1,449,615.36**
Catheter Removal and Insertion	$1,121.17/event	-$1,146,642.98
Outpatient treatment for Bacteremia	$262.19/event	-$630,934.02
Hospitalization for Bacteremia	$22,842.81/event	-$21,116,099.84
Infection Outcome Related Costs of PTO versus SOC*		**-$22,893,676.84**

* Using catheter removal, bacteremia, and hospilitization rates from the HIPPO trial data, the expected number of patients with event in one year in Ontario using the PTO program of care - the expected number of patients with event in one year in Ontario using SOC

Conclusions: This cost analysis demonstrates that PTO has marginally more upfront costs than SOC, but has significant long-term cost savings associated with reduced rates of bacteremia.

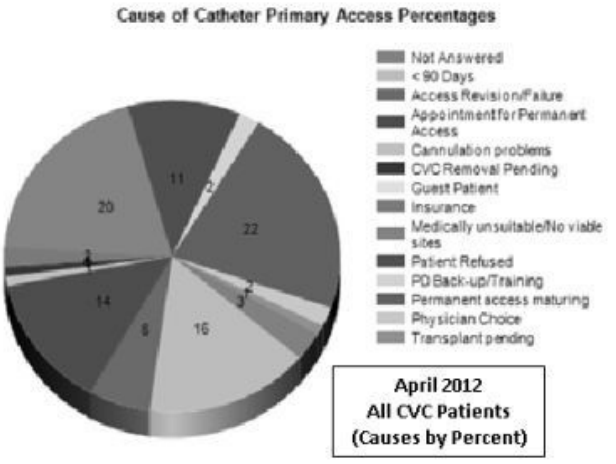
TH-PO240

Identifying and Targeting the Causes of Central Venous Catheters in Chronic Dialysis Patients

Kirk Finchem,[1] Patricia McCarley.[1] *[1]Clinical Operations, Renal Advantage, Inc, Franklin, TN.*

Background: Central venous catheters (CVCs) in patients on hemodialysis are associated with increased morbidity and mortality. The 2012 performance year QIP target for CVC utilization is ≤14% of hemodialysis patients. This study summarizes an initiative to identify and target the reasons that patients have CVCs.

Methods: Clinical staffs at the system of 155 centers in the US (11,000 ESRD patients) self-reported the primary cause for CVCs in patients who were not using AV fistula or graft accesses. Causes were selected from a list of 'expected causes' prepared prior to the study, and revised during the study.



Results: For April 2012, 59.7% of incident patients used CVC accesses and 17.8% prevalent patients had CVC accesses. Twenty percent of prevalent patients with a catheter were identified as "medically unsuitable or no viable access site"; 20% of prevalent patients were identified as "permanent access maturing."

A regression analysis demonstrated that incident CVC rate is an important predictor of prevalent CVC rate (R^2=0.2109, 95% CI slope=0.1287 to 1.1382).

Incident Patient CVC Rate (ICVC) as a Predictor of Prevalent Patient CVC Rate (PCVC)

Variable	DF	Parameter Estimate	Std Error	t Value	Pr > |t|	95% CL - Lower	95% CL - Upper
Intercept	1	-0.1989	0.14112	-1.41	0.1711	-0.4896	0.0918
ICVC	1	0.6334	0.2451	2.58	0.0160	0.1287	1.1382

Conclusions: Understanding patient-specific causes for CVCs are important to systematic interventions to achieving access targets. CVCs are increasingly common in incident patients, and incident CVCs are a predictor of prevalent CVCs. Clinicians must focus efforts to reduce CVCs in the incident population. Developing consistent criteria to evaluate patients who are "medical unsuitability" for permanent access placement will be important to reduce the number of patients with CVCs.

TH-PO241

A Novel Mouse Model to Assess Soluble Epoxide Hydrolase and Pro-Thrombotic Factors in Catheter-Induced Vascular Occlusion Yuxia He,[1] Huan Li,[1] Ilya S. Zhuplatov,[1] Donald Blumenthal,[2] Christi M. Terry,[1] Alfred K. Cheung.[1,3] *[1]Medicine, Univ of UT, Salt Lake City, UT; [2]Pharmacology, Univ of UT, Salt Lake City, UT; [3]Medicine, VASLCHCS, Salt Lake City, UT.*

Background: Indwelling central catheters predispose veins to neointimal hyperplasia (NH) and thrombosis. Pro-inflammatory (soluble epoxide hydrolase or sEH) and pro-thrombotic (common coagulation cascade) pathways that may participate in these events were examined. Vasculo-protective P450 epoxygenase metabolites are catabolized by sEH while factor Xa is central in coagulation.

Methods: A 0.5-cm long section of polyurethane catheter (0.6 mm i.d.) was inserted into the jugular vein of either wildtype (WT) or sEH knockout (KO) mice and left in place for 7 days. Vehicle or rivaroxiban (ROX) (10 ng/kg), a direct factor Xa inhibitor, were administered by daily gastric gavage in a blinded fashion to WT and KO mice. Ultrasound was performed in vivo to assess patency and the animals were euthanized, blood samples obtained and histomorphometry performed on the explanted vein containing the catheter to assess NH. Cell proliferation in the vein wall was assessed by Ki67 immunostaining. Plasma levels of the prothrombotic plasminogen activator inhibitor-1 (PAI1) were assessed by western blotting.

Results: Vein patency and vein wall cell proliferation rates at day 7 are shown in the Table.

Effect of sEH genetic background and rivaroxiban on patency and cell proliferation.

	Vehicle (% patent, % Ki67-positive cells)	Rivaroxiban (% patent, % Ki67-positive cells)
WT	40% (n=5), 72%	80% (n=5), 24% ±11
KO	67% (n=3), 35%±20	100% (n=6), 32% ±6

Higher patency rates and less cell proliferation were observed in sEH-KO mice compared to WT. ROX also increased patency rates and decreased cell proliferation. ROX decreased plasma PAI1 levels in mice of either genetic background. There were no untoward bleeding events in any group.

Conclusions: These preliminary results suggest that sEH may contribute to catheter-induced central venous stenosis and that an inhibitor of sEH may be useful in this and other vascular stenosis settings. ROX was associated with increased patency in both WT and sEH backgrounds and may also be useful as a preventative therapy.

TH-PO242

Vascular Access Type and the Trajectory of the Inflammatory Markers in Hemodialysis (HD) Patients Tanushree Banerjee,[1] Joseph Kim,[2] Brad C. Astor,[3] Tariq Shafi,[4] Josef Coresh,[4] Neil R. Powe.[1] *[1]University of California, San Francisco; [2]University Health Network, Toronto; [3]University of Wisconsin; [4]Johns Hopkins University.*

Background: The contribution of vascular access (VA) type to inflammation in HD patients is unclear. We investigated the role of VA type on serial inflammatory markers in the CHOICE cohort.

Methods: In a national, prospective cohort study of incident HD patients we measured serum C-reactive protein (CRP) and Interleukin-6 (IL-6) after the insertion of the VA type and at subsequent time points after access placement over first 3 years of HD. We limited the analyses to patients with little comorbidity (ICED score=0 or 1) to minimize confounding by comorbid disease status. Type of VA was categorized as central venous catheter (CVC), arteriovenous graft (AVG) and arteriovenous fistula (AVF). We accounted for the changes in VA type over time and corresponding VA type was determined for each available period of cytokine measurement. Multivariate analyses for repeated measures were performed using mixed effects models with adjustment for age, sex, race, BMI, diabetes, CVD, VA type and days after access placement, with CRP and IL-6 as log-transformed dependent variables.

Results: 423 incident HD patients were included (CVC=174, AVG=144, AVF=105). Baseline characteristics did not differ across the 3 types of access except for mean participant age was greater in those with AVG (p=0.01). In multivariate analyses, in comparison to AVFs, the presence of CVC was associated with nearly 40% increase in CRP (p=0.02). IL-6 levels also positively correlated with CVC showing 4% increase in the IL-6 levels, although this did not reach statistical significance (p=0.07). The presence of AVG was associated with 80% increase in CRP (p=0.01) and with IL-6 the change associated was 2% (p=0.06). The levels of CRP decreased over time, with the highest inflammatory state of 30 days after access placement when compared with markers over 180 days (p=0.02). Similar results were obtained for IL-6 levels, though they did not reach statistical significance.

Conclusions: CVCs and AVGs in comparison to AVFs are associated with a greater state of inflammation in incident HD patients.

TH-PO243

An Observational Study of the Effect of Anticoagulation with Warfarin on Femoral Tunnelled Dialysis Catheter Associated Deep Venous Thrombosis and Catheter Patency William G. Herrington,[1] Helen Nye,[2] Richard Haynes,[1] Christopher G. Winearls,[1] Emma C. Vaux.[2] *[1]Oxford Kidney Unit, Oxford University Hospitals NHS Trust, Oxford, United Kingdom; [2]Royal Berkshire Hospital Renal Department, Royal Berkshire NHS Foundation Trust, Reading, United Kingdom.*

Background: To determine the incidence and predictors of femoral tunnelled dialysis catheter (TDC)-associated complications and whether prophylactic warfarin is associated with reduced catheter-associated deep vein thrombosis (DVT) or prolonged catheter patency.

Methods: A retrospective review of femoral TDCs inserted for maintenance hemodialysis, comparing patients from two dialysis units using different strategies to reduce thrombotic complications. One centre routinely considered all femoral TDCS for prophylactic anticoagulation, whilst the other restricted warfarin use to catheters that had required repeated treatment with urokinase locks to maintain patency. Survival analyses were performed to establish complication rates, identify predictors of complications and assess the effect of a policy of prophylactic warfarin use.

Results: Of the 194 identified femoral TDCs, 178 (92%) were associated with at least one complication. Approximately three quarters did not provide adequate small solute clearance; one half were not in use by 3 months; one quarter were associated with at least one proven infection (2.3 per 1,000 catheter days); and one in ten developed a catheter-associated DVT (1.1 per 1,000 catheter days). Prophylactic warfarin use was not associated with significant improvements in rates of catheter blockage (hazard ratio [HR] 1.4 [95% confidence interval 0.7-2.9]; p = 0.33), DVT (HR 0.7 [95% CI 0.3-1.7]; p = 0.39), infection or with improved dialysis adequacy. A previous ipsilateral femoral TDC was identified as a significant predictor of a catheter-associated DVT (HR 3.6 [95% CI 1.4-9.3]; p = 0.01).

Conclusions: Femoral TDCs are associated with poor patency and high complication rates, re-using femoral veins for TDCs should be avoided where possible, and there is no proven benefit of prophylactic anticoagulation with warfarin in patients with femoral TDCs.

TH-PO244

Vascular Access Use and Access Infections from Dialysis Claims Data Craig Solid,[1] Robert N. Foley.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

Background: Starting in July of 2010, Medicare claims billed by outpatient (OP) dialysis facilities include information on the type of vascular access (VA) used for each dialysis session and whether there was a VA infection. This represents the first time that the use of types of VA can be tracked using claims data.

Methods: We used the USRDS database to identify hemodialysis (HD) patients who were either prevalent as of July 1, 2010 or incident during 2010 such that Medicare coverage (day 91) began during July through September of 2010. Outpatient dialysis claims and HCPCS modifier codes were used to identify the type of VA patients used during the remainder of 2010. Patients were grouped based on the type of VA(s) used during the entire study period. A VA infection represents the presence of a HCPCs modifier code indicating such on at least one OP dialysis claim during the study period.

Results: A total of 204,372 prevalent patients were identified, 177,875 (87%) of whom had dialysis claims in all 6 months of July through December of 2010. For these patients, 10% used only a catheter, 56% only an AVF, and 21% only an AVG. Those using only a catheter more often had an indication of a VA infection (7%) compared to those with internal accesses (<1%). Within the 11,290 incident patients having at least 4 months of claims in 2010, 38% used a catheter only,18% an AVF only, 5% an AVG only = 5%, and 38% used catheter and internal access. VA infections occurred in 6% of catheter users and 1.6% of those only using an internal access.

Table 1

	Prevalent Pts		Incident Pts	
Total	117,875	VA Inf	11,290	VA Inf
Catheter Only	10.3%	7.1%	37.6%	5.9%
AVF Only	56.2%	0.9%	18.4%	1.6%
AVG Only	21.3%	0.9%	4.9%	1.6%
Cath+Internal	9.8%	6.3%	38.4%	6.2%

Conclusions: For the first time, vascular access use for each dialysis session used is available from claims. Initial investigations demonstrate that most prevalent patients consistently use one type of access, while for incident patients it is more common to use multiple types. VA infections reported on the dialysis claims are more common for those using catheters than those using internal accesses.

TH-PO245

Procoagulant Antibodies Do Not Predict Catheter Dysfunction Albert J. Power, Janet Lee, Peter Hill, Damien Ashby, David Taube, Neill D. Duncan. *Imperial Renal & Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Thrombotic mechanical dysfunction is the prime reason for inadequate hemodialysis [HD] in patients dependent on central venous catheters [CVC]. The role of procoagulant profiles in access thrombosis has been studied in arteriovenous grafts and fistulae with conflicting results and is very poorly characterized in CVCs. We therefore examined this association in the setting of a prospective trial.

Methods: The VyTes study was a randomized controlled trial comparing CVC performance in adults incident to HD. Patients were randomized to receive either a TesioCath [MedComp] or LifeCath Twin [Vygon] CVC, dialyzed to target blood flow rate [BFR] of 450ml/min and followed up for 12 months. Catheter dysfunction was defined by a BFR ≤250ml/min. Available serum was tested for anticardiolipin [ACA] IgG, IgM & IgA antibodies and lupus anticoagulant [LA]. In addition anti-β2-glycoprotein-1 [b2-GP1] antibodies were tested for in a subset of patients with prior arteriothrombotic disease [e.g. stroke, myocardial infarction, peripheral arterial disease].

Results: 80 patients were enrolled [mean age 61±16 yrs]. There was no significant difference in dialysis adequacy between the TesioCath and LifeCath groups [mean spKt/V 1.81±0.29 vs. 1.85±0.36,p=0.07] or BFR [mean 413±46 vs. 411±43ml/min,p=0.5]. The overall rate of CVC dysfunction was 2.8/1000 catheter days [95% CI, 2.1-3.5]. In total 7/49 [14%] patients assayed were ACA IgM +ve, 2% IgG and 7% IgA +ve. Only 1/36 patients tested was anti-b2-GP1 IgG +ve. No patients tested positive for anti-b2-GP1 IgM or lupus anticoagulant [n=41]. None of the patients testing positive for any antibody subclass experienced CVC dysfunction or a systemic thrombotic event during the period of follow-up.

Conclusions: In the largest prospective study of its kind to date to our knowledge we found no association between ACA, LA and anti-b2-GP1 antibody status and thrombotic CVC dysfunction. Despite the relatively small sample size and low event rate this finding is consistent with prior data in arteriovenous accesses and suggests that screening for procoagulant antibodies has no role in risk stratification for CVC dysfunction.

TH-PO246

Comparison of Tesio and LifeCath Twin Permanent Dialysis Catheters (VyTes): A Randomized Controlled Trial Albert J. Power, Peter Hill, Seema Singh, Damien Ashby, David Taube, Neill D. Duncan. *Imperial Renal & Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Central venous catheters [CVC] for hemodialysis [HD] are designed to deliver high blood flow rates [BFRs] to achieve dialysis adequacy. Despite its good long-term performance the TesioCath [TC] is reported to function poorly immediately post-insertion. We prospectively studied the performance of the TC and a similar twin-catheter CVC, the LifeCath Twin [LC].

Methods: This single-center randomized controlled trial [NCT 01022359] allocated adult incident patients 1:1 to receive either a TesioCath™ [MedComp] or LifeCath Twin™ [Vygon]. All patients dialyzed to target spKt/V≥1.6 and target BFR 450ml/min and followed up for 12 months or until change of dialysis access or modality, death or transfer out. The primary outcome was achievement of the target BFR during the 1st HD post-insertion. Secondary outcomes included thrombotic dysfunction, displacement and CVC-related infection. Dysfunction was defined by a BFR ≤250ml/min and treated with urokinase [UK].

Results: 80 patients were randomized [mean age 61.0±16.1 yrs, 48% diabetic] with 24179 total catheter days follow-up. More LCs reached the primary endpoint compared to TCs [44% vs. 10%,p=0.001] delivering a higher BFR [mean 383±82 vs. 277±79ml/min, p<0.001]. Significant differences in BFR persisted until the 4th session after which both CVCs delivered equivalent BFRs [mean 411±43 vs. 413±46ml/min, p=0.5] and adequacy [mean spKt/V 1.85±0.36 vs. 1.81±0.29,p=0.07]. Rates of CVC-related bacteremia [0.40 vs. 0.51/1000 catheter days,p=0.7] and exit site infection were similar between groups [p=0.4]. The overall rate of catheter dysfunction was 2.8/1000 catheter days with no difference in rates of UK lock use between groups [p=0.3] although the LC group required more UK infusions [6 vs. 0,p=0.01].

Conclusions: The LifeCath CVC can deliver greater BFRs in the first 3 HD sessions following insertion although this did not translate into differences in performance, dialysis adequacy or complication rates with long term use. This data confirms that both CVC types can consistently deliver high BFRs and dialysis adequacy over an extended period of time.

TH-PO247

Catheter Flow Monitoring Can Predict Dysfunction in Maintenance Hemodialysis Albert J. Power, Claire Edwards, Seema Singh, Damien Ashby, David Taube, Neill D. Duncan. *Imperial Renal & Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Access surveillance is advocated for arteriovenous fistulae and grafts with criteria for dysfunction [NKF K/DOQI 2006]. Despite the enduring prevalence of central venous catheter [CVC] use with associated high rates of mechanical dysfunction there are no equivalent studies with this access form. We therefore studied the role of flow monitoring as a predictor of CVC dysfunction.

Methods: We retrospectively studied all patients with CVCs established [>90d] on hemodialysis [HD] receiving protocolised care at 1 dialysis unit at our center [Oct 2008-Feb 2011]. CVC function was assessed by the ratio of blood flow rate:outflow access pressure [BFR:AP]. CathRisk, an indicator variable, was positive when BFR:AP<0.9. Target BFRs were ≥350ml/min with dysfunction defined by consistent BFR<250ml/min and/or declining spKt/V [target ≥1.6]. CVCs were locked with heparin and 2-hour urokinase [UK] dwells used for dysfunction with infusions given in the event of treatment failure.

Results: A total of 40333 HD sessions with 224 CVCs were studied [164 patients, mean age 62.7±15.1yrs, 45% diabetic] spanning 108114 catheter days. 132/224 [59%] CVCs were the first access form. Mean session length was 4.3±0.5hrs, BFR 402±53ml/min and ultrafiltration [UF] volume 1.9±1.1l. 87% HD sessions achieved target BFRs with rates of CVC dysfunction 5.5/1000 catheter days [95% CI 5.1-6.0]. UK locks increased BFR≥40ml/min in 78/254[31%] cases with greater improvement when used in more advanced dysfunction [mean 4.7±0.6ml/min per 10ml.min^{-1} BFR decline,p<0.001]. On multivariate logistic regression the risk of CVC dysfunction was associated with greater dry weight [4%/kg,p=0.009], CVC vintage [2%/month,p=0.003], UF rate [70%/l.hr^{-1},p=0.05] and most significantly CathRisk +ve [OR 7.83,p<0.001].

Conclusions: In the first study of its kind to date to our knowledge we characterized the natural history of CVC function and correlated it to a dynamic performance parameter. This can provide a novel framework for flow monitoring in CVCs with potential to transform care through pre-emptive thrombolysis for incipient dysfunction as opposed to current strategies.

TH-PO248

Infective Endocarditis in Hemodialysis Patients: Association with Increased Utilization of Cardiac Rhythm Devices Brinda Desiraju,[1] Priyanka Singh,[1] Douglas Sepkowitz,[2] Neal Mittman.[1] *[1]Avram Division of Nephrology, SUNY Downstate at Long Island College Hospital, Brooklyn, NY; [2]Division of Infectious Diseases, SUNY Downstate at Long Island College Hospital, Brooklyn, NY.*

Background: Infective endocarditis (IE) is a serious complication of bacteremia in patients (pts) undergoing (HD), especially in those utilizing central venous catheter (CVC) hemoaccess. Transvenous cardiac rhythm devices (CRD) have recently become more common in HD pts, leading to greater recognition of device-related complications, including systemic infection.

Methods: We compared the association of CVC and CRD in HD pts with documented infective endocarditis (positive blood cultures and echocardiographic findings) diagnosed in our urban hospital during the past year to those occurring during the period of 2002-2008.

Results: There were 40 cases of documented IE in HD pts during 2002-2008, of whom 26 had CVC (65%). CRD were present in 3 pts (8%), all of whom were dialyzed with CVC. Mean age was 57.3 yr. There were 21 women. Nine pts expired during the course of IE, six with CVC. During the past year, 9 cases of IE were diagnosed. Six pts were dialyzed with CVC (66%) and 3 pts (33%) with arteriovenous grafts (AVG). Of note, six pts (66%) had CRD, including all three pts with AVG. The mean age was 56.1 yr. There were four women. Only one pt expired during the course, she with CRD and AVG.

Conclusions: CRD have been utilized increasingly in the HD population. Current guidelines recommend the use of CRD in survivors of cardiac arrest, in structural heart disease with malignant dysrhythmias, and as primary prevention in pts with severe cardiomyopathy. However, there have been no studies documenting outcome benefit which included HD pts. The compelling risks of CRD in this population, including central vein stenosis/occlusion and device-related bacteremia, and the common use of CVC during dialysis initiation, require prospective, randomized trials to provide definitive indications for CRD use. Until this is available, alternative treatment paradigms should be explored, including the use of non-endovascular CRD placement or a greater impetus to modality change to peritoneal dialysis.

TH-PO249

Improving Veterans Outcomes through Shared Knowledge: VA Hemodialysis Infection Surveillance Collaborative Susan T. Crowley,[1,2] Karen Sovern,[3] Wissam M. Kourany.[4] *[1]Yale University School of Medicine, New Haven, CT; [2]VA Connecticut HCS, West Haven, CT; [3]IPEC, VHA Office of Analytics, Cincinnati, OH; [4]VA Durham HCS, Durham, NC.*

Background: As part of a national antimicrobial stewardship plan the VA established a partnership amongst its out-patient(pt) hemodialysis(HD) units, initiating a HD vascular access associated infection (HD-VAI) surveillance program in FY'12 to reduce HD-VAI.

Methods: Collaborating with the VA Inpatient Evaluation Center (IPEC), a representative sample of VA out-pt HD units engaged in the HD-VAI surveillance pilot. The Collaborative's goals were to measure outcomes related to HD-VAI and develop/implement tracking systems to support evidence based HD-VAI mitigation strategies. Ten sites were mentored through monthly teleconferences. During calls nomenclature was defined, guidelines established, VA and similar federal initiatives aligned, and a data management infrastructure developed including a SharePoint tool kit and website for data entry/reporting. Shared knowledge also included a facilitated data collection tool ensuring reporting consistency. Infection rates per pt month(mo) were defined as #HD out-pts with a positive blood culture (of uncertain etiology or believed related to vascular access) or a local access site infection (without bacteremia) as numerator, and #HD pts with any access device on the first 2 working days of mo as denominator.

Results: After 8 mo, 22 VAIs occurred in 3441 pt-mo for a national aggregate HD-VAI rate of 0.6/100 pt-mo. Sixteen (73%) VAIs occurred among pts using a tunneled catheter of which 12 (75%) were blood stream infections (BSI). In contrast, only 2 BSI occurred in pts with AVFs.

Conclusions: Through shared knowledge the VA HD-VAI surveillance collaborative developed a transparent data reporting system, aligned a strategic focus for VA Infection Control, Public Health & Specialty Care, and demonstrated the feasibility of creating a data driven national quality assessment plan to reduce HD-VAI in a large integrated healthcare organization. Roll out of the program to all VA out-pt HD units is set for FY12.

TH-PO250

Low Dose Alteplase for Central Venous Catheter Declotting: Impact on CVC Exchanges and Cost Analysis Henry H. Chen, Andre F. Charest, Bharat Nathoo, Grace Leung, Emmelia Lau. *York Central Hospital, Richmond Hill, ON, Canada.*

Background: Hemodialysis (HD) central venous catheter (CVC) occlusions are a common problem in all hemodialysis centers. Usual treatment involves intraluminal Alteplase (tPA) dwell at a dose of 2mg/lumen. When tPA dwells fail, CVC exchanges are typically necessary. On Sep 30, 2010 our dialysis program implemented a new protocol of tPA 1mg/lumen dosing for occluded CVCs. Objective: To determine the impact on the number of CVC exchanges and cost implications when changing from 2mg to 1mg/lumen of tPA for CVC declotting.

Methods: A cohort study was done to look at the number of CVC exchanges and amount of tPA used between Apr 2010–Apr 2012. The cohort was retrospective from Apr 2010-Sep 30 2010, then data was collected prospectively. Study subjects included all patients with CVCs receiving HD. Prevalent subjects with CVCs ranged from 153-192 during the study duration. The number of CVC exchanges was expressed as percentage of prevalent lines changed in the 6 months before, 0-6 months after, and 0-19 months after intervention.The cost of tPA was expressed as Canadian (CDN) dollars spent on tPA (averaged)/prevalent CVC/month.

Results: The total number of CVC exchanges was: 33 at 6 months preceding intervention, 24 at 0-6 months, and 80 at 0-19 months. Expressed as the percentage of prevalent CVCs changed: 3.29% at 6 months preceding intervention, 2.45% (p=0.24) at 0-6 months, and 2.44% (p=0.20) at 0-19 months. Although not statistically significant, the percentage of CVC exchanges trended lower after the intervention of changing from 2mg to 1mg/lumen of tPA. The pre-protocol average cost of tPA/prevalent CVC/month was $52.80. The post-protocol average cost of tPA/prevalent CVC/month was $31.01 at 0-6 months and $23.74 at 0-19 months. This represents an average cost savings of $21.70 (p=0.0054) at 0-6 months and $29.06 (p< 0.0001) at 0-19 months per prevalent CVC/month. As compared to pre-intervention, approximately $23,000 was saved at 6 months and $95,000 was saved at 19 months post-intervention.

Conclusions: Implementing a low dose tPA (1mg/lumen) CVC occlusion treatment protocol did not increase the number of CVC exchanges and resulted in significant cost savings.

TH-PO251

Anticoagulants for the Prevention of Intravascular Catheter Malfunction in Haemodialysis: A Systematic Review and Meta-Analysis Ying Wang,[1] Jessica Ivany,[2] Vlado Perkovic,[1] Martin P. Gallagher,[1] Meg J. Jardine.[1] *[1]Renal and Metabolic Division, The George Institute for Global Health, Camperdown, NSW, Australia; [2]Sydney Children's Hospital, Randwick, NSW, Australia.*

Background: Catheter malfunction (CM), including thrombosis, is associated with reduced dialysis adequacy, as well as an increased risk of catheter-related bacteraemia (CRB) and mortality. The role of anticoagulants in the prevention of CM remains uncertain.

Methods: A systematic review and meta-analysis were performed examining all randomized controlled trials (RCTs) assessing anticoagulants for the prevention of CM in adult patients receiving haemodialysis for end stage kidney disease. Medline, EMBASE and the Cochrane Library database were searched to January 2012. The primary outcome was CM, and secondary outcomes were CRB, all-cause mortality and bleeding events. Relative risks with 95% confidence intervals for individual trials were pooled using random effects models.

Results: The search yielded 27 trials that included 3025 patients and assessed citrate locking solutions, warfarin, low concentration heparin locking solutions, antibiotic locking solutions, tissue plasminogen activator (t-PA) and low molecular weight heparin. The only intervention type that reduced the rate of CM was t-PA (RR 0.52, 95% CI 0.32-0.86), with no effect observed for citrate (RR 0.83, CI 0.69-1.01), warfarin (RR 0.59, CI 0.28-1.22), heparin (RR 0.92, CI 0.54-1.57), or antibiotics (RR 1.48, CI 0.79-2.74). Similarly, no effect on the rate of CRB was observed in trials of citrate (RR 0.64, CI 0.32-1.30), warfarin (RR 2.40, CI 0.88-6.52), heparin (RR 0.77, CI 0.31-1.95), antibiotics (RR 0.26, CI 0.03-2.07), or t-PA (RR 0.31, CI 0.01-10.40). All-cause mortality was not affected by any treatment type (citrate RR 0.81, CI 0.53-1.23; warfarin RR 0.78, CI 0.37-1.65; t-PA RR 0.63, CI 0.15-2.56). Only 6 trials reported bleeding events with no clear effect demonstrated. Trials were mainly of low quality (Jadad score ≤2 in 19 trials).

Conclusions: The net benefit of different anticoagulants for prevention of CM remains uncertain. Further higher quality randomised trials, including safety outcomes, are needed.

TH-PO252

Antimicrobial Activity of Hypertonic Citrate Lock Solution in Hemodialysis Catheters: A New Concept Regarding the Theory of Lock Spillage Gernot Schilcher,[1] Werner Ribitsch,[1] Joerg H. Horina,[1] Alexander R. Rosenkranz,[1] Daniel Schneditz,[3] Christina Strempfl,[2] Bernadette Neuhold,[2] Martin Hoenigl,[2] Thomas Valentin,[2] Jasmin Wagner,[2] Robert Krause.[2] *[1]Division of Nephrology, Medical University of Graz, Austria; [2]Section of Infectious Diseases, Medical University of Graz, Austria; [3]Institute of Physiology, Medical University of Graz, Austria.*

Background: Hypertonic citrate (46.7%) instilled into catheters inevitably spills into the systemic circulation in exchange for blood entering the catheter and diluting the concentration of the lock solution. This process is driven by different densities of whole blood and lock solution. Hence, in a vertical catheter, intra-luminal citrate concentration ranges from 0 (at the tip in catheters with sideholes), 3% (between the sideholes and the relativ highest point of the catheter) to 46,7% (at the luer end) with potential differences in antimicrobial effects. We in vitro investigated the antimicrobial efficacy of pure citrate 46,7%, citrate 46,7% diluted with whole blood (=citrate 3%) and of whole blood, mimicking in vivo conditions in different catheter compartiments.

Methods: Time kill studies (in duplicate) measuring the antimicrobial effect up to 24 h exposure to citrate 46,7%, citrate 3% and whole blood without citrate on overnight cultures ($5x10^8$ cfu/ml) of E. coli and Staph. aureus were performed with each test solution.

Results: Citrate 46,7% reduced E. coli (2 log units) but after 24 h 10^6 cfu/ml were still present. Citrate 3% and whole blood had no antimicrobial effect. Citrate 46,7%, citrate 3% and whole blood had no antimicrobial effect on Staph. aureus within 24 h.

Conclusions: Spillage of catheter lock solution replaced by whole blood leading to reduced intra-luminal citrate concentration considerabely reduces the antimicrobial effect of citrate 46,7% on E. coli. There was no effect on Staph. aureus with all solutions tested. Therefore, the antimicrobial efficacy of hypertonic citrate lock solution has to be seriously questioned. Furthermore, as dilution with whole blood alters antimicrobial activity in general, antimicrobial activity of lock solutions needs to be tested in presence of whole blood.

TH-PO253

Ethanol Lock Technique Causes Protein Precipitation in Vascular Access Devices: An Explanatory Model for Observed Catheter Occlusion Gernot Schilcher,[1] Hubert Scharnagl,[2] Tatjana Stojakovic,[2] Werner Ribitsch,[1] Daniel Schneditz,[3] Robert Krause,[4] Alexander R. Rosenkranz,[1] Joerg H. Horina.[1] *[1]Division of Nephrology, Medical University of Graz, Austria; [2]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Austria; [3]Institute of Physiology, Medical University of Graz, Austria; [4]Section of Infectious Diseases, Medical University of Graz, Austria.*

Background: Ethanol lock technique has been proposed as a potential mechanism to eradicate organisms in biofilms and hence, treat or prevent catheter related infections. Following instillation of ethanol lock solution into the catheter the density difference between whole blood and ethanol causes gravity induced seepage of ethanol paralleled by a reverse whole blood influx into the catheter. Therefore, whole blood is exposed to highly concentrated ethanol, which is a common agent for protein precipitation. We aimed to investigate protein precipitation in ethanol locked catheters as a possible cause of catheter occlusion.

Methods: In vitro, blood plasma and ethanol (concentrations ranging from 7 to 70%) mixtures in a ratio of 1:4, representing the intraluminal catheter conditions, were centrifuged at room temperature and 4000 r.p.m. for 10 min. to visibly assess protein precipitation.

Results: Optically detectable protein precipitation was observed in test solutions containing ethanol lock solutions above a concentration of 30%.

Conclusions: Our in vitro data suggest that observed occlusion of central venous catheters locked with ethanol might be due to intraluminal protein precipitation following exposure of plasma proteins to ethanol. Furthermore, injection or gravity induced leakage of precipitated protein particles into the pulmonary circulation may cause pulmonary embolism. We suggest that ethanol lock solution up to the concentration of 30% can be used safely.

TH-PO254

Effect of Catheter Locking on Catheter Related Bacteremia and Catheter Thrombosis Peter B. De Oreo. *Medical Affairs and Quality Assurance, Centers for Dialysis Care, Cleveland, OH.*

Background: Infections cause morbidity and mortality in ESRD patients. Catheter related bacteremias (CRB) are a significant cause of blood stream infections. We implemented 2 published methods of catheter closure to compare the impact on CRB and the use of tissue plasminogen activator (TPA).

Methods: We chose 2 facilities of similar demographics, comorbidities and all type catheter prevalence. In one facility (320 patients) we locked the catheter to its fill volume with 320 µg/ml gentamicin in 4% sodium citrate (GCL) by a published procedure (Moran, AJKD, 2012). In the other facility (110 patients) we used a needle free heparin free catheter cap (NFHF) according the manufacturer's directions. We compared the incidence of CRB in events per 100 catheter months for the same months of 2011 as the observation months in 2012. We compared the cost of TPA averaged over all treatments in the month. We sent blood cultures to the same lab. Cultures separated by fewer than 15 days were considered the same event. GCL costs $2 per treatment. The NFHF cap costs $2 per week. RNs administers GCL. A patient care technician applies the NHFH cap.

Results: The data show a 72% reduction in CRB for both methods. The monthly CRB range in the GLC facility (0 to 9.6) and NFHF facility (7.4 to 12) fell to 0 to 1.6 and 0 to 9.7 respectively. In the NFHF facility 2 of 3 months had 0 CRB. In the GCL facility there was no difference in TPA use ($2 vs $1.95) per treatment. In the NFHF facility the TPA use fell 69% ($5.33 to $1.69) per treatment. None of the organisms in the GCL facility was resistant to gentamicin.

Table 1. Results

	gent/citrate lock		needle free / heparin free	
	CRB *	TPA^	CRB *	TPA^
Ave 2011	3.7	$1.49	6.7	$3.53
BL 2011	5.0	$2.00	9.2	$5.33
Obs 2012	1.1	$1.95	3.2	$1.69
% Change BL v Obs	- 78%	- 2.5%	- 65%	- 69%

per 100 cath-mos* dollars/treatment^

Conclusions: Both methods were effective in reducing CRB. The GCL had no effect on catheter thrombosis as measured by TPA usage. The NFHF system appears to reduce both CRB and catheter thrombosis. The NFHF eliminates the risk and cost of heparin and exposure to gentamicin. Considering RN time and reagent costs, the NFHF cap appears to be a more cost effective method for reducing CRB.

Risk Factors Associated with Hemodialysis Catheter Malfunction: Results from a Randomized Trial David Ward,[1] Brenda Hemmelgarn,[1] Jennifer M. MacRae,[1] Braden J. Manns,[1] Nairne William Scott-Douglas,[1] Marcello Tonelli,[2] Adeera Levin,[3] Charmaine E. Lok,[4] Louise M. Moist.[5] *[1]University of Calgary, Calgary, AB, Canada; [2]University of British Columbia, Vancouver, BC, Canada; [3]University of Toronto, Toronto, ON, Canada; [4]University of Western Ontario, London, ON, Canada.*

Background: Catheter-locking solutions (CLS) aim to prevent complications such as malfunction and bacteremia in hemodialysis (HD) patients using central venous catheters (CVC). We found a two-fold reduction in CVC malfunction when once-weekly substituting heparin CLS with recombinant tissue-plasminogen activator (rt-PA), compared with thrice-weekly heparin. Determining those who will benefit from prophylactic rt-PA will inform future use and control costs. Using RCT data we sought to determine risk factors associated with CVC malfunction.

Methods: HD patients with newly placed CVC were randomized to rt-PA mid-week and heparin (5000u/ml) on the other HD runs (n=110) or thrice-weekly heparin (5000u/ml) CLS (n=115). We defined CVC malfunction; peak blood flow < 200 mL/min for 30 mins; mean blood flow < 250 mL/min for 2 consecutive HD runs; or inability to initiate HD. Cox regression determined association between patient demographics and HD variables (blood flow, pump speed, CVC reversal) in the 6 runs prior to CVC malfunction (those with primary outcome) or in the 6 runs prior to study end or censoring (those without primary outcome), and CVC malfunction risk.

Results: Baseline patient characteristics were similar between groups. Risks for CVC malfunction were line reversal at the prior run (HR 12.51; 95% CI 7.10 – 22.04), or at least once in the prior 6 runs (HR 9.30; 95% CI 4.36 – 19.84). Malfunction risk increased for each run with a line reversal (HR 1.75; 95% CI 1.55 – 1.98). Reduction in liters of blood processed or blood flow rate were associated with increased malfunction risk.

Conclusions: HD characteristics are associated with CVC malfunction; line reversals demonstrate the highest risk. This study may identify those at increased risk of CVC malfunction who may benefit from once-weekly prophylactic rt-PA. The effectiveness of routine prophylactic rt-PA CLS use in these patients is unknown.

Comparative Effectiveness of Hemodialysis Catheter Care Protocols to Prevent Bacteremia Alex J. Rosenblum, Jill A. Hall, Weiling Wang, Franklin W. Maddux, Eduardo K. Lacson. *Fresenius Medical Care North America, Waltham, MA.*

Background: The CDC published revised recommendations for central venous catheter care in 2011. We streamlined our hemodialysis catheter care procedure and added an alcohol pad "scrub the hub" and cleansing of the exit site using 2% chlorhexidine swab with 70% alcohol.

Methods: In 2011, 422 Fresenius Medical Care North America facilities were matched 1:1 based on access type, size, and location. We randomly assigned 211 facilities to the revised protocol (RP) and the corresponding matched pair (N=211) into usual care (UC). Training and implementation was in July, 2011 with a 3-month baseline (4/1-6/31) compared to a 3-month follow-up (8/1 -10/30) period. The primary outcome was the rate of positive blood cultures ("bacteremia"). Rates of new IV antibiotic starts, hospitalization for sepsis and adverse reactions to chlorhexidine were also tracked. Historically, seasonal increases in infections occurred over the summer, thus the need for concurrent controls.

Results: There were 364,115 (RP) vs. 361,963 (UC) catheter-days at baseline and 351,357 (RP) vs. 352,538 (UC) catheter days during follow-up. The bacteremia rate was 0.86/1000 cath-days each at baseline, but upon follow-up was 0.80 vs. 1.04/1000 cath-days in favor of the RP group (p=0.02). Baseline antibiotic starts were 1.78 (RP) vs. 1.93 (UC) per 1000 cath-days (p=n.s). Follow-up revealed 2.01 (RP) vs. 2.41 (UC) new IV antibiotic starts per 1000 cath-days (p=0.03). Changes in hospitalizations for sepsis were not significant although documentation was poor - RP: 0.14 to 0.16/1000 cath-days vs. UC: 0.21 to 0.22/1000 cath-days – remaining lower in the RP group. Minor skin reactions were reported in up to 2% of patients using chlorhexidine, some alleviated by decreasing 'rubbing' pressure on the swab and allowing more time to dry before dressing.

Conclusions: Over three months, bacteremia rates declined significantly after initiating a revised catheter care protocol that incorporated CDC recommendations, accompanied by fewer antibiotic starts. Limited data did not show a decline in hospitalizations due to sepsis.

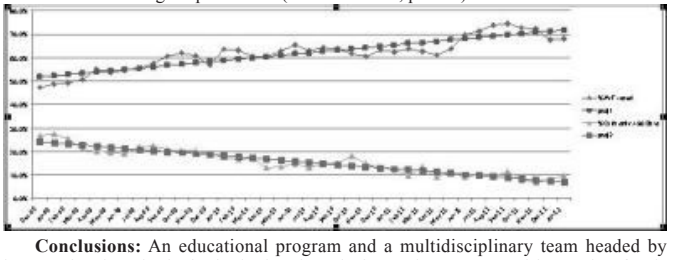
TH-PO257

Catheter Reduction in Hemodialysis Patients: A Multidisciplinary Team Approach Headed by Interventional Nephrology Fawad Qureshi,[1] Tim Deaconson,[2] Stephen S. Cha.[3] *[1]Nephrology & Hypertension, Mayo Clinic Health System, Mankato, MN; [2]Surgery, Mayo Clinic Health System, Mankato, MN; [3]Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN.*

Background: Tunneled hemodialysis catheters continue to be a major contributor to morbidity and mortality. In this analysis, we report the results of our approach to minimizing the use of tunneled hemodialysis catheters.

Methods: Rather than focusing on interventions itself a team based approach (nephrologists, vascular surgeons and dialysis nurses) was implemented to minimize the use of catheters and increase the prevalence of fistulae. Vascular access education delivered on a monthly basis formed the backbone of the approach. Catheter patients who refused to be evaluated to receive an arteriovenous fistula were educated on a weekly basis. Data was collected for all patients dialyzing in our Mankato unit from 2008 to 2012. Regression analyses were performed to check the trend. A positive estimate for slope, or calendar time, indicated an increasing trend, or vice versa. A P-value less than 0.05 were considered statistically significant.

Results: The catheter rates declined from 26.9% to 9.7% (p=0.0001) while the arteriovenous fistula rates increased from 47.4% to 68.1% (p<0.0001). There was no change in the arteriovenous graft prevalence (10.3% to 6.9%; p=0.44).



Conclusions: An educational program and a multidisciplinary team headed by interventional nephrologist is the key in reducing catheter rates and improving fistula prevalence.

TH-PO258

Prevalence, Risk Factors, and Sequelae of Central Venous Stenosis in Hemodialysis Patients at a Hospital-Based Dialysis Center Elaine Ku, Delphine S. Tuot, Anitha B. Toke. *Nephrology, UCSF, San Francisco, CA.*

Background: Subclavian catheters are a known risk factor for central venous stenosis (CVS). Few studies have examined CVS risk factors since the shift towards use of internal jugular tunneled catheters (TCs). USRDS data suggest a recent trend towards increased catheter use, which may increase CVS rates. We examined CVS risk factors and its sequelae in a hospital-based dialysis center.

Methods: A chart review was conducted on prevalent HD patients at an urban hospital-based dialysis center with a large underserved population as part of a quality initiative. CVS was defined by documentation of "central stenosis" at the superior vena cava,

subclavian, or innominate veins in radiology reports. Age, gender, comorbid conditions (diabetes, cardiovascular and peripheral vascular disease), radiology and operative reports were reviewed. HD vintage and race/ethnicity were based on 2728 forms. Multivariable logistic regression adjusting for demographics, comorbid conditions, and HD vintage was used to determine risk factors for CVS and the impact of CVS on arteriovenous fistula and graft (AVF/AVG) failures.

Results: In our cohort, 30% (42/142) have CVS. Odds of CVS are higher with receipt of > 1 TC (vs. 0) [adjusted odds ratio (AOR) =4.51, 95%CI 0.91-22.3)] with each additional catheter conferring a 13% greater odds of CVS (0.94-1.37). In patients with a history of TC, HD vintage was the only significant predictor of CVS (p=0.004), although age 36-65 (vs. 18-35) and diabetes conferred higher odds of CVS (AOR=5.7, 0.98-33.2 and AOR=2.4, 0.97-5.8, respectively). Length of catheter use > 1 year, but not 6 months-1 year, was significantly associated with CVS in our adjusted model (AOR 3.73, 1.13-12.3). In patients with CVS, unadjusted odds of having one or more failed AVF/AVG was 2.63 (1.21-5.69), which was attenuated in the adjusted model (AOR=1.18, 0.46-3.05).

Conclusions: CVS prevalence remains high even with shift to use of internal jugular TCs. Number of lifetime TCs place HD patients at risk for CVS, as do HD vintage, diabetes, age, and length of catheter use, among patients who have a history of TC. CVS may lead to increased risk of failed AVF/AVG.

TH-PO259

Association between Type of Hemodialysis Access and Clinical Outcomes: Meta-Analysis of Cohort Studies Pietro Ravani,[1] Suetonia Palmer,[2] Matthew J. Oliver,[3] Robert R. Quinn,[1] Jennifer M. MacRae,[1] Davina J. Tai,[1] Chandra Mary Thomas,[1] Neesh I. Pannu,[4] Brenda Hemmelgarn,[1] Jonathan C. Craig,[2] Braden J. Manns,[1] Marcello Tonelli,[4] Giovanni F.M. Strippoli,[2] Matthew T. James.[1] *[1]University of Calgary, Canada; [2]Cochrane Renal Group, Australia; [3]University of Toronto, Canada; [4]University of Alberta, Canada.*

Background: Based on observational studies, clinical practice guidelines recommend an arteriovenous fistula as the preferred form of hemodialysis access. However an increasing proportion of individuals treated with hemodialysis never achieve a functioning fistula and use catheters. We sought to examine the association between type of access (fistula, graft and catheter) and patient outcomes.

Methods: We searched MEDLINE (1950 to April 2012) and article reference lists without language restriction. Electronic searching identified 2,309 citations, of which 65 articles (60 cohort studies; n=577,373 participants) met the inclusion criteria. We extracted data on study design, participants, exposure (access type), outcomes (all-cause mortality, infection, and cardiovascular event), and risk of bias. We summarized data across study populations using random-effects meta-analysis.

Results: Patients using catheters experienced increased all-cause mortality (risk ratio, 1.53; 95% confidence interval 1.40–1.67), fatal infections (2.12; 1.79–2.52), and cardiovascular events (1.38; 1.24–1.54), compared to those with fistulas; and increased mortality (1.38; 1.25–1.52), fatal infections (1.49; 1.15-1.93), and cardiovascular events (1.26; 1.11-1.43), compared to patients using grafts. Compared to patients with fistulas, patients using grafts experienced increased all-cause mortality (1.18; 1.09-1.27), and fatal infection (1.36; 1.17-1.58), but not cardiovascular events (1.07; 0.95-1.21). Risk of bias was generally high; all studies except two compared outcomes according to the access achieved, as opposed to that intended.

Conclusions: Patients using catheters for hemodialysis had the highest risk of death, infections, and cardiovascular events, and patients who used fistulas had the lowest risk. There is high risk of selection bias in existing studies.

TH-PO260

Is It Possible to Improve the Management of the Central Venous Catheters (CVC) for Hemodialysis (HD)? Emanuele Mambelli, Elena Mancini, Annalisa Zucchelli, Cinzia Elia, Vincenza Guadagno, Antonio Santoro. *Nefrology, Dialysis and Hypertension, Policlinico S. Orsola-Malpighi, Bologna, Italy.*

Background: The management of the CVC at the beginning of the HD session represents a fundamental point both for the administration of the correct HD dose and for the risk of CVC-related infection. However, the procedure is not standardized and generally poorly considered.

We compared the management protocol for the preparation of the CVC presently in use at our Center with the use of a new device (Hemocatch ®) having a specific indication for the management of the HD-CVC.

The number of syringe connections to the CVC with each procedure was the primary end point. The amount of blood wasted during the manoeuvres and the prediction of the blood flow through the CVC were the secondary end points.

Methods: We studied 12 patients with jugular, permanent or temporary, double lumen CVC, over two months. Each patient underwent the management of the CVC with both the conventional process (C) and with Haemocatch (H), over one week each.

Results: Out of 150 HD sessions (75 C, 75 H) the number of the direct connections to the CVC proved lower with Haemocatch (2.19 ± 0.59 with H vs. 4.23 ± 0.78 with C, $p < 0.05$). The same was for the volume of blood wasted (5.97 ± 2.77 ml for H vs. 14:57 ± 6.3 ml for C, $p < 0.05$).

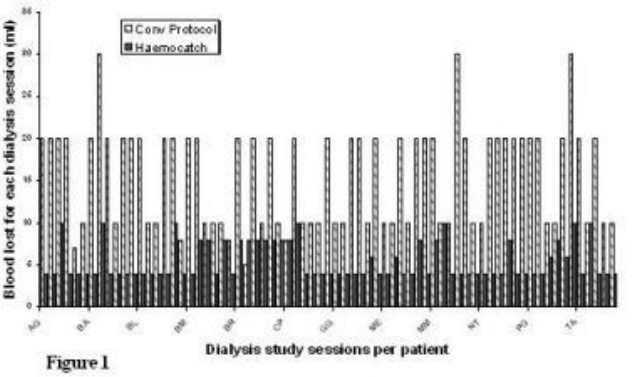

Figure 1

The test for the blood flow forecasting did not show any statistically significant difference between the two procedures.

Conclusions: The use of a device with a specific indication for the CVC management in HD could help in standardizing the procedure and improving the quality of the manoeuvre itself by reducing both the blood loss and the number of syringe connections needed, with a reduction in the infective risk.

TH-PO261

High-Protein Diet Exacerbates Decrease in Muscle Mitochondria and Exercise Endurance after 5/6 Nephrectomy in Mice Masanori Tamaki, Kazutoshi Miyashita, Shu Wakino, Masanori Mitsuishi, Kumiko Tanaka, Koichi Hayashi, Hiroshi Itoh. *Internal Medicine, Keio University School of Medicine, Tokyo, Japan.*

Background: Chronic kidney disease decreases physical performance, although the mechanism is unclear. High-protein diet has been recommended for maintenance of muscle mass and power, although the effect in chronic kidney disease patients is not elucidated. We investigated physical performance of 5/6 nephrectomy mice, a model of mild chronic kidney disease and examined the effect of dietary protein on physical performance under chronic kidney disease.

Methods: C57bl/6 mice which had undergone 5/6 nephrectomy at 6-7 weeks were examined for physical performance in young (up to 20 weeks) and aged (up to 52 weeks old) groups. Protein adjusted diets were fed from 8 weeks old.

Results: A decrease in muscle mitochondria and running distance was identified in young 5/6 nephrectomy mice, although muscle mass and power were preserved. A decrease in grip power and muscle mass became apparent in aged 5/6 nephrectomy mice. High-protein diet further decreased running distance of 5/6 nephrectomy mice, associated with a decrease in pyruvate dehydrogenase activity and an increase in lactate production, although muscle mass was increased. Pyruvate dehydrogenase stimulator dichroloacetate recovered pyruvate dehydrogenase activity in skeletal muscle and exercise endurance.

Conclusions: Muscle mitochondria and exercise endurance were decreased by 5/6 nephrectomy from an early age. Thereafter, muscle mass and strength were decreased in aged 5/6 nephrectomy mice. Decreases in muscle mitochondria and ATP production were identified as potential new mechanisms for a reduction in exercise endurance of chronic kidney disease. Decreased pyruvate dehydrogenase activity would explain why a high-protein diet failed to improve exercise endurance. The findings clarified "Kidney-muscle axis" and suggested a new strategies to improve physical performance of patients with chronic kidney disease.

TH-PO262

Dysregulation of Hepatic Fatty Acid Metabolism in Chronic Kidney Disease Kyu-Bok Jin,[1,2] Keith C. Norris,[3] Nosratola D. Vaziri.[1] *[1]Nephrology and Hypertension, University of California, Irvine, Irvine, CA; [2]Internal Medicine, Inje University Haeundae Paik Hospital, Busan, Republic of Korea; [3]Internal Medicine, Charles Drew University, Los Angeles, CA.*

Background: Chronic kidney disease (CKD) results in hypertriglyceridemia which is largely due to impaired clearance of triglyceride-rich lipoproteins occasioned by down-regulation of lipoprotein lipase and VLDL receptor in the skeletal muscle and adipose tissue and of hepatic lipase and LDL receptor-related protein (LRP) in the liver. However data on the effect of CKD on fatty acid metabolism in the liver is limited and was investigated here.

Methods: Male Sprague-Dawley rats were randomized to undergo 5/6 nephrectomy (CRF) or sham operation (control) and observed for 12 weeks. The animals were then euthanized and their liver tissue tested for nuclear translocation (activation) of carbohydrate-responsive element binding protein (ChREBP) and sterol responsive element binding protein-1 (SREBP-1) which independently regulate expression of key enzyme in fatty acid synthesis i.e. fatty acid synthase (FAS) and acyl-CoA carboxylase (ACC) as well as nuclear PPARα which regulates expression of enzymes involved in fatty acid oxidation and transport i.e. L-FABP and CPT1A. In addition expression of ATP synthase α, ATP synthase β, glycogen synthase, and diglyceride acyltransferase 1 (DGAT1) and DGAT2 were determined.

Results: Compared with the controls the CKD rats exhibited hypertriglyceridemia, elevated plasma and liver tissue free fatty acids, increased nuclear ChREBP and reduced nuclear SREBP-1 and PPARα, upregulation of ACC and FAS and downregulation of L-FABP, CPT1A, ATP synthase α, glycogen synthase, and DGAT in the liver tissue.

Conclusions: Liver in animals with advanced CKD exhibits ChREBP-mediated upregulation of enzymes involved in fatty acid synthesis, down-regulation of PPARα-regulated fatty acid oxidation system, and reduction of DGAT resulting in reduced fatty acid incorporation in triglyceride.

Calcineurin-NFAT Signaling Regulates Atrogin-1 and MuRF1 via microRNA-23a during CKD or Glucocorticoid-Induced Muscle Atrophy

Matthew Hudson, Xiaonan H. Wang, Bin Zheng, Russ Price. *Department of Medicine, Renal Division, Emory University, Atlanta, GA.*

Background: Skeletal muscle atrophy is prevalent in CKD and microRNAs (miR) may play a regulatory role in the process. miR-23a has been reported to negatively regulate the expression of two atrophy-related ubiquitin ligases, atrogin-1 and MuRF1, as well as the atrophy-inducing FoxO transcription factors. In cardiomyocytes, miR-23a expression is positively regulated by the calcineurin (Cn) substrate NFATc3. The objective of this study is to investigate whether Cn/NFATc signaling and miR-23a expression is altered in skeletal muscle during CKD-related atrophy.

Methods: MicroRNA microarray analysis was performed with CKD and control mouse hindlimb muscle. To induce atrophy in C2C12 or L6 muscle cells, myotubes were treated with 100 nM dexamethasone (DEX). Atrogin-1 and MuRF1 mRNAs and miR-23a were measured by qRT-PCR. Cn/NFATc signaling was evaluated by measuring the mRNA of MCIP1.4, a Cn-regulated gene target. NFATc3 was measured by western blot analysis of nuclear extracts from cultured muscle cells.

Results: Microarray analysis of CKD mouse muscle revealed that miR-23a was reduced 74% vs control ($P<0.05$). Treatment of C2C12 myotubes with DEX for 48 h mimicked CKD by reducing miR-23a 68% ($P<0.05$); MCIP1.4 mRNA was decreased 40% ($P<0.05$), indicating that Cn/NFATc signaling was reduced. In contrast, FOXO3a protein was significantly increased 830% ($P<0.05$) as were the levels of atrogin-1 and MuRF1 mRNAs (1110% and 281%, respectively; $P<0.05$). Nuclear NFATc3 was decreased within 1 h of treatment with DEX, indicating that DEX rapidly suppresses Cn/NFATc signaling; miR-23a was also decreased 79% ($P<0.05$) within1 h of treatment.

Conclusions: Collectively, these findings indicate that Cn-NFAT signaling plays an important regulatory role in the wasting process by suppressing miR23a during CKD and glucocorticoid-induced muscle atrophy.

TH-PO264

Ghrelin Attenuates Cachexia, Muscle Wasting, Cardiovascular Complications, Inflammation and Mortality in Chronic Kidney Disease

Wai W. Cheung,[1] Sujana S. Gunta,[1] Nancy Dalton,[2] Yusu Gu,[2] Erika Alvarez,[2] Kirk L. Peterson,[2] Robert H. Mak.[1] *[1]Pediatrics, University of California San Diego, La Jolla, CA; [2]Medicine, University of California San Diego, La Jolla, CA.*

Background: Cachexia, muscle wasting, cardiovascular complications and inflammation are important risk factors associated with high mortality in chronic kidney disease (CKD). Ghrelin is an appetite-regulating hormone with additional effects in the modulation of systemic inflammation and the cardiovascular system. CKD patients with low serum ghrelin have the highest mortality risk and may benefit from ghrelin therapy.

Methods: C57BL/6J mice underwent 5/6 nephrectomy (CKD) or sham operation (S). Ghrelin (150 nmole/kg/day) or saline as vehicle (V) was given to CKD or S mice via osmotic pump subcutaneously.

Results: CKD mice had higher BUN and creatinine levels than S mice ($p<0.001$). CKD+ghrelin, CKD+V and S+V mice were all fed *ad libitum*. Food intake of CKD+ghrelin mice was significantly increased than CKD mice ($p<0.01$). CKD+ghrelin mice gained more weight than CKD mice ($p<0.01$). CKD+ghrelin mice gained lean and fat mass while CKD mice lost lean and fat mass ($p<0.01$). 24 hr metabolic rate was increased and efficiency of food consumption (weight gain/food consumption) was decreased in CKD mice versus S mice ($p<0.001$). Ghrelin normalized these abnormalities in CKD mice ($p<0.01$). Ghrelin corrected systolic hypertension in CKD mice (116.2±2.6 vs 147.8±8.2 mm Hg, $p<0.01$). Left ventricular hypertrophy (LVH, left ventricular mass/body weight) was ameliorated in CKD+ghrelin mice (5.4±0.4 mg/g) versus CKD mice (6.0±0.2 mg/g, $p<0.01$). TNF-α and IL-6 mRNA levels were significantly increased in gastrocnemius and cardiac muscles of CKD mice versus S mice ($p<0.001$). Ghrelin significantly decreased the expression of these inflammatory cytokines in skeletal and heart muscle of CKD mice ($p<0.01$). Over 90-days, mortality rates of 9 month old ghrelin-treated CKD mice (15%) and S mice (0%) were significantly better than those of CKD mice (57.5%).

