Methods: We aimed at investigating IDO metabolites and regulatory T cells (Treg) in 24 children with pIgAN and 23 with HSP (3-14 years) with or without renal involvement; 25 healthy controls (HC) were investigated as well. IDO activity was assessed in sera as change in tryptophan (Trp) and its catabolic product kynurenine (Kyn), which were simultaneously determinated using an isocratic RP HPLC method with UV detection. A Kyn/Trp ratio was also calculated. In mononuclear cells (PBMC) real time PCR (Taqman) was adopted to measure mRNA levels of FoxP3mRNA and TGF-β1mRNA. Results were normalized to Abl gene and expressed as fold increase.

Results: Children with pIgAN and with HSP had significantly increased levels of the Trp metabolite Kyn (pIgAN 2.61 ± 0.72; HSP 2.31 ± 0.54 versus 2.02 ± 0.32 μmol/l; for both diseases P= 0.048 versus HC), while Trp levels were similar to controls. The ratio Kyn/Trp, expression of IDO activity, was significantly increased in pIgAN only (5.74±2.27, p=0.0004). FoxP3 mRNA and TGFβ1 mRNA transcriptional levels were significantly depressed (FoxP3 mRNA: pIgAN 0.94 ± 0.19; HSP 0.85 ± 0.07; HC 1.26 ± 0.09, for both diseases p=0.042 versus HC) (TGFβ1mRNA pIgAN pIgAN 0.85 ± 0.09; HSP 0.91 ± 0.07; HC 1.44 ±0.09, for both diseases p<0.0001).There was a significant inverse correlation between Kyn levels and TGFβ1mRNA values (P= 0.023).

Conclusions: Children with pIgAN and HSP present with a similar reduced expression of regulatory T cells transcription factors, while those with pIgAN have also a selective higher activity of IDO enzyme which regulates T cells reprogramming.

Diagnositic and Predictive Value in Progressive IgA Nephropathy by Measurement of Measurement of MCP-1 and NGAL Jianghua Chen, Pingping Ren. *Kidney Disease Center, The first Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang Province, China.*

Background: To investigate the relationship among IgAN and the level of MCP-1 and NGAL in urine, explore the diagnostic and predictive value in progressive IgAN and the renal survival.

Methods: We examined serum samples from IgAN patients between Januray 2004 and December 2010. 173 patients were enrolled, divided into two subgroups: subgroup 1 (eGFR≥60ml/min) and subgroup 2 (eGFR≥90ml/min). MCP-1 and NGAL was measured in serum samples using a commercial human MCP-1 enzyme-linked immunosorbent assay(ELISA) kit (R&D Systems). A conventional receiver operating characteristic (ROC) curve was applied to determine the sensitivities and specificities for MCP-1, NGAL measurements for mild, moderate, severe IgAN, and for patients with progressive and nonprogressive IgAN, compared to the ROC curve measured by proteinuria, eGFR, sCr. Association was analyzed among urine MCP-1 level, urine NGAL and clinical and histopathological parameters.

Results: The level of urine MCP-1 and NGAL in IgAN were higher than that in healthy controls (P<0.05). It was significant difference among the urine MCP-1 of mild, moderate and severe IgAN in each subgroup (p<0.05). The area under ROC curve of MCP-1 was the largest, and it was significant differcence compared to that of UP, eGFR and sCr in subgroup 1 (eGFR≥60ml/min) and subgroup 2 (eGFR≥90ml/min) (p<0.01). ROC curve was constructed to determine the discriminatory power of MCP-1 and NGAL levels for diagnosis of progressive and nonprogressive IgAN. The area under ROC curve of MCP-1 was the largest, and it was significant differcence compared to that of UP, eGFR and sCr in subgroup 2 (eGFR≥90ml/min) (p<0.01).Urine MCP-1 and NGAL level had association with clinical and histopathological parameters. The level of serum RAGE, urine MCP-1 and NGAL may predict the renal survival.

Conclusions: The monitoring of MCP-1 in urine may be a new and noninvasive approach for early detecting severe IgAN and progressive IgAN, and help predict the renal survival.

Renalase Is Associated with Renal Disease Activity in Human Lupus Nephritis Chaojun Qi, Ling Wang, Shan Mou, Minfang Zhang, Qin Wang, Zhaohui Ni. *Dept of Nephrology, Renji Hospital, School of Medicine, Shanghai Jiao Tong Univ, China.*

Background: Lupus nephritis (LN) is one of the most serious complications of systemic lupus erythematosus (SLE) and accounting for significant morbidity and mortality. Renalase is a novel secretory flavo-protein which have the ability to protect kidney from ischemic and toxic injury independent of its ability to metabolize catecholamine. The current study aimed to explore the association of renalase and LN clinically and propose the preliminary mechanism of renalase in LN.

Methods: 70 LN patients who fulfilled the ACR revised classification criteria after renal biopsy and 35 healthy controls (HC) were included. The blood and renal biopsy samples were collected on the site of recruiting. 20 active LN patients who received prednisone and immunosuppressive therapy were selected and blood samples before and 6 months after therapy were collected. Serum renalase levels were detected by ELISA. Renalase and macrophage in the kidney was measured by immunohistochemistry.

Results: Serum renalase was elevated in LN patients compared with HC (72.95±35.36versus39.80±14.63 μg/ml, *P*<0.001) and it was significantly higher in active LN patients than inactive LN patients (92.19±34.07versus 53.70±24.75μg/ml, *P*<0.001). Serum renalase was positively correlated with 24hours proteinuria (r=0.435, *P*<0.001), ds-DNA(r=0.351, *P*=0.003), ESR(r=0.402, *P*=0.001), active index (AI, r=0.277, *P*<0.001) and negatively correlated with serum C3(r=-0.371, *P*=0.002) and eGFR(r=-0.694, *P*<0.001). Moreover, most of 20 active LN patients got remission and their serum renalase levels went back to lower level after immunosuppressive therapy (80.77±28.46 versus 61.79±24.90 μg/ml, P<0.05).We also found that patients with LN class V had the lowest serum renalase level in all classes. Immunohistochemistry showed that renalase had strong signal and co-localized with macrophages inside the glomeruli but not in tubules of proliferative LN.

Conclusions: Serum renalase levels were associated with disease activity and severity of LN. Serum renalase can indicate different pathological types of LN. Renal macrophages infiltration with high renalase expression may be one of the important mechanisms in the process of LN.

TH-PO386

Evaluation of Clinical Outcomes and Renal Vascular Lesions in Proliferative Lupus Nephritis Beatriz Seves Holanda, Mariana Pin Andrade, Jonatas Dantas, Cristiane B. Dias, Luis Yu, Lectícia Jorge, Viktoria Woronik. *Div of Nephrology, Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Few studies have analyzed the impact of renal vascular lesions(RVLs) on the outcome of proliferative lupus nephritis(pLN). The aim of this study was to evaluate the influence of RVL in the renal outcome of pLN.

Methods: A retrospective analysis was carried out on 196 SLE patients submitted to a kidney biopsy between 2000-13.Clinical and laboratory data were collected at baseline and at the end of follow up. Treatment was decided by the clinical staff based on conventional literature protocols. VRLs were defined as thrombotic microangiopathy (TMA) or arterial sclerosis (AS).

Results: Clinical features are showed in table 1.

	TMA (n=9)	AS (n=80)	No RLVs (n=106)
Age(y)	27±6	33±12*	29±10
Proteinuria(g/day)	3±3.48	4.2±3.5	4.8±5*
Anti-cardiolipin +	3(38%)	21(34%)	27(29%)
eGFR Initial(ml/min)	20.5±12*	44±28	48±33
Follow up(y)	3.5±3.7	4.6±3.7	7.2±9.9*
eGFR end(ml/min)	41.2±40.3	60.5±40.4	63.8±42
ESRD	3(38%)	16(20%)	22(21%)
eGFR<30	5(56%)	25(31%)	29(27,4%)
eGFR<60	6(66.7%)	40(50%)	43(41%)

Results are shown as median±SD or n(%). *p<0,05

TMA, AS, no VRLs groups were similar regarding complement level, ANA, anti-DNA antibody and hemoglobin. TMA was significantly associated with higher histological activity index (TMA 7.1±4.2 versus AS+No VRLs 5.4±2.4,p<0.05). Chronicity index was higher in all renal vascular lesions subgroups versus controls (TMA+AS 3.8±2.3 versus No VRLs 3±2.2, p<0.05). Finally, multiple logistic regression analysis show that TMA or AS weren't significantly associated with a worse renal outcome. Chronicity index and eGFR at baseline were the only predictors of outcome.

Conclusions: Renal vascular lesions are common in SLE patients with nephritis. The RVLs were associated with higher chronicity index and diminished renal function at baseline. These two variables were the independent determinants of poor renal function in the logistic multivariate regression. The associations between renal vascular lesions with renal outcomes were not significant, likely because of insufficient statistical power.

TH-PO387

Mannan-Binding Lectin and C1q and Their Impact on the Immunological Activity of Lupus Nephritis Zofia I. Niemir,[1] Karol Wozniczka,[1] Anna Swierzko.[2] *[1]Dept of Nephrology, Univ of Medical Sciences, Poznan, Poland; [2]Polish Academy of Sciences, Lodz, Poland.*

Background: Mannan-binding lectin (MBL) and C1q are important molecules in the immunity. Serum MBL levels correlate with the presence of low (0/0 and XA/0), intermediate (XA/XA and YA/0) or high producing (YA/YA) MBL2 genotypes. A more severe SLE course in patients deficient in MBL and C1q is implied. We compared the immunological activity of lupus nephritis (LN) in patients with different MBL2 genotypes in relation to C1q serum levels.

Methods: The study involved 57 patients with LN and 65 healthy controls (C). MBL2 genotyping on blood DNA was performed by the PCR-RFLP analysis. Serum MBL, C1q and antibodies to C1q (anti-C1q Ab), double-stranded DNA (anti-dsDNA Ab) and nucleosome (anti-Ns Ab) were determined by the enzyme-linked immunosorbent assays. The activity of SLE was measured using the SLE Disease Activity Index.

Results: In the LN group, the YA/YA, YA /XA, YA /0 or XA/XA, and 0/0 or 0/XA genotypes were carried by 38.6%, 29.8%, 21.1%, and 10.5% of patients. The matching values in the C group were 33.8%, 33.8%, 23.2%, and 9.2%. In both groups, the respective genotypes had a significant effect on serum levels of MBL. Of interest, in LN patients with the MBL-insufficient genotypes median serum C1q was significantly lower compared to those carrying the high and intermediate alleles (p=0.02). In the C group, an opposite trend was observed and subjects presenting MBL-insufficient genotypes had a significantly higher median level of C1q than the patients with corresponding genotypes did (p=0.02). In the whole group of LN patients, a negative correlation between serum levels of C1q and anti-C1q Ab was found (r=-0.38; p=0.0038). Moreover, in patients with active phase of LN (aLN) and MBL-insufficient genotypes, significant negative correlations between serum levels of MBL and anti-dsDNA Ab (r=-0.59; p=0.0251) and MBL and anti-Ns Ab (r=-0.65; p=0.0116) were noted. The highest levels of anti-dsDNA Ab, anti-Ns Ab, and anti-C1q Ab were observed in aLN patients presenting 0/0 or 0/XA genotypes.

Conclusions: Our results show that in LN MBL deficiency associates with that of C1q and they both contribute to the immunological activity of the disease.

Macrophage Differentiation During Pathogenesis of Lupus Nephritis Gregor Leonahrd Olmes, Christoph Daniel, Maike Julia Buettner, Kerstin U. Amann. *Nephropathology, Erlangen, Germany.*

Background: The role of macrophages in pathogenesis of Lupus nephritis, in particular their differentiation to a certain subtype (e.g. M1 or M2) modulating the inflammatory reaction, is unknown. Here we investigated if differentiation in M1 or M2-macrophages is dependent on the stage of Lupus nephritis and correlates with clinical parameters.

Methods: Using immunohistochemistry we analyzed renal biopsies from 73 patients with lupus nephritis (ISN/RPS classes II-V) for infiltration with M1-macrophages (iNOS/CD68 pos.), M2a (CD206/CD68 pos.), M2c (CD163/CD68) as well as FoxP3-positive regulatory T-cells. In addition, retrospective clinical parameters, i.e. blood pressure, proteinuria and serum urea were correlated with the macrophage infiltration using Pearson-test.

Results: The mean number of CD68+ macrophages was related to the diagnosed ISN/RPS class, showing the highest macrophage infiltration in biopsies from diffuse proliferative class IV and the lowest number in ISN/RPS class V. In all ISN/RPS classes we detected more CD163+/CD68+ than CD206+/CD68+ cells. Surprisingly we predominantly detected M2-macrophages independent of ISN/RPS classification in renal biopsies, while M1-macrophages played only a minor role. The majority of M2a- and M2c-macrophages were localized in the tubulointerstitium. Number of renal FoxP3+ cells correlated with CD163+ cells (r=0,785; p<0.001), whereas serum creatinine correlated positively with the number of CD68 positive (r=0.511; p<0.001) and CD206+/CD68+ macrophages in the tubulointerstitium (r=0.359; p=0.005). In addition, the number of CD163+/CD68+ cells was related to serum urea (r=0.420; p=0.01). Interestingly, the number of renal CD163+/CD68+ macrophages correlated negatively with blood pressure (r=-0.386; p=0.042). However, hypertension was positively associated with the number of CD206+/CD68+ macrophages in the glomeruli and the tubulointerstitium (r=0.338; p=0.015 and r=0.304; p=0.03).

Conclusions: M2-type macrophages are key players in lupus nephritis and macrophage subpopulations might be involved in the development of disease progressing hypertension.

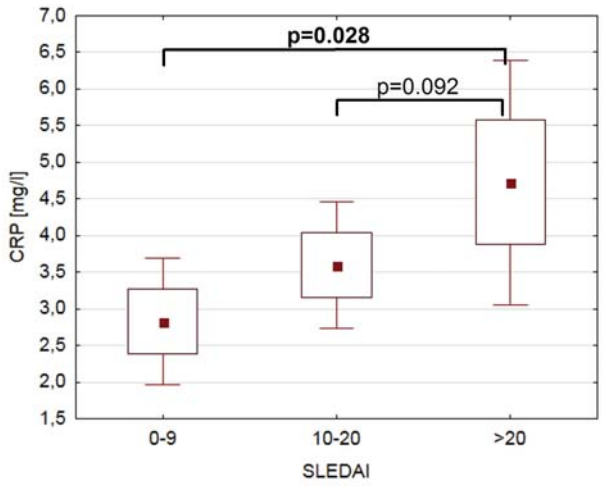
TH-PO389

C-Reactive Protein - Low or High in Systemic Lupus Erythematosus? Katarzyna Jakuszko, Magdalena Krajewska, Katarzyna Koscielska-Kasprzak, Marta Myszka, Dorota Bartoszek, Hanna Bartosik, Marian Klinger. *Dept of Nephrology and Transplantation Medicine, Wroclaw Medical Univ, Wroclaw, Poland.*

Background: Interferon alfa (IFN-α) has a role in the pathogenesis of systemic lupus erythematosus (SLE) and an inhibitory effect on the C-reactive protein (CRP) synthesis. The aim of this study was to evaluate the relationship between serum CRP and the manifestation and activity of SLE.

Methods: The study included 121 patients with lupus nephritis (LN) and 55 with non-renal SLE. A subset of 21 patients with infection (12), pleural effusion (5), pericarditis (2) and chronic synovitis (2) were excluded to eliminate the effects on the CRP levels. The levels of IFN-α, interleukin-6 (Il-6) and CRP were measured using commercially available tests. Disease activity was estimated by SLE Disease Activity Index (SLEDAI).

Results: The CRP levels were lower in patients with measurable (>1pg/ml) IFN-α levels (3.1±4.5 versus 4.6±5.4mg/l, p=0.04), however SLEDAI was significantly higher in this group (16.3±3.6 versus 12.7±7.2, p=0.0003). Moreover CRP levels were lower in patients with LN (3.3±4.7 versus 5.2±6.2mg/l, p=0.03) and hematologic disorder (3.3±4.8 versus 4.2±5.4mg/l, p=0.007) and higher in patients with arthritis (3.7±5.0 versus 2.4±4.1mg/l, p=0.007) and malar rash (3.7±5.1 versus 2.5±4.4mg/l, p=0.03). After excluding patients with measurable IFN-α levels there were significant differences in CRP levels between group with low and high SLE activity (SLEDAI 0-9: 2.8±4.2mg/l; >20: 4.7±5.3mg/l, p=0.028).



Significant correlations between CRP and SLEDAI (r=0.18, p=0.002) and Il-6 (r=0.41, p<0.001) were found.

Conclusions: The range of CRP in SLE exhibits the differentiation related to disease manifestations. The study showed the influence of IFN-α on CRP levels, a potential role and usefulness of CRP evaluation as an indicator of lupus inflammation activity in patients without nephritis and measurable IFN-α levels.

TH-PO390

Efficacy of Treatment for Class III/IV Lupus Nephritis Studied in a Historic Cohort Emilie Rijnink,[1] Ron Wolterbeek,[3] Jan A. Bruijn,[1] Marlies Reinders,[2] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Nephrology, Leiden Univ Medical Center, Leiden, Netherlands; [3]Medical Statistics, Leiden Univ Medical Center, Leiden, Netherlands.*

Background: According to the current guidelines, patients with class III or IV lupus nephritis (LN) require aggressive immunosuppressive therapy including prednisolone and intravenous cyclophosphamide (ivCYC) or mycophenolate mofetil (MMF), which can cause severe side effects. However, studies on the risk of progressive renal failure in mild class III LN are limited. We aimed to answer the question whether these aggressive regimens are justified in patients with class III LN.

Methods: We identified patients with class III and IV LN biopsied at the Leiden University Medical Center between 1969 and 2009. Biopsies were rescored according to the ISN/RPS 2004 classification. Renal function was studied retrospectively during 5-years follow-up and was compared amongst 4 types of induction therapy: corticosteroids (CS) alone; CS combined with azathioprine (AZA); MMF or ivCYC.

Results: In total 22 patients were identified with LN class III and 61 patients with LN class IV. At baseline, serum creatinine, GFR, proteinuria, age and time since diagnosis of systemic lupus erythematosus did not differ significantly between treatment groups for both class III and IV LN. The occurrence of renal impairment (GFR <60mL/min), ESRD (GFR <15mL/min), and doubling of serum creatinine relative to baseline did not differ significantly between treatment groups during 5-year follow-up for class III LN (resp. p=0.66, p=0.57, and p=0.36) and for class IV LN (resp. p=0.85, p=0.92, and p=0.96).

Conclusions: This retrospective, single-center study shows no difference in renal outcome between class III and class IV lupus nephritis irrespective of the type of treatment. Our data may indicate that currently, class III and class IV lupus nephritis are over treated.

TH-PO391

Histopathological Features of Lupus Nephritis in Patients with Positive ANCA Serology Tabitha Turner-Stokes, Massimiliano Morreale, Tom Cairns, H. Terence Cook, Charles D. Pusey, Ruth M. Tarzi, Liz Lightstone. *Imperial College Renal & Transplant Centre, United Kingdom.*

Background: The ISN/RPS classification divided class IV lupus nephritis (LN) into segmental (IV-S) and global (IV-G) subclasses. IV-S lesions tend to have more necrosis and fewer deposits, more characteristic of ANCA associated lesions found in vasculitis. ANCA are found in up to 10% of patients with SLE. The aim of this study was to determine whether Class IV-S LN was more common in ANCA-positive compared with ANCA-negative SLE patients and determine whether this was associated with other histopathological differences.

Methods: Patients with LN were identified from our renal biopsy database (1997-2013). 32/305(11%) patients who had ANCA serology at time of biopsy were MPO or PR3 antibody positive (ANCA+ve) and compared to a control group (n=83) selected randomly and confirmed to have negative serology (ANCA-ve). Biopsy reports were reviewed to determine: ISN class of LN, and presence of necrosis, crescents, endocapillary proliferation and subendothelial deposits.

Results: The ANCA were anti-MPO in 26(84%), anti-PR3 in 2(6%) and dual positive in 3(10%). Comparing the ANCA+ve with ANCA-ve group there was no significant difference in mean age or duration of LN. Histology was different however: ANCA+ve group was significantly more likely to have Class IV-S (37% versus 16%, p=0.02) and less likely to have Class V alone (10% versus 28%, p=0.04). Comparing Class III and IV LN between the 2 groups, endocapillary proliferation was more common in the ANCA+ve group (92% versus 63%, p=0.016). Despite these differences, the extent of endocapillary deposits on EM did not differ between the 2 groups (p=0.50). There was a trend towards more necrosis (36% versus 20%, p=0.11) and crescents (64% versus 42%, p=0.06) in the ANCA+ve group.

Conclusions: Our data suggest that class IV-S LN is more common in SLE patients who are ANCA+ve compared to those who are ANCA-ve, with more endocapillary proliferation and crescent formation. Interestingly there was no difference in the extent of endocapillary deposits in the 2 groups. Further study is required to determine the immunological mechanisms by which ANCA cause these histopathological differences in patients with SLE.

TH-PO392

Autoantibodies to Erythropoietin Receptor Are Related to Disease Activity in Systemic Lupus Erythematosus Junya Yamahana, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Kengo Furuichi, Takashi Wada. *Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.*

Background: In addition to hematopoiesis, erythropoietin (EPO) has protective effects in some injuries, such as ischemia and progressive inflammation. We have reported that anti-EPO receptor (EPOR) antibodies were related to EPO resistant anemia in some diseases. However, little is known about the involvement of anti-EPOR antibodies in progressive tissue injury. Thus, we evaluated anti-EPOR antibodies in systemic lupus erythematosus (SLE) related organ injury in this study.

Methods: Thirty-five SLE cases (32 females and 3 males, 37.5 ± 3.0 years old) were evaluated in this study. Anti-EPOR antibodies were detected by ELISA and the titer was considered as positive when the OD450 ratio of patient serum/ control serum was >1.5. Correlations between anti-EPOR antibodies, SLE disease activity index (SLEDAI), British isles lupus assessment group index (BILAG index) were evaluated. Furthermore, the relevance between clinico-pathological findings and the titer of anti-EPOR antibodies was also analyzed.

Results: Ten out of 35 patients were anti-EPOR positive. Serum levels of anti-EPOR antibodies were correlated with SLEDAI and BILAG index scores (r=0.601, 0.668, respectively, p<0.01). In the anti-EPOR antibodies positive group, the number of injured organs based on BILAG criteria was higher than those of antibodies negative group (4.6 ± 0.4 versus 2.3 ± 0.3, p<0.01). In renal pathology, activity index (r=0.99, p<0.01), cellular proliferation (r=0.82, p=0.04), leukocyte proliferation (r=0.95, p<0.01), cellular crescent (r=0.97, p<0.01) were respectively correlated with serum levels of anti-EPOR antibodies in ISN/RPS 2003 Class IV cases. In the patients with higher level of serum anti-EPOR antibodies, renal function tended to decline rapidly.

Conclusions: Serum levels of anti-EPOR antibodies were related to organ injury in SLE patients.

TH-PO393

The Prognostic Significance of IgG4 Deposition in Membranous Nephropathy and Its Impact on the Therapeutic Regimen Hala M. KFoury, Sufia Husain, Abdulkareem Alsuwaida, Mohammed A. Al-Ghonaim, Saad S. Alobaili, Jamal S. Al Wakeel. *Medicine, King Saud Univ, Riyadh, Saudi Arabia.*

Background: Antiphospholipase A2 receptor antibody(PLA2R1) is identified in most cases of primary/idiopathic membranous nephropathy (iMN) and the auto-antibody to conformational epitope of PLA2R1 is an IgG4 in the majority of cases. On the other hand, renal involvement by IgG4 associated immunological diseases usually presents either as tubulointerstitial nephritis or as membranous nephropathy. The aim of this study is to assess the prognostic value of IgG4 reactivity in a cohort of biopsy proven cases of iMN and to outline its potential in guiding therapy.

Methods: A retrospective study of biopsy proven iMN cases from January 1997 to August 2013 was undertaken. A total of 52 patients were identified and an extensive analysis of the clinical and histological parameters was performed. The primary endpoint was a worse renal outcome which was defined as doubling of serum creatinine of the baseline value.

Results: The study included 52 patients (37 males and 15 females). The mean age of the participants was 38.3 years. The mean baseline creatinine was 96.8 ± 60.2 umol/l among those with positive staining for IGg4 and 118.5 ±172.6umol/l among those with negative staining for IgG4 (P=0.5). The probabilty of doubling serum creatinine was similar among those with or without IgG4 deposition. Follow up of the patients revealed that 23.4% of those with positive IgG4 and 14% of those with negative IgG4 had deteriorationof the renal function. The prevelance and severity of tubulo-interstitial inflammation was the same in the two groups and did not have any statistical significance (P=0.9).

Conclusions: We found that there was no relationship between IgG4 positivity and the severity of clinical and/or histological parameters in patients with iMN. In addition, the IgG4 reactivity had no impact on longterm outcome of the patients, however, further studies are needed to outline the potential use of targeted therapy against IgG4 auto-antibody in a ceratin category of patients with membranous nephropathy.

Expression of PLA2R in Renal Tissues of Children and Adults with Idiopathic Membranuous Nephropathy Xiaoqing Yang, Yanjie Huang, Xia Liu. *Pediatrics, The First Affiliated Hospital of Henan Univ of Traditional Chinese Medicine, Zhengzhou, Henan, China.*

Background: To investigate the location and diagnostic value of Antiphospholipase A2 receptor (PLA2R) in the renal tissue of children and adult with idiopathic membranuous nephropathy (IMN).

Methods: 99 cases of IMN, including 16 children and 83 adults, 17 cases of secondary membranous and 15 cases of non-membranous glomerulopathy were collected between 2012 and 2013. The intrarenal PLA2R and IgG expression, colocalization of PLA2R and IgG, PLA2R and COL4α5, were examined by immunofluorescence (IF) staining, then the positive rates of PLA2R expression were compared between adult and children. The intrarenal IgG4 expression were measured by IF staining in 55 cases. The relationship of PLA2R expression with the atypical pathological features of IMN were also analysed.

Results: The strong positive staining of PLA2R were observed in outer of glomerular capillary basement membrane, its positive rate in adults and in children was respectively 89.16% and 87.50%. PLA2R and IgG colocalized along the peripheral capillary walls. The double positive rate of PLA2R and IgG4 is 90%. PLA2R expression were all negative in renal tissues of secondary membranous glomerulopathy and non-membranous glomerulopathy.

Conclusions: The renal expression of PLA2R combined with IgG4 in glomeruli can be used as a reliable marker to differeratiate IMN from secondary membranous glomerulopathy and non-membranous glomerulopathy. PLA2R is not only a target antigen in adult IMN, but also in children in this study.

Reappraisal of a PLA2R1 Immunofluorescence Study on Idiopathic Membranous Nephropathy: Influence of the Immunostaining Method and Correlation with the IgG4-Dominant/Codominant Immunophenotype Shigeo Hara,[1] Shunsuke Goto,[2] Nozomu Kamiura,[3] Akihiro Yoshimoto,[3] Motoko Yanagita,[4] Shinichi Nishi,[2] Tomoo Itoh.[1] *[1]Div of Diagnostic Pathology, Kobe Univ Graduate School of Medicine, Kobe, Japan; [2]Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan; [3]Div of Nephrology, Kobe City Medical Center General Hospital, Kobe, Japan; [4]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

Background: The M-type phospholipase A2 receptor (PLA2R1) was recently identified as a specific target antigen in idiopathic membranous nephropathy (iMN). However, the influence of different sample preparation techniques in immunostaining on the results is unclear. Published evidence identified IgG4 as the dominant subclass of PLA2R1 antibody; however, it remains unclear whether the IgG subclass profiles of the glomerular immune complex of PLA2R1 positive and negative iMN are similar.

Methods: The subjects were 44 cases of biopsy-proven iMN. The PLA2R1 positivity rates of paraffin-embedded or frozen sections were compared. The comprehensive IgG subclass profile of the glomerular immune deposit was compared between PLA2R1-positve and PLA2R1-negative iMN cases.

Results: The PLA2R1 positivity rate for the paraffin-embedded sections was 58.1%, while that for the frozen sections was 54.3%, although background non-specific staining was observed for the frozen sections. In 3 cases, discrepancy was observed between the results for the paraffin-embedded and frozen sections. With regard to IgG subclass immunoprofiling, 82.3% PLA2R1-positive iMN cases demonstrated an IgG4-dominant/codominant phenotype, whereas 35.7% PLA2R1-negative iMN cases demonstrated this phenotype ($p = 0.009$).

Conclusions: PLA2R1 immunofluorescence results are not affected by the different techniques used for sample preparation, although paraffin-embedded sections merit the histological detection of PLA2R1 because of non-specific background staining in frozen sections. Higher frequency of the IgG4-dominant/codominant phenotype in PLA2R1-positive iMN cases may suggest immunologically heterogeneous subgroups in iMN.

TH-PO396

IgG Subclasses and Phospholipase A2 Receptor in Glomerular Deposits of Membranous Nephropathy: A Retrospective Analysis Hong-Rui Dong, Yan-Yan Wang, Guo-Qin Wang, Li-Jun Sun, Hong Cheng, Yi-Pu Chen. *Div of Nephrology, Beijing Anzhen Hospital, Capital Medical Univ, Beijing, China.*

Background: To investigate the differences in the IgG subclasses distribution and phospholipase A2 receptor (PLA2R) expression in glomeruli between patients with idiopathic membranous nephropathy (IMN), lupus-related MN (LN-MN) and hepatitis B-associated MN (HBV-MN).

Methods: The IgG subclasses and PLA2R in glomeruli were examined by immunofluorescence and/or immunohistochemistry staining.

Results: 77 patients with IMN, 15 with LN-MN and 8 with HBV-MN were enrolled in this study. In IMN patients, the deposition frequencies of IgG1, IgG2, IgG3 and IgG4 were 19.5%, 37.7%, 46.8% and 97.4%, respectively. The frequency of IgG4 was the highest ($P<0.01$) and its immunofluorescence intensity was also the most strong among the four IgG subclasses. The deposition frequencies of IgG1, IgG2, IgG3 and IgG4 in were 73.3%, 93.3%, 66.7% and 6.7%, respectively. The frequency of IgG4 in LN-MN was the lowest in the four IgG subclasses ($P<0.01$). The deposition frequencies of IgG1, IgG2, IgG3 and IgG4 in HBV-MN were 12.5%, 62.5%, 75.0% and 12.5%, respectively. Enhanced expression of PLA2R in glomeruli was found in 96.1% patients of IMN, but not in patients of LN-MN or HBV-MN. In 93.5% patients of IMN, IgG4 deposition and high expression of PLA2R occurred simultaneously in glomeruli.

Conclusions: In IMN patients, IgG4 is the predominant deposit in glomeruli, which is often accompanied with enhanced PLA2R expression. However, In LN-MN and HBV-MN patients, the other IgG subclasses except IgG4 were predominant deposits in glomeruli, and no enhanced PLA2R expression is found. Therefore, this examination may help to make differential diagnosis between IMN and the above two kinds of secondary MN.

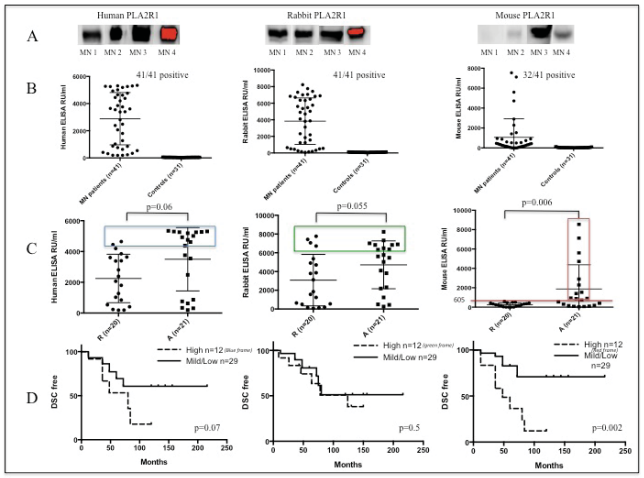
A Specific Anti-PLA2R1 Mouse ELISA Can Predict Long-Term Outcome in Patients with Membranous Nephropathy Barbara Seitz-Polski,[1,2] Nicola M. Tomas,[2,3] Rolf A. Stahl,[3] Vincent L.M. Esnault,[1] Gerard J. Lambeau.[2] *[1]Nephrology, Pasteur Univ Hospital, Nice, France; [2]Inst of Molecular and Cellular Pharmacology, CNRS and Univ of Nice, Valbonne, France; [3]Nephrology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Membranous nephropathy (MN) is an autoimmune disease associated with autoantibodies against the phospholipase A2 receptor (PLA2R1) in 70% of cases. About 30% of MN patients progress to end-stage kidney disease (ESKD) while 30% undergo spontaneous remission. The aim of this study was to identify new prognostic factors for patients with anti-PLA2R1.

Methods: We analyzed the cross-reactivity of sera from 41 MN patients positive against human PLA2R1 on rabbit and mouse PLA2R1 orthologs by Western blotting. We designed three ELISAs using recombinant human, rabbit and mouse PLA2R1.

Results: All sera recognized equally human and rabbit PLA2R1 in Western blot analyses and ELISA, but only 32 sera (78%) were reactive against mouse PLA2R1, suggesting the presence of distinct epitopes that are differentially conserved among species. During the follow-up of 36 months, 21 patients had a persistent nephrotic syndrome and 20 patients went into remission. We analyzed the association between anti-PLA2R1 titers in the different ELISAs and the clinical outcome. The mean anti-PLA2R1 activity was significantly different between active and remission groups in the mouse ELISA in univariate and multivariate analyses (p=0.006, p=0.02 respectively) but not in human and rabbit ELISAs. A ROC curve analysis of the mouse ELISA titers defines a threshold of 605 RU/ml above which 100% of patients had poor prognosis and lower survival without doubling of serum creatinine (p=0.002). A similar threshold could not be defined for rabbit and human ELISAs.



Conclusions: Our results suggest that measuring anti-PLA2R1 titers using a mouse PLA2R1 ELISA can identify MN patients at risk for ESKD.

Glomerular Endothelial Cell Injury and Focal Segmental Glomerulosclerosis Lesion in Idiopathic Membranous Nephropathy Megumi Fukui,[1] Akiko Mii,[1] Akira Shimizu,[2] Shuichi Tsuruoka.[1] *[1]Nephrology, Nippon Medical School, Tokyo, Japan; [2]Analytic Human Pathology, Nippon Medical School, Tokyo, Japan.*

Background: Focal segmental glomerulosclerosis (FSGS) lesions have often been discussed as a negative predictor in idopathic membranous nephropathy (MGN). The mechanism of the development of FSGS lesion in MGN is still uncertain.

Methods: From 250 cases of MGN, 26 cases contained FSGS lesion. We compared the clinicopathological characteristics between MGN cases with FSGS lesion (MGN+FSGS) and age, sex, and stage matched MGN cases without FSGS (MGN-FSGS).

Results: The glomerular filtration rate (eGFR) was significantly lower in MGN+FSGS cases compared to MGN-FSGS, although nephrotic syndrome, hematuria, and systolic blood pressure levels were not significantly different between the two groups. Pathologically, glomeruli in MGN+FSGS cases showed narrowing and loss of glomerular capillaries with separating from GBM or disappearance of CD34+ endothelial cells, and accumulation of extracellular matrix (ECM) in capillary walls, indicating the development of glomerular capillary injury. These findings of endothelial injury were seen even in MGN-FSGS cases, but they were more prominent in MGN+FSGS than MGN-FSGS by computer assessed morphometric analysis. In MGN+FSGS cases, 44 out of 534 glomeruli (8.2%) contained FSGS lesions (n=31, NOS lesion; n=13, perihilar lesion). Significant thickness of GBM with ECM accumulation was evident in MGN+FSGS cases. Podocyte injury with effacement of foot processes was also noted, although the expression of VEGF on podocytes was not different between the two groups, which suggests that the significant thickness of capillary walls may influence the function of VEGF from podocyte resulting in the glomerular capillary injury that contribute to the development of FSGS lesion in MGN.

Conclusions: Glomerular capillary injury was seen in all MGN cases. Furthermore, the prominent injuries of glomerular capillaries may be associated with the deterioration of eGFR and the formation of FSGS lesions in MGN.

TH-PO399

Glomerular Endothelial Cell Injury in Focal Segmental Glomerulosclerosis Megumi Fukui,[1] Akiko Mii,[1] Yukinari Masuda,[2] Akira Shimizu,[2] Shuichi Tsuruoka.[1] *[1]Nephrology, Nippon Medical School, Tokyo, Japan; [2]Analytic Human Pathology, Nippon Medical School, Tokyo, Japan.*

Background: Focal segmental glomerulosclerosis (FSGS) is considered to be podocyte disease manifesting foot process effacement and nephrotic proteinuria but the mechanism of the development of segmental sclerosis in FSGS is still uncertain.

Methods: We selected idiopathic FSGS cases (n=34, male; n=22, female; 12) from a series of biopsies in our department from 1997 to 2013 and examined the clinicopathological characterizations.

Results: The average age was 45±22 (2-83), about 73.5% developed nephrotic syndrome, and mean eGFR was 51 ± 26.6 ml/min/1.73m^2. According to the Columbia classification of FSGS, frequencies were 55.9% cellular, 14.7% perihilar, 11.8% tip or not otherwise specified (NOS), and 5.9% collapsing. All FSGS cases showed endothelial cell injuries characterized by dissociation from GBM and disappearance of CD34+ endothelial cells and narrowing of the capillary lumen. Especially, tip variant showed mildest endothelial cell injury localized to tip lesion, but collapsing variant presented most severe injury in whole glomeruli with tuft collapse, corresponding to the difference in prognosis. Furthermore, by computer assessed morphometric analysis, FSGS cases had significantly smaller capillaries even in non-sclerotic glomeruli than MCD cases, despite the similar pathogenesis in terms of podocyte disease. Electron microscopy findings showed an increase of endothelial cells, loss of fenestra, and widening of the subendothelial space suggesting the endothelial cell damages. Especially in cellular variant, more severe endothelial cell injuries were seen with interposition of macrophage into the widened subendothelial space and differentiation to foam cells. On the other hand, in NOS and perihilar variant, foot processes of podocytes and fenestra of endothelial cells were relatively preserved. It may be suggested that cellular variant reflects acute phase, and NOS or perihilar variant presents chronic phase of FSGS.

Conclusions: All FSGS cases showed endothelial cell injury. Not only podocyte injury but also endothelial cell injury may contribute to develop the sclerotic lesion in FSGS.

TH-PO400

Venous Thromboembolism in ANCA Associated Vasculitis Eoin D. O Sullivan, Sarah Margaret Moran, Michael Clarkson. *Dept of Renal Medicine, Cork Univ Hospital, Cork, Ireland.*

Background: ANCA associated vasculitis (AAV) is associated with increased risk of venous thrombo-embolisim (VTE) 1. The mechanisms underlying this are not fully elucidated but increased endogenous thrombin potential as well as higher circulating factor VIII are potential contributing factors[2]. Our aim was to measure the incidence of VTE in renal AAV, and to observe whether any clinical features or therapies were associated with higher VTE rates.

Methods: Using the Cork Vasculitis Registry, we retrospectively identified 101 patients with renal AAV from 2005 to 2014. VTE events included radiologically confirmed pulmonary emboli and deep vein thrombosis. The incidence of VTE was calculated (VTE/100 person-years) and related to periods of disease activity.

Results: 100 patients were ANCA positive. The mean age at diagnosis was 65 years, and mean follow up was 50 months. VTE occured in 11 patients (11%), an incidence rate of 2.6/100 patient years. The presence of cresentic histology on renal biopsy was associated with development of VTE (p 0.026).Nearly twice as many VTE were found in patients with MPO positive disease. Odds ratio of VTE in MPO disease 2.5 (CI 0.68-9.1) We found no association between VTE rates and age, Birmingham vasculitis activity score, treatment modalities, ANCA titres or glomerular filtration rate.

Conclusions: 11% of patients with renal AAV were diagnosed with VTE. 90 % during disease activity. This has important implications for anticoagulation. Anticoagulation has been shown to be effective in ANCA positive patients despite the risk of pulmonary haemorrhage[3]. We found lower rates of VTE were observed in PR3 positive disease; previous research has demonstrated conflicting rates in this regard[4,1].

TH-PO401

Decreased Degradation of Neutrophil Extracellular Traps Is Associated with Low MPO-ANCA Affinity in MPO-ANCA Associated Vasculitis Patients with Deep Vein Thrombosis Muneharu Yamada, Takashi Oda, Taito Oshima, Yui Tsukano, Shuuhei Komatsu, Go Hirose, Tadasu Kojima, Yasuyo Sudo, Tomohiro Tomiyasu, Noriko Yoshikawa, Masaharu Yoshida. *Dept of Nephrology, Tokyo Medical Univ Hachioji Medical Center, Hachioji, Tokyo, Japan.*

Background: We have recently reported that the ability of neutrophil extracellular traps (NETs) induction correlated with the MPA disease activity as well as with the ANCA affinity to MPO (*JASN 2014*).NETs contribute to deep vein thrombosis (DVT). We therefore investigated the ability of sera from patients with MPO-ANCA associated vasculitis (MPO-AAV) to degrade NETs, and evaluated the correlation between ANCA affinity and NETs degradation in MPO-AAV patients with/without DVT.

Methods: First we measured the level of ANCA affinity to MPO in sera collected from 30 patients with MPO-AVV and 5 healthy volunteers by using the competitive inhibitory ELISA method (*Clin Exp Rheumal 2009*). Then NETs degradation activity in those sera was evaluated. Phorbol myristate acetate-induced NETs from neutrophils isolated from healthy volunteers were incubated with 10% patient sera for 6 hours. NETs degradation ability was evaluated by quantitating the DNA content in the supernatant by the use of fluorescence spectrometry assay with Picogreen.

Results: MPO-AAV patients were divided into two groups based on their ANCA affinity (high and low). Sera from MPO-AAV patients had significantly lower degradation ability than that of healthy controls (36.01±2.29 ng/ml versus 57.38±11.25 ng/ml, p<0.01). High affinity group showed higher degradation potential of NETs compared to low affinity group. DVT was associated more frequently in low affinity group than those in high affinity group. The ability to degrade NETs in patients of low affinity group with DVT was lower than those patients without DVT. Thus, low ANCA affinity group showed lower NETs degradation and more frequent DVT association.

Conclusions: These results suggest that sustained NETs existence due to decreased degradation ability in low ANCA affinity MPO-AAV patients may induce sustained inflammation and DVT.

TH-PO402

MPGN and C3 Glomerulopathies in Children: Does the Presentation and Outcome Vary Based on Histological Findings? Shefali Vyas,[1] Isabel Roberti,[1] Brittany M. Singh,[3] Anup Singh.[2] *[1]Children'S Kidney Center, SBMC, Livingston, NJ; [2]Pediatric Nephrology, SPUH, New Brunswick, NJ; [3]Virginia Tech, VI.*

Background: MPGN has a variable clinical presentation and recently the separation of C3 glomerulopathies (C3GN) has been identified.

Methods: We reviewed charts of children with idiopathic MPGN classified in the traditional categories (Type I, II or DDD and III) and reclassified them as C3GN

(non-immune mediated MPGN) or IM MPGN (immune mediated MPGN) comparing clinical presentation, therapy and outcome data. All patients received steroids and ACEi ± ARBs. Additional therapies, such as CIN, MMF or cyclophosphamide were used if no improvement was seen.

Results: A total of 22 children were studied with a follow-up time of 4 months to 15 years (median=4 yrs). Clinical data at presentation and outcome is presented in Table 1. C3 nephritic factor was done in 5 (2 negative/1 equivocal/1 + titer). Three patients with DDD had genetic testing and were all negative for Factor H and I mutations.

Characteristics	C3GN (N=8)	Immune Mediated MPGN (N=14)
Age at Presentation	5-16 yrs (median 11 yrs)	4-17 years (median 10 yrs)
Male/Female	4/4	5/9
*At presentation: aUA/NS/GH	2/5/3	1/13/5
AKI at presentation	3 (37%)	2 (14%)
Low C3/ C4	8/1	11/6
Hypertension	4 (50%)	10(71%)
** CIN/MMF/CYP	1/1/1 (37%) ***	9/3/1 (71%)
At last F/up: Remission/ Partial remission/ CKD	6/2/0	9/4/1

*aUA = asymptomatic with abnormal UA;NS= nephrotic syndrome, GH= gross hematuria
**CIN=calcineurin inhibitors, MMF= mycophenolate mofetil, CYP=cyclophosphamide
***P=0.01.

There was no difference in age, gender or ethnicity, clinical presentation and outcome among both groups. HTN was noted in 14 children (64%) - 12 stage II and 2 stage I HTN. All were normotensive on last follow-up visit. However, the group with IM MPGN required significantly more therapy including the use of 3 immunosuppressants in 3 patients. A total of 68% were in complete remission, 27% in partial at last follow up- similar among both groups. 80% of the children with AKI achieved remission with only 1 progressing to ESRD (IM MPGN).

Conclusions: C3GN and IM MPGN have excellent long term outcome if treated aggressively with steroids and immunosuppressants.

TH-PO403

Use of C4d Biomarker as a Diagnostic Tool to Classify Membranoproliferative Glomerulonephritis Nirupama Gupta, Eduardo H. Garin. *Pediatric Nephrology, Univ of Florida, Gainesville, FL.*

Background: Membranoproliferative glomerulonephritis (MPGN) in 2013 was reclassified into MPGN type I and C3 glomerulopathy (C3G) based on its pathogenesis involving the complement cascade, either the classical or alternative pathway respectively. This study aimed to evaluate whether C4d biomarker, a cleavage protein of C4, could be used as a diagnostic tool to differentiate between classical or alternative pathway activation in MPGN.

Methods: We conducted a retrospective study including adult and pediatric patients diagnosed with MPGN and minimal change disease (MCD) from January 2000 to December 2012 by using the Informatics for Integrating Biology and the Bedside software**.** Pertinent data from chart review were recorded. The formalin-fixed paraffin-embedded tissues were stained for C4d deposition using rabbit anti-human C4d polyclonal antibody via an immunoperoxidase method. Statistics were done using Mann-Whitney and chi-squared tests.

Results: Eighteen MPGN and 10 MCD patients were included in the study. The control MCD biopsies had none or minimal C4d staining. Using the 2013 MPGN classification, the MPGN group was sub-classified as: MPGN type I (8), C3G (7), and unclassified MPGN (3). Based on C4d immunohistochemical staining, 14 patients had C4d glomerular staining and four patients did not. Seven of these patients had C1q (+) (classical pathway activation) and seven had C4d (+) and C1q (-) (lectin pathway activation). Of the four C4d negative, three had evidence of alternative pathway activation and one was unknown (C4d (-), C1q (-), and C3 (-)). Of the eight MPGN 1 patients categorized by the 2013 classification, two were reclassified as C3G; of the seven C3G patients, three were reclassified as MPGN 1; and of the three unknown patients, two were reclassified as MPGN 1 after C4d staining. The lectin pathway was involved in four of the MPGN 1 and three of the C3G patients.

Conclusions: C4d stain can help differentiate between MPGN type I and C3G. This study also reports for the first time that the lectin pathway also seems to play a prominent role in the pathogenesis of MPGN in some patients.

TH-PO404

Histopathologic Glomerular Damage Score Predicts Outcome in ANCA-Associated Necrotizing Glomerulonephritis Silke R. Brix,[1] Martin Busch,[2] Fedai Özcan,[3] Ulf Panzer,[1] Rolf A. Stahl,[1] Thorsten Wiech.[4] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Klinik für Innere Medizin III, Universitätsklinikum Jena, Jena, Germany; [3]Klinik für Nephrologie und Notfallmedizin, Klinikum Dortmund, Dortmund, Germany; [4]Institut für Pathologie, Sektion Nephropathologie, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: To improve its prognostic value, a detailed analysis of kidney biopsies of 50 patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated necrotizing glomerulonephritis was performed.

Methods: 612 Glomeruli were categorized for different stages of damage, i.e. fibrinoid necrosis, cellular, fibrocellular, and fibrous crescents, and sclerosis. Crescents and glomerular sclerosis were differentiated in segmental (<50%) and global damage (>50%) assuming that glomeruli with less than 50% destruction were able to sustain residual function. A glomerular damage score was determined by counting segmental damage as 0.5 and global damage as 1.

Results: The glomerular damage score correlated with renal function during the two year follow up ($p<0.0001$, $r=0.73$). Renal outcome differed depending on the score when grouped into mild (0-25%), moderate (25-50%) and severe glomerular damage (>50%), respectively ($p<0.01$). Patients who reached end stage renal disease had a higher initial score than patients who preserved renal function ($p<0.001$). This score showed a stronger correlation to renal function than the percentage of unaffected glomeruli ($p<0.01$, $r=0.45$). Using the ANCA classification proposed in 2010, we found nine focal, 19 crescentic, 20 mixed and two sclerotic cases. These groups did not significantly differ in their renal function at two year follow up.

Conclusions: The glomerular damage score predicts renal outcome in ANCA-associated necrotizing glomerulonephritis.

Funding: Government Support - Non-U.S.

TH-PO405

Collapsing Glomerulopathy Is the Dominant Variant of Focal Segmental Glomerulosclerosis in Native Kidney Biopsies with Thrombotic Microangiopathy David Buob,[1] Mélanie Decambron,[2] Viviane Gnemmi,[3] Maxime Hoffmann,[4] Raymond Azar,[5] Christian Noel,[2] Copin Marie-Christine,[3] Francois Glowacki.[2] *[1]Pathology, Tenon Hospital, Paris, France; [2]Nephrology, CHRU de Lille, Lille, France; [3]Pathology, CHRU de Lille, Lille, France; [4]Nephrology, Hôpital Privé de La Louvière, Lille, France; [5]Nephrology, Centre Hospitalier de Dunkerque, Dunkerque, France.*

Background: Acute vaso-occlusive disease, such as thrombotic microangiopathy (TMA), is an under-recognized cause of focal segmental glomerulosclerosis (FSGS), particularly the collapsing variant. The frequency and significance of TMA-associated FSGS have not been specifically studied so far in native kidney.

Methods: Clinicopathological features were retrospectively studied in 53 patients with histologically proven TMA on native kidney biopsies. TMA cases superimposed on immune glomerulonephritis and diabetic nephropathy were excluded.

Results: Histological TMA was related to hypertensive nephropathy (n=30, 56%), drugs (n=10, 19%), complement abnormalities (n=9, 17%), antiphospholipid syndrome (n=2, 4%), and post-partum (n=2, 4%). 47% (n=25) presented with arteriolar TMA, 11% (n=6) with glomerular TMA, and 42% (n=22) with mixed TMA. Acute TMA changes were significantly associated with acute renal failure. Cases with diffuse TMA were significantly associated with severe anemia and higher arterial pressure. Among the 53 patients with histological TMA, 33 (63%) had concurrent FSGS lesions: collapsing FSGS was the dominant variant (n=17, 52% of the FSGS cases), followed by NOS (n=10, 30%), cellular (n=4, 12%), perihilar (n=1, 3%), and tip (n=1, 3%). Cases with FSGS had significantly less laboratory evidence of TMA. There was no significant association between FSGS classification and proteinuria or renal failure. Although non-significant, we noticed a trend toward an association between FSGS lesions and renal survival.

Conclusions: FSGS lesions, and in particular collapsing changes, are frequent in native kidney biopsies with TMA. Although no association was found between TMA-associated FSGS and proteinuria or evolution towards chronic renal failure, our results suggest that endothelial injury related to TMA might play an important role in the pathophysiology of FSGS.

TH-PO406

Characteristics of Renal Biopsies in Children of Low Birth Weight Kentaro Koike,[1] Nobuo Tsuboi,[1] Yohei Ikezumi,[2] Go Kanzaki,[1] Makoto Ogura,[1] Akihiko Saitoh,[2] Takashi Yokoo.[1] *[1]Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan; [2]Dept of Pediatrics, Niigata Uuniversity Medical and Dental Hospital, Niigata, Japan.*

Background: Recent autopsy studies have demonstrated much larger variability in the total number of nephrons in normal populations than previously suspected. In addition, human nephron number has been shown to be closely related to the intrauterine environment and the birth weight. We previously reported a relationship between low birth weight (LBW) and the development of focal segmental glomerulosclerosis (FSGS) accompanied by podocytopenia (Ikezumi Y et al. Am J Nephrol, 2013). We also demonstrated that a low glomerular density (GD; glomerular number per renal cortical area) in renal biopsy specimens can be a marker of future progression to renal failure in adult patients with primary glomerular disease, suggesting the significance of GD as a surrogate for the total number of nephrons.

Methods: The renal biopsy findings of LBW children were compared to those of age-matched normal birth weight (NBW) controls who had been histopathologically diagnosed with FSGS or minimal change nephritic syndrome (MCNS). The GD and glomerular volume (GV) were estimated based on measurements taken using a computed imaging analyzer.

Results: A total of 31 patients, consisting of 8 patients with LBW-FSGS, 10 patients with NBW-FSGS, and 13 patients with NBW-MCNS, were analyzed. In general, GD was significantly correlated with birth weight ($r=0.477$, $p<0.05$). In addition, GD showed significant inverse correlations to the GV($r=-0.61$, $P<0.05$). There were no significant differences in age, body mass index (BMI), or urine protein excretion at renal biopsy between the groups. Compared to the other groups, the LBW-FSGS patients had a significantly lower GD and larger GV

	LBW-FSGS	NBW-FSGS	NBW-MCNS
Birth weight (g)	944±537	3133±323†	3166±393†
Glomerular volume ($\times 10^6 \mu m^3$)	4.2±1.5	1.8±0.5†	1.5±0.4†
Glomerular density ($/mm^2$)	1.4±0.6	3.3±1.2†	3.6±1.1†

(†;p<0.05 versus LBW-FSGS).

Conclusions: LBW children show renal biopsy findings that are characteristic of a decreased number of nephrons.

TH-PO407

IgD Heavy Chain Deposition Disease: Detection by Laser Microdissection and Mass Spectrometry

Sanjeev Sethi,[1] Virginie Royal,[2] Patrick S. Quint,[1] Fernando C. Fervenza,[1] Martine Leblanc,[2] Paul J. Kurtin.[1] *[1]Mayo Clinic; [2]Maisonneuve-Rosemont Hospital.*

Background: Monoclonal immunoglobulin (Ig) deposition disease (MIDD) is a rare complication of monoclonal gammopathy. It is characterized by deposition of monoclonal Ig light, heavy or both heavy and light chains along the glomerular and tubular basement membranes. Most commonly, MIDD is associated with light chain deposition, in particular λ light chains. Less commonly MIDD is associated with heavy chain deposition, with γ chain being the most common heavy chain. IgD heavy chain deposition disease has not been described.

Methods: We describe a 77-year man who presented with proteinuria and renal failure. Kidney biopsy showed a nodular sclerosing glomerulonephritis with extensive focal global glomerulosclerosis and tubular atrophy and interstitial fibrosis. IF was negative for Ig deposits, while EM showed powdery deposits in the glomeruli and along tubular basement membranes. This prompted us to perform proteomic analysis to determine the composition of deposits.

Results: Laser microdissection and mass spectrometry (LMD/MS) of the glomeruli showed large spectra number for IgD.

Probability Legend: over 95% | 80% to 94% | 50% to 79% | 20% to 49% | 0% to 19%

#	Visible?	Starred?	Bio View: Identified Proteins (12)	Accession Number	Molecular Weight	Protein Grouping Ambiguity	Pre Sample blank	Sample 1	Sample 2
1	☑	☆	Ig delta chain C region	IGHD_HUM...	42 kDa			62	54
2	☑	☆	Apolipoprotein E	APOE_HUM...	36 kDa			39	41
3	☑	☆	Complement component C9	CO9_HUMAN	63 kDa			17	22
4	☑	☆	Complement C3	CO3_HUMAN	187 kDa			12	19
5	☑	☆	Complement C5	CO5_HUMAN	188 kDa			15	17
6	☑	☆	Complement component C6	CO6_HUMAN	105 kDa			14	12
7	☑	☆	Complement component C7	CO7_HUMAN	94 kDa			14	11
8	☑	☆	Apolipoprotein A-IV	APOA4_HU...	45 kDa			10	12
9	☑	☆	Complement component C8 alpha...	C08A_HUM...	65 kDa			6	9
10	☑	☆	Complement factor H-related pro...	FHR1_HUM...	38 kDa				7
11	☑	☆	Ig kappa chain C region	IGKC_HUMAN	12 kDa			5	
12	☑	☆	Ig lambda-2 chain C regions	LAC2_HUM...	11 kDa			4	

The findings were validated by immunohistochemistry for IgD that showed intense glomerular and tubular staining for IgD. Together with the kidney biopsy, the findings are consistent with IgD deposition disease. Bone marrow biopsy showed 5% plasma cells. The patient was treated with bortezomib and dexamethasone which resulted in improvement of hematological parameters but with no improvement of renal function.

Conclusions: We describe a unique case of IgD deposition disease. From the diagnostic standpoint, IgD deposition is difficult to diagnose since routine IF does not detect IgD. The diagnosis was based on proteomic analysis by LMD/MS and underscores the value of LMD/MS in further evaluating renal biopsies where routine assessment fails to reach an accurate diagnosis.

TH-PO408

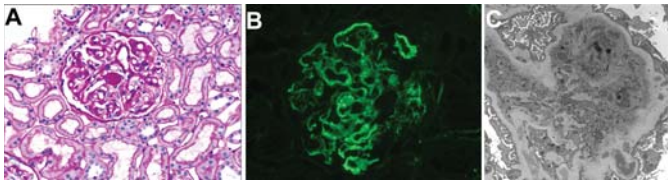
Immune Complex Disease Associated with Chronic Bevacizumab Treatment of Vestibular Schwannomas in Neurofibromatosis 2 Patients

Ivy A. Rosales,[1] A. Bernard Collins,[1] Eugene P. Rhee,[2] David J.R. Steele,[2] Scott Plotkin,[3] Robert B. Colvin,[1] Rex Neal Smith,[1] Kevin Chan.[1] *[1]Pathology, Massachusett General Hospital, Boston, MA; [2]Nephrology, Massachusett General Hospital, Boston, MA; [3]Neurology, Massachusett General Hospital, Boston, MA.*

Background: Bevacizumab, a humanized monoclonal antibody to VEGF is included in treatments of many epithelial malignancies and is also used to treat hearing loss and tumor growth of vestibular schwannomas in patients with neurofibromatosis 2, NF2. Three patients developed persistent proteinuria (>2 gms).

Methods: Patients were treated every two weeks with 5 mg/kg. Patients were treated for 3, 5, or 6 years. One patient had a low C3 and C4 without cryoglobulins, rheumatoid factor and with a normal SPEP. The other two patients had normal SPEP but complements, cryoglobulins, and rheumatoid factors were not evaluated. Creatinines were normal.

Results: Kidney biopsies showed prominent intracapillary hyaline (resembling pseudothrombi), mild mesangial hypercellularity, and diffuse glomerular basement membrane (GBM) duplication (Figure 1A). By immunofluorescence, granular GBM deposits stained for IgM (2+), IgG (none), C3 (1+), IgA (trace – 1+), C1q (none), kappa and lambda (trace-1+) (Figure 1B). Ultrastructurally, prominent duplication, variable subendothelial deposits, subendothelial hyaline like deposits were present (Figure 1C). Diagnoses of mild chronic thrombotic microangiopathy and immune complex disease were made.



Conclusions: Intracapillary hyaline like plus immune deposit disease is a histologic variant of TMA associated with long term bevacizumab. The intracapillary hyaline like deposits stained poorly for immunoglobulins so that they are unlikely to be true immunoglobulin containing pseudothrombi. Long term bevacizumab treatment of NF2 patients may create risk of an immune complex disease superimposed on mild TMA.

Rituximab Therapy in Patients with Primary and Secondary Glomerulonephritis: Relationship between Clinical Response and CD19+ Trend

Selena Longhi, Lucia Del Vecchio, Donatella Casartelli, Maria Carla Bigi, Andrea Cavalli, Mauro Maria Corti, Flavia Tentori, Giuseppe Pontoriero, Francesco Locatelli. *Nephrology and Dialysis, A. Manzoni Hospital, Lecco, Italy.*

Background: Rituximab is an effective therapy in primary and secondary glomerulonephritis (GN). Usually it is given as a single dose (375 mg/m2) or two repeated doses of 1 g (rheumatologic regimen). Little is known for how long CD19+ depletion persists following a single administration and whether CD19+ trend may be predictive of relapses.

Methods: Retrospective analysis of 21 patients (10 M/ 11 F; mean age 58.94 ± 16.47 years), treated with Rituximab in single or multiple doses for ANCA vasculitis (3), membranous GN (8), cryoglobulinemia (6), Lupus Nephritis (3), FSGS (1) between Jun '09 and Feb '14 (median follow up 13 months, range 1 - 47.03 months).

Results: Patients received from 1 to 4 Rituximab infusions according to clinical needs and CD19+ trend over time. 4 patients received a rheumatologic dose regimen. The mean dose for each Rituximab administration was 747 ± 185 mg with a mean cumulative dose of 1305 ± 934 mg. Complete CD19+ depletion (< 5 cell/mm^3) was obtained in all the patients; CD19+ returned ≥ 5 cell/mm^3 in 16 patients after a mean of 8.72 ± 5.2 months (min 3.6, max 20.4 months). The trend of CD19+ was related to clinical manifestations in 4 out of 16 patients (5 patients were excluded for inconclusive data). Treatment response was obtained in 17 patients (4 partial remission, 13 full response).

Conclusions: Rituximab is an effective therapy in adult patients with primary and secondary GN. According to our limited experience, CD19+ depletion cannot always predict patient response to Rituximab and/or disease relapses, even if increased CD19+ levels may anticipate disease relapses in some cases.

Atypical Immunofluorescence Pattern in Adult Patients with X-Linked Alport Syndrome Using Anti Type IV Collagen α1–α6 Antibody

Kensuke Joh,[1] Yasunori Miyasaka,[2] Yoshikazu Sado.[3] *[1]Dept of Pathology, Tohoku Univ Graduate School of Medicine, Sendai-City, Miyagi-ken, Japan; [2]Kidney Center, Japan Community Health care Organization Sendai Hospital, Sendai-City, Miyagi-ken, Japan; [3]Shigei Medical Research Inst, Okayama-City, Okayama-ken, Japan.*

Background: X-linked Alport syndrome (X-AS) is caused by mutations in COL4A5, which prevents the proper production of type IV collagen (COLIV) of the basement membranes (BM). Immunofluorescence (IF) using anti COLIV α1-α6 antibodies (α1-α6) can detect these antigens to diagnose X-AS, where staining patterns for α5 are principally completely negative in male and mosaic in female on the glomerular BM (GBM), whereas the BM of Bowman capsule (BBM) is positive. Electron microscopy (EM) confirms the diagnosis. However, we encounter the cases with atypical pattern of α5 in adult patients (pts) and prompt us to compare the patterns of α5 with other subtypes of α.

Methods: We analyzed 9 pts of X-AS who were diagnosed by clinical findings, IF, and EM. The localization of IF was expressed by GBM pattern (G) and BBM pattern (B). Staining pattern included complete negative as (-), mosaic as (±), and positive as (+).

Results: α1-α4 were normal in 9 pts. α5–α6 showed normal on G and B in 4 pts (3F,1M), who were diagnosed only by EM showing basket-weave appearance. In 2 pts(1F,1M), α5 showed completely negative on BGM and mosaic on GBM, whereas α6 showed negative on BGM. The remaining 3 female pts showed typical mosaic pattern on G and B by α5 stain.

Conclusions: Some adult pts with X-AS appeared to be normal in IF and could not be diagnosed only by IF. In the other pts, phenotypic expression of α5 was atypical together with complete loss of α6 stain suggesting involvement of genotypic abnormality of α6.

TH-PO411

Clinicopathological Comparison Between Nodular and Diffuse Lesion in Diabetic Glomerulopathy Kensuke Joh,[1] Katsuya Ishiyama.[2] *[1]Dept of Pathology, Tohoku Univ Graduate School of Medicine, Sendai-City, Miyagi-ken, Japan; [2]Kidney Center, JCHO Sendai Hospital, Sendai-City, Miyagi-ken, Japan.*

Background: Histological subtype of diabetic glomerulopathy (DG) consists of nodular type and diffuse type. The purpose of this study is to elucidate the clinicopathological difference between these 2 subtypes in Type II diabetics undergoing renal biopsy.

Methods: Among 1077 patients (pts), 217 pts were diagnosed as diabetes mellitus (DM) and were treated more than one year. 75 pts were combined with other glomerulonephritis and were excluded. The remaining 142 pts were divided into 3 groups histologically; these were group with minor lesion in 58 pts (A), group with diffuse lesion in 55 pts (B), and group with nodular lesion in 29 pts (C). Correlation between these subgroups and clinicopathological findings was evaluated statistically.

Results: The clinical profiles were as follows: mean age; 64.2±11.4 yrs old, male in 77%, mean known duration of DM until biopsy (13.2±9.6 yrs), retinopathy in 44%, mean arterial pressure (MAP); 99±13 mmHg, HbA1c; 6.4±1.2 mg/dl, eGFR; 47±21 ml/min/1.73 m^2, amount of proteinuria 0.84 (0.2-2.4) g/d, hematuria (≥5 /hpf) in 26%. There was no difference among A, B, and C in age, eGFR, and MAP. Clinically, C showed shorter known duration of DM (A: 10.7±9.0 yrs, B: 16.7±9.9 yrs, C: 11.3±8.5 yrs, $p<0.05$), lower HbA1c (A: 6.3±0.8 %, B: 6.8±1.4%, C: 6.1±1.2%, $p<0.05$), higher amount of proteinuria (A: 0.2 (0.1, 0.6) g/d, B: 1.3 (0.5, 2.9) g/d, C: 2.7 (1.5, 4.5) g/d, $p<0.01$), and higher frequency of retinopathy (A: 14.6%, B: 51.9%, C: 75.9%, $p<0.05$) in comparison with those of B. In pathology, C showed higher frequency of mesangiolysis (MES) than that of B (A: 0%, B: 16.4%, C: 75.9%, $p<0.001$). There was no difference in extent of interstitial fibrosis and global sclerosis between B and C. In logistic regression, retinopathy (4.8 (1.8-13.0) for C, $p<0.001$ and 5.3 (2.0-14.6) for MES, $P<0.001$) and HbA1c (0.5 (0.3-0.9) for C and MES, $p<0.05$) were selected as independent predictors for C and MES among clinical parameters.

Conclusions: Nodular lesion (C) was not a subsequent lesion of diffuse lesion (B) and was produced together with MES, which was not mainly involved in the formation of B.

TH-PO412

The Significance of Tubuloreticular Inclusions (TRIs) in Allograft Kidney Biopsies Carla L. Ellis,[1] Alton Brad Farris,[1] Gaurav Gupta,[2] Lorraine C. Racusen,[3] Lois J. Arend.[3] *[1]Pathology and Laboratory Medicine, Emory Univ Hospital and School of Medicine, Atlanta, GA; [2]Nephrology, Medical College of Virginia, Richmond, VA; [3]Pathology and Laboratory Medicine, The Johns Hopkins Hospital and School of Medicine, Baltimore, MD.*

Background: Tubuloreticular inclusions (TRIs) are found in renal endothelial cells ultrastructurally. Although they can be seen in native biopsies (lupus nephritis, HIV, interferon therapy) their significance in allograft biopsies has not been fully characterized.

Methods: Renal allograft biopsies with TRIs present (from two medical centers) were selected (n=53) between the period of Mar '08 – May' 14. A control group in which TRIs were not described was identified (n=48). A descriptive analysis of patient and biopsy characteristics for the TRI group was compared with the control group for prevalence of viral infections and other clincopathologic characteristics.

Results: A sizeable proportion (11/28; 40%) of biopsies was obtained from 'high-risk' transplant recipients (ABO incompatible and/or positive-crossmatch) at one institution. 21/53 (40%) biopsies had some form of allograft rejection (cellular and/or antibody mediated rejection). Focal segmental glomerulosclerosis was the predominant cause of end-stage kidney disease (when known, n=41) in the TRI group (8/41; 20%). Only 3 patients in the TRI group had 'classic' pre-transplant associations with TRIs (two with HIV and one with lupus). In comparison with the control group (1/48; 2%), the TRI group had a significantly higher prevalence of hepatitis C infection (10/53; 19%; p=0.007), BK viremia/nephropathy (7/53; 13%) and EBV or CMV viremia (3/26; 12%).

Conclusions: Preliminary findings indicate that the presence of TRIs in renal allograft biopsies is not explained adequately by traditionally reported associations (HIV, lupus or interferon therapy). An associated viral infection (particularly hepatitis C) should be sought in renal allograft biopsies with demonstrable TRIs. Further analyses are needed to find other putative etiologies for the presence of TRIs, including the observed intriguing preponderance in 'high-risk' renal allografts.

TH-PO413

Urinary Sediment Podcalyxin (u-sed-PCX) Indicates Estimated Urinary Podocyte Number (eUPN) in Diabetic Nephropathy Masanori Hara,[1] Yohei Ikezumi.[2] *[1]Dept of Pediatrics, Yoshida Hospital, Tsubame, Niigata, Japan; [2]Dept of Pediatrics, Niigata Univ Hospital, Niigata, Japan.*

Background: Our previous studies by immunofluorescence (IF) revealed that urinary podocyte(pod) number in diabetic nephropathy is low as 0.1-1.0 cells/ml, which does not well explain for the cause for podocytopenia in diabetic nephropathy. In this study we would like to propose the term "estimated urinary podo number (eUPN)" as a better indicator for the detached podo into urine in diabetic nephropathy.

Methods: Urine samples from patients type 2 diabetes (n=71) and healthy controls (n=69) were used for IF study and urinary podocalyxin (PCX) quantification by ELISA. Urine samples were centrifuged at 12000g (to obtain whole cells, fragmented cells and plasma membranes) and the precipitate was air-dried on the slide glass, and stained by IF using the monoclonal antibody to PCX. The amount of PCX in the precipitate (u-sed-PCX) was quantified by ELISA as described previously (diabetologia, 55:2913, 2012).

Results: IF study revealed that the precipitates contained PCX positive cells (whole cells) and other PCX positive structures such as cell-fragment like and also fine granular structures in diabetic patients and the amount of non-whole cell structures is much higher than the whole cells, indicating that u-sed-PCX is originates mostly from these structures rather than whole cells. The level of u-sed-PCX in diabetic patients was significantly correlated with the amount of PCX positive structures including whole podo ($p<0.05$). The amount of u-sed-PCX was elevated in micro- and macroalbumunuric patients ($p<0.05$, respectively). The amount of PCX belonging to one podo was calculated by u-sed-PCX and the lost podo number during the course of diabetic nephropathy (Diabetes 51;3083-3089, 2002), showing 145.6 pg each. Level of u-sed-PCX (u-podo by IF) in micro- and macroalbuminuric patients was 3.7±1.0 (0.2±0.1) and 8.8±3.2 (0.4±0.2) ng/mg creatinine (cells/mg creatinine), which are equivalent to 41.7 and 60.3 cells/mg creatinine as eUPN, suggesting that eUPN is 150-200 times more than u-podo by IF.

Conclusions: U-sed-PCX might indicate eUPN and be a better indicator for detached podo in diabetic nephropathy.

Development of Abnormal Urinalysis in Mixed Connective Tissue Disease Predicts Development of Other Connective Tissue Disease Takeshi Zoshima, Ichiro Mizushima, Kazunori Yamada, Mitsuhiro Kawano. *Div of Rheumatology, Kanazawa Univ Hospital, Kanazawa, Japan.*

Background: Renal involvement occurs in 10-50% of mixed connective tissue disease (MCTD) patients (pts), most commonly membranous nephropathy (MN). It is usually mild, and corticosteroid therapy is effective. MCTD pts sometimes develop other connective tissue diseases (CTDs) such as systemic lupus erythematosus (SLE), and show severe nephropathy. Few reports have evaluated the significance of new development of abnormal urinalysis (AU) in MCTD.

Methods: We enrolled 41 Japanese MCTD pts [34 women, 7 men; mean age 53.9 years (yrs); observation period 11.7 yrs (1-34 years)] at 5 hospitals from 2000 to 2013. All pts met the Kasukawa criteria, and were observed for >1 yr after diagnosis. We defined AU as persistent proteinuria (≥1+) and/or hematuria (≥1+) by dipstick.We analyzed retrospectively the relationships between AU and clinical findings.

Results: AU developed newly in 16 pts (39%).There were no significant differences between normal urinalysis (NU) and AU group in the prevalence of anti-dsDNA antibodies (Abs) or anti-Sm Abs at diagnosis, or hypertension, diabetes mellitus, hyperlipidemia, obesity, or hyperuricemia before AU. Renal biopsy was performed in 12 AU pts, and revealed 5 cases of lupus nephritis (LN) (3 class IV, 1 IV+V, 1 V), 3 MN, and one each of necrotizing crescentic glomerulonephritis (GN), tubulointerstitial nephritis, and mesangial proliferative GN. Eight AU pts (50%) developed other CTDs [5 SLE, and 3 rheumatoid arthritis (RA)], as did 4 NU pts (16%) (2 SLE, and 2 RA) ($p=0.03$). Eight AU pts developing other CTDs were younger at diagnosis ($p<0.01$) than the other 8 AU pts. Five of these 8 pts developed SLE simultaneously with AU, while the remaining 3 did RA >1 yr later. Two of 8 AU pts not developing other CTDs manifested ANCA associated vasculitis (AAV) simultaneously with AU.

Conclusions: New AU in the course of MCTD predicts the appearance of other CTDs, especially LN or AAV. It is important to follow urinalysis frequently in MCTD, and consider the simultaneous development of other CTDs when AU is newly noted, particularly in pts diagnosed with MCTD when young.

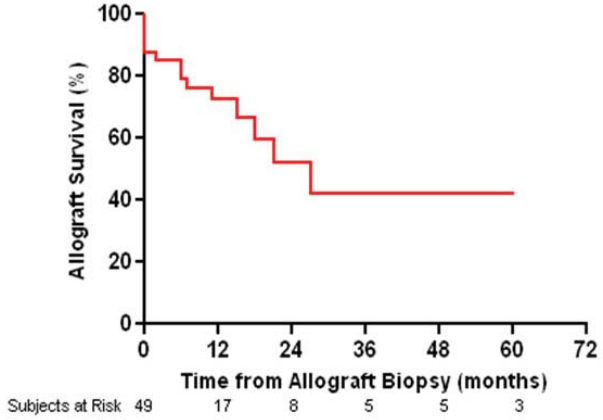
TH-PO415

Diabetic Nephropathy in Kidney Transplant Biopsies Is an Important Contributor to Allograft Failure Steven Salvatore, Sean R. Campbell, Mohamad M. Alkadi, Thangamani Muthukumar, Surya V. Seshan. *Weill Cornell Medical College.*

Background: Diabetic nephropathy (DN) is the most common cause of ESRD in the U.S. and therefore many transplant recipients have or develop diabetes. Our aim is to characterize DN in allograft biopsies and to study its role in long-term graft dysfunction.

Methods: From 2008-2014, 49 patients with kidney transplant biopsy proven DN were studied. Clinicopathologic parameters including biopsy results and outcome data were analyzed.

Results: The 49 patients ranged from 30-81 yrs (mean 57) with a male:female ratio of 32:17. The original cause of ESRD was DN (27 pts), hypertension (2), ADPKD (5), glomerulonephritis (4), FSGS (2), post-nephrectomies (1), or unknown (8). Prior to transplantation, 34 patients had known diabetes, 15 did not. Transplant biopsies were performed for elevated creatinine in 69% of patients and proteinuria 27%. The time to biopsy was mean 5.8 yrs, range 5 d to 15 yrs with average creatinine of 2.8 mg/dL (range 0.84-12.7) and proteinuria mean 2.7 (0-8.6) g/24 hrs. The type of DN was recurrent 61%, de novo 10%, donor related 4%, and unclear 24%. The DN was class I 8%, IIa 69%, IIb 8%, III 6%, and IV 8%. 21 patients (43%) had concomitant rejection: cellular 5, antibody mediated 16. Other superimposed glomerular and tubulointerstitial diseases were found in 27 patients. 30% of the patients lost their grafts in a mean 6.3 years following transplantation (range: 1 d to 15 yrs). An allograft survival curve is shown below.



Conclusions: In diabetic patients, DN is an important contributor to allograft dysfunction which may recur in transplants more rapidly than in native kidneys, or may be present in donor kidneys. Once clinically detected, biopsy proven DN in transplant leads to graft loss in approximately 50% of cases within 2 years. Earlier detection for at risk patients may be amenable for appropriate management and help prevent progression.

TH-PO416

Birmingham Vasculitis Activity Score Does Not Consistently Discriminate Active Disease from Remission in Patients with Anti-Neutrophil Cytoplasmic Autoantibody Vasculitis Elizabeth J. Brant, JulieAnne G. McGregor, William Franklin Pendergraft, Caroline J. Poulton, Susan L. Hogan, Ronald J. Falk. *UNC Kidney Center, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: The Birmingham Vasculitis Activity Score (BVAS) has been used since 1994 to characterize degree of disease activity in patients with anti-neutrophil cytoplasmic autoantibody (ANCA) vasculitis (AAV). The objective of this study was to evaluate whether BVAS, determined at single time points, accurately defines active disease versus remission in AAV.

Methods: A retrospective review of prospectively collected clinical data was performed to distinguish persistent or recurrent AAV from chronic and/or non-AAV symptoms in patients who had been given a BVAS during prior clinic visits or hospitalizations. Patients with a BVAS greater than 0 were designated 'active.' To be classified in remission, patients had to have a BVAS of 0 and no clinical evidence of active disease. Patients who had been assigned a BVAS of 0 in the setting of non-specific or mild symptoms that were believed due to AAV but that did not meet strict BVAS criteria were designated as 'active' despite the BVAS of 0, without reference to severity.

Results: A total of 630 visits from 170 patients were included in the analysis and assigned to 1 of 3 groups: 1) BVAS >0 with active disease, 2) BVAS of 0 in remission, and 3) BVAS of 0 with active disease. All 257 visits given a BVAS > 0 were determined to have active disease. Three hundred twenty-seven of 373 visits (327/373, 87.7%) with a BVAS of 0 were classified as being in remission. However, 46 (46/373, 12.3%) visits with a BVAS of 0 were determined to have active disease.

Conclusions: The BVAS is used at discrete points in time and has strict criteria, so does not consistently discriminate active disease from remission in patients with AAV, particularly in the lower range of disease activity. This may have significant implications with regard to management decisions, as well as development and analysis of research studies of patients with AAV. The BVAS should not be the sole method of classifying disease activity in patients with AAV.

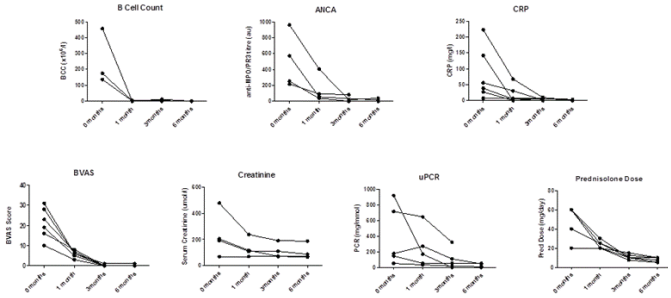
TH-PO417

Use of a Fully Humanized Anti-CD20 Monoclonal Antibody for B Cell Depletion Therapy in ANCA-Associated Vasculitis Stephen Paul McAdoo, Rachna Bedi, Megan Griffith, Ruth M. Tarzi, Charles D. Pusey, Tom Cairns. *Imperial College London and Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Rituximab (RTX), a chimeric anti-CD20 mAb that results in B cell depletion, is an effective treatment for remission-induction in AAV. Ofatumumab is a fully humanized anti-CD20 mAb that is licensed for use in haematological malignancies, although its use in AAV has not been reported.

Methods: This is an uncontrolled open-label cohort study using ofatumumab, in addition to low-dose cyclophosphamide and corticosteroids, for remission induction in new or relapsing disease in patients with AAV.

Results: To date, 8 patients with AAV have been treated, and 6 month follow-up data is available for 7 cases: 4 male, 3 female; 3 GPA, 2 MPA, 2 CSS; 3 new, 4 relapsing. Circulating B cell depletion was achieved in all patients by 1 month and sustained at 6 months. As shown below, this was associated with reduced BVAS scores, inflammatory responses and circulating ANCA. In those with renal involvement (n=6), there was improved renal function in 5 cases. One patient with MPA, who was dialysis-dependent at presentation with renal biopsy showing 50% tubular atrophy, failed to recover renal function (excluded from graph below). One patient had a minor infusion reaction to ofatumumab.



Conclusions: This is the first report of ofatumumab use in AAV. These preliminary data suggests that treatment with ofatumumab results in B cell depletion with similar kinetics to that observed in historical patients from our centre treated with a comparable RTX-based induction regimen. This was also associated with similar clinical and serological responses. Ofatumumab may be an alternative B cell depleting agent for patients with AAV who are intolerant or unresponsive to rituximab. In addition, ofatumumab may be a most cost-effective B cell depletion therapy (cost per course in th UK ≤2548 versus ≤3492 for RTX).

TH-PO418

Rituximab for Remission Induction in Elderly Patients with ANCA Associated Vasculitis Duvuru Geetha, Homa Timlin, Rebecca Manno. *Johns Hopkins.*

Background: Advancing age is a risk factor for treatment related side effects and mortality in AAV patients treated with cyclophosphamide (CYC) and glucocorticoids (GC) for remission induction. The efficacy and safety of rituximab (RTX) in elderly AAV patients has not been well described.

Methods: We performed a single center retrospective review of 31 consecutive AAV patients aged 60 or more at the time of RTX use for remission induction. All patients received RTX with GC for remission induction. 4 patients received concomitant CYC for a mean duration of 52 days. We evaluated clinical and laboratory variables at diagnosis, rates of complete remission defined as Birmingham Vasculitis Activity Score/Wegener's Granulomatosis [BVAS/WG] = 0 and patient survival, renal survival, infections requiring hospitalization and vasculitis relapse 24 months following RTX use.

Results: Of the 31 patients, 77% were Caucasian, 68% female, mean age was 71 ± 6 years, 58% were MPO ANCA positive and 42% had relapsing disease. The mean BVAS/WG score at entry was 4.4 ±1.5, 71% had glomerulonephritis (GN) and 10% had alveolar hemorrhage. The mean baseline e- GFR was 40 ±28 ml/min/1.73 m^2. Thirty patients achieved remission with a mean time to remission of 57 ± 27 days. The single patient with refractory vasculitis responded to CYC. The mean prednisone dose at 6 months was 5.6 ± 4 mg. Remission maintenance therapy was started within 12 months of RTX induction in 6 patients (4 with RTX, 1with azathioprine and 1 with mycophenolate mofetil). One patient suffered a limited relapse 10 months post RTX use. Among the 22 patients with GN at baseline, one developed ESRD. Patient survival was 100%. There were no episodes of infusion reaction or leukopenia. There were 3 episodes of bacterial pneumonia, one episode of candida pneumonia and 1 episode of disseminated cutaneous zoster.

Conclusions: This study demonstrates that rituximab is effective for remission induction in elderly patients with AAV. Furthermore, we observed a high incidence of infectious complications. Our experience was limited by its retrospective design, and further studies are needed to evaluate the efficacy and safety of RTX in elderly AAV patients.

TH-PO419

Rituximab Treatment of ANCA-Associated Vasculitis with Severe Renal Disease Duvuru Geetha, Zdenka Hruskova, Marten Segelmark, Jonathan J. Hogan, Jessica Anne Dale, Matthew David Morgan, Lorraine Harper, Vladimir Tesar, David R.W. Jayne. *Johns Hopkins.*

Background: Rituximab (RTX) is approved for remission induction in ANCA associated vasculitis (AAV). However, data on use of RTX in patients with severe renal disease is lacking.

Methods: We conducted a retrospective multi-center study to evaluate the efficacy and safety of RTX with glucocorticoids (GC) (Group A) versus RTX + GC + concomitant cyclophosphamide (CYC) (Group B) in patients presenting with e GFR less than 20 ml/min/1.73 m^2. We evaluated outcomes of remission at 6 months (6M), renal recovery after acute dialysis at diagnosis, e-GFR rise at 6M, patient and renal survival and adverse events. Remission was defined as stabilization of serum creatinine and resolution of hematuria and absence of signs of extra-renal vasculitis.

Results: Of the 28 patients, 9 patients were in Group A and 19 were in Group B. There were no differences in age (63 versus 58, p = 0.6), baseline e GFR (12 ± 5 versus14± 4, p = 0.4), use of plasmapheresis (17% versus 60%, p = 0.2), RTX dosing regimen (375 mg/m^2 x 4 or 1000 mg x2)(44% versus 63%, p = 0.4) or median follow up days between the groups (790 versus 1118, p = 0.4). No significant differences in outcomes were observed.

	Group A (n=9)	Group B (n=19)	p-value*
Remission (%) (n=25)	100	94	1.00
Median 6 month Prednisone dose (mg) (range) (n=24)	5(0 to 10)	8(0 to 10)	0.12
Median GFR rise at 6 months (range) (n=24)	4(-1 –to 34)	4(-10 to 64)	0.28
Renal recovery %(n=10)	50 (n=2)	50 (n=3)	1.00
Infections (%) (n=21)	25	29	0.61
Leukopenia (%)	13	6	0.55
ESRD (n=28)	3	7	0.86
Death in the first 6 months (n=28)	1	2	0.96

p-value by t-test, Fisher's exact or Wilcoxon rank-sum test

Conclusions: This analysis of AAV patients with severe renal disease treated with RTX and GC demonstrates that the outcomes are equivalent to treatment with RTX + CYC + GC.

TH-PO420

A Single Center Experience of Rituximab for Remission Induction in ANCA Associated Vasculitis

Duvuru Geetha, Homa Timlin, Rebecca Manno. *Johns Hopkins.*

Background: Rituximab (RTX) is approved for remission induction in ANCA associated vasculitis (AAV). This study was undertaken to describe clinical response to RTX and evaluate safety profile.

Methods: We performed a single center retrospective review of 48 consecutive AAV patients who received RTX for remission induction(2005 to 2013). All patients received RTX with glucocorticoids. Nine patients with glomerulonephritis (GN) received concomitant CYC. We evaluated clinical and laboratory variables at diagnosis, rates of complete remission defined as Birmingham Vasculitis Activity Score/Wegener's Granulomatosis [BVAS/WG] = 0 and patient survival, renal survival, infections requiring hospitalization and vasculitis relapse 24 months following RTX use.

Results: Of the 48 patients, 81% were Caucasian, 65% male, mean age at the time of RTX use was 56 ± 22 years, 50% were PR3 ANCA positive and 46% had relapsing disease. The mean BVAS/WG score at entry was 4.4 ±1.6, 69% had GN with 8% requiring dialysis at entry and 21% had alveolar hemorrhage. The mean baseline e- GFR was 49 ±34 ml/min/1.73 m^2. Forty seven patients achieved remission with a mean time to remission of 70 ± 32 days. One patient with refractory vasculitis responded to CYC. The mean prednisone dose at 6 months was 5.0 ± 4 mg. No relapses were observed in 19 patients who received remission maintenance therapy following RTX induction whereas 6 of the 29 patients who did not receive remission maintenance therapy experienced a total of 6 relapses with median days to relapse of 319. All relapsing patients were PR3 ANCA positive. Among the 33 patients with GN at baseline, 2 developed ESRD. Patient survival was 100% at 2 years. One patient experienced an infusion reaction. There were no episodes of leukopenia. There were 3 episodes of bacterial pneumonia, one episode of candida pneumonia and 1 episode of disseminated cutaneous zoster.

Conclusions: This study demonstrates that rituximab is effective for remission induction in patients with AAV. Vasculitis relapse was common in patients who did not receive maintenance therapy. We propose that maintenance immunosuppression be considered after RTX induction therapy.

TH-PO421

Survival Outcomes of Elderly Patients Diagnosed with ANCA Associated Vasculitis

Steven Whatmough, Niamh Sweeney, Ajay Prabhakar Dhaygude. *Dept of Renal Medicine, Royal Preston Hospital, Preston, Lancashire, United Kingdom.*

Background: ANCA associated vasculitis (AAV) is a multisystem disorder with peak incidence at 60 years. Data regarding outcomes of patients older than 75 years is lacking. Mortality rates of untreated generalised AAV approaches 90% at 1 year. In this study we compared outcomes of patients with AAV presenting before and after 75 years of age.

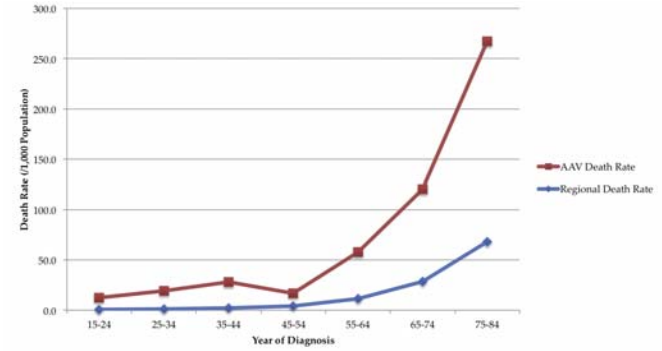
Methods: All patients with biopsy proven pauci immune glomerulonephritis (PIGN) or received cyclophosphamide (CYP) for AAV, between the years 1988 to 2010, were included in this study. Patient demographics, renal survival, patient survival and cumulative CYP dose were compared.

Results: In total 284 patients were identified. The median age at diagnosis was 58 years (range 16 to 87 years). The regional incidence was 12.5 cases per million population.

Table 1. A summary of the patient/renal survival rates and the average CYP dose.

	<75 Years (n=240)	>75 Years (n=44)	P. Value
Male:Female	137:103	25:19	0.1308
Presenting Creatinine (µmol/L)	514.90	548.62	0.6361
Mean Cumulative CYP dose (mg)	4329	2241	0.0126
Patient Survival			
Median (months)	107	45	0.0047
3 Year	72%	54%	0.0266
5 Year	63%	38%	0.0034
Renal Survival			
Median (months)	33	4	0.0738
3 Year	49%	36%	0.1002
5 Year	43%	29%	0.0770
Standardised Mortality Ratio	1106%	393%	

Figure 1. A graph comparing regional mortality rates of general population and AAV patients, by age.



Conclusions: 1. Patients who present with AAV at a younger age have improved patient survival rates.

2. There was a trend towards improved renal survival in younger patients at five years.

3. Older patients received lower CYP dose.

4. Older patients treated with CYP have improved survival compared to untreated counterparts.

Limitations - We only included biopsy proven PIGN and CYP treated patients.

TH-PO422

Improving Outcomes of ANCA Associated Vasculitis - A 22 Year Follow Up

Steven Whatmough, Niamh Sweeney, Ajay Prabhakar Dhaygude. *Dept of Renal Medicine, Royal Preston Hospital, Lancashire, United Kingdom.*

Background: ANCA associated vasculitis (AAV) is a multisystem disorder associated with end stage renal disease and mortality. Early diagnosis and advances in treatment in recent years have improved patient outcomes. A retrospective study of the outcomes of patients treated with AAV, was performed.

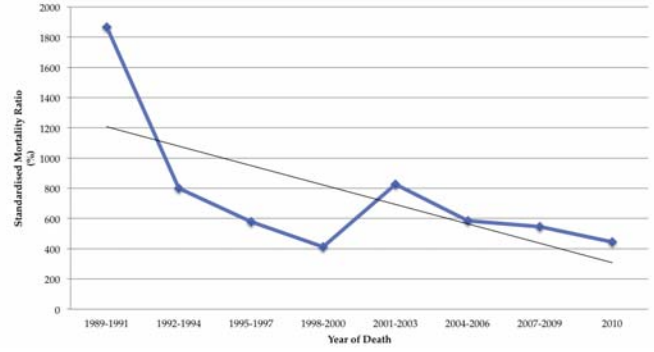
Methods: Data regarding demographics, renal and patient survival were collected for all patients diagnosed with AAV between the years 1988 and 2010. These were divided into two groups - those presenting between years 1988-1999 and 2000-2010.

Results: A total of 314 patients with AAV were identified, of which 30 were lost to follow up. The regional annual incidence was found to be 12.5 cases/million population. A summary of results is presented in Table-1.

Table 1. A table summarising the patient and renal survival rates for each era.

	1988-1999 (n=107)	2000-2010 (n=177)	P. Value
Presenting Age	57	59	0.4905
Presenting Creatinine (µmol/L)	764	427	<0.0001
Patient Survival			
Median (months)	67	125	0.0087
6 Month	79%	88%	0.0214
10 Year	35%	51%	0.0072
Median Survival + Presenting Creatinine <500µmol/L (months)	77	125	0.0536
Renal Survival			
Median (months)	9	43	0.0119
6 Month	35%	51%	0.0463
10 Year	51%	61%	0.0101
Median Survival + Presenting Creatinine <500µmol/L (months)	38.5	121	0.0404

Figure 1. A graph illustrating the standardized mortality ratio.



Conclusions: The results indicate the later cohort had;

1. Significantly lower presenting creatinine, suggesting an early diagnosis.
2. Improved short-term renal and patient survival, probably a result of protocolised treatment, early diagnosis and an improved management of the complications during the first year.
3. Improved long-term renal and patient survival, likely due to improved management of cardio-vascular morbidity.

TH-PO423

Efficacy of Oral C5aR Inhibitor CCX168 on Non-Renal Disease Activity in Patients with Antineutrophil Cytoplasmic Antibody-Associated Vasculitis

David R.W. Jayne,[1] Annette Bruchfeld,[2] Matthias Schaier,[3] Michel Y. Jadoul,[4] Marten Segelmark,[5] Daina Selga,[6] Istvan Szombati,[7] Michael Venning,[8] Christian Hugo,[9] Antonia Potarca,[10] Thomas J. Schall,[10] Pirow Bekker.[10] *[1]Univ of Cambridge, United Kingdom; [2]Karolinska Inst, Sweden; [3]Univ Hosp Heidelberg, Germany; [4]Cliniques Saint-Luc, Belgium; [5]Linkoping Univ, Sweden; [6]Lund Univ, Lund, Sweden; [7]Budaclinic, Hungary; [8]Manchester Univ, United Kingdom; [9]Dresden Univ, Germany; [10]ChemoCentryx.*

Background: A clinical trial in ANCA-associated vasculitis showed renal disease efficacy of oral 30 mg CCX168 twice daily based on eGFR, urinary ACR and MCP-1.

Methods: The purpose here was to evaluate the non-renal disease activity of CCX168 based on BVAS. 25 patients completed this blinded clinical trial; 9 received placebo+cyclophosphamide (CYC)+full dose prednisone (60 mg/day), 8 received CCX168+CYC+low dose prednisone (20 mg/day), and 8 received CCX168+CYC+no prednisone.

Results: Baseline BVAS and Week 12 results are shown in the table.

		CCX168+ CYC+ Low-Dose Steroids (N=8)	CCX168+ CYC+ No Steroids (N=8)	SOC: CYC+ High-Dose Steroids (N=9)
Baseline BVAS Score, median (range)	Total Renal Non-renal	11 (5-30) 5.5 (1-10) 3.5 (0-20)	11 (5-28) 5.5 (4-10) 6 (1-18)	9 (3-15) 5 (0-12) 4 (0-7)
BVAS Total	Response* Remission**	6 of 7 (86%) 2 of 7 (29%)	7 of 8 (88%) 2 of 8 (25%)	4 of 9 (44%) 3 of 9 (33%)
BVAS Renal	Response Remission	5 of 7 (71%) 2 of 7 (29%)	4 of 8 (50%) 2 of 8 (25%)	3 of 8 (38%) 2 of 8 (25%)
BVAS Non-Renal	Response Remission	5 of 6 (83%) 4 of 6 (67%)	7 of 8 (88%) 4 of 8 (50%)	4 of 7 (57%) 3 of 7 (43%)
BVAS Total BVAS Renal BVAS Non-Renal	Mean (SE) %Change	-71 (9)% -64 (10)% -81 (33)%	-65 (11)% -50 (15)% -83 (29)%	-26 (25)% -16 (26)% -15 (6)%
eGFR, mL/ min/1.73 m²	Mean (SE) Change	6.8 (2.1)	0.6 (3.6)	2.2 (3.3)
Urinary ACR	%Change#	-63%	-59%	-9%
Urinary MCP-1:creat	%Change#	-72%	-52%	-37%

* Remission: BVAS 0 plus prednisone dose ≤10 mg/day; ** BVAS response: BVAS decrease ≥50% plus no worsening in any body system. # Based on Week 12/Baseline ratio of geometric means.

Conclusions: Results show that CCX168 has promise in treating not only renal but also non-renal disease activity in patients with ANCA-associated vasculitis.

TH-PO424

Mycophenolate Mofetil for the Treatment of Membranous Lupus Nephritis

Jason Cobb, Jose E. Navarrete, Nnaemezie Emmanuel Odioemene. *Renal Div, Emory Univ, Atlanta, GA.*

Background: Treatment options for membranous (class V) lupus nephritis (LN) includes prednisone, cyclophosphamide (CYC), and calcineurin inhibitors (CNI). Most of the research examining the treatment of pure membranous LN occurred before mycophenolate mofetil (MMF) was readily available. Post-hoc analyses from studies for the treatment of proliferative LN have compared MMF to CYC for pure membranous LN treatment. We are reporting the clinical characteristics and response rates of our pure membranous LN patients treated with MMF in comparison to other treatment options in our single center predominantly black patient population.

Methods: Retrospective chart review of LN patients from 2005-2013 in our single center academic medical practice. We excluded membranous LN with proliferative changes. We analyzed data comparing LN class V patients treated with MMF to other therapy options.

Results: From 2005-2013: 36 patients with membranous LN without proliferative changes, black race (n=35), and 35:1 female to male ratio. For all patients (mean values): initial serum creatinine (sCr) 1.1 mg/dL ± 0.9, final sCr 1.6 mg/dL ± 1.5, initial urine protein 3.3 g/24 h ± 3.2, final urine protein 1.5 g/24 h ± 2.2, initial serum albumin 2.7 g/dL ± 0.8, and final serum albumin 3.3 g/dL ± 0.9. MMF treated (n=15) and other therapies group (n=21). Comparison of MMF treated to other therapies initial sCr 0.78 mg/dL versus 1.3 mg/dL, p=.08. Comparison of MMF treated to other therapies final sCr 1 mg/dL versus 1.88 mg/dL, p =.10. MMF treated versus other therapies initial serum albumin 2.45 g/dL and 2.42 g/dL respectively, p=.94. MMF treated versus other therapies final serum albumin 3.32 g/dL and 2.97 g/dL, p=.34. Initial urine protein levels in MMF treated 3.52 g/24 h and 3 g/24 h in other therapies patients, p=0.62. Final urine protein levels in MMF treated 1.35 g/24 h and 1.25 g/24 h in others, p =.90.

Conclusions: In our Class V LN patient population we did not observe differences in final sCr, final serum albumin, and final urine protein levels in our MMF treated in comparison to other therapies (predominantly CYC, CNI, and prednisone). More data is needed but MMF seems to be a viable treatment option for pure membranous LN.

TH-PO425

Comparison of Lupus Nephritis Evolution According to the Gender in Mexican Patients

Luis Gerardo Gonzalez-Correa, Enrique Rojas-Campos, Benjamin Gomez-Navarro, Alfonso M. Cueto-Manzano, Petra Martínez. *Unidad de Investigación Médica en Enfermedades Renales, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

Background: Systemic lupus erythematosus (SLE) is less frequent, has a worse prognosis and more serious kidney involvement in males. Nevertheless, evolution of lupus nephritis (LN) according to gender is still controversial. We compare the evolution of LN according to gender.

Methods: Retrospective cohort. Medical records of SLE patients with LN diagnosis (biopsy proven) between January 2005 and December 2012 were reviewed; clinical, kidney function (GFR estimated by MDRD simplified formula) and sociodemographical information were obtained during the follow–up. Histopathological findings of the kidney biopsy, LN class and patient status (live/deceased) were also recorded.

Results: 144 patients included, mean follow–up 41±14 months, 83% females, mean age 32±11 years. At follow–up, males had a tendency to higher increase in serum creatinine (Figure 1). Predictors of eGFR decline were: Education level (RR -7.21; IC95% [-12.4 to -2.0], *p* 0.007*)*, Baseline urea level (RR -0.45, IC95% [-0.76 to -0.14], *p* 0.004*)*, Baseline serum creatinine (RR -13.27, IC95% [-20.0 to -6.6], *p*<0.0001*)* and Age (RR -0.38, IC95% [-0.8 to 0.6], *p* 0.09).

Figure 1. Evolution of serum creatinine according to gender in LN patients

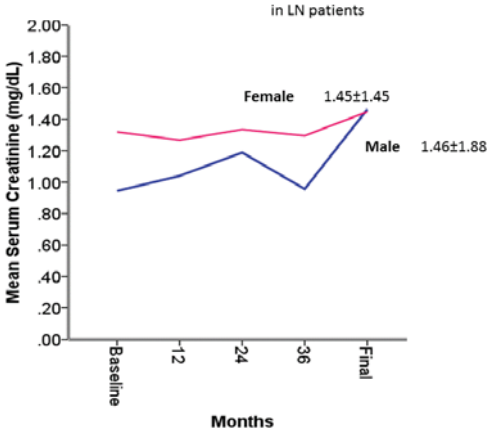

Table 1.Comparison of variables

Variable	Male, n = 25/17%		Female, n= 119/83%	
	Baseline	Final	Baseline	Final
Hypertension, N/%	8/32		42/35	
LN Classification, N/%				
Class II	3/12		20/17	
Class III	8/32		53/45	
Class IV	10/40		29/24	
Class V	4/16		17/14	
Proteinuria (mg/24h)	1500 (626-2400)	652 (124-1375)*	1800 (549-3500)†	360 (210-1200)*

†p‹0.05 vs the same evaluation in male *p‹0.05 vs baseline of the same group.

Conclusions: Males with LN had a tendency to higher increase in serum creatinine compared with females, which might be related to the greater proportion of LN Class IV in males (40% VS females 24%).

TH-PO426

Efficacy and Safety of Sirukumab in Patients with Active Lupus Nephritis: Results From a Phase 2,Multicenter, Randomized, Double-Blind, Placebo-Controlled, Proof-of-Concept Study Brad H. Rovin,[1] Ronald Van Vollenhoven,[3] Cynthia Aranow,[4] Carrie Wagner,[2] Robert Gordon,[2] Benjamin Hsu,[2] Bei Zhou.[2] *[1]Nephrology, Ohio State Univ, Columbus, OH; [2]Janssen Research and Development; [3]Karolinska Inst, Sweden; [4]Feinstein Inst.*

Background: To examine the efficacy and safety of sirukumab, an anti-interleukin-6 monoclonal antibody, in patients (pts) with active class III or IV lupus nephritis (LN).

Methods: Inclusion criteria were class III or IV LN on biopsy within 14 mo of randomization, persistent proteinuria (≥0.5 g/d) despite immunosuppression (MMF or AZA ± corticosteroids), and stable RAAS blockade. Pts were randomized to IV sirukumab 10 mg/kg (n=21) or placebo (Pbo,n=4) q4wks through wk24. The primary endpoint was the percent reduction in proteinuria from baseline. Major secondary endpoints included the proportion of pts with: 1) ≥50% reduction in proteinuria; 2) a meaningful reduction in proteinuria (P/C ratio <0.5 or if nephrotic P/C ratio <3 and ≥50% reduction in P/C ratio; 3) no worsening of glomerular filtration rate (GFR); 4) percent change from baseline in Patient's and Physician's Global Assessments of Disease Activity.

Results: Primary and secondary results are shown in Table 1. There was no consistent reduction in proteinuria in the sirukumab group. Among the 12 sirukumab-treated pts positive for anti-dsDNA at baseline, there was a mean 62.3% reduction in anti-dsDNA at wk 24. Sirukumab was discontinued in 6 patients, 5 because of an AE. Half of the sirukumab group had at least one serious AE, mostly infectious. No deaths occurred and no serious AE occurred in Pbo.

Primary and Secondary Efficacy Endpoints at Week 24	Pbo	Sirukumab
Intent-to-treat patients	4	20
Median % Change in proteinuria from baseline (95% CI)	43.4	0 (-61.8,39.6)
% patients with ≥50% decrese in proteinuria	0	20%
% patients with meaningful reduction in proteinuria	0	15%
% patients with no decline in GFR	75%	55.6%

Conclusions: Sirukumab treatment in patients with active, refractory LN did not result in a percent improvement in proteinuria, but 15-20% of treated pts did show an overall reduction. A high frequency of SAEs was observed in this immunosuppressed population.

TH-PO427

Low Dose IV Cyclophosphamide (IVC) Induction Is Efficacious in Blacks with Lupus Nephritis (LN) Simon K. Winn, Andrea Cove-Smith, Catherine Susanna Vinen. *Renal Unit, Kings College Hospital, London, United Kingdom.*

Background: Based on post-hoc analysis of ALMS[1], it is suggested that MMF may be superior to IVC as induction therapy for LN in black patients[2]. Further subanalysis reveals that MMF was superior to IVC only in Hispanics, not in blacks. Moreover, ALMS compared MMF treatment with a high-dose modified NIH IVC regimen (monthly pulses of 0.5–1.0 g/m2). We report our use of the low-dose Eurolupus strategy (6 fortnightly pulses of 0.5g) to treat black LN patients in an urban centre.

Methods: Retrospective data were obtained for all African, Afro-Caribbean or black patients with biopsy-proven LN treated with IVC from our database. Treatment failure at 6mos was defined as per Eurolupus (serum creatinine (sCr) not <1.3mg/dL if baseline (B/L) 1.3-2.6mg/dL, sCr not <50% if B/L >2.6mg/dL, or no resolution of nephrotic syndrome).

Results: 20 patients given IVC for class III(2), IV(14) or V(4) LN were identified. Average age at biopsy was 30.6yrs (range 17-45); B/L sCr 1.95+/-1.2mg/dL. Other characteristics are tabulated. Average dose of IVC was 2.6g. 15 patients (75%) achieved treatment response at 6mos. Overall, sCr fell by 51% and sAlb increased by 34%. Infective complications were seen in 4 patients.

	Baseline +/- SD (Range)	Remission 6mos +/- SD (Range)	No Remission 6mos +/- SD (Range)
sCr mg/dL	1.95 +/-1.2(0.65-5.5)	0.95+/-0.3(0.7-1.5)	4.13+/-3.6(1.8-10.3)
sAlb g/dL	2.68 +/-0.8(1.2-4.2)	3.58+/-6.8(2.4-4.4)	3.40+/-0.46(2.6-3.7)
C3	0.61 +/-0.32 (0.22-1.46)	0.98+/-0.31 (0.47-1.45)	1.2+/-0.18(0.81-1.13)
dsDNA	144.2 +/-109(4.3-291)	84.23+/-98.8 (6-289)	22.0+/-8.5(16-28)
uPCR mg/mmol	424.1 +/-371(33-1230)	191+/-128(17-409)	415.3+/-191.5 (158-587)
Prednisolone dose mg	34+/-12(20-60)	12+/-7(3.75-20)	17+/-12(7.5-30)

Conclusions: Treatment response rate is comparable to studies in largely white cohorts such as the Eurolupus trial, in which 71% of low-dose IVC group achieved renal remission. Furthermore, disease severity in our cohort appears higher than in Eurolupus and ALMS trials (B/L sCr 1.1 and 1.14mg/dL, respectively). These data support the efficacy of low-dose IVC for induction therapy of class III, IV and V LN in a UK black population. 1 Rheumatology (Oxford). Jan 2010; 49(1):128–140. 2 ACR guidelines 2012.

TH-PO428

A Long-Term Follow-Up Study of Multi-Target Therapy Using a Combination of Tacrolimus and Mycophenolate Mofetil in Patients with Active Lupus Nephritis Hidekazu Ikeuchi, Keiju Hiromura, Ken Kayakabe, Kazuhiko Uchiyama, Hiroko Hamatani, Noriyuki Sakurai, Toru Sakairi, Yoriaki Kaneko, Akito Maeshima, Yoshihisa Nojima. *Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: We previously reported that multi-target therapy using tacrolimus (TAC) and mycophenolate mofetil (MMF) was effective in inducing early remission and in yielding a high remission rate in patients with active class III, IV, V lupus nephritis (LN) (Mod Rheumatol, 2013). Here, we conducted a follow-up study to evaluate the long-term effect and safety of multi-target therapy.

Methods: All 16 patients in the previous study (2 men and 14 women, 34.3±8.3 years old, 9 new-onset and 7 flared) were followed-up for a median of 36 months (range, 27-53) after the initiation of multi-target therapy. Urinary protein/Cr ratio was 4.6±2.8 g/gCr and serum Cr was 0.73±0.29 mg/dl at the initiation of multi-target therapy. Eight patients had mixed membranous and proliferative LN.

Results: All patients achieved a complete remission (CR) at a median of 3.6 months (range, 0.3-14.3). CR rates at 6 and 12 months were 81% and 94%, respectively. After achieving CR, MMF was switched to azathioprine (AZA) in 13 patients and to mizoribine in 2 patients. MMF was stopped in 1 patient because of cytomegalovirus (CMV)-associated gastric ulcer and TAC+AZA was stopped in 1 patient due to abdominal cellulitis. Fourteen patients (88%) remained well without a renal flare. The mean dose of prednisolone was 4.1±2.5 mg/day at the final observation in these patients. Two patients (12%) had a renal flare. Both the patients had experienced renal flares more than 2 times before multi-target therapy. Infection was the most frequent adverse event. CMV viremia was detected in 6 patients (37.5%), which develpoed during the first 6 months. Two out of 6 patients was diagnosed with CMV infection (gastric ulcer in 1 patient and pancytopenia in 1 patient). Varicella zoster was observed in 3 patients (18.8%).

Conclusions: Although some patients experienced a renal flare or severe infection, most patients had a favorable clinical course during 2- to 4-year follow-up after the initiation of multi-target therapy.

TH-PO429

Efficacy of Rituximab in Adult Frequently Relapsing Minimal Change Disease (MCD) Catherine King, Stuart W. Smith, Peter Hewins. *Nephrology, Univ Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

Background: Corticosteroids are the basis of treatment for nephrotic syndrome due to minimal change disease (MCD) but 25% of patients have frequent relapses (FRNS) and 30% become steroid dependent. Prolonged use of steroids and conventional additional immunosuppressants causes significant toxicity. Rituximab (RTX) is now included in KDIGO guidelines for childhood MCD. Evidence for RTX usage in adult MCD is limited. This report describes a single-centre experience of RTX use for adult MCD.

Methods: Outcomes of all adult MCD patients treated with RTX for FRNS 2008-2012 were analyzed retrospectively using patient records. Treatment comprised 2x1g infusions.

Results: 7 MCD patients (5 male) received RTX. All patients had FRNS and 4 were steroid dependent. All had previously taken ≥2 immunosuppressants in addition to steroids. 6 patients had experienced ≥1 major treatment side effect: diabetes (n=1), hypertension (n=3), infection requiring hospitalisation (n=2), osteoporosis (n=1), weight gain (n=4) and biopsy-proven calcineurin inhibitor induced renal damage (n=3). At time of RTX treatment, 4 patients were relapsing. All entered remission post RTX. Median length of follow up was 13 months (range 4-61). After RTX, rate of relapse was reduced (Wilcoxon-signed-rank, p≤0.05). Number of additional immunosuppressants, steroid dependency and anti-hypertensive agents usage also reduced.

	Pre Rituximab	Post Rituximab
Median relapses/year	4	1
Median no. Immunosuppressants (range)	2 (1-4)	0 (0-2)
No. Patients on continued steroids	4	1
No. Patients on antihypertensive therapy	4	2

Four of 7 patients relapsed post RTX after a median of 7 months (range 1-10). All 4 relapsing patients were successfully re-treated with RTX and none developed RTX resistant nephrosis. Median number of courses of RTX per patient was 1 (range 1-4). No RTX related adverse events were observed.

Conclusions: Rituximab was effective and safe in adults with FRNS due to MCD. Median rate of relapse was significantly reduced following RTX. All but one patient remained off all other immunosuppressive medications at follow up. These data support the case for further assessment of the efficacy and safety of Rituximab in adult MCD.

TH-PO430

Long-Term Prognosis of Patients in Adults with Steroid-Dependent Minimal Change Nephrotic Syndrome Treated with a Biannual, Single-Dose Rituximab Regimen Takashi Takei, Yuko Iwabuchi, Kosaku Nitta. *Deaprtment of Medicine, Kidney Center, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan.*

Background: In recent years, several clinical trials have shown the efficacy of rituximab in patients with steroid-dependent minimal-change nephrotic syndrome (MCNS). We previously reported the efficacy and safety of a single dose of rituximab administered twice at an interval of 6 months for patients with steroid-dependent MCNS in adults (Nephrol Dial Transplant 28: 1225, 2013). The objective of this study was to evaluate prognosis after four single-dose rituximab infusions during 24-months.

Methods: We conducted a prospective cohort study with a historical control to evaluate the effect of single-dose infusions of rituximab at 375 mg/m^2 BSA per dose at intervals of 6 months during 24-months followed by continuous rituximab treatment as a maintenance therapy. Seventeen patients were continuously treated with rituximab infusion (RTX group). On the other hand, seven patients discontinued RTX administration after four single-dose infusions of rituximab (non-RTX group).

Results: In RTX group, three of seventeen patients stopped rituximab treatment after fifth infusion and two of seventeen patients stopped after sixth infusion. Complete remission was maintained in all the seventeen patients for a 12-month period after four single-dose rituximab infusion. In non-RTX group, two of seven patients developed relapse after four rituximab infusion and rituximab retreatment started.

Conclusions: : In our trial, rituximab therapy was associated with maintenance of complete remission. Ten patients with B-cell repletion who stopped rituximab therapy also were able to maintain complete remission. The rituximab treatment is rational and should be considered as an important treatment alternative in patients with steroid-dependent MCNS.

TH-PO431

Efficacy of Combined Very Low-Dose Prednisolone and Cyclosporine as an Initial Treatment for Minimal Change Nephrotic Syndrome (MCNS) Yoshihiko Inoue, Eri Kawashima, Yoshikuni Nagayama, Kiyoko Inui, Hironori Tayama, Ashio Yoshimura. *Div of Nephrology, Showa Univ Fujigaoka Hospital, Yokohama, Kanagawa, Japan.*

Background: The mainstay of MCNS therapy is glucocorticoid (prednisolone, PSL) achieving complete remission, however frequent relapses may occur and subsequent necessity of increasing amount of PSL dosage is a critical problem. We evaluated combination of very low-dose of PSL to 50% of conventional therapy with cyclosporine (CsA) as an initial treatment for MCNS in adults.

Methods: Twenty patients who had all biopsy-proven MCNS were studied prospectively for three years. They were randomly assigned to two groups, Group A (PSL 0.8mg/kg/day, n=10) and Group B (PSL 0.4mg/kg/day + CsA 1.5-2mg/kg/day, n=10). eGFR, serum albumin levels (sA), amount of proteinuria (UP), Initial PSL dosage, total PSL dosage, duration for complete remission (CR), average length of hospital stay (HS), side effects by PSL treatment and the number of relapse (NR) were compared between two groups. The daily CsA dosage was sustained by using concentration monitoring with 2-h post-dosing level (C2) (600-1000ng/ml).

Results: There were no differences in eGFR, sA or UP between both groups before treatment. Initial PSL dosage was 49.0±7.0mg/day (mean±SD) in Group A and 24.5±4.4 in Group B ($p<0.01$). Total PSL dosage for three years in Group A (7580.5±719.1mg) was also more than in Group B (4624.0±669.4)($p<0.01$). However, there were no differences in duration for CR between Group A (16.2±6.3days) and Group B (14.7±3.0). Average length of HS was significantly longer in Group A (50.9±16.2days) than in Group B (19.3±3.6) ($p<0.01$). NR was 3 patients in Group A and 2 in Group B. Side effects by PSL treatment was observed in two patients in Group A (steroid induced DM and hypercholesterolemia) but none in Group B. C2 level of CsA was 736.6±167.5ng/ml.

Conclusions: The combination of very low-dose prednisolone with CsA as an initial treatment was effective as well as the conventional therapy with PSL alone. It also didn't increase relapse rate of nephrotic syndrome. Therefore this treatment may provide a new way to decrease PSL dosage, shortening of hospital stay and reduction of side effects by PSL for adult MCNS patients.

TH-PO432

Low-Dose Cyclosporine in Treatment of Nephrotic Syndrome: Effectiveness and Renal Safety Xiao-Juan Yu, Lin Ruan, Xiao-Jing Liu, Gang Liu, Li Yang. *Renal Div, Peking Univ First Hospital.*

Background: To observe the effectiveness and renal safety of low-dose cyclosporine (CsA) in treating patients with membranous nephropathy (MN) and focal segmental glomerulosclerosis (FSGS).

Methods: Seventy-nine patients with primary nephrotic syndrome and normal renal function (baseline Scr<133umol/L), pathologically identified as MN in 72 and FSGS in 7, were enrolled in this prospective cohort study. Prednisone of 0.2-0.5mg/kg/d and CsA of 1.5-2.5mg/kg/d were prescribed on top of RAS inhibition. A decrease in eGFR of >30% or increase in Scr of >30% within the first 3 months of CsA commencement was defined as CsA associated acute renal injury (CsA-ARI). A decrease in eGFR of >30% and a development of eGFR<60ml/min/1.73m2 after 3 months was defined as CsA associated chronic renal injury (CsA-CRI). The median follow-up time was 18 (3-54) months.

Results: Thirty-one patients (39.2%) achieved complete remission at 11 (2-44) months and 25 patients (31.6%) got partial remission at 10 (3-49) months. Fourteen patients (20.3%) developed CsA-ARI during the first 3 months (2.5±0.8 months) and 22 patients (27.8%) developed CsA-CRI at 11.2±6.5 months. The remission rates of patients having ARI, CRI, or no renal injury were 42.9%, 50.0% and 85.1% respectively (P=0.001). By the end of follow up, the decrease of eGFR from baseline was 42.29±16.74, 28.20±18.05 and 15.15±21.93 (P<0.001)ml/min/1.73m2. Of all the factors that were analyzed, urinary protein levels at the time of CsA-ARI development was identified as independent risk factors for CsA-ARI (RR=1.147,95%CI 1.050-1.254,P=0.002); whereas baseline eGFR (RR=0.978,95%CI 0.961-0.996,P=0.015) and a history of CsA-ARI (RR=6.156,95%CI 2.022-18.742,P= 0.001) were identified as independent risk factors for the development of CsA-CRI. Neither the dosage nor the overtime plasma concentration of cyclosporine was found to be associated with the occurrence of acute/chronic renal injury in our patients.

Conclusions: Low dose CsA was effective in treating nephrotic patients of MN and FSGS, with a total remission rate of 70.8%. Whereas CsA associated renal injury was still common at low dosage and needs more attention by nephrologists.

TH-PO433

Prospective Study of Tacrolimus in Adult Onset Steroid Dependent Cyclophosphamide Unresponsive MCD Raja Ramachandran, Harbir Singh Kohli, Ritambhra Nada, Vivekanand Jha, Krishan L. Gupta. *PGIMER, Chandigarh, India.*

Background: KDIGO guidelines recommend cyclophosphamide (CYC) as first line agent in the management of adult onset steroid dependent (SD) minimal change disease (MCD) and limits use of calcineurin inhibitors to patients relapsing after CYC. However, the above recommendation is not based on strong evidence. The present study was undertaken to see the efficacy and safety of Tacrolimus (TAC) in adult patients with SD MCD unresponsive to CYC.

Methods: Adult onset nephrotic syndrome with SD (≥ 2 relapse during taper or within 2 weeks of stopping steroids) CYC unresponsive (relapse occurring within 6 months of a 3-month course of CYC) MCD were enrolled in the study. TAC was started to achieve a target trough level of 5–10 ng/mL and oral prednisolone was tapered by 0.1 mg/kg/week to stop and TAC was continued for 48 weeks from then onwards. Outcome viz complete remission (CR) (reduction of proteinuria to <0.5 g/d and sr albumin ≥3.5gm/dl), partial remission (PR) (reduction of proteinuria to 0.5–3.5 g/d and sr albumin ≥3.5gm/dl) were assessed at the end of 48 weeks. Relapses defined as increased proteinuria after complete or partial remissions were recorded. Adverse events were recorded.

Results: A total of 11 patients completed the study. Ten (91%) patients achieved CR and 01 (9%) patient was unable to maintain remission without steroids. Two patients had relapse of nephrotic syndrome after achieving remission with TAC and responded to short course of oral prednisolone. Reversible nephrotoxicity was seen in 2 (18%), TAC related diarrhea in 3 (27%), infections in 2 (18%), DM in 2 (18%), tremors in 2 (18%) and gum hypertrophy in 1 (9%). There was significant reduction in eGFR at the end of 48 weeks (p=0.04). Seven (64%) patients had a follow-up of >96 weeks, of which 4 (57%) patients relapsed on stopping TAC and were restarted on TAC. At the end of 96 weeks all 4 patients underwent kidney biopsy and 3 (75%) patients had evidence of chronic TAC toxicity.

Conclusions: TAC is an effective steroid-sparing agent in the management of SD CYC unresponsive adults with MCD. However, strict renal function and blood sugar monitoring is required due to its nephrotoxicity and diabetogenic potential.

TH-PO434

Rituximab-Induced B Cell Depletion for Treatment of Refractory Minimal Change Glomerulopathy Landon C. Brown,[1,2] Meghan E. Free,[2] Emily H. Chang,[2] Louis-Philippe Laurin,[3] Ronald J. Falk,[2] Patrick H. Nachman,[2] William Franklin Pendergraft.[2] *[1]Univ of North Carolina (UNC) School of Medicine, Chapel Hill, NC; [2]UNC Kidney Center, Chapel Hill, NC; [3]Dept of Medicine, Univ de Montréal, Montréal, QC, Canada.*

Background: Minimal change glomerulopathy is responsible for 10-25% of nephrotic syndrome cases in adults. The majority of these patients are treated successfully with corticosteroids; however, a subset of patients requires additional immunosuppression. Recent case series suggested that rituximab-induced B cell depletion may be beneficial for inducing remission in patients with minimal change glomerulopathy.

Methods: We performed a retrospective analysis of clinical data from patients at our institution with biopsy-proven minimal change glomerulopathy on initial biopsy who were corticosteroid dependent or resistant and were subsequently treated with rituximab.

Results: Ten adult patients (mean age 49.6 years (S.D. 20.4), 20% female) received rituximab for corticosteroid dependent (n=5) or resistant (n=5) disease. Eight patients received 2 doses of 1 gram IV rituximab spaced two weeks apart, and two patients received 375 mg/m^2 IV weekly for 3 and 4 weeks. Median duration of follow-up after B cell depletion was 17.9 months. Mean urine protein to creatinine ratio was 7.5 (S.D. 4.2) just prior to rituximab therapy and decreased to 0.9 (S.D. 1.7) at date of last test. Mean serum albumin increased from 2.6 g/dL (S.D. 0.8 g/dL) to 4.0 g/dL (S.D. 0.7 g/dL). Seven of the 10 patients achieved sustained remission off other forms of immunosuppression. Median time to remission was 3 months. One patient achieved remission, subsequently relapsed after 23 months, and was successfully re-treated with additional rituximab. This same patient then relapsed 13 months later and was again successfully re-treated. Two patients did not achieve remission; one of whom had not attained peripheral B cell depletion.

Conclusions: These findings suggest that rituximab may have a therapeutic role in adults with treatment refractory minimal change glomerulopathy. A clinical trial is warranted to determine the true efficacy of this approach.

Renal Histological Lesions due to CNI Exposure Are Exceptional in Pediatric Patients with Steroid Dependent Idiopathic Nephrotic Syndrome

Tim Ulinski,[1,2] David Buob,[3] Bilal Aoun.[1] *[1]Pediatric Nephrology, Armand Trousseau Hospital, Paris, France; [2]Univ Pierre et Marie Curie, Paris, France; [3]Renal Pathology, Tenon Hospital, Paris, France.*

Background: Childhood onset idiopathic nephrotic syndrome (INS) is steroid sensitive in 90% of patients but more than 25% run a steroid dependent course and require immunosuppressive drugs. Calcineurin inhibitors (CNI) are efficient in steroid dependent INS. However, CNI can induce two different types of renal toxicity: renal vasoconstriction and arteriolar hyalinosis (AH), the latter is considered irreversible. No biological parameter can distinguish these types of toxicity.

Methods: We investigated prospectively histological lesions in protocol renal biopsies for all INS patients under 18 years who have received CNI for at least 12 months and analysed correlations with other clinical and biological key parameters.

Results: We included 17 patients (12 boys), 5 on cyclosporine (CyA) and 12 on tacrolimus (TAC). All had normal serum creatinine and normal blood pressure. At the time of renal biopsy, serum albumin was normal and was proteinuria negative in all patients. Median (range) age was 7.2 (3.5 – 15.2) years, CNI treatment duration was 2.4 (1.2 – 5.2) yrs, and CyA trough level was 90 (75 – 130) ng/ml and TAC trough level was 5 (3.7 – 8) ng/ml. We found histological signs of CNI renal toxicity (arteriolar hyalinosis) only in one patient who was on a high dose of tacrolimus (0.31 mg/kg per day) with trough levels of 6 to 7 ng/ml for 4.5 years. None of the other patients showed renal lesions attributable to CNI exposure, despite long term exposure in three other patients of 4.2, 4.6, and 5.2 years respectively.

Conclusions: The vast majority of pediatric patients with steroid dependent INS on CNI did not reveal any histological signs of CNI toxicity even after prolonged and relatively high exposure. However, one patient had arteriolar hyalinosis and fibrosis despite tacrolimus trough levels and AUC in the therapeutic range. No biological and clinical parameter seems to predict histological lesions for pediatric INS patients on CNI. Therefore, protocol renal biopsies may be of interest for patients who require long term CNI treatment for severe steroid dependent INS.

TH-PO436

Response to Cyclosporine A in Primary Idiopathic and Genetic Steroid Resistant Nephrotic Syndrome: Discontinuation Is Possible

Markus J. Kemper,[1] Udo Martin Helmchen,[2] Jun Oh.[1] *[1]Pediatric Nephrology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Inst of Pathology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Despite recent advances the prognosis of SRNS is still guarded as uncertain, because the presence of FSGS carries a high risk for the development of chronic renal failure. Duration of treatment in responders and treatment of patients with genetic causes is a matter of debate. With the availability of cyclosporine A (CSA) an improvement has been noticed but long-term follow-up data are scarce.

Methods: We report on 36 patients with SRNS diagnosed since 1991 at a median age of 3 (range 0 .08- 15.0 years) years who were treated with CSA after initial non-response to steroids. Genotyping for at least 3 common mutations (NPHS1 and 2, WT1) was performed in 33/36 (92) patients.

Results: Median follow-up was 15 (range 1.3-29.3 years). 23 (64%) had histological changes that were consistent with FSGS, 13 children had minimal change NS on histology. 19 patients (53%), especially those with MCNS at initial biopsy (12/13 versus 7/23, p<0.002) entered complete remission (CR) with CSA monotherapy. Ten patients entered patients partial remission (PR; 28%, all FSGS). Seven patients (6 FSGS, 1 MCNS) did not respond to treatment and ultimately 8 went into end-stage renal disease; 4 of these patients had mutations in the NPHS2 gene. Two patients with NPHS2 mutations achieved PR, one patient with compound heterozygote NPHS1 and one with heterozygous (dominant) ACTN4 mutation went into CR. In 14 of 19 responders to calcineurin inhibitors discontinuation was attempted after a treatment time of 4.5±3.9years. No further relapses occurred in 10/14 (73%) patients with a median follow-up of 9.7 (0.7-21.6) years.

Conclusions: In summary and conclusion CSA monotherapy is effective in SRNS, even in individual patients with genetic causes. In patients with complete remission a dose reduction and even discontinuation of CSA can be achieved in a significant proportion of patients. In the majority of patients renal function remained stable over prolonged periods indicating, that the prognosis of SRNS may be viewed more optimistic when a response to CSA treatment can be achieved.

TH-PO437

Treatment Response to H.P. Acthar® Gel in Patients with Idiopathic Focal Segmental Glomerulosclerosis and Idiopathic Membranous Nephropathy: A Retrospective Case Series

Arvind Madan,[1] Snezana H. Mijovic-Das,[2] Ana R. Stankovic,[3] Geoffrey S. Teehan,[4] Anupa Khastgir.[5] *[1]Nephrology Associates of Central Florida, Orlando, FL; [2]Albany Medical College, Albany, NY; [3]Parkland Medical Center, Derry, NH; [4]Lankenau Medical Center, Wynnewood, PA; [5]Private Practice, Oklahoma City, OK.*

Background: This retrospective case series examined treatment with H.P. Acthar® Gel (repository corticotropin injection, Questcor Pharmaceuticals, Inc., Hayward, CA), an FDA-approved treatment for remission of proteinuria associated with nephrotic syndrome, in patients with idiopathic focal segmental glomerulosclerosis (FSGS) or idiopathic membranous nephropathy (iMN).

Methods: Eligible cases (N=26) were patients with FSGS or iMN treated with H.P. Acthar Gel, had biopsy-verified FSGS or iMN, and had assessment of 24-hour proteinuria level or spot urine protein:creatinine ratio prior to and following ≥6 months' H.P. Acthar Gel therapy. Percent proteinuria reduction, remission response, estimated glomerular filtration rate (eGFR, mL/min/1.73m^2), and serum albumin (g/dL) were examined.

Results: Of 16 patients with FSGS and 10 patients with iMN, 88% (14/16) of FSGS patients and 90% (9/10) of iMN patients had failed prior immunosuppressive or cytotoxic therapy. After H.P. Acthar therapy, proteinuria reduction from baseline ranged from 32% to 81% in patients with FSGS and from 52% to 94% in patients with iMN, excluding patients with no response (n=1 FSGS [3% reduction]; n=1 iMN [13% reduction]) or early termination (n=2 FSGS; n=1 iMN). Complete remission (n=2 iMN), partial remission (n=9 FSGS; n=4 iMN), or clinical response (n=4 FSGS; n=2 iMN) occurred in 81% of patients. eGFR was stable or increased in 4/13 FSGS patients and 7/10 iMN patients, and serum albumin was stable or increased in 9/10 FSGS patients and 7/10 iMN patients.

Conclusions: The findings from this multisite retrospective case series indicate that H.P. Acthar Gel may help meet an important treatment need in patients with FSGS or iMN. The trend shown in percent proteinuria reduction following ≥6 months H.P. Acthar Gel treatment in patients with FSGS or iMN suggests patients may benefit from treatment extended beyond 6 months.

TH-PO438

Long Term Effects of Rituximab (RTX) in Adult Patients with Idiopathic Membranous Nephropathy (MN) and Focal Segmental Glomerular Sclerosis (FSGS)

Dario Roccatello. *Center of Research of immunopathology and Rare Diseases and Nephrology and Dialysis Unit, San Giovanni Bosco Hospital and Univ of Turin, Italy.*

Background: MN and FSGS are the major causes of adult nephrotic syndrome (NS). RTX appeared effective in reducing proteinuria in MN (but long-term follow-up data are lacking), while the efficacy in adult FSGS is debated and seems to be related to RTX dose.

Methods: Seventeen MN patients (mean age 67 (29-86) years, 6 women, 11 men) and 6 FSGS patients (mean age 65.6 (45-81) years, 3 women, 3 men) with major risk factors precluding corticosteroids or conventional immunosuppression were treated with RTX (4 weekly doses of RTX 375 mg/m2 for MN patients, and 8 weekly doses for FSGS).

Results: In MN patients proteinuria decreased from 5.6 (3-8) g/24h to 2.4 (0.06-13) g/24h after 6 months (p<0.05) and 1.3 (0.06-8) after 12 months (p< 0.01). Four patients received a 2nd course of RTX (one at 6 months because of persistent nephrotic syndrome, and three at 12, 18, or 30 months for relapse. Three out of these 4 became proteinuria-free (< 0.5 g/24 h) in 6 months. The unresponsive patient was lost from the follow-up. Among the 12 patients reaching 24 months of observation two had 1 g/24 h and 10 <0.5 g/24 h of proteinuria at the last observation. Creatinine remained stable: 1 (0.7-1.6) mg/dl at 12 months and 1.1 (0.7-1.7, # 12 patients) at 24 months versus 1 (0.5-2.4) at baseline. In FSGS patients proteinuria did not change: 4.9 (1.7-7.9) g/24 h mean baseline value; 4.9 (1.9-6.7) at six, 4.7 (1.7-9.3) at twelve, and 4.7 (1.3-9.9, # 4 patients) at 24 months. Only 1 out of 6 patients had a substantial response (basal proteinuria 7 g/24 h, 4.9 g/24 h at 12, and 1.3 g/24 h at 24 months) despite a prolonged B cell depletion (lasting more than 2 years). Renal function decreased: mean creatinine 2.2 (1.2-3.7) mg/dl at basal, 3.2 (1.6-6.4) at 12 months. No serious adverse effects were observed.

Conclusions: The 4 weekly infusion protocol of RTX is a reasonable option MN patients with co-morbidities limiting the use of corticosteroids and/or conventional immunosuppression, providing a good safety profile. An intensified regimen with 8 weekly infusions of RTX is instead ineffective in most adult FSGS patients.

TH-PO439

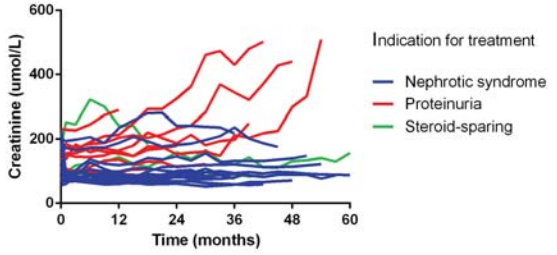
Long-Term Outcome of Tacrolimus Mono-Therapy for Primary Focal Segmental Glomerulosclerosis Thomas Michael Connor, Jack W. Galliford, Ruth M. Tarzi, Liz Lightstone, H. Terence Cook, Charles D. Pusey, Tom Cairns, Megan Griffith. *Hammersmith Hospital, London, United Kingdom.*

Background: Focal segmental glomerulosclerosis (FSGS) is a significant cause of end-stage renal failure. Patients with nephrotic syndrome have a worse prognosis. Tacrolimus (tac) is an effective treatment for the nephrotic syndrome in FSGS, but long-term therapy is often necessary, and there are few data on long-term toxicity. This study reports the long-term outcome of patients treated with tac monotherapy.

Methods: Retrospective review of all patients with primary FSGS treated with tac for >12 months. All patients received maximum tolerated ACE inhibitors +/- ARBs. Complete remission (CR) was defined as normal serum albumin with UPCR <50.

Results: 1. Demographics: 27 patients with primary FSGS were treated with tac (17 for nephrotic syndrome, 7 nephrotic-range proteinuria, 3 steroid sparing). Mean age 48 (19-80). 18 were male. Ethnicity: 10 Caucasian, 6 Afro-Caribbean, 11 Asian. 11/27 patients had received prior immunotherapy. Mean albumin was 22 (9-40) g/L and creatinine 128 (57 – 232) umol/L at presentation. **2. Remission:** 16/17 nephrotic patients achieved CR at a mean 145 days (12-651). 17/27 patients had a stable creatinine over treatment; patients with a lower starting GFR had an increased risk of deterioration;.

Serum creatinine in patients with FSGS during tacrolimus treatment



3. Relapse: 5/17 patients had a relapse of nephrotic syndrome while on tac at 24 (6-39) months, 2/5 following poor adherence. Tac was withdrawn in 3/17 patients; 2/3 relapsed after ceasing therapy. **4. Side effects:** Tac was stopped in 4/27 patients; 3 for reduced GFR, and 1 with metastatic cancer. No admissions for infection.

Conclusions: Most patients on long-term tac for primary FSGS exhibit a stable GFR. Tac offers a good alternative to steroids in these patients. Relapse after long-term therapy is still a problem in some patients and prolonged treatment is often required.

Funding: Government Support - Non-U.S.

TH-PO440

16 Cases of Steroid-Dependent /Resistant Minimal Change Disease Treated with Continuous B-Cell Depletion (Rituximab) John Niles, Andrew P. Murphy, Karen A. Laliberte. *Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Minimal change disease accounts for 10 to 25% of nephrotic syndrome in adults. Of these,over 50% relapse and approximately 25% become steroid dependent or steroid resistant. For those who require additional immunosuppression, Rituximab induced B cell depletion is showing promise for inducing and maintaining remision in patients with minimal change disease.

Methods: We performed a retrospective analysis of clinical data from patients at our clinic with minimal change disease that were corticosteroid dependent or resistant, treated with rituximab and continuous B-cell depletion.

Results: 16 adult patients,12 male and 4 female: mean age 47.5 (IQR 40-56) received rituximab for corticosteroid dependent n=9 or resistant n=7 disease. All 16 received 2 doses of 1gram of Rituximab IV, ~2 weeks apart. Induction also included cytoxan and prednisone. B cell depletion was maintained with 1gm of Rituximab every 4 - 6 months. Median duration of follow up after B cell depletion was 22 months. Mean pre treatment peak urine protein to creatinine ratio was 10.8 and decreased to .62 at date of last test. Mean pre treatment serum albumin increased from 2.0 to 4.2. 12 patients achieved sustained remission, 7 of the 12 were off all other immunosuppression. 1 of 12 patients achieved remission but had early B cell return and was changed to 1gm every 3 months. 1 of the 16 patients died due to a stroke after 24 months of remission. 4 patients achieved remission but follow up is less than 1 year. 1 of these 4 required additional cytoxan and pred. No infections requiring hospitalization occured.

Conclusions: These finding suggest that continuous B-cell depletion with Rituximab has a promising role in the treatment of adults with minimal change disease. Furthermore, induction with overlap of other immunosuppresive agents followed by maintained b cell depletion with Rituximab led to remission in all patients.

TH-PO441

No Additional Effect of Oral Immunosuppressive Agents, Mizoribine, with Steroid Pulse Therapy in Patients with IgA Nephropathy: A Prospective Randomized Controlled Trial Kosuke Masutani,[1] Akihiro Tsuchimoto,[1] Tomomi Yamada,[2] Koji Mitsuiki,[3] Ritsuko Katafuchi,[4] Hideki N. Hirakata,[3] Kazuhiko Tsuruya,[1] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Kyushu Univ Graduate School of Medical Science, Fukuoka, Japan; [2]Dept of Clinical Epidemiology and Biostatistics, Osaka Univ Graduate School of Medicine, Osaka, Japan; [3]Kidney Center, Fukuoka Red-Cross Hospital, Fukuoka, Japan; [4]Dept of Internal Medicine, National Fukuoka-Higashi Medical Center, Koga, Fukuoka, Japan.*

Background: The significance of immunosuppressive agents as an adjunct treatment with corticosteroids for IgA nephropathy (IgA-N) has not been well-demonstrated. This study evaluated the effect of two different treatment regimens, steroid pulse therapy and combined with mizoribine (MZR), imidazole nucleotide which inhibits purine synthesis and T-helper functions.

Methods: Forty IgA-N patients with moderate to severe glomerular injuries were randomly given either pulse methylprednisolone followed by 2-year course of oral prednisolone (P group, n=20) or in combination with MZR (150 mg/day for 2 years, M group, n=20). The primary endpoint was the reduction of proteinuria by 50% or more of the baseline value. The secondary endpoints were increase in serum creatinine (Cr) by 50% or more, or decrease in estimated glomerular filtration rate by 50% or less of the baseline levels.

Results: During the observation period, the urinary protein excretion declined from 1.42 ± 1.25 to 0.33 ± 0.37 g/gCr in P group ($p<0.01$) and from 1.22 ± 0.90 to 0.43 ± 0.42 g/gCr in M group ($p<0.01$), and the lack of statistical difference was found between 2 groups ($p=0.11$). All patients in P group and 19 patients (95.0%) in M group reached the primary endpoint ($p=0.70$). No patient reached the secondary endpoint through the observation period.

Conclusions: Both therapeutic regimens remarkably reduced the levels of proteinuria. We did not find the beneficial effect of MZR on IgA-N in combination with steroids, and terminated the trial. Steroid pulse therapy with 2-year course of oral steroid was effective even in the moderate to severe IgA-N.

TH-PO442

The NEFIGAN Trial: A Randomized, Placebo-Controlled Study to Evaluate the Efficacy and Safety of NEFECON® in IgA Nephropathy Patients at Risk of Developing ESRD: Preliminary Data from the Run-In Phase Bengt C. Fellstrom,[1] Rosanna Coppo,[2] John Feehally,[3] Jürgen Floege,[4] Alan G. Jardine,[5] Francesco Locatelli,[6] Bart D. Maes,[7] Alex Mercer,[8] Manuel Praga,[9] Vladimir Tesar.[10] *[1]Uppsala Univ Hospital; [2]Univ Hospital Regina Margherita; [3]Univ of Leicester; [4]RWTH Univ of Aachen; [5]Univ of Glasgow; [6]Ospedale A.Manzoni; [7]Heilig Hartziekenhuis; [8]Pharmalink AB; [9]Hospital 12 de Octubre; [10]Charles Univ.*

Background: NEFECON is a new oral modified-release capsule formulation of the corticosteroid, budesonide, for the treatment of IgAN patients at risk of developing ESRD despite optimized RAS blockade. The safety and efficacy of NEFECON is currently under evaluation in a prospective, randomized, placebo-controlled study (NEFIGAN Trial). Patients entering the study undertake a 6-month Run-in Phase during which standard-of-care ACEI/ARB therapy is optimized according to KDIGO guidelines. Run-in Phase data are presented.

Methods: 149 primary IgA nephropathy (IgAN) patients at risk of ESRD completed the 6 month Run-in Phase in which ACEI and/or ARB dose was optimized to a maximum recommended or tolerated dose. UPCR, eGFR and systolic / diastolic blood pressure (SBP/DBP) were compared at entry and completion of the Run-in Phase. Run-in Phase inclusion criteria: Biopsy verified IgAN ≥18 years, UPCR ≥0.5 g/g OR urine protein ≥0.75 g/day, eGFR ≥45 mL/min/1.73m^2.

Results: Over the course of the Run-in Phase, mean changes in UPCR, eGFR and SBP/DBP were -1.6%, -1.1% and -3.7/-1.2 mmHg, respectively. For patients entering the Run-in Phase already on an optimized ACEI/ARB dose (n=92), mean changes for UPCR, eGFR and SBP/DBP were +1.7%, -1.8% and -3.4/-0.3 mmHg, while for those requiring ACEI/ARB dose optimization (n=57), mean changes were -7.0%, 0% and -4.2/-2.7 mmHg, respectively.

Conclusions: The majority of patients entering the NEFIGAN Trial had optimized RAS blockade according to KDIGO guidelines at enrolment. Overall, no substantial changes in UPCR, eGFR or SBP/DBP were noted over the duration of the 6 month Run-in Phase. These data illustrate the need for new treatments for IgAN as patients remain at risk of progression to ESRD despite optimized RAS inhibition.

TH-PO443

Prominent IgM Deposition in Glomerulus Is Associated with Initial Higher Level of Proteinuria and Favorable Outcome After Combined Treatment of Tonsillectomy with Steroid Pulse Therapy in Patients with IgA Nephropathy

Tomoaki Miyazaki, Kiyoko Inui, Yoshikuni Nagayama, Eri Kawashima, Hironori Tayama, Yoshihiko Inoue, Ashio Yoshimura. *Div of Nephrology, Dept of Medicine, Showa Univ Fujigaoka Hospital, Yokohama, Japan.*

Background: IgA nephropathy (IgAN) is characterized by mesangial deposition of IgA and C3,often with co-deposits of IgM. Its significance has not fully clarified, therefore we studied the relationship between IgM deposition, clinical features and renal outcome in patients with IgAN with combined treatment of tonsillectomy with steroid pulse therapy (Tx-SP).

Methods: We retrospectively reviewed 74 IgAN patients treated with Tx-SP form December 2006 to March 2014. The patients were divided in two groups: moderate (2+) to severe (3+) measngial IgM deposition (IgM-positive patients, group 1) and negative to faint it (IgM-negative patients, group 2A). Using propensity scores to minimize confounding factors, we selected 22 matched IgM-negative patients (group 2B) from among the 63 unmatched IgM-negative ones and compared them with the 11 IgM-positive ones. The amount of proteinuria, the number of RBC in urine sediment, serum creatinine and histological severity by renal biopsy were also compared between two groups.

Results: Group 1 showed increase in proteinuria than group 2A (urinary protein grade 1.55±0.52 versus1.00±0.97, p = 0.022) and group 2B(1.32±1.09. p =0.057) before Tx-SP. After Tx-SP, proteinuria in group 1 decreased significantly to the same level as the IgM-negative patients (the slope of urinary protein qualitative -1.27±0.47 versus -0.71±0.92 in group 2A, p = 0.006 or -0.95±1.00 in group 2B, p = 0.005). There were no significant differences between the two groups in level of microhematuria, serum creatinine and histological severity.

Conclusions: Prominent IgM deposition in glomerulus is associated with severe proteinuria in patients with IgAN. However, Tx-SP induces sufficient reduction of proteinuria in them as well as IgM-negative IgAN.

TH-PO444

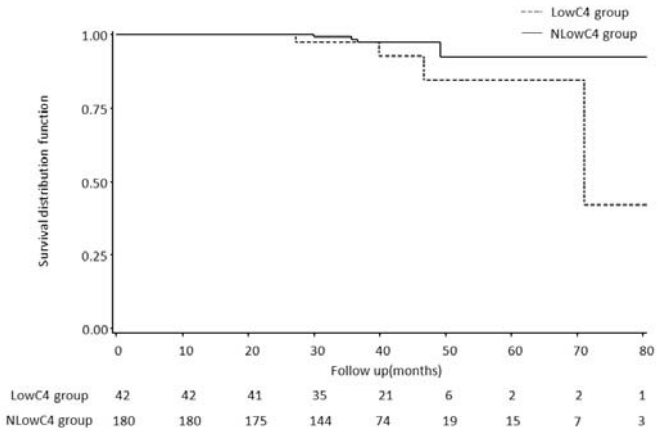
Clinical Characteristics of IgA Nephropathy Associated with Low Complement 4 Levels

Bin Zhu, Hongyu Chen. *Dept of Nephrology, Hangzhou Hospital of Traditional Chinese Medicine (Hangzhou Guangxing Hospital), Hangzhou, Zhejiang, China.*

Background: C4 mediated lectin complement pathway plays an essential role in IgAN. C4 deficiency is the most commonly inherited immune disorder in human. The present study investigated the characteristics of the IgAN patients with low serum C4 levels.

Methods: We performed a cross-sectional and cohort study. Renal clinical as well as histopathologic parameters according to Oxford IgAN classification were assessed. A Kaplan-Meier survival analysis was performed concerning the primary outcome defined as the serum creatinine increased 1.5 fold from baseline. The prognostic significances of clinical and histopathologic parameters were determined using Cox proportional hazards models.

Results: Data from 512 biopsy proven IgAN cases were available for analysis with a median follow-up of 38.4 months. 99 cases (19.34%) presented with low C4 levels (LowC4 group) and the other 413 cases did not (NlowC4 group). At the time of renal biopsy, renal injury were significantly attenuated in the LowC4 group compared with the NlowC4 group which was supported by a subgroup analysis concerning C3 levels. Renal C4 depositon was significantly decreased while IgM deposition was notably increased in the LowC4 group. A spearman correlation analysis shown that low C4 levels were associated with the improved renal injury at biopsy. However, the risk of developing primary outcome was significantly greater in those with low C4 levels. Specifically, during the follow-up period, the risk of developing primary outcome was nearly ten fold higher in those with low C4, compared to those without low C4.



Conclusions: There is a high prevalence of low C4 levels in IgAN patients. These patients with low C4 levels presented attenuated renal injury at the time of renal biopsy, whereas were associated with a poor prognosis.

Funding: Government Support - Non-U.S.

TH-PO445

Urinary Complement Factor H: A Biomarker Predicts Progression of IgA Nephropathy

Maojing Liu, Yuqing Chen, Jicheng Lv, Hong Zhang, Ming-Hui Zhao. *Renal Div, Dept of Medicine, Peking Univ First Hospital.*

Background: Activation of complement system participates in the pathogenesis of IgA nephropathy (IgAN). Complement factor H (CFH) is a crucial factor in inhibiting alternative pathway. The study was to investigate whether urinary CFH associated with renal outcome in IgAN.

Methods: 351 IgAN patients, followed for 51.8±26.6 months, participated in the study. Renal outcome was defined as composite endpoints, including death, ESRD, eGFR decline≥ 50% or doubling of plasma creatinine. Urinary CFH level was measured by ELISA and calculated as urinary CFH over creatinine ratio (uCFH/uCr).

Results: In the whole cohort, uCFH/uCr was independently associated with disease progression either as continuous [log(uCFH/uCr)] or categorical traits (dichotomous and quartile variables) after adjustment (eGFR, proteinuria, mean arterial blood pressure, histological grading, immunosuppressive therapy) in the Cox proportional hazard model. Kaplan-Meier analysis showed that higher uCFH/uCr at baseline predicted worse renal outcome during follow-up (Log rank, P<0.001). ROC curve showed that log(uCFH/uCr) had a predictive value for renal outcome (AUC=0.761), and the AUC increased to 0.818 after being incorporated into eGFR and proteinuria. At early stage of IgAN with eGFR≥60 ml/min/1.73m^2, log(uCFH/uCr) had a better predictive value (AUC = 0.739) for renal outcome compared with eGFR (AUC = 0.604) or proteinuria (AUC = 0.637).

Conclusions: Urinary CFH associated with renal function decline and higher urinary CFH may be an early risk factor for progression of IgA nephropathy.

TH-PO446

Time-Averaged Albumin Predicts the Long-Term Prognosis of IgA Nephropathy Patients Who Achieved Remission

Zhaohui Ni, Yanhong Yuan, Qin Wang, Yuanyuan Xie, Liou Cao, Shan Mou. *Dept of Nephrology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong Univ, Shanghai, China.*

Background: Primary IgA nephropathy (IgAN) is the most common idiopathic glomerulonephritis worldwide. Although most patients are able to achieve remission after therapy with the currently available treatments, a large number of patients will still progress to end-stage renal disease. This study aimed to evaluate the risk factors for progression in patients who achieved remission.

Methods: Patients from a prospective database with IgAN and who were followed up for at least 36 months were included in this study. All the subjects had achieved a complete remission or partial remission following 6 months' therapy. The relationship between the clinical parameters and composite renal outcomes were assessed.

Results: The study comprised 878 IgAN patients recruited between January 2005 and December 2010. Overall, 632 patients were enrolled in this study. The data from the 369 patients who achieved remission were analyzed; the mean follow-up time was 49 months. The median serum creatinine (SCr) was 91.3 μmol/L, and the time-averaged creatinine (TA-SCr) was 91.8 μmol/L. The mean serum albumin (ALB) was 39.4 g/L, and the time-averaged serum albumin (TA-ALB) was 42.1 g/L. Multivariate Cox regression analyses revealed that the TA-ALB and TA-SCr levels were associated with the composite renal outcome.

Characteristics	Univariate analysis				Multi variate analysis	
	HR	95% CI	P value	HR	95% CI	P value
ALB g/L at month 6	0.86	0.76-0.96	0.01			NS
TA-ALB g/L	0.80	0.70-0.93	0.002	0.86	0.75-0.98	0.03
Baseline SCr μmol/L	1.02	1.01-1.04	0.003			NS
TA-SCr μmol/L	1.02	1.01-1.03	<0.001	1.02	1.01-1.03	<0.001
Baseline eGFR (ml/min/1.73 m2)	0.97	0.94-0.99	0.01			NS
TA-eGFR (ml/min/1.73 m^2)	0.96	0.93-0.98	0.001			NS
TA-UPE (g/d)	1.00	1.000-1.002	0.01			NS

The patients with a TA-SCr value > 120 μmol/L and a TA-ALB level < 38 g/L were less likely to recover from renal progression.

Conclusions: The strong predictive relationship of low TA-ALB and high SCr levels with progression observed in this study suggests that TA-ALB may serve as a marker of the long-term renal prognosis of IgAN patients who achieved remission.

Effect of Mycophenolate Mofetil on Expression of Serum microRNA-141 in Immunoglobulin A Nephropathy

Yongcheng He. *Dept of Nephrology, Shenzhen Second People's Hospital, Shenzhen, Guangdong Province, China.*

Background: IgAN is also an important cause of end-stage renal disease.Previous studies showed that a number of miRNAs species,such as miR-141 and miR-200b, miR-205 and miR-192, were regulated in renal cells that are undergoing epithelial-to-mesenchymal transition (EMT). In IgAN, activated tubular epithelial cell may develop EMT and change into activated fibroblast, the main effector of renal fibrosis.In this study,we aim to explore the serum level of miR-141 and the effect of MMF on it in IgAN patients.

Methods: 47 patients treated with MMF as MMF treatment group, 33 patients without any treatment as NIgAN group which matched with MMF treatment group, 15 healthy volunteers as health control group. To explore the serum level of miR-141 through real-time PCR, and compare serum level of miR-141 between the three groups.

Results: As compared with health control group, the serum level of miR-141 in NIgAN group is increased (*P<0.001*). The serum level of miR-141 in MMF treatment group is significantly lower than NIgAN group (*P<0.001*).There is no statistically difference of serum level of miR-141 between MMF treatment group with health controls. Serum level of miR-141 inversely correlates with glomerular filtration rate(GFR)(*r=-0.398, P=0.024*) in IgAN patient,and there is no significant correlation between serum level of miR-141 with urinary protein excretion, blood pressure, and other clinical factors. As comparing Lee grade ≤ 3 with> Lee grade 3 patients, the serum level of miR-141 is higher in the latter, but the difference is not statistically significant.

Conclusions: The serum level of miR-141was significantly elevated in IgAN patients,and its expression is closely related to the progress and severity of renal function. MMF could make the serum level of miR-141 in IgAN significantly reduced. Serum level of miR-141 may be considered as therapeutic target, reflecting the effect of MMF treat with IgAN.

TH-PO448

Clinical Significance and Pathological Characteristics of CD147 in Patients with IgA Nephropathy

Shiren Sun. *Dept of Nephrology, Xijing Hospital.*

Background: Recent studies demonstrated that tubulointerstitial injury can predict renal outcome in patients with IgA nephropathy (IgAN).CD147 is a key regulator of renal tubulointerstitial fibrosis in cellular and animal models. However, it is not clear whether the expression of CD147 correlates with tubulointerstitial injury in IgAN patients.

Methods: We analyzed the degree of CD147 expression and localization in renal biopsies from 86 patients with IgAN and correlated their immunostaining scores with clinical and histological parameters. In particular, we also retrospectively analyzed whether the degree of CD147 expression in the renal interstitium correlated with renal survival.

Results: Elevated CD147 expression was found in the basolateral membrane of renal tubules in IgAN patients; however, in normal kidney samples, positive staining for CD147 was not found in the tubular epithelial cells (p=0.000). CD147 protein expression in the tubulointerstitium showed a negative correlation with estimated glomerular filtration rate (eGFR;r= -0.600, p= 0.000) and a positive correlation with serum creatinine (Scr;r=0.322, p=0.002) and tubulointerstitial lesions (r=0.525, p=0.000). Kaplan-Meier survival curves showed that elevated CD147 expression, which was measured by immunohistochemistry, was associated with decreased renal survival. Multivariate analyses further demonstrated that a high CD147 immunostaining score was an independent predictor of renal outcome in patients with IgAN (HR= 8.731, p=0.041).

Conclusions: CD147 expression is associated with tubulointerstitial injury and predicts renal prognosis in IgA nephropathy. CD147 could be a new marker for tubulointerstitial fibrosis.

TH-PO449

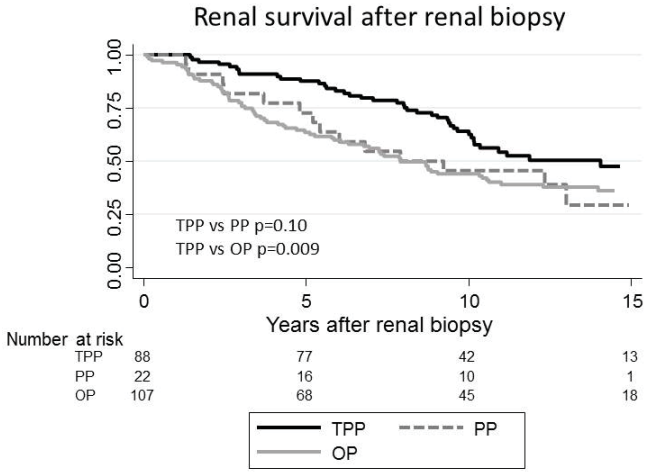
Could Tonsillectomy plus Methylprednisolone Pulse Therapy Improve Renal Outcome in Patients with IgA Nephropathy? Results from 15-Year Follow-Up Study

Junichi Hoshino,[1] Takayuki Fujii,[2] Joichi Usui,[3] Masahiro Kawada,[1] Koki Mise,[1] Keiichi Sumida,[1] Tatsuya Suwabe,[1] Satoshi Suzuki,[2] Kenmei Takaichi,[1] Yoshifumi Ubara,[1] Kunihiro Yamagata.[3] *[1]Nephrology Center, Toranomon Hospital, Tokyo, Japan; [2]Seirei Sakura Hospital, Chiba, Japan; [3]Dept of Nephrology, Univ of Tsukuba, Ibaraki, Japan.*

Background: RAS inhibitors and steroids are considered as first-line therapies for patients with IgA nephropathy. However, it is still unknown whether tonsillectomy plus prednisone pulse therapy (TPP) could decrease risk of ESRD beyond these treatments in patients with IgA nephropathy (IgAN).

Methods: Data on 217 IgAN patients diagnosed by renal biopsy between 1995 to 2005 in our hospital were followed until ESRD or death (mean follow-up, 9.1±0.3 years). Their renal survival was compared after dividing by their initial treatments; TPP, prednisone pulse (PP), or oral prednisone (OP). Factors affecting survival were analyzed using the Cox's hazard model after adjusting the IgAN prognostic score (Goto M et al., NDT 2009) at baseline and other treatment factors (use of RAS inhibitors and antiplatelet/anticoagulants).

Results: 5- and 10-year renal survival were, respectively, 0.88 (95% confidence interval [CI], 0.78-0.93) and 0.64 (0.53–0.73) with TPP (n=88); 0.73 (0.49–0.87) and 0.45 (0.24–0.64) with PP (n=22); and 0.64 (0.54–0.72) and 0.44 (0.34–0.53) with OP (n=107).



Survival curves were significantly different between TPP and OP (p<0.01). After adjusting baseline and treatment factors, hazard ratios for ESRD, with OP as reference, were 0.68 (0.44–1.05, p=0.08) for TPP, 0.77 (0.40–1.47, p=0.43) for PP.

Conclusions: Tonsillectomy plus methylprednisolone pulse therapy may decrease risk of ESRD in patients with IgAN comparing to oral or pulse prednisone therapy.

TH-PO450

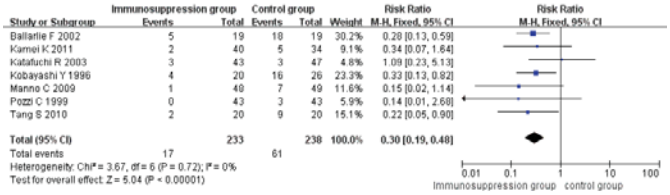
The Long Term Efficacy and Safety of Immunosuppression on the Progression of IgA Nephropathy: A Meta-Analysis of Randomized Controlled Trials with More Than 5-Year Follow Up

Lei Tian, Xinghua Shao, Weijia Xu, Ling Wang, Chaojun Qi, Zhaohui Ni, Shan Mou. *Dept of Nephrology, Molecular Cell Lab for Kidney Disease, Ren Ji Hospital, School of Medicine, Shanghai Jiaotong Univ, Shanghai, China.*

Background: Immunoglobulin A nephropathy (IgAN) is a common glomerulonephritis usually treated with immunosuppression. However, the long-term efficacy and safety of immunosuppression for IgAN is still controversial.

Methods: Articles were identified from PubMed, ISI Web of Science, EMBASE, Google Scholar, Scopus, Science direct and Cochrane library. Randomized controlled trials (RCTs) at least 5 years follow-up were selected to investigate the efficacy and safety of immunosuppression for IgAN. The primary outcome was the progression to end stage renal disease (ESRD). Another outcome was deterioration in renal function defined as doubled serum creatinine or 50% reduction of estimated glomerular filtration rate (eGFR) without going into ESRD.

Results: The eligible 7 RCTs with 471 patients were enrolled in this study. Generally, immunosuppression could lower the risk for the progression to ESRD (RR, 0.30, 95% CI 0.19-0.48) and deterioration in renal function (RR, 0.19, 95% CI 0.07-0.54).



As far as the pooled RRs of progression to ESRD, 4 studies with less than 7-year follow-up, 3 followed for more than 7 years, 4 adopted corticosteroids monotherapy, 2 used corticosteroids plus other immunosuppression, 4 fromAsia, and 3 from Europe were 0.32 (95% CI, 0.18-0.58), 0.28 (95% CI, 0.13-0.59), 0.34 (95% CI, 0.17-0.67), 0.29 (95% CI, 0.15-0.58), 0.37 (95% CI, 0.20-0.68), and 0.23 (95% CI, 0.11-0.47), respectively. Immunosuppression was associated with an increased risk for adverse events (RR=2.13, 95% CI 1.17-3.86).

Conclusions: Immunosuppression for IgAN might reduce long-term risk of progression to ESRD and deterioration in renal function but increase the risk of adverse events to some extent.

Pathological Prognosticators and Therapeutic Impact of Tonsillectomy in IgA Nephropathy

Yoshikatsu Kaneko, Shin Goto, Ichiei Narita. *Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: The Oxford classification of IgA nephropathy consists of four markers, MEST, as the prognosticators. We retrospectively examined the relevance of extracapillary proliferation and arterial sclerotic changes which might correlate prognosis of chronic kidney disease, and efficacy of tonsillectomy in IgA nephropathy.

Methods: Of 727 Japanese patients who were diagnosed with IgAN based on kidney biopsy in our institution, 314 patients with 12 months or more follow-up period and with 8 or more glomeruli per biopsy were included in this study. Patients with complication of systemic disease that would be expected to cause IgA deposition in glomeruli, such as anaphylactoid purpura, or those with complication of diabetes mellitus or with severe kidney injury (initial eGFR <30 ml/min/1.73m^2) were excluded. Presence of extracapillary proliferation (Ex), arteriole hyalinosis (A), and intimal thickening of small artery (SA) were scored 0 in the absence and 1 in the presence of each lesion.

Results: Each intraclass correlation coefficient demonstrated moderate correlation shown as; M:0.409, E:0.489, S:0.616, T:0.533, Ex:0.577, A:0.575, SA:0.59. Then, we investigated the correlation between these pathological scores and renal outcome. The end point was determined as the 50% reduction in initial eGFR or ESRD defined as eGFR <15ml/min/1.73m^2. The median duration of follow-up was 137 months (range 12-491). Steroid therapy was conducted in 126 patients and tonsillectomy was undergone in 54 patients. In the univariate analysis, kidney survival was significantly lower in patients with S1, Ex1 and A1 than in those without, and hazard ration for S, Ex and A was 2.16, 2.01, and 2.07, respectively. In the multivariate model, eGFR at biopsy was the sole risk factor. Tonsillectomy did not improve renal outcome, regardless of combination of steroid theapy.

Conclusions: Segmental sclerosis, extracapillary proliferation and arteriole hyalinosis could be useful as prognosticators, although renal function at baseline would be more important predictor of renal outcome. Tonsillectomy did not have any significant effect in renal outcome.

Funding: Government Support - Non-U.S.

Efficacy and Safety of Rituximab plus Cyclosporine in Idiopathic Membranous Nephropathy; Results of an Ongoing Prospective Trial

Meryl A. Waldman, Michelle Braun, Howard A. Austin. *NIDDK, National Inst of Health, Bethesda, MD.*

Background: Cyclosporine (Csa) has efficacy in reducing proteinuria in idiopathic membranous nephropathy (IMN) but partial remissions (PR), rather than complete (CR) are more common and relapse upon drug withdrawal is problematic. Extending treatment may increase remissions and reduce relapses but potential for nephrotoxicity exists. Rituximab (RTX) monotherapy has shown promise in IMN but PRs are more common and effect on proteinuria tends to be delayed. We are conducting a prospective phase 2 trial in 30 pts with IMN to investigate whether "induction" with RTX + Csa for 6 mos followed by "maintenance" RTX may achieve greater reduction in proteinuria than either agent alone, increase number of remissions (especially CR) and reduce relapse rates. Here we report interim data.

Methods: Patients with IMN, persistent high grade proteinuria despite conservative rx for min 6 mos and eGFR ≥40 ml/min/1.73 m^2 receive RTX (1gm D 1 and 15) + Csa x6 mos, then tapered. A 2nd course of RTX is given after min of 6 mos and evidence of B cell recovery.

Results: To date, 13 pts have enrolled. Mean baseline proteinuria 10.7g/d. All patients have shown response with reduction of proteinuria. Of 8 pts with 24 mos follow up, there were 4 (50%) complete remissions (protein reduction ≤0.3g/d) and 3 (38%) partial remissions (protein reduction≥50% and ≤3.5g/d); 2 pts relapsed (R:≥50% increase in proteinuria) after achieving PR and again achieved PR after RTX monotherapy. Regimen was well tolerated.

Pt#	Baseline proteinuria g/24 hr	3m	9m	12m	18-20m	24m	most recent f/u
1	11.2	10.9	14	5.7	1.8	0.8	1.3
2	10.5	0.1	0.3	0.1	0.1	0.1	0.1
3	14.1	11.3	2.1	1.4	0.8	0.4	0.1
4	13.9	1.1	0.3	0.2	0.2	0.2	0.2
5	8.0	1.9	0.7	0.5	0.6	3.4(R)	0.4
6	9.8	7.2	2.1	7.4 (R)	2.8	0.6	0.7
7	9.6	1.3	0.2	0.2	0.1	0.1	0.1
8	12.6	3.5	0.3	0.2	0.2	0.1	
9	15.9	2.9	1.4	1.3			
10	8.3	1.0	0.2	0.3			
11	5.9	1.4	0.5				
12	12.8	1.1					
13	7.1						

Conclusions: "Induction" with RTX + Csa followed by "maintenance" RTX may be a treatment approach for IMN to achieve a greater number of remissions (complete) and may obviate the need for long term immunosuppression. It appears to be well tolerated. Enrollment continues and longer term follow up is needed.

TH-PO453

Synthetic ACTH in Patients with Idiopathic Membranous Nephropathy: Long Term Follow-Up

Anne-Els van de Logt, Julia M. Hofstra, Jack F. Wetzels. *Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Although alkylating agents improve outcome in idiopathic membranous nephropathy (iMN), these agents often have serious side effects. Synthetic ACTH may be advantageous in patients with iMN with reported remission rates up to 85 % and few side effects.

Methods: We have previously shown preliminary data in 20 patients with high risk iMN treated with ACTH (NCT00694863/kidney week 2011: SA-PO2851). Here we report long term renal outcome. Patients with iMN, a nephrotic syndrome, eGFR> 60 ml/min/m² and high risk for progression were treated with i.m. injections of synthetic ACTH during 9 months (m). Maximal dose was 1 mg twice a week. For comparison, we selected historical controls, treated with cyclophosphamide (CP) (1.5 mg/kg/day for 12 m) and steroids, matched for serum creatinine, proteinuria, age, sex and previous immunosuppressive treatment.

Results: We compared 20 patients treated with ACTH and 20 historical controls treated with CP; the patient characteristics are shown in Table 1. Cumulative remission (PCR <3.5 g/10 mmol) after first therapy was seen in 13 (70 %) patients treated with ACTH versus 19 (95 %) patients in the CP group (p=0.04). Relapse rates were respectively 31% and 26 %. Overall ten (50 %) patients in the ACTH group versus two (10%) in the CP group needed additional immunosuppressive agents because of initial resistance, relapse or progressive disease (p=0.01). At the end of follow-up 15 (75 %) patients in the ACTH group and 17 (85 %) CP group patients were in remission (p=0.70).

	ACTH group (n=20)	CP/Prednisone group (n=20)
Sex (male/female)	15/5	16/4
Age (years)	54 (±14.5)	50 (±13.2)
Serum creatinine (µmol/l)	104 (74-156)	97 (68-165)
Protein creatinine ratio (g/10 mmol)	8.7 (2.4-13.2)	9.4 (4.6-18.6)
Follow-up (months)	46 (±13)	64 (±35)

Conclusions: Treatment with synthetic ACTH is less effective than CP in inducing a remission in high risk patients with iMN. At the end of follow-up an equal rate of remissions was achieved in both groups at the cost of additional treatment in 50 % of patients in the ACTH group. Still 40 % of patients have long term remission with ACTH monotherapy.

TH-PO454

Anti-PLA2R Antibody Titers During ACTH Treatment in Patients with Idiopathic Membranous Nephropathy

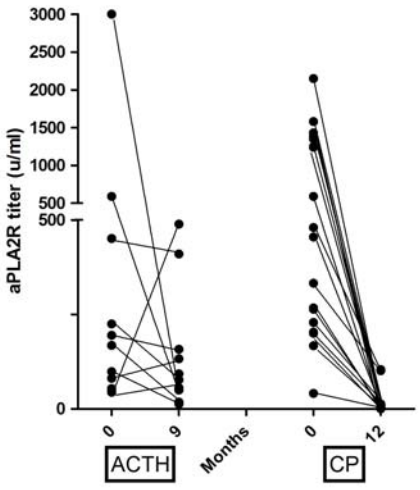
Anne-Els van de Logt,[1] Julia M. Hofstra,[1] Jack F. Wetzels,[1] Paul E. Brenchley.[2] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Nephrology and Transplantation, Manchester Inst, Manchester, United Kingdom.*

Background: Synthetic ACTH may be advantageous in patients with idiopathic membranous nephropathy (iMN) with reported remission rates up to 85 %. In a separate study, we showed that cumulative remission rate (protein creatinine ratio <3.5 g/10 mmol) after first therapy was lower (70 %) in patients treated with ACTH versus 95 % in patients treated with cyclophosphamide (CP). Here we compare antibody response during treatment with either ACTH or CP.

Methods: We selected patients treated with synthetic ACTH (9 months) or with CP (12 months) with positive anti-PLA2R antibodies (aPLA2R) at baseline and a follow-up serum sample available at end of treatment. In all serum samples anti-PLA2R antibodies were measured with an ELISA (Kanigicherla, KI 2013).

Results: The CP treated patients had more severe disease (Table). The course of aPLA2R titers in individual patients is showed in a Figure. At the end of therapy, proteinuria was reduced in both groups (ACTH 1.8 versus CP 1.1 ;p=0.436); remissions were achieved in 6/10 versus 15/18 patients (p=0.207); aPLA2R was negative in 2/10 versus 16/18 patients (p=0.001). Anti-PLA2R antibodies were still present in 4/6 ACTH-treated patients in remission, versus 0/15 CP-treated patients in remission.

	ACTH group (n=10)	CP/Prednisone group (n=18)
Sex (male/female)	8/2	15/3
Age (years)	54 (±12.4)	55 (±9.4)
Serum creatinine (µmol/l)	95 (79-129)	136 (105-278)
Protein creatinine ratio (g/10 mmol)	8.8 (±2.8)	15.5 (±8.8)
Follow-up duration (months)	55 (33-61)	123 (26-192)



Conclusions: aPLA2R antibodies disappear less often or slower with ACTH therapy. This might explain the lower efficacy of ACTH compared to CP. However, our data point to non-immunological effects of ACTH in some patients.

TH-PO455

Prognostic Value of Remission of Proteinuria for the Development of ESRD in the Patients with Idiopathic Membranous Nephropathy Hideo Tsushima, Ken-Ichi Samejima, Masaru Matsui, Yasuhiro Akai, Yoshihiko Saito. *First Dept of Internal Medicine, Nara Medical Univ, Kashihara City, Nara, Japan.*

Background: Prognostic factors for the development of end-stage renal disease (ESRD) in the patients with idiopathic membranous nephropathy with nephrotic syndrome (niMN) have not fully understood.

Methods: We retrospectively investigate the clinical and histological renal prognostic markers in the patients with niMN who were clinically and histologically evaluated from 1981 to 2011.

Results: Seventy-two patients (54 males and 18 females) who had the diagnosis of niMN were enrolled. Mean age at the time of renal biopsy was 59.1±14.1 years old. Diurnal urinary protein was 6.7±3.9 g and serum albumin 2.6±1.5 g/dl at renal biopsy. When clinical parameters were evaluated by univariate analysis, the development of ESRD was closely associated with the remission of proteinuria (< 1.0g/d) but not with the degree of proteinuria, serum albumin, blood pressure, and estimated glomerular filtration rate. Interestingly, the rate of glomerularsclerosis and interstitial fibrosis at initial biopsy did not contribute to the renal prognosis.

Conclusions: Our findings demonstrated that remission of proteinuria is a pivotal prognostic index for the preservation of renal function. The severity of glomerulosclerosis and interstitial fibrosis at initial renal biopsy did not correlated with future development of ESRD.

TH-PO456

Long-Term Outcomes of Idiopathic Membranous Nephropathy: Two-Centre UK Experience Nadia Sarween,[1] Stuart W. Smith,[1] Daniela Farrugia,[2] Mohammed Awais Hameed,[2] Sarah J. Logan,[1] Catherine King,[1] Paul Carmichael, Peter Hewins.[1] *[1]Renal Medicine, Queen Elizabeth Hospital, Birmingham, West Midlands, United Kingdom; [2]Renal Medicine, New Cross Hospital, Wolverhampton, West Midlands, United Kingdom.*

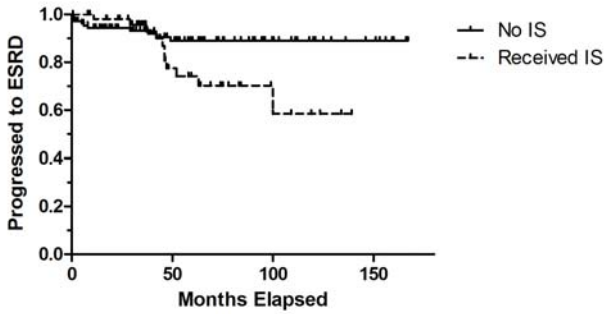
Background: Idiopathic membranous nephropathy (IMN) can respond to immunosuppression (IS). Serious side effects and a high spontaneous remission rate create debate over optimal management and differing practices. We retrospectively reviewed treatment and outcomes of IMN patients at 2 United Kingdom teaching hospitals serving an interconnected urban area.

Methods: Patients with biopsy proven, new-diagnosis membranous nephropathy without a secondary cause were identified from hospital records (2000-2012).

Results: Data were available for 168 patients (centre 1 n=106, centre 2 n=62). Patients that received IS had a higher baseline ACR (p=0.016) and were more likely to have reached ESRD (p=0.03).

Median age (range) years	55 (18-83)
Sex	62% male
Ethnicity	68% Caucasian, 17% South Asian, 6% Black
Median creatinine (µmol/L)*	94 (45-1526)
Median serum albumin (g/L)*	27 (10-50)
Median urine ACR (mg/mmol)*	565 (26-2091)
Median follow up	59.2 months
Received IS	31%
Average time to IS	5.7 months (0-65)
Median urine ACR (mg/mmol) no IS vs IS	487 (no IS), 640 (IS)
Spontaneous remission	73%
Median time to spontaneous remission	19.7 months (0.8-160)
Remission in IS patients	80.8%
Median time to remission in IS patients	14.8 months (1.1-124)
ESRD: no IS vs IS	9.5% (no IS), 21% (IS)
Mortality: no IS vs IS	16.4% (no IS), 13% (IS)

* At presentation. Remission=complete or partial. IS was calcineurin inhibitor (n=36), modified Ponticelli (n=29), steroids only (n=5) and other (n=7)



Conclusions: Outcomes were favourable for most IMN patients including nephrotic patients not treated with IS. Belated spontaneous remissions occur and deferred IS can be considered. A subset of patients develop ESRD and an optimal IS strategy is yet to be devised.

TH-PO457

Hemolytic Uremic Syndrome Induced by Shiga Toxin-Producing Escherichia Coli O104:H4 (STEC) in Adults: A Follow-Up for 12 Months with a Focus on the Outcome of Kidney Function Inge Derad,[1] Birgit Obermann,[2] Martin Nitschke,[1] Juergen Steinhoff.[1] *[1]Dept of Nephrology, Univ of Lübeck, Lübeck, Germany; [2]Dept of Microbiology and Hygiene, Univ of Lübeck, Lübeck, Germany.*

Background: During the Northern German endemic in 2011, hemolytic uremic syndrome (HUS) was induced in 855 patients by Shiga toxin-producing, enteroaggregative Escherichia coli bacteria (STEC). 60 patients were treated according to a standardized protocoll. The present single center, observational study describes the 1-year course of the disease with an emphasis on kidney function. Outcome data are associated with treatment and patient characteristics at onset of HUS.

Methods: According to the rescue guidelines of the German Society of Nephrology patients with severe HUS were treated with eculizumab, on top of the regular treatment with best supportive therapy and a limited number (5) of plasmapheresis. In order to protect patients from an increased risk of meningococcal disease inherent in the therapy with eculizumab, the antibiotic azithromycin was concomitantly administered for two weeks. This decision - to start or omit an additional therapy with eculizumab separated the patients into two groups (EcAz, Non-EcAz), and marked the day zero of the present study. After discharge, treatment was continued in our outpatient clinics. Standardized visits assessed the patients' well-being, bodily functions, kidney function, neurological symptoms, hematologic signs and blood pressure.

Results: 56 patients were regularly seen during the follow-up. All patients had survived without end-stage renal disease. After one year kidney function was affected with increased creatinine (4.4%, maximun:129µmol/l), proteinuria (26.7%), increased cystatin C (46.7%), reduced estimated glomerular filtration rate (<90 ml/min) (46.7%), and newly developed hypertension (25%).

Conclusions: Although STEC-HUS was a severe, life-threatening acute illness, after one year patients showed a good recovery. Kidney function in the severely ill patients treated with eculizumab plus azithromycin improved to the same level as the less severly ill controls. Only HUS patients with severe illness developed chronic hypertension.

Funding: Government Support - Non-U.S.

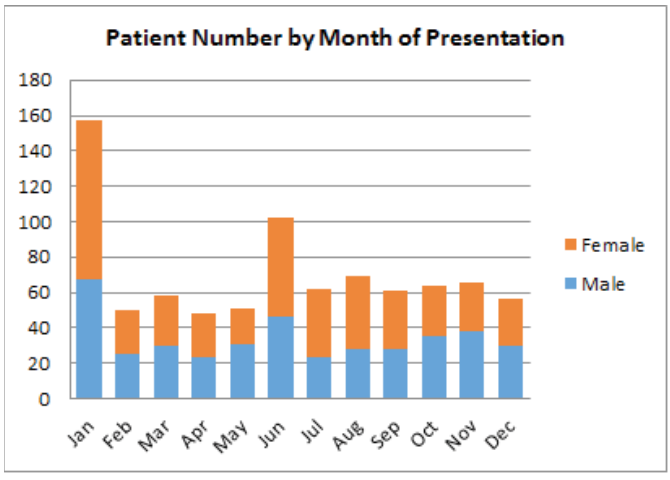
Effect of Seasonal and Temperature Variations on Incidence of Systemic Vasculitis Hsu-Han Wang,[1] Neil Basu,[2,5] Mark Alan Little,[3,5] Michael G. Robson,[4,5] Alan D. Salama.[1,5] *[1]Centre for Nephrology, Univ College London; [2]Musculoskeletal Collaboration, Univ of Aberdeen; [3]Clinical Medicine, Trinity College Dublin; [4]MRC Centre for Transplantation, King's College London; [5]UKIVAS Registry, United Kingdom.*

Background: Seasonal variation has been reported in primary systemic vasculitis, but the cause of this variation remains unknown. The influence of temperature, which affects neutrophil degranulation, has not been investigated.

Methods: Using the UKIVAS national vasculitis registry, residential post code and temperature data provided by UK Climate Projections (UKCP09) which is to a 5x5 km resolution, we analysed the impact of environmental temperature on vasculitis presentation. A ranking of the temperature by month covering the study duration was made to standardize seasonal temperature differences.

Results: 916 patients were included, 844 with accurate presentation dates; 727 (79.3%) had ANCA-associated vasculitis (AAV). There was an increased incidence in January and June months.



We selected two sites (Aberdeen, A, and London, L, N=284) for detailed analysis of the AAV subset. Gender and ANCA distributions were similar in A and L. The mean monthly temperature at diagnosis, one and two month(s) prior were similar for MPO- and PR3-ANCA. However, when we compared mean temperature with historic records we found that the temperature 2 months prior to diagnosis was significantly higher historically for PR3-ANCA compared to MPO-ANCA patients (ranked 62% versus 51% p=0.017), suggesting a higher temperature preceding diagnosis compared to historical means for that month.

Conclusions: There are seasonal variations in presentation of AAV, with peaks in January and June. The mean environmental temperature is historically higher 2 months before diagnosis in PR3-ANCA patients. Further investigations including other environmental factors are necessary to explain the seasonal variation of vasculitis in UK.

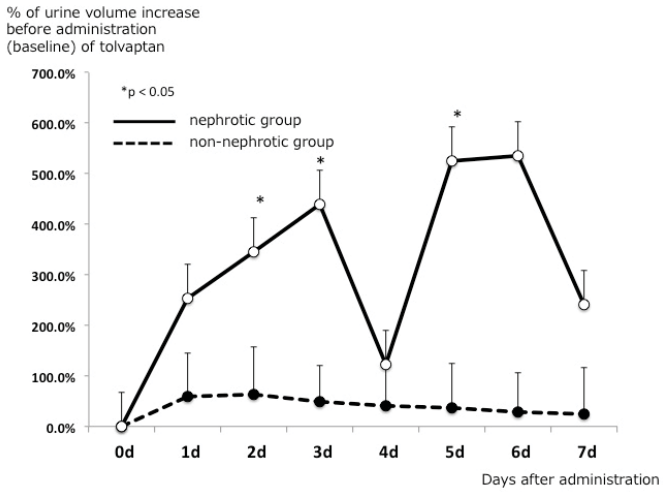
Effectiveness of Tolvaptan in Chronic Kidney Disease Patients with Systemic Edema Kazuhito Fukuoka, Shinya Kaname, Yoshihiro Arimura. *1st Dept of Internal Medicine, Div of Nephrology and Collagen Disease, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan.*

Background: Tolvaptan is a V2R antagonist which has been used for heart failure in Japan. Although most of those patients complicate various degrees of kidney dysfunction, its effectiveness in CKD is unclear.

Methods: This study was a single center, retrospective study that compared the efficacy of tolvaptan in heart failure patients complicated with CKD due to diabetic mellitus, chronic glomerulonephritis and nephrosclerosis. The subjects admitted in our hospital for tolvaptan treatment from 2012 to 2013 were recruited.

Results: A total of 23 patients were analyzed. An average age was 70.3 years and the estimated GFR was 26.7±23.7ml/min/1.73m^2. None of the patients discontinued tolvaptan because of adverse events such as worsening of renal function or hypernatremia. The urine volumes increased at day 2 and reached their peak within 3 days, although the extent of the increase varied by patient. We divided the patients into two groups; the responder group (3%< body weight reduction and/or 10%< urine volume increase) and non-responder group (neither criteria fulfilled). The significant differences in urine protein excretion was observed between the two groups, but there were no differences in other clinical parameters at the baseline such as eGFR, urine and serum osmotic pressure and sodium concentration. Of note was that in 8 cases of nephrotic syndrome the urine volume were more prominently increased after administration of tolvaptan as compared to the non-nephrotic cases.



Interestingly, these nephrotic cases showed higher serum vasopressin levels before applying tolvaptan(8.9±4.67 versus0.43±0.75).

Conclusions: Tolvaptan is effective as a diuretic for some CKD patients, particularly for those with gross proteinuria with increased vasopressin levels due to intra-vascular dehydration.

TH-PO460

Galectin-3 Inhibition with GCS-100 Improves eGFR in Patients with Chronic Kidney Disease Pablo E. Pergola,[1] Geoffrey A. Block,[2] Bhupinder Singh,[3] Robert S. Cohen,[4] William T. Durham,[5] James A. Tumlin,[6] George Tidmarsh,[7] James Rolke.[7] *[1]Renal Associates PA, San Antonio, TX; [2]Denver Nephrology, Denver, CO; [3]Apex Research of Riverside, Riverside, CA; [4]Southwest Kidney Inst, Tempe, AZ; [5]Mountain Kidney and Hypertension Associates, Ashville, NC; [6]SouthEast Renal Research Inst, Chattanooga, TN; [7]La Jolla Pharmaceutical Company, San Diego, CA.*

Background: Galectin-3 has been implicated in interstitial and glomerular fibrosis resulting in progressive loss of kidney function.

Methods: GCS-100, a polysaccharide inhibitor of galectin-3, was evaluated in CKD stages 3b/4 in a multicenter, randomized, placebo-controlled Phase 2 study. 121 consenting adults received placebo or GCS-100 at doses of 1.5 or 30 mg/m^2 IV weekly for 8 weeks followed by a 4 week observation period. The primary endpoint was the change in eGFR from baseline to end of treatment versus placebo. Both T-test and ANCOVA were used for analyses.

Results: Demographics: 117 patients (65 Stage 4) completed treatment (mean age 65; 43 female). Baseline eGFR was 29.2 ml/min/1.73m2 ± 9.00 (SD). Diabetes and HTN were the most common etiologies of CKD. Efficacy: In the 1.5 mg/m^2 group, a change in eGFR of +1.26 ±0.77 versus placebo (-0.58±0.46) was observed (p=0.045). When restricted to diabetic etiology, for 1.5 mg/m^2 the change in eGFR was 2.33 ± 1.13 versus placebo (-0.53±0.56; p=0.028). Galectin-3 and K+ were significantly reduced (p=0.07 each). Uric acid and BUN were significantly reduced versus baseline (p=0.07, 0.08 respectively). No significant changes in eGFR, galectin-3, K+, uric acid or BUN were observed among those receiving 30 mg/m^2. Safety: Four SAEs occurred, 2 in the placebo, 2 in the 30 mg/m^2 group and none at 1.5 mg/m^2. None of the SAEs were drug-related.

Conclusions: Short term therapy with the galectin-3 inhibitor, GCS-100 at 1.5 mg/m^2, resulted in small but significant improvement in eGFR. If future, long term studies confirm these findings, GCS-100 could be used as a disease-modifying agent to slow and potentially reverse the renal fibrosis common in CKD.

Cathepsin L Is Essential for the Development of Proteinuria in Diabetic Mice Marjolein Garsen,[1] Angelique Rops,[1] Toin Van Kuppevelt,[2] Ton J. Rabelink,[3] Jo H.M. Berden,[1] Johan Van der Vlag.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Matrix Biochemistry, Radboud Univ Medical Center, Nijmegen, Netherlands; [3]Nephrology, Leiden Univ Medical Center, Leiden, Netherlands.*

Background: Heparan sulfate (HS) is a negatively charged polysaccharide that is abundantly expressed in the glomerular filtration barrier. Glomerular HS expression is reduced in proteinuric patients, which is associated with an increased expression of the HS-degrading enzyme heparanase (HPSE). HPSE is essential for the development of proteinuria in diabetic nephropathy (DN). Cathepsin L (CTSL) is a lysosomal cysteine protease that cleaves pro-HPSE, thereby making it biologic active. CTSL also degrades the actin-associated protein synaptopodin in podocytes. Both mechanisms may contribute to the development of proteinuria.

Methods: To precise the exact role of CTSL in the development of proteinuria, type 1 diabetes mellitus was induced in wildtype (wt) and CTSL knockout (ko) mice by streptozotocin. Mice were sacrificed after 4, 8 and 16 weeks.

Results: Diabetic wt mice developed proteinuria, starting at 4 weeks, whereas diabetic CTSL ko mice failed to develop proteinuria. 16 weeks after induction of diabetes, CTSL expression was increased in wt mice. Simultaneously, synaptopodin expression was reduced in diabetic wt mice (p=0.1), but not in diabetic CTSL ko mice. Heparanase expression and activity were increased 4 weeks after the induction of diabetes in wt mice, and remained high until 16 weeks. Glomerular HS expression was reduced in diabetic wt mice, but preserved in diabetic CTSL ko mice at all time-points. Finally, macrophage infiltration, a characteristic of DN, was increased in diabetic wt mice, but normal in diabetic CTSL ko mice.

Conclusions: Our data suggest that CTSL is causally involved in the pathogenesis of proteinuria in DN. Most likely CTSL-deficiency causes loss of HPSE activity, which prevents the loss of glomerular HS expression and the development of albuminuria.

TH-PO462

The Role of Krüppel-Like Factor 2 in Endothelial Injury of Diabetic Nephropathy Fang Zhong,[1,2] Peter Y. Chuang,[1] Hongyu Chen,[2] Yongjun Wang,[2] Sandeep K. Mallipattu,[3] John C. He.[1,4] *[1]Dept of Medicine/Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Dept of Nephrology, Hang Zhou Hospital of Traditional Chinese Medical, Zhejiang Chinese Medical Univ, Hang Zhou, Zhejiang, China; [3]Div of Nephrology, Dept of Medicine, Stony Brook Univ School of Medicine, Stony Brook, NY; [4]Renal Section, James J Peters VAMC, New York, NY.*

Background: Elucidating mechanisms that mediate the early stage of diabetic nephrology (DN) may help us identify novel preventive and therapeutic measures for patients with DN. Krüppel-like Factor 2 (KLF2), a shear-stress inducible transcription factor, has endo-protective effects. The role of KLF2 in DN has not been studied.

Methods: Both STZ rat and mouse models were used. The endothelial cell specific Klf2 heterozygous knockout mice (KO) were used to determine the role of KLF2 in DN. HUVEC was used for in vitro studies. The expression of angiogenesis markers and podocyte-specific genes were examined in glomeruli of the mice. The KLF2 expression was examined on human biopsies.

Results: In STZ-rats, *Klf2* expression was reduced in comparison to non-diabetic rats. However, normalization of hyperglycemia by insulin treatment increased *Klf2* expression to a level higher than that of non-diabetic rats, suggesting that Klf2 might be regulated positively by hyperfiltration but negatively by hyperglycemia. In vitro, high glucose suppressed KLF2 expression in HUVEC. KLF2 expression was also reduced in human diabetic kidneys. We found that KO-STZ developed more kidney/glomerular hypertrophy and proteinuria than WT-STZ. Glomerular expression of Vegf, Flk, and angiopoietin 2 increased but expression of Flit, Tie2, and angiopoietin 1 decreased in KO-STZ compared to WT-STZ. Glomerular expression of ZO-1, glycocalyx, and eNOS was also decreased in KO-STZ. Podocyte injury was also more prominent in KO-STZ.

Conclusions: Our data suggest KLF2 is likely regulated by both shear stress and high glucose, and has protective effects against diabetes-induced glomerular endothelial cell injury at the early stage of DN. The data also highlight a potential crosstalk from the glomerular endothelial cell to podocyte.

High Spatial and Spectral Resolution Mass Spectrometry Imaging Reveals Reduced AMP and Elevated ATP Levels in Glomeruli of Diabetic Mice

Satoshi Miyamoto,[1,2,3] Gregory Hamm,[4] Jonathan Stauber,[4] Pieter Dorrestein,[1,5] Kumar Sharma.[1,2,3] *[1]Inst of Metabolomic Medicine, Univ of California, San Diego, La Jolla, CA; [2]Center for Renal Translational Medicine, Univ of California, San Diego, La Jolla, CA; [3]Veterans Affairs San Diego Healthcare System, La Jolla, CA; [4]MS Imaging Dept, ImaBiotech, Lille, France; [5]Therapeutic Discovery Mass Spectrometry Center, Skaggs School of Pharmacy and Pharmaceutical Sciences, Univ of California, San Diego, La Jolla, CA.*

Background: AMPK is a master cellular energy sensor that is activated in states of caloric depletion (high AMP/low ATP). Although renal AMPK activity is reduced in the kidney from humans with diabetic kidney disease (DKD) and in mouse models of DKD, the basis for the reduced AMPK activity is unclear. As it is difficult to quantitatively and spatially assess ATP and AMP in tissues ex vivo, we applied MALDI mass spectrometry imaging (MALDI-MSI) to localize AMP and ATP in intact kidney compartments.

Methods: Kidney tissues were obtained from 23 weeks-aged male diabetic Akita (C57BL/6J-Ins2Akita) mice and age-matched C57BL/6J control mice (n=3/group). Snap frozen kidneys were embedded in CMC and sectioned, and then thaw mounted onto an ITO glass slide. MALDI-MSI was performed in negative ion mode using a SolariX MALDI-FTICR 7.0T Mass Spectrometer and data were processed using Quantinetix™.

Results: ATP and AMP were widely distributed in the normal kidney glomerulus and tubules under standard spatial resolution. Quantitation and visualization of these analytes specifically in the glomerular compartment of control and diabetic kidneys were achieved by analysis under high-special resolution (30 μm). Importantly, relative abundance of AMP and ATP were significantly reduced by 62% and increased by 58%, respectively, in the glomeruli of diabetic mice versus control mice ($p< 0.01$).

Conclusions: Using high resolution MSI we demonstrate for the first time that the AMP/ATP ratio is markedly reduced in intact diabetic glomeruli in mice with type 1 diabetes. MALDI-MSI can provide novel spatial metabolite insights and will be a useful tool for investigating the basis for biochemical processes in kidney disease.

Pathological Angiogenesis in Diabetes Is Regulated by Slit2 and its Robo Receptors

Ahmad Mohammad Omar Sidiqi, Stephen G. Szeto, Mingliang Lu, Lauren Yuk-Sum Chan, Krystale A. De Freitas, Maya Deeb, Lisa Robinson, Darren A. Yuen. *Univ of Toronto.*

Background: Diabetes is the leading cause of kidney failure in the United States. A hallmark of this disease is glomerular endothelial injury, where pathological angiogenesis contributes to hyperfiltration, a common feature linked to renal injury progression. No therapies safely target this process. Slit2 has emerged as a regulator of endothelial function, eliciting either pro- or anti-angiogenic effects through its Robo1 and Robo4 receptors respectively. **Objectives:** To examine whether Slit2-Robo signaling regulates high glucose (HG)-induced glomerular endothelial responses *in vitro* and *in vivo.*

Methods: Glomerular endothelial cell (GEC) expression of Slit2, Robo1, and Robo4 was examined under normal glucose (NG) or HG conditions *in vitro*, and *in vivo* in two models of diabetic nephropathy (db/db mice, streptozotocin (STZ)-induced diabetic Wistar rats). GEC responsiveness to VEGF in tube formation and migration assays was examined under both NG and HG conditions. The effects of Robo4 deficiency (Robo4 knockout mice) and Slit2 administration (2 μg thrice weekly i.p. injections) on diabetes-induced glomerular angiogenesis and hyperfiltration were also analyzed.

Results: While healthy GEC expressed high levels of Robo4 and low levels of Robo1, Robo4 levels fell while Robo1 levels remained unchanged under HG conditions both *in vitro* and *in vivo*, leading to a reduction in the Robo4:Robo1 ratio. Slit2 protein levels were also reduced in rat glomeruli 3 wks after STZ-diabetes induction. These changes in expression of Slit2-Robo signaling components were accompanied by STZ-diabetes-induced glomerular capillary growth and hyperfiltration, both of which were attenuated by exogenous Slit2 administration. Four weeks post-STZ-induced diabetes, Robo4 KO mice kidneys demonstrated increased glomerular endothelial density compared with wild type controls.

Conclusions: Our data suggest that diabetic glomerular angiogenesis and hyperfiltration are promoted by a reduction in anti-angiogenic Slit2-Robo4 signaling, a change which can be overcome with Slit2 therapy. Our results illustrate the potential for Slit2 as a novel treatment for early diabetic nephropathy.

TH-PO465

Inhibition of ASK1/p38 Signaling Suppresses Diabetic Nephropathy in eNOS Deficient Mice

David J. Nikolic-Paterson,[1] Yingjie Han,[1] Frank Yuanfang Ma,[1] David G. Breckenridge,[2] Gregory H. Tesch.[1] *[1]Dept of Nephrology and Monash Univ Dept of Medicine, Monash Medical Centre, Clayton, Victoria, Australia; [2]Gilead Sciences, Foster City, CA.*

Background: Inflammation and oxidative stress induce injury via p38 and JNK signaling and play major roles in the development of diabetic nephropathy. Apoptosis signal-regulating kinase 1 (ASK1), an upstream mediator of p38 and JNK signaling, is activated by inflammatory cytokines and oxidative stress, suggesting that ASK1 may be a therapeutic target for diabetic nephropathy.This study examined whether blockade of ASK1 can prevent the induction and progression of diabetic nephropathy in hypertensive mice.

Methods: eNOS-/- mice were made diabetic by injections of streptozotocin (5x50mg/kg/day). Groups of diabetic eNOS-/- mice received ASK1 inhibitor (0.1% GS-444217 in food) given as either an early intervention (weeks 0-6 of diabetes) or late intervention after renal injury was established (weeks 6-13 of diabetes). Control diabetic and non-diabetic eNOS-/- mice received normal chow. Glomerulosclerosis was assessed on PAS-stained kidneys using a 0-4+ score.

Results: Early intervention with GS-444217 inhibited development of diabetic glomerulosclerosis (diabetic 2.2±0.3 versus treated diabetic 1.2±0.1; $p<0.001$), despite having no effect on albuminuria, ongoing hypertension or fasting blood glucose levels. Late intervention with GS-444217 reduced glomerulosclerosis (non-diabetic 0.6±0.1; diabetic 2.4±0.3 versus treated diabetic 1.9±0.2, $p<0.01$) and improved renal function relative to diabetic controls (serum cystatin-C μg/ml: non-diabetic 320±42; diabetic week 6,765±102; diabetic week 13,701±111 versus treated diabetic week 13, 526±93; $p<0.01$). In addition, kidney gene expression of markers of fibrosis (TGF-β1, PAI-1, collagen-1) and tubular injury (KIM-1) were reduced in treated mice ($p<0.05$). Furthermore, both early and late intervention resulted in a marked suppression of p38 activation in diabetic kidneys.

Conclusions: Intervention with an ASK1 inhibitor can halt the progression of diabetic nephropathy in eNOS-/- mice, which can be attributed to reduced activation of the ASK1/p38 signalling cascade in the kidney.

TH-PO466

Inhibition of Factor Xa with Rivaroxaban Ameliorates Proteinuria and Reduces Inflammatory Cytokines with Diminished Loss of Endothelial Glycocalyx in Diabetic Nephropathy

Anna Bertram, Joon-Keun Park, Torsten Kirsch, Nelly Shushakova, Putri Andina Agustian, Jan Menne, Hermann G. Haller. *Hannover Medical School, Clinic of Nephrology and Hypertension, Hannover, Germany.*

Background: Activated factor Xa(FXa) binds to protease-activated receptors PAR-1 and PAR-2 and may exert cellular function in the endothelium. We and others have shown that the endothelium (EC) and its glycocalyx surface layer (ESL) are important for the initiation of proteinuria and contribute to the early inflammatory changes in diabetic nephropathy. We therefore tested the hypothesis that (1) treatment with a FXa inhibitor prevents or ameliorates proteinuria and inflammatory changes in diabetic mice and (2) that this effect is mediated via endothelial mechanisms.

Methods: Streptozotocin -treated mice (STZ), db/db mice and controls received either sham or rivaroxaban RIVA (300 mg or 150 mg) before (prevention) or during hyperglycemia (intervention). After 4 and 8 weeks of hyperglycemia, the animals were analyzed. Urinary albumin was measured by ELISA. Immunohistochemistry was performed on cryostat or on paraffin sections. Gene and protein expression was analyzed by real-time qPCR and western blot analysis.

Results: Treatment with RIVA reduced the hyperglycemia – induced increase in proteinuria in both STZ and db/db mice. The hyperglycemia-induced reduction in heparansulfate expression and endothelial glycocalyx density was prevented by RIVA. The hyperglycemia-induced increase of Il-6, TNF-alpha and ICAM-1 was also reduced by RIVA treatment. Macrophage infiltration in the diabetic kidney was reduced by RIVA. Lastly, the increased pERK in diabetic glomeruli was diminished by RIVA.

Conclusions: In hyperglycemic mice thetreatment with the factorXa inhibitor rivaroxaban reduces albuminuria and has a significant anti-inflammatory effect. This effect seems to be mediated by a stabilization of the endothelial glycocalyx by rivaroxaban.

TH-PO467

Mitochondrial Protection Preserves Kidney Function in Swine Metabolic Syndrome

Alfonso Eirin,[1] Christopher M. Ferguson,[1] James Krier,[1] Kyra L. Jordan,[1] Stephen C. Textor,[1] Amir Lerman,[2] Lilach O. Lerman.[1] *[1]Divs of Nephrology and Hypertension, Mayo Clinic; [2]Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

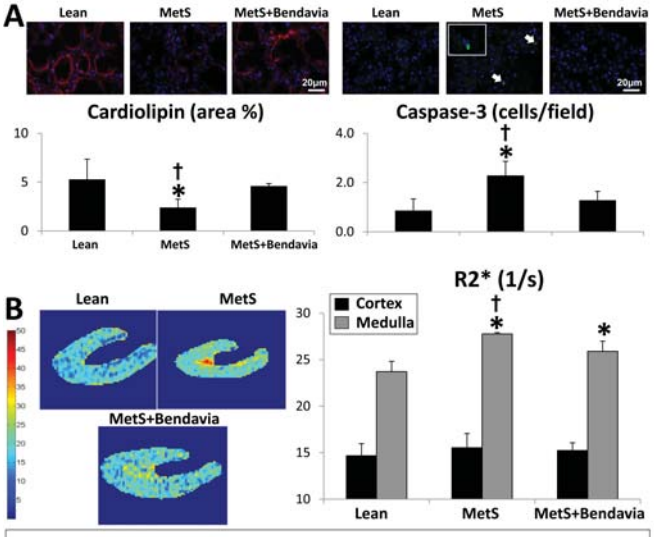
Background: The metabolic syndrome (MetS) induces kidney hyperfiltration, which may accelerate progression to chronic renal failure. Mitochondrial dysfunction might be associated with MetS, thus strategies aimed to preserve mitochondria may attenuate MetS-induced renal structural and functional injury. Bendavia™, a peptide targeting the mitochondria, is reno-protective in experimental ischemic nephropathy. We hypothesized that chronic treatment with Bendavia would attenuate hyperfiltration-elicited renal tissue injury and dysfunction in swine MetS.

Methods: Pigs were studied after 16 weeks of diet-induced MetS (n=6), MetS treated for the last 4 weeks with Bendavia (0.1mg/kg SC q.d, n=4), and Lean controls (n=6). Single-kidney renal blood flow (RBF) and glomerular filtration rate (GFR) were measured with multidetector CT, and oxygenation with BOLD-MRI. Mitochondrial cardiolipin content (nonyl acridine orange) and apoptosis (caspase-3) were assessed ex-vivo.

Results: Blood pressure was elevated in all MetS pigs, and their kidneys were larger compared to Lean. Regional RBF was relatively preserved, yet GFR was elevated in MetS, and medulla oxygenation fell. Bendavia normalized GFR in Bendavia-treated pigs (Table), restored cardiolipin content, decreased apoptosis, and improved medullary oxygenation (Figure).

Conclusions: Chronic treatment with Bendavia preserved mitochondrial cardiolipin, decreased apoptosis, attenuated glomerular hyperfiltration, and improved medullary oxygenation in MetS. These observations implicate mitochondrial damage in renal injury in experimental MetS, and suggest a potential role for Bendavia in preserving kidney function in MetS.

	Lean	MetS	MetS+Bendavia
Weight (kg)	70.0±4.5	93.2±1.0*	92.5±3.3*
Mean arterial pressure (mmHg)	101.3±3.9	124.2±4.0*	114.3±4.8*
Renal Volume (ml)	135.8±9.0	220.9±10.3*	228.5±14.1*
RBF (ml/min/cc of tissue)	3.8±0.3	3.9±0.3	4.0±0.6
GFR (ml/min/cc of tissue)	0.70±0.02	0.81±0.04*†	0.65±0.05



A: Fluorescent staining for cardiolipin (left, red) and caspase-3 (right, green) in renal tissue sections (DAPI=blue) showing restored cardiolipin expression and decreased apoptosis in Bendavia-treated pigs.
B: Blood oxygen level-dependent magnetic resonance imaging (BOLD-MRI) showing hypoxic regions (red), and quantification of the BOLD hypoxia index R2* in the cortex and medulla. *p<0.05 vs. Lean; †p<0.05 vs. MetS+Bendavia.

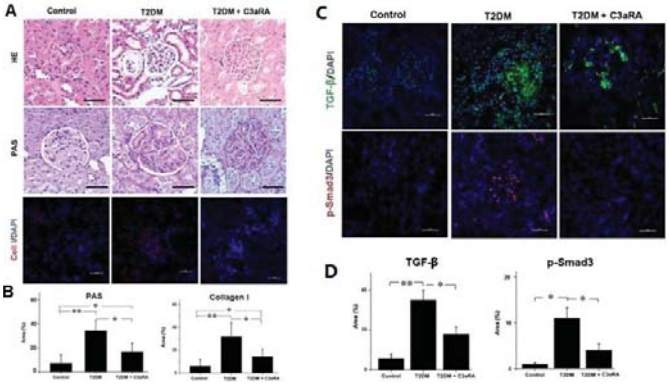
C3a Receptor Antagonist Ameliorates Fibrosis in Type 2 Diabetic Nephropathy By Suppressing the Activation of TGF-β/smad3 Pathway

Ping Fu, Ling Li, Fang Liu. *Div of Nephrology, West China Hospital of Sichuan Univ, Sichuan, China.*

Background: Diabetic nephropathy (DN) is a serious complication for patients with diabetes mellitus (DM). Emerging evidences suggested that complement C3a was involved in the progression of DN. The aim of this study was to investigate the effect of C3a Receptor Agonist (C3aRA) on DN and its potential mechanism in type 2 diabetes mellitus (T2DM) rats.

Methods: SD rat was induced T2DM by high fat diet (HFD) plus repeated low dose of streptozocin (STZ) injection. T2DM rats were treated with vehicle or C3aRA for 8 weeks. Biochemical analysis, HE and PAS stains were performed to evaluate the renal function and pathological changes. Human renal glomerular endothelial cells (HRGECs) were cultured and treated with normal glucose (NG), high glucose (HG), HG + C3a, HG + C3a + C3aRA and HG + C3a + SIS3 (Smad3 Inhibitor), respectively. Real-time PCR, immunofluorescent staining and western blot was performed to detect the mRNA and protein levels.

Results: T2DM rats showed worsened renal morphology and impaired renal function compared to control rats, including elevated levels of serum creatinine (CREA), blood urea nitrogen (BUN) and urine albumin excretion (UACR), as well as increased levels of C3a, C3aR, Collagen I, TGF-β and p-Smad3 in the kidney of T2DM rats and C3a-treated HRGECs. In contrast, C3aRA treatment improved renal function and morphology, reduced CREA, UACR and the intensity of PAS and collagen I staining in the kidney of T2DM rats, and decreased C3a, TGF-β, p-Smad3 and collagen I expressions in HRGECs and T2DM rats.



Conclusions: C3a mediated pro-fibrotic responses and therefore aggravated renal injury in T2DM rats. C3aRA ameliorated T2DN through inhibiting TGF-β/Smad3 signaling and ECM deposition. Complement C3a receptor was a potential therapeutic target for DN.

TH-PO469

PBI-4050 Protects against Diabetic Nephropathy in Type II Diabetes

Ming-Zhi Zhang, Raymond C. Harris. *Medicine, Vanderbilt, Nashville, TN.*

Background: Extensive kidney fibrosis occurs in several types of chronic kidney diseases such as severe diabetic nephropathy (DN). PBI-4050, a novel first-in-class orally active low molecular weight compound, has been shown to exhibit anti-fibrotic and anti-inflammatory properties in different *in vivo* models, including CKD models. Phase II clinical trials are underway to test its efficacy in patients with CKD and DN. In the present studies, we examined whether PBI-4050 affected the progression of DN in a mouse model of accelerated type II diabetes.

Methods: eNOS$^{-/-}$*db/db* mice received vehicle (water) or PBI-4050 (200 mg/kg/day) by gavage either from 8 to 20 weeks of age (early treatment) or from 16-24 weeks of age (late treatment). A subset of mice with late treatment was kept until death to achieve a survival curve.

Results: Early PBI-4050 treatment ameliorated the fasting hyperglycemia and abnormal glucose tolerance tests seen in vehicle-treated mice. In addition, PBI-4050 led to higher blood insulin levels (20 wks: 5.29 ± 1.10 versus 2.23 ± 0.42 ng/ml, $P<0.05$. n=4). Early PBI-4050 treatment preserved kidney function, indicated by higher glomerular filtration rate (GFR at 20 wks: 0.223 ± 0.024 (n=10) versus 0.132 ± 0.031 ml/min/mouse (n=5), $P<0.05$) and lower ACR (20 wks: 1537 ± 201 versus 2808 ± 541 μg/mg, $P<0.05$. n=9). PBI-4050 had no effect on blood pressure. Late PBI-4050 treatment had similar effects on glucose control and prevention of further increases in ACR. Late PBI-4050 treatment also led to increased longevity, with 7/8 PBI-4050-treated mice alive at 25 weeks of age versus only 2/8 in vehicle-treated mice. Both early and late PBI-4050 treatment protected against progression of DN, as indicated by reduced histological glomerular injury and decreased fibrosis and collagen I and collagen IV expression. PBI-4050 inhibited kidney macrophage infiltration, oxidative stress and TGF-β-mediated fibrotic signaling pathways but increased autophagy.

Conclusions: These studies suggest that PBI-4050 attenuates development of DN in type II diabetes through improvement of glycemic control and inhibition of renal TGF-β-mediated fibrotic pathways in association with decreases in macrophage infiltration and oxidative stress and increases in autophagy.

PPARalpha Inhibits the Canonic Wnt Pathway Through Regulating NOX4/ROS in Diabetic Nephropathy

Rui Cheng, Xuemin He, Jian-Xing Ma. *Dept of Physiology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Peroxisome proliferator-activated receptor alpha (PPARα) has displayed reno-protective effects in diabetic animal models. This study was to determine if the beneficial effects of PPARα on renal fibrosis are through suppressing the canonical Wnt pathway and to investigate the mechanism by which PPARα regulates the canonic Wnt pathway.

Methods: Streptozotocin (STZ)-induced diabetic PPARα$^{-/-}$ and age-matched wild-type (Wt) mice were used. Primary renal tubular cells were cultured from Wt and PPARα$^{-/-}$ mice. Reactive oxygen species (ROS) was measured using CM-H_2DCFDA. The extracellular domain deletion mutant of LRP6 (LRP6ΔN) and a point mutant of β-catenin (S37A) were used, both of which can activate the canonic Wnt pathway in the absence of Wnt ligand.

Results: Compared with diabetic Wt mice, diabetic PPARα$^{-/-}$ mice showed more severe proteinuria and prominent activation of the canonic Wnt pathway.The over-expression of PPARα using adenovirus (Ad-PPARα) significantly inhibited Wnt3a-induced increases of phosphorylated LRP6 levels and transcriptional activity of β-catenin. Ad-PPARα has no inhibitory effect on LRP6ΔN- or S37A-induced increases of transcriptional activity of β-catenin. LRP6 stability was decreased by the over-expression of PPARα and increased in PPARα$^{-/-}$ cells compared with Wt cells. We have reported that oxidative stress could activate the canonic Wnt pathway by stabilizing LRP6. ROS scavenger NAC dramatically inhibited Wnt3a-induced increases of phosphorylated LRP6 levels and transcriptional activity of β-catenin. Ad-PPARα significantly decreased 4-hydroxynonenal (4-HNE)-

induced ROS production. 4-HNE-induced ROS production was greater in PPARα$^{-/-}$ cells compared with Wt cells. Over-expression of NOX4, an important enzyme in ROS generation, significantly increased ROS levels and Wnt3a-induced transcriptional activity of β-catenin. Diabetic PPARα$^{-/-}$ mice showed more prominent NOX4 over-expression compared to diabetic Wt mice.

Conclusions: The inhibitory effect of PPARα on the canonical Wnt pathway is mediated, at least in part, through the destabilization of LRP6 and its antioxidant effect.

TH-PO471

Transcriptomic Analysis of Short Duration Endoplasmic Reticulum Stress on Renal Tubular Cells Michelle T. Barati,[1] Yan Zhang,[2] Eric C. Rouchka,[3] Michael Merchant.[1] *[1]Medicine, Univ of Louisville, Louisville, KY; [2]Neuroscience Training, Univ of Louisville, Louisville; [3]Computer Engineering and Computer Science, Univ of Louisville, Louisville.*

Background: Heat, oxidant, or endoplasmic reticulum (ER) stresses are known to induce assembly of ribonucleoprotein structures called stress granules (SG). SG's role is to salvage important proteins and RNA. We have shown diabetic nephropathy (DN) can affect renal SG formation and possibly though the Receptor for Activated C Kinase 1 (RACK1). We hypothesized that RACK1 expression may modify ER stress driven SG-scaffolding of RNA; some of which are relevant to DN.

Methods: Human proximal tubule cells (HK2) were transfected with GFP, GFP-RACK1, or GFP-dnRACK1 for 24hr, then treated with 0.5uM thapsigargin (Tg) or vehicle (DMSO) for 30min. Cells were lysed and 8-fractions isolated using density gradient ultracentrifugation (UC); then analyzed by (A) Agilent 2100 Bioanalyzer to characterize RNA size and quality, (B) immunoblot for SG marker proteins (TIA-1, G3BP), or GFP and. SG-enriched fractions were used for RNAseq analysis with a 50 bp single-end run on an Illumina GAIIx system at Cofactor Genomics (St. Louis, MO). Bioinformatics analysis was conducted by Kentucky Biomedical Research Infrastructure Network using Tophat and Metacore.

Results: Fractions 1-4 contained low MW RNA (no rRNA) and 2-3 contained SG markers (TIA1 or G3BP) and RACK1/dnRACK1 proteins. RNAseq analysis of fractions 1-3 show that Tg induced >2-fold changes (p-value <0.05) in 1,300-1,500 genes (lincRNA, antisense RNA, miRNA, and coding RNA transcripts) in each transfection condition. RACK1 transfection + Tg caused a 80+ fold increase in the coding RNA for CERCAM (ER luminal protein). dnRACK1 transfection +Tg caused a 300+ fold decrease in the coding RNA for KRAP (actin interacting protein regulating IP3R-mediated Ca++ release). The strongest difference for Tg+GFP transfections was increased coding RNA for histone H2 and H3 cluster variants.

Conclusions: ER stress and RACK1 overexpression can alter the HK2 transcriptome. Further work is needed to determine if these RNA are sequestered into SG. Metacore analysis suggests transcriptome changes may modify AMPK and PKA signaling pathways.

Chronic HIV Infection Aggravates Diabetic Kidney Disease through Suppression of Sirt1 and Increase of NF-κB and Stat3-Mediated Inflammatory Response Yifei Zhong,[1] Ruijie Liu,[2] John C. He.[2] *[1]Longhua Hospital, Shanghai Univ of Traditional Chinese Medicine, China; [2]Mount Sinai Medical School.*

Background: Our recent studies suggest that chronic HIV infection aggravates diabetic kidney disease in human and in mice. Recently, we found that Sirt1 is suppressed in diabetic patients and knockout of Sirt1 in podocytes promotes NF-κB and Stat3 acetylation leading to the activation of inflammatory genes. Thus, we liked to determine here whether chronic HIV infection aggravates diabetic kidney disease through suppression of Sirt1 expression and enhancing NF-κB and Stat3 acetylation and activation.

Methods: Sirt1 expression, NF-κB and Stat3 phosphorylation and acetylation, expression of NF-κB and Satt3 target genes were determined in podocytes infected with HIV with or without high glucose and in kidneys from HIV-1 transgenic mice with or without diabetes.

Results: HIV infection of podocytes suppressed Sirt1 expression and induced acetylation and phosphorylation of both NF-κB and Stat3. It also induced expression of NF-κB and Stat3 target genes. High glucose together with HIV infection induced further suppression of Sirt1 and activation of NF-κB and Stat3 target gene expression in podocytes. In Tg26 mice, Sirt1 expression was also suppressed and NF-κB and Stat3 acetylation was enhanced. Expression of NF-κB and Stat3-mediated pro-inflammatory genes was also increased. In HIV-infected diabetic kidney, there was an additive effect on the expression of NF-κB and Stat3-mediated pro-inflammatory genes in HIV-infected diabetic mice. And then we developed a new Sirt1 agonist which suppressed significantly Sirt1 activity and NF-κB and Stat3 acetylation. In vivo, we found that this Sirt1 agonist improves kidney injury in diabetic Tg26 mice.

Conclusions: These findings suggest that chronic HIV infection could aggravate diabetic kidney disease through suppression of Sirt1 and increase of NF-κB and Stat3 acetylation leading to activation of NF-κB and Stat3–mediated pro-inflammatory gene expression in diabetic kidney. Therefore, restoration of Sirt1 expression and inhibition of acetylation of NF-κB and Stat3 could be potential therapy for HIV-infected patients with diabetes.

Mice Transgenic for Apolipoprotein C1 Develop Proteinuria and Nodular Glomerulosclerosis Pascal Bus,[1] Rosalie Bor,[1] Jimmy F.P. Berbée,[2] Jan A. Bruijn,[1] Louis M. Havekes,[2] Emile De Heer,[1] Hans J. Baelde.[1] *[1]Dept of Pathology, Leiden Univ Medical Center, Leiden, Zuid-Holland, Netherlands; [2]Dept of Endocrinology and Metabolic Diseases, Leiden Univ Medical Center, Leiden, Zuid-Holland, Netherlands.*

Background: An association between an *APOC1* polymorphism and the development of diabetic nephropathy has been identified and confirmed in several meta-analyses.In this study we investigate the role of apolipoprotein (apo)C1 in the development of glomerular damage and the role of macrophages in this process.

Methods: Mice transgenic for human apoC1 (apoC1-tg mice) and control wild-type littermates were generated and sacrificed at various ages. Proteinuria was measured using dipstick analysis. Kidneys were sectioned and stained for apoC1, FA-11 (macrophages), WT1 (podocytes), collagen types I, IV and VI and fibronectin. The number of macrophages and podocytes in addition to the glomerular damage and glomerular hypertrophy, were scored. Correlations were assessed using the Pearson's correlation test.

Results: ApoC1-tg mice developed proteinuria (+ to ++) whereas all control mice were negative. Mesangial matrix expansion started at 13 months of age and progressed into nodular glomerulosclerosis at 15 - 16 months of age. Lesions consisted of collagen types I, IV and VI and fibronectin. The amount of podocytes per glomerulus was found to be decreasing with age. An increase of glomerular macrophages was observed at 15 weeks of age and continued to increase in time. These macrophages expressed high amounts of apoC1. There was a strong linear correlation between the number of podocytes, the number of macrophages, glomerular hypertrophy, glomerular damage and age ($P < 0.001$).

Conclusions: Our data demonstrated that apoC1-tg mice develop proteinuria and nodular glomerulosclerosis with increased accumulation of collagen types I, IV and VI and fibronectin in the extracellular matrix, similar to lesions found in patients with diabetic nephropathy. As the increase of apoCI-expressing macrophages in the glomerulus precede glomerular damage, these macrophages may play a crucial role in the development of glomerular damage in apoC1-tg mice.

TH-PO474

A Soluble Guanylate Cyclase Activator Protects from Diabetic Nephropathy in the ZSF1Rrat Paul Harrison, Hongxing Chen, Kathleen A. Lincoln, Hong Wang, Nicholas F. Brown, Holly Clifford, Hu Sheng Qian, Glenn A. Reinhart, Diane Wong, Christopher Sarko, John Ginn, Jehrod Brenneman, Todd Bosanac, Ryan M. Fryer, Jeremy G. Richman, Carine Boustany, Steven S. Pullen. *Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT.*

Background: Therapies which restore cyclic GMP levels within the kidney are hypothesized to slow disease progression. We evaluated the effect of BI 703704, a soluble guanylate cyclase (sGC) activator, on the progression of diabetic nephropathy.

Methods: BI 703704 was administered at 0.3, 1, 3 and 10 mg/kg/day to male ZSF1 obese rats for 15 weeks, during which mean arterial pressure (MAP), heart rate (HR), and urinary protein excretion (UPE) were determined. At term, histological assessments of glomerular and renal interstitial lesions were performed in addition to markers of myofibroblast activation (a-SMA) and tubular damage (KIM-1). Renal cyclic GMP (cGMP) levels were also quantified as a measure of target engagement.

Results: BI 703704 resulted in sGC activation as evidenced by dose-dependent increases in renal cGMP levels (Veh: 18 ± 2, BI 703704 at 0.3, 1, 3 and 10 mg/kg: 17 ± 2; 24 ± 3; 24 ± 2 and 29 ± 3 pmol/kg, respectively). sGC activation resulted in dose-dependent decreases in UPE (Veh: 463 ± 58, BI 703704 at 0.3, 1, 3 and 10 mg/kg, 328 ± 55; 339 ± 24; 258 ± 41 and 105 ± 26 mg/day, respectively). Importantly, these effects were accompanied by a significant reduction in the incidence of glomerulosclerosis (from 16% to 71% dose-dependently) and interstitial lesions (from 14% to 67% dose-dependently). Decreased expression of tubulo-interstitial a-SMA (66-68%) and KIM-1 (from 38% to 72%) was also observed following sGC activation. Decreased MAP (13.5 mmHg) and increased HR (26 bpm) were only observed at the highest dose of BI 703704.

Conclusions: These results support the efficacy of a sGC activator in preventing the progression of diabetic nephropathy. Importantly beneficial effects were observed at doses that did not significantly alter MAP and HR.

Nicotinamide n-Methyltransferase, an NAD Metabolic Enzyme, Protects Proximal Tubular Cells From Lipotoxicity Yuki Tanaka,[1] Shinji Kume,[1] Hisazumi Araki,[1] Masami Kanasaki,[1] Shin-Ichi Araki,[1] Daisuke Koya,[2] Masakazu Haneda,[3] Takashi Uzu,[1] Hiroshi Maegawa.[1] *[1]Medicine, Siga Univ of Medical Science, Otsu, Japan; [2]Diabetology and Endocrinology, Kanazawa Medical Univ, Kahoku, Japan; [3]Metabolism and Biosystemic Science, Asahikawa Medical Univ, Asahikawa, Japan.*

Background: Free fatty acid-bound albumin (FFA-albumin) filtered from glomeruli is reabsorbed in the proximal tubule cells (PTCs). Lipotoxicity induced by FFA-albumin may be one of the major causes of renal failure, especially in the diabetic condition. Nicotinamide adenine dinucleotide (NAD) metabolism has been focused as a therapeutic target for modern diseases. We examined the role of NAD metabolism in the renal lipotoxicity.

Methods: mRNA expression levels of 19 candidate enzymes were analyzed in the kidneys of a FFA-albumin-overload mouse model and cultured PTCs stimulated by FFA-albumin. The functional role of an identified enzyme was also examined.

Results: Of 19 enzymes, mRNA expression level of nicotinamide n-methyltransferase (NNMT) significantly increased in both the kidneys and cultured PTCs stimulated with FFA-albumin. NNMT-overexpressing cultured PTC was established using a retrovirus-mediated gene transfer system. Overexpression of NNMT inhibited FFA-albumin-induced apoptosis; determined by cleavage of caspase 3 and annexin-V-positive cells in FACS analysis. 1-methylnicotinamide (1-MNA) is the methylated product by NNMT. Intracellular 1-MNA concentration decreased in the kidneys and PTCs stimulated FFA-albumin, which was reversed by overexpression of NNMT. Supplementation of 1-MNA significantly inhibited FFA-albumin-induced apoptosis in cultured PTCs, and ameliorated apoptosis, inflammation determined by the expression levels of F4/80 and MCP-1, and fibrosis determined by the expression levels of fibronectin and PAI-1 in the kidneys of FFA-albumin-overload mouse model.

Conclusions: We identified NNMT as a novel enzyme that can reduce proximal tubular cell damage from lipotoxicity. NNMT and its metabolic product, 1-MNA, may become a new target to protect renal damage from lipotoxicity in diabetes.

Sulforaphane Protection from Diabetic Nephropathy Is Possibly Mediated by Increasing Nuclear Factor (Erythroid-Derived 2)-Like 2 Transcriptional Regulation of Metallothionein via Inhibition of Histone Deacetylase2 Activity Hao Wu,[1,2] Zhiguo Zhang,[2,3] Lili Kong,[1,2] Yangwei Wang,[1,2] Paul N. Epstein,[2,4] Lining Miao,[1] Lu Cai.[2,4] *[1]Nephrology, 2nd Hospital of Jilin Univ, Changchun, Jilin Province, China; [2]Pediatrics, Univ of Louisville, Louisville, KY; [3]Cardiology, 1st Hospital of Jilin Univ, Changchun, Jilin Province, China; [4]Pharmacology and Toxicology, Univ of Louisville, Louisville, KY.*

Background: Sulforaphane (SFN) prevents diabetic nephropathy (DN) via upregulation of nuclear factor (erythroid-derived 2)-like 2 (Nrf2) expression and function. However, how Nrf2 protects the kidney from diabetes remains unclear. Gene array analysis revealed that SFN drastically induced metallothionein (MT) which had been repeatedly reported to prevent DN; Reportedly SFN was able to inhibit histone deacetylases (HDACs) and HDAC inhibitor could up-regulate MT expression; Therefore, we hypothesize that SFN protects kidney from diabetes by inhibiting HDACs, which increases the acetylation level at and the occupancy of Nrf2 at the promoter of MT gene, to transcriptionally up-regulate MT expression.

Methods: Mouse model of type 2 diabetes was induced by high-fat diet followed with a single injection of STZ and were then treated with and without SFN for 4 months.

Results: Diabetic mice exhibited albuminuria, renal fibrosis, inflammation, and oxidative damage along with increased HADC activity, effects significantly alleviated by SFN treatment along with Nrf2 and MT upregulation. Mechanistically SFN significantly reduced the binding amount of HDAC2 at MT1 promoter, increased histone acetylation and Nrf2 levels at MT1 promoter in diabetic kidney, resulting in MT transcriptional up-regulation. Immunohistochemical staining of diabetic kidneys showed the same location of Nrf2 and MT expression predominantly in renal tubules with diabetes-induced oxidative damage, inflammation and fibrosis.

Conclusions: These results suggest that SFN-mediated up-regulation of Nrf2 followed by epigenetically transcriptional up-regulation of MT expression may play a critical role in its renal protection from diabetes.

TH-PO477

Peroxiredoxin 2 Deficiency Exacerbates Diabetic Nephropathy via an Induction of Inflammation, Apoptosis and Phenotype Transition of Renal Tubules Eun Sun Ryu, Hyun-Soo Shin, Hack Sun Choi, Kyu Bok Choi, Duk-Hee Kang. *Div of Nephrology, Ewha Womans Univ School of Medicine, Seoul, Korea.*

Background: Enhanced ROS generation is known to play a key role in the pathogenesis of DN. Peroxiredoxins (PRDXs) are the most recently identified family of antioxidant enzymes that catalyze the reduction reaction of peroxides, such as H_2O_2. Our preliminary study revealed an abundant expression of PRDX2 in renal tubular cells, which was up-regulated rapidly with an exposure to HG. We therefore investigated whether PRDX2 deficiency aggravated the progression of DN. Based on a growing body of evidence indicating the importance of renal tubular cells as a pro-fibrotic/inflammatory mediator in DN, we examined the role of PRDX2 on phenotype transition, inflammation and apoptosis of renal tubular cells.

Methods: Diabetes was induced by the injection of STZ in PRDX2 KO and WT mice. Renal functional parameters such as BUN, creatinine and albuminuria were measured with an assessment of renal pathology, inflammatory cell infiltration, apoptosis of tubular cells. In-vitro study was also conducted in NRK52E with an evaluation of phenotype transition, inflammatory markers and apoptosis under HG condition. Effect of PRDX2 gene silencing or overexpression was also investigated.

Results: PRDX2 deficiency in diabetic mice resulted in higher BUN, albuminuria and more accelerated interstitial fibrosis compared to WT mice despite a comparable hyperglycemia. E-cadherin in renal cortex of diabetic PRDX2 KO mice was decreased with an increase in α-SMA and apoptosis of renal tubular cells. NAC administration ameliorated functional and morphologic changes in diabetic PRDX2 KO mice. Interestingly, PRDX2 gene silencing decreased E-cadherin with an increased fibronectin and MCP-1 in NRK52E cells, which was further evident with HG. HG-induced alterations in E-cadherin, fibronectin and MCP-1 were alleviated with PRDX2 over-expression in NRK52E cells. HG-induced apoptosis was also ameliorated by PRDX2 over-expression.

Conclusions: PRDX2 is a key anti-oxidant enzyme which plays an important role in protecting the kidney against HG-induced inflammation, apoptosis and phenotype transition of renal tubular cells in diabetic nephropathy.

BMP7 Reduces Tubular Inflammation and Oxidative Stress in Diabetic Nephropathy Ruixi Li, Wai Han Yiu, Hao-Jia Wu, Dickson W.L. Wong, Loretta Y.Y. Chan, Miao Lin, Joseph C.K. Leung, Kar Neng Lai, Sydney C.W. Tang. *Div of Nephrology, Dept of Medicine, The Univ of Hong Kong, Queen Mary Hospital, Hong Kong, China.*

Background: Bone morphogenetic protein-7 (BMP7) has been reported to confer renoprotective effects in acute and chronic kidney disease models, but its potential role in type 2 diabetic nephropathy remains unknown.

Methods: Primary human proximal tubular epithelial cells (PTECs) were growth-arrested and exposed to glycated human serum albumin (AGEs) with or without BMP7. Nine-week-old db/db mice and their db/m littermates underwent uninephrectomy (Unx) or sham operation, and received BMP7 (300 μg/kg body weight) or vehicle intraperitoneally every other day for 8 weeks before sacrifice.

Results: In cultured human PTECs, exposure to AGEs induced overexpression of ICAM1, MCP1, IL-8 and IL-6, involving activation of p44/42 and p38 MAPK signaling. BMP7 dose-dependently attenuated AGE-induced upregulation of ICAM1, MCP1, IL-8 and IL-6 at both mRNA and protein levels. Moreover, BMP7 suppressed AGE-induced p38 and p44/42 MAPK phosphorylation and reactive oxygen species production in PTECs. Compared with vehicle control, Unx db/db mice treated with BMP7 for 8 weeks had significantly lower urinary albumin-to-creatinine ratio (3,549±816.2 μg/mg versus 8,612±2,037 μg/mg, p=0.036), BUN (33.26±1.09 mg/dL versus 37.49±0.89 mg/dL, p=0.006), and renal cortical expression of ICAM1 and MCP1 at both gene and protein levels. In addition, BMP7-treated animals had significantly less severe tubular damage, interstitial inflammatory cell infiltration, renal cortical p38 and p44/42 phosphorylation, and lipid peroxidation.

Conclusions: BMP7 attenuates tubular pro-inflammatory responses in diabetic kidney disease by suppressing oxidative stress and multiple proinflammatory signaling pathways including p38 and p44/42 MAPK. Its potential application as a therapeutic molecule in diabetic nephropathy warrants further investigation. *This study is supported by a General Research Fund of the Research Grants Council (Grant number: HKU7770/09M) of Hong Kong, and the National Basic Research Program of China 973 program no. 2012CB517600 (no. 2012CB517606).*

Pioglitazone Suppresses miR-124 Leading to Alleviates Dysfunction of Glomerular Endothelial Cells Induced By High Glucose Hui Peng,[1,2] Yuanqing Li,[1,2] Yan-Ru Chen,[1] Jun Zhang,[1] Meirong Zhong,[1] Tan-Qi Lou,[1] Zhaoyong Hu.[2] *[1]Nephrology Div, Dept of Medicine, The third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Nephrology, Dept of Medicne, Baylor College of Medicine, Houston, TX.*

Background: We previously reported that ROCK1 activation in glomerular endothelial cells (GEnCs) is one of the key mechanisms leading to diabetic nephropathy (DN). We also found that miR-124 was decreased in urinary sediment of DN patients, indicating the involvement of miR-124 in DN. According to bioinformatic analysis, ROCK1 contains in its mRNA 3'UTR the combining sites of miR-124. These findings led us to investigate the role of miR-124 in regulation of ROCK1 and the development of DN.

Methods: We assessed miR-124 expression in glomeruli of diabetic db/db mice and in patients with DN. We also examined how high glucose (HG) inhibits the expression of miR-124 in GEnCs, as consequence, leading to ROCK1 up-regulation and GEnCs dysfunctions including down-regulation of tight junction proteins and increased permeability in monolayer of GEnCs. Furthermore, we investigated how pioglitazone (PIO) promotes miR-124 expression and hence, suppressing ROCK1 activation and the development of DN.

Results: Using hybridization in situ, we found miR-124 expression decreased in glomeruli of DN patients, which was confirmed by SmartFlare miR-124 in the glomeruli of db/db and db/m mice, especially in endothelial cells. Meanwhile, HG decreased miR-124 in cultured GEnCs, accompanied with overexpression of ROCK1 protein but not mRNA. Redistribution of tight junction, and hyperpermeability of monolayer cells occurred under HG culture, all of which, however, were alleviated when miR-124 was overexpressed in GEnCs. Furthermore, PIO administration rescued HG-induced down-regulation of miR-124 as well as the dysfunctions of GEnCs.

Conclusions: our results show miR-124 decreased in the glomerular endothelia of DN, which is downregulated by HG. The downregulation of miR-124 results in ROCK1 up-regulation, and causes GEnC dysfunctions. The down-regulation of miR-124 can be rescued by PPAR-γ agonist Pioglitazone, providing a novel mechanism of preventing glomerular endothelial injury under DN.

Funding: Government Support - Non-U.S.

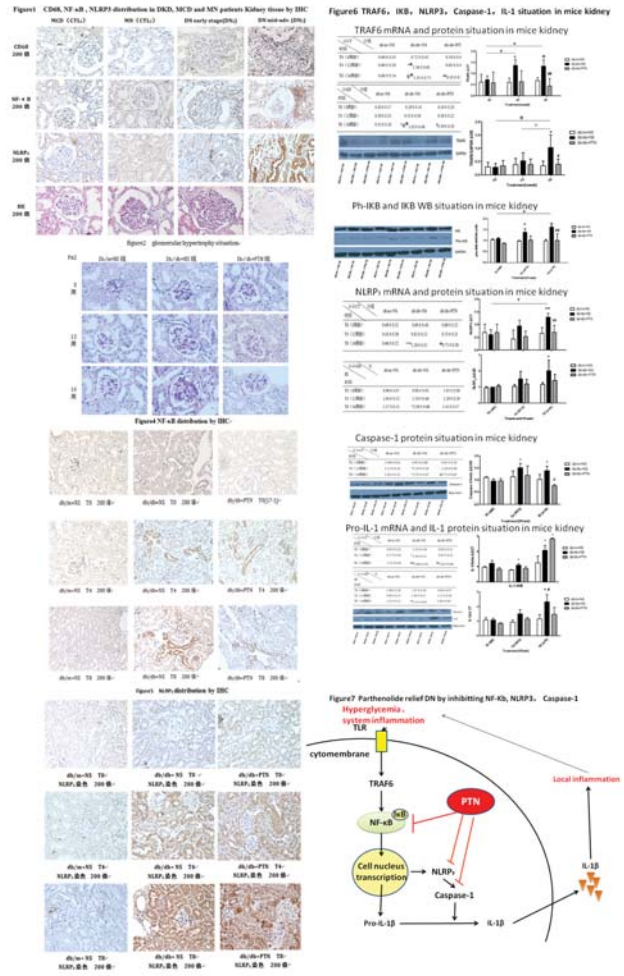
Diabetic Nephropathy (DN) or Diabetic Nephritis (DNs): Inflammasome, Existed in Both Kidney of DN Patients and db/db Mice, Was Rereduced by NF-κB Inhibitor and Therefore Ameliorated the DN

Xiao-Hu Shi,[1] Wei Qiu,[1] Qi Liu,[1] Hai-Yun Wang,[1] Jian-Ling Tao,[1] Xuewang Lee,[1] Chengyu Jiang,[2] Xue-Mei Li.[1] *[1]Dept of Nephrology, Pekin Union Medical College Hospital, Beijing, China; [2]Inst of Fundamental Research, Pekin Union Medical College, Beijing, China.*

Background: To confirm whether or not the NF-κB inhibitor parthenolide, could relief the DN through inflammasome and NF-κB.

Methods: Retrospective analysis 37 DN patients by kidney biopsy, in which 7 of them (DN1) showing only glomerular hypertrophy and the others (DN2) showed as middle-advanced stage. 10 MCD and 15 MN patients were taken as control. CD68, NF-κB and $NLRP_3$ inflammasome pathway were detected through IHC. Meanwhile, 42 eight weeks of age db/db mice and 15 db/m mice were used and divided into 3 groups: 1) db/m+saline (NS), 2) db/db+NS and 3) db/db+parthenolide (PTN). TRAF6—IκB—NF-κB and $NLRP_3$—Caspase-1—IL-1 were detected by IHC, WB, Rt-PCR and IHC at time point 0 week (T0), T4 and T8 respectively.

Results: Most of DN patients have a elevation of hsCRP (6.6±12.1mg/L) compared with MCD and MN patients. CD68 and NF-κB showed the positive result in DN1 group. While the $NLRP_3$ was found only in advanced stage DN2 group. In db/db mice, the level of urinary albumin, blood glucose, serum MCP-1, IL-6 and glomerular hypertrophy is significantly higher than db/m mice ($p < 0.05$). And the expression of TRAF6, ph-I-κB, NF-κB, $NLRP_3$, Caspase-1 and IL-1 (WB T0 1.07±0.20, T4 1.49±0.51, T8 2.33±0.83) increased in db/db mice. All these parameters got decreased after PTN (IL-1 WB T0 0.84±0.07, T4 1.15±0.18, T8 1.46±0.81) (in T8 $P<0.05$). PTN may ameliorate the kidney inflammations in db/db mice.



Conclusions: There was inflammation in both DN patients and db/db mice kidney. NF-κB pathway and $NLRP_3$ pathway were involved in. Parthenolide, the NF-κB inhibitor, could relief both the clinical and pathological characters of DN by these pathways.

High-Fat Diet-Induced Renal Disease Is Aggravated in Clusterin Deficient Mice

So-Young Park,[1] Jung-Yoon Heo,[1] Kyu-Hyang Cho.[2] *[1]Physiology, College of Medicine, Yeungnam Univ, Daegu, Republic of Korea; [2]Internal Medicine, College of Medicine, Yeungnam Univ, Daegu, Republic of Korea.*

Background: We examined the role of clusterin in high fat-induced renal disease in high fat-fed clusterin knockout (KO) and wild-type mice.

Methods: The Seven-week-old male C57BL/6 wild-type and the clusterin KO mice were fed a normal chow diet or a high-fat diet for 12 weeks. Kidney tissues were stained with periodic acid Schiff (PAS) for mesangial expansion and trichrome for collagen fibrosis. Gene expression was measured using real time polymerase chain reaction and protein levels were measured using Western blotting.

Results: Body weight and fat mass were increased in both wild-type and clusterin KO mice after being fed high-fat diet, but there was no difference between wild-type and clusterin KO mice. The plasma levels of lipid were increased by high-fat diet, but there was no difference between the two groups. However, triglyceride contents of the kidney were markedly elevated in the high fat-fed clusterin KO mice when compared with high fat-fed wild-type mice. High-fat diet increased mesangial area and tubulointerstitial fibrosis in both groups. Deficiency of clusterin in the high-fat group considerably increased mesangial matrix accumulation and tubulointerstitial fibrosis compared to the high fat-fed wild-type mice. Under a high-fat diet, clusterin KO mice exhibited a significant rise in urinary albumin-to-creatinine ratio, when compared with high fat-fed wild-type mice. The protein levels of clusterin in wild type mice were increased by high-fat diet. High-fat diet increased the gene expression of scavenger receptor A1 and lectin-like oxidized low-density lipoprotein receptor-1 in clusterin KO mice, but decreased peroxisome proliferator-activated receptor α and acyl-Coenzyme A oxidase compared with high fat-fed wild type mice. Proteins level of sterol regulatory element-binding protein and megalin were also significantly higher in high fat-fed clusterin KO mice than in high fat-fed wild-type mice.

Conclusions: These results suggest that clusterin may have protective effects on renal disease caused by high-fat diet.

TH-PO482

Decreased Autophagy Exacerbates the Development of Renal Hypertrophy and Diabetic Nephropathy

Zhengwei Ma, Zheng Dong. *Dept of Cellular Biology & Anatomy, Georgia Regents Univ, Medical College of Georgia, Augusta, GA.*

Background: Renal hypertrophy is an early characteristic of diabetic nephropathy (DN) that may contribute to the pathogenesis in DN. Autophagy is a cellular process of degradation of cytoplasmic contents, including dysfunctional organelles and proteins. Recent studies have suggested the dysregulation of autophagy in DN. However, role and regulation of autophagy in DN, especially in DN-related renal hypertrophy, is largely unknown.

Methods: In this study, autophagy was examined in kidneys of diabetic Akita mice and STZ-induced B6 mice, and in high glucose treated renal proximal tubular cells (RPTC). The role of autophagy was further examined by using proximal tubule-specific Atg7-deficient (PT-Atg7-KO) mice.

Results: Autophagy was shown to be suppressed in diabetic kidney tissues and in high glucose-treated tubular cells, which was accompanied by decreased expression of autophagy genes, such as LC3 I and LC3 II. In cultured renal tubular cells, autophagy inhibition by chloroquine induced hypertrophy. Both Akita and STZ-induced diabetic mice showed tubular hypertrophy, which was further exacerbated by the deletion of Atg7 from proximal tubules. Moreover, DN-associated renal tubular injury and apoptosis were significantly increased in PT-Atg7-KO mice.

Conclusions: The results indicate that autophagy is suppressed in DN. The suppression of autophagy contributes to tubular hypertrophy and subsequent kidney injury.

TH-PO483

The Role of NEPRILYSIN in Diabetic Nephropathy

Tomoko Obara,[1] Rebecca Powell,[1] Anil K. Singh,[2] Michael H. Elliott,[3] Hiroyuki Matsumoto,[2] Luan D. Truong.[4] *[1]Cell Biology, OUHSC, Oklahoma City, OK; [2]Biochemistry & Molecular Biology, OUHSC, Oklahoma City, OK; [3]Ophthalmology, OUHSC, Oklahoma City, OK; [4]Pathology, The Methodist Hospital and Baylor College of Medicine, Houston, TX.*

Background: Hyperglycemia is a manifestation of diabetes that leads to diabetic nephropathy, which progresses to end-stage renal disease that requires dialysis or kidney transplant. There is a critical need for new therapeutic approaches to preserve kidney function.

Results: Our recent data demonstrate that NEPRILYSIN is downregulated in kidneys in several models of diabetes, including mice and medaka fed a high fat diet (HFD) and rats treated with streptozotocin. Results were confirmed by proteomics, western blot, and subcellular immunohistochemical analysis. NEPRILYSIN is a membrane metallo-endopeptidase expressed in the glomerulus and apical membrane of proximal and distal tubules. It regulates peptides modulating lipid metabolism and glucose maintenance. Downregulation of renal NEPRILYSIN reduced levels of ANGIOTENSIN-(1-7). Subsequent treatment with TELMISARTAN, an ANGIOTENSIN II receptor blocker, restored angiotensin-(1-7) levels and modulated nephropathy and hyperglycemia induced by *NEPRILYSIN* knockdown in medaka. We also confirmed that NEPRILYSIN protein localization in human kidney sections is lower in kidneys from patients with diabetic

nephropathy than in kidneys from healthy patients. Moreover, we discovered that *NEPRILYSIN* knockdown in both mice and medaka adults resulted in diabetic nephropathy, and produced decreased kidney function in response to hyperglycemia.

Conclusions: These data support our hypothesis that NEPRILYSIN in the kidney is indispensable for preventing diabetic nephropathy and modulating hyperglycemia by maintaining a balance between ANGIOTENSIN-(1-7) and ANGIOTENSIN II. Our combination of an innovative discovery-based approach followed by genetic validation in adult animal models will provide mechanistic insight into the roles of NEPRILYSIN, and unveil the potential of new therapeutic approaches.

Chronic Nicotine Exposure Augments High Fat Diet-Induced Renal Oxidative Stress: Potential Relevance to Augmented Renal Lipotoxicity in Obese Smokers Istvan Arany, Samuel Hall, Dustin Reed, Mehul P. Dixit. *Pediatrics, Univ of Mississippi Medical Center.*

Background: Obesity and smoking are independent risk factors in development and progression of chronic kidney disease that involve free fatty acid (FFA)- and nicotine (NIC)-dependent induction of renal oxidative stress and consequent injury. However, the renal risk in obese smokers is elusive. In this work we tested the hypothesis that NIC exposure exacerbates high fat diet-associated renal oxidative stress in mice and in a corresponding in vitro model of proximal tubule cells.

Methods: 8-9-week-old male C57BL/6J mice had ad libitum access to either normal diet (ND: 13% kcal from fat) or high fat diet (HFD: 39.7% kcal from fat) and drinking water that contained either 2% saccharine (vehicle) or 200 mg/ml nicotine-bitartrate in 2% saccharine (NIC) for 12 weeks when markers of renal function (creatinine), injury (KIM1) and oxidative stress (HNE content, MnSOD expression) were determined. In vitro, renal proximal tubule cells (NRK52E) were treated with 100 μM oleic acid (OA) in the presence or absence of 200 μM NIC: ROS production, LDH release as well as promoter activity of MnSOD were determined.

Results: HFD increased body weight by 15±2.7 g versus 3.5±1.13. NIC did not affect this increase significantly but further augmented the already high circulating free fatty acid level in obese animals by 35%. Kidneys of HFD mice showed sign of oxidative stress (↑HNE) as well as injury (↑KIM) that were exacerbated by NIC (↑30 and 40%, respectively). HFD increased renal expression of MnSOD (5-fold), which was significantly attenuated (↓40%) in the presence of NIC. On the other hand, renal function (serum creatinine) remained normal. In vitro, NIC augmented OA-dependent mitochondrial ROS production and consequent mitochondrial depolarization/injury (↑50%) but suppressed OA-dependent induction of the MnSOD promoter (↓50%).

Conclusions: NIC augments renal oxidative stress and consequent injury by increasing FFA-dependent production of mitochondrial ROS and by inhibition of MnSOD transcription. Our results call attention to potential adverse effects of smoking/NIC use (NIC patches, E-cigarettes) on obesity-associated renal lipotoxicity.

Transgenic Mice Over-Expressing Human Gremlin Develop Higher Renal Damage in Experimental Diabetes Alejandra Droguett,[1] Vanessa Marchant,[1] Yenniffer Sanchez,[1] Graciela Valderrama,[1] Maria Eugenia Burgos,[1] Bredford Kerr,[2] Daniel Carpio,[1] Marta Ruiz-Ortega,[3] Jesus Egido,[3] Sergio A. Mezzano.[1] *[1]Nephrology, Univ Austral Valdivia, Valdivia, Los Rios, Chile; [2]Centro Estudios Cientificos, Valdivia, Los Rios, Chile; [3]Nephrology, Fundación Jiménez Díaz, Univ Autónoma, CIBERDEM, Madrid, Spain.*

Background: Gremlin is a glycoprotein that acts as a mediator of Transforming Growth Factor beta (TGF-β) profibrotic events. There is in vitro evidence that a high glucose level induces Gremlin expression in mesangial cells and it has been shown that allelic Gremlin depletion attenuates experimental diabetic kidney disease. Additionally, we have described that Gremlin is over expressed in biopsies from patients with diabetic nephropathy (DN), co-localized with TGF-β, suggesting a role for Gremlin in this nephropathy.

Methods: To study the *in vivo* role of Gremlin in DN, we developed a streptozotocin (STZ) diabetic model in transgenic mice expressing human Gremlin in proximal tubular epithelial cells. In this experimental model, the mice developed blood glucose between 300 and 500 mg/dl. The urinary albumin /creatinine ratio (ACR), determined at week 20 was significantly increased in the diabetic animals, however, no significant differences between transgenic (TG/STZ) and wild type (WT/STZ) mice were observed.To assess the level of kidney damage, renal tissue was analyzed by light microscopy (PAS and Masson staining), electron microscopy (EM) and qPCR.[/italic]

Results: At glomerular level, TG/STZ mice had significant thickening of the basement membrane, increased mesangial matrix and podocytopenia (WT-1 staining) versus WT/STZ mice. At tubulointerstitial level, TG/STZ animals showed increased cell infiltration (CD3, F4/80 staining) and mild interstitial fibrosis. Additionally, the molecular analysis demonstrated a significant decrease expression of podocin and increased expression of inflammatory and fibrosis markers (MCP-1, TGF-b 1, Col1a1, and α-SMA).

Conclusions: Together, these results show that transgenic mice overexpressing Gremlin develop higher diabetic renal damage and suggests that Gremlin plays a role in the development of glomerular and tubulointerstitial injury. FONDECYT 1120480.

Insulin Prevents Nuclear Factor Erythroid 2-Related Factor 2 (Nrf2)-Stimulation of Renal Angiotensinogen Gene Expression, Hypertension and Kidney Injury in Diabetic Mice Shaaban Abdo,[1] Anindya Ghosh,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang,[1] John S.D. Chan.[1] *[1]Research Center, CRCHUM, Univ of Montreal, Montreal, QC, Canada; [2]Res. Ctr, Maisonneuve-Rosemont Hosp., Montreal, QC, Canada; [3]Pediatr Nephrol Unit, Mass Gen Hosp., Boston, MA.*

Background: We previously reported that Nrf 2 stimulates renal angiotensinogen (Agt) gene expression in Akita mice. We tested whether insulin inhibits Nrf2 stimulation of renal Agt gene expression and thus prevent hypertension and kidney injury in Akita mice.

