Characterizing Patterns of Kidney Function Decline Associated with *APOL1* High-Risk Variants: The African American Study of Kidney Disease and Hypertension (AASK) Adrienne Tin,[1] M. Grams,[1] Michelle M. Estrella,[1] Michael S. Lipkowitz,[2] Liang Li,[3] Tom Greene,[4] Wen Hong Linda Kao,[1] Lawrence J. Appel.[1] *[1]Johns Hopkins Univ; [2]Georgetown Univ Medical Center; [3]Cleveland Clinic; [4]Univ of Utah.*

Background: *APOL1* high-risk variants have been associated with faster chronic kidney disease (CKD) progression. Whether trajectories of estimated glomerular filtration rate (eGFR) in patients with *APOL1* high-risk status (≥2 risk alleles) manifest as a steady decline or punctuated decrements in eGFR is unknown.

Methods: Among participants in AASK, we used Bayesian estimates of the probabilities of (a) eGFR progression and (b) linearity to characterize eGFR trajectories. A steady decline in eGFR was defined as the probability of progression over 90% and the probability of linearity over 75% (figure). Logistic regression was used to estimate the odds ratio of steady eGFR decline associated with *APOL1* high-risk status.

Results: Over a mean follow-up of 9 years, 128 of the 622 participants with eGFR trajectory and *APOL1* genotyping data had eGFR trajectories characterized by steady decline. Compared to participants without a steady eGFR decline, those with a steady eGFR decline had lower baseline levels of serum albumin (4.17 versus 4.28 g/dl, p=0.002) and eGFR (45 versus 51 ml/min/1.73 m^2, p<0.001), and a higher proportion with proteinuria (52% versus 19% with urine protein:creatinine >0.22, p<0.001). Participants with a steady GFR decline were also more likely to be of *APOL1* high-risk status (37% versus 16%, p<0.001). This association persisted after adjustment for gender, trial treatment, and baseline age, eGFR, proteinuria, blood pressure, and serum albumin (OR 2.03, p=0.004).

Conclusions: These results showed that more than a third of patients with CKD attributed to hypertension and the *APOL1* high-risk genotype experienced unremitting steady decline in eGFR.

Figure 1. An example of steady eGFR decline

Family History as a Predictor of Renal Outcomes: Results from the Michigan Kidney Translational Core Center Crystal A. Gadegbeku,[1] J. Troost,[2] Jennifer Joyce Hawkins,[2] Susan P. Steigerwalt,[3] Kalyani Perumal,[4] Zeenat Yousuf Bhat,[5] M. Sampson,[2] Frank C. Brosius,[2] Matthias Kretzler,[2] Debbie S. Gipson.[2] *[1]Temple Univ, Philadelphia, PA; [2]Univ of Michigan, Ann Arbor, MI; [3]Renaissance Renal Research Inst, Detroit, MI; [4]Univ of Illinois, Chicago, Chicago, IL; [5]Wayne State Univ, Detroit, MI.*

Background: Epidemiologic studies have identified familial clustering in the ESRD population. However, few studies characterize the impact of family history on progression of renal disease.

Methods: History of kidney disease in first-degree relatives (FHx) was obtained from consented participants in the Clinical Phenotyping Resource and Biobank Core (C-PROBE) of the Michigan Kidney Translational Core Center (2P30-DK-081943). This multi-site core collects clinical, demographic, and social data along with biospecimens from participants with a broad range of nephropathies to facilitate translational research. FHx, eGFR (CKD-Epi equation), ESRD and vital status were analyzed in participants with ≥ 1 annual follow-up visit. Renal outcomes are defined as 40% reduction in eGFR, ESRD (eGFR < 15 ml/min on 2 consecutive visits, dialysis, or kidney transplantation) and/or death. Data are reported as mean (sd). Outcomes were modeled using an unconditional logistic regression (SAS v9.2).

Results: 97 of 433 participants (22%) had a FHx and, overall, were older with a lower eGFR and more likely to have non-glomerular diseases and diabetes. In multivariate regression, adjusting for age, eGFR, diabetes status, FHx was associated with an OR of 1.8 for 40% reduction in eGFR but no difference in ESRD/death in this time interval.

C-PROBE Cohort	FHx	No FHx	p-value
N	97	346	
Mean Follow-Up, yrs	2.3 (1)	2.1 (1)	0.16
Age, yrs	59 (14)	51 (18)	<0.01
Sex (% women)	56%	62%	0.29
Black/African American	43%	40%	0.55
Hispanic	8%	7%	0.73
Baseline eGFR (ml/min)	47 (26)	58 (33)	<0.01
Glomerular Disease	43%	60%	<0.01
Diabetes Status (Yes)	31%	21%	0.03
40% Reduction in eGFR	52%	34%	<0.01
ESRD or Death	15%	10%	0.17

Conclusions: These observations extend the data linking FHx to worse renal outcomes. Future multi-and trans-disciplinary translational research is required to explore complex mechanisms of disease susceptibility and risk.

Funding: NIDDK Support

FR-PO927

A Retrospective Study of Safety and Efficacy of 24-Hour SLED-RCA in Critically Ill Patients Sergio Trevino, John Manllo, Jian Li, Jerry Yee, Stanley Frinak, Lenar T. Yessayan, Balazs Szamosfalvi. *Div of Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Background: Regional citrate anticoagulation (RCA) use is limited by concerns of electrolyte complications. The aim was to evaluate the safety and efficacy of 24-hour sustained low efficiency dialysis (SLED) with RCA.

Methods: Continuous SLED-RCA was performed using a Fresenius 2008 K or K2 hemodialysis machine at blood flow 60 ml/min and dialysate flow 400 ml/min using dialysate Na 140, K 4, Ca 0 and HCO3 32. Acid citrate dextrose-A solution (115 mmol/L) was infused into the arterial limb of the extracorporeal circuit at 150 ml/hr. Calcium chloride solution (136 mmol/L CaCl2 and 19.7 mmol/L MgCl2) infusion rate was adjusted according to a dosing table based on circuit hemoglobin levels as measured by a hemoglobin sensor and daily serum albumin. Laboratory measurements were obtained at baseline and every 12 hours. Age, gender, comorbidity and reason for kidney support were collected. RCA effectiveness was measured in terms of catheter+circuit patency. Electrolyte trends and complications for the first 48 hours are reported using standard boxplots. Complications related to RCA were defined as hypocalcemia with ionized calcium (iCa) <0.9 mmol/L, hypercalcemia iCa >1.3 mmol/L, hypernatremia Na^+ >148 mEq/L and greater than 5 mEq/L rise in Na^+ from baseline, metabolic alkalosis with HCO3 >30 mEq/L, and clinically significant hypophosphatemia as P <2.0 mg/dl.

Results: 187 48-hour sessions of SLED-RCA were analyzed. We did not preclude any patient from receiving SLED-RCA due to liver failure. The percentage of catheters and/or circuits with clotting within 12 h, 24 h and 48 h was 8/187 (4%), 8/187 (4%) and 15/187 (8.5%), respectively. There were no cases of hypernatremia or metabolic alkalosis. Hypophosphatemia developed in 18/555 (3%), hypercalcemia in 9/526 (1.7%; highest iCa=1.39), hypocalcemia in 2/526 (0.3%; lowest iCa=0.74).

Conclusions: SLED-RCA reduces circuit clotting and carries a very small risk of clinically significant hypo- or hypercalcemia. The risk of hypernatremia or metabolic alkalosis is entirely abrogated. Clinically significant hypophosphatemia is mostly avoided by intravenous phosphate replacement.

FR-PO928

A Regional Intensive Care Unit Transition From Heparin to Citrate Anticoagulation as First-Line- Safety, Filter Down-Time, and Cost
Victoria K. Campbell,[1,2,3] David Gutierrez,[1] Chris Anstey,[1,3] Matthew Ostwald.[1]
[1]Dept of Intensive Care, Sunshine Coast Hospital and Health Service, Nambour, Queensland, Australia; [2]Dept of Renal Medicine, Sunshine Coast Hospital and Health Service, Nambour, Queensland, Australia; [3]Dept of Medicine, Univ of Queensland, Brisbane, Queensland, Australia.

Background: Regional citrate anticoagulation (RCA) is being increasingly used for continuous renal replacement therapy (CRRT). Evidence suggests that compared to heparin, RCA prolongs filter life, and may reduce bleeding risk, but there is little data on how this translates into more relevant outcomes such as time on filter or cost. The aim of this study was to establish if a change from heparin to RCA resulted in more achieved time on filter, and calculate any cost difference. Safety parameters were a secondary endpoint.

Methods: A single-center, retrospective observational study from 2006-12 during which a transition from heparin to RCA occurred. Both methods were protocolised, with the RCA protocol aimed at simplicity, using either 14 or 18 mmol (diluted) citrate bags depending on availability. Case note demographic and dialysis data, pathology results and costings were obtained.

Results: 188 patients had 992 dialysis days (heparin 334 versus RCA 658). Demographics were well matched. The RCA group used less filters per day (p=0.03), had more days when prescribed dialysis was achieved (85% versus 60%, p<0.001), had less dialysis days with "down-time" (15% versus 40%, p<0.001), and less time off the filter on those "down-time" days (2.4 versus 6.1 hours, p=0.02). RCA was estimated to cost AU$495 per day, compared to Heparin at $440 per day. There was no statistical difference in clinically significant safety events between the 2 groups, although 2 catastrophic bleeding events in the heparin group were the impetus for the transition, and there was more metabolic alkalosis in the citrate group depending on which formulation was used.

Conclusions: Citrate anticoagulation safely provides less filter down-time, allowing for improved delivery of prescribed dialysis dose, and uses less filter circuits. The cost difference per day favours heparin, but at $55 per day is relatively small.

FR-PO929

Regional Citrate Anticoagulation (RCA) Reduces Blood Transfusion Requirement in Surgical Critically Ill Patients Undergoing Continuous Renal Replacement Therapies (CRRT)
Paola Inguaggiato, Giorgio Canepari, Graziella Gigliola, Carlo Ferrando, Silvio Meinero, Carmelo Sicuso, Alfonso Pacitti. *Nephrology and Dialysis Unit, S.Croce & Carle Hospital, Cuneo, Italy.*

Background: The use of RCA-CRRT in critically ill patients (pts) requiring dialysis is improving. We utilize RCA-CRRT in >50% of about 1000 treatment performed yearly. Blood transfusion requirement is important both for clinical and economical reasons, but available literature on this topic, comparing different types of CRRT, is poor. This retrospective study, focused on critically ill pts who underwent major surgery, has the aim to evaluate the impact of RCA-CRRT on blood transfusions.

Methods: Between January 2011 and December 2012, we treated 293 pts with CRRT. We excluded: pts treated with alternated standard dialysis (STD-CRRT, with heparin or without anticoagulation) and RCA-CRRT; pts with CRRT duration ≤ 2 days. We included 63 pts, who underwent cardiac, vascular or abdominal surgery, treated exclusively with RCA-CRRT or STD-CRRT. Indication to RCA-CRRT was given on clinical basis. Age, length of hospital stay (LOS), CRRT duration, hospital mortality (HM), haemoglobin value at start and end of CRRT period (Hb-S and Hb-E), blood transfusion/CRRT days ratio (CRRT-BT) and blood transfusion/hospital days ratio (tot-BT) were evaluated for each patient. Statistical analysis was performed with Student's *t test.*

Results: RCA-CRRT pts were 50, mean age 72.8 years, male 82%; mean LOS 35.9 days; mean CRRT duration 10 days, 500 total CRRT days; HM 40%; mean Hb-S and Hb-E 9.36 g/dl and 9.43 g/dl respectively (p=NS), mean CRRT-BT 0.56, mean tot-BT 0.45 STD-CRRT pts were 13, mean age 68.5 years, male 77%, mean LOS 26.7 days; mean CRRT duration 10.2 days, 132 total CRRT days; HM 69%, mean Hb-S and Hb-E 10.4 g/dl and 9.2 g/dl respectively (p<0.05), mean CRRT-BT 1.08, mean tot-BT 1.48. Tot-BT and CRRT-BT were significantly lower in RCA-CRRT pts than in STD-CRRT pts.

Conclusions: We observed that RCA-CRRT is associated with significantly lower need of blood transfusions, and higher stability of Hb levels during CRRT. Moreover, HM is lower in RCA-CRRT pts than in STD-CRRT pts, without differences of LOS and dialysis duration.

FR-PO930

Effect of Nafamostat Mesilate as an Anticoagulant during Continuous Renal Replacement Therapy
Min-Jee Han, Chae Rim Kim, Do Hyoung Kim, Su Hyun Kim. *Dept of Internal Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea.*

Background: The use of continuous renal replacement therapy (CRRT) is considered the favored renal replacement therapy modality in patients with hemodynamic intolerability. An important limitation of CRRT is the need for prolonged anticoagulation to prevent extracorporeal filter clotting and failure. Nafamostat mesilate (NM), a serine proteinase inhibitor, is characterized by short half life resulting in little systemic anticoagulation effect. The aim of this study was to evaluate the effect of NM on circuit patency of CRRT and survival rate of patients receivinging CRRT with acute kidney injury (AKI).

Methods: We retrospectively reviewed 115 patients with AKI treated with CRRT between March 2005 and December 2012. We devided the patients into 2 groups according to the anticoagulants used during CRRT. Among 115 patients, 85 patients (73.9%) were treated with continuous NM infusion and remaining 30 patients (26.1%) were treated with unfractinated heparin for anticoagulation.

Results: The median filter survival with NM was significantly greater than heparin (24.2 versus 17.4 hours, p=0.021) and Kaplan-Meier survival plots revealed the longer survival of the circuits using NM than heparin (p=0.014). In cox proportional hazard models, NM predicted longer filter survival (hazard ratio 0.59, 95% confidence interval 0.38-0.92, p=0.020). And NM group showed a significantly lower 30 days mortality rate compared to heparin group (40.0% versus 63.3%, p=0.028). In multivariate Cox analysis, patient survival was significantly higher in the NM group than heparin group (hazard ratio 0.46, 95% confidence interval 0.25-0.84, P=0.011).

Conclusions: As compared with heparin, NM was associated with prolonged filter survival and 30 days patient survival. These data suggest that NM is a good choice for anticoagulant during CRRT in critically ill patients. NM can be used as a safe and effective regional anticoagulant for CRRT.

FR-PO931

Ability of Nafamostat Mesilate to Prolong Filter Patency during Continuous Renal Replacement Therapy in Patients with a High Risk of Bleeding: A Randomized Controlled Study
Yong Kyu Lee,[1] Kyu Hun Choi,[2] Beom Seok Kim.[3] *[1]Nephrology Div, Internal Medicine Dept, National Health Inst Corporation, Ilsan Hospital, Goyang, Republic of Korea; [2]Nephrology Div, Dept of Internal Medicine, Severance Hospital, Yonsei Univ College of Medicine, Seoul, Republic of Korea; [3]Nephrology Div, Dept of Internal Medicine, Severance Hospital, Yonsei Univ College of Medicine, Seoul, Republic of Korea.*

Background: Continuous renal replacement therapy (CRRT) is considered as an effective modality for renal replacement therapy in hemodynamically unstable patients in intensive care units (ICUs). However, role of heparin anticoagulation, which is used to maintain circuit patency, is equivocal due to the risk of bleeding and morbidity. Futhan is an effective anticoagulant for patients prone to bleeding. Hence, we conducted a prospective, randomized controlled study investigating the effect of futhan on CRRT filter life span and the adverse events in the patients prone to bleeding.

Methods: Patients were randomized into either the futhan or no-anticoagulation group. The futhan group received futhan, while the no-anticoagulation group received no anticoagulation medication. Baseline characteristics and appropriate laboratory tests were taken from each group.

Results: Filter life span and numbers of filters used during CRRT were similar in both groups. For the futhan group versus the no-anticoagulation group, the overall number of filters used during CRRT (2.71 ± 2.12 versus 4.50 ± 3.25; $p<0.05$) and the number of filters changed due to clots per 24 hours (1.15 ± 0.81 versus 1.90 ± 1.60; $p<0.05$) were significantly different. When filter life span was subdivided into below and over 12 hours, the number of filters functioning over 12 hours was significantly higher in the futhan group than the no-anticoagulation group ($p<0.05$, odds ratio 1.84). There were no significant differences for transfusion, mortality, or survival between the two groups, and no adverse events related to futhan were uncovered.

Conclusions: Futhan may be used as an effective and safe anticoagulation treatment, without increasing major bleeding complications, in patients prone to bleeding.

FR-PO932

Survival Benefit of Polymyxin B Hemoperfusion in Septic Shock Patients Receiving Continuous Renal Replacement Therapy
Masao Iwagami,[1] Kent Doi,[2] Hideo Yasunaga,[3] Masaomi Nangaku,[2] Eisei Noiri.[2] *[1]London School of Hygiene and Tropical Medicine; [2]The Univ of Tokyo Hospital; [3]The Univ of Tokyo.*

Background: While endotoxin adsorption by polymyxin B hemoperfusion (PMX) has been suggested to improve survival in septic shock (JAMA. 2009), our retrospective analysis showed that postoperative PMX had no survival benefit for patients with lower gastrointestinal tract perforation (Crit Care Med. 2014). However, our cohort had lower mortality. Previous studies have suggested that PMX may be effective for critically ill patients at higher risk of mortality. Therefore, this study was conducted to examine the survival benefit of PMX in septic patients requiring continuous renal replacement therapy (CRRT) who are known to have increased mortality.

Methods: Patients aged 18 years or older in the Japanese Diagnosis Procedure Combination Database satisfying the following criteria were enrolled: hospitalized during 39 months between 2007 and 2012; started CRRT under the diagnosis of sepsis (except Gram-positive bacteremia); and required noradrenaline and/or dopamine. Exclusion criteria included end-stage renal disease, suspected cardiogenic shock, intermittent dialysis, plasma exchange, and not starting PMX on the same day as CRRT. Propensity scores were generated from age, sex, admission diagnosis category, surgical procedure, time from admission to CRRT initiation, vasoactive drugs, ventilator, transfusion, hospital volume and type. After one-to-one matching from those with and without PMX, 28-day mortality counting from CRRT initiation was compared.

Results: Of 4,027 eligible patients, 1,116 received one or two PMX sessions. Propensity score matching created a matched cohort of 1,115 pairs. The 28-day mortality was 40.8 % in the PMX group and 47.0 % in the control group (P=0.003). Logistic regression analysis also showed an association between the use of PMX and 28-day mortality with an adjusted odds ratio of 0.76 (0.63–0.90). Two PMX sessions led to lower 28-mortality than one session.

Conclusions: Although unmeasured confounders need to be carefully considered, this retrospective study suggests that septic shock patients requiring CRRT may be an appropriate target population benefitting from PMX.

FR-PO933

Acute Cast Nephropathy in Multiple Myeloma: Effects of Intensive Polymethylmethacrylate-Enhanced Adsorption Dialysis on Renal Survival

Paolo Fabbrini, Sonia Sirtori, Federico Pieruzzi, Andrea Stella, Maria Rosa Vigano. *Clinica Nefrologica, AO San Gerardo and Univ degli Studi di Milano Bicocca, Monza, Italy.*

Background: Renal recovery in multiple myeloma (MM) cast nephropathy is correlated to an early reduction of sFLC concentrations obtained through chemotherapy combined to extracorporeal sFLC removal. We previously reported that polymethylmethacrylate (PMMA) membranes (BK-F; Toray Inc., Japan) can adsorb high quantities of sFLC especially with a new dialysis procedure called "enhanced adsorption dialysis " (EAD). During 4 hours EAD a specific designed circuit allows to safely use 2 dialyzers sequentially without treatment interruption. Nevertheless no clinical data are available on EAD efficacy in renal recovery. We report our experience of EAD treatment in incident MM patient with dialysis dependent renal failure.

Methods: we treated 12 incident patients with dialysis-dependent renal failure and high levels of sFLC. All patients had highly suspicious (n=8) or biopsy proven (n=4) cast nephropathy. In all patients a bortezomib based chemotherapy was started together with daily EAD treatment to reduce sFLC levels. Through daily sFLC measurement we scheduled dialysis treatments aiming to the greatest sFLC reduction in the shortest time. Renal outcome was measured as dialysis independence at 1, 6 and 12 months. Results are reported as average and (min-max) values.

Results: At presentation eGFR and sFLC levels were 9,7 ml/min (4,3-31,8) and 7868,5 mg/l (2300-25118) respectively. We performed on average 5 (1-8) EAD sessions for patient obtaining a sFLC removal of 36,7% /session (-13 to 71%). sFLC were reduced by 59,2% (0-92%) at 12 days and by 70,2% (0-99%) at 21 days. At present 11 out of 12 patients completed 1 and 6 months follow up while one patient died. At 1 and 6 month follow up 50% and 83,5% of patients recovered renal function respectively. Only 9 patients completed one year of follow up and we registered 78% of dialysis independence (1 dead and 1 ESRD).

Conclusions: PMMA enhanced adsorption dialysis together with bortezomib based chemotherapy was able to efficiently reduce sFLC levels and to promote an high rate of persistent dialysis independence.

FR-PO934

Is the CARPEDIEM a Promising Machine to Treat Neonatal and Pediatric Patients with Acute Kidney Injury?

Johan Vande Walle,[1] Stefaan Claus,[2] Jonathan De Rudder,[2] Martine Dick,[2] Ann Raes,[1] Agnieszka Prytula,[1] Evelien Snauwaert,[1] Raymond C. Vanholder,[2] Sunny Eloot.[2] *[1]Pediatric Nephrology, Ghent Univ Hospital, Gent, Belgium; [2]Nephrology Dept, Ghent Univ Hospital, Gent, Belgium.*

Background: Among neonatal and pediatric patients admitted on intensive care, 8-20% develop acute kidney injury (AKI). With the current hemodialysis machines, non-accurate weight loss and large extracorporeal blood volumes imply important risks. Recently, CARPEDIEM™ (Bellco, Italy) has become available for Slow Continuous Ultrafiltration (SCUF) or Continuous Veno Venous Hemofiltration (CVVH) in pediatric patients weighing 2.5 to 10kg.

Methods: Three roller pumps guarantee accurate flows for blood (2-50mL/min), infusion and ultrafiltration (0-1000mL/h). Fluid balance is controlled by infusion and effluent scales. Three kits are available: HCD0075/015/025 with a polysulfone dialyzer of 0.075/0.15/0.25m² and 27/33/41mL priming volume, and a maximum ultrafiltration of 2.5/4/17mL/min.

Results: In our hospital, we treated 2 patients: a male (M) (14 weeks, 5.2kg, multiple organ failure and cytomegalovirus infection) and a female (F) (30months, 13kg, AKI). A right (M) and left (F) jugular 6.5Fr double lumen catheter was inserted, and the HCD025 kit was used once (M) and twice (F). The kit was primed with albumin (SOPP 4%) (M) and with NaCl and 10mL 20%HA (F). A bolus of heparin was given at start [150IU (M) and 300IU (F)] and during the session [75IU/h (M) and 200IU/h (F)]. Predilution CVVH (substitution 4-4.3mL/min) was performed with blood flow 20-30mL/min (M) and 30-45mL/min (F), and ultrafiltration 500mL/24h. Continuous CVVH however needed to be stopped already after 10h due to hemodynamic instability (M) and after 9h and 8h due to technical problems related to ultrafiltration, respectively, anticoagulation problems while using heparin (F).

Conclusions: CARPEDIEM™ is certainly a promising machine to treat pediatric and neonatal patients with AKI when only ultrafiltration is needed, but offers so far not a solution either when higher dialysis efficiency or citrate dialysis is needed, or when lactate substitution solution should be avoided. Hence, modifications are necessary to fulfill neonatal dialysis needs.

FR-PO935

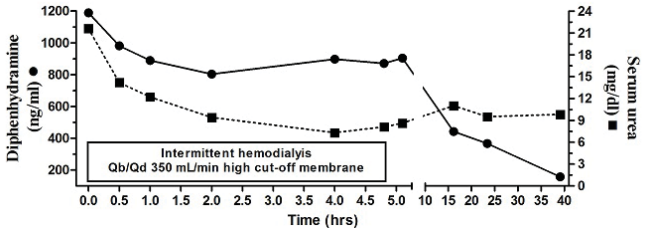
Successful Treatment of Life Threatening Diphenhydramine Intoxication By Intermittent Hemodialysis Using a High Cut-Off Membrane

Julius Schmidt,[1] Eva Baroke,[2] Ann-Kathrin Strunk,[1] Jan T. Kielstein.[1] *[1]Dept of Nephrology and Hypertension, Hannover Medical School; [2]Dept of Pulmonary Medicine, Hannover Medical School.*

Background: Diphenhydramine (DPH) is a first-generation H1-antihistamine of the ethanolamine type. Overdose can result in ataxia, fever and coma. DPH has a molecular weight of 291 D. After oral administration 60 % of the drug is absorbed. Its volume of distribution is 4.5 L/kg and the elimination half-life 8.4 hours. Hemodialysis is the extracorporeal treatment of choice for various life threatening intoxications, except for highly protein bound substances, which are preferably removed by charcoal hemoperfusion. This technique is however limited by its availability and its significant side-effects.

Methods: A 19 year-old Caucasian woman was admitted to the emergency department seven hours after ingesting 500 mg of diphenhydramine in a suicide attempt. Due to the initial diphenhydramine level of 1189 ng/ml and in an attempt to increase body temperature an intermittent haemodialysis using the GENIUS® dialysis systemwas initiated. A 1.8 m² high cut-off polysulfone filter was used.

Results: The initial dialyser clearance of diphenhydramine at the start of a 4.8 hour treatment (blood and dialysate flow of 350 mL/min) was 91 mL/min. After 3 hours of hemodialysis the patient quickly recovered clinically and gained consciousness allowing stating the existence and location of a second poisoned victim. Using a 4.8 hour intermittent hemodialysis resulted in a reduction of the initial diphenhydramine levels by 27 %.



Conclusions: Timely detoxification resulted in rapid gain of consciousness allowing the patient to state the existence and location of a second poison victim.

FR-PO936

Evaluation of a Dialysate Delivery System for Passive-Flow Hemodialysis

Bridger W. Bach, Benjamin Harris Timmins, Martin C. Gregory. *Medicine, Univ of Utah, Salt Lake City, UT.*

Background: Hemodialysis is life-saving treatment for acute renal failure that is economically beyond the reach of many who may benefit from it worldwide. Passive-flow dialysis is a simple method of providing dialysis without the need for external sources of energy, thus potentially making hemodialysis available at low cost for areas without reliable electricity.

Methods: A dialysate delivery system was constructed from 2 concentric closed cylinders of 1/8" acrylic. The space above the inner cylinder was filled with 46 L of water. Tubing connected the top of the space above the inner cylinder via a heat exchanger and dialyzer to the bottom of the space below the inner cylinder. A T-junction in the tubing after the dialyzer and heat exchanger permitted withdrawal of fluid. Ultrafiltration control was achieved by clamping the effluent tubing in a pinch clamp mounted on a scale actuated by collected fluid and controlled by a moveable counterweight.

Results: When the tubing was unclamped the inner cylinder (float) rose and displaced fluid from above the inner cylinder to below it. This fluid flowed through the heat exchanger and dialysate compartment of the dialyzer. Dialysate flow was linear with time at a rate of 634 mL/minute ($R^2 = 0.9996$). Lower flow rates are readily achievable by constricting the dialysate flow path. The ultrafiltration controller removes up to 3 kg of fluid from the circuit in controllable increments. Because the volume of dialysate contained in the space between the 2 cylinders is constant, fluid removed from the T-junction equals ultra filtration across the dialyzer. The performance of the heat exchanger has yet to be fully characterized.

Conclusions: The prototype shows the feasibility of driving dialysate passively at constant flow, and of controlling ultrafiltration with a simple device that does not require external energy beyond that required from the operator to fill the cylinder and to adjust ultrafiltration periodically. For dialysis to be feasible, a method of driving blood through the dialyzer is necessary: this could be obtained from the patient's own blood pressure using a Scribner shunt, as was done many years ago with Kiil dialyzers.

FR-PO937

The Benefit of Specialized Team Approaches in Patients with Acute Kidney Injury Undergoing Continuous Renal Replacement Therapy: Propensity Score-Matched Analysis Eunyoung Lee, Seung Gyu Han, Mi Jung Lee, Hyung Jung Oh, Shin-Wook Kang, Tae-Hyun Yoo. *Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea.*

Background: Continuous renal replacement therapy (CRRT) has been widely used in critically ill patients with acute kidney injury (AKI). To maintain the quality of care for these patients, some centers operate a specialized CRRT team (SCT) composed of physicians and nurses. The aim of this study was to validate the beneficial impact of SCT approach on the clinical outcomes in AKI patients undergoing CRRT.

Methods: A total of 334 patients, who started CRRT for severe AKI between 2007 and 2009 at Yonsei University Health System, were included. Subjects were dichotomized based on SCT application and matched with a propensity score. Kaplan-Meier (KM) analysis was conducted to compare the 28- and 90-day all-cause death rates according to SCT approach. Cox proportional hazard analysis was performed to determine the consequence of SCT approach on the 28- and 90-day mortalities.

Results: During the study period, the 28- and 90-day all-cause death rates were significantly decreased after SCT approach. In addition, down-time per day, lost time per filter-exchange, and RBC-transfused number during CRRT were significantly reduced after SCT approach. Moreover, KM plots showed that the 28- and 90-day all-cause mortality rates were also significantly decreased after SCT approach (log-rank test, P=0.028 and P=0.033, respectively). Furthermore, multivariate Cox regression analysis revealed that SCT approach significantly reduced the 28- and 90-day all-cause mortality rates, after adjusting for age, gender, mean arterial pressure, APACHE II and SOFA scores, RIFLE criteria, and biochemical parameters [28-day mortality, hazard ratio (HR) =0.897, 95% confidence interval (CI) =0.681-0.982, P=0.040; 90-day mortality, HR=0.927, 95% CI=0.725-0.997, P=0.042].

Conclusions: A well-organized and specialized CRRT team could be beneficial for improving patient survival in AKI patients requiring CRRT.

FR-PO938

Patients with Multiple Myeloma Who Recover from Dialysis Dependent Acute Kidney Injury Have Good Long-Term Outcomes Punit Yadav,[1] Colin A. Hutchison,[2] Stephanie J. Stringer,[1] Mark David Jesky,[1] Lesley B. Fifer,[1] Mark Cook,[1] Paul Cockwell.[1] *[1]Univ Hospital Birmingham, Birmingham, United Kingdom; [2]Hawke's Bay Hospital Soldiers' Memorial, Hastings, New Zealand.*

Background: Over 70% of patients with multiple myeloma (MM) and dialysis dependent acute kidney injury (AKI) remain on dialysis and have poor long-term survival (< 1-year). However the overall survival and determinants of survival of patients with MM and AKI who recover independent renal function are unknown.

Methods: This is a single-centre retrospective study of patients with MM and dialysis dependent AKI who recovered renal function between January 2005 and December 2012. We assessed survival and long-term renal outcomes. Cox regression modelling was used to assess determinants of survival.

Results: 27 patients fulfilled criteria for inclusion. The mean age was 61.4 years; 70.4% were males. The median follow-up was 57.5 months. Light chain (LC) only myeloma was seen in 11 (40.7%) patients; IgG in nine (33.3%), IgA in four (14.8%), IgD in two (7.4%) and IgM in one (3.7%). A kappa free light chain (FLC) clone was present in 14 (51.9%) and a lambda FLC clone in 13 (48.1%) patients. 23 of 24 patients with an adequate kidney biopsy had cast nephropathy. All patients were treated with high dose dexamethasone; 25 were treated with regimens including thalidomide or bortezomib. The median time on dialysis was 27 days (IQR 16-53). 51.8% of patients were alive at analysis; the overall median survival was 70 months. 25 patients maintained renal recovery; two restarted dialysis at a median time of 37.5 months and died at a median of 3 months after restarting dialysis. The independent determinants of worse survival were a known history of CKD (P=0.021) and the presence of a lambda FLC clone (P=0.022). Shorter length of time on dialysis and higher percentage clonal serum FLC reduction from baseline at day 21 predicted a better eGFR at 6 months (p 0.029, R^2 0.332).

Conclusions: In this series 92.5% of patients with MM and dialysis dependent AKI who recover renal function have no requirement for further dialysis. Survival following recovery of renal function is good. Early variables are independently associated with renal function and survival.

FR-PO939

Outcomes following Acute Kidney Injury Requiring Renal Replacement Therapy in Wounded Warriors during the Iraq and Afghanistan Conflicts Jonathan Alexis Bolanos, Christina M. Yuan, Dustin J. Little, Kevin C. Abbott, Stephen W. Olson. *Nephrology, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: AKI requiring renal replacement therapy (RRT) is associated with 50-65% in-hospital mortality and with subsequent CKD. We performed a retrospective, descriptive study of post-traumatic AKI requiring RRT in military beneficiaries injured in operations in Iraq and Afghanistan between 2001 and 2013, who were evacuated to the National Capital Region.

Methods: Fifty-one subjects were identified using electronic medical records and nephrology procedure records. Those who required care at a subspecialty burn unit were excluded, as this data has been previously published.

Results: Mean age at injury was 27 ± 7 years. 50 subjects were male; 18% were black, and 57% were white. The presumed cause of AKI was rhabdomyolysis in 67%; the remainder had ATN thought secondary to contrast, nephrotoxic medications, shock, and/or sepsis. 84% of injuries were due to blast or projectiles. Mean days of RRT were 19 ± 11. Eleven patients died in the hospital; an in-hospital mortality rate of 21.6% (95% CI 12.3-34.8%). This was significantly less than the predicted mortality rate of 50% (p<0.0001, Binomial distribution). Of the 40 who survived hospitalization, 1 had end-stage renal disease due to cortical necrosis (demonstrated by biopsy). Of the remaining 39, 1 died subsequently. Median time to the last follow-up creatinine for the 39 subjects discharged from the hospital was 32 months (range 1-110 months). Serum creatinine at last follow-up was not significantly different from discharge creatinine (0.87 ± 0.25 versus 0.82 ± 0.36 mg/dL, p=0.26, paired t-test), and eGFR by CKD-EPI was >60 ml/min/1.73m^2 in all subjects (116 ± 24 ml/min/1.73m^2). However, eGFR in this population may not be accurate due to the great frequency of multiple amputations.

Conclusions: Despite their severe injuries, these subjects had significantly better in-hospital survival than would have been predicted for AKI requiring RRT, possibly because of their youth and lack of pre-existing conditions.

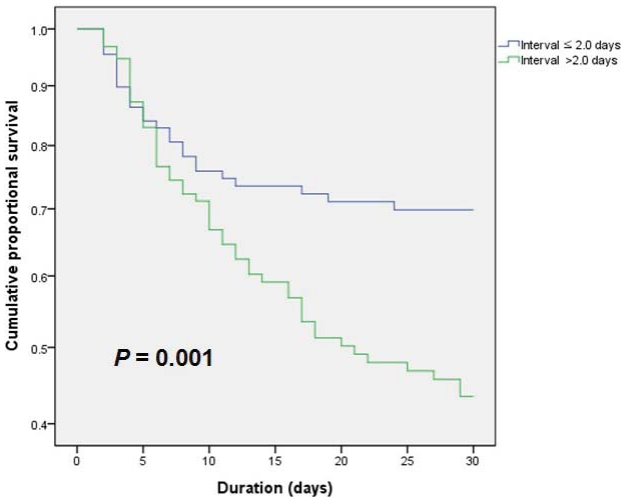
FR-PO940

Early Initiation of Continuous Renal Replacement Therapy May Improve Patient Survival in Acute Kidney Injury Ho Sik Shin,[1] Gyung-Hoon Kang,[1] Ye Na Kim,[1] Yeonsoon Jung,[1] Hark Rim,[1] Hyun Yul Rhew.[2] *[1]Internal Medicine, Kosin Univ College of Medicine, Busan, Korea; [2]Urology, Kosin Univ College of Medicine, Busan, Korea.*

Background: the effects of the timing of CRRT initiation and the characteristics of the infectious process on the clinical outcomes in sepsis patients seem to be controversial. In this study, we tried to elucidate whether the timing of CRRT application, based on the interval between the start time of vasopressors infusion and CRRT initiation, was an independent predictor for mortality in critically ill patients with AKI.

Methods: We evaluated patients with AKI who were treated in ICU of Kosin University Gospel Hospital from January 1, 2010 to December 31, 2011. A total of 200 consecutive patients were included over a 48 month period. Predictors of all-cause death were examined using the Kaplan-Meier and Cox proportional hazards analyses in both treatment groups.

Results: The main contributing factors of AKI were sepsis (38%) and cardiac dysfunction (40%). 28-day overall mortality rates in the early CRRT group were significantly lower than those in the late CRRT group (P = 0.001). Furthermore, early CRRT treatment was independently associated with a lower mortality rate even after adjustment for age, sex, DM, and number of failed organ (P = 0.023).



Conclusions: Early initiation of CRRT may be of benefit.

FR-PO941

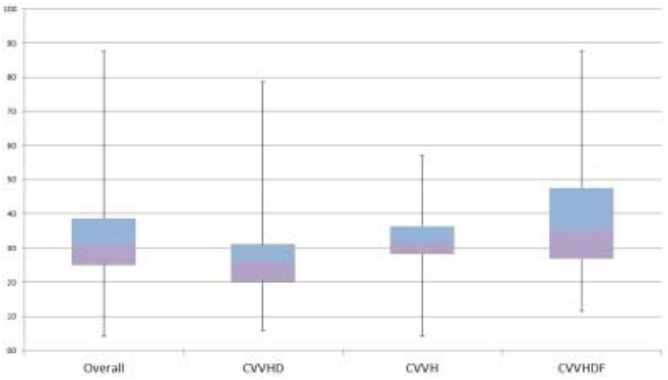
The DoReMIFA (Dose Response Multicenter Investigation Fluid Assesment) Trial: Why a So High Delivered Dose? Francesco Garzotto,[1] Jonah G. Powell-Tuck,[3] David Benavente,[4] Manuel E. Herrera-Gutiérrez,[5] Ciro Tetta,[2] Claudio Ronco.[1] *[1]St. Bortolo Hospital and IRRIV; [2]Fresenius Medical Care; [3]Guy's and St. Thomas' NHS Foundation TrustGuy's and St. Thomas' NHS Foundation Trust; [4]Clinical las condes; [5]Hospital Carlos Haya.*

Background: In the last decade many trials have investigated the potential benefit of more intensive renal replacement therapy (RRT) in critically ill patients with acute kidney injury compared with less-intensive strategies. No improvements have been found in patient survival or recovery of renal function. Our aim was to evaluate the effect of these results on delivered dose in common clinical practice.

Methods: We developed an observational, prospective, multicenter trial (Doremifa) on critically ill patients. Only the RRT section (160 patients) of the entire cohort was analyzed for this purpose. Due to difficulties in carrying out a formal comparison of treatment intensities, we only performed the analysis on continuous RRT (43.1% of the total 1083 records) excluding intermittent RRT and SLED. 172 records were incomplete

and were not considered. Dose was calculated using total effluent (the sum of the dialysate and ultrafiltrate) with correction for percentage pre/post dilution, and expressed as ml/kg/hour. Actual duration was also considered.

Results: Of the 1083 treatments performed, 33.8% were continuous veno venous (CVV) hemofiltration (CVV-H), 25.9% CVV-HD (hemodialysis) and 39.3% CVV-HDF (hemodiafiltration).



The median delivered dose was 31.2 (IQR 28.2 to 36.4), 25.9 (IQR 20.2 to 31.1) and 35.0 (IQR 26.8 to 47.6) ml/kg/h respectively. Overall delivered dose was 31.1 (IQR 24.9 to 38.8). Main reason for RRT discontinuation was Filter/Circuit clotting in 57% of the cases.

Conclusions: Despite the relationship between patient outcome and treatment dose being explored in many studies with conflicting results; 5 years later our data surprisingly showed a 14.7% increase in the delivered dose (31.1 versus 27.1), when compared with the doremi trial.

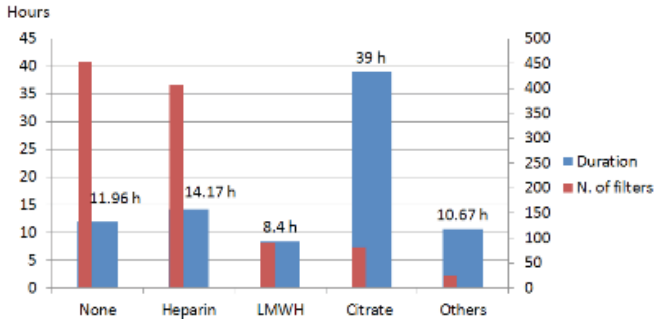
FR-PO942

The (DoRe MIFA) Dose Response Multicenter Investigation Fluid Assesment Trial: A Description of the CRRT Modalities Francesco Garzotto,[1] Anna Lorenzin,[1] David A. Martin-Langerwerf,[2] Lucia L. Cachafeiro,[3] Rene Robert,[4] Jie Teng,[5] Anibal Marinho,[6] Claudio Ronco.[1] *[1]Nephrology IRRIV, St. Bortolo Hospital, Italy; [2]Hospital del Vinalopo, Spain; [3]Hospital Univ La Paz, Spain; [4]CHU de Poitiers, France; [5]Zhongshan Hosp, China; [6]Centro H. Do Porto, Portugal.*

Background: Acute kidney injury (AKI) is an independent risk factor for mortality in critically ill patients.A condition of AKI is defined when serum creatinine concentration is higher than 2mg/dl or the daily increase is 0.3mg/dl;in this settings,AKI patients often need renal replacement therapy (RRT).However,there is not a uniformal worldwide consensus on the management of RRT.We performed a prospective observational multicenter study designed to evaluate how RRT is managed in the intensive care units (ICU) all over the world.

Methods: We developed a web-system for data-entry in order to collect data from 20 ICU centers around the world.On a follow-up of 1415 patients,we considered RRT starting reason,modality,prescribed dose versus actual dose and fluid overload.

Results: We observed 613 AKI patients over 1415,whose 160 (26%) started RRT.The reasons of RRT initiation were divided in:40%azotemia and/or electrolites imbalance,19%fluid overload,34%both.AKI patients started RRT after a mean of 6.8 days after admission.The prescribed RRT are 67%continuous (21%CVVH,20%CVVHD,25%CVVHDF) and 33% Intermittent. The actual duration of the therapy was 90% of the prescribed one. Figure 1 shows time, filters' number and anticoagulation modality used in RRT



Conclusions: We developed a multicentre database to understand more deeply the RRT management over the world.From the data we have collected until now, we can deduce:the actual RRT duration is similar to the prescribed one meaning that downtime is relatively short;citrate anticoagulation therapy allows higher filter's lifetime than others modality;1/3 of RRTs prescribed in ICUs is intermittent instead of continuous.

FR-PO943

Investigation of Carnitine Deficiency in Children Receiving Continuous Renal Replacement Therapy Kristen Sgambat, Asha Moudgil. *Children's National, Washington DC.*

Background: Carnitine deficiency is common in patients receiving chronic hemodialysis (HD) due to inadequate intake, decreased production, and removal during dialysis. The effect of continuous renal replacement therapy (CRRT) on carnitine homeostasis has not been previously studied. We hypothesized that children receiving CRRT may be at risk for carnitine deficiency due to continuous removal, absent intake, and comorbidities related to underlying critical illness.

Methods: Medical records of all patients receiving CRRT at Children's National between 2011 and 2014 were reviewed for total carnitine (TC) and free carnitine (FC) levels. Prevalence of carnitine deficiency at baseline, 13, and 21 days duration on CRRT was determined. Correlation of carnitine level with days on CRRT was assessed by Pearson correlation. Mean TC and FC levels of children on CRRT were compared to those of a prospective comparison group of children on chronic HD for > 3 months by Student's t test.

Results: The study group included 36 CRRT patients with mean age 8.7±1.2 years. At initiation of CRRT, 37.5% of children were TC deficient. After 13 days on CRRT, 65.5% were deficient; prevalence of deficiency significantly increased to 83.3% by day 21 (p=0.03), and 100% of children on CRRT for >21 days were TC deficient (p=0.03). Prevalence of FC deficiency similarly increased with duration of CRRT from 50% at baseline to 71.4% by day 13 and 91.7% by day 21 (p=0.03). There was a significant negative correlation between levels of TC (r=-0.43, p=0.002) and FC (r=-0.41, p=0.003) with number of days on CRRT. Mean carnitine level of children on CRRT for 0.5 week was lower compared with levels of 9 children on chronic HD for mean duration of 9.3±6 months (TC 26.7±3.1 versus 49±1.7, p=0.0001 and FC 18.1±2.4 versus 29±1.2 µmol/L, p=0.006).

Conclusions: Carnitine levels significantly decrease with longer time on CRRT, and the majority of children on CRRT for 1 week are carnitine deficient. Deficiency is more severe after only 0.5 week on CRRT in comparison to children on chronic dialysis for a mean of 9.3 months. Consequences of carnitine deficiency and possible benefits of supplementation in the critically ill pediatric CRRT population should be investigated.

FR-PO944

Use of Arterio-Venous Access in ESRD Patients Receiving Continuous Renal Replacement Therapy Vanya Grover, Aleksey Etinger, Adebayo Shakir Adewale, Sheila Mary Donaghy, Nand K. Wadhwa. *Nephrology, Stony Brook Univ Hospital, Stony Brook, NY.*

Background: Continuous renal replacement therapy (CRRT) is increasingly used in end stage renal disease (ESRD) patients with multi-organ failure admitted to intensive care units (ICU). We report our experience on safety of the pre-existing AV access in ESRD patients as an alternative to a dual lumen catheter for CRRT.

Methods: The AV access was used in all 13 ESRD patients (7 males, 6 females; 10 AV fistulas, 3 AV grafts; mean age 57, range 32-76 years) for CRRT from January 2012 to December 2013. Policy and procedure was established before using AV access for CRRT. Dialysis nursing staff placed 16 gauge plastic angiocaths in AV access, connected using 30" extension tubing (tubing secured with an anchor) to the arterial and venous tubing of M100 set with AN69 hemofilter using Prisma/Prismaflex CRRT system. Angio-catheters were changed every 72 hours with the change of M100 set with AN69 hemofilter or earlier if CRRT was discontinued. PRISMASATE BGK 4/2.5 was delivered at 500-1000 ml/hr as a dialysate and PRISMASOL BGK2/0 or 4/0 was infused at 1500-2000 ml/hr as replacement fluid. All patients received citrate anticoagulation. Data were collected retrospectively.

Results: The indication for CRRT included septic shock in 6, hemorrhagic shock in 4 or cardiogenic shock in 3. The mean blood flow rate was 127 ± 26 ml/min. Minimum effluent rate of 20-25 ml/kg/hour was achieved in each patient. Total duration of CRRT was 892 hours over 49 days. Mean duration of CRRT was 18.8 ± 5.1 hrs/day. All AV accesses were functioning after the CRRT was discontinued. Seven patients survived and received intermittent HD using AV access without complications. No AV access bleeding, infection or technical problems were observed.

Conclusions: Our experience suggests that use of AV fistula or graft as access with an angio-catheter (connected via an extension tube while secured with a tubing anchor) for CRRT can be used safely and obviates the need for a double lumen catheter for a venous access and its potential complications. In addition, the use of AV access may keep fistula or graft patent in these patients.

FR-PO945

Pediatric Nephrology Follow-Up after Continuous Renal Replacement Therapy for Acute Kidney Injury Nicole Christin, Margret E. Bock, Farah N. Ali. *Kidney Diseases, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: Acute kidney injury (AKI), in its most severe form, requires renal replacement therapy. Outcome studies of pediatric AKI show that evidence of chronic kidney disease is commonly present at long-term follow-up. Rates of outpatient Pediatric Nephrology (PN) follow-up after discharge are low and late referral to PN is associated with worse outcomes. We hypothesize that factors contributing to low PN follow-up after AKI include: lack of a scheduled appointment with PN at time of discharge, lack of discharge instructions recommending PN follow-up, non-nephrology primary diagnosis, and lack of a primary medical doctor (PMD).

Methods: A retrospective chart review of patients who received CRRT at our institution from January 1, 2008 to December 31, 2012 was performed.

Results: 115 patients required CRRT; 73 patients were excluded (44 died, 25 had CKD, 2 were adults, 2 had ingestions). 42 pediatric patients with AKI were included; median age was 6.8 years (IQR 3.2-14.3), 64% were male, 38% were Caucasian, 19% African American and 36% Hispanic. 93% had an identified PMD and 62% had public health insurance. 71% of patients requiring CRRT presented for follow-up. At discharge, 62% had instructions to be seen by PN. 74% had a scheduled appointment with PN and 86% of those came to the visit.There was a significant association between presenting for follow-up and having discharge instructions that stated the need for follow-up, eGFR at start of CRRT, and a nephrology primary diagnosis ($p < 0.05$).No association was found between presenting for follow-up and age, gender, race, insurance type or having a PMD. Moreover, primary diagnosis, eGFR at discharge, time on CRRT, dialysis-free interval prior to discharge were not associated with PN follow-up rates.

Conclusions: eGFR at the time of dialysis initiation, non-nephrology primary service and written discharge instructions recommending PN follow-up were linked to higher follow-up rates. Identifying these factors prior to discharge may improve future PN follow-up after severe AKI requiring CRRT and therefore potentially identify and slow the progression of chronic kidney disease.

FR-PO946

Continuous Venovenous Hemodiafiltration to Obtain Therapeutic Hypernatremia in Patients with Renal Failure: A Case Series

Timothy A. Williams, Keith M. Wille, Ashita J. Tolwani. *Dept of Medicine, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Hypertonic saline is used to induce serum hyperosmolality by targeting a sodium (Na) concentration of 145-155 meq/L in patients with elevated intracranial pressure (ICP). Acute kidney injury (AKI) or end-stage renal disease (ESRD) patients with elevated ICP who require continuous renal replacement therapy (CRRT) often require adjustment to the composition of the CRRT solutions to maintain the target Na concentration. We describe a simplified CRRT protocol using 3% saline as the post-filter replacement fluid (RF) to maintain the targeted Na concentration without using customized CRRT solutions.

Methods: We retrospectively analyzed 9 patients with AKI or ESRD and elevated ICP treated with continuous venovenous hemodiafiltration (CVVHDF) using 3% saline as the post-filter RF. Our standard protocol involves performing CVVHDF using the Prismaflex device with a blood flow rate of 200 ml/min and an effluent rate of 25-30 ml/kg/hr. Our standard pre-filter RF and dialysate contain a Na concentration of 140 meq/L and are each delivered at a rate of 1,000-1,500 ml/hr. Normal saline (NS) at 200 ml/hr acts as the post-filter RF as required with the Prismaflex to prevent clotting of the de-aeration chamber. In patients who require therapeutic hypernatremia, we simply change the post-filter RF from NS to 3% saline and deliver it at a rate of 100-150 ml/hr.

Results: Mean age was 45.2 ± 15.5 years. Mean weight was 80.9 ± 20.0 kg. Six had AKI and 3 had ESRD. The most common indications were cerebral edema (5/9) followed by intracerebral hemorrhage (4/9). Median total CVVHDF duration was 45 (range 10-91) hours. Median serum Na concentration prior to the start of 3% saline was 140 meq/L. All patients achieved a therapeutic Na level by a median of 19 (range 0-30) hours of treatment. Serum Na remained between 145-155 meq/L in all patients for the duration of use of 3% saline as the post-filter RF.

Conclusions: We demonstrate a simple method to maintain serum Na levels in the therapeutic range by using 3% saline as post-filter RF with CVVHDF, obviating the need for customized replacement and dialysate solutions with adjusted Na concentrations.

FR-PO947

Determination and Clinical Validation of Half-Life Based Estimation of Dialysis Duration in Methanol Poisoning

Philippe Lachance, Sacha A. De Serres, Simon Desmeules, Mohsen Agharazii. *Nephrology, Laval Univ, Quebec, QC, Canada.*

Background: Treatment of methanol poisoning (MP) by hemodialysis (HD) requires monitoring of serum methanol levels (ML) until a level of < 5 mmol/L is achieved. ML are not readily available and delay in obtaining the results may result in longer duration of dialysis. We hypothesize that based on methanol's half-life ($T_{1/2}$) during HD, dialysis duration can be safely estimated. The objectives of the present study are to 1) define the $T_{1/2}$ of methanol during HD in incident cases of MP (training set) and 2) to validate the $T_{1/2}$ approach in a second cohort of patients with MP (validation set).

Methods: This is a retrospective single center study of incident methanol poisoning from 1997 to 2013 referred to CHU de Québec (Quebec, Canada) for HD. The training set included MP with ≥ 5 measurements of ML during dialysis (n= 27). Dialysis was performed by various filters with Qb of 350- 400 ml/min and a QD of 750 ml/min. A one phase decay exponential regression analysis with Robust fitting method and a plateau constrain to a value of >0 was used to determine $T_{1/2}$. The 95th percentile $T_{1/2}$ was determined. A target ML that will allow the remaining 5% patients to end with a ML < 5 without unduly increasing dialysis duration was determined. These findings were confirmed in the validation set (n=29).

Results: In the training set, the median $T_{1/2}$ was 129 (108,139) minutes and the 95th percentile was 150 min. Targeting ML of < 4 yielded ML < 5 in all patients. In the validation set, the median $T_{1/2}$ was 126 (112,137) minutes and the 95th percentile was 155 minutes. Using a half-life of 150 minutes and targeting ML < 4 yielded a ML < 5 in all patients. The median difference between estimated and observed dialysis duration was - 16 [-75,34] minutes.

Conclusions: In patients with MP, estimation of dialysis time based on a methanol $T_{1/2}$ of 150 minutes and targeting ML level < 4 is safe and does not lead to unduly extension of dialysis duration.

FR-PO948

Platelet Loss in Membrane Therapeutic Plasma Exchange (mTPE)

Dipal Patel, Casey N. Gashti. *Section of Nephrology, Rush Univ Medical Center, Chicago, IL.*

Background: Membrane therapeutic plasma exchange (mTPE) using dialysis equipment is gaining popularity amongst nephrologists. A decrease in the platelet count of 30-53% per treatment has been reported with centrifuge-based therapeutic plasma exchange (cTPE), however, little is known about the effects of mTPE on the patient's platelet count. We performed a retrospective analysis to study the effect of mTPE on the platelet count.

Methods: Data was retrospectively collected on all patients receiving inpatient mTPE at our institution from January 2013 to April 2014. Procedures were performed using the Asahi Plasmaflo™ OP filter with the NxStage® System One™ Machine. No anticoagulation was used. Patients with thrombotic thrombocytopenic purpura (TTP) who are expected to have increasing platelets with plasma exchange were excluded. Pre and post treatment platelet counts were measured on the morning of and the morning after each treatment respectively. Filtration fraction (FF) and transmembrane pressure (TMPa) for each treatment were collected. Bleeding complications were investigated. Paired student's t-test was used for statistical analysis.

Results: A total of 597 mTPE treatments were performed on 141 patients (average 4.2 treatments). Of these, data analysis was performed on 396 treatments (117 patients) for whom platelet counts were available. There was a significant difference in the platelet count before (211 ± 99 thousand) and after (192 ± 96 thousand) each treatment ($p < 0.0001$) with a mean absolute platelet count drop of 18.6 thousand (8.2%) per treatment. The mean absolute drop in the platelet count at the end of the treatment course was 59 thousand (22.9 %); $p < 0.0001$. There was no correlation between FF, TMPa and the change in the platelet count using simple linear regression. There were a total of nine bleeding complications, none related to drop in the platelet count.

Conclusions: Platelet count decreased significantly (8.3% per session, 22.3% per treatment course) in patients undergoing mTPE. No major bleeding complications were correlated to the platelet loss. The platelet count should be monitored during a course of treatment as cumulative drop increases with multiple treatments.

FR-PO949

Pharmacokinetics of Intraperitoneal Cefalothin and Cefazolin in Patients Being Treated for Peritoneal Dialysis-Associated Peritonitis

Dwarakanathan Ranganathan,[1] Darren M. Roberts,[2] Steven C. Wallis,[2] Jeffrey Lipman,[2] Adrian Lawrence Kark,[1] Jason A. Roberts.[2] *[1]Renal Medicine, Royal Brisbane&Women's Hospital, Herston, Queensland, Australia; [2]Burns, Trauma and Critical Research Center, The Univ of Queensland, Herston, Queensland, Australia.*

Background: The standard treatment of peritoneal dialysis (PD)-associated peritonitis (PD-peritonitis) is intraperitoneal (IP) administration of antibiotics. Antibiotic clearance may vary between individuals on PD. Only limited data on the pharmacokinetics (PK) of IP cephalosporins exists and as such it is unclear how appropriate contemporary dose recommendations are for this class of antibiotics. The aim of this study was to describe the PK of IP cefalothin (CLN) and cefazolin (CFZ) in patients treated for PD-peritonitis.

Methods: IP CLN or CFZ was administered with gentamicin in a six hour dwell to 19 patients with PD-peritonitis during routine care. Serial plasma and PD effluent samples were collected for 24 hours. Antibiotic concentrations were quantified using a validated chromatographic method with PK analysis performed using a non-compartmental approach.

Results: 8 patients were administered CLN and 11 CFZ. The median bioavailability for both antibiotics exceeded 92%, but marked interindividual PK variability was observed. Both drugs and dosing regimens achieved high plasma and PD effluent concentrations throughout the antibiotic dwell. The median trough total antibiotic concentrations for CFZ and CLN during the dwell were (plasma 49 versus 8 mg/L, $p<0.01$; PD effluent 37 versus 38 mg/L, $p=0.34$) despite administration of a similar dose (median 1.2 versus 1.1 gram, $p=1.0$), and larger (but highly variable) volume of distribution (35 versus 14 L, $p=0.0506$), respectively. However, antibiotic concentrations were low during PD dwells not containing antibiotic, particularly CLN which was frequently undetectable in plasma and PD effluent.

Conclusions: When IP CLN or CFZ is allowed to dwell for 6 hours, sufficient plasma and PD effluent concentrations are present for common pathogens. There is a risk of subtherapeutic antibiotic concentrations with once daily IP cephalosporins, in particular for CLN for which more frequent dosing may be required.

FR-PO950

Intradialytic Antibiotic Concentrations Predict Pharmacokinetics Between Dialysis Treatments

Rueben Banalagay,[1] Ross Marshall Nesbit,[2] Joseph J. Groszek,[2] Don Mitchell Wilkes,[1] William Fissell.[2] *[1]Electrical Engineering, Vanderbilt Univ, Nashville, TN; [2]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN.*

Background: It is important to dose antibiotics accurately. Underdosing risks treatment failure and emergence of antibiotic resistance while overdosing risks unwanted side effects. The prevalence of advanced age and comorbid organ failures in dialysis patients poses a special challenge for drug dosing. An approach to individualizing pharmacokinetics based on intradialytic sampling would simplify dose personalization. We developed a computational approach based on signal processing techniques to use measurements obtained during a dialysis session to predict plasma drug concentrations between sessions.

Methods: A discrete-time low-pass filter solution to the ordinary differential equations describing two-compartment linear pharmacokinetics was coded in MATLAB. In an IRB-

approved study, patients receiving intermittent dialysis and a b-lactam antibiotic were sampled every five minutes during 30 minutes of hemodialysis followed by 30 minutes of isolated ultrafiltration, and then at 0, 30, 60, 120, and 240 minutes after an antibiotic dose on a day without dialysis. Antibiotic concentrations were measured by HPLC. Filter parameters were fitted to the intradialytic data using a steepest-descent followed by quorum voting approach. The filter then predicted response to a subsequent antibiotic dose. Predicted and actual concentrations were compared.

Results: We report results for the first three subjects. A best fit model could be obtained in each case. Mean error between predicted and observed concentrations was 9.7%.

Conclusions: We have developed a novel computational tool that can individualize drug dosing using only measurements obtained during a hemodialysis treatment. Pilot clinical trials are needed to determine clinical utility of this approach.

FR-PO951

Prospective Single and Multiple Dose Pharmacokinetic Study of Intravenous Colistin in Critically Ill Patients with Acute Kidney Injury Undergoing Extended Daily Dialysis

Ann-Kathrin Strunk,[1] Julius Schmidt,[1] Stefanie M. Bode-Böger,[2] Jan T. Kielstein.[1] *[1]Nephrology and Hypertension, Medical School Hannover, Germany; [2]Inst of Clinical Pharmacology, Otto von-Guericke-Univ, Magdeburg, Germany.*

Background: The lack of new antibiotics for the treatment of multidrug-resistant bacteria renewed interest in antibiotics like colistin. Due to scarce data, we aimed to perform a prospective, observational clinical study on dosing of IV colistin in critically ill patients with anuric acute kidney injury (AKI) undergoing extended daily dialysis (EDD) to develop dosing recommendations.

Methods: So far four subjects were enrolled. Pharmacokinetics on the first day and between the 5th and 9th day of treatment were performed. Blood samples were collected before and at the end of IV administration of CMS (prodrug) and throughout the dialysis session [average:8.1 hrs, polysulfone high-flux dialyzer (1.3 m^2; mean blood and dialysate flow:200/180 ml/min)]. Dialyzer clearance was calculated and samples from the spent dialysate were taken.

Results: Peak levels of colistin after a loading dose (6 million units) were 3.83-10.01µg/ml (CMS: 13.14-24.76µg/ml). Even after five to nine days of treatment with 3 million units q 8 hrs, there was neither an accumulation of colistin (peak level day#5-9: 8.96-10.71µg/ml) nor an accumulation of CMS (7.68-14.07µg/ml). Dialyzer plasma clearances of colistin ranged between 28-88ml/min (CMS: 26-158ml/min). After dialysis, 108-246mg colistin could be recovered in the spent collected dialysate on day#1 and 158-204mg on day#5-9.

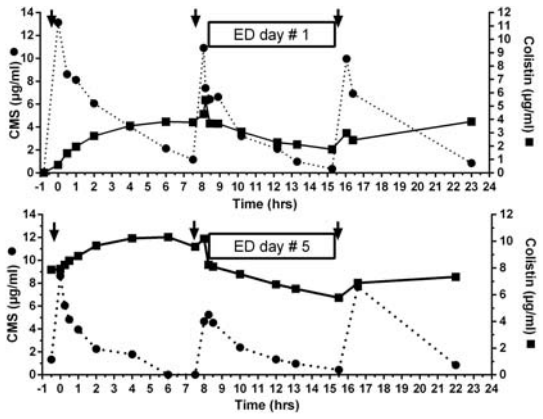

Figure: Plasma concentrations of colistin (•) and CMS (•) in a patient with acute kidney injury undergoing extended dialysis (duration depicted by box size) on day # 1 and day # 5 of colistin treatment (first dose 6 million units, thereafter 3 million units q 8 hours, indicated by arrows)

Conclusions: Our data suggest that EDD eliminates colistin effectively and to a larger extent than reported for IHD. Thus, dosing colistin as recommended for a regular hemodialysis is inadequate and would result in a significant under-dosing. After a loading dose of 6 million units, a dose of 3 times 3 million units yields therapeutic drug levels on EDD.

Hemodialysis Has Minimal Impact on the Pharmacokinetics of AKB-6548, a Once-Daily Oral Inhibitor of Hypoxia Inducible Factor Prolyl-Hydroxylases (HIFPHs) for the Treatment of Anemia Related to Chronic Kidney Disease (CKD)

Akshay Buch,[1] Tasha M. Farmer,[1] Charlotte Hartman,[1] Harry Alcorn,[2] Robert Shalwitz.[1] *[1]Akebia Therapeutics, Inc., Cambridge, MA; [2]DaVita Clinical Research, Minneapolis, MN.*

Background: AKB-6548 is a novel once-daily, oral therapy in development for the treatment of anemia related to CKD (pre-dialysis and patients requiring dialysis). The completed clinical studies have demonstrated its effectiveness for increasing hemoglobin in a dose-responsive manner in CKD patients not on dialysis.

Methods: The safety, tolerability and pharmacokinetics of AKB-6548 were evaluated in an open-label, randomized, crossover study in 12 subjects with anemia secondary to end stage renal disease (ESRD) undergoing chronic hemodialysis (HD). Single doses (450 mg) were administered 4 hours prior to starting a HD session (PRE-HD) or 2 hours after completing a HD session (POST-HD). Plasma samples, collected over 48 hours after each dose, were analyzed for AKB-6548 and two metabolites (phenolic glucuronide and acyl-glucuronide) using validated bioanalytical methods. In addition, dialysate samples were collected at pre-specified time points for the PRE-HD dose.

Results: AKB-6548 was well tolerated by subjects with no subjects discontinuing the study due to an adverse event (AE). Seven subjects reported a total of 7 AEs during the study. All AEs were mild in intensity, except for one of moderate intensity (abdominal pain), and only GI-related AEs were considered related to study drug. All AEs were resolved by the end of the study. No serious adverse events were reported during the 48-hours in-house observation period after the dose administrations. The pharmacokinetic results indicate that administration of the dose before or after the HD session did not have a marked effect on the PK parameters of AKB-6548 or the two glucuronide metabolites.

Conclusions: The exposure based on Cmax and AUC for the major metabolite (O-glucuronide) was 30-50% of AKB-6548 and the exposure to acyl-glucuronide was extremely small (<1%). The terminal half-life of AKB-6548 and O-glucuronide were approximately 9-10 hours. The HD procedure had minimal impact on the clearance of AKB-6548.

FR-PO953

Pharmacokinetics of Intravenous Triferic in Healthy Volunteers

Raymond D. Pratt, Vivian H. Lin, Carrie D. Guss, Ajay Gupta. *R&D, Rockwell Medical, Wixom, MI.*

Background: Triferic™ (soluble ferric pyrophosphate citrate) is an investigational iron salt, administered via the dialysate to replace dialytic iron losses and maintain hemoglobin levels. Triferic conceals the iron (III) core by covalent bonding with pyrophosphate and citrate. Triferic donates iron and pyrophosphate to human apotransferrin directly, thereby bypassing the reticuloendothelial system.

Methods: Triferic administration via IV infusion over 4-hour period has been studied in healthy volunteers in a double-blind, placebo controlled single ascending dose study.

Results: Placebo subjects showed a pronounced diurnal variation in serum iron, necessitating a baseline correction for accurate quantitation of total iron. Single Triferic doses from 2.5 mg to 10 mg iron over 4 hours result in dose proportional increases in serum iron concentration, transferrin bound iron (TBI) and TSAT. The baseline corrected non-compartmental PK parameters are summarized in the table.

	0 mg	2.5 mg	5.0 mg	7.5 mg	10.0 mg
λ_z (1/hr.)	-	0.544	0.668	0.711	0.917
$t_{½}$ (hr.)	-	1.3	1.2	1.3	1.0
T_{max} (hr.)	-	4.9	4.3	4.75	4.33
C_{max} (mg/dL)	62.6	113	151	228	261
$AUC_{0\text{-}4}$ (h*mg/dL)	126	235	329	471	590

Triferic iron is rapidly cleared from the circulation with a $t_{½}$ of approximately 1.2 hours. Measurements of TBI across the dose range demonstrated no non-transferrin-bound iron (NTBI). In CKD-HD patients receiving 2 µM Triferic-iron via dialysate (110 µg/L), the mean incremental pre to post dialysis iron concentration is 115 mg/dL. In healthy volunteers, a 10 mg dose of Triferic yields an incremental increase of 210 mg/dL. Based on these measurements, approximately 5.4 mg of iron is delivered with each hemodialysis treatment. Triferic IV was well tolerated with a safety profile similar to that of placebo.

Conclusions: Triferic is a novel iron replacement product delivered via the hemodialysate and designed to replace dialytic iron losses. The healthy volunteer intravenous clinical pharmacology results demonstrate linear PK without NTBI. The results support the efficacy of Triferic dialysate in Phase 2 and 3 clinical studies in CKD-HD patients demonstrating maintenance of iron balance and hemoglobin levels while reducing the requirements for ESAs.

FR-PO954

Population Pharmacokinetics of AMG 416, a Novel Calcimimetic Peptide, in Patients with Secondary Hyperparathyroidism Receiving Hemodialysis

Ping Chen, Murad Melhem, Jim Xiao, Mita Kuchimanchi, Juan Jose Perez Ruixo. *PKDM, Amgen Inc., Thousand Oaks, CA.*

Background: Activation of the calcium-sensing receptor (CaSR) on the parathyroid gland (PTG) reduces parathyroid hormone (PTH) synthesis and secretion from the chief cells of the PTG. AMG 416 is a novel calcimimetic peptide that is currently being evaluated as a treatment in patients with secondary hyperparathyroidism (SHPT) receiving hemodialysis (HD). The purpose of this analysis is to characterize the population pharmacokinetics (PK) of AMG 416 in patients with SHPT receiving HD.

Methods: A total of 1649 plasma concentrations from 143 patients enrolled in three clinical studies were pooled for this analysis. AMG 416 was administered as single or multiple intravenous bolus doses at the end of hemodialysis at doses ranging from 2.5 to 60 mg. The time course of intact AMG 416 plasma concentration was analyzed with non-linear mixed effect modeling using NONMEM 7.2. The influence of sex, race, and baseline characteristics (age, weight, creatinine, albumin, total bilirubin, liver enzymes, intact PTH, phosphorus, corrected calcium, vitamin D supplements, phosphate binders, and calcium supplements) on PK parameters was explored. The predictive ability of the final model was evaluated using standard diagnostic plots, bootstrapping and predictive checks.

Results: An open three-compartment linear PK model that accounts for the AMG 416 clearance due to HD best described the data.Plasma clearance (inter-subject variability)

was estimated as 0.564 L/h (14.0%). The HD clearance was estimated to be 22.2 L/h. The volume of distribution at steady-state was approximately 624 L (82%). Within the range of covariates studied,no statistically significant associations between the covariates and PK parameters were found. Bootstrapping and predictive checks indicated that the model adequately described the time course of AMG 416 plasma concentrations in patients with SHPT receiving HD.

Conclusions: The integrated analysis of phase I/II PK data demonstrated that AMG 416 exhibits linear and stationary PK within the range of doses evaluated. This analysis suggests that no additional considerations for dose adjustment are warranted on the basis of PK.

FR-PO955

Effect of End Stage Renal Disease on the Expression and Function of Hepatic Reductase Drug Metabolizing Enzymes

Osama Y. Alshogran,[1] Brad Urquhart,[2] Thomas D. Nolin.[1] *[1]School of Pharmacy, Univ of Pittsburgh, Pittsburgh, PA; [2]Schulich School of Medicine and Dentistry, Univ of Western Ontario, London, ON, Canada.*

Background: The expression and function of hepatic drug metabolizing enzymes and transport proteins is altered in end-stage renal disease (ESRD). Hepatic reduction is an important pathway for the metabolism of many drugs and endogenous compounds. Yet to date, the effect of ESRD on hepatic reduction has not been investigated. The aim of this study was to evaluate the effect of ESRD on the expression and function of hepatic reductases in human liver tissue.

Methods: Liver tissue was collected from deceased ESRD patients (n=10) and deceased control patients (n=11), and cytosolic and microsomal cellular fractions were isolated from each tissue sample. Gene (mRNA) and protein expression of multiple hepatic reductases were determined by qRT-PCR and Western blotting, respectively. Metabolic activity was assessed using warfarin as a pharmacological probe substrate, with the formation rate of warfarin alcohols reflecting overall reductase activity. Warfarin alcohols were determined using liquid chromatography-tandem mass spectrometry.

Results: Gene expression of carbonyl reductase 1 (CBR1) and aldo-keto reductases (AKR) 1C1, AKR1C2, AKR1C3, and AKR1C4 was decreased up to 67% in ESRD livers compared to controls (P=NS for all). A significant (65%) decrease in CBR1 protein expression was observed in ESRD livers relative to controls (P<0.05). AKR protein expression was unchanged. The formation rate of *RS/SR*-warfarin alcohol was decreased by 22% and 27% in cytosol and microsomes, respectively of ESRD livers versus controls (P=NS).

Conclusions: Our results demonstrate a trend toward decreased expression and function of selective hepatic reductases in livers of ESRD patients. Given the large interindividual variability observed, future studies with larger sample size are warranted to confirm our findings. The results may provide a mechanism for altered non-renal drug clearance in ESRD.

FR-PO956

Effect of Experimental Kidney Disease on the Functional Expression of Hepatic Reductases

Osama Y. Alshogran,[1] François A. Leblond,[2] Vincent Pichette,[2] Thomas D. Nolin.[1] *[1]School of Pharmacy, Univ of Pittsburgh, Pittsburgh, PA; [2]Service de Néphrologie et Centre de Recherche, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: Chronic kidney disease (CKD) affects the nonrenal clearance of drugs by modulating the functional expression of drug metabolizing enzymes and transporters. The impact of CKD on oxidative and conjugative metabolism has been extensively studied. However, the effect of CKD on hepatic reduction, an important drug metabolism pathway, has not been investigated. Carbonyl reductase 1 (CBR1) and aldo-keto reductase 1C3 (AKR1C3) are important cytosolic reductases, while 11b-hydroxysteroid dehydrogenase type 1 (11b-HSD1) is a key microsomal reductase. Warfarin is reduced stereoselectively by these enzymes to form *RS/SR*- or *RR/SS*-warfarin alcohol. We aimed to assess the effect of experimental CKD on hepatic reduction using warfarin as a pharmacological probe substrate.

Methods: Cytosolic and microsomal cellular fractions were isolated from liver tissue harvested from 5/6th-nephrectomized and control rats (n=10 per group). The enzyme kinetics for warfarin reduction were evaluated in both fractions under optimized conditions. Warfarin alcohol metabolites were measured using LC-MS, and formation of warfarin alcohols was used as an indicator of hepatic reductase activity. Selective inhibitors were employed to identify reductases involved in warfarin reduction. Gene expression of reductases was quantified using qRT-PCR.

Results: Metabolic formation of *RS/SR*-warfarin alcohol was decreased by 39% (P<0.001) and 43% (P<0.01) in cytosol and microsomes, respectively in CKD rats compared to controls. However, *RR/SS*-warfarin alcohol formation was unchanged. The mRNA expression of CBR1, AKR1C3 and 11b-HSD1 was significantly reduced by 34%, 93%, and 35% (P<0.05), respectively in CKD rats compared to controls.

Conclusions: These results suggest that the activity of hepatic reductases is selectively decreased in kidney disease, secondary to the reduced mRNA expression. The findings may explain one mechanism for altered nonrenal clearance, exposure, and response of drugs in CKD patients.

FR-PO957

Apical Shear Stress Enhances Organic Cation Transport in hOCT2/hMATE1 Transfected MDCK Cells

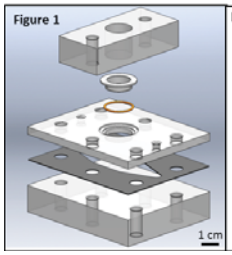
Aishwarya Jayagopal,[1] Peter Soler,[1] Nicholas J. Ferrell,[2] Paul R. Brakeman,[3] Deanna L. Kroetz,[1] William Fissell,[2] Shuvo Roy.[1] *[1]Bioengineering, UCSF; [2]Nephrology, Vanderbilt Univ; [3]Pediatrics, UCSF.*

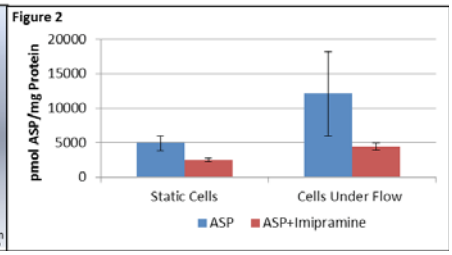
Background: Active transport by renal proximal tubules plays a significant role in human drug disposition and is therefore important to model when developing drugs. However, current *in vitro* drug testing methods fail to mimic important physiological cues, such as flow induced shear stress. In this study, the effect of shear stress on active transport was investigated using a parallel plate bioreactor cultured with MDCK cells expressing human organic cation transporters.

Methods: A polycarbonate parallel plate bioreactor compatible with Snapwell inserts was used in these experiments (Fig. 1). The device provides a flow path across the apical side of the cells and a static media reservoir on the basal side. MDCK cells transfected with a pair of uptake and efflux transporters (hOCT2/hMATE1) were grown on Snapwells under static conditions until confluence and then placed in the bioreactor. Media flow was increased over 7 days until shear stress of 0.2 dynes/cm^2 was reached. Uptake of 25mM 4- (4-dimethylamino) styryl-N-methylpyridinium (ASP+), a fluorescent OCT2/MATE1 substrate, was measured for 1 hour with or without pretreatment (30 minutes) with 500mM imipramine, an OCT2/MATE1 inhibitor. Control cells were cultured under static conditions.

Results: Cells maintained under flow showed a 2.2 fold increase in protein concentration over static controls, confirming previous observations of shear stress effects. Furthermore, cells cultured under shear stress showed a 2.4 fold increase in ASP+ uptake when compared to cells cultured under static conditions and a 63.4±3.7% inhibition with imipramine compared to 48.6±5.5% inhibition in static cells (Fig. 2).

Conclusions: These results indicate that exposure to shear stress increases uptake of the active transport substrate ASP+ compared to static growth conditions.





FR-PO958

Comparison of Pharmacokinetic-Pharmacodynamic Relationship of Atrasentan between Asian Population and Caucasian Population

Hirofumi Makino,[1] Dick de Zeeuw,[2] Hiddo Jan Lambers Heerspink,[2] The RADAR Study Group.[3] *[1]Okayama Univ Hospital, Japan; [2]Univ Medical Center Groningen, Groningen, Netherlands; [3]The RADAR Study Group.*

Background: Previously, we showed that the selective endothelin (ET) A receptor antagonist atrasentan lowers albuminuria both in an Asian and Caucasian diabetic nephropathy population (*de Zeeuw et al, JASN 2014*). As drug responses for many drugs may differ between Asian and Caucasian populations, we compared pharmacodynamics and pharmacokinetics (PK) of atrasentan between Asian population (Japan and Taiwan; n=71) and Caucasian population (U.S. and Canada, n=140).

Methods: We conducted a 12 week randomized, double-blind, placebo-controlled trial, which consists of 3 arms (placebo, atrasentan 0.75 mg, atrasentan 1.25 mg) in type 2 diabetic patients with macroalbuminuria (UACR: ≥300 mg/g) and decreased renal function (eGFR: 30-75 mL/min/1.73 m^2), receiving maximum tolerated labeled dose of a RAS inhibitor (ARB or ACEi). The primary efficacy endpoint was UACR (urinary albumin creatinine ratio). Blood collection for PK analysis was conducted at Weeks 2, 4, 6, 8, 10 and 12 visits.

Results: UACR response was higher in Asian compared to Caucasian patients:, -35.9% versus -25.1% (0.75 mg) and -50.6% versus -27.7% (1.25 mg). Similarly, atrasentan plasma concentration was higher in Asian: 2.2 versus 1.6 (0.75mg), and 4.9 versus 3.4 ng/mL (1.25mg). A strong correlation was observed between plasma concentration and UACR effect at populations/dose level (R^2 0.98; p<0.01). The difference in plasma levels could be partly explained by the significant differences in body weight for both dose groups (67 versus 95 and 65 versus 95kg): correction by body weight left no significant difference in plasma concentration between Asian and Caucasian: 0.06 ng/ml (0.75mg; p=0.92), and 1.05 ng/mL (1.25 mg; p=0.069).

Conclusions: Asian patients show an enhanced antialbuminuric (dose) response to atrasentan compared to Caucasian patients. This difference is correlated with differences in plasma drug concentrations, and in turn partly explained by the difference in body weight/body surface area.

FR-PO959

Gene Expression Analysis of Tacrolimus-Induced Tubulointerstitial Fibrosis After Ischemia/Reperfusion Injury Haruka Shinke,[1] Yuka Tamura,[1] Shunsuke Fujita,[2] Shunsaku Nakagawa,[1] Takahisa Yano,[3] Kazuo Matsubara,[1] Satohiro Masuda.[1,2,3] *[1]Dept of Clinical Pharmacology and Therapeutics, Kyoto Univ Hospital, Kyoto, Japan; [2]Dept of Clinical Pharmacology and Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Dept of Pharmacy, Kyushu Univ Hospital, Fukuoka.*

Background: Tacrolimus-induced kidney injury is a common and unavoidable adverse effect in patients after solid organ transplantation. In this study, we used isolated proximal tubules to examine the trascriptome of a rat model of tubulointerstitial fibrosis induced by tacrolimus administration after ischemia/reperfusion (IR) injury.

Methods: Male Wistar/ST rats (8-week-old) were subjected to IR of both kidneys. Tacrolimus (5 mg/kg/day) or vehicle was administered on consecutive 14 days, starting from the day before IR. All protocols were approved by the Animal Research Committee, Kyoto University.

Results: Immunofluorescence analysis showed that the expressions of the Kim-1 and a-SMA were significantly increased in tacrolimus-treated rats. Hence, these rats were established as rat models of tacrolimus-induced tubulointerstitial fibrosis. The total clearance of intravenously administered metformin, a typical substrate for tubular organic cation transporters, OCT2 and MATE1, decreased to 66 % in tacromilus-treated rats than in the vehicle-treated rats ($p = 0.003$), indicating that tacrolimus-induced tubulointerstitial fibrosis causes the depression of tubular detoxification by drug transporters. Furthermore, microarray analysis (Whole Rat Genome Microarrays, Agilent Technologies) using isolated proximal tubules indicated that the signals for 53 probes, including early growth response-1 (egr-1), increased to more than 2-fold that of vehicle treated rats. It is suggested that the upregulation of these genes is associated with tacrolimus-induced tubulointerstitial fibrosis.

Conclusions: A rat model of tacrolimus-induced tubulointerstitial fibrosis was successfully established, and several genes that are closely associated with the pathology of tacrolimus-induced tubulointerstitial fibrosis were identified.

FR-PO960

Comparison of Mycophenolic Acid Exposure and Gastrointestinal Adverse Effects in Stable Renal Transplant Recipients: Association to Calcineurin Inhibitor Therapy Calvin J. Meaney,[1,2] Rocco C. Venuto,[3] Gregory E. Wilding,[4] Joseph D. Consiglio,[4] Kathleen M. Tornatore.[1,2,3] *[1]Immunosuppressive Pharmacology Research; [2]NYS Center of Excellence, School of Pharmacy; [3]School of Medicine; ECMC; [4]School of Public Health; Univ at Buffalo, Buffalo, NY.*

Background: International consensus guidelines for therapeutic drug monitoring (TDM) of mycophenolic acid (MPA) recommend an area under the concentration-time curve 0-12 hours (AUC) of 30 to 60 mg•h/L for renal transplant recipients (RTR) on cyclosporine (CYA) and mycophenolate mofetil (MMF). There are minimal data to define a target MPA AUC for tacrolimus (TAC) and mycophenolate sodium (ECMPS). This analysis compared MPA AUCs with a novel GI adverse effect (AE) score in RTR receiving CYA-MMF or TAC-ECMPS.

Methods: A prospective cross-sectional analysis of 12 hour pharmacokinetic studies in 147 stable RTR (time post-transplant:4.0±3.2 years) was completed in 80 RTR on CYA-MMF and 67 RTR on TAC-ECMPS without routine MPA TDM. MPA was analyzed by mass spectrometry and MPA AUC was determined by non-compartmental analysis. RTR were assessed for GI AE using a validated scale (diarrhea, dyspepsia, vomiting, acid suppressives) yielding a GI AE score (GI AE). General linear models compared MPA AUC < 30; 30 to 60 and >60 mg•h/L.

Results: Table 1 summarizes the data. RTR on TAC-ECMPS had higher MPA AUCs with 2-fold greater GI AE.

Table 1	CYA-MMF (n=80)	TAC-ECMPS (n=67)	P-value
MPA Dose (mg)	693±215	570±179	<0.001
MPA AUC >60 mg•h/L[+]	71.9±11.8 (13%)	89.9±23.4 (57%)	0.024
MPA AUC 30-60 mg•h/L[+]	44.8±7.2 (56%)	46.1±7.9 (34%)	0.475
MPA <30 mg•h/L[+]	21.3±6.7 (31%)	23.3±3.9 (9%)	0.486
GI AE Score	1.1±1.0	2.5±1.8	<0.001
e-GFR ml/min/1.72m^2	48.8±18.0	55.2±15.7	0.024
Calcineurin inhibitor trough (ng/ml)	129±46.5	7.20±1.89	NA
[+] mean ± standard deviation with (%) RTR in respective AUC range			

Conclusions: The majority of RTR receiving TAC-ECMPS exceeded the recommended MPA AUC range and had more GI adverse effects compared to CYA-MMF. A prospective comparison using TDM is needed to define the optimal 12 hour MPA AUC range that provides immunosuppression with less AE.

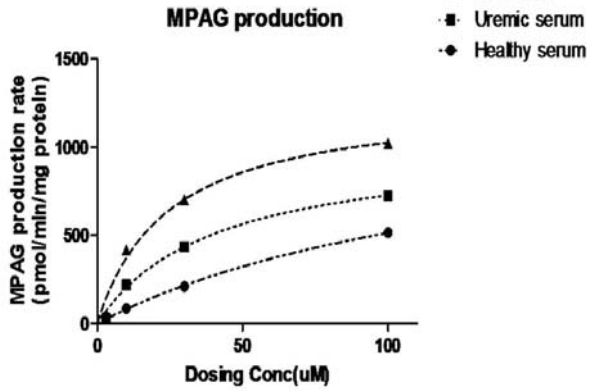
FR-PO961

Explaining Unexpected Drug Toxicities: How Uremic Toxins Alter Hepatic Mycophenolic Acid Disposition Lynda A. Frassetto,[1] Leslie Benet,[1] Jason Baik,[1] Ji Li,[2] Janel Long-Boyle.[1] *[1]UCSF, San Francisco, CA; [2]China Pharmaceutical U, China.*

Background: We have previously studied the effects of uremic serum and specific uremic toxins on uptake and efflux transporters and Phase I metabolizing enzymes (e.g., the cytochrome P450 system), in particular on drug interactions in HIV-infected kidney and liver transplant patients. We now study uremic toxin effects on Phase II metabolizing enzymes, using the glucuronidation of mycophenolic acid (MPA) as our model. MPA clearance can be highly variable; renal function is a strong predictor of unbound (i.e., available) MPA clearance. MPA is taken up in the liver by the organic anion transporter OATP, and glucuronidated to the primary inactive metabolite, MPA 7-O-glucuronide (MPAG).

Methods: Rat hepatocytes and microsomes were incubated with no serum, healthy and uremic human serum, to evaluate MPA uptake and metabolism to MPAG. Rifampin, an inhibitor of OATP was used as a positive control. MPA and MPAG were measured by LC/MS/MS.

Results: MPA uptake by rat hepatocytes was inhibited by 18% in uremic serum ($P<0.05$) and 47% in control serum with rifampin ($P<0.01$) compared with control (healthy) serum. Unexpectedly, microsome studies showed that uremic serum activated metabolism; MPAG production increased and intrinsec clearance increased from 8.7±5.6 to 25.2±10.7 µL/min with the uremic serum compared to the healthy serum, ($p=0.03$, see figure below). There was also a two-fold decrease in MPA protein binding in the presence of uremic serum compared to healthy serum.



Conclusions: Uremic serum plays an important role in MPA disposition through three processes; effects on drug transport, on protein binding and on metabolic enzyme activation leading to increased parent drug clearance. Further studies in human hepatocytes and microsomes are ongoing.

Funding: Clinical Revenue Support

FR-PO962

Uremic Toxins p-Cresol Sulfate and Trimethylamine N-oxide Inhibit the Function of Renal Drug Transporters OAT1, OAT3, and MATE1 Catherine K. Yeung,[1,2] Danny D. Shen,[1,3] Jonathan Himmelfarb.[2] *[1]Dept of Pharmacy, Univ of Washington, Seattle, WA; [2]Kidney Research Inst, Univ of Washington, Seattle, WA; [3]Dept of Pharmaceutics, Univ of Washington, Seattle, WA.*

Background: Renal tubular secretion of drugs and endogenous uremic solutes requires coordinated uptake transport at the basolateral membrane and efflux transport at the apical membrane to effect vectorial movement of drugs from the peritubular vasculature, across the proximal tubular epithelium, and into the tubular lumen for excretion. Inhibition of drug transporter function by circulating uremic toxins leads to altered renal clearance and pharmacokinetic unpredictability in patients with chronic kidney disease, resulting in sub- or supra-therapeutic drug dosing.

Methods: This study evaluated the inhibitory potential of p-cresol sulfate and trimethylamine n-oxide, uremic toxins both associated with cardiovascular disease, on renal uptake (OAT1/3, OCT2) and efflux (MATE1/2K, P-gp, MRP2/4) transporters, using MDCK-II cells expressing recombinant OAT1, OAT3, OCT2, MATE1, MATE2K, or P-glycoprotein and Sf9 vesicles transfected with MRP2 or MRP4.

Results: At 1000 µM p-cresol sulfate, 78.2% ± 1.90% inhibition ($p<0.0001$) was seen for OAT1 and 87.8% ± 17.2% inhibition ($p=0.0027$) was seen for OAT3. Small but statistically significant inhibition was observed for MATE1 (15.0% ± 1.72%, $p=0.0018$) and MRP4 (14.9% ± 5.91%, $p=0.0129$). At a concentration of 1000 µM trimethylamine N-oxide, 12.9% ± 4.96% inhibition ($p=0.0160$) was seen for OAT1 and 22.1% ± 3.88% inhibition ($p=0.0015$) was seen for MATE1. No change was observed in transporter activity for OAT1B3, OAT3, OCT2, or BCRP.

Conclusions: We have shown that p-cresol sulfate and trimethylamine n-oxide inhibit the in vitro activity of multiple renal drug transporters at physiologically relevant concentrations. These alterations in transporter activity may explain the slower and more variable renal drug clearance in subjects with chronic kidney disease. A clearer

understanding of the effects of uremic toxins on proximal tubular drug secretion would allow a more informed strategy for medication selection and dosing in patients with renal impairment.

FR-PO963

The *CYP3A4*22* Allelic Variant Increases the Risk of Tacrolimus Overexposure in Kidney Transplant Recipient

Nicolas Pallet, Eric Thervet. *Hopital Europeen Georges Pompidou.*

Background: A recently described allelic variant of cytochrome P450 3A4, the *CYP3A4*22* allele, is associated with a decreased expression in the liver and lower global metabolic activity. Carriers of this polymorphism have a slower Tac metabolism, and may be at risk of Tac overexposure.

Methods: We tested this hypothesis in a population of 280 kidney transplant recipients.

Results: The frequency of the *CYP3A4*22* allele in the entire cohort was 7.7%, and the vast majority (90%) of the *CYP3A4*22* carriers were non-expressors for the CYP3A5 (*CYP3A5*3/*3*). The risk of Tac overexposure after 6 Tac doses was 12 fold higher in the *CYP3A4*1/*22* patients, and the median serum creatinine concentration was 191 mmol/l in the *CYP3A4*1/*22* patients versus 146 mmol/l, in the *CYP3A4*1/*1* patients, p=0.03. Two months after transplantation, the median Tac dose to reach target concentrations in *CYP3A4*1/*22* patients was 30% lower than in the *CYP3A4*1/*1* patients: 0.08 mg/kg (0.05-0.11) versus 0.11 mg/kg (0.07-0.14), respectively, *p*=0.03.

Conclusions: In conclusion, the presence of the *CYP3A4*22* allele, is associated with a high risk of Tac overexposure 10 days after transplantation, and carriers of this defective allele require 30% lower Tac dose to reach target concentrations.

FR-PO964

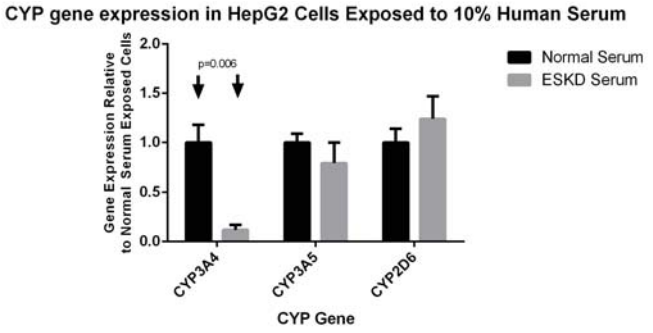
Chronic Kidney Disease Serum Inhibits Transcription of CYP3A4 in a Human Hepatocyte Model

Katie Lane,[1,2] John Dixon,[1,2] Ekram Nabi,[3] Iain Macphee,[2] Barbara J. Philips,[1] Mark E. Dockrell.[3] *[1]Critical Care Medicine, St. George's Univ of London; [2]Renal Medicine, St. George's, Univ of London; [3]South West Thames Inst for Renal Research, London, United Kingdom.*

Background: Hepatic drug metabolism by cytochrome P450 (CYP) is reduced in end stage kidney disease (ESKD). The underlying mechanisms are uncertain. Previous work demonstrated transcriptional and translational inhibition of rodent *CYP3A*, exposing rat hepatocytes to serum from dialysis patients. In the light of known specie-specific differences in CYP regulation, we investigated changes to *CYP3A4, CYP3A5* and *CYP2D6* transcription and protein expression by serum from dialysis patients using a human hepatocyte model.

Methods: Serum was obtained from 10 adults with ESKD immediately prior to haemodialysis and from 6 healthy adults. Pooled serum (1,3,10,30% concentrations) was applied to HepG2 cells (human hepatoma cell line) for 24h. *CYP3A4, 3A5* and *2D6* gene expression was examined by RT-qPCR. CYP protein expression was determined by Western blotting.

Results: Demographics of ESKD patients and controls were similar. There were no significant differences in cell confluence. *CYP3A4* gene expression was suppressed in cells exposed to 10% and 30% ESKD serum, compared to control serum (p=0.006). There was no change in *CYP3A5* or *CYP2D6* transcription.



There was no significant change in CYP3A4 or 3A5 protein abundance with serum type at 24h. CYP2D6 is expressed at low concentration, so could not be detected by Western blotting.

Conclusions: Transcription of *CYP3A4*, but not *CYP3A5* or *CYP2D6,* is suppressed in HepG2 cells following exposure to serum from patients with ESKD, compared to healthy volunteers. Protein abundance is unchanged after 24h serum exposure, longer exposures are under investigation. The responsible molecular pathways have yet to be determined for this pharmacologically important observation.

Tenapanor, a Minimally Absorbed Small-Molecule Inhibitor of NHE3, Reduces Absorption of Sodium and Phosphorus in Healthy Japanese Volunteers

Susanne Johansson,[1] David P. Rosenbaum,[2] Mikael Knutsson,[1] Maria Leonsson Zachrisson.[1] *[1]AstraZeneca R&D, Mölndal, Sweden; [2]Ardelyx Inc., CA.*

Background: Tenapanor (AZD1722) is a first-in-class, small-molecule inhibitor of the Na^+/H^+ exchanger isoform 3 (NHE3) in clinical development for the treatment of patients with kidney disorders. Preclinical and early clinical studies show that tenapanor reduces intestinal absorption of sodium (Na) and phosphorus (P). Here, we report on the safety, pharmacokinetics and pharmacodynamics of tenapanor in Japanese volunteers.

Methods: In this phase 1, double-blind, placebo-controlled study (D5611C00005), healthy Japanese adults received 180 mg single-dose tenapanor hydrochloride or 7 days of tenapanor hydrochloride at one of four doses (15, 30, 60, 90 mg, all bid) or placebo. Participants received a standardized diet across all cohorts. Pharmacodynamic measures included 24-hour stool and urine Na and P.

Results: All reported adverse events were mild, and there were no serious adverse events. Plasma concentrations of tenapanor were above the limit of quantification (0.5 ng/mL) in just three of 516 samples; the highest concentration measured was 0.7 ng/mL. In the single-dose cohort, tenapanor provided numerically higher stool Na and P levels than placebo, in conjunction with lower urine Na and P levels than placebo (table). Similar trends were observed over 7 days in the repeated-dose cohorts.

24-hour excretion, mmol/day, mean (SD)						
	180 mg (n=6)[a]	15 mg bid (n=12)[b]	30 mg bid (n=12)[b]	60 mg bid (n=12)[b]	90 mg bid (n=12)[b]	Placebo (n=13)[c]
Stool						
Na	41.9 (25.5)	21.3 (17.8)	32.2 (16.8)	28.4 (23.4)	30.8 (15.6)	4.1 (3.1)
P	31.0 (11.5)	21.5 (6.5)	23.4 (7.0)	17.6 (7.5)	24.8 (8.6)	16.8 (7.9)
Urine						
Na	110.4 (49.3)	104.8 (17.9)	111.5 (30.7)	105.3 (33.1)	101.2 (32.0)	135.2 (31.8)
P	18.7 (4.4)	17.5 (4.4)	19.4 (3.5)	15.5 (3.9)	15.3 (4.5)	23.5 (4.5)

[a]Single dose; [b]Daily mean over 7 days; [c]Combined data from participants receiving single (n=1) and repeated bid (n=12) doses.

Conclusions: Tenapanor was well tolerated, minimally absorbed and provided reductions in intestinal Na and P absorption in healthy Japanese volunteers. This promising risk–benefit profile suggests that further clinical development of tenapanor is warranted.

FR-PO966

Reduction of Sodium and Phosphorus Absorption Provided by Tenapanor Is Not Affected by Co-Administration of Sevelamer in Healthy Volunteers

Susanne Johansson,[1] David P. Rosenbaum,[2] Maria Leonsson Zachrisson,[1] Mikael Knutsson,[1] Dennis Ruff.[3] *[1]AstraZeneca R&D, Mölndal, Sweden; [2]Ardelyx Inc, Fremont, CA; [3]ICON Development Solutions, San Antonio, TX.*

Background: Tenapanor (AZD1722) is a minimally absorbed small-molecule inhibitor of the Na^+/H^+ exchanger isoform 3 (NHE3) that reduces absorption of dietary sodium (Na) and phosphorus (P). Tenapanor is under investigation for treating patients with chronic kidney disease, who often require therapy with phosphate binders, such as sevelamer, to help to control hyperphosphatemia. *In vitro* studies showed binding between tenapanor and sevelamer, but this finding was not confirmed *in vivo* in rats. Here, we report a human study investigating whether co-administration of sevelamer with tenapanor impacts on the pharmacodynamics of tenapanor.

Methods: In this open-label 2-way crossover study (D5611C00006), 16 healthy adults (median [range] age, 47 [27–58] years; 11 men) were randomized to receive tenapanor hydrochloride 15 mg bid alone for 4 days or tenapanor hydrochloride 15 mg bid and sevelamer carbonate 800 mg tid for 4 days, with a 2-day washout between treatments. A diet standardized for Na content was provided with similar menus in both treatment periods. Pharmacodynamic measures included 24-h stool/urine Na and P levels.

Results: Tenapanor treatment resulted in comparable stool Na and P levels whether administered alone or combined with sevelamer (table). Stool frequency, consistency and weight were also comparable between the regimens. Treatments were well tolerated with no discontinuations due to AEs or serious AEs.

Excretion, mmol/day, mean (SD)			
	Day −1 (n=16)	Tenapanor (n=16) [a]	Tenapanor+sevelamer (n=16) [a]
Stool Na	3.6 (6.2)	29.2 (19.3)	25.7 (17.9)
Urine Na	127.4 (39.8)	133.3 (27.6)	137.2 (30.0)
Stool P	17.1 (9.8)	37.4 (11.4)	37.7 (7.5)
Urine P	31.3 (6.7)	26.2 (5.2)	25.2 (4.9)
[a]Daily mean over 4-day treatment period			

Conclusions: The reductions in intestinal Na and P absorption provided by tenapanor were not affected by co-administration of sevelamer. This suggests that the binding between sevelamer and tenapanor observed *in vitro* does not translate into humans to an extent that is clinically meaningful, if at all.

The Effect of Sodium Nitrite on Blood Pressure, Glomerular Filtration Rate and Fractional Sodium Excretion in Healthy Subjects Jeppe B. Rosenbaek, Safa Al Therwani, Janni Majgaard Jensen, Frank H. Mose, Erling B. Pedersen, Jesper N. Bech. *Univ Clinic in Nephrology and Hypertension, Dept of Medical Research, Holstebro Regional Hospital and Aarhus Univ, Holstebro, Denmark.*

Background: Recent research has shown that sodium nitrite is readily converted to nitric oxide (NO) by enzymes in vivo and exerts a vasodilating effect. The purpose of the present study was to examine the effects of sodium nitrite on blood pressure, heart rate, GFR and fractional sodium excretion.

Methods: In a single blinded, crossover, placebo controlled dose-response study 12 healthy subjects were treated, in a randomized order, with placebo (isotonic NaCl) or one of three doses of sodium nitrite 40, 120 or 240 mg/kg/hour for two hours. Each examination was preceded by 4 days standardized diet**.** The subjects were supine and water loaded throughout the day. Before, during and after sodium nitrite administration we measured diastolic, systolic and mean arterial blood pressure (DBP, SBP and MAP), heart rate, GFR by chrome-EDTA clearance and fractional sodium excretion.

Results: Preliminary data shows no significant change in DBP, SBP, MAP, heart rate, GFR or fractional sodium excretion on either dose of sodium nitrite compared to placebo.

Conclusions: In supine, water loaded subjects the given doses of sodium nitrite exert no hemodynamic or renal effects on the measured parameters. Either the doses are too low, or sodium nitrite has only a marginal effect on renal NO availability in healthy subjects.

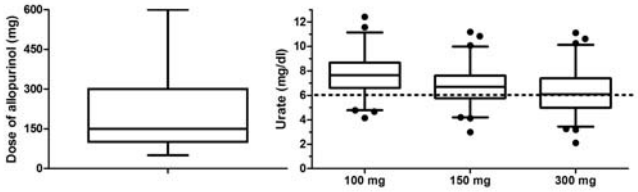
Frequency and Dosing of Uric Acid Lowering Therapy in Patients with CKD 3 – Baseline Data of the German Chronic Kidney Disease (GCKD) Cohort Jan T. Kielstein, Markus Heisterkamp, Stephanie Titze, Johan M. Lorenzen, Martin Busch, Kai-Uwe Eckardt, Anna Kottgen. *GCKD-Study Investigators.*

Background: Uric acid (UA) is a prognostic marker of chronic kidney disease (CKD) progression. Preclinical studies support an independent pathophysiological role of UA in this process. ULT in CKD is challenging as the most frequently used xanthine oxidase inhibitor allopurinol requires dose reduction with reduced GFR. Aim of the study was to analyze the prevalence of ULT and adherence to dose suggested adjustments.

Methods: Baseline data and drug prescription patterns were analyzed in a 1965 patient subset of the GCKD Study, a prospective observational CKD cohort study that enrolled more than 5200 patients with CKD of various aetiologies between 2010 and 2012. At enrollment patients had an estimated glomerular filtration rate (eGFR) of 30-60 mL/min/1.73 m² or overt proteinuria in the presence of a higher eGFR.

Results: Of the 1965 patients (age 62 ± 13 years) investigated 551 (28.1%) received ULT. Median serum urate concentrations in patients without and with ULT were 7.22 [5.98-8.34] and 6.81 [5.72-6.81] mg/dl. The proportion of patients with plasma urate concentrations below a target level of 6 mg/dL was 25% and 31%, resp. Most of the patients with ULT received allopurinol (93.2%). Median allopurinol dose was 150 mg/d. 30.2% of the allopurinol treated patients received a dose of 300 mg/d. Compared with an allopurinol dose of 100 mg/d patients receiving 150 or 300 mg/d had significantly lower urate levels.



Conclusions: Hyperuricemia is frequent in CKD 3 but only less than a third of patients is treated. Treatment frequently fails to lower urate levels below 6 mg/dl. In a third of the patients treated with allopurinol the dose was higher than recommended. Our data indicate that the treatment of hyperuricemia in CKD could be improved in both frequency of treatment and dose adjustment.

Funding: Other NIH Support - The GCKD Study is funded by the Federal Ministry of Research and Education (BMBF) and the nonprofit KfH Foundation of Preventive Medicine. It is conducted under the patronage of the German Society of Nephrology (DGfN)

FR-PO969

An Extended Release Formulation of Torsemide Is More Effective in Enhancing Sodium and Fluid Excretion in Normal Subjects Wen Shen,[1] Salim Shah,[2] Fatima S. Khwaja,[3] Bertram Pitt,[4] Christopher S. Wilcox.[2] *[1]Div of Hypertension & Nephrology, Georgetown Univ Hospital; [2]Georgetown Univ; [3]Sarfez Pharmaceuticals, Inc; [4]Univ of Michigan.*

Background: Despite outstanding acute natriuresis, loop diuretics have limited therapeutic efficacy due to the compensatory renal sodium reabsorption after the diuretic effects wear off. We hypothesized that an extended relases (ER) formulation would enhance salt and water loss.

Methods: Ten normal subjects were randomized to 20mg immediate release (IR) or ER formulation torsemide, and were crossed over to receive the other formulation after 3 weeks. They consumed a fixed diet with 300 mmol·day^{-1} of Na^+. The ER formulation released the drug into solution over 12 hours.

Results: Both formulations increased peak Na and fluid excretion similarly. Natriuresis returned to baseline after 3hrs with IR, but remained elevated for 8-12hrs in ER. This resulted in doubling of fluid (1634 ± 385 versus 728 ± 445 mL; $P < 0.02$) and sodium loss (98 ± 15 versus 42 ± 17 mmol; $P < 0.05$) despite an 18% reduction in torsemide bioavailability with ER. Body weight (-0.5 ± 0.2 kg; $P < 0.05$) and blood pressure (-2.9 ± 1.8 versus +1.3± 1.2 mmHg; $P<0.05$) were reduced only after ER but GFR was reduced only after IR (C_{CR}; -24.5 ± 6.6 ml•min^{-1} per 1.73 m^{-2}; $P < 0.005$). Potassium excretion was unchanged in both groups. The increase of plasma and urine torsemide was delayed and extended after ER, resulting in a 3.5 fold prolongation of Tmax. Increase in sodium excretion was a hysteretic function of the log renal torsemide excretion (an index of delivery to the active site), but the up-trending phase of Na excretion was twice as long with ER.

Conclusions: An ER formulation of torsemide led to weight reduction despite a very high salt intake. It doubled the fluid and sodium loss while maintaing GFR. The enhanced efficacy with ER was related to a reduced time for post-diuretic renal Na^+ retention, a more efficient diuretic effect and a delayed development of within-dose tolerance. This suggests that torsemide ER may be superior to IR under the condition of high salt diet and may be more predictively effective in treating edema and hypertension.

Different Associations of Wall Shear Stress with Lumen Remodeling in Artery and Vein following Arteriovenous Fistula Creation in a Porcine Model Yan-Ting E. Shiu,[1] Daniel B. Pike,[1] Christi M. Terry,[1] Michelle Fitts,[1] Ilya S. Zhuplatov,[1] Alfred K. Cheung.[1,2] *[1]U of Utah, SLC, UT; [2]VASLCHCS, SLC, UT.*

Background: Arteriovenous fistula (AVF) maturation requires the dilation or outward remodeling of the AVF vein. Hemodynamic wall shear stress (WSS) is known generally to affect vascular wall remodeling. However, it is unclear if the relationships between WSS and subsequent lumen area changes are different between the artery and vein of the AVF. We explored these associations in a pig AVF model as a potential explanation for the differential wall remodeling of artery and vein.

Methods: At 1, 2, 6, or 12 wk after the creation of a carotid-jugular AVF in pigs (n=4 at each wk), MR images were acquired to determine the AVF lumen geometry and blood flow rates, which were then used to derive detailed spatial profiles of WSS values (by computational fluid dynamics) and lumen cross-sectional areas. Early WSS values were correlated with later lumen area changes (Darea) over a length of 4 cm, starting from the AV anastomosis.

Results: In both the artery and vein, average lumen area increased from wk1 to wk6 (Table 1); area remained steady thereafter. The absolute and percentage area increases were larger in vein than artery. Average WSS at wk1, wk2, and wk6 was also higher in vein than artery. Importantly, in the artery, WSS at wk1 and Darea from wk1 to wk6 had a *positive* exponential correlation (r^2=0.41, $p<0.0001$) with Darea *increasing* with *increasing* WSS at wk1. In contrast, WSS at wk1 and Darea from wk1 to wk6 had a *negative* exponential correlation (r^2=0.27, $p<0.0001$) in the vein, with Darea generally *decreasing* with *increasing* WSS at wk1.

Table 1: WSS, Area, and Δarea in AVF Artery and Vein

	WSS (dyn/cm²)			Area (mm²)			Δarea wk1 to wk6	
	wk1	wk2	wk3	wk1	wk2	wk3	(mm²)	(%)
Artery	97±40	209±114	272±335	23±3	24±7	44±6	21±7	91±29
Vein	122±67*	383±399†	871±550‡	21±9	69±22‡	64±19‡	43±21‡	205±100‡

Values ± standard deviation.
All comparisons between artery and vein; *p<0.05, †p<0.001, ‡p<0.0001.
Presurgical WSS is 14±3 dyn/cm² in artery and 7±2 dyn/cm² in vein.
Presurgical area is 20±1 mm² in artery and 19±2 mm² in vein.

Conclusions: Our finding of WSS-Darea associations with opposite directions between artery and vein is novel. This difference may partly explain the differences in arterial and venous long-term remodeling observed clinically.

Funding: NIDDK Support

FR-PO971

Effect of Oscillating Shear Stress Derived from Vascular Access on Protein and Gene Expression in Endothelial Cells In Vitro Andrea Remuzzi,[2] Irene Cattaneo,[1] Lorena Longaretti,[1] Marina Figliuzzi,[1] Bogdan Ene-Iordache.[1] *[1]IRCCS Mario Negri Inst, Bergamo; [2]Univ of Bergamo, Dalmine, Italy.*

Background: Failure of arteriovenous fistulas (AVF) for hemodialysis patients is strongly related to progressive stenosis caused by of intimal hyperplasia (IH). Using idealized models of end-to-side AVF we suggested that areas prone to develop IH are exposed to oscillating wall shear stress (WSS) [NDT 2012]. Here we investigated in vitro the effects of oscillating WSS, calculated at the inner wall of the venous segment of AVF, on activation of human umbilical vein endothelial cells (HUVEC), as compared to pulsatile and unidirectional WSS calculated for areas not prone to IH.

Methods: Confluent monolayers of HUVEC were exposed for 48h to oscillating and to pulsatile WSS (range -2.6 to 1.1 and 1.2 to 2.3 Pa, respectively), using a cone-and-plate device. Culture medium was changed each 12 hrs. At 48h we quantified cell morphology. We also quantified MCP1 production (ELISA) by HUVEC and we evaluated mRNA expression of Krüppel-like factor 2 (KLF2, a transcription factor that mediates flow induced anti-inflammatory effects on EC) by real time-PCR.

Results: HUVEC exposed to oscillating WSS did not align nor elongate with flow while pulsatile WSS strongly elongated and aligned cells with flow. MCP1 production was higher ($p<0.05$) in HUVEC exposed to oscillating WSS, as compared to pulsatile flow (5.0+0.7 versus 2.1+0.5 ng/hr/10^6 cell, n=3). In HUVEC exposed to oscillating WSS, KLF2 mRNA levels were comparable to those estimated in static cultures (1.4 fold increase, NS) but they were significantly increased in HUVEC exposed to pulsatile WSS (3.7 fold increase, $p<0.01$).

Conclusions: Our findings indicate that exposure to oscillating WSS importantly affect EC structure and pro-inflammatory state. Thus, disturbed flow importantly increased MCP1 production and decreased KLF2 expression in EC, at variance to unidirectional flow. This pro-inflammatory condition may selectively induce monocyte recruitment in AVF areas subjected to oscillating flow. These changes in protein and gene expression may be responsible for local development of IH and subsequent AVF stenosis.

FR-PO972

Arteriovenous Fistula Remodeling in a Rat AVF Model Timmy C. Lee, Maheshika Srimali Somarathna, Lingling Guo. *Medicine, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Neointimal hyperplasia development and poor vascular remodeling are the most common etiologies of arteriovenous fistula maturation (AVF) failure. The aim of this study was to evaluate in a rat AVF model: (1) serial arterial and venous morphometric changes and (2) changes in expression in the artery and vein of key remodeling proteins, matrix metalloproteinase 2 and 9 (MMP-2 and MMP-9).

Methods: AVFs were created using an end to side anastomosis between the femoral vein and artery in 16 week old Sprague-Dawley rats. These rats were sacrificed at 7, 14, 21, and 28 days after creation. Morphometric analyses of the arterial and venous anastomosis were performed. Immunohistochemical analysis from the vein and arterial anastomosis was performed to evaluate expression of MMP-2 and MMP-9.

Results: A progressive increase in average intima/media area was seen at both the arterial and venous anastomosis, respectively, at 7, 14, 28, and 42 days. MMP-2 expression in both the vein and artery peaked at 7 days with a secondary peak again at 21 days. MMP-9 expression in the vein and artery remained elevated from 7 days to 21 days, with a decline in expression at 28 days.

	7 Days	14 Days	21 Days	28 Days
Average Intima/media area (vein)	2.37	4.17	4.06	6.77
Average Intima/media area (artery)	0.258	0.130	0.521	0.545
MMP-2- % stain (Vein)	26.5%	7.34%	19.9%	14.4%
MMP-2- % stain (artery)	10.6%	4.85%	12.5%	3.5%
MMP-9- % stain (Vein)	50.7%	29.1%	31.1%	19.3%
MMP-9- % stain (Artery)	20.9%	21.8%	22.7%	16.7%

Conclusions: Our results suggest a progressive remodeling pattern in both the vein and artery after AVF creation. MMP expression is substantially elevated early after AVF creation suggesting an initial vascular remodeling response with a decline in expression at later time points. Further pathophysiologic insight of the role MMPs play in AVF remodeling after AVF creation may improve our understanding of AVF maturation failure.

FR-PO973

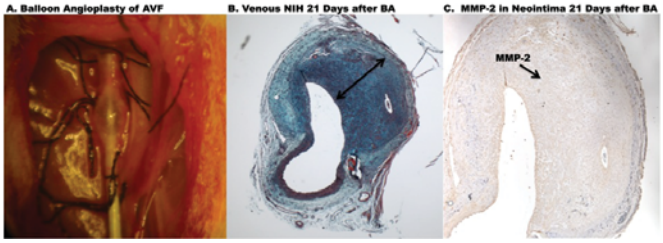
A Novel Model of Balloon Angioplasty Injury in Rat Arteriovenous Fistula Timmy C. Lee, Maheshika Srimali Somarathna, Lingling Guo. *Medicine, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Balloon Angioplasty (BA) remains the primary therapy to treat arteriovenous fistula (AVF) maturation failure and AVF stenosis. However, BA procedures injure the vascular endothelium, leading to recurrent and aggressive neointimal hyperplasia (NIH) development. The lack of a rodent model to study BA injury is a major gap in the field as it hinders insight into the pathogenesis of BA injury in AVF and development of better therapies to prevent and treat BA injury to prolong AVF patency. The aim of this study was to develop a rat model of BA injury in AVF.

Methods: BA of 16 week old Sprague-Dawley rats were performed: (1) in the femoral vein immediately prior to creation of AVF (end to side anastomosis of the femoral vein to femoral artery) (group 1) and (2) in AVFs at the juxta-anastomosis 14 days after creation without pre-AVF creation angioplasty (group 2). We assessed for changes in NIH development and expression of key vascular remodeling proteins, matrix metalloproteinases 2 and 9 (MMP-2 and MMP-9) at serial time points following BA.

Results: In group 1, the mean intima/media area of the venous anastomosis at 14 and 21 day post-angioplasty and AVF creation was 1.99 and 9.27, respectively, with a progressive increase in staining primarily within the neointima for MMP-2 and 9 from 14 to 21 days. In group 2, the mean intima/media area of the venous anastomosis was 2.80 and 11.7 at 7 and 14 days after BA, respectively, with also a progressive increase in MMP-2 and 9 staining primarily within the neointima from 7 to 14 days.

Conclusions: Our novel rat model of BA injury in AVF displays similar features to BA injury in humans. Rats developed progressive NIH with early remodeling following BA injury. Our BA model will allow for future studies to evaluate the pathophysiologic mechanisms of BA injury in AVF and test therapies to prolong AVF survival after BA procedures.



FR-PO974

Assessment of Novel Antithrombotic Fusion Proteins for Inhibition of Arteriovenous Graft Stenosis Christi M. Terry,[1] Ilya S. Zhuplatov,[1] Yuxia He,[1] Daniel Orme,[1] Alfred K. Cheung,[1] Tze-Chein Wun.[2] *[1]Internal Medicine, UofUT, SLC, UT; [2]EVAS Therapeutics, LLC, Ballwin, MO.*

Background: Coagulation generates activated platelets, fibrin and mural thrombi that may promote neointimal hyperplasia (NH) and stenosis of arteriovenous grafts (AVG). Two novel proteins, A6L15 and TAPANV, contain Kunitz protease inhibitor domains that target the tissue factor/VIIa and FVa/Xa coagulation complexes, respectively. The proteins are fused to annexin V domains that target the proteins to thrombogenic membranes to locally inhibit thrombosis. We tested these proteins for efficacy against NH in a pig model of AVG stenosis.

Methods: TAPANV was added to blood (20 mg/mL) and activated clotting times (ACT) were assessed *in vitro* (n=8). Pigs received an i.v. bolus of either protein (300 mg). The synthetic graft lumen and a segment of isolated carotid artery and jugular vein were irrigated with 100 mg/mL of A6L15 (n=11) or TAPANV (n=10) for 5 min during AVG creation. Control pigs with AVG received systemic heparin (n=14) or nothing (n=1). At 4 wks, pigs underwent MRI of the AVG, the AVG was explanted and vein-graft tissue was used for histological assessment of NH. Blood was collected for ACT, prothrombin times (PT) and activated partial thromboplastin times (aPTT) before and after surgery.

Results: TAPANV prolonged ACT *in vitro* compared to no drug (160.5±36 versus 97.9±5.7 sec, $p<0.05$). The AVG of the untreated pig clotted at surgery. Post-surgical ACT and aPTT were unchanged from pre-surgical values with either protein, or with heparin. Post-surgical PT were prolonged with A6L15 and heparin treatments (A6L15: 10.5±0.5 versus 10.8±0.5 sec, $p<0.05$, n=11; Heparin: 10.4±0.3 versus 10.7±0.4 sec, $p<0.05$, n=12) but not with TAPANV ($p=0.254$; n=10). No delays in healing or overt bleeding episodes were observed during follow-up. There was no significant difference between the protein-treated and control groups in NH development at the vein-graft anastomoses, as determined by MRI or histology.

Conclusions: TAPANV or A6L15 were safe and inhibited perisurgical AVG thrombosis yet did not inhibit AVG NH when applied at time of surgery. These results suggest acute localized inhibition of thrombosis does not inhibit NH in AVG.

Funding: Other NIH Support - NHLBI

FR-PO975

Outcomes following Percutaneous Thrombectomy for Polytetrafluoroethylene and Bovine Hemodialysis Grafts Karthik Karanam, Theodore F. Saad. *Section of Renal & Hypertensive Diseases, Christiana Care Health System, Newark, DE.*

Background: Percutaneous thrombectomy (PT) is commonly performed for treatment of thrombosed hemodialysis grafts. Data on PT success and patency for polytetrafluoroethylene (PTFE) versus bovine grafts are limited. Our study purpose was to compare clinical success of PT for PTFE versus bovine grafts and to assess post-PT patency based upon time from surgical graft placement to 1st thrombosis.

Methods: We retrospectively reviewed all PT procedures done by interventional nephrologists for 1st graft thrombosis from 2009-2013. Cases were identified and data collected from a prospectively maintained database containing all procedure outcomes and interventions. We recorded: date of graft placement, graft material (PTFE versus bovine), surgeon, date of 1st thrombosis, procedure clinical success (graft usable for next dialysis treatment), primary patency (PP), secondary patency (SP), and rate of interventions performed to maintain graft patency. Outcomes were determined for all cases combined, and for sub-groups of PT performed at 0-45, 46-90, and >90 days post graft placement.

Results: 302 PT procedures for 1st thrombosis were identified. PT was successful in 204/226 (90.3%) PTFE and 68/76 (89.5%) bovine grafts. For PTFE versus bovine, success

rates were 25/31 (80.6%) versus 10/11 (90.9%) at 0-45 days, 30/35 (85.7%) versus 10/14 (71.4%) at 46-90 days, and 149/160 (93.1%) versus 48/51 (94.1%) at >90 days respectively. Post-PT patency rates are reported in the table:

Kaplan-Meier graft patency % (PTFE vs. bovine)				
Days post graft	6 month PP	6 month SP	12 month SP	24 month SP
0-45	25.8 vs. 0	61.3 vs. 72.7	51.6 vs. 45.5	45.2 vs. 27.3
46-90	22.5 vs. 43.8	74.3 vs. 64.3	71.4 vs. 50.0	68.6 vs. 42.9
>90	35.6 vs. 33.3	81.9 vs. 74.5	78.1 vs. 72.5	74.4 vs. 62.7
ALL	31.9 vs. 31.6	77.7 vs. 72.4	73.2 vs. 68.4	69.2 vs. 60.5

The mean number of interventions to maintain graft patency was 2.6/yr for PTFE and 2.5/yr for bovine grafts. No comparisons achieved statistical significance.

Conclusions: PT clinical success and post-PT primary and secondary patency rates are no different for PTFE versus bovine grafts treated for thrombosis at any time interval post graft implantation. Intervention rates are the same for PTFE and bovine grafts.

FR-PO976

Endovascular Salvage of Immature Hemodialysis Arteriovenous Fistula

Venkatesh Rajkumar Sridharan, Yong-Soo Kim. *Div of Nephrology, Dept of Medicine, The catholic Univ of Korea Seoul St. Mary's Hospital, Seoul, Korea.*

Background: The rising CKD population along with the understanding that arteriovenous fistula (AVF) is the closest to an ideal vascular access has resulted in the creation of a lot of AVF including a number of marginal cases. This has resulted in immature fistulas as one of the common problems associated with AVF.

Methods: A retrospective analysis over a three year period (Jan 2011- april 2014) of all the cases of immature AVF referred to a large tertiary care hospital in seoul,south korea. We have analysed the anatomical causes for immaturity and the success rate of endovascular salvage procedures done.

Results: There were 25 radiocephalic,25 brachiocephalic and 2 transposed brachiobasilic fistulas.Mean interval from access creation to referral for angiography was 103+/-67 days (44-349days).Anatomical problems were identified in all the cases.The causes of immature AVF were stenosis (67.3%),accessory veins (9.6%),both (17.3%) and others (5.8%).Inflow stenosis predominated in forearm AVF whereas in the upperarm AVF outflow stenosis was marginally higher than inflow stenosis.The technical and clinical success rates were 94.2% and 90.4% respectively.

Conclusions: The referral for immature fistulas is late. Close follow up of created AVF is needed to detect immature ones at the earliest and endovascular salvage of them can be done with a good success rate.

FR-PO977

Outcomes of Incisional Percutaneous Thrombectomy for Aneurysmal Arteriovenous Fistulae

Theodore F. Saad.[1] *[1]Section of Renal & Hypertensive Diseases, Christiana Care Health System, Newark, DE; [2]Nephrology Associates, PA, Newark, DE.*

Background: Percutaneous thrombectomy (PT) is commonly performed for treatment of thrombosed hemodialysis fistulae using various methods and devices. Dilated aneurysmal fistulae present a particular challenge and conventional percutaneous methods may not be effective. We describe results of a modified PT technique utilizing a small incision for direct thrombus extraction.

Methods: The incisional PT technique involves bidirectional percutaneous access with balloon occlusion of arterial inflow and venous outflow. A 1 cm incision is made over the fistula, thrombus extracted using Kelly forceps and manual maceration, and the incision sutured closed. All stenoses are treated with angioplasty or stenting as required. We retrospectively reviewed all incisional PT procedures done for fistula thrombosis from 2009-2014. Cases were identified and data collected from a prospectively maintained database containing all procedure outcomes and interventions. We recorded: clinical success (fistula usable for next dialysis session), primary and secondary patency, and interventions performed to maintain fistula patency.

Results: 44 incisional PT procedures were performed in 38 patients (6 had procedure twice). PT was successful in 42/44 (95.5%). Post-PT patency rates following 38 first incisional PT are reported in the table:

Patency				
	3 month	6 month	12 month	24 month
Primary	53%	29%	24%	24%
Secondary	74%	63%	55%	53%

The mean number of interventions to maintain fistula patency was 1.8/yr. There were no immediate procedure complications. 3 required stents at the index procedure and 3 at subsequent procedures. Two subjects required surgical ligation <30 days post thrombectomy due to bleeding and infection from fistula ulcerations, unrelated to the thrombectomy incision.

Conclusions: Incisional PT can be performed with high clinical success for aneurysmal fistulae considered unsalvageable using conventional PT techniques. Primary patency rates are low, in part due to low threshold for early re-intervention. Acceptable secondary patency can be achieved with intervention rates similar to other reports. Ulcerated fistula aneurysms may pose higher risk for infection and hemorrhage post thrombectomy.

FR-PO978

Annual Decline in Pentraxin 3 Is a Risk of Vascular Access Troubles in Hemodialysis Patients

Kei Nagai,[1] Toshiaki Usui,[1] Atsushi Ueda,[2] Chie Saito,[1] Kunihiro Yamagata.[1] *[1]Nephrology, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Nephrology, Univ of Tsukuba, Hitachi Medical Education and Research Center, Hitachi, Ibaraki, Japan.*

Background: Pentraxin 3 (PTX3), a multifunctional modulator of the innate immuno-inflammatory response, is higher in patients undergoing hemodialysis than healthy control. Our study focused on annual change in plasma PTX3 levels in patients with chronic hemodialysis, because regularly undergoing hemodialysis for many years modify vascular inflammatory status.

Methods: To demonstrate whether annual change in PTX3 is associated with vascular events, we measured blood levels of pentraxins (PTX3 and high-sensitivity C-reactive protein [hsCRP]) at baseline and in the next year in 76 hemodialysis patients and observed 20 patients with vascular access troubles during follow-up years.

Results: The annual decline in plasma PTX3, but not serum hsCRP, is a significant risk of the incidence of vascular access trouble that is a critical and specific complication for hemodialysis patients (hazard ratio; 0.732 per +1 ng/mL/year in PTX3, **P*=0.039).

	Unadjusted			Adjusted by DM, sex, age, dialysis-period and BMI		
	Hazard Ratio	95% C.I.	*P*-value	Hazard Ratio	95% C.I.	*P*-value
Baseline PTX3	1.006	0.836 - 1.211	0.951	1.237	0.936 - 1.635	0.136
ΔPTX3	0.849	0.680 - 1.061	0.151	0.732	0.544 - 0.985	*0.039
Baseline hsCRP	3.644	0.469 - 28.30	0.216	2.713	0.389 - 18.92	0.314
ΔhsCRP	9.486	0.108 - 833.2	0.324	3.605	0.033 - 394.7	0.592

The incidence of vascular access troubles during follow-up years were set as the outcome. Co-variants examined in Table.II were used for adjustment. * P < 0.05. Abbreviations: C.I., Confidential Intervals: ΔPTX3, Annual change in pentraxin 3 (ng/mL per year): ΔhsCRP, Annual change in high-sensitivity C-reactive protein (mg/dL per year).

Conclusions: This study is the first to focus on the annual change of pentraxins in a hemodialysis cohort.

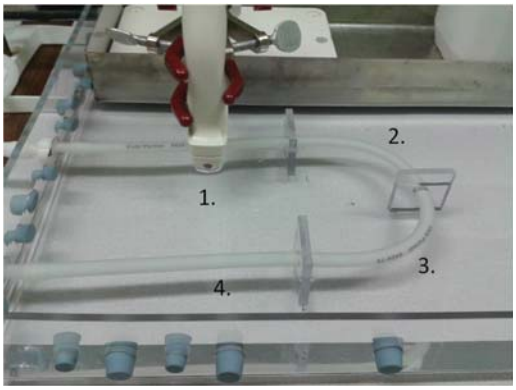
FR-PO979

Re-Introducing Spiral Flow in a Vascular Access Graft Using a Spiral Inducing Stent

Shona Matthew,[1,2] Alexandra Webb,[2] Efstratios Kokkalis,[1] Malcolm Harry Dunn,[2] John Graeme Houston.[1,3] *[1]CVDM, Univ of Dundee, Dundee, United Kingdom; [2]Physics, Univ of St. Andrews, St. Andrews, United Kingdom; [3]Radiology, NHS Tayside, Dundee, United Kingdom.*

Background: Single spiral flow (SSF) patterns observed in arteries are thought to be initiated by the contraction of the heart and maintained by the geometry of the aortic arch. The turbulent flow patterns found around haemodialysis (HD) vascular access (VA) points have been linked to stenosis and are thought to contribute to VA failure at the distal anastomosis (DA). The reintroduction of SSF in vascular grafts has been linked to improved graft patency. This study investigated flow patterns through a U-bend of similar geometry to a HD VA graft before determining the impact of a SSF inducing stent (SSFiS) on flow patterns through the DA and beyond the graft.

Methods: A flow-rig consisting of an acrylic tank, 8mm C-flex vessel-mimic (VM) (Cole-Parmer, UK), SSFiS (Vascular Flow Tech, Ltd, UK), and a UHDC flow-pump (Shelley, Canada). The tank and tubing were filled with tissue-mimic (TM) (9% glycerol in distilled water) and blood-mimic (BM) (Model 707, ATS, U.S.A.).



Colour Doppler Images of flow patterns were acquired using an HDI 5000 ultrasound scanner (ATL US, U.S.A.).

Results: When the SSFiS was placed before the U-bend (brachial artery) the geometry of the vessel-mimic rapidly destroyed the SSF pattern created by the stent. When the

SSFS was placed after the u-bend, (distal graft) the spiral stent consistently re-ordered the flow pattern created by the U-bend into a SSF pattern that propagated through the DA and 20cm downstream.

Conclusions: This study demonstrates that to reintroduce spiral flow in a u-shaped conduit such as VA graft a SSFiS should be inserted in the distal limb of the graft. Although grafts are now being made which induce SSF (VFT), it may be appropriate to consider placement of a SSFiS in distal grafts to re-introduce SSF in the DA.

FR-PO980

Improving Blood Flow Parameters in Central Vein Catheter Dialysis Shona Matthew,[1,2] Alexandra Webb,[2] Efstratios Kokkalis,[1] Malcolm Harry Dunn,[2] John Graeme Houston.[1,3] *[1]CVDM, Univ of Dundee, Dundee, United Kingdom; [2]Physics, Univ of St. Andrews, St. Andrews, United Kingdom; [3]Radiology, NHS Tayside, Dundee, United Kingdom.*

Background: Blood flow in human arteries and veins has been widely reported as single spiral flow and is thought to reduce turbulence that causes stenosis. Turbulent flow is found around central vein catheters (CVC) used for haemodialysis (HD) and has been linked to the formation of a stenosis due to disturbance of the central vein endothelial cells. We investigate the effects of CVC insertion on flow patterns within a vessel during and between simulated HD sessions.

Methods: An in vitro flow-rig consisting of an acrylic tank, 8mm C-flex vessel-mimic (VM) (Cole-Parmer, UK) in an anatomically relevant geometry, with and without a spiral inlet profile (SIP) stent (Vascular FlowTechnologies, UK), and a UHDC flow-pump (Shelley Medical Imaging, Canada). The tank and VM were filled with tissue-mimic (TM) (9% glycerol in distilled water) and blood-mimic (BM) (Model 707, ATS, U.S.A.) respectively. A 25cm HD catheter (Cannon II Access) was inserted into the VM and attached to a HD machine (Fresenius, Germany). Images of flow patterns were acquired using an HDI 5000 ultrasound scanner (ATL Ultrasound, U.S.A.).

Results: When BM flowed at 330ml/min through VM with a laminar inlet profile, Poiseuille flow was observed. When BM flowed through VM with a SIP, a flow pattern suggestive of a single spiral flow was observed to propagated 17.5cm downstream. On insertion of a CVC to VM with SIP, single spiral flow was observed to propagated 15cm downstream of the catheter. Connecting the CVC to the HD machine and passing BM through the CVC at 320ml/min destroyed the spiral flow creating a turbulent profile.

Conclusions: This preliminary study has demonstrated that using a spiral inducing stent before a CVC propagates spiral flow in the vessel 15 cm beyond the end of a CVC in keeping with normal central vein flow which is associated with reduced turbulence. When flow is initiated in the catheter a turbulent pattern is observed, regardless of the inlet profile. These findings may suggest a means of reintroducing normal spiral flow in central veins with a CVC catheter in place in order to reduce turbulence.

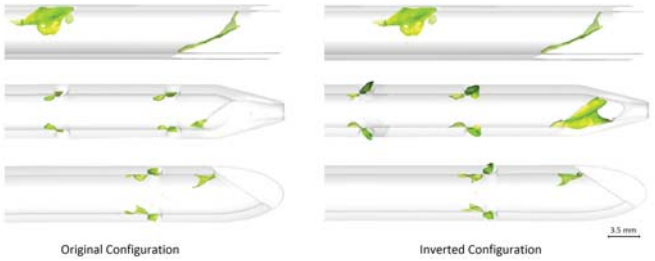
FR-PO981

Comparison of Flow Velocity Reversal among Symmetrical Tip Dialysis Catheters Using Computational Flow Dynamics Timothy Clark,[1] Giuseppe Isu,[2] Diego Gallo,[2] Pascal Verdonck,[3] Umberto Morbiducci.[1] *[1]Radiology, Univ of Pennsylvania, Philadelphia, PA; [2]Mechanical and Aerospace Engineering, Politecnico di Torino, Turin, Italy; [3]Inst Biomedical Technology, Ghent Univ, Gent, Belgium.*

Background: Thrombosis remains a failure mode of all chronic dialysis catheters, in part from flow stagnation from reversal of blood velocity opposite to the main direction of flow. We compared reversed blood velocity among three symmetrical tip catheters using computational flow dynamics (CFD).

Methods: A validated CFD model simulated three symmetrical tip dialysis catheters (Palindrome, Glidepath and VectorFlow) at 400 mL/min within the superior vena cava. To characterize the velocity of blood entering the catheters through the terminal tip and sideholes (before purely laminar, unidirectional flow) we partitioned arterial lumen blood into finite volume elements 5.0 cm distal to the last sidehole, and calculated the volume of blood with reversed velocity at any moment in time with respect to the main direction of flow. Each catheter was run in forward and inverted directions.

Results: The Glidepath showed the highest percentage of reversed velocity within the arterial lumen (6.7% forward, 6.8% inverted) followed by Palindrome (5.6% forward, 5.6% inverted) and VectorFlow (3.3% forward, 3.7% inverted). Blood pathline analysis showed the reversed velocity blood flow in the Glidepath was from geometric asymmetry of the distal guidewire aperture producing flow perturbation when run in inverted configuration. Flow stagnation zones were found most prominently around catheter sideholes and terminal apertures



[Figure, zones shown in green], where laminar flow entering from the catheter tip becomes interrupted by sidehole inflow with resultant areas of velocity reversal.

Conclusions: Blood velocity reversal was seen within each symmetrical tip design which was lowest within the VectorFlow catheter.

FR-PO982

The Relationship between Doppler Parameters and Autologous Arteriovenous Fistulae Dysfunction Xiaotong Xie, Xiaoliang Zhang, Hong Liu. *Nephrology, Zhongda Hospital, Southeast Univ, Nanjing, Jiangsu, China.*

Background: Autologous arteriovenous fistulae (AVF) dysfunction is one of the most common complications in maintenance haemodialysis patients (MHD). Doppler ultrasonography (DU) has been considered as a useful technique to access the function of AVF, whereas the characteristics of doppler parameters are not established. The current study is aimed to reveal the relationship between doppler parameters and AVF dysfunction.

Methods: MHD patients with AVF treated in this hospital were included in this study. DU was used to examine the AVFs in MHD patients. They were grouped according to fistulae's function. Fistula dysfunction was defined as: the blood flow was less than 200 ml/min, except technical and hemodynamic reasons during dialysis. In this study, we analyzed the characteristics of doppler parameters and the relationship between these parameters and arteriovenous fistulae dysfunction.

Results: 1) 145 patients were concluded in this study, aged 23 to 88 years old. There were 126 cases with wrist fistula and 19 cases with elbow fistula. 2) According to the function of AVF, patients were divided into well-functional group (115 cases) and dysfunctional group (29 cases). The blood flow volume and anastomosis diameter showed a significant reduction in dysfunctional group compared with well-functional group (803.84 ± 108.91ml/min *versus* 1150.62 ±63.6ml/min and 0.47±0.02cm *versus* 0.37±0.03cm, respectively, $P<0.05$), the patients' age and the resistance index (RI) showed a significant increase in dysfunctional group compared with well-functional group (66±3years old *versus* 56±1years old and 0.55±0.03 *versus* 0.48±0.01, respectively, $P<0.01$). 3) We further grouped patients according to the quarterback of blood flow, RI, anastomosis diameter and analyzed the incidence of fistula dysfunction within each group. Finally, we found out that the threshold indices for blood flow volume is 641.3 ml/min, the RI 0.41 and the anastomosis diameter 0.39 cm.

Conclusions: DU examination is helpful to early detect AVF dysfunction. The threshold doppler indices provide important experimental evidence for early intervention.

FR-PO983

Morphometric and Histologic Parameters in Veins of Diabetic Patients Undergoing Fistula Placement Ivana Lazich,[1] Anthony Chang,[2] Sydeaka Watson,[3] Mary S. Hammes.[1] *[1]Dept of Medicine, Section of Nephrology, Univ of Chicago; [2]Dept of Pathology, Univ of Chicago; [3]Dept of Health Studies, Univ of Chicago.*

Background: Diabetic patients have higher rates of arteriovenous fistula (AVF) failures due to inadequate vascular remodeling. Upper arm AVFs, such as brachiocephalic fistula (BCF) have superior outcomes in this population, when compared to lower arm AVFs, for unclear reasons. The aim was to compare indicators of vascular remodeling and endothelial dysfunction in veins of patients with or without diabetes at the time of surgical placement.

Methods: Vein samples were collected from patients at time of BCF creation. Morphometric measurements were obtained using Image J software for percentage of luminal stenosis and intimal to medial area and thickness ratios. Histological analysis, for extent of intimal and medial fibrosis, level of endothelial nitric oxide synthase (eNOS) expression and degree of intimal presence of myofibroblasts, was done by immunohistochemical staining and scored in a semi-quantitative manner. Comparison of diabetics and nondiabetics was done using Wilcoxon rank sum and Fisher's exact tests.

Results: 18 patients were included; 10 were diabetics. There were no differences in age, B/P control, phosphorus levels and days spent on dialysis the year preceding BCF placement. There was a significant difference in the measurement of luminal and medial area between groups, with diabetics having a larger luminal area of average 832001.18 μm^2 (317582.17-3695670.36) $p<0.05$. The maximal intimal to medial thickness ratio was higher in diabetic veins (0.24 versus 0.71, $p<0.05$) along with higher maximal intimal thickness (115.14 versus 312.12 µm, $p<0.05$). Degree of eNOS expression, fibrosis and degree of myofibroblast predominance in the intima of diabetic veins, was not found to be different ($p>0.05$).

Conclusions: There is a significant difference in vascular wall remodeling between diabetic and nondiabetic patients veins at the level of the cephalic vein at the time of BCF placement. The unexpected finding of a larger luminal area in diabetic veins could be a major factor positively affecting BCFs outcomes in a patient population with otherwise impaired remodeling.

FR-PO984

Significant Heterogeneity Exists in the Conformation of Native Arteriovenous Fistulae Richard W. Corbett, Lorenza Grechy, Paul Elliot Herbert, Jeremy Crane, Francesco Iori, Wladyslaw M. Gedroyc, Colin Caro, Peter E. Vincent, Neill D. Duncan. *Imperial College London, London, United Kingdom.*

Background: Native arteriovenous fistulae (AVF) for haemodialysis are susceptible to non-maturation due to the formation of peri-anastomotic neointimal hyperplasia (NIH). Features of the flow field are believed to be implicated in the formation of this adverse pathology. Computational fluid dynamic simulations of idealised blood flow highlight the

importance of local geometry, in particular curvature of the native artery. Furthermore, CFD and animal models predominantly consider the fistula as a two-dimensional (planar) structure but little is understood about the three-dimensional geometry of native fistulae in patients.

Methods: As part of a continuing ethically approved observational cohort study, 11 patients underwent creation of an end-to-side radio- or brachio-cephalic fistula within our centre following current surgical best practice. Phase-contrast MRI was performed on the day of surgery to obtain AVF luminal geometry along with Doppler ultrasound to measure bulk flow within each vessel. MRI data was segmented and then reconstructed for use in individualised CFD studies and qualitative analysis of local geometry.

Results: A wide variation in arterial geometry and conformation was noted, with the venous anastomosis arising from both the inner and outer curvature of upper arm arteries irrespective of AVF site. There was a significant heterogeneity in the planarity of both the venous limb and the native artery.

Conclusions: AVF are not planar structures but demonstrate significant non-planarity and variations in arterial curvature within current practice. Non-planarity may have significant theoretical benefits promoting favourable flow conditions. The association of patient-specific CFD studies with clinical outcomes from a larger cohort study may help define the correlates of successful AVF surgery and allow the identification of strategies to minimise the unacceptably high rate of non-maturation in native AVF.

FR-PO985

Intraoperative Measurement of Vessel Wall Oxygenation During Formation of Native Arteriovenous Fistulae Richard W. Corbett, Neil T. Clancy, Paul Elliot Herbert, Jeremy Crane, Peter E. Vincent, Colin Caro, Neill D. Duncan, Daniel Elson. *Imperial College London, United Kingdom.*

Background: Native arteriovenous fistulae (AVF) for haemodialysis are susceptible to non-maturation due to the formation of peri-anastomotic neointimal hyperplasia (NIH). Animal studies have demonstrated the presence of arterial wall hypoxia immediately following the creation of a fistula and a temporal correlation with cellular proliferation, suggesting a causative role for hypoxia in NIH development. This study was designed to assess the feasibility of intraoperative measurement of vessel wall oxygenation.

Methods: As part of a continuing, ethically approved observational cohort study, 11 patients underwent creation of an end-to-side radio-or brachio-cephalic arteriovenous fistula following current surgical best practice. Optical evaluation was made using a novel multispectral imaging system based around a white light source and a liquid crystal tunable filter attached to a monochrome camera. A correlate of oxy- to deoxy-haemoglobin ratio along with indicators of total haemoglobin and oxygen saturations were measured in the peri-anastomotic area with the vessels flushed and after re-perfusion with blood.