Conclusions: Ghrelin ameliorates cachexia, muscle wasting, systemic hypertension and LVH with associated improvement in inflammation and mortality in CKD.

TH-PO265

Lipidomic Analysis of Kidney Tissue in a High-Fat Diet Model: A Key Role of AMPK in Lipid Content and Storage

Anne-Emilie Decleves,[1,2] Joseph Satriano,[1] Zarazuela Zolkipli Cunningham,[1] Alex Thomas,[1] Joelle L. Nortier,[2] Marilyn G. Farquhar,[1] Dorothy D. Sears,[1] Oswald Quehenberger,[1] Edward A. Dennis,[1] Robert K. Naviaux,[1] Kumar Sharma.[1] *[1]University of California, San Diego, San Diego, CA; [2]Université Libre de Bruxelles, Belgium.*

Background: Lipids may contribute to renal cell toxicity. AMP-activated protein kinase (AMPK) is an important energy sensor that may play a critical role in regulating the chronic cellular response to lipid excess.

Methods: To evaluate the role of AMPK, male C57BL/6J mice were randomized to a standard diet, a High Fat Diet (HFD) or a HFD + AICAR (AMPK activator) for 14 weeks. A comprehensive lipidomic approach was combined with renal functional and structural studies along with electron microscopy (EM).

Results: Mice given the HFD showed renal hypertrophy and impaired renal function. Evidence of proximal tubule injury was observed with the presence of enlarged clear vacuoles, and multilaminar inclusions concurrently with an increase of tissue lipid content and a decrease of autophagy. The margins of the clear vacuoles were positive for the endolysosomal marker, LAMP1, suggesting lysosome dysfunction. Characterization of multilaminar inclusions by EM revealed that these contained onion skin-like accumulations of phospholipids. AMPK activation reversed the clinical and structural effects of HFD. To further determine the role of AMPK, we performed an analysis of lipid species by quantitative mass spectrometry to explore the connections between lipid metabolism and biochemical pathways. Lipidomic analysis revealed that HFD significantly affected eicosanoid metabolism, involving arachidonic acid, eicosapentaenoic acid (EPA) and docasahexaenoic acid (DHA), an effect that was modulated by AICAR treatment.

Conclusions: These findings reveal that HFD is a potent source of renal damage. There is likely a contribution of lysosomal dysfunction and lipid species alteration that results in the changes observed. A novel role of AMPK was demonstrated to normalize the changes in renal lipid content despite chronic exposure to lipid challenge. The activation of AMPK may be a potential strategy to improve altered lipid metabolism in HFD-induced chronic kidney disease.

TH-PO266

Mild Chronic Kidney Disease Alters Tissue Vitamin K Status in a Rat Model

Kristin M. McCabe,[1] Xueyan Fu,[2] Michael A. Adams,[1] Rachel M. Holden.[3] *[1]Biomedical and Molecular Sciences, Queen's University, Kingston, ON, Canada; [2]USDA Human Nutrition Research Center on Aging, Tufts University, Boston, MA; [3]Medicine, Queen's University, Kingston, ON, Canada.*

Background: Patients with chronic kidney disease (CKD) develop vascular calcification which leads to an increased risk of cardiovascular disease. Matrix-Gla protein is a vitamin-K dependent protein that inhibits calcification. Phylloquinone (K1), the major form of vitamin K consumed in the diet, is preferentially found in the liver. Menaquinone-4 (MK-4), present in the diet in small quantities, is preferentially found in extra-hepatic tissues. In the present study we assessed tissue concentrations of K1 and MK-4 in the presence of CKD.

Methods: Sprague Dawley rats were fed a diet containing 0.25% adenine (CKD; n=6) or no adenine (control; n=6), both diets containing low vitamin K1 (0.2 mg/kg) for 3 weeks. Kidney function was assessed by measuring serum creatinine. The concentrations of K1 and MK-4 in tissue and serum were determined by reversed phase HPLC and expressed relative to wet weight.

Results: Serum creatinine was elevated in the CKD group (142 ± 27 μM) compared to controls (69 ± 11 μM, $p<0.001$). CKD animals had significantly higher levels of MK-4 in the kidney medulla (73 ± 14 vs 44 ± 21 pmol/g, $p=0.02$), kidney cortex (31 ± 17 vs 9.5 ± 3 pmol/g, $p=0.01$), and the testes (184 ± 11 vs 166 ± 15 pmol/g, $p=0.03$), and lower levels of K1 in the heart (24 ± 7 vs 34 ± 9 pmol/g, $p=0.04$), liver (22 ± 5.5 vs 44 ± 14 pmol/g, $p<0.01$), and spleen (8.4 ± 1.8 vs 19 ± 4.5 pmol/g $p<0.01$).

Conclusions: These results indicate that CKD modifies tissue concentrations of K1 and MK-4 under low dietary conditions. CKD animals had significantly higher MK-4 levels and lower K1 levels in various tissues suggesting two possibilities: (1) there are changes that enhance conversion in CKD of dietary K1 to MK-4 and/or (2) that utilization of MK-4 may be impaired in CKD. UbiA prenyltransferase domain containing 1(UBIAD1), a recently identified MK-4 biosynthetic enzyme, is widely expressed and may be responsible for the regulation of MK-4 production. To confirm this, further studies targeting UBIAD1 expression and activity in CKD are warranted.

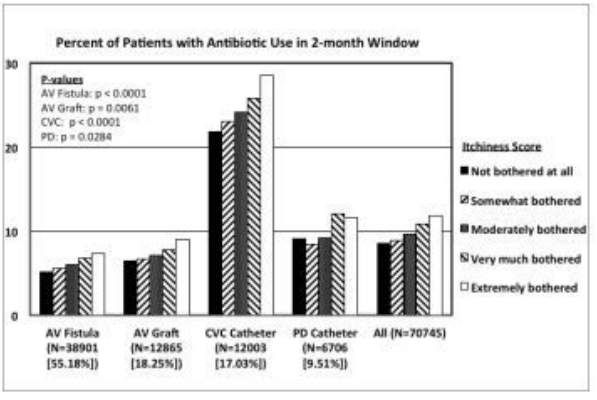
Patient-Reported Pruritus Rates and Indicators of Infection Co-Vary Directly among Patients Receiving Dialysis

T. Christopher Bond, Gilbert Marlowe, Helen M. Wilfehrt, Amy Young, Mahesh Krishnan, Tracy Jack Mayne. *DaVita Clinical Research, Minneapolis, MN.*

Background: Patients on dialysis often report pruritus; scratching may result, disrupting skin integrity and increasing infection risk. The Kidney Disease Quality of Life 36 (KDQOL) questionnaire, administered yearly at a large dialysis organization, assesses itch. We hypothesized increased patient-reported itching would be associated with IV antibiotic use and infection-related inflammation would be associated with increased epoetin alfa (EPO) use (NDT 2009;24(3):919).

Methods: We examined health records for patients undergoing dialysis (1/2009-5/2012) for various characteristics, including IV antibiotic use and mean monthly EPO dose: the former was tracked within a 2-month window of KDQOL administration and other measures were obtained for the month of the questionnaire. Tests for trend in antibiotic use were performed via the Cochran-Armitage test.

Results: On the KDQOL 60% of patients reported itch. IV antibiotics use typically varied directly with increased itch, across access types (Figure). Among patients receiving EPO, mean monthly dose rose with increased itchiness (Table). Other patient characteristics positively associated with degree of itch (not shown).



Pruritus Among Hemodialysis Patients Receiving EPO

During the past 4 weeks, to what extent were you bothered by itchy skin?	Patient-reported itchiness - n (%)	Mean Monthly EPO Dose - U
Not bothered at all	22,255 (39.88%)	55,638.43
Somewhat bothered	16,798 (30.10%)	57,348.48
Moderately bothered	8,545 (15.31%)	58,736.90
Very much bothered	5,210 (9.34%)	62,930.04
Extremely bothered	2,992 (5.36%)	66,133.66

Conclusions: Increased itch varied directly with IV antibiotic usage and EPO dose. These data suggest that increasing pruritus may be directly correlated with increased rates of infection. Research funded by Mitsubishi Tanabe Pharma Corporation.

Circulating Levels of Hepatocyte Growth Factor (HGF) Are Associated with Fat Mass in Chronic Kidney Disease (CKD) Stage 5 Patients

Jiangzi Yuan,[1] Makoto Watanabe,[1,2] Abdul Rashid Tony Qureshi,[1] Jonas Axelsson,[1] Peter F. Barany,[1] Olof Heimburger,[1] Peter Stenvinkel,[1] Bengt Lindholm.[1] *[1]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [2]Nephrology, Showa University School of Medicine, Tokyo, Japan.*

Background: CKD patients have increased serum levels of hepatocyte growth factor (HGF), a multifunctional pleiotropic growth factor implicated in obesity, metabolic syndrome and cardiovascular disease in the general population. However, the association between HGF and body composition in CKD patients remains unknown. Here we investigated determinants of HGF in CKD stage 5 patients and evaluated possible links between body composition, including body fat compartments, and HGF in CKD patients.

Methods: In 224 CKD stage 5 patients (159 males, mean age 53 years, median GFR 6.3 ml/min/1.73m^2) starting on dialysis, fasting blood samples were obtained for analyses of HGF, high-sensitivity C-reactive protein (hsCRP), interleukin-6 (IL-6), leukocytes and intercellular adhesion molecule-1 (ICAM-1; a marker of endothelial dysfunction), insulin and blood lipids. Body mass index (BMI) was recorded and total fat mass (FMI), truncal fat mass (TFMI) and LBM (LBMI) indices, expressed as kg/m^2, were calculated based on body composition assessment by dual-energy X-ray absorptiometry. Nutritional status was assessed by subjective global assessment, SGA.

Results: Higher levels of HGF (median 2.94; interquartile range 2.17–4.3 ng/ml) were associated with high age, cardiovascular disease, malnutrition, BMI, FMI, TFMI, serum albumin, insulin, hsCRP, IL-6, leukocytes, ICAM-1, and low density lipoprotein (all rho<0.05). Multivariate linear regression models adjusting for age, gender, CVD, nutritional status, insulin, blood lipids and inflammation showed that HGF was associated with FMI and TFMI.

Conclusions: In this the first study investigating the relationship between HGF and body composition in CKD stage 5 patients, a high HGF level was associated with increased total fat mass and truncal fat mass, but not lean body mass, as well as with inflammation, insulin and blood lipids. These results support a role of HGF in the metabolic syndrome of CKD patients.

The Glutathione/Glutathione Disulfide (GSH/GSSG) Redox Potential E_h) Is Low in Erythrocyte (RBCs) of Maintenance Hemodialysis (MHD) Patients (Pts) and It Associates with Parameters of Dietary Intake

Khaled Khazim,[1,4] Daniela Giustarini,[5] Ranieri Rossi,[5] Darlene Verkaik,[3] Sue Cunningham,[1] Franco Folli,[2] Shweta Bansal,[1,3] Paolo Fanti.[1,3] *[1]Nephrology, Univ. Texas HSC, San Antonio, TX; [2]Diabetes, Univ. Texas HSC, San Antonio, TX; [3]ALM VA Hospital, San Antonio, TX; [4]Nephrology, W. G. Hospital, Nahariya, Israel; [5]Dept. Evol. Biology, Univ. of Siena, Siena, Italy.*

Background: GSH, a low molecular mass thiol, protects cells from oxidative damage and regulates cell function. Levels of GSH, its disulfide (GSSG) and the GSH/GSSG ratio are abnormal in MHD, but their relationship with clinical outcomes remains elusive. Using an accurate and precise method to analyze GSH and GSSG, we tested the hypothesis that the intracellular GSH/GSSG and GSH/GSSG $E_h$are lower in MHD Pts than in healthy controls (HCs), and that the GSH/GSSG $E_h$correlates with standard clinical parameters in Pts.

Methods: Blood samples were collected from 33 stable Pts and 10 HCs. Samples for GSH analysis were immediately spiked with *N-ethylmaleimide (NEM)* to form stable -SH-NEM adducts and prevent ex vivo artifactual oxidation of -SH groups, and processed in 6 minutes from phlebotomy to frozen storage. GSH and GSSG were measured by HPLC and GSH recycling method respectively.

Results: GSSG levels were higher in the Pts vs. HCs (28.6 ± 15.6 vs. 15.2 ± 4.6 pmol/mg Hb, p<0.01), while GSH levels were virtually identical between groups. Both GSH/GSSG (353.7± 151.1 vs. 602.1 ± 179.6, p<0.001) and GSH/GSSG E_h(-233.9 ± 5.5 vs. -244.7 ± 5.2 mV, p=0.002) were shifted to oxidation in Pts vs. HCs indicating a net loss of reducing capacity. In the Pts, the GSH/GSSG E_h correlated with BUN (r = 0.48, p = 0.004), nPCR (r = 0.39, p = 0.02) and PO_4 (r = 0.36, p = 0.04). The correlations were similar when using GSH/GSSG instead of GSH/GSSG E_h.

Conclusions: The robust correlation of GSH/GSSG E_h with BUN, PO_4 and nPCR demonstrates a previously unrecognized interaction between cell redox potential and dietary protein and PO_4 intake. This could point to a double-edged sword role of foods containing protein and/or PO_4, i.e. nutritionally necessary but also GSH-consuming pro-oxidants.

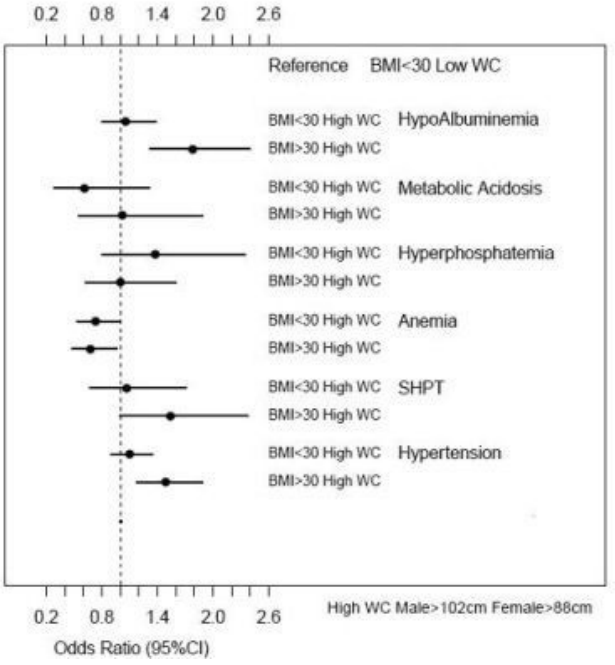
Obesity, Anthropometric Measures and Chronic Kidney Disease Complications

Sankar D. Navaneethan,[1] John P. Kirwan,[2] Susana Arrigain,[3] Martin J. Schreiber,[1] Mark J. Sarnak,[4] Jesse D. Schold.[1,3] *[1]Nephrology, Cleveland Clinic; [2]Pathobiology, Cleveland Clinic; [3]Quantitative Health Sciences, Cleveland Clinic; [4]Nephrology, Tufts Medical Center.*

Background: Anthropometric measures such as body mass index (BMI) and waist circumference (WC) have differential associations with incident chronic kidney disease (CKD) and mortality. We examined the associations of BMI and WC with various CKD complications.

Methods: We conducted a cross-sectional analysis of 2853 adult participants with CKD in the National Health and Nutrition Examination Surveys 1999-2006. The associations of BMI and WC (as continuous and categorical variables) with CKD complications such as anemia, secondary hyperparathyroidism (SHPT), hyperphosphatemia, metabolic acidosis, hypoalbuminemia, and hypertension were examined using logistic regression models while adjusting for relevant confounding variables.

Results: CKD participants with a BMI ≥30 kg/m^2 have higher odds of SHPT, hypoalbuminemia, and hypertension than CKD participants with a BMI <30 kg/m^2. Participants with a high WC (>102 cm in men and >88 cm in women) have higher odds of hypoalbuminemia and hypertension than participants with a low WC. When BMI and WC were examined as a continuous variable (2kg/m^2 increase in BMI and 5 cm increase in WC), similar associations were noted. Participants with BMI ≥30 kg/m^2 and high WC (vs. BMI <30 kg/m^2 and low WC) have higher odds of SHPT, hypoalbuminemia, and hypertension while participants with BMI <30 kg/m^2 and high WC (vs. BMI <30 kg/m^2 and low WC) had no increased odds of CKD complications.



Conclusions: Anthropometric measures such as BMI and WC are associated with SHPT, hypoalbuminemia, and hypertension among those with CKD. These findings suggest the need for closely monitoring the development of these CKD complications among those who are obese.

Is Conventionally Measured Body Mass Index Accurate in African American Populations? Sandra Williams,[2] Dulcie Kermah,[1] Keith C. Norris.[1,3] *[1]Charles R Drew University of Medicine & Science; [2]Department of Endocrinology, Cleveland Clinic; [3]David Geffen School of Medicine at UCLA.*

Background: Racial differences are being increasingly recognized within calculated indices utilized for health assessment. Muscle mass and bone mass are commonly reported to be higher in African Americans compared to their non-African American counterparts. Therefore calculated indices which are dependent on these factors likely require modification for improved accuracy. The now validated and widely utilized "correction coefficient" for estimated glomerular filtration rate (eGFR) in African Americans, represents one example.

Methods: Given the increasing role of increased body mass index (BMI) on cardio-renal outcomes we explored the relationship between BMI and both % body fat and total lean body mass (as assessed by DEXA) for 2,557 blacks and 6,570 non Hispanic whites enrolled in the NHANES 1999-2004.

Results: The estimated correction factor for % body fat for a given BMI for Blacks was 1.082 and for total lean body mass (excluding bone mineral content [g]) was 1.016. The % body fat * total lean body mass correction ratio was 1.099.

Conclusions: Thus a BMI of 25 for the white population is similar to a BMI of 27.48 in regards to the equilibration for % body fat & total lean body mass, the two most metabolically active elements BMI represents. Prospective studies should consider this correction when comparing cardio-renal outcomes across races.

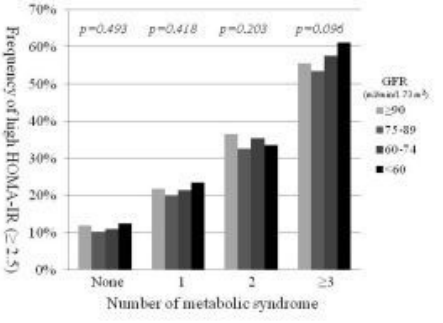
Mild to Moderate Decrease of Glomerular Filtration Rate Is Not Directly Related to Increase of Insulin Resistance Seung Min Lee,[1] Ho Jun Chin,[2] Suhnggwon Kim.[1] *[1]Internal Medicine, Seoul National University Hospital, Korea; [2]Internal Medicine, Seoul National University Bundang Hospital, Korea.*

Background: Insulin resistance is associated with type 2 diabetes, metaolic syndrome, and other cardio-renal risk factors. Decreased glomerular filtration rate (GFR) is assumed to be related to increase of insulin resistance (IR) but the causal relationship between them is not convincing. We tried to confirm whether mild to moderate decline of GFR is directly related to IR without the influence of cardio-renal risk factors.

Methods: We enrolled 17,157 subjects with routine health checkup in SNUBH who were tested fasting blood glucose, insulin, serum creatinine, and components of metabolic syndrome. We calculated HOMA-IR index as a IR marker and GFR by MDRD equation using IDMS traceable creatinine. We estimated the adjusted HOMA-IR index of GFR groups (GFR 1; ≥ 90, GFR2; 75-89, GFR3; 60-74, and GFR 4; <60 ml/min/1.73 m^2) by ANCOVA test adjusted with factors related to HOMA-IR.

Results: The mean GFR in group 1 was 85±6, in group 2, 74±4, in group 3 64±4, and, in group 4, 53±6 ml/min/1.73 m^2. The factors associated to HOMA-IR index were well known cardio-renal riks factors such as, age, gender, number of metabolic syndrome component, hypertension, and etc. The estimated and adjusted HOMA-IR index was highest in GFR group 1 and lowest in GFR group 2. The adjusted HOMA-IR index in GFR group 4 was not different from that of GFR group 2 and 3 (GFR group 1: 2: 3: 4=2.240±0.022: 2.15±0.014 :2.197±0.016 : 2.231±0.045). When we stratified the subjects with number of components of metabolic syndrome, the frequency of high HOMA-IR index (≥2.5) was not different among GFR groups.

Figure 1



(All-p values >0.05)

Conclusions: Mild to moderate decline of GFR was not linearly related to increase of HOMA-IR index, especailly, with controlling the effect of component of metabolic syndrome.

Plasma Obestatin Levels Are Inversely Correlated with Renal Function in Patients Undergoing Conservative Treatment Denise Mafra,[1] Natalia Alvarenga Borges,[2] Amanda Barros,[1] Cristiane Moraes.[1] *[1]Graduation Programme in Cardiovascular Sciences, Federal University Fluminense, Rio de Janeiro, Brazil; [2]Antonio Pedro University Hospital, Federal University Fluminense, Rio de Janeiro, Brazil.*

Background: Patients with chronic kidney disease (CKD) frequently experience loss of appetite, which increases during disease progression. Obestatin hormone, an appetite suppressant, can be altered in these patients due to decreased renal function. The aim of this study was to analyze obestatin plasma levels in CKD patients undergoing conservative treatment and its correlation with creatinine clearance (CrCl), appetite and body composition.

Methods: Thirty-three CKD patients (27.3% men, 48.6% diabetics, 65.5±9.4 yrs, BMI 27.6±4.7kg/m^2, CrCl 38.3 [15.0-84.4mL/min], 10% in stage 2, 10% in stage 3a, 60% in stage 3b and 20% in stage 4 of CKD) were studied. The Cockcroft & Gault formula was used to estimate the creatinine clearance. Obestatin plasma levels were measured using the enzyme-linked immunoabsorbent assay kit (Missouri City, TX, USA). Body composition was assessed through Dual-Energy X-Ray Absorptiometry (DEXA) and appetite by Simplified Nutritional Appetite Questionnaire (SNAQ). Statistical analysis was performed using SPSS 17.0.

Results: The mean of SNAQ score was 15.8±1.8 and 31% of patients presented significant risk of weight loss, the % body fat was 33.9±10.6% for men and, 43.1±6.9% for women, the obestatin plasma levels were (0.9[0.3-3.7ng/mL]) and did not correlate with SNAQ or body composition. However, obestatin plasma levels were correlated inversely with creatinine clearance (rho= - 0.55, p= 0.02). There was no difference between obestatin levels in diabetic and non-diabetic patients.

Conclusions: In CKD patients with low CrCl, undergoing conservative treatment, the obestatin levels are increased, suggesting a role of the kidneys in the clearance of this hormone. Therefore, the appetite in these patients can be decreased with the disease progression, providing worse prognosis.

Daily Activity Levels Are Associated with Estimated Kidney Function in Stage 3-5 Chronic Kidney Disease Sarah L. West,[1] Maryum Chaudhry,[2] Tanya D. Dahonick,[2] Charmaine E. Lok.[1,2] *[1]University of Toronto, Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada.*

Background: Chronic kidney disease (CKD) is associated with a decrease in functional ability and fatigue. Only one study has characterized daily activity levels in patients with stage 1-2 CKD and reported that activity level was negatively associated with worsening kidney function. The purpose of our study was to assess the association between daily activity and kidney function in patients with stage 3-5 CKD.

Methods: In patients age ≥18 years with stages 3-5 CKD (using NKF criteria by MDRD), we measured daily activity by triaxial accelerometry (StayHealthy RT3), worn for 7 consecutive days on the hip, and categorized activity as sedentary, light, or moderate/vigorous. Statistical analyses were performed using SAS.

Results: Overall, 59 men and 44 women completed accelerometry assessments, with a mean age of 64 years. The primary cause of CKD was diabetes (25%) and the mean eGFR was 26±15 ml/min/1.73m^2. On average, subjects expended 397±263 kcal/day performing daily activities (i.e., kcal expended above resting energy expenditure). Subjects were primarily sedentary: 1145±114 minutes/day were spent sedentary, while only 288±114 and 7±10 minutes/day were spent completing light and moderate/vigorous activity, respectively. Increasing eGFR was positively correlated with the number of kcals expended/day (r=0.357, p=0.0002), the amount of light activity performed/day (r=0.312, p=0.001), the amount of moderate/vigorous activity performed/day (r=0.237, p=0.02) and was negatively correlated with sedentary activity (r= -0.193, p=0.05). Results were similar when kidney function was estimated by the Cockcroft-Gault and the CKD-EPI equations.

Conclusions: In our patients with stage 3-5 CKD, those with increased eGFR (better kidney function) were more active. A reduction in energy expenditure and physical activity with progressive CKD may have clinical implications, such as risk of functional decline and its complications (falls and fractures) or dietary advice of caloric needs. Future physical activity intervention studies aimed at improving daily activity levels in those with worsening kidney function may provide further insights.

Cellular Mechanism of Insulin Resistance in CKD: Putative Role of Lipotoxicity in Liver Laetitia Koppe,[1,2] Caroline Pelletier,[1,2] Vella Roxane,[2] Croze Marine,[2] Denis Fouque,[1,2] Soulage Christophe,[2] Fitsum Guebre-egziabher.[1,2] *[1]Department of Nephrology, Hospices Civils de Lyon, Lyon, France; [2]INSA, CarMeN, INSERM U1060, Université de Lyon, Lyon, France.*

Background: Chronic kidney disease (CKD) is associated with insulin resistance (IR). However the molecular mechanisms are unknown. Growing evidence suggest that hepatic IR is related to multiple causes including endoplasmic reticulum (ER) stress, inflammation and hepatic lipid accumulation. Excessive accumulation of fat metabolites may interfere with insulin signaling by activating novel protein kinase (PKCε). Recently, it has also been postulated that dysregulation of the energy sensor, AMPK pathway may in itself be a contributing factor. We hypothesize that IR in the context of CKD, may be related to liver fat accumulation and the subsequent disturbances of these metabolic pathways.

Methods: C57BL/6 mice underwent a 5/6 nephrectomy and were compared to pair fed sham-operated mice. Insulin sensitivity was estimated through intra-peritoneal insulin (ipITT) and glucose tolerance (ipGTT) tests. The phosphorylation of AMPK and the activation of PKCε (membrane translocation) and ER stress markers were studied by Western Blot in the liver. The intra-hepatic lipids were measured.

Results: The CKD mice exhibited a marked decrease in insulin sensitivity (-76%, p<0.01) and altered glucose tolerance (+24 %, p<0.001). Insulin resistance was associated with a significant decrease in white adipose tissue accretion (-57%, p<0.001) and increased liver (+38%, p<0.05) lipid content. Furthermore, we show that this increase in hepatocellular lipid content is associated with PKCε activation (+52 %, p<0.05) and decreased AMPK phosphorylation in the liver (-54%, p<0.01).In contrast, insulin resistance in these mice was not associated with increased ER stress.

Conclusions: Taken together, our data show that ectopic lipid accumulation in liver is associated with PKCε activation and decreased AMPK activation in CKD. This suggests the potential involvement of lipotoxicity in the development of IR and the increased risk of cardiovascular disease in CKD. Furthermore, ER stress might not be a likely contributor to the observed IR.

Effects of Sevelamer-HCl Treatment on Cardiovascular Abnormalities in CRF Mice Julien Maizel, Isabelle Six, Sebastien Dupont, Edouard Secq, Benedicte Dehedin, Fellype Carvalho Barreto, Joyce Benchitrit, Sabrina Poirot, Michel Slama, Christophe M. Tribouilloy, Gabriel Choukroun, Jean-claude A.R. Maziere, Tilman B. Drueke, Ziad Massy. *INSERM 1088, Amiens University Hospital (Univeristy of Picardie), Amiens, France.*

Background: Elevated serum phosphate and FGF23 levels are associated with cardiovascular disease in patients with chronic renal failure (CRF). The calcium-free phosphate binder sevelamer has been shown to decrease both serum phosphorus and FGF23. Limited data indicate that sevelamer may improve CRF-related cardiac and vascular conditions, such as diastolic dysfunction, left ventricular hypertrophy (LVH) and aortic stiffness. We investigated the effects of sevelamer-HCl on cardiovascular abnormalities in a murine model of CRF.

Methods: Groups of CRF and non-CRF mice received either sevelamer-HCl or placebo treatment for 14 weeks, starting 6 weeks after the initiation of CRF or sham operation. Animals underwent echocardiography and arterial blood pressure and pulse wave velocity (PWV) were measured.

Results: After 8 weeks of sevelamer-HCl treatment CRF mice had decreased serum phosphorus levels and improved aortic systolic expansion rate (ESAo), PWV and diastolic function, although LVH remained unchanged. However, following an additional 6-week course of sevelamer-HCl treatment, LVH also improved. In a multiple regression analysis, both serum phosphorus and FGF23 were independently correlated with LV mass. ESAo and LV diastolic parameters were correlated with serum phosphorus but not with FGF23.

Conclusions: Sevelamer-HCl improved aortic stiffness and cardiovascular abnormalities in CRF mice. Whether sevelamer may also improve cardiovascular disease in CRF patients remains to be established.

The Role of Local Bone Vascularization and Paracrine Factors in Chronic Kidney Disease Related Growth Retardation Yael Segev,[1] Ariel Troib,[1] Ralph Rabkin,[2] Daniel Landau.[3] *[1]Shraga Segal Dept. of Microbiology and Immunology, Ben Gurion University, Beer Sheva, Israel; [2]Medicine, Veterans Administration Health Care System, Palo Ato, CA; [3]Padiatrics, Soroka University Medical Center, Beer Sheva, Israel.*

Background: Growth retardation, a major problem in children with chronic kidney disease (CKD) is partly caused by GH resistance with impaired IGF-I bioavailability. Normal longitudinal growth requires chondrocyte maturation in the epiphyseal growth plate (EGP), mediated by numerous autocrine and paracrine factors. We have previously shown evidence for GH-R resistance at the bone level of young growth retarded CKD rats. We now investigated the role of vascularization and paracrine factors in developing bones in the same model.

Methods: Three week-old rats underwent a 2 step 5/6 nephrectomy (CKD) or sham operation (C). Both groups were pair-fed with standard chow and sacrificed after 2 weeks.

Results: As previously shown, there was a significant decrease in weight gain and longitudinal growth in CKD Vs C in spite of pair-feeding. Serum phosphate levels were unchanged but PTH increased 2-fold in CKD (p< 0.01). EGP morphometry showed a wider hypertrophic zone in CKD rats. The decrease in EGP GHR signaling was associated with a decrease in immunostainable IGF-I, mainly in the resting and proliferative zones. Histochemical staining with Movat's pentachrome and Aniline blue showed a decreased vascularization process at the primary ossification center distal to the hypertrophic chondrocytes, as well as a decrease in VEGF mRNA in the CKD group. In addition, indian hedgehog (IHH) protein, which normally synchronizes skeletal angiogenesis and perichondrial maturation with cartilage development, was decreased in the EGP of CKD animals.

Conclusions: Growth retardation in CKD juvenile rats is associated with decreased EGP GHR signaling and IGF-I expression, further explaining GH resistance in CKD. In addition, the widened hypertrophic EGP zone and decreased vasularization, mediated by a decreased VEGF and IHH expression suggesting a chondrocyte maturation arrest in CKD.

TH-PO278

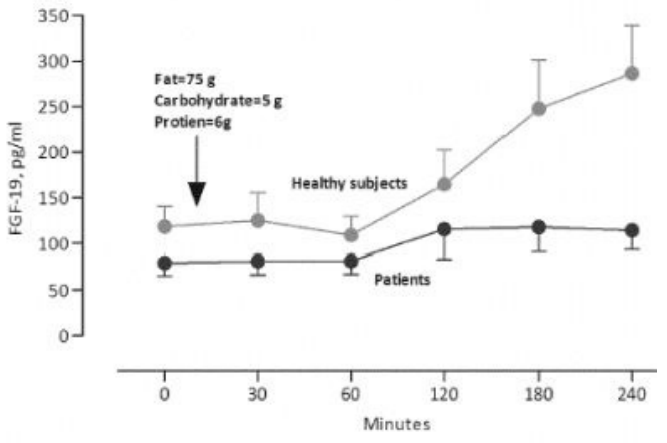
Impaired Postprandial Plasma Fibroblast Growth Factor (FGF)-19 Response in CKD Stage 5 Patients Meng Li,[1] Björn Anderstam,[2] Jonas Axelsson.[1] *[1]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden; [2]Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden.*

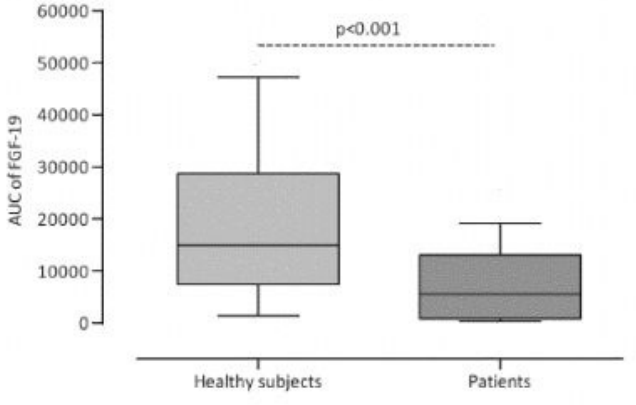
Background: Uraemia is associated with carbohydrate and fat dysmetabolism that predicts mortality. Fibroblast growth factor (FGF)-19 is a hormone-like protein that was recently reported to regulate carbohydrate, lipid and bile acid metabolism. The aim of this study was to evaluate FGF-19 response to a fat- and carbohydrate- rich meal provocation in CKD patients.

Methods: Six CKD patients on maintenance HD and nine matched healthy subjects were studied on a dialysis-free day. A standardized meal (75 g of milk fat, 5 g of carbohydrates and 6 g of proteins/m^2 of body surface area, corresponding to a total caloric intake of 700 kcal/m^2 of body surface area) was administered. Each participant was tested on 4 separate occasions (7 days in between each), and the results were combined for analysis. Blood was collected at baseline (following a 8 hrs fast) and 30, 60, 120, 180 and 240 min following the meal. FGF-19 was analyzed using a commercial ELISA kit (R&D Systems, U.K.).

Results: FGF-19 in plasma from healthy subjects rose following the meal to reach a peak 286.2±53.1 pg/mL at 240 min. However, in uremic patients FGF-19 did not rise significantly in response to the meal (peak 114±20.5 pg/mL at 120 min). We did not see significant differences in circulating glucose or TG concentrations between patients and controls; it is unlikely to explain the blunted FGF-19 response. $AUC_{0\text{-}240min}$ of FGF-19 was thus significantly higher in healthy than in CKD participants (*$P < 0.001$), Figure 1A and B.*

Conclusions: CKD stage 5 patients showed a markedly blunted postprandial FGF-19 response. While mechanisms were not investigated, the blunted FGF-19 response may be linked to uremic dysmetabolism, most likely involving the liver.





Funding: Government Support - Non-U.S.

TH-PO279

Rate of Change in Fibroblast Growth Factor 23 Level Predicts the Progression of Chronic Kidney Disease from Early-Stage in Elderly Patients Eiichiro Kanda,[1] Masayuki Yoshida,[2] Sei Sasaki.[2] *[1]Tokyo Kyosai Hospital; [2]Tokyo Medical and Dental University.*

Background: The level of fibroblast growth factor 23 (FGF23), which regulates phosphate and vitamin D metabolism, increased with the progression of chronic kidney disease (CKD). FGF23 as a risk factor for the progression of CKD in elderly CKD patients has not been fully established.

Methods: 65 elderly CKD patients were enrolled in this prospective cohort study and followed up for one year in Tokyo, Japan. We compared estimated glomerular filtration rate (eGFR) and the levels of CKD-mineral and bone disorder related markers, such as 1,25(OH)2 vitamin D (1,25-VD), intact PTH, and FGF23, at the start of the study as the baseline with those one year later, and identified which marker predicted the progression of CKD. The rate of change in log-FGF23 was determined using the following calculation: change in log-FGF23/baseline log-FGF23. Factors associated with the change in eGFR were assessed by regression models.

Results: 46 patients were male: average age(SD), 72.7(7.7) years; diabetics, 64.6%; eGFR, 51.1(7.7) ml/min/1.73m^2; calcium, 9.4(0.5) mg/dl; phosphate, 3.4(0.7) mg/dl; 1,25-VD, 48.8(21.2) pg/ml; intact PTH, 127.7(92.6) pg/ml; and FGF23, 72.8(83.4)pg/ml. A decreased eGFR was observed in 36.9% of the patients. The average change in eGFR was -0.305(1.41) ml/min/1.73m^2/year. Spearman's rank correlation showed that the change in eGFR significantly correlated with serum calcium level, 1,25-VD level, intact PTH level, log-FGF23, rate of change in log-FGF23 (P<0.0001). In stage-3 patients, adjusted multivariate analysis showed that change in eGFR was associated negatively with rate of change in log-FGF23 (P=0.0087). Adjusted multiple regression analysis showed that the high rate of change in log-FGF23 was associated with the decrease in GFR adjusted odds ratio (1.174; 95% confidence interval, 1.006-1.372). However, these relationships were not observed in stage-4 or -5 patients.

Conclusions: In elderly CKD patients, our findings suggest that the rate of change in log-FGF23 is associated with the progression of CKD, particularly in early stage. FGF23 level is a candidate marker for identifying patients in the state of CKD progression.

TH-PO280

A 16 Week Study on Impact of Vitamin D Supplementation on Endothelial Function in CKD Nihil Chitalia, Tuan F. Ismail, Juan C. Kaski, Debasish Banerjee. *Cardiovascular Research Centre, St Georges, University of London, United Kingdom.*

Background: Atherosclerosis in Chronic Kidney Disease (CKD) patients is the major cause of mortality. We previously demonstrated endothelial dysfunction and its association with atherosclerosis and Vitamin D deficiency. However the effect of Vitamin D supplementation on endothelial function in CKD is unknown.

Methods: This study aimed to investigate the effect of 25(OH) Vitamin D supplementation on endothelial function in patients with CKD stages 3/4 over 16 weeks. The study was approved by NHS Research Ethics Committee. The endothelial function was measured with post-ischaemic brachial artery flow mediated dilatation at a fasting state by trained staff using a method previously established in our laboratory. The central artery stiffness was measured with pulse wave velocity using SphygmoCor machine. Vitamin D was supplemented with 2 doses of 300,000 units of Cholecalciferol (Martindale) at baseline and 8 weeks.

Results: Twenty-one stable CKD patients with Vitamin D <75 nmol/L; and without diabetes, heart failure, infection, malignancy, autoimmune disease, CRP>20 mg/L, hypercalcaemia, recent myocardial infarction or stroke; were enrolled. At baseline the clinical characteristics were; age 52±14 (mean±SD) years, females 33%, Southeast Asian 24%, Afro Caribbean 24%, dyslipidaemia 43%, smokers 24%, BMI 29±5 kg/m^2, systolic BP 133±13 mmHg, diastolic BP 86±9 mmHg, eGFR 38±11 ml/min/1.73m^2, haemoglobin 13.7±1.4 g/dl, vitamin D 45±15 nmol/L, calcium 2.37±0.1 mmol/L, phosphate 1.1±0.2 mmol/L, parathyroid hormone 11.6±9.1 pmol/L. With treatment the vitamin D level increased (45±15 to 79±29 nmol/L; p<0.001), calcium increased (2.37±0.09 to 2.43±0.09 mmol/L; p=0.001), parathyroid hormone decreased (11.6±9.1 to 7.5±2.4 pmol/L;p=0.008). No patients developed hypercalcaemia. Serum phosphate, eGFR levels remained unchanged. Endothelial function improved (2.80±3.87 to 5.59±2.89 %; p<0.004). The pulse wave velocity remained the same (7.9±1.3 and 7.8±2.2 m/s; p=0.78).

Conclusions: This study demonstrated for the first time that a short course of 25(OH) Vitamin D therapy in patients with moderate CKD was safe and improved endothelial function.

TH-PO281

Metabolic Effects of Paricalcitol in Stage 3-4 Chronic Kidney Disease Ian H. de Boer, Michael Sachs, Andrew N. Hoofnagle, Bryan R. Kestenbaum, Kristina M. Utzschneider, Steven E. Kahn, Jonathan Himmelfarb. *University of Washington, Seattle, WA.*

Background: Patients with CKD are often insulin resistant and glucose intolerant, and these abnormalities appear to promote cardiovascular disease. Animal-experimental and human data suggest that vitamin D receptor agonists improve insulin sensitivity and glucose tolerance in CKD.

Methods: We conducted a clinical trial of 22 persons with estimated GFR 15-59 mL/min/1.73m^2 and fasting plasma glucose 100-125 mg/dL. In a cross-over design, each participant was allocated oral paricalcitol 2 µg daily for 8 weeks and matching placebo for 8 weeks, separated by an 8-week washout period. The order of interventions was randomly assigned and blinded to both participants and investigators. The primary study outcome was glucose tolerance measured using the oral glucose tolerance test.

Results: Paricalcitol reduced serum concentrations of parathyroid hormone (29.4 vs 70.9 pg/mL, p<0.001), 1,25-dihydroxyvitamin D (10.8 vs 26.4 pg/mL, p<0.001), and 25-hydroxyvitamin D (23.7 vs 30.4 ng/mL, p<0.001) and increased serum concentrations of fibroblast growth factor-23 (118.4 vs 68.2 pg/mL, p<0.001) and 24,25-dihydroxyvitamin D (3.8 vs 2.6 ng/mL, p<0.001). However, paricalcitol had no effect on glucose tolerance (difference in glucose area under the curve -1.5%, 95% confidence interval -5.9%, 3.2%, p=0.54), insulin sensitivity, beta-cell insulin response, plasma free fatty acid suppression, or urinary F2-isoprostane excretion.

Conclusions: In stage 3-4 CKD, paricalcitol has substantial effects on vitamin D metabolism beyond suppression of parathyroid hormone but does not improve glucose metabolism.

TH-PO282

Gland Sparing Parathyroidectomy with Target Parathyroid Gland Reduction Offers Safe Long-Term Metabolic Control: A Single-Center Experience in the Current Era Christopher Clark,[1] Karen T. Pitman,[1] Mihaly Tapolyai,[2] Mehrdad Hamrahian,[1] Eva Csongradi,[3] Tibor Fulop.[1] *[1]University of Mississippi Medical Center, Jackson, MS; [2]Fresenius Medical Care - Semmelweis University, Hungary; [3]Medical and Health Science Center - University of Debrecen, Hungary.*

Background: Long-term results of surgical parathyroidectomy (PTX) in end-stage renal disease patients with targeted parathyroid hormone (PTH) reduction are less well known in the modern era.

Methods: Retrospective chart review of ESRD patients, who underwent PTX during index period of 08/2006 - 08/2011 and, when records available, follow-up data up to 3 years. All PTX were performed by a single surgeon (KTP) with intra-operative PTH monitoring.

Results: Of the identified 37 patients 94.6% were African-American and 59.5% females. In this relatively young cohort (48.4 ±13.9 years), histology recovered predominantly hyperplasia (94.6%) rather than adenoma. 45.9% received cinacalcet (CNC) before PTX (66.43 ±20.9 mg). Preoperative calcium/phosphorus was 9.6 ±1.2/6.6 ±1.7 mg/dL with PTH of 1,589.1 ±827 pg/mL. Mean length of stay was 5.5 ±2.4 days. Stabilized PTH values (4-8 days after PTX) measured 145.4 ±119.2 pg/mL. Pre-operative PTH strongly correlated ($p<0.0001$) with both Alkaline Phosphatase (ALP) (r 0.596) and length of inpatient days (r 0.545), but not with CNC administration. Long-term follow-up results were available for only a part of the cohort, shown on Table 1.

Table1. Long-Term Biochemical Control in Local Follow-up Cohort

	6 Month	12 Month	24 Month	36 Month
Calcium, (mg/dL)	8.5 ±1.1	8.7 ±0.6	8.5 ±0.7	8.6 ±0.9
Phosphorus, (mg/dL)	6.1 ±2.1	6.8 ±1.8	6.2 ±1.2	5 ±1.6
PTH, Intact (pg/mL)	400 ±366	323 ±227	465 ±326	285 ±202
Alk. Phos, (U/L)	155 ±117	83 ±18	63.8 ±21.7	70.7 ±20.1
Total Bioactive Vitamin-D or Analog Dose, (mg/week)	6.9 ±9	3.7 ±3.60	6.17 ±3.70	4.8 ±4.4
N, (Participant)	12	12	8	6

At 24 months, 2 of the 8 subjects received CNC, 30 mg/day. No clinical fractures were observed.

Conclusions: Gland sparing PTX improved PTH control with less active vitamin-D utilized in our patients. While hyperphosphatemia may be a persisting problem in these patients, ALP and calcium levels remained normalized up to 3 years.

TH-PO283

Parathyroidectomy versus Medical Management for Secondary Hyperparathyroidism in ESRD: Patient Eligibility, Characteristics and Clinical Outcomes Girish N. Nadkarni,[2] Ioannis Konstantinidis,[1] Vijay Lapsia.[1] *[1]Medicine, Mount Sinai School of Medicine, New York, NY; [2]Medicine, St.Luke's Roosevelt Hospital Center, New York, NY.*

Background: Secondary hyperparathyroidism (SHPT) is a common complication of End Stage Renal Disease (ESRD). Parathyroidectomy (PTX) is indicated to manage SHPT refractory to medical management (MTX). We compared baseline characteristics and clinical outcomes of ESRD patients undergoing PTX with those receiving MTX at one year.

Methods: Data on ESRD patients treated between Aug 2007 and Dec 2011 at our institution were retrospectively reviewed. Patients with persistently elevated levels (>800 pg/mL) of intact parathyroid hormone (iPTH) for minimum of six months associated with hypercalcemia and/or hyperphosphatemia for at least 50% of that time period were included. Patients with less than 12 months of follow up were exlcuded. Baseline characteristics, mortality and change in iPTH, calcium, phosphorus, albumin and Alkaline phosphatase (ALP) at baseline and 12 months were compared using chi-square and paired t-tests.

Results: Sixty-one patients satisfied inclusion criteria (PTX=10, MTX=51). At baseline, PTX patients had been on dialysis longer, 12.5 years vs 5.5 years ($p=0.001$), with higher iPTH (2968 vs 1431, $p<0.001$), calcium ($p=0.008$), ALP ($p=0.001$) and were less likely to be African American ($p=0.007$). Seventy percent (n=7) of surgical patients were receiving cinacalcet at the time of inclusion compared to 27% (n=12) of patients in the MTX cohort ($p=0.023$). At 12 months, iPTH decreased 96% ($p<0.001$) and ALP by 67% ($p=0.0004$) in the PTX cohort, whereas iPTH decreased 23% ($p=0.031$) without any significant reduction of ALP in the MTX cohort. All PTX patients who complained of preoperative pruritis and bone pain experienced complete resolution after surgery.

Conclusions: A large proportion of patients did not receive PTX despite meeting criteria. Dialysis vintage, higher levels of iPTH and cinacalcet therapy were more likely to be associated with PTX. Patients in the PTX group had better reduction in PTH and ALP and achieved symptomatic control. Larger studies are required to identify barriers to PTX.

TH-PO284

Association between Plasma Levels of Fructose with Uric Acid and Body Mass Index in Chronic Kidney Disease (CKD) and Peritoneal Dialysis PD Patients (pts) Abdul Rashid Tony Qureshi, Ann-christin Bragfors Helin, Olof Heimburger, Peter F. Barany, Peter Stenvinkel, Bengt Lindholm, Björn Anderstam. *Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

Background: Excessive intake and altered metabolism of fructose have been suggested to play a role in the development and progression of metabolic syndrome, possibly via links to increased formation of uric acid. However, there is a lack of data regarding fructose metabolism in CKD and PD pts. We studied the association between fructose levels, uric acid, and carbohydrate and lipid metabolites in healthy subjects (HS), CKD stage 3-4, non-dialyzed CKD stage 5 (CKD5-ND) pts and PD pts.

Methods: Plasma fructose and uric acid were analyzed in 80 HS [females 29%; median age 63 (range 22-80) yrs], 90 CKD-stage 3-4 [females 28%; median age 60 (range 23-80) yrs], 214 CKD5-ND [females 39%; median age 55 (range 19-70) yrs] pts and 83 PD [females 32%; median age 55 (range 25-85) yrs] pts. Estimated GFR (ml/min) was 85 (72-96) in HS, 23 (15-32) in CKD 3-4 and 6.5 (5-8) in CKD5-ND and 5 (4-7) in PD pts. Data on demographic nutritional and metabolic characteristics at baseline were recorded.

Results: The median (range) level of fructose (umol/L) was 86 (62-109) in HS, 86 (64-116,) in CKD 3-4, 64 (44-87, $p<0.01$) in CKD5-ND pts and 76 (54-112) in PD pts. Uric acid (mg/L) was 330 (range 273-391) in CKD 1-2, 478 (427-544, $p<0.01$) in CKD 3-4, 398 (316-481, $p<0.01$) mg/L in CKD5-ND and 309 (range 265-360, NS) in PD pts. Fructose and BMI were associated in HS (rho=0.41, $p<0.001$) and CKD 3-4 pts (rho=0.22, $p<0.05$), but not in PD (rho=0.21, $p=0.09$) or CKD5-ND (rho=0.11, NS) pts. Fructose and hsCRP were associated in HS (rho=0.56, $p<0.001$) and PD pts (rho=0.31, $p<0.001$). Uric acid and hsCRP were associated in HS (rho=0.37, $p<0.01$) in CKD 3-4 pts (rho=0.22, $p=0.09$) and in CKD5-ND pts (rho=0.22, $p<0.001$).

Conclusions: In comparison to HS, CKD 3-4 pts, PD-pts, fructose levels were lower in CKD5-ND pts. Fructose levels were associated with BMI in HS and CKD 3-4 pts and with inflammation in HS and PD pts.High levels of uric acid in CKD 3-4 and CKD5-ND pts may be associated with inflammation.

TH-PO285

Effects of Febuxostat versus Allopurinol in Reducing Serum Urate in Subjects with Hyperuricemia and CKD Stage 3-5: A 12-Week, Randomized Trial Nobuhito Hirawa,[1] Mari Katsumata,[1] Keisuke Yatsu,[1] Yoshiyuki Toya,[2] Gen Yasuda,[1] Satoshi Umemura.[2] *[1]Nephrology and Hypertension, Yokohama City University Medical Center, Yokohama, Kanagawa, Japan; [2]Nephrology and Hypertension, Yokohama City University Hospital, Yokohama, Kanagawa, Japan.*

Background: Febuxostat (Feb), an orally administered nonpurine selective inhibitor of xanthine oxidase, was developed recently. Compared to alloprinol (Allo), Feb directly inhibits xanthine oxidase and is metabolized by liver, partly. Thus, Feb may be easy to use in patients with renal impairment. In this study, to clarify the urate-lowering efficacy and safety of Feb, we compare the effectiveness of Feb and Allo in subjects with hyperuricemia and CKD stage 3-5.

Methods: Forty patients with CKD stage 3-5 and hyperuricemia (serum urate level > 8mg/dl) were randomized to receive once-daily Feb (10mg) or Allo (50mg) for 4 weeks. After that, Feb and Allo were permitted to increase the dose until 40mg/day (Feb) in all participants, and 100 mg (Allo) in CKD stage 3. The 1st endpoint was the UA values at 12 weeks. Furthermore, we examined the effects on renal function and investigated the safety of Feb and Allo treatments in CKD stage 3-5 patients.

Results: The average age and eGFR of the participants were 63 years old and 22 ml/min/1.73m2. There were no differences in BP, Cr, UA values (9.7 mg/dl) between Feb group and Allo group in the control period. Feb and Allo significantly decreased the serum UA levels at 2 weeks after treatments. The UA values of Feb and Allo were the same until 4 weeks of treatment. Meanwhile, the UA level of Feb group was significantly lower than Allo group in 8 and 12 weeks of treatments (6.8 vs 8.1 mg/dl, $p<0.025$). Serum Creatinine, eGFR were not changed with UA lowering treatments. The changes of the slope of 1/Cr were negatively correlated with the alterations of the serum UA. Using the multivariate analysis, the UA values of 12 weeks treatments were associated with Feb use, baseline UA value and urinary protein / Cr ratio. Obvious side effects were not recognized in Feb treatments.

Conclusions: Febuxostat seem to be effective and safe in patients with hyperuricemia and CKD stage 3-5.

TH-PO286

The Inhibition of NADPH Oxidase 4 Ameliorated the Fibrotic Responses In Vitro, and in Diabetic Mouse Kidneys Rachel Lingling Yong, Sonia Saad, Xinming Chen, Chunling Huang, Carol A. Pollock. *Renal Medicine, Kolling Institute, St Leonards, NSW, Australia.*

Background: NADPH oxidase family has been identified as a major source of superoxide and hydrogen peroxide generation in the cardiovasculature and kidney during health and disease. Nox4 is most accountable for ROS-induced renal hypertrophy and myofibroblasts activation induced by TGFβ1 which plays a central role in diabetic renal fibrosis. This study aimed to investigate the role of Nox4 inhibition on TGFβ1-induced fibrotic responses in vitro and in diabetic kidneys in a mouse model.

Methods: In vitro, immortalised human proximal tubular cells (HK2) were incubated with TGFβ1 (2ng/ml) +/- plumbagin (1.5μM/L), a selective inhibitor of Nox4 for 48 hours. Then the expression of mRNA and protein of collagen 4 and fibronectin were measured by qRT-PCR and Western blotting. In addition, the collagen 4 and fibronectin in Nox4 silenced HK2 cells exposed to TGFβ1 were examined. In vivo, C57BL mice with diabetes induced by Streptozotocin were administered with plumbagin (2 mg/kg/day) or vehicle (DMSO) alone for 3 weeks after induction. At 24 weeks, mice were culled and kidneys were collected for histological analysis.

Results: TGFβ1-induced expression of fibronectin and collagen 4 in HK2 cells was significantly reversed by plumbagin or in Nox4 gene silenced cells compared to control ($P<0.01$). In animal studies, diabetic mice have increased levels of fibronectin and collagen 4 in addition to increased extracellular matrix deposition. All were significantly reduced in the presence of plumbagin in diabetic kidneys compared to vehicle controls.

Conclusions: This study suggests that Nox4 regulates the expression of collagen 4 and fibronectin and Nox4 inhibition ameliorated diabetic kidney nephropathy.

TH-PO287

The Blocking of Renin-Angiotensin-Aldosterone System Decline Both EPO and EPO Receptor in CKD Rat Jae Won Yang,[1] Seung-Ok Choi,[1] Byoung Geun Han,[1] Minseob Eom.[2] *[1]Nephrology, Yonsei University Wonju College of Medicine, Wonju, Gangwon, Korea; [2]Pathology, Yonsei University Wonju College of Medicine, Wonju, Gangwon, Korea.*

Background: While many investigators observe reduced hemoglobin associated with angiotensin-converting enzyme (ACE) inhibitor, the basis for this effect is not well understood. The angiotensin II may be considered as one important physiological modulator of EPO production. We investigated that the ACE inhibitor can modulate the EPO in kidney and EPO receptor in bone marrow.

Methods: A 5/6 nephrectomy was performed in Sprague-Dawley rats (N= 24, male), and divided three groups after 8 weeks. We supplied general diet to the control (N=8), low salt diet to the LSD (N=8) group, and low salt diet with enalapril 50mg/L in drinking water to the ACEI group (N=8) for 2 weeks. After the collection of blood on day 14, the remaining kidney and femur was ressected surgically, the serum EPO and angiotensin II levels by ELISA, and tissues were investigated by IHC stain, and RT-PCR for EPO and EPO receptor.

Results: The Hb levels were increased in LSD group (17.30±1.21g/L) relative to control (12.55±0.86g/L), but decreased in ACEI group (16.40±1.30g/L) relative to LSD group (p=0.002). The serum angiotensin II levels were decreased in ACEI group (1,968.71±101.82pg/mL) compared to control (2,159.93±172.14 pg/mL) and LSD group (2,090.39±323.94pg/mL). The serum EPO levels were increased in LSD (16.02±28.95 mIU/mL) and ACEI group (32.05±30.12mIU/mL) compared to control group (4.67±8.70mIU/mL). Also, In IHC, the EPO in kidney was stained more strongly in ACEI group compared to control and LSD group, but the EPO receptor in bone marrow was stained less strongly in ACEI group relative to control and LSD group. In RT-PCR, the mRNA expression of EPO in kidney was decreased in ACEI group (1.86±0.41) relative to control (5.06±8.59) and LSD group (3.10±4.39) and the mRNA expression of EPO receptor in bone marrow was increased in ACEI group (4.80±2.34) relative to control (1.59±0.61) and LSD group (1.19±0.56).

Conclusions: The blocking renin-angiotensin-aldosterone system in CKD rats can cause anemia via both mechanism to decline erythropoietin in kidney and erythropoietin receptor in bone marrow.