Methods: Male Akita mice were studied from 10-16 weeks of age with or without insulin implants from week 12. Age- and sex-matched non-Akita served as wild type (WT) controls. We performed insulin clamp studies in WT mice using constant intravenous insulin infusion (10 mU/min/kg) plus variable rate of glucose infusion to clamp glycemia at ~ 8 mM for 3 hours (euglycemic-hyperinsulinemic clamp). WT mice infused with saline served as controls. Kidneys were examined by light microscopy and immunohistochemistry were performed for Agt and Nrf2. Gene and protein expression in renal proximal tubules (RPTs) was evaluated by qPCR and immunoblotting, respectively.Immortalized rat renal proximal tubular cells (IRPTCs), stably transfected with rat Agt or Nrf2 gene promoter, were also studied in vitro.

Results: Treatment of Akita mice with insulin normalized blood glucose levels, hypertension and renal oxidative stress, inhibited renal Nrf2 and Agt geneexpression, attenuated renal hypertrophy, glomerular hyperfiltration and tubulointerstitial fibrosis. In WT mice subjected to euglycemic-hyperinsulinemic clamp, renal Agt and Nrf2 gene expression were down-regulated as compared to saline-infused mice. In vitro, insulin inhibited Nrf2 and Agt gene promoter activity induced by high glucose media via the p44/42 MAPK signaling pathway. Transfection with small interfering RNA of Nrf2 enhanced insulin inhibition of Agt gene promoter activity in IRPTCs.

Conclusions: Our data indicate that insulin prevents hypertension and attenuates kidney injury, at least in part, through suppressing Nrf2 stimulation of renal Agt gene transcription in Akita mice, independent of its glucose lowering action.

The Dysregulation of LDL Receptor Pathway Induced by Inflammation Contributes to Podocyte Injury in Diabetic Nephropathy Kun Ling Ma, Yang Zhang, Jing Liu, Wu Yu, Zebo Hu, Bi-Cheng Liu. *Inst of Nephrology, Southeast Univ, Nanjing City, Jiangsu Province, China.*

Background: Diabetic nephropathy (DN) is accepted as a chronic inflammatory disease and often accompanied with lipid disorder. Inflammation and lipid disorder play crucial roles in synergistically accelerating the progression of DN. This study aimed to investigate the potential mechanisms of inflammation with lipid disorder in podocyte injuries of DN via *in vivo* and *in vitro* studies.

Methods: Male non-diabetic db/m mice and diabetic db/db mice were randomly divided into four groups: db/m, db/m+casein, db/db, and db/db+casein for 8 weeks. Casein was subcutaneously injected to induce chronic inflammation. In in vitro study, podocytes were treated with cholesterol loading or IL-1β without or with high concentration of glucose. The levels of inflammatory cytokines in plasma and kidneys were checked by enzyme-linked immunosorbent assay and Western blotting. The renal pathology was checked by pathological staining and electron microscopy. Immunofluorescent staining and Western blotting were used to check the protein expressions of podocyte specific molecules, inflammatory cytokines, and low density lipoprotein receptor (LDLr) related molecules in kidneys.

Results: The kidney morphological changes, podocyte injuries, and epithelial mesenchymal transition (EMT) were more significant in casein-injected db/db mice compared to db/db mice and the control. Moreover, inflammation increased lipid droplet accumulation in kidneys of db/db mice, which was resulted from the increased protein expressions of LDLr, sterol regulatory element–binding protein (SREBP) cleavage activating protein (SCAP), and SREBP-2 in kidneys of db/db mice. In vitro studies further demonstrated that the inflammation increased lipid accumulation in podocytes and induced podocyte EMT, which were correlated with inflammation-mediated increased expressions of LDLr, SCAP, SREBP-2, and enhanced translocation of SCAP/SREBP-2 complex from endoplasmic reticulum to Golgi in podocytes.

Conclusions: Inflammation induced lipid accumulation and EMT of podocytes through the dysregulation of LDLr pathway, which contributed to podocyte injuries and accelerated the progression of DN.

Comparison of GLP-1 Analog versus DPP4 Inhibitor in the Acute Hemodynamic and Renal Effects Xiaoyan Zhou,[1] Chin-Hu Huang,[1] Julie Lao,[1] Alessandro Pocai,[1] Michael J. Forrest,[2] Olga Price,[2] Gail M. Forrest,[2] Sophie Roy,[1] David E. Kelley,[1] Kathleen A. Sullivan.[1] *[1]Dept of Cardiometabolic Diseases, Merck & Co., Kenilworth, NJ; [2]Dept of In Vivo Pharmacology, Merck & Co., Kenilworth, NJ.*

Background: Glucagon-like peptide 1 (GLP-1) analogs and dipeptidyl peptidase-4 (DPP4) inhibitors belong to a new class of anti-hyperglycemic agents known as incretin-based therapies that have shown beneficial effects on the cardiovascular system. However,

there is limited information on their renal effects. We compared the acute effects of a GLP-1 analog, liraglutide, versus a DPP4 inhibitor, MK-0626, on renal function and hemodynamic parameters in rats. Furthermore, we evaluated the GLP-1 dependent effects of MK-0626 by infusing GLP-1 to obtain varying sustained plasma levels of GLP-1 in an acute experimental paradigm.

Methods: Three ascending doses of Liraglutide (3, 9, and 27 nmol/kg) or MK-0626 (1 mg/kg) either alone or with GLP-1 (2.4, 4.8, or 9.6 pmol/kg/min) was administered to the rats. Blood pressure (BP) and heart rate (HR) were recorded from an indwelling catheter. Glomerular filtration rate (GFR) and renal blood flow (RBF) were assessed by Inulin and para aminohippurate clearance, respectively. Renal excretory function was assessed by urine collection from the bladder.

Results: Liraglutide or MK-0626 plus GLP-1 evoked significant diuretic (up to 7 fold) and natriuretic (up to 50 fold) responses and increased GFR (1.3~1.5 fold). The natriuretic and diuretic response evoked by Liraglutide was dose-dependent; MK-0626 plus GLP-1 caused natriuresis and diuresis that correlated with active plasma GLP-1 levels. MK-0626 either alone or with GLP-1 increased RBF (1.2~1.5 fold). The high dose of Liraglutide or MK-0626 plus a high dose of GLP-1 also increased HR (~7.5%), whereas BP was not affected.

Conclusions: Our results demonstrated that Liraglutide and MK-0626 may have beneficial effects on renal sodium and water handling; additionally, the DPP4 inhibitor favorably affected renal hemodynamics by increasing RBF. However, high doses of Liraglutide or supraphysiological levels of GLP-1 may adversely affect cardiovascular system by increasing HR.

TH-PO489

Dapagliflozin Ameliorates Diabetic Nephropathy by Oxidative Stress in Akita Mice Takashi Hatanaka, Daisuke Ogawa, Naoto Terami, Hiromi Tachibana, Naoko Nishii, Jun Wada, Hirofumi Makino. *Dept of Medicine and Clinical Science, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Recently, sodium glucose cotransporter 2 (SGLT2) inhibitors has been prescribed as a novel therapeutic approach for treating type 2 diabetes. SGLT2 inhibitors have been reported to be also effective for type 1 diabetes.

Methods: We examined the effects of Dapagliflozin (Dapa)on early stage of diabetic nephropathy using a mouse model of type 1 diabetes. We also investigated the protective effects of Dapa on cultured renal cells usingmurine proximal tubular epithelial (mProx24) cells. Four groups of male Akita and C57BL6/J mice were used in this study. Eight-week-old Akita mice were treated with 1.0 mg / kg Dapa or insulin for 12 weeks. Diabetic Akita control group and non-diabetic C57BL/6J control group were not treated. We measured blood glucose and adjusted insulin dose to maintain blood glucose levels as same as Dapa treated group.

Results: Compared with non-treated Akita mice, Dapa and insulin improved blood glucose, hemoglobin A1c (Dapa: 6.68±0.46%; insulin: 6.53±0.33%; non-treated: 9.18±0.63%; $p<0.05$), and urinary albumin excretion (Dapa: 22.6±6.5 μg / mgCr; insulin: 26.2±9.1 μg / mgCr; non-treated: 91.3±11.0 μg / mgCr; $p<0.05$). Urine volume and water intake were significantly increased in Dapa treated group compared with those in insulin treated group, but, there were no differences in body weight, creatinine clearance, and blood pressure between the two groups. Interstitial fibrosis and mesangial matrix accumulation were evaluated by histological analysis.Dapa and insulin inhibited interstitial fibrosis and mesangial matrix accumulation of the kidney. Oxidative stress was evaluated by dihydroethidium and NADPH oxidase 4 staining. Compared to insulin, Dapa improved oxidative stress. Moreover, Dapa suppressed oxidative stress in a dose-dependent manner in the flow cytometry with mProx24 cell. Oxidative stress was also decreased by knockdown of gene, when SGLT2 was inhibited by siRNA.

Conclusions: In conclusion, Dapa may ameliorates diabetic nephropathy by improving hyperglycemia along with inhibiting oxidative stress in Akita mice.

TH-PO490

Dapagliflozin AmelioratesGlucose Homeostasis and Diabetic Nephropathy in *db/db* Mice Naoto Terami, Daisuke Ogawa, Takashi Hatanaka, Hiromi Tachibana, Atsuko Nakatsuka, Naoko Nishii, Jun Wada, Hirofumi Makino. *Dept of Medicine and Clinical Science, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Inhibition of sodium glucose cotransporter 2 (SGLT2) has been reported as a novel therapeutic approach for treating diabetes. However, the effect of SGLT2 inhibitors on the kidney is unknown. In addition, whether SGLT2 inhibitors have an anti-inflammatory or antioxidative stress effect is still unclear. To resolve these issues, we evaluated the effects of the SGLT2 inhibitor, dapagliflozin, using a mouse model of type 2 diabetes and cultured proximal tubular epithelial (mProx24) cells.

Methods: Eight-week-old male *db/db* mice were treated with 0.1 or 1.0 mg/kg of dapagliflozinfor 12 weeks. Body weight, blood glucose, hemoglobin A1c, urinary albumin excretion, creatinine clearanceand blood pressure were measured. Mesangial matrix accumulation andinterstitial fibrosis in the kidney and pancreatic β-cell mass were evaluated by histological analysis. Furthermore, gene expression of inflammatory mediators, such as monocyte chemoattractant protein-1, transforming growth factor-β and osteopontin, was evaluated by quantitative reverse transcriptase-polymerase chain reaction. In addition, oxidative stress was evaluated by dihydroethidium and NADPH oxidase 4 staining.

Results: Administration of 0.1 or 1.0 mg/kg of dapagliflozin ameliorated hyperglycemia, β-cell damage and albuminuriain *db/db* mice. Serum creatinine and blood pressure were not affected by administration of dapagliflozin, but glomerular mesangial expansion and interstitial fibrosis were suppressed in a dose-dependent manner. Dapagliflozin treatment markedly decreased macrophage infiltration and the gene expression of inflammation and oxidative stress in the kidney of *db/db* mice. Moreover, dapagliflozin suppressed the high-glucose-induced gene expression of inflammatory cytokines and oxidative stress in cultured mProx24 cells.

Conclusions: These results demonstrate that dapagliflozin ameliorates diabetic nephropathy by improving hyperglycemia along with inhibiting inflammation and oxidative stress in *db/db* mice.

TH-PO491

Oral Treatment with PBI-4547, a Novel First-in-Class Anti-Diabetic and Anti-Fibrotic Compound, Improves Blood Glucose Level and Kidney Function in the Diabetic db/db Mouse Model Lyne Gagnon, Kathy Hince, Liette Gervais, François Sarra-Bournet, Mikaël Tremblay, Marie-Pier Cloutier, Shaun Abbott, Jean-Simon Duceppe, Boulos Zacharie, Pierre Laurin, Brigitte Grouix. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: Worldwide, 171 million people have diabetes, and a number of complications are associated with poorly controlled hyperglycemia. Diabetic nephropathy is one of the most common complications of diabetes. The aim of this study was to investigate the effect of PBI-4547 on blood glucose, insulin level, and kidney function in uninephrectomized (NX) diabetic (db/db) mice.

Methods: Total nephrectomy of the right kidney was performed on day 0 and animals were treated with vehicle or PBI-4547 (10 and 50 mg/kg, oral once a day) from day 1 through 103. Kidney function (GFR) and kidney mesangium lesions were examined.

Results: Blood glucose was significantly increased in NX-db/db mice (45 ng/ml) compared to NX-C57BL/6 mice (less than 10 ng/ml), but reduced, in a dose dependent manner, to the normal level in PBI-4547-treated NX-db/db mice (4-7 ng/ml). Insulin secretion level was reduced overtime in the NX-db/db mice, this insulin secretion loss was reversed with the treatment with PBI-4547. Furthermore. glucose/insulin ratio was significantly reduced to normal level with PBI-4547 treatment. Blood triglyceride level was also reduced to normal level in PBI-4547-treated NX-db/db mice. Kidney function assessed by GFR (inulin clearance) was significantly reduced in NX-db/db mice and significantly increased with PBI-4547 treatment. Db/db mice had larger glomeruli with increased mesangial matrix as shown by periodic acid-Schiff staining.Mesangium lesions scores were significantly reduced in NX-db/db mice treated with PBI-4547.

Conclusions: Taken together, these results suggest that PBI-4547 offers the potential as a novel therapy for regulation of glucose metabolism and reduction of diabetic nephropathy.

TH-PO492

Acceleration of Diabetic Nephropathy Progression in Mice via Renin AAV Delivery Shannon Marie Harlan, Matthew D. Breyer, Josef G. Heuer. *Biotherapeutic Discovery Research, Eli Lilly and Company, Indianapolis, IN.*

Background: Progress in the development of novel therapies for diabetic nephropathy (DN) has been hampered by the lack of a mouse model that completely mimics human DN. Available mouse models of DN typically lack hypertension, exhibit early changes of DN and fail to progress to end stage renal disease (ESRD). We hypothesize that inducing hypertension on diabetic models will drive progression to ESRD.

Methods: An adenoviral associated virus (AAV) that expresses mouse renin 1d (ReninAAV) was administered via retro-orbital injection on type 1 (Akita) and type 2 (db/db) diabetic models. Arterial pressure was measured by tail-cuff plethysmography. Mice were followed for 3 months post injection and kidney disease progression was monitored by weekly urine ACR (albumin creatinine ratio) and measurement of serum creatinine and kidney pathology at necropsy.

Results: In all studies, the effects of ReninAAV on arterial pressure and ACR were seen within a week and persisted for the 3 months of study (end point values for all parameters shown versus LacZAAV control). Akita/B6 mice injected with ReninAAV developed elevated arterial pressure (+33mmHg versus control), but not elevated ACR or serum creatinine, consistent with B6 mice being disease resistant. In contrast, Akita/DBA mice injected with ReninAAV had a 7.5x elevation in ACR and increased kidney pathology versus control. We further tested the ReninAAV on db/db or uninephrectomy (uNx) db/db mice. This resulted in significantly elevated ACR (11x db/db, 56x uNx db/db versus db/db controls) that translated into increased histopathology for tubular protein, interstitial inflammation and fibrosis, and glomerulopathy. ReninAAV on the db/db background appeared to be the best model, and uNx db/db mice had the most severe disease progression with increased ACR values (56,000μg/mg versus 3,467μg/mg), increased serum creatinine (0.16±0.01 versus 0.13±0.01, $p<0.04$) and interstitial fibrosis scores (2.4±0.2 versus 1.0±0.0) as compared to control uNx db/db.

Conclusions: These data support the conclusion that renin driven hypertension contributes to the progression of diabetic nephropathy in mice and is influenced by genetic background.

TH-PO493

IFN-gamma Plays an Important Role in the Progression of Diabetic Nephropathy Akiko Sato, Saori Nishio, Tatsuya Atsumi, Daigo Nakazawa. *Dept of Medicine II, Hokkaido Univ School of Medicine, Sapporo, Hokkaido, Japan.*

Background: Type 2 diabetes is the most frequent type of diabetes, and the increasing prevalence of diabetic nephropathy worldwide is a major societal issue because of the enormous expense associated with kidney replacement therapy. It has been reported that inflammatory cytokines, mainly IL-6, and IL-18 and TNF-α, are involved in the development and progression of diabetic nephropathy. IL-18 is a potent pro-inflammatory cytokine capable of inducing IFN-gamma production by TH1 cells. We hypothesized that IFN-gamma is one of the key cytokine in the progression of diabetic nephropathy. We examined the effects of IFN-gamma in experimental diabetic nephropathy.

Methods: We created IFN-gamma$^{-/-}$·db/db mice by crossing IFN-gamma$^{-/-}$ mice with db/m mice. IFN-gamma$^{-/-}$·db/db mice as the experimental group were compared with IFN-gamma$^{-/-}$·db/db mice as the control group. Body weight, blood glucose and urinary albumin/creatinin ratio (UACR) were determined from 8 weeks of age up to 24weeks of age every 4 weeks. Mice were sacrificed at 24weeks of age and samples of kidney tissue were taken for pathological analysis. The kidney tissues were stained with Periodic acid-Schiff (PAS) stain. We analyzed the proportion of mesangial area per a glomerulus. We performed Elastica-Masson staining to assess degree of interstitial fibrosis.

Results: Blood glucose levels were in excess of 300mg/dl in all of mice. At 24 weeks of age, there were no significant differences in body weights. There were significant differences in UACR ($p<0.01$), 1357.0±406.2 versus 875.8±552.3 mg/g·Cre at 24weeks of age. The proportion of mesangial area were 0.208 ± 0.02 in IFN-gamma$^{+/+}$·db/db mice, 0.164± 0.03 in IFN-gamma$^{-/-}$·db/db mice ($p<0.01$). Interstitial fibrosis was noted in IFN-gamma$^{+/+}$·db/db mice (2.78 ± 0.75%) and IFN-gamma$^{-/-}$·db/db mice (1.85 ± 0.68%). It was significantly decreased in IFN-gamma$^{-/-}$·db/db mice ($p<0.05$). The renal pathological changes in IFN-gamma$^{-/-}$·db/db mice were significantly attenuated compared with IFN-gamma$^{-/-}$·db/db mice.

Conclusions: IFN-gamma$^{-/-}$·db/db mice had less severe diabetic nephropathy. IFN-gamma may play the important role in the pathogenesis and progressions of diabetic nephropathy.

TH-PO494

Knockout (KO) of TRPC6 Attenuates Kidney Disease in Diabetic Akita Mice Liming Wang, Robert F. Spurney. *Medicine, Duke Univ and Durham VA Medical Centers, Durham, NC.*

Background: Diabetic nephropathy (DN) is the most common cause of end-stage kidney disease in developed countries (ESKD). As a result, much effort is directed at identifying new treatment strategies. Accumulating evidence suggests that the calcium-activated phosphatase calcineurin (CN) plays a key role in DN. An important source of enhanced intracellular calcium levels is the transient receptor potential channel C6 (TRPC6). Indeed, gain-of-function mutations in TRPC6 that induce sustained elevations in intracellular calcium cause familial forms of focal segmental glomerulosclerosis (FSGS). Moreover, the AT1 receptor for angiotensin II actives TRPC6 and blockade of AT1 receptors is an established treatment for DN.

Methods: We investigated the effect of TRPC6 KO on diabetic kidney disease in a mouse model of type 1 diabetes mellitus (male FVB/NJ Akita mice).

Results: Wild type (WT) and KO Akita mice had similar levels of hyperglycemia at 12 wks (482 ± 33 [WT Akita] versus 429 ± 23 [KO Akita] mg/dl; P = NS) and 16 wks of age (470 ± 17 [WT Akita] versus 444 ± 19 [KO Akita] mg/dl; P = NS). Systolic blood pressure was also similar at 12 wks of age (129 ± 8 [WT] versus 135 ± 3 [Akita] mm Hg; P=NS). Albuminuria was decreased in KO animals at 12 wks of age compared to WT Akita mice (233 ± 34 [WT Akita] versus 104 ± 16 [KO Akita] ug/24H; P=0.0012). A similar trend was observed at the 16 wk time point but the difference was not statistically significant (276 ± 45 [WT Akita] versus 205 ± 27 [KO Akita] ug/24H; P=0.16). To determine if the diabetic milieu activates CN, we measured mRNA levels of the CN target genes TRPC6 and regulator of CN 1 (RCAN1), using mRNA prepared from enriched glomerular preparations. Diabetes up-regulated both TRPC6 (1.51 ± 0.23 relative expression; P = 0.0342) and RCAN1 (32.3 ± 6.97 relative expression; P = 0.0041) compared to non-diabetic WT mice. KO of TRPC6 blocked the increase in RCAN1 (1.1 ± 0.39 relative expression; P = 0.0002).

Conclusions: These data suggest that TRPC6 plays a key role in the pathogenesis of diabetic kidney disease. Inhibition of TRPC6 is a promising target for the treatment of DN.

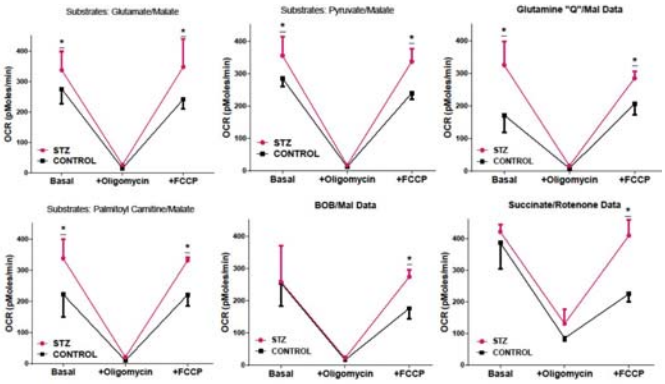
TH-PO495

Elevated Renal Mitochondrial and Proximal Tubule Oxygen Consumption in Early Diabetic Nephropathy Joanna Thomas, Scott C. Thomson, Prabhleen Singh. *Medicine-Nephrology, UC San Diego and VASDHS.*

Background: Diabetic nephropathy is the leading cause of ESRD. Early hypoxia despite an increase in renal blood flow and oxygen delivery has been described in early diabetic nephropathy. We investigated alterations in renal metabolism that may contribute to early hypoxia by examining renal mitochondrial function and tubular oxygen consumption in type 1 diabetes.

Methods: Rats were made diabetic with streptozotocin (STZ) and hyperglycemia was treated with daily insulin. Renal mitochondria and proximal tubules were harvested at 15 days following STZ. The utilization of different energy substrates by mitochondrial oxidative phosphorylation was measured via Seahorse Extracellular Flux Analyzer. Other functional and molecular analyses to evaluate oxidative metabolism and gluconeogenis were also performed. Data represents mean ± SEM.

Results: Basal and protonophore (FCCP) stimulated mitochondrial oxygen consumption were significantly increased for all substrate combinations aside from beta-hydroxybutyrate/malate and succinate/rotenone in diabetic rats (*$p<0.05$).



Ex-vivo proximal tubule oxygen consumption was also significantly increased in diabetic rats (378 ± 40 versus 264 ± 33 pmol O_2/min; $p \leq 0.04$). Renal expression of electron transport chain proteins (OxPhos Complex V-ATP Synthase, IV-1, and I-ND6) and gluconeogenesis proteins (PCK1 and FBP2) were significantly increased in diabetic rat kidneys supporting our renal oxygen consumption results ($p \leq 0.05$).

Conclusions: In early diabetes, there are significant alterations in renal metabolism including increased mitochondrial oxidative phosphorylation and renal gluconeogenesis which leads to increased tubular oxygen consumption. This likely contributes to the early hypoxia which has subsequent detrimental effects on renal function and morphology. Further investigations into therapeutic targets to reverse the metabolic phenotype are being conducted.

TH-PO496

Differential Regulation of Smad Signaling in Experimental Models of Diabetic Nephropathy Lise Thomsen,[1,2] Amaya Garcia de Vinuesa,[3] Troels Krarup Hansen,[2] Jenny Norlin, Emile De Heer,[5] Alexander Rosendahl,[1] Peter Dijke.[3] *[1]Diabetes Complications Biology, Novo Nordisk A/S, Måløv, Denmark; [2]Clinical Medicine – Dept of Endocrinology and Internal Medicine, Aarhus Univ Hospital, Aarhus, Denmark; [3]Molecular Cell Biology, Leiden Univ Medical Center, Leiden, Netherlands; [4]Translational Pharmacology, Novo Nordisk A/S, Malov, Denmark; [5]Pathology, Leiden Univ Medical Center, Leiden, Netherlands.*

Background: Diabetic Nephropathy (DN) is the leading cause of end-stage-renal-disease. In human DN, the development of glomerulosclerosis and tubulointerstitial fibrosis has been suggested to be driven by dysregulation of SMAD signalling by members of the TGF-β superfamily, which includes TGF-bs, activins and bone morphogenetic proteins (BMPs). Experimental models of DN do however not develop progressive renal disease. To identify potential novel therapeutic treatment modalities and improve translation to man, the TGF-β superfamily was evaluated in pre-clinical models.

Methods: Kidneys from db/db mice and streptozotocin induced SV129 mice were stained for H&E, PAS, Sirius red, pSmad1/5/8 and pSmad2, two downstream nuclear effectors of BMP and TGF-b/activin respectively. A transcriptional signature of 44 genes including TGF-β and BMP end-genes, BMP modulators, TGF-b-superfamily ligands and EMT markers was determined.

Results: Limited structural interstitial changes were present in the examined mouse models, except for dilation of distal tubules in the STZ mice. In these mice enhanced nuclear pSmad1/5/8 expression in glomeruli was observed, but in the whole kidney no concomitant regulation was noted on BMP target ID-1 gene level. A highly significant increase of nuclear pSmad2 expression was present in distal tubules in the STZ mice accompanied with an increased transcription level of TGF-β2 and activinA, as well as the TGF-β/activin target-gene PAI-1. By contrast db/db mice showed down-regulated pSmad2 expression in PTECs.

Conclusions: In early experimental DN where only minimal tissue remodelling occurs, nuclear pSmad2 was induced in distal tubules which correlated to dilated lumen of distal tubuli, upregulation of PAI-1, and increased transcription of TGF-β2 and activinA. Our results suggest that this pathway may provide novel therapeutic target opportunities in the treatment of DN.

TH-PO497

Translational Validation and Molecular Characterization of Progressive End Stage Renal Disease (ESRD) in Diabetic eNOS-/-;LepRdb/db Mice Zhonghua Qi, Martin S. Cramer, Dianna L. Jaqua, Yuan Su, Yan Ding, Bhaskarjyoti Sarmah, Shannon Marie Harlan, Josef G. Heuer, Matthew D. Breyer. *BioTDR LRL, Eli Lilly and Company, Indianapolis, IN.*

Background: Most studies of animal models of diabetic nephropathy (DN) focus on renal pathology and albuminuria (ACR) as experimental endpoints, however these are not accepted endpoints for clinical registration trials for DN which requires evidence for slowing renal function loss, measured by serum creatinine (S_{cre}). Preclinical discovery of

therapeutics that confer clinical benefits have been hampered by the absence of studies demonstrating similar endpoints can be used in mice with DN. The diabetic *eNOS$^{-/-}$;LepR$^{db/db}$* mouse exhibits robust albuminuria, renal histopathologic lesions of DN, and reduced inulin clearance. The purpose of the present studies was to determine the feasibility of detecting progressive loss of GFR reflected by increased S_{cre}, to be utilized as experimental endpointinstudies of *eNOS$^{-/-}$;LepR$^{db/db}$ mice.*

Methods: ACR and Enzymatic S_{cre} (mg/dl) were measured every 4 weeks for up to 16 weeks, in *eNOS$^{-/-}$;LepR$^{db/db}$* mice up to 28 weeks of age. Kidneys were analyzed for pathology and genome-wide mRNA expression (M430_2 chip).

Results: S_{cre} was highly correlated with FITC inulin clearance (r^2=0.70). In 259 *eNOS$^{-/-}$;LepR$^{db/db}$* mice a significant increase in S_{cre} from 0.12 to 0.18 was seen ($p<0.004$). A progressive increase in S_{cre} was observed in 77/259 mice (baseline 0.14±0.01 to final 0.35±0.03, $p<0.0001$). In the remaining 70% of mice S_{cre} did not increase (0.120±0.002 to 0.11±0.002). There was no difference in urinary ACR between these two groups. Baseline S_{cre} was significantly greater in progressors ($p<0.001$). Microarray mRNA expression showed that of 679 significantly changed genes, 575 overlapped with those reported to change in human DN (e.g.Smad3, NfKB, and EGFR/RAS/ATK/mTOR pathways) versus 104 genes discordant with human DN changes.

Conclusions: These findings underscore the similarity between renal failure progression in human DN and DN in *eNOS$^{-/-}$;LepR$^{db/db}$* mice. They further support the feasibility of testing therapies that slow the rate of creatinine increase in this model.

TH-PO498

Amelioration of Podocyte Injury by an Oral Adsorbent AST-120 in Metabolic Syndrome/Diabetes Rats Rieko Aoki, Fujio Sekine, Kaori Kikuchi, Shigeaki Miyazaki, Yusuke Yamashita, Yoshiharu Itoh. *Pharmaceuticals Div, Kureha Corporation, Tokyo, Japan.*

Background: Metabolic syndrome is known to be an important risk factor involved in the development of diabetic nephropathy which is a major complication of diabetes and the leading cause of end-stage renal disease. An oral adsorbent AST-120 has been used clinically as a medicine for patients with chronic kidney disease (CKD) to slow down the progression of CKD. However, there is little evidence to support therapeutic efficacy of AST-120 for early stage overt diabetic nephropathy. In this study, we aimed to assess the effect of AST-120 on SHR/NDmcr-cp rats, model rats of metabolic syndrome/ type 2 diabetes.

Methods: Male SHR/NDmcr-cp (SHR/ND) rats, aged 7 weeks, were divided into two groups. One group was administered 0% and the other group was administered 8% of AST-120 for 12 weeks in their diets. WKY rats were used as a normal control. At every 4 weeks, serum and 24-hour urine samples were collected for biomedical studies. We examined the podocyte foot process width (FPW) using Transmission Electron Microscopy as foot process effacement, and urinary podocalyxin by ELISA as podocyte injury. We also investigated the dose-response effect of AST-120 administered at 0%, 1%, 2%, 4% and 8% for SHR/ND rats.

Results: 8% AST-120-administered SHR/ND rats showed significantly lower levels of urinary protein excretion, urinary albumin excretion, urinary podocalyxin excretion and FPW compared to the unadministered SHR/ND rats. The FPW was significantly correlated with the levels of urinary protein excretion (r = 0.9498) and urinary albumin excretion (r = 0.9532). AST-120 reduced the urinary protein excretion and urinary albumin excretion in a dose-dependent manner.

Conclusions: The amelioration of podocyte injury by AST-120 may contribute to the reduction of proteinuria and albuminuria. These results indicate that the administration of AST-120 at an early stage of diabetic nephropathy would be beneficial to protect from the disease progression.

Involvement of Autophagy-Triggered Apoptosis in the Advanced Glycation End Products-Induced Renal Mesangial Cell Injury Chih-Kang Chiang,[1,2,3] Tien-Fong Lu,[1] Tzu-Ming Jao,[2] Jenq-Wen Huang,[2,3] Kuan-Yu Hung,[2] Shing-Hwa Liu.[1] *[1]Graduate Inst of Toxicology, National Taiwan Univ, College of Medicine, Taipei, Taiwan; [2]Dept of Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan; [3]Dept of Integrated Diagnostics & Therapeutics, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: There are 25-40 % of diabetic patients, who develop diabetic nephropathy (DN) within 20-25 years after the onset of diabetes. DN could lead to disability and high mortality rate in diabetic patients. Also, DN is the most common cause of end-stage renal disease (ESRD). It has been reported that the amount of advanced glycation end products (AGEs) in tissue of diabetic patients with ESRD is twice as much as diabetic patients without ESRD. Still, the influence of AGEs on renal glomerular mesangial cells remains unclear. Here, we investigated the effects of AGEs on the activation of autophagy and ER stress, which might influence the growth and function of mesangial cells.

Methods: Mouse mesangial cells (MMCs) were obtained from Food Industry Research and Development Institute. MMCs were treated with 10, 20, 40, 80 and 160 μg/ml AGEs to evaluate the cell viability by MTT assay and flow cytometry. The protein expressions were measured by Western blot assay. Furthermore, MMCs were treated with 3-Methyladenine (3MA), siATG5 and 4-phenylbutyric acid (4PBA) to study the influence of autophagy and ER stress.

Results: AGEs significantly decreased cell viability in a dose-dependent manner. And the result of flow cytometry indicated that the decreasing of cell viability might due to apoptosis. Further, AGEs induced the protein expressions of LC3-II, p-eIF2α, CHOP and caspase-3 in MMCs in a dose-dependent manner. Also, pre-treatment of 3MA reversed the decreasing of cell viability and treatment with 4PBA reversed the number of apoptotic cells. Finally, treatment with siATG5 reversed the protein expressions of LC3-II, p-eIF2α, CHOP and caspase-3. Therefore, knockdown of autophagy might reverse AGEs-induced ER stress and apoptosis.

Conclusions: These results indicated that autophagy-triggered and/or ER stress-triggered apoptosis is involved in the AGEs-induced MMCs injury.

Role of wnt/β-Catenin Signaling in Alsostertone Mediated Podocyte Injury in Experimental Obesity Related Glomerulopathy Jia-Jia Zhu, Jing Dong, Bo-Li Liu, Yang Min, Hong-Liang Rui, Hong Cheng, Yi-Pu Chen. *Div of Nephrology, Beijing Anzhen Hospital, Capital Medical Univ, Beijing, China.*

Background: To investigated role of aldosterone (ALD) in obesity-related glomerulopathy(ORG) and podocyte lesion and if wnt/β-catenin signaling was involved in such process.

Methods: 1. 24 male C57BL/6J mice were randomly divided into 3 groups (n=8) for 12w: control group (low fat diet), model group (high fat diet) and intervention group (HFD for 12w and spirolactone for last 4w). All mice were sacrificed at 12w, the serum, urine and renal tissue were collected and measured. 2. Cultured mouse podocytes (MPC) were divided into different groups with varieties of stimuli, The expression ofnephrin, podocin, podoplanin and podocalyxin of MPC were determined by real-time PCR and Western blots.

Results: 1. The model groups with HFD developed obesity and renal injury, including albuminuria, glomerular hypercellularity and higher tubule injury scores. Furthermore, the mRNA and protein expression of nephrin, podocin, podoplanin and podocalyxin in renal tissue were significantly down-regulated ($P<0.05$). Intervention with ALD receptor antagonist spirolactone could ameliorate HFD -induced obesity and renal injury.

2. Stimulation of ALD up-regulate expression of Wnt1, Wnt2b, Wnt6 in cultured podocyte and downo-regulated phosphorylatd beta-catenin. Intervention of EPL attenuated such effects. These changes also could be attenuated by Dickkopf-1(DKK1) ($P<0.05$). The mRNA and protein expression of nephrin, podocin, podoplanin and podocalyxin were significantly down-regulated ($P<0.05$) in ALD group; and these changes were attenuated by EPL and DKK1.

3. Expression of Wnt1, Wnt2b and Wnt6 were significantly increased in ORG model mice. Spironolactone therapy attenuated such effects.

Conclusions: ALD receptor antagonists can ameliorate HFD-induced obesity and renal injury in mice. ALD-induced podocyte injury is partially through activating Wnt/β-catenin signaling.

Coronary and Renal Vascular Function in Spontaneously Diabetic Leptin Deficient Mice Helena Westergren,[1,2] Julia Gronros,[3] Suvi E. Heinonen,[3] Tasso Miliotis,[3] Karin Jennbacken,[3] Alan Sabirsh,[3] Anette E. Ericsson,[3] Ann-Cathrine Jönsson-Rylander,[3] Sara Svedlund,[2] Li-Ming Gan.[1,2,3] *[1]Dept of Molecular and Clinical Medicine, Inst of Medicine, Univ of Gothenburg, Gothenburg, Sweden; [2]Dept of Clinical Physiology, Sahlgrenska Univ Hospital, Gothenburg, Sweden; [3]AstraZeneca R&D, AstraZeneca R&D, Molndal, Sweden.*

Background: Type 2 diabetes is associated with increased microvascular disease in man. Microvascular dysfunction affects both cardiac and renal function and is recognized as a main driver of cardiovascular risks. For further mechanistic understanding, there is need for validation of a relevant diabetic mouse model with coronary- and renal microvascular dysfunction.

Methods: A longitudinal study was performed in male diabetic C57Bl/6J-*lep^{ob}* mice (ob/ob) lacking atherosclerotic plaque formation, and lean controls. Cardiac echocardiography and coronary flow velocity reserve (CFVR) was measured at 10, 16 and 21 week of age by ultrasound Doppler technique. Renal blood flow velocity was measured prior to termination at 21 weeks of age and renal vascular resistance was assessed by resistivity- and pulsatility indexes. Cardiac and renal capillary density was evaluated histologically, and the nitric oxide-pathway investigated through plasma analysis of L-arginine and asymmetric dimethylarginine (ADMA).

Results: HbA_{1c} was increased in the ob/ob mice at all time points ($p<0.001$). CFVR was reduced in ob/ob mice at 16 (ob/ob: 2.0±0.4; lean: 2.6±0.5, $p<0.05$) and 21 weeks (ob/ob: 2.2±0.5; lean: 2.7±0.5, $p<0.05$) of age. Renal resistivity index (ob/ob: 0.81±0.04; lean: 0.69±0.06, $p<0.001$) as well as pulsatility index (ob/ob: 1.50±0.13; lean: 1.18±0.19, $p<0.001$) were higher in ob/ob mice. Plasma L-arginine was lowered in ob/ob mice (ob/ob: 1.2±2.2; lean: 5.5±2.2, $p<0.001$), while ADMA was unaltered. Furthermore, a significant decrease in renal capillary density was observed in the ob/ob mice ($p<0.05$).

Conclusions: Leptin-deficient ob/ob mice display cardio- and renal microvascular dysfunction in parallel with metabolic disturbances. This model appears suitable for translational mechanistic and interventional studies to further understand diabetic microvascular complications in type 2 diabetes.

Septin 7 and Nonmuscle Myosin IIA Compete for Binding to the SNARE Complex to Regulate Glucose Uptake into Podocytes Sanna H. Lehtonen,[1] Vincent Dumont,[1] Markku Lehto,[2,3] Christopher Fogarty,[2,3] Per-Henrik Groop,[2,3] Tuula A. Nyman,[1] Jukka Pekka Tienari,[3] Anita A. Wasik.[1] *[1]Univ of Helsinki, Finland; [2]Folkhälsan Research Center, Finland; [3]Helsinki Univ Central Hospital, Finland.*

Background: Podocytes are insulin responsive and can develop insulin resistance. However, the molecular mechanisms leading to the development of insulin resistance in podocytes are poorly characterized.

Methods: Protein-protein interactions were studied by co-immunoprecipitation and Duolink proximity ligation assay. Protein knockdowns were achieved by siRNAs. Glucose uptake was measured by 2-deoxy-D-glucose uptake assay, and immunohistochemistry was utilized for protein expression and localization analyses.

Results: We found previously that the small GTPase septin 7 is a negative regulator of glucose transporter trafficking in podocytes. Here we show that nonmuscle myosin IIA (NMHC-IIA) forms a complex with septin 7 and nephrin, and that depletion of NMHC-IIA by siRNA decreases insulin-stimulated glucose uptake into podocytes. Thus septin 7 and NMHC-IIA play opposite roles in glucose transport. Both septin 7 and NMHC-IIA interact with SNAP23, a plasma membrane component of the SNARE complex participating in the GLUT4 storage vesicle exocytosis. Overexpression and siRNA studies further indicate that septin 7 and NMHC-IIA compete for binding to SNAP23. Importantly, we found that depletion of septin 7 increases the complex formation between phosphorylated myosin regulatory light chain (pp-RLC) and SNAP23. Previous studies indicate that phosphorylation of RLC activates NMHC-II and thereby facilitates GLUT4 translocation and glucose uptake. We found that pp-RLC is upregulated in cultured human podocytes exposed to sera obtained from patients with type 1 diabetes with macroalbuminuria, and in the glomeruli of Zucker obese rats. Furthermore, immunohistochemical analysis revealed increased expression of pp-RLC in the podocytes of human patients with type 2 diabetes.

Conclusions: The data indicate that NMHC-IIA facilitates glucose transporter trafficking in podocytes. Activation of NMHC-IIA in podocytes in diabetes suggests that NMHC-IIA may play a role in the development of diabetic nephropathy.

MicroRNAs as Potential Targets in Diabetic Nephropathy Malte Kölling,[1,2] Joon-Keun Park,[2] Hermann G. Haller,[2] Thomas Thum,[1] Johan M. Lorenzen.[1,2] *[1]Inst of Molecular and Translational Therapeutic Strategies, Hannover Medical School, Hannover, Germany; [2]Dept of Medicine, Div of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

Background: MicroRNAs (miRs) are important mediators of diabetic nephropathy (DN). In addition, PKC-β loss is associated with amelioration of long-term complications of DN, including mesangial expansion and tubulointerstitial fibrosis. We aimed to identify PKC-β related microRNAs in the induction of DN and the potential of their therapeutic modulation to prevent diabetic nephropathy.

Methods: DN was induced by streptozotocin in PKC-β knock out and wildtype mice. Microarray analysis revealed several deregulated miRs. Mesangial cells (MC) and renal fibroblasts were subjected to high glucose (HG) and TGF-β treatment. PKC-β was activated by PMA. Ruboxistaurin inhibited PKC-β. The synthetic retinoid 11302 inhibited AP-1 and was analyzed by Luciferase Assay. Real time PCR and Western Blotting were performed. Electrophoretic mobility shift assay revealed transcriptional activation. Proliferation was examined by WST-1 Assay. Elevated miR-21 was silenced in vivo in streptozotocin-induced diabetic mice by locked-nucleic acid (LNA) treatment targeting miR-21.

Results: Several miRs, including miR-21, were upregulated in diabetic mice. In mesangial cells and fibroblasts, HG, TGF-β and PMA increased miR-21 and fibrotic gene expressions (all $p<0.05$). Ruboxistaurin normalized miR-21 levels ($p=0.001$) and CTGF ($p=0.05$) in MC, confirming PKC-β as key factor. AP-1 was activated by TGF-β. Inhibition of AP-1 rescued miR-21, CTGF- and Col1a2 upregulation (all $p<0.0001$) after TGF-β stimulation in MC, indicating AP-1 as a key transcriptional activator. TGF-β induced phosphorylation of AKT, ERK and GSK-3β. Overexpression of miR-21 resulted in both upregulated inflammatory genes, including Il-6 and MCP-1, and increased proliferation. MiR-21 was succesfully silenced in vivo by LNA-21 treatment.

Conclusions: This study elucidates a pathway including PKC-β and miRs. Interfering with this pathway results in less glomerular and interstitial injury. Thus, miRs are novel targets to ameliorate diabetic nephropathy.

TH-PO504

Identification of Novel microRNAs Regulating mTORC1-Dependent Proximal Tubular Cell Apoptosis in Diabetes Shogo Kuwagata,[1] Shinji Kume,[1] Hisazumi Araki,[1] Masami Kanasaki,[1] Shin-Ichi Araki,[1] Daisuke Koya,[2] Masakazu Haneda,[3] Takashi Uzu,[1] Hiroshi Maegawa.[1] *[1]Medicine, Shiga Univ of Medical Sciecne; [2]Medicine, Kanazawa Medical Univ; [3]Medicine, Asahikawa Medical Univ.*

Background: Proximal tubular cell (PTC) damage is associated with progressive renal dysfunction in diabetic nephropathy. Hypoxia from vascular damage is a cause of PTC damage. Cells have mechanisms to cope with hypoxia: inhibition of mTORC1 signal and activation of Hif1α transcriptional activity. Both mechanisms are also altered by diabetic stimuli such as hyperglycemia and free fatty acids (FFA). However, the effects of diabetic stimuli on hypoxic response in cells remains unclear.

Methods: We examined the effect of high glucose and FFAs on stress responses to hypoxia and apoptosis in cultured PTC, and identified novel microRNAs (miRNAs) regulating PTC apoptosis by diabetic stimuli.

Results: Hypoxia adaptively decreased mTORC1 signal and activated Hif1α transcriptional activity to protect PTC from apoptosis. Co-stimulation with high glucose and palmitate, a FFA, abolished hypoxia-induced inhibition of mTORC1 without affecting Hif1α activation, and induced apoptosis; determined by cleavage of caspase 3 and PARP, and TUNEL staining. Rapamycin, an mTORC1 inhibitor, and siRNA against Raptor, a critical component of mTORC1, inhibited co-stimulation-induced exacerbation of apoptosis from hypoxia. MicroRNAs regulate apoptosis. We thus conducted a miRNA microarray to identify novel miRNA regulating PTC apoptosis. Microarray analysis revealed five candidate miRNAs related to co-stimulation-induced exacerbation of apoptosis from hypoxia. Of these, miR-450a-5p and miR-3100-3p were upregulated and miR128-3p, miR148b-3p and miR-185-5p were downregulated. Transfection of inhibitor miRNAs against miR-450a-5p and miR-3100-3p did not influence apoptosis, but mimic miRNAs of miR128-3p, miR148b-3p and miR-185-5p significantly inhibited co-stimulation-induced exacerbation of apoptosis from hypoxia.

Conclusions: Diabetic stimuli impaired mTORC1-dependent cell adaptive mechanism against hypoxia, leading to apoptosis in PTCs. We identified novel miRNAs that can inhibit this process and may improve PTC damage in diabetes.

TH-PO505

Proximal Tubular Sodium Transporter Studies with Azilsartan Identified the New Pharmacological Cues Leading to Salt-Sensitivity Improvements Masaki Hatanaka, Satoko Yamamoto, Jun-Ya Kaimori, Hiromi Rakugi, Yoshitaka Isaka. *Dept of Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Azilsartan, the brand-new potent angiotensin receptor brocker (ARB), is reported to reduces blood pressure more strongly than candesartan and, interestingly, improve sodium sensitivity. However, the mechanism of those effects remain unclear. To explore the mechanistic insight of azilsartan effects, we examined the change in renal tubular sodium handling in mice with this drug.

Methods: 5/6 nephrectomized C57Bl6 mice were given high sodium diet and administrated orally azilsartan, candesartan, and vehicle. After 2 weeks, we examined blood pressure, sodium excretion, and renal sodium transporter protein expressions.

Results: Blood pressure decreased significantly in azilsartan group (93.9 ± 5.0mmHg) compared with candesartan (111.7 ± 2.7mmHg : $p<0.05$) and vehicle (129.7 ± 1.3mmHg:$p<0.0001$) groups. From the pressure-diuresis curve analyses, salt-sensitivity was improved in azilsartan group, but not in candesartan nor vehicle group. From immunohistochemistry and western blotting, the protein of sodium-proton exchanger 3 (NHE3), the major sodium transporter in the proximal tubule, decreased in azilsartan group, but not in candesartan nor vehicle group. However, the transcript level of NHE3 didn't decrease in azilsartan group. The other sodium transporters were not dramatically changed. The same results were obtained from opossum kidney (OK) proximal tubule cells experiments under angiotensin II loading. The farther study revealed that the azilsartan-induced decrease in NHE3 protein was partially regulated by proteasome but not by lysosome, suggesting the sodium sensitivity improvement by azilsartan was possibly through proteasomal NHE3 regulation.

Conclusions: Azilsartan, not candesartan, possibly improves salt-sensitivity by inhibiting NHE3 by increasing NHE3 proteasomal degradation. This new ARB mechanism could lead to new pharmacological cues about salt-sensitivity.

Abstract Withdrawn

TH-PO507

$GABA_B$ Receptor May Regulate the Translocation of AQP2 in the Renal Collecting Duct Kozue Takano,[1] Junichi Yatabe,[1,2,3] Midori Sasaki Yatabe,[1,3] Hironobu Sanada,[3] Tsuyoshi Watanabe,[3] Junko Kimura.[1] *[1]Dept of Pharmacol, Fukushima Med Univ, Fukushima, Japan; [2]Dept of CKD Initiatives, Fukushima Med Univ, Fukushima, Japan; [3]Dept of Nephrol, Hypertens, Diabetol, Endocrinol and Metab, Fukushima Med Univ, Fukushima, Japan.*

Background: Gamma-aminobutyric acid (GABA) induces diuresis/natriuresis and lowers blood pressure. However, its mechanism is unknown. We have shown $GABA_B$ receptor R1 and R2 subtype expressions in rat kidney. Water reabsorption in the collecting duct increases with vasopressin V2 receptor signaling coupled with Gs, which stimulates cAMP production and increases aquaporin 2 (AQP2) on the apical membrane. On the other hand, $GABA_B$ receptor is coupled with Gi/o. In this study, we examined whether $GABA_B$ receptor signal inhibits AQP2 expression and/or translocation through the inhibition of cAMP production.

Methods: To identify the localization of $GABA_B$ receptor protein expression, renal cortices of Wistar-Kyoto rats (WKY) were used for immunofluorescent staining. Expression levels of $GABA_B$ receptor R1 and R2 subtype messenger RNAs in Madin-Darby Canine

Kidney (MDCK) cells were examined by RT-PCR. Cyclic AMP assay was also performed using MDCK cells treated with arginine vasopressin (AVP)/ forskolin and GABA/ baclofen.

Results: $GABA_B$ receptor R1 subtype protein stained mainly in the arterioles and glomeruli in WKY. R2 subtype protein showed strong signal in the collecting duct. Costaining of $GABA_B$ receptor R2 subtype and AQP2 was observed on the apical side of principal cells. In MDCK cells, $GABA_B$ receptor R1 and R2 subtype mRNAs were expressed. Furthermore, the cAMP assay revealed that GABA tended to suppress cAMP stimulated by AVP. Additionally, $GABA_B$ receptor agonist baclofen significantly inhibited cAMP production pre-activated by forskolin (n=5, 67±26%, mean±SD, $p<0.05$).

Conclusions: These findings indicate the possibility that GABA signaling via $GABA_B$ receptor may inhibit the production of cAMP in the renal collecting duct and suppress the translocation of AQP2 to apical plasma membrane. This may in part be the mechanism of GABA-induced diuresis. Further analysis of $GABA_B$ and vasopressin receptor crosstalk in AQP2 regulation may elucidate novel regulatory mechanism in the kidney.

TH-PO508

Renal Mechanisms of Clozapine Induced Hypertension in Mice

Donghai Zhou, Laureano D. Asico, Hai Lin, Jun B. Feranil, Pedro A. Jose, Xiaoyan Wang. *Medicine, Univ of Maryland Medical School.*

Background: Dopamine receptor subtype 4 (D_4R) antagonist clozapine is used in the treatment of schizophrenia. A common side effect of clozapine is hypertension but the mechanism is unknown. D_4R plays an important role in blood pressure (BP) regulation; deletion of the D_4R gene in mice causes hypertension.

Methods: To determine if renal mechanisms are involved in clozapine-induced hypertension, we characterized the distribution of D_4R in mouse kidney and measured BP, water and sodium balance, and renal protein expression of sodium transporters in clozapine- and vehicle-treated mice.

Results: D_4R(immunocytochemistry) was mainly located in thick ascending limb, distal convoluted tubule and cortical and medullary collecting ducts; there is slight staining of D_4R in the proximal convoluted but not straight tubule. Clozapine(20mg/kg/day) or vehicle was delivered subcutaneously to adult male C57BL/6J mice for seven days via osmotic mini-pump(n=5/grp). Inclozapine-treated mice, systolic(110±0.5, mm Hg, under anesthesia) and diastolic(76.6±1) BPs were elevated, relative to vehicle-treated mice(SBP=97.6±1.6, DBP=69.5±2.3). Food and water intake, body weight, serum electrolytes and creatinine, urine volume, and creatinine clearance were similar in the two groups. Thesodium excretion tended to decrease while sodium excretion and BP plot in clozapine-treated mice was shifted to the right of the vehicle-treated mice. Renal protein expressions(immunoblotting) of sodium hydrogen exchanger 3 and sodium phosphate cotransporter 2 were similar in clozapine- and vehicle-treated mice. However, the expressions of sodium potassium 2 chloride cotransporter (180±21, % of control) and sodium chloride cotransporter(171±22%),and the three subunits of epithelial sodium channel, α(140±7%), β(166±21%) and γ(lower band,130±7%), were greater in clozapine- than vehicle-treated mice. α-sodium potassium ATPase expression was slightly increased(118±4%) in clozapine-treated mice.

Conclusions: These findings suggest that inhibition of D_4R by clozapine increases sodium transporters in distal nephron segments. This may cause the impaired sodium excretion that may be responsible for the increased blood pressure in clozapine-treated mice.

Funding: NIDDK Support

TH-PO509

A Role of Renal Megalin in Blood Pressure Regulation

Kasper Schmidt,[1] Vladimir V. Matchkov,[1] Boye Jensen,[2] Rikke Nielsen,[1] Erik I. Christensen,[1] Henrik Birn,[1] Kathrin Weyer.[1] *[1]Dept of Biomedicine, Health, Aarhus Univ, Denmark; [2]Cardiovascular and Renal Research, Univ of Southern Denmark, Odense, Denmark.*

Background: Megalin, a multi-ligand endocytic receptor abundantly expressed in the apical membrane of proximal tubule cells, is important for reabsorption of filtered proteins and peptides including ANGII which is essential for blood pressure (BP) regulation and sodium balance. Angiotensin type 1 and 2 receptors have been identified in the proximal tubule and have been implicated in regulation of proximal tubule sodium reabsorption. As elevations in the intrarenal content of ANGII have been associated with sodium retention and hypertension, we hypothesized that absence of megalin protects against ANGII-induced hypertension.

Methods: Using conditional megalin knockout (KO) mice and wild type (WT) littermate controls, we examined the effects on BP and renal sodium handling of genetic deletion of megalin in the kidney on a normal, low, and high sodium diet as well as under chronic ANGII infusion using osmotic minipumps. Blood pressure was recorded via telemetric probes and urines were collected in metabolic cages.

Results: At baseline, systolic BPs measured were significantly lower in megalin KOs compared to WT controls (111.8 mmHg versus 117.9 mmHg, n=16; $p<0.05$). The difference was greatest during night (115.8 versus 123.8 mm Hg; $p<0.01$). This was associated with increased urine output (1.9±0.38 versus 0.7±0.07 ml/24h/20gBW; $p<0.01$) and renal sodium excretion (177.5±11.6 versus 113.9±22.1 μmol/24H/20gBW; $p<0.05$) in megalin KO compared to WT. When fed a high salt diet, BP increased in both megalin KO and WT mice with a similar magnitude of BP difference between the groups. Chronic infusion of ANGII increased systolic BP in both groups, however, megalin KOs tended to have lower BP which was significantly lower than controls at several time points.

Conclusions: Loss of megalin in the proximal tubule is associated with lower baseline BP and increased renal sodium and water excretion. This is maintained both during sodium loading and ANGII infusion. Thus, megalin function may play a role in renal regulation of BP and provide a new target for intervention in BP modulation.

Preserved Expression of IRS2 Mediates the Stimulatory Effect of Insulin on Renal Proximal Tubule Sodium Transport in Insulin Resistance

Motonobu Nakamura, Osamu Yamazaki, Shoko Horita, Nobuhiko Sato, Hideomi Yamada, Masashi Suzuki, George Seki. *Internal Medicine, Tokyo Univ.*

Background: Insulin receptor substrate (IRS) 1 and 2 mediate distinct insulin signaling pathways. We have previously reported that while the IRS1-dependent stimulatory effect of insulin on glucose uptake into adipocytes is severely impaired, the IRS2-dependent stimulatory effect of insulin on renal proximal tubule (PT) sodium transport is completely preserved in insulin resistant rats and humans. In liver, transcription factors forkhead box class O (FoxOs) are major contributors to specific control of basal IRS2 gene transcription, whereas hyperinsulinemia in insulin resistance may suppress IRS2 expression by augmenting the expression of sterol regulatory element-binding protein (SREBP) 1. However, little is known about the regulatory mechanism of IRS2 expression in kidney.

Methods: We harvested liver and kidney cortex from Wistar rats that were either starved overnight or allowed to feed ad libitum and intraperitoneally injected with insulin (0.75 mU/g body weight) 2 hr prior to sacrifice, and Western blotting was performed to determine the protein expression levels of IRS2, FoxO1, and SREBP1. Quantitative RT-PCR was performed to determine mRNA expression of SREBP1c and IRS2 in liver and kidney in insulin resistant OLETF ratsand control LETO rats.

Results: In Wistar rats, feeding plus insulin markedly decreased the protein expression levels of IRS2 and FoxO1 by 65% and 62%, respectively, while it induced a massive increase in SREBP1 protein by 123% in liver. By contrast, feeding plus insulin did not affect the protein expression levels of IRS2, FoxO1, or SREBP1 in kidney cortex. Compared to LETO rats, OLETF rats showed enhanced expression of SREBP1c mRNA and decreased expression of IRS2 mRNA expression in liver. However, OLETF and LETO rats showed comparable expression of SREBP1c and IRS2 mRNAs in kidney cortex.

Conclusions: Unlike in liver, hyperinsulinemia failed to suppress IRS2 expression through SREBP1c-dependent negative feedback pathway in kidney cortex. The preserved expression of IRS2 in kidney cortex in insulin resistance may play an important role in hypertension associated with metabolic syndrome.

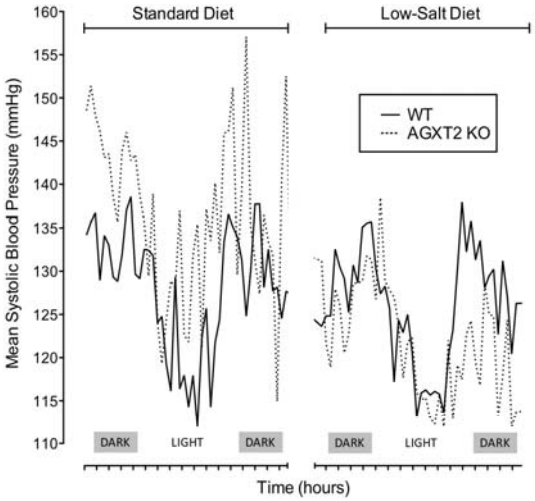
Disruption of Renal ADMA Metabolism Leads to Salt-Sensitive Hypertension

Ben Caplin,[1] David C. Wheeler,[1] James M. Leiper.[2] *[1]UCL Centre for Nephrology; [2]MRC Clinical Sciences Centre, London, United Kingdom.*

Background: Asymmetric dimethylarginine (ADMA) is an endogenous inhibitor of nitric oxide (NO) synthesis found at high levels in patients with CKD and is implicated in the associated increase in cardiovascular (CV) risk. Although increases in ADMA have been proposed to cause endothelial dysfunction this has not been demonstrated at the plasma levels of ADMA observed in CKD. As NO also regulates tubular sodium (Na) handling, ADMA could act via this mechanism. We have recently demonstrated that the tubular enzyme alanine-glyoxylate aminotransferase-2 (AGXT2) regulates circulating ADMA concentrations so we examined the detailed CV phenotype in AGXT2 knockout (KO) mice.

Methods: Renal histology was examined in AGXT2 KO and wild-type (WT) mice. *Ex-vivo* endothelial responses were explored. Telemetry probes were implanted in animals at ~12 weeks of age and after recovery continuous BP recordings performed for 48 hours after 2-weeks on a standard (0.3% Na) diet and again following 2-weeks of a low-Na (0.03%) diet.

Results: Serum ADMA levels were 0.2μMol/L ($P<0.05$) higher in AGXT2 KO versus WT mice. AGXT2 KO animals had morphologically normal kidneys and no evidence of impaired renal function. There was no *ex-vivo* evidence of impaired endothelial-dependent dilatation in aortas from AGXT2 KO mice. Mean systolic BP was 8.8mmHg ($P<0.05$) higher in AGXT2 KO versus WT mice at baseline. Overall systolic BP fell by a mean of 2.1mmHg ($P<0.005$) on a low-Na diet but there was an additional 7.3mmHg ($P<0.005$) fall in the AGXT2 KO mice (Figure).



Conclusions: Vessels from AGXT2 KO mice are functionally normal *ex-vivo*. The increase in BP seen with disruption of AGXT2 is entirely abrogated by a low-Na

diet suggesting that increased Na reabsorption may underlie ADMA-induced vascular dysfunction. Increasing renal tubular AGXT2 activity might represent a novel therapeutic strategy in CKD associated vascular disease.

New Candidate Genes for Salt Sensitive Hypertension Marco Simonini, Chiara Lanzani, Guido Gatti, Nunzia Casamassima, Lorena Citterio, Simona Pozzoli, Stefano Tentori, Paolo Manunta. *San Raffaele Scientific Inst, Milan, Italy.*

Background: Hypertension is an important public health problem affecting more than 60 million individuals in the U.S.A. alone. The most common form, salt sensitive hypertension (SSH), results from the complex interplay between genetic predisposition and environmental influences. Our aim is to identify new genes involved in SSH that explain the different individual variability of to a load/restriction of Na in the everyday diet.

Methods: A GWA study was performed on 321 never treated hypertensive patients, who underwent a Salt-Load test. We performed a case-control analysis by comparing the most salt-sensitive versus most salt-resistent patients. From this analysis, a list of top hits was obtained; we considered top SNPs those with p-value <1-05. The most interesting results were confirmed on a second population (120 pts).

Results: The best result was located on chr. 11 (p=4.38E-07) in the upstream region of DGAT2 gene. In the same region we found, after a process of imputation, 4 different SNPs with p-value <1E-06 not in linkage disequilibirum with the top SNP. Another interesting association was located on chr. 13 (p=5.20E-06). This SNP is on the 5' region of the gene Myosin XVI (MYO-XVI). Also in this region imputation process showed other 3 different SNPs with p-value <1E-04 associated with SSH. Finally, to understand the power on BP regulation, we performed a regression analysis (441 pts) of the difference between diastolic/systolic BP from the baseline to the end of Na-load. This analysis showed a r2 > 4% for both genes.

Conclusions: Our results suggest that DGAT2 and MYO-XVI are involved in regulation of BP after acute saline infusion in primary hypertension. DGAT2 is implicated in the development of Metabolic Syndrome (insulin resistance/diabetes, obesity, increase of blood cholesterol), which makes it a good candidate for SSH. MYO-XVI is a non conventional myosin expressed in many organs. This protein has a structural function that regulates other protein activity. Further investigation will need to understand the gene-gene interaction between these gene and others structural genes responsible of SSH.

TH-PO513

Collectrin in the Kidney Determines Salt-Sensitivity Pei-Lun Chu, Sylvia Cechova, Rosa Chan, Thu H. Le. *Div of Nephrology, Univ of Virginia, Charlottesville, VA.*

Background: Collectrin (*Tmem27*), an ACE-2 homologue and a chaperone of amino acid transporters, is expressed in the endothelium throughout the vasculature and in the renal proximal tubules and collecting duct. Its renal expression is upregulated after reduction of nephron mass and during salt-sensitive hypertension (SSH). We reported that collectrin-deficient (KO) mice have baseline hypertension that is ameliorated by supplementation with L-arginine (L-Arg). Furthermore, they have augmented SSH that is corrected by TEMPOL, a superoxide dismutase mimetic. These phenotypes are associated with impaired cellular uptake of L-Arg, impaired endothelial-dependent relaxation, decreased renal and aortic levels of endothelial nitric oxide synthase (eNOS) dimerization, and a rightward shift of the pressure-natriuresis relationship.

Methods: To begin to delineate the contribution of renal versus extra-renal collectrin on blood pressure (BP) regulation, we next assessed renal neuronal NOS (nNOS) protein levels. Furthermore, we performed renal cross-transplantation (XTP) studies (through a service provided by the Duke O'Brien Center), under normal and high salt conditions, in the following groups: 1) Wild-type (WT) mice with WT kidney (WT->WT), 2) collectrin KO mice with WT kidney (WT->KO), and 3) WT mice with collectrin KO kidney (KO->WT). BP was measured by radiotelemetry.

Results: Similar to that observed for eNOS, the activity or dimerization of neuronal NOS (nNOS) in the renal medulla is also significantly decreased in KO mice. In the renal XTP studies, the collectrin KO->WT group displayed a trend towards higher baseline systolic BP (SBP, mm Hg), but did not reach significance (WT->WT 137.3, WT->KO 133.5, KO->WT 142.4, p = not significant, n = 3-5 per group). By paired analysis, all groups had significantly higher SBP on high salt diet (HSD), compared to normal salt diet. However, collectrin KO->WT group had a statistically significantly higher SBP under HSD (WT->WT 148.9, WT->KO 151.6, KO->WT 168.6, p= 0.037, one way ANOVA).

Conclusions: Collectrin may regulate BP by influencing renal hemodynamics and/or epithelial sodium handling through its central role in mediating cellular L-Arg uptake and NOS dimerization.

TH-PO514

Intrarenal Tumor Necrosis Factor Alpha Contributes to Hypertension in Dahl Salt-Sensitive Rats Baorui Huang,[1,2,3] Kristie Usa,[3] Chun Yang,[3] Yong Liu,[3] Allen W. Cowley,[3] Niansong Wang,[1] Mingyu Liang.[3] *[1]Dept of Nephrology and Rheumatology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China; [2]Medical College of Soochow Univ, Suzhou, Jiangsu, China; [3]Dept of Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Tumor necrosis factor alpha (TNF-a) is a major proinflammatory cytokine which was reported to be elevated in hypertensive states. Inflammation plays an important role in the development of hypertension and renal injury in Dahl salt-sensitive(SS) rats. We hypothesized that TNF-a specifically in the kidney would contribute to the development of hypertension in SS rats.

Methods: Inbred SS and consomic SS-13BN rats were maintained on a 0.4% NaCl diet until 6 or 7 weeks of age.Then 4%(n=9) or 8%(n=6) NaCl diet were used for 7 days. The expression of TNF-a in the kidney were measured through real-time qPCR. Unilateralnephrectomy were performed in another 2 groups of SS rats when 6 weeks of age. And renal interstitial infusion of TNF-a inhibitor Etanercept were used for 8 or 14 days with 4% NaCl diet. Blood presure and a-SMA, miR-29,collagen genes's expression were measured. Histological sections of kidney were stained with Masson's trichrome.

Results: We found that the expression level of TNF-α in the renal medulla of SS rats was significantly increased when rats had been fed 4%(n=9, p<0.01) or 8%(n=6, p<0.01) high-salt diet for 7days.Renal interstitial infusion of Etanercept, which is an inhibitor of TNF-a,in uninephrectomized SS rats significantly attenuated the increase of blood pressure after 14 days(n=5,p<0.01) on a 4% salt diet.In addition,the Etanercept treatment for 8 days attenuated glomerulosclerosis in cortex (n=5, p<0.05). a-smooth muscle actin(a-SMA) was found significantly lower in cortex after 8 days of treatment with Etanercept (n=5, p<0.05). The miR-29 family, which has anti-fibrotic effects, tended to be increased in the kidney of SS rats after 14 days of treatment with Etanercept.

Conclusions: This study shows that intrarenal TNF-a contributes to the development of hypertension and renal injury in SS rats.

TH-PO515

Mesenchymal Stem Cells-Derived Micro-Particles Attenuate Kidney Injury in Swine Metabolic Syndrome and Renal Artery Stenosis Alfonso Eirin,[1] Xiang-Yang Zhu,[1] Kelly A. Mcgurren,[1] Hui Tang,[1] Andre J. Van Wijnen,[2] Joseph P. Grande,[3] Stephen C. Textor,[1] Amir Lerman,[4] Lilach O. Lerman.[1] *[1]Divs of Nephrology and Hypertension, Mayo Clinic; [2]Orthopedic Surgery, Mayo Clinic; [3]Dept of Pathology, Mayo Clinic; [4]Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

Background: Coexisting metabolic syndrome (MetS) intensifies kidney injury in renal artery stenosis (RAS). Mesenchymal stem cells (MSC) have shown renoprotective properties in experimental RAS, but generate concerns regarding their size and potential replication. MSC release membrane microparticles, including microvesicles and exosomes (Mvex), which express many of their characteristics, but the ability of Mvex to improve kidney viability in pre-clinical models remains unknown. We hypothesized that delivery of MSC-derived Mvex would attenuate kidney injury in swine MetS+RAS.

Methods: MetS pigs were studied after 16 weeks of RAS treated 4 weeks earlier with vehicle or a single intrarenal delivery of pre-labeled Mvex, derived from 2.5x10^5/Kg autologous adipose tissue-MSC; Lean and MetS Sham served as controls (n=7 each). Single-kidney function was assessed by multidetector CT, tubular injury by H&E, and fibrosis by trichrome.

Results: Blood pressure was elevated in all MetS groups (Table) and Mvex were detected in the stenotic-kidney 4 weeks after injection (Figure). Renal blood flow (RBF) and glomerular filtration rate (GFR), which fell in MetS+RAS compared to MetS, improved in MetS+RAS+Mvex, and tubular injury and interstitial fibrosis decreased.

Conclusions: Intrarenal delivery of MSC-derived Mvex attenuates renal damage in MetS+RAS. This study suggests a novel therapeutic potential for MSC-derived Mvex in preserving the kidney in chronic experimental MetS+RAS.

TH-PO516

ETS-1 in Salt Sensitive Hypertension: Interactions with the Renin Angiotensin System Wenguang Feng,[1] Phillip H. Chumley,[1] Minolfa C. Prieto,[2] Kayoko Miyata,[2] Gabriel Rezonzew,[1] Edgar A. Jaimes.[3] *[1]Univ of Alabama at Birmingham; [2]Tulane Univ; [3]Memorial Sloan-Kettering Cancer Center.*

Background: The transcription factor ETS-1 regulates the expression of a several growth factors, chemokines and cytokines. We have shown that ETS-1 is a mediator of the proinflammatory effects of Angiotensin II in the kidney (HTN'12). We also showed that ETS-1 is expressed in the cortex of hypertensive Dahl salt sensitive (DS) rats and that ETS-1 blockade reduces the severity of renal injury in DS rats (ASN'13).

Methods: We investigated the effects of ETS-1 blockade and concomitant RAS blockade on blood pressure (radiotelemetry), angiotensinogen (AGT) urinary excretion (ELISA) and protein expression (WB), and prorenin receptor expression (PRR, WB). DS rats (n=6/group) were fed a normal salt diet (0.5% NaCl, NS) or a high salt diet (4% NaCl, HS) for 4 weeks. Four additional groups (n=6) on HS received: ETS-1 dominant negative peptide (HS/DN, 10 mg/kg/day) to block ETS-1, control ETS-1 mutant peptide (HS/MU, 10mg/kg/day), the AT1 receptor blocker Candesartan (HS/ARB. 10 mg/kg/day) or a combination of DN and ARB (HS/DN/ARB).

Results: HS resulted in a significant increase in BP that was not modified by DN or MU but was reduced by ARB and DN/ARB (table). HS resulted in a significant increase in the urinary excretion of AGT that was reduced by DN and DN/ARB but not by MU or ARB. Cortical AGT expression was increased by HS and partially reduced by ARB. HS resulted in non-significant reductions in PRR and not modified by any of the treatments.

	NS	HS	HS/DN	HS/MU	HS/ARB	HS/ARB/DN
MBP (mm Hg)	104±2*	151±12	142±13	151±13	129±6*	108±1*
Urine AGT (ng/mg Creat)	17.6±2*	38.9±3	24.6±6*	54.9±10	30.2±4	12.1±3*
Cortex AGT (Fold change)	1±0.13*	1.8±0.17	1.6±0.14	1.6±0.14	1.3±0.07*	1.4±0.11
Cortex PRR (Fold change)	1±0.37	0.7±0.27	0.5±0.12	0.4±0.14	0.8±0.17	0.5±0.15

* P < 0.05 vs HS

Conclusions: In these studies we have unveiled a novel interaction between ETS-1 and the RAS that may explain at least in part the beneficial effects of ETS-1 blockade on the severity of renal injury in salt sensitive hypertension.

Involvement of Endoplasmic Reticulum Stress and Autophagy in Hypertensive Kidney Disease Masahiro Takami, Yoshihisa Nakatani, Shuji Arima. *Nephrology, Kinki Univ, Osakasayama, Osaka, Japan.*

Background: Recently, involvement of endoplasmic reticulum stress (ERS) and autophagy in kidney disease such as acute kidney injury and diabetic nephropathy has been reported. However, the relation between hypertensive disease and ERS or autophagy is unclear.

Methods: We investigated whether ERS or autophagy was associated with kidney disease, and whether antihypertensive therapy removed kidney damage by the effect of ERS and autophagy in malignant hypertension model rats (malignant stroke prone spontaneously hypertensive rats: M-SHRSP).First, we examined the kidney of Wister-Kyoto rats (WKY) and M-SHRSP by microarray analysis, western blotting, immunohistochemistry and immunofluorescent staining. Then, M-SHRSP in 5 week age was medicated with hydralazine, azelnidipine, olmesartan for 2 months and were sacrificed.

Results: By microarray analysis, in 5 week's M-SHRSP (early stage), IRE1 alpha increased 2.1 folds compared with 5 week's WKY. In 10 week's M-SHRSP (late stage), LC3B decreased about 1 to 2 folds, and ATG10 increased 1.4 folds compared with 10 week's WKY. By western blotting, ER chaperones such as GRP78, ORP150, CHOP increased in the kidney of 13 week's M-SHRSP compared with WKY. LC3B decreased in the kidney of M-SHRSP. We detected ORP150 was decreased in renal cortex and CHOP was also decreased in medulla as compared with the control group. Furthermore, we confirmed that IRE1 alpha, PERK and JNK pathway were suppressed and Cleaved-caspase 3 was decreased by antihypertensive medication. LC3B-II which associated with activation of macroautophagy was increased by antihypertensive medication. LAMP2a was about 2 folds increased in olmesartan group. HSC70 was almost no change. By immunofluorescent staining, LAMP2a and HSC70, which associated with chaperone-mediated autophagy, were colocalized in the olmesartan group compared with the others.

Conclusions: We could confirm ERS and apoptotic pathway was activated in M-SHRSP, while autophagy was inactivated. By antihypertensive therapy, ERS pathway was down regulation and autophagy was up regulation.Involvement of ERS and autophagy could be considered in pathophysiology of hypertensive kidney disease, ERS and autophagy could be new therapeutic targets.

TH-PO518

Nephron Specific Deletion of Angiotensinogen Modulates Blood Pressure Nirupama Ramkumar,[1] Deborah Stuart,[1] Taiji Matsusaka,[2] Donald E. Kohan.[1] *[1]Nephrology and Hypertension, Univ of Utah, Salt Lake City, UT; [2]Inst of Medical Science, Tokai Univ Sch of Med, Kanagawa, Japan.*

Background: It is unknown if intrarenal generation of angiotensinogen (AGT) is important in blood pressure (BP) regulation. Previous studies showed that proximal tubule-specific overexpression of AGT increases BP, while proximal tubule-specific deletion of AGT using the KAP promoter-Cre transgene did not alter BP. The latter study may not have completely eliminated nephron AGT production; in addition, BP was only assessed on a normal salt diet. To evaluate this issue in greater detail, we developed mice with inducible nephron-wide AGT deletion.

Methods: Mice were generated which were hemizygous for the Pax8-rtTA and LC-1 transgenes and homozygous for loxP flanked AGT alleles to achieve nephron-specific AGT disruption after doxycycline induction. Adult Pax8-rtTA/LC-1/floxed AGT mice at 3 months of age were treated with doxycycline 2 mg/ml in drinking water for 11 days and studied 4 weeks after treatment. Blood pressure (recorded via telemetry) and metabolic balance studies were determined during 5 days of normal, high and low Na diets.

Results: Compared to controls, AGT knockout (KO) mice demonstrated significantly lower systolic, diastolic, and mean BPs on all three diets (N=4 each group). The BP reduction was most evident on a low Na diet (mean BP 107 ± 2 mmHg in controls and 88 ± 13 mmHg in AGT KO). Plasma renin concentration was higher in the AGT KO mice as compared to controls on all three diets. There were no detectable differences in weight, urine volume, urine osmolality or urine Na excretion between the controls and KO mice on all three diets, however due to variability, small differences in these parameters may not have been detected.

Conclusions: Taken together, these data suggest that nephron AGT may contribute to BP regulation and this is most evident during low Na intake.

TH-PO519

Elastin Insufficiency-Associated Hypertension Is Mediated, at Least in Part, by Angiotensin II Type 2 Receptor Carmen M. Halabi, Beth A. Kozel, Robert P. Mecham. *Washington Univ School of Medicine, Saint Louis, MO.*

Background: Hypertension and vascular stiffness are major consequences of elastin insufficiency, as seen in patients with Williams syndrome and animal models of elastin insufficiency. Altered reactivity of resistance vessels was recently proposed to contribute to hypertension in elastin insufficiency. Specifically, mesenteric arteries of elastin insufficient mice were shown to be hypercontractile to angiotensin II (AngII) *ex vivo*. Interestingly, this hypercontractile response to AngII was mediated, at least in part, by AngII type 2 receptors (AT2R) as blockade of AT2R by PD123319 abrogated the hypercontractile response to AngII. The purpose of this study was to determine whether AT2R contribute to the hypertension seen with elastin insufficiency *in vivo*.

Methods: Elastin haploinsufficient (Eln^{het}) mice were bred to AT2R knock-out ($AT2R^{KO}$) mice. Three month-old male littermate progeny with the following genotypes ($AT2R^{WT}$;Eln^{WT},

AT2R^{KO};Eln^{WT}, AT2R^{WT};Eln^{het}, and AT2R^{KO};Eln^{het}) were used for experimental studies. Arterial blood pressure was measured in anesthetized mice via a catheter introduced in the right common carotid artery. At the end of blood pressure recording, mice were sacrificed and the left common carotid arteries and ascending aortae were isolated for compliance studies.

Results: As expected, compared to wild type (WT) mice, loss of AT2R had no effect on blood pressure or large vessel compliance in the presence of WT elastin (*AT2R^{KO};Eln^{WT}*), while isolated elastin insufficiency resulted in elevated systolic blood pressure, pulse pressure, and reduced large vessel compliance (*AT2R^{WT};Eln^{het}*). Loss of AT2R in elastin insufficient mice (*AT2R^{KO};Eln^{het}*), however, resulted in significant reduction of systolic and diastolic blood pressures, but no change in pulse pressure or large artery compliance.

Conclusions: These results provide *in vivo* evidence for a role of AT2R in mediating elastin insufficiency-associated hypertension. Furthermore, these data suggest distinct mechanisms for the development of hypertension and vascular stiffness in elastin insufficiency, as loss of AT2R reduced blood pressure, but had no effect on large artery stiffness in this mouse model.

TH-PO520

Renal Medullary (Pro) Renin Receptor Mediates Angiotensin II-Induced Hypertension

Tianxin Yang,[1,2] Xiaohan Lu,[1,2] Yumei Feng,[3] Fei Wang.[1,2] *[1]Internal Medicine, Univ of Utah and Veterans Affairs Medical Center, Salt Lake City, UT; [2]Inst of Hypertension, Sun Yat-sen Univ Zhongshan Medical School, Guangzhou, Guangdong, China; [3]Dept of Physiology, Colorado State Univ, Fort Collins, CO.*

Background: (Pro)renin receptor (PRR) is predominantly expressed in the collecting duct and is stimulated by angiotensin II (AngII) via the COX-2/PGE2/EP4 pathway but the function of PRR is unknown.

Methods: We examined the effect of intramedullary delivery of a novel PRR decoy peptide PRO20 on AngII hypertension via an interstitial catheter chronically placed in the rat medulla and also tested the role of PRR in regulation of ENaC activity in vitro.

Results: Telemetry showed that 1-wk AngII infusion (100 ng/kg/min) elevated MAP from 108 + 5.8 to 164.7 + 6.2 mmHg and this value was lowered to 110.2 + 4.8 mmHg ($p<0.05$) by intramedullary PRO20 infusion (IMPRO) at 120μg/kg/min but was only modestly affected by intravenous PRO20 infusion (IVPRO) (day 7: 151.7 + 4.4 mmHg). Proteinuria (2.7-fold increase in urinary protein), glomerulosclerosis and interstitial fibrosis following AngII infusion were completely normalized by IMPRO so were the polyuria and downregulation of renal AQP2 protein expression. AngII infusion elevated urinary renin activity from 0.17 + 0.013 to 9.3 + 1.7 AngI ng/24h, which was reduced to 0.09 + 0.04 AngI ng/24h by IMPRO. A similar pattern of changes in renin activity was observed in the inner medulla, contrasting to opposite changes in renal cortex and plasma. α-ENaC mRNA and protein were elevated 158% and 180%, respectively, in the inner medulla but not in the cortex or plasma, and the elevations were abolished by IMPRO. By chopstick electrodes, AngII at 500 nM induced a transient 2-fold increase in amiloride-sensitive sodium transport at 5 min, which was completely abolished by PRO20. Similarly, prorenin at 10 nM exhibited a similar stimulatory effect on ENaC activity which was similarly blocked by PRO20 except that prorenin-induced increase in ENaC activity occurred at 1 min, preceding the AngII effect.

Conclusions: Renal medullary PRR mediates AngII-induced hypertension likely via amplifying the local renin response and the activation of ENaC.

Steady-State Profiles of Multiple RAS Peptides in Mouse Plasma and Kidney - New Clues for Enzymatic Processing of Angiotensin Peptides

Jan A. Wysocki, Minghao Ye, Daniel Batlle. *Div. Nephrology & Hypertension, Northwestern Univ, Chicago, IL.*

Background: A major limitation of research on bioactive peptides, such as angiotensins (Ang), has been the lack of direct methods to simultaneously measure multiple components of this cascade network with enough discriminative power and sensitivity.

Methods: We used liquid chromatography tandem mass spectrometry (LC/MS-MS) to measure concurrently levels of 10 Ang peptides in plasma and kidneys from male C57BL mice (n=5) *in vivo* at a physiologically relevant range (pg/mL and pg/g, respectively).

Results: In plasma, the highest concentrations were for: Ang I (1-10) (1295±313 pg/mL) whereas the levels for the main effector peptide, Ang II (1-8) were very low (7.8±2 pg/mL). Angiotensin (1-7), the peptide formed from the cleavage of Ang II (1-8) by ACE2 was also very low (3.5±0 pg/mL). This is in keeping with low levels of circulating ACE2 activity. In contrast, the levels of plasma Ang (2-10) and Ang III (2-8) (products of Ang I (1-10) and Ang II (1-8) degradation by aminopeptidase A (APA), respectively) were relatively high (657±173 and 1047±178 pg/mL, respectively). In the kidney, the highest Ang concentrations were measured for Ang I (1-10) and Ang II (1-8) (468±96 and 307±37 pg/g, respectively). Ang II (1-8) can be converted by APA to Ang III (2-8) and by ACE2 to Ang (1-7) and the levels of these two Ang II degradation products in the kidney were relatively high (172±12 pg/g and 42±19 pg/g, respectively).

Conclusions: LC/MS-MS measurements of multiple RAS peptides unraveled the prevalent pathways of angiotensins processing which appear to be differentially regulated in kidney and plasma. Under steady state conditions, RAS peptides profiles suggest a major role of aminopeptidase A in the metabolism of angiotensin peptides both in plasma and kidney, whereas ACE2 might play a role in kidney but not in plasma angiotensin II degradation.

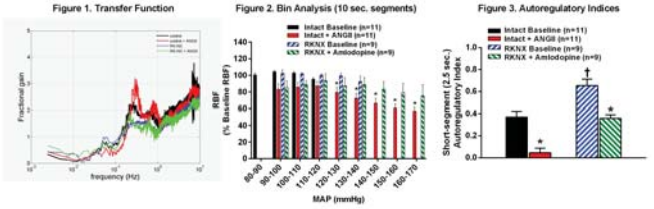
Impact of Renal Mass Reduction on the Effects of Angiotensin II on Renal Hemodynamics and Autoregulation in Conscious Rats

Karen A. Griffin,[1] Aaron J. Polichnowski,[1] Hector Licea-Vargas,[1] Maria M. Picken,[1] Jianrui Long,[2] Geoffrey A. Williamson,[2] Anil K. Bidani.[1] *[1]Medicine/Pathology, Loyola Univ Med Ctr and Hines VA Hosp, Maywood, IL; [2]Electrical and Computer Engineering, Illinois Inst of Technology, Chicago, IL.*

Background: Ang II is widely postulated to play a major role in CKD progression through BP-dependent and independent mechanisms. Although its effects on BP-RBF relationships and autoregulation (AR) are expected to significantly impact the pathogenesis of such injury, only limited data are available as to such effects in conscious animals with and without renal mass reduction (RMR).

Methods: BP and RBF recordings (2-3 at 200Hz for 2-4 hrs on 2-4 separate days) were obtained in conscious male rats with intact renal mass or 3/4 nephrectomy (3/4 NX) before and 48 hrs after Ang II (125ng/kg/min s.c.). The following were assesed (i) transfer functions (Fig 1); (ii) BP-RBF relationships (10 sec segments of BP and corresponding RBF averages separated into 10mmHg BP bins; Fig 2) and (iii) AR indices for adjoining 2.5 sec segments with at least 5mmHg AP difference (>1000/rat; Fig 3).



Results: Transfer function analysis showed that Ang II potentiated the myogenic response (MR) in intact rats. These potentiating effects were blunted in 3/4 NX rats with already attenuated MR. Bin analysis similarly showed that Ang II induced decreases in RBF and the exaggerated vasoconstriction seen with increasing BP in intact rats were greatly attenuated in 3/4 NX rats. AR assessment indicated a significant strengthening of AR by Ang II in both intact and to a lesser degree in the 3/4 NX rats with impaired AR.

Conclusions: These data using 3 different methodologies indicate that in contrast to studies in anesthetized rats, Ang II interacts with and potentiates myogenic AR in conscious rats with intact and to a lesser extent in RMR rats.

The Anti-Hypertensive Effect of Mycophenolate Mofetil Is Mediated By Reducing Vascular Responsiveness to Angiotensin II

Arthur David Moes,[1] David Severs,[1] Koen Verdonk,[2] Nils Van Der Lubbe,[1] Alexander H. Danser,[2] Robert Zietse,[1] Ewout J. Hoorn.[1] *[1]Dept of Nephrology, Erasmus MC, Rotterdam, Netherlands; [2]Dept of Pharmacology, Erasmus MC, Rotterdam, Netherlands.*

Background: Hypertension after kidney transplantation is associated with poorer graft survival and higher cardiovascular risk. While glucocorticoids and calcineurin inhibitors are hypertensinogenic, mycophenolate mofetil (MMF) has anti-hypertensive properties. The mechanism of the blood pressure lowering effect of MMF is unknown.

Methods: Salt-sensitive hypertension was induced in rats by deoxyocorticosterone acetate (DOCA) and 0.9% NaCl as drinking water. 8 rats were also treated with MMF and 8 with vehicle. Blood pressure was continuously monitored using telemetry. The experiment lasted 4 weeks. Kidney homogenates were differentially centrifuged to analyze sodium transporters in plasma membrane fractions. Vascular reactivity was analyzed with Mulvany myographs, and data are expressed as % of the maximum contraction (E_{max}) to 100 mmol/L KCl.

Results: Mean arterial pressure (MAP) at baseline was identical in both groups (97±6 mmHg). DOCA-salt increased MAP in all rats, but was significantly attenuated in the MMF group (MAP after 4 weeks 107±7 versus 126±14 mmHg; $P<0.001$). MMF did not change abundance or phosphorylation status of sodium transporters. The angiotensin (Ang) II E_{max} in iliac arteries was 15.3±2.4% after MMF versus 47.4±9.6% after vehicle ($P=0.007$). Nitric oxide synthase (NOS) inhibition with L-NAME greatly enhanced ($P=0.0005$) the Ang II response in the MMF-treated animals, but the increase after vehicle was non-significant ($P=0.16$). The Ang II type 1 (AT1) receptor antagonist irbesartan prevented all Ang II induced responses, whereas only in vehicle-treated rats the Ang II type 2 (AT2) receptor antagonist PD123319 blocked the effects of Ang II. In mesenteric arteries, endothelin-1-induced constrictor effects were unaffected by MMF.

Conclusions: MMF blunts the development of salt-sensitive hypertension in experimental animals possibly by inhibiting T-cells. This may involve a selective reduction of Ang II responsiveness due to a preservation of vascular NO generation and downregulation of constrictor AT2 receptors.

TH-PO524

A "Sticky" Tag Delivers Therapeutic Angiotensin-Converting Enzyme 2 to the Kidney Glomeruli: A Novel Approach to Protect Ang II-Induced Podocyte Injury Pan Liu,[1,2] Jan A. Wysocki,[1] Minghao Ye,[1] Daniel Batlle,[1] Jing Jin.[1,2] *[1]Dept of Medicine – Nephrology/Hypertension, Northwestern Univ, Chicago, IL; [2]Feinberg Cardiovascular Research Inst, Northwestern Univ.*

Background: Angiotensin-converting enzyme 2 (ACE2) is a cell surface monocarboxypeptidase that degrades angiotensin II (Ang II) to form Ang1-7. Injection of the recombinant enzymatic ectodomain (soluble ACE2/sACE2) has been proposed as a new therapeutic agent for cardiovascular disease and diabetic nephropathy. However, due to a short serum half-life of sACE2, the benefit from such treatment is limited. More importantly, unlike the naturally produced ACE2, circulating sACE2 does not anchor to the cells or tissues such as the kidney glomeruli. We set out to engineer a version of sACE2 in fusion with a heparin-binding domain (HBD - the "sticky" tag) to target the therapeutic protein to the glomeruli that has high heparin sulfate proteoglycan content, and with an Fc-tag to increase stability.

Methods: We engineered plasmids to produce sACE2-Fc and sACE2-HBD-Fc in HEK293 cells and purified ACE2 proteins by affinity chromatography. The function of HBD to anchor ACE2 to the surface of cultured podocytes was confirmed by western blotting and immunofluorescence. Following i.v. injection of the recombinant proteins to mice, we determined the pharmacokinetics of ACE2 activity in blood. Organs were harvested for anti-Fc detection of sACE2 distribution in tissues.

Results: Both sACE2-Fc and sACE2-HBD-Fc are enzymatically active as determined by their catalysis rate of Ang II. We showed sACE2 with heparin-binding domain readily adhering to the cultured podocytes. Following injection to mice, unlike sACE2-Fc without HBD, sACE2-HBD-Fc dissipates more quickly from blood circulation likely into tissues. This is supported by immunohistochemistry of kidney sections showing sACE2-HBD-Fc being exclusively localized to the glomeruli.

Conclusions: Our results suggest that the addition of HBD and Fc tags together could improve kidney glomerulus anchoring and the overall pharmacokinetics of sACE2, features which would make this hybrid protein an attractive approach for treating kidney disease and hypertension.

Deficiency of Smad3 Impairs the Renal NLRP3 Signaling Pathway Mohammed Al-Suraih, Stella Hartono, Joseph P. Grande. *Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.*

Background: Renovascular hypertension (RVH) is a major public health problem that affects up to 7% of individuals over 65 years of age. Our laboratory team has previously showed that induction of oxidative stress is an early event in the development of RVH that leads to development of inflammation and renal atrophy. We have also demonstrated that both Smad3 and NLRP3 deficiencies attenuate renal atrophy, inflammation and interstitial fibrosis in the 2K1C murine model. NLRP3 is one of the most well-known sensors of oxidative stress. Smad3 is a key intermediate in TGF-B signaling. However, the relationship between Smad3/TGF-B and NLRP3 in the development of RVH and subsequent end-organ damage is not well understood. We therefore sought to test the hypothesis that Smad3 is essential for NLRP3 activation in the kidneys of mice subjected to RVH.

Methods: Wild type (WT) and Smad3-/- mice (KO) were subjected to RVH for 4, 7, and 14 days. The right kidneys (stenotic) were analyzed by histology (H&E, Trichrome) and by gene expression (qR PCR). Sham surgeries for both groups were carried as a control.

Results: In accordance with our previous observations, wild type (WT) mice subjected to RVH developed significant degree of renal atrophy (20.9% ±7.13) within 2 week following cuff placement. In contrast, Smad3-/- mice (KO) were protected from atrophy (11.8%±6.39) at 2 weeks. NLRP3 expression was increased at 4, 7, and 14 days in WT mice (1.2-fold at day 4, 1.21-fold at day 7, 7.7-fold at day 14). In contrast, NLRP mRNA was slightly elevated at 4 days in Smad3-/- mice, but returned to baseline levels at later time points (3.3-fold at day 4, 0.6-fold at day 7, 0.9-fold at day 14). Expression of IL-1B and TXNIP, components of NAPL3 signaling, paralleled expression of NLRP3 in both WT and Smad3 KO mice.

Conclusions: We propose that the presence of Smad3, and subsequent TGF-B activation plays a critical role in the signaling of NLRP3, and subsequent activation of inflammasome, which can lead to development of renal atrophy in mice subjected to RVH and represent a potential therapeutic target.

Erythropoiesis and Blood Pressure Are Regulated via AT1 Receptor by Distinctive Pathways Hideki Kato,[1] Taiji Matsusaka,[2] Masaomi Nangaku.[1] *[1]Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Hongo, Tokyo, Japan; [2]Inst of Medical Sciences, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.*

Background: The renin-angiotensin system (RAS) plays a central role in blood pressure regulation. Although clinical and experimental studies suggested that inhibition of the RAS is associated with the progression of anemia, there has been little evidence to support it.

Methods: We generated and analyzed knockout mice which lack angiotensinogen, renin, AT1a, AT1b, AT1a+b, AT2 receptors. Blood pressure was measured by tail-cuff methods. Ang II (0.3 mg/kg/day) was administered by osmotic mini-pump to angiotensinogen knockout mice. Losartan (30 mg/kg/day)was administered in drinking water.

Results: We found that angiotensinogen and renin knockout mice, which lack angiotensin II, displayed anemia. The anemia of angiotensinogen knockout mice were recovered to normal levels by angiotensin II infusion, which was completely blocked by simultaneous AT1 receptor inhibitor administration. We also examined AT1a, AT1b, and AT2 knockout mice, but anemia were not observed in these mice. To examine whether pharmacological AT1 receptor inhibition reproduces anemic phenotype, we administered AT1 receptor antagonist in hypotensive AT1a receptor knockout mice to inhibit the remaining AT1b receptor and found that the hematocrit levels barely decreased, while blood pressure further decreased to the level of angiotensinogen knockout mice. We then generated AT1a and AT1b double knockout mice to completely ablate the AT1 receptors and the mice finally presented anemic phenotype.

Conclusions: Although erythropoiesis and blood pressure are negatively controlled through the AT1 receptor inhibition in vivo, pathways may be complex and distinct, since erythropoiesis is more resistant than blood pressure control to AT1 receptor inhibition.

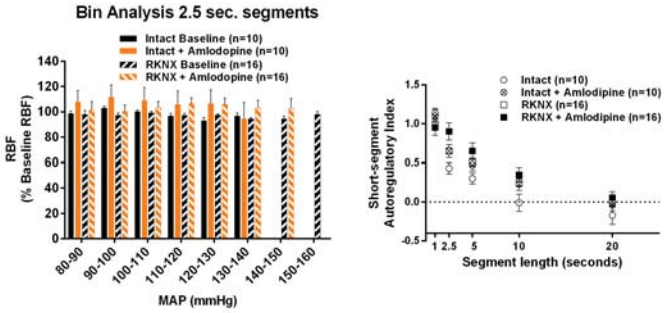
Renal Autoregulation and Dynamics of Glomerular BP Transmission in Conscious Rats: Novel Analysis Methods and Insights Anil K. Bidani,[1] Aaron J. Polichnowski,[1] Hector Licea-Vargas,[1] Jianrui Long,[2] Geoffrey A. Williamson,[2] Karen A. Griffin.[1] *[1]Medicine, Loyola Univ Med Ctr and Hines VA Hospital, Maywood, IL; [2]Electrical and Computer Engineering, Illinois Inst of Technology, Chicago, IL.*

Background: Renal autoregulation (AR) is believed to be the primary mediator of RBF, GFR and P_{GC} stability with changing BP and to protect against hypertensive damage. Conversely AR impairment, assessed by step BP changes under anesthesia, results in enhanced susceptibility to such damage. However, attempts to demonstrate similar AR patterns in conscious animals with spontaneous BP changes have been unsuccessful.

Methods: BP and RBF recordings at 200Hz for 2-4hrs each on 2-4 separate days were obtained in conscious rats with intact AR (controls, n=10); ~50% AR impairment (controls + amlodipine n=10, or 3/4 nephrectomy, NX n=16); and total AR loss (3/4 NX + amlodipine n=16). Each BP and RBF recording was divided into segments of varying lengths (1, 2.5, 5, 10 and 20 sec). The BP and corresponding RBF averages were separated into 10mmHg BP bins (Fig).

Results: Despite marked differences in step AR, no differences were seen in the ability to maintain stable RBF with spontaneous BP changes regardless of segment length. By contrast, when AR indices were calculated for all adjacent short segments with an AP difference of at least 5mmHg (>4000/rat), significant differences similar to step AR were seen with 2.5 sec segments but which tended to dissipate with increasing segment length (Fig.)



Conclusions: These data indicate that AR protection against glomerular transmission of BP fluctuations occurs over rapid time scales (<5 sec) in conscious animals and that AR-independent and as yet unidentified mechanisms, can maintain RBF (GFR) stability with BP changes. This may explain the fact that acute GFR effects are ususally not seen after antihypertensive agents in CKD with impaired AR.

Urinary Aminopeptidase A Is a Novel Biomarker for Renal Dysfunction in the Two-Kidney, One-Clip Mouse Model of Renovascular Hypertension Nadja Grobe, Laale F. Alawi, Sana Elhagi Emberesh, Aline Lopes Dalmazo, Khalid M. Elased. *Pharmacology and Toxicology, Wright State Univ, Dayton, OH.*

Background: Chronic kidney disease (CKD) and its cardiovascular complications remain one of the leading causes of morbidity and mortality. There is an urgent need to identify early biomarkers for CKD as current diagnostic indicators may not predict disease outcome. Elevated angiotensin (Ang) II contributes to the progression of CKD. Aminopeptidase A (APA) is highly expressed in the brush border of renal tubular cells and metabolizes Ang II to Ang III. We tested the hypothesis that urinary APA is increased in the two kidney, one-clip (2K1C) model of renovascular hypertension.

Methods: 2K1C was induced by constricting the left renal artery using silver clips leaving a 0.12 mm gap for ischemic blood flow to the kidney. We developed a new mass spectrometry-based enzyme assay for measuring APA activity in sham and 2K1C animals

at baseline and 2 weeks after surgery. Samples were incubated with the APA substrate, Ang II (*m/z* 1046). Ang III formation (*m/z* 931) was quantified with stable-isotope labeled peptide standard.

Results: Two weeks after surgery, the weight of the left clipped kidneys was significantly reduced compared with contralateral or sham kidneys ($p<0.01$ or $p<0.05$, respectively). 2K1C animals showed a significant increase of blood pressure, heart rate and urinary albumin-to-creatinine compared with baseline or sham animals ($p<0.01$). Renal APA activity was significantly increased in the clipped kidney compared with the contralateral or sham kidney ($p<0.05$ and $p<0.01$, respectively). Similarly, urinary APA activity was significantly increased in the 2K1C group compared to baseline or sham animals ($p<0.05$). Renal and urinary APA activity was blocked by the specific APA inhibitor 4-aminophosphonobutyric acid.

Conclusions: APA is involved in a feedback mechanism counteracting increased Ang II formation in renovascular hypertension. Urinary APA could be used as biomarker for chronic kidney disease and as an index of intrarenal APA status. Identification of the role of APA in Ang II processing and renal function may have clinical implications in patients with renovascular hypertension.

Complex Reinnervation Pattern after Unilateral Renal Denervation in Rats

Kristina Rodionova,[1] Christian Ott,[1] Wolfgang Freisinger,[4] Sonja Heinlein,[1] Roland E. Schmieder,[1] Kerstin U. Amann,[3] Roland Veelken,[1] Tilmann Ditting.[1] *[1]Medical Clinic 4, Nephrology and Hypertension, Friedrich-Alexander Univ Erlangen Nürnberg, Erlangen, Germany; [2]Anatomy 1, Friedrich-Alexander Univ Erlangen Nürnberg, Erlangen, Germany; [3]Pathology, Friedrich-Alexander Univ Erlangen Nürnberg, Erlangen, Germany; [4]I. Medical Clinic & Polyclinic, Dept of Nephrlogy, Johannes Guttenberg Univ Mainz, Mainz, Germany.*

Background: Renal denervation is a potentially beneficial, but controversial treatment procedure for resistant hypertension. Some reinnervation of efferent sympathetic nerves occurs, but reinnervation of renal afferent nerve fibers has only recently been documented in the renal pelvis of rats after unilateral denervation. We hypthesized, that unilateral renal denervation impacts both ipsilateral and contralateral renal sensory and sympathetic innervation following unilateral denervation.

Methods: Immunoreactivity for tyrosine hydroxylase (TH, i.e. sympathetic efferent), calcitonine gene related peptide (CGRP, i.e., peptidergic afferent) and smooth muscle actin (SMA, i.e. vascular area) were determined in 50µm kidney sections from 12 male SD rats. Denervated left kidneys (L) and non-denervated right kidneys (R) were examined 1, 4 and 12 weeks after left renal denervation. We focused on intrarenal perivascular innervation with special emphasis on the corticomedullary zone.

Results: Morphometric analysis revealed that denervation decreased TH^+ and $CGRP^+$ label by 90 and 95%, respectively ($P<0.05$) within one week. After twelve weeks there was an overshooting reinnervation of TH^+ and $CGRP^+$ nerve fibers ($P<0.05$; L12 *versus* R1) with a shift towards CGRP+ label in the denervated kidneys ($P<0.05$; L12 *versus* L1 and R1). Indeed, even in the non-denervated kidneys there was a doubling of TH^+-label and more than doubling of $CGRP^+$-label ($P<0.05$; R1 *versus* R12).

Conclusions: Neither the functional consequences nor the underlying mechanisms of this complex pattern of enzyme and neurotransmitter expression are clear as yet. However, these findings suggest that complex reinnervation patterns may contribute to the unpredictable clinical outcome observed after interventional renal nerve ablation.

Renal Human Liver-Type Fatty Acid Binding Protein Attenuates against Tubulointerstitial Injury in Aldosterone-Induced Renal Injury

Daisuke Ichikawa, Atsuko Ikemori, Takeshi Sugaya, Yugo Shibagaki, Takashi Yasuda, Kenjiro Kimura. *Nephrology and Hypertension, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan.*

Background: Liver-type fatty acid binding protein (L-FABP) is expressed in human renal proximal tubules. Because Renal L-FABP is rarely expressed in rodent kidneys, we previously generated human L-FABP (hL-FABP) chromosomal transgenic (Tg) mice and revealed that hL-FABP attenuates tubulointerstitial damage via antioxidant effect in renin angiotensin system (RAS) activated model. Another investigation found that aldosterone (Aldo) activated the intrarenal RAS through positive feedback reactionsand that its activation led to kidney injury via reactive oxidative stress (ROS) generation. The aim of this study is to demonstrate the pathophysiological significance of renal hL-FABP in a systemic Aldo infusion model.

Methods: Tg and wild-type (WT) mice received systemic aldosterone infusions (0.125 µg/kg per minute) and were given 1% NaCl water for 28 days as obstacle model group. Control mice received saline only and normal food in Tg and WT mice.

Results: In this model, Elevation of systolic blood pressure (SBP), urinary albumin, monocyte chemoattractant protein 1 expression, macrophage infiltration in the interstitium, tubulointerstitial damage, and depositions of type I and III collagens were observed. Elevation of SBP, glomerular sclerosis and urinary albumin did not differ in WT-Aldo versus Tg-Aldo, however renal injury was suppressed in Tg-Aldo compared with WT-Aldo mice. ROS was suppressed in Tg-Aldo compared with WT-Aldo mice. Gene expression of angiotensinogen (AGT) in the kidney was up-regulated and excretion of urinary AGT was increased in WT-Aldo mice. This exacerbation was suppressed in Tg-Aldo mice. Expression of hL-FABP was up-regulated in proximal tubules of Tg-Aldo mice. Urinary excretion of L-FABP was significantly greater in Tg-Aldo than in Tg-control mice.

Conclusions: Renal hL-FABP ameliorated the tubulointerstitial damage in Aldo-induced renal injury via ROS and suppressing activation of the intrarenal RAS.

TH-PO531

Mesenchymal Stem Cells Improve the Architecture and Fibrotic Processes in Both Stenotic and Contralateral Kidneys

Mirian A. Boim,[1] Elizabeth B. Oliveira-Sales,[1] Edgar Maquigussa,[1] Cassia Bergamaschi,[2] Vanessa A. Varela,[1] Ruy Campos.[2] *[1]Medicine - Renal Div, Federal Univ of São Paulo, São Paulo, Brazil; [2]Physiology, Federal Univ of São Paulo, São Paulo, Brazil.*

Background: Chronic stenosis of renal artery leads to chronic renal hypoxia, renovascular hypertension, renal vascular rarefaction, fibrosis and renal failure. Previous data from our Laboratory showed beneficial effects of mesenchymal stem cells (MSC) in the reconstruction of renal parenchyma of the stenotic kidney, improving the vascular rarefaction and fibrosis. Here we evaluated the effect of MSC on the contralateral kidney.

Methods: It was used the 2 Kidney-1 clip (2K-1C) model in rats. Three weeks after left renal artery occlusion, fluorescently tagged mesenchymal stem cells (MSC) ($2x10^5$ cells/animal) were injected weekly into the tail vein of the 2K-1C rats.

Results: Flow cytometry showed labeled MSC in the cortex and medulla of both ischemic (clipped) and contralateral kidneys (unclipped). MSC prevented further increase in the MAP and significantly reduced proteinuria in 2K-1C rats. Other renal function parameters were unchanged. Contralateral kidney presented altered structure including tubular dilation and glomerular atrophy, cellular infiltration and fibrosis. Similar to the stenotic kidney, MSC improved the morphology and decreased the fibrotic areas in the cortex and medulla of contralateral kidney. Stenotic kidney presented overexpression of the components of the renin angiotensin system (RAS), reversed by MSC. RAS overexpression was not observed in the contralateral kidney, except the AT1 receptor, which was not reversed by MSC.

Conclusions: In conclusion, MSC therapy in the 2K-1C model of chronic renal ischemia prevented the progressive increase of MAP, improved renal morphology and reduced fibrosis in both stenotic and contralateral kidneys. MSC therapy may be a promising strategy to treat renovascular hypertension and its renal consequences.

Cryo-Denervation of the Renal Nerve Alters Na Transporter and Channel Abundance in 2-Kidney 1-Clip (2K1C) Rats

Jeena Chorath, Bruce E. Linebaugh, Noreen F. Rossi. *Internal Medicine/Physiology, Wayne State U. & John D. Dingell VAMC, Detroit, MI.*

Background: Renovascular hypertension due to atherosclerosis is increasing in prevalence. The CORAL trial showed angioplasty ± stenting provided no benefit versus medical therapy. Renal denervation has been advocated for hypertension, but it is now less clear who will benefit. Moreover, atherosclerotic renal arteries preclude the use of radiofrequency for denervation.

Methods: We hypothesize that cryo-denervation (cryoDNX) of the renal nerve to the clipped kidney in 2K1C rats will decrease MAP and result in redistribution of Na transporters. Sprague Dawley rats (5 wk) underwent renal artery clipping. MAP was monitored by telemetry. After 6 wk, rats underwent freezing of the renal nerve at -155°C (x3) to the clipped kidney under direct visualization. After 7 days, renal cortex was harvested, homogenized, and fractionated on a 25-66% sucrose gradient: S1-S2 fractions=smooth inner membranes; S3-S4=rough endoplasmic reticulum, trans-golgi, and mitochondria; S5=subapical membrane; S6=plasma membrane. Membrane fractions were subjected to western blot analysis for NHE, NKCC2, NCC, ENaC and the NaK-ATPase.

Results: MAP decreased after cryoDNX of 2K1C rats ($P<0.05$). NHE was most abundant in S5-S6 fractions in both non-clipped and clipped kidneys. After cryoDNX, the S5 fraction in non-clipped kidneys decreased with a shift to S3-S4 in both kidneys. NCC was most abundant in S1-S2 and decreased in S5-S6 after cryoDNX. NKCC2 pattern was similar to NHE. γENaC showed similar abundance across all fractions of the unclipped kidneys with lower abundance in S1 and S6 on the clipped side. After cryoDNX, γENaC from both clipped and non-clipped kidneys was greatest in S3-S4 and S6 fractions. Na,K-ATPase was abundant in all fractions and showed a decrease after cryoDNX in all fractions.

Conclusions: CryoDNX of the clipped kidney in 2K1C rats results in shifts of Na transporters/channels among cellular compartments. NHE and NCC decrease within the plasma membrane and subapical compartments. Modulation of the trafficking of tubular Na transporters by cryoDNX of the renal nerve to the clipped kidney may reduce Na reabsorption and contribute to lower MAP in 2K1C rats.

TH-PO534

Restored Cardiovascular Autonomic Efficiency in Patients after Renal Transplantation Dan Sapoznikov, Rebecca Backenroth, Michal Dranitzki Elhalel, Dvora Rubinger. *Nephrology and Hypertension Services, Hadassah Univ Medical Center, Jerusalem, Israel.*

Background: The present study was undertaken to assess the efficiency of cardiovascular autonomic (CvA) responses during alterations in blood pressure in patients with end-stage renal disease.

Methods: Beat-to-beat systolic blood pressure (SBP) and interbeat interval (IBI) monitoring was performed in non-diabetic patients on chronic hemodialysis (HD, n=73) and after renal transplantation (TX, n=36), and in healthy controls (C, n=28). Differences in variability indices during SBP periods, 10% above (high) or below (low) the mean SBP were cosidered representative of CvA efficiency.

Results: The proportion (%) of baroreflex and nonbaroreflex episodes and SBP and IBI variability in low (LF) or high (HF) frequency ranges (median and interquartile ranges) were:

	C		HD		TX	
	Low-High SBP	p	Low-High SBP	p	Low-High SBP	p
SBP (mmHg)	107(22)-133(21)	0.001	114(24)-155(29)	0.001	109(24)-145(30)	0.001
% Baroreflex episodes	100(8)-100(86)	NS	84(63)-84(68)	NS	32(100)-0(58)*	0.016
sd SBP (mmHg)	5.6(3.6)-6.7(3.1)	0.001	9.2(2.7)-7.0(2.5)	NS	5.1(2.2)-6.8(2.5)	0.001
sd IBI (ms)	42(25)-4(22)	0.009	25(18)-24(19)	NS	21(19)-31(22)	0.001
LF SBP ($mmHg^2$/Hz)	67(91)-139(113)	0.001	119(116)-124(154)	NS	48(65)-103(95)	0.001
HF SBP ($mmHg^2$/Hz)	17(22)-30(28)	0.015	39(42)-41(41)	NS	12(16)-22(20)	0.001
LF IBI (ms^2/Hz)	4192(5744)-5260(5971)	NS	1431(2496)-1360(2896)	NS	1196(2400)-2494(4803)	0.001
HF IBI (ms^2/Hz)	1195(1730)-1860(2682)	NS	508(1023)-590(1063)	NS	360(710)-487(1042)	0.038
LFα (ms/mmHg)	7.8(6.5)-5.8(4.3)	0.001	3.8(2.7)-3.8(2.9)	NS	4.6(5.3)-4.9(4.0)	0.040
HFα (ms/mmHg)	10.2(7.8)-7.5(6.1)	0.002	4.6(3.5)-4.0(3.1)	NS	6.2(5.3)-5.9(3.9)	0.007

sd: standard deviation; α: the square root of the ratio of average power spectral density of IBI and SBI. *p<0.05 vs.C and HD.

Conclusions: 1. Low to high SBP changes are suppressed in HD and enhanced in TX, suggesting restored CvA efficiency in these patients. 2. SBP is predominantly controlled by baroreflex in C and HD, and by nonbaroreflex pathways, most probably sympathetically mediated in TX. Our data may be relevant to the pathogenesis of intradialytic hypotension and post-transplant hypertension.

Indoxyl Sulfate Suppresses Hepatic Fetuin-A Expression through Aryl Hydrocarbon Receptor Akinobu Ochi, Katsuhito Mori, Shinya Nakatani, Masanori Emoto, Koka Motoyama, Tomoaki Morioka, Shinya Fukumoto, Yasuo Imanishi, Tetsuo Shoji, Eiji Ishimura, Masaaki Inaba. *Osaka City Univ Graduate School of Medicine, Osaka, Japan.*

Background: Fetuin-A (FetA), a circulating glycoprotein mainly synthesized by the liver, has a potent calcification-inhibitory effect. It has been reported that low serum FetA levels were associated with all-cause and cardiovascular mortality in hemodialysis (HD) patients. However, it remains obscure how FetA levels are down-regulated in HD patients.

Methods: We hypothesized that indoxyl sulfate (IS), one of uremic toxins, could suppress hepatic FetA production in HD patients. To investigate this, we examined the direct effects of IS on FetA expression in cultured hepatocytes (HepG2 cells).

Results: FetA mRNA expression was suppressed in treatment with IS (38% decrease by 1 mM IS for 24h). Similarly, IS inhibited FetA protein expression in time- and dose-dependent manner (42% decrease by 1 mM IS for 24h). To clarify intracellular signaling events in IS-induced suppression of FetA, we investigated the involvement of MAPK pathway and oxidative stress. Among p38, ERK and JNK, only p38 was phosphorylated by IS treatment. However, knockdown of p38 didn't alter IS-induced FetA suppression. As previously reported, IS clearly generated reactive oxygen species (ROS). Though IS-induced ROS generation was completely abolished by 10mM N-Acetyl-Cysteine (NAC), no effect of NAC on IS-induced suppression of FetA was found. Finally, we focused on aryl hydrocarbon receptor (AhR) that is known as a dioxin receptor since recent reports suggest that IS is an endogenous agonist for AhR. As expected, knockdown of AhR recovered IS-induced FetA suppression in HepG2 cells.

Conclusions: IS directly inhibited FetA expression through AhR in HepG2 cells. These findings suggest that accumulated IS that is usually unavoidable in HD patients may lead to FetA deficiency, resulting in mortality through cardiovascular calcification.

TH-PO536

Stage 3-5 CKD Patient Coronary Artery Calcification Status Correlates Positively with von Willebrand Factor Platelet Binding Cynthia M. Pruss, Spencer Barr, Angie Tuttle, Julie Grabell, Shawn Tinlin, Michael A. Adams, Wilma M. Hopman, Jocelyn S. Garland, Paula James, Rachel M. Holden. *Queen's Univ, Kingston, ON, Canada.*

Background: Increased Von Willebrand Factor (VWF) levels are linked to cardiovascular disease and poor outcomes and rise over the course of CKD. VWF mediates platelet binding to damaged vessels in primary hemostasis. VWF structure changes conformation when subjected to shear forces, such as by arteries which have become rigid due to calcification. This study examines a stage 3-5 CKD cohort to determine if coronary artery calcification (CAC) correlates with VWF quantity or function.

Methods: VWF antigen (VWF:Ag), propeptide (VWFpp), platelet binding (VWF:RicOF) levels were measured in a stage 3-5 CKD cohort (CKD, N=118, 38% female, eGFR 27.9±10.6 ml/min/1.73m^2) and compared to age matched controls (CON,N=49, 58% female). CAC scores were evaluated via CT, with values >10 considered positive. Statistical analysis reported as mean ±SD, student's t-test. Multivariate logistic regression was used to control for age, gender, diabetes, BMI >30 kg/m2, GFR, VWF:Ag, and VWF:RiCof.

Results: VWF:Ag was significantly increased (P<0.001). There was no significant difference in VWFpp or VWF:Ricof between CON and CKD. VWF:Ricof/VWF:Ag (relative platelet binding), VWFpp/VWF:Ag, (1/VWF circulating half-life), and age were significantly lower in the CKD group. In multivariate analysis, age was highly significant (odds ratio (OR) 2.38 /decade, confidence interval (CI) 1.5-3.7, P<0.001). VWF:Ricof was significant (OR 1.225 per 0.1 U/ml, CI 1-1.4, P=0.011). When VWF:Ricof/VWF:Ag replaced VWF:Ricof in the model, VWF:Ricof/VWF:Ag was also significant (OR 1.23 per 0.1, CI 1.04-1.5, P=0.019).

	CON	CKD
VWF:Ag (U/dL)	1.15 ±0.42	1.48 ±0.72***
VWFpp (U/dL)	1.28 ±0.36	1.34 ±0.43
VWFpp/VWF:Ag	1.16 ±0.23	1.01 ±0.35***
VWF:Rco (U/ml)	1.41 ±0.47	1.40 ±0.67
VWF:Rco/VWF:Ag	1.23 ±0.3	1.02 ±0.4***
Age	67.4 ±7.9	61.5 ±12.9 *

Conclusions: This study finds CAC status correlates with the absolute and relative VWF platelet binding activity. This suggests that early calcification modifies VWF, and could contribute to alterations in hemostasis in early CKD.

Funding: Private Foundation Support, Government Support - Non-U.S.

TH-PO537

Role of Stearoyl-CoA Desaturase in the Regulation Vascular Calcification Makoto Miyazaki. *Medicine, Univ of Colorado Denver.*

Background: Vascular calcification is a common complication in patients with chronic kidney disease. Our recent in vitro study indicates that accumulation of saturated fatty acid (SFA) by inhibiting stearoyl-CoA desaturase (SCD) leads to mineralization of vascular smooth muscle cells (VSMCs) through the activation of endoplasmic reticulum (ER) stress. In this study we determine the function of SCD in VSMCs and SFA-mediated ER stress in regulating vascular calcification *in vivo*.

Methods: SMC-specific SCD knockout mice were generated by breeding SMMHC-Cre^{ERT} mice with SCD1/2 floxed mice. Mice were intraperitoneally injected with tamoxifen (1mg/day) for 5 consecutive days beginning at 5 weeks of age. Mice were sacrificed at 18 weeks of age.

Results: Klotho-deficient mice exhibited a drastic reduction of SCD expression in the medial layer of the aorta, resulting in accumulation of stearate, activation of ER stress and vascular calcification. SMC-specific SCD deletion induced ER stress in the medial layer of the aorta, resulting in severe medial calcification.

Conclusions: SFA-mediated ER stress plays a major role in the pathogenesis of medial calcification.

Runx2 Expression in Vascular Smooth Muscle Cells Is Required for Arterial Medial Calcification following Vitamin D Overload in Mice Mu-En Lin, Theodore M. Chen, Elizabeth M. Soberg, Mei Y. Speer, Cecilia M. Giachelli. *Bioengineering, Univ of Washington, Seattle, WA.*

Background: Arterial medial calcification (AMC) is a hallmark of chronic kidney disease-mineral bone disorder (CKD-MBD) and strongly predicts cardiovascular disease mortality. Smooth muscle cell (SMC) transition to an osteochondrogenic (OC) phenotype is a common feature of AMC, and is preceded by expression of Runx2, a master regulator of bone development. The present studies aimed to determine whether Runx2 expression in SMC was required for OC phenotype change and AMC.

Methods: An improved Runx2 targeting construct was used to generate a conditional Runx2 knockout mouse (fl/fl) using Cre-Lox technology. Targeting specificity, efficiency, and compete deletion of Runx2 protein were confirmed by crossing fl/fl mice to Sox2-Cre (global) and SM22a-Cre (ΔSMC) mice. SMC were isolated from mouse aortic media by enzymatic digestion. Vitamin D (VD) overload was used to induce AMC. Serum chemistry, gene expression, and arterial calcium deposition were analyzed.

Results: Global deletion of Runx2 led to severe bone malformation and perinatal death, whereas ΔSMC mice were viable with normal bone and arterial morphology. Following VD overload, arterial SMC in fl/fl mice expressed Runx2, underwent OC phenotype change, and developed severe AMC. In contrast, ΔSMC mice did not express Runx2, maintained SMC phenotype, and did not develop AMC. VD increased serum calcium and FGF23 levels compared to vehicle treated mice, and no differences were observed between fl/fl and ΔSMC. *In vitro*, SMC derived from fl/fl mice calcified to a much greater extent than those derived from ΔSMC mice.

Conclusions: The data indicate that Runx2 expression in SMCs is absolutely required for SMC phenotypic change and subsequent calcification in a mouse model of AMC. Runx2 function in AMC was SMC autonomous, as no differences in systemic mineral homeostasis were observed and the decreased capacity of SMC derived from ΔSMC to calcify was recapitulated *in vitro*. Therefore, Runx2 and downstream signaling pathways that mediate OC phenotypic change may be useful therapeutics targets for treatment of AMC caused by systemic mineral imbalance, such as CKD-MBD.

Klotho: Differential Expression and Regulation by Paricalcitol in the Kidney, Parathyroid, and Aorta of Uremic Rats Cynthia S. Ritter, Sarah Zhang, Jane Finch, James A. Delmez, Eduardo Slatopolsky. *Renal Div, Washington Univ School of Medicine, St. Louis, MO.*

Background: Klotho plays an important role in mineral homeostasis and the pathogenesis of cardiovascular disease in CKD. Klotho is highly expressed in the kidney, parathyroid glands (PTGs), and choroid plexus, but its presence in the vasculature has been debated. It is generally accepted that renal Klotho is decreased in CKD; however, the effect of uremia on expression of Klotho in other tissues is not as clearly defined. There are also conflicting reports concerning the effect of vitamin D receptor activator therapy in CKD on expression of Klotho in the various tissues.

Methods: We compared the effect of a 3-month treatment with and without paricalcitol on Klotho in the kidney, PTGs, and aorta in uremic rats (5/6 nephrectomy). One group of uremic rats was treated with paricalcitol 3 x per week (200 ng/rat administered IP). Klotho expression was analyzed by qPCR and immunohistochemical staining (IHC) in the kidney and by IHC in the aorta and PTGs. Samples of archived human PTG tissue from 6 uremic patients with secondary hyperparathyroidism were also analyzed for Klotho by IHC.

Results: With uremia, Klotho expression was unchanged in the PTGs, was significantly decreased in the kidney (65.5%) and the intimal-medial area of the aorta (69.2%), and was significantly increased in the adventitial area of the aorta (67.0%) compared with controls. Paricalcitol treatment of CKD prevented the decrease in Klotho expression in the kidney, increased expression in the PTGs (31.0%), had no effect in the aortic media, but blunted the increase of Klotho in the aortic adventitia. In the human PTGs, Klotho expression was higher in oxyphil cells compared with chief cells in all 6 patients.

Conclusions: This tissue-specific expression and regulation of Klotho in the kidney, PTG, and aorta in uremic rats suggests that Klotho may have different roles in different tissues. In addition, this is the first report of increased expression of Klotho in the oxyphil cells of PTGs from uremic patients. The fact that the function of the parathyroid oxyphil cell is unknown makes the increased expression of Klotho in this cell even more intriguing.

Heterogeneous Susceptibility of Various Arterial Beds to Uremic Media Vascular Calcification Alexander H. Kirsch,[1] Andrijana Kozina,[2] Sa?a Frank,[2] Alexander R. Rosenkranz,[1] Kathrin Eller,[1] Philipp Eller.[3] *[1]Clinical Div of Nephrology, Medical Univ of Graz, Graz, Austria; [2]Inst of Molecular Biology and Biochemistry, Medical Univ of Graz, Graz, Austria; [3]Div of Angiology, Medical Univ of Graz, Graz, Austria.*

Background: Cardiovascular morbidity and mortality in CKD are strongly linked with arterial calcifications and sudden cardiac death. Uremic media calcification is not only driven by systemic factors such as hyperphosphatemia, but is also dependent on vascular smooth muscle cells. We hypothesized that different developmental origins of vascular smooth muscle cells might lead to a heterogeneous susceptibility to develop media calcification.

Methods: Female DBA/2 mice were maintained on a 2% high-phosphate diet (HPD) and studied after 14 days. Histological, chemical, functional studies were conducted to study calcification and the response to HPD. Furthermore, we used computer tomography to study calcifications in the corresponding vascular segments in a cohort of ESRD patients (n=36).

Results: Uremic DBA/2 mice did not show any signs of vascular calcification in the thoracic aorta (TA), while there was abundant media calcification in the abdominal aorta (AA). The AA of DBA/2 mice on phosphorus-rich diet displayed significantly higher calcium and phosphorus contents, and an impaired contractility in wire myography measurements, when compared to the TA. Upon high-phosphate diet, the transcriptional profile revealed an induction of an inflammatory phenotype only in the AA, but not in the TA. Arterial calcifications in patients with end-stage renal failure showed a similar pattern with significantly lower calcium scores of the ascending TA when compared to coronary or iliac arteries.

Conclusions: There was a similar heterogeneous pattern of uremic media calcification both in mice and in humans, where mesenchyma-derived arteries were more prone to media calcification when compared to neuronal-crest derived arteries such as the thoracic aorta. Thus, smooth muscle cells from different lineages respond differently to morphogenetic cues *in vivo*.

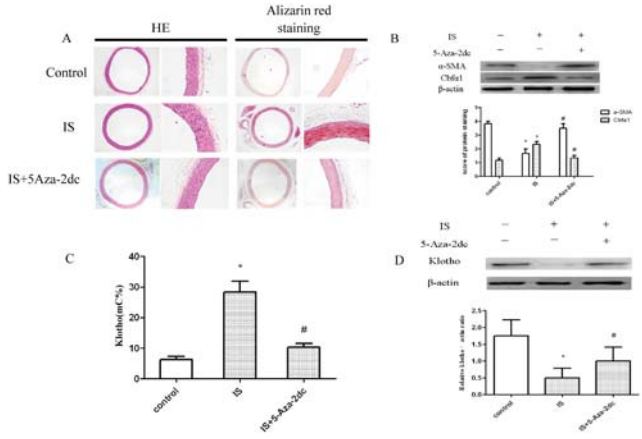
TH-PO541

Vascular Klotho Hypermethylation Potentiates the Development of Vascular Calcification Induced by Indoxyl Sulphate Xiaoyan Zhang, Jing Chen, Yi Fang. *Zhongshan Hospital, Fudan Univ, Shanghai, China.*

Background: Transgenic Klotho overexpressing mice with CKD develop significantly less calcification in comparison with wild-type mice.CKD was a state of vascular Klotho deficiency, a likely explanation for accelerated vascular aging with calcification. It is demonstrated that indoxyl sulfate (IS) can accelerate kidney fibrosis by decreasing Kltho expression via CpG hypermethylation of the Klotho gene. The aim of this study is to investigate whether IS can exacerbates the progression of VC by suppressing vascular Klotho expression by DNA hypermethylation.

Methods: We investigated the effects and possible mechanisms by which Klotho expression is regulated during VC in 5/6 subtotal nephrectomized SD rats (STNx) given IS. Cultured HASMCs treated with IS were used as an in vitro model. 5-aza-2'-deoxycytidine (5Aza-2dc) was used as specific inhibitor of DNA methyltransferase isoform 1.DNA methylation analyses were performed on bisulfite-treated DNA using a quantitative assay based on PCR-pyrosequencing.

Results: Severe vascular calcification was observed by Alizarin red staining in the thoracic aorta of all theSTNx rats given IS, buthardly in the STNx rats. Injections of IS increased CpG methylation level of the Klotho gene and decreased Klotho expression in thoracic aorta. The expression of DNA methyltransferases 1, 3a, and 3b isoforms in HASMCs treated with IS was significantly increase. Specific inhibition of DNA methyltransferase isoform 1 by 5Aza-2dc caused demethylation of the Klotho gene increased Klotho expression and alleviate osteoblast differentiation of HASMCs and vascular calcification.



Conclusions: Inhibition of Klotho gene expression by IS correlates with gene hypermethylation, suggesting that epigenetic modification of specific genes by uremic toxins may be an important pathological mechanism of VC.

TH-PO542

Osteopontin Null Mice on a High Phosphate Diet Develop Vascular Calcification and Elevated FGF-23 Levels Neil Paloian,[1] Elizabeth M. Soberg,[2] Cecilia M. Giachelli.[2] *[1]Nephrology, Seattle Children's Hospital, Seattle, WA; [2]Bioengineering, Univ of Washington, Seattle, WA.*

Background: Chronic kidney disease (CKD) is a common and under recognized disease worldwide. One important cause of morbidity and mortality in this population is vascular calcification (VC). Osteopontin (OPN), a bone protein involved in mineralization regulation, is a known inhibitor of VC and recent clinical studies have demonstrated that FGF-23, a phosphaturic hormone, may also play an important role in VC.

Methods: Wild type (WT) and OPN knockout (KO) mice were placed on normal phosphate (NP) and high phosphate (HP) diets for 11 weeks. At termination serum studies were obtained. Several areas of the aorta were harvested and calcification of the vessels was quantified. Histologic analysis of the vessels and kidneys was performed.

Results: Abundant aortic calcification was observed on histology with alizarin red staining in the HP OPN KO but not the WT group. Total calcium content of the aortic arch + abdominal aorta was 17.3 +/- 4.8 µg Ca/mg dry weight in the HP OPN KO mice compared to 5.1 +/- 2.1 µg Ca/mg dry weight of the WT mice on the HP diet ($p<0.05$). Serum calcium and phosphorus levels were normal for all mice. FGF-23 levels of the HP OPN KO group were 2819 +/- 492 pg/ml compared to 1571 +/- 355 pg/ml in the HP WT mice ($p<0.05$). OPN KO mice placed on the HP diet also developed uremia compared to the WT mice on the HP diet with BUN levels of 36 +/- 4.6 mg/dl and 31 +/- 6.7 mg/dl respectively ($p<0.05$). Renal histology of the HP OPN KO mice with Von Kossa, H+E, and PAS stains demonstrated significant mineral deposits with dilated tubules and increased interstitial inflammation and fibrosis.

Conclusions: We found that the absence of OPN in the setting of a high phosphate diet causes vascular calcification and marked elevation in FGF-23 levels. The VC seen is likely due to the loss of OPN's inhibitory effect on arterial mineralization, the development of kidney disease, and may involve FGF-23. Furthermore, our studies have uncovered a potential novel regulatory role for OPN in relation to serum FGF-23 levels. This has significant therapeutic potential in the prevention and treatment of vascular calcification.

Effect of Magnesium-Based Phosphate Binder on Cardiac Function in a Rat CKD Model Xoana Barros,[2] Nadine Kaesler,[1] Georg Schlieper,[1] Thilo Krueger,[1] Vincent Brandenburg,[1] Kristina Gundlach,[3] Sonja Steppan,[3] Jutta Passlick-Deetjen,[4] Jürgen Floege.[1] *[1]Uniklinikum RTWH, Aachen, Germany; [2]Hospital Clinic, Barcelona, Spain; [3]Fresenius Medical Care, Bad Homburg, Germany; [4]Univ Düsseldorf, Germany.*

Background: A beneficial effect of treatment with Calcium Acetate-Magnesium Carbonate (CaMg) on vascular calcification (VC) in a rat model of uremia was recently described. Magnesium may also exert pleiotropic effects on cardiovascular function. Our aim was to confirm the beneficial effect of CaMg on VC and in addition to asses CaMg effects on cardiovascular function.

Methods: CKD was induced in male Wistar rats by adenine and high phosphate diet (n=52). Treatment groups included CaMg, magnesium carbonate ($MgCO_3$) and calcium acetate (CaAc). Healthy and CKD animals without treatment served as controls. Blood pressure (BP), serum and urine parameters were measured at baseline and after 5 weeks treatment. Echocardiography and assessment of carotid pulse wave velocity (PWV) were performed before sacrifice. Collagen expression was measured by RT-PCR, Sirius red staining and immunohistochemistry. Aortic calcification (AoC) was assessed with Cresolphthalein method and von Kossa staining.

Results: CKD animals exhibited higher serum levels of creatinine, phosphate, calcium, PTH and FGF23 compared to healthy controls. CaMg reduced phosphaturia compared to CKD-controls (-42%, p<0.001), MgCO3 (-35%, p<0.005) and CaAc (-26%, p=0.06) animals. AoC was significantly increased in the untreated CKD-controls compared to healthy rats whereas no significant differences between treated CKD and healthy rats was observed. No significant differences in BP and PWV were observed between groups. Interestingly, $MgCO_3$ and to a lower degree CaMg treatment led to a higher ejection fraction compared with CKD-control animals (+51%, p<0.05 and +34%, p=0.2, respectively). To investigate potential mechanisms underlying this we performed Sirius red staining and examined the cardiac expression of collagens I and III, which were similar between the groups.

Conclusions: CaMg served as an effective PO_4 binder.The positive effect of magnesium on cardiac function does not seem to be related to altered collagen content and needs further evaluation.

TGF-β/Smad3 Signaling Suppresses the Degree of Phosphate-Induced Vascular Smooth Muscle Cell Calcification Aiko Shimokado, Yasuteru Muragaki. *Pathology, Wakayama Medical Univ, Wakayama, Japan.*

Background: The role of transforming growth factor-β (TGF- β) in Pi-induced vascular calcification remains controversial. The aim of this study was to investigate the possible involvement of TGF-β in Pi-induced vascular calcification.

Methods: We compared the degree of Pi-induced vSMC calcification between vSMCs isolated from wild-type ($Smad3^{+/+}$) and Sma3-deficient ($Smad3^{-/-}$) mice.

Results: We found that vSMCs from $Smad3^{+/+}$ mice had less calcium (Ca) than those from $Smad3^{-/-}$ mice when they were exposed to high concentrations of Pi and Ca (Pi + Ca). The phosphorylation of Smad3 was induced in $Smad3^{+/+}$ vSMCsand not in$Smad3^{-/-}$ vSMCs by exposure to Pi + Ca. The concentration of extracellular pyrophosphate (ePPi) was lower in $Smad3^{-/-}$ vSMCs than in $Smad3^{+/+}$ vSMCs and was significantly increased in $Smad3^{+/+}$ vSMCs by treatment with TGF- β1. Also, the addition of a small amount of PPi to culture medium significantly decreased the deposition of Ca in both $Smad3^{+/+}$ and $Smad3^{-/-}$ vSMCs. Extracellular nucleotide phosphatase/phosphodiesterase1 (Enpp1) was decreased at the mRNA, protein, and enzymatic activity levels in $Smad3^{-/-}$ vSMCs compared with $Smad3^{+/+}$ vSMCs. A ChIP assay showed that phosphorylated Smad3 directly binds to the Enpp1 gene. Furthermore, the calcification of aortic segments was attenuated by treatment with TGF- β1 only in $Smad3^{+/+}$ mice.

Conclusions: We conclude that Pi-induced vSMC calcification is suppressed by TGF-β/Smad3 signaling via an increase in ePPi.

Apolipoprotein L1 Gene Associations with Atherosclerosis, Nephropathy, and Mortality in African Americans with Type 2 Diabetes Barry I. Freedman,[1] Carl D. Langefeld,[2] Lingyi Lu,[2] Nicholette D. Palmer,[3] Susan Carrie Smith,[1] Pamela J. Hicks,[3] Jianzhao Xu,[3] Lynne E. Wagenknecht,[2] Laura M. Raffield,[3] Thomas C. Register,[4] Donald W. Bowden,[3] Jasmin Divers.[2] *[1]Internal Medicine/Nephrology, Wake Forest School of Medicine; [2]Center for Public Health Genomics, Wake Forest School of Medicine; [3]Center for Genomics and Personalized Medicine, Wake Forest School of Medicine; [4]Pathology, Wake Forest School of Medicine, Winston-Salem, NC.*

Background: Albuminuria and reduced estimated glomerular filtration rate (eGFR) strongly associate with two apolipoprotein L1 gene (*APOL1*) variants in non-diabetic African Americans. Whether *APOL1* associates with coronary artery calcified atherosclerotic plaque (CAC), carotid artery calcified atherosclerotic plaque (CP), infra-renal aorta CP, and survival remains unclear.

Methods: African American-Diabetes Heart Study participants (n=717) underwent computed tomography to determine CP mass scores in the coronary arteries, carotid arteries and infra-renal aorta; urine albumin:creatinine ratio (UACR), eGFR, and C-reactive protein (CRP) were measured. Associations between CP and *APOL1 G1* and *G2* variants were assessed adjusting for age, sex, African ancestry, body mass index, hemoglobin A1c, smoking, hypertension, use of statins and ACE inhibitors, albuminuria, and eGFR.

Results: Participants were 58.9% female with mean±SD age 56.5±9.6 years, CKD-EPI equation eGFR 89.5±27.7 ml/min/1.73m^2, UACR 169.6±609 mg/g, CAC 610±1412, carotid artery CP 171±531, and aorta CP 5378±10236. In the fully adjusted model, *APOL1* risk variants were associated with significantly lower levels of carotid artery CP (parameter estimate [β] -0.42, SE 0.18, p=0.02 dominant model), with a trend toward lower CAC (β=-0.36, SE 0.21; p=0.08 dominant model), but not with aorta CP, CRP, UACR, or eGFR. After a mean follow-up of 5.0±1.9 years, 89 participants died. *APOL1* nephropathy variants were significantly associated with improved survival (hazard ratio=0.67 for 1 copy; 0.44 for 2 copies, p=0.005).

Conclusions: *APOL1* nephropathy variants were associated with lower levels of subclinical atherosclerosis and reduced risk of death in African Americans with type 2 diabetes.

TH-PO546

Impact of the Stopping of Vitamin K Antagonist Treatment on Concentrations of Dephosphorylated and Uncarboxylated Matrix Gla Protein Pierre Delanaye, Bernard Dubois, Pierre Lukas, Pierre Peters, Jean-Marie H. Krzesinski, Etienne Cavalier. *Univ of Liège, Liège, Belgium.*

Background: Several data suggest that vitamin K antagonist (VKA) therapy is a risk factor for vascular calcifications. Recent data in hemodialysis suggested that fondaparinux, an indirect factor Xa inhibitor, could be safely used in these patients. Matrix Gla protein (MGP) is an 11 kDa protein acting as a potent local inhibitor of vascular calcification. In order to be fully active, MGP must be phosphorylated and carboxylated. This carboxylation is dependent on vitamin K. Inactive dephosphorylated-uncarboxylated (dp-uc) MGP concentrations were higher in hemodialysis patients treated by AVK and could be associated with vascular calcifications. In this study, we measured dp-ucMGP in patients directly after switching from AVK to fondaparinux.

Methods: Switching from AVK (acenocoumarol) to fondaparinux was considered in patients with atrial fibrillation. Seven dialyzed patients were included. Two measurements (T1 and T2) were obtained at the beginning of the dialysis session before stopping AVK. The patients stopped AVK therapy the day before the first dialysis session of the next week. Five measurements were then obtained at the beginning of each dialysis session (T3 to T7). dp-ucMGP was quantified by automated method (IDS, Boldon, UK).

Results: Before switching, median concentrations of dp-ucMGP obtained at two times (T1 and T2) were high but not different: T1 6316 [5485;8693] and T2 6150 [4911;7325] pmol/L. In the first 24 hours following the switch (T3), the median concentration did not change: 5902 [4842;9165] pmol/L. However, all measurements obtained after significantly decreased in comparison to T1: T4 4505 [3295;6791], T5 3810 [2331;4979], T6 3850 [2159;4586], and T7 2948 [1644;3721] pmol/L (p<0.05). Concentrations at T4 were also higher than at T5-T7 but a steady state was then reached and concentrations at T5, T6 and T7 were not different.

Conclusions: Stopping AVK in hemodialysis patients is associated with a rapid reduction of dp-ucMGP concentrations. If this reduction of dp-ucMGP is associated with a better evolution of vascular calcifications remains to be proved.

TH-PO547

Characterization of Circulating Myeloid Calcifying Cells in End-Stage Renal Disease Ryan Gillihan, Cassi Johnson, Shiqin Zhang, Jason R. Stubbs. *The Kidney Inst, Kansas Univ Medical Center, Kansas City, KS.*

Background: Patients with end-stage renal disease (ESRD) exhibit numerous bone and mineral metabolism defects that contribute to vascular calcification and cardiovascular mortality in this population. Recent evidence suggests the presence of osteocalcin-positive (OCN^+) cells in the peripheral circulation of humans that exhibit calcifying abilities both *in vitro* and *in vivo*, raising the possibility that alterations in these circulating OCN^+ cells may contribute to the pathogenesis of vascular calcification.

Methods: The purpose of this study was to characterize levels of circulating OCN^+ cells in healthy volunteers and an ESRD population. Thus, we isolated peripheral blood mononuclear cells (PBMCs) from 16 patients (8 ESRD patients and 8 healthy controls) and evaluated OCN expression in these cells by flow cytometry.

Results: We observed ESRD patients to exhibit a higher percentage of OCN^+ cells from the total PBMC population (6.8% versus 2.7% in controls; P<0.05). Furthermore, in a sub-analysis of myeloid-derived ($CD14^+$) PBMCs, ESRD patients exhibited a higher percentage of $CD14^+OCN^+$ cells compared to controls with normal kidney function (79.2% versus 65.3% in controls; P=NS). Further stratification of the $CD14^+$ cells into $CD16^+$ and $CD16^-$ sub-fractions, revealed ESRD patients to exhibit a higher percentage of OCN^+ cells in the $CD16^+$ subset (39.8% versus 22.3% in controls; *P*<0.05). Culturing isolated $CD16^+$ cells under osteogenic conditions revealed these cells to exhibit calcifying potential *in vitro* as assessed by alizarin red staining. Of note, previously published data from our lab identified this same $CD16^+$ subset of cells to exhibit significantly higher vitamin D receptor expression in ESRD patients following vitamin D therapy, perhaps providing further evidence to support an osteoblast-like phenotype for this cell population.

Conclusions: Patients with ESRD demonstrate higher levels of circulating myeloid-derived, OCN^+ cells, which we propose may contribute to the pathogenesis of vascular calcification. Supplemental functional assays are ongoing to compare the calcifying capacity of OCN^+ cells isolated from ESRD versus control subjects.

Intracellular Calcium Signaling Is Altered in Vascular Smooth Muscle Cells (VSMC) in Chronic Kidney Disease Chad A. Zarse,[1] Mikaela Lee Mckenney,[2] Stacey L. Dineen,[2] Michael Sturek,[2] Neal X. Chen,[1] Sharon M. Moe.[1] *[1]Nephrology, IU School of Medicine, Indianapolis, IN; [2]Physiology, IU School of Medicine, Indianapolis, IN.*

Background: Vascular calcification results in morbidity and mortality in CKD. Pathologic intracellular calcium (iCa) signaling in VSMCs may contribute to abnormalities in contractility and/or calcification. This study examined the alteration of iCa in CKD versus normal rats and the effect of common therapies.

Methods: Three groups of slowly progressive CKD Cy/+ rats (untreated, calcitriol given 15 mg/kg IP thrice weekly, and 3% calcium gluconate in drinking water to mimic phosphate binder use; n=6-7 per group) and one group of normal SD rats (n=6) were studied. Treatments began at 25 weeks and rats sacrificed at 34±1 weeks, representing ~15% of normal kidney function. VSMCs were isolated from freshly dissected thoracic aorta and iCa measured using the fluorescent indicator, fura-2 (iCa=ratio at 360/380nm). Basal iCa was measured in the presence of physiologic salt solution. The sarcoplasmic reticulum (SR) Ca store capacity was assessed in the presence and absence of extracellular Ca with caffeine. Aorta calcification was measured biochemically. Results were compared by ANOVA.

Results: Vascular calcification was higher in all CKD groups compared to normal SD rats (p=0.03). Basal VSMC iCa (ratio 360/380) was elevated in all CKD groups compared to normal (p=0.0029, CKD 0.98±0.02 versus Normal 0.81±0.05; no significant differences were observed among CKD treatment groups). SR store capacity was greater in CKD rats (p<0.0001, CKD 0.64±0.04 versus Normal 0.44±0.06). Following SR Ca store release in CKD VSMCs, in the presence and absence of extracellular Ca, there were differences in iCa returning to basal levels, suggesting increased activity of transient receptor potential channels and/or extrusion impairment through sodium-calcium-exchanger. There was a trend toward correlation between basal iCa and aortic calcification (p=0.09, r=0.35).

Conclusions: VSMC in CKD rats have increased basal iCa and sarcoplasmic reticulum store release and an abnormality of calcium extrusion from VSMC. How this relates to the pathogeneisis of vascular calcification remains to be determined.

Differential Expression and Vascular Calcification Gene Targeting of microRNA Contained in Matrix Vesicles From CKD Compared to Normal Rats Neal X. Chen,[1] Praneet Chaturvedi,[2] Sarath Chandra Janga,[2] Kalisha O'Neill,[1] Jeanette N. Mcclintick,[1] Sharon M. Moe.[1,3] *[1]Indiana Univ School of Medicine; [2]School of Informatics and Computing, IUPUI; [3]Roudebush VAMC, Indianapolis.*

Background: Matrix vesicles (MV) are involved in calcification of vascular smooth muscle cells (VSMC). The protein make up of MV alters activity and mineralization capability, but the role of microRNA (miRNA) in MV induced calcification has not been evaluated. We hypothesized that the miRNA expression profile in MVs isolated from CKD rats that spontaneously develop arterial calcification would differ from normal (NL) littermates.

Methods: VSMC from NL or CKD rats (n=3) were incubated with calcification media and MV isolated. Total RNA was isolated from MV and VSMC and miRNA quantified using Agilent Bioanalyzer. MiRNA array was performed using GeneChip miRNA 3.0 Array. We analyzed the miRNA that changed at least 2 fold in the comparison groups with a p value of < 0.01 and false discovery rate of < 20%. Target gene prediction was performed using bioinformatics programs Targetscan and Miranda.

Results: We demonstrated that miRNAs were concentrated in MV compared to VSMC, confirmed by real time PCR. Analyses demonstrated 3 miRNAs decreased and 6 miRNAs increased in VSMC from CKD versus NL rats. Six miRNAs were decreased and 9 miRNAs increased in MV from CKD versus NL rats. We then asked if the 'packaging' of miRNA from VSMC to MV would alter calcification and identified 28 dysregulated miRNAs in MV compared to VSMC from CKD rats. Target prediction analysis followed by functional enrichment of the targets revealed the existence of an intricate miRNA-mRNA network across multiple pathways. The primary pathways identified included MAPK signaling, focal adhesion, receptor protein signaling and Wnt signaling. We then determined if the 28 miRNA had the potential to alter 25 known genes involved in vascular calcification (Runx2, ALP, annexin 2, etc.) and found 5 miRNAs alter multiple genes involved in calcification.

Conclusions: MV and VSMC from CKD rats have different patterns of miRNA profiles than those from NL rats. MiRNAs in MV may serve as key regulators of various target genes responsible for vascular calcification in CKD.

Calciprotein Particles Induce Calcification of Vascular Smooth Muscle Cells *In Vitro* Parisa Aghagolzadeh,[1] Rakesh Kumar Bijarnia,[1] Prakash Chandak,[1] Matthias Bachtler,[1] Edward Robert Smith,[2] Andreas Pasch.[1] *[1]Nephrology, Hypertension and Clinical Pharmacology, Univ Hospital Bern, Bern, Switzerland; [2]Nephrology, The Royal Melbourne Hospital, Melbourne, Australia.*

Background: Vascular calcification is prevalent in patients with chronic kidney disease (CKD) and is associated with significant cardiovascular morbidity and mortality. Calciprotein particles (CPP) are calcium phosphate-containing nano-aggregates which have been found in the blood of CKD patients. The effect of CPP on vascular smooth muscle cells (VSMC) mineralization has yet to be evaluated.

Methods: Synthetic primary and secondary CPP were generated using phosphate-enriched culture medium (DMEM/10% FBS) incubated at 37°C for either one day (primary CPP) or seven days (secondary CPP). Human VSMC were cultured with these media and mineralization was assessed qualitatively with Alizarin red staining and quantitatively by measurement of calcium and phosphate content.

Results: The supplementation of culture medium with 3.5 mM phosphate and 1mM calcium resulted in a time- and temperature-dependent generation of primary and secondary CPP, as identified by TEM. Exposure of VSMC to secondary CPP led to a pronounced and consistent dose-related accumulation of calcium and phosphate mineral (i.e. calcification) within 5 days, whereas exposure to primary CPP did not. Furthermore, the amount of FBS used for the generation of morphologically indistinguishable secondary CPP corresponded to the extent of VSMC calcification.

Conclusions: CPP form spontaneously in cell culture medium containing high phosphate. Secondary CPP induce VSMC calcifications in vitro, whereas primary do not. This indicates that controlling CPP particle type and transformation may be an important determinant of VSMC calcification *in vitro*.

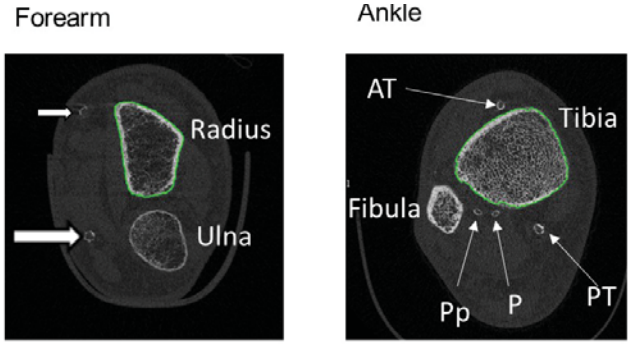
Peripheral Vascular Calcification and Bone Changes in Advanced Chronic Kidney Disease Using High Resolution Peripheral Quantitative Computed Tomography (HR-pQCT) Syazrah Salam,[1,2] Margaret A. Paggiosi,[2] Richard Eastell,[2] Arif Khwaja.[1] *[1]Sheffield Kidney Inst, Northern General Hospital; [2]Academic Unit of Bone Metabolism, Univ of Sheffield, United Kingdom.*

Background: Vascular calcification (VC) in chronic kidney disease (CKD) is linked to abnormal bone mineral metabolism. We aim to evaluate the association between peripheral VC and bone parameters using HR-pQCT in advanced CKD.

Methods: We recruited 31 CKD stages 4-5 (including dialysis) patients and their age- and gender-matched controls with eGFR>60ml/min/1.73m^2. We performed HR-pQCT (XtremeCT, Scanco) at the wrist and ankle to assess bone parameters of distal radius and tibia (82μm resolution, spanning 9.02mm). The same images (figure) were used to quantify peripheral VC in mg hydroxyapatite (mgHA). Abdominal aortic calcification (AAC) was assessed using dual energy X-ray absorptiometry (DXA; Discovery A, Hologic) and AAC-8 score.



Peripheral arteries of the forearm; radial artery (small arrow) and ulnar artery (big arrow). Peripheral arteries of the ankle; anterior tibial artery (AT), posterior tibial artery (PT), peroneal artery (P) and perforating branch of peroneal artery (Pp).

Results: 81% of CKD and 32% of controls had measurable VC. Median VC mass was 0.29 mgHA at the wrist and 0.88 mgHA at the ankle in CKD; whilst controls had median VC mass of 0 mgHA at both sites (p<0.001). Trabecular volumetric bone mineral density (vBMD) was significantly lower in CKD (161.3 versus 184.8 mg/cm^3, p<0.05) at distal radius in addition to lower trabecular bone volume and thickness. At distal tibia, CKD patients had lower total vBMD (277.7 versus 311.8 mg/cm^3, p<0.05) and thinner cortical bone (1.25 versus 1.06 mm, p<0.05). There was a negative correlation between VC and vBMD, especially of cortical bone at distal tibia (r=-0.342, p=0.007). In contrast to VC by HR-pQCT, AAC was only measurable in 48% of CKD and 19% of controls.

Conclusions: CKD was associated with peripheral VC, lower vBMD and thinner cortical and trabecular bone. HR-pQCT is a useful tool for future research in CKD mineral bone disease by allowing simultaneous assessment of peripheral VC, bone density and micro-architecture.

Effect of Rapamycin on High Glucose-Induced Endothelial-To-Chondrocyte Transition in Human Aortic Endothelial Cells

Rining Tang,[1] Min Wu,[2] Dongdong Zhu,[3] Bi-Cheng Liu,[5] Kun Ling Ma.[4] *[1]Insitute of Nephrology, Zhongda Hospital, Southeast Univ; [2]Insitute of Nephrology, Zhongda Hospital, Southeast Univ; [3]Insitute of Nephrology, Zhongda Hospital, Southeast Univ; [4]Insitute of Nephrology, Zhongda Hospital, Southeast Univ.*

Background: Vascular calcification is one of the common complications in diabetes mellitus (DM). Studies showed high glucose (HG) caused cardiovascular calcification. Our previous studies showed HG could induce endothelial cells transdifferentiation into chondrocyte via endothelial mesenchymal transition (EndMT), which was involved in medial calcification. However, its underlying mechanism is not understood. Inflammation plays a role in the development of DM. Evidences showed a significant increase in the expressions of IL-1 in DM. Rapamycin reduced inflammation by inhibiting mammalian target of Rapamycin (mTOR). However, whether it prevented the progression of vascular calcification remained unclear. The aim was to explore the influence of IL-1 on the HG-induced endothelial-to-chondrocytes.

Methods: Primary human aortic endothelial cells (HAECs) were treated with normal glucose (NG; 5.5 mM), HG (30 mM D-glucose) and Rapamycin(10ng/ml) (HG+Rapamycin) for 48 h. Immunofluorescence staining was performed to detect the co-expression of CD31 and fibroblast-specific protein 1 (FSP1). The expressions of CD31, FSP1 and mTOR were detected by Western blot. The expression of the Msenchymal Stell Cells markers STRO-1 and the chondrocyte marker SOX9 was detected by immunofluorescence staining and western blots.

Results: The treatment of HAECs in the HG group resulted in increases in the expressions of IL-1 and FSP1 in dose-and time-dependent manners. Double staining of the HAECs indicated a colocalization of CD31 and FSP1 and some cells acquired spindle-shaped morphologies. The cells undergoing EndMT expressed STRO-1 and SOX9. The expressions of FSP1,IL-1,mTOR and SOX9 were increased in the HG group, and these changes were inhibited by Rapamycin. Consistent with SOX9 expression, calcium deposits were enhanced by the HG treatment.

Conclusions: HG-induced vascular calcification via the IL-1 mediation endothelial-to-chondrocyte transition, which was inhibited by Rapamycin.

Telomere Length, Cardiovascular Risk and Arteriosclerosis in Human Kidneys: An Observational Cohort Study

Katrien De Vusser,[1] Nicky Pieters,[2] Evelyne Lerut,[3] Dirk R. Kuypers,[1] Tim Nawrot,[2] Maarten Naesens.[1] *[1]UZ Leuven, Dept of Nephrology and Renal Transplantation, Leuven, Belgium; [2]U Hasselt, Dept of Toxicology, Diepenbeek, Belgium; [3]UZ Leuven, Dept of Pathology, Leuven, Belgium.*

Background: Replicative senescence, associated with telomere shortening, plays an important role in biological ageing and cardiovascular disease. The relation between cardiovascular risk, telomere length, and kidney histology is unknown.

Methods: Our study consisted of a test cohort of 217 kidney donors for transplantation and a validation cohort of 40 kidney donors. We used quantitative RT-PCR to measure relative telomere length (log T/S ratio) in peripheral blood leucocytes and in kidney biopsies performed prior to implantation. The association between the intrarenal histological lesions, leucocyte and intrarenal telomere length was studied using multiple regression models, adjusted for calendar age, gender and other donor demographics.

Results: Subjects with intrarenal arteriosclerosis had significantly shorter leucocyte telomere length compared with patients without arteriosclerosis (log T/S ratio -0.3 versus 0.1 with versus without arteriosclerosis; p=0.0008). Intrarenal arteriosclerosis was associated with shorter telomere length independent of gender, calendar age, history of hypertension and history of cardiovascular events. For each increase of one standard deviation of the log T/S ratio, the odds for intrarenal arteriosclerosis decreased with 64% (Odds ratio 0.36; 95% CI 0.17-0.77; p=0.02). Leucocyte telomere length was not associated with changes in the tubulo-interstitial and glomerular compartments. In accordance with leucocyte telomere length, shorter intrarenal telomere length associated significantly with the presence of renal arteriosclerosis (log T/S ratio -0.04 versus 0.08 with versus without arteriosclerosis, p=0.007), and not with other histological lesions.

Conclusions: We demonstrate that arteriosclerosis in smaller intrarenal arteries is associated with shorter telomere length, independent of cardiovascular risk factors and calendar age. Our study suggests a central role of replicative senescence in the progression of renovascular disease.

TH-PO554

Intravenous SNF472 Inhibits Vitamin D Induced Cardiovascular Calcification in Rats

Joan Perelló,[1] Carolina Salcedo,[1] Markus Ketteler,[2] Fernando Tur,[3] Eva Tur,[1] Bernat Isern,[1] Pieter H. Joubert,[1] Miquel D. Ferrer.[1] *[1]R&D, Sanifit, Palma, Spain; [2]Div. of Nephrology, Klinikum Coburg GmbH, Coburg, Germany; [3]Lab. Renal Lithiasis Research, IUNICS, Univ of the Balearic Islands, Palma, Spain.*

Background: An in vivo study (1) investigated the effects of SNF472, an intravenous (i.v.) formulation of phytate, on vitamin D_3 (VD) induced vascular calcification. Furthermore an in vitro study (2) evaluated the effect of SNF472 on hydroxyapatite (HAP) binding kinetics.

Methods: 1. Four groups of 5-7 male SD rats were studied. Control group received i.v. vehicle daily. Treated groups received 1 mg/kg SNF472 i.v. either daily (o.d) or every other day (e.o.d). Calcification was induced by 5 daily oral administrations of 75 kIU/kg of VD starting on day 3 of treatment. Rats were sacrificed on day 14. 2. SNF472 binding on HAP was studied in vitro by incubation of HAP in the presence of SNF472 for up to 8 hours. SNF472 release was studied by pre-incubation of HAP in the presence of SNF472 and then the pre-incubated HAP was incubated in fresh buffer for up to 7 days.

Results: The administration of VD induced a marked increase in aortic and heart calcium levels. Both o.d and e.o.d. i.v. SN472 at 1 mg/kg resulted in reductions of calcification by 55-60% in aorta and 70-75% in heart. Calcium and phosphorus concentrations in control serums increased compared to the sham group, and were significantly increased by o.d. SNF472 only. In vitro SNF472 was bound to HAP almost immediately, reaching an 80% of maximum adsorption after 5 minutes of incubation, and maximum adsorption (about 5 mg/g) at 60 minutes. This high affinity was confirmed after studying its release from the crystal surfaces and is compatible with the efficacy found in vivo when administered e.o.d.

Conclusions: SNF472 might be used for the prevention of cardiovascular calcification in ESRD patients and calcification-related pathologies as calciphylaxis.

Prevention of Vascular Calcification in Uremic Rats by Pharmacological Inhibition of Matrix Metalloproteinases

Uwe Querfeld,[1,2] Eva Hecht,[2] Christian Freise,[2] Karoline Websky,[2] Berthold Hocher.[3] *[1]Pediatric Nephrology, Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Center for Cardiovascular Research, Charité Universitätsmedizin Berlin, Berlin, Germany; [3]Institut für Ernährungsforschung, Potsdam, Germany.*

Background: We studied the question whether pharmacological inhibition of matrix metalloproteinases (MMPs) can decrease chondro/osteoblastic transition of VMSC and the development of media calcifications in an aggressive model of uremic vascular calcification.

Methods: Uremia was created by 5/6-nephrectomy and all animals were fed a HP diet (1,2% phosphate). Arterial calcifications were induced by treatment with calcitriol (250ng/kg/d). MMPs were inhibited with doxycycline (100mg/kg/d). Five groups of rats were studied: uremic (n=10), shamp-operated (n=10), uremic treated with doxycyclin (n=6), uremic treated with calcitriol (n=14) and uremic treated with calcitriol and doxycycline (n=14). After 5 weeks of calcitriol treatment, animals were sacrificed and media calcification was quantified in aortic sections after von Kossa staining. Osteoblastic transition of VSMC was quantified by RT-PCR for proteins controlling bone mineralization. Aortic content of MMP-2 and MMP-9 was quantified by staining and RT-PCR.

Results: Creatinine, calcium and phosphate levels were significantly higher in groups receiving calcitriol, and not significantly different in the doxycyline-treated group. Systolic blood pressure was similar in all groups. Uremic rats treated with calcitriol, but not rats treated with calcitriol and doxycycline, showed significantly increased gene expression levels of MMP-2 MMP-9, osteopontin, osteocalcin, Runx2, and osterix. Massive calcifications were found in 5/6 nephrectomized rats treated with calcitriol, whereas MMP inhibition with doxycycline resulted in almost complete absence of media calcification.

Conclusions: Phenotypic transition of VSMC and the development of vascular calcification were almost completely prevented by MMP inhibition with doxycycline. This effect was not due to differences in the degree of uremia, calcium or phosphorus levels or systolic blood pressure. MMP inhibition seems a promising strategy in the prevention of uremic vascular calcifications.

TH-PO556

Vascular Calcification in Diabetes - Correlations with Calcification Potential of Serum and with Klotho Expression In Vitro

Ashish Patidar,[1] Dhruv K. Singh,[2] Peter H. Winocour,[2] Shori Thakur,[1] Ken Farrington,[1,2] Anwar Baydoun.[1]
[1]School of Life and Medical Sciences, Univ of Herts, Hatfiled, Hertfordshire, United Kingdom; [2]E&N Herts NHS Trust, Stevenage, United Kingdom.

Background: Uraemic serum induces calcification of vascular smooth muscle cells outside the disease setting (*in vitro* calcific potential of serum). Vascular calcification (VC) is also prevalent in patients with diabetes. We therefore examined the *in vitro* calcification potential of serum from diabetic subjects. We also investigated the effect of this serum on *klotho* expression as it plays a major role in calcification.

Methods: Serum from 20 healthy controls and 45 age- and sex-matched patients with type 2 diabetes (DM) and MDRD eGFR>60 ml/min were analysed following CT scanning of the femoral arteries. The groups studies were: C- (9 controls without VC), C+ (11 controls with VC), DM- (16 patients with DM without VC) and DM+ (29 patients with DM and VC). Serum-induced calcification in human cultured aortic smooth muscle cells was quantified using the DICA-500 Ca^{+2} assay Kit. *klotho* expression was determined by western blotting.

Results: Diabetes subjects and controls were similar in age, gender, blood pressure, eGFR, serum calcium, phosphate, and albumin. The DM+ group had higher median Agatston score than C+ (785 v 202 Hounsfield units; $p<0.01$). In the whole group, *in vitro* calcification correlated with Agatston score (*rho*=0.445; $p<0.001$), age ($r=0.287$; $p<0.05$), and HbA1c (*rho=0.0432*; $p<0.001$). Induced calcification was higher with serum from DM than from controls (201 ± 12 v 85 ± 12Ca^{+2} nanomoles protein mg^{-1}; $p<0.01$), and higher with DM+ than with DM- (221 ± 12 v 158 ± 23 Ca^{+2} nanomoles protein mg^{-1}; $p<0.05$). Serum from DM- and DM+ groups attenuated *klotho* expression (50% decrease compared to control) while serum from C- and C+ did not change expression. The degree of attenuation correlated negatively with calcification potential (*rho*=-0.320, $p>0.05$) *in vitro* and with Agatston score (*rho*=0.445, $p>0.001$).

Conclusions: Serum from patients with DM possesses enhanced calcific potential which can be demonstrated *in vitro*. These effects are associated with the suppression of *klotho* expression, suggesting a potential mechanism.

Klotho Gene and Transcriptional Profiles of the Uremic, Calcified, and Normal Rat Aorta By RNA-seq

Jakob L. Rukov,[1] Eva Gravesen,[4] Maria Lerche Mace,[2,4] Jacob Hofman-Bang,[4] Jeppe Vinther,[1] Ewa Lewin,[2,4] Klaus Olgaard.[4] *[1]Dept of Biology, Univ of Copenhagen; [2]Nephrology, Herlev Hospital; [3]Pathology, Rigshospitalet; [4]Nephrology, Rigshospitalet, Univ of Copenhagen, Denmark.*

Background: Development of Vascular Calcification (VC) is a tightly regulated process between factors promoting and inhibiting mineralisation. Klotho has been shown to suppress vascular calcification and maintain cell differentiation. It's unresolved whether this effect is due to circulating Klotho only, or if there is locally produced Klotho in the vasculature. Next generation high-throughput RNA sequencing (RNA-Seq) is a powerful tool for profiling gene expression and the detection of differentially expressed genes and rare transcripts.

Methods: Using RNA-seq we examined the rat aorta transcriptome from long term, 14 weeks, uremic rats (U) kept on a high P diet and given alphacalcidol (vit D), compared to normal control (C) and normal rats given vit D. VC was detected by von Kossa staining. Plasma Ca, P, PTH and FGF23 were measured.

Results: Severe VC was induced in U rat aortas and to less extent in vit D rat aortas. Cufflinks analysis of the RNA-seq data showed 10144 genes to be expressed with a expression level > 1 read per kb transript per 10^6 mapped reads (RPKM) in at least one of the three groups. 2663 genes were differentially expressed with 47% up- and 53% downregulation in uremic rats relative to vit D and control rats. Markers of osteogenesis, fibronectin, osteopontin, periostin, matrix Gla protein (MGP), and LTBP2 were among the top upregulated genes, while a number (e.g. elastin and tropomyosin1a) of aorta related genes were strongly downregulated. A gene ontology analysis showed that significantly deregulated genes were enriched for genes related to extracellular matrix, response to wounding, organic substance, carbohydrate binding and ossification. MGP was highly expressed in normal aorta and significantly upregulated in VC becoming the most expressed gene. The Klotho gene was not expressed in normal or calcified aorta.

Conclusions: Extensive changes in the transcriptional profile were induced in the uremic, calcified aorta. The Klotho gene was not expressed in the rat aorta, when examined by RNA-seq.

Progressive Oxalate Nephropathy Depends on TNFR1/2 Because They Are Needed for CaOx Crystal Adhesion to Tubule Epithelium

Shrikant R. Mulay, Jonathan Nicodemos Eberhard, Jyaysi Desai, Santhosh Kumar Vr, Hans J. Anders. *Klinische Biochemie, Ludwig Maximillians Univ, Munich, Germany.*

Background: Kidney stones most commonly contain aggregates of calcium oxalate monohydrate (COM). The attachment of COM to epithelial cells is known to be mediated by anionic molecules and urinary macromolecules. We speculated that transmembrane receptors may mediate COM adhesion to epithelial cells.

Methods: All KO mice were generously provided by V. Vielhauer, Germany. All experimental procedures were approved by the local government authorities. Immunostaining and Paraffin Acid Schiff were used for analysing kidney pathology. RTPCR, ELISA, Immunoblot, computed tomography, AFM were used for further data analysis. Human Biopsy samples were generously provided by A. Evan, U.S.A.

Results: We observed that during human and mouse chronic oxalate nephropathy (ON) renal tubular cells surrounding the plaque express TNF receptor (TNFR) 1 and 2. Also western blot analysis confirmed TNFR1/2 induction in murine ON. *Tnfr1*- and/or *Tnfr2*-KO mice were entirely protected from progressive ON as evidenced by plasma creatinine and BUN levels, leukocyte infiltrates and mRNA expression of injury markers and histology. The reason for this protective effect was the complete absence of intrarenal COM crystals, despite unaffected calcium and oxalate excretion, as determined by Pizzolato stains, computed tomography. In vitro studies confirmed the role of TNFR1/2 for COM crystal adhesion. We used atomic force microscopy to measure adhesion forces between COM crystals and primary tubular epithelial cells isolated from wild-type (WT) or *Tnfr1/2*-KO mice. The adhesive forces were almost nil in *Tnfr1/2*-KO cells as compared to WT tubular cells. Moreover, we found that absence of TNFR1/2 blocked the induction of osteopontin, annexin II and CD44, which are genes responsible for crystal adhesion to tubular epithelium after CaOx crystal exposure. Further, the role of TNFRs was independent of TNF as etanercept treatment had no effect on murine ON.

Conclusions: We conclude that TNFR1/2 mediate COM adhesion to tubular epithelium as a starting point of ON. Interfering with this mechanism may provide novel options to prevent kidney disease in patients with hyperoxaluria.

TH-PO559

High Fat Diet Induces Calcification in Nephrectomized Rats

Ana Isabel Raya Bermudez,[1] Carmen Pineda,[1] Rafael Rios-Varo,[1] Addy Rosa Montes de Oca Gonzalez,[1] Escolastico Aguilera-Tejero,[1] Mariano Rodriguez,[2] Ignacio Lopez.[1] *[1]Medicina y Cirugia Animal, Univ de Cordoba, Cordoba, Spain; [2]Nefrologia, Hospital Univ Reina Sofia, IMIBIC, Cordoba, Spain.*

Background: Vascular calcifications (VC) are very prevalent among patients with chronic renal failure and represent a major cause of morbidity and mortality. High fat diets are associated to metabolic changes (dyslipidemia, chronic inflammation, oxidative stress, etc.) which may impair vascular health. We hypothesized that feeding high fat diets to uremic rats would induce vascular calcification.

Methods: Zucker rats of lean phenotype (n=16) were divided in two groups: one group was fed a diet with 60% energy from fat (HF, n=10) and the second group was fed a standard diet with normal caloric content (NF, n=6). After feeding the diets for two months, all animals were 5/6 nephrectomized and were switched to HF and NF diets with high (1.2%) P content. Rats were maintained on these diets for two additional months. At the end of the experiment, rats were anesthetized with sodium thiopental and sacrificed by exanguination. Blood was collected at sacrifice to measure serum creatinine (Cr), ionized calcium (iCa), phosphate (P) and fibroblastic growth factor 23 (FGF23). Samples of thoracic aorta were obtained and processed for measurement of calcium (CaAo) and phosphate (PAo) content.

Results:

Group	Cr (mg/dL)	iCa (mM)	P (mg/dL)	FGF23 (pg/mL)	CaAo (mg/g)	AoP (mg/g)
HF	1.01±0.10	1.11±0.01	7.8±1.2	11366±1639*	6.3±1.5*	12.4±7.2*
NF	0.91±0.09	1.09±0.03	6.1±1.4	4799±2402	1.4±0.1	0.1±0.1

Values are mean±SE; *P<0.05 vs NF

Conclusions: These data show that feeding a diet with high fat content induces VC in uremic rats. It is interesting to note that in the experimental model of 5/6 nephrectomized rat, treatment with calcitriol is necessary to stimulate VC. However, when fed high fat diets, uremic rats develop VC without calcitriol administration. The significant increases in FGF23 detected in rats fed HF suggest that these diets may influence phosphate handling.

TH-PO560

Calcium Sensing Receptor Expression and Activation Protects against Calcification in Human Aortic Smooth Muscle and Arterial Explants

Thomas F. Hiemstra,[1] Guerman Molostvov,[2] Rosemary Bland,[2] Daniel Zehnder.[2] *[1]School of Clinical Medicine, Univ of Cambridge, United Kingdom; [2]Warwick Medical School, Univ of Warwick, Coventry, United Kingdom; [3]Univ Hospitals Coventry and Warwickshire, Coventry, United Kingdom.*

Background: Vascular calcification (VC) is common in CKD, and contributes to cardiovascular risk. Understanding modulators of VC will facilitate rational treatment design to reduce CV risk in CKD. The Calcium Sensing Receptor (CaSR) is present in human muscular and elastic artery, senses extracellular calcium, and may therefore directly modulate VC. We investigated the role of the CaSR in vascular calcification.

Methods: The effects of CaSR agonists, the calcimimetic R568 on phenotype and calcification were evaluated in human aortic smooth muscle cells (HAoSMC) under static conditions and cyclical strain, and in human arterial explants (9 controls, 11 CKD). The role of the CaSR was further explored by CaSR silencing or over-expression.

Results: In HAoSMC, strain increased CaSR expression by 45% ($p<0.05$). CaSR agonists Ca^{2+} and Gd^{3+} reduced CaSR expression ($p<0.01$), though to a lesser extent under strain. Exposure to high Ca^{2+} increased osteocalcin expression, alkaline phosphatase (ALP) activity and calcification ($p<0.01$), and strain attenuated these responses. R568 limited the reduction in CaSR and the development of calcification, particularly under static conditions. R568 dose-dependently reduced osteocalcin expression, but did not influence ALP activity. Importantly, CaSR silencing greatly enhanced calcification and osteocalcin

expression (p<0.01); conversely, CaSR overexpression reduced calcification, osteocalcin expression and ALP activity. In arterial explants, R568 attenuated the Ca^{2+} induced increase in osteoblast markers (Runx2 and Dmp1) in healthy artery, though this effect was no longer apparent in CKD. R568 did not materially change arterial vessel wall calcium content.

Conclusions: Loss of CaSR expression seen in CKD is permissive to calcification and associated with markers of osteogenic transformation. Calcification is reduced when vascular CaSR expression is preserved or on exposure to R568. These data suggest that the CaSR directly modulates VC.

TH-PO561

Vascular Calcification Scores Improve Cardiovascular Risk Assessment beyond Traditional Risk Factors in CKD Patients

Lucie Desjardins,[1,2] Sophie Liabeuf,[1,2] Momar Diouf,[2] Cédric Renard,[3] Gabriel Choukroun,[1,4] Ziad Massy.[1,5] *[1]INSERM U-1088, Amiens, France; [2]CRC, Amiens Univ Hospital, Amiens, France; [3]Radiology Dept, Amiens Univ Hospital, Amiens, France; [4]Nephrology Dept, Amiens Univ Hospital, Amiens, France; [5]Nephrology Dept, Ambroise Paré Hospital, Boulogne Billancourt, France.*

Background: Chronic kidney disease (CKD) is associated with an elevated incidence of cardiovascular (CV) events.Although a variety of non-invasive methods for measuring CV risk (such as carotid intima media thickness, pulse wave velocity (PWV), coronary and aortic calcification scores (measured either by CT scan or X-ray) and the ankle brachial index (ABI)) have been evaluated separately in CKD cohorts, few studies have evaluated them simultaneously. The objective of the present study was to determine whether these non-invasive methods ameliorate the risk prediction beyond traditional risk factors (TRF) in patients at different CKD stages.

Methods: We performed a prospective, observational study of the relationship between the outputs of non-invasive measurement methods on one hand and mortality and cardiovascular outcomes in 143 patients at different CKD stages on the other. During the follow-up period (mean duration: 2.5 years), 44 patients died and 30 CV events were recorded. We used a Cox model to calculate the relative risk for outcomes. To assess the putative clinical utility, we also determined the net reclassification improvement (NRI) and the integrated discrimination improvement for each method.

Results: PWV, aortic/coronary calcification and ABI predicted all-cause mortality and cardiovascular events in univariate analysis. However, after adjustment for TRF, only aortic and coronary calcification scores were selected in a multivariate analysis as significant, independent variables. Moreover, coronary and aortic calcification scores allowed significant NRI of 27% and 20% respectively beyond the TRF.

Conclusions: Evaluation of vascular calcification scores appears to improve CV risk assessment (beyond TRF) in a CKD population. Since the radiographic evaluation of aortic calcification is relatively simple, routine use of this technique in CKD populations might improve CV risk stratification.

TH-PO562

Pericardial Fat Is Associated with Coronary Artery Calcification in Non-Dialysis Dependent Chronic Kidney Disease Patients

Paulo H.N. Harada,[1] Maria Eugenia F. Canziani,[2] Leonardo Mateus Lima,[1] Marcelo Lemos,[2] Maria A. Kamimura,[2] Carlos Eduardo Rochitte,[1] Lilian Cuppari,[2] Sergio A. Draibe,[2] Raul Santos.[1] *[1]Lipid Clinic, Heart Inst of Sao Paulo Univ, Sao Paulo, Brazil; [2]Nephrology, Sao Paulo Federal Univ, Sao Paulo, Brazil.*

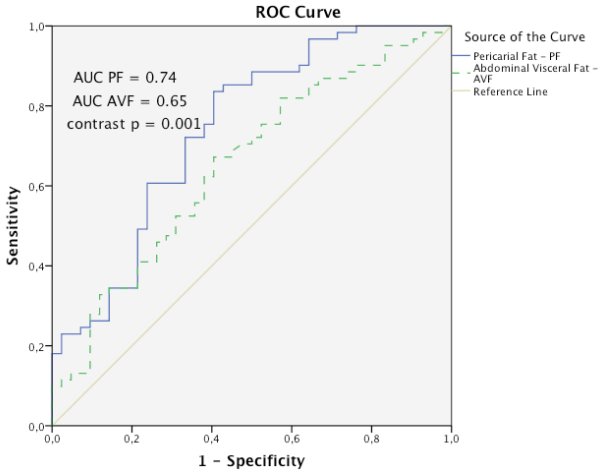
Background: Pericardial fat (PF), a component of visceral adipose tissue has been consistently related to coronary atherosclerosis in the general population. We evaluated the association of PF and coronary artery calcification (CAC) in non-dialysis dependent chronic kidney disease (CKD) patients.

Methods: Cross sectional baseline analysis of a prospective cohort of 117 outward CKD patients without manifest coronary artery disease (age, 56.9±11.0 years, males 64.1%, hypertension 95.1%, diabetics 25.2%, ever smokers 15.5%, CKD stages 2 to 5 and estimated glomerular filtration rate 36.8±18.1ml/m. CAC scores, PF volume and visceral abdominal fat areas were measured by computed tomography. PF association with CAC presence was analyzed by multivariate logistic regression.

Results: 59.2% patients had CAC >0. Those with CAC versus no CAC were 10 years older, had more males (78.7% versus 42.9%,p<0.001), higher waist circumference (95.9±10.7 versus 90.2±13.2cm, p=0.02), higher PF volumes (224.8 ± 107.6 versus 139.1 ± 85.0 cm3, p<0.01) and VAF area (109.2±81.5 versus 70.2±62.9cm², p=0.01). PF was significantly associated with CAC (OR: 1.88 95% CI:1.03-3.43) even after comprehensive multivariable adjustments.

Multivariable Adjusted Associations of Pericardial Fat with Coronary Artery Calcium Presence			
	Hazard Ratio	95% Confidence Interval	p value
Model 1	1.88	1.03 - 3.43	0.04
Model 2	1.89	1.05 - 3.42	0.03
Model 3	1.85	1.00 - 3.42	0.05

HR per one standard deviation
Model 1:age, gender, smoking, diabetes and concentric hypertrophy
Model 2: Model 1 + eGFR
Model 3: Model 1 + phosphate



Conclusions: PF is independently associated with CAC in non-dialysis dependent CKD patients.

TH-PO563

The Role of Calcified Vasculature and Lipids in Chronic Kidney Disease

Berglind Maria Johannsdottir,[1,3] Olafur S. Indridason,[1] Gunnar Sigurdsson,[1,2,3] Runolfur Palsson,[1,3] Margret B. Andresdottir,[1] Lesley Inker,[4] Vilmundur Gudnason,[2,3] Thor Aspelund,[2,3] Hrefna Gudmundsdottir.[1,3,5] *[1]Landspitali - The National Univ Hospital of Iceland; [2]The Icelandic Heart Association; [3]Univ of Iceland; [4]Tufts Medical Center; [5]Icelandic Medicines Agency.*

Background: Vascular calcification and dyslipidemia may adversely affect kidney function. The aim of this study was to examine the association of dyslipidemia and central vascular calcification (CVC) with kidney function in an aging cohort.

Methods: A cross-sectional analysis of 5,212 participants in the AGES-Reykjavik Study I was performed. Estimated glomerular filtration rate (eGFR) was calculated from standardized serum creatinine using the CKD-EPI equation. CVC was measured by quantitative computed tomography as the sum of calcification of the thoracic aorta. High density lipoprotein cholesterol (HDL) and triglycerides (TG) were measured in serum and non-HDL-cholesterol (NHC) calculated. Linear regression used eGFR as outcome and CVC, NHC, HDL and TG as main variables, adjusting for age, body mass index, diabetes mellitus (DM), hypertension (HTN), albuminuria and history of smoking.

Results: Mean (SD) age was 76.5 (5.5) years, 57% were females, 81% had HTN and 12% DM. Mean eGFR was 63,4 (15,2) ml/min/1.73 m². Median CVC was 2,101 (range 0-50,360) Agatston scores. NHC was not associated with eGFR, whereas lower HDL was associated with lower eGFR in males (p<0.05). Higher TG and CVC levels were strongly associated with lower eGFR (p<0.001 and p<0.05 respectively). Individuals with higher level of CVC had lower eGFR in the setting of high TG, significant in females only (p<0.01; table).

	MALES					FEMALES				
		low TG (60 mg/dL)		high TG (200 mg/dL)			low TG (60 mg/dL)		high TG (200 mg/dL)	
CVC**	N	eGFR*	95% CI	eGFR*	95% CI	N	eGFR*	95% CI	eGFR*	95% CI
very low	457	66.5	64.5-68.5	61.7	58.7-64.8	614	62.6	60.2-65.0	59.5	56.9-62.2
low	437	67.8	65.8-69.9	62.8	59.7-65.8	621	67.6	65.1-70.0	55.7	53.3-58.1
medium	451	67.9	66.0-69.8	62.3	59.2-65.4	565	68.0	65.4-70.7	56.9	54.4-59.4
high	412	67.9	65.9-70.0	61.0	58.0-64.0	553	66.9	64.3-69.4	55.3	52.8-57.8
very high	466	66.7	64.6-68.7	56.4	53.6-59.2	636	65.3	63.0-67.6	52.7	50.1-55.2

* mL/min./1.73 m²
** Very low CVC: 0-600 Agatston scores
Medium CVC: 1,500-3,000 Agatston scores
Very high CVC: 6,000-50,400 Agatston scores

Conclusions: Low fasting TG levels may be important for preserving kidney function in the elderly and may abrogate the effect of vascular calcification on the kidneys, particularly in women. This needs to be confirmed in a longitudinal study.

Funding: Private Foundation Support

TH-PO564

Hyperphosphatemia as an Independent Risk Factor of Coronary Artery Calcification Progression in Peritoneal Dialysis Patients

Da Shang, Qionghong Xie, Chuanming Hao, Tongying Zhu. *Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.*

Background: Coronary artery calcification (CAC) is associated with cardiovascular mortality in ESRD patients. The present study aimed to identify modifiable risk factors for CAC progression in peritoneal dialysis (PD) patients.

Methods: Adult PD patients who had received regular peritoneal dialysis for more than 6 months and underwent Coronary artery calcification scores (CaCS) measurements by multislice spiral computed tomography for at least 2 times with the interval ≥ 6 months were included in this prospective, observational cohort study. The demographic characteristics and clinical data including laboratory data and adequacy of PD were collected. Binary

Logistic Regression was used to identify the independent risk factors for CAC progression in PD patients and Multivariate Linear Regression was used to identify the associated factors of hyperphosphatemia.

Results: A total of 207 adult PD patients (116 men, 56.0%) with a mean age of 59.8 ± 15.9 years old were recruited to this study and were divided into the slow progression group (n = 131) and the rapid group (n = 76) according to the velocity of CAC progression. The median interval of the first and last CaCS measurement was 24.6 (13.0-37.9) months. Multivariate logistic regression revealed that age (p = 0.039), BMI (p = 0.007) and serum phosphorus (p = 0.013) were independent risk factors of CAC progression after adjusting for gender, basic CaCS, serum calcium, lipoprotein a, albumin, hs-CRP, total Ccr, residual Ccr and D4/P phosphorus. Multivariate linear regression revealed that hyperphosphatemia was associated with higher transferrin (p = 0.007), serum albumin (p = 0.049), and nPCR (p < 0.001), and lower hemoglobin (p = 0.015), residual Ccr (p < 0.001), and PD Ccr (p < 0.001).

Conclusions: Hyperphosphatemia was an independent risk factor of CAC progression and serum phosphorus level was associated with nutritional intake and PD adequacy. These results provide important information for the clinical management of ESRD patients.

Klotho Expression and Circulating Levels in Renal Failure Hannes Olauson,[1] Karin Edvardsson,[1] Karolina Lindberg,[1] Annika Wernerson,[1] Orson W. Moe,[2] Tobias E. Larsson.[1] *[1]CLINTEC, Karolinska Instt, Stockholm, Sweden; [2]Charles and Jane Pak Center for Mineral Metabolism and Clinical Research, Univ of Texas Southwestern Medical Center, Dallas, TX.*

Background: Membrane-bound Klotho (mKL) is predominantly expressed in the renal tubules where it controls trans-cellular flux of calcium and phosphate and functions as a co-receptor for the phosphate-regulating hormone FGF23. mKL can be cleaved from the cell surface and act as a circulating hormone (cKL) by antagonizing numerous signaling pathways including Wnt and TGFβ. Chronic kidney disease (CKD) is ascribed a state of systemic Klotho deficiency and mKL levels are suppressed by uremic factors, including inflammation and oxidative stress. However, data on cKL in CKD are conflicting with reports of decreased, unaltered or even increased levels.

Methods: Herein, we examined mKL and cKL levels in 42 CKD patients using different approaches; we further analyzed dynamic changes of mKL and cKL in a mouse model of adenine-induced renal failure (ARF). To explore shedding of mKL in ARF we employed an *ex vivo* system where kidneys from healthy and ARF mice were removed, sectioned, and placed in cell culture medium for 2 h at ambient room temperature.

Results: In CKD patients, there was no correlation between cKL and eGFR, neither when measured by a commercially available ELISA nor by immunoprecipitation technique. Similarly, mice with ARF had a rapid decline in renal mKL level without a reciprocal reduction in cKL. *Ex vivo* data demonstrated a close correlation between cKL in conditioned media and tissue levels of mKL in all kidneys examined, indicating unaltered mKL shedding mechanisms in ARF.

Conclusions: In sum, we confirm reduced mKL in CKD patients and in a mouse model of ARF, albeit with an apparent uncoupling between mKL and cKL. The reason(s) for this uncoupling could not be substantiated *ex vivo*, but may be related to methodological limitations, interference with uremic factors or compensatory increased shedding from extra-renal sources of Klotho. This issue warrants more attention in clinical studies reporting on cKL and clinical outcomes.

FGF23 and α-Klotho Acting on Hippocampal Neurons: Impact on Neuronal Morphology and Synapse Formation Ex Vivo Maren Leifheit-Nestler,[1] Anne Schön,[1] Niko Hensel,[2] Timo Konen,[2] Olga Baron,[2] Claudia Grothe,[2] Peter Claus,[2] Dieter Haffner.[1] *[1]Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany; [2]Inst of Neuroanatomy, Hannover Medical School, Hannover, Germany.*

Background: Children with congenital CKD often display impaired cognitive development and memory deficits. Memory formation includes a dynamic control of neuronal morphology and synapse formation in the hippocampus. The circulating levels of the phosphaturic hormone fibroblast growth factor 23 (FGF23) are elevated in CKD while its co-receptor α-klotho decreases with declining renal function. The effects of FGF23 and α-klotho on memory formation are unknown. Here we investigate the impact of FGF23 and α-klotho on morphological outcomes in hippocampal neurons relevant for memory formation.

Methods: Dissociated hippocampal neurons, prepared from postnatal day 5-8 wild-type C57BL/6J mice, were stimulated with FGF23 +/- α-klotho, FGF receptor inhibitor or vehicle. Neuronal morphology was assessed by Sholl analysis including evaluation of neurite length and neurite branching. To analyze whether FGF23 and/or α-klotho affects synaptogenesis, neurons were stained for synaptophysin and post-synaptic density protein - 95 (PSD-95) followed by quantification of morphological synapses. In addition, FGF23/klotho downstream pathways in FGF23 and/or α-klotho treated hippocampal cultures were assessed.

Results: FGF23 increases neurite elongation of hippocampal neurons, and enhances synapse density independent of α-klotho. For FGF23 signaling, FGF receptors as well as the FGF receptor substrate 2 and the FGF23 co-receptor α-klotho with the exception of FGF23 itself are expressed in the hippocampus of neonatal mice. Stimulation of dissociated hippocampal cultures with FGF23 and/or α-klotho differentially induces downstream signaling.

Conclusions: Hippocampal neurons of neonatal mice are a target of FGF23 *ex vivo*. FGF23 on its own increases neurite elongation as well as synapse density without α-klotho. Thus, we hypothesize that excessive FGF23 serum levels might cross the blood-brain barrier and modulate hippocampal function in patients with congenital CKD.

TH-PO567

Delivery of Soluble Klotho Ameliorates Uremic Cardiac Hypertrophy in Mice Jian Xie,[1] Joonho Yoon,[1] Makoto Kuroo,[2] Chou-Long Huang.[1] *[1]UT Southwestern Medical Center, Dallas, TX; [2]Jichi Medical Univ, Tochigi, Japan.*

Background: Klotho (KL) is a membrane protein produced mostly in the kidney; its ectodomain is released as a soluble protein. We have reported that soluble Klotho (sKL) protects the heart against stress-induced cardiac hypertrophy and fibrosis, by inhibiting TRPC6 channel in the heart and independently of serum phosphate (Pi) and FGF23. Here, we examined whether reduced serum sKL contributes to uremic cardiomyopathy and replacement of sKL protects the disease.

Methods: Wild type (WT) and heterozygous (Het) KL-deficient (*kl*) mice (129/SvJ) were rendered CKD by 5/6 nephrectomy (Nx) or sham surgery for 4 wk.

Results: Serum sKL levels (assayed by IP + western blot) were lower in Het versus WT mice, and both were further reduced by 5/6 Nx. CrCl was reduced ~60% by 5/6 Nx, but not different between WT and Het. Heart weight/body weight ratio (HW/BW, mg/g) of WT mice was increased by 5/6 Nx (sham and CKD: 4.1±0.1 and 5.4±0.2, p<0.01); CKD-induced increase was more pronounced in Het (sham and CKD: 4.0±0.1 and 6.2±0.2, p<0.01; also p<0.01, WT/CKD versus Het/CKD). Supporting the HW/BW results, *BNP* expression was increased in hearts of WT CKD versus sham mice, and CKD-induced increase was enhanced in Het *kl* mice. BP, serum Pi and FGF23 levels were not different between WT and Het sham mice, but equally elevated in both CKD mice. Ejection fraction (EF) measured by MRI showed no difference between WT sham and CKD mice (63±3 versus 61±3 %). LV end-diastole volume (LVEDV) was slightly lower and HW/LVEDV ratio increased in WT CKD versus sham, indicating concentric hypertrophy and diastolic dysfunction of WT CKD hearts. In contrast, versus sham, EF was decreased in Het CKD (47±4 versus 62±4 %, p<0.05), LVEDV was markedly increased, and HW/LVEDV unchanged, indicating progression of Het CKD hearts to systolic dysfunction. Tail-vein delivery of cDNA encoding soluble klotho (versus empty vector; weekly x 3 began 5 days post-Nx) to Het CKD mice reduced HW/BW ratio and *BNP* expression without affecting serum Pi and FGF23 levels.

Conclusions: Reduced serum sKlotho in CKD is an important cause of uremic cardiomyopathy, independently of serum Pi and FGF23. Delivery of soluble klotho ameliorates uremic cardiac hypertrophy.

Shedding of Klotho by Disintegrin and Metalloproteinase (ADAM10) in the Kidney Ellen P. Van Loon,[1] Wilco P. Pulskens,[1] Marc G. Vervloet,[2] Harry Van Goor,[3] René J. Bindels,[1] Joost Hoenderop.[1] *[1]Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [3]Pathology and Medical Biology, Univ Medical Center Groningen, Groningen, Netherlands.*

Background: The anti-aging gene klotho is involved in calcium and phosphate homeostasis. Membrane-bound klotho, consisting of a KL1 and KL2 domain, can be cleaved by a disintegrin and metalloproteinase (ADAM)10 and 17, directly above the plasma membrane (α-cut) or between KL1 and KL2 (β-cut). The aim of the present study was to examine klotho shedding in the kidney.

Methods: A Madin-Darby canine kidney (MDCK)I cell line stably-expressing klotho, was used to investigate cellular localization and klotho shedding. Renal expression of klotho, ADAM10 and ADAM17 were determined by immunofluorescence. Dose-dependent ADAM inhibition on klotho shedding was examined *in vitro* using transiently-transfected human embryonic kidney (HEK)293 klotho-expressing cells. *In vivo*, serum electrolyte concentrations and mRNA expression of renal and duodenal electrolyte transporters were determined 24 hours after intraperitoneal administration of ADAM inhibitor or phosphate-buffered saline in 10 mice per group.

Results: Klotho was expressed on the apical and basolateral membrane of renal cells, with a higher abundance of soluble klotho at the apical side. ADAM10 colocalized with klotho in distal convoluted and connecting tubules, but not with ADAM17. *In vitro*, ADAM inhibition dose-dependently decreased full-length klotho shedding (α-cut), while this inhibitory effect was less specific for the β-cut. Interestingly, ADAM inhibition increased renal and duodenal mRNA expression of phosphate transporters, while serum phosphate levels were significantly decreased in ADAM inhibitor treated mice. In contrast, ADAM inhibition did not change urinary klotho levels.

Conclusions: Our data indicate that renal cells preferentially secrete klotho to the apical side and that sheddases other than ADAMs are likely involved in the cleavage of the β-cut of klotho. Moreover, we suggest that ADAM10 is the primary sheddase responsible for klotho cleavage in the kidney.

Fibroblast Growth Factor 23 but Not Klotho Deficiency Ameliorates Progression of Chronic Kidney Disease in Mice Olena Andrukhova, Svetlana Slavic, Sathish Kumar Murali, Reinhold Erben. *Dept of Biomedical Sciences, Inst of Physiology, Pathophysiology and Biophysics, Vienna, Austria.*

Background: Clinical studies have shown that circulating fibroblast growth factor 23 (FGF23) is associated with disease progression, cardiovascular risk, and mortality in patients with chronic kidney disease (CKD). Here, we sought to elucidate further the vitamin D independent role of FGF23 and its co-receptor Klotho in the pathogenesis of CKD in a mouse model.

Methods: CKD was induced by 5/6 nephrectomy in 3-month-old wild-type (WT) mice, vitamin D receptor (VDR) mutant mice, *Fgf23/VDR*, and *Klotho/VDR* compound mutants. All mice were kept on a rescue diet enriched with calcium, phosphorus, and lactose to prevent hypocalcemia and secondary hyperparathyroidism in VDR mutans.

Results: Sham-operated (SHAM) WT, VDR, Fgf23/VDR, and Klotho/VDR mice served as controls. Both WT and VDR mutants developed progressive CKD by 8 weeks after 5/6 nephrectomy as evidenced by reduced glomerular filtration rate (GFR), increased serum creatinine, increased albuminuria, increased serum FGF23 and parathyroid hormone (PTH) levels, hypertension, impaired left ventricular function, as well as reduced body weight and increased mortality, relative to SHAMs. Fgf23/VDR compound mutant CKD mice lacking Fgf23 showed higher GFR and lower urinary albumin but unchanged serum PTH levels as compared to WT and VDR CKD mice. Furthermore, Fgf23/VDR compound mutants were protected against the CKD-induced weight loss, increase in mortality, volume expansion, hypernatremia, hypercalcemia, hyperphosphatemia, hypertension, left ventricular functional impairment, and increase in heart-to-body weight ratio observed in WT. In contrast, lack of Klotho in Klotho/VDR compound mutant CKD mice did not ameliorate the CKD-induced increase in mortality, volume expansion, GFR reduction, albuminuria, hypertension, or left ventricular functional impairment as compared to WT and VDR CKD mice.

Conclusions: Collectively, our data suggest that elevated Fgf23 contributes to the pathogenesis of CKD in a Klotho and vitamin D-independent manner, and may provide a mechanistic explanation for the association between circulating FGF23 and disease progression in CKD patients.

TH-PO570

Influence of Experimental Renal Failure and FGF23 on Endothelial Function and Myocardial Perfusion Melissa Verkaik,[1,2] Rene Musters,[2] Pieter M. Ter Wee,[1] Etto C. Eringa,[2] Marc G. Vervloet.[1] *[1]Dept of Nephrology, VU Univ Medical Center, Amsterdam, Noord-Holland, Netherlands; [2]Dept of Physiology, Inst of Cardiovascular Research ICaR-VU, VU Univ Medical Center, Amsterdam, Noord-Holland, Netherlands.*

Background: Cardiovascular causes account for approximately 50% of mortality in patients with chronic kidney disease (CKD). Among others, FGF23, a phosphate-lowering protein and elevated in CKD, is associated with cardiovascular mortality. We hypothesized that CKD impairs vascular function and myocardial perfusion and that this can be partly attributed to FGF23.

Methods: Eight week old male wild type C57Bl/6J mice were subjected to partial nephrectomy (5/6Nx) or sham-surgery, and after 6 weeks mice were placed into a metabolic cage and subjected to myocardial contrast echocardiography (MCE) to test myocardial perfusion and a pressure myograph setup to test ex vivo vascular function. A second group received either PBS or FGF23 i.p. injections for 7 consecutive days twice daily.

Results: Plasma FGF23 and urinary phosphate significantly increased after Nx surgery (from 182 to 291 pg/ml (p=0.02) and from 19.2 to 114.9 µmol/24h (p=0.001) respectively). 5/6Nx blunted ex vivo vasodilator responses to acetylcholine (p=0.002), whereas responses to sodium nitroprusside (SNP) or endothelin were normal. FGF23 injections in control mice mimicked these vascular responses. Myocardial blood volume, microvascular filling velocity and perfusion were reduced in 5/6Nx mice upon acetylcholine and SNP. Finally, 5/6Nx affects calcium channels in individual cardiomyocytes for both systolic and diastolic parameters.

Conclusions: Diminished endothelium-dependent vasodilation in renal failure is mimicked by FGF23 injections in non-renal failure mice. Also, renal failure compromises myocardial perfusion increments upon stimulation and disturbs cardiomyocyte calcium handling.

Effect of Dietary Fe on FGF23 Level of Adriamycin-Treated Mice Masanori Takaiwa,[1] Kosei Hasegawa,[2] Hiroyuki Tanaka,[3] Nobuyuki Kodani.[1] *[1]Pediatrics, Matsuyama Red Cross Hospital, Japan; [2]Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan; [3]Okayama Saiseikai General Hospital, Japan.*

Background: Parenteral Fe therapy for CKD patients could increase FGF23 and cause hypophosphatemia. However, Fe deficiency worsens FGF23 elevation in patients with inherited hypophosphatemia. FGF23 elevates during the early CKD, and was documented to be associated with poor prognosis of CKD. Hence, we created an early CKD model by intermittent administration of adriamycin (ADR) to C57BL/6J mice (C57) and examined the effect of dietary Fe on FGF23 during the early CKD.

Methods: Using 6 groups (control and 0.6%-Fe-AN groups – fed a 0.6% Fe diet; 2%-Fe and 2%-Fe-AN groups - fed a 2.0% Fe diet; 0.02%-Fe and 0.02%-Fe-AN groups - fed a 0.02% Fe diet), 10-week-old male C57 were administered serine (the control, 2%-Fe and 0.02%-Fe) or ADR weekly (0.6%-Fe-AN, 2%-Fe-AN and 0.02%-Fe-AN) for 28 days. Data were expressed as the mean±SEM. A value of $p<0.01$ was considered significant (Tukey's test).

Results: After treatment, Fe for 2%-Fe and 2%-Fe-AN (275±9 and 280±13µg/dl) were higher, and that of 0.02%-Fe-AN was lower (115±10µg/dl) than the control (161±6µg/dl). Hb of 0.02% Fe-AN (11.5±0.1 g/dl) was markedly lower than the control (13.5±0.1 g/dl). The kidneys of the ADR treated groups were smaller in size. Although not significant, Cr for 0.6%-Fe-AN, 2%-Fe-AN and 0.02%-Fe-AN were higher (1.8±0.2, 2.3±1.7 and 2.8±0.3mg/dl) than the control (0.9±0.1mg/dl). FGF23 tended to be higher among all ADR treated groups, only 0.02%-Fe-AN showed significant elevation (670±134pg/ml) compared with the control (159±10pg/ml). Ca, Pi and PTH showed no significant difference.

Conclusions: The intermittent ADR injection caused the small kidneys associated with slight Cr increase. The ADR treatment caused mild increase in FGF23 without affecting Pi and PTH, hence serving as a reasonable early CKD model. Only the ADR treatment of the Fe depleted mice increased FGF23, hence the negative regulatory effect of Fe on FGF23 was significant during early CKD. Our results suggest that the initiation of oral Fe during early CKD suppresses FGF23 production and has a favorable effect on progression of CKD.

TH-PO572

Iron Status Affects FGF23 Levels in Mice with Chronic Kidney Disease Mark Hanudel,[1] Victoria Rivka Gabayan,[2] Elizabeta Nemeth,[2] Katherine Wesseling-Perry,[1] Tomas Ganz,[2] Isidro B. Salusky.[1] *[1]Dept of Pediatrics, UCLA; [2]Center for Iron Disorders, UCLA.*

Background: Iron deficiency upregulates FGF23 expression, resulting in higher circulating FGF23 levels. However, the effects of iron deficiency, the role of hepcidin, and the effects of iron loading on FGF23 levels in CKD are unclear. Our objectives were to measure FGF23 levels in mice, both wild type and with CKD, fed diets with varying iron content, and to assess whether hepcidin-mediated iron sequestration contributes to elevated FGF23 levels.

Methods: Wild type (WT) and hepcidin knockout (HKO) C57BL/6 mice were fed diets that did or did not contain adenine (known to induce CKD), with low iron (4 ppm), standard iron (335 ppm), or high iron (10,000 ppm) concentrations. HKO mice were not fed the high iron diet, given the risk of fatal iron overload. Mice were on the diets for 8 weeks post-weaning, with hematologic parameters and plasma C-terminal FGF23 assessed at 2 weeks (WT controls only, n=4 per group), 4 weeks (n=8-15 per group), and 8 weeks (n=4-12 per group).

Results: Among the WT mice fed control diets, at 2 weeks, cFGF23 did not differ among the three iron groups. However, at 4 and 8 weeks, both the low and high iron groups had higher cFGF23 than the standard iron group. Among the WT-CKD mice, at both 4 and 8 weeks, the high iron group had the lowest cFGF23 levels. Among the CKD mice, the standard iron HKO group had lower cFGF23 than the standard iron WT group at 4 and 8 weeks, and the low iron HKO group had lower cFGF23 than the low iron WT group at 4 weeks. At 8 weeks, the low iron HKO group had higher cFGF23 than the low iron WT group; however, the HKO group was more anemic than the WT group at this time point, suggesting depletion of iron stores in the HKO group.

Conclusions: In CKD, iron status affects cFGF23 levels in a dose-dependent manner. In CKD, hepcidin-mediated iron sequestration may contribute to elevated cFGF23 levels.

FGF23 Can Directly Target Hepatocytes and Contributes to Inflammation in CKD Saurav Singh,[1] Alexander Grabner,[1] Alexis J. Sloan,[1] Ansel P. Amaral,[1] Karla J. Schramm,[1] Myles S. Wolf,[2] Christian Faul.[1] *[1]Dept of Medicine, Univ of Miami Miller School of Medicine, Miami, FL; [2]Dept of Medicine, Northwestern Univ Feinberg School of Medicine, Chicago, IL.*

Background: Chronic inflammation is a common feature of chronic kidney disease (CKD), and biomarkers of inflammation are among the strongest predictors of poor clinical outcome. The molecular mechanisms underlying the pathological interrelationship between deterioration of renal function and amplification of the inflammatory state are unknown. Patients with CKD develop marked elevations in circulating levels of fibroblast growth factor (FGF) 23. Recent data from our group indicates that FGF23 directly induces cardiac injury by activating FGF receptor (FGFR) 4 in cardiac myocytes, independent of α-klotho, the FGF23 co-receptor in the kidney. Since hepatocytes express high levels of FGFR4, we postulate that FGF23 can directly target the liver.

Methods: Serum starved HepG2 cells, a hepatocellular carcinoma cell line, and primary mouse hepatocytes were treated with FGF23, in the absence and presence of a pan-FGFR inhibitor followed by the isolation of protein and RNA for expression analyses. Serum FGF23 levels were elevated in wild type mice via administration of a high phosphate diet for 3 months or intravenous delivery of recombinant FGF23 for 5 days, followed by the isolation of serum and liver tissue. Age-matched FGFR4 knockout mice were also administered a high phosphate diet.

Results: FGF23 treatment of cultured hepatocytes increases the expression of pro-inflammatory proteins, including C-reactive protein (CRP), by activating calcineurin/NFAT signaling in an FGFR4-dependent and α-klotho-independent manner. The elevation of serum FGF23 increases CRP levels in the liver and in the circulation of wild-type mice, but not in FGFR4 knockout mice.

Conclusions: Our findings provide a potential causative link between FGF23 elevation and the activation of pro-inflammatory processes in the liver, and they suggest a novel mechanism to explain the development of chronic inflammation in patients with CKD. We postulate that pharmacologic FGFR4 blockade might not only have cardio-protective but also anti-inflammatory effects in CKD.

TH-PO574

Neutrophil Gelatinase-Associated Lipocalin (NGAL) and Inflammatory Mediators Stimulate Fibroblast Growth Factor-23 (FGF23) Production in *In Vitro* Osteocytes Culture Shweta Bansal,[1,2] Khaled Khazim,[3] Chakradhar Velagapudi,[1,2] Basant Bhandari,[1] Sherry L. Werner,[4] Paolo Fanti.[1,2] *[1]Medicine/Renal, Univ of Texas Health Sciences Center at San Antonio, San Antonio, TX; [2]Medicine/Renal, South Texas Veterans Healthcare System, San Antonio, TX; [3]Medicine/Nephrology, Western Galilee Hospital, Nahariya, Israel; [4]Pathology, Univ of Texas Health Sciences Center at San Antonio, San Antonio, TX.*

Background: High levels of FGF23, an exclusive product of osteocytes, are not fully explained by abnormal mineral metabolism in chronic kidney disease (CKD) patients. Recently, we have extended prior observations of correlation between FGF23 and inflammatory mediator levels by reporting an independent association of FGF23 with the acute-phase reactant NGAL in diabetic kidney disease patients. The mechanism supporting association of FGF23 with inflammation, however, remains unknown.

Methods: Hypothesis: The association of NGAL and other inflammatory mediators with FGF23 is the result of direct stimulatory effect of these mediators on the osteocytic synthesis and secretion of FGF23. Methods: Cultures of terminally differentiated IDG-SW3 osteocytes were treated with NGAL (50-200 ng/ml), tumor necrosis factor-α (TNF-α; 1-25 ng/ml), and interleukin-6 (IL-6; 0.1-25 ng/ml) for 24 and 48 hours. 1,25$(OH)_2$vitamin D_3(10^{-9}-10^{-7} M) was used as a positive control. Cell lysate was assessed for FGF23 mRNA and protein expression using RT-PCR and western blot technique, respectively. FGF23 protein was measured in media by ELISA.

Results: Incubation with NGAL and TNF-α significantly increased FGF23 mRNA expression dose-dependently, with maximal increments being 44-fold with NGAL, and 80-fold with TNF-α. IL-6 treatment also increased FGF23 mRNA expression up to 2-fold but insignificantly. In addition, all these mediators increased cytosolic concentration of FGF23 protein significantly up to 3-fold in dose-independent manner.

Conclusions: NGAL, TNF-α, and IL-6 directly stimulate osteocytic synthesis of FGF23. Given that CKD is a state of heightened inflammation, these results suggest a possible new mechanism for increased FGF23 levels in CKD.

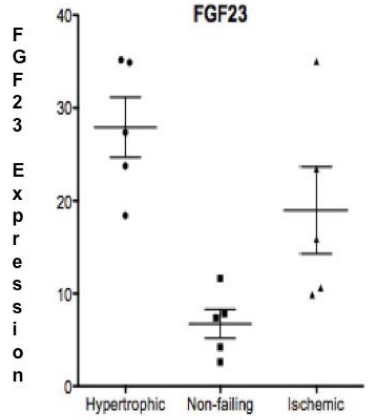
Cardiac Fibroblast Growth Factor Receptor 1-4 and Fibroblast Growth Factor 23 Expression in Adult Cardiac Patients Michel Chonchol, Amrut V. Ambardekar, Lynn Heasley. *Univ of Colorado Denver.*

Background: Experimental and epidemiological studies have demonstrated a relationship between higher serum fibroblast growth factor 23 (FGF23) concentrations and left ventricular hypertrophy (LVH) in patients with and without chronic kidney disease (CKD). The aim of this study was to measure fibroblast growth factor receptor (FGFR) 1-4 and FGF23 expression in human left ventricular tissue samples from hearts with ischemic cardiomyopathy, hypertrophic cardiomyopathy, and normal function.

Methods: We conducted a retrospective study in patients with normal kidney function and end-stage heart failure from either ischemic cardiomyopathy (n=5) or hypertrophic cardiomyopathy (n=5). Left ventricular tissue was collected and flash frozen at the time of heart transplant. Five donor hearts harvested for transplant, but unused for non-cardiac reasons were utilized as the non-failing control samples. FGFR 1-4 and FGF23 expression was evaluated using quantitative real-time PCR.

Results: Age, serum creatinine, and serum phosphorus were similar for those patients with ischemic and hypertrophic cardiomyopathy at the time of transplant. Cardiac FGFR 1-4 were expressed in all non-failing, ischemic, and hypertrophic hearts; this expression tended to be enhanced in samples with end-stage hypertrophic cardiomyopathy when compared to ischemic cardiomyopathy or non-failing hearts. Cardiac FGF23 mRNA expression was increased in samples from patients with hypertrophic cardiomyopathy when compared to ischemic cardiomyopathy or non-failing hearts.



Conclusions: FGFR 1-4 and FGF23 expression are up-regulated in left ventricular samples of patients with end-stage hypertrophic cardiomyopathy and normal kidney function.

Role of Fibroblast Growth Factor 23 and Parathyroid Hormone on Renal Phosphate Handling in Chronic Kidney Disease Sinead Kinsella,[1] Ahad Abdalla,[1] Patrick P. O'Connor,[1] Mark T. Kilbane,[2] John N. Holian,[1] Alan J. Watson.[1] *[1]Nephrology, St. Vincent's Univ Hospital, Dublin, Ireland; [2]Metabolism Laboratory, St. Vincent's Univ Hospital, Dublin, Ireland.*

Background: PTH and FGF23 are both potent regulators of renal phosphate excretion, maintaining normal phosphate levels until advanced CKD and ESKD. However, the relative importance of PTH and FGF23 in phosphate homeostasis in earlier stages of CKD is not established.

Methods: We conducted a cross-sectional observational study examining the relationships between FGF23, PTH and phosphate homeostasis in patients with CKD Stage 3-5. PTH, 25-hydroxyvitaminD (25OHD) and 1,25-dihydroxyvitaminD (1,25OH_2D), renal phosphate threshold (TmP/GFR) and markers of bone turnover were measured. Subjects underwent DXA scanning (Lunar IDXA™) of lumbosacral spine, hip and non-dominant forearm.

Results: 30 patients were included, mean age 55.9 years, mean eGFR 29.2mls/min/1.73m^2. Median PTH 90 ng/ml; 60% had elevated PTH (>65ng/l). Median FGF23 264 RU/ml; 90% had elevated FGF23 (>100RU/ml). Mean phosphate 1.1mmol/L; no patients were hyperphosphatemic or taking phosphate binders. eGFR correlated negatively with PTH (r=-0.605, p<0.001), FGF23 (r=-0.635, p<0.001) and markers of bone-turnover. eGFR correlated positively with TmP/GFR (r=0.394, p=0.031), although this relationship was not significant having controlled for FGF23 and PTH. Both PTH and FGF23 correlated negatively with TmP/GFR, (r=-0.647 and r=-0.559 respectively, p<0.001) and 1,25OH Vitamin D (r=-0.391, p=0.036; and r=-0.558, p=0.002 respectively). PTH and FGF23 correlated positively with markers of bone-turnover. PTH was normal up to CKD Stage 4; FGF23 levels were elevated in CKD Stage 3a (eGFR<60ml/min/1.73m^2) and increased progressively with CKD stage. T-score was lowest at the forearm site. DXA measures did not correlate with PTH or FGF23.

Conclusions: Elevations in FGF23 occurred earlier in the progression of CKD than elevations in PTH and correlated with renal phosphate excretion, decreased 1,25OH_2D and increased markers of bone-turnover, even in moderate CKD.

TH-PO577

Determinants of Change in Fibroblast Growth Factor-23 in Maintenance Hemodialysis Patients Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Kazuomi Yamashita,[1] Kyoka Ono,[1] Kohji Usui,[2] Kenichiro Shigemoto.[1] *[1]Nephrology, Ichiyokai Harada Hospital, Hiroshima, Japan; [2]Nephrology, Ichiyokai Ichiyokai Clinic, Hiroshima, Japan.*

Background: It has been reported that high serum fibroblast growth factor-23 (FGF-23) levels are associated with increased mortality in maintenance hemodialysis (MHD) patients, but the factors responsible for the change in FGF-23 are largely unknown. The aim of this study was to evaluate the determinants of change in FGF-23 in MHD patients.

Methods: We evaluated serum intact FGF-23, age, dialysis vintage, presence of DM, BMI, blood pressure, urine volume, Ccr+Curea/2, Kt/Vurea, high sensitivity CRP, ß2-MG, cystatin C, serum albumin, nPNA, geriatric nutritional risk index (GNRI), serum phosphate, corrected serum calcium (Ca), iPTH, and dosages of active vitamin D and/or phosphate binders in 332 MHD patients at baseline, and performed a reassessment after 1 year. Statistical analyses were performed with Dr. SPSS II.

Results: During the 1 year, 33 patients died, 16 patients changed hospitals, and 283 patients completed the study. The median age and dialysis vintage were 69 years and 66 months at baseline, respectively. There were no increases in mortality after 1 year according to quartiles of FGF-23 levels at baseline. High sensitivity CRP, age, ß2-MG, and GNRI were significantly associated with death ($p<0.02$), but FGF-23 was not. Rise in FGF-23 after 1 year was observed in 176 patients (62.2%). Patients with rise in FGF-23 showed significantly lower serum phosphate and Ca levels and higher active vitamin D dosage at baseline, while significantly higher serum phosphate, nPNA, nPCR with higher active vitamin D dosage after 1 year compared to patients without rise in FGF-23 ($p<0.05$). Multiple regression analysis showed that serum phosphate ($p<0.01$), Ca ($p<0.05$), and dosage of active vitamin D ($p<0.05$) were significant independent factors for rise in FGF-23. Change in FGF-23 was significantly ($p<0.01$) correlated with changes in serum phosphate ($r=0.60$), Ca ($r=0.65$), albumin ($r=0.17$), GNRI ($r=0.18$) and active vitamin D dosage ($r=0.28$).

Conclusions: Rise in serum FGF-23 is related not only to mineral disorders and active vitamin D dosage, but also to improvement in nutritional status in MHD patients.

Fibroblast Growth Factor 23 and Heart Rate Variability in Stage 5 Chronic Kidney Disease Ningning Wang, Lina Zhang. *Nephrology, First Affiliated Hospital of Nanjing Medical Univ, China.*

Background: Lower heart rate variability(HRV) is associated with cardiovascular disease(CVD). We evaluated the relationship between fibroblast growth factor 23(FGF23) and HRV in stage 5 chronic kidney disease(CKD). Their longitudinal changes in parathyroidectomy(PTX) patients were investigated.

Methods: We included 78 controls, 100 CKD patients, and two subgroups classified as successful(n=24) and unsuccessful(n=4) PTX(follow-up for 5 months). Plasma FGF23 was measured by ELISA and Holter were recorded.

Results: In stage 5 CKD, HRV were lower and median plasma FGF23 was higher than controls. FGF23 was correlated with SDNN and SDANN. Serum PTH was correlated with mean NN, SDNN, SDANN, pNN50% and MHR. Successful PTX subgroup had improvements in HRV and laboratory values while unsuccessful PTX not.

	Baseline	After PTX
Successful PTX		
lnFGF23	10.6 ±1.7	8.3±1.2*
Mean 24hHR	87.8±8.1	81.7±8.3*
Mean NN	689.1±60.9	748.1±83.2*
SDNN	66.0±22.5	90.0±25.2*
SDANN	58.8±23.4	81.1±26.6*
rMSSD	16.8±5.9	20.6±8.6#
pNN50 (%)	1.9±2.3	3.9±5.6
lnVLF	5.3±0.7	5.9±0.7*
lnLF	3.9±1.1	3.4±1.6
lnHF	2.7±1.4	1.6±2.5
lnLF/HF	1.2±0.7	1.8±1.2#
Unsuccessful PTX		
lnFGF23	10.8±1.7	8.2±2.0#
Mean 24hHR	76.5±11.4	70.3±10.5
Mean NN	798.3±108.7	871.0±141.0
SDNN	95.5±29.5	116.0±21.6
SDANN	81.5±33.1	102.8±24.3#
rMSSD	23.8±4.6	26.3±14.1
pNN50 (%)	4.4±3.0	6.2±8.4
lnVLF	6.5±0.6	6.6±0.5
lnLF	4.9±1.8	5.0±1.7
lnHF	2.8±2.6	3.5±2.5
lnLF/HF	2.1±0.9	1.4±1.1

Data are mean ± standard deviation (SD). *$P<0.01$ versus baseline; #$P<0.05$ versus baseline.

Conclusions: Higher plasma FGF23 was associated with decreased HRV in stage 5 CKD. Successful PTX reverses these abnormalities and contributes to decrease the risk of CVD.

FGF23 Levels Do Not Differ between Pediatric Pre-Dialysis CKD and Transplant Patients Sabina Susan Thyle, Barbara Gales, Georgina Chow, Isidro B. Salusky, Katherine Wesseling-Perry. *Div of Pediatric Nephrology, UCLA, Los Angeles, CA.*

Background: Fibroblast growth factor 23 (FGF23) excess plays a key role in disordered mineral bone metabolism in patients with chronic kidney disease (CKD). Impaired renal function is prevalent in pediatric renal transplant recipients. Some data suggest that immunosuppressive agents may affect circulating FGF23 values but there are conflicting data as to the effect of transplant status on FGF23 values.

Methods: We performed a cross-sectional study in 30 pediatric, pre-dialysis CKD patients and 61 pediatric renal transplant recipients. Patients with an estimated GFR of 15-89 mL/min/1.73m^2 were included in the study. Biochemical parameters of calcium, phosphorus, PTH, alkaline phosphatase, creatinine and FGF23, along with patient demographics including age, gender, height and time since transplantation were evaluated in all subjects. GFR was estimated according to the Schwartz formula. Values were expressed as means ± SEM or medians (IQ ranges) (Table).

	CKD Stage					
	2		3		4	
Parameter	Pre-dialysis (n=2)	Transplant (n=25)	Predialysis (n=16)	Transplant (n=32)	Predialysis (n=12)	Transplant (n=4)
Age (years)	9.0±2.4	14.4±1.0	14.1±1.1	16.5±0.6*	14.8±0.9	19.5±0.6*
Calcium (mg/dL)	10.0±0.3	10.0±0.1	9.3±0.1	9.7±0.1*	9.5±0.2	9.7±0.2
Phosphorus (mg/dL)	5.0±0.2	4.4±0.2	4.7±0.2	4.0±0.1*	4.6±0.2	5.0±0.4
Time since transplant (years)	-	2.6±0.5	-	5.6±0.7	-	15.7±1.1
iPTH (pg/mL)	55.0(12.0,98.0)	77.0(46.0,143.0)	69.0(50.0,120.0)	65.0(53,110)	121.5(58.5,196.0)	160.0(65.5,303.5)
FGF-23 (RU/mL)	376.5(291.0,462.0)	95.0(43.0,115.0)	142.0(84.0,278.0)	148.0(64.0,196.0)	208.5(137.5,414.5)	369.0(78.5,1267.0)
Alkaline phosphatase (U/L)	259.0(253.0,265.0)	158.0(94.0,232.0)	213.5(114.0,312.0)	104.0(72.5,177.0)	169.5(115.5,220.0)	119.5(98.5,132.0)
Steroid use (%)	0	60.0*	0	87.5*	0	100*
1,25 Vitamin D use (%)	100	0	18.8	0*	75.0	0*

* Indicates a difference ($p<0.05$) between pre-dialysis CKD and transplant patients.

Results: Transplant patients were older, had higher serum calcium levels, and had lower serum phosphorus levels than their pre-dialysis counterparts, and patients with more advanced CKD were older than those with earlier CKD stages. Linear regression analysis showed no difference in FGF23 levels between CKD and transplant patients after controlling for serum calcium, phosphorus, PTH, and estimated GFR. Serum phosphorus ($p<0.05$) and estimated GFR ($p<0.001$) alone were significant predictors of circulating FGF23 values.

Conclusions: These data confirm previous findings from smaller studies suggesting that FGF23 levels rise with decreasing GFR irrespective of transplant status. GFR and phosphorus levels predict FGF23 levels in children with CKD stages 2-4 independent of transplant status, calcium levels, and intact PTH.

TH-PO580

Calcium Carbonate Is Effective for Decreasing Phosphate Loading and FGF-23 in Stage 3 CKD Kraiwiporn Kiattisunthorn, Chanchira Janwijit, Krongkarn Klayklung, Kriengsak Vareesangthip. *Medicine, Siriraj Hospital, Bangkok-noi, Bangkok, Thailand.*

Background: Fibroblast growth factor-23 (FGF23) is driven against phosphate loading to prevent toxicity. FGF-23 is expected to be a superior biomarker to blood phosphate levels to predict phosphate loading in non-dialysis CKD. However, there is no consensus supporting efficacy of phosphate binders to suppress FGF23. The study is conducted to present the efficacy of calcium carbonate ($CaCO_3$) on reduction of phosphate loading and FGF23 in CKD stage 3.

Methods: Stage 3 CKD patients (n=27) were assigned to limit dietary phosphate (PO_4) intake 800-1000 mg/day, then randomized to group A ($CaCO_3$350 mg or 700 mg thrice a day with meal) or group B (placebo), for 9 months. Serum calcium, PO_4, GFR, intact PTH, FGF23, dietary protein and phosphate intake were monitored every 12 weeks. Plasma c-terminal FGF23 was measured by using human FGF23 ELISA kit (Immunotopics, Inc., CA, U.S.A.) [intra- and inter-assay CV 1.4-3% and 2.4-5.1%, respectively]. Estimated GFRs were calculated by CKD-EPI formula using serum creatinine measured by enzymatic assays.

Results: Baseline characteristics were presented in Table 1.

Parameter	Placebo (n=9)	$CaCO_3$ (n=18)
Age (years)	71±10	61±12
Male(%)	67	78
GFR (ml/min/1.73m^2)	40.7±9.8	43.0±7.1
Calcium (mg/dL)	9.5±0.2*	9.1±0.3
PO_4 (mg/dL)	3.2±0.5	3.1±0.5
iPTH (pg/mL)	53.4±24.5	79.9±37.2
FGF-23 (pg/mL)	124.8±114.4	131.4±77.2
nPNA (g/kg/day)	0.9±0.2	1.0±0.3
Urine PO_4 (mg/day)	390+174	369+112
$FePO_4$(%)	18.6±5.5	19.2±10.2
*p<0.05; nPNA=normalized protein nitrogen appearance; $FePO_4$=fractional excretion of phosphate		

There was no statistical significance in changes of serum calcium and PO_4, PTH, GFR, albumin, protein intake, urinary calcium and body weight over 36 weeks. The FGF23 level of gr.A was significantly decreased compared to those of gr.B (-24.7+ 24.7% versus 2.2+28.9%, p=0.045). Sixty percent of the patients in gr.A could achieve a >30% decrease of FGF23 level compared to 20% of those in gr.B (p=0.04). Urinary PO_4 was significantly decreased in gr.A (-25.7+22.0% versus 33.6+61.2%, p=0.02).

Conclusions: Calcium carbonate is an effective phosphate binder for stage 3 CKD without a significant hypercalcemia and hypercalciuria over the 36-week treatment.

Funding: Government Support - Non-U.S.

TH-PO581

Phosphorus Removal and Serum FGF23 Levels in Chronic Dialysis Patients E. Constantz,[2] T. Alp Ikizler,[3] G. Wei,[2] Xiaorui Chen,[2] R. Boucher,[2] Yufeng Huang,[2] Bin Wang,[2] Tom Greene,[2] Srini Beddhu.[1,2] *[1]SLC VAMC; [2]Univ Utah; [3]Vanderbilt Univ.*

Background: Serum phosphorous (P) affects serum fibroblast growth factor 23(FGF-23) levels. We examined the hypothesis that hemodialysis (HD) P removal as estimated from P reduction ratio (PRR) affects serum P and FGF23 levels.

Methods: Midweek pre and post HD serum P levels were measured at baseline (BL) in 117 participants with 6-month (6m) follow-up measurements in 96. PRR was calculated as (pre-post)/pre serum P. 44h urinary P excretion (UPE_{44}) was measured from 44h urine samples in those with residual renal function (RRF). UPE_{44} was considered 0 in anuric pts. Serum FGF23 levels were measured with ELISA. Baseline PRR was related to the average of baseline and 6 month FGF23 levels in mixed effects models.

Results: Mean BL PRR was 57± 15 %. Median FGF23 levels at BL and 6m were 6831 (1718, 16074) RU/ml and 4062 (1048, 12387) RU/ml, respectively. BL characteristics are summarized in the table.

	PRR<52.8%	PRR 52.8 to 65.1%	PRR≥65.1%
	N=39	N=39	N=39
PRR	0.41±0.13	0.59±0.04	0.72±0.06
Age(yr)	54±16	52±16	48±17
Female (%)	30.8	31.6	53.8
Black(%)	7.7	15.4	10.3
Vintage(yr)	2.9(0.8,4.9)	2.6(0.8,4.7)	1.7(0.7,3.2)
Cardiovascular Dis(%)	56.4	53.9	33.3
Diabetes(%)	51.3	42.1	47.4
PreHD Ca(mg/dl)	9.0±0.7	8.9±0.6	9.0±0.7
PreHD P(mg/dl)	5.1±1.3	6.4±1.4	6.3±1.8
PreHD PTH(ng/L)	284.0(206.0,459.0)	469.0(216.0,736.0)	392.0(231.0,557.0)
FGF23(ru/mL)	6950.6 (2165.0,16074.4)	9973.8 (1981.3,16074.4)	5149.9 (1772.8,19738.2)
Anuria(%)	59.0	59.0	48.7
Median UPE_{44} in non-anuric	262.2(100.7,417.5)	259.5(192.5,313.3)	206.7(100.1,458.5)

In mixed effects models, adjusted for demographics, clinical characteristics and UPE_{44}, each SD (12.9%) ↑ in PRR was associated with a 0.76 (95% CI 0.48 to 1.04) mg/dl higher average (of BL and 6m) preHD P and statistically non-significant increase (11.4%, 95% CI -13.0% to 42.6%) in serum FGF-23.

Conclusions: The counter-intuitive association of ↑ PRR with ↑ preHD P levels probably reflects the greater ↓ in serum P when preHD P is higher. As post-HD P levels are affected by equilibration from intracellular compartment, longer HD sessions might result in ↑ P removal and affect FGF23 levels.

Protein Intake, Serum Phosphorous, and FGF23 Levels in Dialysis Patients Xiaorui Chen,[2] T. Alp Ikizler,[3] G. Wei,[2] E. Constantz,[2] R. Boucher,[2] Yufeng Huang,[2] Bin Wang,[2] T. S. Bjordahl,[2] Tom Greene,[2] Srini Beddhu.[1,2] *[1]SLC VA; [2]Univ Utah; [3]Vanderbilt Univ.*

Background: We examined the hypothesis that as high protein intake (PI) could ↑ serum P, it might also affect FGF23 levels.

Methods: 144 hemodialysis (HD) patients (pts) from the Protein Intake, Cardiovascular Disease and Nutrition in CKD Stage V (PICNIC) study were included. PI was estimated from protein nitrogen appearance (PNA), calculated from mid-week pre and post HD BUN. PNA was adjusted for measured 44h urine urea nitrogen in those with residual renal function. PreHD serum P and FGF23 levels were measured. Baseline (BL) and 6 month (6m) PNA were related to the average of BL and 6m serum P and FGF23 levels in mixed effects models.

Results: Of the 144 pts, 121 completed the 6m visit. Mean PNA was 1.00± 0.32 g/kg/d. Mean BL and 6m serum P levels were 5.8 ±1.6 and 6.0 ±2.0 mg/dl, respectively. Mean serum FGF23 levels were 10347± 10153 and 6380± 5722 RU/ml, respectively. BL characteristics of the study population by FGF23 tertiles are summarized in Table 1.

	FGF23<2500 RU/ml	2500≤FGF23 <12500 RU/ml	12500≤FGF23 RU/ml
Median Serum FGF23(ru/ml)	945(470,1719)	6831(4559,10569)	24622(16074,29724)
Age(yr)	52±17	53±16	48±16
Female(%)	39.6	46.8	33.3
AA race(%)	27.1	20.8	10.4
Vintage(yr)*	1.8(0.7,3.1)	2.6(0.9,4.6)	3.1(2.0,5.3)
Cardiovascular Dis(%)	41.7	50.0	39.6
DM (%)	47.9	39.1	41.7
Serum Ca(mg/dl)	8.9±0.7	8.9 ± 0.9	9.2±0.6
Serum P(mg/dl)*	5.0±1.4	6.0 ± 1.5	6.6±1.6
PTH(ng/l)	333 (226,504)	278(185, 625)	468 (280 ,674)
PNA(g/kg/day)	0.94±0.26	1.01±0.33	1.03±0.31
* P value≤0.05			

In a mixed effects model, adjusted for demographics and clinical characteristics, each SD (0.31 g/kg/d) ↑ in PNA was associated with 0.62 (95% CI 0.36,0.88) mg/dl ↑ in the average of BL and 6m serum P. In similar models, each SD ↑ in PNA was associated with 14.9% (95% CI -8.6%, 44.4%) ↑ in serum FGF23 levels. Each SD (1.74 mg/dl) ↑ in serum P was associated 61.2% (95% CI 32.7%,95.8%) ↑ in serum FGF23 levels.

Conclusions: ↑ PI was associated with significant ↑ in serum P but a statistically non-significant ↑ in serum FGF-23. Larger studies are warranted to determine the association of PI with FGF23 levels.

TH-PO583

Effect of a Predominantly Plant Based Diet on Mineral Metabolism and Skeletal Muscle in Chronic Kidney Disease Ranjani N. Moorthi,[1] Kevin M. Janda,[1] Cheryl L.H. Armstrong,[2] Sharon M. Moe.[1] *[1]Medicine, Indiana Univ/ Indiana Univ Health, Indpls, IN; [2]Purdue Univ, West Lafayette, IN.*

Background: CKD is associated with alterations in phosphate (P) excretion, increases in fibroblast growth factor (FGF23) and parathyroid hormone (PTH). Previous short terms studies of a 100% vegetarian diet showed reduction in urinary P compared to a meat diet. For the average American CKD patient, a 70% vegetarian diet is more feasible than a completely vegetarian one. We tested the hypothesis that 4 weeks on a 70% plant based diet would reduce urinary P and improve markers of mineral metabolism without adverse biochemical changes or loss of muscle mass.

Methods: Thirteen subjects with CKD 3-4 underwent an intervention trial of 4 weeks of a study diet. The study diet provided an average of 2300 kcals/d, 0.8-1 mg/kg protein, 3g sodium and 70% of the protein came from plant sources. The primary outcome was change in 24 hour urine P. Two pre-study urine collections and blood draws were performed. All these were repeated at week 2 and week 4 while on the study diet. Body fat content by bioelectrical impedance and hand-grip strength were serially measured. Paired T-tests compared differences between baseline and on-diet. For non-normally distributed variables, Wilcoxon signed rank tests were used.

Results: Mean age of subjects in the study was 54.8 years and mean eGFR was 27.2+11.5ml/min. Urine P significantly decreased by 231 +131mg/d on the study diet (p<0.01). There were no significant changes in serum FGF23, P, PTH, C02, or potassium on the study diet although reductions were seen in some patients. Urine sodium decreased by 32%, and urine pH increased significantly from 6.1 to 6.2.on the 70% plant based diet (p<0.01). Urine creatinine was reduced but 24 hour creatinine clearance was unchanged. Hand grip strength and fat mass% did not change on study diet over the 4 week period.

Conclusions: A 70% plant based diet is efficacious in lowering urine P and sodium excretion, was feasible, and well tolerated. No adverse effects were observed on muscle strength, and there was an overall feeling of improved well-being reported by participants. Long term studies are required to determine if these effects are sustained.

TH-PO584

Effect of Alkali Therapy on Fibroblast Growth Factor-23 in Chronic Kidney Disease Patients Wei Chen,[1] Michal L. Melamed,[1,2] Carolyn A. Bauer,[1] Amanda C. Raff,[1] Thomas H. Hostetter,[3] David A. Bushinsky,[4] Matthew K. Abramowitz.[1,2] *[1]Medicine, Albert Einstein College of Medicine, Bronx, NY; [2]Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY; [3]Internal Medicine, Case Western Reserve Univ School of Medicine, Cleveland, OH; [4]Internal Medicine, Univ of Rochester, Rochester, NY.*

Background: Metabolic acidosis has been demonstrated to increase FGF-23 levels in neonatal mouse bone. This study examines the effect of alkali therapy on FGF-23 levels in patients with chronic kidney disease (CKD).

Methods: In this single-blinded pilot study, 20 adults with eGFR 15-45 ml/min/1.73m^2 and serum bicarbonate 20-24 mEq/L were treated during successive 2-week periods with placebo followed by escalating oral sodium bicarbonate doses (0.3, 0.6 and 1.0 mEq/d/kg ideal body weight). C-terminal FGF-23 were measured at the initial visit, after 2-weeks of placebo and at the end of the study. Values from the initial and post-placebo visits were averaged to determine each individual's baseline. Paired t-test was used to compare serum bicarbonate levels, and Wilcoxon matched-pair signed rank sum test was used to compare FGF-23 levels before and after the intervention.

Results: No correlation was observed between serum bicarbonate and FGF-23 levels at baseline (p=0.37). After 6 weeks of oral sodium bicarbonate supplementation, serum bicarbonate levels increased from 22.6±2.3 to 25.5±2.2 mEq/L (p<0.001), and FGF-23 levels increased from 150.9 (100.8, 267.4) to 191.4 (132.6, 316.9) RU/mL (p=0.048).

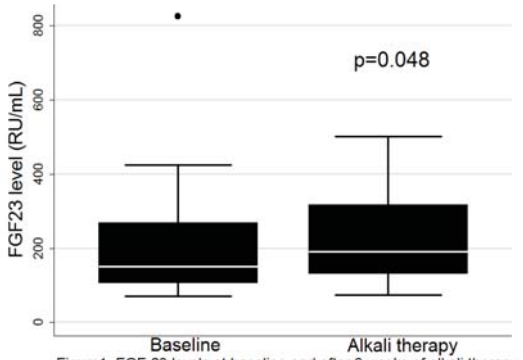

Figure1. FGF-23 levels at baseline and after 6 weeks of alkali therapy

Conclusions: Sodium bicarbonate supplementation increased FGF-23 levels after a short-term intervention in CKD patients with mild acidosis. The study is limited by small sample size and lack of control group. As FGF-23 levels are expected to increase with time in CKD patients, long-term placebo-controlled studies are needed to substantiate these findings.

Are Blood Pressure and Plasma Fibroblast Growth Factor-23 Concentration Changes Interrelated after Cinacalcet Treatment in Hemodialysed Patients with Chronic Kidney Disease and Secondary Hyperparathyroidism? Marcin Adamczak, Piotr Kuczera, Andrzej Wiecek. *Dept of Nephrology, Endocrinology and Metabolic Diseases, Medical Univ of Silesia, Medical School in Katowice, Katowice, Poland.*

Background: It is well known that parathyroid hormone (PTH) plays a role in the pathogenesis of arterial hypertension. Treatment with cinacalcet decreases serum PTH concentration in hemodialysed patients with chronic kidney disease (HDP) and secondary hyperparathyroidism (sHPT). The aim of this study was therefore to assess the influence of 6 month treatment with cinacalcet on blood pressure (BP) in HDP with sHPT.

Methods: In 58 HDP with sHPTserum PTH, fibroblast growth factor-23 (FGF-23), calcium and phosphate concentrations were assessed before the first dose of cinacalcet and after 3 and 6 months of treatment. BP was measured before hemodialysis sessions. The results were shown as means and 95% CI.

Results: Serum PTH concentration decreased significantly after 3 and 6 month of cinacalcet treatment from 1138 (931-1345) to 772 (551-992); p<0.0001 and to 635 (430-839)pg/ml; p<0.0001, respectively. Plasma FGF23 concentration decreased after 3 and 6 months of treatment from 593 (457-730) to 513 (380-645)pg/ml; p=0,099 and to 433 (304-561)pg/ml; p=0.015 respectively. Mean serum calcium and phosphate concentrations remained stable. Systolic BP decreased after 3 and 6 month of treatment from 128 (123-133), to 125 (120-131); p=0.1 and to 121 (115-127)mmHg; p=0.005, respectively. Diastolic BP did not change significantly. There were no significant differences in the number of antihypertensive drugs, alphacalcidol dose and patients' body weight during the treatment period. No significant correlation was found between changes of systolic BP and changes of serum PTH, FGF-23, calcium and phosphate concentration and both cinacalcet and alphacalcidol dose, respectively.

Conclusions: 1. Six-month cinacalcet treatment decreases systolic BP in hemodialysed patients with chronic kidney disease and secondary hyperparathyroidism. 2. Such a decrease of systolic BP might be related to the decrease of plasma FGF-23 concentration, however such a potential relation needs further elucidation.

Fibroblast Growth Factor 23 and Risk of Incident Stroke in Community-Living Adults Bhupesh Panwar,[1] Nancy Jenny,[2] Virginia J. Howard,[1] Virginia G. Wadley,[1] Paul Muntner,[1] Brett Kissela,[3] Suzanne E. Judd,[1] Orlando M. Gutierrez.[1] *[1]Univ of Alabama at Birmingham; [2]Univ of Vermont; [3]Univ of Cincinnati.*

Background: Elevated fibroblast growth factor 23(FGF23) levels are associated with increased risk of cardiovascular disease events, particularly those linked to heart failure. Associations of FGF23 with stroke outcomes are less clear.

Methods: The association of plasma FGF23 levels with incident stroke in the Reasons for Geographic and Racial Differences in Stroke(REGARDS) study, a cohort of black and white adults ≥45 years of age, was examined. FGF23 was measured in 615 participants who developed incident stroke(cases) and in 936 participants randomly selected from the REGARDS cohort(comparison cohort).

Results: In multivariable-adjusted models, higher calcium and phosphorus levels, lower estimated glomerular filtration rate and higher urine albumin excretion were independently associated with higher FGF23. There was no statistically significant association of FGF23 with risk of all-cause stroke in models adjusted for demographic factors and known stroke risk factors (hazard ratio [HR] comparing fourth to first quartile 1.19, 95%CI 0.78, 1.82). When stroke subtypes were investigated, there was a graded association of FGF23 with risk of cardioembolic stroke in fully adjusted models(table). There were no statistically significant associations of FGF23 with other stroke subtypes.

Table. HR (95% CI) of stroke subtypes by quartiles of FGF23

	Events	FGF23 Quartile 1 (<53 RU/ml)	FGF23 Quartile 2 (53-70 RU/ml)	FGF23 Quartile 3 (70.5-100 RU/ml)	FGF23 Quartile 4 (>100 RU/ml)	P_{trend}
All Cause	615	ref	1.34 (0.91-1.99)	1.09 (0.74-1.63)	1.19 (0.78-1.82)	0.77
Ischemic	540	ref	1.33 (0.89-2.01)	1.23 (0.81-1.85)	1.28 (0.81-2.01)	0.56
Cardio-embolic	136	ref	1.48 (0.63-3.47)	1.99 (0.89-4.44)	2.52 (1.08-5.91)	0.04
Large Vessel Athero-sclerosis	85	ref	1.77 (0.74-4.19)	1.26 (0.51-3.12)	1.53 (0.58-4.02)	0.63
Small Vessel Occlusion	104	ref	1.04 (0.49-2.12)	1.15 (0.57-2.32)	0.80 (0.36-1.79)	0.45
Un-classified	245	ref	1.35 (0.79-2.27)	1.23 (0.72-2.09)	1.23 (0.68-2.23)	0.79

Conclusions: Higher FGF23 was an independent risk factor for cardioembolic strokes but not other stroke subtypes in community-dwelling adults.

TH-PO587

Association of Mineral Metabolism Biomarkers with Risk of End-Stage Renal Disease: Chronic Kidney Disease Biomarkers Consortium and the Atherosclerosis Risk in Communities Study C. Rebholz, M. Grams, Pamela L. Lutsey, Lesley Inker, Andrew S. Levey, Elizabeth Selvin, Chi-Yuan Hsu, Paul L. Kimmel, Vasan S. Ramachandran, John H. Eckfeldt, Josef Coresh. *Chronic Kidney Disease Biomarkers Consortium.*

Background: Disordered mineral metabolism is characteristic of impaired kidney function. However, little is known about the associations between circulating levels of fibroblast growth factor-23 (FGF-23), vitamin D binding protein (VDBP), and 25-hydroxyvitamin D [25(OH)D] and end-stage renal disease (ESRD).

Methods: In a nested case-control study within the ARIC Study, incident ESRD cases (n=184) were identified through hospitalization surveillance from 1996-2008. Cases were frequency matched to controls (n=251) on estimated glomerular filtration rate (eGFR) category, urinary albumin-to-creatinine ratio (ACR) category, diabetes status, sex, and race. Baseline serum levels of FGF-23, VDBP, and 25(OH)D were measured. Logistic regression was used to estimate the association between mineral metabolism biomarkers and incident ESRD, adjusting for matching factors, age, and hypertension status. Analyses were repeated after stratifying by race and VDBP SNPs (rs4588, rs7041).

Results: In this case-control study, 57% of participants had diabetes, 48% were women, and 44% were black. After adjustment, one interquartile range increases in FGF-23

and VDBP were associated with incident ESRD (FGF-23 OR: 1.42, 95% CI: 1.06, 1.92; VDBP OR: 1.48, 95% CI: 1.02, 2.14). Overall, 25(OH)D was not statistically significantly associated with ESRD (OR: 0.80, 95% CI: 0.60, 1.07, p=0.14). However, 25(OH)D was more strongly associated with ESRD within racial and VDBP genotype subgroups (blacks OR: 0.48, 95% CI: 0.28, 0.85; rs4588 CC allele OR: 0.65, 95% CI: 0.42, 1.00).

Conclusions: In the general population, serum levels of FGF-23 and VDBP, but not 25(OH)D, were positively associated with new-onset ESRD during follow-up. Further research is warranted to explore the role of free and bioavailable vitamin D in predicting future ESRD risk.

A Test of the Hypothesis That Calcitriol Deficiency Mediates Secondary Hyperparathyroidism of Chronic Kidney Disease Jennifer L. Ennis,[1] John R. Asplin,[1] Fredric L. Coe.[2] *[1]Litholink Corporation, a LabCorp Company, Chicago, IL; [2]Medicine, Univ of Chicago, Chicago, IL.*

Background: Calcitriol down-regulates parathyroid hormone (PTH). Chronic kidney disease (CKD) is known to be a state of calcitriol deficiency and secondary hyperparathyroidism. Calcitriol deficiency is presumed to be a factor mediating the secondary hyperparathyroidism. If this presumption were true, then PTH should be an inverse function of calcitriol in patients with CKD. In order to test this prediction, we analyzed a large dataset from a national clinical laboratory. Our data were not compatible with the hypothesis.

Methods: We performed a cross-sectional analysis of 722 laboratory encounters collected on 437 stage 2-5 U.S. CKD patients from a large national laboratory (LabCorp®) from 2009-2013. Estimated glomerular filtration rate (eGFR), serum calcium (Ca), phosphorus (P), 25-hydroxy vitamin D (25-D), calcitriol and plasma PTH levels were analyzed. Labs were measured as a part of routine clinical care.

Results: By ANOVA with trend analysis,mean PTH values adjusted for Ca, P, 25-D, and calcitriol were higher with progressive CKD stage. In a similar analysis, calcitriol values adjusted for Ca, P, 25-D, and PTH were lower with progressive CKD stage. In the PTH model, Ca (F-ratio=31.5, p<0.001), 25-D (F-ratio=22.4, p<0.001), and CKD stage (F-ratio=15.9, p<0.001) were significant covariates, whereas calcitriol had no effect (F-ratio=0.02, p =0.88). In the calcitriol model, 25-D (F-ratio=74.8, p<0.001), CKD stage (F-ratio=10.1, p<0.001), and phosphorus (F=3.9, p=0.048) were significant covariates, although the effect of phosphorus was minimal. PTH had no effect.

Conclusions: Despite the large data set, we were unable to detect any regression relationship between PTH and calcitriol once adjustments were made for other confounders: Ca, P, 25-D, and CKD stage. Of great interest, we detected a very large effect of 25-D on PTH independent of calcitriol, suggesting an alternative relationship between the vitamin D hormones and PTH in CKD. The simple hypothesis of calcitriol deficiency as an important contributor to secondary hyperparathyroidism of CKD does not seem to have withstood a fairly straightforward test.

TH-PO589

Serum 1,25-Dihydroxyvitamin D Level Is Independently Associated with Endogenous Erythropoietin Resistance in Patient with Chronic Kidney Disease Il Young Kim,[1] Min Jung Kim,[1] Dong Won Lee,[1] Soo Bong Lee,[1] Byeong Yun Yang,[2] Eun Young Seong,[2] Sang Heon Song,[2] Ihm Soo Kwak.[2] *[1]Internal Medicine, Pusan National Univ Yangsan Hospital, Yangsan, Korea; [2]Internal Medicine, Pusan National Univ Hospital, Busan, Korea.*

Background: Resistance to exogenous erythropoietin (EPO) stimulating agent (ESA) has been known to be associated with mortality in patients with chronic kidney disease (CKD). Recent studies have also demonstrated an association between resistance to endogenous EPO and mortality in CKD patients. We aimed to identify factors associated with endogenous EPO resistance, represented by serum EPO concentration and its ratio to hemoglobin (EPO/Hb ratio), with a focus on serum 1,25-dihydroxyvitamin D [1,25-$(OH)_2$D].

Methods: This study included 210 CKD patients [estimated glomerular filtration rate < 60 ml/min/1.73m^2] who were not on dialysis therapy from Pusan National University Yangsan Hospital between 2008 and 2013. The patients were excluded if they were on ESA therapy or had iron deficiency (Transferrin saturation < 20% or ferritin < 200 ng/ml) at the time of study enroll. The association of endogenous EPO resistance (EPO/Hb ratio) with clinical and laboratory variables was investigated by univariate and multivariate linear regression analysis.

Results: In the overall study sample, mean erythropoietin level was 16.4 ± 6.8 mU/ml and mean 1,25 $(OH)_2$D level was 15.5 ± 10.0 pg/ml. In univariate analysis, elevated EPO/Hb ratio was associated with decreased eGFR (β = -0.166, P < 0.05), albumin (β = -0.268, P < 0.001), 1,25-$(OH)_2$D (β = -0.536, P < 0.001) and elevated ferritin (β = 0.677, P< 0.001), CRP (β = 0.663, P < 0.001). In mutivariate analysis, elevated EPO/Hb ratio was independently associated with decreased 1,25-$(OH)_2$D (β = -0.297, P < 0.001) and elevated ferritin (β = 0.376, P < 0.001), CRP (β = 0.345, P < 0.001).

Conclusions: In CKD patients, endogenous EPO resistance was independently associated with not only inflammatory marker such as ferritin, CRP but also 1,25-$(OH)_2$D. This study suggests deficiency of biologically active 1,25-$(OH)_2$D, which has been known to have anti-inflammatory effect, in CKD patients might increase endogenous EPO resistance via augmentation of inflammatory process.

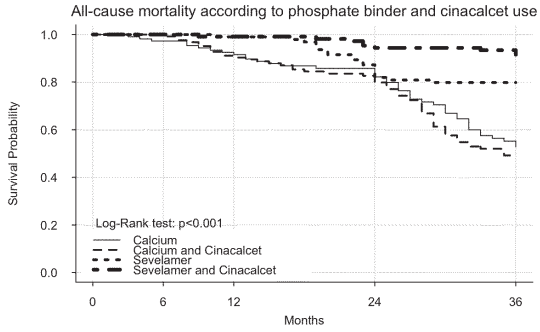
Cinacalcet but Not Vitamin D Use Modulates the Survival Benefit Associated with Sevelamer in the Independent Study Antonio Bellasi,[1] Mario Cozzolino,[2] Domenico Russo,[3] Donald A. Molony,[4] Biagio Raffaele Di Iorio.[5] *[1]Ospedale Sant'Anna-Como; [2]Univ of Milan; [3]Univ "FEDERICO II" Napoli; [4]Univ of Texas-Houston; [5]PO "A Landolfi" – Solofra.*

Background: Whether the concomitant use of calcium sensing modulator or vitamin D with either a calcium free or calcium containing phosphate binder impacts patient-centered outcomes remains to be elucidated.

Methods: Post hoc analysis of an open label, randomized, controlled trial designed to evaluate the impact of sevelamer (SV) versus calcium salts (CS) on survival in incident dialysis patients. All individuals were followed until study completion or death. Cinacalcet and vitamin D were administered to a portion of patients as part of routine care (53% and 42%, respectively). We tested the impact of cinacalcet and vitamin D on survival for the overall study cohort and in both treatment arms of the original study.

Results: We recruited 466 middle-age (65 years) men and women. After a mean follow-up of 28(10) months, SV but not cinacalcet administration was associated with a survival benefit. However, a significant (p=0.003) interaction of phosphate binder and cinacalcet use on mortality was observed.



Calcium	108	105	98	73	47
Calcium and Cinacalcet	126	126	113	89	53
Sevelamer	110	106	95	82	74
Sevelamer and Cinacalcet	122	118	107	101	99

A synergistic survival benefit was noted between SV and cinacalcet (HR 0.41, 95%CI 0.17-1.01, p=0.054 for SV treated subjects receiving versus not receiving cincalcet). In contrast a trend toward an increased mortality was observed for patients receiving CS and cinacalcet concomitantly (HR 1.5, 95%CI 0.96-2.34; p=0.07 for CS treated subjects receiving versus not receiving cincalcet). No effect on mortality or interaction with phosphate binder use was noted with vitamin D.

Conclusions: Though hypothesis generating, these results lend support to a hypothesis that use of a calcium-free versus -containing phosphate binder may increase survival in incident hemodialysis patients, in particular, when patient are treated concurrently with cinacalcet.

TH-PO591

Effects of Soluble Inhibitors of Wnt-Beta Catenine Signaling (Sclerostin and Dkk-1) on Mineral and Bone Metabolism in Patients on Peritoneal Dialysis Shunsuke Yamada,[1] Kazuhiko Tsuruya,[3] Masanori Tokumoto,[1] Hiroaki Ooboshi,[1] Takanari Kitazono.[2] *[1]Dept of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka, Japan.*

Background: Sclerostin and Dkk-1, soluble inhibitors of canonical Wnt-β catenine signaling, negatively regulate bone volume. Studies have shown that these inhibitors are involved in the development of CKD-mineral and bone disorder (MBD). However, it remains unclear how these soluble inhibitors are regulated and whether these inhibitors play roles in the regulation of MBD in patients undergoing peritoneal dialysis (PD).