Results: Comparison of the calculated correlate of total haemoglobin across the visible spectrum revealed a divergence in the red end of the spectrum (over 580nm) when the anastomosis was flushed free of blood in comparison to the fully perfused anastomosis, suggesting that the blue-green signal was influenced mostly by the optical properties of the wall. This could allow the creation of patient specific maps of peri-anastomotic wall oxygenation.

Conclusions: Rapid changes in vessel wall oxygenation may occur after creation of AVF due to impaired luminal mass transfer of oxygen resulting from adverse changes in the flow field. Multispectral imaging could offer a non-invasive technique to differentiate between vessel and luminal oxygenation at the time of surgery, in turn allowing the evaluation of the role of hypoxia in the development of NIH and deleterious clinical outcomes.

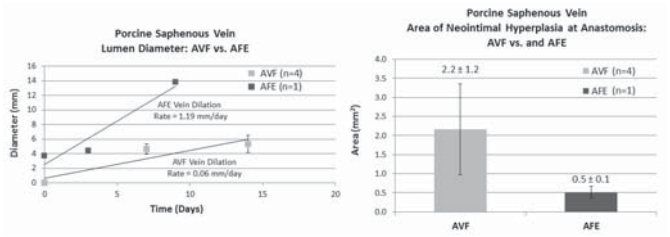
FR-PO986

Improved Vein Maturation in Porcine Model Using Rotary Blood Pump System when Compared to AVF Nicholas Franano,[1] Howard M. Loree,[2] Mark R. Cunningham,[3] Dale M. Groth,[3] Lesley A. Szenay,[3] Barrett S. Hutto,[4] James Lee,[4] Steve P. Woodard,[4] Geoff D. Tansley,[5] Bradley S. Dixon.[6] *[1]Flow Forward Medical, Olathe, KS; [2]Flow Forward Medical, Lowell, MA; [3]Surpass, Osceola, WI; [4]CIRTEC Medical Systems, Los Gatos, CA; [5]School of Engineering, Griffith Univ, Gold Coast, QLD, Australia; [6]Carver College of Medicine, Univ of Iowa, Iowa City, IA.*

Background: The Arteriovenous Fistula Eligibility (AFE) System™ is designed to rapidly dilate peripheral veins prior to AVF surgery by increasing vein wall shear stress (WSS), thereby enhancing AVF eligibility and maturation. Pilot *in vivo* studies compared rates of outflow saphenous vein (SV) dilation and amount of neointimal hyperplasia (NIH) at the venous anastomosis in AFE System and AVF treated pigs.

Methods: The prototype device comprised an extracorporeal centrifugal blood pump, cuffed and heparin-coated inflow/outflow conduits, and a benchtop power unit. It was implanted in a 25 kg pig in a left external jugular vein-to-left SV configuration and the SV was treated for 9 days at a target WSS level of 4 Pa. In two other pigs, bilateral SV-to-femoral artery AVFs were created and allowed to mature for 4 weeks (n = 4 AVFs). Vein dilation and anastomotic NIH area were assessed by angiography and histology, respectively.

Results: Angiography showed a significant increase in the rate of outflow vein dilation with the AFE System (1.19 mm/day) compared to AVF treatment (0.06 mm/day). Histology displayed an important reduction in NIH in veins with the AFE System (0.5±0.1 mm^2) compared to AVF treatment (2.2±1.2 mm^2).



Conclusions: These studies showed 75% less NIH at the venous anastomosis and a 20x greater rate of outflow vein dilation with the AFE System compared to a standard AVF. Use of the AFE System to rapidly dilate veins prior to AVF creation could enable routine use of smaller veins and reduce failure rates.

Funding: Pharmaceutical Company Support - Flow Forward Medical, Inc.

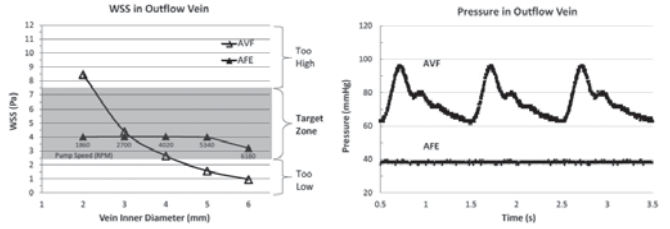
FR-PO987

In Vitro Study of Blood Pump System to Enhance AVF Eligibility and Maturation Howard M. Loree,[1] George Agyapong,[1] Gwendolyn A. Ngai,[1] Geoff D. Tansley,[2] Bradley S. Dixon,[3] Nicholas Franano.[4] *[1]Flow Forward Medical, Lowell, MA; [2]School of Engineering, Griffith Univ, Gold Coast, QLD, Australia; [3]Carver College of Medicine, Univ of Iowa, Iowa City, IA; [4]Flow Forward Medical, Olathe, KS.*

Background: Prior work suggests that outflow vein wall shear stress (WSS) and pulsatility are key factors in AVF failure. The Arteriovenous Fistula Eligibility (AFE) System™ is a small, temporary, wearable rotary blood pump system designed to rapidly dilate peripheral veins prior to AVF creation, enabling AVF placement in patients with small veins, and reducing AVF maturation failure. The AFE System directs non-pulsatile blood flow from the central venous (CV) circulation to a peripheral vein at an adjustable rate. This obviates cyclic vein wall stretching, provides more optimal and consistent WSS levels, and offers better conditions for WSS-mediated remodeling. A mock circulatory loop was used to model hemodynamics after AVF or AFE System placement in the human forearm.

Methods: For the radiocephalic AVF model, a pulsatile VAD and air-charged compliance chamber provided flow to the outflow vein. For the AFE System model, a centrifugal pump provided flow to the outflow vein. An open reservoir represented the CV circulation. Flexible PVC tubing simulated arteries and veins of various diameters, and glycerin blood analog was used. Pressure and flow measurements were made and mean WSS values calculated at various points in the loops.

Results: Outflow vein WSS varied across the range of vein diameters in the AVF but was maintained with the AFE System by adjusting pump speed (**Fig. A**). Outflow vein pressure was pulsatile in the AVF but was nonpulsatile with the AFE System (**Fig. B**).



Conclusions: In contrast to an AVF, the AFE System provides nonpulsatile flow and consistent outflow vein WSS levels, with potential to optimize pre-surgical vein diameter and possibly improve AVF maturation.

FR-PO988

Determinants of Intraoperative Blood Flow of Autologous Radiocephalic Arteriovenous Fistula at the Time of Fistula Construction Myung Jin Choi,[1] Jiwon Ryu,[1] Jwa-Kyung Kim,[1] Ja-Ryong Koo,[1] Jung-Woo Noh,[1] Yeo Jin Bang,[2] Miji Jeong.[2] *[1]Dept of Internal Medicine, Collage of Medicine, Hallym Univ & Hallym Kidney Research Inst, Chuncheon, Republic of Korea; [2]Hemodialysis Center, Chuncheon Sacred Heart Hospital, Chuncheon, Republic of Korea.*

Background: The native radiocephalic arteriovenous fistula (RCAVF) is recommended first choice of hemodialysis access, but 20-60% of RCAVF fail to mature adequately to perform dialysis therapy. Established risk factors for access maturation failure include arterial diameter, venous diameter, presence of diabetes, and race. Recently, several studies reported that intraoperative blood flow is associated with early failure of RCAVF. This study was designed to determine the predictor for intraoperative blood flow measurements.

Methods: From March 2006 to November 2013, 103 consecutive patients who performed autologous RCAVF creation were enrolled. Before surgery, all patients underwent arm venography for vascular mapping and ankle-brachial index (ABI) measurement. Intraoperative blood flow was measured within 5 to 10 minutes of completion of the vascular anastomoses.

Results: Of the 103 patients, the mean age was 61.7 ± 12.6 years and 61.2 % of patients were male. Seventy-one (68.9 %) patients had diabetes and 93 (90.3 %) patients

had hypertension. Mean arterial and venous diameter were 2.85 ± 0.78 and 2.92 ± 0.78 mm, respectively. Mean intraoperative flow was 307.9 ± 150.9 ml/min. Intraoperative blood flow showed a significantly negative association with baPWV and a positive association with artery size and vein size in the univariate analysis. In the multivariate analysis, intraoperative blood flow was independently associated with BaPWV (b=0.070, p=0.026) as well as artery size (b=67.614, p <0.001) and venous diameter (b=46.139, p=0.013).

Conclusions: BaPWV is an important determinant of intraoperative blood flow in autologous RCAVF. Considering the importance of early recognition of AVF maturation failure and timely intervention, preoperative screening by means of ABI and vascular mapping may help to detect a high risk patients for early access failure.

FR-PO989

Retrospective Analysis of High Arteriovenous Fistula Flow Effects on Cardiac Biomarkers Emily Lu, Amanda Jo DeMauro, Madeline R. Sterling, Daniel Edmonston, Cathy Jalali, Jeffrey I. Silberzweig. *Dept of Medicine and Div of Nephrology & Hypertension, Weill Cornell Medical College, New York, NY.*

Background: High A-V fistula (AVF) flow can be associated with increased cardiac output and heart failure. Prior work correlated AVF flow with myocardial wall stress and brain natriuretic peptide. We retrospectively analyzed the association between flow and other cardiac biomarkers (left ventricular hypertrophy (LVH), myocardial injury, atrial fibrillation (Afib), sudden cardiac death (SCD)) to assess the risk profile of high-flow AVF.

Methods: Via e-database, we identified 204 patients (pts) with at least one AVF flow ≥1 L/min measured by Transonic. We collected data on age, gender, fistula flow, fistula duration, QTc, LVH by EKG or echocardiogram, Troponin >0.5, Afib and SCD. Associations between flow parameters, fistula duration and cardiac biomarkers were tested by Pearson correlation coefficient (Pearson); Chi-square; Student's T-test; and linear or logistic regression models (confidence interval (CI) 95%).

Results: We had 58% men and 42% women of mean age 68.2 years with mean flow rate 978 mL/min; maximum (max) flow rate 1769 mL/min; mean flow range 1299 mL/min; mean fistula duration 1679 days; mean QTc 476.5 ms in 118 pts; LVH in 35.7% of 126 pts; Troponin >0.5 in 39.1% of 105 pts; Afib in 19.8% of 202 pts; and SCD in 30.5% of 105 deceased pts. Mean flow rate correlated with max flow rate (Pearson 0.60, p<.001) and mean flow range (Pearson 0.76, p<.001). Max flow rate and mean flow range are correlated (Pearson 0.96, p<.001) and modeled (b=0.92, CI: 0.89, 0.94, p<.0001). We found no statistically significant associations between fistula duration and flow parameters; flow parameters and cardiac biomarkers; or fistula duration and cardiac biomarkers.

Conclusions: Although prior studies led to concern that high AVF flow may be associated with cardiac complications, we demonstrated no association with any of our cardiac biomarkers. The flow parameters' degree of correlation and statistical significance show the high quality of our data. Our retrospective, single-institution study suggests that high AVF flow does not raise cardiac risk, but a larger prospective study may be warranted.

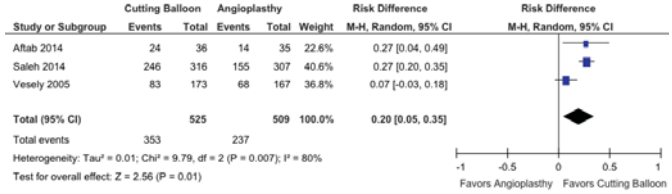
FR-PO990

Comparison of Six Month Patency in Cutting Balloons versus Conventional/ High Pressure Angioplasty for Hemodialysis Vascular Access: A Meta-Analysis of Randomized Controlled Trials Girish N. Nadkarni,[1] Alexandre Benjo,[2] James Jenkins,[2] Neil R. Patel,[1] Ioannis Konstantinidis,[1] Achint Patel,[1] Shiv Kumar Agarwal,[3] Narender Annapureddy,[4] Georges El Hayek,[1] Tyrone Collins,[2] Damodar Kumbala.[2] *[1]Mount Sinai, New York, NY; [2]Oschner Clinic, New Orleans, LA; [3]Univ of Arkansas Medical Sciences, Little Rock, AR; [4]Rush Univ, Chicago, IL.*

Background: Hemodialysis (HD) access failure is a common cause of increased morbidity and healthcare cost in patients with end stage renal disease (ESRD). Six-month restenosis rates with high balloon angioplasty (HPB) remain high. Interventions with cutting balloons (CB) are a potential alternative tool. We aimed to pool existing data from randomized controlled trials (RCT's) to assess difference in 6-month patency between CB and HPB.

Methods: MEDLINE, EMBASE, CENTRAL, Web of Knowledge, and ClinicalTrials were searched through June 2014 for RCTs comparing PTA with HPB and CB. Two authors independently reviewed the studies and extracted the data. RevMan 5.2 was used to estimate risk difference; since there was significant heterogeneity a random-effects model was used.

Results: Of 34 studies, 3 (n=1034) were included. The 6-month patency was higher in CB group as compared to HPB [353/525 (67%) versus 237/509 (46.5%); p<0.01]. There was significantly lower risk of restenosis in patients treated with CB compared to HPB groups (RD 0.20; 95% Confidence Interval: 0.05-0.35; p=0.01) with a number needed to treat of 5 for the CB group.



Conclusions: PTA with CB significantly reduces the incidence of stenosis at 6 months in comparison to the conventional HPB. PTA with CB should be considered routinely as a first-line therapy in ESRD patients with HD vascular access stenosis.

FR-PO991

Measuring Access Blood Flow (Qa) in Arteriovenous Fistulae (AVF): Further Insight on the Relationship Between the Hemoglobin Dilution (HbQa) and the Ultrasound Dilution (UQa) Technique Nicola Tessitore, Valeria Bedogna, Alessia Pendino, Giuseppina Giu Pessolano, Antonio Lupo. *Hemodialysis Borgo Roma, Renal Unit, Verona, Italy.*

Background: Current guidelines recommend routinely screening AVF for stenosis by measuring Qa. The most validated and accepted method is the UQa technique, which requires a dedicated equipment making it expensive and unavailable in all hemodialysis (HD) units. In 2008, Tiranathanagui et al described an alternative methods for measuring Qa based on haemoglobin dilution (HbQa), which has the advantage of being cheaper and accessible to all HD units, and compared well with UQa in a small series of 20 AVF.

Methods: The aim of our pilot study is to assess the interassay variability and diagnostic performance for stenosis of HbQa in 47 HD patients (29 males, age 64±16 y) with an AVF (24 in the lower forearm and 23 more proximally located) by comparison with UQa (Transonic HD03). All patients had Qa measured by both methods in the same HD session and underwent fistulography. In 22 AVFs Qa measurements were repeated 1-4 week later to calculate the interassay coefficient of variation.

Results: Mean [95%CI] Qa values were 962[840-1084] for HbQa and 890[773-1008] ml/min for UQa, with a mean Qa overestimation of 72[21-123] ml/min by HbQa (p=0.007). The two Qa methods were highly correlated (R=0.910,p<0.001) and showed the same interassay coefficient of variation (15±10 for HbQa and 13±7 % for UQa, p=ns). Fistulography identified a significant (>50%) stenosis in 22 AVF. The area under curve for stenosis was 0.929[0.861-0.997] for HbQa and 0.887[0.792-0.982] for UQa (p=ns). A Qa<630 ml/min with HbQa and a Qa<560 ml/min with UQa ensured a similar high positive predictive value (PPV 100%; sensitivity 54%[32-75]). A Qa<1000 with HbQa and a Qa<1150 ml/min with UQa ensured a similar high sensitivity (SE 95%[77-100]; PPV 78%[58-91] and 62%[43-78], respectively).

Conclusions: Our study shows that in AVF HbQa and UQa have similar interassay variability and diagnostic performance for stenosis, suggesting that HbQa is a valid alternative to UQa, bearing in mind that higher Qa thresholds (of approximately 70 ml/min) should be used if one favours PPV and lower Qa thresholds (of approximately 150 ml/min) if one favours SE.

FR-PO992

Sources of Variation in Dynamic Dialysis Venous Pressure (DVP) Measurements: Limitations and Opportunity John Jason White,[1] Anatole Besarab,[2] William D. Paulson.[1] *[1]Medicine, Georgia Regents Univ, Augusta, GA; [2]Medicine, Stanford Univ School of Med, Palo Alto, CA.*

Background: DVP is measured with the blood pump set at prescribed speed Qb, and is widely used by clinicians during rounds as a crude indicator of whether access stenosis should be suspected. However, the relative influence of various factors that determine DVP is unknown. This study determined this influence, and how these factors can be used to predict static VP (SVP, Qb = 0), which is suitable for surveillance.

Methods: We studied 55 patients with native fistulas (n = 43) or grafts (n = 12). DVP and SVP were measured in the first 1/3 of a session. We used multiple regression analysis to determine relations among these variables: DVP (corrected and uncorrected for drip chamber height), SVP (height corrected), Qb, needle gauge, hemoglobin level (Hgb), drip chamber height, mean arterial pressure (MAP).

Results: The multiple correlation coefficient for the relation of DVP (height uncorrected) with 6 independent variables (SVP [height corrected], Qb, needle gauge, Hgb, drip chamber height, MAP) was 0.848 (P<0.001). Thus, 72% of DVP variation was due to its relation with the 6 variables ($0.848^2 = 0.72$). We computed the correlation of DVP with each variable after controlling for the effects of the other 5 variables (R^2 values shown):

Dependent variable	Qb	SVP (height corrected)	Needle gauge	Hemoglobin level	Height	MAP
DVP (height uncorrected)	0.573	0.438	0.344	0.179	0.153	0.058
P value	<0.001	<0.001	<0.001	0.002	<0.001	0.09

Thus, Qb had the largest effect on DVP whereas MAP was not statistically significant. Finally, SVP correlated with DVP (both height corrected), Qb, needle gauge, and Hgb (multiple $R^2 = 0.485$, P<0.001).

Conclusions: This study shows that DVP uncorrected for height (i.e. rounding VP) is dominated by blood pump speed and other factors that are unrelated to intra-access pressure, indicating that DVP provides little access information. However, regression analysis shows that DVP can be used to estimate SVP when additional factors are taken into account. This study supports the concept that changes in estimated SVP can be used in surveillance to determine whether access stenosis should be suspected.

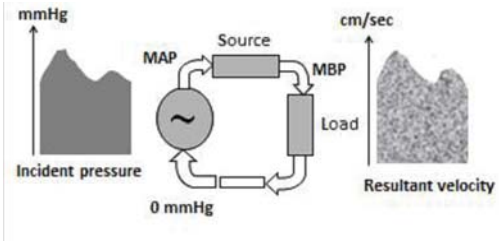
Non-Invasive Arteriovenous Fistula Pressure Mapping Using Pressure from Flow Theory David H. King,[1] William D. Paulson,[2] Mo Al-Qaisi,[1] Abdelgalil Abdelrahman Ali.[1] *[1]Renal Unit, Broomfield Hospital, Chelmsford, Essex, United Kingdom; [2]Dept of Medicine, Regents Univ, Augusta, GA; [3]Cardiovascular Sciences, St. George's Hospital, Tooting, London, United Kingdom.*

Background: Pressure from Flow theory[1] is an unconventional approach pressure estimation independent of anatomical variation and suitable for AVF surveillance.

Methods: Figure 1 is a vascular model. Source ***S*** and Load ***L*** represent the impedance of transit artery and recipient organ, ***Vff*** = pulsatile flow velocity/mean velocity, ***Pff*** = ***(Systolic – Diastolic pressure) /MAP*** measured centrally. ***MBP*** = organ perfusion pressure. The matched state ***S/L=1*** is a unique condition where no reflected waves exist so incident pressure and resultant flow waveforms are identical and ***Pff/Vff =1***. It can also be shown that ***Pff/Vff = S/L*** when ***L*** is infinite or zero. $MBP_{direct} = MAP/(1+S/L)$, therefore $MBP_{estimated} = MAP/(1+Pff/Vff)$.

Results: Femoral artery pressure and blood velocity waveforms were sampled in an anaethetised dog. ***S*** and ***L*** were altered following peripheral vasodilation then iliac artery constriction, resulting in a series of direct (79 to 41mmHg) and estimated mean pressure readings. AVF data was obtained from 14 human volunteer dialysis patients by sampling static needle pressure and Doppler velocity waveforms at the same location. The AVF pressure data (55 to 19mmHg) lies on the same line of identity as the dog data showing the algorithm can be applied anywhere in a vasculature, even with the vascular bed bypassed. All data combined resulted in a best fit straight line with a slope close to 1 and intercept close to the origin, $MBP_{estimated} = 0.907*MBP_{direct} + 0.9368$, $r^2 = 0.920$

Conclusions: This study shows that the 'Pressure from Flow' algorithm may be sufficiently robust to use in studies on fistulae as well as normal vasculature *1.International Patent/ Application No. PCT/GB2010/000436 King and Al-Qaisi.*



FR-PO994

Regular Ultrasound Surveillance of Arteriovenous Fistula with One-Day Management System: A 6-Year Experience Ji In Park, Nara Shin, Eunjin Bae, Sunhwa Lee, Hajeong Lee, Dong Ki Kim, Yon Su Kim, Kwon Wook Joo. *Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: Recent studies revealed elective intervention of subclinical stenosis in arteriovenous fistulas (AVFs) reduces the risk of access loss. Regular surveillance of AVFs with ultrasound seems to be an emerging strategy. Here, we report our 6 year-experience of surveillance of AVFs with ultrasound.

Methods: We set up the AVF surveillance program as an outpatient clinic in Seoul National University Hospital. Patients with AVFs or arteriovenous grafts (AVGs) were recommended to examine the patency with ultrasound every 3 months and whenever they have emergent vascular problem. If significant stnosis or thrombosis were detected, they underwent percutaneous trasluminal angioplasty (PTA) or surgery at the day. We retrospectively reviewed data between 2008 and 2013.

Results: Total of 1752 patients visited the program, of whom 84.2% patients had have the AVF or AVG operation at Seoul National University Hospital. Men were 60% and mean age was 62.2 years. Prevalence of hypertension and diabetes mellitus were 72.4% and 47.4%, respectively. AVFs were dominant (81.4%) compared to AVGs (18.6%). Each patient visited the surveillance clinic for average 5.7 times. Among total of 9972 vitis, 827 (5.3%) cases underwent PTA and 180 (2.1%) did surgery. When we compared AVFs to AVGs, patients with AVFs were significantly younger (61.5 versus 66.1 years), visited less (5.5 versus 6.9 times), underwent intervention less (0.4 versus 1.4 times), and took longer time to first use (88.4 versus 54.5 days) ($P < 0.001$).

Conclusions: The AVF surveillance program found considerable cases who needed PTA or surgery. Especially patients with AVGs visited and underwent interventions more frequently.

FR-PO995

Physician Visit Frequency and Vascular Access Interventions in Hemodialysis Kevin F. Erickson,[1] Matthew Mell,[2] Wolfgang C. Winkelmayer,[1] Glenn M. Chertow,[1] Jay Bhattacharya.[1] *[1]Medicine, Stanford Univ, Palo Alto, CA; [2]Surgery, Stanford Univ, Palo Alto, CA.*

Background: Medicare reimbursement policy encourages frequent provider visits to patients with end-stage renal disease (ESRD) undergoing hemodialysis. Patients survive longer when receiving dialysis through an arteriovenous (AV) fistula or graft compared to a central venous catheter. We hypothesized that more frequent face-to-face provider (physician and advanced practitioner) visits leads to more procedures and therapeutic interventions aimed at preserving AV fistulas and grafts, improved vascular access outcomes, and fewer hospitalizations.

Methods: We used multivariable regression to evaluate the association between provider (physician and advanced practitioner) visit frequency and interventions aimed at preserving vascular access, vascular access survival, hospitalization for vascular access infection, and outpatient antibiotic use in a cohort of 63,082 Medicare beneficiaries receiving hemodialysis in the United States.

Results: One additional provider (physician and advanced practitioner) visit per month was associated with a 13% increase in the odds of receiving an intervention to preserve vascular access (95% CI 11% to 14%), but was not associated with vascular access survival (HR 1.01, 95% CI 0.99 to 1.03). One additional provider visit was associated with decreased hospitalization for vascular access infection (OR 0.90, 95% CI 0.86 to 0.96) and an increase in outpatient intravenous antibiotic administration (OR 1.09, 95% CI 1.05 to 1.13), although the associated changes in absolute probabilities of hospitalization and antibiotic administration were small.

Conclusions: More frequent face-to-face provider (physician and advanced practitioner) visits are associated with more procedures and therapeutic interventions aimed at preserving vascular accesses, but not with prolonged vascular access survival and only a small decrease in hospitalization for vascular access.

FR-PO996

Characteristics of Dialysis Venous Pressure (VP): Criteria That Assist in Deciding Whether to Refer for Evaluation of Stenosis Usman Afzal,[1] John Jason White,[1] Eduard R. Fatakhov,[1] Anatole Besarab,[2] William D. Paulson.[1] *[1]Medicine, Georgia Regents Univ, Augusta, GA; [2]Medicine, Stanford Univ School of Med, Palo Alto, CA.*

Background: Dialysis VP measurements are an important method for determining whether an access should be referred for correction of stenosis. This study determined variation in VP from session to session and applied these results to a practical approach for referral.

Methods: Fifty-five patients with arteriovenous fistulas (n = 43) or synthetic grafts (n = 12) underwent VP measurements in 3 sessions within 2 wks. Sessions were divided into equal thirds, and VP was measured with blood pump speed (Qb) = 0 (static VP: SVP) and at prescribed Qb (dynamic VP: DVP). VP was adjusted for mean arterial pressure (VP/MAP). We determined whether timing of measurements in a session affects VP, and used the student t distribution to determine thresholds for a significant change in VP; all tests were 2-tailed. The SD used in the t distribution was for the difference between 2 VP/MAP values from different sessions.

Results: The median Qb = 450 ml/min; range from 260 to 600 ml/min. The pooled within-patient SD for differences between 2 VP/MAP's from the same third of different sessions are shown below:

Pooled within-patient SD for difference between 2 measurements	First third	Middle third	Last third
SVP/MAP (Qb = 0)	0.156	0.178	0.181
DVP/MAP (Qb prescribed)	0.610	0.611	0.547

Results for grafts and fistulas were not significantly different and are combined in the table. We found that the change in SVP/MAP in in the first third of a session must be >0.313 to be significant at $P<0.05$; the change in DVP/MAP must be >1.222. The values of DVP are higher than SVP, which thereby yields a higher SD. The change must be somewhat larger for SVP/MAP in the middle and last thirds of a session. If measurements are taken any time in a session, then the change in SVP/MAP must be >0.340.

Conclusions: This study defines the variability of VP and provides criteria for determining whether VP has increased or decreased for both static and dynamic VP. These criteria can be a useful aid in assessing whether to refer an access for possible correction of stenosis.

Arteriovenous Fistula Physical Exam: Can It Be Taught? Alexander S. Yevzlin,[1] Amanda M. Valliant.[2] *[1]Nephrolgoy, Univ of Wisconsin, Madison, WI; [2]Nephrolgoy, Univ of Wisconsin, Madison, WI; [3]Nephrolgoy, Univ of Wisconsin, Madison, WI.*

Background: Physical examination (PE) has been shown to be an excellent means of prediction of arteriovenous fistula (AVF) dysfunction. Although quick and inexpensive, PE is seldom used by dialysis staff. We hypothesized that the physical exam can be taught to a non-medical professional, and that, with time, it would be comparable to the physical exam performed by an expert.

Methods: A pre-medical student and an interventional specialist (MD) examined AVF for dysfunction in a tertiary care hospital over a six month period on patients who were referred for due to access dysfunction. Physical exam findings were categorized as inflow, outflow, both or neither. Data was blindly recorded and compared to the gold standard of angiography. Potential confounding variables, including age, gender, diabetic status, and location of AVF were collected. Outcomes were compared using ROC curves. Logistic regression was used to assess the impact of confounding variables on the accuracy of the student's physical exam.

Results: Forty-nine subjects were evaluated with an average age of 58.78. The majority of the subjects were male (61.2%), diabetic (53.1%), and had an upper arm AVF (75.5%). In the first three months of the study the student performed the AVF exam with an AUC of 0.700, a sensitivity of 66.67% and a specificity of 73.33%, compared with the specialist (AUC 0.911, a sensitivity of 88.89% and a specificity of 93.33%), P = 0.0869. In the next

and final 3 months of the study, the student performed the AVF exam with an AUC of 0.883, a sensitivity of 90.00% and a specificity of 86.67%, compared with the specialist (AUC 0.967, a sensitivity of 100.00% and a specificity of 93.33%), P = 0.2817. Among the potential confounding variables of age, gender, diabetes, and AVF location, only wrist AVF were associated with a decrease in PE accuracy (odds ratio 0.1680, P = 0.0233).

Conclusions: AVF exam can be taught to a non-medical professional in a short duration of time and the predictive value of the exam can be similar to that of an interventional specialist.

FR-PO998

Post-Operative Hand Grip Exercise for Arteriovenous Fistula Maturation Danielle L. Kirkman,[1,2,3] Rebecca-Jane Law,[2] Mick John Kumwenda,[3] Mahdi M. Jibani,[3] Jamie Hugo Macdonald.[2] *[1]Univ of Delaware, Newark, DE; [2]Bangor Univ, Bangor, United Kingdom; [3]Betsi Cadwaladr Univ Health Board, United Kingdom.*

Background: More than half of arteriovenous fistulae fail to mature for hemodialysis use, accentuating the need for interventions to enhance fistula maturation. This pilot study aimed to investigate the effect of post operative forearm exercise on fistula vessel diameters, early dialysis suitability failure and maturation time.

Methods: In this controlled trial, 31 participants were randomly allocated to either an EXERCISE (Mean (SD): 52 (14) years) or a CONTROL (60 (11) years) group following fistula surgery. EXERCISE received a home based progressive resistance hand grip exercise program over 8 weeks. Exercise was prescribed four days per week for 30 minutes at an intensity perceived as 'somewhat hard' to 'hard'. CONTROL received routine care. Primary outcomes included fistula feeding artery and draining vein diameters by ultrasound, fistula failure and maturation time. Secondary outcomes were maximal isometric handgrip strength and forearm muscle circumference. Outcomes were measured one day, four and eight weeks post surgery.

Results: Compared to CONTROL, EXERCISE had no effect on arterial diameter (mean change [95% CI], -0.24 [-1.12; 0.51] mm) or venous diameter (0.16 [-1.84; 1.24] mm) with small to trivial effect sizes reported. Nineteen percent and 33% of fistulae failed in EXERCISE and CONTROL, respectively. EXERCISE did not affect maturation time (1 [-16; 28] days). EXERCISE increased handgrip strength (4.5 [0.5; 8.0] kg) but not forearm muscle circumference (0.8 [-1.9; 3.4] cm).

Conclusions: This study infers post operative forearm exercise to have no effect on fistulae vasculature diameters, maturation time or failure rate. A similar protocol implemented *before* arteriovenous fistula creation, however, is hypothesised to reduce immediate vascular access failure and enhance maturation for successful hemodialysis use. Registered clinical trial *NCT01061008.*

FR-PO999

Associations between Preoperative Arterial Function Tests (AFTs) and Postoperative Arteriovenous Fistula Flow in the Hemodialysis Fistula Maturation (HFM) Study Michael Allon, Tom Greene, The HFM Study Group. *NIDDK, NIH.*

Background: Arteriovenous fistula (AVF) maturation requires vascular dilation to permit increases in AVF blood flow. Preoperative functional properties of the vasculature may be determinants and predictors of postoperative vascular remodeling.

Methods: Patients in HFM underwent 4 preop AFTs: (1) Brachial artery flow-mediated dilation (FMD); (2) Brachial artery nitroglycerin-mediated dilation (NMD); (3) Carotid-femoral pulse wave velocity (CF-PWV); and (4) Carotid-radial (CR-) PWV. They also underwent preop ultrasound (US), and US of the AVF at ~1 day, and 2 and 6 weeks postop. We fit regression models of postop AVF flows examining individual AFTs as predictors.

Results: After adjustment for AVF location and preop US variables, there were significant associations between 6-week postop AVF flow and each preop AFT (Table 1). Age, sex, race, diabetes, CAD, PAD, and preop arterial calcification were also individually predictive of postop AVF flow ($p<0.01$). After adjustment for these baseline features, associations of 6-week AVF flow with FMD%, NMD%, and CF-PWV were attenuated and no longer statistically significant.

Table 1: Regressions of 6-week AVF flows on individual AFT predictors

	Controlling for AVF location + preop US variables (art diameter, vein diameter, and upper arm flow)		Controlling for AVF location + preop US variables + baseline patient characteristics *	
Predictor AFTs	Diff in AVF flow (95% CI)	p-value	Diff in AVF flow (95% CI)	p-value
Brachial NMD% (n=361)	17.91 (7.41, 29.45)	0.001	7.28 (-2.23, 17.72)	0.14
Brachial FMD% (n=428)	14.12 (3.10, 26.32)	0.01	4.33 (-5.41, 15.07)	0.40
CF-PWV (n=349)	-8.05 (-14.27, -1.38)	0.02	0.90 (-6.36, 8.71)	0.81
CR PWV (n=350)	17.19 (2.79, 33.60)	0.02	15.49 (1.94, 30.84)	0.02

* Pt age, sex, race, diabetes, CAD, PAD, and arterial calcification

Conclusions: Preop AFTs were associated with 6-week postop AVF flow when adjusted for preop US variables, but only a somewhat paradoxical association with carotid-radial PWV remained statistically significant after adjustment for baseline features. Baseline demographics, vascular US measures, and other clinical factors may confound predictive relationships of preop AFTs to postop AVF flow.

Funding: NIDDK Support

FR-PO1000

Arteriovenous Graft Outcomes Are Not Affected By Failure to Mature Scoring Risk Group Egbert C. Liquete, Rebecca Bajoka, Ruchira Sengupta, Sagger Mawri, Jerry Yee, Lenar T. Yessayan, Lalathaksha Murthy Kumbar. *Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Background: The failure to mature (FTM) was developed to identify patients with high risk for arteriovenous fistula (AVF) maturation failure. Patients at very high risk for AVF failure by FTM scoring are often recommended to alternatively undergo arteriovenous (AVG) constructions. Because the literature on AVG outcomes in these patients is limited, we determined whether the preoperative FTM score risk profile predicts AVG outcomes.

Methods: Retrospective analysis of earliest documented, upper extremity AVG constructions from January 2009 to November 2013. Demographics and data on comorbidities, prior access, subsequent access interventions, and medications were collected. AVGs were classified into 4 groups based on FTM score: Low (<2), Medium (2-3), High (3.1-7.9), and Very High (>8). Primary (abandonment), secondary (thrombosis, angioplasty) outcomes, primary patency, assisted primary patency, and survival probability were collected at 6 and 12 months. Variables of interest were compared among risk groups by Fisher Exact testing; survival by the lifetest method; and times-to-event compared by log-rank tests (SAS 9.4, SAS Inc, Cary, NC, U.S.A.).

Results: Analysis of 169 AVGs was conducted. 85% of patients were classified as medium and high FTM risk (41% versus 45%). The most common procedures among all AVGs were angioplasty (46.8%), thrombectomy (24.9%) and tunneled, catheter placements for any reason (24%). There were no significant differences in primary, assisted primary patency or survivability at 6 and 12 months among various risk groups. However, between the very high risk compared to the low risk group, a trend toward higher cumulative survival at 12 months (91% versus75%) and longer median time to first angioplasty (6.8 versus5.3 months) and thrombectomy (6.4 versus 5.7 months) was noted.

Conclusions: AVG outcomes are not affected by the preoperative FTM score risk profile. AVGs should be the access of choice in patients at very high risk for AVF maturation failure by FTM scoring, in order to minimize hemodialysis catheter prevalence and probable, futile AVF maturation attempts.

FR-PO1001

Can Augmentation Procedures Promote AVF Use without Compromising Access Long Term Patency? Hoon Suk Park, Kyungyoon Chang, Bum Soon Choi, Cheol Whee Park, Chul Woo Yang. *Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: Native arteriovenous fistula (AVF) is superior to arteriovenous graft and central venous catheter due to its favorable long term patency and minimal complication rates associated with its use. To increase the rate of AVF use, salvage therapies for augmentingng immature fistulae are strenuously performed these days. But, there are some controversies that AVF matured by these salvage therapies requires frequent intervention for maintaining its patency and may have resultant decreased long term patency. Therefore, we investigated the effects of salvage therapies on patencies after starting using fistulae.

Methods: From total 361 patients with native fistulae, 266 with AVF matured by salvage therapies and 95 with AVF matured spontaneously without intervention were compared and we investigated the factors that may influence on patencies of AVF.

Results: The group with salvage therapies were older (years, 65 versus 59; $p = 0.005$) and decreased preoperative venous diameter (mm, 2.74 versus 3.18; $p < 0.001$) compared with the other group without it while the other parameters including preoperative arterial diameters, sex, diabetes, presence of coronary artery disease and left ventricular ejection fraction were comparable between two groups. Primary patency was decreased in the group with salvage therapies compared with the other group without it ($p = 0.021$). However, primary assisted patency and secondary patency were comparable between two groups ($p = 0.517$ and $p = 0.127$). In multivariate Cox regression analysis, the presence of salvage therapies before use was not significantly associated with access survival (odds ratio [OR] 0.548, 95% confidence interval [CI]: 0.249–1.205; $p = 0.135$) whereas spontaneous maturation (OR 0.326, 95% CI: 0.159–0.667; $p = 0.0026$), history of thrombosis during use (OR 25.051, 95% CI: 11.015–56.970; $p < 0.001$) and preemptive intervention (OR 0.313, 95% CI: 0.108–0.910; $p = 0.033$) were significantly associated with it.

Conclusions: Augmentation procedures can salvage immature fistulae without compromising access long term survival.

FR-PO1002

Exercise Training in Haemodialysis and Renal Transplant Patients Laura Mason,[1] Michael James Lewis,[1] Ashraf I. Mikhail.[2] *[1]A-STEM Research Centre, Swansea Univ; [2]Morriston Hospital, Swansea, United Kingdom.*

Background: Poor physical functioning is associated with morbity, mortality and poor QOL in haemodialysis (HD) patients. Renal transplant recipients (RTR) with reduced physical function are also more likely to suffer allograft failure and cardiovascular events. Exercise training may help to ameliorate many of the factors which lead to poor physical functioning in these groups. The aim of this study was to compare the effects of a 24-week exercise training program on physical functioning and body composition in HD and RTR patients.

Methods: Thirteen mobile HD patients (F=4,M=9, age:49±18yrs, mass:76±14kg, height:1.70±0.10m) and 12 RTR patients (F=8,M=4, age:45±15yrs, mass:92±28kg, height:1.64±0.08m) volunteered for the study. All participants completed 24 weeks of individualised exercise training on 3 days per week. Physical functioning was assessed during an incremental exercise test and body composition was measured using air displacement plethysmography. Measurements were taken at 0, 12 and 24 wks.

Results: 5 HD and 7 RTR completed 24 wks of training. Peak work rate achieved on the incremental cycle was significantly improved following the training period (HD: 0wks=89±11, 24wks=121±15 W, RTR: 0wks=72±18, 24wks=97±17 W, P≤0.001) as was peak aerobic capacity (HD: 0wks=18.4±3.8, 24wks=21.8±4.2ml·kg^{-1}·min^{-1}, RTR: 0wks=14.5±4.1, 24wks=18.3±5.1ml·kg^{-1}·min^{-1}, P=0.015) with no differences between HD and RTR for either variable (P=0.294, P=0.136 respectively). No significant differences were found in body mass in either group (P=0.137) however percentage body fat significantly decreased in both groups (HD: 0=30.0±15.7, 24=26.5±15.0%, RTR: 0=44.4±11.3, 24=40.0±9.9%, P=0.022). Significant negative correlations were also found at each time point between percentage body fat and peak aerobic capacity (R≥0.689, P≤0.019).

Conclusions: These results show that 24 wks of exercise training can significantly improve physical functioning in both HD and RTR patients, and can reduce percentage body fat in the absence of dietary intervention. This study provides further evidence that regular exercise training should be encouraged both prior to and following kidney transplantation.

FR-PO1003

Effects of a 6 Months Physical Activity during Hemodialysis on Cardiovascular Parameters: Anemia Control, HDL-C, HTA Control...

Myriam Rouchon Isnard, Céline Coutard, Marie-Hélène Mosnier, Nathalie Ramade, François Jamy. *Aura Auvergne, Chamalieres, France.*

Background: Cardiovascular diseases are the main cause of morbidity and mortality in hemodialysis patients. Chronic Kidney Disease is a Cardiovascular Risk Factor (CVRF) associated with Hypertension (HTA), Dyslipidemia (low HDL), Haemoglobin (Hb) variation,etc. Physical Activity (PA) is well known in cardiology to allow a control of the CVRF and a better survival. The impact of PA on blood pressure levels, dyslipidemia and Hb variation has been investigated with intervention studies of per dialysis exercise programs. The aim of our study was to determine if PA per dialysis can decrease CVRF and cardiovascular hospitalizations.

Methods: We studied 84 haemodialysis patients in AURA Auvergne hemodialysis centers. They were voluntarily assigned to either intradialytic exercise training (cycling) group (EX; n=42) or a control group (CON; n=42). Baseline characteristics of the patients:

GROUPS	Number	%Male	Age	Time in Dialysis (year)	Diabetes %	Cardiovascular Risk Factors %
EX	42	71.42	65,11 ± 15,76	4.47 ± 3.94	28.5	95
CON	42	78.5	63,6 ± 16,05	4.732 ± 24.56	28.5	92.6

Results: Statistics comparisons: ANOVA 2 and post-hoc with Newman Keuls.

	Cardiovascular Hospitalizations	Total Hospitalizations
EX	2	19
CON	3	8

In EX Hb remains stable D=0.11g/dl, with lower ESA dose: -10.8%; on the contrary, Hb in CON do not remain stable D=-0.76g/dl (p<0.05). HDL-C rise up significantly in EX: 13.13% (p<0.05) and is stable in CON. The average of antihypertensive treatment is lower in EX after 6 months exercise period. Despite a higher number of total hospitalizations in EX, there is less cardiac causes compared to CON.

Conclusions: Our results show that per dialysis cycling improves HTA and dyslipidemia control. Hb is more stable. So we can conclude that PA lowers CVRF: with a longer follow-up, the cardiovascular events may be reduced. But certainly randomised studies are needed on the subject.

Arterial and Cardiac Alterations and Their Relationships to Exercise Intolerance in Maintenance Hemodialysis Patients

Jin Hee Jeong,[1] Pei-Tzu Wu,[2] Peter J. Fitschen,[1] Brandon Kistler,[1] Annabel Biruete,[1] Hyunwoo Hank Park,[1] Mohamed Ali,[3] Bo Fernhall,[3] Ken Wilund.[1] *[1]Kinesiology, Univ of Illinois, Urbana, IL; [2]Translational Science Section, Univ of California at Los Angeles, Los Angeles, CA; [3]Kinesiology, Univ of Chicago, Chicago, IL.*

Background: Maintenance hemodialysis (MHD) patients experience impaired physical function which significantly reduces their quality of life. Cardiovascular (CV) structural and functional alterations may contribute to the limited functional capacity observed in this population. However, the relationship between arterial and cardiac impairments and exercise intolerance in MHD patients is not fully understood. Identification of the most relevant CV risk factors for impaired exercise capacity could help to direct future research efforts to improve exercise capacity and, ultimately, quality of life in MHD patients.

Methods: 112 MHD patients (age =55.5± 11.4y) were tested for arterial wave reflection (augmentation index (Aix75)), arterial stiffness (carotid-femoralpulse wave velocity (PWV) and b-stiffness)), carotid artery lumen diameters (D), carotid intima-media thickness (cIMT), cardiac systolic function (ejection fraction (EF)), and left ventricular mass index (LVMI) on a non-dialysis day. An incremental shuttle walk test was conducted to estimate aerobic capacity.

Results: cIMT, D, Aix75, PWV, andb-stiffness were positively associated with age (p<0.01 for all). D was positively correlated with PWV and b-stiffness and negatively correlated with EF (p<0.05 for all). By univariate analysis, Aix75, PWV and b-stiffness were all inversely associated with shuttle walk time (p< 0.05 for all). In contrast, there were no significant correlations between shuttle walk time and cIMT, D, EF and LVMI.

Conclusions: Arterial function measures were more closely associated with walking performance than with cardiac structure or function in patients with MHD. These data suggest that peripheral rather than central limitations may be important determinants of exercise intolerance and therefore an important therapeutic target in MHD patients.

Exercise Training During Hemodialysis Is Not Associated with Intradialytic Hypotension

Kelvin Leung,[1] Pietro Ravani,[1,2] Kristen Parker,[3] Nathalie Tang,[3] Stefan Mustata,[1] Tanvir Chowdhury Turin,[2] Zhihai Ma,[2] Jennifer M. MacRae.[1] *[1]Medicine, Univ of Calgary, Calgary, AB, Canada; [2]Community Health Sciences, Univ of Calgary, Calgary, AB, Canada; [3]Southern Alberta Renal Program, Alberta Health Services, Calgary, AB, Canada.*

Background: Intradialytic exercise is associated with improved hemodialysis (HD) efficacy, physical function, and quality of life. However, concerns regarding exercise induced intradialytic hypotension (IDH) have limited its widespread use.

Methods: We performed a 12-week observational study in 48 maintenance HD patients. Patients performed intradialytic exercise (cycle ergometer) up to 3-times per week at moderate intensity (Borg scale 5), with duration at the patient's discretion. Hemodynamic parameters, fluid removal, exercise duration, single-pool urea kinetics (spKt/V), a numerical count of symptomatic (chest pain, shortness of breath, nausea/vomiting, dizziness, fatigue, cramps or anxiety) and asymptomatic IDH episodes were recorded. IDH as defined by an abrupt drop in the systolic blood pressure of ≥20mm Hg. The duration of exercise (minutes exerted and in stratums [presence or absence of exercise; no exercise, <30 minutes, ≥30 minutes]) and IDH were analyzed using a random-effects model.

Results: A total of 1727 HD sessions were recorded with 827 involving exercise. Symptomatic and asymptomatic IDH occurred in 8.3% and 33.5% of all HD sessions, respectively. The rates of symptomatic and asymptomatic IDH were similar with intradialytic exercise (Table 1). Symptomatic IDH and asymptomatic IDH were not affected by intradialytic exercise after adjustments for demographics, comorbidities, and intradialytic fluid removal (<0.01 symptomatic IDH episode per 10 minute exercise, P>0.10). The results were consistent when analyzed across the stratums. The dialysis efficacy was not affected by the presence or duration of intradialytic exercise.

Conclusions: Intradialytic exercise is not associated with hemodynamic instability or IDH.

Table 1: Rates of Symptomatic and Asymptomatic IDH

	Symptomatic IDH	Asymptomatic IDH
No Exercise	13.2 per 100 HD sessions	98.9 per 100 HD sessions
Intradialytic Exercise	9.07 per 100 HD sessions	97.6 per 100 HD sessions

Funding: Government Support - Non-U.S.

FR-PO1006

Achievement of Prescribed Ultrafiltration and Clearance Goals and Incidence of Intradialytic Hypotension among Hospitalized Patients

Dinna Cruz, Christie H. Izutsu, Eileen M. Lischer, Ravindra L. Mehta, Joseph A. Abdelmalek. *Div of Nephrology, Univ of California, San Diego, San Diego, CA.*

Background: Intradialytic hypotension (IDH) is a common complication in outpatient hemodialysis (HD), but its incidence is not well studied in the acute setting. We aim to characterize the frequency of IDH among hospitalized ESRD and AKI patients, as well as ascertain the rate of achievement of prescribed ultrafiltration (UF) goals.

Methods: We conducted a retrospective review of all intermittent HD treatments performed on inpatients in an academic center from December 2013-March 2014. IDH was

defined as the systolic or diastolic blood pressure threshold prespecified by the nephrologist at which a supportive intervention (e.g. saline, decreased UF) should occur. Characteristics of sessions with and without IDH were compared.

Results: A total of 755 HD sessions (ESRD 62%, AKI 38%) were performed in 173 inpatients, with a median of 3 (IQR 1, 5) sessions/patient, and a median of 3h/session. Prescribed UF per session was 3 (IQR 2, 3) L or 9.6 (IQR 4.2, 10.7) ml/kg/hr. Achieved UF per session was 2 (IQR 1, 3) L or 7.3 (IQR 4.2, 10.7) ml/kg/hr. Prescribed UF goals were achieved in 39% of sessions; the median achieved/prescribed UF (APUF) ratio was 0.86 (IQR 0.67, 1.00). IDH complicated 251 (33.2%) sessions; IDH occurred more commonly in sessions in the ICU, and in AKI patients.

	IDH n=251	No IDH n=504
ICU, n (%) **	78 (31)	79 (16)
AKI patients, n (%) *	115 (46)	174 (34)
Actual HD duration (min)	210[185,210]	210[210,210]
Prescribed UF, ml/kg/h	8.9[5.7,12.6]	9.7[6.2, 13.3]
Achieved UF, ml/kg/h**	6.0[3.5,8.3]	8.2[5.2,11.5]
Achieved/prescribed UF ratio**	0.7[0.48, 0.90]	0.95[0.75,1.0]
Kt/V	1.2[0.9, 1.6]	1.3[1.0, 1.5]

* p<0.05; **p<0.001. Data presented as medians and IQ range

The APUF ratio was significantly lower in sessions with IDH. There was no difference in prescribed UF, blood flow, dialysate flow, Kt/V, prescribed or actual duration of HD between the two groups.

Conclusions: Intradialytic hypotension is common among hospitalized patients, and more commonly encountered in those with AKI. This adversely affects the ability to achieve prescribed UF goals, but does not appear to reduce Kt/V.

FR-PO1007

Cardiomegaly Modifies the Effect of Ultrafiltration Rate on Mortality in Incident Hemodialysis Patients

Chi-Chih Hung, Daw-Yang Hwang, Hung-Chun Chen. *Dept of Nephrology, Kaohsiung Medical Univ Hospital, Kaohsiung Medical Univ, Taiwan.*

Background: Higher ultrafiltration rate (UFR) is associated with mortality in hemodialysis patients. The rapid fluid removal could result in intradialytic hypotension, cardiac injury and sympathetic overactivity. These detrimental effects are theoretically more prominent in heart failure. We hypothesized that cardiomegaly, measured by routine chest radiograph, could modify the association between ultrafiltration rate and mortality in hemodialysis patients.

Methods: We studied 2615 incident hemodialysis patients in southern Taiwan from 1997 to 2009. After dialysis for 3 months, the baseline data were collected and they were divided by cardiothorathic ratio (CTR) and UFR.

Results: In the cohort, the mean age was 59.1 ± 14.2 years, 50.4% were women and 48.7% were diabetes.The mean UFR was 9.6 ± 3.8 ml/h/kg and the mean CTR was 49.4 ± 6.5 %. For all population, UFR > 12.5 ml/h/kg group had higher risks for all-cause mortality and cardiovascular (CV) mortality after a median follow-up of 5 years. In the CTR > 50% group (962 patients), both UFR10~12.5 ml/kg/hr and > 12.5 ml/h/kg groups had significantly higher risks for all-cause mortality with adjusted HR 95% CI: 1.37 (1.05 to 1.77) and 1.57 (1.19 to 2.08), respectively, which was not seen in the CTR ≤ 50% group (p for interaction < 0.05). In the CTR > 50% group, UFR > 12.5 ml/h/kg group had a higher risk for CV mortality with adjusted HR 95% CI: 1.50 (1.01 to 2.24), which was not seen in the CTR ≤ 50% group (p for interaction < 0.05).

Conclusions: Our study showed Asian hemodialysis patients with cardiomegaly (CTR > 50%) and higher UFR were associated with higher risks for all-cause mortality and CV mortality while those without cardiomegaly could tolerate higher UFR.

FR-PO1008

Serial Measurements of Pre Dialysis N Terminal Probrain Type Natriuretic Peptide (NT-proBNP), Correlations with Extracellular Water Determined by Bioelectrical Impedance Assessments in Hemodialysis Patients

Kwanpeemai Panorchan, Andrew Davenport. *UCL Centre for Nephrology, Royal Free Hospital, Univ College London Medical School, London, United Kingdom.*

Background: Increased cardiovascular mortality of hemodialysis patients is linked to volume overload and failure to achieve dry weight. Multifrequency bioelectrical impedance assessments (MF-BIA) can aid clinical examination in assessing volume status. However not all patients are suitable for MF-BIA measurements, and so we investigated whether serial N-terminal proBrain Natriuretic Peptide (NT-proBNP) measurements correlated with MF-BIA.

Methods: We prospectively measured pre-midweek NT-proBNP and MF-BIA in 186 stable hemodialysis outpatients, six months apart. The correlations between quartiles of water excess and quartiles of NT-proBNP changes were studied.

Results: We performed total 470 measurements in 186 patients, mean age 62.6±15.7yr, 33.3% male, 42.5% diabetic, 38.7% Caucasoid, 17.2% with a history of myocardial infarction, 9.7% coronary artery bypass surgery. Median predialysis NT-proBNP was 281.0 (129.5-890) pmol/l, and mean predialysis extracellular water (ECW) /total body water (TBW) ratio was 0.396±0.016. Median NT-proBNP change was 127.5 (36-397) pmol/l, and ECW/TBW change 0.5% (-0.45% to1.63%). There was no correlation between predialysis systolic blood pressure and ECW/TBW (r = 0.076, p = 0.305) or ECW excess (r = 0.079, p = 0.289). Patients were then divided into quartiles of ECW/TBW change and ECW excess. The absolute changes in NT-proBNP were significantly higher in the quartile with the greatest increase in ECW/TBW in comparison with all the lower quartiles for both ECW/TBW changes (1231±2044 versus 389±626 and 372±752 and 170±79 respectively, p < 0.05) and ECW excess (1180±2006 versus 518±839 and 232±481 and 194±412 respectively, p < 0.05).

Conclusions: Our data suggests that changes in serial NT-proBNP can help guide clinicians in determining target weight, especially for those patients unsuitable for MF-BIA.

FR-PO1009

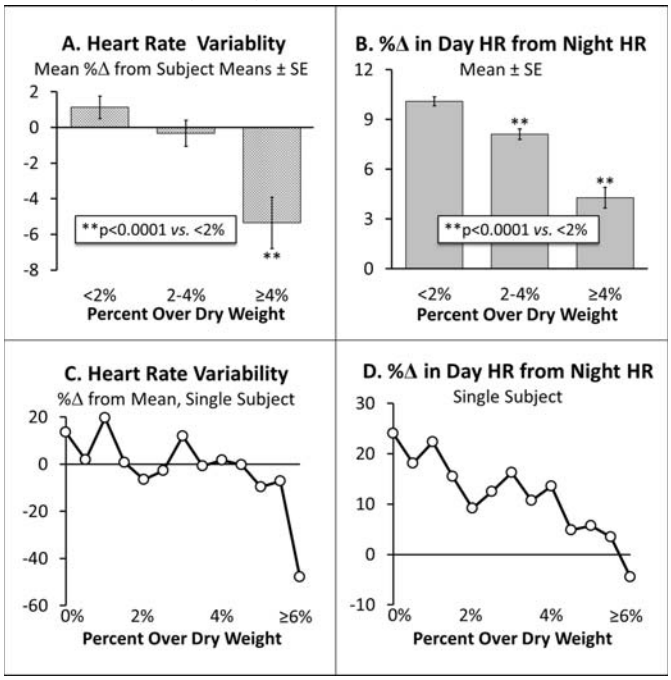
Relationship of Heart Rate Variability (HRV) and Heart Rate to Fluid Load in Hemodialysis (HD) Patients: Preliminary Results from the Monitoring in Dialysis (MiD) Study

Don E. Williamson,[1] David M. Charytan,[2] Amber S. Podoll,[4] Vikranth Reddy,[6] Prabir Roy-Chaudhury,[5] Suresh Chandra Tiwari,[7] James A. Tumlin.[3] *[1]Nephrology Associates, Augusta, GA; [2]Harvard U; [3]U of Tennessee; [4]U of Texas; [5]U of Cincinnati; [6]Care Hospital, Hyderabad, India; [7]Fortis Inst, New Delhi, India.*

Background: Chronic fluid overload is linked to increased hospitalizations and death in ESRD. Volume status affects heart rate and HRV, but continuous monitoring of these parameters has not been explored as a potential fluid management tool.

Methods: MiD is a prospective multi-center study to characterize arrhythmias in 3x weekly HD patients with an implantable continuous cardiac monitoring device, the Medtronic Reveal® XT. HD treatment data are collected concurrently during the initial 6 months. In addition to arrhythmias, Reveal records HRV (SD of normal-normal RR intervals) and mean night- and daytime heart rates for each calendar day. Reveal HRV and heart rate data were analyzed in relation to fluid load. The fluid measure used was the mean percentage over clinical chart dry weight on each calendar day, estimated using observed pre- and post-HD weights and linear interpolation between adjacent weight observations. The sample was restricted to weeks with 3 HD sessions.

Results: The analysis sample included 4976 days of Reveal data from 43 of 45 implanted MiD subjects with concurrent HD session data. Higher excess fluid levels were associated with statistically significant reductions in HRV (Figure A) and compression of daytime heart rate toward nighttime heart rate (Figure B). This pattern was also apparent in data for individual subjects (Figures C and D).



Conclusions: Reduced HRV recorded by implantable continuous cardiac monitoring devices has the potential as a tool to improve fluid management in HD patients which may improve long term cardiovascular outcomes of ESRD patients.

FR-PO1010

Dialysate Sodium Concentration Reduction to Reduce Haemodialysis Induced Myocardial Stunning: An Initial Randomised Controlled Trial

Lisa E. Crowley,[1] Aghogho Odudu,[1] Indranil Dasgupta,[2] Chris W. McIntyre.[3]
[1]Royal Derby Hospital, Derby, United Kingdom; [2]Heart of England NHS Trust, Birmingham, United Kingdom; [3]Univ of Nottingham, Nottingham, United Kingdom.

Background: Large interdialytic weight gains in haemodialysis patients have been linked to higher mortality.Consequent increased ultrafiltration requirements drive HD induced cardiac injury.Reduction of dialysate sodium can reduce IDWG but concerns about tolerability remain.We investigated the effects of stepwise reduction in dialysate sodium on IDWG and HD induced myocardial stunning.

Methods: 19 patients receiving hospital HD underwent stepwise reduction in dialysate sodium (DiNa) over 8 weeks.Patients were randomized into 2 groups with one returning to standard treatment (140mmol/L) and the other continuing at the lowest tolerated sodium level.Studies were conducted at baseline,8 and 20 wks using pre and peak stress echocardiography analysed using 2D speckle tracking software to assess cardiac response.A stunned segment was defined as undergoing a 30% reduction in longitudinal strain.

Results: At 8 wks there was a significant reduction in mean IDWG (2.28kg±0.16 versus 1.61kg±0.17 p=0.008) for all patients but no significant difference in mean number of stunned segments (3.64±2.1 versus 3.71±1.1) or pre-dialysis global longitudinal strain (14.93±3.6 versus 15.14±2.78).Mean lowest tolerated DiNa was 133mmol/L (control) and 135mmol/L (intervention).Pre-dialysis serum sodium was higher in controls *(*138±4.3) than the intervention arm (135±4.6). At 20wks reduction in IDWG was sustained in the intervention group (2.65±0.75 versus 2.05±0.63 versus 1.84±0.65) but not the group returning to standard treatment (1.90±0.33 versus 1.17±0.44 versus 1.41±0.43).After increased exposure to reduced DiNa there was a modest reduction in number of affected segments (2.6±1.51 versus 3.5±0.54) and a small improvement in pre-dialysis GLS (13.58±4.06 at baseline versus 14.62±3.78 at 20wks).There was no difference between pre-dialysis systolic BP or post-dialysis systolic BP nor in episodes of hypotension during HD.

Conclusions: Stepwise reduction of dialysate sodium is a safe and effective method to reduce IDWG and ultrafiltration volumes and results in a modest improvement in cardiac tolerability.

FR-PO1011

Conversion of Facility Standard Dialysate Sodium to ≤138 mEq/L Is Associated with Reduction in Excessive Interdialytic Fluid Gains without Evidence of Adverse Effect

Jason Zhang, Andrew Lee, Steven M. Brunelli, Deborah A. Benner, Irina Goykhman, David B. Van Wyck, Mahesh Krishnan, Allen R. Nissenson. *DaVita HealthCare Partners Inc, Denver, CO.*

Background: Positive dialysate-serum sodium gradient results in intradialytic sodium loading. Therefore, reducing dialysate sodium ($D_{Na[sup]+[/sup]}$) is a potentially useful approach to mitigate thirst, interdialytic weight gain (IDWG), hypertension, and fluid-related morbidity in hemodialysis patients. We examined the effect of facility-level transition to lower $D_{Na[sup]+[/sup]}$ (134-138 mEq/L) on indices of peri-dialytic fluid balance: proportion of dialytic intervals with IDWG >5% of body weight, proportion of treatments with ultrafiltration rate (UFR) >13 ml/h/kg, and frequency of intradialytic hypotension (IDH); each of these indices has been previously associated with greater risk of morbidity and mortality.

Methods: We studied data from patients treated at any of 1,339 hemodialysis facilities whose governing bodies adopted default use of standard $D_{Na[sup]+[/sup]}$ between 134 and 138 mEq/L. Higher $D_{Na[sup]+[/sup]}$ was allowed by exception if deemed necessary by the treating nephrologist.

Results: By April 2014, 96% of all patients treated in these facilities had prescribed $D_{Na[sup]+[/sup]}$ ≤138 mEq/L. Between December 2013 and April 2014, the proportion of dialytic intervals with IDWG >5% of target weight declined by 6.4%, the proportion of treatments with UFR >13 ml/h/kg declined 4.7%, and frequency of IDH declined by 11.8%. Target weight, pre-dialysis serum sodium, and mortality were unchanged.

Conclusions: $D_{Na[sup]+[/sup]}$ in the range 134-138 mEq/L is effective in reducing excessive IDWG and high UFR rates without discernible adverse effects.

FR-PO1012

Determining Blood Pressure Threshold for Intervention in Hemodialysis Patients: A Stratified Treatment Intention Analysis

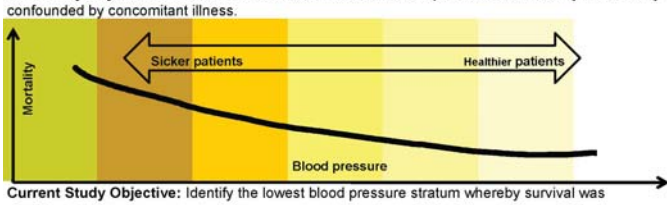
Steven M. Brunelli,[1] David B. Van Wyck,[2] Mahesh Krishnan,[2] Allen R. Nissenson.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita HealthCare Partners, Inc., Denver, CO.*

Background: Although most hemodialysis (HD) patients have pre-dialysis blood pressure (BP) considered hypertensive in other populations, information is lacking on whether interventions to reduce higher-than-normal BP are beneficial. Given the absence of evidence from randomized controlled trials (RCTs) and targeting bias of observational studies, we conducted a stratified treatment intention analysis in order to identify the BP at which intervention versus no intervention is associated with clinical benefit.

Methods: We examined adult patients on HD as of 01-Jan-2012 (N=10,758), stratified by mean pre-dialysis systolic BP recorded during Jan-2012, and categorized patients as having had, or not had, a BP intervention (antihypertensive escalation or target weight reduction) during Feb through Mar-2012. Within each BP stratum, intervention and control patients were matched 1:1 on 18 characteristics. Mortality was considered from Apr-2012 through Mar-2013.

Results: Within BP strata, matched intervention and control patients had balanced characteristics. At BP strata ≥150-159mmHg and higher, risk of death was reduced among intervention patients versus controls, but at lower BP strata mortality risk was greater among intervention patients.

Past Study Objective: Measure the association between blood pressure and mortality that is likely confounded by concomitant illness.



Current Study Objective: Identify the lowest blood pressure stratum whereby survival was significantly better among treated versus non-treated patients. With falling stratum of blood pressure, there is reduced opportunity for confounding. Propensity score matching patients further reduces confounding.

Results: Incidence rate ratios (95% CI) by blood pressure strata

120-129 mm Hg	130-134 mm Hg	135-139 mm Hg	140-149 mm Hg	150-159 mm Hg	160-169 mm Hg	170-179 mm Hg
PS matched Treated vs non-treated (275 pairs)	PS matched Treated vs non-treated (220 pairs)	PS matched Treated vs non-treated (276 pairs)	PS matched Treated vs non-treated (930 pairs)	PS matched Treated vs non-treated (1041 pairs)	PS matched Treated vs non-treated (879 pairs)	PS matched Treated vs non-treated (570 pairs)
1.24 (0.79-1.96) p = 0.35	1.54 (0.92-2.58) p = 0.10	0.75 (0.49-1.13) p = 0.17	1.20 (0.93-1.55) p = 0.17	0.92 (0.71-1.19) p = 0.51	0.86 (0.66-1.14) p = 0.30	0.86 (0.60-1.21) p = 0.38

When considered as a continuous variable, the intervention—mortality association differed significantly according to BP (p-interaction=0.003); crossover from harm to benefit occurred at 155mmHg.

Conclusions: Among HD patients, BP-lowering interventions were associated with a lower risk of death when BP was ≥150mmHg. Our results do not support routine interventions for patients with lower BP. Stratified treatment intention analyses may prove useful when RCT evidence is lacking and robust databases are available.

FR-PO1013

Early Changes in Systolic Blood Pressure and Body Weight Are Associated with Long Term Mortality in Incident Dialysis Patients

Flore Duranton,[1] Yohan Duny,[2] Ilan Szwarc,[3] Sebastien Deleuze,[4] Catherine Rouanet,[4] Isabelle Selcer,[4] Francois Maurice,[4] Jean Pierre Rivory,[4] Jean-Pierre Daures,[2] Angel Argiles.[1,3] *[1]RD - Néphrologie, Montpellier; [2]EA2415, Montpellier; [3]Nephrologie Dialyse St. Guilhem, Sète; [4]NéphroCare, Castelnau le Lez.*

Background: Systolic blood pressure (SBP) and body water are greatly altered in patients with heart and/or renal failure. We hypothesized that early changes in SBP and body weight (BW) could be associated with mortality in incident dialysis patients.

Methods: Patients incident to dialysis in 2004-2010 in 2 centers and surviving 90 days were followed-up for max 8 years. Longitudinal data were obtained from medical records (SBP and BW before dialysis) and REIN registry (outcome). Changes (linear regression slopes) and mean values in the first 15 days on dialysis (period 1) and the following 75 days (period 2: days 16-90) were associated with survival using Cox regression.

Results: 385 patients were included and 46.2% died during follow-up. In period 1 to 2, SBP and BW changed from 125±20 to 141±20mmHg and 61±14 to 70±15kg (p<0.001). Low SBP, low initial SBP slope and decreasing BW were associated with mortality (table). Low initial SBP and decreasing BW (both periods) remained significant in multivariate analysis (table). BW slopes remained significant (p<0.02) after adding heart failure (NS) in the model. Stratifying on heart failure showed that low BW slope in period 2 increased mortality in both groups, while initial BW slope was significant only in those without heart failure.

Table: Age and gender-adjusted hazard ratios of mortality

Effect	Period	Univariate		Multivariate	
		HR and 95% CI	P-value	HR and 95% CI	P-value
SBP ≤ 125 mmHg	1	1.7 [1.2; 2.3]	0.004	1.6 [1.0; 2.5]	0.047
SBP ≤ 130 mmHg	2	1.6 [1.2; 2.3]	0.003	1.2 [0.8; 1.9]	0.43
SBP slope ≤ 5 mmHg/d	1	1.7 [1.2; 2.4]	0.002	1.2 [0.8; 1.8]	0.29
BW slope ≤ -0.1 kg/d	1	1.9 [1.4; 2.7]	<0.001	1.6 [1.1; 2.3]	0.008
BW slope ≤ 0 kg/d	2	2.0 [1.5; 2.8]	<0.001	2.0 [1.4; 2.9]	<0.001

Conclusions: In the first months, patients starting dialysis have important changes in SBP and BW. Patients with BW decrease and additional low SBP have a greater risk of mortality, possibly related to heart failure.

FR-PO1014

Ambulatory Blood Pressure (ABPM) Is Better in Identifying Hypertension (HTN) Associated with Arterial Stiffness than Casual Blood Pressure (BP) in Pediatric (ped) Hemodialysis (HD) Patients (pts) Shweta S. Shah, Jessica Geer, Fallon Campbell, Sarah J. Swartz, Poyyapakkam Srivaths. *Nephrology, Texas Children's Hospital, Houston, TX.*

Background: Few studies in ped HD pts have shown ABPM to be a better predictor of target organ damage (TOD) when compared to casual pre and post HD BP as assessed by LVMI. Pulse wave velocity (PWV) is the gold standard measure of arterial stiffness;it is shown to be elevated in adult HD pts and associated with poor outcome. However no study has assessed PWV as a marker of vascular involvement in ped pts.Aim-Compare ABPM and casual BP in assessing TOD in ped HD pts.

Methods: Casual BPs were obtained pre, intra and post dialysis on chronic HD pts during their mid-week treatment. Pulse wave tonometry to derive Augmentation index (AI), central blood pressure and PWV was done at the same time. 24 hour ABPM was started after HD treatment on same day. Echocardiogram was done to obtain LVMI. Routine monthly blood work completed as per dialysis unit protocol.

Results: 22 pts (16 male) on 3/week HD, duration 4 hrs.Mean age 17 ± 3.8 yrs, vintage 47.8 ±33.7 month, kt/v 1.6 ±0.17, 9 pts had preHD HTN but all normalized after HD. ABPM identified 6 pts with HTN. AI was elevated (>5%) in 17/22 pts but improved in 10/22 pts after HD. PWV did not change after HD. LVMI was elevated in 9/22 pts but was not associated with HTN (either casual or ABPM) or arterial stiffness. HTN identified by ABPM but not by preHD BP was associated with arterial stiffness by PWV

ABPM	Age (yrs)	BMI (%ile)	Hgb (mg/dl)	LVMI ($g/m^{2.7}$)	**PWV* (m/sec)**	AI (%)
Normal N=16	17.5 (15.5,20)	37.5 (6.5,59.5)	11.8 (10.7,12)	36 (30.6,51)	**6.15 (5.4,7.4)**	12 (-13,22)
HTN N=6	18 (12,19)	75 (18,79)	11.6 (11.4,11.8)	56.5 (38,81)	**8.45 (6.8,8.8)**	16 (12,24)

Values expressed as median (IQR), *=P value of 0.015 (Mann-Whitney test)

Conclusions: Casual BP either pre or post HD was not helpful in identifying sustained HTN in our study as most pts BP normalized post HD. ABPM identified sustained HTN which was associated with arterial stiffness. LVMI was not associated with HTN.ABPM should be part of routine monitoring in ped HD pts. Assessment of vascular stiffness in addition to routine cardiac ECHO should be considered even in ped HD pts.

FR-PO1015

Effect of Angiotensin Converting Enzyme Inhibitors on Serum Potassium Concentrations in Hemodialysis Patients. An Observational Study Ezio Movilli, Giovanni Cancarini. *UO of Nephrology Spedali Civili and Univ of Brescia, Italy, Spedali Civili, Brescia, Italy.*

Background: Angiotensin converting enzyme inhibitors (ACEi) are increasingly used in uremic patients (pts). However, their effect on serum potassium concentrations (sK) in anuric pts on chronic hemodialysis treatment (HD) is controversial. Aim of the study: To evaluate sK before and after the start of ACEi therapy.

Methods: From 1-1-2011 to 31-12-2011, 87/206 prevalent anuric HD pts on regular HD started ACEi therapy. Mean age was 67±14 years, 57/87 were men, dialytic vintage was 6-20 months. In the 2 months before and after the start of ACEi therapy, the following variables were evaluated in pre dialysis after the long interdialysis interval: sK (mean value of 8 determinations) (mmol/L), maximum sK (maximum K value observed during observations) (sKmax; mmol/L), serum sodium (Na; mmol/L), hemoglobin (Hb; g/dL), EPO dose (U/Kg/sett), pre dialysis systolic (SBP: mmHg) and diastolic (DBP: mmHg) blood pressure, body weight (BW; Kg), interdialytic weight gain (IWG; Kg), Kt/V. SBP, DBP, IWG are the mean values of the 24 HD sessions. 60 pts were on bicarbonate HD, 27 on HDF. Duration of HD, Qb and Qd were kept constant. Data are expressed as mean±SD, t test for paired data was employed to compare groups. Significant differences were defined as $p<0.05$.

Results: sK increased from 5.0±0.4 mmol/L before ACEi to 5.7±0.5 mmol/L ($p< 0.0001$). sKmax increased from 5.4±0.5 mmol/L before ACEi to 6.2±0.6 mmol/L ($p<0.0001$). 7/87 pts reduced the K in dialysate. 15/87 pts (18%) stopped ACEi therapy. sK in these pts changed from 5.2±0.3 mmol/L to 6.5±0.2 mmol/L at the moment of suspension ($p<0.0001$). sKmax changed from 5.5±mmol/L to 6.9±0.3 mmol/L at the moment of suspension ($p< 0.0001$). After the suspension of ACEi, sK and sKmax concentrations normalized within 1 month. There were no significant changes of BW, IWG, SBP, DBP, Na, Hb, EPO dose, Kt/V.

Conclusions: Treatment with ACEi causes a significant 13% increase of the sK concentrations in HD pts. This can lead, in 18% of cases, to the need to stop the drug for sK values > 6.5 mmol/L and suggests caution in the wider utilization of these drugs in HD patients.

FR-PO1016

Safety of Eplerenone in Hemodialysis Patients: A Randomized Controlled Trial Michael Walsh,[1] Braden J. Manns,[2] Amit X. Garg,[3] Joe A. Bueti,[4] Christian G. Rabbat,[1] Andrew Smyth,[1] Jessica Tyrwhitt,[1] Jackie Bosch,[1] Peggy Gao,[1] Philip J. Devereaux,[1] Ron Wald.[5] *[1]McMaster Univ/Population Health Research Inst; [2]Univ of Calgary; [3]Western Univ; [4]Univ of Manitoba; [5]Univ of Toronto.*

Background: Mineralocorticoid receptor antagonists (MRA) reduce morbidity and mortality in non-dialysis patients with heart failure but their use is limited by hyperkalemia. Whether MRAs have similar benefits and risks in in dialysis patients is unclear. We studied eplerenone in hemodialysis patients.

Methods: We randomly allocated 154 prevalent hemodialysis patients from 5 Canadian centres to 13 weeks of either eplerenone 50 mg daily or a matching placebo. The primary outcome was permanent discontinuation of the study drug for hyperkalemia or hypotension. Eplerenone was considered non-inferior if a discontinuation rate for hyperkalemia or hypotension of greater than 20% could be excluded. Secondary outcomes included rates of hyperkalemia and effects on blood pressure and cardiovascular events.

Results: Seventy-seven participants were allocated to each group and had similar baseline characteristics. The per protocol population (i.e., those taking medication for at least one week) included 74 participants in the eplerenone group and 70 in the placebo group. The primary outcome occurred in 3 in the eplerenone group and 2 (2.9%) in the placebo group for an absolute risk difference of 1.2% (95% confidence interval -4.8% to 7.1%). Eplerenone was therefore considered [non-inferior/inferior] to placebo with respect to permanent discontinuation for hyperkalemia or hypotension. In the eplerenone group, 9 (12%) developed hyperkalemia (>6.5 mmol/L) compared to 2 (2.8%) in the placebo group (relative risk 4.3, 95% CI 1.0 to 19.0). No significant differences in fatal or non-fatal cardiovascular events were seen.

Conclusions: We did not find a substantially increased risk of permanent discontinuation of eplerenone due to hyperkalemia or hypotension. Serum potassium concentrations should be carefully evaluated when aldosterone antagonism is initiated. Large studies are required to determine if aldosterone antagonism reduces cardiovascular morbidity and mortality.

Comparative Effectiveness of Dihydropyridine and Non-Dihydropyridine Calcium Channel Blockers in Chronic Dialysis Patients James B. Wetmore,[1] Jonathan D. Mahnken,[2] Milind A. Phadnis,[2] Edward F. Ellerbeck,[3] Theresa I. Shireman.[3] *[1]Nephrology, Hennepin County Medical Center, Minneapolis, MN; [2]Biostatistics, Univ of Kansas Medical Center, Kansas City, KS; [3]Preventive Medicine & Public Health, Univ of Kansas Medical Center, Kansas City, KS.*

Background: Although there is evidence of benefit for use of calcium channel blockers (CCBs) in dialysis patients, the comparative effectiveness of dihydropyridine (DHP) and non- DHP CCBs has not been well studied.

Methods: A retrospective cohort analysis of effectiveness of DHP versus non-DHP CCBs in dialysis patients was conducted. Medicaid pharmacy claims were linked with USRDS Medicare Parts A and B claims to create a cohort of hypertensive patients initiating dialysis from 2000-05. After excluding patients who were received a CCB in the first 90 days after dialysis initiation, new users were followed from their 1st day of medication exposure until they died (all-cause mortality, or ACM) or, separately, incurred a combined cardiovascular hospitalization or death (cardiovascular morbidity or mortality, or CVMM), or were censored; CCB crossover was not allowed. Cox proportional hazards models generated adjusted hazard ratios (AHRs) comparing the effect of DHPs versus non-DHPs on ACM and CVMM.

Results: There were 7307 and 6121 new users CCBs who were included in the ACM and CVMM models, respectively; approximately 14.3% received non-DHPs. Adjusted for other factors, use of DHPs, compared to non-DHPs, was associated with an AHR of 0.60 (95% CIs, 0.53 – 0.69, $P < 0.0001$) for ACM and 0.77 (0.67 – 0.89, $P < 0.0001$) for CVMM. Results were similar when only individuals who initiated therapy within 90 days of cohort entry were included, with AHRs of 0.77 (0.64 – 0.93, $P = 0.0004$) and 0.86 (0.72 – 1.02, $P = 0.024$) for ACM and CVMM, respectively. Elimination of individuals with chronic atrial fibrillation resulted in similar AHRs of 0.59 and 0.63 for ACM and CVVM, respectively.

Conclusions: DHPs are associated with a reduction in ACM and CVMM by about 40% and 23%, respectively, compared to non-DHPs. This may be related to differential effects of these classes on cardiac inotropy, cardiac chronotropy, or vascular relaxation, but more studies are needed.

Ambulatory Recording of Arterial Stiffness and Wave Reflections during Intra- and Interdialytic Periods in Hemodialysis Patients

Panagiotis I. Georgianos,[1] Pantelis Sarafidis,[2] Antonis Karpetas,[1] Georgios Koutroumpas,[3] Vasilios Raptis,[1] Athanase Protogerou,[4] Christos Syrganis,[3] Dimitrios Stamatiadis,[5] Vassilios Liakopoulos,[1] Aikaterini A. Papagianni,[2] Anastasios Lasaridis.[1] *[1]Div of Nephrology, 1st Dept of Medicine, AHEPA Hospital, Thessaloniki, Greece; [2]Nephrology Dept, Hippokrateion Hospital, Thessaloniki, Greece; [3]Nephrology Dept, General Hospital of Volos, Greece; [4]Hypertension Unit & Cardiovascular Research Laboratory, "Laiko" Hospital, Athens, Greece; [5]Hemodialysis Unit, General Hospital of Serres, Greece.*

Background: Arterial stiffness and wave reflections are strong predictors of cardiovascular mortality in hemodialysis patients. Previous studies evaluating arterial cushioning function in this population included measurements obtained during the peridialytic period. The aim of this study was to investigate potential variations in arterial stiffness and wave reflections during the intra- and inter-dialytic intervals in hemodialysis patients.

Methods: A total of 153 hemodialysis patients underwent 48-hour ambulatory blood pressure monitoring (ABPM) with the Mobil-O-Graph device (IEM, Stolberg, Germany). ABPM included a 4-hour intradialytic period and the subsequent interdialytic interval. Mobil-O-Graph is a validated brachial cuff-based oscillometric device, which records pulse waveforms at brachial artery and assesses pulse wave velocity (PWV) and augmentation index (AIx) via mathematical transformation.

Results: Mean PWV was not changed between the intradialytic and out-of-dialysis intervals of the dialysis-on day (Day 1) (9.31±2.2 versus 9.29±2.3 m/sec, P=0.602). In contrast, heart rate-adjusted AIx (AIx (75)) was significantly lower during intradialytic than during the out-of-dialysis period of Day 1 (24.0±8.6 versus 26.4±7.7 %, P<0.001). Both parameters were increased during the dialysis-off day (Day 2) relevant to the out-of-dialysis period of Day 1 (9.39±2.3 versus 9.29±2.3 m/sec, P<0.001 and 27.5±8.2 versus 26.4±7.7 %, P<0.001 for PWV and AIx (75)).

Conclusions: This study shows a gradual increase in AIx (75) between intra- and inter-dialytic intervals in hemodialysis patients, whereas PWV exhibited only a slight and potentially BP-dependent elevation during the dialysis-off day.

FR-PO1019

Ventriculoarterial Uncoupling in Pediatric Hemodialysis Patients

Jessica Geer,[1] Shweta S. Shah,[1] Poyyapakkam Srivaths,[1] Eric Williams,[2] Ayse Akcan Arikan.[1,2] *[1]Pediatric Nephrology, Texas Children's Hospital/Baylor College of Medicine, Houston, TX; [2]Pediatric Critical Care, Texas Children's Hospital/Baylor College of Medicine, Houston, TX.*

Background: Hemodialysis (HD) patients are at high risk for cardiovascular (CV) morbidity and mortality. Intradialytic hypotension associated myocardial stun has been proposed as a potential cause. Nonivasive cardiac output measurements, validated in children, provide a dynamic bedside assessment of hemodynamic parameters. We sought to investigate intradialytic changes in hemodynamic parameters during pediatric chronic outpatient HD.

Methods: HD was performed using linear fluid removal over 4 hours. Continuous wave Doppler ultrasound was used to measure hemodynamic parameters pre HD, 120 minutes into HD, and post HD during the mid-week treatment. Pulse wave tonometry to derive augmentation index (AI), central blood pressure, and pulse wave velocity (PWV) was done at the same time.

Results: 22 pts (16 male) on 3/week HD, mean age 17 ± 3.8 yrs, vintage 47.8 ±33.7 months, spkt/v 1.6 ±0.17. No patient experienced intradialytic hypotension requiring intervention.

	Cardiac Index (L/min/m^2)	Stroke Volume (cm^3)	Systemic Vascular Resistance Index (dynes-sec/cm–5/m2)	Heart Rate (beat/min)	Pulse Wave Velocity (m/sec)
Pre	3.38 (2.9, 4.58) *	69.6 (58.04, 83.52) *	1973 (1750,2640)	81 (76,93) *	6.55 (5.8, 8.3)
Intra (120 min)	3.24 (2.5, 3.82) *	52.23 (43, 63) *	2100 (1768, 2357)	91 (84,102) *	7.1 (6.7, 8)
Post	3.33 (2.9, 3.74)	55.87 (48.13, 62.31)	1940 (1649, 2373)	91 (80,97)	6.6 (5.6, 7.5)

Values expressed median (IQR); *= p-value < 0.005

Conclusions: CI and SV decreased significantly during the HD session. Expected increase in SVRI to preserve CI was not observed. Increased PWV did not improve with HD. In children and young adults, the ventriculoarterial coupling response is disrupted in chronic HD patients, and increased arterial stiffness fails to improve with fluid removal. Noninvasive cardiovascular monitoring could identify asymptomatic patients with falling CI at risk of intradialytic myocardial stunning.

FR-PO1020

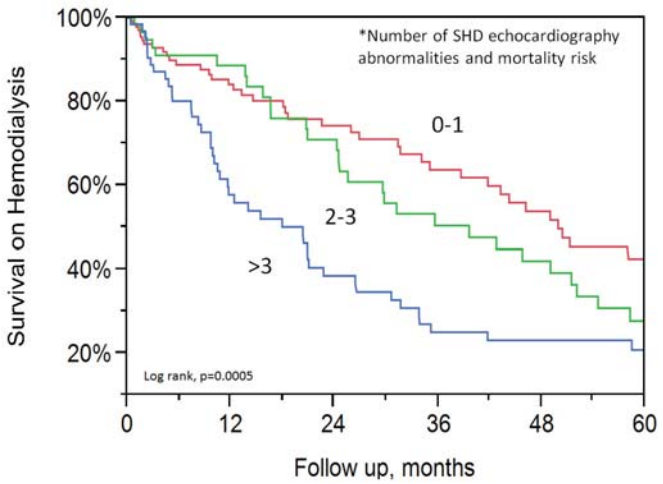
Structural Heart Disease and Outcomes in Incident Hemodialysis Patients: Correlation with Proposed Echocardiographic Criteria by the Acute Dialysis Quality Initiative (ADQI) Workgroup

LaTonya J. Hickson,[1] Andrew D. Rule,[1] Suzanne M. Norby,[1] Robert C. Albright,[1] James T. McCarthy,[1] Edward T. Casey,[1] Sorin V. Pislaru,[2] Hector R. Villarraga,[2] Amy W. Williams,[1] Vuyisile T. Nkomo.[2] *[1]Nephrology, Mayo Clinic; [2]Cardiology, Mayo Clinic.*

Background: Cardiovascular disease is highly prevalent among hemodialysis (HD) patients and relates to increased morbidity. The ADQI Workgroup recently proposed echocardiographic criteria for structural heart disease (SHD) in HD patients, but studies on the prevalence and clinical impact of SHD based on the new proposed classification are lacking.

Methods: AIM: To determine prevalence of SHD and its association with survival among incident HD patients. **METHODS:** A retrospective review of HD patients from a regional dialysis provider, who initiated HD from 2006-2009, and underwent echocardiography (EC) ±6 months of HD start (n=349).

Results: Mean age 65±15, 63% males, 90% Caucasian, 52% diabetes, and 45% coronary artery disease. Median time between EC and HD start was 15 days; 0-182. Accounting for missing variables (left ventricular [LV] volumes), 81% of patients had ≥1 EC finding meeting SHD criteria, and 35% had ≥3. The most common SHD abnormalities were: diastolic dysfunction (DD) (44%), left ventricular hypertrophy (LVH) (40%), aortic/mitral valvular heart disease (VHD) (33%), and LV ejection fraction (EF) ≤45% (25%). Over 1.8±2.1 years of followup, 141 (46%) died. SHD variables age- and gender-adjusted were associated with death; EF≤45% (HR 2.0, CI 1.4-2.8; p<0.01) was a strong positive predictor (DD, LVH, VHD; p>0.05). Presence of ≥2 abnormalities was associated with death (HR 1.5, CI 1.1-2.2; p=0.02) with an increased risk thereafter.



Conclusions: Based on ADQI classification, SHD is common among incident HD patients. The risk of death increases incrementally with higher prevalence of EC abnormalities. Early SHD detection may help improve management and outcomes.

FR-PO1021

Attenuated Cardiovascular Reserve Is a Major Complication of CKD That Is Only Partially Accounted for by Chronic Pressure Overload

Stephen M.S. Ting,[1,4] Gordon Mcgregor,[1] Thomas Hamborg,[4] Kenneth Lim,[2] Nicolas Aldridge,[1] David Oxborough,[3] Susan Hewins,[1] Gail Evans,[1] Rosemary Bland,[4] Chris H.E. Imray,[1,4] Robert Higgins,[1,4] Prithwish Banerjee,[1] Daniel Zehnder.[1,4] *[1]Univ Hospitals Coventry & Warwickshire NHS Trust, United Kingdom; [2]Oregon Health & Science Univ; [3]Liverpool John Moores Univ, United Kingdom; [4]Warwick Medical School, United Kingdom.*

Background: Patients with advanced CKD experience impaired functional cardiovascular reserve with reduced oxygen consumption at peak exercise (VO_2peak). It remains unknown if this abnormality is related to impaired cardiovascular compliance resulting from chronic uremia or hypertension.

Methods: 80 kidney transplant-waitlisted patients and 80 healthy subjects with essential hypertension matched in age (53.3 versus 53.4 years, p=0.82), sex (male: 56.3 versus 51.2 %, p=0.23) and BMI (27.2 versus 27.6 kg/m^2, p=0.55) were evaluated prospectively between 2010 and 2012. Maximal cardiopulmonary exercise testing, TD-echocardiography and pulse-wave-velocity (PWV) were performed.

Results: VO_2peak was significantly lower in CKD subjects compared with the non-uremic hypertensives (18.8 versus 24.5 ml/min/kg, p<0.001). Independent cardiovascular predictors of VO_2peak for CKD included LV filling pressure (E/mean e') (standardized regression coefficient, *B*=-0.5) and PWV (*B*=-0.2); in the hypertensives, these were LV mass index (*B*=0.5), LV end-diastolic volume index (LVEDVI) (*B*=0.6), peak heart rate (HR) (*B*=0.5) and PWV (*B*=-0.2). According to the best fitted model for the CKD population (adjusted R^2=0.43), higher E/mean e' was associated with a lower VO_2peak (*b*=-3.65, p=0.001) after adjusting for demographics, hemoglobin and duration of hypertension.

In the hypertensive cohort, the final model (adjusted R^2=0.66) identified higher LVEDVI (b=0.24, p<0.001), LV mass index (b=0.09, p=0.01) and peak HR as predictors of greater VO_2peak (b=0.12, p<0.001).

Conclusions: LV compliance is significantly associated with VO_2peak in advanced CKD resulting from mechanisms beyond predominantly arterio-ventricular changes associated with hypertension. This highlights the complex kidney-heart interactions that occur in renal failure beyond the effects of pressure overload.

Funding: Private Foundation Support

FR-PO1022

The Clinical Parameters Correlating with Cardiac Dysfunction at the Start of Dialysis Therapy Yoshimichi Urahama,[1] Daijo Inaguma.[2] *[1]Dept of Nephrology, Komaki Municipal Hospital, Komaki-City, Aichi-prefecture, Japan; [2]Kidney Center, Nagoya daini Red Cross Hospital, Nagoya City, Aichi-prefecture, Japan.*

Background: It has been reported that cardiac dysfunction is an important factor of poor prognosis in dialysis patients. In addition at the start of first dialysis there are many patients who have problems with heart function already. The aim of this study was to determine which clinical parameters were associated with left ventricular ejection fraction (LVEF) in end-stage renal disease patients.

Methods: This study, named AICOPP study consisted of 1525 ESRD patients (1420 HD, 105 PD) who began dialysis therapy between October 2011 and September 2013 at 17 dialysis centers. 1255 patients were screened by ultrasonic-echocardiography (UCG). Using a cross-sectional design, the statistical analysis was performed with program JMP 10.0 (SAS Institute).

Results: Total cholesterol level, body math index, use of angiotensin receptor blocker, use of phosphate binder, use of erythropoiesis stimulating agent (positive correlation) and serum uric acid level, eGFR, history of diabetes, left ventricular hypertrophy and atrial fibrillation on electrocardiogram, use of beta receptor blocker, use of loop diuretics (negative correlation) correlated with LVEF. Multiple regression analysis of LVEF (%) demonstrated that serum BNP level (pg/ml, R=-0.00426, P<0.001), heart rate at the beginning of dialysis therapy (/min, R=-0.155, P<0.001), history of ischemic heart disease (R=-3.05, P=0.0070), age (years, R=0.167, P<0.001), systolic blood pressure at the beginning of dialysis therapy (mmHg, R=0.0518, P=0.0055), history of heart failure hospitalization (R=-1.49, P=0.00128) and female (R=1.29, P=0.0157) were significant parameters.

Conclusions: In conclusion high serum BNP level, high heart rate at the beginning of dialysis therapy, history of ischemic heart disease, advanced age, low systolic blood pressure at the beginning of dialysis therapy, history of heart failure hospitalization and male are the clinical parameters correlating with cardiac dysfunction in patients newly initiated into dialysis. ESRD patients with such clinical characteristics are necessary to receive reliable evaluation and care of cardiac function.

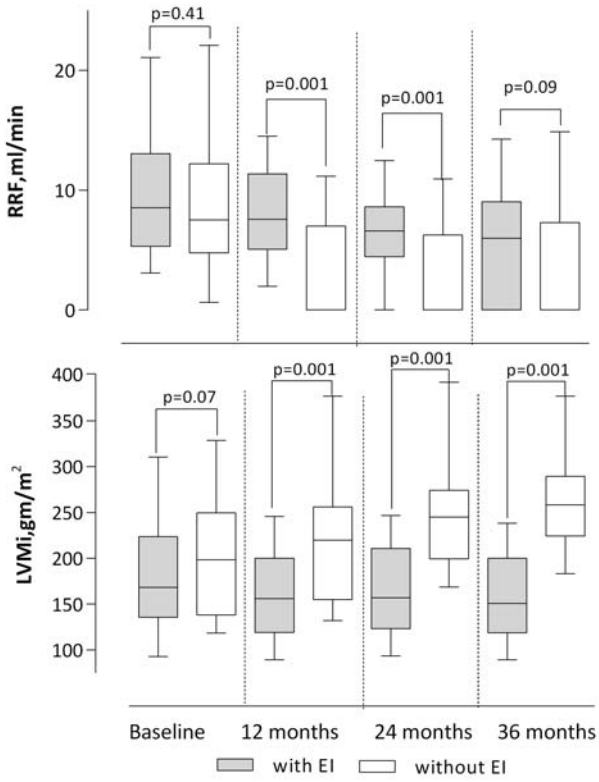
FR-PO1023

Impact of Randomized Educational Intervention on Residual Renal Function (RRF) and Left Ventricular Mass Index (LVMi) in Incident PD and HD Patients (CECODIAR Study) Gustavo Lorenzo Moretta,[1] Amilcar Vinuela,[2] Carlos Florencio Lara,[3] Eduardo Emilio Ducasse,[4] Elsa Graciela Giarrocco,[5] Carlos Alberto Bonanno,[6] Javier De Arteaga,[7] Abdul Rashid Tony Qureshi,[8,9] Jose C. Divino-Filho.[9] *[1]Centro Nefrologico Noroeste, Argentina; [2]Sanatorio de la Mujer, Argentina; [3]Inst Lanari, Argentina; [4]CIMAC, Argentina; [5]Centro de Enfermedades Renales, Argentina; [6]Hospital Militar, Argentina; [7]Dialiquen, Argentina; [8]Dialisis Berazategui, Argentina; [9]Centro Integral Nefrologico, Argentina; [10]Hospital Privado de Cordoba, Argentina; [11]Div of Baxter Novum, Karolinska Instt, Sweden; [12]Div of Renal Medicine, Karolinska Instt, Sweden.*

Background: The prevalence of traditional cardiovascular (CV) risk factors is high in dialysis patients (pts) whereas RRF preservation and LVMi reduction impact positively on survival. To evaluate the impact of educational intervention (EI) on preserving RRF and maintaining CV health status (LVMi) in HD and PD incident pts.

Methods: Prospective, multicenter, randomized EI trial in incident adult dialysis pts. The CV risk factors were evaluated after 12, 24 and 36 months of follow-up.

Results: A total of 171 pts were randomized to either EI (n=88) with median age 63 (38-70), 61% male, DM 39% and 38% initiated with PD. or without EI (n=83) with median age 60 (31-77), 53% male, DM 35% and 35% initiated with PD. Pts assigned to EI had better preservation of RRF and improved LVMi than pts without EI.



No significant survival advantage for the all-cause mortality in pts with EI was observed. The EI PD pts had a positive trend (p=0.07) to survival advantage compared to patients without EI.

Conclusions: EI, may be an important determinant of RRF preservation and LVMi improvement among incident dialysis patients. The role of EI should be further explored and applied to promote cardiac health in dialysis.

FR-PO1024

Association of Preload and Afterload with Left Ventricular Mass in Incident Hemodialysis Patients: Predictors of Arrhythmic and Cardiovascular Risk in End Stage Renal Disease (PACE) Study Esther D. Kim,[1] Stephen M. Sozio,[2] Michelle M. Estrella,[2] Bernard G. Jaar,[2] Tariq Shafi,[2] Lucy A. Meoni,[2] Wen Hong Linda Kao,[2] Joao A.C. Lima,[2] Rulan S. Parekh.[1,2] *[1]Univ of Toronto; [2]Johns Hopkins Univ.*

Background: Higher left ventricular (LV) mass strongly predicts cardiovascular (CV) mortality in hemodialysis (HD). Though several parameters of preload and afterload have been associated with higher LV mass, the relative importance of these parameters in predicting LV mass is unknown.

Methods: In a prospective cohort of 390 incident HD adults in the PACE study, we examined measures of afterload (SBP, SBP, arterial stiffness by pulse wave velocity [PWV]) and preload (volume status using estimated pulmonary pressures by echocardiogram on an interdialytic day and intradialytic weight gain [IDW]). Outcome was LV mass index (LVMI) by echocardiogram.

Results: PreHD and interdialytic SBP, DBP, and pulse pressures were associated with LVMI after adjusting for CV confounders. IDW was also associated with higher LVMI but attenuated effects after adjustment (p=0.01). PWV and pulmonary pressures were not associated with LVMI after multivariable adjustment (p=0.6 and p=0.8, respectively).

Table: Association of preload and afterload measures with LVMI by linear regression

Measurements	Unadjusted		Adjusted*	
	β (95% CI)	P	β (95% CI)	P
Vascular				
BP (per 10 mmHg)				
Predialysis[a]				
Systolic	6.2(3.3,9.1)	<0.001	7.5(4.5,10.5)	<0.001
Diastolic	10.5(6.2,14.8)	<0.001	11.6(6.4,16.8)	<0.001
Predialysis[b]				
Systolic	2.6(0.7,4.5)	0.008	2.5(0.5,4.4)	0.01
Diastolic	6.2(3.1,9.3)	<0.001	4.6(1.2,7.9)	0.008
Interdialytic[c]				
Systolic	4.8(2.9,6.7)	<0.001	5.0(3.0,6.9)	<0.001

Pulse pressure				
Predialysis[a]	0.3(-0.1,0.6)	0.2	0.7(0.3,1.1)	0.001
Predialysis[b]	0.1(-0.2,0.3)	0.5	0.2(-0.1,0.5)	0.1
Interdialytic[c]	0.4(0.1,0.7)	0.004	0.6(0.3,0.9)	<0.001
Arterial stiffness				
Pulse wave velocity	-0.4(-1.8,0.9)	0.5	0.4(-1.2,2.0)	0.6
Volume				
Pulmonary artery pressure	0.3(-0.3,0.9)	0.3	0.1(-0.5,0.7)	0.8
Intradialytic weight[b]	4.0(1.1,6.9)	0.007	3.7(0.8,6.6)	0.01

[a]3 month average
[b]Prior to study visit
[c]Seated
*Adjusted for demographic factors, CV risk factors, antihypertensive medications

Conclusions: Higher systolic, diastolic, or pulse pressure, regardless of timing with HD, is associated with higher LV mass. These results suggest the importance of afterload reduction in preventing increasing LV mass in HD patients.

FR-PO1025

Asymptomatic Arrhythmias on Hemodialysis by Continuous 7-Day ECG Monitoring Rulan S. Parekh,[1] Lucy A. Meoni,[2] Bernard G. Jaar,[2] Stephen M. Sozio,[2] Michelle M. Estrella,[2] Wen Hong Linda Kao,[2] Larisa Tereshchenko.[2] *[1]Univ of Toronto, Canada; [2]Johns Hopkins Univ.*

Background: Sudden cardiac death (SCD) is the most common cause of death in dialysis patients. Asymptomatic arrhythmias may lead to SCD; however, the impact of dialysis therapy on rates of arrhythmia is unknown.

Methods: One-lead surface ECG was recorded continuously for up to 7 days via an ECG patch (ZioPatch, iRhythm Technologies, Inc.) in 28 participants from the Predictors of Arrhythmia and Cardiovascular Events (PACE) Study, a prospective cohort of incident hemodialysis participants. Rates of non sustained ventricular tachycardia (VT), supraventricular tachycardia (SVT), atrial fibrillation (AF), pauses above 3 seconds (sec), and AV block were measured during 6 hours pre-dialysis, during, 6 hours post, and in between treatments.

Results: Mean age was 53.9 years, 59% were men, 14% had prevalent coronary heart disease (CHD), and had a mean left ventricular ejection fraction (LVEF) of 70.3±9%. Average heart rate was 77.3 ± 9 bpm. Nearly half had at least one arrhythmic event detected and 6 patients had at least 2 different types of arrhythmias. All events were non-sustained, lasting < 30s, and asymptomatic except one patient with paroxysmal AF. Non-sustained ventricular tacycardia (NSVT) was more frequent during or immediately postdialysis compared to pre/between dialysis treatments (63% versus 37%, P=0.01). None of the patients with NSVT had CHD. Conversely, SVT was more frequent pre/ between dialysis, as compared to during or post dialysis (84% versus 16%, P=0.01). No events of high degree AV block were detected.

Asymptomatic Arrhythmias among 28 HD Participants with Continuous 7 Day ECG Monitoring

Timing	Between dialysis	Pre-dialysis	During dialysis	Post-dialysis	Unique individuals
Events	n (%)				
Total (n=47)	18 (38)	12 (26)	8 (17)	9 (19)	13 (46)
VT (n=8)	2 (25)	1 (13)	2 (25)	3 (38)	4 (15)
SVT (n=17)	9 (53)	5 (29)	1 (6)	2 (12)	9 (32)
AF (n=21)	7 (33)	6 (29)	4 (19)	4 (19)	2 (7)
Pauses >3 s (n=1)	0	0	1 (100)	0	1 (3.5)

Conclusions: Asymptomatic supraventricular and ventricular arrhythmias are frequent in hemodialysis, and associate temporally with dialysis treatments.

Predictors of Arrhythmia Events in Incident Patients on Hemodialysis – Results from the International MONDO Initiative Viviane Calice-Silva,[1,2] Jochen G. Raimann,[1] Stephan Thijssen,[1] Aileen Grassmann,[3] Daniele Marcelli,[3] Bernard Canaud,[3] Len A. Usvyat,[4] Peter Kotanko,[1] Roberto Pecoits-Filho,[2] Mondo Consortium.[1,2,3,4] *[1]Renal Research Inst, New York; [2]Pontifical Catholic Univ of Parana, Curitiba, Brazil; [3]Fresenius Medical Care, Bad Homburg, Germany; [4]Fresenius Medical Care North America, Waltham.*

Background: Arrhythmias due to electrolytes changes, fluid overload, cardiac dysfunction, and other causes are associate to adverse outcomes in hemodialysis (HD) patients. The aim of this study was to explore predictors of arrhythmia-related events (ARR; hospitalization and mortality) in the MONDO cohort.

Methods: This analysis included incident HD patients from the MONDO database commencing treatment in clinics in the U.S. and Europe. The mean of clinical and laboratory parameters were computed for the first 12 months (baseline-BL) and clinical events (deaths and hospitalizations) were recorded in months 13 to 24 (follow-up). Hospitalizations and causes of death were classified as ARR according to ICD-9 and 10 codes. Poisson regression models were constructed to explore associations between BL parameters and the number of ARR events during follow-up.

Results: We studied 22729 patients (59.3% males, 63.5±14.9 years). Older age, higher serum phosphorus and the previous diagnosis of congestive heart failure (CHF) were associated with higher risk of ARR death and hospitalization. Higher normalized protein catabolic rate (nPCR) and hemoglobin (HGB) levels were associated with lower risk of ARR. (Figure 1; adjusted by region)

Parameter	Estimate	Wald 95% Confidence Limits		P-value
Age [per year]	**0.0228**	**0.0117**	**0.0338**	**<.0001**
Phosphate [per mg/dL]	**0.2129**	**0.0761**	**0.3497**	**0.0023**
Comorbid_CHF [Y/N]	**0.6715**	**0.3357**	**1.0073**	**<.0001**
nPCR [per g/day/kg body weight]	**-1.68**	**-2.5848**	**-0.7752**	**0.0003**
HGB [per mg/dL]	**-0.159**	**-0.3154**	**-0.0025**	**0.0465**
Male [Y/N]	-0.1581	-0.44	0.1239	0.2718
BMI [kg/m2]	0.0124	-0.0105	0.0352	0.2882
Diabetes [Y/N]	0.1967	-0.099	0.4923	0.1923
Treatment time [per hour]	-0.0018	-0.0094	0.0058	0.6466
Pre-HD SBP < 100 mmHg [Y/N]	0.7771	-0.6389	2.1932	0.2821
Pre-HD SBP > 140 mmHg [Y/N]	0.2687	-0.0343	0.5717	0.0821
IDWG [per % of post-HD weight]	0.1402	-0.0102	0.2906	0.0676
Albumin [per g/L]	-0.1611	-0.5543	0.2321	0.4221
NLR [per 1 unit]	0.0315	-0.0085	0.0715	0.1222
Potassium [per 1 mmol/L]	0.2414	-0.0271	0.51	0.0781
Calcium [per mg/dL]	-0.2246	-0.4914	0.0421	0.0988
Myocardial Infarction [Y/N]	-0.425	-1.4277	0.5777	0.4061

Conclusions: In the studied cohort higher nPCR and HGB were associated with a lower risk of ARR events while older age, higher phosphate levels and presence of previously diagnosed CHF were associated with a higher risk of ARR. These findings may assist the identification for HD patients at high risk for ARR and help to define targets for interventions.

FR-PO1027

Predictors of Sudden Death in Incident Patients on Hemodialysis – Results from the International MONDO Initiative Viviane Calice-Silva,[1,2] Jochen G. Raimann,[1] Stephan Thijssen,[1] Aileen Grassmann,[3] Daniele Marcelli,[3] Bernard Canaud,[3] Len A. Usvyat,[4] Peter Kotanko,[1] Roberto Pecoits-Filho,[2] Mondo Consortium. *[1]Renal Research Inst, New York; [2]Pontifical Catholic Univ of Parana, Curitiba, Brazil; [3]Fresenius Medical Care, Bad Homburg, Germany; [4]Fresenius Medical Care North America, Waltham.*

Background: Sudden death (SD) is defined as sudden, unexpected death within an hour of symptoms onset or without obvious non-cardiac cause. In chronic kidney disease (CKD) 5D patients SD is responsible for 25% of deaths. The aim of this study was to explore predictors of sudden death in the MONDO cohort.

Methods: This analysis included incident hemodialysis (HD) patients from the MONDO database commencing treatment in clinics in the U.S. and Europe. The mean of clinical and laboratory parameters were computed for the first 12 months (baseline) and clinical events (deaths) were recorded in months 13 to 24 (follow-up). Mortality was classified as SD-related according to ICD-10 and ICD-9 codes. Poisson regression models were constructed to explore associations between baseline parameters and the number of SD events during follow-up.

Results: We studied 22729 patients (59.3% males, 63.5±14.9 years).Older age, male gender, pre-HD SBP <100 mmHg, greater IDWG (in % of post-HD weight), higher serum calcium levels, higher neutrophil to lymphocyte ratio (NLR) and previous diagnosis of myocardial infarction (MI) were associated with higher risk of SD. Higher nPCR, albumin, hemoglobin (Hgb) levels and pre-HD SBP > 140 mmHg were associated with lower risk of SD. (Figure 1, adjusted by region).

Figure 1. Predictors of sudden death (Poisson regression)

Conclusions: This international study identifies predictors of sudden death in chronic HD patients, including several ones, which are accessible to interventions. Presence of predictors associated with increased risk may alert the health care providers to deploy targeted interventions to reduce the risk of sudden death.

FR-PO1028

Utilization of an Implantable Loop Recorders to Characterize Cardiac Arrhythmias in Hemodialysis Patients Christian Combe,[1] Antoine Benard,[1] Jean-Philippe Bourdenx,[2] Haddj Elmrabet Atman,[3] Keller Adrien,[4] Frederic Lavainne,[5] Julien Ott,[6] Thierry P. Hannedouche,[7] F. Sacher.[1] *[1]CHU & Univ, Bordeaux, France; [2]CTMR St. Augustin, Bordeaux, France; [3]CHU, Rennes, France; [4]CH, Libourne, France; [5]CHU, Nantes, France; [6]CH, Haguenau, France; [7]CHU, Strasbourg.*

Background: Sudden cardiac death (SCD) is the most common mode of death among hemodialysis (HD) patients (pts). However, little is known about the terminal arrhythmic events in these pts. Our objective was to identify the mechanisms which may lead to SCD in HD pts using an implantable loop recorder (ILR, Reveal XT®, Medtronic).

Methods: Pts from 9 HD centers have been included in the study. None of the pts had a cardiac pacemaker or implantable cardiac defibrillator. Continuous monitoring of the cardiac rhythm is performed using the remote monitoring capability of the ILR device (Carelink®). Clinical, biological, and technical HD parameters are recorded.

Results: 72 pts (65.8±8.7 yrs, 50M) have been included. The most common causes of ESRD are diabetes (n=31) and hypertension (n=18). 33 pts had an underlying cardiomyopathy (20 ischemic). 15 pts had Left Ventricular Ejection Franction<60%. Atrial fibrillation (AF) was noted in 9 pts prior to inclusion. 49 pts are still followed-up. 12 pts died after 11±7 months: 6 pts from a non-cardiac cause (sepsis 2, hemorrhage 1, ischemic colitis 1). SCD occurred in 6 pts; a further patient suffered an acute coronary syndrome following vascular graft surgery. In SCD patients, ILR tracings demonstrated progressive bradycardia followed by asystole. No ventricular fibrillation was recorded. With ILR monitoring, AF was diagnosed in 9 pts, a pace-maker was implanted in 2 pts. More than 700 events have been recorded in 36 pts to date.

Conclusions: In our study mortality rate in HD pts was 12%, with 4.4% SCD. In SCD pts, the terminal arrhythmic event was asystole. AF was detected in 9% of previously undiagnosed pts. ILR monitoring will be performed 2 years for each pt; at the end of the 2-yr period, links between events and recorded parameters will be analyzed. We hope to be able to identify factors predictive of SCD, whether linked to the patient or to HD technique.

FR-PO1029

Mortality following Anticoagulation for Atrial Fibrillation in End Stage Renal Disease Patients Matthew J. Diamond,[1] Jennifer L. Waller,[2] Avirup Guha,[1] Jose R. Cuellar Silva,[1] William R. Maddox,[1] Mufaddal F. Kheda,[1] Robert A. Sorrentino,[1] N. Stanley Nahman.[1] *[1]Medicine, Georgia Regents Univ, Augusta, GA; [2]Biostatistics & Epidemiology, Georgia Regents Univ, Augusta, GA.*

Background: Atrial fibrillation (AF) is a major cause of embolic stroke (CVA) and is treated with lifelong oral anticoagulation (OAT). The $CHADS_2$ and CHA_2DS_2VASc (CHAD) risk stratification tools help select anticoagulation therapy in patients with AF. We showed that CHAD scoring predicts CVA and mortality in ESRD patients (Cuellar, JACC, 63:A297 and Murphy JACC, 63:A358). It is unclear, however, what effect OAT may have on mortality in this group. To address this question we queried the USRDS for the effect of OAT on mortality in AF patients.

Methods: All incident adult hemodialysis (HD) cases from the USRDS for 2005-2008 were queried for the determinants of CHAD scores. Data were derived for comorbid diagnoses using ICD9 and CPT codes, or data from Form 2728. Descriptive statistics by CVA or mortality were calculated and simple logistic regression was used to estimate the odds ratio (OR) for each potential risk factor. The administration of anticoagulation was inferred by the presence of at least one prothrombin time per month using CPT code 85610.

Results: 443,890 incident dialysis patients were identified, of whom, 39,387 had a diagnosis of AF at incident date of dialysis (IDD).Table 1 displays the incident of stroke and death during the query period, with detail given to patients on OAT.

Table 1
Patients with AF (39,387);
with AF and OAT (5,048)

	<90d from IDD	>90d from IDD	none
Stroke (3,129)	5.3%	2.6%	92.1%
OAT with Stroke (446)	6.0%	2.9%	91.1%
Death (27,632)	50.8%	19.3%	29.8%
OAT with Death (3,837)	57.4%	18.6%	24.0%
OR for Death Controlling for OAT (95% CI)	1.31 (1.21-1.42)	1.09 (0.99-1.20)	

Conclusions: AF in incident HD patients carries a high mortality within the first 3 months of starting dialysis. OAT therapy appears to substantially increase the risk of death in these patients. The therapeutic benefit of OAT therapy in AF patients on HD cannot be determined form these studies, but suggests it may be equivocal. Additional studies are indicated to assess risk factors and outcomes in this group.

Safety of Warfarin Use in Chronic Hemodialysis Patients: A Prospective Cohort Study Matsuhiko Hayashi,[1] Mieko Iwai,[1] Maho Yamashita,[1] Tadashi Yoshida,[1] Yoshihiko Kanno.[2] *[1]Apheresis and Dialysis Center, School of Medicine, Keio Univ, Shinjuku-ku, Tokyo, Japan; [2]Div of Nephrology, Tokyo Medical School, Shinjuku-ku, Tokyo, Japan.*

Background: Since there are limited data concerning the risks associated with warfarin use in hemodialysis (HD) patients, we conducted a prospective cohort study in the patients on chronic HD in Japan.

Methods: The patients on chronic HD with warfarin use and their controls were recruited from 103 HD centers in Japan. For each patient on warfarin, two dialysis-vintage matched controls were selected at each HD center. Clinical data were collected at the beginning and every 12 months after the registration for 36 months.

Results: Preliminary one-year data was presented at ASN meeting in 2012, and the final data of three-year study is presented, here. At the start, 382 cases with warfarin and 720 controls were registered. In warfarin group, the occurrence of composite incidences (40.3%), which include death, new stroke, and new cardiovascular events, were significantly higher as compared to the controls (31.0 %, $p< 0.01$). The incidence of major bleeding (gastrointestinal, intramuscular, and hemorrhagic stroke) in warfarin users (15.7%) was also significantly higher than in the controls (7.8%, $p<0.0001$). By logistic regression model analysis, however, age (OR 1.004 for each 1-year increase, 95% CI 1.003-1.005, $p<0.0001$) and the antiplatelet drug use (OR 1.58, CI 1.02-3,05, $p<0.05$) but not warfarin use were identified as the risk factors for composite incidences, while warfarin use was the sole risk factor for major bleeding (OR 2.35, CI 1.45–3.82, $p<0.001$). Patients with warfarin for preexisting Af (200 cases) and their corresponding controls (379 cases) were analyzed separately, and warfarin use was not a significant risk factor for increase in composite incidences in this subgroup, either.

Conclusions: The present study showed that occurrences of major bleeding and composite incidences were higher in warfarin group, while age and antiplatelet use but not warfarin were identified as the risk factors for composite incidences in either entire population of the patients or the patients with AF. We conclude that warfarin may be less harmful than previously reported in HD patients.

FR-PO1031

Risk of New Onset Stroke Is Increased in Incident Hemodialysis Patients and Associates with Cardiovascular Risk Factors but Not Atrial Fibrillation Mark Duncan Findlay,[1,2] Peter C. Thomson,[2] Jesse Dawson,[1] Patrick B. Mark.[1,2] *[1]Inst of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom; [2]Western Infirmary, Renal Unit, Glasgow, United Kingdom.*

Background: Hemodialysis (HD) patients are at increased risk of stroke. Risk factors for stroke are defined in the general population but are less clear in HD. We studied incidence and risk factors for new onset stroke in a single center over a six-year period.

Methods: All patients undergoing in centre HD between 1st Jan 2007 and 31st Dec 2012 were identified. Study entry was 1st January 2007 in prevalent HD patients and from HD commencement in incident patients. Baseline clinical, laboratory and demographic data were recorded. The primary endpoint was stroke defined by occurrence of fatal (using death records) or non fatal (using hospital discharge / imaging records) ischemic or hemorrhagic stroke. Follow up was to 31st Dec 2013.

Results: 1382 patients were identified (mean age 62.9 years; 58.5% male; prevalence of ever having atrial fibrillation (AF) 21.2%). 59.4% were incident patients. 164 (11.6%) experienced new stroke (94.5% ischemic) over 3471 patient-years of follow up. Stroke incidence was 39.7/1000 patient-years in prevalent patients and 54.3/1000 patient-years in incident patients. At baseline, patients who had stroke on follow up were older (mean 68.4 versus 62.1 years, $p<0.001$), more likely to have diabetes (34.8 versus 27.2%, $p<0.05$) or prior CeVD (14.0 versus 2.2%, $p<0.001$). There was no greater proportion of strokes in patients with AF compared to without (23.2 versus 20.9%) with no differences in stroke

proportion between warfarin treatment or not in AF patients (log-rank p=0.7) Significant independent risk factors for stroke were age, prior CeVD, diabetes and hypoalbuminemia. In prevalent (but not incident) patients high systolic blood pressure, phosphate and low hemoglobin associated with risk.

Conclusions: Stroke incidence is high in HD patients with high comorbidity burden, particularly when clinical, imaging and mortality data are combined to ascertain cases. Incident and hypoalbuminemic HD patients are high-risk groups. Further studies are required to identify if targeting modifiable risk factors improves outcomes.

FR-PO1032

Cerebrovascular Diseasein China Dialysis Patients Ke Zheng,[1] Xuemei Li.[1] *[1]Renal, Peking Union Medical College Hospital, Beijing, China; [2]Renal, Peking Union Medical College Hospital, Beijing, China.*

Background: Stroke is one of the most common causes of cardiovascular disease death in patients on dialysis therapy, and there will be a series of subsequent consequences of the cerebrovascular disease, especially in cognition function. But by now, there are few data about these problems in China ESRD patients.Our study is a cross-sectional study aimed to disclosure the cerebrovascular disease in our ESRD (hemodialysis and peritoneal dialysis) patients.

Methods: By the end of May 2014, We included 183 participants aged 17 to 88 years who came from our dialysis center. Among them, 116 were on hemodialysis, 63 were on peritoneal dialysis, and 4 of them were on combined dialysis modalities. Basic information, clinical evaluations, laboratory tests, and MRI images were assessed. 99 of them had cognitive tests of MMSE (Mini Mental Test Examination) and MoCA (Montreal Cognitive Assessment).

Results: By MRI, the prevalence of Cerebral hemorrhage haematoma was 6.0% (11/183), microbleeds was 40.9% (75/183), large vascular cerebral infarction was 7.1% (13/183), lacunar infarction was 39.3% (72/183) and white matter lesions 44.3% (fazekas scale≥2,81/183). Abnormal in cognitive test was 81.8% by MoCA (81/99, MOCA <26) and 18.1% by MMSE (18/99, MMSE<26). Of MMSE score, There were no statistical difference between patients with or without lacunar infarction (Z=-1.751, P=0.08); patients with or without microbleeds (Z=-1.609, P=0.11), or Fazekas scales (Z=-0.840, P=0.40). Of MoCA score, there were statistical difference between patients with or without lacunar infarction (Z=-2.011, P=0.044), and Fazekas scales (Z=-2.531, P=0.011), but no statistical difference between patients with or without microbleeds (Z=-1.543, P=0.12).

Conclusions: In our dialysis patients, there are high prevalence of lacunar infarction, microbleeds, and white matter lesions. And these patients showed higher possibility of impaired cognitive function. MOCA may be more sensitive in cognition evaluation. Further studies are needed to discover the potential influence factors on these ESRD patients' brain lesions and cognitive function.

FR-PO1033

Cardiovascular Disease as an Independent Factor Associated with Cognitive Impairment in Hemodialysis Patients -- A Cross-Sectional Analysis of Osaka Dialysis Complication Study (ODCS) Tetsuo Shoji,[1] Katsuhito Mori,[2] Masanori Emoto,[2] Masaaki Inaba.[2] *[1]Dept of Geriatrics & Vascular Medicine, Osaka City Univ Graduate School of Medicine, Osaka, Japan; [2]Dept of Metabolism, Endocrinology and Molecular Medicine, Osaka City Univ Graduate School of Medicine, Osaka, Japan.*

Background: Dementia-cognitive impairment is common in dialysis patients. Since cardiovascular disease (CVD) is also common in this population, we examined the association of CVD with cognitive function in a large sample of hemodialysis patients.

Methods: This is a cross-sectional analysis of the baseline data of our multicenter cohort of prevalent hemodialysis patients. Global cognitive function was evaluated with modified mini-mental state (3MS). We determined CVD as composite of the clinical coronary (CAD), cerebral (CeVD), peripheral artery disease (PAD) and congestive heart failure requiring hospitalization (CHF).

Results: Among the total of 1696 patients, we analyzed data from 1229 subjects who were examined with 3MS. The median age was 67 years, median dialysis vintage was 5 years, 63% were male, 39% had diabetes, and 21% had education of college or higher degree. Pre-existing CVD was found in 36% (N=439). Median (IQR) of 3MS core was 91 (81 to 97) point, and 196 subjects (16%) had 3MS score lower than 77 point, suggesting suspicious dementia. 3MS was lower in patients with CVD, particularly those with CeVD. Other factors associated with a lower 3MS were higher age, shorter dialysis vintage, diabetes, lower BMI, lower serum albumin, lower diastolic BP, and lower education level. Multiple logistic regression analyses indicated that the pre-existing composite CVD was associated with a lower 3MS independent of the potential confounders. When composite CVD was divided into CAD, CeVD, PAD and CHF, only CeVD was a significant factor independently associated with 3MS.

Conclusions: Pre-existing CVD, especially CeVD, was independently associated with cognitive impairment in hemodialysis patients, indicating the presence of vascular cognitive impairment in this population.

FR-PO1034

Predictors of Cardiovascular Events in Incident Hemodialysis Patients – Results From the International MONDO Initiative Rakesh Malhotra,[1,2] Len A. Usvyat,[2] Michael Etter,[3] Peter Kotanko,[2] Xiaoqi Xu,[4] Bernard J. Canaud,[3] Daniele Marcelli.[3] *[1]VUMC; [2]RRI; [3]FMC Germany; [4]FMC Hongkong; [5]MONDO Initiative.*

Background: Hemodialysis (HD) patients have increased risk of cardiovascular morbidity and mortality. We explored predictors of cardiovascular events in the MONitoring Dialysis Outcomes (MONDO) initiative.

Methods: Our cohort includes 22,443 HD patients initiating in-center treatments between 1/2006 and 12/2012, who were enrolled as part of MONDO (MONitoring Dialysis Outcomes) research initiative [Usvyat, Blood Purification 2013]. We extracted data for only those patients who survived at least 12 months after the start of HD. The mean of clinical and laboratory parameters were computed for the first 12 months (baseline). We constructed a Poisson regression model to predict cardiovascular events during months 13-60 (follow-up). Cardiovascular event was defined as combination of cardiovascular death, fatal or non-fatal myocardial infarction, angina and stroke according to ICD-10 and ICD-9 codes.

Results: 22,443 HD patients were studied (Eastern Europe: 4,969, Western Europe: 228, Northern Europe: 1,940, Southern Europe: 7,492, Western Asia: 2,134, North America: 5,680). The mean (SD) age was 63.7 (15.0) years, and 60.5% were males. The model, significant predictors, and b estimates with 95% CI are presented in Figure 1.

Figure 1. Poisson regression results with adjustment by geographical region

Parameter	Estimate	Hazard Ratio	95% Confidence Limits		P-value
Age [per year]	0.0419	1.043	1.035	1.051	<.0001
BMI [kg/m2]	-0.0406	0.960	0.941	0.980	<.0001
Albumin [per g/dL]	-0.5332	0.587	0.472	0.730	<.0001
Hgb [per g/dL]	-0.2033	0.816	0.745	0.894	<.0001
Sodium [per mmol/L]	-0.0469	0.954	0.926	0.983	0.002
IDWG [per % of body weight]	0.1019	1.107	1.005	1.220	0.039
eKt/V [per 1 unit]	-0.8397	0.432	0.280	0.665	<.0001
Diabetes [Y/N]	0.2918	1.339	1.109	1.616	0.002

Conclusions: Our large international study identifies clinical relevant risk factors to predict cardiovascular events in incident HD patients. Inflammatory marker (neutrophil to lymphocyte ratio) and pre-HD SBP>140 mmHg were not associated with cardiac events. These findings may help clinicians in the assessment of cardiovascular risk providing targets for intervention in HD patients.

FR-PO1035

A 12-Year Increasing Trend of Dialysis Incidence in Those Receiving Coronary Angiography in Taiwan Yu-Kang Chang,[1] Jia-Sin Liu,[1] Shang-Jyh Hwang,[2] Chih-Cheng Hsu.[1] *[1]Div of Geriatrics and Gerontology, Inst of Population Health Sciences, National Health Research Insts, Miaoli, Taiwan; [2]Div of Nephrology, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan.*

Background: In patients undergoing coronary angiography (CA), the risk factors and incidence trend of contrast induced dialysis (CID) are unknown.

Methods: With a retrospective analysis of the registration and reimbursement files in the National Health Insurance (NHI) Research Database (NHIRD) in Taiwan from 1997 to 2009, we determined the incidence, the independent predictors, and the trend of CID (defined as developing acute or chronic renal failure requiring at least 2 dialysis therapies within 2 weeks after the index CA).

Results: Of 507,866 patients, in acute myocardial infarction (AMI) and non-AMI patients, the overall incidences of CID were similar (0.75% versus 0.62%). After multivariate regression analysis, the independent risk factors of CID included: female, diabetes, chronic kidney disease, congestive heart failure, bypass surgery and the years after 2002 to receive CA. There was a significant time trend in the increase of CID incidence for the last 12 years: compared with risk in 1998, the risk in 2009 were 3.7 (95%CI = 3.2-4.2) and 3.0 (95%CI = 2.9-3.5) times higher for AMI and non-AMI patients. CID requiring chronic dialysis accounted for 2% of total incident chronic dialysis in 1998 but over 5% in 2009.

Conclusions: The independent predictors of CID were consistent with most traditional risk factors for CIN (contrast induced nephropathy). The persistent increase of CID has become an important factor for heavy loading of end-stage renal disease in Taiwan.

FR-PO1036

Risk Factors and Long-Term Outcome Among Young Dialysis Patients with Acute Coronary Syndrome: A Population-Based Cohort Study in Taiwan Wei-Chih Kan,[1,2] Chih-Chiang Chien.[1,2] *[1]Nephrology, Chi-Mei Medical Center, Tainan, Taiwan; [2]Chung Hwa Univ of Medical Technology, Tainan, Taiwan.*

Background: There are only little studies known about the epidemiology, risk factors, and sex differences of acute coronary syndrome (ACS) in young adult patients on dialysis. The study aims to identify the risk factors for these young dialysis patients and survey for their long-term outcome.

Methods: We conducted an observational cohort study to investigate the risk factors and long-term outcome in the young dialysis patients (18-55 years old), who started maintenance dialysis between January 1999 through December 2007, based on Taiwan's National Health Insurance claim data. 24,520 young dialysis patients were enrolled for this study. The follow-up period was from the start of dialysis to the date of ACS, death, end of dialysis, or December 31, 2008. Several risk factors possibly affecting mortality were analyzed with Cox proportional hazards models. Kaplan-Meier method was also used for their long-term survival status.

Results: ACS was diagnosed in 1,325 patients (1.28/100 person-years) during the follow-up period. Male patients had a higher incidence of ACS (1.61/100 person-years) than female patients (0.97/100 person-years). After adjustment, young male dialysis patients were still found to be at 36% increased risk of ACS (HR 1.36, 95% CI: 1.22-1.53). There was not a notable association between dialysis modality risk of ACS. Patients with baseline comorbidities (diabetes mellitus, hypertension, congestive heart failure, coronary artery disease, cerebrovascular accident, dysrhythmia, dyslipidemia, and hyperuricemia) had a higher incidence of ACS than those without. Overall in-hospital mortality was 8.3%.

Conclusions: Young male adult ESRD dialysis patients were a significantly greater risk than female patients. Having baseline comorbidities was independently associated with higher risk of ACS.

FR-PO1037

Factors Associated with First Myocardial Infarction following the Initiation of Dialysis in U.S. Patients: 1995-2010 Austin G. Stack,[1,2] Mohamed Elsayed,[1,2] Cornelius John Cronin,[1,2] Liam F. Casserly,[1,2] Hoang Thanh Nguyen.[2] *[1]Nephrology, Univ Hospital Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Ireland.*

Background: Cardiovascular disease is the leading cause of death among patients who progress to end stage kidney disease (ESKD). We sought to explore the relationship of patient and treatment-related factors with first major myocardial infarction among new dialysis patients in a population-based cohort study.

Methods: From the U.S. Renal Data System, we constructed a national cohort of 1,097,747 incident patients (n= 86,168 on PD) who were Medicare eligible and began dialysis between 5/1995 to12/2010 and followed until 9/2011. Hospitalizations attributed to first myocardial infarction (MI) [ICD 9 codes; 410.xx] were obtained from the USRDS standard analysis files and merged with data from the medical evidence, treatment history and mortality files. Multivariable logistic regression explored the relationship of patient-related factors, pre-dialysis care and treatment modality with the likelihood [Odds Ratio (OR)] of MI occurring in the period following dialysis initiation. The analysis was repeated using Cox regression with censoring at transplantation, death, recovery of kidney function, or end of study. Approval was granted from University Hospitals Ethics Committee.

Results: The likelihood of MI was significantly higher for older patients, women, patients with diabetes, hypertension, pre-existing cardiovascular conditions, smokers, drug dependence (all P<0.001), and for patients treated with erythropoietin in the pre-dialysis period (OR=1.03*). In contrast, the likelihood was lower for patients classified as underweight (OR=0.90*) and obese (OR=0.98*) compared to overweight (OR=1.03*) or normal weight (OR=1.00); and for peritoneal dialysis versus haemodialysis (OR =0.95*). A trend analysis found that the odds of MI was significantly higher in the period 2000-2005 (OR=1.89*) and 1995-1999 (OR=1.88*) compared to 2006-2010 (OR=1.00, referent). * P< 0.001.

Conclusions: Despite adverse cardiovascular profiles of incident dialysis patients, an encouraging decline in rates of myocardial infarction has occurred from 1995-2010. This trend is associated with the use of Peritoneal dialysis.

FR-PO1039

Pharmacological Stress ^{13}N-Ammonia Positron Emission Tomography Myocardial Perfusion Imaging Indicates Myocardial Microvascular Dysfunction in Hemodialysis Patients Ryo Takahashi,[1] Keiko Kimura,[1] Chieko Matsubara,[1] Kiyohito Kawashima,[1] Satoru Ohshima,[2] Yasuhiko Ito,[3] Hirotake Kasuga.[1] *[1]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; [2]Cardiology, Nagoya Radiology Foundation, Nagoya, Japan; [3]Nephrology, Nagoya Univ, Nagoya, Japan.*

Background: Cardiovascular disease is one of the important complications in hemodialysis (HD) patients. Cardiac dysfunction is caused by not only coronary arterial sclerosis but also by myocardial microvascular dysfunction. ^{13}N-ammonia positron emission tomography (PET) myocardial perfusion imaging (MPI) can evaluate myocardial microvascular function. However, myocardial microvascular function (by PET MPI) was not studied in detail in Japanese HD patients.

Methods: Twenty HD patients, 10 non-dialysis chronic kidney disease (CKD; eGFR<60mL/min/1.73m^2) patients and 17 non-CKD subjects without perfusion defect (Summed Stress Score<3) were enrolled. Myocardial blood flow (MBF) was evaluated at rest and underATP induced hyperemia, and coronary flow reserve (CFR) was examined by ^{13}N-ammonia PET MPI. We assessed MBF and CFR in 3 groups. Also, we compared diabetic (DMHD) and non-diabetic HD (non-DMHD) patients (n=9 and 11, respectively) in MBF and CFR.

Results: MBF at rest in HD patients was 1.13mL/g/min and significantly higher than that in non-CKD patients (0.87mL/g/min, p<0.05). We did not find significant differences in stress MBF between 3 groups. CFR was significantly impaired in HD patients compared with CKD and non-CKD patients (2.21, 2.78, 3.07, P<0.01 versus CKD and p<0.01 versus non-CKD, respectively). No significant correlations between each parameter and hemoglobin or blood pressure were observed. In MBF at rest of HD patients, there was no significant difference between DMHD and non-DMHD. However, stress MBF in DMHD was significantly lower than that in non-DMHD (2.32mg/g/mL and 2.99mg/g/mL, p=0.02). In addition, CFR in DMHD was significantly impaired compared with that in non-DMHD (2.05 and 2.76, p=0.008).

Conclusions: Our data indicate that myocardial microvascular function is impaired in Japanese HD patients, especially in DMHD.

FR-PO1040

Predictive Value of Measures of Vascular Calcification for Risk of Death in Incident Dialysis Patients Antonio Bellasi,[1] Mario Cozzolino,[2] Domenico Russo,[3] Donald A. Molony,[4] Biagio Raffaele Di Iorio.[5] *[1]Ospedale Sant'Anna-Como; [2]Univ of Milan; [3]Univ "FEDERICO II" Napoli; [4]Univ of Texas-Houston; [5]PO "A Landolfi" – Solofra.*

Background: Vascular calcifications (VC) are a useful marker of cardiovascular disease and several methods are available for presence and extension assessment. However, which one of these measures best predicts long-term survival and whether a measure of vascular calcification adds to the predictive value of traditional Framingham risk stratification, has not been determined through a concurrent comparison of these measures in a single prospective cohort.

Methods: To addresses these questions, we examined survival amongst 184 patients followed in the independent study for up to 36 months who had three measures for vascular calcification determined at baseline; coronary artery calcification (CAC) by volume or Agatston score, and abdominal aorta calcification by X-ray (Kauppila score-KS). Regression models, ROC were used.

Results: for each VC assessment separately, the most parsimonious model to predict all-cause mortality was selected starting from a model adjusted for VC measure (CAC or KS), Pulse Wave Velocity, age, Framingham score, diabetes, ASCVD, systolic blood pressure, serum levels of phosphate, calcium, PTH, use of ARBs, beta-blockers, vitamin D, calcium containing phosphate binder, calcium channel blockers and cinacalcet. The predictive value of the model with and without the measurement of VC was calculated.

	CAC-Agatston			CAC-Volume			Kauppila score		
	without	with	p-value	without	with	p-value	without	with	p-value
Overall performance (R-square)	0.12	0.35	-	0.17	0.34	-	0.13	0.27	-
Metrics of discrimination (C-statistics)	0.74	0.9	<.001	0.77	0.89	<.001	0.73	0.84	<.001
Model fit statistics (AIC)	160	225	<.001	162	214	<.001	186	222	<.001
Patients reclassification (NRI)	-	1.27	<.001	-	1.07	<.001	-	0.92	<.001

Conclusions: Overall, it seems that CAC is a better predictor of outcome than abdominal aorta VC though the difference is minimal. Of interest, in each model VC is more important than the Framingham risk score in predicting all-cause mortality.

FR-PO1041

Ankle-Brachial Index Is Associated with Coronary Artery Calcification in Incident Hemodialysis Patients: The Predictors of Arrhythmic and Cardiovascular Risk in End-Stage Renal Disease Study Bernard G. Jaar,[1] Lucy A. Meoni,[1] Stephen M. Sozio,[1] Michelle M. Estrella,[1] Wen Hong Linda Kao,[1] Joao A.C. Lima,[1] Rulan S. Parekh.[1,2] *[1]Johns Hopkins Univ, Baltimore, MD; [2]Univ of Toronto, Toronto, Canada.*

Background: Patients on hemodialysis (HD) have a high prevalence of peripheral artery disease and coronary artery disease. Ankle-Brachial Index (ABI) is an indicator of generalized atherosclerosis, but its association with coronary artery calcification (CAC) has not been well evaluated in HD patients. We aimed to assess the relationships of low (<0.9) and high (>1.4) ABI with CAC in this population.

Methods: This is a cross-sectional study of incident HD patients. At enrollment, patients had CAC assessment by multi-detector computed tomography and were stratified as: 0-99 (none/mild); 100-399 (moderate); ≥400 (severe). ABI was classified into three groups: <0.9 (low), between 0.9 and 1.4 (normal), >1.4 or non-compressible (high). Clinical predictors (age, sex, race, smoking history, hypertension, diabetes, log transformed CRP, LDL, and calcium phosphate product) were assessed at baseline. Multivariable logistic regression was used to determine the association between ABI and CAC adjusting for other risk factors.

Results: A total of 232 patients (mean age 54±13 years, 58% male, 75% African-American, 59% ever smoked, 56% diabetic) were included with a median CAC of 44 (IQR 0, 451). Low ABI was present in 6%, normal in 68% and high in 26%. The table shows the odds of CAC by ABI category. Both low and high ABI categories were significantly associated with higher CAC. Further adjustment with laboratory assays did not change the results.

	100≤ CAC <400	CAC ≥400
ABI*	Odds Ratio (95%CI)	Odds Ratio (95%CI)
Unadjusted		
<0.9	3.94 (0.82-18.95)	5.57 (1.53-20.21)
>1.4	2.14 (0.92-5.00)	2.59 (1.31-5.15)
Adjusted**		
<0.9	4.23 (0.81-22.22)	6.49 (1.57-26.77)
>1.4	2.52 (0.97-6.58)	2.55 (1.09-5.95)
* Reference group: 0.9≤ ABI ≤1.4 ** Adjusted for age, sex, race, diabetes		

Conclusions: Low and high ABI were significantly associated with the extent of CAC in this incident cohort of HD patients. ABI is a non-invasive and inexpensive tool that can be easily used to evaluate cardiovascular health in HD patients.

The Different Cut-Off Value of Ankle Brachial Index of Hemodialysis Patients, which Predict Cardiovascular Diseases, by Presence of Diabetes Mellitus Makoto Harada,[1] Koji Hashimoto,[1] Wataru Tsukada,[3] Yosuke Yamada,[1] Akinori Yamaguchi,[1] Mai Sugiyama,[1] Taro Kanno,[1] Makoto Higuchi,[2] Yuji Kamijo.[1] *[1]Dept of Nephrology, Shinshu Univ School of Medicine, Matsumoto, Nagano, Japan; [2]Dept of Nephrology, National Hospital Organization, Matsumoto Hospital, Matsumoto, Japan; [3]Ueda Kidney Clinic, Ueda, Japan.*

Background: Severe atherosclerosis and vascular calcification, causing coronary artery stenosis and/or peripheral artery diseases, are frequently detected in hemodialysis (HD) patients. Ankle brachial index (ABI) is considered to be one of the useful predictable markers of development of cardiovascular diseases (CVD); however the cut-off value of ABI in HD patients, as well as its difference by presence of diabetes mellitus (DM), has been controversial.

Methods: A retrospective cohort study using 110 maintenance HD patients was conducted. To investigate the cut-off value of ABI which predicts CVD in HD patients, we performed receiver operating curve analysis using all clinical data. To evaluate the difference of the cut-off value by presence of DM, we separated the subjects into DM group and non-DM group, and compared the cut-off value among the groups.

Results: The cut-off value of ABI which predicts CVD in all HD patients was 0.98 (area under curve 0.76, sensitivity 0.67, specificity 0.78). Among these HD patients, the cut-off value of ABI in DM group was 1.05 (area under curve 0.74, sensitivity 0.81, specificity 0.61), while that in non-DM group was 0.96 (area under curve 0.77, sensitivity 0.71, specificity 0.87). Kaplan–Meier method indicated that the patients exhibiting ABI less than the cut-off values appeared to cause CVD with high possibility in each group.

Conclusions: The current study reveals that the cut-off value of ABI in HD patients, which predicts CVD, is higher as compared to that in general population. Moreover, the cut-off value of ABI in DM group would be further elevated. Although the mechanism underlying the elevation of cut-off value of ABI is still unclear, the excess vascular calcification in HD patients, especially that in DM group, may contribute it. When we evaluate the CVD risk in HD patients, we should consider the different cut-off value of ABI by presence of DM.

FR-PO1043

Subjective Global Assessment of Nutritional Status and Mortality in Chronic Dialysis Patients: A Nationwide Prospective Observational Cohort Study in Korea Nara Shin,[1] Eunjin Bae,[1] Ji In Park,[1] Sunhwa Lee,[1] Hajeong Lee,[1] Dong Ki Kim,[1] Yong-Lim Kim,[2] Shin-Wook Kang,[3] Chul Woo Yang,[5] Yon Su Kim.[1] *[1]Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; [2]Internal Medicine, School of Medicine, Kyungpook National Univ, Daegu, Korea; [3]Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea; [4]Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea; [5]Internal Medicine, College of Medicine, the Catholic Univ of Korea, Seoul, Korea.*

Background: Malnutrition is a common and crucial problem because it is associated with higher mortality in chronic dialysis patients. Subjective global assessment (SGA) has been proven as a clinically adequate method for assessing nutritional status in dialysis patients. We explored the relationships between initial and transitions of SGA and all-cause mortality.

Methods: A nation-wide prospective observational cohort study included adult chronic dialysis patients. We selected patients who had baseline and 12 month follow-up SGA. SGA-7 score was categorized as well-nourished (SGA 6~7) and malnourished (SGA 1~5) groups. The changes of SGA were categorized by 4 groups (well-maintained, poorly-maintained, improving, and worsening group).

Results: A total of 2,600 patients were selected and mean age was 55.7±14 years old and 57.2% of patients were male. The mean follow-up period was 28.5 months. During the follow-up period, 202 patients (7.8%) were died. The mortality rate in malnourished patients was higher in both incident (5.2% versus 13%, p<0.001) and prevalent patients (6.3% versus 20.4%, p<0.001). The survival rate was significantly higher in well-nourished patients in 12 month follow-up (p<0.001). Moreover, in terms of SGA transition, improving and well-maintained groups had better survival rate than worsening group and poor-maintained group. These findings were reproducible even afteradjustment of age, gender, smoking, BMI, comorbidity, serum albumin, cholesterol and hs-CRP (HR 2.913, 95% CI, 1.856–4.573, p<0.001).

Conclusions: Malnutrition assessed by SGA was an independent predictor for all-cause mortality. Furthermore, the transition of SGA was also correlated with mortality in chronic dialysis patients.