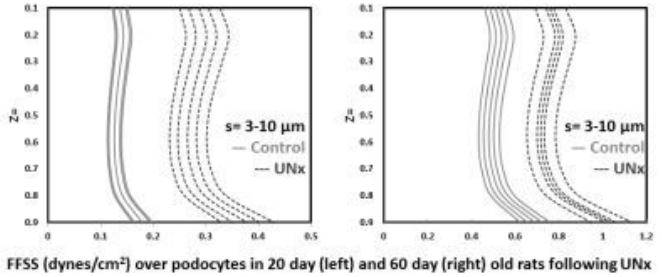
TH-PO288

Increased Fluid Flow Shear Stress on Podocytes Contributes to Glomerular Injury Tarak Srivastava,[1] Ellen T. McCarthy,[2] Alexander Kats,[1] Ram Sharma,[3] Gianni Celsi,[4] Mukut Sharma,[3] Virginia J. Savin.[3] *[1]Section of Nephrology, The Children's Mercy Hospital, Kansas City, MO; [2]Kidney Institute, KUMC, Kansas City, KS; [3]Research and Development, KCVA Medical Center, Kansas City, MO; [4]Uppsala University Hospital, Uppsala, Sweden.*

Background: Podocytes are exposed to mechanical forces arising from both glomerular capillary pressure (P_{GC}) and ultrafiltration. The flow of filtrate into Bowman's space (BS) generates fluid flow shear stress (FFSS) over podocyte. Adaptive hyperfiltration is characterized by increased single nephron GFR (SNGFR) and P_{GC}, and glomerular hypertrophy. Hyperfiltration associated increase in SNGFR increases FFSS. A better understanding of the mechanism underlying hyperfiltration mediated podocyte injury from FFSS is vital. The aim of the study was to determine the effect of uninephrectomy (UNx) on FFSS.

Methods: Sprague-Dawley rats underwent UNx at 5 days of age, and were sacrificed on days 20 and 60 for micropuncture studies. SNGFR, filtration fraction (f) and diameter ($2R_T$) were measured. FFSS to which podocyte is exposed *in vivo* was calculated as: $\tau = [3\eta.f.SNGFR/\prod. s^2(s+2R_T)]x[z/\sqrt{z}.(1-z)]$ [AJP(Renal)2006;F856], where FFSS (τ) is dependent on viscosity (η), f, SNGFR, $2R_T$, width of BS (s) and position between vascular and urinary pole (z). Since 's' is difficult to measure we modeled 's' across a range of values assuming 3 separate scenarios: (a) s=6 µm, (b) s=2 µm (at z=0) to 8 µm (at z=1), and (c) s=3 µm (at z=0) to 10 µm (at z=1).

Results: Calculated FFSS following UNx was increased ~2 fold in all 3 models of 's' on both Day 20 and 60.



FFSS (dynes/cm²) over podocytes in 20 day (left) and 60 day (right) old rats following UNx

Conclusions: The results provide a rationale for the contribution of increased SNGFR and fluid flow to podocyte injury in the constrained BS. We hypothesize that increased FFSS from reduced renal mass will contribute to podocyte injury and to progression of chronic kidney disease.

Identification of Four Major Subsets of Renal Mononuclear Phagocytes in Healthy and Diseased Kidneys Qi Cao,[1] Xin M. Wang,[2] Changqi Wang,[1] Vincent W.S. Lee,[1] Ya Wang,[1] Guoping Zheng,[1] Stephen Alexander,[3] Yiping Wang,[1] David C. Harris.[1] *[1]Centre for Transplantation and Renal Research, Westmead Millennium Institute, University of Sydney, Westmead, NSW, Australia; [2]Flow Cytometry Facility, Westmead Millennium Institute, University of Sydney, Westmead, NSW, Australia; [3]Centre for Kidney Research, Children's Hospital at Westmead, University of Sydney, Westmead, NSW, Australia.*

Background: Renal mononuclear phagocytes (rMP), conventionally comprising macrophages and dendritic cells, play a central role in health and disease of the kidney. However, the classification and functions of rMP remain unclear.

Methods: Multiple markers (MHC-II, CD11c, F4/80, CD103, CD11b) were used to identify four subsets of rMP in kidney of normal BALB/c mice and mice with Adriamycin nephrosis (AN). The distribution, phenotype and function of subsets of rMP were assessed in normal and AN mice. Adoptive transfer of four subsets of rMP was used to assess their *in vivo* functions.

Results: rMP subsets: F4/80+CD11c- (rMP1), F4/80+CD11c- (rMP2), CD11c+CD103+ (rMP3) and CD11c+CD103- (rMP4) accounted for more than 90% of rMP in normal and AN kidneys. rMP1 were found in cortex and medulla of normal and AN kidney, while rMP2, 3 and 4 were confined predominantly to cortex. rMP1 and rMP2 showed high expression of macrophage markers CD68, CD204 and CD206, and high phagocytotic ability. However, rMP3 and rMP4 displayed lower phagocytotic ability but greater antigen presenting ability than rMP1 and rMP2. In AN, rMP1 and rMP2 displayed a typical phenotype of M1 macrophages with high expression of iNOS, IL-1beta, IL-6, TNF-α and MCP-1. rMP2 were different from rMP1 in their slightly higher expression of IL-10. rMP3 and rMP4 expressed IL-6 highly, but not iNOS, IL-1beta, TNF-α and MCP-1in AN mice. Adoptive transfer of rMP1 and rMP2 aggravated the renal injury in AN mice, whereas that of rMP3 and rMP4 had no effect on renal injury.

Conclusions: These four major subsets of rMP displayed distinct properties, including distribution, phenotype and *in vitro* and *in vivo* function, suggesting a distinct role for each in normal and diseased kidneys.

TH-PO290

Prophylactic Angiotensin II Receptor Antagonism Prevents Chronic Kidney Disease Induced by Acute Kidney Injury Roxana Rodriguez, Jonatan Barrera-Chimal, Rosalba Pérez-villalva, Gerardo Gamba, Norma Bobadilla. *Molecular Physiology Unit, Instituto de Investigaciones Biomédicas, UNAM and Instituto Nacional de Ciencias Médicas y Nutrición SZ, Mexico.*

Background: Acute Kidney Injury (AKI) is an important risk factor to develop Chronic Kidney Disease (CKD). Because angiotensin II (ANGII) has been proposed as a key mediator of renal injury and progression, this study was designed to determine if angiotensin I receptor (AT1R) blockade with losartan (L) before and after renal ischemia (I) may prevent or diminish the CKD development.

Methods: 27 rats were divided in: sham-operated (S), treated with L (50mg/kg) 72, 48 and 24h before S (L), underwent bilateral I for 45 min (I), receiving Lo before I (L+I) and receiving L 3 h after I (I+L) groups. All rats were followed throughout 270 days. Proteinuria (UProtV) and creatinine clearance (CrCl) were evaluated every 30 and 90 days, respectively. At the end of the study, renal blood flow (RBF), mean arterial pressure (MAP) was measured, as well as urinary Kim-1. Right kidney was used for IL6 mRNA levels and the left kidney for histopathological analysis. Glomerular diameter (GD) was measured and distributed by ranks.

Results: Rats underwent ischemia developed CKD characterized by a progressive increase in UProtV, together with a progressive decrease in CrC. The Table shows the results at the end of the study, no differences in MAP (data not shown).

Group (n=6)	**RBF** ml/min	**CrC** ml/min	**UProtV** mg/24h	**Kim-1** ng/24h	**GD >176µ** %	**IL6/18s**
S	8.3± 1.1	1.7 +0.1	32+7	27+9	8.5	1+0
L	8.3+0.6	2.2+0.2	25+6	28+4		1.3+0.7
I	6.5+0.9	0.9+0.2[a]	302+29[a]	78+12[a]	36.0	9.6+3.5[a]
L+I	8.9+1.3	1.9+0.1[b]	127+43[b]	24+10[b]	12.0	1.7+0.4[b]
I+L (n=3)	8.7+0.7	1.4+0.3	227+63	71+29	37.6	1.2+0.6

[a] $p < 0.05$ vs Sh, [b] $p < 0.05$ vs I

Conclusions: AT1R antagonism before ischemia slowed CKD progression, since no renal dysfunction, severe UProtV, glomerular hypertrophy, Kim-1 elevation or IL-6 over-expression were observed. In contrast, L administration post-ischemia was not able to prevent or to reduce CKD in spite of reduction of IL-6. These results suggest that ANGII plays an important role during ischemia, but do not play a significant role during reperfusion process.

This study was supported by CONACyT and PAPPIT.

TH-PO291

Induction of Neutral Calponin Expression Suppresses the Development of Interstitial Fibrosis in Both Kidneys and Heart in Old Mice Kiyoko Inui,[1] Yoshihiko Inoue,[1] Shigeki Iwasaki,[2] Ashio Yoshimura.[1] *[1]Nephrology, Showa University Fujigaoka Hospital, Yokohama, Kanagawa, Japan; [2]Nephrology, Seirei Yokohama Hospital, Yokohama, Kanagawa, Japan.*

Background: Onset of CVD is a serious problem in CKD patients. Demonstration of a common factor participating in both kidneys and heart injury may provide a new way to treat CKD. Therfore we studied the effect of neutral calponin (Ncal) overexpression on the interstitial injury of both kidneys and heart because Ncal showed anti-fibrotic property in UUO model mice.

Methods: Both kidneys and heart from Ncal transgenic mice (Ncal-Tg, n=4) or wild type mice (WT, n=4) were studied histologically. All of them were 20-26 months old. Ncal overexpression was induced by cadmium sulfate treatment (0.5mg/kg/day), that was started from six months old and continued to sacrifice (7-10 days/month). Immunohistochemistry for interstitial proliferaing cells (ki-67), macrophages (F4/80), collagen I and TGF-βwas performed for all kidney tissues. Fibrosis of heart was studied by Masson-Trichrom staining. All data (number for positive cells or staining score) were evaluated by computer-analysis system and were expressed as mean±SE.

Results: There was no significant difference in the weight of kidneys (weight(g) / body weight(g) x100, 0.79±0.04 in Ncal-Tg, vs 0.72±0.06 in WT) and heart (g/body weight(g) x 100, 0.22 0.03 vs 0.18 0.02). Interstitial macrophages infiltration (F4/80+ cells/high power field, hpf) was significantly suppressed in Ncal-Tg (15.9±4.4 vs 32.8±1.6 in WT, $p<0.05$), however there was no difference in the number of proliferating cells (ki-67+ cells/hpf) (22.8±4.3 in Ncal-Tg, vs 25.5±2.0 in WT). Staining score for collagen I was reduced in Ncal-Tg than WT (1.22±0.02 vs 1.43±0.05, $p<0.05$). There was no difference in TGF-β staining in kidneys. Masson-Trichrom staining showed interstitial fibrosis of heart was signicantly suppressed in Ncal-Tg (0.079±0.013 vs 0.104±0.004 in WT, $p<0.05$).

Conclusions: Intersittial inflammation and development of fibrosis were suppresed in Ncal- Tg than in WT. Fibrosis was also suppreed in heart in Ncal-Tg compared to WT. Thus, the induction of Ncal is expected as one of the therapeutic strategy for CVD in old CKD patients.

TH-PO292

Nephrogenic Systemic Fibrosis (NSF) and ASARM Induced Release of Gadolinium from Gd3+-Binding Contrast Agents Peter S.N. Rowe,[1] Lesya Zelenchuk,[1] Tarak Srivastava,[2] Ellen T. McCarthy.[1] *[1]Kidney Institute, University of Kansas Medical Center; [2]Childrens Mercy Hospital Kansas.*

Background: Gadolinium binding contrast agents (GBCAs) are used for high contrast magnetic resonance imaging (MRI). Subsets of chronic kidney disease (CKD) patients exposed to GBCAs develop NSF, a progressive disease with multiple organ failure and death. Release of toxic Gd3+ from GBCAs likely plays a role but the etiology of release is unknown. Our previous work showed circulating ASARM-peptides bind to GBCAs. These bone-derived peptides are linked with renal-handling defects and bone-mineralization abnormalities. We hypothesize increased levels of acidic ASARM-peptides also induce release of Gd3+ resulting in NSF pathology.

Methods: To test our hypothesis, we used Liquid Chromatography and Inductively-Coupled Mass-Spectrometry to measure release of Gd3+ from Gadodiamide. We also used a 4.2kDa synthetic peptide (SPR4) that binds specifically to ASARM-peptide to inhibit ASARM-mediated release of Gd3+. A murine model (HYP) with markedly increased circulating ASARM-peptides, mineralization and renal phosphate handling defects was used to measure the effects of GBCAs in the presence and absence of SPR4 peptides *in vivo*.

Results: ASARM induced a 30% increase in free to bound Gd3+ and co-incubation with SPR4 blocked release of Gd3+. GBCA treated HYP mice became normophosphatemic and hypercalcemic with increased renal Na+-phosphate-cotransporters (NPT2a/c) mRNA expression. Also, computed tomography (μCT) showed renal and dermal metastatic calcifications and bone defects in GBCA treated HYP mice. SPR4-peptide inhibited the ASARM-induced changes in tissue, bone and circulation.

Conclusions: In summary: 1. ASARM peptides induce release of toxic Gd3+; 2. SPR4 binds to ASARM and inhibits GD3+ release; 3. co-treatment with SPR4 prevents GBCA induced pathology in HYP mice. In conclusion, ASARM-peptides play a key etiological role in NSF and SPR4-peptide is an ideal candidate adjuvant. These findings have clinical implications for GBCA use in inherited or acquired renal bone-mineral loss disorders with increased circulating ASARM-peptides.

Omniscan-Induced CD163$^+$ Ferroportin$^+$ Osteogenic Cells in Nephrogenic Systemic Fibrosis Sundararaman Swaminathan,[1] Chhanda X. Bose,[1] Sudhir V. Shah,[1] Kim M. Hiatt.[2] *[1]Division of Nephrology, University of Arkansas for Medical Sciences and Central Arkansas VA Health System, Little Rock, AR; [2]Division of Dermatology and Pathology, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Gadolinium contrast is linked to nephrogenic systemic fibrosis (NSF) in patients with renal insufficiency. Its pathology is characterized by abnormal tissue repair—fibrosis and ectopic ossification. The mechanisms by which gadolinium could induce fibrosis and ossification are not known.

Methods: We examined *in vitro* the effect of gadolinium contrast (OmniscanTM) on human peripheral blood mononuclear cells (PBMC) for phenotype and function relevant to the pathology of NSF utilizing immunoflourescence, flow cytometry, RT-PCR, and osteogenic assays. We also examined peripheral blood and tissues of NSF patients with flow cytometry and immunohistochemistry to identify the presence of cells with phenotype induced gadolinium.

Results: Gadolinium contrast induced differentiation of human PBMC into an unique cellular phenotype- CD163$^+$ cells expressing proteins involved in fibrosis and bone formation. These cells express fibroblast growth factor 23, osteoblast transcription factors Runx2 and osterix, and exhibit an osteogenic phenotype in in vitro assays. We demonstrate the in vivo presence of CD163$^+$/procollagen-1$^+$/osteocalcin$^+$ cells in the fibrotic and calcified tissues of NSF patients. We also demonstrate increased circulating CD163$^+$/Runx2$^+$/osteocalcin$^+$/procollagen-1$^+$ cells with an osteogenic phenotype in patients with NSF.

Conclusions: Gadolinium contrast-induced CD163$^+$ ferroportin$^+$ FGF23$^+$ cells with osteogenic potential may play a role in systemic fibrosis and ectopic ossification in NSF.

Three-Dimensional Visualization of Vasculo-Glomerular Alterations with Progression of Chronic Kidney Disease Noriko Uesugi,[1] Takaaki Aoba,[2] Yoshihito Shimazu,[2] Michio Nagata.[1] *[1]Pathology, Tsukuba University, Tsukuba, Ibaragi, Japan; [2]Pathology, Nippon Dental University, Chiyoda, Tokyo, Japan.*

Background: Impairment of intrarenal microvessels promotes chronic kidney disease(CKD). In order to visualize progression of vascular damages and glomerulosclerosis in CKD, we developed high-resolution three-dimensional(3D) tissue reconstruction that enables to inspect a wide-range vasculo-glomerular architecture in human kidney.

Methods: Paraffin embedded specimens were obtained from non-tumor parts of renal carcinoma of four Japanese male (72-78 y.o, with CKD stage 2-3 without proteinuria). Serially-cut 300 sections (3.5um thick) were processed for dual-immunostaining of CD34 and smooth muscle actin(SMA). The images were digitized by whole-slide imaging system (virtual slide). The 3D reconstructions were conducted by computer-assisted image registration and color segmentation using Image J and TRI-SRF2 software.

Results: The 3D image enabled to visualize the intricate vascular network of interlobular arteries/arterioles and glomeruli (Figure) to inspect the details of impaired vascular architecture at discrete stages of CKD. The 3D visualization showed that the regular run and branching of arteries and elliptic -shaped glomeruli were featured in CKD stage 2, while the tortuous run of arteries in CKD stage 3 without hypertension (HT) nor cardiovascular disease (CVD). Of particular interest was the decreased vasculature, the irregular vascular branching, the expanded glomerular SMA- positive area and the anomalous development of extra-afferent and efferent arteriolesin CKD stage 3 with HT or CVD.

Conclusions: High-resolution 3D reconstructions in combination with dual immunolabeling and whole-slide imaging significantly expand our scope to diagnose changes in vascular-glomerulus system with CKD.

TH-PO295

Volume Status and Cardiac Autonomic Neuropathy Were Associated with Progressive Kidney Disease in Chronic Kidney Disease Patients Min Ji Shin, Sang Heon Song, Eun Young Seong, Harin Rhee, Ihm Soo Kwak, Byeong Yun Yang. *Department of Internal Medicine, Pusan National University School of Medicine, Busan, Republic of Korea.*

Background: We investigated the relationship between volume status, cardiac autonomic neuropathy(CAN) and atherosclerosis in predialysis chronic kidney disease(CKD) patients. In addition, we analyzed whether these parameters can predict deterioration of renal function in those patients.

Methods: 54 predialysis CKD patients were enrolled. Volume status was determined by extracellular water(ECW)/total body water(TBW) by bioimpedance analysis. Measurement of brachial-ankle pulse wave velocity(baPWV) was used to assess the vascular stiffness. Intima-media thickness of carotid artery and carotid plaque were measured for assessment of atherosclerosis. CAN was assessed by the Ewing's method and the standard deviation of the normal-to-normal interval(SDNN). The slope of monthly reduction of reciprocal serum creatinine was measured to assess the deterioration of renal function.

Results: 24(44.4%) had CAN. Compared to the patients without CAN, patients with CAN had higher systolic blood pressure(SBP), C-reactive protein(CRP), ECW/TBW, baPWV and lower hemoglobin and SDNN. Patients with edema(ECW/TBW ratio≥0.39) were older and had higher SBP,CRP,HbA1C,CAN score,baPWV than patients without edema. ECW/TBW was positively correlated with CAN score(r=0.450,p=0.001),baPWV (r=0.569,p<0.001) and negatively correlated with SDNN(r=-0.376,p=0.005). CAN score was positively correlated with baPWV(r=0.578,p<0.001) and negatively correlated with SDNN(r=-0.347,p=0.01). In univariate linear regression analysis,SBP,CAN score,ECW/TBW,baPWV,CRP,hemoglobin,albumin,proteinuria were significantly associated with the declining rate of kidney function. In multivariate regression analysis, the declining rate of kidney function was found to associate with CAN score,ECW/TBW and proteinuria.

Conclusions: We found the correlationship among edema, vascular stiffness and cardiac autonomic neuropathy in CKD patients and those variables were related with inflammatory status. Apart from classic risk factors, elevated ECW/TBW and CAN were associated with deterioration of renal function in CKD patients.

TH-PO296

Association of Serum Fibrinogen with Mortality among Subjects with Normal and Reduced Kidney Function in the General Population Urszula Donigiewicz,[1] Ahad Abdalla,[2] Liam F. Casserly,[2] Cornelius John Cronin,[2] Ailish Hannigan,[3] Hoang Thanh Nguyen,[3] Austin G. Stack.[2,3] *[1]Medicine, National University of Ireland Galway, Ireland; [2]Department of Nephrology, Department of Medicine, University Hospital Limerick, Ireland; [3]Department of Medicine, Graduate Entry Medical School, University of Limerick, Ireland.*

Background: It is postulated that novel risk factors contribute to cardiovascular (CV) risk in chronic kidney disease. We explored the association of serum fibrinogen, a thrombotic factor, with total and CV mortality in the setting of reduced kidney function in a population-based cohort.

Methods: A cohort of 8,494 subjects age >40 were identified from the Third National Health and Nutrition Examination Survey (1988-1994) and vital status was obtained through linkage with the National Death Index. Serum fibrinogen levels (mg/dL) were compared across categories of estimated glomerular filtration rate (eGFR) (<60, 60-90, >90 mL/min). Weighted multivariable Cox regression modelled relationships of fibrinogen in quartiles (Q1; 0-261 [referent], Q2; 261-305, Q3; 305-356, Q4 >356 mg/dL) with total and CV mortality.

Results: Mean (±standard error [SE]) fibrinogen levels were inversely correlated with eGFR at 298 (2.9), 305 (2.8) and 352 (6.3) in each lower GFR category. With 10 years of follow-up, total mortality was 17.1 % of which 8.0 % were cardiac. In the unadjusted analyses, the hazard ratios (HR) per 10 mg/dL increase in fibrinogen were 1.03 (95% CI 1.02-1.04) and each increasing quartile of fibrinogen was associated with total and CV mortality [HR=1.00, 1.36 (1.02-1.82), 1.94 (1.54-2.44), 3.78 (3.05-4.68). Adjusting for Framingham factors and eGFR, the relationships were attenuated but remained significant with all-cause [HR=1.00; 1.08 (0.89-1.31), 1.44 (1.20-1.72) and 1.68 (1.32-2.14)] and CV mortality [(HR1.00, 1.18 (0.88-1.59), 1.43 (1.08-1.91) and 1.89 (1.50-2.38) respectively. Further stratification by GFR category yielded virtually identical mortality estimates.

Conclusions: Serum fibrinogen levels are higher among individuals with kidney impairment than those with normal kidney function and contribute independently to increased total and CV mortality.

Renal Biopsy in Elderly Patients: Indication, Diagnosis, Safety and Clinical Use George Greenhall, Chris Jones, Sapna Shah, Satish Jayawardene. *Department of Renal Medicine, King's College Hospital, London, United Kingdom.*

Background: The incidence of renal failure is rising as the elderly population increases. Age is no longer considered a contra-indication to renal biopsy or subsequent treatment. Biopsy has been shown to yield treatable diagnoses in up to 70% of elderly patients.

Methods: We retrospectively examined the indications, complications and outcomes of native renal biopsies in patients aged over 70 years in our tertiary referral unit, between 2005-2010. Data were collected from laboratory reports and clinical notes.

Results: 61 patients were included (51% male, mean age 77.5 years (70-94)). 31% had existing CKD; 18% were diabetic. Primary indications and diagnoses are shown in Table 1. One patient suffered a large peri-nephric haematoma, requiring embolization. Histological findings resulted in a change in the management of 67% of patients. Management alterations comprised: commencing immunosuppression (68%), chemotherapy (20%), ceasing immunosuppression (12%), antibiotics (5%), and plasma exchange (5%). At biopsy, 31% required RRT. Six months after biopsy, 22% required RRT and 7% had died. One year after biopsy, 16% required RRT and 14% had died. Absence of pre-existing CKD was positively associated with a change in management following biopsy (p=0.02).

Conclusions: Biopsy in our elderly population is safe, and yields clinically useful findings.

TH-PO298

Glomerular Volume and Density Associate with Risk Factors among Living Kidney Donors Hisham Elsherbiny, Lynn D. Cornell, Walter Park, Joseph Larson, Lilach O. Lerman, Mikel Prieto, John C. Lieske, Andrew D. Rule. *Mayo Clinic.*

Background: Glomerular hypertension is a characteristic of early kidney injury. In animal models, consequent glomerular and tubular hypertrophy and hyperplasia increases nephron size, which in turn decreases the density of glomeruli per unit cortex. We hypothesized that measures of increased nephron size would relate to chronic kidney disease (CKD) risk factors among relatively healthy adults.

Methods: Living kidney donors had a core needle biopsy of their donated kidney during the transplant surgery at Mayo Clinic Rochester from 2000 to 2009. Two adjacent 3 um thick sections of the biopsy were stained with periodic acid-Schiff and Masson's trichrome and scanned into high resolution images. The areas of cortex and mean glomerular cross-sections were measured. Mean glomerular volume (mm^3) and volumetric glomerular density (mm^{-3}) were estimated using stereological models (Weibel and Gomez), and regressed on kidney function and CKD risk factors ascertained just prior to donation. Multivariable (MV) models identified independent predictors.

Results: The 996 studied donors were 42% men, 6% hypertensive, and 57% with family history of end-stage renal disease (ESRD); age range: 18-77 years; mean±SD measure glomerular filtration rate (GFR): 103±18 ml/min/1.73 m^2, 24-h urine albumin (UAlb): 6±10 mg, body mass index (BMI): 28±5, and serum uric acid: 5.2±1.4. Glomerular volume was 0.0026±0.0010 mm^3 and density was 16±7 per mm^3. Glomerular volume correlated with glomerular density (r_s=-0.63, p<0.001) and both associated with CKD risk factors (table).

Glomerular volume and density regression on donor characteristics

	Glom. Volume		Glom. Density	
Predictor	Unadj. ß	MV-adj. ß	Unadj. ß	MV-adj. ß
Male	.00033*	.00010	-1.7*	-.56
Age per 10 y	-.00002	.00000	-.12	-.25
Family history of ESRD	.00021*	.00017*	-1.03*	-1.05*
GFR per SD	.00004	.00006	.10	-.07
Log 24-h UAlb per SD	.00011*	.00006	-.78*	-.49
BMI per SD	.00110*	.00024*	-1.83*	-1.61*
Uric acid per SD	.00024*	.00013*	-1.43*	-.82*
Hypertension	.00027*	.00015	-.83	.30

*p<.05

Conclusions: In a relatively healthy population, family history of ESRD, obesity, and hyperuricemia are independent predictors of morphological changes on renal biopsy indicative of increased nephron size.

TH-PO299

Increased Kidney Cortical Volume: A Potential Marker of Early Chronic Kidney Disease Xiangling Wang, Ramesh Avula, Walter K. Kremers, Harini A. Chakkera, Terri J. Vrtiska, Lilach O. Lerman, Andrew D. Rule. *Mayo Clinic.*

Background: The kidney cortex is known to atrophy in patients with advanced chronic kidney disease (CKD), however the determinants of cortical volume in normal adults are less clear. We aimed to determine whether cortex volume is reflective of kidney function or CKD risk factors among relatively healthy adults.

Methods: Kidney cortical volume was measured on contrast-enhanced abdominal CT images in 878 potential kidney donors between 2001 and 2008. Cortex volumes were summed between both kidneys. Glomerular filtration rate (GFR) was measured by iothalamate clearance. Cortex volumes were correlated with age, sex, body surface area (BSA), GFR, 24-h urine albumin, and CKD risk factors. Multivariable regression was used to determine independent predictors.

Results: There were 878 potential donors (59% female; 22% smokers; ages range 18 to 75 years; BSA 2.0±0.2 m^2, GFR 117±28 ml/min, urine albumin 8.1±21.8 mg/24 h). Men had larger cortex volumes than women (241 vs. 195 cc; p<0.01). Cortex volume correlated with BSA (r=0.60, p<0.01), age (r=-0.3, p<0.01), GFR (r=0.72, p=<0.01), systolic blood pressure (r=0.07, p<0.01), serum uric acid (r=0.3, p<0.01), HDL cholesterol (r=-0.37, p<0.01), glucose (r=0.15, p<0.01) and urine albumin excretion (r =0.1, p<0.01). Smokers had a cortex that was 18cc larger than nonsmokers (p<0.01). Only male gender, BSA, GFR, urine albumin excretion, and smoking, were independent predictors.

Multivariable predictors of kidney cortical volume (r2=0.64)

Predictor	Beta (change in cc)	P-value
Age per 10 y	-0.48	0.61
Female	-10.6	<0.0001
Smoker	+6.6	<0.0001
BSA per SD	+8.2	<0.0001
24-h urine albumin per doubling	+1.88	0.002
Uncorrected GFR per SD	+22.9	<0.0001
Systolic BP per SD	-0.51	0.67
Diastolic BP per SD	-0.40	0.73
Serum glucose per SD	+0.95	0.37
Serum uric acid per SD	-0.92	0.44
HDL cholesterol per SD	-1.3	0.22

Kidney cortex was 46 cc larger among the 7.8% of donors with a corrected GFR > 130ml/min/1.73m^2 (p<0.01) and 20 cc larger among the 3.7% of donors with a urine albumin excretion > 30 mg/24 h (p<0.01).

Conclusions: In a relatively healthy population, increased cortical volume associates with hyperfiltration and albuminuria and may be an indicator of early CKD.

Malignancies after ANCA-Associated Vasculitis: A Large Single Centre Experience Chinar Rahmattulla,[1] Arda Goceroglu,[1] Marlies E.J. Reinders,[2] Ernst C. Hagen,[3] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden University Medical Center, Netherlands; [2]Nephrology, Leiden University Medical Center, Netherlands; [3]Internal Medicine, Meander Medical Center Amersfoort, Netherlands.*

Background: Recent studies indicate that patients with ANCA-associated vasculitis (AAV) have a significantly higher risk of developing malignancies, that the mortality in AAV patients is 2.6 times higher than that of the general population, and that malignancies are the second cause of death after the first year of diagnosis. Drawbacks from these studies are a relatively short follow-up, and possibly, under-reportage due to lack of access to registries.

Methods: We investigated the occurrence of malignancies in 187 histologically confirmed AAV patients after diagnosis at our center between 1982 and 2011 by performing a search in PALGA, a Dutch national pathology database which covers all the histologically confirmed malignancies diagnosed in The Netherlands.

Results: 136 patients with AAV had a follow-up of at least 1 year; 46 of those developed 93 malignancies during a mean follow-up of 12.3 years. There were 64 skin malignancies, including 63 non-melanoma skin cancers (NMSC). There were 13 multiply occurring malignancies: 4 of the bladder, 4 of the prostate, 3 of colon/rectum and 2 of the lung. There was a variety of one time occurring malignancies. The mean age of AAV patients developing a malignancy was similar to patients without a malignancy (58 years).

Conclusions: This study on the development of malignancies after AAV from a large single center experience shows a higher incidence of malignancies in AAV patients than was recently reported for a European study group. One explanation for this discrepancy could be the accurate data reporting through the Dutch PALGA system by which virtually no malignancy could have been missed. In our study there was no significant age difference between patients with and without malignancies. Notably, there was a high number of NMSCs in our study group which is most likely related to the immunosuppressive therapy these patients receive. In the management and treatment of patients with AAV, it is of major importance to monitor closely for developing malignancies.

TH-PO301

How Does Quality of Life Vary over a Six Month Period in High Risk CKD? Stephanie J. Stringer,[1,2] Mary Dutton,[2] Chantelle Waite,[2] Mark David Jesky,[1,2] Paul Cockwell.[1,2] *[1]Immunity and Infection, University of Birmingham, Birmingham, United Kingdom; [2]Nephrology, QEHB, Birmingham, United Kingdom.*

Background: The EQ5D questionnaire is used to assess quality of life and to formulate quality adjusted life years. The degree of interpatient variation in the absence of intervention is important. There has been little work in this area in the CKD population where patients often have reduced QoL and significant co-morbidity.

Methods: Patients recruited to the Renal Impairment In Secondary Care (RIISC) study undergo assessment at six study visits over a ten year period, assessment of quality of life using the EQ5D is performed at each visit. The EQ5D contains five domains relating to mobility, self care, usual activities, pain and anxiety or depression and a visual analogue scale from 0-100 (0 being the worst perceived health and 100 being the best).

Results: 165 patients have been assessed at baseline and six months, the mean age is 62 (+/-16) years, 70% were white. The majority of patients' scores in the five domains did not change between baseline and six months (78% in mobility, 82% in self care, 67% in usual activities, 65% in pain/discomfort and 75% in anxiety/depression). The baseline median visual analogue score was 60.1 (+/-21.5), the six month mean score was 65.4 (+/-19.5). 62% of patients' six month visual analogue scale score was within 25% of their baseline score, 11% had a six month score that was >25% lower than the baseline score and 27% had a >25% higher score at six months.

Conclusions: We report little interpatient variation in self reported quality of life using the EQ5D instrument in a structured interview. Scores in both the five domains and the visual analogue scale were comparable between visits over this short time period; this was confirmed when both the mean scores of the cohort and the scores obtained by individuals were compared at the two visits. These results suggest that the EQ5D instrument has acceptable degrees of interpatient variability in patients with CKD when administered in a structured interview.

TH-PO302

Quality of Life (QoL) and Functional Status Are Maintained a Cohort of Patients with Progressive Chronic Kidney Disease Despite Significant Co-Morbidity Stephanie J. Stringer,[1,2] Mary Dutton,[2] Chantelle Waite,[2] Mark David Jesky,[1,2] Khai Ping Ng,[1,2] Paul Cockwell.[1,2] *[1]School of Immunity and Infection, University of Birmingham, Birmingham, United Kingdom; [2]Department of Nephrology, University Hospital Birmingham, Birmingham, United Kingdom.*

Background: Impaired quality of life (QoL) and functional status has been described in patients with End stage Kidney Disease but there has been little evaluation of QoL in progressive Chronic Kidney Disease despite that fact that these patients may have significant co-morbidity. We assessed the relationship between QoL and functional status in a prospective cohort of patients with progressive CKD recruited to the Renal impairment In Secondary Care (RIISC) study.

Methods: Patients recruited to the RIISC study undergo a detailed bio-clinical, and socio-economic status (SES) assessment. QoL is ascertained using the EQ5D questionnaire and a visual analogue scale where patients rate their health from 0 (the worst) to 100 (the best).Co-morbidities are scored using the Charlson index.

Results: 277 individuals had been recruited at the time of this analysis, the mean age was 62.7 (+/- 16.7), 58% were male and 69% were of white ethnicity. 20% were in current employment, 30% were unemployed and 48% were retired from employment. 47%, 87% and 52% reported no problems with mobility, self care and usual activities. 52% reported no regular pain or discomfort and 30% reported feelings of anxiety or depression. The mean score on the visual analogue scale was 59.5(+/-21.3). By univariate analysis increasing age**, decreasing eGFR*, educational attainment** and increasing co-morbidity** were associated with lower scores (** p<0.01, *p<0.05); in a multivariate analysis only co-morbidity was associated with lower scores (p= 0.001). Both educational attainment and co-morbidity were associated with poorer functioning (p = 0.009 and p = 0.001 respectively).

Conclusions: In patients with progressive and high risk CKD, co-morbidity was an important determinant of QoL and reported functional status. Employment status, educational attainment and deprivation were not associated with QoL; however patients with lower educational attainment and more co-morbidity did have lower functional scores.

TH-PO303

The Value of Questionnaire Investigation in Recognition of SAS in HD Patients Ilona Miskowiec-wisniewska,[1,2] Rafal Donderski,[1] Jacek Manitius,[1] Jacek Klaew.[2] *[1]Dept. of Nephrology, Hypertension and Internal Disease, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University of Torun, Bydgoszcz, Poland; [2]Dept of Hygiene and Epidemiology, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University of Torun, Bydgoszcz, Poland.*

Background: The prevalence of sleep disorders in CKD is much higher than in general population and such disturbances are detected in almost 50% of pts. The clinical consequences of sleep disorders is increased cardiovascular morbidity and mortality related to higher incidence of HA, LVH,CAD, ventricular arrhythmias and strokes.

Methods: We evaluated 61 HD pts (24F,37M),age 58,2±12,2 y, mean dry weight: 68,16±13,57kg, mean dialysis duration: 73,49±55,33months. In each patients 3 HD a week were performed. HD session time was:4,43±0,43 hours. Epworth Sleepiness Scale (ESS) was used to assess severity of sleep disorders. The patients were asked 22 questions concerning :symptoms of sleep disorders, EDS, insomnia, snoring, narcolepsy,drug administration and others. In 17 male pts complete PSG evaluation was performed.

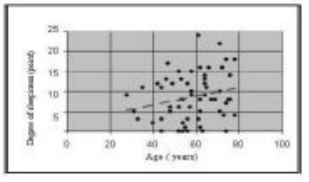
Results:

The comparison of questionnaire investigation and PSG in assessment of severity of sleep disorders.

Patient status	According to Index RDI TST*			According to questionnaire investigation		
	Characteristics	*n*	%	Characteristics	*n*	%
Healthy	AHI<5	2	11.8	up to 50 pt	14	82.4
Mild apnea	5≤AHI<15	6	35.3	51-52 pt	0	0.0
Intermediate apnea	15≤AHI<30	4	23.5	53-58 pt	3	17.6
Severe apnea	AHI≥30	5	29.4	over 58 pt	0	0.0
total:		17	100		17	100

RDI TST* - Respiratory disorders index total sleep time.

		Sleepiness			
		Without sleepiness	intermediate	severe	Total number of pts
Gender	F	18	2	4	24
	M	17	13	7	37
Total number of pts.		35 (57,4%)	15 (24,6%)	11 (18%)	61 (100%)
Test χ^2 (χ^2_{kr}=5.99)	χ^2	6.43			
	p	<0.05			



The correlation table of relationship between degree of daytime sleepiness and gender.

According to questionnaire investigation assessment there were 82,4% of healthy pts in compare to Index RDI TST assessement while we found only 11,8% of healthy subjects (u=4,59>1.96=$u$kr, p<0.0001). There is no correlation between questionnaire investigation and PSG assessment.

Conclusions: Questionnaire investigation may be valuable in preliminary assessment of sleep disorders. PSG is the best test to confirm sleep disorders. Both male gender and elderly age contribute to EDS in HD patients.

TH-PO304

Polysomnography Sleep Parameters in Children, Adolescents and Young Adults with and without Chronic Kidney Disease Ritu K. Soni,[1] Maria-Eleni Roumelioti,[2] Jonathan Yabes,[1] Mark L. Unruh.[1] *[1]Renal-Electrolyte Division, University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Nefroiatriki Dialysis Unit, Athens, Greece.*

Background: There are only limited studies examining sleep disorders in the pediatric and adolescent chronic kidney disease (CKD) population despite their vulnerability to the negative impacts of these disorders. This is the first study using polysomnography (PSG) to evaluate sleep disorders in pediatric and adolescent CKD patients.

Methods: 11 patients with advanced CKD (estimated glomerular filtration rate <30 mL/min/1.73 m^2) or dialysis-dependent end stage renal disease were compared with 26 healthy controls. In-home PSG was performed for objective sleep assessment.

Results: The CKD group had significantly higher mean systolic and diastolic blood pressure. CKD patients were more likely than the non-CKD participants to have higher sleep latency and lower sleep efficiency but the differences did not reach statistical significance. Sleep apnea was significantly more frequent in the CKD group.

Baseline Characteristics and PSG Results

Variable	CKD Patients (N=11)	Controls (N=26)	*P*
Age (y)	18.0 ± 5.75	15.7 ± 3.88	0.122
Male	5 (45.5)	11 (42.3)	1.000
White	7 (63.6)	20 (76.9)	0.442
Body Mass Index (kg/m^2)	22.2 ± 6.39	21.8 ± 4.69	0.769
Systolic blood pressure (mmHg)	130.9 ± 31.52	113.7 ± 10.41	0.064
Diastolic blood pressure (mmHg)	86.3 ± 18.75	72.0 ± 14.16	0.043
Total Sleep time (min)	400.3 ± 146.85	384.9 ± 110.92	0.455
Sleep latency (min)	35.9 ± 32.2	30.2 ± 34.78	0.803
Sleep efficiency (%)	76.7 ± 15.5	80.4 ± 17.18	0.435
Stage 1 (%)	5.5 ± 3.61	3.6 ± 2.99	0.189
Stage 2 (%)	48.1 ± 11.91	48.4 ± 8.88	0.987
REM (%)	29.6 ± 17.23	27.9 ± 11.12	0.934
Apnea-hypopnea index	3.8 ± 4.14	0.9 ± 0.84	0.070
Periodic limb movement index	3.2 ± 1.98	5.4 ± 3.08	0.038
Apnea-hypopnea index >5	3 (27.3)	0 (0)	0.021

Note: Values expressed as mean ± SD or number (%).

Conclusions: This study demonstrates that sleep architecture was preserved in the CKD population. There was evidence for more sleep apnea in the CKD patients but larger studies are needed to define the magnitude of the associations between sleep disorders and CKD.

Neuropsychological Profile of Children and Young Adults with Moderate to Severe Chronic Kidney Disease Divya Moodalbail,[1] Jerilynn Radcliffe,[1] Abbas F. Jawad,[1] Kathryn Reiser,[1] Susan L. Furth,[1,3] Stephen R. Hooper.[2] *[1]Pediatrics, Children's Hospital of Philadelphia; [2]Psychiatry, University of North Carolina School of Medicine; [3]Epidemiology, University of Pennsylvania.*

Background: Few studies have examined the neuropsychological profile of children and young adults with moderate to severe chronic kidney disease (CKD).

Methods: Cross sectional observational study comprising 18 children and young adults with CKD (eGFR below 60 ml/min/1.73m2), ages 8 to 25 years. Demographics and neurocognitive data from the administration of a broad based neuropsychological test battery (including WASI Vocabulary, WASI Similarities, WASI Block Design, WASI Matrix Reasoning, Wechsler Memory Scales-III, WISC-IV Digit Span, Continuous Performance Test-II, and Delis-Kaplan Executive Function Scales) were collected at study visit. We evaluated multiple types of skills within the language, attention, and executive functioning domains in CKD subjects with reference to age based norms. Mean z-scores were computed for each domain. These means were based on results from all measures included within each domain of interest.

Results: Median age was 15 years (range 14 - 17.5 years) and median eGFR was 32 ml/min/1.73m2. The sample included 76% male and 81% Caucasian subjects. About 29%(6) had transplant, and 5%(1) were on dialysis after a failed transplant. Mean z-scores and standard deviations were reported for each functional domain. Overall, weakest performance was shown in the areas of attention (-0.48), verbal memory (-0.44), set shifting (-0.28), and visuo-spatial skills (-0.42). In contrast, language (-0.08), and inhibitory control (-0.05) were relatively stronger.

Conclusions: Neuropsychological findings indicate relative weaknesses in attention, verbal memory, visuo-spatial skills and set shifting, with near-normal performance in language and inhibitory control. However, wide variability in functioning was found within each domain. Ongoing recruitment of 90 CKD subjects and 90 controls and simultaneous evaluation of structural and functional brain imaging will further assess the presence of these deficits and structure/function correlations.

Funding: Other U.S. Government Support

TH-PO306

Carotid-Intima-Media Thickness in Children with Chronic Kidney Disease: Lack of Association with Markers of Oxidative Stress and Inflammation Antonio García-Bello, Rita A. Gómez-díaz, Alicia Contreras, Margarita Díaz-flores, Daniel Hernandez, Juan Manuel Gallardo, Rafael Mondragon, Adan Valladares, Lorena Sanchez, Juan Talavera, Niels Wacher, Alejandra Aguilar, Jesus Lagunas. *Instituto Mexicano del Seguro Social.*

Background: Non-traditional cardiovascular risk factors have been implicated in the pathogenesis of atherosclerosis in CKD. The aim of this study was to evaluate the relationshipbetween markers of oxidative stress, inflammation and carotid artery intima-media thickness (cIMT) and vascular calcifications in children.

Methods: The study included 85 children aged 6-16 with CKD of unknown etiology without acute infectious disease. Variables included time with CKD, dialysis modality, anthropometric and biochemical parameters including intact molecule parathyroid hormone (iPTH), C-reactive protein (hsCRP), IL-1β, IL-6, TNFα, superoxide dismutase (SOD), reduced glutathione (GSH), malondialdehyde (MDA) and nitric oxide (NO). cIMT was measured according to American Heart Association 2009 recommendations. Statistical analysis: Lineal regression was done to identify the variables associated with cIMT. To value the effect of the potential cardiovascular risk factors on cIMT, logistic regression model was built.

Results: Of 85 children 49.6% were female; 17.6% had no dialysis, 30.6% were on hemodialysis and 51.8% on peritoneal dialysis (PD). Mean values were: age 13.1±2.4 years, evolution time 38.6±37.3 months, Hb 10.7±2.4 g/dL, cholesterol 170.1±47.3, TGL 155±72.6, HDL-C 40.0±12.4 mg/dL, iPTH 664 (33-5572) pg/mL, GSH 417.4±134.7 µM, hsCRP 0.91 mg/L (0.07-186.9), IL-6, 0.15 pg/mL (0.00-596.2), IL-1β 1.71 (0-709.7) pg/mL, TNFα 5.27 pg/mL (0-2544.3), MDA 1.75±1.0 nM, NO 51.4±23.4 µM. A significant correlation ($p<0.05$) was found between cIMT and CaxP product, NO and SOD. Logistic regression showed that only cholesterol and PD modality were associated with a cIMT over 0.614 mm (75 Pc). Adding inflammatory and oxidative stress markers to model showed no significant effect.

Conclusions: No association was found between markers of oxidative stress or inflammation and cIMT in CKD pediatric cases.

Restless Legs Syndrome in Pediatric Chronic Kidney Disease: Is Iron to Blame? Sandeep K. Riar,[1] Roberta Leu,[2] Donald L. Bliwise,[3] Laurence A. Greenbaum.[1] *[1]Pediatrics, Nephrology Division, Emory University and Children's Healthcare of Atlanta, Atlanta, GA; [2]Division of Pulmonology, Allergy, Cystic Fibrosis and Sleep Medicine, Emory University and Children's Healthcare of Atlanta, Atlanta, GA; [3]Neurology, Psychiatry and Behavioral Sciences, Emory University School of Medicine, Atlanta, GA.*

Background: Restless legs syndrome (RLS) can adversely affect sleep and is increased in chronic kidney disease (CKD) patients. Central nervous system iron deficiency is thought to be involved in RLS pathogenesis, with serum ferritin levels used to guide treatment. Children with CKD are at risk of iron deficiency, but are also in an inflammatory state, which affects both ferritin and transferrin saturation (TSAT) – standard measures of iron status. We studied the prevalence of RLS in children with CKD and compared serum ferritin and inflammatory status in those with and without RLS.

Methods: Cross-sectional study of RLS in CKD patients (non-transplant, non-dialysis [NT, ND] CKD patients with an estimated GFR < 60 mL/min/1.73 m2; renal transplant [Tx]; and dialysis patients). RLS was diagnosed using an NIH criteria based questionnaire. Serum ferritin <100 ng/mL or TSAT <20% defined iron deficiency. Serum high sensitivity C-reactive protein of ≥ 1 mg/L defined inflammation.

Results: Of 124 patients with CKD, 66 were Tx patients, 23 were on dialysis, and 35 were NT, ND. 15.3% of children with CKD had RLS. RLS prevalence was higher in patients *without* iron deficiency compared to those with iron deficiency (22.6% vs 12.5%, p= 0.15). Median ferritin levels were *higher* in RLS+ patients versus RLS- patients (51.2 vs 40.1 ng/mL; p= 0.08). CKD patients with inflammation had higher RLS rate than those without inflammation (21.6% vs 12.3%, p=0.18).

Conclusions: In pediatric CKD, iron deficiency is not associated with RLS. RLS subjects had higher ferritin values, contrary to non-CKD subjects with RLS. Inflammation may be responsible for this finding. This study suggests that the factors mediating pathogenesis of RLS in pediatric CKD are different from those known to increase risk in non-CKD populations. The role of inflammation in RLS in CKD deserves further study.

From Cultured Muscle Cells to Human Muscle Biopsies: Stat3 Inhibition Is a New Treatment for Muscle Wasting Jenny S. Pan,[1] Liping Zhang,[1] Giacomo Garibotto,[2] Yanlan Dong,[1] Yanjun Dong,[1] William E. Mitch.[1] *[1]Nephrology Division, Baylor College of Medicine, Houston, TX; [2]Nephrology Division, Genoa University, Genoa, Italy.*

Background: There is no effective therapy for the prevalent, costly and debilitating loss of muscle in chronic kidney disease (CKD) or other catabolic conditions. Epidemiologic evaluations implicate inflammatory cytokines (e.g., interleukin-6 (IL-6) and Tumor Necrosis Factor α (TNFα)) plus impaired insulin/IGF-1 signaling as mediators of muscle wasting. However, the molecular mechanisms that link inflammatory cytokines to impaired insulin/IGF-1 signaling and muscle wasting are unknown.

Methods: We examined biopsies of rectus abdominis muscles from CKD patients and control subjects. In C2C12 myotubes treated with a cytokine mixture (IL-6 plus TNFα) and mice with CKD (subtotal nephrectomy), we inhibited STAT3 with a small molecule inhibitor (C188-9).

Results: In muscle biopsies from CKD patients, levels of IL-6, TNFα and activated Stat3 (p-Stat3) were significantly increased. Stat3 activation was also increased in muscles of mice with CKD. To explore how Stat3 regulates the muscle wasting induced by CKD or other inflammatory conditions, we subjected mice to subtotal nephrectomy (CKD) and inhibited Stat3 with C188-9. Stat3 inhibition in CKD mice increased their body and muscle weights vs results from CKD mice treated with D5W (diluent). It also improved muscle metabolism and strength. To examine the pathway that accelerates muscle protein losses, we treated C2C12 myotubes with IL-6 and TNFα; Stat3 was activated at 15 minutes after exposure to IL-6/TNFα, followed by upregulation of Stat3 target genes SOCS3 at 30 minutes, C/EBPδ at 3 hours and myostatin at 24 hours. In cultured C2C12 myotubes or mice with CKD, Stat3 inhibition attenuated IL-6/TNFα and CKD-induced expression of SOCS3, C/EBPδ and myostatin. In muscle biopsies from CKD patients, increased expression of p-Stat3, C/EBPδ and myostatin confirmed activation of the pathway.

Conclusions: Inflammation stimulates muscle proteolysis by a pathway from Stat3 to C/EBPδ to myostatin. Inhibition of Stat3 is a therapeutic target for preventing muscle wasting.

Decreased Circulating Klotho Level Predicts Renal Outcome in Patients with Chronic Kidney Disease Seung Hyeok Han,[1] Dae-Suk Han,[1] Dong Ho Shin,[1] Mi Jung Lee,[1] Shin-Wook Kang,[1,2] Hye-young Kang,[2] Seong Hun Kim.[2] *[1]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea; [2]Severance Biomedical Science Institute, Brain Korea 21, Yonsei University, Seoul, Republic of Korea.*

Background: Klotho is mainly expressed in the renal distal tubules and exerts coreceptor function for FGF-23. It can also be released into the circulation and acts like a hormone that can have anti-oxidative and anti-senescence effects. However, it is unknown whether altered circulating klotho levels may predict renal outcome in patients with chronic kidney disease (CKD).

Methods: We conducted an observational cohort study in 243 subjects who were diagnosed as CKD between January 2006 and December 2011. Demographic and clinical data were reviewed based on medical records. We measured baseline serum concentrations of klotho and FGF-23 using enzyme-linked immunosorbent assay. Primary outcome was the composite of a doubling of the baseline serum creatinine levels and end-stage renal disease (ESRD).

Results: The mean age of the patients was 45.7 years and 52.7% were male. The mean eGFR and the median value of 24-hour urinary protein excretion were 52.2±34.7 ml/min/1.73m^2 and 1.5 (0.5-4.6) g/day, respectively. When patients were categorized into 2 groups according to the median serum klotho levels, 43 patients (35.2%) with α-klotho≤397 pg/ml reached the composite outcome of a doubling of the baseline serum creatinine and ESRD compared with 17 patients (14.0%) with α-klotho>397 pg/ml [hazard ratio (HR), 2.507; P=0.019]. Cox regression analysis revealed that α-klotho concentrations independently predicted the composite outcome after adjustment for age, gender, diabetes, blood pressure, eGFR, FGF-23, proteinuria, C-reactive protein, and parathyroid hormone (per 10 pg/ml increase; HR, 0.952; P<0.001).

Conclusions: Decreased circulating klotho levels may predict adverse renal outcome in patients with CKD.

TH-PO310

Serum Level of Soluble Secreted αKlotho Is a Novel Predictor for Renal Prognosis in CKD Patients Yoshiko Shimamura,[1] Kazu Hamada,[1] Koji Ogata,[1] Kosuke Inoue,[1] Toru Kagawa,[1] Masayuki Ishihara,[1] Kenji Yuasa,[2] Yoshio Terada.[1] *[1]Department of Endcrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Nankoku, Kochi, Japan; [2]Kochi-Takasu-Hospital, Kochi, Japan.*

Background: α-Klotho was first identified as an aging gene and was later shown to be a regulator of phosphate metabolism. We previously reported serum levels of soluble secreted α-Klotho in CKD patients relation with serum creatinine, age, hemoglobine, and log-FGF23 levels. Furthermore, we reported soluble secreted α-Klotho is a potential new biomarker for the diagnosis of CKD. This study was designed to investigate whether serum soluble αKlotho may become new predictor for prognosis of renal function in CKD patients.

Methods: We made a continuously survey of CKD patient characteristics and outcomes in Kochi prefecture (Western area of Japan) for 12 months. Patients of CKD (total N=395, Stage3-5: N=297) were enrolled. Serum sample were collected and measured soluble αKlotho by using an ELISA kits. In addition, serum creatinine, hemoglobin, albumin, calcium, phosphate and FGF23 were measured. This study was approved by Kochi Medical School review board. All patients provided written informed consent.

Results: During the study period of 12 months observation, estimated glomerular filtration rate (eGFR) was decreased (mean -5.10ml/min./1.73m^2 during 12 months) in 87 patients and eGFR was stable in 94 patients (CKD Stage3-5). We compared several parameters between the group of decreased eGFR and the group of stable eGFR. Interestingly, the levels of serum soluble α-Klotho were significantly lower in the group of decreased eGFR compared with stable eGFR group (p<0.05). The group of decreased eGFR was older (p<0.05), and also lower rate of the utilization of Angiotensin II receptor blocker (ARB) (p<0.05). In our study, serum FGF23 levels were not association with the change of eGFR during 12 months (p=0.19).

Conclusions: Our data indicate that soluble α-Klotho level is a novelpredictor for renal prognosis in CKD patients.

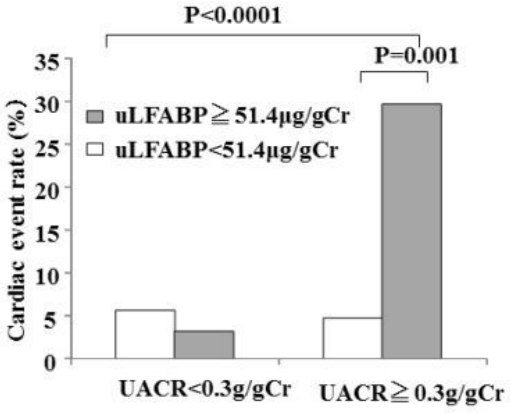
TH-PO311

Urinary Liver-Type Fatty Acid Protein as a Predictor of a Cardiac Event and Progressive Renal Dysfunction in Non-Diabetic Patients with Chronic Kidney Disease Midori Hasegawa, Kyoko Kanayama, Yukio Yuzawa. *Nephrology, Fujita Health University School of Medicine, Toyoake, Aichi, Japan.*

Background: The aim of this study was to evaluate urinary liver-type fatty acid-binding protein (uL-FABP) as a predictor of a cardiac event and progressive renal dysfunction in non-diabetic patients with chronic kidney disease (CKD).

Methods: A total of 273 non-diabetic CKD patients whose eGFR was below 60 mL/min/1.73 m^2 and who were not receiving dialysis were enrolled in this study between March 2009 and September 2010. The median follow-up period was 22 months. The levels of uL-FABP were measured and its relationships with cardiac events and renal outcomes were assessed.

Results: (1) Cardiac events: There were 31 cardiac events. Kaplan-Meier incidence rates of cardiac events were 0.88%, 11.5%, 18.6% and 23.6% among quartiles of uL-FABP levels (p<0.0001). The best cut-off value for a cardiac event was 51.4μg/gCr of uL-FABP (sensitivity 74.2%, specificity 64.5%) according to the ROC curves (AUC0.713). There was a significantly greater tendency for cardiac events among patients with increased UACR and uL-FABP concentrations compared with patients with only increased UACR (P = 0.001) (Fig1).(2) Renal outcomes: The patients were classified as progressors when the eGFR value decreased by 5 ml/min/1.73 m^2/year or the patient received renal replacement therapy. At the end of follow-up, 74 patients were classified as progressors. The initial values of uL-FABP, UACR, eGFR, Hb, and albumin significantly differed between progressors and non-progressors. On logistic regression analysis, initial L-FABP (OR1.002, P value=0.015) and UACR (OR1.001, P value<0.0001) remained as independent variables associated with the progression of renal dysfunction.



Conclusions: Urinary L-FABP may be useful for predicting a cardiac event and the progression of renal dysfunction in non-diabetic patients with CKD.