Methods: The present study was a cross-sectional study consisting of 74 outpatients who received PD therapy during 2010-2013 at Kyushu University hospital. Sclerostin and Dkk-1 levels in the serum, urine, and dialysate were determined by ELISA kits, and we examined the associations with clinical and biochemical parameters. The associations between the serum soluble inhibitors and serum bone metabolic marker levels were also examined.

Results: The mean patient age was 55 years. The subjects included 49 male patients, and the dialysis vintage was 359 (median) days. The serum sclerostin level was 342 (median) pg/mL and the serum Dkk-1 level was 980 (median) pg/mL, which were higher than the values in the general population. The sclerostin levels in the urine and dialysate were positively associated with serum sclerostin level. A multivariable analysis showed that the serum sclerostin level was significantly and positively correlated with age and male gender and significantly negatively correlated with the serum PTH level and the renal Kt/V, while Dkk-1 was correlated with platelet count. The serum sclerostin level was significantly and negatively associated with the serum levels of bone metabolic markers, even after adjusting for confounders, while Dkk-1 was not.

Conclusions: The metabolic regulation of sclerostin and Dkk-1 and the effects of these inhibitors on CKD-MBD might be different in PD patients. The clinical significance of measuring these inhibitors needs further investigations.

TH-PO592

Increased Proliferation and Delayed Mineralization *In Vitro* Suggest Intrinsic Abnormalities in Osteoblast Growth and Differentiation in the Context of CKD

Renata C. Pereira,[1] Anne M. Delany,[2] Nadine Khouzam,[1] Richard E. Bowen,[3] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Center Molecular Biology, Univ of Connecticut Health Center, Farmington, CT; [3]Orthopedic, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Abnormalities in bone remodeling and skeletal mineralization are commonly observed in pts with CKD. Osteocytes are terminally differentiated cells derived from osteoblasts which play an important role in bone and mineral homeostasis. Alterations in osteoblasts or osteocytes may contribute to the skeletal abnormities observed in CKD.

Methods: Thus, proliferation and mineralization characteristics of osteoprogenitors isolated from bone chips of 9 pts with ESKD (3 with adynamic bone (AD), 3 with normal bone turnover (N), and 3 with osteitis fibrosa (OF)) and from 3 healthy controls were evaluated.

Results: Proliferation rate, determined by MTS assay over a 4 day period, was higher in CKD cells than in cells from healthy controls ($p<0.01$ between CKD and controls, NS between subtypes of renal osteodystrophy (ROD)). Mineralized matrix formation, determined by Alizarin Red staining and normalized for cell number as assessed by Crystal Violet staining, was evaluated over a 4 week culture period. In contrast to cell proliferation, mineralization was delayed in CKD cells as compared with controls ($p<0.01$). In this small sample, differences in proliferation and mineralization rates between subtypes of ROD did not reach significance, although mineral content of cells from pts with AD tended to be higher at 2 weeks than in their counterparts with OF ($p=0.19$).

Conclusions: Increased proliferation rates and decreased mineralization in cells obtained from CKD pts suggest that these osteoprogenitors retain an abnormal phenotype in vitro. Thus, this in vitro model may be helpful in better understanding the abnormal bone biology observed in patients with CKD. The role of different subtypes of ROD on proliferation and mineralization warrants further investigation.

TH-PO593

Cultured Osteoprogenitors From Patients with CKD Provide a Novel Model for Studying Abnormal Bone Biology Associated with Kidney Disease

Renata C. Pereira,[1] Nadine Khouzam,[1] Barbara Gales,[1] Richard E. Bowen,[2] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Dept of Pediatrics, UCLA, Los Angeles, CA; [2]Orthopedic Surgery, UCLA, Los Angeles, CA.*

Background: Abnormalities in bone remodeling and skeletal mineralization are commonly observed across the spectrum of CKD. Osteocytes, terminally differentiated cells derived from osteoblasts, play a critical in bone and mineral homeostasis. Alterations in osteoblast differentiation, maturation, and/or osteocytic transition could contribute to the skeletal abnormities observed in CKD. However, model systems for studying the mechanisms regulating these processes, in the context of CKD, are lacking.

Methods: Thus, a model system was established from osteoprogenitors isolated from patient bone biopsies. Iliac crest bone tissue (2 mm in diameter) was obtained from 24 dialysis pts (14M,10F) aged 17.1 + 0.7 (SE)yrs. and 4 healthy controls (median age 16 yrs.), RNA was isolated from one half of each core; the other half was minced, the fragments plated in DMEM, and the emerging cells grown to confluence. qRT-PCR was performed on RNA from both cells and bone cores to evaluate expression of osteoblastic and osteocytic markers and signaling genes.

Results: Expression of analyzed genes was normalized by GAPDH and expression in ESKD samples was normalized by expression in healthy controls.

* different from healthy controls, $p<0.05$

Expression of osteoblast markers was increased in CKD bone and cells and expression of genes critical to PTH, FGF, and vitamin D signaling correlated between cells and bone core itself, suggesting that these cells maintain an abnormal phenotype in vitro.

Conclusions: Hormone signaling mechanisms appear to be preserved in this novel model, providing a potentially useful characteristic by which to evaluate the abnormal bone biology associated with CKD.

TH-PO594

The Importance of Serum TRAP-5b and Sclerostin in Osteocytic Perilacunar/Pericanalicular Remodeling in Dialysis Patients

Aiji Yajima,[1,4] Hironari Shindo,[2,5] Masaaki Inaba,[3] Ken Tsuchiya,[4] Kosaku Nitta.[4] *[1]Kidney Center, Otsuki Municipal Central Hospital, Otsuki, Yamanashi, Japan; [2]Surgery, Otsuki Municipal Central Hospital, Otsuki, Yamanashi, Japan; [3]Endocrinology, Metabolism, and Molecular Medicine, Osaka City Univ, Graduate School of Medicine, Osaka, Osaka, Japan; [4]Medicine, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Sclerostin (Scl) inhibts osteoblastic bone formation and accelerates osteocytic osteolysis and parathyroid hormone (PTH) also accelerates osteoclastic bone resorption and osteocytic osteolysis. However, chronic PTH elevation inhibits Scl, resulting in prevention of severe reduction of bone volume (BV). We investigated the mechanism to prevent an acute and severe reduction of BV and tartrate resistant acid phosphatase-5b (TRAP-5b) derived from the osteocyte in dialysis patients.

Methods: Serum parameters, including TRAP-5b, Scl and intact PTH (iPTH) levels were measured in patients with hypoparathyroidism (Hypo) (N=13) and subjects without hypoparathyroidism (N=23). Histomorphometric parameters, including the number of osteocytes inside resorption predominant osteocyte lacunae (N.Ot.ES/Ct.Ar;N/mm^2) and poorly mineralized BV (PMBV/Ct.Ar;%) were measured in the cortex. The relationships between TRAP-5b and both N.Ot.ES/Ct.Ar and PMBV/Ct.Ar were investigated in Hypo whose osteoclast surface was below 0.3 % in cortex to evaluate TRAP derived from osteocyte. The 25 cortices obtained from 13 Hypo were divided into Group I (N=13) and Group II (N=12) by N.Ot.ES/Ct.Ar and PMBV/Ct.Ar to compare TRAP-5b between these two groups (Nonparametric statics). Both N.Ot.ES/Ct.Ar and PMBV/Ct.Ar values of Group I were greater than Group II. And the relationships between serum parameters were investigated in 36 patients (Linear regression analysis).

Results: Serum TRAP-5b was greater in Group II than Group I when these cortices were divided by N.Ot.ES/Ct.Ar ($P=0.041$) and PMBV/Ct.Ar ($P=0.005$) in Hypo. Scl was negatively associated with iPTH ($P<0.001$, $R=-0.67$) and TRAP-5b ($P<0.05$, $R=-0.41$) in all patients.

Conclusions: Chronic elevation of PTH seems to suppress Scl in dialysis patients. Increased osteocytic osteolysis constitutes a negative-feedback mechanism for lowering TRAP activity.

TH-PO595

The Contribution of Osteocytes to Minimodeling Formation on the Endocortical Surface after Parathyroidectomy for Secondary Hyperparathyroidism

Aiji Yajima,[1,2] Ken Tsuchiya,[2] Kosaku Nitta,[2] Masaaki Inaba,[3] Hironari Shindo.[4,5] *[1]Kidney Center, Otsuki Municipal Central Hospital, Otsuki, Japan; [2]Medicine, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan; [3]Metabolism, Endocrinology and Molecular Medicine, Osaka City Univ, Graduate School od Medicine, Osaka, Japan; [4]Surgery, Otsuki Municipal Central Hospital, Otsuki, Japan; [5]Surgery, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Osteocytes in minimodeling area on the endocortical surface have an important role to increase cortical bone volume after parathyroidectomy (PTX) for secondary hyperparathyroidism (II HPT) because mechanical loading transmits to the cortex and osteocyte is the important mechanical sensor to mechanotransduction. The importance of osteocyte in minimodeling formation was investigated because a significant increase of minimodeling following PTX was reported.

Methods: We measured minimodeling volume (Ml.BV)-referent osteocyte number (N.Ot/Ml.BV; N/mm^2) at the endocortical surface and cortical area-referent N.Ot (N.Ot/Ct.Ar; N/mm^2) in transiliac bone biopsy specimens taken at 2 to 4 (mean; 3.6 ± 0.7) weeks after PTX for IIHPT (n=17, 57.9 ± 9.0 years old, with a HD duration of 13.4 ± 7.2 years). As a result, 34 cortices were obtained and equally divided into the two groups. The relationship between N.Ot/Ml.BV and changes of Ml.BV-referent minimodeling osteoid volume (Δ Ml.OV/Ml.BV; %) after PTX was investigated in specimens from Group I, in which cortical width (Ct.Wi; μm) was over 700 μm, and subjects of Group II, in which with Ct.Wi was below 700 μm (n=17 each).

Results: N.Ot/Ml.BV was greater than N.Ot/Ct.Ar in both Group I (427.0 ± 211.4 versus 151.2 ± 53.6 N/mm^2, $P = 0.004$) and Group II (456.0 ± 205.4 versus 138.2 ± 70.6 N/mm^2, $P = 0.005$). Δ Ml.OV/Ml.BV was associated with N.Ot/Ml.BV in Group I ($P = 0.004$, $R = 0.650$), but not in Group II.

Conclusions: The Osteocyte seems to play an important role in minimodeling formation because of the abundance of osteocytes in minimodeling area. Mechanical loading effectively influences minimodeling formation in Group II patients with severe cortical thinning independently of N.Ot. And N.Ot is so much important in minimodeling formation in Group I.

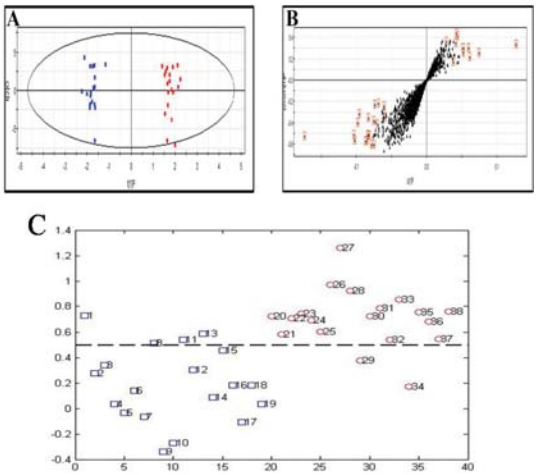
TH-PO596

Metabolic Pattern Shift in Chronic Kidney Disease-Mineral and Bone Disorder by Mass Spectrometry-Based Metabolomics Xueli Lai, Zhiyong Guo. *Dept of Nephrology, Changhai Hospital, Shanghai, China.*

Background: Abnormalities in serum calcium, phosphorus, and parathyroid hormone (PTH) levels are common in patient with CKD, and are the classical markers using in predicting the onset of CKD-MBD. Therefore, CKD-MBD is associated with metabolic disturbances related to its classical markers. Identifying metabolite biomarkers associated with CKD-MBD may have important value for better prognosis, risk assessment and potential target screening. The objective of the study was to find the endogenous metabolic difference associated with iPTH between secondary hyperparathyroidism patients and disease controls.

Methods: This study was a cross-sectional study. Metabolic profiling analysis of serum was performed by ultra-high performance liquid chromatography quadrupole time-of-flight mass spectrometry (UPLC-Q-TOF/MS) in 38 PD patients including 19 disease controls (DC) (iPTH: 150-300 pg/ml) and 19 secondary hyperparathyroidism (SHPT) patients (iPTH > 300 pg/ml).

Results: Metabolic profiling analysis revealed different patterns of endogenous metabolites between SHPT and DC groups, The present study identified total 28 metabolites that performed best in differentiating SHPT group from DC group. The OPLS-DA model obtained revealed a good explained variance and predictability,(1A and 1B). and was assessed by leave-one-out analysis, exhibiting 89.5% sensitivity and 78.9% specificity.



(1C)

Conclusions: Metabolomic analysis is an alternative tool for discriminating SHPT patient from DC. And with this way in this study, we find that uremic toxins, steroid hormones and TCA cycle intermediates are mainly involved in the onset of CKD-MBD, with obvious promise for better prognosis and new target screening.

TH-PO597

Looking inside the Skeleton: Bone Protein Quantification in CKD Patients Patricia T. Goldenstein, Fabiana Graciolli, Rosilene M. Elias, Gisele Antunes Lins, Wagner Dominguez, Luciene dos Reis, Vanda Jorgetti, Rosa M.A. Moyses. *Nephrology, Univ de Sao Paulo, Brazil.*

Background: CKD-MBD is a complex disorder, with several unsolved issues regarding its pathophysiology. Therefore, new study techniques that could help us understand it are welcome. Previous studies have shown high serum concentration of Wnt pathway inhibitors such as Sclerostin (Scl) and Dickkopf 1 (DKK1) in CKD. In addition, high bone Scl expression by immunohistochemistry has already been demonstrated in CKD patients. However, the quantification of this and other CKD-MDB related proteins in bones is still lacking.

Methods: Patients with severe secondary hyperparathyroidism (SHPT) who were referred to parathyroidectomy underwent a transiliac bone biopsy with histomorphometric analysis. A total bone protein lysate was obtained and Scl, DKK1, Osteocalcin (OC) and Osteoprotegerin (OPG) were quantified by MILLIPLEX®, which was also used to measure serum concentration of the same proteins.

Results: Eighteen patients aged 44 ± 13 years; on dialysis for a median time of 60 months; with PTH ranging from 631 to 5418 pg/ml (median = 2124) were included. All patients had histomorphometric pattern of high turnover bone disease. There was no correlation of the same protein in bone and serum for any evaluated protein. The highest bone concentration was found for OC (median = 94 mg/g protein), followed by Scl (median = 0.8 mg/g protein). Patients with higher bone concentration of DKK1 were on dialysis for a longer time, whereas a higher bone Scl was associated with higher serum phosphate, bone eroded surface, and bone OC. Higher serum Scl was found in patients with lower bone OPG.

Conclusions: By using this new technique, we have demonstrated that there is no association between bone and serum protein concentration. Our findings suggest that serum phosphate could stimulate bone Scl, which, in turn, would increase bone resorption. In addition, a higher serum Scl would inhibit bone OPG, also favoring the resorptive process. However, as only patients with severe SHPT were included, further studies are needed. Given these promising preliminary findings, this innovative technique has the potential to help elucidate renal CKD-MBD pathophysiology.

Hyponatremia and Osteoporosis: Perspectives from a Single Academic Center Farsad Afshinnia,[1] Baskaran Sundaram,[2] Robert J. Ackermann,[1] Ka Kit Wong.[1,3] *[1]Univ of Michigan; [2]Thomas Jefferson Univ; [3]Ann Arobor VA Medical Center.*

Background: Independent association of hyponatremia with osteoporosis (OP) is controversial, with few small studies having contradictory results. We aimed at testing for a relationship between hyponatremia with OP in a large cohort of patients undergoing bone densitometry.

Methods: This is a cross-sectional observation of patients who have undergone bone densitometry at the outpatient units of the University of Michigan from 2001 to 2013. Consecutive patients with available demographic, clinical and laboratory data were included. OP was defined as a bone mineral density of ≤2.5 standard deviations (SD) below the mean peak bone mass of young, healthy adults. Hyponatremia was defined as serum sodium ≤135 meq/L, based on time-averaged serum sodium over the past 2 years prior to the date of densitometry. General Electric Lunar iDXA densitometers were used for densitometry. Multiple logistic regressions were used to calculate adjusted Odds Ratio (OR).

Results: Overall 25,117 patients were included. Mean age was 61 years (SD=14). There were 4701 males (18.7%) and 1895 black patients (7.5%). There were 715 patients (2.8%) with hyponatremia, 2672 (10.7%) with neck OP, 1885 (7.5%) with total hip OP, and 4880 (19.4%) with lumbar OP. Using a case mix model OR of OP associated with hyponatremia was 1.6 (95% CI: 1.4 – 1.9) at lumbar spine, 2.2 (95% CI, 1.8 – 2.7) at femoral neck, and 3.0 (95% CI, 2.5 – 3.8) at total hip. After adjusting for age, sex, race, weight, GFR, and use of medications, the OR was attenuated to 1.2 (95% CI, 1.0 – 1.5) at lumbar spine, 1.3 (1.1 – 1.7) at femoral neck, and to 1.9 (1.5 – 2.3) at the total hip site. Subgroup analysis revealed a significantly higher adjusted OR in patients aged ≤ 55 years, and BMI of 25-29 kg/m2 at all anatomical sites as compared to other subgroups. Males had a significantly higher OR at the lumbar site while females had a higher OR at the femoral neck. Similarly, black race had significantly higher OR at all hip anatomical sites.

Conclusions: Hyponatremia was independently associated with OP. This association persisted, though was significantly attenuated after multiple adjustments. It varied by age, gender, race, and BMI.

TH-PO599

Bone Microstructure Evaluated by High-Resolution Peripheral Quantitative Computed Tomography and Low-Impact Fractures in Men with Predialysis Chronic Kidney Disease Maurilo Leite,[1] Francisco Paranhos-Neto,[2] Guilherme Cunha Lima,[2] Alvimar Delgado,[1] Carlos Perez Gomes,[1] Maria Lucia Fleiuss Farias.[2] *[1]Nephrology, Univ Federal do Rio de Janeiro, Brazil; [2]Endocrinology, Univ Federal do Rio de Janeiro, Brazil.*

Background: CKD is associated with increased risk of fractures, not well correlated with findings of dual energy X-ray absorptiometry (DXA). High-resolution peripheral quantitative computed tomography(HR-pQCT) assesses bone microarchitecture, providing information on bone quality. This study aimed to evaluate bone structure by HR-pQCT in male predialysis patients, and correlate these alterations with metabolic parameters and low-impact fractures (LIF).

Methods: Forty-five hypertensive men, between 50-75 years of age, identified as CKD stages 3 or 4, were selected. Men were chosen to avoid the effect of menopause on BMD. Mean values of biochemical parameters, collected from the previous 6 months, as well as serum bicarbonate, iPTH, 25(OH)vitD, and FGF-23 were analyzed. Fifteen patients reported at least one LIF. The remaining group had no history of fractures. Both groups were assessed by DXA (femoral neck, total femur and radius) and HrPQCT (distal radius and distal tibia).

Results: BMD T-scores were lower in the stage 4 compared to 3 CKD patients and were positively correlated with serum bicarbonate levels (P=0.005). There was no correlation between T-scores results and LIF. Regression analysis of the radius HR-pQCT found a negative correlation between low-impact fractures and cortical thickness (P=0.016), cortical perimeter (P=0.036) and cortical density (p=0.029), as well as positive correlation with cortical surface (P=0.014). Serum bicarbonate and FGF-23 were negatively and positively correlated with trabecular area (r=-0.5, P=0.008 and r=0.6, P=0.009, respectively).

Conclusions: These results confirm that DXA is not a reliable tool to investigate CKD patients under the risk of low impact fractures. On the other hand, HR-pQCT can be of significant value. It is suggested that cortical bone trabecularization occurs early in CKD and results in cortical bone fragility. Finally, serum levels of FGF-23 and the degree of metabolic acidosis are crucial determinants of bone fragility.

TH-PO600

Evaluation of Bone Microarchitecture by High-Resolution Peripheral Quantitative Computed Tomography in Patients with Chronic Kidney Disease: Comparison with Transiliac Bone Biopsy Igor Marques,[1] Maria Julia C.L.N. Araujo,[1] Fabiana Graciolli,[1] Luciene dos Reis,[1] Melani R. Custódio,[1] Rosa M. Pereira,[3] Sophie Jamal,[2] Vanda Jorgetti,[1] Elias David-Neto,[1] Rosa M.A. Moyses.[1] *[1]Nephrology Div, Univ de Sao Paulo; [2]Univ of Toronto; [3]Reumathology Div, Univ de Sao Paulo.*

Background: High-resolution peripheral quantitative computed tomography (HR-pQCT) is a noninvasive imaging technique that assesses trabecular and cortical bone microarchitecture in vivo. The purpose of our study is to evaluate, for the first time, the correlation between HR-pQCT measures and transiliac bone biopsy (Bx) in dialysis patients.

Methods: We measured BMD by HR-pQCT and dual energy x-ray absorptiometry (DXA) in 31 CKD stage 5D patients. Bx were analyzed by 2D quantitative histomorphometry; and measures of total and mineralized trabecular bone volume (2D BV/TV and 2D Md.V/TV, respectively), as well as cortical porosity (2D Co.Pt) were obtained.

Results: Patients (19 males) were 41±11 years old, with a dialysis vintage of 28 months, BMI of 24kg/m², serum Ca of 8.4±0.6 mg/dl; P of 3.4±1.5 mg/dl; alkaline phosphatase 93(71-145) U/L; PTH 688±489 pg/ml; 25-vitamin D 22(15-34) ng/ml and sclerostin 1.03(0.51-1.83) ng/ml. 2D BV/TV correlated significantly with height; lumbar spine (r =0.70) and total femur (r = 0.59) DXA; and modestly with HR-pQCT BV/TV at the radius (r = 0.42; p< 0.05) but not at the tibia. 2D Md.V/TV correlated significantly with age; height; lumbar spine (r = 0.67) and total femur (r = 0.63) DXA; and HR-pQCT BV/TV (r = 0.50; p<0.05) only at the radius. Conversely, a strong correlation was found between 2D Co.Pt and HR-pQCT cortical bone density (DComp) both at radius and tibia (r = -0.60 and -0.64, respectively; p <0.05).

Conclusions: There was a good agreement between HRpQCT and 2D BV/TV regarding cortical compartment. On the other hand, in trabecular bone, despite being statistically significant and greater than that described for the general population, the correlations between both methods were modest, indicating that HRpQCT cannot be used to predict 2D BV/TV. Further, larger studies are needed as well as studies to determine if these noninvasive measures can predict fracture.

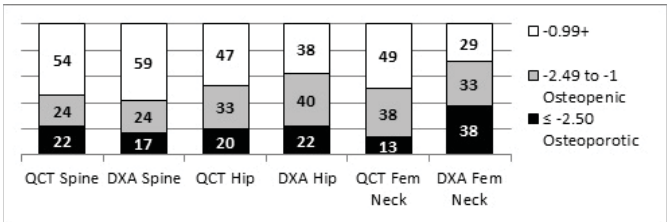
TH-PO601

Determination of Bone Mass By Invasive and Non-Invasive Methods: Evidence for Usefulness of DXA in CKD-5D Gustav A. Blomquist,[1] Daniel Davenport,[2] Hanna W. Mawad,[2] Marie-Claude M. Faugere,[2] Hartmut H. Malluche.[2] *[1]Radiology, Univ of Kentucky, Lexington, KY; [2]Internal Medicine, Div of Nephrology, Univ of Kentucky, Lexington, KY.*

Background: Low bone mass is an integral component of renal osteodystrophy and is seen in virtually all patients with CKD-5D. Bone mass is measured noninvasively by dual-energy x-ray absorptiometry(DXA) and quantitative computed tomography(QCT), or invasively by bone biopsies with histology. DXA is readily available. QCT is less available, higher radiation, and more expensive. Histomorphometric evaluation is considered the gold standard but rarely used because of the bone biopsies. This study evaluates the utility of DXA and QCT for screening of osteoporosis with validation by histology.

Methods: A total of 46 patients(mean age 51yrs, 52% women, median dialysis 46 mos.) had bone biopsies and bone mineral density(BMD) measured by DXA and QCT.

Results: QCT and DXA absolute BMD values(g/cm²) were highly correlated at the femoral neck (rho=0.968), total hip (rho=0.961) and to a lesser degree at the spine (rho=0.612). Both DXA and QCT t-scores were highly correlated, but QCT t-scores were up to 1 S.D. greater than DXA t-scores leading to less recognition of low BMD by QCT(Figure: (%) of BMD t-scores by method and site)



DXA and QCT measurements correlated with histologic cancellous bone volume(BV/TV) and negatively with trabecular separation(TbSp), p<.001.

	DXA Spine	QCT Spine	DXA Fem Neck	QCT Fem Neck	DXA Hip	QCT Hip
BV/TV	.538	.565	.567	.616	.644	.663
TbSp	-.506	-.570	-.577	-.637	-.633	-.653

Conclusions: Current nephrologic and radiologic guidelines were formulated with limited available DXA and QCT data and thus recommend limited use of DXA in CKD-5D. The presented results show DXA is a useful tool for assessment of bone mass in CKD-5D patients and warrants reconsideration of the current guidelines.

TH-PO602

Sotatercept: Initial Signal-Seeking Quantitative Computed Tomography Results for Bone Mass in Hemodialysis Subjects Treated with Escalating Doses: Interim Analysis of ACE-011–REN-001 Hartmut H. Malluche,[1] Keith A. Hruska,[2] Hem N. Singh,[3] William T. Smith.[3] *[1]Univ of Kentucky, Lexington, KY; [2]Washington Univ St. Louis, St. Louis, MO; [3]Celgene Corporation, Warren, NJ.*

Background: High turnover renal osteodystrophy (ROD) is marked by increased cortical porosity, higher trabecular bone mass, and increased risk of fracture. Sotatercept, an activin A RIIA-IgG1 fusion protein ligand trap under study for the correction of anemia in hemodialysis (HD) subjects, blocks activin A signaling and may reduce osteoclastogenesis and promote osteoblast maturation in bone. The current analysis in HD subjects evaluated the effect of sotatercept on bone mineral density (BMD) and vascular calcification using quantitative computed-tomography (QCT).

Methods: In an ongoing studyof sotaterceptin HD subjects for the correction of anemia, subjects who were erythropoietin-stimulating agent (ESA)-responsive were washed out of their ESA effect until Hb was <10 g/dL, then randomized to sotatercept 0.3 mg/kg (n=9), 0.5 mg/kg (n=8), or placebo (PBO; n=7) SC every 28 days for up to 8 dose cycles; a 0.7 mg/kg dose group (n=6) is ongoing. Subjects were assessed for effects on Hb, BMD, and biomarkers of bone turnover. Treatment failures (Hb <9 g/dL) were rescued with ESA/transfusion. QCT of the hip, and lumbar spine, was obtained at baseline and after the 225-day treatment phase. Biomarkers, BSAP and CTX, were measured at baseline and after dose cycles 3, 5, and 7.

Results: Of the 30 randomized subjects, 13 had paired QCT assessments (n=3, 6, and 4 for PBO, 0.3 mg/kg, and 0.5 mg/kg, respectively). Relative BMD changes from baseline for PBO, 0.3 mg/kg, and 0.5 mg/kg were -0.9%, -1.4%, and +1.9% of the femoral neck cortical, and +12.6%, +8.0%, and -1.9% of the lumbar spine, respectively. Biomarker changes with 0.5 mg/kg suggest a beneficial antiresorptive effect.

Conclusions: These interim data suggest an emerging dose effect with sotatercept 0.5 mg/kg, which appeared to reverse the effects of high turnover ROD on cortical and cancellous bone. PBO results were as expected. We anticipate a complete data set to further substantiate these effects.

Risedronate Combined with Menatetrenone May Prevent Glucocorticoid-Induced Osteoporosis in Patients with Chronic Glomerulonephritis Yuko Makita, Hitoshi Suzuki, Masao Kihara, Takashi Kobayashi, Yasuhiko Kanaguchi, Satoshi Mano, Teruo Hidaka, Yasuhiko Tomino. *Nephrology, Juntendo Univ Faculty of Medicine, Tokyo, Japan.*

Background: Glucocorticoid therapy may induce secondary osteoporosis, although glucocorticoid is useful for the treatment of chronic glomerulonephritis (CGN). Bone loss is observed to begin developing just after the administration of glucocorticoid, and the degree of osteoporosis depends on the cumulative doses of glucocorticoid. Although bisphosphonate treatment is well known to improve bone quality and reduce the risk of bone fractures, recent studies have shown that vitaminK2 also stabilizes bone mineral density (BMD). Furthermore, vitamin K2 works with osteocalcin for bone formation. Thus, we examined the clinical efficacy of bisphosphonate alone and bisphosphonate combined with vitamin K2 for the prevention of glucocorticoid-induced bone loss in CGN patients using serum levels of N-terminal telopeptide of type I collagen (NTx) and uncarboxylated osteocalcin (ucOC) with BMD.

Methods: We recruited 62 patients (mean age 42.4 ± 16.9) with CGN who were treated with prednisolone from 2011 to 2013 at Juntendo University Hospital. six-month prospective randomized study was conducted. These patients were randomly assigned to either Risedronate (17.5 mg/week) alone (Risedronate group, n=30) or Risedronate with Menatetrenone (45 mg/day) (Combined group, n=32) treatment groups. Serum levels of NTx and ucOC as well as BMD were measured before and after 6 months of commencing treatment with prednisolone.

Results: In the Risedronate alone group, the percent change of serum levels of NTx was -9.8 % after 6 months, whereas the Combined group observed changes of -27.8 % (P<0.05). Serum levels of ucOC were decent decreased in the Combined group, compared with the Risedronate alone group. Consequently, increased levels of BMD in spine was higher in the Combined group (+15.6%) than in the Risedronate alone group (+4.5%). Notably, the effect of bone formation by combination therapy was remarkable in female patients (P<0.05).

Conclusions: The combination therapy of Risedronate with Menatetrenone may have a synergistic effect to prevent glucocorticoid-induced osteoporosis in patients with CGN.

TH-PO604

Effects of Muscle Strengthening on Bone Mass in Hemodialysis Patients Kei Yoneki,[1] Atsuhiko Matsunaga,[1] Jun Kitagawa,[1] Yoshifumi Abe,[1] Manae Harada,[1] Ryoma Ishikawa,[1] Takaaki Watanabe,[1] Ryota Matsuzawa,[1] Atsushi Yoshida,[2] Kouju Kamata.[1] *[1]Kitasato Univ, Sagamihara, Japan; [2]Sagami Junkanki Clinic, Sagamihara, Japan.*

Background: Muscle strengthening is a recommended preventive strategy against bone loss in the general population. However, how muscle strength affects bone mass in hemodialysis (HD) patients is unclear. We performed cross-sectional (Study 1) and longitudinal (Study 2) studies to examine the association between muscle strength and bone mass in HD patients.

Methods: In Study 1, 172 outpatients with HD (79 men and 83 postmenopausal women; mean age, 66 ± 8 years) were recruited. Clinical characteristics (age, sex, body mass index, HD vintage, and levels of serum albumin, serum phosphorus, corrected calcium, and intact parathyroid hormone [iPTH]) were obtained from clinical records. Bone mass was assessed by quantitative ultrasound measurement (stiffness index) at the calcaneus. Grip strength was assessed as an indicator of general muscle strength. The association between grip strength and stiffness index was assessed by multiple regression analysis adjusted for clinical characteristics for each sex. In Study 2, a 2-year follow-up of subjects of Study 1 was performed in terms of clinical characteristics, stiffness index, and grip strength. Subjects were divided into two groups by the median grip strength both at baseline and endpoint. Multiple regression analysis, adjusted for baseline clinical characteristics, baseline stiffness index, and changes in iPTH, was performed to examine the association between grip strength during the study period and changes in stiffness index for each sex.

Results: In Study 1, adjusted multiple regression analysis revealed a significant association between grip strength and stiffness index for each sex (P<0.05 for both). In Study 2, follow-up of 97 HD patients and subsequent adjusted multiple regression analysis revealed a significant association between grip strength during the study period and changes in stiffness index for each sex (P<0.05 for both).

Conclusions: Our findings suggest that maintaining or improving muscle strength may contribute to the effective prevention of bone loss in HD patients.

TH-PO605

Effects of Acidosis Correction on Chronic Kidney Disease - Mineral Bone Disorder Parameters in Patients on Maintenance Hemodialysis

Alessandra Martins Bales, Rosa M.A. Moyses, Luciene dos Reis, Fabiana Graciolli, James Hung, Manuel Carlos Martins Castro, Rosilene M. Elias. *Nephrology, Univ de São Paulo, São Paulo, Brazil.*

Background: Metabolic acidosis (MA) is common among patients with end-stage renal disease, and is not completely corrected by hemodialysis. Acidosis can cause impairment in nutritional status and worse uremic bone disease. However, few studies evaluated the effects of MA correction on CKD-MBD laboratorial parameters. **Objective:** to investigate the impact of MA correction on CKD-MBD.

Methods: We prospectively studied 48 patients on hemodialysis with age 43 ± 19 years. Individual adjustments in dialysate bicarbonate concentration (dBic) were made. Blood gas analysis was done monthly for 4 months (M1 to M4). Biochemical variables were accessed at M0 and M4.

Results: Bic and pH increased and maintained in the target range during the study (p<0.05). Although there was an increase in sodium, no changes were observed in the interdialytic weight gain and also in the hypotensive drugs need. From M0 to M4, there was an increase in PTH (parathyroid hormone) [from 191 (85, 459) to 446pg/ml (212, 983), p<0.0001], in serum phosphate (from 5.4±1.4 to 5.8±1.1mg/dl, p=0.048), and a decrease in ionized serum calcium (from 5.0±0.5 to 4.7±0.5mg/dl, p=0.002). Serum albumin increased (from 3.5±0.3 to 4.0±0.3g/L, p<0.0001) while $ß_2$ microglobulin decreased (from 27.6±8.3 to 25.8±6.8 µg/ml, p=0.025). Serum leptin decreased in all but 3 patients (p<0.0001). Thirty-one out of 48 patients (64.6%) had PTH <300pg/ml at baseline. Despite the same degree of MA correction and decrease in serum calcium, these patients had much higher percentage increase rate in PTH when comparing to those with PTH >300pg/ml at baseline [250 (62, 330) versus 75 (-2.2, 145), p=0.002]. If we consider the KDIGO recommendation (PTH 2-9 times the upper normal limit of the assay), the percentage increase rate of PTH was higher in those patients with PTH in the lower limit (p=0.008).

Conclusions: MA correction by increasing dBic is safe. This approach might improve nutritional status and decrease inflammation. The benefit appears to be much greater for patients with low PTH, and caution is advised in patients with high PTH.

TH-PO606

Effecst of Parathyroid Function and Bone Turnover on Bone Structural Properties in Dialysis Patients

Junichiro J. Kazama,[1] Koji Matsuo,[1] Suguru Yamamoto,[1] Ichiei Narita,[1] Yoshiko Iwasaki,[2] Masafumi Fukagawa.[3] *[1]Clinical Nephrology and Rheumatology, Niigata Univ, Niigata, Japan; [2]Health Science, Oita Univ of Nursing and Health Sciences, Oita, Japan; [3]Nephrology and Metabolism, Tokai Univ, Isehara, Kanagawa, Japan.*

Background: Although abnormalities in parathyroid function and bone turnover are commonly found among individuals with chronic kidney disease (CKD), the influence of these abnormalities on bone microscopic structural properties remains obscure. Conventional two-dimensional (2D) bone histomorphometry has a limitation in assessing cancellous bone structure.

Methods: Biopsied iliac bone samples from 48 stable dialysis patients were used for the analyses. Quantitative histomorphometric studies were performed in the virtual 3D space generated from the serial micro-computed tomography sections of the samples. These data were compared with those obtained by biochemical and tetracycline labeling–based 2D histomorphometric results.

Results: Neither cancellous bone volume nor trabecular thickness showed significant correlations with the bone formation rate (BFR/BS) at the 3D level. Both the trabecular pattern factor (TBPf) and the structural model index showed significant inverse correlations with the BFR/BS, whereas the marrow cavity star volume, the connection density, and the number of nodes did not. Circulating intact parathyroid hormone (PTH) levels showed a significant inverse correlation with cortical bone thickness, whereas none of the above five parameters showed a correlation with PTH. In the subgroup of 33 patients with osteoid volume>3.0%, those with a mineral apposition rate (MAR) of 0 showed significantly higher levels of TBPf than those with a MAR>0.

Conclusions: In iliac bone samples obtained from dialysis patients, (1) increased bone turnover drove cancelluos bones into more like a plate-shaped pattern with an uneven surface, (2) these morphological changes were not linked to altered trabecular bone connectivity or trabecular bone mass, (3) the bone formation/mineralization step was responsible for the morphological changes, and (4) cortical bone thinning was the only likely findings related to parathyroid function, which would potentially increase the fracture risk.

Funding: Government Support - Non-U.S.

The Pitfall of Treating Low Bone Turnover Through the Stimulation of PTH: Effects on Cortical Porosity

Maria Julia C.L.N. Araujo,[1] Cristina Karohl,[2] Rosilene M. Elias,[1] Fellype C. Barreto,[3] Daniela Veit Barreto,[3] Maria Eugenia F. Canziani,[4] Aluizio B. Carvalho,[4] Vanda Jorgetti,[1] Rosa M.A. Moyses.[1] *[1]Nephrology, Univ de São Paulo, Brazil; [2]Univ Federal do Rio Grande do Sul, Brazil; [3]Pontifícia Univ Católica do Paraná, Brazil; [4]Univ Federal de São Paulo.*

Background: Although it is recognized that cortical bone contributes significantly to the mechanical strength of the skeleton, little is known about this compartment from bone biopsy studies. Recently, it has been described that an increase in cortical porosity (Ct.Po) is a common finding in CKD patients, especially in black patients. However, there is no prospective data of the effects of CKD-MBD therapy on Ct.Po.

Methods: We measured Ct.Po in bone biopsies (Bx) obtained from dialysis patients who have undertaken a prospective study (BRIC). CKD-MBD therapy was adjusted according to the first Bx, trying to normalize bone turnover rate, regardless of baseline serum PTH. After one year of follow-up, a second Bx was obtained and changes in Ct.Po were the variable of interest.

Results: We evaluated 52 patients with baseline PTH 265 pg/ml (124-633). According to TMV, 44% had low turnover disease, 50% had low cancellous volume and 54% abnormal mineralization. High initial Ct.Po was found [29.5% (16.7, 46)], and after one year, increased in 59.6% of patients, with a delta Ct.Po of 6.1% (-11, 23). PTH increased in 30 patients as a result of CKD-MBD therapy. The change in PTH correlated with a change in bone formation rate (r=0.28; p<0.05), but also with the delta of Ct.Po (r=0.30, p<0.05). Delta of Ct.Po was higher in non-white than in white patients (16.6 versus -1.1%, respectively) as well as in patients with baseline PTH <300 pg/ml (p<0.05). Multiple regression analysis showed that the delta of Ct.Po was dependent on delta PTH and race, in a model adjusted for age, gender and therapy.

Conclusions: In this prospective study, we showed that there was an increase in Co.Pt in dialysis patients, which was more pronounced in black patients, despite the continue raise of PTH. Therefore, elevation of PTH as an attempt to normalize cancellous bone formation rate may cause a higher risk of cortical bone loss and probably of fractures.

Prolonged Hyperparathyroidism May Cause Subendocardial Ischemia Risk That Remains after Parathyroidectomy

Adriano Sanjuan, Valeria Hong, Bruno C. Silva, Rosa M.A. Moyses, Rosilene M. Elias. *Nephrology, Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Secondary hyperparathyroidism (SHPT) in patients on hemodialysis is associated with increased risk for myocardial ischemia and endothelial dysfunction. Parathyroidectomy (PTx) can reduce the cardiovascular risk in these patients, but whether PTx improves these conditions is still unknown. The pupose of this study was to investigate the risk of myocardial ischemia and endothelial dysfunction after long term PTx.

Methods: The propensity to myocardial ischemia (Buckberg index) was calculated as the ratio of the area of the diastolic phase to that of the systolic phase in the central aortic profile. This ratio was designated as the subendocardial viability ratio (SEVR), measured by SphygmoCor (AtCor Medical Ltd.). Endothelial dysfunction (accessed as flow mediated dilation – FMD) was done through the reactive hyperemia. Echocardiography was also performed.

Results: 27 patients (41% male) with age 48 ± 13 years, on dialysis for 95 (21, 181) monthswere included. SHPT was seen in 17 (63%) patients in whom PTx was performed in 14. Three patients were still with severe SHPT, defined as PTH >500pg/ml. The median time patients were exposed to severe SHPT was 1049 days. This period corresponds from the first PTH>500pg/ml until the day of PTx (PTx group) or the day of study assessment (including patients with current severe SHPT). FMD correlated to septum thickness (r=-0.715, p=0.0004), and was not different between patients who underwent PTx or who had SHPT. SEVR correlated to 25-vitamin D (r=0.506, p=0.022), and was higher in both group of patients, those submitted to PTx (p=0.033) and those with SHPT (p=0.0003). There was a correlation between the exposure time to SHPT and SEVR (r=-0.612, p=0.003). Multiple linear regression revealed, in a model adjusted for hemoglobin, age and creatinin, that 25-vitamin D (p=0.040), time exposed to SHPT (p=0.001) and gender (p=0.015) were independent associated to SEVR, explaining 57% of its variability.

Conclusions: We demonstrated for the first time that severe SHPT might cause functional myocardial abnormalities, associated to higher myocardial ischemia risk, which remains even after PTx.

22-Oxacalcitriol Ameliorates Diabetic Bone Disease in Diabetic Model Rats through Antioxidative Effects and Increase in IGF-1
Shunsuke Goto,[1] Hideki Fujii,[1] Keiji Kono,[1] Kentaro Nakai,[1] Michinori Hirata,[2] Masami Shinohara,[3] Shinichi Nishi,[1] Masafumi Fukagawa.[4] *[1]Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan; [2]Fuji Gotemba Research Labs, Chugai Pharmaceutical Co., Ltd., Shizuoka, Japan; [3]Plannning and Development Section, CLEA Japan, Inc., Tokyo, Japan; [4]Div of Nephrology, Endocrinology, and Metabolism, Dept of Medicine, Tokai Univ School of Medicine, Isehara, Japan.*

Background: Bone disease is an important complication in patients with chronic kidney disease (CKD). The bone fragility in these patients is caused by not only kidney dysfunction but also concomitant disease. Diabetes is a major cause of CKD and a risk factor for fracture. Although some studies have reported that vitamin D improves bone mineral density and bone formation in diabetes, the mechanisms remains unclear. Our study investigated the effect of 22-oxacalcitriol (OCT) on diabetic bone disease. In addition, we also investigated the effect of OCT on oxidative stress and insulin growth factor-1 (IGF-1).

Methods: We used Spontaneously Diabetic Torii (SDT) rats, which are newly established models of non-obese type 2 diabetes. Sprague-Dawley rats were used as a control group. SDT rats were divided into three groups: the diabetic (DM) group, the insulin (INS) group, and the OCT group at 20 weeks of age. OCT was administered at a dose of 0.2 mg/kg three times per week. We evaluated blood and urine analyses, bone mineral density (BMD), histomorphometry, oxidative stress marker 8-OHdG, and serum IGF-1 at 30 weeks of age.

Results: HbA1c and serum calcium levels were comparable between the OCT and DM groups. BMD, mineral apposition rate, and bone formation rate per bone surface were higher in the OCT group than those in the DM group. Urinary 8-OHdG levels and 8-OHdG positive cells in bone were lower in the OCT group than those in the DM group. Serum IGF-1 levels were higher in the OCT group than those in the DM group.

Conclusions: Our data suggested that OCT ameliorated diabetic bone disease in diabetic model rats partially through its antioxidative effects and increase in IGF-1.

Differential Effects of the Calcimimetic R-568 and Calcitriol on the FGF23-Vitamin D-PTH Axis in the Hyp Mouse as an Animal Model of Post-Transplant Hypophosphatemia
Maren Leifheit-Nestler,[1] Emi Yoshizawa,[1] Dagmar-Christiane Fischer,[2] Dieter Haffner.[1] *[1]Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany; [2]Dept of Pediatrics, Univ Hospital Rostock, Rostock, Germany.*

Background: Post-transplant hypophosphatemia is due to persistent secondary hyperparathyroidism, $1,25(OH)_2D_3$ deficiency, and elevated levels of the phosphaturic hormone fibroblast growth factor 23 (FGF23) resulting in post renal transplant (PRT) osteodystrophy. The Hyp mouse is a murine homolog to the human X-linked hypophosphatemia, displaying all features of PRT hypophosphatemia, and thus is excellently suited to investigate potential new measures.

Methods: The effects of a 7 day treatment with the calcimimetic R-568 (1-30 mg/kg BW/day), calcitriol (150-450 ng/kg BW/day), and vehicle on the FGF23-vitamin D-PTH axis was investigated in male Hyp mice. Wild type mice served as controls. Serum levels of FGF23, PTH, calcium, and phosphate were evaluated. The kidneys were assessed with respect to Cyp27b1, Cyp24 and klotho mRNA and/or protein expression.

Results: Hyp mice showed reduced weight, shorter tibia and femur lengths, reduced serum phosphate levels, and increased FGF23 and PTH serum levels compared to WT animals (each $P<0.01$). Both, treatment with R-568 and calcitriol increased serum phosphate levels, whereas no significant changes in serum calcium levels were observed. FGF23 serum levels were significantly increased by calcitriol in a dose dependent fashion, but decreased by R-568 treatment. PTH serum levels were reduced by low dose calcitriol, stimulated by high dose calcitriol, and generally reduced by R-568 treatment. Renal Cyp24 mRNA and protein expression were stimulated by calcitriol, whereas the corresponding mRNA and protein levels of Cyp27b1 were reduced. Renal *Klotho* mRNA expression was reduced in Hyp mice compared to WT animals, and normalized by calcitriol treatment.

Conclusions: Both, treatment with the calcimimetic R-568 and calcitriol increased serum phosphate levels in Hyp mice. Whereas R-568 decreased FGF23 and PTH serum levels, with calcitriol a dose dependent stimulation of FGF23 and PTH levels was observed.

TH-PO611

A New Early Start Cinacalcet Protocol Demonstrates a Sustained Improvement in Bone Mineral Outcomes in Prevalent Dialysis Patients; a 2-Year Retrospective Study
Ghayas Habach. *Merit Healthcare, Sylacauga, AL.*

Background: End stage renal disease patients are characterized by hypocalcemia and hyperphosphatemia with secondary hyperparathyroidism which impact morbidity and mortality when analyzed as time-dependent covariates. The 2013 United States Renal Data System reported that guidelines for mineral bone disorders (MBD) were poorly achieved (> 30% phosphorous (P) > 5.5 mg/dL). Studies indicate the efficacy of cinacalcet in decreasing serum levels of intact parathyroid hormone (iPTH) and controlling serum P and calcium (Ca) levels when compared to more traditional therapies. We propose a new combination therapy protocol of; (1) early cinacalcet administration, (2) low vitamin D analogue (VitD) dose and (3) oral Ergocalciferol; all in accordance with KDOQI guidelines.

Methods: For initiation, levels of serum iPTH, Ca, P and VitD25 levels were assessed. A starting dose of 30 mg cinacalcet was given if iPTH > 300 pg/mL and Ca > 8.4 mg/dL. If iPTH was 300-600 pg/mL, VitD dose was decreased by 50%. Serum Ca and P were monitored fortnightly and iPTH monthly. Cinacalcet dose was then titrated in 30 mg increments if iPTH > 300 pg/mL, Ca > 8.4 mg/dL and P > 3.5 mg/dL. If Ca < 7.5 mg/dL or symptoms of hypercalcemia persist VitD was increased by 25% if P < 5.5 mg/dL but cinacalcet was withheld if VitD could not be increased.

Results: We report that our patients show annual average levels of {compared to regional and national levels respectively}; (1) 15.3% serum P levels of > 5.5 mg/dL {30% and 29.3%}, (2) 0.0% serum Ca level of > 10.2 mg/dL {3.3% and 2.4%} (3) and VitD dose of 2 mcg per administration {4 mcg and 4 mcg}.

Conclusions: This 2-year retrospective study suggests our newly early start cinacalcet protocol demonstrates sustained improvements in MBD outcomes in dialysis patients; potentially attributed to; (1) higher (50-80%) than national (21-25%) average cinacalcet utilization, (2) lower VitD dose and (3) close dose monitoring (with consequent reduction in side effects) enabling the retaining of patient numbers, unveiling the practical nature of this protocol.

TH-PO612

AMG 416, a Peptide Agonist of the Calcium-Sensing Receptor, Preserved Cortical Bone Structure and Bone Strength in 5/6 Nephrectomized Rats with Established Secondary Hyperparathyroidism
Xiaodong Li, Longchuan Yu, Frank Asuncion, Mario Grisanti, Shawn T. Alexander, Kelly Sue Warmington, Kelly M. Hensley, Chun-Ya Han, Qing-Tian Niu, Denise C. Dwyer, Marina Stolina, Charles E. Dean, William G. Richards, Michael S. Ominsky, Hua Zhu "David" Ke, James Tomlinson. *Metabolic Disorders and Pathology, Amgen Inc.*

Background: Continuous elevation of parathyroid hormone (PTH) is catabolic to cortical bone, causing deterioration in cortical bone structure (eg, cortical porosity), and is a major factor for increased fracture risk in chronic kidney disease. AMG 416 reduces PTH levels in patients on hemodialysis with secondary hyperparathyroidism (SHPT). We hypothesized that AMG 416 would prevent the cortical bone deterioration in a rat model of established SHPT.

Methods: Twelve-week-old male 5/6 nephrectomized (5/6 Nx) rats were fed a special diet (0.9% phosphate and 0.6% calcium) to induce SHPT. Sham-operated rats were used as non-SHPT controls. Following 8 weeks on the special diet, rats were chosen with a baseline PTH level > 750 pg/mL (SHPT rats) and were subcutaneously injected daily with vehicle or AMG 416 for 6 weeks.

Results: Prior to treatment, SHPT rats had significant increases in serum creatinine (2-fold), blood urea nitrogen (BUN, 3-fold), PTH (5-fold), FGF-23 (13-fold) and osteocalcin (12-fold, a marker of bone turnover) compared with the non-SHPT controls. Serum creatinine and BUN continued to increase in both vehicle- and AMG 416-treated SHPT rats during the treatment period. PTH, FGF-23 and osteocalcin continued to increase in vehicle-treated SHPT rats, but were significantly reduced in AMG 416-treated SHPT rats. At the end of treatment, vehicle-treated SHPT rats had deteriorated cortical bone structure (increased cortical porosity: 8.3% in SHPT versus 0.07% in non-SHPT) and lower energy to failure (-30%), a bone strength endpoint, compared with non-SHPT controls. In contrast, cortical bone structure was improved (-72% in cortical porosity) and energy to failure was significantly greater (+54%) in the AMG 416-treated SHPT rats than in vehicle-treated SHPT rats.

Conclusions: AMG 416 preserved cortical bone structure and bone strength in a 5/6 Nx rat model of established SHPT.

Effect of RANK Ligand Inhibition with Denosumab on CKD-MBD Parameters in De Novo Renal Transplant Recipients
Rudolf P. Wuthrich,[1] Diana P. Frey,[2] Markus Blum,[1] Daniel Rodriguez,[1] Marco Bonani.[1] *[1]Nephrology, Univ Hospital, Zurich, Switzerland; [2]Rheumatology, Univ Hospital, Zurich, Switzerland.*

Background: De novo renal transplant recipients (RTXR) are at risk to lose bone mineral density (BMD) in the 1st year after transplantation, heightening the risk for fractures. Denosumab targets RANK ligand, inhibits bone resorption and may be preferred over bisphosphonates due to its lack of nephrotoxicity. We studied selected CKD-MBD parameters in RTXR which correlate with denosumab's therapeutic effect.

Methods: RTXR (n=50; age 48±15 years; 64% males; eGFR 55±17 ml/min/1.73 m^2; 33% osteopenic and 12% osteoporotic by DXA [lumbar spine]) were randomized 1:1 to denosumab (60 mg sc at baseline and 6 months) or no treatment (NCT01377467). All patients were prescribed daily vitamin D (800 IE) and calcium (1000 mg), and were followed at defined visits in the 1st year post-transplant.

Results: RTXR improved or normalized their blood levels of calcium (2.30±0.19 to 2.52±0.15 mmol/L), phosphate (0.62±0.35 to 0.86±0.24 mmol/L), PTH (171.5±174.8 to 105±81.0 ng/L), 25 (OH) vitamin D_3 (17.2±9.0 to 25.9±8.0 µg/L) and 1,25 $(OH)_2$ vitamin D_3 (29.9±20.0 to 51.8 ± 22.1 ng/L) between baseline and 12 months after transplantation (all $p<0.001$), without difference if denosumab-treated or not. Compared with controls, patients treated with denosumab had significantly decreased plasma levels of the bone resorption marker β-CTX (0.79±0.51 versus 0.22±0.20 µg/L; $p<0.001$) and the bone formation markers P1NP (150±93 versus 55±69 µg/L; $p<0.001$) and BSAP (20.5±11.5 versus 10.7±8.9 µg/L; $p<0.02$) at 12 months. The suppression of β-CTX did not correlate with changes in BMD at 12 months, whereas the change in P1NP correlated with the change in BMD at the lumbar

spine (p=0.04) but not at the hip. Denosumab treatment was well tolerated, except for a higher percentage of RTXR with urinary tract infections (60% versus 32%, p=0.047).

Conclusions: The significant decrease of β-CTX, P1NP and BSAP upon treatment with denosumab may be used to monitor the effect of denosumab treatment in de novo RTXR. Further analyses are needed to correlate the change of these biomarkers with the effect of denosumab on BMD.

Funding: Government Support - Non-U.S.

TH-PO614

Denosumab Induced Severe Hypocalcemia in Patients with Advanced Chronic Kidney Disease Vatsa Dave,[1] Cherie Y. Chiang,[2] Jane Booth,[3] Peter F. Mount.[1] *[1]Dept of Nephrology, Austin Health, Melbourne, Victoria, Australia; [2]Dept of Endocrinology, Austin Health, Melbourne, Victoria, Australia; [3]Dept of Pharmacy, Austin Health, Melbourne, Victoria, Australia.*

Background: Patients with severe CKD frequently have low bone mineral density and are at high risk of fracture but treatment options are limited. The RANK-ligand inhibitor denosumab is a potential treatment option for osteoporosis in patients who cannot have bisphosphonates due to severe CKD (eGFR <30 ml/min). Whilst denosumab is not renally cleared, little is known about its effects and safety in patients with severe CKD.

Methods: We retrospectively extracted all patients with CKD stage IV or V who received denosumab since 1/1/2010 at Austin Health. Patients were identified by cross-referencing pharmacy administration records with patient's renal function prior to drug administration. Chart reviews were conducted for clinical parameters, including calcium levels prior to and following administration of denosumab.

Results: 8 patients with stage V and 5 patients with stage IV CKD were identified (all female). Baseline data showed mean(SD) values for calcium of 2.40(0.13) mmol/L, PTH 19.8(15.2) pmol/L and 25-OH vitamin D 71.3(31.7) nmolL. Only one patient had a baseline 25-OH vitamin D level below 50 nmol/L. After denosumab 6 of 8 patients with CKD V, and 2 of 5 patients with CKD IV developed significant hypocalcaemia, (corrected calcium <2.0 mmol/L), with the lowest corrected calcium being 1.18 mmol/L. Of these 8 patients, 3 patients had significant life-threatening complications requiring intensive monitoring. For patients who developed hypocalcaemia, the median time to serum calcium nadir was 26 days and the median time to achieve correction of hypocalcaemia was 71 days. Treatment of hypocalcaemia required large doses of calcium and vitamin D as well as increases to dialysate calcium, consistent with a pattern of hungry bone syndrome.

Conclusions: A high rate of severe hypocalemia was observed in patients with advanced CKD who were given denosumab, despite adequate levels of 25-OH vitamin D. Denosumab is best avoided in patients with advanced CKD but if used very close monitoring is recommended.

TH-PO615

Abstract Withdrawn

TH-PO616

Calciuria May Not Fully Explain the Thiazide-Induced Serum Calcium Elevation on Chronic Kidney Disease Patients Raquel F.V. Vasco, Joice Manes, Gisele G. Maciel, Rosa M.A. Moyses, Rosilene M. Elias. *Nephrology, Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Thiazide therapy is not only useful for blood pressure control but also has an effect on CKD-MBD as can raise serum calcium (Ca) and downregulate PTH. Calciuria is the main mechanism proposed to explain the decrease in Ca. However, other authors described an increase in bone resorption on hemodialysis patients mediated by thiazide. Therefore, we challenged the concept that calciuria is the main accountable factor to induce the increase in Ca and consequent decrease in PTH among CKD patients.

Methods: Electronic charts of all nephrology outpatients clinic, who were given hydrochlothiazide (Hydro) or furosemide (Furo) were included. Estimated glomerular filtration rate (eGFR) based on CKD-EPI equation, biochemical parameters and VitD and calcium supplementation were assessed.

Results: Out of 542, 357 (66%) were taking Furo and 184 (34%) Hydro. Patients on Hydro group presented lower age, alkaline phosphatase, parathyroid hormone (PTH), uric acid, and phosphate. Also, they presented higher eGFR, Ca, bicarbonate, hemoglobin and serum albumin (all p values <0.005). Hypocalcaemia was observed in 50 patients (9%) and hypercalcaemia in 44 patients (8%), which was more frequent in Furo and Hydro groups, respectively (p<0.0001). Dietary VitD and calcium supplementation were prescribed to 37% and 7% of patients, respectively. The median calciuria was 83 (36,161) mg/24 hours. There was a weak correlation between Ca and calciuria (r=0.129, p=0.003). Logistic regression shows that age (RR 1.02), hydrochlorothiazide (RR 1.69) and dietary VitD supplementation (RR 1.62) were independent associated to Ca in a model adjusted for eGFR, calcium supplementation, calcitriol use, VitD levels, and calciuria. Secondary hyperparathyroidism was dependent on age (RR 1.02), Furo (RR 1.77) and Ca (RR 0.75), in a fully adjusted model. Neither Ca nor hyperparathyroidism were dependent on calciuria.

Conclusions: Thiazide effect on calciuria did not fully explain serum Ca levels and PTH among CKD patients. Therefore, the mechanisms by which thiazide may raise Ca and decrease PTH on CKD patients are complex, and warrant further investigation.

TH-PO617

Bone Erythropoietin Receptor Is Depressed in Anemia of Chronic Kidney Disease Daniel Landau,[1,3] Lital London,[2] Yael Segev.[2] *[1]Pediatrics, Ben Gurion Univ, Beer Sheva, Israel; [2]Microbiology and Immunology, Ben Gurion Univ, Beer Sheva, Israel; [3]Pediatrics, Soroka Univ Medical Center, Beer Sheva, Israel.*

Background: Anemia contributes to growth retardation in children with CKD and is due to impaired renal erythropoietin (EPO) synthesis or EPO receptor (EPOR) signaling. We have previously shown reduced epiphyseal growth plate (EGP) GH receptor (GHR) signaling as well as vascularization in growth impaired CKD rats. Both GHR and EPOR signals are transduced through the JAK2-STAT5 pathway. In this study we characterized the expression and signaling pathway of EPO and EPOR in kidney, EGP and bone marrow in juvenile CKD rats.

Methods: We divided young Sprague-Dawley rats (20 days old) into two groups: C versus CKD. CKD was induced by 5/6 nephrectomy while C group was sham operated. Somatic growth was followed throughout the experiment. Rats were sacrificed after 4 weeks. Blood, kidney, bone marrow and proximal tibia EGP tissue were isolated for protein and mRNA analysis and immunohistochemistry.

Results: Hemoglobin levels were significantly reduced after 4 weeks of CKD (14.3 ± 0.2 versus 11.7 ± 0.4 g/dL, p<0.0001). Serum iron and transferrin levels were unchanged. There was a significant decrease in weight gain and longitudinal growth in CKD rats compared to C. Remnant kidney EPO and EPOR protein levels were unchanged. Bone marrow aspirate EPO was also unchanged but EPOR was decreased in CKD. EGP EPO protein levels were unchanged while EPOR levels were significantly reduced in CKD. Immunohistochemicalstaining of the EGP showed decreased EPOR levels in CKD rats in the EGP chondrocytes. IV injection of erythropoietin-alpha (25 U/kg) 5 min prior to sacrifice induced a significant increase in EGP phsopho-STAT5 levels in both C and CKD.

Conclusions: Anemia in rats with early CKD is associated with normal EPO levels in the remnant kidney. However given the loss of kidney tissue in this model, it is likely that total renal EPO production is reduced, thus contributing to the anemia of CKD. Of note bone marrow and EGP EPOR levels were significantly reduced in CKD and this may well be a cause of uremic EPO resistance. Whether downstream defects in EPO signal transduction also exist requires further investigation.

TH-PO618

Geographic Variation in Fracture Incidence in U.S. Patients Receiving Hemodialysis James B. Wetmore,[1] Jiannong Liu,[1] Heidi S. Wirtz,[2] Thy P. Do,[2] David T. Gilbertson,[1] Brian D. Bradbury,[2] Allan J. Collins.[1] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]Center for Observational Research, Amgen, Inc., Thousand Oaks, CA.*

Background: Fracture burden is high in patients on hemodialysis, but whether fracture incidence varies geographically is unknown.

Methods: The United States Renal Data System ESRD database was used to study all U.S. prevalent adult patients receiving hemodialysis from 2007-10, with Medicare as primary payer for ≥ 1 yr. Patients were followed from January 1, 2007, or January 1 of the first calendar year to the earliest date of death, transplant, modality switch, or loss of Medicare coverage. Fractures were identified using ICD-9-CM diagnosis codes and HCPCS procedure codes from inpatient and physician claims. Fractures of the pelvis/hip, femur, lower leg, rib/sternum, shoulder/upper arm, and forearm/wrist were studied. Geographic region was defined by ESRD network. Poisson models were used to calculate rate ratios (RRs), unadjusted and adjusted between each network and the national rate. Adjustment factors were age, race, sex, primary ESRD cause, body mass index, dialysis vintage, and numerous comorbid conditions. Variation of RRs was used to illustrate the disparity in fracture rates among networks.

Results: The national fracture rate was 6.11 per 100 patient-years. Unadjusted RRs (Figure 1, left panel) varied from a low of 0.78 (network 6) to a high of 1.30 (network 1). The variation in RRs across networks did not change materially after adjustment for patient characteristics (Figure 1, right panel), varying roughly 1.5-fold across regions.

Conclusions: Fracture rates among patients on hemodialysis vary substantially by geographic region and are not explained by case mix, suggesting a potential etiologic role for regional differences in the management of chronic kidney disease-mineral and bone disorder.

TH-PO619

Predictors of Hip Fracture in Incident Hemodialysis Patients: Results from the MONDO Consortium Fellype C. Barreto,[1] Viviane Calice-Silva,[1,2] Aileen Grassmann,[3] Bernard J. Canaud,[3] Daniele Marcelli,[3] Peter Kotanko,[2] Len A. Usvyat,[2,3] Roberto Pecoits-Filho.[1] *[1]Pontificia Univ Catolica do Parana, Curitiba, Brazil; [2]Renal Research Inst, New York; [3]Fresenius Medical Care North America.*

Background: Hip fracture (HipF) is a hazardous condition associated with reduced survival in chronic kidney disease patients. HipF predictors are not well established in this population. Our aim was to evaluate the predictors of HipF in incident hemodialysis (HD) patients in MONDO database.

Methods: This analysis included incident HD patients from the MONDO database with in-center treatments between 1/2006 and 12/2012 who survived at least six months. Clinical and laboratory parameters were ascertained for the first 6 months (baseline). HipF were recorded in months 7 to 18 (follow-up). HipF were ascertained by ICD-9, indicating cervical, intertrochantecric, or subtrocanchanteric fractures. Poisson regression models were constructed to explore associations between baseline parameters and the number of HipF during the follow-up.

Results: We studied 18,955 patients (59% male, age 64±15 yrs, diabetics 37%). Baseline levels of calcium (Ca), phosphate (P) and iPTH were 8.8±0.6 mg/dl, 4.8±1.1 md/dl, 334±286 pg/ml, respectively.47 HipF were registered during follow-up. Results of Poisson analysis are shown in table 1. Table 1: Predictors of hip fractures in incident HD patients (significant in bold).

	Estimate	Wald 95% CI	P
Age	**0.067**	**0.027 – 0.106**	**0.001**
Gender (Male)	-0.250	-1.130 – 0.629	0.57
BMI	-0.051	- 0.146 – 0.042	0.28
Catheter	**0.996**	**0.166 – 1.826**	**0.02**
Daibetes	0.550	-0.315 - 1.415	0.21
PreSBP > 140 mmHg	**-1.059**	**-1.969 - -0.149**	**0.02**
IDWG	**0.611**	**0.223 - 0.998**	**0.002**
Ca - KDOQI target	0.655	-0.350 - 1.661	0.20
P - KDOQI target	0.290	-0.638 - 1.219	0.54
iPTH - KDOQ target	-0.300	-1.159 - 0.559	0.49
iPTH standard deviation	**-0.008**	**-0.014 - -0.001**	**0.01**

Conclusions: Since HipF are in most cases the consequence of falls, it is conceivable that higher blood pressure (SBP > 140 mmHg), lower IDWG and younger age are associated with a lower risk. The associations with IDWG and iPTH variability (expressed as SD), but not Ca, P and PTH within target, are novel and call for further studies.

TH-PO620

Prognostic Significance of the Presence of Vertebral Fractures in the Survival of Chronic Kidney Disease Patients Stages 3-5 Not on Dialysis Jose L. Gorriz,[1] Jaume Pomes-Tallo,[2] Cristina Castro,[1] Montserrat del Amo,[2] Ana Isabel Garcia,[2] Pablo Molina,[1] Belen Vizcaino,[1] Marco Montomoli,[1] Daniel A. Molina,[1] Secundino Cigarran,[1] Javier Nieto,[1] Sophie Jamal,[3] Luis M. Pallardo.[1] *[1]On Behalf of the Investigators of OSERCE II Study, Spain; [2]Musculoskeletal Radiology Dep. Hospital Clinic Barcelona; [3]Univ of Toronto, Women's College Hospital.*

Background: There are little data concerning the prevalence of vertebral fractures (VF), risk factors for fracture and relationship between fractures and mortality in chronic kidney disease (CKD) patients. To address this knowledge gap we conducted a "post hoc" analysis using data from the OSERCE II study (a 3-year follow-up prospective multicenter study which included 742 CKD patients stages 3-5 not on dialysis from 39 centres in Spain).

Methods: The OSERCE II study enrolled 742 subjects. Of these 612 had thoracolumbar xrays available for review. Xrays were reviewed by 3 musculoskeletal radiologists and VF identified using Genant semi-quantitavie morphometry. Mean age: 66±12 years, about 1/3 were female, and 1/3 had diabetes. The mean eGFR by MDRD was 27±12 ml/min/1,73m^2).

Results: VF were identified in 110 (18%) subjects. Factors associated with VF were phosphoremia (OR 0.719, P = 0.032, Ankle Brachial Index<0.9 (OR 1.694,P = 0.029) and treatment with biphosphonates (OR 5.636, p = 0.002). Over the 3-year follow-up, 62 subjects(10%) died. The most common causes of mortality were cardiovascular (n = 21, 34%). In the crude analysis, the group of VF patients had poorer survival (p=0.02). Multivariate analysis, (adjusting for age, MDRD, albumin, DM, comorbidity, Adragao Score> 3 and phosphorus), showed age (HR 1.074, 95%, p <0.001), phosphoremia (HR 1.699, 95%, p = 0.005), presence of VF (HR 1.983, P = 0.047) and vascular calcification by Adragao Score> 3 (HR 2.487, P = 0.004) as independent predictors of mortality.

Conclusions: About 20% of subjects in our study had VF. Factors associated with VF were age, low levels of phosphorus and peripheral vascular disease. The presence of VF is an independent risk factor for mortality in patients with CKD stages 3-5 not on dialysis. Clinical trials are needed to confirm whether this relationship is causal and reversible.

TH-PO621

Post-Transplant Bone Disease: A Prospective Bone Biopsy Study Catarina Carvalho, Juliana Magalhães, Luciano Pereira, Liliana Simoes-Silva, Inês Castro Ferreira, Joao M. Frazao. *Nephrology and Infectiology Research and Development Group, INEB, School of Medicine, Porto Univ, Porto, Portugal.*

Background: Post-transplant bone disease results from a combination of factors, which include previous bone and mineral metabolism disturbances, and effects from transplant-related medications. Bone biopsy (BB) remains the gold-standard diagnostic tool.

Methods: 6 patients (5M/1F, age 52.5±9.7, on RRT for 56.5±10.2 months) were prospectively studied after renal transplantation (RT). Dual-X-ray absorptiometry (DXA) and trans-iliac BB after double tetracycline labeling were performed at baseline (BL) in the first 2 months after RT and after 2 yrs of follow-up (1 pt after 5 yrs). We used Paired t-tests and Pearson correlation in statistical analysis.

Results: Comparing to BL biopsy, 2nd biopsy revealed a significant decrease in Ob.S/BS (0.65±0.47 to 0.06±0.13%, p=0.035), ES/BS (3.72±2.21 to 1.87±1.10%, p=0.025), Oc.S/BS (0.63±0.34 to 0.40±0.62%, p=0.035), N.Ob/BS (0.46±0.29 to 0.07±0.18/mm^2, p=0.043). Although a decrease in BV/TV did not reach significance, a significant decrease in TbN (2.29±0.42 to 1.68±0.46/mm, p=0.008) and increase in TbSp (390.53±95.84 to 530.87±163.37µm, p=0.029) in the 2nd biopsy suggest loss in bone quantity. We also did not find significant differences between OV/BV, OS/BS and Oth. All BB demonstrated a marked reduction in BFR, and so no difference was seen between the 1st and 2nd. At T0 3/6 patients had PTHi>300pg. The scarce tetra labeling in the 1st BB was probably a result of high dose corticosteroids in the first weeks after RT, which can lead to miss-interpreted results. Mlt was 4 times higher in the 2nd BB, although not significant, possibly due to small number of patients. At BL, DXA lombar parameters strongly correlated with OV/BV (DMO r=0.822, p<0.05; T score r=0.853, p<0.05; Z score r=0.942, p<0.01). At follow-up BB, this correlation is lost, possibly due to effects of transplant medications on bone density. We found no correlation with femoral site.

Conclusions: The results observed in this population show a reduction in bone activity, namely at cellular level, suggesting increased risk of adynamic bone and loss of bone volume.

TH-PO622

Bisphosphonates and Risk of Fractures after Renal Transplantation: A Unicenter Retrospective Study Ioan-Andrei Iliuta, Sacha A. De Serres, Isabelle Houde, Mohsen Agharazii, Fabrice Mac-Way. *Nephrology, L'Hôtel-Dieu de Québec Hospital, Quebec, QC, Canada.*

Background: Renal transplanted patients have higher risk of fractures, mainly related to the rapid loss of bone mass after transplantation. Bisphosphonates (Bps) have been shown to reduce the bone mass loss and are commonly used to prevent bone fractures. However, it is still unknown whether the use of Bps is associated with reduced fracture risk or not in this population. In this context, the objective of this study was to evaluate the effect of oral Bps on fractures in a population of renal graft recipients.

Methods: A retrospective and comparative study between renal transplant recipients treated with Bps (2001 to 2013) versus no Bps (1987 to 1999) was conducted on patients transplanted at l'Hôtel-Dieu de Québec hospital (Quebec, Canada). Since 2001, all patients in our center are put on Bps at the time of transplantation. The study length time was restricted to 12 years to have comparable exposition time from transplantation between groups. The patient records were reviewed for biochemical, demographic data and comorbidities and the occurrence of fractures was analyzed from time of transplantation to first fracture. Adjusted multivariate regression analysis for predetermined covariables and a propensity score analysis were performed.

Results: 472 patients with mean age of 47±14 (Bps) and 40±12 (no Bps) were included. There were 57 fractures in the Bps group (36.3 %) versus 157 fractures (49.8%) in the no Bps group (p=0.005). When adjusted for age, sex, weight, cause of renal failure, dialysis vintage, presence of diabetes, donor characteristics and previous dialysis modality, the use of Bps was not associated with a reduced risk of fractures. Only female gender and a marginal donor were positively associated with fractures after adjusted multivariate analysis. Propensity score analysis by matching, stratification by quintiles and logistic regression confirmed that Bps use was not associated with reduced fracture risk.

Conclusions: The use of Bps seems not to be associated with reduced risk of first fractures in renal transplanted patients. This is however a retrospective study and does not preclude the need to perform randomized controlled trials.

TH-PO623

Pregnancy Outcomes in Women with Primary Glomerular-Based Disease: A Systematic Review Ayodele Odutayo, Arti Bhasin, Michelle A. Hladunewich. *Nephrology, Sunnybrook Health Sciences Centre, Univ of Toronto, Toronto, ON, Canada.*

Background: Patients with glomerular-based kidney disease are at increased maternal and fetal risk during pregnancy. Divergent opinions exist regarding prognostication of pregnancy risk and individual studies are often small and incompletely reported. We conducted a systematic review to evaluate the quality of reporting of baseline characteristics and to assess disease-specific variations in pregnancy outcomes.

Methods: We searched MEDLINE and EMBASE with no limits on the search strategy. We included studies with at least 5 patients that provided a biopsy-based diagnosis of any of four disease – IgA Nephropathy (IgA), Focal Segmental Glomerulosclerosis (FSGS), Minimal Change Disease (MCD) and Membranoproliferative Glomerulonephritis (MPGN) – and reported on the number of live births in the given disease category. Review of abstracts,

full text articles and extraction of data were performed in single (AO), with a review of 25% of full text articles by a second reviewer (MH). Four baseline characteristics were assessed for frequency of reporting: age, blood pressure, creatinine and proteinuria. The frequency of live births in disease categories was compared with a chi-squared test.

Results: 1272 abstracts were reviewed, 133 full texts were identified and 15 primary reports met the inclusion criteria. The median year in which articles were published was 1989 (inter-quartile range: 1986-1996). Thirteen articles reported on IgA (672 women) whereas only 4 (55), 3 (29) and 5 (170) articles reported on FSGS, MCD and MPGN respectively. For all baseline characteristics, frequency of reporting was poor across disease categories: average age (0%-31% of articles in a disease category), blood pressure (0-39%), creatinine (0-46%) and proteinuria (0-31%). The proportion of live births varied by disease category ($p<0.001$): IgA (99%), FSGS (71%), MCD (74%) and MPGN (84%).

Conclusions: Pregnancy outcomes vary significantly by the type of glomerular-based disease. However, the current literature if out of date and reporting of baseline characteristics is poor. More contemporary and completely reported studies are required to facilitate prognostication of pregnancy-associated risk.

TH-PO624

Pediatric Chronic Kidney Disease (CKD) Treatment Burden and Quality of Life in the CKiD Cohort Maria E. Ferris,[1] Susan L. Furth,[2] Bradley A. Warady,[3] Kelly C. McDermott,[4] Stephen R. Hooper.[1] *[1]Nephrology, Univ of North Carolina, Chapel Hill, NC; [2]Pediatric Nephrology, Childrens Hospital of Philadelphia, Philadelphia, PA; [3]Pediatric Nephrology, Univ of Kansas, Kansas City, MO; [4]Epidemiology, Johns Hopkins, Baltimore, MD.*

Background: The relationship of CKD treatment burden and quality of life has not been characterized.

Methods: In a cross-sectional study, we determined treatment burden and its relationship to health-related quality of life in the CKiD cohort at study initiation. Frequency and administration route of CKD- and non-CKD-related medications were correlated with disease severity based on glomerular filtration rate. Linear regression was used to determine the relationship between treatment burden, adjusted for other covariates, and overall health-related quality of life (PedsQL™) scores, as reported by participants and their parents.

Results: In 699 patients ages 8-19 years, 504 (72%) had child and parent proxy PedsQL™ scores. The sex distribution was similar in all CKD stage with ≥ 56% males. In the CKD 4 group there was significantly more short stature and anemia. The number of CKD related medications increased as GFR decreased ($p< 0.001$). Likewise, the proportions of children on at least one CKD related oral ($p= 0.003$) and at least one CKD related injectable ($p< 0.001$) increased as GFR decreased. Tube feeding was more common among children with lower GFR ($p= 0.027$), and total weekly instances of medication use increased as GFR decreased ($p< 0.001$). As the number of CKD related medications increased, median overall parent proxy QOL scores decreased from 83 (interquartile range (IQR): 70 to 89) for children on zero CKD related medications to 75 (IQR: 59 to 88) for children on ≥ 5 CKD related medications. Overall child QOL scores did not differ by CKD related oral medication use. We observed no differences in parent proxy or child overall QOL scores by CKD related injectables. Comorbidities such as depression, hypertension, ADHD and/or learning disabilities were similar across all CKD Stages.

Conclusions: The number of CKD-related oral/injectable medications, feeding tube nutrition and treatments were directly associated with disease stage.

TH-PO625

The Association of Kidney and Brain Disease in the Elderly Katherine H. Michener,[1] Lenore J. Launer,[2] Farzad Noubary,[1] Gary F. Mitchell,[3] Hrefna Gudmundsdottir,[4] Olafur S. Indridason,[4] Vilmundur Gudnason,[5,6] Mark J. Sarnak,[1] Lesley Inker.[1] *[1]Tufts Medical Center, Boston, MA; [2]The National Inst on Aging, Bethesda, MD; [3]Cardiovascular Engineering, Inc., Norwood, MA; [4]Landspitali- The National Univ Hospital of Iceland, Reykjavik; [5]Univ of Iceland, Reykjavik; [6]Icelandic Heart Association, Kopavogur.*

Background: Due to similarities in the high flow nature of the vasculature of the kidney and brain, we hypothesized that lower kidney function may be associated with brain pathology by MRI and cognitive impairment.

Methods: We utilized data from 804 participants from the Age, Gene/Environment, Susceptibility-Reykjavik Study, a community-based prospective cohort study of cardiovascular disease (CVD) in Iceland. MRI was performed to measure segmental brain matter and white matter hyperintensity (WMH) volumes as well as presence of subcortical, cortical and cerebellar infarcts. Associations of estimated glomerular filtration rate based on creatinine and cystatin C (eGFR) and urine albumin-creatinine ratio (ACR) with these MRI findings as well as cognitive scores on executive function, memory and speed were assessed using linear or logistic regression, adjusting for demographics and standard CVD risk factors.

Results: Mean age was 76 years, mean (SD) eGFR was 69 (15) ml/min/1.73m^2, and median (IQR) ACR was 3 (2-6) mg/g. In adjusted analyses, higher ACR was significantly associated with lower volumes of total brain parenchyma, white and gray matter, and increased WMH. Lower eGFR was only significantly associated with lower white matter and total brain parenchyma volume. ACR and eGFR were not significantly associated with infarcts or cognitive scores.

Relationship of kidney measures and brain structure

	eGFR	ACR
Total brain parenchyma	**0.34 (0.10, 0.59)**	**-0.36 (-0.60, -0.12)**
Gray matter	0.18 (-0.03, 0.38)	**-0.34 (-0.54, -0.14)**
White matter	**0.17 (0.04, 0.30)**	**-0.18 (-0.31, -0.06)**
WMH	0.02 (-0.04, 0.09)	**0.10 (0.04, 0.16)**

Results are % intracranial volume (95% CI) per SD higher eGFR or ln ACR, adjusted for sex, age, MAP, HDL, HbA1c and CRP.
Bold results are statistically significant.

Conclusions: Higher ACR and lower eGFR were associated with smaller brain parenchymal volume but not infarcts or cognition. Higher ACR was associated with greater WMH volume. Further studies are needed to explore disease mechanisms.

Depression in Late Stage Kidney Disease Rimda Wanchoo, Azzour Hazzan, Vipulbhai Sakhiya, Candice Halinski, Anna Mathew, Steven Fishbane. *Nephrology, Hoffstra NSLIJ School of Medicine, Great Neck, NY.*

Background: Patients with CKD experience a high symptom burden with a sub optimal quality of life. The overall prevalence of depression in CKD is varied depending on the stage of kidney disease as well as the diagnostic tool used for identifying it. Prevalence of depression based on patient or clinician administered questionnaire is suggested to be approximately 26 % and is associated with increased hospitalization and mortality. Because psychosocial stressors are likely to be increased in late stage CKD, we studied depression in these patients.

Methods: A cohort of 203 patients with stage 4 or 5 CKD were evaluated for depression using the PHQ-9 (patient health questionnaire) at their first clinic visit. The PHQ-9 is a validated questionnaire that is interpreted based on overall score. Minimal, mild, moderate and severe were defined by total scores of (1-4), (5-9), (10-19) and (20-27) respectively. Patients were divided into two groups based on PHQ-9 score. One group comprised of patients that had none or minimal depression (score 0-4) while the second group comprised of the mild, moderate or severe depression (score >5). Mean age and eGFR were compared between the two groups using a Student's t-test. Proportion of diabetes and congestive heart failure was compared between the two groups using Fishers Exact test.

Results: There were a total of 203 patients, 53 (26%) of which had mild or moderate to severe depression. There was no significant difference among the two groups in the mean age and the presence of diabetes. The mean estimated GFR was 22 ml/min in the group with none or minimal depression and was 16.8 ml/min in the mild/moderate/severe group ($p=0.0001$). Patients with mild, moderate or severe depression were more likely to have congestive heart failure (26% versus 15%) as compared to the group with none or minimal depression; ($p=0.05$).

Conclusions: Our study demonstrates that depression is common in late stage CKD. Lower eGFR and congestive heart failure are correlated with a higher prevalence of depression. Since depression is associated with increased mortality and hospitalization, clinicians should be vigilant in screening for symptoms in this patient population to initiate treatment.

TH-PO627

Patient-Reported Symptoms in Chronic Kidney Disease Stephanie Amy Brown,[1] Amy L. Clarke,[1] Balraj Singh Jagdev,[2] Laetitia H. Lloyd-Davies,[1] Katherine Leigh Hull,[1] Andrew G. Stein,[2] James O. Burton,[1] Carolyn Tarrant,[3] Alice C. Smith.[1] *[1]Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom; [2]Univ Hospitals of Coventry and Warwickshire, United Kingdom; [3]Dept of Health Sciences, Univ of Leicester, United Kingdom.*

Background: Chronic Kidney Disease (CKD) is associated with a range of biochemical abnormalities, precipitates a pro-inflammatory state, and patients experience debilitating symptomatology and reduced quality of life. HMG-CoA reductase inhibitors (statins) are increasingly used for lipid management in these patients. This study aimed to explore the patient-reported symptom experiences in CKD patients not on dialysis, and relationships with biochemical parameters including inflammation, and statin treatment.

Methods: 179 patients completed a symptom questionnaire in which 11 common renal symptoms are rated for frequency and intrusiveness on a scale of 0-8. Additional information was extracted from clinical records (102 male; median age 61 [range 21-93 years]; median eGFR 27ml/min/1.73m^2 [range 5-90]). 92 patients (51%) were receiving statins.

Results: Patients reported a median of 6 symptoms. The most common symptoms were "excessive tiredness" (76.5%), "sleep disturbance" (65.9%) and "pain in bones/joints" (62.6%). The number of symptoms reported correlated with C-Reactive Protein (CRP) levels (rho=.255, p=.029), and patient-rated symptom frequency and intrusiveness both also positively correlated with CRP (rho=.324 and .322, respectively with p=.005). No other biochemical marker was found to relate to the frequency and intrusiveness of the reported symptoms. Statin use was associated with significantly higher muscle symptom scores (median symptom score 3 (IQR 0-6) versus 1 (IQR 0-3.5), $p<0.05$), even after correction for age and eGFR.

Conclusions: Although no direct relationship was found between declining renal function and symptom burden, inflammation in CKD patients appears related to patient symptom experience. Statin use may contribute to muscular symptoms and may require greater consideration when prescribing to minimise patient symptom burden.

Funding: Private Foundation Support

TH-PO628

Association of Fronto-Temporal Gray Matter Volume with Executive Function in Patients with Non-Dialysis Dependent Chronic Kidney Disease
Kazuhiko Tsuruya,[1,2] Hisako Yoshida,[1] Takanari Kitazono.[2] *[1]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: It is well known that cognitive impairment (CI) in patients with chronic kidney disease (CKD) is characterized by executive dysfunction rather than memory dysfunction, although the precise mechanism remains to be elucidated. The purpose of the present study is to examine the association of gray matter volume (GMV) with executive function in CKD patients.

Methods: Ninety-five patients with non-dialysis dependent CKD (NDD-CKD) without overt CI and history of cerebrovascular disease were recruited. The subjects underwent brain MRI and cognitive test of mini mental state examination (MMSE), trail making test part A (TMT-A) and part B (TMT-B). The segmentation algorithm from Statistical Parametric Mapping 8 software was applied to every T1-weighted MRI scan to extract tissue maps corresponding to gray matter, white matter, and cerebrospinal fluid. To normalize for head size variability, GMV ratio (GMR) was calculated as a ratio of GMV to the total intracranial volume, calculated by adding GMV, WMV, and CSFV. Then, GMR was divided into four categories of the brain lobes; frontal lobe (Fr-GMR), parietal lobe (Par-GMR), temporal lobe (Tem-GMR), and occipital lobe (Occ-GMR). We assessed the association of GMR with the scores of these cognitive tests using multivariable regression analysis.

Results: GMR significantly positively associated with the score of MMSE and significantly negatively associated with the scores of TMT-A, TMT-B, and ΔTMT (TMT-B minus TMT-A). These associations were remained significant even after adjustment for the relevant confounding factors. Fr- and Tem-GMR, but not Par- and Occ-GMR, were significantly negatively associated with the scores of TMT-A, TMT-B, and ΔTMT in the multivariable regression analysis.

Conclusions: The present study demonstrates the association of GMR, especially frontal and temporal gray matter, with executive function, suggesting that fronto-temporal brain atrophy might contribute to executive dysfunction in NDD-CKD.

TH-PO629

The Link Between eGFR and Neuropsychological Functioning Among Mexican-Americans
Harold M. Szerlip, Sid O'bryant. *Internal Medicine, Univ of North Texas Health Sciences Center, Fort Worth, TX.*

Background: Although CKD has been linked to cognitive dysfunction, little research has examined the CKD-cognition link among Mexican-Americans. Because prior studies suggest that "established" risk factors for cognitive dysfunction do not apply to Mexican-Americans (hypertension, dyslipidemia, APOE4 genotype), there is a need to understand factors related to cognitive decline among this underserved group. The current study examines the link between eGFR and risk of mild cognitive impairment among Mexican-Americans.

Methods: Data were examined from the Health and Aging Brain among Latino Elders study. The cohort consists of over 500 Mexican-Americans, 377 (292 women, 85 men) whom had calculated eGFR. Each participant underwent an interview, physical, neuropsychological testing and blood draw. The link between eGFR and neuropsychological outcomes was assessed. eGFR categories were broken down as follows: <45 (n=11), 45-59 (n=19) and >=60 (n=347).

Results: In the unadjusted models, lower eGFR was associated with significantly poorer performance in the domains of global cognition, memory, executive functioning, processing speed, visuospatial skills, and language. In the adjusted models, the <45 group performed significantly worse than the 45-59 and >=60 groups in the following domains: memory (WMS-III Logical Memory 1, F=3.4, p=0.03), processing speed (Trail Making Test part A, F=13.5, p<0.001), executive functioning (CLOX1, F=5.8, p=0.003), visuospatial skills (CLOX2, F=16.6, p<0.001) and global cognitive functioning (MMSE, F=7.0, p=0.001). In logistic regression model, eGFR<60 was associated with significant increased risk for MCI among Mexican Americans (OR=2.9, 95% CI= 1.003-8.7, p=0.04).

Conclusions: In Mexican-American adults, eGFR < 60 was associated with significantly poorer neuropsychological functioning. Those with eGFR <45 performed more poorly than all others on cognitive tests of memory, executive functioning, processing speed, visuospatial skills and global cognition. eGFR <60 was also associated with increased risk for MCI diagnosis. Early detection of CKD is important in order to prevent MCI risk. Further research is needed to evaluate other biomarkers to delay cognitive decline.

A Computerized Neurocognitive Battery Reveals Deficits in Executive Control and Complex Cognition in Children and Young Adults with Chronic Kidney Disease
Erum A. Hartung,[1,2] Ji Young Kim,[1] Nina Laney,[1] Stephen R. Hooper,[3] Jerilynn Radcliffe,[1,2] Allison M. Mott,[2] Ruben C. Gur,[2] Susan L. Furth.[1,2] *[1]Children's Hospital of Philadelphia; [2]Univ of Pennsylvania; [3]Univ of North Carolina.*

Background: Neurocognitive (NC) deficits in chronic kidney disease (CKD) patients are well documented, but traditional tests are time-consuming. The 1-hour Penn Computerized NC Battery (CNB) offers a more efficient assessment method; this is the first systematic study of the CNB in youth with CKD.

Methods: The CNB was administered to subjects aged 8-25 yrs with Stage 2-5 CKD, and age-matched healthy controls. We analyzed CNB results from 12 tests in 4 domains: executive control, episodic memory, complex cognition, and social cognition. All tests measure correct responses (CR) and response time (RT). Raw CR and RT results were converted to age-specific z-scores based on norms from the Philadelphia Neurodevelopmental Cohort (n=1790). Each test was analyzed in a linear regression with CR z-score as the dependent variable and CKD versus control as the explanatory variable, adjusted for RT ($z \geq 0$, $z<0$), race, sex, and maternal education.

Results: 74 CKD subjects [mean(SD) eGFR 49(24) mL/min/1.73m^2, age 16.0(4.0) yrs] and 48 controls [mean(SD) eGFR 100(20) mL/min/1.73m^2, age 15.5(4.1) yrs] were studied. CKD subjects had significant deficits versus controls in executive control (attention) and complex cognition (verbal and non-verbal reasoning, and spatial processing). CKD versus control was not associated with performance differences in episodic memory or social cognition.

Domain	Test	Control vs. CKD diff. in CR z-score*	p
Executive Control	Attention	0.43	0.03
Complex Cognition	Verbal reasoning	0.69	<0.001
	Non-verbal reasoning	0.39	<0.01
	Spatial processing	0.66	<0.01

*adj. for RT ($z \geq 0$, $z<0$), race, sex, & maternal education

Conclusions: In youth with CKD, the Penn CNB shows deficits in executive control and complex cognition, with moderate effect sizes. These results are consistent with traditional NC testing in previous studies and in this cohort. The CNB's 1-hour administration time may facilitate NC assessment of CKD patients. Future analyses will include correlating CNB results with structural/functional brain imaging.

Funding: Other U.S. Government Support

Prevalence and Severity of Sleep Apnea in Different Stages of Chronic Kidney Disease
Gary Chan,[1] Sydney C.W. Tang.[2] *[1]Medicine, Queen Mary Hospital, Hong Kong; [2]Medicine, The Univ of Hong Kong, Hong Kong.*

Background: The prevalence and severity of sleep apnea in the non-dialysis chronic kidney disease (CKD) population have not been well characterized. A handful of studies performed to date have yielded highly variable prevalence rates due to cohort heterogeneity and inter-study inconsistencies in sleep apnea definition. This study sought to determine the association of sleep apnea with non-dialysis CKD by recruiting a uniform cohort to undertake overnight polysomnography (PSG).

Methods: 141 male Chinese CKD patients, aged 40 to 60 years old, were recruited to undergo overnight PSG. Height, weight, neck girth, estimated glomerular filtration rate, spot urinary protein excretion and Epworth sleepiness scale (ESS) score were collected at baseline. The prevalence and severity of both sleep apnea and associated nocturnal hypoxemia (NH) were determined across the full spectrum of non-dialysis CKD.

Results: The prevalence of sleep apnea (apnea-hypopnea index [AHI] ≥ 15) and NH (Sleep Heart Health Study arbitrary definition) was 35.5% and 10.6% respectively in this study population, which had a mean (± SD) age and BMI of 51.44 ± 6.05 y and 26.05 ± 4.22 kg/m^2. The adjusted odds ratio (OR) for sleep apnea by body mass index (BMI) and proteinuria were 1.18 (95% confidence interval [CI] 1.02 - 1.37; P ≤ 0.05) and 2.60 (95% CI 2.56 - 2.61; P ≤ 0.05) respectively. The adjusted OR for median cohort oxygen desaturation index (ODI) by BMI and proteinuria were 1.23 (95% CI 1.05 - 1.45; P ≤ 0.05) and 2.60 (95% 2.56 - 2.61; P ≤ 0.05). However, no significant correlation between prevalence and severity of sleep apnea and NH with progressive renal deterioration was observed. Furthermore, an ESS score above 10 showed no significant mean difference in AHI and ODI when compared to a score below 10.

Conclusions: Sleep apnea is prevalent in the Chinese non-dialysis CKD population and strongly correlated with BMI and proteinuria, but not renal function. The study results also indicate that ESS is an investigative tool that lacks discriminatory power in patients with renal insufficiency. This study supports the need to maintain high clinical vigilance for sleep apnea when attending to CKD patients with significant proteinuria.

TH-PO632

Prevalence of Chronic Kidney Disease in Patient with HIV in Ilorin, Nigeria
Ayokunle Samuel Dada,[1] Timothy Olusegun Olanrewaju,[2] Ademola Aderibigbe,[2] Akande O. Ajayi,[1] Chijioke Adindu.[2] *[1]Nephrology Unit, Dept of Medicine, Ekiti State Univ Teaching Hospital, Ado Ekiti, Ekiti, Nigeria; [2]Renal Care Centre, Univ of Ilorin Teaching Hospital, Ilorin, Kwara State, Nigeria.*

Background: HIV/AIDS is an important cause of renal diseases in sub-Saharan Africa. There is paucity of studies on the burden of chronic kidney disease among the HIV/AIDS patients in the North-Central zone of Nigeria.

Methods: A cross-sectional study of 227 newly-diagnosed, HAART-naïve patients with HIV/AIDS seen at the HIV clinic of the medical out-patient department of University of Ilorin Teaching Hospital (UITH). They were matched with 108 control group. Biochemical, heamatological and urinary tests were performed for all the participants. CKD was defined as eGFR ≤60 ml/min/1.73m^2 and albumin creatinine ratio ≥30mg/g.

Results: There were 100(44%) males among the patients and 47(43.5%) among the control group. The mean age of the patients and controls were 40.3 ± 10.3 years and 41.8 ± 9.5years respectively. CKD was observed in 108(47.6%) among the patients and 18(16.7%) of the controls p= 0.01. About half of the patients were in stage 1 CKD The median CD4 counts was significantly lower in patients with CKD (164.5{6-947} cell/µl) than patients

without CKD (247{8-1202} cell/µl) (p=0.01). Ninety-three (41.0%) of the patients had dipstick proteinuria of ≥2+. The median albumin creatinine ratio (ACR) was significantly higher among the HIV-positive patients (272.3mg/g) compared with the HIV-negative controls (27.22mg/g) p=0.01. The CD4+ count correlates positively with eGFR (r =0.463, p =0.001) and negatively with ACR (r = -0.806, p=0.001).

Conclusions: CKD is very common among patients with HIV/AIDS in Ilorin. Screening and early intervention for CKD should be part of protocols in the management of patients with HIV/AIDS.

TH-PO633

Patient Profiles in Calciphylaxis - Data From the German Calciphylaxis Registry Vincent Brandenburg,[1] Jürgen Floege,[2] Markus Ketteler.[3] *[1]Dept of Cardiology, Univ Hospital RWTH Aachen; [2]Dept of Nephrology, Univ Hospital RWTH Aachen; [3]Dept of Nephrology, Klinikum Coburg.*

Background: Calciphylaxis (CUA) is a rare disease and a clinical challenge. For patients, CUA is a devastating condition associated with high mortality. CUA is characterised by painful, ischemic, partly necrotic skin ulcerations. Pathomorphologically, media calcification of cutaneous arterioles and extracellular matrix remodelling are the hallmarks of CUA. Epidemiology and risk factors are incompletely understood.

Methods: We established an international internet-based registry in 2006 (www.calciphylaxie.de) to allow online notification for pts with established or suspected CUA. The registry includes a comprehensive data base with 71 parameters concerning patient and laboratory data, clinical background and presentation as well as therapeutic strategies. The diagnosis of CUA is made on clinical and/or histological grounds by the referring physician.

Results: Until May 2014 n=219 patients with CUA have been documented in 7.5 years: 62% females; 89% dialysis (HD and PD) patients, median age 66 (21-88) years. Stored serum samples were used for central laboratory analysis in core facility in n = 92 dialysis patients: PTH levels varied significantly between undetectably low and > 1100 pg/ml, mean 191 +/-176 pg/mL; fetuin-A: 0.21+/-0.01 g/L. Fetuin-A levels in control HD pts without CUA were significantly higher (n=65; 0.46+/-0.1 g/L, p < 0.01). Oral anticoagulation with Vit K antagonists was common in ESRD pts (53%) prior to CUA diagnosis. Cutaneous lesions were localized in 80% at the lower extremities or gluteal and abdominal region. Among the most frequently recorded therapeutic procedures were: surgical necrosectomy, intensifying dialysis modality, reduction of calcium supply, i.v. sodium-thiosulfat application. The median survival time was 516 days after online notification.

Conclusions: CUA is a rare disease among ESRD pts with increased mortality. Therapeutic strategies vary significantly among centers. The German CUA registry is a valuable tool to collect data and may become a basis for a European registry (EuCalNet, www.calciphylaxis.net) and for prospective controlled trials in the near future.

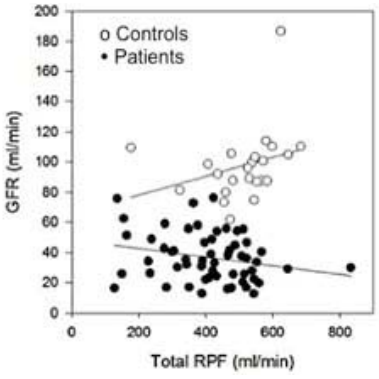
Renal Artery Blood Flow and Oxygenation in Chronic Kidney Disease Determined by Magnetic Resonance Imaging Dinah Sherzad Khatir,[1] Michael Pedersen,[2] Bente Jespersen,[1] Niels Henrik Buus.[3] *[1]Dept of Renal Medicine, Aarhus Univ Hospital, Aarhus N, Aarhus, Denmark; [2]Dept, Dept of Diagnostic Imaging, Aarhus N, Aarhus, Denmark; [3]Dept of Renal Medicine, Aalborg Univ Hospital, Aalborg, Denmark.*

Background: Animal studies suggest that progression of chronic kidney disease (CKD) is related to hypoxia of the renal tissue. Renal blood supply determines oxygen delivery and sodium absorption is the main contributor to oxygen consumption. We aim to describe the relationship between renal oxygenation and renal artery blood flow (RABF) and sodium absorption in patients with CKD and healthy controls.

Methods: 64 stable stage 3-4 CKD patients (61±13 years) were compared with 24 age and sex-matched controls. Glomerular filtration rate was determined by ^{51}Cr-EDTA clearance and sodium excretion was measured in a 24-hour urine collection. Hematocrit was measured to calculate renal plasma flow (RPF). RABF and renal tissue oxygenation was determined by magnetic resonance imaging using cine phase-contrast and blood oxygen level dependent (BOLD) measurements of deoxyhemoglobin relaxation time (R_2*) respectively.

Results: GFR in patients was 37% of controls (36±15 versus 97±23 ml/min/1.73 m^2, P<0.001) and the amount of reabsorbed sodium was 37% of controls (6.9 versus 18.8 mol/24 hours, P<0.001). Single-kidney RABF of patients was 72% of controls (319 versus 443 ml/min, P<0.001). Likewise, RPF was decreased in patients compared with controls (P< 0.05). Glomerular filtration fraction (FF) was 9% in patients and 18% in controls (P<0.001). Patients and controls had similar cortical R_2* (13.4 versus 13.3 s^{-1}, P=NS) and medullary R_2* (26.4 versus 26.5 s^{-1}, P=NS) values.



Conclusions: In CKD, GFR and reabsorbed sodium are reduced more than twice that of RABF while cortical and medullary oxygenation is within the range of healthy persons. Reduction in glomerular FF may prevent renal hypoxia in CKD.

TH-PO635

Effect of Oral Supplementation with Curcumin in Patients with Proteinuric Chronic Kidney Disease Jonathan Salazar,[1] Edilia Tapia,[1] Armando Vazquez-Rangel,[1] L. Gabriela Sanchez-Lozada,[1] Jose Pedraza-Chaverri,[2] Susana Gonzalez Reyes,[2] Susana Gonzalez Reyes,[2] Alejandra Elizabeth Álvarez-Mejía,[2] Sebastián Guerra-León,[2] Magdalena Madero.[1] *[1]National Heart Inst, Mexico; [2]UNAM.*

Background: Proteinuria is the most powerful risk factor for progression of CKD. Despite the use of RAAS blockade, a large percentage of proteinuric CKD patients progress to kidney failure. Curcumin has potent antioxidant and antiinflamatory effects and in animal models and small clinical trials has been associated with proteinuria reduction and attenuation of CKD progression. Our objective was to evaluate the effect of curcumin on proteinuria and kidney disease progression in a randomized trial.

Methods: The study was designed as a randomized double blinded clinical trial conducted at the National Heart Institute in Mexico. Patients were included if they were 18 years or older, had a prot/creat (P/C) > 1 gram in 24 hrs, and were on RAAS blockade. Four grams of curcuma versus placebo were given daily for 8 weeks. The primary outcome was change in proteinuria and secondary outcomes included change in blood pressure (BP) and eGFR.

Results: 99 patients were randomized. 11 patients did not have P/C >1 at baseline and were excluded while 10 participants were lost to follow up leaving 78 patients for the analysis. The median (IQR) age was 52 (34-59) years, 50% had diabetes, mean SBP and DBP were 126.7 mm Hg and 77.9 mmHg, respectively and median(IQR) eGFR and P/C were 28 (19-56) ml/min /1.73 m2 and 3.5 (2.2-6.6) g, respectively. Baseline characteristics were similar between groups except SBP which was higher in the curcumin group (p=0.002) and hemoglobin which has higher in the placebo arm (p=0.02). At the end of follow up the delta P/C change between groups was not significant (p=0.29) for the curcumin -0.04 IQR (-1.20- 1.07) and placebo -0.19 IQR (-2.18- 0.66) units. There was a trend towards less eGFR loss in the curcumin group -0.5 IQR (-2.8- 1.2) versus -2.0 IQR (-6.1- -0.1), p = 0.06. Change in BP was not different between groups (p=0.65).

Conclusions: Curcumin was not associated with proteinuria reduction but was associated with a trend towards less eGFR loss. Our results need to be confirmed in larger trials.

TH-PO636

Vascular Effects of Exercise Training in Chronic Kidney Disease: A Randomized Controlled Trial Amaryllis H. Van Craenenbroeck,[1,3,4] Emeline M. Van Craenenbroeck,[2,3] Katrijn Van Ackeren,[3] Jean-Louis Bosmans,[1,4] Vicky Y. Hoymans,[3] Christiaan J. Vrints,[2,3] Marie M. Couttenye.[1] *[1]Dept of Nephrology, Antwerp Univ Hospital, Belgium; [2]Dept of Cardiology, Antwerp Univ Hospital, Belgium; [3]Laboratory of Cellular and Molecular Cardiology, Antwerp Univ Hospital, Belgium; [4]Laboratory of Experimental Medicine and Pediatrics, Univ of Antwerp, Belgium.*

Background: Endothelial dysfunction is an independent marker of increased cardiovascular (CV) risk and contributes to decreased aerobic capacity in patients with CKD. The aim of this study is to investigate whether a formal ET programme corrects endothelial dysfunction in CKD. Secondary endpoints were aerobic capacity (VO_2peak), arterial stiffness (carotid-femoral pulse wave velocity, PWV) and intima-media thickness (IMT).

Methods: Forty CKD patients in stage 3-4 (age 53 ± 13 yrs, eGFR 38.5 ± 12.9 ml/min/1.73 m^2) without documented CV disease were randomized to home-based ET consisting of daily cycling sessions (4x10 minutes) at moderate intensity (n=19) or usual care (UC, n=21). Aerobic capacity (VO_2peak), circulatory power (VO_2peak × peak systolic BP), endothelial function (flow mediated dilation, FMD), PWV (Sphygmocor) and carotid IMT (high-resolution ultrasound) were measured baseline and at 12 weeks follow-up.

Results: Groups were age- and gender matched. After 12 weeks of ET, VO_2peak increased by 21% (26.6 ± 5.6 to 32.1 ± 6.9 ml/kg/min), whereas no change was observed in the UC group (p<0.001). Circulatory power increased significantly in the ET group (19.6%), but remained unchanged in UC (p<0.001). Whereas FMD was clearly impaired in CKD (ET 4.0 ± 1.9%, UC 5.2 ± 3.4%), no significant changes were observed after follow-up (p=0.7). In addition, PWV and IMT were not significantly altered after follow-up in the 2 groups (all p<0.05). In trained subjects, change in PWV was related to the change in systolic BP (Pearson r=0.603, p=0.01).

Conclusions: In CKD patients stage 3-4 without overt CV disease, 12 weeks of ET at moderate intensity improved VO_2peak, without altering peripheral endothelial function or arterial stiffness, suggesting that other mechanisms may be responsible for the training-induced benefits on aerobic capacity.

TH-PO637

Gadolinium Exposure Induced Systemic Inflammatory Response (GEISIR) Is due to Activation of the Calcium-Sensing Receptor

Hansjörg Martin Rothe,[1] Mariana Köster Cifuentes,[2] Vedat Schwenger,[3] Udo Bahner,[4] Markus Ketteler.[1] *[1]Div of Nephrology, Klinikum Coburg, Coburg, Bavaria, Germany; [2]Inst de Nutricion y Tecnologia de los Alimentos, Univ de Chile, Santiago de Chile, Chile; [3]Div of Nephrology, Univ of Heidelberg, Heidelberg, Rheinland -Pfalz, Germany; [4]Div of Nephrology, Univ of Würzburg, Würzburg, Bavaria, Germany.*

Background: Two clinical syndromes resulting from the administration of gadolinium (Gd)-containing MRI contrast agents to patients with advanced or end-stage kidney disease (ESKD) have been described: nephrogenic systemic fibrosis (NSF) and Gd exposure induced systemic inflammatory response (GEISIR). GEISIR is a peracute event in reaction to Gd-DTPA. We argue that activation of the calcium-sensing receptor (CaSR) by Gd ions causes GEISIR in ESKD patients.

Methods: cell culture – human macrophages, known to trigger early stages of NSF, were cultured and pro-inflammatory cytokines mRNA expression in response to Gd and other agents measured; clinical - 13 ESKD patients who received Gd-DTPA and subsequently developed either GEISIR or NSF were observed for up to 9 years.

Results: Cultured macrophages release Il-6, IL-1b, CCl2 and TNF-alpha in response to Gd, mRNA expression (normalized to vehicle-treated controls) increased by >50% after incubation with 5µM gd chloride for 72h. This response is enhanced by cinacalcet and attenuated by the calcilytic agent NPS, the NPS effect was significant for Il-6 and IL-1b ($p<0,05$ in Wilcoxon mathed pairs test) with a trend for CCl2 and TNF-alpha (p between 0,05 and 0,2). Two patients developed NSF, both had raised CRP levels but lacked the SIRS-like clinical features of GEISIR in the early phase. None of the 11 patients with GEISIR went on to develop NSF during the follow-up. ***Discussion:*** Our findings strongly suggest a causal involvement of the CaSR. GEISIR does not necessarily develop into NSF even after several years. A second event and/or genetic disposition may be required. This and the possible role of uremic toxins such as phenylacetic acid require more studies.

Conclusions: If our hypothesis were true, calcilytics could be beneficial to prevent adverse effects of Gd containing contrast agents in kidney disease patients.

TH-PO638

Sub Acute Kidney Injury (sAKI) Induced by Intravitreal AVASTIN Injection: Time for Concern

Ronit Geron,[1,3] Zvi Segal,[2] Galina Poliansky,[1] Batya Kristal.[1,3] *[1]Dept of Nephrology, Galilee Medical Center; [2]Dept of Ophthamology, Galilee Medical Center; [3]Faculty of Medicine in the Galilee, Bar Ilan Univ, Israel.*

Background: Systemic injection of AVASTIN (Bevacizumab), an anti Vascular Endothelial Growth Factor Ab, is associated with adverse renal events; hypertension and proteinuria. Intravitreal AVASTIN injections are currently used for ophthalmic indication such as age-related macular degeneration and diabetic retinopathy. The aim of this study was to investigate renal side effects of repeated low dose intravitreal Avastin.

Methods: 37 patients (70% diabetic, 81% hypertensive, 27% CKD (eGFR<60 ml/min)) received 3 injections of 1.25 mg/dose, once monthly. Blood and urine were drawn before each injection and one month (1m) following third injection for: Serum creatinine (Scr), eGFR and urine for ACR and PCR. sAKI was defined as Scr rise of > 0.3 mg% over 7-30 days after injection.

Results: Scr increased and GFR decreased each month after injection, as compared to baseline (Bsln).

Renal function changes	N	Mean± Std	p
Scr mg% Bsln	37	1.125 ± 0.74	0.003 *
1m post 1 inj		1.28 ± 1.00	
Scr mg% Bsln	31	1.16 ± 0.81	0.0015 *
1m post 2 inj		1.32 ± 1.00	
Scr mg% Bsln	26	1.19 ± 0.86	0.020 **
1m post 3 inj		1.35 ± 1.31	
GFR ml/min Bsln	37	70.46 ± 23.55	p<0.001 *
1m post 1 inj		65.03 ± 24.01	
GFR ml/min Bsln	37	70.99 ± 25.14	p<0.001 *
1m post 2 inj		64.43 ± 25.44	
GFR ml/min Bsln	26	71.44 ± 26.41	0.0255 *
1m post 3 inj		68.94 ± 26.91	

* Paired sample t-test

** Wilcoxon signed rank test

sAKI occurred in 18.5% (5/37) of patients 1 month after first injection, with Scr rise from 2.41 to 3.2 mg % (p=0.031) and eGFR decreased by mean of 33.50%. In diabetic patients with GFR<60 ml/min, sAKI occured in 33.3% (3/9) after 1 injection compared to 5.9% (1/17) in diabetic patients with GFR>60mll/min. No statistically significant changes were found in blood pressure, albuminuria and proteinuria.

Conclusions: sAKI can occur after a single low dose of intravitreal Avastin. Diabetic patients with GFR<60mll/min are at higher risk for sAKI. More trials are required to investigate long term renal effects of this therapy. Nephrologist follow up should be recommended.

TH-PO639

Acute Weight Change prior to Hospitalization in Late Stage Chronic Kidney Disease

Steven Fishbane, Louis R. Spiegel, Vipulbhai Sakhiya. *Dept of Medicine, Div of Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.*

Background: There is a high rate of hospitalizations in patients with late stage chronic kidney disease (LS-CKD). Because of reduced salt and water excretion and a high prevalence of left ventricular hypertrophy and congestive heart failure (CHF) in these patients there is a great vulnerability to acute volume changes. Accordingly, we studied the relationship between acute weight change and risk for hospitalizations in LS-CKD.

Methods: 203 patients with stage 4/5 CKD were studied for between 4-16 months. All patients used a telephonic informatics system for capture of daily weights. A significant change in weight was considered 1.7% of body weight in any two days compared to the mean of the 5 previous days. Hospitalization data was collected by monthly review and interview of patients and the reason for all hospitalizations was determined. Patients' weights for the 14 days prior to each hospitalization were analyzed. If less than 10 days of weights were available or if the weight on the day prior to hospitalization was missing then that hospitalization was excluded from analysis.

Results: There were a total of 189 hospitalizations occurring in 93 patients. 64 of the hospitalizations were excluded due to missing weight data, leaving 125 hospitalizations analyzed. The leading causes of hospitalization were cardiovascular 30.4%, infection 17.3%, gastrointestinal bleeding 10.0%, syncope 3.6%, CVA 2.2%. There was no significant relationship between weight change in either direction with all cause hospitalization. There was, however, significant weight gain prior to CHF/volume overload admissions in 64% of cases and CV admissions in 31.6% of cases ($p <0.05$ for both compared to all cause admissions). There was significant weight loss prior to syncope in 40% of cases ($p<0.05$).

Conclusions: Weight often acutely increases prior to CHF/volume overload and cardiovascular hospitalizations and declines prior to syncope admissions in late stage CKD patients. Because CHF/volume overload hospitalizations are frequent in this population, weight monitoring and intervention for weight gain might be beneficial.

Urine HBV DNA in the Diagnosis of Hepatitis B Virus-Associated Glomerulonephritis

Lifen Wang, Huaban Liang, Zhiming Ye, Bin Zhang, Lixia Xu, Zhonglin Feng, Shuangxin Liu, Wei Shi. *Dept of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Science, Guangzhou, Guangdong, China.*

Background: Serum hepatitis B virus (HBV) DNA is one of the diagnostic criteria for HBV-associated glomerulonephritis (HBV-GN). However, HBV DNA has been detectedin the urine of patients with HBV-GN, which may have implications for pathogenesis of this disease. This study was conducted to investigate whether urine HBV DNA could be a new diagnostic criterion for HBV-GN.

Methods: A total of 152 patients were enrolled in this study. The patients were divided into the following groups: HBV-GN (66 patients), non-HBV-GN (66 patients), and chronic hepatitis B (CHB) without renal disease (20 patients). Serum and urine HBV DNA levels were determined using polymerase chain reaction (PCR). Other serum HBV markers were detected using enzyme-linked immunosorbent assays.

Results: In the diagnosis of HBV-GN, urine HBV DNA had a high specificity (0.96), a good positive predictive value (PPV, 0.96), and a modest negative predictive value (NPV, 0.60). The combination of urine HBV DNA with serum HBV DNA, the hepatitis B surface antigen (HBsAg) or the hepatitis B e antigen (HBeAg) was inferior to urine HBV DNA in the diagnosis of HBV-GN.

Conclusions: Urine HBV DNA may be a new noninvasive diagnostic criterion for HBV-GN.

Funding: Government Support - Non-U.S.

Urine MMP-7 Is Associated with Mortality in People with Type 2 Diabetes and Kidney Disease

Maryam Afkarian,[1,2] Leila R. Zelnick,[1,2] Rajnish Mehrotra,[1,2] Jonathan Himmelfarb,[1,2] Ian H. de Boer.[1,2] *[1]Kidney Research Inst, Univ of Washington, Seattle, WA; [2]Dept of Medicine, Div of Nephrology, Seattle, WA.*

Background: The renin angiotensin system (RAS), bone morphogenetic protein (BMP) and WNT pathways are involved in pathogenesis of experimental diabetic kidney disease (DKD). Urine excretion of angiotensinogen, gremlin-1 and matrix metalloproteinase-7 (MMP-7), components of the RAS, BMP and WNT pathways, are markedly increased in people with diabetic kidney disease. It is not known whether this increase is associated with subsequent progression to end-stage renal disease (ESRD) or death.

Methods: We measured urine concentration of angiotensinogen, gremlin-1 and MMP-7 in baseline samples from a cohort with type 2 diabetes and kidney disease (n=141). Using time-to-event analyses, we examined the association between creatinine-adjusted urine concentration of these proteins and progression to ESRD or death.

Results: Among the cohort, 38 progressed to ESRD over a mean (standard deviation, SD) follow-up of 3.2 (1.9) years and 39 died over a mean (SD) follow-up of 3.7 (1.9) years. All three proteins were associated with ESRD and death after adjustment for age, sex, race/ethnicity, smoking, hemoglobin A1c, LDL and RAS inhibitor use. After additional adjustment for baseline glomerular filtration rate and albuminuria, only urine MMP-7/

Creatinine remained associated with death (Hazard ratio 3.59 for highest versus lowest tertile), but not ESRD. Serum MMP-7 was not associated with death and did not attenuate the association of urine MMP-7 with death in this cohort (HR 4.03 for highest versus lowest urine MMP-7/Cr tertile, after adjustment for serum MMP-7).

Conclusions: Among people with type 2 diabetes and kidney disease, urine MMP-7/Cr concentration was strongly associated with death, but not progression to ESRD, during a 3.7 year follow-up. Adjusting for serum MMP-7 did not attenuate this association.

Diagnostic Utility of Immunochemical Fecal Occult Blood Tests to Detect Lower Gastrointestinal Lesions in Patients with Chronic Kidney Disease

Hyeon Seok Hwang,[1] Se Young Kim,[1] Youn Mi Song,[2] Hye Eun Yoon,[3] Yoon-Kyung Chang,[1] Chul Woo Yang,[3] Suk Young Kim.[1] *[1]Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Daejeon, Korea; [2]Div of Gastroenterology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea; [3]Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

Background: The patients with chronic kidney disease (CKD) have an increased risk for gastrointestinal (GI) bleeding. However, the diagnostic utility of immunochemical fecal occult blood test (iFOBT) to detect bleeding-related lower GI lesions is undetermined in CKD patients.

Methods: We included a total 783 patients with nondialysis-dependent CKD stages 2–5 or receiving dialysis. The specific type of bleeding-related lower GI lesions was identified by colonoscopy, and the diagnostic utility of iFOBT was evaluated for these lesions.

Results: Bleeding-related lower GI lesions were found in 14.3% of 617 patients with CKD stage 2/3, 20.0% of 70 patients with CKD stage 4/5, and 32.3% of 96 patients receiving dialysis (P< 0.001). Compared to CKD 2/3 patients, dialysis patients had an independent risk for bleeding-related lower GI lesions (adjusted odds ratio, 2.25; P= 0.014). The iFOBT was positive in 125 (16.0%) patients, and the sensitivity of iFOBT for the detection of bleeding-related lower GI lesions was significantly increased as CKD stage worsened (29.5% versus 50.0% versus 58.1%; P = 0.012). However, the specificity of iFOBT was decreased with the severity of CKD stage (92.6% versus 75.0% versus 67.7%; P < 0.001). The negative predictive value was also decreased in a similar pattern (88.8% versus 85.7% versus 77.2%; P = 0.039), and the positive predictive value did not differ between different CKD stages (P = 0.617).

Conclusions: The prevalence of bleeding-related lower GI lesions was increased as CKD stage worsened, and the sensitivity of iFOBT to detect these GI lesions is also increased with the severity of CKD stage. However, iFOBT should be used with caution in patients with higher stage of CKD, because its specificity and negative predictive value is decreased.

TH-PO643

Salviae Miltiorrhizae Liguspyragine Hydrochloride Improved eGFR in Patients with Chronic Kidney Diseases

Hua Zhou, Hairong Tang, Di Lu, Lining Wang. *Dept of Nephrology, The First Hospital of China Medical Univ, Shenyang, China.*

Background: The progressive decline of glomerular filtration rate (GFR) ultimately resulted in end stage renal disease (ESRD) in patients with chronic kidney diseases (CKD). Current ways to slow down progression of CKD to ESRD are to control hypertension, proteinuria, anemia, and unbalance of electrolytes and acid-base. Few medicines have shown effects on maintaining GFR in CKD patients. Salviae Miltiorrhizae Liguspyragine Hydrochloride (SMLH) has been demonstrated an improvement of tissue microcirculation in ischemic heart and brain in patients. The effect of SMLH on renal function in CKD patients remains unclear. We aim to study if SMLH can attenuate GFR in patients.

Methods: 83 patients with CKD (G2~5) were treated with intravenous infusion of 200ml SMLH per day for 1week (n=43) or 2 weeks (n=40). The estimated GFR (eGFR) by CKD-EPI equation and the levels of serum creatinine (SCr), blood urea nitrogen (BUN), serum cystatin C (SCysC), and serum uric acid (SUA) were examined before and after the treatment.

Results: eGFR increased from 30 ± 3 to 45 ±3 ml/min (p=0.0006), SCr decreased from 304 ± 27 to 209 ± 18 umol/L (p=0.004), SUA also decreased from 449 ± 19 to 390 + 18.39 (p=0.032) in all patients after SMLH treatment. With further stratification by 1 week and 2 weeks of SMLH treatment, we found that 2 weeks treatment brought similar increase of eGFR (15 ± 6 versus 14.0 ± 6, p=0.93), but significant large reduction of SCr and SUA level compared to 1week treatment (138 ± 56 versus 66 ± 38, p=0.028 in SCr and 110 ± 46 versus 61 ± 43, p=0.046 in SUA). However, BUN and SCysC were reduced after the treatment but did not show significant difference.The 3 and 6 month follow up study is on the way.

Conclusions: SMLH significantly improved eGFR and decreased the levels of SCr and SUA but not SCysC and BUN in patients with CKD (G2~G5) in this study. The effect of repeated SMLH administration and long-term effects of SMLH need to be evaluated in a longitudinal study in large cohort of CKD patients. The mechanism of SMLH renal function improvement needs to be investigated in CKD animal models. SMLH might be a useful medicine to slow down the decline of eGFR in CKD patients.

TH-PO644

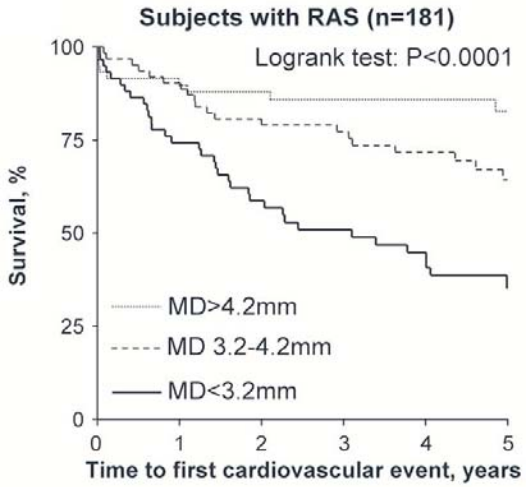
Renal Artery Diameter Is a Predictor of Cardiovascular Events in Subjects with Ischemic Heart Disease and Low-to-Moderate Renal Artery Stenosis

Paolo Lentini,[1] Luca Zanoli,[2] Massimo de Cal,[1] Stefania Rastelli,[2] Anna Basso,[1] Andrea Contestabile,[1] Antonio Granata,[3] Carmelita Marcantoni,[2] Pietro Castellino,[2] Roberto Dell'Aquila.[1] *[1]Nephrology, S. Bassiano Hospital, Bassano Del Grappa, Vicenza, Italy; [2]Internal Medicine, Univ of Catania, Catania, Italy; [3]Nephrology, S: giovanni di Dio Hospital, Agrigento, Italy.*

Background: Several studies report that small renal arteries defined by a low reference diameter(RD)or minimal luminal diameter(MD),are independently associated with low GFR,resistant hypertension and onset of contrast-induced nephropathy and suggested a post-hoc analysis of CORAL trial based on RD categories.We hypothesized that RD and MD are markers of non-traditional cardiovascular risk factors.Aim:To look whether low RD and MD could impact the prognosis of patients with ischemic heart disease.

Methods: Prospective cohort study.We used proportional hazards models to analyse the first-onset of cardiovascular events(CVE) [myocardial infarction,coronary stent implantation,heart failure,stroke and cardiac death]in relation with RD,MD % of RAS in those with low-to-moderate RAS(10-70%)(n=181).

Results: During median follow-up of 4.5yrs(range,0.1-5),27.8% participants(n=623;mean age,64yrs;29%women)experienced a CVE(35.4% in those with RAS10-70%).The presence of low-to-moderate RAS was associated with CVE.In these subjects,those with low MD were associated with higher risk of CVE(MD>4.2mm,HR:1;MD3.2-4.2mm,HR:1.67,95%CI:0.75-3.74,p=0.21;MD<3.2mm,HR 3.76,95%CI:1.67-8.44,p=0.001).When MD was added to a standard risk factor model,risk prediction improvement was4.6%.Results were qualitatively similar if MD was replaced by RD or % of stenosis, but with smaller improvement of risk prediction and model fit.



Conclusions: In patients with ischemic heart disease and low-to-moderate RAS,MD was a significant predictor of CVE, improves risk prediction and may represent a valuable biomarker of cardiovascular disease risk.

TH-PO645

Evaluation of Retinal Microvascular Variation in Hypertension and Chronic Kidney Disease

Amy J. Mc Gowan,[1] Chris C. Patterson,[1] Giuliana Silvestri,[2] Vittorio Silvestri,[2] Evelyn Moore,[2] Alexander P. Maxwell,[1] Gareth J. McKay.[1] *[1]Centre for Public Health, Queen's Univ Belfast, United Kingdom; [2]Centre for Experimental Medicine, Queen's Univ Belfast, United Kingdom.*

Background: The retinal vasculature is accessible to repeated non-invasive assessment, enabling detection of early microvascular changes prior to clinically significant events. Previous studies have associated variation in retinal vessel caliber (RVC) with both chronic kidney disease (CKD) and hypertension. We seek to evaluate RVC with both hypertension and CKD status in elderly white Irish nuns.

Methods: The Irish Nun Eye Study was a cross-sectional analysis of 1242 individuals. Retinal status was assessed by stereo retinal photography in 1122 participants. Retinal arteriolar and venular caliber (central retinal arteriolar [CRAE] and central retinal venular [CRVE] equivalents) were measured from retinal photographs by a standardized computer-assisted method (IVAN). Multiple linear regression was used to compare mean CRAE and CRVE by CKD (eGFR<60 mL/min/1.73 m^2) and hypertension status following adjustment for the potential confounders age, BMI, mean arterial blood pressure, refraction, hypertension, diabetes, CKD and smoking status.

Results: In an adjusted analysis, no significant variation in CRVE was detected in association with hypertension. However, a significant decrease in CRAE was reported in hypertensive individuals (P=0.02; effect size = -1.8; 95%CI: -3.32, -0.27 um). In an adjusted analysis, no significant variation was found in either CRAE or CRVE with CKD (P=0.07; effect size = 2.1; 95%CI: -0.16, 4.34 um).

Conclusions: Variation in retinal vessel caliber was identified in association with hypertension. Hypertensive individuals have significantly narrower retinal arterioles. Several pathological processes including inflammation, hyperglycemia, endothelial dysfunction

and cerebral hypoxia have been implicated in the dilation of retinal venules. Hypertension associated retinal arteriolar narrowing has been linked to increased peripheral resistance through elevated blood pressure. Whether these measurable changes in the microvasculature offer prognostic value remains to be determined.

TH-PO646

C-Reactive Protein Modifies the Association Between Metabolic Syndrome Components, Microalbuminuria, and Race/Ethnicity Satyesh K. Sinha,[1] Magda Shaheen,[1,2] Deyu Pan,[1] Susanne B. Nicholas.[1,2] *[1]Research, Charles R Drew Univ of Medicine and Science, Los Angeles, CA; [2]David Geffen School of Medicine, Univ of California Los Angeles, Los Angeles, CA.*

Background: C-reactive protein (CRP) has been shown to be associated with both the metabolic syndrome (MetS) and chronic kidney disease (CKD). However, little is known about the association of CRP and individual components of the MetS and microalbuminuria, as a marker for CKD.

Methods: We analyzed data from the National Health and Nutrition Examination Surveys 1999-2008 of adults aged ≥20 years with the MetS to study the effect of CRP on the association between microalbuminuria (30-300µg/ml) and the individual components of the MetS and whether this effect is further modified by race/ethnicity. Multivariate analyses were performed to test the association between microalbuminuriaand components of the MetS. We further performed stratified analysis by CRP levels (cutoff ≥0.5mg/dL) to find out if CRP modifies the independent adjusted associations between MetS components and microalbuminuria. Analysis was also done to determine racial/ethnic variation in this association.

Results: In the adjusted multivariate model, microalbuminuria was independently associated with central obesity, pre-diabetes, and low-HDL, p<0.005. In the stratified analysis, CRP levels modified this association. Among those with CRP≥0.5mg/dL, microalbuminuria was independently associated with central obesity (AOR=2.26, 95% CI 1.16-4.43), pre-hypertension (AOR=2.06, 95% CI 1.20-3.56), and low HDL (AOR=1.58, 95% CI 1.15-2.18), p<0.01. Among those with CRP<0.5mg/dL, microalbuminuria was independently associated only with pre-diabetes (AOR=1.59, CI 1.14-2.23), p<0.007. These associations were further varied by race/ethnicity. Among whites, blacks and Hispanics with CRP≥0.5mg/dL microalbuminuria was independently associated with low HDL (AOR=2.34, CI 1.55-3.54), pre-hypertension (AOR=2.63, CI 1.16-5.96), and central obesity (AOR=7.78, CI 1.63-37.13) respectively (p<0.03).

Conclusions: We conclude that CRP and race/ethnicity both modify the independent association between microalbuminuria and components of the MetS.

TH-PO647

Dietary Acid Reduction Provides Adjunctive Kidney Protection to Angiotensin Converting Enzyme Inhibition in Patients with Stage 1 CKD through Amelioration of Tubulo-Interstitial Injury Nimrit Goraya,[1,2] Jan Simoni,[3] Chanhee Jo,[4] Donald E. Wesson.[1,2] *[1]Texas A&M College of Medicine, Medicine, TX; [2]Internal Medicine, Baylor Scott & White Health, Temple, TX; [3]Surgery, Texas Tech Univ Health Sciences Center, Lubbock, TX; [4]Biostatistics, Baylor Scott & White Health, Temple, TX.*

Background: Tubule-interstitial injury (TII) mediates GFR decline in animal models of CKD and is ameliorated by dietary acid reduction. As patients with hypertension-associated nephropathy (HAN) and macroalbuminuria (mg albumin-to-g creatinine ratio [Ualb] > 200) compared to normoalbuminuria (Ualb<20) have higher risk for GFR decline, we examined if 1) macroalbuminuric HAN patients had TII; and 2) adding dietary acid reduction to angiotensin converting inhibition (ACEI) stopped progression of kidney injury.

Methods: We compared urine N-acetyl-D-glucosaminidase (U)-to creatinine (g) ratio (UNAG), an index of TII, in hypertensives with CKD Stage 1 eGFR with macroalbuminuria and with normoalbuminuria to normotensives with normoalbuminuria. We measured UNAG and Ualb after 2 years in CKD Stage 1 macroalbuminuric HAN patients on ACEI, randomized to Usual Care (n=25) or to dietary acid reduction with either fruits and vegetables (F+V, n=23) or oral $NaHCO_3$ (HCO_3, n=23), 0.4 meq/Kg bw/d, each to reduce dietary acid 50%.

Results: Of 281 hypertensives, UNAG was higher in those with macroalbuminuria (n=8) than normoalbuminuria (n=218) (2.5±0.6 versus 1.6±0.5 U/g, p<0.01) and higher than normotensives with normoalbuminuria (1.6±0.9 U, p<0.01, n=10), supporting TII in macroalbuminuria but not normoalbuminuria. At 2 years, UNAG (2.5±0.5 to 2.7±0.4 U/g cr, p<0.01) and Ualb (347±82 to 407±61 mg/g, p<0.01) were higher in Usual Care, consistent with worsening TII and overall kidney injury. By contrast, they were not different at 2 years in F+V (UNAG: 2.5± 0.4 to 2.4±0.4 U/g, p=0.22; Ualb: 350±75 to 341±59 mg/g, p=0.34) or HCO_3 (UNAG: 2.5±0.3 to 2.5±0.3 U/g, p=0.43; Ualb: 341±83 to 330±67 mg/g, p=0.32), consistent with stable TII and stable kidney injury.

Conclusions: Dietary acid reduction in Stage 1 CKD due to HAN appears to provide kidney protection through amelioration of TII that is adjunctive to ACEI.

TH-PO648

Low Fetuin-a and 25(OH) Vitamin D along with High Pentraxin-3 and IL-1ß Levels Are Linked to Increased Left Ventricular Mass Index in Diabetic and Non-Diabetic Chronic Kidney Disease Patients Belda Dursun,[1] Sahan Yasin,[1] Halil Tanriverdi,[2] Rota Simin,[3] Sukriye Uslu.[2] *[1]Nephrology, Pamukkale Univ, Medical School, Denizli, Turkey; [2]Cardiology, Pamukkale Univ, Medical School, Denizli, Turkey; [3]Biochemistry, Pamukkale Univ, Medical School, Denizli, Turkey.*

Background: Increased ventricular stiffness leads to left ventricular hypertrophy (LVH) in chronic kidney disease (CKD) patients. Fetuin-A is involved in mineral metabolism and acts as inhibitor of calcification. Pentraxin-3 (PTX3) and IL-1ß are reliable markers of inflammation. Aim was to investigate relationships between fetuin-A, 25(OH) vitamin D, pentraxin3, IL-1ß and left ventricular mass index (LVMI) in diabetic and non-diabetic CKD patients.

Methods: Stage 3-5 CKD patients (40 diabetic, 40 non-diabetic) and 40 controls were included. Fetuin-a, 25(OH)D, pentraxin-3, IL-1ß and other biochemical parameters were determined. Echocardiographically LVMI was calculated.

Results: LVMI (g/m^2) was higher in diabetic (116.8±20.5) and non-diabetic CKD (112.6±26.9) than controls (78.8±9.4) (p=0,0001). Fetuin-A levels (ng/ml) were lower in diabetic (17.4±10.4) and non-diabetic CKD (18.1±10.5) than controls (42.3±16.8); p=0,0001. 25(OH)D (pg/ml) were lower in diabetic (25.7±9.3) and non-diabetic CKD (26.1±10.9) than controls (42.4±9.8); p=0.001. Ptx-3 level (ng/ml) were higher in diabetic (1.13±0.2) and non-diabetic CKD group (1.04 ±0.24) than controls (0.33 ±0.39), p=0,0001; diabetics had higher levels of PTX3 than non-diabetics (p=0.022). IL-1 ß (pg/mL) was higher in diabetic (7.3±12.9) and non-diabetic CKD (7.9±12.9) than controls (1.82±9.11) (p=0,001).IL-1 ß (pg/mL) was higher in diabetic (7.3±12.9) and non-diabetic CKD (7.9±12.9) than controls (1.82±9.11) (p=0,001). Fetuin-A was positively correlated with 25(OH)D. Pentraxin-3 and IL-1ß showed positive correlations with LVMI (r=0.253, P=0.005 and r=0.243, p= 0.007). Fetuin-A and 25(OH)D showed negative correlations with LVMI (r=-0.229, P=0.012 and r=0.276, p= 0.002).

Conclusions: Based on our results, lower fetuin-a and 25(OH) vitamin D along with higher pentraxin-3 and IL-1ß levels could mediate the progression of left ventricular hypertrophy in diabetic and non-diabetic CKD patients.

TH-PO649

Importance of Assessing the Cell Mass Index (BCMI) Measured By Bioelectrical Impedance Vector (BIVA) as a Marker of Muscle Mass in 240 CKD Patients Guillermina Barril,[1] Angel Nogueira Perez,[1] Maria Bernardita Puchulu,[1] Secundino Cigarran,[2] Jose-Antonio Sanchez-Tomero.[1] *[1]Nephrology, Hospital U. de la Princesa, Madrid, Spain; [2]Nephrology, Hospital Da Costa, Burela, Lugo, Spain.*

Background: BIVA is a noninvasive method for determining body composition. Phase angle (PA) and body cell mass (BCM) are considered as nutritional markers. Body cell mass index (BCMI) may be a marker of muscle mass (MM) AIM:To determine the usefulness of BCMI as MM marker and its relationship to body composition,total body potassium,visceral proteins, inflammation, and dynamometry values with age and sex changes.

Methods: Cross-sectional study of 240 advanced CKD patients xage 71.33±13y (33-96). Diabetics 35.3%. Body composition was performed with BIVA model BIA 101 (Akern,Italy) evaluating: total body water (TBW), BCM, PA, ICW, Na/K and BCMI. Also albumin, prealbumin, CRP,Hb, total lymphocytes, GFR(Cr clearance and MDRD), tricipital skin fold,arm muscle circumference and abdominal circumference were measured. Patients were classified in two groups according BCMI: G1 BCMI<8, 183 patients (73% male) and G2 BCMI>8, 57 patients 81.9% male.

Results: TBW was higher in G2 (p<0.005). We found no significant differences between groups for triceps skinfold and arm muscle circumference, NPNA, Hb, total lymphocytes, GFR and TBW. Regarding BMI no sig. differences between men and women in both groups. In G2 BCMI shows higher sig.values than G1 in: PA, ICW, FFM, muscle mass %, dynamometry, albumin and prealbumin. No differences in MDRD, NPNA or creatinine clearance, lymphocytes or TBW. Patients with BCMI> 8 (G2) showed lower CRP level than G1. Globally significant direct correlation was found between dynamometry (0,000) and BCMI (0.000), %TBW (0.045), albumin and prealbumin (0.000), MDRD (0.05), Hb (0.02), total lymphocyte (0.006), AIC (0,000).and reverse with MIS (0,000) and ECW (0.000).

Conclusions: Our findings suggest that BCMI>8 together with an adequate ICW and PA were correlated with dynamometry and can be considered as parameters of muscle mass and muscle strength.These parameters can be considered as representative as better body composition and muscle strength interrelated with visceral proteins, inflammation,age and sex.

TH-PO650

Bioimpedance Assessment of Volume Status in Referred Patients with Chronic Kidney Disease: Baseline Data from BIO-CANPREDDICT

Mohammed Hadi Tawhari,[1] Azim S. Gangji,[2] Trevor J. Wilkieson,[2] Mila Tang,[3] Adeera Levin,[4] Ognjenka Djurdjev,[5] Catherine M. Clase.[2] *[1]Internal Medicine, Mcmaster Univ, Hamilton, ON, Canada; [2]Nephrology, St. Joseph's Hospital, Hamilton, ON, Canada; [3]Nephrology, St. Paul's Hospital, Vancouver, BC, Canada; [4]Nephrology, Univ of British Columbia, Vancouver, BC, Canada; [5]Nephrology, BC Renal Agency, Vancouver, BC, Canada.*

Background: Volume status in patients with chronic kidney disease is difficult to assess. Establishing construct validity for new methods of assessment is challenging because no criterion measure exists. A modest correlation with other methods of assessment would suggest that the methods assess the same underlying construct, and confirm the potential for bioimpedance to provide more accurate information than the comparator studied.

Methods: We measured bioimpedance, in triplicate, in patients with CKD who were already participating in CANPREDDICT. We analyzed the data according to the method of Piccoli, classifying patients based on the resistance (R) – reactance (Xc) graph.

Results: We recruited 416 patients, median age was 70 (IQR 17) and 61 % were male. Median MDRD GFR was 28 mL/min/1.73 m^2 (IQR 16), median urine albumin-creatinine ratio was 107 mg/L (IQR 391), 44% had diabetes, 26% ischaemic heart disease and 10% a history of congestive heart failure. Median physician-assessed volume status was 1 on a 1-to-7 scale (IQR 1) and volume status by bioimpedance was 1 on a 0-to-3 scale (IQR 2). For both scales higher values reflect worse volume overload. By bioimpedance, 179 (44%) of patients had normal volume status (0), 91 (22%) status of 1, 108 (26%) status of 2 and 33 (8%) status of 3. Correlation between physician-assessed and bioimpedance- measured volume status was 0.31 (p< 0.001). In multivariate analysis, volume status by bioimpedance was associated with age (OR 1.07 per year, 95% CI 1.05-1.10), gender (OR 0.56 for women, 95% CI 0.34-0.92) and diabetes (OR 2.3, 95% CI 1.26-4.09).

Conclusions: Volume overload by bioimpedance is prevalent in referred patients with CKD. The moderate correlation with physician-assessed volume overload establishes construct validity for this method.

TH-PO651

Bioelectrical Impedance Vector Analysis (BIVA) in the Assessment of Volume and Nutrition Status in Hemodialysis Patients

Humaira Jami,[1] Joseph A. Abdelmalek,[1,2] Dena E. Rifkin,[1,2] Alan S. Maisel,[1,2] Navaid Iqbal.[1] *[1]Univ of California San Diego, San Diego, CA; [2]Veteran's Affairs Hospital San Diego, San Diego, CA.*

Background: Determining fluid status in patients with end stage renal disease represents a diagnostic challenge. Bioelectric impedance analysis detects hydration status in the soft tissues and ElectroFluidGraph uses the data generated by an impedance device to generate a Bioelectrical Impedance Vector Analysis (BIVA). We hypothesized that volume overloaded patients, as assessed by BIVA before and after HD would have increased hospitalizations, ER visits, and death over 90 days.

Methods: This was a single-center observational study involving 58 patients receiving chronic hemodialysis at the VA Hospital. BIVA was performed immediately before and after dialysis to assess hydration status. One standard deviation above and below the mean was defined as "normal" hydration. Greater than two standard deviations above or below the mean were designated "over-hydrated" and "under-hydrated," respectively. 90 day outcomes including ER visits, hospitalizations, cardiac events, and death were ascertained via chart review.

Results: Mean age of the cohort was 65.1 ± 9.6 yrs and 93% were male. The mean pre-hydration was 78.56% ±4.66. The mean pre-dialysis hydrations were 72.3 ± 2.1%, 78.5 ± 3.0%, and 85.5 ± 1.5% in the under-, normal, and over-hydrated groups, respectively. The average pre-dialysis weights were 70.1 ± 13.6, 90.4 ± 20.9, and 83.7 ± 30.0 kg respectively. Among the under-hydrated, 50% had ER visits compared to 46% in the normal hydration and 22% in the overhydrated group (p=0.379) Similarly, the under-hydrated group had a 50% hospitalization rate as compared to 41% in the normal hydration group and 33% in the over-hydrated group at 90 day follow up (p = 0.760 for all three groups).

Conclusions: Among elderly hemodialysis patients, BIVA measurements correlating with under-hydration prior to HD were associated with a trend toward higher rates of adverse events and statistical significance may have been limited by small sample size. One possible explanation is that under-hydration may be a surrogate marker for poor nutritional status, a finding which should be explored in larger cohorts.

TH-PO652

Urinary Sodium Excretion Has Positive Correlation with Activation of Urinary Renin Angiotensin System and Reactive Oxygen Species in Hypertensive Chronic Kidney Disease

Ho Jun Chin, Seong Woo Lee, Youn-Su Park, Seon Ha Baek. *Internal Medicine, Seoul National Univ Bundang Hospital, Seong nam, Kyeongkido, Republic of Korea.*

Background: High sodium intake affects blood pressure, proteinuria, and glomerular hemodynamic and causes renal damage. Although the pathophysiology of the harmful effects of high salt intake seems to have been well described in animal studies, it is not well described in human studies.We aim to determine the relationship between salt intake—estimated by measuring 24-hour urine sodium—and urinary biomarkers of the RAS, inflammation, and ROS.

Methods: We analyzed the relationship between the 24-hour urine sodium-to-creatinine ratio (24HUna/cr) and urine angiotensinogen, monocyte chemoattractant peptide-1, and malondialdehyde-to-creatinine ratio (uAGT/cr, uMCP1/cr, and uMDA/cr) by using the data derived from 226 hypertensive CKD patients, followed for 16 weeks, prospectively.

Results: At baseline, the 24HUna/cr group or levels had a positive correlation with uAGT/cr and uMDA/cr adjusted for related factors (p < 0.005 for each analysis). When we estimate uAGT/cr in the 24HUna/cr groups by ANCOVA, the uAGT/cr in patients with ≥200 mEq/g cr was higher than in patients with <100 mEq/g cr [708 (95% CI: 448–967) versus 334 (95% CI: 184–483) pg/mg cr, p = 0.014]. Similarly, uMDA/cr was estimated as 0.17 (95% CI: 0.14–0.21) pM/mg cr in patients with <100 mEq/g cr and 0.27 (95% CI: 0.20–0.33) pM/mg cr in patients with ≥200 mEq/g cr (p = 0.016). During the 16-week follow-up period, an increase in urinary sodium excretion predicted an increase in urinary angiotensinogen excretion.

Conclusions: High salt intake increases renal RAS activation, primarily, and directly or indirectly affects the production of ROS through renal RAS activation.

TH-PO653

Relationship between Aortic Stiffness and Renal Small Artery Sclerosis in Patients with Chronic Kidney Disease

Tsuyoshi Miyagi,[1] Kentaro Kohagura,[1] Yusuke Ohya,[1] Kunitoshi Iseki.[2] *[1]Dept of Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus, Nishihara-cho, Okinawa, Japan; [2]Dialysis Unit, Univ Hospital of the Ryukyus, Nishihara-cho, Okinawa, Japan.*

Background: Arteriosclerosis of medium-to-large arteries was suggested to be linked to small artery sclerosis. We investigated a possible relationship between aortic stiffness and renal small artery sclerosis in patients with chronic kidney disease (CKD).

Methods: A total of 172 CKD patients underwent renal biopsy at our department between 2010 and 2013. We excluded patients receiving calcineurin inhibitors etc and those with diseases such as vasculitis. We then selected patients whose pulse wave velocity between the brachial and ankle (baPWV) had been measured, leaving us with 102 patients for analysis. Small artery sclerosis was analyzed according to mean scores (small artery intimal thickening grade) converted from semi-quantitative evaluations of the degree of intimal thickening of arcuate arteries and relatively thick interlobular arteries (diameter: ≥200 μm).

Results: The mean values for patients' age, body mass index, blood pressure, estimated glomerular filtration rate (eGFR), HbA1c, and baPWV were as follows: 44 years, 24 kg/m^2, 120/74 mmHg, 73 ml/min/1.73 m^2, 5.6%, and 1393 cm/s, respectively.Positive correlations were observed for baPWV with age (r=0.69, P<0.001), small artery intimal thickening grade (r=0.63, P<0.001), pulse pressure (r=0.49, P<0.0001), and HbA1c (r=0.30, P=0.0008). A negative correlation was observed between baPWV and eGFR (r=-0.57, P<0.0001). Multiple logistic analysis of age, sex, hypertension, HbA1c, eGFR, smoking habit, LDL cholesterol, and high baPWV level (mean level or higher) was performed to investigate determination factors for severe small artery sclerosis (median or higher small artery intimal thickening grade). This revealed that high baPWV level was a significant factor (OR=3.8, P=0.03).

Conclusions: Results indicated that aortic stiffness was related to renal small artery sclerosis in CKD patients. Aortic stiffness may be involved in promoting the progression of organ dysfunction via small artery sclerosis in hypertensive target organs.

TH-PO654

The Amount of Albuminuria Does Not Contribute to the Development of Cardiovascular Disease in Diabetic Patients with Renal Insufficiency

Eunyoung Lee, Young Su Joo, Chang-Yun Yoon, Mi Jung Lee, Tae-Hyun Yoo. *Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea.*

Background: Diabetic patients are likely to progress from normoalbuminuria (NA) to microalbuminuria (MA), and eventually to overt proteinuria (P) coincided with renal insufficiency. Recently, however, several studies have demonstrated that diabetic patients show diverse renal presentations and that 20-40% of patients are normo- to micro-albuminuric despite decreased renal function. In this study, the renal and cardiovascular (CV) outcomes in normo-, micro-, or macro-albuminuric diabetic patients with renal insufficiency were investigated.

Methods: Data from 1,136 diabetic patients with chronic kidney disease stage III or IV between 2007 and 2009 were retrospectively collected. Subjects were divided into NA, MA, and P groups. The primary outcome was new-onset CV events or death, and the secondary outcome was the onset of end-stage renal disease (ESRD). Cox proportional hazard analysis was performed to evaluate the association of albuminuria with the clinical outcomes.

Results: The mean age was 61.7±10.1 years and the mean estimated glomerular filtration rate was 38.9 ml/min/1.73m^2. Among 1,136 patients, 255 patients (22.4%) were NA, 275 patients (24.2%) were MA, and 606 patients (53.3%) were P group. During a mean follow-up duration of 44 months, the development of CV disease was not different among the three groups (P=0.67). However, progression to ESRD was significantly more observed in the P group compared to the NA and MA groups (P<0.001). Multivariate Cox analysis revealed that P was an independent predictor of progression to ESRD (odds ratio=2.414, 95% confidence interval=1.730-3.369, P<0.001), whereas the amount of albuminuria was not a risk factor for the development of CV disease.

Conclusions: There are significant and substantial differences in the clinical outcomes of diabetic patients with renal dysfunction according to the degree of albuminuria. In particular, CV outcome was comparable, while renal outcome was significantly different according to the amount of albuminuria in diabetic patients with renal insufficiency.

TH-PO655

Crossover Randomised Clinical Trial to Evaluate the Antialbuminuric Effect of Three Different Types of Diuretics (Spironolactone, Hydrochlorothiazide and Hydrochlorothiazide + Amiloride) on Top of RAAS Blockade in Proteinuric Nephropathies

Enrique Morales, Paula Jara Caro Espada, Eduardo Gutierrez-Martinez, Manuel Praga. *Nephrology, H. 12 de Octubre, Spain.*

Background: Addition of diuretics enhances the effects of RAAS blockade on residual albuminuria in patients with chronic proteinuric nephropathies. However, comparative studies to evaluate the antialbuminuric effect of different diuretics are lacking. We designed a prospective crossover study to compare the effects of spironolactone (SR), hydrochorothiazide (HCT), or HCT plus amiloride (A) administered on top of RAAS blockade in patients with proteinuric nephropathies.

Methods: Patients with residual urine albumin-to-creatinine ratio (ACR)> 300 mg/g on top of enalapril therapy (40 mg daily) and CKD stages 1-3 were selected for the study. Patients were given SR (25 mg/day), HCT (50 mg/day) or HCT+A (50 mg+5mg /day), respectively during three treatment periods of 4 weeks in a ramdom order. Treatment periods were separated by a washout period of one month. Enalapril (40 mg/day) was maintained throughout treatment.

Results: Twenty nine patients (54 ± 12 years) were included. 15 patients (52%) were diabetics. ACR significantly decreased in the three groups

% (95% CI)	SR	HCT	HCT+A
ACR (mg/g)	-31.1*(-7.7,-54.4)	-52.2*(-30.3,-64.7)	-63.1*(-34.4,-78.6)
eGFR (ml/min/1.73m2)	-5.4*(1.6,-9.2)	-11.6*(-2,-18.4)	-10.4*(2.1,-5.9)
Mean arterial pressure (mmHg)	-0.7(0.6,-4.6)	-0.6(0.6,-3.8)	-2.4*(-0.2,-5.9)
Body weight (kg)	-1.2*(0.2,-2.2)	-0.5(0.4,-1.7)	-0.9*(0.2,-2.2)

*p<0.05 (intra-group analysis)

: -31.1% (95% CI –7.7%, -54%, p<0.01) in the group assigned to SR, -52.2% (95% CI -30.3%, -64.7%, p<0.01) in the group assigned to HCT and -63.1% (95% CI -34.4%, -78.6%, p<0.01) in the group assigned to HCT+A. Body weight, blood pressure (BP) and estimated GFR (eGFR) decreased in the three groups, but albuminuria reduction was independent of these changes.

Conclusions: SR, HCT and the combination of HCT+A induced a significant and remarkable reduction in albuminuria. These results are important for the design of clinical trials. The possible renoprotective consequences of diuretic-induced albuminuria reduction should be evaluated by long-term prospective trials.

TH-PO656

The Risk of Cardiovascular Events in Patients with Advanced Glomerulonephritis Is Not Higher Than Those with Other Causes of Chronic Kidney Disease

Holly L. Hutton,[1] Adeera Levin,[2,3] Jagbir Gill,[2] Ognjenka Djurdjev,[3] Sean Barbour.[2,3] *[1]Dept Medicine, Monash Univ, Clayton, Victoria, Australia; [2]Div Nephrology, Univ British Columbia, Vancouver, BC, Canada; [3]BC Provincial Renal Agency, Vancouver, BC, Canada.*

Background: The risk of cardiovascular disease (CVD) in glomerulonephritis (GN) is poorly understood but has been suggested to be high, possibly due to disease-related inflammation promoting atherosclerosis. Therefore, we hypothesize that the risk of CVD in CKD patients with GN should be higher than other CKD patients with similar CV risk factors.

Methods: 2197 patients from CANPREDDICT (N=2544), a prospective cohort study of patients with stages 2-4 CKD with 3 years of follow-up and centrally adjudicated CVD events, were eligible for analysis. GN patients (N=272) were 1:1 direct and propensity score matched to non-GN patients based on age, eGFR, diabetes, prior CVD and sex. Time from cohort entry to CVD events was compared using a shared frailty Cox survival model.

Results: Pre and post matching data is shown in Table 1.

	Pre matching		Post matching	
	GN (288)	Non GN (1899)	GN (272)	Non GN (272)
Age (mean; yrs)	58.9	69.7	60.5	60.4
eGFR (mean; mls/min)	27.7	27.0	27.0	27.1
Caucasian (no, %)	241, 83.7	1703, 89.7	236, 86.8	243, 89.3
Female (no, %)	99, 34.4	715, 27.7	95, 34.9	95, 34.9
Diabetes (no, %)	58, 20.1	1018, 53.6	57, 21.0	61, 22.4
IHD/heart failure (no, %)	82, 28.5	911, 48.0	79, 29.0	72, 26.5

CVD events occurred in 8.7% (N=25) versus 17.8% (N=388) of GN compared to non-GN CKD patients. After matching, CVD events occurred in 9.2% (N=25) of both GN and non-GN CKD patients (HR 1.01 95%CI 0.58-1.78 p=0.96). In sensitivity analyses, GN and non-GN CKD patients had similar CVD risk in subgroups with diabetes (21.4% versus 21.4%, HR 1.03 95%CI 0.46-2.29 p=0.94) or without diabetes (6.1% versus 8.2%, HR 0.75 95%CI 0.36-1.59 p=0.45).

Conclusions: Patients with advanced CKD due to GN do not have a higher risk of CVD compared to otherwise similar CKD patients without GN. These novel findings question the belief that GN contributes directly to CV risk, and emphasizes the need to further prospectively study CVD at earlier stages of GN.

TH-PO657

Increased Malignancy Risk for Patients with ANCA-Associated Vasculitis

Chinar Rahmattulla,[1] Annelies Evaline Berden,[1] Sophie-Charlotte Wakker,[1] Marlies Reinders,[2] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden Univ Medical Center, Netherlands; [2]Nephrology, Leiden Univ Medical Center, Netherlands.*

Background: Recent studies showed a relatively high incidence of malignancies during long term follow-up of patients with ANCA-associated vasculitis (AAV). In this study, we assessed the risk of developing a malignancy for patients with AAV in comparison to the risk for the general population and investigated whether duration of immunosuppressive therapy was related to the development of malignancies.

Methods: 143 patients with biopsy proven AAV diagnosed between 1991 and 2013 at LUMC, The Netherlands, are included in this study. The development of a malignancy after AAV diagnosis was assessed using PALGA, a Dutch national pathology database. To compare the incidence of malignancies in our AAV cohort with that of the general population, Standardized Incidence Ratios (SIRs) were calculated using the Netherlands Cancer Registry incidence rates. To investigate an association between the duration of immunosuppressive therapy and the development of malignancy, the duration of therapy was assessed in 39 patients.

Results: 37 patients developed 82 malignancies during a mean follow-up of 9 years. These comprised 63 skin cancers (42 basal cell carcinomas, 20 squamous cell carcinomas and 1 melanoma), 3 breast cancers, 3 prostate cancers, 3 colon cancers, 2 lung cancers, and a number of infrequently occurring malignancies. Compared to the general population, patients with AAV had a 2.9 (95% CI = 2.2 – 3.8, p=0.01) times increased risk to develop a malignancy. 13 of 39 patients of whom theraphy data were available developed a malignancy during follow-up. Cox-regression analysis did not show a significant association between the duration of cyclophosphamide or azathioprine treatment in patients with and without a malignancy.

Conclusions: AAV patients have a significantly higher risk to develop malignancies compared to the general population. It is generally assumed that this finding could be related to the immunosuppressants these patients receive. However, in the current study we found no association between the duration of immunosuppressive therapy and the development of malignancies in AAV.

TH-PO658

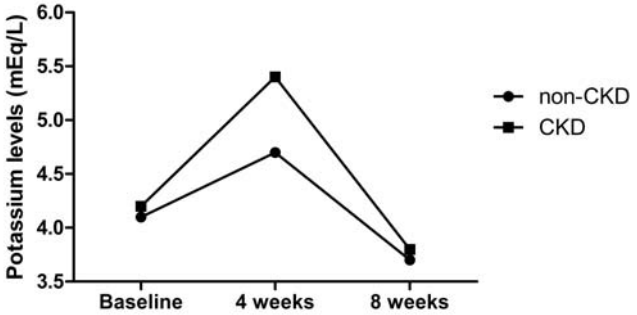
Predictors of Hyperkalemia Risk following Hypertension Control with Aldosterone Blockade According to the Presence or Absence of Chronic Kidney Disease

Ho Sik Shin,[1] Gyung-Hoon Kang,[1] Ye Na Kim,[1] Yeonsoon Jung,[1] Hark Rim,[1] Hyun Yul Rhew.[2] *[1]Internal Medicine, Kosin Univ College of Medicine, Gospel Hospital, Busan, Korea; [2]Urology, Kosin Univ College of Medicine, Gospel Hospital, Busan, Korea.*

Background: Aldosterone antagonists have proven efficacy for management of hypertension and proteinuria reduction; however, they are not widely used due to risk of hyperkalemia. This study assesses predictors of hyperkalemia risk following hypertension control with aldosterone blockade according to the presence or absence of chronic kidney disease.

Methods: Patients used in the analysis were seen between January 1, 2000 through November 30, 2012. 6575 patients with hypertension were evaluated for safety of aldosterone blockade added to preexisting BP-lowering regimens. Hyperkalemia was defined more than serum K 5.0 mEq/L. All patients were on three mechanistically complementary antihypertensive agents including a diuretic and a renin-angiotensin system blocker. Patients were evaluated after 4 and 8 treatment weeks. Incidence of hyperkalemia, significant renal dysfunction (reduction eGFR≥30%) and adverse effects according to the presence or absence of chronic kidney disease was assessed.

Results: After 8 weeks of treatment, the portion of hyperkalemia (serum K ≥ 5.0 mEq/L) according to the presence or absence of chronic kidney disease was 0.5 %, 2.6% respectively.



In logistic regression for predicting hyperkalemia following aldosterone antagonism, predictors of hyperkalemia risk were old age, CKD, male, basal hyperkalemia and reduction in eGFR.

Conclusions: Spironolactone was well tolerated in selected patients with CKD. The risks of serious hyperkalemia or significant renal deterioration appear to be low, particularly after the 2nd month of treatment. Strict monitoring over the first month of treatment followed by standard surveillance as for ACE inhibitors and ARBs is suggested.

TH-PO659

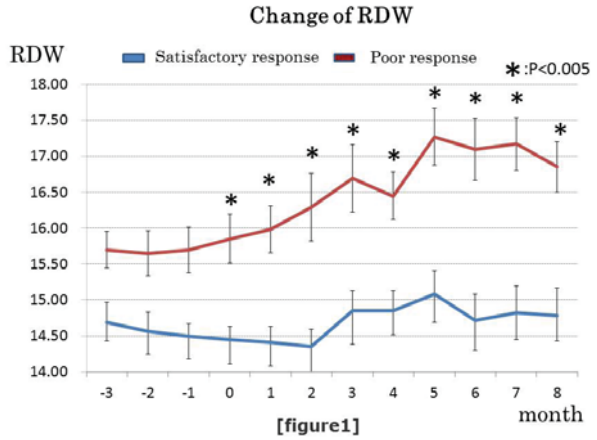
The Relationship Between Red Blood Cell Distribution Width (RDW) and the Resistance to Erythropoiesis-Stimulating Agents (ESA)

Tomohiko Naruse,[1] Yosuke Saka,[1] Shoichi Maruyama.[2] *[1]Internal Medicine, Kasugai Municipal Hospital, Kasugai, Aichi, Japan; [2]Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan.*

Background: There are numerous reports on the relationship between high values of RDW and the onset of cardiovascular events, but there are very few reports on RDW in the renal anemia and ESA-resistance. In the present study, we evaluated patients with chronic kidney disease(CKD) and stratified them according to their responses to ESA.We report the treatment status of patients with renal anemia and the changes in RDW in these patients.

Methods: We studied 40 patients with CKD undergoing treatment for renal anemia who regularly visited our hospital. All of these patients had switched treatment drugs from darbepoetin to epoetin beta pegol. Using the following formula, response to ESA was determined by ESA doses given and Hb levels measured after switching drugs: (mean ESA dose during the 8-month period)/(mean Hb level during the 8-month period)/body weight. Patients with responses of <0.2 were assigned to the satisfactory response group, and those with ≥0.2 were assigned to the poor response group. Changes in Hb and RDW during the 8-month period after switching treatment drugs were the primary focus of this study.

Results: Hb levels increased in both the satisfactory response group (10.26 ± 0.22 g/dl→10.85 ± 0.24 g/dl) and the poor response group (9.05 ± 0.22 g/dl→9.88 ± 0.30 g/dl). RDW after switching drugs was significantly elevated in the poor response group.There was no significant difference in serum ferritin of both groups.



[figure1]

Conclusions: In the group of patients with poor response to ESA, a greater dose of ESA was given in order to correct anemia, and RDW significantly increased. It was suggested that this increase in RDW may be a factor that worsens mortality in patients with high resistance to ESA in the group that received greater doses of ESA.

TH-PO660

Association between Muscle Mass Estimates, Strength, and Physical Performance among Patients with Advanced Chronic Kidney Disease

Francis Perry Wilson, Jordana B. Cohen, Erica D. Palmer, Angela M. Sheridan, Brenden David Connor, Mary B. Leonard, Kathryn H. Schmitz. *Univ of Pennsylvania, Philadelphia, PA.*

Background: Chronic Kidney Disease may be associated with deficits in muscle mass and function. Few studies have rigorously evaluated the association between muscle mass estimates and muscle function in patients with advanced CKD.

Methods: We performed dual-energy X-ray absorptiometry (DXA) assessment of appendicular lean mass (ALM), bio-electrical impedance analysis (BIA) of fat free mass (FFM), and 24-hr urine creatinine collection (UCr) in individuals of age >=45 and <80 years and eGFR >=15 and <=45 ml/min/1.73m^2. Lower extremity strength was assessed via 1 repetition-maximum (1RM) testing using a Life Fitness seated leg-press machine (Rosemont, Il). The short-physical performance battery (SPPB) was used to assess functional status. We used Spearman correlation coefficients to compare the muscle mass and function measures, and Tobit regression to analyze associations with SPPB.

Results: At the time of this writing, 21 participants have undergone all relevant measurements. The median (IQR) age was 63.5 (56.5 - 71) years and 67% were male. Median (IQR) eGFR was 25 (20 - 37) ml/min/1.73m^2. The median (IQR) BMI was 28.4 (27.6 - 30.8) kg/m^2. 1RM capability ranged from 100 to 410 pounds. There were strong correlations between DXA assessment of appendicular lean mass and BIA estimates of FFM (rho=0.97, p<0.001). ALM, FFM, and UCr were correlated with 1RM (rho=0.60, 0.63, and 0.54 respectively, p<0.05). Only 1RM was associated with SPPB score (p=0.04).

Conclusions: In this small population of patients with advanced CKD, BIA, DXA, and UCr excretion all demonstrated significant associations with quadriceps strength but not functional scores. Further studies correlating lower extremity strength with functional status, risk of falls, and other morbidities are necessary.

TH-PO661

Failure to Reach Target Blood Pressure Is Related to Fluid Overload in CKD Patients Treated for Hypertension

Branko Braam,[1,2] Joseph Abinader.[1,2] *[1]Dept Medicine, Div. Nephrology, Univ of Alberta, Canada; [2]Dept Physiology, Univ of Alberta, Canada.*

Background: It is well recognized that hypertension is highly prevalent in patients with CKD. Despite effective medication, target blood pressure is often not achieved. In this study, we tested the hypothesis that not reaching target blood pressure is related to extracellular fluid volume (ECFV) expansion. Moreover, we related fluid overload to arterial stiffness.

Methods: In 26 subsequent hypertensive CKD patients on their routine visit to our outpatient clinic, fluid volume status was assessed using multifrequency bio-impedance (Body Composition Monitor, Fresenius). Fluid overload was defined as exceeding the predicted normal ECFV by >1.1 L. Blood pressure was assessed using an automated device, augmentation index and pressure using a planometry (SphygmoCor, Atcor). Clinical and laboratory data were obtained from the charts and the EMR.

Results: Of the 26 patients, 9 were fluid overloaded; all of these patients were not treated to target (<140/90 for CKD; <130/80 for CKD and DM). Only 2 patients that were not treated to target were normovolemic. Clinical characteristics of both groups are in table 1. Augmentation index was significantly elevated hypertensive patients.

	Fluid expansion (n=9)	No fluid expansion (n=17)	P-value
Age, years	65±11	53±19	NS
Gender, M/F	7 / 2	10 / 7	NS
BMI, kg/m^2	27.0±1.6	32.2±4.5	NS
BP, mmHg	153±9 / 81±13	126±14 / 77±8	<0.0001 / NS
eGFR	43±10	57±26	NS
Fluid status, Δ from normal ECFV, L	1.5±0.4	-0.8±1.3	<0.001
On antihypertensive medication (not diuretic)	9/9	15/17	NS
Treated with diuretic	9/9	6/17	NS
Augmentation index, %	32±11	15±20	<0.05

Conclusions: This study indicates that fluid overload is likely an important but treatable cause for not achieving target blood pressure in CKD patients. The data also indicate that such fluid overload can not be readily appreciated from clinical parameters. Finally, this fluid overload was associated with increased augmentation index.

Uric Acid Associated with Decline of GFR in Diabetic Nephropathy

Sascha Pilemann-Lyberg,[2,3] Morten Lindhardt,[2] Steen Andersen,[1] Peter Rossing.[2,3,4] *[1]Nordsjaellands Hospital, Hilleroed, Denmark; [2]Steno Diabetes Center, Gentofte, Denmark; [3]Aarhus Univ, Aarhus, Denmark; [4]Univ of Copenhagen, Copenhagen, Denmark.*

Background: Diabetes is the major cause of chronic kidney disease (CKD). Evidence from epidemiological and prospective studies indicates that serum uric acid (UA) is a risk factor for development and progression of CKD and loss of kidney function. We evaluated the effect of serum UA on change in GFR in patients with type 1 diabetes (T1DM) in a previous conducted clinical trial.

Methods: Post hoc analysis of a prospective, double-blinded, clinical intervention trial of the long-term renoprotective effect of AT1 receptor blockade (losartan 100 mg) on progression of diabetic nephropathy in T1DM homozygous for the I (n=26) or D (n=27) allele of the ACE/ID polymorphisms. Mean follow-up time was 3 years (range 1.5 – 3.5). Serum UA was measured at baseline. Primary end-point was GFR measured with Cr51-clearance every 6 month. Effect of UA was tested in a linear regression model with and without adjustment for known progression factors (Gender, HbA1c, systolic blood pressure, cholesterol, baseline GFR and baseline urinary albumin excretion rate (UAER)).

Results: Mean baseline UA was 5.7 mg/dL (SD ±1.8), GFR 87 mL/ min/ 1.73m2 (SD ±23), geometric mean of UAER 1023 mg/ 24h (IQR, 631 – 1995). Similar association between UA and change in GFR was present for the two ACE/ID polymorphisms. In an unadjusted linear model UA was positively associated with decline in GFR (r^2 = 0.06, p = 0.09). After adjustment for known progression factors the association increased to a significant level (r^2 = 0.35, p = 0.011). In the backward elimination UA remained in the model, together with baseline UAER and baseline GFR (r^2 = 0.26, p = 0.0031).

Conclusions: Uric acid was positively associated with decline in GFR in type 1 diabetic patients with nephropathy. UA was a significant predictor together with UAER and baseline GFR. The clinical significance of UA is currently investigated in a multicenter clinical trial (PERL Study).

TH-PO663

Effect of Ascorbic Acid on Endothelial Dysfunction and Oxidative Stress in Chronic Kidney Disease Keith Gillis,[1] Kathryn K. Stevens,[1] Scott Morris,[2] Christian Delles,[1] Patrick B. Mark.[1] *[1]Inst of Cardiovascular and Medical Science, Univ of Glasgow, United Kingdom; [2]Renal and Transplant Unit, Western Infirmary Glasgow, United Kingdom.*

Background: The cardiovascular risk associated with chronic kidney disease (CKD) is not fully explained by conventional factors. Oxidative stress is a hallmark of CKD. We investigated the use of ascorbic acid to reduce oxidative stress and endothelial dysfunction (ED) in CKD.

Methods: We performed a crossover study of normal saline (NS) and ascorbic acid (AA) in patients with CKD and matched hypertensive patients with normal renal function (HTN). Biomarkers of oxidative stress were measured after NS, at 10 and 60 minutes after AA (superoxide (O_2^-) production, antioxidant capacity (TAC), isoprostanes and glutathione oxidation ratio (GSH:GSSG), plus asymmetric dimethylarginine (ADMA) and vitamin C). ED was measured as flow mediated dilatation (FMD) using brachial artery ultrasound.

Results: Forty patients were studied (aged 58±11 years; mean blood pressure 145/88±15/12mmHg). eGFR was lower in the CKD group (28±9ml/min/1.73m^2 versus 95±12ml/min/1.73m^2,p<0.001). The CKD group had lower vitamin C (p=0.003), higher ADMA (p=0.001), with higher TAC (p=0.03) and numerically higher O_2^- production (0.514 versus 0.371 AU; p=NS). eGFR was found to be closely associated with ADMA (r=0.59 p< 0.001), ROS (r=0.33 p<0.05), and TAC (r=0.35 p<0.05). No difference was observed in GSH:GSSG or isoprostanes. Baseline FMD was 3.9±2.8% in CKD and 4.1±2.0% in HTN (p=NS), and did not significantly improve after AA, in either CKD (5.1±2.9%) or HTN (5.0±2.9%). In both groups there was a significant rise in both O_2^- production (CKD p<0.05, HTN p<0.05) and TAC (CKD p<0.001 HTN p<0.05) following AA, but no change in GSH:GSSG. In the CKD group there was a significant reduction in ADMA post AA (p=0.03). This was not observed in HTN group.

Conclusions: CKD patients are vitamin C deplete and have elevated ROS production, but markers of OS are otherwise not different to matched patients with HTN. No significant difference in FMD was seen in either group following administration of ascorbic acid but reduction in ADMA levels in the CKD group suggests a mechanism by which antioxidants may have beneficial effects.

TH-PO664

The Associatoin between Anemia and Abnormal Bleeding Times in Patients with Chronic Kidney Disease Ha Yeon Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Dept of Internal Mediciney, Chonnam National Univ Medical School, Gwangju, Korea.*

Background: Platelet dysfunction associated hemorrhagic complications and chronic anemia are often encountered in patients with chronic kidney disease. Decreased hemoglobin (Hgb)level reduces the rheologic interactions between vessel walls and platelets and weakens the ability of red blood cells to scavenge nitric oxide. The present study aimed to evaluate the association of anemia and abnormal bleeding time in patients with chronic kidney disease.

Methods: We retrospectively analyzed the data of 1022 (60.24 ± 15.89 years, men 58.7%). patients with chronic kidney disease, which was estimated glomerular filtration rates (eGFR) < 60 mL/min/1.73 m^2. Age, gender, Hgb, hematocrit (Hct), platelet (PLT), blood urea nitrogen (BUN), creatinine (Cr) levels were determined. Bleeding times were estimated using a platelet function analyzer 100 (PFA-100).

Results: Patients with prolonged bleeding time (bleeding time > 182 sec) were older age and lower eGFR, Hgb, Hct and PLT, and higher BUN and Cr levels compared to those with normal bleeding time.The prevalence of abnormal bleeding time was found to be higher as Hgb declined (25.0% for patients with Hgb ≥ 10 mg/dl (n= 595), 31.9 % for patients with 8 ≤Hgb < 10 mg/dl (n= 343), and 43.4 % for patients with Hgb <8 mg/dl (n= 84), P < 0.001, respectively). eGFR was decreased as a Hgb declined (29.8 ± 19.0 mL/min/1.73m^2 in patients with Hgb ≥ 10 mg/dl, 16.0 ± 13.0 mL/min/1.73m^2 in patients with 8 ≤Hgb < 10 mg/dl, and 10.3 ± 8.61 mL/min/1.73m^2 in patients with Hgb < 8 mg/dl, P < 0.001, respectively). Multivariate analysis revealed that age (OR,1.019; CI, 1.010 – 1.029), 8 mg/dl ≤Hgb < 10 mg/dl (OR,1.214; CI, 0.873 – 1.686), Hg < 8 mg/dl (OR,1.820; CI, 1.084 – 3.055), 15 mL/min/1.73m^2≤ eGFR < 30 mL/min/1.73m^2 (OR,1.616; CI, 1.053 – 2.481), eGFR < 15 mL/min/1.73m^2 (OR,1.668; CI, 1.160 – 2.397), thrombocytopenia (PLT < 150 × 10^9/L) (OR, 2.659; 95% CI, 1.981–3.569) were independently associated with prolonged bleeding time.

Conclusions: Severe anemia (Hgb < 8mg/dl) is independently associated with prolonged bleeding time in chronic kidney disease, even after adjusting for eGFR and other potential confounders.

TH-PO665

Effect of Ferumoxytol on Fatigue in Patients with Iron Deficiency Anemia and Kidney Disease Naomi V. Dahl, William Strauss, Kristine Bernard. *AMAG Pharmaceuticals, Inc.*

Background: Many patients with IDA do not tolerate or adequately respond to oral iron and live with chronic anemia and related negative effects on health-related quality of life (HRQL). While the effect of anemia on HRQL in patients with CKD has been studied, data from double-blind placebo-controlled trials are lacking. The objective of this analysis was to explore the impact of IV iron on patient reported outcomes in IDA patients with CKD and a history of unsatisfactory oral iron therapy or in whom oral iron cannot be used.

Methods: This is a subgroup analysis of a randomized, double- blind, placebo-controlled, Phase 3 study (NCT01114139) of 808 patients (Hgb <10 and >7g/dL, TSAT<20%, and GFR>30 mL/min/1.73m^2), randomized 3:1 to either 2 injections of 510 mg of ferumoxytol (FER) 5±3 days apart or normal saline placebo (PL). Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), and Linear Analog Scale Assessment -Energy (LASA-E) were assessed from Baseline (BL) to Week 5. Patients with evidence of probable CKD were identified by one or more of: GFR<60mL/min/1.73m^2, evidence of kidney damage from medical history, proteinuria >30mg.

Results: 132 patients with a variety of underlying conditions (GI disorders, 39; abnormal uterine bleeding, 36; cancer, 9; other, 48), met criteria for probable CKD. Their BL scores (FACIT-F; FER, n=95, 24.0; PL, n=37, 27.2) were much lower than general U.S. population norms (40.1) and close to those reported in anemic cancer patients (23.9 for FACIT-F, 37.2 for LASA-E). By Week 5, in parallel to a significant increase in mean Hgb (FER 2.2 versus PL -0.1, p<0.0001), FER-treated patients demonstrated significantly greater improvements in mean FACIT-F score than PL, (11.1 versus 6.8, p=0.039), exceeding the minimum important difference (MID=3) and approaching population norms in the FER group. Improvement in LASA-E from BL (35.9) to week 5 in FER-treated patients (16.0, 95% CI 10 to 22) also exceeded the MID (9.61).

Conclusions: This analysis found that patients with IDA and evidence of probable CKD, unsuccessfully treated with oral iron, had very poor baseline HRQL scores and that in concert with increased Hgb, FER treatment resulted in significant improvements in measures of fatigue and energy.

Funding: Pharmaceutical Company Support - AMAG Pharmaceuticals, Inc.

TH-PO666

Benefits of Early Intervention with ESA Therapy on Renal Survival in Patients with CKD Tadao Akizawa,[1] Michiko Kumagai,[2] Yasuo Ohashi.[3] *[1]Showa Univ School of Medicine; [2]Chugai Pharmaceutical Co., Ltd.; [3]Chuo Univ.*

Background: To investigate the relationship between Hb levels of CKD patients at the initiation of ESA therapy and renal outcome in Japanese non-dialysis CKD patients with anemia, the Japan Erythropoietin Treatment survey for STarting hemoglobin level in REnal Anemia Management (JET-STREAM) study was conducted.

Methods: In this prospective, multi-center, observational study, non-dialysis CKD patients with anemia who had never been treated with ESAs were included. Eligible patients were divided into three groups depending on their Hb levels at initiation of epoetin beta therapy (Group I: 10 ≤ Hb < 11 g/dL, Group II: 9 ≤ Hb < 10 g/dL, and Group III: Hb < 9 g/dL). The primary endpoint was time to first occurrence of any renal event (RRT, Cr doubling or eGFR < 6.0 mL/min/1.73 m^2). To account for lead time bias, the primary endpoint was analyzed from the time when the Hb level dropped below 11 g/dL for the first time. Dynamic treatment regime was applied for group comparisons using the IPW Cox regression model to adjust the baseline and time-dependent selection bias in the artificially censored data.

Results: A total of 1113 patients were eligible for primary endpoint analysis. Since there were patients with extreme weights when comparing Groups I and II, the weights larger than 99th were set to the value of 99th percentile. After adjusting the artificial censoring using the IPW methods, the risk of renal events was significantly higher in Group III compared with Group I (HR, 2.52; 95% CI, 1.98 to 3.21; P < 0.0001); the risk was also higher in Group II compared to Group I (HR, 1.48; 95% CI, 0.91 to 2.40, *P = 0.11). When we used a weight truncated at the 98th percentile for the comparison between Groups I and II in the sensitivity analysis, the risk of renal events was significantly higher in Group II compared with Group I (HR, 1.29; 95% CI, 1.02 to 1.64, P* = 0.033).

Conclusions: The JET-STREAM study prospectively demonstrated that initiation of ESA therapy at an early stage when Hb levels have declined below 11 g/dL reduces the risk of renal events in Japanese CKD patients with anemia.

Mortality Risk of Darbepoetin Alfa versus Epoetin Alfa in Patients with Chronic Kidney Disease: Systematic Review and Meta-Analysis of Randomized Trials Emilee R. Wilhelm-Leen, Wolfgang C. Winkelmayer. *Stanford Univ School of Medicine, Palo Alto, CA.*

Background: Darbepoetin alfa (DPO) has been shown to possess similar efficacy compared with epoetin alfa (EPO), yet little is known about the comparative safety of these agents. We conducted a systematic review of randomized trials comparing DPO *versus* EPO in patients with chronic kidney disease (CKD) or end-stage renal disease (ESRD) and tested for differences in mortality in meta-analysis.

Methods: We systematically searched Medline (all years) and documents submitted by Amgen to the U.S. Food and Drug Administration. Two reviewers identified suitable reports and independently abstracted data with resolution *via* conference. We used random effects meta-analysis to estimate the summary odds ratio for mortality.

Results: From 155 search hits, we identified 5 trials; 2 additional unpublished trials were identified from FDA documents. Cumulatively, 1808 (820 EPO, 988 DPO) patients received study drug (modified intent-to-treat) and were followed for up to 52 weeks (wks). The summary odds ratio was 1.34 (95% CI: 0.87-2.04). No treatment heterogeneity across studies was detected (Q-statistic=4.3; P=0.64).

	Population	Duration	Blinding	Mortality (DPO)	Mortality (EPO)	Odds Ratio
Locatelli, et al.	CKD	24 wks	Open Label	5/129 (3.9%)	1/37 (2.7%)	1.45
Allon, et al.	ESRD (HD)	52 wks	Open Label	4/32 (12.5%)	2/15 (13.3%)	0.93
Nissenson, et al.	ESRD (HD)	28 wks	Double-blind	9/169 (5.3%)	23/335 (6.9%)	0.76
Vanrenterghem, et al.	ESRD (HD/PD)	52 wks	Open Label	41/346 (11.9%)	11/173 (6.4%)	1.98
Li, et al.	ESRD (HD)	24 wks	Open Label	0/22 (0%)	1/23 (4.4%)	0
Amgen #20010125	ESRD (HD)	28 wks	Double-blind	11/200 (5.5%)	7/206 (3.4%)	1.65
Amgen #980211	ESRD (HD)	20 wks	Open Label	5/90 (5.6%)	1/31 (3.2%)	1.76
Summary Odds Ratio (95% CI; DPO vs. EPO)	-	-	-	-	-	**1.34 (0.87-2.04)**

Conclusions: Only few studies have randomized patients with CKD or ESRD to DPO *versus* EPO. While no significant difference in mortality was detected between DPO and EPO, the confidence interval was wide and remained compatible with substantial harm in patients randomized to DPO. Further comparative effectiveness studies using observational data are warranted to better delineate the safety profiles of DPO *versus* EPO.

Novel Side Effect Profiles of Sodium Ferric Gluconate IV Injection (Ferrlecit®) in CKD Patients Not on Dialysis

Sanjeev Sirpal,[1,2] Rosa M. Marticorena,[1,2] Sandra M. Donnelly.[1,2] *[1]Medicine/Nephrology, William Osler Health System, Toronto, ON, Canada; [2]Medicine/Nephrology, Univ of Toronto, Toronto, ON, Canada.*

Background: Iron deficiency is a common sequelae of CKD, with an increase in prevalence and severity with gradual loss of kidney function. Ferrlecit®(sodium ferric gluconate complex in sucrose injection) is an IV iron product indicated for the treatment of iron deficiency anemia in patients undergoing chronic HD who are receiving supplemental EPO therapy. Existing studies have suggested that 500mg of Ferrlecit® is well-tolerated when administered over four hours and to date, no study has reported any episodes of unmanageable life threatening adverse events.

Methods: This study was approved by the Research Ethics Board of our Institution. This study was designed as an open-label, dose escalation pilot study to assess the safety and efficacy of Ferrlecit®. Six pre-dialysis patients with anemia were treated with intravenous Ferrlecit® administered at 250mg in 100mL normal saline over 2 hours following the pre-test dose. Patient demographic, clinical, and biochemical parameters were assessed at baseline. Post-infusion serious adverse events were reported on a severity of index scale.

Results: GI symptoms including abdominal pain, cramping or diarrhea were the most commonly reported complaints and all patients experienced these symptoms. Three patients had hemodynamically significant adverse events by the end of infusion. One of the patients experienced hemodynamic adverse events characterized by bradycardia and severe hypotension. One responded to fluid volume, anti-histamine and hydrocortisone. The other required, in addition, temporary inotropic support. The study was terminated due to the severity of adverse effects.

Conclusions: The milder reaction occurred at a dose of 4mg/kgBW, the moderate reaction occurred at a dose of approximately 4.5mg/kg BW, and the severe reaction occurred at a dose of 5.1mg/kg BW. In our study, since there was no difference in the peak post administration drug levels as a result of the constant rate of administration, the data suggests a hypothesis that there may be a body weight limitation on daily doses of 3.5mg/kg/day.

TH-PO669

Altered Clot Structure Predicts Mortality in Hemodialysis Patients

Georg Schlieper,[1] Nadine Kaesler,[1] Nada Dimkovic,[3] Nikolaus Marx,[2] Jürgen Floege,[1] Katharina Hess.[2] *[1]Nephrology, Uniklinik RWTH Aachen, Germany; [2]Cardiology, Uniklinik RWTH Aachen, Germany; [3]Nephrology, Zvezdara Univ, Serbia.*

Background: Chronic kidney disease (CKD) is associated with both increased cardiovascular mortality and coagulopathy. Patients with CKD are known to have a prothrombotic clot structure characterized by small pores and resistance to fibrinolysis. However, the impact of altered clot structure on outcome in CKD patients is unknown. Therefore, the aim of the current work was to investigate whether clot structure is associated with outcome in CKD patients.

Methods: Fibrin clot structure and lysis were determined in plasma of 172 hemodialysis patients (59±11y, 54% male) using a validated turbidimetric assay. Plasma levels of fibrinogen were analysed by ELISA. Fibrinogen was purified from 6 healthy control individuals and 6 patients with CKD stage IV using a calcium dependent IF-1 monoclonal antibody.

Results: Plasma of CKD patients exhibited a denser clot structure when compared to controls with normal renal function (0.44±0.04 (CKD) versus 0.26±0.01 (control) AU, respectively; p<0.01) and prolonged clot lysis (1274±134 versus 468±38 sec respectively; p<0.01). Kaplan Meier analysis revealed that CKD patients with a denser clot structure had an increased mortality risk (log-rank p=0.009). Multivariate Cox regression model (adjusted for age, diabetes, gender, duration of dialysis and fibrinogen) confirmed the massive, independent risk prediction of denser clots (hazard ratio 76, confidence interval= 3 – 1800; p=0.007). Fibrinogen levels were not significantly related to outcome. To further analyze whether the effect of clot structure on mortality was dependent on fibrinogen we purified fibrinogen from healthy controls and CKD patients. Clot density of purified fibrinogen did not differ between both groups (0.15±0.01 and 0.16±0.01 AU, respectively; p=0.6) as did lysis time (3294±182 sec and 3290±209 sec, respectively; p=0.9).

Conclusions: A denser clot structure is a potent, independent predictor of mortality in hemodialysis patients. Using purified fibrinogen clot structure did not differ between CKD patients and controls, suggesting alterations of plasma and not fibrinogen as the driving factors for uremic coagulopathy.

TH-PO670

Post Hoc Analysis of Iron Indices in Dialysis Patients with Lower versus Higher Baseline Ferritin in a Sucroferric Oxyhydroxide Study

Stuart M. Sprague,[1] Adrian Covic,[2] Markus Ketteler,[3] Anjay Rastogi,[4] Bruce S. Spinowitz,[5] Jaco Botha,[6] Viatcheslav Rakov,[6] Jürgen Floege.[7] *[1]NorthShore Univ Health System; [2]'Gr. T. Popa' Univ of Medicine and Pharmacy, Romania; [3]Coburg Clinic and KfH-Dialysis Center, Germany; [4]Univ of California; [5]New York Hospital Queens; [6]Vifor Pharma, Switzerland; [7]RWTH Univ Hospital Aachen, Germany.*

Background: This *post hoc* analysis evaluated the effect of the iron-based phosphate binder, sucroferric oxyhydroxide (SFO; VELPHORO®/PA21) versus sevelamer carbonate (SEV) on iron indices by baseline ferritin levels in dialysis patients.

Methods: 1,059 patients were randomized to SFO (1.0–3.0 g/day) or SEV (2.4–14.4 g/day) for 12 weeks' dose titration plus 12 weeks' maintenance. Eligible patients enrolled in a 28-week extension study.

Results: 549 patients completed the extension study. Changes in mean iron indices stratified by median baseline ferritin levels are shown in the Table. More patients with higher (SFO: 81%; SEV: 88%) versus lower (SFO: 67%; SEV: 72%) baseline ferritin received concomitant intravenous iron.

Table: Mean values at baseline and mean changes at Week 52 endpoint in iron indices by baseline ferritin levels (< or ≥ median 604 ng/mL).

		SFO N=322		SEV N=227	
		< median n=172	≥ median n=150	< median n=102	≥ median n=125
Ferritin, ng/mL	BL	304.4	985.1	301.7	1043.4
	Δ BL to endpoint	211.0	88.2	144.3	13.7
	P-value for Δ from BL	<0.0001	0.0119	<0.0001	0.7465
TSAT, %	BL	22.5	31.0*	23.5	30.5
	Δ BL to endpoint†	6.2	2.9*	2.5	0.17
	P-value for Δ from BL	<0.0001	0.0778	0.0382	0.9120
Hb, g/L	BL	110.6	114.6	113.8	113.4
	Δ BL to endpoint‡	4.8	−2.4	0.06	−1.8
	P-value for Δ from BL	0.0002	0.0485	0.9667	0.0786

Endpoint is last post-baseline non-missing value across both studies. *n=149.
†P=0.0483 and ‡P0.0153 for SFO vs SEV in < median group.
BL, baseline; Hb, hemoglobin; TSAT, transferrin saturation.

Conclusions: Changes in iron indices in patients with lower baseline ferritin levels were more pronounced with SFO versus SEV, likely due to low-grade iron absorption with SFO. In patients with a higher baseline ferritin level, no such differences were noted. There was no indication for a risk of iron overload with SFO in either of the subgroups.

TH-PO671

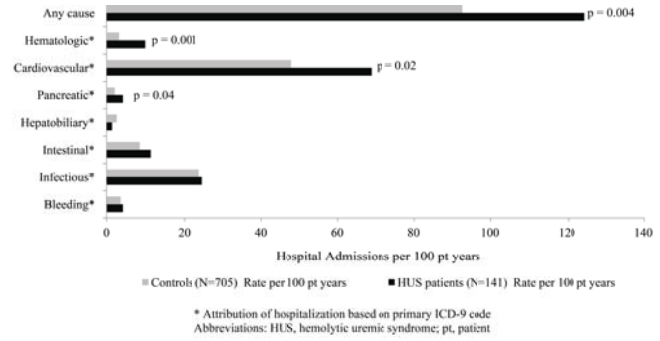
Consequences of Hemolytic Uremic Syndrome Among Dialysis Patients

Steven M. Brunelli,[1] Ami Claxton,[1] Sunil Mehta,[2] Emmanuel A. Anum.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Alexion Pharmaceuticals, Cheshire, CT.*

Background: Hemolytic uremic syndrome (HUS) is described by hemolytic anemia, low platelets, and renal impairment. Resultant thrombotic microangiopathy (TMA), affects nearly every organ system. Most HUS is bacterial in origin, but ~10% (including most patients who progress to end-stage renal disease [ESRD]) are due to genetic complement disease (atypical HUS). We conducted this analysis to better understand the potential consequences of HUS in ESRD patients.

Methods: We identified new dialysis patients at a single provider organization for ESRD due to HUS (ICD-9 code 283.11; n=217). These were propensity-score matched 1:5 to controls (n=1,085) on dialysis for ESRD from any other cause for age, gender, race, dry weight, insurance, access, comorbidities, and Charlson comorbidity index. Mortality and laboratory data were from health records; hospitalization data were from Medicare claims. Comparisons were made using Cox models and linear mixed models. Patients considered at risk until death, censoring, or end-of-study period (Mar 2013; Dec 2010 for hospitalizations).

Results: Compared to controls, HUS patients had significantly greater risk for hospitalizations overall (RR=2.3 [1.3-4.1]) and hospitalization for hematologic (RR=5.8 [1.9-15.9]), CV (RR=2.1 [1.1-4.0]), and pancreatic (RR=7.9 [1.1-59.8]) causes (Figure). Cases also had evidence of ongoing TMA: higher LDH (215.9 versus 193.9 U/L) and RDW (15.6% versus 15.3%), lower platelets (240.1 versus 248.1/mcL) and Hb (11.1 versus 11.3 g/dL), and more frequent spikes in LDH (rise in LDH > 100).



Conclusions: Dialysis patients with HUS had laboratory evidence consistent with ongoing TMA and were at significantly higher risk than matched controls for hospitalizations, particularly those due to CV, hematologic, and pancreatic disease. Trials are needed to see whether targeted therapy for HUS reduces hospitalizations.

Prevalence of Periodic Limb Movement Disorder (PLMD) in Dialysis Patients Seerapani Gopaluni, Mohamed S. Sherif, Sheera Sutherland, Kristine Ventura, David J. Meredith, Philip David Mason. *Renal Unit, Churchill Hospital, Oxford, United Kingdom.*

Background: Abnormal limb movement disorders (PLMD and Restless Legs Syndrome, RLS) are commonly reported in dialysis patients, causing sleep disruption, poor quality of life and increased cardiovascular morbidity. PLMD is marked by episodic jerking limb movements during sleep. Polysomnography establishes the diagnosis but is expensive. Leg worn accelerometers are validated to detect periodic limb movements (PLM) in the general population. We used these to establish the prevalence of PLMD in haemodialysis patients and correlated the PLM index-PLMI(PLM/hr) with sleep quality and overall quality of life measures. We performed simultaneous pulse oximetry to exclude movements occurring during hypoxic dips as the accelerometers pick up non-PLM movements associated with sleep apnoea.

Methods: Participants completed validated questionnaires (Pittsburgh sleep quality index (PSQI), International Restless Legs Syndrome Group Questionnaire, KDQOL-36) and wore an accelerometer on each leg and a wrist pulse-oximeter during sleep for 3 nights.

Results:

	n=35	p
Age Mean	59yr	
M:F	24:11	
Mean PLMI	64.26*	
Mean PSQI	8.07 (n=28)†	
Prevalence of high PLMI (>15)	74.29%	
Prevalence of PLMD (PLM affecting sleep)	14.28%	
Prevalence of RLS	42.85%	
PLMI in good sleepers vs poor sleepers	52 vs 72	0.34
PLMI in patients with RLS vs no RLS	89 vs 46	0.05
SF-12 MCS¶ scores in PLMD vs non-PLMD patients	31.8% vs 53%	0.0005
SF-12 PCS# scores in PLMD vs non-PLMD patients	46% vs 53%	0.08
Correlation between PLMI & RLS	0.31	0.09
Correlation between PLMI & PSQI	0.13	ns
Correlation between RLS & PSQI	0.36	0.06
* >15 movements/hr is considered significant, † >5-associated with bad sleep quality		
¶ Mental & # Physical Component Summary (sub components of KDQOL-36)		

Conclusions: This is the only study of PLMD in dialysis patients using accelerometers. Although the majority had a very high PLMI, sleep quality was not always affected. PLMI was higher in patients with RLS and those with PLMD perceived themselves to have relatively poor mental and physical health. These findings will form the basis of an intervention study to reduce PLMD in symptomatic patients and hopefully improve QOL.

Clinical Correlates of Urinary KIM-1 in Three Cohorts Sushrut S. Waikar, Meredith C. Foster, Gudeta D. Fufaa, Robert G. Nelson, Venkata Sabbisetti, Theodore E. Mifflin, Xiaoming Zhang, Dawei Xie, Harold I. Feldman, Josef Coresh, Vasan S. Ramachandran, Paul L. Kimmel, Chi-Yuan Hsu, Kathleen D. Liu, Joseph V. Bonventre. *CKD Biomarkers Consortium.*

Background: Kidney injury molecule-1 is expressed in proximal tubules following injury. Urinary KIM-1 (uKIM-1) is an AKI biomarker, but is also detectable in CKD. To better understand KIM-1 in CKD, we measured urinary levels in cohorts with a wide range of kidney function.

Methods: We measured uKIM-1/creatinine (uKIM-1/Cr) in 260 Pima Indians with type 2 DM, 361 participants from a nested case-control study of ESRD in the Atherosclerosis Risk in Communities (ARIC) study, and 2320 participants in the Chronic Renal Insufficiency Cohort (CRIC). We compared uKIM-1/Cr across cohorts and examined associations with demographic and clinical variables in each cohort and in a pooled analysis using linear regression.

Results: Median (10^{th} to 90^{th} %ile) uKIM-1/Cr (pg/mg) were 673 (130-2448) in Pima Indians, 795 (267-2622) in ARIC, and 1387 (396-4613) in CRIC. Levels above 2000 pg/mg, typically observed in established AKI, were present in 13.8% of Pima, 17.2% of ARIC and 35.6% of CRIC participants. The direction and statistical significance of associations were consistent across cohorts (Table 1): uKIM-1/Cr was higher with lower eGFR, higher ACR or PCR, older age, non-black race, higher SBP, and in subjects with DM. In multivariable adjusted analyses, DM was no longer associated with uKIM-1/Cr, whereas female sex was associated with higher levels.

Table 1. Associations of log (uKIM-1/Cr)	Unadjusted			Multivariable-adjusted
	Pima	ARIC	CRIC	All three cohorts
Median GFR ml/min/1.73m^2	129.7	67.9	41.5	
	β	β	β	β
GFR (per 10 ml/min/1.73m^2)	**-0.04**	**-0.20**	**-0.09**	**-0.03**
logACR	**0.21**	**0.20**	**0.14**	**0.18**
Age (per 10y)	**0.22**	**0.07**	**0.23**	**0.13**
Black race (vs. other)	-	**-0.31**	**-0.23**	**-0.38**
Women (vs. men)	0.09	-0.02	0.11	**0.14**
DM (yes vs. no)	-	**0.32**	**0.36**	0.01
SBP (per 10mm Hg)	**0.14**	**0.13**	**0.06**	**0.03**
BMI (per 5kg/m^2)	0.06	0.00	0.00	0.01

Bold font: P < 0.

Conclusions: uKIM-1/Cr reflects underlying kidney disease (lower eGFR and higher ACR and/or PCR) in the chronic setting across three diverse cohorts.

GDF-15, Soluble ST2, and Galectin-3 and Risk of Cardiovascular Events, Decline in Kidney Function and Death in Chronic Kidney Disease Cassianne Robinson-Cohen,[1] Bryan R. Kestenbaum,[1] Ronit Katz,[1] Alan S. Go,[2] Jonathan Himmelfarb,[1] Ian H. de Boer,[1] Nisha Bansal.[1] *[1]UW; [2]KPNC.*

Background: Growth differentiation factor (GDF)-15, soluble ST2 (sST2) and galectin-3 are novel biomarkers that may be involved in cardiac inflammation, remodeling and fibrosis. These biomarkers predict cardiovascular events, kidney disease and death in the general population. We studied the association of these biomarkers with cardiovascular and kidney outcomes in a prospective cohort study of chronic kidney disease (CKD).

Methods: Baseline serum concentrations of GDF-15, sST2 and galectin-3 were measured in 297 participants with non-dialysis requiring CKD from the Seattle Kidney Study. We followed participants for a composite cardiovascular event (atherosclerotic events, heart failure events, and death) and a composite kidney event (progression to ESRD or ≥30% loss of eGFR). We used Cox's proportional hazards model to test associations of each biomarker with the study outcomes.

Results: The mean age was 62 years, 18% were women, 24% were Black and mean eGFR was 39.6 ml/min/1.73m^2. During a median follow-up of 2.7 years (IQR 1.5 – 3.8 years), 104 participants died or had a cardiovascular event and 79 progressed to ESRD or lost >30% eGFR. After adjustment for demographics, co-morbidity, and baseline eGFR, high serum concentrations of GDF-15 and sST2, but not galectin-3, were associated with greater risks of the composite cardiovascular outcome and the composite kidney outcome (**Table**).

Conclusions: Higher serum concentrations of GDF-15 and sST2 were significantly associated with increased risk of cardiovascular events, death and progression of kidney disease among patients with CKD. These biomarkers may highlight novel pathways of cardiovascular and kidney disease in the setting of CKD.

Biomarker	Median (IQR)	Cardiovascular events and death* HR (95% CI) per doubling of biomarker	30% decline in eGFR or ESRD** HR (95% CI) per doubling of biomarker
GDF-15 (pg/mL)	2337.8 (1624.8,3498.7)	**2.51 (1.73, 3.65)**	**2.22 (1.51, 3.27)**
sST2 (ng/mL)	32.6 (25.0, 41.0)	**1.68 (1.15, 2.45)**	**1.51 (1.02, 3.97)**
Galectin-3 (ng/mL)	13.5 (9.9, 17.0)	1.23 (0.79, 1.91)	1.07 (0.72, 1.59)

*Adjusted for age, race, gender, eGFR, urine ACR, educational attainment, current smoking status, physical activity, diabetes, cardiovascular disease, systolic blood pressure, anti-hypertensive medication use, diuretic use, CRP
** Adjusted for age, race, gender, eGFR, eGFR-squared, urine ACR, educational attainment, cardiovascular disease, physical activity, diabetes, systolic blood pressure, anti-hypertensive medication use and diuretic use

Longitudinal Association of Inflammation Markers and Endothelial Dysfunction Markers with Left Ventricular Mass in Hypertensive Predialysischronic Kidney Disease Patients Vianda S. Stel,[1] Kyriakos Ioannou,[2] Evangelia Dounousi,[3] Kitty J. Jager,[1] Aikaterini A. Papagianni,[4] Konstantinos D. Pappas,[5] Kostas C. Siamopoulos,[3] Carmine Zoccali,[6] Dimitrios Tsakiris.[7] *[1]ERA-EDTA Registry, Netherlands; [2]Nicosia General Hospital, Cyprus; [3]Univ of Ioannina, Greece; [4]Hippokration General Hospital, Greece; [5]Univ Hospital of Ioannina, Greece; [6]Ospedali Riuniti, reggio Cal, Italy; [7]Papageorgiou General Hospital of Thessaloniki, Greece.*

Background: This is the first longitudinal study investigating the association of inflammation markers C-reactive protein (CRP), interleukin-6 (IL-6) and tumor necrosis factor-α (TNFα) and endothelial dysfunction markers intercellular adhesion molecule-1 (ICAM-1) and vascular cell adhesion molecule-1 (VCAM-1) with left ventricular mass indexed for height2·71 (LVMI) in hypertensive predialysis CKD patients, trying to better understand early mechanisms of increased LVMI in this patient group.

Methods: From 2004 to 2005, 206 incident consecutive adult patients from the outpatient CKD clinics of two hospitals in Greece with CKD and hypertension, were included. CRP (mg/l) and LVMI (g/height2·71) were assessed annually for three years.

Results: The median LVMI was 69 g/m2·71. Using linear mixed modeling we found that a higher IL-6 (ß=2.0 (95%ci:0.30;3.7), inflammation score based on CRP, IL-6 and TNFα (ß=6.7 (95%ci:2.3;11.1) and VCAM-1 (ß=0.014 (95%ci:0.051;0.023) were associated with higher LVMI, after adjustment for age, sex, primary renal disease, smoking, history of cardiovascular disease, HDL/LDL ratio, and the use of ace-inhibitor/arbs, fibrates, diuretics, aspirin, and statins. The association of the inflammation score and LVMI was pronounced in CKD stages 1-3, but absent in CKD stages 4-5.

Conclusions: This study for the first time demonstrates that in hypertensive predialysis CKD patients, inflammation may play a more important role towards the increase in LVMI in the early than in the later CKD stages. The results further suggest that VCAM-1 may have a more crucial role than ICAM-1 in both atherosclerosis and hypertension which contribute to the increased LVMI.

TH-PO676

Soluble Tumor Necrosis Factor Receptors 1 and 2 Predict Outcomes in Advanced Chronic Kidney Disease: A Prospective Cohort Study Nathalie Neirynck, Griet Lrl Glorieux, Eva Schepers, Francis Verbeke, Raymond C. Vanholder. *Nephrology Div, Dept of Internal Medicine, Ghent Univ Hospital, Gent, Belgium.*

Background: Soluble tumor necrosis factor receptors 1 (sTNFR1) and 2 (sTNFR2) have been associated to progression of renal failure, end stage renal disease and mortality in early stages of chronic kidney disease (CKD), mostly in the context of early diabetic nephropathy. The predictive value of these markers in advanced stages of CKD irrespective of the specific cause of kidney disease has not yet been defined. In this study, the relationship between sTNFR1 and sTNFR2 and the risk for cardiovascular events (CVE) and all-cause mortality was investigated in a population with CKD stage 4-5, not yet on dialysis, to minimize confounding by renal function.

Methods: In 131 patients, CKD stage 4-5, sTNFR1, sTNFR2 were analysed for their association to a composite endpoint of all-cause mortality or first non-fatal CVE by univariate and multivariate Cox proportional hazards models. In the multivariate models, age, gender, CRP, eGFR and significant comorbidities were included as covariates.

Results: During a median follow-up of 31 months, 42 events (32.1%) occurred of which 22 deaths (16.8%) and 20 (15.3%) first non-fatal CVE. In univariate analysis, the hazard ratios (HR) of sTNFR1 and sTNFR2 for negative outcome were 1.428 (p<0.001) and 1.127 (p<0.001) respectively. After adjustment for age, gender, CRP, eGFR, diabetes and a history of cardiovascular disease both sTNFR remained independently associated to outcomes (HR: sTNFR1: 1.512, p<0.001; sTNFR2: 1.125, p<0.001). A subanalysis of non-diabetic patients in the group confirmed the same findings.

Conclusions: sTNFR1 and sTNFR2 are independently associated with all-cause mortality or an increased risk for cardiovascular events in advanced CKD. Whether this association is causal and linked to biological functions of these receptors needs further investigation.

Funding: Government Support - Non-U.S.

TH-PO677

The Association between Postoperative Troponin and Mortality in Patients with and without Impaired Kidney Function Michael Walsh,[1] Chew Yin Wang,[2] Amit X. Garg,[3] Philip J. Devereaux.[1] *[1]McMaster Univ/Population Health Research Inst; [2]Univ of Malaysia; [3]Western Univ.*

Background: Postoperative cardiac troponin T (cTnT) is a risk factor for 30-day mortality in patients undergoing noncardiac surgery but there is uncertainty as to whether the risk associated with cTnT is maintained when kidney function is reduced. We evaluated the association between cTnT after noncardiac surgery at different levels of kidney function.

Methods: We performed a p*ost-hoc* analysis of a prospective cohort study of patients at least 45 years old, undergoing noncardiac surgery that required an overnight hospital admission. cTnT was measured for three days after surgery and considered abnormal if the peak was ≥0.02 ng/mL. We examined the interaction between an abnormal cTnT and estimated glomerular filtration rate (eGFR) strata for the outcome of 30 day mortality.

Results: We studied 14,037 patients of which 267 (1.9%) died within 30 days of surgery. The adjusted hazard ratio (aHR) for death with an abnormal cTnT was 4.37, 6.15, 6.30, 1.33 and 1.46 for an eGFR ≥60, 45 to <60, 30 to <45, 15 to <30, and <15 ml/min/1.73m^2 or on dialysis respectively. Compared to the ≥60 ml/min/1.73 m^2 eGFR group, the aHR was significantly lower for the 15 to <30 eGFR group (interaction p-value=0.02). Redefining an abnormal cTnT as ≥0.03 ng/mL or as a change of at least 0.02 ng/mL did not substantially alter results.

Conclusions: The risk associated with postoperative cTnT may be different for patients with an eGFR <30 ml/min/1.73 m^2. Further research is required to determine how to interpret perioperative cTnT values for patients with low eGFR.

TH-PO678

NTpro-BNP and Troponin T Is a Novel Valuable Biomarker for Progression of CKD Patients: A Longitudinal Follow-Up Study Yoshiko Shimamura,[1] Tatsuki Matsumoto,[1] Kazu Hamada,[1] Koji Ogata,[1] Kosuke Inoue,[1] Yoshinori Taniguchi,[1] Taro Horino,[1] Kenji Yuasa,[2] Tetsuro Sugiura,[1] Yoshio Terada.[1] *[1]Kochi Univ, Nankoku, Japan; [2]Kochi-Takasu-Hospital, Kochi, Japan.*

Background: NTpro-BNP and Troponin T(TNT) is known as diagnostic and prognostic biomarker of cardiac events. Recent report showed that cardio-renal interaction is an important problem in CKD patients. Furthermore, FGF23 was reported to injure cardiomyocyte directly in mice and high FGF23 is associated with cardiovascular risk factor. However, only few longitudinal follow-up studies have been reported to evaluate NTpro-BNP/TNT as a biomarker for renal prognosis. Accordingly, we elucidated the relation between NTpro-BNP/ TNT and renal function in CKD patients.

Methods: Alongitudinal follow-up study for 24 months was performed in 396 consecutive CKD patients in Kochi prefecture. NTpro-BNP, TNT, FGF23, serum creatinine, hemoglobin, albumin, calcium, phosphate and urine protein amount were measured. This study was approved by the Kochi Medical School review board. All patients provided written informed consent.

Results: The serum level of NTpro-BNP was positively correlated to creatinine (P<0.0001: r=0.442), FGF23 (P<0.0001: r=0.480), TNT (P<0.0001: r =0.665), phosphate (P<0.0001: r =0.262), PTH (P<0.0001: r =0.412) and urine protein amount (P<0.05:r=0.165) and negatively to eGFR (P<0.0001: r=-0.300), hemoglobin (P<0.0001: r=-0.323) and albumin (P<0.0001: r=-0.262). NTpro-BNP level in patients with heart failure was higher than in those without (P<0.0001). Furthermore, NTpro-BNP level elevated significantly according to the progression of CKD stage. However, TNT level elevated slightly according to the progression of CKD stage. Interestingly, NTpro-BNP and TNT level elevated early phase of CKD (stage 3) as compared with stage2 (P<0.01/ P<0.01). During the study period of 24 months observation, NTpro-BNP/TNT values inversely correlated with ΔeGFR in all the patients (P<0.01: r =-0.210/ P<0.01: r =-0.226).

Conclusions: In CKD patients, serum level of NT-proBNP/TNT inversely correlated with ΔeGFR. Thus, NT-proBNP/TNT might be an novel valuable biomarker to predict the prognosis of CKD patients.

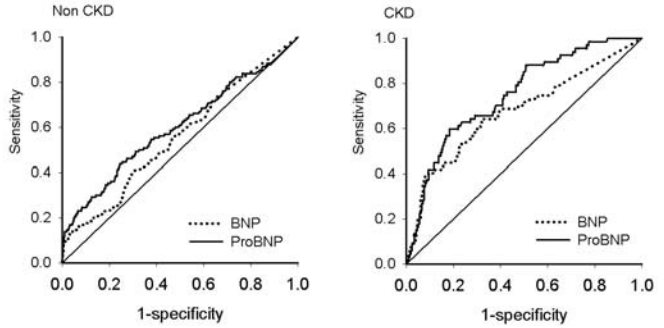
TH-PO679

CKD Modifies the Association of Brain Natriuretic Peptide (BNP) and N-terminal-pro-BNP (NT-pro-BNP) with Death Gates Colbert, Beverley Adams-Huet, Xilong Li, James Delemos, Susan Hedayati. *UT Southwestern, Dallas.*

Background: NT-pro-BNP and BNP are elevated in >50% of asymptomatic CKD patients. NT-pro-BNP has a longer $t_{1/2}$ and may be a better biomarker than BNP for risk assessment. We investigated if the association between BNP and NT-pro-BNP with death was modified by CKD in 3,303 Dallas Heart Study subjects free of CV disease and which natriuretic peptide was a better marker for death in CKD.

Methods: CKD was defined as eGFR<60 mL/min/1.73m^2 by MDRD or ACR ≥17 mg/g in men or ≥25 in women. Logistic regression determined the association between BNP and NT-pro-BNP with all-cause death at 7 years, adjusted for age, gender, race, diabetes, and hypertension. The interaction of CKD with biomarkers was tested. The area under the ROC curve (AUC) for each biomarker was compared for CKD versus non-CKD groups.

Results: Mean age was 44±10 years. 55% were female, 50% African American, 31% Caucasian, 17% Hispanic. 289 had CKD. 201 total deaths occurred. Proportion of deaths was higher if CKD versus no CKD, 23.5 versus 4.4%, p<.0001. Both markers were associated with death, main effect p<.0001; there was an interaction between BNP and CKD, p=.08, such that the OR for death per $\log_e$ unit BNP increase was significant for CKD, aOR 1.36 (1.15, 1.61), p=.0004, but not if no CKD, p=.07. The aOR of NT-pro-BNP per $\log_e$ unit increase for death were 1.40 (1.21, 1.63) if no CKD and 1.66 (1.36, 2.04) if CKD, interaction p>.1. The optimal NT-pro-BNP cutoff for death was 123 pg/mL if CKD versus 56 if no CKD. NT-pro-BNP was a superior marker for death than BNP in CKD (aAUC=0.81 versus 0.75, p=.008). The AUCs for BNP and NT-pro-BNP were not different if no CKD, p=.16.



Conclusions: CKD modifies the association of BNP with death. NT-pro-BNP is a superior marker than BNP for death in asymptomatic CKD patients. Future studies should confirm if NT-pro-BNP can be used as an early biomarker for risk stratification in CKD.

TH-PO680

Serum High-Sensitivity Troponin Concentrations in a Multi-Ethnic Asian Population of Stable Chronic Kidney Disease Patients Boon Wee Teo,[1] Titus W. Lau,[1] Qi Chun Toh,[1] Weng Kin Wong,[1] Sabrina Haroon,[1] Srinivas Subramanian,[1] Sunil Sethi.[2] *[1]Medicine, National Univ Health System, Singapore, Singapore; [2]Pathology, National Univ Health System, Singapore, Singapore.*

Background: Serum troponins may be elevated because of reduced glomerular filtration, reduced renal catabolism, and possibly subclinical myocardial injury as a result of volume overload in chronic kidney disease (CKD) patients. The statistical normal of new troponin assays in asymptomatic CKD patients is unknown. We determined levels of troponin-I (hsTnI) in stable CKD patients in a multi-ethnic Asian population using a high-sensitivity assay.

Methods: This is a prospective, observational, cohort study which recruited 465 stable CKD patients with >125 participants per estimated glomerular filtration rate (GFR) category (<30, 30 to 60, >60 mL/min/1.73m^2). Serum troponin I was measured using a high-sensitivity assay (Abbott Diagnostics). Analyses were performed using JMP.

Results: The median serum creatinine concentration was 137 µmol/L (IQR: 89 to 208), with an estimated GFR of 42 (25 to 73) mL/min/1.73m^2. The median serum hsTnI concentration was 5.5 ng/L (IQR: 3.46 to 9.18). The 90th, 97.5th, and 99.5th percentile observed values were 16.3, 40.1, and 119.8 ng/L, respectively. Serum hsTnI was lower in women than men (p <0.001). Seven patients were admitted to the hospital within 30 days after study recruitment (mean serum hsTnI = 10.1 ± 8.25 ng/L). Only 1 admission is cardiac-related. Reviewing the distribution of data and prior literature, the proposed serum hsTnI upper threshold should be taken at the 90th percentile level in CKD patients by GFR categories.

Table Quantiles of high-sensitivity troponin I.

GFR	Minimum	10%	25%	Median	75%	90%	Maximum
>60	1.1	2.1	2.6	3.5	5.1	7.2	25.7
30-60	1.1	2.9	3.9	5.9	8.9	16.2	140.4
<30	1.3	2.3	3.7	8.7	14.1	29.2	176.1

Conclusions: Patients with CKD represent a population with one of the highest risk for adverse cardiovascular events. Kidney dysfunction confounds the interpretation of serum troponin concentrations. To achieve clinical decision equipoise, we suggest taking the 90th percentile threshold for further evaluation of CKD patients presenting with possible acute coronary syndromes.

TH-PO681

The Association Between Uric Acid and the Rate of Kidney Function Decline in Stage III, IV, and V Chronic Kidney Disease Patients from the Swedish Renal Registry Hakan Nacak,[1] Merel Van Diepen,[1] Friedo W. Dekker,[1] Marie Evans,[2] Juan Jesus Carrero.[2] *[1]Dep. of Clinical Epidemiology, Leiden Univ Medical Center, Leiden, Zuid-Holland, Netherlands; [2]Div. of Renal Medicine, Karolinska Instt, Stockholm, Sweden.*

Background: Although many studies have shown an association between higher uric acid (UA) and both development of CKD and decline in renal function it is not clear whether this effect is consistent through the CKD stages. The aim of this study was to investigate the association between baseline UA and the rate of decline in renal function in stage III-V CKD patients as well as in stage III, IV, and V CKD patients, separately.

Methods: We analyzed data in the Swedish Renal Registry – Chronic Kidney Disease (SRR-CKD) which is a nationwide registry of referred CKD patients. Patients with a visit between January 1, 2005 and December 31, 2011 were followed until initiation of renal replacement therapy, death, or censoring. Change in renal function was assessed with a linear mixed model using all estimated glomerular filtration rate measurements (eGFR) recorded during median 28 months of follow-up, adjusting for important confounders such as demographic factors, primary renal disease, medication, diet, blood pressure, and body mass index.

Results: There were 2094 patients with a baseline UA measurement (mean (standard deviation (SD)) of 7.75 (1.93) mg/dl). The mean decline in renal function was -1.87 (95% CI -2.08; -1.67) ml/min/1.73m^2 per year. The overall adjusted change in the rate of decline in renal function associated with a unit increase in baseline UA was 0.10 (95% CI -0.03;0.22) ml/min/1.73m^2 per year, which corresponds to less decline. In stage III, IV, and V CKD patients the mean decline in renal function was -1.63 (95% CI -2.30; -0.96), -1.89 (95% CI -2.13;-1.66), and -1.57 (95% CI -1.91; -1.22) ml/min/1.73m^2 per year respectively. The adjusted change in the rate of decline in renal function associated with a unit increase in baseline UA was -0.11 (95% CI -0.4;0.19) in stage III CKD, 0.13 (95% CI 0.00; 0.26) in stage IV CKD, and -0.01 (95% CI -0.31; 0.29) in stage V CKD.

Conclusions: Uric acid is not associated with the rate of decline in renal function in stage III, IV, and/or V CKD patients.

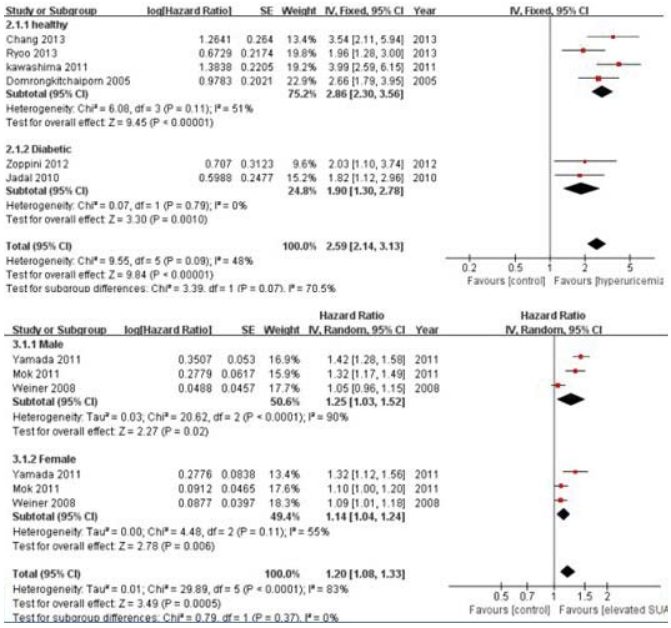
TH-PO682

Is Hyperuricemia an Independent Risk Factor for New-Onset Chronic Kidney Disease? A Systematic Review and Meta-Analysis Based on Observational Cohort Studies Ling Li, Fang Liu, Ping Fu. *Div of Nephrology Dept of Internal Medicine, West China Hospital of Sichuan Univ, China.*

Background: To assess whether an elevated serum uric acid level is an independent risk factor for new-onset chronic kidney disease (CKD).

Methods: A systematic review and meta-analysis using a literature search of online databases including PubMed, Embase, Ovid and ISI Web Web of Science was conducted. Summary adjusted odds ratios with corresponding 95% confidence intervals (95% CI) were calculated to evaluate the risk estimates of hyperuricemia for new-onset CKD.

Results: Thirteen studies containing 190,718 participants were included. A significant positive association was found between elevated serum uric acid levels and new-onset CKD at follow-up (summary OR, 1.15; 95% CI, 1.05-1.25). Hyperuricemia was found be an independent predictor for the development of newly diagnosed CKD in non-CKD patients (summary OR, 2.35; 95% CI, 1.59-3.46). This association increased with increasing length of follow-up. No significant differences were found for risk estimates of the associations between elevated serum uric acid levels and developing CKD between males and females.



Conclusions: With long-term follow-up of non-CKD individuals, elevated serum uric acid levels showed an increased risk for the development of chronic renal dysfunction.

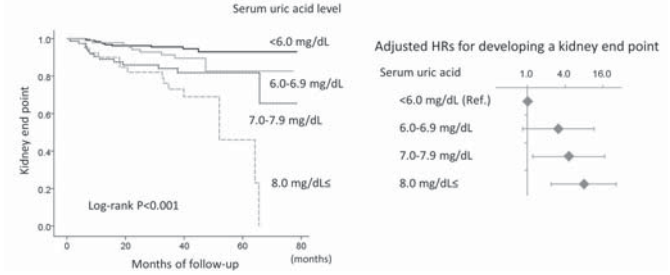
TH-PO683

Relationship between the Serum Uric Acid Level and Renal Progression in Patients with Chronic Kidney Disease: A Prospective, Observational Study Hiroshi Kimura, Kenichi Tanaka, Makoto Kanno, Kimio Watanabe, Yoshimitsu Hayashi, Hiroyuki Terawaki, Koichi Asahi, Masaaki Nakayama, Tsuyoshi Watanabe. *Nephrology and Hypertension, Fukushima Medical Univ, Fukushima, Japan.*

Background: Hyperuricemia is associated with the onset of chronic kidney disease (CKD) and is a risk factor for end-stage renal disease in the general population. However, data on the relationship between serum uric acid (UA) levels and the progression of renal disease in the CKD patient population are limited.

Methods: A prospective, observational study of 409 pre-dialysis patients with CKD was conducted to examine the association between the serum UA level and the progression of renal disease. The kidney end point was defined as a combination of doubling of baseline serum creatinine and end-stage kidney disease requiring kidney replacement therapy.

Results: The median eGFR was 55.8 (40.8-72.4) mL/min per 1.73 m^2, and the median serum UA was 6.0 (5.0-7.2) mg/dL. During a median follow-up period of 3.2 years, 46 (11%) participants reached the kidney end point.Kaplan-Meier curve analysis revealed that patients with a higher serum UA level reached the kidney end point more frequently than those with a serum UA level below 6.0 mg/dL. After adjustment for age, sex, body mass index, smoking history, diabetes, kidney function, hemoglobin, serum albumin, and proteinuria, the risk of developing a kidney end point was 24% higher per 1 mg/dL increase in the serum UA level (HR 1.24, 95% Confidence Interval 1.03-1.49, P=0.02). The risk was significant in patients with a serum UA more than 7 mg/dL in the Cox regression model using patients with serum UAless than 6.0 mg/dL as the reference group.



Conclusions: An independent, graded association was observed between an increased serum UA level and the risk of renal disease progression in pre-dialysis patients with CKD.

TH-PO684

Higher Uric Acid Is a Risk Factor for the Progression of IgA Nephropathy with CKD G3a Takahito Moriyama, Keiko Uchida, Kosaku Nitta. *Dept of Medicine, Kidney Center, Tokyo Women's MEdical Univ, Tokyo, Japan.*

Background: We have been reported 30 year prognosis of IgA nephropathy (IgAN) and higher uric acid (UA), lower estimated glomerular filtration rate (eGFR), and higher amount of proteinuria as independent risk factors to progress to end stage renal disease (ESRD) (ASN 2013, Plos one 2014; 9: e29976). However, it is still unclear the influence of higher UA in IgA nephropathy. Therefore, in this study, we investigated the details of influence of high UA in IgAN.

Methods: In 611 adult IgAN patients diagnosed at our institution between 1974 and 2005, we divided them into high UA group (HUA) and normal UA group (NUA) in each CKD stage (G1, G2, G3a, G3b and G4), and compared the clinical findings at renal biopsy, the histological findings according to the Oxford classification, and the renal survival rate.

Results: The ratio of HUA was increased with the progression of CKD stage [12.3% (HUA versus NUA=23 versus164) in CKD G1, 19.0% (52 versus 222) in G2, 43.7% (45 versus 58) in G3a, 69.0% (29 versus 13) in G3b+4]. Renal survival rate was similar in CKD G1, 2, and G3b+4. However, in CKD G3a, it was significantly lower in HUA than NUA (67.9 versus 89.7 % in 10 years, 49.5 versus 69.3 years in 20 years, and 24.7 versus 51.9 % in 30 years, P=0.0205). In CKD G3a, clinical findings without UA were similar between HUA and NUA, however the ratio of global sclerosis was significantly higher in HUA than NUA (33.3 versus 11.4 %, P=0.0005), though Oxford classification was similar between both groups. Multivariate Cox regression analysis indicated that higher UA (HR 1.36, 95%CI 1.07-1.72, P=0.011) and higher amount of proteinuria (HR 1.38, 95%CI: 1.09-1.74, P=0.0084) were independent risk factors for progression to ESRD in CKD G3a. These results indicated that higher UA induced glomerular impairment in addition to the renal impairment according to IgAN, and accelerated the progression to ESRD.

Conclusions: In IgAN patients with CKD G3a, glomerular impairment was resulted from not only IgA nephropathy but also high UA, and higher UA increased the risk to deteriorate renal function and progress to ESRD. In IgAN patients complicated with high UA, it may be important to control high UA before progress to CKD G3a.

TH-PO685

The Association between Serum Uric Acid, Genotypes of Uric Acid-Related Genes, and Mortality in the Community-Based Population: The Takahata Study Keita Kamei, Hiroko Sato, Atsushi Hirayama, Kazuko Suzuki, Kazunobu Ichikawa, Tsuneo Konta, Isao Kubota. *Dept of Cardiology, Pulmonology, and Nephrology, Yamagata Univ School of Medicine, Yamagata, Japan.*

Background: Serum uric acid is regulated by gender, dietary habit, genetic predisposition and renal function, and is associated with renal and cardiovascular outcomes. This study prospectively investigated the association between serum uric acid, genotypes of uric acid-related genes, and mortality in the community-based population.

Methods: The participants of this study were 3479 subjects (male 45%, mean age 63 years) in Takahata town, Japan, that were registered and followed up for 7 years (median 6.7 years). The single nucleotide polymorphisms of uric acid-related genes including URAT1 (rs505802), ABCG2 (rs2231142), UMOD (4293393) and SLC2A9 (rs16890979) were genotyped.

Results: During the follow-up 142 subjects died, including 30 cardiovascular deaths. Kaplan-Meier analysis showed that all-cause mortality was significantly increased along with the increase in serum uric acid at baseline in females (Log-rank P <0.001), but not in males (P = 0.774). Cox proportional hazard model analysis with the adjustment for possible confounders including age, renal function and comorbidities showed that hyperuricemia (uric acid ≥ 7.0 mg/dL) was an independent risk factor for all-cause and cardiovascular mortalities in females (hazard ratio [HR] 5.56, 95% confidence interval [CI] 1.89-16.3 for all-cause mortality, and HR 18.4, 95%CI 1.68-201.3 for cardiovascular mortality), but not in males. The genotypes of URAT1, ABCG2, and UMOD that modulate urinary excretion of uric acid were independently associated with serum uric acid levels and all-cause mortality, after the adjustment for confounders.

Conclusions: Hyperuricemia was an independent risk for all-cause and cardiovascular mortalities in females in community-based population and the genetic variants of uric acid-related genes were significantly associated with serum uric acid levels and mortality.

TH-PO686

Urinary iC3b Detected at Baseline Independently Predicts Loss of Kidney Function in Stage 3 Chronic Kidney Disease Girish N. Nadkarni,[1,2] Avelino Teixeira,[1,2] Stefano Malerba,[1] Josef Coresh,[2] Chi-Yuan Hsu,[2] Kathleen D. Liu,[2] Joseph V. Bonventre,[2] Harold I. Feldman,[2] Vasan S. Ramachandran,[2] John W. Kusek,[2] Paul L. Kimmel,[2] Emilia Bagiella,[1,2] Erwin P. Bottinger.[1,2] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]CKD Biomarker Consortium, NIDDK, Bethesda, MD.*

Background: We showed significant inverse associations between urine complement fragments C3a, C5b-9 and iC3b and eGFR cross-sectionally (Abstract#1512, ASN 2013). We examined whether these predict CKD progression.

Methods: The three urinary markers were measured in anonymized residual urine specimens from tests ordered in routine clinical care using modified ELISA assays (Quidel® Corp, San Diego, CA). We studied 151 stage 3 CKD patients whose CKD-EPI eGFR was measured at baseline and at six-months intervals over 18 months.

Results: Mean age: 65 years, female: 52%, diabetic: 54% and hypertensive: 88% of patients. Baseline eGFR: 44 ml/min/1.73m^2. Mean (SD) loss of eGFR (ΔeGFR) during follow-up remained significantly increased in patients with detectable markers after adjustment for age, gender, race/ethnicity, diabetes, and hypertension.

Mean (SD) ΔeGFR ml/min/ 1.73m²	Det C3a 76 (51%)	No C3a 58(38%)	Det C5b-9 58 (38%)	No C5b-9 93(62%)	Det ic3b 80 (53%)	No ic3b 71(47%)
6 months	-3.6(6)	-0.1(4.5)*	-2.95(6.02)	1.28(5.28)	-3.83(5.53)	0.36(4.90)*
12 months	-5(7.9)	-1.5(7.9)*	-5.38(7.77)	-2.51(6.81)^	-6.21(7.44)	-0.68(5.97)*
18 months	-8.1(10.1)	-1.5(7.1)*	-7.94(1.42)	-2.5(8.16)^	-8.79(9.77)	-0.40(6.31)*

Table 1: eGFR change at 6,12 and 18 months after sample collection in patients with detectable(det) and undetectable(no) urinary C3a, C5b-9, or iC3b(n=151) ^P value<0.05; * P value<0.01

Baseline urine protein creatinine ratio attenuated C3a and C5b-9, but iC3b marker remained significant (coefficient (95% CI) of -2.78(-4.5 to -1.0), -3.89(-6.2 to -1.6), -6.41(-9.3 to -3.5) at 6,12,18 months). eGFR decline over 18 months was significantly higher in patients with detectable ic3b compared to undetectable (-8.7 versus-1 ml/min/1.73m²).

Conclusions: Presence of complement fragment iC3b in urine of stage 3 CKD patients predicts loss of eGFR independent of proteinuria.

TH-PO687

A Novel Urinary Epigenetic Marker 5'-Methyl-2'-Deoxycytidine in Combination with Albuminuria Significantly Predicts the Renal Outcome in Patients with Chronic Kidney Disease

Akifumi Onishi, Hitoshi Sugiyama, Toshio Yamanari, Ayu Akiyama, Masashi Kitagawa, Hiroshi Morinaga, Keiko Tanaka, Yoko Kikumoto, Tatsuyuki Inoue, Yohei Maeshima, Jun Wada. *Dept of Medicine and Clinical Science, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Epigenetic risk factors for chronic kidney disease (CKD) have only recently been investigated (Epigenetics 2014), and the DNA methylation profile in the blood may be associated with a rapid decline in the renal function (Nephrol Dial Transplant 2014). However, there is no current information available regarding the urinary levels of 5'-methyl-2'-deoxycytidine (5MedCyd), a marker of DNA methylation, in patients with CKD.

Methods: We determined the levels of urinary 5MedCyd in spot urine samples from 512 patients with CKD (median age: 52.4 years, male: 54.0%, glomerulonephritis: 50.0%) using a competitive ELISA and investigated the relationships among 5MedCyd, eGFR, albuminuria, urinary α1-microglobulin (α1MG) and urinary 8-hydroxy-2'-deoxyguanosine (8-OHdG), a marker of oxidative stress. The patients were prospectively followed for three years for doubling of the baseline serum creatinine level and the initiation of renal replacement therapy.

Results: The urinary 5MedCyd levels were significantly decreased in the patients with CKD stage G3 (p=0.031), and this parameter was found to be a significant predictor of CKD G3 in a multiple logistic regression analysis (P = 0.019). The urinary 5MedCyd level significantly correlated with the urinary 8-OHdG level (P < 0.0001), but not albuminuria or the urinary α1MG level. A Kaplan-Meier analysis demonstrated that the patients with a higher urinary 5MedCyd level in combination with macroalbuminuria (log-rank, P < 0.001) or a high α1MG level (log-rank, P < 0.001), had a significantly worse renal prognosis. In addition, the urinary 5MedCyd level was found to be significantly associated with renal endpoints in a multivariate Cox proportional hazard model (P = 0.027).

Conclusions: The present data indicate that the urinary 5MedCyd level in combination with albuminuria or the α1MG level can serve as a novel biomarker to predict the renal outcome in CKD patients.

TH-PO688

Shear Wave Elastography in Chronic Kidney Disease: A Novel Noninvasive Ultrasound Technique as a Marker for Renal Fibrosis

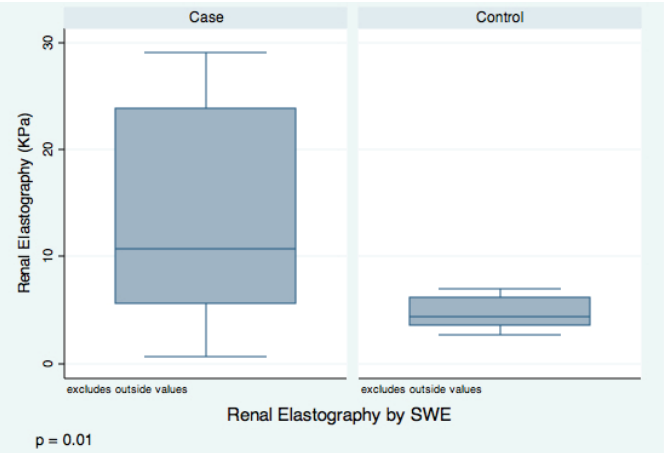
Andrew S. Allegretti,[1] Anthony Samir,[2] Qingli Zhu,[2] Manish Dhyani,[2] Dorothy A. Dobens,[1] Caitlin A. Trottier,[1] Winfred W. Williams,[1] Jodie L. Babitt,[1] Ravi I. Thadhani,[1] Herbert Y. Lin.[1] *[1]Div of Nephrology, Massachusetts General Hospital, Boston, MA; [2]Dept of Radiology, Massachusetts General Hospital, Boston, MA.*

Background: Intrarenal fibrosis is a final common pathway for all chronic kidney disease (CKD). Currently, invasive renal biopsy is the only method to quantify degree of fibrosis. Shear wave elastography (SWE) uses focused acoustic energy pulses to quantify fibrosis via microscopic tissue displacement. SWE is approved for use in staging liver fibrosis and may have a role in measuring fibrosis in CKD.

Methods: Participants with CKD and healthy volunteers underwent SWE imaging. Renal elasticity was estimated as Young's modulus in kilopascals (kPa), where higher values represent stiffer tissue.

Results: Fourteen participants with CKD (median GFR 41.5 mL/min, IQR 38-54) and 19 controls without CKD underwent SWE performed by a single radiologist. Presence of CKD was associated with higher renal elasticity (10.70 KPa, IQR 9.27-11.14 versus 4.40 KPa, IQR 3.55-6.20; p = 0.01).

	Case (n = 14)	Control (n = 19)
Age (years)	61.44 (56-71.6)	33.96 (29.9-49.2)
Male	8 (57%)	5 (26%)
Non-Hispanic	10 (71%)	18 (95%)
Hispanic	4 (29%)	1 (5%)
White	12 (86%)	14 (74%)
Other Race	2 (14%)	5 (26%)
BMI (kg/m²)	25.3 (24.2-25.6)	23.3 (21.8-23.9)
GFR (mL/min) by MDRD	41.5 (38-54)	
Kidney Size (cm)	10.48 (9.27-11.14)	10.43 (10.1-11)
CKD Stage 2	1 (7%)	
CKD Stage 3	11 (79%)	
CKD Stage 4-5	2 (14%)	



Conclusions: SWE estimates of renal stiffness are higher in patients with CKD than in healthy controls. Preliminary data suggests SWE measurement of renal fibrosis is a promising new non-invasive tool for the detection and staging of CKD. Further study is needed to delineate the correlation between this imaging technique and CKD stage measured by biopsy or serum fibrosis markers.

Association between Endothelin-1 Levels and Reduced Kidney Function among African-Americans: Jackson Heart Study

C. Rebholz,[1] Jane L. Harman,[2] M. Grams,[1] Daichi Shimbo,[3] Bessie A. Young,[4] Josef Coresh.[1] *[1]Johns Hopkins Univ; [2]National Heart, Lung, and Blood Inst; [3]Columbia Univ Medical Center; [4]Univ of Washington.*

Background: Endothelin-1, a marker of endothelial dysfunction, is a potent vasoconstrictor released by endothelial cells and is an important regulator of renal physiology. However, the prospective relation between endothelin-1 and kidney function is not well characterized in the general population.

Methods: Jackson Heart Study is a community-based observational study of African-American adults in the Jackson, MS metropolitan area. Serum endothelin-1 was measured at baseline (2000-04; N=5,200). CKD-EPI estimated glomerular filtration rate (eGFR) was calculated at baseline and visit 3 (2009-13). Among those with baseline eGFR≥60 mL/min/1.73 m², incident chronic kidney disease (CKD) was defined conservatively as the development of eGFR<60 mL/min/1.73 m² accompanied by 25% eGFR decline from baseline. Logistic regression were used to estimate the relation between endothelin-1 and kidney function, adjusting for age, sex, body mass index, smoking, hypertension, diabetes, high density and total cholesterol, history of cardiovascular disease, hematocrit, and C-reactive protein.

Results: Among study participants at baseline, mean age was 55 years, 37% were male, and median eGFR was 96 mL/min/1.73 m². At baseline, reduced eGFR (<60 mL/min/1.73 m²) was more prevalent among participants with higher quartiles of endothelin-1 (3.8%, 5.5%, 5.9%, 10.9%, for quartiles 1-4, respectively, p<0.001). This association persisted after adjusting for multiple covariates. During a median follow-up of 12 years, there were 266 incident CKD cases (7.5%). CKD incidence was higher among those with higher quartiles of baseline endothelin-1 (quartile 4 versus 1, OR: 1.83, 95% CI: 1.19, 2.82). After adjusting for multiple covariates and baseline eGFR, one standard deviation higher baseline endothelin-1 was associated with elevated risk of incident CKD (OR: 1.20, 95% CI: 1.06, 1.36).

Conclusions: Baseline serum endothelin-1 is independently associated with contemporaneous kidney function as well as kidney disease progression, which has not been previously reported in the general population.

Funding: Other NIH Support - NHLBI

TH-PO690

Change in Novel Kidney Filtration Markers and Risk of Cardiovascular Disease and Mortality C. Rebholz, M. Grams, Kunihiro Matsushita, Elizabeth Selvin, Josef Coresh. *Johns Hopkins Univ, Baltimore, MD.*

Background: Kidney disease progression, assessed by change in estimated glomerular filtration rate based on creatinine (eGFR-Cr), is a strong risk factor for cardiovascular disease and death. The associations of change in novel filtration markers with these outcomes are uncharacterized.

Methods: Creatinine, cystatin C, and β_2-microglobulin were measured among 9,716 ARIC Study participants in 1990-92 and 1996-98. Cardiovascular events (coronary heart disease, stroke, heart failure) and deaths were ascertained from 1996-98 through 2011.

Results: During a median follow-up of 14 years, there were 1,922 incident cardiovascular events and 2,285 deaths. Substantial decline in filtration markers (<-30%) was significantly associated with two-fold increased risks of cardiovascular disease and all-cause mortality.

Table. Adjusted* Hazard Ratios (95% Confidence Intervals) for Cardiovascular Disease and All-Cause Mortality by Change in Filtration Markers

	Category of Percent Change in Filtration Marker			
Filtration Marker	< -30%	-30% to -10%	-9% to +9%	≥ +10%
Cardiovascular Disease (1,922/9,712)				
eGFR-Cr	**2.02 (1.75, 2.33)**	1.07 (0.96, 1.18)	1 [Ref]	1.15 (0.92, 1.43)
eGFR-Cystatin C	**1.75 (1.48, 2.06)**	**1.16 (1.05, 1.28)**	1 [Ref]	1.18 (0.99, 1.40)
1/β_2-Microglobulin	**2.13 (1.80, 2.51)**	**1.31 (1.19, 1.45)**	1 [Ref]	1.14 (0.98, 1.33)
All-Cause Mortality (2,285/9,716)				
eGFR-Cr	**1.92 (1.68, 2.19)**	1.05 (0.96, 1.15)	1 [Ref]	1.03 (0.84, 1.28)
eGFR-Cystatin C	**2.33 (2.03, 2.68)**	**1.17 (1.07, 1.29)**	1 [Ref]	**1.30 (1.11, 1.52)**
1/β_2-Microglobulin	**2.56 (2.20, 2.93)**	**1.28 (1.16, 1.40)**	1 [Ref]	1.03 (0.88, 1.20)

Bold font indicates statistical significance.
*Adjusted for age, sex, race, body mass index, systolic blood pressure, anti-hypertensive medication use, diabetes status, total and high-density lipoprotein cholesterol, smoking status, 1st eGFR-Cr measurement

Conclusions: Kidney disease progression assessed using change in novel filtration markers is independently associated with risk of cardiovascular disease and death, as we have previously shown for risk of end-stage renal disease. Interventions aimed at stabilizing kidney function may reduce future risk of cardiovascular morbidity and mortality.

Thyroid Hormones and Kidney Function in a Community-Based Population Ulla T. Schultheiss,[1] M. Grams,[2,3] Josef Coresh,[3] Michael Steffes,[4] Elizabeth Selvin,[3] Anna Kottgen.[1,3] *[1]Dept of Medicine IV, Nephrology and Primary Care, Medical Center - Univ of Freiburg, Freiburg, Baden-Württemberg, Germany; [2]Div of Nephrology, Johns Hopkins Univ, Baltimore, MD; [3]Welch Center for Prevention, Epidemiology and Clinical Research, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [4]Dept of Laboratory Medicine and Pathology, Univ of Minnesota Medical School, Minneapolis, MN.*

Background: Patients with reduced estimated glomerular filtration rate (eGFR) have higher prevalence of subclinical/overt hypothyroidism. Little is known about the cross-sectional association of kidney function with individual markers of thyroid function: thyrotropine(TSH), free thyroxine (FT4), thyroid peroxidase antibodies (TPOAb), and, in particular, triiodothyronine (T3).

Methods: We tested the association of thyroid markers and eGFR <60 ml/min/1.73 m^2 at visit 2 (1990-92) in the Atherosclerosis Risk In Communities (ARIC) study, a prospective cohort study in four U.S. communities. Multiple logistic regression models adjusting for age, sex, race-site, CRP, smoking, serum albumin and BMI were run for each thyroid marker individually and in combination.

Results: Median and IQR(p75-p25) were: TSH (mIU/L 1.8, 1.44), FT4 (ng/dL 1.11, 0.21), T3 (ng/dL 126.2, 27.7), TPOAb (IU/mL 10.24, 8.38). Higher TSH, FT4 and lower T3 were significantly associated with eGFR<60 ml/min/1.73m^2 individually and in combination, with little variation in the effect size.

OR for eGFR<60 (95% CI)**	Q1 (lowest)	Q2	Q3	Q4 (highest)	p-trend
TSH	1 (ref)	1.61 (1.06-2.45)*	1.60 (1.06-2.43)*	2.52 (1.68-3.78)*	p<0.001
FT4	1 (ref)	1.00 (0.67-1.48)	1.04 (0.70-1.56)	2.54 (1.79-3.63)*	p<0.001
T3	1 (ref)	0.48 (0.35-0.67)*	0.38 (0.26-0.54)*	0.17 (0.11-0.27)*	p<0.001
TPOAb	1 (ref)	1.15 (0.79-1.67)	1.19 (0.81-1.75)	1.11 (0.75-1.63)	0.47
*p<0.05** Multiple logistic regression including all thyroid markers					

Conclusions: Higher TSH, FT4 and T3 were strongly and independently associated with reduced kidney function in this cross-sectional, population-based study. Our results warrant the evaluation of a full panel of thyroid markers as risk factors for incident kidney disease.

Urine Metabolomics in Patients with Nephrosclerosis Marius Altern Øvrehus,[1,2] Stein I. Hallan.[1,2] *[1]Dept of Cancer Research and Molecular Medicine, Norwegian Univ of Science and Technology, Trondheim, Norway; [2]Dept of Nephrology, St. Olavs Hospital, Trondheim Univ Hospital, Trondheim, Norway; [3]Dept of Biotechnology, Norwegian Univ of Science and Technology, Trondheim, Norway.*

Background: Nephrosclerosis (NS) is one of the most common causes of end stage renal disease but still one of the least studied. Urine metabolomics could potentially be useful to characterize the pathophysiology and prognosis in NS.

Methods: Frozen urine samples from 150 NS patients and 70 healthy controls (mean age 67.5 versus 59.5 years, mean eGFR 64.9 versus 83.2 mL/min/1.73m^2) from the HUNT 3 Study (2006-08, Norway) were analyzed. Nephrosclerosis was defined as eGFR <60 or a loss of >20 mL/min/1.73m^2 over 10 years, with at least 10 years of hypertension, and no diabetes, hematuria or proteinuria. Samples were diluted 1:3 with water, spun through a 3K Da filter, and analyzed non-targeted with liquid chromatography-mass spectrometry (LC-MS) in negative and positive electrospray ionization (ESI) mode.

Results: Raw LC-MS data were processed using Transomics software. 953 compounds were retrieved for analysis. Some metabolites in NS patients with eGFR <60 were over-expressed (47 compounds over 4-fold increased) and some were under-expressed (25 compounds over 4-fold decreased) compared to controls (figure 1). Metabolite identities were not ascertained. Principal component analysis explained only 34% of the total variance. In NS patients with rapid versus slow decline in kidney function (more versus less than 25 mL/min/1.73m2 over 10 years), 7 and 32 compounds were over 4-fold increased and decreased, respectively.

Conclusions: Non-targeted urine metabolomics analysis showed no global metabolite differences in nephrosclerosis patients versus healthy controls. However, large abundance differences were found in some metabolites, indicating a possibility for further characterization of nephrosclerosis.

Symmetric Dimethylarginine's Predictive Role in Chronic Kidney Disease Progression in Children Ellen Brooks,[1,2] Shannon Haymond,[1,2] Rod Passman,[1] Alfred Rademaker,[1] Irene Helenowski,[1] Susan L. Furth,[3] Bradley A. Warady,[4] Craig B. Langman.[1,2] *[1]Feinberg School of Medicine, Northwestern Univ, Chicago, IL; [2]Ann & Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [3]Children's Hospital of Philadelphia, Philadelphia, PA; [4]The Children's Mercy Hospital, Kansas City, MO.*

Background: The rate of CKD progression in children is not fully explained by traditional markers. Methylated arginine (Arg) derivatives (MADs), non-traditional biomarkers, may provide such data in children due to MADs relationship with inhibition of eNOS and NO synthesis.

Methods: Plasma specimens from the baseline (BL) visit were provided by the "Chronic Kidney Disease in Children" (CKiD), an observational cohort study of children with CKD, and analyzed for asymmetric dimethylarginine (ADMA), symmetric DMA (SDMA), and Arg using HPLC-Tandem Mass Spectrometry. We used CKiD data, including directly measured GFR (mGFR) by plasma iohexol clearance (iCL) to assess the contribution of individual MADs as independent predictors and/or co-contributors with traditional markers for rapid CKD progression in multivariate models.

Results: Multivariate modeling was performed in N=288, with mGFR=46.9±18.2 ml/min/1.73m^2 and CKD vintage=3.6±4.7 yrs. SDMA and its ratios were strong predictors for mGFR change (Δ), obtained by iCL at BL and 6-12 mos. later. Partial correlations (ρ) were seen between SDMA, SDMA/ADMA, SDMA/Arg and mGFR Δ, after adjusting for BL mGFR: ρ=-0.24; p<0.001; ρ=-0.28; p<0.001; and ρ=-0.16; p=0.007, respectively. However, inclusion of other covariates into the model: BP index, CKD vintage, Tanner, Ht. and Wt. did not result in improvement of the prediction model beyond BL mGFR.

Conclusions: SDMA and its ratios were predictive of mGFR declines over 6-12 mos. in children and adolescents with CKD. Prospective analyses to define its significance in rapid CKD progression continue.

TH-PO694

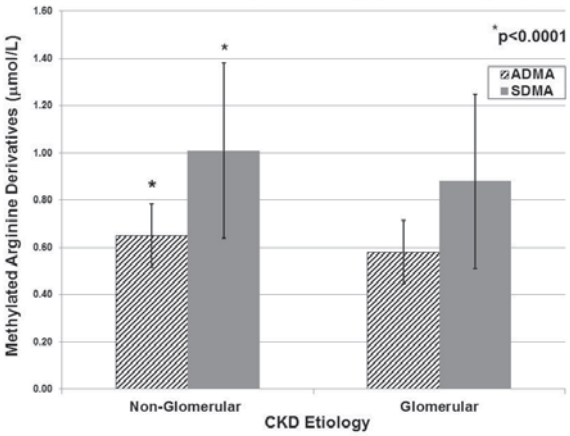
Methylated Arginine Derivative Concentrations Differ Between Non-Glomerular and Glomerular Chronic Kidney Disease in Children Ellen Brooks,[1,2] Shannon Haymond,[1,2] Rod Passman,[1] Irene Helenowski,[1] Alfred Rademaker,[1] Susan L. Furth,[3] Bradley A. Warady,[4] Craig B. Langman.[1,2] *[1]Feinberg Medical School, Northwestern Univ, Chicago, IL; [2]Ann & Robert H Lurie Children's Hosp. of Chicago, Chicago, IL; [3]Children's Hosp. of Philadelphia, Philadelphia, PA; [4]Children's Mercy Hosp., Kansas City, MO.*

Background: CKD GFR decline contributes to an imbalance of circulating methylated arginine (Arg) derivatives (MADs). Decreased asymmetric dimethylarginine (ADMA) catabolism is coupled to renovascular resistance and other pathology, denoting risk for end-organ damage, while symmetric DMA (SDMA) may augment inflammation as GFR declines. Our goal was to establish whether MADs concentrations differ in children and adolescents by their CKD etiology.

Methods: Baseline (BL) visit plasma was provided by the "Chronic Kidney Disease in Children" (CKiD) observational cohort study of children with CKD. Cohort etiology was categorized as non-glomerular (NG) versus glomerular (G). LC-MS/MS analyses for ADMA, SDMA, and Arg and comparison between cohorts using a Wilcoxon Rank-Sum test were completed. Directly measured GFR data (mGFR by plasma iohexol clearance) were similarly tested.

Results: 573 specimen results established that NG subjects had higher ADMA, SDMA, Arg/ADMA (p=0.003) and Arg/SDMA (p=0.002) ratios versus G (figure 1), whereas no difference was found between their BL mGFR (NG=48.8±18.4; G=53.7±25.7 ml/min/1.73m^2). However, the mGFR of NG and G subjects each had large standard deviations.

Figure 1. ADMA and SDMA By CKD Etiology (N=573; Mean±S.D.).



Conclusions: NG related CKD is mainly associated with congenital anomalies and reflux related infections, inflammation and renal scarring. Although, no BL mGFR cohort difference was found, it is possible that protracted infection from chronic bacterial colonization, monocyte migration, cytokine/chemokine upregulation, and oxidative stress may lead to higher MADs levels in NG versus G subjects.