FR-PO1044

Dialysis or Conservative Management in Chronic Kidney Disease (Stage 5) ? Evaluation of Patients in a Tertiary Hospital Who Started Dialysis in 2012 Natacha Rodrigues,[1] Maria João Nunes da Silva,[2] André Fragoso,[5] Maria Ferin Fraga,[2] Luis Santos Pinheiro,[2] Jose António Lopes,[1] Teresa Adragao,[3] Peter G. Lawlor,[4] António Gomes da Costa.[1] *[1]Dept of Nephrology, CHLN, Portugal; [2]Dept of Internal Medicine, CHLN, Portugal; [3]Dept of Nephrology, CHLO, Portugal; [4]Faculty of Medicine, Univ of Lisbon, Portugal; [5]Dept of Nephrology, Hospital de Faro, Portugal.*

Background: Studies suggest that in elderly patients with Stage 5, Chronic Kidney Disease (CKD-5) the survival benefit with dialysis can be lost if there is high comorbidity and low Performance Status, and thus Conservative Management (CM) can be a valid option. **Aims:** Todescribe hospitalised patients who started dialysis in a tertiary hospital in 2012: to determine mortality predictors; and to identify patients who could have benefitted from CM.

Methods: We retrospectively examined data from hospitalised CKD-5 patients, who were followed over a 23-month period. Patient data included their Karnofsky Performance Status (KPS); Mental Status (MS); Charlson (CCI); and Elixauser Comorbidity Index (ECI).

Results: Of our study sample (N=185) 57% were male, 50% were diabetic, 45% were 75 years or older (75+), 51% were admitted to Internal Medicine wards and 35% to a Renal ward. Mean follow-up was 12±6 months; 35% died, 47% during their first hospitalisation. Mortality was associated with age 75+ (p<.001); KPS<50 (p<.001); confusion and dementia (CDMS) (p=.001); ECI>5 (p=.015); CCI>8 (p=.05), heart failure (HF) (p=.002); coronary artery disease (p=.027); arrhythmia (p=.01); and CKDEPI (p<.001). Mortality predictors in a Cox regression model were: 75+ (HR 3.2; p=0.003); HF (HR 1. 9; p=0.03); CCI>8 (HR 3.6; p=0.003); CDMS (HR 2.3; p=0.003); and CKDEPI (HR 1.08; p<0.001). The 75+ patients (n=11) who were referred early to Nephrology with HF and KPS<50, and met standard CM criteria benefitted less with dialysis: 6 died and 1 recovered renal function.

Conclusions: CI and KPS status were useful in predicting mortality. Dialysis use and mortality could possibly be reduced by applying CM criteria. A prospective study in an outpatient renal clinic setting could identify robust CM criteria in frail elderly patients with high comorbidity.

FR-PO1045

Depressive Symptoms and Self-Management among Chronic Dialysis Patients Mi-Kyung Song,[1] Sandra E. Ward,[2] Jessica C. Bridgman,[1] Constance A. Gilet,[3] Gerald A. Hladik.[3] *[1]School of Nursing, Univ of North Carolina-Chapel Hill, Chapel Hill, NC; [2]School of Nursing, Univ of Wisconsin-Madison, Madison, WI; [3]UNC Kidney Center, Univ of North Carolina-Chapel Hill, Chapel Hill, NC.*

Background: Having depressive symptoms as measured by self-report is an independent risk factor for mortality in patients on chronic dialysis. However, evidence about whether dialysis patients recognize such symptoms and how they manage them is largely lacking.

Methods: Data are from an ongoing longitudinal observational study of quality of life in chronic dialysis patients (NCT01530945). Baseline and monthly measurements, including CESD-10, are made for 12 months. 107 patients have completed 926 data collection sessions. If a patient's CESD-10 score was ≥ 10 or if he/she responded affirmatively to a suicidal ideation item, an event report was generated to document the patient's response to symptoms and to determine whether the symptoms required a referral for further evaluation.

Results: There were 297 depression events with an average of 2.8 per patient. Of those, 192 (64.6%) were for mild to moderate symptoms (CESD = 10-14), 104 (35.1%) were for severe depressive symptoms (CESD ≥ 15), and 29 (9.8%) involved suicidal ideation. The most frequent contributing factors were 'being on dialysis' (43 events, 14.5%), 'managing other health issues' (43, 14.5%), 'financial difficulties' (32, 10.8%), 'family/personal relationship issues' (27, 9.1%), and 'pain' (20, 6.7%). In 15 events, patients themselves had been unaware of their depressive symptoms. The most common self-management behaviors for those who recognized depressive symptoms (282 events) were 'did not act on depressive symptoms' (158, 56.0%), 'talked to primary care provider or dialysis staff' (102, 36.2%), and 'did not try to talk to healthcare providers' (99, 35.1%). The primary reason for not informing care providers of their symptoms was distrust in the staff, e.g., 'they don't care', 'they can't do anything.'

Conclusions: Despite the high prevalence of depressive symptoms, many patients on chronic dialysis lack knowledge of effective self-management strategies and do not discuss their depressive symptoms with care providers.

Feasibility and Acceptability of Routine Palliative Care Referral in Severely Ill Hemodialysis Patients: A Pilot Study Ion D. Bucaloiu,[1] Zankhana Mehta,[2] Jamie Alton Green,[1] H. Lester Kirchner,[3] Shiloh D. Erdley,[4] Patricia Maani,[2] Sally J. Regel,[2] Evan Norfolk,[1] Neil M. Ellison.[2] *[1]Nephrology and Hypertension, Geisinger Medical Center, Danville, PA; [2]Palliative Medicine, Geisinger Medical Center, Danville, PA; [3]Center for Health Research, Geisinger Medical Center, Danville, PA; [4]Sociology, Social work and Criminal Justice, Bloomsburg Univ, Bloomsburg, PA.*

Background: ESRD patients with advanced illness have unmet end of life needs. We evaluated the feasibility of a routine in-center palliative care intervention in severely ill dialysis patients.

Methods: Eligible patients were adult prevalent ESRD patients at an academic center dialysis unit for whom their primary nephrologist answered "'No" to the question "Would I be surprised if my patient died in the next 6 months?" or had a 12-month survival probability of less than 50%. We excluded patients with cognitive deficits, deemed non-adherent to dialysis treatment, non-English speaking or already in a hospice or palliative care program. The intervention consisted of 4 monthly palliative care visits during dialysis sessions. Surveys assessing quality of life, depression, illness understanding, symptoms, functional status and satisfaction with life were obtained at baseline and after each visit. Main outcomes included recruitment, retention and palliative care acceptability to patients.

Results: Thirty four (43%) of all unit patients met eligibility criteria. Of these, 22 (65%) consented to participate in the study. Of 22 patients enrolled, 17 (77%) completed all study activities, 2 (9%) withdrew from the study after discussing with family members at home but prior to the first study visit and 1 (5%) patient withdrew after the first study visit. Two (9%) patients died before completing study. Of patients who completed the study 17 (100%) were satisfied with the overall visit experience, and 13 (77%) felt that the palliative care visits would help them in the future.

Conclusions: An in-center routine palliative care intervention in severely ill ESRD patients is feasible and acceptable. Further research evaluating the impact of such collaborative care model in this population is needed.

FR-PO1047

Outcomes of In-Hospital Cardiopulmonary Resuscitation in Maintenance Dialysis Patients in the United States, Years 2005-2011 Fahad Saeed,[1] Jesse D. Schold,[1] Jean L. Holley.[2] *[1]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; [2]Nephrology and Hypertension, Carle Physcians Group and Univ of Illinois at Urbana-Champaign, Urbana, IL.*

Background: There is no recent study on the outcomes of cardiopulmonary resuscitation (CPR) in end-stage renal disease (ESRD) patients requiring maintenance dialysis. Our primary aim was to analyze the outcomes of in-hospital cardiopulmonary resuscitation (CPR) in these patients in comparison with the general population.

Methods: We obtained and analyzed data from the Nationwide Inpatient Sample (NIS 2005- 2011). The study population included all adults (>18 years old) from the general population and those with a history of ESRD. Baseline characteristics, in-hospital complications, and discharge outcomes were compared between the two groups. The effects of in-hospital CPR on mortality, length of stay, cost of hospitalization, and discharge destination were analyzed. Two logistic regression models were created. Model one was used to identify the association between ESRD and odds of in-hospital mortality. Model two included patients who were discharged alive and aimed at identifying the association between ESRD and likelihood of discharge to a nursing facility versus other discharge destinations.

Results: During the study period, 56,069 ESRD patients underwent in-hospital CPR as compared to 323,620 patients from the general population. In-hospital mortality rates were higher in ESRD patients (73.9 % versus 71.8%, p=<.0001) on univariate analysis. On multivariate analysis after adjusitng for age, gender, and potential confounders, ESRD patients had higher odds of mortality: odds ratio 1.2, 95 %; CI 1.1-1.3, p=<.0001. Survivors in the ESRD group were more likely to be discharged to a nursing home (odds ratio 1.1, 95 %; CI 1.0 -1.2, p=<.04).

Conclusions: Survival after in-hospital CPR remains relatively poor. CPR outcomes remain worse in comparison with the general population. ESRD patients who survive are more likely to be discharged to nursing homes. This information should be communicated to dialysis patients during CPR discussions.

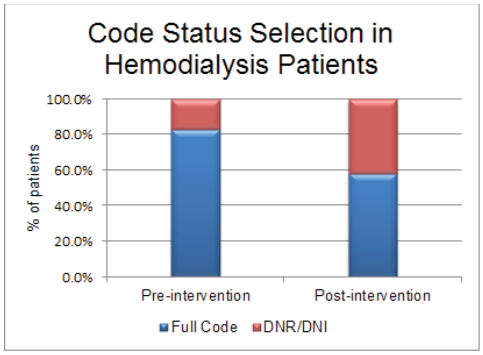
FR-PO1048

Dedicated Clinical Encounter Facilitates Advance Care Planning in Hemodialysis Patients: A Quality Improvement Project Osama W. Amro,[1] Malar Ramasamy,[1] James A. Strom,[2] Daniel E. Weiner,[1] Bertrand L. Jaber.[2] *[1]Nephrology, Tufts Medical Center; [2]St. Elizabeth Medical Center, Tufts Univ School of Medicine, Boston, MA.*

Background: The Renal Physicians Association Clinical Practice Guideline recommends that physicians address advance care planning with their patients. This quality improvement project implemented a standardized approach to educating dialysis patients with limited physician-estimated life expectancy on advance care planning and end-of-life care, with the goal of increasing autonomy and informed decision making.

Methods: Primary nephrologists identified their patients at two dialysis facilities who could most benefit from advance care planning using the 'surprise question: "Would I be surprised if this patient were to die within the next year?" Patients with a 'no' answer were approached in a dedicated clinical encounter on advance care planning. Information on the Massachusetts Medical Orders for Life-Sustaining Treatment (MOLST, a POLST analog) was provided. Family members were encouraged to participate in person or by phone.

Results: Of 201 hemodialysis patients, nephrologists answered no to the surprise question for 50 (25%). Of these, 9 (18%) had a "do not resuscitate/intubate (DNR/DNI)" order and 41 (82%) were "full-code". Following the encounter, 21 (42%) had a DNR/DNI order and 29 (58%) had a full-code order (Figure 1; P = 0.008). Encounters lasted 15-60 minutes. MOLST adoption rate increased from 10 to 90%.



Conclusions: A dedicated encounter targeting hemodialysis patients with limited life expectancy leads to significant changes in code status and identification of preferences on life-sustaining treatment limitations. This likely reflects better understanding of end-of-life care and informed decision making. Our approach was simple, practical, and effective. We will make this discussion routine for patients, repeating the encounter annually.

FR-PO1049

Validation of the Distress Thermometer in a UK Renal Population Helen Alston, Aine Burns. *UCL Centre for Nephrology, Royal Free Hospital, London, United Kingdom.*

Background: Older patients with advanced chronic kidney disease (CKD) and multiple co-morbidities have high symptom and depression scores in cross-sectional studies. However, long-form measurements of depression and symptom burden are not practical for regular routine screening use. We have found the Distress Thermometer (DT), a simple self-scoring visual analogue scale which records global distress (a composite of physical wellbeing, psychosocial and spiritual issues), easy to use in our multi-ethnic CKD population and have used it as a tool to enhance communication and ensure a patient-centred approach at routine CKD clinic patient visits.

Methods: Aim: To validate the Distress Thermometer (DT) in a UK renal population **Hypothesis:** The DT is a quick, acceptable and valid tool in UK renal patients, and correlates with the Beck Depression Inventory II (BDI-II), Hospital Anxiety and Depression Scale (HADS), Memorial Symptom Assessment Score (Short Form) (MSAS-SF) and SF36 scores. **Outcomes of interest:** DT, HADS, BDI-II, MSAS-SF and SF-36 scores **Study Design:** This is a method comparison study, which establishes that DT scores correlate with a variety of symptom, depression and quality of life tools. We also carried out an acceptability feedback questionnaire.

Results: 277 patients completed the study (138 haemodialysis patients, 139 low clearance clinic patients). The Distress Thermometer correlates well with depression (AUC for HADS 0.82, BDI-II 0.84) and symptoms (MSAS). There is inverse correlation with all eight SF-36 subscales, particularly energy, emotional well-being, and general health. Mean time to complete DT was <5mins, no patients found it objectionable.

Conclusions: The Distress Thermometer is correlated with depression and high symptom burden. Unlike many other widely available tools it is quick and easy to use at routine clinic visits, and is acceptable to a wide range of haemodialysis and CKD patients, including older patients and those with visual impairment. In addition, there are currently no copyright restrictions on its reproduction and use. This tool is already widely used as a screening tool in many oncology and palliative care services, and it should be adopted within the nephrology community also.

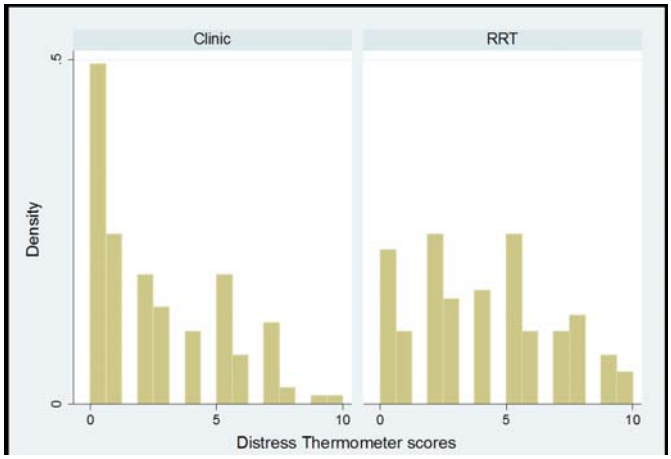
FR-PO1050

Haemodialysis Patients Experience Higher Levels of Psychosocial Distress Than Equivalent CKD Patients Helen Alston, Aine Burns. *UCL Centre for Nephrology, Royal Free Hospital, London, United Kingdom.*

Background: It is known that older patients with advanced chronic kidney disease (CKD) and multiple co-morbidities have high symptom and depression scores in cross-sectional studies. However, few direct comparison studies between CKD patients and haemodialysis (HD) patients have been carried out.

Methods: Aim: To compare the Distress Thermometer (DT) scores in CKD and HD patients **Hypothesis:** Psychosocial distress is higher in HD patients than in CKD patients, even after adjusting for age and comorbidity. **Outcomes of interest:** Distress Thermometer scores **Methods:** The Distress Thermometer is a validated ultra-short screening tool used to measure psychosocial distress. We compared Distress Thermometer scores in 139 CKD patients from our pre-dialysis clinic (with eGFR <20mls/min) and 138 HD patients, and adjusted for age and comorbidity.

Results: Adjusted Distress Thermometer scores for HD patients were significantly higher than those of CKD patients [fig 1]. Median DT score for CKD patients was 2, median DT score for HD patients was 4.



Conclusions: Even after adjusting for age and co-morbidity, DT scores were higher in the HD group. Further work is needed to investigate what factors may be causing these higher levels of distress in HD patients.

FR-PO1051

A Cross Sectional Descriptive Study of Palliative Care Outcome Scale–Symptoms in End Stage Renal Disease (Pos-S-Renal) Reported by Haemodialysis Patients and Staff Thida M. Myint, Swarna Shashi Bhaskara, Michael G. Suranyi, Angela Makris. *Dept of Renal Medicine, Liverpool Hospital, Sydney, NSW, Australia.*

Background: The Palliative care Outcome Scale-Symptoms (POS-S-Renal) is a validated instrument to measure patients' physical and psychological needs in end stage renal disease. We aim to describe the symptom burden in haemodialysis patients, as self-reported by patients and as assessed by nursing staff by using this instrument.

Methods: All prevalent haemodialysis patients from five dialysis centers and their staff were invited to participate this study in March 2013. The participants simultaneously completed POS-S-Renal in the same week. Symptoms were assessed using this 18-item questionnaire, which was offered in several languages. Higher scores were associated with higher disease burden. Data were analyzed by paired t test and multivariate analysis using SPSS v21 and p considered significant if <0.05.

Results: Out of a total of 163, 150 haemodialysis patients were recruited (92% response rate), 57% were males and 28% had 3 or more comorbidities. Mean age was 63 (+/- 14) years and dialysis vintage was 69 (+/- 66) months. There was no difference in age, gender, race, religion and language spoken between the responders and non-responders. Most reported symptoms were weakness or lack of energy (70%), poor mobility (51%), difficult in sleeping (51%), pain (46%) and itchiness (45%). There was a significant difference in total scores between patients with multiple comorbidities and those with fewer comorbidities (11.6 versus 8.8, p = 0.04, 95% CI 0.83 to 5.89). Similarly, In-Centre dialysis patients had higher scores compared with Satellite patients after adjusting for age and sex (p = 0.006). In addition, there was a significant difference in total score between patients and nursing staff (9.71 versus 5.8, p = 0.001, 95% CI 2.81 to 4.99). Staff under-reported patients' symptoms in pain (t (150) = 4.72, p < 0.001), shortness of breath (t (150) = 4.45, p < 0.001), lack of energy (t (149) = 4.74, p < 0.001) and nausea (t (149) = 3.87, p < 0.001).

Conclusions: In-Centre haemodialysis patients and patients with multiple comorbidities had higher disease burden however staff tended to underestimate patient symptoms.

FR-PO1052

Program for the Attention of Terminal Renal Disease Pain in Dialysis Units: Prevalence of Pain in Chronic Hemodialysis Pedro Garcia Piqueras,[1] Daniel Herrero Rivera,[1] Alberto Martin Diaz,[1] Pablo Pagliarani Gil,[1] Roberto Martin,[2] Adriana Puente Garcia,[2] Maite Marin,[2] Ramiro Callejas,[2] Fernando Garcia Lopez,[3] Alberto Tejedor Jorge.[1] *[1]FAC-MED, Univ Complutense, Madrid, Spain; [2]Fundación Renal Iñigo Álvarez de Toledo, Spain; [3]Spanish National Inst of Health, Spain.*

Background: Pain (P) is a frequent symptom among hemodialysis (HD) patients; in some instances it is present in at least 50% of the cases with great impact in health-related quality of life. Our aims are to quantify, identify and assess control in the HD population.

Methods: Multicenter transversal study in a total of 17 dialysis units, 6 hospitals and 11 centers in Spain, with the aim of improving the management of HD P. The sample was calculated with a P prevalence of 70%, a margin of error 5,8%, and an alpha value of 0,05. The samples were stratified by center and sex in 755 patients. Exclusion criteria were the lack of knowledge of the Spanish language and severe cognitive deterioration. Participation was accepted through informed consent. The presence, type and intensity of the P were determined through the McGill-SV, Brief P inventory and CAD (coping to the chronic P) and SF-36 questionnaires. Comorbidity was determined with the Charlson index.

Results: 252 patients were examined with an average age of 65.1 years. The P prevalence found was of 101 cases; as for the intensity 47 (46,5%) quantified the P as moderate-severe, while 27 (27%) quantified it as severe. The P was weak in 10 cases (10,4%), bearable in 46 (48%), intense in 24 (25%), and terribly bothersome in 16 (17%). Among the men, 61 (59%) suffered some kind of P along with 40 (41%) women, while 24 (16%) men and 23 (23%) women suffered from moderate P, odds ratio 1,66 (IC 95% from 0,9 to 3,2).The nociceptive P was the most frequent (54%), followed by the mixed type (42%), and the neuropathic type (3,5%). There was a non-significant tendency toward greater P frequency with higher ages. For VAS<5 the average Charlson age-comorbidity index was 7,81; and for VAS>5 it was 9,38 with a difference of 1,58 (IC 95% from 0,6 to 2,5).

Conclusions: P is very frequent in HD patients and affects almost half of them. Patients who suffer from P have a higher age-comorbidity index.

FR-PO1053

The Hemodialysis Patient Voice: Perspectives of Communication and Advance Care Planning (ACP) within Hemodialysis Units Nwamaka Denise Eneanya, Sarah L. Goff, Michael J. Germain, Mark L. Unruh, Lewis Cohen. *The Renal Supportive Care Study, Patient-Centered Outcomes Research Inst.*

Background: More than 20% of the approximately 400,000 hemodialysis patients in the U.S. die annually yet supportive care at the end of life is underutilized. We qualitatively explored dialysis patient and family experiences regarding supportive care to identify opportunities for improvement.

Methods: In-depth interviews were conducted with purposively sampled patients and family members from dialysis units at two study sites. Applying grounded theory, interviews were audio-taped, professionally transcribed, and analyzed in an iterative process by three research team members. Emergent concepts and themes were identified, discussed and then organized into major themes and sub-themes.

Results: 13 patients and 8 families participated; 12 were female. Patients identified as Black (1), Hispanic (2), Navajo (1), Pacific Islander (1), and White (8). Four major themes and numerous sub-themes were generated from analysis.

Major Themes	Sample quotes
1. Patient's prior experience with prognostic discussions and ACP	"I think a lot of people go on dialysis and they think...of that as a cure and that is not a cure..."
2. Factors that impact patients' perspectives of ACP and prognostic discussions	"...I always felt that she [a nurse] didn't really like [me]… she's never actually talked to me unless she was in charge of the unit...I feel there's a lot of favoritism..."
3. Patient recommendations for carrying out discussions about prognosis and ACP	"I would like to sit down with a physician who is compassionate but direct. Give me the fine points."
4. Family and friends' perspectives	"…I wish there was somebody that could play the role I play [advocate] on behalf [of] each patient" "I would not talk to a social worker or a nurse. I would want a physician to tell me exactly what's going on..."

Conclusions: Participants reported how poor communication and discontentment impact ACP discussions. Life experiences and personal outlook influence perspectives. These findings may be useful in designing interventional studies and protocols to improve patient management at the end of life.

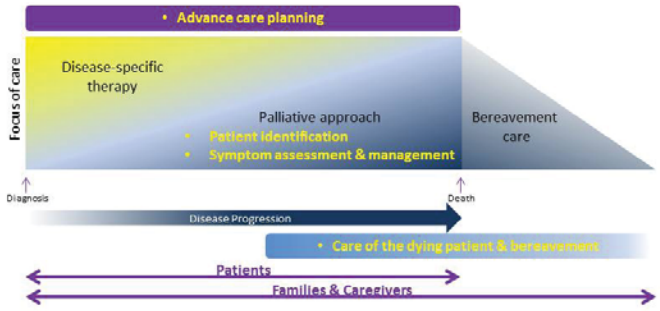
FR-PO1054

Establishing an Integrated Population-Based Approach to Renal Palliative Care Helen Chiu,[1] Donna Murphy-Burke,[1] Ronald Werb,[2] John A. Duncan,[2] Gaylene M. Hargrove,[2] Adeera Levin,[2] Mohamud A. Karim.[2] *[1]BCPRA; [2]UBC, BC, Canada.*

Background: Chronic kidney disease (CKD) is characterized by high symptom burden and poor life expectancy at advanced stage. Functional and cognitive decline results in difficult end-of-life (EOL) conversations involving patients, families and care providers. An integrated approach to timely advance care planning (ACP) and EOL care spanning the CKD care continuum is needed.

Methods: Utilizing the provincial renal network in BC, Canada, an expert panel was formed to create an evidence-based renal EOL Framework that articulates 4 pillars of renal palliative care: patient identification, ACP, symptom assessment and management, and care of the dying patient and bereavement.



EOL champions from the 5 regional renal programs led the local implementation of the Framework. Education and support tools were developed provincially to facilitate uptake and capacity creation among frontline care providers. Progress over a 5 year period was verified with surveys and semi-structured interviews across the province.

Results: The 4 pillars of the EOL Framework were adapted across BC in ways that matched local needs and resources. Formal processes in ACP and symptom control with use of standardized assessment have been established in all renal programs. In a recent survey for frontline nephrologists and staff, 61% of respondents had EOL care training with 50% felt that they need more education to stay current. Enabling an organizational culture open to integrate palliative approach into routine renal care remains a challenge, and cementing relationships with palliative services is key.

Conclusions: Contextualizing the EOL Framework is crucial to integrating supportive care into daily renal care. To promote quality EOL care, there is a need to develop a person-centred evaluative rubric for continual improvement and research activities that bridge the knowledge gaps in renal palliative care.

FR-PO1055

Self-Reported versus Measured Physical Activity in Older Adults with CKD

Stephen L. Seliger,[1,2] Jamie Giffuni,[2] Leslie I. Katzel,[1,2] Roger A. Fielding,[3] Christine Liu,[4] Andrew M. Well,[5] Christopher W. Washington,[1,2] Daniel E. Weiner.[3] *[1]Med, U Maryland Sch Med, Baltimore, MD; [2]Med/GRECC, Baltimore VAMC, Baltimore, MD; [3]Med, Tufts-NEMC, Boston, MA; [4]Med, Boston U., Boston, MA; [5]Med, Emory U., Atlanta, GA.*

Background: It is uncertain to what extent low physical activity contributes to poor physical performance in older CKD patients, and how best to estimate such activity.

Methods: The AWARD study is a randomized trial of exercise training in older adults with CKD stage 3b-4. Self-reported activity at baseline was quantified with the CHAMPS questionnaire, an instrument validated in community-dwelling older adults. Using the Step Activity Monitor over 5 days, we quantified: 1) steps/day, 2) total sedentary time, 3) total time in ≥moderate walking (≥15 strides/min). Lower extremity performance was assessed using the Short Physical Performance Battery (SPPB).

Results: Among N=46 with complete activity data, mean age was 69.5±7.9 years and eGFR was 34±10 ml/min/1.73m^2, 52% were Afr-American, 28% women, and 40% had CVD. Median steps measured were 2,702/day [interquartile range: 2,060-4,873], and median waking time spent inactive was 73.6% [61.9%-79.8%] Self-reported physical activity did not correlate with direct measures of activity (table) nor lower extremity performance. In contrast, directly measured activity and inactive time were both correlated with performance.

Correlation (ρ) of self-reported and directly measured physical activity and performance

Measured Activity/ Performance	Self-Reported Activity			Measured Activity	
	Kcals/week	Kcals/week ≥Mod. Activity	Min/week of ≥Mod. Activity	Steps/day	% Time Inactive
Steps/day	0.03 (p=0.8)	0.11 (p=0.5)	-0.01 (p=0.9)		
% Time Inactive	-0.07 (p=0.7)	-0.10 (p=0.5)	0.09 (p=0.5)	-0.74 (p<0.001)	
% Time ≥moderate pace walking	-0.01 (p=0.9)	-0.05 (p=0.8)	-0.16 (p=0.24)	0.90 (p<0.001)	-0.78 (p<0.001)
SPPB	0.17 (p=0.3)	0.17 (p=0.3)	0.13 (p=0.4)	0.41 (p=0.005)	-0.34 (p=0.02)

Conclusions: Levels of physical activity are very low among ambulatory older adults with CKD and correlate with poor lower extremity performance. However, self-reported activity is not a reliable surrogate for measured activity.

FR-PO1056

Physical Function and Estimated Glomerular Filtration Rate in Advanced Chronic Kidney Disease

Andrew M. Well,[1] Jamie Giffuni,[2] Stephen L. Seliger,[2] Roger A. Fielding,[3] Leslie I. Katzel,[2] Daniel E. Weiner.[1] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Univ of Maryland School of Medicine, Baltimore, MD; [3]Tufts Univ, Boston, MA.*

Background: Older adults with reduced eGFR may have lower physical activity and poorer physical performance. Previous research focused on the relationship between eGFR and daily activity or on objective physical performance testing. This cross sectional analysis seeks to assess the association between eGFR and objective physical functioning independent of daily activity level.

Methods: The Aerobics, Weights and Renal Disease (AWARD) trial is a randomized controlled trial evaluating the effects of exercise versus health education in individuals 55 years and older with CKD stage 3b-4. Participants' physical functioning was assessed through VO_2 peak, 6-minute walk distance, 4 meter walk gait speed, Chair Rise time (CRT), and Get Up and Go time (GUGo). Daily physical activity was assessed by average daily number of steps as recorded by Step Activity Monitor worn for 5 consecutive days.

Results: Of 51 participants enrolled by May 29, 2014, 48 completed baseline testing and were included. Mean age is 69±8 years, 29% are women, 52% are African American and 40% have history of CVD. Mean eGFR is 34±10 ml/min/1.73m^2 and hemoglobin is 12.6±1.7 g/dL. Mean VO_2 is 16.9±6.2 ml/kg/min, gait speed 0.84±0.16m/s, 6 minute walk distance 396.9±114 meters, CRT 12.34±3.38 sec, and GUGo 8.36±2.2 sec. In multivariable analyses controlling for age, sex, race, CVD, Hb, and average daily steps, lower eGFR was significantly correlated with all measures of physical function. For every 10ml/min lower eGFR there was a 2.11 (95% CI: 0.71-3.51) ml/kg/min decrease in VO_2 (p=0.006), a 0.04 (95% CI: 0-0.09) m/s decreased gait speed (p=0.04), a 35.4 (95% CI: 10.4-60.4) meter decrease in 6 minute walk distance (p=0.008), a 1.33 (95% CI: 0.43-2.23) second increase in CRT (p=0.006), and a 0.77 (95% CI: 0.27-1.27) second increase in GUGo (p=0.009).

Conclusions: Lower eGFR is associated with reduced physical functioning as measured by multiple objective testing modalities. This association is not explained by habitual physical activity, demographics, anemia severity, or CVD history.

FR-PO1057

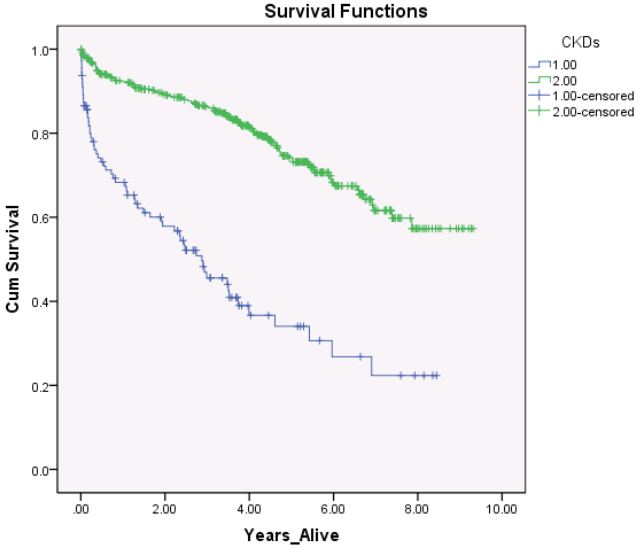
Chronic Kidney Disease Associated with an Increased Mortality Risk in Elderly Patients after Hip Fracture

Cheng Boon Poh,[1] Debajyoti Roy,[1] Hai Kiat Troy Puar.[2] *[1]Dept of Renal Medicine, Changi General Hospital, Singapore; [2]Dept of Endocrinology, Changi General Hospital, Singapore.*

Background: Hip fractures are associated with significant morbidity and mortality. We studied if worsening renal function conferred an increased risk of mortality in patients after sustaining a hip fracture.

Methods: This was a prospective cohort study of all type 2 diabetes mellitus patients (N=850) admitted with a diagnosis of hip fracture from years 2005-2010 to a single institution. Primary end-point was all-cause mortality. Creatinine levels were taken at admission, and estimated glomerular filtration rate (eGFR) was calculated using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation.Patients with eGFR≤30 ml/min/1.73m^2 (Group 1) were compared with patients with eGFR >60ml/min/1.73m^2 (Group 2) and their mortality risk was compared using Kaplan-Meier survival curves and multivariate Cox survival analysis.

Results: The cohort (aged 78.2 ± 8.3 years, 70.9% females) had a mean eGFR level of 62.9± 30.9 ml/min/1.73m^2. During a median follow-up of 7.4 years (range 0- 9.5 years), 295 patients died (33.5%). Patients with eGFR ≤30ml/min/1.73m^2 (N=112) had increased mortality, with median survival of 3.6years (95% CI: 2.9 – 4.3years) after a hip fracture compared to patients with eGFR >60 ml/min/1.73m^2 (N=433) who had better median survival of 7.0years (95% CI: 6.7 – 7.4years). By 5 years, only about 30% of group 1 were still alive compared to approximately 75% of patients in group 2.



Conclusions: Progressive renal impairment appears to be a predictor of poorer outcome in patients who sustained a hip fracture. This highlights the importance of chronic kidney disease (CKD) prevention and the need to look into improving the survival of CKD patients.

FR-PO1058

Only the Fittest Make It into the USRDS. Chart Abstraction versus USRDS Claims Data for Dialysis Patients over 75

Bjoerg Thorsteinsdottir, LaTonya J. Hickson, Priya Ramar, Megan Reinalda, Amy W. Williams, Nilay D. Shah. *Mayo Clinic, Rochester, MN.*

Background: The United States Renal Data System (USRDS) is designed to capture information about patients with ESRD. Most very elderly patients needing renal replacement therapy (RRT), start in the hospital after acute kidney injury. With the policy requirement of ESRD or 90-days of treatment prior to entry into the USRDS population, clinical events such as early death and renal recovery may be missed. Thus, use of this data to predict outcomes for elderly incident RRT patients may be incomplete and misleading Aim: Identify and quantify gaps in the USRDS data base determined outcomes for elderly dialysis patients.

Methods: Setting: regional not-for-profit U.S. health system. A cohort of 272 patients who started RRT in our Network in 2007-2010 and had data abstracted were matched to a USRDS cohort of 7113 patients who dialyzed at our facilities 2000-2010. Patients were grouped based on whether or not they were in the USRDS. Group characteristics and outcomes including survival to hospital discharge, 90 day and 6 month mortality and renal recovery were assessed.

Results: 43% of the cohort was not captured by USRDS. While demographics were not significantly different between the groups, there were significant differences in outcomes. Patients not in the USRDS cohort were more likely to start in the hospital and die in the first 6 months following incident RRT.

	Overall N=272	In USRDS N=155	Not in USRDS N=117
Age Median (IQR)	80.0 (77.0, 84.0)	81.0 (78.0, 84.0)	80.0 (77.0, 85.0)
Male N (%)	185 (68%)	110 (71%)	75 (64%)
Charlson Score Median (IQR)	N=269 8.0 (6.0, 10.0)	N=154 8.0 (6.0, 10.0)	N=115 7.0 (5.0, 9.0)
Hospital start* N (%)	205 (75%)	89 (57%)	116 (99%)
Total Deaths*	230 (84%)	123 (79%	107 (91%)
90 d mortality*	130 (47%)	44 (28%)	86 (73%)
6 mo mortality*	138 (50%)	49 (31%)	89 (76%)
Renal recovery*	47 (24%)	10 (12%)	37 (33%)

Conclusions: Significant differences in outcomes among elderly renal disease patients not captured by USRDS data suggest limited generalizability in drawing conclusions on survival for these patients. The USRDS cohort represents a healthier group of RRT patients significantly overestimating survival for the oldest.

FR-PO1059

Chronic Kidney Disease (CKD) Is Associated with Disorders of Balance

Premila Bhat,[1,2] Ashok Valluri.[1] *[1]Wyckoff Heights Medical Center, Brooklyn, NY; [2]Atlantic Dialysis Management Services, Queens, NY.*

Background: CKD is associated with limitations in physical activity and ADL dependence. Loss of balance can lead to falls, fear of falling, and physical inactivity. The objective of this analysis is to examine the cross-sectional association between CKD and disorders of balance among U.S. adults using the continuous National Health and Nutrition Examination Survey (NHANES).

Methods: A nationally representative sample of adults ≥40 yrs enrolled in NHANES 2001-2004 were included. Balance was tested using Modified Romberg test (MRT) consisting of four conditions (combinations of eyes open/ closed and firm/ compliant foot surfaces) designed to evaluate visual, proprioceptive, and vestibular system input in maintaining balance. Kidney function was estimated using eGFR-Creatinine. Chi-squared tests and uni/ multivariate logistic regression were used to compare prevalence of MRT failure across CKD categories.

Results: Of 5,530 subjects with results for MRT and creatinine, 49.2% were female, 17.3% black, mean age was 59.3±13.0 yrs, mean BMI 28.3±5.3, and 12.6% were diabetic. Prevalence of CKD was: Stages 1-2 (eGFR≥60), 90.6%; 3-5 (eGFR<60), 9.4%. Unadjusted OR for failing MRT was 3.7 (95% CI 3.0, 4.5) comparing those with and without CKD. More subjects with CKD failed every condition of the MRT (Table 1). The association between CKD and failure of MRT was attenuated after adjustment for age and diabetes (adjusted OR 1.53, 95% CI 1.06, 2.25).

Condition	Eyes	Surface	Sensory Input Assessed	CKD+	CKD-
1	Open	Firm	Visual, Proprioceptive, Vestibular	0.6	0.1*
2	Closed	Firm	Proprioceptive, Vestibular	7.5	2.4*
3	Open	Compliant	Visual, Vestibular	4.0	0.9*
4	Closed	Compliant	Vestibular	59.9	37.6*

Table 1. Association of CKD with Balance Disorders as Assessed by %Failing Modified Romberg Test. *p<0.05 for unadjusted comparison of CKD+/-.

Conclusions: Problems with balance, as measured by MRT, are frequent in CKD and are related to dysfunction of visual, proprioceptive, and vestibular senses. While the association between failure of Romberg test and CKD is partially explained by age and diabetes, there remains a significant association between CKD and balance even after adjustment for these factors.

FR-PO1060

Predictors of In-Hospital Mortality among Elderly Patients Treated with Dialysis for Acute Kidney Injury

Ezra Gabbay,[1,2] Yehudit Zangi,[2] Linda Shavit,[1,2] Jawad Atrash,[1] Itzchak N. Slotki.[1,2] *[1]Adult Nephrology Unit, Shaare Zedek Medical Center, Jerusalem, Israel; [2]Hadassah-Hebrew Univ Medical School, Jerusalem, Israel.*

Background: The factors that determine prognosis in elderly patients who are dialyzed for acute kidney injury (AKI) are uncertain. The purpose of this study was to specifically examine predictors of in-hospital mortality in this patient population.

Methods: A retrospective, single-center study of hospitalized patients ≥70 years old treated with intermittent hemodialysis for AKI. Patients with stage 5 chronic kidney disease were excluded. Clinical and demographic variables were compared between survivors and non-survivors; independent predictors of in-hospital mortality were identified by logistic regression.

Results: From March 2006 to October 2013, 137 patients, aged 70-103 met inclusion criteria. Hospital mortality was 66%; 59% of survivors were dialysis dependent at discharge. There was no significant difference in age between survivors (80.2) and non-survivors (80.5) (p=0.829). Non survivors had higher rates of hypotension (29.5% versus 13.6%, p=0.048), decreased level of consciousness (68.2% versus 22.2%, p<0.001), leukopenia/leukocytosis (62.6% versus 42.2%, p=0.024), ICU admission (59.3% versus 34.8% p=0.007), mechanical ventilation (64% versus 21.7% p<0.001), hepatic dysfunction (46.2% versus 21.7%, p=0.005), a diagnosis of sepsis (64.8% versus 26.3%, p=0.04), and vasopressors use prior to initiation of dialysis (69.8% versus 35.6%, p<0.001). Patients with ≥ 5 of these conditions had >90% mortality rate. Non survivors had lower mean serum albumin (2.48 versus 2.91 g/dL, p=0.001), and more failing systems (mean 2 versus 1.0 p<0.001) than survivors. There was no difference in chronic co-morbidities and baseline functional status. Logistic regression showed decreased level of consciousness (OR=7.4, 95% CI=3.0-18.2 p<0.0001) and mechanical ventilation (OR=6.0; 95% CI=2.5-14.6 p<0.001) independently predict in-hospital mortality.

Conclusions: Elderly patients dialyzed for AKI have a very high rate of in-hospital mortality or dialysis-dependent survival. Prognosis appears to be determined primarily by the severity of acute illness. Advanced age per-se should not be the sole criterion for decisions about dialysis in AKI.

FR-PO1061

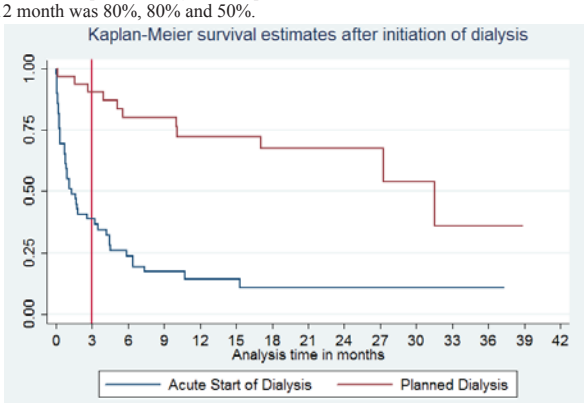
Dialysis in the Elderly- Factors Associated with Poor Survival

Debajyoti Roy,[1] Anupama Roy Chowdhury,[1] Kok-Heong Alvin Ng,[1] Sylvaine Barbier,[2] Chang Yin Chionh.[1] *[1]Nephrology & Geriatrics, Changi General Hospital, Singapore; [2]Centre for Quantitative Medicine, Duke-NUS, Singapore.*

Background: A rapidly aging population worldwide presents challenges in the care of the elderly patient with ESRD. Patients and their families often choose dialysis without a clear understanding of its implications on survival and quality of life.

Methods: This is a retrospective analysis of dialysis patients 75 years and older initiated at our centre, October 1,2010 –Feb 1,2014. Outcomes were identified from our electronic database with follow up from initiation to death or May 1,2014.Univariate then multivariate Cox proportional hazards regression models were performed to assess the predictive values of demographic and clinical factors.

Results: Of the 89 patients initiated on dialysis, 55 (63%) were females, median age was 82 years (Interquartile range (IQR) 78-85), 69% had diabetes.Five patients withdrew within 30 days of initiation and were excluded from the analysis. The median follow up time was 5 months (IQR:0.8-31.5).While age at initiation did not affect survival, having 3 or more comorbid conditions increased the risk of death 3 fold.The majority, 49 patients (61%) started dialysis during an acute admission for acute medical or surgical illness. Continuous renal replacement therapy (CRRT) in the ICU was the initial modality in 32 (40%). In those initiated during an acute admission the mortality was 76% during the first 90 days. Their subsequent survival at 3 month, 6 month and 12 month was 24%,17% and 9%. However in patients dialysed in a planned manner the survival at 3 month, 6 month and 12 month was 80%, 80% and 50%.



Conclusions: This study suggests age alone as a parameter at initiation of dialysis in the elderly does not predict a worse outcome. Multiple comorbidities at initiation predicts a worse outcome. The poorest survival is seen in those with an acute hospital start to dialysis.

FR-PO1062

Predicting Survival on Variations of BMI and Serum Albumin in Elderly Hemodialysis Patients Cédric Villain,[1,2,3,4,5] Rene Ecochard,[1,2,3,4] Denis Fouque.[2,3,5,6] *[1]Service de Biostatistique, Hospices Civils de Lyon, Lyon, France; [2]Univ de Lyon, Lyon, France; [3]Univ Lyon 1, Villeurbanne, France; [4]UMR5558, Equipe Biostatistique-Santé, CNRS, Villeurbanne, France; [5]Service de Néphrologie-Nutrition-Dialyse, Centre Hospitalier Lyon Sud, Lyon, France; [6]CarMeN, U1060, INSERM, Lyon, France.*

Background: In elderly hemodialysis patients, protein-energy wasting is associated with poor outcome but the association between wasting-marker changes over time and survival has been seldom studied.

Methods: We analyzed data on patients aged ≥75 years from the French cohort ARNOS, of whom 556 had ≥2 assessments of body-mass index (BMI) and 576 had ≥2 assessments of serum albumin (SAlb) at six-month intervals. Changes in nutritional markers were estimated by individual linear regression models. Survival analyses used frailty Cox models with random effects on age and dialysis vintage categories. We considered BMI in subgroups of sex and diabetes and analyzed SAlb adjusting on sex, diabetes, and C-reactive protein.

Results: There was a great difference in BMI/survival association between men and women as between diabetic and non-diabetic patients (Table 1) but no association between survival and Baseline BMI or BMI changes in diabetic women. A 0.1 g/dL increase in Baseline SAlb was associated with a 0.95 hazard ratio of death (95% CI: 0.92-0.98, p<0.001). A 0.1 g/dL/year increase in SAlb was associated with a 0.90 hazard ratio of death (95% CI: 0.87-0.94, p<0.001).

Conclusions: Changes in BMI and SAlb over time were strongly associated with the risk of death in elderly hemodialysis patients. Monitoring and enhancing these markers should ensure better outcomes in these frail patients.

Table 1: Association between Baseline BMI, BMI annual variation, and mortality according to sex and diabetes

Sex, Diabetes	BMI criterion	Hazard Ratio	CI 95%	*p*
Men, non diabetic	Baseline BMI*	0.948	0.893-1.006	0.08
	BMI change**	0.655	0.541-0.792	<0.001
Women, non diabetic	Baseline BMI	0.932	0.861-1.008	0.08
	BMI change	0.745	0.603-0.919	0.006
Men, diabetic	Baseline BMI	0.887	0.803-0.981	0.02
	BMI change	0.628	0.515-0.765	<0.001
Women, diabetic	Baseline BMI	1.000	0.908-1.101	1.00
	BMI change	0.912	0.702-1.184	0.49

*per 1 kg/m² increment, **per 1 kg/m²/year increment.

FR-PO1063

Long-Term Clinical Outcomes of Elderly Kidney Transplant Recipients Paula Ferreira Orlandi, Marina Pontello Cristelli, Claudia Rosso Felipe, Tainá Veras de Sandes Freitas, Helio Tedesco Silva, J. Medina-Pestana. *Hospital do Rim e Hipertensão, São Paulo, SP, Brazil.*

Background: The number of elderly patients with chronic renal failure is increasing as the population ages challenging organ allocation algorithms under the current organ shortage. This study investigates the impact of age on post transplant complications, graft and patient survival.

Methods: From 1998-2010 about 7000 kidney transplants were performed in our institution. Information about all 366 patients over 60 years-old in this period were assessed (Group A). As a control group we paired 366 younger patients by sex, donor type (deceased or living donors) and year of transplantation (Group B). The data were analyzed using Kaplan-Meier survival estimates. Multivariate analysis was performed using Cox proportional hazard model.

Results: Diabetes as the cause of chronic renal disease accounted for a significantly higher proportion in the elderly (44%) compared to the younger group (12%) (p=0.002). Cardiovascular complications (12,3%), cancer (6,8%), hospital readmissions (77,3%) and delayed graft function were more common among aged recipients, even though donor characteristics were comparable in both groups. New onset diabetes (25%) and acute rejection (27%) incidences were similar between the groups. 10-year patient (54% versus 83.4%, p <0.001) and overall graft survival (39,4% versus 67,1%, p<0,001) were inferior in elderly compared to younger recipients but no significant differences were observed in death-censored graft survival (75% versus 81,1%, p=0,234). Death with functioning graft accounted for 64% and 44% of all causes of graft loss in the elderly and younger recipients groups (p=0.023). Diabetes was associated with death and graft loss in the multivariate analysis. No significant difference was found related to renal function all over the 10 years of observation.

Conclusions: This is one of the few studies comparing the outcomes of kidney transplants in elderly and younger recipients with 10 years of follow up. Higher mortality rate among the elderly population, probably related to higher prevalence of comorbidities, including diabetes, may account for the inferior allograft survival among elderly recipients.

FR-PO1064

Prevalent Chronic Kidney Disease Is Associated with Inpatient Admission among Long-Term Care Residents with Kansas Medicaid Elizabeth W. Dehmer,[1] Theresa I. Shireman.[2] *[1]Nephrology and Hypertension; [2]Preventive Medicine and Public Health, Univ of Kansas School of Medicine, Kansas City, KS.*

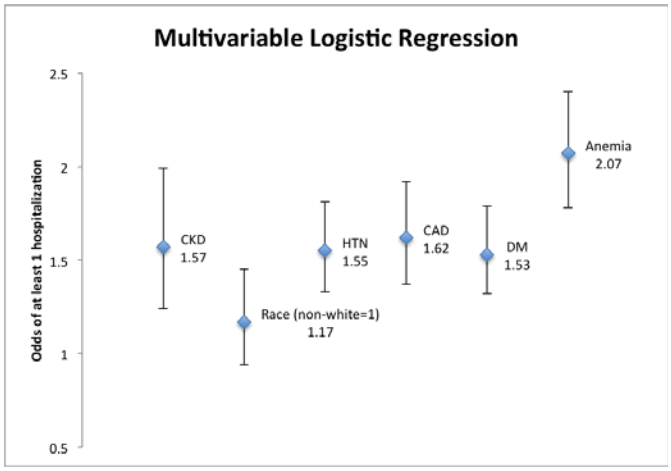
Background: The purpose of this study is to describe the prevalence of chronic kidney disease (CKD) in long-term care (LTC) residents, and to compare demographics, co-morbidities and hospital admissions in LTC residents with and without CKD.

Methods: The study population includes LTC residents (≥180 days in a facility in 2010) with continuous Kansas Medicaid during 2010-11. CKD is defined as one inpatient or two outpatient claims in 2010 containing International Classification of Diseases, Ninth Revision codes 582.xx, 583.xx, 585.xx, 586 or 587. T-tests or Fisher's exact test are used to compare measures between CKD and non-CKD residents. Logistic regression is used to examine the association between inpatient admission during 2011 and CKD.

Results: LTC residents with CKD (6.1%), compared to those without, are more likely to be of non-white race, and have comorbidities of hypertension (HTN), diabetes mellitus (DM), congestive heart failure (CHF), coronary artery disease (CAD) and anemia.

	CKD (n=410) Mean (SD) or N (%)	No CKD (n=6352) Mean (SD) or N (%)	p-value
Age (years)	73.5 (14.2)	74.1 (16.7)	0.4
Male	151 (36.8)	2073 (32.6)	0.08
White	351 (85.6)	5781 (91.0)	0.001
HTN	310 (75.6)	2676 (42.1)	<0.001
DM	244 (59.5)	1648 (25.9)	<0.001
CHF	168 (41.0)	956 (15.1)	<0.001
CAD	171 (41.7)	961 (15.1)	<0.001
Anemia	235 (57.3)	1494 (23.5)	<0.001

Prevalent CKD increases the odds (odds ratio 1.57, 95% confidence interval 1.24, 1.99) of at least one inpatient admission after adjustment for race and co-morbidities.



Conclusions: Even when controlling for co-morbidities, LTC residents with CKD have higher odds of an inpatient admission. Interventions such as review of medication lists, treatment of anemia of CKD, and routine nephrology visits may reduce risk of hospitalizations in this population.

FR-PO1065

Impact of Nursing Home Patients Undergoing Hemodialysis on Emergency Department (ED) and Hospital Admissions in the Northeast Aleef M. Rahman,[1,2] George N. Coritsidis,[1] Marie France R. DeLeon,[1] Jasjit Singh,[1] Carol Lyden,[3] Jaya Bhargava,[3] Roshan A. Patel.[1] *[1]Dept of Nephrology, Elmhurst Hospital Center, Mount Sinai's Icahn School of Medicine, Queens, NY; [2]Dept of Surgery, Elmhurst Hospital Center, Mount Sinai's Icahn School of Medicine, Queens, NY; [3]IPRO, ESRD Networks of New York & New England.*

Background: ED visit and hospitalization rates of dialysis patients are important measures of care in end stage renal disease (ESRD) patients. We are interested to see what impact nursing home patients in HDUs has on ED Visits, Hospitalizations, and LOS outcomes throughout all New England states and New York.

Methods: We retrospectively reviewed the de-identified records of all of Networks 1 and 2 (7 states: New York and New England) for 2010 regarding demographics. ED visits, hospitalization admission rates (HAD) and number of hospital days (LOS) was corrected by percent of nursing home patients (NHP) per dialysis unit.

Results: One-way ANOVAs were used to test for differences between categories. There were no differences between groups in terms of hypertension prevalence and HAD/patient. Percent diabetes, age, and LOS trends increased and differed significantly across categories. ED Visits/Patient decreased and differed significantly across categories.

% NHP/ Dialysis Unit (# of Units)	Average Patients/ Unit	Average Age	Average % of Patients w/ Diabetes	Average LOS/Per Patient	Average ED Visits/Per Patient	Average HAD/ Patient
1-10% (53)	186.7	60.14	38.01	6.81	1.248	0.92
11-20% (176)	150.3	63.6	41.28	6.68	1.37	0.95
21-30% (109)	116.6	66.32	40.46	6.97	1.469	1.0
31-40% (11)	88.18	69.13	43.85	6.72	1.48	1.02
41-50% (4)	115.75	72.53	35.70	7.0	1.09	0.91
≥ 50% (20)	69.2	69.93	51.11	7.9	0.83	0.83
P-Value	**<0.0005**	**<0.0005**	**<0.0005**	**<0.005**	**<0.0005**	**0.164**

Conclusions: As the percentage of nursing home patients rise in a given unit, there are fewer patients sent to the emergency room. This may be due to previous advanced care directives. There are no effects in the number of hospital admissions; however, the units with a higher percentage of nursing home patients have a significantly higher hospital length of stay.

FR-PO1066

Elderly Patients Starting Outpatient Dialysis in Germany Gero D. von Gersdorff,[1] Mathias Schaller,[1] Thomas Benzing.[1,2] *[1]Nephrology - QiN Group, Univ of Cologne Medical Center, Cologne - Köln, Germany; [2]KfH Kuratorium für Dialyse und Nierentransplantation, Neu-Isenburg, Germany.*

Background: Initiation of dialysis in very elderly patients is becoming more common. We evaluated recent trends in frequency and survival of incident dialysis patients (pt) aged 80 years or older in Germany.

Methods: We conducted a retrospective cohort study of pt initiating dialysis aged ≥ 65 years in the electronic health-record based registry of patients on dialysis with the largest non-profit provider in Germany. We determined rates of dialysis initiation 2007 – 2013, clinical characteristics at the start of dialysis and survival.

Results: 13872 pt ≥ 65 years initiated dialysis between 2007 and 2013. The average vintage before entry into the ambulatory setting was 119d. The fraction of pt ≥ 80y increased from 15.8 % to 19.9 % (+4.1%), i.e. an average annual increase of 0.7 % (-0.9 – +1.4). Among these older pt 3.5% were underweight (BMI < 18.5 cm/kg^2), 15.1% had initial albumin < 3.0 g/dL, and 34.3% were anemic (Hb<10 g/dL). 55.8 % had ≥ 4 comorbidities. Average 1-year survival was 74.2% and median survival was 32.3 months. At least 463 (12%) of very elderly pt survived ≥ 5y since first dialysis. These long-term survivors were more likely female and were less likely anemic, underweight, hypalbuminemic or had ≥ 4 comorbidities.

Conclusions: The fraction of very elderly patients starting dialysis continues to rise in Germany. Survival in this cohort was comparably high (cf. Kurella AnnIntMed 2007), underscoring that there is a substantial number even among the very elderly with a good prognosis on dialysis. Although early mortality events were likely not captured in this analysis, age alone is clearly not sufficient as a prognostic marker. Further efforts should be directed at better delineating prognosis for very elderly patients with renal failure.

FR-PO1067

Cognitive Impairment in Advanced Chronic Kidney Disease Simon Richard Walker, Ranveer Singh Brar, Brett M. Hiebert, Frederick Eng, Paul Komenda, Claudio Rigatto, Manish M. Sood, Clara Bohm, Leroy J. Storsley, Navdeep Tangri. *Seven Oaks General Hospital, Univ of Manitoba, Winnipeg, MB, Canada.*

Background: Chronic Kidney Disease (CKD) disproportionately affects the elderly and is associated with frailty and multiple comorbid conditions putting them at risk of developing cognitive impairment. The purpose of this study was to describe the prevalence of cognitive impairment in patients with advanced CKD (eGFR < 30ml/min).

Methods: We approached all patients with advanced CKD who attended an interprofessional non-dialysis CKD clinic at a tertiary care center for enrollment in our study. We excluded patients who did not speak English or were unable to provide informed consent. We collected demographic variables, physical examination measurements, laboratory values, and performed an assessment of cognitive function using the Montreal Cognitive Assessment (MoCA).

Results: We studied 191 patients. Their mean age was 68 years (Standard Deviation [SD]+/- 13), and 74 patients were female (39.4%). The mean eGFR was 21.2 mL/min/1.73m2 (SD +/- 9.4). Sixty seven patients (77.0%) scored < 26 on the MoCA and were thus defined as mildly cognitively impaired. In particular, the recall, visual/executive and language domains were impaired in > 60 % of the participants. Older age, higher pulse pressure, and presence of cardio/cerebrovascular disease were associated with cognitive impairment.

Conclusions: Patients with advanced CKD have a high burden of cognitive impairment. Vascular risk factors appear to be associated with worsening cognition. Further studies on the pathophysiology of cognitive decline and its impact on patient decision making and outcomes are needed.

FR-PO1068

Prevalence of Albuminuria in Older Adults Elke Schaeffner,[1] Olga Jakob,[1] Martin K. Kuhlmann,[2] Jens Gaedeke,[1] Peter Martus,[3] Natalie Ebert.[1] *[1]Nephrology, Charité, Berlin, Germany; [2]Nephrology, Vivantes Klinikum, Berlin, Germany; [3]Biostatistics, Univ of Tübingen, Tübingen, Germany.*

Background: Data on prevalence of albuminuria and associated factors in older adults are rare.

Methods: We cross-sectionally measured random albumin-creatinine-ratio (ACR) in 2054 individuals aged ≥70 (Berlin Initiative Study). ACR was categorized as <30 (no), 30-299 (micro-), or ≥300 (macroalbuminuria) mg/g. Characteristics were compared within strata of albuminuria. Odds ratios were calculated with logistic regression and refer to the second versus first row of each characteristic (Table1).

Results: Of 2054 individuals (mean age 80.4) 26% had albuminuria. Sex, age, diabetes, GFR <60 ml/min/1.73m^2, and hypertension were all statistically significantly associated with albuminuria.

	<30	30-299 (%)	≥300 (%)	Total of albuminuria	Total (%)	OR	95% CI
Whole population	1522 (73.6)	458 (22.1)	74 (3.6)	532 (25.7)	2054 (100)		
Female	851 (55.9)	208 (45.4)	22 (29.7)	230 (43.2)	1081 (52.6)	1.67	1.37-2.03
Male	672 (44.1)	250 (54.6)	52 (70.3)	302 (56.8)	973 (47.4)		
Age <80	843 (55.4)	171 (37.3)	29 (39.2)	200 (37.6)	1043 (50.8)	2.06	1.68-2.52
Age ≥80	679 (44.6)	287 (62.7)	45 (60.8)	332 (62.4)	1012 (49.2)		
Non-diabetic	1197 (78.6)	288 (62.9)	37 (50.0)	325 (61.1)	1522 (74.1)	2.35	1.90-2.90
Diabetes	325 (21.4)	170 (37.1)	37 (50.0)	207 (38.9)	532 (25.9)		
GFR $_{(BIS1)}$ ≥60 ml/min/1.73m^2	642 (42.2)	138 (30.1)	10 (13.5)	148 (27.8)	790 (38.5)	1.90	1.53-2.35
GFR $_{(BIS1)}$ <60 ml/min/1.73m^2	879 (57.8)	320 (69.9)	64 (86.5)	384 (72.2)	1263 (61.5)		
Systolic BP <140 (mmHg)	688 (45.3)	158 (34.5)	21 (28.8)	179 (33.7)	867 (42.3)	1.63	1.33-2.00
Systolic BP ≥140 (mmHg)	831 (54.7)	300 (65.5)	52 (71.2)	352 (66.3)	1183 (57.7)		
Diastolic BP <90 (mmHg)	1184 (77.9)	327 (71.4)	49 (67.1)	376 (70.8)	1560 (76.1)	1.46	1.17-1.82
Diastolic BP ≥90 (mmHg)	335 (22.1)	131 (28.6)	24 (32.9)	155 (29.2)	490 (23.9)		

70% of individuals with albuminuria were treated with an ACE inhibitor or angiotensin receptor blocker (ARB, data not shown).

Conclusions: In a huge cohort of older adults male sex, older age, diabetes, hypertension, and GFR<60 were significantly associated with albuminuria. The number of 30% albuminuric participants without ACE-Inh. or ARBs deserve attention.

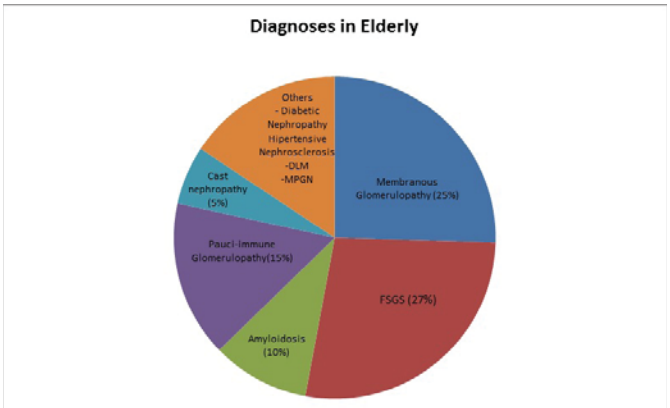
FR-PO1069

Renal Biopsy in Elderly Brazilian Patients: A Clinicopathological Correlation and Complications Alcino Pires Gama, Igor Marques, Victor Sato, Liliany P. Repizo, Simone C. Lo, Ligia Costa Battaini, Luis Yu, Cristiane B. Dias, Lectícia Jorge, Viktoria Woronik. *Div of Nephrology, Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Elderly patients with renal disease have recently attracted increased attention. There has also been an increase in renal biopsies in these patients. The aim of this study is to report the experience of a Brazilian academic center with percutaneous biopsy in elderly subjects.

Methods: Medical and clinical records from renal biopsies registered in one single center between January 2009 and December 2013 were reviewed. Among 668 patients (female/male 394/274; age 41±16y) who underwent renal biopsies, 60 (8.9%) who were aged 65 years and older (male/female 38/22; age 72 ±6y) were selected.

Results: The elderly usually underwent percutaneous renal biopsies for renal diseases such as nephrotic syndrome (53%), acute or rapidly progressive renal failure (28%) and nephritic syndrome (8%). The main findings in pathology were FSGS (27%), membranous glomerulopathy (25%), pauci-immune glomerulopathy (15%) and renal amyloidosis (10%). In nephrotic syndrome, the most common diagnoses were membranous (44%) and FSGS (31%). In acute or rapidly progressive renal failure, the most common diagnoses were pauci-immune glomerulopathy (47%) and FSGS (18%).



The complications rates after biopsy were similar in elderly and non-elderly patients.

	≥65 y (n=60)	<65 y (n=608)	P
Delta Hb ≥ 1.5g/dL	11.7%	15%	0.2
Major complication*	10%	7.6%	0.6

*Defined as macroscopic hematuria, symptomatic hematoma or blood transfusion.

Conclusions: Renal biopsy in elderly patients is a safe and valuable diagnostic tool. This procedure should be performed without any age limitation when a renal biopsy indication emerges in elderly patients. Brazil has a very high incidence of FSGS as shown by Malafrante et al. This diagnosis remains relevant even in an unusual age.

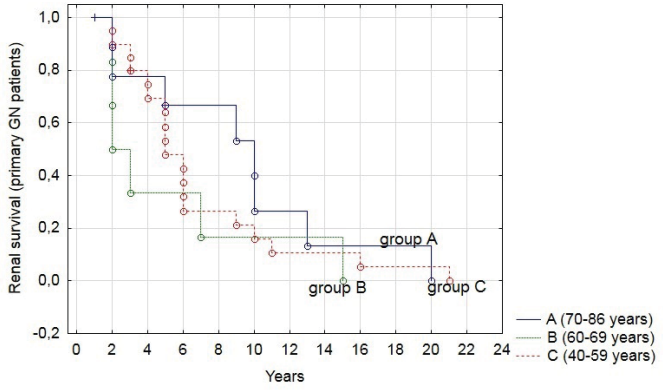
FR-PO1070

Glomerulonephritis in the Elderly – Incidence, Treatment and Outcome
Katarzyna Jakuszko, Magdalena Krajewska, Dagna Rukasz, Joanna Ogórkowska, Katarzyna Madziarska, Waclaw Weyde, Marian Klinger. *Wroclaw Medical Univ, Poland.*

Background: The aging population and doubts about the strength of immunosuppression in elderly patients with comorbidities influence the search of appropriate approach to the glomerulonephritis (GN) treatment. The aim of this study was to evaluate the incidence, treatment and outcomes in elderly patients in the single centre.

Methods: The study group included 84 patients with GN, hospitalized between January 2011 and December 2013 and was divided into 2 subgroups according to age at the time of the study (A:≥70 years; B:60-69 years). The control group consisted of 47 patients with GN, aged 40-59 years (C).

Results: The observation period was 6.6±5.9years (range 0.5-26) for all patients, shorter in group A (4.7±5.2years, p=0.008). Kidney biopsy was performed more often in younger patients 70.2% versus 52.4% (p=0.03). The secondary GN were more common for older patients (53.6% versus 29.8%, p=0.007). In older patients there were 13 cases of primary and 5 cases of secondary membranous GN (21.4%), 16 cases of ANCA vasculitis (19%) and 11 cases of lupus nephritis (LN, 13.1%). The most common primary GN in younger patients was IgA nephropathy (23.4%) and secondary - LN (27.7%). There were no differences between groups in the total dose of intravenous steroids (p=0.12) and cyclophosphamide (p=0.57). However in elderly patients median doses were significantly lower for cyclosporine (A:137.5mg; B:200.0mg; C:237.5mg, p=0.006) and mycophenolate mofetil (A:1000mg; B:1000mg; C:2000mg, p=0.03). Despite the lower doses of immunosuppressive drugs there were no differences between groups in the renal survival defined as no need for renal replacement therapy p=0.63 for all patients and p=0.24 for patients with primary GN.



Conclusions: The study showed that older age does not affect negatively the renal survival of GN patients, regardless of some immunosuppressive regimen lowering.

FR-PO1071

Geriatric Conditions in CKD
Christine Liu,[1] Alyson Heath,[2] Andrew M. Well,[2] Jamie Giffuni,[3] Kieran Reid,[2] Roger A. Fielding,[2] Leslie I. Katzel,[3] Stephen L. Seliger,[3] Daniel E. Weiner.[2] *[1]Medicine, Boston Univ, Boston, MA; [2]Medicine, Tufts Univ, Boston, MA; [3]Medicine, Univ of Maryland, Baltimore, MD.*

Background: Geriatric conditions are constellations of signs and symptoms not specifically linked to a disease; often they are due to deficits in multiple organ systems and impact quality of life. Examples include cognitive impairment or dizziness. Although CKD affects multiple systems, little is known about the association of CKD with geriatric conditions. We examined the prevalence of geriatric conditions and association with quality of life in older adults with CKD.

Methods: The Aerobics, Weights, and Renal Disease Study is an ongoing randomized trial of exercise in adults 55+ years with CKD stage 3b-4. Data are from baseline. Persons were defined with 1) cognitive impairment if Montreal Cognitive Assessment <26; 2) poor physical function if SPPB ≤7; 3) dizziness if answered "yes" to such symptoms on the Memorial Symptom Assessment Scale; 4) fatigue if answered ≥"good bit of time" to feeling worn out" on the SF36; 5) chronic pain if answered ≥"moderate" pain on the SF36; and 6) depression if Beck Depression Inventory ≥15. Poor health status was defined by answering ≥"mostly false" to "my health is excellent" on SF36. Logistic regression assessed the association of geriatric conditions with health status, adjusting for age, sex, race, BMI, eGFR, diabetes and hypertension.

Results: Of 50 persons enrolled (30% female, mean age 68.6±7.8 years, mean BMI 30.4±5.4 kg/m^2), 6% (3) had no conditions; 44% (22) had 1 geriatric condition while 50% (25) had ≥2 conditions (Figure). With each additional condition, odds of poor health status increased (OR 2.94, 95%CI 1.23-7.01) after covariate adjustment.

Conclusions: In older adults with CKD, geriatric conditions are common. Many have multiple geriatric conditions; these likely impact perceived quality of life in this population.

FR-PO1072

The Effect of Age on Nuclear Protein Levels in Rat Kidney Cortex and Medulla
Marianna J. Zamlauski-Tucker, Natalya Mezenina, Briana N. Davis. *Dept of Physiology & Health Science, Ball State Univ, Muncie, IN.*

Background: Studies in vitro and in vivo have reported that total nuclear protein levels increase with age in mouse fibroblasts, liver cells and intestinal epithelial cells. This finding suggests the accumulation of oxidized and misfolded proteins in the nucleus with age. The present study was undertaken to investigate whether total nuclear protein levels increase with age in rat kidney cortex and medulla.

Methods: Young (3 months of age) and Old (22 months of age) female Lewis rats were used. The kidneys were harvested from anesthetized rats, separated into cortical and medullary sections and homogenized. The nuclear fractions were isolated by differential centrifugation and filtered through an 80 micron nylon mesh. The purified nuclear pellets were isolated and lysed. The protein content was isolated by dissolving the remaining pellet in 0.1 M sodium hydroxide. The protein content was measured using the Lowry Protein Assay. Differences were evaluated using a Student's t test.

Results: There was a significant decrease in nuclear protein levels in the cortex of the rat kidney with age. However, there was no change in nuclear protein levels in the medulla of the rat kidney with age. Nuclear protein levels were significantly higher in the medulla than in the cortex in kidneys from both young and old rats.

		Young (n=4)	Old (n=4)
Nuclear Protein	Cortex	11.2 ± 1.0	7.6 ± 0.7*
mg/g kidney wet wt	Medulla	14.2 ± 0.6[a]	13.8 ± 1.4[a]

All data expressed as X + SEM; * significantly different from Young; [a] significantly different from age-matched cortex.

Conclusions: Total nuclear protein levels decrease (i.e, cortex) or do not change (i.e., medulla) with age in the rat kidney.

FR-PO1073

Hemodialysis among the Elderly: Outcomes and Survival in Mexican Patients Karina Renoirte,[1,2] Guillermo Garcia-Garcia,[1,2] Xochitl Guerrero.[1,2] *[1]Nephrology, Hospital Civil, Guadalajara, Mexico; [2]Health Sciences, Univ, Guadalajara, Mexico.*

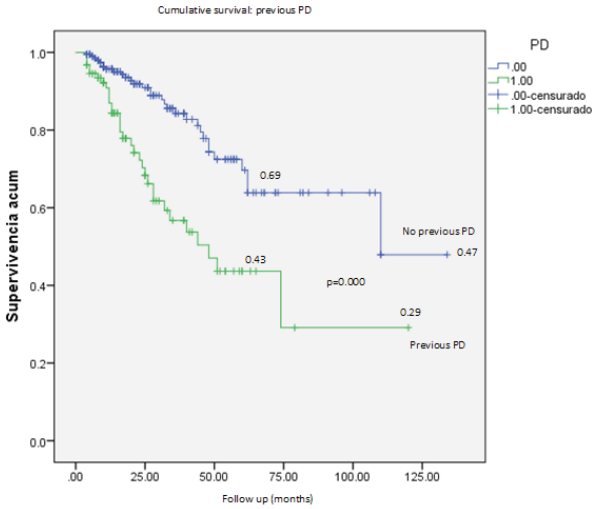
Background: The incidence and prevalence of End Stage Renal Disease (ERSD) patients (pts) in Mexico is constantly rising. In addition, the Mexican population ≥60 years of age (y/a) will duplicate by year 2050 (2.7% of total population was ≥60 y/a in 1990, 6.9% in 2000 and 9% in 2012). In 2012, the average health expectancy was 77.4 y/a, compared with 70.7 in 1990. Thus, more and more ageing pts are initiated in HD instead of PD. The average HD patient's age in the U.S. is 62 y/a compared with Mexican pts average age 46.75 ± 19.6. Nevertheless, 33% of HD pts are ≥60 y/a.

Methods: We prospectively analyzed from Jan 2010 thru Feb 2014 all incident and prevalent HD patient's ≥60 y/a, in 7 non hospital basis HD facilities. All pts were receiving 3 HD treatments per week. We used Excel and SPSS v20.0 program for statistics. We describe survival, vascular access, kt/v, Hb and socio-demographic data.

Results:

	All pts, n=1418	≥ 60y/a, n=463
Age	46.75±19.6	70.27± 6.82
Male (%)	64	63
DM (%)	34.1	64
Previous PD (%)	44	32
Average Hb, gr/dl	9.9	10.4
% pts Hb 10-12gr/dl	37	42
Average kt/v	1.16	1.16
% pts ktv ≥ 1.2	47	44
Temporary catheter (%)	32	24
Permanent catheter (%)	36	40
AV Fistula (%)	32	36

Once renal replacement therapy is initiated, the range of the expected remaining life span in the USRDS report was approx 54 months for those 60 to 64 y/a, compared with 26.3 months in our pts (range 4-110). Overall cumulative survival at 12,24, 36, 48 and 60 months was 0.93, 0.84, 0.75, 0.65, 0.61 respectively**.** Worst outcomes were identified for pts with any kind of catheter (p=0.000), previous PD (p= 0.000) and DM (p= 0.036)



Conclusions: 1/3 of HD pts in Mexico are ≥60y/a. Overall survival at 60months was 0.61. Better survival was observed for those with AV fistula, no previous PD and no DM. Hb and kt/v and were similar to those reached in younger pts.

Assessment of Renal Function in Older Adults Markus Bitzer,[1] Jennifer Yi-Chun Lai,[1] Mindy Katz,[2] Richard B. Lipton.[2] *[1]Medicine, Univ of Michigan, Ann Arbor, MI; [2]Neurology, Albert Einstein College of Medicine, Bronx, NY.*

Background: Chronic kidney disease (CKD) defined by decrease in estimated glomerular filtration rate (eGFR) calculated from serum creatinine levels has the highest prevalence in adults ≥ 70 years and lower eGFR increases mortality and risk for end stage renal disease (ESRD). However, the applicability of current eGFR equations for older adults has been questioned. Here, we described differences among equations in community-based older adults and examined clinical parameters associated with lower eGFR and mortality.

Methods: Subjects ≥ 70 years of age with the first available serum creatinine measurements from 2004 to 2013 were identified from the Einstein Aging Study cohort. Kidney function was estimated using Cockcroft-Gault estimated creatinine clearance (CG CrCl) and three eGFR equations (MDRD, CKD-EPI and BIS1). Kappa statistics were applied to determine the agreement between each two equation regarding CKD staging. Linear and Cox proportional regression models were used to identify factors associated with lower eGFR and mortality.

Results: 774 subjects were included in the analysis (mean age: 79.8 (SD=5.5) years, 62% female). The average kidney function was highest using MDRD (mean=70.4, SD=19.1) and lowest using BIS1 (mean=53.2, SD=12.0). The agreement in CKD staging between MDRD and CKD-EPI was substantial, while it was low to fair between BIS1 and the other equations. Older age, lower serum creatinine levels, gender, and ethnic differences contributed to the discrepancy between equations. Higher serum homocysteine levels and presence of hypertension were associated with lower eGFR whereas presence of diabetes mellitus was associated with higher eGFR across different equations. eGFR<45 ml/min/1.73m2 was associated with increased risk of mortality (HR=2-3.3, P<0.05).

Conclusions: In this community-dwelling older population, the use of different equations to calculate eGFR results in significant differences in CKD classification and assessment of mortality risk for patients with eGFR below 45 ml/min/1.73m2. These findings support efforts to develop improved methods to determine renal function and/or modify the outcome-related CKD staging in older adults.

Knowledge and Attitudes Toward Renal Replacement Therapy Options and Decision Making in Patients with Advanced Chronic Kidney Disease Jamie Alton Green, Ion D. Bucaloiu, James E. Hartle. *Nephrology and Hypertension, Geisinger Medical Center, Danville, PA.*

Background: Little is known about the baseline knowledge and attitudes towards dialysis of patients with advanced chronic kidney disease (CKD) referred to a renal replacement therapy education class.

Methods: We administered a survey to consecutive patients referred to a dialysis education class to assess their baseline knowledge of various renal replacement therapy options, decision making preferences, and advance directive completion.

Results: Twenty-nine patients completed the survey. Mean age was 64, 17 (59%) were female, and 26 (93%) were white. Fourteen (52%) had a less than or equal to high school level of education. Nine (32%) had limited health literacy level based on a single item screen. Fourteen (48%) were unsure how close they were to dialysis start. On a 5-point Likert scale (1=lowest, 5=highest), mean level of self-reported understanding for all modalities was poor (mean 2.3). Thirteen (45%) felt unprepared to make a decision about dialysis. Twenty-three (79%) preferred to share decision making with their doctor, 5 (17%) preferred making decisions by themselves, and only one patient (3%) preferred their doctor make these decisions for them. Fourteen (48%) had no advance directive documents completed.

Conclusions: The majority of patients referred to a renal replacement education class have poor baseline knowledge, feel unprepared to make these decisions, and prefer a shared decision making model. Additional work is needed to determine the most effective educational strategy to facilitate knowledge and shared decision making about renal replacement therapy options.

Predictors of Quality of Life in Patients with End Stage Renal Disease on Hemodialysis Chetana Rondla, Christine Boumitri, Magda Daoud, Marc M. Saad, Youssef El Douaihy, Suzanne E. El Sayegh. *Medicine/Nephrology, Staten Island Univ Hospital, Staten Island, NY.*

Background: Assessment of quality of life (QOL) of End Stage Renal Disease (ESRD) patients (physical, mental, and social well-being) has become an essential tool to develop better plans of care.Objective of this study is to determine which demographic and biochemical parameters correlate with the QOL scores in patients with ESRD on hemodialysis (HD) using Kidney Disease Quality of Life -36 surveys (KDQOL).

Methods: A retrospective chart review of all ESRD patients that underwent HD at an outpatient center.The 5 components of the KDQOL were the primary end points of this study (Burden of Kidney disease, Symptoms and Problems, Effects of Kidney Disease on daily life, MCS-Mental Component Survery, and PCS-Physical Component Survey). Scores grouped into 3 categories (below average, average, and above average).In addition to demographics (age, sex and race) the independent variables: weight gain, number of years on dialysis, URR, Calcium, Phosphorus, PTH, albumin, and hemoglobin in the serum were collected.Chi square analysis for dependent variables and the nominal independent variables was used; t-test analysis was used for continuous independent variables.Ordinal regression using PLUM method was used to weight out possible effects of confounders.

Results: Cohort size of 111 patients.Mean age 61.8 (±15.5), males 64.9%, mean time-on-dialysis 4.3 (4.8) years.About two thirds of responses on all 5 domains of the questionnaire ranked average when compared to national numbers.No significant relationships were found between the 5 dependent variables of interest and the independent variables.This was confirmed by regression analysis.Of note, sex carrrried the strongest statistical significance (p value 0.16) as predictor of "burden of kidney disease on daily life" in ordinal regression.

Conclusions: Prior studies have shown variables such as serum phosphate level, interdialytic weight gain and dialysis adequacy are associated with lower KDQOL scores however this was not evident in our analysis likely due to smaller sample size.Larger size studies are required to better understand the predictors of QOL in ESRD patients on Hemodialysis.

FR-PO1077

Communicating About Choices in Transplantation: Preliminary Evidence of the Efficacy of a Behavioral Communication Intervention for Kidney Transplant Candidates Heather Traino. *Social and Behavioral Health, Virginia Commonwealth Univ, Richmond, VA.*

Background: Previous research highlights the logistical and content-related difficulties patients with end-stage renal disease (ESRD) awaiting kidney transplant face while attempting to initiate and navigate discussions about kidney transplantation. In response, Communicating about Choices in Transplantation (COACH), a behavioral communication intervention, was developed combining education on living and deceased donor transplantation and the skills needed to effectively engage others in transplant-related conversations. This quasi-experimental study was conducted as a preliminary assessment of the intervention's efficacy.

Methods: ESRD patients (n=10) waitlisted for kidney transplantation at one mid-Atlantic transplant center participated in a 2-hour COACH session. Using a pre-post design, with no controls, the intervention's impact on patients' knowledge of deceased and living-donor transplantation; communication difficulties, self-efficacy, and intentions; and self-reported discussion of transplantation was evaluated.

Results: All participants reported previous conversations about transplantation prior to attending the session, however one indicated a desire for no further discussion; after program attendance all were considering, planning or going to continue to hold transplant-related conversations. Results of paired-sample t-tests revealed increases in the number of correct responses to the 12-item knowledge scale improved from 7.6 (SD=2.0; range, 5-12) pre-intervention to 9.5 (SD=1.8; range, 6-11; p=.05) post-intervention. Similarly, averaged ratings of confidence (i.e., self-efficacy) managing aspects of transplant-related conversations increased from 73.9 (SD=14.1; range, 55.9-93.5) to 89.0 (SD=6.7; range, 77.1-94.7; p=.009) post-intervention. Perceived conversational difficulties decreased from a pre-intervention average of 4.5 (SD=3.3) to 3.5 (SD=3.0) post-intervention (p=.53).

Conclusions: Results provide preliminary support for the intervention's efficacy. However, a more definitive test of the intervention is needed using a randomized controlled design and a larger, more diverse sample, with a control group.

FR-PO1078

Predictors and Cost of Renal Crash (Inpatient First Dialysis) Pradeep Arora,[1] John James Bono,[2] Laura L. Argauer,[2] Brian M. Murray,[1] Edwin J. Anand,[1] Rocco C. Venuto.[1] *[1]Medicine, SUNY at Buffalo, Buffallo, NY; [2]Computer Task Group, Computer Task Group, Buffalo, NY.*

Background: Mortality rate and the cost of care in dialysis patients is very high. We studied the factors associated with "crashing" into dialysis and its effect on the cost of care for the first three months after initiating chronic dialysis.

Methods: TThe population for this study was derived from a large upstate NY database spanning 6 years of health insurance claims records. Renal crash was defined if patients (1) developed end-stage renal disease (ESRD) during the observed period; (2) experienced their first instance of dialysis in an inpatient setting; (3) had at least two eGFR values indicative of CKD (less than 60 ml/min/1.73 m^2) before their first dialysis; and (4) had dialysis claims persisting for 90 days after the initial dialysis billing. Logistic regression model were built to evaluate the predictors of renal crash. Similarly MLR model was built to evaluate the impact of renal rash on cost of care in first 3 months.

Results: 332121 of 408,712 patients who had claims records with the data necessary to identify all medications and laboratory results had CKD. 664 patients were started on dialysis for ESRD: 52% had renal crash. Difference in baseline characteristics between these two groups is shown in the table.

	Renal Crash	No renal Crash	P value
Mean Age	66.6	63.4	0.03
Gender (F) %	41	38	0.5
Hypertension (%)	90	85	0.2
Diabetes	66	61	0.4
Coronary artery Disease (%)	47	33	0.01
Arthritis %	40	40	1.0
Anxiety %	6	3	0.2
other mental health	19	24	0.2
Statin use (%)	56	70	0.02
Mean number of Visit in last 12 months	5	6.4	0.001
Days between last Nephrology Visit prior to first dialysis	44	20	0.001
Last Nephrology visit between 0-4 months (%)	88	97	0.05
Last Nephrology Visit 4-12 months (%)	12	3	0.005
Mean cost of care in 3 months after First Dialysis ($)	35,376	22,367	0.00

Multivariate logistic regression revealed that coronary artery disease and less frequent visit to nephrologist were associated with increased odds of renal crash. Use of statin was protective against crash.

Conclusions: Renal crash is very common and leads to increased cost of care. More frequent nephrology visits appears to abrogate crash rates.

FR-PO1079

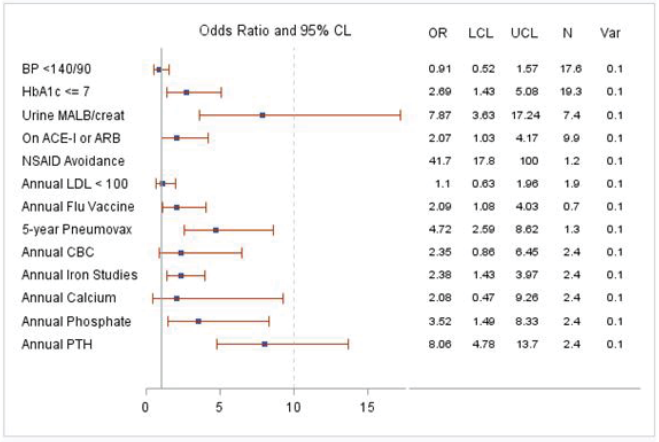
Design and Implementation of a Chronic Kidney Disease Checklist for Primary Care Providers Mallika L. Mendu, Sushrut S. Waikar. *Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Chronic kidney disease (CKD) is associated with significant morbidity, mortality and financial burden. Guidelines outlining CKD management have been published, but there is limited knowledge and application of these guidelines among primary care providers (PCPs).

Methods: We designed a CKD checklist-a tool outlining management guidelines for CKD- and examined whether implementation in a primary care clinic improved guideline adherence. During a one year period we conducted a prospective study involving 13 PCPs, 4 of whom were assigned to utilize a CKD checklist incorporated into the electronic medical record during visits with patients with CKD stages 1-4. All PCPs received education regarding CKD guidelines. The intervention and control groups consisted of 105 and 263 patients, respectively. We examined rates of adherence to CKD management guidelines.

Results: We observed improvements in measures of CKD care in patients assigned to the checklist compared to controls. Patients in the CKD checklist group were more likely to have appropriate annual laboratory testing for albuminuria (72.4% versus 27.8 %), phosphate (65.7% versus 35.4%), and parathyroid hormone (61.0% versus 16.4%) (p <0.001 in all cases). Compared to controls, patients in the checklist group had higher rates of achieving a hemoglobin A1c target <7 (77.1% versus 53.6%), use of an angiotensin-converting-enzyme inhibitor or angiotensin receptor blocker (67.6% versus 48.7%), documentation of non-steroidal anti-inflammatory drug avoidance (71.4% versus 6.5%), and vaccination for influenza (67.6% versus 48.3%) and pneumococcus (65.7% versus 27.8%) (p <0.001 in all cases). After adjustment for PCP, age, and CKD stage, use of a checklist remained significantly associated with increased guideline adherence.

Figure 1. Forest plot depicting adjusted impact of a CKD checklist on adherence to chronic kidney disease management guidelines'



Abbreviations: BP, blood pressure; HbA1c, hemoglobin A1c; urine MALB/creat, urine microalbumin/creatinine ratio; ACE-I, angiotensin converting enzyme-inhibitor; ARB, angiotensin receptor blocker; NSAID, Nonsteroidal anti-inflammatory drugs; LDL, Low-density lipoprotein; CBC, Complete blood count; PTH, parathyroid hormone
a. Accounting for within group correlation by PCP assignment and adjusted for Age, and CKD Stage (1 and 2, 3, 4)
b. Odds ratio greater than 1 (to right of solid vertical line) reflects increased adherence in patients assigned to the CKD checklist

Conclusions: Implementation of a CKD checklist significantly improved adherence to CKD management guidelines.

FR-PO1080

Confidence Level, Knowledge and Practices of Primary Care Physicians in Chronic Kidney Disease Management Jia Hwei Ng,[1] Robert Schoepe,[1] Chike N. Okechukwu,[2] Spencer Ng,[3] Aaroop Haridas,[1] Shaila Smith,[1] Rashmika Potdar,[1] Sonia N. Zaveri.[1] *[1]Internal Medicine, Crozer Chester Medical Center, Upland, PA; [2]Nephrology, Clinical Renal Associates Ltd, Chester, PA; [3]Widener Univ, Chester, PA.*

Background: Recent studies have shown that primary care physicians (PCP) lack confidence in management strategies for chronic kidney disease (CKD). This study aims to evaluate the confidence level, knowledge and practices of PCPs in CKD management.

Methods: A paper-based questionnaire was given to PCPs in an internal medicine residency program. In addition, physicians' actual practices were compared to survey results using a retrospective cohort analysis of 176 CKD patients.

Results: There were 31 out of 34 physicians who responded. Respondents consisted of 45% (14/31) attendings and 55% (17/31) residents. Of all respondents, 74% (23/31) were confident in diagnosing CKD, 74% (23/31) were confident in CKD staging, and 34% (10/31) were aware of CKD guidelines. Attendings were significantly more confident than residents in diagnosing CKD (p=0.0454). However, there were no significant differences between attendings and residents in CKD staging (p=1.000), and awareness of CKD guidelines (p=0.4414). In diagnosing CKD, 77% (24/31) chose eGFR, 35% (11/31) used creatinine clearance and 6% (2/31) used creatinine only. Up to 90% (28/31) of PCPs reported yearly anemia screen and 84% (26/31) urine albumin screen. But only 48% (85/176) of patients were screened for anemia, and 54% (95/176) of the patients had annual urine albumin testing. Reported yearly screening for PTH and phosphorus were 54% (16/31), and 83%

(24/31) respectively. However, bone mineral screening in actual practice was less than 40% (12/48) among patients with eGFR<45. PCPs reported use of ACE inhibitor or ARB 77% (24/31), and 13% (4/31) would use ACE inhibitor and ARB simultaneously. However 50% (75/145) of patients with hypertension were not on ACE inhibitor or ARBs.

Conclusions: Physicians were not confident at CKD management. Physicians' perception of their management did not correlate with actual practice. Making CKD a core quality measure would likely improve adherence to current guidelines.

FR-PO1081

Chronic Kidney Disease Management among Primary Care Physicians in a Residency Program Jia Hwei Ng,[1] Robert Schoepe,[1] Aaroop Haridas,[1] Shaila Smith,[1] Rashmika Potdar,[1] Sonia N. Zaveri,[1] Chike N. Okechukwu.[2] *[1]Internal Medicine, Crozer Chester Medical Center, Upland, PA; [2]Nephrology, Clinical Renal Associates Ltd, Chester, PA.*

Background: The role of primary care physicians (PCP) in managing early chronic kidney disease (CKD) is vital. However, studies have showed that management strategies for CKD by PCP were often suboptimal. This study aims to assess if the PCPs in an internal medicine residency program are managing CKD according to Kidney Disease Improving Global Outcome (KDIGO) 2012 guidelines.

Methods: This retrospective cohort study was performed on 175 patients from two group practices. Patients with two estimated glomerular filtration rates (eGFR) of < 60 for at least 3 months were included. Patients excluded were: ESRD on dialysis, HIV, pregnant, and renal transplant. Parameters measured on different aspects of CKD management included: kidney disease surveillance, hypertension, diabetes, lipids, anemia, bone mineral disease, and acid base disorder. Timely referral to nephrology was also evaluated.

Results: There were 88% (154/176) stage 3 CKD, 13% (22/176) Stage 4 CKD, and no 5 CKD. Fifty five percent (90/165) of patients with hypertension met target blood pressure (BP) of ≤ 140/90. Among diabetic patients, 26% (25/95) reached target BP ≤ 130/80. Up to 50% (75/145) of patients with hypertension were not on angiotensin converting enzyme inhibitor or angiotensin receptor blocker. HbA1C ≤ 7 was met in 51% (49/95) of diabetes patients. Hyperlipidemia screen was 82% (161/176). Yearly anemia screen for CKD Stage 3 was 53% (82/154), and twice a year anemia screen for CKD stage 4 was 32% (7/22). Phosphorus, parathyroid hormone, and vitamin D screening rates for eGFR <45 were 25% (12/48), 38% (15/48), and 52% (25/48) respectively. Only 54% (95/176) of the patients had annual urine protein testing. Appropriate nephrology referral (eGFR < 30) was done 50% (12/22) of the time.

Conclusions: By KDIGO guidelines, management of CKD by physicians in our study is suboptimal. A separate study is being done to assess barriers to physicians' non-adherence to guidelines. Larger studies involving residency programs should be done to evaluate current trends in CKD management.

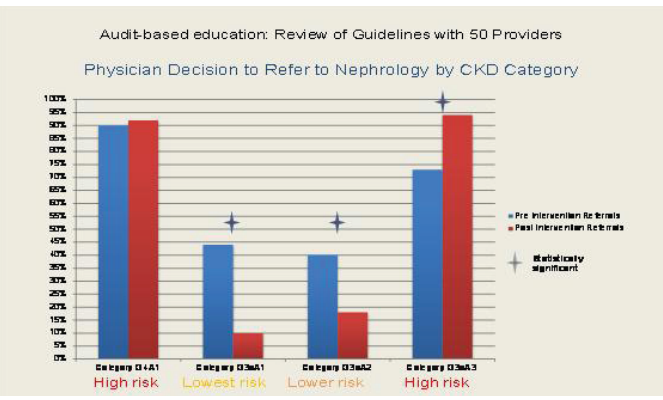
FR-PO1082

Audit-Based Education of Referring Providers Affects Albuminuria Detection and Referral Patterns of CKD Patients Konstantin Abramov, Aditi Ahlawat, Marie A. Sosa, Jayaprakash R. Dasari. *Univ of Mass.*

Background: Early referral to nephrology of low risk CKD patients is common and contributes to over-utilization of resources and prolonged wait time. This affects timely identification and referral of high risk patients. In 2013, 587 new referrals were made to our clinic, 50% for evaluation of CKD. Since 2012, the average wait time for new patient evaluation increased from 30 to 40 days. A common practice is to refer CKD patients for evaluation when eGFR is <60 ml/min. New CKD classification retains 5 GFR stages and adds 3 albuminuria stages, reflecting increased progression and complication risk in albuminuric patients. The KDIGO recommendation is to refer high risk patients to nephrology, those with eGFR <30 ml/min (category G4) or albuminuria >300 mg/day (category A3). Albuminuria is infrequently measured by referring providers.

Methods: A pre-intervention survey asked providers to identify patients for referral, based on different CKD risk categories. After an audit of current referral practices, we initiated a provider education session of the new CKD classification, guidelines and changes to the electronic medical record to facilitate ordering and tracking of urine albumin. A post-intervention survey and referral audit was obtained.

Results: Post-intervention providers indicated they would refer fewer low risk patients and more high risk patients.



Analysis of post-intervention referrals demonstrated fewer patients with low or unknown risk category (reduction from 25% to 15%) and more patients with measured albuminuria at the time of referral (increase from 25% to 85%).

Conclusions: An audit based intervention appears to be effective in changing referral patterns and albuminuria detection. A longer follow up is required to assess sustainability of this change and its effect on the referral wait time.

FR-PO1083

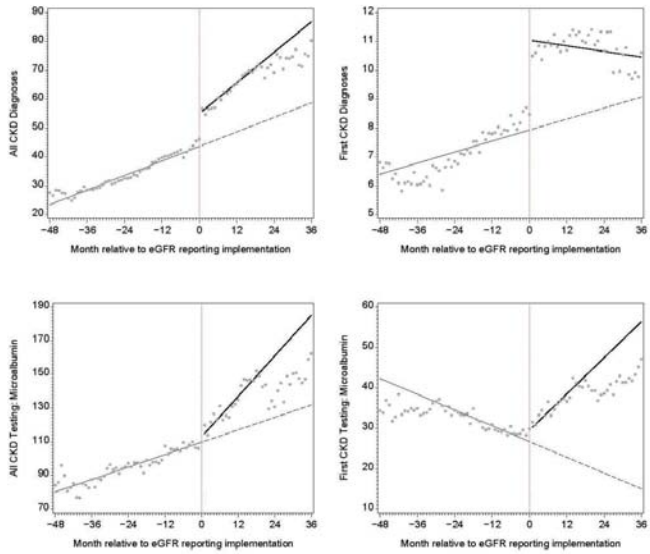
Impacts of Automated Estimated Glomerular Filtration Rate Reporting in the Veterans Health Administration (VHA) Virginia Wang,[1,2] Bradley G. Hammill,[2] Matthew L. Maciejewski,[1,2] Rasheeda K. Hall,[2] Amit X. Garg,[3] Arsh Jain,[3] Uptal D. Patel.[2] *[1]VA Med Ctr, Durham, NC; [2]Duke Univ, Durham, NC; [3]Western Univ, Ontario.*

Background: Automated lab reporting of estimated glomerular filtration rate (eGFR) has been introduced in health systems to improve recognition of chronic kidney disease (CKD), but its impact on health systems remains unclear. We examined the effects of eGFR reporting on CKD recognition and renal services in the VHA.

Methods: Time-series study examined a national cohort of 97 VA outpatient clinics or hospitals with lab data in 2000-09. Health system and patient data was drawn from VA databases. Hierarchical generalized linear models estimated short- and long-term facility-level impacts of eGFR reporting on monthly rates of overall and first outpatient CKD diagnoses, use of microalbumin and kidney ultrasound diagnostic testing, and outpatient nephrology visits.

Results: After eGFR reporting, we found increases in overall CKD diagnoses (74%; mean facility rate from 46 to 80 per 10,000 general VA outpatients per month), microalbumin testing (48%, 110 to 162), kidney ultrasounds (22%; 20 to 24), and nephrology visits (30%; 29 to 38). There was short-term growth and a long-term decline in patients' first CKD diagnoses, but immediate and sustained increases in first microalbumin testing.

Figure 1. Time series of monthly rates of outcomes (per 10,000 general VA outpatients)



In adjusted models, CKD diagnoses increased an average 11.4 per 10,000 general VA outpatients per month, with sustained long-term growth (p<.001). There was long-term growth in microalbumin testing (p<.001) and short-term growth in ultrasounds (p<.05), but no change in nephrology visits.

Conclusions: We found modest system-level effects ofeGFR reporting that may reflect the relative ease of CKD documentation and follow-up diagnostic testing. eGFR reporting had no impact on nephrology visits, suggesting opportunities to improve appropriate follow-up evaluation to confirm and effectively manage CKD.

FR-PO1084

Expenditures for Chronic Kidney Disease (CKD) in the United States: Results from Medical Expenditure Panel Survey (MEPS) 2011 Mukoso N. Ozieh,[1] Kinfe Gebreegziabher Bishu,[1] Leonard Egede.[1] *[1]Nephrology, MUSC, Charleston, SC; [2]Internal Medicine, MUSC, Charleston, SC.*

Background: CKD (defined as eGFR < 60ml/min/1.73m^2) is a global public health problem. According to the National Kidney Foundation, 26 million adults in the U.S. are affected by CKD. The cost of CKD has continued to rise according to the United States Renal Data System, however there are no recent national estimates of the cost of CKD in the U.S. population. This study aims to assess the cost of CKD in adults in the U.S. population.

Methods: Data on 18,945 adults in 2011 MEPS was analyzed. CKD was based on ICD-9 codes from the 2011 MEPS medical condition file which was merged with the consolidated file. Mean total expenditure in 2011 was estimated for the overall sample and by CKD status. We used a generalized linear model with gamma distribution and log

link function to estimate total overall adjusted expenditure and by CKD status. Covariates in the model include age, race, gender, marital status, education, insurance, Metropolitan Statistical Area (MSA), region, poverty status and comorbidities. STATA version 13 was used to account for the complex design of MEPS.

Results: Of the 18,945 adults analyzed, approximately 1.3percent had CKD. CKD was significantly more prevalent amongst individuals 65 years and above, widow/divorced/single individuals and publicly insured. CKD was also more prevalent in individuals with hypertension, CVD, Stroke, high cholesterol and arthritis. In the unadjusted analysis, mean total expenditure was $5,862.08 (95% CI $5,542.28-$6181.93). Mean total expenditure for those without CKD was $5,772.73 (95% CI $5,447.48-$6,097.98) and $12,739.25 (95% CI $9,762.79-$15,715.72) in those with CKD. In the adjusted analysis, mean total expenditure in those without CKD was $6,078.99 (95% CI $5,711.51-$6,446.49) and $8,366.03 (95% CI $6,301.72-$10,430.34) in those with CKD. Extrapolating to the U.S. population in 2011, the mean total expenditure for those with CKD was over $21 billion.

Conclusions: We determined that CKD had an independent effect on cost. This emphasizes the need for prevention, early diagnosis, referral, and treatment of CKD.

FR-PO1085

Barriers to Self-Care in Type 2 Diabetes and Chronic Kidney Disease: A Qualitative Approach Shayan Shirazian,[1] Natalie Crnosija,[2] Joseph Mattana,[1] Amy C. Hammock.[2] *[1]Medicine, Winthrop Univ Hospital; [2]Public Health, Stony Brook Univ.*

Background: The majority of patients with type 2 diabetes (T2DM) and pre-dialysis chronic kidney disease (CKD) are not at goal blood glucose, blood pressure or cholesterol; this has been attributed, in part, to a failure of self-care. Despite National Kidney Foundation guidelines that stress the need for self-care interventions in patients with both T2DM and CKD, few studies have evaluated barriers to self-care in this population. The objective of this qualitative study is to examine barriers to self-care in patients with T2DM and CKD.

Methods: In this IRB approved study, a doctoral level expert in qualitative methods performed two 90-minute focus groups with T2DM and CKD patients. Focus group participants were asked about barriers to self-care in managing both diabetes and CKD. Participants were asked about common barriers when discussion slowed. Focus groups were audio recorded, transcribed, and systematically analyzed to identify emergent common themes.

Results: Sixteen subjects (10 men and 6 women) of varying race and at varying stages of CKD (2-5) participated in 2 focus groups. The most commonly stated barriers to CKD self-care were (1) lack of coordinated care, (2) mechanisms and risks/benefits of medications, (3) unclear dietary recommendations, (4) inadequate information about co-morbid conditions, such as cardiac disease, (5) depressed mood and hopelessness about current health, (6) anxiety about the future possibility of dialysis, and (7) family members' unhealthy food-related behavior. Of the themes that emerged, the investigators found psychological distress regarding kidney disease and the future possibility of dialysis to be additional, unique barriers faced by patients with both T2DM and CKD.

Conclusions: Psychological distress regarding kidney disease, including the future possibility of dialysis, may be important unique barriers to the management of patients with both T2DM and CKD. Patient-centered self-care interventions that target barriers to care may improve treatment target achievement in patients with T2DM and CKD.

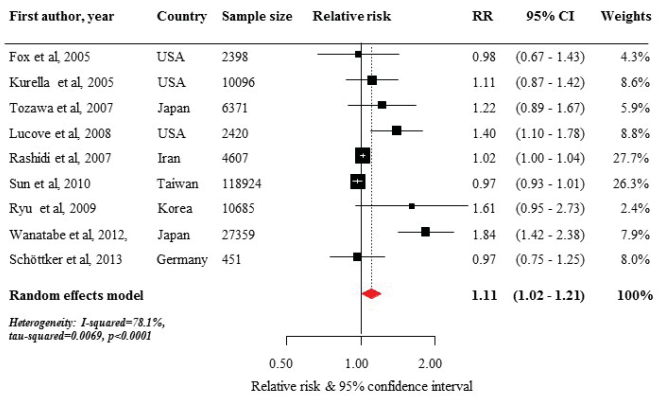
FR-PO1086

Association between Prediabetes and Risk of Chronic Kidney Disease – A Meta-Analysis Justin B. Echouffo Tcheugui,[1,3] K.M. Venkat Narayan,[1] David Weisman,[3] Sherita H. Golden,[2] Bernard G. Jaar.[2] *[1]Global Health, Emory Univ, Altanta, GA; [2]Medicine, Johns Hopkins, Baltimore, MD; [3]Medicine, MedStar Good Samaritan Hospital, Baltimore, MD.*

Background: It is unclear whether non-diabetic range hyperglycemia is a risk factor for chronic kidney disease (CKD). We assessed the prospective association of prediabetes (impaired fasting glucose [IFG] and/or impaired glucose tolerance [IGT]) and CKD.

Methods: We searched PubMed, EMBASE, and bibliographies of retrieved English-language articles pubished until March 2014. We included observational studies reporting measures of disease risk (multivariate-adjusted relativerisks [RRs], hazard ratios [HRs] or odds ratios [ORs] and corresponding 95% confidence intervals [CI] or CKD [kidney damage (microalbuminuria, albuminuria or proteinuria) and/or glomerular filtration rate < 60 cc/min/1.73m^2] to baseline prediabetes.

Results: The searches yielded nine prospective cohort studies, including 183,311 participants, mainly Asians (88%). In eight prospective studies analyzing IFG defined as fasting glucose 110-125 mg/dL, the random effects summary estimate showed an increased risk of CKD after adjustment for established risk factors including age, sex, body mass index and blood pressure (1.12; 95% CI: 1.02-1.21). When the only prospective study defining IFG as fasting glucose 100-125 mg/dL was added, the adjusted random effects summary estimate for CKD was 1.11 (95%CI: 1.02 - 1.21).



Only one study included information on IGT, and its exclusion did not change the prediabetes effect estimate (1.12, 95%CI: 1.02 - 1.21). There was no evidence of publication bias.

Conclusions: Prediabetes is associated with a modest but significantly higher risk of CKD in a diverse population. Screening for CKD among people with prediabetes, as well as aggressive management of prediabetes to prevent CKD occurrence may be warranted.

FR-PO1087

Prevalence of Microalbuminuria in U.S. Adults with Prediabetes Nishkarsh Saxena, Rukevwe Ehwarieme, Arvind R. Kunadi, Jill Gernand, Radhika Kakarala. *Internal Medicine, McLaren Regional Medical Center/ MSU, Flint, MI.*

Background: The risk of mortality with albuminuria level greater than 10 mg/g exists as a continuum. Microalbuminuria (MAU) in prediabetics (pre-DM) is associated with increased risk of diabetes, renal and cardiovascular disease. However, few studies have estimated the prevalence of MAU in the pre-DM state. The purpose of this study was to estimate and compare the prevalence of MAU in pre-DM diagnosed by either fasting plasma glucose (FPG), 2hr OGTT, HbA1c or by both FPG and HbA1c. We also determined the predictors of MAU in pre-DM patients.

Methods: We used the U.S. National Health and Nutrition Examination Survey (NHANES) 2009-2010 to identify participants with pre-DM and albumuria. Participants aged 18 years and above, with pre-DM and albuminuria were included in this study (N= 1,504). Pre-DM was defined by FPG = 100-125mg/dL, 2hr OGTT = 140-199 mg/dL or HbA1c = 5.7-6.4%. Prevalence of MAU was determined for pre-DM status. Multivariate logistic regression was used to determine the independent predictors of MAU. SPSS complex analysis was used to account for the complex sample design of the survey.

Results: Among patients with albuminuria, 5.6% had MAU. Prevalence of MAU in patients with pre-DM diagnosed by FPG only, 2 hr OGTT only, HbA1c only, and both FPG and HbA1c is 4.4%, 9.8%, 2.0% and 10.3% respectively (p-value=0.003). Age, gender, race and SBP adjusted prevalence of MAU was 2.7% and 5.5% for FPG and combined FPG and HbA1c. The odds of having MAU was 6.5 times more likely in patients diagnosed with both FPG and HbA1c compared to HbA1c only (odds ratio 6.45: [CI 2.38 to 17.50]).

Variable	OR	CI	P value
Age <60- ref ≥60	1.00 1.943	(0.777, 4.853)	0.130
Race Caucasian- ref AA Other	1.00 1.292 1.321	(0.474, 3.523) (0.443, 3.940)	0.596 0.596
Gender Male- ref Female	1.00 1.570	(0.596, 4.135)	0.339
Systolic BP <140- ref ≥140	1.00 2.238	(0.424, 11.813)	0.320
Pre DM HbA1C- ref FPG FPG + HbA1C	1.00 3.111 6.451	(1.002, 9.654) (2.378, 17.500)	0.001 0.050

Conclusions: Prevalence of microalbuminuria is higher in prediabetic patients diagnosed by both FPG and HbA1c. This group of patients may benefit from closer surveillance for progression to diabetes and/or chronic kidney disease.

FR-PO1088

Is Tertiary Prevention of Diabetic Kidney Disease with Maximum Tolerated Dose of a Renin Angiotensin System Inhibitor Achievable in Primary Care Setting? Ping Tyug Loh,[1] Shih Hui Ong,[1] Chee Kong Lim,[2] Vathsala Anantharaman.[1] *[1]Div of Nephrology, National Univ Hospital, Singapore; [2]National Healthcare Group Polyclinics, Singapore.*

Background: Singapore has the highest rate of Diabetic Kidney Disease (DKD) as the cause of End Stage Renal Disease in the world, reported at 65.5% in 2012. Despite achieved mean HbA1c of 7.7% and BP<140/90, DKD prevalence was 52.5% at one primary care cluster. A systems approach, coined Nephrology Evaluation, Management and Optimization (NEMO) program, was implemented as a collaborative effort between nephrologists and primary physicians, to augment DKD management in this primary care cohort.

Methods: This program incorporated: Information Technology (IT) to identify patients with early DKD [GFR>60 with either microalbumiuria (MI) or macroalbuminuria (MA)]. Coordinators to counsel and monitor eligible DKD patients not on maximum dose of Angiotensin Converting Enzyme Inhibitor (ACEI) /Angiotensin Receptor Blocker (ARB)

for optimization of ACEI/ARB therapy. Primary physicians to titrate ACEI/ARB dosage until maximum dose (MD), maximum tolerated dose (MTD) or normoalbuminuria (NA) was achieved.

Results: 5,620 patients had been enrolled since 2011. 2,132 have completed optimization over a mean duration of 7.6±5.1 months. Of these, 70% had MI, 30% had MA and 84% were on ACEI/ARB at baseline. Following ACEI/ARB dose titration, 87% were successfully optimized, with 24% achieving NA, 43% and 20% receiving MD and MTD of ACEI/ARB respectively. 2,066 patients with albuminuria result available at completion of program, 35.5% improved in their albuminuria status while 4.6% progressed from MI to MA.

Figure 1.Process Flow

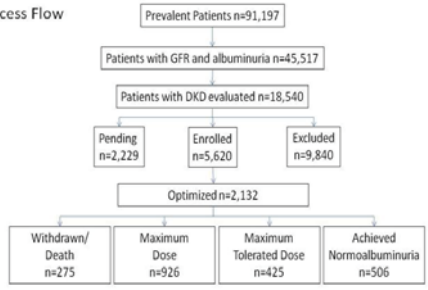


Figure 2. Albuminuria Status Post Optimization

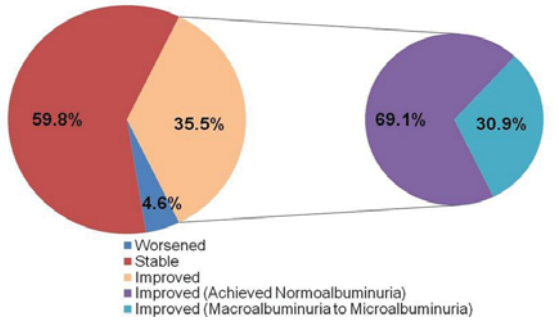

Conclusions: Tertiary prevention of DKD is achievable in a real time, primary care setting, using IT as an enabler for patient selection and coordinators for delivery of planned care strategies, as to mitigate the high prevalence and progression of DKD.

FR-PO1089

Medication Adherence as a Predictor of Health Services Utilization in Adolescents and Young Adults with Chronic Kidney Disease Robyn Nicole Levine, Sarah Elizabeth Cohen, Jessica L. Ryan, Meredith Johnson, Karina Javalkar, Maria E. Ferris. *UNC Kidney Center, The Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Adherence to treatment for CKD and ESRD is difficult to achieve as these conditions require complex medication, diet, and at times, home dialysis regimens. The relationship between medication adherence (MA) and health services utilization by adolescents/young adults (youth) needs to be elucidated.

Methods: Youth with CKD stages 2-5 from the pediatric and adult nephrology clinics at the UNC Kidney Center were invited. MA was measured using the Morisky Medication Adherence Scale, and health services utilization was measured by emergency department (ED) visits, total and preventable lifetime hospitalizations (Samuel SM, *Pediatrics* 2014), and length of in-patient admissions. Regression analyses were performed in SPSS.

Results: We enrolled 180 participants with the following characteristics: 58% female, 41% African-American, 42% White, 47% with public insurance, and 50% with CKD Stage ≥ 4. The mean age was 21 (±5.5), mean GFR was 55 (±33), and mean lifetime number of ED visits was 4.03 (±6.6). When controlling for age, gender, race, insurance, CKD stage, and glomerular filtration rate in a step-wise fashion, MA was a predictor of ED visits. Those with higher adherence had fewer total ED visits (B= -.212, p=.031). Lifetime hospitalizations (total and preventable) and length of admission were directly associated with CKD stage (p=0.000 for each metric), but ED visits were not.

Conclusions: Non-adherent youth with CKD have significantly greater ED visits compared to adherent youth. Targeted interventions to reduce health services utilization should focus on non-adherent patients and those with higher CKD stages.

Funding: Private Foundation Support

FR-PO1090

Study Design and Baseline Characteristics in the "Medication Intervention in Transitional Care to Optimize Outcomes for Chronic Kidney Disease" Clinical Trial Radica Z. Alicic,[1,3] Robert Short,[1,2] Cynthia F. Corbett,[1,2] Brian J. Gates,[2] Joshua J. Neumiller,[2] Celestina Barbosa-Leiker,[2] Sterling Mcpherson,[2] Kenn B. Daratha,[2] Katherine R. Tuttle.[1,2,3] *[1]Providence Health System, WA; [2]Washington State Univ, WA; [3]Univ of Washington Medical School, WA.*

Background: People with chronic kidney disease (CKD) are hospitalized longer and more often than people with other health conditions. Readmission rates are >20% in the 30 days after discharge. The aim of this study is to evaluate a medication information transfer (MIT) intervention in the transition from hospital-to-home for reducing acute care utilization in the CKD population.

Methods: CKD-MIT is a single-center, randomized, controlled clinical trial testing the hypothesis that improving MIT through a home-based pharmacy intervention within the first week of hospital discharge will reduce readmissions and visits to the emergency department or urgent care center for 90 days. The study is enrolling participants in 2 groups: CKD stages 3-5 (not dialyzed, target n=140) and CKD stage 5 (dialyzed, target n=70).

Results: Baseline characteristics of the CKD stages 3-5 (not dialyzed) group are reported as it is almost fully enrolled (n=115). The 3 most common reasons for the index hospitalization are: cardiovascular diseases (33%, 38/115), infections (21%, 24/115), and acute kidney injury (11%, 13/115). Participants' mean age (±SD) is 70±11 years. Nearly half, 47% (54/115) are women. Estimated glomerular filtration rate (eGFR, CKD-EPI) is 41±13 ml/min/1.73m^2. Other measures include: blood pressure 131±22/71±12 mm Hg; body mass index 33±8 kg/m^2; hemoglobin 12±2 g/dL; phosphorus 3.6±0.6 mg/dL; parathyroid hormone 72±59 pg/ml; K 4.6±0.5 mEq/L. The distribution of CKD stages includes: 7% (8/115) stage 2; 29% (33/115) stage 3a, 42% (48/115) stage 3b, 21% (24/115) stage 4; 2% (2/115) stage 5. A few participants are classified as CKD stage 2 because of eGFR shifts in the week between discharge and the baseline visit.

Conclusions: The CKD-MIT clinical trial will determine the effectiveness of an early home-based pharmacy intervention focused on reducing rates of acute care use in this high-risk group.

FR-PO1091

Increased Body Fat Rather Than Body Weight Has Harmful Effects on 4-Year Changes of Renal Function in the General Elderly Population with a Normal or Mildly Impaired Renal Function Jwa-Kyung Kim,[1] Jisuk Han,[1] Myung Jin Choi,[2] Jiwon Ryu,[2] Jung-Woo Noh,[3] Sung Gyun Kim.[4] *[1]Internal Medicine, Hallym Univ Sacred Heart Hospital, Seoul, Republic of Korea; [2]Internal Medicine, Hallym Univ Chuncheon Sacred Heart Hospital, Seoul, Republic of Korea; [3]Internal Medicine, Hallym Univ Gangnam Sacred Heart Hospital, Seoul, Republic of Korea; [4]Internal Medicine and Kidney Research Inst, Hallym Univ College of Medicine, Dongan-gu, Anyang, Korea.*

Background: With increasing age, body fat increases and muscle mass reduces. Even people with a normal weight can have a higher percentage of body fat. The aim of this study is to investigate the association between increased body fat and renal function decline (RFD) in the general elderly population with normal or mildly impaired renal function.

Methods: We conducted a study of 615 healthy individuals in the Korean general population aged ≥ 60 years who participated in two health screening check-ups separated by a 4-year period. Obesity was defined as the highest sex-specific tertiles of the percentage body fat (PBF). The main outcome was changes of estimated glomerular filtration rate (eGFR) during the 4 years. Significant RFD was defined as a decrease of eGFR over the upper quartile (≤–2.1%/yr).

Results: The mean age was 67.2±6.6 years. The median value of absolute decline in the eGFR and percent change were –3.0 mL/min/1.73m^2 and –0.87 %/yr in men and –3.1 mL/min/1.73m^2 and –0.89 %/yr in women, respectively. When stratified by sex-specific PBF tertiles, pronounced differences were observed in both sexes; those at the highest tertile of PBF showed the greatest decline in eGFR. Even after adjustments for traditional risk factors of RFD, PBF was independently associated with eGFR changes (b=-0.181, p<0.001). In addition, the harmful effect of a high PBF was consistently found in subjects with a normal weight, too (b=-0.141, p=0.006). Cases of significant RFD occurred in 181 participants (29.4%) and the risk was higher in obese participants. The odd ratios (95% CI) for significant RFD were 2.76 (1.28-7.74) in men and 2.02 (1.06-4.43) in women in a whole population and 3.15 (1,03-18.52) in men and 1.44 (1.01-3.28) in women with a normal weight, respectively.

Conclusions: Among the elderly population without comorbidites, increased body fat has harmful effect on RFD irrespective of body weight.

FR-PO1092

A Novel Approach to Improve Recognition of Geriatric Conditions among Older Adults with Chronic Kidney Disease C. Barrett Bowling,[1,2] Lynn E. Schlanger,[1,2] Steven M. Gorbatkin.[1,2] *[1]Atlanta Veterans Affairs Medical Center; [2]Emory Univ.*

Background: Nearly one in three older adults require nursing home care when starting dialysis and of these patients 45% are unable to ambulate and 60% need assistance with basic activities of daily living. Early recognition of geriatric conditions including falls,

cognitive impairment and mobility impairment may reduce the risk for functional decline as chronic kidney disease (CKD) progresses. However, assessment for geriatric conditions is not part of the routine clinical work-up for these patients.

Methods: The Comprehensive Geriatric Assessment for CKD (CGA-4-CKD) program is a partnership between Geriatrics and Renal at the Atlanta Veterans Affairs Medical Center (VAMC) designed to improve recognition of geriatric conditions and support the development of patient-centered treatment plans to prevent functional decline. The CGA-4-CKD care model includes: 1) a standardized Geriatric CKD Tool Kit in the electronic medical record, 2) a geriatrician embedded in the Renal Clinic and 3) provider-targeted education. Patients who are ≥ 70 years old with CKD seen in the Atlanta VAMC Renal Clinic had standardized screening for falls, impaired mobility, urinary incontinence and cognitive impairment. This information was reviewed by the embedded geriatrician and results were discussed with the nephrologist using an academic detailing approach.

Results: Between October 2013 and May 2014, 133 patients met inclusion criteria and 106 (80%) received geriatric screening. Eighty one patients (76%) had at least one geriatric condition and received further evaluation by the geriatrician during the clinic visit. Cognitive impairment, falls, urinary incontinence and mobility impairment were present in 24%, 27%, 31% and 46% of those screened. Of the 136 geriatric conditions identified, 92 (68%) had not been previously documented. Individualized, patient-centered care plans were developed and only 17% of patients had geriatric conditions that could not be completely addressed during the Renal Clinic visit and required further geriatric referral.

Conclusions: A CGA-4-CKD program can increase the recognition of geriatric conditions and may support patient-centered care for these patients.

Funding: Veterans Affairs Support

FR-PO1093

Physical Therapy Referral Varies Significantly Across Dialysis Facilities in the ACTIVE-ADIPOSE USRDS Special Study Nancy G. Kutner, Rebecca H. Zhang, Yijian Huang. *Emory Univ, Atlanta, GA.*

Background: Musculoskeletal problems, falling, and physical performance deficits are prominent among patients undergoing maintenance dialysis. Overall health status and collaboration of multiple organ systems to regulate energy expenditure and motor control contribute to these deficits. Physical therapists can identify impairments and activity related challenges and initiate interventions to target specific deficits. Little is known about receipt of physical therapy (PT) services by dialysis patients, however.

Methods: The USRDS special study ACTIVE-ADIPOSE evaluated 771 prevalent patients aged 20-92 undergoing maintenance hemodialysis (HD) 2009-2011 at 14 outpatient clinics located in Atlanta, GA, and the San Francisco Bay Area, CA. Follow-up evaluations were conducted at 12-months and 24-months, through September 2013. Walking disability, falls, and fractures were identified, and receipt of PT services across 24 months was determined among study participants at the 14 clinics.

Results: Almost one-fourth of the study cohort walked slower than 0.6 m/s or could not perform a walk test, indicating a high risk of physical disability, and two-thirds of ambulatory patients walked slower than 1.0 meter/second, a cut point at which individuals would benefit from fall prevention training. Over the 24-month study period, 44% of the cohort fell one or more times. Among fallers, patients who incurred a fracture were significantly more likely than those without fracture to report limitations in daily living activities but they were no more likely to receive PT. Receipt of PT across the 14 participating clinics ranged from 15% to 43% of patients; this variation was not associated with region, clinic size, or average age of patients per clinic.

Conclusions: PT services are reimbursed by third-party payers, and restorative PT is considered a critical need for chronic kidney disease patients, both non-dialysis and dialysis-dependent. Factors contributing to variation in patient referral for PT are important to understand as quality improvement initiatives focus on actionable deficits in patients' functional status.

Supplementary School Services for Children with Mild to Moderate Chronic Kidney Disease at Risk for Poor School Performance Arlene C. Gerson,[1] Allison Berryhill,[2] Matthew Matheson,[1] Stephen R. Hooper,[3] Susan R. Mendley,[4] Rica Garrison Rostad,[5] Susan L. Furth,[6] Bradley A. Warady,[7] Cynthia Wong.[2] *[1]Johns Hopkins; [2]Stanford; [3]Univ of NC; [4]Univ of MD; [5]Orting Sch Dist; [6]CHOP; [7]Childrens Mercy.*

Background: Children with poor school performance may be eligible for supplementary school services (SSS). Previously reported cross-sectional analyses from our group indicate that a sizable proportion of children with CKD receive SSS. Our aim was to longitudinally evaluate the relative significance of various risk factors for poor school performance on the likelihood of receiving SSS.

Methods: Subjects enrolled in the multicenter Chronic Kidney Disease in Children (CKiD) study with >2 yrs of data on SSS were used. Longitudinal logistic regression was done to see if risk factors were associated with concurrent receipt of SSS, and to see if gain, loss or persistence of risk factors resulted in a change in SSS. Risk factors were identified from published literature and included parent or subject report of school problems, absenteeism >20 days/yr, grade retention, below average IQ and attention problems.

Results: Of the 676 subjects, 2/3 had identifiable risk factors, yet fewer than half received SSS. Absenteeism (Odds Ratio, OR=5.0,p=.0002) and cognitive deficits (OR=4.2,p<.0001) were the strongest predictors for concurrent SSS receipt after controlling for socioeconomic status, race, GFR and duration of CKD. Poor attention (OR=2.7, p=0.002), grade retention (OR=2.4,p=.003), and report of school problems (OR=1.8,p=.03) also predicted receipt of SSS. Worsened cognitive functioning was associated with start of SSS during the observation period (OR=3.1,p=.03). Persistence of school problems (OR=2.8,p=.02), cognitive deficits (OR=3.6, p=.003), and poor attention (OR=4.1,p=.004) also predicted acquisition of SSS during the observation period. Of those not receiving SSS at the beginning of the study, 59 (23%) gained access to SSS over time. Of those receiving SSS at the beginning of the study 51 (25%) lost SSS during over time.

Conclusions: Persistent and worsening neurocognitive dysfunction was associated with SSS among CKiD subjects, yet many affected children do not receive these services.

Home Blood Pressure Telemonitoring System Among Patients with CKD: An Attempt to Achieve Optimal Blood Pressure Control with Real-Time Remote Monitoring Yoshinari Yasuda, Misao Niwa, Kanako Shibata, Mayumi Kamiya, Imai Junko, Sawako Kato, Shoichi Maruyama, Seiichi Matsuo. *CKD/Nephrol, Nagoya Univ, Nagoya, Japan.*

Background: Chronic kidney disease (CKD) is a global serious health issue. Due to high CKD prevalence in Japan, medical cooperation between general practitioners (GP) and nephrology specialists is essential. To achieve optimal blood pressure (BP) control among CKD patients treated by GP, home BP telemonitoring system was attempted and its utility was investigated.

Methods: Home BP of 79 CKD patients treated by GP were telemonitored using Medical LINK (Omron). BP data were automatically transmitted to central server by wireless-network and abnormal BP changes were reported to nephrology specialists in Nagoya Univ. Seasonal and daily variations of BP, pulse rate and room temp were analyzed.

Results: Home BP data were telemonitored well in all cases and one AKI due to hypotension was successfully detected. BP was higher in the morning, the lowest in summer and the highest in winter related to room temp. Pulse rates were comparable except winter.

	Male	Female		
Number / Age / BMI	62 / 70.0±12.2 / 24.47±3.66	17 / 73.1±10.7 / 25.39±5.78		
eGFR categories: G2 / G3a / G3b / G4 / G5	7 / 8 / 26 / 16 / 5	1 / 4 / 7 / 5 / 0		
	Spring (March-May)	Summer (June-August)	Autumn (September-November)	Winter (December-February)
Morning SBP / DBP (mmHg) / Pulse rate (/min)	137.8±16.3 / 77.8±8.4 / 67.2±8.6	129.9±12.8 / 73.8±8.4 / 67.0±8.8	134.3±11.7 / 76.6±8.5 / 67.7±8.5	139.5±13.1 / 78.8±8.1 / 69.5±9.0
Evening SBP / DBP (mmHg) / Pulse rate (/min)	130.2±15.3 / 72.6±9.2 / 70.4±9.1	125.0±15.2 / 69.0±8.2 / 69.4±9.4	128.2±12.7 / 71.7±8.6 / 71.4±9.2	131.6±13.2 / 73.6±10.0 / 72.9±8.9
Room temperature morning / evening (centigrade)	19.3±2.4 / 21.2±2.3	27.2±1.3 / 27.5±1.6	22.6±1.8 / 23.7±2.3	14.6±3.5 / 17.5±3.5

Daily BP variation correlated with age. Trend of higher seasonal BP variation was shown in association with eGFR tertiles.

Conclusions: Home BP telemonitoring system would be effective to achieve optimal BP control among CKD patients.

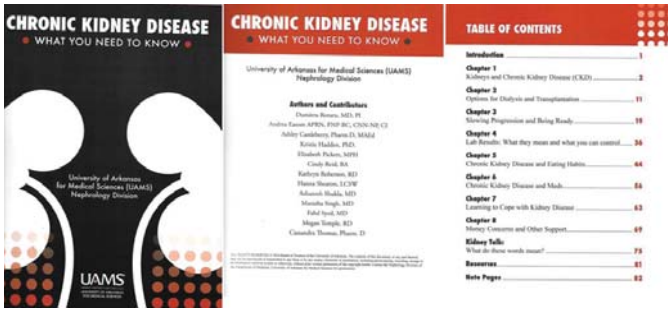
FR-PO1096

Development of Tools for a Telemedicine Based Chronic Kidney Disease Education Program Andrea K. Easom,[1] Dumitru Rotaru,[1] Fahd Syed,[1] Manisha Singh,[1] Ashutosh M. Shukla.[2] *[1]Nephrology, UAMS, Little Rock, AR; [2]Nephrology, Univ of Florida, Gainesville, FL.*

Background: Nationally, only 10% of ESRD patients are on home dialysis. We developed a multidisciplinary CKD education clinic which resulted in over 30% incident rate of home dialysis. Our hypothesis is that telemedicine is an effective tool for CKD education. The initial aim is to develop tools for CKD telemedicine education utilizing rigorous scientific methodology.

Methods: A multidisciplinary expert panel developed knowledge statements that were ranked on importance and used as the framework to create educational tools including a workbook, a questionnaire and slide sets. All materials underwent health literacy editing.

Results: The CKD Workbook is interactive and given to study subjects at the first visit. It consists of 8 chapters each based on knowledge statements.



Renal specific words are highlighted in red and defined in "Kidney Talk" sections on the same page where they first appear and at the end of the book. From a bank of 150 questions, each linked to a knowledge statement, 80 questions were tested in a small group of CKD patients to determine their difficulty. Questions that were important but either too easy or too hard were included at the end of book chapters in "Frequently Asked Questions" or "Test Your Knowledge" sections. A total of 28 questions were selected for the final questionnaire along with 2 questions on the patient's choice of modality. The CKD Questionnaire is given pre and post education to compare baseline knowledge and teaching effectiveness. The teaching slide sets and the program evaluation questions were also linked to knowledge statements.

Conclusions: The tools are now being tested at UAMS and 6 Arkansas Department of Health Telemedicine Sites. Based on this data, further validation and refinement of the tools is needed prior to statewide implementation of the program.

Dialysis Link Improves Clinic and Hospital Communication during Hemodialysis Patient Care Transitions in the Right TraC Program

Kathryn A. McDougall, Rebecca L. Wingard, Billie Axley, Alex J. Rosenblum, Alan Alper, Andrew D. Howard, John W. Larkin, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care, Waltham, MA.*

Background: Deficiencies in healthcare communication during care transition processes are common. Delays or inaccuracies in information transfer among health care professionals may adversely affect patient care and safety. The Right TraC™ Program surveyed standard practices of communication between dialysis services and hospitals and implemented a new method of information transfer utilizing Dialysis Link™. We sought to identify markers of performance associated with use of the Dialysis Link integrated communication system.

Methods: At 14 clinics in West Virginia, surveys were performed prior to the implementation of Dialysis Link. Baseline questions surveyed the frequency of transfer for patient information to the hospital upon admission and the availability of discharge information on return to the dialysis clinic. Dialysis Link has been implemented as of March 2014 in 9 dialysis clinics. This system is a centralized call center approach for exchanging medical information, between dialysis clinics and hospitals. First phase data was collected for utilization and satisfaction of services in the initial implementation of Dialysis Link.

Results: In the 9 clinics that implemented Dialysis Link, survey results qualitatively identified improvements in dialysis clinic and hospital communication parameters, and showed clinic satisfaction with the system (Figure 1).

Figure 1:

Baseline Survey Results in 14 Outpatient Dialysis Clinics	
Percent of clinics that do not send information to inpatient dialysis units when a patient is admitted to the hospital	54%
Percent of clinics that are not routinely notified when a patient is discharged from the hospital	50%
Percent of clinics that receive no information from inpatient dialysis when a patient is discharged from the hospital	67%
Dialysis Link Survey Results in 9 Dialysis Clinics	
Percent of clinics that used the Dialysis Link services since implementation	100%
Percent of clinics that used Dialysis Link for both sending and receiving patient admission and discharge information	67%
Percent of clinics that received more discharge records than before Dialysis Link started	44%
Average time to receive discharge documents	1-7 days
Range of clinic staff satisfaction with the Dialysis Link. Convenience and time savings were the top reasons for satisfaction	Moderate to Extremely Satisfied

Conclusions: In its early intervention stages, Dialysis Link demonstrated that improvement of medical communication and information transfer was streamlined, consistent and time saving for clinic staff. Ongoing analysis of this initiative will determine the potential impact as additional clinics implement Dialysis Link into their daily processes.

FR-PO1098

Telephonic Case Management and Care Coordination Are Associated with Decreased Hospital Admission Rates

Sheetal Chaudhuri,[1] Fern Parlier,[1] Jane Brzozowski,[1] John W. Larkin,[1] Len A. Usvyat,[1] Chester A. Amedia,[2] Peter F. Sauer,[1] Kim L. Sonnen,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America (FMCNA); [2]Fresenius Health Partners.*

Background: Fresenius Health Partners (FHP) provides care coordination to patients (Pts) with End Stage Renal Disease. As part of this, nurses' telephonically outreach to dialysis Pts based on pre-defined clinical pathways, which assess and triage signs and symptoms of hospitalized Pts related to heart failure, fluid overload, sore or open wound, diabetes, blood pressure and infections; reasons for hospitalization are documented and Pts receive targeted education to avoid readmissions.

Methods: FHP Pts treated in FMCNA clinics between Jan 1, 2013 and Mar 30, 2014 was analyzed. The first date of Pt telephone contact was captured. For every Pt, we computed mean Pt clinical and laboratory parameters 120 days before and 120 days after the first telephonic contact. Comparisons were performed using paired t-test analysis for continuous variables and Poisson regression for hospitalization rates. Only Pts with >80 days of the "before" and "after" period were included in the analysis.

Results: Overall, 386 FHP Pts were studied. Significant reductions in post-dialysis weight (0.3%) and pre-dialysis systolic blood pressure (SBP) (1.1%) were associated with implementation of telephonic FHP care coordination. Furthermore, after FHP care coordination was initiated, the hospital admissions and readmissions were identified to have significantly decreased by a notable 14.6% and 33.3% respectively.

Figure 1:	120 days before	120 days after	Percent change	p-value
Albumin (g/dL)	3.89 (SD±0.37)	3.9 (SD±0.36)	0.3%	0.232
Post-dialysis weight (kg)	76.27 (SD±19.77)	76.01 (SD±19.63)	-0.3%	0.043
Pre-dialysis systolic BP (mmHg)	154.26 (SD±19.31)	152.58 (SD±19.26)	-1.1%	0.001
Hospital admissions ppy	1.63	1.39	-14.6%	0.016
Hospital readmissions ppy	0.5	0.33	-33.3%	0.033

Conclusions: These results indicate that addition of telephonic case management is significantly associated with decreases in post-dialysis weight, pre-dialysis SBP, hospital admissions and readmissions. This study suggests that adding telephonic case management to overall patient care may be an effective intervention to decrease hospitalization rates in dialysis Pts.

Funding: Pharmaceutical Company Support - Fresenius Medical Care, North America

FR-PO1099

Development of a Smartphone-Based Kidney Care System for Patient Self-Management Support

Stephanie W. Ong,[1,2] Sarbjit Vanita Jassal,[1] Judith A. Miller,[1] Akib Uddin,[4] Stephanie So,[4] Ashleigh Shier,[4] Emily Seto,[4] Joseph A. Cafazzo,[4] Alexander G. Logan.[1] *[1]Div of Nephrology, Univ Health Network; [2]Dept of Pharmacy, Univ Health Network; [3]Centre of Global eHealth Innovation, Univ Health Network, Toronto, ON, Canada.*

Background: Previously we developed smartphone-based system to support patient self-management of chronic disease. We used Bluetooth-enabled devices to remote monitor vital signs and identify real time non-acute changes in patients' health status. The systems were highly effective and well-accepted, even among older patients. We describe herein the development of a smartphone-based kidney care system for patients with advanced CKD.

Methods: Using qualitative methods, focus groups and semi-structured interviews were held with CKD patients and providers to seek their opinion about a mobile system. The information was used to form the framework and design principles to develop the first prototype. Iterative rounds of usability testing were conducted where participants provided insight on the appropriateness and ease of use of the prototype. Human factors specialists provided recommendations for the next iteration and enhancements of the prototype to improve the user experience. Validation testing helped test and refine the mobile system's features and functionalities to prepare it for the clinical trial phase.

Results: Based on interviews (n=10), we identified key CKD health behaviours and functionalities to be included in the smartphone app. The initial prototype, which included views for blood pressure (BP) monitoring, symptom assessment, CKD-related laboratory results and current medication list, underwent three rounds of usability testing (n=37) to refine the functionalities of the app. Participants commented on its design features, workflow, visual display of BP and laboratory data and ease of navigation. For the healthcare providers, we developed a dashboard which will contain detailed information on data gathered by their patients, a critical alert system and a one-page clinic visit summary report.

Conclusions: The smartphone-based kidney care system is fully developed and being piloted to assess its feasibility, acceptability and effectiveness in advanced CKD patients.

Funding: Private Foundation Support

FR-PO1100

Community-Based Disease Management Program for Patients with Chronic Kidney Disease Ingi Elsayed, Arif Khwaja. *Renal Dept, Sheffield Teaching Hospitals, United Kingdom.*

Background: CKD is common affecting 5-10% of UK, 14% of U.S. population. Cost of providing CKD care is rising; Medicare CKD costs in 1993 was 3.8%, up to 14.2 % in 2008 whereas,NHS CKD care cost in 2009-10 was $2.44 billion/year, 1.3% of NHS spending budget. More sustainable models of providing CKD care are needed. *Aim:* Evaluate impact of a remote, community-based disease management program (DMP) for patients with advanced CKD on disease progression, environmental impact and economical implications, compared to managing CKD in secondary (2ry) care.

Methods: Patients with stable CKD (Neither likely to require RRT in next 12 months, nor on immunosuppressive therapy) attending 2ry care renal clinics were offered choice of remote DMP, where an individualized care plan was generated by consultant. Their monitoring was performed at GP with results forwarded to 2ry care. The 2ry care clinic was replaced by telephone consultation with nurse specialist, detailing any change to patients' management. Written communication was also offered. Patients who declined remote DMP offer, continued to attend 2ry renal clinics. Cost to commissioners for 2ry clinics was $308/visit, while that for remote DMP consultant review was $110/review. We performed prospective analysis of lab data (eGFR, Hemoglobin level, Calcium and Phosphate levels), of all patients in both groups (age- and previous eGFR slope-matched), at time of enrolment on remote DMP and one year later.

Results: There were 75 patients in each group. There was not any statistically significant difference in the mean eGFRs, Hemoglobin, Calcium, Phopshate levels (p=0.667, 0.76, 0.915, 0.493, respectively) between either group one year later. Cost, for commissioners and distance travelled to point of care, were significantly lower in remote DMP group (p=.000, in both) than those attending 2ry care clinics, generating an annual carbon saving of 507 kg CO_2 equivalent.

Conclusions: Our data suggests that remote monitoring of CKD is deliverable, clinically safe in selected patients, whilst delivering significant carbon and cost savings. With prevalence of CKD increasing, remote monitoring of CKD may be a more sustainable model of delivery of CKD care.

FR-PO1101

Are Video Sharing Websites a Useful Source of Information on Dialysis? Neetika Garg,[1] Anand Venkatraman,[2] Ambarish Pandey,[3] Nilay Kumar.[4] *[1]Nephrology, BIDMC, Boston, MA; [2]Neurology, UAB, Birmingham, AL; [3]Medicine, UTSW, Dallas, TX; [4]Medicine, CHA/ HMS, Cambridge, MA.*

Background: End Stage Renal Disease is a growing public health problem. With increasing internet use to seek medical information, video sharing websites such as YouTube can serve as a powerful platform for dissemination of information on dialysis. Here, we analyzed the accuracy and content of videos related to dialysis posted on YouTube.

Methods: Using the search term 'dialysis,' the first 10 pages/ 200 videos on YouTube were screened for content related to dialysis. Two physicians independently categorized them as 'Useful,' 'Misleading' and 'Patient's personal experiences (PPE).' 5 point ordinal scales were used to grade reliability and quality. Information regarding source of upload, viewer interaction parameters (views per day, "likes" and comments) and content domains covered (epidemiology, etiology, signs/ symptoms, dialysis modalities, access, QOL and complications) was gathered.

Results: Of the 115 videos relating to dialysis, 67 (58.2%) were useful, 19 (16.5%) were misleading and 29 (25.2%) represented PPE (kappa statistic for interobservor agreement: 0.98, p<0.001). Useful videos were more informative, and scored highest on quality and reliability scores; however, they consistently ranked lower on viewer interaction parameters.

Variable	Useful	Misleading	PPE	p-value
Views per day Median (IQR)	3 (1–17)	11 (4–43)	14 (5–30)	0.013
Likes	4 (1–18)	43 (15–187)	19 (4–43)	<0.001
Comments	1 (0–3)	2 (0–10)	10 (2-35)	<0.001
Reliability score Mean±SD	3.39±1.03	0.32±0.48	1.93±0.75	<0.001
Quality score	3.54±0.86	1.10±0.32	2.76±0.44	<0.001
Content domains covered (total 7)	4.4± 1.7	1.6± 1.1	3.8 ± 1.6	<0.001

68% of misleading videos, all from un-credentialed sources, recommended unproven alternative therapies e.g. herbs, activated charcoal and enemas.

Conclusions: Scientifically correct information is viewed less compared to misleading videos and patients' personal stories. Authoritative sources should use this medium to provide patient specific and relevant information on dialysis. Including patients' personal stories could make this material more engaging.

FR-PO1102

Prevention Run: Opportunity for CKD Preventive Measures Attilio Di Benedetto,[1] Annalisa Ciotola,[1] Fabrizio Cerino,[1] Daniele Marcelli,[2] Bernard J. Canaud,[2] Annamaria Colao.[3] *[1]NephroCare; [2]Fresenius Medical Care; [3]Univ Federico II Naples.*

Background: Cardio vascular disease (CVD) prevalence is on the rise in industrialised countries, presenting a significant societal and economic burden. Early detection of CVD risk factors may prevent related complications, including chronic kidney disease (CKD). We report the results of a screening program focusing on a healthy population involving blood pressure, waist circumference and BMI evaluations. In addition, simple, rapid and non-invasive fluid overload screening was done by multi-frequency bioimpedance spectroscopy using the Body Composition Monitor (BCM).

Methods: During the "Napoli 2013 Prevention Race" organized by Federico II University, 191 healthy people were screened with collection of blood pressure, weight, height, waist circumference, BMI and BCM results, while CKD and CVD-related aetiology, diagnosis, and prevention were explained.

Results: 72 (37.7%) were male, mean age 52.55+13.9 yrs. Mean BPmax 128.62+19.8 and BPmin 77.57+11.8**.** 67 (35.1%) were overhydrated. 6 (3.1%) had BMI <20, 69 (36.1%) BMI 20-24, 80 (41.9%) BMI 25-29, and 36 (18.8%) BMI>30. Mean waist circumference 93.77+19.6 cm. 7 (3.7%) diabetics; 17 (8.9%) hypertensive; 6 (3.2%) with CKD. According to reference range table, 130 had LTI in a normal (N) range for their features of gender, age and race, 4 had a LTI> N, 57 had a LTI<N range. 149 had FTI in a normal (N) range, 35 had a FTI > N, and 7 had a FTI<N range.