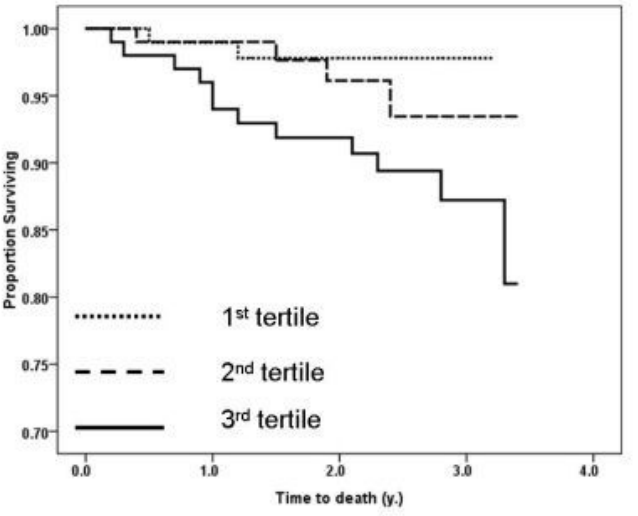
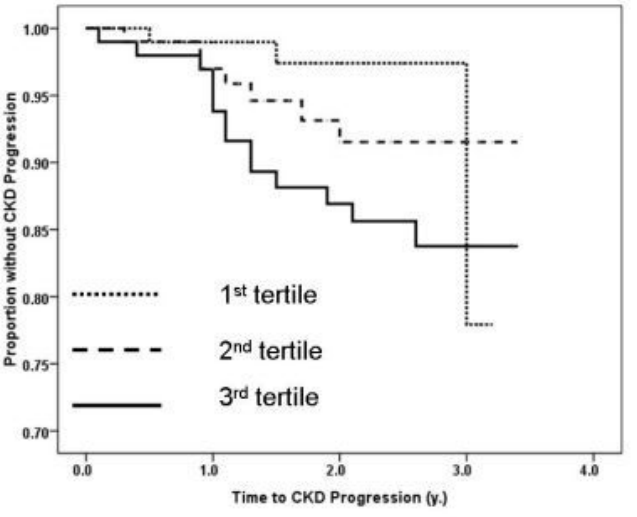
Association of Placental Growth Factor with Chronic Kidney Disease Progression and Mortality: CARE FOR HOMe Study Mehdi Rambod,[1] Sarah Seiler,[2] Kyrill S. Rogacev,[2] Danilo Fliser,[2] Samir S. Patel,[3] Rama Dwivedi,[3] Ali Ramezani,[3] Harry S. Gill,[3] Dominic S. Raj,[3] Gunnar H. Heine.[2] *[1]Texas Tech Health Sciences Center, El Paso, TX; [2]Saarland University Medical Center and Saarland University Faculty of Medicine, Germany; [3]The George Washington University.*

Background: Placental growth factor (PlGF) is a member of the human vascular endothelial growth factor family of signaling proteins, which are associated with inflammation and atherosclerotic disease in the general population. In this study, we examined the association of PlGF with the risk of progression of chronic kidney disease (CKD) and death.

Methods: Serum level of PlGF was measured in 301 CKD patients. Progression of CKD was defined as 50% decrease in glomerular filtration rate (GFR) or need for renal replacement therapy.

Results: Sixty-one percent of participants were male and 39% were diabetic. Mean(SD) age, body mass index (BMI), and GFR were 65.6(11.8) y., 30.3(5.5) kg/m^2, and 44(16) ml/min, respectively. Mean(SD) PlGF was 5.4(3.8) pg/mL ranging from 0.06 to 22.35 pg/mL. PlGF was inversely correlated with high-density lipoprotein (HDL) (r=-0.23, p<0.001), and positively correlated with log triglyceride (r=0.23, p<0.001) and leukocyte count (r=0.16, p=0.006). During 3.4 y. of follow up, 6% (n=18) died and CKD progressed in 8% (n=24). Compared to the first tertile of PlGF, 2nd and 3rd tertiles of PlGF were associated with increased death rate and CKD progression (Figure). After adjustment for age, sex, BMI, albumin, HDL, and diabetes, 2nd and 3rd tertiles of PlGF were associated with increased risk of composite outcome (death or CKD progression) (HR: 2.5, p=0.12; and 6.0, p=0.001, respectively).





Conclusions: In CKD patients not yet on dialysis, PlGF is associated with an atherogenic lipid profile, increased leukocyte count, and higher risk of CKD progression and mortality.

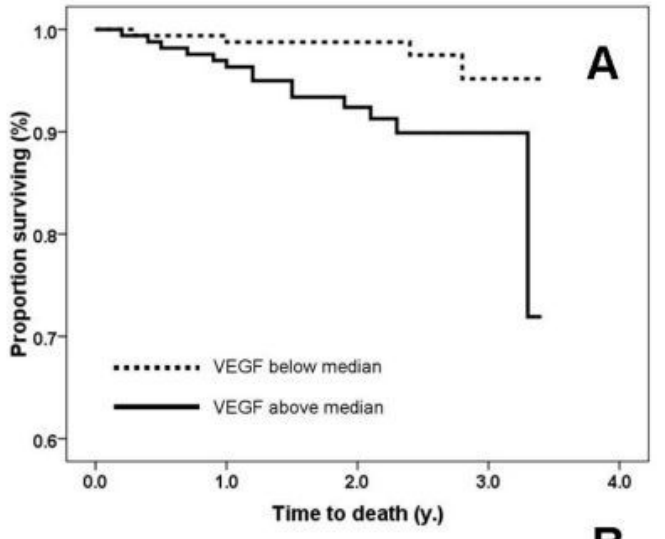
TH-PO313

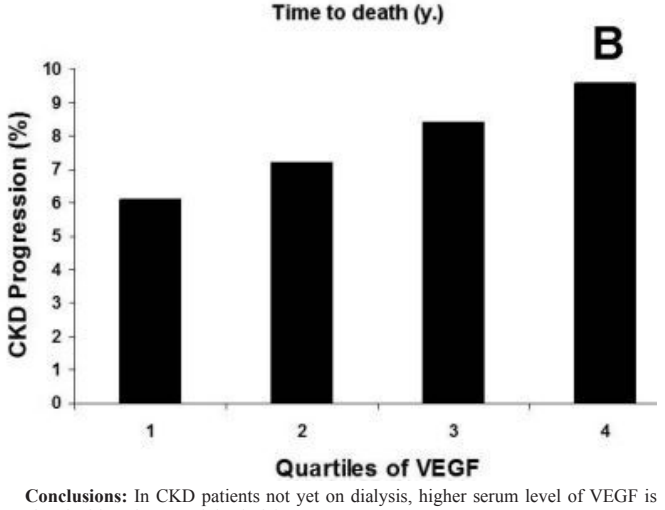
Vascular Endothelial Growth Factor Is Associated with Higher Mortality in Chronic Kidney Disease: CARE FOR HOMe Study Mehdi Rambod,[1] Sarah Seiler,[2] Kyrill S. Rogacev,[2] Danilo Fliser,[2] Samir S. Patel,[3] Rama Dwivedi,[3] Ali Ramezani,[3] Harry S. Gill,[3] Dominic S. Raj,[3] Gunnar H. Heine.[2] *[1]Texas Tech Health Sciences Center, El Paso, TX; [2]Saarland University Medical Center & Saarland University Faculty of Medicine, Hamburg, Germany; [3]The George Washington University, Washington, DC.*

Background: Vascular endothelial growth factor (VEGF), a key regulator of angiogenesis, generally considered renoprotective; conversely, VEGF is reported to be associated with a higher rate of end-stage renal disease, but less is known about association of VEGF and mortality in chronic kidney disease (CKD) patients.

Methods: Serum level of VEGF was measured in 331 CKD patients. Progression of CKD was defined as 50% decrease in glomerular filtration rate (GFR) or need for renal replacement therapy.

Results: Sixty-one percent of patients were male and 39% were diabetic. Mean (SD) age, body mass index (BMI), and GFR were 65 (12) y., 30.4 (5.5) kg/m^2, and 44 (16) ml/min, respectively. Mean (SD) VEGF was 69 (29) pg/mL. VEGF was inversely correlated with GFR (r=-0.12, p=0.028), albumin (r=-0.14, p=0.012) and BMI (r=-0.11, p=0.043) and positively correlated with serum endotoxin level (r= 0.18, p=0.008). During 3.4 y. of follow-up, 5.4% (n=18) died and CKD progressed in 8% (n=26). Compared to the patients with VEGF<median, patients with VEGF>=median had higher death risk [hazard ratio (HR)=3.99; 95%CI: 1.3–12.2, p=0.015] (Figure-A). This increased death risk remained significant after adjustment for age, sex, BMI, GFR, serum albumin and diabetes status (HR=3.4; 95%CI: 1.1–10.7, p=0.034). Moreover, a trend was seen towards increased risk of CKD progression across quartiles of VEGF, though the observed trend was not statistically significant (Figure-B).





Conclusions: In CKD patients not yet on dialysis, higher serum level of VEGF is associated with an increased death risk.

TH-PO314

Serum Alkaline Phosphatase and Risk for ESRD and Death in Stage 3 and Stage 4 CKD Sankar D. Navaneethan,[1] Jonathan J. Taliercio,[1] Anne S. Tang,[2] James F. Simon,[1] Stacey Jolly,[3] John W. Sharp,[3] Martin J. Schreiber,[1] Jesse D. Schold,[2] Joseph V. Nally.[1] *[1]Nephrology, Cleveland Clinic; [2]Quantitative Health Sciences, Cleveland Clinic; [3]Medicine, Cleveland Clinic.*

Background: Higher serum alkaline phosphatase (SAP) increases vascular calcification and may contribute to the cardiovascular deaths in the general population. CKD patients have higher SAP due to the distrubances in the bone mineral metabolism which in turn may contribute to the higher cardiovascular burden. We examined the associations between SAP and end stage renal disease (ESRD) and all-cause mortality in those with stage 3 and stage 4 CKD.

Methods: 28398 patients with stage 3 and stage 4 CKD who had SAP measured one year before the diagnosis of CKD were included. Cox proportional hazards models were used to examine the associations between SAP and the composite end-point of death or ESRD while adjusting for relevant confounding variables including liver function tests.

Results: During a median follow-up of 2.3 years, 5295 participants died or reached ESRD.In the multivariate adjusted analyses, each standard deviation increase in SAP was associated with a 17% increased hazard for death or ESRD (Hazard ratio[HR] 1.17, 95% CI 1.14,1.19). Compared to the lowest quartile (SAP <66 U/L), there was a graded increase in the hazard for death or ESRD in the highest quartiles of SAP (Table 1).

Table 1. Associations between serum alkaline phosphatase levels and death and ESRD

	Adjusted HR (95%CI) Composite	Adjusted HR (95%CI) Death	Adjusted HR (95% CI) ESRD
Categorical			
Q2 vs. Q1	1.10(1.01, 1.20)	1.13(1.03, 1.24)	0.83(0.64,1.09)
Q3 vs. Q1	1.24(1.14, 1.35)	1.26(1.15, 1.38)	1.02(0.80, 1.30)
Q4 vs. Q1	1.68(1.55, 1.82)	1.71(1.56, 1.86)	1.36(1.09, 1.70)
Continuous			
Each SD increase in SAP	1.17(1.15, 1.19)	1.18(1.15, 1.20)	1.17(1.10, 1.23)

Q1: <66 U/L, Q2: 67-81 U/L, Q3: 82-101 U/L, Q4: >102 U/L, SD: Standard deviation, HR: Hazard ratio

When the analysis was restricted to those who had SAP levels within the normal range (<149 U/L),results were similar. In a subgroup analysis that included those who had serum phosphorus data (n=5789), each SD increase in SAP was associated with a 13% increased hazard for the composite end-point.

Conclusions: Higher SAP (even within the normal range) is associated with an increased risk of death and ESRD in those with non-dialysis dependent CKD. Studies examining the mechanisms that explain these associations are warranted.

TH-PO315

Mineral Metabolites and Progression to End-Stage Renal Disease in AASK Julia J. Scialla,[1] Brad C. Astor,[2] Tamara Isakova,[1] Huiliang Xie,[1] Lawrence J. Appel,[3] Myles S. Wolf.[1] *[1]University of Miami; [2]University of Wisconsin; [3]Johns Hopkins University.*

Background: African Americans progress faster to ESRD than Caucasians. Disordered mineral metabolism is particularly severe among African Americans with CKD and may contribute to progression.

Methods: We measured fibroblast growth factor 23 (FGF23), parathyroid hormone (PTH), phosphate and 25-hydroxyvitamin D (25D) in 809 African Americans with hypertensive CKD enrolled in AASK. We analyzed the association of baseline levels (continuously and in quartiles) with risk of ESRD or death over a median of 8 years using Cox models.

Results: Mean GFR was 45 ± 18 ml/min/1.73m^2. 95% of participants were 25D insufficient (<30 ng/ml) and 33% severely deficient (<10). Higher quartiles of FGF23, PTH, and phosphate and lower quartiles of 25D were associated with greater risk of ESRD or death after adjustment for age, sex and randomized group in the trial (each p<0.05). Only FGF23 and PTH remained associated after full adjustment.

		Incidence rate (per 1000 person years)	Hazard ratio of ESRD or death (95% CI)*
FGF23 (pg/ml):	≤30.7	26.2	Ref
	30.8-44.2	47.4	1.47 (0.98-2.20)
	44.3-64.3	70.0	1.67 (1.04-2.69)
	≥64.4	141.3	2.24 (1.39-3.60)
	p-trend	--	<0.01
PTH (pg/ml):	≤24.0	35.6	Ref
	24.1-37.0	38.6	0.80 (0.57-1.13)
	37.1-60.7	71.0	1.01 (0.80-1.27)
	≥60.8	138.2	1.33 (1.01-1.75)
	p-trend	--	0.01

*adjusted for age, sex, income, prior cardiovascular disease, smoking status, body mass index, GFR, proteinuria, serum albumin, and randomized group in the trial

In adjusted continuous models log-FGF23 exhibited a linear dose-response relationship with outcomes (p<0.01), whereas higher log-PTH and phosphate were associated in their higher ranges (PTH >39 pg/ml, p<0.01; phosphate >3.5 mg/dl, p<0.01) and 25D was not associated (p=0.4). The rate of ESRD or death among those with concomitant elevations of FGF23 (>50 pg/ml), PTH (>65 pg/ml) and phosphate (>4.6 mg/dl) was 487/1000 person years, compared to 214/1000 person years in stage 4/5 CKD.

Conclusions: Among African Americans with hypertensive kidney disease, abnormalities of mineral metabolism are associated with greater risk of progression to ESRD and may be useful as adjunctive metrics of CKD severity. FGF23 was most consistently associated with CKD progression and may be a novel therapeutic target. 25D deficiency was prevalent, but not independently associated with outcomes.

TH-PO316

Serum 1,25 Dihydroxyvitamin D and the Development of Chronic Kidney Disease in a Japanese Community: The Hisayama Study Kensuke Izumaru,[1,2] Toshiharu Ninomiya,[1,2] Masaharu Nagata,[1,2] Tomoko Usui,[1,2] Kazuhiko Tsuruya,[2] Takanari Kitazono,[2] Yutaka Kiyohara.[1] *[1]Department of Environmental Medicine, Kyushu University, Fukuoka; [2]Department of Medicine and Clinical Science, Kyushu University, Fukuoka.*

Background: Lower serum 25 hydroxyvitamin D [25(OH)D] level has been reported as a risk factor for end-stage kidney disease. However, there are limited studies addressing whether serum 1,25 dihydroxyvitamin D [$1,25(OH)_2D$] affects the development of chronic kidney disease (CKD) in the general population.

Methods: We followed up 2,417 community-dwelling individuals without CKD aged ≥40 years for 5 years and examined the effects of baseline serum $1,25(OH)_2D$ levels on the development of CKD by using logistic regression model. CKD was defined as eGFR <60 ml/min/1.73m^2.

Results: During follow-up, 378 subjects experienced CKD. The age- and sex-adjusted cumulative incidence rates of CKD increased significantly with decreasing quartiles of serum $1,25(OH)_2D$ concentrations (≥79.3, 66.8-79.2, 56.5-66.7, and <56.5 pg/ml), being 12.0%, 14.0%, 17.9%, and 19.4%, respectively (p for trend <0.01). Compared with those with $1,25(OH)_2D$ of ≥79.3 pg/ml, the multivariate-adjusted odds ratio (OR) for the development of CKD in subjects with $1,25(OH)_2D$ of56.5-66.7 and <56.5 pg/ml were 1.71 (95% confidence interval [CI], 1.17-2.50) and 1.60 (95% CI, 1.08-2.34), respectively, after adjusting for potential confounding factors.Additionally, the rate of change in kidney function for 5 years decreased gradually with lower serum $1,25(OH)_2D$ levels (-1.8, -2.0, -2.2, and -2.4 ml/min/1.73m^2/year, respectively, p for trend <0.001).

Conclusions: Our findings suggest that lower serum $1,25(OH)_2D$ level is a significant risk factor for the development of CKD in the general population.

TH-PO317

The Association of Glycated Hemoglobin with Mortality and ESRD among Persons with Diabetes and Chronic Kidney Disease Chutatip Limkunakul,[1] Ian H. de Boer,[2] Bryan R. Kestenbaum,[2] Cassianne Robinson-Cohen,[2] Michael Sachs,[2] Jonathan Himmelfarb,[2] T. Alp Ikizler.[1] *[1]Nephrology, Vanderbilt University, Nashville, TN; [2]Kidney Rsch Institute, University of Washington, Seattle, WA.*

Background: Glycated hemoglobin (HbA1c) is a measurement of chronic hyperglycemia in diabetes mellitus. While higher HbA1c is clearly associated with increased risk of developing kidney disease, its associations with progression of existing kidney disease, cardiovascular disease, and death are not well defined.

Methods: We performed a cohort study of 513 persons with chronic kidney disease in the Seattle Kidney Study, of whom 275 had diabetes. Subjects with diabetes were grouped by HbA1c (<6.5; 6.5 - 6.9; 7 - 7.9; 8 - 9; >9). The primary outcome was a composite of ESRD and death. Cox models were used to calculate the hazard ratio (HR) after adjustment for clinical and demographic variables.

Results: Compared to participants without diabetes, those with diabetes had higher unadjusted incidence rates of each outcome within any category of baseline HbA1c: range 11.3-14.1 vs 6.6 per 100 person-years for the primary composite outcome, range 5.8-7.3 vs 3.0 per 100 person-years for ESRD, and range 6.1-10.9 vs 3.8 per 100 person-years for death. Among participants with diabetes who were receiving insulin therapy, each 1% higher HbA1c was associated with a 42% lower adjusted increased risk of ESRD (HR 0.58; 95% CI, 0.32 – 1.06; p = 0.078), which was not observed for increased risk of death. Among participants with diabetes who were not receiving insulin therapy, each 1% higher HbA1c was associated with a 91% greater adjusted risk of death (HR 1.91; 95% CI, 1.17 – 3.12), which was not observed for increased risk of ESRD. Risk of ESRD was greatest among participants with diabetes and HbA1c <7%.

Conclusions: Among persons with diabetes and established chronic kidney disease, lower HbA1c was not associated with lower risk of ESRD and death in all patients. There is a differential risk profile according to the use of insulin in diabetic patients. In this population, control of HbA1c to currently recommended levels may be associated with harm in certain individuals.

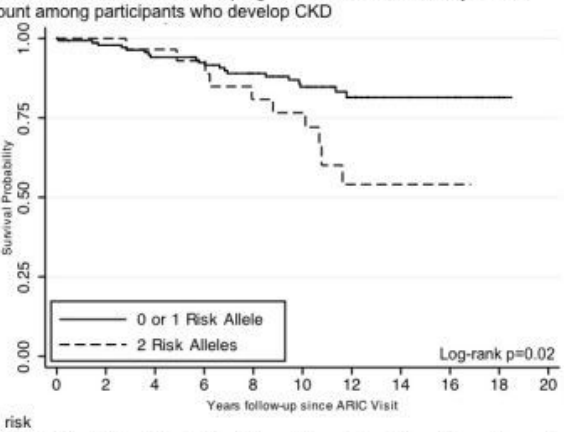
APOL1 and Risk of Incident and Progressive Chronic Kidney Disease (CKD) in African Americans: The Atherosclerosis Risk in Communities (ARIC) Study Meredith C. Foster,[1] Josef Coresh,[1] Myriam Fornage,[2] Brad C. Astor,[3] M. Grams,[1] Nora Franceschini,[4] Eric Boerwinkle,[2] Rulan S. Parekh,[1] Wen Hong Linda Kao.[1] *[1]Johns Hopkins University; [2]University of Texas; [3]University of Wisconsin; [4]University of North Carolina.*

Background: Common variants in the APOL1 gene are strongly associated with prevalent end stage renal disease (ESRD) in African Americans but prospective and general population data are lacking.

Methods: We analyzed data from 3,067 African Americans free of CKD at ARIC baseline to evaluate the association of APOL1 G1 & G2 risk alleles (2 vs. 0 or 1 allele) with incident CKD (eGFR<60mL/min/1.73m^2) and the subsequent progression to ESRD amongst the group with CKD using time-to-event analyses. Cox models were adjusted for age, sex, study center, and European ancestry.

Results: Overall 13.2% carried 2 APOL1 risk alleles, with 8.2% developing CKD compared to 5.9% among those with 0 or 1 risk allele over 8.6 years median follow-up(hazard ratio [HR] 1.5; 95% confidence interval [CI] 1.0-2.2). European ancestry adjustment did not significantly change results. Among those with incident CKD, those with 2 risk alleles were also more likely to progress to ESRD than their counterparts with 0 or 1 risk allele (Figure; HR 2.2; 95% CI 1.0-4.8), especially after about 6 years of follow up. With an interaction term between risk and time, the HR associated with genotype was 0.9 (95% CI 0.2-4.1) during the first 6 years of follow-up and 3.8 (95%CI 1.4-9.0) after the first 6 years.

Figure: Kaplan-Meier survival curves for progression to ESRD event by *APOL1* risk allele count among participants who develop CKD



Number at risk											
0 or 1 Risk Allele	148	134	120	112	95	76	41	19	16	4	0
2 Risk Alleles	32	31	27	23	20	17	8	2	1	0	0

Conclusions: In a large sample of African Americans from the general population, the APOL1 G1/G2 risk alleles increased the risk of developing CKD and progression to ESRD. These results show that the effect of APOL1 on ESRD risk may begin early and become stronger at later stages of CKD, suggesting that earlier intervention or treatment strategies need to be studied.

TH-PO319

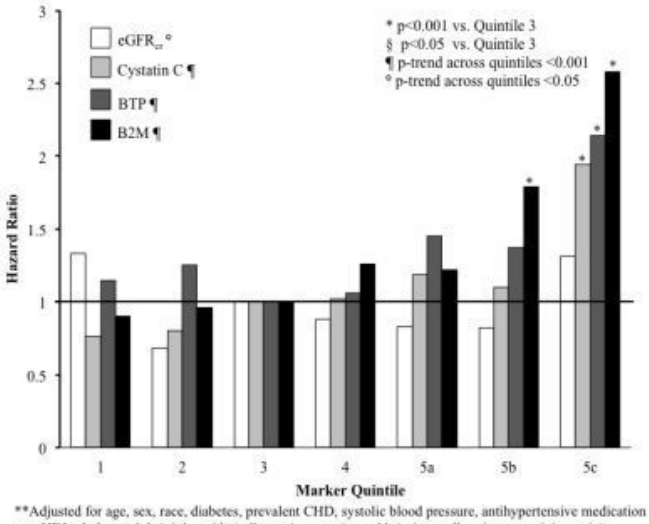
Novel Filtration Markers as Predictors of All-Cause and Cardiovascular Disease (CVD) Mortality in a Representative Sample of US Adults: CKD Biomarkers Consortium Meredith C. Foster,[1] Lesley Stevens Inker,[2] Andrew S. Levey,[2] Elizabeth Selvin,[1] John H. Eckfeldt,[3] Stephen P. Juraschek,[1] Josef Coresh.[1] *[1]Johns Hopkins University; [2]Tufts Medical Center; [3]University of Minnesota.*

Background: It is unclear whether serum concentrations of new filtration markers such as β-trace protein (BTP) and β2 microglobulin (B2M) are similar to cystatin C in having stronger associations with mortality than creatinine-based estimated glomerular filtration rate ($eGFR_{cr}$) in the general US population.

Methods: Adults age 20 and older (n=6,541) from NHANES III with mortality linkage through 2006. Creatinine, cystatin C, BTP and B2M were measured in stored serum samples; $eGFR_{cr}$ calculated with the CKD-EPI equation. Markers were categorized into quintiles, splitting the highest quintile (lowest $eGFR_{cr}$ quintile) into tertiles. Adjusted associations with all-cause, CVD and CHD mortality were evaluated using Cox models weighted for the sampling design.

Results: We observed 2,398 deaths (1,082 CVD & 607 CHD deaths) over a median follow-up of 14.4 years. All four markers were associated with mortality after adjusting for demographics (p-trend<0.02 for $eGFR_{cr}$ and <0.001 for others). Compared to the middle quintile, the adjusted hazard ratio (95% CI) for mortality of the highest sub-quintile was 1.9 (1.4-2.6) for cystatin C, 2.1 (1.6-2.9) for BTP and 2.6 (2.0-3.4) for B2M compared to 1.3 (0.8-2.0) for the lowest $eGFR_{cr}$ sub-quintile (Figure). Similar trends were observed for CVD and CHD mortality and for cystatin-C, BTP and B2M in adults with $eGFR_{cr}$≥60mL/min/1.73m^2 where the $eGFR_{cr}$ association was flat. Novel markers also added prediction beyond $eGFR_{cr}$ (p<0.01 for NRI).

Figure: Multivariable adjusted** hazard ratios of all-cause mortality by filtration marker category.



**Adjusted for age, sex, race, diabetes, prevalent CHD, systolic blood pressure, antihypertensive medication use, HDL-cholesterol, ln(triglycerides), C-reactive protein, and ln(urinary albumin to creatinine ratio)

Conclusions: BTP and B2M share the stronger, linear association of cystatin C with mortality compared to eGFR$_{cr}$ which may under-estimate the kidney function-mortality relationship due to confounding by muscle mass.

TH-PO320

Association between Kidney Function and Telomere Length: The Heart and Soul Study Nisha Bansal,[1] Mary Whooley,[1] Mathilda Regan,[1] Charles E. McCulloch,[1] Joachim H. Ix,[2] Elissa Epel,[1] Elizabeth H. Blackburn,[1] Chi-yuan Hsu.[1] *[1]UCSF; [2]UCSD.*

Background: Telomere attrition has emerged as a novel cardiovascular risk factor in the general population, however studies of telomere length in relation to kidney function are limited. We explored the association of kidney function with telomere length and telomere shortening, which may be important cardiovascular risk factors in patients with chronic kidney disease.

Methods: The Heart and Soul study is a longitudinal study of participants with stable coronary heart disease (CHD). Measures of baseline kidney function included: creatinine-derived estimated glomerular filtrate rate (eGFR$_{CKD-EPI}$), 24-hour urine creatinine clearance, cystatin C eGFR (eGFRcys), and urine albumin to creatinine ratio (ACR). Telomere length was measured from peripheral blood leukocytes at baseline (N=954) and 5 years later (N=608). Linear regression models were used to test the association between kidney function and i) baseline telomere length and ii) change in telomere length over the next 5 years.

Results: At baseline, mean age was 66.7 (±11) years, 18.6% were female and 16.5% were Black. Mean eGFR$_{CKD-EPI}$ was 72.6 (± 21.5) ml/min/1.73 m^2, eGFRcys was 71.0 (± 23.1) ml/min/1.73 m^2 and ACR was 8.6 (±12.3) mg/gm. In cross-sectional analysis, lower baseline eGFR$_{CKD-EPI}$ (but not the other measures of kidney function) was associated with shorter baseline telomere length (9.1 [95% CI 1.2-16.9] shorter in base pairs for every 5 ml/min/1.73 m^2 lower eGFR$_{CKD-EPI}$). Adjustment for age rendered this association no longer significant. In longitudinal analysis, lower baseline eGFR$_{CKD-EPI}$ (and all other measures of kidney function) predicted more rapid telomere shortening (10.8 [95% CI 4.3-17.3] decrease in base pairs over 5 years for every 5 ml/min/1.73 m^2 lower eGFR$_{CKD-EPI}$). After adjustment for age, these associations were no longer statistically significant.

Conclusions: In patients with CHD, the associations between reduced kidney function and i) shorter baseline telomere length and ii) more rapid telomere shortening over 5 years are both entirely explained by older age. Telomere shortening and decrease in kidney function are likely parallel processes that occur with aging.

Renal Biopsy mRNA Profiling Implicates Shared Molecular Pathways in Progression of Chronic Kidney Disease Wenjun Ju,[1] Viji Nair,[1] Felix H. Eichinger,[1] Celine C. Berthier,[1] Ann Randolph,[1] Sebastian Martini,[1] Shahaan Smith,[1] Jennifer Yi-Chun Lai,[1] Jennifer Joyce Hawkins,[1] Frank C. Brosius,[1] Kerby Shedden,[1] Clemens D. Cohen,[2] Crystal A. Gadegbeku,[3] Matthias Kretzler.[1] *[1]University of Michigan; [2]University of Zurich; [3]Temple University, for the ERCB and CPROBE Consortium.*

Background: Molecular markers identifying patients at risk for progression of chronic kidney disease (CKD) are currently lacking and will facilitate our understanding of pathogenesis and development of targeted interventions. The goal of this study is to test if intra-renal mRNA can predict kidney function and functional change over time in patients with CKD.

Methods: We performed array based genome-wide expression profiling followed by qRT-PCR validation on micro-dissected kidney biopsies of patients with a wide range of CKD causes and stages in two independent cohorts: 164 European patients out of ERCB and 42 American patients from Michigan O'Brian Renal Center observational cohort (CPROBE).

Results: We identified 68 genes to be highly correlated with renal function, as assessed by estimated glomerular filtration rate (MDRD eGFR), with significant differential expression between patients and controls (living donor biopsies). Using qRT-PCR the marker-panel was confirmed to predict eGFR in an independent cohort of 56 CKD patients (r^2=0.54, predicted vs. actual eGFR). The GFR prediction also remained robust in the diverse multi-center CPROBE cohort (n=42, r^2=0.46). In 18 CPROBE subjects, eGFR slope could be estimated by mixed effects model using at least 3 serial measurements over 4.2±1.8 years. Notably, 36 of the 68 markers correlated with loss of renal function over time (|r|≥0.48, p≤0.05, FDR<0.1). Functional analysis of predictive transcripts revealed altered signaling pathways in CKD, including beta1 integrin cell surface interactions, antigen processing and presentation, and D4-GDI signaling pathway.

Conclusions: An intra-renal mRNA marker set is able to predict renal functional impairment in CKD irrespective of patients' disease type, stage, race or environment. The marker set provides a foundation for non-invasive marker identification and mechanism-driven intervention.

TH-PO322

Association between Urine Osmolality and Progression of Chronic Renal Failure: A Cohort Study Max Plischke,[1] Maria Kohl,[2] Ammon Handisurya,[1] Martin Haas.[1] *[1]Department of Internal Medicine III, Division of Nephrology and Dialysis, Medical University Vienna, Vienna, Austria; [2]Section for Clinical Biometrics, Center of Medical Statistics, Informatics and Intelligent Systems, Medical University Vienna, Vienna, Austria.*

Background: Vasopressin (VP) has been associated with progression of chronic kidney disease (CKD). Precise measurement of VP is difficult; however, based on its antidiuretic action urine osmolality (Uosm) may be used as a substitute. In this retrospective cohort study the association between urine osmolality and progression of CKD to dialysis was investigated in 273 patients with CKD stage 1-4.

Methods: Mean Uosm values during a run-in phase of one year were used as baseline values. The association between Uosm and the risk of dialysis was assessed by a multivariate proportional sub-distribution hazards model for competing risk data according to Fine and Gray. Co-variables were selected via the purposeful selection algorithm.

Results: Dialysis was reached in 105 patients over a median follow-up period of 92 months. Non-adjusted competing risk analysis suggested a lower incidence of dialysis in patients with a urine osmolality greater than median (510 mOsmol/L). However, after adjustment, a higher risk was found in patients with a higher Uosm. The adjusted sub-distribution hazard ratio for dialysis was 2.04 (95% confidence interval, 1.06 to 3.92) for each doubling of urine osmolality. After 72 months, the estimated adjusted cumulative incidence probabilities of dialysis were 15%, 24%, and 34% in patients with a baseline urine osmolality of 315, 510, and 775 mOsmol/L, respectively.

Conclusions: We conclude that lower urine osmolality is associated with a decreased risk of progression to dialysis in CKD patients. Antagonizing the effect of vasopressin or increasing fluid intake might therefore improve the course of chronic renal failure.

TH-PO323

Urinary Procollagen Type III Aminoterminal Propeptide Predicts the Decline of Renal Function in Pre-Dialysis CKD Patients Akira Suzuki,[1] Kodo Tomida,[1] Tatsuya Shoji,[1] Noriyuki Okada,[2] Yoshiharu Tsubakihara,[3] Terumasa Hayashi.[1] *[1]Kidney Disease and Hypertention, Osaka General Medical Center, Osaka, Japan; [2]Clinical Examination, Osaka General Medical Center, Osaka, Japan; [3]Comprehensive Kidney Disease Research, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Tubulointerstitial fibrosis is the final common pathway in all kidney disease falling into end stage kidney disease. The severity of fibrosis can predict the prognosis of the renal function. Recent studies had demonstrated that the urinary procollagen type III aminoternal propeptide (U-PIIINP) was correlated significantly with the extent of fibrosis in renal biopsy. We hypothesized that the U-PIIINP may be correlated with the decline of renal function in pre-dialysis CKD patients.

Methods: 76 patients with CKD were recruited whose Cr levels were available at 6 month before the recruitment. Each participant measured the PIIINP level and biochemistry tests in urine and serum. Six month later, serum biochemical tests were repeated. All liver diseases and lung fibrosis were excluded. The slope of 1/Cr was calculated using the Cr level during the 12 months.

Results: The population included 41 patients with CKD stage 3, 31 patients with CKD stage4, and 4 patients with CKD stage 5. The etiology of CKD was benign nephrosclerosis; 32 patients, chronic glomerulonephritis; 22 patients, diabetic nephropathy; 19 patients, polycystic kidney disease; 3 patients. Serum PIIINP (S-PIIINP) and U- PIIINP/Cr ratio revealed no significant correlation, suggesting U-PIIINP was derived mostly from kidney. Each of S-PIIINP and U-PIIINP/Cr was correlated with eGFR (R=-0.52434, P<0.0001 and R=-0.38628, P=0.0005, respectively). Slope of 1/Cr was correlated with each of U-PIIINP/Cr (R=-0.50318, P<0.0001), NAG(R=0.27975, P=0.0137) and Urinary protein/Cr ratio (R=-0.31761, P<0.0049), but not with S-PIIINP, Age, BP, BMI, and eGFR. Multiple regression analysis using the factors showing significant correlation revealed the U-PIIINP/Cr was the strongest factor significantly correlated with the Slope of 1/Cr.

Conclusions: The results suggest that U-PIIINP/Cr may predict the decline of renal function in pre-dialysis CKD patients.

TH-PO324

Urine Neutrophil Gelatinase-Associated Lipocalin (NGAL) Level and Risk of Progressive Chronic Kidney Disease: Results from the CRIC Study Kathleen D. Liu, Wei (Peter) Yang, Amanda Hyre Anderson, Harold I. Feldman, Sevag Demirjian, Takayuki Hamano, Jiang He, James P. Lash, Eva Lustigova, Sylvia E. Rosas, Michael S. Simonson, Kelvin Tao, Chi-yuan Hsu. *For the CRIC Study.*

Background: Novel biomarkers may improve our ability to predict which CKD patients are at higher risk for progressive loss of renal function.

Methods: Baseline urine NGAL concentration was determined using the Abbott ARCHITECT platform among 3386 participants of the prospective Chronic Renal Insufficiency Cohort (CRIC) study. Cox models were used to examine the independent association between urine NGAL and risk of CKD progression, defined as halving of estimated GFR or incident ESRD.

Results: Baseline mean eGFR was 42.4 ml/min/1.73m^2; median 24-hr urine protein 0.2 gm/day; median urine NGAL concentration 17.2 (IQR 8.1-39.2) ng/mL. Over an average follow-up of 3.2 years, 689 episodes of CKD progression occurred. Even after accounting for baseline eGFR, proteinuria and other traditional CKD progression risk factors such as diabetes and BP level, urine NGAL was an independent risk factor in CKD progression (HR 1.70 highest vs. lowest quartile; p=0.01)(Table). The association between baseline urine NGAL and risk of CKD progression was strongest within the first 2 years of the biomarker measurement. Within this time frame, adding urine NGAL to a model which included eGFR, proteinuria and other CKD progression risk factors led to net reclassification improvement of 24.7% (95% CI 0.4%-38.5%); but the C-statistic remained nearly identical (0.879 vs. 0.880).

Conclusions: Urine NGAL was an independent predictor of progression among patients with established CKD of diverse etiology but did not substantially improve prediction of outcome events.

Association between urine NGAL concentration and risk of CKD progression (halving of eGFR or ESRD)

Quintiles of urine NGAL concentration (ng/ml)	Unadjusted Hazard Ratio	Adjusted for demographics, eGFR, 24-hr urine protein and other CKD progression risk factors
<= 6.9	Ref	Ref
> 6.9 - <= 12.9	1.75 (1.22-2.51)	1.37 (0.94-1.98)
> 12.9 - <= 22.6	2.52 (1.79-3.56)	1.24 (0.86-1.79)
> 22.6 - <= 49.5	4.30 (3.11-5.93)	1.39 (0.97-2.00)
> 49.5	9.34 (6.86-12.72)	1.70 (1.16-2.48)

TH-PO325

Predicting the Risk of End-Stage Renal Disease in Patients with Stage 3 Chronic Kidney Disease: A Pragmatic Risk Score Micah L. Thorp,[1] David Smith,[1] Eric S. Johnson,[1] Xiuhai Yang,[1] Amanda F. Petrik,[1] Robert Platt.[2] *[1]The Center for Health Research, Kaiser Permanente Northwest, Portland, OR; [2]Department of Epidemiology and Biostatistics, McGill University, Montreal, QC, Canada.*

Background: Chronic kidney disease (CKD) is common, but only progresses to end stage renal disease (ESRD) in a minority of patients. Developing a tool for early identification of patients likely to progress to ESRD would enable clinicians and medical systems to target resources to patients likely to benefit from interventions.

Methods: We conducted a cohort study by linking data among 38,483 patients with stage 3 CKD. We measured patient characteristics during the year before patients became eligible because of their poor kidney function. We followed patients for up to one year. Seven routinely measured patient characteristics predicted accurately the risk of ESRD. By combining those characteristics with numeric weights for their importance, the risk score stratified patients based on risk.

Results: We observed 461 patients who developed ESRD, a one-year risk of 1.6 per 100 patients. We judged the risk score's effectiveness by dividing the cohort into ten equal groups or deciles, which included approximately 3,849 patients. Patients at or above the 90th percentile of predicted risk (top decile) were 60 times more likely to suffer ESRD when compared with patients below the 10th percentile (bottom decile): 11.0 per 100 patients (top decile) versus 0.2 per 100 (bottom decile). The c-statistic was 0.84 and sensitivity 57%.

Conclusions: This pragmatic risk score appears to be the first of its kind for predicting end-stage renal disease in patients with stage 3 CKD. Our risk score can predict a patient's *absolute risk (e.g., 11 per 100 patients) and will allow clinicians to stratify patients with stage 3 CKD based on their 5 year risk of ESRD.*

Example risk score of a 50 year old man with eGFR 40 and microalbuminuria

Predictor	Points
50 years old	72
Man	30
Kidney function of 40 mL/min	47
Small (micro) amount of albumin in urine	36
Systolic blood pressure (130 mm Hg)	21
Diabetes with only one other complication	27
No anemia (hemoglobin in top quartile)	0
Total	233

233 points = 5% five year absolute risk of ESRD

Funding: Other U.S. Government Support

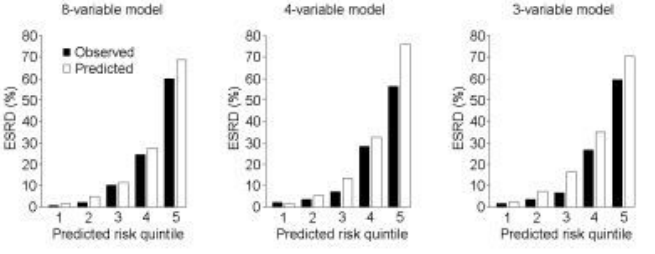
TH-PO326

Validation of the 2011 Kidney Failure Risk Equation in European CKD Patients Mieke J. Peeters,[1] Arjan D. Van Zuilen,[2] Jan A.J.G. van den Brand,[1] Michiel Bots,[2] Peter J. Blankestijn,[2] Jack F. Wetzels.[1] *[1]Radboud University Medical Center, Nijmegen; [2]University Medical Center Utrecht, Utrecht, Netherlands.*

Background: Patients with CKD are at risk of progression to ESRD. Using data of Canadian CKD patients, Tangri *et al* recently developed models to predict progression of CKD stages 3-5 to ESRD within 5 years [JAMA 2011;305:1553-9]. We validated the 2011 Kidney Failure Risk Equation in European CKD patients.

Methods: We selected patients with CKD stages 3-5 from the MASTERPLAN study, a randomized controlled trial in patients with CKD [NDT 2010;25:3647-54]. ESRD was defined as initiation of dialysis or kidney transplantation within 5 years. Mortality before ESRD was defined as no ESRD. Patients followed for less than 5 years, who did not develop ESRD and did not die, were excluded. 5 year ESRD risk was predicted by 3 different models developed by Tangri. MASTERPLAN follow-up data were used to determine actual ESRD rate. Model performance was evaluated using the area under the receiver operating characteristic curve (ROC-AUC) and Net Reclassification Improvement (NRI).

Results: 694 patients were included, 135 developed ESRD. The 8-variable model (including age, sex, eGFR, albuminuria, calcium, phosphate, bicarbonate, albumin) was slightly more accurate than the 4-variable model (including age, sex, eGFR, albuminuria) and the 3-variable model (including age, sex, eGFR, albuminuria); ROC-AUCs were 0.878 (95% CI 0.848-0.908), 0.868 (95% CI 0.834-0.901), and 0.867 (95% CI 0.834-0.900), respectively. The respective NRIs for the 8-variable model compared with the 4-variable and 3-variable model were 10% (p=0.01) and 3% (p=0.61). The Figure shows the mean observed and predicted 5 year ESRD risk.



Conclusions: The 2011 Kidney Failure Risk Equation accurately predicted progression to ESRD in European CKD patients. The benefits of the 8-variable model do not outweigh its added complexity.

TH-PO327

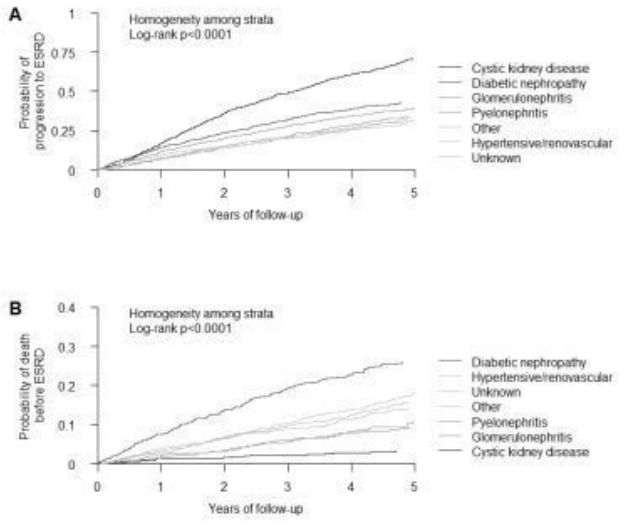
Relevance of Renal Diagnosis to Prognosis of Chronic Kidney Disease: Results from the Study of Heart and Renal Protection (SHARP) Richard Haynes. *On Behalf of the SHARP Collaborative Group, Clinical Trial Service Unit and Epidemiological Studies Unit, University of Oxford, Oxford, Oxfordshire, United Kingdom.*

Background: Previous studies have found conflicting results on the relevance of renal diagnosis to prognosis in CKD, but have been small with short follow-up.

Methods: The SHARP study was a randomized controlled trial of LDL cholesterol lowering with ezetimibe/simvastatin in 9270 patients with CKD (including 6247 not on dialysis). Relative risks of end-stage renal disease (ESRD) and death over 4.9 years were estimated with Cox regression.

Results: Lower eGFR and higher urine albumin:creatinine ratio (ACR) were associated with higher risks of ESRD in all categories of renal diagnosis. The unadjusted rate of ESRD was highest among patients with polycystic kidney disease (PKD) despite lower baseline ACR. Compared with patients with hypertensive/vascular disease, pyelonephritis or other causes of renal disease (reference group), the unadjusted hazard ratio for ESRD in patients with PKD was 3.01 (95% CI 2.69–3.36). There was also an increased risk of ESRD for patients with diabetic nephropathy (DN) (HR 1.57 [1.38-1.78]) or glomerulonephritis (GN) (HR 1.32 [1.17-1.49]). After adjustment (including eGFR and ACR), there was an increased risk of ESRD among those with PKD (HR 3.51 [3.09-3.98]) and DN (HR 1.40 [1.14-1.72]) but not GN (HR 0.97 [0.85-1.10]). Conversely, patients with PKD were at much lower risk of death (and DN at much higher risk) than other diagnoses.

Figure 1. Life table plots of ESRD and death before ESRD by renal diagnosis



Conclusions: Patients with PKD had the highest risk of ESRD despite lower ACR. DN was associated with a 40% increased risk of ESRD but the increased risk associated with GN was fully explained by eGFR and ACR (compared to other renal diagnoses). Patients with PKD were at the lowest risk of death while those with DN were at the highest risk. Renal diagnosis provides useful prognostic information in addition to eGFR and ACR.

Funding: Pharmaceutical Company Support - Merck and Co., Inc.

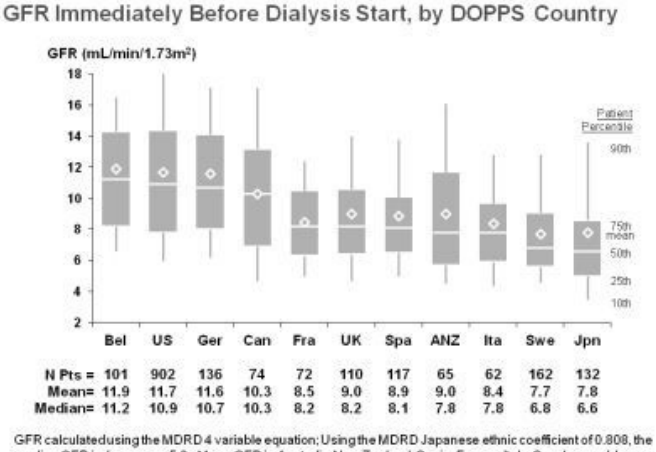
TH-PO328

International Differences in eGFR at Dialysis Start: Results from the Dialysis Outcomes and Practice Patterns Study Brian Bieber,[1] Yun Li,[1,2] David C. Mendelssohn,[5] Panduranga S. Rao,[2] Christian Combe,[3] Joan Fort,[4] Tadao Akizawa,[6] Friedrich K. Port,[1,2] Bruce M. Robinson.[1,2] *[1]Arbor Research; [2]U of Michigan; [3]CHU de Bordeaux; [4]U Hospital Val Hebron; [5]Humber River Regional Hospital; [6]Showa U.*

Background: Though earlier dialysis initiation is not associated with prolonged survival or improved quality of life in clinical trial or observational data, the estimated GFR (eGFR) at dialysis start has risen recently in the US and elsewhere. This study evaluated international differences in estimated GFR at dialysis initiation.

Methods: The DOPPS is a prospective cohort study of HD patients. Data were from 1933 patients in 12 countries with dialysis vintage ≤120 days at DOPPS 4 enrollment (2009-2011). Linear mixed models were used to estimate country differences in eGFR at dialysis start (mL/min/1.73m^2, by 4-var MDRD). Cox regression stratified by country estimated the association of eGFR at start with mortality. Models were adjusted for age, gender, catheter use, 13 summary comorbidities, and pre-dialysis nephrology care.

Results: The median eGFR at dialysis start was highest (>10) in Belgium, Canada, Germany, and US, and lowest (<7) in Sweden and Japan. Findings were similar after adjustment. In patients with 6 months of pre-ESRD data, the average decline in eGFR before dialysis start was 4.9 over 6 months. Higher eGFR at dialysis start was associated with elevated mortality (HR=1.11 per 2.5 mL/min/1.73m^2 [95% CI = 1.01-1.21]).



GFR calculated using the MDRD 4 variable equation; Using the MDRD Japanese ethnic coefficient of 0.808, the median GFR in Japan was 5.3. Mean GFR in Australia-New Zealand, Spain, France, Italy, Sweden, and Japan remained lower than the US even after adjustment for age, gender, 13 summary co-morbid conditions, and timing of pre-ESRD nephrology care

Conclusions: Country differences in average eGFR at dialysis start, of up to 4 mL/min/1.73m^2, may represent an additional six months or more off dialysis (extrapolating from our data and prior publications). Delaying dialysis when feasible may allow for better preparation for dialysis, use of surgical vascular access at dialysis start, cost savings, and improved quality of life for patients with Stage 5 kidney failure.

Funding: Pharmaceutical Company Support - The International DOPPS Is Supported by Scientific Research Grants from Amgen (Since 1996), Kyowa Hakko Kirin (Since 1999, in Japan), Sanofi Renal (Since 2009), and Abbott Laboratories (Since 2009)

TH-PO329

Age and the Association of Kidney Disease Measures with Mortality and End-Stage Renal Disease: A Meta-Analysis of 2 Million Participants from 46 Cohorts (for the CKD-PC Collaborators) Stein I. Hallan, Kunihiro Matsushita, Yingying Sang, B. Khan Mahmoodi, Corri Black, Areef Ishani, Nanne Kleefstra, David M. Naimark, Paul J. Roderick, Marcello Tonelli, Jack F. Wetzels, Brad C. Astor, Ron T. Gansevoort, Adeera Levin, Chi Pang Wen, Josef Coresh. *CKD Prognosis Consortium.*

Background: Chronic kidney disease (CKD) is prevalent in the elderly, but the risk implications of low estimated glomerular filtration rate (eGFR) and high albuminuria across the full age range are controversial.

Methods: We investigated 2,051,244 participants from 46 cohorts. Hazard ratios (HRs) of mortality (112,325 deaths) and ESRD (8,411 events) according to eGFR and albuminuria were meta-analyzed across age categories of 18-54, 55-64, 65-74 and 75+ years. Attributable risks were calculated using HRs and weighted average incidence rates.

Results: Mortality and ESRD risk increased progressively as eGFR decreased and albuminuria increased in every age category. In general/high-risk cohorts, adjusted HRs of mortality for reduced eGFR were lower at older age (e.g., at eGFR 45 [vs. 80] ml/min/1.73m^2, 3.50 [95% CI, 2.55-4.81] in 18-54 years, 2.21 [2.02-2.41] in 55-64 years, 1.59 [1.42-1.77] in 65-74 years, and 1.35 [1.23-1.48] in 75+ years); i.e. a substantial effect-modification by age (*P-values* for overall interaction <0.05 in every age category with 55-64 years as a referent). In contrast, attributable mortality risks were greater at older age (e.g., at eGFR 45, 2.8 extra deaths per 1,000 person-years in 18-54 years, 12.2 in 55-64 years, 26.6 in 65-74 years, and 74.9 in 75+ years). Similar patterns with mortality were observed for albuminuria. Relative and absolute ESRD risk were less influenced by age (*P-values* for interaction >0.1 for eGFR and albuminuria).

Conclusions: Low eGFR and high albuminuria are strongly associated with mortality and ESRD regardless of age.

TH-PO330

Lifetime Risk of Incident Chronic Kidney Disease Stage 3 Shani Shastri,[1] Lesley Stevens Inker,[2] Hocine Tighiouart,[2] Vilmundur Gudnason,[3] Olafur S. Indridason,[3] Runolfur Palsson,[3] Andrew S. Levey,[2] Mark J. Sarnak.[2] *[1]UT Southwestern; [2]Tufts Medical Center; [3]Landspitali -National University Hospital of Iceland.*

Background: To date there are no studies that have assessed the lifetime risk of incident chronic kidney disease (CKD) in the general population.

Methods: Lifetime risk of CKD stage 3 was calculated in 3741 participants in the prospective population-based Reykjavik Study, who attended at least 3 examinations between 1967 - 2005. Estimated glomerular filtration rate (eGFR) was calculated using the CKD-EPI equation. Incident CKD stage 3 was defined as 2 consecutive eGFR < 60 in those with baseline eGFR ≥ 60 ml/min/1.73/m^2. Sex-specific lifetime risk was calculated using left truncated survival analysis adjusted for competing risk of death.

Results: Mean age was 46 years, 48.6% were males, all were Caucasians, 42% had hypertension, 0.6% had diabetes and 1% had dipstick proteinuria. Mean ± SD baseline eGFR and slope of eGFR decline for men and women were 92 ± 13 and 87 ± 13 ml/min/1.73m^2, and -0.74 ± 0.17 and -0.73 ± 0.19 ml/min/1.73 m^2/year, respectively. 361 subjects (9.6%) developed CKD stage 3 over a median follow-up of 27 years (range 2-38 years) & 1025 (27.4%) died without developing CKD. Short- and long-term cumulative risks of CKD stage 3 stratified by sex, are shown in the table below. Cumulative risk of CKD was higher among those with baseline hypertension for all groups.

Age and Sex-Specific Mortality-Adjusted Estimates of Lifetime Risk of Incident CKD Stage 3

		Years from baseline age			
	Age (years)	5	10	20	30
Women					
	50	0.9 (0.4, 1.4)	2.3 (1.6, 3.0)	8.8 (7.4, 10.1)	16.3 (14.2, 18.3)
	60	3.0 (2.2, 3.8)	6.7 (5.4, 7.9)	14.4 (12.4, 16.4)	
	70	5.6 (4.2, 6.9)	8.8 (6.9, 10.5)		
	80	2.9 (0.7, 4.7)			
Men					
	50	0.6 (0.2, 1.1)	1.5 (0.9, 2.1)	3.8 (2.8, 4.7)	7.2 (5.5, 8.6)
	60	0.9 (0.4, 1.4)	2.4 (1.5, 3.2)	6.0 (4.4, 7.3)	
	70	2.4 (1.4, 3.3)	4.1 (2.7, 5.4)		
	80	1.1 (0.0, 2.3)			

Cumulative risks shown as percentages (95% CI)

Conclusions: The cumulative risk of CKD stage 3 increased with age, though among those ≥ 80 years the short-term risk is lower compared to 70 year olds. Lifetime risk of CKD stage 3 was higher in women at all ages and may reflect lower baseline eGFR and increased survival in women.

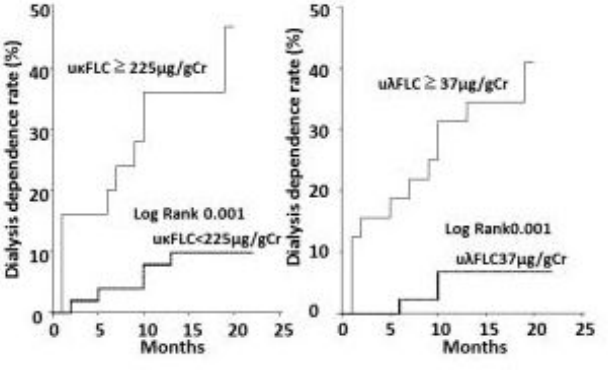
Clinical Significance of Free Light Chains in Patients with Chronic Kidney Disease Kyoko Kanayama, Midori Hasegawa, Yukio Yuzawa. *Nephrology, Fujita Health University School of Medicine, Toyoake, Aichi-ken, Japan.*

Background: The aim of this study was to investigate the clinical significance of serum and urinary levels of free light chains (sFLCs,uFLCs) in ambulatory patients with chronic kidney disease (CKD).

Methods: A total of 76 ambulatory CKD patients whose estimated glomerular filtration rate was below 60 mL/min/1.73 m^2 and who were not receiving dialysis were enrolled between February 2010 and November 2010. The levels of sFLCs and uFLCs were measured and their relationships with clinical characteristics and renal prognosis were assessed.

Results: Both kappa sFLC and lambda sFLCs levels differed significantly among CKD3, CKD4, and CKD5 (P<0.0001). Kappa and lambda sFLCs were negatively correlated with Hb (r=-0.377, P=0.001, r=-0.393, P<0.0001, respectively) and LDL cholesterol(r=-0.358, P=0.002, r=-0.428, P<0.0001, respectively). Log [kappa uFLCs/gCr] was positively correlated with log [urinary albumin creatinine ratio (UACR)] (r=0.378, P=0.0001) and log [urinary liver-type fatty acid-binding protein (uL-FABP)/gCr] (r=0.610, P<0.0001). Log [lambda uFLCs/gCr] was positively correlated with log [UACR] (r=0.413, P<0.0001) and log [uL-FABP/gCr] (r=0.598, P<0.0001). The patients were clinically followed for a median period of 18months. Fifteen patients became dialysis-dependent. The best cut-off value for dialysis dependence was 225μg/gCr of kappa uFLCs/gCr (AUC0.741; sensitivity66.7%, specificity75.4%) and 37μg/gCr of lambda uFLCs (AUC0.783; sensitivity 80.0% specificity 67.3%) according to the ROC curves. Kaplan-Meier survival curves for dialysis dependence according to kappa and lambda uFLCs are presented in Figure 1.



The rate of dialysis dependence was significantly higher among patients with kappa or lambda uFLCs over cut-off levels.

Conclusions: Levels of uFLCs may be useful for predicting renal outcome in CKD patients.

TH-PO332

Serum Free Light Chains (sFLC) Allow Improved Risk Stratification of Chronic Kidney Disease (CKD) Patients for Progression to End Stage Renal Disease (ESRD) Hannah Louise Church,[1] Anne Bevins,[2] Colin A. Hutchison,[1] Paul Cockwell.[1] *[1]Renal Medicine, University Hospital Birmingham, Birmingham, United Kingdom; [2]Research and Development, The Binding Site Group Ltd, Birmingham, United Kingdom.*

Background: Around 12% of adults have CKD. Only a small proportion of these will progress to ESRD, therefore it is important to risk stratify to allow directed and enhanced care. The aim of this study was to assess the utility of serum immunoglobulin free light chain (sFLC) and urinary (uFLC) as independent risk factors for progression to ESRD.