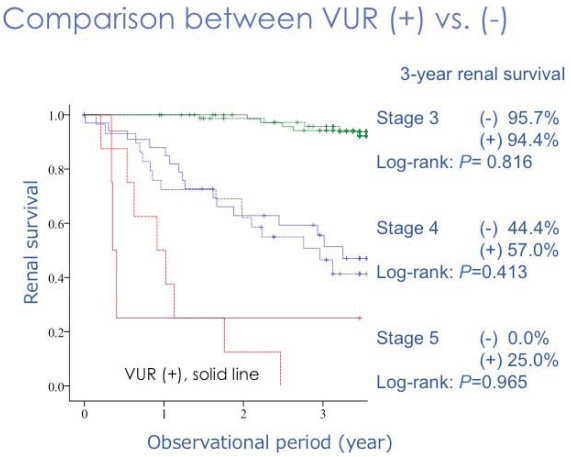
TH-PO695

Impact of Vesicoureteral Reflux on the Progression of Chronic Kidney Disease in Children: Results of a Nationwide Prospective Cohort Study in Japan Kenji Ishikura, Osamu Uemura, Yuko Hamasaki, Hideo Nakai, Shuichi Ito, Motoshi Hattori, Yasuo Ohashi, Ryojiro Tanaka, Koichi Nakanishi, Ryoko Harada, Tetsuji Kaneko, Masataka Honda. *The Pediatric CKD Study Group in Japan.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT), particularly hypoplastic and dysplastic kidneys, are frequent in children with advanced chronic kidney disease (CKD). However, little is known about the effects of vesicoureteral reflux (VUR), a frequent complication of hypoplastic and dysplastic kidneys, on the progression to end-stage kidney disease (ESKD) in such children.

Methods: In 2,010, we started a nationwide prospective study of our established cohort of 447 Japanese children (aged 3 months to 15 years) with stage 3–5 CKD. In the present study, 278 children with CAKUT as a primary etiology of CKD were divided into those with or without VUR. We compared the progression to ESKD between these groups.

Results: VUR was present in 117/278 children, of which 59 had bilateral severe (grade III or worse) VUR. The distributions of CKD stages and age were similar in both groups. The proportion of boys was higher, and more patients had hydronephrosis, megaureter, bladder dysfunction, or posterior urethral valves in the VUR-positive group (all, p<0.001; χ^2 test). However, the 3-year survival rates in each CKD stage did not differ between the two groups.



Multivariate analysis using Cox's proportional hazards model revealed that higher age and greater CKD stage were the only risk factors for progression to ESKD, and that VUR did not contribute to the progression to ESKD.

Conclusions: This 3-year prospective cohort study of children with CKD caused by CAKUT revealed significant differences in the sex distribution and rates of complicated urinary abnormalities between children with or without VUR. However, the presence of VUR did not influence progression to ESKD in these children.

Mortality and Renal Insufficiency among Children with Posterior Urethral Valve, a Longitudinal PHIS Study Vaka Kristin Sigurjonsdottir,[1] Katherine W. Herbst,[2] Cynthia J. D'Alessandri,[3] John H. Makari,[2] Vaka Kristin Sigurjonsdottir.[3] *[1]Univ of Connecticut; [2]Div of Urology; [3]Div of Nephrology, Connecticut Children´s Medical Center, Hartford, CT.*

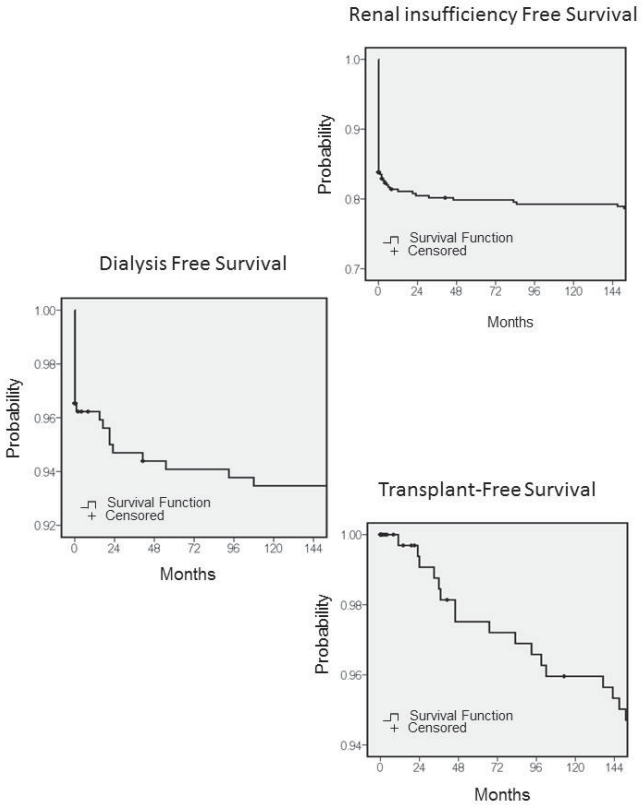
Background: The aim of this study was to determine mortality and estimated time to renal insufficiency, dialysis, or kidney transplant among a large cohort diagnosed with PUV in the neonatal period.

Methods: The Pediatric Health Information System (PHIS) database was searched for inpatient records of neonates admitted ≤30 days of life between 1/1/1992 - 12/31/1999 with an ICD-9 Diagnosis code for PUV (753.6). The database was then searched forward to 12/31/2013, and mortality based on discharge disposition, and all events based on ICD-9 code identified. Events were; renal insufficiency defined as Diagnostic codes 584.8, 584.9, 585, 585.5, 585.6, 585.9, 586; dialysis defined as Procedure codes 38.95, 39.95, 54.98, and transplant defined as Procedure codes 55.6, 55.61, 55.69. Kaplan-Meyer survival analysis was performed on time to first event using a proxy for follow-up of date of birth to study end date.

Results: A total of 346 neonates were identified, with median age at admittance of 2 days. Proxy follow-up was 14 – 22 years. Twenty (5.8%) expired during their neonatal hospitalization at a median age of 2.5 days (range 0-259). Three children expired after their neonatal admission (0.8%) due to renal failure at a median age of 4.12 years (range 14-113

mos). Seventy-eight (22.5%) reported renal insufficiency, 26 (7.5%) underwent dialysis, and 22 (6.4%) underwent transplant. Survival curves show most events, except transplant, occurred within the first 2 years of life (Fig 1).

Fig 1. 12 Year Event-Free Survival from Date of Birth to First Event (Censored for Mortality and Follow-up Duration)



Conclusions: In this cohort, incidence of renal insufficiency was substantial among patients with PUV despite early diagnosis and management. Transplant within this cohort appeared to be a delayed occurrence.

TH-PO697

The Associations of Perinatal Maternal and Offspring Health with Kidney Function in Young Adult Offspring Christine W. Hsu,[1] Jonathan Himmelfarb,[1] Bryan R. Kestenbaum,[1] Hagit Hochner,[2] Yechiel Friedlander,[2] David Siscovick.[3] *[1]Medicine/Nephrology - Kidney Research Inst, Univ of Washington, Seattle, WA; [2]Braun School of Public Health, Hebrew Univ, Jerusalem, Israel; [3]New York Academy of Medicine, New York, NY.*

Background: Prenatal factors including maternity obesity and low birth weight are associated with chronic kidney disease (CKD) in children. The extent to which prenatal risk factors impact adult kidney function is unclear.

Methods: We studied 1376 offspring who enrolled in the Jerusalem Perinatal Study between 1974-1976 and returned for a follow-up examination at a mean age of 32 years. Offspring were all born after a full term pregnancy (>36 weeks) and were free of congenital malformations. We measured serum creatinine and cystatin C in adult offspring and estimated the glomerular filtration rate (eGFR) using the combined CKD Epidemiology-Collaboration (CKD-EPI) equation. We used linear regression to determine associations of maternal pre-pregnancy body mass index (ppBMI), gestational weight gain (GWG), and birth weight (BW) with young adult offspring eGFR, adjusting for potential confounders.

Results: Mean eGFR in young adult offspring was 114.3 ml/min/1.73m^2 (interquartile range 107.2, 122.0 ml/min/1.73m^2). The lowest eGFR was 65.4 ml/min/1.73m^2 After adjustment for offspring gender, ethnicity, parental smoking status, socioeconomic status, maternal comorbidities, maternal age, and parity each 5 kg/m^2 higher maternal ppBMI was associated with an estimated 0.45 ml/mi/1.73m^2 greater eGFR (95% CI -0.87, 1.77). Each 5 kg greater maternal GWG and 500 g greater BW were associated with an estimated 0.25 ml/min/1.73m^2 lower (95% CI -1.38, 0.89) and 0.06 ml/min/1.73m^2 greater (95% CI -0.85, 0.96) eGFR in adult offspring, respectively. Null associations were similar for eGFR based on only creatinine or only cystatin C. Associations did not differ by strata of offspring BMI.

Conclusions: Maternal ppBMI, GWG, and birth weight are not associated with estimated GFR in young adult offspring with a history of full-term gestation. Confidence intervals from these analyses exclude large effects of maternal pregnancy factors on estimated kidney function in young adult offspring.

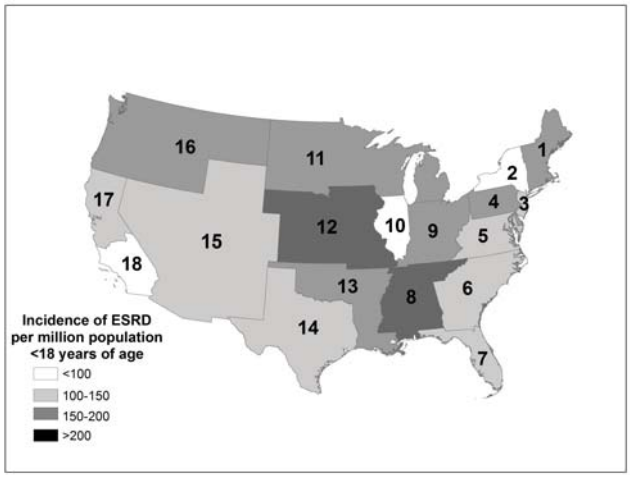
TH-PO698

Geographic Variation in Pediatric End-Stage Renal Disease Incidence Sandra Amaral,[1] Laura Plantinga,[2] Rachel E. Patzer.[3] *[1]Pediatrics, The Children's Hosp of Phila, Phila, PA; [2]Rollins School of Public Health, Emory Univ, Atlanta, GA; [3]Emory Transplant Center, Emory Univ, Atlanta, GA.*

Background: Geographic variation in end-stage renal disease (ESRD) is well-recognized in adults, with the highest rates in the southern and middle Atlantic United States (U.S.). The causes of renal disease differ substantially in children versus adults, with a significant proportion of children having congenital anomalies of the kidneys and urinary tract (CAKUT). We explored whether incidence and etiology of pediatric ESRD vary by U.S. region.

Methods: We identified all incident ESRD patients (2000-2011) <18 years of age in the United States Renal Data System (USRDS) data. We calculated pediatric ESRD incidence by dividing the number of pediatric ESRD patients across the 18 ESRD Network regions by the number of children <18 years within those regions (using census data). We examined geographic variation across the Network regions by etiology of pediatric ESRD (CAKUT, glomerulonephritis, FSGS, lupus, other).

Results: Pediatric ESRD incidence varies across ESRD Network regions, from 71.6 cases per million population (pmp) in Network 18 (S. CA) to 223.3 cases pmp in Network 12 (IA, KS, MO, NE).



ESRD Incidence was highest overall for CAKUT (133.3 pmp) and lowest for lupus (107.6 pmp). Significant geographic variation in disease etiology is observed across Networks (p<0.001), with pediatric ESRD incidence due to CAKUT being highest in Network 8 (AL, MS, TN) and lowest in Network 18 (92.5 versus 24.0 pmp), and incidence due to lupus highest in Network 7 (FL) and lowest in Network 16 (AK, WA, OR, ID, MT) (10.7 versus 1.4 pmp).

Conclusions: There is substantial geographic variation in ESRD incidence and etiology in the U.S. Further studies are needed to explain whether these findings are due to variations in demographics (such as race/ethnicity) or environmental exposures.

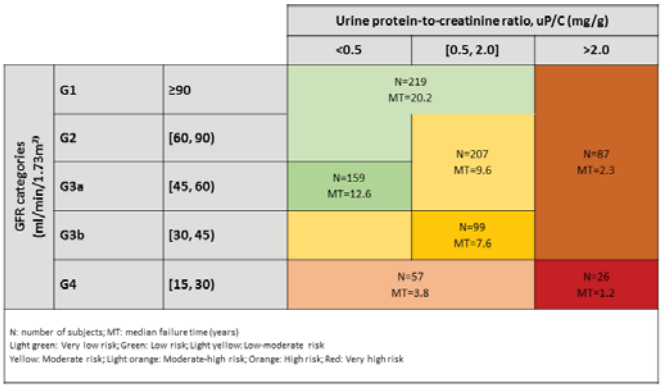
TH-PO699

KDIGO eGFR/Proteinuria Category and Risk in the Chronic Kidney Disease in Children (CKiD) Study Wun Fung Hui,[1,2] Christopher B. Pierce,[2] Alison G. Abraham,[2] Bradley A. Warady,[2] Colin T. White,[2] Susan L. Furth.[1,2] *[1]Dept of Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA; [2]The Chronic Kidney Disease in Children (CKiD) Study Investigators.*

Background: Current KDIGO guidelines suggest incorporating albuminuria/proteinuria with eGFR and underlying disease in classifying and prognosticating patient outcome(s). Using CKiD study data we assessed risk of chronic kidney disease (CKD) progression in children.

Methods: Subjects were classified into 5 categories of eGFR and 3 ranges of proteinuria (table). Prognosis was determined by time (from baseline) to development of (i) a 50% reduction of baseline eGFR (ii) initiation of RRT or (iii) death. Parametric accelerated failure time models were used to model risk for the composite event by baseline eGFR/proteinuria categories. Akaike Information Criteria (AIC) of nested models were used to amalgamate categories of similar risk.

Results: We included 854 children (71% non-glomerular and 29% glomerular) with a median (IQR) age of 11 (8, 15) yr and 63% male. The distribution across the 5 GFR categories was: G1: 4%; G2: 30%; G3a: 29%; G3b: 27% and G4: 10%. The distribution of uP/C across the 3 ranges was <0.5: 57%, 0.5-2.0: 30% and >2.0: 13%. 219 events occurred over a median (IQR) follow-up of 2.8 (1.2, 5.7) yrs. Median time to the composite outcome was best described by 7 stages (table) and was observed to decrease when either a decline in eGFR category or increase in the range of proteinuria occurred. Patients with uP/C>2.0 and eGFR category of G4 carried a nearly 20-fold increased risk in comparison to those with eGFR categories of G1/G2 and uP/C<2.0.



Conclusions: A modified KDIGO classification in pediatric CKD provides valuable prognostic information regarding time to 50% reduction in eGFR, need for RRT or death, and should be implemented across pediatric CKD practice.

TH-PO700

Dyslipidemia Is Common and Persistent in Children with CKD Jeffrey M. Saland,[1] Christopher B. Pierce,[2] Mark Mitsnefes,[3] Joseph T. Flynn,[4] Juan C. Kupferman,[5] Bradley A. Warady,[6] Susan L. Furth.[7] *[1]Pediatrics, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Bloomberg School of Public Health, Johns Hopkins Univ, Baltimore, MD; [3]Pediatrics, Cincinnati Children's Hospital, Cincinnati, OH; [4]Pediatrics, Seattle Children's Hospital, Seattle, WA; [5]Pediatrics, Maimonides Children's Hospital, Brooklyn, NY; [6]Pediatrics, Children's Mercy Hospital, Kansas City, MO; [7]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Dyslipidemia, a risk factor for CV disease, is common in pediatric CKD but its stability over time is not well-described.

Methods: CKiD is a prospective longitudinal cohort study of children aged 1-16 with CKD. Data from 338 subjects with at least 2 fasting lipid measures from year (yr) 2 (baseline), 4, 6, or 8 study visits were analyzed. 199 subjects had ≥3 measures. Total cholesterol (TC), triglycerides (TG), and HDL-cholesterol (HDL-C) were measured; non-HDL-C was calculated.

Results: Dyslipidemia was found in 48% and 53% of children at baseline and after 6 yr of follow-up, respectively; only modest changes in lipids were seen. Specifically, there was no consistent change in average non-HDL-C after 2, 4, or 6 yr. During the same period there were small increases in HDL-C (+2, +3, and +3 mg/dl respectively) and also TG (+5%, +16%, and +12% respectively). For the latter trends, 2 and 4 yr change was statistically significant. Expected pubertal effects occurred: TC declined more in males than females, driven mainly by declines in HDL-C and less by non-HDL-C. These differences were larger with longer follow-up (6 yr> 4 yr > 2 yr). Non-HDL-C trended higher in African American (AA) children over time with statistical significance noted at the 4 yr follow-up. Among AA children with 4-6 yr of follow-up, prevalence of non-HDL>160 mg/dL rose from 10% to 25%, a trend (p=0.04) not seen in non-AA children. Other Factors: Change in HDL-C, non-HDL-C, and TG over follow-up was not associated with age, GFR, proteinuria, or glomerular CKD.

Conclusions: Dyslipidemia is a common and persistent exposure in children with CKD. African American children may be at increased risk of developing elevated non-HDL-C levels.

Funding: NIDDK Support

TH-PO701

Apolipoprotein L1, Income, and Early Kidney Damage Ruth Tamrat,[1] Carmen A. Peralta,[2] Salman Tajuddin,[3] Michele Kim Evans,[3] Alan B. Zonderman,[3] Deidra C. Crews.[1] *[1]Dept of Medicine, Johns Hopkins U., Baltimore, MD; [2]Dept of Medicine, U. of California-San Francisco, San Francisco, CA; [3]National Inst on Aging, NIH, Bethesda, MD.*

Background: High-risk Apolipoprotein L1 (*APOL1*) variants are associated with CKD/ESRD among African Americans (AAs). However, the degree to which genetic or environmental factors explain the risk of early kidney damage among AAs is unknown.

Methods: Among AAs in the community-based Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) cohort (Baltimore, MD), we examined the cross-sectional association of *APOL1* and income with: 1) high urine albumin to creatinine ratio (ACR), defined as ACR >17mg/g in men and ACR >25mg/g in women, 2) continuous eGFR (creatinine-cystatin C equation), and 3) reduced eGFR (<75 mL/min/1.73m²). *APOL1* status was considered 'high risk' if 2 copies of high-risk variants were present or 'low risk' if 0 or 1 copy was present. Income groups were dichotomized as annual household income <$14,000/year (lowest income group) or >=$14,000/year (higher income group). Multivariable logistic regression models included adjustment for age, sex, and % European ancestry.

Results: Among 462 participants (mean age 47y), 72% lived in poverty, and 16% had high risk *APOL1* status. High-risk *APOL1*, but not income, was associated with high ACR [Odds Ratio (OR) 3.8, 95% CI 2.0-7.3]. Neither *APOL1* nor income was associated with continuous eGFR. Lower income, but not *APOL1*, was associated with eGFR <75 (OR 1.8, 95% CI 1.2-2.7). Of note, low-risk *APOL1* participants accounted for the majority of high ACR (71%), and reduced eGFR (78%) in the cohort. Additionally, the lowest income group accounted for a substantial proportion of high ACR (43%) and eGFR<75 (53%). No statistically significant interactions between *APOL1* and income were noted.

Conclusions: High risk *APOL1* is associated with risk of albuminuria, but the polymorphism does not explain the majority of early kidney damage in this urban AA population. Other factors, including those related to socioeconomic status, likely play a greater role in early kidney disease among AAs.

TH-PO702

HDL-C Levels Are Not Associated with MACE in Patients with Advanced Reduced Kidney Function Jiyun Park, Kyung-Hwan Jeong, Chun-Gyoo Ihm, Tae Won Lee, Yang Gyun Kim, Ju-Young Moon, Tae Won Lee, Jong Shin Woo, Weon Kim. *Internal Medicine, Kyung Hee Univ School of Medicine, Seoul, Korea.*

Background: Recent data suggested that HDL-C levels did not associate with coronary artery disease severity in patients with reduced kidney function. But the impact of HDL-C levels on MACEs(Major Adverse Cardiac Events) during 1-year follow-up after AMI in patients with kidney dysfunction has not been defined. This study was based on a retrospective cohort, the Korean Acute Myocardial Infarction Registry (KAMIR) database.

Methods: Among 13897 patients who diagnosed AMI from November 2005 to July 2008, 1165 patients (male : 519, female : 646) with advanced reduced kidney function (eGFR < 30 ml/min per 1.73 m²) were included. We examined the association of pretreatment lipid profiles including HDL-C, total cholesterol, triglyceride, and LDL-C levels with MACEs. MACEs include including cardiac death, recurrent MI, or coronary artery bypass graft (CABG) surgery. Univariate and multivariate analyses were utilized for identifying clinicopathologic factors including lipid profiles predictive of MACEs.

Results: Total 248 patients experienced MACEs.On the Multivariate analyses, lower HDL-C (<40 mg/dl) was not associated with increased risk of MACEs (hazard ratio [HR] of 1.38, 95% confidence interval [95% CI], 0.98–1.94, [P = 0.06]). There was not graded interaction between reduced kidney function with MACEs (hazard ratio [HR] of 1.04, 95% confidence interval [95% CI], 0.69–1.54, [P = 0.83]). Other lipid profiles including total cholesterol, triglyceride, and LDL-C levels, diabetes, cardiovascular disease history, smoking history, age, and BMI were not also associated with MACEs [P > 0.05] in patients with advanced reduced kidney function. Only statin therapy after MI was associated with reduced MACEs (hazard ratio [HR] of 0.71, 95% confidence interval [95% CI], 0.51–1.10, [P = 0.05]).

Conclusions: In conclusion, HDL-C levels are not associated with MACEs and statin therapy could be beneficial after MI in patients with advanced reduced kidney function.

TH-PO703

Low High-Density Lipoprotein Cholesterol Is Associated with All-Cause Mortality in People with Chronic Kidney Disease: Pooled Analysis of 6 Cohort Studies in Japan (EPOCH-JAPAN) Masaharu Nagata,[1] Toshiharu Ninomiya,[2] Yutaka Kiyohara,[1] Yoshitaka Murakami,[3] Yoshihiro Miyamoto,[4] Hiroyasu Iso,[5] Yutaka Imai,[6] Katsuyuki Miura,[7] Hirotsugu Ueshima,[7] Tomonori Okamura.[8] *[1]Dept of Environmental Medicine, Kyushu Univ; [2]Center for Cohort Studies, Kyushu Univ; [3]Dept of Medical Statistics, Toho Univ; [4]Dept of Preventive Cardiology, National Cerebral and Cardiovascular Center; [5]Public Health, Dept of Social Medicine, Osaka Univ Graduate School of Medicine; [6]Dept of Planning for Drug Development and Clinical Evaluation, Tohoku Univ; [7]Dept of Public Health, Shiga Univ of Medical Science; [8]Dept of Preventive Medicine and Public Health, Keio Univ.*

Background: Serum high-density lipoprotein cholesterol (HDLC) has been reported to be inversely associated with mortality in the general population. However, this issue remains unclear in people with chronic kidney disease (CKD).

Methods: Using individual pooled data of 33,180 subjects aged 40 to 89 years participated in 6 prospective cohort studies in Japan, we investigated the association between low HDLC levels defined as HDLC <40 mg/dL and all-cause mortality by CKD status. CKD was defined as eGFR <60 ml/min/1.73 m². The influence of HDLC on the risk of all-cause mortality was estimated by using a stratified Cox proportional hazards model.

Results: During an average of 12.5-year follow-up period, a total of 4,273 subjects died. In the multivariable analysis, low HDLC was associated with 37% (95% confidence interval 3-83%) greater risk of all-cause mortality in subjects with CKD and 17% (5-30%) greater risk in those without CKD. There was no evidence of heterogeneity in the association between subgroups of CKD status (p for heterogeneity=0.58). Subjects with both low HDLC levels and CKD had a 1.83-fold (1.50-2.23) higher risk of all-cause mortality than those with neither of these risk factors.

Conclusions: Our findings suggest that low HDLC levels are a significant risk factor for all-cause mortality in people with CKD, as well as in those without CKD.

TH-PO704

Association Between Non-High-Density Lipoprotein Cholesterol and Coronary Heart Disease According to Chronic Kidney Disease Status: The Hisayama Study Tomoko Usui,[1,2] Masaharu Nagata,[1,2] Toshiharu Ninomiya,[2,3] Kensuke Izumaru,[1,2] Takanari Kitazono,[2,3] Yutaka Kiyohara.[1,3] *[1]Dept of Environmental Medicine; [2]Dept of Medicine and Clinical Science; [3]Center for Cohort Studies, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Growing evidence suggests that elevated non-high-density lipoprotein cholesterol (non-HDLC) levels are causally related to an increased risk of coronary heart disease (CHD) events in the general population. However, it is not clear whether the association is similar for those with and without chronic kidney disease (CKD).

Methods: We evaluated the association between non-HDLC levels and the risk of CHD in a prospective cohort study in Japan. A total of 2,630 community-dwelling subjects (1,107 men and 1,523 women) aged ≥40 years were followed for 19 years. Non-HDLC levels were divided into <150 mg/dL, 150-189 mg/dL, and ≥190 mg/dL. CKD was defined as eGFR <60 ml/min/1.73m² or proteinuria (≥1+ on dipstick). The multivariable-adjusted hazard ratio (HR) and 95% confidence interval (CI) were estimated using a Cox proportional hazards model.

Results: Among all subjects, 357 (13.6%) had CKD. During the follow-up period, 186 CHD events occurred. The age- and sex-adjusted incidence of CHD significantly increased with elevating non-HDLC levels in subjects with or without CKD (p for trend=0.002 in subjects without CKD, 0.019 in subjects with CKD). In subjects without CKD, those with non-HDLC ≥190 mg/dL had a 2.12-fold (95% CI: 1.32-3.38) greater risk of CHD than those with non-HDLC <150 mg/dL after adjustment for potential confounding risk factors. Similarly, in CKD subjects, the risk of CHD was significantly higher in non-HDLC 150-189 mg/dL level and more (adjusted HRs [95% CI]: 1.00 [reference] in non-HDLC <150 mg/dL, 2.23 [1.04-4.77] in 150-189 mg/dL, and 3.20 [1.46-7.03] in ≥190 mg/dL). There was no evidence of interaction in the association for CHD between non-HDLC levels and CKD status (p for interaction=0.61).

Conclusions: Elevated non-HDLC levels are a significant risk factor for the development of CHD not only among people without CKD, but also with CKD.

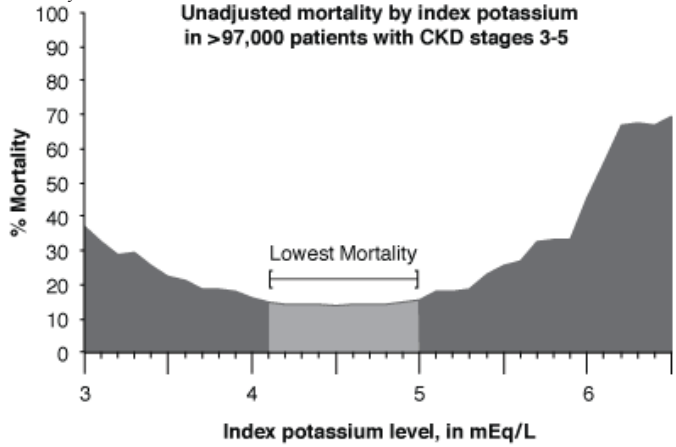
TH-PO705

Potassium Levels and Mortality in Patients with CKD Allan J. Collins,[1] Nancy Reaven,[2] Susan Funk,[2] George L. Bakris,[3] Bertram Pitt,[4] David A. Bushinsky.[5] *[1]Univ of Minnesota, Minneapolis, MN; [2]Strategic Health Resources, La Canada, CA; [3]Univ of Chicago, Chicago, IL; [4]Univ of Michigan, Ann Arbor, MI; [5]Univ of Rochester, Rochester, NY.*

Background: Abnormal serum potassium levels are common in patients with advanced chronic kidney disease (CKD), yet the degree of mortality risk at different levels of potassium is not clear. We evaluated the odds of death in patients with CKD stages 3-5, stratified by potassium level.

Methods: De-identified medical records (2007-2012) from a large U.S. population of individuals ≥ 5 years of age with at least 2 potassium readings were evaluated. Patients with CKD stages 3-5 (n=97,415) were identified from ICD-9 codes and biochemical data, excluding those with acute kidney injury or end stage renal disease. Index potassium value was defined as the last reported value prior to pre-determined cut-off date. Mortality was evaluated through hospital discharge records and Social Security registry information.

Results: Unadjusted mortality rates are shown in the Figure. Patients with index potassium levels below 4.1 mEq/L and above 5.0 mEq/L show a significant increase in mortality, even at levels within the usual normal laboratory range. The increased mortality remained after adjustments for demographic characteristics (sex, age, race) and comorbidities, including heart failure, diabetes, hypertension, cardiovascular disease and acute myocardial infarction.



Conclusions: These findings suggest that there is a significant increase in mortality at serum potassium levels below 4.1 mEq/L and above 5.0 mEq/L in patients with CKD stages 3-5.

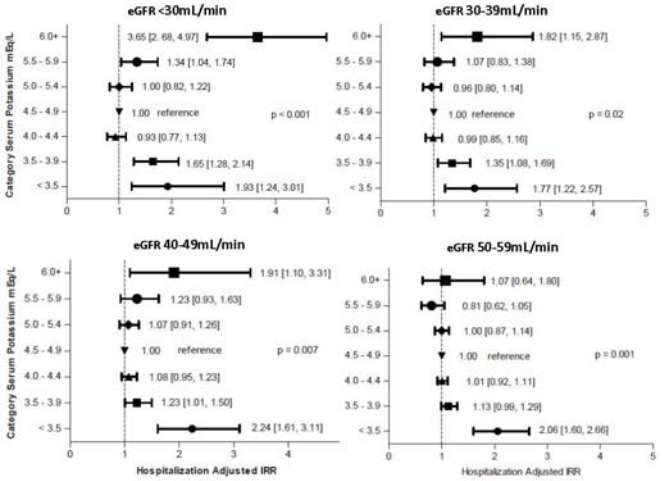
TH-PO706

The Association Between Serum Potassium and Hospitalization in Patients with Chronic Kidney Disease Jiacong Luo,[1] Steven M. Brunelli,[1] Donna E. Jensen,[1] Alex Yang.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]ZS Pharma, Inc, Menlo Park, CA.*

Background: In states of health, serum potassium (K) is tightly regulated, typically between 3.5 and 5.0mEq/L. The resultant transmembrane electrochemical potential is essential to normal physiologic function. Due to impaired excretory capacity, patients with chronic kidney disease (CKD) accumulate K in the serum (hyperkalemia). We studied the association of serum K with hospitalization rates, within narrow estimated glomerular filtration rate (eGFR) strata to understand the potential burden of hyperkalemia and how this may vary by underlying CKD severity.

Methods: We assembled a retrospective cohort of patients who had eGFR <60 mL/min/1.73 m² and available serum K data between Jan-2009 and Jun-2013 (N=55,266). Patients were followed until study end (30-Jun-2013), death, end-stage disease, transplant, or transfer of care. Serum K, eGFR, and covariates, which included 13 demographic, comorbid, and medication utilization characteristics, were considered on a time-varying basis and updated at each K measurement. Hospitalization was considered as events per time at-risk.

Results: At baseline, serum K was <3.5 and ≥5.0mEq/L in 1.6% and 20% of patients, respectively. Graphical representation of the adjusted K-hospitalization association was U-shaped.



Risk associated with higher K was greater at lower levels of eGFR. Compared to K 4.5-4.9mEq/L, K ≥6.0mEq/L was significantly associated with higher adjusted hospitalization rate for eGFR <49 mL/min/1.73m²; K 5.5-5.9mEq/L was significantly associated with higher adjusted hospitalization rate for eGFR <30 mL/min/1.73m².

Conclusions: Higher serum potassium is associated with greater adjusted rates of hospitalization. Hospitalization risk is greater with higher serum K and lower eGFR with almost 4-fold greater risk in CKD stage 4/5 patients with a K ≥6.0 mEq/L.

TH-PO707

The Acute Effect of Red Blood Cell (RBC) Transfusion on Hyperkalemia (HK) in Advanced Chronic Kidney Disease (CKD) Keri Monda,[1] Jeffrey C. Fink,[2] David T. Gilbertson,[3] Karminder S. Gill,[4] Paul Muntner,[5] Richard A. Lafayette,[6] Jeffrey Petersen,[1] Glenn M. Chertow,[6] Brian D. Bradbury.[1] *[1]Center for Observational Research, Amgen, Inc, Thousand Oaks, CA; [2]Dept of Medicine, U Maryland, Baltimore, MD; [3]Chronic Disease Research Group, Minneapolis, MN; [4]Ascentiant Int, Carlsbad, CA; [5]Dept of Epidemiology, U of Alabama, Birmingham, Birmingham, AB; [6]Div of Nephrology, Stanford U School of Medicine, Palo Alto, CA.*

Background: Transfusion may contribute to the development of HK in patients with advanced CKD due to their impaired response to an expanded potassium load. The risk for HK associated with transfusion has not been quantified previously.

Methods: Persons 18-64 years of age with diagnosed stage 4 or 5 CKD (not requiring dialysis) between 2006 and 2010 were followed until their first hospitalization with a diagnosis of HK, termination of insurance coverage, or death, using the OptumInsight claims database. We estimated incidence rates (IRs) and 95% confidence intervals (CIs) for HK using Poisson regression. We estimated the rate ratio (RR) and 95% CI for the association between transfusion and the risk of HK using a case-only design, matching each HK case to multiple (1:m) weekly control periods with no HK, and adjusted for the following time-varying confounders: acute kidney injury, hospitalization, anemia, and GI bleeding. Exposure was assessed in the 3 days immediately preceding the HK or control date.

Results: Overall, 7,829 individuals with stage 4 or 5 CKD met our inclusion criteria; 68% were age 50 or older; 43% were female; 51% had diabetes. During follow-up 711 patients were hospitalized with a diagnosis of HK (IR: 7.9 per 100 PYs [95% CI: 7.3-8.5]). For the 575 cases with at least one week of follow-up there were 24,769 control periods;

2.3% of cases and 0.1% of controls were exposed to transfusion. This corresponded to a crude RR of 21.6 (95% CI: 10.1-46.5), and 6.1 (95% CI: 2.5-15.1) after adjustment for time-varying confounders.

Conclusions: These data provide evidence of a high burden of hyperkalemia in patients with advanced CKD and show a meaningful elevation in risk for hyperkalemia following transfusion.

TH-PO708

The Association of BUN to Creatinine Ratio with Pre-ESRD Mortality and ESRD in Chronic Kidney Disease Georges Saab,[1] Jesse D. Schold,[2] Susana Arrigain,[2] Joseph V. Nally,[2] Robert J. Heyka,[2] Sankar D. Navaneethan.[2] *[1]MetroHealth Medical Center, Cleveland, OH; [2]Cleveland Clinic Foundation, Cleveland, OH.*

Background: An elevated blood urea nitrogen to creatinine ratio (BUN/Cr) has been suggested to be a renal manifestation of neuro-hormonal activation (NHA) in congestive heart failure (CHF). The mediators of NHA may also lead to progressive renal function decline and increased mortality in chronic kidney disease (CKD). Whether an elevated BUN/Cr may be associated with these outcomes in CKD is unknown.

Methods: Patients with stages 3 and 4 CKD with at least 2 measurements of estimated glomerular filtration rate (eGFR) 15-60 at least 90 days apart between January 2005 and September 2009 were examined. For primary analysis, we calculated BUN/Cr from the 2nd eGFR < 60. For sensitivity analysis, we selected patients that had at least one other BUN/Cr ratio drawn in the 4 months prior to 2nd eGFR, and took the average of all the ratios available in that period. Gender specific BUN/Cr quartiles were generated and then combined. We used Cox proportional hazards models to evaluate the association between BUN/Cr quartiles and ESRD, and pre-ESRD mortality.

Results: A total of 38,927 and 13,173 patients were included in the primary and sensitivity analyses, respectively. Higher BUN/Cr quartiles were associated with increasing age and a lower percentage of African Americans. Patients with higher BUN/Cr had an increasing prevalence of diabetes, hypertension, coronary artery disease, CHF, and cerebrovascular disease and more likely to be treated with diuretics, statins, and angiotensin converting enzyme inhibitors or angiotensin receptor blockers. After multivariate adjustment, patients in the 4th quartile had a higher risk of ESRD (HR: 1.40, 95% CI 1.14, 1.72) and pre-ESRD mortality (HR: 1.34, 95% CI 1.25, 1.44) as compared to the 1st quartile. In the sensitivity analysis, the results were similar for ESRD (HR: 1.34, 95% CI 1.00, 1.78) and pre-ESRD mortality (HR: 1.29, 95% CI 1.16, 1.43). These results were not modified by gender nor eGFR.

Conclusions: Patients in the highest BUN/Cr quartile have an increased risk for ESRD and pre-ESRD mortality. The mechanisms behind this require further study.

TH-PO709

Serum Phosphorus Levels Predict All-Cause Mortality without Evidence of Chronic Kidney Disease Kyung Don Yoo, Nam Ju Heo, Dong Ki Kim, Ho Jun Chin, Kwon Wook Joo, Yon Su Kim, Hajeong Lee. *Internal Medicine, Seoul National Univ College of Medicine, Korea.*

Background: Higher serum phosphorus levels were significantly associated with cardiovascular morbidity and mortality in both chronic kidney disease (CKD) and end-stage renal disease patients. However, whether serum phosphorus levels have an influence on mortality in general population without chronic kidney disease remains to be clarified.

Methods: Data had been collected from 136,235 individuals who received routine health check-ups between 1995 and 2009. Among them, participants who were undergone a colonoscopy in same date was excluded. Subjects with possible CKD such as estimated glomerular filtration rate under 60 mL/min/1.73m^2 and urine dipstick albumin more than 1+ were also excluded. Outcome was all-cause mortality extracted from Statistics Korea at December 2011.

Results: A total of 89,193 individuals were included. The mean age was 53.3 years and male participants were 49,078 (55.0 %). Because serum phosphorus levels were distributed differently according to gender, they were analyzed separately. Serum phosphorus levels were categorized by quartile. In men, highest phosphorus quartile group was younger, had higher serum albumin levels, and included more current smoker. In contrast, highest phosphorus quartile group was older and included more diabetes patients in women. In survival analysis, serum phosphorus levels were not associated with mortality in univariate cox-regression analysis in men. Interestingly however, multivariate analysis revealed that higher serum phosphorus levels were independent predictor for all-cause mortality after adjustment for age, diabetes, hypertension, body mass index, calcium, albumin, hemoglobin, glucose, systolic blood pressure, dipstick albuminuria, smoking history (HR 1.27, 95% CI 1.102–1.484, p=0.0012). In case of women, these associations were not observed (HR 1.094, 95% CI 0.837–1.430, p=0.5114).

Conclusions: In this study, we demonstrated that serum phosphorus levels were associated with all-cause mortality in general men without evidence of CKD. Further prospective interventional studies are warranted to elucidate different gender effect to serum phosphorus levels.

TH-PO710

Association of High and Low Serum Bicarbonate with Left Ventricular (LV) Structure and Function in CKD –A Report from the Chronic Renal Insufficiency Cohort (CRIC) Study Mirela A. Dobre,[1] Amanda Hyre Anderson,[2] Nisha Bansal,[2] Jing Chen,[2] Rajat Deo,[2] Paul E. Drawz,[2] Harold I. Feldman,[2] L. Lee Hamm,[2] Thomas H. Hostetter,[1] John W. Kusek,[2] Claudia M. Lora,[2] Akinlolu O. Ojo,[2] Kumar Sharma,[2] Mahboob Rahman.[1] *[1]Case Western Reserve Univ; [2]CRIC Study.*

Background: Heart failure (HF) is a common occurrence in patients with CKD. High bicarbonate levels have been associated with increased rates of HF; however, the mechanisms mediating this association are incompletely known. We aim to evaluate whether bicarbonate levels are also associated with subclinical measures of HF.

Methods: We performed a cross-sectional analysis of the association between serum bicarbonate and echocardiographic measures of cardiac structure and function, including LV hypertrophy, LV mass indexed to height$^{2.7}$, relative wall thickness, LV geometry, ejection fraction and diastolic dysfunction in CRIC. Study participants (n=3483) who did not have HF class III/IV were stratified into 3 groups by levels of serum bicarbonate: Low (<22mEq/L), n=614; Normal [22-26mEq/L], n=2001; and High (>26mEq/L), n=868.

Results: The mean age was 58.9 (10.8) years and baseline eGFR was 42.5±17 ml/min per 1.73m^2. The prevalence of LV hypertrophy (LVH) was 64%, 56% and 53% for serum bicarbonate categories < 22, 22-26 and > 26 mEq/L, respectively. In multivariable analyses adjusted for demographic characteristics, kidney function, traditional cardiovascular risk factors and medications, there was no difference in prevalence of LVH between the low (OR 1.17, 95%CI 0.88-1.55, p = 0.29) and high bicarbonate groups (OR 0.97, 95%CI 0.77 - 1.22, p = 0.79) compared to the normal group. Similarly, there were no differences in the mean left ventricular mass, relative wall thickness, LV geometry, ejection fraction and prevalence of diastolic dysfunction when comparing the low and high to the normal bicarbonate group.

Conclusions: In this large cohort of men and women with CKD, serum bicarbonate was not associated in cross-sectional analyses with measures of abnormal cardiac structure and function. Whether changes in serum bicarbonate over time are associated with changes in cardiac structure and function, or risk of heart failure should be investigated.

TH-PO711

Urinary Ammonia and Long Term Outcomes in Chronic Kidney Disease Pascal Houillier,[1,2] Marion Vallet,[1] Marie Metzger,[3] Jean-Philippe Haymann,[1,2] Martin Flamant,[1,2] Benedicte Stengel.[3] *[1]Assistance-Publique-Hopitaux de Paris, Paris, France; [2]INSERM, Paris, France; [3]CESP, INSERM, Villejuif, France.*

Background: Recent studies suggest that alkalinizing treatments improve the course of chronic kidney disease (CKD), even in patients without overt metabolic acidosis. We hypothesized that a decreased ability in excreting urinary acid rather than overt metabolic acidosis may be deleterious to the course of CKD.

Methods: We studied the associations between baseline plasma total CO_2 level or urinary ammonia excretion and long-term CKD outcomes in 1,065 patients with CKD stage 1 to 4 from the NephroTest cohort. All patients had glomerular filtration rate measured (mGFR) by ^{51}Cr-EDTA renal clearance. Crude and adjusted-hazard ratios (HR) of mortality and end stage renal disease (ESRD) were estimated using Cox models. Crude and adjusted odd ratios of fast decline in GFR (>10 %/year) were estimated by logistic regression.

Results: Median mGFR at baseline was 37.6 mL/min/1.73 m^2. Urinary ammonia excretion decreased with GFR, while net endogenous acid production did not. After a mean follow-up of 4.3 years, 201 patients reached end-stage renal disease (ESRD) and 114 died before ESRD. Twenty-six percent of the patients had mGFR decline rate greater than 10% per year. Hazard ratio for ESRD was significantly and independently increased in those in the lowest tertile of urinary ammonia excretion compared to those in the highest tertile (HR: 1.82, 95% CI 1.06-3.13). Likewise, the odds ratio of fast mGFR decline was borderline significant (OR: 1.84, 95% CI 0.98-3.48). Neither a low plasma total CO_2 level nor metabolic acidosis were associated with ESRD risk or fast renal function decline. None of these biomarkers was associated with mortality.

Conclusions: These results suggest that the inability to excrete the daily acid load is deleterious to renal outcomes, but not to mortality.

Funding: Government Support - Non-U.S.

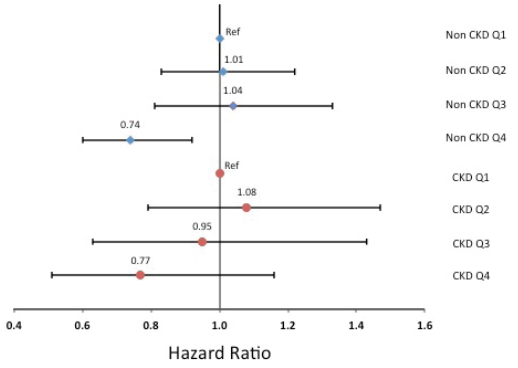
TH-PO712

Net Endogenous Acid Production and Mortality in Chronic Kidney Disease Hunter K. Huston,[1] Matthew K. Abramowitz,[2] Y. Zhang,[1] Tom Greene,[1] Kalani L. Raphael.[1] *[1]Medicine, Univ of Utah School of Medicine; [2]Medicine, Albert Einstein College of Medicine.*

Background: Metabolic acidosis increases mortality risk in chronic kidney disease (CKD). High dietary acid intake may lower serum [HCO_3^-] and influence this relationship. This study investigated whether higher net endogenous acid production (NEAP), an estimate of dietary acid intake, is a mortality risk factor independent of serum [HCO_3^-] in CKD.

Methods: Data from the Third National Health and Nutrition Examination Survey were used in this analysis. Daily NEAP (mEq) was calculated as -10.2 + 54.5 x [protein intake (grams)/potassium intake (mEq)]. Protein and potassium intakes were obtained from dietary recall. Cox models were performed in CKD and non-CKD subgroups and were adjusted for demographic factors, estimated glomerular filtration rate, serum [HCO_3^-], urinary albumin:creatinine, comorbidities, and diuretics. Additional analyses were performed using protein intake and potassium intake as predictor variables in separate Cox models.

Results: In participants without CKD, mortality risk was significantly lower for those in the highest NEAP quartile compared to the lowest. In participants with CKD, there was a trend towards lower mortality risk for those in the highest NEAP quartile, however, this was not statistically significant.



Higher protein intake associated with a trend towards lower mortality risk, whereas potassium intake did not associate with mortality.

Conclusions: Higher NEAP associates with lower mortality risk in non-CKD independent of serum [HCO_3^-]. A similar pattern was observed for those with CKD, but this was not statistically significant, contrary to our hypothesis. Higher protein intake may explain the relationship between lower mortality risk and higher NEAP in NHANES III participants.

TH-PO713

Dietary Habits and Risk of Incident Chronic Kidney Disease in an Urban Population Yang Liu,[1] Marie Kuczmarski,[2] Edgar R. Miller,[1] Alan B. Zonderman,[3] Michele Kim Evans,[3] Neil R. Powe,[4] Deidra C. Crews.[1] *[1]Johns Hopkins U, Baltimore, MD; [2]U of Delaware, Newark, DE; [3]National Inst of Aging, NIH, Bethesda, MD; [4]U of California, San Francisco, CA.*

Background: Adherence to a Dietary Approaches to Stop Hypertension (DASH) –type diet has been shown to lower blood pressure, however, little is known about its potential relation with risk of chronic kidney disease (CKD).

Methods: Among 1,339 community dwelling participants free of CKD at baseline in the Baltimore, MD based Healthy Aging in Neighborhoods of Diversity across the Life Span study, a DASH diet adherence score based on 9 target nutrients (total fat, saturated fat, protein, fiber, cholesterol, calcium, magnesium, sodium, and potassium) was examined for its association with significant decline in kidney function over an average of 5 years of follow up. Cox models were used to adjust for potential confounders.

Results: Participants' mean age was 47 years with the majority being either female (65%) or African American (AA) (59%). Low DASH diet adherence (lowest tertile of DASH score), when compared to higher adherence, was associated with being male, AA, poor, and/or less educated. Low DASH adherence was significantly associated with the composite measure of eGFR decline below 60 ml/min/1.73m^2 and greater than 25% during follow-up.

		eGFR<60 at follow up (N events = 67)		eGFR decline >=25% (N events = 81)		BOTH eGFR decline >=25% & eGFR < 60 at follow up (N events= 35)	
Model	Adjusted for:	HR (95% CI)	P value	HR (95% CI)	P value	HR (95% CI)	P value
1	Crude	1.4 (0.9,2.2)	0.19	1.4 (0.9,2.2)	0.10	2.0 (1.0,4.0)	0.04
2	+ Age, Sex, Race	1.4 (0.9,2.3)	0.19	1.5 (0.9,2.3)	0.09	2.1 (1.1,4.3)	0.03
3	+ Poverty	1.4 (0.8,2.2)	0.21	1.5 (1.0,2.3)	0.08	2.1 (1.1,4.2)	0.03

Further adjustment for albuminuria among 892 participants with available urinary albumin-to-creatinine measures attenuated the association towards the null [HR 0.9; 95% CI 0.4–2.3]. No effect modification by race, poverty status, hypertension or diabetes was noted.

Conclusions: Low DASH diet adherence is associated with higher risk of incident CKD among urban-dwelling adults, and albuminuria may mediate this association.

The Views of Patients on Dietary and Fluid Restrictions in CKD: A Thematic Synthesis of Qualitative Studies Suetonia Palmer,[1] Camilla Sara Hanson,[2] Jonathan C. Craig,[2] Giovanni F.M. Strippoli,[3,4] Marinella Ruospo,[3,4] Katrina L. Campbell,[5] David W. Johnson,[5] Allison Tong.[2] *[1]Univ of Otago Christchurch; [2]Univ of Sydney; [3]Fondazione Mario Negri Sud; [4]Amedeo Avogadro Univ of Eastern Piedmont; [5]Univ of Queensland.*

Background: Negotiating complex fluid and dietary recommendations in chronic kidney disease is very challenging for patients. We aimed to describe patients' perspectives of dietary and fluid management in CKD to inform clinical practice that can incorporate patient experiences as well as to understand and explain patient choices.

Methods: We did a systematic review of qualitative studies in adults with CKD that reported experiences and beliefs about dietary and fluid management. MEDLINE, Embase, PsycInfo, CINAHL, Google Scholar and PhD dissertations were searched. Thematic synthesis was used to analyze findings.

Results: We included 46 studies involving 816 patients living in middle- to high-income countries. Five major themes were identified: preserving relationships (interference with roles, social limitations, and being a burden), navigating change (feeling deprived, disrupting held truths, breaking habits and norms, overwhelmed by information, questioning efficacy, and negotiating priorities), fighting temptation (resisting impositions, mental invasion, and withstanding physiological needs), optimizing health (accepting responsibility, valuing self-management, preventing disease progression, preparing for and protecting a transplant), and becoming empowered (comprehending paradoxes, finding solutions, and mastering change and demands). Limited data were available for low income settings and for adults who had CKD not treated with dialysis or transplantation.

Conclusions: Dietary and fluid restrictions are disorienting and an intense burden for patients with CKD. Patient prioritized education strategies, harnessing patients' motivation to stay well for a transplant or to avoid dialysis, and viewing adaptation to restrictions as a collaborative journey are suggested strategies to help patients adjust to dietary regimens in order to reduce their impact on quality of life.

TH-PO715

The Relationship between Poor Appetite and Clinical Outcomes in Pediatric Patients with Chronic Kidney Disease Frank Ayestaran,[1] Michael F. Schneider,[2] Frederick J. Kaskel,[2] Poyyapakkam Srivaths,[2] Patricia Seo-Mayer,[2] Marva M. Moxey-Mims,[2] Susan L. Furth,[2] Bradley A. Warady,[2] Larry A. Greenbaum.[1,2] *[1]Emory Univ, Atlanta, GA; [2]Chronic Kidney Disease in Children Study (CKiD).*

Background: Poor appetite increases the risk for malnutrition in children with chronic kidney disease (CKD). In adult dialysis patients, self-reported poor appetite is related to lower quality of life (QoL), higher inflammatory markers, hospitalization rates and risk of death. The relationship between self-reported appetite and clinical outcomes hasn't been reported in children with CKD. We plan to describe the relationship between self-reported appetite and GFR, number of ER visits, hospitalizations and QoL in pediatric patients with CKD.

Methods: 802 participants in the Chronic Kidney in Children (CKiD) study, a longitudinal cohort study of children with CKD, contributed 2918 person-visits to analyses. Appetite in the week prior to each annual visit was characterized as very good, good, fair, or poor/very poor. Mixed effects ordinal logistic regression was used to quantify the degree of association that CKD stage had with appetite. Linear regression was used to assess the relationship between QoL and appetite while Poisson regression was used to assess the relationship between both ER visits and hospitalizations and appetite.

Results: Decreasing GFR was associated with a worse appetite; those with GFR < 30 ml/min per 1.73m^2 had a 6.08 greater odds (95% CI: 3.48, 10.63) of reporting a worse appetite than those with GFR > 90. Compared to a report of a very good appetite, a poor or very poor appetite was associated with a higher number of ER visits [Rate Ratio: 1.92 (CI: 1.19, 3.09)], lower parental reported QoL [mean difference: -7.7(CI: -11.5, -3.9)] and lower child reported QoL [mean difference: -6.2 (CI: -10.1, -2.3)].

Conclusions: Self-reported appetite worsens with declining GFR in children with CKD. Poor appetite is associated with worse outcomes in children with CKD, including higher risk for ER visits in the following year and poorer QoL.

TH-PO716

Quality of Life and Depression in Patients with Chronic Kidney Disease: The Systolic Blood Pressure Intervention Trial Suzanne Watnick,[1] Jill C. Newman,[2] Gregory W. Evans,[2] Joni Snyder,[3] Capri G. Foy,[3] Dan Berlowitz,[5] Paul L. Kimmel.[4] *[1]Dept of Veterans Affairs, Portland, OR; [2]Wake Forest School of Medicine, Winston-Salem, NC; [3]NHLBI, Bethesda, MD; [4]NIDDK, Bethesda, MD; [5]Dept of Veterans Affairs, Bedford, MA.*

Background: Depression and diminished quality of life (QOL) are strongly associated with chronic kidney disease (CKD). However, no data exist comparing depression and QOL in CKD to a control group. The Systolic Blood Pressure Intervention Trial (SPRINT) is a unique opportunity to evaluate QOL and depression in a large community-based cohort of hypertensive patients, with and without CKD.

Methods: We performed a cross sectional study of patients in SPRINT, a randomized trial of 9361 hypertensive subjects, including 2648 with CKD stage 3-4. We compared QOL variables at baseline by CKD status, and correlations between QOL parameters, including

mental (MCS) and physical (PCS) scores on the VR-12 instrument, pain perception, and depressive symptoms on the PHQ-9. We performed multivariable logistic regression analyses to examine associations between CKD and the four QOL parameters.

Results: Mean eGFR was 47.9 + 9.5 in CKD and 81.3 + 15.5 ml/min/1.73m2 in non-CKD hypertensive patients. CKD patients had, as expected, worse PCS (43.2 + 10.5 versus 45.3 + 10.1), but unexpectedly, better MCS (53.9 + 9.1 versus 52.8 + 9.7) than those without CKD ($p < 0.0001$ for both). In all patients, pain scores correlated with PHQ-9, MCS and PCS scores. MCS correlated with PHQ-9 scores, and PHQ-9 scores correlated with pain, MCS and PCS scores (all $r>0.3$, $p<0.0001$). In bivariate analyses, CKD was not associated with PHQ-9, but was associated with better MCS and worse PCS. After multivariable adjustment for demographic/personal characteristics, CKD remained associated with worse PCS scores, but not with mental health scores.

Conclusions: We conclude that QOL and depression are related to pain in patients with hypertension, with and without CKD. Although CKD patients in SPRINT had worse physical health scores than non-CKD subjects, unexpectedly depression is not characteristic of hypertensive CKD subjects with early stage CKD. This may be because CKD is usually symptomless at this stage.

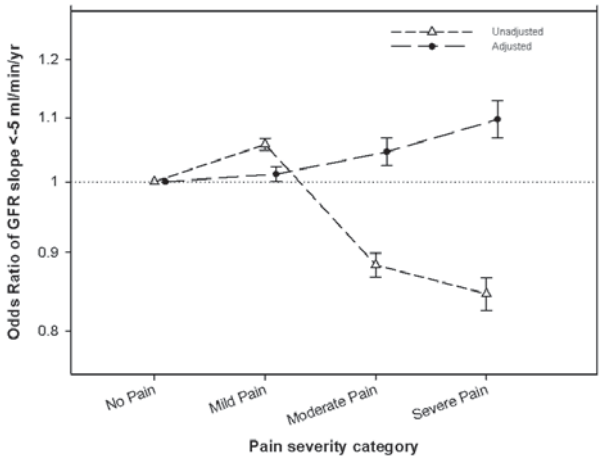
Association of Pain with Progressive Chronic Kidney Disease in over 1.5 Million U.S. Veterans

Joline L.T. Chen,[1] Elani Streja,[2] Vanessa A. Ravel,[2] Miklos Zsolt Molnar,[3] Jun Ling Lu,[3] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[3] *[1]Long Beach VAMC, Long Beach, CA; [2]Harold Simmons, UC Irvine MC, Orange, CA; [3]Memphis VAMC, Memphis, TN.*

Background: Chronic non-malignant pain is prevalent among U.S. veterans. Pain activates the sympathetic nervous system, which may lead to hypertension. It is also associated with higher analgesic and antidepressant use. These may lead to increased risk for CKD and ESRD, which are highly prevalent among U.S. veterans. The risk of incident CKD or worsening kidney function associated with pain in patients with normal kidney function is unclear.

Methods: In a cohort of 1,585,051 Veterans with normal baseline eGFR in 2005-2006, we examined the association of reported pain with incidence of CKD stages 3a, 3b, 4, 5, and slopes of eGFR over median follow up of 7.3 years (IQR: 4.1-8.3). Pain scores reported with the Brief Pain Index were categorized into none, mild, moderate, or severe pain. Associations were examined in crude and adjusted Cox models and logistic regression models (for slopes ≤-5ml/min/1.73m^2/year), with adjustments for demographics, comorbidities, cardiovascular risk factors, and depression.

Results: At baseline, patients were 60±14 yrs, 16.8% African American, 93.6% male with mean baseline eGFR was 84±16 ml/min/1.73m^2. 15.3%, 3.7%, 0.7%, and 0.3% of patients developed CKD stage 3a,3b,4,and 5 respectively. 9.1% of veterans had GFR decline greater than 5 ml/min/1.73m^2/year. Pain severity was associated with higher baseline eGFR, younger age, fewer cardiovascular and other comorbidities. In multivariable adjusted logistic regression models worse pain was associated with incrementally higher odds ratios of kidney function loss greater than 5 ml/min/1.73m^2/yr.



Conclusions: Pain is incrementally associated with faster progression of CKD. Studies to evaluate whether pain management can have a bearing on development and progression of CKD and poor outcomes are warranted.

Cognitive Impairment in Chronic Kidney Disease: The Brain IN Kidney Disease (BRINK) Study

Anne M. Murray,[1,2,3] Brooke Heubner,[1] Paul E. Drawz,[3] Jamilyn Coleman,[1] Yelena Slinin,[3] David Tupper.[2] *[1]MMRF, Minneapolis, MN; [2]HCMC, Minneapolis, MN; [3]Univ of MN, Minneapolis, MN.*

Background: The BRain IN Kidney disease (BRINK) study aims to characterize the burden of and risk factors for cognitive impairment (CI) in 400 CKD and 130 non-CKD subjects. We describe the frequency of domain-specific CI in both cohorts thus far.

Methods: Participants (ppts) with CKD stages 3-5 (eGFR < 60 mL/min/1.73m^2, not on dialysis) and age- and race-matched non-CKD controls, (eGFR ≥ mL/min) were recruited from 4 Minneapolis/St. Paul health systems. Domain-specific neuropsychological testing was performed at baseline using the following tests: Modified Mini-Mental State Exam (3MS), global cognition; Hopkins Verbal Learning Test-Revised (HVLT-R, Immediate and Delayed), verbal memory; Controlled Oral Word Association Test (COWAT), language; Color Trails Test 2 (CTT2), executive function; Symbol-Digit Modality Test (SDMT), executive function; Digit Span, attention; Brief Visuospatial Memory Test-Revised (BVMT-R Immediate and Delayed), visual spatial/memory; and the PHQ Depression Scale. We compared raw scores and T-scores using published norms.

Results: We recruited 423 ppts (CKD [eGFR < 45] N=265, mild CKD (eGFR 45-59) N=76, non-CKD N=82). Mean ages were 70±9.6 (CKD) and 66±10.5 (non-CKD) yrs ($p<0.01$). Baseline eGFR (CKD) was 30±9.1 mL/min. Prevalence of HTN was higher in CKD ppts than in controls (94% versus 65%, $p<0.01$) but was similar for prior stroke (17% versus 15%, $p=0.56$) and diabetes (53% versus 59%, $p=0.35$). CKD ppts scored worse on the 3MS (93±5.9 versus 95±5.6, $p=0.01$), BVMT-R immediate (16±7.0 versus 20±7.9, $p<0.01$), COWAT (35±12.0 versus 40±12.5, $p<0.01$), and SDMT (36±11.3 versus 43±11.8, $p<0.01$); associated T-scores also differed significantly. Scores on the HVLT-R delayed, CTT2, Digit Span, BVMT-R delayed, or PHQ9 depression scale did not differ significantly.

Conclusions: CKD ppts had significantly lower levels of global cognitive function, visual spatial/memory, and executive function/processing speed, consistent with possible mixed neurodegenerative and vascular cognitive impairment. Further analyses will measure factors associated with global and domain-specific CI.

TH-PO719

Associations Between Chronic Kidney Disease, Depression, and Incident Dementia in a Diabetic Cohort

Margaret K. Yu,[1,2] Bessie A. Young.[1,2] *[1]Health Services Research and Development, VA Puget Sound Health Care System, Seattle, WA; [2]Nephrology, Univ of Washington, Seattle, WA.*

Background: Chronic kidney disease (CKD) is a risk factor for dementia in the elderly. Whether CKD is associated with dementia in a primary care population with diabetes is not known. Furthermore, whether the association between CKD and dementia is modified by depression, is not known.

Methods: The Pathways Study is a prospective, observational cohort of ambulatory, diabetic patients from a large managed care population in Seattle, WA. Subjects without baseline dementia were followed for up to 10 years for incident dementia based on ICD-9 codes. Baseline estimated glomerular filtration rate (eGFR) (CKD-EPI) and microalbuminuria were used to categorize patients into early (CKD stage 1-2), moderate (CKD stage 3), or advanced (CKD stage 4-5) stage CKD. Cox proportional hazards regression was used to analyze the associations between CKD and incident dementia after adjusting for age, race/ethnicity, marital status, education, smoking, hypertension, low-density lipoprotein (LDL), body mass index (BMI), hemoglobin A1c, diabetes duration, and major depression.

Results: Of the 3,960 total subjects, 331 developed dementia over a median follow up of 8.7 years (IQR 3.8-10). Compared to subjects with normal renal function, CKD was progressively associated with an increased risk of dementia (adjusted hazard ratio (AHR) 1.65, 95% CI 1.00-2.71 for early CKD; AHR 1.97, 95% CI 1.17-3.31 for moderate CKD; AHR 3.78, 95% CI 1.68-8.50 for advanced CKD). Major depression was associated with a 3.48-fold increased risk of dementia (95% CI 2.42-5.01). There was no evidence for an interaction between CKD stage and major depression. Additional risk factors for dementia included older age and smoking (AHR 1.83, 95% CI 1.02-3.28), but not duration of diabetes or hemoglobin A1c. Moderate obesity and higher LDL were associated with a lower risk of dementia.

Conclusions: All stages of CKD were risk factors for incident dementia in a primary care diabetic population, and these associations were not modified by major depression. Advanced stage CKD poses a similar risk for dementia that is comparable to major depression.

TH-PO720

Association of Systolic Blood Pressure Level with Mortality, ESRD, and Cardiovascular Events in Elderly Patients with CKD

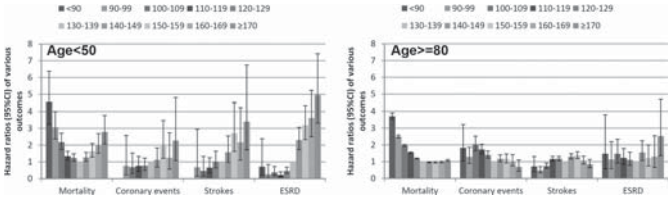
Csaba P. Kovesdy,[1,2] Miklos Zsolt Molnar,[2] Jun Ling Lu,[2] Ahmed Zeen Alabedeen Alrifai,[2] Robert B. Canada,[2] Elvira Gosmanova,[2] Barry M. Wall,[1,2] Kamyar Kalantar-Zadeh.[3] *[1]Memphis VAMC; [2]Univ of Tennessee; [3]Univ of California Irvine.*

Background: Hypertension is considered an important treatable risk factor for vascular and renal outcomes. A large proportion of patients with CKD are elderly, but the ideal SBP levels in these individuals are unknown.

Methods: From among 3,285,684 U.S. veterans with normal eGFR during 2005-2006, we identified 690,380 patients who developed CKD (2 consecutive eGFR values <60, >=90 days apart). Associations of SBP with subsequent clinical end points (all-cause mortality, incident coronary events (MI or CABG), strokes, and ESRD) were examined in time-dependent Cox models adjusted for gender, baseline eGFR, comorbidities, and time dependent DBP and antihypertensive medication use. The effect of age was studied by examining outcomes in patients categorized by age (<50 through >=80 years old, in 10-year increments).

Results: Compared to young patients, older patients showed markedly different associations with all studied outcomes. The lowest all-cause mortality was associated with

SBP 130-140 mmHg in the <50 group, and with SBP 140-160 mmHg in the >=80 group. The risk of coronary events, strokes and ESRD increased linearly with higher SBP in the <50 group, but showed an inverse association for coronary events, and no associations with strokes or with ESRD in the >=80 group (Figure). The transition in risk patterns was gradual, with more marked changes observed above age 70.



Conclusions: SBP shows markedly different associations in young versus old patients with CKD. High SBP shows significant associations with poor vascular outcomes in young patients, but no, or inverse associations in older patients. Until randomized clinical trials become available, caution is warranted when treating hypertension in elderly patients with CKD.

TH-PO721

Swimming Exercise Training (EXE) Decrease the Mortality Rate in Rats with Chronic Kidney Disease (CKD) by 5/6 Nephrectomy (5/6Nx)

Rafael Luiz, Rodolfo Rosseto Rampaso, Kleiton Augusto Santos Silva, Luciana Jorge, Edson Andrade Pessoa, Mario Luis Ribeiro Cesaretti, Nestor Schor. *Nephrology Div, Federal Univ of São Paulo, São Paulo, Brazil.*

Background: The aim of this study was to evaluate the EXE effects on renal function and mortality rate in rats with 5/6Nx.

Methods: Adult Wistar rats were divided in groups (n=8): Control (CTL), Control + Exercise (CTL+EXE), Sedentary 5/6Nx (Nx+SED) and 5/6Nx + Exercise (Nx+EXE). The protocol was employed in 5/6Nx rats after 7 days from the surgical procedures. Swimming periods were 60min/day, 5 days a week during 8 weeks. It was evaluated arterial pressure (AP), maximal exercise test (MEtest), creatinine *clearance* (CrCl), proteinuria (uProt), as well mortality rate.

Results: EXE did not modify the increment in MAP but prevent, at least in part, a lower decline in the MEtest caused by 5/6Nx (29±1 versus 16±2 m/min, p<0.05), Table. A higher CrCl in Nx+EXE was observed compared with Nx+SED, 2.27±0.33 versus 0.96±0..20 ml/min, respectively (p<0.05). Proteinúria was significantly lower in Nx+EXE versus NxS group (42.73 ± 1.50 versus 60.60 ± 2.00 mg/24h, p<0.05). A higher mortality rate was observed in Nx+SED (70%) versus Nx+EXE group (38%, p<0.05).

	C	E	NxS	NxE
AP (mmHg)	125 ± 1	128 ± 2	220 ± 16	210 ± 6
MEtest (m/min)	26 ± 2	36 ± 1	16 ± 2 *#	29 ± 1 #&
CrCL/ (ml/min/BW)	1.77 ± 0.18	1.52 ± 0.21	0.96 ± 0.20	2.27 ± 0.33 &
uProt (mg/24h)	12.00 ± 1.12	17.70 ± 1.38	60.60 ± 2.00 *#	42.73 ± 1.50 *#&
Mortality Rate (%)	0	0	70 *#	39 *#&

* vs C; # vs E; & vs NxS , p<0.05

Conclusions: Results suggested that the EXE minimize the impact of 5/6Nx, by lower decline in the CrCl (42%) and an important reduction in the increment of proteinuria that occurs with 5/6Nx by 30%. Finally, the lower mortality rate in Nx+EXE versus Nx+SED, indicate exercise protection especially in renal function that under this experimental protocol, prevent a potential decline in the progression of renal disease. Thus, it is reasonable to suggest that EXE could be an additional strategy to be employed in CKD.

TH-PO722

Exercise Training Improves Kidney Function, Cardiovascular Health, and Cardio-Respiratory Fitness in Patients with Progressive Stage 3-4 Chronic Kidney Disease: A Randomised Controlled Study

Sharlene A. Greenwood,[1] Pelagia Koufaki,[3] Tom Mercer,[3] Helen L. MacLaughlin,[1] Bruce M. Hendry,[2] Iain C. Macdougall,[1] Hugh Cairns.[1] *[1]Renal Medicine, King's College Hospital, London, United Kingdom; [2]Renal Medicine, King's College London, London, United Kingdom; [3]School of Health Sciences, Queen Margaret Univ, Edinburgh, United Kingdom.*

Background: The leading cause of death in patients with chronic kidney disease (CKD) is cardiovascular disease (CVD). Exercise capacity is significantly reduced in pre-dialysis patients.This pilot study examined the effect of 12-months of exercise training on kidney function and indices of CVD risk in patients with progressive stages 3-4 CKD.

Methods: 20 patients were randomised to a rehabilitation group (REHAB, n = 10) or usual care (UC, n = 10) for 12 months. The REHAB group received exercise training (3x/week) and the UC group received standard care. Kidney function was assessed by comparing individual rate of change slopes in eGFRcr for each participant for a 12 months pre-intervention period, and for the 12-month intervention period using ANCOVA. Pulse Wave Velocity (PWV), VO_2peak, waist circumference (WC), and weight were assessed at 0, 6 and 12 months.

Results: 18 participants completed the study (REHAB, n=8; UC n=10). Following the intervention, a significant mean difference in eGFRcr (+7.8±3.0 ml/min/1.73m^2/year (p=0.03, 95% CI 0.53, 9.79) was observed between REHAB and UC groups. There were significant between group mean differences,after adjustment for baseline values, in PWV (-2.30 m/sec; 95%CI -3.02, -1.59), BMI (-3.3 kg/m^2; 95%CI -5.7, -0.9), weight (-5.6 kg p=0.02, 95%CI -10.1, -1.2), WC (-7.1±2.18 cm; 95%CI -12.4, -3.2), and relative VO_2peak (5.7 ml/kg/min; 95%CI 1.34, 10.10). Change in eGFRcr was inversely correlated with PWV (r = -0.5, p= 0.04), and the change in WC was associated with change in eGFRcr (r = -0.6, p= 0.004) in all patients at 12 months.

Conclusions: The intervention has the potential to improve kidney function, VO2peak, PWV, waist circumference and quality of life in patients with progressing stages 3–4 CKD. This small study suggests that this is a feasible approach for exercising this patient population and sets the scene for a large multi-centre study.

Funding: Other NIH Support - National Institute Health research UK

TH-PO723

Renal Function Reserve in Healthy Subjects by Two Different Oral Protein Load to Evaluate a Standard Method for 'Renal Stress Test'

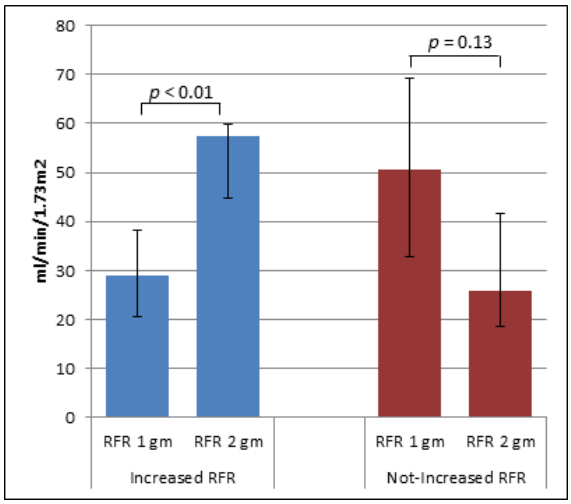
Aashish Sharma, Jose Jesus Zaragoza, Gianluca Villa, Leonardo Claudino Ribeiro, Renhua Lu, Marco Sartori, Massimo de Cal, Valentina Corradi, Carla Estremadoyro, Maria Jimena Mucino-Bermejo, Mauro Neri, Anna Lorenzin, Elena Faggiana, Claudio Ronco. *Nephrology and Renal Transplant Medicine, International Renal Research Inst Vicenza, Vicenza, Italy.*

Background: Renal Function Reserve (RFR) represents the capacity of the kidney to increase glomerular filtration rate (GFR) in response to certain physiological or pathological stimuli.

Methods: An observational study among 18 young healthy individuals for the evaluation of a standard protocol for renal stress test with a protein load of 1 and 2 gram/kg body weight. To evaluate the differences of GFR observed before and after protein load (PL) a t-test was performed in all subjects. Data are expressed as ml/min/1.73m2, median [I-III interquartile] and *p* value. A *p* value <0.01 was considered statistically significant.

Results: Median basal GFR for all subject was 99.7[99.4-106.8]. The maximal GFR after 1 gm PL (139.64[123.2-165.7]) was not statistically different than 2 gm PL (147.2[130.5-155.0]). 44.4% of subject had a statistically significant higher RFR with 2gm than 1 gm (respectively 57.4[44.6-59.8] versus 28.9[20.4-38.2], p<0.01) while 55.6% did not (50.5[32.7-69.2] versus 25.7[18.6-41.5], p>0.01).

Basal GFR 99.7[99.4-106.8]	**Stress GFR 1gm**	**Stress GFR 2gm**	***p***
	139.6[123.2-165.7]	147.2[130.5-155.0]	N.S.
	RFR 1gm	**RFR 2gm**	***p***
Increased RFR (44.4%)	28.9[20.4-38.2]	57.4[44.6-59.8]	<0.01
Not Increased RFR(55.6%)	50.5[32.7-69.2]	25.7[18.6-41.5]	N.S.



Conclusions: With this study we found large variation in the stress GFR and the renal function reserve among individuals. These variations in the stress GFR and RFR can be used to make an ideal standard stress test to predict risk of acute kidney injury and future risk for chronic kidney disease, and to uncover possible loss of renal functional mass.

TH-PO724

Accuracy for Creatinine Test on Dry Blood Drop Sample on Filter Paper for Chronic Kidney Disease Screening

Miguel Luis Graciano, Alan Castro Silva, Jocemir R. Lugon. *Clinical Medicine, Univ Federal Fluminense, Niteroi, RJ, Brazil.*

Background: CKD screening is advisable due to the high morbidity and mortality and is usually performed by sampling blood and urine.

Methods: Here we present an innovative and simpler means, by measuring creatinine in a drop of dry blood on filter paper. 106 individuals at high risk for CKD were enrolled.

Results: Mean age 57 ± 12 years, 74% were female, 40% white, 34% mullatos and 25% black. 76% were hypertensive, 30% diabetic, 37% had family history for CKD, and 22% smoked. The BMI was 29,5 ± 6,9 kg/m^2, systolic blood pressure was 125 mmHg (IQR 120-140 mmHg) and diastolic blood pressure was 80 mmHg (IQR 70-80 mmHg). The validity of the filter paper test was calculated considering CKD as eGFR<60/ml/min. According to MDRD equation, sensitivity was 96%, specificity 55%, predictive positive value was 96%, predictive negative value was 55%, and accuracy was 92%. Results for Cockcroft-Gault and CKD-EPI were similar. A Bland and Altman analysis showed a relatively narrow range of creatinine values differences (+0,68mg/dl to -0,55mg/dl) between ±1,96 SD, without systematic differences.

Conclusions: Accordingly, creatinine measured on dry blood samples is minimally invasive, disclosed excellent accuracy, and may be useful for screening CKD.

TH-PO725

Albumin Creatinine Ratio versus Protein Creatinine Ratio for Nephrology Referral in Primary Care Sohan Shah,[1] Bhavna Pandya.[1,2] *[1]Faculty of Health and Life Sciences, Univ of Liverpool, Liverpool, United Kingdom; [2]Nephrology Dept, Aintree Univ Hospitals, Liverpool, United Kingdom.*

Background: It is well established that spot-urine tests like albumin:creatinine ratio (ACR) and protein:creatinine ratio (PCR) are comparable with values from 24-hour urinary protein collection (24h UPC) within certain ranges of proteinuria. ACR, in particular, has shown to be more sensitive and useful in diabetic patients. Current UK guidelines suggest referral of patients at ACR >70 or PCR >100 mg/mmol. We aimed to compare both tests for referral of nephrology patients from primary care.

Methods: Retrospective analysis of 502 urine samples with data for ACR, PCR and 24h UPC between 2006 and 2013 was conducted. Samples were assessed for corresponding ACR and PCR values for 24h UP >1g/day in order to determine cut-off values for significant proteinuria. Cost analysis was also performed.

Results: ACR [Spearman's $\rho = 0.813$ ($p<0.001$), $R^2 = 0.312$] and PCR [$\rho = 0.918$ ($p<0.001$), $R^2 = 0.845$] correlate well with 24h UP. The correlation between ACR and PCR was also strong [$\rho = 0.822$ ($p<0.001$), $R^2 = 0.276$]. ROC curves were used to analyse the performance of ACR and PCR in predicting significant proteinuria. The area under the curve (AUC) for ACR was 0.953 and 0.978 for PCR. An ACR of 70 mg/mmol had a much lower sensitivity (67.9% versus 82.4%) but marginally higher specificity (98.1% versus 96.0%) than a PCR of 100 mg/mmol in detecting significant proteinuria. The optimal cut-off points for ACR (27.11 mg/mmol) and PCR (69.55 mg/mmol) were determined to maximise the discriminatory ability of each test for significant proteinuria (>1g/day). The average cost per sample for ACR and PCR was ≤0.76 and ≤0.60 respectively.

Conclusions: ACR and PCR spot-urine tests are both suitable for the detection of significant proteinuria in an unselected cohort of patients. PCR is more sensitive and correlates better with 24h UP at lower and higher thresholds; however, the variable proportion of non-albumin proteins contributing to PCR must be accounted for. Still, ACR is the more specific test over different age groups and in the presence of comorbidities. We recommend lower referral cut-off criteria for ACR and PCR.

TH-PO726

Glycated Albumin as an Indicator of Glycemic Control in Pre-Dialysis Diabetic Chronic Kidney Disease Patients Sung Chang Bae, Hyeong Cheon Park, Hoon Young Choi, Sung-Kyu Ha, Ah Ran Choi, Tae Hoon Kim, Miok Cho. *Nephrology Div of Internal Medicine, Gangnam Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Good glycemic control is important to prevent progression of diabetic nephropathy and reduce cardiovascular complications. Recently, several studies suggested that hemoglobin A1c (HbA1c), a widely used glycemic control marker, has serious limitations by falsely underestimating glycemic control in diabetic patients on hemodialysis. In contrast, glycated albumin (GA), which is not influenced by RBC survival time, is thought to more accurately reflect glycemic control in ESRD patients. Study aim was to validate this finding in pre-dialysis diabetic chronic kidney disease (CKD) patients.

Methods: Clinically stable pre-dialysis type 2 diabetic patients were enrolled between March 2009 and August 2012. A total of 497 patients were enrolled and stratified into 6 groups using newly revised KDIGO CKD staging that subdivided stage 3 into 3a and 3b stages. Parameters of glycemic control were investigated along with other biochemical and clinical parameters.

Results: The numbers of patients according to CKD stages 1 to 4-5 were consisted of 168, 151, 76, 47, and 55 subjects, respectively. The HbA1c and GA showed positive correlation at all CKD stages, however, the slope of regression line between GA and HbA1c was significantly steeper (control group versus other CKD stages: $p<0.05$) with decrease in renal function. The GA/HbA1c and serum glucose/HbA1c in CKD stage 3b and 4-5 were significantly higher than in controls, and the GA/HbA1c increased ($r=0.22$, $p<0.001$) with progression of renal failure. In contrast, the glucose/GA remained constant throughout the all CKD stages ($r=0.07$, $p=0.06$). In multivariate analysis, weekly erythropoietin (EPO) dose ($p=0.02$) was associated with HbA1c. The cut off value in ROC curve of weekly EPO dose affecting HbA1c was 6000 U/week (AUC 0.91, 95% CI 0.78–1.00).

Conclusions: Our results indicate that HbA1c may underestimate glycemic control state even in pre-dialysis diabetic CKD patients, especially those who are on EPO treatment. The GA might be an useful indicator of glycemic control in pre-dialysis diabetic CKD patients.

TH-PO727

An Increase in the EPA/AA Ratio Is Associated with Reduction of Proteinuria in CKD Patients Hitoshi Suzuki, Chieko Nogi, Hiroaki Io, Yusuke Suzuki, Yasuhiko Tomino. *Nephrology, Juntendo Univ Faculty of Medicine, Tokyo, Japan.*

Background: Previous epidemiological studies demonstrated that the ratio of n-6 to n-3 polyunsaturated fatty acids is associated with cardiovascular diseases. Recently, there is increasing evidences that dyslipidemia contribute to progression of CKD. We herein investigated whether the beneficial effect of highly purified eicosapentaenoic acid (EPA) on progression of CKD is associated with changes in the ratio of EPA relative to arachidonic acid (AA), in patients with dyslipidemia.

Methods: We measured serum levels of EPA/AA ratio, oxidized-LDL, high sensitive CRP (hs-CRP), Asymmetric Dimethylarginine (ADMA), and urinary albumin and 8-Hydroxydeoxyguanosine (8-OHDG) before and after treatment with highly purified EPA for six months (1.8g daily, n=71). Basic therapy, such as, statin, angiotensin receptor blocker and angiotensin converting enzyme inhibitor were not changed during the clinical study.

Results: Before treatment with EPA, the EPA/AA ratio in CKD patients is lower than those in non-CKD patients ($P<0.05$). Especially, in patients with CKD G4 and G5, the EPA/AA ratio were low, compared to patients with early stage of CKD ($P<0.05$). EPA significantly increased the EPA/AA ratio and decreased serum level of triglyceride ($P<0.05$). Moreover, the levels of urinary albumin significantly decreased at six months (-14.5 %, $P<0.01$). Importantly, a regression analysis revealed that an increase in the EPA/AA ratio significantly determinants of a reduction of proteinuria, but not a decrease of serum triglyceride by EPA($P<0.05$). Highly purified EPA also has effects to reduce serum levels of oxidized-LDL, hs-CRP, and urinary 8-OHDG ($P<0.01$, respectively).

Conclusions: EPA improves the urinary protein in association with an increase in the EPA/AA ratio in CKD patients with dyslipidemia. EPA may have renoprotective role by the anti-inflammatic effect due to the reduction of oxidative stress.

TH-PO728

Dietary and Herbal Supplement in CKD and ESRD on the Internet: Truth versus Myth Helga B. Vamenta-Morris, Emaad M. Abdel-Rahman. *Nephrology, UVA, Charlottesville, VA.*

Background: Interest and use of complementary and alternative medicine have garnered rising interest recently. Natural products including herbs, vitamins, and minerals are the most popularly consumed. The Internet is a ubiquitous source of information and a market for herbal and dietary supplements. Many of these substances have not been validated scientifically. Production and sale are not strictly regulated. Studies showed that the use of some of these supplements may be potentially harmful to CKD patients. **Aim:** Evaluate dietary and herbal supplement product advertisement claims on CKD/ESRD benefit on the Internet and determine if these claims are scientifically validated.

Methods: A questionnaire assessing each website was formulated. Each product ingredient was recorded onto the questionnaire by two independent reviewers. Statistical analysis was performed.

Results: Of the 184 websites reviewed, 9.2 % and 28.7% claimed to have products that are alternative to renal replacement therapy and decrease CKD progression, respectively. Only 39.4% of the sites recommended consulting a doctor. Over 90 % did not caution against potential drug- and disease-interaction and in the use during pregnancy or in children. The ten common plant ingredients found with claims to be beneficial for kidney patients were uva ursi, dandelion, parsley, corn silk, juniper, celery, buchu, horsetail, marshmallow, and stinging nettle. In contrast to their claims, the effects of these substances on kidneys were not validated in humans. The available animal studies showed detrimental effects and potential drug interactions with commonly used medications in the CKD/ESRD population.

Conclusions: Most sites do not offer sufficient cautionary guidelines, and their product claims of renal benefit could not be verified. Nephrologists need to be cognizant of the lack of substantiated proof of benefits of these substances and the potential adverse effects in the animal models that may translate to patients. Most importantly the policy needs to change regarding regulation of manufacture, advertisement, and sale of these products to prevent patient harm and misinformation.

TH-PO729

Treatment of IgANephropathy with Renal Insufficiency Using a Chinese Herbal Medicine Prescription Lin Wang,[1] Pan Gan,[2] Xianwen Zhang,[3] Yueyi Deng,[4] Zhi Qiang Huang,[5] Yiping Chen.[6] *[1]Long Hua Hospital, China; [2]Shanghai Univ of Traditional Chinese Medicine, China; [3]Long Hua Hospital, China; [4]Long Hua Hospital, Shanghai, China; [5]Univ of Alabama at Birmingham, Birmingham, AL, American Samoa; [6]Long Hua Hospital, China.*

Background: Shen'An Decoction (SA) is a Chinese herbal medicine prescription used to treat IgA nephropathy (IgAN) with renal insufficiency in China for decades. To evaluate its efficacy, we compared therapeutic responses to SA with those to SA plus steroids, cytotoxic agents with or without ARB (SA+).

Methods: Seventy-one patients with biopsy-proven IgAN with renal insufficiency were studied. All the pathological findings were at or above Lee Grade III. 32 patients were treated with SA, and 39 patients with SA+. Median follow-up time was 38.5 mos. Average age was 38±10 and 36±8 yrs, respectively. Estimated glomerular filtration rate (eGFR) ranged from 15 to 75 ml/min/1.73m^2 and urinary protein (UP)≥1.0 g in both groups.

Results: In SA group, eGFR improved from 44.81±20.5 to 53.4±22.9, Serum creatinine (Scr) dropped from 2.0±1.13 to 1.72±0.93 mg/dl and UP dropped from 2.60±0.35 to 1.11±0.26 g/24 h after the treatment; in SA+ group, eGFR improved from 56.1±15.2 to

67.8±19.2, Scr dropped from 1.58±0.49 to 1.36±0.44 mg/dl and UP dropped from 1.65±0.19 to 1.27±0.20 g/24 h after the treatment. There was no statistically significant difference between SA *versus SA+ in* ΔeGFR and ΔScr. ΔUP *of SA group was significant greater than that of SA+*. There were no differences in blood pressure among the groups with different treatments. *Among patients treated with SA+, 5 patients developed herpes zoster 12 months after treatment and 6 patients developed upper-respiratory-tract infection followed by exacerbated proteinuria, 3 female patients developed cessation of menstruation and 2 showed increased GPT. No side effects were reported for patients treated with SA only.*

Conclusions: SA improved renal function and proteinuria in severe IgAN with similar efficacy as SA+. Significant side effects were found in SA+ group but not in SA. These data justify future randomized clinical trials to assess the clinical impact of SA in severe IgAN treatment.

TH-PO730

Exploring Clinical and Pharmacological Effects of Nalbuphine HCl Oral Tablets in Hemodialysis Subjects with Pruritus

Thomas Sciascia,[1] Howard Hait,[1] Jolene Kay Berg,[2] Harry Alcorn,[2] Amale Hawi.[1] *[1]Trevi Therapeutics, New Haven, CT; [2]DaVita Clinical Research, Minneapolis, MN.*

Background: Nalbuphine is a mixed mu-antagonist/kappa agonist opioid marketed as a parenteral solution indicated for moderate to severe pain. It has been shown to reduce itch in morphine induced pruritus and Substance-P induced itch mouse model. An extended release (ER) nalbuphine oral dosage form was developed. The literature is sparse on opioid drug class studies in hemodialysis (HD) subjects and there is no literature on the use of nalbuphine in this population. There is no currently approved treatment of uremic pruritus and the literature reports increased morbidity and mortality in the moderate to severe pruritic HD population.

Methods: Nalbuphine ER tablets were studied up to 17 days in an open label multiple escalating dose study in 14 HD subjects with pruritus to assess safety, PK and explore its impact on itch as measured by self-report itch-VAS (visual analog scale) ranging from 0 (none) to 10 (worst possible). Nalbuphine was safely titrated over a wide range (30 mg-240 mg BID).

Results: Safety data included extensive monitoring of EKG, blood pressure, pulse oximetry during waking hours and continuous pulse oximetry at nighttime with no significant findings. The drug was clinically well tolerated over the entire dose range. PK analysis indicated that nalbuphine does not accumulate upon repeated doses and is not dialyzed by HD. Despite the extensive use of concomitant medications, there was no obvious findings indicating safety, PK or pharmacodynamic adverse drug interactions. Nalbuphine suppressed itch in a dose dependent manner in 12/14 subjects from a mean VAS 4.0 (1.3-6.6) to 1.2 at 180 mg BID. Subgroup analysis of 8/14 with moderate to severe pruritus (mean VAS 5.1 (4.2-6.6) showed a pronounced decrease with mean change -1.2, -2.2, -3.4, -3.6, -4.9 at the 30, 60,120, 180 and 240 mg BID doses respectively.The greatest percentage decrements occurred at 60 and 120 mg BID doses.

Conclusions: Nalbuphine ER tablets can be safely administered to HD subjects over a wide dose range and shows promise as an anti-pruritic.

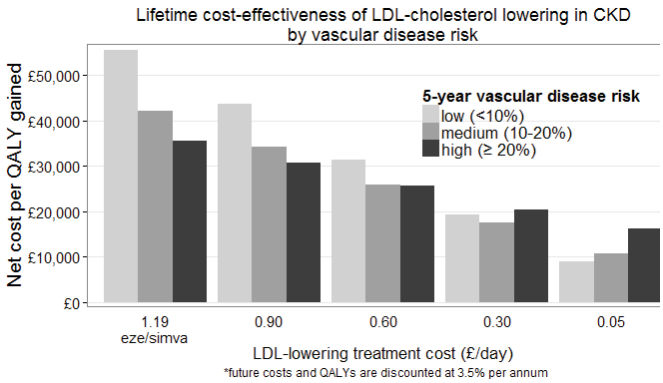
Lifetime Benefits and Cost-Effectiveness of LDL-Cholesterol Lowering in Chronic Kidney Disease: Results From the Study of Heart and Renal Protection (SHARP)

Iryna Schlackow, Borislava N. Mihaylova. *On Behalf of the SHARP Collaborative Group, Nuffield Dept of Population Health, Univ of Oxford, Oxford, United Kingdom.*

Background: The SHARP trial showed that lowering LDL-cholesterol (LDL-C) with simvastatin 20 mg plus ezetimibe 10mg daily (Eze/Simva) safely reduces major atherosclerotic events (rate ratio 0.83, 95% CI 0.74-0.94) in moderate-to-severe chronic kidney disease (CKD). We report lifetime benefits and UK cost-effectiveness of the intervention in categories of CKD patients.

Methods: Vascular disease risks, CKD progression, health-related quality of life and UK hospital costs were estimated using SHARP data and combined into a lifetime CKD model that was externally validated. Cost of LDL-lowering in the analysis was varied from UK ≤1.19/day (Eze/Simva) to ≤0.05/day (equivalent to the cost of a generic statin regimen in the UK). Net healthcare costs (intervention cost minus hospital cost savings) per quality-adjusted life-year (QALY) gained with Eze/Simva are reported for categories of CKD patients subdivided by predicted 5-year vascular disease risk at randomisation.

Results: In SHARP, lifetime use of Eze/Simva compared to no statin treatment increased quality-adjusted life years (QALYs) by 0.22 in high-risk participants with net cost per QALY ≤35,700, and by 0.18 in low-risk participants with net cost per QALY ≤55,500 (Figure).



Conclusions: At current prices, Eze/Simva is unlikely to be judged cost-effective in CKD in UK compared to no treatment. Less costly regimens (e.g. atorvastatin 20mg daily, which lowers LDL cholesterol by slightly less than Eze/Simva), although not assessed directly in this population, may be a more cost-effective means of reducing cardiovascular risk in patients with CKD.

Designing a Patient-Centered Medical Neighborhood (PCMN) for CKD: Identifying a High-Risk, High-Cost Population

Lance D. Dworkin,[1] Brad Crough,[3] Ami Shah,[3] Lynn Mcnicoll,[1] Douglas G. Shemin,[1] Terri L. Montague,[1] Katherine Richman,[1] Jessica A. Devine,[3] Peter Hollmann,[2] Andrew J. Cohen.[1] *[1]Medicine, Alpert Medical School, Brown Univ, Providence, RI; [2]Blue Cross Blue Shield Rhode Island, Providence, RI; [3]Univ Medicine, Providence, RI.*

Background: The PCMN expands the patient-centered medical home by combining primary care and specialty physicians, nurses, pharmacists, and others to provide coordinated, high-quality care. We developed a nephrology PCMN for patients with CKD with 5 academic primary care practices. We first identified a target population.

Methods: We mined an electronic medical record (EMR) to identify non-dialysis patients with CKD 3 or greater using the CKD-EPI formula and 2 serum creatinines > 30 days apart over 2 years. Additional comorbidities including proteinuria (dipstick positivity, protein/creatinine >0.2 g/g or microalbumin/creatinine >30mg/g); hyperkalemia (K.>5.5 mEq/L); heart failure; diabetes; or uncontrolled hypertension (12-month average systolic BP above goal) were identified from EMR data or coding. Claims data from BCBSRI were cross-referenced. A nephrology nurse care manager (NCM) completed screening using a novel tool to stratify risk.

Results: Out of 27,253 patients, 731 had CKD 3A or above. Of 731 with CKD 35% had diabetes, 16% hypertension not at goal, 18% proteinuria, 8% CHF, and 4% hyperkalemia; 71% had never seen a nephrologist. More than 50% of 104 stage 4 and 5 patients had >2 co-morbidities. BCBSRI claims data revealed annual per-patient costs of $22,647 compared with $3,829 in non-CKD patients. (Comparable USRDS data: $23,128/patient-year). Inpatient stays and pharmacy accounted for 38% and 20% of the cost respectively. NCM screening was completed for 95% of the 731 people; 35% were felt to merit nephrology involvement based on CKD stage and/or comorbidities.

Conclusions: EMR based screening of patients in primary care practices using creatinine-based eGFR and other clinical measures defines a validated high-risk, high-cost population, the majority of whom have not seen a nephrologist and might benefit from collaborative care. Whether the PCMN model will improve patient outcomes and/or control costs is being evaluated.

TH-PO733

A Patient-Centered Medical Neighborhood (PCMN) for CKD

Andrew J. Cohen,[1] Brad Crough,[1] Ami Shah,[1] Lynn Mcnicoll,[1] Antonia L. Ross,[1] Douglas G. Shemin,[1] Terri L. Montague,[1] Katherine Richman,[1] Jessica A. Devine,[1] Peter Hollmann,[2] Lance D. Dworkin.[1] *[1]Medicine, Warren Alpert Medical School, Brown Univ; [2]Blue Cross Blue Shield of Rhode Island.*

Background: The PCMN expands the patient-centered medical home (PCMH) by combining primary care, specialty physicians, and others to provide coordinated, high-quality cost-effective care. With support from BCBSRI, we designed a PCMN for patients with CKD with 5, PCMH practices and one nephrology practice. Here we describe our PCMN intervention and model.

Methods: Nephrologists, primary care Physicians, geriatricians, analysts, practice management professionals, nurse care managers (NCM), and medical informatics experts designed the program. The care teams include PCP physicians and NCMs, nephrologists, a nephrology NCM, pharmacist, social worker and office staff.

Results: After screening over 27,000 primary care patients for ≥ CKD 3B or 3A with co-morbidities, 330 patients were identified as requiring intervention. Multiple levels of interaction between Primary Care and Nephrology were planned based on CKD stage and co-morbidities. This includes no interaction, pre-consultation (recommendations without referral) with the nephrology NCM (n=64), pre-consultation with nephrology (n=240),

referral for diagnosis and renal/PCP co-management (n=26), or PCMH within nephrology (n=30). A compact was executed between PCMH and Nephrology defining expectations. A care plan created for each patient sets patient specific goals and clinical responsibilities for each physician/practice. All patient encounters and formal communication are documented in and conducted via a shared EMR. Data on quality outcome measures including blood pressure control, metabolic bone disease screening, anemia management, hospitalizations, ER visits, and overall cost are being tracked.

Conclusions: EMR based screening of patients in several PCMH practices identified a high-risk, high-cost population with CKD for inclusion in a collaborative, team care model. Eventually, we plan to include other specialists in the care team. The impact of the PCMN model on clinical outcomes and costs is being evaluated.

TH-PO734

Not Only Hyperuricemia but also Hypouricemia Is Associated with Glomerular Filtration Rate Decline in Healthy People

Eiichiro Kanda,[1] Toshitaka Muneyuki,[2] Yoshihiko Kanno,[3] Kei Nakajima.[4] *[1]Tokyo Koysai Hospital, Japan; [2]Saitama Citizens Medical Center; [3]Tokyo Medical Univ; [4]Josai Univ.*

Background: The relationship between hyperuricemia and chronic kidney disease (CKD) has been found in various observational studies. Although hypouricemia is associated with cardiovascular events, it was not established as a risk factor for CKD. In 8-year longitudinal study, we investigated the relationship between serum uric acid level (UA) and estimated glomerular filtration rate (eGFR) decline in healthy people.

Methods: 12,819 healthy people were enrolled as subjects in this analysis as part of the Saitama Cardiometabolic Disease and Organ Impairment Study, Japan. Their laboratory data including eGFR-decline speed were examined every three years. The outcome event was the decrease in eGFR by >25%. The subjects were divided into 5 groups on the basis of quintiles of UA at baseline. Then, the group 1 (UA<4mg/dl, n=2365) was further divided into 4 groups on the basis of quartiles of UA.

Results: Mean(SD) age was 42.1(10.8)years; eGFR, 75.7(19.9)ml/min/1.73m^2; and UA, 5.3(1.4)mg/dl. In analysis 1 (all participants), multiple regression analysis showed that eGFR-decline speed was negatively associated with UA (p=0.0001). Logistic regression analysis adjusted for baseline patients' characteristics showed that high-UA groups had a higher risk of the outcome event compared to the group 1; group 3 (5.7<=UA<6.5mg/dl), adjusted odds ratio (aOR) 1.99 (95%CI 1.35-2.92); group 4 (6.5mg/dl<=UA), aOR 2.14 (1.43, 3.20). In analysis 2 (subjects without CKD in group 1), UA positively correlated with eGFR-decline speed (p=0.01). Among the subjects, those with high or very low UA had a higher risk of the outcome event than group B (3.2<=UA<3.5mg/dl); group A (UA<3.2mg/dl), aOR 3.55 (1.45, 8.69); group D (3.8<=UA<4mg/dl), aOR 2.48 (1.10, 5.59). Generalized estimating equation models adjusted for baseline patients' characteristics showed that as increase of 1 in UA decreases the risk of the outcome event; aOR 0.488 (0.454, 0.522).

Conclusions: This study showed that not only high but also very low UA was associated with eGFR decline. Hypouricemia may be also a predictor of kidney function decline in healthy people.

TH-PO735

Uric Acid Control in Stage 1-3 CKD in a Southeast Urban Cohort

Lindsey Norris,[1] Betzaida Rodriguez,[1] Tibor Szarvas,[2] Eva Csongradi,[1,3] Tibor Fulop.[1] *[1]Dept of Medicine, Univ of Mississippi Medial Center, Jackson, MS; [2]Dept of Mathematics, Louisiana State Univ, Shreveport, LA; [3]Dept of Medicine, Univ of Debrecen, Hungary.*

Background: Uric acid is an emerging risk factor for Chronic Kidney Disease (CKD). The effectiveness of uric acid control may have an impact on the risk of future CKD. The effectiveness of current allopurinol dosing has not been well studied in populations affected by multiple risk factors for hyperuricemia.

Methods: We have collected data on multiple clinical and laboratory parameters for 73 consecutive CKD clinic patients with stage 1-3 CKD (68.5% stage CKD), representing a local urban cohort from the Southeast U.S. Data have analysis with SPSS v19 and expressed with means (SD) and percent (%).

Results: Mean age for the was 61.9 (12) years, weight 107.6 (29.9) kg with BMI 37.4 (16.7) kg/m2; 42.5% was female, 68.5% African-American, 53.4% had diabetes and 48% had gout. Aspirin was used in 52% of participants. Overall metabolic control was acceptable: potassium 4.1 (0.5) mEq/l; HCO3 25.4 (3.2)mEq/L, phosphorus 3.2 (0.5) mg/dL, hemoglobin 12.3 (1.9) g/dl and albumin of 4 (0.4) g/dl. Mean allopurinol dose was 195 (100) mg and serum uric acid 7.7 (2.5) mg/dL in the entire cohort. Uric acid correlated significantly with both weight (r: 0.255, p=0.03) and BMI (r: 0.250, p=0.04) but not with allopurinol dosing. Among patient with stage 3 CKD (mean race-adjusted MDRD eGFR: 42.9 (8.1) ml/min/1.73m2), allopurinol dose was 195 (96) mg/day and achieved uric acid was 8.1 (2.6) mg/dL.

Conclusions: Conventional and conservative allopurinol dosing guidelines may not achieve normalization of serum uric acid in the current era of obesity epidemics in CKD.

TH-PO736

Effect of Mycophenolate Mofetil on Expression of Serum and Urine TGF-β1 in Immunoglobulin A Nephropathy

Yongcheng He, Mijie Guan, Tong Li. *Dept of Nephrology, Shenzhen Second People's Hospital, Shenzhen, Guangdong Province, China.*

Background: IgAN is the most common form of glomerulonephritis in the world .TGF-β1 stimulates renal fibrosis in various renal diseases including IgA nephropathy. Previous studies showed that TGF-β1 over expressed in the kidney tissue, serum and urine of IgAN patient.There is few study explore the effect of MMF on the expression of TGF-β1.In this study,we aim to explore the serum and urine level of TGF-β1 and the effect of MMF on it in IgAN patients.

Methods: Samples were divided into three groups: Group C was composed of 19 healthy volunteers, Group MMF included 48 patients treated with MMF and Group IgAN formed by 39 IgAN patients which matched with MMF treatment group .13 patients in Group MMF had been treated with MMF for 3 months after kiney puncture biopsy and finished the follow-up visits.The level of TGF-β1 was detected by ELISA(R&D system).

Results: Comparing with Group IgAN, lower level of TGF-β1 in serum (*P=0.036, P=0.0004*) and in urine (*P<0.001*, *P =0.0001*) were found both in Group C and Group MMF. The level of TGF-β1 in Serum was positively correlated with pathological grading and urinary protein excretion (*p=0.044, 0.001*), while negatively correlated with eGFR (*p=0.012*)and positively correlated pathological grading,and urinary protein excretion(*p*=0.01,*P<0.001*)in urine. The level of TGF-β1 in both serum (*p=0.049*)and urine (*p=0.028*) had significantly difference between the group (n=18) with the LEE clasification>3 and the group (n= 21) with the LEE clasification≤3 as well as between the group with treatment for 3 to 6 months and the group with treatment > 6 months.The level of TGF-β1 in 13 patients that finished prospective follow-up visits showed obvious difference before and after treatment in urine (*p=0.002*) and a downward trend after treatment in serum.

Conclusions: The level of TGF-β1 in serum and urine was significantly elevated in IgAN patients,and MMF could reduce the level of TGF-β1 in serum and urine in IgAN significantly,especially in the treatment > 6 months. Therefore, TGF-β1 can be considered as an important indicator not only to predict the progression of IgAN, but also to assess the therapeutic effect of MMF in IgAN.

TH-PO737

Prediction of 30-Day Readmission after Percutaneous Coronary Intervention: Effect of Post Intervention Glomerular Filtration Rate

Claudine T. Jurkovitz, Paul Kolm, Daniel Elliott, Carla A. Russo, William S. Weintraub. *Value Inst, Christiana Care Health System, Newark, DE.*

Background: Chronic kidney disease is a risk factor for 30-day readmission in patients who undergo percutaneous coronary intervention (PCI). We investigated if adding the post-PCI Glomerular filtration rate (GFR) or the % GFR difference pre-post PCI improved the prediction of 30-day readmission.

Methods: We conducted a retrospective study of patients admitted for PCI in 2010-2014. GFR was estimated using CKD-Epi. Multilevel logistic regression was used to assess the impact of post-PCI GFR and % GFR difference on 30-day readmission after adjusting for age, sex, race, diabetes, congestive heart failure (CHF), chronic obstructive pulmonary disease (COPD), elective procedure, previous 6-month hospitalization, past PCI. Analyses were stratified by pre-PCI GFR (GFR≥60, GFR30-59, GFR<30 mL/min/1.73m^2).

Results: A total of 6,296 patients had PCI; 5,066 had pre-post PCI GFRs. Patients characteristics are listed in table 1; 30-day readmission rate was 6.5%, 12.3%, 14.5% respectively for patients with pre-PCI GFR≥60, 30-59, <30. In patients with pre-PCI GFR≥60, adding the post-PCI GFR improved the c-index (0.76 to 0.78) and the risk of readmission decreased by 12% for each 10 mL/min raise in post-PCI GFR (OR=0.88;95%CI 0.81-0.96). In patients with pre-PCI GFR30-59, the decrease in risk was not significant (OR=0.87;95%CI 0.76-1.01) and the c-index did not change. In those with pre-PCI GFR<30, post-PCI GFR did not impact the readmission or the c-index. Replacing post-PCI GFR with the % GFR difference pre-post PCI did not improve the prediction models.

Conclusions: Adding post-PCI GFR improves the prediction of 30-day readmission in patients with pre-PCI GFR≥60. Adding post-PCI GFR into a risk stratification strategy may be helpful to identify patients at higher risk despite normal baseline kidney function.

	GFR≥60 n=3680	GFR30-59 n=1083	GFR<30 n=303	p

TH-PO738

Variation in Cost and Quality in Kidney Transplantation Carl E. Dean,[1] Suying Li,[2] Nicholas Salkowski,[3] Craig Solid,[2] Mark Schnitzler,[4] Jon J. Snyder,[3,5] Bertram L. Kasiske,[3,7] Ajay K. Israni,[3,5,7] S.J. Kim. *[1]Medicine, Univ of Minnesota, Minneapolis, MN; [2]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [3]Scientific Registry of Transplant Recipients, Minneapolis Medical Research Foundation, Minneapolis, MN; [4]Medicine, St. Louis Univ, St. Louis, MO; [5]Epidemiology, Univ of Minnesota, Minneapolis, MN; [6]Medicine, Univ of Toronto, Toronto, ON, Canada; [7]Medicine, Hennepin County Medical Center, Minneapolis, MN.*

Background: The need to maintain quality while containing costs remains at the forefront of health care policy discussions. The relationship between cost and kidney allograft failure has not been described.

Methods: We compared Medicare claims from the United States Renal Data System for all adult kidney recipients who underwent transplantation between January 1, 2007 and June 30, 2009. Adjusting for recipient, donor and transplant characteristics; region; and local wage index, we calculated and compared the relative cost (observed/expected cost) for the first year post-transplant for all kidney transplant centers. We then calculated the ratio of observed/expected kidney allograft failure over the same time period for each center using the program-specific reports from the Scientific Registry of Transplant Recipients.

Results: Overall, there was no correlation between relative cost and observed/expected allograft failure (r = 0.096, P = 0.22) (Figure 1). Centers with costs and allograft failure rates lower than expected (higher-performing centers) varied significantly from centers with costs and allograft failure rates higher than expected (lower-performing centers) by donor and recipient characteristics and region (Table 1).

Conclusions: Further investigations are needed to determine the specific cost-effective practices of higher- and lower-performing centers to reduce both cost and incidence of allograft failure.

Choice to Accrual for Home Dialysis Ashutosh M. Shukla,[1] Rebecca Hubbard,[2] Michelle Thomas,[2] Teri B. Martinez.[1] *[1]NFSGVHS & Univ of Florida; [2]Dialysis Clinic Inc., Gainesville, FL.*

Background: Comprehensive CKD education (CPE) improves patient awareness, and choice of home dialysis therapies (HoD). However, their impact on patients' eventual renal replacement therapy (RRT), (i.e. Choice to Accrual) has not been well reported.

Methods: We performed a retrospective analysis of the first 14 months of our recently established CPE clinic at University of Florida (UF) aimed to examine this issue. All predialysis patients with stage IV/V CKD followed at UF, were eligible for referral. All patients were advised for a minimum of 3 CPE sessions with each comprised of group education followed by individual counseling, and lasting > 2 hours.

Results: Seventy one, stage IV/V CKD patients, aged 60.2 ±14 years, with a mean follow up of 5.5±4 months, and referral eGFR of 16.3±5.6 ml/min were seen over the study period. Despite a universal mandate within an academic set up, 50% of patients were referred with stage V CKD. The remaining half were distributed between early(eGFR 15-20: 27%) and late(eGFR 21-29: 22%) stage IV CKD. 70% attended only one CPE session, and 30% returned for a second session. None attended the third session. After CPE, Peritoneal Dialysis(PD) was the preferred 'choice' for RRT for 68%, with In-center dialysis(IHD), Home Hemodialysis(HHD) and no dialysis chosen by 16%, 7% and 2% respectively. 4 patients(7%) remained undecided after a single session of CPE and did not return. 25(35%) patients initiated RRT with mean follow-up from the first session to dialysis being 5.2±3.7 months. Overall, 76% of those educated, initiated with RRT of choice. Choice to accrual rate for HoD was 71%; and for IHD was 250% with 10 patients resulting on IHD even though only 4 of them chose IHD. The choice to accrual rate for PD was 76% and HHD was 50%. Unplanned initiation of RRT, and subsequent placement of patients to alternate dialysis facilities, was the primary cause for loss from HoD.

Conclusions: CPE is effective in improving the 'choice' for HoD. However, there is a significant difference between choice to accrual for HoD in favor of IHD. Further objective studies are needed with a larger, and longer followed CPE population to understand the true impact of this, and identify the causes of this loss for HoD.

TH-PO740

A Quantitative Examination Evaluating the Impact of Implementation of Individualized Queuing in an Outpatient Hemodialysis Clinic Setting Robert W. Nappo,[1] Rita E. Alza,[1] Michael C. Blythe,[1] Edward A. Ross,[1] Jean Gordon. *[1]Univ of FL- Shands Healthcare, Gainesville, FL; [2]American Sentinel Univ, Aurora, CO.*

Background: The current model for scheduling a patient's HD therapy is often a group modality, with all patients scheduled to arrive for each shift simultaneously. Due to the lack of a well-developed scheduling model, patients were routinely left in the waiting room for extended periods of time. Patients often arrive hours early in an attempt to secure the first available chair. A strict scheduling model was implemented with disincentives for tardiness. This model eliminated the need for patient's to wait beyond their scheduled treatment times. This defined scheduling system was studied for its effectiveness on HD dose delivery.

Methods: A quantitative methodology was chosen to evaluate the relationship between the means of the control and impact group. The scheduling model was changed to align with clinic staffing and resource availability from a mass schedule to an individualized schedule. Patients are now scheduled to arrive in groups of 8 spaced in twenty-minute intervals; any patient that arrives late is bumped to the end of the shift. The research evaluated the impact of the new scheduling program on patient URR results.

Results: The two tailed matched pairs t-test results demonstrated a (t = 5.6597) with a P < 0.0001 which indicates there is a statistical significance between the mean of the impact group and control group. The data also reveal a decrease in the number of treatments that fall below the (65%) minimum URR threshold from 8 down to 3 failed treatments. The impact group displayed an overall increase in the mean URR from (72.789%) to (75.130%). The standard deviation dropped from 5.9486 to 5.1628 highlighting the increased consistency between individual treatments. Additionally, the minimum URR increased from (51.7%) to (56.1%) and in the maximum URR increased from (83%) to (85.3).

Conclusions: Providing high quality patient care is contingent on the coordination of departmental resources. Placing patients where they need to be at a precise moment in time streamlines the treatment process, improves HD delivery, and maximizes departmental productivity.

TH-PO741

Trends in Timing of Dialysis Initiation in the Veterans Health Administration Margaret K. Yu,[1,2] Adam J. Batten,[1] Ann M. O'Hare,[1,2] Paul L. Hebert. *[1]HSR&D, VA Puget Sound Health Care System, Seattle, WA; [2]Nephrology, Univ of Washington, Seattle, WA.*

Background: Over the last several decades U.S. adults are initiating dialysis at progressively higher levels of estimated glomerular filtration rate (eGFR), but to what extent this trend is occurring in the Department of Veterans Affairs (VA), the largest single integrated non fee-for-service health system in the U.S., is not known. Our objective was to compare temporal trends of eGFR at dialysis initiation within the VA with those in the wider U.S. dialysis population.

Methods: This was a retrospective analysis using data from the U.S. Renal Data System, a comprehensive national registry of end-stage renal disease. Study participants were adults who initiated chronic dialysis within the U.S. between 2000-2009 and had

information on eGFR at initiation (N=971,543). The primary exposure was veteran status and site of dialysis initiation (within versus outside the VA). The main outcome was an eGFR ≥10 mL/min/1.73 m^2 at initiation. Logistic regression was used to estimate the probability of starting dialysis with a high eGFR after adjustment for year, demographics, dialysis characteristics, and comorbidities.

Results: The adjusted probability of starting dialysis at an eGFR ≥10 mL/min/1.73 m^2 increased throughout the study period in all groups and was higher for patients who started outside the VA (39.69%, 95% CI 39.40-39.98 for veterans and 38.88%, 95% CI 38.78-38.98 for nonveterans) compared with patients who started within the VA (30.56%, 95% CI 29.91-32.21). Differences in eGFR at initiation by site were consistent across time periods and in all subgroups, but most pronounced among older cohort members and those with more limited life expectancy.

Conclusions: From 2000-2009, trends in eGFR at initiation within the VA mirrored those in the wider U.S. dialysis population, but eGFR at initiation was consistently lowest for veterans initiating dialysis within the VA. The most pronounced differences in eGFR at initiation within versus outside the VA were among older patients and those with more limited life expectancy, populations for whom the benefits of dialysis are least certain.

TH-PO742

Chronic Kidney Disease Stage 5. Conservative Therapy versus Dialysis: What's the Money Saving?

Pietro Claudio Dattolo, Elena Romoli, Fiammetta Ravaglia, Elisa Ferrari, Marco Allinovi, Marco Amidone, Giuseppe Ferro, Francesco Pizzarelli. *Nephrology, S.M.Annunziata Hospital, Firenze, Italy.*

Background: In previous studies (Dattolo et al, ERA- EDTA, 2013) we have shown that a close clinical follow-up in outpatient dedicated clinics can safely delay the start of dialysis until eGFR values much lower than 10 ml/min, values recommended by current guidelines. In this study we wanted to calculate the hypothetical cost saving achieved with such a conservative attitude.

Methods: We assume 10.766 € the yearly cost of CKD5 patient, according to the S. Anna Institute study conducted on Tuscany CKD 5 population. For CKD 5D, the annual cost/patient of 71.666 € in HD and 23.926 € in PD was derived from an European study (Durand- Zaleski, Int J Health Care Finance Econ 2007). We here analyzed 1 year cost of the 340 patients followed in our dedicated clinics with eGFR≤10 ml/min; 188 of them (55%) remained in conservative follow-up, while the remaining started dialysis earlier, 49 patients (15%) with PD and 103 patients (30%) with HD.

Results: This case mix resulted in an overall cost of 10.577.980 €, e.g. 31.100 € patient/year, the cost would have been 20.308.540 €, e.g. 59.731 € patient/year if all 340 patients were immediately started on dialysis (25% DP).

Conclusions: Our model, compared with guidelines recommendations, implies the yearly saving of about 29.000 € per incident patient with eGFR≤10 ml/min/1,73m2.

TH-PO743

Cost of Chronic Kidney Disease in Adults with Type II Diabetes Mellitus (T2DM) - United States 2011

Mukoso N. Ozieh,[1] Leonard Egede.[1] *[1]Nephrology, MUSC, Charleston, SC; [2]Internal Medicine, MUSC.*

Background: The United States Renal Data System reports 44percent of diagnosed Chronic Kidney Disease (CKD) in 2011 were secondary to diabetes. CKD has impact on utilization and cost of healthcare however there are no recent national estimates on the cost of CKD in the U.S. population. This study aims to assess the cost of CKD in adults with T2DM in the U.S. population using novel cost estimation methodology.

Methods: Data on 2,053 adults with T2DM in 2011 Medical Expenditure Panel Survey (MEPS) was analyzed. Individuals with CKD were identified based on self-report. Mean total expenditure was estimated for the overall sample and by CKD status. We used a two-part model to estimate overall adjusted expenditure and by CKD status. The first part of the model was a probit model to estimate the probability of having expenditures and the second part was a generalized linear model with gamma distribution to estimate total expenditure accounting for the probability of having expenditure. Covariates in both models include age, race, gender, marital status, education, insurance, Metropolitan Statistical Area, region, poverty status and comorbidities. STATA version 13 was used to account for the complex design of MEPS.

Results: Of the 2,053 individuals with T2DM, 9.7percent had self-reported CKD. Those with CKD have lower income, were more likely to be depressed, have hypertension, cardiovascular disease, high cholesterol, arthritis and asthma. These were the only significant difference among those with CKD compared to those without CKD. In the unadjusted analysis, mean expenditure for those without CKD were $9,689.49 (95% CI $8,871.18-$10,507.81) while those with CKD were $20,726.32 (95% CI $16,322.42-$25,130.22). Extrapolating to the U.S. population in 2011, the mean expenditure for those with CKD was over $43 billion. In the adjusted analysis using the two-part model, those with CKD had $8,473 (95% CI $4,957.75-$11,989.28) more expenditure compared to those without CKD.

Conclusions: DM is associated with significant healthcare expenditure but a significant proportion is due to CKD. This highlights the importance of aggressive strategies for prevention, early recognition and treatment of CKD in patients with DM.

TH-PO744

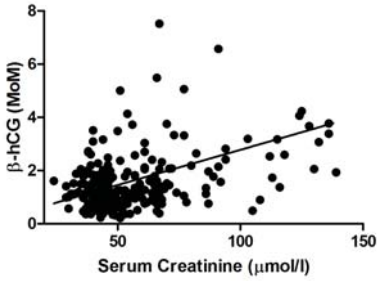
Screening for Down's Syndrome in Women with Renal Disease

Nadia Sarween,[1] Ian Mills,[2] Clara Day,[1] Ellen M. Knox,[3] Graham W. Lipkin.[1] *[1]Dept of Renal Medicine, Queen Elizabeth Hospital Birmingham, United Kingdom; [2]Dept of Clinical Chemistry, Birmingham Women's Hospital, United Kingdom; [3]Dept of Obstetrics, Birmingham Women's Hospital, United Kingdom.*

Background: Screening for Down's syndrome (DS) routinely involves measuring maternal concentrations of a combination of serum markers including beta-human chorionic gonadotrophin (β-hCG) and ultrasound measurement of nuchal translucency. Certain confounding risk factors such as maternal age are corrected for. There is limited data reporting raised β-hCG levels in women with chronic kidney disease (CKD). Our aim was to establish whether current DS screening practices in the United Kingdom are appropriate for pregnant women with CKD.

Methods: We performed a retrospective study identifying all women who had attended our regional renal obstetric clinic and undergone DS screening during 2008-2013. Those patients with a serum creatinine (sCr) or urinary albumin creatinine ratio measured at the time of screening were included and pregnancy outcome followed up.

Results: A total of 240 women were identified of which 32% had a sCr of ≥60 µmol/L (upper limit of normal in pregnancy). There were a higher number of false positive screens in our renal obstetric cohort compared to the general population (adjusted for age) both at first (5.7% versus 3.65%) and second trimester (9% versus 3.52%). We found a significant correlation between sCr and free and total β-hCG (p<0.01) and with DS risk score (p<0.01).



Increased proteinuria also correlated with free β-hCG (p<0.01) and risk score (p<0.02). There were no cases of DS in the renal group although 10% of those with a high risk score had a pre-term birth and 56% delivered a small baby.

Conclusions: Renal impairment appears to affect levels of β-hCG and falsely increase the risk score in DS screening. Alternative screening may need to be considered in this group or renal impairment corrected for.

TH-PO745

Validity of the Berlin Questionnaire to Predict Sleep Apnea in CKD

Shahab Bozorgmehri,[1] Nicole Kay,[2] Areef Ishani,[4] I. David Weiner,[2,3] Richard Berry,[2,5] Rebecca Beyth,[2,5] Muna T. Canales.[2,3] *[1]Univ of Florida, Gainesville, FL; [2]Malcolm-Randall VAMC; [3]UF Div of Nephrology, Gainesville, FL; [4]VAMC, Minneapolis, MN; [5]UF Dept of Medicine, Gainesville, FL.*

Background: The Berlin Questionnaire (BQ) is a validated screening tool for sleep apnea (SA) in the general population. However, whether it is also valid in individuals with CKD is unknown.

Methods: We conducted a cross-sectional interim analysis of 73 veterans aged 18-89 with eGFR of 15-44 ml/min/1.73m^2 enrolled in the SNORE Study. At baseline, subjects completed BQ and Epworth Sleepiness Scale (ESS) questionnaires and underwent complete overnight sleep study. SA was defined using the apnea-hypopnea-index(AHI). We assessed the validity of BQ at a standard cut-off ≥2 and the ESS>10 to predict SA (at cut-points of ≥5, 15, and 30) using sensitivity, specificity, positive predictive value (PPV), negative predictive value(NPV), and area under the receiver operating characteristics curve(AUC).

Results: Baseline characteristics of enrolled subjects: mean (±SD) age, 75±10 years; 98% male; 82% Caucasian; body-mass-index (BMI), 30.2±4.7 kg/m^2; 52% had BMI≥30 kg/m^2; 95% had hypertension.BQ score ≥2 was 68%. Median (IQR) of ESS was 8(5-13); 33% had ESS>10. Median (IQR) AHI was 11 (4.1-21.7). The proportion with AHI≥5, 15, and 30 was 70%, 41%, and 16%, respectively.

Table 1. Predictive validity of BQ with or without ESS to detect SA.

	Sensitivity	Specificity	PPV	NPV	AUC (95%CI)
AHI ≥ 5					
BQ ≥ 2	75%	45%	76%	43%	0.600(0.478-0.722)
BQ ≥ 2 + ESS>10	33%	86%	85%	36%	0.598(0.5-0.697)
AHI ≥ 15					
BQ ≥ 2	80%	39%	48%	74%	0.598(0.494-0.701)
BQ ≥ 2 + ESS>10	43%	84%	65%	68%	0.635(0.529-0.741)
AHI ≥ 30					
BQ ≥ 2	83%	34%	20%	91%	0.589(0.463-0.714)
BQ ≥ 2 + ESS>10	50%	77%	30%	89%	0.635(0.478-0.792)

Differences between AUC values for BQ with and without ESS>10 were not statistically significant (for AHI≥5, ≥15, and ≥30 p for difference=0.8, 0.4, and 0.6).

Conclusions: Among veterans with CKD, a BQ ≥2 was a sensitive but not specific predictor of SA across various cutpoints for SA severity. Addition of ESS to BQ score in screening improved specificity but reduced sensitivity for SA.

TH-PO746

Psychological Characteristics of Adults with Pediatric-Onset End-Stage Renal Disease: Personality and Attachment Scott Mullaney,[1] Mojgan Khademi,[2] Tovah Sirkin,[2] Luciano Giromini,[2] Heidi Miller.[2] *[1]UC San Diego, San Diego, CA; [2]Clinical Psychology, Alliant International Univ, San Diego, CA.*

Background: The role of psychological variables in chronic illness has been investigated with a focus on health related behaviors, but there is limited understanding of possible influences of pediatric-onset chronic illnesses such as End-Stage Renal Disease (ESRD) on personality and attachment style (interpersonal functioning based on the quality of early childhood experiences with caregivers).

Methods: We studied eight adults (six women; two men) who developed ESRD before age 13 using semi-structured interviews (focused on illness and personal/social functioning), the Relationship Scales Questionnaire (which divides respondents into categories of securely or insecurely attached) and the Rorschach Inkblot Method (a performance-based personality test). Statistical analyses focused on seven empirically supported Rorschach variables related to bodily preoccupation and psychosomatic complaints.

Results: Results of t-test comparisons with the international reference normative data were statistically significant for five of the variables at $p < .05$ and in the expected direction, indicating alexithymia (characterized by difficulty identifying and describing feelings) with large effect sizes. The qualitative findings indicated coping through avoidance and rational acceptance of their illness. Participants reported longstanding interpersonal difficulties and limited plutonic and romantic relationships as adults. Majority of the participants were insecurely attached (62% versus 41% in the general population), which is associated with being perceived negatively by others, and among chronically ill patients correlates with fragility and overreacting to stressors.

Conclusions: Alexithymia among medical patients is associated with cold and distant relations, vindictiveness, self-centeredness and with reporting more symptoms in the absence of greater somatic disease. Awareness of and interventions focused on these psychological variables could enhance medical interactions and patient care. Future studies with a larger pediatric-onset sample as well as adult-onset ESRD patients should be considered.

TH-PO747

Prevention of CKD Through Educational Programs and Screening Camps Priyanka Govindan, Arjun V. Sharma. *Nephrology, Univ of Washington, Seattle, WA.*

Background: There are an estimated 55,000 patients on dialysis in India with 44% caused by Hypertension and/or Diabetes Mellitus. Early detection of DM, hypertension, with subsequent control of blood pressure and blood sugars have shown to cause delay in progression of kidney disease. Therefore early screening will take an important role in preventing dialysis rates from continuing to rise. Here we note the efforts of one program aimed at education and prevention of kidney disease.

Methods: The Tamil Nadu Kidney Research Foundation conducted a series of 584 awareness programs and 71 screening camps in Tamil Nadu, India with the goal of educating the general populace and screening for early risk factors for kidney disease. 97,860 people attended the awareness programs which consisted of a presentation with the aim of educating on basic physiology of kidneys, risk factors for CKD, and an overview of Renal Replacement Therapy in India. The talk was on symptoms and warning signs and the importance of adopting a healthy diet and lifestyle modification. 6,415 people attended the screening camps which were designed to screen for hypertension, elevation in creatinine, glucosuria or proteinuria.

Results: Of the 6,415 people screened, 727 had newly detected diabetes, 1170 of those screened had newly detected BP of over 130/90 mmHg and 953 had proteinuria. All people with risk factors were told to follow up with a doctor, referred to the awareness program, and given specific advice depending on their comorbidity.

Conclusions: The screening camps that were initiated by the TANKER foundation were able to diagnose thousands of otherwise seemingly healthy people with risk factors for CKD. The screening methods were not ideal as a one time measurement of glucosuria, hypertension, and proteinuria may have myriad causes which may not be representative of pathology. However, with the knowledge that they are significantly at risk for kidney disease, our hope is that patients with risk factors would be more likely to seek medical attention and pursue lifestyle modifications with an end result of decreasing their risk of developing kidney disease. Thus far there has been no objective evaluation of the program but one is currently being developed.

TH-PO748

Muscle-Kidney Crosstalk via a Myokine, Irisin, Can Suppress Progression of CKD in Mice Hui Peng,[1,2] William E. Mitch,[2] Zhaoyong Hu.[2] *[1]Div of Nephrology, Dept of Medicine, The third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Nephrology, Dept of Medicne, Baylor College of Medicine, Houston, TX.*

Background: beneficial effects of exercise on muscle metabolism are associated with improved survival of patients with ESRD but the mechanisms underlying this observation are unknown. A potential mediator is irisin which is released from muscle by exercise and can counteract obesity and increase the accumulation of brown fat. We hypothesized that irisin could mediate muscle-kidney crosstalk to slow the progression of CKD.

Methods: we created mice with skeletal muscle-specific, forced expression of PGC-1α because this transgene increases circulating irisin. Transgenic and control mice underwent subtotal nephrectomy to create CKD and we evaluated the function and degree of fibrosis in the remnant kidney plus irisin-induced responses in cultured tubular cells.

Results: after 1 month of CKD, serum irisin was 2.8-fold higher in PGC1-α versus wild type (WT) mice. CKD mice expressing PGC-1α had lower values of BUN and serum creatinine ($P<0.05$). In kidneys of WT mice with CKD, there was increased interstitial fibrosis plus tubular cell apoptosis. In contrast, remnant kidneys of PGC-1α mice that were expressing irisin had a 40% lower degree of interstitial fibrosis ($P<0.05$) and 36% less tubular cell apoptosis ($p<0.05$). Cultured tubular cells treated with irisin exhibited less apoptosis plus reduced expression of collagen-1A (31%) and fibronectin (39%; $P<0.05$ for both). Because UCP2 down-regulation is linked to increased reactive oxygen species (ROS) production, it contributes to the development of fibrosis and kidney cell apoptosis. We found that irisin stimulates UCP2 in cultured tubule cells and lowers ROS production, providing a potential mechanism for the protection of the kidney.

Conclusions: Activation of muscle-specific PGC-1α stimulates the release of irisin from muscle. In mice, we found that irisin up-regulation reduces CKD-induced renal tubular cell apoptosis and fibrosis. We conclude that irisin may be a mediator of the beneficial influence of muscle exercise in CKD.

TH-PO749

Urinary Metabonomic Study of Rhubarb as an Effective Treatment for Chronic Renal Injury in Rats Ying-Yong Zhao,[1,2] Ya-Long Feng,[1] Hua Chen,[1] Shuman Liu,[2] Ruichao Lin.[1] *[1]Dept of Traditional Chinese Medicine, Northwest Univ, Xi'an, Shaanxi, China; [2]Div of Nephrology and Hypertension, Univ of California, Irvine, Irvine, CA.*

Background: Chronic kidney diseases (CKD) are a major challenge for the public healthcare, and there is still a significant need for strategies for the treatment of CKD. Rhubarb, a well known worldwide herbal medicine, has long been used for the treatment of CKD.

Methods: Urinary metabolomics based on the ultra-performance liquid chromatography/SYNAPT high-definition mass spectrometry was undertaken to explore the pattern of low molecular mass metabolites in the rat model of CKD induced from adenine excess. Fifty rats were randomized into control, CKD and rhubarb-treated CKD groups. The CKD and rhubarb-treated CKD groups were given 200 mg/kg/d of adenine for 3 weeks. During the adenine gastric gavage after 3 h, rhubard-treated groups were given the petroleum ether, ethyl acetate and n-butanol extracts of rhubarb respectively for 6 weeks. Urine biochemistry, and Masson's trichrome staining and Western blot analysis of kidney tissues were performed. Data were analyzed using principal component analysis, partial least squares-discriminant analysis, heatmap analysis and metabolic pathways analysis.

Results: After treatment with rhubarb, the kidney pathological abnormalities were gradually ameliorated compared to CKD group. This was coupled with a significant change in the global urinary metabolites from rhubarb-treated rats compared to CKD rats at weeks 3 and 6. Among these metabolites, 15 of them including adenine, creatinine, tryptophan, phenylalanine, taurine, adenosine and uric acid were reversed to the control group level in rhubarb-treated group. Combined with biochemistry and histopathology result, the changes in urine metabolites indicate that the perturbations of amino acid and purine metabolisms are related to adenine-induced CKD and to the interventions of rhubarb on these metabolic pathways.

Conclusions: This study not only supplied a systematic view of the development and progression of CKD and the mechanism studies of rhubarb but also provided the theoretical basis for the prevention or treatment of CKD.

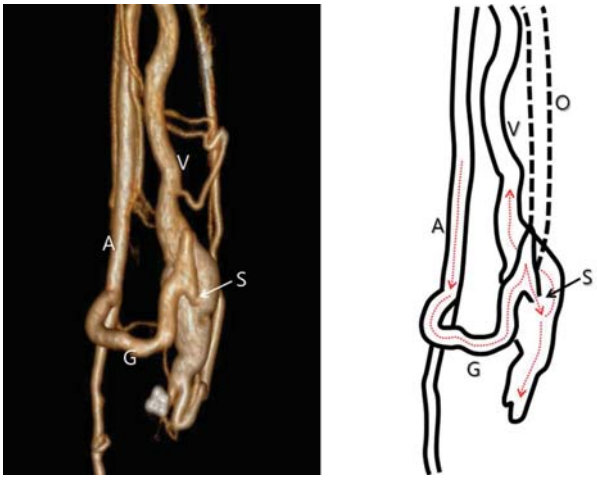
TH-PO750

A Complication of Shunt Formation between Arteriovenous Graft and Cephalic Vein Youngsub Kim, Jae Seok Kim, Jae Won Yang, Byoung Geun Han, Seung-Ok Choi. *Div of Nephrology, Yonsei Univ Wonju College of Medicine, Wonju, Republic of Korea.*

Introduction: Thrombosis and infection are common complications of arteriovenous graft (AVG). But the complication of shunt formation between AVG and natural vein is rare. Here we present a case of AVG - cephalic vein shunt.

Case Description: 63-years old male on hemodialysis(HD) using AVG(Left, brachial artery-axillary vein) presented with fever. He was diagnosed with sepsis and an abscess around AVG was shown. Methicillin-resistant staphylococcus aureus was documented in blood and pus from the abscess. Therefore we believed that sepsis was caused by AVG infection. During admission, bruit and thrill of the AVG were lost and AVG dysfunction developed.Doppler ultrasound(US) showed the shunt flow from the AVG to a near cephalic

vein and luminal thrombosis above the shunt was seen. Computed tomography(CT) angiography showed clearly the cephalic vein was dilated and the AVG was occluded by thrombus.



CT angiography and schema of shunt. (A, brachial artery; G, AVG; S, shunt; V, cephalic vein; O, occluded part of AVG; dotted line, direction of blood flow)

In surgery, we could find the connecting tract between the AVG posterior wall and a near cephalic vein. The AVG was partially removed due to infection and dysfunction. We created a new arterio-venous fistula(AVF) by connecting the dilated cephalic vein to a brachial artery. We expect the new AVF will be usable soon, because the flow of AVF is more than 1400ml/min in doppler US at post-op 7th day.

Discussion: We believe that this process has been progressed from several weeks ago and also may be related to needling during HD. The diameter of connecting tract was similar to the one of needle used in HD. Our hypothesis is that blood flow was divided into the two pathways and the AVG decreased in flow with growing of the cephalic vein. As a result, occlusion with thrombosis occurred.

TH-PO751

Colchicine as Treatment for Culture Negative Peritonitis in Patient with Behcet's Disease on Peritoneal Dialysis Ardeshir Khosraviani, Scott A. Rasgon, Nitin Bhasin. *Nephrology, Kaiser Permanente - Los Angeles Medical Center, CA.*

Introduction: Behçet's disease (BD) is a rare disease characterized by recurrent oral aphthae and several systemic manifestations. Most clinical manifestations of BD are due to the vasculitic nature of the disease. In patients with BD and ESRD, Peritoneal Dialysis (PD) is a favored modality for providing renal replacement therapy. Here we present a patient with BD on PD with culture negative peritonitis.

Case Description: A 61 year old female with history of BD, Diabetes Mellitus (DM) and ESRD receiving PD for five years, presented with abdominal pain and tenderness around her PD catheter insertion site. Patient was afebrile and her vital signs were normal. Her physical examination was unremarkable except for tenderness on palpation around the PD catheter insertion site. The abdomen was otherwise soft and rebound tenderness was absent. The patient was empirically started on intraperitoneal (IP) Ceftazidime and Cefazolin. Analysis of peritoneal fluid revealed 150 WBC per hpf with lymphocytic predominance. The gram stain and cultures for bacterial (including Mycobacterium) and fungal organisms were negative. Patient returned to clinic after two weeks with the same presentation. Peritoneal fluid analysis now revealed 730 WBC per hpf with a similar lymphocytic predominance with negative gram stain and culture. Oral Ciprofloxacin was added to previous regimen. She returned with persistent symptoms and was started on Colchicine due to concern for peritoneal irritation. Her symptoms resolved within twenty-four hours of taking Colchicine and a repeat analysis of her peritoneal fluid revealed no WBC. Cultures remained negative.

Discussion: The incidence of ESRD in patients with BD is very low. PD is the favored renal replacement modality due to the high risk for vascular thrombosis in these patients. PD patients with BD may develop peritoneal irritation from their catheter. Their clinical presentation may be similar to that of peritonitis. It is important that the diagnosis of peritonitis is excluded in these patients. Treatment with anti-inflammatory agents such as Colchicine may result in resolution of symptoms and abnormal laboratory findings.

TH-PO752

***Helicobacter cinaedi* Infection in a Polycystic Kidney Disease Patient Receiving Hemodialysis** Yuka Hibino, Tomoka Nango, Maoto Negishi, Kanna Watanabe, Yuki Fukuhara, Toshikazu Wada, Yume Nagaoka, Yoshihiko Kanno. *Dept of Nephrology, Tokyo Medical Univ, Japan, Tokyo, Japan.*

Introduction: *Helicobacter cinaediis* a bacterium in the family *Helicobacteraceae* that causes mainly enteric and bloodstream infections. A relatively large proportion of patients with chronic kidney disease have *H. cinaedi* bacteremia, as they are immunocompromised. However, there are few reports of cyst infection and bacteremia by *H. cinaediin* patients with polycystic kidney disease (PKD).

Case Description: A 51-year-old male patient with PKD who was receiving hemodialysis developed a high fever and abdominal pain. He had experienced a similar episode 2 years previous to the current admission, and levofloxacin had effectively improved his symptoms. This time, fluoroquinolone antibiotics did not improve his symptoms, and *H. cinaedi* was detected from his venous blood after 14 days of culture. Meropenem controlled his infection until neutropenia was induced by it. After other antibiotics failed to show a clear effect, the patient was examined by CT, diffusion-weighted MRI, and Ga-67 scintigraphy; however, no infected cysts could be identified as targets for injection with antibiotics. After drainage, minocycline was percutaneously injected to 3 randomly selected cysts for 1 week, and the symptoms remitted.

Discussion: The characteristics of *H. cinaedi* include its poor culturability, the need for more than 10 days for its detection, and its tolerance to antibiotics. Primary treatment by fluoroquinolones according to the guidelines from the Japanese Society of Nephrology may not necessarily lead to a favorable response. In the case of refractory cyst infections, *H. cinaedi* should be considered as a causative pathogen, and a long observation period should be expected for its detection. Furthermore, not only antibiotic therapy, but also interventional treatment should be considered in the early phase of its clinical course.

TH-PO753

Atypical Cellulitis in a Hemodialysis Patient Caused by Helicobacter cinaedi Toko Hashimoto, Naomi Sasaki, Nobuo Hashimoto. *H.N.Medic, Sapporo, Hokkaido, Japan.*

Introduction: Helicobacter cinaedi is known to cause diarrhea and bacteremia in immunocompromised hosts, however, few cases are reported in dialysis patients. Our case presented atypical skin manifestation which originally suspected as nephrogenic fibrosing dermopathy in pathological assessment. Difficulty of its diagnosis is due to the fastidiousness of this pathogen requiring specific culture condition.

Case Description: Case Description: A 40-year-old man who had been receiving hemodialysis 3 times per week for a year presented skin redness and swelling with painful induration on his lower limbs for 2 weeks. He was clinically diagnosed idiopathic erythema nodosum which improved with 15 mg of prednisone per day for 2 weeks. Whist ceasing prednisone, he developed spike fever (>38°C) and redeveloped red papular eruptions on extremities.

Systemic autoimmune diseases, malignancy and HIV infection were excluded and nephrogenic fibrosing dermopathy was suspected by skin biopsy. Although the initial blood culture was negative, H. cinaedi was detected from the following sample with the condition of long-term-culture for 9 days. The culture of dialysis fluid from the circuit was negative. He was diagnosed cellulitis caused by H. cinaedi and treated with 100mg of cefcapene per day for 4 weeks. Rapid improvement of the skin rush and decline of fever was observed, and there was no recurrence of any symptoms after the followup of antibiotic treatment.

Discussion: H. cinaedi is one of the most difficult bacteria to detect and its clinical manifestation varies. Thus, the prevalence of this infectious disease might be under estimated. In immunocompromised hosts including hemodialytic patients, skin lesion can be the earliest symptom in presence of H. cinaedi bacteremia. Repeated and long term culture of blood sample is helpful clue for the diagnosis.

TH-PO754

BJP Lambda-Type Multiple Myeloma Successfully Withdrawn from Maintenance Hemodialysis after Long-Term Continuous Bortezomib and Dexamethasone Therapy Wakaba Yamaguchi,[1] Naofumi Yui,[1] Toshikage Nagao,[2] Haruna Azetsu,[1] Soichiro Iimori,[1] Eisei Sohara,[1] Tomokazu Okado,[1] Tatemitsu Rai,[1] Sei Sasaki,[1] Shinichi Uchida.[1] *[1]Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan; [2]Hematology, Tokyo Medical and Dental Univ, Tokyo, Japan.*

Introduction: The effect of bortezomib for multiple myeloma (MM) has been well established, however, how to continue maintenance therapy with this agent on patients requiring regular hemodialysis (HD) due to MM is undetermined. Here, we report a rare

case of cast nephropathy caused by BJPλ-type MM that developed severe renal failure and finally became independent of hemodialysis after long-term bortezomib and dexamethasone (BD) therapy.

Case Description: A 61-year-old Japanese woman with no medical history of kidney disease was referred to our hospital for severe renal dysfunction. On admission, she presented oliguria, and her serum creatinine (sCr) level was at 15.5 mg/dL, requiring HD. BJPλ was detected in her urine. Her serum β2 microglobulin level was increased at 30.8 mg/L. Bone marrow aspiration showed an increase of atypical plasma cells up to 15%, that were λ-positive in immunostaining. Renal biopsy revealed λ-positive cast in tubules with no pathological signs of amyloidosis. We diagnosed that the cause of her renal failure is BJPλ-type MM staged at ISS 3, and started BD therapy. During four cycles of BD therapy, BJP disappeared from her urine, and her urine volume was gradually increased. In addition, no clinical signs of adverse effect were observed. We decided to continue BD therapy for her renal recovery. After eight cycles of the treatment, her pre-dialysis sCr level was decreased to 6.5 mg/dL. We continued monthly BD therapy. During two years of monthly BD therapy, her renal recovery continued, and frequency of HD was successfully decreased to once weekly. Finally, her pre-dialysis sCr level was decreased to 3.7 mg/dL, therefore, we decided to discontinue HD and BD therapy. After 1 year from the discontinuation, her sCr level was at 2.9 mg/dL, and her MM was maintained in complete remission.

Discussion: Our present report supports the usefulness of long-term continuous BD therapy for renal recovery in MM-caused cast nephropathy.

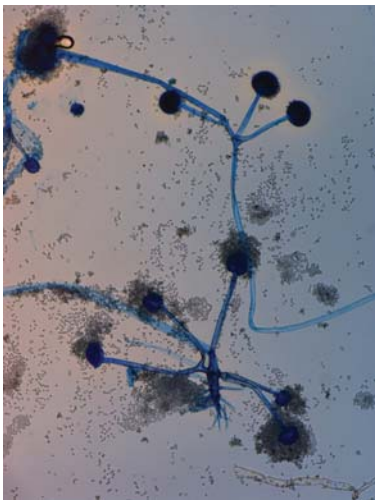
Simultaneous Mucormycosis of Arteriovenous Fistula and Candidial Peritonitis in a Dialysis Patient

Jobert Anjelo,[1] Nitesh Nikilesh Rao,[1] Stephen M. Hogg,[1] Sarah E. Kidd,[2] Tony J. Elias.[1] *[1]Nephrology, Royal Adelaide Hospital, Adelaide, South Australia, Australia; [2]SA Pathology, Royal Adelaide Hospital, Adelaide, South Australia, Australia.*

Introduction: Dialysis access is considered the "lifeline" for patients with end stage renal failure. Fungal infections are relatively uncommon as compared to bacterial infections and therefore access infections are usually treated with empirical antibiotics. This case report describes a potentially life threatening infection of an arteriovenous fistula by mucormycosis masquerading as a persistent bacterial infection. This patient also simultaneously developed candida peritonitis.

Case Description: A 58 year old Caucasian woman with end stage kidney disease secondary to type 1 diabetes mellitus, on peritoneal dialysis, presented with erythema and pain in her left brachiocephalic AV fistula. She had undergone a DRIL procedure for "steal syndrome" about 4 weeks ago in preparation for an elective transition to haemodialysis. She received two weeks of antibiotic therapy which did not result in improvement of the infection. A repeat swab from the wound over the AV fistula demonstrated rhizopus microspores.



At around the same time, the peritoneal fluid became cloudy and the causative organism was found to be candida albicans, mandating tenckhoff catheter removal and transfer to haemodialysis. A CT scan of the head, chest and abdomen did not demonstrate fungal dissemination. She was treated with a prolonged course of antifungals which included IV liposomal amphotericin B and posaconazole. She also required extensive multiple surgical debridement over the arteriovenous fistula. She responded to this therapy after 3 weeks.

Discussion: To our knowledge, this is the first case of mucormycosis infection in an arteriovenous fistula. This case also reinforces the importance of antifungal prophylaxis in patients on peritoneal dialysis, who require long term antibiotics.

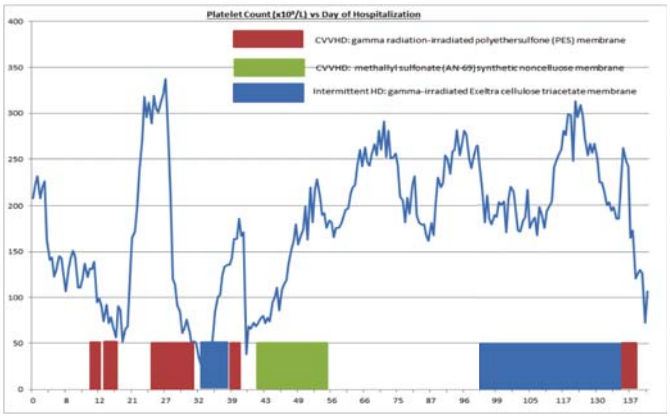
TH-PO756

Dialysis Associated Thrombocytopenia in a Patient with AKI on Continuous Venovenous Hemodialysis

Eugene K. Essandoh, Jonathan J. Hogan. *Nephrology, Columbia Medical Univ Hospital, New York, NY.*

Introduction: Dialyzer-associated thrombocytopenia (DAT) has been observed in case reports of patients with ESRD on HD, with many recently published cases occurring with the use of electron beam-sterilized polysulfone membranes. Here, we report a case of acute, severe and recurrent DAT in a patient on continuous replacement therapy (CRRT) for AKI.

Case Description: An 80 yo woman with a PMH of CHF, CKD and pulmonary HTN was admitted for volume overload. A LVAD was placed after failure of inotrope-assisted diuresis. Her hospital course was complicated by cardiogenic shock and an arterial thrombus requiring heparin. In this setting, she developed AKI for which CVVHD was initiated using a gamma radiation-sterilized polyethersulfone (PES) membrane. Prior to admission, her platelet count was 160 $X10^9$/L, was 143 $X10^9$/L on admission and 92 $X10^9$/L when she returned to OR for a chest washout. Over the next week, her thrombocytopenia worsened with PES membrane exposure and improved with stopping CVVHD [Figure 1]. This temporal relationship of acute and severe thrombocytopenia with PES membrane exposure occurred multiple times, with a platelet nadir of 26 $X10^9$/L and rapid resolution after stopping PES membrane exposure [Fig 1]. A workup for other causes of thrombocytopenia (including peripheral blood smear, SRA, fibrinogen, INR, aPTT, evaluation of medication-related thrombocytopenia) was negative. Given the concern DAT due to PES membrane, CVVHD was re-initiated using a methallyl sulfonate (AN-69) synthetic noncelluose membrane, during which time her plts normalized, and DAT did not recur on intermittent HD with a gamma-irradiated cellulose triacetate membrane.



Discussion: Nephrologists should be aware that acute and severe DAT may occur with CRRT, and in such cases, using a different dialyzer membrane may lead to resolution of thrombocytopenia.

TH-PO757

Post-Dialysis Anaphylactoid Reactions from Alginate-Containing Compression Dressing (ACCD)

Pratima Ghimire,[1] Philip Goldwasser,[1,2] Robert H. Barth.[1,2] *[1]Renal Div, SUNY Downstate College of Medicine, Brooklyn, NY; [2]Nephrology Section, VA NY Harbor Healthcare System, Brooklyn, NY.*

Introduction: Alginates are linear polysaccharides derived from marine brown algae, which have long been used in wound dressings for their non-adherent and hemostasis-inducing properties. This report describes a case of frequent post-hemodialysis generalized anaphylactoid reactions apparently caused by an ACCD, the Gambro TipStop [TM].

Case Description: A 31-year-old woman with ESRD attributed to chronic glomerulonephritis, on hemodialysis (HD) for 8 years, with a history of allergy to isoniazid and radiographic contrast media, began having intermittent severe anaphylactoid reactions after HD, usually 5-10 min after completion of the treatment, occurring 3-5 times a month. Reactions were characterized by generalized flushing and pruritus, with tachycardia, dyspnea, and throat and chest tightness, and responded to antihistamines, steroids, and epinephrine. They were variously ascribed to paricalcitol, iron sucrose, and erythropoietin, but as each medication was discontinued, reactions did not abate, and continued even when no medications at all were given with HD. To test the hypothesis of reaction to backfiltrate from dialysate at the end of the treatment, the last 20 min of each session were limited to isolated ultrafiltration without dialysate, but reactions continued. Finally, it was observed that reactions occurred only after application of the ACCD to cannulation sites, and had begun to occur 4-6 months after the initiation of ACCD use. Skin tests were performed in an Allergy Clinic for hypersensitivity to paricalcitol, iron sucrose, and erythropoietin and all were negative, while a test using a saline extract of the ACCD was positive. Use of the ACCD was discontinued and since that time no reactions have occurred, despite gradual reintroduction of all IV medications.

Discussion: ACCDs have been used extensively with few reported cases of allergy. Nonetheless, fatal anaphylactic shock due to an alginate-containing dental impression material has recently been reported, and this case illustrates that alginate-containing dressings may be associated with severe post-dialysis anaphylactoid reactions.

TH-PO758

Hemodialysis Followed By CVVHDF for Dabigatran Clearance in Acute Subdural Hematoma Salem Almaani, Shashikant Patel, Asish Thakkar, Udayan Y. Bhatt, Jason Prosek. *Dept of Nephrology, The Ohio State Univ, Columbus, OH.*

Introduction: Dabigatran is a direct thrombin inhibitor that is FDA approved for the prevention of stroke in patients with non-valvular atrial fibrillation. It has some advantages over warfarin, such as predictable levels of anticoagulation without the need for monitoring. Despite this, no reliable antidote exists when the need to reverse its anticoagulant effect is needed. Dialysis has been used for drug clearance in a few case reports, but there is concern of a rebound in the drug level after cessation of dialysis because its lipophilic structure and protein binding properties are the basis for a large volume of distribution.

Case Description: A 75 year old male with a past medical history of atrial fibrillation, on dabigatran 150mg b.i.d for stroke prevention, presented to the emergency department after he sustained a fall from a chair. A head CT scan revealed a 1.5cm subdural hematoma. The patient's mental status deteriorated and repeat imaging showed an increase in the size of his hematoma as well as new uncal and transtentorial herniations necessitating open evacuation. The patient's thrombin time (TT), which was used to assess the degree of his ongoing anticoagulation, was found to be elevated to 84.7 sec (normal 13-20 sec). He had a normal renal function when he presented with a serum creatinine of 0.67mg/dl. Hemodialysis was initiated to aid in drug clearance, and serial TTs were obtained. The patient's TT dropped to 75.0 sec after a 4 hour dialysis session. He was switched to CVVHDF for a total of 30 hours. A gradual decrease in TT was observed, and no rebound was noted. The TT at the time of cessation of CVVHDF was 22.4 sec.

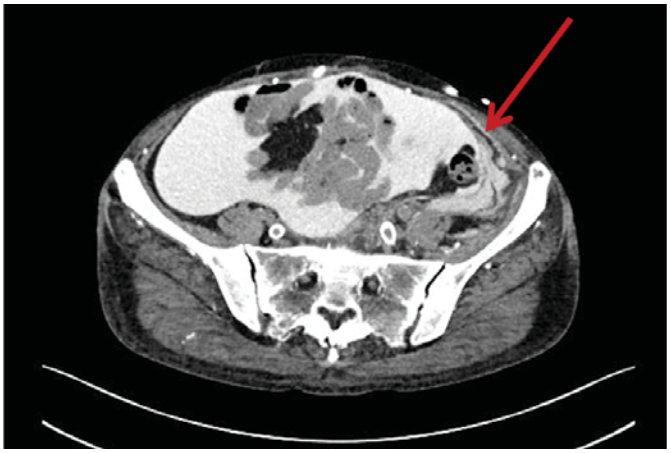
Discussion: Direct dabigatran removal by extracorporeal methods has been described. Most authors reported a rebound in drug levels after cessation of dialysis. A rebound in patients with closed-space bleeding may be catastrophic and the use of continued clearance should be considered to address the anticipated rebound in TT levels as the drug returns to the plasma. The kinetics of dabigatran clearance with CRRT has yet to be defined, but it is clear that it is adequate to prevent the anticipated rebound of this drug.

TH-PO759

Dialysate Leakage From Retroperitoneum in a Long-Term Peritoneal Dialysis (PD) Patients Takafumi Yamakawa, Mao Watanabe, Nanae Matsuo, Yasuyuki Nakada, Izumi Yamamoto, Yudo Tanno, Ichiro Ohkido, Keitaro Yokoyama, Takashi Yokoo. *Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan.*

Introduction: Dialysate leakage can be a common problem in peritoneal dialysis (PD) patients. PD catheter exit sites and less commonly inguinal areas are usual sites of leakage. To this date, retroperitoneal leakage has not yet been reported as a leakage site. Here, we report a case of retroperitoneal leakage of dialysate fluid in a long-term PD patient.

Case Description: A 52 year old woman with end-stage renal disease due to lupus nephritis had begun PD at the age of 26. Because of difficulties to maintaining her vascular access due to prothrombotic nature of Antiphospholipid antibody syndrome, she had to continue with PD ever since. In January 2014, this patient presented with fluid overload owing to poor fluid removal. On CT peritoneography and 99mTc-MAA peritoneoscintigraphy, retroperitoneal leakage was confirmed by observation of increasing edema in the subcutaneous and muscular tissues of the left hip as dialysate fluid was being inserted into the peritoneal cavity. As for treatment, fragility of the peritoneal membrane due to long term steroid therapy and PD was a concern when considering surgical repair. Therefore, a decision was made to change the modality of her PD from continuous ambulatory PD to automated PD which would result in decreased intra-abdominal pressure thus minimizing retroperitoneal leakage. This change resulted in a substantial improvement in her fluid status.



Discussion: Retroperitoneal leakage is a rare presentation, and is likely to be the result of frail peritoneal membrane caused by long history of PD, in this case 26 years, and long term steroid therapy. In such a case, surgical repair is often difficult, and modification of PD modality may be a beneficial solution.

TH-PO760

Dialysis-Related Amyloidosis: It Is Just a Matter of Time Mana Dissadee,[1] Subhash Popli.[2] [1]*Nephrology, Loyola Univ Medical Center, Maywood, IL;* [2]*Nephrology, Edward Hines Jr VA Hospital, Hines, IL.*

Introduction: Dialysis-Related Amyloidosis is a significant disease that affects patients who are on long-term dialysis. It involves predominantly the musculoskeletal and gastrointestinal system. We are presenting a case of peritoneal dialysis patient with full-blown manifestations.

Case Description: A 66-year-old male with ESRD secondary to hypertension was hospitalized with 2-week history of diffuse joint pain, abdominal pain. He had been on hemodialysis for 12 years and changed to peritoneal dialysis 2 years ago due to multiple episodes of vascular access malfunction. He had chronic intermittent shoulders and bilateral hip pain. He had bilateral carpal tunnel decompression 3 years ago. Physical exam revealed macroglossia. Peritoneal fluid analysis showed no leukocytosis. CT scan of the abdomen and pelvis was negative for intra-abdominal processes. Enlarged cystic lesions on left superior acetabulum and femoral head were found. Bone survey revealed multiple cystic lesions on shoulders and hips. Bone marrow aspiration and biopsy were consistent with MGUS. The patient underwent a prophylactic intra-medullary nailing of the left femur. The bone biopsy of the lesion showed amorphous eosinophilic depositions, positive staining with Congo red dye and characteristic apple-green birefringence on polarized light. High performance liquid chromatography tandem mass spectrometry detected a peptide profile consistent with beta 2-microglobulin. His hospitalization was complicated by bacterial peritonitis, C. Difficile infection and intestinal pseudo-obstruction. He expired on 120 days of admission.

Discussion: This case demonstrates the typical presentation of dialysis-related amyloidosis (DRA). Although the incidence of DRA is decreasing with use of high flux dialysis in the last two decades, there is no cure. Findings of carpal tunnel syndrome or cystic bone lesions in dialysis patients warrant physicians of DRA. Definitive diagnosis requires tissue biopsy. Kidney transplantation is the treatment of choice. There are limited studies to compare the efficacy of dialysis modalities. Early diagnosis and effective renal replacement therapy are keys to slowing the occurrence of DRA.

TH-PO761

Successful Treatment of Rare Peritoneal Tunnel Infection with Nocardia Asteroides Rajat Lamba, Savneek S. Chugh, Aromma Kapoor, Anjani K. Dubey, Anita Kaul, Rishikesh Morey. *Nephrology, Westchester Medical Center, Valhalla, NY.*

Introduction: Nocardia is a partially acid fast aerobic bacteria that usually grows in soil rich in organic matter, fresh and salt water. Human infections with Nocardia asteroides manifest as cutaneous, pulmonary and disseminated forms, the most common form being a slowly progressive pneumonia in immunocompromised host. Nocardia asteroides rarely cause peritonitis in patients on Peritoneal Dialysis (PD). Less than 10 cases have been reported, half of which required catheter removal. We are reporting the first case of PD tunnel infection with Nocardia asteroides which was successfully treated with externalization of the catheter, oral Trimethoprim/sulfamethoxazole and topical sulfacetamide.

Case Description: Patient with diabetes and ESRD from FSGS on PD for 5 months, presented to the clinic with reddish brown discharge from PD catheter exit site. He reported to have returned from a recent trip to Poconos where he had a hot tub bath in Jacuzzi. He was on Continuous Cyclic PD with 4 exchanges each of 2.5 liters of 2.5% dextrose and 3.5 meq/l calcium solution overnight and a day fill of icodextrin. He denied any fever, chills, abdominal pain or cloudy effluent. He was given a dose of intravenous vancomycin, gentamycin and oral amoxicillin/clavulanic acid. Cultures were sent from the exit site, blood and PD effluent. Exit site cultures came back positive for Nocardia Asteroides. Patient was subsequently hospitalized for externalization of the PD catheter from subcutaneous tunnel. Antibiotics were switched to oral Trimethoprim/Sulfamethoxazole and topical 10% sulfacetamide ophthalmic solution. Patient was noted to have complete resolution of the exit site infection at 2 week follow up.

Discussion: Nocardia asteroides is a rare cause of peritonitis in patients on peritoneal dialysis. Our patient likely acquired Nocardia from hot tub bath. Nocardia infection, although rare, should be considered as a possible cause of peritonitis and catheter infection especially in cases that do not respond to standard antibiotic regimen. Patients should be instructed to avoid improperly sterilized pools, while on peritoneal dialysis.

TH-PO762

Myoclonic Jerks and Generalized Epilepsy in End Stage Renal Disease due to Gabapentin Sandesh Joshi, William DiFilippo. *Nephrology, Geisinger Medical Center, Danville, PA.*

Introduction: Gabapentin is widely used in our clinical practice. Gabapentin induced myoclonic jerks and epilepsy is a rare and debilitating condition. Appropriate dose reduction or discontinuation of this drug should be considered in patient with chronic kidney disease and end stage renal disease on dialysis.

Case Description: A 66 year old female with end stage renal disease on chronic hemodialysis, seizures on Ethosuximide, restless leg syndrome was admitted to hospital due to dizziness, tremors and a fall. One day prior to admission, pt experienced dizziness for a brief period of time while driving. Later she noticed twitching of her right arm which gradually got worse. Also started to have jerky movement of the same arm and right leg following which she sustained a fall hitting her head. She did not have loss of consciousness and no injuries. Symptoms went away on its own. Later during the night, she woke up with some tremors in her both arms which gradually worsened, started to have jerky movement involving all four extremities. These symptoms persisted throughout the night and during the

day as well which prompted her to come to emergency department for further evaluation. She was hemodynamically stable and on examination was found to have myoclonic jerks of all four extremities. Her blood work was within normal limits and a computed tomography of head was done which was negative for any acute findings. An Electro-enceplalogram was done which was consistent with primary generalized epilepsy corelating with myoclonus. Upon further interviewing, patient revealed that she was started on Gabapentin(400 mg twice daily) a day prior to her symptoms. Neurology was consulted who increased her ethuosiximide. She was dialyzed next day after which her myoclonic jerk was relieved. She was place in continuous EEG monitoring for next few days until elipsy discharge went away. Her Gabapentin was discontinued at the time of discharge.

Discussion: Gabapentin induced myoclonic jerks and epilepsy is a rare and debilitating condition which we should be aware of. Appropriate dose reduction or discontinuation of this medications should be considered in patient with chronic kidney disease and end stage renal disease on dialysis.

TH-PO763

Cefepime Related Neurotoxicity in a Peritoneal Dialysis Patient Veni J. Peram, Sandeep S. Soman, Jerry Yee. *Nephrology, Henry Ford Hospital, Detroit, MI.*

Introduction: Incidence of Cefepime-related neurotoxicity (CRN) has been reported in 4–16% and is associated with impaired renal clearance. Very few cases of cefepime related neurotoxicity have been reported in continuous ambulatory peritoneal dialysis (CAPD) patients, and peritoneal dialysis (PD) does not clear cefepime efficiently. We present a case of CRN in a patient on CAPD, which resolved rapidly after hemodialysis (HD).

Case Description: Case Description:A 60 year-old man with type 2 diabetes and end-stage renal disease (ESRD), underwent right nephrectomy for renal cell carcinoma. Post-operatively, the patient had hypotension and received empiric cefepime therapy for suspected infection: total dose of 9 gms over 72 hours. Forty-eight hours after cefepime initiation the patient developed disorientation and intermittent generalized tonic-clonic jerking, subsequently followed by aphasia. Moderate encephalopathy was demonstrated by an electroencephalogram and an extensive infection workup was negative (CSF, blood, peritoneal fluid and urine cultures). CRN has been reported at variable serum levels (14–716 mcg/ml) and may be mediated by competitive inhibition of the brain's principal inhibitory neurotransmitter, gamma aminobutyric acid (GABA), which could lower the neuronal excitation threshold. Cefepime level which is shown in the table was calculated based on a study by Barbhaiya et al in CAPD patients.

Volume Of distribution (Vd) over 72 hrs	22 L
Percent dose excretion in PD fluid, Urine	26%, <5%
Calculated drug level: 74% total dose/Vd	302 mcg/ml
Estimated drug level for 2 times the Vd	151 mcg/ml (which is still in the toxic range)

The patient remained disoriented for 40 hrs after cessation of cefepime. Neurologic symptoms improved drastically and the patient's mental status returned to baseline after the third session of HD.

Discussion: ESRD patients are vulnerable to CRN from impaired renal clearance. We recommend a substantially lower dose in CAPD patients as treatment of infection(s): 1–2 g per 48 h. The development of untoward neurological symptoms during cefepime administration mandates early recognition, drug discontinuation and possibly, HD for rapid drug clearance, especially in PD patients.

TH-PO764

Intradialytic Abdominal Pain Piangwarin Phaosawasdi, Billy T. Hour, Jane Y. Yeun. *Internal Medicine - Div of Nephrology, Univ of California, Davis, Sacramento, CA.*

Introduction: Abdominal pain occurring only during hemodialysis (HD) is uncommon. The underlying etiology may remain elusive, leading to a significant delay in diagnosis and treatment.

Case Description: 57 year old man with hepatitis C cirrhosis, orthotopic liver transplantation in 2000, and calcineurin inhibitor nephrotoxicity on HD since 2005, developed recurrent severe abdominal pain after 1 hour of HD, necessitating termination of treatment. Pain gradually resolved in an hour. He described intermittent abdominal bloating relieved with belching without other symptoms. Past medical history was remarkable for coronary artery disease and diabetes mellitus. Medications included lanthanum, lisinopril, metoprolol, and tacrolimus. On exam, blood pressure was 196/111 and pulse 87. Abdomen was soft, nontender, without masses or heptosplenomegaly, and bowel sounds were present. Liver tests were normal. Computed tomography (CT) of the abdomen revealed stable mild intrahepatic ductal dilatation, CT angiogram and Doppler study without evidence of mesenteric ischemia. Upper endoscopy and colonoscopy were unremarkable. Reducing the ultrafiltration (UF) rate, changing the dialyzer membrane, pre-treating with antihistamine and steroid, discontinuing lisinopril, and relieving constipation were ineffective. Abdominal pain improved, but patient developed intradialytic hypotension despite minimal UF, transaminitis, marked jaundice, and elevated lipase and amylase. Repeat CT abdomen revealed pancreatic pseudocysts and a large biloma; CT angiogram demonstrated extensive hepatic artery calcification with occlusion, splenic artery calcification, and splenic infarction. Transaminitis and jaundice resolved after percutaneous drainage of the biloma. Intradialytic abdominal pain has not recurred.

Discussion: Intradialytic abdominal pain was due to recurrent liver ischemia from extensive hepatic artery calcification, resulting eventually in liver infarction, disruption of bile drainage, biloma compression of the pancreatic duct, and pancreatitis. The initial focus on mesenteric ischemia and HD reactions delayed the diagnosis. Intra-abdominal vascular catastrophes must be considered when evaluating intradialytic abdominal pain.

TH-PO765

Spontaneous Healing of Acquired Pleuroperitoneal Leak in a Peritoneal Dialysis Patient after Coronary Artery Bypass Grafting Surachit Kumar, Fahd Syed, Dumitru Rotaru. *Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Pleuroperitoneal leak is caused by an abnormal communication between peritoneal and pleural spaces. It can be due to a congenital or acquired defect in the diaphragmatic muscle fibers or connective tissue. In patients on peritoneal dialysis (PD) the increased intraabdominal pressure and negative intrathoracic pressure can cause fluid accumulation in the pleural cavity.

Case Description: A 65 year old male was on Continuous Ambulatory Peritoneal Dialysis (CAPD) for about a year. His PD prescription was 4 exchanges of 2L of 1.5 percent dianeal and 2L of icodextrin overnight. He underwent Coronary Artery Bypass Grafting (CABG) for chest pain. He was on CVVH post operatively for 7 days and resumed PD on discharge. A month later the patient presented in the clinic with increased shortness of breath. A large right sided pleural effusion was diagnosed. Thoracocentesis showed transudative fluid with pleural fluid glucose greater than serum glucose and low pleural fluid LDH consistent with hydrothorax associated with PD. CABG operative report showed no breach of peritoneum during surgery. He had peritoneal scintigraphy done with Technetium (Tc) 99 which showed a communication between the peritoneal and right pleural cavity. He was then switched to Hemodialysis. Cardiothoracic surgery decided to conservatively observe the patient. Approximately 2 months later the patient was restarted on CAPD with 4 exchanges of 1.5 L of 1.5 percent dianeal with 2 liter of overnight last fill with icodextrin. He tolerated PD comfortably with no recurrence of the pleuroperitoneal leak.

Discussion: In this case the etiology of the pleuroperitoneal leak is probably due to an acquired defect post surgery as there was no hydrothorax while the patient was on PD for a year prior to surgery. Although no breach of the peritoneum was reported, the leak is believed to have developed due to mechanical stretch or trauma to diaphragmatic fibers or connective tissue. This case demonstrates a spontaneous healing of acquired pleuroperitoneal leak and the ability of PD to be resumed in such a scenario.

TH-PO766

Unusual Cause of Intra-Abdominal Air in a Patient on Peritoneal Dialysis Waleed W. Siddiqi, Jason M. Kidd, Todd W. Gehr. *Nephrology, Virginia Commonwealth Univ, Richmond, VA.*

Introduction: Volume overload is a common problem in patients on peritoneal dialysis. Failure of ultrafiltration can lead to changes in prescription, tonicity of dialysate and even dialysis modality. This case describes an unusual presentation of ultrafiltration failure due to a mechanical problem.

Case Description: A 69 years old female with end stage kidney disease on peritoneal dialysis was admitted with shortness of breath, abdominal distension and swelling. She had no abdominal pain or cloudy dialysate. On presentation to the emergency department, she was dyspneic and had 3+ lower extremity edema. Lung exam was significant for bibasilar crackles. Abdomen was distended, but soft. Significant intra-peritoneal air was seen on abdominal x-ray. Surgery was consulted and acute surgical etiologies were ruled out. Further investigation revealed the patient had recently increased the length of tubing that was being used to fill her peritoneal cavity, leading to her symptoms. Intra-abdominal air was removed by placing patient in prone trendelenburg position and using a large syringe attached to peritoneal dialysis catheter, leading to resolution of her symptoms.

Discussion: Common causes of volume overload in a peritoneal dialysis patient include dietary indiscretion, inappropriate prescription, and mechanical problems including leaks, obstruction, entrapment and malposition.[1] This case describes an uncommon mechanical problem leading to volume overload and a novel approach to correct this issue. It also illustrates the importance of a thorough history in patients on home dialysis therapies, including queries regarding their equipment. [1]Mujais S et al. Evaluation and management of ultrafiltration problems in peritoneal dialysis. Peritoneal Dialysis International, Vol 20, Suppl. 4. 2000.

TH-PO767

Hypertonic Dialysate to Manage Elevated Intracranial Pressure During Intermittent Hemodialysis Lee M. Ferguson, Divya Monga, Kenneth E. Kokko. *Dept of Medicine, Div of Nephrology, Univ of Mississippi Medical Center, Jackson, MS.*

Introduction: Standard intermittent hemodialysis (HD) is traditionally avoided in patients with elevated intracranial pressures (ICP), as it can lower cerebral perfusion pressure (CPP) by either decreasing the mean arterial pressure (MAP) or increasing the intracranial pressure (ICP). At-risk patients are usually placed on a continuous form of renal replacement therapy (RRT), as this modality provides a slower solute clearance and increased hemodynamic stability, leading to a more stable CPP. We describe the case of a 28-year-old male with end-stage renal disease on intermittent HD, who presented post-motor vehicle collision with a C3 fracture and small brain hemorrhages without midline shift. An intraventricular drain was placed and demonstrated an ICP of 20 mmHg and a CPP of 69 mmHg. The patient was then started on conventional intermittent HD for worsening hyperkalemia via an AV fistula. After one hour of HD, the patient's MAP dropped to 81 mmHg, his ICP increased to 28 mmHg, and his CPP dropped to 53 mmHg. In response to the lower CPP, ultrafiltration was turned off, dialysate sodium was increased to 145 mEq/L, and the patient was given a 500 cc intravenous bolus of normal saline. As a result of these changes, the MAP increased to 86 mmHg, the ICP decreased to 17 mmHg, and his CPP increased to 69 mmHg. He was then able to complete a three hour session of HD. Little is

known about the timing of changes in CPP in patients on conventional intermittent HD. This case illustrates that a drop in CPP can be a late occurrence of conventional hemodialysis, and that it can be corrected with a hypernatremic dialysate. More research should be done to determine how often CPP drops during conventional HD and whether or not there are patients that may have an adverse outcome as a result of a low CPP.

TH-PO768

Hyperlactatemia due to Thiamine Deficiency in a Peritoneal Dialysis Patient
Santhi Voora, Todd Ing, Anuradha Wadhwa. *Div of Nephrology, Loyola Univ Medical Center, Maywood, IL.*

Introduction: Lactic acidosis commonly occurs because of diminished tissue oxygenation leading to anaerobic metabolism and increased lactate production. Here we report an interesting case of persistently elevated serum lactate levels in a peritoneal dialysis (PD) patient, raising concerns about the PD fluid lactate content as a possible cause.

Case Description: A 44-year-old female with end-stage renal disease maintained on PD was admitted with generalized weakness and poor oral intake. She was hypotensive and tachycardic with lab findings notable for leukocytosis, acidosis (CO2 17 mmol/L), anion gap 19 mEq/L and lactate 6 mmol/L (normal 0.9-1.7 mmol/L). Further workup revealed fungal peritonitis which was treated with fluconazole. Patient refused PD catheter removal but all subsequent cultures were negative. Despite improvement in blood pressure and resolution of infection, serum lactate levels remained elevated between 4-7 mmol/L. Her liver function tests were normal except for low serum albumin. There was concern about lactate content of PD fluid as the source of elevated serum lactate. Blood lactate concentrations reflect the balance between lactate production and clearance. Thiamine deficiency inhibits the oxidative decarboxylation of pyruvate, which accumulates and is converted to lactate by lactate dehydrogenase. In our patient, thiamine was low at 59 nmol/L (normal 78-185 nmol/L) and pyruvate was elevated at 2.08 mg/dL (normal 0.3-1.5 mg/dL). Fifty mg of oral thiamine was started daily and the serum lactate normalized to 1.6 mmol/L within days after initiation of therapy.

Discussion: The temporal relationship between thiamine supplementation and lactate normalization supports thiamine deficiency as the cause of this patient's elevated lactate level *rather than lactate from the PD fluid* (which could have contributed as a substrate). While thiamine deficiency-related lactic acidosis has been described in the setting of parenteral nutrition, to our knowledge, our case is the only description of thiamine deficiency-related elevated serum lactate value in the setting of PD. Thiamine deficiency should be included in the differential diagnosis of lactic acidosis, especially in PD patients.

TH-PO769

A Rare Cause of Wide Anion Gap Metabolic Acidosis in Uncommon Calcific Uremic Arteriolopathy
Sahil Garg, Nader S. Bahri, Leighton R. James. *Nephrology, UF Health Jacksonville.*

Introduction: Calcific uremic arteriolopathy (CUA) has high mortality despite treatment. This case highlights the importance of multi-pronged approach to treat CUA. Metabolic acidosis due to STS poses a significant problem, requiring use of high bicarbonate bath during hemodialysis or even reduction in STS dose.

Case Description: A 57 year old morbidly obese caucasian male with history of hypertension, type 2 Diabetes Mellitus, End stage renal disease (on Hemodialysis for 3 years) and atrial fibrillation (on coumadin for 4 months) was admitted to the hospital with complaint of bilateral thigh and calf pain for 1-2 months. Pain was present at rest and worsened on exertion. He admitted being non-compliant with phosphate binders. Physical examination revealed painful, indurated subcutaneous plaques in infra-umbilical region, medial part of bilateral thighs and calves. Subsequently over the next 3-4 days lesions evolved into ulcerations with surrounding violaceous discoloration and erythema. Serological work up for vasculitis including ANA, ANCA, cryoglobulin, anticardiolipin Ab was negative. Complement C3 (174 mg/dl) was normal while C4 (60.9 mg/dl) was elevated. Review of laboratory data revealed phosphorus levels ranging from 7-8 mg/dl, PTH 325-750 pg/ml, and serum calcium 8.8-9 mg/dl in prior 12 months. He was diagnosed with CUA. He was started on Sodium thiosulphate (STS) 25 gm intravenously after each Hemodialysis session, daily hemodialysis to improve clearance, a non-calcium based phosphate binder and cinacalcet. Coumadin was switched to aspirin and plavix. Skin biopsy was not done because of patient's refusal. Skin lesions and pain exhibited substantial improvement in following 2.5-3 months with above-mentioned strategies, but surprisingly he developed wide anion gap metabolic acidosis despite daily hemodialysis. Anion gap increased from baseline of 17-18 to 25-30 after starting STS. Acidosis improved when hemodialysis was performed against higher Bicarbonate bath.

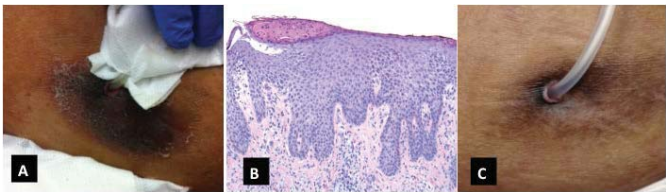
Discussion: CUA can be diagnosed early if there is high index of suspicion. Medical therapy when started in timely manner can improve overall moratlity and morbidity in CUA. STS is a strong acid causing metabolic acidosis as reported in many case reports.

TH-PO770

Gentamicin-Induced Contact Dermatitis Mimicking Peritoneal Dialysis Catheter Exit Site Infection
Ike Ezumba, Kristopher R. Fisher, Elvira Gosmanova. *Nephrology, UTHSC, Memphis, TN.*

Introduction: Topical gentamicin is an effective and widely used antibiotic for the prophylaxis of peritoneal catheter exit site infection in patients undergoing peritoneal dialysis (PD). We describe a rare case of contact dermatitis induced by gentamicin cream that mimicked peritoneal catheter exit site infection.

Case Description: A 54-year old female undergoing PD presented to a dialysis clinic with 2 weeks history of progressively worsening itchy lesion around her peritoneal catheter exit site. 3 weeks ago the patient started topical gentamicin cream for the prophylaxis of exit site infection. On examination, peritoneal catheter exit site had an 8.5 x 4.5 cm nummular plaque, violaceous in color with peripheral rim of erythema with no granulation tissue or discharge (figure 1A). Clinical diagnosis of allergic contact dermatitis due to gentamicin was made and gentamicin cream was discontinued. Patient underwent a skin biopsy that showed psoriasiform spongiotic dermatitis with eosinophils, consistent with contact dermatitis (figure 1B). Exit site lesion slowly resolved over 4 weeks after stopping gentamicin and initiation of 2.5% hydrocortisone cream (figure 1C).



Discussion: Peritoneal catheter associated exit site infection requires a prompt treatment to avoid the development of peritonitis. However, not all peritoneal catheter exit site lesions are due to microbial infection. Allergic contact dermatitis due to topical gentamicin is rare. It is important to be aware of this association to avoid incorrect diagnosis of peritoneal catheter exit site infection and inappropriate antibiotic use in patients undergoing peritoneal dialysis.

TH-PO771

A Case of Successful Conservative Management of End Stage Renal Disease
Phillip Madonia,[1] Mohana B. Karlekar,[2] Rachel B. Fissell.[1] *[1]Dept of Nephrology, Vanderbilt Univ, Nashville, TN; [2]Dept of Internal Medicine, Vanderbilt Univ, Nashville, TN.*

Introduction: End stage renal disease (ESRD) patients often present with multiple comorbid conditions, advanced age, and an increased risk of death. While renal replacement therapy extends life, it does not restore kidney function. This case illustrates successful conservative management of renal failure, achieving expectations of both the patient and the family.

Case Description: The patient is a 95 year old man who was evaluated for stage V chronic kidney disease due to hypertension. Other history included prior cerebrovascular accident,depression, and remote prostate cancer. The patient lived at home with his daughter and her husband, both accompanying him to clinic visits. On initial evaluation, his glomerular filtration rate was 15 ml/min, and he complained of poor energy and occasional nausea. He exercised at home several times weekly. He had fair blood pressure control on three anti-hypertensive medications. After discussions with the patient and his family, the team was able to clearly define the patient's overall goals of care to be maximizing his quality of life and remaining at home with his family. It was agreed that when dialysis became necessary, it would not be initiated. Over the next few months, his renal function slowly declined, and management of the sequelae of kidney disease were managed conservatively. The family voiced satisfaction with his care during this period until he passed away peacefully at home.

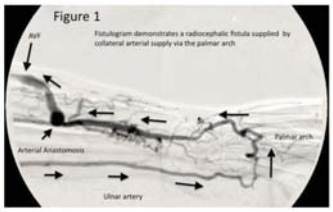
Discussion: The fastest growing demographic among new dialysis patients is people older than 75 years. Given their advanced age and significant comorbid conditions, it is no surprise that dialysis patients have a mortality rate significantly higher than the general population. Dialysis patients who complete an advance directive are more likely to receive palliative care prior to dying than cancer or heart failure patients. Unfortunately, fewer than half of all dialysis patients in the United States complete an AD prior to their death. More work is needed to increase awareness of palliative care resources, and to encourage end of life conversations between ESRD patients, families, and caregivers.

TH-PO772

Operative Salvage of Radiocephalic AVF with Poor Inflows By Formation of a Neoanastomosis to the Proximal Artery Using Tapered PTFE Graft to Complete a Composite Forearm Loop Configuration
Siddiq Anwar, Ravkiran Kaur Khurana, Mansumeet Singh, Daniel C. Brennan. *Renal Div, Washington Univ School of Medicine, St. Louis, MO.*

Introduction: Loss of arteriovenous fistula as access for hemodialysis (HD) leads to significant morbidity and increased mortality risk. Forearm HD access are associated with less cardiovascular remodeling and less steal.

Case Description: We describe a case of a 34-year-old, African-American man with a poorly functioning radio-cephalic fistula (RCF). Venography suggested that the patient's flow into the fistula was through the palmar arch and the patient had a diseased radial artery .A tapered polytetrafluoroethylene graft (4 mm to 7 mm Propaten graft) was inserted to connect brachial artery to distal end of the RCF fistula. This completed a medial segment for a loop graft which would be composed of his old fistula with the arterialized vein on the lateral segment and graft on the medial segment.



Discussion: Operative salvage of radiocephalic AVF with poor inflows by formation of a neoanastomosis to the proximal artery using PTFE graft can be performed with good results. The arterialized vein provides immediate HD access and saves proceeding to elbow fistula formation.

TH-PO773

Massive Pneumoperitoneum in Patients on Chronic Automated Peritoneal Dialysis Vanya Grover,[1] Anu Neerukonda,[2] Cheryl Laveglia,[3] Reem Miller,[3] Heesuck Suh,[1] Nand K. Wadhwa.[1] *[1]Nephrology, Stony Brook Hospital; [2]Medicine, Stony Brook; [3]Stony Brook Kidney Center, DCI, Stony Brook, NY.*

Introduction: A massive pneumoperitoneum (PP) is a rare complication in patients on automated peritoneal dialysis (APD). Infusion of air can occur with catheter insertion or manipulation or faulty PD techniques. We describe two cases of huge pneumoperitoneum due to a faulty technique in setting up of APD.

Case Description: A 68 year-old woman with ESRD due to hemolytic uremic syndrome on APD was admitted with diffuse abdominal pain. She was afebrile and her abdomen was soft, mildly distended, and diffusely tender. She was thought to have peritonitis and was empirically treated with antibiotics. The peritoneal fluid was hazy with a cell count of 411 per mcL and 2% neutrophils. Cultures were negative. APD was resumed and within 24 hours her abdominal pain resolved. She was discharged home and antibiotics were discontinued. Ten days later she developed similar abdominal pain. She was again afebrile and her abdomen was mildly distended. A computed tomography (CT) of her abdomen revealed massive free intraperitoneal air. APD was resumed and her abdominal pain subsided. Repeat peritoneal fluid revealed a cell count of 151 per mcL and 23% neutrophils. Cultures were negative. The second patient is a 48 year-old man with ESRD due to diabetic nephropathy on APD who was admitted with a distended abdomen for one week. He was afebrile. His abdomen was mildly distended, and not tender. The peritoneal fluid was clear with a cell count of 69 per mcL and 9% neutrophils. CT of the abdomen revealed moderate PP. Cultures were negative. APD was resumed and his abdominal pain subsided.

Discussion: Pneumoperitoneum in both cases was due to a faulty technique, as both patients left the fill line clamped during priming. The clinical picture was due to a significant intraperitoneal free air from air entry when initiating APD. The patient's symptoms resolved with the proper technique. These index cases prompted evaluation of all APD patients' technique of APD. All patients underwent retraining of the APD procedure. No further case of pneumoperitoneum was observed after training over a follow up period of 903 patient-months in our program.

TH-PO774

Pre-Emptive Continuous Renal Replacement Therapy in a Patient at High Risk for Tumor Lysis Syndrome Neha Garg, Parth Rao, Miguel Conde, Neil W. Lyman. *Saint Barnabas Medical Center, Livingston, NJ.*

Introduction: Tumor lysis syndrome (TLS) is a life threatening complication occurring either spontaneously or after chemotherapy for hematological tumors. It is characterized by acute kidney injury (AKI) and electrolyte disturbances. Prophylaxis of TLS includes vigorous hydration, control of hyperuricemia, managing electrolyte disorders, and renal replacement therapy (RRT) for patients who develop AKI. We report a case of pre-emptive RRT in a patient at high risk for TLS.

Case Description: A 67 year old African American male with a 10 year history of chronic lymphocytic leukemia was admitted to our hospital with a 50 lbs. weight loss over 1 year, moderate splenomegaly, marked lymphadenopathy and a leukocyte count of 204,000/ µL. He also had dilated cardiomyopathy with ejection fraction of 15-20%, cardio-renal syndrome, diabetes mellitus, chronic kidney disease (CKD) stage 4 with a baseline creatinine (Cr) of 2.2-2.7mg/dl. He received rasburicase and was started on bendamustine and decadron. Continuous RRT was initiated pre-emptively 2 hrs. post chemotherapy. Bendamustine is highly protein bound hence CRRT didn't interfere with its excretion. Uric acid level on admission was 8.4mg/dl and remained low during RRT, however peaked to 11mg/dl after discontinuation of RRT. His hospital course remained stable. Leukocyte count trended down to a nadir of 32,000/ µL. CRRT was discontinued on day8 and patient was discharged on Day12 with a Cr of 2.11mg/dl. Patient's Cr remained stable at 2.23 mg/dl two months post discharge.

Discussion: Our patient had cardiorenal syndrome with CKD stage 4 and congestive heart failure (CHF) which precluded the use of vigorous hydration. We successfully used pre-emptive CRRT to prevent development of AKI and delay the need of chronic dialysis for our patient. Saccente et al (*pediatric nephrology, 1995, 9; 569-573*) had used similar strategy in children with burkitt's lymphoma. Pre-emptive RRT may be used in patients with underlying advanced renal disease with CHF to prevent severe electrolyte imbalance. It may also delay the progression of CKD and the need of chronic dialysis. Further guidelines are required to initiate RRT pre-emptively in high risk patients.

TH-PO775

Intermittent Hemodialysis Prescription with Intracerebral Hemorrhage: Practical Approach Eric Loman, Gaurav Alreja, Kelly Mazurek, Ruchir D. Trivedi. *Internal Medicine and Nephrology, Univ of Connecticut, Farmington, CT.*

Introduction: Patients with intracerebral hemorrhage (ICH) have cerebral edema and increased intracranial pressure (ICP). Intermittent hemodialysis (IHD) potentiates brain injury by increasing water content (cerebral edema) and ICP. The mechanisms involved are "Cerebral Intracellular Urea Trapping" with a rapid fall in serum urea/sodium/osmolality and osmotic water shift across the gradient. Although CRRT is the preferred modality to prevent rapid lowering of urea and slow volume removal to maintain cerebral perfusion pressure, it is not tenable in all cases both due to logistics and need for additional catheter placement. Our case highlights challenges with IHD and suggests practical prescription changes.

Case Description: 68 year old female on chronic IHD presented with altered mental status, uremia (BUN 90 mg/dl) and a large subarachnoid hemorrhage. On her regular prescription (Na-140, Ca-2.0, HCO3-35, BFR-400cc/min, DFR-800cc/min, time-240 min), she became non-responsive with stable hemodynamics. Her dialysis prescription was then altered (raised dialysate Na 5 meq/dl above serum, reduced BFR-250 cc/min, decreased DFR-500cc/min, increased Ca-2.5meq/dL, shortened dialysis time-150 min, limited volume removal-1 L/treatment, cooled dialysate temp: 35.5 C and dialyzed 5-6days/week). Over the duration of the next 2 weeks, the dialysis prescription was changed every third day (decreased Na-2 meq/dl, increased BFR-50 cc/min, increased duration-30 min, increased temp-0.5 C and increased HCO3-1meq/dl) to transition the patient to her routine prescription.

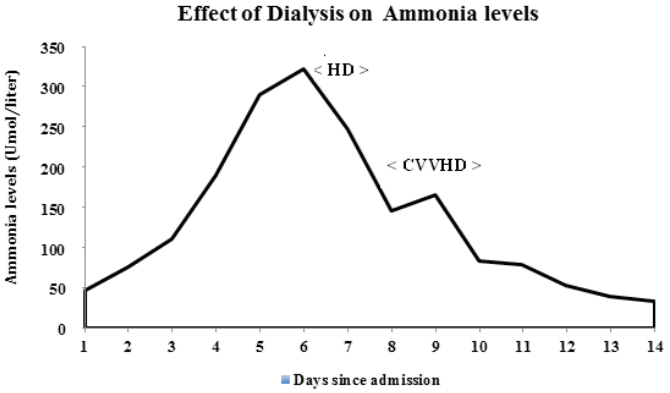
Discussion: IHD lowers serum osmolality rapidly and urea in brain cells is trapped as it moves through slow urea transporters, setting up a large osmotic gradient, resulting in worsening edema and ICP. Slowing the rate of urea reduction, by decreasing BFR and dialysis duration, prevents rapid osmotic shifts. More frequent dialysis provides control over volume (high Na will predispose to volume overload), rapid reduction in urea and hemodynamic stability. Higher Na baths may also partially offset the fall in serum osmolality. Lowering bicarbonate prevents paradoxical intracellular acidosis and high osmolality.

TH-PO776

Role of Dialysis in Multifactorial Hyperammonemic Encephalopathy Prasanna Sujaritha Durairaj, Amanda Fernandes, Ashish Verma. *Internal Medicine, Baystate Medical Center, Springfield, MA.*

Introduction: Hyperammonemia (HA) in adults without liver disease is responsive to dialysis when optimal medical management fails.

Case Description: A 48 year-old white female with history of alcohol abuse, gastric bypass, and bipolar disorder on Valproate for 4 years, presented with altered mental status, non-convulsive status epilepticus, and rising serum ammonia levels. This persisted a week after discontinuation of Valproate and initiation of lactulose, rifaximin, levocarnitine, and sodium benzoate. Valproate levels were initially low normal and then undetectable. Kidney and liver function were normal. No acid-base disorders were evident. Urine toxins screen and lumbar puncture were negative. Brain imaging showed nonspecific changes. Cirrhosis and porto-systemic shunt were absent on imaging. Serum glutamine and lysine were elevated, consistent with **HA** of any etiology. Other amino acids were below normal range. Urine organic acid screen suggested glutathione depletion and ruled out orotic aciduria or other urea cycle defects. Zinc and Vitamin B12 were low and repleted. Pseudomonas pneumonia was diagnosed and treated. She had 2 sessions of intermittent hemodialysis followed by 48 hours of continuous veno-venous hemodialysis. Ammonia levels trended to normal without significant improvement in mental status.



Discussion: Causes for **HA** in this patient included Valproate and its metabolites inhibiting mitochondrial carbamyl phosphate synthetase in the setting of altered gut function, severe catabolic state and past alcohol abuse. Zinc and vitamin B12 deficiencies, Pseudomonas pneumonia and a partial, late-onset urea cycle disorder were also contributory

to her multifactorial **HA** encephalopathy. Ammonia is 17 Daltons in molecular weight and at pH of 7.3, over 90% is in ionized form. Hence, it is successfully dialyzable with clearance similar to that of urea.

TH-PO777

Role of Renal Replacement Therapy in Fioricet® Overdose Disha Narula, Amit A. Deshpande, Shabnum Haleem, Hasan Arif. *Drexel Univ.*

Introduction: Caffeine has a low volume of distribution and is responsive to extracorporeal methods of elimination. Charcoal hemoperfusion has been the conventional method for enhanced elimination of methylxanthines, particularly theophylline. This case is an example of the challenges surrounding data available for role of different hemodialysis modalities in cases of caffeine toxicity.

Case Description: 58 year old F with PMH of Depression and RSD presented with Fioricet® overdose. Patient took 150 pills of Fiorcet® as a suicide attempt .In the ED, the patient was found to be lethargic and hypotensive with a BP of 75/49, pulse of 69 RR of 8, and O2 sat of 99% on RA. The patient was given 3 L of NS, but she remained hypotensive and was started on a norepinephrine drip. Patient was also intubated for airway protection. Labs: Cr 0.28, HCO3 18, Acetaminophen level was 57. Her ALT 19 AST 14 Alk Phos 36. Salicylate level was negative. Ethanol level <5.0. ABG was pH of 7.45, PCO2 33, PO2 135 HCO3 22, and O2 sat 98. Patient was started on NAC for her elevated Tylenol levels. Nephrology was consulted for the role of HD in Fioricet® overdose for the caffeine and barbiturate component.The patient was initiated on hemodialysis and was dialyzed for 6 hours with a high flux dialyzer.

Discussion: Fioricet® is composed of acetaminophen, butalbital, and caffeine. Fioricet® overdose can lead to renal tubular necrosis. Dialysis has been recommended in cases of severe toxicity. Caffeine has a low volume of distribution and is responsive to extracorporeal methods of elimination. Charcoal hemoperfusion has been the conventional method for enhanced elimination of methylxanthines, particularly theophylline. The endogenous rate of theophylline clearance has been shown to be a 50 mL/min, while hemoperfusion rates have been reported up to 4 to 6 times higher. HD has lower clearance rates (100 mL/min) compared with hemoperfusion.The challenge in these cases is to monitor the need for continued HD without butalbital or caffeine levels to trend. Caffeine ingested in large amounts can lead to toxic theophylline levels in some instances,which can be trended to assess the need for further HD. We, however, used her hypotension and pressor requirement as a surrogate for continued HD needs.

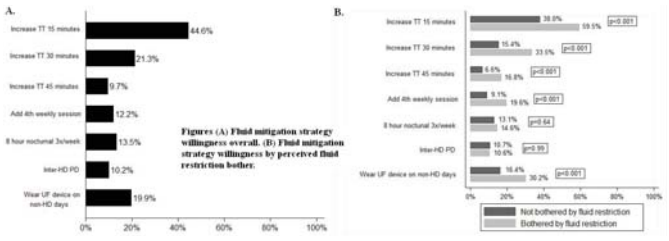
TH-PO778

Patient-Stated Preferences in Fluid Management on Hemodialysis Jennifer E. Flythe,[1,2] Steven M. Brunelli,[2,3] Gary C. Curhan.[2] *[1]Univ of North Carolina Kidney Center; [2]Brigham and Women's Hospital; [3]DaVita Clinical Research.*

Background: Larger interdialytic weight gain (IDWG) and higher ultrafiltration (UF) rates are associated with poorer outcomes among hemodialysis (HD) patients. Dietary restrictions may reduce fluid-related risk; however, adherence is difficult. No data regarding patient preferences for fluid management strategies such as treatment time (TT) extension, more frequent HD, adjunct peritoneal dialysis (PD), and wearable UF devices exist. We designed, tested, and administered a survey to assess patient preferences for fluid management.

Methods: A written survey concerning fluid-related symptoms, patient and HD characteristics, and fluid management preferences was developed. The survey was completed by 600 HD patients at 18 geographically diverse HD units. Comparisons of patient willingness to engage in volume mitigation strategies across patient and fluid-related characteristics were performed.

Results: Survey respondents were 57.6% male, 40.0% age 40-59 years, and 47.6% black. The mean self-reported IDWG was 2.8 ± 1.1 kg and mean TT was 229.7 ± 45.6 minutes. Prescribed fluid restrictions were reported by 74.2% of patients. Overall, if allowed to liberalize fluid intake, >40% of patients were willing to extend TT 15 minutes. Respondents were less willing to engage in other strategies (Figure A). Patients more bothered by their fluid restrictions (versus less bothered) were more willing to engage in fluid mitigation strategies (Figure B). Demographics and symptoms (cramping, dyspnea) were not consistently associated with willingness to engage in the proposed strategies (not shown). >25% of patients were unsure of their dry weights and typical IDWGs.



Figures (A) Fluid mitigation strategy willingness overall. (B) Fluid mitigation strategy willingness by perceived fluid restriction bother.

Conclusions: Patients are generally averse to TT extension greater than 15 minutes and to the other interventions studied. Further study of patient-stated preferences in HD treatment practices is needed to guide patient care.

TH-PO779

Clinical Assessment Cannot Identify Hypovolemia in Hemodialysis Patients Sylvia Kalainy, Kailash K. Jindal, Branko Braam. *Medicine/Nephrology, Univ of Alberta, Canada.*

Background: Determining dry weight of haemodialysis (HD) patients is a challenge. Both underhydration and hypervolemia are associated with HD complications. Therefore, determination of fluid balance to prevent both underhydration and overhydration is an important issue in HD patients. We previously reported that clinical parameters cannot identify HD patients with fluid overload. Using Bio-impedance to assess fluid volume, we hypothesized that a significant number of HD patients could have unidentified hypovolemia.

Methods: Multifrequency Bio-impedance spectroscopy (BCM- Fresenius Canada) measurement was performed before the start of a mid-week dialysis session in 175 patients to assess extracellular fluid volume (ECFV) and overhydration (OH). Physical signs (BP, edema), plasma Na, K and albumin, urea reduction ratio (URR), and a recent CXR (cor-thorax ratio) were investigated as potential markers for volume assessment.

Results: Patients (age 61 (18-91) y, 58% males, 42% diabetic) were divided into 3 groups: normovolemia (OH=>0<1.1L), hypervolemia (OH>1.1L), hypovolemia (OH<0L). BP was significantly lower in hypovolemic patients. Interdialytic weight gain (IDWG) was high in some of the hypovolemic patients. When the entire group was evaluated, no significant correlations between continuous variables and OH was detected except with a weak correlation with pre-dialysis SBP.

	Total (n=175)	Hypovolemic (n=44)	Normovolemic (n=53)	Hypervolemic (n=78)
Gender,M/F	102/73	23/21	30/23	49/29
Age, years	61±15	61±15	60±18	61±13
Hydration status, L.	1±1.8	-1.1±0.8*	0.5±0.3*	2.6±1.4*
Diabetes, %	42	41	37	51
Pre-HD-SBP, mmHg	130±24	125±20*	131±30	138±22*
Pre-HD-DBP, mmHg	73±17	70±15	73±20	73±16
Pre-HD-PP, mmHg	60±20	55±20*	58±23	65±18*
Hypertension, %	32	25	35	41
IDWG,kg	1.6±1.2	1.4±0.9	1.5±1	1.8±1.4

Conclusions: A significant number of our patients were hypovolemic and that could not be predicted by clinical parameters alone. Some of these patients had high IDWG despite hypovolemia. This suggests that some patients purposely have high sodium and fluid intake to correct their own hypovolemia.

Funding: Pharmaceutical Company Support - The BCM was borrowed from Fresenius, Government Support - Non-U.S.

TH-PO780

Blood Volume Monitoring During Hemodialysis Identifies Fluid Overload Not Recognized by Clinical Assessment Wael F. Hussein,[1,2] Rohini Arramreddy,[2] Sheila Doss-McQuitty,[2] Sumi J. Sun,[2] Brigitte Schiller.[1,2] *[1]Div of Nephrology, Dept of Medicine, Stanford Univ School of Medicine, Palo Alto, CA; [2]Satellite Healthcare, San Jose, CA.*

Background: Assessment of dry weight (DW) is critical for fluid management in HD patients, but is a subjective process with several limitations. Blood volume monitoring (BVM) is considered an objective tool that can improve fluid management. We evaluated the performance of BVM for identification of fluid overload in comparison to standard clinical evaluation.

Methods: In this cross-sectional observational study in 5 dialysis centers, BVM using Crit-line was performed once on 213 randomly selected patients during one mid-week HD session. Vascular refill was assessed by stopping ultrafiltration in the last 10 minutes of HD. Patients were considered to have fluid overload at the end of the session when blood volume change (ΔBV) did not fall below -5% during treatment, or if ΔBV increased by more than 1.5% during refill time. Only BVM studies that included a refill test were used in this analysis (n=169). Results of BVM, blinded to staff, were compared to achievement of DW and to fluid status assessment by nurses.

Results: Fluid overload post dialysis was identified in 35 (21%), 65 (40%) and 73 (43%) patients by non-achievement of DW, nurses evaluation, and BVM criteria respectively. There was poor agreement between DW achievement and nurses assessment (kappa 0.28 (95% CI 0.14 to 0.42)). There was no agreement between BVM evaluation and either DW achievement (k 0.10 (-0.03 to +0.23)) or nurses evaluation (k 0.07 (-0.08 to +0.22)). Forty four patients (26%) had volume overload by BVM while having no intradialytic symptoms or interventions, and may be candidates for dry weight reduction.

Conclusions: A substantial proportion of patients have inadequate fluid removal identified by BVM and undetected by clinical assessment in routine outpatient HD. The response to DW reduction in patients identified by BVM to have volume overload remains to be tested. Validated algorithms for BVM in both hemodynamically stable and unstable patients need to be developed to optimize fluid management in HD patients.

Bioimpedance Fluid Analysis in Prevalent Hypertensive Hemodialysis Patients with Different Blood Pressure Patterns

Javier A. Neyra,[1] Xilong Li,[2] Robert D. Toto,[1] Peter N. Van Buren.[1] *[1]Nephrology, Univ of Texas Southwestern, Dallas, TX; [2]Clinical Sciences, Univ of Texas Southwestern, Dallas, TX.*

Background: Extracellular volume overload is common in hypertensive hemodialysis (HD) patients. We hypothesized that patients with different systolic blood pressure (SBP) patterns during HD would have different distribution of fluids from pre to post-HD.

Methods: As part of a case-control study, we used whole body multifrequency bioimpedance spectroscopy to measure intracellular fluid (ICF), extracellular fluid (ECF), total body water (TBW) and the ECF/TBW ratio before and after HD in prevalent hypertensive hemodialysis patients with SBP increases and decreases from pre to post-HD. We compared the percentage change of these variables between groups using T-tests.

Results: We analyzed data from 9 subjects (90% men, 70% African-American) with increased SBP (+21 ± 15 mmHg) after HD and 10 (80% men, 40% African-Americans) with decreased SBP after HD (-37 ± 29 mmHg). The mean age was 47.6 ± 12 and 51 ± 12 years, respectively. The changes in volume compartments from pre to post-HD are presented in Table 1. There was a significantly greater reduction in the ECF/TBW ratio in subjects in whom SBP decreased after HD compared to those in whom it increased. Contrary, there was a greater reduction in ICF in those in whom SBP increased after HD when compared to their counterparts.

Table 1	**SBP Decrease**	**SBP Increase**	**P-value**
% Decrease ECF	12.6 (4.2)	10.7 (3.9)	0.3
% Decrease ICF	0.2 (5.7)	8.0 (6.0)	0.01
% Decrease TBW	6.1 (1.9)	9.2 (4.1)	0.05
% Decrease ECF/TBW	7.0 (4.4)	1.7 (3.7)	0.01
% Volume Removal	3.5 (1.3)	3.1 (1.6)	0.5

Conclusions: In hypertensive hemodialysis patients, heterogeneous changes in body fluid compartments were identified in relation to different SBP patterns during HD and despite similar percentage of volume removal. Identifying the factors governing fluid redistribution may provide further insight how fluids and blood pressure are related.

TH-PO782

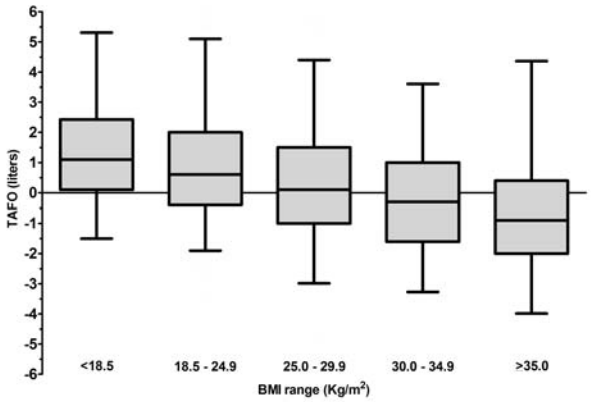
The Potential Bias of Hydration Status Evaluation by Bioimpedance Spectroscopy in Hemodialysis Patients: A Role for the Body Mass Index

Amanda Bedran, Jocemir R. Lugon, Jorge P. Strogoff-de-Matos. *Div of Nephrology, Univ Federal Fluminense, Niteroi, Rio de Janeiro, Brazil.*

Background: Body composition by bioimpedance spectroscopy (BIS) analysis was previously validated by deuterium and bromide dilution methods, but a small number of obese subjects or hemodialysis (HD) patients were included in those studies. We aimed to identify potential bias in the analysis of body composition by BIS in the HD population.

Methods: Prevalent patients on HD of 31 facilities were studied at the time they first underwent BIS (BCM®, Fresenius Medical Care) assessment. Demographic and anthropometric variables were analyzed looking for systematic errors in the evaluation of hydration status. Fluid excess was defined by timed-average fluid overload (TAFO, average pre and post dialysis weight – normohydration weight defined by the BIS device).

Results: A total of 3,358 patients were included in this study (59.7% males, 22.7% diabetics, 54±15years old, 45[3-472] months on HD, body mass index [BMI] 24.9±5.1 Kg/m^2). TAFO (median, interquartile range) was higher in males than females (0.7 [-0.5 to 2.2] and 0.0 [-1.1 to 1.1], respectively; P<0.001). No significant correlation between TAFO and age was found. However, there was an inverse correlation with BMI (r= -0.184, p<0.0001). TAFO significantly varied, according to BMI ranges, from 1.1[0.1 to 2.4] to -0.9 [-2.0 to 0.4] in patients whose BMI were <18.5 and >35 Kg/m^2, respectively.



Despite differences in TAFO, intradialytic changes in blood pressure and the number of hypotensive drugs did not differ between BMI ranges.

Conclusions: The unexpected inverse correlation between BMI and hydration status could be attributed to a bias in the estimation of the normohydration weight by the BIS device. Further studies are desired in order to improve the use of BIS for patients on HD with extreme values of BMI.

TH-PO783

Inaccuracy of Plasma Na Measurement in Hemodialysis (HD) Patients

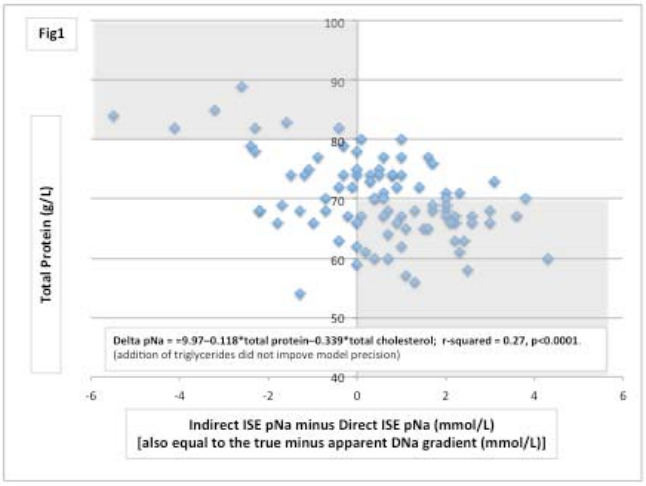
Gabrielle Guilbert- Vandal, Rita Suri. *Univ of Montreal, Montreal, QC, Canada.*

Background: Matching dialysate (D) to plasma (p) Na has been advocated to reduce interdialytic weight gain (IDWG) in HD patients, and requires precise measurement of pNa. Standard indirect ion-selective electrode (ISE) methods normalize serum to pNa by mathematically correcting for plasma protein and lipid fractions. Direct ISE requires no correction. As protein and lipids are often abnormal in HD patients, we compared indirect with direct ISE pNa in this population, and determined if differences could be predicted by a regression equation.

Methods: Pre-dialysis pNa was measured by indirect and direct ISE in all consenting patients at a single HD unit (n=94). All patients had DNa=140mmol/L. Delta pNa = indirect ISE pNa – direct ISE pNa; apparent DNa gradient = DNa – indirect ISE pNa; true DNa gradient = DNa – direct ISE pNa.

Results: Mean age was 64±15yrs, mean vintage was 24 ms, 89% had hypertension, 50% had diabetes, 51% had total protein<70g/L. Delta pNa ranged -5 to 4.3 mmol/L, and was significantly different between the 2 methods (absolute mean delta 1.4±1.1mmol/L, p=0.013); 27% of patients had absolute delta pNa>2mmol/L. IDWG was significantly (albeit weakly) correlated with true (r^2=8%, p=0.0007) but not with apparent DNa gradient (r^2=3%, p=0.19). Whereas the final equation (Fig 1) only weakly predicted delta pNa (r^2=27%, p<0.0001), total protein <70g/L had sensitivity of 80% to detect a true DNa gradient that was at least 2mmol higher than the apparent gradient (NPV=86%). Total protein >80g/L had specificity of 100% to detect a true gradient that was at least 2mmol/L lower than the apparent gradient (PPV=100%).

Conclusions: Indirect ISE pNa may be inaccurate in HD patients with abnormal protein levels. We found total protein of <70 or >80g/L is predictive of a >2 mmol/L error in pNa by indirect ISE. These levels should prompt direct ISE pNa measurement before an individualized dialysate Na is prescribed.



TH-PO784

Assessment of Intradialytic Calcium Balance Based on a Single Pool Variable-Volume Calcium Kinetic Model

Salvatore Di Filippo,[1] Vincenzo La Milia,[1] Fabio Carfagna,[1] Leano Violo,[1] Giustina Casagrande,[2] Camilla Bianchi,[2] Maria Laura L. Costantino,[2] Giuseppe Pontoriero,[1] Francesco Locatelli.[1] *[1]Nephrology and Dialysis, A. Manzoni Hospital, Lecco, Italy; [2]Chemistry, Material, and Chemical Engineering, Politecnico di Milano, Milano, Italy.*

Background: Low dialysate calcium may cause hyperparathyroidism and acute arrhythmias whereas high dialysate calcium may cause soft tissue calcification. We describe the results of a single-pool kinetic model for the quantitative assessment and of intradialytic calcium balance.

Methods: Twenty-one patients on chronic bicarbonate high-flux HD and a total of 97 dialysis sessions performed using a nominal total calcium concentration in the dialysate of 1.5 mM/L were examined. The calcium distribution volume (V_{Ca}) was estimated 1/3 of urea distribution volume; ionized calcium concentration in the dialysate (Cd_{Ca}) and in plasma water (Cp_{Ca}) were measured using direct ionometry; calcium dialysance (D_{Ca}) was estimated from conductivity dialysance; the Donnan factor (α) was rated as equal to 0.938. The accuracy of the model was evaluated by comparing the end-dialysis ionized plasma water calcium concentration predicted by the model, $Cp_{Ca}(t)P$ and the measured values normalized to pH 7.40, $nCp_{Ca}(t)M$. Predicted values were calculated according to the equation: $Cp_{Ca}(t)P=1/\alpha\bullet[Cd_{Ca}-(Cd_{Ca}-\alpha\bullet Cp_{Ca}(0)\bullet(V_{Ca}(t)/V_{Ca}(0))^{DCa\bullet\alpha\bullet(1/QF-1/Qpi)}]$.

Results: Mean $V_{Ca}(0)$ and $V_{Ca}(t)$ were respectively 13.6 ± 2.2 L and 10.9 ± 2.2 L; Cd_{Ca} and $Cp_{Ca}(0)$ were 1.27 ± 0.03 and 1.19 ± 0.06 mM/L; D_{Ca} was 0.156 ± 0.023 L/min; mean plasma water flow (Qpi) was 0.179 ± 0.015 L/min and mean ultrafiltration flow (Qf) was 0.009 ± 0.003 L/min.

	Predicted	Measured	Difference	p value
$nCp_{Ca}(t)$ (mM/L)	1.34 ± 0.04	1.33 ± 0.04	0.00 ± 0.04	NS
Balance (mM/session)	-1.17 ± 1.44	-1.20 ± 1.44	0.03 ± 0.21	NS

Mean calcium balance resulted negative and was not statistically different from the balance calculated using the predicted value. Finally PTH reduction was not statistically significant.

Conclusions: Our calcium kinetic model allows an accurate prediction of calcium exchange during hemodialysis and can be used to select the dialysate calcium concentration necessary to obtain the desired calcium balance.

The Association between Incidence of Cardiovascular Events, Hip Fractures, and Dialysate Calcium Concentration, Stratified by Pre-Dialysis Serum Calcium Concentration in Japanese Hemodialysis Patients

Shinichi Sueta,[1] Miho Tagawa,[2] Takayuki Hamano,[3] Seiji Hashimoto,[3] Satoshi Ogata.[3] *[1]Kidney, Japanese Red Cross Nagoya Daini Hospital, Hospital, Nagoya City, Aichi, Japan; [2]Neohrology Kyoto Katsura, Hospital, Kyoto City, Japan; [3]Comittee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan.*

Background: Previous studies showed that hypercalcemia and higher dialysate Ca concentration were associated with increased mortality. Whether the associations between cardiovascular events, hip fractures and dialysate Ca concentration differ depending on predialysis serum Ca concentration has not been studied.

Methods: This was a longitudinal study based on the Japan Renal Data Registry (JRDR) from 2008 to 2009. Data were divided into three groups by tertiles of predialysis albumin corrected Ca (corrected Ca8.9mg/dl, 9.0-9.5, and 9.6mg/dl). Predictor variable was dialysate Ca concentration (dialysate Ca 2.5 mEq/L versus 3.0 mEq/L). Outcome variables were incidence of myocardial infarction (MI), cerebral hemorrhage (CH), cerebral infarction (CI), amputation, and hip fracture during 1 year observation period. Statistical analyses were performed using multivariable logistic regression model, adjusted for potential confounders.

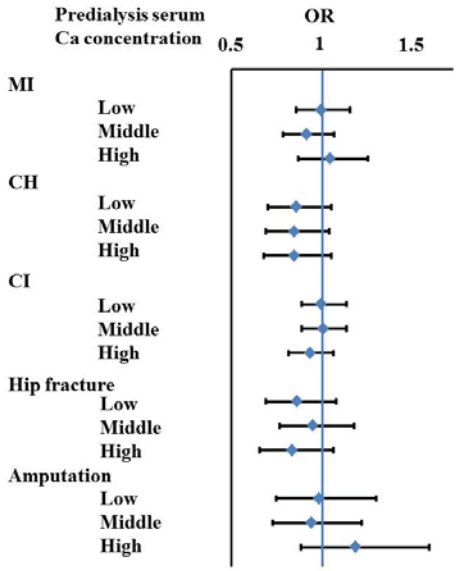

Figure. Odds (95% CI) of incident events for higher dialysate Ca users compared with lower dialysate Ca users

Results: There were data on 263,225 patients on JRDR database. After excluding patients with missing data, data for 76,820 patients were available for analysis.

Conclusions: There were no significant associations between dialysate Ca concentration and cardiovascular events and hip fracture in all tertiles of pre-dialysis serum Ca concentration. Adjusting dialysate Ca concentration depending on serum Ca concentration might not affect clinical outcomes.

TH-PO786

Conversion From Parenteral Paricalcitol to Oral Calcitriol for the Management of Hyperparathyroidism in Hemodialysis

Jennifer Kumar, Ngoc Gia Tran, John Paul Schomberg, Elani Streja, Kamyar Kalantar-Zadeh, Madeleine V. Pahl. *Nephrology, Univ Calif, Irvine, Irvine, CA.*

Background: The management of hyperparathyroidism in hemodialysis (HD) patients involves the administration of phosphate binders, vitamin D analogs and calcimimetics. IV paricalcitol has been preferred over oral calcitriol as it may cause less hypercalcemia and hyperphosphatemia. However, there is little data looking at the efficacy and tolerability of oral calcitriol in the calcimimetic era particularly in a real practice-based experience. Our free-standing Dialysis Center converted from routine IV paricalcitol to oral calcitriol because of pharmacy purchasing preferences. We report the feasibility, efficacy, safety and cost of such a change.

Methods: Of the 139 ESRD HD patients (age 54±16 yrs, 53% female, 57% DM) on dialysis, 83 were receiving IV paricalcitol. All were converted to in-center, oral calcitriol (0.25 mcg =1 mcg paricalcitol) 3 times a week. Additional dose adjustments were made by the nephrologists based on clinical indications. We compared data 5 months pre and post conversion.

Results: At the end of the 5 month observation period 69 of those converted were still on oral agent and 25 new patients had initiated calcitriol such that 94 patients were on oral therapy. Laboratory values 5 months before and after conversion reported as mean±SD and as % within KDOQI guidelines are shown in Table 1. No adverse events were reported with use of oral calcitriol. Estimated vitamin D cost savings were $564 per person/year. Cinacalcet use rose from 47 patients pre- to 57 post-conversion. Sevelamer use dropped from 98 patients pre- to 68 post, while calcium acetate use rose from 57 patients pre- to 73 post conversion. No change in the incidence of cardiovascular events was observed.

Table 1.	Calcium mg/dl	Phosphorous mg/dl	iPTH pg/ml
IV paricalcitol	8.9±1.4	5.2±1.6	423.1±374.2
% within KDOQI guidelines	85	52	58
PO calcitriol	8.9±1.5	5.15±1.76	434.5±508.6
% within KDOQI guidelines	88	51	64

Conclusions: We conclude that in-center distributed pulse oral calcitriol is an effective, safe and economical treatment option for the management of hyperparathyroidism in HD patients.

TH-PO787

Intradialytic Calcium Kinetic Reveals High Calcium Burden with Standard Dialysate Calcium Concentrations in Chronic Hemodialysis Patients

Markus Pirklbauer, Gert J. Mayer. *Internal Medicine IV, Medical Univ Innsbruck, Innsbruck, Tirol, Austria.*

Background: Currently most hemodialysis (HD) patients are treated with a dialysate calcium concentration (dCa) of 1.25 mmol/l. In this setting, intradialytic calcium mass balance (Ca_{MB}) is expected to be close to neutral. However, this assumption is based on the stability of serum calcium (Ca) levels. We evaluated intradialytic Ca_{MB} in chronic HD patients to account for possible Ca storage in acutely accessible buffers.

Methods: Dialysate-sided Ca_{MB} was measured during 2 HD sessions in chronic HD patients (10 patients using 1,25 mmol/l dCa and 28 patients using 1,75 mmol/l dCa). Change in extracellular fluid Ca (ΔCa_{ECF}) and $\Delta Ca_{ECF}/Ca_{MB}$ (reflecting Ca buffer capacity) were calculated. Measurements were based on ionized Ca concentrations.

Results: Prescribed dCa values significantly differed from measured precapillary dCa (1,09 ± 0,04 and 1,45 ± 0,05 versus 1,25 and 1,75 dCa, respectively), the difference being mostly explained by a linear influence of HCO3 levels on dCa. Consequently, individual pre- to postcapillary HCO3 decline (leading to a diffusion-independent postcapillary dCa increase) was considered for dialysate-sided Ca_{MB} calculations: Ca_{MB} was invariably positive for both 1,25 and 1,75 dCa, with a median of 465 and 721 mg/HD, respectively. At both dCa used, Ca_{MB} showed interindividual differences, which were highest in the first 30min of HD and determined by the dialysate to blood Ca gradient. Ca_{MB} - ΔCa_{ECF} was consistently positive with a median of 425 mg at 1,25 dCa and 539 mg at 1,75 dCa. Acute Ca buffer capacity was 97% and 80% (median at 1,25 and 1,75 dCa). Using 1,75 dCa, Ca_{MB} significantly correlated with ΔCa_{ECF} (r=0,69, p<0,01) and predialysis Ca gradient (r=0,59, p<0,01) but not with Ca buffer capacity. Multivariate regression analysis showed significant association of Ca_{MB} with LDL levels (β= 0,497, p<0,003) and male sex (β= 0,382, p<0,017) and of Ca buffer capacity (at 30 min) with LDL levels (β= -0,544, p<0,000).

Conclusions: Our studies of intradialytic Ca kinetic reveal high Ca burden with standard dCa. Our results also provide strong evidence for the existence of a rapidly accessible Ca storage pool that counteracts acute Ca deviations.

TH-PO788

Two-Pool Model for Phosphorus Removal During Hemodialysis Using an Intercompartmental Clearance That Rises Exponentially as Serum Phosphorus Falls

John T. Daugirdas. *Univ of IL at Chicago.*

Background: Previous studies have suggested that a conventional 2-pool model cannot be used to predict intradialytic and postdialysis phosphorus (P) concentrations.

Methods: A conventional 2-pool urea model was modified by increasing distal compartment volume from 0.67 to 2-3 times the total body water and by using a exponentially increasing intercompartmental P clearance that ranged from 90 to 2000 ml/min as the serum phosphorus level ranged from greater than 6.0 down to below 1.5 mg/dl. Daily absorbed P amount was estimated as a multiple of protein nitrogen appearance rate minus an adjusted phosphorus-binder equivalent dose. After calculating a weekly serum P profile, the absorbed amount was iteratively adjusted until predicted predialysis serum P level matched the measured value. Predicted intradialytic postdialysis, and early (30 min) postdialysis serum P values then were compared to measured values in 450 patients who had such measurements made in the HEMO Study.

Results: The model predicted median measured P levels at various time points well, at both the highest and lowest deciles of predialysis serum P. Prediction accuracy was not affected by alkaline phosphatase or serum PTH levels but was slightly affected by sex and body size. The model predicted higher predialysis serum P levels on Monday versus Wednesday versus Friday. In further, non-HEMO, simulations the model predicted hypophosphatemia with intensive frequent dialysis, and predicted observed changes in

predialysis serum P after applying different schedules of dialysis; however in non-HEMO data, the model underestimated intradialytic P values late in dialysis with session lengths longer than 5 hrs and was unable to model a subset of patients in whom serum P decreased very little during a hemodialysis treatment, including many patients on long nocturnal dialysis.

Conclusions: A modified 2-pool diffusion-based model using an expanded distal compartment and a serum P-dependent intercompartmental P clearance, while far from perfect, can be used to predict serum P level during and shortly after conventional dialysis and might be useful to predict the impact of changes in diet, binder dose, or dialysis schedule on predialysis serum P.

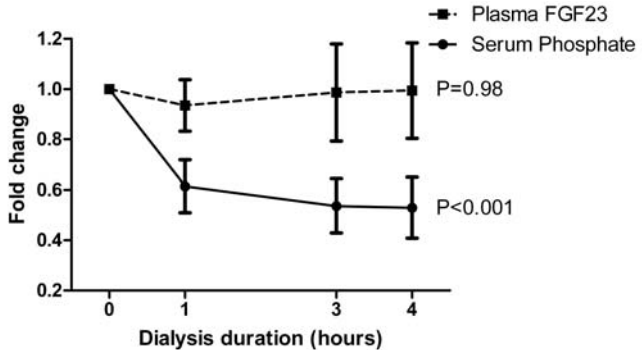
TH-PO789

Discordant Courses of Plasma Fibroblast Growth Factor 23 and Serum Phosphate During Hemodialysis Jelmer K. Humalda,[1] Ineke J. Riphagen,[1] Solmaz Assa,[1] Marc G. Vervloet,[2] Gerjan Navis,[1] Casper F.M. Franssen,[1] Martin H. De Borst.[1] *[1]Nephrology, Univ Medical Center Groningen, Netherlands; [2]Nephrology, VU Medical Center, Amsterdam, for NiGrAm.*

Background: A high fibroblast growth factor 23 (FGF23) level is a risk factor for mortality in hemodialysis (HD) patients. Phosphate binders require days to lower FGF23 levels, however the effect of acute phosphate reduction in HD on FGF23 is unknown. We aimed to assess intradialytic changes in FGF23 in relation to phosphate levels.

Methods: Plasma C-terminal FGF23 levels were determined by ELISA at 0, 1, 3, and 4 hrs after onset of a standardized low-flux HD session in 109 HD patients. We corrected plasma FGF23 for hemoconcentration (Schneditz, ASAIO Journal, 2012). The intradialytic courses of FGF23 and serum phosphate were analyzed with linear mixed models, and correlations between FGF23 and phosphate changes with Pearson's test. In a subgroup (n=10), FGF23 was measured in samples before and after the dialyzer and in the dialysate.

Results: Median age was 66 [IQR 51-75] yrs, dialysis vintage 25.4 [8.5-52.5] mo, Kt/V 4.31±0.71, 65% was male. FGF23 did not change during dialysis (Figure; t=0h: 7627 [3300-13514] RU/mL; t=4h: 7503 [3109-14433] RU/mL; P=0.98). Conversely, serum phosphate decreased from 5.14 [4.06-6.02] mg/dL to 2.60 [2.21-3.10] mg/dL, respectively (P<0.001). Changes in FGF23 and phosphate did not correlate at any timepoint. We could not detect FGF23 in the dialysate (<85 RU/mL), and FGF23 levels were similar before (3472 [2657-9626] RU/mL) and after (3564 [2725-10346] RU/mL) the dialyzer.



Conclusions: The discordant courses of phosphate and FGF23 during HD are in line with insights pointing to additional triggers that up-regulate FGF23 in advanced CKD. The absent effect of HD on FGF23 may partly explain the extremely high FGF23 levels in HD patients. Whether intensified or high-flux HD may lower FGF23 should be addressed in future studies.

Impact on Serum Magnesium Normalization and Blood Pressure By Different Dialysate Magnesium Concentrations in Hemodialysis Patients Li Wang, Daqing Hong. *Renal Dept, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Magnesium ion plays an important role in maintenance dialysis patients. Abnormal magnesium ion concentration during hemodialysis is associated with fluctuations in blood pressure, weakness, arrhythmia and other complications. The objective of this study was to compare the effect on serum magnesium normalization and blood pressure by using dialysates of 0.5mmol/L and 1.0mmol/L of magnesium ion concentrations.

Methods: 168 maintenance hemodialysis patients were enrolled and randomized to group A (dialysate with 0.5 mmol/L magnesium concentration) or group B(dialysate with 1.0 mmol/L magnesium concentration). Serum concentration of magnesium and blood pressure was measured before and after dialysis. The rate of magnesium normalization and blood pressure was compared between two groups.

Results: The concentrations of serum magnesium were abnormal in 72 patients, and were normal in 10 patients before hemodialysis in group A. After hemodialysis, they were abnormal in 7 patients and normal in 75 patients. The concentrations of serum magnesium were abnormal in 56 patients, and were normal in 27 patients before hemodialysis in group B. After hemodialysis, they were abnormal in 79 patients and normal in 4 patients. Serum magnesium concentrations were significantly lower in group A compared to group B (0.9 ± 0.2mmol/L *versus* 1.4 ± 0.2mmol/L; *P*<0.05). Serum magnesium normalization rate after dialysis was higher in group A (91.4%) than that in group B (4.8%), (*P*<0.01). There was no significant difference in blood pressure before and after dialysis between two groups. 1 case of hypotension occured during hemodialysis in each group.

Conclusions: Hemodialysis with dialysate of 0.5mmol/L magnesium ion concentration is associated with lower serum magnesium concentrations and higher serum magnesium concentration normalization rate, compared to hemodialysis with dialysate of 1.0 mmol/L magnesium ion concentration. There is no obvious adverse effect between two dialysate groups. These findings require longer follow up and confirmation in further study.

TH-PO791

Microcirculatory Changes Observed on Hemodialysis Using Novel Incident Darkfield Imaging Hui Xue,[1] Marcela Zhou Huang,[1] Anderson Paz,[2] Frank Messie,[3] Can Ince,[4] Ravindra L. Mehta.[1] *[1]Nephrology and Hypertension, Univ of California San Diego, CA; [2]Univ Federal do Amazonas, Brazil; [3]Braedius Medical V; [4]Dept of Intensive Care, Erasmus MC Univ Hospital Rotterdam, Netherlands.*

Background: Rapid fluid removal during hemodialysis (HD) has been shown to be associated with a greater risk of all-cause and cardiovascular death. Blood pressure (BP) and symptoms are used to guide fluid removal to dry weight, but may be insensitive to changes in the microcirculation. We hypothesized that fluid removal during HD would be associated with changes in the microcirculation measured sublingually.

Methods: Patients undergoing chronic HD at an academic medical center were evaluated for changes in their sublingual microcirculation using a novel hand-held image-sensor, CytoCam, based on IDF(incident darkfield imaging). Measurements were performed at the start, mid-point, and at the end of HD. At each time, microscopy videos of capillary (diameter <25µm) flow were recorded from at least three locations in sitting and in Trendelenburg(Trend) position with results averaged. Sublingual microcirculatory function was evaluated as Functional Capillary Density(FCD), the total number of functional capillaries (eg capillaries with flow) per unit field of view. The difference in capillaries FCD at the start, mid, and end of HD was compared in the sitting versus Trend (delta FCD= FCD Trend-FCD Sit). BP, heart rate, and volume removed were recorded at each time point and fluid removal rates were correlated with FCD.

Results: 12 HD sessions in 7 patients were recorded. Mean FCD Sit at start, mid point and end of HD were 1.629, 1.580, and 1.619 mm vessels/mm2 respectively. Delta FCD was greater for start to mid-point (0.06031mm vessels/mm2 (95% CI, 0.0083, 0.1124), than from mid-point to end of HD (-0.05813 mm vessels/mm2 (95% CI, -0.1102, -0.0061; P =<0.01). Fluid removal rates correlated with Delta FCD by Delta FCD=-0.04+6.075*L removed/kg/hr (R2=0.258, p<0.01).

Conclusions: Fluid removal during HD is associated with changes in microcirculation and could be utilized to monitor tissue perfusion during HD. Future studies will develop this technique further to guide fluid management in HD.

TH-PO792

Myocardial Ischemia and Sympathetic Innervation Abnormalities Coincide during Renal Replacement Therapy Akin Ozyilmaz,[1,4] Walter Noordzij,[2] Esther Goet,[1,4] Casper F.M. Franssen,[1] Rene A. Tio,[3] Riemer Hja Slart.[2] *[1]Dept of Nephrology, Univ Medical Center Groningen, Groningen, Netherlands; [2]Dept of Nuclear Medicine and Molecular Imaging, Univ Medical Center Groningen, Groningen, Netherlands; [3]Dept of Cardiology, Univ Medical Center Groningen, Groningen, Netherlands; [4]Dialysis Center Groningen, Groningen, Netherlands.*

Background: Patients with chronic kidney disease (CKD) undergoing hemodialysis (HD) show altered sympathetic tone, increased norepinephrine levels and decreased global myocardial perfusion, which are related to higher cardiovascular mortality. Impaired cardiac sympathetic innervation recovers after renal transplantation. However, the effect of transition from pre-dialysis to HD has not been investigated before.

Methods: Patients with CKD were included in this prospective study between January 2008 and December 2013. All patients underwent technetium-99m labelled tetrofosmin and iodine-123 labelled meta-iodobenzylguanidine (^{123}I-MIBG) scintigraphy prior to (baseline) and six months after the start of HD (follow-up). Early (15 min) and late (4 hrs) heart-to-mediastinum ratio (HMR) and wash-out rate were determined after administration of ^{123}I-MIBG. Results of ^{123}I-MIBG scans were compared to healthy control (HC) subjects.

Results: 17 patients and 9 HC subjects, mean age 58±18 and 52±17 years (ns) respectively, were included. Between baseline and follow-up, two patients developed myocardial ischemia, and two other patients developed myocardial infarction from ischemia at baseline. Late HMR did not differ between baseline and follow-up. There was also no difference between patients and HC. However, wash-out rate was lower in HC than in patients at follow-up (median 1.0 (range -22-12) versus 3.0 (-2-41), p = 0.018). At follow-up, four patients showed sympathetic denervation. Two patients already had denervation at baseline, of which one developed myocardial ischemia, whereas in the other patient ischemia did not change. Of two other patients one developed infarction out of pre-existing ischemia, whereas the last patient did not show perfusion defects.

Conclusions: Shortly after the start of HD cardiac sympathetic denervation seems to occur with coexisting perfusion abnormalities.

TH-PO793

Angiopoietin-2 Associates with Markers of Inflammation, Fluid Overload, and Cardiac Damage in Dialysis Patients and Predicts Cardiovascular Events Welmoet H. Westendorp,[1] Solmaz Assa,[2] Harry Van Goor,[3] Ralf Westerhuis,[2] Casper F.M. Franssen,[2] Henri G.D. Leuvenink.[1] *[1]Surgery, Groningen Transplant Center, Univ Medical Center Groningen, Groningen, Netherlands; [2]Nephrology, Univ Medical Center Groningen, Groningen, Netherlands; [3]Pathology, Univ Medical Center Groningen, Groningen, Netherlands.*

Background: Ang2 plays an important role in vascular stability, permeability and inflammatory balance through binding to Tie2. Its pro-inflammatory role is shown in chronic kidney disease and cardiovascular disease. We investigated the effect of dialysis on Ang2 levels and studied its potential predictive value.

Methods: In 100 HD patients with a mean age (±SD) of 63±16 and median (IQR) dialysis vintage of 1.8 (0.7-4) years, plasma Ang2 levels were measured pre-HD, at 60 and 180 min intra-HD and post-HD (240 min), next to markers of inflammation, endothelial function, and cardiac damage. Associations with log-transformed Ang2 were tested with multivariate analyses. Follow-up for all-cause mortality and cardiovascular events was 2 years.

Results: Ang2 levels increased significantly during HD and peaked at 60 min intra-HD (pre-HD: 3331±2380; 60 min intra-HD: 4362±3635 pg/ml; $p<0.05$) and subsequently decreased to 3447±2557 at 180 min intra-HD and 3060±2291 pg/ml post-HD. Pre-HD Ang2 was significantly associated with pre-HD levels of pentraxin-3, IL-6, pro-endothelin, NT-pro-BNP, and cardiac troponin T ($p<0.05$).Pre-HD Ang-2 levels were associated with a higher incidence of cardiovascular events after correction for age, sex, diabetes, and dialysis vintage (HR 2.1; CI 1.2-3.6; p=0.007).

Conclusions: Ang2 levels associate with markers of inflammation, fluid overload, and cardiac damage and higher levels are associated with worse outcome. Together these findings suggest that Ang2 levels are a marker of endothelial dysfunction that contributes to the dismal prognosis of dialysis patients.

TH-PO794

Does Hemodialysis Create the Potential for a Perfect Storm? A. Harford,[1,2] Philip Zager,[1,2] S. Paine.[2] *[1]UNM, Albuquerque, NM; [2]DCI, Nashville, TN.*

Background: There is increasing awareness of the preventable complication of sudden death occurring during or shortly after hemodialysis (HD). Allan Collins, past Director of the USRDS, has suggested that dialysis may create the "perfect storm".

Methods: To explore the hypothesis that HD may lead to life threatening electrolyte abnormalities we measured serum sodium (Na), potassium (K), magnesium (Mg) and bicarbonate (CO_2) during the last 10 minutes of the procedure or immediately post-dialysis. The blood samples were drawn prior to equilibration since this may be the period of highest risk. The study was done in 340 patients treated at five facilities operated by DCI in Albuquerque, Stony Brook and Syracuse. All values are expressed as mEq/L.

Results: Although the mean values of Na (138.7), K (3.3), Mg (1.5) and CO_2 (25.5) were not unexpected some results were disturbing. The distributions of the postdialysis values are shown.

Distribution of Postdialysis Lab Values							
Percentile	**Na**	**K all**	**K_1**	**K_2**	**K_3**	**Mg**	**CO_2**
1st	131	2.4	2.0	2.6	3.0	1.2	20
5th	133	2.7	2.2	2.8	3.2	1.2	21
10th	134	2.9	2.2	2.9	3.3	1.2	22
25th	136	3.1	2.5	3.1	3.5	1.3	24
50th	139	3.3	2.8	3.2	3.6	1.5	25
75th	141	3.6	3.3	3.5	3.9	1.7	27
90th	142	3.9	3.5	3.8	4.1	1.8	29
95th	144	4.1	3.5	3.9	4.2	1.8	30
99th	145	4.4	3.9	4.3	4.5	1.9	32
K all: All K baths. K_1, K_2, K_3 refer to K baths of 1, 2, 3 mEq/L.							

Median values for each variable, except K (3.3) were within normal range. The 25th percentiles for K (3.1) and Mg (1.3) were significantly below the normal range. The 90th percentile for CO_2 (29) was elevated. The mean predialysis K was 5.1, 5.0, and 4.6 among patients dialyzed on 1.0, 2.0, and 3.0 K dialysate, respectively. The mean postdialysis K was 2.9. 3.3, and 3.7 among patients dialyzed on 1.0, 2.0, and 3.0 K dialysate, respectively. The median postdialysis serum K, stratified by dialysate K, was 2.8, 3.2, and 3.6 among patients dialyzed on 1.0, 2.0, and 3.0 K dialysate, respectively. Among patients dialyzed with ordered CO_2 36-37 and 38-40, 25% and 50%, respectively, had a postdialysis $CO_2 \geq 28$. A combination of postdialysis $K < 3.5$ and $CO_2 > 27$ was present in 43 patients (12.8%).

Conclusions: The use of a dialysate with a low K and high CO_2 has the potential to develop into a "Perfect Storm".

TH-PO795

High Convection Volumes in On-Line Hemodiafiltration - Do We Know What We Prescribe? Angel Argiles,[1,2] Nathalie Gayrard,[1] Flore Duranton,[1] Caroline Guzman,[1] Ilan Szwarc,[2] Philippe Brunet,[3] Alain Ficheux.[1] *[1]RD - Néphrologie and EA7288, Univ Montpellier 1; [2]Néphrologie Dialyse St. Guilhem, Sète; [3]Hôpital de la Conception, Univ Aix-Marseille.*

Background: Although rarely used in U.S.A., on-line hemodiafiltration with high convective volumes could improve survival. However, there is scant information on the feasibility and immediate consequences of prescribing high convection volumes.

Methods: Twelve dialysis patients were sequentially treated with different dialyzers (Xevonta 1.8 and 2.3m²) and convection settings: hemodialysis (HD), maximal global ultrafiltration coefficient of the dialysis setting ($_GK_{D\text{-}UF}$-MAX), 40% UNDER and 40% OVER $_GK_{D\text{-}UF}$-MAX. Dialysis feasibility and efficacy were assessed in terms of TMP, convection volumes, and middle molecule removal.

Results: With 1.8 m² dialyzers, obtained convection volumes were 3.1L in HD (weight loss) and 12.9, 20.6 and 24.5L with UNDER, $_GK_{D\text{-}UF}$-MAX and OVER conditions respectively. Mean TMP significantly increased with prescribed convection (from 79 in HD to 242mmHg in OVER). TMP alarms occurred in 9 and 83% of $_GK_{D\text{-}UF}$-MAX and OVER sessions, leading to infusion reduction and fewer convection volume achievements (94 and only 33% of sessions, respectively). Using a larger dialyzer reduced TMP and TMP alarms and enhanced achievement of prescribed convection volume. Convection increased high mol wt-compound removal, particularly with the larger surface (figure 1).

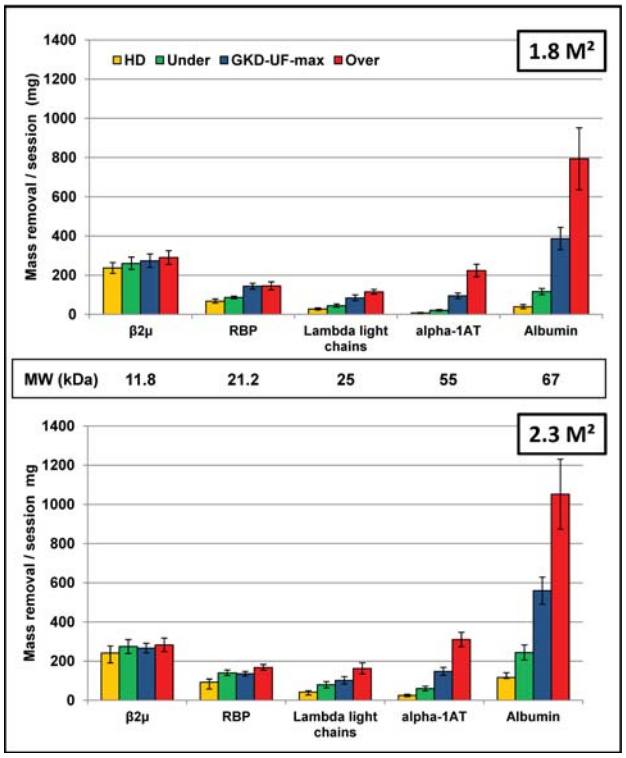

Figure 1: Dialysate removal of 5 middle molecules with different convection settings.

Conclusions: Maximal convection in OL-HDF increases TMP instability, prevents from achieving the prescription and increases albumin leakage. Larger surface improved system stability and reduced alarms but increased albumin loss. Setting the Quf at $_GK_{D\text{-}UF}$-MAX resulted in high convection volumes, with little risk of alarms, deviation from prescribed convection or albumin loss.

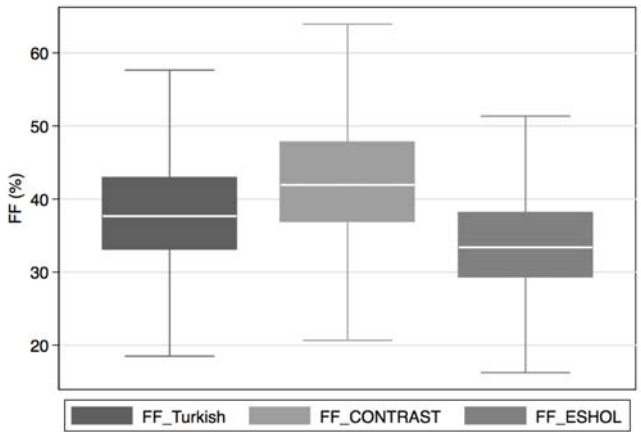
TH-PO796

What Proportion of Patients in the Australia and New Zealand Dialysis and Transplant Registry (ANZDATA) Can Practically Achieve High-Volume Hemodiafiltration (hvHDF)? Mark R. Marshall,[1] Kevan Polkinghorne,[2] Stephen P. McDonald.[3] *[1]Faculty of Medicine and Health Sciences, Univ of Auckland, Auckland, AKL, New Zealand; [2]Dept of Nephrology, Monash Medical Centre, Clayton, VIC, Australia; [3]Australia and New Zealand Dialysis and Transplant Registry, The Royal Adelaide Hospital, Adelaide, SA, Australia.*

Background: hvHDF may have mortality benefits compared to conventional thrice-weekly HD. hvHDF is defined by outcomes in various studies - in the Turkish HDF study, it is defined by a filtration volume (FV) ≥20 L/treatment (Rx) in post-dilution mode, in CONTRAST ≥22 L/Rx, and in ESHOL ≥18 L/Rx. To minimize the procoagulant effects of hemoconcentration, it is generally recommended to keep the filtration fraction (FF, the ratio of ultrafiltrate flow (QF) to filter plasma water flow rate (QP), both mL/min) to <30% during post-dilution hvHDF. This may limit achievable FV per Rx, and ability to achieve hvHDF.

Methods: We examined all patients ≥40kg in ANZDATA receiving conventional HD (thrice-weekly, <=6 hours/Rx) as of 31st Dec 2011. We calculated the FF for each patient had they been receiving hvHDF with targets for FV specified by the above studies, under the assumption of routine ultrafiltration of 3% of their dry weight to achieve target. FF(%) = (QF×100)/QP, where QP = QB×(1-hct)×0.93, where QB is blood flow rate and hct hematocrit.

Results: n=10,250. Median (IQR) QB was 300 mL/min (300-330), weight was 74 kg (63-88), duration/Rx was 4.5 hours (4-5), hct was 0.34 (.37-.40). 76% had AVFs, 7% AVGs, and the rest CVLs. FF by study target is shown below



Conclusions: Using the Turkish target, 12% of patients were able to achieve post-dilution hvHDF using their current operating parameters, with CONTRAST 4%, and with ESHOL 28%. Increasing the FF partition value to 40% increases these proportions, but may not be clinically workable. In everyday practice, hvHDF is likely to be unachievable for many patients.

TH-PO797

Energetic Expenditure during Hemodiafiltration with and without Exercise

Ana C. Duarte-Molina, Bertha Alicia Diaz-Sanchez, Miguel Angel Cadena-Mendez, Magdalena Madero, Hector Alejandro Perez-Grovas. *Inst Nacional de Cardiologia.*

Background: Dialysis patients are at risk for malnutrition and this is a major risk factor for mortality. Higher resting energy expenditure in dialysis has been associated with adverse outcomes. To our knowledge the caloric expenditure (CE) during hemodiafiltration (HDF) and the impact of exercise in CE has not been described. Our aim was to determine by indirect calorimetry the CE and the carbon/oxygen quotient to determine substrates consumed before dialysis and during HDF with and without exercise.

Methods: Twenty four determinations were performed on 6 individuals on chronic HDF. At their arrival to their HDF unit a baseline calorimetry was performed. Subjects where then prescribed a 3 hour HDF session and 90 minutes into the treatment another calorimetry was performed. This process was repeated in 4 different HDF sessions for each patient, 2 of them without exercise and 2 with aerobic exercise (stationary bicycle). Energetic expenditure (EE) and carbon/oxygen quotient were determined with calorimeter MGH3 (UAM-INCICh).

Results: The mean age of the population was 29±8, 50 % were male and none of the subjects were diabetic. EE during HDF was 1600±301 Kcal before dialysis, 1752±280 Kcal (*P*= 0.02) for HDF without exercise and 1784±360 Kcal (*P*=0.002) for HDF with exercise. No significant difference was found between EE with or without exercise (*P*=0.29). Substrates consumed during the 3 phases are shown in table.

	Carbohydrate(%)	Fat(%)	Protein(%)	*P* value
Before Dialysis	26±16	53±17	21±4	
HDF without exercise	42±7	39±7	19±3	<0.001
HDF with exercise	48±16	34±15	18±3	<0.001

No significant difference was found between substrates consumed during HDF with or without exercise (P=0.45). CE was 214 ± 44 Kcal and 213 ± 39 Kcal (P=0.95) for HDF without and with exercise, respectively.

Conclusions: HDF produces a raise in CE and carbohydrate consumption that does not appear to be modified by exercise. This may be explained by a physiologic stress response in increase CE caused by HDF. Our data reflects that HDF patients have high CE and this may explain in part the risk for protein malnutrition syndrome.

TH-PO798

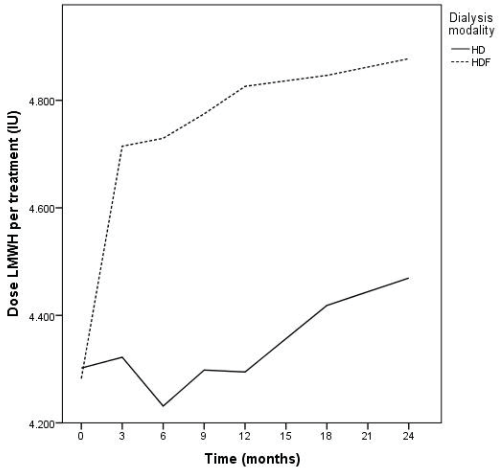
The Prescribed Dose of Anticoagulation Increases After Assigning Patients to Hemodiafiltration (HDF) Treatment

Camiel L.M. de Roij van Zuijdewijn,[1] Menso Jan Nubé,[1,2] Peter J. Blankestijn,[3] Pieter M. Ter Wee,[1,2] Michiel Bots,[4] Muriel P. Grooteman.[1,2] *[1]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Inst for Cardiovascular Research, VU Univ Medical Center, Amsterdam, Netherlands; [3]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [4]Julius Center for Health Sciences and Primary Care, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: to prevent coagulation in the dialyzer during hemodialysis (HD), anticoagulation - in Europe most often low molecular weight heparin (LMWH) - is administered. Both the intradialyzer hemoconcentration and trans membrane pressure are higher during HDF compared to HD. Therefore, we investigated if the prescribed dose of LMWH differs between HD and HDF patients.

Methods: a cohort study was performed using data from the CONvective TRAnsport STudy (CONTRAST, NCT 00205556), a RCT evaluating the survival effect of HDF compared to HD (mean follow-up 3.04 years). At baseline (M0) and at 3 (M3), 6, 9, 12, 18, 24 months, LMWH type, dose and frequency were registered and standardized to number of anti Xa international units (IU) per treatment. The LMWH dose over time was analyzed with linear mixed models.

Results: patients were assigned to HD (n=356) or HDF (n=358). Baseline characteristics did not differ between groups. Baseline LMWH dose was 4288 IU for patients randomized to HDF and 4279 IU for HD patients. Mean LMWH dose was 4300 IU for HD and 4699 IU for HDF at M3. The slope from M0 to M3 differed significantly between the groups (*p* interaction 0.002). From M3 onwards, LMWH dose increased over time in both groups, but the slope was not different (*p* interaction 0.123).



Conclusions: At M3, the prescribed dose of LMWH was ±10% higher in HDF patients compared to HD. Thereafter, the LMWH dose increased in both groups with a similar slope. Whether these findings are clinically relevant remains to be determined.

TH-PO799

Change in Convection Volume Over Time in Online Post-Dilution Hemodiafiltration Patients. Results From the CONvective TRAnsport STudy (CONTRAST)

Irina Mostovaya,[1] Camiel L.M. de Roij van Zuijdewijn,[2] Peter J. Blankestijn,[1] Michiel Bots,[3] Isabelle Chapdelaine,[4] Renee Levesque,[5] Pieter M. Ter Wee,[2,6] Menso Jan Nubé,[2,6] Muriel P. Grooteman.[2,6] *[1]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [3]Julius Center for Health Sciences and Primary Care, Univ Medical Center Utrecht, Utrecht, Netherlands; [4]Nephrology, Hopital de Sacré-Coeur de Montréal, Montréal, QC, Canada; [5]Nephrology, Centre Hospitalier de l'Univ de Montréal, Montréal, QC, Canada; [6]Inst for Cardiovascular Reserach, VU Univ Medical Center, Amsterdam, Netherlands.*

Background: Recent RCTs showed a relation between a high convection volume (CV) and a low mortality risk. It is unclear whether an individuals CV remains stable over time. If so, that would argue in factor of hospital characteristics as the main drivers for the level of received CV, since patient characteristics do tend to change over time. Therefore, this study examines the rate of change of CV in patients undergoing online post-dilution hemodiafiltration (HDF).

Methods: Data from 339 HDF patients from CONTRAST (NCT 00205556) were used for the present analysis. CV was measured every 3 months up to 6 years. The rate of change over time in CV and its components were estimated using linear mixed effects models.