	Overhydration (% of ideal BW)			LTI			FTI			Waist circumference (cm)		N pts
Age	<-1.0	>-1.0 < 1.0	>1.0	low	normal	high	low	normal	high	<88 (f) <102 (m)	>=88 (f) >=102 (m)	total
<20	0%	33.3%	66.7%	33.3%	66.7%	0%	0%	66.7%	33.3%	100%	0%	3
20-44	20.8%	47.9%	31.3%	27.1%	70.8%	2.1%	6.3%	77.1%	16.7%	66.0%	34.0%	48
45-64	14.6%	52.4%	33%	31.1%	66.0%	2.9%	2.9%	77.7%	19.4%	44.7%	55.3%	103
65-74	10.3%	51.7%	37.9%	34.5%	65.5%	0%	0%	82.8%	17.2%	48.3%	51.7%	29
>75	0%	50.3%	35.1%	12.5%	87.5%	0%	12.5%	75.0%	12.5%	62.5%	37.5%	8
Total Count	28	96	67	57	130	4	7	149	35	99	92	191
%	14.7%	50.3%	35.1%	29.8%	68.1%	2.1%	3.7%	78.0%	18.3%	52.1%	47.9%	100%

Figure 1. Overhydration , LTI , FTI and waist circumference results according to age ranges

Conclusions: 35% of participants had significant FO, and 18-48% had various degrees of metabolic syndrome. BCM measurements were easily incorporated into the screening for CVD and counselling. These data may constitute a useful healthy-matched reference database for advanced CKD patients. Screening is indicated for early detection of CVD risk factors in an apparent healthy population, helping to reduce public healthcare costs.

FR-PO1103

Metabolic Syndrome, Blood Pressure and Glycemic Risk amongst East Carolina University Freshman Hsiao Ling Lai,[1] Brittany S. Brown.[2] *[1]Internal Medicine and Pediatrics, East Carolina Univ, Greenville, NC; [2]College of Public Health, East Carolina Univ, Greenville, NC.*

Background: Obesity-metabolic syndrome is an increasing cause of subspecialty referral for management of hypertension and chronic kidney disease in youth.

Methods: Cardiometabolic risk in young adults of eastern North Carolina was investigated by sampling a cohort of East Carolina University (ECU) entrant undergraduates. From June to October 2010, 525 or 12% of Freshmen were screened for metabolic risk factors. Participants were classified with glycemic risk if blood glucose (BG) exceeded 140 mg/dL on random testing; or as meeting diabetic criteria if random BG exceeded 200mg/dL or previously diagnosed with diabetes. Elevated blood pressure was defined as systolic blood pressure (SBP) ≥ 140 mm Hg, diastolic blood pressure (DBP) ≥ 140 mm Hg or under treatment for hypertension.

Results: Seven participants (1.3%) met criteria for metabolic syndrome with four-fold increased risk amongst Black participants (RR 4.2, p=0.0562). Blacks had highest propensity for obesity (RR 3.9, p<0.0001). Black females (BF) had particularly high risk of obesity and inactivity (RR 3.904, p<0.0001, RR 1.59, p=0.019). Elevated BG was detected in 7% of participants. Asians and White males (WM) had highest glycemic risk (RR 4.6, p=0.007 and RR 1.7, p=0.065) and Hispanic participants most often met diabetic criteria (RR 3.5, p=0.01). Low HDL defined as HDL <50mg/dL in women and <40 mg/dL in men was the most common lipid risk factor with three-fold prevalence in BF versus Black males (BM) (35 versus 10.3%; RR 2.82, p=0.053). WM were characterized by elevated SBP (RR 2.439, p=0.003), BM by elevated DBP (RR=11.48, p<0.0001).

Conclusions: High BMI in Blacks, DBP elevation in BM and sedentary behavior in BF contribute to high incidence of cardiometabolic findings amongst Black ECU undergraduates. Glycemic risk is more prevalent in undergraduates of Asian, Hispanic and WM demographics. Improving our understanding and management of obesity-metabolic syndrome is important in impacting the long-term health of the young CKD population.

FR-PO1104

Unrecognized Chronic Kidney Disease: Effectiveness of Referral to Primary Care Units and Subsequently to Nephrologists Maria Goretti M.G. Penido,[1] Marcelo S. Tavares,[1] Celina De Faria Rezende,[2] Joao Milton Penido,[3] Mariana G. Penido de Paula,[2] Uri S. Alon.[4] *[1]Pediatric Nephrology Unit, Federal Univ of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil; [2]Nephrology Center, Santa Casa de Belo Horizonte Hospital, Belo Horizonte, Minas Gerais, Brazil; [3]Internal Medicine, Federal Univ of Ouro Preto, Ouro Preto, Minas Gerais, Brazil; [4]Bone and Mineral Disorders Clinic, Children's Mercy Hospital and Clinics, Kansas City, MO.*

Background: Progression of chronic kidney disease (CKD) may be prevented by early diagnosis and referral to a nephrologist. The aim of this study was to evaluate whether primary care provider (PCP) is following individuals with CKD and refer them to a nephrologist.

Methods: During a community action on 2012 World Kidney Day in Belo Horizonte city, Brazil (2.74 million inhabitants), individuals were invited to participate. Participants underwent: blood pressure evaluation, measurement of serum creatinine and urinary protein, estimated glomerular filtration rate (MDRD/proteinuria). Individuals with grade III (A and

B) and IV, and those with grades I and II with proteinuria were referred to their PCP with a referral letter detailing our findings. Two years later the subjects were contacted by phone to find out if the PCP received our letter and referred them to a nephrologist.

Results: 298 individuals (66% female) with a mean age of 50.5±17.6 years were evaluated. We found: grade I CKD with proteinuria in 1.3%, grade II with proteinuria in 5%, grade III A and B in 20%, grade IV in 1.3%. No individual had grade V. All eighty-two individuals (grades I and II with proteinuria, grade III A and B and grade IV) were referred to their PCP. Telephone contact made two years later with 70 of these individuals showed that all provided our letter to their PCP; 45 are in regular follow-up with their PCP. Twenty-five individuals had no follow-up and only 6/45 were referred to a nephrologist.

Conclusions: A significant number of patients with CKD are not being followed and most others only by their PCP, with only a small minority referred to a nephrologist. Strategies are needed to enhance the referral rate of patients with CKD to a nephrologist.

FR-PO1105

Epidemiology and Referral Patterns of Patients with Chronic Kidney Disease in the Emirate of Abu Dhabi

Nicholas T. Richards,[1] Mohamed H. Hassan,[2] Abdulkarim M. Saleh,[2] Bassam O. Bernieh,[3] Samra Abouchacra,[3] Marie Richards,[1] Daniele Marcelli.[4] *[1]SEHA Dialysis Service; [2]Sheikh Khalifa Medical City; [3]Tawam Hospital; [4]Fresenius Medical Care.*

Background: According to estimates the dialysis prevalence in Abu Dhabi is around 370 ppm. The annual growth is 12-15%, and the dialysis population is likely to double in the next 5 years. Most patients present to dialysis as an emergency, only 2.7% have an arteriovenous fistula at first dialysis. The prevalence of chronic kidney disease (CKD) in the Emirate is undefined. A study of CKD epidemiology and referral patterns was undertaken.

Methods: SEHA, the Abu Dhabi Health Service delivery company, has a unified IT system containing all measurements made in its laboratories. This study considered all serum creatinine measurements performed between Sept 1, 2011 and Oct 31, 2012 from outpatient departments or emergency rooms. Estimated GFR (eGRF) was calculated using the Modification of Diet in Renal Disease formula (the Schwartz formula was used for children).

Results: We identified 331,360 samples from 212,314 individuals. Mean serum creatinine was 61+48 µMol/L in females (59+43 µMol/L Emiratis, 63+54 µMol/L expatriates) and 87+69 µMol/L in males (80+59 µMol/L Emiratis, 92+74 µMol/L expatriates). Among Emiratis, 4.6% of males and 2.8% of females had an eGFR between CKD 3-5. Among expatriates, 4.2% of males and 3.2% of females had an eGFR between CKD 3-5. On average, 8 to 3 months elapsed before a patient with CKD 3 to 5 attended a nephrology clinic respectively.

Conclusions: This study has defined the prevalence of CKD within Abu Dhabi and demonstrated the need to improve identification and referral of CKD patients. Possible solutions include campaigns to increase public and physician awareness of CKD.

FR-PO1106

Pre-Dialysis Education Program in a Tertiary Care Center of Northeast Malaysia

Azreen Syazril Adnan,[1] Fauziah Jummaat,[2] Nurul Jannah Ambak,[1] Azhar Amir Hamzah,[1] Amer Hayat Khan,[1,3] Yusra Habib Khan,[3] Muhammad Salman,[1,3] Tauqeer Hussain Mallhi.[3] *[1]Chronic Kidney Disease Resource Center, Univ Sains Malaysia, Kubang Kerian, Kelantan, Malaysia; [2]Dept of Obstetrics and Gynecology, Univ Sains Malaysia, Kubang Kerian, Kelantan, Malaysia; [3]Dept of Clinical Pharmacy, Univ Sains Malaysia, Penang, Malaysia.*

Background: The prevalence of chronic kidney disease (CKD) and end-stage renal disease (ESRD) is increasing worldwide. Educational programme can slow down the progression of renal disease, improved survival rate on renal replacement therapy (RRT), enhance illness-knowledge and encourage better quality of life. Throughout this educational program, comprehensive information can be provided at an early stage to the CKD patients and their family members. This study meant to examine the distribution of RRT modalities opted by patients after pre dialysis education program.

Methods: We retrospectively reviewed the modalities chosen by patients who were attending CKD Talk from August 2011 to April 2014. Patients with CKD stage IV and V were invited to attend this program. Total patients attending CKD Talk were 571, but only 365 patients responded.

Results: Three hundred and sixty five patients, mean (SD) age was 61.46 (11.53) years. RRT modalities; HD, CAPD and CCPD were chosen by 93 (25.5%), 46 (12.6%) and 5 (1.4%) patients respectively. The remaining 221 (60.5%) patients were undecided which RRT they prefer and have been on follow-up by phone-calls after 2-3 months attending the program. Nineteen (8.6%) patients died, 124 (56.1%) alive and 78 (35.3%) were uncontactable. RRT modalities chosen by patients after follow-up were 43 (34.7%) HD; 6 (4.8%) CAPD and 75 (60.5%) were still undecided. Eight patients underwent arteriovenous fistula (AVF) creation. Possible reasons for not opting for RRT were lack of family support, in denial state and still undecided on the mode of RRT.

Conclusions: Although pre-dialysis education program is useful in assisting healthcare professionals and patients, however the results of our study revealed half of study population were unable to decide. More comprehensive measures should be taken in creating awareness of such pre-dialysis education programs.

FR-PO1107

Dialysis Patients Seeing Primary Care and Nephrologists Are More Likely to Get Preventive Services Than Those with No Primary Care

Bjoerg Thorsteinsdottir, LaTonya J. Hickson, Megan Reinalda, Priya Ramar, Amy W. Williams, Robert C. Albright, Nilay D. Shah. *Mayo Clinic, Rochester, MN.*

Background: Dialysis patients are a high risk patient population with a poor prognosis. United States Preventive Services Taskforce recommendations developed for the general population may not be appropriate for subsets in this population. With attention placed on delivering valued healthcare, one has to consider the value added of screening for patients with complex chronic disease and limited survival. We compared rates of preventive services for dialysis patients with or without primary care (PC).

Methods: Patients over 18 dialyzing in a regional dialysis network starting 2001-2010 were linked to USRDS. Analysis was limited to patients with outpatient dialysis claims, Medicare as primary payer and > 90d follow up. Family Practice, Internal Medicine, Pediatrics, Geriatrics and Preventative Medicine office visits counted as PC. Preventive services were based on CPT codes.

Results: Patients without PC were younger (56+16 versus 64+15), healthier (Charlson 5.5+3.0 versus 7.1+3.1), more likely male (66% versus 59%) and on transplant list (34.3% versus 12.1%); less likely to have DM (49% versus 62%) or CHF (39% versus 60%). Use of preventive services was low and lower in the patient group that had no PC.

Prev serv within 2 years of dialysis start			
	Primary Care		Total
	No (N=429)	Yes (N=2556)	(N=2985)
Influenza Vac*	63 (15%)	772 (30%)	835 (28%)
Pneumococcal Vac*	14 (3%)	194 (8%)	208 (7%)
Hep B Vac*	16 (4%)	256 (10%)	272 (9%)
Tetanus Vac*	5 (1%)	123 (5%)	128 (4%)
Lipids*	105 (25%)	1144 (45%)	1249 (42%)
Hgb A1C*	90 (43%)	963 (61%)	1053 (59%)
DM screening*	39 (9%)	488 (19%)	527 (19%)
Prostate ca screening*	23 (8%)	207 (14%)	230 (13%)
Colon Ca screening*	32 (8%)	405 (16%)	437 (15%)
Mammogram*	25 (17%)	379 (36%)	404 (33%)
PAP*	11 (8%)	180 (17%)	191 (16%)
Aortic aneurysm*	21 (7%)	200 (13%)	221 (12%)

Conclusions: Dialysis patients seeing PC have higher utilization of preventive services. However, in this population, specifically those ineligible for transplant with low life expectancy, services such as cancer screening may constitute overtreatment, leading to unnecessary spending and increased patient stress and burden.

FR-PO1108

Healthy Transitions: A Nursing and Informatics Program to Improve Outcomes in Late Stage Chronic Kidney Disease

Candice Halinski, Azzour Hazzan, Sofia Agoritsas, Steven Fishbane. *Dept of Medicine, Div of Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.*

Background: Late stage chronic kidney disease (CKD stages 4-5) is a period characterized by poor outcomes and high costs. Suboptimal care is evidenced by high rates of hospitalization, inadequate patient preparation and education on ESRD modality choices, inappropriate initiation of dialysis for patients who may not be dialysis candidates, and failure to initiate hemodialysis utilizing an appropriate vascular access. The Healthy Transitions (HT) project was designed to improve processes of care and outcomes in late stage CKD while effectively controlling the rising cost of care.

Methods: All eligible patients with eGFR < 30 ml/min were enrolled into the program. Key components of the HT care delivery model include nurse care managers, disease and diet education, focused modality selection, a fistula planning protocol, daily weights, home safety evaluation, outpatient dialysis safe start program and an informatics system that drives clinical processes with daily alerts to the nurses.

Results: 162 patients were enrolled with 1024 patient-months of program follow up. Average patient age was 69.0±x years. 62% of enrolled patients were male. 71% of patients were white, 10% black or African American, 19% other. 88% of eligible patients made a modality selection within 3 months of enrollment. Of patients initiating renal replacement therapies 24% started peritoneal dialysis, 11% received preemptive transplantation and 65% hemodialysis (HD). Of HD pts 41% started without a hospitalization. Access for the first HD treatment was an AVF in 68% and only 22.7% had a catheter in place at the first HD treatment. The hospitalization rate was 1.14 per pt/year compared to 1.41 in the year prior to enrollment (RR 0.81, $p<0.05$) and 1.99 for physicians in the same practice not participating in the program (RR 0.57, $p<0.05$). The mortality rate was 0.04 per patient-year. Greater than 95% of the enrolled population reported being satisfied or extremely satisfied with program services.

Conclusions: The HT late stage kidney disease program resulted in improved patient outcomes utilizing nursing and informatics interventions.

FR-PO1109

The Rate of Change of Estimated Glomerular Filtration Rate in a Mainly Indo-Trinidadian Population: A Retrospective Database Study

Sharda L. Sharma,[1,2] Neal Bhagwandass,[1,2] Sarah Ann Rhodes,[1] Terence A.R. Seemungal.[1] *[1]The Univ of The West Indies, Trinidad and Tobago; [2]San Fernando General Hospital.*

Background: Despite the global health burden of Chronic Kidney Disease (CKD) very little is known about the rate of progression in the West Indies.This study seeks to determine the rate of change in estimated glomerular filtration rate (eGFR) in patients and the factors affecting rate of decline.

Methods: A retrospective observational analysis was done on patients in renal outpatient clinic in southern Trinidad.The CKD patients were staged based on the eGFR (ml/min per1.73m^2) calculated from the Modification of Diet in Renal Disease (MDRD) equation.A linear mixed regression model was used to determine the mean annual rate of decline of the eGFR per patient and multivariate analysis was done to determine the factors affecting the rate of decline.

Results: 150 CKD patients had mean age (SD) 63.61 (9.33) years, 61.3% males, 48% were 65 or older.Indo-Trinidadians were 73.3% of the study population 24.0% were Afro-Trinidadians.There were 74.0% diabetics and 94.7% hypertensives.94% patients were stage 3 CKD or lower at presentation.Mean (SD) baseline eGFR was 34.98 (12.90) for Indo-Trinidadians and 44.10 (15.64) for Afro-Trinidadians, (p=0.001). Serum phosphate level was inversely related to baseline eGFR (B=-4.93, p=<0.001).Mean (SD) final eGFR was 28.04 (13.15) for Indo-Trinidadians and 34.91 (13.49) for Afro-Trinidadians, (p=0.006). The mean annual rate of decline in eGFR was 2.57 (95% CI 2.04 to 3.10). Decline in kidney function was seen in 84.67% patients,16 patients had progressed to stage 5 CKD, 87.3% patients had a final eGFR <45 compared with 71.3% initially.Multivariate analysis showed that the rate of decline in eGFR was slower for older patients (B = 0.007, p = 0.021) but was not related to comorbid conditions, gender or ethnicity. 37.3% patients had a rapid annual rate of decline in eGFR of >3.

Conclusions: Diabetes and hypertension were found to have no impact on rate of decline of eGFR once CKD was established.Gender and ethnicity were not associated with rate decline in this study.Older patients were associated with a slower rate of decline in renal function.

FR-PO1110

Patient's Perception Regarding Their Erythropoiesis Stimulating Agent Using a Choice Based Conjoint Analysis

Gabriel Choukroun,[1] Olivier Moranne,[2] Cecile M. Vigneau,[3] Corinne Isnard-Bagnis,[4] David Pau,[5] Nadra Belamri.[5] *[1]Nephrology - Dialysis - Transplantation, CHU Amiens, Amiens, France; [2]Nephrology, CHU Nice, France; [3]Nephrology, CHU Rennes, France; [4]Nephrology, CHU Pitié Salpetriere, France; [5]Medical Affairs, Roche, France.*

Background: Treatment adherence is essential to improve quality of care in chronic diseases. This study aimed to assess in real-life conditions patients preference and satisfaction regarding erythropoietin stimulating agent (ESA) use for the treatment of renal anemia in patients with chronic kidney disease not on dialysis (CKDnd).

Methods: This French, 6-month, non-interventional, multicentre, prospective study was conducted by 106 nephrologists. Eligible patients were on stage 2 to 5 CKD and started continuous erythropoietin receptor activator (C.E.R.A.) treatment at inclusion. They were naive or previously treated with an ESA for their anemia. The primary endpoint was the relative importance according by the patient preference to different characteristics of ESA treatments. Choice-based conjoint (CBC) analyses were performed (7 product characteristics, 2 or 3 levels per characteristic) at baseline and after 6 months under C.E.R.A. treatment.

Results: 789 patients were included, 356 ESA-naïve and 433 previously receiving an ESA. The mean age was 73±14 years, 54% men, 74% were on CKD stages 4 or 5. More than 80% of patients declare treatment efficacy as the most important expectative in ESA choice process but CBC analyses revealed that frequency of injections was more crucial, relative mean weight: ~30% versus ~20% for efficacy. Pain at injection site and hemoglobin not exceeding the recommended target were confirmed as important criteria for patients with a relative mean weights of ~15%. No new or unexplained safety signals were noted. Similar results were found for ESA naïve and non-naïve patients.

Conclusions: Using choice-based conjoint design for the first time in a non-interventional ESA study, these data showed that monthly injections, treatment efficacy and pain at the site of injection are key patients' expectations relative to ESAs use.

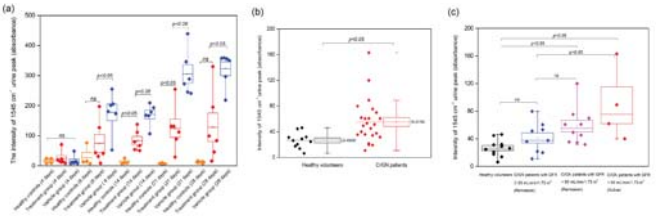
Mid-Infrared Spectroscopy: Detection of Therapeutic Response in Experimental Glomerulonephritis and Application in Patients

Mei-Ching Yu,[1] Peter R. Rich,[2] Jennifer Smith,[1] Robert J. Unwin,[3] Frederick W.K. Tam.[1] *[1]Imperial College Kidney & Transplant Centre, Hammersmith Hospital; [2]Structural and Molecular Biology, Faculty of Life Science, UCL; [3]UCL Centre for Nephrology, Royal Free Hospital, London.*

Background: We recently reported several potential markers of progressive renal injury in experimental GN using Fourier transform infrared (FTIR) spectroscopy.However, it remains uncertain whether this technique may be applicable in clinical situation.Thus, we aimed to find out whether the FTIR method was capable of detecting therapeutic response in nephritic rats treated with corticosteroid and in patients with crescentic GN (CrGN).

Methods: Experimental GN: Nephrotoxic nephritis (NTN) was induced in Wistar Kyoto (WKY) rats. The groups were **control** (n=4):normal WKY rats;**treatment** (n=6):NTN rats treated with 0.25 mg/kg of dexamethasone (DXM),*ip* every 4 days;**vehicle** (n=6):NTN rats treated with PBS,*ip*. During the course of NTN, 24 hour urine was collected at 4,8,14,21,and 28 days and plasma was taken at the time of cull. **Clinical GN**: urine was collected from 11 healthy volunteers and 24 CrGN patients. All samples were measured by FTIR spectro- scopy and analysed by the established method.

Results: In experimental GN, the intensity of the 1545 cm^{-1} urine peak was reduced in response to DXM treatment [figure1]$_a$. A similar response was also shown in three previously detected potential markers in plasma at 1705,1460 and 1240 cm^{-1}. The urinary 1545 cm^{-1} peak was significantly higher in CrGN patients compared to healthy volunteers



$_b$. Among CrGN patients,the intensity of 1545 cm^{-1} peak was higher in active CrGN patients with eGFR< 60 units [figure1]$_c$.

Conclusions: FTIR spectroscopy is a potential tool for rapid-screening and/or diagnosing patients at risk of progressive kidney disease and monitoring therapeutic response. The 1545 cm^{-1} peak of urine is the spectral marker most likely to be valuable in detecting severe CrGN.

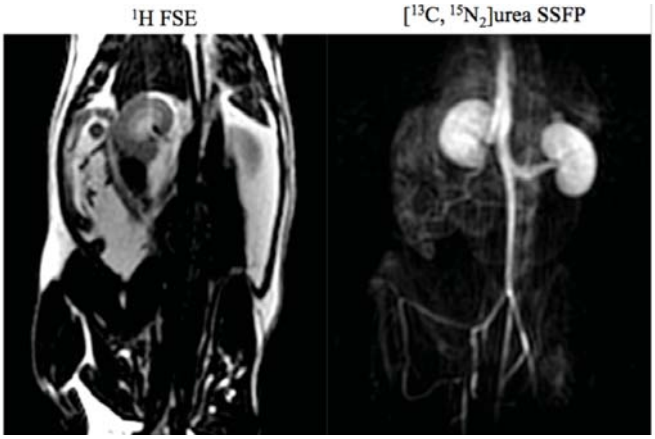
High Resolution MRI Renography Using Hyperpolarized [^{13}C]Urea

Cornelius von Morze,[1] Galen Reed,[1] Robert Bok,[1] Jeff M. Sands,[2] John Kurhanewicz,[1] Dan Vigneron.[1] *[1]Dept of Radiology and Biomedical Imaging, Univ of California, San Francisco; [2]Renal Div, Dept of Medicine, Emory Univ.*

Background: Dissolution dynamic nuclear polarization (DNP) enables >50,000-fold NMR signal enhancement of ^{13}C-labeled molecules in the liquid state, introducing a new class of endogenous intravenous MRI contrast agents (Ardenkjaer-Larsen et al. *PNAS*. 2003.). A recent first clinical trial demonstrates feasibility of this approach for investigating human disease (Nelson et al. *Sci Transl Med*. 2013.). Hyperpolarized (HP) [^{13}C]urea has excellent potential as a MRI contrast agent due to high polarization and exceptional safety profile. Here we demonstrate the application of HP [^{13}C]urea for *in vivo* high resolution (<1mm) MRI renography in rats.

Methods: Preparation of HP ^{13}C media is detailed elsewhere (Ardenkjaer-Larsen et al.). Anesthetized rats placed in a clinical 3T MRI were infused with 2mL 150mM [^{13}C,^{15}N$_2$] urea over 10s via tail vein. Our group recently discovered that secondary labeling with ^{15}N extends the T_2 relaxation times of urea, resulting in greatly improved image quality (Reed et al. *IEEE Trans Med Imaging*. 2013.). Rats were imaged 30s after infusion, using a sub-mm coronal 2D projection imaging sequence with steady state free precession (SSFP).

Results: A sub-millimeter [^{13}C]urea renogram is shown in Fig. 1 (right).



The renal urea signal is primarily tubulointerstitial, according to separate experiments where chasing the HP bolus with a high MW paramagnetic complex (thereby quenching the intravascular signal) has no effect on renal urea signal. Modulating physiologic state between diuresis and anti-diuresis produces urea-specific imaging changes, evidencing differential urea transport (von Morze et al. *AJP Renal*. 2012.).

Conclusions: Sub-millimeter renography is possible using HP [^{13}C]urea MRI, with no significant potential for nephrotoxicity and no radiation exposure.

Predicting Clot Formation in Implanted Hemofilters Amanda Buck,[1,2] Joseph J. Groszek,[4] Shuvo Roy,[3] William Fissell.[4] *[1]Radiology, Vanderbilt Univ, Nashville, TN; [2]Vanderbilt Univ Inst of Imaging Science, Vanderbilt Univ, Nashville, TN; [3]Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, CA; [4]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN.*

Background: A common failure mode of vascular devices is clotting related to the local hemodynamic environment. Computational fluid dynamics (CFD) models can be used to predict flow fields, and we have used this approach to model flow in an implantable hemofilter using a realistic flow waveform. We hypothesized that CFD simulations of blood flow would demonstrate pathophysiologically-relevant flow patterns that coincide with locations of clot formation.

Methods: We designed an implantable blood conduit to test hemofiltration membranes *in vivo*. Blood flow in the device was modeled with pulsatile flow boundary conditions based on *in vivo* ultrasound measurements. Regions of recirculation and slow near-wall flow were identified in each computational model. Hemofilter models were implanted in large animals anastamosed to iliac artery and vein for 30 days, or until thrombosis, then explanted.

Results: CFD simulations predicted two persistent recirculation regions: one along the outer wall of the proximal curve, and one zone of near-wall recirculating/slow flow along the inner wall of the distal bend (Fig. 1). Of 4 implants, 2 showed localized clot formation and two more diffuse thrombosis. Clot formation was identified in the same two areas in which CFD models predicted recirculation (Fig 1).

Conclusions: Pulsatile flow simulations predicted pathophysiologically relevant flow patterns in the same regions in which clot formation occurred. In the future, similar physiologically realistic simulations may prove useful for eliminating recirculation regions in subsequent device design.

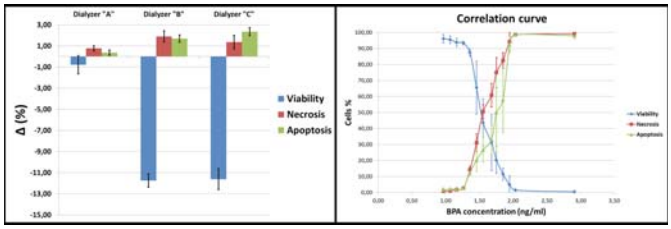
FR-PO1114

Cytotoxicity of Bisphenol A in Hemodialyzers Mauro Neri, Grazia Maria Virzì, Alessandra Brocca, Francesco Garzotto, Federico Nalesso, Monica Zanella, Claudio Ronco. *International renal Research Inst Vicenza (IRRIV).*

Background: Bisphenol A (BPA) is an environmental hormones or endocrine disrupting molecular compound and is used for the production of some plastics. In particular, in many dialyzers, polycarbonate (PC) of the housing and polysulfone (PSu) of the membranes are plastics based on polymerization of BPA. However, the release of BPA into the extracorporeal circuit may lead to cytotoxic events for blood components. Consequently, dialyzers made of different materials may avoid or reduce the BPA elution into the blood of the patients. We compared in vitro viability, necrosis and apoptosis on monocytes cell line deriving from BPA elution using 3 different dialyzers.

Methods: We compared dialyzer "A" (polypropylene housing and polynephrone membranes) versus dialyzer "B" (PC housing and PSu membranes) versus dialyzer "C" (PC housing and polynephrone membranes).We circulated in in vitro circuit 600 ml of cells medium RPMI for 240 minutes, repeating the same experiments using the 3 different dialyzers. We incubated U937 monocytes for 24 hours in medium samples taken before and after the treatments and we evaluated the differences between viability, necrosis and apoptosis by flow cytometer in the 3 dialyzers. We also tested the correlation between BPA concentrations (range between 0.97 to 2.91 ng/ml) and its cytotoxicity.

Results: Dialyzer "A" releases less BPA (46.5±53.5ng/treatment) than dialyzer "B" (232.4±32.8ng/treatment) and "C" (157.1±52.8ng/treatment). Moreover the viability of the monocytes is higher, necrosis and apoptosis are lower. The BPA citotoxicity is evident in the correlation curve with viability, necrosis and apoptosis.



Conclusions: Viability, necrosis and apoptosis of monocytes are influenced by BPA concentration. Use of alternative polymers for dialyzer's components,in particular in state of PC, may reduce this cytotoxic effect.

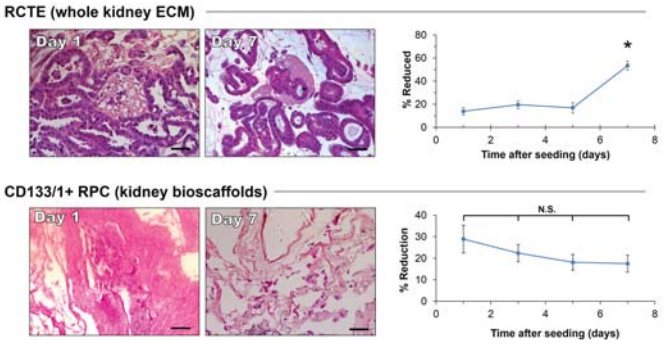
Decellularized Kidney Extracellular Matrix Supports Human Renal Parenchymal Cell Maturation in Three-Dimensional Culture Joseph S. Uzarski,[1] Heather Hilary Ward,[2] Angela Wandinger-Ness,[3] Jason Wertheim.[1] *[1]Comprehensive Transplant Center, Northwestern Univ Feinberg School of Medicine, Chicago, IL; [2]Dept of Medicine, Univ of New Mexico HSC, Albuquerque, NM; [3]Dept of Pathology, Univ of New Mexico HSC, Albuquerque, NM.*

Background: Generating a patient-specific kidney on demand would combat the donor graft shortage, extending transplantation to more patients with renal failure. Our objective was to investigate the capacity of decellularized renal extracellular matrix (ECM) to facilitate the growth and maturation of human renal parenchymal cells that could ultimately restore functionality to decellularized kidneys.

Methods: Rodent kidneys were decellularized using detergents and then repopulated with human renal cortical tubular epithelial (RCTE) cells via infusion through the renal artery. Alternatively, 1 mm kidney bioscaffold sections were seeded with primary human CD133/1+ renal progenitor cells (RPC) in multi-well dishes. We monitored cellular metabolism, dispersion, and morphological adaptation within the renal ECM over time.

Results: RCTE cells infused into whole kidney matrices dispersed in the peri-tubular space and formed patent tubular structures with recellularization of over 50% of the ECM after 24 hours. RCTE cells proliferated within the ECM over one week of perfusion culture with a significant increase in viability measured at day 7 ($p<0.001$).



RPC adhered to kidney bioscaffolds with similar efficiency, migrated into the ECM, and remained viable over one week of culture.

Conclusions: The bioactive kidney ECM supports repopulation with renal parenchymal cells and maturation into structures resembling native kidney tubules. We conclude that as a substrate the renal ECM facilitates renal cellular differentiation, and has potential as a 3D scaffold system for developing a bioartifical kidney graft.

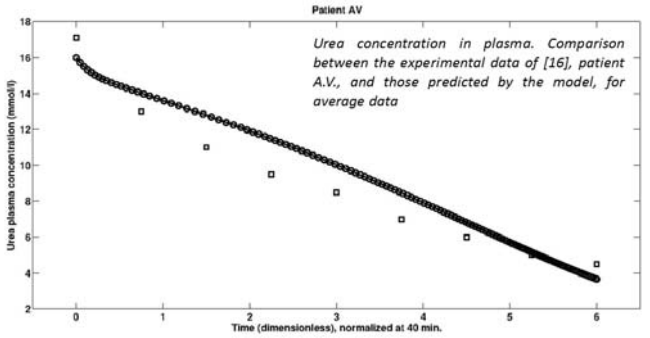
FR-PO1116

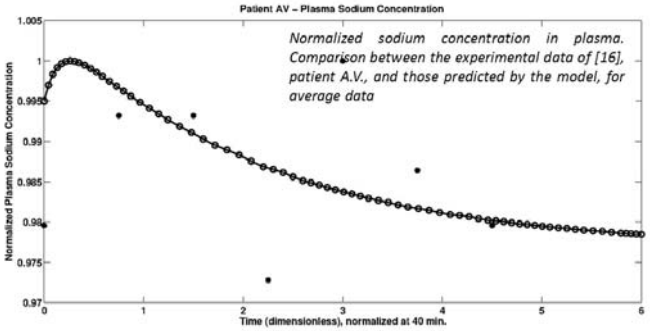
Modeling Blood Filtration in Hollow Fibers Dialyzers Matched with Patient's Dynamics Claudio Ronco,[1] Francesco Garzotto,[1] Jeong Chul Kim,[1] Antonio Fasano,[2] Angiolo Farina.[2] *[1]Nephrology-IRRIV, St. Bortolo Hospital, Italy; [2]Matematica e Informatica Dini, Univ di Firenze, Italy.*

Background: We develop a mathematical model for cross filtration in a hollow fibers dialyzer,taking into account not only the phenomena occurring within the machine,but also the redistribution of chemicals between intra-and extracellular compartments in the patient's body.

Methods: We report for brevity only steps in the derivation of the model write the full fluid dynamical equations for the blood (with some rheological model) and Darcy's law for the flow in the membrane,use a *double rescaling* of the space and velocity coordinates (e.g. $x=x^*/L^*$, $r=r^*/R^*$) and rewrite all equations in dimensionless form,select suitable time scales (one for the physics of the dialyzer,one for the dynamics of the body compartments),expand the unknowns (pressures,velocities,hematocrit,concentrations) in powers of e,match the terms of equal exponents (those with negative exponents and the zero order terms,disregarding higher order contributions).The model consists of two differential systems:one describing the three flows in the dialyzer (blood,dialyzate and cross flow),the other illustrating the dynamics of water and solutes in the organism,triggered by the modification of blood composition taking place in the device.

Results: We have performed 2 classes of numerical simulations.First we have validated the model with the experimental data reported in"A simple mathematical model applied to selection of the sodium profile during profiled haemodialysis,Nephrol Dial Transplant,Colì L et al."then we have performed some numerical experiments.In Figure we have reported the comparison between the simulation and the experimental data for a specific patient.





Conclusions: Both simulation and the experimental data for a specific patient show a good agreement,particularly in consideration of the fact that simulations refer to average data.

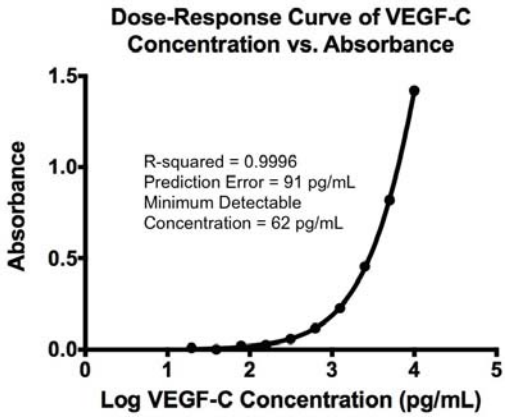
FR-PO1117

A Novel Device for the Detection of VEGF-C, a Biomarker of Chronic Allograft Rejection Demetrios S. Maxim.[1,2] *[1]Div of Nephrology, Dept of Medicine, Brigham and Women's Hospital, Boston, MA; [2]Dept of Biomedical Engineering, Tufts Univ, Medford, MA.*

Background: Long-term graft survival following renal transplantation will only become a reality when chronic allograft rejection (CAR), the leading cause of late organ loss following transplantation, can be effectively treated. If detected early enough, there can be intervention to minimize the disease. To date, however, no non-invasive test exists for routine screening. In this project, we aim to develop a simple, rapid, inexpensive, and minimally invasive device to quantitatively screen for VEGF-C, a biomarker of CAR, in human blood samples.

Methods: Test strips were prepared by coating the wells of 8-microwell strips with capture antibody directed against human VEGF-C. Biotinylated detection antibody and streptavidin-HRP conjugate were diluted in stability buffers to preserve activity and suspended in solution in the microwells. The optimal concentration for each antibody was determined by titration. Following the addition of samples, the strip was inserted into the portable device, where the wells were incubated, washed, and developed with colorimetric substrate. After stopping the reaction with sulfuric acid, the device measured the absorbance of each microwell.

Results: The completed device produced a dose-response curve with an R-squared value of 0.9996, a prediction error of 91 pg/mL, and a minimum detectable concentration of 62 pg/mL. Each test takes 25 minutes, achieves similar sensitivity to that of a commercially available ELISA, and is 12 times faster and 16 times less expensive.



Conclusions: These data show that the novel device described can serve as a simple, rapid, inexpensive, and minimally invasive screening tool for chronic allograft rejection. In addition, the device can easily be modified (simply by using different antibodies) to detect other biomarkers, and therefore other diseases.

FR-PO1118

Point of Care Monitoring of Haemodialysis Patients with a Breath Ammonia Measurement Device Based on Printed Polyaniline Nanoparticle Sensors Frank Ward,[1] Troy Hibbard,[2] Karl Crowley,[2] Frank A. Kelly,[1] Patrick P. O'Connor,[1] John N. Holian,[1] Alan J. Watson,[1] Anthony J. Killard.[2,3] *[1]Dept of Renal Medicine, Saint Vincent's Univ Hospital, Dublin, Ireland; [2]Biomedical Diagnostics Inst, Dublin City Univ, Dublin, Ireland; [3]Centre for Research in Biosciences, Dept of Biological, Biomedical and Bioanalytical Sciences, Univ of the West of England, Bristol, United Kingdom.*

Background: Breath is an excellent candidate for diagnostic technology development. Breath ammonia levels are elevated in kidney dysfunction. Current instrumental measurements are large, heavy and expensive, thus impractical as point-of-care devices.

Methods: A device for measuring breath ammonia was developed based on a single use, disposable, inkjet-printed ammonia sensor, fabricated using polyaniline nanoparticles. The device was optimized for sampling ammonia in human breath samples and validated in normal volunteers. Breath ammonia and blood urea nitrogen (BUN) levels were sampled pre- and post-haemodialysis in patients in a single centre to assess the degree of correlation.

Results: The 20 patients recruited underwent 44 episodes of sampling. The mean pre-dialysis breath ammonia level was 930 parts per billion by volume (ppbv), (range 164 - 2243 ppbv) reduced significantly post-dialysis to a mean level of 227 ppbv (range 19 – 1138 ppbv) ($p<0.01$). The mean pre-dialysis BUN was 22 mmol/L (range 9 to 35mmol/L), reduced significantly post-dialysis to a mean level of 6 mmol/L (range 3 to 10 mmol/L) ($p<0.05$). Correlation of the combined pre- and post-dialysis breath ammonia levels with BUN yielded a Pearson coefficient of 0.61 ($p<0.01$). 11 patients underwent pre- and post-dialysis sampling on multiple occasions, with the intra-individual Pearson correlations between breath ammonia and BUN varying between 0.86 and 0.96 ($p < 0.07$ to 0.0001).

Conclusions: These findings demonstrate the potential of this system to be used in the monitoring and treatment of patients with kidney disease. Future studies should focus on similar validation in peritoneal dialysis and CKD.

FR-PO1119

Implantable Hemofilter: 32 Day Patency in a Canine Surgical Model Clark David Kensinger,[1] Seth J. Karp,[1] Joseph J. Groszek,[2] David Christopher LaNeve,[3] Phillip E. Williams,[3] Baoxia Mi,[4] Mark S. Goodin,[5] Rishi Kant,[6] Torin Yeager,[6] Shuvo Roy,[6] William Fissell.[2] *[1]Dept of General Surgery, Vanderbilt Univ Medical Center; [2]Dept of Medicine, Vanderbilt Univ Medical Center; [3]Div of Surgical Research, Vanderbilt Univ Medical Center; [4]Dept of Civil and Environmental Engineering, Univ of Maryland; [5]Dept of Bioengineering and Therapeutic Sciences, Univ of California San Francisco; [6]Dept of Bioengineering and Therapeutic Sciences, Univ of California San Francisco.*

Background: An implantable artificial kidney using silicon nanopore membranes is in development to provide the benefits of transplantation to all dialysis patients. The major challenge in implementation of chronic blood contacting devices is thrombosis. We report a successful 32-day device implant in a canine model.

Methods: A single-channel, parallel-plate hemofilter was manufactured from polycarbonate. To determine the influence of the hemofilter blood path on thrombosis and long-term patency, two silicon chips coated with biocompatible polymer (sulfobetaine methacrylate) were mounted in the hemofilter in lieu of the planned silicon nanopore membranes. The device was attached to 6 mm Polytetrafluoroethylene (PTFE) grafts anastomosed to the common iliac artery and vein. Therapeutic heparin (100 U/kg) was administered intra-operatively. The animal had no restrictions post-operatively. The dog received lovenox (0.5mg/kg) once a day at a venous thromboembolic prophylactic dose to demonstrate device patency in the absence of full anticoagulation. The grafts were serially assessed post-operatively with a pulse wave doppler ultrasound. The device was explanted at Day 32.

Results: The inflow and outflow PTFE grafts showed patent, pulsatile flow with peak flow rates between 1.7 L/min to 1.9L/min throughout the 32 day experiment. The device was patent without thrombus formation on explant. The animal had no complications.

Conclusions: Hemofilter device patency in the absence of therapeutic anticoagulation highlights successful surgical technique, nonthrombogenic blood flow conduit geometry, and manufacturing biocompatibility providing the foundation for further preclinical canine experiments.

Mapping Murine Diabetic Nephropathy Using CEST-MRI Technique Feng Wang,[1] David J. Kopylov,[2] Keiko Takahashi,[3] Zhongliang Zu,[1] Yuna Park,[3] Christopher Chad Quarles,[1] Raymond C. Harris,[3] Takamune Takahashi.[3] *[1]Vanderbilt Univ Inst of Imaging Science, TN; [2]Drexel Univ, NJ; [3]Nephrology, Vanderbilt Univ, TN.*

Background: Diabetic nephropathy (DN) is the leading cause of renal failure. The imaging technique that enables non-invasive assessment of this disease, identifying the early stage of DN or predicting its progression, should facilitate the intensified treatment to high-risk populations. DN is associated with the changes in tissue metabolites (e.g. glucose, glycogen, glycosaminoglycan) that exhibit significant chemical exchange saturation transfer (CEST) effects in MRI. Therefore, here we evaluated the utility of CEST-MRI in this disease.

Methods: Mice were scanned on 7T MRI using CW CEST sequence and SE-EPI readout. Fat saturation was applied at RF offset (-1042 Hz). A control scan was performed with an RF offset of 100 kHz. The MTR_{asym} maps were created by asymmetric analysis. A peak fitting algorithm was used to decompose overlapped amide, amine, hydroxyl, direct saturation on free water, and aliphatic peaks around 3.5, 2.2, 1.2, 0 and -3.3 ppm RF offsets, respectively. The CEST signals, NOE, and MT effect were mapped in each kidney. Sensitivity of CEST imaging was evaluated across db/m, db/db, and db/db eNOS-/- mice at 16 wks, and longitudinally in db/db mice at week 8, 12, 16, 20 and 24 wks.

Results: Compared with db/m mice, the glucose/glycogen signals (RF offset ~1.2 ppm) were increased by 55% in outer medulla (OM) in db/db kidneys (p=0.002) at 16 wks of age, while those were more evidently increased in OM (175%) and cortex (110%) in db/db eNOS -/- kidneys (p<0.001). Glucose/glycogen signals in inner medulla (IM) and papilla (P) was increased comparably in db/db and db/db eNOS-/- kidneys (p<0.001). Longitudinally, db/db mice exhibited moderate increases (p=0.082) in glucose/glycogen levels in IM+P at 8 wks, and it is significantly and progressively increased in IM+P, OM, and cortex at 12, 16 and 24 wks.

Conclusions: The characteristic CEST features observed herein could enable the non-invasive detection of DN and differentiation between moderate (db/db) and advanced (db/db eNOS -/-) DN. This MRI technique may be effectively used for the assessment of this disease.

Funding: NIDDK Support

FR-PO1121

Athymic Rat Reduced Kidney Mass Model: A Screening Tool to Identify Human-Sourced Cell-Based Therapeutic Prototypes for Regeneration and Stabilization of Renal Function Kelly I. Guthrie, Elias Rivera, Namrata D. Sangha, Andrew T. Bruce, Tim Bertram, Deepak Jain, Joydeep Basu. *Tengion, Winston-Salem, NC.*

Background: Elucidating multi-modal mechanisms of action and efficacy of human-sourced autologous cell based therapeutic candidates is supported by availability of short-term pre-clinical models of kidney disease. The NIHRNU rat is permissive to xenogeneic transplant of human cells and Reduced Kidney Mass (RKM) models in rodents are used to identify potential CKD therapies. Selected Renal Cells (hSRC) have been identified as an autologously-sourced therapeutic for CKD patients.

Methods: NIHRNU rats underwent kidney mass reduction (KMR); removing one kidney and, approximately 1 week later, cortical tissue from remaining kidney. Proof-of-concept rats utilized for prototype testing underwent KMR in 2 pilot groups with kidney weight-based reduction averaging 59% (Grp 1) or 67% (Grp 2). Remnant kidneys were injected with hSRC formulations: Grp 1: 3D SRC aggregates (organoids) (n=4), Grp 2: SRC, 48hr hold (n=7), SRC, 72hr hold (n=8). Serum /urine chemistries, survival, terminal histology and HLA1 staining of implanted cells were employed.

Results: (1) For groups 1 and 2 respectively, 4 weeks post-KMR average sCre was 0.5 versus 1.5 mg/dL; BUN was 33 versus 108 mg/dL; 2 weeks post-KMR survival was 100% versus 64%; 18 weeks post- KMR survival was 100% versus 5%. (2) In Grp 2 rats with starting sCre>=1 at delivery, hSRC formulations provided significant survival benefit (p=0.05) and stabilization of clinically relevant biomarkers associated with independent functional niches (sCre, BUN, Hct, sPhos, sAlb, Cholesterol, UPC, p<0.05). (3) HLA1 + staining (human-origin):1-2 cells/ 20uM transverse section within tubules and interstitium at 4 months.

Conclusions: (1) Extent of KMR in NIHRNU rats significantly impacts rate of disease progression in creating short-term screening model (2) Detection of hSRC and stabilization of kidney function in this xenogeneic model (Grp 2) is consistent with that demonstrated in autologous/longer term rodent models. (3) Current POC study demonstrates application of model to SRC process development. Increased rat count in Grp2 model may assist identification of optimal process.

FR-PO1122

Effect of Blood Vessel Wall Deformation on Simulated Hemodynamics in Arteriovenous Vascular Access Models Yan-Ting E. Shiu,[1] Daniel B. Pike,[1] Michelle Fitts,[1] Christi M. Terry,[1] Alfred K. Cheung.[1,2] *[1]U of Utah, SLC, UT; [2]VASLCHCS, SLC, UT.*

Background: Previous computational fluid dynamics (CFD) simulations of blood flow in arteriovenous (AV) accesses have generally assumed a rigid vessel wall, because of computational time and power limitations as well as difficulties in measuring the deformation of thin venous wall. Here we included wall deformation in CFD, by using 2-way coupled fluid structure interaction (FSI) modeling between the fluid (blood) and solid (vessel wall) domains.

Methods: The structural boundary was an idealized AV fistula (AVF) or graft (AVG), with 300-mm thick vessel walls that were rigid or deformable (with an elastic modulus of 800 kPa). The inflow and outflow blood flow rates (Fig. 1 bottom) were actual values obtained by MRI in our porcine AVF and AVG models. FSI simulation was run in ANSYS Workbench.

Results: Fig. 1 displays color maps of velocity streamline and wall shear stress (WSS) from CFD simulations. When compared to the rigid wall models of AVF (a) and AVG (e), flow patterns in deformable AVF (b) and AVG (f) exhibit more eddy currents. The deformable AVF model has higher velocity and WSS (b, d) than the rigid model (a, c). In contrast, the deformable AVG model has similar velocity and WSS (f, h) to the rigid model (e, g).

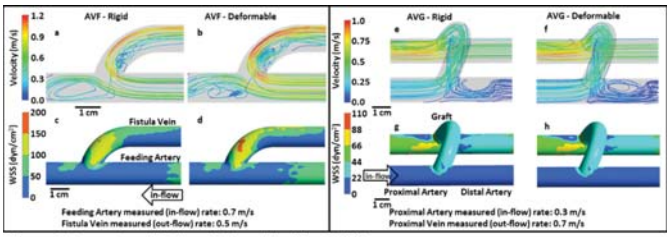

Figure 1: Comparison of Rigid and Deformable AVF and AVG.

Conclusions: Comparing the effects of rigid and deformable vessel walls on hemodynamics in AV accesses is novel. The different effects of deformable vessels on velocity and WSS between AVF and AVG may be because motion in the AVG is constrained by the presence of the rigid graft. Arterial- and venous-specific wall thickness and elastic properties will next be incorporated to further improve the accuracy of CFD models. The different influences of wall deformation on velocity and WSS in AVF versus AVG could yield further insight into the effects of blood flow on stenosis formation and maturation of AVF.

Flow-Mediated Dilation and Acute Kidney Injury Prediction in Vascular Surgeries Etienne Macedo,[1] Mauricio Teixeira,[1] Daniela Calderaro.[2] *[1]Renal Div, USP, São Paulo, Brazil; [2]INCOR, USP, São Paulo, Brazil.*

Background: Among the pathophysiologic mechanisms involved in the development of Acute Kidney Injury (AKI), endothelial dysfunction (ED) and abnormal vascular reactivity may play important roles in the association of AKI and cardiovascular acute events. The endothelium is an important regulator of arterial elasticity, and assessment of Flow Mediated Dilation (FMD) is a tool to evaluate ED in coronary artery disease. We hypothesized that the Flow Mediated Dilation (FMD) could be a marker to predict AKI in patients undergoing vascular surgeries.

Methods: We analyzed data from a prospective cohort of 96 patients. All patients had been submitted to major vascular surgery and FMD had been assessed.The measurement of FMD was made with an ultrasound evaluation of the brachial artery that follows a brief compressive ischemia of the forearm. AKI was classified by KDIGO SCR criteria.

Results: All 96 patients had chronic kidney disease (19% SI, 44% SII and 37% SIII), 14% were diabetic and 95% had hypertension. 33 (35%) were submitted to endovascular procedures. The main procedure was aortic aneurysm correction (61%). During the first 7 days after the procedure, 31 patients developed AKI and 18 had cardiovascular acute events. AKI and non-AKI patients had similar rates of cardiovascular events. The median FMD was 5,7%, and was not different in patients that developed AKI or cardiovascular events.

Conclusions: Even though there is a logical pathophysiologic association between markers of endothelial function and AKI, FMD was not a predictor of AKI or cardiovascular events in this cohort of CKD patients. The high incidence of hypertension and CKD, associated with a very low mean of FMD, could be a determinant for the low discrimination. Further studies should include CKD patients in order to establish if the Endothelia Dysfunction markers could be predictors of AKI in this high-risk population.

SA-PO002

Assessing Intravascular Volume Using Inferior Vena Cava Ultrasound in ICU Patients with Renal Failure Matthew Kaptein,[1] John Kaptein,[2] Elaine Kaptein.[1] *[1]Nephrology, LAC+USC, Los Angeles; [2]Research Laboratory, Kaiser Permanente, Los Angeles.*

Background: Accurate intravascular volume assessment is essential to manage critically ill patients. Physical exam, CVP, and PCWP poorly reflect intravascular volume. IVC ultrasound (IVC US) reliably indicates right atrial pressure, and is most useful when IVC is overtly "flat" (ascending limb of Starling curve) or "fat" (descending limb). We defined IVC US parameters to accurately predict whether ≥ 1L ultrafiltration (UF) was tolerated.

Methods: 1) Population: From a convenience sample of 145 ICU patients with renal failure in 400 encounters, we analyzed a subset of 66 patients in 175 encounters who had HD/CRRT within 24h of IVC US. 2) Intravascular volume assessment: Clinical assessment recorded prior to IVC US. IVC parameters: IVCmin, IVCmax, Collapsibility Index (CI) = [IVCmax-IVCmin]/IVCmax. "Fat" IVC has large diameter and small CI = intravascular hypervolemia. "Flat" IVC has small IVCmax or large CI = intravascular hypovolemia. 3) Clinical strategy: Treatment decisions based on clinical data + IVC US ("fat or flat"). Accepted criteria of CI > 50% or collapsed to predict hypovolemia, thus pre-emptively gave volume or dialyzed without ultrafiltration. We ultrafiltrated patients predicted to be hypervolemic by small CI (~<20%), or with overriding need for volume removal and CI <50%. 4) Analysis: Pre-US intravascular volume assessment was compared to IVC US. In HD/CRRT subset, we used logistic regression to predict, using CI, the "gold standard" endpoint of whether removal of ≥ 1L UF was tolerated.

Results: Logistic regression analysis suggests CI ≤ 15% is optimal cutoff that maximizes sensitivity (90%) and specificity (90%) to predict whether ≥ 1L UF will be tolerated. Volume therapy directed by serial IVC US assessment well-tolerated. UF was possible in most with "fat" IVC, despite hypotension or vasopressors. Poor concordance of pre-US intravascular volume assessment with IVC US. Poor correlation of CVP, PCWP, CO with either IVC US or "gold standard".

Conclusions: Ours is the first study showing IVC US accurately predicts ability to rapidly remove volume in critically ill patients. Prior studies showed IVC US reliably predicts benefit from volume resuscitation.

SA-PO003

Renal Replacement Intensity and Urine Volume in Critically Ill Patients – Results from the ATN Study Finnian R. Mc Causland,[1] Josephine K. Asafuadjei,[2] Rebecca A. Betensky,[2] Paul M. Palevsky,[3] Sushrut S. Waikar.[1] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Div of Biostatistics, Harvard School of Public Health, Boston, MA; [3]Nephrology, VA Pittsburgh Healthcare System, Pittsburgh, PA.*

Background: Randomized trials of higher versus lower intensity renal replacement therapy (RRT) have failed to show improvement in outcomes. We wished to test the hypothesis that higher intensity RRT may have adverse effects on kidney function by examining the differences in urine output between randomized groups of higher versus lower RRT intensity in the ATN Trial.

Methods: We performed a post-hoc analysis of the ATN Study (n=1124), a multi-center trial that randomized critically ill patients with acute kidney injury to higher (hemodialysis 6/week or CVVHDF 35ml/kg/hour) versus lower (hemodialysis 3/week or CVVHDF 20ml/kg/hr) RRT intensity. We modeled the rate of change in 24h urine output over time using mixed linear regression models with inverse probability weighting to account for dropout due to death.

Results: Mean age of participants was 59.6 ±15.3 years; 70.5% were male; 15.9% were black and 29% were diabetic. In unadjusted analyses, compared with higher intensity RRT, lower intensity was associated with an average of 72.4 mls greater urine output per day (p=0.003). Patients randomized to lower intensity RRT experienced an increase in mean urine output of 5.6 ml/day (95% CI 1.9 to 9.4); those randomized to higher intensity RRT experienced a 0.4 ml/day decrease (95% CI -3.9 to 3.2). The difference between the two groups suggested that higher intensity RRT was associated with a decrease of 6.0 ml/day in average daily urine output (p-difference=0.02).

Conclusions: Higher intensity RRT may lead to more rapid loss of residual urine output in critically ill patients with severe acute kidney injury.

Administration of Allogeneic, Human Mesenchymal Stem Cells to Phase I Human Study Subjects Does Not Elicit an Immune Response, But Does in Rats with Acute Kidney Injury Anna Gooch,[1] Ping Zhang,[1] Zhuma Hu,[1] Christof Westenfelder.[1,2] *[1]Medicine, U of Utah and VAMC, Salt Lake City, UT; [2]Physiology, U of Utah, SLC, UT.*

Background: Human Mesenchymal Stem Cells (hMSC) do not express DR (HLA-II) and blood group antigens, and are negative for co-stimulatory CD40, -80 and -86. This profile predicts that the infusion of allogeneic MSC to humans should not elicit an antibody response. However, recent publications have questioned the immune privileged status of MSCs (Nat Biotech 2014). Indeed, if hMSC are cultured in fetal calf serum, as is routinely done, retained bovine antigen may induce allo-antibody production. To avoid this possibility, we cultured hMSC without animal products for our Phase I Trial in which allogeneic hMSC were infused to open heart surgery patients known to be at high risk for post-op AKI (Nat Rev Nephrol 2010). Administration of hMSC was safe overall, and none of the study subjects developed post-op AKI or CKD, while ~ 20% of closely matched historical controls experienced post-op AKI and progressively lost renal function.

Methods: To test whether administered hMSCs had elicited an immune response in the subjects, allogeneic hMSC from the stock that had been used in the Phase I Trial (dose escalating protocol) were incubated with the sera of the study subjects collected 40 days post cell infusion, then incubated with FITC-labeled anti-human IgG antibodies and FACS analyzed.

Results: Such analysis failed to detect, in all subjects, antibodies to allogeneic hMSC. Sera collected 14 days after rats with AKI had been treated with hMSC were tested in identical fashion, using FITC labeled anti-rat IgG. Although hMSC infusion had prevented development of AKI as judged by SCr, sera from all hMSC treated animals exhibited robust antibody responses to hMSC.

Conclusions: Allogeneic hMSCs cultured without animal serum infused x 1 do not elicit an antibody response in humans, while they do in rats, the latter despite MSCs' known inhibitory effects on antibody production. These data confirm the immunologic safety of clinically used allogeneic hMSC when cultured without animal serum. While effective, Xenogeneic protocol elicits an anti-body response, rendering such use unsafe.

HLA Associations with Acute Tubulointerstitial Nephritis in a Chinese Adult Population Cui Li,[1,2] Tao Su,[1] Jiawei Tang,[1] Yafang Wang,[1] Xiaomei Li,[1] Li Yang.[1] *[1]Renal Div, Renal Div, Peking Univ First Hospital, Beijing, China; [2]Renal Div, Renal Div, Beijing Shijitan Hospital, Beijing, China.*

Background: It has been reported that certain human leukocyte antigen (HLA) alleles are associated with acute tubulointerstitial nephritis (ATIN), especially tubulointerstitial nephritis with uveitis syndrome (TINU). Whereas no observation has been reported in Chinese population.

Methods: A prospective cohort of clinical-pathologically diagnosed ATIN patients, including Drug induced ATIN (DATIN) in 56 cases and TINU in 22 cases, was enrolled in the study. Two hundred healthy individuals were included as control. Typing of HLA-DRB1, DQA1, DQB1 alleles was performed by bi-directional sequencing of exon 2. Renal outcome was determined at 12m post biopsy by eGFR.

Results: A significant association was found between the HLA alleles DQA1*0104, DQA1*0105, DQA1*0303 and ATIN. These three types of HLA alleles were detected in 82% of ATIN cases but in none of the controls [risk ratio (RR) 5.6, 95% confidence interval (CI) 3.5-9.0]. Linkage disequilibrium of DRB1*1405 and DQB1*0503 was associated with ATIN (RR 70.4, 95% CI 23.7-209.1). The HLA class II haplotype DQA1*0104/ DQB1*0503/ DRB1*1405 was the most common combination in our ATIN cases (53.9%). Patients having this combination, compared with those who had not, presented more significant systemic inflammation [CRP 9.4(5.0~17.8)mg/L versus 6.7(2.0~15.2)mg/L, P=0.048], higher Peak Scr level [313.0(256.0~538.0)umol/L versus 269.3(182.8~408.8) umol/L, P=0.013], higher urinary a1-MG secretion [221.5(152.0~336.0)mg/L versus 135.0(28.0~214.0)mg/L, P<0.001], and more diffuse interstitial inflammation (P=0.035) and tubulitis (P=0.028). However, there was no association between HLA alleles and renal outcome at 12m post biopsy. No difference was found in the HLA genotypes between DATIN and TINU patients in our study cases.

Conclusions: We found a strong association between HLA-DQA1 genotypes and ATIN, whereas the alleles that were studied could not distinguish DATIN from TINU. HLA haplotype DQA1*0104/DRB1*1405/DQB1*0503 was associated with more severe renal injury but did not predict renal outcome.

SA-PO006

The Effect of Mineralocorticoid Receptor Blockade on the Incidence of Acute Kidney Injury After Cardiac Surgery

Salvador Roberto Lopez,[1] Michael Eduard Wasung,[1] Mirell Tapia,[1] Ruben Dario Barba Navarro,[1] Pamela Tella,[1] Antonio R. Villa,[2] Silvana Bazua-Valenti,[3] Norma Bobadilla,[3] Magdalena Madero,[1] Gerardo Gamba.[3] *[1]Dept of Nephrology, INCICH, Mexico City; [2]Faculty of Medicine, UNAM; [3]Molecular Physiology Unit, INCMNSZ-IIB-UNAM, Mexico City, Mexico.*

Background: Extensive experimental data from our group show that the mineralocorticoid receptor blocker spironolactone (Sp) prevents renal injury induced by ischemia-reperfusion.

Methods: We conducted a pilot, prospective, open, comparative analysis to determine the effect of Sp on the incidence of acute kidney injury (AKI) in adult patients undergoing cardiac surgery. Patients received 100 mg Sp orally 12-24 hours before surgery. Subsequently, patients received three doses of 25 mg Sp on days 1, 2 and 3 and were followed for 5 days. Patients who had not given consent served as controls. Primary and secondary outcomes were AKI incidence and length of stay in intensive care unit (ICU), respectively.

Results: The average age of the population was 54 ± 14.9 years (53.5% male). Most variables were similar between groups, except that the control group exhibited slightly higher preoperative serum potassium and lower aortic clamp time and bleeding during surgery. AKI incidence in the Sp and control groups was 36.2 versus 46.2% (p=0.12), respectively. The numbers of patients with AKIN 3 and who required renal replacement therapy were lower in the Sp group (3.1% versus 8.1%), nonetheless these results did not reach statistical significance (p= 0.097). Length of stay in the ICU was shorter in the Sp group (3.9 ± 2.2 versus 4.7 ± 3.1 days, p<0.03). Logistic multivariate analysis presented Sp as protective against AKI and length of stay in the ICU. There was no difference in the incidence of postoperative hyperkalemia (>5.5 mEq/L) between groups (14.6% versus 12.6%, Sp versus control, respectively).

Conclusions: Perioperative administration of Sp is safe and could potentially reduce the incidence of AKI in cardiac surgery patients. A randomized controlled study is going on to confirm our findings.

The Effects of Renin-Angiotensin-Aldosterone System Blockades on Acute Kidney Injury in Critically Ill Patients in Intensive Care Unit

Hye Jin Lim,[1] Ae Jin Kim,[1] Han Ro,[1] Jae Hyun Chang,[1] Hyun Hee Lee,[1] Wookyung Chung,[1] Yun Jung Oh,[2] Ji Yong Jung.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Gachon Univ Cil Medical Center, Incheon, Republic of Korea; [2]Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea.*

Background: Acute kidney injury (AKI) is a major clinical problem and predictor of outcome especially in critically ill patients in intensive care unit (ICU). Renin-angiotensin-aldosterone system (RAAS) blockades are commonly used but can cause AKI during inter-current illness. RAAS blockades on outcomes in patients undergoing AKI in hospital remain uncertain. The aim of this study was to evaluate whether the use of RAAS blockades affected major outcomes of AKI in ICU patients.

Methods: We conducted a large retrospective study of 26,287 patients who admitted to an ICU of a tertiary care academic hospital from January 2003 to December 2013. AKI was defined according to RIFLE and AKIN criteria. Main outcomes measured were AKI occurrence, all-cause mortality, and hospital and ICU length of stay.

Results: AKI developed in 3,192 (12.1%) according to RIFLE criteria and 5,238 (19.9%) according to AKIN criteria. We grouped the cohort into RAAS blockades users (n=2,157) and non-users (n=24,130). There were significant differences between RAAS blockades users and non-users in the incidence of AKI during the ICU stayby RIFLE criteria (27.1% versus 10.8%, p<0.01) and AKIN criteria (49.7% versus 17.3%, p <0.01). RAS blockades users group also significantly increased all-cause mortality within 90 days of ICU admission (Hazard ratio: 1.91, 95% Confidence interval: 1.65-2.22, p<0.01) than non-users. The hospital day (17.64 days versus 20.32 days, p=0.12) and ICU length of stay (3.61 days versus 3.76 days, p=0.63) among the survivors were not different between the two groups.

Conclusions: In this study, use of RAAS blockades was associated with increased development of AKI and mortality. Large, multi-center randomized trials are needed to confirm whether temporary withholding of these medications can affect outcomes in ICU patients.

SA-PO008

Does Adjustment of Serum Creatinine for Changes in Weight Improve the Definition of AKI in Premature Infants?

David J. Askenazi,[1] Rajesh Koralkar,[1] Namasivayam Ambalavanan,[2] Russell Griffin,[3] Neha Patil.[1] *[1]Pediatrics, Univ of Alabama at Birmingham (UAB); [2]Neonatology, UAB; [3]Epidemiology, UAB.*

Background: Newborn often lose up to 10% of their weight in the first days of life. Studies in children and adults suggest that correcting serum creatinine (SCr) for fluid changes may improve the ability to predict clinical outcomes.

Methods: We enrolled 125 infants (birth weight (BW) <1200 grams or gestational age < 31 weeks) between February 2012 and June 2013. We prospectively collected daily SCr, AKI status was first categorized according to the neonatal AKI definition (adapted from KDIGO definition using lowest prior SCr value as a baseline for each SCr). We then adjusted each SCr value by changes in total body water (TBW = 0.8 x weight) to define AKI. The adjusted SCr was defined as SCr x [TBW + (current wt. – BW)]/ TBW. AKI was compared between unadjusted and adjusted SCr measurements using Bowker's test of symmetry. A logistic regression was used to estimate odds ratios (ORs) for mortality and combined bronchopulmonary dysplasia (BPD)/ mortality between adjusted and unadjusted SCr definition.

Results: Using SCr, 34/122 (28%) met the neonatal KDIGO AKI definition, [(5/34 (15%) had class 2 or 3 AKI]. Using the adjusted SCr, 23/122 (18.9%) had AKI [(6/23 (26%) had class 2 or 3 AKI)]. The SCr and adjusted SCr definitions were significantly different (p=0.044), with most discordance in those classified as AKI 1 using unadjusted SCr and AKI 0 using adjusted SCr. The association between AKI and the composite of BPD/Mortality was stronger for the SCr-adjusted definition (OR 2.72, 95% CI 1.08-6.89) than unadjusted SCr definition (OR 2.14, 95% CI 0.96-4.81), with only the former being statistically significant.

Conclusions: These results suggest that not accounting for changes in fluid status may results in an overestimation of the true incidence of AKI and an underestimate of the association between AKI and BPD/mortality, which can potentially result in an increased type-II error (i.e., saying no association exists when truly one does). Evaluation of larger cohorts and performance of AKI damage markers with adjusted and unadjusted SCr definitions are greatly needed.

SA-PO009

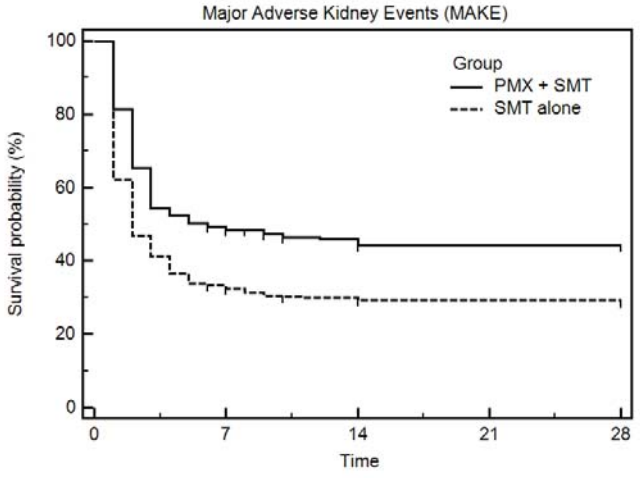
Polymyxin B Hemoperfusion Improves Renal Outcomes in Septic Shock

Dinna Cruz,[1] Tsukasa Nakamura.[2] *[1]Univ of California San Diego; [2]Shinmatsudo Hospital, Japan.*

Background: Septic acute kidney injury(AKI) is a common ICU complication associated with high mortality. Hemoperfusion with Polymyxin B fiber column (PMX) reduces blood endotoxin levels and vasopressor requirement, and improves blood pressure, which may improve renal perfusion. In-vitro studies suggest PMX reduces proapoptotic activity of plasma of septic patients on cultured renal tubular cells. We hypothesized that PMX may improve renal outcomes in sepsis.

Methods: Retrospective study of septic shock patients eligible for PMX in Japan. Patients were offered PMX if they met all criteria: SIRS, documented/suspected infection, vasopressors despite adequate fluid resuscitation, ≥1 organ failure, Gram(-) organism and/or elevated endotoxin levels. If patient consented, PMX was performed twice, in addition to standard medical therapy(SMT). If no consent, they were treated with SMT alone. PMX and SMT groups were compared using survival curve analysis and multivariable Cox regression for Major Adverse Kidney Events (MAKE; composite of RRT, death, increase in renal SOFA score) at 28 days.

Results: We compared 337 PMX patients versus 360 SMT alone. PMX group was younger, more likely to be male, had higher SOFA, APACHE and endotoxin levels. ICU admission sCr was lower in PMX than SMT (2.3 versus 2.4 mg/dl, p<0.001). PMX group had shorter ICU and hospital stays. PMX group was less likely to have MAKE compared to SMT (log rank test, p<0.001). After adjustment for age, sex, SOFA score, type of organism and endotoxin levels, PMX remained associated with lower risk for MAKE.



Adjustments	OR(95%CI) for PMX	p
None (univar)	0.66(0.55-0.80)	<0.001
Age, Sex	0.66(0.55-0.80)	<0.001
Age, Sex, SOFA, sCr, endotoxin level, organism	0.67(0.55-0.82)	<0.001

Conclusions: PMX, when added to SMT, appears to improve renal outcomes in septic shock. These results warrant further exploration with prospective trials.

SA-PO010

An Acute Kidney Injury Follow-Up Clinic: Initial Experience Samuel A. Silver,[1,4] Ziv Harel,[1,4] Andrea K. Harvey,[1] Andrew Slack,[2] Neill Adhikari,[2,4] Chaim Bell,[3,4] Ron Wald.[1,4] *[1]Nephrology, St. Michael's Hosp; [2]Crit Care, Sunnybrook Hosp; [3]Internal Med, Mt. Sinai Hosp; [4]Univ of Toronto.*

Background: Survivors of acute kidney injury (AKI) are at increased risk of chronic kidney disease (CKD) and death. Despite this, the kidney care offered to AKI survivors is fragmented and inconsistent. To address this problem, we established an AKI follow-up clinic (AKIFC). Our objective was to assess 50% of KDIGO stage 2/3 AKI survivors within 30 days of hospital discharge and to characterize the interventions provided at the AKIFC.

Methods: All patients who developed KDIGO stage 2/3 AKI in a single teaching hospital were eligible. Exclusion criteria included ongoing Nephrology post-discharge care, kidney transplantation, glomerulonephritis or a pre-hospitalization eGFR≤30mL/min/1.73m^2. The Nephrology consult service patient census was audited daily to identify eligible patients, who were automatically scheduled into the AKIFC at hospital discharge. AKIFC visits consisted of a standardized assessment by a nephrologist that highlighted blood pressure and albuminuria control, cardiovascular risk, CKD complications, medication reconciliation and specialist referrals.

Results: Between September 2013-April 2014, we identified 64 eligible patients of whom 47 (73.4%) were seen within 90 days of discharge, and 25 (39.1%) within 30 days of discharge. The mean pre-hospital serum creatinine was 103(SD 36)µmol/L (eGFR 66.7(SD 24)mL/min/1.73 m^2). The mean serum creatinine was 141(SD 69)µmol/L at the initial AKIFC visit. A medical intervention was provided for 70% of AKIFC patients at their initial visit. These included medication addition (29.8%), medication discontinuation (21.3%), radiologic investigations (25.5%) and specialist referrals (17%). Added medications included renin-angiotensin inhibitors (n=4), diuretics (n=3) and statins (n=3). Discontinued medications included renin-angiotensin inhibitors (n=5), oral hypoglycemics (n=3) and NSAIDs (n=2).

Conclusions: An AKI follow-up clinic for AKI survivors after hospital discharge was feasible and led to interventions for most patients. Our ongoing research program will assess whether structured follow-up for AKI survivors reduces kidney and cardiac events compared to usual care.

SA-PO011

Renal Oxygen Supply and Demand Balance in Congenital Heart Disease Is Associated with AKI After Cardiopulmonary Bypass Catherine Morgan, Nicholas Majaesic, Sudeshna Bhattacharya, Mohamad Alaklabi, Lindsay Ryerson, Dominic Cave. *Univ of Alberta, Edmonton, AB, Canada.*

Background: Cardiac surgery associated AKI (CS-AKI) increases morbidity and mortality in children with congenital heart disease(CHD). Mechanisms of injury may include ischemia-reperfusion injury and tissue damage from glomerular filtration of free hemoglobin and labile iron generated during CPB. Ischemic preconditioning could have a protective role in CS-AKI. Regional near-infrared spectroscopy (NIRS) can provide a non-invasive measure of renal oxygen supply and demand balance before, during, and after cardiopulmonary bypass (CPB).

Methods: This is a preliminary analysis of an ongoing study of intra-operative renal oxygen saturation (rSO_2) as a predictor of AKI in children with CHD. CS-AKI was defined according to the KDIGO definition. A NIRS oximeter was placed on the flank of 26 children undergoing CPB and rSO_2 was recorded every 30 seconds preCPB, during CPB, and postCPB until skin closure. Non-parametric methods were used for testing associations.

Results: 18/26 (69%) children developed CS-AKI. Pre-CPB $rS0_2$ was higher in children with CS-AKI compared to those without (median of 74.6% (IQR 16.3) versus 66.4% (IQR 19.1)). Median $rS0_2$ during CPB was 81.6% (IQR 11.1) and 73.8% (IQR 17.7) in children with and without AKI, respectively. Total time with rSO_2 below a threshold value of 70% or 50% during CPB between those with and without AKI was the same, however, only 4 children had rSO_2 <50%. In children with CS-AKI, there was a significant increase in $rS0_2$ following CPB relative to baseline (p=0.004) but not in those without AKI.

Conclusions: Renal NIRS suggests that a relative ischemic state preCPB may be protective against CS-AKI. Also, children with a larger increase in oxygen supply relative to demand from baseline may be at increased risk of CS-AKI; reduced demand for oxygen postoperatively in the setting of injury, excessive reperfusion/ oxygenation postCPB, or failure of renal auto-regulation may play a role. Analysis of a larger dataset needs to confirm these findings and kidney injury biomarker evaluation will provide further insight.

SA-PO012

Rationale and Design of the Genetic Contribution to Drug Induced Renal Injury Study (DIRECT) Linda Awdishu,[1] Caroline M. Nievergelt,[2] Andrew Davenport,[3] Patrick T. Murray,[4] Etienne Macedo,[5] Jorge Cerda,[6] Rajasekara Chakravarthi Madarasu,[8] Arthur L. Holden,[9] Satish P. Ramachandrarao,[2] Stuart Goldstein,[7] Ravindra L. Mehta.[2] *[1]Pharmacy, UC San Diego; [2]Medicine, UC San Diego; [3]Royal Free Hospital, United Kingdom; [4]Univ College Dublin, Ireland; [5]Univ Sao Paolo, Brazil; [6]Albany Medical College; [7]Univ of Cincinnati; [8]CARE Hospitals, India; [9]International Serious Adverse Events Consortium.*

Background: Drug induced renal injury (DIRI) accounts for 18-27% of cases of acute kidney injury. DIRI is characterized as Type A (dose dependent) and B (idiosyncratic) reactions. Determining the genetic predisposition can play a role in minimizing risk. The aims of this study are to ascertain for DIRI: 1. To determine if a genetic predisposition exists, using genome-wide association and whole genome sequencing studies. 2. To describe the frequency, course, risk factors, resolution and outcomes. 3. To investigate the role of ethnic/racial variability. 4. To explore the use of different tools establishing causality.

Methods: 1000 patients will be enrolled worldwide and blood samples for DNA collected. Data on the DIRI course, drug exposure, risk factors, vital signs, and laboratory parameters will be recorded in web based database. A panel of nephrologists will adjudicate all cases. Genome wide association studies will be conducted using population controls matched on biogeographic ancestry. This study is funded by the International Serious Adverse Events Consortium.

Results: The primary endpoint is identification of specific drug-related polymorphisms associated with DIRI. Secondary endpoints include frequency of DIRI by causal drug and drug combinations; DIRI genetic variability; exploration of causality assessment tools; risk factor identification; description of the course of DIRI; and mortality and dialysis dependency at hospital discharge, 28 and 90 days post-event.

Conclusions: The DIRECT study is the first observational study investigating genetic determinants of DIRI. The findings from this study may translate into safer patient outcomes, through genotypic individualization of therapy and minimization of harm.

Funding: Private Foundation Support

SA-PO013

Phenotype of Drug Induced Renal Injury: Initial Results from the DIRECT Study Linda Awdishu,[1,2] Satish P. Ramachandrarao,[3] Marcela Zhou Huang,[3] Andrew Davenport,[4] Etienne Macedo,[5] Jorge Cerda,[6] Michael Zappitelli,[8] Dinna Cruz,[3] Rajasekara Chakravarthi Madarasu,[9] Stuart Goldstein,[7] Ravindra L. Mehta.[3] *[1]On Behalf of the DIRECT Investigators; [2]Pharmacy, UC San Diego; [3]Medicine, UC San Diego; [4]Royal Free Hospital, United Kingdom; [5]Univ of Sao Paolo, Brazil; [6]Albany Medical College; [7]Univ of Cincinnati; [8]McGill Univ, Canada; [9]CARE Hospitals, India.*

Background: Drug induced renal injury (DIRI) accounts for 18-27% of cases of acute kidney injury. However, there is a lack of prospective studies on the phenotype.

Methods: This is a prospective study enrolling 1000 patients with DIRI in 12 countries to identify drug-related polymorphisms associated with two phenotypes (AKI and glomerular injury) by genome wide association studies. Data on the DIRI course, drug exposure, risk factors, vital signs, and laboratory parameters are recorded.

Results: Preliminary results from the first 192 patients (151 adult and 41 pediatric patients) are described. The most common causal drugs were vancomycin, piperacillin/tazobactam, tacrolimus, ibuprofen, diclofenac, amphotericin and acyclovir. Multi-drug injury was common with 33% on more than one causal drug. The mean Scr increased from 1.22±0.64 to 3.77±2.38 mg/dL in adults and 0.66 + 0.37 to 2.01 + 0.92 mg/dL in pediatrics. The cases were non-oliguric and need for dialysis was low. Concomitant use of additional nephrotoxins was common. The doses of the common causal drugs appear to be within the standard ranges (adults: vancomcyin 2417.5 ± 1053.8 mg/day, tacrolimus 5.2 ± 2.9 mg/day, ibuprofen 917 ± 422 mg/day and pediatrics vancomcyin 2687 ± 1578 mg/day, ibuprofen 800 ± 283 mg/day). However, accompanying trough concentrations are above accepted targets (vancomcyin 23.7 ± 9.7 ng/mL in adults and 24.7 ± 31.1 ng/mL in pediatrics).

Conclusions: DIRECT is the first international observational study to investigate the genetic determinants of DIRI. Preliminary data suggest that certain patients may be susceptible to kidney injury from standard drug dosing. Genotyping studies will further elucidate the mechanisms for these injuries.

Funding: Private Foundation Support

SA-PO014

Frequency of Nephrotoxicity in Patients Receiving Intravenous Vancomycin Gina Marotto, Dinna Cruz, Ravindra L. Mehta, Linda Awdishu. *UC San Diego Health System.*

Background: Vancomycin nephrotoxicity is frequently suspected in hospitalized patients however the incidence and prevalence is variably described. We hypothesized that vancomycin related acute kidney injury (AKI) would be common and would correlate with vancomycin serum concentrations.

Methods: Retrospective study of adult patients who received intravenous vancomycin for at least 48 hours during June 2013 at an academic medical center. All patients had therapeutic drug monitoring and adjustment by a pharmacist. Exclusion criteria included pregnancy, history of dialysis, renal transplant, or CKD stage 5. The primary endpoint was the frequency of AKI (AKIN Scr criteria (≥ 0.3mg/dl change over 48 hrs or 50% rise over 7 days) during vancomycin treatment.

Results: AKI developed in 17 (13.5%) of 126 patients. 76% developed AKIN Stage 1; only 1 patient required dialysis. The mean Scr increased from 1.02±0.56 (pre-drug) to a peak of 1.73± 0.9 mg/dL during drug treatment. The mean Scr at hospital discharge was 1.3 ± 0.64 mg/dL and Scr returned to baseline in 6 (35%) patients. AKI patients were older than those without AKI (AKI 61.8±12.9 versus non-AKI 52.4 ±18.1 yrs, p=0.014). There was no difference in the loading doses or maximum daily dose (AKI 2550±1038 mg and non-AKI 2929 ±1099 mg, (p=0.18) for the AKI and no AKI groups. Supra-therapeutic vancomycin concentrations occurred more often in patients with AKI (53%) than controls (28%). Stepwise logistic regression revealed surgery (odds ratio [OR] and [95% CI]) (3.71 [1.05-14.28]; P = 0.04) and heart failure (OR, 8.52 [1.71-50.04]; P = 0.01) as independent risk factors for AKI. Duration of vancomycin (9.4±6.8 versus 6.6±4.8 days; P = 0.013) and hospital length of stay (19.1±18.4 versus 13.4±15.4 days, P = 0.011) were longer in the AKI group. There was no significant difference in mortality.

Conclusions: Vancomycin nephrotoxicity was common and associated with longer duration of therapy. A significant number of patients had toxicity despite therapeutic concentrations. This may indicate an underlying pre-disposition to this injury or the need for more frequent therapeutic drug monitoring.

SA-PO015

Vancomycin Associated Acute Kidney Injury Ramapriya Sinnakirouchenan, Anne M. Larosa, Hariprasad S. Trivedi. *Medicine, Div of Nephrology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Recently, we have observed a high incidence of vancomycin-associated acute kidney injury (VAAKI), possibly related to higher targeted trough levels to avoid treatment failures. The present study aims to characterize the clinical features of VAAKI and we present preliminary results.

Methods: The design is a single center, retrospective study. The inclusion criteria are age ≥ 18 years and a nephrology consult indicating VAAKI. Data collected include demographics, weight, body mass index, dose, duration and level of vancomycin, course of acute kidney injury, temporal characteristics, clinical features and course, need for renal replacement therapy, renal function, and biopsy findings, if any. Acute kidney injury is defined as 0.3mg/dl or more rise in serum creatinine.

Results: Over a 6-month period, out of 272 patients with acute kidney injury 21 patients with VAAKI (8%) were identified. There was a male preponderance (62%) with 71% of them being between 40-70 years of age. No race predilection was noted. All patients were overweight or obese (mean BMI 32.1+ 9) and 33% had a body weight of >100 kg (mean body weight 95.48 + 26 kg). Mean maximum dose of vancomycin per day was 3.13 + 0.87 g/day (average 32.8 mg/kg/day); mean cumulative dose was 14.44 + 17.8 g; mean highest vancomycin level was 41.06 + 14.8 mg/L; the average duration of vancomycin therapy was 5.25 + 4 days; mean time to the development of AKI from the start of therapy was 3.8 + 3.8 days and the mean time to peak plasma creatinine from the start of therapy was 9.5 + 5.6 days; mean time to peak plasma creatinine after the development of AKI was 5 + 3.1 days. There were insufficient data to establish mean time to reach the nadir. Only one patient underwent a biopsy that showed acute interstitial nephritis and he was the only one treated with steroids. Three patients needed dialysis.

Conclusions: Our preliminary results suggest a high preponderance of VAAKI in overweight patients possibly indicating that dosing should be based on ideal body weight rather than actual body weight. More studies are necessary to further characterize this entity, to develop better dosing protocols and design interventions.

SA-PO016

Risk of Everolimus-Associated Acute Kidney Injury Was Increased in Cancer Patients with Impaired Kidney Function Seung Yeon Son, Jung Eun Lee, Hye Ryoun Jang, Wooseong Huh, Yoon-Goo Kim, Dae Joong Kim, Ha Young Oh. *Of Medicine, Samsung Medical Center, Seoul, Republic of Korea.*

Background: Everolimus has been recently introduced as second-line treatment for renal cell carcinoma (RCC) and many other cancers. A few prospective studies have shown that serum creatinine levels increase in a significant proportion of the patients receiving everolimus. However, there are sparse data on the occurrence of acute kidney injury (AKI) during everolimus treatment in clinical practice. Therefore, we conducted this retrospective study to examine incidence, risk factors and clinical significances of AKI associated with everolimus in patients with cancer.

Methods: We analyzed patients who received everolimus for more than 4 weeks in Samsung Medical Center. AKI was defined as increase of creatinine more than 1.5 fold from baseline or decrease of estimated glomerular filtration rate (eGFR) more than 25% from baseline. AKI was divided to 3 categories: Risk (AKI-R increased creatinine less than 2 times from baseline), Injury (AKI-I 2.0?3.0 times baseline), and Failure (AKI-F 3.0 times baseline). Recovery from AKI was defined as returns of creatinine within 1.2 fold of baseline.

Results: One hundred twenty patients were enrolled in this study. Majority of patients were RCC (N=93, 84.5%). AKI was developed in 21 (23%) of RCC patients and none of the patients (N=27) with other cancers showed AKI. Fourteen out of 21 were considered to be an everolimus-associated AKI in which there were no other nephrotoxic insults. The incidence of AKI was increased progressively as baseline GFR decreased (12% in subjects with eGFR 60-90 mL/min/1.73m2, 17% in eGFR 30-60, 100% in eGFR 15-30, P=0.001 for trend). Baseline eGFR was an independent risk factor for development of AKI (HR for 10 increases, 0.70; 95% CI, 0.49-0.99; p=0.044). However, most common reason of treatment withdrawal was progression of underlying malignancy for both AKI and non-AKI group.

Conclusions: The study suggested that AKI was common adverse effect of everolimus, especially in subjects with impaired renal function. However, AKI occurrence did not require discontinuation of drug and treatment decision should be made through multidisciplinary approach.

SA-PO017

First Cases of "Warfarin-Related Nephropathy" Induced By Fluindione Leonard Golbin,[1] Cecile M. Vigneau,[1] Guy Touchard,[3] Pascale Siohan,[4] Elie Zagdoun,[5] Nathan Lagoutte,[1] Nathalie Rioux-Leclercq,[2] Frouget Thierry.[1] *[1]Nephrologie, CHU Pontchaillou, Rennes, France; [2]Anatomie et Cytologie Pathologiques, CHU Pontchaillou, Rennes, France; [3]Nephrologie, CHU Miletrie, Poitiers, France; [4]Nephrologie, CH Cornouaille, Quimper, France; [5]Nephrologie, CH Memorial, Saint-Lô, France.*

Background: Acute Kidney Injury (AKI) caused by fluindione is usually due to immunoallergic reaction. AKI with tubular obstruction by Red Blood Cells (RBC) casts have been recently described with warfarin and defined as " Warfarin-related nephropathy " (WRN) (Brodsky and al., 2009). Does WRN could be extensible to other anticoagulant drugs?

Methods: All suspected cases of AKI with tubular obstruction by RBC casts in patients treated by Vitamin K antagonists (Vka) have been searched in all hospitals from the french West Society of Nephrology, between January 2006 and October 2013. Clinical and histological data have been analyzed in order to confirm cases with tubular obstruction by RBC casts on kidney biopsy.

Results: Kidney biopsies have been systematically reviewed and we found tubular RBC casts, acute tubular necrosis and an underlying kidney disease (IgA, acute post-infectious glomerulonephritis, IgG kappa glomerulonephritis) in 7 patients (5 under fluindione and 2 under warfarin). They all have developed gross hematuria during overanticoagulation (median INR was 4,2) complicated by severe AKI (median serum creatinine (SCr) 473 µmol/L). WRN was initially suspected in patients treated with warfarin while initial diagnosis was incorrect in 4 of 5 patients treated with fluindione (acute interstitial nephritis for 3 patients and acute tubular necrosis for the last patient). One patient died, 5 kept chronic kidney disease (median SCr was 162 µmol/L) and 1 fully recovered renal function after 1-year following.

Conclusions: We describe the firsts cases of AKI by obstructive tubular with RBC casts induced by fluindione. With the recent publication of WRN cases under dabigatran and acenocoumarol, " Anticoagulant-related nephropathy " appears more appropriate than WRN. Development of gross hematuria during Vka treatment, in patients with underlying kidney disease, needs rapid INR control and close monitoring of renal function because of nephropathy prognosis.

SA-PO018

Risk Factors of Intravenous Acyclovir Associated Acute Kidney Injury According to RIFLE Classification Eun Ju Lee, Kyungo Hwang, Hyun Seop Cho, Hyun-Jung Kim, Se-Ho Chang, Dong Jun Park. *Div of Nephrology, Dept of Internal Medicine, Gyeongsang National Univ Hospital, Jinju, Gyeongsangnam-do, South Korea, Korea.*

Background: Intravenous (IV) acyclovir is commonly administered medication for viral infection but is well known for its nephrotoxicity. However, there was no study for risk factors of acyclovir associated acute kidney injury (AKI).

Methods: We retrospectively reviewed the medical records of 287 patients who were medicated IV acyclovir from January 2008 to May 2013 in Gyeongsang National University Hospital. All had documented medical histories and underwent medical review. Demographic data, risk factors, concomitant drugs, laboratory findings and outcome were gathered from the medical records and analyzed.

Results: AKI occurred in 51 patients (17.8%). As per RIFLE classification, renal injury was graded as either at risk of renal dysfunction (62.7%), renal injury (15.6%), and renal failure (21.6%). There was no significant difference in age, sex, total dose, drug duration, and presence of hydration between AKI and non-AKI group. However, both occurrence and severity of AKI according to RIFLE criteria was high in diabetes (p=0.001, 0.002, respectively). Concomitant vancomycin and NSAIDs use was positively correlated with AKI occurrence (p=0.005, 0.037, respectively) whereas mannitol and renin angiotensin blockade was not. Higher mortality was observed in AKI patients (p=0.001) and this was also correlated with AKI severity (p=0.006). Multivariate analysis also presented that presence of diabetes, concomitant NSAIDs, and vancomycin use was independent risk factor of acyclovir associated with AKI (p=0.000, OR 4.284 (CI:1.945-9.434), p=0.025, OR 3.014 (CI :1.150-7.899), p=0.007, OR 4.650 (CI :1.523-14.195), respectively).

Conclusions: AKI is relatively common in patients administrating acyclovir injection. Physicians should attempt to prevent, detect, and manage acyclovir associated AKI in patients prescribing acyclovir due to possible association of poor prognosis.

SA-PO019

Factors Used by United States Nephrologists to Stop Dialysis when Acute Kidney Injury Resolves Mary C. Mallappallil,[1] Ravindra L. Mehta,[2] Ellen H. Yoshiuchi,[3] Gary R. Briefel,[1] Edgar V. Lerma,[4] Moro O. Salifu.[1] *[1]Internal Medicine, Div o f Nephrology, State Univ of New York at Downstate, Brooklyn, NY; [2]Dept of Medicine, Univ of California, San Diego, San Diego, CA; [3]National Kidney Foundation, New York, NY; [4]Dept of Medicine, Univ of Illinois Chicago School of Medicine, Advocate Christ Medical Center, Chicago, IL.*

Background: Despite attempts to define, classify and standardize Acute Kidney Injury (AKI), there is considerable variation in management and no standard approach to withdraw dialysis in the setting of AKI. We conducted a survey of of U.S. nephrologists to determine what parameters they use to wean patients with AKI off dialysis when renal function improves.

Methods: We designed an anonymous electronic survey with 16 questions and sent it to the U.S. National Kidney Foundation database of practicing nephrologists after IRB approval. The collected data had no duplicate reponses and was de-identified. Only aggregate data was analyzed with descriptive statistics. In addition to factors showing recovery of kidney function and weaning criteria, we used comparative situations to determine what was considered the most important factor to discontinue dialysis.

Results: 264 U.S. nephrologists responded to the survey, 80% of whom, were in Nephrology practice for at least 10 years. Most responders (88%) treated over 20 cases of AKI annually. The most important criteria to take a patient off dialysis with resolving AKI was resolution of oliguria (51%). In decreasing order of importance were: improvement of volume overload (48%) and respiratory parameters (37%). Of lesser importance were: correction of metabolic acidosis and hyperkalemia. Interestingly, only a minority would get a timed urine collection to assess creatinine clearance.

Conclusions: Although, the most common indicator used to discontinue dialysis in AKI was resolution of oliguria (51%) there still is considerable variation among U.S. nephrologists while discontinuing dialysis. This variation suggests that there may be a benefit in having a standardized set of criteria when withdrawing dialysis in the setting of improving AKI.

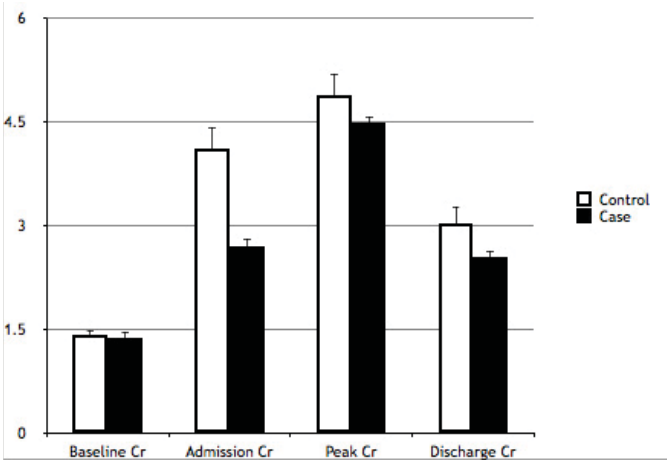
SA-PO020

Intravenous Iron in Acute Kidney Injury Jones S. John, Annie Culver, Liliana Osadchuk, Richard J. Marcus, Barbara A. Clark. *Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

Background: Little is known about benefit versus risk in treating anemia with IV iron in patients with acute kidney injury. Concerns about adverse outcomes with infection or worsening of acute kidney injury due to exposure to free oxygen radicals may dissuade use of IV iron.

Methods: We performed a retrospective case control study of patients identified over a two-year period with a diagnosis of acute kidney injury who received IV iron (cases) compared to those with AKI without IV iron (controls).

Results: We identified 67 cases and 67 controls matched for age (66±16 versus 68±12yr), stage of CKD (1.7±1.7 versus 1.7±1.7) and severity of anemia (Hgb, 7.7±0.1 versus 7.5±0.1mg/dl). They were also similar in comorbidities including diabetes, congestive heart failure, coronary artery disease, liver disease, and hypertension. Cases tended to be sicker with longer length of stay (27±4 versus 15±1.3 d, p<0.05) and more ICU days (13±2 versus 5±1, p<0.05), diagnosis of sepsis (51% versus 39% p=0.16), number of antibiotics used (2.7±0.3 versus 1.8±0.2, p<0.05). Sepsis diagnosis and antibiotic use preceded use of IV iron. Despite this there was no difference in need for dialysis (38.8 versus 34.3%, NS), mortality (24 versus 21%, NS) or severity or recovery of AKI (sCr in mg/dl).



In most cases iron levels were checked and IV iron use was in response to resistant anemia rather than proactive. Therefore use of Procrit and transfusion tended to be higher in the cases rather than the controls. Discharge Hgb was similar, (9±0.1 versus 9.1±0.1 mg/dl, NS).

Conclusions: No adverse effect of IV iron use in AKI was seen even in patients with a diagnosis of sepsis and antibiotic use. A prospective randomized control trial of timely assessment of iron stores and preemptive use of IV iron in AKI with anemia is warranted to determine risk versus benefit including possible reduction in procrit use, transfusion and associated cost.

Provider Acceptance of a Short Messaging System-Based, Electronic Alert for Acute Kidney Injury Muhammad Ubaid Ullah, Yevgeniy Gitelman, Yuliya Borovskiy, Iram Aqeel, Dan Negoianu, Barry D. Fuchs, Francis Perry Wilson. *Univ of Pennsylvania.*

Background: The implementation of electronic health records in the inpatient setting has facilitated the development of automated alert systems for acute kidney injury. Few studies have evaluated provider opinions on these systems.

Methods: We identified a convenience sample of physicians and pharmacists who had received an electronic alert for acute kidney injury as part of a randomized, controlled trial at our institution (clinicaltrials.gov #01862419). Providers were asked to provide demographic and occupational information, and to complete a brief survey regarding their opinions of the alert system within one month of receiving an alert. Alert approval was defined as the proportion of providers who indicated they would like to continue receiving alerts at the conclusion of the study. We used chi-square and Fisher exact testing to compare responses among groups of providers. We used logistic regression to evaluate the impact of survey-timing on alert approval.

Results: Of 98 individuals participating in the survey, 62 were physicians, 7 were non-physician practitioners and 27 were pharmacists. Alert approval was high at 69% of respondents. There was no significant difference in AKI alert approval by specialty, with 82% of surgeons approving of the alert compared to 62% of medical practitioners (p=0.31). There was evidence of alert fatigue as the trial progressed with the odds ratio for alert approval 0.79 (0.65 – 0.97, p=0.02) for each additional month after alerting began. Four percent of participants stated that the alert impeded their care of patients, and one percent indicated it impeded their workflow. 79% of participants stated that they were already aware of the presence of AKI "all of the time" or "most of the time" when they had received an alert.

Conclusions: An electronic alert for AKI was well-received at our institution, though alert approval declined over time. Most practitioners stated that they were already aware of the presence of AKI when the alert fired. The study is limited by the convenience nature of the sample surveyed.

SA-PO022

Bile Pigment Nephropathy in Advanced Liver Disease and Predictors of Bile Pigment Nephropathy Suman Nayak,[1] Rajendra Prasad Mathur,[1] Sivaramakrishnan Ramanarayanan,[1] Suresh Chandra Tiwari,[2] Gyan Prakash,[1] Shiv Sarin,[1] Chitranshu Vashishtha,[1] Archana Rastogi,[1] Chhagan Bihari,[1] Amar Mukund.[1] *[1]Inst of Liver and Biliary Sciences; [2]Fortis vasant kunj.*

Background: Acute kidney injury (AKI) is a major cause of mortality in patients with advanced liver disease. Majority of them have acute tubular necrosis (ATN) secondary to sepsis and ischemia. Since majority of patients are sick and coagulopathic there is paucity of literature on structural renal failure in this group.

Methods: We reviewed the post mortem kidney biopsy reports of 43 patients with severe liver dysfunction with acute kidney injury (AKI). Biopsy tissues were processed and subjected to light microscopy and immunofluorescence. In patients with pigment casts in tubules, additional special stains for iron (Pearl's stain) and bile (Fouchet's) were used to characterise the pigments.

Results: Of 43 patients bile pigment nephropathy was found in 20/43 (46.51%) and acute tubular necrosis in 23/43(53.49%) patients. Mean age of study population was 43.26±11.44 years. The Mean CTP score was higher in bile pigment nephropathy group (12.6±1.1) as compared to ATN group (11.9±1.2) (p = 0.046). The Mean MELD score was higher in bile pigment nephropathy group (39.3±7.9) as compared to ATN group (31.3±7.8) (p = 0.002). The mean urea (98.80±55.78 versus 90±44.68 mg/dl, p value = 0.294) and creatinine (4.02±2.3 versus 3.42±1.5 mg/dl, p value = 0.081) were higher in bile pigment nephropathy group compared to ATN group. The Mean total bilirubin was higher in bile pigment nephropathy group (26.1±9.3) as compared to ATN group (9.2±5.2) (p <0.001). On multivariate logistic regression analysis high bilirubin was found to be an independent predictor of bile pigment nephropathy.

Conclusions: Bile pigment nephropathy is a common pathological finding in patients of advanced liver dysfunction with AKI and high serum bilirubin was a strong predictor.

SA-PO023

Burden of Prescription Related Acute Kidney Injury in Acute Care Setting: A Quality Improvement Program Paras Dedhia,[1] Anthony C. Leonard,[1] Kotagal Shashi Kant,[1] Charuhas V. Thakar.[1,2] *[1]Nephrology, Univ of Cincinnati, Cincinnati, OH; [2]Renal Section, Cincinnati VA, Cincinnati, OH.*

Background: Acute kidney injury (AKI) is an area of focus for Medicare in reducing patient harm. Yet characterization of hospital acquired (HA) AKI and the burden of prescription related AKI (PR-AKI) is not well studied.

Methods: A 3-month clinical quality improvement (QI) program assessed 108 AKI patients out of 252 renal consults at a tertiary care hospital. We recorded clinical information and exposure to nephrotoxic drugs temporally associated with AKI. AKI, defined by KDIGO guidelines, was codified on the day of consult as: Rx related, Multifactorial, and Rx unrelated. Multifactorial AKI was scored (Rx score) based on an association with prescribed agents (1 to 10 scale). PR-AKI was defined as Rx related or with Rx score > 5. AKI was also classified as community acquired (CA-AKI) or HA-AKI, if it occurred within 2 or > 2 days after admission respectively. Primary composite outcome was death/dialysis at discharge/length of stay (LOS) of 1.5 times the median. Bivariate analysis compared patients with and without PR-AKI. Multivariable models (adjusting for age, gender and baseline creatinine) examined the associations between HA-AKI and composite outcome; PR and HA-AKI; and expressed as odds ratios (OR) and 95% confidence intervals (CI).

Results: Of the 108 AKI subjects, 65% were male. Average age was 58 years, and the median LOS was 12 days. PR-AKI occurred in 38 cases (35%). The commonest drugs associated with PR-AKI included diuretics (66%), nephrotoxic antimicrobials (63%), and contrast (45%), among others. Of the 31 cases with HA-AKI, 55% had PR-AKI compared to 27% in CA-AKI (p=0.008). Compared to CA-AKI, HA-AKI had higher odds of association with PR-AKI (OR, 2.9, CI, 1.2 – 7.4). 63% of AKI patients experienced the composite outcome; and it occurred with 3.0 times greater odds in HA- versus CA-AKI (CI 1.1 – 8.2).

Conclusions: PR-AKI occurs 1-in-3 renal consults, and this association needs to be examined in all hospitalized AKI patients. HA-AKI consults are at a higher risk of being PR-AKI, and also face poor hospital outcomes. This calls for a hospital-wide QI program to reduce the burden of nephrotoxic AKI.

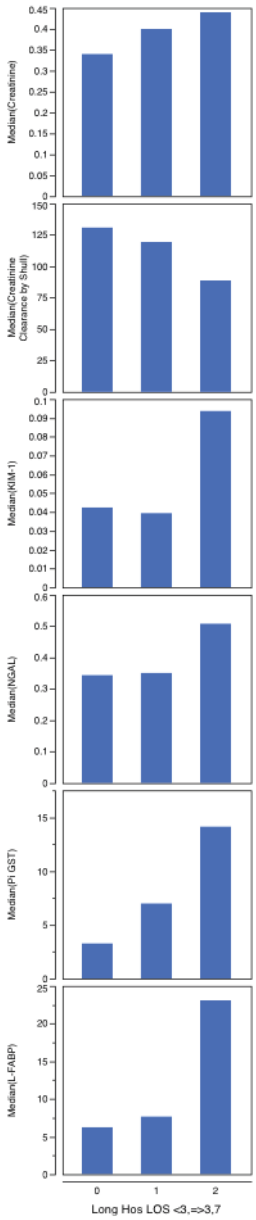
SA-PO024

The Validation of an Estimated Creatinine Clearance Formula in the Emergency Department for the Diagnosis of Acute Kidney Injury in Children: A Pilot Study Marie-Carmelle Elie-Turenne,[1] Emily Weeks,[1] Mark S. Segal.[1,2] *[1]Emergency Medicine, Medicine, Div of Neurology, Univ of Florida, Gainesville, FL; [2]Renal Service, Veterans Association Medical Center, Gainesville, FL.*

Background: The early identification of children at risk for renal failure is challenging in the acute setting, where baseline serum creatinine (SCr) and length are not readily available to perform estimates of creatinine clearance (eCrCl) by pediatric formulas. Consequently, there is no validated tool for the eCrCl among children in the emergency department (ED). We propose a modified formula, p_{ED}RIF for the assessment of acute kidney injury (AKI) by comparing its performance with renal biomarkers.

Methods: This is a pilot enrollment of 30 age-matched children <18 years with and without sepsis from the ED prior to inpatient admission. Those with prior diagnosis of chronic kidney disease or dialysis were excluded. Demographic and laboratory data was collected including SCr to calculate eCrCl and assess for AKI by p_{ED}RIF (ED modification of pRIFLE criteria using the Shull equation). Urine samples were collected in the ED to assess for urine AKI biomarkers: kidney injury molecule (KIM-1), neutrophil gelatinase associated lipocalin (NGAL), alpha and pi glutathione S-transferase (aGST, pGST), and liver-fatty acid fatty binding protein (L-FABP) by standard ELISA.

Results: Among children with AKI by p_{ED}RIF (5/30, 17%), median aGST, pGST, and NGAL were above 75% IQR of non-AKI subjects, though not statistically different. Elevation in injury biomarkers trend inversely with decreased eCrCl by p_{ED}RIF, predicting ICU admission and longer hospital stays >7 days.



Conclusions: Detection of compromised renal function using p_{ED}RIF is a relevant and simple diagnostic tool that forecasts poor outcome in the pediatric ED. Future studies are needed to validate its utility.

SA-PO025

Defining Baseline Renal Function to Improve Acute Kidney Injury Diagnosis Kerry L. Horne,[1] Rebecca A. Packington,[1] Timothy T. Reilly,[1] John Monaghan,[1] Nitin V. Kolhe,[1] Richard J. Fluck,[1] Nicholas M. Selby.[1,2] *[1]Royal Derby Hospital, United Kingdom; [2]Univ of Nottingham, United Kingdom.*

Background: Detecting acute kidney injury (AKI) in clinical practice is often hampered by lack of a baseline creatinine within the preceding 7 days. We aimed to describe the time between available baseline and AKI episode in a group of hospitalized patients and evaluate the impact on performance of AKI diagnostic criteria.

Methods: All patients sustaining AKI at our centre between 1st Jan and 31st Dec 2013 were studied.AKI was defined using KDIGO serum creatinine criteria, applied by an electronic AKI detection system.Each positive AKI result and choice of baseline was manually checked.We defined baseline creatinine as the most recent stable creatinine value in the last 12 months.In those without a baseline, a value was estimated using MDRD equation and eGFR of 75ml/min.

Results: 3578 AKI episodes occurred in 3375 patients; the cohort was representative of a generalized AKI population (mean age 76±14yrs, 30 day mortality was 27%, 54.5% AKI stage 1). 1996 patients (59.1%) had community acquired AKI (c-AKI). 579 (17.2%) patients did not have creatinine measurement within the preceding 12 months; this represented 25% c-AKI patients but only 5.7% hospital acquired AKI (h-AKI) p<0.001. 9.8% c-AKI patients had a baseline within the preceding 7 days versus 62.9% h-AKI (p<0.001). Median time between baseline and AKI episode was 58 days (IQR 121) in c-AKI and 3 days (IQR 13) in h-AKI (p<0.001). In patients with AKI stages 2/3, mortality rates were unaffected by increasing time between baseline and AKI episode. In those with AKI stage 1, mortality rates fell significantly when the time between baseline and AKI was >90days compared to those with more recent baseline values (24.3% versus 12.0%, p<0.001).

Conclusions: The majority of patients with c-AKI do not have a baseline creatinine value within 7 days. In these patients it seems reasonable to use baseline values from the preceding 12 months to compare with large increments in serum creatinine; greater caution is needed when diagnosing AKI stage 1 without baseline values within 90 days. This has relevance to clinical practice as well as research study and electronic detection system design.

N-acetylcysteine Prevents Acute Kidney Injury in Patients Undergoing Myocardial Revascularization Eduesley Santana Santos,[1] Valéria A. Costa-Hong,[2] Suely Pereira Zeferino,[1] Luiz Aparecido Bortolotto,[2] Jose Jayme Galvão De Lima.[2] *[1]Intensive Care Unit - Post Operative Care, Heart Inst (InCor) Univ of Sao Paulo Medical School, São Paulo, SP, Brazil; [2]Hypertension Unit, Heart Inst (InCor) Univ of Sao Paulo Medical School, São Paulo, SP, Brazil.*

Background: The prevention of acute kidney injury using N-acetylcysteine (NAC) in the diverse clinical settings is controversial. The objective of this study was to test efficacy of maximum IV dose of NAC on the incidence of kidney injury in 70 patients underwent elective coronary artery bypass graft (CABG).

Methods: We assessed the renoprotective effect of the highest dose of N-acetylcysteine sanctioned for clinical use. This was a prospective, double-blind placebo-controlled study which included 70 chronic kidney disease patients (stage 3 or 4) who underwent CABG and were randomized to receive either N-acetylcysteine 150 mg/kg followed by 50 mg/kg for 6 h in 0.9% saline (NAC group) or just 0.9% saline (Control group). Acute kidney injury was defined by the Acute Kidney Injury Network (AKIN) classification.

Results: The incidence of acute kidney injury was reduced in the NAC group (57.1% versus 28.6%, p=0.016; figure 1). Non-use of NAC (RR= 3.58 95% CI 1.04 to 12.33, p=0.04) and cardiopulmonary bypass (RR=4.55, 95% CI 1.28 to 16.15, p=0.02) were independent predictors of acute kidney injury.Whereas NAC reduced the incidence of AKI, the reverse was observed when patients underwent CPB.The risk of AKI developing was 20-fold higher among patients with the latter characteristic than with the former (p = 0.008). Among patients treated with CPB, the use of NAC was associated with a fall in the incidence of AKI from 63% to 41%. Oxidative stress was increased in Controls (p=0.01).

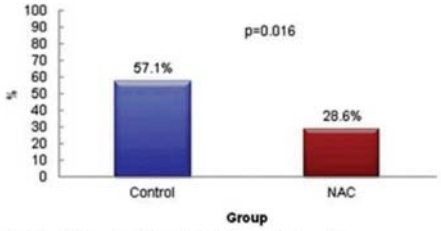

Figure 1: Effect of N-acetylcysteine (NAC) on the incidence of acute kidney injury in patients.

Conclusions: High-dosages of IV N-acetylcysteine was associated with reduction on the incidence of acute kidney injury in patients undergoing CABG.

Outcomes of Albumin Use in Treatment of Hepatorenal Disorders - A Single Center Experience Krishna Pothugunta, Santhi Voora, Holly J. Kramer, Anil K. Bidani, Kavitha Vellanki. *Dept of Nephrology and Hypertension, Loyola Univ Medical Center, Maywood, IL.*

Background: Intravenous albumin along with Midodrine and Octreotide is recommended for treatment of type I hepatorenal syndrome (HRS). The dose and duration of albumin infusions along with cautions for use are not generally addressed. We reviewed patient outcomes by amount of albumin infused in patients with HRS at our institution. We hypothesized that patients receiving albumin infusions with no renal recovery have a higher risk for pulmonary edema.

Methods: A total of 93 cirrhotic patients were admitted to Loyola University Medical Center between 2011 and 2013 and received intravenous albumin for treatment of HRS. All patients had a normal CXR and were not receiving dialysis at hospital admission. Fisher's extract test was used to compare frequency of pulmonary edema stratified by renal recovery. Logistic regression was used to examine the association between renal recovery and pulmonary edema while adjusting for total albumin infused, presence of oliguria and MELD score.

Results: Among the 93 patients, 20 had complete renal recovery,17 had partial recovery and 56 had no recovery. Risk of pulmonary edema was 47%, n=44 and was significantly higher in patients with no renal recovery versus those with partial or full recovery (63% versus 24%; P = 0.003) compared to patients with renal recovery. In the logistic regression model, those with no renal recovery had 4.5 fold (95% CI 2.0-13.0) higher odds of pulmonary edema versus those with full or partial recovery.

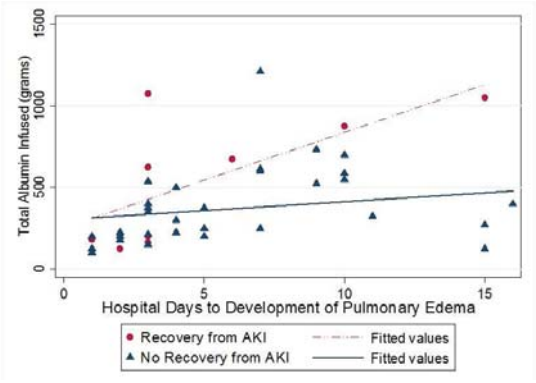

Figure 1 shows the hospital days to pulmonary edema by presence or absence of renal recovery.

Conclusions: In summary,Continued administration of intravenous albumin did not have a significant effect on renal recovery, but the risk of new onset pulmonary edema was significantly higher in patients with no renal recovery.

SA-PO028

Efficacy of Midodrine/Octreotide or Norepinephrine in the Treatment of Hepatorenal Syndrome, and Its Dependency on Rise in Mean Arterial Pressure Manish Kadian,[1] Margarita Taburyanskaya,[3] Paul Nietert,[2] Andrew Goodwin,[4] Timothy Whelan,[4] Juan Carlos Q. Velez.[1] *[1]Div of Nephrology, MUSC; [2]Div of Public Health Sciences, MUSC; [3]Dept of Clinical pharmacy, MUSC; [4]Div of Pulmonary, Critical Care, Allergy, and Sleep Medicine, MUSC.*

Background: Studies suggest that midodrine and octreotide (M/O) combination leads to improvement in kidney function in ~50% of patients with hepatorenal syndrome (HRS). We hypothesized that the success rate of M/O outside of clinical trials is lower than 25%, and that the lack of success is associated with failure to attain a substantial rise in mean arterial pressure (MAP). In addition, we explored the benefit of norepinephrine (NE) as alternative therapy in HRS.

Methods: Retrospective chart review of patients was done with a discharge diagnosis of HRS who received ≥3 doses of M/O for HRS over the last 5 years. Improvement in kidney function was defined as ≥50% decrease in serum creatinine (sCr).

Results: We identified 73 subjects treated with M/O for HRS and found a significant correlation between attained increase in MAP and improvement in sCr [mean absolute change in sCr from the value at therapy initiation: +0.45 ± 0.4, +0.04 ± 0.4, +0.08 ± 0.5 and -0.19 ± 0.5 mg/dL, for quartile I (-14.1 to +1.8 mmHg), II (+1.9 to +7.5 mmHg), III (+7.8 to +15.8 mmHg) and IV (+15.9 to +29.4 mmHg) of change in MAP from baseline, respectively; p=0.0008]. This correlation remained unchanged after adjusting for baseline MAP, sCr or MELD. Eleven patients were either transitioned from M/O to NE (n=8) or treated de novo with NE (n=3). Only 30.1% (22/73) of M/O-treated patients achieved an increase in MAP >15 mmHg, compared to 63.6% (7/11) of those treated with NE (p=0.029). Compared to M/O therapy, more patients improved kidney function when treated with NE [45.5% (5/11) versus 13.6% (10/73), p=0.011].

Conclusions: During M/O therapy for HRS, a fall in MAP is associated with worsening kidney function, whereas a rise in MAP correlates with improvement in kidney function. NE appears to be more effective than M/O in raising MAP and thereby improving kidney function in HRS.

SA-PO029

Acute Kidney Injury Risk Assessment Among VA Patients Undergoing Diagnostic Angiograms: Insights from the National VA CART Program Michael Edwin Matheny,[1,2] Thomas M. Maddox,[3,4] Jeremiah R. Brown,[5] Thomas T. Tsai,[3,4] Edward D. Siew,[1,2] James Fly,[1,2] Mary E. Plomondon,[3,4] Theodore Speroff,[1,2] John S. Rumsfeld,[3,4] Frederic S. Resnic.[6] *[1]VA Tennessee Valley Healthcare System, Nashville, TN; [2]Vanderbilt Unversity, Nashville, TN; [3]VA Eastern Colorado Health Care System, Denver, CO; [4]Univ of Colorado, Denver, CO; [5]Dartmouth Inst, Hanover, NH; [6]Lahey Clinic, Burlington, MA.*

Background: Acute kidney injury (AKI) following cardiac catheterization is a common iatrogenic complication of the procedure with strong variability in risk-adjusted AKI rates among catheterization centers. We evaluated the national catheterization registry for peri-procedural AKI risk assessment practices.

Methods: Data were from the VA Clinical Assessment Reporting and Tracking (CART) Program and the VA corporate data warehouse for all cardiac catheterizations performed in the VA between 07/01/2012 to 06/30/2013. Baseline renal function was defined as the most recent pre-procedural serum creatinine up to one year prior to the procedure. Chronic kidney disease (CKD) was stratified by KDOQI Stages IIIa-b and IV. AKI following cardiac catheterization was defined as ≥0.3 mg/dL within 48 hours of the procedure or ≥50% increase in serum creatinine from baseline at any time during the hospitalization or up to 7-days following the procedure.

Results: total of 46886 cardiac catheterizations among 40925 patients were performed in the study period. Pre-procedural serum creatinine measurement was performed within 30 days prior for 45,273 (97.2%) procedures. 24,494 (52%) of patient procedures had baseline and follow-up creatinine measurements. AKI occurred for 1426/17065 (8.4%), 688/4511 (15.3%), 550/2058 (26.7%), and 283/579 (48.9%) of patients with GFR values of >=60, 45-59, 30-44, and 15-29 mL/min/1.73 m2, respectively. A total of 2168, 607, and 79 patients with GFR values of 45-59, 30-44, and 15-29 mL/min/1.73 m2, respectively, had baseline creatinine measured but no follow-up value.

Conclusions: Post-procedural AKI ascertainment rates were low, even among CKD patients, and AKI rates among CKD patients were over double those with normal renal function.

Acute Kidney Injury Risk Management Practices for Veterans Affairs Patients Undergoing Diagnostic Angiograms: A Survey of Laboratory Directors Michael Edwin Matheny,[1,2] Freneka F. Minter,[1,2] Thomas M. Maddox,[3,4] Jeremiah R. Brown,[5] Thomas T. Tsai,[3,4] Edward D. Siew,[1,2] Mary E. Plomondon,[3,4] Theodore Speroff,[1,2] John S. Rumsfeld,[3,4] Frederic S. Resnic.[6] *[1]TVHS Veterans Administration, Nashville, TN; [2]Vanderbilt Univ Medical Center, Nashville, TN; [3]VA Eastern Colorado Health Care System, Denver, CO; [4]Univ of Colorado, Denver, CO; [5]Dartmouth Inst, Lebanon, NH; [6]Lahey Clinic, Burlington, MA.*

Background: Acute kidney injury (AKI) following cardiac catheterization is a common iatrogenic complication of the procedure. We conducted a national Veterans Affairs (VA) survey to ascertain patterns of care surrounding pre-procedural AKI risk assessment and management.

Methods: A survey was administered to characterize local care protocols for pre- and peri- procedural AKI risk management of patients. All VA cardiac catheterization directors were identified through the Clinical Assessment, Reporting, and Tracking Program. Surveys were administered from 07/2013 to 11/2013 by email attachment. Re-contact was performed at 1 month and 3 months for non-responders.

Results: A total of 21/77 (27%) directors responded to the survey. Nine sites used an established protocol for AKI risk assessment. All sites required a serum creatinine measurement prior to the procedure, but the measurement interval allowed varied widely: <1 day (1), <5 days (1), <7 days (7), <14 days (2), <30 days (7), and no response (2). Sites used the following GFR (mL/min/1.73 m^2) thresholds to determine increased AKI risk: <60 (13), <50 (1), <40 (1), <30 (2). One site used a risk prediction model for risk stratification. Nine sites provided pre-procedural volume expansion patient education, and 14 sites had protocols for overnight hospitalization and/or IV hydration for high risk elective procedures. 19 sites practiced strategies for minimizing contrast volume, 7 calculated a maximum contrast load, and 7 used an automated contrast injection device.

Conclusions: There is significant practice variation in AKI risk stratification and management among the surveyed VA cardiac catheterization laboratories. Opportunities exist for care protocol standardization with validated management strategies.

SA-PO031

Modified Acute Kidney Injury Classification Does Not Predict Survival after Orthotopic Liver Transplantation (OLT) Thais Nemoto Matsui, Adriano Luiz Ammirati, Nadia K. Guimaraes, Maria C.C. Andreoli, Marcio Dias Almeida, Jose Ben-Hur Ferraz-Neto, Marcelo Costa Batista, Marcelino Souza Durao, Virgilio Gonçalves Pereira, Oscar Santos, Bento C. Santos. *Hospital Israelita Albert Einstein, Sao Paulo, SP, Brazil.*

Background: Recently, a modified AKIN criteria (ModAKI) incorporating the traditional definition of kidney impairment (serum creatinine [SCr]>1.5mg/dL) has been associated with lower survival rates in hospitalized cirrhotic patients. The aim of this study was to determine the impact of preoperative AKI assessed by the ModAKI classification on survival at 28 days and at 1 year after OLT.

Methods: This study included 283 patients with chronic liver disease who were consecutively admitted in a medical center to undergo OLT. AKI score was determined at the moment of admission and immediately before OLT. ModAKI classification was defined as follows: A) AKI stage 1 and SCr<=1.5mg/dL; B) AKI stage 1 and SCr>1.5mg/dL; and C) AKI stage 2/3.

Results: From the 283 included patients (52.4±11.7yrs), 54% had viral-related disease, with a MELD of 19.4±9.7, and 22% had pre-OLT diabetes. AKI at admission and on the day of OLT was observed in 83 and 73 subjects, respectively, with the following ModAKI scores: A=19%, B=29%, C=52% at admission; and A=19%, B=29%, C=52% on the day of OLT. RRT was required in 28%. Mortality rate at 28 days was 6%, with similar rates across ModAKI scores (0=7%, A=13%, B=4%, C=5% at admission, p=0.627; and 0=6%, A=14%, B=0%, C=8% on the day of OLT, p=0.967). Likewise, the mortality rate 1yr after OLT (14%) was not influenced by ModAKI score on the day of OLT (0=13%, A=21%, B=5%, C=18%, p=0.685). ModAki scores B and C at admission tended to be associated with higher mortality 1yr after OLT (0=12%, A=13%, B=21%, C=21%, p=0.061). After adjustment for MELD score and pre-OLT diabetes, RRT (OR 4.036, CI95% 1.793–9.084, p=0.001) and older age (OR 1.039, CI95% 1.002–1.078, p=0.039) were independently associated with death within 1yr of OLT.

Conclusions: The modified AKIN criteria proposed for cirrhotic patients could not accurately predict the survival rate at 28 days and within 1yr of OLT. The most important prognostic factor for survival was the need for peritransplant RRT.

SA-PO032

Erythropoietin May Ameliorate Acute Kidney Injury after Cardiac Valves Surgery Nanmei Liu. *Dept of Nephrology, Jimin Hospital of Shanghai, Shanghai, China.*

Background: A series of studies have provided evidence that Erythropoietin (EPO) administration exerts significant renal protective effects in various experimental models, but it had not been verified in clinical trial. To value if EPO can reduce Acute kidney injury (AKI) in patients undergoing cardiac valve replacement surgery.

Methods: Prospective, random, control clinical study was conducted in 18-70 years old patients need cardiac valves replacement. 1wu of EPO was injected subcutaneous before operation and 24h after operation in EPO group, other treatment was the same to the control group. AKI was defined as Serum creatinine was increased more than 0.3mg/dl within 48~72h after operation. (clinical trial registered number : ChiCTR-TRC-12002266).

Results: 105 patients was selected, 3 was excluded because of serious complications in surgery, 1 was excluded because of insufficiency data. 101 patients had been completed, 47 in EPO group, 64 in control group. There was no significant difference in Age, weight, height, baseline Serum creatinine, eGFR, operation time, CBP time and aorta block time between the two groups. The total incidence of AKI was 24.8%, 19.2% in EPO group, 29.6% in control group (P=0.09).The difference of serum TNF-α, IL-6 2h after operation was not significant. AKI patients compared with no AKI patients, 24h after operation Scr were 165±64 and 83.8±22 μmol/L, Uric acid were 398±144 and 235±97mmol/L, insulin 45.8±26.4 and 28.0±19.1(P<0.05). AKI patients were more older (62.5±6.9 versus 50.1±13.2 years), had longer operation time(301.4 ±108.0 versus 229.6±60.5 minutes) and longer CBP time (151.3±53.5 versus 114.7±39.4 minutes).

Conclusions: 1. primary results showed that EPO may ameliorate acute kidney injury after cardiac valves surgery. The study sample needs to be enlarged to confirm the result. 2. AKI patients had longer operation and CBP time, it is indicated that operation insult may play more important role in the development of AKI in cardiac valves surgery patients.

SA-PO033

Development of an Electronic Algorithm to Identify Acute Kidney Injury Ioannis Konstantinidis, Girish N. Nadkarni, Rajiv Nadukuru, Vaneet Lotay, Stephen B. Ellis, Omri Gottesman, Erwin P. Bottinger. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Acute kidney injury (AKI) is a commonly occurring event that is a risk factor for morbidity and mortality and adds to healthcare cost. Epidemiological studies often rely on billing codes to classify patients; however, these were shown to have poor sensitivity and moderate negative predictive value (NPV). A tool for accurate identification of AKI from electronic medical records would have significant utility for research purposes. We aimed to assess an algorithm that uses International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) codes, laboratory results, and textual information from clinical notes.

Methods: We deployed the algorithm in 2,000 randomly selected Mount Sinai BioMe Biobank participants. AKI was defined by the 2012 KDIGO criteria (increase in serum creatinine of ≥0.3 mg/dl over 48 hours or ≥50% over 7 days or urine volume <0.5 ml/kg/hour for 6 hours). Two blinded physicians performed manual chart review. We calculated the sensitivity, specificity, NPV and positive predictive value (PPV) with 95% confidence intervals (CI) for both the algorithm and ICD-9-CM codes.

Results: We identified 104 cases and 346 controls. The sensitivity of algorithm-identified AKI was 100% compared to 59.6% for billing code-identified AKI. The NPV of algorithm-identified AKI was 100% compared to 89.2% for billing code-identified AKI. Specificity and PPV were 100% in both cases.

Table 1: Summary statistics for algorithm and ICD-9-CM codes

	Chart review				Chart review		
Algorithm	Case	Control	Total	**ICD-9-CM codes**	Case	Control	Total
Case	104	0	104	Case	62	0	62
Control	0	346	346	Control	42	346	388
Total	104	346	450	Total	104	346	450
Sensitivity (95% CI)	100% (95.6-100)			Sensitivity (95% CI)	59.6% (49.5-69.0)		
Specificity (95% CI)	100% (98.6-100)			Specificity (95% CI)	100% (98.6-100)		
PPV (95% CI)	100% (95.6-100)			PPV (95% CI)	100% (92.7-100)		
NPV (95% CI)	100% (98.6-100)			NPV (95% CI)	89.2% (85.5-92.0)		

Conclusions: We developed an automated algorithm that outperformed identification of AKI by billing codes. This can be deployed to identify AKI in health systems with EMR for research and quality improvement.

The Impact of a Renal Intensivist in a Surgical Trauma Intensive Care Unit (STICU) Roshan A. Patel,[1] Aleef M. Rahman,[2] Viral G. Gandhi,[1] Omar Mudallal,[1] George N. Coritsidis.[1,2] *[1]Medicine, Elmhurst Hospital Center (EHC), Icahn School of Medicine, Elmhurst, NY; [2]Surgery, EHC, Icahn School of Medicine, Elmhurst, NY.*

Background: Nephrology is one of 3 medical subspecialties that require a year of critical care fellowship for eligibility to work as an intensivist. Our program is one of few in the U.S. that offers an opportunity for both. It has been shown that early involvement by renal services in acute kidney injury (AKI) decreases morbidity and mortality. We were interested to see the impact on the STICU when primarily managed by a renal intensivist (2005) as compared to earlier management by surgical intensivists (2002).

Methods: A retrospective chart review of adult STICU admissions for the first half of 2002 and 2005.Total 418 charts were reviewed. Medical records with insufficient information, patients with terminal extubation and on palliative care were excluded. The data was further divided between trauma and nontrauma. Data was analyzed using STATA v. 12.0 (Austin, Texas). Unpaired t-tests and chi-squared analysis were utilized.

Results: 418 patients were identified, of which 218 were non-trauma. In the total population, there were no differences between groups except for significantly more trauma patients in 2005. Data was then stratified by trauma status. Significant differences were only seen in the non-trauma surgical group.

Non-trauma Surgical Patients	2005-Renal Intensivist	2002-Surgical Intensivist	P value
Number of Patients	113	103	
Age	54.03+ 1.74	55.20 + 1.48	0.5901
APACHE II score	10.02 + 0.60	11.60 + 0.80	0.1163
Mortality	9.56 + 0.03	18.44 + 0.04	0.0617
ICU LOS	6.85 + 1.16	10.19 + 1.43	0.0720
Ventilator days	2.04 + 0.40	5.42 + 1.57	0.4770
Δ Weight(lbs)	-1.38 + 0.82	1.12 + 0.72	**0.0221***
AKI	0.10 + 0.03	0.13+ 0.03	**0.0398***

Δ Weight=ICU discharge minus ICU admission weight, AKI=RIFLE criteria Injury stage. APACHE II score=Acute Physiology, Age, Chronic Health Evaluation.LOS=length of stay, *denotes significance.

Conclusions: The benefits of the renal intensivist seems to be primarily in non-trauma surgical patients. Within that cohort, there was significantly less AKI with better volume management. Benefits in mortality and ICU LOS approached significance.

SA-PO035

Calciprotein Particles Induce an Inflammatory Response in Macrophages Prakash Chandak,[1] Rakesh Kumar Bijarnia,[1] Edward Robert Smith,[2] Andreas Pasch.[1] *[1]Nephrology, Hypertension and Clinical Pharmacology, Univ Hospital Bern, Bern, Switzerland; [2]Nephrology, The Royal Melbourne Hospital, Melbourne, Australia.*

Background: Calciprotein particles (CPP) are nanoscale mineral-protein aggregates, which have been found in the blood of patients with chronic kidney disease (CKD). These particles contain amorphous (primary CPP) or crystalline (secondary CPP) calcium phosphate along with serum proteins. We investigated whether CPP might induce an inflammatory response in macrophages.

Methods: Prim. and sec. CPP were generated using phosphate- and calcium-enriched cell culture media with varying amounts of FBS. Particles were characterized morphologically by transmission electron microscopy (TEM). Murine RAW-264.7

macrophage-like cells were exposed to increasing amounts of CPP for 24 hrs. RT-PCR was performed to assess interleukin (IL)-6, IL-1β, IL-10, MCP-1, TNF-α and NLRP3. The involvement of toll-like receptor-4 (TLR-4), nuclear factor-kappa B (NF-κB) and NLRP3-dependent pathways were evaluated using selective chemical inhibitors.

Results: TEM imaging of synthetic CPP revealed populations of amorphous spherical (prim. CPP) and larger crystalline spindle-shaped particles (sec. CPP). Exposure of RAW-264.7 cells to sec. CPP resulted in a dose-dependent increase in the expression of pro-inflammatory cytokines IL-6, IL-1β, MCP-1 and TNF-α. IL-10 expression was unaffected by sec. CPP exposure. In contrast, no inflammatory response was detected upon exposure to prim. CPP. Inhibition of TLR-4, NF-κB and NLRP3 pathways reduced the sec. CPP-induced inflammatory response in RAW-264.7 cells.

Conclusions: Sec., but not prim. CPP induce pro-inflammatory cytokine expression in the macrophage and this effect may be mediated by activation of TLR-4/NF-κB and NLRP3 pathways. CPP-II might be involved in the induction and maintenance of the chronic inflammatory state commonly encountered in CKD patients.

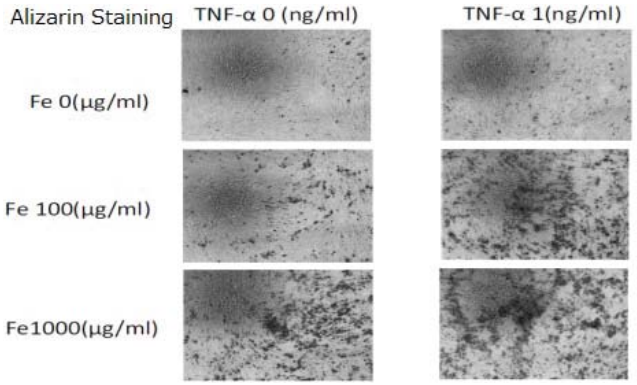
Iron Stimulation Enhanced Calcification in Vascular Smooth Muscle Cells

Sayuri Kawada,[1] Yasuyuki Nagasawa,[1] Mutsuki Kawabe,[2] Aritoshi Kida,[1] Mana Yahiro,[1] Yukiko Hasuike,[1] Takahiro Kuragano,[1] Hideki Ohyama,[2] Keiji Nakasho,[2] Takeshi Nakanishi.[1] *[1]Internal Medicine, Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Japan; [2]Dept of Pathology, Hyogo College of Medicine, Nishinomiya, Japan.*

Background: In CKD patients, atherosclerosis is one of important key factors which determine their prognosis. It was reported the calcification induced by TNF-alpha was related with iron in HUVEC cells by our group (Nanami-M, et al, Atreriscler Thromb Vasc Biol, 2005). The feature of the atherosclerosis in CKD patients was called as Moenckeberg's arterisclerosis which was seen in vascular media. To reveal the relationship between calcification in vascular media and iron stimulation using vascular smooth muscle cells.

Methods: The aorta smooth muscle cells were cultured for three weeks. At day 0, we changed the usual culture medium to calcification medium, and TNF-alpha and iron were added to the calcification medium. Calcification in each condition was confirmed by Alizarin staining. And to reveal early mechanism to enhance the calcification by iron and TNF-alpha stimulation, we compared the gene expression profile between each condition in day 1 and day 3 using microarray analysis.

Results: We confirmed both iron TNF-alpha stimulation enhanced calcification by Alizarin Staining. Moreover iron TNF-alpha stimulation at the same time enhanced calcification more strongly than single stimulation (shown below).



There were several gene expressions which increases more than 45 times one day after iron stimulation, such as CABS1,OR10V1, FBP2, CRAMP1L.

Conclusions: Iron stimulation enhanced calcification in vascular smooth muscle cells along with TNF-alpha stimulation. The mechanism of this calcification seemed to begin from early phase through gene expression changes.

SA-PO037

Adiponectin: A Novel Regulator of Calcium and Phosphate Balance?

Joseph M. Rutkowski, Orson W. Moe, Philipp Scherer. *The Univ of Texas Southwestern Medical Center, Dallas, TX.*

Background: Mineral homeostasis is a key factor in chronic cardiovascular disease and osteoporosis with the kidney at the center of a complex interplay of hormones regulating calcium and phosphate storage, excretion, and uptake. Adiponectin is an important adipose tissue-derived hormone in energy homeostasis; it has also been characterized as cardioprotective, but is potentially detrimental in osteoporosis through osteoclast activation. Several recent studies have identified adiponectin to be renoprotective in the restoration of renal function following injury.

Methods: We sought to identify how adiponectin regulates renal calcium and phosphate homeostasis in adiponectin knockout (ADN-KO), wildtype, and adiponectin overexpressing transgenic (ADN-Tg) mice.

Results: At baseline, ADN-KO mice exhibited lower serum Ca^{2+} levels, lower urinary Ca^{2+}excretion (UCaV), and lower fractional excretion of Ca^{2+} (FECa). In contrast, ADN-Tg mice showed the opposite with increased serum Ca^{2+}. A 2 month 2% phosphate enriched diet challenge resulted in many changes that diversified across adiponectin levels. While we observed increases in serum PTH, 1,25-vitamin D, and FGF23 and decreases in secreted klotho in all mice, ADN-Tg mice were "hyper-responsive" exhibiting 2-fold higher serum FGF23 levels and a concomitant increase in FEPi. Similar to their baseline state, these mice had higher UCaV and FECa with Pi-enriched diet. In contrast, ADN-KO mice exhibited a significantly smaller increase in both phosphaturic hormones; PTH levels were half those of wildtype mice; FGF23 levels were also significantly less. Chronic Pi loading also induced interstitial fibrosis with increased susceptibility in ADN-KO mice. Removal of the Pi-enriched diet for one month restored hormones and clearance to near baseline values for all mice. ADN-Tg mice exhibited the greatest decrease in histologic fibrotic area.

Conclusions: Adiponectin plays a role in hormonally regulating calcium and phosphate homeostasis and exerts protective effects from a fibrotic challenge. This highlights the importance of adipokines in kidney and cardiovascular disease and has potentially identified a new mechanism by which adiponectin regulates bone mass.

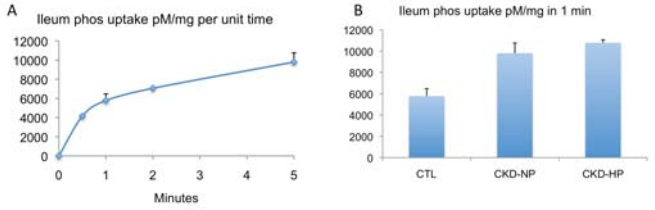
Passive Gut Phosphate Absorption Is Increased in CKD Mice

Wei Ling Lau,[1] Sogol Pahlevan,[1] Kamyar Kalantar-Zadeh,[1] Cecilia M. Giachelli,[2] Nosratola D. Vaziri.[1] *[1]Nephrology, UC Irvine; [2]Bioengineering, U Washington.*

Background: Dietary phosphate absorption occurs by sodium-dependent active uptake (Npt-2b transporter) or passive diffusion (paracellular pathways). Chronic gut inflammation with breakdown of intercellular tight junctions is present in CKD and is a likely source of systemic inflammation. The potential impact of this gut inflammation on phosphate uptake has not been explored. We used an *in situ* gut loop assay to measure active and passive phosphate uptake in the ileum of CKD and control mice.

Methods: CKD was induced in adult mice via adenine diet x18 days. Mice were then placed on normal 0.5% (NP) or high 1.5% (HP) phosphate diet for 6 weeks. Mice were re-exposed to adenine diet x1 week in the midst of special phosphate diet to maintain CKD. Under isoflurane anesthesia, 2.5 cm ileum loops (with intact blood supply) were created and injected with sodium- or choline-phosphate buffer radiolabeled with P-33. Phosphonoformic acid (Npt-2b inhibitor) was added to the choline-phosphate buffer to ensure exclusion of Npt-2b active transport. Amount of absorbed phosphate, normalized to mg protein, was calculated after timed incubation. Adjacent ileum tissue was processed for histology and Western blot.

Results: Passive phosphate uptake (measured with sodium-free buffer) in the ileum of control mice plateaued after 1-minute incubation (Figure A). Active transport was less than passive uptake and sometimes measured out as a negative value, suggesting efflux transport into the gut lumen. CKD mice on NP and HP diet (n=4 per group) showed increased passive phosphate uptake compared to controls (Figure B, P<0.05). Histology showed influx of macrophages in the CKD ileum wall, and expression of the tight junction protein claudin-2 was significantly decreased.



Conclusions: Passive phosphate uptake is increased in the gut of CKD mice and may contribute to systemic phosphorus overload.

Small Returns for Big Investment: CKD-MBD Therapy from 2005 to 2013

Katrina Chau,[1] Lee Er,[2] Ognjenka Djurdjev,[2] Adeera Levin.[1] *[1]Div of Nephrology, Univ of British Columbia, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada.*

Background: Although significant resources are devoted towards the control of phosphorus (Pi), calcium (Ca) and parathyroid hormone (PTH) in dialysis patients as treatment for chronic kidney disease–mineral bone disorder (CKD-MBD), there is a deficiency of evidence supporting this practice. We aimed to describe the trends in Pi, Ca, PTH in a prevalent dialysis cohort following the introduction of non-calcium based phosphate binders (NCBPB)–sevelamer (year introduced into formulary:2002) and lanthanum (2007) – and cinacalcet (2006).

Methods: An observational cohort study was conducted on 7645 patients receiving dialysis in British Columbia (BC) from 2005–2013 entered into the PROMIS (Patient Records and Outcome Management Information System) database. Demographic, clinical, medication and laboratory data were obtained from the database. All results of laboratory investigations performed for these patients within BC were automatically uploaded into PROMIS. Target ranges of Ca, Pi and PTH were defined according to the 2009 KDIGO (Kidney Disease Improving Global Outcomes) guidelines.