Methods: Data was collected from 867 patients attending a secondary care CKD clinic with CKD stages 1-5 (pre-dialysis) with a median follow up of 1210 days. At recruitment laboratory markers were measured including serum (s) and urinary (u) FLC. Progression was defined as initiation of dialysis or pre-emptive renal transplantation (renal replacement therapy, RRT).

Results: 169 patients (19.5%) progressed to RRT; this group had higher polyclonal (kappa, κ and lambda, λ) s(κ median 60.20mg/L, range 10.10-278.0, λ 56.80mg/L, 9.09-256.0) and u(κ 115.0, 1.66-640.0, p<0.001, λ 34.2, 0.07-225.0, p<0.001) FLC compared to those who did not progress to RRT (s κ23.25, 0.78-184.0, λ 29.02, 3.31-210.0; u κ 32.3, 0.31-663.0, λ 5.01, 0.7-215.0). Univariate analysis showed that both s(κ OR 10.929, 7.445-16.044, λ 14.723, 9.506-22.803) and u(κ OR 2.045, 1.654-2.528, p<0.001, λ 2.044, 1.689-2.475, p<0.001) FLC were predictive of RRT. Multivariate analysis of categorical results, including all significant variables (p<0.1) without co-linearity showed that ACR (mg/mmol) ≥30 (OR 11.508), eGFR (OR 31.594) and λ sFLC (2.668) were independently predictive. Using the same model with combined λ and κ sFLC (cFLC) showed that eGFR (OR 28.202), ACR ≥30 (OR 12.542, p<0.001), ACR 3.5-30 (OR 3.705, p=0.036), eGFR (OR 28.202, p<0.001) and cFLC (OR 3.521, p=0.006) were independently predictive. Using this model 91.7% of patients progressing to ESRD would have been identified (ROC, AUC = 0.917, p<0.001). uFLC provide no additional utility over ACR and were therefore excluded from the final model.

Conclusions: Combined sFLC allows improved risk stratification of RRT in patients with CKD.

TH-PO333

Combined Serum Free Light Chains Independently Predict Progression in Chronic Kidney Disease James Ritchie,[1] Lakhvir Assi,[2] Richard Hoefield,[1] Paul Cockwell,[3] Stephen Harding,[2] Philip A. Kalra.[1] *[1]Vascular Research Group, Salford Royal NHS Foundation Trust, Manchester, United Kingdom; [2]The Binding Site Group Ltd, Birmingham, United Kingdom; [3]The Renal Research Group, Queen Elizabeth Hospital, Birmingham, United Kingdom.*

Background: Chronic kidney disease (CKD) is a heterogeneous condition, in which the majority of patients will not reach end-stage renal disease (ESRD). It is therefore important to accurately risk assess patients for disease progression so that treatment can be targeted accordingly. The aim of this study was to evaluate the prognostic value of polyclonal serum free light chains (FLC) in CKD stage 3-5 patients.

Methods: FLC (Freelite™) were determined in CKD patients enrolled as part of the Chronic Renal Insufficiency Standards Implementation Study (CRISIS). Established normal ranges were used (κ: 3.3-19.4mg/L, λ: 5.71-26.3mg/L). Combined FLC (cFLC; κ+λ) and κ/λ ratios were also calculated. 75/756 (10%) were CKD stage 5 patients. Time to renal replacement therapy (RRT) was assessed using Kaplan Meier and Cox regression analysis, using variables on a linear scale. Mortality was included as a competing endpoint in the analysis. The median follow-up time was 40 months.

Results: At baseline, cFLC were elevated (>50mg/L) in 566/756 (75%) patients and 161/756 (21%) patients had gone on to require RRT. Of these patients, 98% had cFLC>50mg/L (median: 98.6mg/L, IQR: 52.8). Patients who did not require RRT had significantly lower cFLC (median: 63.05mg/L, IQR: 46.33), p<0.001. cFLC were significantly associated with RRT (p<0.001). Multivariate analysis identified elevated cFLC (hazard ratio (HR: 1.007, p<0.001)), gender (HR: 1.9, p=0.004), reduced eGFR (HR: 0.89, p<0.001), high sodium (HR: 1.15, p<0.001) and erythrocyte sedimentation rate (ESR) (HR: 0.9, p=0.05) to be independently associated with reduced time to RRT. Interestingly, proteinuria, a known risk factor for CKD progression, was not significantly associated, suggesting cFLC may be a more sensitive predictor.

Conclusions: cFLC provide independent prognostic information for CKD patients who progress to ESRD requiring RRT. Further work will determine how cFLC can be prognostically used to manage these patients.

TH-PO334

Renal Prognosis in Atherosclerotic Renovascular Disease: Effects of Baseline Proteinuria and eGFR James Ritchie, Darren Green, Philip A. Kalra. *Vascular Research Group, Salford Royal Hospital.*

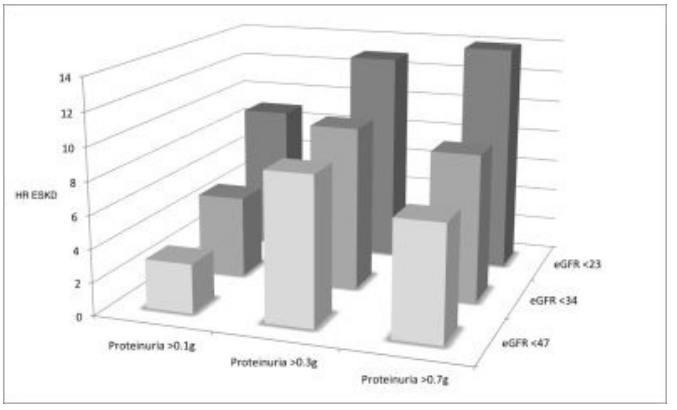
Background: In atherosclerotic renovascular disease (ARVD) associations are described between severity of renal impairment and risk for death, and between proteinuria >0.6g/day and progressive eGFR loss after revascularization. Little data exist describing the effects of these baseline variables on renal prognosis.

Methods: Tertiles of baseline eGFR and 24-hour proteinuria were identified in 333 patients within our ARVD database. Cox regression was used to calculate hazard ratios (HR) for progression to ESKD (eGFR<10ml/min or dialysis) for all combinations of these groups.

Time averaged change in eGFR was calculated for all patients and logistic regression used to calculate odds ratios (OR) for loss of eGFR >1ml/min/year.

Analyses were adjusted for age, gender and blood pressure.

Results: For each eGFR tertile, an increase in proteinuria associated with an increased HR for ESKD. The same was observed for reducing eGFR within each proteinuria tertile. Even mild renal impairment and low-grade proteinuria (eGFR <47ml/min/1.73m^2, proteinuria >0.1g/24 hours) significantly increased HR for ESKD (HR 3.4, p=0.003). The highest risk was observed for patients in the uppermost tertile for renal impairment and proteinuria - eGFR <23ml/min/1.73m^2 and proteinuria >0.7g/24 hours (HR ESKD 13.8, p<0.001).



Baseline renal function was not associated with a change in OR for more rapid eGFR loss, but patients with baseline proteinuria in excess of 0.7g/24 hours were significantly more likely to lose eGFR at a more rapid rate (OR 2.3, p=0.029).

Odds Ratio for eGFR loss >1ml/min/year

eGFR	**<23**	**23-34**	**34-47**	**>47**
OR	Referent	1.3	0.8	0.7
Proteinuria	**<0.1g**	**0.1-0.3g**	**0.3-0.7g**	**>0.7g**
OR	Referent	1.2	1.7	2.3*

* p<0.05

Conclusions: Changes in baseline eGFR and proteinuria have a synergistic effect on risk profile for ESKD in ARVD. Baseline proteinuria, but not eGFR, alters risk for rapid loss of eGFR during follow-up.

TH-PO335

Predicting Progression to ESKD in Atherosclerotic Renovascular Disease: A Decision Tree Analysis James Ritchie, Darren Green, Philip A. Kalra. *Vascular Research Group, Salford Royal Hospital.*

Background: Trial data have shown patients with atherosclerotic renovascular disease (ARVD) have a 2% annual rate of progression to dialysis. Whilst large elevations in serum creatinine (sCr) or proteinuria have been associated with a worse renal prognosis, the values of these variables with the greatest prognostic significance have not been defined. As such it is challenging for clinicians to identify ARVD patients at the highest risk for progression to ESKD.

Methods: Our tertiary renal center has prospectively recorded data on all referred ARVD patients since 1995 (n=819). All records were updated to identify any patients progressing to chronic dialysis or ESKD without dialysis (eGFR<10ml/min^2). Using a combined vector of sensitivity plus specificity, the threshold value of the baseline variable that maximally discriminated for progression to ESKD was identified. This value dichotomized our patient group. The analysis was repeated for both patient groups to generate a decision tree that classified the hierarchal rank of baseline variables and their threshold values. Analyses were repeated until statistical power was exhausted. A scoring system to assess baseline risk of progression to ESKD was generated from the decision tree, with greatest weight placed on most commonly identified variables. The scoring system was applied to the study population, with hazard ratios and c-statistics calculated to internally validate this system.

Results: Identified baseline variables and threshold values were:

1 - sCr (130, 200, 300μmol/L)

2 - urine protein:creatinine ratio (40, 60mg/mmol)

3 - previous stroke or transient ischemic attack

4 - use of statin and angiotensin blockade. Applying an ordinal scoring system to these parameters, patients with a score ≤3 had a significantly reduced, and patients with a score ≥4 a significantly increased HR for ESKD. A score of ≥4 had a sensitivity of 67% and specificity of 72% for identifying patients progressing to ESKD.

SCORE	**HR for ESKD**	**c-statistic**	**Sensitivity/Specificity**
0-3 (n=524)	0.25*	0.72	33/28
4-8 (n=295)	4.06*	0.75	67/72

* = p<0.001

Conclusions: This study suggests identification of ARVD patients with highest and lowest risk for ESKD may be possible at time of diagnosis.

TH-PO336

Chronic Kidney Disease, Lipids and Apolipoproteins and Coronary Heart Disease: The Atherosclerosis Risk in Communities Study Julio A. Lamprea-Montealegre,[1] A. Richey Sharrett,[1] Elizabeth Selvin,[1] Kunihiro Matsushita,[1] Moyses Szklo,[1] Brad C. Astor.[2] *[1]Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Medicine, University of Wisconsin, Madison, WI.*

Background: Chronic kidney disease (CKD) is associated with altered apolipoprotein A-1 (apo A-1) and apolipoprotein B (apo B) to A-1 ratios. It is not known whether these ratios are more strongly associated with the risk of coronary heart disease (CHD) in CKD than traditionally measured lipids and lipoprotein cholesterol concentrations.

Methods: We investigated the association of baseline apo B and A-1 ratios with risk of CHD in 10,137 individuals free of CHD at baseline (Visit 4) in the ARIC Study. CKD was defined as an estimated glomerular filtration rate (eGFR)<60ml/min/1.73 m^2 based on a cystatin C measurement. Cox proportional hazards regression models were used to evaluate the association of lipid and apolipoprotein ratios with the risk of CHD in those with and without CKD with adjustment for demographic factors and established cardiovascular risk factors.

Results: The median follow-up time for the entire cohort was 11.13 years. A coronary heart disease event developed in 498 individuals without CKD (incidence rate: 5.2 events per 1,000 person-years) and in 138 individuals with CKD (incidence rate: 12.0 events per 1,000 person-years). CKD was present in 1,217 (12%) individuals at baseline. Individuals with CKD had a lower mean concentration of apo A-1 and a higher apo B to A-1 ratio than those without (p<0.001). Among individuals with CKD, the apo B to A-1 ratio and the non-high density lipoprotein cholesterol (non-HDL-c) to high density lipoprotein cholesterol (HDL-c) ratio were both associated with the risk of CHD: hazard ratios (HR) and 95% confidence intervals (CI) per one standard deviation increase= 1.22 (1.04-1.42) for the apo B to A-1 ratio and 1.30 (1.06-1.59) for the non-HDL-c to HDL-c ratio.

Conclusions: Although prevalent CKD was associated with a lower apo A-1 concentration and with a higher apo B to A-1 ratio at baseline, we found no evidence that these apolipoproteins are more strongly associated with CHD incidence than the non-HDL-c to HDL-c ratio.

TH-PO337

Unrecognised Chronic Kidney Disease: Who Is at Risk? Andrew Smyth,[1,2] Michelle Canavan,[1] Liam G. Glynn,[3] Martin O'Donnell,[1] Donal N. Reddan.[2] *[1]HRB Clinical Research Facility Galway, National University of Ireland, Galway, Galway, Ireland; [2]Nephrology, Galway University Hospitals, Galway, Ireland; [3]General Practice, National University of Ireland, Galway, Galway, Ireland.*

Background: Chronic kidney disease (CKD) is highly prevalent but often unrecognized in primary care. MDRD formula and CKD-EPI definitions of CKD have limitations and may result in misclassification of CKD. In this study, we explore which patient populations are at risk of unrecognised CKD, using either formula.

Methods: The *C*ardiovascu*lar* Mulitmorbid*ity* in Primary Care Study (CLARITY) is a cross-sectional study of community-dwelling adults ≥50 years recruited from a university-affiliated primary care research network. Of 9,816 patients recruited, 8,932 had serum creatinine measured from which estimated glomerular filtration rate (eGFR) was calculated. For this study, we included only participants with CKD defined as an eGFR≤60ml/min/1.73m^2 using either the MDRD or CKD-EPI equation. Risk factors for unrecognised CKD, defined as no documentation of CKD in the patients case file, were identified by step-wise multivariable logistic regression that included the following predictor variables: age, gender, smoking history, outpatient clinic attendance, hypertension, heart disease and diabetes mellitus. Analysis was performed using SPSS version 20.0.

Results: Using the MDRD equation, 1,319 patients were identified with CKD; 81.8% (n=1,079) were unrecognised and independent risk factors included female sex (OR 1.68, 1.22-2.34) and older age (OR 1.02, 1.00-1.04) on multivariable analysis. Using the CKD-EPI equation, 1,587 patients were identified with CKD; 83.9% (n=1,332) were unrecognised and independent risk factors continued to include female sex (OR 1.59, 1.16-2.17) and older age (OR 1.04, 1.02-1.06) on multivariable analysis. Patients with unrecognized CKD had higher systolic and diastolic blood pressure and were less likely to be prescribed ACE/ARB than patients with recognized CKD.

Conclusions: A large proportion of CKD is unrecognised and older females are at particular risk, independent of the equation used for eGFR. Patients with unrecognized CKD have higher blood pressure and are less likely to be prescribed ACE/ARB.

TH-PO338

GFR Variability and Risk of ESRD among Patients with Stage 3 CKD Robert M. Perkins, H. Lester Kirchner, James E. Hartle, Ion D. Bucaloiu. *Geisinger Clinic.*

Background: Dynamic changes in estimated GFR (eGFR) predict death among patients with CKD. Whether variability in serial eGFR measurements is associated with risk of ESRD has not been reported.

Methods: We retrospectively analyzed the risk of ESRD as a function of eGFR variability (defined as the absolute value of the difference between the obtained clinical eGFR value at a given time and the eGFR value estimated by the linear regression line at the same time point) among a cohort of patients with stage 3 CKD. The source population was adult primary care patients enrolled at Geisinger Clinic between January 1, 2004 and December 31, 2006, and who had stage 3 CKD. Patients were excluded for a prior history of solid-organ transplant or metastatic cancer. Cohort members were followed through March 31, 2011 for ESRD (identified through linkage with the USRDS dataset of ESRD, or first outpatient eGFR < 15 ml/min/1.73m^2). A multivariate Cox proportional hazard model (adjusted for demographic factors, co-morbid conditions, medications, hospital-associated acute kidney injury, proteinuria, kidney function, and serum albumin, among other factors) was developed to test the association of eGFR variability with ESRD.

Results: 4219 patients met study criteria. Those with greater eGFR variability were more likely to have diabetes, cardiovascular disease, and better baseline kidney function than those with lesser variability. 193 (4.6%) of the overall cohort developed ESRD during a median follow-up of 3.8 years, while 596 (14.1%) died prior to study end and without ESRD. Results of the multivariate-adjusted Cox proportional hazard model showed that eGFR variability is not associated with ESRD (HR 1.00 for the highest-variability quartile, relative to the lowest; 95% CI 0.66-1.51).

Conclusions: EGFR variability does not predict ESRD among patients with stage 3 CKD, and may have potential as a risk discriminator for the outcomes of death and ESRD among those with stage 3 CKD.

TH-PO339

Predictors of the Rate of Progression to Dialysis Dependence in Stage Five Chronic Kidney Disease David Langsford,[1] Karen Wills,[3] Lisa Shelverton,[2] Matthew D. Jose,[2,3] Geoffrey S. Kirkland,[2] Richard Yu.[2] *[1]Department of Nephrology, St Vincent's Hospital, Melbourne, Australia; [2]Department of Nephrology, Royal Hobart Hospital, Hobart, Australia; [3]Menzies Institute Tasmania, Australia.*

Background: There is little data on markers that predict the progression of the rate of decline of chronic renal failure (CKD) to the commencement of dialysis in incident stage V CKD patients. We investigated whether objective clinical markers may be independent predictors of progression to dialysis dependence in patients with stage V CKD.

Methods: Data from all CKD patients commencing dialysis at the Royal Hobart Hospital between 2009-2011 was captured. The time interval between the first recorded eGFR of 15ml/min/1.73m^2 or less and commencement of dialysis was recorded. Other baseline variables recorded at the time of eGFR 15ml/min/1.73m^2 were age, gender, smoking status, diabetes status, blood pressure, erythropoetin stimulating agent use, body mass index,haemoglobin, albumin, calcium, phosphate, ferritin, bicarbonate and urinary albumin:creatinine. The data was analysed using Cox proportional hazard regression and log-rank test of equality.

Results: Ninety-one patients were recruited, of which sixty-eight have progressed to dialysis dependence. The mean age of the all patients was 60.8 years, 63.7% were male and 38.5% were diabetic. Baseline blood pressure was not predictive of dialysis dependence and older age tended to attenuate rate of progression to dialysis dependence (p=0.06). Of the biochemical markers for every 1gm/litre decrease in serum albumin there was a 6.7% increase in the risk of progression to dialysis dependence (p=0.000). In those patients who progressed to dialysis dependence those with a serum albumin of less than 35gm/litre had a mean rate of decline of eGFR of 1.18ml/min/1.73m^2 per month compared with those with a serum albumin greater than 35gm/litre who declined at a rate of 0.41ml/min/1.72m^2 per month (p=0.01).

Conclusions: Low serum albumin at the time of reaching stage V chronic kidney disease is an independent predictor of time to dialysis dependence. In patients with serum albumin less than 35gm/litre the rate of decline is 2.6 times faster than those with serum albumin greater than 35gm/litre.

TH-PO340

Postoperative Renal Function after Uninephrectomy in Patients with Chronic Kidney Disease Stage 3 to 5: Predictive Factors of Renal Function Loss Dominique Dupuis,[1] Georges Ouellet,[2] Louise Roy.[1] *[1]Nephrology, Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Nephrology, Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: The rapid compensation of renal function loss by a normal controlateral kidney after uninephrectomy (NPX) is established. The purpose of this study is to determine if this initial compensatory capacity of the controlateral kidney is still present in CKD stage 3 to 5 patients undergoing NPX and which factors influence it.

Methods: We reviewed all cases (142) of NPX in patients with eGFR (following MDRD equation) < 60ml/min/1,73m^2, between 2003 and 2010, in 2 University of Montreal affiliated teaching hospitals. Baseline eGFR, patients comorbidities and surgical characteristics and complications were noted. The expected post-op eGFR, if no compensation by the controlateral kidney following surgery, was estimated according to the pre-op split renal function measured with scintigraphy (DTPA) (or assuming 50% if scintigraphy not available); this result was compared to the actual eGFR at hospital leave.

Results:

Renal Function at Baseline and at Hospital Leave

	Baseline eGFR ≤40ml/min/1,73m2 (n=34)	Baseline eGFR 40 to 59ml/min/1,73m2 (n=108)
Baseline eGFR	33±7	52±5
Expected postoperative eGFR	18±6*	28±6*
Actual eGFR at hospital leave	29±13	47±14
Variation between baseline eGFR and eGFR at hospital leave	-3±10 (-13%)	-6±14 (-10%)
Variation between expected and actual postoperative eGFR	-13±10#	-19±13

Results are Mean ± SEM (eGFR ml/min/1,73m2) / * p<0.001 vs eGFR at hospital leave; # p0.025 vs group baseline eGFR > 40

In the multivariate model, pre-op arterial hypertension and radical NPX significantly decreased the variation between expected and actual post-op eGFR by 7ml/min/1,73m^2 (p<0,05). Our model did not demonstrate a significant impact of other comorbidities and surgical considerations on the outcome.

Conclusions: After NPX, the controlateral kidney in patients with CKD stage 3 to 5 has a clinically significant initial compensatory capacity. The compensation is statistically smaller if initial eGFR is lower, if patient had hypertension or a radical NPX. This compensation is rapid and most probably hemodynamic (hyperfiltration).

TH-PO341

Fibroblast Growth Factor 23 and Peripheral Artery Disease in the Cardiovascular Health Study Pranav S. Garimella,[1] Joachim H. Ix,[2] Ronit Katz,[3] M. Chonchol,[4] Bryan R. Kestenbaum,[3] Ian H. de Boer,[3] David Siscovick,[3] Shani Shastri,[5] Jade S. Hiramoto,[6] Michael Shlipak,[6] Mark J. Sarnak.[7] *[1]Cook County Hospital; [2]UC San Diego; [3]University of Washington; [4]University of Colorado; [5]UT Southwestern Medical Center; [6]UC San Francisco; [7]Tufts Medical Center.*

Background: High serum fibroblast growth factor 23 (FGF23) is associated with increased risk of cardiovascular disease and progression of kidney disease, but its association with the ankle brachial index (ABI) and clinical peripheral artery disease (PAD) is unknown.

Methods: We investigated the cross sectional relationship between serum FGF23 (1996-97) and ABI (1998-99) in 2,432 individuals and the longitudinal association of FGF23 and incident PAD (events committee adjudicated) in 3,143 persons without clinical PAD. Multinomial logistic and Cox regression models were used for the respective analyses.

Results: Mean (SD) age was 77 (4) years, 60% were women and 15% were blacks. Median FGF23 was 68 RU/ml. In cross-sectional analyses, FGF23 was not associated with ABI. For each doubling of FGF (with ABI of 1.0-1.4 as the reference group) the OR's and 95% CI were: ABI<0.90, 0.91 (0.76-1.08); ABI 0.90-1.10, 0.88 (0.77-1.01); and ABI >1.40, 1.06 (95% CI 0.75-1.51).There were 114 incident PAD events with median follow up of 9.8 years. Higher FGF 23 was associated with PAD; however, this relationship was attenuated by measures of kidney function.

Association of FGF23 with incident PAD

Continuous FGF23 (per doubling)	Model 1*	Model 2**	Model 3†
<53.63	1.00 (ref)	1.00 (ref)	1.00 (ref)
53.63 – 70.84	1.11 (0.59, 2.06)	1.03 (0.55, 1.92)	0.89 (0.48, 1.67)
70.85 – 100.38	1.81 (1.02, 3.20)	1.50 (0.84, 2.67)	1.12 (0.66, 2.14)
>100.38	3.25 (1.88, 5.62)	2.40 (1.37, 4.22)	1.51 (0.82, 2.78)

* Age, gender and race ** Smoking, DM, HTN, CHD, CHF, CVA, LDL, HDL, CRP, albumin, triglycerides. † Model 2 plus cystatin C and albuminuria

Conclusions: High FGF23 is associated with incident PAD but this relationship is not significant after adjusting for kidney function. It remains to be determined whether kidney function is a confounding or mediating variable in this relationship.

TH-PO342

FGF23 and Asymmetrical Dimethylarginine (ADMA) Are Interactive Factors in the High Risk for CKD Progression in Stage 2-5 CKD Patients Carmine Zoccali, Daniela Leonardis, Giovanni Tripepi, Giuseppe Enia, Francesca Mallamaci. *On Behalf of MAURO Working Group, Nephrology Unit and CNR-IBIM, Reggio Calabria, Italy.*

Background: FGF-23 is a phosphate-regulating factor which has been associated with endothelial dysfunction and raised plasma ADMA in stage 3-4 CKD patients. Since both FGF23 and ADMA induce renal damage in experimental models, these associations may be implicated in the risk of CKD progression.

Methods: We investigated a) the cross-sectional association between FGF23 and ADMA with the GFR and their interaction in a large cohort (n=759) of stage 2-5 CKD pts and b) tested the interaction between FGF-23 and ADMA for predicting renal disease progression in the same cohort (follow-up: 3 yrs).

Results: FGF23 and ADMA were directly inter-related (r=0.15, P<0.001) and associated with the eGFR (r=-0.48 and r=-0.21, both P<0.001). These relationships held true (P<0.001) in analyses adjusting for potential confounders including proteinuria. The FGF23-eGFR link varied across ADMA quartiles (P=0.016 for effect modification) because a 100 pg/ml difference in FGF23 signalled a 4.0 ml/min decrease in GFR in the 1st ADMA quartile but only a 2.0 ml/min decrease in the 4th ADMA quartile. In the cohort study, 244 pts had renal events (>30% GFR decrease/dialysis/transplantation). Both FGF23 [HR: 1.12, 95% CI: 1.05-1.19, P=0.001] and ADMA [HR:1.08, 95% CI: 1.01-1.15, P=0.027] predicted renal events in analyses adjusting for eGFR, proteinuria and other confounders. Similarly to the cross-sectional analysis, an effect modification by ADMA was found on the relationship between FGF23 and renal events because the risk for these events portended by a 100 pg/ml increase in FGF23 was maximal in patients in the 1st ADMA quartile (HR:1.25, 95% CI: 1.13-1.39, P<0.001), intermediate in those in the 2nd and in the 3rd quartiles and minimal in the 4th ADMA quartile (HR: 1.06, 95% CI: 0.97-1.17, P=NS).

Conclusions: High levels of FGF-23 and ADMA interact for predicting renal disease progression in stages 2-5 CKD pts. The effect of FGF23 on the risk of CKD progression is modified by ADMA suggesting that the nitric oxide system is a relevant pathway whereby FGF23-klotho may affect health outcomes.

TH-PO343

A Dynamic Predictive Model for the Progression of Chronic Kidney Disease to Kidney Failure Navdeep Tangri, Lesley Stevens Inker, David M. Kent, John Griffith, Ognjenka Djurdjev, David M. Naimark, Adeera Levin, Andrew S. Levey. *Medicine, University of Manitoba, Winnipeg, MB, Canada.*

Background: Predicting the progression of CKD is important for treatment decisions and for informing patient provider communication. We have previously developed a highly accurate *static* prediction model for the progression of CKD that used one time values. In this analysis, we describe a *dynamic* prediction model for CKD progression that includes changes in laboratory variables between visits as additional predictors of outcome.

Methods: We developed the dynamic prediction model using longitudinally collected data from patients with CKD Stages 3 to 5 referred to nephrologists. Our static model included age, gender, and eGFR, urinary ACR, serum albumin, phosphorous, calcium and bicarbonate. The dynamic model added change in laboratory variables between visits. We used cox proportional hazards models and compared discrimination (IDI), calibration (Hosmer Lemeshow Chi Square), model fit (AIC) and net reclassification (NRI) at 3 years.

Results: We studied 3,004 patients with an average of 5 visits (range 1-22) over a median follow up period of three years. The addition of change in eGFR, as well as an interaction term of the change in eGFR and subsequent eGFR were independently associated with the outcome, and improved model fit and discrimination (Table 1).

Table 1: Performance characteristics of static vs dynamic model

Visit	N	Static Model Chi Square	Dynamic Model Chi Square	Static Model AIC	Dynamic Model AIC	IDI	NRI
1	3,004	140	N/A	3988	N/A	N/A	N/A
2	2,582	327	156	3455	3447	1.0 (-0.7, 3.0)	9.1 (-0.7, 27.3)
3	2,250	179	37	3123	3112	3.2 (1.1, 5.4)	19.6 (5.3, 37.8)
4	1,965	180	21	2770	2743	2.8 (-0.1, 6.1)	10.4 (-6.4, 27.4)
5	1,721	156	11	2449	2435	2.8 (4.5, 6.2)	22.4 (6.7, 42.2)
6	1,512	193	7	2303	2269	4.6 (1.0, 7.4)	42.8 (21.8, 62.1)

Improvements in model fit, calibration and reclassification were also noted after 5 visits. (HL chi square <20 for dynamic model, continuous NRI 22.4 %). Changes in the remaining laboratory parameters did not significantly improve model performance (p IDI > 0.10).

Conclusions: A dynamic predictive model combining changes in eGFR between nephrology clinic visits can improve risk prediction for kidney failure over a static model that uses only a single eGFR. Integration of dynamic models in electronic health records deserves further study.

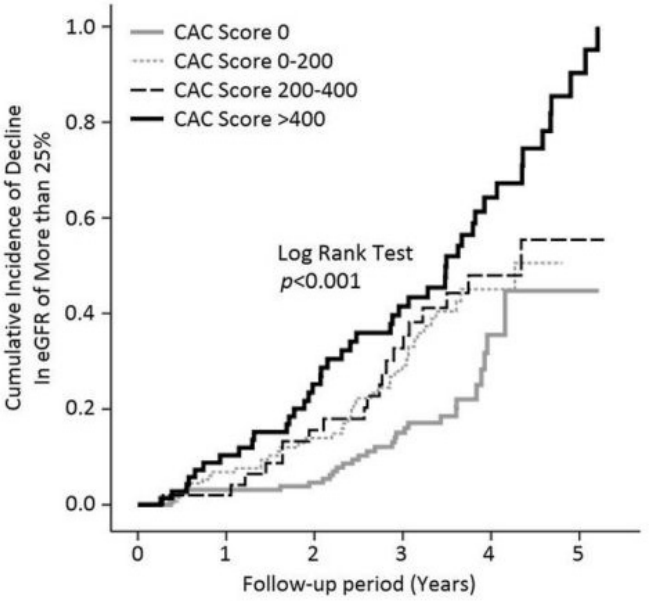
TH-PO344

Coronary Artery Calcification as a Predictor of Chronic Kidney Disease Progression Shuo-ming Ou,[1] Der-Cherng Tarng,[1,2] Yao-ping Lin,[1,2] Jinn-Yang Chen,[1,2] Chih-Ching Lin,[1,2] Wu-Chang Yang.[1,2] *[1]Division of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan; [2]School of Medicine, National Yang-Ming University, Taipei, Taiwan.*

Background: Chronic kidney disease is known to have a higher risk for increased coronary artery calcification (CAC); however, little is known about whether increased CAC itself has a pathogenic link to microvascular disease, leading to renal function deterioration.

Methods: This retrospective cohort study enrolled 422 adults (M/F 305:117; age= 61.0±11.9 years) who received electron-beam computed tomography examinations of the coronary arteries during physical check-up and had been followed for ≥ 2 years. These patients were categorized into 4 groups according to their CAC score by Agatston system (Q1: 0, n = 163; Q2: 1~199, n= 136; Q3: 200~399, n=51 and Q4: ≥400, n=72). Glomerular filtration rate (eGFR) was estimated by the Modification of Diet in Renal Disease formula. Primary end point was defined as a decline in eGFR ≥ 25%.

Results: The baseline eGFR was comparable among these 4 groups (mean eGFR=93.5~99.2 ml/min/1.73m2, $p = 0.386$). During a follow-up period of 1,120 patient-years, 32% of patients had a decline in eGFR ≥ 25%. The independent risk factors for decline in eGFR ≥ 25% include diabetes (HR= 1.975, $p < 0.001$), age≥60 (HR= 1.824, $p < 0.001$), higher body mass index (HR= 1.055, $p = 0.045$), higher coronary artery calcification score (HR 1.004, $p = 0.003$ per 10 scores). Patients with higher CAC score had significantly higher risks for renal function deterioration.



Conclusions: Our findings showed that the long-term outcome of increased CAC score is associated with a higher risk of renal function deterioration. The possible mechanism is that patients with macrovascular disease might have established pre-existing microvascular diseases leading to further renal function deterioration.

TH-PO345

Risk Factors for End Stage Renal Disease and Death in Advanced Chronic Kidney Disease Patients Laura Sola,[1,2] Nancy De Souza,[1,2] Pablo German Rios,[2] Emma Schwedt,[2] Nelson Mazzuchi.[2] *[1]Advanced CKD Clinic, Hospital Maciel, Uruguay; [2]Renal Healthcare Program, Uruguay.*

Background: Patient's referral to nephrologists allows implementing measures to slow progression and reduce the risk (R) of death in patients (Pts) with advanced chronic kidney disease (ACKD). The objective of this study is to evaluate R factors (RF) for death and End Stage Renal Disease (ESRD) in ACKD Pts in the Renal Health Program of Uruguay (RHP-U) Registry.

Methods: Pts registered in the RHP-U (10/1/2004-10/1/2011) were included if estimated glomerular filtration rate (eGFR) was < 30 ml / min in ≥ 2 controls and follow-up≥ 90 days. At each visit were registered: systolic (SBP) and diastolic (DBP) blood pressure, proteinuria, cholesterol and triglycerides levels, renin angiotensin system blockers (RAS-B) use. Late referral was defined as registered in ACKD. Formal multidisciplinary team (FMT) was compared to usual care. ESRD and death rates were calculated and RF were analyzed with Cox regression model. Was considered significant p <0.05.

Results: Of 991 Pts, 483 (48.7%) males, mean age 69.9 ± 13.5 years (ys), 405 (41%) had diabetes (D), and 235 (23.8%) ischemic heart disease (IHD). Most frequent nephropathies were D 187 (18.9%) and vascular 398 (40.2%). During follow-up (median 1.57 (IQ: 0.90-2-57) ys) 123 Pts died (6.63 /100 pts-ys) and 161 Pts reached ESRD (8.68 / 100 pts-ys). Rapid progression (eGFR loss ≥ 3 ml/min/year), in 399 pts (40.3%) increased with higher SBP (OR: 1.015: 1,007-1.024), proteinuria (OR 1.383: 1.166-1.641), and D nephropathy (OR 1,485: 1047-2104). ESRD risk increased with SBP (HR 1.016: 1.006-1.026), proteinuria (HR 1.183: 1.056-1.325), age <45 ys (HR 2.35: 1.25 -4.41), phosphatemia(HR 1.20: 1.09-1.31), and late referral (HR 3.77: 2.39- 5.95); and decreases with RAS-B use (HR 0.59: 041-084) and FMT (HR 0.56:0.36-0.86). Death risk increased in males (HR 1.66: 1.14-2.43), age (HR 1.05: 1.03-1.07) proteinuria (HR 1.24:1.06-1 .44) and IHD (HR1.97:1.44-2.71) and was reduced by FMT (HR 0.58:0.35-0.94).

Conclusions: Proteinuria is a common RF for death and ESRD. Using RAS-B and PAS control reduces ESRD risk. Early referral to nephrologists and a FMT care allow the reduction of CKD progression and death.

TH-PO346

Hyperuricemia Is Associated with Proteinuria in Women, but Not in Men: A Cross-Sectional Study of Japanese General Population Masao Kikuchi,[1] Shouichi Fujimoto,[2] Yuji Sato,[1] Kazuo Kitamura,[1] Tsuneo Konta,[3] Kunitoshi Iseki,[3] Toshiki Moriyama,[3] Hideaki Yoshida,[3] Koichi Asahi,[3] Tsuyoshi Watanabe.[3] *[1]First Department of Internal Medicine, University of Miyazaki Hospital, Miyazaki, Japan; [2]Department of Hemovascular Medicine and Artificial Organs, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan; [3]Steering Committee for the 'Research on the Positioning of Chronic Kidney Disease (CKD) in Specific Health Check and Guidance in Japan', Japan.*

Background: Hyperuricemia is associated with an increased risk of metabolic syndrome, type 2 diabetes mellitus, cardiovascular disease and chronic kidney disease, as well as gout. However, there is pronounced sex difference in the levels of uric acid.

Methods: We assessed the prevalence of proteinuria according to serum uric acid (SUA) among 228,778 patients in a Japanese nationwide database. There were 89,877 men and 138,901 women. We designed the basic model with SUA decile as categorical variable. Proteinuria is defined as 1+ or more by a dipstick method. We examined the association among SUA, age, body mass index (BMI), systolic blood pressure (SBP), diastolic blood pressure (DBP), pulse pressure (PP), fasting glucose, hemoglobin A1c (HbA1c), triglycerides (TG), high density lipoprotein-cholesterol (HDL-C), low density lipoprotein-cholesterol (LDL-C) and estimated glomerular filtration rate (eGFR) separately in men and women.

Results: In both men and women, TG, LDL-C, BMI, SBP, DBP and PP increased with increased levels of SUA, but HDL-C and eGFR decreased with increased levels of SUA. On the other hand, fasting glucose, HbA1c and age decreased with increased levels of SUA in men, but increased in women. In a multivariable logistic regression analysis, prevalence of proteinuria increased with increased levels of SUA in women, but not in men.

Conclusions: Hyperuricemia is associated with proteinuria in women, but not in men. Further studies are necessary to clarify the cause that the sex difference of uric acid influences proteinuria.

TH-PO347

Predictors of New-Onset of Proteinuria in Japanese Population: MIYAKO (Multicenter Investigation for Yearly Medical Check Assessment in KyotO) Surveillance Shinji Yasuno,[1] Kenji Ueshima,[1] Koji Oba,[2] Sachiko Tanaka,[1] Masato Kasahara,[1] Akira Fujimoto,[1] Yoko M. Nakao,[1] Takashi Miyawaki,[3] Izuru Masuda,[4] Kazuwa Nakao.[1] *[1]Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Hokkaido University, Sapporo, Japan; [3]NTT West Kyoto Hospital, Kyoto, Japan; [4]Takeda Hospital, Kyoto, Japan.*

Background: Hypertension (HT), diabetes mellitus (DM) and dyslipidemia (DL) are known to be modifiable risk factors for proteinuria (PU). Early intervention would be desirable to prevent against new-onset of PU (NOPU), if the risk of NOPU is already increased at the lower levels than those of diagnostic criteria of HT, DM, and DL. We examined the predictors of NOPU in Japanese population, as a retrospective cohort study.

Methods: There were 29,677 and 21,824 persons who underwent an annual medical checkup in Takeda Hospital from 1998 to 2009 and NTT West Kyoto Hospital from 1996 to 2009, respectively. In this study, subjects were 23,322 individuals (mean age, 47.1; mean BMI, 23.0kg/m^2) without PU and treatment of HT, DM, and DL at baseline, who had at least more than two visits and whose first visit was before 2005. PU was defined as ≥1+ of dipsticks. Hazard ratios were calculated with the Cox regression analysis adjusted for age, sex, estimated glomerular filtration rate, body mass index (BMI), systolic blood pressure (SBP), fasting blood sugar (FBS), uric acid, and one of the following lipid parameters: total cholesterol, high density lipoprotein cholesterol (HDL-C), Triglyceride (TG), and non-HDL-C.

Results: For 6.0 years of mean follow-up, 1,806 subjects experienced NOPU. The multiple Cox regression analyses showed that higher level of SBP, FBS, and TG and lower level of HDL-C were significantly associated with the risk of NOPU. Categorical analyses revealed that the risk significantly increased at BP≥130/80mmHg, FBS≥110mg/dL, and HDL-C<40mg/dL.

Conclusions: The risk of NOPU is already increased at the lower levels than those of diagnostic criteria of HT and DM. Early intervention to those people will be needed to prevent against NOPU.

TH-PO348

Association of Visit-to-Visit Variability in Blood Pressure on Renal Function in Chinese Daoxin Yin, Dongliang Zhang, Wenhu Liu. *Department of Nephrology, Beijing Friendship Hospital, Beijing, China.*

Background: This study aimed to clarify the clinical significance of visit-to-visit variability in blood pressure on renal function in Chinese.

Methods: We enrolled 152 stage 3-4 CKD patients with hypertension at our department. All patients had been treated for at least 3 months before participating in this study. We excluded those who had atrial fibrillation, or renal artery stenosis. All patients had BP measured at outpatient visits 15 or more times during the 18 months follow-up. There are no changes in patients' antihyper-tensive regimens within follow-up. Visit-to-visit variability in BP was defined as the SD in BP, which was calculated from BP measurements at all the visits.Subjects underwent biochemical examination of the blood and urine.Clinical parameters included BMI, eGFR, albumin to creatnine ratio(ACR), current smoking, history of diabetes. Correlations between the changes in eGFR and clinical variables were analyzed by the multivariable regression analyses.

Results: Mean age was 61.5±8.8 years, mean eGFR was 41.7±15.1ml·min^{-1}·1.73m^{-2}. 94 patients were men and 58 were women. 134 patients(88.2%) were receiving anti-hypertensive agents, and 38 patients (25%) had diabetes. There is no significant difference on baseline BMI, eGFR, SBP, DBP, ACR, and percentage of diabetes and current smoking between lower SD in SBP group and higher SD in SBP group. Multivariate analysis revealed that SD in SBP and SD in DBP were independent risk factors for renal function. Without adjustment, SD in SBP and SD in DBP were significantly correlated with eGFR decline(P<0.001). In model 1, adjusted for sex, age, BMI, current smoking, baseline eGFR, baseline SBP and DBP, SD in SBP and SD in DBP were also significantly correlated with eGFR decline(P<0.001). In model 2, adjusted for model 1+with or without diabetes, SD in SBP and SD in DBP were still significantly correlated with eGFR decline(P<0.001). In model 3, adjusted for model 2+ACR, SD in SBP and SD in DBP were significantly correlated with eGFR decline too.(SD in SBP: P=0.006; SD in DBP: P<0.001).

Conclusions: Visit-to-visit variability in blood pressure was significantly associated with renal function independent of proteinuria and diabetes.

Funding: Government Support - Non-U.S.

TH-PO349

Visit-to-Visit Varibiability in Estimated Glomerular Filtration Rate Does Not Predict Worsening of Renal Prognosis Keita Uehara, Takashi Yasuda, Naohiko Imai, Yugo Shibagaki, Kenjiro Kimura. *Nephrology and Hypertension, St. Marianna University of Medicine, Kawasaki, Kanagawa, Japan.*

Background: In the AKI setting, subtle increases in serum creatinine (sCr) levels affect prognosis. Although we observed visit-to-visit fluctuations in estimated glomerular filtration rate (eGFR) in ambulatory patients, the significance of these variations on renal outcome is unknown. We examined the significance of visit-to-visit variability in eGFR on subsequent renal events.

Methods: This retrospective cohort study included patients with CKD and/or hypertension in our outpatient clinic who had eGFR measured ≥5 times at ≥4-week intervals over 2 years until August 2009. We used eGFR variability with the coefficient of variation of eGFR (eGFR-CV) and residual eGFR-CV (R-eGFR-CV), derived from a regression line of eGFR. At the time of the latest measurement of sCr among the five serial values, we performed ABPM and various tests as baseline data, and observation period started from this day. The primary endpoint was ESRD during the observation period.

Results: We examined 278 consecutive patients. At baseline, mean age was 65.0±12.7 years and mean eGFR was 47.9±24.0 ml/min/1.73 m^2. Median eGFR-CV was 0.067 (IQR: 0.045-0.079), and median R-eGFR-CV was 0.034 (IQR: 0.017-0.067), we classified subjects into 4 groups (Q1 to Q4) according to eGFR-CV and R-eGFR-CV quartiles, respectively. During a median observation period of 2.9 years (IQR: 2.1-3.5), 39 patients reached the primary endpoint. The cumulative incidence of the primary endpoint differed significantly by eGFR-CV quartiles. Multivariable Cox regression with adjustment for baseline covariates showed that eGFR-CV was a significant factor predicting the primary end point: HR for Q4, 16.9 (95%CI: 2.1-136.5) and HR for Q3, 9.8 (95%CI: 1.2-79.6) compared with Q1. On the other hand, there was no difference in the cumulative incidence of primary endpoint between each R-eGFR-CV quartile in a univariate analysis.

Conclusions: Although eGFR variability is common in patients with CKD and/or hypertension, it does not predict renal outcome when variability was adjusted by the regression line of eGFR.

TH-PO350

Associations of GFR and Albuminuria with Ischemic versus Hemorrhagic Strokes B. Khan Mahmoodi,[1] Hiroshi Yatsuya,[2] Kunihiro Matsushita,[1] Yingying Sang,[1] Rebecca F. Gottesman,[1] Brad C. Astor,[3] Mark Woodward,[1] W. T. Longstreth,[4] Bruce M. Psaty,[4] Michael Shlipak,[5] Aaron R. Folsom,[6] Ron T. Gansevoort,[7] Josef Coresh.[1] *[1]Johns Hopkins University; [2]Nagoya University (Japan); [3]University of Wisconsin; [4]University of Washington; [5]University of California, San Francisco; [6]University of Minnesota; [7]University of Groningen (Netherlands).*

Background: Although low GFR and high albuminuria have been reported associated with incident stroke, few studies compare their contribution to risk of ischemic and hemorrhagic strokes separately.

Methods: Individual participant data from four community-based cohorts from United States (ARIC, CHS, MESA) and The Netherlands (PREVEND) were pooled. To estimate adjusted hazard ratios (HRs) for stroke types, multivariable study-stratified Cox-regression was used. Standard errors for test of differences in HRs of stroke types were obtained by bootstrapping. GFR was estimated using cystatin-C-based equation (eGFR), and albuminuria was quantified by urinary albumin-to-creatinine ratio (ACR). Only adjudicated incident intraparenchymal hemorrhagic and ischemic strokes were considered.

Results: During average follow-up of 9.1 years, 1,151 of 29,429 participants developed stroke (13% hemorrhagic). Both eGFR and ACR risk-associations were roughly linear. Adjusted HRs associated with 1 SD (~22 mL/min/1.73m^2) decrease in eGFR were 1.16 (95%CI, 1.07-1.26) for ischemic versus 1.10 (0.89-1.37) for hemorrhagic stroke. In contrast, ACR showed significant association with both stroke subtypes. In fact, ACR association with hemorrhagic strokes was stronger as compared to ischemic strokes (P difference=0.026).

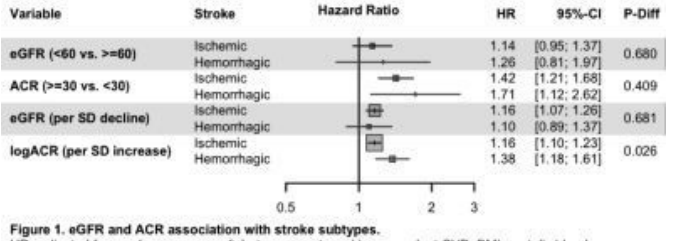

Figure 1. eGFR and ACR association with stroke subtypes.
HRs adjusted for gender, age, race, diabetes, current smoking, prevalent CVD, BMI, systolic blood pressure, cholesterol, antihypertensives and statins use. SD denotes standard deviation; P-Diff is P-value for difference of HRs of ischemic and hemorrhagic strokes.

Conclusions: While both low GFR and high albuminuria were independently associated with ischemic strokes, only ACR showed strong association with hemorrhagic strokes.

TH-PO351

The Association of Parathyroid Hormone (PTH) with ESRD and Pre-ESRD Mortality in the Kidney Early Evaluation Program (KEEP) Georges Saab,[1] Andrew S. Bomback,[2] Samy I. Mcfarlane,[3] Suying Li,[4] Shu-cheng Chen,[4] Peter A. McCullough,[5] Adam Whaley-Connell.[6] *[1]MetroHealth Medical Center, Cleveland, OH; [2]Columbia University, New York, NY; [3]SUNY Downstate, Brooklyn, NY; [4]Chronic Disease Research Group, Minneapolis, MN; [5]St. John Providence Health System, Novi, MI; [6]University of Missouri, Columbia, MO.*

Background: Elevated PTH levels in CKD may lead to an increased risk for progression to ESRD and/or premature death.

Methods: 10,823 participants in the KEEP with CKD (eGFR < 60 ml/min/1.73m^2) were examined from 2005-2010. The association of PTH levels with ESRD and pre-ESRD mortality was ascertained by linking KEEP data to the Social Security Administration Death Master File and the United States Renal Data System (USRDS) and by using competing risk survival models.

Results: Participants were divided into 5 PTH quintiles (1st (<=41), 2nd (>41-59), 3rd (>59-80), 4th (>80-114, and 5th (>114) pg/mL). Higher PTH levels were associated with increasing age, black race, lack of a high school education, CVD, hypertension, and lower GFR. Among the cohort, the incidence of ESRD and pre-ESRD mortality was 6.4 and 20.1 events per 1000 person years with the incidence of both outcomes lowest in the 2nd PTH quintile. After multivariate adjustment, including calcium, phosphorus and GFR, the risk of ESRD was not statistically different from the 2nd quintile in the 1st (subhazard ratio (SHR): 1.42 (95% CI: 0.54-3.77), p = 0.47), 3rd (SHR: 1.62 (95 % CI: 0.65-4.05), p=0.30), 4th (SHR: 0.98 (95% CI: 0.39-2.48), p=0.97), and 5th (SHR: 2.06 (95% CI: 0.91-4.69), p=0.08) quintiles, respectively. Conversely, after similar adjustment, there was a graded risk of pre-ESRD mortality for the 3rd (SHR: 1.52 (95% CI: 1.04-2.24),p=0.03), 4th (SHR: 1.73 (95% CI: 1.19-2.52),p=0.004), and 5th (SHR: 1.86 (95% CI: 1.28-2.52),p=0.001) quintiles, respectively. There was no effect modification for diabetes, gender, race (black vs non-black), and GFR status (<= 45 vs > 45) for either outcome.

Conclusions: Elevated PTH levels are associated with increased pre-ESRD mortality but not with ESRD.

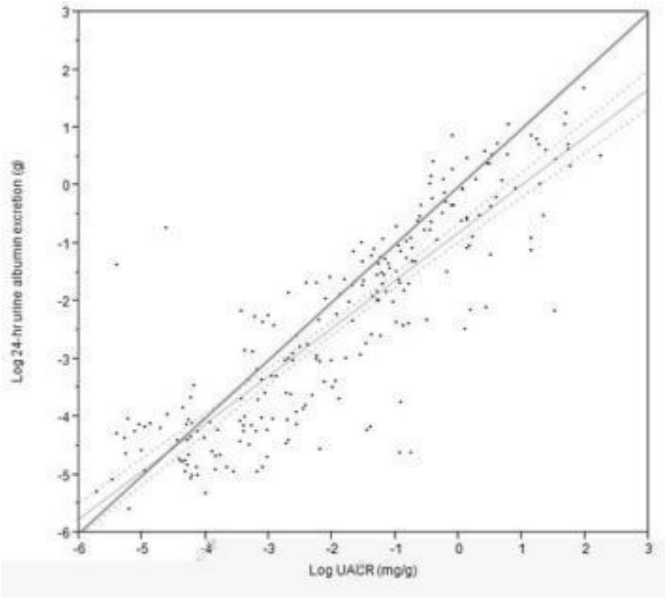
Equations for Converting Estimations of Urine Protein Excretion to 24-hr Urine Collections Ping Tyug Loh, Boon Wee Teo, Titus W. Lau, Evan J.C. Lee. *Medicine, National University Health System, Singapore, Singapore.*

Background: Spot urine protein-creatinine ratio (UPCR, mg/g) and albumin-creatinine ratio (UACR, mg/g) estimations of 24-hour urine protein excretion rate (24UPE, g) and 24-hour urine albumin excretion (24UAE, g), respectively, are used in clinical practice and research. But the established accuracy of these ratios predated the standardization of creatinine assays and proteinuria assessments vary with assay methods. We developed converting equations between ratios and 24-hr measurements from a multi-ethnic Asian population with a variety of CKD.

Methods: The Asian Kidney Disease Study (n=232) prospectively collected 24-hour urine followed by early morning spot urine, which were analyzed for protein (pyrogallol-based assay), albumin (turbidimetry), and creatinine (enzymatic assay). Variables were natural log-transformed before linear regression to correct for non-normal distribution and non-constant variability of observed points around the regression line.

Results: Four patients had 24UPE >3.5g. UACR predict 24UAE better as the slope is closer to 1. UPCR has poorer correlation to 24UPE (r = 0.79743) than UACR is to 24UAE (r = 0.86291). UACR is highly correlated to UPCR (r = 0.99237). 24UAE is also highly correlated to 24UPE (r = 0.99275). UACR is less correlated with 24UPE (r = 0.78334) than UPCR is with 24UAE (r = 0.80716). The prediction equations are (all p <0.001):

Log 24UPE = -0.617019 + 0.7150918 × Log UPCR
Log 24UAE = -0.800153 + 0.8257142 × Log UACR
Log UACR = -0.656352 + 1.3881178 × Log UPCR
Log UPCR = 0.3216439 + 0.6394674 × Log UACR
Log 24UAE = -0.504333 + 1.4810344 × Log 24UPE
Log 24UPE = 0.1624472 + 0.5991885 × Log 24UAE
Log 24UPE = -0.35059 + 0.4767755 × Log UACR
Log UACR = -0.270587 + 1.2870223 × Log 24UPE.



Conclusions: Spot urine albumin to creatinine ratio correlates better with 24-hr urine albumin excretion than proteinuria assessments.

Prevalence of Chronic Kidney Disease and Associated Risk Factors: First Results from a Population Based Screening Program in Morocco (MAREMAR) Mohammed Benghanem Gharbi,[1] Zamd Mohamed,[1] Monique M. Elseviers,[2] Abdelali Belghiti Alaoui,[3] Mohammed El Hassane Trabelssi,[3] Naima Benahadi,[3] Benyounès Ramdani,[1] Bayahia Rabia,[1] Marc E. De Broe.[4] *[1]Moroccan Society of Nephrology; [2]Epidemiological Research, University of Antwerp, Wilrijk, Belgium; [3]Ministry of Health, Morocco; [4]International Society of Nephrology.*

Background: The MaReMar study is a project carried out by the Ministry of Health in Morocco in a partnership with the International Society of Nephrology, the WHO and the Moroccan Society of Nephrology. The aim is to estimate the prevalence of chronic kidney disease (CKD) and its associated risk factors in a representative sample of the population of Morocco aged 26-70.

Methods: The study was performed in two middle sized towns. A stratified random sample of the population, using official voting lists, was taken. Baseline screening was performed using a number of clinical (BMI, blood pressure, hip waist ratio) and laboratory investigations [dipstick, microalbuminuria (Hemocue), serum creatinine, fasting glycemia) and a structured questionnaire.

Results: 10524 subjects were enrolled. The prevalence of CKD [defined as presence of an eGFR < 60 ml/ min/1.73 m^2 or macroalbuminuria or dipstick abnormalities (proteinuria ≥ ++ or haematuria: ≥ ++) or diabetes type 1 associated with microalbuminuria] was 2.9% and increased with age (26-40 y.o: 1.4%; 41-55 y.o.: 2.7%; 56-70 y.o.: 8.5%). The main aetiologies of CKD were diabetes (32.79%), hypertension (28.2%) and nephrolithiasis (9.8%). The prevalence of associated factors was as follow: hypertension: 16.7%; hyperglyceamia (≥ 1.26 g/l): 13.8%; microalbuminuria (30-299 mg/l): 5.26% and obesity (BMI ≥ 30): 23.2%. The most frequent health related habits were traditional medicines (2.9%), analgesics (4.7%), smoking (4.7%) and occupational exposure (3.9%).

Conclusions: Maremar generated, for the first time, quantitative and scientifically correct information on the prevalence of CKD, hypertension, and diabetes in Morocco. This information is highly relevant for future national health strategies in this country and may be in other merging and emerging countries.

TH-PO354

JC Polyoma Virus Interacts with Apolipoprotein L1 Genetic Risk in African Americans with Non-Diabetic Nephropathy Barry I. Freedman, Mariana Murea, Michael V. Rocco, Lijun Ma, Donald W. Bowden, David A. Ornelles, Steven Kleiboeker, Carl D. Langefeld, Jolyn Turner, Jasmin Divers. *Wake Forest School of Medicine, Winston-Salem, NC.*

Background: Approximately 50% of pts with untreated HIV infection and 2 *APOL1* nephropathy risk variants develop kidney disease. Other environmental factors, particularly non-HIV viral infections could interact with *APOL1* and contribute to nephropathy. We tested whether urine JC (JCV) and BK polyoma virus (BKV) and plasma Human Herpes Virus 6 (HHV6) and cytomegalovirus (CMV) influenced nephropathy risk via interactions with *APOL1*.

Methods: *APOL1* genotypes and presence of viral DNA via quantitative polymerase chain reaction were tested for impact on urine albumin:creatinine ratio (UACR), serum cystatin C, and estimated glomerular filtration rate (eGFR) in 300 first-degree relatives of African Americans (AAs) with non-diabetic nephropathy. Linear and non-linear mixed models were used to account for familial relationships.

Results: Two, one and zero *APOL1* risk variants were present in 130, 88 and 82 relatives, respectively. Urine JCV and BKV were detected in 30% and 9.7% of subjects; HHV6 and CMV were rare. Demographic data (mean±SD) were age 51.4±12.8 years, UACR 233±840 mg/g, cystatin C 1.0±0.5 mg/L, eGFR 86.5±28.0 ml/min/1.73m^2 and African ancestry 81±10%. Adjusting for family age at ESRD, sex and ancestry, JCV genomic DNA in urine and increasing number of *APOL1* risk alleles were negatively associated with high cystatin C (>0.95 mg/L; p=0.006), albuminuria (UACR>30 mg/g; p=0.0002), and kidney disease (eGFR<60 ml/min/1.73 m^2 and/or UACR>30 mg/g; p=0.000017); whereas BKV genomic DNA in urine was not associated with kidney disease.