Results: At baseline, mean age was 64±14.9 years and 56% were male. Baseline CV was 19.8±4.6 L/treatment. CV increased significantly over time by 0.34 L/treatment/year (95%CI 0.14-0.54, *p*=0.001). Intradialytic weight change remained stable over time (Δ=0.01L/treatment/year, *p*=0.83), while the amount of substitution volume increased

(Δ=0.33L/treatment/year, 95%CI 0.13-0.53, p=0.001). Rate of change of CV did not differ in subgroups of age, gender, body surface area and medical history. Large differences were observed in change of CV between treatment facilities.

Conclusions: Achieved CV tends to increase over time, although this may not be clinically relevant. As patient characteristics were not related to rate of change and large differences in rate of change exist between dialysis centers, this supports the hypothesis that mainly treatment characteristics determine the volume of convection.

TH-PO800

Modified Ionic Strength Hemodiafiltration, a Novel Dialysis Technique for Increased Protein Bound Toxin Removal Detlef H. Krieter,[1] Thomas Koerner,[1] Eric Devine,[2] Marieke Rueth,[2] Joachim Jankowski,[3] Christoph Wanner,[1] Horst-Dieter Lemke.[2] *[1]Nephrology, Univ Hospital, Würzburg, Germany; [2]EXcorLab GmbH, Obernburg, Germany; [3]Medicine IV, Charité-Universitätsmedizin, Berlin, Germany.*

Background: Protein bound uremic toxins (PBT) are involved in dialysis associated morbidity, but are inadequately removed by hemodialysis (HD). Purpose of the present pilot trial was to demonstrate the clinical feasibility of a modified hemodiafiltration technique, which enhances PBT removal based on modification of the ionic strength in plasma.

Methods: In a prospective, randomized, controlled trial enrolling 8 maintenance dialysis patients (*NCT01923961*), HD was compared with online predilution hemodiafiltration (HDF) and predilution HDF using an infusion fluid loaded with NaCl (HDF_{NaCl}). Blood and dialysate flow rate (250 and 575 mL/min, resp.), treatment time (240 min), and high-flux dialyzer (PUREMA® H, 2.1 m²) were always identical. In HDF, the infusion flow rate was 125 mL/min. In HDF_{NaCl}, the infusate Na^+ was adjusted at 240 mmol/L in blood entering the dialyzer and dialysate Na^+ was set at the given minimum of 130 mmol/L. Removal of free and total para-cresyl sulfate (pCS) and indoxyl sulfate (IS) was determined. Hemocompatibility was assessed by the courses of white blood cells, platelets, hemolysis (free hemoglobin, LDH), complement C5a, and thrombin-antithrombin III (TAT). Na^+ was monitored in blood.

Results: All treatments were well tolerated without adverse events. Compared to HD and HDF, the reduction ratios of free and total PBT were highest in HDF_{NaCl} (free pCS, 66.5±14.4, 72.0±14.6 versus 74.0±13.8 %; total pCS, 43.0±9.4, 42.9±14.3 versus 46.0±12.9 %; free IS, 60.4±16.5, 68.4±8.2 versus 72.6±6.1 %, (P=0.026); total IS, 47.8±10.3, 45.2±7.7 versus 52.0±12.9 %). Between treatments no differences in hemocompatibility were observed. In HDF_{NaCl}, Na^+ slightly increased over time (P<0.001) in arterial (0 and 240 min, 132±2 versus 136±3 mmol/L) and venous blood (132±2 versus 140±3 mmol/L).

Conclusions: HDF_{NaCl} is technically feasible and may enhance the removal of PBT without adverse effects. More effective HDF_{NaCl} will require higher Na^+ in blood. To avoid Na^+ accumulation, reduction of the minimum dialysate Na^+ is indispensable.

TH-PO801

Differences in Bisphenol A (BPA) Serum Levels in Hemodialysis (HD) Patients with Two Different Membranes Emilio E. Gonzalez-Parra,[1] Vanesa Camarero,[2] Didier Sanchez-Ospina,[1] Enrique Bosch,[1] Sebastian Mas,[1] Maria Vanessa Perez Gomez,[1] Pedro Abaigar,[2] Jesus Egido.[1] *[1]Nephrology, Fundación Jimenez Diaz, Madrid, Spain; [2]Nephrology, Hospital General, Burgos, Spain.*

Background: FDA and EU Health Programme are studying the BPA in medical devices, especially in CKD patients. BPA is an industrial chemical used in dialyzers. BPA is excreted by kidney. Its cytotoxic and mutagenic. The potential healthy implications of blood BPA accumulation in ´HD patients using different dialyzer membranes is not well established. We have studied BPA and its effects in a group of patients using two dialyzers with or wlthout BPA in its composition. Objectives: 1.- To determine whether there are changes in BPA serum levels in HD patients underthe two different dialyzers. 2.- To examine the factors that influence those potential differences.

Methods: Crossover trial we compared Polinephron (PN), without BPA versus polysulphone (PS) with BPA in membrane and housing composition. Patients were dialyzed for 3 months with either dialyzers. For all basal BPA values, 3 and 6 months were done. The BPA was determined by high-sensitive comercial ELISA and HPLC with fluorescence detection. General data (age, sex, months in HD, TA), dialysis KTV, conventional analysis (Ca, P, PTH, vitamin D, Col, Tg, PCR) were collected. Intracelular BPA were messured (lymphocytes), and proinflammatory cytokines (Tweak, IL1, IL6).

Results: 69 HD patients, mean age 65.06±13.2y, with 63.28±92.04 months HD, 40 males. 41 patients baseline trated with PS, basal BPA 0.091 ng/ml versus PN 0.082 ng/ml. 30 normal renal function control BPA was 0.00318 (p.0001). After 3 months PS group incresed 0.023 (p0.0161), and PN decreased 0.016 (p 0.1527). When percentages are compared PS increases 80.35%, PN decreced 53.7% (p0.021). Intracelular BP in 10 patients with both dializers was 4.4 x 10^{-6}, and It did´t change in 3 months with both diailizers. BPA does not correlate with time in dialysis (p 0.1447).

Conclusions: The baseline BPA levels are greater than control group, but are not different in both groups. In PN group BPA decrease in 3 months, and PS group increase being these difference significant. BPA not correlate with months on HD. We are analyzing their clinical implications.

TH-PO802

Prominent Accumulation in Hemodialysis Patients of Numerous Solutes Cleared by Secretion in the Native Kidney Tammy L. Sirich, Natalie Plummer, Timothy W. Meyer. *Medicine, Stanford & VA Palo Alto, Palo Alto, CA.*

Background: We previously demonstrated that high plasma levels of four organic anions in hemodialysis (HD) patients can be accounted for by the inability of hemodialysis to replicate the native kidney's tubular secretory function (JASN 25:3; 2014). This study employed untargeted high resolution mass spectrometry to test whether other normally secreted solutes accumulate to similar high levels in hemodialysis patients.

Methods: Plasma solute concentrations and clearances in 6 patients maintained on HD and in 6 normal subjects were compared.

Results: A total of 740 solutes were detected in the plasma of HD patients. Of these, 153 solutes were classified as normally secreted based on the finding of a native kidney clearance that was at least twice that of creatinine. For these normally secreted solutes, the ratio of the average pre-treatment plasma level in HD patients to the average plasma level in normal subjects ([HD]/[NL]) was 139±69 and the ratio of the average dialytic clearance to the average normal kidney clearance (K_{HD}/K_{NL}) was 0.48±0.47. For 70 of the normally secreted solutes, the [HD]/[NL] concentration ratio was greater than 100. For these solutes, the average [HD]/[NL] concentration ratio was 254±193 and the average K_{HD}/K_{NL} was only 0.31±0.17. In contrast, the standard dialysis index solute urea had an [HD]/[NL] concentration ratio of 3.6 and a K_{HD}/K_{NL} of 3.9. Mathematical modeling showed that the low K_{HD}/K_{NL} combined with the intermittency of treatment accounted for the high [HD]/[NL] concentration ratios of the normally secreted solutes.

Conclusions: Hemodialysis patients have high plasma levels of a large number of solutes secreted by the native kidney because dialysis fails to replicate the tubular secretory function and the dialytic clearance of these solutes is therefore low relative to the native kidney clearance. Adoption of urea as our index solute for dialysis efficacy has had the unintended effect of concealing how poorly conventional treatment controls the levels of these solutes.

TH-PO803

Trimethylamine Oxide (TMAO) Circulates at Very High Levels in Hemodialysis Patients Xin Hai,[1] Veeda O. Landeras,[1] Mirela A. Dobre,[1] Peter B. De Oreo,[1] Timothy W. Meyer,[2] Thomas H. Hostetter.[1] *[1]Medicine, Case Western Reserve Univ, Cleveland, OH; [2]Medicine, Stanford Univ, Palo Alto, CA.*

Background: TMAO has been identified as a cardiovascular risk factor in the general population (Tang et al, NEJM 368:1575, 2013). People with end stage renal disease (ESRD) have a very high incidence of cardiovascular disease.

Methods: We measured TMAO levels and its handling by hemodialysis and the normal kidney in subjects on chronic hemodialysis (ESRD, n= [6- 10]) and in normal controls (NLS, n=6).

Results: The ESRD patients had much higher plasma levels than NLS (118±100 versus 2±1 μM, respectively, mean ± SD, p<0.05). For comparison, predialysis BUN levels in ESRD subjects were 45±11 mg/dl and 15±3 mg/dl in NLS. Thus TMAO levels in ESRD average about 50 fold those in NLS while BUN is 3 fold NLS. However, the fractional reduction of TMAO concentration during dialysis, was in fact greater than that of urea (83±4 versus 77±4 %, TMAO versus urea, p < 0.05) but with smaller volumes of distribution for TMAO compared to urea (23±6 % versus 42±11 % body weight, respectively, p<.05). Also production rates were similar (581±210 versus 533±248 μ moles/day, ESRD versus NLS, p>0.05). In NLS the urinary clearance of TMAO was high (219±78 ml/min) compared to their urinary urea and creatinine clearances (55±14 and 119±21 ml/min, respectively).

Conclusions: Thus, TMAO levels are especially high in ESRD patients due at least in part to 1) its relatively high secretory clearance by the normal kidney and 2) its small volume of distribution, which renders standard intermittent hemodialysis less efficient than for urea.

TH-PO804

An Economic Assessment Model for Remote Rural Satellite Hemodialysis Units Thomas W. Ferguson,[1] James M. Zacharias,[1] David Thomas Collister,[2] Simon Richard Walker,[1] Navdeep Tangri,[1] Claudio Rigatto,[1] Paul Komenda.[1] *[1]Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [2]Medicine, Univ of Alberta, Edmonton, AB, Canada.*

Background: CKD and kidney failure are epidemic in Manitoba, Canada's remote rural communities. In-centre hemodialysis is provided for these settings in satellite hemodialysis units termed Local Centre Dialysis Units (LCDUs). The total costs and key cost drivers of this program have not been fully described. Such information is crucial in informing the design of future programs aimed at delivering dialysis care in remote communities.

Methods: We constructed a cost model based on data from 16 of Manitoba's rural and remote LCDUs. We included all costs determined on an annual, per-patient basis for operation of the unit, transportation to dialysis or for medical care in Winnipeg, treatment expenses, and capital costs. All costs were inflated and exchanged to 2013 U.S. dollars. Information on costs was obtained from a search of the available literature, review of financial statements, and consultation with service providers.

Results: The annual per-patient cost of providing hemodialysis in the LCDUs ranged from $80,450 to $226,940 per patient, per year. The median per patient, per year cost of LCDU care was $105,450 with an interquartile range of $88,400 - $130,270. The primary factors that drove the high cost estimates were the capital costs of the LCDU construction, human resource expenses, and expenses for return to tertiary care centers for health care.

Costs related to transport increased estimates in units that required plane or helicopter transport for both returns to tertiary centers for emergency medical care and during regular dialysis treatment. Smaller and more remote units tended to be more costly to operate.

Conclusions: LCDUs in rural and remote areas of Manitoba are considerably more expensive on a per-patient basis than in-centre hemodialysis provided in larger urban areas. The differences in these costs are driven by the difficult nature of providing care in sparsely populated, remote regions with limited and expensive transportation. These findings support more aggressive measures to improve home dialysis utilization, particularly in rural and remote regions.

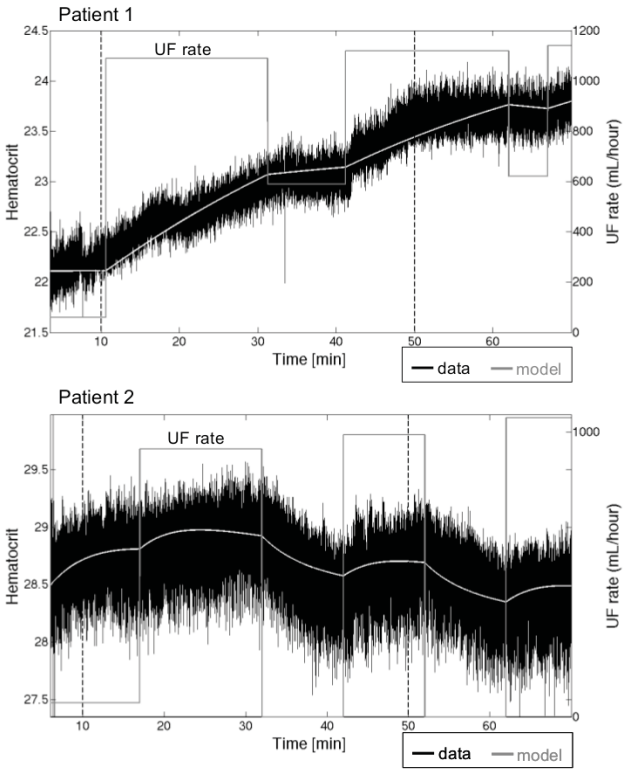
TH-PO805

Mathematical Model Providing New Insights into Vascular Refilling During Dialysis Aurelio A. de los Reyes V,[1] Doris Helene Fuertinger,[2] Franz Kappel,[3] Anna Meyring- Wosten,[2] Stephan Thijssen,[2] Peter Kotanko.[2] *[1]Univ of the Philippines Diliman; [2]Renal Research Inst, NY; [3]Univ of Graz, Austria.*

Background: Intradialytic monitoring of relative blood volume (RBV) can be applied to assess fluid status and aid the prescription of ultrafiltration targets. RBV dynamics are clinically relevant and determined by 2 components: fluid removal from the intravascular compartment by ultrafiltration (UF) and vascular refill from the interstitium. We aimed to characterize these dynamics by development of a 2-compartment mathematical model describing the short-term dynamics of vascular refilling and UF.

Methods: Fluid flow is set as lymphatic and microvascular fluid shifts; protein flux is described by convection and diffusion in the model. Patient specific parameters are identified based on hematocrit (Hct) measurements by the Crit-Line® monitor, including Lp, which is hydraulic conductivity x surface area, the hydrostatic capillary pressure (Pc) and the lymphatic flow (κ).

Results: The estimated parameters are well identifiable using the Hct data between 10 to 50 min. Further, the model shows a good prediction for the following 20 min (Fig.1). Patient 1 shows values within the normal range (Lp=2.89 mL/mmHg/min, Pc=20.42 mmHg), whereas patient 2 has elevated values for Lp and κ (Lp=30.3 mL/mmHg/min, Pc=21.2 mmHg, κ=10.3 mL/min).



Conclusions: This novel mathematical model provides insights into the qualitative and quantitative characteristics of intradialytic vascular refill. Parameters reflecting patients' (patho)physiological characteristics can be identified and the short-term dynamics of vascular refilling predicted. The parameter estimates can be used to assess fluid and inflammatory status. High values of Lp suggest leakiness of capillary wall, which may indicate inflammatory processes, and large κ values indicate a strong lymphatic flow, possibly due to fluid overload.

TH-PO806

A Comparison of Dynamic Blood Pressure Variability between Haemo and Non-Haemodialytic Blood Purification Therapies Scott Wilson, Stephen Harrap. *Univ of Melbourne.*

Background: The harmful effect of significant intradialytic blood-pressure (BP) variability during haemodialysis (HD) is well established. It remains unclear if such volatility is a function of the dialysis or the extracorporeal circulation. To refine our understanding we studied BP variability in patients undergoing peritoneal dialysis (PD) or isovolaemic plasma exchange (PE).

Methods: We measured continuous beat-to-beat systolic BP by the Finometer Midi in 5 PD patients undergoing peritoneal equilibration testing, 5 non-dialysis requiring patients undergoing PE and 46 standard outpatient HD treatments. Variability was assessed across the continuous BP time-series by standard deviation per-treatment and rate-of-change momentum analyses where threshold BP changes were defined by an absolute (+20mmHg) or relative (+15%)over continuously moving 500 heartbeat intervals.

Results: Mean SD (+SEM) of the continuous BP record was 4.2+0.61mmHg, 10.4+0.76mmHg and 15.9+1.18mmHg on a per-treatment basis across PD, PE and HD respectively. No PD patient recorded significant short-term fluctuation in BP in either absolute or relative terms however the mean number (+SEM) of absolute BP swings >20mmHg was 1.6+0.81 and 9.71+0.98 episodes per-treatment for PD and HD respectively. Using a relative definition of BP change saw no events captured during PD but 0.2+0.2, and 7.68+0.9 per PE and HD respectively. All BP fluctuations were asymptomatic. Irrespective of the comparison metric, BP variability was significantly higher in the HD cohort than PD ($p<0.01$). When compared with PE the frequency of absolute or relative threshold changes in BP was significantly greater in the HD group ($p<0.01$) however the difference in SD did not reach significance ($p=0.1$).

Conclusions: This is the first comparative study of continouously monitored haemodynamic stability between blood purification techniques. PD demonstrated a significantly lower degree of BP variability per-treatment than both extracorporeal modalities, with patients undergoing HD being at greatest risk of cardiovascular instability.

TH-PO807

Sodium-Based Potassium Resin and Inter Dialytic Weight Gain (IDWG), Is There a Relevant Link? A Case Report Mahen Al Badawy, B. Coevoet, David Attaf. *CH Saint-Quentint, France; SANTELYS Saint-Quentin, France; Fresenius Medical Care, France.*

Background: Regarding hyperkalemia, studies show equivalent efficacy of both Potassium-Binding Resins (PBR) available : Na^+ and Ca^{++}-based PBR. Nevertheless, Na^+-PBR provide 60 mmol of Na^+ i.e. 1650 mg of NaCl. A DOPPS's study indicates a positive correlation between IDWG and Na^+-PBR. This mechanism should be mediated by salt intake. To illustrate this hypothesis we report a case report of a hemodialysis patient.

Methods: A dialysis patient clinicaly stable, without change in his diet, with a good adherence with his Ca^{++}-PBR to allow a fair control of Kaliema. At D_0 his Ca^{++}-PBR was switched to a Na^+-PBR in order to compare 6 dialysis sessions before and after D_0. 2 consecutive periods of one week were compared: P1 (Ca^{++}-PBR) / P2 (Na^+-PBR). Dry Weight, dialysis prescription, medication and diet were not modified during P1 and P2. To assess impact of Na^+-PBR we estimate (1) dialytic (IMT, dNa^+, eKtV), (2) biologic (Na^+, K^+), and (3) clinical parameters (BLood Pressure (BP), IDWG) at P1 and P2 (unpaired t-test).

Results: Immediately after switching Ca^{++}-PBR to a Na^+-PBR mean dialysate conductivity increase (14,08 (P1)-14,34 mS/cm2 (P2), p=0,05). At the same time mean pre dialysis plasma Na^+increased (134 (P1)-140 mmol/l (P2), p=0,04). Post dialysis plasma Na+ P1 and P2 are equivalent (p=0,7). Mean Ionic Mass Transfer increases from 357 +/- 76 (P1) to 504 +/- 42 mmol/l (P2), p<0,001). Average pre-Dialysis K+ level decreases from 6,82 (P1) to 6,47 mmol/l (P2), as for post-Dialysis K+ level from 4,42 (P1) to 4,18 mmol/l (P2). Average BP (SBP/DBP) evolves from 150 /91 (P1) to 161/101mmHg (P2), p=0,001. IDWG increases significantly from 3,07 +/- 0,4 (P1) to 3,6 +/- 0,3 kg (P2), p<0,03. Prédialysis K+ was superior at the start of the period P1 under Ca^{++}-PBR (difference linked to a higher K^+ intake?). eKt/V was higher during P2.

Conclusions: A Na^+-PBR is associated with an increase of IDWG and BP in this case report. Several case reports show equivalent iatrogenic effect. It should be keep in mind in case of unexplained rise of IDWG. Long-term studies are needed to confirm this effect.

TH-PO808

Activation of the Contact System in Blood Plasma by Hemodialysis Membrane Michael E. Henrie,[1] George M. Rodgers,[2] Nancy J. Brown,[3] Chih-Hu Ho.[1] *[1]Fresenius Medical Care North America, Ogden, UT; [2]Div of Hematology, Univ of Utah Health Science, Salt Lake City, UT; [3]Vanderbilt Univ School of Medicine, Nashville, TN.*

Background: Negatively-charged biomaterial surfaces have been shown to activate the contact system of intrinsic coagulation using *in vitro* models. Reports have shown angiotensin-converting enzyme inhibitors (ACEi) used with negative charged dialysis membranes may lead to bradykinin accumulation within hemodialysis (HD) patients, potentially resulting in anaphylactoid reactions.

Methods: This study compared the effect of different HD membranes on contact system activation. *In vitro* generation of bradykinin (BK) and kallikrein (KLK) was measured from HD membrane exposure to plasma incubated with ACEi. Extracorporeal test circuits were comprised of miniature dialyzers manufactured with various membranes [polysulfone

(PS); polyacrylonitrile (PAN); experimental PS membrane] attached to custom bloodlines. Citrated plasma was used to test for BK generation, while diluted citrated plasma was used to test for KLK generation.

Results: Test results show substantial generation of BK was associated with AN69 membranes (70.1 ± 32.6 ng). All other tested membranes generated BK slightly higher than native levels (527 – 712 pg) measured within the plasma. AN69 membranes were also associated with a substantial generation of KLK (7.5 ± 1.0 units); all other membranes exhibited KLK concentrations closer to native levels (1.3 – 1.7 units). These results were compared with membrane surface electronegativity (zeta potential) to determine if a correlation exists between contact system activation and zeta potential, however a relationship was not found. No significant difference in BK or KLK generation was observed for similar PS membranes using different sterilization methods.

Conclusions: Overall, the results suggest contact system activation is not governed exclusively by specific membrane characteristics. The results demonstrate that dialysis membrane interaction with blood/plasma leading to activation of the contact system is likely multifactorial – a function of membrane materials, membrane surface characteristics, and fluid dynamics.

TH-PO809

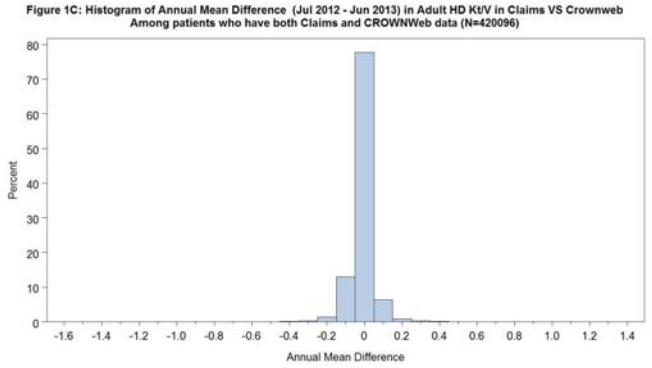
Agreement Between Medicare Claims and CrownWeb Kt/V Data

Douglas E. Schaubel, Cong Zhu, Valarie B. Ashby, Rajiv Saran. *Univ of Michigan, Ann Arbor, MI.*

Background: Dialysis facilities in the U.S. are currently evaluated through analyses based on CMS Medicare Claims data. It has been proposed to instead use the CROWNWeb (CW) database for this purpose. Therefore, it is of great interest to evaluate the level of consistency between CROWNWeb and Claims data with respect to laboratory parameters used to construct the measures through which facility performance is assessed. One key component in this regard is Kt/V, a marker of small solute (urea) clearance.

Methods: Our analysis was based on the 251,641 unique hemodialysis patients and 1,995,404 patient months from July 2012 to June 2013 for which Kt/V values were available from both CW and Claims. We computed sample correlations for the paired Kt/V values, as well as 2x2 tables based on Kt/V>1.2 (yes, no). Regression models based on generalized estimating equations were used to determine patient- and facility-level characteristics associated with degree of difference between CW and Claims Kt/V values (linear regression) and agreement (yes, no) with respect to Kt/V>1.2 (logistic regression). Agreement with respect to facility-level percentage of patients with Kt/V>1.2 was also evaluated.

Results: Histograms for Kt/V based on CW and Claims data were virtually indistinguishable. 91.0% of the differences in paired (by patient-month) Kt/V values were less than 0.05.



The correlation between CW and Claims Kt/V values was 0.94. For 98.9% of pairings, CW and Claims data were consistent in terms of Kt/V>1.2 (yes, no). The average correlation between CW and Claims data with respect to facility-level of percentage of patients with Kt/V>1.2 was 0.82.

Conclusions: Overall, there is very strong agreement between CROWNWeb and Medicare Claims Kt/V values, both at the patient- and facility-level. This is reassuring with respect to reliability of CROWNWeb as a data source for evaluation of the Kt/V measure for dialysis facilities in the United States.

TH-PO810

Gamma-Glutamyltransferase Levels and Patient Mortality in Hemodialysis Patients

Wooyeong Park,[1] Su Hyun Kim,[2] Euy Jin Choi,[1] Yon Su Kim,[3] Chul Woo Yang,[1] Yong Kyun Kim.[1] *[1]Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea; [2]Dept of Internal Medicine, College of Medicine, Chung-Ang Univ, Seoul, Korea; [3]Dept of Internal Medicine, College of Medicine, Seoul National Univ, Seoul, Korea.*

Background: Serum gamma-glutamyltransferase (GGT) level has been reported associated with oxidative stress and elevated serum GGT levels are associated with mortality the general population. However, the association between serum GGT levels and mortality in hemodialysis (HD) patients is uncertain. Our aim is to investigate the relationship between serum GGT levels and mortality in HD patients.

Methods: HD patients were selected from Clinical Research Center registry for End Stage Renal Disease cohort in Korea. Patients were categorized into three groups by tertiles of serum GGT levels as follows: Tertile 1, GGT < 14 U/L ; Tertile 2, GGT = 14-25 U/L; Tertile 3, GGT > 25 U/L. Cox regression analysis was used to calculate the adjusted hazard ratio (HR) of mortality with a serum GGT levels of tertile 1 as the reference.

Results: A total of 1,129 HD patients were included. The median follow-up period was 28 months.The multivariate Cox proportional hazard model showed that the highest tertile of serum GGT levels were associated with highermortality with tertile 1 as the reference (HR 1.81, 95% CI, 1.05-3.13, p=0.033) after adjustment for clinical variables, while there was no significant difference in mortality between tertile 1 and tertlie 2 (HR 1.15, 95% CI, 0.62-2.13, p=0.655).

Conclusions: Our data showed that the highest serum GGT levels were significantly associated with increased mortality in HD patients. These findings suggest that serum GGT levels are useful predictor for mortality in HD patients.

TH-PO811

A Reliable Method to Assess the Water Permeability of a Dialysis System: The Global Ultrafiltration Coefficient

Alain Ficheux,[1] Nathalie Gayrard,[1] Flore Duranton,[1] Caroline Guzman,[1] Ilan Szwarc,[2] Philippe Brunet,[3] Angel Argiles.[1,2] *[1]RD-Nephrologie and EA7288, Unversité Montpellier 1; [2]Nephrologie Dialyse St. Guilhem, Sète; [3]Hôpital de la Conception, Univ Aix-Marseille.*

Background: Recent RCTs on hemodiafiltration (HDF) suggest that high convection improves survival in dialysis patients. When convection flow (Q_{UF}) is high, ultrafiltration coefficient required by FDA does not reflect system permeability. The global ultrafiltration coefficient of the dialysis system ($_GK_{D\text{-}UF}$ defined as Q_{UF}/TMP) is better adapted. $_GK_{D\text{-}UF}$ over Q_{UF} follows a parabolic function and its maximum ($_GK_{D\text{-}UF}$-max) is the highest water permeability which occurs at a specific Q_{UF}. The present study analyses in vivo the factors influencing $_GK_{D\text{-}UF}$-max and its Q_{UF}.

Methods: 12 stable dialysis patients were closely monitored as for the $_GK_{D\text{-}UF}$ in HDF setting for 2 months. Blood and dialysate flow was respectively 368±9 and 602±1 mL/min. Weight loss was 2.9±0.1 kg/session. $_GK_{D\text{-}UF}$ was weekly determined at the start of session, and could be repeated during treatment.

Results: $_GK_{D\text{-}UF}$ always followed a parabolic function (least R^2=0.96 of 150 determinations). For every patient, initial $_GK_{D\text{-}UF}$-max and related Q_{UF} were very reproducible (VC, 4.7%±0.5%, max 11%; 3.9±0.3%, max 7.8%). $_GK_{D\text{-}UF}$-max greatly varied across patients (from 31 to 45 mL.h^{-1}.mmHg^{-1}), and associated Q_{UF} changed from 82 to 99 mL/min. Multivariate analysis showed that $_GK_{D\text{-}UF}$-max and Q_{UF} at $_GK_{D\text{-}UF}$ max were influenced by patient, dialyzer and blood flow (all p≤0.01). The $_GK_{D\text{-}UF}$-max and associated Q_{UF}decreased during dialysis treatment. Decrease in $_GK_{D\text{-}UF}$-max was not related to convection, but to patients and associated with weight loss (R^2=0.66;p<0.001).

Conclusions: $_GK_{D\text{-}UF}$-max translates the convection ability of the whole system including the patient and dialyzer. It decreases during dialysis, in association with weight loss, suggesting that hemoconcentration and refilling capacity could be involved. $_GK_{D\text{-}UF}$ is a reliable method to assess the water permeability of a system, more adapted to modern dialysis with high convection than current methods requested by National Authorities. Monitoring $_GK_{D\text{-}UF}$ may help prescribe and deliver high convection volume therapies.

TH-PO812

Safety, Efficacy, and Dose Adjustment of Chemotherapy in Lymphoma Patients Requiring Hemodialysis - A Case Series

Abdurrahman M. Hamadah,[1] Heidi Diann Finnes,[2] Carrie Thompson,[2] Nelson Leung.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Hematology, Mayo Clinic, Rochester, MN.*

Background: Cancer, including hematologic malignancies, is the third leading cause of death in hemodialysis (HD) patients and is associated with increased mortality in this population. A paucity of data, however, exists in the literature to guide the timing and dose adjustment of chemotherapy in HD patients.

Methods: We present a case series of 9 patients who underwent chemotherapy for lymphoma while on HD between 2007 and 2014.

Results: There were 5 men and 4 women with the following diagnoses: 5 diffuse large B-cell lymphoma, 1 high grade B-cell lymphoma and 3 T-cell lymphoma. Median age was 66 years (range 46-83) and median follow-up was 7 months (range 1-79 months). Of the 9 patients, one patient had 6 cycles of chemotherapy, another had 3 cycles, and the rest received a single cycle each for a total of 16 cycles of chemotherapy. The majority of the cycles (n=15) were CHOP (Cyclophosphamide (CTX), doxorubicin, vincristine, and prednisone), either alone (2), or with rituximab (4) or with etoposide (2). Of the chemotherapy drugs, only CTX was dose reduced due to HD: 20-25% in 6 patients (13 out of 16 chemotherapy cycles), 50% in 1 patient, and no reduction in 2 patients. CTX was given 7-12 hours before HD. Good tolerability with no significant adverse reactions was noted in 8 of the 16 cycles, and events in the other cycles were: febrile neutropenia/ pneumonia (3), blood stream infection (1), tumor lysis syndrome (2), and altered mental status of unknown etiology (2). Six of the patients (representing 13/16 cycles) did well long term and 5 continue to be in remission, while 1 died in remission of unrelated causes 6 years post-chemotherapy. Two patients died within 4 weeks of regimen due to altered mental status of unknown etiology and transitioned to comfort care. Another patient died of infectious complications of subsequent peripheral blood stem cell transplant.

Conclusions: Chemotherapy for lymphoma while undergoing HD with 20-25% dose reduction of CTX was fairly well tolerated in this small group. Timing of HD at 7 to 12 hours after CTX administration allows for therapeutic effect while minimizing toxicity.

TH-PO813

Impact of a Quality Management System (QMS) on Key Performance Indicators (KPIs) in a Belgian Predialysis Clinic and Dialysis Unit

Eric E. Gheuens,[1] Wendy Engelen,[1] Koen De Boeck,[1] Monique M. Elseviers,[2] Koenraad Peter Bouman,[1] Ronald Daelemans.[1] *[1]ZNA Nierkliniek, Ziekenhuis Netwerk Antwerpen, Antwerpen, Belgium; [2]Centre for Research and Innovation in Care, Univ Antwerpen, Wilrijk, Belgium.*

Background: We evaluated the impact of a QMS (ISO 9001:2008) on KPIs in a predialysis kidney clinic and dialysis unit.

Methods: The approach in the multidisciplinary predialysis clinic (MPC; n=69) was compared with standard care (n=62). Initiatives to improve quality were taken and evaluated in PDCA-cycles (Plan-Do-Check-Act). After 2 years an analysis of the KPIs in our balanced score card was made. A survey of patients and co-workers of our unit was performed in 2011 (before acquisition of an ISO certification) and repeated in 2013, based on standardized and validated questionnaires: CQ-Index (Consumer Quality Index) for patients and a combination of JCQ (Job Content Questionnaire) and COPSOQ (Copenhagen Psychosocial Questionnaire) for co-workers.

Results: Patients in the MPC: - needed significantly less urgent start of dialysis (23.5 % versus 43.5 %, p <0.015) - more frequently had an AV fistula present at the start of dialysis (38.2 % versus 19.4 %, p <0.018) - more frequently were dialysed with an AV-fistula after 1 year (58.8 % versus 23.8%, p=0.002) Mortality trended to be lower after 1 year in the MPC group (30.6 % versus 41.9 %, p = 0.171). We noticed an increase in the proportion of patients with a Kt/V > 1.2 of almost 10% over 2 years. Patient satisfaction (48 % of our patients returned the questionnaire) increased from 87 % to 90 %. Net Promotor Score (NPS) increased from 47 to 51 (+ 4 %). Satisfaction of co-workers (60 % of co-workers returned the questionnaire) decreased from 77 % to 68 % due to 'too much ISO' (too much change, imperfect communication and increased work load). Job typology showed that 46 % experienced their work as a 'high risk job' and 21 % as a 'high strain job'. Systematic appraisal of co-workers resulted in a decrease of absence through illness with 37 %.

Conclusions: Implementation of a QMS (ISO 9001:2008) in a predialysis kidney clinic and dialysis unit resulted in improvement of several KPIs (less urgent start of dialysis, presence of AV fistula, hemodialysis.

TH-PO814

Large Variation among U.S. Facilities in Red Blood Cell Transfusion Frequency, 2010-2012

Douglas S. Fuller,[1] Brian Bieber,[1] Hal Morgenstern,[2] Bruce M. Robinson,[1,2] Ronald L. Pisoni.[1] *[1]Arbor Res Collab Hlth, Ann Arbor, MI; [2]Univ of MI, Ann Arbor, MI.*

Background: The % of U.S. Medicare-insured dialysis patients (pts) receiving a red blood cell transfusion (RBCT) rose in 2011-2012, coincident with the start of the CMS Prospective Payment System (PPS). Pt characteristics and facility (FAC) practice variation likely affect RBCT rates. We describe U.S. dialysis FAC variation in RBCTs from 2010 to 2012.

Methods: Pts w/8+ CMS Medicare outpatient claims for hemodialysis (HD) in a month during 2010-2012 were assigned each month to the FAC with the most HD claims. Analyses were restricted to FACs with 20+ pts (FAC 20+) or 60+ pts (FAC 60+). RBCT claims were identified by revenue center and other claim codes. The % of pts in each FAC receiving 1+ RBCT in each 1-, 3-, or 6-mo period (FAC %RBCT) was estimated overall and within strata of FAC geographic region, for-profit status, affiliated chain size, and rural-urban commuting area score.

Results: Median: From Jan 2010 to Dec 2012, 1-mo FAC %RBCT rose from 2.4% to 2.7% (FAC 60+) and from 2.4 to 2.9% (FAC 20+); 6-mo FAC %RBCT rose from 13.0% to 13.8% (FAC 60+) and from 13.0 to 14.3% (FAC 20+). Range: In Dec 2012, 5th-95th %iles for 1-mo FAC %RBCT were 0-9% (FAC 60+) and 0-7% (FAC 20+); 5th-95th %iles for 6-mo FAC %RBCT were 6-24% (FAC 60+) and 5-28% (FAC 20+). FAC comparisons: No clear differences were seen by rurality or for-profit status. Median FAC %RBCT was lower in large-chain versus small-chain/independent free-standing FACs (2.7% versus 3.4% in Dec 2012, p<0.001). Median FAC %RBCT was slightly lower in West/East versus Central/South regions (2.7% versus 2.9%, p=0.04).

Conclusions: The effect of the 2011 payment and regulatory changes on RBCT was small compared to overall variation in FAC %RBCT (>4-fold for 6-mo %RBCT; some FACs >20%). While effect of case-mix needs to be considered, efforts to limit RBCT should focus on FAC performance and specific RBCT-related FAC practices.

TH-PO815

Transfusion Events in Hemodialysis Patients by Hemoglobin Level, ESA Users versus Non-ESA Users

Allan J. Collins, Thomas Matlon, Yi Peng, David T. Gilbertson. *Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN.*

Background: Assessing Hb levels and transfusion use had been possible only for ESA-treated dialysis patients due to Medicare reporting requirements. In 2012, CMS required Hb levels to be reported for all dialysis patients. Hb levels from the prior month are reported on the current month's claim. We assessed differences in transfusion use by prior Hb level among ESA users versus non-ESA users.

Methods: Monthly cohorts, April-December 2012 (first complete reporting), were created from Medicare ESRD standard analysis files. Patients receiving hemodialysis (HD) as of the first day of the month were included and followed from that day until death, kidney transplant, loss to follow-up, or the last day of the month. ESA use and transfusion events were evaluated during the follow-up period.

Results: In April 2012, for HD patients with Hb ≥ 13 g/dL, 2.84% of ESA users and 0.45% of non-ESA users received transfusions. For patients with Hb at 12 g/dL, 1.45% of ESA users and 0.85% of non-ESA users received transfusions. Transfusion use was similar for ESA users and non-ESA users when Hb was 10 to < 12 g/dL. Transfusion use was 5.41% and 16.03% for ESA users with Hb at 9-< 10 g/dL and < 9g/dL; corresponding percentages were 16.10% and 27.60% for non-ESA users. Similar patterns in monthly transfusion use were observed for the May-December cohorts (data for July-Dec not shown).

Hb levels	ESA use	Apr	May	Jun
<9 g/dL	Non-ESA users	27.60	27.02	32.98
	ESA users	16.03	16.90	16.89
9-<10 g/dL	Non-ESA users	16.10	15.34	11.22
	ESA users	5.41	5.49	5.30
10-<11 g/dL	Non-ESA users	2.93	2.88	3.10
	ESA users	2.26	2.32	2.15
11-<12 g/dL	Non-ESA users	1.22	1.01	0.98
	ESA users	1.58	1.60	1.45
12-<13 g/dL	Non-ESA users	0.85	0.85	0.47
	ESA users	1.45	1.82	1.71
13+ g/dL	Non-ESA users	0.45	0.42	0.36
	ESA users	2.84	2.50	2.62

Conclusions: For patients with low Hb levels (< 10g/dL), transfusion risk is higher among non-ESA users than among ESA users in the next month. Longer-term assessment is needed to determine the sustained risk of transfusions when Hb falls below 10g/dL.

Funding: Pharmaceutical Company Support - Amgen

TH-PO816

Standardized Transfusion Ratios and Standardized Hospitalization Ratios Are Positively Correlated among Dialysis Facilities

Eric D. Weinhandl,[1] David T. Gilbertson,[1] Allan J. Collins.[1,2] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]School of Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: As Medicare beneficiaries undergoing maintenance dialysis are hospitalized 1.8 times per person-year and experience most blood transfusions in inpatient settings, dialysis facility standardized transfusion ratios may reflect the incidence of hospitalization more than the adequacy of anemia management. We aimed to estimate correlation of standardized transfusion ratios with facility-level metrics regarding hospitalization and anemia management.

Methods: We analyzed data from Dialysis Facility Compare. For each included provider, we extracted the standardized transfusion ratio (STrR), the standardized hospitalization ratio (SHR), and the percentage of patients with hemoglobin less than 10 g/dL (% patients with low Hb), each measured from January 1, 2012, to December 31, 2012. We retained providers with recorded data for all of these metrics. We fit linear regression models of STrR as a function of SHR and % patients with low Hb.

Results: We identified 5172 providers. Median STrR was 0.92, with 10th and 90th percentiles 0.46 and 1.68; median SHR was 0.96, with 10th and 90th percentiles 0.65 and 1.35; and median % patients with low Hb was 8%, with 10th and 90th percentiles 2% and 21%. In univariate models, the proportion of explained variation (R^2) in STrR was 18.9% for SHR and 5.4% for % patients with low Hb. In a multivariate model of STrR with SHR and % patients with low Hb, R^2 was 22.9%; each standard deviation increment in SHR and % patients with low Hb associated with increments in STrR equal to 0.22 and 0.09, respectively ($P < 0.01$ for each).

Conclusions: Standardized transfusion ratios are more strongly correlated with standardized hospitalization ratios than with facility-level percentages of patients with low hemoglobin. Common risk factors for blood transfusion and hospitalization may be currently omitted from risk adjustment schema. Alternatively, hospitalists may tend to transfuse dialysis patients at relatively high hemoglobin concentrations. The role of hospitals in the decision to transfuse blood merits further scrutiny.

TH-PO817

Dialysis Facility-Level Transfusion Rates Can Be Unreliable due to Variability in Hospital-Level Billing Patterns for Blood Eric D. Weinhandl,[1] David T. Gilbertson,[1] Allan J. Collins.[1,2] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]School of Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: Methods to estimate standardized transfusion ratios from Medicare claims depend partially on accurate identification of transfusion incidence during hospitalizations. We aimed to describe variability of billing patterns for blood among hospitalized dialysis patients.

Methods: For Medicare beneficiaries undergoing dialysis in 2011 or 2012, we searched Medicare claims for hospital admissions with any billing for blood (ICD-9-CM procedure codes 99.0x, revenue center codes 038x-039x, and value code 37). We classified stays into 4 mutually exclusive categories: whole blood (WB)/red blood cell (RBC) transfusion, non-WB/RBC transfusion, transfusion administration (without explicit coding for components transfused), and blood processing alone (without explicit coding for transfusion administration). We examined variability of the distribution of categories across states and hospitals.

Results: We identified 309,650 admissions with billing for blood (ABB) between Jan 1, 2011, and Dec 31, 2012; 63% were for WB/RBC transfusion, 4% for non-WB/RBC transfusion, 12% for transfusion administration, and 21% for blood processing alone. In states (n = 34) with >1000 ABB, percentages of ABB with WB/RBC transfusion ranged from 47% to 79%; percentages with blood processing alone ranged from 7% to 36%. In hospitals (n = 1041) with >100 ABB, the 10th and 90th percentiles of the percentages of ABB with WB/RBC transfusion were 2% and 88%, respectively; corresponding percentiles with blood processing alone ranged from 0% to 63%.

Conclusions: The incidence of WB/RBC transfusion among hospitalized dialysis patients is uncertain, primarily because of frequent coding of blood processing without evidence of transfusion. Between-hospital variability in billing patterns for blood was large. Thus, for methods relying on specific definitions of WB/RBC transfusion, dialysis facility-level transfusion rates are likely to be highly influenced by billing patterns of nearby hospitals. Multicenter validation studies of hospital billing for blood are needed.

TH-PO818

Comparison Between CMS CROWNWeb and Medicare Claims Data with Respect to Hemoglobin Douglas E. Schaubel, Lan Tong, Valarie B. Ashby, Debabrata Ray, Rajiv Saran. *Univ of Michigan.*

Background: CROWNWeb (CW) is intended to replace Medicare Claims as the primary CMS data source for evaluating dialysis facilities' performance. Thus, it is of interest to quantify the consistency between the two sources.

Methods: The study population included adult (age ≥18) end-stage renal disease patients treated during 7/2012 to 6/2013 who, according to both sources (CW and Claims), were on dialysis ≥ 90 days, were prescribed erythropoietin, and had a valid hemoglobin (HB) value (5≤HB≤20). A total of 270,561 patients, 2,786,075 patient-months in Claims, 3,199,149 patient-months in CW, and 5,216 dialysis facilities were included. The analyses consisted of patient-, center-, and population-level comparisons between CW and Claims HB records. Means, standard deviations and histograms were compared at the population-level. Center- and patient-level analyses consisted of 2 x 2 tables, correlations, and linear and logistic regression modeling.

Results: At the population level, HB distributions were very similar. A subset of the patient- and center-level findings are summarized in the Table:

Quantity	Restrictions	Level	N	Value
Mean annual HB	None	Patient	289,961	Correlation=0.77
Mean annual HB	CW: HB≤12	Patient	284,303	Correlation=0.77
Mean annual HB	CW: HB>12	Patient	5,658	Correlation=0.13
Mean annual HB>12 (yes, no)	None	Patient	289,961	Agreement=97.9%
HB>12 (yes, no)	Jan 2013 only	Patient	179,824	Agreement=90.7%
% patients with annual mean HB>12	None	Center	5,216	Correlation=0.44
Mean annual HB	None	Center	5,216	Correlation=0.79

Linear regression modeling of the patient-level difference in HB values (CW minus Claims) revealed age, sex, race, diabetes, region, facility size, large dialysis organization, and free-standing facilities as significant predictors. Logistic models of patient-level agreement (HB>12: yes, no) indicated generally similar patterns except that ethnicity was also significant.

Conclusions: Agreement between CW and Claims HB data ranged from moderate to very good depending on the degree of averaging. Future work should investigate why (i) the correlation is lower for higher HB values and (ii) the level of disagreement depends on patient- and center-level characteristics.

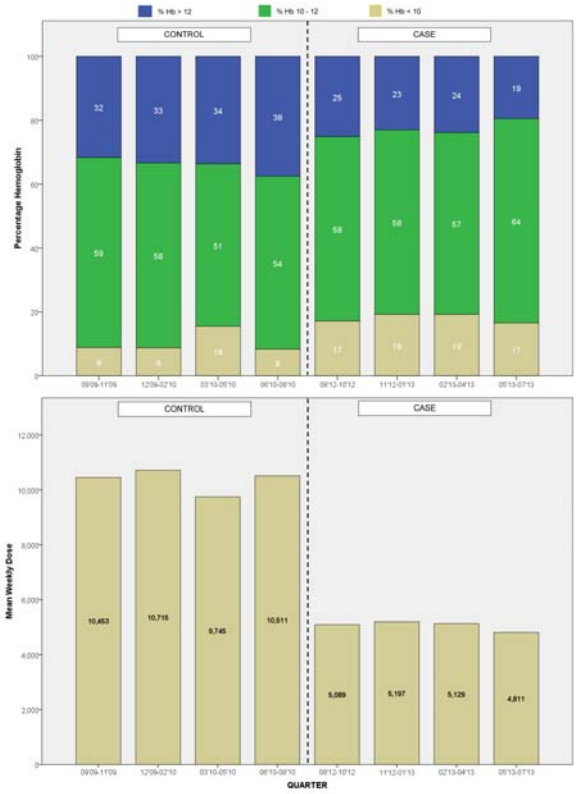
TH-PO819

Individualized Anemia Management: Pragmatic Study Adam E. Gaweda,[1] Michael E. Brier,[1] Alfred A. Jacobs,[1] George R. Aronoff.[1,2] *[1]Dept of Medicine, Univ of Louisville, Louisville, KY; [2]Renal Ventures Management, LLC, Denver, CO.*

Background: Current product label for Erythropoiesis Stimulating Agents (ESA) stipulates individualization of anemia treatment in End Stage Renal Disease (ESRD). We developed a computer-assisted approach to individualized ESA dosing and recently demonstrated its efficacy through a randomized controlled clinical trial. We now present the results of a pragmatic study showing the utility of this approach in a daily clinical practice.

Methods: We began implementing our approach at University Kidney Center (UKC), Louisville, KY in 09/10 and introduced it as a standard of care in 04/12. We performed a case-control study of all ESRD patients undergoing uninterrupted treatment at our facility between 09/10 and 09/13. 80 patients satisfied this criterion. We compared Hemoglobin (Hb) percentages below, within, and above the target range 10-12 g/dL, as well as ESA utilization over 12-month periods: 09/09-09/10 (control) and 08/12-08/13 (case). We excluded the washout period 04/12-08/12 from analysis. At all times, anemia managers were allowed to modify the recommended dose based on their judgment.

Results: Individualized ESA dosing resulted in a modest but consistent improvement of Hb distribution within and above the target range and a two-fold decrease in ESA utilization, when compared to dosing driven by a standard population-oriented protocol.



Outcome	Control	Case	P-value
%Hb<10	10.4	18.0	0.04
%Hb 10-12	55.6	59.1	0.04
%Hb>12	34.0	22.9	0.04
Mean Hb (± Std)	11.6 ± 1.4	11.1 ± 1.6	<0.001
Median ESA dose per week (min, max)	4,500 (0 ... 97,500)	2,000 (0 ... 63,400)	<0.001
Mean ESA dose per week (± Std)	10,356 ± 15,233	5,083 ± 7,904	<0.001

Conclusions: Individualized ESA dosing such as the one implemented at our facility improves cost-effectiveness of anemia management in daily clinical practice.

Study of an ESA Treatment Algorithm for Treatment of Renal Anemia – Stable Hb Value Obtained with CERA Administered Once Every 2 Weeks

Teruhiko Maeba, Shigeru Owada. *Internal Medicine, Asao Kidney Clinic, Kawasaki, Japan.*

Background: When treating renal anemia in hemodialysis patients, it is necessary to maintain a stable Hb value and to administer a correct ESA dose. In Japan, twice monthly measurement of the Hb value by blood sampling is recommended, and the ESA dose is decided based on the results of this measurement. We have created an algorithm for the use of ESA (CERA: Continuous Erythropoietin Receptor Activator) with hemodialysis patients.

Methods: We administered CERA based on the algorithm to 102 hemodialysis patients who were being treated with rHuEPO and observed them for 1 year. When we reviewed the algorithm after 1 year, we found cases in which the Hb value fluctuated as a result of suspending and restarting ESA treatment. We therefore revised the algorithm and observed the patients for an additional year. The target Hb value was 10.5 – 11.0 g/dl, and we observed the Hb value, CERA dosage, ERI (Erythropoietin Resistance Index), and iron dosage. CERA was administered once every 2 weeks, and the dosage was increased or decreased within a range of 25 mg per dose according to the measured Hb values. The standard for iron dosage was not changed during the evaluation period.

Results: The Hb values at the start of evaluation, after 1 year, and after 2 years were respectively 10.9 g/dl, 11.1 g/dl, and 11.2 g/dl. The corresponding CERA dosages were 62±16 mg/2w, 37.5±25.4 mg/2w, and 35.9±22.7 mg/2w. The corresponding ERI were 0.11±0.04, 0.06±0.05, and 0.06±0.04. Compared with the evaluation start, there were significant decreases in both CERA dosage and ERI after 1 year and after 2 years. Hb fluctuation was reduced by minimizing the suspension of CERA treatment to the extent possible. There was no change in the serum level of ferritin during the evaluation period, and the iron dosage decreased significantly from 13.0±1.5 mg/w/patient before the start of the evaluation to 10.9±2.6 mg/w/patient.

Conclusions: CERA administered once every 2 weeks based on an ESA treatment algorithm can maintain a stable Hb value and improve ERI, and can also reduce the dosage of iron.

TH-PO821

Clinical Assessment of Pleiotropic Effects of Erythroid-Stimulating Agents in End-Stage Renal Disease

Takashi Naito,[1] Kosaku Nitta.[2] *[1]Medicine, Nephrology, Tokyo Rousai Hospital, Tokyo, Japan; [2]Medicine, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Several lines of evidence have shown that circulating endothelial progenitor cells (EPCs) play a pivotal role in vasculogenesis and that they promote angiogenesis by secreting growth factors. Recent studies have suggested that erythropoietin (EPO) may accelerate not only angiogenesis but also vasculogenesis, beyond erythropoiesis. In this study we investigated whether two erythroid-stimulating agents (ESAs) modulate vascular-related factors, including the mobilization of EPCs, in patients with end-stage renal disease (ESRD).

Methods: We conducted a 12-week prospective study on 55 patients with ESRD. We treated 21 patients with recombinant human EPO (rhEPO) (EPO group, 4565.5 ± 435.2 IU/week) and 19 patients with darbepoetin (DA) (DA group, 39.2 ± 14.2 μg/week). The other 15 patients did not receive ESA therapy (no-ESA group). Vascular mediators such as EPCs, vascular endothelial growth factor, matrix metalloproteinase-2 (MMP-2), high-sensitivity C-reactive protein, and asymmetric dimethyl arginine were measured at 0 and 12 weeks. EPCs were measured by flow cytometry as $CD45^{low}CD34+CD133+$ cells.

Results: The change in EPC count from 0 to 12 weeks increased significantly in a dose-dependent manner in the EPO group ($p<0.01$). In the DA group, the change in EPC count was not dose-related, but the change in serum MMP-2 concentration from 0 to 12 weeks decreased significantly in a dose-dependent manner ($p<0.01$). Meta regression analysis showed the same results as above.

Conclusions: EPC mobilization and modulation of circulating MMPs in ESRD patients differ depending on the ESA used in treatment.

Longer-Term Outcomes of Darbepoetin Alfa *versus* Epoetin Alfa in Patients with End-Stage Renal Disease Initiating Hemodialysis: A Quasi-Experimental Study

Wolfgang C. Winkelmayer,[1] Tara I. Chang,[1] Aya Alice Mitani,[1] Glenn M. Chertow,[1] M. Alan Brookhart,[2] Benjamin A. Goldstein.[1] *[1]Stanford Univ School of Medicine, Palo Alto, CA; [2]Univ of North Carolina, Chapel Hill, NC.*

Background: Epoetin alfa (EPO) and darbepoetin alfa (DPO) are erythropoiesis-stimulating agents (ESA) used for anemia treatment in patients undergoing dialysis. We compared rates of mortality and cardiovascular events in patients treated with EPO *versus* DPO in incident hemodialysis patients akin to a cluster-randomized trial by exploiting the natural experiment that occurs when facilities make a formulary decision to provide one or the other drug to all their patients.

Methods: From the USRDS, we identified all facilities that switched from EPO to DPO (2003-2010). We matched each DPO facility with one EPO facility on geographic location, profit status, and facility type (free-standing *versus* hospital-based). Patients subsequently initiating hemodialysis were assigned their facility-level ESA exposure regardless of their actual treatment received. Patients were followed for mortality and cardiovascular mortality. Among patients covered by fee-for-service Medicare, we evaluated the composite of cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke.

Results: Of 508 dialysis facilities that switched to DPO, 492 were matched with a similar EPO facility; 19,932 (EPO: 10,467; DPO: 9465) incident hemodialysis patients were followed for 21,918 person-years during which 5550 deaths occurred. Most baseline characteristics were balanced; however, fewer patients in DPO facilities were Hispanic or Asian, and serum albumin was slightly lower. The demographics-adjusted mortality hazard ratio (HR) for DPO (*versus* EPO) was 1.06 (95% confidence interval [CI]: 0.99-1.13) and remained materially unchanged after adjustment for other baseline characteristics. Among 9455 patients with fee-for-service Medicare, there was no significant difference in the demographics-adjusted composite cardiovascular endpoint (HR=1.09; 95%CI: 0.96-1.24) or any individual event type.

Conclusions: In incident hemodialysis patients, rates of mortality and cardiovascular events did not differ among patients treated at facilities predominantly using DPO *versus* EPO.

TH-PO823

Use of the Darbopoietin Resistance Index to Optimize Anemia Management

Edward A. Ross, Jennifer L. Paugh-Miller, Xuerong Wen, Robert W. Nappo. *Univ of Florida, Gainesville, FL.*

Background: Guidelines that minimize ESA usage in ESRD reduce financial burden and possible dose-related adverse effects. Instead of absolute dose or dose/kg body weight, adjustment for hemoglobin has been suggested as the Erythropoietin or Darbopoietin Resistance Index (ERI, DRI): dose/kg wt/g/dl hgb. Unlike ERI, DRI data are lacking so we studied it in all our pts and in a hematologically healthy subset.

Methods: We retrospectively reviewed 94 clinically stable chronic HD subjects for darbopoietin (D) dose, weight, DRI, chemistry, hematology and iron studies, URR, iPTH, catheter usage, medications and diseases with hematologic effects, and primary heme disorders. Analyses were repeated for the subset of pts deemed hematologically healthy. Based on those "normal" ESA dosing ranges, we identified pts from the entire group in whom high or low doses/kg were out of synch with their DRI values.

Results: For all 94 pts: 54% male, age 52.5 ± 1.6 yrs (mean ± SEM), hgb 10.0 ± 0.1 g/dl, Fe sat 29.1 ± 1.25%, ferritin 553 ± 100 ng/ml, URR 73.5 ± 0.8%, iPTH 386 ± 35 pg/ml, and 46 had heme-active factors. The D dose was 46.9 ± 6.3 mcg/wk (range 6.3-200), 0.61 ± 0.06 mcg/kg (0.06-2.55), DRI 0.06 ± 0.01 (0.01-0.27). For the 48 heme-healthy pts: 44% male, 57.1 ± 1.9 yrs, hgb 10.4 ± 0.16 g/dl, Fe sat 29.6 ± 1.6%, ferritin 434 ± 52 ng/ml, URR 74.3 ± 1.0%, iPTH 354 ± 45 pg/ml. The D dose was 38.5 ± 3.5 mcg/wk (6.3-120), 0.50 ± 0.05 mcg/kg (0.06-1.60), DRI 0.05 ± 0.01 (0.01-0.19). Using target D/kg of 0.45-0.55 and DRI of 0.04-0.06, the two indices were out of synch in 16/94 pts (17%) despite hgb at goal. With DRI within range, 9 had low D/kg, 6 high D/kg. With D/kg within range, 1 had high DRI.

Conclusions: ESA management protocols based on D doses adjusted for both body weight and hemoglobin are promising for improved anemia control and provide better guidelines than when using weight alone. We suggest that a high DRI is particularly useful for identifying pts reaching hgb targets but who nevertheless may have remediable causes of ESA hyporesponsiveness (e.g. functional iron deficiency). Larger studies are needed with the goal that pts with elevated DRI levels undergo protocolized evaluation for entities that cause ESA resistance.

TH-PO824

The Use of Epogen via Intravenous and Subcutaneous Routes

Farhanah Yousaf, Opeyemi Oladele, Chaim Charytan, Bruce S. Spinowitz. *New York Hospital Queens.*

Background: In the new era of payment bundling, dialysis centers are incentivized to be more efficient in delivery of health services including ESA administration. We investigated the use of intravenous(IV) Epogen versus subcutaneous(SQ) Epogen.

Methods: Medical records of all hemodialysis(HD) patients that received Epogen during the study periods were reviewed. Study period for IV Epogen and SQ Epogen was May to Jul 2010 and May to Jul 2011, respectively. Patients who received darbepoietin within 6 months; were hospitalized for > 1 day; or were not registered for HD for at least 3 months prior to and during both study periods were excluded. Patients who continued to receive IV Epogen beyond Mar 2011 were also excluded. Paired t-test was used for analysis.

Results: Mean age of patients was 67±14 years that included 23 females and 33 males with estimated dry weight of 71±22Kg. During the 3-month study period, mean IV Epogen administered was significantly higher compared to mean SQ Epogen (106677±113331 IU versus 85228±83381 IU;p=0.024). Mean hemoglobin and TSAT were similar during the two study periods. However, mean ferritin was significantly increased during SQ Epogen study period compared to IV Epogen study period (457±243 versus 650±321, $p<0.0001$) in spite of increased iron supplementation during IV Epogen study period compared to SQ Epogen study period (731±798 versus 445±506; p=0.014).

Conclusions: SQ administration of Epogen resulted in a 20% reduced Epogen dose in 56 HD patients during May 2011 to July 2011 compared to IV Epogen during May 2010 to July 2010 in spite of increased iron supplementation during IV Epogen study period.

TH-PO825

Epoetin Beta Pegol Promotes Utilization of Iron for Erythropoiesis through Intensive Suppression of Serum Hepcidin Levels in Inherited Super-Anemic Mice Yusuke Sasaki,[1] Yasushi Shimonaka,[1] Mitsue Kurasawa,[1] Keigo Yorozu,[1] Norio Suzuki,[2] Masayuki Yamamoto.[2] *[1]Chugai Pharmaceutical Co., Ltd., Kamakura, Japan; [2]Tohoku Univ Graduate School of Medicine, Sendai, Japan.*

Background: Epoetin beta pegol (C.E.R.A.) is a novel, long-acting erythropoiesis-stimulating agent (ESA). We previously reported that C.E.R.A. has the potential to induce sustained reduction of serum hepcidin levels in normal mice. In the present study, we investigated how long-term suppression of hepcidin following C.E.R.A. administration affects iron utilization associated with correction of anemia in inherited super-anemic mice (ISAM) as a mouse model of adult-onset anemia caused by erythropoietin deficiency.

Methods: Hemoglobin (Hb) levels, cardiac weight, and iron indices (serum hepcidin levels, serum iron levels, and hepatic and splenic iron contents) were analyzed in ISAM and control mice. ISAM were treated with a single subcutaneous injection of C.E.R.A. (3 μg/kg), recombinant human epoetin beta (rhEPO) (3 μg/kg), or vehicle.

Results: Hb levels were lower and the ratios of cardiac weight to body weight were higher in ISAM than in control mice. ISAM showed higher serum hepcidin levels and hepatic iron contents than did control mice. Serum hepcidin levels were significantly suppressed on Day 3 after both C.E.R.A. and rhEPO treatment, but only C.E.R.A.-treated ISAM showed significantly lower serum hepcidin levels than vehicle-treated ISAM on Day 7. High Hb levels were sustained for 14 days and the cardiac hypertrophy was improved following C.E.R.A. treatment. Serum hepcidin levels, serum iron levels, and hepatic and splenic iron contents were significantly lower in the C.E.R.A.-treated ISAM than in vehicle-treated ISAM over 14 days.

Conclusions: ISAM developed anemia associated with a decrease in utilization of iron for erythropoiesis. Our results indicated that the novel long-acting ESA C.E.R.A. has the potential not only to correct anemia but also to improve utilization of iron for erythropoiesis by mobilizing stored iron through the intensive suppression of serum hepcidin levels.

TH-PO826

Peroxynitrite Scavenger Ebselen Modulates Erythrocyte Intracellular ROS and Eryptosis *In-Vitro* Viktoriya Kuntsevich,[1] Nijal R. Sheth,[1] Nikolas B. Harbord,[1] James F. Winchester,[1] Andrea Novais Moreno-Amaral,[2] Roberto Pecoits-Filho,[2] Stephan Thijssen,[3] George A. Kaysen,[3] Peter Kotanko.[3] *[1]MSBI, New York, NY; [2]PUCPR, Curitiba, Brazil; [3]RRI, New York, NY.*

Background: Multiple factors contribute to anemia in hemodialysis (HD) patients. We recently reported that levels of total intracellular ROS (IC-ROS) in red blood cells (RBC) from HD patients are significantly higher compared to RBCs from healthy controls (HC). To further explore contribution of specific ROS to RBCs redox balance we investigated if short-term incubation of RBCs with hydrogen peroxide scavenger pyruvate (PYR), hydroxyl radical scavenger mannitol (MANN), peroxynitrite scavenger ebselen (EBS) and uremic toxin indoxyl sulfate (IS) can modulate IC-ROS and influence eryptosis.

Methods: RBCs from HC Li heparin blood were treated for 30 min at 37°C with PYR (5mM), MANN (20mM), EBS (20uM) or IS (50ug/ml) alone or were pretreated with PYR, MANN, EBS or ROS inhibitor N-acetyl-L-cysteine (NAC, 5mM) following by 30 min incubation with IS. Levels of eryptosis and RBCs IC-ROS were assessed using flow cytometry with Annexin-V-FLUOS (Roche) and Total ROS/SO Kit (Enzo). Statistical analysis was done with K-S statistics, P<0.05 was considered significant; results presented as mean±SD.

Results: Incubation of RBCs with IS resulted in significantly increased IC-ROS (54.38±3.59% versus 32.22±7.28%) and elevated eryptosis (1.84±0.42% versus 1.06±0.38%) compared with RBCs incubated in Ringer. Pretreatment of RBCs with MANN orPYR did not affect fluorescent signals triggered by subsequent incubation with IS (53.16±5.55% or 45.70±7.11%). Pretreatment of RBCs with EBS significantly decreased ROS signal before and after incubation with IS (13.52±14.24% and 19.03±15.27%), but resulted in massive eryptosis (22.04±7.16% and 28.58±5.9%). NAC abolished IS triggered ROS production (30.61±13.41%) and eryptosis (1.64±0.82%).

Conclusions: Short-term incubation of healthy RBCs with IS resulted in significant increase in intracellular ROS and eryptosis, suggesting additional mechanism of IS uremic toxicity. Modulation of ROS and eryptosis by scavenging of peroxynitrite indicates its significance in redox balance and RBCs lifespan and warrants further investigation.

TH-PO827

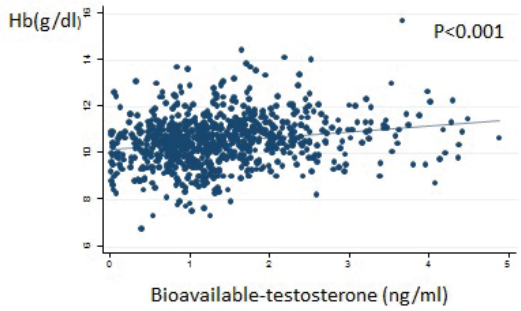
Bioavailable-Testosterone Affects Renal Anemia in Male Hemodialysis Patients Akio Nakashima,[1] Ichiro Ohkido,[1] Keitaro Yokoyama,[1] Mitsuyoshi Urashima,[2] Takashi Yokoo.[1] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan; [2]Div of Molecular Epidemiology, Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Among hemodialysis patients, low serum testosterone was reported to associate with high mortality. Recently, bioavailable-testosterone (BT) has been suggested more accurate than total-testosterone (TT) to know testosterone deficiency. However, there are no reports to study relationship between BT and renal anemia. Therefore, we aimed to investigate the relationship between serum BT levels and anemia in hemodialysis patients. We also analyzed the copy number variants (CNVs) of *UGT2B17* gene, of which product metabolizes testosterone. Deletion of *UGT2B17* gene, which may increase the serum levels of testosterone, is known to highly prevalent in Japanese.

Methods: The prospective cohort study was carried out at 17 dialysis units in Tokyo Japan. We included 820 male hemodialysis patients who were older than 20 years and agreed to participate in this study. DNA was isolated from leukocytes from peripheral blood. We used real-time polymerase chain reaction to detect CNVs of *UGT2B17*.

Results: Median age was 63.4 years, and average duration of dialysis was 8.75 years. Mean BT was 1.37ng/ml and mean hemoglobin was 10.5g/dl. CNVs of *UGT2B17* gene were as follows: 0-copy: 645; 1-copy: 173; 2-copies: 2. Although TT did not show significant associations with hemoglobin levels (r=0.038 P=0.144), BT strongly correlated with it (r=0.2, P<0.001) in both single and multivariate analysis using age, PTH, Alb, TSAT and CRP.There was no relationship between the levels of BT and *UGT2B17* CNVs.

【The relationship between Bioavailable-testosterone and hemoglobin】



Conclusions: BT may associate with anemia in male hemodialysis patients, which imply testosterone as a novel therapeutic use for anemia in dialysis male patients with low levels of BT.

TH-PO828

Ergocalciferol Supplementation Does Not Reduce the Requirement of Erythropoietin (EPO) Stimulating Agent in Hemodialysis (HD) Patients Gaurav Agarwal, Padam Hirachan, Paolo Fanti, Shweta Bansal. *Div of Nephrology, Univ of Texas Health Science Center, San Antonio, TX.*

Background: Vitamin D deficiency (VDD) is highly prevalent in dialysis patients and has been associated with anemia and EPO resistance. The aim of this study was to evaluate the effect of ergocalciferol supplementation on EPO dose.

Methods: We conducted a case-control study of 186 patients, who were on HD for at least 3 months and had 25-hydroxyvitamin D (25OHD) level < 30 ng/ml. Over a period of one year, 107 patients were treated with protocol based ergocalciferol (case) and 79 were not (control). Parameters of erythropoiesis, mineral metabolism and monthly doses of EPO, intravenous iron and paricalcitol were assessed at 6- and 12- months of ergocalciferol treatment.

Results: The baseline characteristics including demographics and clinical parameters were similar in the two groups except for serum ferritin and transferrin saturation levels which were significantly higher in cases. At 12 months, mean 25OHD level increased from 16.2±7.5 to 30.5±11.7 ng/ml in cases compared with 19.2±6.8 to 14.2±9.3 ng/ml in the control group (p<0.001). However, there was no significant difference between the two groups in EPO dose requirements (28401±27203 versus 25758±32882 U/month, p=ns). Hemoglobin level and other iron parameters were similiar by the end of the study between 2 groups. There was a significant reduction in the paricalcitol dose in the cases compared to the controls (23.7±19.7 versus 38.1±28.2 μg/month, p<0.001); however, the cases had higher parathyroid hormone (452±547 versus 328±220 pg/ml, p=0.059) and phosphorus levels (5.7±1.8 versus 5±1.3 mg/dl, p=0.01). On multivariate regression analysis there was consistently no effect of ergocalciferol treatment on EPO dose (p=ns). Over an extended observation of 30 months, when some of the patients in the control group received ergocalciferol, we found no difference in EPO dose according to different levels of 25OHD (p=ns).

Conclusions: Treatment of VDD with one year of ergocalciferol was not associated with reduction in EPO dose in HD patients. Further studies are warranted to determine definitive role of nutritional vitamin D in HD patients.

TH-PO829

Vitamin B6 Supplementation Increases Resistance to Erythropoiesis-Stimulating Agents in Prevalent Hemodialysis Patients: A Bicenter, Open-Label, Randomized Controlled Trial Yoshitsugu Obi,[1] Takayuki Hamano,[2] Daisuke Mori,[1] Yasuo Kusunoki,[1] Akihiro Shimomura,[1] Isao Matsui,[1] Hiromi Rakugi,[1] Yoshitaka Isaka,[1] Yoshiharu Tsubakihara.[2] *[1]Dept of Geriatric Medicine & Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Dept of Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Resistance to erythropoiesis-stimulating agents (ESA) is a risk factor of cardiovascular events and death in hemodialysis patients. Vitamin B6 deficiency, which may cause sideroblastic anemia, is common in this population. We conducted this open-label, randomized controlled trial to determine whether vitamin B6 supplementation could reduce ESA resistance index (ERI).

Methods: We screened 231 prevalent hemodialysis patients from 2 dialysis facilities in Japan. ERIs were calculated for all patients in July 2013. After excluding patients with iron

deficiency, 60 prevalent patients with ERI above the median were recruited. Participants were randomly assigned to a vitamin B6 group (60 mg of intravenous pyridoxal after each thrice-weekly hemodialysis session) or a control group. The primary outcome was change in ERI between baseline and the 12th week. We employed intention-to-treat approach and last observation carried forward imputation for missing values at 12th week.This trial is registered with the University Hospital Medical Information Network Clinical Trials Registry (UMIN-CTR), number UMIN000011786.

Results: The mean baseline ERI was 9.5 (SD, 5.3) and 10.1 (SD, 5.6) IU/kg per g/dL in the control group and the vitamin B6 group, respectively. None was lost to follow-up and 53 patients completed the study. Contrary to our hypothesis, the vitamin B6 group showed significantly increased ERI at 12th week compared with the control group by 2.4 (95% CI 0.3–4.5) IU/kg per g/dL after adjustment for baseline ERI and type of ESA (p=0.028). There were no severe or moderate adverse events associated with vitamin B6 supplementation.

Conclusions: Vitamin B6 supplementation with 60 mg of intravenous pyridoxal phosphate thrice-weekly does not improve the response to ESA in hemodialysis patients. Rather, it does increase resistance to ESA.

TH-PO830

The Role of Convection on the Long-Term Variations (Δ) of Serum Beta 2 Mycroglobulin (B_2M), C-Reactive Protein (hsCRP) Concentrations, and ESA Requirement (Δ ESA) in Uremic Patients Treated By Post Dilutional On-Line HDF

Ezio Movilli, Giovanni Cancarini. *U.O. Nephrology, Spedali Civili and Univ of Brescia, Brescia, Italy.*

Background: Inflammation and increased ESA requirement are frequently associated in patients on dialysis. On-line Hemodiafiltration (Ol-HDF), putting together high levels of diffusion and convection could improve both conditions. However, it is still not known which depurative component predominate in determining this result. Aim of the study**:** to evaluate the role of convection and diffusion on ΔB_2M, ΔhsCRP), and ΔESA in Ol-HDF.

Methods: 30 patients, 26 men, age 57±13 years, dialytic vintage 12-108 months, were switched from conventional HD to Ol-HDF**.** At 12 months the effect on ΔhsCRP, ΔB_2M, and ΔESA (U/Kg/sett) were evaluated. Other variables considered: Body weight (BW), serum albumin (sAlb), Hemoglobin (Hb), Kt/V. Iron therapy and ESA were administered IV according to the K/DOQI guidelines. Qb, treatment time and Qd remained constant. Ol-HDF was performed utilizing High-flux membranes 1.9-2.1 sqm. Ultrapure dialysate was employed in both HDF and HD treatments. Data are expressed as mean±SD. Paired t test, Mann-Whitney U test, simple and multiple regression analysis were employed for statistical evaluation.

Results: Total convective volume (TCV) was 21.8±1.7 l/session. Significant reduction of hsCRP: (from 5.3±7.5 to 2.1±2.7 mg/dl; p<0.01), B_2M (from 29.0±14.4 to 21.3±12.3 mg/dl; p<0.0001) and ESA (from 92±6 to 57±35 U/Kg/week; p<0.008). No significant variations of Kt/V, Hb, BW, sAlb. A significant inverse correlation was found betweenTCV and ΔB_2M (r: 0.74; p<0.0001), and TCV and ΔhsCRP (r: 0.41; p<0.02), no correlation between TCV and ΔEPO. No correlation was found between Kt/V and ΔB_2M, ΔhsCRP, and ΔESA. Multiple **r**egression analysis with ΔEPO as dependent variable showed ΔhsCRP as the only significantly associated independent factor (p<0.008).

Conclusions: Ol-HDF induces a long-term significant reduction of B_2M and hsCRP concentrations. This reduction is directly correlated to the amount of TCV. The observed reduction in ESA requirement is associated to decrease of inflammation and is independent from convection.

TH-PO831

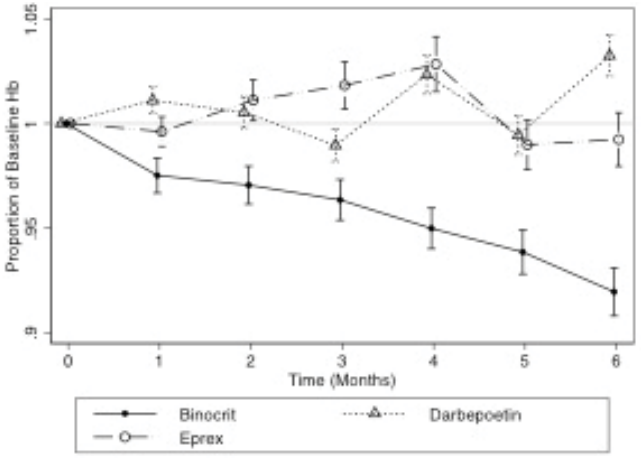
Efficacy Comparison of HX575 (Biosimilar Epoetin Alpha, Binocrit) with Epoetin Alpha (Eprex) and Darbepoetin Alpha (Aranesp)

Thomas F. Hiemstra,[1] Andrew C. Fry,[2] Nicholas R. Pritchard.[2] *[1]School of Clinical Medicine, Univ of Cambridge, United Kingdom; [2]Addenbrooke's Hospital, Cambridge, United Kingdom.*

Background: Biosimilar erythropoiesis stimulating agents (ESAs) hold promise of effective anaemia treatment at reduced cost. In a climate of austerity and escalating healthcare cost, many healthcare providers have adopted their use. However, real-world evidence of relative efficacy is limited.

Methods: In a retrospective cohort study, we identified stable dialysis patients receiving ESA treatment and converting to a different agent. We abstracted demographics, haemoglobin (Hb), CRP, PTH, phosphate, ESA and drug dose from an electronic database for the period January 2002 to December 2013, and compared Hb response after conversion between ESAs using response feature analysis and multilevel mixed effects regression.

Results: During the study period, 1545 patients receiving ESA had 109,334 Hb measurements. We identified 513 conversions, from existing treatment onto Darbepoetin (179), Binocrit (89) and Eprex (85). Baseline characteristics and starting Hb did not differ between groups. Using AUC for change in Hb over the first 6 months for each treatment as response feature, Binocrit resulted in a lower Hb over time than Darbepoetin (p=0.01), and non-significantly lower than Eprex (p=0.08)



Hb on Binocrit declined over time independent of dose, but was maintained on Eprex or Darbepoetin. In mixed effects linear regression models for repeated measures of Hb, only treatment with Binocrit (-3.2, 95% CI -5.6 to -0.7 g/L, p=0.01) and Darbepoetin (3.6, 95% CI 1.6 to 5.5 g/L, p<0.001) were associated with haemoglobin level.

Conclusions: We identified an inferior Hb response in patients changing from any ESA to Binocrit compared to those changing to Darbepoetin or Eprex. While the cost of biosimilar ESA may be lower, conversion to biosimilar ESA may result in inferior Hb responses.

Methods to Detect Candidate Serum Biomarkers of ESA Resistance

Michael Merchant,[1] Steven Alan Hawkins,[1] Daniel Wade Wilkey,[1] Susmita Datta,[2] Brad H. Rovin,[3] Jon B. Klein,[1,4] Jonathan Himmelfarb,[5] Michael E. Brier.[1] *[1]Medicine, Univ of Louisville; [2]Bioinformatics and Biostatistics, Univ of Louisville; [3]Ohio State Univ; [4]Robley Rex VAMC; [5]Univ of Washington.*

Background: Approaches to managing anemia in ESRD patient receiving dialysis include: transfusions, iron supplementation, and erythropoiesis stimulating agents (ESA). Substantial difficulties exist for predicting each patient's response to ESA dosing. We hypothesized those surrogate serum biomarkers reflect the individual's response to ESA's exist in the low abundant serum proteome (LASP).

Methods: We developed a discovery strategy using hexapeptide-bead library (Proteominer, BioRad) enrichment of LASP and isobaric tagging reagents (TMT, ThermoFisher) allow semi-quantitative LC-MS methods to establish candidate biomarkers. LASP were isolated from the serum of individuals with high (n_1=3) and low (n_2=3) erythropoietic response indexes. Enriched proteins were eluted and digested according to the FASP protocol. Samples (100ug) were labeled with TMT 6-plex reagents, admixed and analyzed using 2DLCM methods comparing 1st dimension separation with strong cation exchange (SCX) and high pH reverse phase (>pH-RP) chromatography then by 1D-LCMS analysis on an Orbitrap ELITE. Data were searched using Mascot and PD 1.4 using decoy database and PeptideProphet strategies to control FDR levels <0.1%. There were 206 proteins commonly identified within the two groups. ANOVA with an interaction was performed on the identified proteins to determine if it is differentially abundant between the two groups of ESA responders.

Results: 700+ serum proteins were identified and 206 proteins were common to the SCX and high pH RP experiments. 53 proteins were differentially abundant (FDR<0.10) including three proteins mainly expressed by the liver: haptoglobin, hepatocyte growth factor activator, and mannan-binding lectin serine protease 1. Neither the SCX or >pH-RP methods show a significant benefit based on observed protein identifications.

Conclusions: Differentially abundant proteins from these data suggest that the LASP can be used to define the response to ESA dosing.

Isocitrate Ameliorates Anemia of Inflammation in Mice Injected with Heat-Killed *Brucella abortus*

Airie Kim, Eileen Fung, Victoria Rivka Gabayan, Elizabeta Nemeth, Tomas Ganz. *Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Anemia of inflammation (AI) is a multifactorial disorder whose effects are mediated by hepcidin-induced iron restriction, interferon-γ (IFN-γ)-induced erythropoietic suppression and shortened erythrocyte lifespan. Hepcidin and IFN-γ may also act synergistically to switch the hematopoietic program from erythropoiesis to monocytopoiesis through the transcription factor PU.1. The iron-sensitive enzyme aconitase, which acts in the Krebs cycle to convert citrate to isocitrate, is thought to sense iron levels in erythroblasts and together with IFN-γ influence erythropoietin (EPO) signaling through an incompletely-defined mechanism that converges on PU.1 (Richardson, et al. JCI 2013). We explored the effects of isocitrate in our recently established mouse model of AI induced by heat-killed *Brucella abortus* (HKBA).

Methods: After two weeks on an iron-adequate diet, the mice were injected with HKBA or saline on day 0, and with isocitrate 1000 μg/g/day or saline from days -3 to 5. The mice were analyzed on day 7, 14, and 21 for iron, hematological, and inflammatory parameters.

Results: On day 7, the isocitrate-treated mice had a dramatically attenuated anemia (Hb 11.7 versus 6.3, p<0.001), but this difference was no longer evident on days 14 and 21. Reticulocyte product indices showed increased erythropoiesis of the treated mice on days 7 (7.6 versus 3.0, p<0.05) and 14 (15.1 versus 10.2, p<0.05), despite similar serum EPO levels in isocitrate and control mice. SAA1 mRNA, regulated by IL-6, and hepcidin mRNA, which causes iron restriction, were both unchanged or increased in treated mice (SAA1 day 7: 0.018 versus 0.002; hepcidin day 14: 0.158 versus 0.103; p<0.05, the rest unchanged). White blood cell count (day 7: 19.9 versus 9.7, p<0.001) and platelet count (day 7: 538 versus 238, p<0.05) were also increased in the isocitrate-treated mice.

Conclusions: Isocitrate treatment in our mouse model of acute and severe AI results in a dramatic but transient improvement in anemia. The treated mice have increased erythropoiesis despite similar EPO levels and increased inflammation. The mechanism of these effects remains to be elucidated.

TH-PO834

Erythropoietin Resistance Index Does Not Represent Physiological Resistance

Yossi Chait,[1] Joseph Horowitz,[1] Christopher V. Hollot,[1] Rajiv P. Shrestha,[2] Michael J. Germain.[3] *[1]Univ of Massachsuetts, Amherst, MA; [2]4Octet Research Inc., Watertown, MA; [3]5Western New England Renal & Transplant Associates, PC, Springfield, MA.*

Background: The Erythropoietin (EPO) resistance index (ERI) is commonly used to study the association between EPO and all-cause and cardiovascular disease morbidity and mortality. Our objectives were to show that ERI is a poor measure of the physiological notion of resistance, and to propose a new measure, the patient-specific resistance (PSR).

Methods: ERI was calculated using retrospective data on 43 ESRD patients receiving EPO. A linear relation between ERI and corresponding EPO doses was used to predict ERI based only on EPO. Patient-specific resistances, the inverse of the sensitivity of Hb to changes in EPO dose, were computed from patient-specific parameters in a validated erythropoiesis model.

Results: ERI was weakly correlated with Hb (Figure, left top) and strongly linearly related with EPO doses based on ERI = (population mean of 1/Hb)×EPO (left bottom). This relation predicted 86% of weekly ERIs within 15% of actual values. Results for ERI computed from monthly and 3-month EPO and Hb averages were similar. For 20 patients, a single, individualized model was valid over the 16-month study period and the corresponding PSR remained constant over that time. For the others, PSR remained constant for periods ≥ 90 days, changing once for 20 patients and twice for 1 patient. Correlation between EPO and PSR was low for < 8600 IU/week (right).

Conclusions: ERI is strongly linearly related to, and thus closely tracks EPO doses. Hence it is a surrogate of EPO dose and does not reflect physiological resistance. In contrast, PSR accurately reflects resistance since it is computed from an individualized and physiologically-motivated erythropoiesis model.

Treatment with High Dose of Erythropoiesis-Stimulating Agents and Mortality: A Sequential Cox Approach and Marginal Structural Model

Marit M. Suttorp,[1] Tiny Hoekstra,[1] Moshe Mittelman,[2] Raymond T. Krediet,[3] Friedo W. Dekker,[1] Hein Putter.[4] *[1]Dept of Clinical Epidemiology, Leiden Univ Medical Center, Netherlands; [2]Dept of Medicine, Tel Aviv Sourasky Medical Center, Israel; [3]Dept of Nephrology, Academic Medical Center, Univ of Amsterdam, Netherlands; [4]Dept of Medical Statistics, Leiden Univ Medical Center, Netherlands.*

Background: Anemia-correction trials in chronic kidney disease patients indicated higher mortality rates in patients assigned to higher hemoglobin targets. The safety of the high erythropoiesis-stimulating agent (ESA) doses that these patients received was therefore questioned. Thus we aimed to estimate the effect of high ESA dose on mortality in a cohort of incident dialysis patients.

Methods: NECOSAD is a Dutch cohort study of incident dialysis patients in which ESA dose, co-morbidities and laboratory parameters were collected every 6 months. Mortality in patients with a high ESA dose (above median 6000 units/week) was compared to patients with a low ESA dose with Cox regression analyses. To handle time-dependent confounding, a sequential Cox approach was used conditional on baseline covariates, with inverse probability of censoring weights (IPCW) for any dependent censoring, including ESA treatment switch and kidney transplant. Analyses were repeated with a Marginal Structural Model (MSM) with inverse probability weights for ESA treatment and IPCW for ESA treatment switch and kidney transplant. Weights were stabilized and based on age, gender, primary kidney disease, co-morbidities, nutritional status, hemoglobin, ferritin, albumin, residual renal function and dialysis modality.

Results: Hazard Ratio (HR) for high ESA dose was 1.20 (95% CI 0.83-1.73) with a sequential Cox and 1.54 (95% CI 1.08-2.18) with a MSM. Truncation of weights in the MSM did not affect estimates. To compare: conventional Cox analyses indicated a baseline adjusted HR of 1.66 (95% CI 1.20-2.31).

Conclusions: Patients treated with high ESA dose have a 1.2-1.5 increased risk of mortality. Our analyses support guidelines advising a conservative ESA dosing regimen, which carefully weighs the patients benefits and risks.

Hemoglobin Outcomes During Routine Use of Continuous Erythropoietin Receptor Activator (C.E.R.A.)

Dirk Markus Henrich,[1] Michael Rambausek.[2] *[1]Dialysezentrum Saarlouis, Saarlouis, Germany; [2]Dialyse, Heilbronn, Germany.*

Background: Continuous erythropoietin receptor activator (C.E.R.A.) permits once-monthly dosing of ESA therapy in the maintenance phase compared to up to thrice weekly dosing with shorter-acting agents. The aim of the current study was to evaluate hemoglobin (Hb) outcomes associated with routine C.E.R.A. use in CKD patients at German nephrology centers, and compare outcomes by center size.

Methods: This was a 12-month prospective, observational study of adult patients with dialysis-dependent or non-dialysis-dependent CKD receiving *de novo* or ongoing C.E.R.A.

Results: During December 2009 to February 2013, 1,510 evaluable patients (78.4% dialysis-dependent, 21.6% non-dialysis-dependent) were recruited at 33 centers: 14 large centers (>100 patients), 19 small centers (≤100 patients). In the 16 weeks prior to study entry, 1,061 patients (70.3%) had received ESA therapy, including C.E.R.A. (n=482), darbepoetin alfa (n=257), epoetin beta (n=235) and epoetin alpha (n=131). Overall, C.E.R.A. dose (mean±SD) was 109±76μg at study entry; final dose was 121±99μg. The median number of dose changes was 3.0 (range 0–14) in large centers versus 1.0 (0–12) in small centers. Mean Hb was 11.2±1.3g/dL at study entry versus 11.6±1.2 at month 12. Mean intra-individual Hb fluctuation during the 12-month study was 1.5±0.8g/dL. Patients at larger centers maintained stable Hb values within 10–13g/dL more frequently than patients at smaller centers. Five patients discontinued C.E.R.A. due to adverse events (0.3%). At the final study visit, 45.4%, 39.9%, 9.0% and 2.1% of physicians were very satisfied, satisfied, undecided or dissatisfied with C.E.R.A. therapy; for patients, the proportions were 39.3%, 47.2%, 7.5 and 1.1% of patients.

Conclusions: Hb level showed a small increase during this 12-month observational study, accounted for by C.E.R.A. initiation in ESA-naïve patients. There was a low rate of Hb fluctuation during C.E.R.A. therapy. More frequent C.E.R.A. dose adjustments at larger centers were associated with more frequent achievement of Hb target range (10–13g/dL). Over 85% of physicians and patients were very satisfied/satisfied with C.E.R.A. therapy.

TH-PO837

Responsiveness to Erythropoiesis-Stimulating Agent and Long-Term Outcomes in Chronic Hemodialysis Patients

Kosaku Nitta. *Dept of Medicine, Kidney Center, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan.*

Background: Responsiveness to erythropoietin-stimulating agent (ESA) may be associated with mortality risk in hemodialysis (HD) patients. The aim of the present study was to assess the relationship between responsiveness to ESA and long-term outcome in chronic hemodialysis (HD) patients.

Methods: Patients on HD therapy for more than 6 months were enrolled in this cohort study. The first year was used to assess the longitudinal dialysis status of patients; the subsequent years were used to assess the time-dependent risk of all-cause mortality. Hazard ratios were estimated using a Cox proportional model for the association between ESA dose and hemoglobin (Hb) level and mortality, adjusting for potential confounders. The ESA resistance index (ERI) was determined as the weekly weight-adjusted dose of ESA divided by Hb concentration. Patients were divided into three groups by tertiles of ERI.

Results: Of the 320 subjects enrolled, 105 died during the follow-up period of 70.4 ± 29.0 months. When subjects were stratified by epoetin dose and Hb level into four groups, those who had low Hb despite a high dose of epoetin were associated with the highest risk of mortality among the four groups (adjusted hazard ratio 1.86; 95 % confidence interval 1.25–2.75). These highest-risk subjects had older age, lower body mass index, and lower serum levels of albumin, triglyceride and transferring saturation. The impact of serum albumin and serum ferritin on mortality risk in an adjusted Cox proportional hazards model was in accordance with low Hb and higher ESA. There was no significant difference between the mortality risk and tertile of ERI.

Conclusions: High ESA dose and low Hb level were associated with an increased risk of all-cause mortality. However, the responsiveness to ESA estimated by ERI was not related to mortality risk. These findings suggest that the responsiveness to ESA should be evaluated by different methods in HD patients.

TH-PO838

Are Hemodialysis (HD) Patients (Pts) Treated by Antiplatelet Agents (CA) and/or Vitamin K Antagonists (VKA) Really Bleeding: An Evidence by the Anemia Management (AM) Jacques B. Rottembourg. *Hemodialysis Unit, Diaverum, Paris, France.*

Background: HD Pts required frequently treatments by CA (Clopidrogel+Aspirin) and/or VKA, for atrial fibrillation (AF), cardiovascular diseases (CVD), deep-vein thrombosis (DVT), pulmonary embolism (PE), or arteriovenous fistula problems (AVF). The conséquences on AM in these Pts were never investigated.

Methods: Out of 300 Pts, 60 of them (Gr2), received CA and/or VKA and 240 did not (Gr1).We matched Gr2, with 60 Pts, included in Gr1, for age, sex, renal disease and co-morbidity (Gr3). Pts received ESA, darbepoetin alfa (DA), every 2 weeks (Q2W) and IV iron (IS). Hb level was assessed Q2W and iron parameters (ferritin [F], and TSAT), albumin level and CRP every 3 months; hospitalizations (H) were recorded.

Results: Gr1 included 240 Pts, male 65%, mean age (SD) 54.2 (16.7) years, diabetes (25%), Charlson index 7.9 (3.7); Gr2 included 60 Pts, male 75%, mean age 62.1 (12.1), diabetes in 35%, Charlson index 9.7(3.8); reasons for CA and/or VKA were AF for 18, DVT for 8, CVD for 15, PE for 8, and AVF for 11 Pts respectively. Gr3 was strictly matched with Gr2. Main results were:

Parameters	Gr1: 240 Pts	Gr2: 60 Pts	p: G1 vs Gr2	Gr3: match 60 Pts
Hb g/dl mean (SD)	11.64 (0.75)	11.20 (0.75)	p<0.0001	11.64 (0.63)
F µg/L mean (SD)	562 (341)	562 (235)	NS	588 (422)
TSAT % mean (SD)	37.5 (8.9)	35.4 (6.2)	p<0.04	39.3 (8.4)
CRP mg/L mean (SD)	9.52 (9.46)	15.9 (14.5)	p<0.001	10.3 (9.5)
Albumin g/L mean (SD)	39.9 (3.1)	38.1 (3.0)	p<0.0001	39.8 (3.3)
DA µg/kg/week mean (SD)	0.53 (0.37)	0.79 (0.47)	p<0.0001	0.48 (0.21)
IS mg/week mean (SD)	77.2 (26.3)	81.4 (28.4	NS	78.5 (26.4)
H days/pts/year mean	2.41	6.46	p<0.01	2.1

HD Pts receiving CA and/or VKA present a lower Hb level and required 1/3 more ESA; they have more co-morbidities, are more hospitalized, and present more severe biological values for CRP and albumin. Matched Pts (Gr3) have same results than Gr1. Bleeding (minimal chronic or severe) is the most common adverse event associated with CA and/or VKA.

Conclusions: HD Pts receiving for any reason CA and/or VKA, are particularly at risk, and the decision to recommend them in any clinical condition should be based on an individualized risk-benefit approach.

TH-PO839

The Impact of Erythropoietin Stimulating Agents on Quality of Life in Patients with CKD: A Systematic Review and Meta-Analysis Ravindi M. Gunasekara,[1] Yang Xu,[1] Brett M. Hiebert,[1] Blake R. Lerner,[1] Frederick Eng,[1] Kerry Macdonald,[2] Claudio Rigatto,[1] Paul Komenda,[1] Navdeep Tangri.[1] *[1]Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [2]Library Services, Univ of Manitoba, Winnipeg, MB, Canada.*

Background: Anemia is common in patients with chronic kidney disease (CKD) and those on dialysis. The use of erythropoietin stimulating agents (ESAs) has reduced the need for transfusions in CKD, but at the expense of increased cardiovascular risks and health care costs. Previous systematic reviews have suggested that ESAs have a small positive impact on quality of life (QoL), but have failed to include several recently published randomized trials. Our objective was to evaluate published randomized controlled trials examining the effect of lower versus higher doses of ESA or different hemoglobin targets on QoL in patients with CKD and those on dialysis.

Methods: We performed a systematic review and meta-analysis of studies evaluating the impact of ESAs have on all aspects of QoL in dialysis and non-dialysis CKD WE searched PubMed, EMBASE, and Cochrane Library ranged from their establishment until June 2013. The primary outcome was the change in baseline and follow up scores of two QoL instruments: Short Form (36) Health Survey (SF-36) and Kidney Disease Questionnaire (KDQ).

Results: Sixteen studies including 9842 patients met our inclusion criteria. Data from eight domains of the SF-36 and three domains of the KDQ were meta- analyzed using a random effects model. Difference in each SF-36 domain and KDQ domain were summarized. For the SF-36 domains, small clinically non-significant changes in the physical function (-1.8; 95% CI, -2.9 to -0.7) and physical role (-2.4; 95% CI, -4.0 to -0.7) domains were noted. Findings from the KDQ were similar in magnitude (Physical Domain (-0.6; 95% CI, -1.0 to -0.1), Fatigue (-0.5; 95% CI, -0.8 to -0.1).

Conclusions: In this contemporary systematic review and meta-analysis, treatment with ESA to a higher hemoglobin target did not result in any meaningful improvements in health related quality of life. Our findings support lower targets for anemia management in CKD, and recommend revisions of cost-effectiveness analyses of ESA use.

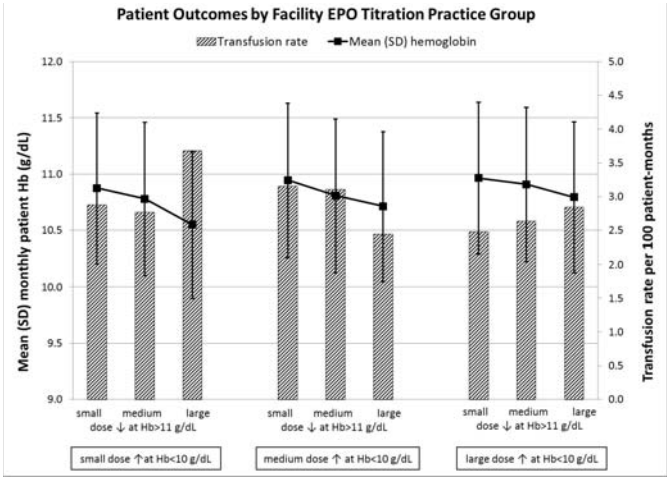
TH-PO840

Facility EPO Titration Practices, Hb Levels, and Transfusion Use Julia T. Molony,[1] Keri Monda,[2] Suying Li,[1] Anne C. Beaubrun,[2] David T. Gilbertson,[1] Brian D. Bradbury,[2] Allan J. Collins.[1] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]Amgen, Inc, Thousand Oaks, CA.*

Background: Epoetin alfa (EPO) doses and Hb levels have declined and RBC transfusion rates have risen following implementation of Medicare's prospective payment system (Jan 2011) and EPO labeling changes (June 2011) advising initiating at Hb<10 g/dL and reducing or interrupting at Hb>11 g/dL. We investigated facility-level EPO dosing practices in 2012 and their effects on Hb levels and RBC transfusion use.

Methods: Adult (≥18) patients with Medicare Parts A and B as primary payer undergoing hemodialysis in 2012 were included. From Jan-June, the month-to-month EPO dose titrations over 5 consecutive 2-month intervals were assessed. Then, for each facility, the median EPO dose titrations when Hb<10 g/dL and Hb>11 g/dL were calculated; these summary values were used to classify each facility into 1 of 9 titration practice groups. Dose escalations and reductions when Hb<10 g/dL and Hb>11 g/dL, respectively, were categorized as small (<20%), medium (20-30%), and large (>30%). The mean (SD) monthly patient Hb and RBC transfusion rate over the next 6 months was assessed by facility titration group.

Results: Each titration group included on average 7271 patients at 147 facilities. The mean and SD for monthly patient Hb was similar across all facility titration groups. Titration patterns that involved both greater dose reduction at Hb>11 g/dL and smaller dose escalation at Hb<10 g/dL produced more Hb measurements below 10 g/dL and more transfusion use. Conversely, titration patterns with both smaller dose reductions at Hb>11 g/dL and greater dose escalations at Hb<10 g/dL were associated with fewer transfusions.



Conclusions: FacilityEPO titration practices that minimize Hb<10 and Hb>11 g/dL and limit RBC transfusion may help achieve the appropriate balance of maximizing benefits while minimizing risks in accordance with product labeling.

TH-PO841

Centralized Anemia Case Management Program Is Associated with Improved Anemia Outcomes and More Efficient Medication Delivery Len A. Usvyat, Phyllis Brenda Berggren, Fern Parlier, Debra Marshall, Cindy Allegretti, Barbara Williams, John W. Larkin, Kim L. Sonnen, Jeffrey L. Hymes, Franklin W. Maddux. *Fresenius Medical Care, Waltham, MA.*

Background: FMCNA utilizes a remote centralized anemia case management (CACM) program in collaboration with clinic-based staff and physicians to improve outcomes in clinics where clinical leadership is missing, or in transition (i.e. clinic manager (CM) position is temporarily vacant). During CACM, hemodialysis (HD) patient (Pt) nurse case managers, provide comprehensive review of laboratory findings and root cause analysis for Pts with anemia issues. We investigated whether clinics enrolled in CACM experienced improvements in anemia management.

Methods: We studied all clinics enrolled in CACM from Jan 1, 2013 to Dec 31, 2013; clinics were enrolled proximal to the CM's position becoming available. Endpoints were hemoglobin (Hgb), transferrin saturation (TSAT), Epogen® (EPO) dose/HD treatment (tx) and IV iron dose/HD tx for 90 days before and after enrollment in CACM (or sooner if CM's position was filled). Paired t-tests were used to compare results.

Results: Overall, 119 clinics and 9,421 Pts in the CACM program were studied. During CACM there was reductions in both Hgb <10g/dL (p<0.0001) and >12g/dL (p=0.008), as well as, increases in Hgb in the 10-11g/dL target range (p=0.012). EPO dosing requirements did not have any significant change during CACM, although decreased by 3.7% (NS). Iron dosing had risen by 11.9% (p<0.0001) during CACM and was correlated with increases of 2.9% in TSAT ≥30% (p<0.0001).

Figure 1:	90 days before	90 days after	% change	p-value
EPO dose per HD tx	4166 (SD±4925)	4011 (SD±4726)	-3.7%	NS
% of pts with Hgb<10 g/dL	26.4%	25.2%	-4.6%	<.0001
% of pts with Hgb 10-11 g/dL	37.4%	37.8%	1.1%	0.012
% of pts with Hgb>12 g/dL	11.8%	11.1%	-5.8%	0.008
Iron dose per HD tx	19.1 (SD±21.1)	21.4 (SD±21.8)	11.9%	<.0001
% of pts with TSAT>=30%	49.4%	50.8%	2.9%	<.0001

Conclusions: This analysis identified that CACM is associated with significant improvements in meeting anemia management target outcomes without changes in EPO dosing requirements. The CACM program may be an effective tool for helping clinics with missing clinic leadership or anemia case managers.

TH-PO842

Trends in Anemia Management in U.S. Patients on Dialysis, 2005-2011

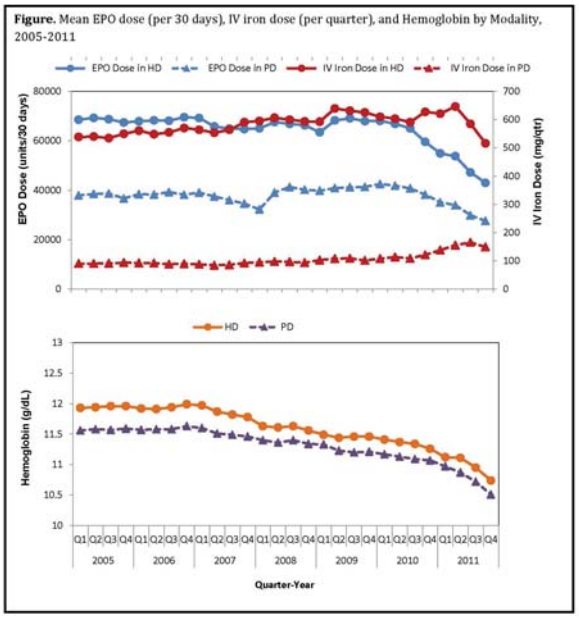
David T. Gilbertson,[1] Anne C. Beaubrun,[2] Jiannong Liu,[1] Akhtar Ashfaq,[2] Wolfgang C. Winkelmayer,[3] Glenn M. Chertow,[3] Allan J. Collins.[1] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]The Center for Observational Research, Amgen, Inc., Thousand Oaks, CA; [3]Stanford Univ, Palo Alto, CA.*

Background: The landscape of anemia management practice changed with clinical trials in the 2000s showing increased risk of adverse events with higher targeted Hb levels using ESAs, a new bundled payment system, and an ESA label revision in 2011. We investigated the impact of the most recent policy and clinical events on anemia management in dialysis patients.

Methods: We used the CMS ESRD database and included all adult (≥18) patients on hemodialysis (HD) or peritoneal dialysis (PD) for ≥9 months, 2005-2011, with Medicare as primary payer for ≥6 months. By modality, we summarized quarterly Hb levels and EPO and IV iron use and dose. As almost all patients on dialysis receive EPO, patients receiving other ESAs were excluded.

Results: About 90% of HD patients used EPO from 2005-2010; this fell to 85% in 2011. EPO use remained constant at about 70% in PD patients. Between 2005-2011, the mean monthly EPO dose in HD patients fell from ~69000 to 43000 units; the dose was more consistent for PD patients but began to decline in 2010, reaching a low of 28000 units in 2011 from a peak of 41000 in 2008. In HD and PD patients, respectively, quarterly iron use rose from 69% and 21% in 2005 to 75% and 39% in 2011. Iron dose, in contrast, rose from 2005-2010 before declining in 2011 in both groups. Hb levels, higher in HD patients, fell from 11.9 and 11.6 g/dL in 2005 to 10.7 and 10.5 g/dL in 2011 in HD and PD patients, respectively.

Figure. Mean EPO dose (per 30 days), IV iron dose (per quarter), and Hemoglobin by Modality, 2005-2011



Conclusions: Anemia management practices shifted in response to regulatory and reimbursement events, particularly recently. The clinical consequences for anemia-related outcomes warrant further study.

Funding: Pharmaceutical Company Support - Amgen, Inc.

Intravenous Iron Reverses Anemia-Induced Inflammation and Improves Cardiac Function in Anemic Rats

Jorge E. Toblli, Jorge F. Giani, Fernando Pablo Dominici, Gabriel Cao. *Univ of Buenos Aires.*

Background: Iron deficiency anemia (IDA) is very common in CKD patients greatly contributing to patient outcomes. Recent trial data with intravenous (IV) iron indicate favorable outcomes on cardiac function in iron deficient patients. This study evaluates whether IV iron therapy modifies oxidative-nitrosative stress and proinflammatory markers in the heart together with the left ventricular performance in anemic rats.

Methods: Sprague-Dawley rats, Group A: Control; Group B: IDA; Group C: IDA+IV iron. Group A received standard diet, Group B and C low iron diet for 16 weeks, after which hematology variables were evaluated (baseline). Groups continued with their corresponding diet for 4 more weeks, during which Group C received weekly administrations of IV iron sucrose (10mg Fe/kg bw) and Group A and B saline solution. Malondialdehyde (MDA) and GSH:GSSG were assessed in heart homogenates. Nitrotyrosine, heme oxygenase-1 (HO-1), NFkB(p65), TNF-a and heat shock proteins (HSP) in the heart were evaluated. Echocardiogram and tissue Doppler were also performed.

Results:

Mean ± SD	**Group A** Control	**Group B** IDA	**Group C** IDA+IV iron
Hb (g/dl)	14.6±0.5*	7.8±0.5#	11.7±0.7
Serum Iron (mg/dl)	225.9±21.7*	36.0 ±14.5#	179.6±19.9
TSAT (%)	42.2 ±2.9*	9.2 ± 2.0#	25.6 ± 4.7
MDA (nmol/mg prot.)	0.8±0.2	2.5±0.6*	1.0±0.3
GSH:GSSG (ratio)	6.5±0.9*	3.3 ± 0.6#	5.1±0.5
Heart weight to BW ratio (g/kg)	2.6±0.2*	4.1±0.4#	3.1±0.1
Cardiomyocyte size (μm)	20.7±1.0*	28.5±2.2#	23.2±1.3
Nitrotyrosine (%/mm^2)	1.9±0.4	16.1±2.7*	2.3±0.6
HO-1(%/mm^2)	2.9±0.6	21.5±1.8*	3.4±0.9
$NFkB_{65}$ (positive cells/mm^2)	2.8±0.8	15.1±2.0*	3.2±0.9
TNF-a (%/ mm^2)	1.6±0.4	10.5±1.6*	2.0±0.4
HSP27 (%/mm^2)	2.6±0.5	18.9±2.1*	3.5±0.8
HSP70 (%/mm^2)	0.9±0.2	9.8±1.9*	1.0±0.2
Fractional shortening (%)	54.8±1.5†	37.0±1.2*	49.7±1.6

*p<0.01 versus all groups #p<0.01 versus C †p<0.05 versus C

Conclusions: IV iron significantly reduced oxidative-nitrosative stress, modified favorably the inflammatory response, and improved cardiac function in anemic rats.

TH-PO844

Heme Precursor, 5-Aminolevulinic Acid (ALA), Decreases Fataxin Expression in Polymorphonuclear Leukocytes (PMNLs)

Tomoko Kimura, Kiyoko Yamamoto, Masayoshi Nanami, Yukiko Hasuike, Takahiro Kuragano, Takeshi Nakanishi. *Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Japan.*

Background: Frataxin is a mitochondrial protein and essential for utilization of iron as the synthesis of iron-sulfur clusters and heme. We have already demonstrated that mRNA levels of frataxin is significantly decreased in polymorphonuclear leukocytes (PMNLs) from the patients on maintenance hemodialysis (MHD) (Clin Exp Nephrol 2013). However, the factors affecting frataxin in MHD has not been determined. In the present study, we screened the causative substances, which could be accumulated in uremic serum.

Methods: PMNLs were obtained by differential centrifugation from healthy volunteers. PMNLs were cultured in the media added with several candidate substances including ALA, LPS, TNFα, IL-6, cysteine, β2-microglobulin for 2 hours. For determining PMNL frataxin mRNA, the quantitative PCR was performed using TaqMan polymerase. FRX mRNA was normalized using the expression of GAPDH. For the analysis of PMNL FRX protein, Western blot analysis was performed using anti-FRX polyclonal antibody.

Results: ALA decreased FRX mRNA levels dose dependently, but other substances tested did not (ALA 0; 100%, ALA 500 μM; 70 ±8 %, ALA 750 μM; 62 ±7%, ALA 1000 μM; 55 ±8 %). Western blot analysis similarly showed the decrease in FRX protein expression((ALA 0; 100%, ALA 500 μM; 69 %, ALA 750 μM; 62%, ALA 1000 μM; 42%) We also confirmed that serum ALA concentrations were higher in patients on MHD than control (84 versus 8.9 μg/L).

Conclusions: This is the first report that the expression of FRX in PMNL was significantly affected by heme precursor, ALA, which might be linked with erythropoiesis and mitochondrial dysfunction. ESA hyporesponsiveness could be associated with the dysregulated synthesis of heme and iron- sulfur clusters.

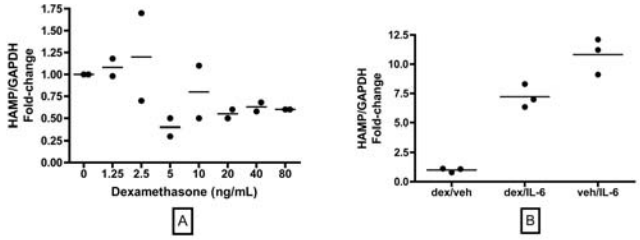
TH-PO845

Glucocorticoids May Inhibit *HAMP* (Hepcidin) mRNA in HEPG2 Cells Adam Rumjon, Iain C. Macdougall. *King's College Hospital, London, United Kingdom.*

Background: Hepcidin is the circulating hormone responsible for regulating the absorption and distribution of iron. Hepcidin levels are elevated in advanced renal failure, and this may impact on anaemia management. Previous studies have shown that hepcidin is suppressed by the sex steroids, oestrogen (*in vivo* and pre-clinical) and testosterone (clinical studies), but no data currently exist that examine the effect of glucocorticoids on hepcidin.

Methods: HepG2 cells, from a hepatoma cell line (ATCC), were cultured in Dulbecco's Modified Eagle's medium (DMEM) supplemented with 10% fetal calf serum and 5% penicillin and streptomycin. Cells were serum-starved overnight before the addition of increasing doses of dexamethasone (Sigma-Aldrich) from 1.25 ng/mL to 80 ng/mL, for a period of 18 hours. HepG2 cells were pre-treated with dexamethasone (10ng/mL) (or vehicle) for 4 hours before the addition of interleukin-6 (Life Technologies) at a concentration of 12.5 ng/mL, or vehicle, for 2 hours. Total cellular RNA was extracted (RNeasy - Qiagen) (1µg) and reversed transcribed (High Capacity RNA-to-cDNA kit-Applied Biosystems). Quantitative RT-PCR amplification reactions were performed using Taqman HAMP and GAPDH (housekeeping) primers.

Results: The dexamethasone-Hamp dose-response curve showed no suppression of HAMP at lower concentrations (<5 ng/mL), with maximal (40-50%) suppression demonstrated at concentrations ≥ 5 ng/mL (Figure A) up to 20 µg/mL (data not shown). In these preliminary experiments, IL-6 stimulated HepG2 cells that were not pre-treated with dexamethasone showed an 11-fold rise in HAMP compared to only a 7.5-fold increase in cells that were pre-treated with dexamethasone (p=0.028).



Conclusions: These preliminary data suggest that the glucocorticoid, dexamethasone suppresses HAMP expression *in vitro*, and it is possible that this is mediated via IL-6. Further confirmatory experiments will be required to test these hypotheses fully.

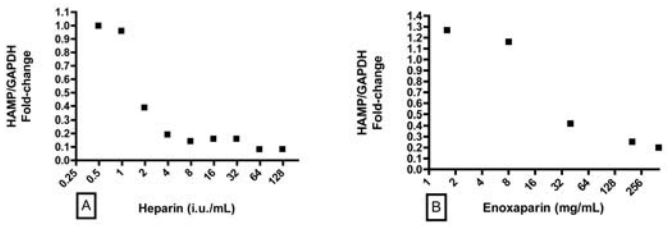
TH-PO846

Heparin May Reduce Hepcidin Levels in Dialysis Patients by Inhibiting *HAMP* mRNA Adam Rumjon, Iain C. Macdougall. *King's College Hospital, London, United Kingdom.*

Background: Hepcidin is the master regulator of iron homeostasis, and is key to the pathogenesis of anaemia in dialysis patients via its effect on regulating iron availability to the bone marrow. Understanding factors that impact on hepcidin levels are important in planning future strategies of anaemia management in CKD. A recent report suggested that there may be an effect of heparin on BMP-6-induced expression of hepcidin, and the aim of the present study was to further investigate this by examining the effect of varying concentrations of both unfractionated heparin and a low molecular weight heparin (enoxaparin) on *HAMP* mRNA.

Methods: HepG2 cells (ATCC), were cultured and grown to 70% confluence in Dulbecco's Modified Eagle's medium (DMEM) supplemented with 10% fetal calf serum and 5% penicillin and streptomycin. Cells were serum-starved overnight. Nine treatments of unfractionated heparin (LEO Pharma) (dose ranging from 0.5 to 125 i.u./mL) and six treatments of enoxaparin (Sanofi-Aventis) (0.32 to 400 mg/mL), were applied for a period of 18 hours. Total cellular RNA (1µg) was extracted using RNeasy kits (Qiagen) and reversed transcribed (High Capacity RNA-to-cDNA kit-Applied Biosystems). Quantitative RT-PCR amplification reactions were performed using Taqman HAMP (encoding hepcidin) and GAPDH (housekeeping) primers. All reactions were performed in triplicate.

Results: Both heparins inhibited hepcidin (*HAMP*) expression; maximum suppression of HAMP occurred with heparin from 4 i.u./mL (Figure A), and with enoxaparin from upwards of 32 mg/mL (Figure B).



Conclusions: This study provides further *in vitro* evidence that heparin has an inhibitory effect on hepcidin *HAMP* expression. Given that systemic anticoagulation is routinely used in haemodialysis patients to prevent extracorporeal line clotting, consideration should be given to the potential impact of regular heparinisation on hepcidin activity in this patient population.

TH-PO847

Impact of Iron Regimen on Iron Indices and Hepcidin during Roxadustat Anemia Correction in Incident Dialysis Patients Anatole Besarab, Lynda Szczech, Kin-Hung Peony Yu, Thomas B. Neff. *FibroGen, Inc, San Francisco, CA.*

Background: Roxadustat (FG4592) corrects anemia in incident ESA-naïve HD/PD patients assigned to no Fe, oral Fe, or IV Fe over a 12 wk period. Initial 6 wk ΔHb response was equal but maximal ΔHb and Hb at 12 weeks (EOT) was blunted with no Fe, while Hb response with oral iron was comparable to IV iron. This study evaluates the effect of each Fe regimen.

Methods: Post hoc study.

Results: Results are mean±SEM. At baseline (BL), iron parameters among iron regimens were similar reflecting iron depletion (TSAT/Ferritin (Ftn), but mean CHr 30.6pg; CRP 2 to 55 ng/ml; entry Hb 8.3 g/dL. CRP did not change; ΔHb was independent of BL CRP. Changes in iron parameters from BL to EoT are shown

Iron regimen (N)	ΔHb (g/dL)	Δ TSAT (%)	ΔCHr (pg)	ΔHepcidin (µM)	ΔFtn (µM)
No Iron (23)	1.98 ± 0.28[a]	-7.8 ± 1.43 [a]	-2.91 ± 0.63 [a]	-63.4 ± 13.3 [c]	-121.5 ± 12.2 [a]
Oral Iron (22)	2.68 ± 0.33 [c]	1.07 ±1 .87 [b,c]	-0.91 ± 0.13 [c]	-54.1 ± 18.4 [c]	- 51.9 ± 18.6
IV Iron (10)	3.25 ± 0.36 [c]	0.69 ± 2.89 [b,c]	-1.02 ± 0.14 [c]	-12.6 ± 31.6 [a,b]	-25.2 ± 33.5 [b]

[a] p <0. 01 from other 2 gps; [b] not different from zero; [C] no difference between pair TIBC increased in all 3 gps. Largest changes occurred in no Fe group. IV iron blocked hepcidin suppression and Ftn reduction. EOT TSAT (R^2 = 0.40), Ftn (R^2 = 0.41), and TIBC (R^2 = 0.31) correlated with EOT hepcidin in the no Fe group. EoT Ftn (R^2 = 0.73) and TIBC (R^2 = 0.40) correlated with EoT hepcidin in the po Fe group. No correlations in IV iron group. BL and EoT Ftn levels correlated (R^2 = 0.43 BL and 0.73 EOT) with hepcidin. Hepcidin correlated weakly with CRP [R^2=0.11, p=0.015] at BL but not at EoT.

Conclusions: FG4592 therapy is not impacted by inflammation and prevents iron-deficient erythropoiesis, removing parenteral iron-induced risks associated with IV iron. Even with IV iron, iron overload is avoided, likely attributable to HIF homeostasis. With FG4592, po Fe regimen was optimal and physiologic. The combination of FG4592 and po Fe offers short term and perhaps long term benefits for many intermediate iron markers and other benchmarks of anemia care.

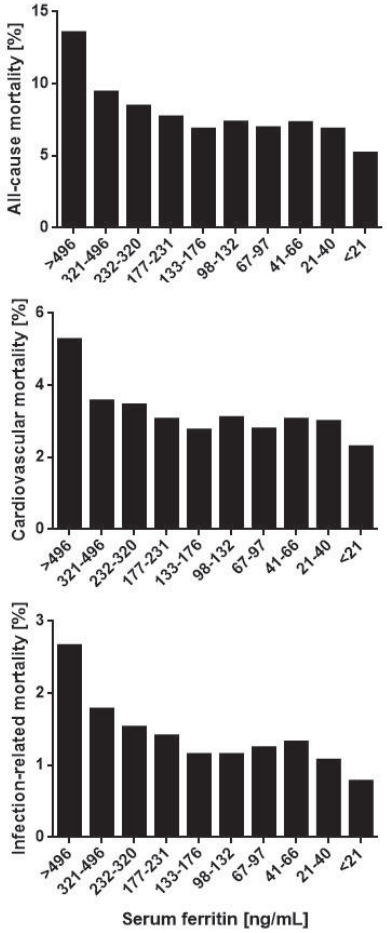
A Higher Serum Ferritin Is Associated Not Only with All-Cause Mortality but also Infection-Related Mortality among Patients Receiving Hemodialysis in Japan Yukio Maruyama,[1] Keitaro Yokoyama,[1] Takashi Yokoo,[1] Takashi Shigematsu,[2] Kunitoshi Iseki,[2] Yoshiharu Tsubakihara.[2] *[1]Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan; [2]Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan.*

Background: The monitoring of serum ferritin is widely recommended in the management of anemia in patients receiving dialysis. However, target ferritin level varies by guidelines.

Methods: We collected the baseline data of 162,818 patients receiving HD thrice weekly (65 ± 13 years, males 61.4%, and median HD vintage of 61 months) extracted from a nationwide dialysis registry at the end of 2007 in Japan. Then we evaluated the patient survival and development of complication using the registry at the end of 2008.

Results: During one-year follow-up, 12,800 (7.9%) died of all causes including 5,216 (3.2%) cardiovascular death and 2,230 (1.4%) infection death. All-cause mortality, cardiovascular mortality, and infection-related mortality were higher in line with the increase of baseline serum ferritin.



Especially, a serum ferritin >500 ng/mL was associated with a markedly elevated mortality. In a multivariable logistic regression analysis, patients of the highest quartile of serum ferritin had higher all-cause, cardiovascular, and infection-related mortality compared with those of the lowest quartile (OR, 1.24; 95% CI, 1.13 to 1.36, and OR, 1.10; 95% CI, 0.96 to 1.26, and OR, 1.24; 95% CI, 1.02 to 1.52, respectively).

Conclusions: In this large observational cohort study, higher levels of serum ferritin were independently associated not only with all-cause mortality but also infection-related mortality among Japanese HD patients. Close monitoring of serum ferritin is thought to be useful for the management of renal anemia.

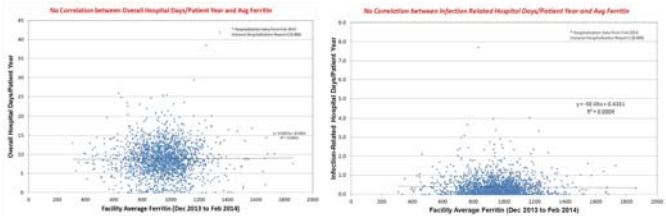
TH-PO849

Facility-Wide Mean Ferritin Levels of Hemodialysis Patients Are Not Associated with Either All-Cause Hospitalization Rates or Infection-Related Hospitalization Rates Norma J. Ofsthun, Julia I. Brennan, John W. Larkin, Len A. Usvyat, Jeffrey L. Hymes, Franklin W. Maddux. *Fresenius Medical Care North America (FMCNA).*

Background: In hemodialysis (HD) patients, higher ferritin levels are generally associated with higher levels of inflammatory markers, as well as, higher IV iron utilization. After observing that mean ferritin levels in HD patients had trended upwards with the availability of a Venofer® algorithm that includes maintenance IV iron administration, physicians in one of four geographic-based divisions of FMCNA requested an analysis to determine if hospitalization rates correlate with ferritin levels. Our aim was to determine whether there is a relationship between facility-based mean ferritin levels and all cause, or infection-related hospitalization rates.

Methods: A total of 1,984 FMCNA facilities met the inclusion criteria of ≥12 months of hospitalization data in the centralized data warehouse, and ≥25 patients with ferritin values between Dec 2013 and Feb 2014. Individual ferritin values of >10,000ng/mL were excluded. In total, 163,726 patients and over 250,000 ferritin results were analyzed. We computed each facility's mean ferritin for Dec 2013-Feb 2014, as well as, the number of all-cause and infection-related hospital days per patient year for Mar 2013-Feb 2014 in all permanent (non-transient) patients.

Results: Among FMCNA facilities, we found no relationship between all-cause hospital days and mean ferritin levels (r^2=0.0004), as well as, no association between infectious hospital days and mean ferritin levels (r^2=0.0001).



Conclusions: Among in-center HD patients, no relationship was observed on a clinic-wide basis between ferritin levels and all-cause hospitalization rates, or infection-related hospitalization rates.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America

Oxidative Stress Response to Intravenous Iron Administration to CKD Patients: Impact of Haptoglobin Genotype Zaher Armaly,[1] Amir Abd Elkadir,[1] Kamal Hassan,[3] Adel Rafik Jabbour,[1] Rawi Ramadan,[2] Bishara Shafik Bisharat.[1] *[1]Nephrology, Nazareth Hospital EMMS, Nazareth, Israel; [2]Nephrology, Rambam Health Campus, Haifa, Israel; [3]Nephrology, Western Galilee Hospital, Nahariya, Israel.*

Background: Anemia is a common disorder in CKD patients. It is attributed to decreased erythropoietin (EPO) production and iron deficiency. Therefore, besides EPO, therapy includes iron replenishment. However, the latter induces oxidative stress. Haptoglobin (Hp) protein is the main line of defense against the oxidative effects of Hemoglobin/Iron.There are 3 genotypes: 1-1, 2-1 and 2-2. Hp 2-2 protein is inferior to Hp 1-1 as antioxidant. So far, there is no evidence whether haptoglobin genotype affects iron-induced oxidative stress in CKD patients. The aim of the current study was to examine whether Hp genotype influences intravenous iron administration (IVIR)-induced oxidative stress in CKD patients, and its impact on the response of these patients to L-Carnitine therapy.

Methods: This study included 26 anemic (Hb=10.23±0.28) CKD patients (stages 2-4) that were given a weekly IVIR (Sodium ferric gluconate, [125 mg/100 ml] for 8 weeks, and during weeks 5-8 also received Carnitine (20mg/kg, IV) prior to IVIR. Weekly blood samples were drawn before and after each IVIR for Hp genotype, C-reactive protein (CRP), advanced oxidative protein products (AOPP), neutrophil gelatinase-associated lipocalin (NGAL), besides complete blood count and biochemical analyses.

Results: 8% of CKD patients were Hp 1-1, 19% Hp 2-1, and 73% Hp 2-2. IVIR for 4 weeks did not significantly increase hemoglobin levels, yet worsened the oxidative burden as was evident by elevated plasma levels of AOPP. The highest increase in AOPP was observed in Hp 2-2 patients. Simultaneous administration of Carnitine with IVIR abolished the IVIR-induced oxidative stress as was evident by preventing the elevations in AOPP and NGAL, preferentially in patients with Hp 2-2 genotype.

Conclusions: This study demonstrates that Hp 2-2 is a significant risk factor for IVIR-induced oxidative stress in CKD patients. Our finding, that co-administration of Carnitine with IVIR preferentially attenuates the adverse consequences of IVIR, suggests a role for Carnitine therapy in these patients.

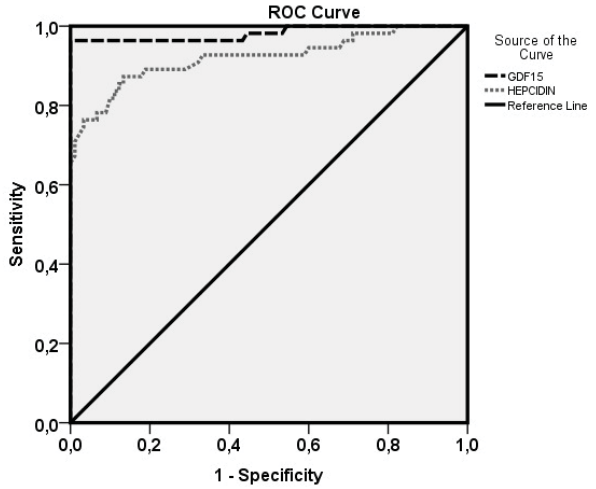
Can Serum GDF-15 Be Associated with Functional Iron Deficiency in Hemodialysis Patients? Hakki Yilmaz,[1] Osman Inan,[2] Huseyin Tugrul Celik,[3] Ayse Mukadder Bilgic,[1] Nuket Bavbek,[1] Ali Akcay.[1] *[1]Internal Medicine, Section of Nephrology, Turgut Ozal Univ, School of Medicine, Ankara, Turkey; [2]Internal Medicine, Yenimahalle State Hospital, Ankara, Turkey; [3]Biochemistry, Turgut Ozal Univ, School of Medicine, Ankara, Turkey.*

Background: The incidence of functional iron deficiency(FID) is gradually increasing in hemodialysis(HD) patients. Recently, high levels of GDF-15 supressed the iron regulatory protein of hepcidin and expression of GDF-15 increased in patients with iron deficiency. The relationship between FID and GDF-15, hepcidin is not known exactly up to now. The aim of the present study was to evaluate the association between GDF-15, hepcidin and FID in chronic HD patients.

Methods: Serum GDF-15 and hepcidin concentrations were measured in 105 HD patients and 40 controls. FID is defined as serum ferritin>800ng/mL, TSAT<25%, Hb levels <11g/dL and reticulocyte haemoglobin content (CHr) <29pg.

Results: Serum GDF-15, hepcidin levels were increased significantly in HD patients with FID, compared with HD patients without anemia and the controls. GDF-15 correlated with ferritin, hepcidin and CRP in whole group. But GDF-15 was related to ferritin and CRP in HD patients with FID. GDF-15 is better diagnostic marker than hepcidin for detection of FID [AUC=0.982(0.013) versus AUC=0.921(0.027); P=0.0324].



Conclusions: GDF-15 was appeared to be promising tool for detection of FID. High levels ferritin and CRP correlated with GDF-15. Our results supported that GDF-15 may be a new mediator of FID via hepcidin, chronic inflammation or unknown pathways.

TH-PO853

Reduction of Oxidative Stress Marker with Enhancement of Iron Metabolism following Epoetin Beta Pegol Administration in Db/db Mice Mariko Noguchi-Sasaki, Yusuke Sasaki, Yukari Matsuo, Mitsue Kurasawa, Keigo Yorozu, Yasushi Shimonaka. *Product Research Dept, Chugai Pharmaceutical Co., Ltd., Kamakura, Kanagawa, Japan.*

Background: Erythropoietin (EPO) exhibits tissue protective effect by hypoxia improvement and EPO signaling activation. Epoetin beta pegol (C.E.R.A.), a novel long-acting erythropoiesis-stimulating agent (ESA) could promote utilization of iron for erythropoiesis through intensive suppression of serum hepcidin levels. Although iron is an essential element for various biological processes such as erythropoiesis, it has potential to induce oxidative stress. We hypothesize that the reduction of iron-induced oxidative stress by utilization of iron for erythropoiesis contribute the tissue protective effect of ESA, and investigated whether C.E.R.A. could ameliorate oxidative stress with enhancement of iron metabolism in db/db mice.

Methods: Eleven-week old male db/db mice were intravenously treated with 0.5 mg/head of Iron-Dextran (Fe0.5 group) or vehicle (Fe0 group). Five days after, C.E.R.A. (10 μg/kg) or vehicle were administered intravenously to both groups (Day0). Hemoglobin (Hb), serum hepcidin level and hepatic iron content were determined. Serum derivatives of reactive oxygen metabolites (d-ROMs) were analyzed as an oxidative stress marker by measuring the total amount of hydroperoxides via the Fenton's reaction.

Results: Serum d-ROMs and hepatic iron content significantly increased in Fe0.5 group compared to Fe0 group on Day0. On Day8, Hb level significantly increased after C.E.R.A. treatment in both Fe0 and Fe0.5 groups, whereas serum hepcidin level and hepatic iron content significantly decreased. Moreover, serum d-ROMs significantly decreased after C.E.R.A. treatment in Fe0.5 group on Day8.

Conclusions: C.E.R.A. treatment promoted iron utilization for erythropoiesis through mobilization of hepatic iron storage, consequently serum oxidative stress marker was decreased in db/db mice. Our results suggest a possibility that enhancement of iron metabolism by ESA, leading to the decrease in oxidative stress, contributes to tissue protective properties. ESA may have beneficial implications for improving prognosis by correcting oxidative stress-related disorders.

Iron Sucrose (IS) and Iron CarboxyMaltose (ICM): Comparative Study in Hemodialysis Patients V. Menoyo, M. Touam, David Attaf, C. Muresan. *Echo Vannes, Vannes, France; Necker, Paris, France; Fresenius Medical Care, France; ECHO Vannes, France.*

Background: ICM, next-generation i.v. iron, is given as a bolus–push injection in haemodialysis (HD) while Iron Sucrose (IS) is given by perfusion of 100 mg. We aim to compare efficacy, safety and oxidative activity of both IS and ICM in HD.

Methods: 124 pts (73 y) are treated successively by IS 100 mg (01/2010 - 07/2011 = Period 1 (P1)) and by ICM 100 mg (08 /2011 - 12/2013 = Period 2 (P2)). P1 and P2 are compared according to : (1) biology (Hb, F, TSAT), (2) clinical status (Iron, ESA dose) and (3) oxidative stress (TSAT, generation of free iron). For the latter we assess TSAT and free iron in serum by Bleomycin-Detectable Iron (BDI) assay for different doses of i.v. iron (n=9 patients).

Results: Biology is reported in the following table:

	Hb g/dl	Ferrit. mg/l	TSAT %	ASE microg/w	Fer mg/month
P1	11,3 +/- 1	694 +/- 332	32,5 +- 15	98,8	694 +/- 332
P2	11,7 +-1,2	854 +/- 349	34,4 +- 12,5	61,8	854 +- 349
p	< 0,05	< 0,001	< 0,002	< 0,0001	< 0,07

FCM is tolerated, incidence of adverse events related to i.v. iron are similar in P1 and P2. Oxydative activities of IS (100 mg) and FCM (200 mg) are reported in the figure below:

	IS 100 mg		ICM 100 mg		ICM 200 mg TDI	
	TSAT %	BDI	TSAT %	BDI	TSAT %	BDI
Before i.v. iron	20±12	0.03±0.02	19±12	0.02±0.02	17±12	0.03 ±0.02
5 min	67±29	0.14±0.28	63±19	0.13±0.28	67±29	0.12 ±0.17
30 min	59±28	0.07±0.11	51±18	0.02±0.11	55±28	0.07 ±0.38
90 min	66±27	0.12±0.24	66±27	0.10±0.24	58±27	0.15 ±0.12
210 min	83±27	0.29±0.34	83±37	0.21±0.34	90±27	0.15 ±0.16
2-3 days after i.v. iron	20±16[a]	0.06±0.01[b]	18±06[a]	0.01±0.01[b]	19±16[a]	0.02 ±0.02[b]
Ref.	17–52 %	<0.10 µmol/l	17–52 %	<0.10 µmol/l	17–52 %	<0.10 µmol/l

Conclusions: ICM dose of 100 mg / session is well tolerated and provides comparable efficacy compared to FS. Morever ICM is less time consuming for the paramedical staff. The improvement of oxidative profile with ICM should be evaluated in appropriate clinical trials.

TH-PO855

Soluble Ferric Pyrophosphate (Triferic) Does Not Oversaturate Transferrin and Preserves Plasma Unsaturated Iron Binding Capacity Ajay Gupta,[1] Leanne Goldstein,[2] Vivian H. Lin,[1] Carrie D. Guss,[1] Raymond D. Pratt.[1] *[1]Rockwell Medical, Wixom, MI; [2]City of Hope, Duarte, CA.*

Background: Unsaturated iron binding capacity (UIBC) of transferrin in blood serves as a vital buffer for iron from dietary absorption or released from the RE system. UIBC minimizes labile plasma iron (LPI) and oxidative stress. The low molecular weight fraction of IV iron preparations contains free iron that can oversaturate transferrin, making UIBC undetectable.

Methods: Triferic™ is an investigational parenteral iron salt comprising covalent Fe-pyrophosphate-citrate complex that specifically donates iron to plasma transferrin. SFP was delivered continuously via hemodialysate (2 µM iron) to 47 CKD-HD patients at every hemodialysis session for 36 weeks (PRIME study).

Results: Changes in serum iron parameters observed during a single hemodialysis treatment using SFP dialysate are presented below.

Serum Iron Parameter Mean (SD) [Range]	Pre HD	Post HD	Post HD – Pre HD	Repeated Measures t-test P-value
Iron (µg/dL)	64.5 (25.2) [18.0-159.0]	212.8 (57.7) [54.0, 377.0]	148.2 (50.6) [4, 316.0]	<0.0001
TSAT (%)	27.8 (9.9) [10.1, 68.3]	74.8 (11.9) [35.5, 91.3]	47.1 (11.1) [1.6, 68.4]	<0.0001
TIBC (µg/dL)	232.1 (33.8) [127.0, 318.0]	281.5 (49.6) [147.0, 437.0]	49.4 (33.7) [-24.0, 185.0]	<0.0001
UIBC (µg/dL)	167.5 (33.6) [64.0-254.0]	68.8 (31.1) [26.0, 182.0]	-98.8 (30.9) [-170.0, -5.0]	<0.0001

There was no oversaturation of transferrin during 197 HD treatments with SFP. The minimum post HD UIBC was 26 µg/dL demonstrating significant residual iron binding capacity. The determinants of intradialytic decrease in UIBC were examined using a mixed effects linear regression model to evaluate change in average post HD UIBC. Significant model covariates included pre HD serum iron and TSAT, intradialytic iron and TSAT change and TIBC. Non-significant covariates were HD duration, average Qd, and IV iron during a previous hemodialysis visit.

Conclusions: Triferic delivered via dialysate (2 µM iron) does not oversaturate transferrin and preserves plasma UIBC throughout dialysis. The UIBC serves to buffer administered and dietary iron, thereby preventing oxidative stress and inflammation.

TH-PO856

Overcoming Functional Iron Deficiency in CKD-HD Patients: Triferic Bypasses RE Block and Reduces ESA Use Ajay Gupta, Carrie D. Guss, Vivian H. Lin, Raymond D. Pratt. *R&D, Rockwell Medical, Wixom, MI.*

Background: Uremic inflammation increases hepcidin levels leading to iron sequestration in the reticuloendothelial system (RES). As a consequence, functional iron deficiency (FID) and hyporesponsivness to ESAs develops.

Methods: Triferic™ (Soluble ferric pyrophosphate citrate) is a parenteral iron salt that donates iron directly to transferrin. A series of randomized, placebo-controlled clinical trials have now shown that Triferic delivered via hemodialysis can sustain iron balance by replacing obligatory iron losses, sparing ESA use [PRIME] and maintaining hemoglobin (Hgb) [CRUISE 1 and 2].

Results: The PRIME study randomized 104 iron-replete CKD-HD patients to Triferic or placebo for up to 36 weeks. ESA was titrated to maintain a target Hgb level and IV iron could be administered for serum ferritin <200 µg/L. At the end of treatment, Triferic reduced prescribed ESA by 35% (p=0.045) and IV iron by 51% (p=0.044) versus placebo while maintaining reticulocyte Hgb (CHr) and serum soluble transferrin receptor (sTfR) near baseline levels. The placebo group showed a significant decrease in CHr with increase in sTfRs (0.8±0.35 mg/L; p=0.03). Triferic did not increase serum hepcidin levels or increase markers of inflammation (CRP and IL-6) and oxidative stress (8-iso PGF2a, malondialdehyde (MDA) and isofurans). The CRUISE studies treated iron-replete CKD-HD patients with Triferic (N=299) or placebo (N=300) for up to 48 weeks. Once randomized, ESA dose change and IV or oral iron were prohibited. Triferic maintained Hgb at baseline in both studies, while placebo treated subjects showed significant declines. The primary endpoint, the mean change in hemoglobin from baseline to end of treatment between groups was 3.6 g/L in each study (p-value = 0.011). The safety profile of Triferic was similar to placebo in all studies, with no anaphylaxis and no increases in intradialytic hypotension, vascular access thrombosis, cardiovascular events or infections compared to placebo.

Conclusions: Triferic delivered via hemodialysate represents a new paradigm for iron therapy in CKD-HD patients addressing iron-restricted erythropoiesis and FID by circumventing iron sequestration syndrome.

TH-PO857

Changes in Reticulocyte Hemoglobin Equivalent Level and Efficacy of Continuous Erythropoietin Receptor Activator in Hemodialysis Patients Tadashi Kuji,[1,2] Tetsuya Fujikawa,[2,3] Midori Kakimoto-Shino,[2] Yoshiyuki Toya,[2] Satoshi Umemura.[2] *[1]Yokodai Central Clinic; [2]Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine; [3]Center for Health Service Sciences, Yokohama National Univ, Yokohama, Kanagawa, Japan.*

Background: Epoetin beta pegol or CERA (continuous erythropoietin receptor activator), a recently approved erythropoiesis-stimulating agents, has unique receptor-binding characteristics and has a long half-life. CERA was reported to cause transient decrease in reticulocyte hemoglobin equivalent (Ret-He) levels. However, the implication of the decrease in Ret-He on the erythropoiesis is unclear. This study assessed the relation between changes in Ret-He and efficacy of CERA treatment in hemodialysis patients.

Methods: A total of 47 patients were studied in treatment with monthly CERA. The target hemoglobin level was 10–11 g/dL. Maintenance CERA doses of 0, 50, 75, 100 and 150 µg were administered as appropriate. Iron supplementation was administered to maintain serum ferritin levels within the range of 50–200 ng/mL and TSAT within the range of 20%–40%.

Results: During a cycle of once-monthly CERA treatment, hemoglobin levels were higher at week 1 and 2 than those at time 0 ($P < 0.01$) and Ret-He levels were lower at week 1 and 2 than those at time 0 ($P < 0.01$). There were significant inverse correlations of changes in Ret-He levels within 2 and 3 weeks with administered CERA dose (r= -0.710, P <0.01; r=-0.515, P <0.01, respectively). Changes in hemoglobin levels were not significantly correlated with CERA doses. Significant inverse correlations were detected between changes in Ret-He within 2 weeks and changes in hemoglobin within 3 to 4 weeks (r= -0.498, P <0.01; r=-0.515, P <0.01, respectively).

Conclusions: CERA causes a significant increase in hemoglobin levels peaking 2 weeks and decrease in Ret-He level peaking one week of treatment. Greater decrease in Ret-He within 2 weeks is associated with greater increase in hemoglobin level. Decreased Ret-He levels during 2 weeks suggest relative shortage of available iron for highly-activated erythropoiesis by CERA, which may indicate the possibility of further improvement of CERA efficacy.

TH-PO858

Measurement of Annual Iron Loss By Blood Sampling and Residual Blood After Regular Hemodialysis Procedure in Japan Tatsuo Tsukamoto, Motoko Yanagita. *Nephrology, Graduate School of Medicine, Kyoto Univ, Kyoto, Japan.*

Background: Blood sampling and residual blood in the hemodialysis circuit mainly cause inevitable iron loss in hemodialysis patients. The standard of iron supplementation is different among guidelines, such as those of KDIGO and Japanese Society of Dialysis Therapy (JSDT). Since iron overload may lead not only to hemosiderosis and hemochromatosis but also worsening of systemic infection, the intravenous administering iron at the dialysis session, that is a common procedure in hemodialysis, must be strictly monitored. Although the annual iron loss by hemodialysis procedure had been reported as 1000mg~2000mg in 1990s, the advance of the technique might reduce this iatrogenic iron loss. For example, the rinse method with saline after hemodialysis is different between that in 1990s and the present in Japan. Thus, we measured iron in residual blood after hemodialysis, and calculated the annual iron loss by the JSDT standard hemodialysis.

Methods: 239 patients of Otowa Memorial Hospital were enrolled after informed consent. Men were consisted in 65.7%, and the mean age was 67±6.4 (m±SD). 43.2% was diabetic. The residual blood sample of each patient after a dialysis session was collected and diluted uniformly by 250ml saline after removal of the needle. The iron concentration was measured by the atomic absorption spectrometry methods.

Results: Since the mean concentration of iron in the residual blood diluted by saline was 670±433.5µg/dL (m±SD), the total iron loss was around 670x2.5x156=261.3mg. As the iron of the whole blood is predominantly distributed in hemoglobin (Hb), the 1mL of blood contains 34200µg/dL of iron when the Hb is 11g/dL. Thus, the iron loss by blood sampling was 205.2mg when the regular blood sampling volume is 50mL a month. Thus, the annual iron loss in hemodialysis patients would be 450~500mg.

Conclusions: 500mg of annual iron supplementation might be sufficient to maintain the iron status in hemodialysis patients in Japan, which is less than the recommendation dose by guidelines (1~2g/year). Further study is required to verify our measurement.

Funding: Government Support - Non-U.S.

TH-PO859

J-Shaped Effect of the Serum Ferritin Level on Adequate Hemoglobin Levels and a Good Prognosis in Hemodialysis Patients Chie Ogawa,[1] Fumiyoshi Kanda,[1] Kunimi Maeda,[3] Ken Tsuchiya,[2] Teiryo Maeda.[1] *[1]Maeda Inst of Renal Research, Kawasaki, Kanagawa, Japan; [2]Div of Nephrology, Dept of Medicine IV, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan; [3]Div of Nephrology, Juntendo-Nerima Hospital.*

Background: The assessment of optimal iron storage for adequate anemia control and a good prognosis for hemodialysis (HD) patients is now on moving point and thought to be important. To clarify the appropriate iron status, a 10-year survey was performed to investigate the relationships among the serum ferritin (s-ft) level, transferrin saturation (TSAT), and mortality in HD patients.

Methods: 125 HD-outpatients treated with erythropoiesis-stimulating agents (ESA) were followed from May 2002 to April 2013. The ESA and low-dose iron supplement dosages were adjusted to maintain a hemoglobin (Hb) level of 10-11 g/dL, according to Japanese guidelines. Kaplan-Meier and log-rank tests were used to analyze the patient data. The Cox proportional hazards model was constructed to assess the relative risk of death, and the interaction among the Hb level, s-ft, and TSAT was analyzed using a multiple linear regression model.

Results: The patients were classified according to TSAT and s-ft cut-off values as follows: group 1 (s-ft < 30 ng/mL, n = 15); group 2 (s-ft, 30-80 ng/mL, n = 28); and group 3 (s-ft ≥ 80 ng/mL, n = 48). A TSAT < 20% was a predictor of a poor outcome. The survival rate in group 2 was significantly higher than in the other groups ($P = 0.013$), and a Cox hazard model analysis revealed a J-shaped effect of s-ft on the survival of the patients. The cause of death was analyzed, and the low TSAT and high s-ft groups had higher mortality rates from multiple causes. A multiple linear regression model showed that s-ft had a strong effect on Hb (log [s-ft], β-coefficient -0.45: 95% CI -0.65 to -0.26, $P < 0.001$).

Conclusions: Taken together, s-ft had a J-shaped effect on the outcome of patients with renal anemia and appeared to play a larger role than the TSAT based on an analysis of the 10-year survival ratio. The present study suggested that the s-ft level should be considered in detail for the ideal control of renal anemia and that this level might be lower than the previously established level.

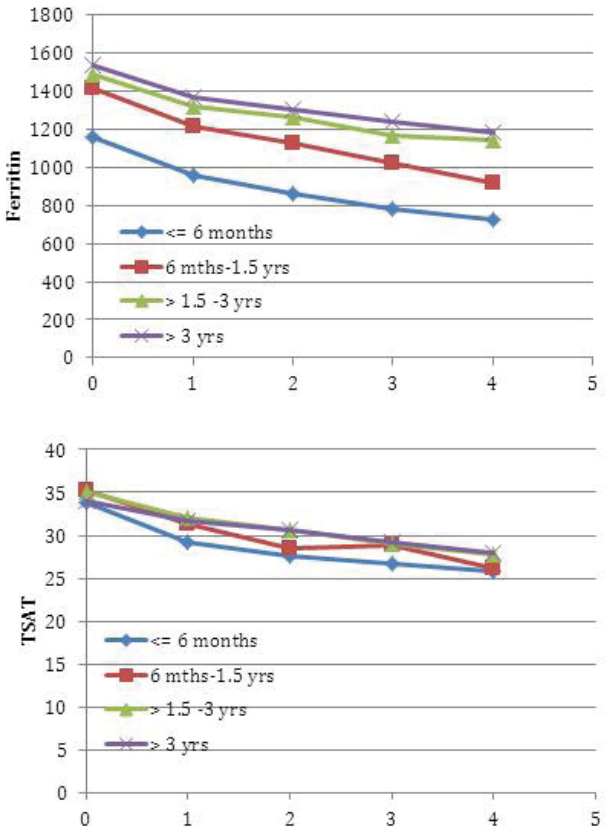
TH-PO860

Dynamics of Serum Ferritin and Transferrin Saturation (TSAT) in Hemodialysis Patients D. Miskulin,[2] S. Paine,[3] O. Myers,[1] Klemens B. Meyer,[2,3] A. Harford,[1,3] Philip Zager.[1,3] *[1]UNM, Albuquerque, NM; [2]Tufts, Boston, MA; [3]DCI, Nashville, TN.*

Background: In response to recent clinical trials and inclusion of ESAs in the 'bundle' providers are administering higher doses of iron. This has led to serum ferritin levels significantly in excess of KDIGO and the European Best Practices Guidelines. In order to design a clinical trial to assess the safety and efficacy of this practice it is important to assess serum ferritin and TSAT dynamics in response to increasing vintage and discontinuing iron therapy.

Methods: We studied patients (n=5876) dialyzed in facilities operated by DCI during 2012 and 2013. Baseline values for ferritin and TSAT were measured 13.8 ± 4.3 days after administration of ≥500 mg of iron in the preceding month. Ferritin and TSAT were then measured at regular intervals over periods of 1 to 4 months in which iron was not administered. To reduce confounding due to infection, we did not include ferritin or TSAT measurements within 14 days of an antibiotic order. Data were analyzed using mixed model regression analyses with patient random effects.

Results: Baseline least squares mean levels of ferritin (ng/ml) adjusted for age, sex and race were 1154, 1404, 1478, 1529 in patients who had been on dialysis ≤ 6, 6-18, 19-36 and >36 months, respectively ($p < 0.0001$). In contrast, there was no linear association between vintage and baseline TSAT values (p=0.27). Ferritin and TSAT decreased after iron was stopped with significant heterogeneity in the rates of decline by vintage p<0.001. Declines were faster in patients on dialysis ≤ 1.5 versus >1.5 yrs.



Conclusions: Baseline levels of ferritin but not TSAT increased with vintage, suggesting ongoing inflammation. The slow rates of decline in ferritin and TSAT after discontinuing iron suggests that a clinical trial of high versus low dose iron should be conducted among incident HD patients.

Assessing the Extent to which Research in Dialysis Is Consistent with Research Priorities Identified by Patients on Dialysis

Min Jun,[1] Braden J. Manns,[1] Andreas Laupacis,[2] Liam Manns,[1] Bhavdeep Singh Rehal,[1] Brenda Hemmelgarn.[1] *[1]U of Calgary, Canada; [2]Li Ka Shing Knowledge Inst, Canada.*

Background: There is a growing recognition that research focusing on priorities and outcomes considered relevant to patients is important. We sought to assess the extent to which recent research in patients on or nearing dialysis is consistent with the top-10 research priorities identified by dialysis patients, caregivers and clinicians.

Methods: We systematically searched the medical literature, national government and kidney research funders of Canada, U.S., UK, and Australia, and international randomized controlled trial(RCT) registries(2010-2013) to identify published original articles and funded studies(all designs-clinical studies) and registered RCTs, respectively, of adults on or nearing dialysis. All studies were grouped based on their correspondence with the top-10 dialysis research priorities(DRP) identified through a national Canadian survey and an in-person workshop of patients on or nearing dialysis, caregivers and clinicians.

Results: The search yielded 1123 published articles, 69 funded studies and 401 RCTs. The majority did not address the top-10 DRP; 195 articles(17%), 15 funded studies(22%) and 86 RCTs(21%), respectively, were relevant to these DRP.

Top-10 research priorities identified by patients on or nearing dialysis, their caregivers, and clinicians	Published medical literature; n=1123 (%)	Funding organizations; n=69 (%)	Clinical trial registries; n=401 (%)
1. How can communication between patients and care providers be improved?	1.5	8.7	0.5
2. How do the different dialysis modalities compare with one another?	4.4	1.5	0.8
3. What are the causes/effective treatments of itching in dialysis patients?	0.4	0	1.5
4. What is the best strategy to increase kidney transplantation?	1.9	0	0
5. What is the psychological/social impact of kidney failure?	0.8	0	1
6. What are the best ways to promote heart health?	5.6	4.4	9.2
7. What is the impact of dietary restrictions in dialysis patients?	0.5	0	0.5
8. What are the best ways to manage/prevent complications during/after hemodialysis?	0.9	2.9	4.5
9. What are the causes/effective treatments of depression in dialysis patients?	0.6	2.9	1.3
10. What is the best type of access for people on hemodialysis?	0.8	1.5	2.3
Not in the top-10 dialysis research priorities	82.6	78.3	78.5

In published articles not in the top-10 DRP, hemodialysis research outside the top-10 DRP(eg dialyzers;16.7%), other dialysis epidemiology(12.9%) and bone diseases(9.5%) were the most common research areas. Studies of symptom-related issues(eg itching), identified as high priority to dialysis patients, were lacking.

Conclusions: The majority of recently published or ongoing research in patients on or nearing dialysis is in areas outside the top research priorities identified by patients, caregivers and clinicians. Future dialysis studies should consider including the identified patient-centred research priorities in their design.

TH-PO862

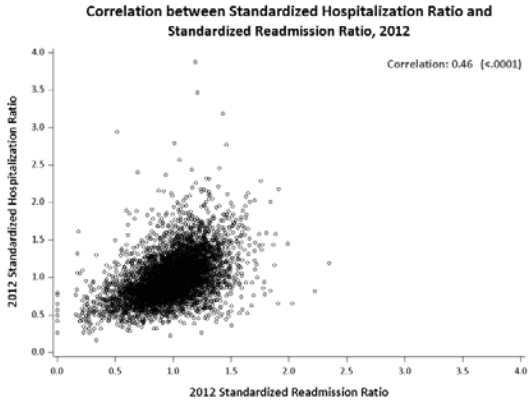
Measuring Dialysis Facility Performance on Hospital Utilization

John Kalbfleisch,[1] Zhi He,[1] Deanna Chyn,[1] John Wheeler,[1] Rajiv Saran,[1] Tempie H. Shearon,[1] Sarah Casino,[1] Claudia Dahlerus,[1] Jennifer Sardone,[1] Richard Hirth,[1] Joel S. Andress,[2] Yi Li.[1] *[1]Univ of Michigan; [2]Centers for Medicare & Medicaid Services.*

Background: Medicare uses the longstanding Standardized Hospitalization Ratio (SHR) and the more recent Standardized Readmission Ratio (SRR) to assess dialysis facilities' (DF) performance with respect to hospital usage. SHR is the number of hospital admissions divided by the expected number of admissions, adjusted for patient characteristics. The SRR is the number of hospital discharges that result in an unplanned readmission within 30 days divided by the expected number of readmissions, adjusted for similar variables plus discharging hospital.

Methods: We examined 2012 dialysis Medicare claims data for covariability in SHR and SRR among 5849 DFs and 534,609 patients. Using 95% intervals, we classified DF outcomes as being "as expected (E)," "better than expected (B)" or "worse than expected (W)."

Results: The correlation of SHR and SRR was 0.46 ($p<0.001$; see figure). 90.6% of DFs were classified E on both measures. 106 DFs classified E on SHR were classified W on SRR (see table). Although overall hospitalizations for these DFs are within national norms, they may have an opportunity to improve patient care after discharge through better care coordination. 205 DFs classified E on SRR were classified W on SHR; the rate of readmission for these DFs was within the national norm, but their higher SHR suggests an opportunity for improvement in preventing hospitalizations.



2012 Categorization of Facilities*, SHR v. SRR

	SHR Category			
SRR Category	Better than Expected	As Expected	Worse than Expected	Total
Better than Expected	11 (0.2%)	87 (1.6%)	1 (0.0%)	99
As Expected	49 (0.9%)	5077 (90.6%)	**205 (3.7%)**	5331
Worse than Expected	0 (0.0%)	**106 (1.9%)**	67 (1.2%)	173
Total	60	5270	273	5603

Note. Kappa statistic = 0.227 (SE = 0.024; 95% CI = 0.180–0.274).
*Restricted to facilities with an SHR and SRR.

Conclusions: Although there is an intrinsic correlation between SHR and SRR, the two measures are sufficiently distinct that they each carry important information about different aspects of quality of care as related to hospitalization. DFs can use SHR and SRR to motivate quality improvement and coordination in the post-discharge transition.

TH-PO863

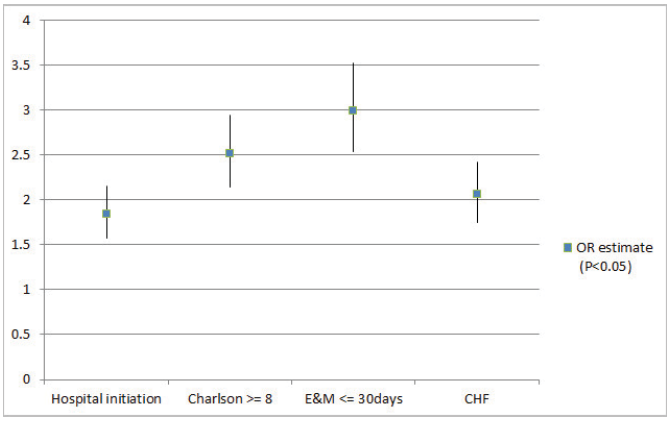
Predictors of 30-Day Readmissions among Incident Dialysis Patients: Registry Linkage to United States Renal Database System (USRDS) Data

LaTonya J. Hickson,[1] Bjoerg Thorsteinsdottir,[2] Megan Reinalda,[2] Priya Ramar,[2] Amy W. Williams,[1] Robert C. Albright,[1] Macaulay A. Onuigbo,[1] Andrew D. Rule,[1] Nilay D. Shah.[2] *[1]Nephrology, Mayo Clinic; [2]Health Care Policy &Research, Mayo Clinic.*

Background: Nearly 35% of Medicare's ESRD dollars are spent on inpatient care, much due to readmissions (ReADM). Identifying risk factors associated with Re-ADM is crucial in planning for outcome optimization.

Methods: AIM: To determine the cause, frequency, and predictors of 30-day Re-ADM over the first 2 years of dialysis in a systemwide registry. **METHOD:** Review of events in incident dialysis patients continuing therapy for ≥90 days from 2000-2010 with linkage to USRDS Medicare claims (n=2985).

Results: Mean age was 63±16, 59% males, 50% initiated dialysis in the hospital, 57% heart failure (HF), Charlson score≥8 (41%), and diabetes ESRD-cause (36%). Over 1.6±0.6 years, 81% patients were hospitalized with a rate of 1.8 PPY. Mean time to hospitalization after initiating dialysis was 6±6 months. Mean time to 30 day ReADM was 13.6+8.5 days. While, 924 (31%) patients had at least one Re-ADM, 467 had ≥2 Re-ADM. Primary diagnoses for Re-ADM were cardiovascular (21%), vascular (14%), infectious (13%), gastrointestinal (14%), and endocrine (11%). Aftercare E&M visits post ReADM were performed ≤30 days in 66%. Hospital dialysis start, Charlson≥8, HF, and an E&M visit were associated with an increased risk of ReADM (below)while gender, diabetes-ESRD, and time from first hospitalization were not.



In multivariable analysis, hospital dialysis start (OR 1.5, CI 1.3-1.8; p <0.001) and Charlson≥8 (OR 2.3, CI 1.9- 2.7; p <0.001) were the only independent predictors of readmission.

Conclusions: 30-day readmissions are common, especially within the first year of dialysis initiation. Hospital dialysis starters and those with multiple comorbidities appear to be at highest risk. Targeted interventions to reduce readmissions are needed.

TH-PO864

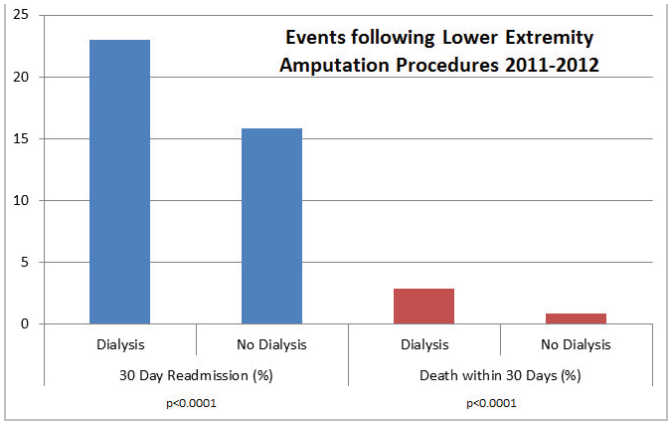
Increased Risk of 30-Day Readmissions following Lower Extremity Amputations among Dialysis Patients: American College of Surgeons National Surgical Quality Improvement Program Data (ACS-NSQIP)

LaTonya J. Hickson,[1] Andrew D. Rule,[1] Nilay D. Shah,[2] Bjoerg Thorsteinsdottir,[2] Raymond C. Shields,[3] Mark D. Fleming,[4] Daniel S. Ubl,[2] Amy W. Williams,[1] Elizabeth B. Habermann.[2] *[1]Nephrology, Mayo Clinic; [2]Health Care Policy and Research, Mayo Clinic; [3]Cardiology, Mayo Clinic; [4]Vascular Surgery, Mayo Clinic, Minnesota.*

Background: Dialysis patients have a heightened risk of lower extremity (LE) amputation. Identifying risk factors for readmissions (ReADM) and postoperative complications is crucial in care planning for optimizing outcomes following lower extremity (LE) amputation.

Methods: AIM: To determine the rate of 30-day ReADM and death following LE amputation based on dialysis-dependency. **METHODS**: Review of outcomes in all patients receiving thigh/femur and tibia/fibula amputation in the ACS-NSQIP database from 2011-2012. Patients with index length of stay >20 days were excluded.

Results: Of 5,346 patients (mean age 66±14, 37% females), 911 (17%) were dialysis dependent and 53% underwent thigh amputation. Comorbidities included: American Society of Anesthesiologists Physical Status Classification System (ASA) score ≥4 (39%), heart failure (HF) (6%), wound indication (12%), and history of revascularization or amputation (60%). Dialysis patients had more frequent ReADM and death events within 30 days of procedure.



In multivariable analysis, dialysis (OR 1.5, CI 1.22-1.76; p<.0001), ASA score ≥4 (OR 1.3, CI 1.09-1.48; p=0.002), HF (OR 1.5, CI 1.3-1.95; p=0.005), and female gender (OR 1.2, CI 1.02-1.37; p=0.03) were independent predictors of ReADM while age, race, prior revascularization, thigh amputation, and wound indication were not.

Conclusions: Independent of comorbidities, dialysis dependence is an important predictor of 30-day readmission and early death following LE amputation. Interventions aimed specifically at reducing perioperative morbidity in this high-risk population may be beneficial.

TH-PO865

Reductions in Hospital Admissions Associated with Interventions for Patients Predicted to Be at High-Risk for Hospitalization

Lisa A. Pacelli,[2] Paul M. Zabetakis,[2] Heather J. Ansede,[2] Peter Kotanko,[2] Brian Scott Ash,[1] Robert C. Sepucha,[1] Joseph A. Kuhn,[1] Dugan Maddux,[1] Terry Ketchersid,[1] Karen G. Butler,[1] Alex J. Rosenblum,[1] Susan C. Rogers,[1] John W. Larkin,[1] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Renal Research Inst (RRI), New York, NY.*

Background: Frequent hospital admissions in dialysis patients (Pts) are linked to increases in morbidities and mortalities. The aim of this pilot study was to investigate the potential impact of a high risk predictive model (PM) and clinical intervention program that was designed to reduce hospital admissions in dialysis Pts.

Methods: Six RRI dialysis facilities were utilized from March to October of 2013. Hospitalization rates were measured 90 days before and after initiating the program. Four of the dialysis facilities had high risk PM Pt identification and clinical interventions implemented, and two were controls. PM was performed to identify and target high risk Pts using clinical parameters and facility personnel assessments. Interdisciplinary facility personnel teams were deployed to design and implement clinical and non-clinical interventions.

Results: The high risk PM identified 44 Pts at four facilitates. Targeting of Pts and performing clinical interventions for 90 days was associated with a 44% reduction in hospital admissions and a decrease of 43% in hospital days, as compared to 90 days prior to any interventions. Control dialysis facilitates were monitored during the same time period; hospital admission rates were observed to have decreased by 17%, and hospital days were reduced by 15%. Accounting for concurrently matched controls, this high risk PM and intervention pilot study was associated with a 27% reduction in hospital admissions and a decrease of 28% in hospital days.

Conclusions: Predictive analytics can assist in identifying Pts at higher risk of hospitalizations. This process has the potential to aid renal care teams in understanding which Pts are at a priority to target for preventive interventions. Our project suggests that targeting of and interventions for Pts at higher risk of hospital admissions are associated with a significant reduction in hospitalizations.

TH-PO866

Hemodialysis Patient Emergency Department Visits Frequently Result in Admission to Hospital with a High Proportion to Critical Care Areas

Eduard A. Iliescu, Frances Macleod, M. Khaled Shamseddin, Alexander R. Morton. *Kingston General Hospital, Kingston, ON, Canada.*

Background: Previous studies suggest that there is excessive use of the Emergency Department (ED) by Hemodialysis (HD) patients, however recent literature on the topic is lacking. The objective of this study is to measure the frequency of ED visits by HD patients and to examine their diagnoses and disposition.

Methods: This is a retrospective cohort study of prevalent HD patients in the Region of Southeastern Ontario. The study period was 6 months (January 1 to June 30, 2013). Patients were censored if they died, transferred out, recovered or were transplanted. Kingston General Hospital (KGH) is the only in-center regional dialysis program in the region. The primary variable was the frequency of visits to the KGH ED calculated as number of visits per patient-year. The other variables were diagnosis and disposition. The data were extracted electronically from the hospital ED database using unique patient KGH identifier.

Results: There were 429 patients, mean (SD) age 65 (15) years, 196 (46 %) female, 298 (69 %) satellite patients for a total observation time of 189 patient-years. During the observation time there were 306 ED visits for a frequency of 1.62 visits per patient-year. The visits occurred among 153 (36 %) of the HD patients (range 1 - 12 visits per patient). Of the 306 visits 115 (38 %) led to hospital admission, and of these 43 (37 %) were to critical care areas. The most frequent diagnoses were infection (22 %), cardiac (14 %), and bleeding unrelated to HD access (9 %).

Conclusions: The results of this study suggest the use of the regional center ED by HD patients is relatively low at 1.62 visits per patient-year, and that these visits are justified with a high proportion of them resulting in hospital admission often to critical care areas. The strength of this study is the regional respective excluding selection bias. The main weakness is that the study does not include visits to other types of urgent health care institutions or primary care physicians, however the objective of the study was to examine the use of the regional center ED by HD patients and not their use of health care in totality.

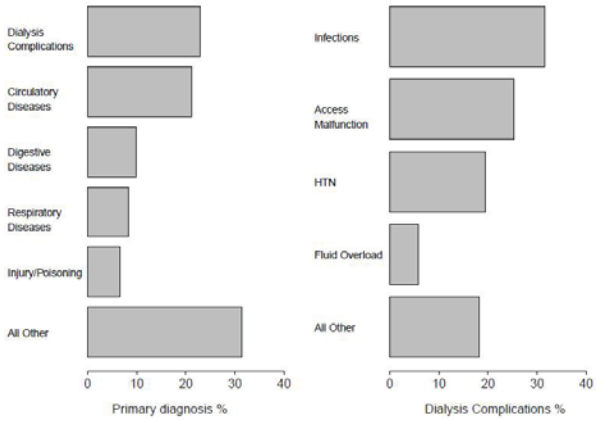
TH-PO867

Real Time Monitoring of Reasons for Inpatient Admissions among Maintenance Dialysis Patients Janet J. Singh, Fanna Liu, Jesse D. Schold, Susana Arrigain, Victoria Konig, Robert J. Heyka, Joseph V. Nally, Sankar D. Navaneethan. *Medicine, Quantitative Health Sciences and Nephrology, Cleveland Clinic.*

Background: Hospitalization rates in the dialysis population are associated with high morbidity and expenditures. We developed an inpatient dialysis registry that is being updated regularly and studied the rates and reasons for inpatient hospitalization in our health system.

Methods: We created an electronic health record (EHR) based dialysis registry that included adult patients on maintenance dialysis and met the following criteria: a) at least one overnight in-patient hospitalization, b) no previous transplantation, c) had no diagnosis for acute kidney injury within 8 weeks and d) billing details from the hospital records. Reasons for inpatient hospitalizations were categorized based on Clinical Classification System developed by the Agency for Healthcare Research and Quality.

Results: Our registry includes 6,247 maintenance dialysis patients with a total of 25,478 admissions (from January 2006 to May 2014). Mean age was 62.8 +/- 15.1 years, with 56% men. Median number of hospitalizations per patient was 2. Among the reasons of hospitalizations, dialysis related complications (23%) followed by cardiovascular diseases (21%) and gastrointestinal diseases (10%) were the leading causes. Among dialysis related hospitalizations. infection related admissions (32%) followed by dialysis access malfunction and hypertension related disorders were the common reasons for inpatient admissions.



Conclusions: In maintenance dialysis patients, dialysis related complications and cardiovascular disease accounts for half of inpatient admissions. Such real-time recognition of hospital admissions via EHR based registry may assist in developing programs to prevent rehospitalization in this high risk population.

Funding: Private Foundation Support

TH-PO868

Hospital Readmissions within 14 Days and 30 Days of Discharge: Differing Risks in Hemodialysis Patients Piangwarin Phaosawasdi,[1] Andrew I. Chin.[1,2] *[1]Dept of Medicine - Div of Nephrology, Univ of California, Davis School of Medicine, Sacramento, CA; [2]Dept of Medicine - Div of Nephrology, VA Health Systems, Mather Field, CA.*

Background: Patients on long-term hemodialysis (HD) have a high hospitalization and readmission rate. We postulate that factors associated with <14 day readmissions differ from those associated with <30 day readmissions.

Methods: Number of days from index hospitalization discharge to readmission were determined via CQI data over 2 years in adult HD patients. Factors analyzed before and after index hospitalization included: demographic data at the time of index hospitalization; HD vital signs before hospitalization and after discharge; HD access; serum albumin and hemoglobin before hospitalization; reason for admission; length of stay; and pre-existing co-morbidities.

Results: In a prevalent population of 351 HD patients, there were 1022 hospitalizations in 281 patients, 30 (11%) of whom were readmitted within 14 days (mean of 7.2 days from prior discharge) and 54 (20%) were readmitted within 30 days. Approximately 30% of patients were readmitted for a similar diagnosis as their index hospitalization, regardless of time to readmission. Using logistic regression analysis, significant factors associated with readmission included:

Factor	Odds for readmission	CI (95%)
14-day readmission		
Vintage	1.010	1.001 to 1.018
CHF co-morbidity	5.78	1.650 to 20.25
Serum albumin	0.33	0.12 to 0.93
Higher Systolic BP	0.96	0.95 to 0.98
Infection as admission Dx	0.034	0.002 to 0.535
30-day readmission		
CHF co-morbidity	2.28	1.021 to 5.099
Higher Systolic BP	0.98	0.97 to 0.99

We also looked at vital signs before and after hospitalization and noted that pre-HD systolic BP was significantly higher in those who did not get readmitted within 14 or 30 days. Pre-hospitalization weights were higher than post hospitalization weights, with no difference between <14 and <30 day groups.

Conclusions: Adult HD patients have a high rate of hospitalization and readmission. Factors associated with <14 day readmission versus <30 day readmission differ. Aggressive management of HD treatment parameters may decrease readmission rates; however, we found some factors that may not be easily modifiable.

Funding: Clinical Revenue Support

TH-PO869

The Clinical Outcomes in the Six Months after Initiation of Dialysis among Patients with Chronic Kidney Disease: A Nationwide Observational Study Hung-Bin Tsai,[1] Hsin-Ming Lu,[2] Likwang Chen.[2] *[1]Div of Hospital Medicine, Dept of Traumatology, National Taiwan Univ Hospital, Taipei City, Taiwan; [2]Inst of Population Health Sciences, National Health Research Insts, Miaoli County, Taiwan.*

Background: Prediction of survival and outcomes among chronic kidney disease (CKD) patients, especially those with geriatric multi-morbid condition is important for clinical shared decision-making.

Methods: We conducted a population-based cohort study based on the Taiwan National Health Insurance Research Database from 2000 to 2010. The CKD status was adopted at least one hospital stay or at least three outpatient visits with CKD diagnosis in one year immediately before the index day of dialysis initiation. The incident CKD dialysis patients were selected from those without any dialysis for at least two years before this index dialysis. The primary outcome is short-term mortality within 6 months of dialysis vintage. We applied the Cox proportional hazard and logistic regression model stratified by gender, age, or selected morbid conditions then performed post-estimation simulations to depict outcomes among selected patient subgroups.

Results: 50,276 incident CKD dialysis patients (49.48% male) were underlying 54% over 65 years, 6.8% malignancy including 10 reported metastasis, 5.21% severe heart failure, 1.65% severe stroke, 0.88% advanced liver cirrhosis, 0.48% organ transplant, 0.4% using mechanical ventilation at least 4 months, and 0.35% severe obstructive airway disease. The top six characteristics contributing to 1-month, 3-month, and 6-month mortality were those with prolonged mechanical ventilation (25.13%, 56.78%, 77.39%), cancer metastasis (40%, 40%, 70%), lymphoma (29.51%, 50%, 63.11%), advanced liver cirrhosis (27.5%, 51.36%, 60.91%), esophagus cancer (24%, 48%, 60%) and aged over 85 (25.67%, 56.78%, 58.88%) respectively.

Conclusions: Incident CKD dialysis patients with late stages of malignancy, advanced liver cirrhosis, oldest old had poor prognosis, and ventilator dependence had particularly worse outcome. Palliative dialysis or renal palliative care may be optional for both healthcare authority and providers to offer CKD patients with comprehensive holistic care.

Funding: Government Support - Non-U.S.

TH-PO870

Reducing Hemodialysis Therapy Non-Adherence: A Social Worker Initiated Program Stephanie Johnstone, Nien-Chen Li, Franklin W. Maddux, Amy R. Weissman-Hunt, Jessica Demaline, Eduardo K. Lacson. *Fresenius Medical Care, North America, Waltham, MA.*

Background: Missed hemodialysis (HD) treatments associate with poor outcomes. As a quality improvement (QI) project, a social worker (SW) initiated intensive program was implemented to improve treatment adherence.

Methods: The cohort included 348 patients completing ≥6 of the 8 session intervention (1 session every 1-2 weeks) from 195 FMCNA centers between 2/1/13 and 10/30/13, with at least a 6-month baseline and 6-month follow-up period. The intervention included patient-empowerment education and cognitive/behavioral counseling designed to address causes of non-adherent behavior and aggravating factors from 5 surveys: CESD-10, Stressors Screen, Sleep Quality Screen, and KDQOL-36. Pre- and Post-intervention survey scores were compared using paired t-tests, as well as 6-month baseline versus follow-up rate of missed treatments.

Results: The patients' mean age was 54 years, with 47% males; 61% white, 35% black; 56% had DM, 17% CAD, and 36% CHF. The baseline versus follow-up missed treatment rate was 146 versus 127 per 100 patient-months (p=0.008). Significant improvement (all p<0.05) of pre- to post-intervention survey scores were: Declines in CESD-10 (10 versus 7.5), Financial/Insurance Stressor (5.0 versus 4.3), Family/Relationship Stressor (4.7

versus 3.7), Health Symptoms Stressor (5.0 versus 4.6), Loss/Grief Stressor (2.7 versus 2.3), Difficulty Falling Asleep (4.3 versus 3.9), Difficulty Staying Asleep (4.5 versus 3.8), Difficulty Awakening (2.5 versus 2.1), Interrupted Sleep (4.4 versus 3.7), and Restless Legs (3.5 versus 3.0); with increases in PCS (35.7 versus 37.7), MCS (46.3 versus 49.2), Burden (60 versus 65.8), Symptoms (69.6 versus 76.7), and perception of Kidney Disease Effects (54 versus 62.6).

Conclusions: Preliminary results indicated that the intensive SW-initiated program reduced missed treatments in the short term (6 months). Furthermore, indicators of quality of life and well-being that potentially contributed to the non-adherent behavior also improved, which may help sustain the favorable results over the long term. This QI study is ongoing and updated outcomes will subsequently be reported.

TH-PO871

Dramatic Cost Reduction in a Globally Integrated ESRD Care Model: Population Management at the Top of the Care Pyramid Robert C. Albright, Kathryn Zavaleta, Jeffrey Sigrist, John J. Dillon, Ziad El-Zoghby, James T. McCarthy, Bradley D. Wick, Robert Warda, Jerilyn Sue Wilson, LaTonya J. Hickson, Amy W. Williams. *Div of Neph & HTN, Mayo Clinic, Rochester, MN.*

Background: Improving the value of care for patients with ESRD, improving outcomes while decreasing costs, requires focus on global care processes. Data from integrated care systems for ESRD patients capturing all costs along the trajectory of disease and across care sites are lacking, yet are crucial determinates of effective care. In 2010 an institution-wide project Reengineering Dialysis(RED) (CKD through renal replacement and death) began, emphasizing standardization of best practices including:robust patient education, smooth care transitions, pharmacy and palliative care partnerships.

Methods: Three years of global cost data was analyzed for an incident ESRD population whose entire care was provided by an academic multispecialty practice. Data were provided from the institutional Decision Support System, capturing all patient costs for the population studied from 2011(baseline)-2013. Costs per day reflect total cost of care divided by total calendar days of chronic dialysis care stated as % 2011(baseline) cost and were adjusted for inflation.

Results:

	2011	2012	2013	2011 vs 2013 (%)	P value (Mood median)
Number of Patients	191	181	182		
Age median	66.4	65.4	64.3		
Males (%)	116 (60.7)	110 (60.7)	111 (61.7)		
Global costs/day (*inflation adjusted stated as % of 2011 costs)	100.0	83.23	78.44	-21.6	0.004
Inpatient costs/day (*)	100.0	71.74	78.75	-21.5	0.014
Outpatient costs/day (*)	100.0	105.91	88.45	-11.6	0.024
n hospitalized (%)	129 (67.5)	108 (59.7)	100 (54.9)	-22	0.04 (Fisher exact)

Conclusions: A dramatic decrease in global costs of care among a cohort of ESRD patients exclusively managed by a multispecialty academic medical center was realized by designing and implementing a patient-centered population management strategy. This study demonstrates the value of downstream effects from managing the continuum of care for CKD and may serve as the future model of population care management, particularly in complex chronic diseases as the reimbursement structures for healthcare in our society change.

TH-PO872

Survival, Convection Volume and Treatment Time in Hemodiafiltration: A Substudy of CONTRAST Camiel L.M. de Roij van Zuijdewijn,[1] Menso Jan Nubé,[1,2] Peter J. Blankestijn,[3] Pieter M. Ter Wee,[1,2] Renee Levesque,[4] Michiel Bots,[5] Muriel P. Grooteman.[1,2] *[1]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Inst for Cardiovascular Research, VU Univ Medical Center, Amsterdam, Netherlands; [3]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [4]Nephrology, Centre Hospitalier de l'Univ de Montréal, Montréal, QC, Canada; [5]Julius Center for Health Sciences and Primary Care, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: In hemodialysis (HD) patients, survival is positively influenced by treatment time. In hemodiafiltration (HDF) patients, it was recently shown that a high convection volume (CV>21.95L) is associated with a lower mortality as compared to patients treated with HD. Treatment time, however, is one of the major determinants of CV. The present study was designed to investigate whether the survival benefit of high CV HDF is mainly due to the magnitude of the CV itself or to treatment time.

Methods: Patients from CONTRAST (NCT 00205556) were subdivided into 4 groups: HD and 3 tertiles of CV in HDF (<18.18L, 18.18-21.95L and >21.95L). Death was used as end point. Patients were censored if alive at the end of follow-up, at renal transplantation, at the occurrence of a non-fatal adverse event or moving to a non-participating center. Using Cox regression, the effect of CV on survival was investigated in 3 models: (1) crude analysis, (2) adjusted for confounders and (3) as in model 2 and adjusted for treatment time. Any change in HRs between models 2 and 3 results from treatment time as this variable is the only difference. 95% CIs of models 2 and 3 were compared to investigate if the survival benefit of high CV HDF depends on treatment time.

Results: 700 patients were analyzed. Baseline characteristics did not differ between high CV HDF patients (n=115) and HD patients (n=356). Crude analysis showed a HR of 0.61 (p=0.02) for death in high CV HDF compared to HD. HR of high CV HDF in the model adjusted for confounders was 0.62 (p<0.05) and in the model adjusted for confounders plus treatment time 0.62 (p<0.05). No difference was observed between the two models.

Conclusions: The survival benefit of high CV HDF over HD is independent of treatment time.

TH-PO873

Extended Treatment Time on Hemodialysis: Effect on Hydration and Nutritional Status Seema Singh,[1] Lina Johansson,[1] Albert J. Power,[2] Charles D. Pusey,[1] Neill D. Duncan,[1] Edwina A. Brown.[1] *[1]Imperial College Hospital NHS Trust, United Kingdom; [2]North Bristol NHS Trust, United Kingdom.*

Background: The association of nutritional status on mortality is established. However the effect on nutritional status by extending Treatment time (TT) on in-centre day HD is unknown.

Methods: Randomised cross-over study of 29 in-centre HD patients with extended TT of 6 hr or standard TT of 4 hr for a period of 24 wks with a 4wk washout period between the two arms (NCT01721421). Nutritional status was measured using hand grip strength (HGS), bioimpedance spectroscopy (BIA) and Malnutrition inflammation score (MIS).

Results: Results are summarised below.

	Pre 6 hr	Post 6 hr	p value	Pre 4 hr	Post 4 hr	p value
Extracellular water (Kg)	17.6 +/- 2.9	18.2 +/- 3.1	0.33	17.5 +/- 2.9	18.4 +/- 2.7	<0.01
Dry Weight (Kg)	77.3 +/- 11	76.7 +/- 12	0.39	76.8 +/- 14	77.4 +/- 14	0.26
Malnutrition Inflammation Score	5.6 +/- 2.1	4.7 +/- 1.2	0.06	4.9 +/- 1.5	5.1 +/- 1.7	0.56
Serum phosphate (g/dl)	1.67 +/- 0.5	1.27 +/0.5	<0.0001	1.51 +/- 0.5	1.94 +/- 0.6	<0.01
Serum albumin (g/dl)	35.2 +/- 4.9	36.5 +/- 4.9	0.17	36.2 +/- 3.8	36.7 +/- 4.6	0.57
Hand Grip Strength (Kg)	18.6 +/- 9.9	20.3 +/- 9.4	0.21	18.3 +/- 9.3	18.0 +/- 7.8	0.83

29 HD patients (27 male, mean age 65.2 ± 15.2 years, pre study TT 4.6 ±0.4hrs) were assessed.There was a significant increase in extracellular water (ECW) on the 4 hr arm which may have masked a decline in flesh weight. On the 6 hr arm, there was no change in hydration status, but there was a trend towards improved nutritional status with a lower MIS (p=0.06). There was also a significant reduction (p<0.0001) in serum phosphate levels without increased phosphate binder use, despite matching blood volume processed to that of the 4 hr arm.

Conclusions: This randomised crossover study shows increased ECW during 4 hr TT and some improvement in nutritional markers during 6 hr TT. Further studies are needed to more robustly investigate the presence of a nutritional effect.

TH-PO874

Extended Treatment Time on Hemodialysis Is Associated with Improved Blood Pressure Control and Reduced Time to Recovery Seema Singh,[1] Albert J. Power,[2] Charles D. Pusey,[1] Neill D. Duncan,[1] Edwina A. Brown.[1] *[1]Imperial College Hospital NHS Trust; [2]North Bristol NHS Trust.*

Background: Observational studies and registry data suggest improved clinical outcomes with extended treatment time (TT) on haemodialysis (HD). This has not been rigorously studied for in-centre day time HD. We report the effects of extended TT on blood pressure (BP), time to recovery (TTR) and dialysis related parameters.

Methods: Randomised cross-over study of 29 in-centre HD patients with extended TT of 6 hrs or standard TT of 4 hrs for a period of 24 wks with a 4wk washout period between the two arms (NCT01721421).

Results: Results are summarised below.

	Pre 6 hr	Post 6 hr	p value	Pre 4 hr	Post 4 hr	p value
TTR (min)	425 +/-284	134 +/- 200	<0.001	382 +/- 319	505 +/- 524	0.07
MAP (mmHg)	103 +/- 17	93 +/- 12	<0.05	99 +/- 12	104 +/-15	<0.05
UFR (ml/min/Kg)	8.2 +/- 2.4	6.1 +/- 1.8	<0.001	9.2 +/- 1.4	9.3 +/- 2.1	0.97
IDWG (Kg)	2.3 +/- 1.0	2.2 +/- 1.2	0.92	2.2 +/- 0.8	2.5 +/- 1.3	0.22
BP Drugs (n)	1.6 +/- 1.2	0.8 +/- 1.2	<0.001	1.5+/- 1.3	1.5 +/- 1.3	0.58

29 HD patients (27 male, mean age 65.2 ± 15.2 years, pre study TT 4.6 ±0.4hrs)were assessed.Pre dialysis mean arterial pressure (MAP) was significantly reduced on the 6 hr arm accompanied by a significant decrease in the number of BP drugs. Intra- dialytic weight gain (IDWG) was not significantly changed on either treatment arm, but ultra-filtration rate (UFR) was significantly lower on the extended TT arm. This could explain the significantly lower TTR during the 6 hr arm.

Conclusions: This randomised trial confirms the positive effects of extended TT on BP control achieved with lowered UFR and less reliance on antihypertensive agents. The improvement in TTR may serve to promote the acceptability of extended TT to in-centre HD patients.

TH-PO875

Mortality Risk for Incident Hemodialysis Patients in Beijing Area: A Retrospective Cohort Study Xinju Zhao, Mei Wang, Li Zuo. *Nephrology, Peking Univ People's Hospital, Beijing, China.*

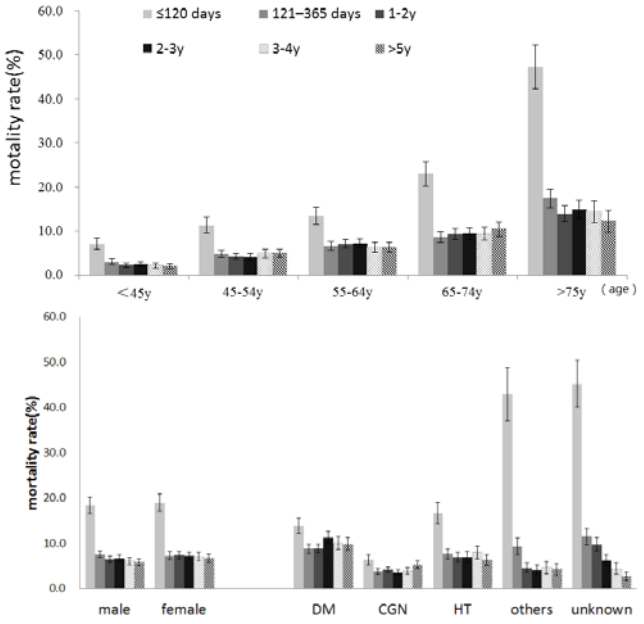
Background: Studies have shown that mortality is high for maintenance hemodialysis (MHD) patients, especially in their early dialysis stage. Here we demonstrate data from Beijing Hemodialysis Quality Control and Improvement Center (BJHDQCIC) to determine the mortality risk and pattern for incident MHD patients.

Methods: this study is based on reviewing all the incident MHD patients recorded in BJHDQCIC register system from Jan 1st2007 to Dec 31st 2012, with follow-up to the end of 2013. Their demographics, mortality, primary causes are investigated. Patients are divided into 6 groups according to their survival length, that is, whether or not died in Period (P) 1-6 (<120, 121–365 days; 1-2, 2-3, 3-4 and >5years) after initiation of dialysis. Stratified analysis by sex, age and primary disease are used.

Results: During a 6-year inclusion period, there are 11,955 patients. The patient characteristics are listed below.

follow-up time (months)	24.6±20.8
Age (mean)	57.7
18-44	22.0%
45–54	19.8%
55–64	21.8%
65–74	20.3%
≥75	16.2%
Male	56.4%
Primary causes (%)	
Diabetes(DM)	29.5
Chronic glomerulonephritis(CGN)	26.9
Hypertension(HT)	19.1
Unknown and others	24.5
Deaths	2561

The overall mortality rate is 8.2 per 100 patient-years. The rates are 7.9, 8.5 for male and female. Motality rates are 18.7, 7.5, 6.9, 6.9, 6.5 and 6.2 respectively in period 1-6. Higher mortality is observed in patients who are older, female and with other or unknown causes of ESRD. CGN group has the lowest rate. The early (P1) mortality constitutes 57.6% of the 1-year mortality and 25.2% of all death.



Conclusions: The overall mortality is relatively low in Beijing incident MHD patients. Generally, the mortality increases with age and varies among different etiology groups. Long-term survival is stable after the early dialysis period. Strategic improvement can be achieved by decreasing the early mortality rate.

TH-PO876

Dialysis Modality and Mortality in Elderly Patients: Korean National Database and Meta-Analysis Seung Seok Han,[1] Jae Yoon Park,[1] Kyung Don Yoo,[1] Dong-Ryeol Ryu,[2] Hyunwook Kim,[3] Kwon Wook Joo,[1] Chun Soo Lim,[4] Yon Su Kim,[1] Dong Ki Kim.[1] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Internal Medicine, School of Medicine, Ewha Womans Univ, Seoul, Korea; [3]Internal Medicine, Wonkwang Univ College of Medicine, Gyeonggi-do, Korea; [4]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea.*

Background: Identifying the appropriate choice between hemodialysis (HD) and peritoneal dialysis (PD) is an unresolved issue in elderly patients with end-stage renal disease, who are at high risk for mortality but have a low chance of receiving kidney transplantation.

Methods: Data on 13065 elderly Korean patients (HD, 10675; PD, 2390) were obtained from the Korean Health Insurance dataset. Multiple statistical approaches, including the multivariate Cox model, propensity score-adjusted model, marginal structural model, and one-to-one matching model were used to compare mortality between PD and HD patients. We then used a meta-analysis to provide a pooled hazard ratio (HR) based on previous comparison studies as well as the present study.

Results: During the follow-up period of 1.8 years (max. 5 years), the PD group had a higher mortality rate than the HD group [HR, 1.20 (1.125–1.275); $P < 0.001$ by multivariate Cox model]. The discrepancy between the two modalities was greater in the presence of certain conditions, such as diabetes mellitus or longer dialysis duration. These trends were similar across several statistical models. In the meta-analysis, 15 studies involving over 631421 elderly patients were reviewed. Compared with HD, the pooled HR of PD was 1.10 (1.008–1.198). When the meta-analysis was stratified by confounding factors, the survival benefit from HD was shown to be particularly strong in subgroups that had diabetes mellitus, had long dialysis durations (> 1 year), or contained cohorts starting dialysis in the 1990s.

Conclusions: Korean national data and a meta-analysis suggest a higher risk of mortality in elderly patients on PD than HD. A more precisely tailored choice of dialysis modality is needed under certain conditions.

TH-PO877

Early Mortality on Dialysis. Data from Emilia-Romagna Dialysis Registry Elena Mancini, Antonio Santoro. *Nephrology Dialysis Hypertension, Teaching Hospital Policlinico S.Orsola Malpighi, Bologna, Italy.*

Background: The mortality rates of chronic dialysis patients are much higher than those of the general population. Many Dialysis Registries do not include patients who die in the first three months of replacement therapy, so the actual mortality rate is highly underestimated, particularly as concerns the first few months of therapy. Increasing age and comorbidity of the incident dialysis patients instead greatly worsen the risk of early death.

Methods: Emilia-Romagna is a region of northern Italy, with nearly 4,500,000 inhabitants. The Dialysis Registry was established in 1994; at Dec 31, 2012 the prevalence on dialysis was 734.3 pmp (2,955 patients on HD and 324 patients on DP). Any patient entering on a chronic dialysis program is recorded in the Registry from the start of the substitution therapy. We analyzed the mortality of incident dialysis patients over 3 years (2009-2011), focusing on crude EARLY MORTALITY, defined as death occurring during the first 12 months of dialysis (the early mortality of a certain year thus includes both the incident patients of that year and the incident patients of the previous year).

Results: Early mortality was found for as many as 524 out of 1,714 patients who died in the period 2009-2011 (HD+PD), corresponding to nearly one third (30.6%) of the overall mortality. Most of the patients dying early (63.6%) were over 75 years of age. More than half (52.6%) of the patients with early mortality actually died before the third month of dialysis treatment. Nearly half of the patients on HD who died early had a temporary vascular access, often secondary to a late nephrological referral. The Karnofsky Score shows that most of the patients presented a medium-high level of inability. Cardiovascular events were the main causes of death (46.3%), especially for those patients who died in the first three months (54.9%).

Conclusions: Early mortality is a dramatic phenomenon that can be captured only by those Dialysis Registries recording all the patients incident to dialysis, independent of the survival period. The possibility of an early death should be discussed with the families of the older and more comorbid patients before starting up a chronic dialysis program.

TH-PO878

Excess Mortality Among HD Patients Compared with the General Population: Leading Causes of Death and Demographic Risk Factors Using Multiple Causes of Death Eliezer Golan,[1,2] Carmit Libruder,[3] Tamy Shohat.[2,3] *[1]Meir MC; [2]Sackler Faculty of Medicine Tel-Aviv Univ; [3]IsraelCDC.*

Background: Multiple cause of death analysis is particularly relevant for assessing patterns of mortality in patients with chronic diseases, such as dialysis patients. We compared cause-specific mortality rates among HD patients with the Israeli general population and measured the risk associated with HD treatment, adjusted for age, sex, time periods and population group (Jews/Arabs).

Methods: The study cohort included incident HD patients aged >20 from the Israeli End Stage Renal Disease Registry, treated between1990-2008. Multiple causes of death were available for the years 1998-1999, 2003 and 2007-2008.Mortality data for the general population were obtained from the Central Bureau of Statistics. Causes of death were coded

according to ICD-10.We used direct standardization to correct for age differences between patients and the general population. Cause-specific mortality rates per 100 person-years were calculated and a negative binominal regression was used to determine the effects of established risk factors on mortality in HD patients, compared with the general population.

Results: 2,646 HD patients aged ≥45 died during the follow-up period. The age adjusted mortality rates were 9.4, 6.1, 5.8, and 2.5 times higher in patients compared with the general population, for heart disease, infectious diseases, diabetes and CVA respectively. Female sex was significantly associated with increased mortality risk from heart disease, diabetes, CVA and infectious diseases (HR=1.28, 1.30, 1.36 and 1.55 respectively). Arabs had a significantly decreased mortality risk from heart disease, diabetes and infectious diseases (HR=0.59, 0.63 and 0.78 respectively). The differences in mortality rates between patients and the general population decreased with age.

Conclusions: As expected, mortality from heart disease, infectious diseases and diabetes is markedly higher among HD patients compared with the general population. Further research is needed to explore survival advantage among Arabs and survival disadvantage among females on HD, with particular attention to mortality by infectious diseases.

Funding: Government Support - Non-U.S.

TH-PO879

Improved Survival Rate of Korean Patients Initiating Dialysis in 2008

Dong-Ryeol Ryu,[1] Hyunwook Kim,[2] Hee Sung Ko,[1] Shina Lee,[1] Jung-Hwa Ryu,[1] Mina Yu,[1] Seung-Jung Kim,[1] Duk-Hee Kang,[1] Kyu Bok Choi.[1] *[1]Dept of Internal Medicine, School of Medicine, Ewha Womans Univ, Seoul, Korea; [2]Dept of Internal Medicine, Wonkwang Univ College of Medicine Sanbon Hospital, Gunpo, Korea.*

Background: The aim of this study is to investigate whether survival rate among Korean dialysis patients was significantly improved during the period between 2005 and 2008, and to compare the survival rate between HD patients and PD patients initiating dialysis in 2008 in Korea.

Methods: A total of 32,357 patients who began dialysis between January 1, 2005 and December 31, 2008 were eligible for analysis. Baseline demographics, comorbidities and mortality data were obtained from the database of the Health Insurance Review and Assessment Service.

Results: Kaplan-Meier curves according to the year of dialysis initiation showed that the survival rate was significantly different (log-rank test, $P = 0.005$), most notably among PD patients ($P = 0.000$), but not among HD patients ($P = 0.497$). In multivariate analysis, however, patients initiating either HD or PD in 2008 also had a significantly lower risk of mortality compared to those who began dialysis in 2005. Subgroup survival analysis among patients initiating dialysis in 2008 revealed that survival of PD patients was significantly higher than HD patients ($P = 0.001$), and the survival benefit of PD over HD remained in non-diabetic patients aged less than 65 years after adjustment of covariates.

Conclusions: Survival of Korean patients initiating dialysis from 2005 to 2008 has improved over time, particularly in PD patients. Younger non-diabetic patients may have a survival benefit of PD over HD.

TH-PO880

Development and Validation of a Modified Charlson Comorbidity Index to Predict Mortality in Incident Hemodialysis Patients: Result From a National Population-Based Database and a Nationwide Cohort in Korea

Jae Yoon Park,[1] Seung Seok Han,[1] Dong-Ryeol Ryu,[2] Hyunwook Kim,[3] Hajeong Lee,[1] Jung Pyo Lee,[4] Sejoong Kim,[5] Kwon Wook Joo,[1] Chun Soo Lim,[4] Yon Su Kim,[1] Dong Ki Kim.[1] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Internal Medicine, School of Medicine, Ewha Womans Univ, Seoul, Korea; [3]Internal Medicine, Wonkwang Univ College of Medicine Sanbon Hospital, Gyeonggi-do, Korea; [4]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea; [5]Internal Medicine, Seoul National Univ Bundang Hospital, Seoul, Korea.*

Background: Prediction of survival for patients with end-stage renal disease is difficult. The Charlson comorbidity index(CCI) has been used and validated to evaluate the influence of comorbidity on survival in patients with various kinds of diseases.The purpose of this study is to adjust the CCI in incident hemodialysis(HD) patients to develop a new scoring system;to validate in a separate cohort;and to compare its performance with the CCI.

Methods: We used data from a nationwide patient registry cohort to identify Korean citizens who received their first HD between 2005 and 2008(N=24,738). They were characterized by 15 comorbidities as used in CCI.The risk score was developed from coefficients of independent risk factors from Cox proportional hazard model.Findings were validated in a separate nationwide prospective cohort(N=1,309).

Results: Mortality correlated with the new scoring system(log-rank $P<0.001$).The appearance of survival curves across increasing comorbidity scores was similar for both indices,with anticipated worse survival for the higher scores($P<0.05$).The new scoring system showed higher ***c*** statistics than the CCI at 1,2,and 3 years follow-up($P<0.05$).The analyses using continuous net classification index revealed that the new scoring system improved the risk classification of mortality for 3 years since first HD started(25.8%, 29.8%, and 43.9%,$P<0.05$).The integrated discrimination improvement showed that the new scoring system improved the model performance at 2 and 3 years follow-up(0.009 and 0.016,$P<0.05$).

Conclusions: The new scoring system might predict mortality of incident HD patients more accurately than original CCI.

TH-PO881

Survival of Patients with Multiple Myeloma or Light Chain Amyloidosis on Chronic Dialysis: Data From the French REIN Registry from 2002 to 2011

Alexandre Decourt,[1] Bertrand Gondouin,[1] Jean Christophe Delaroziere,[2] Philippe Brunet,[1] Ariane Duval-Sabatier,[1] Stephane Burtey,[1] Noemie Jourde-Chiche.[1] *[1]Nephrology, Aix-Marseille Univ, Marseille, France; [2]Public Health, Aix-Marseille Univ, Marseille, France.*

Background: Multiple myeloma (MM) and light chain amyloidosis (LCA) with renal involvement can lead to end stage renal disease (ESRD). Few studies have focused on the prognosis of patients with MM or LCA on chronic dialysis. This study evaluated the survival of patients with MM or LCA on chronic dialysis in France.

Methods: Between 2002 and 2011, a total of 1459 patients with MM or LCA started chronic dialysis and were registered in the Renal Epidemiology and Information Network (REIN). We analysed survival censored for renal transplantation, recovery of renal function and loss to follow-up. Risk factors and causes of death were analyzed.

Results: A total of 860 (59%) patients with acute myeloma kidney, 265 (18%) with LCA and 334 (23%) light chain deposition disease (LCDD) were registered. Mean age was 70.5 years, and 56% were men. Within a median follow-up of 14.3 months, 977 (67%) patients died. Median survival on dialysis was 17.6 months. Causes of death were progression of hematologic malignancy in 348 (36%), infections in 119 (12%) and cardio-vascular in 102 (10%) patients. Risk factors of death were: age (OR = 1.05 [95%IC 1.03-1.073]), initiation of dialysis on a central venous catheter (OR = 1.84 [95%IC 1.05- 3.24]). Protective factors were: walking autonomy (OR = 0,44 [95%CI 0.29-0.66]), serum albumin (OR = 0.97 per g/L [95%CI 0.94-0.99]) and year of dialysis initiation (OR = 0.64 per year [95%CI 0.57-0.71]).

Conclusions: Survival of patients with MM and LCA on chronic dialysis is poor, but has improved over the past decade. Progression of hematologic malignancy is the main cause of death in this population.

TH-PO882

Enrollment of Hemodialysis (HD) Patients in an Integrated Pharmacy Management Program Is Associated with Reduced Mortality

Steven M. Brunelli,[1] Steven M. Wilson,[2] May Hoang,[3] Erik Michael Bengtsson,[3] Tracy Furgiuele.[3] *[1]DaVita Clinical Research; [2]DaVita HealthCare Partners Inc; [3]DaVita Rx.*

Background: DaVita Rx is a specialty dialysis pharmacy service providing delivery of medications to patients' homes or dialysis facilities, prescription reviews, prior authorization assistance, and refill management. We assessed the impact of DaVita Rx enrollment on mortality of HD patients, overall and within subgroups of patients treated with different drugs.

Methods: Patients received in-center HD at DaVita from Jan 2011 to Sep 2012. DaVita Rx patients were considered from time of enrollment and were propensity score-matched (2:1) to eligible controls who had never enrolled. DaVita Rx patients were censored on disenrollment. We assessed mortality rates over all follow-up time and over the intervals 0-6, 6-12, and 12-18 months following index month. Comparisons were made between DaVita Rx and controls, overall and in subgroups defined by baseline use of ACEi/ARB and beta-blockers. Incidence rate ratios (IRR) were estimated using Poisson regression.

Results: A total of 4949 DaVita Rx patients were matched to 9898 controls. Mortality rate was lower for DaVita Rx patients versus controls over all study time (9.3 versus 14.9 deaths/100 pt-years; IRR 0.63; $p<0.001$). The protective association of DaVita Rx was more pronounced over months 0-6 than later time periods, but was potent and statistically significant for all time periods. The protective association of DaVita Rx was more pronounced among ACEi/ARB (IRR 0.56; $p<0.001$) and beta-blocker users (IRR 0.60; $p<0.001$) than for the overall cohort. Temporal patterns were similar to the overall cohort.

Conclusions: DaVita Rx enrollment was associated with 37% lower mortality over the 18-month study. The association between DaVita Rx and improved survival was more potent among subgroups of ACEi/ARB and beta-blocker users than for the cohort overall.

TH-PO883

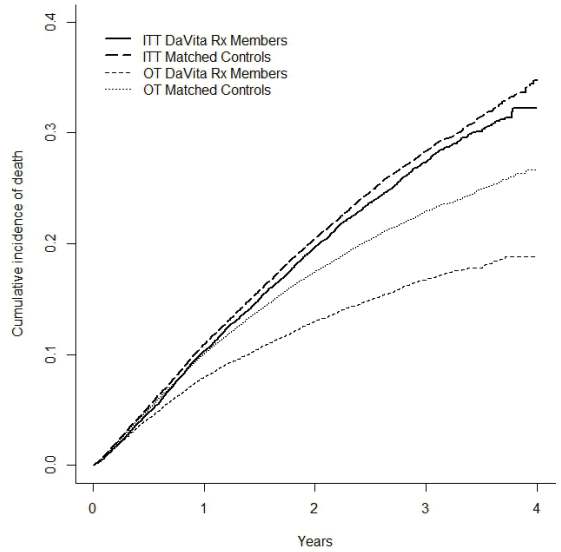
Lower Risks of Death and On-Treatment Hospitalization in DaVita Rx Members versus Matched Controls

Eric D. Weinhandl,[1] Wendy L. St. Peter.[1,2] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]College of Pharmacy, Univ of Minnesota, Minneapolis, MN.*

Background: Receiving integrated pharmacy services from DaVita Rx was associated with lower rates of death and hospitalization among poor hemodialysis patients, 2006-2008 (*AJKD*, 2012). We aimed to replicate these associations in a study of more contemporary patients, with broader inclusion criteria and stronger control of confounding.

Methods: We linked DaVita records with United States Renal Data System (USRDS) records. New DaVita Rx members had Medicare Parts A, B, and D coverage and first filled a Part D-covered medication at a DaVita Rx pharmacy between Jan 1, 2007, and Dec 31, 2010. For each member, we identified 3 matched controls at within-state DaVita facilities, according to an 81-factor propensity score of new DaVita Rx membership. We followed patients until Dec 31, 2010, with intention-to-treat (ITT) and on-treatment (OT) rules. We ascertained incidence of death and hospitalization from USRDS records.

Results: We identified 19,354 new DaVita Rx members and 58,045 matched controls. At 1 year, the ITT (OT) cumulative incidence of death was 10.3% (8.0%) versus 10.9% (10.1%) for members versus controls (figure). Overall, ITT and OT hazard ratios of death for members versus controls were 0.94 (95% CI, 0.90-0.98) and 0.82 (0.77-0.87), respectively. ITT and OT relative rates of hospital admissions were 0.98 (0.96-1.00) and 0.94 (0.92-0.96), respectively; for hospitalized days, corresponding relative rates were 0.96 (0.94-0.99) and 0.90 (0.87-0.92). In OT analysis, rates of hospitalized days due to heart failure and infection, particularly sepsis, were significantly lower among members ($P < 0.05$).



Conclusions: Receiving integrated pharmacy services was associated with significantly lower risk of death and, in on-treatment analysis, modestly lower risk of hospitalization.

TH-PO884

Increases in Medication Use after New Membership in DaVita Rx

Eric D. Weinhandl,[1] Wendy L. St. Peter.[1,2] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]College of Pharmacy, Univ of Minnesota, Minneapolis, MN.*

Background: Initiation of integrated pharmacy services, including medication management and refill management, may alter medication use. For medications related to cardiovascular disease and mineral and bone disorder, we aimed to compare treatment prevalence and adherence in DaVita Rx members and matched controls immediately after initiation of services.

Methods: We linked DaVita records with United States Renal Data System (USRDS) records. New DaVita Rx members had Medicare Parts A, B, and D coverage and first filled a Part D-covered medication at a DaVita Rx pharmacy between Jan 1, 2007, and Dec 31, 2010. For each member, we identified 1 matched control at a within-state DaVita facility, according to an 81-factor propensity score of new DaVita Rx membership. We followed patients until the earliest of death, kidney transplant or Dec 31, 2010, and retained pairs in which member and control were followed for >6 mo. We ascertained medication use during 6 mo before and after the start of follow-up and estimated treatment prevalence and the proportion of days covered (PDC) among users.

Results: We identified 13,114 pairs. Treatment prevalence and mean PDC were balanced at baseline. During follow-up, percentages of members with ≥1 fill of an ACE inhibitor/ARB, beta blocker (BB), and calcium channel blocker (CCB) were 3 to 4 percentage points greater than percentages of controls; for cinacalcet and phosphate binders, corresponding differences were +6 and +9 percentage points, respectively (table). Among users, mean PDC among members was 11 to 20 percentage points greater than among controls. All differences were significant ($P < 0.01$), before and after adjustment for small differences at baseline.

	Treatment Prevalence (%)		Mean PDC among Users	
	Member	Control	Member	Control
ACE inhibitor/ARB	56	52	73	60
BB	68	64	75	61
CCB	54	51	72	61
Cinacalcet	42	36	72	53
Phosphate binder	89	80	71	51

Conclusions: For medications related to cardiovascular disease and mineral and bone disorder, initiation of integrated pharmacy services was associated with increases in percentages of patients treated and proportions of days covered.

Medication Adherence to Phosphate Binders: The CHEOBS Study

Philippe Chauveau,[1] Abdallah Guerraoui,[2] Corinne Isnard-Bagnis.[3] *[1]Aurad-Aquitaine, Bordeaux, France; [2]Pitie Hospital Univ, Paris, France; [3]Calydial, Vienne, France.*

Background: Noncompliance (NC) is not always intentional. The medical team rarely takes into account the non--intentional NC linked to the difficulty of taking drugs regularly and feelings of the patient, unless objective evidence is present. Better understanding of the triggers and determinants of NC would allow elaboration of educational tools designed to help out chronic patients with their treatment.

Methods: 340 hemodialysis patients in 9 centers in three areas in France were included on a voluntary basis. Among them, 10 patients responded to a qualitative interview focused on individual beliefs, attitudes and motivations towards phosphate binders' therapy. 26% of patients attended an educational program. Statistical methods consist of frequencies analysis and Exploratory Factor Analysis to determine combination of factors which significantly influence the compliance to phosphate binders. The semi--structured interviews were analyzed according to qualitative content analysis.

Results: 329 self--administered questionnaires (50 items) were analyzed, 297 were complete for analysis (mean age 61 years, 62% male, dialysis duration 4.5 years, number of medication 9 per day). The majority of patients considers treatment as important (80%). However, they mostly relativizes the treatment as vital (45%). Factor analysis helped to identify two kind of independent behaviors: those which indicate concerns for the treatment and those relative to the use of the treatment as a necessity. Age, level of education and gender influence these two factors. Older patients are more compliant. The higher the level of education the more frequently patients adapt the treatment. The swallowable tablets are preferred (75%). The shape and color has little influence on decision. 60% of the patients consider they received enough pre therapeutic information. The involvement into educational formation has a not high enough influence on adherence.

Conclusions: In conclusion, this large study provides clues to better understanding of non compliance to phosphate binders determinants. Based on these assumptions, educational program should be more efficient and fruitful to chronic dialyzed patients.

Sevelamer versus Calcium-Phosphate Binders on Dialysis Patients—A Meta-Analysis Xun Liu,[1,2] Caixia Wang,[1] Chenggang Shi,[1] Linsheng Lv,[3] Zhenda Zheng.[4] *[1]Dept of Nephrology, The Third Affiliated Hospital of Sum Yat-sen Univ, Guangzhou, Guangdong, China; [2]Div of Nephrology, Tufts Medical Center, Boston, MA; [3]Operating Room, The Third Affiliated Hospital of Sum Yat-sen Univ, Guangzhou, Guangdong, China; [4]Dept of Cardiology, The Third Affiliated Hospital of Sum Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Compared with calcium-phosphate binders, the impact of sevelamer on cardiovascular calcification, all-cause mortality and other side effects of end-stage renal disease (ESRD) patients on dialysis is still uncertain.

Methods: We performed a meta-analysis. We searched the Medline, PUBMED, ASN-ONLINE, EMBASE, the Cochrane Library and 30 RCts with 7205 participants were included.

Results: In an analysis pooling, there was no difference in all-cause mortality or cardiovascular mortality, hospitalization, adverse events (AEs). But there showed a significant difference in change of coronary artery calcification scores (CACS) by -115.34 (mean difference, MD, 95% confidence interval, CI, -194.18, -36.49) and aortic calcification scores (ACS) by -451.91 (MD, 95% CI -742.88, -160.95) between sevelamer and calcium-based phosphate binder. Therapy of sevelamer, rather than calcium-based phosphate binders, decreased total cholesterol (MD, 0.55mg/dL, 95% CI -0.64, -0.45), LDL (MD, 0.72mg/dL, 95% CI -0.82, -0.61) and HDL (MD, 0.24 mg/dL, 95% CI -1.72, 1.24). Sevelamer also has a significant association with higher iPTH levels (MD, 0.23pg/ml, 95% CI 0.12 to 0.35), lower serum bicarbonate levels (MD, -1.76 mEq/L, 95% CI -2.18, -1.35), lower triglycerides levels (MD, -3.5 mg/dl, 95% CI -18.29, 11.28), higher alkaline phosphatase levels (MD, 38.34 U/L, 95% CI 32.37, 44.31), higher bone alkaline phosphatase levels (MD, 6.02 U/L, 95% CI 3.05, 9.00). The rate of hypercalcemia (defined as serum calcium >10.2-10.5 mg/dl and serum calcium >11.0mg/dl) was significantly smaller in sevelamer (Risk Ratio, RR = 0.44, 95%CI, 0.33, 0.58; RR = 0.24, 95%CI, 0.14, 0.41).

Conclusions: This meta-analysis suggests that sevelamer benefits dialysis patients in CACS, lipid, alkaline phosphatase, bone alkaline phosphatase, triglycerides and hypercalcemia.

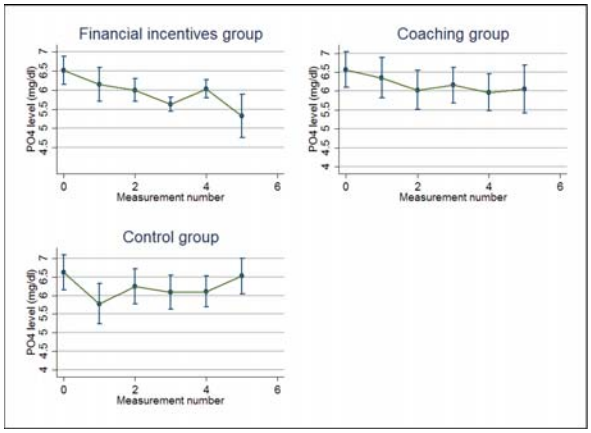
TH-PO887

A Pilot Randomized Controlled Trial of Financial Incentives or Coaching to Lower Serum Phosphorus in Dialysis Ofole Mgbako,[1] Adam S. Mussell,[1] Vishnu S. Potluri,[3] Simona Levsky,[1] Scarlett L. Bellamy,[1] Chirag R. Parikh,[2] Justine Shults,[1] Karen Glanz,[1] Harold I. Feldman,[1] Kevin Volpp,[1] Peter P. Reese.[1] *[1]Penn; [2]Yale; [3]Lankenau.*

Background: Among hemodialysis (HD) patients, hyperphosphatemia is common and associated with elevated mortality. Behavioral economics and behavior change theories may offer novel approaches for achieving PO4 control. The objective of this pilot RCT was to determine the feasibility of implementing these approaches in the HD setting.

Methods: In 3 urban HD units, we randomized 36 adults (1:1:1) with high PO4 (median >5.5 mg/dl over 3 months) to receive: 1) financial incentives for reducing or maintaining normal-range PO4, 2) structured coaching about medication/dietary adherence, or 3) usual care for 70 days. Serum PO4 was measured during routine unit operations. Each financial-incentives arm subject received the equivalent of $1.50/day if the PO4 was ≤5.5 mg/dl or >5.5 mg/dL, but had decreased by ≥0.5 mg/dl. In the coaching arm, the coach and subjects were instructed to be in contact at least 3X/week.

Results: Among 66 eligible patients, 36 (55%) enrolled. Median age was 53 years, 30 (83%) were black race and 28 (78%) were male. Mean final PO4 was 5.8 (+/-0.9) in the financial incentives arm, 5.9 (+/-1.7) in the coaching arm and 6.1 mg/dl (+/-1.4) in usual care. Median change in PO4 from initial to final measurement was -0.60 in the financial incentives arm, -0.80 in the coaching arm, and -0.45 mg/dl in usual care. All patients in the financial incentives and coaching arms expressed interest in receiving similar support in the future. The figure suggested that among subjects with more PO4 measurements, those receiving incentives had greater success lowering PO4.



Conclusions: Implementing novel behavioral health strategies to lower PO4 is highly feasible. A longer, larger trial is needed to determine if these strategies can achieve significant reductions in PO4.

TH-PO888

Short-Term Efficacy of Intensive Propaganda and Education for Hyperphosphatemia in Patients with Maintenance Hemodialysis Xun Liu,[1,3] Huijuan Ma,[1] Yitong Yao,[2] Huanling Guo,[4] Jianxiong Shi,[4] Ronglang Zhou.[5] *[1]Div of Nephrology, Dept of Internal Medicine, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Guanghua School of Stomatology, Hospital of Stomatology, Sun Yat-sen Univ, Guangzhou, Guangdong, China; [3]Div of Nephrology, Tufts Medical Center, Boston, MA; [4]Zhongshan School of Medicine, Sun Yat-sen Univ, Guangzhou, Guangdong, China; [5]School of Public Health, Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Hyperphosphatemia is an important determinant of mortality in chronic kidney disease patients undergoing hemodialysis. We aimed to assess the influence of intensive propaganda and education on serum phosphorus in patients with maintenance hemodialysis (MHD).

Methods: A total of 84 hemodialysis patients with hyperphosphatemia (serum phosphorus > 1.78 mmol/L) were enrolled, with 52 assigned to intensive propaganda and education group and 32 assigned to general propaganda and education group. Both of two groups received calcium carbonate ($CaCO_3$ 3.0g/day) for 12 weeks, with different follow-up intervals. Patients were guided to recognize the impact of phosphate on disease progression and be aware of the presence of phosphate in food and drinks and the benefit of phosphate binders. Blood phosphorus, blood calcium and blood intact parathyroid hormone were recorded.

Results: Five patients were excluded from intensive propaganda and education group and two from general propaganda and education group because of reasons such as death or renal transplantation. In all, 77 patients completed the analysis. In intensive propaganda and education group, the decreases of serum phosphorus in weeks 4 (P=0.001), 8 (P=0.006) and 12 (2.32 to 1.94 mmol/L, P<0.001) were significantly relative to that in week 0, whereas in the general group, it revealed no significant difference (2.21 to 2.07 mmol/L, P=0.182) after 12 weeks treatment. The decline of blood phosphorus in intensive propaganda and education group was significantly greater than that in general propaganda and education group (P=0.02).

Conclusions: Intensive propaganda and education could be more effective in the control of hyperphosphatemia in patients with MHD.

TH-PO889

Effects of Lanthanum Carbonate to Serum Phosphate and Serum FGF-23 in Hemodialysis Patients with Hyperphosphatemia Xuemei Li, Jie Ma, Yang Yu. *Nephrology, Peking union Medical College Hospital, BeiJing, China.*

Background: High levels of circulating fibroblast growth factor 23 (FGF-23) are associated with chronic kidney disease (CKD) progression and high mortality. Klotho is a transmembrane protein that acts as a cofactor for fibroblast growth factor 23 (FGF23). Klotho also exists as a soluble circulating protein. The primary objective of this study was to assess the effects of 4 weeks of treatment with lanthanum carbonate on intact FGF23 (iFGF23) and Klotho levels in hemodialysis patients.The secondary objectives was to assess the effects of lanthanum carbonate on other factors including circulating levels of intact parathyroid hormone (iPTH), calcium, and phosphate.

Methods: A single center, open-labeled study from Peking Union Medical College Hospital was performed. Phosphate binders were discontinued during a two-week washout period.Patients with more than 1.78 mmol/L serum phosphorus after two-week washout period were eligible for the study.Lanthanum carbonate was administered to 12 MHD patients for 4 weeks.The dose was adjusted after first two weeks as necessary to achieve serum phosphorus control.

Results: All patients fulfilled the whole study.By the end of 4 weeks of lanthanum carbonate treatment, mean serum level of phosphorus was 1.77±0.10mmol/L, compared with the level before treatment 2.21±0.58mmol/L, *P*=0.005. Before treatment calcium-phosphate product was 5.36±0.21mmol^2/L^2, after 4 weeks treatment calcium-phosphate product was 4.39±0.28mmol^2/L^2, *P*=0.016;FGF-23, before:7554.9±1421.9pg/ml, after: 5605.8±1036.9pg/ml, *P*=0.027. Klotho levels, before: 597.2±53.2pg/ml, after:356.4±122.7pg/ml, *P*=0.001. While the level of serum calcium and serum intact parathyroid hormone kept steady. Of the 12 involved patients, 3 had adverse drug reaction, 2 had constipation, 1 had rash, the two patients all relieved after symptomatic treatment.

Conclusions: Lanthanum carbonatecan effectively control the serum phosphorus, reduce the levels of calcium-phosphorus product, serum FGF-23 and Klotho protein in the short term.

TH-PO890

Improvements in Relative Blood Volume Change during Hemodialysis Associates with Increases in Albumin, Declines in Systolic Blood Pressure and Lower Epogen® Utilization Cindy Allegretti,[1] Patricia McCarley,[1] Portia R. Scott,[1] Athena Palearas,[1] Patrice B. Taylor,[2] John W. Larkin,[1] Linda H. Ficociello,[1] Paul Balter,[1] Kevin Chan,[1] Len A. Usvyat,[1] Franklin W. Maddux,[1] Jeffrey L. Hymes.[1] *[1]Fresenius Medical Care North America (FMCNA); [2]FMC Renal Therapies Group.*

Background: Suboptimal volume control associates with increased morbidity and mortality in hemodialysis (HD) patients (Pts). FMCNA started utilizing Crit-Line® Blood Volume Monitors (CLM). We evaluated the temporal association of CLM implementation on hypertension, albumin, and Epogen (EPO) requirements in HD Pts.

Methods: From Jun 17, 2013 to Mar 31, 2014, BV was documented in 369 HD clinics. Pts with >36 treatments (tx) and >75% of tx with CLM were selected; average monthly slope of ending BV/tx/Pt was computed. Pts were stratified by ***declining BV*** (slope of BV negative and p-value significant), ***increasing BV*** (slope of BV positive and p-value significant), and remaining Pts were considered to have ***no change in BV***. Average monthly slope of albumin, post-dialysis weight, pre- and post-dialysis systolic blood pressure (pre-SBP/post-SBP), and EPO dose were computed; groups were compared using ANOVA.

Results: 1875 Pts were studied. Pts with declining ending BV had increases in albumin and pre-SBP, and decreases in post-dialysis weight, post-SBP, and EPO dose/tx. Conversely, Pts with increases in ending BV had decreases in albumin and post-dialysis weight, and increases in pre-SBP (more pronounced than Pts with a decline in BV), post-SBP, and EPO dose/tx. There were significant differences between Pts with declining, stable, and increasing BV in albumin change, post-dialysis weight, and post-SBP.

Figure 1. Comparison of groups of BV change

BV change	Number of patients	Monthly change in albumin (g/dL/month)	Monthly change in post-dialysis weight (kg/month)	Monthly change in Pre-SBP (mmHg/month)	Monthly change in Post-SBP (mmHg/month)	Monthly change in EPO dose (U/month)
Declined	180	0.031	-0.29	0.11	-1.33	-117
No significant change	1511	0.004	0.01	0.15	-0.21	-64
Increased	184	-0.016	-0.08	0.61	1.28	15
p-value		<.0001	0.0016	0.315	<.0001	0.561

Conclusions: Lower relative ending BV in HD Pts associates with increases in albumin and smaller increases in pre-SBP, as well as, declines in post-SBP, post-dialysis weight, and EPO dose requirements as compared to Pts with an increasing ending BV.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America

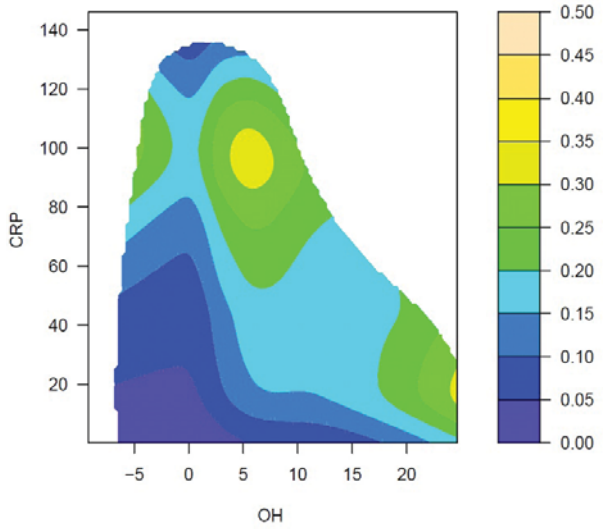
TH-PO891

Fluid Overload, Inflammation and Mortality: Results from a Large International Study Marijke J.E. Dekker,[1,2] Len A. Usvyat,[3,6] Constantijn Konings,[2] Frank van der Sande,[1] Karel M. Leunissen,[1] Peter Kotanko,[3] Yuedong Wang,[5] Daniele Marcelli,[4] Nathan W. Levin,[3] Bernard J. Canaud,[4] Jeroen Kooman.[1] *[1]Internal Medicine, Div of Nephrology, Univ Hospital, Maastricht, Netherlands; [2]Internal Medicine, Catharina Hospital, Eindhoven, Netherlands; [3]Renal Research Inst, New York; [4]Fresenius Medical Care, Bad Homburg, Germany; [5]Univ of California, Santa Barbara California; [6]Fresenius Medical Care North America, Waltham.*

Background: Fluid overload (FO) and systemic inflammation are associated with a higher mortality in hemodialysis (HD) patients. Previous studies showed a relation between FO and inflammation, the effect of the interaction between FO and inflammation on outcome however, has not yet been studied. The aim of this research is to evaluate the interaction between FO, inflammation and outcome.

Methods: We studied prevalent HD patients from the European Fresenius network (17 countries). Hydration status was assessed by Body Composition Monitor (BCM) measurements. We included patients with ≥ 1 BCM measurement and at least one C-reactive protein (CRP) measurement between 1/2011 and 12/2011 and recorded their survival between 1/2012 and 6/2012 (follow up). Probability of death was computed using a multivariate semi-parametic logistic regression model.

Results: We included 9,463 patients (mean age 63 years, 57.4% male, mean dialysis vintage 5.1 months). Of these patients, 476 (5.03%) died during the follow up period. FO and increased CRP levels were both associated with a higher mortality rate. However, especially the combination of OH and elevated CRP level was associated with an increased mortality.



Contour plot depicting the probability of death in 6 months as a function of hydration status (measured by BCM in liters) and CRP levels during the 12 months before.

Conclusions: HD patients with FO and high CRP levels have an increased mortality risk. However, especially the combined presence of both FO and inflammation is associated with a greatly increased risk of adverse outcome.

TH-PO892

6-Year Outcomes from a National Treatment Options Education Program for Chronic Kidney Disease Patients Eduardo K. Lacson, Shu-Fang Lin, Keith Lester, Teresa J. Close, Franklin W. Maddux. *Fresenius Medical Care, Waltham, MA.*

Background: We previously reported early outcomes from a national pre-dialysis Treatment Options (TOPs) program offered at no cost to patients with advanced CKD. This report provides a 6-year overview of outcomes since its initial launch in 2008.

Methods: Our CQI program tracked CKD patients initiating chronic dialysis therapy in all FMCNA facilities annually from 2008 to 2013. We tracked TOPs penetration rates and compared rates of home dialysis (PD and HD), vascular access for patients opting for HD, and dialysis survival 120 days later, between patients who attended TOPs and those who did not (non-TOPs).

Results: As incident patient admissions increased annually, the proportion attending TOPs increased each year from 8% (2008) to 18.5% (2013). The median age increased from ~65 to 66 years (Non-TOPs steady at ~64.5 years). The percentage of males increased from ~56.5% to 58% overall, similar in both TOPs and Non-TOPs patients. While a 7% gap in the proportion of black race attendees existed in 2008, it was abrogated to <1% difference between TOPs and Non-TOPs patients in 2013. Diabetes prevalence was similar in 2008, but only 40% of TOPs attendees had DM for 2013 (44% non-TOPs). With more TOPs attendees, patients opting for home dialysis decreased from 23% in 2008 to just over 16% in 2013, in contrast to a small but steady increase in home dialysis by non-TOPs attendees (+2% by 2013). Non-TOPs patients had ~0.5% decline to ~70% CVC for HD patients' 1st treatment, while TOPs attendees' CVC use declined from 54% (2008) to 47% (2013). Fistulas at 1st HD increased in both groups: 16% to 20% (Non-TOPs) and 33% to ~41% (TOPs). By 120 days, 9-10% more TOPs attendees proportionately remain in FMCNA care each year.

Conclusions: While a greater percentage of patients starting dialysis at FMCNA attended TOPs education, increased referrals are needed to cover more pre-dialysis CKD patients. Amid potential selection biases, trends for greater penetration of home therapies, favorable vascular access distribution in HD patients, and better >120 day high-risk period survival in TOPs attendees were maintained for 6 years.

TH-PO893

The Dialysate Purification and Introduction of High Flux Dialyzers in Cambodia Sovandy Chan,[1] Toru Hyodo,[1,2,3] Tomotaka Naramura,[3,4] Kenichi Kokubo,[3,5] Fumitaka Nakajima,[1,3,6] Haruki Wakai,[3,7] Nobuhisa Shibahara,[3,8] Sabo Ojano.[1] *[1]Cambodia-Japan Friendship Blood Purification Center, Sen Sok International Univ, Phnom Penh, Cambodia; [2]Kuratakai Eijin Clinic, Hiratsuka, Japan; [3]NGO Ubiquitous Blood Purification International, Yokohama, Japan; [4]Dept of Medical Engineering, Faculty of Health Sciences, Jubshin Gakuen Univ, Fukuoka, Japan; [5]School of Allied Sciences, Kitasato Univ, Sagamihara, Japan; [6]Moriguchi Keijinkai Hospital, Moriguchi, Japan; [7]Reiseikai Shinagawa Garden Clinic, Tokyo, Japan; [8]Arisawa General Hospital, Hirakata, Japan.*

Background: Dialysate purification systems have not been established in developing countries and so high flux dialyzers have not been introduced in such countries.

Methods: Blood Purification Center of Sen Sok International University (SSIU) Hospital was established at March 1st in 2010. The dialysis was performed by using low

flux dialyzers. At July in 2011, the endotoxin(ET) measurements and bacterial counting of the tap water, reverse osmosis water and dyalysate were checked in order to reveal whether high flux dialyzers could be used or not.

Results: The results of dialysate ET were 309, 246, 395 EU/mL and the bacterial counting were 800, 800, 900 cfu/mL. At July in 2013, the ET retentive filter (ETRF) was installed and the line after the ETRF was changed into the new one. Until December in 2013, no ET and bacteria were determined. We have started to use high flux dialyzers since December 14th in 2013. Mean B2-microglobrin(B2-MG) reduction rate was 56.9±1.4% (N=5) in the first use of dialyzers. The value of B2-MG in the 1st, 2nd, 3rd and 4th use of the single dialyzer (under reuse principle) were 37.9, 33.7, 31.9 and 30.1 mg/L (N=1).

Conclusions: The ET retentive filter is very useful to purify dialysate and make it possible to use high-flux dialyzers even under hard conditions in developing countries. But more efforts to clean RO water line should be needed.

Funding: Pharmaceutical Company Support - Nipro Japan Co. Ltd.

TH-PO894

Reduced Mortality Associated with Acetate-Free Dialysis: Findings From the French End-Stage Renal Disease Registry Lucile Mercadal,[1,2] Jeanna-Eve Franck,[2] Marie Metzger,[2] Wenlun Yuan,[2] Christian Jacquelinet,[3] Benedicte Stengel.[2] *[1]Nephrology Dpt, CHU Pitié-Salpêtrière, Paris; [2]INSERM U1018, CESP, Villejuif; [3]Biomedicine Agency, Saint-Denis.*

Background: Dialysis using hydrochloric acid (HCl) dialysate or acetate-free biofiltration improves cardiac output and per-dialysis tolerance when compared to standard hemodialysis (HD) using small amount of acetate. Whether acetate-free dialysis (AFD) is associated with reduced mortality is unknown.

Methods: Using the REIN registry, we classified all patients who started HD from 2008 to 2010 in 13 French regions into 3 exposure categories according to the type of dialysate used in their dialysis center: 100% HCl dialysate, both standard and AFD (mixed center) or standard dialysate only. Cox survival analysis was performed in 15,160 incident patients, adjusted for 15 baseline co-morbidities and biological data. We accounted for patient clustering within centers and used age as time-scale. Patient AFD exposure and hemodiafiltration (HDF) status were treated as time-dependent variables. Analysis was censored at Dec 31, 2011, or at kidney transplantation, lost to follow-up, dialysis weaning or transfer to peritoneal dialysis.

Results: Medians (interquartile range) of follow-up and age were 1.8 years (1.2-2.6) and 70.5 years (58.1-78.8) respectively. A total of 658 patients were dialyzed at least once in a 100% HCl center and 3,021 were dialyzed at least once in a mixed center and never dialyzed in a 100% HCl center. There was an interaction with age in the relation between AFD and mortality: patients older than 70 years had significant lower mortality risk associated with AFD, while no association was found in younger patients (table 1). Using HDF was associated with lower mortality risk at all ages.

	Person-years	Deaths	<70 years HR (95% CI)	≥70 years HR (95% CI)
AFD exposure status Dialyzed in a standard dialysis center	20,921	3,115	1	1
Dialyzed in a mixed dialysis center	3,489	544	1.03 (0.85-1.24)	0.83 (0.74-0.94)
Dialyzed in a 100% HCl center	775	132	1.24 (0.87-1.77)	0.79 (0.67-0.93)
HDF (ref: without HDF)	3,292	536	0.73 (0.59-0.90)	0.85 (0.76-0.96)

Conclusions: HD without acetate and HDF were associated with better survival in the REIN registry.

TH-PO895

Up-Regulation of Inflammatory Mediators and Markers of Metabolic Deraignment in End Stage Renal Disease as Studied by Biochip Array Analysis Vinod K. Bansal,[1] Daneyal Syed,[2] Debra Hoppensteadt,[2] Mushabar Syed,[3] Jawed Fareed.[2] *[1]Nephrology, Loyola Univ Medical Center; [2]Pathology, Loyola Univ Medical Center; [3]Cardiology, Loyola Univ Medical Center.*

Background: End stage renal disease represents a complex syndrome with multiple pathophysiological processes involving vascular, inflammatory, thrombotic, and metabolic deraignment. This study was designed to utilize biochip array technology to compare the inflammatory and metabolic syndrome biomarker profiles of a maintenance hemodialysis cohort (n=81) with healthy normal male and female volunteers (n=41).

Methods: The ESRD group represented patients who are under maintenance hemodialysis at the Loyola University Clinic (n=81) and a group of healthy normal individuals (n=50). High sensitivity inflammatory cytokine chips to profile IL-2, IL-4, IL-6, IL-8, IL-10, VEGF, IFN-gamma, IL1-alpha, IL1-beta, MCP1, and EGF and metabolic array chip to analyze C-Peptide, ferritin, resistin, insulin, leptin, and PAI-1 were used employing Evidence Investigator (Randox, UK).

Results: In the inflammatory biochip array analysis, except for IL-2 and EGF, all the inflammatory biomarkers were found to be significantly higher than the normal group ($p<0.0001$). The ESRD group exhibited marked variations in the circulating levels of the inflammatory mediators and the extent of increase also varied. In the metabolic chip array analysis, all of the markers of metabolic deraignment were significantly increased ($p=<0.001$), except insulin, where a trend towards increased levels was noted.

Conclusions: These results clearly demonstrate the complexity of the pathophysiologic event in ESRD patients. A widespread increase in the inflammatory mediators, coupled with the higher levels of metabolic deraignment markers suggest that the ESRD patients not only have an ongoing inflammatory process but also sustain metabolic deraignment. Profiling of these mediators not only provides an understanding of the pathogenesis of this condition, but may be helpful in the risk stratification and clinical management of these patients.

TH-PO896

Imbalance of CD39/CD73 Cells and ROS in Maintenance Hemodialysis Eun Hye Seo,[1] Young-Il Jo.[1,2] *[1]BK21 plus, Konkuk Univ School of Medicine, Seoul, Republic of Korea; [2]Nephrology, Konkuk Univ Medical Center, Konkuk Univ School of Medicine, Seoul, Republic of Korea.*

Background: Recent evidences indicate that CD39 and CD73 expression by regulatory T (Treg) cells may contribute to renal protective effect in renal injury. CD39 is expressed on the surface of human Tregs that are important in constraining pathogenic Th17 cells. Our previous study showed that the frequency of Th17 cells had a decreasing tendency with decreased eGFR in chronic kidney disease. However, the role of CD39 and CD74 Tregs remain poorly understood. This research was designed to evaluate the frequency and role of Treg, CD39 and CD73 cells in ESRD patients on maintenance HD.

Methods: Fifteen ESRD patients on maintenance HD (age 61.8±3.0 yr, male 9, duration of HD 10.0±2.1 yr) and 15 healthy controls (age 45.0±3.1 yr, male 10) were recruited. Flow cytometry was used to analyze the proportion of CD39 and CD73 expressed by CD4+ T cells and intracellular reactive oxygen species (ROS) in Tregs in the peripheral blood of the subjects.

Results: ESRD patients on maintenance HD revealed an increased frequency of Treg (Control versus HD, 3.5±0.3 versus 11.0±3.1, p=0.001). An increase in the frequency of CD39+ Tregs increased (13.6±2.5 versus 37.2±6.0, p=0.01) and a decrease in the frequency of CD73+ Tregs decreased (10.0±2.2 versus 5.3±0.2, p=0.02) was observed ESRD patients on HD, in turn, the ratio of CD39+/CD73+ Tregs was significantly decreased in ESRD patients on HD [Figure1]. Intracellular ROS in Treg was significantly increased in ESRD patients on HD compared with healthy controls (8.8±2.2 versus 52.2±9.5, p=0.01). In addition, the expression of CD39+ Tregs was positively correlated with the expression of cellular ROS in Tregs (r=0.602, p=0.018).

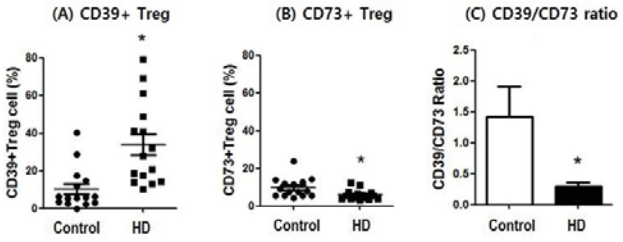


Figure. The expression of CD39+ and CD73 cells in healthy controls and ESRD patients receiving hemodialysis. (A) The frequency of CD39+ Treg , (B) The frequency of CD 73+ Treg, (C) The ratio of CD39/CD73 cells.

Conclusions: These results suggest that dysregulated balance of CD39+/CD73+ Tregs may play a role in the immune response of ESRD patients receiving maintenance hemodialysis.

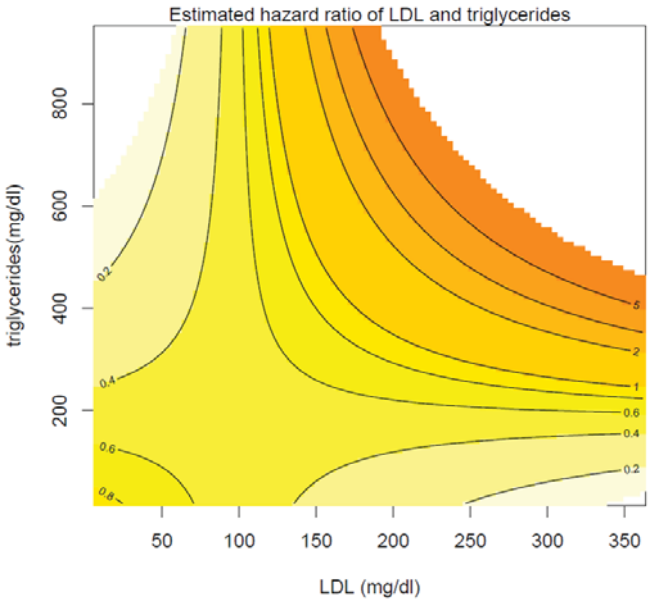
Higher Low Density Lipoprotein Cholesterol Is Associated with Lower Infectious Events in a Large International Population of Hemodialysis Patients George A. Kaysen,[1,2] Yuedong Wang,[3] Len A. Usvyat,[2] Daniele Marcelli,[4] Bernard J. Canaud,[4] Peter Kotanko.[2,5] *[1]Medicine, UC Davis, Davis, CA; [2]Renal Research Inst, New York, NY; [3]UC Santa Barbara, Santa Barbara, CA; [4]FMC, Bad Homburg, Germany; [5]The MONDO Initiative.*

Background: Reduction in low density lipoprotein (LDL) is without effect on morality in hemodialysis (HD) patients. The second leading cause of death in HD after cardiovascular diseases is infectious. LDL absorbs and inactivates bacterial toxins. Human LDL can prevent endotoxin induced lethality in mice.

Methods: We explored the relationship between blood lipid levels and infectious outcomes in databases from Renal Research Institute (RRI) and Fresenius Medical Care (FMC) Europe (22,746 patients). All patients who had baseline measures of lipids and survived 12 months were selected. Time to all death. cardiovascular (CV) or infectious death or numbers of all cause, infectious or CV hospitalizations during the next 12 months were analyzed by Cox or Poisson models respectively.

Results: Risk of infectious mortality was significantly reduced by albumin and BMI, and increased by age, C reactive protein (CRP) and neutrophile lymphocyte ratio (NLR). LDL was protective against all cause and infectious mortality when TG was less than 200 mg/dL.



LDL was also protective against all cause and infectious hospitalizations when TG was less than 200 mg/dl. TG was less than 200 mg/dL in 75.3% of the population. LDL had no significant effect on CV death or hospitalizations regardless of the level of TG.

Conclusions: Higher LDL levels are associated with decreased all cause and infectious death and hospitalizations when TG are less than 200, a value present in over 75% of patients, possibly accounting for the observation that reducing LDL cholesterol has a limited effect on mortality outcomes despite potential adverse CV effects of LDL.

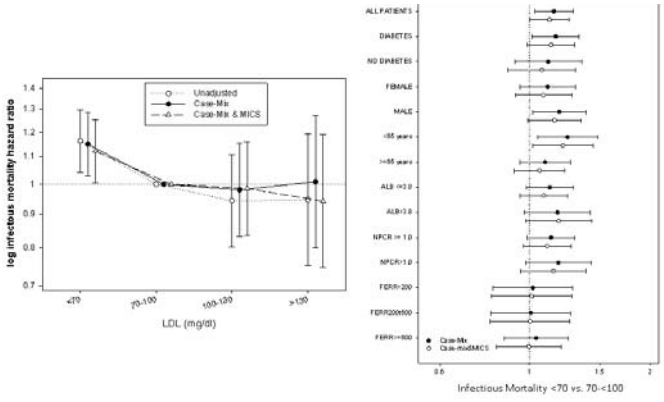
TH-PO898

Association of Low Density Lipoproteins with Infectious Mortality in Hemodialysis Patients Hamid Moradi,[1] Pouya Abhari,[1] Vanessa A. Ravel,[1] Elani Streja,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2] Rajnish Mehrotra,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons, UC Irvine MC, Orange, CA; [2]Memphis VA MC, Memphis, TN; [3]Univ Washington, Seattle, WA.*

Background: Most studies on the association between plasma LDL and mortality have focused on the role of LDL in pathogenesis of cardiovascular (CV) disease and mortality. However, we have found paradoxical associations between plasma LDL level and all-cause mortality in hemodialysis patients, with low LDL levels being associated with worse outcomes. Numerous studies indicate that in an infectious or septic setting, LDL can sequester LPS and other endotoxins and potentially play a beneficial role. Since infection is the second leading cause of death in dialysis patients and based on the mentioned literature, we hypothesized that low plasma LDL levels may portend a worse infectious outcome in patients on maintenance hemodialysis (MHD).

Methods: We examined the association of plasma LDL level with infectious mortality in a 2 yr (2004-2006) cohort of 26412 MHD patients treated in clinics of a large dialysis organization using Cox models adjusted for demographics, case-mix and markers of malnutrition-inflammation complex (MICS).

Results: Patients were 58±15 yrs old and included 46% women, 18% Blacks, and 50% diabetics. Plasma LDL concentrations <70 mg/dL were associated with a significant increase in risk of infectious mortality when compared with levels of 70-100 mg/dL. Subgroup analysis revealed that this was most significant in men, diabetics and patients <65 yrs. Increasing levels beyond 100 mg/dL did not have an additional protective effect.



Conclusions: Reduced plasma LDL levels are associated with a significant increase in infectious mortality in MHD patients. Given that infections are the second leading cause of mortality in this patient population, therapies aimed at lowering LDL levels should be pursued with caution in light of these findings.

TH-PO899

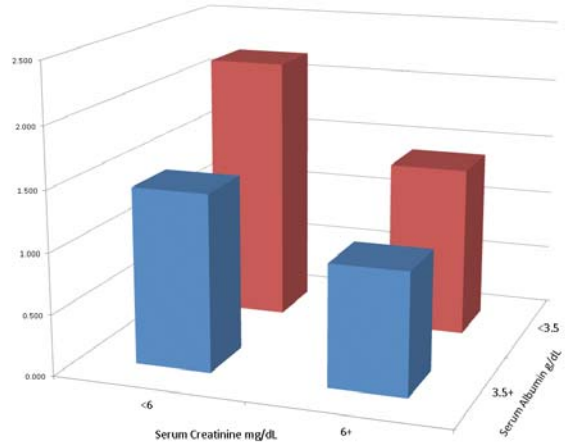
Concurrence of Serum Creatinine and Albumin with Mortality in Twice-Weekly Hemodialysis Patients Jialin Wang,[1,2] Elani Streja,[1] Connie Rhee,[1] Steven M. Brunelli,[1] Miklos Zsolt Molnar,[3] Rajnish Mehrotra,[4] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons UC Irvine MC, Orange, CA; [2]Tianjin Union MC, Tianjin, China; [3]Univ of Toronto, Toronto, ON; [4]Univ of Washington, Seattle, WA.*

Background: Previous studies have found that both albumin (as measure of visceral proteins) and creatinine (as measure of skeletal muscle mass) are linearly associated with lower mortality in hemodialysis (HD) patients. But no data exist for <3 times/wk (usually twice-weekly) HD patients in whom larger residual kidney function may confound nutritional predictors. We hypothesize that the survival advantages of higher serum albumin and creatinine hold in these patients.

Methods: We identified 1,123 twice-weekly HD patients between 2007-2011 from a dialysis cohort of over 120,000 incident HD patients. Combination of serum creatinine (<6 versus≥6 mg/dl) and albumin dichotomies (<3.5 versus≥3.5 g/dl) yielded 2x2=4 groups. All-cause death risk was estimated using Cox models adjusting for demographics, comorbidities and laboratory measures.

Results: Patients were 70±14 yrs old and included 48% women, 13% Blacks, and 54% diabetics. In twice-weekly HD patients, compared to patients with combined higher creatinine and albumin levels, patients in the other 3 groups had higher mortality. Patients with combined lower creatinine and albumin had a 2.2-fold increased risk of mortality (HR:2.193, 95%CI:1.36-3.537).

Baseline Cr(mg/dl)	Baseline Alb(g/dl)	Mortality N	Total N	Mortality (%)	HR (95% CI)
<6	<3.5	90	287	31.36%	2.19 (1.36–3.54)
≥6	<3.5	14	55	25.45%	1.40 (0.70–2.80)
<6	≥3.5	137	588	23.30%	1.45 (0.93–2.28)
≥6	≥3.5	28	193	14.51%	Ref (1.0)



Conclusions: Lowest serum creatinine and albumin levels in twice-weekly HD patients are associated with highest mortality. Higher visceral protein and skeletal mass combined may confer greatest survival in twice-weekly HD patients, warranting controlled trials.

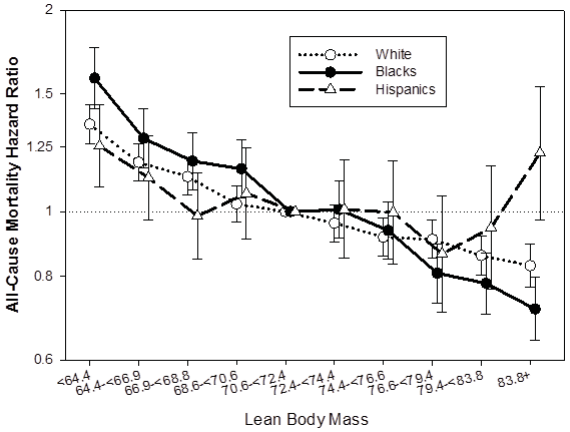
TH-PO900

Roles of Race and Ethnicity in the Risk of Mortality According to Estimated Lean Body Mass in Hemodialysis Patients Jialin Wang,[1,2] Elani Streja,[1] Connie Rhee,[1] Steven M. Brunelli,[1] Csaba P. Kovesdy,[3] Rajnish Mehrotra,[4] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons UC Irvine MC, Orange, CA; [2]Tianjin Union MC, Tianjin, China; [3]Memphis VA MC, Memphis, TN; [4]Harborview MC, Univ of Washington, Seattle, WA.*

Background: Lean body mass (LBM) is an important nutritional measure representing fat-free muscle mass and somatic protein compartments. Some observational studies have found that higher LBM is related to greater survival in hemodialysis (HD) patients, but there is little data on the role of LBM in the race/ethnicity-mortality relationship in HD patients. We hypothesized that there is no difference across race/ethnicity.

Methods: We identified 56,303 white, 35,382 black and 17,318 Hispanic HD patients between 2007-2011 in a large national dialysis cohort. We estimated LBM using the formula by Nouri/Kalantar-Zadeh: eLBM=0.34*Serum Creatinine (mg/dl) +5.58*gender+0.30*weight (kg) +0.67*height (inch)-0.23*URR-5.75. All-cause mortality risk was estimated using Cox models with adjustment for demographics, comorbidities and laboratory measures.

Results: Among whites, blacks and Hispanics treated with HD, the mean±SD age was 66±14, 58±15, and 58±15 years; 41%, 48% and 42% were women; 56%, 58% and 69% were diabetics, respectively. Compared to the reference eLBM group (70.6-<72.4), whites with the lowest eLBM (<64.4) had a 1.4-fold increased risk of mortality (HR:1.35, 95%CI:1.27-1.44) and blacks had a 1.6-fold risk of mortality (HR:1.58, 95%CI:1.43-1.76). Whites with the highest eLBM (≥83.8) had 17% lower death risk (HR:0.83, 95%CI:0.77-0.89) and blacks had 28% lower death risk (HR:0.72, 95%CI:0.63-0.80). Hispanics had a 1.3-fold increased death risk associated with both lowest and highest eLBM groups.



Conclusions: The relationship between mortality risk and eLBM is similar across race/ethnicity except among Hispanics with the highest eLBM. These discrepancies warrant further investigation.

TH-PO901

Interventions to Improve Restless Legs Syndrome Among Patients on Dialysis: A Systematic Review Kevin Quach, Mandark Gandhi, K. Scott Brimble, Michael Walsh. *McMaster Univ.*

Background: Restless legs syndrome (RLS) is common amongst patients receiving dialysis. It is unclear how to optimally treat RLS in dialysis patients. We conducted a systematic review to identify therapies to reduce the severity of RLS.