Results: Phosphate binders (PB) of any kind were used by 86–91% of the population. 18–21% were prescribed NCBPB/cinacalcet +/- conventional PB. Pi was unchanged over the study period (p=0.77). There was a decrease in Ca of 0.01 mmol/L per year (95% CI=-0.02 – -0.001, p=0.03) and increase in log(PTH) of 0.04 per year (95% CI = 0.03–0.04,

p<0.001). There was no significant change in % of patients within target range of Pi (OR=1.01, 95% CI = 0.99–1.02, p=0.09) or PTH (OR=1.01, 95% CI=0.99 – 1.02, p=0.05) but patients were less likely to have low PTH (OR=0.93, 95% CI=0.92 – 0.95, p<0.001). Patients within target range of Ca decreased (OR=0.97, 95% CI=0.96–0.98, p<0.001) and patients were less likely to be hypercalaemic (OR=0.95, 95% CI=0.92–0.98, p=0.005).

Conclusions: Following prescription of new treatments for CKD-MBD there has been a reduction of patients with high Ca and low PTH. However, the proportion of patients reaching target ranges for Pi and PTH is unchanged. These data bring into question the utility of these costly therapies.

SA-PO040

Mineral Metabolism and Outcomes in Long-Term Kidney Transplantation Sinee Disthabanchong. *Div of Nephrology, Dept of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ, Phayathai, Bangkok, Thailand.*

Background: In non-dialysis chronic kidney disease and chronic dialysis populations, phosphate retention, increased PTH and FGF-23 levels, and 25-hydroxyvitamin D deficiency predict future patient outcomes including ESRD and mortality. The relationships between mineral metabolism and outcomes in long-term kidney allograft recipients have not been extensively studied. This is a prospective cohort study that examined the relationship between mineral parameters and the composite outcome of allograft loss and mortality in long-term kidney allograft recipients.

Methods: Two hundred twenty nine kidney allograft recipients from Ramathibodi Hospital, Mahidol University, Bangkok, Thailand who were at least 1 year post-transplantation were enrolled between March, 2009 to January, 2010. Demographic and laboratory data including serum calcium, phosphate, intact PTH, c-terminal FGF-23 and 25-hydroxyvitamin D were collected at baseline. The composite outcome of allograft loss and mortality were followed until February 2013.

Results: The median follow-up time was 38 months. Thirteen patients died and 16 patients lost the allograft. In univariate Cox regression analyses, increased systolic blood pressure, deceased donor transplantation, increased serum phosphate, FGF-23 and PTH and decreased 25-hydroxyvitamin D were associated with the outcome. There was no association between serum calcium and the outcome. After adjustment for cardiovascular risk factors and other mineral parameters, the highest tertile of serum phosphate, FGF-23 and PTH remained significantly associated with the outcome. However, these associations were lost after further adjustment for allograft function (eGFR).

Conclusions: In conclusion, increased serum phosphate, PTH and FGF-23 predict future outcome of allograft loss and mortality in long-term kidney allograft recipients.

SA-PO041

Serum Phosphorus and Prevalence of Cardiovascular Disease within a Large, Diverse CKD Population Dean A. Kujubu, In-Lu Amy Liu, Michael Batech, John J. Sim. *Nephrology and Hypertension, Kaiser Permanente LAMC, Los Angeles, CA.*

Background: Elevated serum phosphorus has been associated with greater morbidity and mortality among ESRD patients. We sought to determine whether incremental increases in serum phosphorus are associated with prevalent cardiovascular disease across the spectrum of eGFR from the large, diverse population of Kaiser Permanente Southern California (KPSC).

Methods: A cross sectional study of KPSC members age >/= 18yrs was conducted during 1/1/1999 - 12/31/2009. Individuals w 1yr continuous membership who had serum phosphorus and eGFR determinations were included. Dialysis and transplants excluded. The cohort was stratified by eGFR (>89ml/min, 60-89, 30-59, and < 30). Coronary artery disease (CAD), congestive heart failure (CHF), and cerebrovascular accident (CVA) were identified using inpatient and outpatient ICD9 codes. The primary outcome was risk for combined cardiovascular disease. Subsequent analysis examined each individual outcome separately stratified by eGFR. Multivariable logistic regressions used to calculate odds ratio's after adjusting for age, gender, race, and Charlson Comorbidity Index.

Results: 195,097 individuals were identified in the study cohort. There was no association between every 0.5 mg/dl increment in serum phosphorus and risk of the combined cardiovascular diseases across all eGFR strata (Table 1), though there was a higher risk for CHF. For eGFR >89 ml/min. every 0.5 mg/ml of phosphorus increased risk for combined cardiovascular disease. For all other categories of eGFR, there was no significant risk of either combined or individual cardiovascular prevalence with higher serum phosphorus.

All GFR		OR	95% CI
	Combined	0.99	0.92-1.07

	CHF	1.07	0.96-1.19
	CAD	0.951	0.86-1.06
	CVA	0.874	0.67-1.14

Conclusions: In a large, diverse population, we did not observe increased risk of prevalent CAD, CHF, and CVA with higher serum phosphorus levels among individuals with eGFR<89ml/min. Whether phosphorus binder use will modify these results remains to be seen.

SA-PO042

Serum Phosphorus May Be an Incomplete Surrogate Endpoint for the Prediction of a Phosphate Binder's Impact on Mortality in Non-Dialysis-Dependent Chronic Kidney Disease Lisa Bernard,[1] Elizabeth S. Dunn,[2] Daniel Grima.[1] *[1]Cornerstone Research Group Inc., Burlington, ON, Canada; [2]Consultant to Cornerstone Research Group Inc., Brookline, MA.*

Background: Surrogate endpoints are often used to predict the effect of a therapy on final clinical outcomes such as survival, when clinical outcomes are rare and/or occur over a long time period. Serum phosphorus (SP) has been used as a surrogate endpoint in the clinical and health economic assessment of phosphate binders for treatment of hyperphosphatemia in non-dialysis dependent chronic kidney disease (NDD-CKD). The objective of this study was to assess the ability of SP to predict the difference in survival between sevelamer and calcium-based binders (CBBs).

Methods: The hazard ratio (HR) for mortality over three years associated with sevelamer compared to CBBs from the INDEPENDENT CKD Study (Di Iorio, 2012) was compared to the HR produced by a published model that predicts mortality based on SP levels. This model used previously published data on the association between SP and mortality.

Results: Modeling via the surrogate endpoint of SP underestimated the survival benefit associated with sevelamer relative to CBBs compared to empirically measured survival reported in the INDEPENDENT CKD study. The calculated HR based on SP was 0.84 compared to the observed HR of 0.36 [95% CI 0.0.15-0.83]) (Di Iorio, 2012).

Conclusions: Based on this comparison of the INDEPENDENT CKD Study and a model of SP and mortality risk, SP may be an incomplete surrogate endpoint for predicting the effect of phosphate binders on survival in NDD-CKD patients. The discrepancy could be due to several factors, including sevelamer's previously demonstrated benefits beyond SP control, such as attenuation of coronary calcification and reduction of low-density lipoprotein (LDL) cholesterol, which may positively impact clinical outcomes. Unless phosphate binder trials measure mortality directly, further work is warranted to develop a multivariate predictive model for survival in NDD-CKD.

SA-PO043

Increased Infection-Related Mortality in Dialysis Patients with Low Serum Phosphorus Level: A Prospective Multicenter Cohort Study Ji-Eun Lee,[1,2] Jang-Hee Cho,[1,2] Hye Min Jang,[1,2] Yon Su Kim,[1,3] Shin-Wook Kang,[1,4] Chul Woo Yang,[1,5] Eugene Kwon,[1,2] Jeung-Min Park,[1,2] Hee-Yeon Jung,[1,2] Ji-Young Choi,[1,2] Sun-Hee Park,[1,2] Chan-Duck Kim,[1,2] Yong-Lim Kim.[1,2] *[1]Clinical Research Center for End Stage Renal Disease (CRC for ESRD) in Korea; [2]Kyungpook National Univ; [3]Seoul National Univ; [4]Yonsei Univ; [5]The Catholic Univ of Korea.*

Background: It remains unknown whether mineral metabolism parameters are associated with infection-related death. This study investigated the effect of the serum calcium and phosphorus level on the infection-related mortality in dialysis patients.

Methods: Maintenance patients on hemodialysis and peritoneal dialysis were enrolled from a multicenter prospective cohort study in Korea. The patients were divided into low, normal, and high groups according to their serum calcium or phosphorus levels. Cox proportional analysis was used to calculate hazard ratios(HRs) for the association of serum calcium and phosphorus levels with all-cause, infection-related and cardiovascular-related death. Time-dependent values of calcium and phosphorus were also evaluated to assess the effect of longitudinal change in mineral metabolism parameters on various mortalities.

Results: A total of 3,226 dialysis patients were followed up for mean 19.8 ± 8.2 months. The patients with baseline low phosphorus level showed significantly increased infection-related death compared to patients with normal phosphorus level (HR = 1.75, confidence interval [CI] = 1.08-2.83, p = 0.024). The low phosphorus level was also significantly associated with all-cause and infection-related death using time-dependent values (HR =

1.48, CI = 1.11-1.97, p = 0.008 and HR = 1.83, CI = 1.13-2.96, p = 0.014, respectively). However, the baseline and time-dependent calcium levels were not related with infection-related mortality. Serum phosphorus was correlated with nutritional factors such as serum albumin, creatinine, and body mass index.

Conclusions: Low serum phosphorus in maintenance dialysis patients was an independent risk factor for infection-related death. Persistently low serum phosphorus levels might be a nutritional biomarker to predict the susceptibility to infection and in turn worse outcomes in dialysis patients.

Inorganic Phosphate Handling in Salivary Glands Kayo Ikuta, Hiroko Segawa, Shohei Sasaki, Ichiro Kaneko, Yuji Shiozaki, Sawako Tatsumi, Ken-Ichi Miyamoto. *Molecular Nutrition, Institution of Health Bioscience, Univ of Tokushima Graduate School, Tokushima, Japan.*

Background: Hyperphosphatemia is contributes to vascular calcification in patients with chronic kidney disease and hemodialysis patients and is associated with cardiac mortality. Recently, several studies reported the relationship among salivary phosphate concentration, renal function, serum phosphate concentration, and the potential target of new therapy for hypephosphatemia. However, it is unclear the inorganic phosphate (Pi) handling mechanisms in salivary glands. In the present study, we investigated the Pi handling in salivary glands using several models mice.

Methods: Normal C57B6J mice, type II sodium-phosphate (NaPi) transporters knockout (KO) mice; NaPi-2a KO, NaPi-2c and NaPi-2a/NaPi-2c double KO (DKO) mice, and X-linked hypophosphatemia hypophosphatemic (Hyp) mice were used. Mice fed several phosphorus-modified diet, or administered fibroblast growth factor (FGF) 23 and parathyroid hormone (PTH) were used. We examined Pi concentration in saliva and urinary Pi excretion, and transporter expression.

Results: Hypophosphatemic Npt2a KO and Npt2a/Npt2c DKO mice did not show a reduction of salivary Pi concentration. Hyp mice showed hypophosphatemia, but not the reduction of salivary Pi levels. Furthermore, FGF23 and PTH lowered plasma Pi levels, but not saliva.In mice fed a high phosphorus diet, salivary Pi and urinary Pi excretion levels were significantly higher than in those fed the low Pi diet. Furthermore, high Pi diet, but not FGF23 and PTH, decreased the NaPi-2b expression levels, which localized at the apical side of duct cells.

Conclusions: The present study suggests that salivary Pi levels correlate with dietary Pi content, but not plasma Pi.

Funding: Government Support - Non-U.S.

Relationship between Timed Urine and Spot Urine Collections for Measurement of Phosphate Excretion Sven-Jean Tan,[1,2] Michael Cai,[1,2] Eugenia Pedagogos,[1] Edward Robert Smith,[1,3] Stephen G. Holt,[1,2] Timothy Hewitson,[1,2] Nigel David Toussaint.[1,2] *[1]Dept of Nephrology, The Royal Melbourne Hospital, Parkville, Victoria, Australia; [2]Dept of Medicine (RMH), The Univ of Melbourne, Parkville, Victoria, Australia; [3]Monash Univ, Clayton, Victoria, Australia.*

Background: Twenty-four hour UPE reflects intestinal phosphate absorption in steady state and can be used to evaluate effects of phosphate-lowering interventions. UPE may be more informative than serum phosphate(sPi) in assessing phosphate homeostasis. However, timed urine collections are cumbersome and prone to inadequate collection. Spot uPiCr assessment may be a useful, simple surrogate for UPE, but is yet to be systematically evaluated in CKD. **Aim:**To determine the relationship between spot urine phosphate:creatinine ratio(uPiCr) and total urinary phosphate excretion(UPE) in chronic kidney disease(CKD) patients.

Methods: Blood samples, spot and 24-hour urine were collected from patients with CKD(Stages 1-5). Serum biochemistry was analysed. Urine phosphate concentration(uPi) and creatinine concentration measurements were performed on spot and 24-hour urine collections. Pearson's correlation coefficients, multiple regression analysis and Bland-Altman plots were used to assess agreement between spot uPiCr and UPE.

Results: 65 CKD patients (49 male) were studied, median age 67yrs (IQR 53-74) and mean(±SD) serum creatinine 182(±84)µmol/L. Mean(±SD) spot uPi, spot uPiCr and total UPE were 12.6(±6.2)mmol/L, 1.58(±0.55)mmol/mmol and 24.5(±11.7)mmol/d respectively. There was no significant correlation between spot uPiCr and UPE (r=0.116, p=0.336). Spot uPi correlated with 24-hour UPE significantly (r=0.306, p=0.019). Bland-Altman analysis of 24-hour versus spot uPi showed acceptable agreement with bias +0.2mmol/L(95%CI -1.2284 – 1.6508). Multiple regression analysis was undertaken to predict UPE from gender, sPi, spot uPi and eGFR. Apart from eGFR, these variables significantly predicted UPE, $F(3,51)$=5.321, p=0.003, R^2=0.238. Gender, sPi and spot uPi added significantly to the prediction, p<0.05.

Conclusions: This study suggests that normalisation of uPi to uCr on spot urine samples may not be appropriate when evaluating urinary phosphate excretion in adults with CKD.

SA-PO046

Parameters of Phosphorus Homeostasis at Normal and Reduced GFR Kenneth R. Phelps,[1,2] Darius Mason.[1,2,3] *[1]Stratton VAMC, Albany, NY; [2]Albany Medical College, Albany, NY; [3]Albany College of Pharmacy and Health Sciences, Albany, NY.*

Background: At equilibrium, influx (I_P) determines urinary excretion of phosphorus (E_P). Contributions of I_P and reabsorption (TR_P) to serum P ($[P]_s$) can be depicted by normalization to C_{cr} (E_P/C_{cr} and TR_P/C_{cr}) or by fractional excretion and reabsorption of P (FE_P and FTR_P). We analyzed $[P]_s$, E_P/C_{cr}, TR_P/C_{cr}, FE_P, and FTR_P at normal and reduced GFR.

Methods: We measured [cr] and [P] in fasting morning serum and urine in 28 controls (C) and 29 patients with stages 3-4 CKD. We calculated E_P/C_{cr} as $[cr]_s([P]_u/[cr]_u)$, TR_P/C_{cr} as $[P]_s - E_P/C_{cr}$, FE_P as $(E_P/C_{cr})/[P]_s$, and FTR_P as $1 - FE_P$. We compared means and examined pertinent linear regressions.

Results: $[P]_s$ was not different in CKD and C. $[Cr]_s$, E_P/C_{cr}, and FE_P were higher and TR_P/C_{cr} and FTR_P were lower in CKD. $[P]_u/[cr]_u$, a surrogate for I_P, was similar in both groups. In CKD, $[P]_s$ correlated with E_P/C_{cr} and TR_P/C_{cr}; E_P/C_{cr} with $[P]_u/[cr]_u$ and $[cr]_s$; and FE_P with E_P/C_{cr}, TR_P/C_{cr}, $[P]_u/[cr]_u$, and $[cr]_s$. In C, $[P]_s$ correlated with TR_P/C_{cr}; E_P/C_{cr} with $[P]_u/[cr]_u$; and FE_P with E_P/C_{cr} and $[P]_u/[cr]_u$. Despite wide ranges of TR_P/C_{cr}, FTR_P was > 80% in 26 of 28 C and < 80% in 27 of 29 CKD.

Group	CKD (n=29)	C (n= 28)	P	Group	CKD (n=29)*	C (n = 28)	
Parameter	Mean (SEM)	Mean (SEM)		Regression	R^2	R^2	P
$[P]_s$, mg/dL	3.7 (0.2)	3.4 (0.1)	0.27	$[P]_s$ on E_P/C_{cr}	0.52	0.046	0.27
$[P]_u/[cr]_u$	0.52 (0.02)	0.48 (0.03)	0.35	$[P]_s$ on TR_P/C_{cr}	0.37	0.95	<0.001
$[cr]_s$, mg/dL	2.5 (0.2)	0.9 (0.03)	<0.001	E_P/C_{cr} on $[P]_u/[cr]_u$	0.48	0.81	<0.001
E_P/C_{cr}, mg/dL	1.4 (0.1)	0.4 (0.03)	<0.001	E_P/C_{cr} on $[cr]_s$	0.74	0.03	0.38
TR_P/C_{cr}, mg/dL	2.3 (0.1)	3.1 (0.1)	<0.001	FE_P and FTR_P on E_P/C_{cr}	0.71	0.81	<0.001
FE_P, %	36.5 (2.3)	12.1 (0.9)	<0.001	FE_P and FTR_P on TR_P/C_{cr}	0.34	0.12	0.07
FTR_P, %	63.5 (2.3)	87.9 (0.9)	<0.001				

*P < 0.001 for all regressions.

Conclusions: GFR affected parameters of P homeostasis. E_P/C_{cr} varied with influx ($[P]_u/[cr]_u$) and GFR ($[cr]_s$) in CKD, but with influx only in C. $[P]_s$ varied with influx (E_P/C_{cr}) and reabsorption (TR_P/C_{cr}) in CKD, but with reabsorption only in C. FE_P varied with influx (E_P/C_{cr}) and reabsorption (TR_P/C_{cr}) in CKD, but with influx only in C. FTR_P depicted reabsorption imprecisely in CKD and C.

SA-PO047

Phosphorus Clearance Is Associated with Mineral Metabolic Parameters in Peritoneal Dialysis Patients Yongjin Yi, Hajeong Lee, Dong Ki Kim, Yon Su Kim, Kwon Wook Joo, Jin Suk Han, Curie Ahn, Kook-Hwan Oh. *Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: The present study was undertaken in order to explore the influence of phosphorus (P) clearance on the serum P level and other mineral metabolic parameters in the peritoneal dialysis (PD) patients.

Methods: In this cross-sectional study, measurements of dialysis adequacy and P clearance conducted between April 2013 and May 2014, were collected. The impact of P clearance on the serum P levels, and other parameters such as heart-to-femoral pulse wave velocity (hfPWV) and abdominal aortic calcification score (AAC) were analysed by using multiple linear regression analysis.

Results: Among total 187 subjects, 110 were male and the age was 48.0 ± 14.7 years. Duration of PD was 48.0 ± 45.7 months and total Kt/V were 1.90 ± 0.48, respectively. 107 subjects had residual renal function. The mean peritoneal, renal and total P clearances (PPhCl, RPhCl and TPhCl) were 35.3 ± 13.4, 11.7 ± 17.8 and 47.0 ± 18.9 L/week/1.73m^2, respectively. In multiple linear regression analysis, serum P level was associated with TPhCl (β= -0.019 ± 0.005, p<0.001), non-calcium based P binder uses (β= 1.136 ± 0.222, p<0.001) and age (β= -0.016 ± 0.007, p=0.022, r^2 = 0.240). However, neither PPhCl nor UPhCl was associated with the serum P level. Aortic stiffness, represented by hfPWV, was only associated with conventional risk factors such as age (β= 9.840 ± 1.636, p<0.001) and presence of diabetes (β= 295.988 ± 55.970, p<0.001, r^2 = 0.393). In case of vascular calcification, AAC score was also associated with conventional factors such as age (β= 0.107 ± 0.024, p<0.001), diabetes (β= 2.902 ± 0.851, p=0.001), duration of PD (months, β= 0.028 ± 0.008, p=0.001), and male gender (β= 1.645 ± 0.681, p=0.017, r^2 = 0.368). Neither hfPWV nor AAC score was associated with P clearance.

Conclusions: In PD patients, total phosphorus clearance, non-calcium based P binder and age were independently associated with the serum P level. Total P clearance accounted for the serum P level more than Kt/V, D/P creatinine ratio, and creatinine clearance. Monitoring P clearance may be warranted for the adequate control of mineral metabolic parameters in PD patients.

Potential Therapeutic Target for Hyperphosphatemia: Sulforaphane Reduces the Expression of the SLC34a2 Gene through Pregnane X Receptor

Lei Chen, Hongli Jiang. *Dialysis Center of First Affiliated Hospital of Medicine School, Xi'an Jiaotong Univ, Xi'an, Shaanxi Province, China.*

Background: NaPi-IIb sodium-dependent phosphate transporter protein, which is encoded by SLC34 gene, plays a dominant role in intestinal phosphorus absorption. The suppression of SLC34 gene expression leads to the reduction of intestinal phosphorus absorption. Therefore, SLC34a2 gene provides a potential therapeutic target for hyperphosphatemia. Previous research also indicates that pregnane X receptor (PXR) is the transcription factor of SLC34a2 gene, which can increase the expression of SLC34a2 gene. On the other hand, sulforaphane (SFN) is the antagonist of pregnane X receptor (PXR), which can suppress the activity of PXR. The objective of this paper is to demonstrate that SFN reduces the expression of SLC34a2 gene through PXR.

Methods: The human colon cancer cell LoVo was selected as its both PXR mRNA and SLC34a2 mRNA expression level were high. In the first stage, LoVo cells were incubated with SFN at a series of concentrations in DMEM (0, 10, 25μmol/ml) for 24[thinsp]h. Then the agonist of PXR, rifampin (RFP), was added into the medium for 24h before SLC34a2 mRNA extraction. Quantitative RT-PCR was conducted to evaluate the expression of SLC34a2 mRNA. In the second stage, the expression of PXR was knocked down by an anti-PXR siRNA. After that, SFN was injected into the PXR-knockdown stable LoVo cells. The SLC34a2 expression level was compared in three groups: the PXR-knock down cells with SFN, the PXR-knock down cells without SFN and the normal cells without SFN.

Results: For the first stage, it was observed that cells treated by SFN showed low expression of SLC34a2 mRNA. Moreover, the expression of SLC34a2 mRNA decreased as concentration of SFN increased. For the second stage, the results showed that PXR-knockdown cells expressed much lower level of SLC34a2 mRNA than that of normal cells. In addition, the gene expression in PXR-knockdown cells with SFN was lower than that of PXR-knockdown cells without SFN.

Conclusions: In conclusion, our study demonstrated that SFN reduced the expression of SLC34a2 gene through its suppressive effect on the activity of PXR. In addition, the effects of SFN was concentration-dependent.

SA-PO049

A Novel, Plant-Derived Natural Polymer, VS-505, Is a Non-Absorbed, Calcium- and Aluminum-Free, Highly Effective Phosphate Binder

J. Ruth Wu-Wong, Yung-Wu Chen, Jerry Wessale. *Vidasym, Chicago, IL.*

Background: Inadequate control of serum phosphate in chronic kidney disease can lead to pathologies of clinical importance. Effectiveness of on-market phosphate binders is limited by safety concerns and low compliance due to high pill size/burden and gastrointestinal discomfort.

Methods: VS-505, a non-absorbed, calcium- and aluminum-free, chemically-modified, plant-derived polymer, was evaluated for its efficacy and potential side effects in various studies including chronic dosing (1 month) in 5/6 nephrectomized (NX) uremic SD rats.

Results: In vitro studies show that VS-505 has a high density (density by helium pycnometer: 1.95 versus 1.27 g/cm^3 for sevelamer) and a low swell volume when exposed to simulated gastric fluid (0.4 versus 4 cm^3/0.1g for sevelamer). VS-505 binds phosphate within a wide physiologically relevant pH range, enabling it to bind phosphate along much of the GI tract. Results from drug-drug-interaction studies show that VS-505 exhibits minimal interaction with enalapril, ciprofloxacin, digoxin and warfarin. In 5/6 NX uremic SD rats on high-phosphate diet, increasing dietary phosphate led to an increase in serum phosphate, which was prevented in rats treated with VS-505 or sevelamer (0.2 - 5% in food). Urinary phosphate increased from 67 ± 40 at Week 0 to 932 ± 108 μmol/24 hr at Week 4 ($p<0.001$) in the vehicle-treated group; VS-505 or sevelamer (0.2 - 5% in food) reduced urinary phosphate in a dose-dependent manner (to 40 ± 7 and 54 ± 9 μmol/24 hr for 5% VS-505 at Week 2 and 4, respectively). High phosphate diet also increased serum FGF-23 and parathyroid hormone in 5/6 NX rats, which was prevented by VS-505 or sevelamer. VS-505 or sevelamer increased fecal phosphate in a dose-dependent manner. More aortic calcification was observed in 5/6 NX rats treated with 5% sevelamer, while VS-505 and sevelamer did not show significant effects on cardiac parameters, fibrosis, intestine histology and intestinal sodium-dependent phosphate cotransporter gene expression.

Conclusions: These results strongly support the conclusion that VS-505, a high density plant-derived polymer, effectively controls phosphate imbalance in the uremic rats by adsorbing phosphate in the GI tract with minimal swell volume.

Serum Phosphate Intervention in Renal Replacement Therapy

Ramya Bhargava,[1] Paul E. Brenchley,[1] Philip A. Kalra,[2] Helen Hurst,[1] Alastair J. Hutchison.[1] *[1]Manchester Royal Infirmary, United Kingdom; [2]Salford Royal Hospital.*

Background: Although hyperphosphatemia is statistically associated with vascular calcification and decreased life span in observational studies (CKD 3-5d), no randomised controlled trials exist to prove cause and effect. The ideal target for serum phosphate (SPhos) in dialysis patients is unknown. We wished to assess the feasibility of a future large prospective multicentre RCT of 'lower range' versus 'higher range' control of SPhos in dialysis patients, to investigate clinical end-points including mortality.

Methods: Two centre, prospective RCT feasibility study, with titration to target (8 wks) then maintenance phase (10 mths). After a binder wash-out of 3 to 5 weeks, those whose SPhos rose to >1.7mmol/L at end of washout were randomized to lower range group (LRG) or upper range group (URG). LRG was titrated to SPhos 0.8-1.4mmol/L and URG to SPhos 1.8-2.4mmol/L using only non-calcium based binders. Outcomes include physician acceptance, number of patients screened and suitable, number consenting and ITT, separation of groups by SPhos, drop-out.

Results: 768 dialysis patients screened, 263 suitable, 202 approached, 131 consented (64.9%). 104/131 patients randomized at end of washout. 60 patients have completed 20 weeks follow-up

	SPhos LRG (median,IQR)	S Phos URG (median,IQR)	P
Randomisation	2.01 (1.87-2.32) N=29	2.03 (1.8-2.29) N=31	0.8
4 week	1.53 (1.17-2.01) N=29	1.96 (1.62-2.12) N=31	*0.05
8 week	1.67 (1.23-2.03) N=26, 3 withdrew consent	2.18 (1.71-2.48) N=30, 1 transplanted	*0.02
12 week	1.69 (1.39-2.25) N=25, 1 withdrawn - severe GI effects	1.95 (1.64-2.35) N=29, 1 death	0.3
16 week	1.65 (1.16-2.06) N=25	1.96 (1.34-2.22) N=27, 2 transplanted	0.39
20 week	1.46 (1.20-2.02) N=23, 1 transplanted, 1 death	1.87 (1.52- 2.1) N=26, 1 death	0.09

Table 1: Serum phosphate levels for LRG and URG. Mann-Whitney U test (data not all normally distributed)

Conclusions: A significant difference in SPhos was achieved by end of titration and maintained to week 20. It appears possible to establish and maintain 2 cohorts with separation by SPhos of 0.3 - 0.4 mmol/L. 12 month follow-up will enable feasibility assessment and power calculation for a future large multinational study.

Dietary Barley β-Glucans Markedly Attenuate Uremia- and High Phosphate-Induced Renal and Vascular Lesions in Experimental Kidney Disease

Anabel Castro,[1] M. Vittoria Arcidiacono,[1] Petya Valcheva,[1] Anna Cardus,[1] Maria Jose Motilva,[2] Adriana S. Dusso.[1] *[1]IRBLleida, Spain; [2]Lleida Univ, Spain.*

Background: In chronic kidney disease (CKD), systemic inflammation aggravates the renal and vascular aging causing high mortality rates. Increases in renal ADAM17 and in ADAM17 release of the pro-inflammatory cytokine TNFα contribute to CKD- and inflammation-driven Klotho loss, oxidative stress, damaged-DNA accumulation, and tissue lesions. In LPS-induced sepsis, specific silencing of monocyte ADAM17 to suppress TNFα release suffices to prevent fatal organ lesions. Since yeast β-glucans reduce LPS-driven lesions in normal rats, this study examined the efficacy of dietary barley β-glucans to attenuate uremia- and high phosphate (P)-induced renal damage and vascular calcification (VC).

Methods: Nephrectomized rats were fed a high P diet (0.9% P) with or without barley flour sufficient to provide 2mg of β-glucans/g diet, for a month. Immunohistochemistry measured tissue ADAM17, Klotho and cathepsin L (CTSL) content.

Results: Dietary β-glucans had no effect on body weight, serum P or Ca levels, but markedly reduced serum BUN ($p<0.05$), proteinuria ($p<0.001$), and the prevalence of aortic calcification (None (n=13) versus 36% (n=14)) despite marginally significant reductions in serum PTH (3107 versus 2044pg/ml; $p=0.06$). β-glucans renoprotection is partially accounted for by an effective attenuation of both, increases in renal ADAM17 ($p<0.001$) and Klotho loss ($p<0.01$), two contributors to CKD progression and VC. Furthermore, direct exposure to extracts of barley β-glucans effectively prevented LPS-induced increases in ADAM17 and oxidative stress (superoxide production) in the murine monocyte-macrophage cell line Raw264.7. In addition, in rat CKD, dietary β-glucans also attenuated renal and vascular increases in CTSL, a protease that contributes to the loss of podocyte filtration barrier causing proteinuria, and the accumulation of damaged DNA causing VC.

Conclusions: Dietary barley β-glucans effectively reduce oxidative stress, ADAM17 and CTSL expression and renal klotho loss thereby attenuating CKD- and high P-driven pro-inflammatory and pro-aging signals that cause renal and vascular lesions.

SNPs Associated with Serum Phosphorus Concentration in Japanese

Misaki Katsumoto,[1] Michiyo Yamasaki,[1] Yutaka Taketani,[1] Hisami Okumura,[1] Hironori Yamamoto,[2] Eiji Takeda.[1] *[1]Dept of Clinical Nutrition, Univ of Tokushima, Tokushima, Japan; [2]Dept of Health and Nutrition, Jin-ai Univ, Echizen, Fukui, Japan.*

Background: Previous GWAS study has identified 7 SNPs associated with serum phosphorus (P) concentration in European ancestries. Here, we investigated whether the associations can be similary found in Japanese population.

Methods: We investigated 85 young healthy Japanese (45 men and 40 women, 21 to 34 years old). Blood samples were collected in the morning fasting and measured serum level of P, intact-PTH (iPTH), FGF23, and soluble alpha-klotho (s-klotho). In addition, we also investigated the effect of genotype on phosphatemic response after high P diet (1200 mg P/

meal). Subjects were genotyped by TaqMan SNP genotyping assay for 7 SNPs as previously described (rs1697421, rs17265703, rs4074995, rs9469578, rs453639, rs947583, rs2970818).

Results: In our population, subjects with AA genotype in rs1697421 trended to be higher serum P level in men (p=0.06) than those with GG genotype. Subjects with TT genotype in rs9469578 were significantly higher serum P level than those with CT genotype (p<0.05). Conversely, no significant relationship was observed between serum P concentration and other SNPs. We also found that subjects with AC genotype in rs453639 showed significantly higher increase in serum P level after the ingestion of high P diet than those with AA genotype (p<0.05).

Conclusions: Our study suggests that rs1697421 located adjacent to the tissue-nonspecific ALP gene and rs9469578 located in inositol hexakisphosphate kinase 3 genes can be possible genetic factor to determine fasting serum P level in Japanese population as well as European ancestries. In addition, rs453639 located adjacent to ectonucleotide pyrophosphatase/ phosphodiesterase 3 gene may be associated with phosphatemic response after the ingestion of high P diet.

Funding: Government Support - Non-U.S.

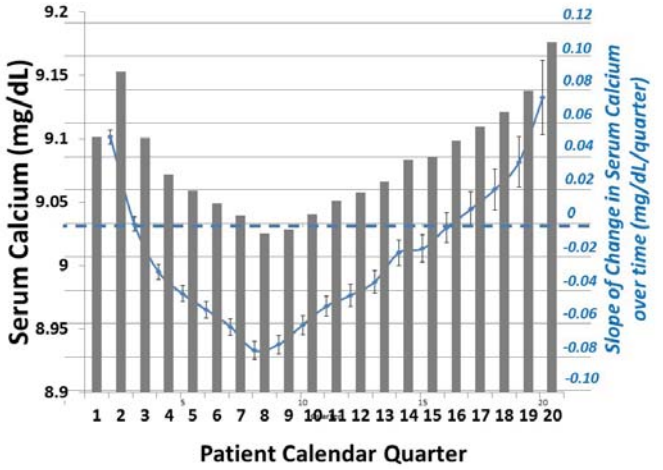
Time-Varying Trends in Serum Calcium over 5-Years in 135,854 Incident Dialysis Patients

Wei Ling Lau,[1] Rajnish Mehrotra,[2] Elani Streja,[1] Vanessa A. Ravel,[1] Joline L.T. Chen,[1] Connie Rhee,[1] Maryam Taheri,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]Univ California Irvine, Harold Simmons Center, Orange, CA; [2]Univ Washington, Renal, Seattle, WA; [3]Univ Tennsessee, Renal, Memphis, TN.*

Background: Serum calcium (Ca) may change over time upon transition to renal replacement therapy given impact of dialysis therapy, dietary regimens, and medications. We hypothesized that serum Ca shows an upward tendency over time independent of secular trends.

Methods: We examined changes in serum Ca for up to 5 yrs in 135,854 incident dialysis patients (125,892 HD and 9,779 PD) who initiated therapy between 2007-2011 in one of the clinics of a large dialysis organization across the U.S.A. We examined mean serum Ca in each patient quarter (91-day increments) from the day of transition to dialysis for up to 20 quarters and calculated the rate of change in serum Ca from the first quarter to the nth quarter using time-varying mixed models.

Results: The 135,854 incident dialysis patients were 61±15 yrs old and included 43% women, 30% African Americans, 14% Hispanics, and 57% diabetics. Mean serum Ca (±SD) at the start of dialysis (Qtr 1) was 9.10±0.56 mg/dL, peaking at 9.15±0.54 mg/dL during the 2nd qtr, followed by consistent drop for the next 7 qtrs and reaching a nadir of 9.02±0.55 mg/dL in the 8th qtr. There was subsequently an upward trend reaching 9.17±0.65 mg/dL in the 16th qtr. The slope of change in rate of serum Ca change showed a similar downward trend for the first 2 yrs followed by an upward trend.



Conclusions: After an initial rise in serum Ca in the first few months of transition to dialysis, we observed a consistent drop in serum Ca for the first 2 yrs followed by a consistent rise in serum Ca from Year 3 to 5. The discovery of this complex pattern of changes in serum Ca over time and its potential impact on patient outcomes warrants additional studies.

Serum Calcium Reductions among Patients on Hemodialysis Initiating Cinacalcet

Steven M. Brunelli,[1] Paul Dluzniewski,[2] Kerry Cooper,[2] Thy P. Do,[2] Scott Sibbel,[1] Brian D. Bradbury.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Amgen Inc, Thousand Oaks, CA.*

Background: Cinacalcet lowers parathyroid hormone (PTH) and serum calcium (Ca) levels as a result of its mechanism of action. The frequency and degree of, physician response to, and patient recovery from Ca reduction after initiating cinacalcet has not been described.

Methods: The cohort included all new cinacalcet users with Ca >8.4 mg/dL at cinacalcet initiation who received in-center hemodialysis at a large dialysis organization (LDO), and were enrolled in the LDO's prescription benefits service (N=13,291). Patients were categorized as those who did not experience a reduction in Ca to ≤8.4 and those in whom Ca fell to levels 8-8.4, 7.5-7.9, and <7.5 mg/dL. Baseline patient characteristics were compared between these levels. We examined the frequency of physician response and the likelihood of Ca recovery according to different levels of Ca reduction.

Results: Overall, 6763 (50.9%) patients experienced a reduction in Ca to ≤8.4 mg/dL. The majority of these (76%) had a Ca level of 8-8.4 mg/dL, while only 5% had a Ca <7.5 mg/dL. Higher baseline PTH and alkaline phosphatase were associated with lower resulting Ca levels. Among patients with Ca reductions, 48.2%-63.5% received intervention, 16.5%-28.8% discontinued cinacalcet, and the majority of patients recovered to Ca >8.4 mg/dL within 90 days. Only modest recovery differences were noted between patients who did versus did not receive intervention and patients who did versus did not discontinue cinacalcet.

	Calcium Maintained	Calcium Reduction Levels		
	> 8.4 mg	8-8.4 mg/dL	7.5-7.9 mg/dL	< 7.5 mg/dL
	n = 6528	n = 5165	n = 1253	n = 345
At cinacalcet initiation				
Age (y), mean ± SD	54.9 ± 14.6	56.0 ± 14.3	56.6 ± 14.6	56.3 ± 15.1

Without intervention[a]		82.9	69.8	62.9
Recovered to calcium > 8.4 mg/dL, %	NA			
Discontinued cinacalcet		88.3	85.4	71.1
Continued cinacalcet		82.5	70.4	62.4

a. Any of added/increased vitamin D, stopped/decreased cinacalcet, added/increased calcium binder, or increased dialysate calcium.
Abbreviations ESRD, end-stage renal disease; IV, intravenous; m, months; PTH, parathyroid hormone; y, years

Conclusions: After cinacalcet initiation, Ca reductions to ≤8.4 mg/dL were common, but Ca levels below 7.5 mg/dL were infrequent. Patients with more severe secondary hyperparathyroidism were more likely to manifest Ca reductions to ≤8.4 mg/dL following cinacalcet initiation. Recovery was common with or without directed intervention.

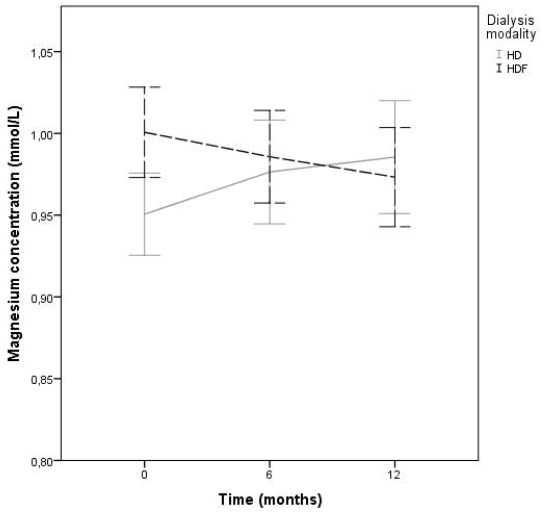
Serum Magnesium (Mg) Is a Strong, Independent Predictor of Mortality in ESKD Patients and May Be Influenced By Dialysis Modality

Camiel L.M. de Roij van Zuijdewijn,[1] Muriel P. Grooteman,[1,2] Menso Jan Nubé,[1,2] Peter J. Blankestijn,[3] Pieter M. Ter Wee,[1,2] Janine Buechel,[4] Sonja Steppan,[4] Michiel Bots,[5] Marc G. Vervloet.[1,2] *[1]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Inst for Cardiovascular Research, VU Univ Medical Center, Amsterdam, Netherlands; [3]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [4]Fresenius Medical Care, Bad Homburg, Germany; [5]Julius Center for Health Sciences and Primary Care, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: Magnesium (Mg; mmol/L) may be associated with survival in hemodialysis (HD) patients. The type of dialysis treatment (HD versus hemodiafiltration [HDF]) may modulate Mg concentrations.

Methods: We performed a post-hoc analysis on the CONTRAST study (NCT 00205556), a RCT evaluating the survival effect of HDF compared to HD (mean follow-up 3.14 years). Patients were followed until death or censored if alive at the end of the study. Mg was measured at baseline and after 6 and 12 months. Cox regression model, adjusted for confounders, was used to calculate the predictive value of baseline Mg regarding mortality. A linear mixed model (LMM) was used to investigate the change of Mg over time and if this change differed between HD and HDF, using an interaction term.

Results: Mean age of 372 analyzed patients was 63.5±14.0 years and 61.6% was male. Baseline Mg was 0.98±0.18 and strongly related to mortality with an adjusted HR of 0.86 (p=0.003) for every 0.1 mmol/L increase in baseline Mg. Baseline Mg differed between HD (0.96) and HDF (1.00). Mg increased in HD and decreased in HDF over time with a significant difference in Mg slope between the 2 modalities (p=0.003 for interaction in LMM).



Conclusions: Mg is a strong, independent predictor of mortality. At M12, Mg levels were increased in HD and decreased in HDF. Whether these alterations result from differences in Mg balance deserves further study.

SA-PO056

Proton Pump Inhibitors Increase the Risk of Hypomagnesemia in the General Population Brenda C.T Kieboom,[1] Robert Zietse,[1] Albert Hofman,[1] Bruno H. Stricker,[1] Ewout J. Hoorn.[1] *[1]Erasmus MC; [2]Erasmus MC; [3]Erasmus MC.*

Background: Proton pump inhibitors (PPIs) are one of the top selling drugs because of the wide range of indications, the high efficacy and the low risk of adverse effects. Since 2006, however, cases of severe hypomagnesemia have been reported in association with the use of PPIs. The mechanism of PPI-induced hypomagnesemia is unclear and it is unknown if this is an idiosyncratic drug reaction. Therefore, we investigated if PPI-use is associated with hypomagnesemia in the general population.

Methods: We used data from 9820 participants aged 45 and over from the population-based Rotterdam Study to construct multivariable linear and logistic regression models to analyze the association between PPI-use, serum magnesium levels, and hypomagnesemia. Hypomagnesemia was defined as ≤ 0.71mmol/L. The following potential confounders were included in the analyses: age, sex, body mass index, estimated glomerular filtration rate, diabetes mellitus, and the use of thiazide or loop diuretics.

Results: PPI-users (n = 407) had a significantly lower serum magnesium level compared to non-users (β:-0.013 [95%CI: -0.019; -0.007] P < 0.001), adjusted for confounders. This association was even stronger in loop diuretic users (β:-0.041 [95%CI: -0.068; -0.013] P= 0.004). No association was found in thiazide users. We also found no effect in H2-receptor antagonist users, making residual confounding by indication less likely. There was an increased risk of hypomagnesaemia (OR: 1.80 [95%CI: 1.03;3.15] P=0.04) in PPI-users. When stratifying by duration of PPI-use, this effect was only observed in the highest tertile (183 – 1351 days), resulting in an almost four times increased risk of hypomagnesemia (OR: 3.83 [95%CI 1.86;7.88] P<0.001).

Conclusions: PPI-use is strongly associated with lower serum magnesium levels, leading to a nearly fourfold increased risk of hypomagnesaemia in long-term users. Therefore, health care professionals should be aware of the risk of hypomagnesemia in chronic PPI-users, especially when there is concomitant use of loop diuretics.

SA-PO057

Low Serum Magnesium Is Associated with Severe Coronary Artery Calcification in Non-Dialyzed CKD Patients Yusuke Sakaguchi,[1] Takayuki Hamano,[2] Chikako Nakano,[3] Yoshitsugu Obi,[1] Isao Matsui,[1] Akihiro Shimomura,[1] Yasuo Kusunoki,[1] Daisuke Mori,[1] Hiromi Rakugi,[1] Yoshiharu Tsubakihara,[2] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Japan; [2]Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Japan; [3]Internal Medicine, Kisei Hospital, Osaka, Japan.*

Background: Low serum magnesium is associated with an increased risk of cardiovascular mortality in patients with CKD. Although experimental studies have shown inhibitory effects of magnesium on calcification of vascular smooth muscle cells, clinical evidence regarding the relationship between magnesium and vascular calcification is scarce. Here we studied the relationship between serum magnesium levels and severity of coronary artery calcification (CAC) in non-dialyzed CKD patients.

Methods: Stage3-4 CKD patients with either diabetes mellitus or prior history of cardiovascular disease were enrolled. We excluded patients with atrial fibrillation or who had received percutaneous coronary intervention. Patients were classified as a lower (serum magnesium levels <2.1 mg/dL) or a higher (>=2.1 mg/dL) magnesium group. CAC scores (CACS) were calculated according to Agatston scoring using multidetector computed tomography.

Results: Seventy-nine CKD patients with mean age of 69.6 years and mean estimated glomerular filtration rate (eGFR) of 34.4 ml/min per 1.73 m^2 were examined. Median CACS was 240, and 46.8% of the patients had severe CAC (i.e., CACS >400). Those patients in the lower magnesium group were significantly younger and had a higher eGFR. After adjustment for age and eGFR, the lower magnesium group was significantly associated with severe CAC (odds ratio 3.77; the higher magnesium group as a reference, p=0.04). This association was robust after additional adjustments for traditional coronary risk factors or CKD-MBD related factors.

Conclusions: In non-dialyzed CKD patients, low serum magnesium is associated with severe CAC. Interventional studies are warranted to clarify whether magnesium supplementation can retard CAC progression.

Association of Proton-Pump Inhibitor Use and Urinary Magnesium Excretion Jeffrey H. William, Kenneth J. Mukamal, John Danziger. *Dept of Medicine, Beth Israel Deaconess Medical Center, Boston, MA.*

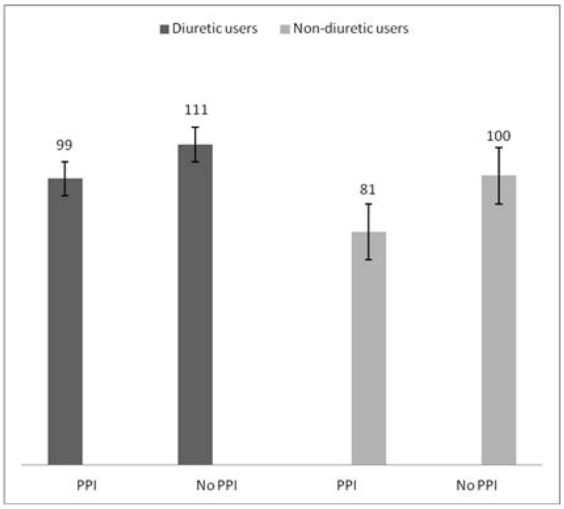
Background: Although multiple recent studies have confirmed an association between chronic proton-pump inhibitor (PPI) use and hypomagnesemia, the physiologic explanation for this association remains uncertain. To address this, we investigated the association of PPI use with urinary magnesium excretion.

Methods: We measured 24-hour urine magnesium excretion in collections performed for nephrolithiasis evaluation in 278 consecutive ambulatory patients and determined PPI use from contemporaneous medical records. A total of 18% of patients used PPIs.

Results: The mean daily urinary magnesium was 83.9±43.9 mg in PPI users, compared to 102.2±45.0 mg in non-PPI users (p=0.01). In adjusted analyses, PPI use was associated with 11.4 ± 5.7 mg/day (p=0.04) lower daily urinary magnesium excretion. Diuretic use was associated with increased magnesuria, but did not significantly modify the effect of PPI on urinary magnesium. As a control, PPI use was not associated with other urinary indicators of nutritional intake.

	Proton-pump inhibitors		*H_2-receptor antagonists*	
	Urinary Mg (β-coefficient ± SE)	**p-value**	**Urinary Mg (β-coefficient ± SE)**	**p-value**
Unadjusted model	-18.23 ± 7.04	0.01	0.55 ± 12.37	0.96
Model 1[a]	-13.38 ± 6.81	0.05	5.19± 11.81	0.66
Model 2[b]	-11.49 ± 5.71	0.04	0.50 ± 9.90	0.96

Figure 1. Urinary magnesium in PPI users, stratified by diuretic use (mg/24 hours)



Conclusions: Our findings suggest that PPI use decreases urinary magnesium excretion, reflecting decreased overall enteric absorption. When combined with diuretic-induced urinary magnesium wasting, PPI use may provide a "second hit", resulting in hypomagnesemia.

SA-PO059

The Effect of Calcium and Vitamin B6 Supplementation on Oxalate Excretion in a Gastric Bypass Model of Hyperoxaluria Benjamin Canales,[1] Christopher Anthony Monsour,[1] Saeed R. Khan,[2] Marguerite Hatch,[2] Jesse Gregory.[3] *[1]Urology, Univ of Florida, Malcom Randall VAMC, Gainesville, FL; [2]Pathology, Immunology and Laboratory Medicine, Univ of Florida, Gainesville, FL; [3]Food Science and Human Nutrition, Inst of Food and Agricultural Sciences, Univ of Florida, Gainesville, FL.*

Background: Patients who develop enteric hyperoxaluria and oxalate stones after Roux-en-Y gastric bypass (RYGB) surgery are encouraged to supplement with calcium or vitamin B6 to lower stone risk. We tested the effect of these therapies on urinary oxalate excretion in an established RYGB animal model of hyperoxaluria.

Methods: Obese male Sprague Dawley rats underwent sham (n=7) or RYGB (n=10) surgery. Animals were maintained on low oxalate/fat (LOF), normal calcium (NC) diet and completed a 2-phase crossover metabolic study. During each 2-week phase, groups were fed LOF, high calcium (HC) and LOFNC with high vitamin B6 (1600% of laboratory rodent requirement) diets with 2 week washout. Urine was collected before and after each intervention. Plasma levels of pyridoxal phosphate and associated metabolic products were determined twice before supplementation.

Results: Urinary oxalate excretion remained low and unchanged in shams on each of the 3 diets. RYGB animals on LOFHC had a 28% decrease in urine oxalate (16.9 ± 1.6 versus 12.2 ± 1.1 umol/day, p<0.001) without affecting urinary calcium. Prior to B6 supplementation, RYGB animals had similar plasma pyridoxal phosphate and biproduct levels to sham except for slightly higher plasma homocysteine (hcy) (5.25 ± 0.5 versus 3.7 ± 0.3 umol/L, p=0.001) that remained within normal range. Vitamin B6 supplementation lowered urinary oxalate excretion 15% (20.2 ± 3.0 versus 17.1 ± 1.7 umol/day; p=0.055) although not statistically significant.

Conclusions: In our obese RYGB model, increasing dietary calcium lowered urinary oxalate excretion more than B6 supplementation, and neither affected urinary calcium. RYGB animals were B6 sufficient with variations in plasma hcy likely reflective of greater protein turnover and catabolism. Both calcium and B6 appear to be reasonable therapies in hyperoxaluric RYGB patients who already maintain a low fat and low oxalate diet.

Zn^{2+} and Zip10 Knockdown Alter In Vivo and Ex Vivo Calcium Oxalate (CaOx) Crystal Formation in Drosophila Stone Model Kari A. Strohmaier,[1,2,3] Paige Nicole Williams,[1,2] Taku Hirata,[1,2] Pablo Cabrero,[4] Julian A.T. Dow,[2,4] Eva Furrow,[2,3] Michael F. Romero.[1,2] *[1]Physiology and BME; Nephrol and Hypertens, Mayo Clinic, Rochester, MN; [2]O'Brien Urology Res Center, Mayo Clinic, MN; [3]Veterinary and Biomed Sci, U MN College Veterinary Med, St. Paul, MN; [4]Biomedical and Life Sciences, U Glasgow, Glasgow, United Kingdom.*

Background: Zn^{2+} has an implicated role in calcium oxalate (CaOx) stone formation. We have developed a model of CaOx crystallization in Drosophila (fly)[Hirata, PMID22993075]. Canine studies indicate that Slc39a10 (Zip10) may be involved. Zip10 is identifiable in human, dog and fly and all transport Zn^{2+} [Williams et al, FASEB J 28, 2014]. The crystallization effects of Zn^{2+} and Ox were assessed using Malphigian tubules (MT, renal tubule) ± Zip10-knockdown. CaOx crystal phenotypes were also analyzed after dietary alterations in flies.

Methods: Zip10 knockdown flies (dZip10 KD) were created using the GAL4-UAS system: UAS-RNAi-CG10006 x Uro-GAL4 (MT-specific). MTs were dissected from WT and dZip10 KD flies and immersed in a Na_2Ox solution. Next, other metals (Zn, Mn, Cd) were added to Ox solutions to assess the metal effect on CaOx crystal formation (*ex vivo*). These results were compared with those of feeding experiments (*in vivo*), in which Ox combined with Zn, Mn, or Cd were added to fly food, followed by MT dissection and analysis after 48 h. All crystals were visualized by DIC microscopy, photographed (Zeiss Observer), and quantified (AxioVision software).

Results: In ex vivo experiments, the average crystal volume in all solutions tested increased in Uro::dZip10 KD flies in comparison to WT flies. In feeding experiments, Ox only diets resulted in significantly larger stones in Uro::dZip10 KD flies v WT flies. However, when placed on an Ox diet plus Zn^{2+}, Uro::dZip10 KD flies formed significantly smaller crystals than WT flies. In both ex vivo and feeding experiments performed on WT flies, the presence of Zn^{2+} significantly increased mean stone volume.

Conclusions: Our results suggest that Zn^{2+} transport by Zip10 interacts with CaOx crystal formation. The changes in crystal size and dynamics could reveal important aspects of initial crystallization in oxalate nephrolithiasis. **Support**: DK92408, DK083007/DK100227.

SA-PO061

Involvement of Renin Angiotensin Aldosterone System in Calcium Oxalate Crystal Induced Activation of NADPH Oxidase and Renal Cell Injury Hidenori Tsuji,[1] Atsunori Esa,[1] Nobutaka Shimizu,[2] Masahiro Nozawa,[2] Kazuhiro Yoshimura,[2] Hirotsugu Uemura,[2] Joshi Sunil,[3] Saeed R. Khan.[3] *[1]Urology, NTT WEST Osaka Hospital, Osaka, Osaka, Japan; [2]Urology, Kinki Univ Faculty of Medicine, Osakasayama, Osaka, Japan; [3]Pathology and Laboratory Medicine, College of Medicine, Univ of Florida, Gainesville, FL.*

Background: Reactive oxygen species (ROS) are produced during the interaction between oxalate/CaOx crystals and renal epithelial cells and are responsible for the various cellular responses through the activation of NADPH oxidase (Nox). CaOx crystals also activate the renin-angiotensin aldosterone system (RAAS). Aldosterone stimulates ROS production through activation of Nox with the involvement of mineralocorticoid receptor (MR), Rac1, and mitogen-activated protein kinases (MAPK). We investigated RAAS pathways in vivo in rat model and in vitro by exposing renal eithelial cells to CaOx crystals.

Methods: Group of SD rats with hyperoxaluria was additionally given apocynin. Normal rat kidney epithelial cell line (NRK-52E) were incubated with aldosterone and CaOx crystals with or without MR inhibitor, spironolactone, a selective inhibitor of SRC family of kinases, pp2,and DPI. Rac1 expressions were measured by Western blotting analysis. Superoxide levels were determined by dihydroethidium staining.

Results: Genes encoding for angiotensinogen (AGT), Renin 1 (Ren 1), aldosterone synthase (Cyp11b), and mineralocorticoid receptor (Nr3c2) were assessed. The relative expression of these genes was upregulated in the kidneys of rats with hyperoxaluria. Treatment with apocynin negatively affected gene expressions. Both aldosterone and COM crystals activated Nox and Rac1 expression, while spironolactone inhibited Nox and Rac1 expression. Increased Rac1 expression was significantly attenuated by treatment with SRC inhibitor; PP2 and MR antagonist spironolactone.

Conclusions: The relative expressions of the genes of AGT, Ren1, Cyp11b and Nr3c2 were upregulated in the kidneys of rats with hyperoxaluria. The treatment with apocynin attenuated these gene expressions in vivo. Apparently, CaOx crystals stimulate ROS production through activation of NADPH oxidase with the involvement of MR, Rac1, and MAPK.

SA-PO062

Interleukin-1R-Deficiency Unexpectedly Accelerates Early Renal Failure in Chronic Oxalate Nephropathy Felix Knauf,[1,2] John R. Asplin,[3] Peter S. Aronson.[1] *[1]Internal Medicine/Nephrology, Yale Univ School of Medicine, New Haven, CT; [2]Internal Medicine/Nephrology, Univ Erlangen, Erlangen, Bavaria, Germany; [3]Internal Medicine/Nephrology, Litholink Corporation, Chicaco, IL.*

Background: Severe hyperoxaluria is a serious condition associated with chronic kidney disease. We have recently established a model of chronic oxalate nephropathy. Using this model we have demonstrated that progressive renal failure in oxalate nephropathy results primarily from NLRP3-mediated inflammation. Since NLRP3-activation can trigger IL-1β cytokine release, we used IL-1 receptor (IL-1R)-null mice to test the hypothesis that IL-1β drives inflammation and renal failure in chronic oxalate nephropathy.

Methods: We placed age- and gender-matched wild-type and IL-1R-null mice on an oxalate- and calcium-free diet to determine baseline BUN and creatinine. We then switched the animals to a diet high in soluble oxalate (high oxalate, no calcium). Progression of renal failure was measured longitudinally by measuring plasma creatinine and BUN via retroorbital blood collections, and animals were monitored for mortality. In addition, urine oxalate levels were measured.

Results: Renal failure was accelerated in IL-1R-null compared with wild-type mice at early time points (day 12) as indicated by increased BUN and creatinine. However, at later time points BUN and creatinine became similar between the two groups (day 25), with a subsequent trend to worsen in wild-type versus IL-1R-null mice at day 40. Wild-type mice demonstrated markedly increased mortality as compared with IL-1R-null mice, likely secondary to worsening renal function. Urinary oxalate excretion was identical between wild-type and IL-1R-null mice, excluding differences in intestinal oxalate handling to explain the observed phenotypes.

Conclusions: Taken together, these data indicate an unexpected biphasic effect of IL-1R knockout on development of oxalate nephropathy, with accelerated renal dysfunction during the first two weeks, but then protection against renal failure and death at later time points.

Calcium Oxalate Monohydrate Crystals Internalized Into Renal Tubular Cells Are Degraded By Endolysosomes Visith Thongboonkerd, Sakdithep Chaiyarit, Nilubon Singhto. *Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.*

Background: Interaction between calcium oxalate crystals and renal tubular cells has been recognized as one of the key mechanisms for stone formation. While crystal adhesion and internalization have been extensively investigated, subsequent phenomena (i.e. crystal degradation and dissolution) remained poorly understood.

Methods: To explore these mechanisms, we used fluorescein isothiocyanate (FITC)-labelled calcium oxalate monohydrate (COM) crystals (1,000 μg/ml of crystals/culture medium) to confirm crystal internalization into MDCK renal tubular cells after exposure to the crystals for 1 h and to trace the internalized crystals. Crystal size, intracellular and extracellular fluorescence levels were measured using a spectrofluorometer for up to 48 h after crystal internalization. Moreover, markers for early endosome (Rab5), late endosome (Rab7) and lysosome (LAMP-2) were examined by laser-scanning confocal microscopy.

Results: Fluorescence imaging and flow cytometry confirmed that FITC-labelled COM crystals were internalized into MDCK cells (14.83 ± 0.85%). The data also revealed a reduction of crystal size in a time-dependent manner. In concordance, intracellular and extracellular fluorescence levels were decreased and increased, respectively, indicating crystal degradation/dissolution inside the cells and the degraded products were eliminated extracellularly. Moreover, Rab5 and Rab7 were both up-regulated and were also associated with the up-regulated LAMP-2 to form large endolysosomes in the COM-treated cells at 16-h after crystal internalization.

Conclusions: We demonstrate herein, for the first time, thatCOM crystals could be degraded/dissolved by endolysosomes inside renal tubular cells. These findings will be helpful to better understand the crystal fate and pathogenic mechanisms of kidney stone formation.

Pathogenesis of Inflammatory Bowel Disease-Associated Hyperoxaluria

Hatim A. Hassan,[1] Yong-Chul Jung,[1] Ignacio Granja,[2] John R. Asplin.[2] *[1]Medicine, Univ of Chicago, Chicago, IL; [2]Litholink Corp, Chicago, IL.*

Background: Patients with IBD have increased risk of kidney stones, with hyperoxaluria being the major risk factor. Hyperoxaluria is largely attributed to fat malabsorption, which occurs in CD but not UC; however, hyperoxaluria is also seen in UC. Therefore, additional factor(s) must be contributing to the IBD-associated hyperoxaluria (IBDAH), and that an ideal model for the IBDAH is needed.

Results: To this end, we used the SAMP1/YitFc (SAM; a model of human CD-like ileitis) mice and their AKR controls. The SAM mice were found to have significantly higher (>1.8-fold) urine oxalate compared to AKR. Intestinal oxalate absorption is predominantly passive through the paracellular pathway, while anion exchanger SLC26A6 (A6) plays a critical role in transcellular intestinal oxalate secretion. We observed significant reduction in ileal (>87%) and jejunal (>45%) A6 mRNA expression in SAM mice compared to AKR using qPCR, without a change in SLC26A1 expression. We also observed significant reduction in ileal (>90 and 86%) and colonic (>40 and 48%) occludin and ZO-1 protein expression, respectively, in SAM mice compared to AKR. We hypothesize that the observed reduction in A6 and occludin/ZO-1 expression is likely mediated by proinflammatory cytokines (PCs: e.g. TNF-α and IFN-γ, which are elevated in IBD), leading to reduced intestinal oxalate secretion and/or increased intestinal oxalate absorption, and thus contribute to the observed hyperoxaluria. Indeed, we previously found (JASN 24:277A, 2013) that PCs significantly increased ^{14}C-oxalate absorption both in vitro and ex-vivo, effects completely blocked by the peptides AMP-18 and GLP-2. We also observed that PCs significantly inhibited apical ^{14}C-oxalate uptake by Caco2 cells through mechanisms involving reduced A6 mRNA/total protein expression. Importantly, TNF-α caused significant inhibition (>55%) of mouse jejunal oxalate secretion.

Conclusions: We conclude that SAM mice have significant hyperoxaluria and that reduced A6 and occludin/ZO-1 expression, which is likely mediated by PCs, contribute to the observed hyperoxaluria by decreasing active intestinal oxalate secretion and/or increasing passive paracellular intestinal oxalate absorption.

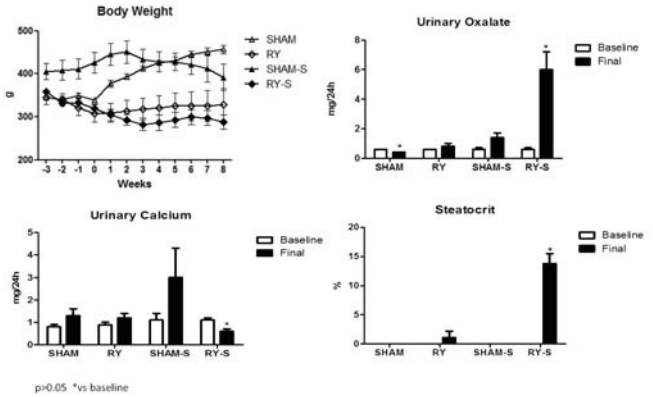
Fat Malabsorption Contributes to Hyperoxaluria after Roux-en-Y Gastric Bypass in Rats

Milene Subtil Ormanji, Fernando Korkes, Renata Meca, Leandro Cunha Baia, Renato Ribeiro Nogueira Ferraz, Ita Pfeferman Heilberg. *Nephrology Div, Univ Federal de Sao Paulo, São Paulo, Brazil.*

Background: It has been previously shown that increased intestinal absorption of dietary oxalate is a predisposing mechanism for enteric hyperoxaluria among Roux-en-Y (RY) gastric bypass patients (Froeder et al CJASN 7:2033, 2012). However, the contribution of fat intestinal malabsorption to hyperoxaluria after RY surgery remains controversial. Therefore, we aimed to investigate the presence of steatorrhea and its relation with urinary oxalate and other parameters in a RY gastric bypass model in rats.

Methods: Wistar rats underwent RY or Sham surgeries, and after 2 weeks, started supplementation with either 1% sodium oxalate + 18% lipids (RY-S, n=8 and Sham-S, n=5) or with a regular chow (RY, n=8 and Sham, n=8) during 8 weeks. Twenty-four urine collections (for lithogenic parameters) and stool samples (for determination of fecal fat by steatocrit) were obtained before surgery (baseline) and at the end of study (final).

Results:



At the final period, both RY groups lost weight regardless of the diet. As shown in the figures, urinary oxalate and steatocrit were markedly and significantly increased and urinary calcium significantly decreased compared to baseline only in the RY-S group. Their final urinary pH and uric acid were significantly lower, urinary sodium was significantly higher and urinary creatinine did not differ from baseline.

Conclusions: We concluded that a high fat and oxalate rich diet in this RY model, induced a significant and marked increase in urinary oxalate and fecal fat suggesting that under these dietary conditions, fat malabsorption leads to hyperoxaluria after RY gastric bypass.

SA-PO066

The Causal Role of Salt Wasting and Volume Depletion in Hypercalciuria, Nephrogenic Diabetes Insipidus and Kidney Stone Generation

Manoocher Soleimani,[1,2,3] Sharon L. Barone,[1,2,3] Jie Xu,[1,2] Marybeth Brooks,[1,2] Kamyar A. Zahedi.[1,2,3] *[1]Internal Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Center on Genetics of Transport, Univ of Cincinnati, Cincinnati, OH; [3]Research Services, Veterans Affairs Medical Center, Cincinnati, OH.*

Background: The most common cause of nephrolithiasis is excess calcium in the urine, which in the context of volume depletion, high levels of oxalate, phosphate or uric acid or low levels of citrate can lead to the formation of calcium crystals in kidney tubules. The role of salt wasting and the subsequent volume depletion in the pathogenesis of hypercalciuria and its association with nephrolithiasis is not clear.

Methods: Kidney sections of NCC/pendrin double KO mice were examined and DNA microarray analysis, northern and western blot analyses, immunofluorscent microscopy and relevant enzymatic assays were performed.

Results: Salt wasting and volume depletion in NCC/pendrin dKO mice leads to the up-regulation of prostaglandin E synthase and Cyp450a12a, and increased synthesis of PGE2 and 20-HETE. The dKO animals displayed multiple defects in renal ion- or fluid-transport systems, including: the downregulation of uromodulin and NKCC2, resulting in salt wasting and impaired calcium absorption in the thick limb; aberrant regulation of Aquaporin 2, leading to nephrogenic diabetes insipidus despite severe volume depletion and elevated AVP levels, and phosphate and oxalate wasting. Collectively, these defects resulted in hypercalciuria, exacerbation of salt wasting and volume depletion, and calcium stone formation in medullary collecting ducts. Inhibition of PGE2 or 20-HETE synthesis significantly improved nephrogenic DI, hypercalciuria and salt wasting in dKO mice. in parallel, correction of volume depletion with salt replacement improved calcium wasting and inhibited PGE2 and 20-HETE synthesis.

Conclusions: Salt wasting followed by volume depletion activates PGE2 and 20-HETE, resulting in hypercalciuria, exacerbation of salt wasting and volume depletion, and nephrolithiasis. Our results suggest that patients with salt wasting and volume depletion are at increased risk of nephrolithiasis due to dysregulated production of arachidonic acid metabolites.

Evidence for a Blunted Response of the 25-Hydroxyvitamin D 1-Hydroxylase to Fibroblast Growth Factor-23 in First Time Stone Formers

Hemamalini Ketha, Ravinder Singh, Stefan Grebe, Eric J. Bergstralh, Andrew D. Rule, John C. Lieske, Rajiv Kumar. *Dept of Medicine, Health Sciences Research and Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.*

Background: First time stone formers (SF) have higher serum 1,25-dihydroxyvitamin D ($1,25(OH)_2D$) concentrations, reduced serum 24,25-dihydroxyvitamin D/25-hydroxyvitamin D ($24,25(OH)_2D/25(OH)D$) ratios, and increased fractional phosphate excretion (FE Pi) compared to a group of matched control subjects (C) (JASN, 24: 2013, 276A).

Methods: We correlated concentrations of full-length serum FGF-23, a peptide which reduces serum $1,25(OH)_2D$ and increases Pi excretion, in 160 SF (mean age 46 ± 14) and 201 C (age 45 ± 15) subjects with serum $1,25(OH)_2D$ and FE Pi using age and gender-adjusted multivariate analysis.

Results: The results and relationships amongst variables are shown in Table 1.

Variable	*Controls (201)*	*Stone Formers (160)*	*P value*
Serum Chemistries			
Ca, mg/dL	9.2 ± 0.7	9.4 ± 0.5	*0.01*
Pi, mg/dL	3.4 ± 0.5	3.4 ± 0.6	0.47
PTH, pg/mL	38.8 ± 17.1	42.9 ± 20.6	*0.04*
$1,25(OH)_2D$, pg/mL	38.1 ± 13.3	44.0 ± 13.8	*<0.001*
25(OH)D, ng/mL	32.1 ± 9.4	33.7 ± 11.8	0.16
$24,25(OH)_2D$, ng/mL	3.2 ± 1.5	3.1 ± 1.6	0.51
$24,25(OH)_2D/25(OH)D$	0.097 ± 0.028	0.087 ± 0.027	*0.002*
FGF-23, pg/mL	59.2 ± 22.5	61.8 ± 28.3	0.33
Urine Chemistries			
FE Pi, %	14.9 ± 5.0	16.0 ± 6.8	0.08
FE Ca, %	1.9 ± 1.0	2.0 ± 1.2	0.32
Associations between variables: input (x) and response (y) adjusted for age and gender	C Slope, p	SF Slope, p	SF vs. C slope
X=FGF-23, Y=$1,25(OH)_2D$	-0.163, *<0.001*	-0.05, 0.2	*0.04*
X=$1,25(OH)_2D$, Y=FE Pi	-0.03, 0.3	-0.10, *0.005*	0.08
X=FGF-23, Y= FE Pi	0.03, *0.01*	0.004, 0.81	0.14

Conclusions: Although there are no differences amongst FGF-23 concentrations in the C and SF groups, serum $1,25(OH)_2D$ decreases to a greater extent in association with increases in serum FGF-23 in C compared with SF, demonstrating a blunted response of the 25(OH)D 1-hydroxylase to FGF-23 in SF. Adjusting for PTH, Ca and Pi does not alter this relationship. The blunted response to circulating FGF-23 in SF could partially be responsible for the increase in serum $1,25(OH)_2D$ seen in SF.

Vitamin D3 Prophylaxis or Repletion in Children with Nephrolithiasis Does Not Increase the Risk of Hypercalciuria and Renal Stone Disease

Ismail Dursun, Rulan S. Parekh, Elizabeth A. Harvey, Jun Chuan Teh, Lisa Robinson. *Hospital Sick Children.*

Background: Hypercalciuria is the most detected metabolic abnormality in nephrolithiasis and is an important risk factor for decreased bone mass. Many pediatricians hesitate to treat these patients with vitamin D3 because of the theoretical risk of hypercalciuria and renal stone formation. Our aim is to evaluate whether vitamin D prophylaxis or repletion in children with nephrolithiasis secondary hypercalciuria adversely affects urinary calcium excretion and formation of renal stones.

Methods: We reviewed the medical records of 388 children with nephrolithiasis of which 71 children had evidence of hypercalciuria. Of these patients, 14 were treated with vitamin D3 (vitamin D group) and 57 were not (non-vitamin D group). By vitamin D3 status, baseline and follow-up measurements of serum calcium, phosphate, PTH, 25-hydroxy vitamin D, urinary calcium and creatinine were obtained. The primary end point was the urinary calcium: creatinine ratio (Uca/Ucr) and the secondary end point included new renal stones 5 years after initial presentation.

Results: 64% of children in vitamin D group and 5% of children in non-vitamin D group had various co-morbid conditions, risk factors for stone formation. The average daily vitamin D intake was 21.8±10.8 IU/kg*in vitamin D group.* We found no statistical difference for the primary and secondary end points between the groups. Median Uca/Ucr at baseline was 1.32 *mol/mol* in vitamin D group and 1.06*mol/mol* in non-vitamin D group ($p<0.05$), and on follow-up, the ratio was 0.74*mol/mol* in vitamin D group and 0.70 *mol/mol* in non-vitamin D group ($p>0.05$). There was a significant reduction in Uca/Ucr in both groups at follow up as compared to baseline ($p<0.05$). We did not find any differences between the two groups in *treatment modalities including hydration, diuretics and alkaline supplement.* The percent of the patients with hypercalciuria at last follow-up was similar in both groups ($p>0.05$).

Conclusions: Our results suggest that vitamin D3 can be given safely to children with nephrolithiasis associated with hypercalciuria, even in children with co-morbid diseases predisposing them to hypercalciuria and kidney stone formation.

SA-PO069

Hypercalciuria in Patients with Osteoporosis Is Independent of the Underlying Bone Turnover

Amit Kumar Chakraborty,[1] Saqib Inayatullah,[1] Xiaoli Kong,[2] Yanyan Chen,[2] Heather M. Bush,[2] B. Peter Sawaya.[1] *[1]Div of Nephrology, Bone and Mineral Metabolism, Univ of Kentucky; [2]Dept of Statistics, Univ of Kentucky, Lexington, KY.*

Background: It is well documented that patients with osteoporosis (OP) have high incidence of hypercalciuria (HC). However, the mechanism of HC in patients with OP is not well established. It is thought to be the result of high bone turnover (HBT) with excessive bone resorption. There are few reports of HC in patients with low bone turnover (LBT) OP. The purpose of this study is to compare urinary calcium (UCa) excretion in patients with HBT and LBT OP diagnosed by bone biopsy.

Methods: This is a retrospective study of patients with OP who underwent diagnostic bone biopsy and 24-hr UCa measurement at the University of Kentucky between January 2010 and December 2012. Patients were divided according to the underlying bone turnover. The following information was collected from the medical records: demographic data, history of kidney stones, serum calcium (Ca), phosphorus (P), creatinine (Cr), parathyroid hormone (PTH), 25-hydroxy vitamin D (25VD) levels as well as 24-hr UCa and creatinine (UCr).

Results: A total of 132 patients were identified. Fifty-nine had HBT and 73 LBT. Patients' age, UCa, UCa/UCr and incidence of HC are reported in Table 1 (mean ± SD; * = $p<0.05$).

	HBT	**LBT**
Age (yrs)	56 ± 15	61 ± 12*
UCa (mg/day)	236 ± 126	214 ± 107
UCa/UCr (mg/mg)	0.23 ± 0.1	0.21 ± 0.1
% HC (> 250 mg/day, male; > 200 mg/day, female)	45.5%	43.7%
% HC (> 4 mg/kg/day)	30.3%	26.4%

There was no difference in Ca, P, PTH and 25VD between the groups. Also, there was no correlation between UCa and oral Ca or VD supplementation. Presence of HC defined as >4 mg/kg/day was significantly associated with kidney stones ($n = 12$; $p=0.01$).

Conclusions: HC is very common in patients with OP regardless of underlying bone turnover. HC is not explained by oral calcium or vitamin D supplementation. Further studies are needed to understand the underlying mechanism(s), assess for possible long term effect(s), and address the potential role of the kidney in this clinical syndrome.

Urinary Metabolic Profile and Stone Composition among Stone Formers with and without Heart Disease

Pietro Manuel Ferraro,[1,2] Shabbir H. Moochhala,[2] William G. Robertson,[2,3] Giovanni Gambaro,[1] Robert J. Unwin.[2] *[1]Dept of Medical Sciences, Div of Nephrology, Columbus-Gemelli Univ Hospital, Catholic Univ of the Sacred Heart, Rome, Italy; [2]Centre for Nephrology, Royal Free Campus Medical School, Univ College Hospital, London, United Kingdom; [3]Nuffield Dept of Surgical Sciences, Univ of Oxford, Oxford, United Kingdom.*

Background: Kidney stone disease seems to be associated with increased risk of incident cardiovascular outcomes. The reasons for this association are still unknown. We analyzed differences in 24-h excretory profiles and stone composition among stone formers with and without heart disease (HD).

Methods: We used data from patients attending the UCL Centre for Nephrology's metabolic stone clinic from 1995 to 2012. We divided the sample into two groups according to the presence or absence of a history of HD (myocardial infarction, angina, coronary revascularization, or surgery for calcified heart valves) and analyzed 24-h urines and stone composition measurements for differences between groups with univariate and multivariate regression models.

Results: 1826 patients had available data for 24-h urine analysis. Among these, 108 (5.9%) had a history of HD. Those with HD were older (59±13 *versus* 46±13 years, $p<0.001$), whereas the prevalence of males was similar (73 *versus* 70%, $p=0.52$). Univariate analyses showed that patients with HD had significantly lower urinary excretions for citrate (2.4±1.5 *versus* 2.6±1.4 mmol, $p=0.04$) and magnesium (3.9±1.3 versus 4.2±1.3 mmol, $p=0.03$); adjustment for age and sex did not change these findings. A subgroup of 677 patients had available data for stone composition analysis. The proportion of calcium oxalate (57 *versus* 53%, $p=0.99$), calcium phosphate (19 *versus* 28%, $p=0.76$), and uric acid (16 *versus* 12%, $p=0.64$) in analyzed stones was similar for those with and without HD.

Conclusions: Stone formers with HD have lower urinary excretions for citrate and magnesium. Since both citrate and magnesium have been implicated in the pathogenesis of arterial plaque formation, as well as being protective factors in nephrolithiasis, this may indicate a common mechanism underlying the processes of kidney stone formation and of arterial calcification and plaque formation.

SA-PO071

Use of Lipid-Lowering Drugs and the Risk of Incident Kidney Stones

Pietro Manuel Ferraro,[1,2] Eric N. Taylor,[2] Giovanni Gambaro,[1] Gary C. Curhan.[2] *[1]Dept of Medical Sciences, Div of Nephrology, Columbus-Gemelli Univ Hospital, Catholic Univ of the Sacred Heart, Rome, Italy; [2]Channing Div of Network Medicine, Dept of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston.*

Background: A history of kidney stones has been associated with an increased risk of cardiovascular disease; whether this association is due to common pathophysiological mechanisms is not known. Abnormal serum lipids, a known predictor of cardiovascular disease, might be related to kidney stone disease. A cross-sectional study found the use of lipid-lowering drugs (LLD) was associated with a decreased prevalence of kidney stones. However, this association has never been examined in prospective longitudinal studies.

Methods: We analyzed data from three large prospective cohorts, the Health Professionals Follow-up Study (HPFS) and Nurses' Health Studies (NHS) I and II. Information on use of LLD and other covariates was collected through biennial questionnaires. Incidence of kidney stones was confirmed through further validated questionnaires. The risk of kidney stones in participants according to use of LLD was assessed using Cox proportional hazards regression adjusted for age, BMI, race, geographic region, diabetes, high blood pressure, use of thiazides, calcium supplements and intakes of sodium, calcium, potassium, magnesium, caffeine, animal protein, vitamin C, fructose, oxalate, phytate, alcohol and total fluid.

Results: The analysis included 263,712 participants, mean age 54 (HPFS), 53 (NHS I) and 37 (NHS II) years. After up to 20 years of follow-up, 5,987 incident cases of kidney stones occurred. After multivariate adjustment, there was no statistically significant associations for risk of kidney stones among participants who used LLD compared with those who did not (HPFS: HR 0.91, 95% CI 0.74, 1.10, p=0.32; NHS I: HR 1.19, 95% CI 1.00, 1.41, p=0.05; NHS II: HR 0.98, 95% CI 0.70, 1.36, p=0.89). Analyses restricted to statins did not change the findings.

Conclusions: In three large prospective cohorts, there was no association between the use of LLD and incidence of symptomatic kidney stones.

SA-PO072

Physical Activity, Energy Intake, and the Risk of Incident Kidney Stones

Pietro Manuel Ferraro,[1,2] Gary C. Curhan,[2] Giovanni Gambaro,[1] Eric N. Taylor.[2]
[1]Dept of Medical Sciences, Div of Nephrology, Columbus-Gemelli Univ Hospital, Catholic Univ of the Sacred Heart, Rome, Italy; [2]Channing Div of Network Medicine, Dept of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston.

Background: It has been reported that among postmenopausal women, physical activity was inversely associated and energy intake was positively associated with risk of kidney stones. Whether these associations can be reproduced in other populations after accounting for lifestyle and dietary factors is not known.

Methods: We analyzed data from three large prospective cohorts, the Health Professionals Follow-up Study (HPFS) and Nurses' Health Studies (NHS) I and II. Information on physical activity, dietary intake, and incidence of kidney stones was collected through validated biennial questionnaires. The relative risk of incident stones among participants within different categories of physical activity (<5, 5-9.9, 10-19.9, 20-29.9, ≥30 METs/week) and energy intake (<1,800, 1,800-2,000, 2,000-2,200, 2,200-2500 and >2,500 Kcal/day) was assessed with Cox proportion hazards regression adjusted for age, BMI, race, comorbidities, medical treatments, calcium supplement use, fluid and nutrient intakes.

Results: The analysis included 215,133 participants, mean age 54 (HPFS), 53 (NHS I) and 37 (NHS II) years. After up to 20 years of follow-up, 5,355 incident cases of kidney stones occurred. In age-adjusted analyses, higher levels of physical activity were associated with a lower risk of incident kidney stones in women (NHS I and II) but not men. However, after multivariate adjustment, there was no significant association between physical activity and risk of kidney stones (HPFS: HR for highest versus lowest category 1.00, 95% CI 0.87, 1.14, p for trend=0.94; NHS I: HR 1.01, 95% CI 0.85, 1.19, p=0.88; NHS II: HR 1.03, 95% CI 0.90, 1.18, p=0.64). Analyses restricted to postmenopausal women did not change the results. Energy intake was not associated with stone risk.

Conclusions: In three large prospective cohorts, there were no independent associations between physical activity, total energy intake, and incidence of symptomatic kidney stones.

SA-PO073

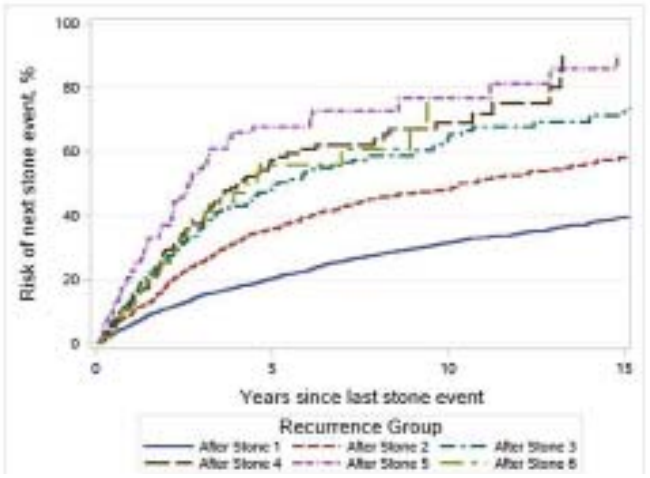
Risk of Clinical Care for a Kidney Stone Event Increases with Number of prior Stone Events: A Rochester Epidemiology Project Study

Prince Singh,[1] Eric J. Bergstralh,[1] John Knoedler,[1] Amy E. Krambeck,[1] William E. Haley,[2] John C. Lieske,[1] Andrew D. Rule.[1] *[1]Nephrology and Hypertension, Mayo Clinic; [2]Nephrology and Hypertension, Mayo Clinic, FL.*

Background: The risk of symptomatic events in kidney stone formers (SF) as predicted by the number of prior stone events is unknown. The long-term benefit of prevention interventions in SF with increasing number of past events is unclear.

Methods: We identified, validated and abstracted the comprehensive medical record of symptomatic adult first-time kidney SF in Olmsted County, Minnesota, from 1984 to 2012. We identified the number of stone events, use of stone prevention medications(potassium citrate, thiazides, allopurinol or other) and stone prevention clinic referral (included diet interventions). Cox models estimated impact of interventions at each event on risk of subsequent events.

Results: There were 3057, 845, 334, 162, 87, and 26 stone formers with at least 1 to 6 stone events. The figure shows the risk of future events increased with number of past events until the 6th stone. Stone prevention clinic referral was 15%, 39%, 57%, 69%, 81%, and 88% and medication use was 10%, 24%, 30%, 36% and 49% after stone events 1 to 6. After adjusting for number of past stone events, stone clinic referral (HR=1.4, p<0.001) but not medication use (HR=1.0, p=0.5) associated with an increased risk of future events.



Conclusions: Risk of future symptomatic events leading to clinical care progressively increases with the number of past events;this increase is limited, possibly by SF learning to manage stone events on their own. For the same number of past stone events, risk of future events is not lower among SF who have interventions compared to those who do not have interventions. Higher-risk patients selectively receiving interventions may explain this finding.

Funding: NIDDK Support, Other NIH Support - Rochester Epidemiology Project (AG034676)

SA-PO074

Comparison of Chronic Kidney Disease Markers between Incident Symptomatic Stone Formers and Controls

Prince Singh,[1] William E. Haley,[2] Eric J. Bergstralh,[1] Amy E. Krambeck,[1] John C. Lieske,[1] Andrew D. Rule.[1] *[1]Mayo Clinic, MN; [2]Mayo Clinic, FL.*

Background: Retrospective studies have demonstrated an increased risk of CKD in kidney stone formers, but prospective studies are lacking.

Methods: Continuous surveillance of clinical databases at the Mayo Clinic in Rochester, MN and Jacksonville, FL were used to identify and recruit local incident symptomatic adult stone formers (SF). Controls without stones (age and sex frequency matched) were recruited through local mailings and community flyers. Participants were examined and administered a survey on co-morbidities. Blood and 24-hour urine were collected at this 1st visit and at a 2nd visit at least 90 days later. The kidney function of SF was compared to controls with and without adjusting for age, sex, hypertension, diabetes, and body mass index. CKD was defined by an estimated GFR-Cr (CKD-EPI)< 60ml/min/1.73m^2 or urine albumin > 30 mg/day at both visits.

Results: There were 374 SF (12% from FL, 54% men, 98% white, mean age 47 y) and 449 controls(13% from FL, 49% men,97% white, mean age 47y) at visit 1 and 307 SF and 402 controls at visit 2. Visit 1 was a median 81 days and visit 2 was a median 178 days after the incident stone event. SF had more obesity and a higher cystatin C, urine protein, and urine albumin at both visits compared to controls.

	SF	Control	p-value
Hypertension	25%	22%	0.29
Diabetes	11%	9%	0.38
Body mass index, kg/m^2	29.5	27.6	<0.001
First Visit			
Serum creatinine, mg/dl	0.88	0.84	0.14
Cystatin C, mg/L	0.92	0.87	<0.001
Urine Protein, mg	35	24	<0.001
Urine Alb>5 mg	28.5%	19%	0.003
Second Visit			
Serum creatinine, mg/dl	0.85	0.84	0.45
Cystatin C, mg/L	0.90	0.86	0.001
Urine Protein, mg	32	25	<0.001
Urine Alb>5 mg	31%	21%	0.006

In multivariable-adjusted analysis at visit 1, SF had a 43% higher urine albumin (p=0.002), 127% higher urine protein (p<0.001), 0.02 mg/dl higher serum creatinine (p=0.15), and a 0.04 mg/L higher cystatin C (p=0.01) than controls. Only 1.5% of SF and 1.9% of controls had CKD (p=0.39).

Conclusions: Even early after their 1st kidney stone event, stone formers had more altered CKD markers (but not overt CKD) compared to controls that was not explained by conventional risk factors.

Funding: NIDDK Support, Other NIH Support - Rochester Epidemiology Project (AG034676)

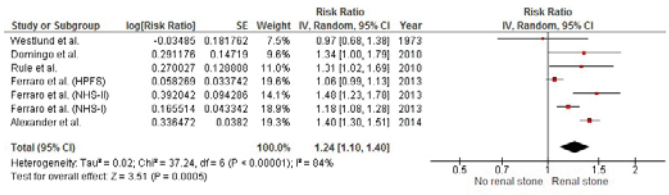
SA-PO075

The Risk of Coronary Heart Disease in Patients with Kidney Stones: A Meta-Analysis Wisit Cheungpasitporn,[1] Charat Thongprayoon,[2] Michael A. Mao,[1] Stephen B. Erickson.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Anesthesiology, Mayo Clinic, Rochester, MN.*

Background: The reported risk of coronary heart disease (CHD) in patients with a history of kidney stones is conflicting. The objective of this meta-analysis was to evaluate the association between the history of kidney stones and CHD risk.

Methods: A literature search was performed using MEDLINE, EMBASE, and Cochrane Database of Systematic Reviews until April 04, 2014. Studies that reported odd ratios or hazard ratios comparing the risk of CHD in patients with kidney stones versus those without history of kidney stones were included. Pooled risk ratios (RR) and 95% confidence interval (CI) were calculated using a random-effect, generic inverse variance method.

Results: Seven study populations from four cohort studies and one cross-sectional study were identified and included in the data analysis. The pooled risk ratio (RR) of CHD in patients with kidney stones was 1.24 (95% CI, 1.10 - 1.40). The result remained significant (RR, 1.23 [95% CI, 1.08-1.41]) when the sensitivity analysis was restricted to only cohort studies. History of kidney stones was associated with increased CHD risk in females (RR, 1.43 [95% CI, 1.12 - 1.82]), whereas the association was not significant in males (RR, 1.14 [95% CI, 0.94-1.38]).



Conclusions: Our study demonstrates a statistically significant increased risk of CHD in female patients with prior kidney stones. This finding suggests that a history of kidney stones is a risk factor for CHD in females and may impact clinical management.

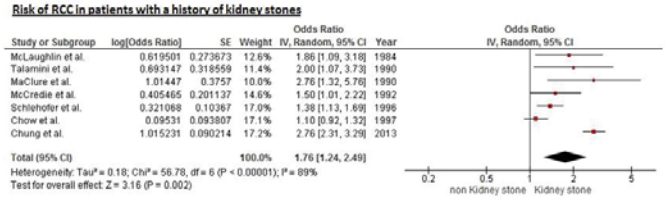
SA-PO076

The Risk of Renal Cell Carcinoma and Transitional Cell Carcinoma in Patients with Kidney Stones: A Meta-Analysis Wisit Cheungpasitporn,[1] Charat Thongprayoon,[1] Patompong Ungprasert,[2] Oisin O Corragain,[3] Stephen B. Erickson.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Internal Medicine, Bassett Medical Center, Cooperstown, NY; [3]Univ College Cork, Cork, Ireland.*

Background: The risk of renal cell carcinoma (RCC) and transitional cell carcinoma (TCC)in patients with a history of kidney stones is controversial. The objective of this meta-analysis was to evaluate the association between kidney stones and the two most common kidney cancers, RCC and TCC.

Methods: A literature search was performed using MEDLINE, EMBASE, and Cochrane Database of Systematic Reviews from inception until May 06, 2014. Studies that reported odd ratios or hazard ratios comparing the risk of RCC and TCC in patients with the history of kidney stones versus those without the history of kidney stones were included. Pooled risk ratios (RR) and 95% confidence interval (CI) were calculated using a random-effect, generic inverse variance method.

Results: Seven studies were included in our analysis to assess the association between a history of kidney stones and RCC. The pooled risk ratio of RCC in patients with kidney stones was 1.76 (95% CI, 1.24 - 2.49). The subgroup analysis found that the history of kidney stones was associated with increased RCC risk only in males (RR, 1.41 [95% CI, 1.11 - 1.80]), but not in females (RR, 1.13 [95% CI, 0.86-1.49]). Five studies were selected to assess the association between a history of kidney stones and TCC. The pooled risk ratio (RR) of TCC in patients with kidney stones was 2.14 (95% CI, 1.35 – 3.40).



Conclusions: Our study demonstrates a statistically significant increased risk of RCC and TCC in patients with prior kidney stones. However, the increased risk of RCC was noted only in male patients. This finding suggests that a history of kidney stones is associated with kidney cancer and may impact clinical management and cancer surveillance.

SA-PO077

Impact of Being Overweight (OW) on Urinary Metabolic Risk Factors for Kidney Stone Formation Linda Shavit,[1,2] Nikhil Johri,[1] William G. Robertson,[1] Stephen B. Walsh,[1] Pietro Manuel Ferraro,[3] Shabbir H. Moochhala,[1] Robert J. Unwin.[1] *[1]Centre for Nephrology, Royal Free Campus Medical School, Univ College Hospital, London, United Kingdom; [2]Adult Nephrology Unit, Shaare Zedek Medical Center, Jerusalem, Israel; [3]Div of Nephrology, Catholic Univ of the Sacred Heart, Italy.*

Background: Obese and overweight (OW) patients share most of the same risk factors for cardiovascular morbidity, while the impact of being OW, rather than obese, on urinary metabolic parameters of kidney stone formers (KSF) is less well known. In this study urinary metabolic parameters, stone composition, and probability of stone formation (Psf) in OW KSF were compared with normal weight (NW) and obese KSF.

Methods: Patients with a recorded BMI and confirmed diagnosis of kidney stone disease were divided into three categories – BMI ≤ 25.0 kg/m2 (NW group), BMI of 25 to 30 kg/m2 (OW group), and BMI >30.0 kg/m2 (obese group). 24 hour urinary volume (U.Vol), pH (U.pH), calcium (U.Ca), oxalate (U.Ox), citrate (U.Cit), uric acid (U.UA), magnesium (U.Mg), sodium (U.Na) and potassium (U.K) excretions along with stone composition and Psf were then compared among the groups.

Results: . A total of 2230 patients were studied, of whom 852 (38.2%) were NW, 902 (40.4%) were OW, and 476 (21.3%) were obese. OW and obese KSF were older, demonstrated increased female predominance and higher prevalence of diabetes, hypertension and gout. There were no statistically significant differences in U.Vol, U.Ca, U.K and U.Mg. However, significantly higher levels of U.Ox (p< 0.001 for trend), U.Cit (p= 0.005 for trend), U.UA (p<0.001 for trend), U.Na (p<0.001 for trend) and lower U.pH (p< 0.001 for trend) were demonstrated in OW and obese KSF by both crude and age- and sex-adjusted models. Stone composition data (N=677) showed significantly higher incidence of uric acid stones in OW KSF.

Conclusions: Similar to obese KSF, OW KSF demonstrate clear alterations in metabolic urinary profiles that are associated with increased overall risk of stone formation. This greater risk is primarily due to raised U.UA, U.Ox, U.Na and lower U.pH. Whether modest weight loss in OW KSF will have a favorable impact on their metabolic urinary profiles is worth exploring.

SA-PO078

Vascular Calcifications and Bone Mineral Density in Recurrent Kidney Stone Formers (KSF) Linda Shavit,[1,2] Daniela Girfoglio,[1] Vivek Vijay,[1] Pietro Manuel Ferraro,[3] Shabbir H. Moochhala,[1] Robert J. Unwin.[1] *[1]Centre for Nephrology, Royal Free Campus, Univ College London Medical School, London, United Kingdom; [2]Adult Nephrology Unit, Shaare Zedek Medical Center, Jerusalem, Israel; [3]Div of Nephrology, Catholic Univ of the Sacred Heart, Rome, Italy.*

Background: Recent epidemiological studies have provided evidence for an association between nephrolithiasis and cardiovascular disease (CVD), though the underlying mechanism is unclear. Vascular calcification (VC) is a strong predictor of CVD; the hypothesis that VC is more prominent in KSF has been investigated in the current study. The aims of this study were to: 1) determine whether recurrent KSF have more VC and osteoporosis compared with control; 2) evaluate an association between hypercalciuria and VC/osteoporosis.

Methods: We investigated 111 subjects, of whom 57 KSF and 54 age- and sex-matched controls. Abdominal aortic calcification (AAC) and vertebral body mineral density (CT BMD) were assessed using existing CT imaging. Manual calcium scoring was undertaken to calculate total aortic calcium load. The prevalence, severity and associations of AAC and CT BMD between KSF and controls were then compared.

Results: Mean age was 46.7 ± 6.4 years in KSF and 46.9 ± 5.6 in controls, 57 % of the patients in both groups were male. The prevalence of diabetes, HTN and dyslipidemia was higher in KSF, and smoking history was more prevalent in controls. AAC was found in both groups, the incidence was slightly higher in KSF (39% versus 35%). However, the severity of AAC was significantly higher in KSF by both univariate and multivariate models adjusted for age, sex, HTN, diabetes and smoking status (p-value < 0.001). Similarly, KSF had significantly lower CT BMD by both crude and adjusted analyses (p-value < 0.001). Among stone formers, the association between AAC score and hypercalciuria was not statistically significant (p-value 0.86).

Conclusions: VC might be an underlying pathogenic mechanism explaining reported associations between nephrolithiasis and CVD. Moreover, bone demineralization is much more prominent in KSF, providing preliminary evidence of possible common underlying pathways leading to increased extraosseous calcium deposition and osteoporosis.

SA-PO079

Effect of Potassium Citrate on Urine Supersaturation and Stone Formation in Genetic Hypercalciuric Stone-Forming Rats Kevin K. Frick,[1] John R. Asplin,[2] Nancy S. Krieger,[1] Ignacio Granja,[2] Christopher D. Culbertson,[1] David A. Bushinsky.[1] *[1]Medicine, Univ of Rochester, Rochester, NY; [2]Litholink, LabCorp, Chicago, IL.*

Background: Potassium citrate (K-cit) is commonly used to decrease recurrent stone formation in patients with calcium (Ca) nephrolithiasis. The increased alkali load should decrease urine (u) Ca excretion through both a direct reduction of bone resorption and an increase in renal tubular Ca reabsorption. The increased dietary citrate should bind both intestinal Ca and u Ca but will increase u pH. Citrate binding of intestinal Ca should allow greater absorption and u excretion of both phosphate (P) and oxalate (Ox). Thus, the effect of K-cit on u supersaturation (SS) with respect to CaOx and CaP and stone formation is complex and difficult to predict. To study the effects of K-cit on u SS and stone formation we utilized the inbred Genetic Hypercalciuric Stone-forming (GHS) rats which form CaP stones.

Methods: GHS rats were fed a fixed amount of a normal Ca (1.2% Ca) diet supplemented with either K-cit or KCl (each 4 meq/d) for 18 wks. Urine was collected at 6, 12 and 18 wks and mean values determined. At study end stone formation was visualized by X-ray.

Results: Urine citrate was higher with K-cit as compared to KCl (K-cit: 182±3.4 mg/d versus KCl: 110±2.7, p<0.001) and u Ca was lower (K-cit: 16.1±0.5 mg/d versus KCl: 18.6±0.3, p<0.001). Urine P (K-cit: 0.029±0.001 g/d versus KCl: 0.020±0.001, p<0.001), Ox (K-cit: 1.11±0.04 mg/d versus KCl: 0.62±0.02, p<0.001) and pH (K-cit: 7.51±0.04 versus KCl: 6.71±0.05, p<0.001) were all increased with K-cit. In rats fed K-cit, CaOx SS was higher (K-cit: 9.8±0.5 versus KCl: 5.5±0.2, p<0.001), as was CaP SS (K-cit: 8.5±0.6 versus KCl: 4.9±0.2, p<0.001); however, uric acid SS was lower with K-cit (K-cit: 0.003±0.0005 versus KCl: 0.022±0.003, p<0.001). Stone formation was present in all rats in both groups.

Conclusions: Thus K-cit effectively raises u citrate and lowers u Ca; however, the increases in u pH, Ox and P lead to an increase in u SS with respect to CaOx and CaP. K-cit did not alter stone formation. Provision of K-cit induces complex changes in u chemistries and resultant u SS which may not be beneficial in preventing CaP stone formation.

Activation of Nucleotide Binding Oligomerization Domain-Like Receptor Family, Pyrin Domain Containing -3 Inflammasomes in Hyperoxaluric Rats, Is It Caused By Oxalate or Calcium Oxalate Crystals? Sunil Joshi, Wei Wang, Saeed R. Khan. *Dept of Pathology, College of Medicine, Univ of Florida, Gainesville, FL.*

Background: Hyperoxaluria is a major risk factor for calcium oxalate (CaOx) crystal deposition in the kidneys, renal injury and inflammation. Recent studies have shown activation of innate immunity through nucleotide binding oligomerization domain-like receptor family, pyrin domain containing -3 (NLRP3) inflammasomes in hyperoxaluric mice and rats. What provokes the activation, oxalate or CaOx crystals is unknown.

Methods: Male rats were divided into two groups. Rats in one group were fed normal diet and the other group diet supplemented with hydroxy proline (HP). After 28 days rats were euthanized, kidneys explanted and total RNA extracted for micro array analysis using Illumina bead array reader™. Gene ontology (GO) and KEGG pathway analyses was performed. Micro array data were verified by quantitative RT PCR and immunohistochemical staining for inflammasome associated gene products.

Results: All rats became hyperoxaluric and at day 28, 3 of 6 rats had deposition of CaOx crystals in their kidneys.Gene analysis showed that in rats with renal CaOx crystal deposits, 20 and 33 pathways were up regulated in cortex and medulla, respectively and in rats with hyperoxaluria but no renal CaOx crystals, 17 and 26 pathways were up regulated. The expression of genes involved in activation of NLRP-3 inflammasome, genes encoding for NLRP-3, TXNIP (thioredoxin interacting protein), Caspase-1, PYCARD (ASC: apoptosis –associated spec-like protein containing a CARD), IL-1β, and IL-18 were up regulated in the HP treated hyperoxaluric rats that developed renal CaOx crystal deposits. Same genes were however, down regulated in HP treated rats that developed hyperoxaluria only. Results were confirmed by RT-PCR and IHC analyses.

Conclusions: Results highlight the prominent role of CaOx crystals in activation of NLRP-3 inflammasome in hyperoxaluric kidneys. As we have suggested elsewhere, retained CaOx crystals are more injurious than hyperoxaluria alone.

SA-PO081

Comparison of Morning versus Evening Administration of Chlorthalidone (CTD) for Idiopathic Hypercalciuria Hasan Fattah,[1] Ignacio Granja,[2] Daniel A. Wollin,[1] John R. Asplin,[2] David S. Goldfarb.[1] *[1]Nephrology, New York Harbor VAMC and NYU Langone MC, New York, NY; [2]Litholink Corp, Chicago, IL.*

Background: Hypercalcuria is common in calcium stone formers. As the result of higher post-dinner urine calcium excretion (UCa) and lower urine volume (V) while sleeping, higher calcium oxalate (CaOx) supersaturation (SS) occurs in the evening. Thiazides (TZ) decrease UCa and prevent recurrent calcium stones. This prospective crossover study examined if TZ is more effective in lowering CaOx and calcium phosphate (CaP) SS if taken at night as compared to daytime.

Methods: We enrolled 5 men with history of calcium kidney stones and hypercalciuria (>200mg/24h). Participants ate self-selected diets and kept food diaries so that the diet 1 day before and on the day of the urine collections could be replicated for each of 3 experimental periods: 1) no drug; 2) 25 mg CTD in AM and 3) 25 mg CTD after dinner (PM). Two 12h urine collections were done from awakening to 12 hours later ("daytime") and then from 12 hours to awakening the next day ("nighttime"). Urine was sent to Litholink (Chicago, IL) for analysis of urinary analytes. Results were compared by non-parametric Wilcoxon paired analysis.

Results: Comparing TZ to control, 24h V was unchanged (2.9 L at baseline, 2.8L with CTD AM, 2.9L CTD PM). CTD reduced both 24h UCa and SS CaOx significantly when given in AM (UCa 136 mg, SS CaOx 10) and PM (UCa 143 mg, SS CaOx 10.2) compared with no drug (UCa 280 mg, SS CaOX 15.7); P=0.04. Nighttime 12h UCa, SS CaOx and SS CaP did not differ when CTD was administered in AM (69 mg, 4.4, 0.9) or PM (65.9 mg, 5.6, 1.4; P=NS). Daytime values were also not affected by time of taking CTD.

Conclusions: TZ significantly reduced 24h UCa excretion in men with hypercalciuria. V and UCa were the same in the control period during daytime and nighttime. TZ was equally effective in reducing both daytime and nighttime UCa excretion whether given in AM or PM. We conclude that the time of day of administration of CTD does not affect its effectiveness. CTD is a relatively long acting TZ; a different result might be seen with varying time of administration of hydrochlorothiazide, a drug with a shorter duration of action.

Inhibitory Effect of Febuxostat, a Non-Purine Xanthine Oxidase Inhibitor, on Renal Urate Transporters Promsuk Jutabha, Naohiko Anzai. *Pharmacology and Toxicology, Dokkyo Medical Univ, Mibu, Tochigi, Japan.*

Background: Febuxostat, a non-purine xanthine oxidase (XO) inhibitor, is an effective drug superior to allopurinol for treatment of hyperuricemia, a risk factor of hypertension and cardiovascular diseases. In addition to its XO inhibitory effect, we aim to test its action on renal urate transporters URAT1, URATv1 and OAT10.

Methods: *In vitro* XO activity assay was tested among 3 drugs; febuxostat, allopurinol and benzbromarone using commercial fluorometric determination kit. The [^{14}C]urate transport was determined in *Xenopus* oocytes expressing URAT1, URATv1 and OAT10 in the presence or absence of the test drugs, IC_{50} value of febuxostat against urate transport was also determined.

Results: Febuxostat had strong inhibitory effect on *in vitro* XO activity with an IC_{50} value of 0.22 ± 0.11 nM compare to 9.20 ± 1.14 μM of allopurinol. The urate transport via an apical urate exchanger URAT1 and a basolateral voltage-driven urate transporter URATv1 were inhibited by febuxostat with IC_{50} values of 13.41 ± 1.29 μM and 20.36 ± 1.64 μM, respectively. Febuxostat did not show any significant inhibition on urate transport by organic anion transporter 10 (OAT10).

Conclusions: The efficacy of febuxostat in reducing serum urate level might be due to its inhibition both on xanthine oxidase which subsequently reduced uric acid production and on renal urate reabsorption via URAT1 and URATv1 transporters.

Transcriptional Heterogeneity of the SLC2A9 Gene Encoding the GLUT9 Urate Transporter David B. Mount, Asim Mandal. *Renal Divs, Brigham and Women's Hospital and VABHS, Boston, MA.*

Background: There is a strong genetic basis for hyperuricemia, with almost 30 associated genes. Variation in SLC2A9, which encodes the urate transporter GLUT9, remains the major single genetic determinant; however, the causal variant(s) within SLC2A9 have not been identified. Two N-terminal isoforms, GLUT9a and GLUT9b, are generated by alternative 5' ends. We have characterized the 5' end of SLC2A9 to further understanding of how variation in this gene generates hyperuricemia.

Methods: 5' UTR exons, alternative splicing, and transcriptional start sites were identified by 5'-RACE PCR and RT-PCR. GLUT9 cDNA expression constructs were characterized by ^{14}C-urate uptakes in Xenopus oocytes. Promoter analysis utilized the dual luciferase system.

Results: Seven novel 5' UTR exons were identified, with substantial alternative splicing. Alternative splicing that deletes coding exon 3 was also identified, in both isoforms. Exon 3 encodes most of transmembrane domain 1 (TM1) and part of the first, glycosylated extracellular loop. GLUT9b constructs with deletion of exon 3 were functional (GLUT9b-delta3), generating urate uptakes that were 10-fold higher than that of water-injected control Xenopus oocytes. Western blotting indicated that GLUT9b-delta3 protein is not glycosylated, presumably due to altered topology of the first extracellular, glycosylated loop. A single GLUT9a transcriptional start site was identified, flanking exon 1a. Luciferase constructs for this promoter were highly active in multiple cell lines (66-fold > vector controls), with a minimal promoter construct of 200 bp. Four GLUT9b start sites were identified, including one ~35 kb 5' of exon 1b flanking a novel 5' UTR exon. Only 2 out of 4 GLUT9b promoters were functional, with substantially lower activity (6-fold > controls) than the GLUT9a promoter.

Conclusions: We have identified substantial transcriptional heterogeneity in SLC2A9, identifying seven new 5' UTR exons and five transcriptional initiation sites. Alternative splicing that removes TM1 generates functional GLUT9 urate transporters. The single GLUT9a promoter is strongly active in multiple cell lines, whereas only 2 out of 4 GLUT9b promoters are weakly active.

Fructose Reabsorption in the Proximal Tubule Is Enhanced by a Moderate Fructose Diet Pablo D. Cabral, Agustin Gonzalez-Vicente, Jeffrey L. Garvin. *Physiology and Biophysics, Case Western Reserve Univ, Cleveland, OH.*

Background: Fructose consumption, and by inference plasma fructose, is implicated in the epidemic of diabetes, obesity and hypertension. The factors controlling plasma fructose concentrations during enhanced fructose consumption are not understood. The proximal tubule (PT) expresses several potential fructose transporters including Na-glucose linked cotransporter 5 (SGLT5) and glucose transporters (GLUT) 2 and 5. Indirect data suggest that fructose is reabsorbed in the PT; however, direct evidence of fructose reabsorption by this nephron segment has not been shown. We hypothesized that fructose is reabsorbed by isolated PTs and its reabsorption is enhanced by consumption of a moderate fructose diet.

Methods: We studied the localization of SGLT5, GLUT2 and 5 by immunofluorescence in PTs. We measured SGLT5 protein expression in PT lysates by Western blot and we directly assessed luminal fructose reabsorption using a microfluorometric fructose assay in isolated, perfused PT. Sprague Dawley rats that were fed either a control standard diet or a 20% fructose diet for one week.

Results: We found expression of SGLT5 in the luminal and GLUT2 and 5 in the basolateral membrane. PTs isolated from rats that were fed a normal diet reabsorbed fructose at a mean rate of 12.8±2.5 pmol/min/mm (n=5). In the presence of Phlorizin (100 uM), a non-selective SGLT inhibitor, fructose reabsorption decreased to 3.4 ± 1.7 pmol/min/mm ($p<0.03$;n=3). In PTs isolated from rats that were fed a 20% fructose diet, fructose reabsorption was 19.3 ± 0.5 pmol/min/mm, significantly greater than controls ($p<0.03$;n=5). Fluid reabsorption was not significantly different among all groups. SGLT5 expression increased by 59±11% in PTs from rats fed a 20% fructose diet compared to rats fed a control diet ($p<0.02$;n=6).

Conclusions: Fructose is reabsorbed by the PT. Fructose possibly enters the cell via luminal SGLT5 and exits the cell via GLUT2/5. A 20% fructose diet enhances reabsorption in part by increasing SGLT5. Fructose-enhanced fructose reabsorption likely contributes to elevated plasma fructose when dietary fructose increases.

Rehydration with Fructose-Containing Beverages Produce Renal Oxidative Stress and Injury in both Passive and Active Dehydration States L. Gabriela Sanchez-Lozada,[1] Fernando E. García-Arroyo,[1] Magdalena Cristobal,[1] Edilia Tapia,[1] Abraham Said Arellano-Buendia,[1] Horacio Osorio,[1] Virgilia Soto,[2] Magdalena Madero,[1] Carlos Alberto Roncal-Jimenez,[3] Richard J. Johnson.[3] *[1]Lab. Renal Physiopathology and Nephrology, INC Ignacio Chavez, Mexico, D.F., Mexico; [2]Pathology, INC Ignacio Chavez, Mexico, D.F., Mexico; [3]Renal Diseases, U. of Colorado, Aurora, CO.*

Background: Elevated vasopressin and sugary beverages are associated with renal damage. In the present study we evaluated the effect of mild intermittent dehydration, and subsequent fluid replacement with a sweetened beverage on plasma copeptin and renal alterations.

Methods: Mild intermittent dehydration was induced either passively (daily water restriction) or actively (daily exposure to heat). After both maneuvers animals rehydrated for 2 h with water, or water sweetened with either a non-caloric edulcorant (stevia) or 11% fructose-glucose. All groups were studied for 4 weeks.

Results: The animals which received a sweetened beverage as rehydration fluid, in both active or passive mild dehydration, developed a heightened vasopressin response, noted by an increase in plasma and urine osmolality, increased plasma copeptin, decreased electrolyte-free water clearance, development of mild renal lesions with increased plasma creatinine, urinary excretion of NAG, N-GAL and nephrin, greater oxidative stress in renal cortex, tubular alterations, mild fibrosis, and overexpression of fructokinase, aldose reductase and the vasopressin AV1a receptor in the renal cortex.

Conclusions: We report that mild intermittent dehydration (active or passive), when combined with sweetened beverage ingestion, leads to a heightened vasopressin response associated with renal injury and oxidative stress. These data is also relevant to the general increased consumption in the population of sweetened beverages with reduced intake of plain water. Thus current rehydration practices might have a deleterious effect on the kidney.

SA-PO086

A Mathematical Model of the Rat Nephron: Renal Glucose Transport Alan Mark Weinstein. *Dept of Physiology and Biophysics, Weill Medical College of Cornell, New York, NY.*

Background: Mathematical models of proximal tubule (PT), loop of Henle (LOH), and complete distal nephron have been combined to simulate transport by rat renal tubules.

Methods: The ensemble is comprised of 24000 identical superficial (SF) nephrons and 12000 juxtamedullary (JM) nephrons in 5 classes (according to LOH length); all coalesce into a single set of 7200 connecting tubules. Medullary interstitial solute concentrations are specified. The model requires iterative solution so that each nephron GFR satisfies a tubuloglomerular feedback (TGF) relation, and each initial hydrostatic pressure yields a common end-distal tubule pressure for all nephrons; that common initial connecting tubule pressure is determined from an overall distal hydraulic resistance to flow. By virtue of the greater GFR for JM nephrons, overall fluid processing by SF and JM tubules is comparable. Glucose reabsorption is restricted to proximal tubule, cotransported with one Na in convoluted tubule (SGLT2), and two Na in straight tubule (SGLT1).

Results: Increasing ambient glucose from 5 to 10 mM, increases proximal Na reabsorption, and decreases distal delivery. This is mitigated by a TGF-mediated increase in GFR, but there is still a decrease in Na and K excretion. Conversely, when distal delivery is increased by inhibition of SGLT2, the increase in distal hydrostatic pressure is transmitted back to PT, distending the tubule, and thus slowing axial fluid velocity. By virtue of glomerulotubular balance, slower flow blunts proximal Na reabsorption, amplifying renal Na and K wasting. In this case, TGF acts to reduce GFR, reduce proximal tubule distention, and thus limit natriuresis.

Conclusions: In sum, the model captures TGF-mediated diabetic hyperfiltration, and predicts glomerular protection with SGLT2 inhibition.

SA-PO087

Proximal Tubular Claudin 2 Expression Is Necessary for Paracellular Water Reabsorption and Is Sensitive to Nephrotoxin Exposure Paul Jennings, Lydia Aschauer, Alice Limonciel, Gerhard Gstraunthaler, Walter Pfaller, Anja Wilmes. *Div of Physiology, Innsbruck Medical Univ, Innsbruck, Austria.*

Background: Claudins are the major proteins of the tight junctions and the composition of claudin subtypes is critical for the selective permeability of the paracellular route and thus tissue specific function. It has been suggested that claudin 2 acts not only as paracellular cation channel but is also a paracellular water channel.

Methods: RPTEC/TERT1 cells were cultured on microporous growth supports or solid cell culture plates in serum free hormonally defined DMEM/F12. Cells were exposed to nephrotoxins and claudin 2 expression was determined at an mRNA and protein level. Claudin 2 knock down cells were generated with shRNA and puromycin selection.

Results: We have shown that several nephrotoxic compounds including Adefovir, Cyclosporine A (CsA), cadmium, chloracetaldehyde, Cidofovir, potassium bromate and Zoledronate decreased claudin 2 expression in cultured human proximal tubule cells (RPTEC/TERT1). Since the cellular changes due to these compounds were not limited to claudin-2 we investigated the transport properties of RPTEC/TERT1 cells with and without claudin 2 knock down using shRNA. Knock down of claudin 2 had no discernable effect on transepithelial electrical resistance (TEER) or dome formation, but severely attenuated apical to basolateral water reabsorption when cultured on microporous filters. Generation of an osmotic gradient in the basolateral compartment rescued water transport in claudin 2 knock down cells. Inhibition of Na^+/K^+ ATPase with ouabain inhibited dome formation in both cell types. Thus, dome formation is primarily due to transcellular water transport following a solute driven osmotic gradient. However, in RPTEC/TERT1 cells cultured on filters under iso-osmotic conditions, water transport is primarily paracellular, via pore-forming claudin 2, most likely due to local increases in osmolarity in the intercellular space.

Conclusions: In conclusion, we provides strong evidence that claudin 2 is required for paracellular water transport in the proximal tubule and that claudin 2 expression is sensitive to nephrotoxin exposure.

SA-PO088

Renal Effects of Sortilin-Deletion in Mice Kamila Bikulowa, Aljona Borschewski, Christin Dathe, Sebastian Bachmann, Kerim Mutig. *Anatomy, Charité- Universitätsmedizin Berlin, Berlin, Germany.*

Background: The family of the VPS10P-domain receptors comprises five l-type transmembrane proteins which share as a common hallmark the VPS10P-domain and are involved in intracellular sorting of diverse ligands in various cell types. Two of the family members, the sorting-protein-related receptor with A-type repeats (SORLA) and the sortilin, are abundantly expressed in the distal nephron of the kidney. We have previously described decreased NKCC2 phosphorylation and activity in SORLA-deficient mice and suggested that SORLA mediates intracellular trafficking of kinases and phosphatases responsible for the phosphoregulation of the transporter. In this study we focus on the role of the sortilin in the regulation of epithelial transporters and channels along the distal nephron.

Methods: Sortilin-deficient (Sort-/-) mice were analyzed for their physiologic kidney performance, kidney morphology, and biochemical profile of renal transporters.

Results: In wildtype (WT) mouse kidneys, sortilin was expressed along the distal nephron and in the principal cells of collecting duct. Sortilin deficiency had no major effects on kidney morphology. Physiologic evaluation of WT and Sort-/- mice showed significantly increased urinary volume and calcium excretion upon sortilin disruption. Immunoblotting evaluation of major distal epithelial salt transporters and water channels revealed decreased levels of the Na-Cl cotransporter (NCC) and of the phosphorylated, activated aquaporin 2 (AQP2) in sortilin-deficient kidneys compared to WT controls.

Conclusions: In sum, our results suggest that sortilin facilitates the reabsorptive function of renal distal epithelia by interfering with function of NCC and AQP2.

SA-PO089

TRPC3 Channel Regulates Sensitivity of Murine Distal Nephron Cells to Hypotonicity Mykola Mamenko, Oleg L. Zaika, Nabila Boukelmoune, Roger G. O'neil, Oleh Pochynyuk. *Integrative Biology and Pharmacology, The Univ of Texas Health Science Center at Houston, Houston, TX.*

Background: Mechanical stimuli, such as changes in tubular flow and fluid composition, are important regulators of transport rates of water and ions in distal nephron (DN). DN cells respond to mechanical stimuli with increase of $[Ca^{2+}]_i$. Our group has recently identified that TRPV4 channel is essential for flow-induced $[Ca^{2+}]_i$ elevations in DN cells, however little is known about molecular nature of the response to osmotic gradients.

Methods: Here, we employ Fura-2 Ca^{2+} imaging in split-opened distal nephrons of C57BL/6 and genetically modified mice to study molecular determinants of $[Ca^{2+}]_i$ response to hypotonicity in DN.

Results: We found that hypotonic stimulus elicits a uniform and reproducible increase of $[Ca^{2+}]_i$ in DN cells. $[Ca^{2+}]_i$ elevations in response to osmolality changes occur in a dose-dependent manner. Hypotonicity-induced response is mainly mediated by the entry of extracellular Ca^{2+} through the plasma membrane. However, in contrast to flow-induced $[Ca^{2+}]_i$ elevations, pharmacological inhibition or genetic ablation of TRPV4 channel fails to abrogate $[Ca^{2+}]_i$ increase elicited by hypotonic stimuli, pointing to involvement of another membrane channel. Indeed, we found that pharmacological inhibition of TRPC3 channel with pyr3 significantly attenuates elevations of $[Ca^{2+}]_i$ induced by hypotonicity. Moreover, half-maximal response to decreased osmolality requires a stronger shift in tonicity of the bath solution in TRPC3-/- mice, indicating that TRPC3 channel determines sensitivity of DN cells to hypotonic stimuli.

Conclusions: Thus, $[Ca^{2+}]_i$ elevation induced by hypotonicity is a multifactorial response. While the channel triggering $[Ca^{2+}]_i$ increase in response to low osmolality remains to be identified, our results argue that TRPC3 channel serves as a regulator of sensitivity to hypotonic stimuli in DN cells.

STIM1 Dysfunction Causes NDI-Like Symptoms in Rats Mykola Mamenko,[1] Oleg L. Zaika,[1] Nabila Boukelmoune,[1] Oleh Pochynyuk,[1] Peter A. Doris.[2] *[1]Dept of Integrative Biology and Pharmacology, The Univ of Texas Health Science Center at Houston, Houston, TX; [2]Inst of Molecular Medicine, The Univ of Texas Health Science Center at Houston, Houston, TX.*

Background: Arginine Vasopressin (AVP)-regulated water transport in the collecting duct (CD) is a critical determinant of bodily fluid homeostasis. AVP promotes water reabsorption in CD via expression and trafficking of Aquaporin 2 water channel (AQP2) to the luminal membrane of principal cells. Inability of CD cells to properly respond to AVP results in a devastating disorder – nephrogenic Diabetes insipidus. A paramount role of V2 receptor – cyclic AMP – PKA pathway in AQP2-dependent water transport has been well established. At the same time, an emerging body of evidence shows that AQP2 trafficking and AVP-induced osmotic water permeability in CD cell lines require $[Ca^{2+}]_i$. However, molecular mechanisms underlying AVP-induced $[Ca^{2+}]_i$ response remain obscure. Recent studies point to the involvement of store-operated Ca^{2+} entry (SOCE) in AVP-stimulated $[Ca^{2+}]_i$ signaling.

Methods: Here we use spontaneously hypertensive stroke-prone rats (SHR-A3) as an animal model for SOCE disruption.

Results: While being 87% genetically identical to stroke-resistant spontaneously hypertensive rats (SHR-B2), SHR-A3 have a nonsense mutation in *STIM1* gene. This results in truncation of C-terminal region of STIM1 protein – an endoplasmic reticulum Ca^{2+} sensor, responsible for interactions with plasma membrane Ca^{2+} channels. Using Fura-2 Ca^{2+} imaging in freshly isolated split-opened CDs, we demonstrate that truncation of STIM1 disrupts SOCE in SHR-A3. AVP-stimulation elicits a sustained $[Ca^{2+}]_i$ elevation in CD cells from SHR-B2, as opposed to a transient $[Ca^{2+}]_i$ response in SHR-A3. SHR-A3, but not SHR-B2, manifest increased water intake and decreased urine osmolality, while having elevated plasma AVP levels.

Conclusions: This suggests that STIM1-activated Ca^{2+} entry is critical for AVP-induced water reabsorption. Disruption of STIM1 signaling compromises ability of the kidney to concentrate water resulting in a pathological state, closely resembling nephrogenic Diabetes insipidus.

Transepithelial Sodium Permeabilities in Isolated Perfused Segments of Rat Renal Inner Medullary Thin Limbs of Henle's Loops and Vasa Recta Kristen K. Evans, William H. Dantzler, Thomas L. Pannabecker. *Physiology, Univ of Arizona, Tucson, AZ.*

Background: Sodium fluxes and resulting sodium permeabilities in specific segments of thin limbs of Henle's loops are critical to concentrating urine in rat renal inner medulla (IM) but have not yet been well defined. There are no published accounts of isolated perfused inner medullary vasa recta. To better understand the role that sodium fluxes may play in the urine concentrating mechanism, sodium permeabilities (P_{Na}) were determined in inner medullary thin limbs of Henle's loops and vasa recta. Transepithelial sodium flux in thin limbs is believed to occur by way of the paracellular pathway.

Methods: P_{Na} was determined from ^{22}Na fluxes in perfused rat descending (DTLs) and ascending (ATLs) thin limbs isolated from 1) initial 2.5 mm below the outer medullary-inner medullary border (upper IM) or 2) terminal 2.5 mm of the IM (lower IM). P_{Na} was determined in isolated perfused vasa recta from the lower IM.

Results: P_{Na} (x 10^{-5} cm/s, mean ± SE) was 71.8 ± 21.9 (n=9) in upper IM DTLs and 329.6 ± 18.5 (n=2) in lower IM DTLs. P_{Na} from the lower IM ATL was 397.8 ± 66.0 (n=5). In isolated perfused papillary vasa recta P_{Na} was 385 ± 83.2 (n=2). For all segments, temperature reduction to 16° C produced little or no change in permeability.

Conclusions: As previously shown for urea permeability, P_{Na} is similar in lower DTL and ATL, segments that lack water channel AQP1 and have no osmotic water permeability, but is significantly lower in upper DTLs, segments that express AQP1 and have high osmotic water permeabilities. The very high P_{Na} in the lower DTL was not considered in original formulations of the passive hypothesis mechanism. P_{Na} in the isolated perfused papillary vasa recta is comparable to P_{Na} determined with in vivo microperfusion. The isolated perfused tubule technique offers potential to gain new insights into inner medullary vasa recta function.

Gout Patients Differ from Healthy Subjects in Their Renal Response to Serum Uric Acid Alterations, Suggesting Less Saturated Uric Acid Reabsorption Systems in Gout Patients Sha Liu, Jeffrey N. Miner. *Ardea Biosciences, San Diego, CA.*

Background: The literature is discrepant with regard to the impact of changing sUA levels on the fractional excretion of uric acid (FEUA) in gout patients. The objectives of this study are to determine whether a change in sUA induced by xanthine oxidase inhibitors (XOI) results in a corresponding change in FEUA and to determine whether the effects are different in gout patients compared to normal healthy volunteers (NHV).

Methods: An analysis based on data from 4 Phase I/Ib studies, in which XOI were given to either NHV or gout patients, was conducted. Plots were created denoting change in FEUA versus baseline FEUA, as well as FEUA versus sUA. Change in FEUA per mg/dL change in sUA was calculated, and NHV and gout patients were compared using Student's *t*-test.

Results: A total of 62 subjects, 55 of whom had sUA and FEUA values at screening (baseline) and day 7, were pooled for analysis (NHV, n=23; gout patients, n=32). The correlation coefficient between baseline FEUA and change in FEUA was -0.83, $P<0.0001$, indicating the higher the baseline FEUA, the greater change in FEUA. When FEUA versus sUA before and after XOI treatment were plotted, the magnitude of FEUA change was greater in NHV (who have higher baseline FEUA) than gout patients (Figure). The slope of the FEUA curve in NHV was significantly steeper than that for those with gout (0.81 ± 0.114 versus 0.22 ± 0.036; $P<0.0001$).

Figure. The magnitude of changes in the FEUA are different between gout and NHV when sUA is lowered with XOIs.

	FEUA at baseline	FEUA with XO inhibitor	P value vs baseline (paired t-test)	delta FEUA per mg/dL change in sUA	P-value vs gout (t-test)
Healthy	7.0 ± 0.36	5.0 ± 0.26	<0.0001	0.81 ± 0.114	<0.0001
Gout	3.8 ± 0.15	3.0 ± 0.11	<0.0001	0.22 ± 0.036	

Conclusions: Reduction of sUA with XOI treatment results in differential effects on FEUA in gout patients versus NHV. Gout patients demonstrate a smaller change in FEUA than NHV with a similar reduction in sUA. This suggests the possibility of a less saturated uric acid reabsorption system in gout patients compared to that in NHV.

Integrated Collecting Duct Response of Cilia, Polycystins, ATP, NO, and ET-1 to Flow Donald E. Kohan,[1] Rajeev Rohatgi,[2] G. Luca Gusella,[2] Jing Zhou,[3] Edward W. Inscho,[4] Tsugio Seki,[4] Bellamkonda K. Kishore,[1] Meghana Pandit.[1] *[1]Univ of Utah, Salt Lake City, UT; [2]Icahn School of Medicine, NY, NY; [3]Brigham and Women's Hospital/Harvard Medical School, Boston, MA; [4]Georgia Regents Univ, Augusta, GA.*

Background: Collecting duct (CD)-derived endothelin-1 (ET-1) is an autocrine inhibitor of Na and water reabsorption. CD-specific ET-1 knockout causes marked hypertension. CD ET-1 production is increased by Na or water loading, however the responsible mechanisms remain unclear.

Methods: To address this, regulation of ET-1 synthesis by mouse IMCD3 cells was studied. Shear stress of 2 dyne/cm^2 increased ET-1 mRNA by 230% as compared to no flow; the effect was first evident after 1 hr of flow.

Results: The flow response required intracellular and extracellular Ca^{2+}, PKC, PLC, calmodulin and calcineurin. Examination of known flow-dependent Ca^{2+} channels in CD cells revealed that the ET-1 flow response required purinergic P2X receptors and polycystin-2, but not TRPC3, TRPC6 or TRPV4. Absence of polycystin-1 or cilia deletion with chloral hydrate blocked the flow response. Both $P2Y_2$ and P2X receptors were required for the flow response. IMCD3 cells lacking polycystin-2 did not increase ET-1 mRNA in response to exogenous ATP, while ATP release was reduced in PKD2-deficient cells. Western and PCR analysis revealed that IMCD3 cells express virtually all known P2X and P2Y receptors. Flow also increased IMCD3 nitric oxide (NO) production; blockade of NO synthesis reduced the ET-1 flow response by 50%.

Conclusions: These findings indicate that luminal flow, likely via ciliary bending, activates polycystins-1 and -2, releasing ATP which acts upon P2X and $P2Y_2$ receptors, increasing intracellular Ca^{2+}, which in turn activates PKC, calmodulin/calcineurin and NO synthase which augment CD ET-1 production. Since ATP and NO can independently inhibit CD transport, we propose that the CD contains a highly interactive network of factors wherein NO and ATP cause both acute (via their own direct actions) and chronic (via ET-1) inhibition of CD transport. These findings demonstrate, for the first time, how discrete autocrine factors in the CD may interact to exert an immediate and sustained response to volume loading.

Enhanced Autophagy in the Proximal Tubule with Intracellular Vacuoles from AQP11 Null Mice Leading to the Development of Polycystic Kidneys Yasuko Tanaka,[1] Mayumi Watari,[1] Emi Takagi,[1] Yuki Sakamoto,[1] Yoshiyuki Morishita,[2] Kenichi Ishibashi.[1] *[1]Pathophysiology, Meiji School of Pharmacy, Kiyose, Tokyo, Japan; [2]Nephrology, Jich School of Medicine, Shimotuke, Tochigi, Japan.*

Background: AQP11 is an intracellular water channel, which is selectively expressed at ER of the proximal tubule in the kidney as well as other tissues. Its disruption leads to intracellular vacuole formation at 1-wk old and eventually to the development of the polycystic kidney at 3-wk old. We previously reported the upregulation of genes involved in ER stress and apoptosis in the kidneys from 1 to 4-wk old AQP11 null mice. However, some of the vacuolated cells should survive to be the cyst epithelium since all cysts are derived from the proximal tubule.

Methods: To visualize autophagy in tissues, we introduced GFP–LC3 as a marker for autophagy in AQP11 null mice by crossing with GFP-LC3 transgenic mice kindly provided by Dr. N. Mizushima. We examined the tissues from 1, 2, 4, and 5-wk old wild and AQP11 null mice.

Results: The expression of GFP-LC3 puncta was limited to the proximal tubule in the kidney, whose amount was higher in the proximal tubule of 2-wk old AQP11 null mice than wild mice. Its expression was particularly high at the deep cortex where the intracellular vacuoles were smaller with PAS-positive inclusion bodies. The GFP-LC3 puncta expression was also observed in the cyst-lining epithelial cells which still had vacuoles. The active autophagy was also documented by electron microscopy to reveal autophagosomes, mitophagy, and their fusion with lysosomes in the proximal tubule from 1 and 2-wk old AQP11 null mice. Quantitative PCR revealed the enhanced expression of LC3 and beclin-1 in the kidney of 2-wk old AQP11 null mice. On the other hand, the expression of GFP-LC3 puncta was not increased in hepatocytes and intestinal epithelial cells with intracellular vacuoles, suggesting the kidney-specific augmentation of autophagy in the absence of AQP11.

Conclusions: In conclusion, the proximal tubule of AQP11 null mice undergoes active autophagy especially at the deep cortex at 2-wk old with extensive intracellular vacuoles, which may support the survival for later development and maintenance of cysts.

Negative Transcriptional Regulation of Aquaporin-1 By Unfolded Protein Response Ayaka Kato, Hiroko Sonoda, Kanako Shigemura, Saki Takahashi, Masahiro Ikeda. *Veterinary Pharmacology, Univ of Miyazaki, Miyazaki, Japan.*

Background: The unfolded protein response (UPR) is an intracellular signaling pathway in response to the accumulation of misfolded proteins in the endoplasmic reticulum (ER). When misfolded proteins accumulate in the ER, the dissociation of GRP78 (an ER chaperon) from the ER stress sensor proteins (PERK, ATF6, and IRE1) activates downstream signaling pathways characterized by the transcriptions of several genes including CHOP mRNA. Renal ischemia-reperfusion (I/R) injury is a major cause of acute kidney injury. So far, renal UPR activation has been observed following renal I/R and this activation is suggested to protect against the injury. Aquaporin-1 (AQP1) is a water channel protein and its expression has been shown to be decreased following renal I/R.

Methods: In this study, we investigated whether AQP1 expression is directly regulated by UPR activation in rat renal proximal tubular epithelial (NRK52E) cells.

Results: When NRK52E cells were treated with chemical UPR inducers, including tunicamycin and thapsigargin, AQP1 mRNA and protein expression were decreased in association with up-regulation of CHOP mRNA. Since GRP78 knockdown is expected to activate the UPR pathway due to the increase in the free form of the sensor proteins, we examined the effect of GRP78 siRNA on the expression of AQP1 and CHOP mRNAs. As a result, the knockdown of GRP78 caused a decrease in AQP1 and an increase in CHOP mRNAs. Similarly to Aqp1 gene, the expression of Glut1, Hmox1, Ldha, Akr1b1, and Smit1 has been reported to be increased by either hypoxia or hypertonicity, and we then checked the effects of chemical UPR inducers on the expression levels of these genes. Consequently, chemical UPR inducers did not dramatically lower the expression of these genes. Finally, reporter assay with 1991 bp of 5'-flanking region of rat Aqp1 gene was performed, and the result showed that this region did not contain silencer elements in response to UPR activation.

Conclusions: In conclusion, these findings suggest that AQP1 is selectively down-regulated by UPR activation and this regulation might be involved in decreased expression of AQP1 following renal I/R.

SA-PO096

Prostanoid Receptors EP2 and EP4 Regulate Aquaporin-2 Membrane Targeting and Phosphorylation Through Multiple Signaling Pathways Emma T.B. Olesen,[1] Christian Berg,[3] Mette Marie Rosenkilde,[3] Nanna Macaulay,[2] Robert A. Fenton.[1] *[1]Dept of Biomedicine, Aarhus Univ, Aarhus C, Denmark; [2]Inst for Cellular and Molecular Medicine, Copenhagen Univ, Copenhagen, Denmark; [3]Dept of Neuroscience and Pharmacology, Molpharm, Copenhagen Univ, Copenhagen, Denmark.*

Background: Aquaporin-2 (AQP2) is the vasopressin-sensitive water channel expressed in the kidney collecting duct principal cells. Upon stimulation of the Gs coupled vasopressin type 2 receptor, intracellular vesicles containing AQP2 mobilize and fuse with the plasma membrane, causing AQP2 membrane accumulation (MA) and phosphorylation at 3 COOH-terminal sites. This process can be mediated by a Gαs induced increase in cAMP. We have previously shown that the prostanoid receptor EP4 induces AQP2 MA through a signaling pathway that does not involve an increase in cAMP in kidney epithelial cell lines, whereas the prostanoid receptor EP2 increases cAMP and AQP2 MA. EP4 is a known Gs coupled receptor, that can also signal via the pertussis toxin sensitive G-protein Gi, which decreases cAMP through the Gαi subunit and activates PI3K most likely through Gβγ.

Methods: To explore the novel EP4 signaling pathway, we stimulated Madin-Darby Canine Kidney cells, which natively express EP2 and EP4 and are stably transfected with AQP2, with the EP4 agonist CAY10580 (CAY) or EP2 agonist butaprost (BUTA) and studied AQP2 MA by cell surface biotinylation.

Results: Inactivation of Gαi with pertussis toxin did not affect 1 μM BUTA or 3 μM CAY mediated AQP2 MA. The Gβγ inhibitor gallein markedly inhibited 3 μM CAY mediated AQP2 MA, whereas gallein did not prevent 50 nM BUTA mediated AQP2 MA. Gallein enhanced 50nM BUTA induced phosphorylation of AQP2 at ser-264. Gβγ signals through pathways with a variety of second messengers, including cAMP, Ca^{2+} and inositol 1,4,5-triphosphate (IP3). However, neither 3 μM CAY nor 1μM BUTA significantly increased intracellular Ca^{2+} or IP3.

Conclusions: EP4 mediated AQP2 membrane accumulation may be instigated at least in part by the Gβγ subunit via a pathway that does not involve an increase in cAMP or Ca^{2+}/IP3, whereas Gβγ modulates the effect of the EP2 receptor on AQP2 phosphorylation at ser-264.

Increased Phosphorylation of Ser-269 Is Not Sufficient for Regulated AQP2 Apical Accumulation Naofumi Yui, Sei Sasaki, Shinichi Uchida. *Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan.*

Background: Ser-269 is one of the vasopressin (VP)-sensitive phosphorylation sites in the C-terminus of AQP2, and this AQP2 phspho-form is observed in the apical plasma membrane after VP stimulation for several tens of minutes. Therefore, it is recently supposed that S269 phosphorylation occurs in the apical plasma membrane preventing its endocytosis for the regulated AQP2 apical accumulation.

Methods: In this study, we studied its subcellular localization by using specific pS269-AQP2 polyclonal antibody in MDCK cells that express wild-type rat-AQP2 with no tag sequence.

Results: Immunoblotting analysis revealed that pS269-AQP2 was dramatically increased just after 1 min forskolin (FK, 20 μM) treatment with a faint increase of pS256-AQP2. In immunofluorescence, pS269-AQP2 was accumulated in the apical regions after 10 min FK treatment. Unexpectedly, it was mainly detected in the intracellular sites at 1 min. Next, we investigated whether or not all of pS269-AQP2 is stably inserted in the apical plasma membrane after 10 min FK stimulation. To elucidate this question, we applied cold shock (4 °C, 15 min) to AQP2-MDCK cells. Briefly, cold shock instantly arrested clathrin-mediated endocytosis, therefore, it successfully revealed the previously unrecognized AQP2's basolateral targeting that is usually undetectable due to its rapid internalization. Cells were treated with FK for 10 min, then subjected to cold shock, and fixed at 4°C.

Surprisingly, significant amount of pS269-AQP2 was detected in the basolateral plasma membrane after cold shock. Site-specific biotinylation assays also revealed basolateral targeting of pS269-AQP2 after 10 min FK treatment.

Conclusions: In summary, pS269-AQP2 was localized intracellularly at the initial phase of FK stimulation. Even after 10 min FK stimulation, pS269-AQP2 was not exclusively inserted into the apical membrane, but some were targeted to basolateral membranes. In conclusion, the increased S269 phosphorylation might be an essential trigger but not sufficient for the VP-regulated AQP2 apical accumulation. Following mechanisms induced by S269 phosphorylation for the regulated AQP2 apical accumulation have to be elucidated.

Integrin Linked Kinase Regulates the Transcription and Phosphorylation State of Aquaporin2 Jose Luis Cano-Peñalver,[1] Mercedes Griera,[1] Maria P. Ruiz-Torres,[1] Diego Rodriguez-Puyol,[2] Sergio De Frutos Garcia,[1] Manuel Rodriguez-Puyol.[1] *[1]Dept of Physiology, Univ de Alcalá, Alcalá de Henares, Madrid, Spain; [2]Research Unit, Hospital Univ Principe de Asturias, Alcalá de Henares, Madrid, Spain.*

Background: The water channel Aquaporin2 (AQP2) is regulated both transcriptionally and location-based phosphorylation stages. We recently published (FASEB J 2014) that depletion of the scaffold protein integrin-linked kinase (ILK) diminishes AQP2 abundance and membrane presence. Here we show that the lack of ILK reduce AQP2 transcription and phosphorylation in conditional ILK knock-down mice (cKD-ILK) and ILK-depleted inner medullary collecting duct cells (mIMCD3).

Methods: To decrease ILK activity, mIMCD3 were transfected with ILK siRNAs (Si-ILK) or treated with collagen I (COL I), an extracellular matrix component increased in renal interstitial fibrosis. ILK activity was determined measuring the phosphorylation levels of its substrates GSK and AKT. The AQP2 transcriptional stage was measured in mIMCD3 transfected with AQP2 promoter or NFAT transcriptional activity reporter plasmids. The AQP2 phosphorylation in ser256 was determined by immunoflorescence in kidney slides from WT and cKD-ILK.

Results: Decreased phosphorylations in GSK and AKT were observed in ILK-depleted or COL I-treated mIMCD3, compared with control. ILK-depleted cells reduced their AQP2 promoter activity basally, and it was not completely restore when cAMP-based AQP2 activation was performed by forskolin. The lack of ILK reduced the NFAT activity basally or under activation of NFATc/AP1 tandem of transcription factors by ionomycin and PMA. Finally, AQP2 phosphorylation at s256 and its plasma membrane presence were diminished in cKD-ILK slides.

Conclusions: ILK depletion reduces the phosphorylation of GSK and AKT, and this may initiate the further signaling in AQP2 regulation. ILK depletion reduced the AQP2 promoter activity. ILK mediates AQP2 transcriptional activity independently of cAMP-dependent activation, probably by NFATc/AP1. In-vivo depletion of ILK reduced the ser256-phosphorylated AQP2 quantity and apical location in the kidney, attributing ILK a new role in post-transcriptional control of the AQP2 relocation to the plasma membrane.