Conclusions: AAs at risk for *APOL1*-associated nephropathy with detectible JCV in the urine had a lower prevalence of kidney disease. This suggests that JCV interacts with *APOL1*-associated risk. Potential mechanisms include inhibition of urinary tract replication by other more nephropathic viruses or impact on gene expression profiles that alter susceptibility to *APOL1*-associated nephropathy. These data suggest that non-HIV viral infections can serve as second hits impacting nephropathy risk in those with *APOL1* risk variants.

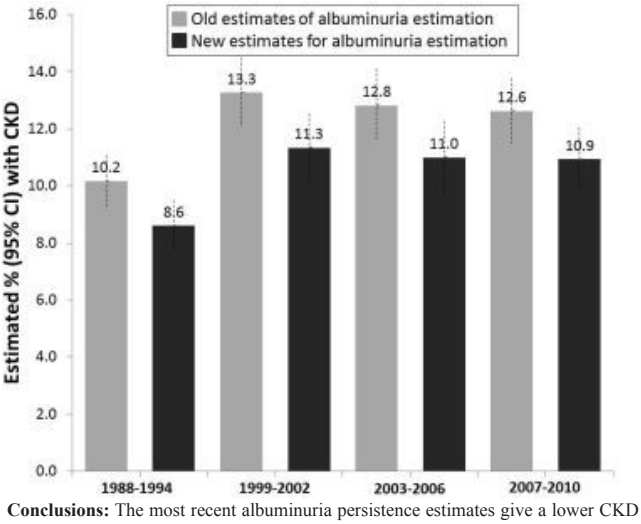
TH-PO355

Time Trends in Chronic Kidney Disease (CKD) Prevalence Appear Similar Regardless of Albuminuria Persistence Estimates Laura Plantinga,[1] Chi-yuan Hsu,[2] Yi Li,[3] Rajiv Saran,[3] Neil R. Powe.[2] *[1]Emory University, Atlanta, GA; [2]University of California, San Francisco, CA; [3]University of Michigan, Ann Arbor, MI.*

Background: CKD prevalence differs based on whether elevated albuminuria is confirmed by two random urine samples or a random and first-morning sample. We explored how the different methods influence estimated time trends in U.S. CKD prevalence.

Methods: "Persistent" albuminuria was defined in 2009-2010 National Health and Nutrition Examination Survey (NHANES) adult (>20 years) non-pregnant participants (N=4,938) by concordance [urinary albumin:creatine ratio (UACR) >30 mg/g in both samples] of data from random spot and first-morning urine samples collected 10 days apart. Persistence of elevated UACR was estimated separately within categories determined by eGFR (ml/min/1.73 m^2) and UACR (mg/g): eGFR ≥90/UACR 30-299, 33.9%; eGFR ≥90/UACR ≥300, 90.5%; eGFR 60-89/UACR 30-299, 41.8%; eGFR 60-89/UACR ≥300, 78.1%). We estimated U.S. population-weighted prevalence of CKD by survey year, using bootstrapping techniques incorporating these estimates vs. older persistence estimates from a subset of NHANES III [1988-1994; eGFR ≥90/UACR 30-299, 50.9%; eGFR 60-89/UACR 30-299, 75.0%; UACR ≥300 (any eGFR), 100%].

Results: Updated albuminuria persistence estimates gave a prevalence of 11.1% (95% CI, 10.3-12.0%) over 1999-2010, vs. 12.9% (12.0-13.8%) with older persistence estimates. There was similar overestimation of prevalence in each time period but similar patterns over time. Changes from 1988-1994 to 2007-2010 were similar for old vs. new persistence estimation (absolute change, 2.5% vs. 2.3%; relative change, 24.2% vs. 27.1%).



Conclusions: The most recent albuminuria persistence estimates give a lower CKD prevalence in the general population, but overall time trends are similar.

TH-PO356

Awareness of Chronic Kidney Disease May Be Underestimated by Random Albuminuria Measurement Laura Plantinga,[1] Delphine S. Tuot,[2] Brenda W. Gillespie,[3] Hal Morgenstern,[3] Sharon Saydah,[4] Nilka Rios Burrows,[4] Neil R. Powe.[1] *[1]Emory University, Atlanta, GA; [2]University of California, San Francisco, CA; [3]University of Michigan, Ann Arbor, MI; [4]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Estimation of awareness of chronic kidney disease (CKD) may be limited by misclassification of albuminuria, a strong independent predictor of CKD awareness. Single spot urine albumin:creatinine ratio (UACR) may overestimate the prevalence of albuminuria, leading to underestimation of CKD awareness among those classified as having albuminuria.

Methods: In the 2009-2010 National Health and Nutrition Examination Survey, both random spot and first-morning samples were provided by 4,927 non-pregnant adults (≥20 years) and assayed (by the same method in the same laboratory) for UACR. We compared U.S. population-weighted prevalence of awareness ("yes" to questionnaire item "Have you ever been told by a healthcare provider that you have weak or failing kidneys?") among those with albuminuria (UACR ≥30 mg/g) by type of sample and characteristic (age, gender, race/ethnicity, eGFR, diabetes, hypertension), using separate logistic regression models for each UACR measure with estimated margins (adjusted for all characteristics).

Results: When albuminuria was measured by random spot (prevalence, 7.7%) and first-morning (prevalence, 4.6%) measurements, respectively, CKD awareness was estimated at 5.6% (95% CI, 4.1-7.1%) and 8.2% (6.6-9.9%). Those with normal vs. reduced kidney function (eGFR ≥60 vs. <60 ml/min/1.73 m²) had lower prevalence of awareness: 1.5% vs. 19.1% (P<0.001) and 2.5% vs. 23.8% (P<0.001) for the random and first-morning samples, respectively. Regardless of sample type, older, female, and non-Hispanic white individuals with albuminuria were less likely to be aware of CKD and those with diabetes and hypertension were similarly likely to be aware, compared to their counterparts.

Conclusions: CKD awareness differs based on albuminuria measure. Method of albuminuria measurement should be considered alongside population estimates of CKD awareness, particularly those used to gauge the effectiveness of educational interventions.

TH-PO357

Visceral Obesity Is a Risk Factor of Microalbuminuria Hyun Suk Kim,[1] Hyo Eun Park,[2] Su-yeon Choi,[2] Jin Suk Han,[1] Nam Ju Heo.[2] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Korea; [2]Internal Medicine, Healthcare System Gangnam Center, Seoul National University Hospital, Seoul, Korea.*

Background: Microalbuminuria is known as a marker of cardiovascular and kidney disease. Few studies have examined the effect of visceral obesity on microalbuminuria. The aim of this study is to investigate the association between visceral adipose tissue (VAT) and the prevalence of microalbuminuria.

Methods: We conducted a cross-sectional study of 1,154 subjects who underwent routine checkups, including CT scans of abdominal adipose tissue at the Healthcare System Gangnam Center of Seoul National University Hospital from September 2006 through December 2010. VAT area was defined as intra-peritoneal fat bound by parietal peritoneum or transversalis fascia. Microalbuminuria was defined as albumin to creatinine ratio 30~300 mg/g of morning spot urine. Since the standard for normal abdominal fat has not been established, we used the lowest tertile as a reference group after dividing abdominal fat into three groups.

Results: Overall, 10.4% had microalbuminuria. Individuals with higher VAT showed higher level of albuminuria (*p* for trend of men<0.001, of women=0.049), and higher prevalence of microalbuminuriain in men (*p* for trend<0.001), but not in women (*p* for trend=0.106). Also, higher VAT was associated with higher insulin resistance (HOMA-IR) and higher incidence of metabolic syndrome. (*p* for trend of men<0.001, of women<0.001). After multivariate adjustment, highest tertile group of VAT was associated with higher prevalence of microalbuminuria (odds ratio [OR] 1.882; 95% confidence interval [CI] 1.064-3.330, *p* for trend= 0.030). In subgroup analysis, among men, highest tertiles of VAT was associated with higher prevalence of microalbuminuria (VAT; OR, 2.705; 95% CI, 1.430-5.118). Among women, there was no significant association between VAT and microalbuminuria.

Conclusions: Visceral obesity was significantly associated with microalbuminuria. Higher VAT is also related with higher insulin resistance and higher prevalence of metabolic syndrome.

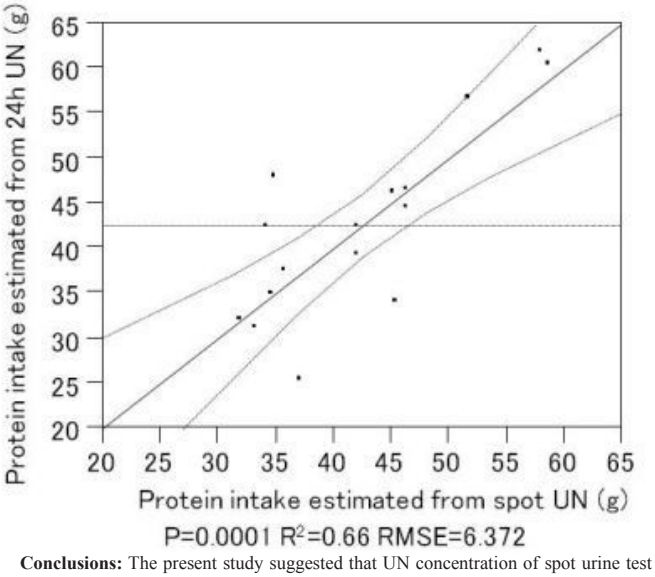
TH-PO358

Estimating Daily Protein Intake by Urea Nitorogen Concentration in Spot Urine Yoshihiko Kanno,[1] Eiichiro Kanda,[2] Kaori Sakamoto,[3] Kei Nakajima,[4] Yoshihiro Matsumoto,[5] Sanae Watanabe,[3] Toshitaka Muneyuki,[6] Tomoya Hirayama.[7] *[1]Apheresis and Dialysis Center, Keio University, Tokyo, Japan; [2]Department of Nephrology, Tokyo Kyosai Hospital, Tokyo, Japan; [3]Kagawa Nutrition University, Sakado, Japan; [4]Department of Medical Dietetics, Josai University, Sakado, Japan; [5]Shizuoka City Hospital, Shizuoka, Japan; [6]Saitama Citizens Medical Center, Saitama, Japan; [7]Department of Nephrology, Kitasaito Hospital, Asahikawa, Japan.*

Background: It is not easy to know the amount of daily protein intake in CKD management. Recording dietary intake is inaccurate, and estimation from total urea excretion is also not easy to ask patients to collect whole urine for 24 hours (h). Spot urine became to be used as indicator of daily sodium intake, and daily urinary protein excretion. In this cross sectional study, we investigated whether urea nitrogen (UN) concentration (C) of spot urine would replace 24h urine collection.

Methods: 17 Japanese young healthy female provided their urine for 24h with diet record. They provided one spot urine on the next day of 24h urine collection. UN and creatinine C were measured in all samples (BML, Inc. Tokyo, Japan).

Results: Bodyweight of objects was 50.0±4.3 kg, UN excretion was 6.08±2.19 g/day. Estimated protein intake was 47.7±13.95 g/day (Maroni formula). Creatinine-adjusted UNC of spot urine on the next morning was significantly correlated with 24h UN excretion than other samples (Spearman's rank correlation coefficient ρ=0.0155, *P=0.*0155). The creatinine-adjusted UNC of spot urine could predict the amount of 24h UN excretion, and protein intake using an univariate linear regression model (Protein intake=24.5 + 3.4 x creatinine-adjusted UNC, adjusted R^2=0.66, P=0.0001).



Conclusions: The present study suggested that UN concentration of spot urine test could estimate daily protein intake, and would help nutritional control in CKD patient.

TH-PO359

Prevalence and Awareness of Chronic Kidney Disease and Cardiovascular Risk Factors in a Large Canadian Survey: The CARTaGENE Study Jacobien Verhave,[1] Stephan Troyanov,[1] Frederic Mongeau,[1] Philip Awadalla,[2] Lorraine Fradette,[2] Josee Bouchard,[1] Francois Madore.[1] *[1]Nephrology, Hôpital du Sacré-Cœur, Montreal, QC, Canada; [2]Medical and Population Genomics Laboratory, University of Montreal, Montreal, QC, Canada.*

Background: Chronic kidney disease (CKD) and cardiovascular (CV) diseases are associated with significant morbidity and mortality. Patient awareness of these conditions is an essential component of CV risk management. We sought to determine the prevalence and awareness of CKD and CV risk factors in the general population and evaluate treatment of CV risk factors.

Methods: CARTaGENE is a cohort study of 20,004 randomly selected Canadian subjects, aged 40-69. Participants had anthropometric and blood pressure (BP) measurements, evaluation of medical conditions using self-administered questionnaires (including medication use) and blood sample collection. Regarding kidney disease, subjects were asked: Has a doctor ever told you that you have kidney disease, renal failure, renal infection or kidney stones?

Results: The prevalence of stage 3 CKD was 6.8% (MDRD) and 3.9% (CKD-EPI). CKD awareness was low: 92.3% of subjects were unaware of their renal condition. The prevalence self-reported hypertension, diabetes and hypercholesterolemia was 25, 7.5 and 28%, respectively. In self-declared normotensive subjects, 12% had a measured BP ≥140/90 mmHg. In those without self-reported diabetes, 2.8% had diabetes defined as HbA1c level ≥6.5% or hyperglycemia. One third of individuals without a history of hypercholesterolemia had LDL levels above ATPIII recommendations. With regard to treatment of known conditions, a measured BP ≥140/90 was present in 31% of the subjects with self-reported hypertension. BP was ≥130/80 in 53% of subjects who reported diabetes or CKD in addition to hypertension. Among self-reported diabetic subjects, 41% had an HbA1c ≥7 and 13% an HbA1c ≥8.5. More than half of the subjects with a moderate or high Framingham risk score had LDL levels above the target.

Conclusions: In this large sample of the general Canadian population, stage 3 CKD and CV risk factors are common. Awareness of these conditions is low and treatment goals are not achieved in the majority of subjects.

Funding: Government Support - Non-U.S.

TH-PO360

Prevalence of Albuminuria in a General Pediatric Population: National Health and Nutrition Examination Survey 2009-2010 Lauren F. Loeffler, Alicia M. Neu, Jeffrey J. Fadrowski. *Pediatric Nephrology, Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Albuminuria is a well-known marker of kidney disease. In children, however, albuminuria is often transient or orthostatic in nature and not pathologic. The prevalence of albuminuria, and microalbuminuria in particular, has been poorly described in the general pediatric population.

Methods: Children aged 6-17 years participating in the National Health and Nutrition Examination Survey (NHANES) 2009-2010, a cross-sectional survey of non-institutionalized US civilians, had albumin and creatinine measured in a random and first morning urine collection. Prevalence estimates were calculated for microalbuminuria (albumin to creatinine ratio ≥ 30 mcg/mg) and for albuminuria (albumin to creatinine ratio ≥ 300 mcg/mg). Glomerular filtration rate was estimated (eGFR) by the bedside Chronic Kidney Disease in Children (CKiD) equation (mL/min/1.73m^2).

Results: Of 1,876 children, 48% were female, 13% Black, 58% White, and 21% Hispanic. The median albumin to creatinine ratio was 8.9 mcg/mg and 6.3 mcg/mg on random and first morning urine samples, respectively.

Prevalence of Albuminuria in Children, NHANES 2009-2010

	Prevalence Microalbuminuria (%)			Prevalence Albuminuria (%)		
Urine Sample	Overall	6-11 y	12-17 y	Overall	6-11 y	12-17 y
Random	13.9	12	15.6	1.4	0.8	2
First Morning	4.5	3.8	5.2	0.4	0.3	0.5
Both	2.2	1.4	2.9	0.2	0.1	0.3

Of those with microalbuminuria and albuminuria on a random sample, 84% and 86%, respectively, did not have albuminuria on the subsequent first-morning urine collection, and thus may be classified as having transient or orthostatic albuminuria. Differences in prevalence by age were not statistically significant. Of those with first morning microalbuminuria, 7% and 15% had an eGFR <75 and <60, respectively. Of those with first morning albuminuria, 72% and 72% had an eGFR <75 and <60, respectively.

Conclusions: Although limited by a single urine collection, the prevalence of albuminuria and microalbuminuria in this population is of interest and supports that a significant proportion of adults with chronic kidney disease may have the earliest signs during childhood or adolescence.

TH-PO361

The Relationship between Vascular Disease and Albuminuria Testing in a Guideline Based and Incentivized Health-Care System Mark David Jesky,[1,2] Paul Cockwell,[1,2] Andrew Felix Burden.[3] *[1]Nephrology Department, University Hospitals Birmingham NHS Foundation Trust, United Kingdom; [2]Department of Infection and Immunity, University of Birmingham, United Kingdom; [3]Birmingham and Solihull NHS Cluster of CCGs, United Kingdom.*

Background: The UK employs national guidelines and financial incentives to optimize the monitoring of individuals at high-risk of chronic kidney disease (CKD), including proteinuria monitoring by albumin:creatinine ratio (ACR). Previous studies have shown the success of this approach. However, utilization of ACR testing in non-diabetic high-risk groups is unclear; a shortfall this study addresses.

Methods: In a UK primary-care catchment area data are collected electronically for individuals identified on vascular disease registers. For patients on these registers monitoring of eGFR and ACR 12-monthly is recommended. Utilizing the 2011 dataset, we analyzed the proportion of this population who had a creatinine checked, an eGFR reported and an ACR analyzed within the previous 15 months. We then focused on utilization of ACR testing in the non-diabetic high risk group.

Results: 47,329 (14.7%) people were on one or more vascular disease register. Creatinine, eGFR and ACR were reported in 83.2%, 66.3% and 46.8% respectively. ACR was checked in 15125 of 21529 (70.3%) diabetics. For those not on the diabetic register, ACR was checked in 7028 of 25800 (27.2%). Amongst the non-diabetic group, multivariate logistic regression demonstrated the key determinant of ACR testing was prior inclusion on the CKD stage 3-5 register (odds ratio 5.84, 95% confidence interval 5.40 – 6.32, p<0.001). Only 20.6% (4,395/21,339) of people not on the CKD 3-5 or diabetes register had their ACR checked. 25.0% of these 4,395 had a high ACR (above 30mg/g); in comparison, 27.9% of registered diabetics and 37.7% of individuals on the CKD register had a high ACR.

Conclusions: As ACR represents a major tool for assessing risk and directing management, continuing primary care initiatives to increase albuminuria testing are critical. This study indicates the need for an enhanced emphasis on non-diabetic, vascular disease risk groups, where there is a high prevalence of albuminuria, but monitoring rates are low.

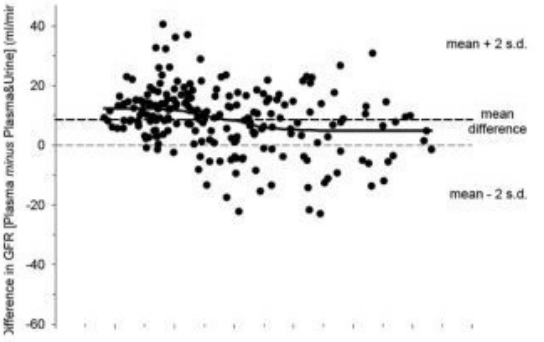
Differences between Plasma and Urinary Isotopic Glomerular Filtration Rate in Diabetic Nephropathy Shih-Han S. Huang,[1] Guido Filler,[2] Andrew A. House.[1] *[1]Medicine, Nephrology, Western University, London, ON, Canada; [2]Paediatric, Nephrology, Western University, London, ON, Canada.*

Background: Kidney function is assessed by measurement of the glomerular filtration rate (GFR). Isotopic GFR (iGFR) measurement is comparable to inulin method. In this study, we compared urinary and plasma iGFR methodologies in patients with diabetic nephropathy.

Methods: Ninety-Three patients were selected from the London Health Sciences Center participants in the Diabetic Intervention with Vitamins to Improve Nephropathy (DIVINe) trial. They had both urinary and plasma iGFR measurements during their first clinic visits. The two measurements were compared using intra-class correlation method, paired-t test, non-parametric test, Bland-Altman analysis and multivariable regression analysis. P-value < 0.05 was considered significant.

Results: The median age was 62 years (inter quartile range; IQR= 51.5, 69.0). The median plasma and urinary iGFR values were 65.3 ml/min/1.73m^2 (IQR= 47.2, 89.0) and 53.7 ml/min/1.73m^2 (IQR= 34.0, 82.4), respectively (p<0.001). There was a statistically significant correlation (r = 0.86; p<0.001) and a statistically significant difference between the plasma and urinary values.

Figure 1.The Bland-Altman analysis between plasma and urinary iGFR values (bias: 9.4 ml/min/1.73m^2; standard deviation of bias: 15.1 ml/min/1.73m^2)



Bland-Altman analysis demonstrated an overall bias of 9.4±15.1 ml/min/1.73m^2. The bias was greatest in chronic kidney disease (CKD) stage 4 (16.9±12.9 ml/min/1.73m^2). The multi-variable regression analysis using two variables, height and CKD stage provided a model that explained 26% (p<0.001) of the variation between the urinary and plasma iGFR.

Conclusions: The plasma clearance method of iGFR estimation consistently gave higher results than the urinary method. The bias increased with increasing CKD stage. Plasma iGFR may not be the gold-standard reference method in studies that are aimed to measure GFR in patients with more advanced CKD.

TH-PO363

Comparison of Algorithms to Identify Non-ESRD Chronic Kidney Disease (CKD) in Medicare Claims over Time Diane Steffick,[1] Vahakn B. Shahinian,[1] Hal Morgenstern,[1] Tanushree Banerjee,[2] Neil R. Powe,[2] Sharon Saydah.[3] *[1]University of Michigan, Ann Arbor, MI; [2]University of California San Francisco; [3]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Medicare claims are a valuable data source for CKD surveillance in the US, although they currently lack laboratory values. We used 3 algorithms for identification of non-ESRD CKD from Medicare claims; 2 based on the Medicare Chronic Conditions Warehouse algorithm–2+ hospital outpatient (OP) claims or 2+ non-hospital ambulatory care (AC) claims or 1 inpatient (IP) claim within a 2 yr (CCW2y) or 1 yr period (CCW1y), & one requiring only 1+ OP, AC, or IP claim during 1 yr (1Dx1y). To provide context for the pattern of CKD identification over time, we also show hypertension (HTN) & diabetes (DM).

Methods: We analyzed the 5% Medicare inpatient, outpatient & ambulatory care files. Eligible persons were aged 65+, not in managed care, enrolled in Part A&B all year & had 1+ outpatient visits each year, 2004-2010. A persistent pattern was defined as having the condition (CKD/DM/HTN) detected in every year. For simplicity, we limited the persistent pattern analysis to persons with claims in all 7 yrs & 1+ claim for the condition in 2004.

Results: CCW2y & 1Dx1y gave similar estimates of the prevalence of CKD, while CCW1y was lower. CCW2y had the highest fraction (33%) with a persistent pattern. In contrast, 79% of CCW2y DM cases & 83% of HTN cases had the persistent pattern.

Conclusions: When using only 1 year of claims data, researchers should consider relaxing the requirement for 2 outpatient claims to avoid undercounting CKD. Furthermore, Medicare patients rarely have claims for CKD consistently over time while the majority of patients with DM and HTN claims did. Whether this indicates a lack of attention to CKD, lack of referral to nephrology, or something else requires further investigation.

TH-PO364

GFR Estimating Equations Based on Standardized Serum Cystatin C

Masaru Horio,[1] Enyu Imai,[2] Yoshinari Yasuda,[2] Tsuyoshi Watanabe,[3] Seiichi Matsuo.[2] *[1]Functional Diagnostic Science, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Nephrology, Nagoya University Hospital, Nagoya, Japan; [3]Nephrology, Fukushima Medical University School of Medicine, Fukushima, Japan.*

Background: Serum cystatin C (Scys) is a potential alternative GFR marker. We developed GFR estimating equations based on standardized Scys that was traceable to a primary reference material, ERM-DA471/IFCC.

Methods: Development dataset (413 subjects) and validation dataset (350 subjects) were used. GFR was measured using inulin renal clearance. Serum creatinine was measured by IDMS-traceable enzymatic method. Serum cystatin C was measured by nephelometric immunoassay (Siemens, Dade Behring) previously. 727 freezed samples were re-measured by colloidal gold immunoassay (Alfresa Pharma) that was traceable to ERM-DA471/IFCC. Residual 36 of 763 samples were calibrated to the standardized values. GFR equations based on Scys (Eq-Cys1), Scys with constant non-renal elimination of cystatin C (Eq-Cys2) and Scys in combination with serum creatinine (Scr) (Eq-Cr-Cys) were developed. The Eq-Cys1, Eq-Cys2, Eq-Cr-Cys, average value of Eq-Cr and Eq-Cys2 (Eq-average), Japanese GFR equation based on Scr (Eq-Cr), and a equation based on standardized Scys reported by Inker LA (Eq-Inker) were compared.

Results: Ethnic coefficient (95% CI) of Eq-Inker for Japanese was 1.02 (0.99-1.05). In validation dataset, median (IQR) of difference between mGFR and eGFR by Eq-Cr, Eq-Inker, Eq-Cys1, Eq-Cys2, Eq-combined and Eq-average were 7.4 (13.2), 7.1(11.9), 7.3 (11.7), 6.7 (10.3), 6.2(9.9) and 6.1(9.3) ml/min/1.73m^2, respectively. Accuracy within ±30%(P30) of mGFR were 75%, 76%, 77%, 78%, 81% and 82%, respectively. Eq-Cys1, Eq-Cys2 and Eq-Inker were as accurate as or more accurate than Eq-Cr. Performance of the GFR estimation was more improved by Eq-Cr-Cys and Eq-average.

Conclusions: The equation based on Scys was as accurate as or more accurate than the equation based on Scr. Estimated GFR based on both Scr and Scys was more accurate. Ethnic coefficient of Eq-Inker was about 1.0, suggesting the possibility that equations based on serum cystatin C could be used in patients with different race.

TH-PO365

Performance of Estimating Glomerular Filtration Rate (eGFR) Formulas in Indigenous Australians with and without Diabetes

Richard J. MacIsaac,[1] Elif I. Ekinci,[2] Jaquelyne T. Hughes,[3] Paul D. Lawton,[3] Graham Ross Dallas Jones,[4] Andrew G. Ellis,[5] Alan Cass,[6] Wendy E. Hoy,[7] Kerin O'Dea,[8] George Jerums,[2] Louise J. Maple-Brown.[3] *[1]St Vincent's Hospital & University of Melbourne, Australia; [2]Austin Health & University of Melbourne, Australia; [3]Menzies School of Health Research & Charles Darwin University, Australia; [4]St Vincent's Hospital Sydney, Australia; [5]Austin Health, Australia; [6]George Institute for Global Health & University of Sydney, Australia; [7]University of Queensland, Australia; [8]University of South Australia, Australia.*

Background: The CKD-EPI formula has been proposed as a more accurate marker of GFR than the MDRD formula. However, the best method for estimating GFF in Indigenous Australians with diabetes is still unclear.

Methods: Indigenous Australians with (n=234) or without (n=345) type 2 diabetes were studied. A reference GFR measurement was obtained using the plasma disappearance of iohexol (mGFR) over 4 hours. Serum creatinine was measured by an enzymatic method. Performance was determined as bias, derived from mGFR-eGFR and accuracy (percentage of eGFR within 30% of mean mGFR).

Results: In the entire study population, the performance of the CKD-EPI formula was superior to the MDRD formula. However, in Indigenous Australians with diabetes, the CKD-EPI formula underestimated mGFR to a greater extend and was less accurate than in those without diabetes (Table, †p < 0.05 compared with no diabetes).

Performance of the MDRD and CKD-EPI formulas in people with and without diabetes

	Diabetes (n=234)	No Diabetes (n=354)
Measured GFR (ml/min/1.73m²)	83 (77, 89)	101 (98, 104)
MDRD		
Bias (ml/min/1.73m², median, 95%CI)	8.8 (6.5,11.1)	8.8 (6.9, 12.3)
Accuracy (%, 95%CI)	79 (74, 84)	89† (89, 92)
CKD-EPI		
Bias (ml/min/1.73m², median, 95%CI)	6.1 (3.5, 7.9)	1.8† (-0.5, 4.3)
Accuracy (%, 95%CI)	81 (76, 86)	92† (88, 94)

Conclusions: Overall, the CKD-EPI formula outperforms the MDRD formula for estimating GFR in Indigenous Australians. However, in Indigenous Australians with diabetes, the CKD-EPI formula has a greater negative bias and is less accurate compared to those without diabetes.

TH-PO366

Validation of Kidney Disease Hospitalizations in a Prospective Cohort: The ARIC Study

M. Grams, Wen Hong Linda Kao, Brad C. Astor, Josef Coresh. *JHU.*

Background: Many cohorts classify kidney disease solely by visit-based laboratory measures. Use of interim hospitalizations improves estimation in time-to-event analyses, event capture among those who miss visits, and identification of AKI, a transient yet potent predictor of outcomes. However, the validity of identifying interim kidney disease hospitalizations by discharge *ICD-9-CM* codes is uncertain, and many previous studies do not adjust for sampling technique.

Methods: Records were randomly selected within 9 *ICD-9-CM* code strata from 9,104 hospitalizations (3,784 participants at a single center, 1996 -2008), oversampling strata containing a kidney code. Inpatient labs, the admission note, nephrology consult, and discharge summary were abstracted. A blinded nephrologist adjudicated events as follows: **CKD**, chart mention or eGFR ≤ 60 (CKD-Epi equation); **Stage 4+ CKD**, eGFR ≤ 30; **AKI**, chart mention or 50% increase in creatinine; **ESRD**, RRT at admission and/or discharge, or death from progression of kidney disease (baseline CKD Stage 3+). Total events were estimated using inverse probability weighting (1/number sampled/total number in strata).

Results: The initial sample contained 191 charts; 91% had sufficient data. Sensitivity ranged from 20.8% (AKI) to 68.5% (Stage 4+ CKD); specificity was >92% for all outcomes.

Validity of ICD-9-CM-coded kidney hospitalizations

	AKI	CKD (Stage 4+ CKD)	ESRD
Sensitivity (%)	20.8	44.3 (68.5)	38.0
Specificity (%)	99.6	98.3 (92.1)	99.1
Positive Predictive Value (%)	91.3	91.2 (49.1)	76.8
Negative Predictive Value (%)	85.4	81.4 (96.3)	95.3

Positive predictive value (PPV) was lower for rarer events. In association studies, these estimates would result in little bias (e.g., the relative risk of AKI would decrease from 2.0 to 1.9, were sensitivity unrelated to exposure). Incorporation of the sampling design is critical for avoiding spectrum bias: ignoring sample weights grossly overestimates sensitivity (61, 86, and 77% for AKI, CKD, and ESRD, respectively) and underestimates specificity (95, 86, and 94%).

Conclusions: *ICD-9-CM* codes for kidney events have high specificity but low sensitivity. Validity varies with the spectrum of disease, and calculations should be adjusted based on sampling technique.

Renal Function Decline in Older Adults and Association with C-Reactive Protein: Results from the Einstein Aging Study

Jennifer Yi-Chun Lai,[1] Mindy Katz,[2] Richard B. Lipton,[2] Markus Bitzer.[1] *[1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Neurology, Einstein, Bronx, NY.*

Background: Decreased kidney function is an independent risk factor for increased morbidity and mortality in all age-groups, but risk factors for decreased or declining kidney function in older adult population remain unclear. Markers of inflammation including C-reactive protein (CRP) increase with age and have been linked with increased risk for cardiovascular in young and middle-aged adults. Therefore, we examined rates and predictors of estimated glomerular filtration rate (eGFR) decline in a sub-study of the Einstein Aging Study (EAS).

Methods: We identified 369 subjects with 2 to 5 yearly serum creatinine measurements and calculated creatinine-based eGFR using three different formulas (Cockgroft-Gault (CG), Modification-of-Diet-in-Renal-Disease (MDRD), and Chronic-Kidney-Disease-Epidemiology-Collaboration (CKD-EPI) formula. eGFR decline rates were determined by mixed effect modeling. Multivariate linear regression was used to identify factors associated with baseline eGFR and mixed effect eGFR decline rate.

Results: The mean age of 369 subjects was 78 years old (68-95 years; 232 female and 137 male). The mean eGFR decline percentage change was -4.3% in CG, -3.1% in MDRD, and -3.5% in CKD-EPI formula. In addition, the 5th percentile eGFR decline percentage change was -5.8% in CG, -4.6% in MDRD, and -5.0% in CKD-EPI formulas. In multivariate linear regression with baseline eGFR as the outcome, higher CRP levels were associated with lower eGFR (β=-0.006, P-value=0.01 in CG; β=-0.006, P-value=0.005 in MDRD; β=-0.006, P-value=0.007 in CKD-EPI). In multivariate linear regression predictinge GFR

decline percentage change, lower baseline eGFR was associated with more eGFR decline (β=0.02, P-value=0.0001 in CG; β=0.02, P-value=0.0001 in MDRD; not significant in CKD-EPI). However, baseline CRP or CRP change over period of time was not associated with eGFR decline.

Conclusions: Whereas lower eGFR is significantly associated with more rapid eGFR decline, serum CRP levels are associated with cross-sectional eGFR but not with eGFR decline in subjects in the EAS.

TH-PO368

Two Novel Equations to Estimate Kidney Function in Persons Aged 70 and Above Elke Schaeffner,[1] Natalie Ebert,[1] Pierre Delanaye,[2] Ulrich Frei,[1] Jens Gaedeke,[1] Olga Jakob,[3] Martin K. Kuhlmann,[4] Mirjam Schuchardt,[1] Markus Toelle,[1] Reinhard Ziebig,[6] Markus van der Giet,[1] Peter Martus.[5] *[1]Nephrology, Charité, Berlin, Germany; [2]Nephrology, CHU Sart Tilman, Liège, Belgium; [3]Biostatistics, Charité, Berlin, Germany; [4]Nephrology, Vivantes Klinikum im Friedrichshain, Berlin, Germany; [5]Biostatistics, Eberhard Karls University, Tuebingen, Germany; [6]Laboratory Medicine, Charité, Berlin, Germany.*

Background: In older adults current equations to estimate glomerular filtration rate (GFR) are not validated and might misclassify elderly persons in terms of their chronic kidney disease stage.

Methods: We developed two new equations based on creatinine alone and creatinine and cystatin C in a cross-sectional analysis. We used two separate original data sets for equation development (n=285) and validation (n=285) of an elderly population based sample (mean age 78 yrs) of the Berlin Initiative Study (BIS). GFR was measured using plasma clearance of iohexol. Creatinine and cystatin C assays were traceable to high-level reference materials.

Results: The new creatinine-cystatin C-based BIS2 equation yielded the smallest bias and highest accuracy followed by the creatinine-based BIS1 equation. All other equations overestimated GFR considerably. The BIS equations confirmed a high prevalence of people >70 yrs with a GFR <60 ml/min/1.73m^2 (BIS1 50.4%, BIS2 47.4%, mGFR 47.9%). Total misclassification rate for this criterion was smallest for BIS2 equation, followed by the cystatin C3 equation proposed by the CKD-Epi-Collaboration. Among the creatinine-based equations BIS1 had the smallest misclassification rate followed by the CKD-Epi equation.

Performance of eGFR equations in people >70 yrs

Equation	Bias	Precision (1st/3rd quartile)	Accuracy P_{30}(%)	Total misclassified (%)
BIS1	0.8	-5.03/6.11	95.1	49 (17.2)
MDRD	11.29	3.85/17.68	70.9	66 (23.3)
CKD-Epi	9.69	2.45/15.49	77.9	58 (20.4)
BIS2	0.87	-4.40/4.98	96.1	33 (11.6)
CysC3	9.22	3.46/14.42	81.4	58 (20.4)

CysC3: $177.6 \times \text{Creatinine}^{-0.65} \times \text{Cystatin C}^{-0.57} \times \text{age}^{-0.20} \times 0.82$ (if female)

Conclusions: In people >70 yrs with either no or mild to moderately reduced kidney function the new BIS equations are more precise and accurate tools than current equations to estimate GFR.

TH-PO369

Impact of Body Composition on the Accurate Assessment of Kidney Function in Indigenous Australians: The eGFR Study Louise J. Maple-Brown,[1,2] Jaquelyne T. Hughes,[1,2] Leigh Ward,[3] Leonard Sunil Piers,[4] Graham Ross Dallas Jones,[5] Paul D. Lawton,[1] Andrew G. Ellis,[4] Richard J. MacIsaac,[4] Alan Cass,[6] Wendy E. Hoy,[3] Kerin O'Dea,[7] George Jerums.[4] *[1]Menzies School of Health Research; [2]Royal Darwin Hospital; [3]University of Queensland; [4]University of Melbourne; [5]St Vincents Hospital; [6]George Institute; [7]University of South Australia.*

Background: Differences in body composition raise the question that creatinine-based estimates of glomerular filtration rate (eGFR) derived for use in European populations may not be appropriate for Indigenous Australians. This study aimed to assess if incorporation of fat-free mass (FFM) measurement improves performance of eGFR in Indigenous Australians.

Methods: We measured GFR (mGFR) by plasma disappearance of iohexol over 4 hours and eGFR by modification of diet in renal disease (MDRD-4) and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations, without African-American correction factor. Body composition was assessed by dual-energy X-ray.

Results: Indigenous Australians (n=135) were aged 47±15 years, 41% male, 40% with diabetes, 18% CKD stages 3-5, BMI 31±6 kg/m^2, FFM 58±14kg, mGFR 88ml/min/1.73m^2. On multiple regression of mGFR, addition of FFM (β 0.005, p<0.001) to the model (including age, gender, creatinine) resulted in improved model performance (relative reduction root mean square error 5.3%). An equation was derived for eGFR using FFM(kg), creatinine(μmol/l), age(years), sex: $\text{FFM eGFR} = 4482 \times \text{Creatinine}^{(-0.864)} \times (0.993)^{\text{Age}} \times (1.005)^{\text{FFM}} \times 0.823$ if female. Median bias(95% CI) = mGFR – eGFR:

	MDRD eGFR	CKD-EPI eGFR	FFM eGFR
All (n=135)	9.3 (6.8, 13.6)	2.6 (-0.7, 5.6)	1.2 (-1.8, 4.0)
BMI<30 kg/m2 (n=64)	8.4 (3.9, 16.1)	1.1 (-2.6, 6.3)	4.2 (-2.0, 7.4)
BMI≥30 kg/m2 (n=71)	10.3 (6.3, 14.5)	3.6 (-0.2, 6.5)	-0.1 (-5.5, 2.2)
BMI≥30 & Male (n=27)	19.3 (10.3, 23.7)	9.8 (4.2, 16.0)	-1.4 (-5.9, 3.6)*

*p<0.05 compared to CKD-EPI

Conclusions: Addition of FFM to age, gender and creatinine significantly enhanced the model assessing GFR in Indigenous Australians. However, the FFM eGFR equation derived in this cohort demonstrated significantly improved performance to CKD-EPI eGFR only in obese males.

Funding: Government Support - Non-U.S.

Predicting Outcomes after Myocardial Infarction by Using the Chronic Kidney Disease Epidemiology Collaboration Equation in Comparison with the Modification of Diet in Renal Disease Study Equation: Results from the Korea Acute Myocardial Infarction Registry Joon Seok Choi, Chang Seong Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Department of Internal Medicine, Chonnam National University Medical School, Gwangju, Korea.*

Background: The presence of chronic kidney disease is an independent prognostic factor in patients with myocardial infarction (MI). We compared the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation and the Modification of Diet in Renal Disease (MDRD) study equation with regard to prognostic value in patients with MI.

Methods: This study analyzed a retrospective cohort of 11,050 consecutive patients who had myocardial infarction and were enrolled in the Korea Acute Myocardial Infarction Registry (KAMIR) from November 2005 to August 2008. We applied the CKD-EPI equation and the MDRD study equation to determine the estimated glomerular filtration rate (eGFR) in a cohort of patients with MI.

Results: The mean $\text{eGFR}_{\text{CKD-EPI}}$ was slightly higher than $\text{eGFR}_{\text{MDRD}}$ (73.16 versus 72.23 mL/min/1.73m^2, P < 0.001). The prevalence of $\text{eGFR}_{\text{CKD-EPI}}$ <60mL/min/1.73m^2 was 26.9%, whereas that of $\text{eGFR}_{\text{MDRD}}$ was 28.5%. The area under the receiver operator characteristic curve was significantly larger for predicting 1-year major adverse cardiovascular event (MACE) and 1-year all-cause mortality with $\text{eGFR}_{\text{CKD-EPI}}$ (0.648 versus 0.641, 0.768 versus 0.753, respectively; P < 0.001). The net reclassification index for improvement in risk of 1-year MACE and 1-year all-cause mortality were 4.09% (P < 0.001) and 9.25% (P < 0.001), respectively.

Conclusions: The application of the $\text{eGFR}_{\text{CKD-EPI}}$ demonstrated better predictive values for clinical outcomes than $\text{eGFR}_{\text{MDRD}}$ in a cohort of patients with MI.

TH-PO371

Pregnancy Outcomes in Women with Autosonal Dominant Polycystic Kidney Disease Sajeda Youssouf,[1] Matt Hall,[2] Liz Lightstone,[3] Graham Graham Lipkin,[4] Nigel J. Brunskill,[1] Sue Carr.[1] *[1]The John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom; [2]Nottingham City Hospital, Nottingham, United Kingdom; [3]Imperial College Kidney and Transplant Institute, London, United Kingdom; [4]Queen Elizabeth Hospital, Birmingham, United Kingdom.*

Background: Pregnancy is associated with adverse fetal and maternal outcomes in women with advanced chronic kidney disease. There is little evidence that the aetiology of maternal renal disease has an effect on outcomes but most information is based upon retrospective, historical data. In this study we analysed fetal and maternal renal outcomes in pregnancy in women with known Autosomal Dominant Polycystic Kidney Disease (ADPKD) at the time of conception.

Methods: Prospective data from three specialist renal obstetric services has been collected since 2003. In this analysis we identified those with a diagnosis of ADPKD at the time of conception and reviewed pregnancy outcomes and long term maternal outcomes in this group.

Results: We identified 17 pregnancies in 12 women aged 26-43. One woman had CKD 4 at conception, there were 5 pregnancies in women with CKD 3 at conception and the remainder (11 pregnancies) had CKD 1-2. Five women had treated hypertension. Five women (42%) had previously had a miscarriage or fetal loss. Fifteen pregnancies (88%) resulted in a live birth, with one stillbirth and one termination due to severe congenital malformation. Two babies (13%) were admitted to NNU and 3 (20%) had a low birth weight. Twelve (75%) were born at term, the remaining 3 were born at 34-37 weeks. Renal function remained stable in pregnancy in all women. Four women developed worsening proteinuria in pregnancy. Two women went on to develop progressive renal impairment post-partum including one woman who developed ESRD at 4 years post-partum. Both women had CKD 3b/4 at the time of conception. No woman with CKD 1-2 had progression of renal dysfunction.

Conclusions: Fetal outcomes in ADPKD are better than reported in historical case series of pregnancy in women with CKD. There is no evidence that ADPKD has an impact on maternal renal dysfunction post-partum, except in those with pre-existing advanced CKD.

TH-PO372

Estimated Glomerular Filtration Rate Equations for Non-Obese Population Can Predict Measured Glomerular Filtration Rate in Obese Population Kearkiat Praditpornsilpa, Krittaya Tiskajornsiri, Somchai Eiam-Ong, Kriang Tungsanga. *Division of Nephrology, Faculty of Medicine, Chualongkorn University, Bangkok, Thailand.*

Background: High body mass index(BMI) has been an independent risk of CKD and ESRD. The currently available methods of estimated GFR(eGFR) were not validated in high BMI or obese population. The difference of body compositions of non-obese and obese patients may affect the precision and accuracy of eGFR equations. This study aimed to validate the eGFR equations used to assess renal function in obese population.

Methods: Thai adults>18years old, BMI≥30kg/m^2 were recruited. Body composition was assessed by bioimpedance analysis. The reference GFR was determined by ^{99m}Tc-DTPA plasma clearance. A single intravenous bolus of ^{99m}Tc-DTPA was injected and blood samples were drawn at5,10,20,30,60,90,120,180,and 240 minutes post ^{99m}Tc-DTPA injection. Serum creatinine was measured by using enzymatic assay and were adjusted by IDMSreference serum creatinine. The eGFR values were calculated by eGFR equations. Thai eGFR equation and re-expressed MDRD equation with Thai racial factor are $375.5xCr^{-0.848}xAge^{-0.364}x0.712$ if female and $175xCr^{-1.154}xAge^{-0.203}x0.742$ if femalex1.129 if Thai.

Results: 104 cases were studied. The average age was43.9±13.2years. The mean BMI, BSA and waist were 36.16±6.15kg/m^2, 1.93±0.22m^2 and40.9±4.7cm, respectively. The mean skeletal muscle mass, body fat mass and percent body fat were 29.6±14.5kg, 39.1±12.6kg and 43.3±6.9% respectively. The mean Cr was 0.86±0.89mg/dL. The mean reference GFR was 109.36±8.75mL/min/1.73 m^2. The mean eGFR by re-expressed MDRD equation, CKD-EPI equation, re-expressed MDRD equation with Thai racial factor, and Thai eGFR equation were 100.0±24.3, 96.9±30.8, 100.8±26.5, and 109.4±34.7mL/min/1.73 m^2,respectively. The mean differences between referenceGFR and re-expressed MDRD,CKD-EPI, re-expressed MDRD formula with Thai racial factor, and Thai eGFR equation were expressed as 12.6±23.6, 9.3±19.2, 0.1±25.5,and 9.0±20.5 mL/minper 1.73m^{2}respectively.

Conclusions: eGFR equations for non obese population can predict measured GFR in obese population. The specific racial eGFR equation or racial correction factor improve the accuracy of eGFR calculation.

Funding: Government Support - Non-U.S.

TH-PO373

Creatinine and/or Cystatin C-Based GFR Estimation in HIV Patients Amandine Gagneux-brunon,[1,2] Pierre Delanaye,[3] Xavier Delavenne,[4] Thierry Basset,[4] Frederic Lucht,[2] Christopher R. Mariat.[1] *[1]Nephrology, Universitary Hospital of Saint-Etienne, Saint-Etienne, France; [2]Infectious Diseases, Universitary Hospital of Saint-Etienne, Saint-Etienne, France; [3]Nephrology, Universitary Hospital of Liege, Liege, Belgium; [4]Pharmacology, Universitary Hospital of Saint-Etienne, Saint-Etienne, France.*

Background: CKD is a major comorbidity in HIV+ individuals. Screening these patients for CKD and its related complications is necessary. Among the numerous GFR-estimating equations available, it is not known whether one provides a better prediction and should be privileged in this population. We aimed to determine and compare the performance of creatinine and/or cystatin C-based equations in a cohort of HIV+ patients whom true GFR was measured by a reference method.

Methods: HIV+ outpatients who have undergone a plasma iohexol clearance (mGFR) along with IDMS-traceable serum creatinine and IFFC-traceable serum cystatin C (cyst) measurement were included. Equations considered were: Cockcroft-Gault, MDRD, CKD-EPI$_{creat}$, CKD-EPI$_{cyst}$ and CKD-EPI$_{creat+cyst}$. We compared bias, precision and accuracy and the performance of each equation to detect mGFR under 60 mL/min/1.73 m².

Results: 191 patients (93% whites, 158 men, 93% under highly active retroviral therapy, mean mGFR of 94 (±26) ml/min/1.73m^2) were included. CKD was found in 19 patients (9.9 %). As compared to others equations, the Cockcroft-Gault formula was significantly most biased, less precise and less accurate. Accuracy-30% for the MDRD and all others CKD-EPI Equations was similar (from 75% to 80%). CKD-EPI$_{creat+cyst}$ was significantly better for detecting stage 3 CKD as compared to the MDRD (ROC AUC of 0.84 vs 0.73, p<0.05) as well as to the CKD-EPI$_{creat}$ (0.84 vs 0.74, p<0.05).

Conclusions: In an apparent "nephrologically" healthy, almost exclusively Caucasian HIV+ population, equations developed by the CKD-EPI group significantly outperform the Cockcroft-Gault formula. In terms of GFR estimation, MDRD and CKD-EPI$_{creat}$ display similar performance. In terms of detection of CKD, CKD-EPI$_{creat}$ is unexpectedly not superior to the MDRD study equation. In contrast, CKD-EPI$_{creat+cyst}$ is significantly better and might be an estimator of choice for this purpose.

TH-PO374

Accuracy of eGFR Equations in Adults with Sickle Cell Disease: Impact on the Estimation of the Prevalence of CKD Antonio Guasch, Mitzi W. Near, Sasikala Selvaraj. *Renal Division, Dept of Medicine, Emory University, Atlanta, GA.*

Background: Renal involvement is common in sickle cell disease (SCD). In prevalence studies in adult patients with HbSS, abnormally high albuminuria occurs in >60% of adults and may reach 80% in individuals over 40 years of age. However, the prevalence of renal insufficiency (CKD) has been reported to be low, 4-7% in previous studies, based on abnormal serum creatinine values. We hypothesized that the apparent low prevalence of CKD in SCD is due to the poor accuracy of serum creatinine and eGFR equations to detect renal insufficiency.

Methods: We determined glomerular filtration rate (GFR) by the urinary clearance of inulin in 112 adults SCD patients (43 males, 63 females, median age 34 years, range 17-65, Hb SS=81, other sickle Hb=41) studied on 203 occasions (median 1, range 1-4). The average GFR and serum creatinine values were 80±4 ml/min/1.73 (range 5-199), and 1.0±0.1 mg/dL (range 0.3-7.7), respectively. The following eGFR equations were calculated: Cockcroft-Gault (C-G), aMDRD, MDRD and CKD-epi.

Results: All estimation equations systematically overestimated GFR: C-G by 51%, aMDRD by 64%, MDRD by 53% and CKD-epi by 50%. The accuracy of the prediction was low; for instance, in CKD stages 2-3, the respective percentage of patients falling within 30% and 50% range of estimates for each equation were: C-G: 23% and 40%, aMDRD 17% and 32%,MDRD 30% and 42%, and CKD-epi 19% and 29%. When we restricted the analysis to individuals with GFR 60-89 ml/min/1.73 (n=68), the percentage of patients correctly identified as CKD-2 were 21% (C-G), 21% (aMDRD), 21% MDRD and 15% (CKD-epi), vs 9% based on abnormal serum creatinine values.

Conclusions: We conclude that current eGFR equations and serum creatinine lack accuracy to estimate true GFR in adults with SCD, and systematically overestimate GFR. In CKD stage 2, less than 25% of patients are correctly identified by eGFR. Thus, the true prevalence of CKD in the SCD population may be grossly underestimated. Specific modifications of eGFR equations may be needed in SCD patients.

TH-PO375

Ethnicity, Proteinuria, and Diabetes Predict Faster Decline in Renal Function among Minority Populations Albert M. Osei,[1] Amit J. Joshi,[1] Kalyani Perumal,[1] Huiyuan Zhang,[2] William Trick,[2] Peter D. Hart.[1] *[1]Division of Nephrology, Stroger Hospital of Cook County, Chicago, IL; [2]Collaborative Research Unit, Stroger Hospital of Cook County, Chicago, IL.*

Background: Ethnic minorities bear a disproportionately higher burden of chronic kidney disease (CKD) in the United States. Improved understanding of CKD risk factors may facilitate the adoption of new prevention and treatment strategies for this vulnerable population. We examined and here in describe the clinical characteristics of such patients at a large inner city hospital.

Methods: Adult patients (≥18 years) with CKD followed in our nephrology clinics from Jan 2008 until March 2012 were identified. CKD was defined as: (i) persistent proteinuria (>2+ on urine dipstick or >100 mg/dL) or (ii) estimated glomerular filtration rate (eGFR) <60ml/min/1.73m^2 BSA; on two separate occasions 3 months apart using MDRD formula. Patients with initial eGFR <15 were excluded.

Results: 2646 (63%) of 4198 patients had adequate data points for clinical analysis. Mean age was 59.4 (±13.5) years, and women accounted for 45% of the study cohort. African Americans constituted 56%, Hispanics 25%, Caucasians 8%, and other races 11%. Patients with CKD stages 1, 2, 3, 4 were 11%, 26%, 51% and 12% respectively; 1700 (64%) of whom had diabetes. Baseline mean eGFR was 55.8 (±23.6), and after an average follow up of 2.9 (±1) years, it declined to 44.1 (±24.6). There was no statistical difference in initial eGFR among the different ethnic groups. Patients with proteinuria had higher initial eGFR (57.3 vs. 51.3, P<0.05). Proteinuria (irrespective of diabetic status) predisposed to faster decline in renal function (-5.6 vs -1.3, P<0.05). Annual eGFR decline was much faster in diabetics compared to non- diabetics (-5.6 vs -2.9, P<0.05), and among Hispanics and African Americans compared to Caucasians (-5.5, -4.7 and -3.7 respectively, P<0.05).

Conclusions: Proteinuria, diabetes, and African American or Hispanic ethnicity is associated with increased risk of CKD progression in minority patients. Further studies are needed to better characterize risk factors and develop interventions to reduce the CKD burden in this high risk patient population.

TH-PO376

Use of Glomerular Filtration Rate Estimating Equations for Drug Dosing in HIV Aghogho A. Okparavero,[1] Hocine Tighiouart,[1] Zipporah Krishnasami,[2] Christina M. Wyatt,[3] Hiba Graham,[4] James Hellinger,[1] Lesley Stevens Inker.[1] *[1]Tufts Medical Center, Boston, MA; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Mt. Sinai Hospital, New York, NY; [4]Gilead Sciences, Inc., Foster City, CA.*

Background: Current HIV treatment guidelines recommend the use of creatinine clearance estimated by the Cockcroft-Gault (CG) equation for drug dosing adjustments in HIV-positive patients. The use of other more accurate estimating equations for drug dosing has not been studied in this population.

Methods: In a cohort of 200 HIV-positive patients on stable antiretroviral therapy (ART) with measured GFR (mGFR), we evaluated the concordance of assigned kidney function categories (>80, 50-80, 30-50 and <30 mL/min), designated by the Food and Drug Administration (FDA) Guidance for Industry for pharmacokinetic studies using mGFR to GFR estimated using the MDRD Study, CKD-EPI and CG equations.

Results: Mean mGFR was 87±26 mL/min per 1.73 m^2. The number of subjects in each of FDA kidney function categories were >80 (135), 50-80 (54), 30-50 (9) and<30 (2). Overall, the CKD-EPI equation showed the highest concordance with mGFR (79%) while the MDRD Study equation had the lowest concordance (71%). All estimating equations led to lower kidney function categories compared to mGFR. This pattern was consistent across most subgroups (Table). There was a high degree of concordance between the CKD-EPI and MDRD Study equations to the CG equation (85% and 79%, respectively).

Concordance between assigned Kidney Function Categories using Measured versus Estimated GFR.

	Concordance to mGFR (%)		
	CKD-EPI	MDRD	CG
Overall	79	71	77
Tenofovir use			
Yes	80	70	78
No	77	72	75
Age group (years)			
≤50	84	75	81
>50	69	63	68
Sex			
Women	80	69	78
Men	79	72	76
Race			
African American	84	79	74
White or other	74	63	79
BMI group (kg/m^2)			
<22	66	66	54
22-30	82	74	79
>30	81	67	89
HIV RNA viral load (copies/mL)			
Undetected	76	66	79
<1000	84	79	79
≥1000	79	79	64

Conclusions: The CKD-EPI estimating equation has the highest concordance with mGFR for FDA assigned kidney function categories. Thus, its use may lead to lower dosing related errors in HIV-infected US adults on stable ART.

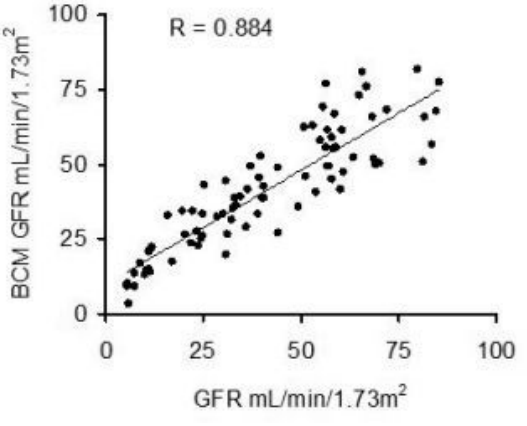
TH-PO377

Prediction of GFR in Aged Patients with a Formula Based on Serum Creatinine Adjusted for Body Composition Carlo Donadio. *Internal Medicine - Nephrology, University of Pisa, Pisa, PI, Italy.*

Background: The measurement of GFR is not feasible to clinical practice. Serum creatinine (SCr) is a simple marker of GFR impairment, unfortunately it lacks sensitivity, particularly in aged patients. Different formulas have been proposed to predict GFR from SCr, avoiding 24-hour urinary collection which is a major problem in aged patients. The aim of this study was to evaluate a new method to predict GFR in aged patients from the body cell mass (BCM) and SCr, avoiding urine collection.

Methods: Eighty adult chronic kidney disease (CKD) patients (43 males), aged 65-81 years, mean 71, with different renal function (SCr 0.7-8.8mg/dL) participated in this study. GFR was measured as the renal clearance of ^{99m}Tc-DTPA. SCr was determined with a standard laboratory method. The values of BCM were obtained by means of body impedance analysis, with a single frequency impedance analyzer. The relationship of GFR with Scr and BCM demonstrated a very high correlation between GFR and the ratio BCM/SCr. Form this relationship we derived a formula to predict GFR from the values of SCr and BCM: $_{BCM}$GFR(mL/min)= Patient's BCM (kg) x 2.69 / SCr (mg/dL). For comparison, GFR was predicted also according to Cockcroft and Gault formula ($_{CG}$GFR), and to the simplified MDRD formula ($_{MDRD}$GFR).

Results: $_{BCM}$GFR gave the most precise estimate of GFR.