Methods: We systematically searched MEDLINE and EMBASE and hand searched narrative reviews for randomized controlled trials that assessed the use of pharmacological or non-pharmacological interventions to reduce the severity of RLS among patients receiving dialysis. The primary outcome was RLS symptoms.

Results: Of 621 abstracts identified, 11 studies that included 13 interventions met the inclusion and exclusion criteria. All trials reported interventions that significantly improved RLS severity. The interventions included dopamine agonists (n=6), gabapentin (n=2), intradialytic exercise (n=2) intravenous iron (n=1), and vitamins (n=2). In studies thats compared two interventions, ropinirole gabapentin, and intradialytic exercise were all more effective than L-dopa in indirect comparisons. However, all studies were at high risk of bias with the most common causes due to lack of allocation concealment, high losses to follow-up, and missing data. Further, follow-up for these studies was short-term ranging from 1 to 24 weeks.

Conclusions: Ropinirole, gabapentin, and intradialytic exercise appear promising to reduce RLS in dialysis patients.However, methodologically rigorous, appropriately powered, longer term RCTs are required to determine the optimal treatment strategy for RLS among dialysis patients.

TH-PO902

Pre-End-Stage Renal Disease Care and Mortality in Incident End-Stage Renal Disease Patients with Multiple Myeloma as Cause of Renal Failure Jason Cobb,[1] Laura Plantinga,[1] Janet R. Lynch,[2] Edwin D. Huff,[3] Sumit Mohan,[4] William M. McClellan.[1] *[1]Emory Univ, Atlanta, GA; [2]Mid-Atlantic Renal Coalition, Richmond, VA; [3]Centers for Medicare & Medicaid Services, Boston, MA; [4]Columbia Univ, New York, NY.*

Background: The relationship between mortality and pre-ESRD care in incident end-stage renal disease (ESRD) patients with multiple myeloma (MM) has not been examined. Most patients with MM are receiving medical care, and here, we hypothesized that pre-ESRD care would be more prevalent among these patients compared to other ESRD patients and that receipt of that care would be associated with lower mortality among MM-ESRD patients.

Methods: Among 439,206 incident U.S. hemodialysis patients with a primary cause of renal failure due to MM (6/1/05-5/31/09) identified using the U.S. Renal Data System, odds ratios for reported pre-ESRD care by ESRD due to MM (n=4561) versus other causes (n=434,645) were obtained using adjusted multivariable logistic regression models. The association of pre-ESRD care with subsequent mortality was examined using Cox proportional hazard models.

Results: MM-ESRD patients were less likely to have any pre-dialysis nephrology care (34.8% versus 58.5%, adjusted odds ratio [OR] =0.38, 95% CI 0.34-0.43) and less likely to have 6 months or more pre-dialysis care (26.2% versus 47.5%, OR=0.40, 95% CI 0.35-0.45) compared to patients with ESRD due to other causes. MM-ESRD patients more likely to have catheters on first dialysis (91.8% versus 75.6%, OR=4.16, 95% CI, 3.54-4.86). Receipt of any and 6 months or more pre-dialysis nephrologist care were significantly associated with lower 1-year mortality (fully adjusted HR for death 0.89, CI 0.82-0.97 and 0.88, CI 0.80-0.96 respectively). Catheter use was associated with 1.6-fold higher 1-year mortality (fully adjusted HR for death 1.55, CI 1.32-1.83).

Conclusions: MM-ESRD patients were less likely than their counterparts to have pre-dialysis nephrology care and were more likely to use catheters on first dialysis. However, pre-dialysis care is independently associated with reduced mortality in incident MM-ESRD patients. These results suggest that pre-ESRD care should be prioritized in MM patients approaching ESRD.

TH-PO903

Prediction Model of AV Fistula Failure in Elderly Hemodialysis Patients Alexander S. Goldfarb-Rumyantzev,[3] Bhanu K. Patibandla,[1] Akshita Narra.[2] *[1]Dept of Medicine, St. Vincent Hospital, Worcester, MA; [2]Dept of Medicine, Univ of Connecticut, Farmington, CT; [3]Div of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: AV fistula is the preferable access for hemodialysis and is associated with better clinical outcome. In some patients AVF established long time in advance of dialysis initiation is never used if the patient dies or transplanted prior to dialysis start. Furthemore, significant number of AVF established prior to dialysis fail, by some estimate close to 50% in specific populations. The goal of this study was to develop and validate a prediction model and risk-stratification tool to identify patients at greater risk for predialysis AVF failure.

Methods: We used United States Renal Data System (USRDS) data of ESRD patients 67 years of age and older, linked with Medicare claims. The AVF failure is defined by the fact that despite AVF being the initial access placed, dialysis was initiated using other than AVF vascular access. We used logistic regression to create our prediction model. Variables that demonstrated significant association with outcome were included in the prediction model. Prediction model was tested using calibration and ROC curve.

Results: The entire study cohort consisted of 20,360 subjects with mean age of 76.2±6.02 years, 58.5% males and 41.5% females. The dataset was divided into training subset (n=13,574) used for model development and testing subset (n=6,786) used for model validation. Prediction model and risk stratification algorithm were developed based on patient age, race, sex, cause of ESRD, history of diabetes, cerebro-vascular disease and CHF.

Conclusions: We developed prediction model and risk-stratification algorithm to identify ESRD patients 67 and older at risk for pre-dialysis AVF failure. Results of model validation might allow its practical use.

Citrasate versus Acetate Dialysate on Intradialytic Heparin Dose: A Randomized Crossover Study Kelvin Leung, Pietro Ravani, Robert R. Quinn, Nairne William Scott-Douglas, Jennifer M. MacRae. *Medicine, Univ of Calgary, Calgary, AB, Canada.*

Background: Citrasate dialysate (CD) has an anticoagulant effect which may lead to a reduced cumulative heparin dose (CHD) as compared to standard acetate dialysate (AD).

Methods: We performed a randomized double-blind, crossover trial in maintenance HD patients to determine if CD is associated with a 30% lower CHD than AD (NCT01466959). Adults receiving HD three times per week who used heparin for anticoagulation were included. Heparin dose was adjusted with a heparin reduction protocol during a two-week, run-in phase. Patients who remained on heparin were then randomized to two weeks of CD or AD. Each patient underwent a one-week washout period before crossing over to the other arm. The primary outcome was CHD per HD session; secondary outcomes included changes in serum calcium, magnesium, and bicarbonate; QTc interval; and hemodynamic stability.

Results: Twenty-five patients entered the run-in phase, five achieved heparin free status, the remaining 20 were randomized; 19 completed the study. The mean CHD per session at baseline was 3646±1386 units and was reduced by 28% (2592±2234 units; p<0.01) at the

end of the run-in phase. At study end, CHD per session in the AD group was 2608±2120units compared to 2403±2427units in the CD group. This corresponded to a reduction of 1285units in CHD with AD and 1490units with CD (p=0.73, Figure 1). Results remained unchanged after adjustments. Ionized calcium was unchanged with AD, but decreased 0.10mmol/L with CD (p<0.01). There were no differences in serum magnesium or bicarbonate, QTc interval, number of intradialytic hypotensive events, or other hemodynamic parameters.

Conclusions: CD is a safe alternative to acetate dialysate, but the data does not support our study hypothesis of a reduction in the CHD.

TH-PO906

Rotigotine in Patients with Restless Legs Syndrome and End-Stage Renal Disease Requiring Hemodialysis Virpi Rauta,[1] John W. Winkelman,[2] Yves Dauvilliers,[3] Markku Partinen,[4] Heike Benes,[5,6] Hanna Schröder,[7] Nadine Goldammer,[7] Elisabeth Dohin,[8] Erwin Schollmayer.[7] *[1]Helsinki Univ Central Hospital, Helsinki, Finland; [2]Massachusetts General Hospital, Boston, MA; [3]Hospital Gui de Chauliac, Montpellier, France; [4]Helsinki Sleep Clinic, Vitalmed Research Center, Helsinki, Finland; [5]Somni Bene Institut für Medizinische Forschung und Schlafmedizin, Schwerin, Germany; [6]Rostock Univ, Medical Center, Rostock, Germany; [7]UCB Pharma, Monheim, Germany; [8]UCB Pharma, Brussels, Belgium.*

Background: Restless legs syndrome (RLS) occurs in ~20% of end-stage renal disease (ESRD) patients and is linked to increased morbidity and mortality. RLS may be particularly bothersome when patients are immobile during dialysis. Periodic limb movements (PLMs) in sleep frequently occur in RLS. PLM Index (PLMI; PLMs/hs in bed) is an objective severity measure.

Methods: Double-blind polysomnographic (PSG) study (RenaLys:NCT01537042) of rotigotine (RTG) in patients with RLS (International RLS Rating Scale [IRLS]≥15; PLMI≥15) and ESRD requiring hemodialysis. Patients randomized to optimal dose (1-3mg/24h) RTG/placebo (PBO). PSG assessment at baseline (BL) and end of 2-week maintenance (EoM). Primary efficacy outcome: PLMI, assessed by ratio EoM/BL. Other outcomes (*p*-values exploratory): IRLS, Clinical Global Impression severity (CGI-1). Patients with evaluable BL and EoM data assessed for efficacy.

Results: Of 30 randomized patients (RTG:20; PBO:10), 25 (15;10) completed study with evaluable data. Mean±SD PLMI ratio at EoM: 0.7±0.4 for RTG; 1.3±0.7 for PBO (ANCOVA RTG/PBO ratio: 0.44 [95%CI: 0.22,0.88], *p*=0.0232). Mean±SD change in PLMI score: -23.7±38.7 for RTG (BL:81.8±37.5); 10.3±21.0 for PBO (BL:85.3±67.3). Mean±SD change in IRLS: -15.9±9.1 (BL:25.7±5.0) for RTG; -8.6±7.2 for PBO (BL:24.4±5.1); LS-mean treatment difference (RTG versus PBO): -6.08 [95%CI: -12.18,0.02], *p*=0.0508. 10/15 RTG and 2/10 PBO patients were CGI-1 responders (≥50% improvement). LS-mean treatment difference for CGI-1: -0.81 [95%CI: -1.94,0.33], *p*=0.1534. Hemodialysis did not impact unconjugated RTG concentrations. Adverse events were typical of dopaminergic stimulation.

Conclusions: RTG improved PLMs and RLS symptoms in ESRD patients requiring hemodialysis.

TH-PO907

The Effects of Rotigotine Patch for Restless Legs Syndrome in Japanese HD Patients Hirotake Kasuga,[1] Ryo Takahashi,[1] Keiko Kimura,[1] Chieko Matsubara,[1] Kiyohito Kawashima,[1] Yasuhiko Ito.[2] *[1]Nephrology, Nagoya Kyoritus Hospital, Nagoya, Japan; [2]Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.*

Background: Restless legs syndrome (RLS) is a common disease. The occurrence of this disease in HD patients is higher than general population. Recently, Rotigotine patch could be used for RLS in Japan. However the effect was not studied in detail in Japanese HD patients. The purpose of this study was to investigate morbidity and characteristics of RLS and the effects of Rotigotine patch in Japanese HD patients.

Methods: Two hundred nineteen HD outpatients in our hospital were screened based on the diagnosis criteria of International RLS Study Group (IRLSSG). We compared the patients' characteristics between RLS and non-RLS group. Nine patients with RLS were treated by Rotigotine patch for 3months. The effects of Rotigotine were evaluated by International Restless legs syndrome Rating Scale (IRLS) and Pittsburgh Sleep Quality Index (PSQI) before and 3 months after treatment.

Results: Twenty one (10.0%) HD patients were diagnosed as RLS by criteria of IRLSSG. Mean age of RLS patients was younger than that of non-RLS patients (59.1±9.2 years old versus 64.9±10.9 years old ; p=0.01), however there was no significant difference in sex, presence of diabetes and serum ferritin levels. Mean IRLS of 9 RLS patients before Rotigotine treatment was 23.9±7.2. Mean IRLS after treatment were 14.5±5.7 at 1 month (p<0.05, versus before treatment), and 18.9±7.5 at 3 months (p<0.05, versus before treatment). In 10 questions of IRLS, "daily affairs" (1.6±1.3 versus 0.9±1.1, p<0.05) and "mood disturbance" (2.1±0.9 versus 1.6±1.2, p<0.05) were significantly improved at 3 months. PSQI didn't improve significantly 3 months after treatment.

Conclusions: Morbidity of RLS in Japanese HD patients was similar to that of Western HD patients. Rotigotine patch was useful for RLS treatment in Japanese HD patients.

TH-PO908

Clinical Analysis of Restless Legs Syndrome in Long-Term Japanese Hemodialysis Patients Kazunori Yamada,[1] Toru Shibata,[2] Toshiaki Kimura,[2] Tsutomu Matsushima,[2] Remon Otake,[2] Akira Junicho,[2] Masatsune Hasegawa,[2] Mitsuhiro Kawano,[1] Toru Hasegawa.[2] *[1]Div of Rheumatology, Kanazawa Univ Hospital, Kanazawa, Japan; [2]Hasegawa Hospital, Toyama, Japan.*

Background: The reported prevalence of Restless legs syndrome (RLS) in end stage renal disease patients varies (6-70%) probably due to race and dialysis conditions including dialysis period. DOPPS annual report described that dialysis duration in Japan is longest in participating countries. RLS in long-term dialysis has not been well characterized. Our aim is to clarify RLS in long-term dialysis patients.

Methods: We enrolled 137 Japanese patients on HD (32 women and 105 men; mean age 64.5±12.3) in our hospital in Decenter 2013.Average HD period was 126.7±96.1 months. We analyzed the prevalence and severity of RLS. RLS was diagnosed using the criteria of the International Restless Legs Syndrome Study Group (IRLSSG), and severity of RLS was estimated using the International Restless Legs Syndrome Rating Scale. We retrospectively analyzed the impact and severity of RLS versus duration of HD, clinical data and complications. The impact of RLS on sleep disturbance was assessed with Epworth sleepiness Scale (ESS).

Results: The prevalence of RLS was 16.1% (22/137). The average IRLS was 7.4 (0-30). Six patients had moderate or severe RLS. The RLS group was significantly younger (59.7 years old versus 65.4 years, p=0.040) with higher serum calcium (9.5 mg/dL versus 9.3 mg/dL, p=0.041) than non-RLS group. No significant differences were seen in other factors including HD duration. Next, we divided RLS patients to two groups by IRLS: mild (n=16) and moderate-severe group (n=6). Patients in the latter showed significantly lower KT/V than those in mild group (1.31 versus 1.50, p=0.049), and tended to have a high prevalence of cardiovascular complications (66.7% versus 25.7%, p=0.140) and high ESS score (7.0 versus 4.5), p=0.145).

Conclusions: These results suggest young HD onset and serum level of calcium to be risk factors of RLS. Patients with moderate to severe RLS may be at increased risk for cardiovascular and sleep disorders.

TH-PO909

Assessing the Utility of Testing Aluminium Levels in Dialysis Patients Ashish K. Sharma,[1,2] Nigel David Toussaint,[1,2] Edward Robert Smith,[1] Stephen G. Holt.[1,2] *[1]Dept of Nephrology, The Royal Melbourne Hospital, Parkville, VIC, Australia; [2]Dept of Medicine (RMH), The Univ of Melbourne, Parkville, VIC, Australia.*

Background: Plasma aluminium (Al) is routinely tested in many dialysis patients. Al exposure may lead to acute toxicity and levels in excess of ~2.2µmol/L (60µg/L) should be avoided. Historically toxicity has been caused by excessive dialysate Al but modern reverse osmosis (RO) water should be Al-free. Nevertheless many units continue to perform routine annual Al levels on dialysis patients.

Methods: This single-center study retrospectively analysed plasma Al levels between Jan 2010 and Dec 2013 using our database (Nephworks 6), as well as assessing levels in the raw water feed and RO product with the aim of determining the utility of these measurements.

Results: 2058 plasma Al tests in 755 patients (61.9% male, mean age 64.7 years) were reviewed showing mean +/-SD of 0.41 +/-0.30µmol/L. 111 (5.4%) tests from 61 patients

had Al levels >0.74µmol/L and 45 (73.8%) of these patients were or had been prescribed Al hydroxide (AlOH) as a phosphate binder. Seven patients had Al concentrations >2.2µmol/L. In one of these patients, who was on home dialysis at the time, no source of Al was identified but the repeat Al level was normal. 166 patients taking AlOH (78.7% of all patients on AlOH) had levels ≤0.74µmol/L, the odds ratio of plasma Al >0.74µmol/L on AlOH was 9. The cost of plasma Al assay is AU$30.60, thus costs were AU$62,974.80 over the study period or over AU$1300/month. Despite RO feed water Al levels as high as 48µmol/L (1300µg/L), Al output from the RO was almost always undetectable (<0.1µmol/L). We detected dialysate Al levels >2.2µmo/L only 3 times since Jan 2010, and never in last 3 years.

Conclusions: Routine unselected testing of plasma Al appears unnecessary and expensive and more selective testing in dialysis patients should be considered.

TH-PO910

Relationship between Serotonin 1A Receptor Polymorphism and Emotional Distress and Health Related Quality of Life in Hemodialysis Patients

Hyeong Cheon Park,[1] Jeong-Ho Seok.[2] *[1]Internal Medicine, Yonsei Univ College of Medicine, Gangnam Severance Hospital, Seoul, Korea; [2]Psychiatry, Yonsei Univ College of Medicine, Gangnam Severance Hospital, Seoul, Korea.*

Background: Emotional distress such as anxiety and depression may have significant impact on quality of life (QoL) in hemodialysis (HD) patients. Genetic polymorphism may be an important modulating factor in emotional distress and QoL in these patients. Serotonin 1A receptor polymorphism may be associated with vulnerability to emotional distress. Aim was to investigate the relationship between emotional distress and health-related QoL and genetic polymorphism in Korean hemodialysis patients.

Methods: Clinically stable HD patients were asked to participate in the study. Thirty-six-item Short-Form Health Survey (SF-36), Hospital Anxiety and Depression Scale (HADS) were used to assess health-related QoL and emotional distress, respectively. Sociodemographic factors such as age, sex, education and HD-related clinical factors (dialysis vintage and frequency, Kt/V), and laboratory parameters were assessed. Serotonin 1A receptor polymorphism was assessed using PCR. Regression analyses were conducted to find significant associations among these variables.

Results: Two hundred and sixty HD patients were enrolled. Mean age was 54.7 ± 11.9 years old and mean anxiety and depressive symptoms scores were 5.5 ± 3.8 and 7.4 ± 3.9, respectively. Age, depression symptom severities, and serotonin 1A receptor polymorphism were significantly associated with mental QoL but also with physical QoL in the final regression models. Anxiety symptom severity was only significantly associated with mental QoL. The comorbidity numbers, total HD duration were significantly associated with physical QoL in the final regression model.

Conclusions: After controlling multiple clinical variables, age, depressive symptoms, serotonin 1A receptor polymorphism were significantly associated with mental and physical QoL in HD patients. Chronic ongoing distress related to HD and genetic polymorphism may contribute to increase emotional distress and decreased QoL in HD patients.

TH-PO911

Association of the Geriatric Nutritional Risk Index and the Glasgow Prognostic Score at the Initiation of Hemodialysis Therapy with All-Cause Mortality in the Nation-Wide Registry Cohort Study in Japan

Takayuki Tsuji,[1] Yukitoshi Sakao,[2] Naro Ohashi,[1] Hideo Yasuda,[1] Seiji Hashimoto,[3] Kunitoshi Iseki,[3] Yoshiharu Tsubakihara,[3] Akihiko Kato.[1] *[1]First Dept of Medicine, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Blood purification Unit, Hamamatsu Univ Hospital, Hamamatsu, Shizuoka, Japan; [3]Committee of Renal Data Registry, Japanese Society for Dialysis Therapy (JSDT), Bunkyo-ku, Tokyo, Japan.*

Background: The geriatric nutritional risk index (GNRI) is a screening tool for nutritional status in chronic dialysis patients. The Glasgow prognostic score (GPS) is known as an independent prognostic factor in cancer patients. Although the prognosis is still poor in incident dialysis patients, it remains unknown whether these composite scores are useful in predicting outcomes. So, we aimed this study to examine whether GNRI and GPS assessed at the introduction of hemodialysis (HD) are associated with overall mortality.

Methods: We studied 4,329 patients (male: 66%, age: 66.8±12.7 years) from the Japanese nation-wide registry data, who had started HD during 2006. We calculated GNRI and GPS using the data collected at the initiation of HD, and surveyed their outcomes at the end of 2007. GNRI was calculated by following formula, [14.89 × ALB (g/dL)] + [41.7 × (Dry weight / Ideal body weight (equivalent to 22 kg/m^2 of BMI))]. The patients were divided into the quartiles (Q) by GNRI; Q1: <81.1, Q2: 81.2-88.0, Q3: 88.1-94.8, Q4: >94.8. We also divided all patients into the 3 categories (C) of GPS as follows; C0: CRP ≤ 1.0 (mg/dL) and ALB ≥3.5, C1: CRP > 1.0 or ALB < 3.5, C2: CRP >1 and ALB < 3.5.

Results: During the almost 1-year follow-up, 421 patients (9.7%) had expired. Multivariate logistic regression analysis adjusted by cofounders identified that both GNRI and GPS were independent risk factors for overall mortality.

	OR	95% CI	p-value		OR	95% CI	p-value
GNRI Q1 (vs Q4)	3.166	2.257-4.440	<0.0001	GPS C1 (vs C0)	1.743	1.316-2.310	<0.0001
GNRI Q2	1.696	1.280-2.605	0.004	GPS C2	3.629	2.712-4.856	<0.0001
GNRI Q3	1.103	0.750-1.622	0.619				

Conclusions: A lower GNRI (< 88.0) and a higher GPS (≥ score 1) at the initiation of HD are both useful in predicting a short-term mortality in incident HD patients.

TH-PO912

Impact of Weight Evolution on Mortality and Nutritional State in Hemodialysis Patients

Ana Rita Mateus Martins,[1] Inês Filipa Moreira,[1] Maria Gabriela Teixeira,[1] Patricia Quadros Branco,[2] Teresa Adragao,[2] Andre L. Weigert.[1] *[1]Davita Obidos, Davita Portugal, Caldas da Rainha, Portugal; [2]Nephrology Dept, Hospital Santa Cruz, Lisbon, Portugal.*

Background: Nutritional status is a key factor for patient survival and malnutrition is a major risk factor for mortality and inflammation in hemodialysis (HD) patients (pts). Our aim was evaluate the impact of weight evolution in prevalent HD pts.

Methods: Observational prospective study in 149 prevalent Portuguese HD pts. We obtained baseline demographic data, blood biochemistry, comorbidities and prevalence of malnutrition by mini-nutritional assessment (MNA) and patient-generated subjective global assessment (PG-SGA). The follow up period time was 12 months. Risk of mortality was investigated adjusted to comorbidities, age and time on HD using log-rank test and cox proportional model.

Results: In our cohort 93 were male, mean age was 67 years, 39% had diabetes (DM) and average time on HD was 54 months. Comorbidity Charlson score was on average 4.4±2.3 and body index mass was 27±4.5. During the follow up, 6 pts died of CV events. According to MNA and PG-SGA, 59 and 71% of our pts were well nourished. 31% of the pts lost at least 5% of their weight. PG-SGA in pts with unintentional weight loss (WL) was 3.8±4 VS pts who maintained or increased weight 2.4±2.1(p=0.05). In a Kaplan Meier test, pts with WL had a lower survival (172 VS 331months; log rank 8.9; p=0.003). In a linear regression, lower serum albumin was associated with comorbidity Charlson score (Exp(B)-1.9;p=0.009; IC 95% -3.2 to -0.5). Hypoalbuminaemia was associated with higher mortality (binary regression: Exp(B)0.025; p=0.001; IC 95% 0.003 to 0.2). Both models were adjusted to time on HD. In a cox hazards model, unintentional WL was an independent predictor of mortality (HR=10.4; p=0.034; IC 95% 1.2-91.3), adjusted to age and DM. Basal MNA and PG-SGA were not predictor of death, but PG-SGA was an independent predictor of unintentional WL (Exp(B)0.86; p=0.023; IC 95% 0.8-0.98).

Conclusions: Unintentional weight loss in pts on HD was an indepent predictor of mortality. Basal nutrition screnning and close monitoring of weight evolution can be a tool of classification of risk and for prioriting pts care.

TH-PO913

Using a Simpler Creatinine Index as a Surrogate of Lean Body Mass Predicts Long-Term Survival in Chinese Hemodialysis Patients

Jui Weng-Lin, Chiung-Ying Huang, Chih-Kang Chiang, Jenq-Wen Huang. *Dept of Internal Medicine, National Taiwan Univ College of Medicine and Hospital, Taipei, Taiwan.*

Background: Reduced lean body mass (LBM) is an indicator of malnutrition inflammation syndrome and is common in dialysis patients. Muscle mass and LBM inversely correlate with mortality in hemodialysis (HD) patients. Recently, a simpler creatinine index (CI) formula is developed. The aims of this study were to investigate the impact of LBM derived from the simple CI formula on HD patient outcomes.

Methods: We enrolled 1269 incident HD patients between Feb. 1981 and Feb. 2012 in three HD center of Taiwan and followed them until Feb. 2013. Clinical characteristics, HD-associated parameters, and serum chemistry profiles of each patient were collected at 1 month after initiating HD. LBM was estimated using creatinine index formula. Multiple linear regression analysis, Kaplan–Meier survival analysis, and Cox regression proportional hazard analysis were used to define independent variables and compare survival between groups.

Results: All patients were divided to three groups according to the tertile of estimated LBM between men and women. The patients in group 1 had the lowest LBM (n=423), group 2 had the intermediate LBM (n=423), and group 3 had the highest LBM (n=423) in men and women. Group 1 patients had shorter overall survival ($p < 0.01$). Each point increase in LBM reduced the hazard ratio for mortality by 22% after adjustment.

Conclusions: CI derived from the simple creatinine kinetic formula could be a surrogate of LBM to evaluate nutrition status and predict survival in HD patients. Besides, the simple formula could extend its use in clinical practice for HD patients.

Nutritional Status and RFLP Analysis in Patients Receiving Hemodialysis over 30 Years

Kaori Sakamoto,[1] Yoshihiko Kanno,[2] Mami Hiraoka,[4] Matsuhiko Hayashi,[3] Sanae Watanabe,[1] Yoshiko Kontai,[5] Yasuo Kagawa.[1] *[1]Dept of Clinical Nutrition and Dietetics, Kagawa Nutrition Univ, Japan; [2]Dept of Nephrology, Tokyo Medical Univ, Japan; [3]Apheresis and Dialysis Center, Keio Univ, Japan; [4]Dept of Nutrition, Shukutoku Univ, Japan; [5]Dept of Health and Nutrition, Univ of Niigata Prefecture, Japan; [6]Dept of Medical Chemistry, Kagawa Nutrition Univ, Japan.*

Background: Only 4% of 0.3 million patients receiving hemodialysis survive over 25 years after their initiation of hemodialysis even in Japan. To elucidate the clinical characteristics of long survival patients, we investigated their life-style and genetic factor. TT allele of methylene tetrahydrofolic acid reductase (MTHFR) C677T was reported as high risk factor for cardiovascular event and poor survival in CKD patients.

Methods: 78 of Japanese patients receiving hemodialysis over 30 years are enrolled. Their clinical profile, dietary intake and daily life activity was evaluated with diet history

questionnaires (DHQ), geriatric nutritional risk index (GNRI), and basal activity of daily life(BADL) scores. As their genetic factor, restriction fragment length polymorphism (RFLP) of MTHFR C677T were analyzed by PCR using their genomic DNA.

Results: Patients were 63.2±8.1 years old and included no diabetes. Male was 39.7%. Daily intake of energy, protein, and their achievement rate for Japanese guideline 2007 were 30.6±9.3 kcal/kg (97.7%),1.1±0.4 g/kg (101.9%). The frequency of TT allele was 26.9% and it was almost twice as average in Japanese population. BADL was 90, and their daily activities were highly maintained. In patients with TT allele, serum folic acid concentration were significantly lower, and serum homocysteine concentration was significantly higher than other groups, though daily intake of folic acid did not show significant difference.

Conclusions: Although the frequency of TT allele was higher than average population, our patients showed longer survival with high QOL and nutritional status based on our guideline. It is suggested that the proper life-style might overcome the genetic risk factors in patients receiving hemodialysis.

Efficacy of Oral Administration of LebeninS®, a Lactic Acid Bacteria Preparation, to HD Patients Yasuhisa Kurata,[1] Miho Hida,[1] Toru Hyodo.[2] *[1]Dept of Nephrology, Kuratakai Kurata Hospital, Hiratsuka, Japan; [2]Dept of Urology, Kuratakai Eijin Clinic, Hiratsuka, Japan.*

Background: The plasma levels of indoxyl sulfate (=indican, IS) are markedly increased in uremic patients and cannot be efficiently reduced by hemodialysis (HD) due to its albumin-binding property.Uremic toxicins as IS are produced in the intestine as bacterial putrefactive metabolites, and accumulate to a great degree in the feces of HD patients. We had demonstrated that oral administration of lactic acid bacteria in HD patients is effective in reducing the serum IS levels by inhibiting bacterial production by correcting the intestinal microflora[Nephron. 1996;74(2):349-55].

Methods: We administered LebeninS®, a lactic acid bacteria preparation, to 25 HD patients and assessed the mortality, complication, plasma IS and pentosidine levels, and the pulse wave velocity (PWV). The patients were divided into two groups: 11 of the patients were administrated 6g of LebeninS® daily for 12 months (LebeninS® group, Age: 79.0±0.68ys, HD history: 6.7±8.4ys, 4 diabetic, 5 female), and the other 14 patients(Age: 72.9±8.7 ys, HD history: 9.5±7.7ys, 6 diabetic, 7 female) were given nothing(control group). No statistical differences between these groups were observed in age, HD history, sex, diabetic, body mass index, and systolic and diastolic blood pressure.

Results: The frequency of complication during 12 months was 9.1% in LebeninS® group and 50% in the control group (P=0.0421). The plasma IS level (P=0.041) and PWV (P=0.006) significantly increased in the control group after 12 months. No adverse effects were observed.

	0 Month	12 months
PWL (Cont.) (cm/sec)	2173.6±415.8	2861.5±1042.3*
PWL (Lebenin)	2467.9±1003.8	2193.7±791.2
I S (Cont.) (mg/L)	190.0±70.1	257.0±102.7*
I S (Lebenin)	147.8±55.3	163.3±89.1
Pentosidine (Cont.) (ug/mL)	0.3±0.1	0.5±0.2*
Pentosidine (Lebenin)	0.3±0.1	0.4±0.2*

*: significant change.

Conclusions: These results demonstrate that oral administration of lactic acid bacteria preparations to HD patients is effective not only in reducing the plasma levels of uremic toxins such as IS, but also in clinical aspects including arteriosclerosis.

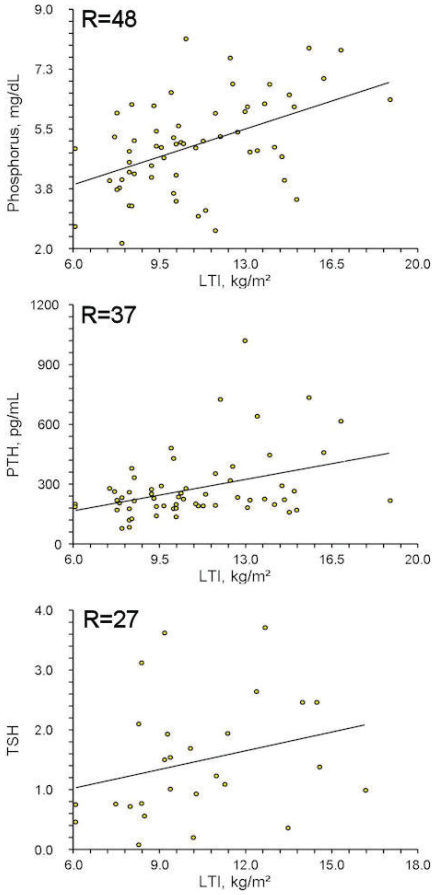
Bioeletrical Impedance Analysis for Nutritional Status in Hemodialysis Patients: Two Sides of the Same Coin? Paolo Lentini,[1] Luca Zanoli,[2] Massimo de Cal,[1] Stefania Rastelli,[2] Anna Basso,[1] Andrea Contestabile,[1] Antonio Granata,[1] Roberto Dell'Aquila.[1] *[1]Nephrology, S. Bassiano Hospital, Bassano Del Grappa, Italy; [2]Internal Medicine, Univ of Catania, Catania, Italy; [3]Nephrology, S.Giovanni di Dio Hospital, Agrigento, Italy.*

Background: Malnutrition is a common feature associated with increased mortality in dialysis patients. Principal causes of malnutrition include dietary restrictions, metabolic acidosis, hormonal alterations, dialytic nutrient losses, catabolic properties of dialysis, and chronic inflammation. Inversely, excessive nutrition may yield to obesity and lead to high levels of phosphorus and hyperparatyrodism, with a high risk of vascular calcifications, fractures and CV events. Multifrequency bioimpedance spectroscopy, a tool for bioelectrical impedance analysis (BIA), is a practical, simple, repetitive, non-invasive, and inexpensive method to measure the body composition.**Aim** To determine the optimal nutritional status in HD patients.

Methods: HD patients underwent standardized evaluation of their fluid and nutritional status with a portable bioimpedance monitor (Body Composition Monitor-BCM Fresenius® Medical Care). All measurements were carried out after the short interdialytic interval. Lean Tissue Index (LTI), an index of the nutrition status, was calculated as the quotient of LTM/Height² (kg/m²).

Results: 60 HD patients were enrolled(age 64±16yrs,males 55%).High LTI was significantly associated with high phosphorus, PTH, TSH and Ca-P product (R=0.52),known markers of nutrition status,increased number of drugs for calcium-phosphorus metabolism (R=0.39) and mean blood pressure (R=0.31).



Conclusions: BIA is useful to monitoring nutritional status in HD and to select patients at higher risk for vascular calcification and cardiovascular events.Changes in body composition detected by BIA measurements may yield an overall picture of the patient's nutritional status.

TH-PO917

High Ferritin Level and Low Nutrition Status Predicts Higher Risk of Infection-Related Hospitalization in Incident Dialysis Patients: A Japanese Prospective Cohort Study Sawako Kato,[1] Shoichi Maruyama,[1] Bengt Lindholm,[2] Yukio Yuzawa,[3] Yoshinari Tsuruta,[4] Seiichi Matsuo.[1] *[1]Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [2]Baxter Novum & Renal Medicine Karolinska Inst, Stockholm, Sweden; [3]Fujita Health Univ School of Medicine, Toyoake, Japan; [4]Meiyo Clinic, Toyohshi, Japan.*

Background: Iron management, evaluation of iron overload and its possible association with infections in dialysis patients (pts) are topics lacking consensus. This study aimed to clarify relations between ferritin and infection risk.

Methods: We enrolled 129 Japanese incident dialysis pts (84 males, 59 ± 11 years, 121 HD / 8 PD) and followed them prospectively for a median of 38 (range 1-74) months. We reviewed hospitalization due to infections and checked biomarkers and nutrition status by global subjective assessment (SGA: A, well nourished, B, mild/moderately malnourished, C, severely malnourished). The pts were divided into higher-ferritin group (H) and lower-ferritin group (L) by the median value.

Results: The median of serum ferritin levels was 82.0 (range 45.5-186.0) ng/ml. At dialysis initiation, 13.7% used a central venous catheter (CVC) and the ferritin levels of CVC users were significantly higher than in non-CVC pts (253 ± 280 versus 128 ± 138 ng/ml, P=0.02). In group H, the rate of hospital admissions due to infections was 0.23 (with 10.9 hospital days) per pts year, and in group L 0.09 (with 1.57 hospital days) per pts year. Moreover, the hospitalization days in pts with category A, B and C of SGA were 2.5, 10.1 and 27.7 days per pts year in group H and 0.2, 1.4 and 6.4 days in group L. The duration from dialysis initiation to first hospitalization due to infection was significantly shorter in group H (Log rank 4.44, P=0.035). High ferritin associated with significantly increased relative risk (Cox hazard model; crude RR 1.52 95% CI; 1.06-2.17), even after adjustments for age and CVC use (RR 1.50. 95% CI; 1.04-2.14).

Conclusions: Although ferritin levels and doses of iron administered to dialysis pts in general are lower than in Western counties, a higher ferritin level among these Japanese pts still associated with increased risk of hospitalization due to infection, especially in pts with poor nutritional status.

TH-PO918

Associations of Appetite with Quality of Life and Depressive Symptoms in Hemodialysis Patients with and without Major Comorbidities
Barbara De Alencar Costa,[1] Luciana Ferreira Silva,[2] Gentil Luz Junior,[1] Jean M. Monteiro,[1] Lucas Resende,[1] Gildete Barreto Lopes,[1] Antonio Alberto Lopes.[1] *[1]Univ Federal da Bahia, Salvador, Brazil; [2]Univ do Estado da Bahia.*

Background: Reduced appetite, malnutrition, poor health-related quality of life (HRQOL), depression and comorbidities are problems that impair the well being of maintenance hemodialysis (MHD) patients. We explored associations of reduced appetite with HRQOL and depression symptoms and assessed if the associations is explained by nutritional status in patients with and without major comorbidities.

Methods: Cross-sectional analysis of data of 543 MHD patients (60.2% males, mean age of 48.1±13.7 yr) enrolled (Jan 2010-Jan 2011) in the PROHEMO cohort in Salvador, Brazil. 171 patients were diagnosed and 372 were not diagnosed with any of the following comorbidities: diabetes, heart diseases, cerebral vascular disease, peripheral vascular disease, pulmonary diseases and cancer. The patients were asked to rate the degree (absent, light, moderate, intense) of persistent reduction in appetite. The Malnutrition-inflammation score (MIS) was used to assess nutritional status (higher worse). SF-36 was used for HRQOL scores (higher better) and BDI for depression symptoms scores (higher worse). Linear regression was used for covariate adjustments and interaction.

Results: HRQOL scores decreased and both depression symptoms scores and MIS increased monotonically across the four categories of appetite rate (P for trend<0.01). In patients without major comorbidities, linear regression analysis with adjustments for sociodemographis, hemoglobin, vintage and vascular access showed higher BDI scores (difference=4.0, P=0.001) and lower scores for all HRQOL scales in patients referring reduced appetite with differences larger than 7 points for several components (P<0.05). Differences in HRQOL and depression symptoms were largely reduced after adjustments for MIS. Similar associations were seen in patients with major comorbidities (interaction coefficients appetite*comorbidity>0.15).

Conclusions: The results are consistent with a role of malnutrition in explaining the lower HRQOL and higher probability of depression in MHD patients with reduced appetite.

TH-PO919

Low Serum Neutrophil Gelatinase-Associated Lipocalin Level as a Malnutrition Marker in Hemodialysis Patients
Hirotaka Imamaki,[1] Akira Ishii,[1] Hideki Yokoi,[1] Masato Kasahara,[2] Takashige Kuwabara,[1] Keita P. Mori,[1] Yukiko Kato,[1] Akira Sugawara,[3] Kazuwa Nakao,[4] Motoko Yanagita,[1,4] Masashi Mukoyama,[5] Kiyoshi Mori.[2,4] *[1]Nephrology, Graduate School of Medicine, Kyoto Univ, Kyoto, Japan; [2]Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan; [3]Nephrology, Osaka Red Cross Hospital, Osaka, Japan; [4]Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [5]Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: Circulating concentration of neutrophil gelatinase-associated lipocalin (NGAL or LCN2) is elevated in acute or chronic kidney diseases and shows a positive correlation with poor renal outcome and mortality, but its clinical significance in maintenance hemodialysis (HD) patients remains elusive.

Methods: Serum NGAL levels were determined by ELISA in 79 HD patients. Their correlation to laboratory findings and morbidity (as development of severe infection or serum albumin reduction) was investigated using linear and logistic regression analyses.

Results: In a cross-sectional study, serum NGAL concentrations were determined independently by % creatinine generation rate (an indicator of muscle mass, standardized coefficient β=0.44), white blood cell count (β=0.37) and anion gap (which likely reflects the amount of daily protein intake, β=0.23, P<0.01 each). In a longitudinal study, serum albumin levels a year later were predicted by baseline NGAL (β=0.36) and age (β=-0.37, P<0.005 each). Within a year, patients with the lowest NGAL tertile showed significantly increased risk for marked decline in serum albumin levels [≥0.4 g/dl; adjusted odds ratio (OR) 4.6, 95% confidence interval (CI) 1.1-18.9, P< 0.05] and tendency of increased occurrence of severe infection requiring admission (OR 2.9, CI 0.5-16.0, not significant) compared to the middle and highest tertiles.

Conclusions: Low serum NGAL levels appear to be associated with current malnutrition and also its progressive worsening in maintenance HD patients.

TH-PO920

Serum Ferritin Level Is an Independent Risk Factor for All-Cause Mortality in Incident Hemodialysis Patients
Shin-Wook Kang,[1,2] Eunyoung Lee,[1] Seonghun Kim,[2] Mi Jung Lee,[1] Jung Tak Park,[1] Tae-Hyun Yoo.[1] *[1]Dept of Internal Medicine, College of Medicine Yonsei Univ, Seoul, Korea; [2]Brain Korea 21 PLUS, Severance Biomedical Science Inst Yonsei Univ, Seoul, Korea.*

Background: Serum ferritin has been regarded as an indicator of inflammation as well as a marker of body iron storage in patients with end-stage renal disease (ESRD). In addition, high serum ferritin levels were significantly associated with poor clinical outcomes in prevalent dialysis patients. However, little is known about the prognostic impact of serum ferritin concentrations on the clinical outcome in incident hemodialysis (HD) patients.

Methods: A prospective cohort of 939 incident HD patients from 36 dialysis centers of the Clinical Research Center for ESRD in Korea was selected for this study. Serum ferritin levels were measured at the time of HD initiation. Patients were divided into tertiles according to log ferritin concentrations; <2.17, 2.17-2.50, and >2.50 ng/mL. Cox proportional hazard analysis was performed to determine the independent prognostic value of serum ferritin levels for all-cause mortality.

Results: The median ferritin concentrations were 217.8 (118.7-381.1) ng/mL. Pearson's correlation analysis showed that log ferritin levels were positively correlated with white blood cell counts (r=0.108, P=0.001) and log C-reactive protein concentrations (r=0.151, P<0.001), while negatively associated with serum albumin levels (r=-0.116, P<0.001). During a median follow-up duration of 20.7 months, 85 (9.1%) patients died. Kaplan-Meier analysis showed that all-cause mortality rates were significantly higher in the highest tertile ferritin group compared to the lowest tertile group (P<0.001). Multivariate Cox proportional hazard analysis demonstrated that log ferritin was independently associated with an increase in all-cause mortality risk after adjustment for confounding variables (per 1 ng/mL increase, hazard ratio=2.62, 95% confidence interval=1.45-4.73, P=0.001).

Conclusions: Serum ferritin concentration was a significant independent predictor of all-cause mortality in incident HD patients, suggesting that determining serum ferritin levels might be helpful to stratify mortality risk in these patients.

TH-PO921

Sex-Specific Difference According to Different Types of Cancer in End-Stage Renal Disease Dialysis Patients: Taiwan National Cohort Study
Chih-Chiang Chien. *Dept of Nephrology, Chi-Mei Medical Center, Tainan City, Taiwan.*

Background: The distribution of site-specific cancer mortality and mortality between men and women in end-stage renal disease (ESRD) dialysis patients is unknown.

Methods: We enrolled, from the Taiwan National Health Insurance Research Database, a cohort of 40,833 ESRD patients who started maintenance dialysis between 1999 and 2004. They were followed from dialysis initiation until death, discontinuation of dialysis, or the end of 2008. We calculated the survival rate and mortality risk of ESRD patients with cancer.

Results: Of 40,833 dialysis patients, 2352 (5.76%) had new cancer diagnosed. Older age, diabetic mellitus, chronic lung disease, and chronic liver disease were associated with a significantly increased risk for cancers. Liver cancer (20.63%) was most frequent in men, followed by bladder (16.88%) and kidney (11.61%) cancers. In women, bladder cancer (25.57%) was most frequent, followed by kidney (16.31%) and breast (11.20%) cancers. Older age, male gender, DM, and cardiovascular diseases were independent predictors of all-cause mortality in patients with cancer. However, there were no statistical differences between women and men after site-specific cancer analyses. When comparing 5-year survival rates for various cancers, kidney cancer and bladder cancer were higher than others; in contrast, those for lung cancer, stomach cancer and liver cancer were lower.

Conclusions: The distribution of site-specific cancer mortality is different between men and women in ESRD dialysis patients. Higher mortality for men than women for cancer is due to difference in types of cancers. The survival rate for kidney cancer was the highest in ESRD dialysis patients while it was worst for lung cancer.

TH-PO922

Health Service Usage in Rural versus Urban End Stage Kidney Disease in Australia
Sradha S. Kotwal,[1] Angela C. Webster,[2,3] Alan Cass,[1,4] Martin P. Gallagher.[1,5] *[1]The George Inst for Global Health, The Univ of Sydney, Sydney, Australia; [2]Sydney School of Public Health, The Univ of Sydney, Sydney, Australia; [3]Centre for Transplant and Research, Westmead Hospital, Westmead, Australia; [4]Menzies School of Health Research, Charles Darwin Univ, Darwin, Australia; [5]Concord Clinical School, Univ of Sydney, Sydney, Australia.*

Background: ESKD is a significant burden upon health systems and health services are used differently by rural and urban patients. To compare health service usage in rural versus urban end stage kidney disease (ESKD) patients in Australia.

Methods: We identified all New South Wales (NSW) residents receiving renal replacement therapy 2000-2010 using the ANZDATA Registry. Patients were linked to the NSW Admitted Patient Data Collection (APDC- records all NSW hospitalizations). We separated people into rural (living out of highly accessible areas) and urban (living in highly accessible areas), using postcodes and the Accessibility remoteness index of Australia scores. Rates of hospitalization, inter-hospital transfers and lengths of stay (LOS) were compared excluding day-only and dialysis admissions.

Results: ANZDATA identified 11,036 people, 531 did not match within APDC or had missing data, leaving 10,505 patients (120,828 hospitalization records), with median follow-up of 4.41 years (IQR 2.24-7.82). Of these, 1,527 (15%) lived rurally and 8,978 (85%) urban. The rate of hospitalization/patient year was 1.77 for rural residents compared to 1.47 for urban residents. In univariate analysis, rurality increased likelihood of admission by 43% (IRR 1.43 95%CI 1.31-1.56; p<0.001). A total of 3,181 patients underwent an inter-hospital transfer, 774 rural and 2407 urban. In univariate analysis, rurality increased the likelihood of requirement for transfer by 163% (IRR 2.63 95%CI 2.49-2.77; p<0.001). There was no difference in LOS (4.0 days versus 4.0 days respectively; p=0.08), further confirmed in univariate analysis (IRR 1.00 95%CI 0.96-1.05; p=0.98).

Conclusions: Rural residents are hospitalized and transferred more than urban residents, but LOS is similar. Risk adjustment for differences in baseline characteristics will help explore the reasons underlying these differences.

TH-PO923

Socioeconomic Deprivation and Patient Survival on Chronic Dialysis

Frank Ward,[1] Patrick O'kelly,[1] Fionnuala Donohue,[2] Coilín O. Oh Aiseadha,[2] Trutz Haase,[3] Jonathan Pratschke,[3] Declan G. de Freitas,[1] Howard Johnson,[2] Conall M. O'Seaghdha,[1] Peter J. Conlon.[1] *[1]Dept of Tranplantation and Renal Medicine, Beaumont Hospital, Dublin, Ireland; [2]Health Intelligence Unit, Health and Wellbeing Directorate, Health Service Executive, Dublin, Ireland; [3]Social and Economic Consultants, Health Service Executive, Dublin, Ireland.*

Background: Socioeconomic deprivation has been linked to worse end-stage kidney disease survival. The effect of socioeconomic deprivation on survival following initiation of chronic dialysis, including the impact of transplantation, was examined.

Methods: A retrospective, observational, cohort study was conducted to investigate the association of socioeconomic deprivation with patient survival on chronic dialysis, with censoring at the time of transplantation. All adult patients, with a valid postal address, commencing dialysis from 1990 to 2009 in a tertiary centre in Ireland were given a deprivation index (DI) score using the Pobal Haase-Pratschke Deprivation Index 2011. Cox proportional hazard and Kaplan Meier survival analysis were used to examine any association of socioeconomic deprivation with survival.

Results: The 1,794 patients included had a median follow-up of 3.8 years. The most deprived quartile were significantly younger than the most affluent, mean age 56.7 years versus 59 years, p=0.006, respectively. There was no association between DI score and survival in an unadjusted model (hazard ratio (HR) 1.00, 95% CI 0.99-1.01). However, survival in the most affluent quartile was superior to the most deprived in a multivariable adjusted model including age, gender and dialysis modality (HR 0.83, 95%CI 0.7-0.99, p=0.04). These results were largely unchanged by censoring at time of transplantation (least deprived versus most deprived, HR 0.85, 95% CI 0.7-1.03, p=0.09).

Conclusions: Whereas socioeconomic deprivation was not associated with poorer survival in dialysis patients in the Irish healthcare model, socioeconomically deprived patients tended to be younger and increasing affluence attenuated the mortality risk due to ageing in this setting. Further research should focus on identifying modifiable targets for intervention that account for this survival advantage in the more affluent.

TH-PO924

Fate Tracing Reveals Submesothelial Fibroblasts and Not Mesothelial Origin of Myofibroblasts in Peritoneal Fibrosis

Fang Ling Liao,[1] Yi-Ting Chen,[1,2] Yu-Ting Chang,[1] Szu Yu Pan,[1] Yu-Hsiang Chou,[1] Fan-Chi Chang,[1] Jeremy Stuart Duffield,[3] Shuei-Liong Lin.[1] *[1]National Taiwan Univ Hospital, Taipei; [2]E-DA Hospital, Kaohsiung, Taiwan; [3]Biogen Idec, Cambridge, MA.*

Background: Understanding the origin of myofibroblasts in peritoneum is of great interest because these cells are responsible for scar formation in peritoneal fibrosis after peritoneal dialysis. Recent studies suggest mesothelial cells are an important source of myofibroblasts through epithelial-mesenchymal transition; however, confirmatory studies *in vivo* are lacking.

Methods: We used tamoxifen-inducible Cre/Lox techniques to genetically label and fate map mesothelial cells and submesothelial fibroblasts in models of peritoneal fibrosis induced by sodium hypochlorite, peritoneal dialysis solution, or adenovirus expressing active TGF-β1.

Results: After pulse labeling induced by tamoxifen, the genetically red fluorescence protein labeled mesothelial cells did not generate transcripts of *collagen I (α1)* in normal peritoneum. Using red fluorescent protein as the fate marker, we found no evidence that mesothelial cells transmigrated into the thickened basal lamina and differentiated into α smooth muscle actin+ myofibroblasts *in vivo* although α smooth muscle actin could be induced in the primary culture of mesothelial cells *ex vivo* treated by recombinant TGF-β1. Cytokeratin+ mesothelial cells were found to express *collagen I (α1)* but not α smooth muscle actin after injury. No dilution of genetically labeled mesothelial cells was found, indicating the injured mesothelium was repaired by surviving mesothelial cells who had been genetically labeled. In contrast to no contribution of mesothelial cells to peritoneal myofibroblasts, genetically labeled submesothelial fibroblasts expanded and differentiated into myofibroblasts after peritoneal injury, accounting for a majority of myofibroblasts. No genetically labeled submesothelial cells expressed cytokeratin in peritoneal surface.

Conclusions: These data suggest that therapeutic strategies directly targeting myofibroblastic differentiation of submesothelial fibroblasts and promoting repair of mesothelium by surviving mesothelial cells may productively impact fibrotic peritoneal disease.

Vasopressin - 2 - Receptor Antagonist, Tolvaptan Provides Better Fluid Management and Improved Left Ventricular Hypertrophy in Peritoneal Dialysis Patients with Diabetes Mellitus

Takeyuki Hiramatsu, Akiko Ozeki, Kazuki Asai, Marie Saka, Akinori Hobo, Shinji Furuta. *Dept of Nephrology, Konan Kosei Hospital, Konan, Aichi, Japan.*

Background: Last year we reported vasopressin-2-receptor antagonist, tolvaptan preserved residual renal function and ameliorated left ventricular hypertrophy. Here, we evaluated the effect of tolvaptan on peritoneal dialysis (PD) patients with DM for the relationship between urine volume (UV) and phosphate elimination, LVH, and inferior vena cava caliber (IVC).

Methods: Last year we reported tolvaptan preserved residual renal function and ameliorated left ventricular hypertrophy. Here, we evaluated the effect of tolvaptan on peritoneal dialysis (PD) patients with DM for the relationship between urine volume (UV) and phosphate elimination, LVH, and inferior vena cava caliber (IVC).

Results: At baseline, there was no difference in laboratory data between the groups. In Tolvaptan group renal Kt/V, and CCr were preserved, and LVMI and IVC at 12 months were lower and phosphate elimination in urine was higher than that of control group.

	baseline		at 6 months		at 12 months		p value		
	Control	Tolvaptan	Control	Tolvaptan	Control	Tolvaptan	Time	Treat	Time* Treat
Urine volume (mL/day)	1305 ± 389	1023 ± 297	573 ± 312	1096 ± 432	179 ± 288	883 ± 418	0.001	0.001	0.209
Phosphate elimination in urine (mg/day)	162 ± 71	177 ± 77	91 ± 54	171 ± 55	61 ± 52	149 ± 89	0.037	0.001	0.932
LVMI (g/m^2)	197 ± 42	229 ± 56	214 ± 74	175 ± 32	201 ± 49	161 ± 26	0.200	0.030	0.960
IVC (mm)	15.2 ± 3.0	16.6 ± 4.0	15.0 ± 4.1	12.7 ± 3.9	15.4 ± 2.4	12.3 ± 2.5	0.660	0.033	0.568

Significant correlation between LVMI and IVC was observed (r = 0.50, p = 0.0128). IVC was correlated with UV at 6 and 12 months (r=-0.403, p=0.037). ΔLVMI(LVMI at 12 month/ LVMI at baseline) and average UV was inversely correlated (r=-0.413, p=0.045).

Conclusions: Short term usage of tolvaptan was effective for residual renal function, phosphate elimination and IVC. Moreover, IVC indicates the predictor of short term volume control. While LVMI indicates the predictor of long term volume control.

TH-PO926

Cuboidal Change and Increased Pro-Fibrotic Reactions Accompanying Epithelial Mesenchymal Transition in Peritoneal Mesothelial Cells by Peritoneal Dialysis Solution with Enhanced Oxidative Stress in Rats

Wan-Jun Zhu, Masaaki Nakayama. *Kidney and Hypertension Dept, Fukushima Medical Univ, Fukushima, Japan.*

Background: Functional change w/wo EMT of PMCs plays a pivotal role for progression of peritoneal fibrosis (PF) and sclerosis (PS) in patients on PD, and morphological change, i.e. increased surface area of PMCs, could reportedly predict extent of PS leading to encapsulating peritoneal sclerosis. High glucose and oxidative stress (OS) are supposed to be involved with the pathological mechanisms. Therefore, the present study aimed to elucidate the impact of PD solution, and solution with $FeCl_3$, on morphologic change and biological reactions of PMCs in vivo.

Methods: Male SD rats (8~10 weeks) were used for PD model: Sham group (n=4); PD dialysate only (neutral type, 2.5% glucose), group-A (n=5); PD dialysate with 0.5%$FeCl_3$ group, group-B (n=5). Rats were given the allocated test solution daily (20 mL) by intra-peritoneal injection for two weeks, and were subjected for peritoneal analysis. PMCs were collected by suspending of peritoneal tissue in trypsin solution. They were confirmed by flow-cytometry with HBME1 antibody staining. The pooled RNA of the respective groups was subjected for real-time PCR (housekeeping:CPH).

Results: Histologically, PMCs presented cuboidal shape (80%<) in group B, while they were flat in group A and sham. The fold changes of mRNA (versus sham) were shown in Table 1.

	Col-1	FN	TGF	MMP-2	SMA	Vimentin	E-cadherin	VEGF
PD (2.5%G)	x 4.57	x 8.72	x 1.87	x 66.14	x 0.82	x 2.42	x 1.33	x 1.42
$FeCl_3$					x 1.43	x 4.52	x 1.64	X 4.03

Conclusions: PD solution (glucose) increased pro-fibrotic reactions in PMCs, and oxidative stress enhanced EMT with accompanying angiogenetic reaction, indicating the primary pathological role of high glucose for PF and the critical role of oxidative stress for PS development. The cuboidal change of PMCs may be one of the histological step for enhanced PS in PD therapy.

TH-PO927

Heme Oxygenase-1 Polymorphisms and Peritoneal Membrane Characteristics in Peritoneal Dialysis Patients

Kristien El Daenen,[1] Benedict Sars,[1] Conny Colson,[3] Koenraad J. Stas,[2] Bert Bammens.[1] *[1]Nephrology, KU Leuven, Leuven, Belgium; [2]Nephrology, Jessa Hospital, Hasselt, Belgium; [3]Nephrology, Stuivenberg Hospital, Antwerpen, Belgium.*

Background: Baseline peritoneal membrane transport characteristics vary between individuals. Fast peritoneal small solute transport (PTR) is associated with oxidative stress and inflammation. Heme oxygenase 1 (HO-1) is an anti-oxidative and anti-inflammatory heme-degrading enzyme, expressed in the human peritoneum. Two functional promotor polymorphisms of the HO-1 gene are known: a $(GT)_n$ repeat polymorphism (short/long repeat: S/L) and a single nucleotide polymorphism (SNP) A(-413)T (S,A: higher activity). We studied the association between these polymorphisms and baseline PTR assessed by modified (3.86%) peritoneal equilibration test (PET) in peritoneal dialysis (PD) patients.

Methods: This is a retrospective study of 167 PDpatients from 3 Belgian hospitals (University Leuven n=123; Stuivenberg Antwerp n=30; Jessa Hasselt n=14) between 2002-2013. Baseline clinical and PET data ($D/P_{creatinine}$ and $D/D0_{glucose}$) were retrieved from patient files. Stored whole blood was used for DNA extraction and HO-1 genotyping.

Results: 56% of the patients were male. Mean age was 51±17 years. Distribution of the $(GT)_n$ repeat and A(-413)T SNP was: SS 10%; LL 48%; SL 42%; AA 30%; TT 18%; AT 52%. 35% of the patients had at least one S-allele AND one A-allele. This combination (Group A) is considered with higher HO-1 activity as compared to the remainder of the patients (Group B). Comparison of these groups revealed statistically significant differences in $D/P_{creatinine}$, $D/D0_{glucose}$, body mass index (BMI), serum albumin, total cholesterol and C-reactive protein (CRP) levels.

	Group A	Group B	p-value
D/P_{creat}	0,66 ± 0,14	0.69 ± 0.12	0,041
D/D_0 Glucose	0,33 ± 0,1	0,31 ± 0,13	0,015
BMI kg/m^2	23 ± 5	25 ± 5	0,004
Albumin g/L	39,4 ± 4,8	37,8 ± 4,4	0,024
cholesterol mg/dL	197,3 ± 50	177,1 ± 41,4	0,022
CRP g/L	5,0 ± 7,0	12,9 ± 36,2	0,011

Conclusions: Our data are supportive for a role of the HO-1 polymorphisms in the variability of PTR characteristics. Patients with higher HO-1 expression have a slower PTR and lower levels of inflammatory markers.

TH-PO928

LPA-LPA$_1$ Signaling Directs Peritoneal Mesothelial Cell Migration and Myofibroblast Differentiation in the Pathogenesis of Peritoneal Fibrosis Norihiko Sakai,[1] Takashi Wada,[1] Andrew M. Tager.[2] *[1]Div of Nephrology, Kanazawa Univ, Kanazawa, Ishikawa, Japan; [2]Pulmonary and Critical Care Unit, Massachusetts General Hospital, Boston, MA.*

Background: Peritoneal fibrosis is a serious complication of peritoneal dialysis, but the mechanisms by which it develops remain to be fully determined. We have previously found that the lipid mediator lysophosphatidic acid (LPA), acting through one of its receptors, LPA_1, stimulates peritoneal mesothelial cells (PMCs) to produce connective tissue growth factor through a myocardin-related transcription factor (MRTF)-serum response factor (SRF) pathway. In this study, we investigated additional effects of LPA-LPA_1 signaling on PMC biology, focusing on their migration and acquisition of a myofibroblast-like phenotype.

Methods: We isolated PMCs from wild-type(WT) and LPA_1-deficient (LPA_1KO) mice and determined their chemotaxis and expression of alpha smooth muscle actin (αSMA), a marker of myofibroblast differentiation, induced by LPA.

Results: WT-PMCs migrated toward LPA in a dose-dependent manner, whereas LPA did not stimulate LPA_1KO-PMC migration. The chemotactic activity of LPA on WT cells was completely inhibited by pertussis toxin, an inhibitor of the $G\alpha_i$ class of G proteins. In addition to migration, we found that LPA induced αSMA gene expression by PMCs, also in an LPA_1-dependent manner. To determine the molecular mechanisms through which LPA-LPA_1 signaling induces αSMA expression, we performed a series of experiments by inhibiting components of the MRTF-SRF pathway. We found that LPA-LPA_1 signaling mediates αSMA expression dependent on the MRTF-SRF pathway, through the $G\alpha_{12/13}$ class of G proteins. In a mouse model of peritoneal fibrosis induced by intraperitoneal injection of chlorhexidine gluconate (CG), we observed the presence of αSMA and E-cadherin co-expressing cells in WT mice throughout their mesothelium which was greatly expanded by extracellular matrix. In CG-challenged LPA_1KO mice, far fewer αSMA and E-cadherin co-expressing cells were present in the matrix of the peritoneum.

Conclusions: Our results suggest that LPA-LPA_1 signaling contributes to the pathogenesis of peritoneal fibrosis by driving PMC migration and myofibroblast differentiation.

TH-PO929

Decorin Ameliorates Peritoneal Fibrosis in Peritoneal Dialysis Related Peritonitis Susan Yung, Na Jiang, Mel Chau, Qing Zhang, Daniel Tak Mao Chan. *Dept of Medicine, The Univ of Hong Kong.*

Background: Peritonitis is a leading cause of peritoneal membrane failure in patients on peritoneal dialysis (PD). Decorin is a dermatan sulfate proteoglycan that possesses anti-fibrotic properties. Its role in peritoneal fibrosis remains to be fully defined. This study examined the relationship between dialysate decorin level and that of pro-inflammatory and fibrotic mediators in patients with PD associated peritonitis, and investigated the role of decorin in fibrogenesis.

Methods: Serial PD fluid samples were collected from 43 patients with PD related peritonitis. Dialysate samples from 23 PD patients without peritonitis in the past 12 months were included as controls. Dialysate concentrations of decorin, TGF-β1, IL-1β, IL-6 and IL-8 were measured using commercially available ELISAs. Mesothelial cells were incubated with spent PD fluid in the presence or absence of exogenous decorin, and the expression of SNAIL and fibronectin assessed.

Results: Dialysate decorin level was significantly higher at the onset of peritonitis compared to non-peritonitis dialysate (6345.23±1169.38 versus 257.6±26.9 pg/ml, P<0.05). Decorin level peaked 3 days after the onset of peritonitis and remained significantly higher than non-peritonitis levels 3 months later (8729.14±1145.21 pg/ml, P<0.05). Dialysate decorin levels showed an inverse relationship with dialysate IL-1β, IL-6 and IL-8 levels (r= -0.34, -0.38 and -0.32 respectively, P<0.05 for all), but correlated with TGF-β1 levels (r= 0.31, P<0.05). Peritoneal dialysate obtained at the onset of peritonitis significantly induced SNAIL and fibronectin synthesis in mesothelial cells, and this induction was reduced by exogenous decorin. SNAIL, but not fibronectin, expression inversely correlated with dialysate decorin level (r= -0.46, P=0.0024).

Conclusions: Our data suggested a role of decorin in ameliorating the peritoneal fibrotic process induced by peritonitis, and that decorin may suppress epithelial-to-mesenchymal transition and fibrogenesis in peritoneal mesothelial cells.

TH-PO930

The Peritoneal Endothelial Glycocalyx in Rats with Chronic Kidney Disease Exposed to Dialysis Solutions Carmen A. Vlahu,[1] Jan Aten,[2] Dirk Gijsbert Struijk,[1,3] Raymond T. Krediet.[1] *[1]Dept of Nephrology, Academic Medical Center, Amsterdam, Netherlands; [2]Dept of Pathology, Academic Medical Center, Amsterdam, Netherlands; [3]Dianet Foundation, Amsterdam, Utrecht, Netherlands.*

Background: Peritoneal dialysis (PD) leads to exposure of the peritoneal membrane to high concentrations of glucose and its degradation products, causing inflammation and angiogenesis, which may all alter the endothelial glycocalyx. Here, we investigated the changes in peritoneal endothelial glycocalyx induced by chronic kidney disease (CKD) and by long-term PD, using a conventional or a 'biocompatible' dialysis solution.

Methods: Forty-four Wistar rats were divided in 4groups: normal kidney function (NKF), CKD (induced by 70%nephrectomy), CKD exposed to Dianeal 4.25% (CKDD), or Physioneal 3.86% (CKDP). At 16 weeks, plasma levels of Syndecan-1 were measured by ELISA, and a peritoneal function test and Sidestream Darkfield imaging of the peritoneal vasculature were performed. The perfused boundary region (PBR), which reflects the erythrocyte permeable part of glycocalyx, and the valid microvascular density (VMD) were measured. The expression of syndecan-1, a heparan sulfate (HS) proteoglycan, and HS (10E4 epitope) was determined in peritoneal tissue specimens.

Results:

	NKF	CKD	CKDD	CKDP
Renal creat clearance (ml/min)	4.3±0.7	1.8±0.5*	2.3±0.5*	1.8±0.6*
D/P creatinine	0.4±0.06	0.5±0.03	0.6±0.08*	0.6±0.05*
PBR(μm)	2.2±0.2	2.1±0.4	2.1±0.2	2.1±0.1
Syndecan-1 (ng/ml)	9.4±6.1	19.6±10.0*	20.3±19.9*	12.2±6.7

*p<0.05 versus NKF.

Rats exposed to dialysis solutions had a higher VMD compared to NKF and CKD (p=0.04, p=0.007). A positive relationship was present between both PBR and VMD, and D/P creatinine (p=0.08, p=0.07). Syndecan-1 expression was decreased in rats exposed to dialysis solutions compared to NKF. HS as stained for the 10E4 epitope, was present mainly on the abluminal side of the endothelial cells.

Conclusions: Although the PBR was not different between groups, the decreased syndecan-1 expression in peritoneal blood vessels from the rats exposed to dialysis solutions suggests an alteration in the glycocalyx adjacent to the endothelial cell.

CCL18 Production by Peritoneal Macrophages Is Down-Regulated by the Vitamin D Receptor Agonist Paricalcitol Rafael Selgas,[1] M. Auxiliadora Bajo,[1] Marta Ruiz-Ortega,[3] Guadalupe González- Mateo,[1,2] Teresa Bellon.[1] *[1]Nephrology, H. U La Paz. IdiPAZ. REDinREN.IRSIN, Madrid, Spain; [2]CBM, Madrid, Spain; [3]Univ Autonoma de Madrid. REDinREN, Madrid, Spain.*

Background: The use of peritoneal dialysis (PD) is limited by the membrane capacity to perform long-term diffusive and convective transports, whose worst functional consequence is ultrafiltration failure and peritoneal fibrosis. Continuous stress for PD fluids and peritonitis represent a risk for both.M2 polarized macrophages (MF) have been involved in fibrosis in numerous clinical settings and experimental models. CCL18, a product of M2 MF, has been related to fibrosis in different diseases. We identified a population of M2 MF secreting high levels of CCL18 in peritoneal effluents from PD patients suffering peritonitis. Anti-inflammatory properties have been attributed to Paricalcitol. **Aim** To determine the effects of Paricalcitol on fibrosis and CCL18 production of peritoneal MF.

Methods: a) Paricalcitol effects were explored in a mouse model of peritoneal membrane injured by PD fluids (3.86% glucose and PDGs). b) Purified CD66-CD14+ MFpopulations (N=9) isolated from PD effluents from patients with peritonitis were incubated with Zemplar® (equivalents of 10^{-9}M, 10^{-8}M, and 10^{-7}M paricalcitol) or vehicle. CCL18 production was evaluated in supernatants by ELISA at 24, 48 and 72 h. CCL18 levels were also measured in peritoneal effluents from patients with peritonitis.

Results: a) Paricalcitol attenuated fibrosis in the PD mouse model, significantly reducing IL-17 local levels. b) Peritoneal effluents from patients with peritonitis were highly enriched in CCL18 whose level was related to peritoneal MF counts. In vitro, CCL18 production was significantly reduced in peritoneal MF upon culture with Zemplar® (paricalcitol 10^{-8}M or 10^{-9}M). The results were confirmed by incubation with purified active drug paricalcitol and with Vit D3 in a few samples.

Conclusions: Paricalcitol attenuates peritoneal fibrosis in a PD mouse model, associated with reduced levels of IL-17, and down-regulates CCL18 production by M2 polarized macrophages in the human inflamed peritoneum. Both mechanisms might result in a synergistic protective action against fibrosis at the peritoneum.

Mesenchymal Stem Cells Inhibit Peritoneal Fibrosis Resulting From Peritoneal Dialysis via snail-1 Signaling Pathway Xiang-Mei Chen, Diangeng Li, Yan Mei, Kai Hou, Wang Nan. *Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center of Kidney Diseases, Beijing, China.*

Background: Peritoneal dialysis (PD) is the main renal replacement therapy for end-stage renal disease (ESRD). However, PD associated chronic peritoneal fibrosis could cause ultrafiltration failure, which has been the most important reason for the dropout of PD patients and greatly limited the application and promotion of PD. Mesenchymal stem cells (MSCs) could inhibit inflammation and have the anti-fibrosis effect via paracrine secreting bioactive factor, thereby promoting injury repair. This study aimed to define whether MSCs could improve chronic peritoneal fibrosis resulting from peritoneal dialysis solution through inhibiting epithelial-mesenchymal transition (EMT) of peritoneal mesothelium cells (PMCs), and explore the specific mechanism for efficacy of MSCs.

Methods: In order to simulate chronic peritoneal fibrosis resulting from PD in clinical practice, we gave intraperitoneal injection of 4.25% peritoneal dialysis solution (100ml/kg per day) for 28 consecutive days to establish a chronic rat model of peritoneal fibrosis resulting from peritoneal dialysis solution. MSCs was used to make intervention in vivo via the tail vein injection on experimental model.

Results: The results showed that MSCs could improve peritoneal ultrafiltration function (29.65±20.33ml/kg, 28d), reduce peritoneal glucose transport function (16.88±1.74mmol/kg, 28d), peritoneal fibrosis degree (61.08±24.50μm, 28d) and blood vessel density (1.59±0.29/mm^2, 28d), inhibit the reduction of PMCs (the expression of E-Cadherin increasing), reduce the increase of peritoneal fibroblasts (the expression of α-SMA reducing), reduce the expression of TGF-β1. MSCs could increase the expression of E-Cadherin and reduce the expression of α-SMA by up-regulate the expression of snail-1 when co-culturing with PMCs stimulated by PD.

Conclusions: Our study suggest that MSCs could inhibit EMT of PMCs via snail signaling pathway in the model of PD associated chronic peritoneal fibrosis.

TH-PO933

Nano-Kidney Possessing Oxidative Stress Suppression Character Yukio Nagasaki,[1] Tatsuya Yaguchi,[1] Takuma Matsumura,[1] Toru Yoshitomi,[1] Yutaka Ikeda,[1] Atsushi Ueda,[2] Aki Hirayama.[3] *[1]Dept of Materials Science, Master's School of Medical Sciences, and Satellite Laboratory, International Center for Materials Nanoarchitectonics (WPI-MANA), National Inst for Materials Science (NIMS), Univ of Tsukuba, Tsukuba, Ibaraki, Jap; [2]Tsukuba Univ Hospital Hitachi Medical Education and Research Center, Univ of Tsukuba, Hitachi, Ibaraki, Japan; [3]Center for Integrative Medicine, Tsukuba Univ of Technology, Tsukuba, Ibaraki, Japan.*

Background: The prevention of encapsulating peritoneal sclerosis (EPS) and the enhancement of dialysis efficiency are two important strategies that can improve the quality of life of patients undergoing peritoneal dialysis. We have thus far developed bionanoparticles that effectively scavenge reactive oxygen species (redox nanoparticles; RNPs). The objective of this study was to apply RNPs as a component of dialysate to reduce oxidative stress.

Methods: ROS scavenging nanoparticle was prepared by self-assembling of amhiphilic block copolymer possessing nitroxide radicals as a side chain of the hydrophobic segment. Porous silica nanoparticles were combined with RNPs to enhance the effective adsorption capacity of low-molecular weight compounds. Since the size of the siRNP thus prepared was ca. 40 nm, the dialysate was completely transparent even with siRNP in it.

Results: The silica-containing RNPs were confirmed to statistically decrease the level of creatinine and blood urea nitrogen in vivo. EPS model rats that underwent an intraperitoneal injection of chlorhexidine gluconate exhibited dysfunction of the peritoneal membrane. siRNP administration did not result in dysfunction of the peritoneal membrane. An LMW nitroxide compound, TEMPOL, also showed a weak peritoneal protective effect, although its efficiency was limited. No blood uptake of siRNPs was observed when they were administered into the peritoneal cavity. However, LMW-TEMPOL diffused into the blood stream, which might have decreased its effective concentration in the peritoneal cavity and led to adverse effects across the entire body.

Conclusions: Considering the above results, siRNPs are expected to be a new multi-functional nanomaterial for high performance peritoneal dialysis.

TH-PO934

Vascular Endothelial Growth Factor Receptor-3 Can Be a New Target to Improve Ultrafiltration Dysfunction in Methylglyoxal-Induced Peritoneal Injury Takeshi Terabayashi,[1] Yasuhiko Ito,[1] Masashi Mizuno,[1] Yasuhiro Suzuki,[1] Hiroshi Kinashi,[1] Fumiko Sakata,[1] Shoichi Maruyama,[1] Yoshifumi Takei,[2] Seiichi Matsuo.[1] *[1]Nephrology, Nagoya Univ, Nagoya, Aichi, Japan; [2]Biochemistry, Nagoya Univ, Nagoya, Aichi, Japan.*

Background: Ultrafiltration failure (UFF) is a major reason for discontinuation in peritoneal dialysis (PD). We recently reported that lymphangiogenesis developed in the peritoneal cavity associated with fibrosis via the TGF-b-vascular endothelial growth factor C (VEGF-C) pathway. The aim of this study is to investigate whether VEGF receptor-3 (VEGFR-3), the receptor for VEGF-C and -D, is a target to improve UFF by suppression of lymphangiogenesis.

Methods: Peritoneal injury model was induced by intraperitoneal injection of MGO in C57Bl6 mice. Lymphatic vessel proliferation in their parietal peritoneum and diaphragm was evaluated by immunohistochemistry (IHC) and quantitative PCR (qPCR). Subsequently, we performed inhibition studies of lymphangiogenesis using adenovirus (Ad) expressing soluble VEGFR-3 (sVEGFR-3). MGO models were treated with (1) Ad-LacZ or with (2) Ad-sVEGFR-3, and were assessed at day 22; (3) MGO models were treated with (3) AdLacZ+peritoneal lavage from day22 to day50 or with (4) AdsVEGFR-3+peritoneal lavage from day22 to day50, and were assessed at day 50. The mice were submitted to a peritoneal equilibration test using 4.25% glucose-based solution (G-PET) and 7.5% icodextrin solution (Ico-PET) at day22 or day50.

Results: Lymphangiogenesis was presented in MGO model especially in the diaphragm with upregulation of VEGF-D mRNA ($P<0.001$), LYVE-1 ($P<0.01$) and VEGF-R3 ($P<0.01$). Serum sVEGFR-3 was detected at day 50 after administration via tail vein injections. Ad-sVEGFR-3 successfully suppressed lymphangiogenesis in MGO models without significant impact on neoangiogenesis, inflammation and fibrosis. Drained volume in Ico-PET was improved by Ad-sVEGFR-3 at day 22 ($P<0.05$) and day 50 after inflammatory resolution ($P<0.01$)indicating that Ico-PET identifies changes of lymphangiogenesis. However, G-PET did not discriminate changes in lymphatic absorption.

Conclusions: These results indicate that VEGFR-3 is a new target to prevent UFF by suppressing lymphatic absorption.

Survival of Propensity Matched Incident Peritoneal and Hemodialysis Patients in a United States Healthcare System Victoria A. Kumar,[1] Margo A. Sidell,[2] Edward F. Vonesh.[3] *[1]Internal Medicine, Kaiser Permanente, Los Angeles, CA; [2]Research and Evaluation, Kaiser Permanente, Pasadena, CA; [3]Dept of Preventative Medicine, Northwestern Univ, Feinberg School of Medicine, Chicago, IL.*

Background: Favorable clinical conditions among patients who initiate peritoneal dialysis (PD) likely impact results of survival studies. In an effort to reduce case-mix bias, we compared survival among incident PD patients to propensity matched hemodialysis (HD) patients at our organization. All HD patients received pre-dialysis care and initiated dialysis with either a functioning arterio-venous fistula or graft.

Methods: We utilized databases at Southern California Kaiser Permanente to identify all adult patients who initiated PD or HD at our institution between 2001 and 2013. HD patients who used a central venous catheter (CVC) at any time period during the first 90 days of dialysis were excluded. Stratefied Cox proportional hazards models were used to compare survival in both intent-to-treat (ITT) and as-treated (AT) analyses.

Results: A total of 1,003 matched pairs were obtained from 11,301 incident patients (10,298 HD and 1,003 PD). Cumulative hazard ratios for death can be seen in the table below.

	As-treated			Intent-to-treat		
Year	Survival % PD	Survival % HD	Adjusted time dependent cumulative HR (95% CI)	Survival % PD	Survival % HD	Adjusted time dependent cumulative HR (95% CI)
1	96	91	2.38 (1.68-3.40)	96	91	2.10 (1.50-2.94)
2	91	87	1.38 (1.05-1.82)	90	87	1.26 (0.98-1.63)
3	86	82	1.26 (0.98-1.63)	84	82	1.09 (0.87-1.38)
4	78	78	0.95 (0.74-1.22)	76	78	0.84 (0.67-1.05)
5	73	74	0.93 (0.72-1.21)	70	73	0.84 (0.67-1.06)
6	68	68	0.99 (0.75-1.32)	64	67	0.87 (0.68-1.11)
7	64	59	1.19 (0.85-1.65)	57	59	0.95 (0.72-1.26)
8	53	50	1.10 (0.72-1.70)	49	50	0.93 (0.67-1.30)
9	38	48	0.72 (0.35-1.52)	42	47	0.83 (0.57-1.23)

Conclusions: The cumulative risk of death, as estimated by the cumulative hazard ratio, favored PD for nearly 3 years of follow-up in the AT analysis and nearly 2 years of follow-up in the ITT analysis with no differences thereafter. The higher adjusted rate of death observed for HD patients cannot be attributed to initial use of CVC's or lack of pre-dialysis care.

Successful Use of Two Icodextrin Exchanges Alone Laura K. Troidle,[1] Fredric O. Finkelstein,[1,2] Peter Juergensen.[1] *[1]Metabolism Associates, New Haven, CT; [2]Medicine, Yale Univ School of Medicine, New Haven, CT.*

Background: Patients starting CPD therapy (Rx) often use several dextrose based solutions for dialysate. The use of such solutions exposes the patient to potential long-term peritoneal membrane damage. Some patients starting CPD Rx have significant residual renal function (RRF) that permits the achievement of a total Kt/V urea of >1.7 using low amounts of dialysate. Thus, CPD Rx using two long dwell icodextrin exchanges (2ICDE) has been effective in patients starting CPD therapy in meeting international standards of dialysis adequacy.

Methods: We previously reported our experience using 2ICDE and now expand our observations (Awuah et al, Adv Perit Dial 29:1-3, 2013). All patients starting CPD Rx with adequate RRF were considered to be candidates for 2ICDE. A total of 12 patients started CPD Rx with 2ICDE since January 2011.

Results: The patients were maintained on 2ICDE for an average of 9.3 months (range 1-26 months). The average Kt/V urea, including RRF, after starting 2ICDE was 1.97 (range 1.75-2.24). Additional manual or cycler therapy was added to the 2ICDE for patients unable to maintain adequate clearances with 2ICDE alone. Two patients were unable to continue beyond one week. One of these patients developed and ICD allergy, and, the other patient preferred to change to cycler therapy. Since there has been a concern that the use of 2ICDE may result in false glucose readings with certain glucometers, we obtained simultaneous glucometer and lab glucose determinations in seven patients. The glucometer reading was an average of 10.6% higher than the serum glucose lab measurement (range 8-18%) in 5 patients who had elevated serum glucose measurements. Two patients with normal serum glucose had an 18-33% higher reading with the glucometer.

Conclusions: We conclude that 2ICDE can provide adequate Kt/V urea for patients with RRF, thus, limiting glucose exposure as well as the amount of time needed to perform CPD Rx. Glucose determinations may be 10% higher with a glucometer in patients using 2ICDE. Patients with normal serum glucose measurements still had normal readings with a glucometer.

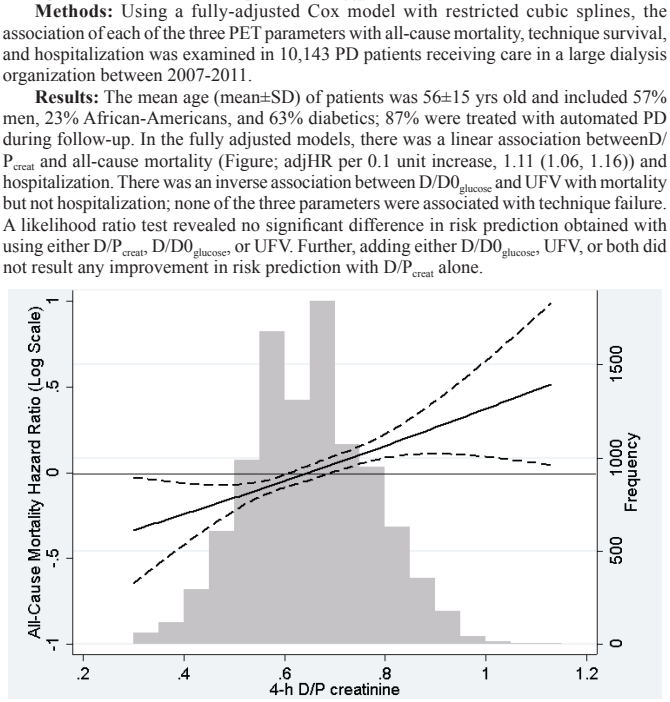
TH-PO937

Peritoneal Equilibration Test (PET) and Patient Outcomes in a Multi-Ethnic Contemporary Cohort Vanessa A. Ravel,[1] Elani Streja,[1] Sooraj Kuttykrishnan,[2] Miklos Zsolt Molnar,[3] Kamyar Kalantar-Zadeh,[1] Rajnish Mehrotra.[2] *[1]Harold Simmons UC Irvine MC, Orange, CA; [2]Univ of Washington, Seattle, WA; [3]Univ of Toronto, Toronto, ON.*

Background: Even though a standard PET yields data on three different parameters (4-hr dialysate-plasma creatinine, D/P_{creat}, 4-hr to 0-hr dialysate glucose, $D/D0_{glucose}$, ultrafiltration volume, UFV), virtually all studies have focused on the prognostic value of D/P_{creat}. Since $D/D0_{glucose}$ and UFV may be superior to predicting total daily ultrafiltration, the likely mechanism that explains the association of PET results with patient outcome, we hypothesized that they are superior to D/P_{creat} for risk prediction.

Methods: Using a fully-adjusted Cox model with restricted cubic splines, the association of each of the three PET parameters with all-cause mortality, technique survival, and hospitalization was examined in 10,143 PD patients receiving care in a large dialysis organization between 2007-2011.

Results: The mean age (mean±SD) of patients was 56±15 yrs old and included 57% men, 23% African-Americans, and 63% diabetics; 87% were treated with automated PD during follow-up. In the fully adjusted models, there was a linear association betweenD/P_{creat} and all-cause mortality (Figure; adjHR per 0.1 unit increase, 1.11 (1.06, 1.16)) and hospitalization. There was an inverse association between $D/D0_{glucose}$ and UFV with mortality but not hospitalization; none of the three parameters were associated with technique failure. A likelihood ratio test revealed no significant difference in risk prediction obtained with using either D/P_{creat}, $D/D0_{glucose}$, or UFV. Further, adding either $D/D0_{glucose}$, UFV, or both did not result any improvement in risk prediction with D/P_{creat} alone.



Conclusions: Analysis of data from a large contemporary multi-ethnic cohort validates for the first time D/P_{creat} as the most robust predictor of outcomes in patients undergoing peritoneal dialysis.

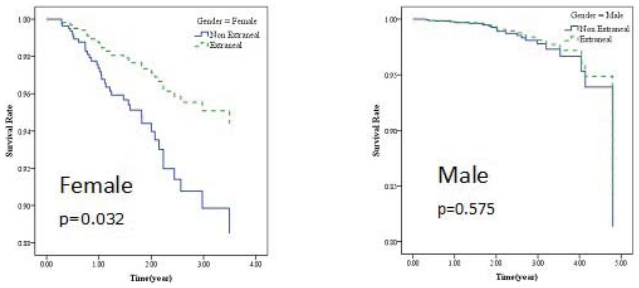
Once-Daily-Use of Icodextrins Improved Survivals of Asian Peritoneal Dialysis Patients- A Propensity Score Matched, Nationwide Population Study Chiu-Ching Huang,[1,2] Wen-Yin Kuo,[3] I-Kuan Wang,[1,2] Wen-Chen Tsai.[3] *[1]Kidney Inst, China Medical Univ Hospital, Taichung, Taiwan; [2]College of Medicine, China Medical Univ, Taichung, Taiwan; [3]Dept of Health Services Administration, China Medical Univ, Taichung, Taiwan.*

Background: There are controversies whether icodextrin (ICO)-use can improve patient survivals in incident PD patients. This Asian study compared the risk of death between ICO-users (study group)and propensity score matched non-ICO-users (control group).

Methods: All incident PD patients in Taiwan National Health Insurance Research Database who had at least survived more than 90 days after PD from January 1, 2004 to June 30, 2009 were recruited. ICO were prescribed once daily for high risk patients, e.g. (1) diabetic with HbA1C > 7%, or (2) high transporters, or (3) used high-glucose containing dialysates. Patients were followed until death or transfer to HD or renal transplantation or Dec 31, 2009. Patient survivals were compared between ICO users and propensity score matched controls. The multivariate Cox regression models were used to calculate the impact of ICO-use on mortality and to plot survival curves.

Results: A total of 1627 incident PD patients were identified. Among them, 524 ICO-users were matched with 524 non-ICO-users for age, sex, co-morbidities, and monthly incomes. Ico-users had better patient survivals than control cohort (HR 0.6 for ICO versus non-ICO users, 95% CI: 0.37-0.99, p=0.045). Female ICO users had significently better patient survival than non-ICO users (HR 0.48, 95% CI: 0.25-0.94, p=0.032). but it is not significant in male patients (HR 0.79, 95%CI 0.35-1.79,p=0.575)



Conclusions: Comparing to a propensity score matched control cohort, once-daily-use of ICO in high risk Asian PD patients are beneficial to patient survivals, particularly in female population. Further randomized controlled studies are necessary to confirm our observations.

TH-PO939

Association of Alternative Approaches to Normalizing Peritoneal Dialysis Clearance with Clinical Outcomes Suzanne Boyle, Yimei Li, Francis Perry Wilson, Joel D. Glickman, Harold I. Feldman. *Univ of Pennsylvania, Philadelphia, PA.*

Background: Kt/V is the standard for assessing PD adequacy. Calculation of V, the volume of total body water, ignores variability in fat:fat-free mass ratio potentially distorting Kt/V among those at extremes of BMI, leading to inappropriate PD prescriptions and promoting earlier mortality or technique failure (TF). We explored the relationship of mortality and TF to non-normalized Kt and to peritoneal Kt/V calculated with V based on actual body weight(standard practice), ideal body weight, and adjusted body weight.

Methods: The Dialysis Morbidity and Mortality Study Wave 2, a prospective study of incident dialysis patients enrolled from 1996-1997 at 799 randomly-selected U.S. dialysis facilities, was linked with USRDS data for ESRD treatment history and mortality through 2010. Patients were included in the analysis if data to calculate peritoneal Kt/V at study entry were available.The association of 4 metrics of peritoneal urea clearance with death and TF were assessed with Cox proportional hazard models.

Results: 534 individuals had sufficient data for analysis. Median age was 59. 54% were male; 72%, white; 91% on CAPD. 5-year mortality was 37% and 5-year TF, 60%.Varying normalization strategies led to profound differences in calculated clearance, particularly among the underweight and obese (Table).

Median and IQR of Achieved Peritoneal Clearance by BMI

BMI (kg/m²)	KT	Kt/V_{actual}	Kt/V_{ideal}	$Kt/V_{adjusted}$
Underweight < 18.5 (n=27)	47.9 (42.6-55.5)	1.75 (1.56-2.06)	1.61 (1.41-1.98)	1.66 (1.48-2.02)
Normal 18.5 – 25 (n=207)	58.6 (51.8-66.4)	1.73 (1.44-1.97)	1.74 (1.42-1.98)	1.72 (1.44-1.98)
Overweight 25 – 30 (n=172)	57.8 (51.9-64.7)	1.54 (1.27-1.77)	1.70 (1.41-2.03)	1.63(1.37-1.90)
Obese >30 (n = 128)	61.7 (56.4-67.8)	1.42 (1.20-1.61)	1.83 (1.57-2.16)	1.65 (1.42-1.92)

After multi-variable adjustment, we did not detect a relationship between any clearance metric and the outcomes of mortality or TF in either the whole cohort or within any BMI stratum.

Conclusions: Patients at extremes of BMI are at risk for false estimation of V. Although we did not detect an association between any clearance metric and clinical outcomes, large variation in clearance across BMI groups suggests the need for studies to optimize PD clearance targets among the underweight and obese.

The Impact of Timing of Dialysis Initiation on Mortality in Patients with Peritoneal Dialysis Yong Kyun Kim, Ho Cheol Song, Euy Jin Choi, Chul Woo Yang. *Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: The impact of timing of dialysis initiation on mortality is controversial in patients with peritoneal dialysis (PD). In this study, we analyzed the impact of timing of dialysis initiation on mortality in the incident PD population.

Methods: Incident patients with PD were selected from the Clinical Research Center (CRC) registry for end-stage renal disease (ESRD), a prospective cohort study on dialysis in Korea. Patients were categorized into three groups according to the estimated glomerular filtration rate (eGFR) at the initiation of PD using the Modification of Diet in Renal Diseaseequation.Group Awas defined as eGFR < 5 ml/min/1.73m^2, group Bas eGFR 5-10 ml/min/1.73m^2, and group Cas eGFR > 10 ml/min/1.73m^2. Cox regression analysis was used to calculate the adjusted hazard ratio (HR) of mortality with group B as the reference. The primary outcome was all-cause mortality.

Results: A total of 495 incident PD patients were included. The number of patients in group A was 109, group B was 279, and group C was 107. The median follow-up period was 23 months. Multivariate Cox regression analysis showed that group A had a significantly higher risk of all-cause mortality compared with group B (HR 4.13, 95% CI, 1.55-11.03, P = 0.005) after adjustment for age, gender, cause of ESRD, serum albumin level, diabetes mellitus, and cardiovascular diseases. There was no significant difference in mortality between group C and group B (HR 1.50, 95% CI, 0.59-3.80, P = 0.398) after adjustment for clinical variables.

Conclusions: An eGFR < 5 ml/min/1.73m^2 at the initiation of PD was a significant risk factor for death, while an eGFR >10 ml/min/1.73m^2 at the initiation of PD was not associated with improved survival compared with an eGFR of 5-10 ml/min/1.73m^2 at the initiation of PD.

TH-PO941

Lower Education Level Is a Risk Factor for Peritonitis and Technique Failure but Not a Risk for Overall Mortality in Peritoneal Dialysis
Hyo-Jin Kim, Hajeong Lee, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim, Curie Ahn, Jin Suk Han, Kook-Hwan Oh. *Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea.*

Background: It is speculated thata lower education levelis a risk factor for higher peritoneal dialysis (PD)-associated peritonitis, potentially resulting in technique failure. We have analyzed the influence of lower education level on the development of peritonitis, technique failure and overall patient mortality.

Methods: This is a single-center, retrospective cohort study. Subjects who started PD at Seoul National University Hospital between January 2000 and December 2012 were enrolled. Subjects were divided into three groups: lower (academic year≤9 years, n=102), intermediate (9 <academic year≤ 12 years, n=229), and higher (academic year>12 years, n=324) education groups.Cox proportional hazards models were employed to analyze the influence of the education level on the outcomes.

Results: A total of 655 incident PD patients (60.9% male, age 48.4±14.1 years) were analyzed. Mean follow-up duration was 48.1±33.8 months. During follow-up, 250 subjects (38.2%) experienced more than one episode of peritonitis, 140 subjects (21.4%) underwent technique failure and 78 subjects (11.9%) died. After adjustment to the age, gender, diabetes, other comorbidities, visual disturbance, hemoglobin, C-reactive protein, albumin, glomerular filtration rate, lower education level was shown to be an independent risk factor for peritonitis (hazard ratio [HR] 1.66; 95% confidence interval [CI] 1.13-2.43) and technique failure (HR 1.71; 95% CI 1.01-2.90). However, it was not associated with increased overall mortality (HR 1.28; 95% CI 0.63-2.59).

Conclusions: Although lower education level was a significant risk factor for peritonitis and technique failure, it was not associated with increased mortality in PD patients. Subjects with lower education level should not be discouraged from choosing PD as their first-line renal replacement therapy. Comprehensive training in PD exchange procedures and multidisciplinary education is warranted for overcoming the lower education level in subjects undergoing PD therapy.

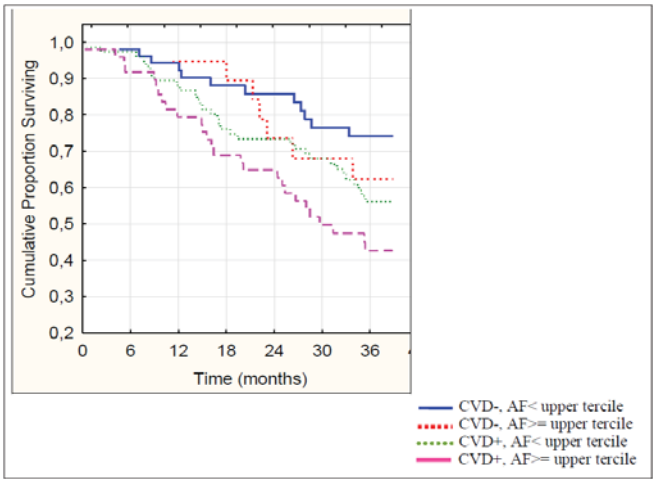
TH-PO942

Skin Autofluorescence as Mortality Predictor in Patients on Peritoneal Dialysis
Emilia Mácsai,[1] Attila Benke,[1] Istvan Kiss.[2] *[1]3rd Dialysis Centre, B.Braun Avitum Hungary CPLC, Veszprém, Hungary; [2]1st Dialysis Centre, B.Braun Avitum Hungary CPLC, Budapest, Hungary.*

Background: Skin autofluorescence (SAF) is a known and accepted prognostic factor of mortality in hemodialysis patients. Traditional and non-traditional risk components are similar in peritoneal dialysis (PD), and as well cardiovascular disease (CVD) is the leading cause of death. Moreover peritoneal glucose absorption accelerates degenerative processes of the connective tissues, like in diabetes. In our study we examined the predictive value of SAF for mortality in PD population.

Methods: Data were taken from 198 prevalent adult Caucasian PD patients. Initially we evaluated the factors affecting SAF and CVD by multivariate linear regression. Registering the clinical and demographic data associations with mortality during the next 36 months were estimated using Kaplan-Meier method, analysis were stratified on presence of CVD and SAF level above or below the upper tercilis 3.61.

Results: SAF was influenced by CVD (p<0.01; CI 0.1-0.5) and white blood cell count (p<0.001; CI 0.031-0.117). According Spearman correlation it connected with peritoneal cumulative glucose exposure (p=0.02) and elapsed time in PD (p=0.008). CVD related with age (p<0.001; CI 1.24-1.65) and diabetes (p<0.001; CI 2.58-10.66). More death were observed in the high SAF group, than in the low SAF group (34/68 v. 44/130; p=0.04). Comparing the CVD(-) low SAF group survival (mean 33.9 month; SE 1.39) to CVD(+) low SAF (mean 30.5 month; SE 1.37; p=0.03) and to CVD(+) high SAF group (mean 27.1; month; SE 1.83; p=0.001) the difference was significant.



Conclusions: Among patients on PD the SAF value over 3.61 seems to be predictor of mortality. Relationship with glucose-exposure, CVD and diabetes suggests its suitability to characterize systemic cumulative glucose load.

TH-PO943

Endothelial Dysfunction Is Associated with Major Adverse Cardiovascular Events in Peritoneal Dialysis Patients
Seonghun Kim,[1] Chang-Yun Yoon,[2] Mi Jung Lee,[2] Hyung Jung Oh,[2] Jung Tak Park,[2] Seung Hyeok Han,[2] Tae-Hyun Yoo,[2] Shin-Wook Kang.[1,2] *[1]Brain Korea 21 PLUS, Severance Biomedical Science Inst, Yonsei Univ, Seoul, Korea; [2]Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea.*

Background: Endothelial dysfunction is implicated in high cardiovascular risk in the general population. However, the impact of endothelial dysfunction on cardiovascular outcome has not been extensively investigated in peritoneal dialysis (PD) patients. In this prospective observational study, therefore, we elucidated the prognostive value of endothelial dysfunction in PD patients.

Methods: Endothelial function was determined by brachial artery endothelium-dependent vasodilation (flow-mediated dilation; FMD) in 143 non-diabetic PD patients and 32 sex- and age-matched controls. The primary outcomes were major adverse cardiac and cerebrovascular events (MACCEs). Cox proportional hazard analysis was performed to ascertain the independent prognostic value of brachial FMD for MACCEs.

Results: Brachial FMD was significantly lower in PD patients than that in controls [2.9 (1.3-4.7) versus 6.2 (5.4-8.3)%, P<0.001]. During a mean follow-up duration of 42 months, the primary outcomes were observed in 25 patients (17.5%). When patients were dichotomized by the median value of FMD (2.9%), the incidence rates of MACCEs were significantly higher in patients with lower FMD compared to the higher FMD group (7.2 versus 3.0 per 100 person-years, P=0.03). In multivariate Cox analysis, low FMD (≤2.9%) was a significant independent predictor of MACCEs (hazard ratio=2.73, 95% confidence interval=1.03-7.22, P=0.04). Furthermore, multivariate fractional polynomial analysis showed that the risk of MACCEs increased steadily with lower FMD values.

Conclusions: Impaired brachial FMD was a significant independent predictor of MACCEs in PD patients. Determining endothelial dysfunction by brachial FMD may be useful for stratifying cardiovascular risk in these patients.

TH-PO944

Cardiac Performance Is Improved in Incident Peritoneal Dialysis Patients with Slow Rates of Residual Renal Function Decline
Seonghun Kim,[1] Chang-Yun Yoon,[2] Seung Gyu Han,[2] Tae-Hyun Yoo,[2] Shin-Wook Kang.[1,2] *[1]Brain Korea 21 PLUS, Severance Biomedical Science Inst Yonsei Univ, Seoul, Korea; [2]Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea.*

Background: Reduced residual renal function (RRF) is associated with left ventricular (LV) hypertrophy as well as all-cause and cardiovascular (CV) mortality in patients with end-stage renal disease. However, the serial changes in echocardiographic findings according to the decline rates of RRF have not been fully elucidated in incident peritoneal dialysis (PD) patients.

Methods: A total of 81 patients, who started PD between 2005 and 2012 at Yonsei University Health System and underwent baseline and follow-up echocardiography within the first year of PD, were recruited. Based on the 1-year median RRF decline slope (-1.6 mL/min/yr/1.73m^2), patients were divided into 'faster' and 'slower' RRF decline groups. Time-dependent serial changes in echocardiographic parameters were compared between the two groups by linear mixed model (LMM).

Results: Baseline RRF and echocardiographic parameters were comparable between the two groups. The decline rate of RRF was an independent factor for the changes in LV end diastolic volume index (LVEDVI) (r=17.95, P=0.019), left atrial volume index (LAVI) (r=8.54, P=0.006), and LV mass index (LVMI) (r=21.00, P=0.005). The LMM further confirmed that LVEDVI, LAVI, and LVMI were significantly more improved in the 'slower' RRF decline group than those in the 'faster' RRF decline group (P=0.047, P=0.048, and P=0.001, respectively). Compared to the 'faster' RRF decline group,

composite CV outcome (P=0.098), technique failure (P=0.006), and PD peritonitis (P=0.064) occurred less frequently in patients with 'slower' RRF decline. Multivariate Cox regression analysis revealed that 'faster' RRF decline was a significant risk factor for each clinical outcome [composite CV outcome, HR=4.82, 95% CI=1.15-20.22, P=0.03; technique failure, HR=4.44, 95% CI=1.15-17.18, P=0.03; PD peritonitis, HR=7.37, 95% CI=1.43-38.04, P=0.02].

Conclusions: Cardiac performance was significantly improved in incident PD patients with slow RRF decline, which might partly contribute to better clinical outcomes in this group.

TH-PO945

A Prognostic Model for Risk of Encapsulating Peritoneal Sclerosis Incorporating the Risk of Death During Peritoneal Dialysis: Results From PD-CRAFT

Mark Lambie,[1] Lucy Riley,[1] David W. Johnson,[2] Simon J. Davies.[1] *[1]Health Services Research Unit, Keele Univ; [2]Univ of Queensland.*

Background: Encapsulating peritoneal sclerosis(EPS) is an uncommon complication of peritoneal dialysis (PD), where the risk increases significantly with time on therapy. To aid decision making around switching from PD to haemodialysis to minimise the risk of EPS, we developed prognostic models for death and EPS.

Methods: We combined Australia and New Zealand Dialysis and Transplant (ANZDATA) and Scottish Renal Registry (SRR) datasets with complete data on EPS diagnosis and the denominator population. Patients aged ≥15 years were included in competing risks models with outcomes of EPS or death. Comorbidity was classified by primary renal diagnosis. Prognostic models were developed with hierarchical backwards stepwise selection, using calibration, discrimination, and goodness-of-fit to determine the best models after 3, 4 and 5 years of PD, predicting the 5 year risks in each case.

Results: Therewere 112 cases in 17,912 patients. EPS incidence differed markedly between ANZDATA and SRR (10 year incidence 0.04 in ANZDATA, 0.25 SRR, p<0.001). Models were therefore generated for ANZDATA, to be updated using SRR and Dutch registry data. Age and high comorbidity were associated with a decrease in EPS risk. Predicted risks for sample patients are shown in the table.

		Age 40, Low comorbidity, No Diabetes	Age 60, Low comorbidity, No Diabetes	Age 80, High Comorbidity With Diabetes
3 years	EPS	2.59%	1.27%	0.07%
	Death	18.94%	41.55%	84.88%
4 years	EPS	4.51%	1.68%	0.19%
	Death	23.12%	46.13%	84.17&
5 years	EPS	6.45%	2.55%	0.35%
	Death	28.75%	49.90%	91.31%

Conclusions: The predicted risks for EPS and death show marked differences between patients, supporting the use of a prognostic model when discussing whether to stop PD. Results for ANZDATA showed lower risks, likely due to ascertainment bias, so the updated model will predict higher EPS risks.

TH-PO946

Long-Term Prevalence of Lipid Abnormalities in Children on Peritoneal Dialysis

Nur Canpolat, Lale Sever, Mehmet Tasdemir, Gulseren Pehlivan, Rumeysa Yasemin Cicek, Salim Caliskan. *Ped. Nephrol., Istanbul Univ Cerrahpasa Med. Faculty, Turkey.*

Background: Little data is available for dyslipidemia in pediatric peritoneal dialysis (PD) patients. The aim of the study is to determine long-term prevalence of lipid abnormalities in these patients and its relationship with age, PD duration and treatment modality.

Methods: Fifty-eight pediatric PD patients (33 boys; 34 CCPD) who underwent PD at least 24 months were retrospectively analyzed. All available data on lipid parameters [serum triglyceride(TG), total cholesterol(TC), LDL-C, HDL-C] were documented and mean values were calculated for the baseline, second and fifth year on PD. Dyslipidemia was defined as TC≥200mg/dl, LDL-C≥130mg/dl and non-HDL-C≥145mg/dl. Hypertriglyceridemia was defined as serum TG≥100mg/dl (0-9 yr) and TG≥130mg/dl (10-19 yr). The cases were divided into three groups according to the age at the initiation of PD; Group I; 0-2 yr (n=17), Group II; 2-9 yr (n=17) and Group III; 10-19 yr (n=27).

Results: Median age at the initiation of PD was 9.6(0.1-17.4) years and median duration of PD was 41(24-107) months. The prevalence of dyslipidemia and the prevalence of hypertriglyceridemia were 83%(n=43), 70%(n=58), 76%(n=21), and 70%(n=45), 66%(n=58), 58%(n=21) at the baseline, second and fifth year on PD,respectively. TG levels showed significant difference between the three groups at the baseline (p=0.015) and the second year (p<0.001). The mean TG levels were significantly higher in Group I as compared to Group II and Group III at the baseline (383±279, 214±91, and 176±77mg/dl,respectively) and at the second year on PD (326±139, 215±105 and 163±69mg/dl, respectively). Baseline TG level was an independent predictor of a high level of TG at the second year on PD (β=0.339,p=0.02). Any other lipid parameters at the baseline or at the second year and none of the fifth year lipid parameters did not differ between the three groups. Neither TG nor TC levels changed during the 5 years of PD. None of the lipid parameters differed between CAPD and CCPD patients.

Conclusions: These findings underline the high prevalence of dyslipidemia in pediatric PD patients. Children younger than 2 years are especially at higher risk of hypertriglyceridemia.

TH-PO947

First Year Mortality in Peritoneal and Hemodialysis Patients: An Instrumental Variable Analysis

Hui Liu,[1] Douglas Lehmann,[2] Yun Li,[2] Yi Li,[2] Rajiv Saran.[1] *[1]Div of Nephrology, Univ of Michigan Health System, Ann Arbor, MI; [2]Univ of Michigan School of Public Health, Ann Arbor, MI.*

Background: Peritoneal dialysis (PD) has been proposed as a better initial modality compared with hemodialysis (HD). We postulate that PD-first patients (where PD is the initial dialysis modality) will have lower first-year mortality compared with HD-first patients.

Methods: A total of 175,323 adult patients from 4,303 dialysis facilities (with >10 patients) who initiated and remained on the same dialysis modality for 90 days between 01/2010 and 12/2012 were analyzed using national U.S. End Stage Renal Disease (ESRD) data. To reduce potential confounding-by-indication, we used a two-stage residual inclusion instrumental variable (IV) methodology, adjusting for relevant covariates and using percentage of patients utilizing PD in each facility as the instrumental variable.

Results: The PD utilization rate varied greatly across facilities (mean 7.8%; range 0-100%). Facilities in the upper quartile of the PD utilization had a mean rate of 28.4%, while 60.7% of facilities had 0% PD utilization. PD-first patients were younger, healthier, more likely to be Asian and White, with a higher rate of being insured or employed than HD-first patients. Facilities with higher PD utilization rate had more patients, HD stations, nurses, social workers, dietitians and more patients having received pre-ESRD nephrology care and were located in geographic areas with higher income and education level. The adjusted hazard ratio (HR) for 1-year mortality among PD-first patients was 0.65 [95% CI (0.60, 0.69)] in comparison with HD-first patients. Results from the IV analysis, which further account for unmeasured confounding, confirmed a lower hazard ratio of 0.68 [95% CI (0.61, 0.75)] for PD-first patients.

Conclusions: This national study shows low utilization of PD-first and association of both facility and geographic factors with this practice. PD-first patients had lower one year mortality compared with HD-first patients. Whether overall facility-level outcomes could be improved by increased utilization of PD should be studied prospectively.

TH-PO948

Development of Telemedical Service Using Smartphones for PD Patients

Yudo Tanno, Ichiro Ohkido, Kyoko Watanabe, Keitaro Yokoyama, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.*

Background: The 2011 Great East Japan Earthquake had a vast impact on dialysis patients. Peritoneal dialysis (PD) was shown to be a more favorable dialysis modality than hemodialysis in the affected areas (AJKD2012). During evacuation, medical records including PD prescriptions were left behind or lost, but smartphones were the item, which many PD patients carried. Taking this into account, we have developed a system using smartphones to manage medical records. This allows checking of the patients' PD status in real time as well as confirmation of their safety and locations using GPS at the time of disaster.

Methods: We have invented a smartphone application for management of PD patient with a robust security system to ensure confidentiality. Not only will this application be useful at the time of disaster, but also it is a helpful tool in daily clinical practice.

Results: The aim of this application is to provide telemedicine to PD patients using smartphones. Using this application, patients can compile vital signs, body weight, urine and PD output with a function that allows fluid balance to be calculated automatically. Photographs of exit sites and characteristics of PD fluid drained out can also be stored together with other vital information on the cloud server. Using this information, messages can be sent from doctors to patients with appropriate advice in this application. Daily PD manuals and those for the time of disaster are also accessible to the users if necessary. Furthermore, automatic summarization of the data facilitates identification of clinical problems. This system enables doctors to receive detailed medical information in real time from remote places, helping to bring about early detection of PD peritonitis and exit-site infections. Early signs of hypervolemia can also be picked up in a timely manner. Therefore, patients can be encouraged to seek medical advice before developing congestive cardiac failure.

Conclusions: Telemedicine using smartphones is useful for management of PD patients in both emergencies and daily clinical practice.

Evaluation of Patient-Related Factors in Peritoneal Dialysis Selection

Hironori Nakamura, Anayama Mariko, Yasushi Makino, Masaki Nagasawa. *Dept of Nephrology, Shinonoi General Hospital, Nagano, Japan.*

Background: There are patients who initially intend to undergo peritoneal dialysis (PD) but instead eventually select hemodialysis (HD). These patients select HD because of a number of obstacles to PD. Identification of the factors that limit the selection of PD may be important to provide specific support or interventions that would better enable patients to select it.

Methods: The aim of this study was to identify patient-related factors that are obstacles to PD selection. One hundred twenty-three patients who selected HD as initial renal replacement therapy at our hospital were enrolled and completed a questionnaire survey. The rates of factors such as physical factors (abdominal appearance), social factors (absence of family support or caregiver), technical factors (inability for self-care), and mental factors (safety concerns) were statistically compared between the group that intended to select PD and the group that did not intend to select PD.

Results: The mean age of the studied population was 66.9 years, and 56.7% of the patients were male. Thirteen percent of the study population intended to select PD. The reasons listed by the group of patients who did not intend to select PD included safety concerns (42.9%), concerns regarding self-care (40.1%), and the absence of a caregiver (20.5%). The factors that influenced the group of patients who intended to select PD, as compared with the group that did not intend to select PD, included technical problems (56.2% versus 37.3%, respectively), safety concerns (62.5% versus 42.9%, respectively), and lack of time for predialysis education (12.5% versus 6.5%, respectively). The rates of these factors were higher in those patients that intended to select PD as compared to those that did not intend to select PD, but there were no statistically significant differences between the two groups.

Conclusions: Technical and mental factors, rather than social factors, were the major obstacles listed by the patients who intended to select PD. Therefore, careful patient education with a greater emphasis on eliminating their safety concerns and ensuring them that PD is safe would be useful for those patients who initially intend to select PD.

TH-PO950

Comparison of 30 Day Readmission Rates between Hemodialysis (HD) and Peritoneal Dialysis (PD) Patients Julio E. Pena, Heidi Mae G. Timbol, Priyanka Khatri, Shirin Shirani, Chirag R. Parikh, Fredric O. Finkelstein. *Yale New Haven Hospital, New Haven, CT.*

Background: Readmissions for hospitalized ESRD patients are common and have a high economic burden to the health care system. Over 30% of ESRD patients admitted to the hospital are readmitted within 30 days of discharge. The present study was designed to retrospectively compare the 30 day readmission rates of HD and PD patients.

Methods: Discharge summaries between 2009 and 2012 of all HD and PD patients from 4 dialysis centers in New Haven admitted to the hospital were examined. A comorbidity scoring system (modification of the Davies score) was used to assess comorbidities (1 point each for CAD, HTN, CHF, and DM). The cause of readmission was adjudicated based on detailed chart review as the same, related or unrelated to the index hospitalization.

Results: 433 HD patients and 110 PD patients were hospitalized during the study period. The total number of admissions in the HD group was 2071 and 538 in the PD group. The mean ages of admitted HD and PD patients were 68 ± 14 and 64 ± 15. The mean comorbidity scores of admitted patients were 2.28 ± 1.11 for HD and 2.2 ± 1.04 for PD patients (p= 0.49). 705 hospitalizations in the HD group (34.0%) and 137 (25.5%) in the PD group were readmissions within 30 days of discharge (p= 0.0002). The mean comorbidity scores of readmitted patients (HD 2.35 ± 1.07 and PD 2.52 ± 1.07) were higher than the patients not readmitted (HD 2.19 ± 1.14 and PD 1.85 ± 0.89). 32.5% of the patients in the HD group and 31.4% in the PD group were readmitted for the same cause as for the index hospitalization; 21.6% and 17.1% for a related cause; and 45.9% and 51.3 % for an unrelated cause. 61% of the readmitted patients in the HD group and 69% in the PD group were readmitted within 2 weeks of discharge.

Conclusions: The 30-day readmission rate of PD patients was significantly lower than HD (p= 0.0002) despite similar ages and comorbidities. Comorbidity was higher in patients readmitted than in those not readmitted. About half of the readmissions in both groups were for a cause unrelated to the index hospitalization. More than 60% of the patients were readmitted within 2 weeks of discharge in both groups.

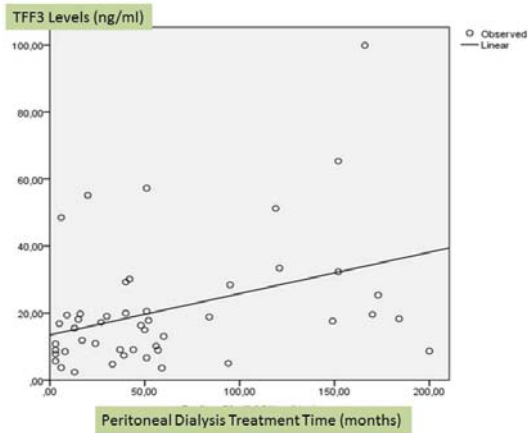
TH-PO951

Trefoil Factor 3 Levels in Peritoneal Effluents of Peritoneal Dialysis Patients Gökmen Aktas, Izzet Hakki Arikan, Derya Guler, Mehmet Koc, Serhan Tuglular, Cetin Ozener. *Nephrology, Marmara Univ Hospital, Istanbul, Turkey.*

Background: Peritoneal fluid of PD patients includes various substances. Trefoil Factor 3 (TFF3) is secreted from different kinds of epithelial cells. It increases survival of epithelial cells and facilitates the restoration of cells aganist any kind of injury. TFF3 levels in the effluent and serum of PD patients were measured and associated factors were investigated. Effluent CA-125 levels which is known as indicator of mesothelial cell mass were ascertained for the potential association.

Methods: Peritoneal fluid and serum samples of 48 patients were collected after a 12 hour dwell. ELISA kit (BioTek Instruments U.S.A.) was used for the detection of TFF3 levels. The patients' demographic and laboratory data as well as peritoneal membrane characteristics were recorded.

Results: Fourty-eight PD patients (24 men; mean age: 51,6 ± 13,9 years) who have a median treatment time of 43 months (range:3-200 months) were included. Median effluent TFF3 level was 17,07 ng/ml (range: 2,38-99,4 ng/ml). There was a positive correlation between effluent TFF3 levels and treatment time (r=0,349, p<0,015). Median serum TFF3 level was 1,56 ng/ml (range: 0,79-11,05ng/ml). There was no statistical association between effluent and serum TFF3 levels and effluent CA-125 levels. There was no statistical association with demographic features, labaratory results and treatment modalities except serum PTH levels (p<0,05).



Conclusions: High serum TFF3 levels were comparable with other studies including patients with chronic kidney disease. Effluent TFF3 levels increases with treatment time may be emanated from local production or peritoneal transport. Tissue localization of TFF3 in peritoneal microcirculation, determination of peritoneal clearance of TFF3 and indicating the association with pro-inflamatory cytokines could make TFF3 possible to be used as a biomarker in PD patients.

TH-PO952

Platelet-Derived Growth Factor Receptorβ (PDGFRβ) Expression in Human Peritoneum Stephan Segerer,[1] Harald Seeger,[1] Joerg Latus,[2] Mark Dominik Alscher,[2] Dagmar Biegger,[4] Rudolf P. Wuthrich,[1] Niko Braun.[2] *[1]Div of Nephrology, Univ Hospital, Zurich, Switzerland; [2]Dept of Internal Medicine, Div of General Internal Medicine and Nephrology, Robert-Bosch-Hospital, Stuttgart, Germany; [3]Dept of Diagnostic Medicine, Robert-Bosch-Hospital, Stuttgart, Germany; [4]Margarete Fischer-Bosch Inst of Clinical Pharmacology, Stuttgart, Germany.*

Background: Simple peritoneal fibrosis and encapsulating peritoneal sclerosis (EPS) are important lesions in the peritoneum of patients on peritoneal dialysis (PD). We previously described a population of podoplanin positive myofibroblasts in peritoneal biopsies from patients with encapsulating peritoneal sclerosis (EPS). PDGF receptor β (PDGFRβ) is a marker of pericytes and PDGFs might be involved in the fibrotic response of the peritoneum. This study aimed to describe PDGFRβ in the human peritoneum.

Methods: In this retrospective analysis we localized PDGFRβ in peritoneal biopsies from patients with EPS (n=6), on PD without signs of EPS (n=5), and compared them with normal peritoneum (n=4) and peritoneum from uremic patients (n=5). Consecutive sections were stained for smooth-muscle actin and podoplanin. Slides were scored semiquantitatively by two observers blinded to the diagnosis.

Results: PDGFRβ was expressed by cells of arterial walls in all biopsies. A prominent population of PDGFβR positive cells was present in the normal peritoneum. In EPS the majority of podoplanin positive cells were positive for PDGFRβ. In peritoneal biopsies from normal and uremic patients the expression of smooth muscle actin was mainly restricted to cells of arterial walls. Podoplanin expression was restricted to lymphatic vessels in normal peritoneum, in uremic patients, and patients on PD without EPS.

Conclusions: As podoplanin positive myofibroblasts express PDGFRβ, these cells might be related to pericytes (rather than other sources of fibroblasts). PDGFRβ might turn out to be a therapeutic target.

Does Peritoneal Dialysis Associated Peritonitis Risk Vary By Time on Treatment? Jeffrey Perl,[1] Sameer Parpia,[2] Sharon Nessim.[3] *[1]Nephrology, St. Michael's Hospital, Univ of Toronto, Toronto, ON, Canada; [2]Oncology, McMaster Univ, Hamilton, ON, Canada; [3]Nephrology, Jewish General Hospital, McGill Univ, Montreal, QC, Canada.*

Background: Retraining patients shortly after peritoneal dialysis (PD) initiation is recommended to reduce the risk of peritonitis due to breaches in technique. We sought to understand if peritonitis-risk varied by time on therapy and by organism.

Methods: Using the multicenter Baxter POET database (n=4247), time on PD was divided into 3-month intervals. Using prespecified organism categories, time-to-first peritonitis was analyzed by Kaplan-Meier analysis and using an adjusted multivariable model.

Results: Peritonitis-risk (all organisms) was highest in the first 3 months on PD (p=0.001). Organism-specific analyses revealed an increased risk of culture negative peritonitis in the first 3 months (p<0.001), but not for other organism categories.

Time (Months)	All Organisms	Coagulase Negative Staphylococcus (CNS)	S. *Aureus*	Gram Negative	Streptococcus	Culture-Negative

TH-PO954

The Peritoneal Dialysis Outcomes and Practice Patterns Study: Unifying Efforts to Improve Global Outcomes in Peritoneal Dialysis Jeffrey Perl,[2] Simon J. Davies,[3] Ronald L. Pisoni,[1] Keith McCullough,[1] David W. Johnson,[5] Hideki Kawanishi,[6] James A. Sloand,[4] Friedrich K. Port,[1] Bruce M. Robinson.[1] *[1]Arbor Research Collaborative For Health, Ann Arbor, MI; [2]Nephrology, St. Michael's Hospital, Toronto, ON, Canada; [3]Univ Hospital of North Staffordshire, Stoke-On-Trent, United Kingdom; [4]Baxter Healthcare, Deerfield, IL; [5]Univ of Queensland, Brisbane, Australia; [6]Tsuchiya General Hospital, Hiroshima, Japan.*

Background: Extending technique survival on peritoneal dialysis (PD) is a challenge to optimizing outcomes for patients on PD. The primary objective of The Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS) is to identify modifiable practices associated with improvements in PD technique and patient survival. In collaboration with the ISPD, PDOPPS also seeks to standardize PD-related data definitions and provide a forum for ongoing international collaborative clinical research in PD.

Methods: PDOPPS is an international prospective observational cohort study initially in Australia, Canada, Japan, the United Kingdom, and the United States. Countries are enrolling a random sample of incident and prevalent patients from national samples of 20 to 80 facilities that care for 15+ patients on PD. Enrolled patients will be followed over an initial 3-year study period. Demographic, comorbidity, and treatment-related variables, as well as patient reported data, will be collected over the study course. Outcomes data include PD technique failure (TF), cause-specific TF, death, and hospitalizations, with all-cause TF or death as the primary outcome.

Results: A high proportion of the targeted facility number has been recruited to date in each country. Several ancillary studies have already been funded, and local interest in expansion to new countries is high.

Conclusions: PDOPPS is the first large, coordinated study to follow a cohort of patients on PD longitudinally. With the breadth, detail, and standardization of data collected, PDOPPS will serve as an invaluable resource as a research platform for the PD community, as a means to understand variation in PD practices and outcomes, identify optimal practices, and to ultimately improve outcomes for patients on PD.

Funding: Pharmaceutical Company Support - The DOPPS program is supported by grants to Arbor Research from Amgen, Kyowa Hakko Kirin, AbbVie, Sanofi Renal, Baxter Healthcare, and Vifor Fresenius Medical Care Renal Pharma, Ltd. Additional support for specific projects is provided in Canada by Amgen, BHC Medical, Janssen, Takeda, Kidney Foundation of Canada (for logistics support); in Germany by Hexal, DGfN, Shire, WiNe Institute; for PDOPPS in Japan by the Japanese Society for Peritoneal Dialysis; for PDOPPS by Fresenius Medical Care, Government Support - Non-U.S.

TH-PO955

Reliability of Markers of Sarcopenia in Peritoneal Dialysis Patients George Greenhall, Andrew Davenport. *Royal Free Hospital, London, United Kingdom.*

Background: Recently new definitions for muscle wasting (sarcopenia) have been proposed for patients with chronic kidney disease, including reduced percentage body fat (%BF) or skeletal muscle mass (%SMM), coupled with markers of inflammation (serum albumin, C-Reactive protein (CRP) and ESA resistance (ESAR, calculated as weekly ESA dose/gHb/kg).

Methods: To determine whether these proposed definitions would be appropriate for peritoneal dialysis (PD) patients, we examined the relationship between body composition and markers of inflammation. We correlated multifrequency bioelectrical impedance assessments (MFBIA) with laboratory data in 136 adult PD patients.

Results: Mean age was 54±15.7 years; 47% male; 28% diabetic; mean body mass index was 26.1±4.3kg/m^2. On multiple linear regression analysis, %BF was positively associated with age (β=0.159, p=0.02) and negatively associated with intracellular water (β=-0.649, p<0.001), dietary protein intake (as determined by total PD dialysate effluent and urinary urea losses, nPNA, β=-18.5, p<0.001), extracellular water over hydration (β=-3,62, p=0.001) and male sex (β=-4.06, p=0.026). Whereas %SMM was positively associated with male sex (β=0.61, p<0.001) and nPNA (β=9.7, p<0.001), and negatively associated with age (β=-0.43, p<0.001). Neither %BF or %SMM showed any association with serum albumin, CRP or ESAR.

Conclusions: In our cohort of PD patients, we found that body composition had no association with routine laboratory markers of inflammation or ESA resistance. However, %BF was negatively correlated with loss of cell mass, extracellular water overload and dietary protein intake; whereas %SMM was only associated with sex, age and protein intake. As such, definitions of sarcopenia in PD patients should use %BF rather than %SMM.

TH-PO956

Hepatocyte Growth Factor Is Associated with Uremia and Peritoneal Membrane Function Pedro M.S. Vieira, Ana Paula Bernardo, Maria Joao Carvalho, António Manuel Nunes Cabrita, Anabela Rodrigues. *Nephrology Dept, Hospital de Santo António, Porto, Portugal.*

Background: Biopsy studies have demonstrated peritoneal membrane(PM) submesothelial fibrosis before peritoneal dialysis(PD), implicating uremia as an injury factor. The antifibrotic Hepatocyte Growth Factor (HGF) can counteract epitelial mesenchymal transdiferentiation, and be a valuable marker of PM status. We aimed to investigate the relationship between uremia, HGF and PM function.

Methods: Cross-sectional study, 74 stable PD patients, mean age 50 years, 53% male, 60% PD-first. Uremia was assessed by residual renal function(RRF) and small solute adequacy parameters, average area under curve of RRF since PD initiation(avAUC_RRF) and by previous and total renal replacement therapy(RRT) vintages. Peritonitis were retrieved. A 4-hour modified 3,86% Peritoneal Equilibration Test(PET) was performed where effluent levels of HGF(eHGF) and transport of small solutes/fluid were determined.

Results: Median time on PD was 7(IQR 4-29) months. At the time of the PET 27% of the patients were anuric, the remaining had a mean RRF 6,1±3,7ml/min. We found significantly negative correlations between RRF/avAUC_RRF and eHGF(r=-0.244, P=0.036 and r=-0.283, P=0.015, respectively); conversely, previous and cumulative RRT vintages had significantly positive correlations with HGF (r=0.440, P=0.001 and r=0.416, P=0.001, respectively). On subset analysis, anuric versus non-anuric and non PD-first versus PD-first evidenced significant differences with higher eHGF on the first. Remarkably, concerning PM evaluation we found positive correlation between eHGF and D/P creat (r=0.29, P=0.012) and negative correlation with % corrected Free Water Transport (FWTc) (r=-0.39 P=0.001). In a multivariable linear regression model (r^2=0,43), previous RRT time, age, number of peritonitis, effluent VEGF and %FWTc remained independently associated with eHGF.

Conclusions: Uremia assessed by lower RRF and higher previous/cumulative RRT vintages is associated with higher eHGF. Moreover eHGF is associated with PM function changes possibly signaling an injured PM ongoing repairing process. Our study highlights the relevance of studying this effluent biomarker.

TH-PO957

Variations in KT/V Urea Measures in Peritoneal Dialysis (PD) Patients with Different Anthropometric Models of Volume Assessment Ranil S.P. Gajanayaka, Joni H. Hansson, Beth Holden, Neera K. Dahl, Fredric O. Finkelstein. *Yale New Haven Hospital, CT.*

Background: Kt/V urea is used to assess the efficacy of solute removal in dialysis patients. Current CMS guidelines target a minimum KT/V urea of 1.7 in PD patients. The denominator V represents total body water (TBW) and is generally estimated from different anthropometric formulas. Currently, the two largest dialysis organizations in the U.S.A. use different methods, Hume and Watson, to assess the TBW in PD patients. Furthermore, there is some controversy whether actual or ideal body weight should be used to calculate V. The present study was conducted to examine how the different ways of determining V impact Kt/V urea measurements.

Methods: We performed a retrospective analysis of data from all PD patients (age> 18) cared for by New Haven Home Dialysis. TBW was calculated from Watson and Hume formula for both actual and ideal body weight. Kt/V was then calculated and comparisons were made among BMI categories of<20, 20-39 >40.

Results: 28 males and 27 females were included. The mean age was 61.3 ± 16.3. The mean Kt/V difference between Hume and Watson with actual body weight was 0.4 ± 0.5 (0.1 – 2.4). This difference was 1.1± 1.4 (0.1-6.0) with ideal weight. The most striking differences occurred in patients with BMIs >40. The Kt/V values with different methods in each BMI categories are shown below.

	BMI (kg/m^2)		
Kt/V Formula	**<20**	**20-39**	**>40**
Actual weight-Hume	2.0 ± 0.5	2.3 ± 0.6	3.1 ± 1.2
Actual weight-Watson	2.2 ± 0.5	2.1 ± 0.4	2.5 ± 0.7
Ideal weight-Hume	1.5 ± 0.7	2.8 ± 1.3	4.6 ± 2.6
Ideal weight-Watson	2.0 ± 0.5	2.4 ± 0.4	3.3 ± 0.9

Conclusions: The present study shows significant variations of Kt/V urea measurements with the two most commonly used methods for assessing V. These differences are most marked in patients with BMIs >40. The differences in Kt/V using ideal or actual body weights to determine V is most dramatic in patients with high BMIs. These data suggest that it is important to develop standardization of Kt/V urea guidelines in terms of how V is determined if dialysis facilities are to be held accountable for achieving targeted Kt/V urea measures in PD patients.

TH-PO958

Effectiveness of Flushing and UV Light in the Disinfection of Peritoneal Dialysis Catheter Connections Glenn M. Chertow,[1] Julia Rasooly,[1] Tiffany L. Cummings,[2] Justin A. Lance,[2] Jim R. Kermode,[1] Niaz Banaei.[1] *[1]PuraCath Medical, Mountain View, CA; [2]Phoenix deVentures, Morgan Hill, CA.*

Background: Peritonitis remains the most common complica-tion associated with peritoneal dialysis (PD) and is associated with significant morbidity and technique failure. The aim of this in vitro study is to determine the individual and combined effects of flushing and the application of UV light on the growth of microorganisms within the fluid path of peritoneal dialysis connections.

Methods: The inside fluid path of the Y-set connector and transfer catheter were inoculated with 2.5µl of diluted inoculum containing Staphylococcus aureus. After connecting the transfer catheter to the Y-set, the fluid path was either flushed with 3mL of the aliquoted dialysate, exposed to UV light (UVC exposure = 254nm for 60 seconds), or a combination of both methods. Positive, negative and inoculant controls were also performed. Four samples were utilized for each test group with a single sample for each control. Following testing, dialysate from each group was collected, diluted, plated and stored overnight at the appropriate temperature. The log rate for reduction in bacterial growth for each test group was then determined.

Results: All test methods produced a significant reduction in growth of S. aureus versus the inoculant control. There was a significant reduction ($p = 0.0025$) in the viable count of S. aureus bacteria in the UV + flush group (2.12 $\log_{10}$ CFU/mL) compared to the UV (1.00 $\log_{10}$ CFU/mL) alone group.

Conclusions: This in vitro study suggests the application of UV light to the peritoneal dialysis fluid path in combination with a dialysate flush results in a significant reduction in bacterial growth compared to UV alone. Combining a UV light delivery system with the flush-before-fill method in Y-set systems may permit a reduction in the risk of peritonitis in PD patients.

TH-PO959

Evaluation of Quick Start Use of Peritoneal Dialysis Catheter Ozair M. Ziauddin, Ankit Rawal, L. Tammy Ho, Stephen Haggerty. *NorthShore Univ HealthSystem, Evanston, IL.*

Background: PD is underutilized in the U.S. with est prevalence of 6.6% in adults initiating dialysis. Reasons cited include perceived high risk of infections, concern about inadequate dialysis, catheter issues and comfort level of physician. After placement of PD catheter (PDc), at least a 2 wk wait period is generally advised, depending on mode of placement. Hence, patients (pts) with ESRD requiring urgent initiation of dialysis will usually start HD with a central venous cath. As well pts who may opt for PD, often delay placement of PDc, leading to urgent HD start. Changing modalities after initiation is often difficult. Establishment of quick start PD (QS) may address these problems.

Methods: A pilot study was initiated to compare complications and dialysis adequacy associated with QS (use ≤7 days post catheter placement) to more traditional PD protocol (use >7 days post catheter placement, Trd). Between 2012-2014, 50 pts were initiated on PD via laparoscopic placement. 30 pts began using their catheter ≤ 7 days and 20 used their catheter > 7 days after placement. Outcomes, assessed at 1, 2, 4, 6, 12, 18, and 24 mos, included infection rate, catheter related complications, and dialysis adequacy.

Results: Mean age of pts was 63 versus 75 yrs (QS versus Trd respectively). QS pts used catheter on avg in 5.5 days, and Trd pts used catheter in 47.8 days. A total of 14,365 pts days were evaluated with QS and 10,012 pts days with Trd. No leaks were noted in either group. No significant difference in infections was noted in either group. Days to adverse event were 126 ±176 in QS and 234±204 in Trd (NS). There was 1 non-functioning catheter in QS. Episodes of pain were greater in QS (6 versus 1 pt in Trd ($p <0.22$)). Kt/V at the 1 mo interval was 2.61±0.6 in the QS group versus 1.74±0.3 in the Trd group ($p<0.01$). By 2 mo interval, Kt/V was not statistically different (2.6±0.5 and 2.3±0.8, respectively). Albumin levels were not statistically significant between the 2 groups.

Conclusions: Use of laparoscopically placed PDc does not appear to increase the frequency of mechanical and infectious complications. Achievement of adequate dialysis is not different. Quicker use of PDc may allow for direct initiation of PD eliminating the need for urgent HD.

TH-PO960

Initial Experiences with Urgent Peritoneal Dialysis Starts for New End Stage Renal Disease Patients in the United States Eduardo K. Lacson,[1] Leslie P. Wong,[2] Nien-Chen Li,[1] Joseph Kessler,[1] Stephanie Curd,[1] Keith Lester,[1] Melissa Herman,[1] Sheru Kansal,[2] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, North America, Waltham, MA; [2]Cleveland Clinic, Cleveland, OH.*

Background: Peritoneal dialysis (PD) has routinely been used urgently for ESRD patients with imminent need for dialysis outside the U.S. We report the early combined experiences from 12 newly established American urgent start PD programs.

Methods: 28 of 29 referrals initiated urgent start PD from 12 FMCNA centers between 7/1/13 and 5/14/14. One patient had PD catheter malfunction due to adhesions and was unable to start therapy. We describe the characteristics, course, and outcomes of the 28 patients as of 5/15/14.

Results: The cohort's mean age was 50.5±14.5 years, 54% male, 50% white/46% black, and median BMI of 27.5 kg/m2. Eight patients (29%) did not have any insurance. PD catheters were inserted by laparoscopy in 82% and were problem free in 57%. Patients were followed on PD for a median of 84 days (range: 6-317). Of these, the median time for training was 10 days (range: 0-20), with one patient not getting a single full training day due to hospitalization and withdrew from dialysis therapy by day 6. Additionally, by the end of follow-up, 19 (68%) remained active on PD, 1 died, 1 recovered kidney function, and 6 switched to HD – 2 after peritonitis, 2 from catheter dysfunction (inability to drain/pain on drain), 1 for hernia and 1 by choice. 3 of the patients who switched had coexisting HD catheters in place while the 3 others had a new HD catheter placed. Among the latter, fistulas were subsequently placed within 11, 24, and 26 days of the switch.

Conclusions: Preliminary outcomes of urgent PD from 28 patients in 12 U.S. centers indicated that urgent start PD is a viable option – keeping 68% of patients active for a median of 127 days on PD as of 5/15/14. It allows for potential avoidance of HD catheters in a population that would most certainly have had to use them. Further evaluation with longer term follow-up and direct outcome comparisons to matched conventional PD/HD patients is planned.

TH-PO961

Educational Level and Survival in a Cohort of Incident Brazilian Peritoneal Dialysis Patients Kleyton Andrade Bastos,[1] Abdul Rashid Tony Qureshi,[2,3] Natalia Maria da Silva Fernandes,[4] Roberto Pecoits-Filho,[5] Antonio Alberto Lopes,[6] Jose C. Divino-Filho.[2] *[1]Dept of Medicine, Federal Univ of Sergipe, Aracaju, Brazil; [2]Div Renal Medicine, CLINTEC, Karolinska Instt, Stockholm, Sweden; [3]Baxter Novum, Karolinska Instt, Stockholm, Sweden; [4]Federal Univ, IMEPEN Foundation, Juiz de Fora, Brazil; [5]Center of Health and Biological Sciences, Catholic Univ of Paraná, Curitiba, Brazil; [6]Dept of Medicine, Federal Univ of Bahia, Salvador, Brazil.*

Background: There is evidence that limited educational level (EL) contributes to differences in health outcomes. The goal of this study was assessing the effect of EL on survival in a cohort of Brazilian peritoneal dialysis (PD) patients.

Methods: Prospective cohort study of incident PD patients enrolled in the Brazilian Peritoneal Dialysis Multicenter Study (BRAZPD) from December 2004 to October 2007. EL was categorized by school years: low EL, <4 (1309 patients); and high EL, ≥4 (643 patients). Survival analysis comparing low and high EL groups was performed using Kaplan-Meier survival curves and Cox proportional hazards model adjusting the results for age, gender, PD modality, first renal RRT, pre-dialysis care, family income, comorbidities, and calendar year.

Results: Median age was 59 years, 54% were women, 60% White, 41% diabetics, and 24% had cardiovascular disease. More than half were in continuous ambulatory PD (51%), had not received pre-dialysis care (58%), had <5 minimum wage (MW) monthly family income (80%), and <4 school years (67%). Low EL was associated with worse socioeconomic position indicators. High EL patients were predominantly men, White, older and more often on Automated PD. Cumulative patient survival was lower in the low EL group (Log Rank test $\chi2=4.29$, $p=0.03$) but technique survival did not vary significantly (Log Rank test $\chi2=0.90$, $p=0.34$) between the EL groups. In Cox-regression adjusted analyses, differences were not observed in the hazards of all-cause mortality (HR(hazard ratio)=0.97; 95% confidence interval [CI]=0.73-1.29; p=0.84) and technique survival (HR=1.06; CI=0.81-1.38; p=0.67).

Conclusions: EL is not independently associated with outcomes in this large cohort and should not be considered a barrier for PD indication.

TH-PO962

Paricalcitol, Vitamin D Receptor Activator Prevents Cardiovascular Fibrosis and Inflammation of 5/6 Nephrectomy Rat on Peritoneal Dialysis Min Jung Kim,[1] Il Young Kim,[1] Dong Won Lee,[1] Soo Bong Lee,[1] Byeong Yun Yang,[2] Sang Heon Song,[2] Eun Young Seong,[2] Ihm Soo Kwak.[2] *[1]Internal Medicine, Pusan National Univ Yangsan Hospital, Korea; [2]Internal Medicine, Pusan National Univ Hospital, Korea.*

Background: Vitamin D receptor expressions in kidney, myocardium and also peritoneum suggest the potential role of vitamin D receptor activators (VDRAs). We investigated whether the selective VDRA, paricalcitol (19-nor-1.25-dihydroxyvitamin D2) suppresses rennin-angiotensin-aldosteron system (RAAS), and thus reduces cardiovascular inflammation and fibrosis as well as peritoneal pathology of 5/6 nephrectomy rat model on peritoneal dialysis (PD).

Methods: Vitamin D receptor expressions in kidney, myocardium and also peritoneum suggest the potential role of vitamin D receptor activators (VDRAs). We investigated whether the selective VDRA, paricalcitol (19-nor-1.25-dihydroxyvitamin D2) suppresses rennin-angiotensin-aldosteron system (RAAS), and thus reduces cardiovascular inflammation and fibrosis as well as peritoneal pathology of 5/6 nephrectomy rat model on peritoneal dialysis (PD).

Results: After 4 weeks of PD, BUN and serum creatinine in group C and D were decreased ($p<0.05$ versus group B). D/P urea in group C and D were significantly increased ($p<0.05$). Paricalcitol treatment (group D) increased E-cadherin, and decreased αSMA and TGF-β significantly ($p<0.05$, versus group C). Peritoneal fibrosis scores and neovascularization in group D were decreased (p=NS versus group C). Peritoneal inflammation scores, thickness(μm) and αSMA staining in group D were decreased ($p<0.05$ versus group C). Moreover, myocardial fibrosis scores and aortic inflammation scores were decreased in group D ($p<0.05$ versus group C).

Conclusions: A selective VDRA, paricalcitol attenuates cardiovascular as well as peritoneal inflammation and fibrosis of 5/6 nephrectomy rat model on PD.

TH-PO963

Higher Serum 7-84 PTH Levels in Peritoneal Dialysis Than in Hemodialysis Patients. A Potential Contribution to the Higher Prevalence of Low Turnover Bone Remodeling in Peritoneal Dialysis?

Carmen Sanchez-Gonzalez,[1] Maria Luisa Gonzalez Casaus,[2] Emilio E. Gonzalez-Parra,[3] Jose-Vicente Torregrosa,[6] Victor Lorenzo,[4] Mariano Rodriguez,[5] Elvira Fernandez,[7] Albalate Marta.[8] *[1]Nefrologia, Hospital Univ La Princesa, Madrid, Spain; [2]Nefrologia, Hospital Univ De La Defensa, Madrid; [3]Nefrologia, Fundacion Jimenez Diaz, Madrid, Spain; [4]Nefrologia, ACJ Dialisis Tenerife, Spain; [5]Nefrologia, Hospital Reina Sofia, Cordoba, Spain; [6]Nefrologia, Hospital Clinic, Barcelona, Spain; [7]Nefrologia, Arnau De Vilanova, Lleida, Spain; [8]Nefrologia, Hospital Infanta Leonor, Madrid, Spain.*

Background: Intact PTH (iPTH) assays do not reliably identify patients with low turnover bone disease (LTBD) and bone biopsy is not used in routine clinical care.

Methods: Cross-sectional study. Two dialysis units at tertiary care hospitals: 129 hemodialysis and 73 peritoneal dialysis (PD) patients. **Measurements:** iPTH (1-84PTH plus 7-84PTH), bio-PTH (1-84PTH), total serum calcium (tCa); ionized calcium (iCa) and carboxy-terminal telopeptides of collagen type I (βCTx). Calculation of PTH fragment ratios.

Results: iCa accounted for a higher percentage of tCa in PD than in hemodialysis (53% versus 39% $p < 0.001$) and 1-84PTH as a percentage of iPTH was lower in PD (44.0 ± 12.28 % versus 60.3 ± 10.82 %; $p < 0.001$). In the total group iCa was inversely correlated with serum 1-84PTH and 1-84PTH/7-84PTH ratio but not with iPTH. Serum levels ofβCTx correlated with 1-84PTH, 1-84PTH/ 7-84PTH ratio and iPTH. Use of the combined iPTH and 1-84PTH/7-84PTH ratio criteria proposed by Herberth et al (coexistence of 1-84PTH/7-84PTH ratio < 1 and iPTH < 420 pg/mL) resulted in a higher percentage of PD patients predicted to have LTBD (72.7% versus 16.3%, < 0.001). In a multivariate logistic regression analysis, dialysis modality was the main determinant of the percentage of calcium present as iCa. Similarly, the main determinant of LTBD (defined according to Herberth) was iCa.

Conclusions: PD is associated to a higher proportion of 7-84PTH fragments. This may be related to higher serum iCa and might contribute to the higher prevalence of LTBD in PD.

TH-PO964

Serum Response Factor Accelerates the High Glucose-Induced Peritoneal Membrane Fibrosis via Snail Signaling

Shiren Sun. *Dept of nephrology, xijing Hospital.*

Background: Epithelial-to-Mesenchymal Transition (EMT) induced by glucose in human peritoneal mesothelial cells (HPMCs) is a major cause of peritoneal membrane (PM) fibrosis and dysfunction.

Methods: To investigate serum response factor (SRF) impacts on EMT-derived fibrosis in PM, we isolated HPMCs from the effluents of patients with end-stage renal disease (ESRD) to analyze alterations during peritoneal dialysis (PD) and observe the response of PM to SRF in a rat model.

Results: Our results demonstrated the activation and translocation of SRF into the nuclei of HPMCs under extensive periods of PD. Accordingly, HPMCs lost their epithelial morphology with a decrease in E-cadherin expression and an increase in α-smooth muscle actin (α-SMA) expression, implying a transition in phenotype. PD with 4.25% glucose solution significantly induced SRF up-regulation and EMT in rat peritoneal mesothelial cells and increased peritoneal thickness, which could be protected by SRF inhibition. In immortal HPMCs, high glucose (HG, 60 mmol/L) stimulated SRF overexpression, nuclear translocation and a transformed fibroblastic phenotype. SRF-siRNA preserved HPMC morphology, SRF expression and localization, while transfection of SRF plasmid into HPMCs caused the opposite effects. Snail, a potent inducer of EMT, showed a similar response to HG with SRF in HPMCs. Evidence from electrophoretic mobility shift, chromatin immunoprecipitation and reporter assays further supported the hypothesis that SRF transcriptionally regulated Snail by directly binding to its promoter.

Conclusions: Our data suggested that activation of SRF/Snail pathway might contribute to the progressive PM fibrosis during PD.

Peritoneal Equilibration Testing in Practice: Errors and Efficacy

Eoin D. O Sullivan, William D. Plant. *Dept of Renal Medicine, Cork Univ Hospital, Cork, Ireland.*

Background: Peritoneal dialysis is the most common form of home renal replacement therapy in Ireland, representing 10% of all dialysis modalities. The functional integrity of the peritoneal membrane is central to the delivery of effective dialysis to patients. Peritoneal equilibrium testing(PET) is a semi quantitative measurement of peritoneal membrane transport capacity, and allows tailoring of dialysis prescriptions to patients, as well as having prognostic significance. Performing a PET is time consuming and prone to errors. An consistent and accurate PET is a requirement for good clinical care. Our aim was to examine PET accuracy, identify the most common errors, as well as establish risks for inaccurate testing.

Methods: All PET tests performed over a twenty year period were obtained (1993-2013) from an electronic database, and the patient demographic, clinical and technical variables were recorded.Technical variables included dialysate volumes as well as dialysate and serum glucose, creatinine and urea at specific time points.

Results: 215 patients have undergone peritoneal dialysis since 1993, receiving a mean of 5 PETs each. 1076 individual PETs were analysed. 54% of all PETs had an error rendering the results questionable. 71% of patients have had at least one invalid test at some stage during their care. The most common error was abnormally low dialysate glucose at initiation of the test (29%). This suggests incomplete emptying of the overnight dwell is the most common error in performing a PET. No correlation between any comorbidities, patient characteristics or membrane transport type and risk of PET errors were identified.

Conclusions: Peritoneal equilibrium testing is prone to errors, which can consequently lead to suboptimal dialysis prescriptions. The most common technical error was an incomplete drain of the overnight dwell at initiation of the test. Identification of the more common errors could help to improve the quality of PET testing, and allow more specific local protocols. This would save money by decreasing the need for repeat testing and improve patient care by ensuring dialysis prescriptions are based on accurate tests of membrane transport function.

TH-PO966

Hyperosmolality (Mannitol) Promotes Angiotensin II (AngII) AT1 Receptor (AT1R) Activation in Rat Peritoneal Tissue

Thomas Morinelli,[1] Linda Walker,[1] Megan Hicks,[1] Michael E. Ullian.[1,2] *[1]Medicine/Nephrology, Medical Univ of South Carolina, Charleston, SC; [2]Ralph H. Johnson VA Medical Center, Charleston, SC.*

Background: Our laboratory has demonstrated that exposure of peritoneal mesothelial cells (PMC) in vivo and in vitro to peritoneal dialysis (PD) solutions resulted in increased peritoneal membrane thickness and increased cyclooxygenase-2 (COX-2) synthesis. The increases were mediated by activation of AT1R, particularly through NF-κB. The current study was designed to examine the role of one aspect of PD (ie high osmolality) on AT1R activation in rat peritoneal mesothelium.

Methods: PMC cultures were used to study the effects of high osmolality (mannitol) on AT1R trafficking, transcriptional activation of COX-2 (RT-PCR), and COX-2 protein synthesis (immunoblotting). HEK-293 cells expressing AT1R/GFP were used to examine the effects of mannitol on AT1R trafficking by laser scanning confocal microscopy. PMC surface AT1R were evaluated through radioligand binding assays. In order to examine the in vivo effects of long-term exposure of PMCs to high osmolality, male Sprague-Dawley rats were injected intraperitoneally twice daily with either 0.9% saline (controls) or 4.25% mannitol (high osmolality). At the end of 5 weeks, the peritoneal layer was examined for thickness and collagen deposition (Masson's Trichome stain).

Results: Compared to cells exposed to control isoosmotic conditions, cells exposed to high osmolality (240 mM mannitol) resulted in a 5-fold increase in AT1R internalization and a greater than 90% reduction in surface AT1R. PMC exposed to mannitol produced a 3-fold increase in mRNA levels and a 6-fold increase in protein expression for COX-2, compared to PMC under control conditions. These increases were blocked by the AT1R antagonist losartan or the NF-κB inhibitor RO-1069920. In vivo, experimental PD with hyperosmotic saline (240 mM mannitol) produced a significant thickening of sub-mesothelial collagen versus PD with isoosmotic saline (27.2 ± 4.8 versus 13.8 ± 4.6 μm, $P<0.05$, n=3-5).

Conclusions: These results indicate that the hyperosmotic nature of PD solutions may contribute to fibrosis associated with chronic PD by activating AT1R.

Mupirocin versus Gentamicin in the Prevention of Exit-Site Infection and Peritonitis in Peritoneal Dialysis: A Meta-Analysis

Napat Leeaphorn, Patompong Ungprasert, Pongsathorn Kue-A-Pai. *Internal Medicine, Bassett Medical Center and Columbia Univ College of Physicians and Surgeons, Cooperstown, NY.*

Background: Peritoneal dialysis (PD)-related infections remain the major causes of morbidity and mortality in PD patients. Exit-site infections (ESI) can be prevented by application of topical antibiotics. We conducted this systemic analysis to compare the efficacy of mupirocin versus gentamicin in the prevention of ESI and peritonitis in patients undergoing PD.

Methods: Recruited studies met the following criteria: they were randomized controlled trials (RCT) or cohort studies; subjects consisted of PD patients aged 18 and

older; mupirocin was administered to one arm and gentamicin was administered to the other arm. The primary extracted data were the difference in the episodes of ESI and peritonitis among mupirocin and gentamicin groups.

Results: Five studies (4 cohort studies and 1 RCT) and a total of 338 patients in mupirocin group versus 351 patients in gentamicin group were included in the analysis. There was no significant difference in the rate of ESI between mupirocin and gentamicin arms [mean difference (MD) 0.08/episode/patient-year, 95% confidence intervals (CI) -0.05 to 0.20; heterogeneity χ^2= 20.46, I^2= 80%, P= 0.004). There was also no significant difference in the rate of peritonitis [mean difference (MD) 0.10/episode/patient-year, 95% CI -0.04 to 0.24; heterogeneity χ2= 8.57, I^2= 53%, P= 0.07).

Conclusions: Gentamicin cream was not superior to mupirocin in the prevention of ESI and peritonitis.Both drugs can be recommended for prophylaxis of PD-related infections.

TH-PO968

Peritoneal Dialysis and Kidney Transplantation: No Fear for Encapsulating Peritoneal Sclerosis! Valerio Vizzardi, Massimo Sandrini, Silvio Sandrini, Elisabetta Devoti, Laura Bregoli, Giovanni Cancarini. *O.U. of Nephrology, Spedali Civili and Univ of Brescia, Brescia, Italy.*

Background: Objectives. Encapsulating peritoneal sclerosis (EPS) is the more dangerous complication of peritoneal dialysis (PD). Its prevalence has been reported as 0.3% to 3.3%; about 50% of cases of EPS are diagnosed after kidney transplantation (TX). PD discontinuation, use of calcineurin inhibitors (CNIs), corticosteroids (Sts) and mammalian target of rapamycin inhibitors (mTOR-Is) can affect the onset of post-transplantation EPS.

Methods: A retrospective study on PD patients undergoing TX in single Center, evaluation of immunosuppressive therapy and EPS prevalence.

Results: From July 1979 to December 2013, 920 patients started on PD. One hundred-seventy-two of them (18.7%) were transplanted. Median PD duration before transplantation: 27 months (IQR 17-47, range 1-148), median TX duration: 81 months (IQR 34-163, range 1-353). Therapy: CNIs= 49%; Sts= 13%; Sts + CNIs= 68 %; mTOR-Is associated with CNIs and/or Sts= 49%. During the time with functioning graft, two EPS cases occurred, 6 and 51 months after PD discontinuation. Three more episodes of EPS were diagnosed during dialysis in patients previously transplanted: one on hemodialysis (HD), two during PD. The median PD time at EPS diagnosis in the five patients previously transplanted was 79 months (IQR 54-95, range 36-100). Overall EPS prevalence on TX patients: 5/172 (2.9%). Two patients died for EPS (10 and 45 months after EPS diagnosis), one is on HD (78 months after) and two are on TX respectively (44 and 86 months after). At the end of 2013, 128/172 patients (74.5%) were on TX, 21 (12.2%) were on dialysis, 23 (13.3%) were died. During the same period other 21 EPS cases (2.8%) are occurred among the 748 PD patients never transplanted. No cases of EPS was manifested after direct transfer from PD to HD.

Conclusions: EPS prevalence among transplanted and not transplanted PD patients is similar. The reason could be both the low exposure to potential EPS risk factors (PD time <5 years, no peritonitis in 69% of cases) and the use of the mTOR-Is and/or corticosteroids. The transfer to hemodialysis or transplantation does not appear be a heavy risk factor for EPS.

TH-PO969

Title: Does Energy Expenditure Correlate with Standard Dosing of Dialysis in Peritoneal Dialysis Patients, or Are There Other Players in the Back Ground? Sally Salah El-Kateb,[1] Sivakumar Sridharan,[2] Ken Farrington,[2] Andrew Davenport.[1] *[1]UCL Centre for Nephrology (Royal Free Hospital), London, United Kingdom; [2]Lister Hospital, London, United Kingdom.*

Background: Guideline committees have proposed urea clearance targets (Kt/V) for peritoneal dialysis (PD) patients based on volume of distribution as surrogates for achieving adequate dialysis. However studies have failed to demonstrate any survival advantage from increasing weekly Kt/V urea clearance. We investigated whether differences in body composition determine total energy expenditure (TEE), and as such some patients may generate more waste products thus need greater clearance targets.

Methods: We assessed TEE in PD patients who had body composition measured by whole body Dual Energy x-ray absorptiometry (DEXA) and multi-frequency bioelectrical impedance assessments (MF-BIA) including extracellular water ECW) and total body water(TBW). TEE, resting EE (REE) and active EE (AEE) were calculated using validated equations.

Results: 148 PD patients (66.7% M), age: 60.7years (+/-1.4). DEXA showed a mean percentage of body fat (PBF%) 28.9%(+/- 1). MF-BIA determined mean ECW/TBW of 0.39 (+/-0.001). There were correlations between % body fat (PBF%) and both AEE (r=-0.33,p<0.001),and TEE (r=-0.33,p<0.001). ECW/TBW correlated with both AEE(r=-0.26,p=0.0056) and TEE(r=-0.26,p=0.0055). Protein intake (nPNA) was noted to be correlated with AEE (r=0.36,p=0.00091), TEE (r=0.36,p=0.00081), and REE (r=-0.31,p=0.004). On multiple regression analysis AEE correlated with PBF%[(β=-0.076, %CI(-.130 to-0.022),p=0.0005], In addition age was correlated with TEE [β=-6.27,95%CI(-0.8.7to-3.75),p=0.000019]. However there was no association between AEE, REE or TEE and weekly KT/V urea (total, peritoneal, urine) or litres of creatinine cleared per week (total, peritoneal or urine).

Conclusions: We showed that in PD patients TEE has no correlation with small solute clearance achieved. TEE is negatively associated with age, increasing PBF%, and volume overload (ECW/TBW) while it is positively associated with nPNA. As such, PD prescriptions should take into account TEE and body composition when deciding upon individual adequacy targets.

TH-PO970

Does Faster Peritoneal Protein Transport Lead to Extracellular Water Overload in Peritoneal Dialysis Patients? Cate Goodlad, Andrew Davenport. *Nephrology, Royal Free Hospital, London, United Kingdom.*

Background: Faster transport status (4h D/P creatinine) has been associated with both extracellular water (ECW) expansion and adverse outcomes in peritoneal dialysis (PD) patients. Faster peritoneal transport is associated with increased peritoneal capillary surface area due to body size, hyperglycaemia or local peritoneal inflammation. Increased peritoneal protein clearance, through large pores, may be a marker of local peritoneal inflammation.

Methods: We studied the relationships between 4h D/P protein and ECW excess, using multifrequency bioimpedance assessments (MFBIA), in 103 PD patients with up to four years of annual prospectively collected PET results.

Results: The number of patients with data at start, 1, 2, 3 and 4 years was 103, 84, 82, 70 and 38 respectively. The 4hD/P protein was stable over time (K-W test, p=0.063). A trend to lower values was seen at 4 years (Dunn's test: start v 4 years, p < 0.05: median 0.0081 v 0.006), but this might represent a survivor effect. The 4hD/P creatinine was also stable in this group of PD patients (K-W analysis, p = 0.3357). Significant correlations between 4hD/P protein and 4hD/P creatinine were noted at all time points.

Conclusions: At the start of PD therapy, over-hydration (ECW excess) was seen with higher 4hD/P creatinine and 4h/P protein values, suggesting that initial exposure to PD fluids causes local inflammation. As 4hD/P protein was then stable over 3 years, continued exposure to dialysate did not lead to increasing peritoneal inflammation; 4hD/P protein correlated with 4hD/P creatinine at all time points. Over time we found no relationship between ECW over-hydration and faster large pore transport, suggesting perhaps that appropriate changes in PD prescriptions prevented ECW expansion.

TH-PO971

Limitation of Peritoneal Dialysis by Kidney and Liver Volume in Autosomal Dominant Polycystic Kidney Disease Satoshi Hamanoue,[1,2] Junichi Hoshino,[2] Tatsuya Suwabe,[2] Toshiharu Ueno,[2] Koki Mise,[2] Noriko Hayami,[2] Keiichi Sumida,[2] Kenmei Takaichi,[2] Yoshifumi Ubara.[2] *[1]Nephrology Center, Japanese Red Cross Kumamoto Hospital; [2]Nephrology Center, Toranomon Hospital.*

Background: In patients with autosomal dominant polycystic kidney disease (PKD), peritoneal dialysis (PD) can be limited due to excessive kidney volume(KV)and liver volume(LV). We evaluated how nephromegaly and hepatomegaly influenced the continuation of PD in patients with PKD.

Methods: Twenty-two PKD patients on PD at our hospital were evaluated retrospectively after being divided into two groups: **group 1** was 15 patients who started PD at our hospital and **group 2** was 7 patients who were referred from other hospitals at 47.1 ± 21.8 months after commencing PD for treatment of renomegaly by transcatheter arterial embolization(TAE).

Results: In group 1, KV was 2787±1945 mL and total volume (TV = KV + LV) was 4985 ± 1815 mL. In one patientwith a KV of 6816 mL (TV of 8912 mL) showing the largest TV, TV/BW ratio, and TV/BMI ratio among all 15 patients in group 1, PD was stopped due to dialysate leakage after infusion of peritoneal dialysate up to a maximum volume of 700 mL. The other 14 patients less than TV(7963 mL), TV/BW ratio (130.5), and TV/BMI ratio(353) did not experience any dialysate leakage with infusion volumes of 1200 ml to 1500 mL, although larger infusion volumes have not been employed because of abdominal fullness. In group 2, KV was 5822±1597 mL and TV was 7597 ± 1431 mL before TAE. Across both groups, 6 patients developed new abdominal hernias during 36 ± 5 months (6 - 55 months) after starting PD. At 12 months after TAE, KV showed a significant decrease from 5822 ± 1597 mL to 2925 ± 1326 mL (P<0.01), while the infusion volume was significantly increased from 1.53±0.37 L to 1.94±0.52 L (P=0.02).

Conclusions: Our data suggest that PD is limited by KV and LV in patients with PKD, and a TV/BMI ratio of 353 might represent the limit for dialysate leakage. TAE is a therapeutic option for these patients when residual renal function is minimal.

TH-PO972

Comparisons of Propensity-Based Matching to Marginal Structural Models in Mortality Comparisons of Peritoneal Dialysis and Haemodialysis John P. Ferguson,[2] Austin G. Stack.[1,2] *[1]Nephrology, Univ Hospital Limerick, Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Limerick, Ireland.*

Background: The optimal method for comparing non-randomised treatments between groups is debated with some favouring propensity-based matching while others advocate use of marginal structural models. We compared each approach in mortality comparisons of Peritoneal (PD) and Haemodialysis (HD).

Methods: From the U.S. Renal Data System, we matched PD and HD patients from 1,336,441 HD and 109,216 PD patients using 25 clinical characteristics and a propensity-based matching algorithm. Patients were followed from 90 days after dialysis initiation until death, transplantation, lost to follow-up, 31/12/2010. Interval Cox regression models evaluated the relative hazard of death (HR) by dialysis modality using an as-treated analysis. Marginal structural models compared HD to PD by calculating the probability of modality assignment to each modality during follow-up and using inverse probability weights to control for confounding using conditional logistic regression.

Results: The hazards of death for PD relative to HD decreased significantly from 1995-1998 to 2003-2006 with follow-up for 4 years. Time-dependent models gave similar results.

	Propensity Matched Model (HR)		
	1995-1998	**1999-2002**	**2003-2006**
Year1-Year4	1.14 (1.11-1.17)	1.01 (0.98-1.03)	0.89 (0.87-0.91)
Year 1	1.01 (0.97-1.06)	0.87 (0.83-0.90)	0.71 (0.68-0.74)
Year 2	1.32 (1.25-1.38)	1.19 (1.14-1.25)	1.08 (1.03-1.14)
Year 3	1.27 (1.20-1.34)	1.19 (1.13-1.25)	1.17 (1.11-1.23)
Year 4	1.33 (1.24-1.41)	1.22 (1.15-1.30)	1.09 (1.03-1.16)
	Marginal Structural Model (HR)		
	1995-1998	**1999-2002**	**2003-2006**
Year1-Year 4	1.09 (1.07-1.11)	0.96 (0.94-0.98)	0.86 (0.85-0.88)
Year 1	0.99 (0.95-1.03)	0.92 (0.87-0.96)	0.83 (0.78-0.88)
Year 2	1.21 (1.16-1.26)	1.05 (1.01-1.09)	0.93 (0.90-0.97)
Year 3	1.25 (1.20-1.31)	1.08 (1.04-1.12)	0.98 (0.94-1.02)
Year 4	1.27 (1.21-1.34)	1.08 (1.03-1.13)	1.01 (0.97-1.06)

Conclusions: The results from the marginal structural model were similar to those of the propensity-based method. Each method confirmed that PD survival has improved substantially from 1995 to 2006 and is significantly greater than HD over the first 4 years of treatment.

TH-PO973

Secondary Hyperparathyroidism Among Incident Peritoneal Dialysis Patients Scott Sibbel,[1] Paul Dluzniewski,[2] Thy P. Do,[2] Susan V. Yue,[2] Steven M. Brunelli,[1] Brian D. Bradbury.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Amgen, Inc., Thousand Oaks, CA.*

Background: Data regarding secondary hyperparathyroidism (SHPT) among patients receiving peritoneal dialysis (PD) are sparse. We evaluated biochemical parameters and treatments for SHPT among a representative cohort of incident PD patients in the United States to better understand the burden of the disease and current treatment practices.

Methods: The cohort included all patients whose first renal replacement modality was PD at a large dialysis organization (LDO) between Jan 1, 2008, and Feb 28, 2014 (N=11,376). Demographic and clinical characteristics were evaluated during baseline (30 days following PD initiation). Laboratory indices for the entire cohort and medication use among the sub-sample enrolled in LDO pharmacy benefits program [n=4268] were evaluated over 1 year or until censoring for modality change, death, transfer, or transplant.

Results: Among the cohort, mean (±SD) age was 57±15.5 years, 43% were female, 57% were white, 21% were black, and 58% had diabetes. Laboratory values (total cohort) and medication utilization (subsample) are shown in the figure. Median parathyroid hormone (PTH) levels rose from 254 to 302 pg/mL over the first year. At baseline, mean (±SD) calcium and phosphorus levels were 8.9±0.9 mg/dL and 5.1±1.4 mg/dL, respectively, and remained fairly constant through follow-up. SHPT medication use among the cohort subsample was low at baseline, but increases in utilization over the 12-month follow-up reflected evidence of progressive disease: vitamin D use increased from 31% to 49%, while overall binder use increased from 11% to 31% and cinacalcet use increased from 1% to 7%.
Conclusions: SHPT was modest, yet progressed after PD initiation over the first year as evidenced by increases in PTH despite greater utilization of PTH-lowering therapies.

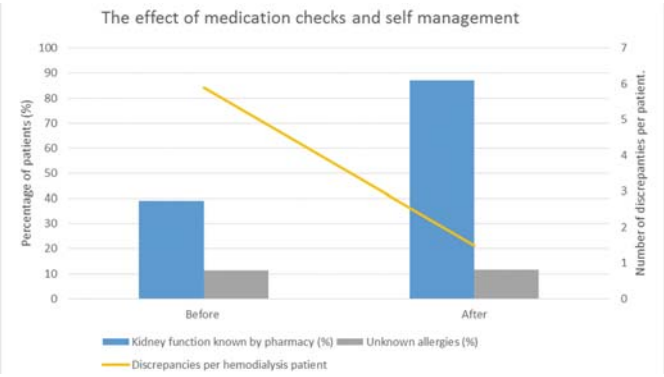
Frequent Medication Checks and Structured Self Mangement Programme Improve Medication Safety in Hemodialysis Patients Marieke Kerskes,[1,2] Marijke J.E. Dekker,[1] Evelyn Cramer,[2] Johanna Bogers,[1] Maaike Hengst,[1] Constantijn Konings.[1] *[1]Nephrology, Catharina Hospital, Eindhoven, Netherlands; [2]Clinical Pharmacy, Catharina Hospital, Eindhoven, Netherlands.*

Background: In 2010 a prospective risk analysis showed that the medication registration process of hemodialysis patients on our ward was a high risk process. A prospective observational study (n = 143) showed that there were many discrepancies between public pharmacy drug records and drug records on our dialysis ward. In 60.8% of our patients the public pharmacy was even unaware of their chronic kidney disease.

Methods: In 2014 a second prospective observational study was performed (n = 77) to determine whether a series of interventions on the medication registration process, implemented on our ward in 2010, was effective in improving medication safety in our hemodialysis patients. The interventions consisted of a 3 monthly medication check, communication of this check with the public pharmacy and the use of a standardized and validated checklist on medication self management abilities of our patients.

Results: Awareness of chronic kidney failure of our hemodialysis patients in the public pharmacy (39.1% to 87.0%) and discrepancies in drug records between public pharmacy and our dialysis ward (5.9 to 1.5 per patient) were significantly improved.



Discrepancies consisted of prescribed dialysis medication unknown in public pharmacy (39.1%), dose discrepancies (17.3%) and medication prescribed by other physicians (30.9%), mainly ocular and dermal preparations. The nature of the discrepancies did not differ between the both studies.

Conclusions: Frequent medication checks and a standardized self management programme improve adequate medication registration of dialysis patients and may therefore be a usefull tool to improve medication safety in this group of patients.

Telehealth Delivery of Medication Therapy Management (MTM) in ESRD Patients Harold J. Manley,[1] Graham E. Abra,[2] Revkah Balingit,[2] Jessica L. Baugh,[1] Margaret Mcnamara,[1] Janet Beryl Mackay,[2] Jeraldyn Santiago,[2] Maria Lourdes L. Deguzman.[2] *[1]Reach MTM, Dialysis Clinic Inc, Albany, NY; [2]Satellite Health Plan, Satellite, San Jose, CA.*

Background: Medicare Part D plan sponsors offer MTM to targeted patients (pts) to ensure medications are appropriately used and therapeutic outcomes are optimized. Resolution of medication-related problems (MRP) via MTM programs improve clinical outcomes and reduce hospitalizations and costs. Unfortunately only 11-14% pts receive MTM despite meeting eligibility criteria.

Methods: An interdisciplinary (RN, RPh, MD) approach using telehealth (video and phone) technology to increase MTM services was provided to all enrolled ESRD pts. The principal RPh roles were to conduct comprehensive and targeted medication reviews (CMR, TMR respectively), create MTM intervention(s) for patient and provider(s), and generate patient and provider medication reports. The principal RN roles were to facilitate RPh-Patient video conference during dialysis sessions and to facilitate resolution of RPh recommendations to MDs. Weekly interdisciplinary calls were conducted to determine MTM interventions outcome(s).

Results: From June 2013-May 2014, 86 pts (age 58.7± 13.2 yrs; 12.2± 4.4 medications) received 224 MTM encounters (2.6± 1.5 per patient). 99 CMR (82.8% video; 17.2% telephonic) and 125 TMR were provided. CMR completion rate was 92.3%. 423 MRPs (mean 3.1 MRPs per pt). MRPs were related to dosage too high (19.4%) or too low (12.1%), compliance (16.8%), drug without indication (16.5%), indication without drug therapy (15.6%), adverse drug reaction (11.4%) and different drug needed (8.3%). MTM interventions were accepted 73.4%, rejected 5.9%, and noted 20.7% of time by the treating physician.

Conclusions: An interdisciplinary team approach increases the likelihood that pts receive MTM services. This improved CMR completion rate will hopefully lead to improved adherence, reduced patient risks, and lower drug and total cost of care.

TH-PO976

Home Visit Audits: Ensuring Patient Safety in Home Hemodialysis? Karlien Francois, Christopher T. Chan. *Div of Nephrology, Univ Health Network Toronto General Hospital, Toronto, ON, Canada.*

Background: Home visits (HV) and HV audits (HVA) are standard practice in home dialysis programs however with limited clinical evidence.

Methods: We performed a single-centre retrospective cohort study in patients starting home hemodialysis (HHD) at University Health Network (UHN). Data from the HVA, a questionnaire addressing the practice of HHD and patient well-being, surveyed at the start of HHD were collected to evaluate deficiencies noted as potential safety risk factors (SRF). All incident HHD patients starting dialysis at home between July 18, 2008 and June 30, 2013 and with baseline HVA available were included in the cohort and were followed until death, kidney transplantation, transfer to another center or study end, December 31, 2013. All medical and nursing HHD professionals involved in UHN's HHD program scored the SRF (0-5, 0 being unimportant) to grade degree of importance. Data are presented as mean±SD or median with IQR. Technique survival was assessed by Kaplan Meier analysis.

Results: HVA was surveyed in 56 patients. 35 items assessed by the HVA were considered a potential SRF. Overall scores for the degree of importance of SRF ranged from 13–31 with a median of 20 (IQR 18-26). We defined a SRF being an important SRF

when its overall score was ≥median. Overall, 18 SRF were at least once deficient. 7/20 important graded SRF were at least once deficient. Proportional to the total of questioned important SRF, 1.9% were answered deficiently and 18.2% unanswered. 11/15 unimportant graded SRF were at least once scored deficient with an overall deficiency rate of 4.0% and unanswered rate of 15.4%. 33/56 subjects presented ≥1 deficiencies in SRF with 17 patients presenting ≥1 deficiencies in the important graded SRF and 23 patients having ≥1 deficiencies in the unimportant graded SRF. Compared to the absence of SRF deficiencies, the identification of ≥1 SRF deficiencies, in the important or in the unimportant SRF group, did not affect technique survival (p= 0.98, 0.45 respectively).

Conclusions: The lack of association between safety concerns and technique survival warrants further refinement of risk assessment coupled with judicious resource use in HHD program.

TH-PO977

The Development of a Hemodialysis Safety Checklist Using a Structured Panel Process Samuel A. Silver,[1,3] Alison Thomas,[1] Andrea Rathe,[1] Pamela L. Robinson,[1] Ron Wald,[1,3] Chaim Bell,[2,3] Ziv Harel.[1,3] *[1]Nephrology, St. Michael's Hosp; [2]Internal Med, Mt. Sinai Hosp; [3]Univ of Toronto.*

Background: Research has demonstrated that 2% of deaths are a direct result of dialysis complications. The World Health Organization created a Surgical Safety Checklist to help reduce preventable adverse events in the operating room. A similar tool, to be completed by nurses and patients during a hemodialysis session, may also improve patient safety. Our objective was to develop a Hemodialysis Safety Checklist (Hemo Pause) to improve provider/patient communication and consistency of care, thereby reducing preventable adverse events.

Methods: A modified Delphi consensus technique was used to develop the Hemo Pause checklist. This involved an iterative process consisting of a literature review to identify safety measures (using PubMed and major society guidelines), individual rating of each measure by the panel, an in-person meeting wherein the panel refined the measures, and a final anonymous survey that assessed consensus among panelists. A 75% agreement threshold was required for consensus. The final version of the checklist was created using human factors engineering concepts, which address safety problems that arise due to the interaction between people, technology, and work environments.

Results: The literature review produced 31 patient safety measures. Examples included patient identity confirmation, medication administration, and patient falls. Individual review by panelists reduced the list to 25/31 measures, followed by a reduction to 19/25 measures at the in-person meeting. The final round of scoring yielded the following top 5 measures: 1)patient identification, 2)pre-dialysis weight, 3)physician orders transcribed, 4)dialysis solution administered as prescribed, and 5)pre-dialysis blood pressure. Revision using human factors principles yielded a final checklist of 17-items.

Conclusions: A novel 17-item Hemodialysis Safety Checklist (Hemo Pause) has been developed to standardize the hemodialysis procedure and improve provider/patient communication. Quality improvement efforts are underway to test the feasibility of using this checklist to reduce adverse events and strengthen the safety culture in the hemodialysis unit.

TH-PO978

Decreasing After Hours Hemodialysis in Hospitals: A Way to Improve Patient Safety and Reduce Hospital Costs Natasha Sharda, Omid Bakhtar, Sangeetha Murugapandian, Bijin Thajudeen. *Nephrology, Univ of Arizona, Tucson, AZ.*

Background: Inpatient Hemodialysis (HD) is ideally performed under a controlled setting with a team of medical professionals available. Staff is paid overtime when HD is initiated after business hours, resulting in extra costs to the hospital. In addition, safety issues may arise as ancillary staff is not readily available. This quality improvement project sets out to analyze and reduce the number of after-hours HD cases.

Methods: A Chart review for all after-hours HD cases between July 2011 and June 2012 was completed. Initial variables collected included: reason for HD, time of order / start time, reasons for delay if present and adverse events. After-hours HD was defined as HD started between 8PM and 6AM Monday to Saturdays and anytime on Sundays. A standard protocol was subsequently developed for initiating after-hours HD. This included anticipating dialysis treatments early and placing orders before 8AM, bedside presence of ordering physician, enforcing laboratory parameters/ clinical criteria, and postponement of HD to the next day in non-emergent cases.

Results: A total of 3360 cases were reviewed. Of these 2.26% (75) met criteria for after-hours HD despite 79% of orders being placed during working hours. Indications for HD in patients whom met criteria were as follows: 13.1% for acidosis, 13.1% for fluid status and 23.6% for hyperkalemia. Identifiable treatment delays are as shown.

Reason for delay in HD	N=38
Dialysis catheter placement	3
Major surgery	3
Chest tube placement	1
Transfer to ICU	4
Imaging	2
Other procedures	2
Unknown	23

Overall 9 adverse events were reported for patients within this group. Once the standard protocol was implemented a dramatic decrease in after-hours HD was noted. Within 3 month only 11/798(1.3%) cases occurred after-hours with no reported delays and no adverse events.

Conclusions: This quality improvement project demonstrates an effective way to reduce hospital costs, by promoting HD during business hours which can also help ensure patient safety. In addition, coordination between health care providers is imperative to prevent treatment delays.

TH-PO979

Impact of Hurricane Sandy on Hemodialysis (HD) Patients and Preparedness for Natural Disasters Naoka Murakami, Hira B. Siktel, James F. Winchester, Nikolas B. Harbord. *Medicine/ Nephrology, Mount Sinai Beth Israel, New York, NY.*

Background: Dialysis patients live in a complex sociomedical situation and are highly dependent on technologies to sustain their lives; such as transportation, electricity and water for the dialysis apparatus. Interruption of this infrastructure by a natural disaster can result in devastating outcomes. We measured the impact of Hurricane Sandy on HD patients to explore possible interventions to improve natural disaster-related outcomes.

Methods: The study included adults receiving outpatient maintenance HD during the landfall of Hurricane Sandy in NYC (October 2012) at 5 regional centers in Manhattan where electricity had been deprived. Demographic data and dialysis-specific preparation for natural disasters (from National Kidney Foundation recommendations) were assessed between November 2013 and April 2014.

Results: 357 patients completed the study; average age 60±14.8 years, 60% male, 30% African American, 29% Hispanic/Latino. 94 (19.9%) missed dialysis (2.12±1.54 sessions (mean±s.d.)) and 236 (66.1%) received dialysis away from their regular unit. 61 (17.1%) patients reported improvement in their dialysis-specific preparedness from before the storm. The improvement was significantly higher in the centers which distributed "emergency information package" after the storm (p<0.001, Fisher's exact test). The Poisson regression assessed the impact of variables on the frequency of missed HD sessions. Higher dialysis-specific preparedness scores were predictive of a significant reduction in the incidence rate of missed HD sessions (IRR=0.914, 95% CI 0.87-0.98, p=0.001). (Table 1).

Conclusions: HD patients are underprepared for natural disasters. The intervention by facilities to provide emergency instructions effectively improved disaster preparedness among dialysis patients, which may reduce disaster-related missed dialysis sessions in the future.

Table 1: Poisson regression analysis on the number of missed dialysis sessions

	IRR	95% CI	*p* value
Dialysis-specific preparedness	0.91	0.87-0.98	0.001
Racial Ethnicity (compared with African American)			
Caucasian	0.67	0.40-1.1	0.129
Hispanic/Latino	0.81	0.58-1.1	0.199
Other	0.34	0.20-0.57	0.000
HD in other units (compared with none received)			
ER	1.1	0.73-1.8	0.569
Other affiliated units	0.69	0.51-0.94	0.019
Evacuation			
Yes	1.6	1.1-2.3	0.018
Living situation affected			
Yes	2.3	1.6-3.2	0.000
Age	0.98	0.97-0.99	0.000

TH-PO980

Disaster Preparedness in Dialysis Patients via Multidisciplinary Approach Anuradha Wadhwa, Stephanie Pesenko, Vinod K. Bansal, Karen A. Griffin. *Loyola Univ.*

Background: Emergencies and disasters can occur with or without notice, placing dialysis patients in life threatening situations: they rely on dialysis treatment to survive. Patient education on an individual level is the cornerstone of a successful disaster plan. Despite the availability of informational brochures, preparedness of dialysis patients is suboptimal. In this quality improvement study, we assessed disaster preparedness in our hemodialysis patients and evaluated multidisciplinary approach to disseminate this information.

Methods: The study consisted of a similar initial and follow up survey (yes/no answers). Patients were approached during dialysis to participate. On completion of the initial survey, patients were provided disaster preparedness related education by a multidisciplinary team of physicians, nurses, dieticians and social workers. Each member reviewed preparedness-relevant topics with the patients. Disaster preparedness was defined as subjective preparedness (survey question) and a positive response to at least three key questions-having a plan they have had discussed with a family member or dialysis unit, knowledge of backup dialysis facility and familiarity with emergency diet plan. A follow up survey was provided to the patients at the end of the month.

Results: Of the 132 eligible subjects, 124 completed all the surveys. Average age of the participants was 62 years, 52% were males and 58% were African Americans. While 60% of the patients thought they were prepared for an emergency (subjective), based on our defining criteria:80% of patients were *not* prepared for an emergency. About 50% of them did not have a plan or know about a backup facility. 35% were unaware of an emergency diet plan. 95% of the patients were interested in learning about emergency preparedness and 99% found the information provided during the project useful. Using similar criteria for preparedness, follow up survey showed 80% of the patients were better prepared.

Conclusions: Emergency preparedness in dialysis patients was lacking, but they were willing to learn. This study highlights that a multidisciplinary approach in an outpatient dialysis unit setting is feasible and effective in educating patients about disaster preparedness.

TH-PO981

Incidence of Angioedema with Lisinopril and Losartan in the Veteran Population Joseph A. Abdelmalek,[1,2] Jill Susan Simonian,[1] Margaret Mendes,[1] Rashid Kazerooni,[1] Nermeen Madkour,[1] Dena E. Rifkin.[1,2] *[1]Veterans Administration, San Diego, CA; [2]UCSD, San Diego, CA.*

Background: Angioedema is a well-recognized, potentially fatal adverse effect of angiotensin converting enzyme inhibitor (ACE-I) and angiotensin receptor blocker (ARB) use. We aim to characterize and compare rates of this adverse event in the veteran population for lisinopril and losartan, the first-line ACE-I and ARB, respectively.

Methods: The number of unique patients for lisinopril and losartan during fiscal year 2013 nationally was obtained using ProClarity, a VA outpatient prescription data repository. Combination products with hydrochlorothiazide for each respective product were also included in the analysis. The number of documented cases of angioedema for this analysis was retrieved from VAADERS (VA Adverse Drug Event Reporting System).

Results: We identified 1,626,863 unique patients prescribed lisinopril during the study period, with 1,592 cases of documented angioedema (incidence of 0.98 events per 1000 patients). There were 308,797 unique patients prescribed losartan, and 60 documented cases of angioedema (incidence of 0.19 events per 1000 patients). The incidence ratio of angioedema for lisinopril compared to losartan was 5.16. If, as described in the literature, there is minimal cross-reactivity between ACEI and ARB angioedema, prescribing losartan primarily instead of lisinopril would have resulted in approximately 1,267 fewer cases of angioedema in 2013. This translates into an estimated cost savings of approximately 2.3 million dollars per year nationally, based on 2013 VA expenses (assuming an ER visit and 24 hour inpatient observation per case).

Conclusions: Angioedema is associated with significant morbidity, and more commonly encountered with ACE-I use than ARBs. With the increasing number of indications for ARB use and the suggestion of a better safety profile, it may be beneficial to consider ARBs as first line therapy over ACE-Is in disease states where both drugs are considered equally efficacious.

TH-PO982

Objective Quantification of Fall Risk in Hemodialysis Patients Ken Wilund, Hyunwoo Hank Park, Peter J. Fitschen, Brandon Kistler, Jacob J. Sosnoff. *Dept of Kinesiology and Community Health, Univ of Illinois, Urbana, IL.*

Background: Maintenance hemodialysis (MHD) patients are at an increased risk of falling and are likely to suffer greater consequences such as hip fracture when they do fall. Yet, there is a significant lack of research on falls in MHD patients. Improving fall-risk prediction would be an important step in preventing falls in this high risk population.

Methods: 44 MHD patients from clinics throughout Illinois were recruited. All patients provided demographic information, a blood sample, fall history over the previous 12 months, and underwent a series of assessments including a multidimensional assessment of physical function, mobility, and postural control.

Results: Fourteen participants (31.8% of the sample) reported at least one fall in the previous 12 months, with a further 11 of these 14 fallers (78.6% of fallers) reporting two or more falls during the same period. Fallers were more likely to be diabetic but had normal albumin levels. Fallers had significantly lower physical function status (reduced endurance and muscle strength), balance, and mobility function than non-fallers.

Conclusions: The observations identify potentially modifiable targets for fall reduction interventions in MHD patients.

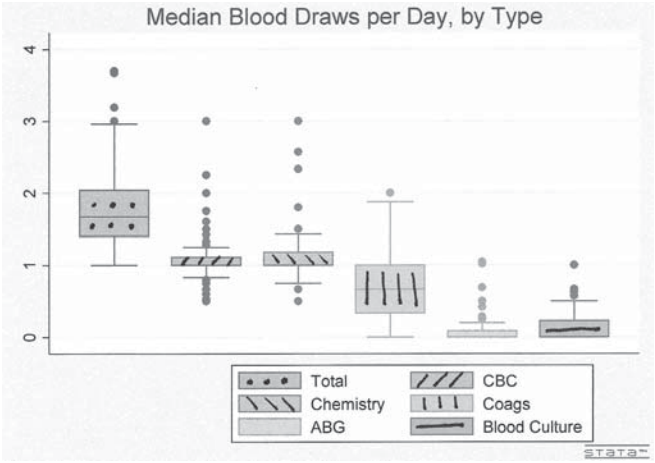
TH-PO983

Laboratory Venipuncture in a Tertiary Care Hospital Sushil Ratnaparkhe,[1] Sneha Shrivastava,[1] Rita L. McGill.[2] *[1]Internal Medicine, Allegheny General Hospital, Pittsburgh, PA; [2]Nephrology, Allegheny General Hospital, Pittsburgh, PA.*

Background: "Routine daily labs" have become a cultural expectation without an obvious evidence base. Potential harms include discomfort, iatrogenic anemia, and venous injury. In patients with CKD, venipuncture ought to be minimized. This study aims to describe laboratory testing behavior in the medicine population in a teaching hospital.

Methods: We analyzed 100 consecutive admissions on a hospital teaching service. For each subject, lab drawing behavior was recorded, including frequency, "stat" versus routine orders, and category of labs ordered. Hemoglobin was recorded at admission and discharge.

Results: All data were right-skewed by outliers with excess labwork, so data are presented as median and IQR, illustrated by box plots. Length of stay was 4(3,7) days. Patients underwent lab punctures 1.67(1.4,2.04)/day for lab testing, which was primarily driven by daily complete blood counts [1(1,1.12)/day] and chemistries [1(1,1.18)/day].



20(13,33)% of labs were ordered stat. Hemoglobin dropped by 0.7(0,1.7) grams over admissions. Few patients had CKD, precluding a subgroup analysis.

Conclusions: Medical inpatients in a teaching hospital are exposed to a high burden of daily lab testing due to an expectation of 'routine' daily blood counts and chemistries, exposing patients to significant blood loss, discomfort, and depletion of peripheral veins. This practice may explain the explosive increase in PICC use, and presents obvious hazards for patients who develop CKD. Given the prevalence of CKD in the general population, outreach toward Internal Medicine trainees and Patient Safety Committees is warranted. Evidence-based lab ordering parameters may improve vascular access prospects, and promote more cost-effective care.

TH-PO984

Usefulness of Doppler Ultrasound for Detection and Management of Complications following Renal Biopsy (RB) Maite Rivera, Nuria Rodriguez Mendiola, Victor Burguera, Viviana Raoch Michaels, Sandra Elias, Rodrigo Hernandez Loyola, Fernando Liano, Carlos Quereda. *Nephrology, Hospital Univ Ramón y Cajal.UAH Univ, Irycis, Madrid, Spain.*

Background: Asymptomatic vascular complications following renal biopsy can only be detected using doppler ultrasound, and it is of great help to decide surgery or embolization. We analyze the utility of doppler ultrasound in the detection and management of the RB complications.

Methods: 238 consecutive RB were analyzed. Data were collected prospectively from the database of our Diagnostic and Interventional Nephrology Unit. 64% were men. Mean age 55±15 years. All patients underwent a routine doppler ultrasound (color and pulsed) into the 24 h following RB. 113 (47.5%) were renal transplants (RT) and 125 (52.5%) native kidneys (NK). All RB were performed with an automatic biopsy-gun. Patients with RT and NK were similar in age, diabetes, number of samples and glomeruli obtained. Antiagregants and/or anticoagulants intake was similar in both groups (13.3% RT, 12% NK). There were more men in RT Group (71.7% versus 42.4%) and more HBP (85.8% versus 60.8%). Complications were divided into clinical (macroscopic hematuria, transfusion with or without shock and embolization) and ultrasound detected complications (hematoma, pseudoaneurysm (PSA) and arteriovenous (AVF)). All RB and ultrasounds were performed or supervised by a senior nephrologist.

Results: The rate of clinical complications was 4.2 % (2.6% in RT (2 hematuria, 1 transfusion+ shock+embolization) and of 5.6% in NK (6 hematuria, 1 transfusion without shock) and embolization was of 0.8% (2 RT). There were no nephrectomies or deaths. Ultrasound detected 38 hematomas<2 cm (4RT, 34 NK) and 7 hematomas>2 cm (7 NK). Doppler detected 30 asymptomatic AVF (19RT, 11NK) and 1 asymptomatic PSA (1RT) wich was later embolized.

Conclusions: Ultrasound-guided RB is an invasive procedure but safe. The post biopsy doppler ultrasound detects potentially serious vascular complications which clinically go unnoticed. We recommend the routine performance of Doppler- ultrasound following RB in order to know the real rate of complications and improve patient management by making it possible to individualize the postbiopsy care.

Funding: Government Support - Non-U.S.

TH-PO985

Safety and Hemoglobin Effect of the First 28-Day Dose Cycle of Sotatercept 0.7 mg/kg Compared with Lower Doses and Placebo for Correction of Anemia in Hemodialysis Subjects: Interim Analysis Mohamed A. El-Shahawy,[1] James Cotton,[2] Charles J. Kaupke,[3] Nelson P. Kopyt,[4] Suktae Choi,[5] William T. Smith.[5] *[1]Academic Medical Research Inst, Los Angeles, CA; [2]Tyler Nephrology Associates PC, Tyler, TX; [3]Nephrology Specialist Medical Group, Orange, CA; [4]Lehigh Valley Health Network, Allentown, PA; [5]Celgene Corporation, Warren, NJ.*

Background: This ongoing randomized, single-blind, placebo-controlled study of sotatercept, an ActRIIA-IgG1 fusion protein ligand trap for the correction of anemia in hemodialysis (HD) subjects, evaluated the PK, safety, tolerability, and hemoglobin (Hb) effect. We previously reported interim results of the 0.3 and 0.5 mg/kg dose groups.

Methods: Erythropoietin-stimulating agent (ESA)-responsive subjects were washed out of ESA effects until Hb was <10 g/dL and randomized to sotatercept or placebo (PBO). Reported are interim results for PK, safety, Hb, and home BP effects of PBO (n=8) versus sotatercept 0.3 mg/kg (n=9), 0.5 mg/kg (n=8), and 0.7 mg/kg (n=6) administered subcutaneously every 28 days for up to 8 dose cycles, without intrasubject dose escalation permitted. Treatment failures (Hb <9 g/dL) were rescued with ESA or transfusion. Enrollment in the 0.7 mg/kg group is ongoing.

Results: Cumulative safety shows that AEs occurred in 63%, 89%, 75%, and 100% and serious AEs in 25%, 44%, 13%, and 33% of PBO, 0.3, 0.5, and 0.7 mg/kg subjects, respectively. Events were mostly mild/moderate, unrelated to study drug, relatively similar between groups, and generally consistent with subjects' medical histories. No antidrug antibodies, injection site reactions, or hypersensitivity reactions were observed. One death occurred in the PBO group. In the first 28-day dose cycle, peak mean Hb responses were 0.0, 0.5, 0.8, and 1.0 g/dL and rescue was required in 38%, 12%, 13%, and 0% of PBO, 0.3, 0.5, and 0.7 mg/kg subjects, respectively. There were no dose-dependent changes in home BP.

Conclusions: Sotatercept 0.7 mg/kg appears to be tolerated with an acceptable safety profile in HD. There are dose-dependent peak Hb responses in the first dose cycle, with improved long-term efficacy and no increase in home BP.

TH-PO986

Quality Improvement Protocol for Administration of Epoetin Alfa in Admitted Patients with End Stage Renal Disease Elliot M. Charen, Oladayo O. Bolarinwa, Nazia A. Siddiqi, Christina L. Bradshaw, Nijal R. Sheth, Hira B. Siktel, Nikolas B. Harbord, James F. Winchester. *Div of Nephrology and Hypertension, Mount Sinai Beth Israel, New York, NY.*

Background: Anemia is common in hemodialysis (HD) patients and is treated with intravenous iron and Erythropoietin Stimulating Agents (ESA) at outpatient hemodialysis centers. Admitted End Stage Renal Disease (ESRD) patients are at risk for worsening anemia in the setting of illness and frequent blood draws.

Methods: Chronic HD patients dialyzed during hospitalization and followed by the renal consult service were included. Data on admission hemoglobin and ESA dosing were collected retrospectively for the "study phase" (January 1-31, 2014). The hospital medication record was checked to see if ESA was ordered and administered by the day of first HD or within 72 hours of admission. If not given, the reason why was determined. In the "implementation phase" of the study (March 1-31, 2014), the ESA protocol for admitted HD patients was implemented with Kidney Disease Improving Global Outcomes (KDIGO) anemia guidelines as a reference.

Results: In the implementation phase (March) as compared to the study phase (January), a significantly greater percentage of patients had ESA ordered within 48-72 hours of admission or by first HD (74% versus 21%, p<0.005); had ESA dosed within 48-72 hours of admission or by first HD (53% versus 10%, p<0.005) and were administered ESA during their hospitalization (84% versus 34%, p<0.005). The most common reason for missed ESA dosing was that the patient was not going for dialysis that day.

Conclusions: Instituting a program for ESA ordering improves ESA dosing.

TH-PO987

Pediatric Left Renal Vein Entrapment Syndrome Diagnosed by ^{99m}Tc-Albumin-Conjugate Scintigraphy Keisuke Sugimoto,[1] Tomoki Miyazawa,[1] Takuji Enya,[1] Hitomi Nishi,[1] Shinsuke Fujita,[1] Hidehiko Yanagida,[2] Mitsuru Okada,[1] Tsukasa Takemura.[1] *[1]Pediatrics, Kidai Univ Faculty of Medicine, Osakasayama, Osaka, Japan; [2]Pediatrics, Sakai Hospital Kidai Univ Faculty of Medicine, Sakai, Osaka, Japan.*

Background: Left renal vein entrapment syndrome (LRVES) sometimes manifests as gross hematuria after intense exercise, and abdominal or flank pain with exacerbation. Ultrasonography is usually performed first in imaging to demonstrate LRVES, however it may make misdiagnosis of LRVES regarding the accuracy of this examination. Procedures for diagnosis of LRVES in children have been either invasive or limited in accuracy. To establish a noninvasive diagnostic protocol for children whose ultrasonographic, MRA, and/or 3-dimensional computer tomography (3D-CT) results suggest LRVES, we compared pressures between the IVC and LRV using a simplified Bernoulli equation in interpreting Doppler ultrasonography (DUS), and also performed ^{99m}Tc -HSA-D scintigraphy.

Methods: Thirteen patients provisionally diagnosed with LRVES by ultrasonography combined with other imaging such as magnetic resonance angiography and 3D-CT were examined. We examined ^{99m}Tc-HSA-D scintigraphy in childhood LRVES, demonstrating selective left renal nuclides excretion. We also measured peak velocity using pulse DUS, calculating pressure differences between inferior vena cava and left renal vein using a simplified Bernoulli equation.

Results: Four children showing repeated gross hematuria all showed pressure differences exceeding 3.0 mmHg. Selective left renal albumin excretion was demonstrated by ^{99m}Tc-HSA-D scintigraphy. SPECT also showed accumulation in a site consistent with the left renal pelvis. Among 9 children manifesting mainly orthostatic proteinuria, selective left renal albumin excretion examined by ^{99m}Tc-HSA-D scintigraphy was demonstrated only in those with proteinuria exceeding 1 g/g•Cr after standing in a lordotic position. Pressure differences in patients with orthostatic proteinuria were unrelated to proteinuria severity.

Conclusions: The newly method combining US and SPECT added to ^{99m}Tc-HSA-D scintigraphy is noninvasive and safe in children, may suffice for diagnosis of LRVES, especially with gross hematuria.

TH-PO988

Iatrogenic Hypoglycemia following Hyperkalemia Treatment in the Emergency Department: A Common and Preventable Complication Bairbre A. McNicholas, Katrina Carli, Arthur E. Anderson, Hien Pham, Bessie A. Young. *Div of Nephrology, Univ of Washington, Seattle, WA.*

Background: Hyperkalemia is a common presentation in the emergency department (ED), with fatal complications if untreated. Insulin and dextrose are frequently used to treat hyperkalemia as part of treatment plans. Protocolized treatment plans may leave patients at risk for iatrogenic hypoglycaemia if not carefully monitored.

Methods: Retrospective study of all patients who presented with K^+>6mEq/L to an ED from June 1 to December 31 2013. Data related to presentation, laboratory values and pharmacological management were collected using chart review. Two tailed student t-test and chi-squared statistics were used to determine significance for continuous and categorical variables.

Results: Over a 6 month period 125 patients were treated for 155 presentations of K^+>6mEq/L. End stage renal disease was present in 49(39%), acute/chronic kidney disease in 62(49%). 32(26%) were diabetics. EKG changes were present in 60(48%). Laboratory values and treatment is outlined in table 1. Pharmacological treatment was used in 99(63%) of cases and 62(40%) were part of a protocolized plan. Of those receiving insulin, 21(27%) received 10 units of IV insulin. 19(23%) who received IV insulin developed hypoglycemia. Mean time to a hypoglycemic event was 2.1±1.2 hours. There was no difference in incidence of hypoglycemia when treatment was protocolized or when treated with 5 versus 10units of insulin, There was a trend for ESRD patient who were treated with 10 units of insulin to develop hypoglycemia versus those treated with 5 units of insulin (4/28 versus 5/13 p=0.1)

Laboratory Values on Admission	
Potassium	6.7±0.7mEq/l
Glucose	186±227mg/dl
Creatinine	7.5±5.8mg/dl
Pharmacological treatment	
IV Calcium	78(50%)
Sodium bicarbonate	40(25%)
Beta-agonist	26(16%)
Resin	64(41%
Insulin	76(49%)
Dextrose	73(96%)

Conclusions: Hyperkalemia is a common problem in the ED and treatment with IV insulin is commonly associated with iatrogenic hypoglycemia. Careful monitoring of blood glucose and adjustment of dextrose/insulin dosage are critical particularly in patients with reduced renal function and should be part of protocolled treatment plans.

TH-PO989

Urinary Markers and Renal Function in Hepatitis C Experienced Patients on Pegylated Interferon/Ribavirin and Boceprevir Triple Therapy in a Third-Level Hospital in Mexico City Juan Carlos Garcia Ya?ez, Karen Andrade. *Nephrology, Inst Mexicano del Seguro Social Hospital de Especialidades La Raza, Distrito Federal, México Distrito Federal, Mexico.*

Background: Recently there is some evidence that the use of boceprevir is associated with decline in eGFR and the mechanism by which it could cause it has not been demonstrated. We aimed to identify alterations in serological and urinary markers of renal function during triple therapy treatment.

Methods: We conducted an observational, longitudinal, prospective study, in hepatitis C experienced patients, partial or null responders which started triple therapy with PEG-IFN/RBV and Boceprevir. Serum and urinary markers were taken at baseline and at weeks 4, 8, 12 and up to week 24 during treatment with triple therapy, eGFR was estimated using the MDRD-4 creatinine equation. Fractional excretion rates (FER) of calcium, phosphate and uric acid as well as urinary creatinine and protein in urine were tested.

Results: We included 21 patients (17 with urinary markers); 52% were men, median age was 51 years old (IQR 44-58), median weight was 67 kg (IQR 60-74). Median baseline eGFR was 87.4 ml/min (IQR 78.2-97.8) and at week 12, 87.7 ml/min (IQR 79-98) (p=0.825). Median baseline FER of calcium, phosphate, and uric acid were; 1% (IQR 0.7-1.5), 9.7% (IQR 8.9-11.9), and 5.5% (IQR 4.5-7.5) respectively. At week 12; 0.75% (IQR 0.3-1.39), 9.7% (IQR 7.1-11.7), and 6.1% (IQR 4.7-11), with p=0.064, p=0.245 and p=0.460 respectively when Wilcoxon rank test whas performed. At week 24; 0.85% (IQR 0.59-1.7), 9.8% (IQR 8-10.6%), and 6.5% (IQR 4.3-8.5), with p=0.062, p=0.534, and p=0.285.

Conclusions: no significant alterations of urinary markers could be identified. However, patients on triple therapy require complete and periodical renal function assessment.

TH-PO990

Low Dose Tinzaparin as Venous-Thromboembolism Prophylaxis in Advanced Kidney Disease Suzanne H. Forbes,[1] Sean Platton,[2] Peter Maccallum,[2] Neil Ashman.[1] *[1]Dept of Nephrology & Transplantation, Royal London Hospital, London, United Kingdom; [2]Dept of Haematology, Royal London Hospital, London, United Kingdom.*

Background: Many hospital policies advocate low molecular weight heparins (LMWH) for venous thromboembolism (VTE) prophylaxis. The dose, predictability and safety of LMWHs in advanced chronic kidney disease (CKD), a population at increased bleeding

risk, is uncertain. Most trials exclude these patients. We conducted a prospective study to ascertain prescribing practice in our unit and to assess safety, as guided by evidence of drug accumulation and clinical events.

Methods: We performed a spot audit of all renal inpatients on a given day to identify those prescribed LMWH (tinzaparin) VTE prophylaxis and prospectively followed them for up to 5 days, monitoring regular trough anti-Xa levels and one peak. Haemodialysis (HD) patients also receiving tinzaparin for HD anticoagulation had peak dialysis anti-Xa levels measured. We noted any bleeding or thrombotic events. We repeated this cycle 5 times.

Results: Overall we assessed 214 patients. Of these 64 received tinzaparin.

Modality (eGFR ml/min/1.72m^2)	n
CKD (<15)	7
CKD (>15)	5
Transplant (<15)	7
Transplant (>15)	4
HD	29
PD	2

We excluded acute kidney injuries and those with eGFRs >40ml/min/1.73m^2 leaving 54 patients followed prospectively for an average 4 days. Mean age was 64 and median eGFR 9ml/min/1.73m^2. Median dose of tinzaparin was 47.8 IU/kg. We measured an average of 4 troughs per patient; 16 were >0.05units(u)/mL, the highest 0.17u/mL (<0.2u/mL is expected with prophylaxis). The highest peak was 0.34u/mL (bioaccumulation is >0.4u/mL). Anti-Xa levels with iv tinzaparin on HD are well described, the peak at 30 minutes expected to be <1u/mL. In the HD patients also receiving prophylaxis all were <0.6u/mL. There was no correlation between anti-Xa level and weight, dose/kg or non-dialysis eGFR. In the LMWH group there was 1 fatal intracerebral bleed (TP eGFR 17ml/min/1.73m^2). In those not given prophylaxis there were 13 bleeding events. No patient had a thrombotic event.

Conclusions: This study shows low dose tinzaparin in patients with advanced CKD is not associated with accumulation of anti-Xa activity and has no impact on HD anti-Xa levels.

TH-PO991

Management of Cancer Patients with Simultaneous Chronic Kidney Disease or at Risk of Developing It. Three Years' Experience of an Ambulatory of Onco-Nephrology Laura Cosmai,[1] Wanda Liguigli,[2] Marina Foramitti,[1] Maurizio Gallieni,[3] Camillo Porta,[4] Fabio Malberti.[1] *[1]Nephrology, Istituti Ospitalieri, Cremona, Italy; [2]Medical Oncology, Istituti Ospitalieri, Cremona, Italy; [3]Nephrology, San Carlo Borromeo Hospital, Milan, Italy; [4]Medical Oncology, IRCCS San Matteo Univ Hospital Foundation, Pavia, Italy.*

Background: Onco-Nephrology is a novel subspeciality dealing with: renal toxicity from chemotherapy (CT), targeted agents (TA) or contrast medium (CM), active cancer treatment (aTx)-related electrolyte disturbances, alterations of the Ca-P metabolism and hypertension, management of pts nephrectomized for a malignancy. Here we report 3 years' experience of an ambulatory of Onco-Nephrology.

Methods: This ambulatory, run by a Nephrologist, takes place once a week within an Oncology outpatient ward, in order to allow closer interaction between specialists and easier access to pts' data. Until now, we have followed 349 cancer pts with CKD on aTx, and 92 untreated cancer pts with CKD; 127 pts were nephrectomized for a localized or metastatic renal cell carcinoma (RCC); beyond RCC, patients had also lung (48 cases), gastric (50), prostate (34), bladder (38), or other cancers (52).

Results: Among 47 pts nephrectomized for metastatic RCC under aTx, we had only 4 aTx interruptions, while among the 80 previously nephrectomized pts for a localized RCC (not on aTx), at a median follow-up of 12 months, we did not observe any CKD progression (versus an expected percentage of 63% at 3 years). Only one patient (out of 15) treated with cisplatin had to discontinue CT because of renal toxicity. Only 10 pts have developed an episode of acute kidney injury (AKI), but all were able to resume aTx; 6 pts with advanced CKD began dialysis while on aTx. Furthermore, no cases of AKI from CM were observed, thanks to the implementation of specific protocols. Finally, previously unreported renal toxicities were observed.

Conclusions: Our experience shows that an early Onco-Nephrological assessment may improve pts' outcome. Further development of Onco-Nephrology (e.g. dedicated ambulatories and specific trials) is warranted.

TH-PO992

PJP - *Pneumocystis* (*carinii*) *jiroveci*: A Reemerging Threat to the Immunosuppressed Patient John Niles, Andrew P. Murphy, Katherine M. Cosgrove, Karen A. Laliberte. *Renal, Massachusetts General Hospital, Boston, MA.*

Background: PJP is one of the most common opportunistic infections. Newer immunosuppressive therapies in autoimmune disease poses a potential threat of more or different opportunistic infections. PJP chemoprophylaxis with trimethoprim/sulfamethoxazole (T/S), atovaquone or dapsone is widely recommended but there is no consensus about the exact indications and durations for these therapies.

Methods: Two pts from outside clinics, with ANCA vasculitis, were seen. At the time of referral, neither had been given PJP prophylaxis and both subsequently developed PJP. Pt #1: 16yo newly diagnosed ANCA with RPGN presented after 2.5 months of tx with Rituxan (RTX), plasma exchange, cyclophosphamide, high dose prednisone plus 13 pulses. Prednisone was at 40mg/d at the visit. Prednisone tapered to 30mg /day was initiated with T/S prophylaxis. The next day she developed fever, hypoxia and LDH was 656. Pt #2: 79yo male with relapsing ANCA disease and CKD 4 treated with RTX x 4 doses and prednisone 40mg/day for 3 months because of nonspecific pulmonary findings. He was admitted from clinic with hypoxia and LDH of 886. Hospital: Both required high flow oxygen. Pt #1 was treated with T/S and continued steroids. Pt # 2 was given Atovaquone and steroids. Early on, both had pulmonary deterioration with attempts to wean steroids.

Results: Both pts were treated with immunosuppressive therapy without prophylaxis and had extended steroid courses for severe and persistent mainfestations of vasculitis. Examination of the medical records of pt #1 revealed an elevated LDH at week 7 of treatment, 3 weeks before admission. Pt #2 had a very high LDH at the time of consultation. With steroid taper both developed severe hypoxia and required hospitalization. During hospitalization, both had worsening pulmonary status during attempts to wean their steroids, despite institution of full anti-PJP antibiotics.

Conclusions: There has been a shift in treatment to biologic agents, with rapid steroid tapers. However, steroids are often used to help with persistent or severe disease. These two cases demonstrate the ongoing need for safe prophylaxis in patients requiring immunosuppressive therapy, including biologic agents.

TH-PO993

An Exploration of 30-Day Re-Admissions in Chronic Hemodialysis Patients David J.R. Steele, Merranda S. Logan. *Div of Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: The United States Renal Data System's 2013 report revealed that among hemodialysis patients prevalent in 2011, 36 percent of hospitalized patients were re-hospitalized within 30 days of discharge. In comparison only 17.4 percent of patients aged 66 and above without chronic kidney disease required re-hospitalization within 30 days of discharge. The aim of this quality improvement project was to determine common characteristics amongst chronic hemodialysis patients re-hospitalized within 30 days of hospital discharge and to identify system factors that may reduce preventable re-admissions.

Methods: All attending nephrologists participated in directed chart reviews of chronic hemodialysis patients re-admitted to our hospital within 30 days of hospital discharge over a 6 month period. Patients re-admitted to other hospitals were not included. Baseline data on factors related to re-hospitalization were collected. Reviewers were asked to rate the preventability of each re-hospitalization.

Results: Forty-eight re-hospitalizations were reviewed. Common themes associated with re-hospitalization included polypharmacy, greater than five medication changes during the index admission, ESRD diagnosis for less than 90 days and anemia. Common themes associated with preventable re-admissions included patient education, communication between inpatient and outpatient providers, medication side-effects and medication reconciliation.

Conclusions: Systematic review of re-hospitalized patients enabled us to identify potentially actionable opportunities for improvement in care delivery. As a result of this study, quality improvement projects directed at standardizing discharge communications, anemia management and discharge medication reconciliation were recommended.

TH-PO994

Evaluation of Antibiotic Dosing in Patients Receiving Sustained Low-Efficiency Dialysis Leigh A. Keough,[1] Joanna Hudson,[1,2] Amy G. Krauss,[1] Beth Segars.[1] *[1]Methodist Univ Hospital, Memphis, TN; [2]The Univ of Tennessee College of Pharmacy, Memphis, TN.*

Background: Sustained low efficiency dialysis (SLED) is a form of dialysis that combines aspects of conventional intermittent hemodialysis (IHD) with features of traditional continuous renal replacement therapy (CRRT). As a "hybrid" dialysis modality, SLED combines the use of conventional IHD machines with smaller filters and reduced blood and dialysate flow rates that typically are "in between" that of IHD and other types of CRRT. Antibiotic dosing recommendations for IHD and CRRT are not appropriate for SLED. Antibiotic dosing during SLED is variable and there is substantial concern for underdosing. In this study, we characterized the adequacy of dosing of select antibiotics during SLED treatment.

Methods: A retrospective chart review was performed on patients admitted to the Methodist Le Bonheur System from October 2010 through August 2013 who received SLED and at least one of the selected antibiotics: cefepime daptomycin, piperacillin/tazobactam, meropenem, and vancomycin. For all patients identified, the administered antibiotic dosing regimen was defined as "adequate" or "inadequate" based on recommendations available in the literature. Dosing regimens were evaluated each day the patient was receiving one of the selected antibiotics concurrently with SLED. Reasons for inadequate dosing were also evaluated.

Results: A total of 59 patients met inclusion criteria: 59% male, 53% African-American, mean age 57 + 13 yrs. SLED was required for 69% of patients with AKI and 31% with ESRD. SLED parameters were: average blood flow rate 220 + 24 ml/min, dialysate flow rate 265 + 39 ml/min, and duration 9.3 +1.7 hours. The median number of days on SLED of 7 + 5. The total percent of adequate antibiotic days was vancomycin 85%, cefepime 64%, daptomycin 57%, meropenem 37%, and piperacillin/tazobactam 22%. Underdosing accounted for 63% of inadequate antibiotic days.

Conclusions: A high percentage of the antibiotics being administered were inadequate based on current literature recommendations. There is a need to educate prescribers on appropriate dosing practices in this patient population as more data become available.

TH-PO995

Exposure to Ionizing Radiations in Patients on Hemodialysis

Adil Mohammad Hazara,[1] Greg A. Chambers,[1] Tracy Alison Cathcart,[1] Sunil Bhandari.[1,2] *[1]Hull and East Yorkshire Hospitals NHS Trust, Hull, United Kingdom; [2]Hull York Medical School, United Kingdom.*

Background: Patients on hemodialysis often carry a large burden of co-morbidities and are frequently exposed to ionizing radiations (IR) through various radiological examinations. We aimed to estimate exposure to IR in a cohort of hemodialysis patients.

Methods: Records of previous radiological examinations were obtained for patients receiving maintenance in-centre hemodialysis at a teaching hospital and affiliated centres in United Kingdom (covering five dialysis units). Exposure to IR per patient was assessed by determining cumulative effective dose (CED) for all radiological examinations.

Results: 126 patients, who consented for their records to be accessed, were included; median age: 69 (range: 22-87) years; males 82 (62%). The median duration on hemodialysis was 3.8 (range: 0.2 - 31.8) years which collectively represented 617 person-years of dialysis treatment. In this period, exposure to IR was recorded at 2,749.5 millisieverts (mSv) for the whole cohort; mean CED therefore was estimated to be 4.5 mSv per person per year. Investigation types and their relative contribution to total IR exposure are presented in figure 1. Cardiac investigations accounted for the largest contribution (35.6%) to this exposure followed by vascular (28.7%), gastrointestinal (15.8%), respiratory (7.2%), musculoskeletal (2.3%), urinary system (1.7%) and other (8.7%) examinations.

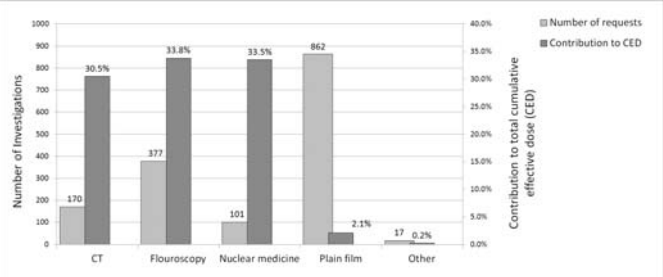

Fig 1: Numbers and types of investigations, and their relative contribution to total cumulative effective dose (CED) in 126 patients on hemodialysis. CT: computed tomography.

Conclusions: Exposure to IR due to radiological examinations among patients on hemodialysis is higher than that reported in general population. Certain radiological and nuclear medicine scans deliver a particularly high dose of radiation; their targeted use must be encouraged in order to reduce this burden.

TH-PO996

Maternal Diabetes Modulates Kidney Formation in Progeny: The Functional Interaction Between Catalase and Hedgehog Interacting Protein (Hhip)

Xin-Ping Zhao,[1] Shiao-Ying Chang,[1] Min-Chun Liao,[1] Isabelle Chenier,[1] Julie R. Ingelfinger,[2] John S.D. Chan,[1] Shao-Ling Zhang.[1] *[1]Research Center, CRCHUM, Montreal, QC, Canada; [2]Pediatric Nephrology, Mass. Gen. Hosp, Boston, MA.*

Background: Previously, we reported that impaired nephrogenesis induced by maternal diabetes is mediated, at least in part, via augmented Hhip gene expression. Overexpression of catalase (CAT) in renal proximal tubular cells (RPTCs) could prevent maternal diabetes-impaired kidney formation. The present study aims to investigate the functional interaction between Hhip and CAT gene expression in maternal diabetes modulated kidney formation in progeny and examine the potential underlying mechanisms *in vivo* and *in vitro.*

Methods: Young male offspring (newborn to 3 weeks of age) of non-diabetic and diabetic dams of Hoxb7-green fluorescence protein (GFP)-transgenic (Tg) and Hoxb7/Catalase (CAT)-Tg mice were studied. Renal morphology, immunohistochemistry, reactive oxygen species (ROS) generation and gene expression were assessed by standard methods. Mouse *endothelial cells (SVEC4-10)* and rat immortalized RPTCs (IRPTCs) were used as *in vitro* studies.

Results: As compared to the offspring from non-diabetic Hoxb7-GFP-Tg dams, renal dysmorphogenesis, nascent nephron apoptosis, increased ROS and heightened Hhip and TGFβ1 gene expression were observed within the kidneys of offspring of Hoxb7-GFP-Tg dams with severe maternal diabetes. These changes were ameliorated in male offspring of diabetic Hoxb7/Cat-GFP-Tg dams. In studies *in vitro*, high glucose stimulated Hhip gene expression, and subsequently targeted TGFβ1 signaling. CAT promoted Pax2, Shh andp27^{Kip1} expression to counter the stimulatory effects of high glucose on Hhip gene expression.

Conclusions: Our data suggest that the counterbalance of CAT and Hhip gene expression plays a key role in the impaired nephrogenesis that is induced by maternal diabetes, both *in vivo* and *in vitro.*

TH-PO997

DNA Methyltransferase 1 Is Required for Rat Metanephric Development and Its Abundance Is Reduced by Maternal Nutrient Restriction

Midori Awazu, Mariko Hida. *Dept of Pediatrics, School of Medicine, Keio Univ, Tokyo, Japan.*

Background: We previously reported that ureteric bud branching and metanephric growth were inhibited by maternal nutrient restriction in the rat. Maternal nutrient restriction also reduced global DNA methylation of the embryonic kidney and the methylation of genes involved in the negative regulation of branching morphogenesis. Decreased DNA methylation may be due to the downregulation of DNA methyltransferases (DNMTs). DNMT1 is essential for the maintenance of DNA methylation, and DNMT 3A and 3B are required for *de novo* methylation. In the present study, the expression of DNMTs during normal kidney development was investigated and compared with that in kidneys of offspring from nutrient deprived mothers. The role of DNMT1 in ureteric bud branching and metanephric growth was further investigated in an organ culture system.

Methods: The kidneys of embryonic day 15 (E15) to 18 (E18) fetuses and neonatal day 1 (N1) to 15 (N15) rats from dams given food ad libitum (CON) and those subjected to 50% food restriction throughout pregnancy (NR) were examined. The expression of DNMTs was assessed by immunoblot analysis. Embryonic day 13 metanephroi from normal rats were subjected to organ culture in the presence or absence of a DNMT1 inhibitor 5-aza-2 '-deoxycytidine (Aza) 20 μM for 3 days. Ureteric buds were visualized by whole-mount staining with pancytokeratin.

Results: DNMT1 and DNMT3B were expressed up to N1 and N15, respectively, with expression becoming downregulated as development proceeds. On the other hand, DNMT3A was expressed only at E15. The expression of DNMT1 was dramatically and that of DNMT3A was slightly reduced in the NR kidney at E15. These differences were no more observed at E18. The ureteric tip number was significantly reduced by Aza (3.0±0.6 versus 8.2±1.4, n=6, P<0.005). The kidney surface area of Aza-treated metanephroi was also significantly reduced (1.39±0.10 versus 3.51±1.01, n=6, P<0.005).

Conclusions: DNMTs are strongly expressed in the E15 kidney, and DNMT1 is essential for the metanephric development. Reduced abundance of DNMT1 may play a role in the inhibited ureteric branching and metanephric growth by maternal nutrient restriction.

Novel Roles for Uroplakin 1b in Terminal Differentiation, Urothelial Homeostasis, and Structural Integrity in the Urinary Tract

Ashley R. Carpenter,[1] Brian Becknell,[2] Kirk M. McHugh.[3] *[1]Biomedical Sciences Graduate Program, The Ohio State Univ; [2]Div of Nephrology, Nationwide Children's Hospital; [3]Div of Anatomy, The Ohio State Univ.*

Background: Urothelium is uniquely specialized to maintain a barrier between tissue and urine. To do this, terminally differentiated cells elaborate a rigid apical plaque (urothelial plaque), composed of four major uroplakin (Upk) proteins. We hypothesize that disruption of a tetraspanin Upk, Upk1b, can lead to plaque destabilization and trigger widespread defects within the entire urinary tract.

Methods: Bladders and kidneys from *Upk1b*$^{+/+}$ (wild type) and *Upk1b*$^{RFP/RFP}$ (Upk1b disrupted) mice were analyzed by immunohistochemistry, brightfield and electron microscopy, western blot, and ultrasound.

Results: *Upk1b*$^{RFP/RFP}$ bladder urothelium was devoid of urothelial plaques and was consistently dysplastic compared to *Upk1b*$^{+/+}$. In addition to widespread proliferation, *Upk1b*$^{RFP/RFP}$ bladder urothelium exhibited increased expression of progenitor cell markers Krt5, Krt14, and Sonic hedgehog and loss of terminal differentiation markers Krt20 and uroplakins. In contrast to *Upk1b*$^{+/+}$, *Upk1b*$^{RFP/RFP}$ renal urothelium exhibited absent urothelial plaques, and renal ultrasound revealed progressive hydroureteronephrosis. Expression of uroplakins and additional urothelial proteins was significantly altered in the stratified *Upk1b*$^{RFP/RFP}$ renal urothelium as compared to the monolayered *Upk1b*$^{+/+}$. Interestingly, 12 of 85 (14%) *Upk1b*$^{RFP/RFP}$ and 0 of 138 *Upk1b*$^{+/+}$ and *Upk1b*$^{RFP/+}$ mice exhibited renal collecting system duplication, where parallel ureters exit both orthotopic and ectopic pelves (P < 0.0001, Fisher's exact test).

Conclusions: We implicate Upk1b and urothelial plaques in terminal differentiation, regulation of the urothelial progenitors and urinary tract development. Our data suggests that the acquisition of terminal differentiation by urothelial cells is important for the negative regulation of progenitors and the maintenance of urothelial homeostasis. Although, Upk1b is regarded as a structural protein in differentiated urothelial cells, our data indicates for the first time a role for Upk1b in metanephric development.

TH-PO999

The Prorenin and Soluble (Pro)renin Receptor May Be Associated with Prenatal Renal Development in Humans

Tomomasa Terada,[1] Maki Urushihara,[1] Shuji Kondo,[1] Toshiaki Tamaki,[2] Shoji Kagami.[1] *[1]Dept of Pediatrics, The Univ of Tokushima Graduate School, Tokushima, Japan; [2]Dept of Pharmacology, The Univ of Tokushima Graduate Schoo, Tokushima, Japan.*

Background: The renin-angiotensin system (RAS) plays a key role in the development of the kidney. Although recent study demonstrated that (pro)renin receptor [(P)RR] was highly expressed in the developing kidney during embryonic development in the mouse, the mechanism by which (P)RR supports renal development in human are not fully understood. In this study, we examined plasma levels of prorenin and soluble (P)RR [s(P)RR] in cord blood and neonates, and the expression of (P)RR in kidney tissue.

Methods: Umbilical cord blood samples were collected from 56 preterm and 67 full-term neonates at birth. Blood samples were also obtained in 4 days and 4 weeks after birth. Prorenin and s(P)RR levels were measured using enzyme-linked immunosorbent assays. Additionally, we performed immunohistochemical (IHC) analysis of kidney tissues from neonates (n = 3, 33 to 37 weeks-gestation) and healthy children (n = 5, 3 to 7 years-old) in order to assess (P)RR expression in kidney.

Results: Mean plasma prorenin and s(P)RR levels in cord blood were significantly higher in preterm neonates than in full-term neonates ($P < 0.0001$ and $P = 0.0295$, respectively). Mean plasma prorenin levels in 4 days after birth were higher in preterm neonates than in full-term neonates ($P = 0.0001$), but s(P)RR levels were not ($P = 0.3809$). These differences were no longer evident for either plasma prorenin or s(P)RR levels between the two groups, 4 weeks after birth ($P = 0.2742$ and 0.5754, respectively). Importantly, the plasma prorenin levels in cord blood and in 4 days after birth were inversely correlated with gestational age ($P<0.001$). Furthermore, IHC study showed that renal expression levels of (P)RR in neonates was stronger than that in healthy children ($P < 0.0001$).

Conclusions: These results suggest that prorenin-s(P)RR signaling pathway is associated with prenatal renal development in humans.

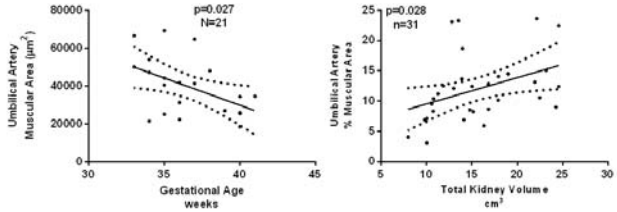
TH-PO1000

Umbilical Artery Histomorphometry Provides Insight into Angiogenesis and Nephrogenesis in Term and Preterm Infants Marissa J. Defreitas,[1] Deepan Mathur,[2] Teresa C. Cano,[1] Wacharee Seeherunvong,[1] Chryso P. Katsoufis,[1] Marta G. Galarza,[3] Salih Y. Yasin,[4] Maria Matilde Rodriguez,[2] Carolyn L. Abitbol.[1]
[1]Pediatric Nephrology, Univ of Miami/ Holtz Children's Hospital, Miami, FL; [2]Pediatric Pathology, Univ of Miami, Miami, FL; [3]Neonatology, Univ of Miami/ Holtz Children's Hospital, Miami, FL; [4]Obstetrics/ Perinatology, Univ of Miami/ Holtz Children's Hospital, Miami, FL.

Background: Preterm birth is associated with early and late renal insufficiency, a nephron deficit, hypertension and cardiovascular disease in later life. Since the umbilical arteries ultimately develop into the aorta, we hypothesized that the morphometry of these vessels could provide insight into the process of angiogenesis at birth.

Methods: A cohort of 155 infants were enrolled at birth into the Infant Kidney Study with assessment of renal mass as total kidney volume (TKV) by ultrasound. The umbilical cords of 31 infants were cut and sectioned for histomorphometric analysis including 9 term controls, 12 singleton and 10 preterm infants. The transverse section analyzed the amount of muscle and collagen within inner and outer layers of each artery by trichrome stain, averaging the measurements of the 2 vessels. The ratio between muscle and collagen was calculated.

Results: The density of the outer muscular-rich area was greater in preterm compared to term infants and correlated inversely with gestational age ($p<0.03$) in singleton infants. Moreover, per cent of inner muscular area correlated positively with renal mass ($p<0.03$) in all subjects.



Conclusions: Umbilical artery histomorphometry provides insight into early vascular morphology that is in synchrony with the development of the central vascular tree (aorta) and renal mass. This non-invasive technology merits further investigation with prospective follow-up of the infants identified at risk.

Funding: Private Foundation Support

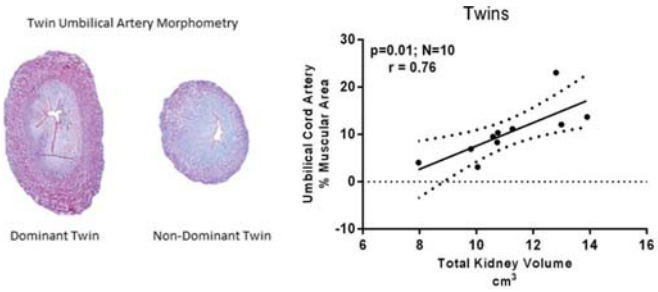
TH-PO1001

Umbilical Artery Histomorphometry Provides Insight into the Fetal Development of the Central Vascular Tree (Aorta) in Preterm Twins Marissa J. Defreitas,[1] Teresa C. Cano,[1] Wacharee Seeherunvong,[1] Salih Y. Yasin,[4] Shahnaz Duara,[3] Deepan Mathur,[2] Maria Matilde Rodriguez,[2] Carolyn L. Abitbol.[1]
[1]Pediatric Nephrology, Univ of Miami/Holtz Children's Hospital; [2]Pediatric Pathology, Univ of Miami/Holtz Children's Hospital; [3]Neonatology, Univ of Miami/Holtz Children's Hospital; [4]Obstetrics/Perinatology, Univ of Miami, Miami, FL.

Background: Prematurity is a risk factor for hypertension, aortic stiffness, nephron deficit, and adult onset cardiovascular and renal disease. The effect of preterm birth on angiogenesis is largely unknown. Twin gestation offers a venue for studying angiogenesis in a competitive intrauterine environment. We hypothesized that the umbilical artery would provide insight into the central vascular tree (Aorta) in preterm twin infants.

Methods: A cohort of 155 newborn infants was enrolled into the Gerber Infant Kidney Study. Ultrasound was used to measure total kidney volume (TKV). Umbilical cord specimens were obtained in 9 term singleton, 12 preterm singleton, and 10 preterm twin infants. The umbilical cord was sectioned, stained with Trichrome, and then digitalized. Muscular and collagenous areas of the umbilical artery were measured in pixels using Image J 1.48q software and converted to μm^2.

Results: The dominant twins had an increased umbilical artery muscle wall area (40 ± 19 versus 24 ± 12 nm^2; $p<0.03$) and an increased TKV (15 ± 5 versus 10 ± 1 cm^3; $p<0.05$) when compared to the co-twins. There was also a significant positive correlation between umbilical artery muscular area and kidney mass ($r=0.76$; $p=0.01$).



Conclusions: Twin gestation imposes discordance in vascular muscular endowment with the dominant twin having an advantage in vascular wall muscle density and presumed elasticity as well as renal mass. Prospective longitudinal studies are needed to determine if this anatomical discordance predisposes to functional impairment in twins.

Angiotensin Converting Enzyme Inhibitor Fetopathy: A Report of the Midwest Pediatric Nephrology Consortium (MWPNC) Shahid Nadeem,[1] Katherine Davis Westreich,[3] Ibrahim F. Shatat,[5] Marissa J. Defreitas,[2] Carolyn L. Abitbol,[2] Myra L. Chiang,[4] Donald J. Weaver,[6] Julia M. Steinke,[7] Larry A. Greenbaum.[1]
[1]Pediatrics, Emory, Atlanta, GA; [2]Pediatrics, Univ of Miami, Miami, FL; [3]Pediatrics, UNC, Chapel Hill, NC; [4]Pediatrics, WVU, Charleston, WV; [5]Pediatrics, MUSC, Charleston, SC; [6]Pediatrics, Levine Children's Hospital, Charlotte, NC; [7]Pediatrics, Helen DeVos Children's Hospital, Grand Rapids, MI.

Background: Renin angiotensin system (RAS) blockers are commonly used to treat hypertension and to reduce microalbuminuria or proteinuria. Fetopathy from in utero exposure to these agents was described more than 30 yrs ago; however, cases continue to occur. There are limited studies describing the full spectrum of this entity and no information on why fetal exposure occurs despite the presence of a black box warning.

Methods: This was a retrospective study performed through the MWPNC. Centers were asked to identify cases of ACE or ARB fetopathy. Case data included renal and extrarenal manifestations, timing of exposure, and the explanation for the fetal exposure.

Results: 13 cases were identified. RAS blocker exposure after the first trimester was associated with more severe renal manifestations. Chronic renal replacement therapy (RRT) was required in 6/7 patients (pts) with RAS blocker exposure after the first trimester and 0/6 pts with exposure restricted to the first trimester ($p=0.0047$). Pts had a variety of extrarenal manifestations, some not previously noted, including CNS anomalies (cystic encephalomalacia, cortical blindness, sensorineural hearing loss, arachnoid cysts) and pulmonary complications (pneumothorax, pneumomediastinum). RAS blocker exposure was usually secondary to absent or poor prenatal care or undiagnosed pregnancy.

Conclusions: ACE fetopathy continues to be a cause of considerable morbidity, with the need for chronic RRT more likely in affected pts exposed after the first trimester. A variety of serious extrarenal manifestations occur in these pts. Clinicians should emphasize the risk of fetopathy when prescribing RAS blockers to women of childbearing age.

Serum Creatinine During Physiological Perinatal Dehydration May Estimate Individual Nephron Endowment Gianluigi Ardissino,[1] Francesca Tel,[1] Ilaria Possenti,[1] Mariangela Pavesi,[2] Bianca Castiglione,[1] Sara Testa,[1] Patrizia Salice,[3] Dario Consonni.[4]
[1]Pediatric Nephrology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Dept of Radiology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Pediatric Cardiology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [4]Epidemiology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.

Background: It is well known that the nephron endowment of healthy subjects is highly variable and that individual nephron mass has potentially important implications both in health and disease. However nephron count is technically still impossible in living subjects. We hypothesised that serum creatinine levels during the physiological perinatal dehydration, might be helpful in identifying subjects with a reduced nephron mass.

Methods: The serum creatinine levels of normal Caucasian neonates were determined 48-96 hours after birth and their association with a family history of arterial hypertension (AH) was evaluated. Moreover, renal volume measured between the second and third month of life, in a subset of subjects, was correlated with the level of perinatal serum creatinine.

Results: Serum creatinine levels were determined in 182 normal newborns (90 males) at a mean of 61+8 hours after birth (range 46-82). Newborns with paternal AH had a higher mean serum creatinine level (0.7+0.3 versus 1.0+0.3; p<0.006). No differences in mean serum creatinine levels were found in relation with mother or grandparent's history of AH. Kidney volume negatively correlated (slope of -13.5 mL per unit of serum creatinine; 95% CI: -26.2 to -0.9; p=0.04) with serum creatinine levels in the subset of children who underwent kidney ultrasonography.

Conclusions: The determination of serum creatinine level during perinatal dehydration seems a promising tool for identifying normal subjects with a reduced nephron mass with potential important implications in understanding the individual outcome of renal diseases (including drug toxicity), expanding our knowledge on the pathophysiology of common renal and extrarenal diseases and providing clues for individualized preventive measures.

Enalapril Induces Dysregulation of Angiogenesis-Related Genes and Loss of Microvasculature in the Neonatal Rat Kidney Hyung Eun Yim, Kee Hwan Yoo, In Sun Bae, Young Sook Hong, Joo Won Lee. *Pediatrics, Korea Univ Guro Hospital, Seoul, Republic of Korea.*

Background: Pharmacological inhibition of the renin angiotensin system (RAS) during the neonatal period in rodents has shown vascular abnormalities that are followed by deterioration of kidney structure and function. Although angiotensin II appears to play an important role in kidney angiogenesis, mechanisms that govern the development of the kidney vasculature by the RAS are poorly understood. We aimed to investigate the effect of angiotensin II inhibition on the localization and expression of angiogenesis-related genes and microvasculature endothelial cells in the developing rat kidney.

Methods: Newborn rat pups were treated with enalapril (30 mg/kg/d) or vehicle for 7 days after birth. We investigated the intrarenal expression of angiopoietin-1, angiopoietin-2, the angiopoietin receptor Tie-2, and thrombospondin-1 with Western blotting and immunohistochemical staining at postnatal day 8. For determination of glomerular and peritubular capillary density, the endothelial cell markers of CD-31 and aminopeptidase P (JG-12) were also assessed.

Results: Light microscopic survey of kidney sections from enalapril-treated rats revealed fewer and immature glomeruli and disrupted tubules. In the enalapril-treated group, angiopoietin-2, Tie-2 and thrombospondin-1 protein expression were significantly increased, whereas angiopoietin-1 expression was decreased, compared with the control group ($P < 0.05$). Immunohistochemical staining of kidney sections for the endothelial cell markers of CD-31 and JG-12 showed a dense capillary network in cortex and medulla from control rats; however, enalapril-treated kidney showed a reduced endothelial immunostaining within both the glomeruli and the tubulointerstitium.

Conclusions: Our findings suggest that inhibition of the RAS during kidney development induces imbalanced angiopoietin signaling, upregulation of angiogenesis inhibitor, and loss of microvasculaturein the developing rat kidney. Angiotensin II-stimulated angiogenesis can play an important role in postnatal microvascular development and maturation in the developing rat kidney.

TH-PO1006

Next-Generation-Sequencing-based Molecular Diagnostics for Congenital and Inherited Kidney Disease Bert van der Zwaag, Albertien M. van Eerde, Martin Elferink, Patrick Van Zon, Marijn F. Stokman, Kirsten Y. Renkema, Nayia Nicolaou, J.k. Ploos van Amstel, Nine V. Knoers. *Medical Genetics, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: Congenital and inherited kidney diseases constitute the leading cause of chronic kidney disease in children. Molecular diagnostic analysis of heterogeneous renal disorders has long been hampered by the size and numbers of genes involved, but has become feasible with the advent of Next-Generation-Sequencing (NGS).

Methods: We set up and implemented an NGS-based test in our ISO15189 certified laboratory to enrich and sequence 376 genes known to be causal in or associated with kidney and urinary tract disorders. To reach a genotyping accuracy of at least 99%, a minimal vertical coverage of 15 individual reads per base is required. To deliver a comprehensive analysis of the genes collected in a genepanel, a horizontal coverage of at least 98% of targeted bases is requested. When the coverage by NGS drops below requested coverage thresholds, additional "Sanger"-based sequencing is performed to fill in the gaps. In this fashion, a mutation detection rate of >95% is achieved for the genes analysed.

Results: Based on the enrichment design 23 disease related genepanels were formed, including renal cysts (50 genes), Bardet-Biedl syndrome (14 genes), Joubert syndrome (21 genes), nephronophthisis (15 genes), congenital anomalies of the kidney and urinary tract (40 genes), nephrotic syndrome (16 genes) and focal segmental glomerulosclerosis (8 genes).

Conclusions: To conclude, comprehensive genetic testing by NGS will boost the diagnostic yield from 3-5% per gene tested to potentially >40-50% molecular diagnoses within one clinical genepanel analyzed. Thereby delivering a swift answer to the patient and a leap in efficacy and cost reduction for healthcare providers.

ARegPKD - A Web-Based European Registry Study on ARPKD Kathrin Ebner,[1] Carsten Bergmann,[2] Anke Doyon,[3] Ali Duzova,[4] Heike Goebel,[1] Dieter Haffner,[5] Bernd Hoppe,[6] Thomas Illig,[5] Martin Konrad,[7] Mieczyslaw Litwin,[8] Djalila Mekahli,[9] Bruno Ranchin,[10] Sara Testa,[11] Lutz Thorsten Weber,[1] Dorota Wicher,[8] Franz S. Schaefer,[3] Max C. Liebau.[1] *[1]Univ Hospital of Cologne, Germany; [2]Bioscentia Center for Human Genetics Ingelheim, Germany; [3]Univ Children's Hospital Heidelberg, Germany; [4]Hacettepe Univ Faculty of Medicine Ankara, Turkey; [5]Hannover Medical School, Germany; [6]Univ Hospital Bonn, Germany; [7]Univ Hospital Muenster, Germany; [8]The Childrens Memorial Health Inst Warsaw, Poland; [9]Univ Hospitals Leuven, Belgium; [10]Univ de Lyon, France; [11]Fondazione IRCCS Milano, Italy.*

Background: Autosomal Recessive Polycystic Kidney Disease (ARPKD) is the rare but frequently severe pediatric form of polycystic kidney disease. Morbidity and mortality remain relatively high even in most-advanced medical centers and there is currently no causative treatment for ARPKD. There are also no clinical classifications, known clinical risk factors or detailed treatment guidelines. Experience remains sparse even in large pediatric centers.

Methods: The multinational ARegPKD registry study aims to provide an observational evidence base for clinical treatment concepts for ARPKD. We characterize patients in a pseudonymized way using a web-based retro- and prospective registry study approach. A detailed basic data questionnaire and yearly follow-ups visits will give insights into phenotypic variability and long-term clinical developments. An ARPKD-specific biobank and reference histology complete the approach.

Results: Here we present data of the first included international patients. Im May 2014 we are following 30 patients of 0 to 43 years of age, including patients on renal replacement therapy, patients after isolated kidney transplantation or after combined liver-and-kidney transplantation. Detailed retrospective data exist for up to seven years of follow-up. Almost 50 centers in 10 different countires have already registered for ARegPKD.

Conclusions: ARegPKD is a novel web-based registry study for ARPKD in Europe and aims to contribute to the understanding of this severe renal disorder of early childhood.

TH-PO1008

Differential Urinary Proteomics in Primary Hyperoxaluria-1 Ellen Brooks,[1,2] Bernd Hoppe,[3] Dawn S. Milliner,[4] Gulsah Vural,[2] Eduardo C. Salido,[5] Craig B. Langman.[1,2] *[1]Feinberg Medical School, Northwestern Univ, Chicago, IL; [2]Ann & Robert H Lurie Children's Hosp, Chicago, IL; [3]Univ of Bonn Children's Hosp, Bonn, Germany; [4]Mayo Clinic, Rochester, MN; [5]Hospital Univ Canarias, La Laguna Tenerife, Spain.*

Background: Primary Hyperoxaluria-type 1 (PH1) is marked by hepatic oxalate (Ox) over production, high urinary (U) Ox, renal Ox crystal deposition, calculi, nephrocalcinosis, and progressive CKD. However, mechanisms mediating CKD remain relatively unknown.

Methods: 24 Hr. urine aliquots were analyzed for proteomic profiles using proprietary Luminex-based bead technology with families of proteins statistically tested.

Results: 47 PH1 patients were dichotomized into 2 subgroup sets by median (Md) UOx= 1.045(IQR=0.26-3.05)mmoL/L/1.73m^2 or Md eGFR=77.8(IQR=8.0-164.1)ml/min/1.73 m^2. No differences were seen for eGFR between UOx>Md or UOx<Md or for UOx level between eGFR>Md or eGFR<Md. See Table 1 for protein differences by subgroup.

Table 1. Differential PH1 Proteomic Responses

Variables	UOx>Md	UOx<Md	eGFR>Md	eGFR<Md
IGF-1; IL-15	↑			
KIM-1, NGAL		↑		↑
Apo C-III & D; B_2 Microglobulin, CD40, CD40L, IL-1rα, IGFBP-2, SOD-1, TNFR-2, VCAM-1, VEGF		↑		↑
Calgranulin, HGF, ICAM-1, IFN-γ, LOX-1, MMP-7, RANTES, TRAIL-3		↑		
OPN		↑	↑	
THP			↑	
α_1AT, α_1M, Fetuin A, IL-1β, IL-8, Microalbumin, TIMP-1				↑
TFF-3	↓		↓	

Conclusions: Patients with lower but not higher levels of UOx [UOx<Md] had increased tubular injury, inflammation, oxidative stress, lipid peroxidation, apoptosis, and fibrosis markers. We noted similarities with eGFR<Md, which also had a higher TIMP-1 level, another fibrotic inhibitor. Increased mineralization inhibitors were present in UOx<Md and eGFR>Md; but only eGFR<Md had higher Fetuin A. The data imply an overwhelming protective response to tissue injury in PH1 but only when UOx is lower, suggesting that the response is limited and insufficient as Ox rises. In those with UOx>Md, IL-15, and low TFF-3, factors to reduce apoptosis and augment tissue growth and repair were present uniquely. Our findings may lead to novel therapeutic approaches in PH1 based on the UOx phenotype.

Molecular Effects of Four Mutations Identified in the D3 Region of Thrombomodulin in Patients with Atypical Hemolytic Uremic Syndrome
Akira Ashida,[1] Daisuke Yamamoto,[2] Yoko Yoshida,[3] Masanori Matsumoto,[3] Toshiyuki Miyata,[4] Motoshi Hattori,[5] Yoshihiro Fujimura,[3] Hiroshi Tamai.[1] *[1]Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan; [2]Biomedical Computation Center, Osaka Medical College, Takatsuki, Osaka, Japan; [3]Blood Transfusion Medicine, Nara Medical Univ, Kashihara, Nara, Japan; [4]Molecular Pathogenesis, Research Inst National Cerebral and Cardiovascular Center, Suita, Osaka, Japan; [5]Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Atypical hemolytic uremic syndrome (aHUS) has been associated with dysregulation of the alternative complement pathway. Mutations in CFH, CFI, CFB, thrombomodulin (THBD), C3, and MCP predispose to the development of aHUS. We analyzed the molecular effects of four THBD gene mutations including T500M, identified in Japanese patients, on the alternative pathway of complement activation.

Methods: We examined four missense mutations in the THBD gene (D486Y, P495S, T500M and P501L). These mutation residues were located in the third domain (D3) of THBD. The molecular structure of D3 was theoretically constructed on the basis of 5000-picosecond molecular dynamic simulation, because the homologous structure of D3 has not been established.

Results: We carried out structural analysis of the D486, P495, T500 and P501 residues on the molecular surface of our THBD D3 model. The D3 sequence has the glycosaminoglycan (GAG) attachment site motif All of 4 mutation residues were located at positions near the motif, and the mutation at T500 in particular appeared to affect the GAG binding function. In addition, mutations of two proline residues were considered to affect the thrombin-binding function by changing the molecular direction to the lipid bilayer of the membrane, because D3 was directly connected to the sixth EGF-like domain of the thrombin binding site.

Conclusions: We conclude that these mutations of the THBD gene including mutations T500M are causative mutations of aHUS.

TH-PO1010

Glomerular Basement Membrane Injuries in Thin Basement Membrane Disease
Yusuke Kajimoto,[1] Seiichiro Higo,[1] Go Kanzaki,[1] Shinya Nagasaka,[1] Kiyotaka Nagahama,[1] Yukinari Masuda,[1] Shuichi Tsuruoka,[2] Akira Shimizu.[1] *[1]Analytic Human Pathology, Nippon Medical School, Tokyo, Kanto, Japan; [2]Nephrology, Nippon Medical School, Tokyo, Kanto, Japan.*

Background: Thin basement membrane disease (TBMD) is diagnosed by diffuse thinning of glomerular basement membrane (GBM) in electron microscopy (EM), and is characterized clinically by benign familial hematuria. The presence of hematuria may indicate GBM injury in diffuse thinning of GBM. In the present study, we analyzed the clinico-pathological characteristics of TBMD, focusing on GBM injuries, using immunostaining for α2(IV) and α5(IV) chains of Type IV collagen, and a new technique, low-vacuum scanning EM (LV-SEM), which can exhibit the three dimensional surface of GBM.

Methods: Between 2006 and 2014, TBMD was identified in 23 cases (1.8%) of 1275 renal biopsies in our department. We investigated their clinical, laboratory and histopathological findings. In 13 cases, we also carried out double immunostaining of α5(IV) and α2(IV), as well as LV-SEM.

Results: The average age of the 23 cases is 38±19 years (5-64). 22 cases have hematuria and 16 cases have proteinuria.17 cases (73.9%) were indicated to have hematuria or proteinuria from under 20 years of age. In 4 adult cases, moderate to severe decline in eGFR developed. In TBMD cases, all cases we had examined showed morphological and qualitative abnormalities of the GBM, in addition to the diffuse thinning of GBM. Alterations of the expression of α2(IV) and α5(IV) of type IV collagen were noted, including reduced α5 expression with or without increased α2(IV) in the wavy GBM. In addition, in the LV-SEM observations, various alterations of the three dimensional surface of the GBM were evident, including thinning and flattering of GBM with multiple small holes. These GBM alterations were more prominent in the adult cases than those in the young cases.

Conclusions: GBM alterations were frequently noted in TBMD, and were morphologically and qualitatively characterized by irregular attenuation of α5(IV) with or without enhancement of α2(IV) in type IV collagen, and thinning and flattering of GBM with multiple small holes. All of these findings might be associated with the hematuria, proteinuria, and/or renal dysfunction in TBMD.

Metabolic Phenotyping in Steroid Resistant Nephrotic Syndrome
Claire Boulange,[1] Manuja Kaluarachchi,[1] Isabel Garcia-Perez,[1,2] Anthony Dona,[2] Samantha Louise Lodge,[2] Elaine Holmes,[1,2] John C. Lindon,[1,2] Sven Schnaidt,[3] Franz S. Schaefer.[4] *[1]Metabometrix Ltd, Metabometrix Ltd, London, United Kingdom; [2]Computational Systems Medicine, Imperial College London, London, United Kingdom; [3]Inst of Medical Biometry and Informatics, Univ of Heidelberg, Heidelberg, Germany; [4]Pediatric Nephrology Div, Heidelberg Uiversity Hospital, Heidelberg, Germany.*

Background: Metabolic phenotyping of biofluids and tissues characterises changes in small molecule metabolites due to genetic differences, environmental influences and disease or drug perturbations. NMR spectroscopy and mass spectrometry provide sensitive and reproducible detection of hundreds to thousands of metabolites. SRNS is an etiologically heterogeneous disorder that may be caused by immune-mediated podocyte dysfunction or genetic abnormalities of podocyte specific proteins. Here we investigated whether metabolic phenotyping of urine can be utilized to identify specific molecular signatures of individual SRNS entities.

Methods: We report preliminary findings in spot urine samples obtained from children with genetic (28 NPHS2, 5 WT1 nephropathy), immunosuppressant-sensitive (IS) in disease relapse (n=20) or remission (n=23), or multidrug resistant SRNS (MDR, n=36). Samples were analysed by 600 MHz ^{1}H NMR spectroscopy (detecting predominantly small molecules >1uM) and UPLC-MS (detecting water-soluble molecules > 0.05 nM). Multivariate statistical modelling was used to elucidate class differences and to determine the spectroscopic discriminators.

Results: Whereas no differences between genetic, IS, and MDR groups were detected by NMR, multivariate modelling of the UPLC-MS profiles discriminated genetic from IS-REL SRNS. The metabolite profiles of MDR resembled those observed in genetic SRNS. Notably, both NMR and UPLC-MS identified a signal discriminating NPHS and WT1 nephropathy, which was tentatively assigned as phenylacetyl-glutamine. Further biomarker validation is ongoing, as well as application of additional metabolic profiling technologies.

Conclusions: Urine metabolic profiling may prove useful to classify renal disorders such as different SRNS entities by their specific renal metabolite signatures and lead to the discovery of novel molecular disease biomarkers.

TH-PO1012

Do B Cells Have a Role in Minimal Change Disease?
Atul Poudel, Eduardo H. Garin. *Dept of Pediatrics, Div of Nephrology, Univ of Florida, Gainesville, FL.*

Background: Proteinuria in Minimal Change Disease (MCD) is currently thought to be due to a T-cell mediated circulating factor. Rituximab, which induces B cell depletion, has been recently reported to induce or prolong remission in MCD. The purpose of this study is to see the effect of stimulated B cell on T cell number and function in MCD.

Methods: Seventeen MCD patients (10 remission and 7 relapse) and 10 controls were selected. Peripheral blood mononuclear cells (PBMC) obtained by Ficoll gradient were cultured in RPMI 1640. For each patient, PBMC were stimulated in vitro with antihuman mouse IgM antibody at 10 microgram/ml. At 48 hours, B and T cell proliferation was assessed using flow cytometry. B and T cell count with and without stimulation as well as the fold changes in B and T cell proliferation for relapse, remission patients and control were compared. Supernatant from the PBMC culture were obtained at 24 and 48 hours. IL -10,IL-2, INFγ and TGFβ were measured by ELISA. Statistical analysis was performed using Kruskall Wallis and Wilcoxon paired tests. *P* value <0.05 was considered to be statistically significant.

Results: Analysis of non-stimulated versus stimulated PBMC showed a significant difference in B and T cell count within each group (relapse, remission and control). But when B and T cell count were compared among the 3 groups, there was no significant difference in B and T cell count both on non- stimulated and stimulated PBMC. There were no significant differences in PBMC culture cytokine (IL-10, IL-2, INFγ and TGFβ) production at 24 hrs and 48 hours among MCD patient (relapse and remission) and control.

Conclusions: 1) Non stimulated B cells do not induce T cells proliferation in MCD during relapse. (2) Stimulated B cells induce a significant T cell proliferation both in MCD patients and in controls. (3) In MCD, T-cell proliferation induced by B cell was no different than those seen in the control group. (4) In MCD, T-cell cytokine production by B cell activation was no different than those seen in the control group. These studies do not support role of B cell in MCD.