Estradiol Attenuates Increased Cortical AQP2 Expression and Water Retention in Rats Subjected to Ovariectomy for 7 Days Rikke Norregaard, M.Umar Cheema, William A. Miller-Little, Jorgen Frokiaer. *Inst of Clinical Medicine, Aarhus Univ, Aarhus, Denmark.*

Background: Female sex hormones are suggested to be involved in the regulation of renal water handling. We hypothesize that changes in renal water handling in response to ovariectomy (OVX) is associated with dysregulation of renal aquaporin-2 (AQP2) and can be improved with estradiol or progesterone treatment.

Methods: To examine this, rats were subjected to OVX for 7 days and received subcutaneous administration of estradiol (25 μg/kg/day) or progesterone (10 mg/kg/day) for 7 days. Expression and trafficking of AQP2 and phospho-Ser256-AQP2 (pAQP2) were examined in cortex and inner medulla. Using cortical collecting duct (mpkCCD) principal cells, the effect of estradiol exposure on AQP2 expression and cAMP production was investigated.

Results: OVX was associated with decreased serum estradiol and progesterone levels. Rat subjected to OVX had increased bodyweight (BW) and food intake which was normalized by estradiol treatment, whereas progesterone had no effect. Decreased urine output and increased urine osmolality after 7 days OVX were prevented by estradiol treatment. AQP2 and pAQP2 expression were increased in cortex from OVX rats and this was prevented by estradiol administration whereas progesterone had no effect. Furthermore, confocal microscopy analysis showed decreased apical distribution of both AQP2 and pAQP2 in cortical collecting duct principal cells in estradiol treated OVX rats compared to untreated OVX rats. In inner medulla, there was no significant change in AQP2 and pAQP2 abundance among the four groups. Transcript of estrogen receptors including the G protein-coupled estrogen receptor 1 (GPER1) as well as estrogen receptors ERα and ERβ was detected in mpkCCD cell. Moreover, estradiol attenuated the vasopressin induced AQP2 expression and cAMP production in mpkCCD cells.

Conclusions: In conclusion, estradiol attenuates dysregulation of AQP2 in cortical collecting duct principal cells and water retention in rats subjected to OVX for 7 days.

SA-PO100

The Decreased Excretion of Urinary Exosomal Aquaporin-2 During Gentamicin-Induced Urine Concentrating Defect in Rats Hiroko Sonoda, Ahmed Abdeen, Masahiro Ikeda. *Veterinary Pharmacology, Univ of Miyazaki, Miyazaki, Japan.*

Background: Urinary exosomes are nano-sized vesicles secreted into urine from various renal cells. It has been reported that urinary exosomes containmany types of renal functional proteins that are involved in renal reabsorption and secretion of water and solutes. Aquaporin-2 (AQP2), a member of water channels, is known to be excreted into the urine via exosomes. As renal water reabsorption is known to be regulated by the level of renal AQP2 expression, it is considered that urinary exosomal AQP2 excretion reflects the changes of renal urine concentrating ability. Gentamicin (GM), an aminoglycoside antibiotic, is used for treatment of many types of bacterial infection. One serious limitation to the use of GM is that it can cause acute kidney injury. Besides this injury, GM has been reported to cause urine concentrating defect. By employing this action of GM, in this study we examined whether excretion of exosomal AQP2 was related to urine concentrating ability.

Methods: GM (160 mg/kg/day) or saline was intraperitoneally administered to male rats once every day starting on day 0. Urinary exosomes were isolated by ultracentrifugation.

Results: Plasma creatinine levels were significantly increased at day 5 and beyond in the GM group. GM caused polyuria and urinary concentrating defect at day 7. GM significantly increased urinary exosomal AQP2 excretion at day 1, whereas decreased it at day 7. GM increased urinary excretion of TSG101, frequently used as an exosome marker protein at day 1, but did not have any significant effect on it at day 7. Renal AQP2 expression level in the GM group was slightly decreased at day 2 and was markedly decreased at day 8.

Conclusions: These data suggest that the urinary exosomal AQP2 excretion was decreased in GM-induced urine concentrating defect in association with the reduction of renal AQP2 expression level. Furthermore, the use of urinary exosomal AQP2 may allow early detection of GM-induced nephrotoxicity and the underlying mechanism may be related to the number of exosomes.

SA-PO101

Urinary Excretion Patterns of Exosomal AQP1 and AQP2 in a Rat Model of Renal Tubulointerstitial Fibrosis Minami Kinouchi,[1] Hiroko Sonoda,[1] Saki Takahashi,[1] Naoko Yokota-Ikeda,[2] Masahiro Ikeda.[1] *[1]Veterinary Pharmacology, Univ of Miyazaki, Miyazaki, Japan; [2]Nephrology, Miyazaki Prefectural Miyazaki Hospital, Miyazaki, Japan.*

Background: Chronic kidney disease (CKD), characterized by renal tubulointerstitial fibrosis, affects more than 10% of adult population in the U.S.A. and Japan. The reason for this high incidence is a lack of reliable non-invasive biomarkers. Urinary exosomes secreted from all nephron segments are known to contain many types of renal functional proteins such as aquaporin-1 (AQP1) and AQP2, which suggests that urinary exosomes represent a potential reservoir of biomarkers for renal diseases. Renal AQP1 and AQP2 have been reported to be down-regulated in a rat model of tubulointerstitial fibrosis, suggesting that the urinary excretion of exosomal AQP1 and AQP2 would be altered in tubulointerstitial fibrosis. In this study, we examined urinary excretion of exosomal AQP1 and AQP2 in an experimental model of renal tubulointerstitial fibrosis.

Methods: Because a strong epidemiologic linkage between episodes of acute kidney injury (AKI) and subsequent development of CKD has been reported, in this study we employed an AKI [renal ischemia/reperfusion (I/R)]-induced renal tubulointerstitial fibrosis model.

Results: Blood biochemistry and urine analyses showed that the levels of urea nitrogen and creatinine were significantly increased until 7 days and 21 days, and urinary osmolality was significantly decreased 3 days after renal I/R. Masson-Trichrome stain demonstrated progressive renal tubulointerstitial fibrosis from 7 to 35 days after renal I/R. Immunoblotting studies showed that urinary exosomal AQP1 was significantly decreased until 7 days and AQP2 was decreased only 3 days after renal I/R. Moreover, urinary exosomal Alix and TSG101, commonly used as marker proteins of exosomes, were significantly increased from 7 to 21 days after renal I/R.

Conclusions: These data suggest that urinary exosomal AQP1 and AQP2 can be used to detect early renal injury following renal I/R, and exosomal AQP2 excretion might be related to urinary osmolality. Furthermore, urinary exosomal Alix and TSG101 excretion could be useful for detection of progressive process of renal fibrosis.

Eps15 Homology Domain Containing Protein 4 (EHD4) Is a Novel Player in the Control of Urine Volume Shamma Shakila Rahman, Alexandra Elizabeth Jane Moffitt, Andrew Trease, Hamid Band, Erika I. Boesen. *Univ of Nebraska Medical Center.*

Background: Eps15 Homology Domain containing protein 4 (EHD4) belongs to a family of endocytic recycling regulatory proteins. Our preliminary data show that EHD4 is expressed in the kidney, including the collecting duct, but the role of EHD4 in renal function is unknown. Accordingly, we tested whether whole body knockout of EHD4 affects baseline urinary salt and water excretion, systolic blood pressure, or acute excretory responses to diuretics or a water load.

Methods: Female wildtype (WT) and EHD4-/- mice were studied (n=4 per group). Urine was collected via metabolic cages: 24h for baseline; for 6h following 2ml of water i.p.; for 4h following i.p. injection of furosemide (40mg/kg), hydrochlorothiazide (HCTZ; 50mg/kg), amiloride (5mg/kg) or vehicle. NKCC2, αENaC and AQP2 were measured by Western blot. Systolic blood pressure was measured by tailcuff plethysmography.

Results: Spot urine osmolality was significantly lower in EHD4-/- versus WT mice (768±152 versus 1645±270mOsmol/kgH_2O; P<0.05). Baseline 24h urine flow was higher in EHD4-/- versus WT mice (1.17±0.24 versus 0.56±0.11ml/d; P=0.06), and urinary osmolality was lower (2198±121 versus 3178±155mOsmol/kgH_2O in WT; P<0.01). Basal Na^+, K^+ or Cl^- excretion did not differ between groups. EHD4-/- mice excreted significantly more of the 2ml i.p. water load in 6h than WT (1.5±0.2 versus 1.0±0.1ml; P<0.05). Urine flow but not Na^+ excretion was higher in EHD4-/- versus WT mice following vehicle injection (0.57±0.11 versus 0.30±0.03ml/4h; P=0.06). Urine flow and Na^+ excretion were significantly higher in EHD4-/- versus WT mice following amiloride (48±6 versus 23±8umolNa^+/4h; P<0.05). Responses to furosemide and HCTZ did not differ significantly between groups, nor did αENaC, NKCC2, or AQP2 protein levels in cortex, outer or inner medulla respectively. Systolic blood pressure was similar in EHD4-/- and WT mice (95±5 and 97±2mmHg). These data were from female mice, but similar trends were observed in male mice (EHD4-/- n=2).

Conclusions: Our data show that EHD4-/- mice produce higher volumes of more dilute urine than WT mice, suggesting a role for EHD4 in water homeostasis. Whether EHD4 regulates subcellular localization of AQP2 remains to be tested.

SA-PO103

Renal Inner Medullary Architecture of Human, Rabbit, and Pig Guojun Wei, William H. Dantzler, Thomas L. Pannabecker. *Physiology, Univ of Arizona, Tucson, AZ.*

Background: The architecture of the simple type of renal outer medulla (human, rabbit, guinea pig) has long been known to be distinct from that of the complex type outer medulla (rat, mouse, kangaroo rat). In contrast, distinctions between architecture of the inner medullas of these two animal groups have not been reported.

Methods: Human, rabbit and pig medullas were fixed in PLP or glutaraldehyde and embedded in paraffin or Spurrs. Immunofluorescence histochemistry was conducted using antibodies against water channels AQP1 and AQP2 and urea transporters UTA and UTB. Tissue prepared for electron microscopy was stained with uranyl acetate. Architecture is compared with prior studies of rat and kangaroo rat.

Results: Expression of UTB in human descending vasa recta (DVR) declines with depth below the outer medulla. Similarly, AQP1 in human is abundantly expressed in long loop descending thin limbs (DTLs) and declines with depth below the outer medulla. In the outer region of the human inner medulla AQP1-positive long-loop DTLs are juxtaposed with DVR lying in vascular bundles. DTLs and DVR lie at margins of CD clusters. In rat and kangaroo rat inner medulla, fenestrated capillaries (ascending vasa recta, AVR) abut approximately 25-50% of CD surface area along their entire lengths. In contrast, rabbit AVR abut less than 5% of CD surface area. Interstitial nodal spaces consisting of one CD with two abutting AVR and one ascending thin limb, that may allow preferential mixing of water, NaCl and urea, are virtually absent in the simple type medulla of rabbit. UTB is abundantly expressed along the papillary epithelium.

Conclusions: Water or urea transepithelial permeabilities in human DTLs or DVR likely decline at progressively deeper levels below the outer medulla. Because of the physical separation of DTLs and DVR from CDs, fluid and solute reabsorbate from DTLs and DVR and diffusion of oxygen from DVR may have limited exchange with CDs. Absence of interstitial nodal spaces in the rabbit and their abundance in the complex type medulla of rat and kangaroo rat correlates with low and high urine concentrating capacity, respectively. UTB may provide a transcellular pathway for urea flux across the human papillary epithelium.

Lithium-Induced NDI, Hypercalcemia and Urinary PGE2 Excretion Develop Independently in Mice Theun de Groot,[1,2] Lena K. Ebert,[1,2] Ruben Baumgarten,[3] Peter M.T. Deen,[2] Ron Korstanje.[1] *[1]The Jackson Laboratory, ME; [2]Radboud Univ Med. Center, Netherlands; [3]St. Exp. Lab. Med., Netherlands.*

Background: Lithium is the mainstay treatment for bipolar disorder. However, it leads to nephrogenic diabetes insipidus (NDI) and hypercalcemia in 10-20% of patients. Lithium-induced NDI is caused by the inability of the renal collecting duct to reabsorb water. In C57BL/6 mice, lithium-NDI develops in all animals and its extent correlates with the level of excreted prostaglandin E2 (PGE2). Lithium-induced hypercalcemia is ascribed to a decreased sensitivity of the parathyroid gland to blood Ca^{2+} levels, however, as hypercalcemia is known to induce NDI independently of lithium, its development may aggravate lithium-NDI. As lithium-induced NDI and hypercalcemia only occur in a subset of patients, we investigated whether these processes are linked by analyzing their development in 15 different inbred mouse strains.

Methods: Starting at 10 weeks of age, female mice had unlimited access to normal chow or lithium diet (40mmol/kg). At day 8 and 26 mice were housed for 48 hours in metabolic cages to collect urine and at day 10 and 28 blood was isolated.

Results: Lithium treatment for 10 days significantly elevated the urine production of several strains, including C57BL/6J and FVB/NJ, while other strains like A/J and NZW/LacJ were not affected. Differences in urine output highly correlated with changes in urine osmolality. Interestingly, in none of the strains lithium significantly affected urinary PGE2 levels. Furthermore, lithium did not significantly alter blood pH, while urinary proton excretion was elevated in several strains. Lithium-induced hypercalcemia was observed in 4 strains, and did not correlate with the effect of lithium on urine production. Lithium treatment for 28 days only mildly modified the results obtained at 10 days.

Conclusions: Our results demonstrate that development of lithium-induced NDI, hypercalcemia and excretion of PGE2 varies among inbred strains, indicating an independent development of these lithium-related features. Moreover, the diversity in response reveals that inclusion of additional strains may allow identification of susceptibility genes for these lithium-induced disorders.

Transcriptome Changes in Rat Cortical Collecting Duct (CCD) during Vasopressin Escape Carolyn M. Ecelbarger,[1] Jae Wook Lee,[2] Mark A. Knepper.[2] *[1]Dept of Medicine, Georgetown Univ, Washington, DC; [2]Epithelial Systems Biology Laboratory, NHLBI/NIH, Bethesda, MD.*

Background: Vasopressin escape is a physiological phenomenon by which the kidney is able to overcome the antidiuretic effects of vasopressin when levels are inappropriately high (SIADH). Previously we showed escape was associated with a decrease in aquaporin-2 (AQP2) protein and mRNA. However, the mechanism remains obscure.

Methods: To identify genes that change during escape, we utilized RNA-seq in microdissected CCDs from rats infused with dDAVP (5 ng/hr) and consuming either a normal or a high-water volume (escape) for 1, 2, or 4 days. RNA-seq, a sensitive method to profile the entire transcriptome in small samples, was used to generate CCD transcriptomes (>6000 transcripts) in a total of 24 rats (n = 3-6/time point/group). The generated 50-bp reads were aligned to a rat reference genome. Individual mRNAs were quantified in terms of "reads per kilobase exon normalized to million mapped reads" (RPKM). Data were filtered to eliminate low abundance transcripts.

Results: AQP2 and several other transporters were found to change significantly ($p < 0.05$ and outside the 95% CI): AQP3 (down days 2 and 4), Slc2a1 (facilitated glucose transporter, down day 2) and Rhbg (ammonium transporter, up day 2), Slc38a3 (glutamine transporter, up days 2 and 4), Atp6v1b1 (H-ATPase subunit, up day 2). Overall, transporter transcripts expressed primarily in principal cells were decreased while those in intercalated cells were increased, suggesting reciprocal regulation. Thirteen transcription factors (TFs) with possible roles in initiating escape were significantly altered on day 1, including *Cebpg* (down), *Bmyc* (down) and 4 zinc-finger TF transcripts (2 up, 2 down). The secreted frizzled related protein 2 (*Sfrp2*), an inhibitor of Wnt signaling, was reduced on all 3 days (5-, 16-, and 100-fold on days 1, 2, and 4, respectively). The frizzled family receptor 4 (*Fzd4*) was increased on day 4. These changes might suggest a role for Wnt signaling in CD remodeling.

Conclusions: Overall, several novel transcripts were identified in vasopressin escape. Future studies will evaluate relationships between these transcripts and protein expression.

SA-PO106

Regulation of Antidiuretic Hormone (ADH) Secretion in End-Stage Renal Disease (ESRD): Evidence for the Role of Urea during Acute Hemodialysis (HD) Usman Z. Bhutta,[1,2] Kai Lau.[1,2] *[1]Medicine, Univ of Oklahoma Health Sciences Center, OKC, OK; [2]Medicine, VAMC, Oklahoma City, OK.*

Background: Of the 3 normal blood osmotic species, due to intrinsic reflection coefficients, Na is the most effective, urea the least, and glucose intermediate, depending on transport and insulin. In insulin deficiency, hyperglycemia is known to exert hydro-osmotic forces to shrink cell volume and stimulate ADH. In insulin-repleted diabetics or normal, acute hyperglycemia fails to raise ADH despite increased serum osmolality (S osm), findings attributed to ready cell entry of glucose and dissipation of the osmotic gradient. Small and uncharged, urea is thought to freely diffuse across cells and osmotically ineffective. However, marked drop in BUN during the 1st HD in some uremic patients is known to precipitate the dysequilibrium syndrome, raising the hypothesis that before the elevated intracellular urea diffuses back to blood, water is abstracted into neurons to cause swelling. If true, ADH should go down with HD.

Methods: To test this hypothesis, in 13 stable ESRD patients, we measured ADH pre- and post-HD x 3.5 h, using a bath with 138 mM Na and 200 mg% glucose.

Results: Mean S creatinine fell from 15 to 6 mg%. Mean ultrafiltration was 4 L. Mean arterial blood pressure and heart rate were stable between the first and last 30 min of HD. S [Na] rose from 138 to 140 mM. S [Glucose] rose from 113 to 147 mg% as BUN fell from 126 to 47 mg%. Although the component of S osm due to Na and due to glucose rose by 3.4 and 1.9 mOsm/kg respectively, that due to urea fell by 28.3 mOsm/kg, causing a net drop in S osm of 23.1 mosm/kg (329 to 305). Mean plasma ADH fell from 4.9 pre- to 1.3 pg/ml post-HD ($p<0.001$). Plasma ADH did not correlate with S osm based on [Na] x 2 ($r=0.1$) or [Na] x 2 + [glucose]/18 ($r=0.26$), but it was linearly correlated with S osm based on Na, glucose and urea ($r=0.7$, $p<0.01$).

Conclusions: 1. These data support our hypothesis that acutely urea exerts a significant effective hydro-osmotic force to abstract water across cells and alter ADH secretion. 2. They suggest the utility of ADH as an acute cell volume marker in monitoring cerebral edema in patients with head trauma or brain tumor getting mannitol or hypertonic saline.

Urinary Arginine Vasopressin and Aquaporin-2 in Edema Patients Byoung Geun Han, Youngsub Kim, Jae Seok Kim, Jae Won Yang, Seung-Ok Choi. *Div of Nephrology, Dept of Internal Medicine, Yonsei Univ Wonju College of Medicine, Wonju, Republic of Korea.*

Background: Edema is frequently uncertain whether it really exists. Especially, idiopathic edema is difficult to diagnose because it has a cyclic feature of edema. BIS (Bioimpedance spectroscopy) is a useful method to estimate body fluid excess. However,

other useful markers for edema have not been investigated sufficiently. This study aims to investigate urinary AVP (arginine vasopressin) and AQP-2 (aquaporin-2) in edema patients.

Methods: The subjects included thirty-three patients complaining of edema. We measured body fluid excess using BIS which was presented as OH value (overhydraion, liter). We collected 24-hr urine samples, in which we measured the excretion amounts of AVP, AQP-2. We also investigated patients with idiopathic edema. We made the subjects to check their body weight at morning and evening in the nude to diagnose idiopathic edema that is characterized by cyclic swelling.

Results: The subjects had normal range of OH value (0.1 liter), while they showed decreased urinary AVP excretion (5.9 ng/day, reference value by Merkelbach U, 1975; 34-70 ng/day) and AQP-2 excretion (0.9 ug/day, reference value by Rai T, 1997; 11 ug/day). The urinary AVP excretion had a significant negative correlation with OH value (r= - 0.438, p=0.020). The subjects with body fluid excess whose OH value was more than 1 liter showed more decreased urinary AVP excretion than the one whose OH value was less than 1 liter (2.6±0.9 versus 7.4±3.7 ng/day, p=0.018). Also in the patients with idiopathic edema, the subjects showed no finding of body fluid excess (OH= - 0.28 liter), while urinary AVP excretion decreased (8.7 ng/day) and urinary AQP-2 also decreased (0.9 ug/day).

Conclusions: We believe that decrease in urinary excretion of AVP and AQP-2 suggests the status of edema. This study demonstrates that in patients who are complaining of edema but show uncertain finding of edema, the measurement of urinary AVP and AQP-2 excretion can be useful for diagnosis of edema. In particular, it is believed that in idiopathic edema which is difficult to diagnose because of the cyclic feature of swelling, it can be also helpful to diagnose.

SA-PO108

Acute and Chronic Regulation of the Osmoprotective Transcription Factor NFAT5 Yuichiro Izumi,[1] Maurice B. Burg,[2] Joan D. Ferraris.[2] *[1]Nephrology, Kumamoto Univ, Kumamoto, Japan; [2]National Heart, Lung, and Blood Inst, National Insts of Health, Bethesda, MD.*

Background: Nuclear Factor of Activated T-Cells 5 (NFAT5) is a transcription factor that increases expression of osmoprotective target genes in response to high NaCl. High NaCl activates NFAT5 by increasing its transcriptional and transactivating activities and its mRNA and protein expression. Despite multiple investigations, regulation of NFAT5 expression has not been completely elucidated.

Methods: We examined acute and chronic effects of high NaCl on the expression of NFAT5 mRNA and protein in HEK293 cells. Cells were incubated either at 300 or 500 mOsm/kg·H_2O (NaCl added) for 2, 4, 8, 24, or 48h and harvested to extract total RNA and protein. Alternatively, cells were first adapted to 300 or 500 mOsm through several passages ("chronic" high NaCl). We quantified the abundance of NFAT5 mRNA and protein by real time PCR and Western blot analysis, respectively. We used actinomycin D and cycloheximide chase to test the effect of high NaCl on NFAT5 mRNA and protein stability, respectively.

Results: High NaCl increased the abundance of NFAT5 mRNA 2.8-fold by 8h, the abundance remained elevated 1.6-fold at 48h (n=3). In cells adapted to 500 mOsm the abundance of NFAT5 mRNA was 1.7-fold greater than in cells adapted to 300 mOsm (n=3). High NaCl increased the abundance of NFAT5 protein 4.1-fold by 24h. The abundance remained elevated 2.6-fold at 48h (n=3). In 500 mOsm adapted cells, the abundance of NFAT5 protein was 1.5-fold greater than in 300 mOsm adapted cells (n=3). ActinomycinD chase showed no difference in stability of NFAT5 mRNA comparing 300 and 500 mOsm, either acutely (n=3) or chronically 500 mOsm (n=3). Cycloheximide chase showed that high NaCl stabilizes NFAT5 protein both with acute (n=3) and chronic high NaCl (n=2).

Conclusions: In HEK293 cells, acute high NaCl increases NFAT5 expression by increasing its transcription and stabilizing its protein both acutely and chronically. The chronic effect of high NaCl explains how NFAT5 activity can remain high in renal medullary cells even following prolonged adaptation to high NaCl.

SA-PO109

Erythropoietin Production by the Nephron Yuichiro Izumi,[1] Yukiko Yasuoka,[2] Takanori Nagai,[3] Yushi Nakayama,[1] Hideki Inoue,[1] Takeshi Nakanishi,[3] Masashi Mukoyama,[1] Katsumasa Kawahara,[2] Hiroshi Nonoguchi.[4] *[1]Nephrology, Kumamoto Univ, Kumamoto, Japan; [2]Physiology, Kitasato Univ School of Medicine, Sagamihara, Japan; [3]Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Japan; [4]Internal Medicine, Kitasato Univ Medical Center, Kitamoto, Japan.*

Background: Erythropoietin (Epo) production is known to occur in the peritubular fibroblasts in the kidney. Since the Epo production in the nephron is controversial, we examined erythropoietin production in the kidney.

Methods: We examined Epo mRNA expressions in the kidney using high-sensitive in situ hybridization (ISH). The mRNA expression of Epo (dots/10 cells) was quantified in basal and hypoxia states. To investigate the mechanism of Epo production, we examined mRNA and protein expressions of HIF PHD2 using ISH and immunohistochemistry (IHC), respectively. We further investigated the Epo production by hypoxia using rat intercalated cell line (IN-IC cells).

Results: ISH in mice showed Epo mRNA expression in PCTs, DCTs and CCDs but not in the peritubular cells (PTEC) under normal conditions. Hypoxia (7% O_2, 4hr) induced Epo mRNA expression largely in PTEC and slightly in PCTs, DCTs, and CCDs.

Epo mRNA (dots/10cells), * p<0.05 vs. control	PCT	MTAL	DCT	IC	PTEC
control	0.50±0.12	0.68±0.06	0.68±0.15	2.27±0.10	0.00±0.00
hypoxia	1.85±0.16*	0.71±0.04	1.19±0.11*	2.97±0.07*	8.90±0.58*

Double staining with AQP3 or AE1 indicated that Epo mRNA expresses mainly in β- or non α/non β-intercalated cells of the collecting ducts. ISH showed mRNA expression of HIF PHD2 in PCTs, DCTs, and CCDs in control and its increase by hypoxia in DCTs, CCDs, and peritubular cells. IHC in rats showed the expression of HIF PHD2 in CCDs and peritubular cells and its increase by anemia in peritubular cells. In IN-IC cells, hypoxia (1% O_2, 24hr) increased Epo mRNA expression, Epo concentration in the medium and protein expression of PHD2.

Conclusions: Epo is produced by the cortical nephrons mainly in the intercalated cells, but not in the peritubular cells, in normal hematopoietic condition and by mainly peritubular cells in hypoxia, suggesting the different regulation between the nephrons and peritubular cells.

Hyperaldosteronism in $K_{Ca}1.1$ Channel β_2-Subunit Knockout Mice Jens G. Leipziger, Mads Vaarby Sorensen, Helle A. Praetorius, Casper K. Larsen. *Biomedicine, Physiology, Aarhus Univ, Aarhus, Denmark.*

Background: Whole body K^+ homeostasis depends on matching K^+ excretion to the daily K^+ intake. K^+ is excreted via the colon and the kidney, the latter handling the majority of the total K^+ excretion. Aldosterone is an important regulator of both renal and colonic K^+ excretion. Renal K^+ secretion depends on 2 apical K^+ channels, ROMK and $K_{Ca}1.1$, while colonic K^+ secretion depends on apical $K_{Ca}1.1$ channels. We have acquired a novel global knockout mouse for the β_2-subunit of the $K_{Ca}1.1$ channel, which is the only $K_{Ca}1.1$ β-subunit expressed in murine colonic epithelium.

Methods: Ussing chamber, Metabolic balance studies, Q-PCR, Plasma Aldo measurement.

Results: The β_2 KO mice have increased plasma aldosterone. Primary hyperaldosteronism is characterized by low plasma K^+, low renin and hypertension. β_2 KO mice have normokalemia and low renin, indicating a secondary cause of hyperaldosteronism. The low renin in β_2 KO mice indicates that a K^+ handling deficiency, rather than hypotension, is causing the hyperaldosteronism. BK channel-dependent colonic K^+ secretion was not disturbed in β_2 KO mice. In contrast, urinary K^+ excretion was reduced in β_2 KO mice (P=0.06, n=5), suggesting that β_2 KO mice have a reduced capacity for renal K^+ secretion. mRNA expression of the β_2 subunit has previously been found in rabbit cortical collecting ducts, where expression is increased by K^+ loading and reduced by K^+ depletion.

Conclusions: These data indicate an important function of the β_2 subunit of the $K_{Ca}1.1$ in renal K^+ excretion.

Funding: Private Foundation Support, Government Support - Non-U.S.

Novel *KCNJ5* Mutations in Sporadic Aldosterone-Producing Adenoma Reduce Membrane Abundance of Kir3.4 Channel Chih-Jen Cheng, Chih-Chien Sung, Shih-Hua P. Lin. *Dept of Medicine, Div of Nephrology, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: Aldosterone-producing adenoma (APA), the second most common cause of primary aldosteronism, has been recently linked to mutations in *KCNJ5* gene, which encodes inward rectifying potassium Kir3.4 channel. The reported prevalence of *KCNJ5* mutation in APA is 30-70%. These mutations abolished the potassium selectivity of Kir3.4, and consequently led to sodium leak current, constant depolarization of membrane potential and nonsuppressible aldosterone secretion in zona glomerulosa cells. Here we investigate the *KCNJ5* mutations in Taiwanese APA patients.

Methods: We screened *KCNJ5* gene in resected adrenal adenoma and peripheral blood of 69 Taiwanese patients with APA and functionally characterized novel Kir3.4 mutations using electrophysiological and biochemical methods.

Results: 37.6% (26/69) of Taiwanese APA patients carried heterozygous somatic mutations in KCNJ5 gene. Other than three previously reported mutations (G151R, L168R and E145Q), we identified two novel mutations (R115Q, E246G) in five patients. E145Q mutant conducted choline-sensitive but barium-insensitive sodium-leak current. In contrast, R115W and E246G mutants showed barium-sensitive Kir current, which were 30% and 10% of wild-type current, respectively, and preserved potassium selectivity. The biotinylation assays revealed markedly reduced membrane abundance of R115W and E246G mutants. All mutants exerted dominant-negative inhibition on wild-type Kir3.4 via disrupting membrane insertion (R115W and E246G) or potassium selectivity (E145Q) of wild type channel. Furthermore, tertiapin-Q, a Kir3.x antagonist, depolarized membrane potential and increased *CYP11B2* mRNA transcript in human adrenocortical H295R cells.

Conclusions: Novel Kir3.4 mutations reduce the membrane abundance of wild type Kir3.4 channel. Pharmacological inhibition of human Kir3.4 channel induced membrane depolarization and aldosterone synthesis in H295 cells. Reduced Kir3.4 membrane abundance in zona glomerulosa cells could be a new disease mechanism of APA.

SA-PO112

KLHL2 Mediates Angiotensin II-WNK3 Signaling Involved in the Regulation of Vascular Tonus Moko Zeniya, Daiei Takahashi, Yutaro Mori, Takayasu Mori, Fumiaki Ando, Naohiro Nomura, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Dept of Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan.*

Background: Recently, Kelch-like protein 3 (KLHL3)-Cullin3 complex was identified as E3 ubiquitin ligase for WNK kinases, and the impaired ubiquitination of WNK4 causes hereditary hypertensive disease, pseudohypoaldostronism type II (PHAII). However, the involvement of WNK kinase regulation by ubiquitination in the situation other than PHAII has not been identified. Previously, we identified With-no-lysine kinase 3 (WNK3)–STE20/SPS1-related proline/alanine-rich kinase (SPAK)–Na/K/Cl cotransporter isoform 1 (NKCC1) phosphorylation cascade in vascular smooth muscle cells, which constitutes an important mechanism of vascular constriction by angiotensinII (AngII). In this study, we investigated the involvement of KLHL proteins in AngII-induced WNK3 activation in vascular smooth muscle cells.

Methods: We determined which KLHL was expressed in aorta and mouse vascular smooth muscle cells (MOVAS) by RT-PCR, and investigated whether the protein levels of KLHL and WNK3 was regulated by different salt diets and AngII. Then, we performed cell culture study using MOVAS to investigate the molecular mechanisms of reregulation of WNK3 and KLHL2 by AngII.

Results: In mouse aorta and MOVAS, KLHL3 was not expressed but KLHL2, the closest homologue of KLHL3, was expressed. Salt depletion and acute AngII infusion decreased KLHL2 and increased WNK3 in mouse aorta. Surprisingly, AngII-induced KLHL2 decrease and WNK3 increase occurred in minutes in MOVAS. Overexpression and knockdown experiments of KLHL2 in MOVAS confirmed that KLHL2 is the major regulator of WNK3 protein abundance. AngII-induced KLHL2 decrease was not caused by its decreased transcription, but by its increased autophagy-mediated degradation.

Conclusions: We identified that KLHL2 is a novel component of signal transduction in AngII-induced vascular contraction, which could be a promising drug target.

Funding: Government Support - Non-U.S.

SA-PO113

Molecular Pathogenesis of PHAII in KLHL3$^{R528H/+}$ Knock-In Mice Koichiro Susa,[1] Eisei Sohara,[1] Tatemitsu Rai,[1] Moko Zeniya,[1] Yutaro Mori,[1] Takayasu Mori,[1] Motoko Chiga,[1] Daiei Takahashi,[1] Yuichi Inoue,[1] Kiyoshi Isobe,[1] Naoki Takeda,[2] Sei Sasaki,[1] Shinichi Uchida.[1] *[1]Dept of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental Univ, Tokyo, Japan; [2]Div of Transgenic Technology, Inst of Resource Development and Analysis, Kumamoto Univ, Kumamoto, Japan.*

Background: Pseudohypoaldosteronism type II (PHAII) is a hereditary disease characterized by salt-sensitive hypertension, hyperkalemia, and metabolic acidosis, due to activation of the WNK kinase-OSR1/SPAK kinase-NaCl cotransporter (NCC) phosphorylation cascade, and mutations in the WNK1 and WNK4 genes are known to be responsible. Recently, Kelch-like 3 (KLHL3) and Cullin3, components of KLHL3-Cullin3 E3 ligase, were newly identified as responsible for PHAII. However, it remains unclear which molecule is the target(s) of KLHL3.To clarify the pathophysiological role of KLHL3, a mouse model of PHAII caused by mutant KLHL3 was required.

Methods: We generated KLHL3$^{R528H/+}$ knock-in mice that carry the same mutation as autosomal dominant type PHAII patients. To analyze phenotypes of KLHL3$^{R528H/+}$ knock-in mice, blood pressure measurement, blood analysis, immunoblot analysis, quantitative PCR, and immunofluorescence were performed.

Results: KLHL3$^{R528H/+}$ knock-in mice exhibited salt-sensitive hypertension, hyperkalemia, and metabolic acidosis. Moreover, the phosphorylation of NCC was increased in the KLHL3$^{R528H/+}$ mouse kidney, indicating that the KLHL3$^{R528H/+}$ knock-in mouse replicates human PHAII. Interestingly, the protein expression of both WNK1 and WNK4 was significantly increased in the KLHL3$^{R528H/+}$ mouse kidney, confirming that increases in these WNK kinases activated the WNK-OSR1/SPAK-NCC phosphorylation cascade in KLHL3$^{R528H/+}$ knock-in mice.

Conclusions: The activation of OSR1/SPAK-NCC signaling by the increased protein levels of WNK1 and WNK4 caused PHAII in the KLHL3$^{R528H/+}$ knock-in mice. The impaired degradation of both WNK1 and WNK4 by the mutant KLHL3 would be the major pathogenic mechanism.

Funding: Private Foundation Support, Government Support - Non-U.S.

SA-PO114

Mutations in Familial Hyperkalemic Hypertension Gene KLHL3 Disrupt Binding of ROMK Endocytic Regulatory Protein ARH and Increases ARH Abundance Owen M. Woodward, Boyoung Kim, Liang Fang, Paul A. Welling. *Physiology, Univ of Maryland School of Medicine, Baltimore, MD.*

Background: Mutations in CUL3 and KLHL3, components of an E3 ligase complex, cause Familial Hyperkalemic Hypertension (FHHt). CUL3 /KLHL3 have been proposed to ubiquitinate two key kinases, WNK1 and 4, which regulate sodium reabsorption via NCC and K+ excretion via ROMK in the distal nephron. Unrestrained ROMK endocytosis contributes to urinary potassium retention and hyperkalemia in FHHt. Here we explore a new target of the CUL3/ KLHL3 complex, ARH (LDLRAP1) an endocytic protein that controls the surface expression of ROMK.

Methods: Mutagenesis, cell culture, and invitro protein-protein assays were employed.

Results: We found that KLHL3 /CUL3 directly targets ARH for ubiquitination and proteasomal degradation. KLHL3 directly bound ARH, with the KLHL3 propeller domain (aa 300-585) and the ARH PTB domain (aa 1-187) necessary and sufficient for the interaction. Presence of another known KLHL3 substrate, WNK1, did not prevent the ARH/KLHL3 interaction. Next we focused on the molecular consequences of KLHL3 FHHt mutations. Surprisingly, we found many of KLHL3 propeller mutant proteins are not efficiently expressed, revealing a mechanism for lost-of-function. One mutant, S433G, which did not disrupt stability, significantly blocked ARH interaction. And finally we found co-expression of mutant KLHL3 and ARH results in increased ARH abundance as compared to wt KLHL3.

Conclusions: FHHt mutations in KLHL3 disrupt direct ARH binding and increase ARH abundance, a finding consistent with increased ROMK endocytosis and reduced K+ excretion, contributing to the hyperkalemia in FHHt patients.

SA-PO115

Phosphorylation of KLHL3 in the Kelch-Repeat Regulates Its Binding Ability to WNK4 Yuki Yoshizaki, Eisei Sohara, Takayasu Mori, Yutaro Mori, Mai Wakabayashi, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Nephrology, Tokyo Medical and Dental Univ, Bunkyo-ku, Tokyo, Japan.*

Background: Mutations in the WNK1 and WNK4 genes result in an inherited hypertensive disease, pseudohypoaldosteronism type II (PHAII). In addition, the KLHL3 and Cullin3 genes were also identified as responsible genes for PHAII. Recently, we have reported that WNK kinases are substrates of KLHL3-Cullin3 mediated ubiquitination. However, the physiological regulation of ubiqutination of WNK kinases by KLHL3-Cullin3 complex is still unknown.

Methods: We analyzed phosphorylation site of KLHL3 using mass spectrometry. We further generated phosphor-specific antibody of KLHL3 against a specific phosphorylation site we found.

Results: Mass spectrometry analysis determined a phosphorylation site of KLHL3 at S433, located within the kelch repeats that directly bind toWNK kinases. Interestingly, a phospho-mimicking S433D KLHL3 mutant exhibited decreased binding ability to WNK4, leading to decreased ubiquitination and increased protein expression of WNK4. In addition, immunoprecipitated KLHL3 by WNK4 showed decreased phosphorylation at S433, compared to native KLHL3 protein before immunoprecipitation. These data indicated that phosphorylated KLHL3 at S433 resulted in the decreased binding ability of KLHL3 to WNK4. Since S433 is a component of PKA and Akt motif, we further examined the effect of forskolin and insulin on phosphorylation of KLHL3 at S433. As expected, both forskolin and insulin stimulation increased phosphorylation of KLHL3 at S433 in cultured cells.

Conclusions: We identified a novel phosphorylation site of KLHL3, which was regulated by insulin and forsklin. This phosphorylation of KLHL3 at S433 decreased the binding ability of KLHL3 to WNK4, suggesting that WNK ubiqutination mechanism by KLHL3 could be physiologically regulated by KLHL3 phosphorylation at S433.

SA-PO116

p62-Mediated Selective Autophagy Is Involved in KLHL3-Dependent WNK4 Degradation Yutaro Mori, Mai Wakabayashi, Takayasu Mori, Moko Zeniya, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Dept of Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan.*

Background: We reported that KLHL3 binds to WNK4 and Cullin3 (CUL3) and ubiquitinate WNK4 and that the impaired WNK4 ubiquitination and degradation cause human hypertensive disease through the activation of WNK-OSR1/SPAK-NCC cascade. We also found that KLHL3-induced WNK4 degradation could not be inhibited completely by proteasome inhibitors. Recently, Kelch-like ECH-associated protein 1 (Keap1), which belongs to the same Kelch family as KLHL3, was reported to be degraded by p62/SQSTM1(p62)-mediated selective autophagy under oxidative stress. Therefore, we investigated whether WNK4 degradation induced by KLHL3 was also mediated by autophagic mechanisms.

Methods: Transient expressions, knockdown by si-RNA, and co-immunoprecipitation experiments of WNK4, KLHL3 and p62 were performed in HEK293T cells We also performed immunofluorescenct staining of p62 in mouse kidney.

Results: Co-immunoprecipitation assays revealed that KLHL3 bound to p62 by the kelch repeat domain like Keap1. WNK4 did not directly bind to p62. p62 overexpression increased WNK4 degradation, which was not inhibited by proteasome inhibitors but by autophagy inhibitors, and p62 knockdown dramatically increased the transiently expressed WNK4 protein level. In mouse kidney, p62 was confirmed to be present in distal convoluted tubules even under normal condition.

Conclusions: WNK4, which is ubiquitinated by KLHL3-CUL3 E3 ligase complex, is degraded not only by proteasomes but also by p62-mediated selective autophagy. The WNK4 degradation by autophagy may be involved in the regulations of WNK signaling under certain pathophysiological conditions.

SA-PO117

Rare Mutations in NKCC2 Gene Associated with Protection From Hypertension Differentially Regulate NKCC2 Isoforms A and F

Elie Seaayfan, Sylvie Demaretz, Nadia Defontaine, Kamel Laghmani. *CRC, INSERM/UPMC/CNRS-U1138, ERL8228, Paris, France.*

Background: Apical bumetanide-sensitive Na-K-2Cl co-transporter, NKCC2, is the major salt transport pathway in kidney thick ascending limb (TAL). Recent studies revealed that nine rare mutations in NKCC2 are associated with a reduction of blood pressure and protection from hypertension. However, the functional characterization of these variants addressed by two independent groups, revealed that some of these mutations do not reduce NKCC2 activity. In addition, there are some discrepancies between the findings of the two reports. Consequently, the molecular mechanisms underlying NKCC2 regulation by five of these nine mutations remain unclear. Moreover, the two groups focused on the regulation of only one NKCC2 isoform, whereas two active NKCC2 isoforms (A and F) are expressed in TAL cells. The aim of the present study was to examine the consequence of these five NKCC2 mutations on the expression and activity of NKCC2A and NKCC2F.

Methods: NKCC2 protein expression was monitored in transiently transfected OKP and HEK cells, using immunoblot and confocal imaging. NKCC2 activity was measured as bumetanide sensitive NH4 influx using BCECF fluorescence of intracellular pH.

Results: NKCC2A-P348L displayed partial loss of complex glycosylation at the cell surface, whereas NKCC2F-P348L showed only immature form and was trapped in the ER. Consequently, these mutants exhibited dramatically diminished basal transport activity. In contrast, no obvious effect on the protein expression and trafficking of NKCC2A and F was seen with the four remaining mutants. Nevertheless, these mutations were able to differentially compromise the activity of NKCC2 isoforms. Indeed, N399S reduced the activity of NKCC2F, whereas it had no effect on NKCC2A. Likewise, P250A, Y1070C and P1083A decreased NKCC2A activity, while they did not affect NKCC2F.

Conclusions: In sum, our findings indicate that all nine rare mutations in NKCC2 associated with protection from hypertension exhibit, actually, impaired transport function. Most importantly, they reveal that some of these mutations exert their effects on NKCC2 by differentially compromising the expression and/or activity of its isoforms, A and F.

Moesin, a Cytoskeletal-Associated Protein, Plays an Important Role in the Regulation of Membrane Localization of NKCC2

Ryo Hatano, Kotoku Kawaguchi, Shinji Asano. *Molecular Physiology, College of Pharmaceutical Sciences, Ritsumeikan Univ, Kusatsu, Shiga, Japan.*

Background: Electrolytes as Na^+, K^+, and Cl^- have a vital role in maintaining body fluid homeostasis. In the thick ascending limb of Henle (TALH), 20 to 40 % Na^+ filtered by glomerulus are reabsorbed by NKCC2 (Na-K-2Cl cotransporter 2), which plays essential roles in the reabsorption of electrolytes and volume balance regulation. Despite of the physiological importance of NKCC2 in the regulation of NaCl homeostasis, the molecular mechanisms for its membrane trafficking are not elucidated. Recently, it is reported that Moesin, which is a member of ERM (Ezrin-Radixin-Moesin) family, plays an important role in the apical membrane trafficking of NKCC2 by *in vitro* experiments.

Methods: We examined the physiological importance of Moesin in the regulation of renal function by using Moesin knockout (KO) mice. Wild type (WT) and Moesin KO mice were kept in metabolic cages and daily urinary volume and urinary contents of electrolytes were measured.

Results: We found that moesin deficient mice exhibited the significant increase in the fractional urinary excretion of electrolytes (Na^+, K[sup+[/sup], and Cl[sup-[/sup]), whereas total urinary contents of these electrolytes were not different between WT and Moesin KO mice. Furthermore, Moesin deficient mice showed moderate hypotensive phenotype and significantly reduced glomerular filtration rate, suggesting the possible compensation for the urinary loss of electrolytes. Immunofluorescent analysis also indicated the reduced apical surface expression of NKCC2 in Moesin deficient mice.

Conclusions: In summary, our study suggests that Moesin plays an important role in the maintaining the apical surface expression of NKCC2 in TALH and regulation of the electrolyte reabsorption *in vivo.*

Genetic Deletion of $P2Y_2$ Receptor Offers Long-Term (5 mo) Protection against Lithium-Induced Polyuria, Natriuresis and Kaliuresis

Kristina M. Heiney, Yue Zhang, David L. Strasburg, Noel G. Carlson, Donald E. Kohan, Bellamkonda K. Kishore. *VA Medical Center and Univ of Utah, Salt Lake City, UT.*

Background: Chronic lithium(Li) administration for bipolar disorder is associated with polyuria, natriuresis and kaliuresis. Using a 2-week model, previously we reported that $P2Y_2$-R knockout (KO) mice are significantly resistant to Li-induced polyuria, natriuresis and kaliuresis as compared to the wild type (WT) mice. Here we show that this protection is long-lasting.

Methods: Groups of age-matched adult WT and KO mice were fed regular (n = 5/genotype) or Li-added diet (40 mmol Li/kg chow; n = 10/genotype) with free access to food, water and salt blocks for 5 months. Twenty-four hour water intake and urine output and osmolality were monitored every month. At the end of the experimental period mice were euthanized and serum and kidneys were analyzed.

Results: Li-fed KO mice consistently had significantly lower polyuria, natriureis and kaliureis over the 5 mo period as compared to Li-fed WT mice. Table presents data of terminal urine and AQP2 protein in the kidney. Furthermore, there were no significant differences in serum Li between the WT and KO mice, and serum BUN and Na levels were within normal limits in both groups.

Group	Water Intake[a]	Urine Output[a]	Urine Osmolality[b]	Urine Na[c]	Urine K[c]	AQP2 in Cortex[d]	AQP2 in Medulla[d]
WT-CT	4.2 ± 0.5	1.3 ± 0.2	2184 ± 168	112 ± 11	424 ± 45	100 ± 5	100 ± 24
WT-LI	8.1 ± 0.6*	3.1 ± 0.2*	1474 ± 95*	380 ± 15*	670 ± 26*	15 ± 7*	23 ± 4*
KO-CT	4.9 ± 0.6	1.7 ± 0.4	1934 ± 252	129 ± 8	442 ± 45	100 ± 10	100 ± 7
KO-LI	6.3 ± 0.7	1.4 ± 0.1	2136 ± 84**	240 ± 17**	427 ± 33**	34 ± 2**	73 ± 7**

[a]ml/day/20 g bw; [b]mOsm/Kg H_2O; [c]μEq/day/20 g bw; [d]band density as % or respective control diet; CT - control diet; LI -lithium diet: $P < 0.05$ vs. WT-CT (*) or WT-LI (**)

Conclusions: Our results demonstrate that genetic deletion of $P2Y_2$-R protects against Li-induced polyuria, natriuresis and kaliuresis on long-term basis, and thus underscore the potential utility of $P2Y_2$-R antagonism for the treatment of Li-induced nephrogenic diabetes insipidus.

Computational Analysis of the Effect of Aldosterone and Low pH on Gene Expression and Cell Function

Yuichiro Izumi,[1] Yushi Nakayama,[1] Hideki Inoue,[1] Tomoaki Onoue,[1] Hiroshi Nonoguchi,[2] Masashi Mukoyama.[1] *[1]Dept of Nephrology, Kumamoto Univ, Kumamoto, Japan; [2]Internal Medicine, Kitasato Univ Medical Center, Kitamoto, Japan.*

Background: Metabolic acidosis is a major problem in chronic kidney disease. Although aldosterone is produced in response to the decrease of blood pH and stimulates collecting duct to excrete proton into urine, we hypothesize that there may be urinary acidification mechanisms in aldosterone independent manner. Since low pH is accompanied by the increase of aldosterone *in vivo*, it is difficult to examine the individual effect of aldosterone and low pH. In the present study, we attempted to distinguish the effect of low pH from that of aldosterone on gene expressions and cell functions using computational analysis.

Methods: We searched publications and picked up gene transcripts that are induced in epithelial cells in the kidney either by administration of aldosterone or acid loading. We applied bioinformatic tools to analyze the genes. Using DAVID Bioinformatics Database, we examined Gene Ontology (GO) analysis for the gene transcripts. Using oPOSSUM, we analyzed promoter regions of the genes and estimated enriched consensus motifs in the promoters of the genes.

Results: Among publications, 57 and 125 genes were picked up as aldosterone- and acid-stimulated genes, respectively. 5 genes were overlapped between two stimulations. GO analysis showed 10 and 17 terms in molecular function ($p > 0.05$) for aldosterone- and acid-stimulated genes, respectively. There were 9 terms overlapped such as hydrogen ion and inorganic cation transmembrane activities between two stimulations. The promoter analysis raised 28 and 21 consensus motifs for aldosterone- and acid-induced genes, respectively (Z-score > 5.0). There were 10 motifs overlapped between two stimulations, which include the hormone response element, a target of mineralocorticoid receptor. Specific motifs for acid-induced genes include the motifs for Ets and NFAT5 TF families, and they locate on the promoter region of SLC26A7 (Cl^-/HCO_3^- exchanger) and ATP6AP2 (a component of H^+-ATPase).

Conclusions: The results suggest that there should be aldosterone independent mechanisms which are stimulated directly by low pH.

SA-PO121

Active, Sex-Dependent Fluid Secretion in the Collecting Duct

Charles S. Wingo,[1,2] I. Jeanette Lynch,[1,2] Amanda K. Welch.[1,2] *[1]North Florida/South Georgia Veterans Health System, Gainesville, FL; [2]Univ of Florida, Gainesville, FL.*

Background: The focus of the present study was to evaluate the mechanism of collecting duct (CD) fluid transport by in vitro microperfusion of mouse cortical CD (CCD) and outer medullary CD (OMCD).

Methods: Water flux, J_V, was measured by using the radiolabeled volume marker, [methoxy-^{3}H]inulin, exhaustively dialyzed, in the perfusate during two experimental periods.

Results: Data from our laboratory show that in the absence of an osmotic gradient, the collecting duct actively secretes fluid. A lumen-to-bath osmotic gradient reversed fluid secretion to reabsorption. An unbiased analysis of the rate of fluid secretion versus the percent leak into the bath in 67 consecutive experiments demonstrated no correlation of these two measurements under symmetrical, isosmotic conditions. Interestingly, fluid secretion in the CCD of female mice (n = 8) was twice that of male mice (n = 10, P <0.02). In paired, time-control experiments, fluid secretion did not change between the two collection periods in either sex. We further tested the effect of inhibiting Na absorption with luminal 1 μM benzamil. Application of 1 μM luminal benzamil significantly reduced fluid secretion, and this inhibition occurred in both sexes. Fluid secretion persisted in the CCD of desoxycorticosterone pivalate-treated male mice (1.7 mg IM and 0.4% Na diet, 6-8 days). However, in the OMCD of male mice (n = 4) the rate of fluid secretion was approximately 2.5 times greater compared to the rate in the CCD (n = 10, P < 0.01). The greater rate of fluid secretion in the OMCD compared with the CCD of male mice indicates that this mechanism exhibits axial heterogeneity. The difference in fluid secretion between

the CCD of male and female mice implies that a primary or secondary sex characteristic influences this process, which may be inhibited by in vivo hormones or signaling factors.

Conclusions: The collecting duct possesses the capacity for active fluid secretion which is sex-dependent and exhibits axial heterogeneity between the cortex and outer medulla.

SA-PO122

Impact of Shifts in Renal Tubular Reabsorption Sites on Kidney Oxygen Consumption

Anita T. Layton,[1] Aurelie Edwards.[2] *[1]Dept of Mathematics, Duke Univ, Durham, NC; [2]Centre National de la Recherche Scientifique ERL 8228, Centre de Recherche des Cordeliers, Paris, France.*

Background: The vast majority of the kidney's oxygen consumption (QO2) is attributable to the reabsorption of ~99.5% of filtered sodium. The ratio of QO2 to sodium reabsorption (TNa) has been shown to vary; e.g., QO2/TNa has been observed to be higher in spontaneously hypertensive rats than in Wistar-Kyoto rats. Changes in QO2/TNa may occur when the burden of reabsorption is shifted from the proximal tubule to the loop of Henle, which is less energy efficient in reabsorbing sodium.

Methods: To understand the impact of changes in tubular reabsorption on renal metabolism, we have developed a mathematical model of detailed epithelial solute transport and metabolism of a rat superficial nephron. We simulated the application of benzolamide, a proximal diuretic that inhibits membrane carbonic anhydrase (CA).

Results: Model simulations of benzolamide application predict a reduction in TNa and a paradoxical increase in QO2, as observed experimentally. Our results confirm the hypothesis of Deng et al. (AJP Renal 2006) that the inhibition of CA increases the active reabsorption of chloride in the proximal tubule while reducing passive NaCl transport, thereby raising QO2. Additionally, we have conducted model simulations to investigate the impact of pathophysiological changes in renal structures and functions (e.g., changes in membrane transporter density, altered tight junction permeabilities, mitochondrial uncoupling, etc., as observed in diabetes and hypertension) on renal solute transport and oxygen consumption.

Conclusions: Oxidative stress associated with conditions such as hypertension and hyperglycemia reduces tubular transport efficiency and causes metochondrial uncoupling. The resulting increase in kidney QO2, without a corresponding increase in oxygen supply, may lead to intrarenal tissue hypoxia.

Renal Tubular NHE3 Expression Is Not Required for Caffeine-Induced Diuresis and Natriuresis

Timo Rieg,[1] Manoocher Soleimani,[2] Samantha De la Mora Chavez,[1] Jessica A. Dominguez Rieg,[3] Robert A. Fenton.[4] *[1]Medicine, UCSD and VASDHS, San Diego, CA; [2]Medicine, Univ of Cincinnati, Cincinnati, OH; [3]Basic Sciences, Bastyr Univ California, San Diego, CA; [4]Biomedicine, Aarhus Univ, Aarhus, Denmark.*

Background: The diuretic and natriuretic effects of the methylxanthine caffeine are well-known and our previous data indicated that both effects are mediated by blockade of adenosine A1 receptors (A1R). While it is assumed that the increase in cAMP levels, due to blockade of A1R, inhibits NHE3 and therefore proximal tubule-induced diuresis and natriuresis, this hypothesis has never been tested *in vivo.*

Methods: To test if tubular expression of NHE3 is required for caffeine-induced diuresis and natriuresis we generated tubulus-specific NHE3 knockout mice by crossing floxed NHE3 mice with Pax8Cre mice. Renal NHE3 knockout was determined by immunohistochemistry and semi-quantitative immunofluorescence. To test for caffeine-induced diuresis and natriuresis, $NHE3^{lox/lox}$ (Con, n=8) and littermate $NHE3^{lox/loxCre}$ (knockout, n=8) mice were randomized to acute application of caffeine (caff, 45 mg/kg) or vehicle (veh, 0.85% NaCl) via oral gavage (3% of body weight) and placed in metabolic cages for quantitative urine collection over 3 hours. Urinary flow rate and excretion of Na and Cl were determined.

Results: In $NHE3^{lox/loxCre}$ mice, cortical NHE3 expression was absent and medullary NHE3 abundance was reduced by >80%. In Con, caff significantly increased urinary excretion of fluid, Na and Cl (Con-caff versus Con-veh: 324±16 versus 203±19 nl/min/g; 35±2 versus 24±2 nmol/min/g; 25±2 versus 16±2 nmol/min/g, respectively, P<0.05 versus veh). Urinary excretion between Con and $NHE3^{lox/loxCre}$ was not different when given veh alone and in $NHE3^{lox/loxCre}$ a comparable response to caff was observed ($NHE3^{lox/loxCre}$-caff versus $NHE3^{lox/loxCre}$-veh: 331±22 versus 208±10 nl/min/g; 36±4 versus 23±1 nmol/min/g; 27±3 versus 18±1 nmol/min/g, respectively, P<0.05 versus veh).

Conclusions: In contrast to the accepted hypothesis that NHE3 mediates caffeine-induced natriuresis, our data demonstrate that tubular expression of NHE3 is not required for these effects. We conclude that different transport protein(s) are mediating these effects.

The Pathogenesis of Metabolic Alkalosis in Cystic Fibrosis: Dysregulation of Pendrin and Impaired HCO_3^- Secretion in the Kidney

Sharon L. Barone,[1,2] Jie Xu,[2] Saeed Alshahrani,[2] Marybeth Brooks,[2] Kamyar A. Zahedi,[1,2] Manoocher Soleimani.[1,2] *[1]Research Services, Veterans Affairs Medical Center, Cincinnati, OH; [2]Dept of Medicine, Univ of Cincinnati, Cincinnati, OH.*

Background: Cystic fibrosis (CF) is the most common life-threatening genetic disease in the United States. It is caused by mutations in CFTR, a cAMP-activated chloride channel expressed in epithelial tissues, and affects lung, pancreas and intestine. However, no apparent kidney phenotype has been identified in CF patients, despite abundant expression of CFTR in the kidney, including B-intercalated cells (AJP Renal, 1996). Patients with CF are prone to the development of metabolic alkalosis, which produces a diminution of respiratory effort that can be detrimental in CF patients, who suffer from lung injury. However, the pathogenesis of metabolic alkalosis in CF remains unknown. CFTR plays a vital role in HCO_3^- secretion in tracheal eithelial cells by activating the apical Cl^-/HCO_3^- exchangers SLC26A4 (pendrin) (JBC, 2011). We hypothesized that a synergistic interaction could occur between CFTR and pendrin in B-intercalated cells, specifically during volume depletion.

Methods: CFTR knockout (CF-KO) mice with the intestinal rescue (overexpressing wt CFTR in their intestine-Science 1994) were examined for pendrin expression and function.

Results: Baseline parameters, including acid-base status and urine pH were comparable in CF-KO and WT mice. Compared to WT animals, CF-KO mice demonstrated significant increase in blood HCO_3^- concentration (23.5 in wt versus 28.2 mEq/l in CF-KO mice, p<0.04) and pH (7.28 in wt and 7.38 in CF-KO, p<0.05) and impaired HCO_3^- excretion (urine pH 8.1 in wt and 7.2 in CF-KO mice, p<0.02) following a 3-day oral bicarbonate load. Immunofluorescence labeling in CF-KO mice demonstrated reduction in apical expression and increased cytoplasmic and basolateral localization of pendrin at baseline state and in response to bicarbonate load, consistent with impaired trafficking.

Conclusions: We propose that patients with cystic fibrosis are prone to the development of metabolic alkalsosis secondary to the impairment of pendrin, specifically during volume depletion, which is a common occurrence in CF patients.

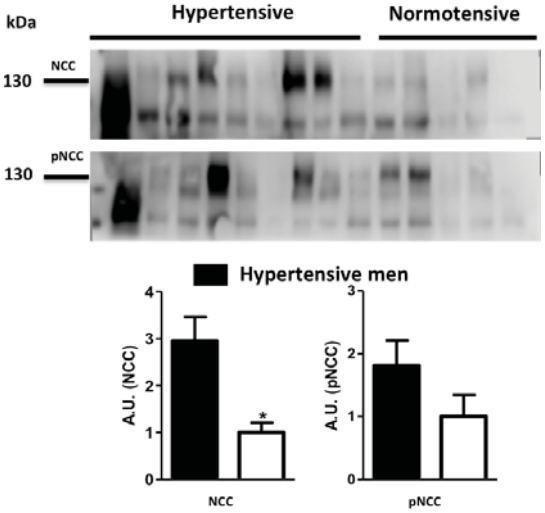
Increased Phosphorylation of the Renal NaCl Cotransporter in Transplant Patients with Hypertension

Aldo R. Jimenez,[1] Lorena Leonor Rojas,[1,2] Isidora D. Arroyo Garza,[1,2] Josefina Alberú,[3] Luis E. Morales-Buenrostro,[1] Gerardo Gamba.[1,2] *[1]Nephrology, INCMNSZ; [2]Molecular Physiology Unit, IIB-UNAM; [3]Transplantation, INCMNSZ.*

Background: In roedent models tacrolimus-induced arterial hypertension is associated with increased activity and phosphorylation of the renal NaCl cotransporter (NCC) in the distal convoluted tubule. In this study we assessed if a similar situation occurs in humans after renal transplantation.

Methods: From January 2013 all adult patients receiving a kidney allograft in our institution and consented to be included were enrolled into a prospective, longitudinal and observational study. All patients received tacrolimus as immunosuppresive therapy. At three, six, and 12 months after surgery we assessed general clinical and laboratory variables, tacrolimus blood levels, and arterial blood pressure. At six months blood pressure was determined by ambulatory blood pressure monitoring (ABPM). At three, six, and twelve months urinary exosomes were extracted to perform Western blot analysis using total and phospho-NCC antibodies. The amount of exosomes per lane was adjusted according to urinary creatinine.

Results: At this report 21 patients (66% male) have been followed for six months after surgery and completed ABPM. Mean age and serum creatinine 37.8 ± 14.3 years and 1.2 ± 0.3 mg/dl, respectively. Of seven women only one had hypertension. Of 14 males 9 were hypertensive and 5 normotensive (mean blood pressure 91.7 ± 8.8 versus 83.2 ± 6 mmHg, p<0.01), with tacrolimus blood levels of 11.7 ± 4 and 7.3 ± 1.8 ng/ml, respectively (p<0.005).Western blot analysis of urinary exosomes of these 14 male patients revealed a significant difference in NCC expression and phosphorylation between normotensive and hypertensive patients (Figure; *p<0.05).



Conclusions: Hypertension in renal transplant patients is associated with increased activity of NCC.

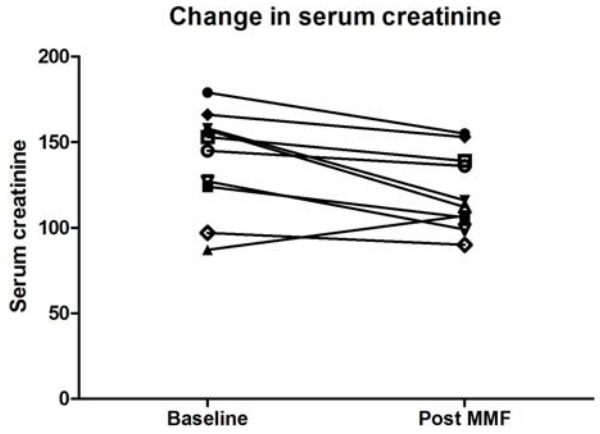
SA-PO126

Mycophenolate Improves Renal Function in Tubulointerstitial Nephritis (TIN) due to Primary Sjögren Syndrome (pSS) Rhys David Russell Evans, Maryam Khosravi, Chris Laing, Stephen B. Walsh. *UCL Centre for Nephrology, Univ College London, United Kingdom.*

Background: pSS is characterized by lymphocytic infiltration of epithelial tissue. Renal involvement occurs in up to 30%. Histologically, the predominant lesion is TIN, impairing tubular function and GFR. No treatment is of proven benefit in pSS. We report the response of 10 patients with pSS TIN to treatment with MMF.

Methods: We recorded patient demographics, baseline symptoms and organ involvement, immunology, excretory renal function, urinary acidification testing and renal histology. We reviewed the response to MMF treatment.

Results: 90% were female with a mean age of 54.7 ± 3.5 years. 70% had sicca symptoms and all were ANA and anti-Ro positive. 50% were anti-La positive; 80% had raised IgG levels. 80% of patients had a urinary acidification test. Of those, 75% had distal renal tubular acidosis (dRTA). Renal histology revealed TIN in all patients. Treatment was with MMF 500mg-2g/day. 30% of patients were also treated with hydroxychloroquine, 70% had prednisolone (weaned in 57%). Treatment was well tolerated by all bar one patient in whom it caused leucopenia. Those with dRTA were treated with potassium citrate. Mean follow up was 20 months: 80% of patients had an improvement in renal function; it was stable in 10%, and progressive in 10% (fig 1). There was a significant improvement in renal function with treatment (mean creatinine 139.5 ± 9.5 mmol/L to 121.3 ± 7.2 mmol/L; p=0.013). IgG levels improved after treatment, but not significantly (mean IgG 20.6 ± 1.3 g/L to 17.1 ± 1.5g/L, p=0.09) In patients with improved renal function, symptoms stabilized but did not resolve. Treatment had no effect on the need for supportive treatment of dRTA.



Conclusions: Immunosuppression with MMF results in an improvement of renal function in the majority of patients with pSS TIN, with a partial but incomplete effect on extrarenal symptoms.

SA-PO127

Thiazide-Induced Hyponatremia (HN): Report from the HN Registry Volker Rolf Burst,[1] Franziska Grundmann,[1] Torsten Kubacki,[1] Arthur Greenberg,[2] Despina Rudolf,[3] Joseph G. Verbalis.[4] *[1]Univ Hospital Cologne, Germany; [2]Duke Univ Medical Center, Durham, NC; [3]Otsuka Pharma GmbH, Germany; [4]Georgetown Univ Medical Center, Washington, DC.*

Background: Thiazide-induced HN (TIH) is common but insufficiently characterized. This analysis of the HN Registry (5028 pts, 225 sites, NCT01240668) compared pts with thiazide-associated HN (TAH, presumably TIH) and SIADH pts.

Methods: Demographics, choice and efficacy of treatment, uni- and multivariate analysis of biochemical parameters.

Results: Of 1946 SIADH pts classified by treating physicians, only 1556 were confirmed with SIADH; 390 were re-categorized as TAH during adjudication. TAH pts were older and more likely to be female. Serum [K^+] (3.8±0.65 mEq/L versus 4.2±0.6 mEq/L), urine osmolality (373±170 mOsm/kg versus 421±182 mOsm/kg) and urine [Na^+] (62.8±40.3 mEq/L versus 81.9±50.5 mEq/L) were significantly lower and serum creatinine (79±38 µmol/L versus 69±34 µmol/L), BUN (6.5±5.9 mmol/L versus 4.9±2.8 mmol/L), and serum uric acid (268±123 µmol/L versus 185±86 µmol/L) were significantly higher in the TAH group. However, in 12% of TAH and 11% of SIADH pts, none of the lab tests required to properly evaluate euvolemic HN were performed. Normal saline (NS) was the most common treatment applied in TAH pts (28.9%, SIADH pts 22.6%, P=0.01). With NS use efficacy endpoints including serum [Na^+] rise to >130 mEq/L or ≥135 mEq/L, and increment ≥5 mEq/L were achieved significantly more often in TAH than SIADH (32.0% versus 16.4%, 13.4% versus 3.9%, 60.8% versus 36.7%, respectively). Overly rapid correction occurred in 3.6% of TAH versus 1.7% of SIADH pts. Other treatments used in TAH pts: fluid restriction (FR, 23.1%), FR plus NS (9.7%), hypertonic saline (5.7%), NS plus loop diuretic (4.4%), and salt tablets (3.6%).

Conclusions: In the HN Registry, clinicians frequently failed to recognize thiazide use as a cause of HN. Compared to SIADH pts, the better response of TAH pts to NS administration is in line with its pathophysiology and confirms accepted treatment recommendations. Although significant differences can be detected in the biochemical profile, these parameters probably only mirror the volume depletion seen in some TAH patients and do not reliably distinguish TAH from SIADH.

Clinical Severity of Hyponatremia: Thiazides versus Psychotropics versus Combination of Both Hyunju Yoon, Jeong Gwan Kim. *Nephrology Div, Dept of Internal Medicine, Presbyterian Medical Center, Jeonju, Jeonbuk, Korea.*

Background: The aim of this study is to evaluatethe difference of clinical characteristics in patients with hyponatremia, according to the causative drugs such asthiazide diuretics and psychotropic drugs, including tricyclics, selective serotonin reuptake inhibitors, and monoamine oxidase inhibitors, phenothiazines and butyrophenones.

Methods: From 2007 to 2013, 266 patients were diagnosed with hyponatremia (P-Na < 130 mmol/L). We compared clinical characteristics among thiazide (T) group (n=93), psychotropic drug (P) group (n=83), and combination (C) group (n=90). We investigated the severity of hyponatremia based on initial level of serum sodium, initial symptom of the patients and correction time (serum sodium level ≥ 130 mmol/L).

Results: The mean age was younger in P group than in other two groups (65±8 versus 71±10 versus 74±13 year, P=0.000). There were no difference in initial urine osmolality (378±131 versus 396±154 versus 341±168 mmol/L, P=0.061) and serum osmolality (249±30 versus 244±17 versus 245±37 mmol/L, P=0.528), but serum uric acid level was significantly different among groups T, P and C(3.85±2.41 versus 2.87± 1.27 versus 3.42±2.03 mg/dL, P=0.003). Serum uric acid level was higher in group T than in group P by Scheffe's post-hoc analysis (P=0.046). All patients were divided into three categories based on the serum sodium level (mild: >125 mmol/L, moderate: 120-125 mmol/L, severe: <120 mmol/L), patient's symptom (mild: general weakness, moderate: nausea or vomiting, severe: syncope or seizure). Incidences of severe hyponatremia and severe symptoms were not different among groups T, P and C(73.1 versus 67.5 versus 71.1 %, P=0.710, 20.4 versus 30.1 versus 17.8 %, P=0.192). Correction time was significantly different among groups T, P and C (41.98±26.89 versus 34.91±23.96 versus 51.10±43.86 mg/dL, P=0.026). Correction time was longer in group C than group P by Scheffe's post-hoc analysis (P=0.010).

Conclusions: Serum sodium level and severity of symptoms were not different among groups T, P and C. Serum uric acid level was higher in group T than in group P. Correction time was longer in group C than in group P.

SA-PO129

Mild Chronic Hyponatremia and Risk of Hip Fracture in the Elderly Juan Carlos Ayus,[1] Nora Angelica Fuentes,[2] Armando Luis Negri,[3] Diego Giunta,[2] Kamyar Kalantar-Zadeh,[4] Fernan De Quiros.[2] *[1]Renal Consultants of Houston, Houston, TX; [2]Internal Medicine, Hospital Italiano, Buenos Aires, Argentina; [3]Univ del Salvador, Buenos Aires, Argentina; [4]Univ of California Irving, CA.*

Background: Bone has recently been identified as a target for hyponatremia, with fractures occurring as a result. Hip fractures are common in the elderly. We analyzed if there is an independent association between chronic hyponatremia and hip fracture in the elderly.

Methods: We designed a Cohort study of patients >60 years old who had chronic hyponatremia defined as two or more consecutive plasma sodium measurements <135 mmol/L during a period of more than 90 days. Patients were considered normonatremic if they never had a plasma sodium <135 mmol/L. The study was carried out between January 2005 and December 2012. We calculated the hip fracture incidence rate and used multivariate Cox regression analysis to determine hip fracture risk associated with chronic hyponatremia, adjusting for the hyponatremia propensity score, baseline characteristics, comorbidities, and clinical risk factors for hip fracture. Follow-up continued until the time of hip fracture or the end date of the study period.

Results: Of the 31,527 patients evaluated, 288 had chronic hyponatremia and 31,299 were normonatremic. The mean plasma sodium level was 132±5 mmol/L in hyponatremic patients, and 139±3 mmol/L in normonatremic patients (P < 0.001). The incidence rate of hip fractures in hyponatremic patients was 781 per 100,000 person-years (95% CI, 463-1320), which was higher than that of normonatremic patients (365/100,000 person-years; 95% CI, 333-400). The incidence rate ratio was 2.4 (95% CI, 1.26-3.94). The cumulative risk of hip fracture was higher in the hyponatremic group than in the normonatremic group (P < 0.001). The unadjusted and adjusted hazard ratios for hip fracture in patients with chronic hyponatremia were 6.7 (95% CI, 3.2-14.2) and 4.52 (95% CI, 2.14-9.6), respectively. Mortality among chronic hyponatremic patients was double that of normonatremics and the time from surgery to death much shorter.

Conclusions: Mild chronic hyponatremia is an independent risk factor for hip fracture in the elderly.

SA-PO130

Prevalence of and Risk Factors for Hyponatremia in Individuals with Hypertension Kausik Umanath,[1] Jamie P. Dwyer,[2] Alfred K. Cheung,[3] Raymond R. Townsend,[4] Ana C. Ricardo,[5] David Reboussin,[6] Paul L. Kimmel,[7] Daniel E. Weiner.[8] *[1]Henry Ford Hospital, Detroit, MI; [2]Vanderbilt Univ Medical Center, Nashville, TN; [3]Univ of Utah, Salt Lake City, UT; [4]Univ of Pennsylvania, Philadelphia, PA; [5]Univ of Illinois - Chicago, Chicago, IL; [6]Wake Forest Univ, Winston-Salem, NC; [7]National Insts of Health, Bethesda, MD; [8]Tufts Medical Center, Boston, MA.*

Background: The prevalence of and risk factors for hyponatremia are unclear. The Systolic Blood Pressure INTervention (SPRINT) trial randomized individuals with hypertension and CKD or cardiovascular disease risk to assess the effect of intensive blood pressure control on outcomes, providing a large sample of well characterized individuals to evaluate hyponatremia.

Methods: Outcomes in this cross-sectional study included moderate (serum Na 130-134 mEq/L) and severe hyponatremia (serum Na <130 mEq/L). Logistic regression was used to assess factors associated with hyponatremia.

Results: Among 9336 SPRINT participants, 204 (2.2%) had Na 130-134 mEq/L and 20 (0.2%) had Na <130 mEq/L. Table 1 presents characteristics and results of univariate regression. In multivariable logistic regression models, older age, higher eGFR, RAAS blocker use, higher SBP, lower BMI and female gender were associated with hyponatremia. Notably, hyponatremia prevalence among women above 65 was more than twice that of men and younger women, after adjusting for other covariates.

	Serum Na (mEq/L)				
Characteristic	≥145 (n=210)	135-144 (n=8902)	130-134 (n=204)	<130 (n=20)	Univariate p-value
Age, years	69±9	68±9	71±9	73±11	<0.01
Women	41%	35%	54%	35%	<0.01
eGFR (mL/min/1.73m^2)	65±20	72±20	76±25	74±21	<0.01
eGFR <60	41%	28%	24%	40%	0.28
Systolic BP (mm Hg)	142±18	140±15	144±16	139±18	<0.01
Diastolic BP (mm Hg)	77±13	78±12	77±12	72±13	0.02
BMI (kg/m^2)	30±6.4	30±5.7	27±5.7	27±4.3	<0.01
Loop Diuretic Use	11%	4.4%	2.4%	5%	0.18
Thiazide Diuretic Use	38%	39%	43%	55%	0.11
RAAS Blocker Use	56%	57%	66%	80%	<0.01
NSAID Use	38%	38%	40%	35%	0.80

Conclusions: The prevalence of moderate or severe hyponatremia was 2.4% in SPRINT. Hyponatremia is associated with older age, female sex, lower BMI and SBP, RAAS blockade and higher eGFR. Diuretic use was not associated with hyponatremia.

Funding: NIDDK Support

SA-PO131

Efficacy and Safety of Tolvaptan in Hyponatremic Octogenarians Cem I. Sungur. *Nephrology, Medicana International Ankara Hospital, Ankara, Turkey.*

Background: Hyponatremia is the most common electrolyte imbalance and it affects %15 of the elderly population. Approximately %50 of chronic hyponatremia is due to SIADH. V2 receptor antagonists offer a new therapeutic approach to hyponatremia and improve patient outcomes. We present the short term efficacy and safety of tolvaptan in five octogenarian patients with long-standing hyponatremia due to SIADH.

Methods: Five female patients with an average age of 83 (Range: 81 - 87) and with chronic hyponatremia due to SIADH, were admitted to the hospital because of symptomatic hyponatremia. The average serum Na level was 123 mEq/L (Range 117 - 126 mEq/L) on admission. Three patients were on low dose (12.5 mg/day) thiazide previously. Four patients were hypertensive and one had pumonary hypertension. Their left ventricular systolic functions were normal by echocardiogram. None of them had chronic kidney disease. All were euthyroid and hypocortisolism was ruled out. Simultaneous serum and urine osmolality measurements confirmed SIADH.

Results: All patients were treated with tolvaptan 15 mg/day as a single daily dose. None of them received hypertonic sodium chloride infusions. The serum Na level was monitored every 8 hours during the initial 72 hours and their body weights measured daily. ALT and GGT levels were also monitored. In two patients who were on oral furosemide 40 mg/day treatment, this treatment was maintained.The average hospitalization period was 4 days (Range 3-7 days). Average weight loss was 2.8 kg (Range 2.5 -3.8 kg). The average serum Na level at the end of 72 hours was 136 mEq/L (Range 134 - 141 mEq/L). Liver function tests were stable and no neurologic implications were encountered. Three patients were followed for 3 months of which two were on furosemide treatment. When these patients were treated with 15 mg/day, thrice weekly, the serum Na level remained within normal limits.

Conclusions: These findings provide additional information that low dose tolvaptan therapy in elderly hyponatremic patients due to SIADH, may be a safe and effective treatment. Maintenance treatment with thrice weekly 15 mg/day tolvaptan was able to provide a stable serum Na levels and prevent hyponatremic episodes in three patients during a follow-up period of three months.

SA-PO132

Desmopressin-Associated Hyponatremia in Elderly Patients with Nocturia Eun Young Choi, Joon-Sung Park, Gheun-Ho Kim. *Internal Medicine, Hanyang Univ College of Medicine, Seoul, Republic of Korea.*

Background: Desmopressin is being used for treatment of nocturia, but hyponatremia is concerned because of its further impairment of urine dilution in the elderly. This study was undertaken to characterize hyponatremia occurring in adults using desmopressin for nocturia and to examine risk factors for desmopressin-associated hyponatremia.

Methods: Data were retrospectively analyzed from patients who were prescribed desmopressin for nocturia at a urology clinic from September 2010 through February 2013. A total of 236 patients were reviewed, and 61 and 3 patients were excluded due to absence of follow-up serum sodium data and due to prior hyponatremia (< 135 mmol/L), respectively. In addition to demographic and laboratory parameters, hyponatremia-predisposing comorbidities and concurrent medications were evaluated to estimate risk factors.

Results: In 172 patients (144 men, 28 women), age was 69.5 ± 9.6 years. The basal serum sodium was 140 ± 2 mmol/L, and follow-up serum sodium measured at 21 ± 22 days after using desmopressin was 138 ± 5 mmol/L. Desmopressin-associated hyponatremia occurred in 24 patients (14%), and 7 were severe (< 126 mmol/L). In hyponatremic patients, serum sodium decreased by 11 ± 6 mmol/L. Patients with hyponatremia were older than those with normonatremia (78 ± 7 versus 68 ± 9 years, P<0.0001). Notably, none of the patients younger than 65 years had hyponatremia. Although women tended to increase the frequency of hyponatremia (7/28 versus 17/144), the statistical significance was not reached. Presence of either comorbidities or concurrent medications was associated with hyponatremia. Patients with hyponatremia had lower basal hemoglobin (11 ± 2 versus 13 ± 2 g/dL, P<0.001) and serum sodium (139 ± 2 versus 140 ± 2 mmol/L, P<0.05) than those with normonatremia. Multiple logistic regression showed that advanced age (OR, 1.15; 95% CI, 1.03-1.27) and lower hemoglobin levels (OR, 0.64; 95% CI, 0.43-0.94) were independently associated with hyponatremia.

Conclusions: Hyponatremia is not infrequently associated with desmopressin use in adult nocturia patients. Those with advanced age (≥65 years) and anemia are at risk of desmopressin-associated hyponatremia and need to be carefully monitored.

SA-PO133

Trimethoprim Associated Hyponatremia Revekka Babayev, Demetra Tsapepas, Maya K. Rao, Sumit Mohan. *Columbia Univ Medical Center.*

Background: Trimethoprim-sulfamethoxazole (TMP-SMX) is a commonly prescribed antibiotic used at high doses for treatment of pneumocystis pneumonia and other infections. Trimethoprim is structurally related to the potassium-sparing diuretic amiloride and has been associated with hyperkalemia and hyponatremia through blocking of epithelial sodium channels in the distal nephron. Objective: To determine the incidence of hyponatremia in hospitalized patients treated with high dose TMP-SMX.

Methods: We performed a single center retrospective chart review for all hospitalized patients who received high dose TMP-SMX (n=215) in 2012. Patients with congestive heart failure, cirrhosis, Stage 4 chronic kidney disease or higher, baseline hyponatremia, and those on other medications associated with hyponatremia were excluded. Hyponatremia was defined as a serum Na <136 meq/L.

Results: Analysis was restricted to 48 patients who received more than 8mg/kg/day of TMP-SMX for ≥3 days. The population had a mean age of 46.1± 16yrs, was mostly male (68.75%), with eGFR >60 ml/min/1.73m2 (95.8%). Majority of the patients were being treated for a pulmonary infection (91.6%). 77% of patients developed hyponatremia while on therapy with more than half of these patients (20/37, 54%) developing significant hyponatremia (serum Na < 130 mEq/L). Hyponatremia was noted on average 5.3 days after initiation of therapy, was more severe with higher cumulative dose of TMP-SMX and often resolved within a week of drug discontinuation (63.8%).

Nadir sodium	>135	130-135	<130	Total
N (%)	11 (22.9)	17 (35.4)	20 (41.7)	48 (100)
Baseline GFR (ml/min/1.73m^2) >60 30-59	10 1	16 1	20 0	46 (95.8) 2 (4.2)
Daily TMP dose (mean mg/day ± SD) IV PO Day of nadir Na (mean ± SD)	840 ±243 3 8 4.6 ±3	903.5 ±252 0 17 4.1±1.7	969 ± 274 5 15 6.9±5	916 ± 260
Cumulative TMP dose to nadir	3816 ± 3000	3614± 1773	6647 ± 4928	4924 ± 3870

Limitation: In 12 cases we did not have follow up serum Na off of therapy.

Conclusions: There is a high incidence (77%) of hyponatremia associated with the use of high dose of TMP-SMX among hospitalized patients. This is an overlooked and potentially reversible cause of hyponatremia.

SA-PO134

A Low Salt Diet Increases the Estimated Net Endogenous Acid Production in Non-Diabetic CKD Patients Treated with Angiotensin Receptor Blockade

Seon Ha Baek,[1] Sejoong Kim,[1] Dong Ki Kim,[2] Jung-Hwan Park,[3] Sung Joon Shin,[4] Sang Ho Lee,[5] Bum-Soon Choi,[6] Ho Jun Chin,[1] Chun Soo Lim.[7] *[1]Dept of Internal Medicine, Seoul National Univ Bundang Hospital, Korea; [2]Seoul National Univ Hospital, Korea; [3]Konkuk Univ School of Medicine, Korea; [4]Dongguk Univ Ilsan Hospital, Korea; [5]Kyung Hee Univ Medical Center, Korea; [6]Seoul St. Mary's Hospital, Korea; [7]Seoul National Univ Boramae Medical Center, Korea.*

Background: High net endogenous acid production (NEAP) levels precede renal disease progression in patients with chronic kidney disease (CKD). Angiotensin receptor blockade (ARB) exacerbates metabolic acidosis by inducing a distal-tubular acidification defect. Little is known about the acid-base effects of low salt diet (LSD) on patients treated with ARB. Therefore, we evaluated the effects of LSD on the NEAP in non-diabetic patients with CKD treated with ARB.

Methods: A total of 202 adult subjects from the original trial (ESPECIAL trial: NCT01552954) were enrolled in the present study. Non-diabetic CKD patients were divided into a good LSD compliance group and a poor LSD compliance group. All patients were treated with olmesartan for 8 weeks.

Results: During the interventional 8 weeks, the NEAP in the good compliance group increased compared with the control group (12.9 ± 32.0 versus -2.0 ± 35.0, P = .002). NEAP was positively associated with the good LSD compliance after adjusting for age, gender, body mass index, levels of serum creatinine, sodium, cholesterol, and uric acid, and the NEAP baseline, with previous randomization (r = .135, P = .016). A decrement of 1 g/d of salt intake predicted an increment of 1.75 mEq/d in the NEAP (r = -.180, P = .008). The additional reduction of 2.39 g/d of protein intake with the reduction of 1 g/d of salt intake does not increase the NEAP under ARB treatment with LSD (r = .546, P < .001).

Conclusions: We found that LSD may increase the NEAP in non-diabetic CKD patients using ARB, which suggests that additional dietary protein restriction should be required for maintaining the NEAP in non-diabetic CKD patients with ARB and LSD.

SA-PO135

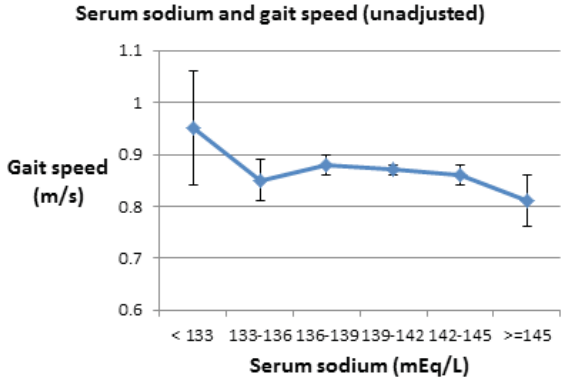
Serum Sodium and Physical Function in SPRINT

Daniel E. Weiner,[1] Pranav S. Garimella,[1] David Reboussin,[2] Edward J. Horwitz,[3] James R. Powell,[4] Dena E. Rifkin,[5] Dawn F. Wolfgram,[6] Mary Ann Banerji,[7] Kausik Umanath.[8] *[1]Tufts Medical Center; [2]Wake Forest Univ; [3]Case Western Reserve; [4]Eastern Carolina Univ; [5]UC San Diego; [6]Medical College Wisconsin; [7]SUNY Downstate; [8]Henry Ford Hospital.*

Background: Dysnatremias are common electrolyte disturbances in clinical medicine. Although limited data suggest that hyponatremia may be associated with subtle motor and functional disturbances including gait speed and falls in older adults, this has not been studied in large outpatient populations.

Methods: We analyzed data from participants in the Systolic Blood Pressure Intervention Trial (SPRINT) who underwent gait speed testing (n=2,513) or completed the Falls Efficacy Scale International (FESI) questionnaire (n=2,307) in addition to having measures of serum sodium (Na). Cross-sectional association of serum Na levels with gait speed and FESI score was assessed using linear regression.

Results: Mean (SD) age was 68 (9.4) years and 36% were women. Median (IQ) Na level was 140 (139-142) mEq/L and 387 had a Na level of <135 mEq/L. Estimated GFR decreased with increasing Na levels. Gait speed was fastest (0.95 m/s) in participants with serum Na <133 mEq/L and slowest (0.81 m/s) in those with serum Na >145mEq/L.



In univariate analyses, serum Na levels, age, female sex, CKD, diastolic BP and loop diuretic use were associated negatively with gait speed (p<0.05). Each 10 mEq higher serum Na was associated with 0.05 m/s lower gait speed after adjusting for above variables (p<0.01). Serum Na levels were not associated with FESI scores.

Conclusions: In community dwelling older adults, higher rather than lower serum Na levels are associated with reduced gait speed after adjustment. Further studies are needed to confirm our findings in specific populations such as those with hyponatremia, and in persons with other causes for mobility limitation like dementia and arthritis.

Funding: NIDDK Support

SA-PO136

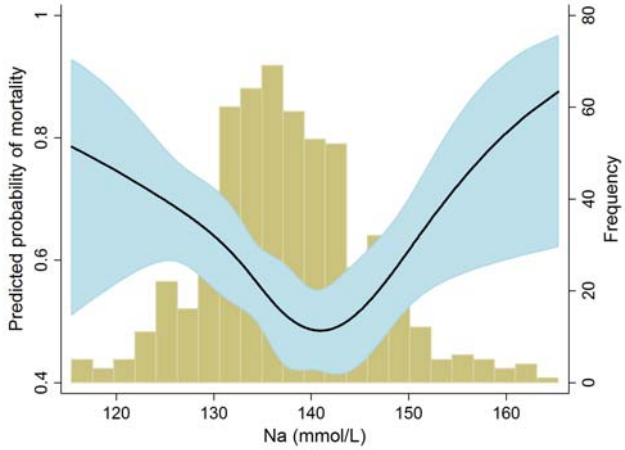
Initial Serum Sodium Level Predicts Mortality in Patients Undergoing Continuous Renal Replacement Therapy

Seung Seok Han, Jae Yoon Park, Dong Ki Kim, Yon Su Kim, Jin Suk Han, Kwon Wook Joo. *Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea.*

Background: Although dysnatremia is known to be related to the mortality risk, this issue remains unresolved in the patients undergoing continuous renal replacement therapy (CRRT). Furthermore, it is not determined whether the correction of dysnatremia leads to the reduction of mortality risk.

Methods: A total of 569 patients were prospectively enrolled at the time of starting CRRT from May 2010 through September 2013. The patients were divided into 5 groups: normonatremia (135–145 mmol/L), mild hyponatremia (131.1–134.9 mmol/L), severe hyponatremia (115.4–131.0 mmol/L), mild hypernatremia (145.1–148.4 mmol/L), and severe hypernatremia (148.5–166.0 mmol/L). The non-linear relationship between sodium and mortality was initially explored. Next, the odds ratios (ORs) for mortality were calculated after adjustment of multiple covariates.

Results: The relationship between baseline sodium and mortality was U-shaped.



The mild hyponatremic, severe hyponatremic, and severe hypernatremic groups had greater ORs of 30-day mortality (1.65, 1.91, and 2.32, respectively) than the normonatremic group (all Ps < 0.05). However, sodium levels at 24- and 72-hour after the start of CRRT did not predict 30-day mortality. Furthermore, the changes of sodium during 24 or 72 hours did not have any relationship or significance with 30-day mortality, irrespective of baseline sodium level.

Conclusions: Sodium level at the time of starting CRRT was a strong predictor of mortality. However, the change of sodium level or the degree of sodium correction was not associated with the mortality risk.

SA-PO137

Quantifying Vanished Sodium after Hypertonic Saline Infusion in Healthy Subjects

Nienke M.G. Rorije,[1] Rik Hg Olde Engberink,[1] Jaap Homan Van Der Heide,[1] Bert-Jan Van den Born,[2] Liffert Vogt.[1] *[1]Nephrology, AMC, Amsterdam; [2]Vascular Medicine, AMC, Amsterdam.*

Background: Sodium (Na^+) is important in maintaining volume homeostasis and blood pressure (BP). Regulation of total body Na^+ and extracellular volume is mainly attributed to the kidney. Recent animal studies have demonstrated non-osmotic Na^+ storage in skin interstitium in response to high Na^+ intake via glycosaminoglycan (GAG) binding. Studies in humans are limited, especially regarding acute salt loading.

Methods: 9 healthy male volunteers pursued a low sodium diet (<50 mmol Na^+/d) for 8 days. In order to achieve 3 mM increase of serum Na+ (according to the Adrogue-Madias formula), on day 8 hypertonic saline was administered IV in 30 minutes, adjusted for total body water (TBW=0.6 x body weight). Before infusion subjects were instructed to void. Urine was collected after 240 min. Blood samples were collected after 0, 10, 60, 240 min. BP was measured with an automatic device (Omron). Cardiac output (CO) and systemic vascular resistance (SVR) were measured with Nexfin (Edwards Lifescience).

Results: Baseline median 24h-urine Na^+ excretion was 15.5 mmol (IQR12.2-25.6) and calculated TBW was 43.9L (43.5-45.8). Ten minutes after infusion (median 220 mmol Na+ in 542 mL), baseline serum Na^+ (137.8 mM (136.5-139.0)) increased to 140.8 mM (139.0-142.5). This was in line with the expected calculated rise of 3.2 mM. Thereafter, serum Na^+ decreased with 1.0mM after 60 min and 2.0 mM after 240 min. According to the Adrogue-Madias formula, this 2.0 mM Na^+ drop at 240 min with median TBW of 44.4L, expected urinary Na^+ excretion would be 95.7 mmol. However, observed total urinary Na^+ excretion after 240 min was 20.6 mmol (median: 49.9 mM in 413 mL) after 240 min, leaving 75.1 mmol Na^+ undetected. This calculation was not corrected for potential residual bladder volume or extrarenal Na^+ loss. BP, CO and SVR remained stable after infusion. Ht (p=0.007) decreased significantly after 240 min, indicating intravascular volume expansion.

Conclusions: After acute hypertonic saline infusion in healthy subjects, 78% of Na^+ expected to be excreted via urine was missing, suggesting that Na^+ may be stored elsewhere, possibly at GAG binding sites.

Association Between Extracellular Water Excess and Renal Outcomes in Patients with Chronic Kidney Disease Reibin Tai,[1] Yasushi Ohashi,[1] Toshiyuki Aoki,[1] Sonoo Mizuiri,[2] Yoshihide Tanaka,[1] Atsushi Aikawa,[1] Ken Sakai.[1] *[1]Nephrology, School of Medicine, Faculty of Medicine, Toho Univ, Tokyo, Japan; [2]Nephrology, Ichiyokai Harada Hospital, Hiroshima, Japan.*

Background: Extracellular water (ECW) excess is a major clinical problem in patients with chronic kidney disease (CKD). However, it is unclear whether ECW excess is associated with disease progression. We investigated whether ECW excess is a risk factor for adverse renal outcomes.

Methods: We performed a retrospective cohort study of 149 patients with CKD who underwent bioelectrical impedance analysis (BIA) between 2005 and 2009. Patients were categorized according to tertiles of extracellular volume status. ECW excess was assessed by examining the ratio of ECW measured by the BIA device (ECW_{BIA}) to total body water calculated using the Watson formula (TBW_{Watson}). Main outcomes were adverse renal outcomes, as defined by a decline of 50% or more from baseline glomerular filtration rate or initiation of renal replacement therapy.

Results: Patients with a higher percentage of ECW_{BIA} to TBW_{Watson} tended to: be older and male; have diabetes mellitus, resistant hypertension, lower renal function and serum albumin, higher proteinuria, and higher frequency of furosemide use. The $\%ECW_{BIA}/TBW_{Watson}$ had a weak negative correlation with body mass index (BMI) (r = -0.36 in male, P = 0.001 and r = -0.28 in female, P = 0.02). In multivariate analysis, male sex, BMI, and proteinuria remained independently associated with $\%ECW_{BIA}/TBW_{Watson}$. During a median follow-up of 4.9 years, patients in the highest tertile of $\%ECW_{BIA}/TBW_{Watson}$ were at greater risk of adverse renal outcomes (16.6 per 100 patient years) compared with those in the lowest tertile (6.0 per 100 patient years) or those in the second tertile (7.5 per 100 patient years) (P = 0.005). After adjustment for covariates, $\%ECW_{BIA}/TBW_{Watson}$ was significantly associated with adverse renal outcomes (hazard ratio 1.21, 95% confidence interval 1.09–1.33, P < 0.001).

Conclusions: ECW excess was independently associated with adverse renal outcomes during a relatively long follow-up period.Proteinuria is independently associated with ECW excess, and leaner patients with CKD may be more susceptible to volume overload.

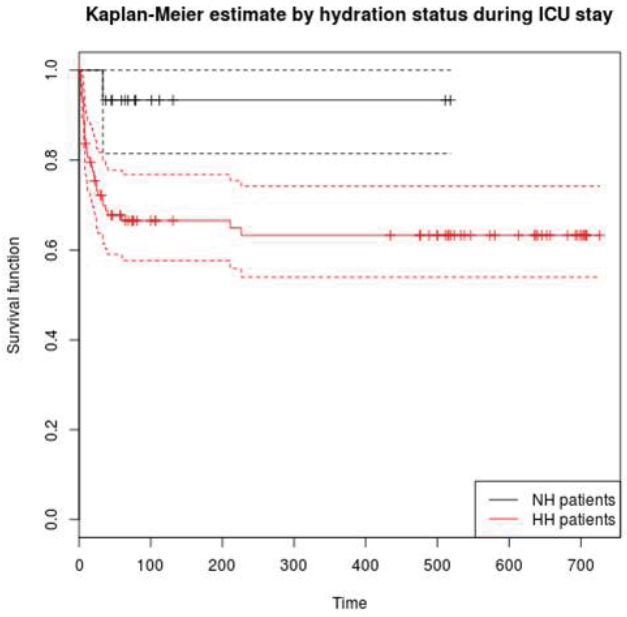
SA-PO139

Evaluation of the Impact of Persistent Fluid Overload on Outcome in Critically Ill Patients Sara Samoni,[1,2] Federico Nalesso,[1] Valentina Vigo,[2] Enrico Tonini,[1] Flavio Basso,[1] Alessandra Brendolan,[1] Monica Zanella,[1] Leonardo Claudino Ribeiro,[1] Jose Jesus Zaragoza,[1] Alessandra Spinelli,[1] Gianluca Villa,[1] Carla Estremadoyro,[1] Carlo Donadio,[2] Claudio Ronco.[1] *[1]IRRIV; [2]Univ of Pisa.*

Background: Data indicate role of fluid overload(FO) in increased mortality,non-recovery of kidney function in patients with acute kidney injury(AKI) and higher rates of complications.Also,mortality seems to be higher till the patient with AKI is exposed to FO.Aim of this study is to evaluate the impact of persistent FO on outcome in critically ill patients.

Methods: A prospective,dual-center study in critically ill patients. Anthropometric,medical history and laboratory data of patients admitted in ICU with expected stay of 72 hours or more were recorded.Assessment of body fluid status was performed using Bioelectric Impedance Vectorial Analysis(BIVA),using a single frequency analyzer,at the baseline and daily for a period of 72-120 hours.Patients were considered normo-hydrated(NH) if hydration level was 72.7%-74.3% of fat-free body mass and hyper-hydrated(HH) if hydration level was >74.3%.

Results: 483 BIVA measurements were taken in 114 patients.A Cox model studied the relation between mortality and hydration status,ceteris paribus.We found that not only the maximum level of hyper-hydration reached in observation period,but also the percentage of days in which patients had FO,was correlated with mortality(p=0.0235),either in patients with or without AKI.



Conclusions: FO is a relevant risk factor for mortality in critically ill patients. Therefore,assessment of body fluid volume in ICU is of great importance,but there are currently few methods to obtain an accurate and timely assessment of hydration status.We suggest the use of BIVA,which is simple,non-invasive and feasible to repeat measurements,in addition to clinical evaluation to estimate hydration status in critically ill patients in ICU.

SA-PO140

Classification of Acid-Base Disorders by Simultaneous Arterial and Venous Blood Gas - An Observational Study Mohamed A. Sheta,[1] Thomas H. Hostetter,[2] Paul E. Drawz.[1] *[1]Univ of Minnesota, Minneapolis, MN; [2]Case Western Reserve Univ, Cleveland, OH.*

Background: Arterial blood gas (ABG) is the gold standard for defining acid-base disorders. A high correlation between arterial and venous pH has led to the routine use of venous blood gases (VBG) to classify acid-base disorders at some institutions. However, the rate of agreement between acid-base diagnoses based on arterial and venous blood gases is unknown.

Methods: All patients at the University of Minnesota Medical Center with a VBG within 60 minutes of an ABG between November 2010 and November 2013 were included in this retrospective study. Patients' acid-base status was categorized based on pH (<7.35 or > 7.45), pCO2 (<40 or >40), and bicarbonate (<24 or >24) from both the ABG and VBG (after applying a correction factor of 0.05 for pH and 5 for pCO2 to VBG values). Primary analyses focused on patients with mild to moderate acid-base disturbances (ABG pH 7.25-7.50).

Results: 1814 patients had a VBG within 60 minutes of an ABG with an ABG pH between 7.25 and 7.50. The average age (SD) was 61.0 (15.7) years and average eGFR was 61.1 (26.4) mL/min/1.73m^2. 318 patients were unclassified based on their ABG. Concordance between acid-base diagnosis based on ABG and diagnosis based on VBG ranged from 37% for respiratory alkalosis to 64% for mixed alkalosis. Results were similar in the subset of patients with a VBG within 15 minutes of an ABG.

	Diagnostic cutoffs				VBG category same as paired ABG	
ABG category	**pH**	**pCO2**	**bicarb**	**Total N**	**N**	**%**
metabolic acidosis	< 7.35	< 40	< 24	120	66	55%
metabolic alkalosis	> 7.45	> 40	> 24	35	21	60%
mixed acidosis	< 7.35	> 40	< 24	172	78	45%
mixed alkalosis	> 7.45	< 40	> 24	56	36	64%
respiratory acidosis	< 7.35	> 40	> 24	118	66	56%
respiratory alkalosis	> 7.45	< 40	< 24	52	19	37%
Total with abnormal pH				**553**	**286**	**52%**
normal ABG pH	≥ 7.35 and ≤ 7.45			943	816	87%
Total				**1496**	**1102**	**74%**

Conclusions: In this study, concordance between acid-base diagnoses based on an ABG and a VBG was only 52% among patients with an abnormal pH on ABG. While there may be a high degree of correlation between pH measured on an ABG and a VBG, classification of patients by ABG and VBG differs significantly.

Funding: NIDDK Support

SA-PO141

Acid-Base Status in Circulatory Failure: Relationship between Arterial and Peripheral Venous Blood Gas Measurements in Hypovolemic Shock

Richard M. Treger,[1,2] Tristan Grogan,[2] David Elashoff,[2] Craig Anderson,[3] Scott Rudkin.[3] *[1]Nephrology, VHAGLA, LA, CA; [2]Medicine and Biostatistics, UCLA, LA, CA; [3]Emergency Medicine, UCI, Orange, CA.*

Background: In severe circulatory failure agreement between arterial and mixed or central venous values is poor; venous values are more reflective of tissue acid-base imbalance. No prior study has examined the relationship between peripheral VBGs and ABGs in hemodynamic compromise.

Methods: Data were obtained prospectively from adult trauma patients. Patients were excluded if the ABG and VBG were drawn > 10 minutes apart.

Results: 178 patients were included. The correlations between arterial (A)-peripheral venous (PV) pH, A-PV pCO_2, and A-PV bicarbonate and systolic blood pressure (SBP) were not statistically significant (p=0.55, 0.17, and 0.09, respectively). Although hypotensive patients had a lower mean A and PV pH and bicarbonate compared to the hemodynamically stable patients, mean A-PV differences for pH, pCO_2, and bicarbonate were similar between hypotensive and normotensive groups. Table 1: ABG and Peripheral VBG Values [Mean (SD)].

	SBP≤90	SBP > 90
n	15	163
A pH	7.26 (0.18)	7.41 (0.09)
PV pH	7.20 (0.16)	7.36 (0.10)
A-V diff pH	0.03 (0.06)	0.05 (0.06)
A pCO_2	38.86 (12.40)	37.62 (7.84)

A-V diff Bicarb	-0.22 (3.80)	-1.81 (2.41)

Conclusions: In hypovolemic shock, the peripheral VBG does not demonstrate a higher CO_2 concentration and lower pH compared with arterial blood. Therefore, the peripheral VBG is not a surrogate for the tissue acid-base status in hypovolemic shock, likely due to peripheral vasoconstriction and central shunting of blood to essential organs. This contrasts with the selective venous respiratory acidosis previously demonstrated in central and mixed venous measurements in circulatory failure, which is more reflective of acid-base imbalance at the tissue level than arterial blood. Further work needs to be done to better define the relationship between ABG and both central and peripheral VBG values in various types of shock due to ↓ cardiac output versus ↓ systemic vascular resistance.

SA-PO142

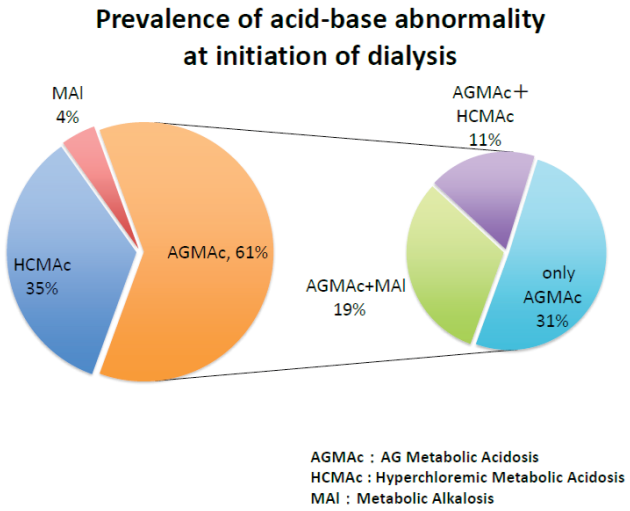
Acid-Base Disorders at Dialysis Initiation: A Multicenter Cross-Sectional Study in Japan

Akihiro Ryuge,[1] Hideaki Shimizu,[1] Yoshiro Fujita,[1] Daijo Inaguma.[2] *[1]Chubu-Rosai Hospital, , Nagoya City, Japan; [2]Japanese Red Cross Nagoya Daini Hospital, 2-9 Myoken-cho Showa-ku, Nagoya City, Japan.*

Background: Although anion gap metabolic acidosis (AGMAc) is a major acid base disorder of end stage renal disease (ESRD), only a few studies have investigated the prevalence of acid-base abnormalities of ESRD. The aim of the present study was to clarify the prevalence of acid-base abnormalities and their associated factors in patients at dialysis initiation.

Methods: This study included 1,525 patients starting maintenance dialysis between 10/1/2011, and 9/30/2013. Eighteen care centers in Japan participated in the Aichi Cohort Study of Prognosis in Patients Newly Initiated into Dialysis "AICOPP". After exclusion of 501 (32.8%) patients without acid base data, 1024 (67.1%) patients were enrolled. We defined 5 groups as 1)AGMA+Metabolic alkalosis (MAl) : AG ≥ 16 + corrected $HCO3^-$ ($cHCO3$) ≥ 28, 2)AGMAc : AG ≥ 16 + ($cHCO3^-$) 23 ≥ to < 28, 3)AGMAc + HCMAc (Hyperchloremic metabolic acidosis) : AG ≥ 16 + $cHCO_3^-$ < 23, 4)HCMA : AG8 ≥ to < 16 + HCO_3 < 23 + pH < 7.4, 5)Mal :HCO_3 > 28 + pH ≥ 7.4. Multiple logistic regression analyses were used to identify factors associated with AGMAc.

Results: Prevalence of acid-base abnormality at dyalysis initiation.



In multivariate analyses, estimated eGFR [Odds Ratio(OR) 0.81; 95% confidence interval(CI) = 0.75-0.87], and GI symptoms [OR 1.80; 95% CI = 1.45 - 2.23], not planned initiation [OR 1.98; 95% CI = 1.49 - 2.64], pulmonary edema [OR 1.57; 95% CI = 1.24 - 1.95] were independently associated with AGMAc.

Conclusions: Although AGMAc values increased as eGFR levels decreased, significant AGMA at dialysis initiation was observed only in 61.1% in this study. Mixed acid base types were up to 30% ; MA were 23%. We should not overtreat metabolic acidosis with $NaHCO_{[sup]3[/sup]}$.

SA-PO143

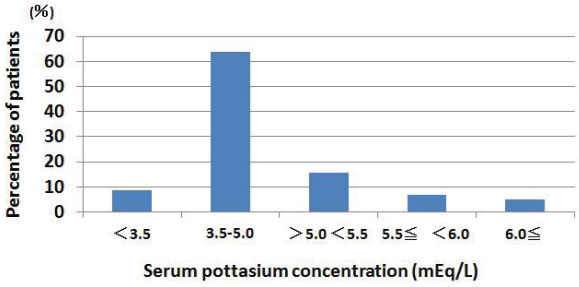
Prevalence of Hyperkalemia and Associated Factors in End-Stage Kidney Disease Patients at Dialysis Initiation-AICOPP Study in Japan

Akihiro Ryuge,[1] Hideaki Shimizu,[1] Yoshiro Fujita,[1] Daijo Inaguma.[2] *[1]Nephrology, Chubu-Rosai Hospital, Nagoya, Japan; [2]Nephrology, Japanese Red Cross Nagoya daini Hospital, Nagoya, Japan.*

Background: CKD is an important risk of hyperkalemia, and recent studies showed prevalence and associated factors of hyperkalemia in various stages of CKD. GFR of these patients were not so low, and patients at dialysis induction were not evaluated. This is the first study which investigate prevalence and associated factors of hyperkalemia in End-Stage Kidney Disease patients at dialysis initiation.

Methods: This study is a cross-sectional study which data was collected by "Aichi Cohort study of Prognosis in Patients" (AICOPP) newly initiated into dialysis. This study enrolled 1,525 patients (mean age, 67.4 ± 13.0 years; mean eGFR level, 5.40 ± 2.2 mEq/l) who started chronic dialysis between 10/1/2011 and 11/30/2013. We evaluated prevalence of hyperkalemia in these patients, and multiple logistic regression analyses were used to identify factors associated with hyperkalemia in End-Stage Kidney Disease patients at dialysis initiation in Japan.

Results: This research showed the prevalence of hyperkalemia.



In multiple logistic regression analyses showed male sex (OR 1.637, 95%CI 1.027-2.611), eGFR (OR 0.794, 95%CI 0.697-0.904), pH<7.35 (OR 4.310, 95%CI 2.661-6.981), emergency dialysis initiation (OR 2.061, 95%CI 1.252-3.392) were independently associated with hyperkalemia. Gastrointestinal symptom, heart failure, use of angiotensin converting enzyme inhibitor, angiotensin receptor blocker, and diuretics were not associated with hyperkalemia.

Conclusions: In this study, prevalence of hyperkalemia was 27.4% in dialysis induction, and male sex, low eGFR low, pH<7.35, emergency dialysis initiation were associated with hyperkalemia.

SA-PO144

Associations of Serum Bicarbonate Concentration with Cardiovascular Outcomes in the Multi-Ethnic Study of Atherosclerosis (MESA)

Jessica B. Kendrick,[1] Leila R. Zelnick,[2] Michel Chonchol,[1] Joachim H. Ix,[3] Michael Shlipak,[4] Mark J. Sarnak,[5] Bryan R. Kestenbaum,[2] David Siscovick,[2] Andrew N. Hoofnagle,[2] Ian H. de Boer.[2] *[1]Univ of Colorado Denver; [2]Univ of Washington Seattle; [3]Univ of California San Diego; [4]Univ of California San Francisco; [5]Tufts Medical Center Boston.*

Background: Metabolic acidosis is associated with increased risks of mortality and heart failure in patients with CKD. Whether serum bicarbonate concentrations are associated with incident cardiovascular disease (CVD) in the general population is unknown.

Methods: We performed a cohort study of 6230 participants in MESA, who were free of clinical CVD at baseline. Serum bicarbonate was examined as a continuous variable and in clinically significant categories (<21, 21-22, 23-24, ≥25 mEq/L). Multivariable Cox proportional hazards models were used to test associations of serum bicarbonate with incident cardiovascular events (CVE) (composite of myocardial infarction, resuscitated cardiac arrest, stroke, coronary heart disease death and stroke death) and incident heart failure.

Results: The mean bicarbonate concentration was 23.1 ± 1.8 mEq/L. 331 (5.3%) participants had an incident CVE and 174 (2.8%) had incident heart failure during a median (IQR) follow-up of 8.5 (7.7-8.6) years. Participants with bicarbonate levels <21 mEq/L were more likely to be younger, to be Hispanic, and to have diabetes, higher body mass index, and higher estimated GFR. We found no association between serum bicarbonate and incident CVE or heart failure in unadjusted or adjusted analysis. After excluding patients on diuretics, we found that each 1 mEq/L higher serum bicarbonate concentration was associated with a 14% higher risk of incident heart failure in models adjusted for demographics and CVD risk factors (Adjusted HR 1.14, 95% CI 1.02 to 1.28). Bicarbonate concentrations were not associated with incident CVE in patients not on diuretics.

Conclusions: In a cohort of participants initially free of CVD, higher not lower serum bicarbonate concentrations were associated with an increased risk of incident heart failure in patients not on diuretics. There was no association between serum bicarbonate and incident atherosclerotic CVE.

SA-PO145

Association of Serum Bicarbonate Levels with Ankle Brachial Pressure Index in the Third National Health and Nutrition Examination Survey

Shyamal K. Palit,[1] Jessica B. Kendrick.[1,2] *[1]Univ of Colorado Denver; [2]Denver Health Medical Center.*

Background: Metabolic acidosis, as reflected by a low serum bicarbonate level, may be a modifiable risk factor for cardiovascular disease. Several studies have found that metabolic acidosis is associated with incident and prevalent hypertension. Whether metabolic acidosis is associated with arterial stiffness is unknown.

Methods: The cross-sectional association between serum bicarbonate concentration and peripheral vascular disease as measured by an ankle brachial pressure index (ABPI) >1.3, was examined among 1002 participants in the Third National Health and Nutritional Examination Survey. Serum bicarbonate was examined as a continuous variable and in clinically significant categories (<21, 21-22, 23-24 and ≥ 25 mEq/L). Multivariable logistic regression was used to examine the relationship between serum bicarbonate concentration and an ABPI >1.3.

Results: The mean ± SD age and serum bicarbonate concentration of the study population was 47 ± 21 years and 28.8 ± 4.3 mEq/L, respectively. 72 (7.2%) had an ABPI >1.3. Eighty-four percent and 1.4% had a bicarbonate level >25 mEql/L and <21 mEq/L, respectively. There were no significant differences in age, sex, race, body mass index, smoking status, diabetes, hypertension, estimated glomerular filtration rate, C-reactive protein, low density lipoprotein cholesterol or high density lipoprotein cholesterol levels between participants with higher versus lower ABPI. We found no significantly increased risk of an ABPI > 1.3 in unadjusted or adjusted analyses with serum bicarbonate levels <21, 21-22 or ≥25 mEq/L when compared to the reference group (23-24 mEq/L). When serum bicarbonate was examined as a continuous variable, we found a U-shaped relationship in that lower and higher bicarbonate levels compared to 29.6 mEq/L were increasingly more associated with an increased risk of an ABPI > 1.3 (p=0.013 each for linear and quadratic bicarbonate terms).

Conclusions: We found a U-shaped relationship between serum bicarbonate and risk of ABPI >1.3. Further studies are needed to confirm our results and to evaluate the potential mechanism by which bicarbonate may contribute to arterial stiffness.

Metabolic Alkalosis in Critically Ill Patients: Learning What We think We Already Know

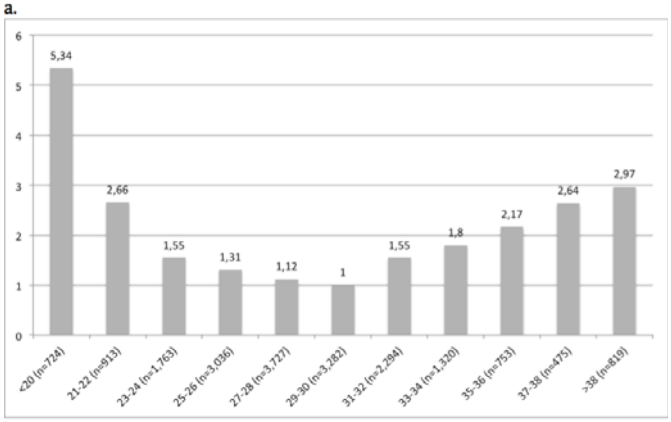
Alexandre Braga Liborio,[1] Evandro Faria,[2] Eder Pinheiro Arantes.[1] *[1]Clinical Medicine, Univ Federal of Ceara, Fortaleza, Ceara, Brazil; [2]Pronefron, Fresenius Medical Care, Fortaleza, Ceara, Brazil.*

Background: Although commum in intensive care unit (ICU), m has not been studied in controlled studies regarding its associated factors and prognostic implications.

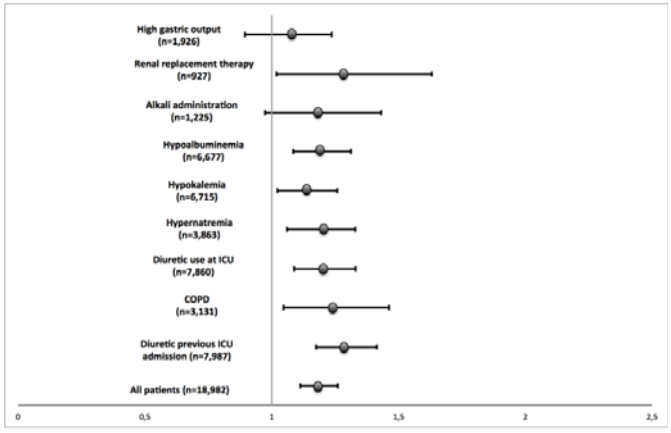
Methods: Retrospective study performed using extracted data from the Multiparameter Intelligent Monitoring in Intensive Care II (MIMIC -II) database.

Results: 18,982 patients were included. Mean age on admission was 63.8±17.5 years and 8,159 were females (43.0%). The mean SOFA and SAPS-I scores on admission were 5.9±4.0 and 13.5±5.9, respectively. Serum bicarbonate (sBIC) showed an inverted J-shaped association with mortality (fig1a). There was an increment in mortality when maximum sBIC was less than 25 or higher than 30mEq/L.

a.



b.



During ICU stay, 5,565 patients (29.3%) had at least one day of sBIC > 30mEq/L. Patients with at least one sBIC level > 30mE/L had higher severity scores at ICU admission. The majority of patients were exposed to multiple possible etiologies - mainly, diuretic use, hypernatremia, hypokalemia and high gastric output. Patients with sBIC>30mEq/L had higher ICU LOS (5.6 [2.8-12.0] versus 2.2 [1.5-3.6], p<0.001), more days on mechanical ventilation (677.4 versus 291.6 per 1,000 patient days of ICU stay, p<0.001) and higher inhospital mortality. After multivariate adjustment, each 5-mEq/L increment in sBIC above 30mE/L was associated with a 22% higher risk of inhospital death. Also, duration of such high sBIC in relation to ICU LOS was associated with mortality. Subgroup analysis showed that the association between high sBIC level and mortality occurs independently of its etiologies, except when associated with high gastric output(fig1b).

Conclusions: Elevated sBIC is common in critically-ill patients; it can be attributed to multiple factors in the majority of cases and its presence and duration has a negative impact on outcome.

SA-PO147

Effect of ZS-9 on Serum Bicarbonate and BUN in a Phase 3 Randomized, Double-Blind, Placebo-Controlled Trial

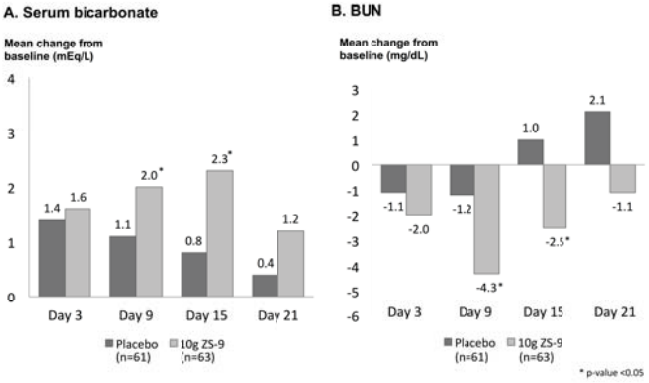
Simon D. Roger,[1] Henrik S. Rasmussen,[2] Philip T. Lavin,[3] Alex Yang,[4] Bhupinder Singh.[5] *[1]Renal Research, Gosford, Australia; [2]ZS Pharma, Inc., Coppell, TX; [3]Boston Biostatistics Research Foundation, Framingham, MA; [4]Xelay Acumen, Inc., Belmont, CA; [5]Apex Research, Riverside, CA.*

Background: Increase in serum bicarbonate (HCO_3) may benefit chronic kidney disease (CKD) patients (pts) by delaying disease progression (Kovesdy 2012, Goraya 2013). In addition, even small increases in HCO_3 can enhance insulin sensitivity, which may be important for CKD pts who are diabetic. ZS-9, a non-absorbed cation exchanger that specifically traps K^+ in the gut, was well tolerated and acutely reduced and maintained serum K^+ over 15 days in a Phase 3 study in pts with hyperkalemia (HK; Singh 2014). Here we present the effects of ZS-9 versus placebo (PBO) on serum HCO_3 and blood urea nitrogen (BUN).

Methods: Pts (N=753) with K^+ 5.0-6.5 mEq/L were randomized (1:1:1:1:1) to ZS-9 (1.25, 2.5, 5 or 10g) or PBO 3×/day for 48 hours (acute phase), after which those with K^+ ≤4.9 mEq/L were re-randomized to PBO or the same ZS-9 acute dose 1×/day on Days 3-15 (extended phase). Serum HCO_3 and BUN were measured on Days 1, 3, 9, 15 and 21. Results from the 10g dose group are presented (n=61 PBO; n=63 ZS-9).

Results: At baseline (BL), mean HCO_3 was 22.8 mEq/L and BUN was 35.8 mg/dL. HCO_3 increased in the ZS-9 10g dose group by 2.0 and 2.3 mEq/L, and BUN decreased by 4.3 and 2.5 mg/dL on Days 9 and 15, respectively ($p < 0.05$; Figure). Pts who switched to PBO exhibited no changes in HCO_3 or BUN. There was a dose-proportional effect on percentage of pts with >10% changes in HCO_3 or BUN.

Figure. Changes in serum bicarbonate and BUN through Day 21.



Conclusions: In HK pts treated with ZS-9, the increase in serum HCO_3 may be explained by removal of ammonium, as illustrated by the decrease in BUN. As prior studies have suggested that amelioration of metabolic acidosis may be kidney-protective (Loniewski 2013), longer term studies are needed to determine whether ZS-9 can delay progression of CKD.

SA-PO148

The Association of Serum Potassium with Cardiovascular Events and Mortality in Community-Dwelling Individuals: The Multi-Ethnic Study of Atherosclerosis (MESA) Jan M. Hughes-Austin,[1] Dena E. Rifkin,[1] Tomasz Beben,[1] Ronit Katz,[2] Andrew N. Hoofnagle,[2] Rajat Deo,[3] Shunichi Homma,[4] Mark J. Sarnak,[5] David Siscovick,[6] Michael Shlipak,[7] Ian H. de Boer,[2] Bryan R. Kestenbaum,[2] Joachim H. Ix.[1] *[1]UCSD; [2]Univ Washington; [3]UPenn; [4]Columbia Univ; [5]Tufts Univ; [6]NYAM; [7]UCSF.*

Background: High serum potassium (K) is associated with death in chronic kidney disease (CKD) patients, and in acute illness. Associations in other settings are uncertain. We determined associations between K concentrations with cardiovascular (CV) events and mortality in a community-dwelling population.

Methods: Among 6484 MESA participants, we evaluated associations between serum K categories [< 4.0, 4.0-4.5, 4.5-5.0, and ≥ 5.0 mEq/L] with fatal and non-fatal CV events and all-cause mortality using Cox proportional hazards models; and whether associations differed by ACE/ARB use, diuretic use, and CKD status.

Results: Mean age was 62 years, 47% were male, 39% were White, 12% were Chinese, 28% were African, and 22% were Hispanic. Older persons, lower eGFR, higher glucose, and use of ACE/ARB were associated with higher K levels; and diuretics with lower K levels. There was no significant association between serum K and CV events; however, the association differed by ACE/ARB use ($p_{int} = 0.037$), and this interaction was qualitative. Compared to the 4.0-4.5 mEq/L reference category, those with K ≥ 5.0 mEq/L were at 55% higher risk of all-cause mortality in fully adjusted models (95% CI: 1.12-2.14). These associations did not significantly differ by diuretic or ACE/ARB use or by CKD status (p_{int} = 0.84, 0.47, and 0.55 respectively).

Hazard Ratios and 95% Confidence Intervals for Serum Potassium Categories, CV Events, and All-Cause Mortality^

	K < 4.0 mEq/L (n=960)	4.0 ≤ K < 4.5 mEq/L (n=3398)	4.5 ≤ K < 5.0 mEq/L (n=1882)	K ≥ 5 mEq/L (n=249)
CV Events				
All (n=6484)	1.15 (0.90-1.46)	1.0 (ref)	0.84 (0.33-2.14)	1.54 (0.33-7.08)
No ACE/ARB Use* (n=5338)	0.90 (0.67-1.22)	1.0 (ref)	1.09 (0.87-1.36)	**1.61 (1.07-2.43)**
ACE/ARB Use* (n=1149)	**1.81 (1.18-2.77)**	1.0 (ref)	1.35 (0.92-1.96)	0.71 (0.32-1.61)
All-Cause Mortality				
All (n=6484)	1.21 (0.96-1.52)	1.0 (ref)	**1.20 (1.00-1.43)**	**1.55 (1.12-2.14)**

*ACE/ARB use p for interaction = 0.037; bold type indicates statistical significance

^Analyses adjusted for age, sex, race eGFR, urine albumin/creatinine ratio, diabetes, systolic blood pressure, and use of any ACE/ARB, diuretics, other anti-hypertensive medications, NSAIDs, and K supplements

Conclusions: High serum K is independently associated with all-cause mortality in community-dwelling individuals. A similar association was seen for CV events, but was limited to non-ACE/ARB users.

SA-PO149

Logistic Organ Dysfunction System Score Predicts the Prognosis in Patients with Alcoholic Ketoacidosis Kyungo Hwang, Eun Ju Lee, Hyun Seop Cho, Hyun-Jung Kim, Se-Ho Chang, Dong Jun Park. *Div of Nephrology, Dept of Internal Medicine, Gyeongsang National Univ Hospital, Jinju, Gyeongsangnamdo, Korea.*

Background: Although alcoholic ketoacidosis (AKA) is rarely diagnosed, it might be associated with various organ dysfunctions and death in chronic alcoholics. However, there have been no studies for prognostic factors in these patients. Therefore, we analyzed clinical and laboratory data to evaluate prognostic factors in patients with AKA.

Methods: We retrospectively reviewed the medical records of patients who were diagnosed as AKA from January, 2011 to December, 2013 in Gyeongsang National University Hospital. We enrolled total 34 patients diagnosed as AKA confirmed by clinical manifestations and various laboratory findings.

Results: The mean age was 50.7 years old and male patients were dominant (85.3%). Initial mean arterial pH was 6.92 and anion gap was 39.4.The mean logistic organ dysfunction system (LODS) score was 6.8. Probability of mortality based on LODS score was 38.8% and actually fourteen patients (41.2%) among them was dead. Prevalence of acute kidney injury (AKI) as per RIFLE criteria was 88.2% including risk (23.3%), injury (30.0%), and failure (46.7%). Twelve patients (32.3%) received hemodialysis. There were no differences in age, arterial pH, anion gap, bicarbonate level, lactate level, and occurrence and severity of AKI between survival and non-survival group. However, total LODS score was significantly high in non-survival group, compared with survival group (5.3 versus 9.0, p=0.014). Prothrombin activity, serum platelet number, and albumin level were significantly high in survival group (64.4% versus 42.6%, 209.9 versus 108.4 $x10^3/mm^3$, 3.6 versus 3.1 g/dL, p=0.001, p=0.004, p=0.016, respectively). There was a significant correlation between LODS score and the following parameters: arterial pH (r= .563, p=0.001), albumin level (r= .396, p=0.020), and PT activity (r= .558, p=0.001).

Conclusions: High mortality was found on patients with AKA and LODS score well reflected the prognosis of patients of AKA. Clinician might just as well to use LODS score for predicting the prognosis of AKA patients.

SA-PO150

Preoperative Potassium Disorder and Perioperative Complications Pradeep Arora,[1,2] Prateek Shukla,[4] Leili Pourafkari,[4] Rajiv Ranjan,[1,2] Poorva Bindal,[4] Nader Nader.[3,4] *[1]Medicine, SUNY at Buffalo, Buffalo, NY; [2]Medicine, VAMC, Buffalo, NY; [3]Anesthesiology, VAMC, Buffalo, NY; [4]Anesthesiology, SUNY at Buffalo, Buffalo, NY.*

Background: Potassium disorders have been linked to increased morbidity and mortality in a variety of medical conditions. However, the association of preoperative serum potassium (K) level with postoperative outcome has not been studied. We aimed to study whether preoperative hypokalemia (<4 mEq /l) or hyperkalemia (.>5.5 mEq /l) compared to normal K (4-5.5 mEq/l) were associate with increased 30 days mortality and adverse cardiac outcome (MACE).

Methods: We conducted a cohort study using a prospective database of patients undergoing surgical procedures since 2000in the VA Western New York Healthcare System which are in part reported to the National Surgical Quality Improvement Program (NSQIP). We used multivariate logistic regression to estimate the risk of MACE within 30 days of surgery.

Results: Study included total of 10,861 patients who underwent surgery,between 1998-2013. The differences in baseline characteristics of patients in 3 groups, Group 1- Normal K (4-5.5 mEq/l), group 2 Hypokalemia and group 3 hyperkalemia are shown in Table 1.

	Hypokalemia (n=6914)	Normokalemia (n= 3635)	Hyperkalemia (n=312)
Age	66.3±12.1	65.8±12.6	69.3±10.9
Body Mass Index	28.2±7.4	28.7±6.9	27.8±7.2
Serum Creatinine (mg/dl)	1.35±1.23	1.29±1.09	2.83±2.97
Hematocrit	38.1±6.4	39.5±5.8	35.4±6.6
Serum Sodium (mEq/l)	138±3.6	138.8±3.0	138.2±3.7
Anesthesia Time (min)	185±107	150±79	150±92
Duration of Surgery (Min)	140±107	105±79	105±92
Preopertaive Probability of Death	0.046±0.124	0.022±0.124	0.61±0.123
Probability of Complications	0.172±0.157	0.104±0.092	0.169±0.154
Postop Creatinine	1.65±1.65	1.37±1.20	3.38±3.23
MACE (%)	10	3.3	18.6
30 Day Mortality (%)	5	2.1	16

Multivariate logistic regression analysis revealed that compared to group 1, group 2and group 3 both had increased odds of MACE. (1.34 (1.05-1.87) for hypokalemia and 1.18 (1.12-1.36) for hyperkalemia. Adjusted linear regression analysis showed that decrease of K by 1mEq/l from 5.5 increases MACE by 7%.

Conclusions: Preoperative low and high K are associated with increased risk of MACE at 30 days.

SA-PO151

Overview of Interventions and Outcomes in Hospitalized Patients with Hyperkalemia

Saif A. Muhsin,[1] Patricia M. Myers-Gurevitch,[1] Jeffrey I. Silberzweig.[1,2] *[1]Dept of Medicine, NewYork-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY; [2]The Rogosin Inst, New York, NY.*

Background: Hyperkalemia is a frequent problem in patients who are admitted to the emergency room and the medical floors, especially in patients with kidney disease. The evaluation for effects of hyperkalemia as well as the interventions performed to treat it are sometimes based on individual judgement rather than a standardized protocol. Some medications given to patients with hyperkalemia might not be warranted and can lead to adverse effects.

Methods: Electronic charts for patients who presented to our hospital from the period between January 1, 2012 to December 31, 2013 were reviewed. Patients with serum potassium levels above 6 were identified. The charts were reviewed for symptoms, ECG findings, interventions performed, repeat serum potassium level, repeat ECG findings, and clinical outcomes.

Results: In our population, the average serum potassium level was 6.5. An ECG was obtained in 70% of the cases; 28% had findings consistent with hyperkalemia (peaked T waves). 40% of patients received intravenous calcium gluconate and 60% received hemodialysis. There was a 20% mortality among this group of patients. 20% of patients were on an ACE-i or an ARB. In our population, there was no correlation between the degree of hyperkalemia and ECG findings, symptoms or outcomes.

Conclusions: Evaluation and management of hyperkalemia varies greatly in our institution even among patients with similar potassium values and similar underlying medical conditions. Given our inability to predict risks from symptoms or objective data, the high mortality rate and the risk of complications from the treatments provided to these patients, we plan to institute a protocol for management of hyperkalemia to try to improve patient outcomes.

SA-PO152

Once Daily ZS-9 for Treatment of Hyperkalemia: Achievement and Maintenance of Normokalemia in Black Patients in a Phase 3, Multicenter, Randomized, Double-Blind, Placebo-Controlled Trial

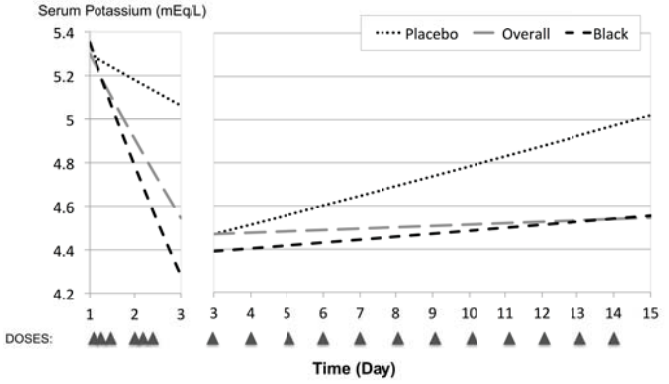
Mohamed A. El-Shahawy,[1] Henrik S. Rasmussen,[2] Philip T. Lavin,[3] Alex Yang,[4] Wajeh Y. Qunibi.[5] *[1]Academic Medical Research Inst, Los Angeles, CA; [2]ZS Pharma, Inc., Coppell, TX; [3]Boston Biostatistics Research Foundation, Framingham, MA; [4]Xelay Acumen, Inc., Belmont, CA.*

Background: Compared with other races, black patients (pts) have a lower incidence of hyperkalemia (HK) but derive less clinical benefit from RAAS therapies, which are limited by HK (Vardeny 2013). Control of HK facilitates use of cardio- and renoprotective RAASi. ZS-9 is a nonabsorbed cation exchanger that traps K^+ in the gut. A subgroup analysis was conducted in black pts from a large Phase 3 trial of ZS-9 for HK.

Methods: Pts (N=753) with K^+ 5.0-6.5 mEq/L were randomized (1:1:1:1:1) to ZS-9 (1.25, 2.5, 5 or 10g) or placebo (PBO) orally 3× daily for 48hr (acute phase). Pts with K^+ 3.5-5.0 mEq/L (n=542) were re-randomized 1:1 to the same acute dose of ZS-9 or PBO 1× daily on Days 3-15 (extended phase). RAASi was maintained. Results from black pts in the 10g ZS-9 dose group are presented.

Results: Of 753 pts, 87 (11.6%) were black; 36 were in the 10g dose group (n=17 PBO; n=19 ZS-9). Mean baseline (BL) K^+ was 5.4 mEq/L. At 48h, mean K^+ declined to 4.4 mEq/L for ZS-9, compared with 5.2 mEq/L for PBO. In the extended phase, mean BL K^+ was similar between the 10g ZS-9 black subgroup (n=8, 4.4 mEq/L) and the overall 10g ZS-9 and PBO groups (4.5 mEq/L for each; Figure). Mean K^+ was maintained through Day 15 in black pts on 10g ZS-9 (4.6 mEq/L), similar to the overall 10g group, whereas mean K^+ increased with PBO (5.0 mEq/L).

Figure. Phase 3 Mean K^+ (Acute, Extended Treatment) – Placebo (n=158) vs. 10g ZS-9 (n=143) vs. 10g ZS-9 Black subgroup (n=8)



Conclusions: Efficacy and safety of ZS-9 in black pts were similar to the overall population. Hence, by achieving and maintaining normokalemia, ZS-9 may allow use of cardio- and renoprotective drugs in black pts with HK.

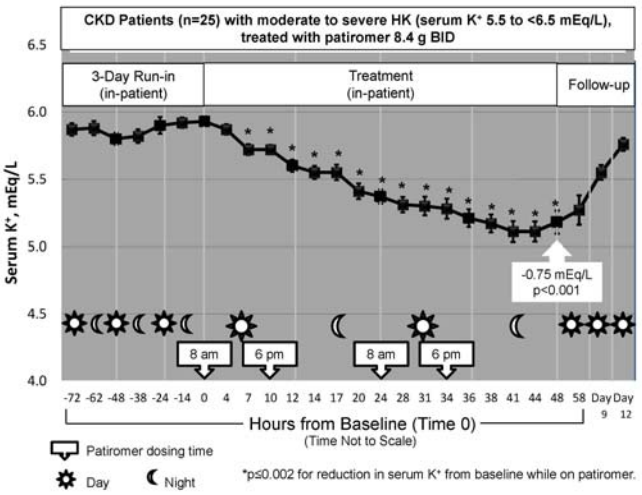
Patiromer Induced a Rapid Onset of Action and Sustained K^+ Lowering throughout the Dosing Period in CKD Patients with Hyperkalemia

David A. Bushinsky,[1] George L. Bakris,[2] Gordon Williams,[3] Bertram Pitt,[4] Martha Mayo,[5] Dahlia Garza,[5] Yuri Stasiv,[5] Elizabeth Li,[6] Lance Berman.[5] *[1]Univ of Rochester, Rochester, NY; [2]Univ of Chicago, Chicago, IL; [3]Harvard Medical School, Cambridge, MA; [4]Univ of Michigan, Ann Arbor, MI; [5]Relypsa, Redwood City, CA; [6]PharmaStat, Newark, CA.*

Background: Patients (pts) with CKD on RAAS inhibitors (RAASi) have a high risk of hyperkalemia (HK), which increases mortality and can lead to RAASi dose reduction/discontinuation. Patiromer, a novel, nonabsorbed metal-free polymer with high K^+ binding capacity and good GI tolerability, has previously been shown to normalize serum K^+ in CKD pts with HK on RAASi. In this study, we determined the onset-of-action of patiromer in CKD pts with HK taking ≥1 RAASi.

Methods: After a 3-day controlled diet (K^+ intake, 60 mEq/d) pts with serum K^+ from 5.5 to less than 6.5 mEq/L received patiromer 8.4 g/dose with AM/PM meals for a total of 4 doses. Serum K^+ was assessed: at baseline (0 hr), 4 hr post-dose, then every 2-4 hr to 48 hr, and at Day 9 and 12.

Results: From a mean baseline serum K^+ of 5.93 mEq/L, a numerical reduction in mean serum K^+ occurred 4 hr after the 1st dose, with a significant reduction (p=0.002) at the next assessment (7 hr after 1st dose). Significant reductions occurred at all subsequent assessments through 48 hr (p<0.001; Figure). Mean serum K^+ <5.5 mEq/L was achieved within 20 hr (p<0.001). At 48 hr (14 hr after last dose), the mean reduction was -0.75 mEq/L (p<0.001). There was no rebound in mean K^+ levels overnight.



Patiromer was well tolerated, with no serious AEs and none leading to withdrawal. The most common AE was mild constipation (2 pts [8%]). No hypokalemia (serum K^+ <3.5 mEq/L) was observed.

Conclusions: Patiromer induced an early and sustained reduction in serum K^+ with no nighttime rebound and was well tolerated in CKD pts with HK on RAASi.

Efficacy and Safety of Phosphate Binders for Hyperphosphatemia in Maintenance Hemodialysis Patients: A Systematic Review and Bayesian Network Meta-Analysis

Yan Jiang, Jingyi Zhou, Xishao Xie, Jianghua Chen. *Kidney Center, The 1st Affiliated Hospital of Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Hyperphosphatemia is one of the most common complications of end-stage renal disease, which can cause secondary hyperparathyroidism, bone diseases, and cardiovascular calcification. Phosphate binders are widely used to control serum phosphorus levels in ESRD patients. Currently, calcium carbonate, calcium acetate, sevelamer, and lanthanum carbonate are four popular phosphate binders. The objective of this study is to evaluate the efficacy and safety of these four different phosphate binders for the treatment of hyperphosphatemia in ESRD patients.

Methods: Three major database, including Pubmed, ISI Web of Science and Cochrane Central Register of Controlled Trials (CENTRAL), are searched. Bayesian network meta-analysis which combines direct and indirect evidence is used to estimate the relative effects among these five treatments and the probabilities of ranking for each treatment.

Results: Twenty-five trials (3,111 patients) were included in this systemic review. Calcium carbonate, calcium acetate, sevelamer and lanthanum carbonate showed no evident difference in affecting the change of serum phosphorus, Ca×P and parathyroid hormone levels. In contrast to calcium carbonate and calcium acetate, sevelamer and lanthanum carbonate had no significant influence on the change of serum calcium. Compared with calcium carbonate and calcium acetate, the incidence of hypercalcemia is much lower

in treatments using sevelamer or lanthanum carbonate. Existing data are insufficient to conduct a network meta-analysis of the effects of these four phosphate binders on mortality or other patient-level outcomes.

Conclusions: Non-calcareous phosphate binders (lanthanum carbonate and sevelamer) are effective and riskless in treating hyperphosphatemia patients in hemodialysis. Compared with the calcareous phosphate binders, lanthanum carbonate and sevelamer can reduce the incidence of hypercalcium. Additional large randomized, double blinded clinical trials are still required to investigate the effects of different phosphate binders on mortality or other patient-level outcomes.

SA-PO155

Magnesium Lactate in the Treatment of Gitelman Syndrome: Patient Reported Outcomes Caroline M. Robinson, Fiona E. Karet. *Medical Genetics, Univ of Cambridge, Cambridge, United Kingdom.*

Background: Gitelman Syndrome (GS) is an inherited renal electrolyte wasting disorder characterised by hypomagnesemia and hypokalemic alkalosis. The need for magnesium (Mg) and potassium replacement is lifelong and dose requirements may be very high. Oral Mg preparations are often poorly tolerated due to gastro-intestinal side effects. Few studies have assessed efficacy or tolerability of different Mg compounds, either in healthy volunteers or patients with renal disorders. In an effort to improve quality of life for our GS patients, we have trialled use of slow release Mg Lactate (SRMgL).

Methods: Using a purpose-designed questionnaire, we evaluated the experiences of 26 patients with genetically proven GS, whose usual Mg formulation (Mg Glycerophosphate n=19; Mg Oxide n=1; Mg Chloride ± Glycinate or Aspartate n=3) was replaced with SRMgL or who commenced it de novo (n=3).