In fact, $_{BCM}$GFR had the best agreement with true GFR (^{99m}Tc-DTPA), while $_{CG}$GFR and $_{MDRD}$GFR significantly overestimated true GFR. The coefficients of variation of all prediction formulas were markedly lower than that of 24h CCr (22.4%). Finally, the error of prediction of $_{BCM}$GFR was definitely lower than that of $_{CG}$GFR and $_{MDRD}$GFR.

Conclusions: In aged patients, GFR can be predicted from the values of BCM and serum creatinine. In the mean time, the impedance analysis allows to evaluate the nutritional status and the balance of body fluids compartments.

FGF-23 in Children with a Solitary Functioning Kidney: The KIMONO-Study Rik Westland,[1] Yael Abraham,[1] Michiel F. Schreuder,[2] Joanna Van Wijk.[1] *[1]Pediatric Nephrology, VU University Medical Center, Amsterdam, Netherlands; [2]Pediatric Nephrology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: Fibroblast Growth Factor 23 (FGF23) has been identified as an important 'early' marker for chronic kidney disease (CKD) in adults. However, data on pediatric patients are scarce. An important patient group with a risk for CKD is children with a solitary functioning kidney. THE KIMONO-STUDY (KIdney of MONofunctional Origin) explores the applicability of FGF23 in children with a solitary functioning kidney.

Methods: 84 children (51 congenital and 33 acquired) were included in this study. Serum FGF23 was measured by C-terminal assay (Immutopics), which measures both active and inactive FGF23. GFR was estimated with the Schwartz-equation (eGFR). Serum PTH and 25OH-vitamin D were simultaneously determined. Renal injury was defined as the presence of hypertension, micro-albuminuria, eGFR < 60 ml/min/1.73m² and/or use of antihypertensive/antiproteinuric medication. CKD stage was classified by the K/DOQI guidelines.

Results: Median serum FGF23 was 106 (interquartile range 55) RU/ml at a mean age of 10.8 (SD 4.8) years, whereas mean eGFR was 100 (SD 31) ml/min/1.73m². Serum FGF23 levels showed an inverse relationship with eGFR (r = -0.403, P < 0.001) and were positively associated with PTH (r = 0.541, P < 0.001) and 25OH-vitamin D (r = 0.139, P = 0.007). Furthermore, children with CKD ≥ stage 3 had increased FGF23 levels compared to children with CKD 1 and 2 (P = 0.031) and children in the highest FGF23 tertile demonstrated a higher incidence of renal injury than children in the lowest FGF23 tertile (64% vs. 36%, respectively; P = 0.043).

Conclusions: THE KIMONO-STUDY shows that FGF23 is a potential marker for CKD in children with a solitary functioning kidney. Furthermore, FGF23 levels are elevated in a subclinical stage of CKD, which suggests an important role for FGF23 to identify early renal damage in these children. We therefore underline the need for further studies to fully substantiate the prognostic impact of FGF23 in children with CKD, and children with a solitary functioning kidney in particular.

HARPE Study: Prevalence of Renal Abnormalities (RA) in Chronic Hepatitis B Virus Infection (HBV+) Sabine Amet,[1] Vincent Launay-vacher,[1] Stanislas Pol,[2] Jean-pierre Bronowicki,[3] Dominique Thabut,[4] Fabien Zoulim,[5] Marc Bourliere,[6] Philippe Mathurin,[7] Victor De Ledinghen,[8] Yves Benhamou,[4] Dominique Larrey,[9] Elfie Bruce,[1] Nicolas Janus,[1] Gilbert Deray.[10] *[1]Service ICAR, Nephrology, Pitie Salpetriere, Paris; [2]Hepatology, Cochin, Paris; [3]Hepatology, Brabois, Nancy; [4]Hepatology, Pitie Salpetriere, Paris; [5]Hepatology, Croix Rousse, Lyon; [6]Hepatology, Saint Joseph, Marseille; [7]Hepatology, Claude Huriez, Lille; [8]Hepatology, Haut Leveque, Pessac; [9]Hepatology, Saint Eloi, Montpellier; [10]Nephrology, Pitie Salpetriere, Paris.*

Background: A few data are available on RA prevalence in HBV+ patients (pts). The HARPE study (Hepatitis And Renal Parameters Evaluation), multicentric, prospective, evaluated the prevalence of renal impairment (RI), and RA (electrolytes, urinary sediment) in chronic HBs antigen-positive (HBsAg(+)) pts, with active or inactive infection.

Methods: Included pts were adult, mono-infected and oral anti-HBV treatment (AT)-naïve: 268 pts were prospectively included over 2 years by 8 liver units. Statistical univariate tests and multiple linear regressions comparing the RA between inactive and active pts were performed with the SAS software 8.02 (Inc.,Cary,NC).

Results: Pts characteristics: 58% males, mean age: 42 ± 14 years, 59.6% inactive carriers, 35% had an active HBV infection including 58.2% with abnormal transaminase levels (TL), 3.8% immune tolerant and 1.5% with fluctuating TL. 47 pts (47.2% of the active pts) were supposed to start an AT. Prevalences: proteinuria: 37.4%, hematuria: 20.8%, glycosuria: 3.9%, leukocyturia: 11.7%. 55.8% of pts had a glomerular filtration rate under 90 ml/min/1.73m². 27% of pts had chronic kidney disease (CKD) stage 1 to 3 and none had CKD stage 4 or 5. Diabetes, hypertension and dyslipidemia were observed respectively in 4.6%, 9.2%, 38.8% pts. There were no significant differences in RA between active and inactive pts.

Conclusions: RA are present in 1/3 and CKD in 1/4 of HBsAg (+) pts, whatever the immune stage and before any oral AT, evidencing the need of: 1. a renal evaluation in all; 2. a regular renal monitoring before and during AT to diagnose and manage RI and adjust dose of AT to the renal function.

Association of Hepatitis C Virus Infection with Chronic Kidney Disease: A Meta-Analysis Motaz Ashkar,[1] Amani Yamani,[1] Paweena Susantitaphong,[1,2] Bertrand L. Jaber.[1,2] *[1]Department of Medicine, Division of Nephrology, St. Elizabeth's Medical Center, Boston, MA; [2]Department of Medicine, Tufts University School of Medicine, Boston, MA.*

Background: Recent studies examining the association of hepatitis C virus (HCV) infection with development of chronic kidney disease (CKD) using markers of kidney damage (proteinuria or estimated glomerular filtration rate [eGFR] <60 ml/min/1.73 m²)

have yielded conflicting results. We conducted a meta-analysis to examine the association of HCV infection with prevalence and incidence of CKD, including development of end-stage kidney disease (ESKD).

Methods: We searched the literature for cross-sectional and cohort studies using MEDLINE (through December 2011), the Cochrane Central Register of Controlled Trials, the American Society of Nephrology abstracts and the bibliographies cited in the retrieved articles. The search strategy was limited to human studies with no language restrictions. Using random-effects model meta-analyses, we computed pooled adjusted odds ratios (ORs) (for cross-sectional studies) and pooled hazard ratios (HRs) (for cohort studies) of HCV infection status with outcomes of interest including proteinuria, low eGFR (<60 ml/min/1.73 m²), and ESKD.

Results: 9 cross-sectional and 6 cohort studies were identified (n=863,123). By meta-analysis, in 5 cross-sectional studies, there was a significant association between HCV infection and proteinuria (adjusted OR 1.57; 95% CI 1.18, 2.10; P=0.002; I^2 index 74%); however, in 7 cross-sectional studies, there was no association with low eGFR (adjusted OR 1.00; 95% CI 0.81, 1.24; P=0.97; I^2 index 94%). In 4 cohorts, there was no association between HCV infection and incident CKD as defined by low eGFR (pooled adjusted HR 1.12; 95% CI 0.86, 1.48; P=0.40). However, in 2 cohorts, there was a significant association between HCV infection and incidence of ESKD (pooled adjusted HR 1.67; 95% CI 1.54, 1.81; P<0.001; I^2 index 0%).

Conclusions: This meta-analysis demonstrates that HCV infection is associated with proteinuria and incident ESKD. Although there was substantial heterogeneity of effect size estimates across studies, these observations require further study.

TH-PO381

Use of Various Weight Descriptors in the Cockcroft-Gault Equation for Estimating Creatinine Clearance in an Asian Diabetic Population Priscilla P. How,[1,2] Hui Yang Lim,[1] Christine Teng.[1,3] *[1]Pharmacy, National University of Singapore; [2]Medicine (Nephrology), National University Hospital, Singapore; [3]Pharmacy, Tan Tock Seng Hospital, Singapore.*

Background: The Cockcroft-Gault (CG) equation is used to estimate creatinine clearance (CrCl) and determine drug doses for patients with renal impairment. Different weight descriptors such as ideal body weight (IBW), lean body weight (LBW), adjusted body weight (ABW) and no body weight (NBW) have been proposed for more accurate estimated CrCl (eCrCl) for different patients. Rounding of serum creatinine (SCr) to 1mg/dL is also practised in elderly patients though with limited evidence. The objectives of this study were to determine which weight descriptor in the CG equation best approximates measured CrCl (mCrCl) and whether rounding of SCr to 1mg/dL with use of TBW in the CG equation is appropriate in estimating CrCl in our local elderly patients.

Methods: This retrospective cross-sectional study included adult diabetic patients from the Tan Tock Seng Hospital, Singapore. Patients' age, gender, weight, height, SCr and mCrCl from 24-h urine collection were obtained. The eCrCl was calculated using CG equation with different weight descriptors to yield CG_{TBW}, CG_{IBW}, CG_{LBW}, $CG_{ABW0.3}$, $CG_{ABW0.4}$ and $CG_{NBW,}$ respectively. These were compared to mCrCl for bias, precision and accuracy using one-way ANOVA followed by a post-hoc Tukey's test.

Results: A total of 1230 cases (625 male, 605 female) were included for analysis. Mean mCrCl was 61.9±33.3 ml/min. Of the eCrCl calculated using various weight descriptors, $CG_{ABW0.3}$ and $CG_{ABW0.4}$ yielded CrCl of 62.0±29.6 ml/min and 63.5±30.5 ml/min respectively, which were similar to mCrCl (P>0.05). Furthermore, $CG_{ABW0.3}$ and $CG_{ABW0.4}$ had relatively high levels of precision and accuracy to mCrCl than other weight descriptors. For patients aged ≥65 with SCr <1mg/dL, CG_{NBW} (eCrCl 61.5±6.9 ml/min) provided an unbiased estimate of mCrCl (63.1±22.4 ml/min) when SCr was rounded to 1 mg/dL (P>0.05).

Conclusions: The use of ABW in the CG equation to estimate CrCl ($CG_{ABW0.3}$ or $CG_{ABW0.4}$) provided the best estimates of mCrCl in our local diabetic population. CG_{NBW} is most appropriate when using rSCr in elderly patients with SCr <1mg/dL.

TH-PO382

Performance of Untimed Urine Protein-to-Creatinine Ratio for Estimation of 24-Hour Proteinuria among Morbidly Obese Patients: A Prospective Cohort Study Ion D. Bucaloiu, H. Lester Kirchner, Evan Norfolk, James E. Hartle, Robert M. Perkins. *Nephrology Department, Geisinger Medical Center.*

Background: Reduced lean body mass (e.g., in the elderly) results in lower creatinine generation and misleading proteinuria estimates using untimed urine protein-to-creatinine ratios (PCR). In morbidly obese (MO) patients, creatinine generation differs from lean individuals and thus it is unknown whether PCR accurately estimates 24-hr proteinuria. We conducted a prospective cohort study to test the hypothesis that in MO patients, PCR performs poorly for the estimation of proteinuria.

Methods: Adults with BMI > 40 kg/m² evaluated in the Nephrology and/or Weight Management Clinics at Geisinger were eligible; those >65 years, with active malignancy, ESRD, solid organ transplantation, or pregnancy were excluded. Patients returned 24-hr urine collections at the time of blood and untimed urine sample collection. 24-hr urine collection accuracy was defined as measured creatininuria within 35% of expected, with expected creatininuria derived using a previously validated formula. The primary analysis examined the correlation, bias, and precision between PCR and 24-hr proteinuria.

Results: 54 patients submitted 24-hr urine collections. Among those with accurate collections (n = 35), median age was 47 years, 88.6% were Caucasian, and 48.6% male. Median (IQR) BMI was 45.1 (41.7, 52.1) kg/m². Median (range) proteinuria was 0.09 (0.03, 9.8) g. In sensitivity analyses using alternative collection accuracy thresholds (40, 45, 50, and 55 % of expected creatininuria), results were similar.

Performance characteristics of untimed protein-to-creatinine ratio compared with 24-hour proteinuria in morbidly obese. (n=35)

Bias, mean (sd), g proteinuria.	Precision, mean of the square root of the difference between actual and estimated 24-hour proteinuria, g proteinuria	Correlation* (p-value)
-0.05 (0.27)	0.253	0.59 (0.0002)

Conclusions: PCR estimates 24-hr urine poorly among MO patients, and should not be relied upon for clinical decision-making in this population.

Contrast Intensity Following CT Scan Correlates with Kidney Function Katherine Yang,[1] Brittany E. Yee,[1] Cynthia Santillan,[2] Ravindra L. Mehta.[1] *[1]Nephrology, School of Medicine, University of California, San Diego, San Diego, CA; [2]Radiology, University of California, San Diego, San Diego, CA.*

Background: Iodinated contrast agents are utilized to measure glomerular filtration rates (GFR) since their elimination correlates with inulin clearance. Since these agents are almost entirely removed by glomerular filtration we hypothesized that the duration and intensity of the kidney image would correlate with underlying kidney function and could be used to approximate GFR.

Methods: Data was reviewed from 191 consecutive patients who had abdominal CT scans at a single center over a 1 month period and had detailed information on the type, amount and timing of contrast agent and had baseline and serial creatinine measurements over the first 7 days following the scan. GFR was estimated (eGFR) from the baseline serum creatinine using the CKD Epi equation. The time to appearance, duration and intensity of the image were recorded using a standardized method for ascertaining the pixel intensity in Hounsfield units over specific regions in each kidney. The rate of change of contrast intensity between the venous and delayed phases was computed as the log slope and was correlated with the eGFR.

Results: 33(17.3%) patients had a baseline sCr >1 mg/dl (mean eGFR of 62 ml/min) and had a slower change in contrast intensity in comparison to those with sCr<1 (mean eGFR 99 ml/min). The change in contrast intensity correlated with the underlying eGFR.

Rate of change of contrast intensity

eGFR ml/min	Number	Mean sCr mg/dl	Mean eGFR	Mean L Kidney Slope*	Mean R Kidney Slope*
<60	14	1.61	45	.29	.28
60-90	89	.87	77	.36	.37
>90	88	.67	110	.36	.36

* p value =.043

Conclusions: Our data shows a good correlation between the rate of change in contrast intensity in kidney CT images and eGFR. This information could be used as a non-invasive method to measure GFR. Further studies are needed to confirm these findings in patients with other co-morbidities.

Funding: NIDDK Support

TH-PO384

Estimated Glomerular Filtration Rate Is a Good Marker of Renal Clearance for Indoxyl Sulfate and p-Cresyl Sulfate Bjorn Meijers, Liesbeth Viaene, Ruben Poesen, Bert Bammens, Kathleen Claes, Pieter Evenepoel. *Department of Nephrology, University Hospitals Leuven, Leuven, Belgium.*

Background: Indoxyl sulfate (IS) and p-cresyl sulfate (PCS) contribute to CKD progression and cardiovascular disease. Clearance of these solutes predominantly is by active tubular secretion. For any given stage of CKD IS and PCS serum concentrations show a wide inter-individual dispersion. From this it is inferred that eGFR is inadequate to estimate renal clearances of IS and PCS. Renal clearance studies have not been performed to date.

Methods: We studied renal clearances of IS and PCS in the Leuven CKD study cohort (NCT00441623). Associations between eGFR (CKD-EPI) and clearances of creatinine, IS and PCS were analyzed using Spearman rank coefficients. Multivariate linear regression models were built to evaluate the relative contribution of eGFR, demographics and generation rates to IS and PCS concentrations.

Results: We analyzed renal clearances in 203 patients with CKD 1-5. IS renal clearances (median 18, min-max 1.6 - 142 ml/min) exceed PCS clearances (median 7, min-max 0.9 - 43 ml/min) about threefold (clearance ratio mean 2.8, SD 0.9). eGFR was closely associated with measured creatinine clearance (r=0.91), but also with renal clearances of IS (r=0.84) and PCS (r=0.82) (all P<0.0001). In multivariate regression, IS concentrations are determined (R^2 0.74) by eGFR, IS generation rate (both P<0.0001), age and sex (both P<0.05). PCS concentrations are determined (R^2 0.74) by eGFR and PCS generation rate (both P<0.0001).

Conclusions: Estimated GFR provides an acceptable estimate of renal solute clearance of indoxyl sulfate and p-cresyl sulfate. Intriguingly, while renal clearances of indoxyl sulfate and p-cresyl sulfate are closely associated, absolute indoxyl sulfate clearances exceed those of p-cresyl sulfate by threefold and show important interindividual variation. These data suggest substantial differences between tubular transporter affinities and/or the involvement of separate transporter systems for IS and PCS.

TH-PO385

Long-Term Renal Function after Tandem High-Dose Chemotherapy and Autologous Stem Cell Transplantation in Pediatric Patients with High-Risk Solid Tumors Heeyeon Cho. *Department of Pediatrics, Samsung Medical Center, Seoul, Korea.*

Background: High-dose chemotherapy and autologous stem cell transplantation (HDCT/autoSCT) has improved the survival of children with high-risk solid tumors. However, long-term organ damage such as renal insufficiency has emerged as a major cause of treatment-related mortality and morbidity in patients who have undergone HDCT/autoSCT. Little is known about the incidence of chronic kidney disease (CKD) in pediatric patients with HDCT/autoSCT.

Methods: We undertook as retrospective study in order to assess the incidence, risk factors and outcome of HDCT/autoSCT-associated CKD in 58 pediatric patients who were transplanted at Samsung Medical Center from 2008 to 2010. Various renal function parameters were evaluated before each HDCT/autoSCT, and 1 year after the second HDCT/autoSCT.

Results: Thirty-nine patients were male, and 19 were female and the median age at first HDCT/autoSCT was 4.2 years. Primary disease included neuroblastoma (42%), retinoblastoma (6%), and brain tumor (52%). Twelve months after second HDCT/autoSCT, CKD [e.g. glomerular filtration rate (GFR) estimated using Schwartz formula < 90 ml/min/1.73m^2] was noted in 27 patients (46.5%) and the mean GFR was 59.1 ± 27.6 ml/min/1.73m^2. CKD with GFR < 60 ml/min/1.73m^2 was noted in 11 patients (18%). Four of these patients had severe CKD stage 4 and 5, with a GFR < 30 ml/min/1.73m^2 and 2 patients needed dialysis. Three patients received renal replacement therapy during early posttransplant period and progressed to CKD. There was no significant difference in the sex, primary disease, or the baseline GFR between the patients with or without CKD. The age at 1st HDCT/autoSCT was younger in the patients with CKD compared to those without CKD (3.9 ± 3.2 vs. 6.1 ± 4.9 years, P=0.053). Subclinical tubular dysfunctions during early posttransplant period were associated with the development of CKD (P=0.037).

Conclusions: CKD is a relatively common late complication of HDCT/autoSCT. Because renal function may decline with time, there is a risk to progress to end-stage renal disease in pediatric patients. The current findings suggest the necessity for long-term follow-up of vulnerable patients with CKD.

Effect of Renal Failure on Metabolic Rate Using the Doubly-Labeled Water Isotope Technique Enric Vilar,[1,2] Beverley Summerhayes,[1,2] Ashwini Machado,[1] Andrew Garrett,[2] David Wellsted,[2] Ken Farrington.[1,2] *[1]Renal Unit, Lister Hospital, Stevenage, Hertfordshire, United Kingdom; [2]University of Hertfordshire, Hatfield, United Kingdom.*

Background: Renal failure is associated with metabolic disturbances including lean body mass depletion. Metabolic rate in CKD is poorly understood and predictive algorithms are required for provision of accurate dietary advice. Defining the effect of renal failure on metabolic rate is required to develop improved algorithms for calculating dialysis dose in end-stage renal failure. We investigated the impact of CKD on Total Energy Expenditure(TEE) using the gold-standard multi-point doubly-labeled water technique.

Methods: Subjects with CKD were prospectively recruited, half with CKD1-3 and half CKD4-5. All undertook a metabolic analysis with indirect calorimetry to measure basal metabolic rate and respiratory quotient. Over 14 days, TEE was measured using doubly-labeled water. After ingestion of ^{18}O and ^{2}H doses, isotope excretion was measured using mass spectroscopy of interval urine samples allowing CO_2 production and TEE to be calculated. Estimates of TEE were compared between those CKD1-3 and CKD4-5. To determine whether eGFR predicted TEE, multiple linear regression was used.

Results: 40 subjects were recruited of mean age 60±SD15 years. There was no significant difference in body size parameters and comorbidities between the CKD1-3 and 4-5 groups. Serum hemoglobin was lower in those with CKD4-5(p=0.02) but albumin and CRP were similar. The doubly-labelled water technique was successfully used with high correlation of isotope excretion curves(r=-0.99 for both ^{18}O and ^{2}H). Basal metabolic rate was non-significantly lower in the CKD4-5 compared to the CKD 1-3 group(mean 1488 v 1638kCal/day, p=0.11). TEE was non-significantly lower in the CKD4-5 group (2429 v 2620, p=0.17). In multiple regression for TEE, eGFR was not a significant predictor of TEE (p=0.94).

Conclusions: The doubly-labelled water technique is effective for measuring TEE in the CKD population. There was a non-significant trend towards lower basal metabolic rate and TEE in those with CKD4-5. We did not find evidence that advanced CKD is associated with substantial changes to metabolic rate.

Prevalence, Outcome, and Predictors of Cardio-Renal Syndrome in Children with Dilated Cardiomyopathy Ahmad Kaddourah,[1] Stuart Goldstein,[1,2] Jeffrey A. Towbin,[2] John L. Jefferies.[1,2] *[1]Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center (CCHMC), Cincinnati, OH; [2]The Heart Institute, CCHMC, Cincinnati, OH.*

Background: Cardio-renal syndrome (CRS) describes variety of acute or chronic conditions where the primary failing organ can be either the heart or kidney. The prevalence, predictors and outcome of CRS has not been reported in children with dilated cardiomyopathy (DCM).

Methods: Data from patients > 1 year of age with DCM enrolled in the Pediatric Cardiomyopathy Registry (PCMR) was assessed. CRS was defined as glomerular filtration rate <90 ml/min/1.73m^2 estimated by modified Schwartz formula (eGFR). Patients with eGFR>150 ml/min/1.73m^2 were excluded. CRS prevalence was determined by cross-sectional design in patients newly diagnosed with DCM using the baseline PCMR data. Survival analysis compared patients with vs. without CRS using annual PCMR data. Regression models were applied on both baseline and annual data to study the interactions between eGFR and different echocardiographic measures.

Results: The baseline data had 484 children with DCM. Serum Cr data to calculate eGFR were available for 92 patients. Fifty six (62.0%) patients had eGFR < 90 ml/min/1.73m^2, which is greater than the 48% prevalence published in 3256 healthy historical controls (P<0.001). CRS patients had a mean eGFR of 61 (±22.6) vs. 108 (±14) (P<0.001). Death occurred in 8 (14%) of CRS patients compared to no deaths in patients without CRS (P=0.052) after 7 years follow-up. Univariate regression models showed a significant positive correlation between fractional shortening (FS) and eGFR (P= 0.0013, r^2 = 0.09). No correlation was observed between eGFR and ejection fraction (EF), left ventricular end-diastolic dimension (LVEDD) and LVEDD Z-scores.

Conclusions: This is the first study to show that CRS is common in children newly diagnosed with DCM and is associated with higher risk of subsequent death. Worsening FS was associated with decreasing eGFR which suggests that patients with poor FS might have significant CRS. We suggest kidney functions should be evaluated systematically in children with DCM to assess for chronic kidney disease and direct potential management.

TH-PO388

Kidney Injury Molecule-1 (KIM-1) Is a Promising Urinary Biomarker to Detect Cardiorenal Syndrome in Children with Dilated Cardiomyopathy (DCM) Ahmad Kaddourah,[1] Stuart Goldstein,[1,2] John L. Jefferies.[1,2] *[1]Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center (CCHMC), Cincinnati, OH; [2]The Heart Institute, CCHMC, Cincinnati, OH.*

Background: Type II cardiorenal syndrome (CRS) describes renal dysfunction in the presence of chronic heart dysfunction. Novel urinary acute kidney injury biomarkers (NUB) have not been studied in children with DCM. We aim to 1) Evaluate the correlation between four NUB and severity of LV dysfunction, and 2) Determine the best marker to detect CRS in children with DCM.

Methods: We are conducting a cross-sectional study in children with DCM and LV dysfunction. Enrolled children had an echocardiogram to measure the LV ejection fraction (EF). Urine samples were collected at the same visit to measure the NUB: KIM-1, NGAL, IL-18, and L-FABP. NUB levels were adjusted for each mg of urinary creatinine. Glomerular filtration rate was estimated using modified Schwartz formula (eGFR) when Creatinine level (Cr) is available. Univariate analysis was conducted between patients (pts) with EF< 45% and EF ≥ 45%. ROC analysis was performed for all NUB and GFR. 2x2 tables were constructed from NUB cutoffs to maximize specificity for EF <45%.

Results: 30 pts (14.2 ±6.4 years old) have been enrolled to date. 13 (43%) had EF<45%. Although all NUB levels were higher in pts with EF <45%, only KIM-1 was significantly higher [836.5 (±844.1) vs. 442.8 (±249.5) pg/mg$_{cr}$, $P_{one\text{-}tailed}$=0.04]. Area under the curve for KIM-1 was 0.61 to predict EF <45%, compared to 0.53 for eGFR. A KIM-1 cutoff of 900 pg/mg$_{cr}$ yielded highest correct EF classification (38% sensitivity, 94% specificity). 6/30 (20%) pts had KIM-1 >900; 5/6 (83%) had EF of <45% vs. 8/24 (33%) with KIM-1<900 ($P_{one\text{-}tailed}$=0.03).

Conclusions: Our pilot data suggest DCM pts with EF<45% tend to have higher NUB urinary levels indicating worse CRS than pts with EF≥45%. Urinary KIM-1 may be the most predictive test to detect CRS compared to other NUB and eGFR. We anticipate confirming this finding by increasing the study's power.

TH-PO389

Evaluation of a Non-Invasive Survey to Identify Individuals with Chronic Kidney Disease in a Community-Based Screening Program Donna H. Harward,[1] Heejung Bang,[2] Yichun Hu,[1] Abhijit V. Kshirsagar.[1] *[1]University of North Carolina at Chapel Hill; [2]University of California Davis.*

Background: We previously developed the SCORED questionnaire based on nine readily available characteristics (age, gender, anemia, hypertension, diabetes, cardiovascular disease, heart failure, peripheral vascular disease, and proteinuria)to identify individuals with a high likelihood of having prevalent CKD.Individuals are given a numeric value for the presence of these characteristics, and those having a cumulative integer score of ≥ 4 have a 20% chance of having CKD, defined as an estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^2. While SCORED is well validated in national datasets such as NHANES and ARIC, its utility has not been demonstrated in community screenings where it could be a simple and inexpensive test. This study sought to evaluate SCORED in an ongoing community screening program in rural North Carolina with a predominantly African American population.

Methods: We conducted screenings as part of the UNC Kidney Education Outreach Program from December 2010 through August 2011. The study employed a cross-sectional design where the SCORED questionnaire was administered at the same time that blood was collected. Serum creatinine was used to calculate MDRD and CKD-EPI eGFR. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of SCORED for eGFR < 60 ml/min/1.73 m2 were calculated.

Results: Of the 359 persons who participated in the 16 separate screenings, 169 participants provided blood for measuring creatinine. The average age of the group was 55 years, 80% were African American, and 73% female. About 9% of the participants

providing blood had eGFR < 60 ml/min/m2. The sensitivity and specificity of SCORED was 100% and 34% respectively; PPV was 13%, and NPV was 100% using the MDRD eGFR. Similar test characteristics were seen using the CKD-EPI eGFR to define CKD.

Conclusions: The SCORED questionnaire demonstrated good screening test characteristics in a community based setting with a predominantly African American population. It may provide a simple and cost-effective alternative to invasive screening tests for CKD.

TH-PO390

Association of Body Composition and Estimated Glomerular Filtration Rate in Elderly Males and Females Hrefna Gudmundsdottir,[1,4] Margret B. Andresdottir,[1] Lesley Stevens Inker,[3] Runolfur Palsson,[1,4] Vilmundur Gudnason,[2] Andrew S. Levey,[3] Olafur S. Indridason,[1] Thor Aspelund.[2,4] *[1]Landspitali University Hospital, Iceland; [2]Icelandic Heart Association, Iceland; [3]Tufts Medical Center, Boston, MA; [4]University of Iceland, Iceland.*

Background: Changes in body composition (BC) and kidney function are commonly seen with aging. Limited data is published on the association of kidney function and BC in the elderly population. The goal of the study was to determine if there was an association between BC, strength and estimates of kidney function in elderly males and females.

Methods: The data were obtained from the population based Age, Gene/Environment Susceptibility - Reykjavik Study. A total of 1.610 males and 2.059 females had complete data. BMI (kg/m2) was calculated from height and weight and abdominal circumference (AC) measured using standardized protocols. Fat% was measured by bio-electrical impedance and prediction equations were used to calculate fat free mass (FFM) and total fat mass (TFM). Leg muscle strength (LMS) was measured using an adjustable dynamometer chair. Estimated GFR (eGFR) was calculated by the CKD-EPI equation using IDMS-standardized creatinine. Descriptive statistics and linear regression analysis adjusted for age, hypertension (HTN) and diabetes (DM) were performed.

Results: All participants of the study were white and 56.1% were females. The mean (SD) age of the population was 76.2 (5.5) years, 79.8 % had HTN and 12.1 % DM. The changes in BC measures and LMS associated with 10 ml/min/1.73m^2 increase in eGFRare shown in the Table for males and females, respectively. A significant interaction with sex was found for the association of eGFR with AC and LMS (p<0.05).

Table

	Males	Females
BMI (kg/m^2)	-0.14 ± 0.07 *	-0.31 ± 0.07 ***
FFM (kg)	-0.41 ± 0.13 **	-0.36 ± 0.01 ***
FAT (kg)	-0.12 ± 0.12	-0.37 ± 0.11 ***
Abd (cm)	-0.33 ± 0.19	-0.86 ± 0.19 ***
Str (Nwt)	-5.73 ± 1.81 **	1.70 ± 1.08

*p<0.05, **p<0.005, ***p<0.0001

Conclusions: Measures of BC and strength are negatively associated with GFR estimated from serum creatinine in older adults and this relationship can be different for men and women. These findings need to be confirmed with measured GFR.

TH-PO391

Renal Biopsy in the Elderly Is Safe, Leads to Disease Specific Treatment and Prevents End Stage Renal Failure Candice Clarke, Megan Griffith, H. Terence Cook, David Taube, Khrishanthne Sambasivan. *Imperial College Kidney and Transplant Centre.*

Background: With the growing aging population elderly patients make up a large proportion of new nephrological referrals but pragmatically are less likely to be offered renal biopsies. A caveat to this is that they may be disadvantaged in not receiving disease specific treatment. Evidence on whether older patients benefit from such intervention is limited. The aim of this study was to analyse the indications, histological features and outcomes from biopsies in elderly patients.

Methods: We retrospectively studied patients ≥70yrs of age who underwent a first native renal biopsy at our unit between 2005-2011.

Results: 306/2583 [11.9%] of all native biopsies were performed in patients ≥70yrs. Mean age at time of biopsy was 74.6±3.8yrs. 202[66.0%] were males,198[64.7%] were caucasoid. Mean follow up was 3.2±1.7yrs.

Patient survival at 1,3 and 5yrs was 93.4,84.0 and 70.1%. Dialysis free survival at 1,3 and 5yrs was 89.3,83.4 and 76.2%.24[7.8%] patients were dialysis dependent at the time of biopsy,20 received specific therapy and 8 recovered function. Dialysis dependence was associated with increased risk of death,p=0.0088.

The indications for biopsy were CKD:171[55.9%],AKI:63[20.6%],nephrotic range proteinuria with preserved function:43[14.1%] and nephrotic with renal impairment:29[9.5%]. The main histological findings were:pauci-immune glomerulonephritis [GN] in 34[11.1%],other primary GN:72[23.5%],diabetes:45[14.7%],tubulo-interstitial nephritis:38[12.4%],amyloid/myeloma:16[5.2%],ATN:13[4.4%],non-specific scarring:75[24.8%] and other pathologies 14[4.6%].101[33.0%] had a positive serological screen and 180[58.8%] had an abnormal urinary sediment. Patients with pauci-immune GN were more likely to be dialysis dependent at the time of biopsy,p=0.001.147[48.0%] of patients required disease specific treatment.Complication rates were low with only 5[1.6%] of patients developing perinephric haematomas or macroscopic haematuria.

Conclusions: This study shows that full evaluation of renal disease in elderly patients is important. Specific treatment can be indicated, without which there may be increased risk of ESRF and mortality.

TH-PO392

Comparison of Performance for Estimating Glomerular Filtration Rate Using MDRD and CKD-EPI Equation in the Korean Population Yun Jung Oh,[1] Su Mi Lee,[1] Hajeong Lee,[1] Dong Ki Kim,[1] Yon Su Kim.[1,2] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [2]Kidney Research Institute Medical Center, Seoul National University Hospital, Seoul, Republic of Korea.*

Background: The Chronic Kidney Disease Epidemiology Collaboration(CKD-EPI) equation was developed to resolve limitation of the Modification of Diet in Renal Disease(MDRD) equation that was derived from CKD patients. The CKD-EPI equation shows better accuracy in estimating glomerular filtration rate(GFR) than MDRD equation in most studies, but not all. Furthermore, it has not been externally validated in Korean population.

Methods: We compared the estimations of MDRD and CKD-EPI equations to a gold standard GFR measurement using plasma ^{51}Cr-EDTA clearance. All subjects from the study population composed of 30 healthy volunteer and 102 CKD patients underwent a GFR measurement and simultaneous renal function assessment including serum creatinine. Bias, precision, and accuracies between estimated and measured GFR were calculated. These values were analyzed within strata of variables.

Results: Overall, CKD-EPI equation had less bias(-3.4 versus -8.4) and high accuracy than MDRD equation(*P*=0.004). CKD-EPI equation demonstrated better agreement between measured GFR and estimated GFR in the classification into CKD stages (Cohen's κ 0.714 versus 0.575). While both equations underestimated GFR in the subjects with GFR≥60 ml/min/1.73m^2, overestimated in GFR<60 ml/min/1.73m^2. In case of GFR≥60 ml/min/1.73m^2, CKD-EPI equation had higher accuracy (P=0.004) than MDRD equation. In GFR<60 ml/min/1.73m^2, MDRD equation had less bias but, the accuracy was not significantly different from CKD-EPI equation. The accuracy of CKD-EPI equation was higher in younger than 60 years(*P* <0.001), but was not different in subjects older than 60 years.

Conclusions: In general, CKD-EPI equation was superior to MDRD equation for estimating GFR, and these were influenced by GFR and age.

Funding: Government Support - Non-U.S.

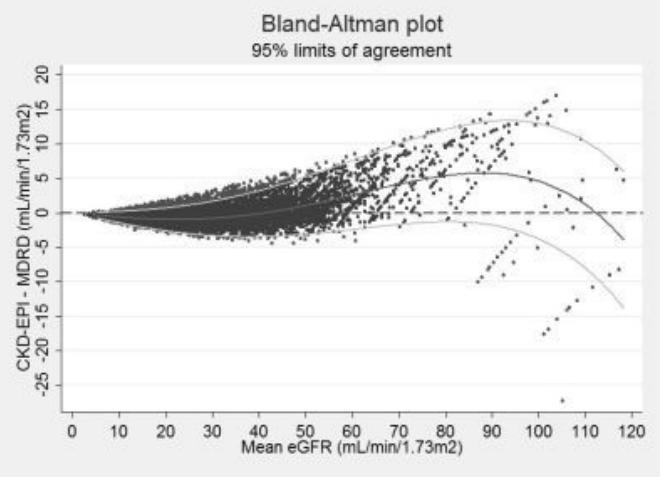
TH-PO393

Comparison of MDRD and CKD-EPI Equations: An Alternative Method Based on Bland-Altman Plot and Fractional Polynomial Regression Antonio Santoro,[1] Jacopo Lenzi,[2] Marcora Mandreoli,[1] Paola Rucci,[2] Mattia Corradini,[3] Dino Gibertoni,[2] Maria Pia Fantini.[2] *[1]Nephrology, Dialysis and Hypertension, Policlinico S. Orsola-Malpighi, Bologna, Italy; [2]Department of Public Health and Statistc, Alma Mater Studiorum University of Bologna, Bologna, Italy; [3]Nephrology and Dialysis, Arcispedale S. Anna IRCSS, Reggio Emilia, Italy.*

Background: Evidence from the literature suggests that the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation more accurately estimates glomerular filtration rate (GFR) than the Modification of Diet in Renal Disease (MDRD) Study equation using the same variables, especially at higher GFR. The Bland-Altman graphical method has been used to compare the two equations, but it is biased because the assumption that the mean and the standard deviation of the difference between the two equations are constant across all GFR values does not hold. This study is aimed to suggest an alternative method, based on polynomial fractional regression, to compute the confidence interval of the difference between the two equations.

Methods: The data used are drawn from the Italian PIRP (Prevention of Progressive Renal Insufficiency) registry, that collects prospectively demographic and clinical information on 10,687 outpatients with CKD in the Emilia-Romagna region since 2004.

Results: Evaluation of the agreement between these formulas showed that there was a good correlation between CKD- EPI and MDRD for values of eGFR between 40 and 10 mL/min/1.73m^2. In this range the two formulas may be interchangeable.



Conclusions: In the patients with CKD in its early stages (CKD2, CKD3a), we suggest to monitor the time course of renal function with the same estimation formula, because the deviation between the values obtained is quite large. Clinical implications of this method in terms of accurate prediction of risk of renal failure will be discussed.

Funding: Government Support - Non-U.S.

TH-PO394

Poor Outcome in Incident Dialysis Patients with High Estimated GFR (eGFR), but Not with High Measured GFR (mGFR), Is due to Confounding by Protein-Energy Wasting (PEW) Olof Heimburger, Peter F. Barany, Peter Stenvinkel, Bengt Lindholm, Abdul Rashid Tony Qureshi. *Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

Background: Several studies have shown that a high eGFR at initiation of dialysis is predictive of a poor outcome. The aim of the present study was to assess to what extent this was due to confounding by PEW.

Methods: We studied 399 patients with CKD 4-5 (248 males, mean age 53 years) close to start of dialysis. Renal function was measured using the average of urinary urea and creatinine clearance from a 24-h urine collection (mGFR) and compared to eGFR from the body surface area corrected Cockroft Gault equation (CG), the 4 and 6 variable MDRD equations, and the CKDepi equation. 3-year survival (censored for transplantation) was calculated using the Cox model. The relationships between eGFR and nutritional variables (e.g., lean body mass DEXA (LBM), hand-grip strength (HGS), subjective global assessment (SGA)) were studied.

Results: There were strong correlations between eGFR CG and the other eGFRs (r^2=0.76-0.81), and particularly between eGFR MDRD 4V, 6V and CKDepi (r^2=0.94-0.89), but the correlations between mGFR and the eGFRs were less strong (r^2=0.38-0.45). Using the Cox model (including age, sex, diabetes, cardiovascular disease and p-CRP) a high eGFR (any method) predicted poor outcome, but there was no difference in survival between the tertile groups of mGFR. When SGA was added in the model, the impact of eGFR on outcome was borderline or non-significant. Though correlations between mGFR and nutritional variables were weak (except for LBM), negative correlations were found between eGFR and nutritional variables, for all eGFR methods:

	mGFR	eGFR CG	eGFR MDRD4V	eGFR MDRD6V	eGFR CKDepi
ml/min/1.73m²	6.7±2.1	10.2±3.1	6.8±2.3	7.0±2.6	6.8±2.7
vs. HGS	rho= -0.02, ns	rho= -0.21***	rho= -0.28***	rho= -0.25***	rho= -0.28***
vs. LBM	rho= -0.17**	rho= -0.11, ns	rho= -0.15**	rho= -0.16**	rho= -0.18***
vs. SGA	rho= 0.03, ns	rho= 0.23***	rho = 0.35***	rho = 0.29***	rho= 0.34***

Values are mean ±SD, **p<0.01, ***p<0.001

Conclusions: Poor prognosis with high eGFR at start of dialysis is to a large extent due to confounding by PEW.

Funding: Pharmaceutical Company Support - Baxter Healthcare Corporation, Government Support - Non-U.S.

TH-PO395

A New Risk Scoring System for Predicting ESRD within One Year: A Tool for Judging, When to Prepare for Renal Replacement Therapy (RRT) Fumika Taki,[1] Keita Hirano,[1] Kenichiro Koitabashi,[1] Kumiko Shimasaki,[1] Masahiko Nagahama,[1] Tomio Omata,[2] Yasuhiro Komatsu.[1] *[1]Department of Internal Medicine, Division of Nephrology, St.Luke's International Hospital, Tokyo, Japan; [2]Clinical Epidemiology, St.Luke's International Hospital, Tokyo, Japan.*

Background: On the late stage of CKD patients, nephrologists need to consider RRT. Timing of starting the preparation of RRT for these patients should be, not too early or late. For judging the timing, knowing the last one year risk for ESRD may be useful. We developed the new scoring system predicting ESRD within a year, from our previous clinical data.

Methods: From 2004 to 2011, CKD stage 4 to 5 patients in St.Luke's international hospital, Tokyo, Japan, were participated. We determined these patients' development of ESRD by initiation of dialysis or GFR<5ml/dl/min. Their characteristics of clinical parameters; baseline GFR, laboratory data, co-morbidity and medications were assessed. Logistic regression was used to identify one year ESRD risk factors, and these factors were used to construct a risk score predicting one-year ESRD risk.

Results: 265 patients were included, 52.3% were male, mean age was 64.6 years and their baseline eGFR was 16.5±7.2mg/dl/min. 30 patients (11.2%) turned in ESRD within a year: they tend to have higher rates of diabetes (70% vs. 37%) and higher usage of diuretics (80% vs. 38%), more existing proteinuria (5.2g/day vs. 1.2g/day) and lower baseline GFR (13.8 vs. 16.8 mg/dl/min) compared with non-ESRD patient within a year. We included these factors and made risk scores (Table 1). This scoring system has 0.78 sensitivity and 0.84 specificity, for predicting dialysis within a year. From these scores, "total risk score over 6" patients have more than 80% risk of ESRD within a year. These patients need starting RRT education.

Conclusions: Our new risk scoring system contributes to show appropriate timing for starting RRT education for the late stage of CKD patients.

Risk score predicting ESRD within a year

Risk	Risk Score	Total Risk Score/ ESRD risk within a year (%)
eGFR 20-30mg/dl/min	0	0/12%
eGFR 10-20mg/dl/min	1	1/25%
eGFR <10mg/dl/min	2	2/37%
Proteinuria <1g/day / >1g/day	0/2	3-5/62%
Diabetes -/+	0/2	6-7/82%
Diuretics -/+	0/2	8/94%

TH-PO396

Prevalence of Chronic Kidney Disease in Patients Treated with Lithium Compared to Other Psychiatric Patients Olafur S. Indridason,[1] Engilbert Sigurdsson,[2,3] Matthias Halldorsson,[2] Runolfur Palsson.[1,3] *[1]Division of Nephrology; [2]Division of Psychiatry, Landspitali - the National University Hospital of Iceland; [3]University of Iceland, Reykjavik, Iceland.*

Background: We have previously reported an increased prevalence of chronic kidney disease (CKD) in adult patients on long-term lithium treatment compared to healthy controls. The purpose of this study was to examine if the same holds true when patients with psychiatric disorders are used as controls.

Methods: In this retrospective study, we obtained information on all adult subjects taking lithium during the years 2003-2010 by examining records of serum lithium measurements performed at the University Hospital in Reykjavik and prescriptions for lithium in the National Drug Prescription Database. The control group consisted of all patients above the age of 18 years who attended the Psychiatry Outpatient Clinic at the University Hospital and had at least one serum creatinine (SCr) measurement available in the hospital records, excluding those on lithium therapy. SCr was obtained from medical records and the eGFR was calculated from the lowest SCr value in the last year of measurement for each subject using the MDRD equation. CKD was defined as eGFR <60 mL/min/1.73 m².

Results: A total of 1577 subjects received at least one lithium prescription during the study period, 454 (25.2%) of whom had no recorded measurements of serum lithium or SCr. The remaining 1123 subjects had a median (range) age of 46 (18-98) years, and 659 were female (58.7%). The control group comprised 4549 subjects with a median age of 36 (18-89) years, 2623 (57.7%) of whom were female.

Prevalence of CKD in the lithium and control groups, by age

Age group (years)	Lithium group	Control group	P-value	OR (95% CI)
18-30	0%	0.1%	-	-
30-40	3.2%	0.2%	<0.001	17.0 (3.5-82.4)
40-50	6.9%	0.4%	<0.001	20.2 (6.0-69.1)
50-60	13.9%	1.2%	<0.001	13.4 (6.0-30.0)
60-70	25.5%	2.9%	<0.001	11.6 (5.4-24.8)
>70	41.8%	7.6%	<0.001	8.7 (4.3-17.5)

Conclusions: Patients receiving lithium therapy have a significantly increased risk of CKD, compared to other patients with psychiatric disorders. These findings are comparable to those of our previous study with controls drawn from the general population.

TH-PO397

Creatinine and Cystatin-C Based Equations in Comparison with 51-Chromium EDTA in Prediction of Glomerular Filtration Rate in Malay Population in University Malaya Medical Centre Maisarah Jalalonmuhali, Kok Peng Ng, Soo Kun Lim, Li Ping Tan, Tee Chau Keng, Yip-Boon Chong, Wai Yew Kong, Chew Ming Wong. *Division of Nephrology, University Malaya Medical Centre, Kuala Lumpur, Malaysia.*

Background: Accurate measurement of renal function is very important, however gold standard measurement of GFR can only be used on a very limited scale. Creatinine based eGFR equations are widely used but the performance may vary depending on ethnicity. We propose a study to validate the accuracy of available eGFR formulas in Malay population.

Methods: This was a cross-sectional study recruiting patients from UMMC Renal clinic. All patients underwent 51-Chromium EDTA clearance for measurement of GFR. Blood was obtained for serum creatinine and plasma cystatin-C. Serum creatinine was determined by IDMS reference modified Jaffe kinetic assay. The predictive capabilities of Cockcroft-Gault (CG), CG corrected for body surface area (CGBSA), 4-MDRD, CKD-EPI and cystatin-C based equations were calculated. Data were analysed using SPSS version 20 and bias, precision and accuracy were determined.

Results: A total of 51 subjects with mean age of 58.7 years and BMI of 26.5 kg/m² were recruited. The mean reference GFR was 42.04 (17.70 – 111.10) ml/min/1.73m². Estimated GFR based on CG, CGBSA, 4-MDRD, CKD-EPI and cystatin-C formula were 42.25 (16.90 – 98.20), 40.47 (16.52 – 115.52), 35.90 (14.00 – 98.00), 37.24 (14.00 – 121.00) and 49.76 (21.00 – 90.00) respectively. While all eGFR formulas correlated well with the reference GFR (0.860, 0.877, 0.848, 0.854, 0.811), overall the 4-MDRD equation performed the best. Subgroup analysis showed similar performance for CKD-EPI and 4-MDRD equations in patients with GFR < 60 ml/min/1.73m², while CG was noted to be superior in patients with GFR ≥ 60 ml/min/1.73m² and in patients with BMI < 23 kg/m². For patients with BMI ≥ 23 kg/m², the 4-MDRD equation performed better. Interestingly, in non-diabetics, cystatin-C formula was the most accurate equation.

Conclusions: The 4-MDRD equation was better in estimating GFR in Malay population specifically in the subgroup of GFR < 60 ml/min/1.73m² and BMI ≥ 23 kg/m². Cystatin-C formula was better in non-diabetic group.

TH-PO398

Prevalence and Risk Factors for Chronic Kidney Disease in a Community-Based Population in Japan Hiroyuki Watatani, Yohei Maeshima, Hiroko Yamasaki, Norikazu Hinamoto, Haruyo Ujike, Hitoshi Sugiyama, Hirofumi Makino. *Dept. of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Okayama, Japan.*

Background: Chronic kidney disease (CKD) is associated with increased risk for end-stage renal disease and cardiovascular morbidity and mortality. Recent reports indicate CKD affects 10–15% of the adult population worldwide. We aimed to determine the prevalence and the risk factors for CKD in general population of Okayama, Japan.

Methods: We conducted a community-based cross-sectional cohort study with 8239 adults aged 40 years and over (40-75 yo) who received the national health checkup program in Japan (Specific Health Checkups and Guidance System) in 2011 living in Okayama city. CKD was determined by estimated glomerular filtration rate (eGFR) calculated by modified MDRD equation for Japanese, and proteinuria assessed by urine dipstick. Clinical and anthropometric data were collected. Descriptive statistics, Anova, Chi-square test, multiple-logistic regression test were performed.

Results: Mean age of participants was 67±8 yo, 28% had overweight (BMI>25). The prevalence of CKD was 22.8%. The adjusted risk factors of CKD included age, hyperuricemia (> 7.0 mg/dl) (OR 3.2 [2.72-3.8], p<0.0001), obesity (BMI>25) (OR 1.21 [1.06–1.37], p= 0.0034), and past history of cardiovascular events (OR 1.38 [1.12–1.69], p =0.0021). In subjects with hypertension and prehypertension and a normal blood pressure (over 140/90 mmHg), the risk for CKD was significantly greater (OR 1.19) than those with optimal blood pressure (less than 120/80 mmHg). Subjects with hyperuricemia (7.0-7.9 mg/dL), high normal serum uric acid level (6.0-6.9) exhibited increased risk for CKD (OR 3.89, 2.17, respectively) than those with normal level (less than 6.0). Gender differences and past history of stroke were not identified as significant risk factors.

Conclusions: In the current rather elderly general population, CKD was very common with a prevalence of 22.8%. These results suggest that subjects with elderly age, obesity, mildly elevated serum uric acid, hypertension and previous history of cardiovascular events possess increased risk for CKD, requiring appropriate instruction and follow-ups.

TH-PO399

Prevalence of Chronic Kidney Disease in Primary Care in a Central European Country: A Cross-Sectional Study Yuki Tomonaga,[1] Thomas D. Szucs,[2] Lorenz Risch,[3] Patrice M. Ambuehl.[4] *[1]Institute of Social and Preventive Medicine, University of Zurich, Zurich, Switzerland; [2]European Center of Pharmaceutical Medicine, University of Basel, Basel, Switzerland; [3]Labormedizinisches Zentrum Dr. Risch, Schaan, Liechtenstein; [4]Renal Division, Stadtspital Waid, Zurich, Switzerland.*

Background: As severe chronic kidney disease (CKD) is usually identified based on typical symptoms, little information is available on the prevalence of clinically silent mild to moderate CKD in a primary care setting. Our aim was to estimate the prevalence of CKD in primary care in Switzerland.

Methods: A multicenter, cross-sectional study with randomly selected general practitioners (GP) was performed. Adults visiting the GPs during defined periods were asked to participate. Demographic and social variables, clinical status and co-morbidities were reported on a questionnaire. Urine and blood samples were analyzed in a central laboratory. Renal status was assessed using the KDIGO classification [1]. Extrapolation to national level was adjusted for age and gender.

Results: 1000 individuals were included. 57% were females and the mean age was 57±17 years. Overall, 41% of the patients had normal estimated glomerular filtration rate (eGFR) and albumin creatinine ratio (ACR), whereas 36% of the subjects had slightly reduced excretory renal function with physiological albuminuria based on normal ACR. About one tenth of the patients had a substantially reduced eGFR of <60 ml/min/1.73m^2, and 17% showed relevant proteinuria (ACR >30 mg/g creatinine). Almost one fourth of the subjects had either a substantial reduction in renal function or high levels of proteinuria. Extrapolation to national level suggests that about 18% of primary care patients may suffer from CKD.

Conclusions: CKD prevalence in a primary care population is high. Screening may be advisable, in particular as CDK prevalence is likely to rise over the next decades due to an ageing population and common epidemiological risk factors.

Characteristics of Renal Insufficiency in Korean Multiple Myeloma Patients: Reversible Factors from Renal Dysfunction Hyun Chul Whang, Eun Sil Koh, Yu Ah Hong, Sungjin Chung, Cheol Whee Park, Yong-Soo Kim, Yoon-Sik Chang. *Department of Internal Medicine, The Catholic University of Korea College of Medicine, Seoul, Korea.*

Background: Multiple myeloma (MM) is frequently accompanied by renal insufficiency which has been regarded as a poor prognosis factor for MM. It has been known that the incidence and characteristics of MM in Asia are different from those in western countries. The aim of this study is to evaluate risk factors of renal impairment and to investigate reversible factors from renal failure in patients with MM.

Methods: The patients newly diagnosed with MM from 2005 to 2008 at a single center in Korea were included. We investigated factors associated with renal insufficiency and those related to recovery from renal dysfunction after 12 week of treatment of MM.

Results: Renal insufficiency was recognized in 79 (36%) of 221 patients at the time of diagnosis of MM. When comparing characteristics between patients with renal insufficiency (n=79) and patients with normal kidney function (n=142), there were no significant differences in types of immunoglobulin and amounts of serum free light chains. In the binary logistic regression analysis, presence of diabetes (OR=4.12, p=0.02), β2–microglobulin level (OR=1.01, p=0.02) and serum calcium level (OR = 1.936, p<0.01) were independence risk factors of renal failure in MM patients. After 12 weeks treatment, 24 (30%) of 79 patients with renal insufficiency recovered normal renal function. No improvement of renal function was seen mainly in patients with male gender, IgA type MM, high β2–microglobulin level, increased 24 hour urine protein excretion and poor response to chemotherapy. In the binary logistic regression analysis, only good response to chemotherapy (OR=4.9, p<0.01) was associated with renal function recovery.

Conclusions: Diabetes, β2–microglobulin and amount of urine protein were independent risk factor for development of renal failure in Korean MM patients, and the response to chemotherapy significantly influenced recovery of renal function.

TH-PO401

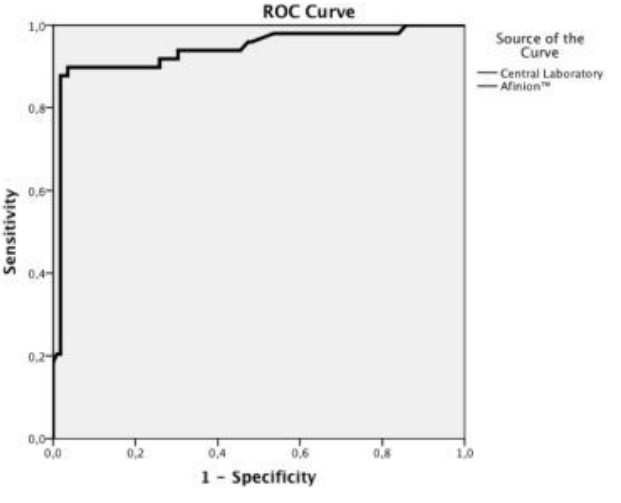
Utility of a Point of Care Device in the Diagnosis of Albuminuria in Type 2 Diabetes Mellitus Patients Laura Cortes-sanabria, Miguel Tapia Alanis, Victor Omar Frías-navarro, Blanca Liliana Maldonado-ruiz, Erika Fabiola Gómez-garcía, Karla Gabriela Meza-torres, Héctor R. Martínez Ramírez, Alfonso M. Cueto-Manzano. *Unidad de Investigacion Medica en Enfermedades Renales, Hospital de Especialidades, CMNO, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

Background: Albuminuria (Album) is a key measurement for diagnosis of nephropathy in high risk groups. Afinion™ ACR is a point of care test for quantitative determination of albumin/creatinine ratio (ACR) in urine, which uses a solid phase immunochemical assay for Album and an enzymatic colorimetric test for creatinuria. A portable device may have obvious advantage in certain situations, for example screening programs; however, the accuracy of the method should be adequately demonstrated.

Aim: To establish the accuracy of Afinion™ ACR compared to central laboratory methods (spectophotometry for Album measurement and two-point kinetic measurement for creatinuria) in DM2.

Methods: DM2 patients of any age, sex and duration DM were included. In a first morning urine sample, both Afinion® ACR and central laboratory methods were performed. All measurements in the central laboratory were performed by the same personnal, blinded to details of the samples. Microalbuminuria (MA) was defined as ACR 30-300 mg/g, and macroalbuminuria (MAA)>300 mg/g.

Results: 161 patients with age of 62 ± 11 years were studied; 88 (55%) women, and 79 (49%) with hypertension. MA was found in 31 (19%) patients, and MAA in 18 (11%). Sensitivity of Afinion™ ACR was 90% and specificity 98%; both positive and negative predictive values were 95%. Global accuracy of the test was 0.96% (maximum value 1). The best cut-off point for MA was 28.7 mg/g, and the area under the curve (±SE) was 0.94 ± 0.02 (95% confidence interval of 0.89-0.99).



Conclusions: Afinion™ ACR is a rapid, valid, and reliable method for albuminuria diagnosis in DM2 patients.