TH-PO1013

Calcineurin Inhibition Is Not Nephroprotective in Experimental Podocin Nephropathy
Helga Denc,[1] Tanja Wlodkowski,[1] Mansoureh Tabatabaeifar,[1] Ivana Simic,[1] Geraldine Mollet,[2] Corinne Antignac,[2] Franz S. Schaefer.[1] *[1]Pediatric Nephrology Div, Heidelberg Univ Hospital, Germany; [2]Inserm U983, Hopital Necker, France.*

Background: Anecdotal observations have suggested a non-immune mediated antiproteinuric effect of calcineurin inhibitors (CNI) in hereditary nephrotic syndrome, which has been attributed to preservation of synaptopodin abundance and stabilization of podocyte actin cytoskeleton. Mutations in NPHS2 (podocin) constitute the most common cause of hereditary nephrotic syndrome. In order to investigate the antiproteinuric and nephroprotective efficacy of CNI in podocin nephropathy, we administered tacrolimus in knock-in mice carrying the most common human NPHS2 mutation. Analogous to human disease, these mice develop heavy proteinuria, podocyte loss, focal segmental glomerulosclerosis and progressive renal failure.

Methods: In C57BL/6 mice with Nphs2$^{Flox/R140Q}$, Cre^{+} genotype hemizygosity for mutant podocin was induced by tamoxifen injection. Starting at the time of induction, the animals were administered tacrolimus at 0.33 (L) or 0.66 mg/kg/d (H) or vehicle (V) via subcutaneous osmotic mini-pumps. Weight, blood pressure and proteinuria were monitored weekly. Biochemical and histopathological changes were examined after 4 weeks of treatment.

Results: All animals developed massive proteinuria, without a difference between the groups (H, 139%; L, 118% of controls). Hypoalbuminemia at 4 weeks was also not attenuated (H, 23.4 L, 20.4 V, 21.8 g/dl; n.s.) whereas serum urea levels were increased (H, 162, L, 182, V, 92 mg/dl; $p<0.05$) in the tacrolimus-treated animals. Podocyte loss was unchanged (podocytes per glom: H, 75%, L, 82%, V, 62% of healthy animals), and the glomerular sclerosis index was higher in both CNI groups compared to controls (H, 2.2 L, 1.8 V, 1.3; $p<0.001$). Podocin abundance was totally lost in all treatment groups.

Conclusions: In an *in vivo* model of hereditary podocin nephropathy, CNI showed no beneficial effect on proteinuria and podocyte loss but aggravated glomerulosclerosis and renal failure. Our findings argue against a nephroprotective action of CNI in this hereditary podocytopathy.

TH-PO1014

Urinary Angiotensinogen as a Specific Biomarker of Intrarenal Renin-Angiotensin System Status Associated with Glomerular Injury in Pediatric IgA Nephropathy Patients Maki Urushihara,[1] Shuji Kondo,[1] Hiroyuki Kobori,[2] Toshiaki Tamaki,[3] Shoji Kagami.[1] *[1]Dept of Pediatrics, The Univ of Tokushima Graduate School, Tokushima, Japan; [2]Dept of Pharmacology, Faculty of Medicine, Kagawa Univ, Kida, Kagawa, Japan; [3]Dept of Pharmacology, The Univ of Tokushima Graduate School, Tokushima, Japan.*

Background: We recently demonstrated that the renal expression levels of angiotensinogen (AGT) are enhanced and urinary AGT levels are increased in pediatric patients with chronic glomerulonephritis including IgA nephropathy (IgAN). This study was performed to test the hypothesis that urinary AGT level provides a specific index of intrarenal renin-angiotensin system (RAS) status related to the RAS blockades treatment in pediatric IgAN patients.

Methods: Paired renal biopsies were done before and after 2 years of RAS blockades treatment in 24 participants with IgAN in childhood. We performed immunohistochemical analysis of AGT, angiotensin II (Ang II), and TGF-β, that is fibogenic molecule induced by Ang II, and measured plasma and urinary AGT levels and urinary TGF-β levels. Paired test were used to analyze changes from baseline to study end.

Results: Although there was no change in plasma AGT levels ($P=0.1264$), urinary AGT ($P<0.0001$) and TGF-β ($P=0.0158$) levels were significantly decreased after the treatment with RAS blockades, accompanied by the expression levels of AGT ($P<0.0001$), TGF-β ($P<0.0001$), and Ang II ($P<0.0001$), and the scores for mesangial hypercellularity ($P<0.0001$), mesangial matrix ($P=0.0205$) in renal tissues. Baseline urinary AGT levels positively correlated with diastolic blood pressure ($P=0.0126$), urinary protein levels ($P=0.0240$), scores for mesangial hypercellularity ($P=0.0150$), and the renal expression levels of AGT ($P=0.0031$), Ang II ($P=0.0023$), and TGF-β ($P=0.0043$). Multiple regression analysis showed that the expression level of Ang II and urinary protein level can account for urinary AGT level ($R^2=0.7688$, $P<0.0001$).

Conclusions: These data indicate that urinary AGT is a useful biomarker of intrarenal RAS activation and involved with glomerular injury during the course of treatment by RAS blockades in pediatric IgAN patients.

TH-PO1015

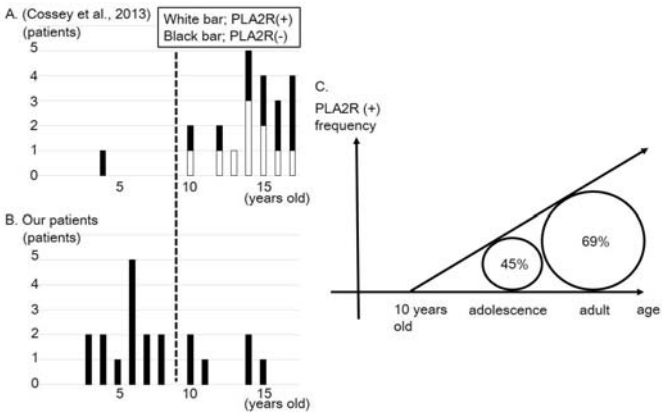
Antiphospholipase A2 Receptor (PLA2R) Expression in Glomeruli in Pediatric Idiopathic Membranous Glomerulopathy (iMN) Patients Shoichiro Kanda, Yuko Akioka, Tomoo Yabuuchi, Yuri Nawashiro, Naoto Kaneko, Norimasa Tada, Ohara Shinichiro, Takayuki Miyai, Noriko Sugawara, Kiyonobu Ishizuka, Motoshi Hattori. *Dept of Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: PLA2R is detected in sub-epithelial deposits along glomerular capillary loops of 69% of adult iMN patients (Hoxha et al., 2012) (Svobodova et al., 2013). On the other hand, this antigen is detected in 45% of pediatric iMN patients, the mean age of which is 14.0±3.0 years old (Cossey et al., 2013). The involvement of PLA2R in younger pediatric patients remains unclear.

Methods: During the time of observations, 20 pediatric iMN patients visited our hospital. We evaluated the expression of PLA2R using rabbit polyclonal anti-PLA2R antibodies (Sigma-Aldrich) at a dilution of 1:50. We also examined other candidate antigens, neutral endopeptidase, manganese superoxide dismutase and bovine serum albumin. We also examined the deposition of IgG subclasses along the glomerular capillary wall.

Results: The mean age, when the disease developed, was 8.0±3.7 years old. Male female ratio was 3:1. IgG1 deposition was occurred in all patients. IgG3 was detected in 13/20 (65%) patients and IgG4 was in 5/20 (25%). We confirmed PLA2R expression along the capillary wall in concurrence with IgG deposition in adult iMN samples. However this staining was not exhibited in all pediatric iMN patients. Other candidate antigens were not detected in all pediatric iMN patients either.

Conclusions: Considering our data and Cossey's data, no PLA2R-positive patient under 10 years old has been reported and the proportion of PLA2R-positive patients increases with age.



The etiology of pediatric iMN is different from that of adult patients and remains to be clarified.

TH-PO1016

The Long-Term Follow-Up of Children Presenting with Atypical Hemolytic Uremic Syndrome in Australia Between 1994 and 2001 Anne M. Durkan,[1] Elizabeth Elliott.[2] *[1]Nephrology, Children's Hospital Westmead, Sydney, NSW, Australia; [2]APSU, Australia.*

Background: There is no data available about the presentation and outcomes of atypical Hemolytic Uremic Syndrome (aHUS) in Australian children prior to the use of eculizumab.

Methods: The Australian Paediatric Surveillance Unit (APSU) prospectively collected data on all children presenting with HUS between Jul 1994 and Dec 2001. The clinicians of children with aHUS identified in this study were then sent questionnaires, at the time of patient transition to the adult services.

Results: In the initial APSU study 146 children were diagnosed with HUS of whom 14 had atypical HUS. Nine children had a diarrhoeal prodrome for a mean of 3 days and 2 children had bloody diarrhoea. Ten children required acute dialysis and two children died in the acute phase of the illness. Nine children received plasma exchange and a further two had infusions of FFP. Of the twelve children surviving to 1 year follow up data was available on 11. Nine children were on maintained on dialysis and 6 had recurrent bouts of aHUS. Long-term data was available on all of these 11 children at a mean of 14.3 years after initial presentation. Three further children had died. Eight children had been transplanted and 5 had developed recurrent aHUS. Five children received plasma exchange beyond the acute phase and 2 of these children reacted to the FFP causing the cessation of treatment in 1. Six primary transplants were lost at a mean of 5.3 years (5 due to aHUS and 1 due to BK virus). Five children have been retransplanted with recurrent disease in 3 and loss of the graft in 2. Only 2 children have maintained normal native renal function. Six children have a family history of aHUS, including 2 siblings in the study. Three children have mutations in complement factor H (CFH) and one had low CFH levels. Six children had no genetic testing or complement investigations.

Conclusions: Atypical HUS is a devastating disease with significant morbidity and mortality. The results presented here are worse than those from registries and this may reflect the prospective nature of the data. The outcomes are also affected by the level of knowledge and treatment options available at the time the children presented.

TH-PO1017

Adequate 25-Hydroxyvitamin D Levels Are Associated with Less Poteinuria and Attenuate Renal Failure Progression in Children with CKD Rukshana Shroff,[1] Helen Aitkenhead,[1] Augustina Jankauskiene,[2] Stefano Picca,[3] Aleksandra Zurowska,[4] Mieczyslaw Litwin,[5] Antonella Trivelli,[6] Ali Anarat,[7] Franz S. Schaefer,[8] Elke Wuehl.[8] *[1]Great Ormond Street Hospital, London, United Kingdom; [2]Vilnius, Lithuania; [3]Rome, Italy; [4]Gdansk, Poland; [5]Warsaw, Poland; [6]Genova, Italy; [7]Adana, Turkey, Turkey; [8]Univ of Heidelberg, Heidelberg, Germany.*

Background: Angiotensin converting enzyme inhibitors [ACEi] for renin-angiotensin-aldosterone system (RAAS) blockade are routinely used to slow CKD progression. Studies have shown that vitamin D may promote renoprotection by suppressing renin transcription, and possible antiproliferative and antifibrotic effects through cross-talk between RAAS and vitamin D-FGF23-klotho pathways. We hypothesise that vitamin D levels influence proteinuria and CKD progression in children with non-proteinuric renal disease.

Methods: This is a post-hoc analysis of the ESCAPE (Effect of Strict Blood Pressure Control and ACE Inhibition on Progression of CKD in Pediatric Patients) cohort. Serum 25-hydroxyvitamin D [25(OH)D], FGF23 and klotho were measured at baseline (before ACEi treatment) and after a median of 8 months on ACEi. Annualized GFR loss and renal survival analysis (composite end-point of loss of GFR>50% or start of renal replacement therapy) were measured.

Results: Of the 167 children (median 11.4 yrs, 96 males), 129 had renal hypodysplasia, 15 glomerulopathies and 23 hereditary or other renal diseases. Median eGFR was 51 ml/min/1.73m^2, median urinary protein/creatinine ratio 0.79 (IQR 0.2-2.1) and none

had nephrotic syndrome. Serum 25(OH)D showed an inverse association with urinary protein/creatinine ratio both at baseline (p=0.01) and follow-up (p=0.01). ACEi treatment significantly increased FGF23 and klotho (p<0.001 for both), without notable changes in calcium or phosphorus. The annualized loss of eGFR was lower in patients with higher baseline 25(OH)D (p=0.0003, r=0.28). 5-year renal survival was 75% in patients with baseline 25(OH)D >50nmol/L compared to 50% in patients with lower 25(OH)D (p<0.0001).

Conclusions: 25(OH)D is inversely associated with proteinuria and loss of eGFR in children with CKD. Prospective studies on the renoprotective effects of vitamin D are required.

The Canadian Childhood Nephrotic Syndrome (CHILDNEPH) Project

Susan M. Samuel,[1] Shannon Scott,[2] Catherine Morgan,[2] Allison Dart,[3] Cherry Mammen,[4] Rulan S. Parekh,[5] Alberto Nettel-Aguirre,[1] Allison A. Eddy,[4] Rachel Flynn,[2] Maury N. Pinsk,[2] Andrew W. Wade,[1] Steven Arora,[6] Geneviève Benoit,[7] Martin M. Bitzan,[8] Robin L. Erickson,[9] Janusz Feber,[10] Guido Filler,[11] Pavel Geier,[10] Silviu Grisaru,[1] James B. Tee,[12] Kyle Kemp,[1] Michael Zappitelli.[8] *[1]U Calgary; [2]U Alberta; [3]U Manitoba; [4]U British Columbia; [5]Hospital for Sick Children; [6]McMaster U; [7]Hopital Sainte-Justine; [8]McGill U; [9]U Saskatchewan; [10]Children's Hospital of Eastern Ontario; [11]London Health Sciences Centre; [12]IWK Health Centre.*

Background: Evidence-based clinical practice guidelines are available for childhood nephrotic syndrome. However, dose and duration of steroid treatment for first presentation and relapses are variable among physicians and care centers. Reasons for variability and how these affect patient outcomes are unknown.

Methods: This mixed methods study will determine center-, physician-, and patient-level factors associated with cumulative steroid exposure and length of steroid treatment. The quantitative component is a national, 13-center prospective observational cohort study of 400 steroid-sensitive children over 2.5 years. Qualitative focus groups with nephrology team members (MDs, RNs, pharmacists) at each site will provide an understanding of the attitudes, beliefs and local factors driving treatment variation. Our analytic approach will integrate quantitative and qualitative results to explain care variability.

Results: To date, 3 centers have consented 27 patients (15M, 12F; median age 3.5 years, IQR 2.0-5.3). Median cumulative steroid dose (mg/m^2) for: first presentation=2,206 (range: 691-4,350); first relapse=998 (range: 348-2,171); second relapse=805 (range: 389–3,273). Median length of treatment (days) for first presentation=112, IQR 72-112. Four sites completed focus groups. Emerging themes explaining treatment variability are physician preferences based on prior training and experience, and the need to individualize therapy for patients.

Conclusions: This is the first national, Canadian population-based evaluation of children with nephrotic syndrome. Early results suggest wide variation in steroid prescriptions for first presentation and relapses. Physician factors play key roles in care variability.

Renal Disease Progression and Complications in Autosomal Recessive Polycystic Kidney Disease (ARPKD): A Report from the Chronic Kidney Disease in Children (CKiD) Study

Katherine M. Dell,[1] Matthew Matheson,[2] Erum A. Hartung,[3] Bradley A. Warady,[4] Susan L. Furth.[3] *[1]Ctr for Pediatric Nephrology, Cleveland Clinic Children's, Case Western Reserve Univ, Cleveland, OH; [2]Dept of Epidemiology, Johns Hopkins Univ, Baltimore, MD; [3]Div of Nephrology, Children's Hospital of Phila, Phila, PA; [4]Div of Pediatric Nephrology, Children's Mercy Hospital, Kansas City, MO.*

Background: ARPKD is an inherited renal cystic disease with a high rate of ESRD, but prospectively collected data are limited. The goal of this study was to define the rates of GFR decline, hypertension (HTN), proteinuria and growth complications in CKiD subjects with ARPKD versus 2 control groups w/other congenital renal diseases.

Methods: We compared ARPKD subjects (n=22) w/controls from 2 groups: aplastic/hypoplastic/dysplastic(n=44) and obstructive uropathies(n=44). Subjects were matched 2:1 w/controls for baseline GFR, age at study entry and at diagnosis. GFR decline, HTN control (#of meds, LVH), proteinuria, height (Ht)%ile and growth hormone (GH) use were analyzed and differences between 2 study groups (ARPKD versus each control group) were examined by Wilcoxon rank sum test. GFR annualized change (ml/min/1.73m^2 and %change) and Ht Z-score were examined and matched differences analyzed with Wilcoxon signed rank tests.

Results: ARPKD subjects and controls were successfully matched on the selected factors. GFR annualized change was not different among the groups (-1.4 versus -1.0 versus -2.7 ml/min/1.73m^2; -6% versus -2% versus -7%). There were no significant differences in HTN or LVH rates, but ARPKD subjects had more ACEI use (82% versus 36% [p=0.0004] versus 27% [p=0.0001]) and a higher % on ≥3 BP meds (32% versus 0% in control groups, p<0.0001). ARPKD subjects had less proteinuria (prot:creat=0.1 versus 0.6 in control groups, p<0.005). There were no significant differences in median Ht%ile (14 versus 20 versus 28), % <3rd%ile (14% versus 19% versus 23%) and GH use (18% versus 9% versus 14%). Matched analyses showed no significant differences in GFR decline or Ht trajectory.

Conclusions: Rates of GFR decline, HTN, LVH and growth complications in ARPKD subjects did not differ from those of other congenital renal diseases. ARPKD subjects had lower rates of proteinuria, which may reflect high rates of ACEI use.

TH-PO1020

Prevalence of Sleep Disorders in Pediatric Nephrology Patients

Neena R. Gupta,[1] Louise Maranda,[2] Rakesh Gupta.[3] *[1]Pediatric Nephrology, UMass Memorial Medical Center, Worcester, MA; [2]Quantitative Health Sciences, UMass Medical School, Worcester, MA; [3]Sleep Medicine, PrimaCare Sleep Center, Somerset, MA.*

Background: Sleep disorders are associated with hypertension, chronic kidney disease, metabolic syndrome and obesity. Our objective was to do a comprehensive study of prevalence of sleep disorders in children visiting Nephrology clinic using validated questionnaires.

Methods: Children attending pediatric nephrology (PN) and general pediatric clinic (GP) completed pediatric sleep questionnaire (PSQ) and pediatric daytime sleepiness scale (PDSS). Sleep related breathing disorder (SRBD) and periodic limb movements in sleep (PLMS) scores of >0.33 (calculated from PSQ) were considered to indicate high probability of these disorders.

Results:

	PN (N=60) Mean ± SD or n(%)	GP (N=94)Mean ± SD or n(%)	p-value
Age (yrs)	14.1 ± 3.5	12. 2 ± 3.4	0.001
Gender M/F (%)	35 (58%)	47 (50%)	0.31
BMI percentile	70.3 ± 27.8	66.4 ± 30.0	0.42
SRBD scale >0.33	13 (22%)	16 (17%)	0.47
PLMS Scale >0.33	22 (37%)	11 (12%)	0.0002
Weekday sleep time (WDST) minutes	531.9 ± 85.3	551.1 ± 82.3	0.33
Insufficient Sleep WDST≤ 8 hrs (%)	21 (35%)	23 (24%)	0.16
PDSS total	11.6 ± 5.1	11.4 ± 6.3	0.80
Excessively Sleepy (≥4 questions on PDSS as ≥3	6 (10%)	17 (18%)	0.17

A linear relationship was seen between SRBD score and SBP (r^2=0.275,β=0.177,p=.001) as well as DBP (r^2=0.265,β=0.194,p=.002) in PN group adjusting for age, gender and BMI SDS but not in GP group. WDST showed significant inverse correlation with SBP (r^2=0.275,β=-0.214,p=.001) and DBP(r^2=0.23,β=-0.01,p=.005) in PN group adjusting for age, gender and BMI SDS.

Conclusions: There was a high prevalence of sleep disorders (probable SRBD, probable PLMS, insufficient sleep and excessive sleepiness) in our patients. The prevalence of probable PLMS was significantly higher in PN group. In adults, CKD is associated with PLMS but CKD was rare in our patients. It is possible that renal disorders without CKD may predispose to PLMS too. SRBD score was directly and WDST was inversely correlated with BP parameters suggesting they may be risk factors for hypertension. These relationships need further exploration in children.

Are Pediatric Oncology Patients Clinically Hydrated prior to Chemotherapy? How Do We Know?

Mark Diachinsky,[1] Shirley Perry,[2] Ryan Fung,[2] David D. Eisenstat,[2,3] Maury N. Pinsk.[2,4] *[1]Pharmacy, Stollery Children's Hospital, Edmonton, AB, Canada; [2]Northern Alberta Children's Cancer Program, Stollery Children's Hospital, Edmonton, AB, Canada; [3]Pediatrics, Univ of Alberta, Edmonton, AB, Canada; [4]Pediatric Nephrology, Stollery Chidlren's Hospital, Edmonton, AB, Canada.*

Background: Chemotherapy-associated renal toxicity is ameliorated with hydration. The Children's Oncology Group (COG) protocols assess hydration by urine specific gravity (SG) before starting chemotherapy. Despite receiving aggressive volume expansion, patients often miss targets for SG, forcing oncologists to make decisions to begin chemotherapy without supporting laboratory evidence of hydration. We sought to assess markers of hydration prior to chemotherapy administration in pediatrics.

Methods: Chart reviews determined the amount of fluid administered prior to chemotherapy, urine output prior to chemotherapy administration, urine specific gravity before and after hydration therapy, admission weight and the next available weight post hydration and admission serum creatinine and the next available creatinine post hydration. Using Pearson correlation coefficients, we estimated a sample size of 47 pre-chemotherapy hydration instances to achieve moderate (r=0.4) correlation with p<0.025.

Results: Eight patients received 120 cycles of pre-chemotherapy hydration between May 2011 and September 2013, of which 93 cycles had sufficient data to analyze. Patient gender (3F:5M), age (16.0 +/- 3.3 years), diagnosis (7 osteosarcoma, 1 Ewing's sarcoma), fluid administered (45.6 +/- 17.5 ml/kg) and urine output during hydration (23.3 +/-14 ml/kg) were noted. Correlation between fluid balance and % body weight change (r=0.07, p=0.25), % change in eGFR (Schwartz) (r=-0.06, p=0.21), and % change in urine SG (r=-0.12, p=0.12) were not statistically significant.

Conclusions: Our study demonstrated that existing markers of hydration are not well correlated and that calculated relationships are weak, supporting the observation that existing measures of pre-chemotherapy hydration are unreliable. Existing protocols recommending the use of SG as a measure of pre-chemotherapy hydration should reflect the diagnostic uncertainty of these bedside assessments.

TH-PO1022

Measuring Health Care Transition Readiness among Mexican Adolescents with Chronic Kidney Disease Guillermo Cantu,[1] Mara Medeiros,[2] Sarah Elizabeth Cohen,[3] Maria E. Ferris.[3] *[1]Medicine and Ehtics, Univ Panamericana, Mexico City, DF, Mexico; [2]Pediatric Nephrology, Hospital Infantil de México Federico Gómez, Mexico City, DF, Mexico; [3]UNC KIdney Center, Univ of North Carolina, Chapel Hill, NC.*

Background: There is a lack of valid health care transition readiness (HCT) scales in Spanish. We determined initial validation of the UNC TRxANSITION Scale™ among Mexican youth with chronic kidney disease (CKD) at the Hospital Infantil de Mexico Federico Gómez.

Methods: We performed translation and back translation of the 10-domain, provider-administered UNC TRxANSITION Scale™. This 33-question scale measures knowledge about diagnosis, treatment, diet, reproductive health, school/work, insurance, and the ability to self-manage or look for new providers (max score of 10). We invited 10-18 year-old patients. Univariate linear regression determined how sensitive the Scale was to increasing age. Dialysis patients were compared to others (excluding transplant patients) and transplant patients were compared to others (excluding dialysis patients).

Results: The 103 participants had a mean age of 14.8 (± 2.23) and 51 were females (49.5%). Of those with known cause of CKD, 38 had glomerular disease and 33 had non-glomerular disease. There were 9 dialysis patients (9%), 21 (20%) transplant patients and 73 (71%) had CKD. The cohort's overall total score ranged from 0.97 to 9.5 with a mean of 5.45 (± 2.10); 5.29 (±2.17) for males and 5.62 (±2.03) - no significant difference by sex-. The univariate linear regression yielded a beta coefficient of 0.197 ($p < .05$). Dialysis patients new more about their diet/food labels than those not on dialysis. ($F=6.913$, $p=.010$). Transplant patients had higher self-management ($F=16.063$, $p=.000$) and knew more about insurance ($F=12.135$, $p=.001$). ESRD patients had the highest level of self-management, while patients with non-glomerular disease had the lowest ($F=4.876$, $p=.003$). Patients with ESRD also had the highest knowledge of insurance, while patients with glomerular disease had the lowest ($F=5.383$, $p=.002$).

Conclusions: The Spanish version of the UNC TRxANSITION Scale™ for youth appears to be a useful tool to measure HCT readiness. Further validation is underway.

Acute Peritoneal Dialysis in Premature Infants Weighing Less Than 1,000 g: A Single-Center Experience Mariko Sawada.[1] *[1]Pediatrics, Kurashiki Central Hospital, Kurashiki, Okayama, Japan; [2]Nephrology, Kurashiki Central Hospital, Kurashiki, Okayama, Japan.*

Background: Acute renal failure (ARF) is a common complication in premature infants. We performed peritoneal dialysis (PD) in neonates with ARF several decades ago, but there are no guidelines for PD in neonates and no appropriate devices, such as catheters, circuits, and peritoneal dialysates. Each center follows its own PD protocols for premature infants. Here we report our single-center experience with PD in premature infants.

Methods: We retrospectively analyzed the medical records of all patients treated with PD at the neonatal intensive care unit of Kurashiki Central Hospital between December 2001 and March 2014 and analyzed the patients' characteristics, cause of ARF, and 1-and 3-month outcomes.

Results: A total of 386 extremely low birth weight infants (ELBWIs) underwent neonatal intensive care during this period. Ten ELBWIs (2.95%; 5 with cardiogenic shock, 5 with septic shock) underwent PD during this period, 7 of whom were boys. The average gestational age was 25.4 ± 2.4 weeks, while the average age and body weight were 22 ± 15 days and 607 ± 147 g, respectively. All of these patients had multiple organ failure. The mean PD duration was 17.3 ± 20.2 days. We used nephrostomy catheters (5 Fr in 7, 6.5 Fr in 3) as PD catheters. The patients underwent 24 cycles of PD each day using bicarbonate of lactate dialysate. All of the patients were treated manually. PD-related peritonitis was noted in 3 patients. The overall 1- and 3-month mortality rates were 40.0% and 60.0%, respectively. After 2010, 3 of 4 patients survived and discontinued PD at the time of discharge.

Conclusions: Our results indicate that the mortality rate has decreased since 2010 and that peritonitis is much more common in premature neonates. PD might become a more effective and safer therapeutic method in neonates with ARF who weigh < 1,000 g if appropriate devices are used.

TH-PO1024

Novel Screening Algorithm for Identification of Renal Magnesium Wasting in Children with Renal Disease Kazuya Matsumura, Midori Awazu. *Dept of Pediatrics, School of Medicine, Keio Univ, Tokyo, Japan.*

Background: Fractional excretion of magnesium (FE_{Mg}) is reported to predict tubulointerstitial fibrosis in adults. No such studies have been performed in children. Also, FE_{Mg} can be affected by serum creatinine concentration (SCr). Therefore, we have developed a screening algorithm to detect Mg wasting using serum Mg (SMg), FE_{Mg}, and urine Mg-to-creatinine ratio (Mg/Cr), and investigated the prevalence of Mg wasting in children with renal disease especially in those with chronic renal insufficiency.

Methods: One hundred and nineteen subjects (59 males and 60 females, aged 2 months-48 years, median 15 years) with renal disease were studied. Estimated GFR (eGFR) was determined by new Schwartz formula (<2 years), quintic equation for Japanese children (2 to 19 years), or formulas for Japanese adults (≥19 years) by age and gender. Renal Mg wasting was defined as 1) FE_{Mg} above 2% if SMg is less than 1.8 mg/dL, and in subjects with normal SMg, 2) FE_{Mg} above 4% if eGFR is normal (≥90 ml/min/1.73 m^2), and 3) Mg/Cr above age-specific reference values if eGFR is reduced.

Results: A total of 43 patients (36%) were categorised as having Mg wasting. Sixteen of all the patients (13%) had hypomagnesemia (1.2-1.7 mg/dL) and all had high FE_{Mg} (9.5 ± 11.7%, mean±SD). In normomagnesemic patients with normal eGFR, 31% (21/67) had high FE_{Mg} (5.8 ± 2.0%). In normomagnesemic patients with low eGFR, 78% (28/36) had high FE_{Mg} but only 17% (6/36) had high Mg/Cr. Among 21 patients with normal SMg and eGFR categorised as having Mg wasting by FE_{Mg}, 14 (67%) had high Mg/Cr. In these subjects, ROC curve analysis (AUC = 0.934) determined that a cut-off point for FE_{Mg} 4.1% yielded 93% sensitivity and 82% specificity for high Mg/Cr. This cut-off value precisely agreed with that used in the present study. Underlying conditions associated with Mg wasting included low eGFR (15/45, 33%), CAKUT (12/34, 35%), hematuria (8/13, 62%), nephrolithiasis (7/12, 58%), Fanconi syndrome (8/11, 73%), ciliopathy (2/5, 40%), and calcineurin inhibitor (2/4, 50%).

Conclusions: We have developed a novel screening algorithm to detect Mg wasting. Mg wasting is not uncommon in children with renal disease including chronic renal insufficiency.

TH-PO1025

Racial Disparities in Children on Renal Replacement Therapy in Western Europe Lidwien Tjaden,[1,2] Marlies Noordzij,[1] Karlijn J. Van Stralen,[1] Franz S. Schaefer,[3] Jaap Willem Groothoff,[2] Kitty J. Jager.[1] *[1]Dept Medical Informatics, Academic Medical Center, Amsterdam, Netherlands; [2]Dept Pediatric Nephrology, Emma Children's Hospital, Amsterdam, Netherlands; [3]Dept Pediatric Nephrology, Univ Children's Hospital, Heidelberg, Germany.*

Background: Racial disparities have been reported in the quality of care among adult patients with end-stage renal disease (ESRD), but little research exists for the paediatric renal replacement therapy (RRT) population. We aimed to assess differences in patient and treatment characteristics between racial groups in children on RRT in Western Europe.

Methods: Using data from the ESPN/ERA-EDTA Registry, we included patients aged <19 years who started RRT in 2006-2011. To avoid confounding by economic factors, analyses were restricted to high-income countries. Racial groups were defined as white, black, Asian and other. Differences between groups were examined by ANOVA and Chi-square tests. We studied access to transplantation using Cox regression analysis whilst adjusting for gender, country of residence and age at the start of RRT.

Results: 769 patients from 6 countries (Belgium, Greece, the Netherlands, Portugal, Slovakia, UK) were included. 77.9% were white, 5.9% black, 8.6% Asian and 7.7% from other racial groups. Black patients were 40% (HR 0.60; 95%CI 0.41-0.89) and Asians 39% less likely (HR 0.61; 95%CI 0.45-0.83) to receive a kidney transplant compared with white patients. This difference could partly be explained by a higher proportion of living kidney transplants in white (34.9%) versus black (17.9%), Asian (21.6%), and other (17.1%) patients ($P<0.01$). In addition, among those who received a kidney transplant from a deceased donor we found longer waiting times in non-white patients (medians 17.4-18.3 months) compared with white patients (14.7 months, $P<0.01$).

Conclusions: This is the first European study examining racial disparities in quality of care in the pediatric RRT population. We found that white pediatric ESRD patients are more likely to receive optimal treatment compared to racial minority groups. Further research is required to identify and address the contribution of medical and sociocultural barriers to optimal treatment among these groups.

TH-PO1026

Medication Adherence in Adolescents with Chronic Kidney Disease or Kidney Transplant: Patient/Caregiver Report versus Provider Perception Cozumel S. Pruette,[1] Tammy M. Brady,[1] Susan R. Mendley,[2] Barbara A. Fivush,[1] Shamir Tuchman,[3] Angela M. Green,[1] Michelle N. Eakin,[1] Kristin Riekert.[1] *[1]Johns Hopkins Univ; [2]Univ of Maryland; [3]Children's National Medical Center.*

Background: Medication adherence in children with chronic kidney disease (CKD) is not well described and adherence in adolescent kidney transplant (KT) recipients is poor, with non-adherence (NA) ranging 5-71%. It is important to identify appropriate measures of adherence to identify patients at risk for NA. The aim of this study is to compare two measures of medication adherence.

Methods: 53 teens from 3 medical centers, age 11-19 with CKD or KT and prescribed antihypertensive medication, and their caregiver completed the Morisky Adherence Scale. Categories of adherence were based on the number of affirmative responses: low adherence= >2, medium adherence= 1 or 2, high adherence= 0. Provider-perceived adherence was determined post-clinic visit, with adherent defined as ≥75% and NA as <75%. Chi-squared analyses and kappa statistics were used to compare teen and caregiver-reported to provider-perceived adherence.

Results: Teen-mean age 14.8yrs; 47% female; 40% Caucasian, 47% Black; 75% CKD, 25% KT. Caregiver-87% female, 29% household income <$50,000/yr. Provider-n=15; 80% female. Providers perceived 72% of patients as adherent while 0%, 34% and 66% of teens reported themselves as high, medium and low adherent and parents also reported 0% high, 36% medium and 64% low adherence. There were no significant differences in teen/caregiver demographics between those perceived by the provider as adherent versus NA. Agreement between provider and teen (41.5% agreement; kappa -0.11±0.06) and provider and caregiver (38% agreement; kappa -0.15±0.06) was poor. Positive predictive value (PPV) of provider-perceived adherence was 42% and negative predictive value (NPV) was 87% when compared to teen-reported adherence, and PPV was 47% and NPV was 93%compared to caregiver report.

Conclusions: Providers overestimate medication adherence for many teens with CKD or KT and their ability to identify NA is worse than that expected to occur by chance alone. Use of a simple adherence measure, like the Morisky Scale, may help identify NA in this population.

TH-PO1027

Nutritional and Metabolic Bone Disease Markers for a Global Sample of Children and Young Adult Hemodialysis Patients Maria E. Ferris,[1] Daniele Marcelli,[2] Xiaoqi Xu,[3] Cristina Marelli,[4] John W. Larkin,[5] Aileen Grassmann,[2] Roberto Pecoits-Filho,[6] Michael Etter,[3] Peter Kotanko,[7] Len A. Usvyat.[5] *[1]Univ of North Carolina, NC; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]Fresenius Asia Pacific, Hong Kong, Hong Kong; [4]Fresenius Latin America, Buenos Aires, Argentina; [5]Fresenius Medical Care, Waltham; [6]PUCPR, Curitiba, Brazil; [7]Renal Research Inst, NY.*

Background: Nutritional and metabolic bone disease need to be characterized in hemodialysis (HD) patients (Pts) of the global Pediatric Investigation and Close Collaboration to examine Ongoing Life Outcomes in the MONitoring Dialysis Outcomes (PICCOLO MONDO) Consortium.

Methods: From 2000-2012, 3244 Pts from 0-30 years of age (13% pediatric, age 0-18; 87% young adults, age 19-30) were grouped into 4 regions: North America (NA), South America (SA), Europe, and Asia. The mean of clinical/laboratory parameters were computed in the first 365 days on HD. Analyses of continuous variables was conducted using multiple linear regression.

Results: Among pediatric Pts (mean age: 14.7±3.3 years) with known ESRD cause, glomerular disease (GD) was most common in Asia and NA, while genitourinary causes were most common in Europe. In young adults, GD was most common cause in Asia and Europe, while "other" was listed most commonly in NA. Using SA as a reference, albumin was highest in Asia in both age groups ($p<0.01$). In pediatric patients, lower albumin was observed in Pts with GD ($p=0.05$). In young adults, diabetics had lower albumin ($p<0.001$), while males had higher albumin ($p<0.001$). Using SA as a reference, in pediatric patients, phosphate levels were higher in NA ($p<0.001$) and male ($p=0.05$). For young adults, phosphate was higher in Europe and NA ($p<0.001$), in males ($p<0.001$) and lower in Pts with ESRD of genitourinary etiology ($p<0.05$). Furthermore, intact-PTH was higher in NA in both pediatric and young adult patients ($p<0.001$) with SA as reference. In young adults with GD and diabetes as cause of ESRD, intact-PTH was lower ($p<0.001$).

Conclusions: In this global cohort, GD was the most common cause of ESRD. Markers of nutrition and metabolic bone disease vary by region and age group warranting further investigation.

TH-PO1028

Clinical Manifestations and Metabolic Evaluation in Korean Children with Urolithiasis Heeyeon Cho, Sang Taek Lee. *Pediatrics, Samsung Medical Center, Seoul, Republic of Korea.*

Background: There is little data for the metabolic etiology and prognosis in pediatric patients with urolithiasis. The aim of this study was to assess the clinical findings, metabolic etiology, and treatment in Korean children with urolithiasis.

Methods: The medical records of 52 children (29 boys, 23 girls) diagnosed as having urolithiasis from January 2012 to December 2013 were retrospectively analyzed. Data of clinical symptoms, urinary tract abnormality, serum biochemistry, urine metabolic evaluation, and treatment were recorded.

Results: The mean age at diagnosis was 10.5 years (range 0.6 – 18 years). The most common presenting symptom was renal colic (40.0%, n=21). The other symptoms included gross hematuria (17.3%, n=9) and renal colic with gross hematuria (9.6%, n=5). Sixty seven percent of the stones were unilateral. Urinary tract abnormality was found in 1 patient with dupex kidneys. Metabolic abnormalities were found in 20 (38.4%) patients, including hypercalciuria in 19.2% (n=10), hyperuricosuria in 7.7% (n=4), hypomagnesuria in 5.8% (n=3), hyperoxaluria in 3.8% (n=2), and cystinuria in 1.9% (n=1). Stone analyses were performed in 13 patients, including calcium oxalate (n=7), carbonate apatite (n=1), calcium apatite (n=4), and cystine stone (n=1). Spontaneous passage of stone occurred in 5.7 % (n=3) of patients.Extracorporeal shock wave lithotripsy and surgical evacuation were performed in 15.3% (n=8) and 1.9% (n=1) of patients, respectively.

Conclusions: The most common metabolic abnormalities in children with urolithiasis were hypercalciuria and hyperuricosuria. There is the need for extensive evaluation to find underlying metabolic disturbances in children presented with renal colic and/or gross hematuria.

TH-PO1029

Risk and Prevention of Hepatitis B Virus and Hepatitis C Virus Infections in Pediatric Hemodialysis Patients Ihab Z. Elhakim,[1] Ahmed Hussein Hassan,[1] Ahmed Hosam el-Din Baranek,[1] Manal H. El-Sayed.[2] *[1]Pediatric Nephrology, Ain Shams Univ, Cairo, Egypt; [2]Pediatric Hematology/Hepatology, Ain Shams Univ, Cairo, Egypt.*

Background: Children on hemodialysis are at a high risk of HBV and/or HCV infection-related chronic liver disease. HBV immunization is protective in healthy children, yet remains unsettled in those on hemodialysis. This study determines the prevalence of HBV and HCV infections, the immune status and response to HBV vaccination among pediatric hemodialysis patients.

Methods: One year prospective study for all children on hemodialysis in a single center (n=50; median age: 14 years; M:F 28:22). All were tested for liver transaminases, iron profile, HBsAg and HBsAb titre by ELISA and HCV using Oraquick HCV rapid antibody test (anti-HCV and HCV-RNA for positive cases). Children with HBsAb titre <100 IU/L were randomly assigned to receive HBV recombinant intramuscular vaccine either at 0, 1 and 2 months (group 1) or 0, 1 and 6 months (group 2) schedule. HBsAb titer was measured one month following the last dose in both groups.

Results: Seven (14%) were HCV positive by Oraquick (6 confirmed anti-HCV and 5 HCV-RNA positive) and 6 (12%) were immune against HBV infection (HBsAb titre >100 IU/L). Both groups had a highly significant increase in post vaccination HBsAb titer (group 1: mean 12.5±5.6 IU/L rising to 909.5±240.6 IU/L and group 2: mean 16.7±16.08 rising to 808.7±334.2 IU/L; $p=0.0000$), with no significant difference between both schedules.

Conclusions: Hemodialysis children have a lower prevalence of HCV than previously reported and not adequately protected against HBV infection. HBV vaccination at 0, 1 and 2 months has a similar seroprotection rate as the 0, 1 and 6 months schedule.

TH-PO1030

Bacteria and Calcium Kidney Stones Andrew L. Schwaderer,[1] David S. Hains,[2] Evan Barr-Beare,[1] Vijay Saxena,[1] Evann E. Hilt,[3] Alan J. Wolfe.[3] *[1]Research, Nationwide Children's, Columbus, OH; [2]Nephrology, LeBonheur Children's, Memphis, TN; [3]Microbiology, Loyola Univ, Chicago, IL.*

Background: The role of bacteria in formation of struvite stones is established. If bacteria also have a role in calcium oxalate stone formation has not been extensively evaluated. We hypothesize that the interaction between bacteria, calcium oxalate crystals and host immune response is an important lithogenesis component.

Methods: Human studies: Following consent, upper tract urine, bladder urine and kidney stone fragments were obtained at the time of surgical stone removal. An enhanced quantitative urine culture protocol that included aerobic, CO_2 and anaerobic atmospheric conditions and sequencing for bacterial DNA were performed on urine and pulverized kidney stones. In vitro studies: Calcium oxalate monohydrate and dihydrate crystals were generated and incubated with FITC-labeled Escherichia coli. Bacterial adherence along with crystal size, number and structure were evaluated. Mouse studies: Kidney stones were induced in C57Bl/6 mice (n=6) and RT^2 PCR bacterial response arrays (Qiagen) to evaluate for altered regulation of 84 key bacterial response genes were performed and compared to control mice (n=6).

Results: Five patients with calcium kidney stones were recruited. We found viable bacteria in 2/5 kidney stones and detected bacterial DNA in all kidney stone samples. Bacteria identified included *E. coli, Gardnerella vaginalis, Pseudomonas* and *Phyllobacterium.* Time-lapse microscopy revealed that *E.coli* preferentially adhered to calcium oxalate monohydrate crystals by 8 hours. By 10 hours, bacteria also became adherent to the dihydrate phase. RT^2 PCR arrays revealed upregulation (> 4-fold, p value < 0.01) of 16 bacterial response genes; none were downregulated. Key upregulated genes included the NLR family, apoptosis inhibitory protein 1, and toll-like receptor 2.

Conclusions: Bacterial DNA is consistently identified in calcium oxalate kidney stones. Calcium oxalate crystals attract *E. coli* and elicit a marked antibacterial response. Murine studies to assess if isolates of bacteria from human kidney stones enhance lithogenesis are ongoing.

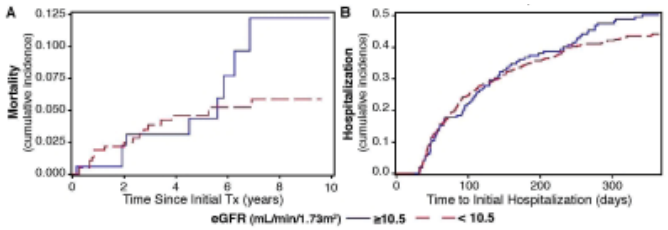
TH-PO1031

The Association of Timing of Dialysis Initiation with Hospitalizations and Mortality in Children Allison Dart,[1,8] Susan M. Samuel,[2,8] Manish M. Sood,[3,8] R. Todd Alexander,[4,8] Steven Arora,[5,8] Robin L. Erickson,[6,8] Braden J. Manns,[2,8] Michael Zappitelli.[7,8] *[1]Pediatrics and Child Health, Univ of Manitoba, Winnipeg, MB, Canada; [2]Univ of Calgary; [3]Univ of Ottawa; [4]Univ of Alberta; [5]McMaster Univ; [6]Univ of Saskatchewan; [7]Univ of Montreal; [8]CANN-NET.*

Background: Evidence guiding timing of dialysis initiation in children is limited. We assessed time to first hospitalization and mortality in children starting dialysis with an eGFR ≥ *versus* < 10.5 ml/min/1.73m^2.

Methods: Incident Canadian dialysis patients <22 yo, between 2001-2010 from 9 Canadian provinces were identified from the Canadian Organ Replacement Registry. Outcomes were time to first hospitalization and mortality *after* dialysis initiation, evaluated in competing risk Cox Proportional Hazards models (with transplant). The primary exposure was early *versus* late dialysis initiation (eGFR ≥ *versus* < 10.5 ml/min/1.73m^2). Models were adjusted for age at dialysis initiation, sex, ethnicity, ESRD etiology, initial modality (peritoneal *versus* hemodialysis), and income quintile. Sensitivity analyses were performed using eGFR thresholds of 6 and 15 ml/min/1.73m^2.

Results: 254/562 (54%) were hospitalized in the first year and 39 (6.7%) children died. There were no statistically significant mortality differences (Hazard Ratio (HR) 1.25; 95% CI 0.55-2.82) (Fig. A) or in first year hospitalizations (HR 0.98; 95% CI 0.77-1.26) between ≥ *versus* < 10.5 groups (Fig. B). Children 0-4 yrs old had a HR of death of 9.28 (95% CI 1.08-79.59) *versus* 5-14 yrs. Caucasians were less likely to be hospitalized (HR 0.78; 95% CI 0.62-0.97). Sensitivity analyses using eGFR thresholds of 6 and 15 ml/min/1.73m2 had similar results.



Conclusions: Early initiation of dialysis was not associated with clinical benefit in this study. A prospective randomized study is required to confirm these results.

TH-PO1032

Impact of Histological Abnormalities on Implant Biopsy in Living Kidney Donors on Allograft Outcomes Silvi Shah,[1] Andres G. Chiesa-Vottero,[2] Saul Nurko,[1] Richard A. Fatica,[1] Brian R. Stephany,[1] Ziad S. Zaky,[1] Emilio D. Poggio.[1] *[1]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; [2]Pathology, Cleveland Clinic, Cleveland, OH.*

Background: Renal transplantation is the best treatment for patients with end stage renal disease. Living kidney donation (LKD) is associated with better outcomes than deceased donation (DD). Donor histological changes found on implant biopsies is independently associated with allograft outcomes in DD. However, these associations are not well studied in LKD.

Methods: Data was retrospectively collected on 234 donor-recipient pairs transplanted between 2005 and 2011. Implant biopsies were routinely obtained in all donated kidneys. Acute tubular necrosis (ATN) in the implant biopsy was reported if at least two of the following histological changes were present: tubular dilation, tubular vacuolization or mitotic figures. Chronic histological changes recorded were arteriosclerosis, glomerulosclerosis, interstitial fibrosis and tubular atrophy (IFTA) and were reported positive if any involved greater than 5% of the biopsy specimen. Recipient estimated GFR (eGFR) was calculated using the CKD-EPI equation. The primary outcome analyzed was allograft function at 12 months post-transplant.

Results: ATN was present in 20.7% of implant biopsies. The prevalences of arteriosclerosis, glomerulosclerosis and IFTA were 30.3%, 16.3% and 9.2% respectively. Implant biopsies with versus without ATN were associated with lower recipient eGFR at 12 months [(56 ml/min/1.73m2 versus 50 ml/min/1.73 m2), P = 0.01]. Implant biopsies with IFTA were also associated with lower recipient eGFR at 12 months [(55 ml/min/1.73m2 versus 44 ml/min/1.73m2), p= 0.003)]. There was no significant association between arteriosclerosis and glomerulosclerosis on implant biopsy and recipient eGFR at 1 year.

Conclusions: ATN and IFTA on LKD implant biopsies predict lower allograft function at 1 year. However their long-term impact is not known and merits further study.

TH-PO1033

Cost Analysis of Incidental Findings during Living Kidney Donor Evaluation Anubha Mutneja,[1] Lauren Saling,[2] Motoyo Yano,[2] Anitha Vijayan.[1] *[1]Renal Div, Washinton Univ in St. louis, St. Louis, MO; [2]Mallinckrodt Inst of Radiology, Washington Univ in St. Louis, St. Louis, MO.*

Background: Living kidney donor (LKD) transplantation is an important alternative for the ESRD population and is preferred due to superior outcomes when compared to dialysis or deceased donor transplantation. LKD evaluation includes a computed tomography angiogram (CTA) for assessment of renal anatomy. Incidental findings noted on CTA often lead to additional testing and procedures. Their economic impact for transplant programs and donors remains uncertain.

Methods: We conducted a retrospective analysis of the incidental findings noted during CTA of 632 LKDs evaluated at our institution from 2008 to 2013. Follow-up evaluation of incidental findings was ascertained after thorough chart review. Cost analysis was performed using Medicare reimbursement data.

Results: There were 525 extra-renal incidental findings in 632 potential living donors. These findings were further categorized based on organ systems.

	Number of incidental findings N (%)	% requiring further testing	Follow-up cost (USD)
Pulmonary	82 (13)	39	14,277
Hepatic	159 (25)	9	7,732
Pancreatic-biliary	38 (6)	23	11,675
Adrenal	19 (3)	21	5,268
Bowel	76 (12)	7	4,087
Gynecological	63 (10)	27	10,435
Miscellaneous	88 (14)	24	9,611
Total	**525 (83)**	**20**	**63,035**

Appropriate clinical follow-up (further diagnostic imaging and lab tests, physician consultations and procedures) were required in 20% at an additional cost of USD 63,035. Additional cost per incidental finding requiring follow-up was USD 407±818. The median cost for follow-up was USD 168 (168-317).

Conclusions: This is the largest study evaluating the economic impact of the incidental findings noted during living kidney donor CT angiograms. Incidental findings during imaging lead to apprehension for the donor and contribute to additional costs. There is significant variability among transplant centers regarding payments for additional testing. Typically if a donor is rejected based on the incidental finding, then the responsibility for further evaluation is dependent on their insurance coverage. Appropriate counseling is warranted prior to evaluation of the living kidney donor.

TH-PO1034

Co-Morbidity Risk Score at Initiation of Renal Replacement Therapy in Living Kidney Donors Who Developed End Stage Renal Disease Amarpali Brar,[1] Rahul Jindal,[2] Moro O. Salifu.[1] *[1]Dept of Medicine, SUNY Downstate Medical Center, Brooklyn, NY; [2]Walter Reed National Military Medical Center, Uniformed Services Univ of Health Sciences, Bethesda, MD.*

Background: Although rare, there are living kidney donors who progress to End Stage Renal Disease (ESRD), but data is limited on co-morbidities at initiation of dialysis in this population.

Methods: We used USRDS (U.S. Renal Database System) retrospectively to identify living kidney donors who progressed to ESRD from 1995-2009. We identified co-morbidities and cause of ESRD in these patients .We also calculated a co-morbidity risk score (CRS) comprising of history of diabetes mellitus, hypertension, ischemic heart disease, cerebrovascular disease and age greater than 55 years, by assigning a value of 1 to each co-morbidity. Data on these variables was obtained from 2728 forms. Analyses were performed using SPSS. Chi square testing for categorical variables and Student's t test for continuous variables.

Results: A total of 70373 transplants were performed in U.S. in the study period .We identified 477 cases using code V59.4 for kidney donor using Medicare claims. Cause of ESRD was listed as diabetes in 104 (21.8%), glomerulonephritis in 154 (32.2%) and polycystic kidney disease in 19 (3.9%) patients. Sixty three percent were male. Race was listed as White in 326, Black in 78 and Asian in 15 patients. Majority were on hemodialysis (73.6%). Mean co-morbidity risk score was 1.138+- 0.91. Mean CRS in Blacks was 1.32+-0.76 versus 1.06+-0.94 in Whites (p=0.33). Mean CRS was significantly higher in diabetics 2.34+-0.76 versus non-diabetic with mean CRS 0.86+- 0.68 (p=0.03).

Conclusions: A small percentage (0.67%) of living kidney donors develop ESRD. We found a high prevalence of de novo diabetes and glomerulonephritis in presumably healthy kidney donors who developed ESRD. These findings may be due to variability in selection criteria of living kidney donors. Prospective studies with uniform selection criteria are needed to assess if long-term follow-up with serial CRS with emphasis on life style modification and early intervention could reduce this risk of ESRD in this population.

TH-PO1035

Malignancy following Live Kidney Donation Hassan N. Ibrahim,[1] Danielle M. Berglund,[2] Robert N. Foley,[3] Arthur J. Matas.[2] *[1]Medicine, Univ of Minnesota, Minneapolis, MN; [2]Surgery, Univ of Minnesota, Minneapolis, MN; [3]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN.*

Background: While living kidney donors are screened for cancer, the risks of cancer development following nephrectomy have not been adequately studied. We therefore sought to determine the incidence of cancer in donors compared to controls.

Methods: In 2003 we began efforts to ascertain the outcomes of all living kidney donors from our institution of which 85% have actively participated with follow-up > 2 years from donation. Information regarding cancer diagnoses was gathered from self-reports, medical records, and death certificates as available. Standardized incidence ratios (SIR) of the various cancer types were compared to the National Cancer Institute Surveillance, Epidemiology, and End Results Program (SEER) database.

Results: In our donor population (n=4188), we found non-skin cancer diagnosis in 371 individuals; prostate (n=65), breast (n=46), lung (n=34), colon (n=22), and kidney cancer (n=9). Compared to the SEER data, donors had a 40% lower incidence of breast cancer (SIR = 0.6, 95% CI 0.6, 0.6), 40% lower incidence of lung cancer (SIR = 0.6, 95% CI 0.6, 0.6), and 50% lower incidence of colon cancer (SIR = 0.5, 95% CI 0.5, 0.6). However we observed a 10% higher incidence for prostate cancer (SIR 1.1, 95% CI 1.1, 1.1) and a 60% higher incidence for cancer in the remnant kidney.

Cancer Type	Incidence per 100,000 years (95% CI)	SIR (95% CI)	*p*-value
Remnant Kidney(n=9)	13.4 (12.5-14.3)	1.6 (1.4-1.6)	<0.05
Lung(n=34)	50.7 (49-52.4)	0.6 (0.6-0.6)	<0.05
Colon(n=22)	32.9 (31.5-34.3)	0.5 (0.5-0.6)	<0.05
Prostate (n=65)	97.4 (95.1-99.8)	1.1 (1.1-1.1)	<0.05
Breast, female (n=46)	68.8 (66.8-70.7)	0.6 (0.6-0.6)	<0.05

Conclusions: Donors studied have a lower incidence of breast, lung, and colon but higher incidence of prostate and kidney cancer. These data need to be continued as a larger cohort as the event rate particularly for renal cell cancer is low.

TH-PO1036

The Long Term Follow-Up of Renal Dynamics following Living Donor Nephrectomy Colin R. Lenihan, Bryan D. Myers, Jane C. Tan. *Divison of Nephrology, Dept of Medicine, Stanford Univ, CA.*

Background: Over five thousand living kidney donor nephrectomies are performed in the U.S. annually. While the physiological changes early post-nephrectomy are well described, less is known about late post-donation glomerular dynamics.

Methods: We enrolled 21 adult living kidney donors to undergo detailed long term clinical, physiological, morphometric and radiological evaluation before, early (median 0.8 years) and late (median 6.3 years) after kidney donation. Blood pressure was measured using Dynamap. Glomerular filtration rate and renal plasma flow were quantified by urinary clearances of iothalamate and para-aminohippuric acid, respectively. Renal cortical volumes were estimated using either CT or MR imaging.

Results: Parallel increases in single-kidney renal plasma flow, renocortical volume and glomerular filtration rate occurred early and were sustained through to late post-donation. Using the equation derived by Deen et al to model whole kidney ultrafiltration coefficient (K_f), assuming a fixed glomerular transcapillary pressure (ΔP) of 40 mmHg, we found that K_f increased early post-donation and remained elevated late post-donation (figure 1). When we modelled whole kidney K_f based on the observed magnitude of renocortical hypertrophy, we found that post-donation GFR was maintained without any increase in ΔP (figure 2).

Figure 1

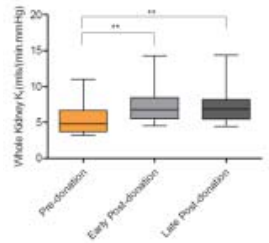

Figure 2

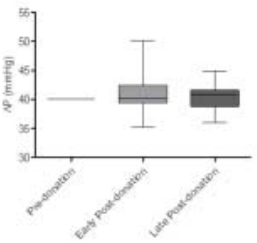

The use of hypertensive medication increased from 14% to 57% late post-donation. No subjects had albuminuria at any time.

Conclusions: We conclude that persistent hyperfiltration post-donation can be attributed exclusively to compensatory renocortical hypertrophy with ensuing glomerulomegaly. The resulting enhancement of glomerular filtration surface area explains K_f elevation which, along with hyperperfusion, accounts for the observed constant level of post-donation hyperfiltration in these donors.

TH-PO1037

Validity of Current Equations to Estimate Glomerular Filtration Rate in Middle Eastern Kidney Donors Post Nephrectomy Osama M. El-Minshawy,[1] Eman Elbassuoni.[2] *[1]Medicine/Nephrology, El-Minia Univ School of Medicine, El-Minia, Egypt; [2]Physiology, El-Minia Univ Schoolf Medicine, El-Minia, Egypt.*

Background: Kidney donation is associated with little bad outcome in living donors, accurate determination of donor kidney function has important long term implications for donor health. **Aim:** is to investigate accuracy of eGFR equations to predict renal function in kidney donors after donation 10±4 month versus measurement of true GFR by diethylene triamine pentaacetic acid (^{99m}Tc- DTPA).

Methods: The study included160 living kidney donors 93 males (58%), GFR was estimated using MDRD, aMDRD, Walser, Nankivell, Cockcroft-Gault, Mayo clinic and CKD-EPI.

Results: All 7 eGFR correlated with ^{99m}Tc- DTPA clearance ($p<0.05$), but their r^2 was low ranging from 0.69 to 0.54. Their respective r^2 values were; MDRD 0.69, CKD-EPI 0.63, aMDRD 0.62, Cockcroft-Gault 0.58, Mayo Clinic 0.55, Walser 0.55, Nankivell 0.54

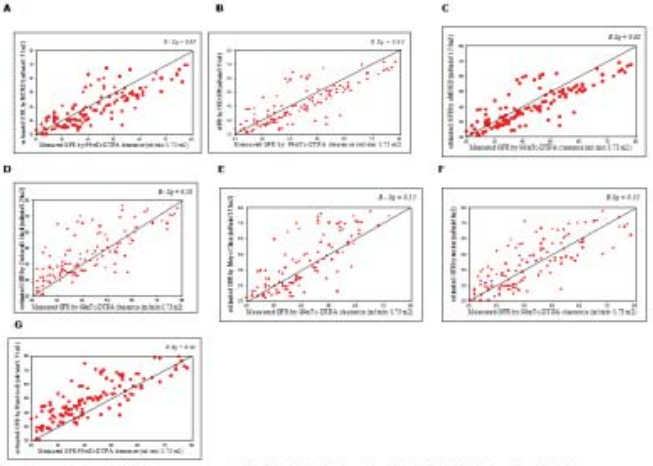

Figure 1: Correlation between measured GFR by ^{99m}Tc- DTPA and estimated GFR by 7 Equations in all Donors

Conclusions: After kidney donation all 7 equations are far from being ideal but eGFR MDRD was superior to other equations in precision and accuracy

Abdominal Aortic Calcification in Older Living Kidney Donors: Effect on Graft Function and Histology David Wojciechowski,[1] Benjamin M. Yeh,[2] Meyeon Park,[1] Antonio C. Westphalen,[2] Zhen Jane Wang,[2] En-Haw Wu.[2] *[1]Medicine/Nephrology, UCSF; [2]Radiology, UCSF.*

Background: Many living kidney transplants are from older donors, who have a greater risk of vascular calcification. We assessed the prevalence of abdominal aortic calcification (AAC) in older donors and the effect of AAC on recipient graft function and histology.

Methods: We identified 292 consecutive living donor-recipient pairs with donor age ≥50 between 2003-2014 (mean age 56; range 50-78; F/M: 1.8). Donor AAC was determined by pre-nephrectomy unenhanced CT. Recipient 12, 24, and 36-month eGFR and spot urine protein: creatinine ratios (UPCR) were recorded and compared with student t-test in allografts from donors with versus without AAC. 180 recipients had 6-month protocol biopsies; presence of interstitial fibrosis (IF), tubular atrophy (TA), vascular intimal thickening (cv), and arteriolar hyaline thickening (ah) was recorded. Fisher's exact test was used to compare the percentage of allografts with any abnormal pathology from donors with versus without AAC. Multivariable regression analysis was used to assess the independent predictors (donor AAC, age, gender, recipient age, gender, and tacrolimus level at biopsy) of the 4 categories of abnormal pathology.

Results: AAC was present in 40.7% (119/292) of donors. Donors with AAC were older ($p<0.0001$) and more likely to be male ($p=0.004$). There was no significant difference in eGFR or spot UPCR in recipients of allografts from donors with versus without AAC up to 36-months. On protocol biopsy, there was a higher % of allografts with vc and ah from donors with versus without AAC ($p<0.0001$ for both). Multivariable regression found that presence of donor AAC independently predicts presence of vc (OR:6.3; CI:2.4-16.2) and ah (OR:8.6; CI:2.8-26.1) in allografts at 6 months. Tacrolimus level was not an independent predictor of ah. Donor age independently predicts allograft IF (OR: 1.1; CI: 1.02-1.18) and TA (OR: 1.1; CI: 1.05-1.22).

Conclusions: AAC was common and independently predicts cv and ah in allografts from older donors. The presence of donor AAC may improve prediction of graft histology and may identify recipients who would benefit from a less nephrotoxic immunosuppression regimen.

TH-PO1039

Risk Factors of Impaired Renal Adaptation following Nephrectomy in Kidney Donors Hee Jin Kwon,[1] Do Hee Kim,[1] Kyungho Lee,[1] Seung Yeon Son,[2] Hye Ryoun Jang,[2] Jung Eun Lee,[2] Wooseong Huh,[2] Yoon-Goo Kim,[2] Dae Joong Kim,[2] Ha Young Oh.[2] *[1]Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine; [2]Nephrology Div, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea.*

Background: Compensatory hyperfiltration that occurs in the remaining nephrons following donor nephrectomy was reported as a main mechanism of maintaining adequate renal function in kidney donor. Although postoperative renal function recovers smoothly by early renal adaptation in many donors, some donors show impaired recovery of renal function. The aim of this study was to identify factors predicting the degree of renal adaptation after donor nephrectomy and to identify donors with a high risk of developing chronic kidney disease (CKD).

Methods: A total of 265 living kidney donors receiving donor nephrectomy from January 2010 to October 2013 were retrospectively analyzed. Serum creatinine was serially followed up pre- and post-operative periods (1st, 2nd-3rd, and 4-14th postoperative day, 1st and 3rd-6th postoperative month). Renal function recovery was defined as the percentage of postoperative MDRD-based eGFR versus preoperative eGFR (%MDRD). Post-donation CKD was defined as eGFR measured at 3rd-6th months < 60 ml/min/1.73m^2.

Results: The mean age (M:F= 133:132) was 41.1±9.9 years. During follow-up, 148 donors (55.8%) developed CKD. Donor age (p=0.0115), BMI (p=0.0295), preoperative MDRD-eGFR (p<0.001), and change in eGFR at postoperative day (POD) 1 (p=0.0447) and 1 month after surgery (p=0.0003) compared to baseline were identified as independent predictors of developing CKD. Impaired renal recovery (defined as %MDRD < 66%) positively correlated with age (p=0.0001) and changes in eGFR from baseline to POD 2-3 (p=0.0024) and to 1 month after surgery (p=0.0001). Early renal adaptation (eGFR decline in immediate postoperative period within one month) determined renal function in postoperative 3rd-6th months. Old age, male, and lower residual kidney volume of CT angiography were associated with poor early renal adaptation.

Conclusions: The degree of early renal adaptation may help identify donors at high risk for poor recovery of renal function and development of postoperative CKD.

TH-PO1040

Impact of Obesity on Short-Term Outcomes After Kidney Donation Harini A. Chakkera,[1] Yu-Hui Chang,[1] William Knowler,[2] Hatem Amer,[3] Lilach O. Lerman,[3] Aleksandar Denic,[3] Andrew D. Rule.[3] *[1]Mayo Clinic Arizona; [2]NIDDK, Phoenix; [3]Mayo Clinic Rochester.*

Background: Coexistence of donor obesity and reduced number of functioning nephrons after nephrectomy is a risk for kidney disease. The body mass index (BMI) threshold to exclude an otherwise healthy potential donor is not uniform across transplant centers.

Methods: Cohort study of 1073 living kidney donors between 1999 -2008 at the Mayo Clinic in Rochester, MN. **Aims: 1.** Examine association of glomerular volume (estimated from the biopsy at time of donation) and measures of obesity. Cohort included a subgroup of 20 donors with the largest glomerular volume similar in age and gender to the 20 donors with the smallest glomerular volume –mean age 44 years and 70% female in both groups. Measures of obesity included BMI and pre-donation abdominal CT scan parameters (waist circumference, subcutaneous fat, visceral fat and peri-renal fat). **2**. Among 1073 donors, examine the association of strongest associative measure of obesity identified in Aim 1 and short-term kidney function in donor including GFR (iothalamate clearance), 24-hr urine albumin, and systolic BP in the 1st year after donation.

Results: BMI was most strongly associated with higher glomerular volume compared to all other measures of abdominal obesity: OR=5.03 (per 5 kg/m^2 difference), p=0.002. Thus, we assessed the association of BMI at donation with short-term outcomes in kidney function among 1073 donors (mean follow up 6.8 months), but found no significant association (Table).

BMI	Uncorrected Iothalamate clearance (% change, p value)	Systolic BP (% change, p value)	24 hour urine albumin >20 mg (OR, p value)
< 25 kg/m^2	Referent	Referent	Referent
25-30 kg/m^2	-4.1%, 0.25*	2.3%, 0.06*	1.53, 0.35*
30-35 kg/m^2	-4.5%, 0.26*	-0.05%,0.97*	1.31, 0.61*
≥ 35 kg/m^2	-4.1%, 0.45*	-0.06, 0.97 *	1.95, 0.29*

Models: age and gender adjusted * versus <25 kg/m^2.

Conclusions: Donor BMI is the obesity measure that most strongly associates with underlying glomerulomegaly, but does not clearly affect kidney function in the first year after donation. Long-term follow up is required to ascertain effect of BMI at donation on the renal function.

TH-PO1041

Impact of Donor Renal Reserve on 1-Year Post-Transplant Kidney Graft Function Maria Cora Giordani, Carlos Schreck, Silvia Rosana Groppa, Cesar Andrés Mombelli, Carlos Guido Musso, Nora Cristina Imperiali, Guillermo Javier Rosa Diez. *Nephrology, Hospital Italiano de Buenos Aires, Ciudad Autonoma de Buenos Aires, Argentina.*

Background: Renal reserve is defined as a 20% or larger increase in GFR (glomerular filtration rate) after an acute protein load. Presumably, a higher renal reserve would correlate with a higher capacity to adapt to a diminished nephron mass in kidney transplant receptors. We analyzed the renal reserve in living donors as a predictor of 1 year post-transplant kidney graft function.

Methods: Renal Reserve (> 30% versus < 30%) of living donors (2008-2011) was retrospectively correlated with 1-year post-transplant receptor Scr (serum creatinine). Other variables were used for univariate and multivariate analysis. From donors: age, hypertension, BMI (body mass index) and gender. Receptor variables included: age, gender, BMI, rejection, immunosuppression, missmatch number and DGF (delayed graft function). Statistics: T-test was used for continuous data with normal distribution. Wilcoxon analysis was used for those without normal distribution. Chi^2 test was used for categorical variables. Multivariate regression analysis was done using STATA software. p<0,05 was considered significant.

Results: n= 59 donor-receptor pairs. Data are expressed as mean ± SD. Univariate analysis

	SCr (mg/dl)	SCr (mg/dl)	p
Renal Reserve (>30% vs < 30%)	1.25 +/- 0.52	1.62 +/-0.76	0.02
Donor age (<50 vs > 50 years old)	1.05 +/- 0.37	1.65 +/- 0.66	<0.001
Receptor gender (female vs. male)	1.03+/- 0.17	1.39 +/- 0.23	<0.001
Receptor age (<33 vs >33 years old)	1.22 +/- 0.6	1.5 +/- 0.6	0.04
Rejection (no vs. yes)	1.14 +/- 0.5	1.8 +/- 0.54	<0.001
Receptor BMI (>24 vs < 24)	1.14 +/- 0.42	1.53 +/- 0.7	0.006
DGF (no vs yes)	1.3 +/- 1.1	2.29 +/- 0.87	<0.001

Multivariate analysis (odds ratio-p) for donor age (> 50 years old), receptor gender and rejection were: 8.99-0.042, 19.8-0.02 and 11.9-0.019.

Conclusions: Donor Renal Reserve >30 % correlates with a significantly lower 1 year-post transplant receptor Scr when analyzed separately (univariate analysis). In multivariate analysis, however, renal reserve does not affect 1 year-post transplant receptor Scr.

TH-PO1042

The Biomarker of Deceased Donor for the Prediction of Renal Graft Outcomes Tai Yeon Koo,[1] Jong Cheol Jeong,[1] Hee Jung Jeon,[1] Hyuk Yong Kwon,[2] Sik Lee,[3] Sung-Joo Kim,[6] Seok Ju Park,[4] Kook-Hwan Oh,[5] Curie Ahn,[1,5] Jaeseok Yang.[1] *[1]Transplantation Center, Seoul National Hospital, Seoul, Republic of Korea; [2]Dept of Internal Medicine, BHS-Han Seo Hospital, Busan, Republic of Korea; [3]Dept of Internal Medicine, Chonbuk National Univ Hospital, Jeonju, Republic of Korea; [4]Dept of Internal Medicine, Inje Univ Busan Paik Hospital, Busan, Republic of Korea; [5]Dept of Internal Medicine, Seoul National Univ, Seoul, Republic of Korea; [6]Dept of Surgery, Samsung Medical Center, Seoul, Republic of Korea.*

Background: Acute kidney injury(AKI) negatively impacts on renal allograft outcomes after kidney transplantation(KT). Neutrophil gelatinase-associated lipocalin(NGAL), kidney injury molecule-1(KIM-1), clusterin, and liver-type fatty acid binding protein(L-FABP) are biomarkers known to be associated with AKI. We performed a prospective, multicenter study to evaluate the predictive values of these biomarkers from deceased donor (DD) for renal allograft outcomes including graft recovery and acute rejection(AR).

Methods: We included 59 DDs and their 59 recipients from 4 transplantation centers in Korea (Seoul National University Hospital, Chonbuk National University Hospital, Samsung Medical Center and Inje University Busan Paik Hospital). The biomarkers were detected using donor urine samples before the operations. Graft recovery was classified into immediate graft function, slow graft function(SGF) and delayed graft function(DGF).

Results: The mean age of DDs and recipients were 43±16 and 45±13 years. The incidence of AR and graft loss were 18(31)% and 3(5%), respectively. SGF and DGF were observed in 20 and 14% of recipients. The median levels of NGAL, KIM-1, clusterin, and L-FABP were 6484μg/mgCr, 0.13ng/mgCr, 1.45ng/mgCr and 328ng/mg, respectively. KIM-1(p=0.006) and L-FABP(p=0.008) were significantly higher in patients with AR than those in patients without AR. Receiver operating characteristic curve analysis showed that KIM-1(area under the curve (AUC) 0.74) and L-FABP(AUC 0.73) predicted AR. However, no biomarkers predicted DGF or graft failure.

Conclusions: Biomarkers of AKI such as KIM-1 and L-FABP obtained from donor urine samples can predict adverse renal allograft outcomes after KT.

TH-PO1043

Knowledge, Attitudes, and Counseling Practices for CDC High Infectious Risk Donor Organ Offers: A National Survey of Nephrologists Lauren Marie Kucirka, Mary G. Bowring, Natasha Gupta, Eric Chow, Michael J. Choi, Bernard G. Jaar, Tariq Shafi, Dorry L. Segev. *JHU.*

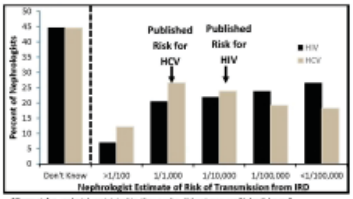
Background: Kidneys from donors classified by the CDC as increased infectious risk (IRDs) comprise >13% of transplants, yet have 1.5-fold higher odds of discard. In considering organ offers, studies show that patients most highly value the opinions of their nephrologists. The goals of this study were to 1) describe nephrologists' knowledge and attitudes towards IRDs, and 2) examine how knowledge influences counseling practices.

Methods: We surveyed 519 nephrologists caring for ESRD patients in Dec 2013. Modified Poisson regression was used to examine associations between nephrologist characteristics, IRD knowledge, and routinely recommending IRD decline (defined as recommending acceptance < 10% of the time).

Results: Of nephrologists who discuss organ offers with their patients, 62% had been asked about an IRD. However, 35.4% reported they are minimally/not familiar with IRDs, and 39% that they are not prepared to counsel a patient regarding an IRD offer. When asked what they would tell a patient about the risk of HIV and HCV transmission from an IRD, >40% answered "I don't know"; among those who said they knew, perceived risk estimates ranged from >1/100 (much higher than published risks) to <1/100,000 (much lower, Figure 1). Likelihood of recommending decline and being uncomfortable giving a recommendation increased with increasing patient age and dialysis vintage(Figure 2). Among those who reported being asked about IRDs, there was wide variation in counseling practices (25.7% never recommend IRD acceptance; 29.5% recommend >80% of the time.) Reporting minimal/no preparation for IRD patient counseling was associated with 1.78 times the rate of routinely recommending IRD decline in adjusted analysis (Table 1).

Conclusions: IRD education for nephrologists is critical to facilitate shared decision making.

Figure 1: Responses to Survey Question, "What would you tell a patient who asked about the probability of contracting HIV and HCV from a kidney donor classified as "IRD/CDC High Risk" who tested negative for HIV by ELISA?



*Percent for each risk restricted to those who did not answer "I don't know"

Figure 2: Responses to Survey Question: "For each hypothetical patient, please indicate whether you would recommend acceptance or decline of a CDC High Risk Donor Kidney"

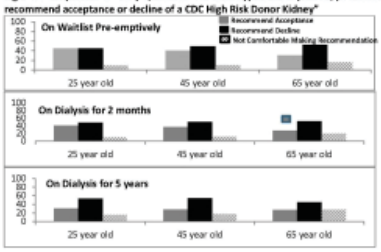


Table 1: Characteristics Associated with Routinely Recommending Decline Among Patients Receiving Kidney Offers from Infectious Risk Donors in a Multivariate Model

Characteristic	IRR (95% CI)	p-value
Gender		
Male	Referent	
Female	1.12 (0.76-1.65)	0.6
Years practicing since fellowship	1.01 (1.00-1.03)	0.1
Currently completing/have completed Transplant Nephrology Fellowship	0.52 (0.29-0.92)	0.03
Affiliated with University Hospital Performing Transplants	0.87 (0.61-1.25)	0.4
Not at all or minimally prepared to counsel a patient on acceptance or decline of an IRD-KT offer	1.78 (1.23-2.57)	0.002

TH-PO1044

"Expanding the Donor Pool": Successful Use of Cancer Survivors as Kidney Donors Alekhya Potluri,[1] Gregory Malat, PharmD,[1] Oleg Grapp,[1] Sharon M. West,[2] Karthik M. Ranganna,[1] Alden Michael Doyle.[1] *[1]Transplant Nephrology, Drexel Univ College of Medicine, Philadelphia, PA; [2]Gift of Life Donor Program, Philadelphia, PA.*

Background: There is a burgeoning disparity between supply and demand for transplantable kidneys, with over 100,000 patients on the waitlist this year. One way to address this shortage is to broaden the acceptance criteria for suitable donors. Herein, we report a long term follow up of a large series of patients transplanted with kidneys from donors that were felt to be marginal based on a history of documented treated cancer.

Methods: We retrospectively examined 125 kidney transplant recipients from our local Region 2 Organ Procurement Organization, who received an allograft from 72 different deceased donors who had been previously treated for cancer. We used descriptive data analysis to compute our results.

Results: Donors were 68% female, with median age of 56.5 years. Donors had a variety of cancers including breast, prostate, cervical, uterine, lymphoma, melanoma, bladder and thyroid. All donors were felt to be cancer-free at the time of their death. Median kidney donor risk index was 1.35. Median for number of turndowns by patients for cancer donor kidneys offered was 122.5. Of the 144 kidneys from 72 donors, only 125 have been transplanted. Recipients were 55% males with median age of 62 years. Unadjusted median patient and graft survival post-transplant were 47.29 and 42.37 months respectively. 36.6% had delayed graft function, 6.6% patients experienced rejection leading to allograft loss. 7.5% had pre transplant and 6.7% had post-transplant malignancies, all of which were unrelated to donor pathology. Of these, 3 patients died of complications of this malignancy. 24.2% patients have since died due to other causes.

Conclusions: We believe that these data represent successful transplantation with donors that would commonly be turned down based on their history of malignancy. Although not definitive, this experience adds to what has been previously reported and suggests that there may be an opportunity to further broaden our current acceptance criteria to best utilize the scarce resource of suitable transplant organs.

TH-PO1045

Kidney Donor Profile Index: The Older You Are, the Harder It Gets Ankit P. Shah,[1] Amay Parikh,[1] Michelle Gagnon,[2] Sheenu Chandwani.[2] *[1]Dept of Medicine / Div of Nephrology, Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Public Health, Rutgers-School of Public Health, New Brunswick, NJ.*

Background: The Kidney Donor Profile Index (KDPI) as part of the new Organ Procurement and Transplantation Network allocation scheme raises concerns given its unproven advantages. This study examines the association between KDPI, mortality and graft failure, and explores its potential negative impact for older recipients.

Methods: United Network for Organ Sharing data on adult transplants from January 2004 to December 2009 receiving deceased donor kidneys were analyzed. KDPI was calculated where a lower percentage predicts better graft survival. Estimated Post-Transplant Survival (EPTS) was calculated where a lower percentage predicts better recipient survival. Associations of ≤20 versus >20% KDPI (BTRK versus WRSK) and <50 versus ≥50 years of age (YNGR versus OLDR) with patient mortality and graft failure were examined using Cox proportional hazards models.

Results: A total of 51,434 recipients were included (WRSK 79.3%). Among OLDR patients, the unadjusted hazard ratio (HR) for mortality for WRSK versus BTRK was 1.5 ($p<0.001$). Compared to BTRK/YNGR, HRs were BTRK/OLDR 1.5 (1.3, 1.8), WRSK/YNGR 1.2 (1.02, 1.41), and WRSK/OLDR 1.9 (1.6, 2.3) for mortality ($p<0.05$) after adjusting for race, gender, expanded criteria donor status, EPTS, and treatment for rejection within 1 year post transplant. There was no significant interaction by age. Graft survival was significantly higher for BTRK irrespective of age (p=NS); however WRSK/YNGR had better graft survival than all OLDR ($p<0.05$). Applying the new allocation scheme, an additional 9,176 YNGR candidates would be eligible for BTRK kidneys, and an additional 3,372 OLDR candidates would be eligible for WRSK kidneys.

Conclusions: Allocating better functioning kidneys to the younger may limit transplants for older recipients. This new scheme widens the gap of potential recipients favoring either YNGR/BTRK or OLDR/WRSK pairings. Older patients are more likely to experience poor outcomes despite KDPI levels. Under the new scheme, transplant centers cognizant of outcome measures will be less likely to transplant this population.

TH-PO1046

The Impact of Zero Time Biopsy on Graft Outcomes after Deceased Donor Kidney Transplantation Ana C. Matos,[1] Niels O.S. Camara,[1,2] Lucio Roberto Requiao-Moura,[1] Marcelino Souza Durao,[1,3] Alvaro Pacheco-Silva.[1,3] *[1]Renal Transplantation Unit, Hospital Israelita Albert Einstein, Sao Paulo, Brazil; [2]Immunology, Univ of São Paulo, Sao Paulo, Brazil; [3]Renal Transplant Unit, Univ Federal de Sao Paulo, Sao Paulo, Brazil.*

Background: Zero-time biopsy (T0-Bx) provides important information about the organ quality; however its role as acute or chronic renal function predictor is not established.

Methods: We analyzed data from 136 T0-Bx in deceased transplant patients realized from 11/2008 to 5/2012. Patients had a follow up of at least 6 months. We analyzed presence of ATN, arteriolar hyalinosis (AH), intimal thickness (IT), interstitial fibrosis (IF) and glomerulosclerosis (GS). We also analyzed the impact of donor features with the following outcomes: delayed graft function (DGF), renal function measured by CrCl at hospital discharge, 6 and 12 months and chronic allograft dysfunction (CAD) defined as CrCl < 60ml/min.

Results: We studied 136 patients with a mean follow up of 805 days. The age of donors were 41 yr, 26% were extended criteria donors (ECD), 33% had hypertension and 50% had cerebral vascular accident (CVA) as the cause of death. ATN was present in 87% of these bxs, AH in 31%, IF in 21% and GS >10% in 7%. DGF occurred in 80% and CAD in 53% of our patients. No histological finding at zero-time biopsies was associated with DGF. CrCl at discharge and at 6 mo had no association with histological findings. Patients with AH had a lower CrCl at 12mo, compared to patients without it (49.8 ml/min x 64.5 ml/min, p=0.02). In a multivariate analysis, variables associated with CAD at one year were acute rejection OR:8,9 IC 95%: 2,2-35,9, p=0,002, HA OR: 3,9 IC 95%: 1,4-10,7, p=0,007, male gender OR:3,2 IC 95%: 1,2-8,2, p=0,018 and donor hypertension OR:2,9 IC 95%: 1,1-7,8, p=0,031. In multivariate analysis, risk factors for AH were donor age > 50 yr OR:2,4 IC 95%:1,1-5,4, p=0,03 and CVA as the cause of death OR:2,3 IC 95%: 1,0-5,1 p=0,04.

Conclusions: Vascular abnormalities were associated with a one year poorer renal function. T0-Bx can be useful to manage immunosuppression in order to improve long term graft function.

TH-PO1047

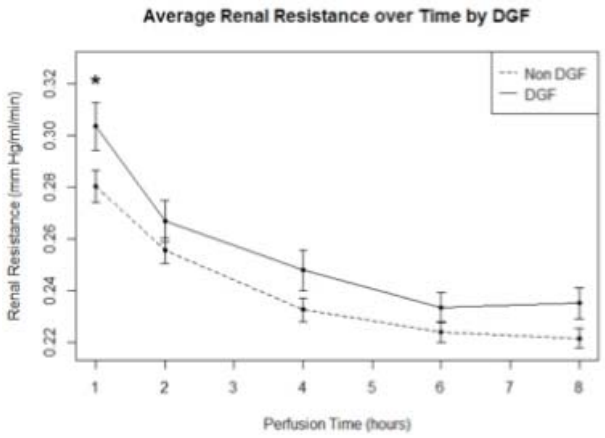
Association of Perfusion Parameters with Kidney Allograft Function after Deceased-Donor Kidney Transplantation Ronik S. Bhangoo,[1] Peter P. Reese,[2] Isaac E. Hall,[3] Mona D. Doshi,[4] Francis L. Weng,[5] Bernd Schroppel,[6] Chirag R. Parikh.[3] *[1]Univ of Arizona College of Medicine, Phoenix, AZ; [2]Univ of Pennsylvania, Philadelphia, PA; [3]Yale Univ, New Haven, CT; [4]Wayne State Univ, Detroit, MI; [5]Barnabas Health, Livingston, NJ; [6]Univ Hospital, Ulm, Germany.*

Background: Marginal quality kidneys are often placed on a pump to improve graft outcomes. We conducted a prospective multi-center observational study to determine the relationship between machine perfusion parameters and allograft outcomes after deceased-donor kidney transplantation.

Methods: Deceased donors were enrolled at four organ procurement organizations. Pump parameters (renal resistance and perfusate flow) were recorded at five time-points (1^{st}, 2^{nd}, 4^{th}, 6^{th}, and 8^{th} hour) or until the kidney was prepared for transplantation. Univariate and multivariate analyses (adjusted for the Kidney Donor Risk Index) were performed to determine the effect of perfusion parameters on delayed graft function (DGF, defined as dialysis in the first week) and one year graft failure.

Results: 748 kidneys from 405 donors were analyzed. 34% of kidneys met criteria for DGF (n=258) and 5% for one year graft failure (n=39). Renal resistance at one hour was significantly higher in the DGF group (0.28 versus 0.26 mmHg/ml/min, p=0.033) and decreased over time for both DGF and non-DGF recipients (Figure 1). Perfusate flow at one hour was significantly lower in the DGF group (100 versus 105 ml/min, p=0.016). In multivariable analysis, renal resistance at one hour demonstrated an independent association with DGF (relative risk 1.89 [1.01-3.55]). At no time point was renal resistance or perfusate flow significantly associated with one year graft failure.

Conclusions: Renal resistance at one hour is an independent risk factor for DGF in deceased-donor kidney transplantation, but is not associated with graft failure at one year.



Funding: NIDDK Support

TH-PO1048

Machine Perfusion following Static Cold Storage in Kidney Transplantation Decreases the Duration of Delayed Graft Function and Time to Hospital Discharge Alvaro Pacheco-Silva,[1,2] Marcelino Souza Durao,[2] Lucio Roberto Requiao-Moura,[2] Ana C. Matos.[2] *[1]Laboratory of Clinical and Experimental Immunology, /Nephrology, Escola Paulista de Medicina- UNIFESP, Sao Paulo, Brazil; [2]Transplantation, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.*

Background: In Brazil the incidence of DGF is very high (60-70%) mainly due to an inadequate care of the donors and long cold ischemia time. This high incidence of DGF is associated to a longer hospitalization and poorer long term graft survival.

Methods: The objective of this work is to analyze the incidence of DGF, its duration and the time of hospitalization after transplantation in patients who received a kidney preserved in the machine perfusion (MP Group) after a long time of cold storage.

Results: We report the data from forty kidneys from DD preserved in the MP transplanted from 2/2013 to 12/2013 and compare their evolution to 136 kidney transplants preserved by Cold storage (Control Group), realized from 11/2008 to 5/2012 at our hospital. Results: The mean total ischemia time was 32,8±6,5 (22,7±5,1 CS plus 10±2,1 MP) for MP and 22,7±4,8 for Control Group (P<0,0001). Donor age (46,5 x43 Y), Creatinine (1,35 X 1,30) and death by stroke (57,1% X 50%) were not significantly different between MP and Control group patients. DGF incidence was 62,5% for MP compared to 76% in the control group (P= 0,14). However, DGF duration (days on dialysis) was 3,8 in the MP compared to 10 days in the control group (p=0,021). The hospital discharge was 13,8 days after transplantation for the MP and 19 days for the control group ((p=0,011) and the mean creatinine at discharge was 2,14 for MP and 2,6 for the control group.

Conclusions: In conclusion, in a group of patients with a high incidence of DGF the use *of MP after cold storage did not decrease DGF but contributed to a faster recovery of renal function and to a shorter time of hospitalization.*

Funding: Government Support - Non-U.S.

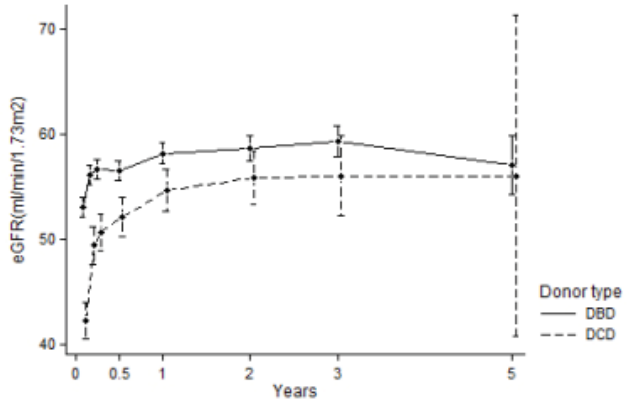
TH-PO1049

Outcomes af Donation after Cardiac Death Kidney Recipients in Australia Vinoi George David,[1] Kristine De Jesus,[2] Philip A. Clayton,[3] Richard Allen,[4] Stephen P. McDonald.[1,3] *[1]Renal Unit, Royal Adelaide Hospital, North Terrace, Adelaide, SA, Australia; [2]Univ of Sydney, Sydney, NSW, Australia; [3]ANZDATA Registry, Adelaide, SA, Australia; [4]Renal Unit, Royal Prince Alfred Hospital, Sydney, NSW, Australia.*

Background: A growing discrepancy between demand for organs and their availability from donors after brain deaths(DBDs) has led to an increase in the use of donors after circulatory death(DCDs) in Australia.We examined trends in use and outcomes of DCD kidney transplants.

Methods: Retrospective review of the ANZDATA registry cohort over 2007-12. Descriptive statics,linear models and Cox regression were used for the analysis.

Results: Of 2976 transplants over 2007-12, 542(18%)of were DCDs when compared to less than 2% of DCDs in the preceding 5 years. Compared to DBDs,DCDs were predominantly male(70 versus 55%, p<0.01),fewer diabetic donors (4.6%) and higher rates of cerebral hypoxia as cause of death.Donor creatinine at admission was similar to DBD,but terminal creatinine was significantly lower (median 74 versus 69 umol/l,ranksum p<0.05).Recipients of the DCDs had a longer waiting period (median 3.6 versus 3.1 years from first dialysis, p<0.01) for transplant, similar HLA and total ischemic time but had significant higher rates of delayed graft function (dialysis post transplant 53 versus 20%, p<0.01).Compared to DBD kidneys, mean eGFR of DCD recipients kidneys at 1,2,3,6,12 months(p<0.01) was significantly lower.The difference waned by 2 years (p=0.06).



There was no difference in rejection(21 versus 20%),patient and graft survival.In multivariate analysis,DCD remained a predictor for lower eGFR.Survival analyses of graft failure did not show a significant difference,p=0.22.

Conclusions: DCD kidneys were associated with higher rates of delayed graft function and lower eGFR in the first 2 years.There was no difference observed in graft survival,however this may become apparent with a longer duration of follow up.

TH-PO1050

HLA -DP Mismatch among the Zero HLA -A, -B, and -DR Mismatched Deceased Donor Kidney Transplant Population Is Associated with Higher Risk of Both Graft Rejection and Death Censored Graft Loss Nissreen S. Elfadawy,[1] Stuart M. Flechner,[1] Peter Lalli,[2] Jesse D. Schold,[1] Emilio D. Poggio,[1] Richard A. Fatica,[1] Saul Nurko,[1] Brian R. Stephany,[1] Medhat Askar.[1] *[1]The kidney Transplant program, Cleveland Clinic, Cleveland, OH; [2]Histocompatibility and Flow Cytometry Laboratory, Carolinas Healthcare System, Charlotte, NC.*

Background: Zero HLA mismatch (0MM) is defined by UNOS as the absence of HLA-serologic level mismatches at HLA-A, B, and DR antigens (Ag), and results in better graft outcomes after kidney transplantation. It is unclear whether mismatches at HLA- Cw, DQ or DP also have an independent impact on graft outcome.

Methods: In this retrospective study, we identified 265 recipients who had shared 0MM deceased donor (DD) kidney transplants at our center (1990-2012). The study population was classified according to HLA –CW, -DQ, -DP allele mismatch to investigate the isolated impact of mismatch on graft outcomes. Kaplan–Meier plots and log-rank tests were used to determine incidence of biopsy-proven acute graft rejection and graft loss in the different groups.

Results: The prevalence of HLA –CW, -DQ, and –DP mismatch in our 0MM cohort was 27%, 12%, and 77% respectively. HLA –DP mismatches were an independent risk factor for graft rejection (12 versus 3%, HR 4.0, 95% CI 1.1-26.1, p=0.03), death censored graft loss (26 versus 18%, HR 1.9, 95% CI 1.1-3.9, p=0.03), and shorter graft half-life (6 versus 8 years, p 0.01); after adjusting for other HLA-loci mismatches and confounding factors such as previous transplant history and degree of sensitization prior to transplantation. There was no association between groups stratified by HLA –CW, or -DQ mismatch with graft outcomes.

Conclusions: These results suggest that the majority of HLA -A, -B, -DR 0MM transplants are mismatched for HLA -DP. Our findings provide evidence to suggest that HLA –DP matching in renal transplant is clinically relevant and prospective typing and matching warrant further prospective investigation.

TH-PO1051

What Kinds of Graft/Body Size Mismatches Do Influence the Renal Outcomes of Recipients and Donors? Mikiko Yoshikawa, Kentaro Nakai, Shunsuke Goto, Hideki Fujii, Shinichi Nishi. *Div of Nephrology, Kidney and Dialysis Center, Kobe Univ Graduate School of Medicine, Kobe, Hyogo, Japan.*

Background: Several previous reports proved body size mismatches between graft and recipient or graft and donor affected the post-operative graft function. However, which parameters can precisely predict the deterioration of graft and donor remnant kidney function has not been clearly elucidated yet.

Methods: We performed a retrospective cohort study including 60recipient and donor pairs who received living kidney transplantation at our center from April 2003 to March 2013 and surveyed their post-operative clinical courses focusing on the mismatches between graft and recipient or graft and donor body sizes.

Results: Donor body weight (DBW), BSA (DBSA), and BMI (DBMI) were significantly correlated with graft weight. Among them, DBW showed the strongest correlation with graft weight (GW) (r= 0.714, p<0.001). DBW/RBW, DBSA/RBSA, DBMI/RBMI, and GW/ recipient body sizes revealed statistically significant correlation with recipients' ΔeGFR within post-operative 1year. Among them DBW/RBW showed the most significant negative correlation with recipients' ΔeGFR. (r= 0.469, p<0.001). Multiple regression analysis also proved that DBW/RBW was the most significant independent predictor of recipients' ΔeGFR. (β=–13.8, 95% confidence interval: –6.7 to –21.0, p<0.001). On the donor side, the lower GW/donor body size highly developed to CKD stage 3.

Especially, GW/DBMI < 8.0 (g/Kg/m^2) of donor was a high risk marker suggesting the progression to CKD stage 3 (P=0.001). Cox regression analysis also showed that GW/DBMI < 8.0 (g/Kg/m^2) was an independent risk marker to the progression of CKD stage 3 (HR=2.09, 95% confidence interval: 1.105 to 3.947, p=0.023). Recipient / donor body sizes or GW / donor sizes had no significant relationship with proteinuria.

Conclusions: DBW/RBW and GW/DBMI were the best predictors of graft and donor kidney function in our cases. Obesity and body weight control of recipient and donors before kidney transplantation is very important for prevention of recipient and donor size mismatches.

TH-PO1052

Association Between Preconception GFR and Pregnancy Outcomes in Female Kidney Transplant Recipients Serban Constantinescu,[1] Peter Axelrod,[1] Lisa Coscia,[2] Michael J. Moritz,[3] Vincent T. Armenti.[2] *[1]Temple Univ School of Medicine; [2]Gift of Life Inst, Philadelphia, PA; [3]Lehigh Valley Health Network.*

Background: Graft function may influence pregnancy outcomes in kidney recipients.

Methods: Data were collected by the National Transplantation Pregnancy Registry via questionnaires, phone interviews and hospital records. We analyzed 984 singleton pregnancies in 695 kidney recipients, divided in 4 groups according to preconception eGFR (MDRD). Analyses for linear trends were done by Chi square and least squares regression.

Results: With stepwise decrease in GFR, there was a significant increase in rejection and hypertension during pregnancy and graft loss within 2 yrs post-pregnancy. In parallel, there was a significant decrease in live births, and increased prematurity, low and very low birthweight and miscarriages.

	GFR ≥60	GFR≥45 to <60	GFR≤30 to <45	GFR <30	p value
Recipients	241	237	174	43	
MATERNAL FACTORS					
Pretransplant pregnancy	25.5%	30.6%	31%	42%	0.04
Age at transplant (yrs)	23.9±6.2	24.8±6.3	23.1±5.8	24.8±5.5	NS
Planned pregnancy	61.3%	67.1%	62%	60.5%	NS
Transplant to conception interval (yrs)	5.6±4.2	5.4±4.1	5.4±3.9	5.8±4.5	NS
Treated hypertension during pregnancy	41.9%	51.5%	59%	79.6%	<0.001
Preeclampsia	27.1%	24.7%	31.3%	50%	NS
Treated rejection during pregnancy	0.3%	1.8%	2.1%	6.1%	0.004
Graft loss within 2 yrs	2.5%	5.1%	6.1%	28.6%	<0.001
PREGNANCY OUTCOMES	359	331	245	49	
Miscarriage	10.3%	18.1%	15.5%	22.5%	0.006
Live births %(n)	87.5% (314)	78% (258)	82% (201)	71.4% (35)	0.003
Mean gestational age (wks)	36.8±2.9	36.2±3.3	35.6±3.4	34.2±3.1	<0.001
Prematurity (<37 wks)	38%	43%	57%	77%	<0.001
Mean birthweight (g)	2822±685	2654±742	2420±743	2022±724	<0.001
Low-birthweight (<2500 g)	25.8%	36.8%	47.8%	80%	<0.001
Very low-birthweight (<1500 g)	5.1%	7.4%	14.9%	23%	<0.001
Cesarean section	56.9%	52%	45.8%	60%	NS

Conclusions: Progressive decrease in preconception GFR is associated with increased maternal complications, graft loss, and adverse fetal outcomes. Graft function preconception should guide transplant professionals in counseling female kidney recipients contemplating pregnancy.

TH-PO1053

Living Donor Kidney Transplantation (LDKT) from HBsAg (+) Donor to HBsAg (-) Recipient with or without Anti-HBs Jin M. Kong, Hyuk Yong Kwon, Sung Hyun Son. *Internal Medicine, Han Seo Hospital, Pusan, Korea.*

Background: HBsAg positivity is currently regarded as a contraindication of kidney donation to HBsAg(-) recipients due to the risk of HBV transmission. Donor organ shortage is serious on this planet. The use of the HBsAg(+) donor organ may help to increase the opportunity of transplantation. We developed a protocol that enables LDKT from a HBsAg (+) donor to a HBsAg(-) recipient.

Methods: 1) Hepatitis B vaccine in recipients without protective titer (≥10 mIU/ml) of anti-HBs 2) Entecavir in donors with detectable HBV DNA in serum to reduce the viral load for 1-2 months before transplantation 3) HBIG in recipients on transplant day 4) Entecavir prophylaxis in recipients for 2-3 post-transplant months 5) Monitoring of HBV transmission in recipient.

Results: Seven LDKT from a HBsAg(+) donor to a HBsAg(-) recipient in 6 patients. In one case, anti-HBs of the recipient was negative, which was converted to positive (15mIU/ml) by HB vaccine before transplantation. All recipients had undetectable HBV DNA after LDKT and maintained HBsAg(-)/anti-HBs(+) status throughout the median follow up of 32(2-52) months.

Conclusions: Kidneys from HBsAg (+) living donors can be safely transplanted to HBsAg (-) recipients with or without anti-HBs.

TH-PO1054

Physical Activities Does Not Recover in 6 Months after Living Kidney Donor Transplantation Makoto Tsujita, Yoshihiko Watarai. *Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan.*

Background: Since renal dysfunction and immunosuppressive drugs cause muscle degeneration, physical activities decrease in CKD, dialysis patients and transplant recipients. In addition, elderly kidney transplant recipients are increasing in Japan, so improving physical activities and increasing muscle strength and volumes are important to prevent fracture and fall accident.

Methods: Consecutive 41 patients older than 40 years were enrolled in this study from 2012. Immunosuppression basically contains steroid, cyclosporine or tacrolimus, and mycophenolate mofetil or everolimus. Parameters of physical activities such as hand grip, SMI (skeletal muscle index) using by DEXA(dual-energy x ray absorptiometry) and CPX(Cardio Pulmonary exercise test) were measured and compared at prior and 6 months after kidney transplantation. Recipients were encouraged to do daily exercise for 30 to 60 minutes everyday.

Results: There were not significant differences between male and female demography.

	Male (n = 22)	Female (n = 19)
Mean age (year)	55.2	53.7
Preemptive kidney transplantation (n)	11(50%)	10 (53%)
Mean duration of dialysis (month)	34.8	49.7
Diabetes mellitus (n)	7 (32%)	3 (16%)
Cyclosporine use (n)	10 (45%)	12 (63%)
Tacrolimus use (n)	12 (55%)	7 (37%)
Mycophenolate mofetil use (n)	16 (73%)	15 (79%)
Everolimus use (n)	6 (27%)	4 (21%)

Hand grip increased at 6 months, but any other tests did not improve after transplantation in male patients. BMI and SMI decreased at 6 months but any other tests was unchanged in female patients(Table2).

Table 2 Results of this study for male

	Male (n = 22)			Female (n = 19)		
	Baseline	6 months after transplantation	P value	Baseline	6 months after transplantation	P value
Body weight (kg)	63.6±12.8	63.2±11.8	0.72	50.0±8.1	49.9±8.7	0.85
BMI (kg/m^2)	22.4±3.4	21.9±3.3	0.33	20.4±3.2	19.6±3.3	< 0.05
Body fat mass (kg/m^2)	4.8±3.7	4.6±2.5	0.18	5.2±2.2	5.4±2.1	0.55
SMI (kg/m^2)	7.1±0.8	7.0±0.9	0.65	5.7±0.8	5.1±0.8	< 0.05
Hand Grip (kgw)	28.0±9.4	30.0±11.1	< 0.05	20.1±5.9	20.8±8.0	0.67
Peak VO2 (ml/kg/min)	17.8±4.5	18.4±4.9	0.33	16.1±4.4	16.5±9	0.43
BMI : body mass index						

Physical activities seemed rather worse after transplantion in female patients.

Conclusions: In both male and female recipients, physical activities do not seem to recover in 6 months after kidney transplantation. More interventions and more studies are needed to know the effect of daily exercise on physical activities.

TH-PO1055

HLA Gene Dosage Effect on Renal Allograft Survival Ji-Eun Lee,[1,2] Eugene Kwon,[1,2] Jeung-Min Park,[1,2] Hee-Yeon Jung,[1,2] Ji-Young Choi,[1,2] Jang-Hee Cho,[1,2] Sun-Hee Park,[1,2] Yong-Lim Kim,[1,2] Chan-Duck Kim.[1,2] *[1]Dept of Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; [2]Clinical Research Center for End Stage Renal Disease, Republic of Korea.*

Background: Matching for the HLA-A, B and DR antigens has a beneficial long-term effect on renal allograft survival. However, gene dosage effect of mismatched HLA on transplant outcomes has not been known. We investigated influence of HLA gene dosage on allograft survival in kidney transplant recipients (KTRs).

Methods: We analyzed HLA typing of KTRs and kidney donors at Kyungpook National University Hospital from January 1982 to December 2012. KTRs were divided into two groups: recipients from homozygous HLA donor and those from heterozygous HLA donor. Death-censored graft survival of KTRs was compared according to allele state of kidney donors.

Results: 697 KTRs were enrolled in the study. According to the Kaplan–Meier analysis, mean survival of recipients from homozygous HLA-DR donor and homozygous HLA-B donor was 14.7 and 6.4 years compared to 16.9 and 20.1 years in those from heterozygous HLA-DR donor and heterozygous HLA-B donor respectively. In the multivariate Cox's proportional hazards model, homozygosity of HLA-DR gene and HLA-B gene was an independent risk factor for death-censored graft survival (hazard ratio [HR], 3.521 {95% confidence interval [CI], 1.227-10.104}; P=0.019 for HLA-DR gene, HR, 6.093 {95% CI, 1.305-28.454}; P=0.022 for HLA-B gene). Death-censored graft survival was not associated with HLA-A and HLA-A, B, DR allele states.

Conclusions: Allograft survival was influenced by gene dosage of HLA, especially DR and B. As well as HLA mismatch, allele state of donor was also considered to predict transplant outcomes.

The Role of Hemodialysis Social Networks in Transplantation: Five Year Follow Up of an Urban Hemodialysis Cohort

Akshta Pai, Avrum Gillespie. *Nephrology, Hypertension and Kidney Transplantation, Temple Univ Hospital, Philadelphia, PA.*

Background: Racial and socioeconomic disparities are well known barriers to kidney transplantation (KT), especially among minority populations. Emerging evidence suggests social networks exist within hemodialysis clinics. The role of these social networks on KT is not yet fully understood.

Methods: A convenience sample from two urban hemodialysis clinics in Philadelphia resulted in a cohort of 116 English-speaking patients. The survey was conducted between July 2008 and December 2008 using the Dialysis Patient Transplant Questionnaire (DPTQ) to address barriers to KT. The survey was self administered by 29% of the cohort. Clinical and transplant data were extracted from the electronic medical record. Data was analyzed using independent t-tests, Fischer's exact test, and chi-square analysis.

Results: The mean age at enrollment was 58-years-old (22-87). Eighty seven percent self identified as non-Hispanic black, 9% as Hispanic, and 1% as White or other. Over a 5-year period, 12% of the cohort received a KT. The majority of the KT recipients (73%) were listed on the transplant list at the time of the interview (p=0.001). The rate of transplant was 11% among non-Hispanic blacks, and 40% among Hispanics (p=0.003). When asked about the likes and dislikes of hemodialysis, patients who received a KT liked the social aspect of hemodialysis (p=0.049) and did not like the physical benefits of hemodialysis treatment (p=0.031). There were no differences in the external social networks of patients who received a KT. There were also no racial/ethnic differences in liking the social aspects of hemodialysis.

Conclusions: In this cohort of urban patients with a low transplant rate, the hemodialysis clinic social network seems to provide a positive role toward transplantation. The dichotomy of transplant rates within the same hemodialysis clinic social network among Hispanics versus non-Hispanic blacks requires further study in order to help develop effective interventions.

TH-PO1057

The Effects of Organ Procurement Organization Network Centrality on Kidney Discard and Transplant Outcomes

Neel Butala,[1] Peter P. Reese,[2] Richard Formica,[3] Chirag R. Parikh.[3] *[1]Massachusetts General Hospital; [2]Perelman School of Medicine; [3]Yale School of Medicine.*

Background: Given growth in kidney transplant waiting lists and discard rates, donor kidney acceptance is an important problem. We hypothesize that kidneys may be more likely to be accepted when OPOs form more relationships that can lead to regular exchange of organs. We apply the novel tools of social network analysis to examine whether OPO network properties have an effect on discard rates and recipient outcomes.

Methods: We identified 106,160 deceased-donor kidneys recovered for transplant from 2000-2010 in SRTR. We constructed the transplant network by year with each OPO representing a node and each kidney-sharing relationship between OPOs representing a directed tie between nodes. Primary exposures were OPO out-degree centrality and in-degree centrality. Primary outcomes were discard, cold-ischemia time, delayed graft function, and 1-year graft loss. We constructed multivariable regression models, restricting analysis to the 50% of OPOs with highest discard and stratifying remaining OPOs into 2 groups by kidney volume. Models controlled for kidney donor risk index, waitlist time, and year/region dummies.

Results:

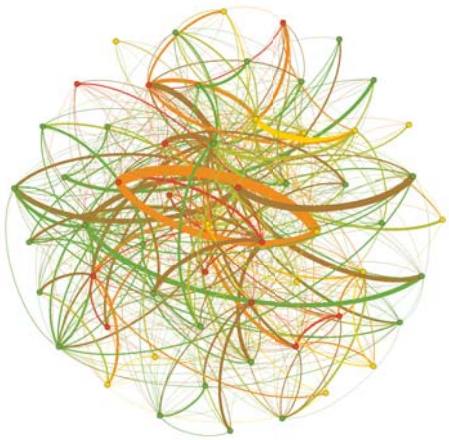

Figure 1 shows the 2010 kidney transplant network with edge size weighted by sharing volume. Among OPOs procuring high kidney volume, an increase in one additional OPO to which a kidney was given or from which a kidney was received by a procuring OPO in a year was associated with a 2% lower likelihood of discard for a given kidney (OR:0.979, CI:0.967,0.991 and OR:0.978, CI:0.963,0.994, respectively) with mixed associations with recipient outcomes.

Conclusions: Our study highlights the value of social network analysis in revealing how broader kidney sharing between OPOs may lead to greater organ acceptance. We conclude interventions to promote broader inter-OPO sharing could be developed to reduce discard.

TH-PO1058

UCF-101 Protects against Cold Storage Induced Renal Tubular Cell Apoptosis

Swati Jain, Daniel Keys, Charles L. Edelstein, Alkesh Jani. *Renal, Univ of Colorado, Aurora, CO.*

Background: Delayed graft function (DGF) independently predicts reduced 5 yr kidney transplant survival. Cold ischemia (CI) is a major risk factor for DGF and results in renal tubular cell (RTEC) apoptosis, but the mechanism by which this occurs is unknown. RTEC apoptosis of donor kidneys predicts the development of DGF. Our published data show that mouse kidneys subjected to CI have significantly increased RTEC apoptosis and cleaved caspase-3 (CC3). X-linked inhibitor of apoptosis (XIAP) is the most potent, naturally occurring inhibitor of CC3. UCF-101 is a chemical inhibitor of XIAP degradation. We hypothesized that (a) CI leads to reduced XIAP resulting in increased CC3 and RTEC apoptosis (b) Treatment of donor kidneys with UCF-101 will prevent activation of CC3 and RTEC apoptosis.

Methods: RTEC apoptosis, XIAP, and caspase-3 protein and activity were examined (a) *in vivo* in C57BL/6 mouse kidneys exposed to 24 hrs of CI with and without 100 uM UCF-101 (b) *in vitro* in LLCPK cells subjected to CI in UW solution with and without 50 uM UCF-101. Apoptosis *in vivo* was quantified by a nephropathologist in a blinded fashion. Annexin V and PI staining was used to evaluate apoptosis *in vitro* by flow cytometry.

Results: Kidneys exposed to CI *in vivo,* and RTEC exposed to CI *in vitro* had significantly decreased XIAP expression and increased CC3 protein, caspase-3 activity and apoptosis. UCF-101 treatment during CI (a) increased XIAP expression (b) decreased CC3 protein, caspase-3 activity and apoptosis.

	In vivo			***In vitro***		
	control	CI	CI+UCF-101	control	CI	CI+UCF-101
CC3	+	+++	+	ND	+++	+
XIAP	++	+	+++	+++	+	+++
caspase-3 activity (fold change)	1±0.1	10±0.01*	5±0.02	1±0.003	4±0.004*	2±0.005
Apoptotic cells/10hpf	0.1±0.1	10±2*	3.3±0.8	3.9±0.5%	40±0.3*%	13±0.4%

n=4;*p<0.01 vs. control and CI+UCF-101, ND=not detectable.

Conclusions: CI injury results in degradation of XIAP and subsequent RTEC apoptosis. Prevention of XIAP degradation by UCF-101 results in decreased CC3, caspase-3 activity and prevention of apoptosis during both *in vitro* and *in vivo* CI. UCF-101 may be an important therapy to prevent apoptosis during CI of donor organs and potentially improve DGF.

Acute Tubular Injury at Reperfusion and Transplant Outcomes

Yaa Oppong, John Farber, Maria P. Martinez Cantarin. *Thomas Jefferson Univ, Philadelphia, PA.*

Background: Conflicting data exist with respect to pathological features that predict allograft outcomes at the time of kidney reperfusion. Acute tubular injury is common at reperfusion, but its relationship with graft function is unclear. The present study aimed to evaluate in reperfusion biopsies the relationship between severity of acute tubular injury, as assessed by a new standardized scoring system, and the extent of chronic changes as defined by Banff criteria and graft outcomes.

Methods: Reperfusion biopsies from kidney transplants performed at our institution from January 2004 to December 2012 were retrospectively reviewed. Data from 476 biopsies were analyzed. Acute tubular injury (AI) was assessed by scoring apical blebbing, hydropic swelling, and cell sloughing. Chronic injury (CI) used the Banff grading system. Graft outcomes included graft rejection (GR), creatinine levels, and estimated glomerular filtration rate (eGFR) at 1 and 5 years. This study had the approval of the Institutional Review Board of Thomas Jefferson University Hospital.

Results: We reviewed 292 biopsies from deceased donors and 184 from live donors. A little over half of patients were male and white, with an average age of 51 years. In multivariable analysis, the AI score was not significantly associated with graft rejection, creatinine levels, or eGFR at 1 or 5 years post transplantation. On the other hand, an association was evident between the CI score and eGFR at 1 year. Patients with a moderate/severe CI score had significantly lower eGFR at 1 year (p=0.002) and a significantly higher creatinine at 1 year than those with mild scores (p=0.019). The association between the CI score and eGFR was not apparent at 5 years of follow up. No association was evident between the CI score and rejection in our cohort.

Conclusions: In summary, mild to moderate acute tubular damage at implantation does not affect transplant outcomes during the first year. Chronic changes graded by Banff are associated only with eGFR at 1 year and not at 5 years.

TH-PO1060

Effect of Early HHV-6 Viremia on Short- and Long-Term Kidney Transplant Outcomes Michael E. Seifert,[1,2] Ana Paula Rossi,[2] Timothy A. Horwedel,[2] Gregory A. Storch,[2] Daniel C. Brennan.[2] *[1]Southern Illinois Univ; [2]Washington Univ in St. Louis.*

Background: Reactivation of latent herpesviruses such as cytomegalovirus (CMV) is associated with poor kidney transplant outcomes. We previously reported the incidence of human herpesvirus (HHV)-7 viremia at 89%, as well as its resistance to antiviral therapy. The impact of HHV-6 reactivation is unclear. We sought to characterize the incidence of early HHV-6 viremia post-kidney transplant, examine interactions between HHV-6 and CMV, and determine the effects of early HHV-6 viremia on short- and long-term outcomes.

Methods: This was a prospective study of kidney transplant recipients (n=193) previously enrolled in a polyomavirus monitoring study with 10 years of follow up. We grouped subjects by donor/recipient CMV status to analyze interactions between HHV-6 activity and CMV exposure: CMV+ (donor or recipient positive) or CMV- (donor and recipient negative). Primary exposure was HHV-6 viremia through 16 weeks post-transplant determined by weekly PCR. Primary outcomes were leukopenia and anemia during year-1 post-transplant and a composite of acute rejection, graft loss, or death by 10 years post-transplant.

Results: HHV-6 viremia occurred in 10/193 (5.2%) during the first 16 weeks post-transplant, with 9/10 cases in the CMV+ group. Leukopenia occurred in 11% and and anemia in 6% of HHV-6 negative subjects but neither occurred in HHV-6 viremic subjects. In Kaplan-Meier analysis we observed a trend for more HHV-6 viremic subjects achieving the composite outcome than HHV-6 negative subjects (P=0.10). Using Cox regression, HHV-6 viremia was independently associated with the composite outcome after including age at transplant, CMV exposure and number of HLA-antigen mismatches in the final model [HR 2.422 (95% CI 1.002, 5.854)].

Conclusions: To our knowledge, this is the largest kidney transplant cohort assessed for HHV-6 reactivation. Early HHV-6 viremia occurs infrequently compared to other herpesviruses, but may occur more often in CMV-exposed subjects. HHV-6 viremia is not associated with leukopenia or anemia. Early HHV-6 viremia may be predictive of poor 10-year transplant outcomes, but the low incidence of HHV-6 viremia limits broad statistical inference.

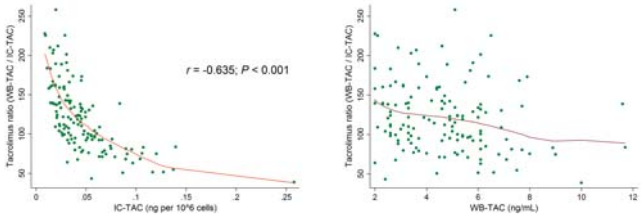
TH-PO1061

Monitoring Intracellular Tacrolimus Concentration in Kidney Transplant Recipients with Stable Graft Function Seung Seok Han,[1] Seung Hee Yang,[2] Ji In Park,[1] Hajeong Lee,[1] Jung Pyo Lee,[3] Dong Ki Kim,[1] Yon Su Kim.[1] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Kidney Research Inst, Seoul national Univ, Seoul, Korea; [3]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea.*

Background: Monitoring the intracellular concentration of immunosuppressive agents can be promising to improve and individualize clinical practice in patients receiving transplantation. However, this issue remains unresolved in kidney transplant recipients.

Methods: Both whole blood and intracellular concentrations of tacrolimus (WB-TAC and IC-TAC, respectively) were simultaneously measured in 215 kidney recipients with stable graft function using LC-MS/MS. The tacrolimus ratio was defined as WB-TAC/IC-TAC. Furthermore, the genetic polymorphisms of P-glycoprotein 1, such as rs1128503, rs2032582, and rs1045642, were examined.

Results: The ranges of the WB-TAC and IC-TAC levels, and tacrolimus ratio were 2.0–11.7 ng/mL, 0.009–0.258 ng/mL, and 38.7–258.0, respectively. The correlation coefficient (r) between WB-TAC and IC-TAC was 0.759 (P < 0.001). The tacrolimus ratio was more strongly influenced by IC-TAC.



Genetic polymorphisms of P-glycoprotein 1 were not associated with IC-TAC or the tacrolimus ratio. Among baseline covariates, the duration of transplantation was the strongest predictor of IC-TAC and the tacrolimus ratio: patients who had a long period since transplantation had lower IC-TAC and higher tacrolimus ratio. Among the other covariates, patients with deceased donor, high proportion of lymphocyte, and high hematocrit level had lower IC-TAC and high tacrolimus ratio than their counterparts.

Conclusions: To our knowledge, this is the first study to identify the factors associated with the IC-TAC. These results will be helpful for monitoring and predicting IC-TAC or the tacrolimus ratio in kidney transplant recipients.

Funding: Government Support - Non-U.S.

TH-PO1062

Proton Pump Inhibitors Are Associated with Severe Hypomagnesemia in Renal Transplant Patients Mohamad Alhosaini, David J. Leehey, Kavitha Vellanki. *Medicine, Loyola Univ Medical Center, Maywood, IL.*

Background: Proton pump inhibitors (PPI) have replaced H2 receptor blockers (H2B) for GI prophylaxis at many transplant centers, despite lack of evidence for superior efficacy of PPI. Although PPI are generally safe medications, hypomagnesemia due to impaired GI absorption can occur. We hypothesized that PPI would result in a higher prevalence and severity of hypomagnesemia when compared to H2B.

Methods: Medical records of all adults receiving kidney alone transplants at our center between January 2010 and December 2012 were reviewed. Exclusion criteria were: delayed graft function, death within one year of the transplant date, and use PPI or H2B for less than one year. Outcomes were incidence of hypomagnesemia (mean serum Mg of < 1.8 mg/dL during the first year after transplant), incidence of severe hypomagnesemia (serum Mg < 1.3 mg/dL on any occasion) and use of Mg supplements.

Results: Of 187 patients receiving kidney transplants during the study period, 83 met the above eligibility criteria. Mean age was 52.2 ± 15.8; 59% were male and 59% were Caucasian. All were taking CNI. 43 patients were treated with PPI and 40 patients were treated with H2B. Overall, 65% had hypomagnesemia. Mean serum Mg was 1.70 ± 0.12 in the PPI group versus 1.79 ± 0.17 in the H2B group (p = 0.006). Hypomagnesemia occurred in 77% of patients taking PPI and in 60% of patients taking H2B (p = 0.10). However, severe hypomagnesemia was more common in patients taking PPI versus H2B (21% versus 5%, p =0.032). Use of magnesium supplements was more common in the PPI group than the H2B group (47% versus 23%, p = 0.022). Incidence of diabetes mellitus, serum albumin, and diuretic use were similar between the two groups. On logistic regression analysis, both PPI and diuretic use were independent risk factors for severe hypomagnesemia.

Conclusions: The use of PPI after renal transplantation causes more severe hypomagnesemia and leads to greater use of oral magnesium supplements compared to H2B. Given the lack of confirmed superior benefit of PPI versus H2B and the potential harmful effect of hypomagnesemia, we suggest restricting prophylactic PPI use in renal transplant patients to those who are at high risk for GI bleeding.

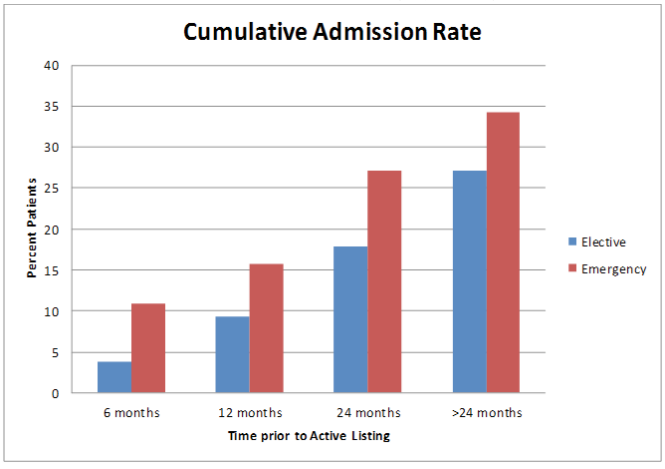
TH-PO1063

Novel Report of Fitness of Wait-Listed Dialysis Patients and Prevalence of Occult Cardiovascular Disease Arunraj Navaratnarajah, Menelaos Pipis, Bev M. Nicol, Ruhena Sergeant, Damien Ashby, David Taube, Neill D. Duncan. *Imperial College Renal and Transplant Centre, London, United Kingdom.*

Background: Our aim was to evaluate fitness of patients wait-listed at our centre based upon protocolised care.

Methods: An exhaustive examination of 4 haemodialysis centres and the peritoneal dialysis programme was made 21 Nov 2013. 184/676 dialysis patients were active on deceased donor wait-list. Last clinical review and hospitalisations were recorded. Our protocol is for 3 monthly general medical review, and coronary angiography in all symptomatic patients and asymptomatic high risk patients (aged >50 years and all diabetics). Biochemical surrogates a month prior to censure were used for nutrition (albumin), CKD-MBD (PTH), inflammation (CRP) and anaemia (Hb and erythropoietin requirement EPO/Wk).

Results: Median time from clinical review 40 days (1-227 days).



One third of emergency admissions were due to sepsis, 9.5% cardiac cause. 40% patients had clinical review <6 months of hospital admission. 7 patients (4%) had cardiac symptoms. 71% of listed patients had coronary angiography (99% of those >50 years and 95% diabetics). 20% of patients with angiography proceeded to revascularisation. Echocardiography performed in 66%, 16% systolic dysfunction, 9% valvular disease, and 25% others; diastolic dysfunction, regional wall abnormalities, pulmonary hypertension. Month prior to census, 5% had albumin <30g/L, 25% had PTH >70pg/ml, 16% had CRP >10mg/dL. 9% had Hb <10g/dL and 6 patients were EPO resistant with EPO/Wk >24k units.

Conclusions: Our study demonstrates acuity of illness in wait-listed patients, and the need for frequent clinical surveillance of patients. A minority of patients had cardiac

symptoms, there was adherence to protocol for high risk asymptomatic patients and 20% required revascularization. Biochemical surrogates also demonstrate a significant burden of chronic disease.

TH-PO1064

Impact of Cytomegalovirus Infection in Kidney Transplant Recipients. Experience at Our Centre Lourdes de la Vara Iniesta, Inmaculada Lorenzo Gonzalez, Francisco Llamas Fuentes, Carmen Gomez Roldan. *Univ Hospital of Albacete.*

Background: Cytomegalovirus (CMV) is one of the most important pathogens in kidney transplant patients. Early detection and prophylactic treatment reduce the impact of the disease. Objective: to analyse and describe our centre's experiences.

Methods: 235 transplant patients were observed. Prophylaxis was performed in the high-risk patients (D+/R- or treatment with antilymphocyte globulin), the remaining patients were monitored with Ag-pp65/PCR-CMV for 16 weeks or when there was suspicion of affectation. We considered infection (CMVI): Ag-pp65>10 cells/PCR>1000 copies, without associated clinical, and disease (CMVD) when associated symptomology.

Results: Of 235 patients, 151(64.30%) were male. 69 patients (29.36%) considered high-risk, the average prophylaxis period: 17.62±5.54 weeks (range:6.43-32.86). Of these, 16(23.18%) presented CMVI and 1(1.44%) developed CMVD (post-prophylaxis). The average onset period (AOP), since the transplant: 5.85±3.66 months. The remaining 166 patients (70.60%) were considered low-risk, 43(25.90%) presented CMVI, 2(1.20%) developed CMVD, AOP: 2.61±3.75 months. We did not find differences in the incidence of CMV when comparing both groups, or between patients that received a different period of prophylaxis, ≤ or >15 weeks. There were 7 relapses (5 in low-risk patients). Comparing patients treated <7, ≥7 and <15, y ≥15 weeks, we found 37.5%, 12.5% and 8.3% relapses respectively (p=0.20). On comparing affected patients with healthy, in the multivariate analysis, being male acts as a risk factor (p=0.001), glomerular filtration in the first year post-transplant was worse in affected patients, and no increase was observed in the incidence of neoplasms and acute rejection, or decrease patient and graft survival.

Conclusions: Early detection and prophylactic treatment in situations of risk have reduced the impact of the disease. The prophylaxis period >15 weeks does not improve the results and increase costs. With a longer treatment period, there are fewer relapses. CMV infection is associated to males and poorer kidney function during the first year post-transplant, without repercussion for survival of either the graft or the patient.

Comparison of Outcomes From Spousal Donor Graft Between ABO Compatible and Incompatible Kidney Transplantation Ji Hyun Yu,[2] Byung Ha Chung,[1,2] Bum-Soon Choi,[1,2] Cheol Whee Park,[1,2] Yong-Soo Kim,[1,2] Chul Woo Yang.[1,2] *[1]Transplantation Research Center; [2]Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: In recent era of organ shortage, both spousal donor and ABO incompatible kidney transplantations (KTs) are good alternatives for living related ABO compatible donor KT. The aim of this study was to compare the outcomes of spousal donor in ABO compatible and ABO incompatible KTs.

Methods: Between Jan. 2009 and Dec. 2012, total 326 living donor KTs were performed at Seoul St. Mary's hospital. We compared the clinical characteristics and outcomes including survival rates for grafts and patients between two spousal donor groups.

Results: Percentage of spousal donor in ABO incompatible KT group (group1, 22 of 56 KTs, 39.3%) was higher than that of in ABO compatible KT group (group2, 62 of 270 KTs, 23%)(p=0.013). 3-year BPAR-free survival rate was higher in group 2 (65.3 versus 86.5%, p=0.043). But after exclusion of high titer (defined as baseline anti-A or anti-B immunoglobulin G isoagglutinin titer over 1:512) ABO incompatible KT recipients (n=5), 3-year BPAR-free survival rates showed no difference between two groups. 3-year grafts survival rate (85.2 versus 95%, p=0.065) and patients survival rate (95.5 versus 100%, p=0.093) were comparable between two groups. Serum creatinine level was lower at first 3 months in group 1 (1.25 ± 0.24 versus 1.45 ± 0.37 mg/dL, p=0.028), but after first 3 months, the difference of renal function between two groups has been disappeared. In ABO compatible KT recipients, there was no difference in 3-year BPAR-free, grafts and patients survival rates among living related donor (LRD), living unrelated donor (LUD) and group2. In ABO incompatible KT patients, there was no LUD. 3-year BPAR-free, grafts and patients survival rates also showed no difference between ABO incompatible LRD KT recipients and group1. Spousal donor KT itself and spousal type did not affect the grafts survival.

Conclusions: Outcomes of spousal donor graft in ABO incompatible KT is comparable to those of ABO compatible KT in respect of grafts and patients survival rates.

TH-PO1066

Prevention of Complications Associated with Benign Prostatic Hypertrophy After Renal Transplantation Michelle L. Lubetzky, Maria Ajaimy, Anjali Gupta, Layla Kamal, Graciela De Boccardo, Enver Akalin, Liise K. Kayler. *Transplantation, Montefiore Medical Center, Bronx, NY.*

Background: More than half of males over 50 have benign prostatic hypertrophy (BPH). As most patients with ESRD are anuric, BPH is under diagnosed in this population. BPH, if diagnosed late, may increase complications following kidney transplantation (KTX).

Methods: A single center retrospective cohort review of consecutive male patients over 50 years of age transplanted from Jan. 1, 2010 until Sept. 30, 2013 was performed to assess outcomes between patients with and without BPH. We also reviewed whether pre-transplant diagnosis of BPH and initiation of medical therapy had an effect on acute urinary retention (AUR), discharge with foley catheter, urinay tract infection (UTI), graft function, and patient survival.

Results: Of 147 patients, BPH was diagnosed in 34.2%, 15.1% prior to KTX and 19.1% after KTX. Mean follow-up was 673.9± 394.8 days and was not different between those with and without BPH (p=0.37). Compared to those without BPH, BPH was significantly associated with older age, higher pre-transplant PSA, discharge with Foley catheter, re-admission for AUR, and UTI after KTX. Patients who were placed on medical therapy at the time of transplant (Pre-KTx diagnosis of BPH) had significantly less UTIs, AUR, and hospital readmissions with AUR. There were no differences in graft function or graft/patient survival between the groups.

	No BPH (n=94)	BPH (n=53)	P Value
Mean Follow up (days)	653.9±402.7	709.5±381.5	0.37
Age	61.0±6.7	64.6±6.7	0.002
Race (AA)	23.4%	18.9%	0.52
Induction (Thymo)	80.1%	73.6%	0.31
Pre-KTX PSA	1.16±0.86	2.40±2.9	0.001
Most recent creatinine	1.8±1.4	1.7±1.0	0.95
Double J Ureteral Stent	42.6%	41.5%	0.90
Graft Loss	3.3%	0%	0.18
P[illegible]t surv[illegible]	98.9%	96.2%	0
Uri[illegible]tion after transp[illegible]	0%	2[illegible]	<[illegible]1
D[illegible]arge w[illegible] Foley	0%	13[illegible]	<[illegible]1
Re-admission for Urinary Retention	0%	28.3%	<0.01
UTI (within 1 year)	18.0%	45.2%	<0.01

	Pre-KTX BPH diagnosis (n=25)	Post-KTX BPH diagnosis (n=28)	P Value
Mean Follow up (days)	652.2±341.3	760.7±341.3	0.29
Urinary retention after transplant	4%	46.4%	<0.01
Discharge with Foley	4%	21.4%	0.06
Re-admission for Urinary Retention	8%	46.4%	<0.01
UTI (within 1 year)	24%	57.1%	0.01

Conclusions: Following KTX, urinary tract complications are common in patients with BPH. Pre-transplant assessment of BPH and initiation of medical therapy significantly diminished the incidence of complications. This data points to the need for earlier diagnosis of BPH in pre-transplant assessment of ESRD patients.

TH-PO1067

Sarcopenic Obesity in Male Renal Transplant Recipients Vasileios Devetzis, Uyen Huynh-Do, Spyridon Arampatzis. *Nephrology, Hypertension and Clinical Pharmacology, Bern Univ Hospital, Bern, Switzerland.*

Background: Although abnormal body compositions such as sarcopenic obesity (SO), which describes the condition in which high fat mass (obesity) co-exists with low muscle mass (sarcopenia), are clinical relevant phenotypes, data on their prevalence and impact on bone mineral status in renal transplant recipients (RTR) are currently lacking.

Methods: To investigate the prevalence of sarcopenia and obesity after renal transplantation and their impact on bone mineral density, we conducted during a 48 months period a cross sectional analysis in 78 male RTR with a stable renal function (eGFR>30 ml/min). Body composition and bone mineral density were evaluated by dual X-ray absorptiometry (DXA). Obesity was defined as percentage of whole body fat mass >27% and sarcopenia as appendicular skeletal muscle mass ≤7.26 kg/m2.

Results: The prevalence rates of sarcopenia and obesity in our cohort were 28% (22/78), and 51% (40/78), respectively. Sarcopenic obesity was present in 15% (12/78) of RTR. Those classified as SO had similar clinical (age, months after transplantation, BMI, glucocorticosteroid doses, rejection episodes) and biochemical (eGFR, serum intact parathyroid hormone and 25-hydroxyvitamin D levels) profiles when compared to non-sarcopenic RTR. Bone mineral density was significantly lower at any measured skeletal site in SO (mean ± SD lumbar spine: 1.030 ± 0.168 g/cm^2, femoral neck: 0.764 ± 0.125 g/cm^2 and proximal femur: 0.916 ± 162 g/cm^2) compared to non- sarcopenic RTR (lumbar spine: 0.930 ± 0.142 g/cm^2 p=0.03, femoral neck: 0.645 ± 0.137 g/cm^2, p=002 and proximal femur: 0.790 ± 0.154, p=0.008).

Conclusions: Obesity and sarcopenia are highly prevalent after renal transplantation and may potentiate each other, thus maximizing their deleterious effects on skeletal health.

TH-PO1068

Immunization Status of HIV Positive Patients on Kidney Transplant List: A Single Center Experience Purna Bindu Nandigam,[1] Talal A. Khan,[1] Ankit Parikh,[2] Amit A. Deshpande,[1] Akshay Sharma,[1] Karthik M. Ranganna,[1] Dong Heun Lee,[2] Alden Michael Doyle.[1] *[1]Div of Nephrology, Drexel Univ, Philadelphia, PA; [2]Div of Infectious Disease, Drexel Univ, Philadelphia, PA.*

Background: Immunizations are a key component of transplant care, as patients who are immunosuppressed are at heightened risk for infectious diseases. The best time to vaccinate is prior to transplantation as the response rates are higher before the

immunosuppressive medications have been added. Although the recommendations are clear, rates of immunization for transplant recipients have remained stubbornly below target. We sought to examine the rates of vaccination of an especially at-risk population, HIV+ patients who have been waitlisted for kidney transplantation in order to begin to develop a plan to boost pre-transplant immunity rates.

Methods: We retrospectively reviewed charts of 52 HIV+ ESKD patients who were waitlisted for kidney transplant. We recorded their immunization status including flu, pneumonia, Tdap and hepatitis B vaccination.

Results: The mean age of our cohort was 49 years old with 39/52 males, 40/52 Black, 8/52 White, 4/52 Hispanic. Patients had serologic evidence of exposure to EBV (41/52) and CMV (42/52). HIV was generally well-controlled, with 50/52 patients with CD4 counts over 200, 38/52 had undetectable viral loads. HCV co-infection was present in 4/52 patients. The vaccination rates of our patients are shown below:

Number of Patients	Flu vaccine administered	Pneumonia vaccine administered	Tdap vaccine administered	Hepatitis Bs Ab +
52	23/52(44.2%)	26/52(50%)	15/52(28.8%)	37/52(71.15%)

Conclusions: We found a relatively low rate of vaccination in HIV+ patients wait listed for kidney transplant. We surmise that we would find as low or lower rates of vaccination for HIV- populations who did not have an infectious disease provider. At our center we are developing educational and outreach programs to target wait listed patients so that patients that are called for organ offers have been immunized as completely as possible and have been educated about the central role that vaccines play in transplant care.

TH-PO1069

The Effects of Thyroid Function on Clinical Outcomes after Kidney Transplantation Jung Nam An,[1] Yun Kyu Oh,[1] Su-Kil Park,[2] Chun Soo Lim,[1] Jung Pyo Lee.[1] *[1]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Asan Medical Center and Univ of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: The abnormalities in thyroid function, especially triiodothyronine (T3) levels, are observed in patients with chronic kidney disease and end stage renal disease. Few previous studies evaluated the correlation between thyroid function after kidney transplantation and various clinical outcomes, in particular, in Asian patients.

Methods: During the period of January 1997 to January 2012, the data about a total of 400 kidney transplantation recipients who had thyroid function test measured within 5 years after kidney transplantation was analyzed through the retrospective review of electronic medical records of two medical centers.

Results: Posttransplant thyroid-stimulating hormone (TSH) level was 1.9 ± 4.2 μIU/mL, free thyroxin (fT4) level was 1.3 ± 0.4 ng/dL, and T3 level was 112.4 ± 34.1 ng/mL. After follow up duration of 77.3 ± 53.0 months, 41 patients (10.3%) were diagnosed allograft failure. In cox-regression analysis model, posttransplant T3 level was negatively correlated with graft failure (hazard ratio [HR] 0.98; 95% confidence interval [CI] 0.97-0.99; $P = 0.001$), however, posttransplant TSH and fT4 level were not associated. Divided to four groups of T3 level, the risk for development of graft failure was the highest in the lowest group of T3 level (HR 6.90; 95% CI 1.45-32.85; $P = 0.015$). After adjusting other risk factors for graft failure, posttransplant T3 level was also significantly associated with kidney allograft failure. In Kaplan-Meier curves, in patients with lower T3 level had the higher risk for allograft failure (Log Rank $P = 0.037$).

Conclusions: Triiodothyronine level measured after kidney transplantation is an independent risk factor for allograft failure. Regular measurement and monitoring of thyroid function test should be the critical focus of post-transplant care.

TH-PO1070

Incidence of CMV (Cytomegalovirus) Viremia in High Risk Kidney Transplant Recipients Induced with Alemtuzumab. A Single Center Experience Pradeep Vaitla,[1] Ushma Patel,[2] Catherine G. Staffeld-Coit,[1] Ryan C. Mascarenhas,[1] Antonio G. Jimenez,[1] Stephanie Anders,[2] George E. Loss,[3] Ari J. Cohen,[3] Abdul Moiz,[1] Jorge C. Garces,[1] Humberto Bohorquez.[3] *[1]Nephrology, Ochsner Clinic Foundation; [2]Pharmacy, Ochsner Clinic Foundation; [3]Transplant Surgery, Ochsner Clinic Foundation.*

Background: It is still a matter of debate the risk of CMV infection in recipients receiving induction therapy with T-cell depleting versus other agents.

Methods: We performed a retrospective review of electronic medical records from November 2007 to December 2011. A total of 441 kidney transplants were performed during that period. Three hundred and eleven were induced with Alemtuzumab 30 mg IV single dose. Patients also received Methylprednisolone 500, 250 and 125 post-operative days 0, 1 and 2, they were maintained on Tacrolimus (target level 7-10 ng/ml) and Mycophenolate mofetil 500 mg oral twice daily. They received Valgancyclovir (VGC) prophylaxis. Our protocol dictates to use VGC for 180 days for high risk recipients (D+R-) and 90 days for everybody else.

Results: Fifty three patients were considered high risk (D+/R-) for CMV infection and 258 low risk. Among the patients induced with Alemtuzumab 18 patients developed CMV viremia (5.78%), 9 in the high risk (16.9%) and 9 in the low risk group (3.48%).

Conclusions: After a median follow-up of 12 months Alemtuzumab showed a better risk profile for the development of CMV infection compared with data from recent literature using induction therapy with ant-thymocyte globulin reporting rates as high as 24% in high risk groups compared with 16.9% in our cohort.Alemtuzumab seems to be safe in this particular population however long-term data and randomized controlled studies are needed.

TH-PO1071

BK Nephropathy in Kidney Transplant Recipients Induced with Alemtuzumab. A Single Centre Experience Pradeep Vaitla,[1] Ushma Patel,[2] Ryan C. Mascarenhas,[1] Antonio G. Jimenez,[1] Abdul Moiz,[1] George E. Loss,[3] Stephanie Anders,[2] Catherine G. Staffeld-Coit,[1] Ari J. Cohen,[3] Jorge C. Garces,[1] Humberto Bohorquez.[3] *[1]Nephrology, Ochsner Clinic Foundation; [2]Pharmacy, Ochsner Clinic Foundation; [3]Transplant Surgery, Ochsner Clinic Foundation.*

Background: BK nephropathy is increasingly identified as a cause of kidney injury and graft failure. Current literature suggests, higher dose of immunosuppression is associated with increased incidence of BK viruria, viremia and nephropathy. Most transplant centers across the country use antibody induction with rabbit antithymocyte globulin or Alemtuzumab to minimize maintenance immunosuppression. Our current protocol for immunosuppression includes single dose of Alemtuzumab 30 mg, Tacrolimus to achieve serum trough level 7-10 ng/ml, Mycophenolate mofetil (MMF) 500 mg oral twice daily, methylprednisolone 500 mg post opertive day(POD) 0, 250 mg POD 1 and 125 mg POD 2 with rapid steroid withdrawal.

Methods: We performed a retrospective chart review of 441 kidney transplants performed from November 2007 to December 2011 of which 311 recipients received Alemtuzumab for induction immunosuppression and we obtained demographic, laboratory and clinical data including biopsy proven acute rejection during one year of follow up. Our current protocol includes screening with PCR for BK virus in urine at 3,6,9,12,18 and 24 months post transplant. A BK viral load >10 million copies/ml is an indication for serum BK PCR every 2 weeks and a possible kidney biopsy.

Results: The incidence of BK viruria was 29% (90 out of 311 recipients), incidence of BK viremia was 9% (9 of 311) and incidence of BK nephropathy was 0.9% (3 of 311). For the entire cohort the incidence rate of biopsy proven rejection rate was 8% and graft survival rate was 99% at the end of 1 year. No allografts were lost due to BK nephropathy during the follow up period.

Conclusions: Induction therapy with Alemtuzumab in renal transplant recipients, combined with screening protocol with BK virus PCR is effective and has a low incidence of BK nephropathy compared with other protocols reported in the transplant literature.

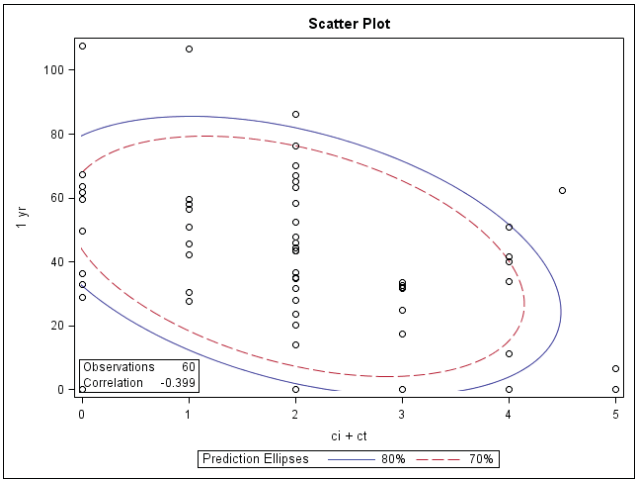
TH-PO1072

The Correlation between eGFR with Degree of Allograft Histological Changes in HIV + Kidney Transplants Recipients Amit A. Deshpande, Disha Narula, Alden Michael Doyle, Gregory Malat, PharmD. *Drexel Univ.*

Background: Hahnemann University Hospital Kidney Transplant Program has performed over 100 HIV (+) kidney transplants. Allograft biopsies were performed as needed and per protocol. These biopsies were analyzed as a tool for establishing an association between eGFR and degree of Interstitial Fibrosis and Tubular Atrophy.

Methods: 62 HIV+ kidney transplant recipients had allograft biopsies approximately 1 year post-transplant. This cohort was further stratified according to 1 yr eGFRs; eGFR> 40ml/min (group1) and eGFR<40ml/min (group2). Biopsies reported no IFTA, mild IFTA, and moderate/severe IFTA. Demographics were compared between the groups. Results analyzed correlation between eGFRs at 1 year and the degree of IFTA.

Results: Please See Scatter Plot for results.



Conclusions: Preliminary results indicate that moderate to severe interstitial fibrosis and tubular atrophy can be present even in groups with higher eGFRs in the HIV (+) kidney transplant recipients. This demonstrates the need for biopsies in this population to determine graft survival rather than relying on eGFRs.

TH-PO1073

Urinary Exosomal mRNA Analysis for Non-Invasive Diagnosis of Post Kidney Transplant Complications Taku Murakami,[1] Masato Mitsuhashi,[1] Hiroshi Harada.[2] *[1]Hitachi Chemical Research Center, Inc., Irvine, CA; [2]Sapporo City General Hospital, Sapporo, Hokkaido, Japan.*

Background: Monitoring of post-transplant kidney condition is important for the management of long term graft survival. Conventional urinary markers are not sensitive and specific, and kidney biopsy is invasive. Exosomes and microvesicles (EMV) are released into the urinary space from all the areas of the nephrons by encapsulating the functional cytoplasmic molecules of the cell of origin. To evaluate the diagnostic values of EMV, we analyzed EMV mRNA profiles of urine samples from kidney transplant patients.

Methods: Urine samples were collected from post-transplant patients (N=225). Post-transplant complications were diagnosed based on eGFR, urinary protein and kidney biopsy with Banff criteria. After urinary cells and casts were removed by low speed centrifugation, urine supernatants containing EMV were applied to EMV collection tubes (Hitachi Chemical Research Center, Inc. (HCR)), followed by mRNA isolation and cDNA synthesis using oligo(dT)-immobilized microplate (HCR) and real-time PCR. The obtained mRNA data were analyzed based on the diagnosis of post-transplant complications and Banff codes of kidney biopsy.

Results: Among 68 mRNAs we analyzed, several mRNAs including CCL2, DEFA3 and SLC12A3 were down regulated in both T-cell mediated rejection (TCMR) (N=5) and antibody-mediated rejection patients (ABMR) (N=12) comparing to those with stable recovery (N=165). Specifically to TCMR patients, several mRNAs such as AQP1, CCL4, GMFG, IL1B and CXCL10, were differentially expressed. Logistic regression analysis suggested that combinations of 3 to 4 genes including the above genes diagnose TCMR with 100% sensitivity and >95% specificity, and ABMR with >75% sensitivity and >85% specificity.

Conclusions: We analyzed urinary EMV mRNA from kidney transplant patients. We discovered differentially expressed genes in TCMR and ABMR patients comparing to those with stable recovery. We further developed preliminary diagnostic formulas to identify these complications using logistic regression analysis. Such formula will be a candidate of future diagnostics of TCMR and ABMR where only invasive kidney biopsy is available.

TH-PO1074

Use of Urine Biomarkers to Predict Favorable Kidney Allograft Histology Wisit Cheungpasitporn, John C. Lieske, Fernando G. Cosio, Hatem Amer. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Allografts with minimal fibrosis and without inflammation on protocol (surveillance) biopsies have a good prognosis. This study evaluated the ability of a panel of specific urinary proteins that reflect different pathophysiologic processes to identify allografts with favorable histology, in order to reduce the need for surveillance biopsies.

Methods: Urine samples of 391 KTx patients were biobanked beween 2005 and 2009 at the time of allograft biopsy. Patients with urine total protein (tP) to creatinine (Cr) ratio greater than 1 g/g were excluded (n=14). Urinary α1microglobulin (α1m), retinol binding protein (RBP), neutrophil gelatinase-associated lipocalin (NGAL), Immunoglobulin (Ig) G, IgM, albumin (A), and tP, were measured and normalized to Cr concentration. Acute tubulointerstitial, chronic tubulointerstitial, and acute and chronic glomerular damages were graded using combined tubular + interstitial (t+i), chronic tubular + chronic interstitial (ct+ci), and acute glomerular + chronic glomerular (g+cg) scores, respectively. Favorable allograft biopsies were defined as no inflammation (t+i scores=0), minimal fibrosis (both ct and ci scores<2) and no glomerular findings (no glomerulonephritis and g+cg=0).

Results: Correlations(r) between urine biomarkers and combined severity scores are summarized in the Table.

Combined scores	Log NGAL/ Cr	Log IgM/ Cr	Log α1M/ Cr	Log IgG/ Cr	Log RBP/ Cr	Log A/ Cr	Log tP/ Cr
t+i scores	0.12	0.27	0.21	0.17	0.24	0.23	0.22
ct+ci scores	0.01	0.26	0.12	0.18	0.21	0.28	0.28
g+cg scores	0.01	0.14	0.17	0.26	0.20	0.34	0.36

Favorable biopsy findings were present in 239 biopsies. The best-fit parsimonious model employed IgM, α1m and A with an AUC of 0.71. A score>1.03 predicted a favorable allograft biopsy with 27% sensitivity and 95% specificity, potentially eliminating the need for 64 of 368 biopsies (17%).

Conclusions: RBP and IgM are good indicators of acute and chronic tubulointerstitial injury, whereas albumin correlates better with glomerular injury. A pattern of urinary protein excretion predicts favorable renal allograft histology, and could potentially be used to eliminate the need for nearly 20% of allograft biopsies.

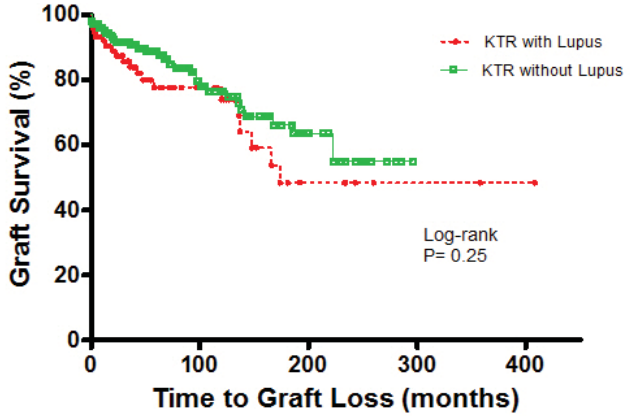
TH-PO1075

Kidney Graft Survival in Lupus Nephritis: A Mexican Cohort with 25 Years of Follow-Up Hugo Enrique Chavez,[1] Michael P. Wagner,[2] Olynka Vega,[1] Juan Carlos Ramirez-Sandoval,[1] Ricardo Correa-Rotter.[1] *[1]Nephrology and Mineral Metabolism, Inst Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [2]Univ of Minnesota, Minneapolis, MN.*

Background: Long-term graft survival of kidney transplant recipients (KTR) with end-stage kidney disease due to lupus nephritis (LN) is still controversial. Our aim was to evaluate the 25 years follow-up survival of KTR with LN compared with paired controls in a single center cohort in Mexico.

Methods: We performed a retrospective case-control study in which we analyzed KTR with diagnosis and biopsy proven LN (cases). To compare overall-survival, graft survival (serum creatinine>5mg/dl or dialysis), and time elapsed between transplant surgery and first immunological rejection, we paired these patients with non LN KTR (controls, 1:2) matched by age, sex, immunosuppressive treatment, HLA matches, transplant period, and immunosuppressive treatment.

Results: We identified 74 cases, 61 were female (82 %), mean age 32 years (± 10.2), 49 grafts were obtained from a living related donor (66%), of which 11 had 0-HLA matches. The 148 controls were paired as described. Graft loss occurred in 20 cases (28%) and 32 controls (22%). The mean graft survival time was 246 months (95% confidence interval [CI] 189-303) in cases and 214 months (95% CI 191-238) in controls. There were no differences between both groups for graft survival (log Rank test p=0.25) and overall-survival (p=0.31).



Similarly, there were no differences between the mean time elapsed from transplant surgery to first episode of immunological rejection (141 months [95% CI 89-194] versus 146 months [95% CI 120 -171], Log-Rank Test p=0.18). Only six cases had biopsy-proven lupus nephritis recurrence.

Conclusions: KTR with LN had a long-term overall survival, graft survival, and immunological risk similar to KTR matched by confounding factors.

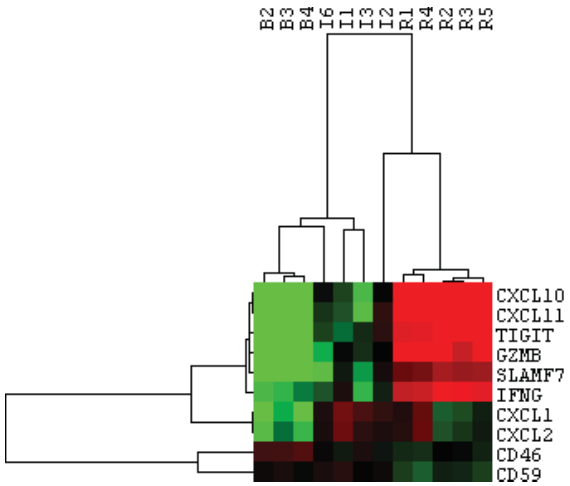
TH-PO1076

Gene Expression Patterns May Help in the Differential Diagnosis of Acute Rejection and Acute Pyelonephritis in Renal Allograft Biopsies Anjali A. Satoskar, Steve Oghumu, Uday S. Nori, Cherri N. Bott, Gyongyi Nadasdy, Sergey V. Brodsky, Ronald Pelletier, Tibor Nadasdy. *Ohio State Univ Wexner Medical Center, Columbus, OH.*

Background: Differentiating between acute rejection (AR) and acute pyelonephritis (APN) on renal allograft biopsies can be challenging, since both show mixed tubulointerstitial inflammation and urine culture results because of long-term prophylaxis with sulfa antibiotics. Our aim was to look for differences ivariable n gene expression between AR and APN using biopsy tissue.

Methods: Gene expression profiling was performed using Nanostring assay (total 513 genes) on a training set of 12 allograft biopsies (3 baselines, 4 unequivocal APN and 5 AR). Ten selected genes were validated using real-time PCR. A test set with 15 biopsies (2 baselines, 11 APN by histology and 2 AR), were studied for the same ten genes by PCR.

Results: Gene expression pattern in APN appears to be intermediate between normal and AR biopsies. AR shows profound upregulation of inflammation-related genes compared to APN and normal kidney. Differential expression of selected CXC-chemokine transcripts was seen. Significant upregulation of CXCL10 and CXCL11 but low CXCL1 and CXCL2 was seen in all AR biopsies (R in fig). Opposite pattern (low CXCL10 and CXCL11, comparable or lower than CXCL1 and CXCL2) was seen in the 4 unequivocal APN biopsies (I in fig) in the training set.



In the test set, 5/11 APN biopsies showed this profile, 5/11 APN biopsies showed AR pattern and 1/11 was indeterminate. In the test set 6/11 APN cases, had negative concomitant urine cultures and 4 of these improved after steroids.

Conclusions: Histologic features of APN in renal transplant biopsies may not be specific. Some cases may actually represent AR or a combination of APN and AR and steroid treatment may be helpful in selected cases. Chemokine profiling may help better design treatment.

TH-PO1077

Carotid Intima-Media Thickness of Pediatric Kidney Transplant Recipients

Kristen Sgambat, Sarah Clauss, Margaret Lasota, Asha Moudgil. *Children's National, Washington DC.*

Background: Increased carotid intima-media thickness (CIMT) is a known predictor of increased cardiovascular (CV) risk in adults, but there are limited data in pediatric kidney transplant (Tx) recipients. A prospective controlled study was conducted to investigate CIMT of lean and obese children in a predominantly African American (AA) pediatric kidney Tx cohort compared to healthy controls as well as change in CIMT over time after Tx.

Methods: Pediatric Tx recipients had the following parameters measured at baseline, 18, and 30 months post tx: CIMT, fasting glucose, HDL, triglycerides (TG), HbA1c%, waist circumference percentile (WC), and blood pressure (BP). CIMT was measured using B-Mode ultrasound imaging of right and left common carotid arteries and carotid bulbs. Tx children with metabolic syndrome (MS) were identified as those meeting ≥ 3 of the following criteria: HbA1c%>5.6 or fasting glucose>100, BP>90th percentile, central obesity (WC≥95th percentile), HDL <5th percentile, TG > 95th percentile. CIMT of Tx recipients were compared to 24 healthy pediatric controls using Wilcoxon ranksum analysis.

Results: Study group was comprised of 28 pediatric kidney Tx recipients (8 obese, 20 lean), mean age 13.1±0.75 years, 59.2% AA. Controls were 24 healthy children of similar age and race. CIMT of Tx was greater compared to healthy controls (0.47±0.002 versus 0.46±0.001, p=0.05). CIMT of AA Tx was greater than AA controls (0.49±0.002 versus 0.47±0.002, p=0.000). Mean CIMT of tx group improved over time from 0.47±0.002 mm at baseline to 0.46±0.002 mm at 18 months (p=0.01) and 0.44± 0.003 mm (p=0.000) at 30 months post-tx. Obese Tx had greater CIMT than lean Tx (0.48±0.004 versus 0.46±0.002, p=0.001). Tx with MS had greater CIMT than those without MS (0.49±0.004 versus 0.46±0.002 mm, p=0.000). AA Tx had greater CIMT compared to non-AA Tx (0.49±0.002 versus 0.43±0.001, p=0.000).

Conclusions: In conclusion, pediatric kidney Tx recipients carry increased CV risk, particularly those with MS, obesity, and AA race. This is the first study to demonstrate that AA have higher CIMT compared with non-AA pediatric Tx recipients. Further studies are needed to investigate strategies for decreasing CIMT after kidney Tx, particularly in the higher risk groups.

TH-PO1078

Impact of Tonsillectomy on Recurrent IgA Nephropathy after Kidney Transplant Recipients Based on Protocol Biopsy

Ken Sakai, Yasushi Ohashi, Toshiyuki Aoki, Reibin Tai, Nobuhiko Joki, Seiichirou Shishido, Atsushi Aikawa. *Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan.*

Background: Recurrent nephritis leads to graft-loss. Recently, tonsillectomy and additional steroid pulse therapy has been established as therapeutic option for primary IgA nephropathy (IgAN), but therapy for recurrence of IgAN is yet to be established.

Methods: Since 1984, kidney transplantation was performed 697 patients at our institution. Among those patients, 23 (24%) were diagnosed as recurrent IgAN in 96 recipients with IgAN confirmed as primary nephropathy. Recurrent IgAN was defined as newly appearance of urinary findings with histologic IgA deposition, but carried-in IgAN has been eliminated. Among 23 recurrent IgAN, 12 recipients (32.8 ± 9.4 yrs. at transplantation) who could follow up more than 5 years were enrolled and divided into 2 groups: with tonsillectomy (n=5) and without (n=7). After showing therapeutic option of tonsillectomy, we performed it in only the obtained agreement. Protocol biopsy was evaluated by Banff 2007 and Oxford classification. Usual immunosuppressive therapy has continued with ARB/ACE-I since diagnosis of recurrent IgAN.

Results: During the study period (117.4 ± 29.5 months), in no tonsillectomy group, the proteinuria at recurrence was 0.07 ± 0.19 g/gCr, and was significantly increased to 0.97 ± 1.09 at 60 months after recurrence (p=0.043). But in tonsillectomy group, proteinuria did not change (0.33 ± 0.52 to 0.40 ± 0.53, p= 0.87). eGFR decreased as follow: tonsillectomy group, 47.7 ± 14.6 ml/min/1.73m^2 to 34.8 ± 12.2 (p=0.11); no tonsillectomy group, 39.1 ± 5.8 to 30.4 ± 10.2 (p=0.03). Tonsillectomy group did not show any histopathological alteration. However, in no tonsillectomy group, mesangial matrix (mm) increased from 0.14 ± 0.38 to 2.14 ± 0.69 (p=0.002), mesangial hypercellularity (MS) increased from 0.20 ± 0.36 to 0.69 ± 0.37 (p=0.003), and segmental glomerulosclerosis (SS) increased from 0 to 0.57 ± 0.54 (p=0.03). The pathological rejection except borderline changes was absent in both.

Conclusions: While the natural history of recurrent IgAN remained stable with less amount of proteinuria in both groups (<1g/day), tonsillectomy protected from the histological damage.

TH-PO1079

Type 2 Diabetes Patients on Renal Replacement Therapy: Probability to Receive Renal Transplantation and Survival after Transplantation

Marjo Helena Kervinen,[1] Seppo Lehto,[2] Jaakko Helve,[3,4] Carola Gronhagen-Riska,[3,4] Patrik Finne.[3,4] *[1]Dept of Internal Medicine, Kuopio Univ Hospital, Kuopio, Finland; [2]Varkaus Hospital, Varkaus, Finland; [3]Finnish Registry for Kidney Diseases, Finnish Registry for Kidney Diseases, Helsinki, Finland; [4]Dept of Medicine, Div of Nephrology, Helsinki Univ Central Hospital, Helsinki, Finland.*

Background: Type 2 diabetes (T2DM) patients on renal replacement therapy (RRT) seldom receive a kidney transplant, which is partly due to age and comorbidities. Adjusting for case mix, we investigated whether T2DM patients have equal opportunity for renal transplantation compared to other patients on dialysis, and whether survival after transplantation is comparable.

Methods: Patients who entered RRT in Finland in 2000-2010 (n=5314) were identified from the Finnish Registry for Kidney Diseases. Of these, 20% had T2DM, 14% type 1 diabetes (T1DM) and 66% other than diabetes as cause of ESRD. Univariate and multivariate survival analysis techniques were employed to assess probability of kidney transplantation after start of dialysis and survival after transplantation.

Results: T2DM patients had a relative probability of renal transplantation of 0.16 (95% CI 0.13-0.21, P<0.001) compared to T1DM patients, this increased to 0.48 (95% CI 0.33-0.71, P<0.001) after adjustment for case mix (age, gender, laboratory values and comorbidities). When T2DM patients were compared to other than diabetes patients, the corresponding relative probabilities were 0.22 (95% CI 0.18-0.28, P<0.001) and 0.53 (95% CI 0.36-0.77, P<0.001). The risk of death within five years from transplantation was 12% (95% CI 5-19%) for T2DM, 10% (7-13%) for T1DM and 6% (5-8%) for other patients. After adjustment for age and gender, relative risk of death was 1.42 (95% CI 0.81-2.50) for T1DM patients and 0.62 (0.37-1.03) for other patients compared to T2DM patients.

Conclusions: T2DM patients had a considerably lower probability of receiving a kidney transplant, which could not be fully explained by differences in the patient characteristics studied. Survival after transplantation is comparably good in T2DM patients. This should encourage procedures to make kidney transplantation better available in this patient group.

TH-PO1080

Fludrocortisone Use in Tacrolimus Induced Hyperkalemia: A Pilot Study

Pavan K. Annamaraju,[1,2] Megan Mescher,[1,2] Siegmund Teichman,[1] Navin Jaipaul.[2] *[1]Nephrology Section, Loma Linda Univ; [2]VA Medical Center, Loma Linda, CA.*

Background: Tacrolimus (FK-506) induced hyperkalemia is a serious concern among renal transplant patients. FK-506 induced hypoaldosteronism and mineralocorticoid receptor downregulation are implicated mechanisms. The utility of fludrocortisone, a mineralocorticoid, in the treatment (tx) of FK-506 induced hyperkalemia is unclear.

Methods: We collected data on our single center retrospective cohort by chart review. We defined hyperkalemia as K≥5meq/dl. K level on day 0 (pre tx) and day 90 (post tx) of fludrocortisone were compared. Exclusion criteria: ACEi, ARB, or ß blocker use; kayexalate use; fasting glucose≥ 300mg/dl; serum TCO_2 ≤15meq/dl; and biopsy-proven rejection or acute kidney injury. Paired T-test or Wilcoxon rank sum test was used to compare quantitative variables pre and post tx. Analyses were performed using SAS, v.9.3.

Results: The mean age of the study population (N=25) was 55±10.5 years, predominantly men (80%) and hispanic (47.6%) and white (33.3%) race. Serum K, creatinine (Cr), TCo_2, sodium (Na), weight, and blood pressure (BP) changed significantly pre and post tx with fludrocortisone (table1). The decrease in serum K remained significant after adjustment for Cr, TCo_2, Na, weight, and BP (p<0.001).
Paired Analysis

		PRE TX	POST TX	
	N	**Mean ± SD**	**Mean ± SD**	**P- Value**
Weight Kg	15	71.4 ± 12.3	74.4 ± 12.1	0.001*
SBP mmHg	15	129.7 ± 21.0	140.5 ± 18.3	0.045
DBP mmHg	14	72.9 ± 17.7	84.9 ± 27.5	0.048**
Na meq/L	21	138.9 ± 5.1	141.5 ± 6.1	0.008**
K meq/L	21	5.9 ± 0.5	4.8 ± 0.5	< 0.001
TCO2 meq/L	21	20.7 ± 2.7	24.0 ± 2.8	< 0.001
Cr mg/dl	21	2.2 ± 2.3	1.29 ± 0.24	< 0.001**
Glucose mg/dl	20	126.2 ± 75.6	118.6 ± 57.2	0.709**
Mg mmol/dl	17	0.9 ± 0.1	0.8 ± 0.1	0.062**
FK trough	20	11.3 ± 4.5	9.5 ± 3.1	0.131

*p-value for Paired T test,
**p-value for Wilcoxon rank sum test

Conclusions: Fludrocortisone significantly reduced FK-506 induced hyperkalemia, independent of renal function and metabolic acidosis in our study. A modest but significant rise is serum Na, weight, and BP was also observed. Larger studies are needed to confirm these findings.

TH-PO1081

Mechano-Growth Factor and VEGF Expression Are Increased in Glomeruli of Chronic Allograft Rejection Kidneys, and via GLUT1 May Promote Glomerulosclerosis

Zaid Brifkani,[1] Raafat Farag Makary,[1] Yongxin Gao,[1] Carmela B. Monteiro,[1] N. Stanley Nahman,[2] Charles W. Heilig.[1] *[1]Medicine, Univ of Florida College of Medicine - Jacksonville, Jacksonville, FL; [2]Medicine, Georgia Regents Univ, Augusta, GA.*

Background: Our previous work in human Chronic Allograft Rejection (CAR) identified increased GLUT1 glucose transporter expression in CAR glomeruli and renal tubules. Excess GLUT1 increases cellular glucose uptake, metabolism, and in mesangial cells (MC) leads to excessive extracellular matrix (ECM) production. Here we investigated potential regulators of GLUT1 in CAR glomeruli to better understand how the increase in GLUT1 develops.

Methods: All studies were approved by the IRB for the University of Florida. Deidentified, archived, formalin-fixed, paraffin embedded kidney samples of normal controls (n = 3 – 6) and CAR (n = 3 – 6) kidneys were cut in 5µm sections for examination and semiquantitation of Mechano-Growth Factor (MGF), PKCß1, TGFß1, and VEGF immunolabeling, scored 0 – 4+ and normalized to open tuft area. Immunohistochemistry for MGF in individual glomerular cell types and renal cortical tubules was noted as positive or negative. The Mean ± SD (and ± SEM) for each measurement was determined for statistical comparisons with P < .05 significant.

Results: PAS staining of NL and CAR kidneys revealed a 2.5-fold increase of matrix in CAR, P < .02. The increased MGF correlates with 6.8-fold higher glomerular GLUT1 we previously identified in CAR. In contrast, active-PKCß1 and TGFß1 did not increase in CAR. VEGF, a stimulus to MC GLUT1, was increased 3.3-fold in CAR glomeruli, P < .001. Glomerular cell types expressing MGF included podocytes, parietal epithelial cells, and MC, in both NL and CAR. MGF was also identified in cortical collecting ducts, and to a lesser extent proximal tubules, in NL and CAR.

Conclusions: 1. This is to our knowledge, the first report of MGF in human kidneys. 2. Glomerular MGF and VEGF, both GLUT1 inducers, were increased in CAR, with potential to facilitate glomerulosclerosis. 3. Neither active-PKCß1 nor TGFß1 contributed to CAR. 4. Future investigation should identify signaling pathways from MGF, VEGF and GLUT1 to excess ECM production in CAR.

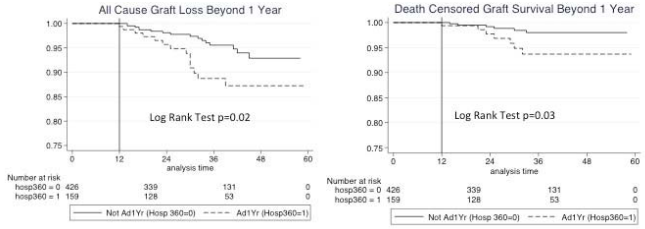
Post Kidney Transplant Re-Admissions between 30 and 365 Days

Angela Elizabeth Mcinerney, Patricia Geerdes, Terry Fettes, Randall Craig Walker, Fernando G. Cosio, Hatem Amer. *Wiliam J von Liebig Center For Transplantation and Clinical ReGeneration, Mayo Clinic, Rochester, MN.*

Background: In 2010 we established an ongoing quality assessment and practice improvement project (QAPI) monitoring early post kidney transplant readmissions for which there is scarcity of data regarding predictors, causes and effects. Previously we reported on admissions within 30 days (Ad30) from transplant. Here we focus on admissions from 30 to 365 days (Ad1yr).

Methods: We developed a working group that reviews all readmissions of solitary kidney transplant recipients to ascertain causes of readmissions within one year following kidney transplant surgery. Causes for readmission were grouped into 7 categories. We assessed the predictive ability of nine easily obtained and objective baseline characteristics on Ad1yr (Age, Gender, Race, Live Donor, Pre-emptive transplant, Re-transplant, BMI, diabetes, vitamin D levels).

Results: From 2009 through 2012, 607 patients received solitary kidney transplants at our institution. Mean age 52 (±14) years, 58% males, 90 % Caucasian, 83% living donor, 41% preemptive, 80% first transplants, 25% diabetic, with a mean BMI 28.5 (±5.9). 141 (23%) of patients were readmitted within 30 days and 166 (27%) experienced an admission between 30-365 days. Of the pre transplant characteristics only Age OR (p) 1.2 (0.01) per decade, BMI 1.04 (0.008) per unit, and diabetes 2.0 (0.001) predicted Ad1yr. Causes of Ad1yr were N (%): Surgical 65 (23) Allograft 50 (17), Cardiovascular 29(10), Fluids/Lytes 5 (2) GI 22(8), Infection 77(27), and Other 39 (14). Ad1yr portended worse graft survival HR (p) 2.3 (0.02) censored for death 3.1 (0.04) see Figure 1.



Conclusions: Re-admissions beyond 30 days and within one-year of transplant can be predicted, have varied causes and identify patients who could benefit from closer follow-up.

Early Hospital Re-Admission and Outcomes After Kidney Transplantation

Esther D. Kim, Olusegun Famure, Johnny Huang, Roman Zyla, Joseph Kim. *Div of Nephrology and the Kidney Transplant Program, Toronto General Hospital, Univ Health Network, Univ of Toronto, Toronto, Canada.*

Background: Early hospital re-admission (EHR) after kidney transplantation has been identified as a risk factor for subsequent hospitalizations, and increases graft failure and patient mortality. However, the associations between EHR, late hospital readmissions (LHRs), and graft outcomes remain unclear in the Canadian healthcare context.

Methods: This single-centre cohort study included 1,531 kidney transplant recipients from 1 Jul 2004 and 31 Dec 2012, with at least 1 year of follow-up. EHR was defined as hospitalization within 30 or 90 days post-discharge from the transplant admission. Recipient, donor, and transplant characteristics were measured at baseline. The primary outcomes were kidney function (using the CKD-EPI formula) at 1-year post-transplant, total graft failure (including death), and LHR (i.e., hospitalizations between 31 and 365 days [for 30-day EHR) or 91 to 365 days [for 90-day EHR) post-transplant). Multivariable linear regression models were used to assess kidney function while Cox proportional hazards models were used to examine EHR, LHR, and graft outcomes.

Results: EHRs at 30 days and 90 days were significantly associated with lower kidney function at 1 year post-transplant (β = -5.33 [95% CI: -8.23, -2.44], and β = -6.14 [95% CI: -8.69, -3.58], respectively). EHRs at 30 days and 90 days were also significantly associated with a greater risk of LHR (hazard ratio or HR 3.76 [95% CI: 2.66, 5.32], and HR 3.81 [95% CI: 2.64, 5.51], respectively). EHR was significantly associated with an increased risk of total graft failure (HR 1.57 [95% CI: 1.08, 2.30] at 30 days, and HR 1.91 [95% CI: 1.35, 2.70] at 90 days) and death-censored graft failure (HR 2.22 [95% CI: 1.31, 3.78] at 30 days, and HR 2.56 [95% CI: 1.55, 4.22] at 90 days). LHR was not associated with graft failure.

Conclusions: EHR is associated with adverse clinical outcomes for kidney transplant recipients. This reaffirms the need to develop and implement strategies to reduce EHR after kidney transplantation.

TH-PO1084

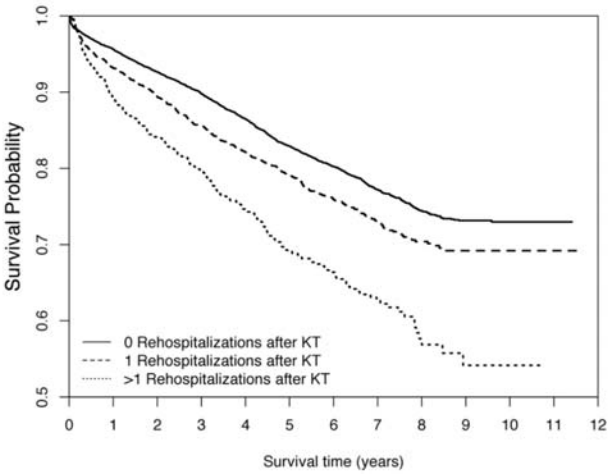
Distinct Predictors of Single versus Multiple Early Hospital Readmissions after Kidney Transplant

Meera Nair,[1] Wei Wang,[2] Alexander Stephen Hill,[2] Adam S. Mussell,[1] Roy D. Bloom,[1] Harold I. Feldman,[1] Peter P. Reese.[1] *[1]Medicine, Univ of Pennsylvania School of Medicine, Philadelphia, PA; [2]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Early hospital readmission (EHR) within 30 days of discharge after kidney transplant (KT) is a common and costly event with diverse causes. Many KT recipients are readmitted more than once within 30 days. Risk factors for 1 EHR after KT may be distinct from multiple EHRs.

Methods: We linked datasets from the Organ Procurement and Transplantation Network and Medicare and performed a retrospective cohort study of 10,483 adults on dialysis who received KT from 6/12/2000 – 6/13/2010. KT recipients were categorized as having 0, 1, or >1 EHRs. We fit a multinomial logistic regression model using 0 EHRs as the reference category.

Results: Median age was 50 years; 34% were black and 63% male. 2048 subjects (19.5%) experienced 1 EHR after KT while 624 subjects (6%) experienced >1 EHR (max=4). Compared to 0 EHRs, the following variables were associated with having either 1 or >1 EHRs: older age (>70 years), diabetes, more years on dialysis, greater number of hospitalizations in 12 months prior to KT, an expanded criteria kidney donor, and delayed graft function. Black race (OR 1.14, p=0.02) and long wait times (1.4, p=0.04) were independently associated with having 1 EHR, but not >1. Lower rates of survival at 5 years were associated with a greater number of EHRs after KT (0.83, 0.79, 0.69 for 0, 1, and >1 EHRs, respectively, p<0.0001).



Conclusions: Our results suggest that distinct patient attributes predict single versus multiple EHRs after KT. Recipients with multiple EHRs after KT have the highest risk of death. A single EHR after KT may be less indicative of medical complexity/complications than >1, and these differences warrant further investigation.

Funding: NIDDK Support

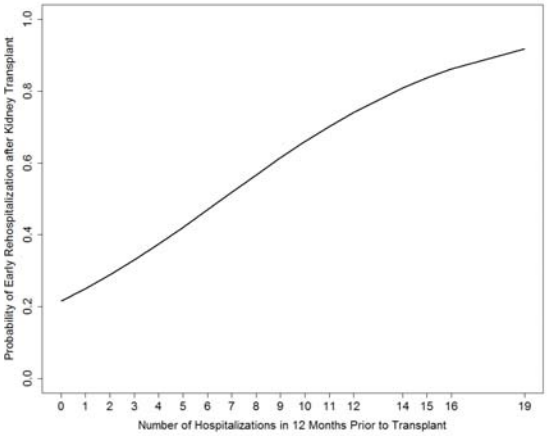
TH-PO1085

Pre-Transplant Hospitalizations Predict Early Hospital Readmission after Kidney Transplantation Meera Nair,[1] Alexander Stephen Hill,[2] Wei Wang,[2] Adam S. Mussell,[1] Roy D. Bloom,[1] Harold I. Feldman,[1] Peter P. Reese.[1] *[1]Renal Electrolyte & Hypertension Div, Univ of Pennsylvania School of Medicine, Philadelphia, PA; [2]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: While many patients awaiting kidney transplant (KT) have high rates of health care utilization, KT results in rapid changes in health status. The association of previous hospitalizations with early hospital readmission (EHR) within 30 days from discharge after KT is unknown.

Methods: We linked datasets from the Organ Procurement and Transplantation Network and Medicare and performed a retrospective cohort study of 10,483 adults on dialysis who received KT from 6/12/2000 – 6/13/2010. Our primary exposure was number of hospitalizations to an acute care facility in the 12 months prior to KT.

Results: Median age was 50 years; 34% were black and 62% male. 2672 KT recipients (25.4%) experienced EHR. Median time to EHR was 9 days (mean 11.1, SD 7.9). 5575 recipients (53.2%) had >1 hospitalization in the 12 months prior to KT (max=19). In multivariable adjusted analysis, number of prior hospitalizations was an independent predictor of EHR (OR=1.2 per hospitalization, p<0.001). Older recipients (age>70, OR=1.5, p=0.0003), those with prior KT (OR=1.2, p=0.01), greater years on dialysis (1.04 per year, p<0.0001), diabetes (OR=1.2, p=0.0001), and delayed graft function (OR=1.6, p<0.001) were also at increased risk of EHR. Adjusting for prior hospitalizations, EHR remained a predictor of mortality at 1 and 5 years post KT (OR=1.5, p < 0.0001 and OR=1.3, p<0.0001, respectively).



Conclusions: While KT improves health status and survival among patients with advanced chronic kidney disease, prior health care utilization is strongly associated with EHR after KT. Knowledge of prior hospitalizations can help clinicians risk stratify patients at the time of discharge from KT.

Funding: NIDDK Support

TH-PO1086

Early Hospital Readmission After Kidney Transplantation: Incidence, Causes, and Risk Factors Olusegun Famure, Esther D. Kim, Johnny Huang, Roman Zyla, Joseph Kim. *Kidney Transplant Program, Univ Health Network, Toronto, ON, Canada.*

Background: In the immediate post-transplant period, kidney transplant recipients are at an increased risk for a number of potentially serious medical or surgical complications that can result in early hospital readmission (EHR). Understanding the risk factors and causes of EHRs is essential to identifying strategies for reducing this burden of this problem for both patients and hospitals.

Methods: This single-centre cohort study included 1,531 kidney transplant recipients from 1 Jul 2004 and 31 Dec 2012, with at least 1 year of follow-up. EHR was defined as hospitalization within 30 or 90 days post-discharge from the transplant admission. Recipient, donor, and transplant characteristics were measured at baseline. Associations between these baseline characteristics and EHR within 30 days and 90 days post-transplant were determined using multivariable Cox proportional hazards model.

Results: The rates of EHR were 20.3% at 30 days, and 27.7% at 90 days post-transplant. The median times to the first EHR were 8 days and 13 days within 30 and 90 days post-transplant, respectively. Infectious complications were the most common reasons for EHR within 30 and 90 days post-transplant. Factors associated with EHR within 30 and 90 days in multivariable models were recipient history of peripheral vascular disease (hazard ratio or HR 2.16 [95% CI: 1.19, 3.91]), chronic lung disease (HR 1.98 [95% CI: 1.12, 3.5]), time on dialysis (HR 1.09 [95% CI: 1.01, 1.17]), and length of transplant hospitalization (HR 1.02 [95% CI: 1.00, 1.05]). Additional factors associated with EHR at 90 days after adjusting for baseline covariates were recipient history of cancer (HR 0.45 [95% CI: 0.21, 0.95]), and donor history of hypertension (HR 1.47 [95% CI: 1.01, 2.15]).

Conclusions: Early hospital re-admission is common after transplantation in Canadian kidney transplant recipients. The 30-day re-admission rate of 20.3% compares favourably to the 31% rate in the U.S. but strategies to reduce the burden of early hospital re-admissions is needed for all patients.

TH-PO1087

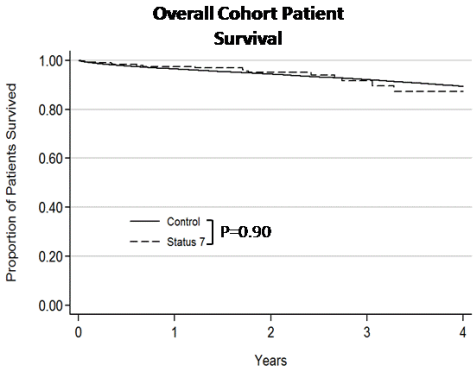
Pre-Transplant Weight Loss and Survival After Kidney Transplant Edmund Huang, Anake Yoosabai, Nattawat Klomjit, Suphamai Bunnapradist. *Nephrology, UCLA School of Medicine, Los Angeles, CA.*

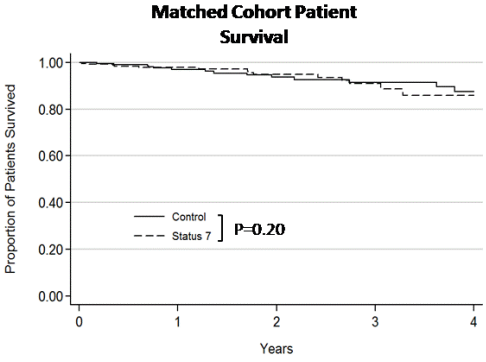
Background: We studied patient/graft survival of kidney transplant (txp) recipients who were once temporarily listed inactive (status 7) due to obesity and explored the impact of pre-txp weight loss on txp outcomes.

Methods: Adult kidney recipients from OPTN/UNOS registered with a BMI≥30 kg/m^2 from 2006-10 and designated status 7 due to a "weight inappropriate for txp" were included (n=328). Patient/graft survival were compared to a contemporaneous control of all other adult recipients (n=74,006). To assess if pre-txp weight loss associated with differences in outcomes, patient/graft survival were compared within status 7 stratified into quartiles of % BMI change while waitlisted. Status 7 recipients (n=257) were then 1:1 matched to controls on age, gender, diabetes, donor type, and list BMI for status 7 and txp BMI for controls.

Results: Median list and txp BMI for status 7 exceeded controls (38 versus 27 kg/m^2; 36 versus 27; p<0.001). Actuarial 4-year patient (status 7=87%;control=89%;p=0.90) and graft survival (status 7=83%;control=82%,p=0.75) did not differ. After multivariate analysis, status 7 was not associated with death (HR: 0.96, 0.59-1.57) or graft loss (0.95; 0.66-1.38). No difference in patient/graft survival was seen when status 7 was stratified into quartiles of % BMI change while waitlisted. In the matched cohort, median waitlist BMI change was greater for status 7 than controls (-1.6 versus 0.6 kg/m^2;p=0.001), but no difference in patient (status 7, 86%; control, 87%, p=0.20) and a slight increase in graft survival was seen (status 7, 82%; control, 79%,p=0.03).

Conclusions: Obese status 7 recipients had comparable survival to the overall kidney population. Pre-txp weight loss in obese kidney candidates had limited benefit on post-txp outcomes with no mortality benefit seen with greater weight loss and only a modest increase in graft survival when compared to matched controls.





TH-PO1088

Referral of Dialysis Patients for Transplant Based on Hypothetical Patient Scenarios Kevin C. Roe,[1] Ming Wang,[2] Surju Patel,[1] Ankita Tandon,[1] Nasrollah Ghahramani.[1] *[1]Medicine, Penn State College of Medicine, Hershey, PA; [2]Public Health Sciences, Penn State College of Medicine, Hershey, PA.*

Background: Compared to dialysis, kidney transplant (KT) is associated with expected improved quality of life and increase in expected life years. We analyzed the referral decisions of nephrologists to evaluate factors that influence KT in end-stage renal disease (ESRD) patients on dialysis.

Methods: In an online survey, 250 nephrologists were asked whether they would recommend kidney transplant for hypothetical patients who were already on dialysis. The 15 scenarios varied in age, race, sex, living situation (alone or with spouse), employment, and rural location.

Results: 214 nephrologists provided complete responses. In multivariate analysis, age <50 (OR:1.70; p<0.005) and living with spouse (p<0.01) were associated with higher likelihood of being recommended for KT; unemployment (OR:0.55;p=0.01) and rural location (OR:0.52;p=0.001) were associated with lower likelihood. Based on logistic regression, the following nephrologist-related variables were associated with higher likelihood of choosing KT for their patient: academic affiliation (OR:2.23;p=0.04), attending 4 or more national nephrology meetings (OR: 4.62; p<0.01), and a coordinator for workup of KT candidates (OR:3.21;p=0.05). Rural practice (p= 0.04), years from fellowship (p= 0.001), and fewer years practicing in the current location (p=0.02) were associated with lower likelihood of recommending KT.

Conclusions: Identifying factors that influence referral practices and educating physicians may improve KT distribution by acknowledging the ways in which location, patient living situations, patient age and physician education affect nephrologists' and ultimately patients' decisions to pursue transplant.

TH-PO1089

The Influence of Socioeconomic Deprivation on Allograft and Patient Survival following Kidney Transplantation Frank Ward,[1] Patrick O'kelly,[1] Fionnuala Donohue,[2] Coilín O. Oh Aiseadha,[2] Trutz Haase,[3] Jonathan Pratschke,[3] Declan G. de Freitas,[1] Howard Johnson,[2] Peter J. Conlon,[1] Conall M. O'Seaghdha.[1] *[1]Dept of Tranplantation and Renal Medicine, Beaumont Hospital, Dublin, Ireland; [2]Health Intelligence Unit, Health & Wellbeing Directorate, Health Service Executive, Dublin, Ireland; [3]Social and Economic Consultants, Health Service Executive, Dublin, Ireland.*

Background: Whether socioeconomic deprivation confers worse allograft or patient outcomes after kidney transplantation is not known. We examined its influence on allograft and patient survival following kidney transplantation in Ireland.

Methods: We identified all adult deceased donor first kidney transplant recipients from 1990 to 2009, inclusively. Those with a valid Irish postal address on record were assigned a deprivation score based on the Pobal Hasse-Pratschke deprivation index (2011). Cox proportional regression analysis and Kaplan Meier survival analysis by quartile were used to investigate any association of socioeconomic deprivation with allograft and patient survival.

Results: We identified 1,977 eligible kidney transplant recipients, with 33 subsequently excluded due an invalid/missing address. The median follow-up time was 8.2 years (interquartile range 4.4 – 13.3 years). Patient survival was not associated with deprivation score (HR 1.0, 95% CI 0.93-1.08, p=0.88). The deprivation score was not associated with reduced uncensored or death-censored allograft survival (HR 0.997, 95% CI 0.989-1.003, p=0.33 and HR 0.995, 95% CI 0.986-1.004, respectively), with no difference amongst quartiles in either uncensored or death-censored allograft survival at 5- and 10-years. The most deprived quartile had a longer duration of dialysis therapy before transplantation compared to the least deprived (22months versus 18months, p=0.02).

Conclusions: In a healthcare model affording free or subsidised medication and healthcare coverage for eligible patients, there was no disparity in allograft or patient outcomes following kidney transplantation based on socioeconomic status. This gives further impetus to calls in other jurisdictions for universal healthcare and medication coverage for kidney transplant recipients.

TH-PO1090

Reduction in Perioperative Antibiotic Exposure After Kidney Transplantation Leads to a Decrease in Urinary Tract Infections with Extended Spectrum Betalactamase-Producing Bacteria Anja Susanne Muehlfeld,[1] Felix Wenzel,[1] Jürgen Floege,[1] Simone Scheithauer.[2] *[1]Div of Nephrology, Uniklinik RWTH Aachen, Aachen, Germany; [2]Zentralinstitut für Krankenhaushygiene und Infektiologie, Universitätsmedizin Göttingen, Göttingen, Germany.*

Background: Because of the high incidence of urinary tract infections (UTI) after kidney transplantation, especially with multiresistent strains, we changed our perioperative protocol in November 2008 from a prophylactic antibiotic treatment with cefuroxime (mean 11.2±6.0 days) during the time of percutaneous urostomy (group 1) to preoperative single shot antibiotic administration and internal urinary stenting with a double J catheter (group 2).

Methods: We performed a retrospective cohort study in 183 consecutive patients who received a renal transplant at our center between 2006 and 2011. The incidence of UTI, the spectrum of pathogens as well as the antimicrobial sensitivities during the first year after kidney transplantation were recorded.

Results: The abandonment of prolonged antibiotic prophylaxis reduced the time of antibiotic treatment from 35±38 to 25±47 d/patient within the first year after kidney transplantation (p<0.001). Despite this, there was no increase in the incidence of UTI (2.1±2.0 UTI/patient in group 1 versus 1.9±2.7 UTI/patient in group 2) while the incidence of UTI with ESBL (extended spectrum betalactamase) producing bacteria fell from 48% of all UTI to 23% during the two time periods (p<0.001). This was in contrast to the general trend at our hospital where UTI with ESBL producing bacteria increased in the same time from 4 to 14 %. In addition, the bacterial spectrum changed with respect to more UTI with E. coli (33% in group 1 versus 43% in group 2; p<0.05) and fewer UTI with pseudomonas aeruginosa (19% versus 8%; p<0.05).

Conclusions: A reduction in perioperative antibiotic exposure did not increase the rate of UTI within the first year after kidney transplantation and rather reduced the incidence of UTI with ESBL producing bacteria. In addition, the spectrum of isolated bacteria changed to more cefuroxime sensitive E. coli and fewer cefuroxime resistant strains (pseudomonas).

TH-PO1091

Secular Trends in Cardiovascular Disease in Kidney Transplant Recipients: 1994 to 2009 Ngan Lam,[1] Kyla Lynn Naylor,[1] Eric Mcarthur,[2] Joseph Kim,[3] Greg A. Knoll,[4] Salimah Z. Shariff,[2] Amit X. Garg.[1,2] *[1]Western Univ; [2]Inst for Clinical Evaluative Sciences; [3]Univ of Toronto; [4]Univ of Ottawa.*

Background: Cardiovascular death remains the number one cause of mortality in kidney transplant recipients. Cardiovascular events alone are associated with significant morbidity.

Methods: We conducted a retrospective cohort study using Ontario's linked healthcare databases to follow all first-time kidney-only transplant recipients between 1994 to 2009. Our primary outcome was a composite of death or first major cardiovascular event defined as one of myocardial infarction, coronary angioplasty, coronary bypass surgery, or stroke within three years of the transplant date.

Results: There were 4954 first-time kidney-only transplant recipients during the study period, of which 63% were male. The median age steadily increased from 43 years (interquartile range [IQR] 33-54) in 1994 to 53 years (IQR 42-62) in 2009 as did the proportion of recipients aged 65 years old older (3.8% in 1994 to 20.4% in 2009). There was also an increase in the proportion of recipients with coronary artery disease (23.7% in 1994 to 37.7% in 2009) and diabetes (19.2% in 1994 to 29.9% in 2009). A total of 444 recipients (9.0%, 95% confidence interval 0.082 to 0.098; 3.15 events per 100 person-years) died or experienced a major cardiovascular event within three years of transplantation with no significant change over time (P=0.59).

Conclusions: Despite transplant centres accepting recipients who are older with more co-morbidities, the three-year incidence of death or major cardiovascular event has remained stable from 1994 to 2009. These results are reassuring for transplant programs.

TH-PO1092

Early Post-Operative Acute Myocardial Infarction in Kidney Transplant Recipients: Incidence, Risk Factors, and Outcomes Maya Deeb,[1,2] Christopher Brian Overgaard,[2] Yanhong Li,[1] Olusegun Famure,[1] Joseph Kim.[1,2] *[1]Multi-Organ Transplant Program, Toronto General Hospital, Toronto, ON, Canada; [2]Univ of Toronto, Toronto, ON, Canada.*

Background: The epidemiology of acute myocardial infarction early after kidney transplantation has not been well studied. We examined the incidence, risk factors, and outcomes of early post-operative acute myocardial infarction (EAMI) in a cohort of Canadian kidney transplant recipients.

Methods: A total of 1,464 patients who underwent kidney transplantation at our center from 1 Jan 2000 to 30 Sep 2012 (followed until 30 Sep 2013) were included. A nested case-control design was used to study EAMI risk factors with a conditional logistic regression model. EAMI cases (within 3 months post-transplant) were adjudicated by a single cardiologist using the consensus definition set by the American Heart Association. Each case was matched to 5 controls on follow-up time, transplant year, and donor type. To assess the association of EAMI with graft loss and/or death, a Cox proportional hazards model was fitted to the total study cohort.

Results: A total of 49 (3.3%) kidney transplant patients had an EAMI episode. Most cases occurred within 3 days post-transplant (61.2%). Recipient factors that predicted EAMI included older age (OR 1.06 [95% CI: 1.03, 1.09]), female sex (OR 0.36, [95% CI: 0.16, 0.79],) pre-transplant diabetes (OR 3.91 [95% CI: 2.05, 7.45]), history of cardiac disease (OR 8.70 [95% CI: 4.04, 18.73]), and smoking (OR 1.97 [95% CI: 1.02, 3.80]). History of cardiac disease (OR 5.11 [95% CI: 2.23, 11.73]) and longer duration of dialysis (OR 1.21 [95% CI: 1.07, 1.37]) independently predicted EAMI after multivariable adjustment. EAMI was associated with significantly elevated relative hazards for total graft failure (HR 2.12 [95% CI: 1.24, 3.64]) and death with graft function (HR 2.42 [95% CI: 2.42 [95% CI: 1.27, 4.62]), but not death-censored graft failure (HR 1.58 [95% CI: 0.61, 4.08]).

Conclusions: Patients with a cardiovascular history and longer duration of dialysis were at elevated risk of EAMI. While the incidence of EAMI in kidney transplant recipients is low, it is associated with a significant risk of graft failure (including death).

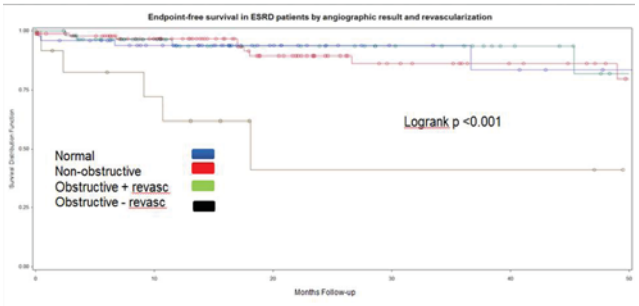
TH-PO1093

Cardiovascular Assessment in Pre-Renal Transplantation Candidates Eric M. Lindley,[1] Amanda K. Hall,[2] Jo Abraham.[2] *[1]Cardiovascular Medicine, Univ of Utah, Salt Lake City, UT; [2]Nephrology, Univ of Utah, Salt Lake City, UT.*

Background: There is lack of uniformity in the cardiovascular (CV) assessment of prospective kidney transplant recipients. In 2012, the American Heart Association (AHA) and the American College of Cardiology (ACC) issued a scientific statement, endorsed by the National Kidney Foundation, suggesting noninvasive stress testing for candidates who had 3 or more CV risk factors (age >60, diabetes, hypertension, dyslipidemia, >1 yr on dialysis, smoking, left ventricular hypertrophy, or known CV disease). However, many transplant programs take a more aggressive approach.

Methods: We conducted a historically prospective study evaluating the CV assessment, outcomes in a single center.

Results: Overall, 685 patients were evaluated. 472 candidates underwent some form of stress testing. 229 patients underwent coronary angiogram and 72 (31%) of those patients had obstructive coronary artery disease (CAD). Of the 72 patients, 10 were not revascularized. Patients who had normal coronaries, non-obstructive CAD, or CAD with intervention had significantly higher event free survival compared to patients with obstructive CAD without intervention.



The sensitivity of stress testing to detect obstructive CAD was (0.26). There were 338 patients transplanted in the follow-up period. In transplanted patients who had an angiogram (n=77), there were no clinic events (death, myocardial infarction (MI), stroke, urgent revascularization, graft failure) in the first 30 days post-transplant. Of transplanted patients who did not have an angiogram (n=289), there were 8 clinical events (6 MI's), in the first 30 days (p=0.15).

Conclusions: Our results indicate that stress testing in an ESRD population being evaluated for renal transplantation has a very poor sensitivity, and that none of the patients who had angiograms had a clinical event in the first 30 days post-operatively.

TH-PO1094

Cardiovascular Work Up for Kidney Transplantation Shuaib Ahmed Quraishi, Shankar Kumar, Hwee Jeon, Juan Carlos Kaski, Rajan Sharma, Debasish Banerjee. *Renal Dept, St. George's Healthcare NHS Trust, United Kingdom.*

Background: Cardiovascular (CV) event rates in CKD patients are high, during waiting, peri-operative and post-operative transplant periods. The aim of this study was to explore the value of pre-operative cardiac investigations to predict such events.

Methods: Data was collected retrospectively in 201 patients. The cardiac investigations were performed using a pre-specified protocol. The low risk patients had exercise treadmill testing (ETT) and echocardiogram. High risk patients (>60 y, diabetes, CAD) underwent dobutamine stress echocardiography (DSE). Patients underwent coronary angiogram (CA) if the ETT or DSE were positive or had angina. The patients were followed up from the time of the first cardiac testing to first event including ACS, stroke, CHF, PVD or death.

Results: The clinical characteristics were: age 54±12 years, BMI 28±5 kg/m^2, women 41%, diabetes 31%, hypertensive 92%, smokers 18% and dyslipidaemia 58%. During the follow up there were total of 45 events. 42 low risk patients performed ETT and 7 had positive test. 6 out of 7 with positive ETT had a dobutamine stress echocardiography (DSE) and 4/6 were negative. 2 patients with positive DSE had normal angiogram. The remaining 1 patient with abnormal ETT also had a normal angiogram. There was no significant difference in event rates between patients with abnormal ETT 0/7 and with normal ETT 3/32 (chi sq 5.17 p=1.00). 73 high risk patients underwent DSE. 18 patients with positive DSE had angiogram of which 7 were normal. The patients with abnormal DSE had higher rates of events, 7/19 compared to patients with normal DSE 7/54 (chi sq 5.17, p=0.039). 53 patients underwent CA and 31 were abnormal. 16 patients underwent coronary interventions. Patients with abnormal CA were more likely to be diabetics (24/31 versus 9/20; p=0.034). There was no statistically significant difference in event rates between patients with abnormal CA 6/22 and normal CA 16/31 (chi sq 3.1, p=0.096).

Conclusions: This study shows the value of DSE as a predictor of CV events, ETT in low risk patients did not predict CV events, while CA in selected patients resulted in interventions but did not predict events.

TH-PO1095

Exploring Variation in the Practice Patterns of Assessing Patient Suitability for Renal Transplantation in the United Kingdom Rishi Pruthi,[1] Paul J. Roderick.[2] *[1]UK Renal Registry, United Kingdom; [2]Univ of Southampton, on Behalf of ATTOM Study Group, United Kingdom.*

Background: The Access to Transplant and Transplant Outcome Measures (ATTOM) study is the largest UK transplant study to date exploring equity in access to renal transplantation. In conjunction with ATTOM this national survey aimed to investigate whether centre variation existed in the assessment of patients for deceased-donor renal transplantation in the UK.

Methods: Thematic analysis of 43 semi-structured qualitative interviews with key stakeholders conducted across a purposive sample of 9 renal centres in the UK informed the development of an online survey distributed to the Clinical Directors of all renal centres in the UK. This survey measured differences in centre assessment processes and their evaluation of patient's age, body mass index(BMI), cardiovascular disease(CVD) and malignancy.

Results: All 71 renal centres(100%) in the UK responded, including all 23 transplanting centres. 26% of centres did not discuss transplantation as a treatment option with all their patients aged <75 years and 28% did not have a formal assessment protocol. Only 3 centres in the UK had a cut-off age limit(<75 years) although 83% of centres excluded patients with a high BMI, median 35(range 30-40). There was considerable variation in the investigation of CVD and exclusion criteria based on cardiovascular status of the patients. Cardiac investigations were risk-stratified in 90% of centres. In high-risk patients a thallium stress test was the first line investigation in 32% of centres, while only 3 centres opted for coronary angiography. 59% of centres did not routinely screen for malignancies. Surgical involvement in assessing suitability varied with 10% of centres listing patients for transplantation without any formal surgical review.

Conclusions: There was marked variation in the assessment of patients for renal transplantation across the UK. Future work will investigate if unit factors influence listing independently of patient factors in a prospective cohort in ATTOM. Further research and high quality evidence-based guidelines are necessary to inform a uniform assessment process and to ensure equity of access to the renal transplant waiting list.

TH-PO1096

Long-Term Evaluation of Coronary Calcifications in Kidney Transplanted Patients: A Follow Up of 5 Years Carlo M. Alfieri,[1] Laura Forzenigo,[2] Maria Meneghini,[1] Biljana Danilovic,[2] Anna Regalia,[1] Donata Cresseri,[1] Piergiorgio Messa.[1] *[1]Nephrology, Dialysis and Kidney Transplantation, Fondazione IRCCS Ca' Granda Ospedale Policlinico, Milan, Italy; [2]Radiology, Fondazione IRCCS Ca' Granda Ospedale Policlinico, Milan, Italy.*

Background: Coronary artery calcifications(CAC) have been related to the increased CV mortality in CKD patients. Few data are available on the long term behavior of CAC in kidney transplantation (KTx). Using coronary CT we evaluated: 1) the prevalence,the clinical and biochemical factors related with CAC; 2) the factors implicated with CAC progression in the long run.

Methods: We evaluated 87 pts (M=51) transplanted in our unit between 2007 and 2008. Clinical parameters, blood and urinary samples were collected for 5years. For the statistical analysis the mean values of these parameters were considered. At baseline

(T0) and 5yrs after KTx (T5), coronary TC for the evaluation of CAC (Agatson score) was performed. Both at T0 and at T5, the patients were categorized in 4groups according to the Agatson score: 1)0-10;2)10-100;3)100-400;4)>400. The progression of CAC was determined using the formula proposed by Sevrukov(A-progr),or as passage in a higher CAC score group(B-progr).

Results: At T0 and T5,43% and 33% of pts were in the 1st group,15% and 17% in the 2nd,24% and 23% in the 3rd, 13% and 26% in 4th, resp. CAC at T5 were higher than T0. Both at T0 and T5,CAC correlated directly with age. The CAC-score values at T5 were highly dependent on the T0 levels.The 22%of pts, who had a significant increase in CAC score (A-progr), had lower mean levels of PTH and ALP. The 27% of pts, who worsened their category of CAC(B-progr), had only moderately lower levels of PTH. In a logistic model, PTH was the only independent factor inversely related with CAC progression (A-progr). During the 5 year of KTx one patient died for cerebral hemorrhage and 4pts restarted dialysis for chronic allograft dysfunction.

Conclusions: The prevalence of CAC in CKD patient is quite high, and is related to the patient age. CAC worsening on the long term was observed in almost ¼ patients characterized by higher T0 CAC score. CAC progression resulted mostly associated with lower PTH levels and, at a lesser extent, lower ALP levels.

TH-PO1097

Effects of Kidney Transplantation on Left Ventricular Remodeling and Risk Factors for Post-Transplant Left Ventricular Hypertrophy

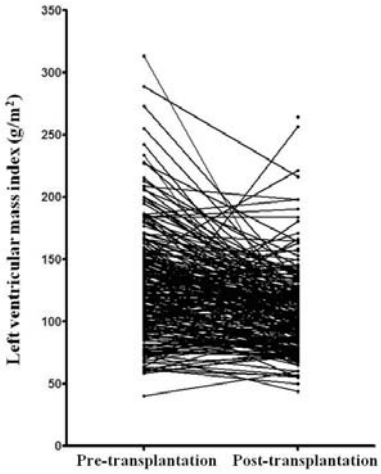
Jung Nam An,[1] Yun Kyu Oh,[1] Su-Kil Park,[2] Yon Su Kim,[3] Chun Soo Lim,[1] Jung Pyo Lee.[1] *[1]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Asan Medical Center and Univ of Ulsan College of Medicine; [3]Dept of Internal Medicine, Seoul National Univ Hospital.*

Background: Cardiovascular disease is a leading cause of mortality in patients with end-stage renal disease, even undergoing transplantation. Left ventricular hypertrophy (LVH) is the most common feature and an independent risk factor for cardiac complications in kidney transplant recipients. The aim of this study was to identify cardiac alteration after kidney transplantation (KT) and analyze predictors of the post-transplant LVH.

Methods: Among 2957 kidney transplant recipients in a multicenter cohort from 1997 to 2012, a total of 221 patients who conducted echocardiography before and one year after transplantation were enrolled in this study. LVH was defined as left ventricular mass index (LVMI) > 95 g/m^2 for women and > 115 g/m^2 for men, respectively.

Results: KT significantly reduced mean LVMI from 130.5 ± 46.9 g/m^2 to 108.0 ± 34.4 g/m^2 ($p < 0.001$).

Figure 1.



After KT, prevalence of LVH decreased (66.1% versus 49.3%, $p < 0.001$), and ejection fraction improved (59.5 ± 7.6% versus 62.3 ± 6.2%, $p < 0.001$). Diastolic dysfunction and valvular regurgitations also decreased. After adjusting other risk factors including age, gender, underlying renal diseases, and immunosuppressants, higher pre-transplant LVMI (OR 1.02, 95% CI 1.01-1.02, $p < 0.001$) and uncontrolled blood pressure after transplantation (OR 1.02, 95% CI 1.00-1.05, $p = 0.025$) were independently associated with persistent LVH after KT.

Conclusions: Cardiac morphology and function were significantly improved by kidney transplantation. Optimal management of hypertension is crucial in regression and prevention of persistent LVH in kidney transplant recipients.

TH-PO1098

The Prognostic Significance of Preoperative Diastolic Dysfunction of the Left Ventricle and Left Atrial Enlargement on Clinical Outcomes in Kidney Transplantation

Jung Nam An,[1] Hyosang Kim,[2] Jaeseok Yang,[3] Curie Ahn,[3] Su-Kil Park,[2] Yon Su Kim,[4] Jung Pyo Lee.[1] *[1]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Asan Medical Center and Univ of Ulsan College of Medicine; [3]Transplantation Center, Seoul National Univ Hospital; [4]Dept of Internal Medicine, Seoul National Univ College of Medicine.*

Background: Echocardiography is commonly performed as a screening test to evaluate cardiac function before kidney transplantation (KT). Identification of high-risk patients for cardiovascular (CV) disease is important to offer appropriate management before KT.

Methods: We reviewed 2,957 adult recipients who underwent pretransplant echocardiography from 1997 to 2012 in order to evaluate the prognostic significance of preoperative markers of LVDD and LAE. The LVDD was defined referring to the recommendations of the European Study Group on Diastolic Heart Failure and was divided by 4 grades: 0 (normal); 1 (relaxation abnormality); 2 (pseudonormalization); and 3 (restrictive pattern). The patients with grade 0 and grade 1 and patients with grade 2 and grade 3 were combined and analyzed, respectively.

Results: During the observation period (mean 54.1 months), the recipients with LVDD grade 2-3 showed higher occurrence of major adverse cardiac events (MACE) (P=0.001) and graft failure (P=0.005). All-cause mortality was not different between the groups depending on the LVDD grades. The recipients with LAE tend to be associated only with the occurrence of the MACE (P=0.002). In a multivariate analysis, increased age (P=0.001), previous history of CV event (P<0.001) and LVDD of grade 2-3 (HR 4.076; 95% CI 1.667-9.966; P=0.002) were associated with MACE. The recipients with LAE also showed significantly higher occurrence of MACE in a multivariate analysis (HR 3.172; 95% CI 1.069-9.410; P=0.037). Graft failure and all-cause mortality were not showed significant differences in both recipients with LVDD and LAE in a multivariate analysis.

Conclusions: The echocardiographic findings of LVDD and LAE before kidney transplantation may increase the risk of developing cardiovascular event.

TH-PO1099

Cardiac and Vascular Changes in Patients with Chronic Kidney Disease Before and After Kidney Transplantation: A Prospective Study

Azhar Ali,[1] Andrea Dell'Aquila,[1] Louise E. Ross,[1] Nabeel Sheikh,[1] David Gaze,[1] Juan Carlos Kaski,[1] Debasish Banerjee.[1,2] *[1]St. George's Univ of London, United Kingdom; [2]St. George's Healthcare NHS Trust, United Kingdom.*

Background: Chronic kidney disease (CKD) is associated with increased risk of cardiovascular (CV) morbidity and mortality with event rates being almost fifty times higher than those in the general population. Recent studies suggest that CV event rates improve following kidney transplantation, however the exact mechanism of the changes is not known. We investigated functional and structural changes taking place in the CV system following kidney transplantation in patients with CKD.

Methods: 10 non-diabetic (3 predialysis, 7 dialysis) patients were enrolled in the present study. Cardiac structure and function using the echocardiogram, endothelial function using brachial artery flow mediated dilatation techniques and circulating biomarkers were assessed within 7 days before and 6 to 12 months after renal transplantation. Blood biomarkers of inflammation, oxidative stress and cardiac function in the study included: hsCRP, ICAM-1, SOD, H_2O_2 and NT-proBNP using standard ELISA techniques. Left ventricular mass (LVM) was calculated using the Penn formula and further indexed to height and corrected for body surface area to give the left ventricular mass index (LVMI).

Results: The clinical characteristics of the patients at baseline were; age (51±13 years), women (20%), BMI (24.9±5.3 kg/m^2), hypertensives (80%), dyslipidaemics (30%), current smokers (0%), history of MI (10%), history of TIA/stroke (10%), systolic BP (138±22 mmHg), diastolic BP (78±12 mmHg), total cholesterol (4.9±1.4 mmol/L), haemoglobin (111±190 g/L), corrected calcium (2.32±0.14 mmol/L) and phosphate (1.66±0.48 mmol/L). During follow up (244±25 days), LVMI improved from 140±37 g/m^2 to 115±30 g/m^2 ($p<0.05$). FMD increased from 2.45±1.67% to 4.67±1.23% ($p<0.05$). Furthermore, hsCRP levels decreased from 1.4±14.1 mg/L to 0.7±2.3 mg/L ($p<0.05$).

Conclusions: This study demonstrates an improvement of hsCRP, FMD and LVM in non diabetic patients 6-12 months post kidney transplantation. We propose that a reduction in low grade inflammation may result in improved endothelial function and LVM.

TH-PO1100

Aspirin Use and Cardiovascular Disease and Kidney Outcomes in Stable Kidney Transplant Recipients: The FAVORIT Trial

Taimur Dad,[1] Alin A. John,[1] Hocine Tighiouart,[1] Myra A. Carpenter,[2] Lawrence G. Hunsicker,[3] John W. Kusek,[4] Marc A. Pfeffer,[5] Andrew S. Levey,[1] Daniel E. Weiner.[1] *[1]Tufts Medical Center; [2]North Carolina; [3]Iowa; [4]NIDDK; [5]Brigham and Women's Hospital.*

Background: Cardiovascular disease (CVD) is the leading cause of death in kidney transplant recipients. The role of aspirin for primary or secondary prevention of CVD and reduction of other adverse outcomes is uncertain.

Methods: This *post hoc* analysis of FAVORIT, an RCT evaluating the role of homocysteine-lowering vitamin therapy to reduce CVD in 4,110 stable kidney transplant recipients, used a propensity score with a 0.1 standard deviation caliper to match aspirin users to aspirin non-users. Outcomes were primary cardiovascular (CV) events, all-cause death, kidney failure, and a composite of kidney failure and death. Stratified Cox models,

adjusting for patient characteristics, including age, sex, race, diabetes, self-reported CVD history, hypertension, smoking status, cholesterol, eGFR, urine ACR, and transplant donor type and vintage, evaluated the effect of aspirin use on study outcomes.

Results: There were 1125 aspirin users matched to 1125 non-users, with no standardized difference above 5%. Mean age was 52 years with 37% women and 16% African Americans; 44% had history of diabetes, 93% history of hypertension, and 20% history of CVD. Mean eGFR was 49 ml/min/1.73m^2, median ACR 22 mg/g and mean graft vintage 5.2 years. Over 4 years of follow-up, there were 331 CV events, 271 deaths, 158 kidney failure events and 387 composite events. In adjusted models, there was no difference in CV events [HR=1.17 (0.85,1.60)], all-cause death [HR=0.84 (0.59,1.19)], kidney failure [HR=0.81 (0.35,1.90)] or composite events [HR=0.95 (0.70,1.28)] by aspirin use. When examining the subset without baseline CVD in whom aspirin was presumptively taken for primary prevention, results were similar: HR=0.99 (0.64,1.51), HR=0.86 (0.52,1.41), HR=0.71 (0.23,2.16) and HR=0.89 (0.59,1.23) for CV, mortality, kidney failure and composite outcomes, respectively.

Conclusions: We found no association between aspirin use and adverse events in stable kidney transplant recipients with a low prevalence of CVD overall and in persons without CVD at baseline.

Does African American Race Impact Statin Efficacy in Renal Transplant Outcomes? Mukoso N. Ozieh,[1] David J. Taber,[1,2] Prabhakar Baliga,[1] Titte Srinivas,[1] Leonard Egede.[1,2] *[1]Nephrology, MUSC, Charleston, SC; [2]Internal Medicine, Ralph H. Johnson VAMC, Charleston, SC.*

Background: In the general population, compared to Caucasians, African Americans (AA) have smaller LDL particle size and are less likely to receive statin therapy. Yet, AAs equally benefit from this therapy. However no studies have assessed if race impacts the efficacy of statins in renal transplant (RTX).

Methods: This was a retrospective analysis of solitary adult RTX at our center between June 2005 and May 2013. Cox proportional regression modeling was used to examine the impact of statin therapy on graft loss, death and acute rejection and determine if significant interactions exist between statin therapy and race. Models were adjusted for demographics, socioeconomic status, cardiovascular history, medication use and transplant characteristics. SPSS version 21.0 was used for statistical analysis.

Results: 1,176 RTX were included (624 AA versus 552 non-AA). AAs and non-AAs were equally likely to receive statin therapy (45% versus 45%, p=0.922). RTX patients on statin therapy were older, had more CV disease burden, received more marginal kidneys and were more likely to be on ACEIs/ARBs, antiplatelet therapy or beta-blockers. The mean LDL and TG in AA was 94 mg/dL and 133 mg/dL compared to 90 mg/dL and 163 mg/dL in non-AA. AAs did not experience a significant reduction in LDL with statin therapy (p=0.133), while non-AAs did (p=0.006). Overall, after adjusting for covariates, patients who received statins were 37% less likely to have graft loss (HR 0.63, 95% CI 0.43-0.94) and 29% less likely to die (HR 0.71, 95% CI 0.42-1.18). Acute rejection was not influenced by statin use (HR 0.88 95% CI 0.58-1.32). There was a statistically significant interaction between race and statin therapy for death, but not for graft loss or rejection. After stratifying the analysis by race, statins reduced the risk of death in AAs (HR 0.43, 95% CI 0.20-0.94), but not in non-AAs (HR 1.09, 95% CI 0.49-2.44).

Conclusions: Statin therapy significantly reduces the risk of graft loss in RTX, with AAs experiencing a significant mortality benefit from this therapy. These results highlight the importance of optimizing statin therapy in RTX, especially in AAs.

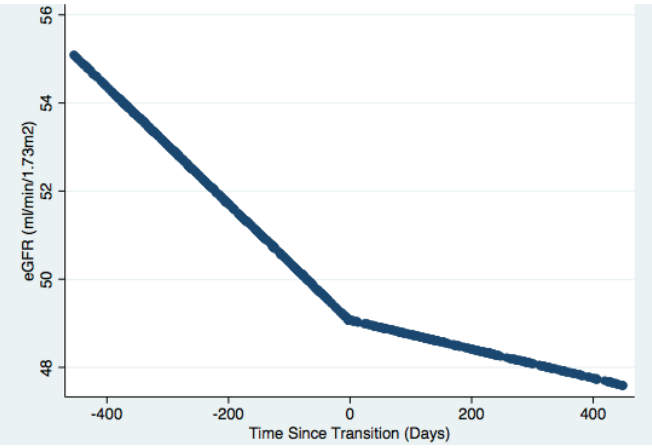
TH-PO1102

Effect of Transition to Adult Transplant Care on Kidney Function for Pediatric Kidney Transplant Recipients Hilda E. Fernandez,[1] Sandra Amaral,[2] Pamela A. Shaw,[1] Alden Michael Doyle,[3] Roy D. Bloom,[1] Melanie A. Mariano,[2] Alekhya Potluri,[3] H. Jorge Baluarte,[2] Susan L. Furth.[2] *[1]UPenn; [2]CHOP; [3]Hahnemann Univ.*

Background: Transition of care from pediatric (peds) to adult healthcare settings has been hypothesized as a risk factor for non-adherence and graft loss, however prior studies have been inconsistent in their findings and have focused on the late outcome of graft loss. We explored the effect of transition of care on changes in eGFR slope w/in a cohort of peds renal transplant (txplt) pts in a single center who transitioned from peds to adult txplt care.

Methods: Retrospective chart review study of peds kidney txplt pts (1999-2011) in a single U.S. peds txplt center. We examined change in eGFR (modified Schwartz formula) for all pts who transitioned txplt care from peds to adult healthcare through 2012. Date of transition was defined as last peds txplt clinic visit. Analysis was performed to assess change in eGFR pre versus post transition via a mixed-effects model.

Results: 48 patients had at least 2 time points pre/post transition to analyze. Median age at txplt was 16.5y (8.5-19.5). Most subjects were male (69%), white (65%), had CAKUT (42%), and HLA MM>3 (83%). 50% had LRKT. Median age at transition was 20y (17.4-23.6) and median eGFR at time of transition was 49 ml/min/1.73m2 (9-104). 6 pts had allograft loss w/in 365 days post-transition (24-347). Compared to pre-transition eGFR (prior to day 0 in Figure) there was a decrease in the decline of eGFR following transition (p<0.05).



After excluding pts w/ allograft loss w/in 1 yr after transition, this interaction was non-significant.

Conclusions: Transition of care was not independently a/w acceleration in eGFR decline, rather declines in eGFR preceded changes in healthcare settings. Future analysis will investigate effects of race, age at transition, acute allograft rejection, *dn*DSA as risk factors for decline in eGFR over time.

TH-PO1103

Outcomes of Renal Transplantation in HIV Associated Nephropathy: Experience at a Tertiary Care Hospital in Maryland Sana Waheed, Mohamed G. Atta. *Dept of Medicine, Johns Hopkins Univ, Baltimore, MD.*

Background: Recent studies have shown that renal transplantation in both safe and effective in HIV infected patients. However, none of these studies have specifically looked at outcomes in patients with HIVAN. The focus of our study was to evaluate outcomes of renal transplantation in biopsy proven HIVAN patients.

Methods: Transplant and pathology records of all adult HIV infected patients undergoing kidney transplantation at Johns Hopkins Hospital between September 2006 and January 2014 were reviewed. Clinical characteristics and demographics of renal transplant recepients with biopsy proven HIVAN were compared to HIV infected transplant recepients without HIVAN. Graft survival and rejection rates over a 3 year period were calculated using the Kaplan-Meier method.

Results: Of the 16 HIV patients who underwent a renal transplant, 11 had HIVAN as the cause of their ESRD. 64 % of HIVAN patients developed delayed graft function (DGF) and 54% required post-operative dialysis within one week of transplant, compared to none in the non-HIVAN group. Antithymocyte globulin was the induction agent used in all but one of our patients and there were no serious infectious complications. The median follow up was 3.3 years. The 1 and 3-year graft survival rates in HIVAN patients were 100% and 81% respectively compared to 100% and 80% in non-HIVAN patients. The 1 and 3 year rejection rates were 18% and 27% in the HIVAN group, which were similar to rates of 20% and 40% in the non-HIVAN group.

Characteristics and Outcomes of patients with HIVAN compared to patients without HIVAN

Characteristics	HIVAN	No HIVAN	p-value
Patients	11	5	
Demographics			
Age [Mean(SD)]	47.6 (15.4)	46.1 (8.1)	0.26
Male [Number (%)]	9 (82)	4 (80)	0.70
African American [Number (%)]	10 (91)	4 (80)	0.54
Hepatitis C infection [Number (%)]	4 (36.4)	1(20)	0.5
Apolipoprotein homozygosity[Number (%)]	100 (3/3)	100 (1/1)	0.25
Transplant Related Variables			
Deceased Donor [Number (%)]	9 (82)	5 (100)	0.46
CD 4 count [Mean (SD) cells/mm^3]	606 (243.6)	648(301.4)	0.80
Delayed Graft Function [Number (%)]	7 (63.6)	0 (0)	0.03
Postoperative Dialysis [Number (%)]	6 (54.5)	0 (0)	0.06
CMV viremia [Number (%)]	1 (20)	0 (0)	0.33
BK viremia [Number (%)]	0 (0)	0 (0)	NA
Immunosuppression			
Induction with anti-thymocyte globulin [Number (%)]	10 (91)	5(100)	0.69
Induction with daclizumab [Number (%)]	1 (9)	0 (0)	
Long Term Follow up			
Follow up Duration [Mean (SD) years]	3.33 (1.9)	3.34 (2.8)	
One year rejection rate (%) [95% CI]	18 (4-53)	20 (1-70)	
Three year rejection rate (%) [95% CI]	27 (39-93)	40 (17-93)	
One year graft Survival (%)	100%	100%	
Three year graft Survival (%)	81%	80%	
Creatinine at 24 months post-transplant [Mean (SD) mg/dL]	2.01 (1.41)	2.03 (1.36)	0.98
Long Term Dialysis [Number (%)]	2(18)	1(20)	0.70
Graft Failure [Number (%)]	2(18)	1(20)	0.70
Malignancy [Number (%)]	1 (9.1)	1 (20)	0.54

Conclusions: Despite higher rates of DGF and need for post-operative dialysis, renal graft survival and rejection rates in HIVAN patients are similar to patients with HIV and an alternate cause of renal failure. However, overall rejection rates remain higher than the general population which can partially be explained by interaction of antiretroviral therapy with immunosuppressants.

TH-PO1104

Hyperuricemia and Mortality Post-Liver Transplantation Sana Waheed,[1] Christine Adefuin Murakami,[1] Joseph Craig Longenecker,[2] Mohamed G. Atta.[1] *[1]Dept of Medicine, Johns Hopkins Univ, Baltimore, MD; [2]Dept of Community Medicine, Kuwait Univ Faculty of Medicine.*

Background: The impact of hyperuricemia on renal function and mortality after orthotopic liver transplant (OLT) is poorly understood. This non-concurrent cohort study assessed the prevalence of hyperuricemia in the pre- and post OLT period, and its association with post-OLT mortality.

Methods: Medical records of 304 adult patients undergoing OLT at Johns Hopkins Hospital from 1996 to 2009 were reviewed. Clinical data, including a median of 90 post-OLT uric acid (UA) values per patient, were recorded. Mortality was assessed using NDI and UNOS. Post OLT hyperuricemia was defined as a mean UA level >6.5 mg/dl, averaged over all values during the first quarter after OLT. The primary outcomes were 1) change in UA level from the quarter before to the quarter after OLT; and 2) total mortality during follow-up after OLT. Post OLT survival according to UA level was assessed using the Kaplan Meier method. Multivariate Cox proportional hazards models were constructed to adjust for age, gender, and time-dependent eGFR category.

Results: The prevalence of hyperuricemia increased from 3 months pre-OLT (26.6%) to 3 months post-OLT (53.5%; p<0.0001). Overall, UA levels increased by +1.1 mg/dl from pre- to post-OLT period. The increase was higher in those with eGFR<60 mL/min/1.73m^2 (+1.5 mg/dl) compared to eGFR≥60 (+0.3 mg/dl; p=0.048). In both the pre- and post-OLT period, a GFR<60 mL/min/1.73m^2 was significantly associated with higher mean serum UA (p= <0.0001). Older patients were more likely to have a higher UA level (p=0.02). The overall mortality rate was 48.9 deaths/1000 person-years. Post-OLT hyperuricemia was independently associated with mortality, but only among those with GFR <60 mL/min/1.73 m^2 (HR=3.7; [C.I. 1.1-12.0] p=0.03), and not those with GFR>60 mL/min/1.73 m^2 (HR=1.0, p=0.95; p-value=0.046).

Conclusions: The pre- to post-OLT increase in UA levels is greater in patients with CKD compared to no CKD. Hyperuricemia in the post-OLT period is an independent predictor of mortality in patients with CKD. Further studies are needed to assess the effect of treatment of hyperuricemia on kidney function and mortality.

TH-PO1105

Increased Cancer Incidence among Dialysis and Transplant Patients Is Not Associated with Increased Dialysis Duration Vathsala Anantharaman,[2] Gek Hsiang Lim.[1] *[1]National Registry of Diseases Office, Singapore; [2]National Univ Centre for Organ Transplantation, Singapore.*

Background: There is an increased risk of cancer in End stage renal disease (ESRD). Skin cancer, Kaposi's, lymphoma and cervical cancer are more frequent after kidney transplant (KTX) whereas genitourinary (GU) cancers are more common after dialysis (DIAL). Although GU cancer is more common after KTX, there is controversy over whether increased DIAL duration increases this risk. This Registry analysis evaluated cancer incidence in KTX and DIAL patients and examined its relationship to demographics and DIAL duration.

Methods: 9565 DIAL patients and 937 KTX performed between 1998 and 2012 were studied. Incident cancers were ascertained through cross referencing with the Singapore Cancer Registry. Standardised Incidence Ratios (SIRs) of cancer were computed using age-, sex- and calendar-year specific population cancer incidence rates.

Results: 537 and 73 cancers were detected among DIAL and KTX respectively; compared to the general population, SIR for cancer for KTX was 3.9 (95%CI:3.1-4.9) versus 1.8 (95%CI:1.7-2) for DIAL patients. GU cancer was the most common for both KTX and DIAL patients (mean interval of 3 years after KTX or DIAL). Cancer risk was highest during the 1st year of either DIAL or KTX and decreased with time.

	DIALYSIS			KTX		
	No of Cancers	Crude SIR	95%CI	No of Cancers	Crude SIR	95%CI
	537	1.8	1.7-2.0	73	3.9	3.1-4.9
Years after DIAL/ KTX						
<1	90	5.5	4.4-6.9	12	29.8	16.5-53.8
1-2	105	2.8	2.3-3.4	9	8.1	4.2-15.7
3-5	188	1.6	1.4-1.8	24	4.5	3.0-6.7
6-10	128	1.4	1.2-1.7	21	2.7	1.7-4.2
>10	26	1.1	0.7-1.6	7	1.7	0.8-3.6
Total Therapy Time (Years)						
0-9	476	1.8	1.6-2.0	12	7.7	4.4-13.6
10-19	25	1.1	0.7-1.6	46	4.2	3.1-5.6
>19	0	-	-	11	2.3	1.3-4.2

SIR for cancers after KTX, in relation to DIAL duration pre-KTX, were 5.0(<1.5 years), 5.5(1.5-2.5 years), 3.5(2.5-4.5 years), 3.7(>4.5 years).

Conclusions: Cancer risk is higher among KTX than DIAL and higher in both groups than the general population. DIAL duration was not associated with increased cancer risk in either group. These results advocate for increased cancer surveillance, especially GU cancer, early after renal replacement therapy initiation.

TH-PO1106

Recommendation of Pre-Emptive Transplant Based on Hypothetical Case Scenarios Surju Patel,[1] Ming Wang,[2] Kevin C. Roe,[1] Ankita Tandon,[3] Nasrollah Ghahramani.[1] *[1]Dept of Nephrology, Penn State College of Medicine, Hershey, PA; [2]Div of Biostatistics and Bioinformatics, Penn State College of Medicine, Hershey, PA; [3]Dept of Internal Medicine, Penn State College of Medicine, Hershey, PA.*

Background: Pre-emptive renal transplant (PRT) is recognized as an underutilized option for patients with end-stage renal disease (ESRD). Reasons for the infrequent use of PRT remain unclear. We assessed Nephrologists' decisions regarding patient referral for PRT to identify factors influencing choices.

Methods: In an online survey, 250 Nephrologists were asked whether they would recommend pre-emptive kidney transplant (PKT) for hypothetical patients with stage 4 CKD not yet on dialysis. The 6 scenarios varied in age, sex, living situation (alone or with spouse), distance from transplant center (TC), rural location.

Results: 213 Nephrologists provided complete responses. In multivariate analysis, distance from TC< 10 miles (OR:3.26;p< 0.001) was associated with higher likelihood, and rural location (OR: 0.31;p < 0.001) with lower likelihood of being referred for PKT. Based on logistic regression, academic affiliation was associated with higher likelihood of recommending PKT (OR=5.12; p=0.045). Practice as non-transplant Nephrologist (p<0.01), increased years from fellowship (p<0.001), and fewer years practicing in the current location (p<0.001) were associated with lower likelihood of recommending PKT.

Conclusions: PRT avoids dialysis associated morbidity and reflects early access to kidney transplant. The underutilized nature of PRT has been attributed to lack of education of Nephrologists and patients, and notably the late referral for transplant evaluation. We identify close proximity to the transplant center and academic affiliation as increasing likelihood of PRT. Lack of transplant specific training, increasing years from fellowship or practicing in an area of a shorter period of time all decrease the likelihood of PKT.

Survey of Protocol Kidney Transplant Biopsy Practices Adam Safdi,[1] Daniel R. Salomon,[2] John J. Friedewald.[1] *[1]Northwestern Medicine, Chicago, IL; [2]The Scripps Research Inst, La Jolla, CA.*

Background: Protocol kidney transplant biopsies (PBx) done at fixed intervals post transplant are used to monitor the graft. Our center performs PBx on all kidney recipients (KTR) but this practice varies. We developed a survey to explore this practice and opinions on PBx.

Methods: An 11-question survey on SurveyMonkey.com was distributed to the Centerspan transplant email listserv. We asked respondents who care for kidney recipients to best represent the practices of their home institution.

Results: Survey data were collected from 50 respondents from 33 transplant centers in the U.S.A. and 3 international centers. 34% routinely performed PBx on all KTR, 38% do not perform any PBx, and 28% only for certain patients, with the most common reasons being delayed graft function or ABO incompatibility. For those who do not perform PBx, when asked why not, 34.3% said they do not believe there is an indication for PBx, 31.4% said they believe in Pbx only for selected patients, and 22.9% said the logistics were difficult to arrange for PBx at their centers (answers not mutually exclusive). Respondents indicated an array of time intervals for PBx. When asked who performs the majority of PBx, 59% reported nephrologists, 24% interventional radiologists, and 16% transplant surgeons. Regardless of who performs the biopsies, the nephrologist responds to the biopsy results 78% of the time, unless it is a new (< 3 months) graft, then it is either the surgeon alone or a team response. When there is rejection on the PBx without graft dysfunction (subclinical acute rejection), 91% favor treating, but only 47% will repeat a biopsy after treatment. 51% treat Banff borderline cellular rejection, 20% do not, and 29% say it depends on the clinical situation. When asked if they would use a biomarker to replace PBx, 69% of respondents said yes, 10% said no, and 21% weren't sure.

Conclusions: The practice and attitudes towards PBx still vary widely throughout the kidney transplant community. More comprehensive data regarding the effectiveness of a PBx protocol are likely still needed. Clinicians are open to the use of biomarkers to replace PBx.

TH-PO1108

Infection and Immunosuppression following Renal Transplant Failure Claire T. Kassakian, George P. Bayliss. *Nephrology, Alpert Medical School at Brown Univ, Providence, RI.*

Background: Renal transplant patients whose grafts have failed are frequently kept on an immunosuppressive regimen. Continuation of such regimens introduces an increased risk of infections, malignancy, and side effects from long-term corticosteroid utilization. Infection remains one of the most common causes of mortality in this population. Small published retrospective studies have previously illustrated that patients who continue on even low dose immunosuppressive regimens are at an increased risk of infection. The objective of this study is to evaluate the risk and type of infection in renal transplant patients whose allografts have failed, comparing those who continue on an immunosuppressive regimen to those who do not.

Methods: Retrospective cohort study of renal transplant recipients from Lifespan who received transplants between 1999 to the present described as either on hemodialysis or deceased. Patients were excluded if no allograft failure was present prior to death or if inadequate data was present in the electronic medical record. Electronic chart review. The primary outcome is the incidence of infections requiring hospitalization.

Results: There were 189 patients with failed renal transplants in the cohort, 110 of whom had adequate data for review in the electronic medical record. There were a total of 112 infections. The incidence of developing any infection in the immunosuppressed group was 71%, and 64% for the non-immunosuppressed group (p-value 0.45). The odds ratio (OR) of developing an infection was 1.4. The three most common types of infections in the immunosuppressed group were pneumonia, UTI, and dialysis catheter infections.

Conclusions: In this study population, there is a greater incidence, albeit non-statistically significant, of infections in renal allograft failure patients who are continued on an immunosuppressive regimen. As prior literature has established, there is an increased risk of line infections in patients who are continued on immunosuppressive regimens. This study also demonstrates that these patients also have a higher incidence of other infections as well.

TH-PO1109

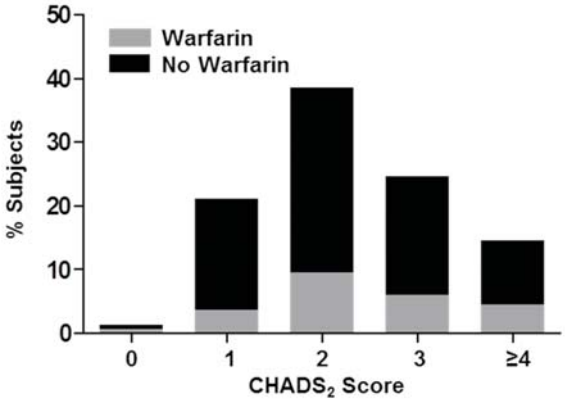
Correlates and Outcomes of Warfarin Initiation in Kidney Transplant Recipients Newly Diagnosed with Atrial Fibrillation Colin R. Lenihan, Maria E. Montez-Rath, Jenny I. Shen, John D. Scandling, Tara I. Chang, Wolfgang C. Winkelmayer. *Divison of Nephrology, Dept of Medicine, Stanford Univ, CA.*

Background: In the kidney transplant population with atrial fibrillation (AF), evidence regarding the effectiveness and safety of warfarin treatment is lacking.

Methods: We used fee-for-service Medicare claims to identify kidney transplant recipients with newly diagnosed AF from the U.S. Renal Data System. Warfarin use within 30 days of AF diagnosis was ascertained from Medicare Part D prescription claims (2007-2010) or using a validated algorithm (1997-2010). The study endpoints were 1) the composite of death, stroke or gastrointestinal (GI) bleed, 2) death and 3) death-censored graft failure. Warfarin user and non-users groups were balanced using inverse probability of treatment weighting and hazard ratios estimated using Cox regression.

Results: Among 434 subjects with available prescription data, 25.6% initiated warfarin treatment within 30 days of AF diagnosis. Age was the only independent correlate of warfarin use (odds ratio=1.02 per year; 95% CI: 1.00-1.04). Figure 1 shows warfarin use stratified by CHADS2 score.

Figure 1



In the larger cohort of 6170 patients with AF, warfarin use [22.3%] versus non-use [77.7%] was associated with a 13% reduction in the composite of death, stroke or GI bleed (table 1).

Table1	Hazard Ratio (95% CI) Warfarin use versus non-use
Composite of Death, Stroke or GI Bleeding	0.87 (0.78-0.98)
Death	0.89 (0.79-1.01)
Death-censored graft failure	0.87 (0.72-1.05)

Conclusions: Our data suggest a benefit for warfarin treatment in kidney transplant recipients with newly diagnosed AF. Given this evidence, warfarin appears to be underutilized in this population.

Simultaneous Liver and Kidney Transplantation in the Nephrologist Led Era: Characteristics and Outcomes Scott Reule, Donal J. Sexton, Hassan N. Ibrahim. *Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: Formal metrics to decide between liver transplant alone (LTA) versus simultaneous liver-kidney transplantation (SLK) have not been developed. On January 1st, 2009, the University of Minnesota adopted an approach whereby a nephrologist is given full autonomy to decide whether LTA versus SLK should be offered to patients with end stage liver disease and impaired kidney function. Whether this policy has impacted patient outcomes such as survival and rehospitalization, is unknown.

Methods: Chi-square analysis was performed for categorical variables and logistic regression was performed for comparisons of type of transplant performed, adjusted for age, race, sex and era. Clinical outcome comparisons were performed using Cox proportional hazards models, with hazards ratios adjusted for age, sex and race (AHRs).

Results: Outcomes of LTA (n =384) and SLK (n = 63) were compared before and after policy implementation. Overall percentage of SLK decreased over the time (17.1% in 2003 to 8.1% in 2012). The strongest associations with transplantation in a recent era included Hepatitis C positivity for those receiving LTA (20.4% versus 40.9%; AOR 3.34) and a lower likelihood of hypertension for those receiving SLK (97.4% versus 62.5%; AOR 0.05). Survival of recipients of SLK was comparable ($p = 0.07$) whereas those receiving LTA appeared to have improved survival in the most recent era ($p < 0.05$). No era differences in hospitalization post transplantation were observed in those receiving LTA, whereas those receiving SLK were less likely to be hospitalized in the first 30 days post transplantation in the most recent era ($p = 0.03$). No significant differences in dialysis post transplantation by era were observed (SLK; $p = 0.86$, LTA $p = 0.8$).

Conclusions: These data suggest that delegating the responsibility of allocating LTA versus SLK in patients with kidney disease to nephrology may result in more efficient use of kidneys with no appreciable adverse consequences to recipients.

TH-PO1111

Risk Factors for Asymptomatic Bacteriuria after Renal Transplantation and Its Impact on Renal Allograft Function Ramandeep Singh,[1] Suzanne E. Geerlings,[2] Ineke Ten Berge,[1] Frederike J. Bemelman.[1] *[1]Renal Transplant Unit, Academic Medical Center, Amsterdam, Netherlands; [2]Div of Infectious Diseases, Academic Medical Center, Amsterdam, Netherlands.*

Background: Asymptomatic bacteriuria (ASB) is common after renal transplantation. In 2007 we implemented the administration of trimethoprim-sulfamethoxazole (TMP-SMX) as *Pneumocystis jiroveci* pneumonia (PJP) prophylaxis. The aims of this study are to describe the risk factors for the development of ASB, as well as the influence of TMP-SMX its incidence. We also evaluated the impact of ASB on renal allograft function 1 year after transplantation.

Methods: Retrospective cohort study with adult renal allograft recipients transplanted between 2004 and 2009, with follow-up of 1 year after transplantation. Bacteriuria events occurring after discharge of the renal transplant ward were analysed. ASB was defined as positive urine culture without symptoms of the urinary tract, fever/malaise. Bacteriuria with these symptoms was considered as urinary tract infection (UTI).

Results: In total 431 recipients were analysed; 48 (11.1%) had only ASB within 1 year after transplantation, 85 (19.7%) had a UTI and 298 (69.1%) did not develop any bacteriuria at all. Multivariable analysis showed that in comparison to the group who did not develop any bacteriuria, the risk factors for ASB were age, OR=1.05 (95%CI=1.05-1.08,p=0.003); female gender, OR=2.15 (95%CI=1.05-4.39,p=0.037) and indwelling urological catheters, OR=18.76 (95% CI= 6.20-40.06,p<0.001). TMP-SMX did not reduce the incidence of ASB, (OR=1.62, 95%CI=0.81-3.27,p=0.17). With TMP-SMX prophylaxis, the rate of TMP-SMX resistance was higher than without prophylaxis (74% versus 38%,p=0.02). Recipients who experienced ASB had comparable median eGFR (MRDR) of 50.5 ml/min/1.73m^2 versus 52.0 ml/min/1.73m^2 in the group without bacteriuria, p=0.251. The median 24 hour urine protein excretion was also comparable; 200 mg in the group with ASB versus 160 mg in the group without bacteriuria, p=0.269.

Conclusions: Age, female gender and indwelling urological catheter are associated with ASB. TMP-SMX as PJP prophylaxis does not reduce the incidence of ASB, but increases TMP-SMX resistance. ASB does not impair renal allograft function.

TH-PO1112

Time-Dependent Kidney Function Is a Risk Factor for Cardiovascular Disease in Kidney Transplant Recipients Johnny Huang,[1] Monica Abdelmasih,[1] Olusegun Famure,[1] Yanhong Li,[1] Joseph Kim.[1,2] *[1]Multi-Organ Transplant Program, Toronto General Hospital, Toronto, ON, Canada; [2]Div of Nephrology, Toronto General Hospital, Toronto, ON, Canada.*

Background: The relation between kidney function and cardiovascular disease (CVD) in kidney transplant recipients is complex due to time-varying confounding by factors like blood pressure (BP). BP may simultaneously confound and mediate the effect of kidney function on the future risk of CVD. We used novel statistical methods to examine the role of kidney function as a risk factor for CVD while accounting for the time-varying role of BP.

Methods: A cohort of 1221 kidney transplant recipients from 1 Jan 2000 to 31 Dec 2011 at a single center was studied. Kidney function was based on the CKD-EPI estimated glomerular filtration rate (eGFR) formula. The primary outcome was major adverse cardiovascular event (MACE), which included non-fatal MI, target lesion revascularization, or death. The secondary outcome was MACE excluding death. We used time-fixed, time-varying, and marginal structural Cox proportional hazards models to assess the association of time-dependent eGFR and MACE while accounting for time-varying BP. Other baseline recipient, donor, and transplant characteristics were also included in multivariable models.

Results: During 5696.7 person-years of follow-up (median 3.9 years), 172 MACE were observed (including 65 deaths). A time-fixed Cox model showed that every 10 mL/min decrease in eGFR was associated with an increased risk of MACE (hazard ratio or HR 1.15 [95%CI: 1.04, 1.27]) and MACE excluding death (HR 1.15 [95%CI: 1.01, 1.31]). Somewhat stronger associations were observed using a time-varying Cox model (HR 1.25 [95%CI: 1.16, 1.36] for MACE and HR 1.31 [95%CI: 1.17, 1.46] for MACE excluding death). Furthermore, the marginal structural Cox model confirmed that eGFR is a significant independent risk factor for MACE and MACE excluding death (HR 1.26 [95%CI: 1.13, 1.41] and HR: 1.32 [95%CI: 1.14, 1.52], respectively) after accounting for time-varying BP.

Conclusions: Time-dependent eGFR is an independent risk factor for MACE (and MACE excluding death) in kidney transplant recipients after accounting for time-varying BP and other factors.

TH-PO1113

Renal Transplant Recipient Perspectives on Physical Activity and Exercise
Laetitia H. Lloyd-Davies, Amy L. Clarke, Stephanie Amy Brown, Katherine Leigh Hull, James O. Burton, Alice C. Smith. *Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom.*

Background: Transplantation offers those with end stage renal failure improved quality of life and increased functional capacity, but many renal transplant recipients (RTR) are undesirably sedentary despite the increasing appreciation of the risks involved with such behaviour. Patient-centred strategies to increase physical activity are required. As a first stage in intervention development, this study aimed to explore RTR attitudes and perspectives towards exercise using a mixed-methods approach.

Methods: 220 RTRs completed Exercise Self-Efficacy (ESE) and Stage of Change (SoC) questionnaires (time with graft >3 months, 53% male, median age 52, range 19-83 years). A purposive sample of 18 RTRs were recruited to 6 semi-structured interviews and 2 focus groups to explore perspectives in greater depth. Audio files were transcribed verbatim and qualitative analysis was completed using a framework approach.

Results: From the SoC, only 19% of respondents were in Pre-Contemplation stage (not interested in exercise). ESE correlated with intention to increase activity (rho=0.448, p<0.001). In the qualitative phase, patients anticipated a number of health and wellbeing benefits of exercise but described many physical barriers including fatigue, breathlessness and muscular pain at the site of surgery, and psychological fears of injury and damaging the graft. Messages around exercise from health professionals were primarily cautionary and mainly given soon after the time of surgery, leaving patients wanting specific advice about how to exercise safely. Positive effects of peer support and education were seen in the focus groups, and showed the potential of group interactions to contextualise these concerns and increase self-efficacy.

Conclusions: This study indicates that many transplant recipients want and need more help to build confidence around exercise and increase habitual activity levels. It supports the inclusion of peer education and vicarious learning in a structured intervention with different levels of support and instruction tailored to the needs of the individual.

TH-PO1114

The Effect of Renin-Angiotensin System Blockade on Long-Term Outcomes in Renal Transplant Recipients
Jung-Im Shin,[1] Arjang Djamali,[2,3] Dixon Kaufman,[3] Brad C. Astor.[1,2] *[1]Dept of Population Health Sciences, Univ of Wisconsin-Madison, Madison, WI; [2]Dept of Medicine, Univ of Wisconsin-Madison, Madison, WI; [3]Dept of Surgery, Univ of Wisconsin-Madison, Madison, WI.*

Background: Blockade of the renin-angiotensin system (RAS) with angiotensin converting enzyme inhibitors or angiotensin II receptor blocker reduces cardiovascular mortality in the general population and among patients with diabetic chronic kidney disease (CKD). Similarly, RAS blockade decreases proteinuria in CKD. It remains controversial, however, whether this translates to improved patient or graft survival among transplant recipients.

Methods: We analyzed 2967 renal transplant recipients at the University of Wisconsin-Madison between 1990 and 2010 who survived at least 6 months after transplantation to assess the association of RAS blockade use with patient and graft survival.

Results: 429 (14.5%) patients used RAS blockade at the start of follow-up. More than half (n=1680; 56.6%) of patients used RAS blockade at some point during follow-up, though only 227 (7.7%) patients used RAS blockade during the entire follow-up. Median follow-up time was 5.6 years. 392 deaths, 396 death-censored graft failures, and 765 total graft failures occurred during follow-up.

Outcome	Unadjusted HR (95% CI)	Adjusted† HR (95% CI)
Mortality	0.93(0.76-1.13)	0.65(0.53-0.81)
Death-censored graft failure	1.26(1.03-1.54)	0.61(0.48-0.76)
Total graft failure	1.09(0.94-1.26)	0.62(0.53-0.72)

HR; hazard ratio, CI; confidence interval
†Adjusted for year of transplantation, duration of dialysis before transplantation, number of prior transplants, donor type, recipient age, gender, race, body mass index, sensitization, delayed graft function, biopsy-confirmed acute rejection, glomerular filtration rate at discharge, diabetes, preexisting cardiovascular disease, blood pressure, albuminuria, LDL cholesterol, and hematocrit

Conclusions: Our findings suggest that RAS blockade use is associated with improved patient and graft survival after renal transplantation. Widespread use of RAS blockade may improve patient and graft survival in renal transplant recipients.

TH-PO1115

Survival, Morbidity, Sensitisation and Retransplantation Outcomes in a Cohort of Dialysis Patients After Renal Graft Loss and Transplant Nephrectomy by Indication
Andrew K. Coutinho, Richard W. Corbett, Sarah Hildebrand, David Taube, Neill D. Duncan. *West London Transplant and Renal Centre, Imperial College Healthcare NHS Trust, London, United Kingdom.*

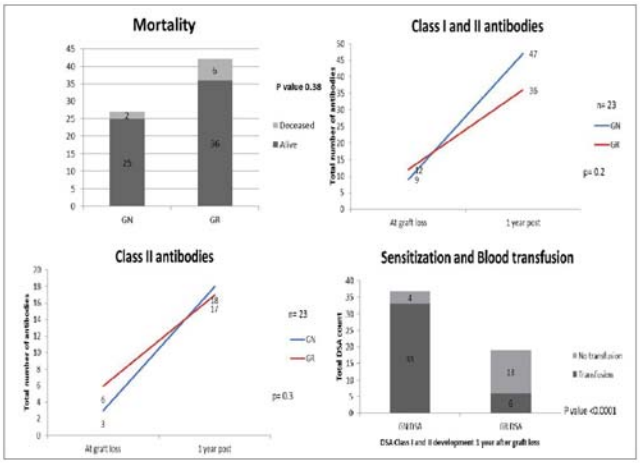
Background: A quarter of prevalant dialysis patients have Dialysis After Graft Loss with unique factors modifying outcomes. The indication for graft nephrectomy in patients with DAGL at our centre is evidence of systemic inflammation.

Methods: 121 patients had DAGL between Jan 2007-Aug 2013, we excluded those with previous, multiple or immunologically complex grafts. We made a retrospective observational study in the 69 patients with DAGL after exclusions. 27 patients had graft nephrectomy(GN), 42 had graft retained(GR).The median age at transplantation was GN-38.5 yrs versus GR-53 yrs.

Results: Total deaths in the GN (2/27) and GR (6/42) groups was not significant (p=0.38). Hospitalisation rate over a year for GN group was lower.

	GN group	*GR group*	*p-Value*
All hospital admissions	97/100 patient yrs	168/100 patient yrs	0.03
Non cardiac and non infective admissions	58/100 patient yrs	110/100 patient yrs	0.01
Outpatient antibiotic use	30.4/100 patient yrs	13.3/100 patient yrs	0.6

No difference was seen in surrogate markers of inflammation measured monthly - CRP, albumin and haemoglobin (p=0.2, 0.14 and 0.45 respectively) and in retransplant waitlisting between the groups (13/27 GN group versus 12/42 GR group, p=0.09).More DSA's were seen after graft loss in both groups of waitlisted patients but this was statistically significant with relation to blood transfusions only.



Using the UK NHSBT Relative Chance of Kidney Transplantation Calculator, 4/13 waitlisted GN patients had a 50% or greater chance of a retransplant versus 2/12 waitlisted GR patients at 5 years (p=0.7).

Conclusions: Hospitalisation was higher for GR patients. Graft retention did'nt adversely affect rates of survival, infection, markers of inflammation or chances of retransplantation.

TH-PO1116

Current Practices in Screening and Management of Prostate Cancer in Renal Transplant Recipients: A Survey of U.S. Transplant Centers
Ross Beckman,[1,2] Dorothy Skierkowski,[3] Reginald Y. Gohh,[1,4] George P. Bayliss.[1,4] *[1]Alpert Medical School, Brown Univ, Providence, RI; [2]Surgery, Johns Hopkins, Baltimore, MD; [3]Biostatistics, Rhode Island Hospital, Providence, RI; [4]Medicine, Rhode Island Hospital, Providence, RI.*

Background: Immunosuppression following renal transplantation is thought to put patients at increased risk of malignancy. But prostate cancer is often slow-growing and relatively low-risk, and its response to immunosuppression has not been widely studied. Optimal management of potential transplant recipients found to have prostate cancer prior to transplantation also has not been established.

Methods: After receiving institutional review board approval, a 16-question survey was sent to 225 transplant center medical and surgical directors at 135 centers asking about each center's practices in screening for and managing prostate cancer found during pre-transplant evaluations and post-transplant follow-up.