Results: In the majority, serum Mg levels were reported as improved. Maximal SRMgL doses ranged from 14-126 mEq (2-18 tablets)/day. Median dosage time was 15 months (range 4-40), excluding 3 patients who discontinued it immediately due to difficulty swallowing the tablets. Tablet swallowing was judged more difficult by 8 patients. Overall, 15 patients (65%, n=23) reported an improvement in symptoms since commencing SRMgL, with 7 (30%) reporting no change and 1 (4%) reporting some worsening. None perceived significant worsening. Compared with previous replacement regimens, their reported side-effect profile was lessened or had resolved in 11, similar in 7 and worse in 2. Laxative effect was the principal problem reported with all Mg formulations: for SRMgL this was mild-moderate in 8 patients (35%), more severe in 3 (13%) but absent in over half. Gastrointestinal loss of Mg is counterproductive and dose reduction was sufficient to improve tolerability in the 'severe' group, with all tolerating 2-12 tablets/day (median 6). Other reported side-effects were stomach cramp (n=3), increased thirst (n=1) and insomnia (n=1).

Conclusions: Thus in terms of patient experience, SRMgL is useful for treating hypomagnesemia and is particularly appropriate for those with GS where large doses of Mg may be required to maintain adequate serum Mg levels.

Adolescent Alcohol Use and the Development of Hypertension in Early Adulthood Sarah A. Twichell,[1] Alison Field,[1,3,4] Alan Flint,[3,4] John P. Forman.[2,4] *[1]Medicine, Boston Children's Hospital, Boston, MA; [2]Renal Div, Brigham and Women's Hospital, Boston, MA; [3]Epidemiology, Harvard School of Public Health, Boston, MA; [4]Channing Div of Network Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: While there is extensive literature regarding adult alcohol use and hypertension, little is known about the associations of alcohol use during adolescence and hypertension. This study evaluated associations between pattern and quantity of adolescent and young adult alcohol use and the development of hypertension in early adulthood.

Methods: We analyzed data from the Growing Up Today Study (GUTS), a prospective cohort study of children aged 8-14 years in 1996 and followed with detailed surveys every 1-2 years. We assessed associations of pattern of alcohol use, quantity of alcohol use, and age at alcohol use initiation with the development of hypertension among the 8,605 participants who completed the 2010 survey.

Results: In young men, frequent binge drinking over the past year was associated with a significantly increased odds of hypertension after adjusting for potential confounders (OR 1.70, 95% CI 1.03-2.78). However, there was no significant association between binge drinking during adolescence or quantity of alcohol use and hypertension in early adulthood among males. In young women, binge drinking was not associated with hypertension. However, light (OR 0.55, 95% CI 0.35-0.88) and moderate (OR 0.38, 95% CI 0.19-0.78) alcohol use in young adult females was associated with a significantly reduced odds of hypertension. There was no significant association between age at alcohol use initiation and the development of hypertension in either gender.

Conclusions: Alcohol use patterns in adolescence were not associated with the development of hypertension in early adulthood. However binge drinking in early adulthood was associated with an increased odds of hypertension in males; whereas, low to moderate alcohol use in early adulthood was associated with a decreased odds of hypertension in females. Further study of alcohol use in early adulthood, particularly among boys who are frequent binge drinkers, may provide insights into the early development of hypertension.

Initial Screening by Ambulatory Blood Pressure Monitoring Avoids Unnecessary Testing in Children with White Coat Hypertension Peter C. Shorter,[1] M. Khurram Faizan.[2] *[1]Dept of Medicine, Rhode Island Hospital; [2]Dept of Pediatrics, Hasbro Children's Hospital, Providence, RI.*

Background: Ambulatory Blood Pressure Monitoring (ABPM) is a validated method for assessing blood pressure in pediatrics. Children with elevated clinic BP (CBP) often undergo a workup for secondary hypertension (HTN) before a diagnosis of true HTN is confirmed. This leads to unnecessary costs as well as patient and parental anxiety. Pediatric study models using ABPM in the initial evaluation of HTN suggest significant cost savings.

Methods: Retrospective cohort study on children referred by their pediatrician due to elevated CBPs who underwent an ABPM for initial screening. Prehypertension (PH) (90th percentile) and HTN (95th percentile) was defined using age and height criteria outlined in the 4th report (2004). Children with elevated CBP but normal ABPM studies were defined as having White Coat Hypertension (WCH). CBP, ABPM measurements, and diagnostic testing for secondary HTN ordered by the referrer were obtained from patients charts. Reimbursement rates of the common tests for evaluation of HTN including metabolic, lipid, and thyroid panels, EKG, renal ultrasound, pediatric echocardiogram, plasma renin activity and plasma free metanephrines were obtained from the 2013 Medicaid Fee Schedule.

Results: 391 children were referred to the Nephrology Clinic for evaluation of HTN from 2007-2013. 314 children met criteria. 259 (82.4%) were males. Mean age was 14.2 yrs. An ABPM study showed WCH, HTN and PH in 206 (65.6%), 86 (27.4%) and 22 (7%) children, respectively. Of the 206 children confirmed to have WCH, 116 (37%) had diagnostic testing to evaluate for secondary HTN prior to the ABPM study. 302 tests were ordered (2.6 tests/pt) for a total cost of nearly $11,500, with an average of nearly $100 spent per patient with WCH.

Conclusions: Our data show that about a third of children with WCH undergo unnecessary testing and procedures. Postponement of a diagnostic evaluation until after the presence of HTN is confirmed with an ABPM study, may reduce both cost and anxiety. ABPM serves as a cost-effective method not only to streamline the clinical evaluation, but also to minimize needless and expensive testing in children with WCH.

SA-PO158

Risk Factors for Hypertension in Obese Children Emine Sonmez,[1] Salim Caliskan,[2] Nur Canpolat,[2] Lale Sever.[2] *[1]Pediatrics, Istanbul Univ Cerrahpasa Medical Faculty, Istanbul, Turkey; [2]Pediatric Nephrology, Istanbul Univ Cerrahpasa Medical Faculty, Istanbul, Turkey.*

Background: In the present study, we aim to determine i) the risk factors for hypertension in obese children, and ii) its association with artherosclerosis.

Methods: A cross-sectional study was carried out in 60 obese children aged between 10-18 years and 20 age-matched healthy children. Ambulatory blood pressure monitoring was performed in the controls and obese children. Obese children were classified into two clinical groups. Twenty seven of them who had 24h mean arterial pressure >95th percentile and/or who were using antihypertensive drugs were described as hypertensive (HT-obese group), and the remaining 33 were described as normotensive (non HT-obese group). Antropometric parameters [height, weight, body mass index, waist circumference, fat mass (by multi-frequency bioelectrical impedance analysis)], biochemical markers (serum glucose, insulin, HbA1c, LDL, HDL, total cholesterol and triglyceride), inflammation markers [serum high sensitive C reactive protein (hsCRP), interleukin 6 (IL-6), tumor necrosis factor-α (TNF-α), and adiponectin] and the carotid artery intima media thickness (cIMT) were measured in the study population.

Results: In the HT-obese group, waist circumference–SDS, fat mass-z score and serum IL-6 levels were significantly higher as compared to non HT-obese group (p=0.007, p=0.005 and p=0.003, respectively). Logistic regression analysis showed that IL-6 was the only predictor of hypertension in the obese children. In the HT-obese group, cIMT-SDS was significantly higher than the healthy controls (p=0.021); however, there was no significant difference in cIMT-SDS between the HT-obese and the non HT-obese groups.

Conclusions: Our results suggested that both central obesity and increased fat mass seem to be the risk factors for hypertension;however, inflammation appears to play a key role in obesity-associated hypertension. In addition, hypertension itself may be a risk factor for arteriosclerosis in this population.

SA-PO159

The Relationship Between Adiposity and Left Ventricular Mass in Children with Hypertension Tammy M. Brady,[1] Barbara A. Fivush,[1] Kathryn W. Holmes,[2] Edgar R. Miller.[1] *[1]Johns Hopkins Medical Institutions, Baltimore, MD; [2]Oregon Health and Science Univ, Portland, OR.*

Background: Left ventricular hypertrophy (LVH) is highly prevalent at diagnosis of hypertension in children, yet degree of blood pressure (BP) elevation does not predict its presence. We hypothesized that obesity and obesity-related risk factors are associated with left ventricular mass index (LVMI) in hypertensive children and that the relationship between adiposity and LVMI is mediated by both BP dependent and independent pathways.

Methods: We conducted a longitudinal study of 49 treated hypertensive children 3-19 yrs for 1 yr. Student's t-tests, Fisher exact tests and Wilcoxon Rank sum were used to compare those with and without LVH as appropriate. Multivariable regression analyses were used to investigate the relationship of body mass index (BMI) z-score with ΔLVMI and to determine which cardiovascular (CV) risk factors mediated this relationship.

Results: At baseline, 51% were overweight/obese and 41% had LVH. Those with LVH had greater BMI z-score than those without LVH, but this was not associated with 24-hr

ambulatory BPs. Over time, measures of adiposity increased while BP was unchanged. Children overweight/obese at both study visits had the greatest increase in LVMI over time: mean change=6.4 g/m$^{2.7}$ [95% confidence interval (CI) 2.4, 10.5] versus 0.95 g/m$^{2.7}$ (95% CI -3.2, 5.1) among children of healthy weight at each visit (p=0.056). Overweight/obese children with and without baseline LVH had a larger increase in LVMI compared to healthy weight children. Only healthy weight children with LVH had LVMI decrease over time. Baseline BMI z-score was associated with ΔLVMI (β 4.08, 95% CI 1.54, 6.61, p=0.002) after adjusting for age, sex, race, and baseline LVMI. After sequential adjustment for postulated mediating pathways between BMI z-score and ΔLVMI, only pulse pressure and serum aldosterone partially mediated this relationship.

Conclusions: Hypertensive children demonstrate a high BMI z-score which was the greatest risk factor for LVH and increasing LVMI over time. This suggests that greater emphasis on overweight/obesity prevention and treatment should be made among hypertensive children.

SA-PO160

Neonatal Hypertension and Antenatal Exposure to Non-Steroidal Anti-Inflammatory Drugs Mounira Habli,[4] Tammy M. Brady,[1] M. A. Eschenbacher,[2] Zahidee Rodriguez,[3] Emily Defranco,[3] Beena D. Kamath-Rayne.[3] *[1]Pediatric Nephrology, Johns Hopkins Univ School of Medicine, Balitmore, MD; [2]TriHealth Hatton Research Inst, Good Samaritan Hospital, Cincinnati, OH; [3]Perinatal Inst, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]Maternal-Fetal Medicine, TriHealth, Cincinnati, OH.*

Background: Non-steroidal anti-inflammatory drugs (NSAIDS) are known to affect nephrogenesis, yet little is known about the association between NSAIDs used antenatally for tocolysis and neonatal hypertension (HTN).

Methods: We performed a case/control study, identifying premature infants with HTN from a single Level III NICU from 2007-2012. HTN cases were defined as neonates ≥35 weeks corrected gestational age (GA), with systolic blood pressure >100 mm Hg on 3 consecutive days. Controls were randomly chosen from a list of births with similar GA, plurality, and delivery dates. Maternal/neonatal charts of 40 cases and 134 controls were reviewed. Groups were compared for differences in NSAID exposure and maternal/neonatal factors.

Results: Maternal demographic/medical factors were similar between groups. Infants with HTN were slightly more premature (27.7 versus 28.9 weeks), had higher rates of bronchopulmonary dysplasia, umbilical artery catheter placement, and longer hospital stay (all p<0.05). Infants with HTN had higher rates of antenatal exposure to indomethacin (40% versus 24.5%) and sulindac (25% versus 17%), but neither reached statistical significance. Infants without HTN had higher rates of exposure to calcium channel blockers (CCB, 17% versus 24%, p<0.01). In multivariable regression, days of indomethacin exposure was associated with greater odds of neonatal HTN (OR 1.17 [1.00-1.38], p=0.055), after adjustment for days of sulindac exposure, doses of antenatal steroids, CCB exposure, maternal race, infant sex, and GA at birth.

Conclusions: Our data suggest an association of antenatal NSAIDs use with neonatal HTN. Our study was not powered to fully examine the effects of NSAIDs, but longer exposure time may play a role. These findings are worth further investigation in larger studies to assess short and long term neonatal effects of antenatal NSAIDs.

SA-PO161

Risk Factors for Increased Blood Pressure among Aboriginal Children and Adolescents Siah Kim,[1,2] Petra Macaskill,[2] Elisabeth M. Hodson,[1,2] Jennifer Daylight,[1] Rita Angeline Williams,[1] Nicola Vukasin,[1] Rachael Kearns,[1] David M. Lyle,[3] Jonathan C. Craig.[1,2] *[1]Centre for Kidney Research, The Children's Hospital at Westmead, Westmead, NSW, Australia; [2]School of Public Health, Univ of Sydney, Camperdown, NSW, Australia; [3]Dept of Rural Health, Univ of Sydney, Camperdown, NSW, Australia.*

Background: Hypertension is a risk factor for adult chronic kidney disease (CKD). Aboriginal Australian children have a higher prevalence of overweight/obesity, a known risk factor for hypertension in adolescence. We aimed to determine relative changes in blood pressure between Aboriginal and non-Aboriginal children as move into young adulthood.

Methods: A prospective cohort of Aboriginal and non-Aboriginal children commenced in 2002 across 213 high schools across urban, regional and remote NSW. Blood pressure and BMI were measured every 2 years. Systolic blood pressure (SBP) and diastolic blood pressure (DBP) were standardized for sex, age and height. We fitted a series of mixed linear regression models adjusting for age, sex, BMI SDS, Aboriginality, birth weight and socioeconomic status (SES).

Results: 3418 (1949 Aboriginal) participants were screened over a total of 11, 387 participant years follow up. At baseline, the prevalence of systolic hypertension was 7.2% (mean age 11 yrs) which increased to 15.4% at eight years follow up. The prevalence of diastolic hypertension remained at 3% from baseline to eight years follow up. Multivariate analysis showed mean SBP SDS increased with age (0.06 SDS per yr, P<0.01) but there was no significant difference between Aboriginal and non-Aboriginal children. Low birth weight was significantly associated with an increase in SBP (0.12 SDS, P=0.01) as was increasing BMI (0.31 SDS per BMI SDS, P<0.01). Lower SES was associated with increasing SBP (<25th quartile: 0.20 SDS, P <0.01). DBP also increased with age (0.03 SDS per yr, P<0.01) and BMI (0.14 SDS per BMI SDS, P<0.01), but lower SES was associated with a lower DBP (<25th quartile: -0.12 SDS, P<0.01).

Conclusions: Increasing BMI remains the greatest modifiable risk factor for SBP and DBP, with prevention of low birth weight and improving SES also important to reduce cardiovascular risk in children and adolescents.

Funding: Government Support - Non-U.S.

SA-PO162

Fat Free Mass, Serum Uric Acid and eGFR as Determinants of BP Levels in an Early Adulthood Lean Cohort: A Cross Sectional Survey to Plan Lifestyle Changes Interventions Antonino Sidoti,[1] Santi Nigrelli,[2] Alberto Rosati,[3] Raffaele Caprioli,[4] Luigi Tonelli,[5] Roberto Bigazzi.[6] *[1]Nephrology, Ospedale Alta Val D'Elsa, Poggibonsi, Siena, Italy; [2]Nephrology, Ospedale dell'Annunziata, Firenze, Italy; [3]Nephrology, Ospedale San Luca, Lucca, Italy; [4]Nephrology, Azienda Ospedaliera Pisana, Pisa, Italy; [5]Consiglio Sanitario Regionale, Regione Toscana, Firenze, Italy; [6]Nephrology, Spedali Riuniti, Livorno, Italy.*

Background: Actual body weight, serum uric acid(UA) are linked with subsequent hypertension(HTN). In pediatric age UA as HTN causal factor seems not related with renal function.

Methods: 18-21y.o. high school last year students, n=2092, 999 females, BP double oscillometric measurements in two different days, height, weight, waist circumference (Wc) were measured. Fat Free Mass (FFM) was calculated (Janmahasatian 2005). In a subset n=60, 29 females, UA, eGFR -via CKD-EPI- were measured. Pearson per quartiles and cluster analysis in n=2092 for FFM, BMI Wc, linear regression (LinReg) with SBP -dependent variable- were performed and in n=60 subset also for UA.

Results: Overweight 11%, obesity 1.1 %, HTN 0.7%, high-normal BP 21.9%, SBP 124.1±12 DBP 70.7±8 BMI 21.8±2.8 Wc 79.6±9cm FFM 48.5±11Kg UA 4.55±0.97mg/dl eGFR 113±13. No DBP relationships. No SBP sex clustering with BMI or Wc. SBP-FFM sex centroids were: females 116-39, males 131-57. SBP-FFM mantained a relationship 1st thru 4thquartile, respectively: 0.223, 0.135, 0.125, 0.206, SBP-BMI and SBP-Wc instead only on4thquartile: 0.162 and 0.142, p<.001. LinReg n=2092, R=0.492, partial r-β: FFM 0.373-0.478, BMI 0.095-0.132, Wc -0.077 and -0.113, p<.001 for all three. LinReg n=60: multiple R=0.655, partial r-β: FFM 0.139-0.161 NS, BMI 0.114-0.106 NS, UA 0.456-0.503 p<.001: males multiple R=0.614, partial r-β 0.530-0.544 p<.001, in females FFM and UA NS, BMI 0.316-0.492 p<0.098. eGFR-UA relationship was -0.55 females, -0.42 males.

Conclusions: In an early adulthood lean cohort, FFM best describes relationship between body weight and SBP in both sexes. UA is related with SBP independently from FFM, BMI and Wc particularly in males. Precocious dietary interventions aiming at reducing UA could be of help in preventing HTN and also in preserving renal function.

SA-PO163

Effects of Catheter-Based Renal Denervation on Ambulatory Blood Pressure, Renal Function and Albuminuria Daniel Greinert, Alexander Plehn, Matthias Girndt, Silke Markau. *Martin Luther Univ (MLU); Dep. of Internal Medicine, Nephrology, Halle (Saale), Germany; MLU; Dep. of Internal Medicine, Cardiology, Halle (Saale), Germany; MLU; Dep. of Internal Medicine, Nephrology, Halle (Saale), Germany; MLU; Dep. of Internal Medicine, Nephrology, Halle (Saale), Germany.*

Background: Catheter-based renal denervation (CBRD) is an invasive procedure, developed to treat resistant hypertension. Few studies focus on renal outcome. Patients with diabetes (DM) and impaired renal function (IRF) were neglected or excluded from the majority of the studies so far. Aim of this study was to emphasize on these patients, evaluate the impact of CBRD on ambulatory blood pressure measurement (ABPM) and renal parameters.

Methods: All adult patients with therapy resistant hypertension undergoing CBRD (Symplicity Flex Catheter, Medtronic Inc.) from Jan. 2011-Mar. 2013 and completing the 6 month follow up were analysed concerning their ABPM, renal function and albuminuria. Patients with secondary hypertension causes were excluded. Additionally evaluated were two subgroups of patients with DM and IRF (cystatin c levels >1.11 mg/l).

Results: All patients and patients with IRF showed no significant effects regarding ABPM. A significant decline of ABPM was found in patients with DM. The renal function improved in patients with IRF. Albuminuria was generally reduced, though significantly only in patients with DM.

ABPM (mmHg)	Baseline	6 month	Diff.	P
All patients (AP) n=129	153,6	149.8	3.8	0.08
Diabetes (DM) n=61	155.2	148.7	6.5	0.044
Renal impairement (RI) n=27	155.2	150.3	4,9	0.36
Creatinin (umol/l)				
AP n=134	88.0	83.0	5.0	0,31
DM n=60	88.6	82.3	6.3	0.24
RI n=29	123.1	84.7	44.4	0.035
Albuminuria (mg/d)				
AP n=91	197.5	146.6	50,9	0.44
DM n=48	307.5	128.4	179.1	0.038
RI n=20	523.9	148.6	375.3	0.11

Conclusions: Only patients with DM showed significant decline in ABPM and albuminuria. IRF seems to improve over time following CBRD. In conclusion CBRD is a controversially discussed procedure with varying published results. Further high quality studies are necessary to find out what the benefits of CBRD are, not only regarding blood pressure, but determining predictors of blood pressure response and impact on target organ damage.

SA-PO164

Effect of Renal Denervation in Patients with Multiple Renal Arteries Margreet F. Sanders,[1] Eva Vink,[1] Willemien Verloop,[2] Peter J. Blankestijn.[1] *[1]Nephrology and Hypertension, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]Cardiology, Univ Medical Center Utrecht, Utrecht.*

Background: During the diagnostic work-up of patients with treatment resistant hypertension we found in approximately one third of patients multiple renal arteries. These patients are often excluded from renal denervation (RDN) conform guidelines. The aim of this study was to investigate the relation between presence of multiple arteries and blood pressure (BP)-lowering effect of renal denervation. Moreover the role of renin angiotensin aldosterone system (RAAS) in the pathophysiology of hypertension in patients with multiple arteries is investigated.

Methods: Hundred-twenty-six patients referred for RDN who underwent non-invasive imaging of the renal arteries before treatment were included in present analysis.

Results: Thirty-four percent had multiple arteries. Sixty-nine patients underwent RDN. Office BP significantly changed from 195(±26)/ 106(±14) mmHg to 165(±24)/ 95(±14) mmHg (P<0.001). BP-reduction in patients with multiple arteries which were all treated was comparable to patients with solitary arteries. However patients with multiple arteries which were not all treated showed a trend towards a less pronounced effect of RDN (ß:12.2, P=0.09). Renal function at 6 months did not differ from baseline in all subgroups. In a multivariable model adjusting for kidney function, PAC determined in standing position was significantly higher in patients with multiple renal arteries compared to patients with single arteries (ß:0.293, 95%CI: 0.020-0.565, p=0.04).

Conclusions: Current analysis suggests that BP reduction may be less pronounced in patients with multiple renal arteries of whom not all arteries were treated with renal denervation. Patients with multiple renal arteries have higher levels of aldosterone, this can be involved in the pathogenesis of hypertension in these patients.

SA-PO165

The Effect of Renal Denervation on Kidney Oxygenation as Determined by Blood Oxygen Level Dependent MRI in Patients with Hypertension Eva Vink,[1] Anneloes De Boer,[1] Willemien Verloop,[2] Wilko Spiering,[3] Michiel Voskuil,[2] Evert-Jan Vonken,[4] Hans Hoogduin,[4] Michiel Bots,[5] Tim Leiner,[4] Peter J. Blankestijn.[1] *[1]Nephrology and Hypertension, UMC Utrecht, Netherlands; [2]Cardiology, UMC Utrecht, Netherlands; [3]Vascular Medicine, UMC Utrecht, Netherlands; [4]Radiology, UMC Utrecht, Netherlands; [5]Julius Center for Health Sciences and Primary Care, UMC Utrecht, Netherlands.*

Background: Renal denervation (RDN) is a promising therapy for resistant hypertension. RDN is assumed to decrease sympathetic activity. Consequently, RDN can potentially increase renal oxygenation. Blood oxygen level dependent MRI (BOLD-MRI) provides a non-invasive tool to determine renal oxygenation in humans. The aim of current study was to investigate the effect of RDN on renal oxygenation as determined by BOLD-MRI.

Methods: Patients with resistant hypertension or the inability to follow a stable drug regimen due to unacceptable side effects were included. BOLD-MRI was performed before and 12 months after RDN.

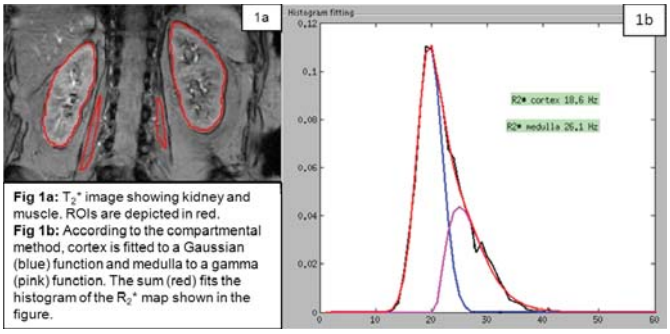

Fig 1a: T_2* image showing kidney and muscle. ROIs are depicted in red. **Fig 1b:** According to the compartmental method, cortex is fitted to a Gaussian (blue) function and medulla to a gamma (pink) function. The sum (red) fits the histogram of the R_2* map shown in the figure.

Results: 54 patients were included, 46 patients (23 males, mean age 57) completed the study. Mean 24-h BP changed from 163(±20)/98(±14) mmHg to 154(±22)/92(±13) mmHg (p=0.001 and p<0.001). eGFR did not change after RDN (77(±18) versus 79(±20) mL/min/1.73m^2 p=0.13). RDN did not affect renal oxygenation (1.5T: cortical R2*: 12.5(±0.9) versus 12.5(±0.9)p=0.94, medullary R2*: 19.6(±1.7) versus 19.3(1.4) p=0.40, 3T: cortical R2*: 18.1(±0.8) versus 17.8(±1.2) p=0.47, medullary R2*: 27.4(±1.9) versus 26.7(±1.8) p=0.19).

Conclusions: RDN does not lead to changes in renal oxygenation one year after RDN as determined by BOLD-MRI.

SA-PO166

The Effect of Renal Denervation on Left Ventricular Hpertrophy Determined by Cardiac Magnetic Resonance Imaging Eva Vink,[1] Willemien Verloop,[2] Wilko Spiering,[3] Evert-Jan Vonken,[4] Tim Leiner,[4] Michiel Bots,[5] Michiel Voskuil,[2] Peter J. Blankestijn.[1] *[1]Nephrology and Hypertension, UMC Utrecht, Netherlands; [2]Cardiology, UMC Utrecht, Netherlands; [3]Vascular Medicine, UMC Utrecht, Netherlands; [4]Radiology, UMC Utrecht, Netherlands; [5]Julius Center for Health Sciences and Primary Care, UMC Utrecht, Netherlands.*

Background: Renal denervation (RDN) is a promising treatment for resistant hypertension. One can hypothesize that as a consequence of decreased sympathetic activation and blood pressure (BP), left ventricular hypertrophy (LVH) will decrease after RDN. The aim of the current study was to investigate the effect of RDN on LVH assessed by cardiac magnetic resonance imaging (cMRI). cMRI has an high accuracy and reproducibility in the evaluation of LV-mass.

Methods: Patients with a SBP ≥160mmHg despite the use of ≥3 antihypertensive drugs or the inability to follow a stable drug regimen due to unacceptable side-effects, meeting in- and exclusion criteria for RDN were included. Patients underwent cMRI before and 12 months after RDN. Body surface area-corrected myocardial mass was quantified by end-diastolic contour tracing on short axis balanced steady state free precession. Left ventricular trabeculae were included in myocardial mass. To assess the effect of RDN on blood pressure (BP), 24-h ambulatory BP measurements at 12 months follow-up were compared to baseline values.

Results: 54 patients were included. Mean age was 58±10 years, 50% was male. One year after RDN, mean ABPM decreased by -7±18 /-5±11 mm Hg (P=0·01/P<0·01). In the patients followed-up in a standardized fashion ABPM decreased by -5±18/-4±12 mm Hg(p=0·11/p=0·09). Mean body surface area indexed left ventricular mass decreased by 3·3±11·5 g/m^2 (corresponding to a 3±11% reduction; P= 0·09).

Conclusions: The current study shows no change in LV-mass, as assessed with cMRI, 12 months after treatment with RDN. However, in patients classified as responder, LV-mass decreases after RDN.

SA-PO167

Activity of Vasocontrictor Systems Is Inversely Related to Renal Oxygenation: A Blood Oxygen Level Dependent MRI Study Eva Vink,[1] Anneloes De Boer,[1] Hans Hoogduin,[2] Michiel Voskuil,[3] Tim Leiner,[2] Michiel Bots,[4] Jaap A. Joles,[1] Peter J. Blankestijn.[1] *[1]Nephrology and Hypertension, UMC Utrecht, Netherlands; [2]Radiology, UMC Utrecht, Netherlands; [3]Cardiology, UMC Utrecht, Netherlands; [4]Julius Center for Health Sciences and Primary Care, UMC Utrecht, Netherlands.*

Background: The renin angiotensin aldosterone system (RAAS) and sympathetic nervous system (SNS) are key factors in the pathophysiology of hypertension. Renal hypoxia is the putative mechanism stimulating both systems. Blood oxygen level dependent MRI (BOLD-MRI) provides a non-invasive tool to determine renal oxygenation in humans. The aim of the current study was to investigate the relation between blood pressure (BP), kidney function and direct and indirect variables of the RAAS, and SNS with renal BOLD-MRI.

Methods: 75 hypertensive patients (38 males) were included. Antihypertensive medication was temporarily stopped. Patients collected urine during 24-hr (sodium, catecholamines), blood samples were taken (creatinine, renin, aldosterone), a captopril challenge test was performed and ambulatory BP was taken.

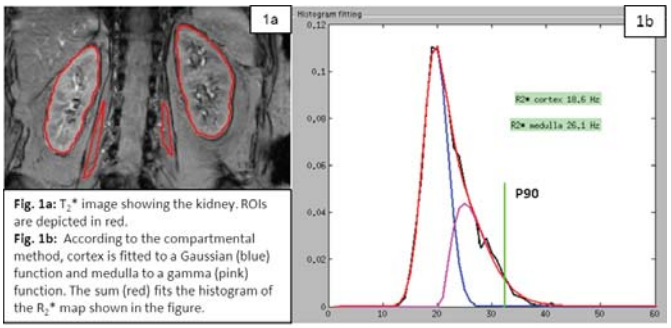

Fig. 1a: T_2* image showing the kidney. ROIs are depicted in red.
Fig. 1b: According to the compartmental method, cortex is fitted to a Gaussian (blue) function and medulla to a gamma (pink) function. The sum (red) fits the histogram of the R_2* map shown in the figure.

Results: Mean age was 58 (±11) years, day-time BP was 167(±19) /102(±16) mmHg, eGFR was 75 (±18) mL/min/1.73m^2. In multivariable regression analysis, renal medullary R2*-values inversely related to eGFR (p=0.02). Moreover the BP-lowering effect of captopril positively related to cortical- (p=0.02) and medullary (p=0.008) R2*-values as well as to P90 (p=0.02).

Conclusions: In patients with hypertension,kidney function as well as direct and indirect variables of the RAAS and SNS relate to renal R2*-values, which can be interpreted as a measure of renal oxygenation.

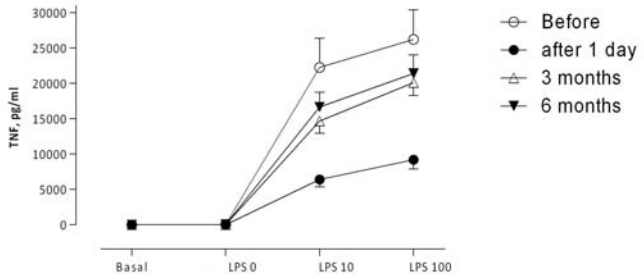
SA-PO168

The Cholinergic Anti-Inflammatory Pathway in Refractory Hypertension Treated with Renal Denervation Marie Hilderman,[1] Abdul Rashid Tony Qureshi,[1] Nils Witt,[2] Björn Anderstam,[1] Annette Bruchfeld.[1] *[1]Renal Medicine, CLINTEC, Karolinska Instt, Stockholm, Sweden; [2]Cardiology, Karolinska Insititutet, Södersjukhuset, Stockholm, Sweden.*

Background: Modulation of renal sympathetic-nerve activity through renal denervation (RDN) has recently been introduced as a treatment for resistant hypertension. By reducing sympathetic tone it may be possible to alter the sympathetic-parasympathetic balance. The autonomic nervous system is partly a regulator of innate immunity via the cholinergic anti-inflammatory pathway (CAP), also referred as the inflammatory reflex which via the vagus nerve inhibits inflammation by an α-7 nicotinic acetylcholine receptor (α7nAChR) mechanism. The aim of this study was to investigate if modulation of renal sympathetic nerve activity could affect CAP and thereby inflammation.

Methods: Ten patients with refractory hypertension (median BP 180/100 mmHg) were analysed for TNF, IL-1 and IL-10 before RDN (Medtronic Inc), 24-h after and at 3 and 6 months follow up. Whole blood samples were stimulated *ex vivo* at each time point with two concentrations of LPS (10 and 100 ng/mL) to induce an inflammatory reaction and TNF, IL-1 and IL-10 were again measured at these concentrations.

Results: Median blood pressure was significantly lower (p=0.03) at 6 months (median BP 162.5/91.5). Levels of **TNF** were significantly lower 24-h after RDN (LPS 0, 10 and 100 ng/mL; p=0.0009, p=0.0009 and p=0.001) (see fig.) **IL-1** (p=0.0001, p=0.002 and p=0.005) whereas **IL-10** levels were significantly higher (p=n.s, p=0.02 and p=0.01). These differences however declined during follow up and were at 6 months similar to baseline.



Conclusions: RDN affects the CAP and cytokine release ex vivo but the effect seems to wane over time. Modulation of parasympathetic nerve activity is an emerging anti-inflammatory treatment but current RDN techniques may not have long-lasting beneficial effects.

SA-PO169

Real Life' Experience of Renal Denervation for Resistant Hypertension From Two NHS Hospitals in Birmingham, UK Mohammed Awais Hameed,[1] Mark R. Pucci,[2] Dr Una Martin,[2] Richard Watkin,[1] Sagar N. Doshi,[2] Jonathan S. Freedman,[1] Peter Riley,[2] Jonathan N. Townend,[2] Lisa J. Tebbit,[1] Louise Beesley,[2] Paul Crowe,[1] Graham W. Lipkin,[2] Indranil Dasgupta.[1] *[1]Heart of England NHS Foundation Trust, Birmingham, West Midlands, United Kingdom; [2]Univ Hospitals Birmingham NHS Foundation Trust, Birmingham, West Midlands, United Kingdom.*

Background: Resistant hypertension is common in the hypertensive population with reported prevalence of 5-30%. Renal denervation has been a promising new treatment option for such patients, however, the recently published SIMPLICITY HTN-3 trial did not meet its primary (change in office systolic BP at 6 months) or secondary (change in mean 24-hour ambulatory systolic BP) efficacy endpoints, but has been shown to be safe.

Methods: We report our experience of renal denervation from combined data of two specialist hypertension clinics in Birmingham. Patients who were identified to have truly resistant hypertension (by careful exclusion of secondary causes and non-adherence) underwent renal denervation. Baseline demographics, clinic BP, ambulatory BP and medications were recorded. Patients were followed up for six months with repeat measurements.

Results: Thirty Three patients have completed the six months follow up. Eighteen were males. The mean age [±SD] was 53.7 [±11.3] years. On average patients were taking 4.40 [±1.79] medications at baseline and 4.30 [±1.66] medications at six months. Mean [±SD] clinic systolic BP at baseline was 184.3 mmHg [±23.6] and mean daytime ambulatory systolic BP was 163.4 mmHg [±18.3]. There was a significant reduction in clinic systolic BP of 13.5 mmHg at six months (95% CI -4.54 to -22.5; p=0.005). There was a statistically non-significant drop in daytime ambulatory systolic BP (11.4 mmHg; 95% CI +4.76 to -27.6; p=0.159). 42% of patients had a clinically significant reduction in clinic BP of 10 mmHg or more (mean 30.2 mmHg; 95% CI -19.6 to -40.9; p<0.001) and 39% had reduction in daytime ambulatory systolic BP of 5 mmHg or more (mean 19.5 mmHg; 95% CI -13.0 to -25.9; p<0.001).

Conclusions: Our 'real life' data suggest that renal denervation does appear to be an effective treatment option for some patients with resistant hypertension, whilst in others it has no effect.

SA-PO170

Estimated 24 Hour Urine Sodium Is Correlated with Blood Pressure in General Population: 2009-2011 Korean National Health and Nutritional Examination Survey Ho Jun Chin,[1] Jieun Oh,[2] Jeonghwan Lee,[3] Eun Jung Kim,[2] Jung-Woo Noh.[4] *[1]Internal Medicine, Seoul National Univ Bundang Hospital, Seongnam, Republic of Korea; [2]Internal Medicine, Hallym Univ, College of Medicine, Kangdong Sacred Heart Hospital, Seoul, Republic of Korea; [3]Internal Medicine, Hallym Univ, College of Medicine, Hangang Sacred Heart Hospital, Seoul, Republic of Korea; [4]Internal Medicine, Hallym Univ, College of Medicine, Kangnam Sacred Heart Hospital, Seoul, Republic of Korea.*

Background: We analyzed population-based data from a nationwide cross-sectional health survey to determine the association of estimated urine sodium excretion over 24-h (24HUNa) with hypertension.

Methods: To investigate the relationship of blood pressure to salt consumption, we analyzed data from 19,476 participants in the 2009-2011 Korean National Health and Nutritional Examination Survey. Urinary sodium excretion over 24-h was estimated from spot urine tests using Tanaka's equation. The study subjects were stratified into hypertensive and normotensive groups.

Results: Hypertensive participants (n=6,552, 33.6%) had higher estimated 24HUNa, 150.4 ± 38.8 mEq/day, than normotensive participants, 140.5 ± 34.6 mEq/day (P < 0.001). The association between 24HUNa and blood-pressure outcomes was not affected by adjustment for other risk factors for hypertension (odds ratio 0.001; 95% confidence interval 0.001 - 0.003; P < 0.001). Differences in 24HUNa between hypertensive and normotensive subjects were significant in the young and middle-aged populations. Although 24HUNa did not differ significantly in elderly subjects (> 65 years old), SBP and DBP of hypertensive persons were significantly higher than those of normotensive persons. Increases in 24HUNa of 100 mEq/day were associated with a 6.1 ± 0.3/2.9 ± 0.2 mmHg increase in systolic/diastolic blood pressure in all participants.This effect was stronger in hypertensive participants (increase of 8.1 ± 0.5/ 3.4 ± 0.3 mmHg) and smaller in normotensive participants (2.9 ± 0.3/ 1.3 ± 0.2 mmHg).

Conclusions: These results support recommendations for low salt intake in Korean population and suggest the importance of moderating sodium intake beginning in the early life.

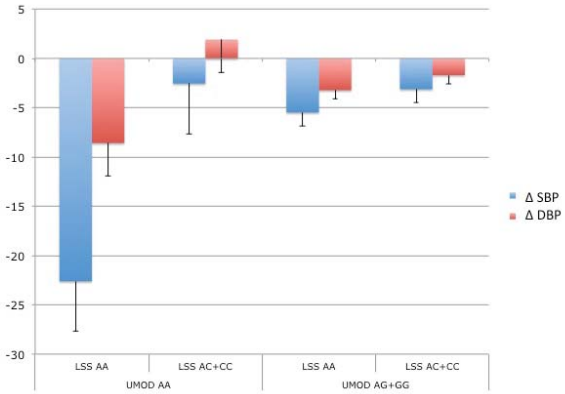
SA-PO171

Genes Involved in Blood Pressure Response to Chronic Low Salt Intake: Identification of a New Pathway Chiara Lanzani,[1] Guido Gatti,[1] Lorena Citterio,[1] Elisabetta Messaggio,[1] Simona Delli Carpini,[1] Chiara Maggioni,[1] Marco Simonini,[1] Nunzia Casamassima,[1] Laura Zagato,[1] Luca Rampoldi,[1] John Hamlyn,[2] Paolo Manunta.[1] *[1]San Raffaele Scientific Institution, Milan, Italy; [2]Univ of Maryland, Baltimore.*

Background: Due to the 'preventive paradox' and to the large inter-individual variation in blood pressure (BP) response to salt reduction, it is not always the case that every individual will ultimately benefit from a moderate reduction in salt intake. A moderate reduction in salt intake reduces BP in most but not all individuals. Recently, the uromodulin (UMOD) gene has been associated with renal damage and hypertension. The present study evaluated the response of Endogenous Ouabain (EO), candidate genes related to its synthesis sterol synthase (LSS), and UMOD polymorphisms in response to a chronic low Na diet.

Methods: 394 naïve hypertensives followed a low Na intake. In the analysis, only compliant patients who reduced urinary sodium at least of 40% of basal value or achieved a urinary sodium less than 100 mmol/day were included.

Results: In the compliant group (170 m, f ~60% of all patients), the reduction of UNa excretion was associated with significant increases in PRA ((β=-0.228, p=0.006) and aldosterone (β=-0.252, p=0.002) as expected. A direct (β=0.213) relationship (p=0.026) between the change in EO and BP was found. When LSS and UMOD gene variants were analyzed together, a significant interaction was detected: those patients homozygous for the AA alleles of both genes displayed a 5-fold greater decline in SBP than patients carrying other allele combinations.



Conclusions: In response to a low salt intake, circulating EO and BP both increased in some patients, and may be linked with adverse outcome. Among other patients, the interaction of LSS and UMOD amplifies the drop in BP evoked by reduced Na intake.

SA-PO172

Effects of Atorvastatin on Salt Sensitivity and Blood Pressure in Hypertensive Patients (DUET Study) Akira Ishii,[1] Masato Kasahara,[2] Hideki Yokoi,[1] Takashige Kuwabara,[1] Shinji Yasuno,[2] Kiyoshi Mori,[3] Akira Fujimoto,[2] Sachiko Tanaka,[2] Noriko Satoh-Asahara,[4] Takashi Sakamoto,[5] Narito Morii,[6] Kazuko Horii,[7] Takeru Sakai,[8] Masashi Mukoyama,[1] Kenji Ueshima.[2] *[1]Dept of Nephrology, Kyoto Univ Graduate School of Medicine; [2]Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital; [3]Medical Innovation Center, Kyoto Univ; [4]National Hospital Organization, Kyoto Medical Center; [5]Fukuchiyama City Hospital; [6]Morii Clinic; [7]Horii Clinic; [8]Kyoto Ohashi General Hospital.*

Background: It is reported that statins have an anti-hypertensive effect, but precise mechanisms have not yet been revealed. In order to clarify the effects of atorvastatin on salt sensitivity and blood pressure (BP) in hypertensive patients, we conducted DUET study.

Methods: Hypertensive patients with high LDL-C levels without taking any anti-dyslipidemia drugs were registered. (1st phase) After they started taking amlodipine, they took low-salt diet (6 g/day, 3d) and collected 24-hr urine sample, measured BP. Then they took normal-salt diet (10 g/day, 3-7d), and collected 24-hr urine and measured BP. (2nd phase) Then, they started atorvastatin additionally. After one to four weeks, they repeated the same regimen. The primary endpoint was a slope change of pressure-natriuresis curve. The secondary endpoints were the changes of BP, sodium excretion, urinary and blood laboratory data.

Results: Of 32 registered patients, 30 (mean, 59.5 years) were eligible for this study (FAS). The initial systolic BP was 141.0±16.2 mm Hg, and LDL-C level was 166.8±20.6 mg/dl. There was no significant change in the slope of pressure-natriuresis curve after atorvastatin treatment. Atorvastatin significantly decreased mean BP under low-salt diet (93.3±7.1 versus 90.4±6.5 mmHg, p=0.016), but not under normal-salt diet. Serum LDL-C, TG and potassium levels decreased significantly, but urinary protein, sodium and potassium did not change after taking atorvastatin.

Conclusions: Treatment with atorvastatin did not change the slope of pressure-natriuresis curve. However, atorvastatin enhanced the BP-lowering effect under salt restriction, suggesting its additional mechanism of BP handling.

Subclinical Adrenomedullin Levels Help Distinguish between Future Aldosterone Producing Adenoma and Essential Hypertension Ryan J. Altenburg,[1] Austin Parker,[2] Dustin J. Little,[1] Stephen W. Olson.[1] *[1]Nephrology, Walter Reed National Military Medical Center; [2]Nephrology, Naval Medical Center Portsmouth, Portsmouth, VA.*

Background: Adrenomedullin levels (ADM) are elevated at diagnosis of aldosterone producing adenoma (APA) and reduced after surgical resection. APA cells have ADM receptors. ADM both stimulates APA cell proliferation and inhibits angiotensin-II driven aldosterone secretion in vitro without altering basal production. This dysregulation could manifest an autonomous adenoma. We hypothesize that ADM is a principle participant in the early pathogenesis of APA.

Methods: We performed a Department of Defense Serum Repository case-control study comparing ADM before histopathologic diagnosis of 11 APA patients to 30 age, race, sex, and age-of-serum-matched essential hypertension disease controls (HTN-DC). ADM were measured by ELISA. Data analysis was performed with Fisher's exact test and Student's t test for categorical and continuous data, respectively.

Results: APA patients had a higher average index ADM than matched HTN-DC (17.6 VS. 7.5 pg/ml; p<0.001). There was no change in ADM from index to last (mean 15 and 5.1 years before diagnosis respectively) sample (17.6 versus 17.5 pg/mL, p=0.98). A higher percent of APA patients had index ADM >9.9 pg/ml and >19.9 pg/ml compared to matched HTN-DC prior to diagnosis (82% versus 20%, p<0.001 and 46% versus 3%, p=0.003 respectively).

Conclusions: ADM are elevated at least 15 years prior to APA diagnosis compared to HTN-DC. ADM remains unchanged over time which supports an innate overproduction. ADM levels could help distinguish which hypertensive patients are at risk to develop APA. ADM may also assist in APA diagnosis because it is unaffected by Renin Angiotensin Aldosterone System (RAAS) blockade medications. Finally, ADM may represent an attractive future target for medical intervention. Future prospective evaluation is required.

Adrenal Vein Sampling: OHSU Experience 1995-2013 Adam Protain,[1] Frederick S. Keller,[2] Kevin C.J. Yuen,[3] Jose F. Rueda.[1] *[1]Nephrology, OHSU, Portland, OR; [2]Dotter Interventional Inst, OHSU, Portland, OR; [3]Endocrinology, OHSU, Portland, OR.*

Background: Distinguishing unilateral aldosterone-producing adenomas (APAs) from bilateral idiopathic hyperplasia is mandatory for surgical treatment of primary aldosteronism (PA). Adrenal venous sampling (AVS) is considered the gold standard for identification and localization of the lesion causing PA. However, the success rate of this procedure depends on the expertise of the angiographer. Success rates have been reported to be up to 96% in some centers in the U.S. with a complication rate of 2.5%.

Methods: A retrospective analysis of all AVS procedures performed at Oregon Health and Science University for PA between June 1995 and June 2013. A ratio of adrenal vein to IVC cortisol concentration of 5:1 or greater was used to confirm successful catheterization of the adrenal veins (SI: Sensitivity Index). Right and the left adrenal vein aldosterone concentrations were divided by their respective cortisol concentrations, and the ratio from high to low was calculated (LI: Lateralization index). A ratio of more than 4:1 was used as the cutoff for diagnosing unilateral disease. Concurrently, CT/MRI reports were reviewed, when available, and complications were noted.

Results: AVS for PA was performed successfully in 105 of 126 (83.3%) procedures and 101 of 115 patients (87.8%). AVS was successfully repeated in 10 of 11 attempts (90.9%). More than half [54/105 (51.4%)] of the successful AVS procedures had a LI ≥4:1, and 31/54 (57.4%) patients of this group underwent an adrenalectomy at OHSU. Pathology reports yielded 23 APAs, 6 glands adrenal hyperplasia, 1 normal adrenal gland, and 1 adrenal gland with hemorrhage. CT/MRI and AVS concordance was 53%, and 5.8% of AVS lateralized to opposite side of a mass seen on CT/MRI. Asymptomatic adrenal hemorrhage during adrenalectomy was the only noted complication (complication rate 0.8%).

Conclusions: Adrenal vein sampling was performed successfully in 87.8%of patients at our institution with minimal complications. The high success rate of AVS at our institution is highly dependent on the proficiency of the angiographer.

SA-PO175

Blood Pressure, Graft Survival and Renal Function in Kidney Allograft Recipients – The Effect of Intervention Christian Morath,[1] Peter Schnuelle,[1] Vedat Schwenger,[1] Martin G. Zeier,[1] Gerhard Opelz.[2] *[1]Dept of Nephrology, Univ of Heidelberg, Heidelberg, Germany; [2]Transplantation Immunology, Univ of Heidelberg, Heidelberg, Germany.*

Background: Long-term kidney allograft function is strongly correlated to the blood pressure. Systolic blood pressure (bp) above 140mmHg determines reduced graft survival. The database of the Collaborative Transplant Study (CTS) provides a high number of renal transplant recipients and their long-term follow-up.

Methods: A total of 18982 patients with continuous information on blood pressure, s-creatinine and graft outcome were followed over a time period of 10 years. Systolic blood pressure at year 1 and year 5 was categorized either <140mmHg or >140mmHg. Only patients with normal renal function s-creatinine <1.4mg/dl at year 1 post transplantation were analysed. At year 10 renal function and graft survival were analysed. Altogether four groups were followed: A: bp<140 at year 1 and year 5; B bp>140 at year 1 and <140 at year 5; C: bp <140 at year 1 and >140 at year 5 and bp >140 at year 1 and >140 at year 5.

Results: 10-year graft survival according to A-D was: A 83.3%(p<0.00001 compared to B,C and D), B 78.2% (p<.007 compared to C and p<0.0001 compared to D), C 75% and D 71.8%. Kidney function, e.g. the relative number of recipients with s-creatinine < 1.4mg/dl was: A 68.9% (p<0.0005 A compared to C and D; p n.s. for A compared to B), B 66.4% (p<0.02 B compared to D), C 63% and D 60.7%. The relative number of patients with bp >140mmHg after year 10 was 41.6%.

Conclusions: Blood pressure control significantly improves graft function and increases the number of patients with excellent graft function 10 years plus. In addition treatment intervention between year 1 and 5 (group B) has a significant impact on graft survival and renal function. In contrast inadequate blood pressure control (group C and D) resulted in an inferior graft outcome and a reduced relative number of recipients with excellent renal function. After 10 years of follow-up a significant number of patients has no adequate blood pressure control.

SA-PO176

Nocturnal Hypertension Is the Dominant Component of the Blood Pressure Burden in Renal Transplant Patients Francesca Mallamaci, Rocco Tripepi, Daniela Leonardis, Angela Mafrica, Maria Carmela Versace, Pasquale Fabio Provenzano, Giovanni Tripepi, Carmine Zoccali. *CNR-IFC/IBIM and Nephrology and Transplantation Unit, Reggio Calabria, Italy.*

Background: 24h ambulatory monitoring (ABPM) is formally recommended for the diagnosis of hypertension at community level (BMJ. 2012 Jan 13;344:e181). Hypertension is common in renal transplant patients but the relevance of ABPM for the care of these patients is undefined.

Methods: We performed systematic ABPM recordings and carotid intima media thickness measurements (echo-color Doppler) in a series of 240 renal transplant patients representing the 90% of the whole renal transplant population at a single institution.

Results: The average 24h ABPM was 125±12/77±9 mmHg and the daytime and night time average BPs values were 126±12/78±9 mmHg and 123±13/74±10 mmHg, respectively. Ninety-six patients were classified as hypertensive (40%) by ABPM criteria (>130/80, ESH Guidelines 2013) and 44 (18%) by conventional, office criteria (>140/90 mmHg). As much as 35% of patients had a night/day systolic BP ratio >1 denoting a nocturnal rise in BP. The average night-time Systolic BP (r=0.24, P=0.001) and the night day systolic ratio (r=0.21, P=0.001) were strongly related to IMT and these associations were much more robust than that of average 24h systolic BP with the same outcome measure (r=0.16, P=0.04). In contrast average day-time and office systolic BP did associate with IMT (r=0.12, P=0.13 and r=0.11, P=0.17). In analyses adjusting for age, gender, triglycerides, hemoglobin, 24h average systolic ABPM, eGFR and past CV comorbidities both average night-time systolic BP and the night/day ratio remained independently related (β=0.32, P=0.03 and β=0.14, P=0.03, respectively) with IMT indicating that nocturnal hypertension is a relevant component of the BP burden in renal transplant patients.

Conclusions: Nocturnal hypertension is exceedingly frequent (35%) in renal transplant patients and it is the sole BP component showing an association with carotid atherosclerosis in this population. Current recommendations by transplant guidelines to diagnose and monitor hypertension exclusively by conventional BP measurements need to be reconsidered.

SA-PO177

In Preeclampsia, Early Hyperuricemia Is due to Increased Renal Reabsorption Refael Gery. *Nephrology and Hypertension Unit, Ziv Medical Center, Safed, Israel.*

Background: Hyperuricemia is frequent in preeclampsia (PE) .In these pregnancies, plasma levels of uric acid (UA) may start to rise early, long before hypertension and proteinuria develop. This is mainly due to reduced renal excretion.We postulated that since the GFR is usually preserved at these stages, the reduced excertion of UA is due to increased Urate reabsorption reflecting changes in volume status. Hence, we investigated the Fractional Excertion of UA (FEua) in mid (week23)and late(week37)pregnancy as well as other traditional parameters of clinical PE.

Methods: · 48 pregnant women were recruited. Women with chronic hypertension, renal disease, DM, morbid obesity, any other systemic diseases, and those with PE in previous pregnancies were excluded. · All participants were examined during their 23rd and 37th weeks, and during delivery. serum and urine creatinine and uric acid, and urine microalbumin were measured at each visit. Sitting BP and BMI were also recorded. · Preeclampsia was diagnosed according to the accepted criteria.

Results: · Five of the 48 women (10.4%) developed preeclampsia past the 37th week. · In the preeclampsia group,the mean serum uric acid was significantly higher,(3.8MG/dL versus 3.0mg/dL p;0.025 at week and 4.2mg/dL versus 3.0mg/dl P;0.001A at week37)and the mean FEua was significantly lower(2.0% versus 4.2% P;0.003 at week23 and2.9% versus 4.0% P:0.025 at week37) than in the normal group. At 23 weeks,Mean diastolic(69.0mmHg versus 61.3mmHg P;0.032) but not systolic (102mmHg versus 110.8mmHg P;0.293), BP was higher in the preeclampsia group. · ACR in the preeclampsia group was slightly(Mean 0.030 versus 0.023 P;0.093) but not significantly higher compared with the normal group at 23 weeks.

Conclusions: 1. In pregnant women who will develop PE, plasma levels of UA are elevated in early pregnancy before overt hypertension and proteinuria appear. 2.The findings in week 23 of reduced FE of UA that indicates enhanced tubular reabsorption, and of higher diastolic BP(althought within normal), may reflect a state of relative plasma depletion and vasoconstriction, conditions known to characterize the fully expressed PE syndrome. 3. It is suggested that these pathophysiological events start in early pregnancy, long before clinical PE appears.

SA-PO178

Serial Measurements of Proteinuria in Normal and Hypertensive Pregnancy Andrea G. Kattah,[1] Wendy White,[2] Vesna D. Garovic.[1] *[1]Div of Nephrology and Hypertension, Mayo Clinic; [2]Dept of Obstetrics and Gynecology, Mayo Clinic.*

Background: The optimal method for monitoring proteinuria in pregnancy is still debated. Urine protein to creatinine (P/Cr) ratio correlates well with 24-hr urine protein, but issues, such as false positives, remain. There is little data on albumin to creatinine (Alb/Cr) ratios in pregnancy. Our goal was to compare P/Cr and Alb/Cr ratios in women with normal pregnancy, gestational hypertension (GH) and preeclampsia at different gestational ages.

Methods: We prospectively enrolled women with normal pregnancy (n=204), GH (n=14) and preeclampsia (n=15), with diagnosis being made at time of delivery using standard criteria through 2012. Serial measurements of P/Cr and Alb/Cr ratios were collected between <13 weeks, 14-28 weeks and >28 weeks gestation and the last value in each period was used. There were 24-hr urine proteins in 18 women.

Results: The median P/Cr and Alb/Cr ratios were significantly higher in those with preeclampsia versus normal pregnancy and GH at >28 weeks (all p<0.02, Wilcoxon-rank sum test).

Proteinuria Measurements	Gestational Age (weeks)	Normal (n=204)		Gestational Hypertension (n=14)		Preeclampsia (n=15)	
		n	Median (IQR)	n	Median (IQR)	n	Median (IQR)
Albumin/Cr ratio (mg/g Cr)	<13	181	3.6 (2.1-6.5)	12	2.2 (0.15-4.1)	14	3.7 (0.5-9,4)
	14-28	110	4.1 (2.4-6.4)	10	7.5 (3.9-14.2)	9	5.3 (1.9-7.8)
	> 28	165	18.6 (6.4-65.8)	14	22.8 (5.7-35.8)	15	100.5 (17.8-703.5)
Protein/Cr ratio (mg/mg Cr)	<13	181	0.02 (0.01-0.03)	12	0.02 (0.01-0.02)	14	0.03 (0.01-0.03)
	14-28	110	0.04 (0.03-0.05)	10	0.04 (0.02-0.07)	9	0.05 (0.02-0.08)
	> 28	165	0.08 (0.04-0.17)	14	0.06 (0.04-0.11)	15	0.26 (0.07-1.20)

Table 1 - Protein measurements at various gestational ages in each pregnancy group.

The correlation between P/Cr and both Alb/Cr ratio and 24-hr urine protein was strong (Spearman ρ 0.66 and 0.75, respectively). In those with normal pregnancy, 23/456 (5%) of P/Cr ratios were >0.3 mg/mg Cr and 79/456 (17%) of Alb/Cr ratios were >25 mg/g Cr.

Conclusions: P/Cr ratio was significantly increased in those with preeclampsia only in late pregnancy, supporting its use as a measure of proteinuria. Alb/Cr ratios correlated well with P/Cr ratios, but would increase the number of false positives.

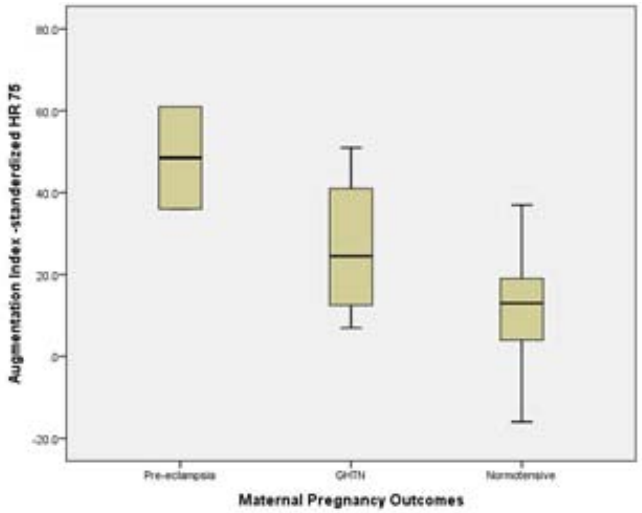
SA-PO179

Central Aortic Pressure and Arterial Stiffness as Early Predictors of Gestational Hypertension and Preeclampsia Simarta F. Brennan-Prescod, Paul G. Schmitz, Thinh Nguyen, Suwan Mehra, Ashraf M. Mohammed. *Nephrology, St. Louis Univ, St. Louis, MO.*

Background: Parameters of arterial stiffness using SphygmoCor Excel® are viewed as important markers of cardiovascular disease. This novel technique may become a useful screening tool to identify pregnant women at higher risk for developing preeclampsia and gestational hypertension during pregnancy.

Methods: A prospective study was done of 61 pregnant women in an outpatient clinic. During first half of pregnancy, noninvasive assessment of central aortic pressure and arterial stiffness was performed. The subjects were followed postpartum to determine maternal and fetal outcomes.

Results: Among the 61 women, 11.4% had central pulse pressure >50mmHg and 26% had central systolic pressure >125mmHg. In addition 26% had elevated augmentation pressures and an increase of 39% augmentation index with standardized heart rate of 75 (Ax75). There was a strong positive correlation between central pulse pressure and brachial pulse pressure (R^2=0.847, p < 0.01). Subgroup analyses of 18 women who delivered to date revealed that 2 developed preeclampsia, 4 developed gestational hypertension, and 12 were normotensive. The patients who developed preeclampsia and gestational hypertension had higher indices of arterial stiffness, such as Ax75, in the first trimester of pregnancy.



Conclusions: Results suggest that noninvasive methods to measure arterial stiffness identify patients at risk for pregnancy-induced hypertension. Patients with elevated pulse and central systolic pressures are at high risk for cardiovascular disease. The patients with higher augmentation pressure and augmentation index who later develop hypertensive disease may respond to agents that target arterial compliance (e.g. CCB). Over the next 3 months, outcomes on the remaining subjects will provide further insights into the role of central pressure monitoring during pregnancy.

Independent Association of Vegetarian Diet with Vascular Endothelial Function Lea Borgi, John P. Forman. *Renal, Brigham and Women's Hospital, Boston, MA.*

Background: Vegetarian and vegan diets have been associated with a lower prevalence of hypertension when compared to animal-based diets in cross-sectional studies. Small, short-term interventional trials reported that replacing an omnivorous diet with a vegetarian diet led to a reduction in blood pressure. The mechanisms by which vegetarian diets are linked to a reduced prevalence of hypertension are not well understood, but endothelial dysfunction induced by eating meat has been proposed.

Methods: We performed a cross-sectional analysis of the NIH-funded ongoing Modifiable Effectors of Renin System Activation Treatment Evaluation (MODERATE) trial. Dietary information and endothelial-dependent vasodilation (EDV, a measure of endothelial function using brachial artery ultrasound) were ascertained at baseline, as were other factors including demographics and 24-hour blood pressure. We used multivariable linear regression to analyze the independent association of self-reported long-term dietary pattern (which we categorized as vegetarian/vegan or non-vegetarian) and EDV, while controlling for multiple potential confounders.

Results: At the time of the analysis, 174 participants had completed their baseline visits. The mean (SD) of EDV for the entire study population was 7.0±4.4%. Compared with non-vegetarians, those who were vegetarian or vegan had significantly greater endothelial function in fully-adjusted models (difference in EDV = 3.0 ± 1.4%). By comparison, the difference in EDV associated with a 1 year younger age was 0.13±0.03% in fully-adjusted models. Thus, the magnitude of the difference in EDV associated with being vegetarian or vegan was approximately equivalent to the difference observed with being 23 years younger.

Conclusions: This preliminary analysis found that a vegetarian or vegan diet was associated with substantially better endothelial function as compared with a non-vegetarian diet. Future prospective studies should examine the effects of animal-based foods on endothelial function and other potential mechanisms of hypertension and cardiovascular disease.

Urinary Angiotensin-Converting Enzyme 2 Is Associated with Urinary Liver-Type Fatty Acid Binding Protein and Albuminuria in Patients with Chronic Kidney Disease Masanori Abe, Kazuyoshi Okada. *Nephrology, Hypertension and Endocrinology, Nihon Univ School of Medicine, Tokyo, Japan.*

Background: Angiotensin converting enzyme 2 (ACE2) is a recently identified member of the renin-angiotensin system (RAS), and degrades Angiotensin (Ang) II to the seven-amino acid peptide fragment Ang-(1-7). ACE2 is thought to function as a negative regulator in this respect to counterbalance the Ang II-forming activity of ACE. ACE2 is expressed in the kidney and may be a renoprotective enzyme. In addition, ACE2 has been detected in urine from patients with chronic kidney disease (CKD).

Methods: To determine the associated of ACE2 with urinary liver-type fatty acid binding protein (L-FABP) and albuminuria in CKD, we assessed 152 patients with CKD, including 72 with diabetes. Parameters were urinary ACE2, urinary albumin/creatinine ratio (UACR), urinary L-FABP, estimated glomerular filtration rate, and other factors determined to be associated with elevated urinary ACE2.

Results: Urinary ACE2 was significantly higher in patients with diabetes (P = 0.01) and in patients with CKD stage G4 compared with stages G1–G3 (P < 0.0001). Multivariable regression analysis revealed that urinary L-FABP and UACR were significantly associated with urinary ACE2 levels, indicating that urinary ACE2 is increased in patients with diabetes and advanced stage CKD.

Conclusions: ACE2 might continuously protect from both glomerular and tubulointerstitial injury during CKD progression. Taken together, urinary ACE2 could be a marker of kidney renin-angiotensin system activation in such patients.

SA-PO182

Severity of Burn Injury in Active Duty Military Personnel Is Associated with the Development of Long Term Hypertension Ian J. Stewart,[1] Brian Snow,[1] Jonathan Sosnov,[1] Mary Bollinger,[2] Kevin Chung.[3] *[1]San Antonio Military Medical Center; [2]South Texas Veterans Health Care System; [3]U. S. Army Inst of Surgical Research.*

Background: There is a paucity of data regarding long term morbidity in patients that survive a burn injury. We hypothesized that the severity of burn injury is associated with the subsequent development of hypertension (HTN) in a population of military personnel burned while supporting of combat operations in Iraq and Afghanistan.

Methods: Patients were included for analysis if they were admitted to our institution from Jan 2003 to Nov 2008, were injured in Iraq or Afghanistan, survived their hospitalization and did not have pre-existing HTN. Data on age, eGFR by CKD-EPI, race, presence of inhalation injury (IH), injury severity score (ISS), and total body surface area (TBSA) of burn injury were collected at hospital admission. To determine the diagnosis of HTN, we used ICD-9 codes from both the Department of Defense and Veteran's Affairs medical records systems. To determine factors associated with subsequent HTN, we used a cox regression model with step wise selection (p<0.1 for inclusion and output).

Results: A total of 637 patients were included in the analysis. The patients had an average age of 25.3±5.7 years. The majority (97.6%) were male and 7.5% were African American. Median ISS and TBSA were 9 (IQR 1,18) and 8% (IQR 4%, 20%), respectively. IH was present in 13.4%. Mean eGFR at admission was 112±20 ml/min/m^2. Average patient follow up was 5.5±1.7 years. On univariate analysis, ISS (HR 1.04, p<0.01), age (HR 1.05, p<0.01), absence of inhalation injury (HR 0.45, p<0.01), non-black race (HR 0.6, p=0.06), TBSA (HR 1.03, p<0.01), and eGFR (HR 0.99, p<0.01) were associated with subsequent HTN. On multivariable analysis, only age (HR 1.04, p<0.01), TBSA (HR 1.03, P<0.01), and non-black race (HR 0.56, p=0.04) were independently assocaited with HTN. eGFR trended towards significance (p=0.06).

Conclusions: Our data suggests that the size of a burn injury may impact a patients risk of developing HTN as after adjustment, TBSA was associated with subsequent HTN. Each 1% increase in burn size results in a 3% increase in the risk of developing HTN.

SA-PO183

Renal Prognosis in Patients with Essential Hypertension: Role of Serum Phosphorus Changes During Follow-Up Enrique Morales, Sara Santana, Julian Segura, Luis M. Ruilope, Manuel Praga. *Nephrology, Hospital 12 de Octubre, Madrid, Spain.*

Background: Our aim was to analyze whether changes in plasma phosphorus (P) were associated with renal prognosis in a cohort of patients with essential hypertension.

Methods: 1361 patients with essential hypertension, 50.2% male, age 60.5±12.3 years, usually followed at our center, were analyzed. All were followed for a minimun of three years. We classified the patients in two groups, defined by the presence of renal event (development of albuminuria ≥30 mg/g or progression of albuminuria during follow-up) or absence of renal event (maintenance of albuminuria <30 mg/g during the follow-up). Changes in plasma phosphorus (ΔP) were assessed absolutely (final P - initial P) and relatively ((final P – initial P)/(initial P) x100).

Results: At baseline the mean serum creatinine was 1.0±0.4 mg/dl, estimated glomerular filtration rate (eGFR) using the formula CKD-Epi was 78.4±25.1 ml/min/1.73m2, and mean plasma phosphorus was 3.3±0.5 mg/dl. Patients with renal event (n=363, 26.7%) were older (64.2±11.5 versus 59.2±12.3 years), higher systolic blood pressure (144±20 versus 136±18 mmHg), higher requirements of antihypertensives drugs (2.7±1.2 versus 2.1±1.2), higher serum creatinine (1.18±0.51 versus 0.93±0.27 mg/dl) and lower eGFR (71.1±32.7 versus 81.1±21.1 ml/min/1.73m2) (p<0.001 for all comparisons). Serum phosphorus showed no significant difference (3.29±0.56 versus 3.28±0.52 mg/dl). Mean absolute ΔP was 0.11±0.55 mg/dl in patients with renal event and 0.06±0.50 mg/dl in patients without renal event (p=0.083). Mean relative ΔP was 4.9 % among patients with renal event and 2.9% among patients without event (p=0.048). The logistic regression analysis showed that independent factors for the occurrence of renal event were age, female sex, baseline serum creatinine, diabetes and relative ΔP.

Conclusions: In conclusion, in a cohort of essential hypertensive patients regularly followed in our center, changes in plasma phosphorus during follow-up are an independent risk factor for the development or progression of renal disease.

Relevance of Central versus Brachial Blood Pressure in Chronic Kidney Disease Patients Naman Barman,[1] Vinaya R. Soundararajan,[2] Ramesh Soundararajan.[3] *[1]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Nephrology, Univ of Illinois College of Medicine, Chicago, IL; [3]Nephrology, Midwestern Univ College of Medicine, Downers Grove, IL.*

Background: Central blood pressure may be more relevant to end organ damage and a more appropriate target than brachial blood pressure. The purpose of this study is to evaluate the role of brachial versus central blood pressure in patients presenting to a nephrology clinic. We wanted to determine the percentage of patients in which the central systolic pressure was controlled, but the brachial systolic pressure was higher than optimal.

Methods: Central and brachial blood pressures were measured during the nephrology clinic visit by the SphygmoCor XCEL by AtCor Medical. Central blood pressure was considered controlled if systolic was less than or equal to 130 mmHg. Brachial systolic was considered controlled if it was less than or equal to 140 mmHg.

Results: Of the 109 adult patients who presented to the clinic, 23 patients (21%) had controlled central systolic blood pressure, but suboptimal control of brachial systolic blood pressure. On evaluating home blood pressure medications of each patient, 46% of patients were on an angiotensin converting enzyme inhibitor (ACE) or angiotensin receptor blocker (ARB), 50% were on calcium channel blockers, 23% were on diuretics and 16% were on beta blockers. Of the 64 chronic kidney disease (CKD) stage III patients alone, 14 (21%) had controlled central but high brachial systolic pressures. There were no CKD III patients with elevated central blood pressure and optimal brachial blood pressure. Evaluating their medications, 43% were on ACE/ARB, 35% were on calcium blockers, 23% were on diuretics and 16% were on beta blockers.

Conclusions: Results demonstrate that if therapy was solely based on brachial blood pressure, 21% of patients may be over treated, putting them at higher risk for side effects, medication intolerance, and noncompliance. Treatment based on central blood pressure may be better tolerated by the patients. Additionally, in this setting ACE/ARB and calcium blockers seemed to be more effective at controlling central blood pressure than diuretics and beta blockers.

SA-PO185

Comparison of Central Aortic and Brachial Blood Pressure during a 48-Hour Ambulatory Recording in Hemodialysis Patients Antonis Karpetas,[1] Pantelis Sarafidis,[2] Panagiotis I. Georgianos,[1] Georgios Koutroumpas,[3] Vasilios Raptis,[1] Thanasis Bikos,[1] Athanase Protogerou,[4] Dimitrios Stamatiadis,[5] Christos Syrganis,[3] Vassilios Liakopoulos,[1] George Efstratiadis,[2] Anastasios Lasaridis.[1] *[1]Div of Nephrology, 1st Dept of Medicine, AHEPA Hospital, Thessaloniki, Greece; [2]Nephrology Dept, Hippokrateion Hospital, Thessaloniki, Greece; [3]Nephrology Dept, General Hospital of Volos, Greece; [4]Hypertension Unit and Cardiovascular Research Laboratory, Laiko Hospital, Athens, Greece; [5]Hemodialysis Unit, General Hospital of Serres, Greece.*

Background: In clinical states of accelerated arterial stiffening, brachial blood pressure (BP) cannot accurately reflect BP in the aorta, due to the phenomenon of "aortic-to-brachial BP amplification". End-stage renal disease (ESRD) is characterized by elevated arterial stiffness and in these patients aortic BP was shown to be better predictor of mortality than brachial BP. This study includes comparative evaluation of aortic versus brachial BP during a 48-hour ambulatory BP monitoring (ABPM) in hemodialysis patients.

Methods: Aortic and brachial ABPM was performed with the Mobil-O-Graph device (IEM, Stolberg, Germany) for a 48-hour period covering a dialysis session and the following interdialytic interval in 153 hemodialysis patients. Mobil-O-Graph is a new brachial cuff-based device, which records oscillometric brachial BP and pulse waveforms and assesses central BP via mathematical transformation.

Results: Mean 48-hour aortic systolic BP (SBP) and pulse pressure (PP) was significantly lower than SBP and PP at brachial artery (120.1±14.6 versus 131.9±16.7 mmHg, P<0.001 for SBP and 40.4±9.4 versus 53.8±12.8 mmHg, P<0.001 for PP). In contrast, 48-hour diastolic BP was higher in the ascending aorta than in brachial artery (79.7±10.8 versus 78.1±10.6 mmHg, P<0.001). These differences were observed in both day-time and night-time periods, as well as during the hemodialysis-on and hemodialysis-off days.

Conclusions: This study shows a difference of 12 mmHg in ambulatory SBP and PP between the ascending aorta and brachial artery, consistent during the 48-hour period in hemodialysis patients. Future studies are warranted to investigate any possible effects of this difference on cardiovascular risk.

SA-PO186

Comparison of Home Blood Pressure Recordings and Office Blood Pressure Recordings with Respect to Ambulatory Blood Pressure Recordings Among Post Renal Transplant Recipients Amit Kumar,[2] Sivaramakrishnan Ramanarayanan.[1] *[1]Inst of Liver and Biliary Sciences, India; [2]All India Inst of Medical Sciences, India.*

Background: Ambulatory blood pressure monitoring (ABPM) is currently the gold standard for the diagnosis of hypertension. However, ABPM is not widely available in primary care practice and is not a feasible method to monitor blood pressure in post renal transplant patients. Office based blood pressure recordings (OBPM)may not be representative of true blood pressure recordings as it is influenced by many other factors. Home blood pressure monitoring (HBPM), may co-rrelate well with ABPM, but this has not been studied well among renal transplant patients. This study assess the agreeement between OBPM, HBPM and ABPM among renal transplant recipients.

Methods: The study enrolled 52 adult kidney transplant recipients. Apart from baseline clinical, demographic and laboratory parameters, measurements of **OBP, HBP**, **ABP** and Echocardiography were done at 3 months. ABPM was performed using automated electronic ABPM instrument(Bravo automated Ambulatory blood pressure monitor). HBPM was performed by automated electronic BP instrument. The patients were instructed to measure blood pressure at home two a day i.e. in morning and evening for three days. Each time they should take at least, 3 reading while sitting comfortably as in office BP recording and write the readings in diary. The average of all readings were then used. Office BP was recorded with automatic oscillometric device on non- fistula hand for at least 3 time over at least 5-10 minute interval and average of systolic and diastolic blood was taken.

Results: In patients at 3 months after transplant the mean difference of agreement for systolic BP with HBPM versus ABPM was 0.3±20.9 and for OBP versus ABPM was 2.6±22.3. Similarly for diastolic BP after transplant the mean difference of agreement was 2.3±13.9 for HBP versus ABPM and 4.8±24.0 for OBP versus HBPM. This suggests Both HBP and OBP has acceptable agreement with ABPM in post-transplant setting but the agreement with home BP was better.

Conclusions: Home BP is an acceptable alternative to ABPM for monitoring of blood pressure among renal transplant patients.

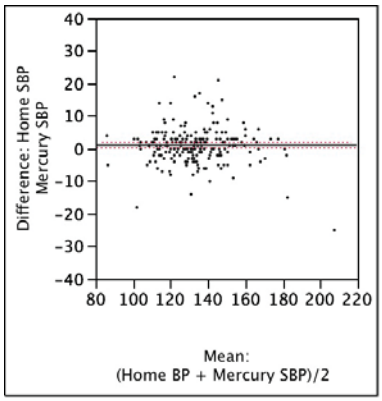
SA-PO187

Are Home Blood Pressure Monitors Accurate Compared to Validated Devices? Eva Bruketa, Ayub Akbari, Marcel Ruzicka, Swapnil Hiremath. *Div of Nephrology, Dept of Medicine, The Ottawa Hospital and Univ of Ottawa, Ottawa, ON, Canada.*

Background: Hypertension remains the most common cause of morbidity and mortality from cardiovascular disease. Major guidelines recommend home blood pressure (BP) monitoring to guide diagnosis and treatment of hypertensive patients. Notwithstanding this, little data exists on the real-world accuracy of home BP monitors used by patients. The objective of our study was to compare measurements from Home BP monitors with validated mercury sphygmomanometers.

Methods: We conducted a retrospective review and abstracted data from patient charts who had home BP monitor validated in the hypertension clinic at a tertiary care academic centre. After casual measurements, 3 resting measurements are taken with the home monitor and an office mercury sphygmomanometer using standard methods. The means of these three measurements taken with each method were compared with the t-test. In addition, we analyzed the proportion of home BP readings within 5 and 10 mm Hg of the mercury readings.

Results: We analyzed data from 210 patients (60% men, mean age 67 + 14 years). The mean body mass index was 29 kg/m^2, and the mean arm circumference was 32 + 5 cms. There was a significant difference between the resting mercury systolic BP (SBP) (132.3 + 18.5 mm Hg) compared to the home monitor resting SBP (133.4 mm Hg + 18.1 mm Hg), p = 0.011.



For diastolic BP (DBP) the difference was 71.4 + 11.9 versus 68.9 + 12.7 mm Hg (p<0.001). 63/210 of the Home Monitor SBP readings (30%) were > 5 mm Hg different and 16 (8%) were > 10 mm Hg different from the mercury SBP measurement. For DBP, these proportions were 32% (67/210) and 9% (18/210) respectively.

Conclusions: A large proportion of home BP monitors were not accurate when compared to mercury sphygmomanometers when validated in our clinical practice. Validation is a necessary step before relying on home BP monitor measurements.

SA-PO188

Impact of Cuff Inflation on Ambulatory Blood Pressure in Type 2 Diabetes Emilie Hein Petersen,[1] Simone Theilade,[1] Tine Hansen,[1] Morten Lindhardt,[1] Peter Rossing.[1,2,3] *[1]Steno Diabetes Center; [2]Aarhus Univ; [3]Univ of Copenhagen.*

Background: 24-hour ambulatory blood pressure (BP) measurement is increasingly recommended in guidelines and applied in daily clinic. Discomfort related to cuff inflation might bias the measurements, especially during nighttime. We assessed the impact of cuff

inflations by measuring 24-hour BP with previously validated devices: a cuff-less wrist device based on tonometry and an upper-arm cuff device in patients with type 2 diabetes. Reproducibility of both devices was evaluated.

Methods: Clinical trial with random assignment to sequence of cuff device (Takeda, TM2431) and cuff-less device (BPro, HealthStats) in a cross-over study with 4 visits. 24-hour BP was measured with BPro at visit 1 or 2 (after randomization) 3 and 4.Takeda device was used at visit 1 or 2, and 4. Day- and nighttime was defined based on patient's diary. Antihypertensive treatment was unchanged 4 weeks prior to and during the study. Paired t-test compared inter- and intra-device differences for systolic 24-hour, nighttime BP and nocturnal BP decline.

Results: We included 53 patients, mean (±SD) age was 64 (±9.6) years, office BP was 134 (±15)/75 (±10) mmHg, 21% female, and 74% had albuminuria (≥30 mg/g). There was no significant difference in 24-hour or nighttime BP between the two BPro recordings mean difference of 2.8 (±15.3) and 2.9 (±16.4) mmHg, $p \geq 0.19$ for both; or between the two Takeda recordings 1.5 (±8.9) and 3.1 (±12.3) mmHg, $p \geq 0.09$ for both. However, 24-hour and nighttime BP was significantly higher when measured with Takeda than BPro, 141.6 (±14.6) versus 128.3 (±14.6), and 130.0 (±16.6) versus 123.1 (±15.5), $p \leq 0.01$ for both. The nocturnal BP decline was significantly lower measured with BPro than Takeda (6.7±5.3% versus 10.3±7.6%, $p<0.01$). Few patients reported sleep disturbances in general, but most patients preferred BPro when asked.

Conclusions: In type 2 diabetic patients ambulatory BP measurements with BPro or Takeda were reproducible, but revealed significantly higher values for Takeda - both for 24-hour and nighttime BP. Overall, nocturnal BP decline was higher for Takeda suggesting that cuff inflation did not increase nighttime BP.

SA-PO189

Losartan and Ambulatory Blood Pressure Variability Koichi Azuma,[1] Kouichi Tamura.[2] *[1]Naruse jin Clinic, Zenjinkai Group, Yokohama, Kanagawa, Japan; [2]Dept of Medical Science and cardiorenal Medicine, Yokohama City Univ School of Medicine, Yokohama, Kanagawa, Japan.*

Background: Previous studies have shown increases in ambulatory short-term blood pressure (BP) variability to be related to cardiovascular disease. In this study, we examined whether an angiotensin II type 1 receptor blocker losartan would improve ambulatory short-term BP variability in hypertensive patients on hemodialysis.

Methods: 40 hypertensive patients on hemodialysis therapy were randomly assigned to the losartan treatment group (n=20) or the control treatment group (n=20). At baseline and 6 and 12 months after the treatment, 24-h ambulatory BP monitoring was performed. Echocardiography and measurements of brachial-ankle pulse wave velocity (baPWV) and biochemical parameters were also performed before and after therapy.

Results: After 6- and 12-months of treatment, nighttime short-term BP variability, assessed on the basis of the coefficient of variation of ambulatory BP, was significantly decreased in the losartan group, but remained unchanged in the control group. Compared with the control group, losartan significantly decreased left ventricular mass index (LVMI), baPWV, and the plasma levels of brain natriuretic peptide and advanced glycation end products (AGE). Furthermore, multiple regression analysis showed significant correlations between changes in LVMI and changes in nighttime short-term BP variability, as well as between changes in LVMI and changes in the plasma levels of AGE.

Conclusions: These results suggest that losartan is beneficial for the suppression of pathological cardiovascular remodeling though its inhibitory effect on ambulatory short-term BP variability during nighttime.

Poor Sleep Quality Are Responsible for Nondipping Pattern in CKD with Hypertension Patients Jun Zhang. *Div of Nephrology, Dept of Medicine, 3rd Hospital of Sun Yat-sen Univ, GuangZhou, GuangDong, China.*

Background: This study aimed to evaluate the relationship between sleep quality and hypertension and to determine if there was any association between the non-dipping status and sleep quality in CKD patients.

Methods: A total of 565 pre-dialysis CKD patients (normotensive patients 224, hypertension patients 341) defined as dippers or nondippers by ambulatory blood pressure monitoring were recruited in this study. Demographics and clinical correlates, including BMI and eGFR etc, were collected. The sleep quality was measured by Pittsburgh Sleep Quality Index (PSQI).

Results: A total of 134(59.8%) CKD normaltensive and 253(74.2%) hypertensive patients had a nondipping BP pattern. Hypertension group had higher prevalence of nondipping BP, smoking, alcohol intaking, diabetes mellitus and had lower eGFR level and poorer sleep quality than normaltensive group ($P<0.05$). Patients with nondipping BP pattern had worse renal function and poorer sleep quality when compared with dipping BP pattern in hypertension CKD patients ($p<0.05$). Nondipping BP pattern group had higher bedtime BP than dipping BP pattern in all CKD patients ($p<0.05$). The rate of decline of nocturnal BP correlated significantly with PSQI in hypertension CKD patients ($p<0.05$). We failed to prove the association between poor sleep quality and hypertension in CKD patients ($p>0.05$). But poor sleep quality was an independent factor affecting BP pattern in hypertension CKD patients after multivariate logistic regression analyses ($p<0.05$).

Conclusions: Poor sleep quality, which is commonly found in pre-dialysis CKD patients, is an independent associated factor of nondipping BP pattern in hypertension CKD patients.

Funding: Private Foundation Support

SA-PO191

Long Term Effect of Deviced-Guided Breathing Exercises on Sympathetic Nervous System Activity in Primary Hypertension Silvana de Barros,[1] Giovanio Vieira da Silva,[1] Josiane Lima de Gusmão,[1,2] Tatiana Goveia de Araujo,[1] Decio Mion Junior.[1] *[1]Nephrology Div, Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]Univ Guarulhos, Guarulhos, SP, Brazil.*

Background: Deviced-guided breathing exercises reduce blood pressure and are indicated as a non-pharmacological treatment for hypertension. However, the physiological mechanism involved in the reduction of blood pressure is unknown. The reduction in sympathetic nervous system activity may be one explanation.

Methods: 19 patients with primary hypertension (systolic blood pressure (SBP) between 140 and 179 mmHg and/or diastolic blood pressure (DBP) between 90 and 109 mmHg) and without any other co-morbidities were selected. Participants were randomly allocated into two groups: Control Group (CG, n=8) or Guided Breathing Group (GBG, n=11). For 8 weeks, participants in the CG used MP3 player that reproduced loud music, daily, for 15 minutes. Participants in the GBG used RESPeRATE® device for the same period of time. The device induces reduction in breathing rate while prolonging exhalation: patients were requested to synchronize breathing with the guiding tones. Before and after the intervention period, patients underwent ambulatory blood pressure monitoring (ABPM), dosage of plasma catecholamine and measurement of sympathetic nerve activity by microneurography.

Results: There was no change in mean mean 24 hour SBP (129±8 versus 133±11, p=0,20) and DBP (89±5 versus 91±7, p=0,19) before and after intervention in GBG. However, in the CG SBP (128± 8 versus 123±8, p = 0,01) and DBP (90±5 versus 86±6, p = 0,02) showed decrease. There was no difference in plasma catecholamine concentration (pg/ml) before and after the intervention in both groups: GBG (302 (220-256) versus 234 (156-318), p = 0,35) and CG (201 (144-230) versus 221 (179-274), p = 0,97). The peripheral sympathetic nerve activity (bursts/min) measured by microneurography also showed no change: GBG (20±8 versus 18±5, p=0,36) and CG (21±4 versus 21±6, p= 0,92).

Conclusions: Device-guided breathing showed no change in blood pressure and sympathetic nervous system activity after 8 weeks. Other mechanisms should be involved in the reduction of blood pressure observed in other studies.

The Effect of the Addition of Allopurinol on Blood Pressure Control in African Americans Treated with a Thiazide-Like Diuretic Mark S. Segal,[1,4] Titte Srinivas,[2] Jogiraju V. Tantravahi,[1,4] Richard J. Johnson.[3] *[1]Medicine, Malcom Randall VA Medical Center; [2]Medical Univ of South Carolina; [3]Univ of Colorado; [4]Medicine, Univ of Florida.*

Background: Since in African-Americans there may be a strong association between hyperuricemia and hypertension, we decided to test the hypothesis that xanthine oxidase inhibition in African-Americans receiving diuretics can result in improved blood pressure (BP) control with few side effects. We tested this hypothesis in a randomized double blind, placebo controlled study of African-Americans with stage I hypertension in the absence of clinically significant renal disease.

Methods: 150 African-American men and women between the ages of 18 and 65 years of age who meet the exclusion/inclusion criteria with untreated or treated hypertension were started on chlorthalidone (25mg/day) and potassium chloride after stopping current anti-hypertensives. After 5 weeks we performed baseline testing and randomized subjects to allopurinol (300mg/dl) or placebo. After 2 weeks, if their uric acid was above 5.5mg/dl the allopurinol or placebo was doubled. After another 6 weeks they were brought in to repeat baseline testing.

Results: The baseline BP after 5 weeks on chlorthalidone was 119.9±13.6 in the allopurinol group and 116±11.2 in the placebo group. After at least 8 weeks following randomization to placebo or allopurinol, there was a change in the clinic BP between the placebo and allopurinol group that did not quite reach significance (p=0.1). The group randomized to allopurinol saw a 3.32 mm Hg decrease in systolic BP at visit 8 compared to visit 5 whereas the group randomized to placebo saw a 0.58 mm Hg increase in systolic BP at visit 8 compared to visit 5. The same trend was seen in the clinic diastolic BP.

Conclusions: Although allopurinol treated subjects had a reduced BP compared to placebo treated subjects, the decrease in BP did not quite reach significant difference. We believe the negative result was due to the excellent BP control achieved with chlorthalidone. Importantly allopurinol was well tolerated. Decreasing uric acid levels deserves to further study as a mechanism to control hypertension.

Different Effects of Febuxostat and Allopurinol on Renal Function and Blood Pressure in Patients with Hypertension Kentaro Kohagura,[1] Takeshi Tana,[3] Yusuke Ohya,[1] Kunitoshi Iseki.[2] *[1]Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus, Nishihara-cho, Okinawa, Japan; [2]Dialysis Unit, Univ Hospital of the Ryukyus, Nishihara-cho, Okinawa, Japan; [3]Shuri Jokamachi Clinic, Naha, Okinawa, Japan.*

Background: Hyperuricemia was reportedly associated with elevated renal vascular resistance and developing hypertension. However, the effect of allopurinol (AP) and febuxostat (Feb), on renal function and blood pressure (BP) was unknown.

Methods: We retrospectively examined 223 hypertensive patients (152 men and 71 women) who were newly started with either AP (n=153) or Feb (n=70) without any change of other drugs in outpatient clinic. We examined the short-term changes (from the starting to next visit) in estimated glomerular filtration rate (eGFR) and BP after starting these drugs.

Results: The mean ± standard deviation values for patients' age, blood pressure, serum uric acid, eGFR were as follows: 64 ± 13 years, 127 ± 17/72 ± 12 mmHg, 8.8 ± 1.4 mg/dl and 47 ± 19 ml/min/1.73 m^2, respectively. Baseline uric acid and SBP were higher, while eGFR was lower in Feb group compared with those of AP group. Moreover, Feb decreased in serum uric acid greater than that of AP (-2.5mg/dl v.s -2.0mg/dl, p=0.03). In Feb group, eGFR (ml/min/1.73m^2) was significantly increased (43 v.s 46, p=0.01), while systolic BP (mmHg) tend to be decreased (131 v.s 128, p=0.06). Higher baseline SBP was significantly associated with higher increased in eGFR(r=0.35, p=0.003). Furthermore, the changes in SBP, but not in uric acid was negatively correlated with the changes in eGFR (r=-0.26, p=0.03). In contrast to the effects of Feb, neither systolic BP nor eGFR showed significant changes in AP group.

Conclusions: These results suggested that Feb might increase eGFR, independent of lowering effects of uric acid, by reducing vascular resistance of preglomerular vessel in the patients with hypertension.

SA-PO194

The Overlooked Effects of Sulodexide on Blood Pressure: A Systematic Review and Meta-Analysis Rik Hg Olde Engberink,[1] Nienke M.G. Rorije,[1] Bert-Jan Van den Born,[2] Dick de Zeeuw,[3] Hiddo Jan Lambers Heerspink,[3] Liffert Vogt.[1] *[1]Nephrology, Academic Medical Center, Amsterdam, Netherlands; [2]Vascular Medicine, Academic Medical Center, Amsterdam, Netherlands; [3]Clinical Pharmacy and Pharmacology, Univ Medical Center Groningen, Groningen, Netherlands.*

Background: Sulodexide, a highly purified mixture of glycosaminoglycans, has been hypothesized to be renoprotective. Recent large randomized, placebo-controlled trials (RCT) in diabetic nephropathy failed to demonstrate significant effects on any renal endpoint, including albuminuria. Because glycosaminoglycans affect the composition of the endothelial surface layer, thereby improving endothelial function and possibly blood pressure (BP), we performed a systematic review of antihypertensive potency of sulodexide.

Methods: Medline, Embase and Cochrane were searched. RCTs that investigated sulodexide treatment of at least one month, and reported BP measurement at baseline and after sulodexide/control treatment were included. Two reviewers independently selected studies and extracted data. Primary outcome was the BP change after sulodexide treatment, corrected for the observed BP changes in parallel control groups. Meta-regression analysis was used to explore whether BP changes were associated with anti-albuminuric effects or patient characteristics.

Results: 8 studies, totalling 13 comparisons and 3,060 subjects (mean follow-up: 4.4 months) were included. Four comparisons were performed in hypertensive patients. Sulodexide treatment resulted in a significant systolic (-3.5 mmHg [95% CI -6.2,-0.9]; p=0.010) and diastolic (-2.3 mmHg [95% CI -3.9,-0.8]; p=0.004) BP reduction. Hypertensive patients displayed largest BP reductions (systolic/diastolic BP, -9.6/-4.9 mmHg; p<0.001). Higher baseline mean arterial pressure (MAP) was significantly associated with larger MAP reductions after sulodexide treatment (R^2 0.73, p<0.001). In addition, MAP reduction showed a significant association with albuminuria reduction (%) by sulodexide (R^2 0.66, p=0.019).

Conclusions: Sulodexide treatment results in a significant BP reduction with hypertensive patients showing the largest BP reduction. Greater BP reductions by sulodexide were associated with larger reductions in albuminuria.

Funding: Private Foundation Support, Government Support - Non-U.S.

SA-PO195

Single Pill-Based Combination Therapy with Amlodipine and Atorvastatin Improves Renal and Vascular Function and Clinic Blood Pressure Variability in Hypertension with Chronic Kidney Disease Kouichi Tamura,[1] Kengo Azushima,[1] Kazushi Uneda,[1] Hiromichi Wakui,[1] Masato Ohsawa,[1] Ryu Kobayashi,[1] Kohji Ohki,[1] Koichi Azuma,[2] Toru Dejima,[1] Tomohiko Kanaoka,[1] Yoshiyuki Toya,[1] Satoshi Umemura.[1] *[1]Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan; [2]Dept of Nephrology and Hypertension, Yokohama Dai-ichi Hospital, Yokohama, Kanagawa, Japan.*

Background: The study aimed to examine the effects of single pill-based combination therapy with amlodipine and atorvastatin on clinic blood pressure (BP) profile including within-visit BP variability, a recently emerging marker of linking between kidney and vasculature, and parameters of vascular and renal function in hypertensive CKD patients who did not achieve the target BP and lipid level.

Methods: Hypertensive CKD patients who did not achieve the goal of BP (clinic systolic BP≥130 mmHg and/or diastolic BP≥80 mmHg) and lipid (LDL-C≥100 mg/dL) were enrolled. The patients were given a single pill of amlodine/atorvastatin tablet (amlodipine/atorvastatin; 2.5/5, 2.5/10, 5/5, 5/10 mg) for 16 weeks. The dose of the single amlodipine/atorvastatin tablet was titrated up as needed to achieve the BP and lipid goal.

Results: The combination therapy with amlodipine and atorvastatin for 16 weeks decreased clinic BP, and achievement of target BP control was attained in an average of 45% after the combination therapy in spite of the presence of no achievement at baseline. In addition, the combination therapy decreased the within-visit BP variability. With respect to the effects on renal damage markers, combination therapy with amlodipine and atorvastatin for 16 weeks significantly decreased albuminuria (UACR, 1034±1480 versus 733±1218 mg/g-Cr, P<0.05) without decline in eGFR. Concerning parameters of vascular function, the combination therapy significantly improved both baPWV and cSBP (baPWV, 1903±353 versus 1786±382 cm/sec, P<0.05; cSBP, 148±19 versus 129±23 mmHg, P<0.01).

Conclusions: These results suggest that the combination therapy with amlodipine and atorvastatin may exert additional beneficial effects on renal and vascular damages as well as BP profile in addition to BP lowering in hypertension with CKD.

SA-PO196

Effect of Antihypertensive Agents on the Severity of Obstructive Sleep Apnea: A Systematic Review and Meta-Analysis Kiran Khurshid,[1] Jonathan Yabes,[1] Patricia Weiss,[1] Mark L. Unruh,[2] Manisha Jhamb.[1] *[1]Nephrology, Univ of Pittsburgh, Pittsburgh, PA; [2]Nephrology, Univ of New Mexico, NM.*

Background: Adults with hypertension (HTN) have a high prevalence of obstructive sleep apnea (OSA). OSA is a known risk factor for HTN. However, the relationship may be bi-directional. The treatment of HTN to a lower BP target may improve sleep apnea both by improving upper airway tone and by reducing the nocturnal rostral fluid shifts through the use of a low-sodium diet and diuretics. The evidence on this is very limited. The aim of this study was to conduct a systematic review and meta-analysis of the effect of anti-hypertensive medications on OSA severity among hypertensive adults.

Methods: A literature search of PubMed and Embase was carried out for studies from 1980 to 2013 by a research librarian. Search concepts of sleep apnea, hypertension and drug classes used to treat HTN were used. Studies that reported objectively measured sleep apnea severity as an outcome were included. We excluded studies involving surgery or benzodiazepines as an intervention. If the sleep apnea was due to obesity-hypoventilation syndrome or high altitude sickness, it was excluded. There were no language restrictions, both published and unpublished articles were considered. Data was abstracted by 2 reviewers independently.

Results: Initial search yielded 18,577 articles, out of which 23 studies met our inclusion and exclusion criteria. These included 4 randomized controlled trials, 8 single arm studies, 5 cross-sectional studies, and 3 abstracts. Here we present results of meta-analysis of the 7 RCTs having a total of 198 participants including 28 women (6.5%). Trial quality was assessed by using Jadad scoring. Pooled estimate [95%CI] =-0.2752 [-0.4611, -0.0893] by fixed effects model. Pooled estimate [95%CI]= 0.5749 [-1.1712,0.0215] by random effects model.Test for homogeneity was rejected. (Q=84.2112, p<0.001). A funnel plot of the random effects model using REML showed asymmetry.

Conclusions: Evidence from small, single center studies with short-term follow-up suggests that use of anti-hypertensives may reduce severity of OSA in adults with hypertension.

SA-PO197

Evaluating the Impact of High-Dose Chemotherapy and Autologous Stem Cell Transplantation on Blood Pressure and Glomerular Filtration Rate in Multiple Myeloma Patients Chadi Y. Saad,[1] Joshua Fogel,[3] Leah Balsam.[1] *[1]Nephrology, NUMC, East Meadow, NY; [2]Finance and Business Management, Brooklyn College, Brooklyn, NY.*

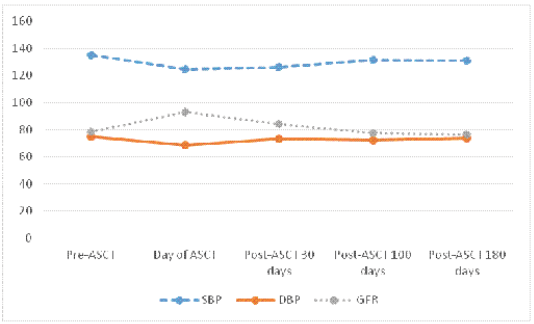
Background: Renal insufficiency is found at the time of diagnosis in almost 50% of multiple myeloma patients. Hypertension occurs in 35.8% -84.1%, of patients with CKD stages 1-5. Autologus stem cell transplantation (ASCT) may reverse kidney failure in one-third of multiple myeloma patients, which can lead to blood pressure improvement. We are not aware of any study that evaluates the impact of ASCT on improving blood pressure in multiple myeloma patients.

Methods: We studied 192 patients with an established diagnosis of multiple myeloma that underwent ASCT. We compared blood pressure readings and glomerular filtration rate GFR at 4 weeks before ASCT and then at day of ASCT and post-ASCT at 30, 100 and 180 days.

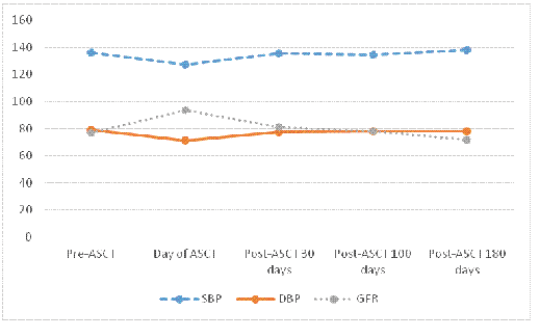
Results: For systolic blood pressure (SBP) and diastolic blood pressure (DBP), there was significantly lower mean SBP and DBP at day of ASCT and at both 30 and 100 days post-ASCT as compared to pre-ASCT SBP and DBP. For GFR, there was significantly higher mean GFR at day of ASCT and 30 days post-ASCT and significantly lower mean GFR at 180 days post-ASCT as compared to pre-ASCT. Whites had similar patterns for SBP, DBP, and GFR except for SBP which was still significantly lower and GFR which was not significantly different at 180 days. However, Blacks showed no significant reductions in the mean values of SBP and DBP and no significant increases for GFR in follow-up after day of ASCT. Furthermore, the mean value of GFR was significantly lower at 180 days post-ASCT.

Figure 1

Impact of ASCT on BP and GFR in White patients.



Impact of ASCT on BP and GFR in Black patients.



Note: SBP=systolic blood pressure, DBP=diastolic blood pressure, GFR=glomerular filtration rate.

Conclusions: ASCT in multiple myeloma patients had a positive impact on SBP and DBP and GFR but the impact was minimal for Black patients. We recommend that clinicians should consider more intense therapy for elevated blood pressure and closer follow-up of kidney function in Blacks.

SA-PO198

Immediate Blood Pressure Effect of Furosemide in Peritoneal Dialysis Patients

Caroline Lamarche, Vincent Pichette, Jean-Philippe Lafrance, Georges Ouellet, Robert Zoël Bell, Sarah Bezzaoucha, Michel Vallee. *Nephrology, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada.*

Background: Blood pressure (BP) lowering effect of furosemide is well documented and may be explained by a reduction in plasma volume. Nevertheless, some studies point out a possible immediate vascular effect, which could be mediated by the inhibition of the cotransporter NKCC1. Large doses of furosemide are frequently used in peritoneal dialysis (PD) patients to maintain residual diuresis. The aim of our study was to evaluate the immediate BP effect of large doses of oral and intravenous (IV) furosemide in PD patients.

Methods: The study was carried out on twelve PD patients. Each patient was given an oral dose of 500 mg of furosemide after a washout period of 7 days. BP was measured before the medication administration, at 30 minutes and one, two, four, six and twelve hours after furosemide administration. We also repeated the experiment in the same patient cohort with 250 mg of IV furosemide, after another washout period.

Results: In both oral and IV treatment there were no significant differences between systolic and diastolic BP at any time. Especially, BP was the same at baseline and 30 minutes after furosemide administration (139±15 / 76±11 to 137±20 / 78±15 mmHg, $p > 0.30$ for oral and 137±22 / 78±11 to 136±21 / 79±11 mmHg, $p > 0.44$ for IV). Thereafter the systolic BP decrease slowly, reaching a nadir at 12h which was not significant (-6.92 mmHg, $p = 0.070$ for oral and -2.58 mmHg, $p = 0.41$ for IV), whereas there was no effect on diastolic BP, even at 12h (+4.5 mmHg, $p = 0.28$ for oral and +3.08 mmHg, $p = 0.37$ for IV). In a mixed model analysis, the results was the same but the drop in systolic BP at 12h became significant (-6.92 mmHg, $p = 0.009$).

Conclusions: Large furosemide doses do not induce immediate blood pressure reduction in PD patients. There was a significant drop on systolic BP only twelve hours after furosemide administration. This may be explained by a natriuretic effet. As some authors point out, in vivo arterial response may occur only at supratherapeutic concentration, which is not achieved in a real clinical context.

SA-PO199

Impact of 2014 Evidence Based Guidelines for Hypertension on Patients with CKD

Ankit Sakhuja, Stephen C. Textor, Sandra J. Taler. *Mayo Clinic.*

Background: The recently published 2014 Evidence-Based Hypertension Guideline (2014 EBG) revised goal blood pressure for those 60 years or older, and for those with chronic kidney disease (CKD) or diabetes. The impact of these guidelines on the prevalence of uncontrolled hypertension in these subgroups is of interest to Nephrologists, particularly in regard to control rates in CKD.

Methods: The prevalence of uncontrolled hypertension was estimated by 2014 EBG and JNC 7 guidelines using data from the National Health and Nutrition Examination Survey for the years 2011 and 2012**.** We estimated the prevalence of uncontrolled hypertension stratified by age-group, sex, race and presence of CKD or diabetes. Predictors to being reclassified to controlled hypertension by the 2014 EBG were assessed using multivariable logistic regression.

Results: Prevalence of uncontrolled hypertension was 12.8% by the 2014 EBG in comparison to 16.6% by JNC 7 ($p<0.001$). 23.0% of those with uncontrolled hypertension by JNC 7, were reclassified to controlled hypertension by the 2014 EBG. Those reclassified to controlled hypertension were more likely to be in the 60-74 year age group (OR 3.89; 95% CI: 1.58-9.59), female (OR 1.88; 95% CI: 1.30-2.73) and with diabetes (OR 2.03; 1.24-3.30). When stratified based on the presence of CKD or diabetes, those with CKD only were least likely to be reclassified (22.1% for CKD alone versus 35.8% with Diabetes alone, 34.2% with CKD and diabetes and 41.4% for those ≥60 years old without diabetes or CKD; $p=0.01$).

Conclusions: The prevalence of uncontrolled hypertension has declined from 16.6% to 12.8% using the 2014 EBG in comparison to JNC 7 guidelines. The greatest impact of reclassification from uncontrolled to controlled hypertension is on the elderly, females and those with diabetes. Those with CKD only were less often reclassified, indicating a group where greater attention to treatment is still needed.

SA-PO200

Tetrahydrobiopterin and Exercise Capacity in Patients with Chronic Kidney Disease

Jeanie Park,[1,2] Arshed A. Quyyumi.[3] *[1]Renal Div, Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA; [2]Research Service Line, Atlanta VA Medical Center, Decatur, GA; [3]Cardiology Div, Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA.*

Background: Patients with chronic kidney disease (CKD) have poor physical capacity and exercise intolerance. Our prior studies have shown that CKD patients have an exaggerated blood pressure (BP) response during acute exercise, which could contribute to reduced exercise capacity and adverse cardiovascular events. Nitric Oxide (NO) levels increase substantially during exercise to increase muscle blood flow and prevent excessive hypertension; therefore, reduced NO bioavailability may be one major factor contributing to the exaggerated exercise pressor response, since CKD is characterized by decreased NO bioavailability. Tetrahydrobiopterin (BH4) is an essential cofactor for endothelial nitric oxide synthase (eNOS) that has been shown to increase NO bioavailability in experimental models of CKD. Therefore, we hypothesized that long-term BH4 supplementation may ameliorate the exaggerated increase in BP during exercise, and improve exercise capacity in patients with CKD.

Methods: We conducted a randomized, double-masked, placebo-controlled trial testing the potential benefits of oral BH4 treatment on exercise capacity and exercise pressor responses in 36 patients with CKD Stages II and III. Patients were randomized to 12 weeks of: 1) 200mg BH4 twice daily + 1mg folic acid once daily; versus 2) matching placebo twice daily + 1mg folic acid once daily. The primary endpoints were change in exercise capacity measured via peak oxygen uptake (V02 max) during maximal exercise treadmill testing, and change in BP during maximal exercise. Secondary endpoints included change in exercise-induced oxidative stress.

Results: We observed no significant difference in change in exercise capacity measured as V02 max between patients treated with BH4 versus placebo. We also observed no differences in BP responses, or oxidative stress responses during exercise between the groups.

Conclusions: Chronic BH4 treatment does not improve exercise capacity or lower BP responses to maximal exercise in hypertensive patients with CKD.

Hypertension and Blood Pressure Variability in NEPTUNE

Christine B. Sethna,[1] Laura H. Mariani,[2,7] Robert J. Weyant,[7] Tammy M. Brady,[6] Kevin E.C. Meyers,[4] Keisha L. Gibson,[5] Larysa T. Wickman,[2] Crystal A. Gadegbeku.[3] *[1]Cohen Children's Medical Center of New York, NY; [2]U. of Michigan, MI; [3]Temple U., PA; [4]The Children's Hospital of Philadelphia, PA; [5]U. of North Carolina, NC; [6]Johns Hopkins U., MD; [7]Arbor Research, MI.*

Background: The prevalence, variability and treatment of hypertension (HTN) in nephrotic syndrome (NS) are not well described. Increased visit-to-visit blood pressure variability (BPV) has been associated with progression of renal disease, but has not been characterized in NS.

Methods: Data were from 376 participants in the multicenter Nephrotic Syndrome Study Network (NEPTUNE). HTN was defined as BP ≥140/90 mmHg for adults and ≥95% for children, and was the reference for BP index (BPi). Pre-HTN was defined as BP≥120/80

or ≥90% for children. BPV was measured as standard deviation (SD) and average real variability (ARV) in 246 participants with ≥3 BP readings. Regression models examined the association of BPV with eGFR at last visit.

Results: 248 adults (45.7±16.6 yr, 61% M, 21% Black) and 128 children (9.7±5.1 yr, 57% M, 40% Black) with mean eGFR of 81.7±37.8 ml/min/1.73m^2 and UPC 3.4±4.1 were evaluated. At baseline, 26% and 34% had pre-HTN and HTN, respectively. 55% were on RAAS blockade. Children were more likely hypertensive (43% versus 29%, p<0.001) and less likely on anti-hypertensives compared to adults. SD (β=-0.91, p<0.01) and ARV (β=-0.74, p<0.01) were associated with eGFR at last visit, adjusting for demographics, diagnosis, medications and baseline eGFR.

	Adults	Children	All	P
Pre-HTN	88(35%)	13(10%)	101(26%)	<0.0001
HTN	75(29%)	57(43%)	132(34%)	
SBP/DBP	125±18/77±12	112±14/70±12	121±18/75±12	<0.0001
SBP%/DBP%		73±26/77±25		
SBPi	0.90±0.13	0.94±0.11	0.91±0.13	<0.001
DBPi	0.86±0.13	0.93±0.19	0.88±0.16	<0.0001
SD	11.5±5.6	8.2±4.4	10.4±5.7	<0.0001
ARV	12.2±7.2	8.4±5.1	10.9±8.4	<0.0001
Steroid	61(24%)	78(59%)	139(36%)	<0.001

Conclusions: In NEPTUNE, HTN is common and under-treated despite significant use of anti-hypertensives. Differences in prevalence, BPV and treatment were found between adults and children. Lastly, BPV is an independent predictor of renal function in this cohort.

SA-PO202

Practice Audit of Renal Denervation Procedure for Drug-Resistant Hypertension Praveena Sivapalan,[1] John Floras,[1,5] Douglas Jeffrey Ing,[1,5] George Dimitrios Oreopoulos,[2,3,5] Dheeraj K. Rajan,[3] Coimbatore Srinivas,[4] Duminda N. Wijeysundera,[4] Alexander G. Logan.[1] *[1]Medicine, Univ Health Network (UHN) and Mount Sinai Hospital, Toronto, ON, Canada; [2]Surgery, UHN, Toronto, ON, Canada; [3]Interventional Radiology, UHN, Toronto, ON, Canada; [4]Anesthesia, UHN, Toronto, ON, Canada; [5]Peter Munk Cardiac Center, UHN, Toronto, ON, Canada.*

Background: While two seminal but unblinded trials demonstrated substantive reductions in office blood pressure (BP) following renal denervation (RDN) in patients with drug-resistant hypertension (DRH), this was not confirmed in the large American randomized, sham-controlled Symplicity HTN-3 trial. Thus, we suspended our institution's RDN program pending audit of our "real-world" experience with the procedure, which we report herein.

Methods: In a retrospective office chart review, we assessed the effects of RDN in patients with 'true' DRH at 6- and 12-months after the procedure. Office BP was measured sitting quietly alone 5 times using an automated device.

Results: Of 105 patients referred for initial evaluation, 21 were eligible and agreed to have the procedure. BP averaged 170.0±26.3/89.6±18.8 (mean ± SD) mm Hg at baseline, 148.6 ± 23.0/81.9±19.0 at 6 months (p = 0.01 and 0.18 for systolic BP and diastolic BP, respectively) and 156.5±22.4/83.0±18.3 mm Hg at 1 year (p = 0.16 and 0.27). 63 and 42% of patients achieved a systolic BP reduction of > 10 mm Hg at 6 and 12 months, respectively. There was no significant change in the average number of antihypertensive drugs used at 6 months or 1 year (p = 0.18, 0.22). Serum creatinine, which averaged 90.4±22.9 umol/L at baseline, rose to 106.8±42.3 umol/L at 1 year (p = 0.03). There were 9 peri-procedural complications, including a renal artery dissection and acute renal failure, which resolved.

Conclusions: RDN had no effect on diastolic BP and only lowered systolic BP significantly at 6 months. Moreover, there was a wide variation in BP response and we observed several serious complications with a trend towards worsened renal function. Based on the outcomes of this audit, we are reserving RDN for patients who are adherent to antihypertensive drug treatment and suspected to have neurogenic DRH.

SA-PO203

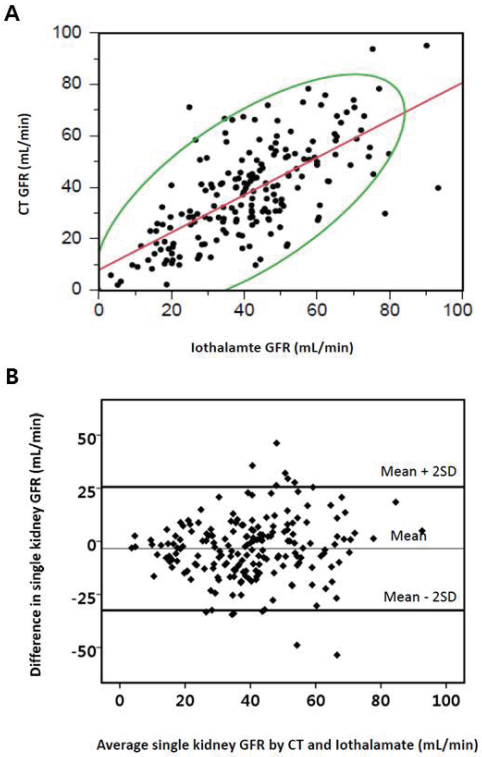
Determination of Single-Kidney Glomerular Filtration Rate in Human Subjects By Computed Tomography Soon Hyo Kwon,[1] Ahmed Saad,[1] Sandra Herrmann,[1] Cynthia H. Mccollough,[2] Stephen C. Textor,[1] Lilach O. Lerman.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Medical Physics and Biomedical Engineering, Mayo Clinic, Rochester, MN.*

Background: Determination of single-kidney glomerular filtration (SK-GFR) is important in various clinical settings, but difficult to obtain noninvasively. Multi-detector computed tomography (MDCT) provides reliable GFR measurements in animal models. This study assessed the feasibility and validated MDCT assessments of SK GFR in human subjects (n=96).

Methods: Patients with essential hypertension (EH; n=50) or renovascular hypertension (n=46) were prospectively studied under controlled conditions (sodium intake and renin-angiotensin blockade). GFR were measured using MDCT (calculated from contrast-media time density curves), and compared to GFR measured by iothalamate clearance, which was assigned to the right and left kidney by their relative volumes. The reproducibility of CT-GFR over a 3-months period was assessed in patients with renal artery stenosis (RAS) on stable medical treatment (n=21).

Results: SK CT-GFR values were similar to SK iothalamate clearance (38.2±1 versus 41.6±17 mL/min). Stenotic kidney CT-GFR was lower compared to contralateral GFR and to EH single kidney GFR (23.6±14 versus 37.2±17 and 45.2±16 mL/min, respectively, both p<0.0001), as was iothalamate clearance. CT-GFR correlated well with iothalamate-GFR (r=0.66, p<0.0001), and Bland-Altman analysis confirmed their agreement.

Figure 1.



CT-GFR also showed high reproducibility over 3 months.

Conclusions: CT assessments of SK-GFR are reproducible and agree well with a reference standard. CT can be useful to estimate noninvasively bilateral SK function in human subjects.

Left Ventricular Hypertrophy (LVH) Assessment by Cardiac Magnestic Resonance Imaging (cMRI) in Relation to 24 Hour Ambulatory Blood Pressure Monitoring (ABPM) in Children Katarina Supe-Markovina, James Nielsen, Laurie E. Panesar, Robert Woroniecki. *Pediatrics, Stony Brook Children's Hospital, Stony Brook, NY.*

Background: LVH is a clinical marker of hypertensive end-organ damage. In adults cMRI is considered "gold standard" for left ventricular mass (LVM) measurement, whereas in children LVM is derived from ECHO measurements indexed to age/height norms to assess for presence of LVH. Although ECHO is widely available, there are several issues with its ability to assess LVM. ECHO has technical, observer, and patient variables which may hinder its clinical use especially in overweight children. Quantification of volumes and mass relies on geometric assumptions that do not apply to ventricles undergoing asymmetric cardiac remodeling.

Methods: Our objective is to compare LVM measurements by ECHO and cMRI in relation to severity of hypertension assessed by ABPM. We collected existing data on children evaluated in our Hypertension Center. Each subject had ECHO, cMRI, ABPM, urine microalbumin, eGFR (modified Schwartz formula). LVM by ECHO was obtained and calculated by m-mode utilizing Devereux equation. cMRI LVM was measured from standard short-axis diastolic cine-images covering the entire left ventricle.

Results: We had a total of 15 subjects, 33% females, 66% caucasian, 15±3.8 years old; BMI 28.6±6.6, eGFR=83.8 ± 19.8 ml/min/1.73m^2. 1/15 subjects had microalbuminuria, 7/15 subjects had LVH by ECHO and 6/15 had LVH by cMRI. By ECHO LVM was 172.5 ± 60.9g and by cMRI 152.8 ± 43.6g, p=0.099 (paired t-test). 10/15 patients had consistent ECHO and cMRI results, 2 subjects who had normal ECHO had abnormal cMRI. 3 subjects with abnormal ECHO had normal cMRI, p=0.31 (Fisher's exact). Pairwise correlation of abnormal LVM between ECHO and cMRI was 0.76, p=0.003. We found no statistically significant correlation among ABPM variables with ECHO and cMRI including LVM/volume.

Conclusions: In our hypertensive children cMRI and ECHO showed different LVM yet the difference was not statistically significant. Relationship of ABPM parameters and LVM were not statistically different between the 2 methods. Our study is limited by small sample size and longitudinal assessment in the future will be required.

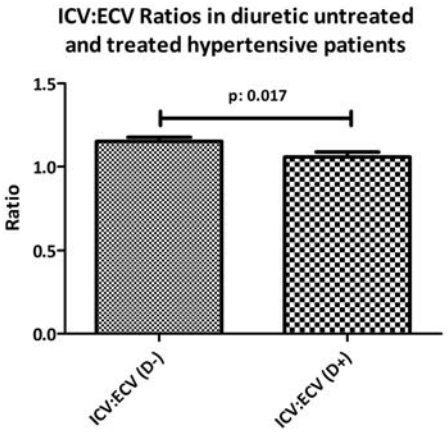
SA-PO205

Effect of Diuretics on Body Fluid Spaces in Hypertensive Patients as Measured by Bioimpedance Neville R. Dossabhoy,[1] Tibor Fulop,[2] Istvan Barna,[3] Maria Faludi,[4] Klara Berta,[4] Zsolt Lengvarszky,[5] Tibor Szarvas,[5] Mihaly B. Tapolyai.[3] *[1]Medicine, VA Medical Center, Shreveport, LA; [2]Univ Medical Center, Jackson, MS; [3]Semmelweis Univ, Budapest, Hungary; [4]Fresenius SOTE, Hungary; [5]LSUS, Shreveport, LA.*

Background: Many of the side-effects of diuretics come from a reduction in Extracellular Fluid Volume (ECV). We examined the association of diuretics and body fluid spaces in hypertensive patients.

Methods: This is a cross-sectional study of 60 hypertensive patients - with no known endocrine, urological or renal abnormalities - in a hypertension clinic who underwent a multichannel bioimpedance analysis.

Results: The use of diuretics had no correlation with achieved blood pressure (diuretics treated *versus*. untreated: 137/76 *versus*. 135/81 mmHg; P=0.66), but it did with the total number of antihypertensive medications (3.1 *versus*. 1.3; P<0.0001) and age (66.7 *versus*. 75.2 years; P<0.0001). Overhydration is greater numerically in the diuretic-use group only to a non-significant degree (5.9 *versus*. 2.9%; P=0.21). The total body water (39.8 *versus*. 40.5 L; P=0.64), ECV (18.5 *versus* 19.7 L; P=0.35) and Intracellular Fluid Volume (ICV) (21.3 *versus*. 20.8 L; P=0.75) were not significantly different in the untreated v. treated group. The ratio of ICV:ECV, however, seems to have been affected significantly; this ratio is 1.15 among patients who do not take diuretics, but 1.05 among those who do (P=0.017).



Conclusions: These results seem to challenge the notion that the ICV would be constant or inaccessible to renal function or fluid loss by diuresis. The diuretic-related distortion of ICV:ECV ratio indicates that the intracellular space is also affected or the fluid is redistributed in the body. To clarify the effect of diuretics, further studies are needed. The use of bioimpedance analysis may represent a potential clinical tool to help achieve euvolemia in hypertensive patients.

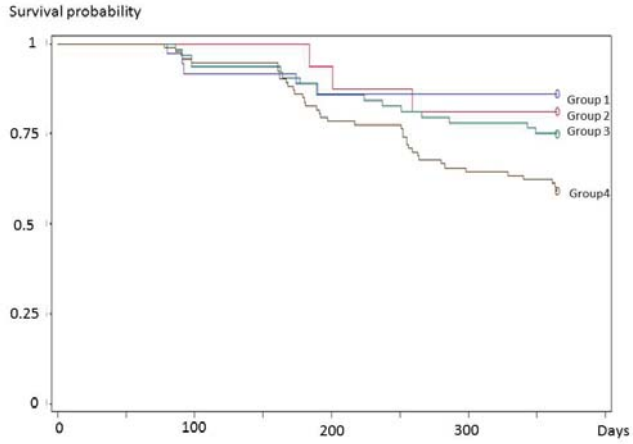
SA-PO206

Changes in Protein and Salt Intakes Are Associated with the Progression of Chronic Kidney Disease Eiichiro Kanda,[1] Masumi Ai,[2] Renjiro Kuriyama,[3] Masayuki Yoshida,[2] Tatsuo Shiigai.[4] *[1]Tokyo Kyosai Hospital, Japan; [2]Tokyo Medical and Dental Univ; [3]Kokubunji Minamiguchi Clinic; [4]Shiigai Clinic.*

Background: Although protein and salt restriction prevents the progression of chronic kidney disease (CKD), adhering to such dietary restriction is sometimes difficult. In this retrospective cohort study, we investigated the longitudinal effects of changes in protein and salt intakes on the progression of CKD.

Methods: CKD patients (249) under a low-protein (0.6 to 0.8g/kg/day) and low-salt (<6g/day) diet were enrolled in this study in Japan. Their protein intake was determined by Maroni's formula every three months for one year. The longitudinal changes in protein and salt intakes were evaluated by their coefficients of variation (CVs), on the basis of which patients were categorized into 4 groups. The primary outcome was a 25% decline in estimated glomerular filtration rate (eGFR) or starting dialysis. Dietary intakes were treated as time-dependent variables.

Results: Mean age (SD) was 70.6(7.0)years; eGFR, 22.2(14.1)ml/min; protein intake, 0.85(0.22)g/day, CV, 0.14(0.08); salt intake, 7.8(3.1)g/day, CV, 0.22(0.12); follow-up period, 322.5(82.6)days. The primary endpoint was observed in 65 patients (26.1%). Kaplan–Meier survival curves showed that group 1 (low CV) had a higher survival of kidney function than group 4 (high CV).



Time-dependent Cox proportional hazard models adjusted for patient characteristics showed that the outcome was associated with very low protein intake (<0.6g/kg/day) [aHR 7.125 (1.233, 41.160)] and high salt intake [aHR 8.446 (1.482, 48.140)]. A generalized estimating equation model showed a positive longitudinal relationship between protein and salt intakes (p=0.0001).

Conclusions: Protein and salt intakes and their changes are associated with CKD progression. It is important to maintain stable dietary intakes to prevent CKD progression.

SA-PO207

Long Term Impact of Low Protein Diet on Outcomes in Patients with Chronic Kidney Disease Elaine Ku,[1] David V. Glidden,[1] Kirsten L. Johansen,[1] Barbara A. Grimes,[1] Mark J. Sarnak,[2] Hocine Tighiouart,[2] Chi-Yuan Hsu.[1] *[1]UCSF; [2]Tufts.*

Background: We previously reported that in extended follow-up of the Modification of Diet in Renal Disease (MDRD) study (Ku SA-OR048, ASN 2013), strict blood pressure control appeared to confer lower risk of mortality post-ESRD (although it did not change risk of ESRD). In this study, we hypothesized that exposure to lower protein diet during CKD would lead to higher risk of death post-ESRD due to malnutrition.

Methods: We extended follow-up of the MDRD trial (1989-1993) via cross-linkage with U.S. Renal Data System and National Death Index to ascertain ESRD onset and vital status through 12/31/2010. MDRD Study A participants had GFR between 24.5 and 55 mL/min/1.73 m^2 and were randomized to 1.3 versus 0.58 g protein/kg/day (N=423). Study B participants had GFR ranging from 13 up to 24.5 mL/min/1.73 m^2 and were randomized to 0.58 versus 0.28 g protein/kg/day (N=417). We pooled both studies and compared the long-term effect of higher versus lower protein diet using a Cox model for risk of death with ESRD as a time-dependent covariate.

Results: Of the 840 MDRD enrollees, 627 developed ESRD by 12/31/2010. Contrary to our hypothesis, we found no difference in risk of death post-ESRD among patients assigned to lower protein diets during the study. There were 157 deaths in the lower protein diet arm and 167 deaths in the higher protein diet arm (unadjusted hazard ratio [HR] 1.13; 95% CI 0.91-1.41; p = 0.26). We also noted no difference in risk of death pre-ESRD (unadjusted HR 0.93; 95% CI 0.65-1.32; p = 0.67). For the subset of patients who started dialysis after 1995 in whom we had laboratory data per CMS-2728 form, no significant differences were noted in body mass index (p=0.25) or serum albumin (p=0.34) among those previously randomized to higher versus lower protein diet. We did note a lower risk of ESRD in the lower protein diet arm (unadjusted HR 0.84; 95% CI 0.72-0.98; p = 0.03). Results were similar when study A and B were analyzed individually.

Conclusions: Unlike strict BP control, low protein diet during CKD did not appear to impact mortality post-ESRD.

SA-PO208

Low Score of Dietary Approaches to Stop Hypertension (DASH) Diet Is Associated with Chronic Kidney Disease (CKD) Risk in U.S. Adults Tanushree Banerjee,[1] Deidra C. Crews,[2] Jennifer L. Bragg-Gresham,[3] Rajiv Saran,[3] Meda E. Pavkov,[4] Desmond Williams,[4] Neil R. Powe.[1] *[1]UCSF; [2]JHU; [3]UM; [4]CDC.*

Background: In addition to lowering blood pressure, a DASH-type diet reduced kidney function loss in women with mildly decreased estimated glomerular filtration rate (eGFR), an effect primarily associated with reduced red meat intake.We investigated whether a DASH diet, rich in fruits, vegetables, nuts and legumes, is associated with prevalent CKD.

Methods: We conducted a national cross-sectional study using the 24-hr dietary recall of 15,171 adults aged ≥20 years enrolled in the National Health and Nutrition Examination Survey III, between 1988 and 1994. We calculated a DASH-diet adherence score based on 9 target nutrients: total fat (TF), saturated fat, protein, fiber, cholesterol, calcium (Ca), magnesium (Mg), sodium (Na), and potassium (K). Adherence was defined as score ≥4.5 out of a possible score of 9. Logistic regression was used to explore the relation of DASH

score tertile and (i) eGFR<60 ml/min/1.73 m^2 and (ii) albumin-to-creatinine ratio (ACR) ≥ 30 mg/g, adjusting for demographics, socio-economic factors, smoking, diabetes, and hypertension.

Results: The mean age of participants was 48.6 years, 46.9% were males, 26.9% were blacks, and median DASH score was low (2.5, interquartile range 2.0-4.0). 7.8% of participants had an eGFR<60 ml/min/1.73 m^2. Those in the lowest DASH tertile were more likely to be males, poor, current smokers, and have lower education level while those in the highest tertile were more likely to have diabetes and hypertension. Among those with CKD (15≤eGFR<60 ml/min/1.73 m^2 or ACR≥30 mg/g), 5.5% were adherent. Intake of fiber, Mg, Ca, K were lower while cholesterol, Na, TF, and protein were higher among the CKD versus non-CKD group (v P<0.05). The lowest DASH tertile compared to highest was associated with greater odds of eGFR<60 (OR [95% CI]:1.6[1.2-2.0]) but no statistically significant association with high ACR was found (1.1[0.9-1.3]), after full adjustment.

Conclusions: A low Dash diet score was associated with lower eGFR but not ACR levels. More studies are needed to examine the role of diet on both the prevalence and progression of CKD.

SA-PO209

Dietary Acid Load and Incident Chronic Kidney Disease: The Atherosclerosis Risk in Communities Study C. Rebholz, M. Grams, Deidra C. Crews, Lawrence J. Appel, Josef Coresh. *Johns Hopkins Univ.*

Background: Higher dietary acid load can result in metabolic acidosis and is associated with faster kidney disease progression in chronic kidney disease (CKD) patients. However, this relationship has not been evaluated in the general population.

Methods: We conducted prospective analyses of ARIC Study participants without CKD at baseline (1987-89, N=15,100). Dietary acid load was estimated by calculating potential renal acid load of usual dietary intake assessed by a food frequency questionnaire (PRAL=0.49*protein+0.037*phosphate-0.021*potassium-0.026*magnesium-0.013*calcium). Incident stage 3 CKD was assessed from baseline through 2010. Cox proportional hazards regression was used to estimate the association of dietary acid load (PRAL) with incident CKD, adjusting for age, sex, race, total caloric intake, and baseline eGFR. Analyses were repeated after stratifying by race.

Results: Median (25th, 75th percentiles) PRAL was 4.37 (-3.86, 12.79) mEq/day. At baseline, higher levels of PRAL were associated with younger age, black race, and male sex (p for all <0.001). During a median follow-up of 24 years, there were 2,351 (15.6%) incident CKD cases [765 (19.6%) in blacks, 1,586 (14.2%) in whites, p<0.001]. Those participants who developed CKD had higher dietary intake of protein, and lower intake of magnesium and calcium than those participants who did not develop CKD. Dietary intake of phosphate and potassium was similar by CKD status. In the overall study population, higher levels of PRAL were significantly associated with risk of incident CKD. The findings were significant only among blacks.

Population	Hazard Ratio	95% Confidence Interval	P for interaction
Overall	1.06	1.00, 1.11	
Blacks	1.13	1.03, 1.24	0.14
Whites	1.02	0.96, 1.09	

Conclusions: Dietary acid load is associated with incident stage 3 CKD among blacks, but not whites. Reducing dietary acid load, previously associated with slower rates of kidney disease progression in CKD patients, might also prevent CKD.

High Protein Diet Alters the Metabolic Status of Mice Comparable to Changes in Uremic Toxin Levels Observed in Renal Failure Patients Jitske Jansen,[1,2,3] Henricus A.M. Mutsaers,[1,2,3] Lambertus P.W.J. Van den Heuvel,[2] Joost Hoenderop,[3] Rosalinde Masereeuw.[1] *[1]Pharmacology-Toxicology, Radboudumc, Netherlands; [2]Pediatrics, Radboudumc, Netherlands; [3]Physiology, Radboudumc, Nijmegen, Netherlands.*

Background: Many of the well-studied uremic toxins originate from the diet and are generated in the colon due to protein fermentation by intestinal bacteria. Here, we examined the impact of a high protein diet on the plasma concentration of a variety of uremic toxins to obtain insight in the interplay between dietary protein and uremic solutes.

Methods: Wild type (WT) Friend leukemia virus B (FVB) mice were fed control (21% crude protein; n=10) or high protein (HP; 45% crude protein; n=10) diet for 21 days, after which mice were sacrificed and uremic toxins were measured by LC-ESI-MS/MS.

Results: Mice fed HP diet developed polyuria (HP: 0.8 ± 0.2 mL/18 h versus control: 0.3 ± 0.04 mL/18 h; p=0.025), implying the presence of renal failure, and showed higher plasma levels of the phenol-derived metabolites phenylacetic acid (1.9 ± 0.3 μM, p=0.01), phenyl sulfate (3.9 ± 0.8 μM, p=0.0061), phenyl glucuronide (0.2 ± 0.05 μM, p=0.0095), p-cresyl glucuronide (1.6 ± 0.3 μM, p=0.0093) and hippuric acid (0.1 ± 0.01 μM, p=0.0002) compared to mice provided with control diet (1.1 ± 0.1 μM, 1.4 ± 0.3 μM, 0.03 ± 0.007 μM, 0.7 ± 0.1 μM and 0.04 ± 0.008 μM, respectively). In addition, a reduction in tryptophan concentration (HP: 93 ± 11 μM versus control: 127 ± 5 μM, p=0.011) was observed as well as 1.2 fold increase in indoleamine 2,3-dioxygenase (IDO) activity (P=0.0389). Furthermore, in mice fed HP diet, indoxyl sulfate levels significantly increased from 3.6 ± 0.7 μM (control) to 7.1 ± 1.7 μM (p=0.015). In contrast, p-cresyl sulfate and kynurenic acid levels remained unaltered, and kynurenine and indole-3-acetic acid concentrations diminished (p<0.05).

Conclusions: A HP diet alters the metabolic status of mice comparable to changes observed in chronic kidney disease patients. This supports the hypothesis that managing the levels of dietary protein intake in patients may be of key importance since high protein intake will augment uremic toxin levels, whereas a restriction in dietary protein might cause protein-energy wasting.

SA-PO211

Influence of a High Protein Diet on the Human Metabolome Ruben Poesen,[1] Karen Windey,[2] Rosalinde Masereeuw,[3] Petra Van Den Broek,[3] Pieter Evenepoel,[1] Kristin Verbeke,[2] Bjorn Meijers.[1] *[1]Nephrology, Univ Hospitals Leuven, Belgium; [2]TARGID, Univ of Leuven, Belgium; [3]Pharmacology and Toxicology, Radboud Univ Medical Center, Netherlands.*

Background: There is a long held belief that protein restriction may attenuate CKD progression. Lately, there is a renewed interest in metabolites originating from protein fermentation as potential driving forces behind adverse outcome in renal disease. Indoxyl sulfate and p-cresyl sulfate, both protein fermentation metabolites, have been associated with CKD progression, supporting the so-called protein metabolite hypothesis. The influence of protein intake on these and other metabolites has not been fully elucidated.

Methods: 29 healthy volunteers were randomized to a high or a low protein diet for 2 weeks. Blood and urine were sampled before and after intervention. All samples were analyzed by liquid chromatography mass spectrometry for measurement of a panel of metabolites, focusing on tryptophan and phenol metabolites. Urinary collections were used to calculate 24h urinary excretion rates as a surrogate of intestinal generation. Differences in plasma levels and urinary excretion rates were compared with the Wilcoxon rank sum test.

Results: After randomization, 14 subjects received a high protein diet and 15 subjects were allocated to a low protein diet. There were no between-group differences in age, gender and BMI. In the high protein group, we observed a significant increase in plasma levels of indoxyl sulfate (median 19% increase in high protein group versus 18% decrease in low protein group, P 0.004). When considering urinary excretion rates, we also noted significant increases of indoxyl sulfate (+33% versus -9%, P 0.001), indoxyl glucuronide (+80% versus -6%, P 0.01), kynurenic acid (+34% versus -4%, P 0.006) and quinolinic acid (+15% versus -6%, P 0.02).

Conclusions: High protein intake is associated with increased plasma levels and generation rates of different metabolites, including indoxyl sulfate, indoxyl glucuronide, kynurenic acid and quinolinic acid. As part of these metabolites are known uremic retention solutes possibly contributing to CKD progression, these findings give additional insights in the presumed beneficial effects of protein restriction in CKD.

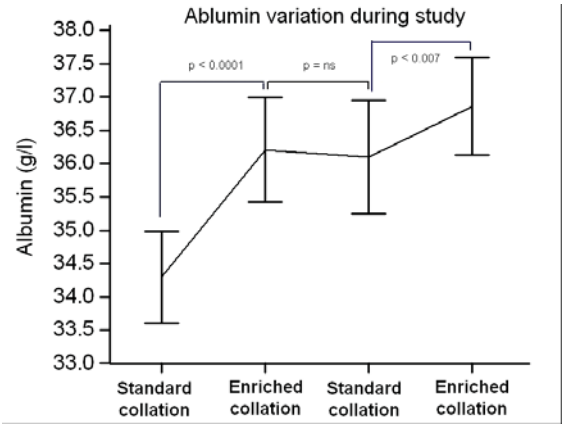
SA-PO212

Nutritional Impact of a Protein-Enriched Snack During the Hemodialysis Session: Results of the COLENDIA Study Patrik Deleaval, Anne-Lise Bernollin, Guillaume Jean, Charles Chazot. *Nephrology and dialysis, Nephrocare Tassin Charcot, Sainte-Foy-Les-Lyon, France.*

Background: Protein energy wasting (PEW) is frequent in hemodialysis (HD) patients. Therefore, it is necessary to develop simple but effective nutritional strategies to prevent this complication. The aim of our study was to assess the impact of an intradialytic protein-enriched snack on nutritional parameters.

Methods: The study design was a prospective double-cross over study during 4 periods of 4 months each. Patients were given alternatively standard (protein : 8.2 g) or protein-enriched (28.2g) snack (hot drink, DELICAL floridin® cream and 3 DELICAL Nutra'cake® biscuits). 73 patients on 3 weekly HD sessions for more than 3 months and receiving the usual snack during dialysis were included. Patients receiving immunosuppressive therapy, treated for active cancer or hospitalized for more than 4 weeks were excluded. No selection on nutritional criteria was applied.

Results: Albumin increased significantly from 34.29 ± 2.83 g/l to 36.20 ± 3.21 g / l (p <0.0001) between the first (standard snack) and second period (enriched snack). In the third period (standard snack), the albumin concentration remain stable (36.09 ± 3.52 g/l). After the 4th period (enriched collation) there was a further significant increase in serum albumin (36.86 ± 3.02 g/l) as compared to the second as third period (respectively p = 0.05 and p = 0.007).



Prealbumin, weight and NPNA did not vary significantly during the 16-month study. A bioimpedance was conducted at the end of each period. The hydration status did not change throughout the period.

Conclusions: This study demonstrates that the distribution of a protein-enriched snack during the haemodialysis session in unselected patients significantly increases their serum albumin. As markers of PEW are powerful predictors of mortality, this simple and effective strategy can be of great interest.

SA-PO213

High Amylose Resistant Starch Diet Ameliorates Oxidative Stress, Inflammation, and Progression of Chronic Kidney Disease (CKD) Shuman Liu,[1] Sohrab Nazertehrani,[1] Seyed Farzaneh,[1] Wei Ling Lau,[1] Mahyar Khazaeli,[1] Sean H. Adams,[2] Dorothy Kieffer,[2] Martin Roy J,[2] Nosratola D. Vaziri.[1] *[1]Div of Nephrology, UC Irvine; [2]Dept of Nutrition, UCD.*

Background: The gut microbiome is profoundly altered in advanced CKD due, in part, to: influx of urea in the intestinal tract which leads to the dominance of urease-possessing bacteria and restriction of potassium-rich fruits and veggies which are the main source of dietary fiber. The latter leads to contraction of bacteria that convert fiber to short chain fatty acids (SCFA). Conversion of urea to NH_3 by bacterial urease damages epithelial tight junction which evokes inflammation via influx of endotoxin in the circulation. This is compounded by diminished supplies of SCFA which are essential for growth of anti-inflammatory regulatory T cells. We, therefore, hypothesized that soluble fiber supplementation may attenuate oxidative stress, inflammation and CKD progression.

Methods: SD rats were fed a chow containing 0.7% adenine for 2 weeks to induce chronic interstitial nephropathy (CKD). They were then placed on either regular or 30% resistant starch containing diet for 3 weeks. Rats fed regular diet served as controls.

Results: Compared with the controls, CKD rats exhibited impaired urinary concentrating capacity, reduced creatinine clearance, interstitial fibrosis, leukocyte infiltration, tubular damage, activation of NF_kB, upregulation of pro-inflammatory (MCP-1, COX-1, COX-2, iNOS), pro-oxidant (gp91, and NOX-4) and pro-fibrotic (PAI-1, TGF-β, and α-SM actin) molecules; impaired Nrf2 activity, and down-regulation of antioxidant/cytoprotective enzymes (catalase, superoxide dismutase, glutathione peroxidase and heme oxigenase-1). The resistant starch diet improved creatinine clearance, urine concentrating capacity, interstitial fibrosis, inflammation, and tubular damage and attenuated oxidative, inflammatory, and fibrotic pathways and partially restored Nrf2 activity.

Conclusions: Resistant starch supplementation retards CKD progression, attenuates oxidative stress and inflammation, and improves endogenous cytoprotective pathways in CKD rats. Future studies are needed to explore the impact of high fiber diet in CKD patients.

SA-PO214

Obesity Induced Chronic Inflammation in Long-Term High Fat Diet Challenged C57Bl6j Mice Is Associated with the Development of Renal and Cardiac Amyloidosis Roel A. van der Heijden,[1] Johannes Bijzet,[2] Davith De Vries,[1] Bouke P. Hazenberg,[2] Grietje Molema,[1] Peter Heeringa.[1] *[1]Dept Medical Biology, ; [2]Rheumatology, Univ Medical Center Groningen, Netherlands.*

Background: Obesity-induced chronic inflammation is considered an accelerating factor in the development of age-associated cardiovascular diseases (CVD) and is a risk factor for chronic kidney diseases (CKD). Little is known about the sequence of events involved in obesity induced CVD. The aim of the current study was to investigate the effects of obesity on the evolution of age associated CV complications in high fat diet challenged C57Bl6j mice.

Methods: C57Bl6J male mice (99 in total) were fed a low (10% lard; LFD) or high (45% lard; HFD) fat diet for a maximum of 52 weeks. Mice were monitored for development of obesity, metabolic alterations and cardiovascular complications. Blood and urine samples were taken at monthly intervals. Cohorts of mice were sacrificed after 24, 40 and 52 weeks, and organs were collected for histological and gene expression analyses.

Results: High fat feeding induced an obese phenotype characterized by increased body and organ weights, altered lipid and insulin homeostasis, low grade systemic inflammation, and increased adipokine release in time. Renal and cardiac gene expression analyses showed upregulation of pro-inflammatory and pro-fibrotic genes, along with elevated urinary albumin and NGAL levels. A progressive sclerotic phenotype in kidney and heart was observed in time in both LFD and HFD mice, but was more extensive in HFD mice. Lesions stained positive for Congo red and exhibited birefringence in polarized light consistent with the development of amyloidosis. The degree of amyloidosis correlated significantly with body weight. By immunohistochemistry, the amyloid deposits stained positive for serum amyloid A (SAA) protein. Moreover, plasma levels of SAA were chronically elevated upon HFD and significantly higher compared to LFD mice.