TH-PO402

Prevalence and Associations of Proteinuria in Australian Scleroderma Patients: A Retrospective Review Holly L. Hutton,[1] Joanne Maree Sahhar,[2] Gene-siew Ngian,[2] Peter G. Kerr,[3] Kevan Polkinghorne.[3] *[1]Nephrology, The Geelong Hospital, Geelong, Victoria, Australia; [2]Rheumatology, Monash Medical Centre, Clayton, Victoria, Australia; [3]Nephrology, Monash Medical Centre, Clayton, Victoria, Australia.*

Background: Previous studies suggest that proteinuria is a predictor of death in this multisystem, chronic autoimmune disease. However whether the presence of proteinuria is related to traditional cardiovascular risk factors or Scleroderma itself is unclear. We aimed to assess the prevalence and associations of dipstick positive proteinuria in a cohort of 659 patients with scleroderma.

Methods: Subjects with scleroderma without missing data at baseline (N=659 of 1104) were obtained from the Australian Scleroderma Cohort Study (ASCS). Proteinuria was defined as trace or more positive on urine dipstick. Predictors of proteinuria were assessed using logistic regression and mortality assessed using Cox models.

Results: 582 (88%) subjects were female with median age 57.5 years. 67% had limited scleroderma, 26% diffuse disease, 6% mixed connective tissue disease (MCTD). 7.9% had coronary artery disease (CAD), 31.8% hypertension and 2.7% diabetes. Prevalence of proteinuria was 8.5% (3.6% trace, 4.9% one plus or greater). On univariate analysis, scleroderma disease classification (p=0.022) but not hypertension (p=0.065) was associated with proteinuria. On multivariate analysis, subjects with MCTD were three times as likely to have proteinuria (OR 2.99) compared to limited disease. Other independent predictors of proteinuria were eGFR and age, but not diabetes, hypertension or CAD. Pulmonary hypertension (HR 3.49, 95% C.I. 1.69-7.25) but not proteinuria (HR 2.17, 95% C.I. 0.70-6.74) independently predicted mortality.

Conclusions: The prevalence of proteinuria in this cohort was higher than in age matched Australian population estimates. Associations were age, eGFR and scleroderma subtype but not traditional cardiovascular risk factors.

TH-PO403

Estimating Glomerular Filtration Rate in Elderly Chinese Patients with Chronic Kidney Disease Xun Liu,[1] Chenggang Shi,[1] Linsheng Lv,[2] Cailian Cheng,[1] Hua Tang,[1] Tan-qi Lou.[1] *[1]Division of Nephrology, Department of Internal Medicine, The Third Affiliated Hospital of Sun Yet-sun University, Guangzhou, Guangdong, China; [2]Operating Room, The Third Affiliated Hospital of Sun Yet-sun University, Guangzhou, Guangdong, China.*

Background: Chronic kidney disease (CKD) has become a world widely problem needed particularly special attention. In the previous study, a group of 103 elderly CKD patients were investigated to evaluate the applicability of formulas based on serum creatinine (SC) levels. In this study, we increased the sample size and sought to evaluate these formulas again.

Methods: 319 elderly Chinese patients with CKD were enrolled. SC was determinedenzymatically. The ^{99m}Tc-DTPA-GFR was used as the standard GFR (sGFR). The mean age was 70.0 ± 6.8 years. The mean sGFR was 39.4 ± 21.8 ml/min/1.73 m^2. The Cockcroft-Gault-equation, 4-variable MDRD equation, 6-variable MDRD equation, Jelliffe-1973-equation and Hull-equation were tested.

Results: On the Bland–Altman plot, the precision ranged from 58.5 ml/min/1.73 m^2 to 76.4 ml/min/1.73 m^2. Median of difference ranged from -0.3 ml/min/1.73 m^2 to -4.3 ml/min/1.73 m^2. Accuracy with a deviation less than 15% ranged from 27.9% to 32.9%. Accuracy with a deviation less than 30% ranged from 53.6% to 57.7%. Accuracy with a deviation less than 50% ranged from 74.9% to 81.5%. CKD stage misclassification ranged from 42.9% to 44.2%. However, none of the equations had accuracies that reached the 70% while differing less than 30% from the sGFR. And the agreement limits of the equations except the Cockcroft-Gault equation exceeded the prior acceptable tolerances defined as 60 ml/min/1.73 m^2.

Conclusions: When SC was measured by the enzymatic method, GFR estimation equations mayshow great bias in elderly Chinese patients with CKD. Further improved equations are needed. If conditions are not available, the Cockcroft-Gault equation may be more accurate for elderly Chinese patients with CKD.

TH-PO404

Comparison of Calculated CRUSADE Bleeding Risk with MDRD and Cockroft Gault Formulae in Patients Presenting with Non ST Elevation MI Muhammad Ali Abdool,[1] Hsu Pheen Chong,[2] Matthew George Parry, Mahvash Zaman,[1] Andrew Kuk,[1] Bhavna Pandya.[2] *[1]Aintree Cardiac Centre, Aintree University Hospital, Liverpool, United Kingdom; [2]Aintree Renal Unit, Aintree University Hospital, Liverpool, United Kingdom.*

Background: Patients with NSTEMI are at risk of bleeding with antithrombotics and invasive investigations. It is practice to calculate this risk using the evidence-based formula from the CRUSADE trial using the CG formula. However, since 2006, the 4 variable MDRD formula has been used to establish eGFR and define the stage of CKD in the UK and worldwide. This potentially results in the use of two different formulae (MDRD & CG) to calculate renal function and hence CRUSADE bleeding scores.

Methods: A total 165 patients admitted to Aintree University Hospital, Liverpool over a 5 month period between April and August 2011 with the diagnosis of NSTEMI were included in the analysis. MDRD and CG eGFR values and the respective CRUSADE bleeding risks were calculated.

Results:
Calculated CRUSADE risks with different eGFR formulae

	CG risk						
		Very Low	Low	Moderate	High	Very High	Total
	Very Low	11	3	0	0	0	14
Low		10	14	11	2	0	37
MDRD Risk	Moderate	1	6	18	6	0	36
	High	1	0	10	18	7	36
	Very High	0	0	0	3	44	47
	Total	23	23	39	29	51	165

There was adequate correlation between the calculated values for eGFR (R=0.7, p<0.005) although not enough to be considered interchangeable. There was correlation in calculated risk between the 2 formulae for 105 patients (63%). Only 4 (2.4%) patients had more than one grade risk difference and only 1 (0.6%) of these was 2 risk grades different.

There is no impact on the 38 patients who have a low or very low bleeding risk as calculated by both formulae. Out of the remaining 127 patients, there was correlation in 88 (69.3%) patients, with the rest (30.7%) having a discrepancy in bleeding risks. This has an influence on choice of antithrombotic therapy, invasive investigations and most importantly can be an indication of clinical outcome.

Conclusions:

· None of the very high risk patients were missed by either eGFR calculations.

· 2.4% of patients had the risk scores differ by more than 1 grading

· 30.7% of patients with moderate or higher CRUSADE bleeding risk differed in calculated estimations as per the 2 formulae.

TH-PO405

Comparison of Creatinine-Based Estimations of Glomerular Filtration Rate with Iohexol Glomerular Filtration Rate in Obese Subjects Philip D. Evans,[1] Tim J. James,[2] Garry Tan,[1] Chris W. McIntyre.[1,3] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]Clinical Biochemistry, Oxford Radcliffe Hospitals, Oxford, United Kingdom; [3]School of Graduate Entry Medicine and Health, University of Nottingham, Derby, United Kingdom.*

Background: Obesity is an established risk factor for chronic kidney disease. Current methods for estimating glomerular filtration rate(GFR) in the obese can be inaccurate and the most appropriate equation is uncertain.

Methods: 23 obese subjects were recruited from a single centre. Each participant underwent iohexol GFR(iGFR) assessment and serum biochemistry tests. GFR was estimated using MDRD and CKD-EPI equations, corrected and uncorrected for body surface area(BSA). The Cockcroft-Gault(CG) formula, using actual and lean body weight(LBW), was used to estimate creatinine clearance(CrCl). Comparison of equations to iGFR were performed using the Bland-Altman method.

Results: The mean age(SD) was 50±11yrs, 61% were male, mean weight(SD) was 150.1±21.6kg, and mean iGFR was 124.7±24.6mL/min. Comparisons between iGFR and estimating equations of GFR are shown in table 1.
Comparison of Estimating Equations with iGFR

	MDRD(mL/min/ 1.73m2)	MDRDBSA (mL/min)	CKD-EPI (mL/min/ 1.73m2)	CKD-EPIBSA (mL/Min)	CGCrCl(mL/min)	CGCrClLBW (mL/min)
Mean±SD	83.1±14.2	124.0±24.3	89.5±12.5	134.2±24.2	191.3±42.5	95.8±24.5
Mean Difference with iGFR (95%CI)	41.6 (33.7 to 49.5)	0.7 (-5.8 to 7.2)	35.2 (27.8 to 42.5)	-9.5 (-15.4 to -3.6)	-66.6 (-76.7 to -56.6)	27.7 (21.7 to 33.6)
Upper Limit of Agreement (95%CI)	87.7 (74.1 to 101.3)	38.7 (27.5 to 49.9)	78.1 (65.5 to 90.7)	25 (14.9 to 35.2)	-7.4 (-24.9 to -10.1)	61.2 (51.3 to 71.1)
Lower Limit of Agreement (95%CI)	-4.46 (-18.1 to 9.1)	-37.3 (-48.5 to -26.1)	-7.7 (-20.3 to 4.9)	-44.0 (-54.2 to -33.9)	-125.8 (-143.3 to -108.3)	-5.8 (-15.7 to 4.1)

MDRDBSA and CKD-EPIBSA had the smallest mean differences with iGFR but both still had large ranges between upper and lower limits of agreement.

Conclusions: Creatinine based equations for estimating GFR show little agreement with iGFR in obese subjects. This may have significant repercussions in the diagnosis and management of kidney disease in the obese. Further study of how these equations perform in obese subjects with reduced GFR would be of benefit.

TH-PO406

Estimation of Glomerular Filtration Rate in South Asians from the General Population in Pakistan Saleem Jessani,[1] Andrew S. Levey,[2] Rasool Bux,[1] Lesley Stevens Inker,[2] Muhammad Islam,[1] Nish Chaturvedi,[3] Christopher R. Mariat,[4] Christopher H. Schmid,[2] Tazeen H. Jafar.[1,5] *[1]Aga Khan University, Karachi, Pakistan; [2]Tufts Medical Center, Boston, MA; [3]Imperial College London, United Kingdom; [4]University de Saint-Etienne, Saint-Etienne, France; [5]Duke-NUS Graduate Medical School, Singapore.*

Background: Unlike the US and UK, laboratories in South Asian countries do not routinely report estimated glomerular filtration rate (eGFR). The objectives of the study were to 1) evaluate the performance of existing eGFR equations in South Asians, and 2) modify the existing eGFR equations and/or develop a new eGFR equation specific to this population.

Methods: We measured GFR (mGFR) using urinary clearance of inulin in 581 adults in Karachi, Pakistan. The performance of the CKD-EPI and MDRD Study equations was assessed. A modified CKD-EPI equation and a new estimating equation with age, gender

and serum creatinine were developed using linear regression. The main outcome measures were bias (median difference between eGFR and mGFR), accuracy (P_{30} percent of eGFR values that were within 30% of mGFR), precision (the inter-quartile range (IQR) of the bias) and root mean squared error (RMSE); reported as bootstrapped estimates and 95% confidence intervals (CIs) based on 1000 replications.

Results: The South Asian correction factor for CKD-EPI was $0.721 \times eGFR^{1.049}$.

Performance of GFR Estimating Equations

GFR Estimating Equations	RMSE (95% CIs)	Median Bias (95% CIs)	IQR (95% CIs) ml/min/1.73 m2	P30 (95% CIs)
MDRD Study Equation	0.273 (0.253, 0.293)	8.4 (6.4, 9.8)	28.7 (25.8, 31.9)	68.6 (64.6, 72.7)
CKD-EPI Equation	0.243 (0.226, 0.259)	7.0 (6.0, 9.3)	22.7 (20.3, 25.3)	76.8 (73.1, 80.2)
South Asian CKD-EPI Equation	0.243 (0.224, 0.260)	NA	22.3 (20.0, 25.0)	82.3 (79.0, 85.4)
South Asian New Equation 1	0.238 (0.223, 0.255)	NA	22.5 (20.3, 24.9)	82.6 (79.7, 85.8)

NA, Not applicable

Conclusions: The original CKD-EPI is more precise and accurate than the MDRD Study equation in estimating GFR in South Asian population in Karachi and would be preferred for eGFR reporting. The application of a South Asian correction factor may further improve the performance of CKD-EPI and should be evaluated in other studies.

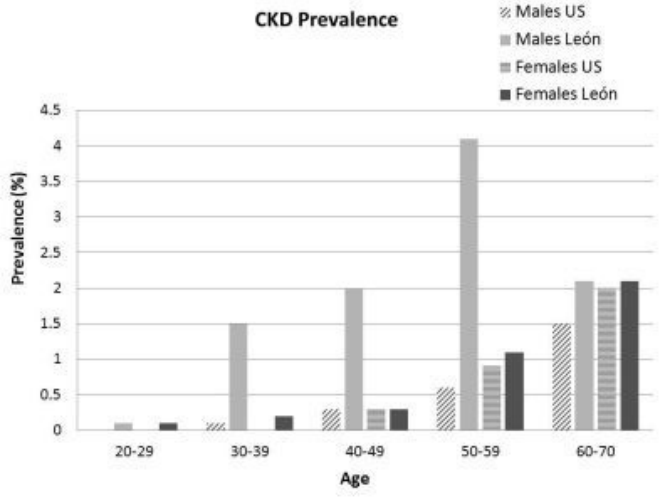
TH-PO407

Prevalence of Chronic Kidney Disease in León, Nicaragua Jill Lebov,[1] Douglas Morgan,[1] Edgar M. Pena,[3] Scott Leonard Sanoff,[2] Yichun Hu,[1] Romulo E. Colindres,[1] Susan L. Hogan.[1] *[1]UNC, Chapel HIll, NC; [2]UVA, Charlottesville, VA; [3]Centro de Investigación e Intervenciones en Salud, León, Nicaragua.*

Background: Several epidemiologic studies have pointed to an excess of chronic kidney disease (CKD) in the Pacific coastal regions of Nicaragua and El Salvador, particularly among males aged 18-50. These studies have been conducted in small, non-random samples, mainly in rural areas. Population prevalence of CKD has not been estimated in this region.

Methods: The Pacific coastal municipality of León, Nicaragua is home to a demographically and geographically diverse population. A random sample was selected from the León Health and Demographic Surveillance system, a unique resource representative of all León residents. Blood specimens collected from 2033 participants were analyzed for serum creatinine level, using the kinetic Jaffe method with calibrated instruments. Glomerular filtration rate was estimated (eGFR) using the CKD-EPI equation, with CKD defined as eGFR<60 ml/min/1.73m^2. León estimates were compared to US estimates based on NHANES 2001-2008 data, stratified by age and sex.

Results: In this large, population-based study, CKD prevalence was 6.1% in Leon versus 2.9% in the US. Leon CKD prevalence was significantly greater among males (9.9%) compared to females (3.7%) and increased with age. León CKD prevalence was highest among males age 50-59 (4.1%), whereas US prevalence was highest among females age 60-70 (2.0%). León estimates were greater than US estimates across all strata of age and sex.



Conclusions: León CKD prevalence estimates are comparable to those found in regional studies, but are more than double the prevalence observed in the US, and validate the growing body of research indicating a CKD epidemic in Pacific coastal Central America.

Funding: Other NIH Support - Fogarty International Center

TH-PO408

Comparison of Elevated Albuminuria: First Morning with Random Urine in National Health and Nutrition Examination Survey Adults, 2009-2010 Sharon Saydah,[1] Meda E. Pavkov,[1] David A. Lacher,[2] Mark Eberhardt,[2] Cindy Zhang,[2] Nilka Rios Burrows,[1] Andrew S. Narva,[3] Paul W. Eggers,[3] Desmond Williams.[1] *[1]DDT, CDC, Atlanta, GA; [2]NCHS, CDC, Hyattsville, MD; [3]NIDDK, NIH, Bethesda, MD.*

Background: In the United States, over 10% of the adult population meets diagnostic criteria for chronic kidney disease (CKD) based on single estimated glomerular filtration rate (eGFR) <60 ml/min/1.72 m² or elevated albumin/creatinine ratio (ACR ≥30 mg/g) in a random urine specimen. Clinical guidelines for diagnosis of CKD, however, recommend elevated ACR to be confirmed in at least two urine specimens. We report measures of agreement between two urine collections in National Health and Nutrition Examination Survey (NHANES) participants and their impact on CKD estimates.

Methods: In 2009-2010, NHANES participants provided two untimed urine specimens for sequential ACR measurement: an initial random urine collected in the NHANES Mobile Examination Center and a subsequent first morning void collected at home. Elevated albuminuria was calculated overall, by demographics, diagnosed diabetes and hypertension status, and eGFR.

Results: The distribution of ACR differed from the random compared to the first morning sample. The median ACR was 6.0 mg/g for the random sample and the median ACR was 4.5 mg/g for the first morning sample. Overall, 43.5% of adults with elevated ACR in a random urine also had elevated ACR in a first morning urine. This percent was higher among those 50 years and older (48.9%), males (53.3%), those with diagnosed diabetes (56.3%), hypertension (51.5%) or eGFR <60 ml/min/1.72 m² (56.9%). The observed agreement for ACR status between random and first morning void urine was 94.3% and the kappa coefficient was 0.51. Using the confirmed elevated ACR to define CKD resulted in a lower prevalence (11.6%, 95% CI 10.2-13.6) than using random spot urine level only (15.2%, 95% CI 13.7-17.4).

Conclusions: The prevalence of elevated ACR was significantly higher in random urine specimens than in first morning urine collections. Measuring persistence of albuminuria and the correct assessment of albumin excretion are both key steps in the early detection of CKD.

TH-PO409

Urinary Excretion of Liver-Type Fatty Acid-Binding Protein as a Marker of Progressive Kidney Function Deterioration in Patients with Chronic Glomerulonephritis Shan Mou, Qin Wang, Beili Shi, Jialin Li, Zhaohui Ni. *Renal Division, Renji Hospital, Shanghai JiaoTong University School of Medicine, Shanghai, China.*

Background: Liver type fatty acid binding protein (L-FABP) is expressed in human proximal tubules. The aim of this study was evaluation of urinary L-FABP and the value of basal urinary L-FABP excretion as a prognostic indicator of the progression of kidney function impairment in patients with chronic glomerulonephritis (CGN) was also assessed.

Methods: 123 patients with newly diagnosed, biopsy-proven primary CGN were included in the study. In all patients, and in 28 healthy subjects, L-FABP was measured using an ELISA. In the patients, risk factors of the progression of impairment of kidney function were evaluated. The patients were in follow-up for 5 years.The progression of kidney function impairment was defined as a reduction of GFR > 5 mL/min/ 1.73 m² / year during follow-up.

Results: Urinary excretion of L-FABP in the patients with CGN (76.58±34.61 ug/g. cr) was greater than in the healthy subjects. A significant negative correlation between L-FABP excretion and eGFR (R=-0.565, P < 0.01) and a positive correlation between L-FABP excretion and proteinuria (R=0.501, P < 0.01), serum creatinine (R=0.601, P < 0.01) were found. Kaplan–Meier analysis revealed that L-FABP excretion >76.58 ug/g. cr predicts progression of renal function. The cut off values for L-FABP at 119.8μg/g cr was found to be more sensitive. The sensitivity and specificity of were 87.5% and 90.5%.

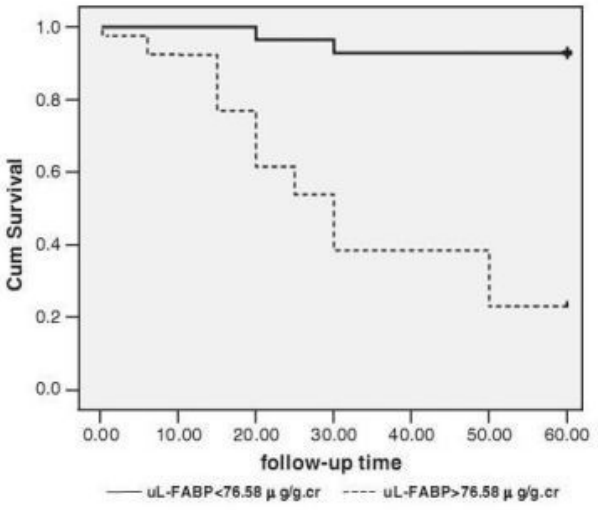


Fig. 1. Survival and uL-FABP in the whole group. uL-FABP > 76.58 µg/g.cr at presentation was associated with a significantly poorer outcome. Log rank = 24.47.

Conclusions: Urinary L-FABP excretion may be considered as a good marker of an activated L-FABP pathway in patients with newly diagnosed CGN and as a potentially risk factor of progressive kidney function impairment.

TH-PO410

Double-Blind, Randomized Placebo-Controlled Clinical Trial for the Efficacy of Tacrolimus in the Patients with Albuminuric, Normotensive IgA Nephropathy

Yong Chul Kim,[1] Ho Seok Koo,[2] Hajeong Lee,[1] Ho Jun Chin,[3] Suhnggwon Kim.[1] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Korea; [2]Internal Medicine, Inje University Seoul Baik Hospital, Korea; [3]Internal Medicine, Seoul National University Bundang Hospital, Korea.*

Background: The optimal treatment for IgA nephropathy (IgAN) remained unknown in patients with mild to moderate proteinuria with normal blood pressure who are not tolerable to the renin angiotension aldosterone inhibitor (RASI), well. Tacrolimus reduces proteinuria by suppressing the immune response and by non-immunological mechanisms of stabilization of the podocyte cytoskeletone. We performed this study for 16 weeks to investigate the anti-proteinuric effect of tacrolimus in IgAN with significant albuminuria and normal blood pressure (NCT01224028).

Methods: The patients with biopsy proven IgAN were randomly assigned to tacrolimus treatment (TAC 0.05-0.1 mg/kg/day, 20 patients) and placebo(PLACEBO, 20 patients) with stratification by one RASI. We enrolled normotensive patients (<130/80 mmHg) with urine albumin to creatinine ratio (UACR) 0.3-3.0 g/g creatinine (g/g Cr) who did not use steroid or other immunosuppressive treatment. The primary outcome was the change of albuminuria after 16 weeks of trial [UACR at 16weeks/UACR at baseline] compared to baseline between TAC and PLACEBO.

Results: RASI was used in 11 patients in TAC and 9 in PLACEBO ($p>0.05$). At enrollment, systolic blood pressure and diastolic blood pressure were 118.2±6.5 and 72.7±4.8 mmHg in TAC and 119.3±6.1 and 73.1±5.1 mmHg in PLACEBO, respectively ($P>0.05$). The creatinine clearance was 73.4±18.8 in TAC and 79.8±21.3 ml/min in PLACEBO ($P>0.05$). The UACR was 1.10±0.64 in TAC and 0.96±0.46 g/g Cr in PLACEBO ($P>0.05$). After 16 weeks, The change of UACR was 0.52±0.25 in TAC and 0.18±0.30 in PLACEBO ($P=0.001$). Among users of RASI, the change of UACR was 0.40±0.29 in TAC and 0.22±0.34 in PLACEBO ($P=0.246$) and, among non-users of RASI, it was 0.67±0.12 in TAC and 0.15±0.27 in PLACEBO ($P=0.246$) ($P<0.001$).

Conclusions: Tacrolimus showed an effective anti-proteinuric effect in albuminuric and normotensive patients with IgAN who were not tolerable to RASI during short-term period of clinical trial.

Effects of Mycophenolate Mofetil Combined with Corticosteroids for Inducing Remission of Henoch-Schönlein Purpura Nephritis

Pingping Ren, Fei Han, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

Background: Henoch-Schönlein purpura (HSP) can progress to Henoch-Schönlein purpura nephritis (HSPN), and the most effective treatment remains controversial. Our aim was to compare the effects of oral mycophenolate mofetil (MMF) with low dosage prednisone and the full dosage corticosteroids(CS)(prednisone) for the induction therapy of HSPN with large proteinuria.

Methods: This was a retrospective study. The patients were enrolled from January 2007 to September 2011;The diagnosis of HSP was in accordance with the criteria from the American College of Rheumatology in 1990. All the patients received renal biopsy with urine protein ≥2.0g/d. The exclusion criteria included: (1) age less than 14 years or greater than 65 years; (2) prescription of a cytotoxic drug or full dosage of CS within the previous 6 months before the start of MMF or full dosage of CS; (3) severe infection within the previous three months; (4) active phased hepatitis. 53 adults with biopsy-proved HSPN with large proteinuria (greater than 2.0g/24hr) were divided into two groups: MMF group(n=27) that received oral MMF 1.0g/day (1.5g/day for patients with a body weight >70kg) combined with low dosage prednisone (0.4-0.5mg/kg/d), and CS group (n=26) that received the full dosage prednisone (0.8-1.0mg/kg/d).We compared the effects of inducing remission at 6-month follow-up and the overall remission rate at the end of the follow-up between two groups.

Results: At 6 months, the eGFR level remained stable, while the urine protein decreased significantly in both groups, and the remission rate was 76.9% in CS group and 55.6% in MMF group($p=0.101$).With a median follow-up 28.8months in CS group,28.2months in MMF group, the overall remission rate was 80.8% in CS group and 77.8% in MMF group ($p=0.788$). The MMF group had less side effects than the CS group (48.1% VS 76.9% $p=0.031$). the relapse was in 4/21(19.0%) in CS group and 0/21 in MMF group ($p=0.115$).

Conclusions: MMF is useful for inducing remission and maintaining remission in Chinese HSPN with large proteinuria, and may represent an alternative treatment to the full dosage of CS.

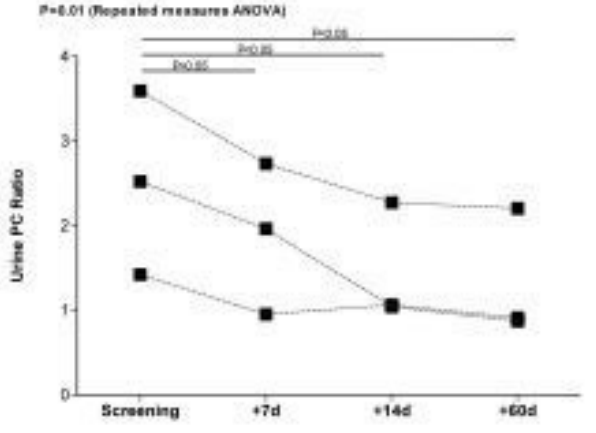
Bortezomib for Treatment of IgA Nephropathy

Choli Hartono,[1,3] Miriam H. Chung,[1,3] Surya Seshan,[2] Manikkam Suthanthiran,[1] Thangamani Muthukumar.[1] *[1]Medicine/Nephrology, Weill Cornell Medical College, New York, NY; [2]Pathology, Weill Cornell Medical College, NY, NY; [3]Rogosin Institute, NY, NY.*

Background: IgA nephropathy is the most common form of glomerulonephritis and its pathogenesis involves an autoimmune antibody response to abnormal galactose-deficient IgA1 antibodies. Bortezomib is a proteasome inhibitor that targets plasma cells and inhibits release of NF-kB-inducible cytokines. We are conducting a pilot study testing the effects of bortezomib in subjects with biopsy proven IgA nephropathy and significant renal disease manifested by greater than 1000mg of daily proteinuria.

Methods: Bortezomib infusion was given at 1.3mg/m^2 for a total of 4 doses over a 2-week period after enrollment. Daily proteinuria, estimated as urine protein to creatinine ratio, was assessed following infusion of bortezomib at predetermined intervals. Any adverse events, renal function, and hematologic parameters were subsequently followed.

Results: Four subjects (1 male, 3 female) met inclusion criteria and were enrolled in the pilot study. The mean (±SD) age, baseline serum creatinine, and proteinuria were 37±17 years, 1.68±0.89 mg/dL, and 2.34±0.95 gram/day respectively. The cumulative mean (±SD) bortezomib exposure was 9.70±1.15 mg. Common side effects of neutropenia, thrombocytopenia, and neuropathy were not seen at 60 days of follow-up. One subject developed varicella zoster at 4 months after bortezomib infusion. The mean (±SD) proteinuria and serum creatinine were 1.33±0.76 gram/day and 1.84±1.0 mg/dL, at 60 days follow-up. Figure 1: Only 3 subjects depicted at 60 days follow-up.



Conclusions: We present our early experience testing bortezomib in 4 subjects with native IgA nephropathy and severe proteinuria. For the first time, we show that a single cycle of bortezomib therapy was tolerated and has the potential to reduce proteinuria in IgA nephropathy.

Validation Study of Oxford Classification of IgA Nephropathy: A Proposal of Prediction of Kidney Outcome According to Numbers of Selected Pathological Parameters Ritsuko Katafuchi,[1] Masaharu Nagata,[2] Toshiharu Ninomiya,[2] Koji Mitsuiki,[3] Hideki N. Hirakata.[3] *[1]Kidney Unit, National Fukuoka-Higashi Medical Center, Koga, Fukuoka, Japan; [2]Department of Medicine and Clinical Science, Graduate School of Medical Science, Kyushu University, Fukuoka, Japan; [3]Kidney Unit, Fukuoka Red Cross Hospital, Fukuoka, Japan.*

Background: We published a validation study of Oxford classification of IgA nephropathy (IgAN) and found a significant association of extracapillary proliferation (Ex) with risk of endstage renal failure (ESRF). Our next question is how we can use the Oxford classification as a prognosticator in patients with IgAN.

Methods: 702 patients with IgAN were included. Pathologic parameters were estimated according to the definition of the Oxford classification. Mesangial hypercellularity score (M) was defined as M0, 0.5 or less, and M1, over 0.5. Endocapillary hypercellularity (En), segmental glomerulosclerosis (S), and Ex were scored 0 in absence and 1 in presence. Tubular atrophy/interstitial fibrosis (T) was graded according to the percentage of involved area as T0, less than 25; T1, 25 or more. We examined the kidney survival and risk for development of ESRF according to the status of each pathological parameter, separately and also according to the number of pathological parameters (0 or 1, 2, 3 and 4 or 5).

Results: The kidney survivals in M1, Ex1, S1 and T1 significantly lower than in M0, Ex0, S0 and T0, respectively. The presence of M1, Ex1, S1 and T1 showed a significant association with the risk of ESRF compared to M0, Ex0, S0 and T0, respectively. The 5 and 10 years kidney survival was 100 and 98, 97 and 89, 88 and 77, 80 and 60% in patients with 0 or 1, 2, 3, and 4 or 5 pathological parameters, respectively. Three and 4 or 5 pathological parameters were associated with 8.35 and 13.2-fold increased risk of ESRF compared to 0 or 1 parameter.

Conclusions: The prognosis can be predicted according to the number of pathological parameters. The patients with three or more parameters might have poor outcome. This method is simple and could be the first step of clinical use of Oxford classification.

TH-PO414

Histological Predictors of Treatment Efficacy in Severe Childhood IgA Nephropathy (IgAN): Validation of the Oxford Classification of IgAN (Ox C) Yuko Shima,[1] Koichi Nakanishi,[1] Taketsugu Hama,[1] Hironobu Mukaiyama,[1] Hiroko Togawa,[1] Shingo Ishimori,[2] Hiroshi Kaito,[2] Ryojiro Tanaka,[3] Kazumoto Iijima,[2] Norishige Yoshikawa.[1] *[1]Pediatrics, Wakayama Medical University, Wakayama, Japan; [2]Pediatrics, Kobe University, Kobe, Hyogo, Japan; [3]Pediatric Nephrology, Hyogo Prefectural Kobe Children's Hospital, Kobe, Hyogo, Japan.*

Background: We previously demonstrated that Ox C appears to be valid for predicting renal outcome in children without intensive treatments (Pediatr Nephrol 2012;27:783-92). However, predictive value of Ox C in treatment efficacy has not been fully examined in children.

Methods: We analyzed retrospectively consecutive 92 children newly diagnosed as severe IgAN showing diffuse mesangial proliferation (DMP) from May 1987 to May 2009 and treated with prednisolone (PSL) only or combination (PSL + azathioprine or mizoribine) for 2 years. We assessed the ability of each variable in Ox C as a predictor of the 2-yr treatment efficacy defined as proteinuria remission using logistic regression analysis.

Results: The mean mesangial score (M), and ratios of endocapillary hypercellularity (E), segmental glomerulosclerosis (S), tubular atrophy (T), and crescents (C) were 1.93, 19.9%, 9.6%, 4.7%, and 15.7%. After the 2-yr treatment, 53 of the 92 patients (58%) showed proteinuria remission. There was no significant difference in clinical findings (MAP, urinary protein excretion and eGFR) between remission group and non-remission group at the start of treatment. As to histological variables, there was no significant difference in M, E, S, and C between the groups. Prevalence of T was significantly lower in remission group (37.7% vs 87.2%, *P=0.006* Fisher's exact test). The prognostic factor related to proteinuria remission after the 2-yr treatment was presence of T in univariate and multivariate analyses adjusted by all histological variables (OR 3.8, 95%CI 1.3-13.5, *P=0.018)*.

Conclusions: In severe childhood IgAN showing DMP, the presence of T was a predictor of refractoriness, therefore, other options of treatments may have to be considered in severe IgAN with T. Further studies seem to be needed for evaluation of the total performance of Ox C for prediction of treatment efficacy.

TH-PO415

Bacteria Specific to Tonsil in IgA Nephropathy Patients Predicts the Remission by the Treatment of Tonsillectomy and Corticosteroid Pulse Yasuyuki Nagasawa,[1,2] Kenichiro Iio,[2] Hirotsugu Iwatani,[2] Ryohei Yamamoto,[2] Maki Shinzawa,[2] Enyu Imai,[2] Takeshi Nakanishi,[1] Hiromi Rakugi,[2] Yoshitaka Isaka.[2] *[1]Department of Internal Medicine, Division of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [2]Department of Nephrology and Geriatric Medicine, Osaka University, Suita, Osaka, Japan.*

Background: Immunoglobulin(Ig)A nephropathy (IgAN) is the most common form of primary glomerulonephritis in the world. Some bacteria were reported to be the candidate of the antigen or the pathogenesis of IgAN, but systemic analysis of bacterial flora in tonsil with IgAN has not been reported. Moreover, these bacteria specific to IgAN might be candidate for the indicator which can predict the remission of IgAN treated by the combination of tonsillectomy and steroid pulse.

Methods: We made a comprehensive analysis of tonsil flora in 68 IgAN patients and 28 control patients using Denaturing gradient gel electrophoresis methods. We also analyzed the relationship between several bacteria specific to the IgAN and the prognosis of the IgAN.

Results: *Treponema sp.* were identified in 24% IgAN patients, while in 7% control patients (P=0.062). *Haemophilus segnis* were detected in 53% IgAN patients, while in 25% control patients (P=0.012). *Campylobacter rectus* were identified in 49% IgAN patients, while in 14% control patients (P=0.002). Multiple Cox proportional-hazards model for proteinuria revealed that *Treponema sp.* or *Campylobactor rectus* are significant for the remission of proteinuria (Hazard ratio 2.18, p=0.027). There was significant difference in remission rates between IgAN patients with *Treponema sp.* and those without the bacterium (p=0.046) by Kaplan-Meier analysis. There was also significant difference in remission rates between IgAN patients with *Campylobacter rectus* and those without the bacterium (p=0.037). There was no significant difference in remission rates between IgAN patients with *Haemophilus segnis* and those without the bacterium.

Conclusions: This insight into IgAN might be useful for diagnosis of the IgAN patients and the decision of treatment of IgAN.

Funding: Government Support - Non-U.S.

TH-PO416

Mortality of IgA Nephropathy Patients: A Review of 30-Years of Experience Hajeong Lee,[1] Hayne C. Park,[1] Yon Su Kim,[1] Dong Wan Chae,[2] Suhnggwon Kim,[1] Ho Jun Chin.[2] *[1]Internal Medicine, Seoul National University Hospital; [2]Internal Medicine, Seoul National University Bundang Hospital.*

Background: Research on the prognosis in IgA nephropathy (IgAN) has focused on renal survival, with little information being available on the patient survival of IgAN patients. This investigation aimed to explore long-term patient outcome in IgAN patients.

Methods: Clinical and pathologic characteristics at the time of renal biopsy were reviewed from 1979 to 2008 in 1,364 IgAN patients. The outcomes were patient death and end stage renal disease (ESRD) progression. The relative mortality rate of IgAN was estimated by the standardized mortality ratio (SMR) with 95% confidence interval (CI).

Results: 71deaths (5.3%) and 277 ESRD cases (20.6%) were developed during 13,916 person-years. 10-, 20-, and 30-year patient survival rates were 96.3%, 91.8%, and 82.7%, respectively. Among the deceased, more than half died before ESRD progression and their most common cause of death was malignancy. Overall mortality was elevated by 43% from the age/sex matched general population (SMR 1.43, 95% CI 1.04-1.92). Men showed comparable survival (SMR 1.22, 95% CI 0.82-1.75), however, women exhibited an increased mortality rate more than double (SMR 2.17, 95% CI 1.21-3.57). Patients with well-known renal risk factors including renal dysfunction (GFR <60 ml/min/1.73m^2, SMR 1.70 95% CI 1.13-2.46), higher systolic blood pressure (≥130 mmHg, SMR 1.51, 95% CI 1.00-2.18) and proteinuria (≥1 g/day, SMR 1.66, 95% CI 1.16-2.29) also showed elevated mortality rate than general population, whereas patients with preserved renal function, normotension, and proteinuria less than 1 g/day revealed similar mortality rate compared with general population.

Conclusions: This investigation demonstrated that overall patient survival of IgAN was higher than general population, especially in women or patients with renal risk factors. However, patients without renal risk factors survived as similar to general population. Therefore, optimized strategies to alleviate renal risk factors are also warranted to reduce patient mortality.

Urinary Neutrophils Gelatinase-Associated Lipocalin Level Is Closely Associated with Tubulointerstitial Injury in IgA Nephropathy Su Mi Lee, Seung Min Lee, Dong Ki Kim, Yon Su Kim. *Seoul National University Hospital, Seoul, Republic of Korea.*

Background: IgA nephropathy (IgAN) was thought to be relatively benign but several studies reported that IgAN eventually progresses to end-stage renal failure. Renal tubulointerstitial injury plays an important role in the progression of IgAN. Neutrophils gelatinase-associated lipocalin (NGAL) was thought to be a sensitive biomarker for tubule injury. The aim of this study is to investigate which relationship is present between severity of tubulointerstitial injury and urine NGAL levels in IgAN patients.

Methods: We analyzed data for 123 IgAN patients who were biopsy-proven and 26 healthy controls who were age and sex matched. Urinary NGAL levels were measured by enzyme-linked immunosorbent assay and were corrected by urinary creatinine. We evaluated percentage of global sclerosis, segmental sclerosis, and extent of tubulointerstitial damage. The correlation between urinary NGAL levels with clinical, histopathological features were evaluated.

Results: The patients were 41.2±14.5 years old, presented with 1.7±1.8 g/day proteinuria. Individuals with IgAN had higher urinary NGAL levels than in normal controls (1.8±4.1 versus 0.8±0.8 ng/mg urinary Cr, P = 0.02). Baseline urinary NGAL levels were significantly correlated with urinary protein excretion($r = 0.40$, $p < 0.001$), serum creatinine($r = 0.47$, $p <0.001$), creatinine clearance($r = -0.221$, $p = 0.007$), urinary β_2 microglobulin($r = 0.707$, $p < 0.001$). The urinary NGAL levels and urinaryβ_2 microglobulin in patients with tubular atrophy and interstitial fibrosis Grades 1, 2, and 3 were significantly higher than in normal controls. In addition to, similar results were identified in patients with different grades of interstitial infiltration. The patients with severe mesangial proliferation, global sclerosis had higher urinary NGAL levels than that in patients without.

Conclusions: Our study shows that urinary NGAL levels may be a useful biomarker to evaluate tubulointerstitial injury of IgA nephropathy.

TH-PO418

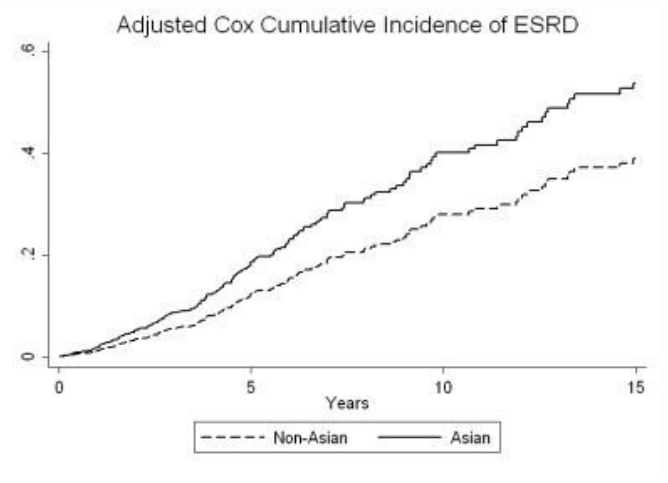
Asians with IgA Nephropathy Have an Increased Risk of Progression to End-Stage Renal Disease Sean Barbour,[1,3] Daniel C. Cattran,[2,3] Joseph Kim,[2] Ron Wald,[2] Adeera Levin,[1] Michelle A. Hladunewich,[2,3] Heather N. Reich.[2,3] *[1]Nephrology, University of British Columbia, Vancouver, BC; [2]Nephrology, University of Toronto, Toronto, ON; [3]Toronto Glomerulonephritis Registry, Toronto, ON.*

Background: IgA nephropropathy (IgAN) is the most common cause of glomuerulonephritis (GN) worldwide, however it accounts for a far higher proportion of end-stage renal disease (ESRD) in Asia compared to North America. It is not known if this is entirely due to higher disease prevalence in Asians or a higher risk of disease progression. The lack of an adequately diverse population followed longitudinally in a single center has previously precluded the ability to address this question.

Methods: To determine if Asians with IgAN have a higher risk of ESRD, we analyzed a cohort of 669 adults from the Toronto GN Registry with biopsy-proven IgAN, in which 30% of subjects were of self-reported Asian race. Patients were followed prospectively for a median of 46 months. The primary outcome was time from kidney biopsy to ESRD (dialysis, transplantation or eGFR<15), which occurred in 213 patients, and was analyzed using Cox survival regression analysis.

Results: The mean age, eGFR and proteinuria were 39.7 years, 59.6ml/min/1.73m^2 and 1.8g/day. After adjusting for age, sex, baseline eGFR, MAP and proteinuria over time, the use of ACEi/ARB and the use of immunosuppression, the risk of ESRD was significantly higher in Asians compared to non-Asians (HR=1.56 95%CI 1.10-2.22 p=0.01, see figure). This was supported by both a 1.62ml/min/1.73m^2/year faster rate of eGFR decline in Asians (95%CI -3.19--0.5 p=0.04), and an increased risk of a 50% reduction in eGFR (HR=1.81 95%CI 1.25-2.62 p=0.002).

Conclusions: We have shown that in a large multi-racial cohort of patients with IgAN, Asians have a higher risk of progression to ESRD compared to non-Asians, after adjusting for known prognostic factors.



TH-PO419

Comparison of Clinical Outcomes between Adult Patients with Henöch-Schönlein Purpura Nephritis and Immunoglobulin A Nephropathy Mi Jung Lee,[1] Dae-Suk Han,[1] Dong Ho Shin,[1] Shin-Wook Kang,[1,2] Hye-young Kang,[2] Seong Hun Kim,[2] Seung Hyeok Han.[1] *[1]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea; [2]Severance Biomedical Science Institute, Brain Korea 21, Yonsei University, Seoul, Republic of Korea.*

Background: Henöch-Schönlein purpura nephritis (HSPN) is considered a systemic form of immunoglobulin A nephropathy (IgAN). Although these two diseases may be different manifestations of a single disease, little is known whether the long-term outcomes are different between HSPN and IgAN.

Methods: We studied 120 patients with biopsy-proven HSPN and 1,070 patients with IgAN who were recruited between Jan 2000 and Sep 2010 from 4 medical centers in Korea. The primary outcome was the composite of a doubling of the baseline serum creatinine concentrations, the onset of end-stage renal disease (ESRD), or death. Secondary outcomes included the individual renal outcome of a doubling of the baseline serum creatinine concentrations, ESRD, and the rate of decline in estimated glomerular filtration rate (eGFR). We compared the clinical outcomes between the two groups using 1:2 propensity score (PS) matching.

Results: In the unmatched cohort, HSPN patients had more vasculitis symptoms and more favorable histologic features and were more commonly treated with steroids than IgAN patients. The risk of reaching the primary outcome was significantly lower in HSPN than IgAN patients (hazard ratio [HR], 0.67; 95% confidence interval [CI], 0.43-0.96; P=0.044). The 1:2 PS matching yielded matched pairs of 89 HSPN and 178 IgAN patients, resulting in no differences in baseline characteristics. In the matched cohort, 16 patients (18.0%) with HSPN reached the primary outcome compared to 38 patients (21.3%) with IgAN (HR, 0.78; 95% CI, 0.47-1.36; P=0.166). The risk of reaching a doubling of the baseline serum creatinine levels (HR, 0.74; 95% CI, 0.49-1.52; P=0.132) and developing ESRD (HR, 0.77; 95% CI, 0.59-1.53; P=0.181) did not differ between the two groups. The rate of decline in eGFR was also comparable.

Conclusions: There was no significant difference in clinical outcomes between patients with HSPN and IgAN, suggesting that these two diseases have a similar prognosis.

TH-PO420

Effect of Cigarette Smoking on Renal Function and Renal Pathological Injury in IgA Nephropathy Patients Han Zhang, Xiaoyan Zhang, Yi Fang, Xiaoqiang Ding. *Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: Immunoglobulin A nephropathy (IgAN) is the most common chronic glomerulonephrititis worldwide. Recently, smoking has been demonstrated as a risk factor in the progression of IgAN. The aim of this study was to illuminate the effect of cigarette smoking on renal function and renal pathological lesions in IgAN patients.

Methods: One hundred biopsy-proved IgA nephropathy patients were involved. Smoking status, gender, age, height, body weight, blood pressure, urine routine, renal function and proteinuria were recorded. The estimated glomerular filtration rate (eGFR) was calculated by MDRD formula. We assessed pathological lesions in glomerular, tubulointersitial and vascular tissue semiquantitatively according to Katafuchi score.

Results: There ware 32 somkers in 100 IgA nephropathy patients. There were more male patients in smokers (31/1) than nonsmokers (47/21) (*P<0.01*). Smokers were older than nonsmokers (44.8±12.9 *vs.* 39.3±12.7, *P<0.05*). Smokers had lower eGFR(64.9±27.9 *vs.* 92.0±29.8, *P<0.01*) and serum HDL(1.04±0.32 *vs.* 1.33±0.41, *P<0.01*) than nonsmokers. Tubulointersitial score(4.23±1.97 *vs.*2.90±1.89, *P<0.01*) and index of intrarenal vessel wall thickening (1.69±1.45 *vs.*0.88±1.31, *P<0.01*) were higher than nonsmokers. The relationship between smoking and intrarenal vessel hyaline change was not proven.Multiple linear regression analyses revealed that hypertension (β=-0.51, *P<0.01*), proteinuria (β=-0.45, *P<0.01*) and smoking (β=-0.22, *P<0.05*) were correlated significantly with lower eGFR in 52 male patients. Multiple binary logistic regression analyses revealed that age (OR=1.05, 95%CI (1.02, 1.09), *P<0.01*) and smoking (OR=2.54, 95%CI (1.02, 6.36), *P<0.05*) were correlated significantly with higher prevalence intrarenal vessel wall thickening.

Conclusions: Smoking was an independent risk factor of eGFR decline in male IgA nephropathy patients, and renal tubulointerstitial lesions and intrarenal vessel wall thickening in IgA nephropathy patients.

TH-PO421

Novel Diagnostic Approach for IgA Nephropathy Hiroyuki Yanagawa,[1] Hitoshi Suzuki,[1] Yusuke Suzuki,[1] Bruce A. Julian,[2,3] Jan Novak,[3] Yasuhiko Tomino.[1] *[1]Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL; [3]Microbiology, University of Alabama at Birmingham, Birmingham, AL.*

Background: There is increasing evidence that galactose-deficient IgA1 (Gd-IgA1) and Gd-IgA1-containing immune complexes are important players in the pathogenesis of IgA nephropathy (IgAN). Moreover, serum levels of Gd-IgA1-specific antibodies, responsible for the formation of immune complexes with Gd-IgA1, are also elevated in IgAN. However, due to the clinical heterogeneity of this disease, there is no biomarker to replace the diagnostic renal biopsy. In the present study, we assessed a novel noninvasive multi-biomarker approach combined with analysis of clinical data by a logistic model as a diagnostic test for IgAN.

Methods: Serum samples were collected from 2006 to 2011 at the time of renal biopsy from 135 IgAN patients and 79 patients with other renal diseases such as lupus nephritis, diabetic nephropathy, and membranous nephropathy. We also collected serum samples from 106 healthy controls. We measured serum levels of IgA, IgG, Gd-IgA1, Gd-IgA1-specific IgG and Gd-IgA1-specific IgA by ELISA. Each data was analyzed by multivariate analysis.

Results: Although serum levels of IgA, Gd-IgA1, Gd-IgA1-specific IgG and Gd-IgA1-specific IgA were elevated in patients with IgAN compared with disease and healthy controls, none of the biomarkers alone fully differentiated IgAN patients from disease controls. Therefore, we re-analyzed these biomarkers and compared them with clinical data, such as age, gender, serum creatinine, urinary protein/creatinine ratio and degree of microscopic hematuriausing a logistic model. This model differentiated IgAN patients from disease controls with 81% specificity and 91% sensitivity.

Conclusions: Our results suggest that serum Gd-IgA1 and Gd-IgA1-specific antibodies (IgG and IgA) are useful biomarkers for diagnosis of IgAN. The novel quantitative scoring system can be applied for diagnosis of IgAN besides renal biopsy.

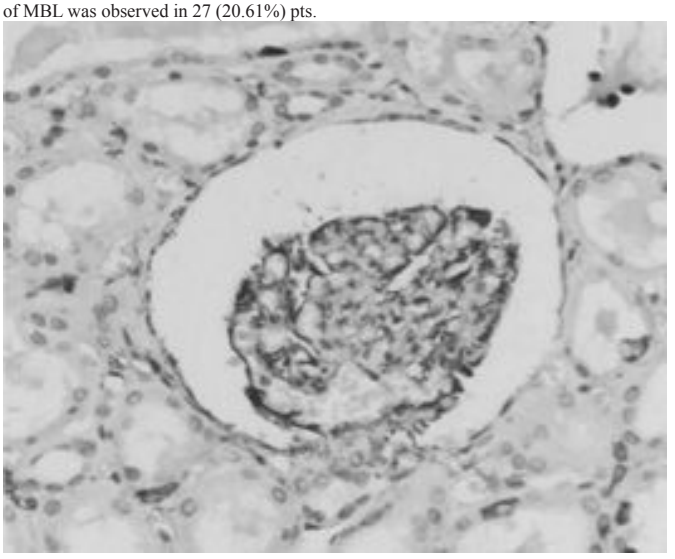
TH-PO422

Mannose-Binding Lectin Gene Polymorphism Is Closely Associated with Clinic-Pathological Manifestation and Renal Prognosis in IgA Nephropathy Patients Beili Shi, Zhaohui Ni, Shan Mou, Liou Cao, Min Zhang, Qin Wang, Yucheng Yan, Mingli Zhu, Wei Fang, Jia Qi Qian. *Renal Division, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.*

Background: IgA nephropathy (IgAN) is one of the most worldwide primary GN. Recently, mannose-binding lectin (MBL) was suggested to play an important role in the pathogenesis and progress of IgAN.

Methods: Patients who were diagnoseed as primary IgAN, 18-65 year-old, followed up >=12 months were enrolled. Primary secondary end-point were defined as entering ESRD, and Scr increased >50% of baseline, respectively. 1) Renal biopsy specimens were immuno-histochemical staining by MBL mono-antibody. 2) Integrated capillary electrophoresis was used to detect MBL gene polymorphism in peripheral blood DNA. 3) ELISA was used to detect serum MBL level.

Results: 131 IgAN pts (60 males, 37.59±11.60 years old) were enrolled and followed 52 (20-82) months, among who 12 entered end-point (4 ESRD). 1) Glomerular deposition of MBL was observed in 27 (20.61%) pts.



Compared with MBL+, MBL- cases showed severer glomerular/segmental sclerosis (GGS), higher BP and Scr, accompanied with poorer renal prognosis (P=0.004). 2) In 93 patients' DNA samples, we found SNP in promoter -221 (G→C) and exon 1 +54 (G→A). Compared with wild-type, exon 1 +54 variants had significantly lower serum MBL levels (P<0.001), higher baseline Scr (P=0.048), higher percentage of GGS (P=0.024) and pronouced tubular-interstitial damage (TID) (P=0.049). Among 10 patients entered end-point, exon 1 +54 variants had higher occurrence (P<0.001). Cox analysis found that exon 1 (+54) SNP (β=2.460, P=0.033), baseline Scr (β=0.966, P=0.04) and TID (β=0.202, P=0.048) were independent factors of renal prognosis.

Conclusions: IgAN patients with MBL gene variation had severer clinical and histological manifestation, accompanied with poorer renal prognosis.

TH-PO423

Reduction in Urine Protein as a Surrogate Marker for Kidney Disease Outcomes in IgA Nephropathy Lesley Stevens Inker,[1] Hocine Tighiouart,[1] Neal B. Shah,[1] Gerald B. Appel,[2] Bart Dirk Maes,[3] Philip K.T. Li,[4] Manuel Praga,[5] Tom Greene,[6] Christopher H. Schmid,[1] Andrew S. Levey.[1] *[1]Tufts Medical Center; [2]Columbia University; [3]Heilig Hartziekenhuis; [4]Prince of Wales Hospital; [5]Hospital 12 de Octubre; [6]University of Utah.*

Background: Clinical trials in IgA nephropathy using GFR decline as an endpoint require long duration of follow-up with high expense and complexity. The use of early reduction in urine protein (delta UP) as a surrogate endpoint may accelerate testing of new therapies.

Methods: In a patient level analysis of 6 randomized controlled trials of drug interventions in IgA nephropathy, we evaluated: 1) Treatment effect for the ratio of delta UP from baseline to early follow-up (defined as first UP between 2.5 and 13 months); 2) Treatment effect for the composite outcome of doubling of serum creatinine or ESRD or death. 3) Patient level association of delta UP with the composite outcome.

Results: The table shows the results by study. There is a strong relationship between delta UP and outcomes. Stronger associations were observed in studies of fish oil and the renin-angiotensin system inhibition than in those of immunosuppression.

Study	Intervention type	N patients/N events	Treatment effect on delta UP in Tx group relative to control*	Treatment effect on composite outcome in Tx group relative to control	Hazard ratios per 2X of UP on composite outcome**
1	Fish oil	90/17	23%	**74%**	2.21 (1.09, 4.51)
2	Fish oil	65/14	-37%	**0**	3.96 (1.82, 8.61)
3	ACEI	44/15	**27%**	**57%**	2.44 (1.09, 5.43)
4	ARB	107/8	**39%**	61%	9.63 (2.63, 35.26)
5	MMF	34/3	-15%	55%	5.25 (0.50, 54.75)
6	MMF	20/4	-41%	55%	0.99 (0.40, 2.50)
Overall		360/61	**15%**	55%	2.37 (1.72, 3.28)

Bolded number indicate statistical significance. *% decline UP from baseline to early follow-up for the ratio of treatment to control groups; **adjusted for baseline urine protein.

Conclusions: Our results may be taken as preliminary evidence for the role of proteinuria as a surrogate marker for kidney disease outcomes in IgA nephropathy.

TH-PO424

Urinary Protein of Three Years after Diagnosis Is the Strongest Predictor of Renal Outcome in IgA Nephropathy Takayuki Fujii,[1] Satoshi Suzuki,[1] Tanaka Hiroaki,[1] Kunihiro Yamagata.[2] *[1]Kidney Center, Seirei Sakura Citizen Hospital, Sakura, Chiba, Japan; [2]Department of Nephrology, Faculty of Medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan.*

Background: Level of proteinuria (UP) has a strong association with poor prognosis in IgA nephropathy. However, recent studies using the Oxford classification suggested that UP at diagnosis of IgA nephropathy was not an independent prognostic factor. We evaluated the usefulness of not only clinical and pathological findings at the time of renal biopsy, but also urinary findings 3 years after diagnosis for the accurate prediction of outcomes.

Methods: Between January 1980 and June 2008, 481 patients were diagnosed as IgA nephropathy in our hospital, and could be followed up for 3 years or more. We performed a retrospective cohort study in 350 out of the 481 patients who showed eGFR≥60 ml/min/1.73m^2. The endpoint of this study was a 50% decrease in eGFR during follow-up. In addition to renal histological findings according to the Oxford classification, eGFR, the mean blood pressure, age, sex, and the treatment method, we applied urinary findings at the time of renal biopsy (UP≥0.5g/day or not, and presence of hematuria or not) in Model A, and we applied urinary findings 3 years after diagnosis in Model B for variables factors. The association between these factors and renal outcomes was evaluated using Cox's proportional hazard model.

Results: Hematuria waa the only risk factor (HR, 2.58; 95% CI, 1.26-5.45) in model A, while UP≥0.5g/day (HR, 7.37; 95% CI, 3.14-20.4), hematuria (HR, 5,57; 95% CI, 2.29-13.1), and the mean blood pressure (HR, 1.56; 95% CI, 1.06-2.32) were significant risk factors for poor renal outcomes in model B. There was no significant association between renal histological findings or treatment methods and renal outcomes in both models.

Conclusions: For the prediction of the outcome of IgA nephropathy with normal renal function, irrespective of the treatment methods, not UP at diagnosis but UP 3-years after diagnosis is useful and strong predicting factor of renal prognosis.