Results: We received 37 responses from 33 unique transplant centers representing all UNOS regions. 91% of respondents said they screened for prostate cancer pre-transplant, but only 50% said their institution screened patients in the general population; 34% said they did not know if they screened for prostate cancer in the general population. There was no significant difference between pre-transplant handling of low grade prostate cancer and whether respondents thought low-risk prostate cancers should always undergo definitive surgical treatment before transplantation. Those respondents who felt that the risk of dying from prostate cancer on immunosuppression was no greater than in the general population were significantly more likely to consider the risk of death from delaying transplant to be higher than of cancer post transplant. Those who said they were more aggressive in treatment of low-grade prostate cancers post transplant were significantly more likely to base their decision on experience rather than evidence.

Conclusions: We conclude there is no consensus among U.S. renal transplant centers on the management of prostate cancer in the transplant population, likely due to a lack of evidence to guide such practices.

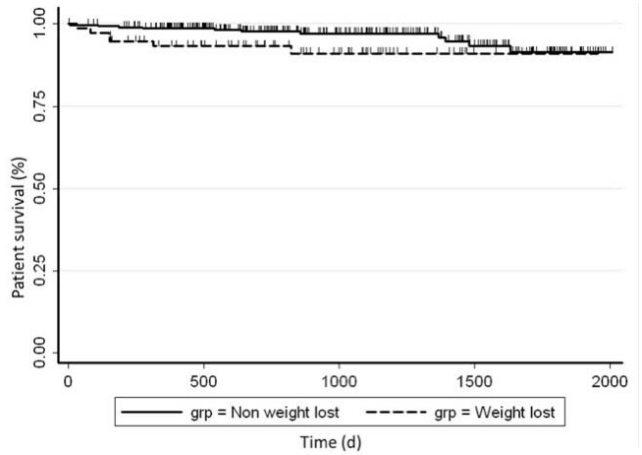
TH-PO1117

Impact of Weight Loss Before Renal Transplantation in Obese Patients: Risk of Early Mortality Anne-Elisabeth Heng,[23] Fernando C. Fervenza,[4] Mikel Prieto.[1] *[1]Div of Transplant Surgery, The William J von Liebig Center for Transplantation and Clinical ReGeneration, Mayo Clinic, Rochester, MN; [2]Nephrology Dept, Pole R.E.U.N.N.I.H.R., CHU G Montpied, Clermont-Ferrand, Puy de Dome, France; [3]Faculté de Médecine, Univ d'Auvergne, Clermont-Ferrand, Puy de Dome, France; [4]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: The obese patient's survival is significantly better after transplantation than dialysis. Some doctors encourage patients to lose weight but it could be harmful than beneficial.

Methods: In a retrospective study from the Mayo Clinic Rochester database (893 renal transplanted patients from 2007 to 2010) we compared data from non obese patients with those from patients with an history of obesity (obese patients). In this group, datas from patients with a significant weight loss (decrease in weight observed during waiting before transplant > 10% of initial weight) (WL) were compared to those from obese patient who have not lost weight (NWL).

Results: 42% of the transplanted patients were obese. In comparison with non obese, obese patients are older, have more comorbidities and surgical complications, warm ischemia time tends to be longer but patient and graft survivals are the same. A significant weight loss is observed in 78 of 380 patients. No differences in demographic characteristics were observed between WL and NWL group exept a greater proportion of African-American in the WL. No difference in surgical or medical complications was seen between the WL and NWL groups. However, the patients survival adjusted to age and comorbidities was less good especially the first year post transplantation.



Conclusions: Weight loss before transplantation in obese patients do not decrease surgical complications and may be harmful.

TH-PO1118

Induction Regimen and Status of Epstein-Barr Viral Infection in Pediatric Renal Transplants Dongmei Huang,[1] Fu L. Luan,[2] Neal B. Blatt.[1] *[1]Univ of Michigan, Ann Arbor, MI; [2]Saint Barnabas Medical Center, Livingston, NJ.*

Background: Post-transplant lymphoproliferative disorder (PTLD) is more likely to occur in children due to their frequent EBV naïve status. Induction regimens incorporating Thymoglobulin show increased the risk of PTLD compared to regimens using anti-interleukin-2 receptor (aIL2R) antibodies, however, the rates of Epstein-Barr Virus (EBV) viremia following these induction regimens is unknown. We hypothesized that Thymoglobulin induction would be associated with increased EBV viremia.

Methods: EBV viral loads were monitored for 2 years post-transplant by PCR in all pediatric kidney transplant patients from 1998-2011 at C.S. Mott Children's Hospital. Positive EBV viremia was defined as any detectable copies and high titer EBV as ≥2000 copies/mL. Multivariate logistic regression analysis was used to test the relationships between EBV viral load, time to EBV viral load, and induction regimen.

Results: Similar numbers of patients received thymoglobulin or aIL2R induction and they had similar rates of PTLD (see Table). 73 patients were EBV naïve at transplant with 81% (N=59) having an EBV(+) donor. More aIL2R patients were EBV naïve at transplant. In multivariate analysis, the odds of having a high titer EBV was higher with aIL2R induction [OR 10.7 (2.8-41.47), p 0.001], AA race [(OR 12.8 (2.0-82.8), p 0.007], and having a EBV D(+)/R(-) status at transplant [7.2 (2.4-21.6), p<0.001]. Patients who received aIL2R had significantly shorter time to high titer EBV than those who received Thymoglobulin [HR 2.74 (1.1-6.9), p=0.032].

Table 1:

	Total	Thymoglobulin	aIL2R	p-value
Induction (N, %)	159	71 (45%)	88 (55%)	
PTLD	14 (9%)	7 (10%)	7 (8%)	0.67
EBV naive	73 (46%)	26 (37%)	47 (53%)	0.035
EBV PCR(+)	84 (53%)	32 (45%)	52 (59%)	0.003
EBV ≥2000	39 (46%)	6 (8%)	33 (38%)	<0.001
Age (mean±SD)	11.3 ± 5.4	11.7 ± 5.5	11.0 ± 5.3	0.29

Conclusions: Contrary to our hypothesis, aIL2R induction was associated with increased risk of developing high titer EBV, but did not result with increased PTLD. Although our study is retrospective and limited to a single center, our findings challenge the hypothesis that EBV viremia post-transplant is associated the development of PTLD.

TH-PO1119

Reduced Rejection Rates and Improved Graft Survival with a Dedicated Young Adult Service Jeroen Bastiaan van der Net, Paul N. Harden. *Oxford Kidney Unit, Oxford Univ Hospitals NHS Trust, Oxford, United Kingdom.*

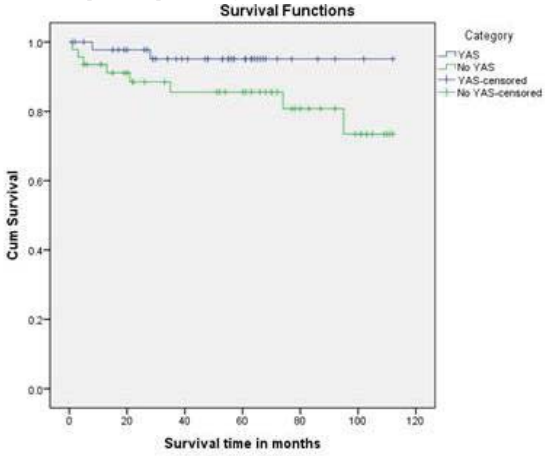
Background: Non-adherence results in the poorest 5yr allograft survival rates in 18-29 year old kidney transplant recipients (KTRs) compared with all other age categories. We explored the impact of a restructured dedicated young adult service(YAS) for 16-30 year old KTRs comparing rejection rates and graft survival with standard clinic care between 2005 to 2014 in a single adult center.

Methods: Eligible patients were identified using the electronic patient record; all patients records were carefully reviewed to document demographics, immediate and late outcomes of transplantation.

Results: Since January 2005, 93 KTRs aged 17-30 were transplanted (60m,33f; 79(85%) white); 47 (51%) were involved in the YAS. Main causes of ESKD were reflux nephropathy (17.2%), IgA nephropathy (10.8%) and dysplastic kidneys (8.6%). 53 (57%) received a kidney from a living donor. Mean age at transplantation was 24.2 (17-29) years, HLA mismatch 2.15 (0-5), 19/87 (21.8%) pre-emptive, 19/93 (20.4%) previously transplanted, 83/93 (89%) primary function. YAS patients were more frequently male and less likely to have graft loss 2/47 (4%) versus 8/46 (17%), p-value 0.041, or late rejection 1/47 (2%) versus 6/46 (13%), p-value 0.046.

	YAS (n=47)	No YAS (n=46)	p value
Age at transplantation (years)	23.5(0.48)	24.9(0.55)	0.08
Living Donor recipient (%)	30 (64%)	23(50%)	0.18
HLA mismatch	2.15 (0.19)	2.14 (0.17)	0.98
Male sex (%)	40 (85%)	20 (44%)	<0.001
Pre-emptive (%)	11(23%)	8(20%)	0.70
Median Serum Creatinine at 12 months post-transplant (umol/L)	125 (107-148)	118 (100-151)	0.57

Survival analysis of graft loss shows diverging Kaplan Meier curves for YAS patients versus non-YAS patients (p-value log rank 0.095).



Conclusions: The YAS resulted in a significant reduction in late rejection and graft loss, and is a useful tool to improve patient outcomes and reduce healthcare costs.

TH-PO1120

Immunosuppression and Pregnancy Outcomes in Female Kidney Transplant Recipients Serban Constantinescu,[1] Peter Axelrod,[1] Lisa Coscia,[2] Michael J. Moritz,[3] Vincent T. Armenti.[2] *[1]Temple Univ School of Medicine; [2]National Transplantation Pregnancy Registry, Gift of Life Inst, Philadelphia, PA; [3]Lehigh Valley Health Network.*

Background: Immunosuppressive regimen may influence pregnancy course and outcomes in kidney recipients.

Methods: Data were collected by the National Transplantation Pregnancy Registry via questionnaires, phone interviews and hospital records. All pregnancies with mycophenolate (MMF) exposure were excluded.

Results: We analyzed 1514 pregnancies in 895 kidney recipients on 3 immunosuppressive regimens: azathioprine (AZA) cyclosporine (CsA) and tacrolimus (TAC).

	AZA	CsA	TAC	p value
Conception yrs	1967-2013	1982-2013	1993-2013	
Recipients/Pregnancies	240/441	466/778	189/295	
MATERNAL FACTORS				
Planned pregnancy	59%	58%	73%#	<0.001
Mean SCr preconception (mg/dL)	1.1±0.4	1.4±0.4#	1.1±0.3	<0.001
Mean SCr during pregnancy (mg/dL)	1.2±0.5	1.4±0.7#	1.2±0.6	0.003
Mean SCr postpartum (mg/dL)	1.2±0.6	1.6±0.9#	1.3±0.5	<0.001
Treated hypertension during pregnancy	26.1%#	61.5%#	51%#	<0.001
Treated rejection during pregnancy	0.5%	0.9%	1.4%	NS
Graft loss within 2 yrs	4.2%	7.2%	4.8%	NS
PREGNANCY OUTCOMES*	456	808	303	
Miscarriage	10.8%	13.5%	19.1%#	0.004
Live births %(n)	81.6% (372)	77.8% (629)	77.6% (235)	NS
Mean gestational age (wks)	36.5±3.3#	35.8±3.4	35.4±3.7	<0.001
Prematurity (<37 wks)	46.2%	52.2%	53.2%	NS
Mean birthweight (g)	2745±710#	2502±750	2530±828	<0.001
Low-birthweight (<2500 g)	34.7%	44.8%	41.6%	<0.01
Birth Defects	2.2%	4.2%	6.8%	0.02

*includes multiple births, # p<0.01 compared to each other group

TAC group had significantly more planned pregnancies and miscarriages. CsA group had significantly higher HTN and serum creatinine (SCr). The incidence of rejection and graft loss was comparable among groups. While live births were similar among groups, AZA newborn had significantly higher gestational age and birthweight.

Conclusions: Pregnancy outcomes in kidney recipients on AZA, CsA or TAC, without MMF exposure resulted in similar rates of live births, and low incidences of rejection and graft loss within 2 yrs of pregnancy. For all groups birth defect rate was comparable to the general population.

TH-PO1121

Pregnancy and Maternal Outcomes in Kidney Transplant Recipients with the Diagnosis of Alport Syndrome Lisa Coscia,[1] Michael J. Moritz,[2] Serban Constantinescu,[3] Vincent T. Armenti.[1] *[1]National Transplantation Pregnancy Registry, Gift of Life Inst, Philadelphia, PA; [2]Lehigh Valley Health Network, Allentown, PA; [3]Temple Univ School of Medicine, Philadelphia, PA.*

Background: The purpose of this study was to analyze pregnancy and maternal outcomes in female kidney transplant recipients with the diagnosis of Alport syndrome.

Methods: Data were collected by the National Transplantation Pregnancy Registry (NTPR) via questionnaires, phone interviews and medical records.

Results: Out of 960 kidney recipients reporting 1,687 pregnancies to the NTPR, there are 15 female recipients with Alport syndrome. The kidney donors were: living related 6, living unrelated 2, deceased 6, and unknown 1. There were 22 pregnancies with 24 outcomes (includes twins); 22 live births and 2 miscarriages. The mean age at transplant was 24.8±5.5 yrs. and mean transplant to conception interval was 4.8±2.96 yrs. Immunosuppression during pregnancy was tacrolimus based in 9, cyclosporine based in 8 and azathioprine in 5. Comorbid conditions during pregnancy included: hypertension 50%, insulin use 14%, preeclampsia 20% and rejection 0. Two recipients had rejection postpartum; 1 treated with OKT3, lost graft 6 mos. postpartum and was re-transplanted, and 1 effectively treated with methylprednisolone. Graft function at last maternal follow-up (11.9±8.4 yrs): 10 adequate, 1 reduced, 3 had died, and 1 lost to follow-up. Mean gestational age was 35.8±2.1 wks and mean birthweight was 2665±655 g. There were 16 male and 6 female newborn. Two infants had birth defects: 1 pyloric stenosis and megaureter and 1 undescended testicle. There were 5 children (4 male, 1 female) diagnosed with Alport syndrome, one of whom required a transplant; another female child was identified as a carrier of the disease. At last child follow-up (mean age 11.2±6.9 yrs; range 0.09-21.9 yrs), all were reported developing well.

Conclusions: Kidney transplant recipients with the diagnosis of Alport syndrome are able to have successful pregnancies. As with all pregnancies post-transplant they are considered high-risk and should be managed by a multi-disciplinary team. Genetic counseling is particularly important in the pre-pregnancy planning for these recipients.

Growth Post Pediatric Renal Transplantation after Steroid Withdrawal or Avoidance: A Meta-Analysis Anne K. Tsampalieros,[1,2] Amber O. Molnar,[2,3] Dean Fergusson,[3] Greg A. Knoll.[2,3] *[1]Nephrology, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada; [2]Epidemiology, Ottawa Hospital Research Inst, Ottawa, OH, Canada; [3]Medicine, Ottawa Hospital, Ottawa, ON, Canada.*

Background: A variety of steroid withdrawal and avoidance protocols have been developed for after kidney transplantation. The objective of this meta-analysis was to identify and evaluate the literature published on the use of steroid withdrawal and/or avoidance after pediatric kidney transplantation that focused specifically on analyzing growth. As a secondary objective we evaluated its safety using risk of acute rejection and graft function.

Methods: A systematic search using MEDLINE and EMBASE was performed from 1990 to February 2014. This review included all pediatric randomized controlled trials (RCT's) which compared either early (within 7 days post transplant), intermediate (>7 days to < 1 year), late (>1 year) steroid withdrawal or complete avoidance to participants who were maintained on daily or alternate day steroids after kidney transplantation. The primary outcome assessed was growth post transplant (measured as change in height standard deviation score [SDS]) and secondary outcomes included acute rejection, graft function, graft and patient survival.

Results: We screened 855 citations of which 184 were selected for full text review. Five studies met eligibility criteria (n=522).

Study	Total Sample Size	Intervention	Follow up
Meriqc et al, 2013	24	Early Withdrawal	1 year
Sarwal et al, 2012	130	Complete Avoidance	1 year
Benfield et al, 2010	132	Intermediate Withdrawal	1 year
Grenda et al, 2010	196	Early Withdrawal	6 months
Weber et al, 2010	42	Late Withdrawal	1 year

Using pooled data, we found the experimental group (those who underwent steroid withdrawal or avoidance) had improved growth, with a mean height SDS difference of 0.16 95% C.I. of 0.09-0.23, p=0.01 compared to controls (those who continued on steroids). The risk of a rejection episode did not differ significantly between the two groups (p=0.63) nor did the final reported eGFR (p=0.4).

Conclusions: Based on the summarized findings of these trials, steroid withdrawal and/or avoidance post pediatric kidney transplantation allows for better growth.

TH-PO1123

Kinetic Estimation of GFR Improves Prediction of Dialysis or Recovery After Kidney Transplantation Timothy J. Pianta,[1] Zoltan H. Endre,[1] John W. Pickering,[2] Nicholas Buckley,[1] Philip Peake.[1] *[1]Prince of Wales Clinical School, Univ of New South Wales, Australia; [2]Medicine, Univ of Otago, New Zealand.*

Background: Prediction of delayed graft function (DGF) after kidney transplantation is suboptimal. Kinetic estimates of GFR under non-steady-state conditions, KeGFR, have been advocated in assessment of acute kidney injury (AKI) and renal recovery.

Methods: We investigated KeGFR in the prediction of DGF. KeGFR derived from sCr ($KeGFR_{sCr}$) was calculated at 4h, 8h and 12h in 81 patients using initial serum creatinine (sCr) concentrations, the estimated creatinine production rate, volume of distribution, and the difference between consecutive sCr values. The utility of sCr for prediction of DGF was compared with $KeGFR_{sCr}$, plasma cystatin C (pCysC), and $KeGFR_{pCysC}$ similarly derived from pCysC concentrations.

Results: At 4h the area under the receiver operator characteristic curve (AUC) for prediction of DGF was 0.60 (95% CI: 0.45 – 0.76) for sCr. Prediction of DGF was improved by using $KeGFR_{sCr}$ [AUC: 0.76 (0.62 – 0.90), p = 0.04]. After adjustment for pre-operative variables, integrated discrimination improvement analysis showed that sCr provided no benefit for predicting DGF at 4h and 8h, and only modest benefit at 12h. In contrast, the $KeGFR_{sCr}$ improved the prediction of DGF at each time point. pCysC and $KeGFR_{pCysC}$ similarly outperformed sCr. In this cohort, a $KeGFR_{sCr}$ between 12 and 16 mL/min/1.73 m^2 predicted DGF at 4h, 8h or 12h with 90% sensitivity.

Conclusions: Calculation of $KeGFR_{sCr}$ facilitates early prediction of DGF within 4h of renal transplantation and may allow trials of early intervention aimed at ameliorating ischemia reperfusion injury.

The Role of Plasma Exchange in Focal Segmental Glomerulosclerosis Recurrence Post Renal Transplant: A Systematic Review Abdullah Kashgary,[1,2] William F. Clark.[2] *[1]Dept of Medicine, King Abdulaziz Univ Hospital, King Abdulaziz Univ, Jeddah, Saudi Arabia; [2]Dept of Nephrology, Western Univ, London, Canada.*

Background: The role of plasmapheresis in recurrent focal segmental glomerulosclerosis post renal transplant has not been well established.To assess the effectiveness of plasmapheresis in the treatment of recurrent FSGS post renal transplant and to evaluate its long-term effect on graft function.

Methods: We performed a systematic literature review of English-language articles. We included all study designs of recurrent FSGS post renal transplant treated with plasmapheresis from 1950-2012.Key measures included patient characteristics,time to recurrence,histological features at diagnosis and recurrence,proteinuria at diagnosis,treatment,use of Rituximab therapy,and graft outcomes.Our primary outcome was FSGS remission; the secondary outcome was end-stage renal disease (ESRD) at end of follow up.

Results: Out of 77 articles included,420 patients met the inclusion criteria.Median follow-up time was 19 months. Three quarters of patients responded to plasmapheresis (25% of these had partial remission);the remaining 24% were non-responders. Responders were younger than non-responders (23 versus 26 years, respectively),had lower pre-treatment proteinuria(7.0 mg/day versus 9.3 mg/day),were less likely to progress to ESRD(12% versus 63%),and had a longer time from diagnosis to ESRD(3.0 versus 2.3 years).Histological evidence for FSGS at the time of the recurrence diagnosis was similar in both groups.Of 41 patients treated with Rituximab for FSGS recurrence,70% experienced remission.Rituximab responders were younger than non-responders(17 versus 41, respectively),but had higher levels of pre-treatment proteinuria(9.6 g/day versus 4.7 g/day).Responders were less likely to develop ESRD(0 versus 40%) and time to ESRD was longer(5.0 versus 3.5 years).

Conclusions: Our study suggests that plasma exchange may be effective in treating post renal transplant recurrence of FSGS. The majority of patients experienced remission and

preserved their renal function with this treatment.The level of proteinuria at diagnosis,older age and shorter time from diagnosis to ESRD could predict the non-responsiveness to plasmapheresis.

TH-PO1125

Urinary Potassium Excretion and Risk of Graft Failure and Mortality in Renal Transplant Recipients Michele F. Eisenga,[1] Michel M. Joosten,[1] Sabita Soedamah-Muthu,[2] Else Van den Berg,[1] Petronella Deetman,[1] Gerjan Navis,[1] Rijk O.B. Gans,[1] Carlo A. Gaillard,[1] Stephan J.L. Bakker.[1] *[1]Internal Medicine, UMCG; [2]Human Nutrition, Wageningen Univ, Netherlands.*

Background: Low potassium intake has consistently been shown to induce kidney injury in experimental animal models. This is thought to be mediated through stimulation of ammoniagenesis. We hypothesized that urinary potassium excretion (UKV) as gold standard for dietary potassium intake is inversely associated with graft failure in renal transplant recipients (RTR).

Methods: Dietary intake was assessed by 24 hour UKV and food-frequency questionnaires (FFQ). Graft failure was defined as return to dialysis or retransplantation. Cox regression analyses were used to investigate prospective associations with outcome.

Results: We included 705 stable RTR (age 53±13 yrs; 57% males at 8.1±7.6 yrs after Tx). UKV was 73±24 mmol/d and urinary ammonia excretion was 21±12 mmol/d. During follow-up for 3.1 (2.7–3.9) yrs, 45 RTR developed graft failure and 83 RTR died. UKV was positively correlated with potassium intake according to FFQ (r=0.44, p<0.001). RTR in the lowest tertile of UKV were at increased risk of graft failure (HR 2.70 [95%CI 1.13-6.44]) and mortality (2.36 [1.35-4.12]) compared to the highest tertile (figure 1). In multivariable analyses with UKV as a continuous variable, UKV was inversely associated with both graft failure (0.76 [0.64-0.91]; p=0.002) and mortality (0.84 [0.75-0.94]; p=0.002), independent of potential confounders, including eGFR, plasma potassium, SBP, and urinary ammonia.

Conclusions: Low potassium intake measured by UKV is associated with higher risk of graft failure and mortality. This association seems not mediated through stimulation of ammoniagenesis. Because many RTR are advised to limit potassium intake prior to transplantation, specific attention for adequate potassium intake after transplantation may be warrented.

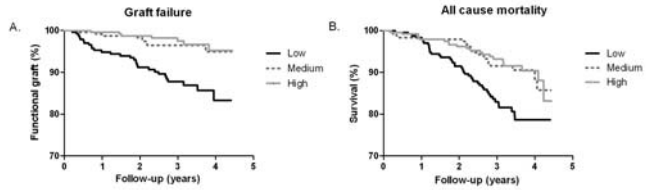

Figure 1 Survival curves for graft failure (A) and mortality (B) according to tertiles of UKV

TH-PO1126

Proximal Tubular Dysfunction Is Common after the First Year of Kidney Transplantation Gaël Ensergueix,[1] Julien Allard,[1] Franck Saint-Marcoux,[2] Benoît Marin,[3] Sandra Bodeau,[2] Jean-Claude Aldigier,[1] Pierre Marquet,[2] Marie Essig.[1] *[1]Nephrology, Dialysis, Transplantation, CHU Limoges, France; [2]Pharmacology, Toxicology, CHU Limoges, France; [3]Epidemiology, Biostatistics, Methodology, CHU Limoges, France.*

Background: After the initial period of kidney transplantation, the prevalence of proximal tubular dysfunction (PTD) and its consequences are unknown. The aim of this study was to evaluate PTD prevalence in kidney transplant recipients, after the first year, and to analyze its risk factors.

Methods: We conducted an observational and cross-sectional study between April 2012 and April 2013 at Limoges university hospital (France). The inclusion criteria were: kidney transplantation for at least one year, and eGFR [MDRD] > 15 mL/min/1,73m². PTD was assessed by the association of urine cystatin C (UCC)/urine creatinine > 20 µg/mmol and UCC > 100 µg/L.

Results: 356 patients were included, among them 335 could have a full analysis (64.8% males and 35.2% females, with a mean age of 57.8 years (20.0 to 84.4)). 92.9% of patients were treated with calcineurin inhibitors, (Cyclosporine (CsA) : 51.6%, Tacrolimus (Tac) : 41.3%), 81.8% with anti-metabolites (Azathioprine : 3.3%, Mycophenolic Acid : 7.5%, Mycophenolate Mofetyl (MMF) : 71%) and 7.5% with m-TOR inhibitors. PTD prevalence was 22.7 %. The tubular proteinuria and the fractional excretion of uric acid were significantly associated with PTD (p < 0.0001). The prevalence of PTD increased with donor age (OR = 1.4, 95% CI [1.1 ; 1.7]) but was independent of cold ischemia time (p = 0.9980). An eGFR [MDRD] above 30 mL/min/1,73m² was protective (OR : 0.36, 95% CI [0.144 ; 0.92]). The immunosuppressive regimens " MMF + m-TOR inhibitors " and " MMF + Tac " were more frequently associated with PTD than " MMF + CsA " (OR = 6.4, 95% CI [1.8 ; 23.0] and OR = 3.0, 95% CI [1.3 ; 6.8], respectively).

Conclusions: In renal transplant patients, after the first year post-transplantation, about one quarter of the recipients are affected by PTD, which seems partly related to the immunosuppressive regimen. Since proximal tubular cells lesions could progressively lead to tubular atrophy and interstitial fibrosis, PTD early detection and treatment may help to increase graft survival.

TH-PO1127

Magnetic Resonance Elastography: A Novel Non-Invasive Modality for Chronic Renal Allograft Injury Detection Darren A. Yuen, General Leung, Nishigandha Burute, Stephen G. Szeto, Derek Sun, Serge Jothy, Jeffrey S. Zaltzman, G.V. Ramesh Prasad, Warren Foltz, Craig A. Simmons, Anish Kirpalani. *Univ of Toronto, Toronto, ON, Canada.*

Background: Chronic allograft injury (CAI) is a common cause of renal transplant loss, and is driven by multiple factors, including apoptosis and fibrosis. Biopsy is the gold standard for diagnosis and prognosis of CAI, but is limited by risk and sample bias. While preliminary reports suggest that injured organs stiffen due to fibrosis, apoptosis-mediated parenchymal loss and diminished perfusion may conversely lead to reduced stiffness. We report our preliminary results using MR elastography (MRE), a gadolinium-free imaging technique that can detect renal stiffness, in a cohort of renal transplant patients.

Methods: Patients with grafts > 1 yr were eligible for recruitment. All subjects underwent MRE to measure kidney stiffness. 12 regions of interest (ROI) were placed per kidney on a coronal section cut through the hilum, with two ROIs each in the upper, middle and lower pole cortex and medulla. Clinical data (age, gender, donor type, transplant vintage, plasma creatinine, eGFR, urinary albumin excretion) was also collected. All patients underwent graft biopsy, and interstitial fibrosis was measured on trichrome-stained sections.

Results: 4 patients were studied. Mean age was 42 ± 17 yrs and 75% were male. 2 of the 4 patients received a living donor kidney, and transplant vintage was 59 ± 7 mos. Plasma creatinine was 147 ± 25 µM (eGFR 46 ± 8 mL/min/1.73 m²), and urinary albumin:creatinine ratio was 7.8 ± 13 mg/mmol. Mean cortical and medullary stiffness values were 5.0 ± 2.0 kPa and 4.3 ± 1.4 Pa respectively. Stiffness was reduced in patients with eGFR < 45 mL/min (n = 2) versus those with eGFR > 45 mL/min (n = 2) (cortex: 3.5 ± 0.3 kPa versus 6.6 ± 1.0 kPa and medulla: 3.2 ± 0.2 versus 5.4 ± 0.7 Pa).

Conclusions: MRE-derived stiffness measurement in the transplant kidney is feasible. In this pilot study, bulk measures of graft stiffness appear to decline with more severe injury. Further studies are required to confirm this finding, and to delineate the underlying mechanisms. Development of MRE may enable non-invasive quantitation of injury in patients with CAI.

The Clinical Impact of BK Virus Surveillance on Outcomes in Kidney Transplant Recipients Se-Hee Yoon,[1] Jang-Hee Cho,[2] Hee-Yeon Jung,[2] Won Min Hwang,[1] Sung-Ro Yun,[1] Ji-Young Choi,[2] Sun-Hee Park,[2] Yong-Lim Kim,[2] Chan-Duck Kim.[2] *[1]Internal Medicine, Konyang Univ Hospital, Deajeon, Republic of Korea; [2]Internal Medicine, Dept of Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Korea & Clinical Research Center for End Stage Renal Disease, Republic of Korea.*

Background: The objective of this study was to investigate the clinical impact of BK virus surveillance to prevent BK virus associated graft injury in kidney transplantation.

Methods: We evaluated the prevalence of BK viremia using plasma quantitative polymerase chain reaction (PCR) and BK virus associated nephropathy (BKVAN) and the clinical impact of BK viremia on graft outcomes in the kidney transplant recipients between January 2008 and June 2013.

Results: In this study, 213 kidney transplant recipients were included. The prevalence of BK viremia and high BK viremia (>1X10⁴ copies/mL) were 66.7% (142/213) and 17.4% (37/213) respectively. Nine cases (4.2%) were finally diagnosed as BKVAN by allograft biopsy. Although low BK viremia (<1X10⁴ copies/mL) group had comparable eGFR after transplantation, high BK viremia group showed significantly lower eGFR at 18 months after transplantation when compared with no viremia group. In receiver operating characteristic curve analysis, area under the curve of peak BK viremia for the diagnosis of BKVAN was 0.980. We found 92,850 copies/mL was significant cut-off level to predict BKVAN with 89% sensitivity and 94.6% specificity. The risk factors for viral loads ≥ 10000 copies/ml were CMV infection, steroid pulse therapy and acute rejection.

Conclusions: Early detection of BK viremia after renal transplantation using a frequent screening standardized surveillance protocol and treatment of those with significant viremia with systematic reduction in immunosuppressant are effective strategies that identify subclinical BKVAN, preserve renal function, and prevent graft loss from BKVAN.

TH-PO1129

Low Rate of BK Viremia and Nephropathy in Large Single Center Series of HIV+ Kidney Transplant Recipients Shabnum Haleem, Talal A. Khan, Gregory Malat, PharmD, Karthik M. Ranganna, Alden Michael Doyle. *Drexel Univ College of Medicine, Philadelphia.*

Background: BK virus is a polyoma virus that is benign in immunocompetent hosts but can lead to allograft graft dysfunction and loss for kidney transplant recipients .The reported estimated prevalence of BK-induced nephritis is 1 to 10 percent, with a mean of approximately 5 percent. There are multiple risk factors associated with BK virus nephropathy(BKVN) including male gender, glucocorticoids maintenance immunosuppression, diabetes mellitus, treatment of acute rejection, delayed graft function and ureteral trauma. The dominant risk factor is intensity of immunosuppression and the primary treatment modality is reduction in immunosuppression. Although the risk of BK viremia and nephropathy has not been well characterized in HIV+ kidney transplant recipients, it stands to reason that it might be greater than seen in HIV- populations because of the immune dysregulation imposed by the HIV virus on the host's immune system.

Methods: We retrospectively examined 59 consecutive HIV+ patients who received kidney transplant at our center between 2004-2014.At our center Urine BK virus PCR was checked sporadically .After 2009 serum BK virus PCR was checked as a protocol. We recorded their induction and maintenance immunosuppression, Urine and serum BK virus PCR, any evidence of rejections and any allograft biopsy proven diagnosis of BK nephropathy.

Results: Six out of 59 cases of HIV positive kidney transplant recipients had BK viuria. Only 1 out of 6 had BK viremia. None of the patients had evidence of BKVN from allograft biopsies. Most of the patients had induction with basiliximab and they were on standard triple maintenance immunosuppression with calcineurin inhibitors, mycophenolic acid and prednisone. All patients were maintained on stable ART therapy for HIV control. Thirty seven patients had episodes of acute rejections.

Conclusions: Our results suggest that despite the compound immunosuppression imposed by the combination of HIV serostatus and maintenance immunosuppression, HIV+ kidney transplant recipients were found to have a low risk for BK virus nephropathy. Why there is a lower risk for BK viremia and BKVN is not clear but deserves further inquiry.

TH-PO1130

Cerebral Lymphoma in Renal Transplantation in Australia and New Zealand Jobert Anjelo,[1] Vinoi George David,[1] Blair S. Grace,[2] Stephen P. McDonald,[2] Randall James Faull.[1] *[1]Nephrology, Royal Adelaide Hospital, Adelaide, South Australia, Australia; [2]ANZDATA Registry, Royal Adelaide Hospital, Adelaide, South Australia, Australia.*

Background: Post-transplant lymphoma is a major complication of organ transplantation, but cerebral lymphoma (CL) is rarely reported in literature.

Methods: Retrospective review based on ANZDATA Registry of patients with CL after renal transplantation in Australia and New Zealand from 1989-2012 cohort.

Results: Among 21390 people who received 24832 grafts, there have been 34 reports of cerebral lymphoma post transplantation, 327 reports of lymphoma in other sites, and 103 reports of PTLD CL was not reported in grafts prior to 1980, but was reported among 0.12, 0.32 and 0.15% respectively of recipients transplanted in the 1980s, 1990s and 2000s.

	Cerebral Lymphoma	Lymphoma[not Cerebral 0r PTLD]	PTLD	No lymphoma
Number of Recipients	34	302	102	20952
Age at first transplant [Median, years]	45[30-53]	43[30-53]	41[23-53]	44[31-54]
Age at diagnosis [Median,years)]	51[47-61]	52[42-63]	48 [35-61]	
Time from first transplant	2570	3183	2185	
EBV IgG neg recipient [OR=odds ratio]	7/20[35%] OR 2.7 [1.1- 6.7] P <0.04	36/90[40%] OR 3.3 [2.2- 5.1], P<0.001	30/57(53%) OR 5.5[3.3-9.3] P<0.001	
Use of CD3 agent [OR]	OR 2.5 [1.2-5.2] p=0.04	1.4 [1.1-1.9] P<0.001	1.3 [0.8-21], P=0.3	
Number of deaths	21	199	55	
Survival post diagnosis [median (IQR),days]	603[26-3486]	1264[76-5410]	1605[45-.]	

Risk factors: previous exposure to CD3 agents and seronegative recipient EBV IgG (collected from 1990) were associated with increased incidence. While median survival of people with CL was almost 20 months after diagnosis, this was poorer than other groups and more than 25% had died within 1 month.

Conclusions: Cerebral lymphoma is a rare presentation of post-transplant lymphoma in renal transplantation. Like lymphomas at other sites, it is associated with EBV negative serostatus and previous use of ATG / ALG / OKT3. It carries poor prognosis once diagnosed.

TH-PO1131

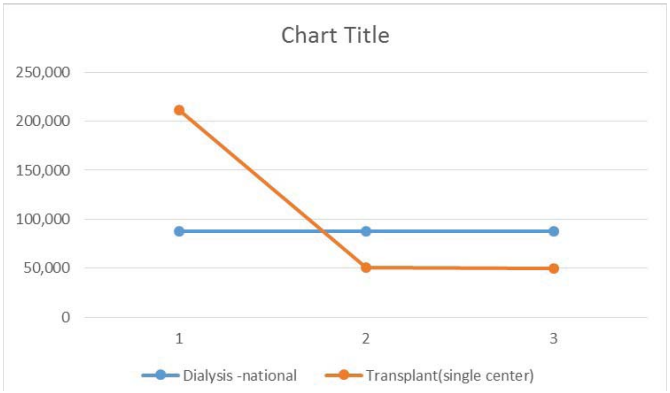
Comparative Cost Analysis of Renal Transplantation and Dialysis Therapy Neenu Sukumaran, Parvathy Madhavan, Sapna M. Jairath, Aditya Kadiyala, Umashankar Chandrashekaran, Celenia Reynoso, Madhu C. Bhaskaran, Ernesto P. Molmenti. *Renal Transplant Center, North Shore Univ Hospital, Manhasset, NY.*

Background: Multiple studies have demonstrated the cost effectiveness of renal transplantation in comparison to long term dialysis therapy in ESRD patients. However many changes in the cost structure for dialysis and renal transplant have occurred in recent years including, new cost saving measures and incentives for institutions. Also the criteria for transplant recipient selection is more aggressively regulated. We are determining the break-even point in the costs of these treatment modalities at a single center under the current payment system and evaluating the cost efficiency against the national financial average.

Methods: We conducted analysis of average annual costs of dialysis per patient and compared it to the average annual cost of renal transplant per patient using data collected from a single center. The values calculated were weighted against the national averages of dialysis and transplant costs. Several variables including reimbursements per visit, comorbidities, complications, length of inpatient stay and variation in reimbursements depending on these were recorded. Evaluating the above, we determined the time frame at which the cost of renal transplantation matched the cost of dialysis (break-even point).

Results: The results are as stated in the table and graph below:

	Single Center	National Costs
Average cost per transplant recipient in 2011	$211,313	$262,900



Conclusions: On analysis of the average costs of renal transplant versus dialysis in our center, the data obtained shows values comparable to the national average. Costs at this center are reduced through reduction in post-surgical hospital stay and the use of generic medication.

FR-PO001

Volume Replacement Improves Vasoconstriction but Not Glomerular Filtration Rate (GFR) Reduction Induced by Furosemide in Rats
Magali Araujo, Christopher S. Wilcox, William J. Welch. *Medicine, Georgetown Univ, Washington, DC.*

Background: Although loop diuretics reduce GFR by unknown mechanisms, we tested the hypothesis that a rise in proximal tubule hydrostatic pressure (P_{PT}) reduces GFR despite inhibition of tubuloglomerular feedback (TGF) and evaluated the effect of volume replacement (VR).

Methods: GFR and renal blood flow (RBF) were measured by inulin/PAH clearance in SD rats before and after i.v infusion of furosemide (F) (0.1, 0.3 and 1.0 mg/kg.h^{-1}) versus vehicle and TGF by changes in PT stop flow pressure (SFP) during loop perfusion of artificial tubular fluid (ATF) at 40 nl min with F (10^{-10} M to 10^{-4} M) versus vehicle.

Results: There was a dose-dependent increase in diuresis with F of 100%, 250% and 400% respectively. Both GFR and RBF decreased significantly 40-60 minutes following the higher i.v.doses of F by 40% and 46% respectivelly, $p<0.01$) without changes in MAP or heart rate. Volume replacement simultaneously with F (0.3mg/kg/h^{-1}) prevented a significant fall in RBF (6.1±0.8 versus 5.4±0.4 ml/min/g kidney, NS) but not in GFR (1.3±0.1 versus 0.9±0.1 ml/min/g kidney, $p<0.02$). P_{PT} (mmHg) increased 20 minutes after high dose of F (13.5±0.2 versus 22.4±0.4 mmHg, $p<0.01$) but returned to baseline within 60 minutes, yet the GFR and RBF remained reduced. Direct intratubular perfusion of F blunted TGF at 10^{-5} and 10^{-4} M.

Conclusions: Although P_{PT} increased sufficiently after F to reduce GFR, it cannot account for the persistent falls in GFR and RBF. A reduction in extracellular volume after F could account for the fall in RBF but not in GFR. Therefore, the reduction in GFR after F is largely independent of increases in P_{PT} or decreases in extracellular volume and occurs despite inhibition of TGF.

FR-PO002

The Intrinsic Circadian Clock in Renal Tubular Cells Does Not Play a Major Role in the Maintenance of Water and Salt Balance and Blood Pressure
Natsuko Tokonami,[1,2] Gabriel Centeno,[1] Sylvain Pradervand,[1] David Mordasini,[1,3] Robert Koesters,[2] Dmitri Firsov.[1] *[1]Univ de Lausanne, Lausanne, Switzerland; [2]Inserm, Paris, France; [3]DKF, Inselspital, Bern, Switzerland.*

Background: Recent study demonstrated that the renal circadian timing system plays an important role in maintaining extracellular fluid homeostasis and blood pressure. However, the role of the intrinsic circadian timing system located in specific renal cell types is largely unknown.

Methods: To study role of the intrinsic circadian timing system in renal tubules, we generated inducible nephron specific knockout mouse model for Bmal1, an essential element of the molecular clock. Bmal1$^{lox/lox}$ mice were crossed with mice expressing Cre recombinase in renal tubular cells upon doxycycline administration (hereafter Bmal1$^{lox/lox}$/Pax8:LC1Cre mice).

Results: Bmal1 was inactivated in the renal tubules as well as partially in the liver in Bmal1$^{lox/lox}$/Pax8:LC1Cre mice. Bmal1$^{lox/lox}$/Pax8:LC1Cre mice showed no difference in body weight but a significant reduction in kidney weight/body weight ratio by more than 20% comparing to control mice. Histological analysis revealed the presence of mesangial sclerosis in Bmal1$^{lox/lox}$/Pax8:LC1Cre mice. There was no difference in water, sodium and potassium excretory rhythms between Bmal1$^{lox/lox}$/Pax8:LC1Cre and control mice. The blood pressure and blood pressure dipping pattern were not different between control and Bmal1$^{lox/lox}$/Pax8:LC1Cre mice. These findings correlated with the fact that all major water, sodium and potassium transporters exhibited similar expression levels between control and Bmal1$^{lox/lox}$/Pax8:LC1Cre mice. However, deep sequencing has revealed important differences in genes related to several cellular pathways, including glucose homeostasis (GYS2, GSK3b, PYGL, PPARd) and oxidative stress (fibrinogen alpha beta and gamma chains, Arg2, Cdkn1a, Loxl4, Angptl4).

Conclusions: Our data suggest that the intrinsic circadian timing system in renal tubules does not have a significant impact on salt/water transport and blood pressure homeostasis. Further studies are required to define the role of the clock system in renal metabolism and oxidative stress protective mechanisms.

FR-PO003

$[Ca^{2+}]_i$ Oscillations and Il-6 Release Induced by a-Haemolysin from *Escherichia coli* Require P2 Receptor Activation in Renal Epithelia
Mette G. Christensen, Steen K. Fagerberg, Randi G. Bjaelde, Jens G. Leipziger, Helle A. Praetorius. *Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark.*

Background: Urinary tractinfections are commonly caused by a-haemolysin (HlyA)-producing *E. coli*. HlyA forms pores in cell membranes that renders the attacked cells permeable to ions and water. In erythrocytes, the effect of HlyA is strongly amplified by P2X receptor activation and our recent data support that ATP pass through the HlyA pore itself as an early event after pore insertion into the membrane. We therefore hypothesise that HlyA-induced $[Ca^{2+}]_i$ oscillations in renal epithelia is mediated by ATP release and following P2 receptor activation.

Methods: Here we confirm that HlyA, added at a concentration that cause 50% lysis of human erythrocytes, initiate marked $[Ca^{2+}]_i$ oscillatory activity in renal epithelia. This was quantified by live cell fluorescence microscopy in both MDCK cells and freshly isolated medullary thick ascending limb (mTAL) from mice.

Results: HlyA clearly triggered ATP release from MDCK cells and accordingly the HlyA-induced $[Ca^{2+}]_i$ oscillations were completely prevented by non-selective P2 receptor antagonists and by ATP-scavenging in MDCK cells. The HlyA-induced oscillations were reversible and did not cause permanent cell damage. To confirm these results, we tested the effect of HlyA on ATP biosensor cells. In native 132-1N1 astrocytoma cells that do not express any P2 receptors, HlyA barely caused any changes in $[Ca^{2+}]_i$. Transfection of the cells with a hP2Y_2 receptor resulted in an extensive increase in the HlyA-induced $[Ca^{2+}]_i$ oscillatory activity, which were sensitive to P2 receptor inhibition. Moreover, the HlyA-induced $[Ca^{2+}]_i$ oscillations were markedly reduced in mTAL isolated from P2Y_2 receptor deficient mice compared to wild type. Interestingly, the HlyA-induced interleukin 6 (Il-6) release was absent in the P2Y_2 receptor knockout (P2$Y_2^{-/-}$) mice, whereas it was readily detectable in the wild type (P2$Y_2^{+/+}$) mice.

Conclusions: These results suggest that HlyA triggers ATP release from renal epithelia, which via P2 receptor activation is responsible for the HlyA-induced $[Ca^{2+}]_i$ oscillations and following Il-6 release.

Claudin-2 Null Mice Reveal Increased Renal Transcellular Na Transport and Kidney Oxygen Consumption
Lei Pei,[1] Glenn Solis,[2] Mien T.X. Nguyen,[3] Nikhil Kamat,[3] Lynn Magenheimer,[1] Alicia A. McDonough,[3] William J. Welch,[2] Alan S.L. Yu.[1] *[1]Univ of Kansas Medical Center; [2]Georgetown Univ Medical Center; [3]Univ of Southern California.*

Background: 60% of filtered Na is reabsorbed in renal proximal tubules (PT), 40% of which is transported paracellularly. Claudins are a family of tight junction proteins that regulate paracellular permeability. Cation-selective claudin-2 (cldn2) is expressed in PT.

Methods: To evaluate the role of cldn2 in renal salt handling, we placed wild-type (WT) and cldn2 knockout (KO) mice on a Na deficient diet, and urine was collected every 8 hours. To test if there is any functional increase in transcellular Na transporters, we performed diuretic challenge test.

Results: The cldn2 KO mice were able to conserve Na to the same extent as WT.Quantitative RT-PCR did not reveal compensatory upregulation of other claudin isoforms. Immunoblotting for a panel of transcellular Na transporters showed a 23% decrease in the abundance of Na-H antiporter 3, only borderline increases in phosphorylated NaCl cotransporter and the l subunit of the epithelial Na channel, and no change in total or phosphorylated Na-K-2Cl cotransporter (NKCC2). The natriuretic response to the NKCC2 inhibitor, furosemide (25 mg/kg ip), was 25% higher in KO compared to WT ($P<0.05$), while the responses to hydrochlorothiazide and benzamil were not significantly different. Thus, loss of PT Na transport was compensated distally, primarily by a functional increase in transcellular Na transport in the thick ascending limb. We hypothesized that the increased transcellular transport would lead to increased renal oxygen consumption. Thus, we determined the ratio between whole kidney Na reabsorption (T_{Na}) and oxygen consumption (Q_{O2} = RBF X A-V_{O2}) in WT and KO mice. Cldn2 null mice exhibited lower T_{Na}/Q_{O2}. Renal O_2 extraction was also higher in KO mice.

Conclusions: These data indicate that the efficiency of oxygen utilization is decreased in cldn2 null mice. In conclusion, our findings suggest that in cldn2 KO mice, loss of PT paracellular Na transport is compensated by increased Na reabsorption by distal transcellular transporters maximally conserving Na at the expense of increasing kidney oxygen consumption.

FR-PO005

Protein Carbonylation of the Na/K-ATPase a1 Subunit Regulates Na/K-ATPase Signaling and Sodium Transport in Renal Proximal Tubular Cells
Yanling Yan,[1] Anna P. Shapiro,[2] Deepak K. Malhotra,[2] Zi-Jian Xie,[3] Nader G. Abraham,[1] Joseph I. Shapiro,[1,2] Jiang Liu.[1] *[1]JCE School of Medicine at Marshall Univ, Huntington, WV; [2]Univ of Toledo College of Medicine, Toledo, OH; [3]Marshall Inst for Interdisciplinary Research (MIIR), Marshall Univ, Huntington, WV.*

Background: We have shown that cardiotonic steroids signaling through the Na/K-ATPase regulate sodium reabsorption in renal proximal tubule (RPT). Here we report that oxidative modification of the a1 subunit is critical in modulation of Na/K-ATPase signaling and sodium transport.

Results: In pig RPT LLC-PK1 cells, ouabain (100nM) and glucose oxidase (GO, 1 and 3 mU/ml) induced ROS production, stimulated activation of c-Src and accumulation of Na/K-ATPase a1 and NHE3 in early endosome (EE) fractions, and inhibited active transepithelial $^{22}Na^+$ flux. Pretreatment with the antioxidant, N-Acetyl-L-Cysteine (NAC) can either partially or completely prevent these effects in a dose-dependent manner. Induction of heme oxygenase-1, an enzyme with potent antioxidant capacity, by CoPP attenuates ouabain-induced signaling and protein carbonylation. Furthermore, disruption of the Na/K-ATPase signaling (a1 subunit knock-down, caveolin-1 knock-out, or Src knock-out) abolished ouabain-induced protein carbonylation. LC-MS/MS analyses identified that ouabain/GO stimulated direct carbonylation of Pro^{222} and Thr^{224} in pig a1. These two amino acid residues are located in the a1 actuator (A) domain, highly conserved and exposed, facing the nucleotide binding (N) domain. To test the role of Pro^{222} carbonylation, two stable a1 mutant cell lines were generated. Mutation of Pro^{222} appears to abolish ouabain-induced protein carbonylation and activation of c-Src and ERK1/2. However, a "scramble" control mutation of Ala^{414} appears to have no effect on ouabain-induced protein carbonylation and activation of c-Src and ERK1/2.

Conclusions: Protein carbonylation of the Na/K-ATPase a1 subunit regulates Na/K-ATPase signaling and related sodium handling in RPTs. The data indicate that direct carbonylation of Pro^{222} might dictate the Na/K-ATPase signaling and that the Na/K-ATPase might be a functional receptor of ROS.

FR-PO006

NKCC2 Phosphorylation Attenuates Its Clathrin-Mediated Internalization Anna Daigeler,[1] Christin Dathe,[1] Bridget S. Wilson,[2] Sebastian Bachmann,[1] Kerim Mutig.[1] *[1]Vegetative Anatomie, Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Cancer Research Facility, Univ of New Mexico School of Medicine, Albuquerque, NM.*

Background: The Na-K-2Cl cotransporter (NKCC2) of the thick ascending limb of Henle's loop (TAL) plays an important role in renal salt handling. Activity of the transporter depends on its surface expression and phosphorylation at conserved N-terminal threonine and serine residues. We have recently shown that phosphorylation of NKCC2 interacts with its apical trafficking. In this study we focused on the endocytic retrieval of NKCC2. We hypothesized that the activating phosphorylation attenuates its clathrin-dependent internalization and thereby facilitates its function.

Methods: Cellular distribution of NKCC2, phospho-NKCC2, and clathrin was evaluated in cultured TAL cells and rat kidney using immunofluorescence and immunogold labelling. Protein-protein interactions were studied by GST pull-down assay. Vasopressin (AVP)-deficient Brattleboro rats were treated with a vasopressin V2 receptor agonist dDAVP (1 ng/g of body weight; 30 min) to study the interaction between NKCC2 phosphorylation and internalization *in vivo*.

Results: Fine structural analysis of the apical TAL membrane using immunogold labeling showed significant co-localization of NKCC2- and clathrin-signals (~20%), whereas phospho-NKCC2 was barely co-localized with clathrin. GST pull-down assays performed with rat kidney lysates using N- or C-terminal tails of rat NKCC2 as baits revealed association of clathrin with both cytoplasmic NKCC2 moieties. Analysis of interactions between clathrin and NKCC2 mutants mimicking (de) phosphory-lation of the transporter at functionally relevant N-terminal residues (T96, T101, T114, and S126) suggested that phosphorylation abrogates N-terminal binding of NKCC2 with clathrin. Along the same line, stimulation of the vasopressin (AVP) /V2 receptor axis in AVP-deficient Brattleboro rats substantially increased NKCC2 phosphorylation and surface expression and simultaneously inhibited its interaction with clathrin.

Conclusions: Our data suggest that N-terminal NKCC2 phosphorylation may facilitate its function by reducing its clathrin-mediated internalization.

FR-PO007

Changes in Distal Sodium Transporters in the Development and Maintenance of Obesity-Related Hypertension Matthew R.P. Davies,[1,2,3] Marina Katerelos,[1] Kurt Gleich,[1] Scott Andrew Fraser,[1] Peter F. Mount,[1,2,3] David A. Power.[1,2,3] *[1]Nephrology, Austin Health, Australia; [2]Medicine, Univ of Melbourne, Australia; [3]Inst of Breathing and Sleep, Australia.*

Background: Enhanced tubular reabsorption of Na^+ is critical in the pathogenesis of obesity-related hypertension (ORH). Initially Na^+ is actively retained; later Na^+ retention is maintained despite hypertension. The Na^+ transporters responsible have not been identified. The distal transporters NKCC2 (target for frusemide) and NCC (target for thiazides) can be regulated by expression, membrane trafficking and phosphorylation; key activating sites are S126- and T96/101-NKCC2, and T58-NCC. ENaC (target for amiloride) is primarily regulated through membrane trafficking. We studied the status of distal Na^+ transporters at different time points in the development of ORH.

Methods: C57BL/6 mice were fed control or high fat diet (HFD) for 2.5 or 14 weeks. Protein expression and phosphorylation were determined by Western blotting. Surface expression was determined by IF. Serum, BP and diuretic studies were performed at 14 weeks.

Results: After 2.5 weeks of HFD, expression of NCC was increased 2-fold ($p<0.001$) with a similar increase in pT58-NCC. No differences were found in NKCC2 or ENaC at this time. At 14 weeks HFD mice were obese, hypertensive, hyperinsulinaemic and hyperleptinaemic. At this time the changes in NCC had returned to baseline but phos (S126)-NKCC2 was increased 2.5-fold ($p<0.001$) while phos (T96/T101)-NKCC2 remained unchanged in whole kidney preparations. Natriuretic response to frusemide *in vivo* was increased 1.6-fold ($p<0.05$), confirming increased NKCC2 activity. Response to amiloride was also increased ($p<0.05$), but no increase in subunit expression or surface localisation was found to explain enhanced ENaC activity.

Conclusions: In this HFD model increased expression of NCC was the key early change identified that could help explain the establishment of Na^+ retention in the pathogenesis of ORH. In contrast, increased phos (S126)-NKCC2 was identified as a mechanism that would maintain Na^+ overload in the presence of hypertension. ENaC activity was also increased in established obesity, but the mechanism causing this remains elusive.

FR-PO008

The Natriuretic Effect of the Glucagon-Like Peptide 1 Receptor Agonist, Exendin-4, Is Independent of eNOS and Phosphorylation of NKCC2 and NCC, and Absent in STZ-Diabetic Mice Yiling Fu,[1,2] Maria Gerasimova,[2] Takahiro Masuda,[1] Yasaman Alam,[1] Falk Bernhard Batz,[1] Volker Vallon.[1,2] *[1]Div. Nephrology, Univ of California San Diego, La Jolla, CA; [2]VA San Diego Healthcare System, San Diego, CA.*

Background: Exendin-4 (EX-4) activates the glucagon-like peptide 1 receptor (GLP-1R) and is used as an antidiabetic drug, but also induces natriuresis, as reported in normoglycemia as well as in type 2 diabetic db/db mice. The natriuretic effect has been proposed to involve endothelial nitric oxide synthase (eNOS) in renal vascular and phosphorylation/inhibition of Na-H-exchanger 3 in proximal tubules, but the renal localization of the GLP-1R and the involvement of the distal nephron remains ill defined.

Methods: i) In eNOS ko/wild type (WT) mice and ii) in streptozotocin (STZ)-diabetic mice, EX-4 (10 mg/kg) or vehicle was applied i.p. together with an oral NaCl load (30 ml/g bw of 0.85% saline) and the urine was quantitatively collected over 3 hours in metabolic cages. iii) One hour after EX-4 or vehicle application to WT mice, kidneys were harvested and renal membrane expression of phosphorylated Na-2Cl-K cotransporter NKCC2 (pS126) and Na-Cl cotransporter NCC (pS71) (phosphorylation of both associated with transporter activation) determined by Western blot (normalized to b-actin).

Results: i) Absence of eNOS did not affect the natriuresis during vehicle application (23±1 versus 22±1 nmol/min/g in wild type) or the EX-4-induced increase in natriuresis (14±2 versus 13±2 nmol/min/g) (not significant different (NS); n=8/group). The EX-4-induced natriuresis ii) was absent in STZ-diabetic mice (EX-4 versus vehicle: 17±2 versus 17±2 nmol/min/g, NS; n=8), and iii) in WT mice occurred in the absence of significant changes in the renal membrane expression of pS126-NKCC2 or pS71-NCC (94±5 and 101±8% of vehicle, respectively; NS; n=5/group).

Conclusions: The results argue against a role of eNOS or the phosphorylation of NKCC2 and NCC in the EX-4-induced natriuresis in mice. The mechanism for the blunted natriuretic effect in STZ-diabetic mice remains unclear.

FR-PO009

A Role for aENaC in Connecting Tubules in PPARg Agonist-Induced Fluid Retention Yiling Fu,[1,2] Maria Gerasimova,[2] Falk Bernhard Batz,[1] Alexander Kuczkowski,[1] Yasaman Alam,[1] Edith Hummler,[3] Volker Vallon.[1,2] *[1]Div of Nephrology, Univ of California, San Diego, La Jolla, CA; [2]VA San Diego Healthcare System, San Diego, CA; [3]Univ of Lausanne, Switzerland.*

Background: Thiazolidinediones (TZDs, such as rosiglitazone (RGZ)) are peroxisome proliferator–activated receptors (PPARg) agonists used to treat type 2 diabetes. TZDs can induce fluid retention, and studies with amiloride suggested a possible role for the epithelial sodium channel ENaC. ENaC in the connecting tubule (CNT), but not in the collecting duct (CD), appears critical for normal NaCl and K balance. Since RGZ-induced fluid retention was maintained in mice with aENaC knockdown in the CD, here we aimed to test the role of ENaC in the CNT.

Methods: Mice with conditional inactivation of aENaC both in CD and CNT were generated using aquaporin2 (AQP2)-Cre (aENaC lox/lox AQP2-Cre; aENaC CD/CNT KO) and compared with littermate controls (aENaC lox/lox; WT). Mice were treated with RGZ (320 mg/kg diet) for 10 days in regular cages. Body weight (BW) was monitored, and body water volume determined by bioelectrical impedance analysis (BIA) before and after RGZ.

Results: On regular NaCl diet, aENaC CD/CNT KO had normal BW, body water volume, hematocrit, and plasma Na and K, whereas plasma aldosterone was modestly increased compared with WT (686±85 versus 503±42 pg/ml; $P<0.05$). The RGZ-induced increase in BW observed in WT was attenuated in aENaC CD/CNT KO (6.1±0.4 versus 3.4±0.3%, n=12-20; $P<0.05$). In WT, RGZ increased total body water (TBW) by 8±3% and extracellular fluid (ECF) by 10±1% (each $P<0.01$) and tended to increase intracellular fluid by 8±4% ($P=0.052$). No significant changes were observed in TBW (1±2%), ECF (4±2%) and ICF (0±2%) in aENaC CD/CNT KO in response to RGZ. Consistent with effective knockdown, we confirmed the impaired NaCl and K homeostasis in aENaC CD/CNT KO when challenged with a low NaCl diet.

Conclusions: Knockdown of aENaC in CNT/CD attenuated RGZ-induced fluid retention. Together with previous studies showing fully maintained RGZ-induced fluid retention in mice with knockdown of aENaC in the CD, the current results indicate a role for ENaC in CNT in this response.

FR-PO010

Regulation of NCC by WNK4 and by High Dietary K Intake Yih-Sheng Yang, Jian Xie, Chou-Long Huang. *Internal Medicine, UT Southwestern Medical Center, Dallas, TX.*

Background: The role of WNK4 and SPAK cascade in the activation of NCC in DCT remains unclear. High K intake decreases the activity of NCC, which is expected to increase Na delivery and reabsorption via ENaC and thus K secretion by K channels in CNT/CCD. Role of WNK4, other WNKs and SPAK in the regulation of NCC by high K diet is unknown.

Methods: WT or WNK4-KO mice were pair-fed a control K (CK; 1% K) or a high K (HK; 5.25%) diet for 48 hr (day -2 to 0), and administered at day 0 (at 10 AM) either vehicle, furosemide (5mg/Kg BW), hydrochlorothiazide (HCTZ; 50 mg/Kg BW) or amiloride (5mg/Kg BW). Urinary Na and K excretion rate (mmole/hr) was measured for 24 hr pre-diuretic (baseline) and for two periods (0-4 hr and 4-24 hr) after diuretic.

Results: NCC activity ([HCTZ-induced Na excretion at 0-4 hr] minus [vehicle-induced Na excretion]) was reduced in WNK4-KO mice (versus WT) by ~67% (19±6 versus 56±3; $p<0.01$). NKCC2 and ENaC activity was respectively increased in WNK4-KO mice (versus WT), likely reflecting compensatory upregulation. Consistently, baseline Na excretion rate was not significantly different between WT and WNK4-KO. High K diet decreased NCC activity by ~35% (HK versus CK: 37±4 versus 56±3; $p< 0.01$) in WT mice. The inhibition of NCC by high K intake appeared blunted in WNK4-KO mice; significance of this finding yet remains uncertain because the low baseline activity of NCC in WNK4-KO mice may prevent detectable inhibition by high K diet. Thus, we are further generating mice that carrying homozygous Wnk4-null allele and a constitutive-active SPAK kinase

allele. These mice may have NCC constitutively phosphorylated and activated by SPAK kinase independently of WNKs and thus allow us to examine the role of phosphorylation by WNKs-SPAK cascade and/or role of de-phosphorylation by phosphatases in the regulating NCC by high K intake.

Conclusions: Our results support the notion that, under a normal Na and K diet, WNK4 is a positive regulator of NCC. Decrease of NCC activity in WNK4-KO mice is accompanied by compensatory upregulation of NKCC2 and ENaC activity. High K intake inhibits NCC activity. Future studies will elucidate role of WNK4, other WNKs and SPAK cascade in regulating NCC by high K diet.

Role of SPAK/OSR1 in WNK1 Regulation of NKCC2 and NCC

Yih-Sheng Yang, Jian Xie, Chou-Long Huang. *Internal Medicine, UT Southwestern Medical Center, Dallas, TX.*

Background: Mice with intron deletion of Wnk1 gene mimicking human PHA2 disease exhibit increased phosphorylation and activation of NCC, phenocoping human disease. Compared to WNK4, functional evidence supporting WNK1 activation of SLC12 transporters, NKCC2 and NCC, via OSR1/SPAK yet remains relatively scarce. WNK1-null mice die in utero from angiogenesis defects. Here, we investigate the role of OSR1/SPAK in WNK1 regulation of NKCC2 and NCC using genetic mouse models.

Methods: We generated mice carrying a constitutive-active (CA) SPAK kinase allele and crossed with Wnk1-null mice. Baseline BP and urinary Na excretion of WT and mutant mice and their response to furosemide (5mg/kg BW), hydrochlorothiazide (50 mg/kg BW) or vehicle were studied. Diuretic-induced urinary Na excretion rate (mmole/hr) was measured for 24 hr pre-diuretic and for two periods (0-4 hr and 4-24 hr) afterward. The activity of NKCC2 and NCC was assessed using urinary Na excretion (mmole/hr) induced by respective diuretic under pair-feeding (excretion at 0-4 hr post-diuretic minus vehicle-induced excretion).

Results: Wnk1-null mice carrying CA-SPAK allele ("WS" mice) were born alive and with no gross defects except a smaller body weight, supporting that WNK1 regulates angiogenesis via OSR1/SPAK cascade. Body weight (g at 3 mo: 17±1 versus 25±1.3; $p<0.05$) and SBP was lower for mutant WS versus WT mice (mmHg: 83±12 versus 112±12; $p<0.05$). Steady-state daily urine output (1.7±0.1 versus 0.69±0.1 ml) and Na excretion (170±7 versus 119±15 mmole) were significantly higher in WS mutant versus WT with free access to normal rodent diet and water, indicating Na wasting in mutant WS mice. Mice were fed a normal Na diet for a week and switched to a Na-deficient (ND) diet. While urinary Na excretion fell during Na-deficient diet for both, it was significantly higher for WS than WT (day4 ND diet, mmole/day: 2.3±0.6 versus 1.3±0.2, $p<0.05$). NCC activity was not different between WS mutant and WT mice. NKCC2 activity was decreased in WS mutant versus WT (14.9±2.0 versus 23.3±1.6; $p<0.01$).

Conclusions: SPAK/OSR1 acts downstream of WNK1 to regulate NCC. Reduced NKCC2 activity in WS mutant suggests presence of a SPAK-independent mechanism for activation of NKCC2.

Disruption of STE20/SPS1-Related Proline/Alanine-Rich Kinase (SPAK) Binding Lowers Blood Pressure and Recapitulates Gitelman Syndrome in Mice

Keith Siew,[1] Jinwei Zhang,[2] Kevin O'Shaughnessy,[1] Dario Alessi.[2] *[1]Clinical Pharmacology Unit, Dept of Medicine, Univ of Cambridge, Cambridge, Cambridgeshire, United Kingdom; [2]MRC Phosphorylation and Ubiquitylation Unit, Univ of Dundee, Dundee, Scotland, United Kingdom.*

Background: The salt-wasting hypotensive phenotype of Gitelman syndrome is caused by low Na^+-Cl^- Cotransporter (NCC) activity. In the kidney WNK4 phosphorylates SPAK (p-SPAK) at threonine residue 243. This activated p-SPAK increases NCC phosphorylation (p-NCC) and thus NCC activity. Previously we demonstrated SPAK T243A mutant mice recapitulate Gitelman syndrome, thus confirming the integral role of SPAK activity in blood pressure control. For signalling to occur WNK4 and NCC bind to SPAK at leucine residue 502 in the conserved C-terminal.

Methods: To test this *in vivo* we generated homozygous SPAK L502A mice which we hypothesised would exhibit a Gitelman syndrome phenotype. To investigate renal salt-wasting, wildtype and SPAK L502A mice (n=14) were fed a 3% w/w sodium diet for 10 days and switched to a 0.03% w/w sodium diet with urine electrolytes measured at 0hr, 3hr, 6hr, 12hr, 24hr and 96hr post-switch and normalised to urine creatinine. Two weeks post-switch blood pressure was measured by catheterisation of the right carotid artery under anaesthesia (isoflurane). After sacrifice by exsanguination, the kidneys were harvested for western blot analysis. All data are mean±SEM.

Results: Na^+ wasting at 6hr post-switch was observed in SPAK L502A versus wildtype mice [77±17 versus 41±7 arbitrary units; $P<0.05$]. Mean arterial blood pressure on 0.03%w/w sodium diet was also strikingly lower in the SPAK L502A [62±1mmHg versus 78±1mmHg; $P<0.001$] and the inhibition of SPAK binding resulted in a 3-fold decrease in levels of p-NCC in SPAK L502A from whole kidney blots.

Conclusions: In conclusion, SPAK binding is crucial for blood pressure maintenance and pharmacological inhibition of this binding is an attractive antihypertensive strategy.

FR-PO013

Acute Potassium Intake Does Not Reduce Renal Na-Cl Cotransporter Phosphorylation during Chronic Angiotensin II Hypertension

Julie Jiyang Han, Donna Lee, Luciana C. Veiras, Alicia A. McDonough. *Dept of Cell and Neurobiology, Keck School of Medicine of USC, Los Angeles, CA.*

Background: Potassium (K) rich diets have the beneficial effect of lowering blood pressure, but molecular mechanisms are not clear. We aimed to investigate whether K could exert a beneficial effect in experimental Angiotensin II (AngII) dependent hypertension. Two findings stimulated the study: 1) During Ang II hypertension, DCT Na-Cl cotransporter phosphorylation (NCCp) and NCC mediated Na transport increase 2-4 fold; 2) a single K rich meal provokes a 50% decrease in NCCp, which drives Na reabsorption downstream to CCD ENaC which powers K secretion. Motivated by these findings, we aimed to test the hypothesis that the elevation in NCCp observed during AngII dependent hypertension would be reduced by a K rich meal.

Methods: Three groups (n=5-6) of male Sprague Dawley rats were compared: 1) Control rats fed 0%K meal over 3 hr, 2) AngII infused rats (400 ng AngII/kg/min x 14 d) fed 0%K meal, and 3) AngII infused rats fed a 2%K meal. Renal Na transporter abundance and -p were assayed by immunoblot in cortical homogenates.

Results: The following changes in abundance were measured in AngII infused versus controls after 0%K meal: NCC (2.2 fold), NCCpS71 (3.4), NCCpT53 (3.4), NCCpS89 (5.2), SPAK (2.5), SPAKpS373 (2.3), and cleaved ENaC-gamma (3.3). The 3 hr 2%K meal did not change abundance or –p of these in the AngII infused rats. Further, AngII infused rats exhibited kaliuresis and K depletion compared to controls: overnight urine K (UKV,mM) was 4.3 ± 0.1 in AngII infused versus 2.3 ± 0.3 mM in controls, plasma [K, mM] was 3.3 ± 0.1 in AngII infused versus 3.9 ± 0.1 in controls. After a K rich meal, plasma [K] climbed to 4.6 ± 0.1 mM in AngII infused versus to 5.5 mM in controls. Additionally, UKV was not elevated in the AngII infused fed a 2%K meal suggesting K conservation status.

Conclusions: The results indicate that a K rich meal does not reduce NCCp in AngII infused rats, perhaps due to the accompanying K deficiency. That is, AngII infused rats use the K meal to replenish K stores rather than excrete it. The rise in NCCp during AngII hypertension may be, at least in part, a compensatory response to conserve K.

FR-PO014

The Effect of WNK4 on the NaCl Cotransporter Is Modulated by Intracellular Chloride

Silvana Bazua-Valenti,[1] Maria Chavez-Canales,[1] Lorena Leonor Rojas,[1] Norma Hilda Vázquez,[1] Alejandro Rodriguez-Gama,[1] Zesergio Melo,[1] Consuelo Plata,[1] David H. Ellison,[2] Juliette Hadchouel,[3] Gerardo Gamba.[1] *[1]Molecular Physiology Unit, INCMNSZ-IIB-UNAM, Mexico City; [2]Oregon Health Science Univ, Portland; [3]Inserm970, Paris.*

Background: The phenotype of the Familial Hyperkalemic Hypertension (FHHt) is mostly a consequence of increased activity of the renal Na^+:Cl^- cotransporter (NCC), due to altered regulation by WNK1 or WNK4. However, the effect exerted by WNK4 on NCC has been a matter of debate since inhibition and activation by this kinase have been reported in both, *in vitro* and *in vivo* systems. It was recently shown that WNK1 is a chloride-sensitive kinase, activated by a low Cl^- concentration (Piala et al. Science Sig, 2014). We thus hypothesized that contradictory results in WNK4 activity could be due to modulation of WNK4 activity by intracellular chloride concentration $[Cl^-]_i$.

Methods: We assessed the functional expression of NCC using *Xenopus* oocytes by measuring the thiazide-sensitive $^{22}Na^+$ uptake and the N-terminal phosphorylation by Western blot, two days after microinjection with NCC cRNA alone or together with mouse or human wild type or mutant WNK4 or SLC26A9 transporter cRNA. Site directed mutagenesis was used in human WNK4 for L322F, L324F, and/or D321A substitutions. For uptake assay or protein extraction oocytes were exposed to control conditions or to low chloride hypotonic stress (hypotonic medium with no chloride) that is known to reduce the $[Cl^-]_i$.

Results: In control conditions NCC activity was either decreased or unaffected by WNK4. The reduction of $[Cl^-]_i$ either by low chloride hypotonic stress or co-injection of oocytes with the SLC26A9 cotransporter, turned WNK4 into an NCC activator, increasing NCC-dependent Na^+ transport in a kinase-dependent manner by 3 fold. L322F substitution in WNK4 (homologous to that forming a chloride-binding pocket in WNK1), converted WNK4 into a constitutively NCC activating kinase because reduction of $[Cl^-]_i$. was not longer required for WNK4 to increase the activity (3 fold) and phosphorylaiton of NCC.

Conclusions: Our study shows that WNK4 inhibitory and activating effect on NCC coexist and are modulated by intracellular chloride concentration.

Choride-Sensing by WNK Kinases Mediates Effects of Dietary Potassium on Systemic Ion Balance

Andrew Terker,[1] James A. McCormick,[1] Alan Mark Weinstein,[2] WenHui Wang,[3] Chao-Ling Yang,[1] David H. Ellison.[1] *[1]Oregon Health & Science Univ; [2]Cornell Univ; [3]New York Medical College.*

Background: Low dietary K^+ stimulates the sodium chloride cotransporter (NCC). We investigated how plasma K^+ signals NCC.

Methods: Mouse diets: Normal salt (0.49% NaCl), high salt (HS, 6% NaCl), normal K^+ (NK, 1%), and low K^+ (LK, 0%) Drug treatments: Amiloride (50 mg/L) Cells: HEK 293 cells transfected with indicated constructs. Intracellular Cl measurements: MQAE dye.

Results: HS/LK diet increased NCC and pNCC compared with HS/NK. Plasma aldosterone remained unchanged, while plasma angiotensin II decreased. Effects on

NCC were preserved in type I angiotensin II receptor null mice. These data suggest the changes in NCC were not mediated by the RAAS. To determine if plasma K^+ signals NCC independent of diet, we treated animals with amiloride (Amil). Amil caused hyperkalemia and volume contraction and decreased NCC and pNCC, suggesting K^+ was determining NCC status. LK diet, which normalized plasma K^+, prevented effects of Amil on NCC. In cells, low K^+ medium increased pNCC and pSPAK/pOSR1, signaling via WNK kinases, as shown through siRNA studies. Treatment with Ba^{2+}, which depolarizes cells, reduced pNCC. Transfection with EAST syndrome mutant KCNJ10 channels, depolarized cells compared with wild (WT) type KCNJ10; mutant KCNJ10 also reduced pNCC, compared with WT. Low K^+ conditions decreased $[Cl^-]_i$, and the KCNJ10 mutants increased it. To test if decreased $[Cl^-]_i$was required for low K^+ to increase pNCC, we showed that effects of low K^+ on pNCC were inhibited by culture in high Cl^- medium or treatment with DIDS. As chloride exit from DCT cells is mediated partly by CLCNKB, which is mutated in type III Bartter syndrome, we compared effects of mutant and WT CLCNKB channels. Mutant channels decreased effects of low K^+ on NCC compared with WT channels. Disrupting the Cl^--binding motif of WNK1 (which mediates its inhibition by Cl^-(Sci Sig 2014)) also prevented effects of low K^+ on pNCC.

Conclusions: Results suggest plasma K^+ stimulates NCC directly, independent of signaling hormones; this effect likely requires WNK-SPAK/OSR1. Cl^- sensing by the DCT may mediate the effects of dietary K^+ on systemic ion balance.

FR-PO016

The European Eel NCCb Gene Encodes a Non-Thiazide Sensitive NaCl Cotransporter Eduardo R. Argaiz,[1] Erika Moreno,[1] Christopher Cutler,[2] Norma Hilda Vázquez,[1] Maria Chavez-Canales,[1] Gerardo Gamba.[1] *[1]Molecular Physiology Unit, INCMNSZ-IIB-UNAM, Mexico City; [2]Georgia Southern Univ, Statesboro, GA.*

Background: Thiazides are among the most frequently prescribed drugs in the world for their antihypertensive effect through inhibition of the renal Na^+:Cl^- cotransporter, NCC, which in mammals is encode by one gene (SLC12A3). In contrast, two NCC genes are expressed in the European eel (Anguila anguila): NCCa and NCCb. Flounder and mammalian NCC exhibit different affinity for thiazides and we have previously reported a single amino acid residue (C575 in rat NCC) responsible for this difference (Castañeda-Bueno et al AJP Renal 2011), but nothing is known regarding residues conferring specificity for thiazide diuretics in NCC.

Methods: To study the functional properties of NCCb, a full length cDNA encoding NCCb from eel intestine was constructed by RT-PCR, inserted into pgh19 vector and fully sequenced. Functional expression was assessed by $^{22}Na^+$ uptake using *Xenopus laevis* oocytes microinjected with NCCb cRNA. Rat and flounder NCC cRNA were used as controls.

Results: NCCb encodes a 1043 amino acid residues exhibting a 55, 55, and 43 degree of identity with flounder, rat and human NCC, respectively. It is expressed along the eel gastrointestinal tract and absent in the kidney. NCCb cRNA injection into oocytes induced the appearance of a Na^+ uptake pathway that is Cl^- dependent, K^+ independent, but is not sensitive to a variety of thiazide type diuretics (up to 1 mM concentration), to furosemide, DIDS or DIOA. A small 30% inhbition was observed with acetazolamide (100 mM). No $^{86}Rb^+$ uptake was induced by NCCb. The Cl^- transport kinetics revealed a Km for Cl^- about 13 mM (previously observed for flounder NCC was 15 mM and rat NCC 2 mM). Interestingly, in contrast to flounder and mammalian NCC, eel NCCb is not activated by intracellular chloride depletion or co-injection with WNK informs.

Conclusions: NCCb encodes for an electroneutral Na^+:Cl^- cotransporter that is not sensitive to thiazide-type diuretics, with different regulatory properties when compared with mammalian NCC. Structure function studies of NCCb could lead to define the amino acid residues responsible for thiazide specificity in the NaCl cotransporter.

FR-PO017

Dissecting WNK Complex Formation and Signaling with the CRISPR/Cas9 System Ankita Roy,[1] Bridget F. Donnelly,[1] Joshua H. Goodman,[1] Arohan R. Subramanya.[1,2,3] *[1]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA; [2]Cell Biology, School of Medicine, Univ of Pittsburgh, Pittsburgh, PA; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA.*

Background: The cation chloride cotransporter NCC mediates salt reabsorption in the distal convoluted tubule, where it is activated by the kinases SPAK and OSR1. With-No-Lysine (WNK) kinases are the only known upstream SPAK/OSR1 activators, although the contributions of individual WNKs to downstream kinase activation are unclear. WNKs can associate with each other, although the composition of native WNK complexes in cells remains unknown.

Methods: To clarify the role of the individual WNKs in activating downstream targets, we are employing RNA-guided CRISPR/Cas9 nucleases to delete WNK kinases in mammalian cells. The WNK KO cell lines were used for biochemical assessment of protein abundance, Co-IP interaction, and downstream kinase activity toward SPAK/OSR1 and NCC.

Results: We present our experience generating a genetically and biochemically validated WNK1 KO cell line with this method. The knockout cells were generated by using a single guide RNA targeting exon 1 of the WNK1 gene, which generated indels that completely abrogated WNK1 protein expression. WNK1 KO cells exhibited a 43% reduction in endogenous WNK4 protein, indicating that WNK1 is required for WNK4 stability. Consistent with its critical role in SPAK/OSR1 activation, WNK1 KO cells exhibited a 90% reduction in SPAK/OSR1 regulatory domain phosphorylation. Surprisingly, the reduced SPAK/OSR1 activity did not downregulate NCC abundance and phosphorylation, which were increased by 12.5% in WNK1 KO cells. This unexpected increase in NCC activation correlated with enhanced WNK3 interaction.

Conclusions: In summary, we successfully used the CRISPR-Cas9 system to create a WNK1 knockout cell line that will be useful for studying cation chloride cotransporter regulation. Our data are consistent with a model in which the WNKs form interdependent complexes and can compensate for each other. They also support the stimulatory effect of WNK3 on NCC, and suggest that NCC phosphorylation at its activation sites may be subject to regulators other than SPAK and OSR1.

14-3-3 Gamma Modulates NCC through a Nedd4-2-Dependent Mechanism Xiuyan Feng,[1,3] Dingying Gu,[4] Courtney Marie Caroti,[1,3] Abdel A. Alli,[2] Robert S. Hoover,[1,3] Hui Cai.[1,2,3] *[1]Renal Div, Emory Univ School of Medicine; [2]Dept of Physiology, Emory Univ School of Medicine; [3]Renal Section, Atlanta VAMC; [4]Renal Div, Second Affiliated Hospital, Wenzhou Medical Univ; [5]Dept of Anesthesiology, Vanderbilt Univ Medical Center.*

Background: To investigate whether 14-3-3 gamma modulates the sodium chloride cotransporter (NCC) through a Nedd4-2-dependent mechanism.

Methods: Cell culture, transfection, RT-PCR, western blot analysis, immunostaining and immunoprecipitation were used in this study.

Results: We transfected HEK 293 cells with GFP-NCC and a series of doses of 14-3-3 gamma. Western blot analysis showed that over-expression of 14-3-3 gamma significantly inhibited NCC total protein expression in a dose-dependent manner (1 ± 0.032, 0.757 ± 0.085, 0.288 ± 0.080, $p<0.01$) whereas it did not change the NCC mRNA level. Surface biotinylation results showed that 14-3-3 gamma decreased the NCC surface expression in a dose-dependent manner. We also found that 14-3-3 gamma binds to NCC by immunoprecipitation. In addition, immunostaining and confocal microscope showed that both 14-3-3 gamma and NCC co-localized in the distal convoluted tubule (DCT). We further found that 14-3-3 gamma increased ubiquitinated-NCC in a dose-dependent manner. Furthermore, when we knocked down the 14-3-3 gamma expression by 60% using siRNA technique in mDCT cells, we found that total endogenous NCC expression increased by 2.02 times while the levels of both total-Nedd4-2 and phospho-Nedd4-2 (S448) decreased compared to the control group.

Conclusions: These results suggest that 14-3-3 gamma modulates NCC through a Nedd4-2-dependent mechanism.

FR-PO019

Aberrant Activation of WNK-SPAK/OSR1 Signaling in Drosophila Pacemaker Neurons Disrupts Circadian Rhythm Aylin R. Rodan, Jeffrey N. Schellinger. *UT Southwestern, Dallas, TX.*

Background: Circadian fluctuations in intracellular Cl^- in mammalian pacemaker neurons have been proposed to play a role in circadian rhythmicity, and could be controlled by the relative amount of Cl^- ingress and egress by the sodium-potassium-2-chloride cotransporter (NKCC) and potassium-chloride (KCC) cotransporters, respectively. Here, we tested roles for fly NKCC and KCC, as well as the chloride-sensitive WNK-SPAK/OSR1 kinase cascade, in *Drosophila* pacemaker neurons.

Methods: Circadian rhythm period was determined by measuring 24-hour locomotor activity of male flies. Pacemaker cell expression and knockdown of genes of interest was performed using the GAL4-UAS system.

Results: Flies carrying a homozygous null mutation in the NKCC Ncc69 (*Ncc69^{r2}*) have increased period length (25.2±0.3 versus 24.0±0.05 hours in controls, $p<0.0001$). Expression of wild-type Ncc69 in the pacemaker neurons rescued the long-period phenotype (23.8±0.08 hours). Pacemaker neuron number and morphology were normal in the *Ncc69^{r2}* mutants. The long period of *Ncc69^{r2}* mutants was suppressed by knockdown of fly *kcc* in the pacemaker neurons (23.9±0.3 versus 26.4±0.2 hours in *Ncc69^{r2}*, $p<0.0001$), suggesting that the *Ncc69^{r2}* long-period phenotype may be due to low intracellular Cl^-. Since Cl^- inhibits WNK autophosphorylation and activation, we tested whether the long-period phenotype is due to aberrant activation of WNK-SPAK/OSR1 signaling. *wnk* knockdown in the pacemaker neurons suppressed the long-period phenotype of *Ncc69^{r2}* (24.7±0.3 versus 26.7±0.1 hours in *Ncc69^{r2}*, $p<0.0001$). Similarly, knockdown of *fray* (the fly SPAK/OSR1 homolog) also suppressed the *Ncc69^{r2}* long period (24.3±0.1 versus 26.3±0.1 hours in *Ncc69^{r2}*, $p<0.0001$). Conversely, expression of constitutively active Fray^{T206E} in the pacemaker neurons resulted in a long period (25.6±0.3 versus 24.3±0.09 hours in controls, $p<0.0001$) that was dependent on the kinase activity of Fray. This phenotype was suppressed by the *Ncc69^{r2}* mutation (23.8±0.1 hours), suggesting a feedback loop.

Conclusions: Coordinated activity of NKCC and KCC are required to maintain appropriate WNK-SPAK/OSR1 signaling in the regulation of circadian rhythm by the pacemaker neurons, suggesting precise regulation of intracellular Cl^-.

FR-PO020

Inwardly-Rectifying Potassium Channels in Drosophila Renal Tubule Function Aylin R. Rodan, Yipin Wu, Michel G. Baum, Chou-Long Huang. *UT Southwestern, Dallas, TX.*

Background: Flies eat a K^+-rich diet and secrete a KCl-rich fluid from the main segment of the renal tubule. We have previously shown that ~1/3 of transepithelial K^+ flux through the cation-conducting principal cell is via the basolateral NKCC, Ncc69. Ncc69 function is dependent on the Na/K-ATPase, but is not required for the kaliuretic effect of cAMP. Here, we examined the role of inwardly-rectifying K^+ (Kir) channels.

Methods: Transepithelial potential difference (TE_{PD}) was measured in isolated perfused tubules, and transepithelial K^+ flux was measured in isolated tubules using the Ramsay assay. Principal cell knockdown of the three fly Kir channels, Ir, Irk2 and Irk3, was performed using the GAL4-UAS system. Knockdown efficiency was determined by qRT-PCR.

Results: 2 mM peritubular barium, a Kir inhibitor, reversibly decreased TE_{PD} from 30.5±5 to 9.5±2 mV ($p<0.05$), returning to 30.5±4 mV after washout. K^+ flux was also decreased in 1 mM barium-treated tubules, but unchanged with vehicle treatment (Table). Knocking down *Irk3*, alone or in combination with *Ir* or *Irk2*, did not alter K^+ flux, nor did knocking down *Ir* or *Irk2* individually, despite similar efficiencies of transcript knockdown. Double knockdown of *Ir* and *Irk2* significantly decreased K^+ flux, without a further decrease in *Ir,Irk2,Irk3* triple knockdown tubules (Table). K^+ flux was increased by 1 mM cAMP and decreased by 100 mM ouabain in both control and *Ir,Irk2* double knockdown tubules (Table).

Genotype/condition	K^+ flux pmol/min/tubule	p value
Control, pretreatment	48±10	NS
Control, vehicle	56±19	
Control, pretreatment	43±9	<0.0001
Control, barium	9±7	
Control	109±10	<0.01
Ir,Irk2 knockdown (KD)	60±12	
Ir,Irk2,Irk3 KD	77±12	NS (compared to *Ir,Irk2)*
Control, vehicle	56±8	<0.01
Control, ouabain	25±6	
Ir,Irk2 KD, vehicle	43±9	<0.05
Ir,Irk2 KD, ouabain	15±3	
Control, vehicle	35±6	<0.05
Control, cAMP	64±10	
Ir,Irk2 KD, vehicle	11±3	<0.05
Ir,Irk2 KD, cAMP	37±9	

Conclusions: The principal cell Kir channels Ir and Irk2, acting basolaterally, have redundant roles in fly renal tubule transepithelial K^+ transport, act independently of the Na/K-ATPase, and are not required for tubule kaliuretic response to cAMP.

Funding: NIDDK Support

Collecting Duct (CD) Prorenin Receptor (PRR) Contributes to Renal Sodium Reabsorption *via* Regulation of ENaC Expression Renfang Song, Graeme James Preston, Ihor V. Yosypiv. *Pediatrics, Tulane Univ, New Orleans, LA.*

Background: We demonstrated that targeted inactivation of the *PRR* in the ureteric bud (UB) epithelia in mice using *Hoxb7*^{Cre} (*PRR*$^{UB-/-}$) is essential for the concentration of the urine (PloS One, 2013). Here, we hypothesized that CD PRRcontributes to renal sodium reabsorption *via* regulation of epithelial sodium channel (ENaC) expression.

Methods: *PRR*$^{UB-/-}$ and control mice (n=4 mice per genotype) were housed in metabolic cages, fed a standard chow and allowed free access to water. Plasma and urine creatinine, sodium (Na) and potassium (K) was measured on P30 by HPLC and flame photometry, respectively. ENaC a subunit mRNA and protein levels in the cortex and/or medulla were determined by qRT-PCR, Western blotting and immunohistochemistry (StressMarq). The intensity of aENaC immunostaining was quantitated by Slidebook 4.1 software.

Results: Although plasma Na levels did not differ (132±0.9 versus 135±2.1, p=0.12), urinary Na excretion was reduced in mutant compared with control mice (mM/L: 47±4 versus 82±3, $p<0.01$; mM/24h: 143±4 versus 199±13, $p<0.01$). qRT-PCR and Western blotting demonstrated that aENaC mRNA ($p<0.05$) and protein ($p<0.05$) levels were increased in the cortex of mutants compared with controls.aENaC immunostaining was increased in the CD of mutant compared with control kidneys (1.99±0.13 versus 1.41±0.04 pixels, $p<0.01$). Plasma K levels did not differ (9.0±0.17 versus 8.9±0.18, p=0.56). Urinary K excretion was reduced in mutant compared with control mice (mM/L: 89±5 versus 165±14, $p<0.01$; mM/24h: 279±9 versus 412±37, $p<0.01$), suggesting that reduced urinary Na excretion in *PRR*$^{UB-/-}$ mice is not mediated by aldosterone.

Conclusions: We conclude that CD PRR regulates renal ENaC expression and contributes to sodium reabsorption in the CD.

FR-PO022

AMP-Activated Protein Kinase Regulates the Epithelial Na^+ Channel and Nedd4-2 Phosphorylation in Kidney Collecting Duct Cells Suet-Wan Choy,[1] Hui Li,[1] Edwin Kamau,[1] Dietbert Neumann,[2] Kenneth R. Hallows.[1] *[1]Renal-Electrolyte Div, Univ of Pittsburgh, Pittsburgh, PA; [2]Molecular Genetics, Maastricht Univ, Maastricht, Netherlands.*

Background: Kidney collecting duct epithelial Na^+ channels (ENaC) play a key role in total body volume and blood pressure regulation. The metabolic sensor AMP-activated protein kinase (AMPK) inhibits ENaC by enhancing ENaC binding to the ubiquitin ligase Nedd4-2 through unclear mechanisms. We hypothesized that AMPK phosphorylation of Nedd4-2 is required for the regulation of ENaC by AMPK and is a key determinant of Nedd4-2 protein stability in cells and *in vivo*.

Methods: We used mass spectrometry to define AMPK phosphorylation sites in Nedd4-2 *in vitro*. We used mouse polarized kidney cortical collecting duct ($mpkCCD_{c14}$) cells for Western blot analysis and short-circuit current (I_{sc}) measurements of ENaC following AMPK activity modulation. We monitored Nedd4-2 phosphorylation at the AMPK target site using a phospho-specific (pS328) antibody and examined the role of Nedd4-2 phosphorylation by AMPK regulation of ENaC and Nedd4-2 stability.

Results: Mass spectrometry studies revealed that AMPK phosphorylates Nedd4-2 *in vitro* at S444 (Xenopus numbering, S328 in mouse). AMPK activation decreased stability of the b and cleaved g subunits of ENaC in cycloheximide chase assays performed in $mpkCCD_{c14}$ cells. Preliminary studies suggest that acute AMPK activation increases pS328 in $mpkCCD_{c14}$ cells as detected by an antibody directed against pS328. However, inducible shRNA-mediated AMPK-a1 knockdown in $mpkCCD_{c14}$ cells did not inhibit phosphorylation at S328. We propose that the lack of inhibition by AMPK knockdown may be due to a chronic compensatory increase in phosphorylation at that site by other participating kinases.

Conclusions: AMPK phosphorylates Nedd4-2 at S444, which enhances Nedd4-2 protein stability. AMPK also induces cellular ENaC turnover/degradation. Additional studies in stably transfected $mpkCCD_{c14}$ cells that overexpress wild-type or mutant Nedd4-2 will provide insight into the effect of these mutations on ENaC stability. Further studies to assess the physiological relevance of AMPK phosphorylation of Nedd4-2 *in vivo* are also underway.

NBCe2 Mediates Thiazide-Sensitive Sodium Reabsorption in the Distal Nephron Donghai Wen,[1] Ryan J. Cornelius,[1] Thomas Boettger,[2] Steven C. Sansom.[1] *[1]Cellular and Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE; [2]Cardiac Development and Remodeling, Max Planck Inst for Heart and Lung Research, Bad Nauheim, Germany.*

Background: A previous study reported that the Na^+-dependent Cl^-/HCO_3^- exchanger NDCBE mediates thiazide-sensitive Na^+ reabsorption in the cortical collecting duct (CCD). The electrogenic Na^+- HCO_3^--co-transporter (NBCe2) is also located in the apical membrane of principle cells in the CNT and collecting duct, where it functions to reabsorb Na^+ and HCO_3^- under acidic conditions. In the present study, we determined whether NBCe2 also mediates thiazide-sensitive Na^+ reabsorption in the distal nephron.

Methods: Wild type (WT) and NBCe2 knockout (KO) mice were fed a Na^+ deficient diet plus acid water for 7-10 days. Hydrochlorothiazide (HCTZ), amiloride (Amil), inhibitor of the epithelial Na^+ channel (ENaC), or polyethylene glycol (Veh) was administered intraperitoneally and the mice placed in metabolic cages for 12 hours. Urine was collected and the rates of Na^+ and K^+ excretion (UNaV; mmol/day and UKV; mmol/day, respectively) were determined.

Results: In Veh, UNaV was not significantly different in KO, compared with WT (WT: 3.9 ± 0.5, KO: 9.8 ± 3.0), while UKV was much higher in KO (WT: 91.8 ± 19.4; KO: 185.3 ± 27.9). With HCTZ treatment, both UNaV (WT: 106.1±8.4; KO: 38.6 ± 7.) and UKV (WT: 439.9 ± 24.0; KO: 156.4 ± 27.1) were much higher in WT, compared with KO. However, with Amil treatment, UNaV was higher in KO, compared with WT (WT: 99.4 ± 13.9; KO: 206.6 ± 31.4), while there was no difference in UKV (WT: 27.4 ± 6.2; KO: 27.1 ± 12.7). The HCTZ-sensitive urinary Na^+ reabsorption (WT: 102.1 ± 8.4; KO: 28.9 ± 7.9) and K^+ excretion (WT: 318.7 ± 30.9; KO: -29 ± 38.9) were significantly higher in WT compared to KO, while the Amil-sensitive urinary Na^+ reabsorption (WT: 114.6 ± 21.9; KO: 196.8 ± 37.1) and K^+ excretion (WT: 64.3 ± 20.4; KO: 154.3 ± 15.5) were higher in the KO.

Conclusions: Our results reveal that NBCe2 mediates thiazide-sensitive Na^+ reabsorption in the distal nephron, and deficiency of NBCe2 causes up-regulation of ENaC-mediated Na^+ reabsorption.

FR-PO024

Epigenetic Control of Epithelial Sodium Channel a-Subunit (a-ENaC) Transcription by Lysine-Specific Demethylase 1 (LSD1) Zhiyuan Yu, Qun Kong, Bruce C. Kone. *Internal Medicine, The Univ of Texas Medical School at Houston, Houston, TX.*

Background: ENaC in the distal nephron constitutes the rate-limiting step for renal sodium reabsorption. aENaC transcription in collecting duct is under complex genetic and epigenetic control in part coordinated by DNA-binding protein Af9, which binds to the aENaC promoter. LSD1 is a histone H3K4 and H3K9 demethylase that also interacts with histone deacetylases (HDAC) and corepressor of repressor element 1 silencing transcription (CoREST). We explored the role of LSD1-mediated histone demethylation and HDAC interaction in regulating aENaC transcription in mIMCD3 cells.

Methods: Transient overexpression and siRNA knockdown were used to test the effects of LSD1 and HDAC2 on aENaC mRNA and the activity of an aENaC promoter-luciferase construct stably expressed in mIMCD3 cells. ChIP and re-Chip assays were used to determine LSD1 occupancy and histone methylation states along the aENaC promoter. Co-immunoprecipitation (co-IP) assays were used to assay interaction of LSD1 with HDAC1, HDAC2, and CoREST.

Results: LSD1 overexpression resulted in 30% higher aENaC promoter activities versus control. Conversely, LSD1 depletion lowered aENaC mRNA levels and promoter activity by 30%. Mutation of the Af9 site in the aENaC promoter abrogated the LSD1 effect, but co-IP assays failed to detect LSD1-Af9 interactions. ChIP/qPCR assays revealed that LSD1 is basally enriched at multiple subregions of the aENaC promoter and mediates H3K4me2 and H3K9me2 demethylation. Co-IP and ChIP/re-ChIP assays showed that LSD1 complexes with HDAC2 and CoREST in mIMCD3 cells and the three proteins co-occupy the aENaC promoter. Like LSD1, overexpression of HDAC2 increased aENaC promoter activity. Combined overexpression of LSD1 and HDAC2 synergistically enhanced aENaC promoter activity.

Conclusions: LSD1, through H3K4me2 and H3K9me2 demethylation and functional interactions with Af9 and HDAC2, serves as an epigenetic activator of aENaC transcription in mIMCD3 cells. Our data also provide the first example of dual erasure of these histone marks associated with a single gene. The balance of histone lysine methylation and demethylation at the aENaC promoter governs aENaC transcription.

Distinct Subunit Requirements for N-Glycans During Epithelial Na^+ Channel Processing and Expression Ossama B. Kashlan,[1] Carol L. Kinlough,[1] Mike M. Myerburg,[1] Brandon M. Blobner,[1] Teresa Buck,[2] Paul A. Poland,[1] Jeffrey L. Brodsky,[2] Rebecca P. Hughey,[1] Thomas R. Kleyman.[1] *[1]Medicine, Univ of Pittsburgh, Pittsburgh, PA; [2]Biological Sciences, Univ of Pittsburgh, Pittsburgh, PA.*

Background: The three epithelial Na^+ channel (ENaC) subunits undergo N-linked glycosylation in the ER where they assemble into a trimeric abg complex. There are six, thirteen and five consensus sites (Asn-x-Ser/Thr) for N-glycosylation within the extracellular domains of the mouse a, b and g subunits, respectively. Previous studies suggest that most of these sites are used. N-glycans on newly synthesized proteins facilitate their interaction with ER folding chaperones, and are required for recognition by quality control mannosidase-like proteins. Most N-glycans on folding-competent glycoproteins that transit to the Golgi complex are remodeled to a complex type. These complex N-glycans on mature proteins have varied functions including (i) stabilization of the folded state, (ii) protection of the protein core from protease digestion, and (iii) interaction with other proteins, such as galectins.

Methods: Using site-directed mutagenesis, we removed all of the consensus N-glycosylation sites from each ENaC subunit. We then biochemically and functionally characterized channels where one or more subunits lacked N-glycosylation sites.

Results: Although prior work indicated that a subunit N-glycans are dispensable for expression of functional channels, we found that a lack of N-glycans on the b or g subunit dramatically reduced channel activity, surface and whole cell ENaC protein expression, as well as a and g subunit proteolytic processing. Furthermore, the inhibitory response to external Na^+ was largely lost, suggesting a defect in channel folding. In addition, we observed that the b subunit co-precipitated with GST-tagged galectins-1, -4, -8 and -9, suggesting that ENaC surface expression may be modulated by crosslinking of the b subunit with galectins.

Conclusions: In summary, our results suggest that N-glycans on both the b and g subunits are required for proper processing and expression of ENaCs.

FR-PO026

The Role of Renal Collecting Duct Cathepsin D Overexpression in Regulating ENaC Activity Franziska Theilig, Alina Khramova, Suresh K. Ramakrishnan. *Medicine, Anatomy, Fribourg, Switzerland.*

Background: The epithelial sodium channel (ENaC) plays an important role in the maintenance of the sodium balance, extracellular volume and blood pressure. Proteolytic cleavage of ENaC is one of the key regulatory steps in the channel activation process. It has been reported that proteolytic cleavage of ENaC was executed by endogenous and /or exogenous serine proteases acting directly or in an indirect fashion. In many disease states, such as nephrotic syndrome, a dysregulation of the ENaC was identified.

Results: Performing microarray studies, we have detected significantly increased Cathepsin D expression levels in rats with puromycin aminonucleoside (PAN) induced nephrotic syndrome (NS) and with glomerulonephritis (GN) compared to controls (CatD mRNA (control=61,4; PAN=230,7; GN=122,7). Western blot analysis of renal membrane preparations and urine showed a 3 to 10-fold increase of CatD expression level and excretion, respectively, in rats with PAN-induced NS and GN compared to control. Next, to elucidate the effects of CatD overexpression an inducible CatD overexpressing collecting duct cell line was produced. In this cell line analysis of ENaC subunits demonstrated the occurrence of an increased cleavage of the aENaC, whereas b and gENaC remained unaffected. In agreement, epithelial voltage measurements showed a significantly higher conductance in CatD overexpressing clones (90+/-5 $\mu A/cm^2$ versus 11+/- 3 $\mu A/cm^2$) compared to normal $mpkCCD_{cl14}$ cells.

Conclusions: In conclusion, CatD plays a putative role in maintaining sodium balance by cleaving the a-subunit of ENaC and thereby proteolytically activating the channel.

Epithelial Sodium Channel Activity in the Distal Nephron Is Modified by the Aldosterone Induced Protein, Ankyrin G Christine Anne Klemens, Michael Butterworth. *Cell Biology, Univ of Pittburgh, Pittsburgh, PA.*

Background: The heterotrimeric epithelial sodium channel (ENaC) is the limiting entry step for sodium (Na^+) reabsorption in the aldosterone sensitive distal kidney nephron. Aldosterone instigates a number of changes to augment Na^+ reabsorption, including increasing ENaC subunit translation and modifying key regulators that alter ENaC function and/or membrane density. We identified ankyrin G (AnkG), as a novel aldosterone induced protein, capable of regulating ENaC activity. AnkG is a scaffold protein that traffics transmembrane proteins to the plasma membrane and links them to the cytoskeleton. The bENaC subunit contains a putative AnkG binding motif 6 amino acids downstream to the Nedd4-2 PY motif. We propose that AnkG regulates ENaC mediated Na^+ transport by modulating the Nedd4-2--ENaC interaction, to stabilize ENaC at the apical membrane and increase residency time.

Methods: ENaC activity was determined by short-circuit current measurements in Ussing chambers in either a mouse kidney collecting duct epithelial cell line (mCCD-cl1) or Fisher rat thyroid (FRT) cells.

Results: AnkG co-immunoprecipitates with bENaC. Deletion of the purported AnkG binding motif reduced ENaC current by 25%±4% compared to WT in a heterologous expression system. AnkG over expression in mCCD-cl1 cells increased ENaC current by 67%± 11% (n=12), whereas knockdown reduced ENaC activity by 69%±2% (n=15). Membrane permeabilization experiments confirmed the reduction in Na^+ transport was due to reduced ENaC function, and not Na^+/K^+ATPase activity.

Conclusions: These findings confirm AnkG as an aldosterone induced protein and novel regulator of ENaC that therefore alters Na^+ reabsorption in the distal nephron. Future studies will investigate the interplay between AnkG and Nedd4-2 in regulating ENaC surface expression.

A Common Golgi Export Signal Patch in Basolateral Kir Channels of the Distal Nephron Xiangming Li, Paul A. Welling. *Physiology, Univ of Maryland SOM, Baltimore, MD.*

Background: Polarized distribution of inward rectifying K^+ (Kir) channels the distal nephron is essential for K^+ excretion. Here we explore a new polarized trafficking mechanism, focusing on a Golgi trafficking step, which couples Apical/Basolateral membrane (BLM) cargo selection and clathrin-coated vesicle (CCV) formation to Golgi export. Our previous work on the prototypical Kir channel, Kir2.1, identified a novel signal patch embedded within its tertiary structure that forms a recognition site for interaction with the AP1A adaptor, marking channels for inclusion into CCVs at the trans-Golgi network (*Ma et al Cell, 2011*). Here we test if the Golgi export patch is conserved in the basolateral Kir channels for polarized trafficking to the BLM.

Methods: Common residues in the Golgi export patch of Kir2.1 were identified by sequence analysis and atomic resolution modeling. A common "SY" motif at the focal point of the putative signal was found. External HA-tagged Kir channels bearing deletions on "SY" motif (DSY) were compared to WT channels.Channel cell surface expression was quantified by surface antibody binding and analytical luminometry. Intracellular localization was evaluated by fluorescence microscopy.

Results: Kir4.1, mutations in which underlie EAST/SeSAME syndrome, Kir 5.1, and Kir2.3 contribute to the basolateral K^+ conductance in the distal nephron. Kir4.1 forms heteromers with Kir5.1; oligomerization of the subunits is thought to "mask" an ER retention signal in Kir5.1. We found Kir4.1, Kir2.3 and Kir4.1/Kir5.1 channels bearing DSY mutations fail to traffic to the cell surface, and accumulate in the Golgi, consistent with disruption of a common Golgi export signal. Coexpressing WT Kirs with the DSY mutants, does not rescue the surface expression of Kir4.1DSY or Kir5.1DSY, and these heteromultimeric channels largely accumulate in the Golgi, further supporting a dominant role of "SY" motif in Golgi export. WT Kir4.1/Kir5.1DSY channels, accumulate in the ER as well as the Golgi, suggesting the ER retention signal can be unmasked when channels are unable to exit the Golgi.

Conclusions: Basolateral Kir channels in the distal nephron rely on a common Golgi export signal patch to gain access to the cell surface.

FR-PO029

Are Potassium Homeostasis and Adaptation Similar in Male and Females Rats? Luciana C. Veiras, An Tran, Julie Jiyang Han, Donna Lee, Alicia A. McDonough. *Cell and Neurobiology, Keck School of Medicine of USC, Los Angeles, CA.*

Background: Plasma potassium (K) must be maintained within a narrow range because it is a key determinant of membrane potential. Dietary potassium (K) intake reduces phosphorylation (-P) and abundance of renal Na-Cl cotransporter (NCC) in male rodents. This response redistributes sodium (Na) downstream for reabsorption by epithelial sodium channels (ENaC) which powers K secretion via K channels. Previous studies have not addressed whether there are sex differences in K homeostasis. This study aimed to compare both K homeostasis and adaptation in female versus male Sprague Dawley rats.

Methods: Sprague Dawley rats (n=6/group) were studied in metabolic cages and fed defined gelled diets. Electrolytes were determined by flame photometry and renal transporter abundance by immunoblot of cortex homogenates.

Results: At baseline (after overnight fast), UV, UNaV, UKV and food intake were similar in both sexes. However, plasma Na, K and osmolality were lower in females versus males ([Na]: 115±1 versus 118±1 mM, [K]: 3.20±0.06 versus 3.90±0.06 mM, Osm: 296±3 versus 306±2 mOsm; $p< 0.05$; n=6 for all). The lower plasma K in females may be due, in part, to significantly higher abundance of renal ENaC subunits (alpha: 1.4 fold and cleaved gamma: 1.5 fold higher versus males). Additionally, in females, higher NCC (1.8 fold) and NCC-P (4.3 fold) abundance were observed versus males. Previously, we reported that in males fed a 2%K meal, plasma K increased to 5.5± mM. After females consumed a 2%K containing meal, urinary K increased 7 fold and plasma K increased from 3.20±0.06 to 3.9±0.1 mM, $p< 0.05$; n=6; in 0%K fed females K remained at 3.2±0.1. Even though plasma K remained below 4 mM in females, the 2% K meal decreased renal NCC and NCC-P to 0.8 and 0.5 fold versus the 0% K fed females (no changes in ROMK or ENaC subunits).

Conclusions: We conclude that baseline plasma K set point is significantly lower in female than male SD rats, perhaps secondary to higher ENaC activity, and that the renal responses to an acute K meal are indistinguishable in males and females. NIH DK 083785.

FR-PO030

Role of the H,K-ATPase Type 2 in the Regulation of Blood Pressure during K^+-Depletion

Gilles Crambert, Katia Igoudjil, Christine Lamouroux. *Centre de Recherche des Cordeliers, INSERM/UPMC/CNRS, France.*

Background: Alteration of blood pressure (BP) level is one of the side effects associated to K^+-depletion. However, the mechanisms linking K^+ balance to BP remain unsettled and debated. Adaptation to K^+-depletion requires ability to retain K^+. In kidney and colon, this is handled by the stimulation of H,K-ATPase type 2 (HKA2) and its absence leads to severe K^+-depletion under low-K^+ diet condition. Our aim is to investigate whether HKA2 may contribute to determination of BP level under low-K^+ diet.

Methods: Wild-type (WT) and HKA2-null mice (HKA2 KO) were fed a normal or a low-K^+ diet for up to 13 days and their blood pressure and metabolic parameters were measured daily. At day 4 of a normal or low-K^+ diet, plasma volume (Blue Evans dye), renal expression of ion transporter (PCR and WB), sensitivity to thizaide and to vasopressin were measured in both WT and HKA2 mice.

Results: Wild-type mice (WT) displayed a decrease of BP after 10 days of low-K^+ diet (from 113 to 103 mm Hg). In HKA2-null mice, the decrease of BP (109 to 100 mm Hg) occurred much earlier (day 2-3). At early stage of K^+-depletion, plasma volume remained constant in WT but decreased by 20% in HKA2-null mice, indicating that decrease of BP is linked to a the development of hypovolemia. The origin of this hypovolemic status is the transient renal "leak" of Na^+ and water observed in HKA2-null mice the first four days of the low-K^+ diet. The mechanisms of this salt and water loss could be related to a differential regulation of renal Na^+ transporter expression (mainly NCC) and a blunted response to vasopressin.

Conclusions: The presence of HKA2 is therefore required to limit the decrease of plasma K^+ value and to protect against development of hypotension.

FR-PO031

Aldosterone Induces a BK-a/b4-Mediated Kaliuresis in Mice on a Low Na, High K Diet

Ryan J. Cornelius, Donghai Wen, Steven C. Sansom. *Cellular and Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE.*

Background: BK-a/b4 channels mediate K secretion in mice on a low Na, high K, alkaline diet (LNaHK) in association with a 5-fold increase in urinary flow. The LNaHK diet yields a very high plasma [aldosterone] (P[aldo]), which increases K secretion via enhanced Na reabsorption and apical BK-a/b4 expression in the distal nephron. However, the relation between the high P[aldo] and distal flow rate is not yet understood.

Methods: To study this, we used C57BL/6 wild type mice (WT) or BK-b4 knockout mice (KO) that underwent sham or bilateral adrenalectomy (ADX). ADX mice were given a low or high dose aldo replacement by osmotic pump before being fed LNaHK.

Results: The low dose aldo (ADX-LA; 25 mg/kg/day) yielded a P[aldo] of 300-600 pg/ml and the high dose aldo (ADX-HA; 500 mg/kg/day) yielded a P[aldo] of 3,000 to 6,000 pg/ml. The K excretion rate (UKV) and transtubular K gradient (TTKG) were decreased in WT ADX-LA compared with WT sham, but were reversed to WT sham levels in WT ADX-HA. KO sham exhibited a decreased UKV and TTKG compared to WT sham; however, the UKV and TTKG of KO ADX-LA were not different from WT ADX-LA. Immunofluorescent staining showed decreased apical and total cellular BK-a expression in WT ADX-LA compared to WT sham; whereas BK-a expression of WT ADX-HA was similar to WT sham. Urinary flow was decreased in WT ADX-LA, compared to WT sham, and returned to WT sham levels in WT ADX-HA. To determine the effect of cortical distal K secretion on flow, mice were treated with amiloride to inhibit the ENaC-mediated Na reabsorption for K secretion exchange. When given amiloride (versus vehicle), WT control diet, WT LNaHK and KO LNaHK had increased isotonic luminal [Na], and decreased isotonic [K]. Amiloride caused an increased distal flow and isotonic luminal [K] + [Na] in WT control, a decreased distal flow and decreased isotonic luminal [K] + [Na] in WT LNaHK, and did not affect distal flow and luminal [K] + [Na] in KO LNaHK.

Conclusions: These results show that mice on LNaHK have increased urinary flow due to an aldo-induced increase in BK-a/b4-mediated K secretion. The increased ratio of K secreted per Na reabsorbed in mice on LNaHK creates an osmotic kaliuresis.

FR-PO032

Cholesterol (chol)-Rich Lipid Rafts (LRs): Mechanosensitive Structures to Transduce Fluid Flow in the Collecting Duct (CD)

Rajeev Rohatgi,[1,2] Yu Liu,[1] Daniel Flores,[1] Rolando Carrisoza-Gaytan.[2] *[1]Medicine, James J. Peters VAMC, Bronx, NY; [2]Pediatrics, Icahn School of Medicine, NY, NY.*

Background: Essential hypertension (eHTN) is associated with hypercholesterolemia, but how chol contributes to eHTN is unknown. Chol increases plasma membrane (PM) viscosity, partly, by incorporating into LRs. Dietary chol induces ENaC-dependent surge in blood pressure while salt-sensitive rats have elevated PM viscosity and suppressed renal prostaglandin E2 (PGE2) synthesis to augment Na absorption. Flow rate in CDs effects PGE2 release, and led us to hypothesize that chol, and its presence in LRs, regulates flow-mediated cyclooxygenase-2 (COX-2) and PGE2 expression in the CD.

Methods: PGE2 and COX-2 are measured in CD cells and dissected CDs after manipulating chol.

Results: Cortical CDs (CCDs) were microperfused at 0, 1, and 5 nL/min and then incubated in media. Secreted PGE2 was similar between no and low flow (151±28 versus 121±48 pg/mL/mm) CCDs; but, PGE2 was greatest from high flow (578±146 pg/mL/mm; $p<0.05$) CCDs. Next, mice were fed 0% or 1% chol diet, injected with saline to produce high urine flows, and CCDs microdissected for PGE2 secretion. PGE2 secreted from control was 271±73 versus 117±25 pg/mL/mm ($p<0.05$) from chol-fed mice. To evaluate total COX activity, PGE2 was measured after incubating CCDs in arachidonic acid. The induced PGE2 from control was 668±58 versus 313±36 pg/mL/mm ($p<0.05$) in chol-fed mice. Next, chol was extracted (with methyl b-cyclodextrin) from a CD cell-line which stimulated PGE2 release and COX-2 expression, similar to cells exposed to fluid shear stress (FSS), while chol integration suppressed PGE2 and COX-2. We tested whether chol, within PM LRs, constrained activation of mechanosensitive signaling proteins. To test this, extraction of chol mimicked FSS induced-PGE2 and COX-2 expression through p38 activation. Next, p38 was localized to LRs containing mechanosensitive caveolin-1, but chol extraction translocated p38 from LRs to heavier fractions.

Conclusions: LR chol regulates COX-2 expression, in part, by constraining p38 activity. We speculate that FSS raises LR fluidity to release p38, similar to chol extraction, which stimulates PGE2 and COX-2 expression.

Fluid Shear Stress (FSS) Induces the Translocation of BK Channels Out of Lipid Rafts in the Cortical Collecting Duct (CCD)

Rolando Carrisoza-Gaytan,[1] Daniel Flores,[2] Rajeev Rohatgi,[2] Marcelo D. Carattino,[3] Thomas R. Kleyman,[3] Lisa M. Satlin.[1] *[1]Pediatrics, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Medicine, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: The Ca^{2+}- and stretch-activated BK channel, present in principal (PC) and intercalated (IC) cells of the CCD, mediates flow-induced K secretion (FIKS), enhanced by dietary K loading. BK channel activity is tonically inhibited under low flow conditions by MAPKs (Li *et al*, *PNAS*, 2006) and PKA (Liu *et al*, *AJP*, 2009). Cumulative evidence suggests that FIKS requires release of BK channel inhibition directly or indirectly by these kinases. Studies by others have shown in non-renal cells that the activity of BK channels, localized to sphingolipid-cholesterol-rich lipid rafts (LRs), is regulated by the composition and/or integrity of LRs. We hypothesized that BK channels in the CCD localize to LRs which provide a structural foundation for signaling complexes that regulate channel activity.

Methods: Monolayers of MDCK C7 and C11 cells (PC and IC models, respectively) were stably transfected with c-myc-tagged BKa, grown on glass slides and subjected to 0, 0.1 (low) or 0.4 (high) dynes/cm2 of FSS x 30 min. LRs were isolated from MDCK cells by sucrose density fractionation and analyzed by Western blotting (WB) for c-myc (BKa), ERK1/2, and Cav-1.

Results: MDCK C11 cells express more apical BKa than C7 cells, but in both lines, the channel colocalizes with Cav-1. Immunodetectable BKa, ERK1/2 and Cav-1 were identified in the same sucrose buoyant fraction, corresponding to the migration pattern of LRs, in cells exposed to no or low FSS, but after high FSS, BKa was detected in a denser fraction consistent with a translocation of the channel out of the LRs.

Conclusions: BKa in the CCD localizes to LRs under no and low FSS conditions, where it is tonically inhibited. High FSS stimulates translocation of BKa to non-raft plasma membrane domains where we speculate it can be activated to mediate FIKS.

Hypokalemia and Diabetes Insipidus in a Kidney Specific Kir4.1 Knock Out Mouse

Daniel A. Gray,[1] Sundeep Malik,[2] David J. Field,[1] Salvador Pena.[3] *[1]Dept of Medicine, Univ of Rochester, Rochester, NY; [2]Pharmacology and Physiology, Univ of Rochester, Rochester, NY; [3]Dept of Pathology, Univ of Rochester, Rochester, NY.*

Background: We recently developed a kidney specific Kir4.1 KO mouse using the cadherin 16 promoter to investigate SeSAME/EAST syndrome (Gray D et al, JASN 24 (2013), 539A). On control diet, a severe urinary concentrating defect associated with hypernatremia, grossly enlarged kidneys but normokalemia was seen. On low K, low Mg diet x 1 wk, KO mice showed marked hypokalemia (K 1.5 versus 3.0 mM in WT), metabolic alkalosis and the concentrating defect but hypomagnesemia was not seen, suggesting intact DCT function.

Methods: Immunoblots were done on whole kidney lysates. Snap frozen kidneys were homogenized in lysis buffer with protease inhibitors. Samples were spun at 1000g x 15 min, the supernatant spun at 18,000g x 6 hrs at 4C, pellets resolubilized in lysis buffer, samples then BCA quantified, treated with DTT, loaded onto SDS-PAGE gels, transferred and blotted.

Results: Immunoblots on whole kidney lysates showed a ~40% reduction in Kir4.1 protein expression in KO versus WT. Immunofluorescence using antibodies to Kir4.1 along with nephron specific markers showed bright staining for Kir4.1 in DCT > CNT and CCD for WT. In the KO, DCT staining was mildly reduced but signal in the CNT and CCD was minimal or absent, consistent with the preserved Mg transport (in DCT) but compromised K transport (in CNT and CCD) seen in the functional studies described above. To determine the etiology of the urinary concentrating defect, immunoblots were done using aquaporin 2 and aquaporin 3 antibodies. Neither showed decreased expression in the KO. In addition, no significant reduction in surface expression was seen in KO versus WT kidney sections stained with these 2 antibodies. However, the Na/K/2Cl cotransporter was decreased in KO immunoblots, suggesting that a disrupted medullary gradient may underlie the diabetes insipidus seen in these mice.

Conclusions: Basolateral K recycling by Kir4.1 in the CNT and CCD is essential for K adaptation when dietary K is restricted. A disrupted medullary gradient may underlie the concentration defect seen with the KO.

FR-PO035

Differential Regulation of K Channels in the Aldosterone Sensitive Distal Nephron by WNK1 Isoforms Tennille N. Webb,[1] Rolando Carrisoza-Gaytan,[2] Anna Rued,[1] Arohan R. Subramanya,[1] Lisa M. Satlin,[2] Thomas R. Kleyman,[1] Marcelo D. Carattino.[1] *[1]Renal-Electrolyte Div, Univ of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Pediatrics, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Renal K^+ secretion is accomplished in the aldosterone sensitive distal nephron by the ROMK and the Ca^{2+}- and stretch-activated BK channel. Familial hyperkalemic hypertension (FHHt) is an inherited form of low-renin hypertension with decreased K^+ secretion and increased Na^+ reabsorption, which has been linked to genes encoding WNK1 and WNK4. The WNK1 gene produces two isoforms by alternative promoter usage, a long WNK1 (L-WNK1) that is ubiquitously expressed and a kidney specific (KS-WNK1) isoform that lacks the kinase domain.

Methods: We examined the role of WNK1 isoforms on BK channel whole-cell and surface expression in HEK293 cells.

Results: Our studies showed that the overexpression of L-WNK1 promotes a significant increase in BK channel whole-cell and surface expression. Noticeably, the overexpression of a kinase dead L-WNK1 mutant (K233M) did not alter whole-cell BK expression, suggesting that catalytic activity is required for L-WNK1-mediated regulation of BK expression. When we coexpressed BK channel with L-WNK1, KS-WNK1 or a combination of both in HEK293 cells, we observed that KS-WNK1 antagonized the effect of L-WNK1 on BK whole-cell expression. In immunoperfused CCDs, L-WNK1 labeling, identified in intercalated but not principal cells, was enhanced in rabbits fed a high K^+ (HK) diet for one week.

Conclusions: Taken together, our studies and previous studies suggest that L-WNK1 exerts different effects on renal K secretory channels, inhibiting ROMK and activating BK. A HK diet-induced increase in L-WNK1 expression may contribute to enhanced BK channel-mediated K^+ secretion. An increased expression of BK in individuals with FHHt due to WNK1 mutations may explain why hyperkalemia is corrected with a thiazide diuretic in this setting.

Mechanisms of Intracellular pH Regulation of Native Renal ClC-K2 Chloride Channel Laurent Pinelli, Stéphane Lourdel, Jacques Teulon, Marc Paulais. *INSERM/UPMC/CNRS U1138 ERL8228, Paris, France.*

Background: Basolateral ClC-Ka/b Cl^- channels, two members of the ClC transporters family, are distributed along the distal nephron. In the thick ascending limb, where ClC-Kb plays a key role in NaCl absorption, loss-of activity ClC-Kb mutations result in type III Bartter syndrome. Still, the physiologically relevant regulations of ClC-Kb properties that might influence chloride transport have to be described.

Methods: Using the inside-out configuration of the patch-clamp technique, the sensitivities of ClC-K2 channels to membrane voltage and intracellular pH (pH_i), two hallmarks of most ClC channels, were investigated in the basolateral membrane of intercalated cells of microdissected mouse connecting tubule, where ClC-K2 is thought to underlie the major chloride channel (*Nissant et al, Am. J. Physiol. 290, F1421-F1429, 2006*).

Results: Channel activity (*NPo*) was highly dependent upon membrane voltage, *NPo* increasing from 24 ± 0.6 % at -80 mV to 100 % at +80 mV at pH_i 7.4 (n = 19). Varying pH_i had a dramatic effect on this voltage-dependence, intracellular alkalinization flattening the channel *NPo/V* relationship through an increase in the maximal number of active channels per patch (from 12 ± 1.3 at pH_i7.0, n = 8, to 49 ± 8.6 at pH_i 7.8, n = 6). At either positive (+80 mV) or negative (-80 mV) clamp membrane voltages, rising pH_i from 7 to 7.8 induced dramatic increases in patch activity, *NPo* rising from ~ 20 % at pH_i 7.0 to 100% at pH_i 7.8 (n = 5). The apparent maximal number of active channels (*N*) was clearly the most sensitive parameter at both +80 and -80 mV, *N* rising from ~25% at pH_i 7.0 to 100% at pH_i 7.8, while single channel activity (*Po*) did not change with pH_i at +80 mV, although increasing with pH_i at -80 mV.

Conclusions: The present study demonstrates that pH_i regulates renal ClC-K2 channel by reducing its voltage-dependence and increasing the number of active channels upon intracellular alkalinization and suggests that it may have a significant impact on the physiology of HCO_3^- transporting intercalated cells.

2Cl/H Exchange Function of CLC-5 Is Required for the H-ATPase-Mediated Maximal Endosome Acidification Nobuhiko Sato,[1] Hideomi Yamada,[1] Osamu Yamazaki,[1] Shoko Horita,[1] Masashi Suzuki,[1] Motonobu Nakamura,[1] Yoshitsugu Kaku,[2] Daisuke Yamamoto,[3] Akira Ashida,[3] Takashi Sekine,[4] George Seki.[1] *[1]Internal Medicine, Tokyo Univ; [2]Fukuoka Children's Hospital; [3]Osaka Medical College; [4]Toho Univ.*

Background: In a typical Dent's disease patient with low-molecular-weight proteinuria and hypercalciuria we have identified a novel "gating glutamate" mutation E211Q that may alter the functional mode of CLC-5, but its disease-causing mechanism remains to be clarified.

Methods: In Xenopus oocytes, CLC-5 currents and surface pH were measured by two-electrodes voltage-clamp method and pH-sensitive microelectrodes, respectively. In HEK293 cells, cell pH recovery from acid-load was monitored with BCECF in hypotonic Na-free solution to estimate the vacuolar H-ATPase activity, and the pH sensitive ratiometric GFP mutant VAMP2-pHluorin was used to measure endosome pH.

Results: Analyses of CLC-5 currents and cell surface pH responses to depolarizing pulses in Xenopus oocytes confirmed that E211Q as well as the artificial mutant E211A functioned as a pure Cl channel with linear I-V curve. In HEK293 cells, the bafilomycin-sensitive basal H-ATPase activity was very low (0.03 +/- 0.001 pH/min). Although the H-ATPase activity was stimulated by E211Q (0.22 + 0.02 pH/min) and E211A (0.28 +/- 0.04 pH/min), these effects were less than that by WT CLC-5 (0.60 +/- 0.08 pH/min). While the basal endosome pH (6.89 +/- 0.04) was significantly lowered by E211Q (6.67 +/- 0.04) and E211A (6.67 +/- 0.05), these effects were again less than that by WT (6.25 +/- 0.05). Bafilomycin abolished the effects of CLC-5 constructs on endosome pH. Analyses with confocal microscopy and Western blotting confirmed that WT, E211Q, and E211A showed the similar intracellular distribution, without changing total or cell surface expression of H-ATPase B2 subunit.

Conclusions: Consistent with the proposed model for CLC-7, our data indicate that 2Cl/H exchange is more efficient than simple Cl conductance in the functional activation of H-ATPase. Loss of 2Cl/H exchange function of CLC-5 by E211Q mutation may cause Dent's disease by impairing maximal endosome acidification.

Chloride Channel Activity of ApoL1 John C. Edwards. *Internal Medicine, Saint Louis Univ, St. Louis, MO.*

Background: Variants in the protein ApoL1 are known to contribute to accelerated progression of chronic kidney disease in people of African descent. ApoL1 is thought to function as a chloride channel in trypansomes, but the properties of the ApoL1 channel have not been fully described. Whether it functions as a channel in kidney cells is unknown. A more complete characterization of the channel activity of ApoL1 and the disease-associated variants may shed light on the mechanism by which variant ApoL1 exacerbates kidney disease.

Methods: ApoL1 was expressed as a fusion protein in bacteria, with GST replacing the N-terminal signal sequence, and with a C-terminal V5/6His tag. A thrombin cleavage site separates the GST domain from ApoL1 sequence. Protein was purified from crude bacterial lysate in the presence of detergent by binding to glutathione agarose. ApoL1 with C-terminal tag was released by thrombin digestion. Protein was further purified over mono Q column. A control preparation was generated from bacteria expressing GST alone with no fusion protein, subjected to the exact same purification. Purified protein was reconstituted into lipid membranes by detergent dialysis. Alternatively, detergent was removed by dialysis and detergent-free protein was incubated with pre-formed vesicles. Channel activity was detected as potential-driven chloride efflux detected by a chloride-selective electrode. Analysis of variance was used to determine significance of any differences.

Results: For reconstituted samples, initial rates of efflux were 0.804%/sec for purified ApoL1, and 0.308%/sec for the control ($P<0.01$). Activity from direct insertion was assayed at pH 5.0 and at pH 7.5. At pH 5.0, initial efflux rates were 0.112 %/sec for ApoL1 and 0.076 %/sec for control ($P<0.05$), while at pH 7.5, rates were 0.86 %/sec for ApolL1 and 0.72 %/sec for the control (n.s).

Conclusions: Purified recombinant ApoL1 supports chloride selective, voltage driven efflux when reconstituted into phospholipid vesicles, or when allowed to directly insert into pre-formed vesicles. The direct insertion activity shows strong pH sensitivity, with activity at low but not neutral pH. The activity of the kidney disease associated variants has not yet been characterized.

Paracellular Properties of Isolated Perfused Inner Medullary Collecting Ducts and Ascending Thin Limbs of Loop of Henle at Different States of Diuresis Nina Himmerkus, Svenja Sonntag, Annalisa Krause, Markus Bleich. *Inst of Physiology, Christian-Albrechts-Univ, Kiel, Germany.*

Background: The ability of the mammalian kidney to concentrate urine strongly depends on the counter current flow and on the properties of the medullary epithelia namely the descending and ascending parts of the loop of Henle together with the vasa recta and the collecting ducts. We investigated the paracellular properties of inner medullary collecting duct (IMCD) and inner medullary ascending thin limbs (IMaTL) under different states of diuresis.

Methods: 4-6 week old rats were kept for three days either under water restriction (0.18 ml/gBW/d) or water load (0.53 ml/gBW/d). Urinary output and urine osmolality were monitored. Paracellular properties were assessed in isolated perfused IMCDs or IMaTLs by measurement of transepithelial resistance R_{te} and of diffusion potentials. These potentials were generated by perfusion of luminal 245 mM NaCl versus basolateral 50 mM NaCl, both 600 mosm/kg.

Results: Water restriction led to a daily urinary production of 0.05±0.003 ml/gBW/d and a urine osmolality of 2090±121 mosm/kg. Water load increased the urinary flow to 0.29±0.012 ml/gBW/d at 351±8 mosm/kg. In IMCDs R_{te} (27±3.5 Wcm^2 versus 24±3.5 Wcm^2) as well as the permeability ratio P_{Na}/P_{Cl} (0.98±0.02 versus 0.99±0.01) were not different between the two experimental groups. In contrast IMaTL showed a more cation selective paracellular pathway (P_{Na}/P_{Cl} 1.31±0.18) after water-load in comparision to P_{Na}/P_{Cl} 0.99±0.04 under water restriction. R_{te} was not significantly different (9.9±4.8 Wcm^2 versus 3.6±1.0 Wcm^2, respectively).

Conclusions: IMaTLs but not IMCDs change their paracellular properties under different states of diuresis. Under water load with nearly plasma isotonic urine the paracellular pathway of IMaTL became more cation selective.

The Effects of Sodium Glucose Transporter Type 2 (SGLT2) Inhibitions on the Renal Medullary Circulation Yusuke Ohsaki,[2] Takefumi Mori,[1] Kento Akao,[1] Yoshimi Nakamichi,[2] Chika Takahashi,[2] Sadayoshi Ito.[1] *[1]Nephrology, Endocrinology and Vascular Medicine, Graduate School of Medicine, Tohoku Univ, Sendai, Miyagi, Japan; [2]Div of Integrative Renal Replacement Therapy, Graduate School of Medicine, Tohoku Univ, Sendai, Miyagi, Japan.*

Background: Renal medulla is generally hypoxia and reduction of medullary circulation by body fluid loss could result in ischemia. Sodium glucose transporter type 2 (SGLT2) inhibitor reduces sodium and glucose reabsorption in the proximal tubule and thereby control blood glucose level in diabetes but induces osmotic diuresis. Therefore, the present study designed to evaluate the effect of SGLT2 inhibitor tofogliflozin on renal medullary blood flow (MBF) and renal madullary oxygen pressure (pO_2).

Methods: Catheter was inserted in femoral artery and vein in male Sprague-Dawley rats, to monitor blood pressure, heart rate and to infuse drugs, respectively. Renal MBF and pO_2 were measured with laser-Doppler flowmetry or oxygen microelectrode, respectively. Tofogliflozin (1 mg/kg bw/h) or furosemide (0.5mg/kg bw/h) was intravenously administered for 90 min. Urine was collected in 30 min interval.

Results: Tofogliflozin and furosemide administration significantly increased urine volume from 0.39±0.09 to 1.42±0.24, from 0.28±0.03 to 1.38±0.31 g/30 min respectively) but not different between groups. Blood pressure and heart rate did not change either by tofogliflozin or furosemide treatment. Furosemide significantly reduced MBF and increased pO_2 (92.6±1.6% and 119±7.1%, average of 76-90 min data compared to baseline period, respectively), while tofogliflozin did not show significant difference in MBF and pO_2 compared to baseline period (107.3±3.3% and 104.2±4.4%, respectively).

Conclusions: Tofogliflozin did not alter renal medullary circulation and local pO_2 despite of significant increase in urine volume, while furosemide decreased renal MBF but increased renal medullary pO_2 by inhibition of oxygen dependent Na transport. These results indicate that SGLT2 inhibition could play a beneficial role in the body fluid control without altering medullary circulation and oxygen.

Interplay between Disulfide Bonding and N-Glycosylation Defines SLC4 Na^+-Coupled Transporter Extracellular Topography Quansheng Zhu, Liyo Kao, Rustam Azimov, Natalia Abuladze, Debra Newman, Ira Kurtz. *Medicine, Univ of California, Los Angeles, Los Angeles, CA.*

Background: The extracellular loop 3 (EL-3) of SLC4 Na^+-coupled transporters contains 4 highly conserved cysteines and multiple N-glycosylation consensus sites. In the electrogenic Na^+-HCO_3^- cotransporter NBCe1-A, EL-3 is the largest extracellular loop and is predicted to consist of 82 amino acids. The role of these conserved cysteines in NBCe1-A-EL-3 topological folding and NBCe1-A ion transport function has been unclear.

Methods: In the present study, we designed various cysteine and N-glycosylation mutant combinations in NBCe1-A-EL-3 and analyzed their roles in EL-3 topological folding. These constructs were expressed in the HEK293 cells and subjected for protein chemistry analysis, chemical labeling, cross-linking studies and functional measurement.

Results: Our results demonstrate that the 4 highly conserved cysteines form 2 intramolecular disulfide bonds, Cys583-585 and Cys617-642 respectively that constrain EL-3 in a folded conformation. The formation of the second disulfide bond is spontaneous and unaffected by the N-glycosylation state of EL-3 or the first disulfide bond, whereas formation of the first disulfide bond relies on the presence of the second disulfide bond and is affected by N-glycosylation. Importantly, EL-3 from each monomer is adjacently located at NBCe1-A dimeric interface. When the two disulfide bonds are missing, EL-3 adopts an extended conformation highly accessible to protease digestion.

Conclusions: The unique adjacent location of two symmetrically-folded EL-3 loops from each monomer resembles a domain-like structure that is potentially important for NBCe1-A function *in vivo*. Moreover, the formation of this unique structure is critically dependent on the finely tuned interplay between disulfide bonding and N-glycosylation in the membrane processed NBCe1-A dimer.

Identification of a Unique Inhibitory Region in the N-terminal Segment of the Pancreatic Na+:HCO3- Cotransporter NBCe1B Electrogenicity Hong Chao Li,[1,3,4] Jingyu Xu,[3] Sunil Yeruva,[3] Brigitte Riederer,[3] Manoocher Soleimani,[1,2] Ursula E. Seidler.[3] *[1]Dept of Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Affairs Medical Center, Cincinnati, OH; [3]Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Lower Saxony, Germany; [4]Pharmacology, Physiology and Toxicology, Joan C. Edwards School of Medicine, Marshall Univ, Huntington, WV.*

Background: The sodium bicarbonate cotransporter NBCe1 plays a crucial role in the reabsorption and secretion of HCO3- in the kidney and pancreatic ducts, respectively. The two major isotypes of NBCe1 include NBCe1A (kidney) and NBCe1B (pancreatic), which exhibit differential tissue distribution and electrogenicity. It is hypothesized that an inhibitory mechanism in the unique N-terminal region of NBCe1B regulates its activity. Inhibitory motif (s) in the unique N-terminal region of NBCe1B regulate its function and electrogenicity.

Methods: Various pNBCe1 mutant constructs were generated via mutagenesis and expressed in either *Xenopus laevis* frog oocytes or HEK 293 cells. The activities of cells expressing the wild-type NBCe1 protein and its mutants were analyzed and compared in the presence of HCO3-.

Results: Deletions of a. a. 31 to 41 and substituted mutations: V35A, P36A, Y39A in subdomain 31 to 41 of NBCe1B resulted in the disinhibition and increased NBCe1B activity in the oocyte expression system. The intracellular pHi recovery rates following intracellular acidosis were significantly higher in HEK293 cells transfected with NBCe1B del 31-41 and Y39A mutants than those in cells transfected with the wild type NBCe1B.

Conclusions: Our results suggest that there are multiple specific subdomains and individual amino acid residues located in NBCe1B unique N-terminal end that are responsible for its inhibition and reduced electrogenicity. In particular, the amino acid residue Y39 of the unique N-terminal domain of NBCe1B plays an inhibitory role in the activity and electrogenicity of NBCe1B. Whether the inhibitory effect of this amino acid or motif is mediated through changes in the conformational structure of the cotransporter or is via binding with other molecules remains to be determined.

FR-PO043

Effect of Aging on Basal and Acidosis-Stimulated Renal Ammonia Metabolism Hyun-Wook Lee,[1] Mary E. Handlogten,[1] Gunars Osis,[1] Jill W. Verlander,[1] I. David Weiner.[1,2] *[1]Div of Nephrology, Hypertension and Transplantation, Univ of Florida, Gainesville, FL; [2]Nephrology and Hypertension Section, NF/SGVHS, Gainesville, FL.*

Background: Aging is associated with functional changes in the kidney. Because renal ammonia metabolism is a primary method through which the kidneys maintain acid-base homeostasis, we examined age-related changes in basal and acidosis-stimulated ammonia metabolism.

Methods: We studied young (6~10 months) and aged (18~28 months) C57Bl/6 mice. Mice were acid-loaded by feeding chow mixed with HCl, 0.4 M for 7d; daily 24 hr urines were collected, and then tissue was obtained. Mice with combined collecting duct-deletion of both Rhbg and Rhcg (CD-Rhbg-Rhcg-KO), generated using Cre-loxP technique, were used to examine the role of Rhbg and Rhcg in aging.

Results: Under basal conditions, urinary ammonia excretion, urine pH, and urine volume were similar in young and old mice. In aged mice, cortical Rhbg expression was decreased; outer medullary Rhbg and cortical and outer medullary PEPCK, PDG, glutamine synthetase (GS) and Rhcg expression were unchanged. Acid-loading increased ammonia excretion in both young and old mice and the increase did not differ significantly between groups; urine pH was lower in young mice than in aged mice on days 2 and 5 of acid-loading. After acid-loading, aged mice exhibited greater changes in renal cortical Rhcg, outer medullary Rhbg, and cortical PEPCK expression than did young mice. To determine the functional importance of Rhbg and Rhcg in aged mice, we examined effects of CD-Rhbg-Rhcg-KO on response to acid loading. CD-Rhbg/Rhcg-KO in aged mice decreased acidosis-stimulated ammonia excretion, compared to Cre-negative littermates, by ~35%; this was despite greater changes in GS expression.

Conclusions: We conclude: 1) ammonia excretion in response to an acid load is maintained in aged mice through mechanisms involving age-related changes in acidosis-stimulated PEPCK, Rhbg and Rhcg expression; (2) Acidosis-induced changes in Rhbg and Rhcg are greater in aged than in young mice, and are essential for the response to metabolic acidosis in aged mice; and (3) GS changes in aged, acid-loaded Cre-neg mice are submaximal.

FR-PO044

Effect of Low Protein Diet on Renal Ammonia Metabolism Hyun-Wook Lee,[1] Mary E. Handlogten,[1] Gunars Osis,[1] Jill W. Verlander,[1] I. David Weiner.[1,2] *[1]Div of Nephrology, Hypertension and Transplantation, Univ of Florida, Gainesville, FL; [2]Nephrology and Hypertension Section, NF/SGVHS, Gainesville, FL.*

Background: Both low protein diets and systemic acid-base status can affect chronic kidney disease progression. Because ammonia metabolism is a major determinant of renal acid-base homeostasis, we examined the effect of dietary protein restriction on ammonia metabolism in normal mice and in mice with deletion of Rhbg and Rhcg.

Methods: Wild-type C57Bl/6 (wt) mice were fed either control (20%) or low (6%) protein diets for 13 days with daily 24 hr urine collection, then tissue was obtained for immunoblot analysis and immunohistochemistry (IHC). To determine the functional necessity for either Rhbg or Rhcg, we studied mice with global Rhcg deletion (Rhcg KO) or with collecting duct-specific Rhbg deletion (CD-Rhbg-KO).

Results: In wt mice, low protein diet decreased urinary ammonia excretion by ~80%. PEPCK and cortical PDG expression decreased, consistent with decreased ammonia production. In addition, cortical glutamine synthetase (GS) increased, consistent with increased glutamine regeneration via GS. Rhcg expression was unchanged. Rhbg expression in inner stripe of outer medulla (ISOM) increased significantly and in the cortex was unchanged. Quantitative IHC showed increased Rhbg expression in ISOM intercalated cells. Rhcg KO did not alter the ammonia excretion response to low protein diet, but resulted in greater changes in PEPCK, cortical PDG, and cortical GS expression than occurred in mice with intact Rhcg expression. CD-Rhbg-KO did not alter ammonia excretion in response to low protein diet.

Conclusions: (1) Low protein diet decreases ammonia excretion by decreasing ammoniagenesis and by increasing GS-mediated reaction of ammonia with glutamate to reform glutamine. (2) It also increases Rhbg expression; because Rhbg deletion did not alter ammonia excretion, Rhbg may have roles unrelated to ammonia excretion. (3) Changes in PEPCK, PDG and glutamine synthetase expression in Rhcg KO mice suggest they compensate for the absence of Rhcg in low protein conditions, indicating Rhcg is involved in response to dietary protein changes.

FR-PO045

Hypercalcemia in Mice with High CaP Diet Co-Operatively Stimulated Renal Alpha and Beta Intercalated Cells (IC-A and -B) via Basolateral Ca-Sensing Receptor in IC-B Yukiko Yasuoka,[1] Yuichi Sato,[2] Hiroshi Nonoguchi,[3] Katsumasa Kawahara.[1] *[1]Physiol., Kitasato U. Sch. of Med., Sagamihara, Japan; [2]Mol. Diagnostics, Kitasato U. Sch. of Allied Health Sci, Sagamihara, Japan; [3]Internal Med., Kitasato U. Medical Center, Kitamoto, Japan.*

Background: It is believed that hypercalciuria stimulates the urinary acid excretion to prevent urolithiasis through activation of luminal Ca-sensing receptor (CaSR) in IC-A. Basolateral CaSR in IC-B (Yasuoka Y, ASN 2011) may co-operatively stimulate alkali excretion to maintain the plasma pH in normal.

Methods: C57Bl/6J mice (10 weeks, male) were fed with a control diet (1% Ca by $CaCO_3$ (CaC)) or high calcium diet (control diet + CaC or Ca-phosphate (CaP)) for 7 and 28 days. Blood and urine samples were analyzed. By using a quantitative in situ hybridization technique, we examined changes in the anion exchanger (AE1), carbonic anhydrase (CAXII), H^+-ATPase, Pendrin and CaSR mRNAs expression in collecting ducts.

Results: No unexpected changes were observed in blood and urine samples of mice with CaP diet of 7 d and in mice with CaC diet of 7 and 28 d. In mice with CaP diet (28 d), plasma [Ca^{2+}] slightly, but significantly increased (hypercalcemia) and urinary Ca excretion markedly and significantly increased from 96.0 to 139.2 (μg/d). Further, urinary pH significantly decreased from 6.5 to 6.2. Interestingly, the expression levels of H^+-ATPase, AE1 and CAXII mRNAs in IC-A and of Pendrin and CaSR mRNAs in IC-B increased co-operatively. The cell heights of IC-A and IC-B increased similarly by 29.3% and 38.1% ($P < 0.05$). On the other hand, in mice with CaC diet (28 d),Ca excretion significantly and more largely increased from 90.1 to 341.0 (μg/d). However, urinary pH oppositely increased from 6.7 to 7.6 ($P < 0.05$). The cell height of IC-B, not IC-A, increased by 23.1% and its expression levels of Pendrin and CaSR mRNAs increased significantly.

Conclusions: There was no evidence to indicate that hypercalciuria stimulated urinary acidification through the direct activation of IC-A. Co-operative activation of IC-A and IC-B during chronic high CaP diet may prevent urolithiasis and maintain plasma acid-base balance by increasing urinary acid and alkali excretion.

Direction-Dependent Block of an Electroneutral Na-HCO_3 Cotransporter: Insights from Simultaneous Intracellular and Surface pH Measurements in the Presence of $DIDS^=$ Raif Musa-Aziz,[1,2] Mark Parker,[2] Fraser John Moss,[2] Walter F. Boron.[2] *[1]Physiol and Bioph, Univ of Sao Paulo, Sao Paulo, Brazil; [2]Physiol and Bioph, Case Western Reserve Univ, Cleveland, OH; [3]Physiol and Bioph, SUNY at Buffalo, Buffalo, NY.*

Background: Na^+-coupled HCO_3^- transporters (NCBTs) play important roles in cellular and whole-body acid-base homeostasis. Most are blocked by the divalent anion $DIDS^=$. Previous studies of NBCe1, an electrogenic NCBT, demonstrate that the initial, rapid phase of NCBT inhibition by $DIDS^=$ is reversible and mainly results from ionic interaction of $DIDS^=$ with conserved lysine residues at the outer end of transmembrane segment 5. Preliminary voltage-clamping studies have shown that reversibly bound $DIDS^=$ blocks NBCe1-mediated HCO_3 influx better than efflux, an observation consistent with the idea that exiting HCO_3 knocks $DIDS^=$ off from its extracellular interaction site. In the present study, on an electroneutral NCBT, we further investigate the phenomenon of direction-dependent block by monitoring the effect of reversibly-bound $DIDS^=$ on HCO_3 influx and efflux without imposing an electrical field that could in itself influence DIDS binding.

Methods: We expressed a hyperactive human-NBCn2 (lacking its N-terminal autoinhibitory-domain) in *Xenopus* oocytes and exposed the cells to a solution containing 5%CO_2/33mM HCO_3. We used microelectrodes to simultaneously monitor membrane potential (V_m), intracellular pH (pH_i), and the maximum transient change in surface pH (DpH_S).

Results: Following the familiar fall in pH_i caused by the rapid influx of CO_2, we observed a slower pH_i recovery and a pH_S that was consistently more acidic than the bulk extracellular pH, indicating HCO_3 uptake. We observed no substantial changes in pH_i or pH_S in parallel experiments performed on H_2O-injected oocytes. The addition of 200mM DIDS to the bath affected a complete yet reversible block of NBCn2-mediated HCO_3 influx. When we reversed the direction of transport by replacing extracellular Na^+ with Li^+, pH_i declined and pH_S transiently increased—indicating HCO_3 efflux—regardless of the presence of $DIDS^=$.

Conclusions: This work shows that $DIDS^=$ affects a directional block of NBCn2, reinforcing the idea that exiting HCO_3 displaces reversibly-bound $DIDS^=$.

FR-PO047

A Novel Assay for Quantitating Carbonic Anhydrase Activity and Assessing Red Blood Cell Hemolysis R. Ryan Geyer,[1,2] Pan Zhao,[2] Mark Parker,[3] Walter F. Boron.[2] *[1]Biochemistry, Univ of Sao Paulo, Sao Paulo, Brazil; [2]Physiology and Biophysics, Case Western Reserve Univ School of Medicine, Cleveland, OH; [3]Physiology and Biophysics, State Univ of New York at Buffalo, Buffalo, NY.*

The primary role of the red blood cell (RBC) is to transport O_2 to and CO_2 away from tissue and cells. The RBC membrane is an extremely resilient structure, capable of withstanding extreme mechanical stress and harsh conditions. However, with certain genetic diseases, bacterial infection, or age, RBC fragility can increase appreciably, and hemolysis can have a variety of untoward consequences. We hypothesized that we could exploit the release of carbonic anhydrase II (CAII) from RBCs to quantitate the degree of hemolysis. Here we report a novel method that combines stopped-flow fluorescence spectroscopy, out-of-equilibrium (OOE) CO_2/HCO_3^- solutions, and the pH indicator dye pyranine to monitor the acceleration of pH changes by carbonic anhydrases, including CAII released during hemolysis. One OOE component was buffered with 16mM HEPES (pH 7.05 at 10°C) and the other, with 44 mM HCO_3^- (pH 8.41, ~1%CO_2). Mixing of the two components yields the following initial OOE values: [CO_2]=0.5%, [HCO_3^-]=22 mM, and pH@7.23 at 10°C. Over time, the reaction $HCO_3^- + H^+ \rightarrow CO_2 + H_2O$ produces an exponential pH increase (rate constant, *k*). Adding purified bovine CAII substantially increases *k* in a [CA]-dependent fashion. As a proof of concept, we combined varying amounts of freshly prepared, intact murine RBCs (0.3% hematocrit) with RBC lysate, keeping the total [hemoglobin] constant at 5 mM to simulate different degrees of hemolysis (0-100%). In the OOE assay, *k* increases linearly with simulated % hemolysis. We found that although the initial hemolysis before loading into the SF machine is <1 %, the estimated initial hemolysis in the OOE SF assay is ~5%, presumably due to mechanical forces of rapid mixing. Our results show that the OOE stopped-flow fluorescence approach can measure CAII activity with high resolution in a simplified system composed of only CAII, as well as in a more complex system that mimics hemolysis.

Effect of Varying Electrode Tip Diameter on Extracellular Surface-pH (pH_S) Changes Caused by CO_2 Fluxes across an Oocyte Plasma Membrane Rossana Occhipinti,[2] Jessica Kabutomori,[1] Walter F. Boron,[2] Raif Musa-Aziz.[1] *[1]Physiol and Bioph, Univ of Sao Paulo, Sao Paulo, Brazil; [2]Physiol and Bioph, Case Western Reserve Univ, Cleveland, OH.*

Background: The use of a blunt electrode to monitor pH_S of an oocyte provides insights into CO_2 fluxes across the membrane. Exposing an oocyte to CO_2/HCO_3 leads to a rapid influx of CO_2, which causes a fall in intracellular pH (pH_i). The CO_2 influx also creates a CO_2 deficit at the extracellular surface, which is replenished by diffusion of CO_2 from the bulk and the reaction $HCO_3+H^+ \rightarrow CO_2+H_2O$. This reaction causes (surface pH) pH_S to rise to a peak and then decay, following a single exponential (t_{pHS}) as the CO_2 influx wanes. The opposite occur as we remove extracellular CO_2/HCO_3.

Methods: We record the pH_S signal with a microelectrode (20-mm tip diameter), controlled by an ultra-fine micromanipulator that positions the pH_S electrode on the oocyte surface, near the equator, until we observe a slight dimple of 40mm in the membrane. The maximal height of the pH_S transient (DpH_S) reflects the maximal CO_2 influx or efflux. A reaction-diffusion mathematical model developed by our collaborators and us suggests that the special volume between the pH_S electrode and oocyte surface may accentuate the effect of the extracellular reaction $HCO_3+H^+ \rightarrow CO_2+H_2O$, thereby amplifying the DpH_S sensed by the electrode. Here, we investigate this special volume on H_2O-injected oocytes by systematically varying the inner diameter (ID) of the pH_S electrode tip from 5 to 20 (our standard), to 40, to 80mm—the maximal feasible diameter.

Results: We observe that the maximal rate of pH_i change and the magnitude of the CO_2-induced pH_i decrease are identical for all IDs, and that reducing the ID to 5mm has little effect on DpH_S or t_{pHS}. On the other hand, increasing ID from 20 to 40 to 80mm

raises DpH_S and t_{pHS}, both for CO_2 addition and removal. The time to peak for pH_S—time difference between the initiation of the CO_2-induced upswing in pH_S and the peak of the pH_S spike—also increases as ID rises from 20 to 80mm.

Conclusions: These data confirm that increasing the ID beyond 20mm accentuates reaction ($HCO_3+H^+ \rightarrow CO_2+H_2O$) within, and reduces CO_2/HCO_3 diffusion to/from, the special environment beneath the pH_S electrode.

Vacuolar H^+-ATPase (V-ATPase) Regulation by Aurora Kinase A (AURKA) in Kidney Carcinoma Cells Mohammad M. Al-Bataineh,[1] Rodrigo Alzamora,[3] Allison L. Marciszyn,[1] Hui Li,[1] Fan Gong,[1] Kenneth R. Hallows,[1,2] Nuria M. Pastor-Soler.[1,2] *[1]Medicine, Univ of Pittsburgh, Pittsburgh, PA; [2]Cell Biology, Univ of Pittsburgh, PA; [3]Physiology and Biophysics, Univ of Chile, Chile.*

Background: The V-ATPase mediates ATP-driven transport of H^+ across membranes against a gradient and is involved in metastasis. V-ATPase A subunit phosphorylation at Ser-175 is important for PKA-mediated V-ATPase activity in intercalated cells (ICs). Although Ser-175 is a target for PKA, this residue is also located within a larger phosphorylation consensus sequence for Aurora kinases, which are important in the phosphorylation of proteins that contribute to the pathogenesis metastatic carcinomas. We thus hypothesized that AURKA overexpressed by aggressive carcinomas regulates the V-ATPase in human kidney carcinoma cells (Caki-2) via Ser-175.

Methods: We used Caki-2 cells transfected with either wild-type V-ATPase A subunit (WT-A) or a phosphorylation-deficient mutant A subunit at Ser-175 (S175A-A). We performed co-immunoprecipitation and immunoblot studies and phosphorylation assays *in vitro* and in intact Caki-2 cells. Extracellular pH measurements, *in vitro* wound-healing assays, immunoflorescence labeling and confocal microscopy were also performed on Caki-2 cells.

Results: AURKA is abnormally expressed in Caki-2 cells, where it directly binds the V-ATPase A subunit in an AURKA phosphorylation-dependent manner. An AURKA activator increased V-ATPase expression and activity at the plasma membrane of cultured Caki-2 cells. AURKA phosphorylates the V-ATPase A subunit at Ser-175 *in vitro* and in Caki-2 cells. Furthermore, immunolabeling revealed that an AURKA activator induced marked membrane accumulation of WT-A subunit in cell projections of transfected Caki-2 cells compared to untreated cells. Moreover, the AURKA activator did not induce plasma membrane accumulation of the phosphorylation-deficient mutant S175A-A. Finally, AURKA activation enhanced the rate of wound healing in Caki-2 cells compared to untreated cells.

Conclusions: AURKA mediated V-ATPase regulation via Ser-175 phosphorylation may have a role in the metastatic potential of kidney carcinomas and may represent a potential therapeutic target.

The Auto-Recessive Mutation R298S of the Sodium Bicarbonate Cotransporter NBCe1-A Leads to a Trafficking Defect That Underlies Proximal Renal Tubule Acidosis and Myriad Ocular Pathologies Harry S. Gill, Kun-Young R. Choi, Anastas Popratiloff. *Medicine, The George Washington Univ & Medical Faculty Associates, Washington, DC.*

Background: Proximal renal tubule acidosis (pRTA) is a devastating disease in which afflicted individuals fail to reabsorb bicarbonate in the proximal segment of the nephron and thus are unable to maintain blood pH. The electrogenic NBCe1-A is an integral membrane co-transporter that normally reabsorbs Na^+ and $HCO3^-$ across the basolateral membrane. A naturally occurring mutation, R298S, in the cytoplasmic, N-terminal domain (Nt) of NBCe1-A leads to pRTA. We hypothesize that the R298S genetic mutation results in a fragile monomer-dimer equilibrium of NBCe1-A, leading to intracellular aggregation and the inability to incorporate into the plasma membrane.

Methods: To investigate the basis of the R298S, we expressed NBCe1-A and NBCe1-A-R298S in cultured human proximal tubular (HK-2) cells to monitor intracellular trafficking and localization by confocal microscopy. The molecular basis of the disease was investigated by in-depth biophysical studies of the Nt and Nt-R298S (including determining Nt crystal structure at 2.4-Å resolution, homodimer dissociation constant analyses, molecular mass measurements by multiangle-light scattering, and hydrodynamic radii temperature dependence).

Results: Confocal studies show that, unlike NBCe1-A, NBCe1-A-R298S is largely retained in the endoplasmic reticulum and post-Golgi vesicles of proximal tubule cells. The Nt crystal structure reveals a dimer with putative conduits in the interior responsible for substrate transport. But biophysical experiments reveal a significantly higher K_D of the NBCe1-A-R298S dimer compared to wildtype, with a propensity to fall out of solution that is dependent on pH, temperature, and concentration.

Conclusions: The R298S mutation is predominantly a trafficking defect, where cellular localization at the plasma membrane is dependent on growth temperature of the cell line and expression levels. Patients afflicted with this mutation can be characterized with a failure to recover bicarbonate in the proximal tubule due to low expression levels of the cotransporter at the plasma membrane.

Silencing Prolyl hydroxylases 2 Protects against Cobalt Induced Hypoxia Injury in Human Renal Epithelial Cells by Autophagy Inactivation Hui Zhang, Bingying Zhang, Sheng Wu, Yi Fang. *Nephrology, Zhangshan Hospital, Fudan Univ, Shanghai, China.*

Background: Prolyl hydroxylase domain protein 2 (PHD2) is a cellular oxygen sensor that regulates hypoxia-inducible factor, a key transcription factor involved in cell survival. Here we studied whether and how PHD2 silencing in cultured human renal proximal tubular epithelial cell (HK2) enhances their renoprotective effects under hypoxia.

Methods: We studied the role of HIF/PHD pathway in $CoCl_2$-induced cell apoptosis/autophagy by employing small-interfering RNA (siRNA). Dynamic profiles of apoptosis/autophagy markers of HK-2 cells within 48h after exposing to $CoCl_2$ (200mM) were recorded.

Results: Our results showed that silencing PHD2 had significantly increased the expression of HIF-1a ($P < 0.01$) but had little effect on HIF-2a. Meanwhile, both knockdowning PHD2 or 3-Methyladenine (an autophagy inhibitor) treatment rescued cell death through autophagy inactivation ($P<0.01$). Of interest, coadministration of HIF-1a siRNA with PHD2 siRNA abrogated renoprotetive effect conveyed by PHD2 siRNA alone, suggesting that activation of endogenous HIF-1a-dependent pathways mediated the autophagy inactivation effects of PHD2 silencing.

Conclusions: Apoptosis and autophagy are crucial mechanisms regulating cell death and homeostasis under hypoxia condition. Direct inhibition of PHD2 promoted renal epithelia cell survival against $CoCl_2$-induced cell apoptosis/autophagy. Activation of the HIF-1a signaling pathway is required to reduced apoptosis and autophagy via up-regulating the expression of Bcl-xl protein.

Evaluation of Bardoxolone Methyl as a Modulator of Human Kidney Cell Injury Amandla Roque Atilano,[1] Lauren Aleksunes,[3] Melanie S. Joy.[1,2] *[1]Univ of Colorado, Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; [2]Div of Renal Disease and Hypertension, Univ of Colorado, School of Medicine, Aurora, CO; [3]Rutgers Univ, School of Pharmacy, Piscataway, NJ.*

Background: Cisplatin is prescribed for the treatment of solid tumors and exhibits toxicity to kidney tubules. Nuclear factor, erythroid 2-like 2 (NRF2) is a transcription factor in the antioxidant pathway. This investigation sought to study short-term treatment with BARD (NRF2 activator) as a nephro-protectant against cisplatin injury.

Methods: Human proximal tubule epithelial cells (hPTCs) were exposed to cisplatin (0-100mM) or control (DMSO) to measure cell viability by MTT assay. Studies conducted to determine changes in expression of *NFE2L2,* selected detoxifying enzymes (*GCLC*, *NQO1),* and transporters *(SLC22A2, ABCC2)* administered cisplatin (5, 25, 80uM) alone, BARD (100 nM) alone and given pre- or post-exposure (3h) to cisplatin. Cells were harvested, mRNA isolated, RT-PCR and immunofluorescence performed.

Results: Cisplatin 25-100uM resulted in reductions in cell viability *versus* control. Pre- and post-treatment with BARD yielded statistically significant increases in cell viability: 40% and 27% with pre-treatment at 24h and 48h, respectively, and 25% and 16% with post-treatment at 24h and 48h, respectively *versus* control. An increase in *NFE2L2* expression (2.7-fold) and dose and time dependent increases in *NQO1* (5.2-fold) and *GCLC* (4.7-fold) were demonstrated after exposure to cisplatin alone. Treatment with BARD alone resulted in increased *GCLC* (1.9 and 4.4-fold) and *NQO1* (9.3 and 41-fold) expression at 12h and 24h, respectively. Treatment with BARD pre- or post-cisplatin resulted in increased *GCLC* (1.8 and 68-fold*), NQO1* (9.9 and 13-fold), and *SLC22A2* (1.6-fold) and decreased *ABCC2* (0.36 and 0.41-fold) expression. Immunofluorescence demonstrated decreased NRF2 expression over time.

Conclusions: Human PTCs exposed to cisplatin demonstrated enhanced cell viability and increased mRNA expression of detoxifying enzymes (*NQO1* and *GCLC*) and *NFE2L2* with BARD administration. Bardoxolone methyl, given intermittently with planned exposures to cisplatin is a promising approach to mitigate acute kidney injury.

Cell Specific Gene Expression of Collecting Duct in Response to Cystitis Using RNA-Tagging Technique Neal A. Paragas, Tian Shen, Jonathan M. Barasch. *Medicine, Columbia Univ, New York, NY.*

Background: Many components of the mammalian immune system are likely involved in the protection of the urinary tract from bacterial invaders. As bacteria ascend the urinary tract they may encounter more than 50 different epithelial and mesenchymal cell types, each of which might contribute to innate defense. As a result, understanding host transcriptional responses at a cellular and temporal level requires a new technology. To determine gene expression in a single cell type at a single time point during a urinary infection (UTI) we generated a Lox-Stop-Lox Rosa26 uracil phosphoribosyltransferase (R26-UPRT) knock-in mouse that can convert 4-thiouracil (4TU) to 4-thiouridine. 4-thiouridine is incorporated into newly transcribed RNA where UPRT is expressed and the thio-RNAs can be biotinylated and isolated with streptavidin beads. We crossed the R26-UPRT mouse with a HoxB7-Cre mouse to specifically label and pull down RNAs from the HoxB7 expressing compartment of the nephron in mice with a UTIs.

Methods: (1) Developed Rosa26-UPRT knockin mouse. (2) Developed bioluminescent uropathogenic bacteria. (3) Pulled down labeled RNAs during the acute phase of a UTI.

Results: 14 week old Rosa26-UPRT/HoxB7-Cre mice with C57BL/6 background where challenged with a transurethral bladder injection of a bioluminescent strain of uropathogenic E. coli (UPEC-Lux, CFT073). Cystitis was confirmed 24 hrs after UPEC-Lux challenge by optical imaging. UPRT mouse was i.p. injected with a 4-thiouracil (4TU) which is converted to 4-thiouridine. TU-tagged RNAs where biotintylated and pulled down and analyzed by qPCR. qPCR of cell type specific markers of the collecting duct confirmed labeling and enhancement of the HoxB7 cell lineage (Pendrin >20-fold increased). Markers of epithelial bacterial activation also showed enrichment (NGAL, IL1a1, Cxcl1 all > 2-fold).

Conclusions: Using the R26-UPRT mouse we showed that specific cells of the distal nephron responded to a distant acute UTI. These data imply that a yet unknown mechanism activates the antimicrobial response of the kidney before bacteria ascend. Furthermore, we were able to show cell specific and time dependent labeling of RNAs for gene expression analysis.

In Vivo versus in Culture Dynamic Mobility of Renal Epithelial Cell Tight Junction Proteins Kurt Amsler,[1] Josephine Axis,[1] Danielle Janosevic,[1] Robert L. Bacallao.[2] *[1]Biomedical Sciences, NYIT College of Osteopathic Medicine, Old Westbury, NY; [2]Medicine, Indiana Univ School of Medicine, Indianapolis, IN.*

Background: Transepithelial reabsorption of water and solutes across the renal epithelium is mediated by transcellular pathways, through cells, and paracellular pathways, between cells through the tight junction (TJ). Both in vivo and in vitro studies have demonstrated that the permeability of the TJ can be modulated under both physiologic and pathophysiologic conditions. The TJ is composed of multiple membrane proteins, e.g., claudins and occludin, and multiple associated cytoplasmic proteins, e.g., ZO1, -2, -3, and cingulin, organized into an extended multiprotein complex. Recent studies on cultured renal and other epithelial cell types have indicated that multiple TJ proteins can move into and out of the TJ structure.

Methods: We examined the dynamic behavior of GFP-tagged occludin protein (GFP-occludin) transfected into MDCK cells by Fluorescence Recovery After Photobleaching.

Results: Transfected GFP-occludin was localized to the TJ structure/region. Following photobleaching of a portion of the TJ joining a cell couplet, GFP-occludin from outside the photobleached area moved into the photobleached area. The halftime for fluorescence recovery was 50 +/- 22 seconds (n=29). A small number of experiments yielded a substantially longer recovery halftime (189 seconds; n=2). Treatment with hydrogen peroxide at concentrations that increased paracellular permeability 1.5X-3X increased recovery halftime (64 +/- 30 seconds; n=42; p=0.022). The fraction of GFP-occludin that did not move during the experiment timeframe was 53% +/- 16% (n=31). Treatment with hydrogen peroxide did not alter this parameter (54% +/- 14%; n=42; p=0.402). In rats in vivo, transfected GFP-ZO-1 protein was localized to the TJ. GFP-ZO-1 was immobile following photobleaching, i.e., there was no recovery of GFP-ZO-1 into the photobleached area over the timeframe of the experiment.

Conclusions: These results indicate that, in vitro, TJ proteins are dynamic and mobility can be affected by hydrogen peroxide treatment. In vivo, however, at least some TJ proteins are not mobile under basal conditions.

FR-PO055

Identification of a Receptor for Extracellular Renalase Gary V. Desir,[1,2] Ling Wang,[1,3] Heino Velazquez,[1,2] John J. Chang,[1,2] Robert L. Safirstein.[1,2] *[1]Medicine, Yale School Med, New Haven, CT; [2]Medicine, VACHS; [3]Medicine, Renji Hsopital, Shanghai.*

Background: An increased risk for developing essential hypertension, stroke and diabetes is associated with single nucleotide gene polymorphisms in the gene for renalase, a newly described secretory protein. Gene deletion causes hypertension, and aggravates acute ischemic kidney (AKI) and cardiac injury. As a monoamine oxidase, renalase binds and degrades catecholamines; it also acts as an oxidase/anomerase to convert a-NAD (P) H to ß-NAD+, with hydrogen peroxide as reaction byproduct. Independent of its intrinsic enzymatic activities, extracellular renalase activates MAPK signaling and prevents acute kidney injury (AKI) in wild type (WT) mice. Therefore, we sought to identity the receptor for extracellular renalase.

Methods: RP-220 is a previously identified, 20 amino acids long renalase peptide that is devoid of any intrinsic enzymatic activity, but it is equally effective as full-length recombinant renalase at protecting against toxic and ischemic injury. We used biotin transfer studies with RP-220 in the human proximal tubular cell line HK-2, and protein identification by mass spectrometry.

Results: PMCA4b was identified as a renalase binding protein. This previously characterized plasma membrane ATPase is involved in cell signaling and cardiac hypertrophy. Co-immunoprecipitation and co-immunolocalization confirmed protein-protein interaction between endogenous renalase and PMCA4b. Down-regulation of endogenous PMCA4b expression by siRNA transfection, or inhibition of its enzymatic activity by the specific peptide inhibitor caloxin1b each abrogated RP-220 dependent MAPK signaling and cytoprotection. In control studies, these maneuvers had no effect on epidermal growth factor mediated signaling, confirming specificity of the interaction between PMCA4b and renalase.

Conclusions: We conclude that PMCA4b functions as a renalase receptor, and a key mediator of renalase dependent MAPK signaling.

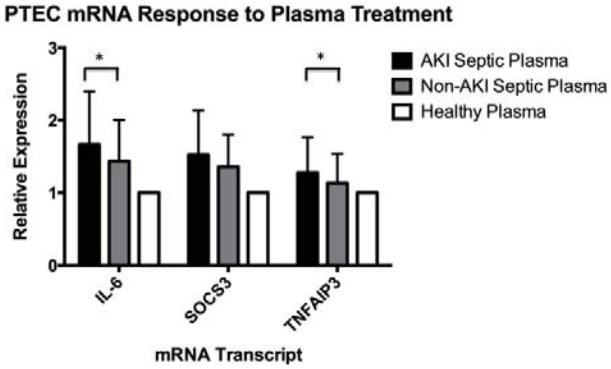
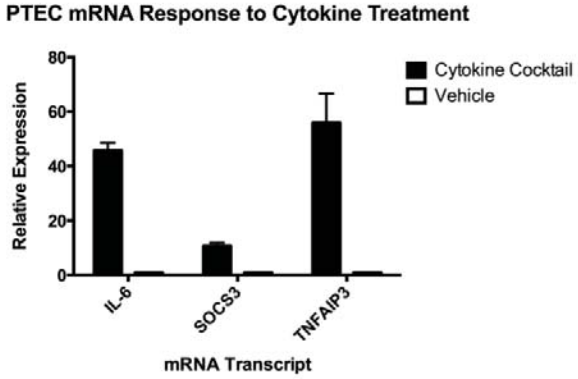
Human Septic Plasma Induces Inflammatory Gene Expression Response in Proximal Tubular Epithelial Cells Jennie Lin, Michael G. Shashaty, Nuala J. Meyer, Muredach Reilly. *Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA.*

Background: The pathophysiology of sepsis-associated acute kidney injury (AKI) is not well understood, necessitating novel human translational approaches to gain mechanistic insight.

Methods: We collected plasma from patients with severe sepsis and followed them for subsequent development of AKI, defined by Acute Kidney Injury Network (AKIN) criteria. We stimulated immortalized HKC-8 human proximal tubular epithelial cells (PTECs) for 12 hours with 5% plasma from 12 patients who developed AKI and 12 who did not. Controls included PTECs treated for 12 hours with 5% plasma from healthy subjects, cytokine cocktail (50 ng/mL IL-6, 50 ng/mL TNF-a, 20 ng/mL IFN-g), and serum-free cell culture medium. Real-time quantitative polymerase chain reaction targeting five genes previously associated with either inflammatory pathways or AKI was performed on cDNA reverse transcribed from PTEC RNA from each experimental condition.

Results: Across six experiments performed in triplicate, plasma from septic AKI patients, compared to plasma from septic non-AKI patients, induced increased expression of IL-6 (up to 1.73-fold, $p < 0.001$) and TNFAIP3 (up to 1.39-fold, $p = 0.037$), with a similar trend for SOCS3. PTECs treated with supraphysiologic doses of cytokines similarly had increased IL-6, SOCS3, and TNFAIP3 expression compared to cells treated with serum-free medium (all $p<0.001$), though the increases were more marked than those seen in PTECs exposed to septic AKI versus septic non-AKI plasma. NGAL and IL-18 were not differentially expressed after stimulation with either septic plasma or cytokine cocktail.





Conclusions: PTEC stimulation with septic human AKI plasma induces a differential transcriptional response for inflammation-associated genes such as IL-6 and TNFAIP3, supporting use of this model to study inflammation's contribution to sepsis-associated AKI.

Molecular Mechanism of Hsp70 Inhibitable, Nucleophosmin-Mediated Apoptotic Renal Cell Death Steven C. Borkan, Ramon G. Bonegio, Andrea Havasi, Zhiyong Wang. *Dept of Medicine, Boston Univ Medical Center, Boston, MA.*

Background: During stress, nucleophosmin (NPM), a nuclear DNA binding protein, is released from nucleoli, exits the nucleus and accumulates in the cytosol, presumably acting as a mitochondrial Bax chaperone. We hypothesize that stress-induced cell death is preventable by: (1) reducing NPM nuclear translocation into the cytosol and/or (2) limiting NPM-Bax complex formation required for Bax-mediated mitochondrial injury. To test these hypotheses, the effects of over-expressing wild type Hsp70, an anti-apoptotic protein, or Hsp70 mutants with translocation defects on NPM-mediated cell death were investigated.

Methods: To selectively over-express target proteins, Hsp70-knockout cells were infected with lentivirus containing empty vector (EV), wild-type Hsp70 (WT) or Hsp70

mutants with defective nuclear (985A) or nucleolar (M45) localization. These cells were subjected to ATP depletion, an insult that activates Bax and releases NPM into the cytosol. Cell survival, Hsp70 localization, cytosolic NPM, NPM-Hsp70 and NPM-Bax complex formation, mitochondrial Bax accumulation as well as mitochondrial membrane injury (AIF leakage) were compared in each group.

Results: ATP depletion caused marked nuclear accumulation of only WT and M45 Hsp70. However, WT and both Hsp70 mutants significantly increased cell survival after stress. Only 40% of EV-exposed cells survived stress. In contrast, 90% of WT, 86% of M45 and 60% of 985A expressing cells survived ($P < 0.05$ for each group *versus* EV). WT and both Hsp70 mutants enhanced Hsp70-NPM interaction, reduced NPM-Bax complex formation, mitochondrial Bax accumulation and outer membrane injury. However, only Hsp70 with nuclear access (wild type and M45) decreased the cytosolic accumulation of NPM after stress.

Conclusions: Both cytosolic NPM translocation and NPM-Bax complex formation mediate stress-induced renal cell death. Nuclear Hsp70 inhibits death by preventing nuclear NPM release and cytosolic Hsp70 inhibits NPM-Bax complex formation. Interference with NPM-mediated mitochondrial injury represents a novel mechanism by which Hsp70 protects renal epithelial cells and identifies a new target for preventing stress-induced acute kidney injury.

Protective Effects of Cilastatin on Gentamicin-Induced Apoptosis, Oxidative Stress and Renal Injury in Rats Juan Carlos Jado,[1] Blanca Humanes,[1] Jose Manuel Lara Martinez,[2] Emilia Cercenado,[3] Alberto Tejedor Jorge,[1] Alberto Lázaro Fernández.[1] *[1]Medicine and Surgery Unit, Inst I.S. Gregorio Marañón, Madrid, Spain; [2]Pathology, Hospital G.U. Gregorio Marañón, Madrid, Spain; [3]Clinical Microbiology, Hospital G.U. Gregorio Marañón, Madrid, Spain.*

Background: Gentamicin (G) is an antibiotic that unfortunately causes nephrotoxicity in 10-20% of therapeutic courses, side effect that seriously limits its use. We have found that cilastatin, a renal dehydropeptidase I inhibitor has protective effects from cisplatin-induced renal damage. Here, we have investigated the potential use of cilastatin as protector on G-induced renal injury in vivo.

Methods: Male Wistar rats were divided into 4 groups: control rats, cilastatin-control rats, G-injected rats (80 mg/kg, daily ip), cilastatin-treated G-injected rats (150 mg/kg, daily, ip). Nephrotoxicity was assessed 9 days after the first dose of G treatment, by measuring serum creatinine, BUN, proteinuria and renal morphology. Renal apoptosis was measured by determination of TUNEL-positive cells and apoptotic mediator's levels. Renal oxidative stress (OS) was assessed by determining lipid peroxidation (4 hidroxy-2-nonenal -4HNE-) and antioxidant capacity. G uptake into kidneys was measured by TDX specific assay.

Results: G-treated rats showed significant elevations in BUN, creatinine and proteinuria, with severe morphological changes such as vacuolization and hyaline cast in the tubular lumen. The treatment with cilastatin resulted in amelioration of renal functions as shown by reduction of these parameters and improved histological damage. Cilastatin also reduced renal caspase 3-activation, bax, bax/Bcl-2 ratio, Fas ligand and TUNEL-positive apoptotic cells, previously increased by G. Moreover, G increased the levels of OS, increasing 4-HNE and decreasing total antioxidant capacity and specifically Cu/Zn SOD and catalase levels. Cilastatin reversed these changes significantly and also attenuated G uptake by kidney tissue.

Conclusions: This study provides evidence that cilastatin reduces in vivo G nephrotoxicity by ameliorating apoptosis and OS. The mechanism of the beneficial effect could be attributed, at least in part, to a decrease in drug accumulation by the cells.

FR-PO059

Synchronized Tubular Cell Death Is Mediated by Ferroptosis in Acute Kidney Injury Andreas Linkermann,[1] Nina Himmerkus,[2] Shrikant R. Mulay,[3] Matthias Hackl,[4] Agnes Prokai,[4] Christin Dewitz,[1] Markus Bleich,[2] Ulrich Kunzendorf,[1] Hans J. Anders,[3] Joel M. Weinberg,[5] Stefan Krautwald.[1] *[1]Nephrology and Hypertention, Christian-Albrechts-Univ, Kiel, Germany; [2]Inst for Physiology, Christian-Albrechts-Univ, Kiel, Germany; [3]Nephrology Unit, Medizinische Klinik und Poliklinik IV, Munich, Germany; [4]Dept II of Internal Medicine and Centre for Molecular Medicine, Univ of Cologne, Cologne, Germany; [5]Div of Nephrology, Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MN.*

Background: Necroptosis (Linkermann and Green, NEJM 2014) depends on receptor-interacting protein kinase 3 (RIPK3), and we recently found RIPK3-ko mice to be protected from ischemia-reperfusion injury (IRI) (Linkermann et al., PNAS 2013). However, these studies could not exclude a direct effect of RIPK3 on organ perfusion which was suspected given the high RIPK3-expression in renal endothelial cell lines.

Methods: To directly investigate the effect of necroptosis in kidney tubules, we generated conditional inducible tubule-specific caspase-8 and FADD-deficient mice, both of which show no major abnormalities upon transgene induction and thus could not explain synchronized tubular cell death, but rather suggested a vascular effect which was quantified by intravital microscopy.

Results: In contrast to necroptosis-deficient primary isolated RIPK3-ko and MLKL-ko tubules prevention of ferroptosis in primary tubules increased tubular survival in diverse disease settings. Different IRI settings and four *in vivo* models of acute kidney injury demonstrate the pathophysiological importance and the immunogenicity of ferroptosis. We developed a novel thrird generation ferrostatin which is stable *in vivo,* and demonstrate strong renoprotective effects employing this compound *in vivo* and *ex vivo*.

Conclusions: Ferroptosis appears to be the central cell death mechanism relevant in vivo in tubules whereas RIPK3 mediates a perfusion-effect, but does not directly affect the tubules themselves in AKI. Therefore, the beneficial effects of prevention of necroptosis (Linkermann and Green, NEJM 2014) may be largely mediated by perfusion benefits, but the parenchymal cell death occurs through ferroptosis.

Osteopontin and Monocyte Chemotactic Protein-1 Are Targets of Meprin A During Acute Kidney Injury Christian Herzog, Sudhir V. Shah, Gur P. Kaushal. *Internal Medicine, UAMS, Little Rock, AR.*

Background: Meprin A, an oligomeric metalloproteinase composed of a- and b-subunits is anchored to the brush border membrane (BBM) by its b-subunit. During AKI meprin A is redistributed towards the basolateral side. We recently demonstrated that following AKI, meprin A is shed by ADAM-10 by cleaving at the b-subunit (JBC: 289, 2014). Shed meprin may be deleterious in AKI due to its high degradative potential. We have previously reported that meprin A is able to activate proIL-1b to IL-1b. In the present study we examined whether other proinflammatory chemokines like osteopontin (OPN) and monocyte chemotactic protein-1 (MCP-1) are proteolytic targets of meprin A.

Methods: Recombinant OPN was digested with activated promeprin a and b purified from stably transfected HEK cells in a time dependent manner. Likewise OPN was digested with meprin A purified from rat kidney. OPN proteolysis was visualized by westerns blot. Similarly the chemokine MCP-1 was digested with meprin a and b as well as with meprin A and the resulting digests visualized on western blots. Cleaved fragments of MCP-1 were analyzed by Edman degradation and LC/MS/MS to determine their peptide sequence. Urinary excretion of MCP-1 was monitored *in vivo* by ELISA in a mouse model of cisplatin AKI.

Results: OPN was rapidly (within 1 min) and completely degraded by meprins without forming a stable intermediary fragment. Meprin b cleaved OPN much faster than meprin a and meprin A. The cleavage of OPN may play an important role in AKI since OPN deficiency causes apoptosis in IR. MCP-1 was cleaved by meprins into stable fragments. As determined by LC/MS/MS meprin b cleaved MCP-1 after ^{74}Ser. Both meprin a and meprin A truncated MCP-1 into a 10 kDA fragment (N-terminally of ^{7}Ala and C-terminally most likely after ^{73}Arg). The P1 cleavage sites for MCP-1 differed from the sites obtained for proIL-1b.

Conclusions: The findings that meprins can degrade the proinflammatory OPN completely and cleave MCP-1 into fragments together with the already established fact of meprins ability to activate proIL-1b highlight the importance of meprins in the modulation of the inflammatory processes following AKI. Meprins may become targets for therapeutic intervention.

FR-PO061

Blocking JAM-C Promotes the Recovery of Cisplatin-Induced Acute Kidney Injury Sun Chul Kim, Hyojeong Chang, Myung-Gyu Kim, Sang-Kyung Jo, Won-Yong Cho. *Korea Univ Anam Hospital.*

Background: For resolution of inflammation, infiltrated leukocytes should be removed. Recent studies demonstrating 1) presence of neutrophil transendothelial migration in a reverse direction (rTEM) following ischemia/reperfusion injury (IRI), 2) endothelial junctional adhesion molecule-C being a negative regulator of rTEM, 3) identification of neutrophils that have migrated in a reverse direction by their high expression of ICAM-1 led us to test the effect of JAM-C blocking antibody on the resolution of kidney injury and inflammation in a mouse model of cisplatin-induced acute kidney injury (AKI).

Methods: Male C57BL/6 mice (19-23g) were given a single intraperitoneal (i.p.) injection of cisplatin (18mg/kg). Monoclonal anti-mouse JAM-C blocking antibody (clone H33; Millipore; Billerica, MA, U.S.A.) or control IgG was administered i.p. at 1.5mg/kg and the injection was delayed until day 4 and 5 following cisplatin injection to restrict the effect of antibodies on recovery phase. Biochemical, histological analyses as well as flow cytometry to detect reverse migrated ICAM-1$^+$ neutrophils were performed at 4, 5 and 6 days after cisplatin injection.

Results: After cisplatin injection, serum creatinine and histologic injury peaked on day 4. Treatment with a JAM-C blocking antibody on day 4 and 5 promoted the functional and histologic recovery of cisplatin induced AKI on day 5 and 6. Facilitating recovery by JAM-C blocking Ab was associated with significantly increased circulating ICAM-1$^+$ Tomm Horsfall protein (THP)$^+$ neutrophils as well as significantly decreased renal neutrophil infiltration and IL-6 levels, indicating that facilitating rTEM of neutrophils from kidney to peripheral circulation partially mediate resolution of inflammation and recovery.

Conclusions: We suggest that rTEM is involved in resolution of neutrophilic inflammation in cisplatin induced AKI and JAM-C is an important regulator of this process. Therefore, blockade of JAM-C could be considered for the new strategies to facilitate recovery in cisplatin induced AKI.

FR-PO062

NQO1 Regulate Autophagy in Cisplatin Induced Renal Injury Youngjung Kim, Sora Park, Hyun Tae Kim, Tae Won Kim, Si Yun Ryu, Ju Young Jung. *Veterinary Medicine & Inst of Veterinary Science, Chungnam National Univ, Daejeon, Korea.*

Background: Autophagy is a catabolic process that degrades damaged proteins and organelles in mammalian cells and activated under various pathologic condition including acute renal failure. It is generally accepted that ROS induce autophagy. NADPH:quinone oxidoreductase 1 (NQO1) is known as antioxidant enzyme, regulate the generation of ROS.

Methods: To invest regulation of autophagy by the NQO1, we used the NQO1 deletion and pretreated b-Lapachone known as NQO1 activator in cisplatin induced acute nephropathy *in vivo* and *in vitro*. We measured the serum blood urea nitrogen (BUN), creatinine (Cre) and performed the immunoblot and immunohistoemistry.

Results: NQO1 deletion (NQO1 -/-) mice was increased BUN and Cre under the cisplatin treatment, compared with wild type mice. NQO1 deletion resulted in increased autophagy with LC3B, LAMP2 and ATG7 levels and intense immunoreactivity of these proteins founded in the proximal tubule of outer medulla. However, treatment of b-Lapachone decreased autophagy and related proteins in cisplatin nephropathy. We also show the cisplatin induces autophagy in human kidney adenocarcinoma cells (ACHN). Levels of LC3B, LAMP2 and ATG7 were increased in treatment of Si NQO1 and decreased in b-Lapachone treatment.

Conclusions: These finding suggested NQO1 may be regulate renal autophagy in acute nephropathy induced by cisplatin treatment.

Cisplatinum-Induced Nephrotoxicity Activates ATM-Associated DNA Damage Response (DDR) and Offers Novel Avenues for Renal Protection Samriti Dogra,[1] Sriram Bandi,[3] Preeti Viswanathan,[2] Yogeshwar Sharma,[3] Sanjeev Gupta.[3] *[1]Pediatric Nephrology, Montefiore Medical Center, Bronx, NY; [2]Pediatric Gastroenterology, Montefiore Medical Center, Bronx, NY; [3]Medicine and Pathology, Albert Einstein College of Medicine, Bronx, NY.*

Background: Better insights into mechanisms of drug-induced nephrotoxicity will assist discovery of therapeutic agents to prevent or to promote tissue repair in kidneys. We first studied DDR typical of toxic chemotherapy, e.g. cisplatinum, in mouse renal tubular epithelial cells and next examined the possibility of renal protection within the context of DDR.

Methods: The studies were performed in MCT proximal tubular epithelial cells from the mouse. After exposing cells to IC50 concentrations of cisplatinum, we performed MTT assays for cell viability, qRT-PCR arrays for DNA damage associated changes, including ATM signaling pathway members, Comet assays for double-stranded DNA breaks, and cytostaining for gH2AX expression. To determine potential protection through ATM signaling, we examined ATM promoter expression with tdT reporter in MCT cells, with or without cisplatinum and growth factors. For in vivo effects, we treated mice with 30 mg/kg cisplatinum i.p. and sacrificed mice 3 d later for analysis of kidney tissue, including Comet assays and gH2AX staining.

Results: These studies showed typical evidences of DDR in cisplatinum-treated MCT cells. Specifically, we observed gH2AX expression, Comet formation and altered expression of ATM-related genes at mRNA level. Moreover, treatment of MCT cells with cisplatinum induced ATM promoter activity. Also, gH2AX expression in proximal tubular epithelial cells of cisplatin-treated kidney tissue indicated DDR in vivo. In a miniscreen of cytotrophic growth factors, we found G-CSF, VEGF, and FGFs could decrease cisplatinum-induced ATM promoter activity and improve cell viability.

Conclusions: Cisplatinum-induced DDR related to ATM signaling was observed in MCT cells as well as kidneys of intact mice. The ability to interfere with DDR through regulation of ATM promoter activity indicated potential protective role of growth factors in cisplatin-induced nephrotoxicity. These findings will be of clinical significance.

Role of Sirt3 in Cisplatin-Induced Nephrotoxicity Won Kim, Dal Kim, Aesin Lee, Yujin Jung, Tung Nguyen-Thanh, Sik Lee, Sung Kwang Park, Kyung Pyo Kang. *Internal Medicine, Chonbuk National Univ Medical School, Jeonju, Republic of Korea.*

Background: Cisplatin based chemotherapy is commonly used in therapeutic strategies for solid tumor. However, limitation of this agent is adverse effect on normal tissue such as kidney, ear, and peripheral nerves. Mechanisms of cisplatin nephrotoxicity are proposed as oxidative stress, inflammation, cellular apoptosis and death, and cell cycle regulation. Sirt3 is one of sirtuins family, which is NAD^+-dependent enzymes with homology to the *Saccharomyces cervisiae* gene silent information regulator 2 (Sir2). Sirt3 is located in mitochondria and involved in mitochondrial energy metabolism and function. However, the role of sirt3 in cisplatin-induced is not yet clarified. In this study, we investigated the role of sirt3 in cisplatin-induced nephrotoxicity *in vivo*.

Methods: We used Sirt3 knockout mice (*Sirt3*$^{(-/-)}$) and their wild type mice. Cisplatin nephrotoxicity was induced by intraperitoneal injection of cisplatin (20 mg/kg). After 3 days after cisplatin injection, blood and kidney tissues were harvested. Renal function and histology were evaluated. Tubular apoptosis, cell adhesion molecule expression, cytokines and inflammatory cells were evaluated by immunohistochemistry, Western blot analysis and ELISA.

Results: After induction of cisplatin nephrotoxicity, renal function was significantly aggravated in *Sirt3*$^{(-/-)}$ mice group. Tubular injury and inflammatory cell infiltration was significantly increased in *Sirt3*$^{(-/-)}$ mice group compared to wild type mice. TUNEL positive tubular cells and renal MCP-1 expression were increased in *Sirt3*$^{(-/-)}$ mice group compared to wild type mice.

Conclusions: In summary, absence of Sirt3 is more aggravated in renal injury by increase of renal inflammation and tubular apoptosis. Sirt3 may have important role in cisplatin-induced nephrotoxicity. We need to further studies for their molecular mechanisms.

FR-PO065

Identification of CDK4/6 Inhibitors That Ameliorate Cisplatin Nephrotoxicity Through Inhibition of OCT2 Function and Suppression of Cell Cycle Progression Navjotsingh P. Pabla, Alice A. Gibson, Alex Sparreboom. *Pharmaceutical Sciences Dept, St. Jude Children's Research Hospital, Memphis, TN.*

The organic cation transporter 2 (OCT2) mediates renal uptake of cisplatin and is a critical regulator of cisplatin nephrotoxicity. Pharmacological compounds that inhibit OCT2 have the potential to significantly mitigate cisplatin induced renal injury. In a chemical screen for OCT2 inhibitors, we identified two CDK4/6 inhibitors (palbociclib and LEE011) that potently inhibit OCT2 function. Mechanistically, palbociclib and LEE011 inhibit OCT2 in a non-competitive manner. Importantly, in mouse models of cisplatin nephrotoxicity, a single dose of palbociclib (150 mg/kg) prior to cisplatin administration significantly reduced cisplatin nephrotoxicity markers BUN and serum creatinine (vehicle versus palbocilib, P>0.05). Cisplatin nephrotoxicity was reduced by palbociclib in both wild-type and OCT2-null mice, indicating that the protective effects are mediated through OCT2 and an OCT2-independent mechanism, presumably cell cycle inhibition. We also found that CDK4/6 pathway is activated *in vivo* during cisplatin nephrotoxicity, and this is significantly inhibited by palbociclib. These results suggest that the CDK4/6 pathway is a therapeutic target for acute kidney injury and support the future clinical exploration of CDK4/6 inhibitors as modulators of cisplatin toxicity.

Functional Analysis of iPSC-Derived Myocytes from a Patient with Carnitine Palmitoyltransferase II Deficiency Tetsuhiko Yasuno. *Internal Medicine, Fukuoka Univ, Fukuoka, Japan.*

Background: Carnitine palmitoyltransferase II (CPT II) deficiency is an inherited disorder involving b-oxidation of long-chain fatty acids (FAO), which leads to rhabdomyolysis and subsequent acute renal failure. The detailed mechanisms of disease pathogenesis remain unknown; however, the availability of relevant human cell types for investigation, such as skeletal muscle cells, is limited, and the development of novel disease models is required.

Methods: We generated human induced pluripotent stem cells (hiPSCs) from skin fibroblasts of a Japanese patient with CPT II deficiency. Mature myocytes were differentiated from the patient-derived hiPSCs by introducing myogenic differentiation 1 (*MYOD1*), the master transcriptional regulator of myocyte differentiation. Using an *in vitro* acylcarnitine profiling assay, we investigated the effects of a hypolipidemic drug, bezafibrate, and heat stress on mitochondrial FAO in CPT II-deficient myocytes and controls.

Results: CPT II-deficient myocytes accumulated more palmitoylcarnitine (C16) than did control myocytes. Heat stress, induced by incubation at 38°C, leads to a robust increase of C16 in CPT II-deficient myocytes, but not in controls. Bezafibrate reduced the amount of C16 in control and CPT II-deficient myocytes.

Conclusions: In this study, we induced differentiation of CPT II-deficient hiPSCs into mature myocytes in a highly efficient and reproducible manner and recapitulated some aspects of the disease phenotypes of CPT II deficiency in the myocyte disease models. This approach addresses the challenges of modeling the abnormality of FAO in CPT II deficiency using iPSC technology and has the potential to revolutionize translational research in this field.

FR-PO067

Effects of Vesicules (Vs) Derived from Renal Pluripotent Stem Cells (rPSCs) on the LPS Toxicity in Immortality Human Mesangial Cells (iHMCs) and Renal Epithelial LLCP-K_1 Cells Luciana Aparecida Reis,[1] Gerson D. Keppeke,[2] Rita De C.S.G. Coimbra,[3] Nestor Schor.[1] *[1]Nephrology Div, UNIFESP/EPM, Sao Paulo, Brazil; [2]Rheumatology Div, UNIFESP/EPM, Sao Paulo, Brazil; [3]Eletronic Microscopy Div, UNIFESP/EPM, Sao Paulo, Brazil.*

Background: In this study we investigate the effect of Vs derived from rPSCs on the iHMCs or LLCP-K_1 treated with LPS.

Methods: rPSCs and characterized by immunofluorescence and FACS and Vs by TEM and Western blot. In order to enhance the production of Vs, the rPSCs were treated with LPS (100µg/ml), gentamicin (G; 2mM) or cisplatin (Cis; 6mM) (preconditioned - PC) or not (nPC) for 24 h. iHMCs or LLCP-K_1were treated with LPS (100µg/ml) or PBS (vehicle) for 72 h. iHMCs and LLCP-K_1 were treated with LPS+Vs nPC (35µg/ml) or PC (35µg/ml) for 24 h with LPS, G or Cis. Cellular viability were evaluated for Tripan blue and acridine orange; caspase 3, IL2, IL6 and IL10 by Western blot and NO by Griess.

Results: rPSCs were positive by Wnt1, CD24, PAX2 and ZO1 and Vs to CD9, CD81 and CD63. LPS decreased cell viability *versus* PBS 24h (150±7.9 *versus*408±18.8; 82.3±7.6 *versus* 97.8±9.3 %; p<0.05) or 72h (67.5±7.4 *versus* 385±12.6; 74.3±6.7 *versus* 98.1±13.4%; p<0.05). nPC Vs increase in cell viability 24h (312±7.4 *versus* 150±7.9; 89.4 *versus* 74.3±6.7%; p<0.05) or 72h (266±14.6 *versus* 76.6±5.7; 88.4±4.9 *versus* 76.6±5.7%; p<0.05) in iHMCs. LPS 72h increased caspase 3, IL2, IL6 and decreased IL10 *versus* CTL. When iHMCs received nPC-Vs decreased IL2, IL6 and caspase 3 and increased IL10. NO (nmoles/mg) increased in LPS *versus* CTL 72 h in iHMCs (82.8±9.5 *versus* 171.2±27.8; p<0.05) and LLCP-K1 (24.5±1.8 *versus* 129.8±16.4; p<0.05) and decrease in nPC-Vs (145.4±4.6 *versus* 171.2±27.8; p<0.05); (129.8±16.4 *versus*72.6±6.6; p<0.05) and PC-Vs with LPS, G or Cis for 24h (109.5±11.2; 115.8±5.8; 103.2±9.3; p<0.05); (76.3±5.9; 41.7±5.1; 33.8±1.3; p<0.05); respectively.

Conclusions: Results suggested that the Vs derived from rPSC have the ability to protect the toxicity in iHMCs and LLCP-K_1 induced by LPS. The protective effects were mediated by Vs-derived from rPSCs and intensified when the Vs-rPSC were previously stimulated by toxins, especially with different insult. In this case the stimulation by Cis presented higher protective effects.

Mesenchymal Stem Cell Homing to Kidneys Is Suppressed by Disrupting Interleukin 1 Alpha, Tumor Necrosis Factor Alpha, or Cyclooxygenase-2 Signaling

Scott R. Burks,[1] Saejeong Kim,[1] Jonathan Street,[2] Peter S.T. Yuen,[2] Robert A. Star,[2] Joseph Frank.[1] *[1]Radiology and Imaging Sciences, NIH, Bethesda, MD; [2]NIDDK, Bethesda, MD.*

Background: Optimal homing of iv-infused mesenchymal stem cells (MSC) may improve regenerative medicine therapies. Pulsed focused ultrasound (pFUS) enhances renal MSC homing sufficient to rescue cisplatin AKI 3 days after injection. pFUS generates a "molecular zip-code" of increased chemoattractants (cytokines, chemokines, cell adhesion molecules) in healthy murine kidneys. The molecular zip-code includes early elevations of TNFa, IL1a, and cyclooxygenase-2 (COX2) expression. We examined if inhibiting these molecules with clinically-relevant drugs abrogates the molecular zip-code and suppresses renal MSC homing.

Methods: C3H mice received inhibitors or vehicle pretreatment then unilateral kidney pFUS (8MPa). Kidneys were harvested 10min-72hr after pFUS. Pretreatment with drugs included: ibuprofen (30mg/kg, po, 15min before pFUS); etanercept (100mg, ip; 72 and 24hr before); or anakinra (IL-1a inhibitor, 200mg, ip; 48, 24, and 1hr before). In a second set, animals were given MSCs (10^6 human MSC iv) 3 hrs after pFUS. Kidneys were harvested 24hr later and MSC were detected by immunofluorescence.

Results: Renal pFUS elevated kidney TNFa and IL-1a early (10min) and upregulated COX2 (1–4hr). The subsequent (2-24hr) molecular zip-code included many chemoattractants necessary for MSC homing, and returned to baseline by 72hr. Kidneys from mice pretreated with ibuprofen, etanercept, or anakinra did not generate the molecular zip-code after pFUS. There was a mean decrease of ~64%, ~63%, and ~50% in MSC homing post pFUS for mice pretreated with ibuprofen, etanercept and anakinra, respectively. MSC also failed to home to pFUS-treated kidneys in COX2-knockout mice, demonstrating a specific, essential role for COX2.

Conclusions: pFUS increases MSC homing via signaling mechanisms that are TNFa, IL-1a, and COX2 dependent. Drug/MSC interactions remain unexplored and uncontrolled for in clinical trials. These data suggest common drug-host interactions could undermine cell-based therapies in regenerative medicine.

The Bone Marrow-Derived Mesenquimal Stem Cells (MSC) or Conditioned Medium (MSC-CM) Repair the Acute Kidney Injury (AKI) Induced By Acyclovir (ACY)

Joelma Santina Christo,[1] Nestor Schor.[1] *[1]Nefrologia, Unifesp, São Paulo, SP, Brazil; [2]Nefrologia, Unifesp, São Paulo, SP, Brazil.*

Background: The ACY is an antiviral drug used to treat herpes simplex type 1 and 2 and varicella zoster and may induce nephrotoxicity with AKI.Several groups have reported the contribution MSC in repair AKI processes. The aim of this study was to investigate the role of MSC or its conditioned medium BMSC-CM in this model of AKI.

Methods: After standart characterization the MSC were used at 4th passages for all experiments. The female Wistar rats received ACY (80mg/Kg/BW) or water (CTL) daily, for 5 days i.p. (N=10) and 72 hours after the 5th day of treatment, they received i.v. MSC ($1X10^6$cells) or MSC-CM (500ml) injection (1 doses). Then, blood were collected for urea (U) and creatinine (Cr). As well as histological evaluation.

Results: The AKI model was confirmed by increase in in creatinine (1.7±0.1versus0.7±0.01mg/dl) and urea (174.5±0.2versus56.0±0.1mg/dl; p<0.05),respectively after ACY, compared CTL.The ACY+MSC, after 72 h,presented lower creatinine (0.9±0.2 versus1.3±0.1mg/dl) and urea (89.2±0.2versus143.5±0.2 mg/dl; p<0.05) compared with ACY. Also the ACY+MSC-CM presented lower values for creatinine (1.0±0.1versus1.7±0.1mg/dl, p<0.05) compared with ACY. The MSC or CM decreased in pro-inflammatory cytokines and increased in anti-inflammatory cytokine.

Serum cytokines (pg/mL)	CTL	Acyclovir 5 days	Acyclovir+ PBS 72 hours	Acyclovir +MSC 72 hours	Acyclovir+Cell culture medium conditioned 72 hours
IL-1α	9.0±8	50.1±9	48.2±9	29.4±07*	29.3±4#
IL-1β	40.2±6	220.0±4	240.0±1	130.0±8*	165.0±6#
IL-10	12.2±3	25.6±7	34.2±9	120.0±5*	84.8±5#
TNF α	7.0±8	42.9±2	41.0±3	11.8±4*	24.5±5#
IFNγ	30.3±4	110±9	98.0±5	35.2±3*	64.8±12#
IL-6	60.1±10	417.0±9	378.0±7	227.0±8*	246.0±12#

Values are expressed as the mean±SEM *P<0.05 CTL vc Acyclovir+MSC 72 hours (n = 5), vs acyclovir+cellculture medium conditioned 72 hours # (n = 5), (One-Way ANOVA tukey pos-test).

Conclusions: These results strongly suggest that MSC and MSC-CM minimize AKI induced by ACY and thus, could be a new strategy to treat this nephrotoxicity.

FR-PO070

Inhalation of Hydrogen Gas Is Beneficial for Preventing Contrast-Induced Acute Kidney Injury in Rats

Tadashi Yoshida,[1] Koichiro Homma,[2] Maho Yamashita,[1] Matsuhiko Hayashi.[1] *[1]Apheresis and Dialysis Center, Keio Univ School of Medicine, Tokyo, Japan; [2]Dept of Emergency and Critical Care Medicine, Keio Univ School of Medicine, Tokyo, Japan.*

Background: Oxidative stress plays a key role in the pathogenesis of contrast-induced acute kidney injury (CIAKI). Administration of contrast media has been shown to increase the concentration of reactive oxygen species, resulting in the renal vascular constriction and tubular cell apoptosis. The present study aimed at investigating the effect of novel anti-oxidant, hydrogen (H2) gas, on the severity of CIAKI in a rat model.

Methods: CIAKI was induced in rats by intravenous injection of contrast medium, Ioversol, in addition to reagents inhibiting prostaglandin and nitric oxide synthesis. During the injection of these reagents, the rats inhaled H2 gas or control gas.

Results: One day after the injection, serum levels of urea nitrogen were significantly lower in H2 gas-inhaled CIAKI rats (17.6 ± 2.3 mg/dl) than those in control gas-inhaled CIAKI rats (36.0 ± 7.3 mg/dl), although they both were elevated as compared to untreated rats (14.9 ± 0.9 mg/dl). Consistently, creatinine clearance in H2 gas-treated CIAKI rats was higher than control gas-treated counterparts. Moreover, renal histological analysis revealed that the formation of proteinaceous casts and tubular necrosis was improved by H2 gas inhalation. Mechanistic analyses showed that inhalation of H2 gas significantly reduced renal tubular cell apoptosis, expression of cleaved caspase 3, and expression of an oxidative stress marker, 8-hydroxy-deoxyguanosine, in injured kidneys.

Conclusions: These results suggest that H2 gas inhalation is effective in ameliorating the severity of CIAKI in rats by reducing renal cell apoptosis and oxidative stress.

The Role of Nrf2 Expression in Radiocontrast Induced Nephropathy

Gang Jee Ko, So Yeon Bae, Yu Ah Hong, Sun Woo Kim, Heui-Jung Pyo, Young-Joo Kwon. *Dept of Internal Medicine, Korea Univ School of Medicine, Seoul, Korea.*

Background: Radiocontrast induced nephropathy (CIN) is the third common cause of acute renal failure. Although the number of patients taken the exams using radiocontrast is increasing, little has been progressed in the treatment for CIN. The pathophysiology of CIN was known as tubular injury by oxidative stress. Nuclear factor-erythroid-2-related factor 2 (Nrf2) has been known as a key player to coordinate intracellular antioxidative process. We investigated the role of Nrf2 in CIN.

Methods: CIN were established in vivo and vitro model by administration of iohexol in C57BL/6J mice and rat tubular cells (NRK-52E) according to previous study. To determine the role of Nrf2 in CIN, Nrf2 expression was reduced in vivo study using Nrf2 KO mice (B6.129X1-Nfe2l2tm1Ywk/J) or by siRNA treatment in vitro study. Tubular cell injury was examined after iohexol treatment.

Results: Increased expression of Nrf2 was noted after iohexol treatment both in mice kidneys and rat tubular cells. Serum creatinine at 24hrs after iohexol injection was significantly increased in Nrf2 KO mice compared to controls (control versus KO: 1.41±0.28 versus 2.11±0.44 mg/dL, p<0.05). Histologic examination showed tubular vacuolization and structural disruption induced by iohexol were aggravated in Nrf2 KO mice, and significant increase of apoptosis and F4/80 (+) inflammatory cells infiltration were also demonstrated in Nrf2 KO mice compared to controls. In vitro study, Nrf2 inhibition with siRNA decreased cell viability measured by MTT assay (vehicle versus siRNA: 0.480±0.05 versus 0.346±0.05, p<0.05) and increased caspase 3 expression. Increase of reactive oxygen species (ROS) after iohexol treatment was augmented with Nrf2 inhibition both in vivo and vitro study measured by CM-DCFDA. Decreased expression of anti-oxidant factor such as HO-1 was accompanied after Nrf2 inhibition, which led to increase of cytochrome c and NF-kB expression examined by western blot.

Conclusions: Nrf2 was suggested to be implicated in the pathogenesis of CIN through modulating anti-oxidant, anti-apoptotic, and anti-inflammatory process. Targeted therapy for proper function of Nrf2 to mitigate CIN should be studied further.

FR-PO072

Heme Oxigenase 1 Counteracts Contrast-Induced Acute Kidney Injury in Diabetic Rats Cassiane Dezoti Fonseca, Mirian Watanabe, Maria de Fatima Vattimo. *Experimental Laboratory of Models Animals, School of Nursing- USP, Sao Paulo, Brazil.*

Background: Contrast-induced acute kidney injury (CI-AKI) is a toxic nephropathy that results from intrarenal vasoconstriction and direct tubular toxicity with generation oxygen species (ROS). The decreased tissue oxygen in medula in preexisting renal dysfunction, as in Diabetes Mellitus (DM), can be a risk factor for CI-AKI. This study evaluated the effect of HO 1 in the restoration of oxidant injury of CI-AKI in diabetic rats.

Methods: Adult male Wistar rats (250-300g) were used. Physiological parameters; renal function (creatinine clearance, crCl); oxidative injury (urinary peroxides, UP, tiobarbituric acid reactive substances-TBARS and thiols in renal tissue) and kidney histological analysis were evaluated. Rats were submitted to left uninephrectomy (Nx) on the 1° day. The DM was induced by a single dose of intravenous streptozotocin (65mg/kg i.v.) on the 20° day. The iodine contrast (IC) meglumine ioxithalamate (6ml/kg) and hemin (HO 1 inducer;10mg/kg; i.p.;60 minutes before IC) were infused on the 85° day. Groups: Control (Nx+Citrate); Nx+DM; Nx+DM+IC; Nx+DM+IC+H.

Results: Diabetic groups showed polyphagia, polydipsia, polyuria, increase in the blood glucose and reduction in body weight ($p<0.05$). IC reduced the crCl and thiols in renal tissue with a proeminent increase in UP and TBARS. These paramethers were significantly changed by hemin. Kidney histology showed tubular cells vacuolization and edema with moderate injury in IC animals.

Groups/n	cr/Cl/100g ml/min	Urinary Peroxides nmol/g creatinine	TBARS nmol/g creatinine	Thiols nmol/mg total protein
Control/6	0.5±0.8	9±2	0.2±0.7	12±4
Nx+DM/6	0.3±0.5α	46±21α	2.2±0.6α	7±2
Nx+DM+IC/6	0.2±0.3αβ	45±10α	4.2±1.0αβ	5±1α
Nx+DM+IC+H/6	0.4±0.7αβδ	26±13αβδ	1.6±0.2αδ	14±3βδ

Renal function, oxidative index.αp<0.05vsControl;β vs Nx+DM;δ vsNx+DM+CI.

Conclusions: The data confirm DM as risk factor for CI-AKI and highlight the HO 1 renoprotective effect in oxidative damage in this model of nephropathy.

Abreu,[2] Denize Monaris,[2] Tatiana B. Gotti,[2] Larissa R. Matos,[2] Thales de Brito,[1] Antonio J. Magaldi.[1] *[1]LIM-12 Nephrology, Hospital das Clínicas FMUSP, São Paulo, Brazil; [2]Lab. de Bacteriologia, Inst Butantan, São Paulo, Brazil.*

Background: Acute kidney injury (AKI) in leptospirosis is frequently nonoliguric with hypo or normokalemia. Higher serum potassium levels were observed in nonsurvivor patients and may have been caused by more severe AKI, metabolic derangement, or rhabdomyolysis. An association between the creatine phosphokinase (CPK) level and the maximum serum creatinine level was observed in these patients and could suggest that rhabdomyolysis may contribute to severe AKI and hyperkalemia (Clin Infect Dis 1999;29:1561). LipL 32 and Lp25 are membrane proteins from pathogenic *Leptospires*. The purpose of this study was to evaluate the effect of these proteins on renal function in guinea pigs.

Methods: Three groups of animals were studied: 1- Sham (phosphate-buffered solution), n=7; 2- LipL32, n=7 and 3- Lp25, n=8. All animals received daily 400µl injections intraperitoneally of each substance (160µg of LipL32 or Lp25/dose) for 4 days, after which they were placed in metabolic cages for 24 hour urine collection. We measured urinary volume (Ur V mL/24h), creatinine clearance (ml/min/100gBW), serum potassium (mEq/L), CPK (U/L), uric acid (mg/dL), phosphate (mg/dL). Data are mean±SEM.

Results:

	Cr Cl	Ur V	K	CPK	Uric acid	P
sham	1.10±1.18	27.7±4.8	4.8±0.3	499±48	1.08±0.19	6.9±0.3
LipL32	1.08±0.11	19.4±6.1	5.7±0.6	656±152	1.07±0.31	6.1±0.3
Lp25	$0.48±0.05^{b,d}$	$11.1±1.8^{a}$	$6.8±0.5^{a}$	$2852±495^{b,e}$	$4.15±0.48^{c,e}$	$9.6±0.6^{c,e}$

$^{a}p<0.05$ $^{b}P<0.01$ $^{c}p<0.001$ versus sham $^{d}p<0.05$ $^{e}p<0.001$ versus LpL32.

Conclusions: These data demonstrated that Lp25 is a membrane protein from pathogenic Leptospires responsible for the development of oliguric AKI in leptospirosis associated with hyperkalemia induced by rhabdomyolysis (elevated CPK, uric acid and serum phosphate). Therapeutic maneuvers to inhibit this protein or even to attenuate rhabdomyolisis- induced AKI may protect animals and even patients from severe forms of this disease and decrease mortality. (CNPq,FAPESP).

Curcumin Prevents Maleate-Induced Nephropathy, Oxidative Stress, Apoptosis and Decrease of Mitochondrial Oxygen Consumption and in the Activity of Respiratory Complex I Edilia Tapia,[1] L. Gabriela Sanchez-Lozada,[1] Wylly Ramses Garcia,[2] Fernando E. García-Arroyo,[1] Horacio Osorio,[1] Magdalena Cristobal,[1] Abraham Said Arellano-Buendia,[1] Maria L. Loredo,[3] Eduardo Molina-Jijon,[4] Jacqueline Hernandez-Damian,[2] Mario Negrette-Guzmán,[2] Jose L. Reyes,[4] Cecilia Zazueta,[5] Magdalena Madero,[1] Jose Pedraza-Chaverri.[2] *[1]Laboratory Renal Physiopathology. Nephrology, INCIC, Mexico City, DF, Mexico; [2]Biology, Facultad de Quimica, UNAM, Mexico City, D.F., Mexico; [3]School of Medicine, U Panamericana, Mexico City, D.F., Mexico; [4]Physiology CINVESTAV, IPN, Mexico City, D.F., Mexico; [5]Cardiovasc Med, INCIC, Mexico City, D.F., Mexico.*

Background: The potential protective effect of the dietary antioxidant curcumin against the renal injury induced by maleate was evaluated.

Methods: Maleate was injected IP (400 mg/Kg) by a single injection in rats; other group received curcumin (120 mg/kg for 6 days) in addition to maleate. RBF, GFR, urine sodium, glucose, NAG, NGAL, renal structural changes, and the expression of claudin-2 and KIM-1, tubular proteinuria were evaluated. Oxidative stress was determined by measuring the oxidation of lipids and proteins and diminution in renal Nrf2 levels. Studies were also conducted in mitochondria isolated from kidneys of all groups and in renal epithelial LLC-PK1 cells.

Results: Maleate-induced renal injury included increase in RVR, proteinuria, glucose, sodium, NGAL and NAG, upregulation of KIM-1, decrease in RBF and claudin-2 expression besides of necrosis and apoptosis of tubular cells on 24 h. Maleate treatment reduced oxygen consumption in ADP-stimulated mitochondria and diminished respiratory control index when using malate/glutamate as substrate. The activities of both complex I and aconitase were also diminished. In *in vitro* studies, maleate-induced cell death and reactive oxygen species (ROS) production in LLC-PK1 cells in culture. All the above-described alterations were prevented by curcumin.

Conclusions: Curcumin is able to attenuate maleate-induced nephropathy. The *in vivo* protection was associated to the prevention of oxidative stress and preservation of mitochondrial oxygen consumption and activity of respiratory complex I and the *in vitro* protection was associated to the prevention of ROS production.

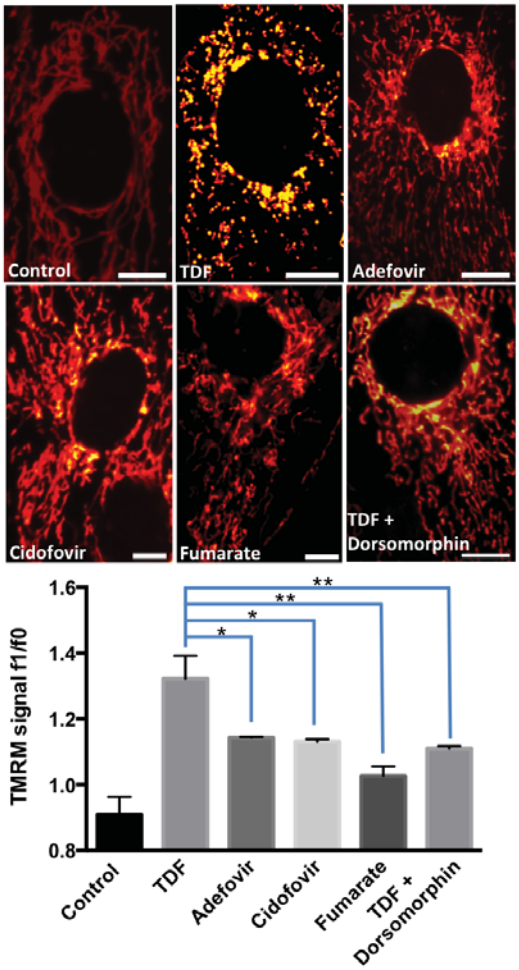
Tenofovir Induces Mitochondrial Dysfunction in the Kidney via AMP Activated Protein Kinase Holly R. Courtneidge,[1] Eilidh Craigie,[2] Claire M. Peppiatt-Wildman,[3] Robert J. Unwin,[1] Andrew Michael Hall.[2] *[1]Centre for Nephrology, UCL, London, United Kingdom; [2]Swiss National Centre of Competence in Research, Univ of Zurich, Zurich, Switzerland; [3]Urinary System Physiology Unit, The Univs of Kent & Greenwich at Medway, Medway, United Kingdom.*

Background: Renal proximal tubule (PT) toxicity is recognized in patients taking the NtRTI Tenofovir disoproxil fumarate (TDF). *In vitro* tests suggest TDF is not toxic to mitochondria, but abnormalities in mitochondrial morphology are a feature of TDF toxicity. We used live multiphoton imaging to establish the mechanism of TDF toxicity, revealing TDF as a direct activator of AMPK.

Methods: To study mitochondrial membrane potential (DY_m) and reactive oxygen species (ROS) production, we used TMRM (tetramethylrhodamine-methyl-ester) and MitoSOX, respectively, with multiphoton microscopy.

Results:



TDF 200 µM caused a rapid increase in DY_m in Llcpk-1 cells. After 30 minutes, mean TMRM signal in TDF cells was greater (≤P<0.05) than: control, fumarate, NtRTIs cidofovir and adefovir. DY_m increase was followed by mitochondrial fragmentation (<30 min) and cell death in TDF cells. Fumarate, cidofovir and adefovir did not change mitochondrial morphology. Effects were blocked by treatment of AMPK inhibitor dorsomorphin prior to TDF insult (fig1). Similar changes were seen in PT cells in live kidney slices. TDF increased ROS production in Llcpk-1 cells; after 30 minutes MitoSOX signal was higher (P<0.05) in TDF cells than in control cells.

Conclusions: Live imaging in cultured cells *and* intact tissue, show TDF directly activates AMPK in PT cells. DY_m and ROS production are increased, leading to mitochondrial fragmentation and cell death. Effects of TDF are blocked by an AMPK inhibitor, and are unique to the drug rather than a class effect. Our findings implicate AMPK in TDF nephrotoxicity, and suggest inhibition of this pathway could be an effective preventative strategy.

FR-PO076

SRT1720 Prevents Renal Mitochondrial Biogenesis Suppression in Cholestatic Mice Zhi Zhong,[1] Qinglong Liu,[1] Hasibur Rehman,[1] Yasodha Krishnasamy,[1] Gyda C. Beeson,[1] Craig Cano Beeson,[1] Rick G. Schnellmann.[1,2] *[1]Drug Discovery & Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC; [2]Ralph H. Johnson VA Medical Center, Charleston, SC.*

Background: Cholestasis causes liver cirrhosis and frequently leads to acute kidney injury (AKI) by unclear mechanisms. This study tested the hypothesis that suppressed mitochondrial biogenesis (MB) during cholestasis contributes to AKI.

Methods: Mice were subjected to sham operation or bile duct ligation (BDL) and received vehicle or SRT1720 (2 mg/kg, ip, daily), a MB stimulator, for 2 wks.

Results: Blood bile acids increased ~150-fold after BDL and hepatic focal necrosis and overt liver fibrosis were observed. Serum creatinine increased >2-fold. Moderate histological changes were observed in the kidney, including loss of brush border and dilation of proximal tubules, atrophy and vacuolization of tubular cells in the cortex and medulla, and decreased cortical thickness. Renal ATP synthase-b (AS-b) and NADH dehydrogenase-3 (ND3), mitochondrial oxidative phosphorylation (OXPHOS) enzymes that are encoded by nuclear and mitochondrial DNAs, respectively, decreased markedly after BDL, suggesting suppression of MB. Expression of PGC-1a, the master regulator of MB, decreased substantially after BDL, revealing disruption of MB signaling in vivo. Incubation of primary cultures of renal proximal tubular cells (RPTC) with 0-200 mM chenodeoxycholic acid for 24 h reduced maximal oxygen consumption in a concentration-dependent manner, demonstrating direct inhibition of mitochondrial function in RPTC by toxic bile acids. SRT1720 treatment of cholestatic mice increased PGC-1a deacetylation and expression and enhanced AS-b and ND3 expression in the kidney. SRT1720 treatment also prevented decreases in renal cortical thickness, attenuated other renal pathological changes, and reduced serum creatinine.

Conclusions: MB suppression most likely plays an important role in AKI occurrence in mice with cholestatic liver fibrosis. MB is a novel therapeutic target to prevent/treat hepatic failure-induced AKI.

The Specific Sphingosine Kinase-2 (SK2) Inhibitor ABC294640 Decreases Renal Injury after Orthotopic Liver Transplantation in Rats Zhi Zhong,[1] Qinglong Liu,[1] Yasodha Krishnasamy,[1] Hasibur Rehman,[1] John J. Lemasters,[1] Charles D. Smith,[1,2] Rick G. Schnellmann.[1,3] *[1]Drug Discovery & Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC; [2]Apogee Biotechnology Corporation, Hummelstown, PA; [3]Ralph H. Johnson VA Medical Center, Charleston, SC.*

Background: Acute kidney injury (AKI) occurs frequently in perioperative liver transplant (LT) recipients, which increases hospital stay, acute rejection, infection and mortality. This study investigated whether ABC294640 attenuates renal injury after LT.

Methods: Livers were explanted from Lewis rats and stored in the UW storage solution with/without ABC294640 (100 µM) for 18 h before implantation in Lewis recipients. Liver, kidney and blood were collected 18 h after transplantation.

Results: Focal necrosis, apoptosis and inflammatory responses occurred in liver grafts and serum ALT and total bilirubin increased markedly after LT. ABC294640 decreased liver injury and inflammation and improved liver graft function. Seven-day survival after LT was reduced to 25% and ABC294640 increased survival to ~85%. After LT, serum creatinine increased >2 fold and NGAL expression in the kidney increased ~17 fold. Mild to moderate histological changes were observed in the kidney, including loss of brush border, vacuolization of tubular cells in the cortex, cast formation and necrosis in some proximal tubular cells. TLR4 expression, NF-kB p65 phosphorylation, myeloperoxidase and ED-1 increased in the kidney after LT, indicating inflammatory responses. ABC294640 treatment attenuated pathological changes and inhibited inflammatory responses in the kidney and decreased serum creatinine after LT.

Conclusions: AKI occurs after transplantation of liver grafts exposed to extended cold storage, which may also contribute to increased mortality after LT. ABC294640 attenuates hepatic graft failure-induced AKI.

Cardiac Mitochondria Injury Induced by Renal Ischemia: Possible Role of Heart-Kidney Crosstalk in AKI Maki Sumida,[1] Kent Doi,[2] Emi Ogasawara,[1] Tetsushi Yamashita,[1] Yoshifumi Hamasaki,[1,3] Naoki Yahagi,[2] Masaomi Nangaku,[1] Eisei Noiri.[1,4] *[1]Nephrology and Endocrinology, Univ of Tokyo; [2]Emergency and Critical Care Medicine, Univ of Tokyo; [3]22nd Century Medical and Research Center, Univ of Tokyo; [4]Science and Technology Research Partnership for Sustainable Development, Japan Science and Technology Agency/ Japan International Cooperation Agency, Tokyo, Japan.*

Background: Experimental evidences have clarified distant organ dysfunctions induced by acute kidney injury (AKI). Although crosstalk between kidney and heart, which has recently been recognized as cardiorenal syndrome, appears to play an important role in the clinical settings, the mechanisms by which AKI causes cardiac injury remains poorly understood.

Methods: Renal ischemia reperfusion (IR) injury was induced by bilateral renal artery clamping for 30 minutes in eight-week old male C57BL/6 mice. Mitochondrial morphology in the heart at 24 hours after renal IR was evaluated by electron microscopy. Mitochondria dynamics regulatory proteins including Drp1, Mfn1/2, OPA1 were analyzed by western blot. Apoptosis in the heart was examined by cytochrome c release, activation of caspase-3, and TUNEL staining. A Drp-1 inhibitor mdivi-1 at the dose of 50mg/kg was administered to clarify the role of Drp-1 in mitochondrial fragmentation in the heart in renal IR model.

Results: Renal IR significantly reduced mitochondrial area in the heart compared with sham-operation (IR 0.45±0.26mm^2 versus Sham 0.85±0.35mm^2, n=5/group, p<0.01). Among the mitochondria regulatory proteins, only Drp1 was increased in the mitochondrial fraction of heart tissue (p<0.05). Apoptosis in cardiac cells were confirmed by increased cytochrome c in the cytosol fraction, positive staining of TUNEL and immunohistochemistry of activated casepse-3. Treatment of mdivi-1 suppressed decrease of mitochondrial area (IR 0.51±0.27mm^2 versus IR+midiv-1 0.88±0.44mm^2, n=8-10/group, p<0.01) and subsequent apoptosis in the heart, although renal dysfunction was partially improved by mdivi-1.

Conclusions: The present study demonstrated that renal IR injury induced mitochondria fission and apoptosis in the heart. This remote organ injury induced by AKI was mediated by mitochondrial fission protein Drp1.

FR-PO079

Charting the Course of Renal Cryo-Injury and Repair Brian B. Ratliff, Wasan Abdulmahdi, Joseph A. Zullo, Lauren M. Nesi, Kei Matsumoto, Michael S. Goligorsky. *New York Medical College, NY.*

Background: Advancement in therapeutic strategies targeting kidney injury and repair has been hampered due to the lack of a relevant and consistent injury model that permits examination of renal repair processes. We sought to characterize a novel renal cryo-injury that allows investigation into endogenous repair mechanisms and the potential to maximize these processes intrinsically and exogenously.

Methods: We examined kidney repair in mice after induction of a cryo-injury, in which the transient superficial application of a liquid nitrogen cooled cryo-probe to the exposed kidney induces a localized injury. The resulting cryo-injury (and its subsequent repair) was examined immunohistochemically and by Laser-Doppler flowmetry.

Results: Within hours of cryo-injury induction, substantial glomerular, tubular and vascular injury was observed (H&E staining), while blood flow in the injured area was reduced over 60%. The injured area demonstrated a peak in tubular and perivascular cell proliferation (Ki-67 staining) at 4 days post-injury, while apoptosis (TUNEL staining) peaked at 7 days. Infiltration of macrophages into the injured area was first observed at day 4 (F4/80 and CD11 staining), and peaked at 7 days post-injury. Vascularization of the injured area (CD31 staining) was lowest 7 days after injury, while fibrosis peaked at this same time point. After 4 weeks, the area of damage was reduced by 75% (H&E staining), while blood flow in the injury's penumbral area was restored to normal levels despite continued flow impediment in areas where damage was most severe. The exogenous application of LIF (Leukemia Inhibitory Factor), an inducer of epithelial repair, enhanced tubular and perivascular cell proliferation as well as vessel repair.

Conclusions: Kidney cryo-injury provides a facile model for the study of endogenous repair processes and dynamics. Furthermore, the cryo-injury model also allows examination of the therapeutic potential of various factors that can be introduced exogenously to the injury, such as LIF which exhibited therapeutic relevant effects when applied.

Recovery of Electrogenic Transport and Intracellular pH in Isolated Perfused Thick Ascending Limb After Acute Metabolic Ischemia Nina Himmerkus,[1] Andreas Linkermann,[2] Markus Bleich,[1] Paul S. Steels.[3] *[1]Inst of Physiology, Christian-Albrechts-Univ, Kiel, Germany; [2]Clinic for Nephrology and Hypertension, Christian-Albrechts-Univ, Kiel, Germany; [3]Biomed Inst, Univ Hasselt, Hasselt, Belgium.*

Background: We investigated the recovery of electrogenic transport and intracellular (pH_i) under different extracellular pH (pH_e) conditions after metabolic ischemia (MI) on the thick ascending limb of the loop of Henle (TAL) from mouse kidneys.

Methods: Freshly isolated TAL were microperfused and transepithelial voltage (V_{te}) and resistance (R_{te}) monitored parallel to pH_i using BCECF- microfluorimetry. NaCl transport was estimated by calculating the equivalent short circuit current (I'_{sc}). After an initial control period at pH_e 7.4 MI was induced by 10 mM 2-deoxy-glucose and 2.5 mM Na-cyanide for 5min and the subsequent washout and recovery period was investigated according to 3 different pH_e protocols: (a) MI at pH_e 6.8, 10 min recovery at pH_e 7.4, (b) MI at pH_e 6.8, 10 min recovery at pH_e 6.8 followed by 5 min at pH_e 7.4, (c) MI as well as 10 min recovery at pH_e 7.4. Cell height at several positions along the tubule was measured before, during and after ischemia.

Results: We observed a fast I'_{sc} recovery to 30 ± 6 % of pre-ischemic I'_{sc} after protocol (a) and to 35 ± 10 % after protocol (b). Protocol (c) led to a recovery of 72 ± 10 %. The initial fast drop in pH_i was comparable between groups, however, a pH_e of 7.4 during MI allowed a partial recovery already in the ischemic phase and a fast and robust recovery (103 ± 3 %) in the wash-out phase in comparison to protocol (a) (96 ± 2 %). During the pH_e 6.8 recovery phase of protocol (b) pH_i dropped again markedly and only showed full recovery in the additional pH_e 7.4 wash-out phase (98 ± 3 %). In all cases cell height as a measure of cell swelling increased during MI and recovered afterwards. The time-point of regulatory cell volume decrease coincided with the beginning of I'_{sc} recovery.

Conclusions: In comparison to acidic pH_e during an acute pathophysiological state of MI, physiological pH_e of 7.4 during this period counteracted the drop in pH_i and ameliorated the transport function of TAL immediately after ischemia/reperfusion injury.

Megalin Recycling in Proximal Tubule: Compartments and Sorting Mechanisms Involved Andres E. Perez Bay, Ryan Schreiner, Enrique Rodriguez-Boulan. *Dept of Ophthalmology, Margaret Dyson Vision Research Inst, Weill Cornell Medical College, New York, NY.*

Protein reabsorption from the glomerular ultrafiltrate is an important function of the kidney proximal tubule (PT), mediated by the apical co-receptors Megalin/Cubilin. Mutations in these receptors that impair protein absorption cause proteinuria in several human syndromes. Furthermore, abnormally high absorption of immunoglobulin light chains in multiple myeloma patients by Megalin/Cubilin causes acute kidney failure. Megalin endocytosis requires endocytic signals, clathrin and the clathrin adaptors ARH, DAB2 and AP-2. In contrast, the recycling branch of Megalin is poorly understood: whereas a tyrosine apical sorting signal has been identified, the sorting adaptor (s) and the sorting compartments involved remain unknown. Here we studied the recycling pathway of Megalin comparatively with that of the well-characterized fast-recycling basolateral receptor, transferrin receptor (TfR), using the prototypical kidney cell line MDCK and a human PT cell line (RPTEC-hTERT) that polarizes efficiently and preserves the phenotype of kidney PT. Apically internalized Megalin recycles successively through WGA-positive apical sorting endosomes, TfR-positive common recycling endosomes (CRE) and Rab11a-positive apical recycling endosomes (ARE) with half-times of 7, 12 and 17 minutes, respectively. Apically internalized Megalin mixes with basolaterally internalized TfR at CRE, suggesting that this is the compartment where sorting of these recycling receptors occurs. From CRE, Megalin recycles back to the apical domain via ARE and TfR translocates directly to the basolateral domain, mediated by clathrin and the clathrin adaptor AP-1B. AP-1B knock-down in MDCK cells promotes TfR translocation from CRE to ARE and the apical surface via a novel transcytotic route that utilizes non-centrosomal microtubules, the kinesin KIF16B, the small GTPase rab11a (Perez-Bay et al, EMBO J 2013), a N-glycan apical signal in TfR and the sorting lectin galectin-4 (Perez-Bay et al., in revision). Current experiments are focused on characterizing the role of clathrin and clathrin adaptors in apical recycling of Megalin.

Unique Transcriptional Programs in Subtypes of Acute Kidney Injury: Implications for Reclassification Katherine Xu,[1] Paul Rosenstiel,[1] Paolo Guarnieri,[1] Neal A. Paragas,[1] Christian Hinze,[2] Kai M. Schmidt-Ott,[2] Jonathan M. Barasch.[1] *[1]Columbia Univ; [2]Max Delbrueck Center for Molecular Medicine.*

Background: The current diagnosis of AKI is contingent on the rise of a single analyte, serum creatinine (sCr), but this test is confounded by delay (>24hrs), insensitivity (sometimes >50% of the kidney must be damaged), and non-specificity (causes include volume depletion [VD], ischemia, nephrotoxins, and obstruction).

Methods: To study AKI subtypes, we used laser capture to isolate glomeruli, cortex, outer and inner stripes of the outer medulla from kidneys of mice subjected to 10min of bilateral ischemia reperfusion injury (IR) or mice subjected to 72h of VD by water deprivation. Transcriptional profiles, differentially expressed genes (DEGs), and altered pathways were detected in each region of the kidney by RNA-Seq. To identify candidate secreted proteins we filtered genes with annotation databases (Secreted ProteinDB, Max Plank Unified Proteome) and then validated using urine samples collected in Emergency Departments.

Results: The two groups demonstrated similar changes in sCr, but VD mice demonstrated higher sNa and hemoconcentration. IR induced a greater transcriptional effect than VD (10x more DEGs). Overlapping transcriptional changes were only a small fraction of IR (2.6%) and VD (27%) DEGs. The outer stripe showed the strongest contribution in IR while the inner stripe was most activated in VD. In addition, functional enrichment analyses demonstrated little overlap in pathways. Identification of secreted proteins revealed 109 unique to IR and 10 to VD. In fact, some of these proteins may serve as biomarkers, because they distinguished prolonged (typical of IR) from rapidly reversible (typical of VD) AKI in patients.

Conclusions: We found that despite similar elevations of sCr, IR and VD affected (i) different regions of the kidney, (ii) different sets of genes and secreted proteins, and (iii) different pathways. Hence the diagnosis of AKI based solely on sCr erroneously combines conditions with region specific transcriptional profiles that have little overlap. Novel biomarkers of VD and IR may reclassify sCr-based diagnoses and provide appropriate patient management in urgent settings.

Delayed Administration of a Glycogen Synthase Kinase 3b (GSK 3b) Inhibitor Improves Function and Ameliorates Renal Fibrosis following Acute Kidney Injury (AKI) Chunming Jiang,[1,2] Evelyn Tolbert, Weiwei Xu,[1] Hui Bao,[1] Rujun Gong,[1] Lance D. Dworkin.[1] *[1]Nephrology, Medicine, Brown Univ, Rhode Island Hospital, Providence, RI; [2]Nephrology, Drum Tower Hospital, Nanjing Univ, Nanjing, Jiangsu, China.*

Background: Specific inhibition of GSK 3b prior to kidney insult attenuates AKI and accelerates recovery. However, most patients with AKI present after injury is established and whether delayed inhibition of GSK 3b is similarly protective is unknown. The long term effects of GSK 3b inhibition on renal fibrosis and development chronic kidney disease (CKD) after AKI are also unclear. This study examined the effects of delayed administration of TDZD-8, a specific inhibitor of GSK 3b, on the acute and chronic phases of disease in mice with folic acid (FA) induced kidney injury.

Methods: C57BL/6 mice were randomly divided into four groups; sham, FA, TDZD-PRE (30 minutes prior to FA), and TDZD-POST (36 hours after FA). Kidney tissue was examined on days 0, 3, and 28 after FA.

Results: Kidney function assessed by serum creatinine was significantly improved in TDZD-PRE and TDZD-POST at day3 and 28 as compared to FA. Mice in both treated groups showed less tubular injury and apoptosis, more dedifferentiation and proliferation by staining for KIM-1 and NGAL, TUNEL, Pax-2 and Ki-67. Three days after injury, expression of TGF-β and CTGF was significantly decreased to 24.0% and 28.6%, 28.6% and 57.1% in TDZD-PRE and TDZD-POST, respectively. This was associated with a significant reduction in chronic renal fibrosis at 28 days assessed morphologically by Masson's Trichrome, collagen I and fibronectin staining. Quantitatively compared to FA, total kidney collagen was reduced by 42.5% (TDZD-PRE) and 54.7% (TDZD-POST).

Conclusions: More clinically relevant, delayed administration of a small molecule GSK 3b inhibitor improved kidney function and attenuated chronic persistent renal fibrosis effectively in mice with AKI. Reduction in renal fibrosis probably resulted from amelioration of acute injury and reduced expression of pro-fibrotic growth factors TGF-β and CTGF. Longer term studies are needed to determine if therapy also reduces the risk of progression to ESRD.

Soluble RAGE Prevents Unilateral Ureteral Obstruction-Induced Renal Fibrosis Tae-Hyun Yoo,[1] Seonghun Kim,[2] Eunyoung Lee,[1] Hye-Young Kang,[2] Ji Sun Paeng,[2] Bo Young Nam,[2] Shin-Wook Kang.[1,2] *[1]Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea; [2]Brain Korea 21 PLUS, Severance Biomedical Science Inst, Yonsei Univ, Seoul, Korea.*

Background: Tubulointerstitial fibrosis is a typical pathological finding in chronic kidney disease and is also associated with the progression of renal dysfunction. Recently, high mobility group protein box1 (HMGB1) and receptor for advanced glycation end products (RAGE) have been demonstrated to be implicated in the pathogenesis of epithelial-mesenchymal transition in renal tubular cells (RTCs). Although soluble RAGE (sRAGE) has been proposed as a potential therapeutic agent by competitively inhibiting to bind RAGE, however, little is known about the efficacy of sRAGE on renal fibrosis in unilateral ureteral obstruction (UUO) model.

Methods: In vivo, Sprague-Dawley rats were treated 1 hour before and every 48 hours after UUO operation either with diluent (n=6) or sRAGE (n=6) intraperitoneally. At the time of sacrifice, blood and renal tissues were collected. In vitro, NRK-52E cells were cultured in DMEM media with or without HMGB1 (10 mg/mL). To examine the effect of sRAGE on HMGB1-induced RTCs injury, NRK-52E cells were also incubated with sRAGE (1 mg/uL).

Results: The protein expression of RAGE was significantly higher in the kidney of UUO rats compared to controls. The renal protein expressions of JNK, ERK, and fibrosis-related molecules such as fibronectin and collagen I were also significantly higher in UUO rats compared to controls. These changes in UUO rats were significantly ameliorated by sRAGE treatment. Moreover, histological tubulointerstitial injury was significantly improved after sRAGE injection in UUO rats. In vitro, the expressions of fibronectin and collagen I protein were significantly higher in RTCs stimulated by HMGB1 and these increases were significantly attenuated by sRAGE. NF-kB and MAPK pathways were also activated in HMGB1-stimulated RTCs, which were significantly abrogated by RAGE inhibition.

Conclusions: These findings suggest that RAGE plays a role in the pathogenesis of renal fibrosis and its inhibition by sRAGE may be a potential therapeutic strategy for renal fibrosis.

FR-PO085

Loss of Alpha (E)-Catenin Disrupts Actin Organization in the Aging Kidney LaNita A. Nichols, Elizabeth A. Borgmann, Alan R. Parrish. *Medical Pharmacology and Physiology, Univ of Missouri School of Medicine, Columbia, MO.*

Background: As the kidney ages, morphological and functional changes lead to renal dysfunction. We have previously shown the aging kidney has a marked loss of the cadherin/a-catenin complex in the proximal tubular epithelium. Cadherin-mediated cell adhesion influences cytoskeletal organization while the actin cytoskeleton is necessary for cadherin-mediated adhesion. a-catenin is a key regulator of the actin cytoskeleton, inhibiting Arp2/3 formation of branched actin while increasing formation of linear actin. Therefore, we hypothesize the loss of a-catenin leads to disruption of the cytoskeleton of the aging kidney leading to renal dysfunction.

Methods: Stable shRNA knock-down of a (E)-catenin was generated in NRK-52E cells. Single cell clones were selected for a non-targeted (NT3) control and a targeted knock-down (C2).

Results: qPCR and Western blots confirmed not only reduced a-catenin levels, but N-cadherin as well. Phalloidin staining of C2 showed overall reduced F-actin staining with increased branching and disorganization as compared to NT3 control; disorganization of the actin cytoskeleton was also seen in the tubular epithelium in the aged rat kidney. Gene expression from migrating C2 and NT3 cells was quantified using RT^2 Profiler PCR for Cytoskeleton Regulators (SA Biosciences). Was, a member of the WASP family, increased 2.87 fold in C2, and is one of only two up-regulated genes. Myosin Light Chain Kinase 2 (Mylk2), required for cellular contraction, is the most reduced at 0.19 fold. Fscn2 (Fascin homolog2), an actin bundling protein is also reduced. Interestingly, Arpc2 and Arpc3 gene expression was not significantly changed. Gene expression of young (4m) versus aged (24m) Fischer 344 rats for Was, Mylk2, and Fscn2 was confirmed by qPCR. Was increased 5.42±1.55 at 24m while Mylk2 and Fscn2 decreased 0.56±0.20 and 0.47±0.09, respectively.

Conclusions: These data demonstrate that the loss of a (E)-catenin affects the regulation of the cytoskeleton in the aging kidney, which has implications in renal function, as well as in injury.

No Evidence for an Improved Safety Profile of Oral Sodium Phosphate By Using Intestinal Phosphate Binders Stef Robijn, Geert Dams, Benjamin Arthur Vervaet, Patrick C. D'Haese, Anja Verhulst. *Laboratory of Pathophysiology, Univ of Antwerp, Antwerp, Belgium.*

Background: Prior to colonoscopy, bowel cleansing is performed for which OSP is frequently used. An increasing number of patients developing acute kidney injury (AKI) referred to as APN and characterized by severe nephrocalcinosis (NC) is reported after the use of OSP. US-FDA issued a safety alert stating that OSP should only be available by prescription and suggested that investigation should focus on preventing intestinal P absorption to improve the safety profile of OSP. In the current study it was evaluated whether the acute effects of OSP could be prevented by the use of intestinal P-binders without affecting bowel cleansing efficiency. Hereto a rat bowel cleansing model using OSP and resulting in APN was optimized.

Methods: OSP was administered by gavage to male Wistar rats in 2 doses of 1.2 g phosphate with a time interval of 12 hours. Serum P, calcium (Ca), creatinine, iPTH and iFGF-23 concentrations were measured at several time points after gavage. The degree of NC was assessed by measuring total Ca in renal tissue. P-binders were administrated to rats by gavage (1000mg lanthanum carbonate or aluminum hydroxide) immediately preceding OSP gavages.

Results: OSP administration resulted in significantly increased serum P levels (21.8±5.1mg/dl 6h after the 2nd dose versus 8.4±5.1mg/dl at baseline) and concomitantly decreased serum Ca levels (8.7±0.8 versus 11.3±0.5 mg/dl). Serum iPTH and iFGF-23 levels increased significantly 12h after the 1st and 3h after the 2nd gavage, respectively. Renal Ca content of rats receiving OSP increased significantly (0.815 versus 0.068mg/g ww in controls). Serum creatinine significantly increased (factor 1.5) in OSP treated animals. Finally severe diarrhea inherent to bowel cleansing was observed in OSP treated animals. P-binder treatment did not affect any of these parameters.

Conclusions: In conclusion, a clinically relevant rat model to study APN as a result of OSP was developed: animals showed an increase in serum P-levels similar to that reported in humans and developed APN (NC and increased serum creatinine levels). No evidence was found for an improved safety profile of OSP by using intestinal P-binders.

Estrogen Is Protective against the Development of Acute Renal Damage Induced By Aristolochic Acid Li Zhou, Ping Fu. *Nephrology/Medicine, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

Background: Aristolochic acid (AA) is a Traditional Chinese Medicine with anti-inflammatory properties and has been shown to be a key mediator of Aristolochic Acid Nephropathy (AAN). AAN is characterized by progressive renal fibrosis and renal failure, with unclear mechanisms and therapy. Apoptosis and transformation of renal tubular epithelium cell (TEC), together with matrix accumulation are main mechanisms in AAN. In patients with acute AAN, acute kidney injury (AKI) in male is more severe than in female. Our premier data also show that with the same dose, AKI in male mice is more severe than in female mice.

Methods: The present study further tested the hypothesis that estrogen is protective against the development of acute renal damage in mice AAN model in vivo. AA at a dose of 10mg/ (kg•day) for 3 days i.p. was used to inducing acute AAN in C57BL/6 male mice. Estrogen is injected i.p. one day before AA injection and last everyday. Histology, serum creatinine, Western blot for cleaved caspase-3 and TUNEL staining for apoptosis cells have been examined.

Results: AA at a dose of 10mg/ (kg•day) for 3 days i.p. was capable of inducing acute AAN in C57BL/6 male mice. In contrast, estrogen was protected against the development of acute AAN. This was determined by the findings that estrogen prevented AA-induced acute renal injury such as histology, an increase in serum creatinine, and reduced the severity of tubular apoptosis as evident by inhibiting cleaved caspase-3 and TUNEL+ cells.

Conclusions: Estrogen is protective against the development of acute renal damage induced by aristolochic acid. Fund support: The National Basic Research Program of China (973 Program): 2012CB517700.

Kainate Receptors in Renal Injury Jason A. Funk,[1] Stacy Steele,[1] P. Darwin Bell.[1,2] *[1]Div of Nephrology, Medical Univ of South Carolina, Charleston, SC; [2]Ralph H. Johnson Veterans Affairs Medical Center, Charleston, SC.*

Domoic acid (DA) is a glutamate analog, structurally similar to kainic acid (KA), and a well-characterized neurotoxin. Because the kidney is the primary site of systemic DA elimination, and because it expresses ionotropic glutamate receptors (GluR), we chose to evaluate the renal effects of DA exposure in four-month-old Sv129/Black Swiss mice. There was evidence of renal histopathology, including proximal tubule necrosis and apoptosis, at doses ≥1.0 mg/kg. More sensitive markers, such as urinary kidney injury molecule-1 (KIM-1) and neutrophil gelatinase-associated lipocalin (NGAL), were elevated at doses ≥0.1 mg/kg, and the early response genes *c-fos* and *junb* were increased in the kidney at doses ≥0.005 mg/kg. Pretreatment with the kainate receptor antagonist CNQX attenuated the toxic response, and administration of KA (5 mg/kg, i.p.) produced a similar toxic response. When 12-month-old mice were administered DA for 24 to 72h, renal *kim-1* mRNA and urinary KIM-1 were elevated compared to their younger counterparts, demonstrating an age effect on susceptibility to DA toxicity. HK-2 cells, a human proximal tubule cell line, robustly

expressed the kainate receptor (KR) subtypes *grik2* and *grik5*, similar to what was previously observed in the mouse kidney. DA induced rapid accumulation of intracellular calcium in HK-2 cells loaded with Fluo-4, and *c-fos*, and *kim-1* mRNA were elevated with 1-10uM DA or KA. Taken together, the data suggest that DA, and potentially other KR agonists such as KA, is a potent nephrotoxicant that elicits direct effects on renal epithelial cells. Furthermore, renal toxicity may be potentiated in aged and other susceptible populations, and thus stricter precautions may be necessary to limit DA exposure in these individuals.

Specific Macrophage Subtypes Participate in Rhabdomyolysis-Induced Kidney Injury Julie Belliere,[1,2] Audrey Casemayou,[1] Alexia Zakaroff-Girard,[1] Frederic Martins,[1] Jason S. Iacovoni,[1] Benedicte Buffin-Meyer,[1] Bernard R. Pipy,[1] Dominique Chauveau,[1,2] Joost Schanstra,[1] Jean-Loup Bascands.[1] *[1]U1048, Inserm, Toulouse, France; [2]Nephrology, Hospital, Toulouse, France.*

Background: Acute kidney injury (AKI) is a life threatening complication of rhabdomyolysis. While macrophage infiltration has been reported in a rat glycerol-induced AKI model and in a kidney biopsy from a patient with rhabdomyolysis, the role or phenotype of the macrophages remains to be determined.

Methods: In a mouse model of glycerol-induced rhabdomyolysis, macrophages were obtained from digested kidney and characterized using multi-color flow cytometry phenotyping and a new method coupling cell-sorting with microfluidic-based single-cell qPCR. Liposomal clodronate (LC) was used to deplete macrophages in a systemic manner.

Results: Diverse renal macrophage phenotypes were observed depending upon the stage of the disease. Two days after rhabdomyolysis, F4/80^{low}CD11b^{high}Ly6b^{high}CD 206^{low} kidney macrophages were dominant. By day 8, we observed a shift whereby the F4/80^{high}CD11b^{+}Ly6b^{low}CD206^{high} cells became the predominant macrophage cell-type. Single-cell analyses revealed that the subpopulations were heterogeneous and that individual cells simultaneously expressed both M1 and M2 markers. Liposomal clodronate-mediated macrophage depletion improved mice survival, kidney structure and function. This indicated that the early infiltration of F4/80^{low}CD11b^{high}Ly6b^{high}CD206^{low} macrophages plays an important role in disease progression. Transcriptionally regulated targets (such as fibronectin, collagen III and chemo-attractants) that could participate in the progression of the disease, were identified via single-cell analysis and verified to be expressed in kidney in a macrophage-dependent manner *in situ.*

Conclusions: These data suggest that early depletion of a macrophage subtype limits rhabdomyolysis-induced AKI.

Novel Near Infra-Red Fluorescent Probe for Measurement of Kidney DNase I Activity *In Vivo*, *In Situ* and *In Vitro* Alexei G. Basnakian,[1,2] Tariq Fahmi,[1] Eugene Apostolov,[1] Dae Song Jang,[1] Todd Fite,[1] Alena Savenka,[1] Sudhir V. Shah.[1,2] *[1]Pharmacology and Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Nephrology, Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Background: Kidney injury results in activation of apoptotic deoxyribonuclease I (DNase I), responsible for the fragmentation of DNA before and after cell death. This DNA fragmentation occurs in all kinds of cell death including necrosis, and is the most reliable marker of irreversible cell death.However, methods are not available to measure DNase I in its natural environment *in vivo*, *in situ* and *in live* cultured cells.

Methods: We have developed a novel cell-permeable near infra-red fluorescent (NIRF) DNA probe which can be used for *in vivo, in situ* and *in vitro* measurement of enzymatic DNA cleavage by DNase I.

Results: Intravital use of this probe in mice demonstrated that most of DNase activity is located in the kidneys as opposed to other organs, mainly in cytoplasm of tubular epithelium, not in glomeruli. Patterns of the images were, therefore, very similar to the TUNEL staining indicating that the TUNEL-type DNA fragmentation is likely catalyzed by DNase I. Comparison of DNase I knockout and wild-type mice showed that DNase activity in the kidney, pancreas and salivary gland is mainly presented by DNase I, while liver and spleen have mainly other endonucleases.

Conclusions: Kidney ischemia-reperfusion injury was associated with significant increase of the intravital DNase I activity in the kidney. Overall, the probe is a new useful tool for studying DNase activity in live kidney cells, frozen/thawed kidney sections, and the kidney during injury.

Non–Invasive GFR Assessment in Conscious Rats with Puromycin Induced Nephropathy Lena William-Olsson, Ulrika Lagerkvist, Charlotte Ericson, Majlis Hermansson, Anette E. Ericsson, Anna Granqvist. *Bioscience, AstraZeneca R&D Molndal, Molndal, Sweden.*

Background: Current methods for serial assessment of renal function in conscious animals are cumbersome and time consuming with considerable stress for the animals during repeated restrainment and blood sampling.We tested a novel device for transcutaneous measurement of GFR (1) in an acute kidney disease model.