Conclusions: Our data suggest a causal link between obesity induced chronic inflammation and amyloidosis in C57Bl6J mice and indicate obesity-enhanced chronic secretion of SAA may lead to extravascular misfolding and accumulation in time due to SAA's amyloidogenic properties.

SA-PO215

Protein-Energy Wasting and Quality of Life in Chronic Hemodialysis Patients Camiel L.M. de Roij van Zuijdewijn,[1] Muriel P. Grooteman,[1,2] Menso Jan Nubé,[1,2] Peter J. Blankestijn,[3] Michiel Bots,[4] Pieter M. Ter Wee.[1,2] *[1]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Inst for Cardiovascular Research, VU Univ Medical Center, Amsterdam, Netherlands; [3]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [4]Julius Center for Health Sciences and Primary Care, Univ Medical Center Utrecht, Utrecht, Canada.*

Background: Protein-energy Wasting (PEW) describes the state of decreased bodily protein and energy fuels and is associated with mortality. Despite various nutritional tests, it is currently unknown how PEW can best be measured. As this syndrome is highly prevalent among hemodialysis (HD) patients and is associated with an impaired quality of life (QoL), the nutritional test that correlates best with QoL may be the preferred test to assess PEW.

Methods: a cross-sectional study was performed using data from CONTRAST (NCT 00205556), a cohort of ESRD patients treated with HD or hemodiafiltration. Subjective Global Assessment (SGA), Malnutrition Inflammation Score (MIS), Geriatric Nutritional Risk Index (GNRI), composite Protein Energy Nutritional Score (cPENS), normalized Protein Nitrogen Appearance (nPNA), Body Mass Index (BMI), serum albumin and serum creatinine were assessed at baseline. QoL was assessed with the Kidney Disease Quality of Life Short Form 1.3, which summarizes QoL in 2 general and 12 kidney-disease specific (KDS) domains. Higher scores indicate better QoL. As none of the values is normally distributed, Spearmans rho (ρ) was calculated to determine relations between the nutritional tests and domains of QoL.

Results: 489 patients were analyzed. SGA, MIS, cPENS, GNRI, nPNA, albumin and creatinine correlated significantly with the Physical Component Score (ρ 0.222, -0.467, 0.216, 0.196, 0.103, 0.196 and 0.185, respectively; $p \leq 0.03$). SGA and MIS correlated significantly with the Mental Component Score (ρ 0.128 and -0.202, respectively; $p \leq 0.01$). SGA correlated significantly with 10 KDS QoL domains with ρ's between 0.095 and 0.213 ($p < 0.04$) and MIS with 11 KDS QoL domains with ρ's between -0.124 and -0.494 ($p < 0.01$).

Conclusions: The MIS correlates strongest with the different aspects of QoL and may therefore be the preferred test to assess the relation between PEW and QoL.

SA-PO216

To Eat or Not to Eat - International Experiences with Eating during Hemodialysis Treatment Brandon Kistler,[1] Deborah A. Benner,[2] Mary B. Burgess,[2] Maria Melts Stasios,[2] Kamyar Kalantar-Zadeh,[3] Ken Wilund.[1] *[1]Univ of Illinois, Urbana, IL; [2]DaVita Healthcare Partners, Denver, CO; [3]UC Irvine, Irvine, CA.*

Background: Poor nutritional status is common in hemodialysis (HD) patients and may lead to reduced quality of life, increased hospitalizations, and higher death risk. Providing food or nutrition supplements during HD is associated with improved nutritional status and reduced mortality, yet despite these benefits eating policies vary across countries and clinics.

Methods: To examine practices related to eating at HD treatment we surveyed clinicians about their clinic policies during the 2014 International Society of Renal Nutrition and Metabolism Conference.

Results: We received 73 responses from six continents. Respondents were primarily dietitians (71%) and nephrologists (26%) working at units housed in a hospital (63%). Sixty-one clinics (85%) allowed patients to eat during treatment, with 47 of these (65%) actively encouraging eating. Of the 53 clinics (73%) providing food during HD, 49 (93%) provided food at no cost to the patient. Generally, clinics provided meals high in carbohydrates. However, none of the nine clinics from North America (100%) provided food during treatment. The majority (47 clinics; 64%) provided supplements during treatment, with 43 (92%) providing at no cost. Among clinics that allow eating, providing energy (89%) and teaching opportunities (47%) were the primary reasons. We also asked clinicians about their experience with six commonly cited reasons to restrict eating using a four-point scale. Clinicians responded they observed the following "rarely" or "never": choking (98%), reduced Kt/V (98%), infection control issues (96%), spills or pests (85%), GI issues (72%), and hypotension (63%).

Conclusions: Our results indicate that internationally eating is common during treatment, disparities may exist in global practices, and most of the proposed negative sequelae of eating during HD are not commonly observed in clinical practice. These data describe current nutrition practices globally, provide a potential contributor to global differences in albumin, and highlight the need for more research to inform decisions regarding eating during HD.

SA-PO217

Changes in Practices and Opinions on In-Center Food Consumption in a Large Dialysis Organization in the United States Mary B. Burgess,[1] Deborah A. Benner,[1] Maria Melts Stasios,[1] Becky Brosch,[1] Rich Mutell.[2] *[1]DaVita Healthcare Partners, Denver, CO; [2]APEX Health Innovations, Simi Valley, CA.*

Background: Oral nutritional supplement (ONS) provided during dialysis is associated with improved mortality. Limitations in ONS programs include restricted patient participation due to eligibility criteria; supplement intolerance and taste fatigue. A complimentary program that encourages appropriate food consumption during dialysis may demonstrate similar clinical improvement as ONS programs in a larger population and provide opportunities for counseling on "usual food" choices. The purpose of this pilot

was to measure changes in practices, opinions and perceived barriers to consuming food on dialysis in a large dialysis organization (LDO) with an ONS program where facility specific policies related to food consumption are determined by the Medical Director and facility.

Methods: In May 2011 and June 2014, registered dietitians (RDs) within an LDO in the U.S. were surveyed on facility practices and opinions on food consumption during dialysis using an online survey. RDs provided input on facility practice and collected Medical Director responses. In 2013, optional guidelines and educational materials on Eating at Treatment (EAT) were developed and shared with RDs.

Results: Analysis of responses to these two questions show significant differences between the 2011 and the 2014 survey (X2, $p < .001$) and indicate a practice pattern change toward increased consumption of food on dialysis.

Facility – "What is the current practice in this facility regarding consuming food on dialysis?"

			Facility Practices					
			Not allowed, does not occur	Not allowed, does occur	No guidelines	Allowed, not encouraged	Allowed, encouraged	Total
Year	2011	Count	60	288	64	580	218	1210
		% within Year	5.0%	23.8%	5.3%	47.9%	18.0%	100.0%
	2014	Count	59	254	91	566	437	1407
		% within Year	4.2%	18.1%	6.5%	40.2%	31.1%	100.0%

Medical Director – "What is your opinion on allowing patients to consume food on dialysis?"

			Medical Director Opinion					
			Strongly Discourage	Discourage	No Opinion	Encourage	Strongly Encourage	Total
Year	2011	Count	255	161	160	212	49	837
		% within Year	30.5%	19.2%	19.1%	25.3%	5.9%	100.0%
	2014	Count	226	152	170	291	124	963
		% within Year	23.5%	15.8%	17.7%	30.2%	12.9%	100.0%

RDs reported top reasons some Medical Directors provided for not allowing eating at dialysis remain unchanged: potential increased hypotension, chance of choking, infection and GI problems.

Conclusions: This pilot demonstrates that food consumption patterns during dialysis are evolving. Further studies are warranted to understand the risks and benefits of consuming food on dialysis.

SA-PO218

Concordance of Sodium and Phosphate Load in Western Diet: Implications for Dietary Counseling Charlotte A. Keyzer, Jelmer K. Humalda, Arjan J. Kwakernaak, Maartje C.J. Slagman, Martin H. De Borst, Gerjan Navis. *Nephrology, Univ Medical Center Groningen, Netherlands.*

Background: Both sodium and phosphorus load are associated with cardio-renal risk and require dietary management. Sodium and phosphate are both abundantly present in processed food, but counseling dietary phosphate restriction is limited since phosphate content is uncommonly reported on food labels. We hypothesized that dietary sodium and phosphate load are associated in Western populations, both in healthy individuals and various patient cohorts.

Methods: We calculated habitual sodium and phosphate load from 24h urinary excretion of sodium and phosphate in healthy subjects, diabetic (DM) patients and renal transplant recipients (RTR) in the Netherlands and tested their association. We also tested the effect of dietary counseling to limit sodium intake on phosphate load in two independent cohorts, with non-DM and DM-CKD.

Results:

Population	Number of patients	Urinary sodium excretion (mmol/day)	Urinary phosphate excretion (mmol/day)	Correlation coefficient
Healthy volunteers	252	195±76	28±10	0.435
Renal transplant recipients	706	157±62	25±9	0.519
Diabetic patients	95	205±89	27±12	0.452
CKD regular sodium diet	46	189±56	31±10	0.494
CKD low sodium diet	48	106±48*	28±10*	0.463
DM-CKD regular sodium diet	43	224±76	26±11	0.747
DM-CKD low sodium diet	41	148±65*	23±9*	0.560

Urinary sodium and phosphate excretion were correlated in all cohorts ($P<0.001$), despite absolute differences. Moreover, successful dietary sodium restriction also reduced phosphate excretion, both in non-DM-CKD and DM-CKD (Table, * $P<0.05$ versus regular sodium diet).

Conclusions: Dietary exposure to sodium and phosphate are robustly associated across several Western populations. Successful dietary sodium restriction also reduces phosphate intake. Given this concordance, dietary phosphate load can be lowered by counseling aimed at dietary sodium restriction which is more efficient since sodium but not phosphate content is indicated on most food labels.

SA-PO219

Sodium Reduced Meat and Poultry Products Contain a Significant Amount of Potassium from Additives Arti Sharma Parpia,[1,2] Marc B. Goldstein,[1,3] Joanne Arcand,[2] Mary R. L'abbe,[2] Pauline Darling.[1,2] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]Dept of Nutritional Sciences, Univ of Toronto, Toronto, ON, Canada; [3]Dept of Medicine, Univ of Toronto, Toronto, ON, Canada.*

Background: Sodium reduced food products are becoming increasingly available to consumers, however it is unclear if they are suitable for inclusion in a renal diet. Food manufacturers may use phosphate and potassium additives to replace the functional and flavor properties of sodium, and the amount is usually not listed on food labels. Increased intake of phosphorus and potassium in individuals with chronic kidney disease (CKD) can cause hyperkalemia and hyperphosphatemia, both of which are associated with increased risk of mortality. The objective of our study was to determine if the reduction of sodium in meat and poultry products is associated with increased amounts of phosphorus and potassium from food additives.

Methods: Grocery stores from the top 3 grocery chains in Canada were scanned for all sodium reduced meat and poultry products. Protein, sodium, phosphorus and potassium content were analyzed using the Association of Analytical Communities (AOAC) official methods 992.15 and 984.27, and values for sodium reduced products were compared with their non-sodium reduced counterparts.

Results: Sodium reduced meat and poultry products (n=19) contained 25-55% less sodium (mg/100g) than their non-sodium reduced counterpart (mean difference (95%CI): 460 (225-585)mg/100g, $p<0.001$). Potassium content of sodium reduced products ranged from 210-1500 mg/100g and was significantly higher than non-sodium reduced products by 195 (106-284)mg/100g, $p < 0.001$). Potassium containing additives were found on the ingredient list in 63% of the sodium reduced products and 25% of the non-sodium reduced products ($p = 0.02$). The amounts of phosphorus, protein and phosphorus: protein ratio did not differ significantly between the two groups.

Conclusions: Potassium additives are frequently added to sodium reduced meat and poultry products in amounts that significantly contribute to the potassium load for CKD patients. Patients requiring a potassium restriction should limit their intake of sodium reduced meat and poultry products.

SA-PO220

Potassium Restriction and Dietary Satisfaction Are Associated with Quality of Life in Patients on Dialysis Junichi Yatabe,[1] Midori Sasaki Yatabe,[2] Kozue Takano,[2] Koichi Asahi,[1] Hiroyuki Terawaki,[1] Kohji Nomaki,[3] Kenichi Nakazawa,[3] Masaaki Nakayama,[1] Tsuyoshi Watanabe.[1] *[1]Dept of CKD Initiatives, Fukushima Med Univ, Fukushima, Japan; [2]Dept of Pharmacol, Fukushima Med Univ, Fukushima, Japan; [3]Fujitsu Home and Office Services Limited, Kawasaki, Japan.*

Background: Dietary potassium (K) restriction for dialysis patients may decrease dietary satisfaction and compromise quality of life (QOL). However, the associations between K restriction, eating satisfaction and QOL have not been examined.

Methods: Fukushima Patient Association of Kidney Disease in Japan conducted the survey on 759 subjects on dialysis (66.6±11.3 years old, male:female=399:345). Kidney disease-related QOL was assessed by KDQOL version 1.3.

Results: The percentage of subjects satisfied with their diet was lower in patients on dialysis compared to healthy subjects (68% versus 89%). Majority of patients (94.8%) know the risks of serum K elevation, and 76% work on K restriction, but 46% feel it stressful to reduce K intake. In the QOL survey, patients on dialysis had lower physical component summary score (33.5) and relationship component summary score (41.0) than the standardized Japanese average of 50. Mental component summary (MCS) score (50.3) was close to national average. Dietary dissatisfaction and the level of stress due to K restriction were significantly associated with lower MCS score independent of age, sex and number of years on dialysis (R^2=0.153, $P<0.01$). The level of K restriction-related stress positively associated with the severity of kidney disease-related symptoms, effects of kidney disease, burden of kidney disease and work status. Furthermore, the stress of K restriction was associated with less satisfaction with dialysis care. Many patients (81%) answered that they would like to include low-K produce in their diet as a method to manage dietary K.

Conclusions: There was a strong inverse relationship between the stress of K restriction and dietary satisfaction. Mental stress of dietary restriction may affect not only QOL but also the tolerability of dialysis therapy. Efforts to include a variety of low-K produce may be essential to alleviate the burden of K restriction and improve quality of life among patients on dialysis.

SA-PO221

Low-Potassium Lettuce Grown with Novel Technology Can Be Safely Enjoyed Fresh by Patients on Dialysis

Junichi Yatabe,[1] Midori Sasaki Yatabe,[2] Kozue Takano,[2] Hiroyuki Terawaki,[1] Koichi Asahi,[1] Kohji Nomaki,[3] Kenichi Nakazawa,[3] Shigeru Matsunaga,[4] Masaaki Nakayama,[1] Tsuyoshi Watanabe.[1]
[1]Dept of CKD Initiatives, Fukushima Med Univ, Fukushima, Japan; [2]Dept of Pharmacol, Fukushima Med Univ, Fukushima, Japan; [3]Fujitsu Home and Office Services Limited, Kawasaki, Japan; [4]Aizufujikako Co., LTD., Aizuwakamatsu, Japan.

Background: End-stage renal disease (ESRD) patients are instructed to reduce potassium (K) intake. In a separate study, 73% of patients on dialysis answered that they work on K restriction and 45% take K binders, but they still want to eat fresh vegetables and fruits. Therefore, companies in Japan developed a unique hydroponics technology to grow low-K produce.

Methods: Low-K lettuce cultivation method is licensed by Akita Prefectural University. Seedlings were grown using a special "zero K" solution to produce low-K lettuce. Eighty-two patients consumed salad prepared with 30-40 g of fresh (raw) low-K lettuce during each dialysis for 2 weeks. Participants took blood tests and completed questionnaires before and after the study, which included quality of life scores by SF-36 version 2. (UMIN000013058).

Results: Low-K lettuce contained 49.8 ± 16.9 mg of K per 100 g, close to 90% less K than regular lettuce, with similar dietary fiber and vitamin contents. Eighty participants completed the study, with no dropout due to serum K elevation. Rather, serum K decreased after the study (4.83 ± 0.09 versus 4.57 ± 0.08 mEq/L, P<0.01). Weight gain between dialyses and blood concentrations of albumin, CRP, sodium, calcium, zinc, and vitamins A, B1, B2, C and E were not affected. Many (79%) liked the taste of low-K lettuce, and 84% want to include low-K produce in their diet. SF-36 mental health subscore significantly improved after the study in subjects not satisfied with their diet (44.2 ± 23.2 versus 48.9 ± 21.0, N=13, P<0.05) and those who felt stressed by K restriction (45.3 ± 11.9 versus 49.5 ± 9.3, N=23, P<0.05).

Conclusions: Low-K lettuce is safe for patients on dialysis. Being able to eat fresh low-K lettuce may alleviate the stress of dietary restrictions and bring better eating satisfaction and mental health among ESRD patients. A growing number of advanced-stage CKD patients may benefit from a variety of low-K produce.

Vitamin C Overload Leads to Secondary Hyperoxalosis in Young Pediatric Dialysis Patients

Sabina Susan Thyle,[1] Ashley Perilloux,[1] Renata C. Pereira,[1] Garry J. Handelman,[2] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Div of Pediatric Nephrology, UCLA, Los Angeles, CA; [2]Health and Clinical Sciences, Univ of Massachusetts, Lowell, MA.*

Background: Vitamin C supplementation is recommended in dialysis patients to prevent anemia, gingival disease and scurvy. Case reports suggest that intake of very large doses of vitamin C led to secondary hyperoxalosis in some adult dialysis patients. The impact of current enteral formulas on oxalate levels in dialyzed children is unknown.

Methods: We identified oxalate crystal deposits in bone of two 5-year-old hemodialysis patients who underwent routine bone biopsy prior to parathyroidectomy. Gene analysis of *AGXT* ruled out primary hyperoxaluria, and both had a history of high vitamin C intake from enteral feeding. Therefore, we assessed the daily recommended intake (DRI) of vitamin C from enteral feedings in 13 pediatric patients aged 8 months to 8 years fed primarily formula through a gastrostomy tube, treated with either hemodialysis (n=3) or peritoneal dialysis (n=10) in order to assess the impact on oxalate burden. Total vitamin C intake, serum oxalate levels and ascorbic acid levels were assessed in these patients.

Results: All patients were receiving 1.2-8.3 times the DRI for vitamin C from enteral feedings. Ascorbic acid levels ranged from 1.5 to 10.0 mg/dL (ref range: 0.2-1.9 mg/dL); values were elevated in 85% of patients. Oxalate levels were elevated (>30 µmol/L) in 69% of patients and ascorbic acid levels did not correlate with oxalate levels (r=0.44, p=0.13). Ascorbic acid and oxalate levels did not correlate with the amount of vitamin C received corrected by the DRI (r=0.42, p=0.15 and r=0.09, p=0.77 respectively).

Conclusions: Oxalate deposition in bone of two index cases demonstrates that oxalate is present in toxic levels in some dialyzed children; excess vitamin C ingestion contributes to secondary oxalosis in predominantly formula-fed infants and children. Plasma ascorbic acid levels vary, correlate poorly with oxalate levels, and may not reflect total body stores, suggesting that a portion of ascorbic acid is unavailable for clearance during dialysis.

SA-PO223

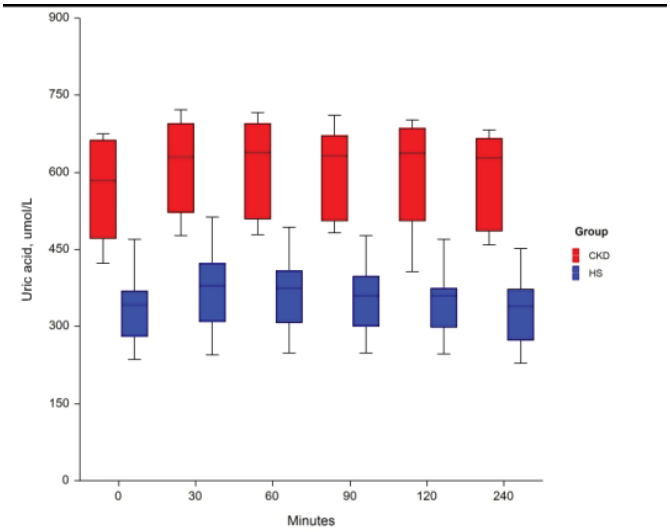
Acute Fructose Loading and Marked Metabolic Increases in the Circulation of Uric Acid, Triglycerides and IGFBP-1 in Chronic Kidney Disease Patients

Björn Anderstam,[1] Abdul Rashid Tony Qureshi,[1] Ann-Christin Bragfors Helin,[1] Neda Rajamand Ekberg,[2] Monica Irene Eriksson,[1] Bengt Lindholm,[1] Peter Stenvinkel.[1] *[1]Dept of Renal Medicine and Baxter Novum, CLINTEC, Karolinska Instt, Sweden; [2]Dept of Endocrinology, Metabolism and Diabetes, MMK, Karolinska Instt, Sweden.*

Background: The consumption of fructose has increased in recent decades and coincides with the prevalence of the metabolic syndrome and chronic kidney disease (CKD). Fructose uses fructokinase and ATP when metabolized in the liver and this can lead to that ATP degrades into uric acid. This may occur normally in healthy state, but does it occur differently in CKD? We studied the acute metabolic effects of low fructose or sucrose loading in patients (pts) with CKD (stages 4-5, GFR<30 mL/min, n=10,) and healthy subjects (HS, n=10).

Methods: All subjects underwent 6 interventions, i.e. a pure fructose drink, coca-cola or blueberry juice, containing 35 g carbohydrate and consumed with or without a pizza slice (442 Kcal). Metabolites in plasma were analyzed post-prandially up to 240 min after consumption. Factors which may statistically influence the variability were studied in a mixed model. The fixed parameters (group, intervention and time) and factors which may have different impact by fructose in CKD pts (uric acid, triglycerides (trig) and IGFBP-1).

Results: We found significant differences between CKD pts and HS of fructose intervention compared to coca-cola or blueberry juice. Fructose intervention increased circulating plasma levels of uric acid (p<0.001), trig (p=0.04) and IGFBP-1 (p=0.002), without affecting the insulin levels.



Conclusions: The hepatic degradation of fructose is quick and complete however this is unknown in CKD pts. Fructose consumption, increases amplitude and time of its metabolites which remain in circulation in CKD pts. Further analyses are in progress to study the carbohydrate metabolism in CKD pts.

SA-PO224

Phosphorus-Containing Food Additives in Processed Foods in Brazil

Margareth Lage L. de Fornasari,[1,2] Maria Raquel Manhani,[2] Yvoty As Sens.[1]
[1]Santa Casa of Sao Paulo School of Medical Sciences, Sao Paulo, Brazil; [2]Sao Judas Tadeu Univ, Sao Paulo, Brazil.

Background: An increased body of evidence implicates serum phosphorus as a risk factor for cardiovascular morbidity, metabolism bone disorders and mortality in individuals with or without chronic kidney disease. The addition of phosphorus to processed foods is permitted but frequently not specified on food labels. The purpose of this study was to determine the actual phosphorus content of a number of products often consumed by hemodialysis patients and to compare the actual content with that estimated in a reference source.

Methods: Thirty-two frequently processed products consumed in the diet of the patients treated at the hemodialysis unit were analyzed. Among these processed foods were: milk in cartons, a type of cream cheese, cold cuts, instant noodles, salad dressings, sodas, and powdered juices. The concentration of phosphorus (mg P/100g of food) was determined according to the Adolfo Lutz Institute methodology, and in triplicate. This method is based on phosphorus complexation with vanadomolybdate of amonium and determined by spectrophotometry in the visible UV region. The comparison of the phosphorus obtained with the expected phosphorus was based on two national reference tables.

Results: Twenty-nine (90.6%) of the products had phosphorus-containing additives listed among their ingredients. For the category of milk in cartons, a type of cream cheese, cold cuts (salami, bologna and turkey breast), instant noodles and sodas, all containing additives, the actual phosphorus content was greater than the content expected from the reference tables. Two food categories, salad dressings and powdered juices, contained less than the expected levels. The difference between the actual and expected phosphorus content (mg/100g or mL) ranged from 22.83 to 52.87 for milk in cartons; -37.15 to 155.12 for powdered milk; 28.3 to 603.09 for a type of cream cheese; 258.47 to 632.15 for cold cuts; 41.32 to 189.15 for instant noodles, and 1.06 to 3.78 for sodas.

Conclusions: Processed foods with phosphorus additives contain higher levels of phosphorus than those listed in reference tables. Variation among similar products difficults the orientation of the patients.

SA-PO225

Creatinine Index as a Surrogate Marker of Lean Body Mass in Hemodialysis Patients: Comparison with Anthropometric and Bioimpedence Assessment

Lucia Del Vecchio,[1] Valeria Aicardi,[2] Vincenzo La Milia,[1] Leano Violo,[1] Selena Longhi,[1] Giuseppe Pontoriero,[1] Francesco Locatelli.[1] *[1]Nephrology ad Dialysis, A Manzoni Hospital, Lecco, Italy; [2]Unidad de Dialisis, Clinica INDISA, Santiago, Chile.*

Background: Assessment of malnutrition in HD patients is still debated. The creatinine index was proposed as a surrogate of Lean Body Mass (LBM), but its calculation was complex. Recently, a simplified formula has been proposed by Canoud et al. Aim of the study is to compare the simplified formula of creatinine index with classical anthropometric measurements and Lean Tissue Index (LTI) with bioimpedance.

Methods: 111 prevalent HD patients (mean age 69.02 ± 13.51 years; F/M 43/68, in HD for a mean of 74.49 ± 89.15 months, 36.9% of diabetics) underwent nutritional evaluation with both traditional anthropometric parameters and BCM).

Results: At anthropometric measurement, 72 (65%), 6 (6%), 17 (15%) and 16 (14%) had a normal, mild, moderate and severe decrease in LBM, respectively. Creatinine index was significantly lower in patients with severe decrease in LBM (16.8 ± 1.7 mg/kg/day) compared to the other groups (Normal: 19.5 ± 2.3; Mild 20.2 ± 2.8; Moderate: 19.4 ± 2.5). At linear regression we found a moderate relationship between creatinine index and either LBM measured with anthropometry (R = 0.47, B = 14.8, P< 0.0001; figure 1) or LTI. The capability of the formula to detect malnutrition is less effective in women and patients younger than 65 years. The highest degree of correlation with LBM (R = 0.63, B = 9.76, P =0.001) and LTI (R = 0.56, B = 13.1, P=0.035) was in patients with severe reduction of LBM. At logistic regression analysis creatinine index was the only independent variable influencing severe loss of LBM (B - 0,595, ES 0.249, P = 0.017); transferrin was and albumin, PTH, LTI were not significant.

Conclusions: Creatinine index as a moderate degree of correlation with LBM measured with anthropometric evaluation and bioimpedance. The formula may be more reliable in patients with severe malnutrition.

SA-PO226

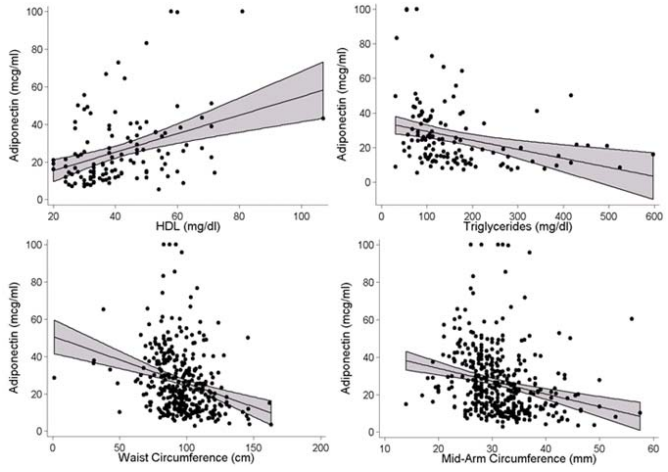
Adiponectin, Lipids, and Body Composition in Hemodialysis Patients

Connie Rhee,[1] Ramanath B. Dukkipati,[2] Hamid Moradi,[1] Steven M. Brunelli,[3] Jennie Jing,[1] Tracy Nakata,[1] Csaba P. Kovesdy,[4] Gregory Brent,[5] Kamyar Kalantar-Zadeh.[1] *[1]UCI, Irvine, CA; [2]Harbor-UCLA, Torrance, CA; [3]DaVita Clinical Research, Minneapolis, MN; [4]Memphis VAMC, Memphis, TN; [5]UCLA, Los Angeles, CA.*

Background: In the general population, circulating adiponectin is inversely associated with triglycerides (TG), LDL, and body fat; and positively associated with HDL and lean body mass (LBM). Hemodialysis (HD) patients have higher adiponectin levels, but its association with lipids and body composition in HD is not well defined.

Methods: In cross-sectional analyses of 501 HD patients in the MADRAD study from 13 large dialysis organization centers (2011-2013), we estimated unadjusted (uR) and adjusted Pearson correlations (aR) of adiponectin with lipids and body composition surrogates: visceral fat (waist circumference, WC), subcutaneous fat (biceps/triceps skinfold, SF), LBM (mid-arm muscle circumference, MAMC, mid-arm circumference MAC), and near infrared body fat%. We examined associations between lipids and body composition with high adiponectin (>50th percentile) using multivariable logistic regression.

Results: Adiponectin was positively correlated with HDL (uR=0.37) and inversely correlated with TG, WC, biceps SF, triceps SF, MAMC, MAC, and body fat%: uR=-0.30,-0.27,-0.15,-0.11,-0.20,-0.23, and -0.12, respectively (p<0.05 for all).



In adjusted analyses, adiponectin remained positively correlated with HDL and had strongest inverse correlation with WC: aR 0.31 and -0.30, respectively (p≤0.001 for both). TG, LDL, cholesterol, WC, biceps SF, triceps SF, MAMC, MAC, and body fat% were associated with ↓ odds of high adiponectin, while HDL was associated with odds of high adiponectin.

Conclusions: In HD patients, inverse associations of adiponectin with TG, LDL, visceral and subcutaneous fat, as well as positive associations with HDL are preserved. In contrast to the general population, adiponectin is associated with ↓ LBM.

SA-PO227

Effects of Lifestyle Interventions on the Serum Concentration of Soluble (Pro)renin Receptor

Yasutoshi Akiyama,[1,2] Eikan Mishima,[1,2] Sadayoshi Ito,[2] Takaaki Abe,[2,3] Hideyasu Kiyomoto.[1,2] *[1]Dept of Community Medical Supports, Tohoku Medical Megabank Organization (ToMMo), Tohoku Univ, Japan; [2]Div of Nephrology, Endocrinology and Vascular Medicine, Tohoku Univ Hospital, Japan; [3]Div of Medical Science, Tohoku Univ Graduate School of Biomedical Engineering, Japan.*

Background: The blood levels of soluble form of (pro)renin receptor (sPRR) have been reported to be affected by various pathophysiological conditions, such as diabetes mellitus, heart failure, sleep apnea and renal insufficiency. However, it is largely unknown whether lifestyle interventions such as exercise and diet affect the blood sPRR levels.

Methods: The study population consisted of 112 subjects who participated in the health promotion program conducted in Motoyoshi Town, Kesennuma, Japan. The program consisted of 2 interventions: (1) weekly 90-min instructor-led group sessions of mild aerobic exercise, and (2) monthly dietitian-led educational group sessions focused on salt restriction. The participants were free to choose to attend either exercise (EX) sessions or salt restriction (SR) sessions, or both. Before and after 5 month of the intervention period, we collected the blood and urine samples from the participants and measured biochemical parameters including serum sPRR levels.

Results: Fifty-eight persons (51.3 %) attended the SR sessions. At the end of the program, the mean estimated 24-hour sodium excretion in SR sessions-attending group (SR group) was significantly lower compared with non-SR group (166.9 ± 6.3 versus 185.3 ± 6.5 mEq/day, p<0.05), suggesting that the SR sessions were effective in the reduction of dietary sodium intake. Although the serum sPRR levels in non-SR group were not changed significantly, those in SR group significantly decreased from 34.5 ± 1.3 to 30.6 ± 1.3 ng/ml (p<0.05). Attending the SR sessions was associated with the decrease in serum sPRR levels, even after multivariable adjustment for confounding factors including age, gender, attending EX sessions and blood pressure change. In contrast, attending the EX sessions did not affect the serum sPRR levels.

Conclusions: Educational intervention to reduce dietary salt intake was associated with the decrease in serum sPRR levels.

SA-PO228

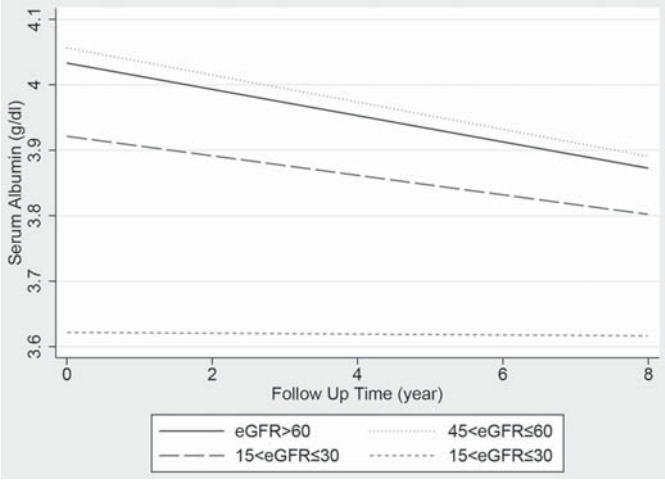
Effect of Estimated GFR on Serum Albumin Deterioration in Patients with Chronic Kidney Disease

Jun Ling Lu,[1] Miklos Zsolt Molnar,[1] Jennie Z. Ma,[2] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,4] *[1]Univ of Tennessee; [2]Univ of Virginia; [3]Univ of California Irvine; [4]Memphis VAMC.*

Background: Protein-energy wasting (PEW) represents a major risk factor in patients with CKD. Serum albumin (ALB) level is one of the criteria used to evaluate PEW. The independent effect of impaired kidney function on serum albumin deterioration over time is unclear.

Methods: Among 3,582,478 U.S. veterans with eGFR≥60 ml/min/1.73m^2, we identified 643,535 patients who developed incident CKD (defined as the first two eGFR values <60 at least 90 days apart). After excluding patients with pre-existing conditions that could affect ALB independent of nutritional status (liver diseases, metastatic malignancies, and chronic inflammatory conditions), our final cohort consisted of 479,491 incident CKD patients. The association of time dependent eGFR with intra-individual changes (slopes) of serum albumin was examined in mixed models stratified by estimated GFR levels.

Results: Over a mean follow-up time of 6.7 years the median (IQR) number of ALB measurements/individual were 10 (6, 15). The mean age (Standard Deviation [SD]) was 66.1(10.4) years, 12.9% were African American, 39.4% patients had diabetes and the mean baseline eGFR (SD) was 74.9 (12.8) ml/min/1.73m^2. Serum albumin levels were lower in patients with lower eGFR. However, decrease in albumin over time was not associated with lower eGFR (Figure).



Conclusions: Lower kidney function was associated with lower serum albumin, but not with worsened deterioration of ALB over time in non-dialysis dependent CKD patients.

Funding: NIDDK Support, Veterans Affairs Support

SA-PO229

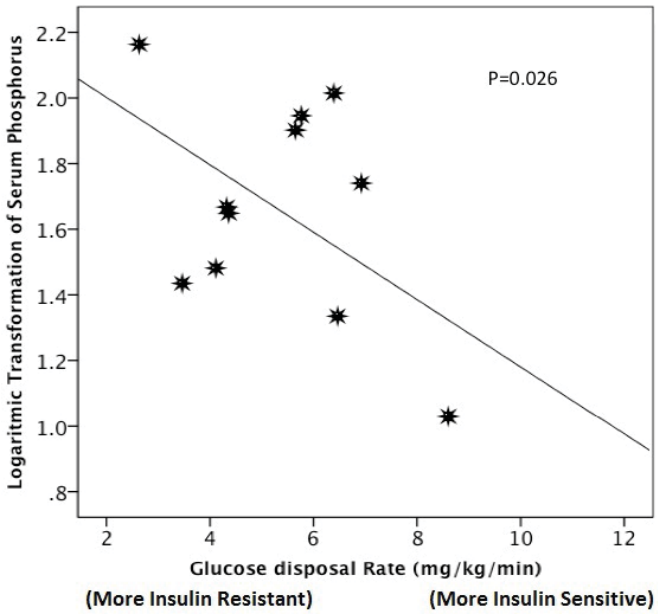
Hyperphosphatemia Is Linked to Insulin Resistance in Maintenance Hemodialysis (MHD) Patients

Serpil Muge Deger,[1] Natjalie Salas,[1] Edward D. Siew,[1] Rafia I. Chaudhry,[1] Charles D. Ellis,[1] T. Alp Ikizler,[1,2] Adriana Hung.[1,2]
[1]Div of Nephrology, Vanderbilt Univ Medical Center, Nashville, TN; [2]Nephrology, 2CSR&D Veterans Administration TVHS, Nashville, TN.

Background: Markers of mineral bone disorders (MBD), especially higher levels of serum phosphorus are associated with cardiovascular events and all-cause mortality in MHD patients. Insulin resistance (IR) is common in MHD patients and recent data suggest a potential role of phosphorus homeostasis in IR in non-dialyzed CKD patients. In this study, we examined the association between phosphorus levels and IR measured using the gold standard hyperinsulinemic euglycemic clamp (HEGC) in MHD patients.

Methods: The HEGC procedure was performed using an insulin rate of 2.0 mU/kg/min through 120 min in twelve African American MHD patients. IR was measured as the glucose disposal rate (GDR) in the last 30 minutes of the clamp. Pearson correlation and multivariate analysis were performed to evaluate the association of phosphorus and GDR. Variables were log transformed to achieve normality.

Results: Mean age was 50±9.4 years, 67% were male, 42% had diabetes, mean BMI was 33.3 +/-7.4, median dialysis vintage was 46 months. The mean GDR was 5.7 (IQR: 4.1, 6.8) mg/kg/min. The mean serum calcium, phosphorus and iPTH levels were 9.0±0.6 mg/dL, 5.2 (IQR: 3.9, 6.9) mg/dL and 285 (IQR; 228, 474) pg/mL, respectively. GDR was significantly correlated with serum phosphorus (r= -0.635, p=0.026) (Figure 1). In the multivariate analysis, serum phosphorus levels remained an independent predictor for GDR after adjusting for a) *model 1*: iPTH and Calcium (p=0.007) and b) *model 2*: age and gender (p=0.02).



Conclusions: Our results suggest that high phosphorus levels are significantly associated with IR in MHD patients. These findings represent a novel pathway for MBD-associated cardiovascular disease and all-cause mortality in ESRD patients.

Microbiome Perturbation Reduces Production of Uremic Toxin in ESRD

Julia Roberts, Prabhjot Singh, Sachin Jhawar, Lama Nazzal, Jerome Lowenstein.
Medicine, New York Univ Langone Medical Center, New York, NY.

Background: Indoxyl Sulfate (IS), a major protein-bound uremic toxin, is produced by the action of bacterial digestion of tryptophan to indole; indole enters the portal circulation and is hydroxylated and sulfated in the liver to produce IS. Given the evidence that high affinity protein-binding, largely to albumin, greatly limits the capacity of hemodialysis to remove this uremic solute which has been implicated in the pathogenesis of accelerated cardiovascular disease in ESRD, alternate means to reduce IS are needed. We have examined the effect of disturbing the gut microbiome on IS production in patients with ESRD.

Methods: A single dose (250 mg) of Vancomycin VANCO, an orally non-absorbable antibiotic, known to alter the gut microbiome (IKS Yap et al Proteome Res. 2008 7:3718-28) was administered to 10 subjects with ESRD undergoing hemodialysis. Plasma samples, pre- and post-dialysis, were obtained prior to and 2,4, 7, 14. 21 and 28 days following the administration of VANCO. Stool specimens for assessment of the microbiome, were collected prior to, one week following and 28 days following VANCO. IS was measured by HPLC. The gut microbiome was assessed by comparison of 16S rRNA gene sequences in stool samples collected pre- and post VANCO.

Results: Pre-dialysis IS averaged 42.7±26.4 μgm/ml prior to VANCO and decreased in all subjects. Indoxyl sulfate concentration at the nadir, usually at day 4 following VANCO, averaged 50.5 % of control. IS returned to baseline (40.2±41.6 μgm/ml) by day 28 following VANCO.

	Pre-dial	Day 2	Nadir	Nadir %	Day 28
Indoxyl sulfate (μgm/ml)	42.7 ±26.4	35.4±27.8	19.6±16.7	50.5±23.5	40.2±41.6

Conclusions: The finding that VANCO reduced the plasma concentration of IS is consistent with the evidence that bacterial flora in the gut are responsible for the production of IS. The present findings suggest that perturbing the gut microbiome, with an antibiotic or other agent such as a probiotic, by reducing the generation and plasma levels of IS, might decrease the incidence or severity of accelerated arteriosclerosis in ESRD. This would constitute a paradigm shift in the treatment of ESRD.

Association between "Obesity Paradox" and Fluid Volume Imbalance between Intra- and Extracellular Water in Patients with Chronic Kidney Disease

Yasushi Ohashi,[1] Reibin Tai,[1] Toshiyuki Aoki,[1] Sonoo Mizuiri,[2] Yoshihide Tanaka,[1] Atsushi Aikawa,[1] Ken Sakai.[1] *[1]Nephrology, School of Medicine, Faculty of Medicine, Toho Univ, Tokyo, Japan; [2]Nephrology, Ichiyokai Harada Hospital, Hiroshima, Japan.*

Background: Body mass index (BMI) correlates inversely with mortality in patients with chronic kidney disease (CKD). We assessed the association of fluid volume status with BMI and whether fluid imbalance between intra- (ICW) and extracellular water (ECW) is a risk factor for adverse outcomes.

Methods: Body fluid composition was measured in 149 patients with CKD from 2005 to 2009, who were followed until 2013. Patients were categorized according to the ECW/ICW ratio tertile. ECW excess was assessed by examining the ratio of ECW measured by bioimpedance analysis (ECW_{BIA}) to total body water calculated using the Watson formula (TBW_{Watson}). Main outcomes were adverse renal outcomes, as defined by a decline of 50% or more from baseline glomerular filtration rate or initiation of renal replacement therapy, cardiovascular events, and all-cause mortality.

Results: The decreasing ICW slope with age was steeper than the decreasing ECW slope. The shift in the balance between ICW and ECW led to an increase in the ECW/ICW ratio. The $\%ECW_{BIA}/TBW_{Watson}$ had a negative correlation with BMI (r = -0.36 in male, P = 0.001 and r = -0.28 in female, P = 0.02). Compared with patients in the lowest tertile during a median 4.9-year follow-up, those in the highest tertile had the worst adverse renal outcomes (15.9 versus 5.1 per 100 patient-years, P < 0.001), cardiovascular events (4.1 versus 0.3 per 100 patient-years, P = 0.002), and mortality (11.2 versus 1.3 per 100 patient-years, P < 0.001) by Kaplan–Meier survival analysis. The adjusted hazard ratio (95% confidence intervals) for adverse renal outcomes, cardiovascular events, and all-cause mortality were 1.15 (1.03 – 1.26, P = 0.011), 1.12 (0.93 – 1.31, P = 0.217), and 1.29 (1.11 – 1.50, P <0.001), respectively.

Conclusions: Leaner or elderly patients with a decreased ICW were more susceptible to ECW excess. Fluid imbalance between ICW and ECW was independently associated with adverse renal outcomes and mortality, which may indicate the reserve capacity for volume overload in patients with CKD.

SA-PO232

Associations Between Body Mass Index (BMI) and Body Fat with Markers of Inflammation and Nutrition Among Patients on Hemodialysis (HD) Cynthia Delgado, Lorien S. Dalrymple, Glenn M. Chertow, George A. Kaysen, John Kornak, Barbara A. Grimes, Kirsten L. Johansen. *USRDS Nutrition Special Studies Center.*

Background: BMI does not distinguish between visceral and subcutaneous fat, which may have opposite metabolic and inflammatory effects. The purpose of this study was to determine the extent to which BMI, waist circumference (WC) and percent fat mass (%FM) are associated with markers of inflammation and nutrition in patients on HD.

Methods: We measured C-reactive protein (CRP), interleukin 6 (IL6), pre albumin (pre-alb) and albumin (alb) among 531 prevalent HD patients in the USRDS ACTIVE/ADIPOSE study. We used linear regression with BMI, WC and %FM as independent variables, along with age, sex, diabetes mellitus and race as covariates.

Results: Higher BMI was associated with higher concentrations of CRP and IL6 but not pre-alb or alb. WC associations were similar to those of BMI, but % FM was associated with higher pre-alb in addition to higher CRP. When WC* and %FM* were considered together, higher WC* was associated with higher CRP and IL6 but lower pre-alb and alb, whereas higher %FM* was associated with lower CRP and IL6 and higher pre-alb and alb.

Multivariable Association between Body Composition and Inflammatory and Nutritional Markers

Parameter	CRP, mg/L	IL6, pg/ml	Pre-alb, mg/dL	Alb,g/dL
BMI per 10kg/m2	0.59 (0.42,0.75)	0.17 (0.06,0.30)	-0.24 (-0.11,0.064)	-0.025 (-0.07,0.02)
WC, per 10cm	0.24 (0.18,0.31)	0.07 (0.02,0.12)	-0.7 (-0.43,0.30)	-0.02 (-0.04,-0.002)
%FM	3.0 (1.71,4.4)	0.05 (-0.88,0.98)	7.0 (0.05,13.9)	0.03 (-0.31,0.37)
WC*, per 10cm	0.25 (0.16,0.34)	0.12 (0.06,0.19)	-0.55 (-1.03,-0.07)	-0.037 (-0.06,-0.01)
%FM*	-0.05 (-1.76,1.65)	-1.50 (-2.7,0.27)	13.8 (4.7,23)	0.50 (0.04,0.94)

Conclusions: Visceral fat and subcutaneous fat show distinct associations with markers of inflammation in patients on dialysis with visceral fat directly associated with inflammatory markers and inversely associated with the negative acute phase/nutritional proteins. A better understanding of fat distribution may help to explain the obesity paradox in HD.

Is There a Reverse Epidemiology of Triglyceride in Patients with Chronic Kidney Disease Stage 3-5 or Hemodialysis? Chi-Chih Hung,[1] Daw-Yang Hwang,[1] Hung-Chun Chen.[1] *[1]Dept of Nephrology, Kaohsiung Medical Univ Hospital, Kaohsiung Medical Univ, Taiwan; [2]Dept of Nephrology, Kaohsiung Medical Univ Hospital, Kaohsiung Medical Univ, Taiwan.*

Background: A reverse association is observed between cholesterol and mortality in chronic kidney disease (CKD) and hemodialysis (HD) patients. As a part of metabolic syndrome, hypertriglyceridemia causes inflammation and atherosclerosis and is prevalent in CKD and HD patients. However, whether a reverse epidemiology between triglyceride and mortality is also true in these patients is little known.

Methods: We enrolled 3300 CKD stage 3-5 patients and 2615 incident HD patients in two cohorts from southern Taiwan between 1997 and 2009. Baseline data were used for analysis.

Results: In the CKD cohort with a mean eGFR 24.7 ml/min/1.73 m^2,the mean triglyceride and cholesterol level were 155 mg/dl and 196 mg/dl, respectively. In the HD cohort, the mean triglyceride and cholesterol level was 173 mg/dl and 187 mg/dl, respectively. In the general linear regression, factors positively associated with triglyceride were HD (versus CKD), diabetes mellitus, female, cholesterol, nutritional factors and inflammation markers. In CKD patients, triglyceride <50mg/dl and 50-100 mg/dl were associated with higher risks for all-cause mortality with the hazard ratio (HR) 95% CI:2.13 (1.22-3.75)and 1.71 (1.18-2.47), respectively, compared with triglyceride 200~250 mg/dl. In contrast, in the HD patients, triglyceride 200~250 mg/dl and >250mg/dl were associated with higher risks for all-cause mortality with the HR 95% CI: 1.26 (1.11-2.27) and 1.30 (1.05-1.61), respectively, compared with triglyceride 50~100 mg/dl. The association between triglyceride and CV events showed similar results in both cohorts. Furthermore, cholesterol was not significantly associated with mortality in both CKD and HD patients.

Conclusions: Lower triglyceride in CKD stage 3-5 patients and higher triglyceride in HD patients were associated with higher mortality, while cholesterol was not associated with mortality in these patients. Treatment of hypertriglyceridemia should need further investigation in HD patients.

Association of Appendicular Lean Body Mass and Truncal Fat Mass Indexes with All-Cause Mortality in Hemodialysis Patients Akihiko Kato,[1] Yukitoshi Sakao,[1] Takayuki Tsuji,[2] Naro Ohashi,[2] Hideo Yasuda,[2] Hiromichi Kumagai.[3] *[1]Dialysis Unit, Hamamatsu Univ Hospital, Hamamatsu, Shizuoka, Japan; [2]Inter Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [3]School of Nutritional and Food Sciences, UNiversity of Shizuoka, Shizuoka, Japan.*

Background: Skeletal muscle wasting commonly causes frailty, thereby leading to comorbidities such as reduced activity of daily life and bone fracture in patients with chronic kidney disease (CKD). Central body fat accumulation is also associated with survival rate in CKD patients. So, we aimed this study to examine whether appendicular skeletal muscle wasting or truncal fat accumulation may be associated with clinical outcomes in regular hemodialysis (HD) patients.

Methods: We enrolled 176 male (age: 57±12 years old, time on HD: 9±7 years) and 85 female patients (age: 64±12 years old, time on HD: 9±7 years). We measured appendicular lean body mass and truncal fat mass volumes (kg) by dual-energy X-ray absorptiometry (DEXA), and calculated as appendicular lean body mass index (ALBMI) and truncal fat mass index (TFMI) dividing those by height square (m^2). We then followed all of the patients for the 5 years, and assessed the impact of changes of body composition on total mortality.

Results: Mean ALBMI was 5.8±1.0 [0.9-8.9] in male and 4.5±0.7 [3.1-7.0] kg/m^2 in female patients. There was 91% in men and 92% in women who had met the Asian criteria of sarcopenia (cut-offs: <7.0 kg/m^2 for men and <5.4 kg/m^2 for women by using DEXA). Mean TFMI was 2.2±1.3 [0.4-7.2] in male and 2.7±1.3 [0.4-6.7] kg/m^2 in female. ALBMI was correlated with age, serum creatinine and albumin in male, while with time on HD in female. TFMI was positively correlated with total cholesterol and triglyceride in both sexes. Cox proportional hazards regression analyses revealed that ALBMI was independently associated with the 5-year mortality in male patients (RR 0.71 [0.51-0.98], p<0.05). TFMI became a significant predictor of mortality in female patients (RR 0.44 [0.24-0.81], p<0.01).

Conclusions: These findings suggest that higher appendicular skeletal mass associates with better survival in male, while higher truncal adiposity affords protection in female patients.

p53 Inhibition Causes a Glycolytic Shift in Renal Glucose Metabolism Takashi Hato, Timothy A. Sutton, Pierre C. Dagher. *Medicine, Indiana Univ, Indianapolis, IN.*

Background: It is increasingly recognized that glycolytic reprogramming is coupled to biosynthesis thus permitting sustained cell growth and survival under stress. Therefore, inducing renal glycolytic reprogramming could be an attractive preventative and therapeutic approach against various forms of renal injury. The tumor suppressor p53 was recently shown to be involved in the regulation of key metabolic pathways. In particular, the genetic absence of p53 was implicated in the glycolytic phenotype of tumors. Here we investigated whether the acute inhibition of p53 can also induce glycolysis in the healthy kidney *in vivo*.

Methods: To examine the effect of acute p53 inhibition on basal glucose metabolism in the kidney, wild-type mice and rats were treated with vehicle control or pifithrin-α (a pharmacologic p53 inhibitor). A combination of tools was applied including traditional biochemical analysis, PET scan and intravital imaging of the kidney in order to examine the balance between glycolysis and oxidative phosphorylation in the setting of p53 inhibition.

Results: Intravital imaging revealed increased uptake of fluorescently-labeled deoxyglucose by proximal tubules of pifithrin-α treated animals as compared to controls. Whole body ^{18}fluoro-2-deoxyglucose PET scan replicated the findings. Concomitant to increased glucose uptake, intravital imaging showed decreased mitochondrial membrane potential in proximal tubules of pifithrin-α treated animals. In kidney homogenates from pifithrin-α treated animals, pyruvate dehydrogenase activity and the ATP/AMP ratios were both significantly reduced. Finally, the expression of TIGAR (TP53-inducible glycolysis and apoptosis regulator, which downregulates glycolysis) was reduced in pifithrin-α treated kidneys. Collectively, these findings indicate that acute inhibition of p53 induces a shift towards glycolysis in otherwise normal kidney tissues.

Conclusions: We show *in vivo* evidence that renal glucose metabolism can be modulated via p53. Whether the glycolytic switch translates into renal protection in injury models remains to be determined.

Genetic Deletion of Growth Differentiation Factor 15 Accelerates High Fat Diet Induced Renal Injury in Mice Sebastiaan Lambooy, Hendrik Buikema, Robert H. Henning, Leo E. Deelman. *Clinical Pharmacy and Pharmacology, Univ Medical Center Groningen, Univ of Groningen, Groningen, Netherlands.*

Background: The incidence of both Type 2 Diabetes and Metabolic syndrome (MetS) are increasing on a global scale, particularly in the Western World. In diabetes, we previously demonstrated that GDF15 plays a protective role in diabetes induced kidney damage. As high fat diet is known to increase GDF15 expression in fat, we speculate that GDF15 may also be renoprotective in a model of MetS.

Methods: The progression of kidney damage in an experimental model of MetS was compared in mice that were genetically deleted for GDF15 and in their wild type controls. Mice were given 6 weeks of high fat diet or control diet. Renal damage was assessed by the use of Real Time PCR, Western Blot and Immunohistology.

Results: Genetic deletion of GDF15 accelerated renal hypertrophy. Further, kidneys of GDF15ko mice demonstrated an increased inflammatory state and enhanced ROS production, even on normal diet. Enzymes involved in H_2S production were found to be reduced in the GDF15KO groups.

Conclusions: GDF15 exerts a protective effect against high fat diet induced kidney damage in an early model of MetS.

Funding: Government Support - Non-U.S.

Does Autophagosome-Proteolysis Contribute to CKD-Induced Muscle Atrophy? Xiaonan H. Wang,[1] Zhen Su,[1,2] Janet D. Klein,[1] William E. Mitch.[3] *[1]Renal Div, Dept of Medicine, Emory Univ, Atlanta, GA; [2]Nephrology, The First Affiliated Hospital of Wenzhou Medical College, Wenzhou, China; [3]Nephrology, Dept of Medicine, Baylor College of Medicine, Houston, TX.*

Background: We have demonstrated that the ubiquitin-proteasome (UPS) system is a major pathway for the degradation of protein in CKD-induced muscle wasting. The trigger activating the UPS is a decrease in IGF-1-stimulated intracellular signaling. Since decreased IGF-1/PI3K activity can also stimulate autophagy in epithelial cells, we hypothesized that proteolysis through autophagosomes may contribute to the muscle wasting of CKD. We examined whether autophagosome activity contributes to CKD-induced muscle atrophy; and since we have shown that exercise increases the IGF-1 pathway, we asked whether exercise ameliorates CKD muscle wasting by blunting autophagosome activity.

Methods: In 25 g mice, we induced CKD by subtotal nephrectomy and examined the effect of resistant exercise (i.e., overloading of hindlimb plantaris muscles by removing gastrocnemius and soleus muscles) on muscle atrophy.

Results: mRNA expression of 4 markers of the autophagy-lysosomal proteolysis pathway in isolated plantaris muscles were measured to assess autophagosome activity. The markers were microtubule-associated protein 1A/1B-light chain 3 II (LC3 II, indicates autophagosome number), BCL2/adenovirus E1B 19 kDa protein-interacting protein 3 (BNIP3, indexes autophagosome formation), Vps34 (class III PI 3-kinase, a regulator of autophagic sequestration) and P62 (induction of reduced autophagosome clearance). CKD increased the mRNA expression of the 4 markers ($P<0.05$) and exercise reversed this back to levels in control mice. Protein levels of Bnip3, LC3-II and Beclin-1 (an upstream regulator of autophagic sequestration) were increased in muscle from CKD mice *versus* controls. Exercise reversed these increases in autophagosome protein markers.

Conclusions: We conclude that autophagosome-mediated proteolysis contributes to CKD-induced muscle atrophy. Exercise slows the development of muscle atrophy by up-regulating the IGF-1 signaling pathway in part by inhibiting autophagy-lysosomal proteolysis pathway in CKD.

SA-PO238

Quantity and Quality of Nodular Sclerosis (Kimmelstiel - Wilson Lesion) Is Important in the Evaluation of Diabetic Nephropathy Fumihiko Yasuda,[1] Akiko Mii,[2] Megumi Fukui,[2] Yukinari Masuda,[1] Shuichi Tsuruoka,[2] Akira Shimizu.[1] *[1]Analytic Human Pathology, Nippon Medical School, Tokyo, Japan; [2]Nephrology, Nippon Medical School, Tokyo, Japan.*

Background: One of the most impact pathological characteristics of diabetic nephropathy (DN) is nodular sclerosis. In pathologic classification of DN (DN classification RPS 2010), nodular sclerosis is inclusion criteria of Class III. We examined clinic-pathological characterization of DN, focusing on the importance of quality and quantity of nodular sclerosis in DN, using DN classification RPS 2010.

Methods: We selected renal biopsy cases of DM (n=49) from our 5500 renal biopsy cases. We examined the clinico-pathological characterization of DN, focusing on the quality and quantity of nodular sclerosis in DN.

Results: Our DM cases (n=49) included class I (n=2), class IIA (n=6), class IIB (n=7), class III (n=24), and class IV (n=10). DN classification (RPS 2010) was significantly correlated with the duration of DM ($p<0.05$), degree of proteinuria ($p<0.05$), decreased eGFR ($p<0.001$) at the biopsy. In addition, DN classification (RPS 2010) was also significantly correlated with the degree of clinical DM stage ($r=0.451$, $p<0.01$) and CKD stage ($r=0.392$, $p<0.01$). In the cases with DN classification (RPS 2010) class III, the broad rage of proteinuria (0.2 to 11.4 g/day) was noted, however, there were correlated with the percentage of glomeruli with nodular sclerosis ($r=0.635$, $p<0.001$). If nodular sclerosis ratio (A <25%, B 25-50%, C 50-75%, D >75%) was added in the class III in DN classification (RPS 2010), more good correlation was evident between these pathologic classification and the levels of proteinuria ($r=0.444$, $p<0.01$), and degree of clinical DM stage ($r=0.506$, $p<0.001$) and CKD stage ($r=0.472$, $p<0.001$). In addition, nodular glomerular lesions that formed by predominant or only extracellular matrix (ECM) than cellular component were correlated with renal dysfunction and proteinuria.

Conclusions: DN classification (RPS 2010) is useful as pathologic DN classification that has good correlation with clinical characterization of DM. If DN classification includes quantity and quality of nodular sclerosis in class III, more increase of specificity is evident in this classification.

SA-PO239

Comparison of the Rate of Renal Function Decline in Nonproteinuric Patients with and without Diabetes Liliane Hobeika, Kelly J. Hunt, Benjamin Neely, John M. Arthur. *Internal Medicine - Nephrology, Medical Univ of South Carolina, Charleston, SC.*

Background: Patients with DM and CKD without proteinuria are often thought to have a cause of CKD other than DM. We hypothesized that if this is true, the rate of decline of renal function should be similar among non-proteinuric patients with and without DM. We compared the rate of renal function decline in patients with HTN with and without DM.

Methods: We searched the electronic medical record database for patients from the nephrology, endocrinology and general internal medicine clinics at our institution seen between 2008 and 2012, with an initial mean eGFR >35ml/min/1.73m^2 MDRD and identified 5035 patients. We used ICD9 diagnosis codes to identify patients with HTN and DM. We excluded patients with <2 measures of serum creatinine (Cr), with no urine studies and with proteinuria. We calculated the yearly eGFR for each patient from the lowest Cr in each year using CKD-EPI. 472 patients met the inclusion and exclusion criteria and had an initial eGFR between 35 and 80ml/min/1.73m^2. Annual rate of decline in eGFR was estimated by fitting a regression model with random intercept and slope.

Results: Data from 472 patients were analyzed. 38% were male, 37% African-American (AA), 65% had DM. Baseline eGFR was similar between groups (64±12 in non-diabetics versus 63±12ml/min/1.73m^2 in diabetics, $p=0.42$). In unadjusted analyses the rate of eGFR decline was greater in patients with DM than without DM (-0.74 versus -0.33ml/min/yr, $p=0.03$). After adjusting for age, race, gender, baseline eGFR and use of medications that block the RAS, the rate of decline was still greater among diabetics than non diabetics (-0.71 versus -0.39ml/min/yr, $p=0.03$). There was more decliners (defined as a decline in eGFR ≥3.3%/yr) among diabetics than non diabetics (34.43 versus 21.56%, $p=0.003$). The rate of eGFR decline in the diabetic group was much greater in those with a baseline eGFR <60 than with a baseline eGFR >60 (-2.09 versus 0.05ml/min/yr, $p<0.001$).

Conclusions: Patients with DM had more rapid decline in kidney function compared to those without DM in spite of the absence of proteinuria. These results suggest that even in the absence of proteinuria DM may be the cause of CKD.

SA-PO240

Does Pathogenesis of Diabetic Nephropathy Differ in Type 1 and Type 2 Diabetes? Katarzyna Madziarska, Slawomir C. Zmonarski, Magdalena Krajewska, Maria Magott, Hanna Bartosik, Oktawia Mazanowska, Miroslaw Banasik, Jan Penar, Katarzyna Jakuszko, Marian Klinger. *Nephrology and Transplantation Medicine, Medical Univ, Wroclaw, Poland.*

Background: Renal damage in diabetes mellitus type 1 (T1DM) and type 2 (T2DM) share similarities, but there is still an open question whether the pathogenesis of diabetic nephropathy (DN) is the same in T1DM and T2DM.We analyzed the association between proinflammatory cytokines (IL1β, IL6, IL18, TNFα) and potentially protective factors (25[OH]D3, C-peptide) with DN in T1DM and T2DM patients (pts). Data were compared with proteinuric pts with primary glomerulonephritis (GN).

Methods: In our preliminary study we assessed 68pts (18 T1DMpts, 26 T2DMpts, 24 biopsy proven GNpts) and 20 control. In all pts Hb, eGFR, lipids, glucose, albumin, CRP, C-peptide, HbA1c, insulin, Ca, P, homocysteine were examined. Using urinary albumin creatinine ratio (UACR) DMpts were divided into normo-, micro- et macroalbuminuric. DN was diagnosed in pts with micro- or macroalbuminuria and retinopathy. GNpts had proteinuria (range 0,6–2,9 g/d) and all were treated with ACEI. In all group we assessed IL1β, IL6, IL18, TNFα in blood and urine(u) and 25[OH]D3 in serum(s). All pts had stage 2 or 3 of CKD.

Results: T2DM pts were older, had higher: BMI, TG, C-peptide; lower HDL-cholesterol; shorter duration of DM thanT1DMpts. There were positive correlations of sIL6 and sTNFα with DN in T1DMpts. sIL1β, sTNFα and uIL6 directly correlated with DN in T2DM pts while 25[OH]D3 correlated inversely. In GNpts sTNFα, uIL6, uIL18 directly and 25[OH]D3 inversely correlated with proteinuria. Using univariate analysis of regression we assessed the risk of renal damage: DN in DMpts and proteinuria in GN pts. We found no relationship between analyzed factors and DN in T1DMpts while T2DMpts higher level of sIL1β was associated with DN. We revealed negative association between level of 25[OH]D3 and severity of proteinuria in GNpts.

Conclusions: The factors involved in pathogenesis of DN seem to be different in T1DM and T2DM. Higher level of sL1β can be predictor of DN in T2DMpts. 25[OH] D3 treatment may be a successful strategy in proteinuric GNpts. Our study didn't confirm nephroprotective role of C-peptide.

SA-PO241

Predictors of Early Renal Function Decline in Type 1 Diabetes Trevor J. Orchard,[1] Janet Snell-Bergeon,[2] Tina Costacou,[1] Rachel G. Miller,[1] David M. Maahs,[2] Marian Rewers.[2] *[1]Dept of Epidemiology, Univ of Pittsburgh, Pittsburgh, PA; [2]Barbara Davis Center for Diabetes, Univ of Colorado Denver, Aurora, CO.*

Background: The prediction of diabetic nephropathy (DN), one of the leading type 1 diabetes complications, remains a challenge. The presence of microalbuminuria may not be an adequate marker of early renal function decline (ERFD). We thus explored additional predictors of rapid estimated glomerular filtration rate (eGFR) decline in two type 1 diabetes cohorts.

Methods: Baseline DN risk factors were assessed by the Epidemiology of Diabetes Complications (EDC, 1996-98) and Coronary Artery Calcification in Type 1 Diabetes (CACTI, 2000-02) studies. In this report, we included only participants diagnosed in 1965-80, before age 17 yrs with duration >7 yrs. Participants were followed for up to 8 yrs for development of ERFD (annual eGFR decline of >3 ml/min).

Table 1. Models predicting ERFD in the CACTI and EDC cohorts

	CACTI (n=191)		EDC (n=170)	
	OR	p-value	OR	p-value
eGFR (per 19.74 ml/min/1.73m^2)	3.9	<0.0001	1.8	0.02
Log uACR (per 1.5)	2.3	<0.0001	2.0	0.0004
Duration (per 10 yrs)	1.6	0.05	0.8	0.67
Women	1.3	0.40	1.0	0.99
Black/Hispanic/Asian vs. White	0.7	0.55	0.9	0.96
HbA1c (per 1%)	1.1	0.69	1.3	0.05
Hypertension	1.1	0.90	0.9	0.92
ACEi use	0.4	0.02	1.7	0.36

Results: Though the cohorts were similar in terms of diagnosis age, duration, sex and race/ethnicity, CACTI participants had better glycemic control: mean HbA1c 7.7% (7.5%-7.9%) versus EDC 8.5% (8.3%-8.7%) and were more likely to use hypertension medications (39.5% versus 12.3%), including ACE inhibitors (33.8% versus 16.8%). ERFD incidence was 27.5% (20.9% - 34.2%) in CACTI and 23.1% (16.8%-29.4%) in EDC. In logistic models controlling for baseline eGFR (Table), higher urinary albumin to creatinine ratio predicted ERFD in both cohorts. ACE inhibitor use was associated with less ERFD in CACTI while higher HbA1c was associated with ERFD in EDC.

Conclusions: Despite glycemic control differences, ERFD incidence did not differ between the cohorts and glycemia was only weakly related to ERFD. Interestingly, ACE use appeared to be protective only in CACTI, where the prevalence of use was twofold higher compared to the EDC.

Predictors of Progressive Renal Decline Differ among Patients with Type 1 Diabetes and Advanced Stages of Chronic Kidney Disease

Masayuki Yamanouchi,[1] Monika A. Niewczas,[1] Jan Skupien,[2] William Walker,[1] Adam Smiles,[1] Andrzej S. Krolewski.[1] *[1]Genetics and Epidemiology, Joslin Diabetes Center, Boston, MA; [2]Jagiellonian Univ, Poland.*

Background: It is recognized that two major factors determine the time to progression to ESRD: baseline eGFR and the speed of renal decline (eGFR slope). In this study, we search for predictors/determinants of eGFR slope in patients with diabetic nephropathy and impaired renal function.

Methods: The study group is derived from the Joslin Proteinuria Cohort that has been followed for 7 to 18 years to ascertain ESRD and estimate eGFR slopes using serial measurements of serum creatinine (using linear regression estimates). For this analysis, we focused on the 193 T1D patients in this cohort whose renal function was in CKD stage 3 (N=106, median eGFR=46.4 ml/min/1.73m^2), and in CKD stage 4 (N=86, median eGFR=24.0) at entry into the study.

Results: The medians (25th, 75th percentile) of eGFR slope are -3.9 (-8.9, -2.0) ml/min/1.73m^2/year in CKD stage 3 and -5.9 (-10.1, -3.5) in CKD stage 4, respectively. Systemic and urinary biomarkers were determined at baseline. Spearman correlation between eGFR slope and following predictors: HbA1c, serum TNFR1, ACR, urine KIM-1, urine MCP-1, and urine NGAL were significant in patients with CKD stage 3 and CKD stage 4. In multiple regression analysis, while HbA1c (β coefficient= -1.4 ml/min/1.73m^2/year for 1 % increase in HbA1c, p-value=0.001), TNFR1 (β=-1.9 ml/min/1.73m^2/year for 1000 pg/mg increase in TNFR1, p=0.040), urine KIM-1 (β=-1.3 ml/min/1.73m^2/year for 1000 pg/mg increase in KIM-1, p=0.037), urine MCP-1 (β=-3.1 ml/min/1.73m^2/year for 1000 pg/mg increase, p=0.027), and urine NGAL (β=-2.3 ml/min/1.73m^2/year for 100 ng/mg increase in NGAL, p=0.035) were significant predictors of eGFR slope in CKD stage 3, only ACR (β=-1.2 ml/min/1.73m^2/year for 1000 mg/g increase in ACR, p=0.042) was a significant predictor of decline of renal function in CKD stage 4. The R-Squared for these models were 0.522 in CKD stage 3 and 0.2794 in CKD stage 4, respectively.

Conclusions: In conclusion, our findings suggest that predictors of renal decline may vary in T1D patients according to advanced CKD stages.

SA-PO243

Predictors of Progression to Albuminuria in Patients with Type 1 Diabetes by Metabolomics

Carol Forsblom,[1] Jeff E. Cobb,[2] Per-Henrik Groop,[1] Ele Ferrannini.[3] *[1]Helsinki Univ Central Hospital, Helsinki, Finland; [2]Metabolon, Durham, NC; [3]Univ of Pisa, Pisa, Italy.*

Background: Nephropathy in type 1 diabetes (T1D) is associated with significant excess morbidity and mortality. While estimated glomerular filtration rate (eGFR) and albuminuria (AER) are routine for assessing renal impairment in clinical practice, new biomarkers could improve prediction of progression and risk stratification.

Methods: From the FinnDiane cohort we extracted 102 T1D pts with AER <30 mg/d and eGFR ≥45 ml·min^{-1}·1.73m^2 (60% male, age 34±12 yrs [mean±SD], eGFR 97±21 ml·min^{-1}·1.73m^2, AER 17±11 mg/d) who developed albuminuria over a median 3.2 years, and a sex-, age-, BMI, and eGFR-matched group of 98 T2D pts who did not develop albuminuria over a median 7.6 yrs. Non-targeted metabolomic profiling was carried out on fasting serum samples using gas chromatography or ultra-HPLC coupled with tandem mass-spec. Biomarker identification was carried out by random forest analyses using progression to albuminuria as the endpoint. Associations were tested by multivariate logistic regression and Cox proportional hazards modeling, and ROC area was calculated.

Results: Significant (p≤0.05) clinical covariates (age of onset, HbA_{1c}, and baseline AER) predicted progression with a ROC of 0.797. The top 18 identifiable metabolites most closely correlated with progression were tested for their ability to improve the clinical prediction. We selected 6 biomarkers (3-phenylpropionate, g-glutamylglutamate, sorbitol, C-glycosyltryptophan, cis-Cyclo[L-ala-L-Pro], and cortisone) which were each independently associated with the outcome. A linear combination of these biomarkers (*Pr. Index*) raised the clinical prediction ROC to 0.883 (p<0.0001). In a Cox model, pts in the top quartile of *Pr.Index* distribution had a risk ratio (RR) of progression of 2.59 [95%CI:1.66-4.02] along with RRs of 1.27 [1.05-1.54] for age of onset, 1.36 [1.10-1.67] for baseline HbA_{1c}, and 1.47 [1.22-1.75] for baseline AER.

Conclusions: A limited number of circulating intermediates mostly of amino acid metabolic pathways carry clinically significant predictivity for progression to albuminuria in pts with type 1 diabetes.

SA-PO244

The Effect of Hyperglycemia on Plasma Uric Acid Levels in Patients with Uncomplicated Type 1 Diabetes

Yuliya Lytvyn,[1] Marko Skrtic,[1] Ronnie Lok-Hang Har,[1] Paul M. Yip,[2] David Cherney.[1] *[1]Dept of Medicine, Div of Nephrology, Toronto General Hospital, Univ of Toronto, Toronto, ON, Canada; [2]Dept of Clinical Biochemistry, Univ Health Network, Toronto, ON, Canada.*

Background: Uric acid (UA) levels are associated with metabolic, cardiovascular and renal abnormalities in patients with type 2 diabetes. The role of UA in uncomplicated type 1 diabetes (T1D) and the physiological factors that influence UA are less well understood. The aim of the present analysis was to compare plasma UA levels in T1D patients versus healthy controls (HC), and to examine the effect of UA and clamped hyperglycemia on renal hemodynamic function in T1D.

Methods: Plasma UA levels, blood pressure (BP), glomerular filtration rate (GFR-inulin), effective renal plasma flow (ERPF - paraaminohippurate), renal blood flow (RBF), renal vascular resistance (RVR) and filtration fraction (FF) were evaluated in T1D (n=68) and HC (n=41) during clamped euglycemia (glucose 4-6 mmol/L). Studies were repeated in T1D during clamped hyperglycemia (9-11 mmol/L).

Results: T1D had lower plasma UA levels within the normal range compared to HC (232±63µmol/L versus 287±69 µmol/L, p<0.0001). During clamped hyperglycemia in T1D, UA levels further decreased to 202±62 µmol/L (p<0.0001). UA levels were positively correlated with systolic BP in T1D under euglycemic conditions (r=0.27 p=0.027), but not in HC or in T1D under hyperglycemic conditions. UA levels were negatively correlated with GFR in the HC group (r=-0.44, p=0.0042), but not in T1D under either glycemic condition. UA levels were, however, negatively correlated with ERPF in T1D during hyperglycemia (r=-0.24 p=0.048). Larger high-glucose induced declines in UA correlated with smaller increases in GFR and ERPF in response to clamped hyperglycemia in T1DM patients (r=-0.28 p=0.024 and r=-0.25 p=0.045 respectively). There were no interactions between UA and RBF, RVR, or FF in either group.

Conclusions: Plasma UA correlates with BP and ERPF in patients with T1D but not HC. Plasma UA is also lower in T1D versus HC, an effect that is amplified by clamped hyperglycemia. Studies examining blood pressure and renal effects of UA lowering are warranted in T1D.

SA-PO245

Plasma KIM-1, a Marker of Tubular Injury, Predicts Risk of Early Progressive Renal Decline in Non-Proteinuric Patients with Type 1 Diabetes (T1D)

Natalia Z. Nowak,[1] Monika A. Niewczas,[1] William Walker,[1] Adam Smiles,[1] Joseph V. Bonventre,[2] Andrzej S. Krolewski.[1] *[1]Joslin Diabetes Center; [2]Brigham and Women's Hospital, Boston, MA.*

Background: It has been suggested that tubular injury contributes to the development of early diabetic nephropathy. The aim of this study was to assess whether plasma and urine levels of KIM-1 are associated with risk of early progressive renal decline in patients with T1D.

Methods: The study group included 260 participants with T1D and normoalbuminuria (NA) and 204 patients with microalbuminuria (MA). At baseline all patients had normal renal function. They were followed for a median of 8 yrs with serial measurements of serum creatinine and cystatin C to determine $eGFR_{cre\text{-}cys}$ slopes. Early progressive renal decline was diagnosed if $eGFR_{cre\text{-}cys}$ slopes were <-3.3% per year. CKD≥ Stage 3 was diagnosed when $eGFR_{cre\text{-}cys}$ decreased below 60 ml/min/1.73m^2. Baseline plasma and urinary KIM1 were measured using the Kidney Biomarker Kit (R&D).

Results: During follow-up 114 patients developed early progressive renal decline, while 71 patients reached CKD Stage ≥ 3. The risk of early progressive renal decline rose with increased plasma KIM-1. It was 4.5%, 13.8%, 21.4% and 47% (p value for trend <0.001) accordingly in patients with non-detectable KIM-1, 1st, 2nd and 3rd tertiles of the distribution of KIM-1 in plasma. A similar trend was observed for incidence of CKD ≥ Stage3 (p<0.001). Similar patterns were seen in patients with NA and MA. In multiple logistic analysis, which included all relevant covariates, the association between plasma KIM-1 and risk of early progressive renal decline remained the same as in univariate analysis. Analyses between baseline urinary levels of KIM-1 and risk of early renal function decline and CKD ≥ Stage 3 showed much weaker associations.

Conclusions: In conclusion, single determination of plasma KIM-1 predicts the risk of kidney loss in non-proteinuric T1D patients. Our findings support the view that damage of proximal tubules plays a very important role in the initiation of early progressive renal decline.

Does the Combination of Two *ABCC9* Promoter SNPs Predict Microalbuminuria and Renal Function Decline in Type 1 Diabetes (T1D)? Pittsburgh Epidemiology of Diabetes Complications (EDC) Study

Kevin Ho, Rachel G. Miller, Trevor J. Orchard. *Univ of Pittsburgh, Pittsburgh, PA.*

Background: In prior analyses cardiovascular gene *ABCC9* promoter SNP genotypes rs17335932 (AA) and rs35677639 (GG) each predicted a higher incidence of microalbuminuria (MA) in the EDC T1D cohort, while alternate genotypes predicted lower risk. We tested if combining genotypes for both SNPs affected prediction of MA, incidence of renal function decline (RFD), low eGFR.

Methods: Data were available in 483 participants. Genotypes were combined into groups: (1) rs17335932 AG/rs35677639 AA/AG, (2) rs17335932 AA/rs35677639 AA/AG, (3) rs17335932 AA/rs35677639 GG. No rs17335932 GG genotypes were observed. At baseline 268 individuals were free of MA (AER ≥20 μg/min). Analyses were performed for incident or persistent MA (2 consecutive visits with MA or worse renal status). At baseline 438 individuals had an eGFR >60 mL/min/1.73 m^2 (CKD-EPI) and were followed to determine incidence of RFD (eGFR decrease >30 mL/min/1.73 m^2 from baseline) and low eGFR (eGFR <60 mL/min/1.73 m^2).

Results: After 22 years, incidence of MA by group was: (1) 11.1%, (2) 41.2%, (3) 58.3% (p=0.004). Group (2) combining high-/low-risk genotypes exhibited an intermediate outcome. Analyses for persistent MA showed similar but weaker results (p=0.07). With multivariate adjustment, groups (2) and (3) were at significantly higher risk of incident MA compared to group (1) (HR=4.7, p=0.03 and HR=7.6, p=0.008, respectively). Group (3) also predicted RFD incidence (HR=2.2, p=0.04). No association occurred with incidence of low eGFR.

Conclusions: Combined genotypes for 2 *ABCC9* promoter SNPs predict incidence of MA. Combining high-risk rs17335932 AA and rs35677639 GG conferred greatest risk, while combining high-(rs17335932 AA) and low-(rs35677639 AA/AG) risk genotypes conferred intermediate risk. The highest risk group further predicted RFD but not low eGFR.

Histopathological Review of Native Renal Biopsies in Type 2 Diabetes and Patient Outcomes

Jasmine L. Tan,[1] Jonathan Zwi,[2] John F. Collins,[3] Tim Cundy.[1] *[1]Auckland Diabetes Centre, Greenlane Clinical Centre, Auckland, New Zealand; [2]Anatomical Pathology, Auckland City Hospital, Auckland, New Zealand; [3]Renal Medicine, Auckland City Hospital, Auckland, New Zealand.*

Background: The natural course of diabetic nephropathy (DN) in type 2 diabetic patients is complex. We aimed to identify clinical parameters associated with non-diabetic kidney disease (NDKD) and correlate the histopathological findings with patient outcomes.

Methods: We conducted a retrospective study of type 2 diabetic patients with native renal biopsies performed between 2002 and 2008. Patients' clinical records and histopathology were examined independently, and categorised to histopathological diagnoses of pure DN, NDKD and Mixed (NDKD and DN). We followed this cohort until ESRD (eGFR ≤10ml/min/1.73m^2 or dialysis), death or December 2013.

Results: There were 260 patients (164(63%) men) predominantly of Maori (37%) or Pasifika (29%) ethnicity. The mean age was 57±11 years and median duration of diabetes 8(4-15) years. 84(32%) subjects had DN alone, 72(29%) NDKD and 104(40%) Mixed diagnoses. Diagnoses in the NDKD alone category included focal segmental glomerulosclerosis (35%), immune complex glomerulonephritis (10%), minimal change disease (10%) and membranous glomerulonephritis (6%). Compared to DN and Mixed groups, patients with NDKD had a shorter duration of diabetes, lower HbA_{1c}, less proteinuria, and higher eGFR at the time of biopsy (p<0.05). Maori ethnicity (OR 0.24, 95%CI 0.06 – 0.99), male gender (OR 0.18, 95%CI 0.06 – 0.60), the presence of diabetic retinopathy (OR 0.14, 95%CI 0.047 – 0.45), a lower HbA_{1c} (OR 0.96, 95%CI 0.93 – 0.99) and higher eGFR (OR 1.03, 95%CI 1.0 – 1.05) were significantly associated with NDKD diagnosis (R^2=0.47). Patients with NDKD had significantly better renal prognosis (p=0.000) and survival outcomes (p=0.0003) compared to those in the DN and Mixed groups.

Conclusions: The risk of mortality and ESRD is high in patients with pure or mixed DN. 68% of our cohort had NDKD alone or superimposed on a background of DN. Some traditional clinical parameters, in particular the absence of retinopathy, are useful at distinguishing pure NDRD from DN.

SA-PO248

Clinical and Pathological Predictors of Estimated GFR Decline in Patients with Type 2 Diabetes and Overt Proteinuric Diabetic Nephropathy

Koki Mise,[1] Junichi Hoshino,[1] Toshiharu Ueno,[1] Keiichi Sumida,[1] Tatsuya Suwabe,[1] Kenmei Takaichi,[1,2] Yoshifumi Ubara.[1,2] *[1]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Kanagawa, Japan; [2]Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background: Clinical predictors of the decline of the estimated glomerular filtration rate (eGFR) in patients with type 2 diabetes and relatively preserved kidney function have been investigated previously. However, the impact of various clinical and pathological parameters on the decrease of the eGFR has not been assessed in patients with type 2 diabetes and overt proteinuric biopsy-proven diabetic nephropathy (DN).

Methods: Among 223 patients with diabetes who underwent renal biopsy and were confirmed to have pure DN according to the recent classification, 128 patients with type 2 diabetes and overt proteinuria were enrolled. Receiver operating characteristic analysis was performed and the area under the curve (AUC) was calculated using models adjusted for various clinical and pathological covariates to determine the best predictors of rapid eGFR decline (defined as > 14.9 %/ year [median eGFR decline]).

Results: A model that incorported proteinuria showed a significantly larger AUC than a model with only the covariates (0.812 versus 0.661, respectively, P=0.002), and it also demonstrated the largest AUC among clinical models. Although a model incorporating interstitial fibrosis and tubular atrophy (IFTA) score did not display a significantly larger AUC than the model with proteinuria (0.843 versus 0.812, respectively, P=0.47), a model with both IFTA score and proteinuria had a significantly larger AUC than the model with proteinuria alone (0.875 versus 0.812, respectively, P=0.014).

Conclusions: Our results suggest that not only proteinuria but also tubulointerstitial lesions should be assessed to predict rapid eGFR decline in patients with type 2 diabetes who have overt proteinuria and biopsy-proven DN.

Funding: Private Foundation Support

SA-PO249

Impact of Tubulointerstitial Lesions on Anemia in Patients with Biopsy-Proven Diabetic Nephropathy

Koki Mise,[1] Junichi Hoshino,[1] Toshiharu Ueno,[1] Keiichi Sumida,[1] Tatsuya Suwabe,[1] Kenmei Takaichi,[1,2] Yoshifumi Ubara.[1,2] *[1]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Kanagawa, Japan; [2]Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background: An association between anemia and the renal prognosis has been reported in patients with diabetic nephropathy (DN). The aim of this study was to investigate the relationship between the progression of anemia and renal pathological findings in patients with DN.

Methods: Among 223 patients with diabetes who underwent renal biopsy from 1985 to 2010 and were confirmed to have pure DN according to the recent classification, 113 patients (baseline hemoglobin ≥ 11 g/dl) were enrolled in this study. Linear regression analysis was used to estimate the changes of hemoglobin during the follow-up period.

Results: In a multivariate model adjusted for clinical and histopathological parameters, higher interstitial fibrosis and tubular atrophy (IFTA) scores were more strongly associated with the decrease of hemoglobin than lower IFTA scores. Compared with an IFTA score of 0, the standardized coefficients for IFTA scores of 1 to 3 were -0.20 (95% CI: -0.93 – 0.31), -0.34 (-1.34 – 0.22), and -0.47 (-1.96 – -0.07), respectively. On the other hand, a higher glomerular class, a higher vascular lesion score, and the presence of exudative lesions were not strongly correlated with the decrease of hemoglobin.

Conclusions: More advanced tubulointerstitial lesions are significantly associated with the progression of anemia in patients with DN after adjustment for numerous covariates. This finding suggests that tubulointerstitial lesions may be a useful prognostic indicator for anemia in patients with DN, and that decreased erythropoietin production due to the progression of tubulointerstitial lesions is a major cause of anemia in these patients.

SA-PO250

Insulin Resistance as a Predictor of Cardiovascular Morbidity and Chronic Kidney Disease Progression

André Fragoso, Ana Paula Silva, Pedro Neves. *Nephrology Dept, Hospital de Faro, Faro, Portugal.*

Background: Cardiovascular disease (CVD) is the main risk factor of morbidity and mortality in chronic kidney disease (CKD) patients. Insulin resistance (IR) has been reported to be a strong risk factor for CVD. The purpose of this study was to examine the usefulness of IR as a predictor of cardiovascular morbidity and CKD progression.

Methods: We followed during a period of 56 months 119 type 2 diabetic CKD patients without history of CVD at the beginning of the study. Several laboratory parameters and left ventricular mass index (LVMI) were analyzed. The degree of IR was estimated by the Homeostasis Model Assessment (HOMA-IR). Cardiovascular morbidity was assessed according to the presence of cardiovascular hospital admission during the study period and the population was divided in two groups: G-1 with cardiovascular admission (n=48) and G-2: without admission (n=71). Multivariable models were used to predict cardiovascular morbidity using HOMA-IR either a continuous or qualitative variable. CKD progression was assessed by dialysis beginning and logistic regression models were used to determine predictors for CKD progression.

Results: We found that G-1 patients showed significantly higher age, iPTH, phosphorus, IL-6, HOMA-IR (3.8 versus 0.77, p=0.0001), LVMI and lower Hg, albumin and eGFR. HOMA-IR upper tercile showed significantly higher age, eGFR, LVMI, phosphorus, iPTH and IL-6 than the other terciles. In a multivariate model HOMA-IR and IL-6 were independent risk factors of cardiovascular morbidity (HR=5.328, 95% CI, 2.884 to 32.105, p=0.048), (HR=6.239, 95% CI, 1.238 to 31.452, p=0.027), respectively. In a logistic regression model patients in the upper tercile presented significantly more cardiovascular admissions that in the lower tercile. CKD progression was observed in 24 patients and those in the upper HOMA-IR tercile showed a higher CKD progression than the rest of study patients. A multivariable logistic regression model showed that urine ACR, eGFR, IL-6 and HOMA-IR (HR=1.034, 95%CI, 1.065 to 1.650 p=0.40) were independent predictors for CKD progression.

Conclusions: In our study IR is an important risk factor for cardiovascular morbidity and CKD progression in a diabetic CKD population.

SA-PO251

Prediabetes and Its Contributing Factors in Non-Diabetic Patients with Chronic Kidney Disease Hui Peng, Qianqian Wang, Yan-Ru Chen, Jun Zhang, Xun Liu, Meirong Zhong, Yuanqing Li, Tan-Qi Lou. *Nephrology Div, Dept of Medicine, The third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Prediabetes is a condition including impaired fasting glucose (IFG) or/ and impaired glucose tolerance (IGT). Since prediabtes increases the risk of developing cardiovascular disease (CVD) or chronic kidney disease (CKD), we examined the prevalence of prediabtes in a CKD clinic in Guangzhou.

Methods: From Jan, 2013 to May 2014 all non-diabetic non-dialysis CKD patients attending the Third Affiliated Hospital of Sun Yat-sen University were analyzed in a cross-sectional observational study. CKD was defined as either an UACR≥30mg/g or eGFR <60 ml/min per 1.73m^2. Blood pressure, serum biochemistries and urine protein were collected. eGFR was calculated as described by Zhang L et al, JASN, 2006.

Results: 167 non-diabetic non-dialysis CKD patients were enrolled, 64(38.32 %) had prediabetes with age averaging 50.8±15.1yr. Prediabetes was associated principally with an increasing in IGT (90.63 %). Moreover prediabetes was associated with more hypertension (48.44% versus 21.36%, p < 0.001), higher values of serum albumin (36.70 **VS**. 34.05, p=0.019), serum creatinine (377.80 **VS**.116.7μmol/L, p<0.001), homocysteine (20.13 versus 14.81, p=0.001). Thus there were lower values of eGFR (15.75 versus 73.12 ml/min per 1.73m2, p<0.001), hemoglobin (105.50 versus 123.5g/L, p=0.002), and LDL cholesterol (2.91 versus 3.43mmol/L, p=0.029). There were more prediabetes with CKD stage 5 (50.0% versus 33.6%, p<0.001) and fewer with CKD stage 1 (12.5% versus 37.9%, p<0.001). Multivariable logistic regression analysis shows plasma creatinine (OR=1.002, 95% CI=1.001~1.003, P=0.001) was still remained significantly associated with the presence of prediabetes after multivariable adjustment.

Conclusions: Our results from a CKD clinic in China indicate that prediabetes is frequent and potentially is associated with the presence of CKD. Prediabetes in U.S. is associated with evidence of diabetic micro- and macro-vascular disease (Diabetes and vascular disease, 2014), and our results suggest that prediabetes in CKD may be linked to vascular disease.

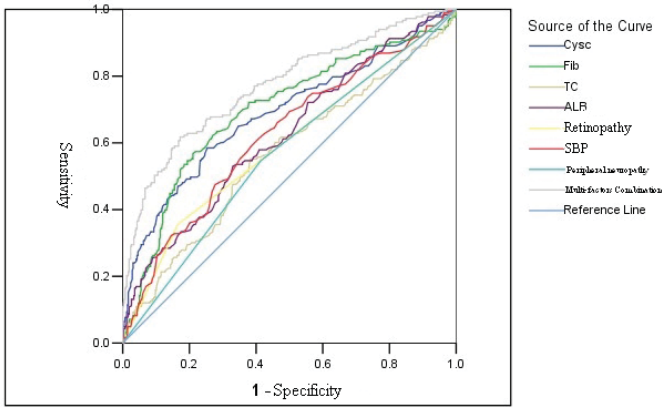
SA-PO252

A Screening Model of Correlation Factors for Type 2 Diabetes Mellitus with Microalbuminuria Wenbo Zhao, Cailian Cheng, Jun Zhang, Xun Liu, Hui Peng, Tan-Qi Lou. *Nephrology, The Third Affi liated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: To study the clinical characteristics of patients with type 2 diabetic nephropathy, analyze of the impact of the risk factors for the development of diabetic nephropathy, and establish screening model for the early stage diabetic kidney damage.

Methods: The 601 cases of the hospitalized patients with type 2 diabetes are enrolled, and recorded the patient's clinical data. Logistic regression analysis was used for finding the main risk factors for microalbuminuria Performance in type 2 diabetes. With the ROC curve principle, Multiple factors were combined to establish clinical prediction or outpatient screening equation of early diabetic kidney damage.

Results: Multivariate analysis showed that peripheral neuropathy, systolic blood pressure, diabetic retinopathy, ALB, TC, Fib, CysC, were main risk factors for the progress of the disease. The predictive value regression equation: $P = 1/[1+ e^{(-4.991+1.331X1+0.348X2+0.265X3-0.055X4+0.589X5+0.014X6+0.509X7)}]$. The under area of the ROC curve was 0.801. The maximum Value of Youden index was 0.445 and obtained 0.3518 as the diagnosis point.



Diagonal segments are produced by ties.

Conclusions: Theearly stage of diabetic kidney damage, associated with multi-factors, The screening equation of multi-factors combination can be applied to clinical risk prediction.

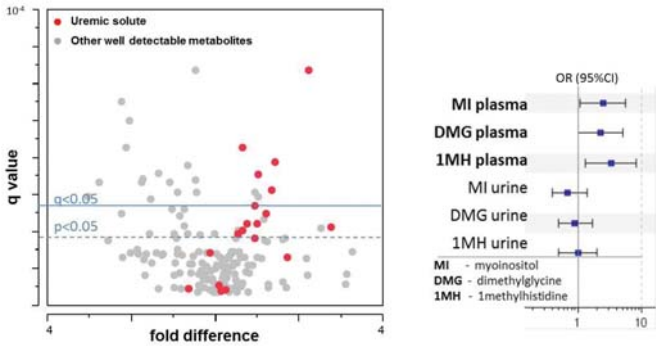
SA-PO253

Metabolomic Signature of Subjects with Type 2 Diabetes (T2D) at Higher Risk of Renal Function Decline - Replication Study Monika A. Niewczas,[1] Vladimir Tolstikov,[2] Stephanie E. Croall,[1] James R. Voelker,[2] Adam Smiles,[1] Melissa Major,[1] Kevin P. Mcdonnell,[1] Mingshang Kuo,[2] Dennis Laska,[2] Matthew D. Breyer,[2] Andrzej S. Krolewski,[1] Kevin L. Duffin.[2] [1]*Genetics and Epidemiology, Joslin Diabetes Center, Harvard Medical School, Boston, MA;* [2]*Lilly Research Laboratories, Eli Lilly, Indianapolis, IN.*

Background: In the Joslin Kidney Study of subjects with T2D we showed that plasma metabolomic signatures were associated with progression to ESRD and these included uremic solutes and branched chain (BC) derivatives. In order to test the generalizability of those findings we performed a replication study in the independent population of subjects with T2D.

Methods: Our study group consisted of 38 subjects with T2D, participants of the MBDL trial, who were followed for 3 years. At baseline mean eGFR was 80±22 ml/min and median (25th, 75th) ACR was 17 (9-74) μg/gcr. Decliners (n= 22) were defined as subjects whose eGFR loss ≥ 3.3ml/min/year. Metabolomic measurements were performed in plasma and urine of the study subjects with the usage of ABSCIEX LC/MS/MS system.

Results: 183 metabolites were detected in at least 80% of the study subjects. 26 metabolites were significantly different between decliners and non-decliners (q value <0.05). 13 uremic solutes were significantly increased (volcano plot) and certain BC derivatives were significantly decreased. Respective concentrations in urine did not correlate with plasma levels and were not different between cases and controls.



Conclusions: We confirmed associations of certain uremic solutes and BC derivatives with subsequent progression of diabetic nephropathy in an independent replication study of subjects with T2D. Further, we have shown that urinary concentrations of those uremic solutes were not altered suggesting that an increase in those solutes in plasma in subjects at risk are not a simple result of kidney filtration impairment.

Morning Hypertension and Night Non-Dipping in Patients with Diabetes and Chronic Kidney Disease Sewon Oh,[1] Kum Hyun Han,[1] Ran-Hui Cha,[2] Sejoong Kim,[3] Sunae Yoon,[4] Dong-Ryeol Ryu,[5] Jieun Oh,[6] Eun-Young Lee,[7] Dong Ki Kim,[8] Yon Su Kim,[8] Sang Youb Han.[1] *[1]Dept of Internal Medicine, Inje Univ College of Medicine, Republic of Korea; [2]National Medical Center, Republic of Korea; [3]Seoul National Univ Bundang Hospital, Republic of Korea; [4]Catholic Univ College of Medicine, Republic of Korea; [5]Ewha Womans Univ College of Medicine, Republic of Korea; [6]Hanlim Univ College of Medicine, Republic of Korea; [7]Soon Chun Hyang Univ College of Medicine, Republic of Korea; [8]Seoul National Univ College of Medicine, Republic of Korea.*

Background: Morning hypertension (MH) and non-dipping (ND) are closely associated with organ damage and cardiovascular events. The risk of MH and ND are unknown in chronic kidney disease (CKD) and diabetes (DM).

Methods: A total of 1,312 patients were prospectively recruited from 21 centers in Korea between October 2009 and May 2011. All patients had hypertension and 15-89 ml/min/1.73m^2 of estimated glomerular filtration rate (eGFR). Ambulatory 24 hour blood pressure was assessed. We divided the patients into 4 groups by status of DM and CKD (eGFR<60); no DMCKD, DM only, CKD only, and DMCKD.

Results: The rate of MH (13.6% versus 25.2%, P<0.001) and ND (48.2% versus 58.2%, P=0.002) were higher in diabetics than in non-diabetics. The level of eGFR was correlated with ND in all patients (P<0.05), and MH in only non-diabetics (P=0.005). Proteinuria (PU) was related with ND in all patients (P<0.05), and with MH in only diabetics (P=0.001). In regression analysis, the risk of MH was 2.093 (95%CI, 1.070-4.094) for the DM only group, 1.634 (95%CI, 1.044-2.557) for the CKD only group and 2.236 (95%CI, 1.401-3.570) for the DMCKD group compared with the no DMCKD group. PU was also risk factor for MH (1.591, 95% CI, 1.100-2.300). The risk of ND was not significant in the DM only group compared with the no DMCKD group. The risk of ND was significantly high in CKD: 1.581 (95%CI, 1.180-2.120) for the CKD only group; 1.872 (95%CI, 1.348-2.601) for the DMCKD.

Conclusions: Both DM and CKD are significant risk factors for MH and ND, and PU is also risk factor for MH. The risk of MH is higher in diabetics and non-diabetics with advanced CKD stages.

SA-PO255

A Urinary Peptide Classifier Predicts Albuminuria Response to Spironolactone in Patients with Type 2 Diabetes and Hypertension Morten Lindhardt,[1] Christina Stolzenburg Oxlund,[2] Harald Mischak,[3] Ib A. Jacobsen,[2] Peter Rossing,[1,4,5] Hiddo Jan Lambers Heerspink.[6] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Odense Univ Hospital, Denmark; [3]Mosaiques Diagnostics, Hannover, Germany; [4]Aarhus Univ, Denmark; [5]Univ of Copenhagen, Denmark; [6]Univ Medical Centre Groningen, Groningen, Netherlands.*

Background: We previously fund that mineralocorticoid blocker spironolactone significantly reduce albuminuria (UACR) in type 2 diabetic patients with hypertension (*Oxlund JHypertension 2014)*. However a large variability in UACR reduction was observed (5th to 95th percentile -90 to +212%) during spironolactone. We previously developed and validated a urinary proteomic classifier that predicts worsening of albuminuria (*Roscioni Diabetologia 2013)*. Here we tested whether the proteomic classifier predicts UACR response to spironolactone.

Methods: We performed a *post hoc* analysis in a randomized controlled double blind trial with allocation to either spironolactone 12.5 - 50 mg/day (n=61) or placebo (n=54) for 16 weeks. Treatment was adjuct to diuretics, calcium channel blockade and renin-angiotensin-system inhibition. UACR response was defined as change from baseline to week 16. Capillary electrophoresis mass spectrometry was used to quantify urinary peptides. A previously validated combination of 273 known urinary peptides was used as proteomic classifier (CKD273).

Results: None of the baseline clinical characteristics predicted the variability in UACR response to spironolactone at week 16. Higher values of the CKD273 classifier at baseline were associated with a larger reduction in UACR at week 16 in the spironolactone group (β=-0.70 p=0.05), but not in the placebo group (β=0.39 p=0.25). When the population was stratified in tertiles of baseline CKD273, the UACR response to spironolactone (placebo adjusted) was -13% (Cl 95%;-52 to +59) in the low, -48% (-75 to +10) in the middle, and -64% (-84 to -20) in the high CKD273 tertile (p=-0.025 for heterogeneity).

Conclusions: A urinary proteomics classifier can be used to identify individuals more likely to respond to spironolactone. These preliminary results may pave the way for more individualized therapy but need to be confirmed in a large clinical trial.

Elevated Baseline Plasma Lipoprotein(a) Levels Are Associated with Decline in Estimated Glomerular Filtration Rate Over Time Jennie Lin, Muredach Reilly, Francis Perry Wilson. *Univ of Pennsylvania, Philadelphia, PA.*

Background: Chronic kidney disease (CKD) is associated with dyslipidemia, but the role of atherogenic lipid fractions in CKD progression remains unclear. Here we assess whether baseline plasma levels of lipoprotein(a) [Lp(a)] and apolipoprotein C-III (apoC-III), causal cardiovascular (CV) risk factors being studied as therapeutic targets, are associated with decreasing glomerular filtration rate (GFR) over time.

Methods: In the Penn Diabetes Heart Study (PDHS), a single-center observational cohort of type 2 diabetes patients without clinical CV disease, we performed linear mixed effect modeling to evaluate the effects of baseline plasma Lp(a) and apoC-III on the slope of estimated GFR (eGFR) over time in subjects with longitudinal data (n=550). Adjustment for covariates was performed in the following incremental models: Model 1, demographic factors and baseline serum creatinine; Model 2 also included lipid-lowering medications, body mass index, and hypertension; Model 3 further included for hemoglobin A1c; and Model 4 additionally included urinary albumin to creatinine ratio (ACR). eGFR was calculated with the CKD-Epi equation.

Results: Each two-fold higher plasma Lp(a) level was associated with a decline in eGFR by 0.24 mL/min/year in the unadjusted model (p<0.001) and by 0.28 mL/min/year in the fully adjusted model (p<0.001). Baseline Lp(a) levels greater than the atherogenic cut-point of 30 mg/dL were associated with a decline in eGFR by 0.66 mL/min/year in the unadjusted model (p<0.001) and by 0.82 mL/min/year in the fully adjusted model (p<0.001). Although each log-transformed unit of apoC-III was associated with a decline in eGFR by 0.68 mL/min/year in the unadjusted model, the association was attenuated after adjusting for hemoglobin A1c and urinary ACR.

Conclusions: Elevated baseline plasma Lp(a) levels are associated with a decrease in eGFR over time independent of race, lipid medication use, and albuminuria. Additional longitudinal studies, including Mendelian randomization for CKD as an outcome, are needed to determine if Lp(a) is a causal risk factor for CKD progression.

Clinical Predictors of Non-Diabetic Renal Disease in Patients with Type 2 Diabetes Yong Pey See, Yue-Harn Ng. *Renal Medicine, Tan Tock Seng Hospital, Singapore, Singapore.*

Background: Non diabetic renal disease (NDRD) is common amongst diabetic patients and tends to portend a better prognosis. Differentiating diabetic nephropathy (DN) from non diabetic renal disease is crucial for early diagnosis and intervention. Our study aims to identify clinical predictors that differentiate NDRD from DN.

Methods: We performed a retrospective case-control study on our diabetic patients who underwent a renal biopsy at our institution from February 2010 to May 2014. Biopsy findings were classified as DN or NDRD. Clinical parameters including age, blood pressure (BP), duration of diabetes, HbA1c, complications of diabetes including peripheral vascular disease (PVD), proteinuria, hematuria and retinopathy, were collected by chart review and compared between DN and NDRD groups.

Results: 100 diabetic patients underwent a renal biopsy during this period, 2 of whom were excluded for inconclusive biopsy findings. The mean age was 58.3 ± 12 years old and 61.2% were male. The most common indication for biopsy was for rising creatinine (43.9%), followed by sub-nephrotic range proteinuria (25.5%), nephrotic syndrome (18.4%) and hematuria (8.2%). DN was identified in 47/98 (48%) of the biopsies while 51/98 (52%) were NDRD. The most common NDRD are lupus nephritis and IgA nephropathy with 9/51 (17.6%) cases each. Male gender, presence of diabetic retinopathy, PVD, dyslipidaemia, average systolic BP, average HBA1c and HbA1c > 9% were associated with DN on univariate analysis. In the multivariate model, only diabetic retinopathy remained significantly associated with DN (OR 14.7; p <0.05) Traditional risk factors such as duration of diabetes, BP, presence of microalbuminuria, macroalbuminuria and macrovascular complications did not predict DN. Presence of diabetic retinopathy carries a positive predictive value of 78% and a negative predictive value of 87%.

Conclusions: In this study, diabetic retinopathy is strongly associated with diabetic nephropathy. The absence of diabetic retinopathy carries a strong negative predictive value for DN. Hence diabetic patients without documented retinopathy, especially in the setting of atypical features, should raise suspicion for NDRD and warrants early renal biopsy.

SA-PO258

Renal Anemia in Diabetic Patients with Nearly Normal Estimated Glomerular Filtration Rate (eGFR) Takayuki Hamano,[1] Hiromi Rakugi,[2] Yoshitaka Isaka,[2] Yoshiharu Tsubakihara.[1] *[1]Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Serum erythropoietin (EPO) levels are reported to be elevated in anemic subjects with normal renal function. Renal anemia derives mainly from inadequate EPO production by the kidney relative to hemoglobin levels and is considered to emerge at chronic kidney disease (CKD) stage 3B. Diabetic patients with CKD are reported to have severer anemia, however, renal anemia has not been studied well in diabetic patients with nearly normal eGFR.

Methods: In this cross-sectional study, we enrolled 1,621 patients with eGFR>=45mL/min/1.73m^2 from 2,264 diabetic outpatients seen by diabetologists. The definition of anemia is based on WHO criteria. We performed multiple logistic regression analyses with the presence of anemia as a dependent variable. One third of the anemic patients was chosen randomly from this cohort for additional measurement of serum EPO in addition to ferritin and TSAT. We conducted a multiple linear regression analysis with serum EPO as a dependent variable.

Results: Anemia was observed in 470 patients (29%). Massive proteinuria (dipstick 3+) was significantly associated with presence of anemia after adjusting for age, sex, eGFR, triglyceride, LDL, and HbA$_1$C (Odds ratio: 2.33; 95%CI 1.02-5.29). The fact that the percentage of anemic patients increase with the increase in proteinuria suggest the presence of renal anemia even in nearly normal range of eGFR. In subgroup analysis of 166 patients, serum EPO levels were lower than upper limit of normal range despite anemia(relative EPO

deficiency)in substantial percentage of patients (61%). This percentage of EPO deficiency increases with decrease in eGFR and with the increase in urinary albumin(eGFR>90, 50%; eGFR 60-90, 58%; eGFR<60, 63%, P<0.05 for trend). The determinants of serum EPO were found to be eGFR and albuminuria in addition to BMI, serum Alb, and hemoglobin.

Conclusions: Substantial percentage of diabetic patients are relative EPO deficient even if their eGFR are normal or nearly normal, possibly due to diabetic tubulointerstitial injury.

Glomerular MRP8 Expression Predicts Progression of Proteinuria in Obese or Type 2 Diabetic Patients Takashige Kuwabara,[1] Kiyoshi Mori,[2] Hideki Yokoi,[1] Shinji Yasuno,[3] Masato Kasahara,[3] Kenji Ueshima,[3] Kazuwa Nakao,[2] Masahito Imanishi,[4] Akira Nishiyama,[5] Motoko Yanagita,[1] Masashi Mukoyama.[1,6] *[1]Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [2]Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [3]EBM Research, Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan; [4]Nephrology and Hypertension, Osaka City General Hospital, Osaka, Osaka, Japan; [5]Pharmachology, Kagawa Univ Medical School, Kagawa, Japan; [6]Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: Our previous report indicated that toll-like receptor 4 and one of its endogenous ligands, myeloid-related protein 8 (MRP8), play an important role in diabetic nephropathy in mice. We performed this study to evaluate significance of renal MRP8 expression in obese or type 2 diabetic patients.

Methods: In obese, diabetic or control subjects, MRP8 mRNA and protein expressions in renal biopsy samples were determined by real-time RT-PCR and immunohistochemistry (n = 28 and 65, respectively) and their associations with baseline and prognostic parameters were analyzed.

Results: Kidney MRP8 expression was significantly higher in obese or diabetic groups than in control group both in mRNA and protein levels. At baseline, univariate analysis showed that glomerular MRP8-positive cell count and tubulointerstitial MRP8-positive area were correlated not only with various known risk factors for diabetic nephropathy (such as systolic blood pressure, proteinuria and serum creatinine) but also with extent of glomerulosclerosis and tubulointerstitial fibrosis. Multiple regression analyses were performed to identify explanatory factors predicting renal outcomes including proteinuria and renal event. Glomerular MRP8-positive cell count ($\beta = 0.59$, $P < 0.001$) was an independent predictive factor for the extent of proteinuria a year later, as well as baseline proteinuria ($\beta = 0.37$, $P = 0.002$) and systolic blood pressure ($\beta = 0.21$, $P = 0.04$) after adjustment for known risk factors.

Conclusions: Glomerular MRP8 expression appears to be associated with progression of proteinuria in obese or type 2 diabetic patients.

Zinc Alpha 2 Glycoprotein Predicts Early Renal Function Decline in Type 2 Diabetes Sharareh Saadat,[1] Kelly J. Hunt,[1,2] Nishant M. Bhensdadia,[1] Alison Bland,[1] John M. Arthur.[1,2] *[1]Dept of Medicine, Medical Univ of South Carolina, Charleston, SC; [2]Dept of Medicine, Ralph H. Johnson VA Medical Center, Charleston, SC.*

Background: Albumin to creatinine ratio (ACR) is used to predict future renal disease in patients with diabetes but it has inadequate specificity and sensitivity. We previously used proteomic analysis to identify a novel group of protein candidates to predict early renal function decline (ERFD) in patients with diabetes. One of the candidates was zinc alpha 2 glycoprotein (ZAG).

Methods: We measured ZAG concentration in 231 urine samples from type 2 diabetic patients without known kidney disease from the VADT study. Annual rate of eGFR decline (MDRD) over a median 4.4 years of follow-up was defined by fitting a regression model with random intercept and slope for each patient. We compared urinary ZAG levels between diabetic patients with and without ERFD (defined as a decrease in eGFR of ≥3.3% per year).

Results: Age, diabetes duration, baseline creatinine, blood pressure and use of ACE inhibitors were not different between subjects with ZAG concentration above and below the median. 57 patients (25%) had ERFD. Patients without ERFD had a natural log ZAG concentration of 3.03 compared to those with ERFD with a ZAG concentration of 3.40 (P=0.05). Respective natural log values for urine creatinine adjusted ZAG were -4.26 and -3.91 (P=0.09). One standard deviation change in ZAG concentration (adjusted for treatment group and ACEI use at baseline) was associated with an odds ratio of 1.38 (95% CI 1.00, 1.92, p=0.05, AUC=0.619) for ERFD. ACR had similar prognostic ability but interestingly there was a poor correlation between concentrations of the two biomarkers (0.34). The use of ZAG in combination with ACR resulted in selection of a group with higher risk for ERFD. Having high ACR and ZAG (compared to the median split) conferred a 2.7 fold risk of ERFD compared to the group with low ACR and ZAG.

Conclusions: Urinary ZAG concentrations were found to be elevated in type 2 diabetic patients who had early renal function decline. Combination of ACR with ZAG may provide better prediction of ERFD in patients with type 2 diabetes.

SA-PO261

CNDP1 (CTG)5 Homozygosity in Type 2 Diabetic Patients: Relevance for Nephropathy and Hemodialysis Sibylle Jenny Hauske, Shiqi Zhang, Thomas Albrecht, Bernhard K. Krämer, Benito Yard. *Vth Med. Clinic, Med. Faculty Mannheim, Univ of Heidelberg, Mannheim, Germany.*

Background: Although several studies in type 2 diabetic (T2DM) patients (pat.) showed that homozygosity for the (CTG)5 allele (homCTG5) of the Carnosinase 1 (CN1) gene is associated with reduced susceptibility for diabetic nephropathy (DN),it is unclear why not all homCTG5 pat. are protected.We assume that independent factors influence CN1 concentration and activity (c+a).We performed an epidemiological study to shed light on CN1 metabolism in a T2DM cohort.

Methods: We included pat. with (n=127) and without DN (n=145).We assessed CN1 genotype and CN1 c+a.

Results: Female pat. without DN showed higher homCTG5 frequency compared to females with DN.When applying more stringent criteria for DN frequency for homCTG5 became also significant in male pat.

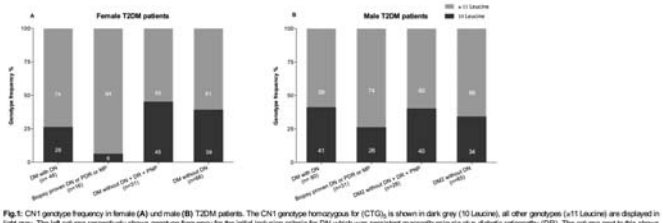

Fig.1: CN1 genotype frequency in female **(A)** und male **(B)** T2DM patients. The CN1 genotype homozygous for $(CTG)_5$ is shown in dark grey (10 Leucine), all other genotypes (≠11 Leucine) are displayed in light grey. The left column respectively shows genotype frequency for the initial inclusion criteria for DN which was persistent macroalbuminuria plus diabetic retinopathy (DR). The column next to this shows genotype frequency with more stringent inclusion criteria for DN which means only biopsy proven DN or macroalbuminuria in combination with advanced stages of DR (PDR=proliferative DR, MP=maculopathy). The right column respectively shows the initial inclusion criteria for no DN which were a diabetes duration of at least 15 years in combination with normoalbuminuria and no higher stage of DR than mild non-proliferative DR. Next to this column the genotype frequency with more stringent inclusion criteria for no DN are shown which means no microvascular complications at all were allowed (PNP=peripheral neuropathy). The comparison of CN1 genotype frequency showed significant differences in both female and male patients (χ^2 test for trend; p<0.0001 **(A)** und p=0.036 **(B)**).

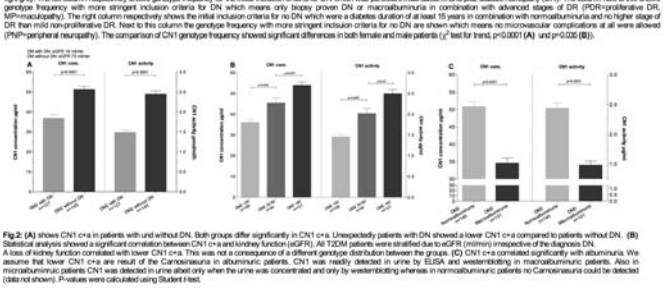

Fig.2: **(A)** shows CN1 c+a in patients with und without DN. Both groups differ significantly in CN1 c+a. Unexpectedly patients with DN showed a lower CN1 c+a compared to patients without DN. **(B)** Statistical analysis showed a significant correlation between CN1 c+a and kidney function (eGFR). All T2DM patients were stratified due to eGFR (ml/min) irrespective of the diagnosis DN. A loss of kidney function correlated with lower CN1 c+a. This was not a consequence of a different genotype distribution between the groups. **(C)** CN1 c+a correlated significantly with albuminuria. We assume that lower CN1 c+a are result of the Carnosinasuria in albuminuric patients. CN1 was readily detected in urine by ELISA and westernblotting in macroalbuminuric patients. Also in microalbuminuric patients CN1 was detected in urine albeit only when the urine was concentrated and only by westernblotting whereas in normoalbuminuric patients no Carnosinasuria could be detected (data not shown). P-values were calculated using Student *t*-test.

Pat. with DN showed lower CN1c+a as compared to pat. without DN and furthermore declining eGFR correlated with serum CN1c+a.In pat. with macroabluminuria CN1 was detected in urine by ELISA+WB. CN1c+a inversely correlated with time on hemodialysis (HD),the longer pat. were on HD the lower CN1c+a was and frequency for homCTG5 increased over time on HD (<12 versus >120 months 30 versus 67%, p<0.0001).

Conclusions: In addition to female also male pat. with homCTG5 seem to be protected if inclusion criteria for DN are chosen more stringent. Our data also indicate a correlation between loss of renal function and CN1c+a, which can be explained by the onset of canosinasuria.We speculate that CN1 might be reabsorbed in the proximal tubules where it may further deplete carnosine concentrations.Hence, not only serum CN1c+a plays an important role for progression of DN but also increased local CN1c+a in the kidney does. Finally we hypothesize that homCTG5 T2DM pat. which develop ESRD may still benefit above other genotypes as it seems to be associated with a lower mortality rate amongst these pat.

SA-PO262

Associations of Serum Bicarbonate with Renal and Cardiovascular Outcome in Patients with Diabetes and Nephropathy Elise Schutte,[1] Hiddo Jan Lambers Heerspink,[1] Helen L. Lutgers,[1] Stephan J.L. Bakker,[1] Bruce Wolffenbuttel,[1] Kausik Umanath,[2] Dick de Zeeuw,[1] Julia Lewis,[3] Ron T. Gansevoort.[1] *[1]UMC Groningen, Groningen, Netherlands; [2]Henry Ford Hospital, Detroit; [3]Vanderbilt Univ, Nashville.*

Background: Low serum bicarbonate has been reported to be an independent predictor of renal function decline and mortality. To date, no study has investigated this association in a population with diabetes and nephropathy. We therefore aimed to investigate the association of serum bicarbonate with renal and cardiovascular (CV) outcome in this population.

Methods: Post hoc analysis of 2 multicenter randomized controlled trials (RENAAL and IDNT). Cox regression models were built to examine the longitudinal associations of baseline serum bicarbonate with endpoints. Bicarbonate was studied as continuous variable and stratified in quartiles to allow assessment of non-linear associations. Outcomes were incidence of end stage renal disease (ESRD), the combined endpoint ESRD or doubling of serum creatinine (DSCR) and CV outcome (incidence of fatal/non-fatal stroke/myocardial infarction).

Results: We included 2628 patients (mean age 60 ± 7 (SD) years, 65% male, 61% white) with a mean estimated GFR (eGFR) 44 ± 16 mL/min/1.73m2 and median UACR of 1366 mg/g (IQR 682 – 2653). Mean serum bicarbonate was 24.3 ± 3.7 mEq/L. During follow-up for 2.8 ± 1.0 years, 576 (22%) patients died, 491 (19%) developed ESRD, 731 (28%) had DSCR or ESRD, and 457 (17%) a CV event. Cox regression showed that bicarbonate had a negative association with incident ESRD (HR 0.91 (95% CI 0.90-0.93), P<0.001), and

with the incidence of the combined endpoint of ESRD or DSCR (HR 0.94 (0.92-0.96), P<0.001). These associations were independent of age, gender and CV risk factors, but lost significance when adjusting for baseline eGFR. Analysis of bicarbonate quartiles showed similar results. There were no significant associations of bicarbonate with CV events.

Conclusions: In this type 2 diabetes cohort with nephropathy, serum bicarbonate was not independently associated with renal or CV endpoints, contradicting earlier studies in non-diabetic populations.

SA-PO263

Urinary Trefoil Factor 3 Levels in Association with Albuminuria in Patients with Early Stages of Diabetic Nephropathy Naoto Terami, Daisuke Ogawa, Hitoshi Sugiyama, Toshio Yamanari, Takashi Hatanaka, Hiromi Tachibana, Naoko Nishii, Jun Wada, Hirofumi Makino. *Dept of Medicine and Clinical Science, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Trefoil factor (TFF) peptides are coexpressed with mucins in the gastrointestinal tract stomach, colon and are also expressed in kidney tubules. Serum levels of TFF3 have been reported a possible biomarker of gastric cancer. Furthermore, Yu et al. reported that urinary TFF3 (uTFF3) levels were reduced, and urinary albumin levels increased in response to renal tubular injury in mice (Nat Biotechnol 2010). In this study, we determined whether uTFF3 is an efficient biomarker in patients with early staegs of diabetic nephropathy.

Methods: Spot urine samples were obtained from 79 male and 64 female type 2 diabetic patients (n=143) in Okayama University Hospital. The levels of uTFF1, uTFF2, and uTFF3 were measured quantitatively by specific ELISAs to analyze the correlation between uTFF1, uTFF2, uTFF3 and various clinical parameters. Furthermore, we also examined the correlation between Liver-type Fatty Acid-Binding Protein (L-FABP), N-acetyl-β-D-glucosaminidase (NAG), α1-microglobulin (α1-MG), β2-microglobulin (β2-MG) and uTFFs to evaluate the relation between renal tubular dysfunction and urinary levels of TFFs.

Results: The level of uTFF3 significantly increased in diabetic patients with microalbuminuria compared to those with normoalbuminuria (p=0.0139). In contrast to the level of uTFF3, the level of uTFF1 or uTFF2 did not significantly elevate in diabetic patients with microalbuminuria compared to those with normoalbuminuria.

Conclusions: These data indicate that the excretion of uTFF3 is selectively associated with microalbuminuria in patients with diabetes mellitus. Further studies are necessary to elucidate whether the selective elevation of uTFF3 in association with microalbuminuria can predict the progression of diabetic nephropathy.

SA-PO264

Two New Biomarkers in Urine (Peptides and Ceruloplasmin) for Diagnosing Early Diabetic Nephropathy Krishnamurthy P. Gudehithlu,[1] Jane Vernik,[1,2] Sandya Shivashankar,[1] Keerti K. Bhanushali,[1] Bhavi Paresh Pandya,[1] Mark A. Kraus,[1,2] Peter D. Hart,[1,2] Jose A.L. Arruda,[1,3,4] George Dunea,[1,3] Ashok K. Singh.[1,3,4] *[1]Div of Nephrology, John H. Stroger, Jr. Hospital of Cook County (JSH), Chicago, IL; [2]Dept of Internal Medicine, Rush Univ Medical College, Chicago, IL; [3]Section of Nephrology, Univ of Illinois at Chicago, Chicago, IL; [4]The Hektoen Inst of Medicine, Chicago, IL.*

Background: Early diagnosis of diabetic nephropathy (DN) is important for its optimal management. Functional change in the glomerulus leading to microalbuminuria is currently believed to be the first sign of DN. There is a growing recognition that functional renal tubular changes occur earlier than glomerular changes in DN (J.V.Bonventre, Semin Nephrol. 32:452-462, 2012). These include tubular growth, tubular hyperactivity manifested as solute hyper-absorption, oxidative stress and inflammation. We hypothesized that measuring specific tubular markers in urine may aid in the early diagnosis of DN.

Methods: Urinary peptides (a function of tubular activity and growth) and exosomal ceruloplasmin (a marker of tubular inflammation) were estimated in early DN patients with microalbuminuria (30-300 μg/g creatinine) (earlyDN, n=25) and non-diabetic controls (nonDb, n=23). Urine samples were collected from the renal and diabetes clinics at JSH. Peptide concentration in whole urine was determined by subtracting values obtained by the Lowry assay (measures peptides and proteins) from the BioRad assay (measures proteins). Ceruloplasmin level was determined in exosomes (prepared by differential ultracentrifugation) using a sandwich ELISA kit. Both, peptides and ceruloplasmin, were corrected by urinary creatinine.

Results: In earlyDN patients compared to nonDb controls, peptide levels increased by 210% (p<0.05), and ceruloplasmin levels increased by 560% (p<0.05).

Conclusions: We conclude that marked increase of peptides and ceruloplasmin in urine of earlyDN suggests a significant dysfunction of the tubular system in early diabetic kidney disease. Peptides and ceruloplasmin in urine are two potential biomarkers that need to be explored further for early diagnosis of DN.

The Association of Adiponectin with Diabetic Complications in Type 2 Diabetic Patients Sung Jin Kim, Jungyeon Ghee, Jung Eun Kim, Hye Sook Min, Jin Joo Cha, Young Sun Kang, Dae R. Cha. *Korea Univ Medical College Ansan Hospital, Ansan, Republic of Korea.*

Background: Adiponectin is a 244-amino acid collagen-like protein that is solely secreted by adipocytes and acts as a hormone with anti-inflammatory and insulin-sensitizing properties and regulates the metabolism of lipids and glucose. It plays important role in the development of insulin resistance and atherosclerosis. However, it is uncertain that the association of adiponectin with diabetic complications. We investigated the association of serum adiponectin level with diabetic complications in type 2 diabetic patients.

Methods: We conducted a prospective study of 161 patients with type 2 diabetes from 2002 to 2013. Spearman's correlation coefficients were calculated to evaluate the relationship between adipokines and biomarkers associated with diabetic complications. Linear by linear association test was performed with grouping each adiponectin, diabetic complications and biomarkers. All statistical analyses were performed using SPSS version 18.0.

Results: Age, sex, diabetes duration, cholesterol, LDL cholesterol, calcium channel blocker, thiazolidinedione, diabetic neuropathy, dialysis and 24hr protein efficiency ratio were positively correlated with serum adiponectin level(all p<0.05). eGFR was negatively correlated with serum adiponectin level(p<0.05). Quartile group of serum adiponectin was significantly linear relationship with age, sex, diabetes duration, cholesterol, LDL cholesterol, thiazolidinedione, diabetic nephropathy and chronic kidney disease stage (all p<0.05).

Conclusions: At present, medical research has shown that synthetic adiponectin may be able to raise adiponectin levels and medications could exist to prevent diabetes. Taken our research together, serum adiponectin level was significantly relationship with hyperlipidemia, diabetic neuropathy and nephropathy. Our research showed that adiponectin was potential pharmacologic treatment modality of the diabetic complication of type 2 diabetic patients.

SA-PO266

The Association of Adipokine with Diabetic Complications in Type 2 Diabetic Patients Sung Jin Kim, Jung Eun Kim, Jungyeon Ghee, Hye Sook Min, Jin Joo Cha, Dae R. Cha, Young Sun Kang. *Korea Univ Medical College Ansan Hospital, Ansan, Republic of Korea.*

Background: Glypican-4 is enhanced insulin signaling through direct interaction with the insulin receptor and promoted adipocyte differentiation. Irisin is related to glucose tolerance status and known to be lower in type 2 diabetes. RBP4(retinol binding protein 4) is known to cause insulin resistance, prediabetes, metabolic syndrome and myocardial infarction by adipose tissue inflammation. Visfatin has insulin-like activity and is able to bind to the insulin receptor. However, it is uncertain that the association of them with diabetic complications.

Methods: We conducted a prospective study of 161 patients with type 2 diabetes from 2002 to 2013. Spearman's correlation coefficients were calculated to evaluate the relationship between adipokines and biomarkers associated with diabetic complications. Linear by linear association test was performed with grouping each adipokine, diabetic complications and biomarkers.

Results: Glypican-4 was positively correlated with ACEI and beta blocker, and negatively correlated with irisin and eGFR. Quartile group of glypican-4 was linear relationship with beta blocker. Irisin was positively correlated with 2hrs post-prandial plasma glucose level, and negatively correlated with sulfonylurea, retinopathy, urine protein creatinine ratio and glypican-4. Quartile group of irisin was linear relationship with sulfonylurea, retinopathy, urine protein creatinine ratio and 2hrs post-prandial plasma glucose level. RBP4 was positively correlated with hypertension, beta blocker, calcium channel blocker, serum creatinine, nephropathy and dialysis, and negatively correlated with eGFR. Quartile group of RBP4 was linear relationship with hypertension, beta blocker, calcium channel blocker, nephropathy and CKD stage. None of them are associated with serum visfatin level.(all p<0.05).

Conclusions: Glypican4, irisin and RBP4 were correlated with hypertensive medication and renal injury. Especially, quartile group of irisin and RBP4 were linear relationship with renal injury. In type 2 diabetic patients, the measurement of serum adipokine is possible to predict the renal disease among the diabetic complications.

SA-PO267

Residual Proteinuria as a Risk Factor for Rapid Renal Function Decline During Pre-Dialysis Phase in Type 2 Diabetic Patients with Severely Impaired Renal Function Yuichiro Kitai,[1,2] Masao Koshikawa,[1] Motoko Yanagita,[2] Akira Sugawara.[1] *[1]Dept of Nephrology, Osaka Red Cross Hospital, Osaka, Japan; [2]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

Background: Proteinuria is an established risk factor for progression of renal disease, including diabetic nephropathy. The predictive power of proteinuria for progressive renal function decline has been well demonstrated in diabetic patients with normal to relatively preserved renal function. However, little is known about the impact of proteinuria on renal outcome in pre-dialysis diabetic patients with severely impaired renal function.

Methods: We identified 125 incident dialysis patients with type 2 diabetes. The purpose of this study was to retrospectively analyze the relationship between nephrotic range proteinuria (urinary protein-creatinine ratio above 3.5 g/gCr) and renal function decline during the three months just prior to dialysis initiation.

Results: In total, 103 patients (82.4%) had nephrotic range proteinuria. The median rate of decline in the estimated glomerular filtration rate (eGFR) in this study population was 0.98 (interquartile range 0.51-1.46) ml/min/1.73m^2 per month. Compared to patients with non-nephrotic range proteinuria, patients with nephrotic range proteinuria showed significantly faster renal function decline (0.46 [0.24-1.25] versus 1.07 [0.64-1.54] ml/min/1.73m^2 per month; p = 0.007). A multivariate analysis after adjusting for systolic blood pressure, hemoglobin, serum albumin, total cholesterol, hemoglobin A1c, and use of renin angiotensin system inhibitors revealed that patients with nephrotic range proteinuria showed a 4.23-fold (95% confidence interval: 1.12-16.6) increased risk for rapid renal function decline defined as a decline in eGFR ≥0.5 ml/min/1.73m^2 per month.

Conclusions: Nephrotic range proteinuria is the predominant renal risk factor in type 2 diabetic patients with severely impaired renal function receiving pre-dialysis care. Reduction of residual proteinuria to the lowest achievable level might be better considered as a goal for renoprotective treatment.

Urine Proteomics in Proteinuric DKD Maryam Afkarian, Leila R. Zelnick, Jonathan Himmelfarb. *Div of Nephrology, Dept of Medicine, Kidney Research Inst, Seattle, WA.*

Background: Our understanding of the mechanisms underlying various stages of diabetic kidney disease (DKD) in humans is largely derived from studies in animal models of DKD. Large-scale analysis of urine proteins may provide information on pathways dysregulated in human DKD.

Methods: We used mass spectrometry-based proteomic analysis to compare urine proteins in type 1 diabetes with (n=32) and without (n=29) kidney disease. DKD was defined as an albumin to creatinine ratio (ACR) > 300 mg/g or eGFR <60 ml/min/1.73m^2 and ACR > 30 mg/g. Absence of DKD was defined as eGFR > 90 ml/min/1.73m^2 and ACR <300 mg/g after > 30 years of type 1 diabetes.

Results: Analyzing cases and controls as groups, we identified 3065 and 3051 proteins, respectively, 1401 of which were higher in cases. Analyzing cases and controls individually, we identified 3209 proteins with 670 identified in > 50% of cases and > 50% of controls. Of these, 215 were higher in cases, 95 of which reached nominal significance (p<0.05). Cases showed an overexpression of proteins involved in cytoskeleton, response to hypoxia, immune response, cell cycle and apoptosis, as well as the endo-phagocytic machinery. The latter group included proteins involved in all steps of endo-phagoyctosis, from membrane invagination to lysosomes and lytic vacuoles, possibly reflecting the increase in proximal tubular endocytosis and intracellular proteolysis of tubular proteins in proteinuric DKD. Among overexpressed lysosomal proteins were several cathepsins, whose increase in DKD urine was confirmed using immunoassays. As cathepsins can convert angiotensin I to angioteins II and are not blocked by ACE inhibitors, their increase provides a potential mechanism of renal RAAS escape from ACE inhibition in proteinuric DKD.

Conclusions: Examination of urine proteins using mass spectrometry-based proteomics shows overexpression of proteins involved in cytoskeleton, response to hypoxia, immune response, cell cycle and apoptosis, as well as the endo-phagocytic machinery in proteinuric DKD. The latter included an increase in lysosomal cathepsins, which may provide a mechanism for renal angiotensin II generation despite ACE inhibition in proteinuric DKD.

Glycemic Markers and 1-Year Diabetic Hemodialysis Outcomes from the GIDE Study Mark E. Williams,[1] Neal Mittman,[2] Lin Ma,[3] Julia I. Brennan,[4] Curtis D. Johnson,[4] Franklin W. Maddux,[3] Eduardo K. Lacson.[3] *[1]Joslin Diabetes Center, Boston, MA; [2]Kidney Care of Brooklyn and Queens, Brooklyn, NY; [3]Fresenius Medical Care, North America, Waltham, MA; [4]Spectra Laboratories, Rockleigh, NJ.*

Background: Prognostic implications of glycemia in HD patients based on hemoglobin A1c (HgbA1c), albumin-adjusted and unadjusted fructosamine (AlbF; F) and glycated albumin (GA) or percent GA (%GA) have been proposed. From the multi-year prospective observational Glycemic Indices in Dialysis Evaluation (GIDE) Study, we report 1st year outcomes associated with hyperglycemic thresholds for these markers per the literature and/or manufacturer recommendations.

Methods: As of April 1, 2013, 1,392 active HD patients with DM from 26 FMCNA facilities with glycemic markers from Jan-Mar 2013 were followed until Mar 31, 2014. Poor glycemic control was based on: HgbA1c>7% (sensitivity analysis >8%), AlbF≥974 µmol/g, F>285 µmol/L, %GA>15.7%, and GA>300 µmol/L. Cox models with and without adjustment for age, sex, race, ethnicity, vintage (log), BMI, HD catheter, and baseline comorbid illnesses were utilized to determine associations between each dichotomized glycemic index with death and with hospitalization.

Results: Poor glycemic control was found in 28% (HgbA1c>7%), 13% (HgbA1c>8%), 35% (AlbF), 87% (F), 81% (%GA) and 69% (GA) of patients. AlbF was associated with 1-year hospitalization risk with HR=1.28 (1.11, 1.48) and adjusted-HR=1.33 (1.14, 1.54), both p<0.001; but not with mortality. For the other glycemic indices, Cox model analyses for both outcomes showed no significant associations.

Conclusions: Early GIDE study findings indicated an association between poor glycemic control determined by AlbF and worse 1-year hospitalization risk. No 1-year outcome associations were detected with other markers evaluated, including with HgbA1c at either 7% or 8% thresholds. Further evaluation will include use of continuous values for glycemic indices to determine other potential thresholds for risk, incorporating repeated measures of glycemic indices, adding more adjustment variables, outcomes analyses of hospital events/days and cause-specific deaths, and longer term follow-up.

SA-PO270

Predictive Factors for Non-Diabetic Nephropathy in Diabetic Patients Sheila Bermejo,[1] Maria Jose Soler,[1] Javier Gimeno,[2] Clara Barrios,[1] Eva Rodriguez,[1] Julio Pascual.[1] *[1]Nephrology, Parc de Salut Mar, Barcelona, Spain; [2]Pathology, Parc de Salut Mar, Barcelona, Spain.*

Background: Renal biopsies taken in diabetic patients are increasing in number and complexity. The objective of this study is to determine the predictability of a renal biopsy (non-diabetic nephropathy or diabetic nephropathy) by clinical and laboratory data in diabetic patients.

Methods: Retrospective descriptive study based on pathology of 110 biopsies taken at our institution in diabetic patients (DM) during 1990-2013.

Results: 110 patients, 87 men (79%), mean age 62a (50-74) were included in the study. Mean duration of DM 10.6 years, creatinine 2.6 mg/dl (0.9-4.3), estimated glomerular filtration rate MDRD 4 3.7 mL / min / 1.73 m2 (14.4-73), glycosylated hemoglobin 6.8% (5.1-8.5), basal glucose 141 mg / dl (77.2-205.8), and proteinuria of 3.5 g/24 h (0.5-6.5). The reason for renal biopsy was 25% nephrotic syndrome or rapid increase in proteinuria, 14% fast decline in GFR, 13% nephrotic range proteinuria without diabetic retinopathy and 11% proteinuria> 1 g DM and less than 5 years of DM evolution. Renal biopsy results: 38% diabetic nephropathy(DN), 5.4% DN plus-non-diabetic nephropathy(NDN). IgA nephropathy 7.3%, 5.5% nephrosclerosis, 4.5% focal and segmental glomerulosclerosis, 3.6% membranous nephropathy and chronic interstitial nephritis and others. In the multivariate binary logistic regression analysis, variables independently associated with NDN were: serum creatinine (HR: 1.48,95% CI:1,011-2, 172, p=0.044), proteinuria/24 hours (HR: 0.813,95% :0,679-0, 974, p=0.025), duration of DM (HR: 0.992, 95% CI :0, 987-0, 998, p=0.004), t age (HR: 1.068, 95% CI :1,010-1, 129, p=0.022) and diabetic retinopathy(DR) (HR 0.23, 95% CI: 0.066-0.808 p= .022). The discriminatory capacity of the model was tested using the ROC curve (95% CI): 0.805 (0.708 to 0.902).

Conclusions: 38% of diabetic patients biopsied at our center have diabetic nephropathy. Patients with serum creatinine and older have increased risk of NDN; while these patients showed shorter duration of diabetes, and less incidence of DR and proteinuria. The most frequent cause of NDN in our environment is the IgA nephropathy.

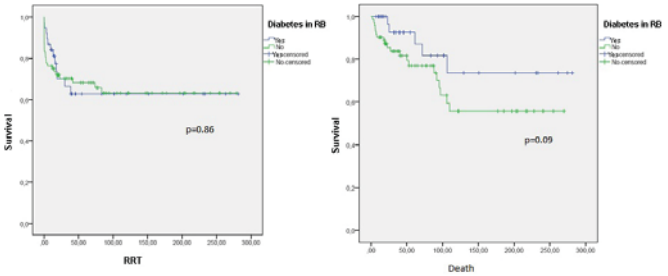
SA-PO271

Renal Prognosis and Survival of Diabetic Patients with Kidney Disease: A Comparative Analysis between Diabetic and Non Diabetic Nephropathy Sheila Bermejo,[1] Maria Jose Soler,[1] Javier Gimeno,[2] Clara Barrios,[1] Eva Rodriguez,[1] Julio Pascual.[1] *[1]Nephrology, Hospital del Mar, Spain; [2]Pathology, Hospital del Mar, Spain.*

Background: The difference of the renal and patient survival between diabetic nephropathy (DN) and non-diabetic nephropathy (NDN) in diabetic patients is not well known.

Methods: Retrospective descriptive study and analysis of renal function and survival in diabetic patients that undergoing renal biopsy at our institution between 1990-2013. We analyzed the need for renal replacement therapy and mortality between 1990 and 2013 in those diabetic patients.

Results: 110 patients were included, 87 men (79%), mean age 62 years (50-74), creatinine 2.6 mg/dl (0.9-4.3), glycosylated hemoglobin 6.8% (5.1-8.5), basal glucose 141 mg / dl (77.2-205.8) and proteinuria of 3.5 g/24 h (0.5-6.5). In renal biopsy, 35% had DN and 65% non-DM nephropathy with or without DN (NDN). 33% of patients needed renal replacement therapy.1:2 ratio between DN and NDN (11 versus 22%) at the time of renal biopsy, 1 patient in DN group and 9 patients in NDN group began dialysis. The overall mortality of the patients was 23%, 5% from the DN group and 18% from the NDN group. No differences in patient or renal survival between both patient cohorts studied by Kaplan-Meier curves were observed.



Conclusions: No differences are observed in renal and patient survival between NDN or DN in our diabetic patients. Although the crude mortality is higher in diabetic patients with NDN as compared to DN, no significant differences were observed in the actuarial survival curves.

SA-PO272

Urinary Tubular Biomarkers Predict Renal Injurious Progress in Early Diabetic Nephropathy Patients Feelan Chong,[1] Yigang Wan.[2] *[1]Oriental Academy of Chinese Medicine, Puchong, Selangor, Malaysia; [2]Dept of Traditional Chinese Medicine, The Affiliated Hospital of Nanjing Univ Medical School, Nanjing, China.*

Background: Diabetic nephropathy (DN) is a dominant cause of end-stage renal disease in China. Therefore, noninvasive detections and dynamic managements in clinic are of major importance of preventing progress. The early diagnosis of DN has focused on measurement of UAlb excretion rate, but it is not sensitive marker for DN patients with inchoate injuries in glomeruli and renal tubules. This study thus aimed to evaluate clinical significance of urinary tubular biomarkers in predicting development of DN patients at early stage.

Methods: The study was performed on 92 diabetes mellitus with different levels of UAlb and certain range of Scr (<106μmol/L). According to albumin-to-creatinine ratio (ACR) in urine, all patients were categorized into 3 groups, normoalbuminuria (A) group, microalbuminuria (B) group and macroalbuminuria (C) group. In addition to UAlb, Scr and ACR, levels of tubular biomarkers including UNAG, URBP and UCysC in urine were tested respectively before renal protective drugs intervention.

Results: Compared with A group, levels of UNAG, URBP and UCysC in B and C groups were significantly different (P<0.01). Along with UAlb, stepwise increases in levels of UNAG, URBP and UCysC were detected respectively in B and C groups. Moreover, in univariate analysis, there was immediate relevance between UAlb, ACR and tubular biomarkers including UNAG (r=0.706, P<0.01; r=0.808, P<0.001), URBP (r=0.687, P<0.01; r=0.701, P<0.001) and UCysC (r=0.727, P<0.01; r=0.790, P<0.001) in all groups. In addition, we found that UNAG was positively correlated with URBP (r=0.652, P=0) and UCysC (r=0.785, P=0). URBP was also definitely related to UCysC (r=0.673, P=0). Multivariate logistic regression showed that body mass index and fasting blood glucose were two predictive factors of increased UCysC.

Conclusions: At early stage of DN, increased levels of UNAG, URBP and UCysC are independently associated with UAlb, and these urinary tubular biomarkers similar to UAlb may be widely used as practical targets in clinic in detecting and managing DN, and predicting renal tubular damaged progression.

SA-PO273

Diabetic Nephropathy Underdiagnosed: Results from an Autopsy Study Celine Klessens,[1] Kimberley Veraar,[1] Tess Dorine Woutman,[1] Malu Zandbergen,[1] Elisabeth J. Valk,[1] Joris I. Rotmans,[2] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden Univ Medical Center; [2]Nephrology, Leiden Univ Medical Center.*

Background: The reported incidence of diabetic nephropathy (DN) in both type 1 and type 2 diabetes patients varies considerably. In clinical practice, a renal biopsy is often not performed to confirm a suspected DN. In this study, we report the incidence of DN on the basis of an autopsy study with 150 patients with either type 1 or type 2 diabetes.

Methods: Renal tissue specimens were collected from cases from 1984-2004 who were reported to have diabetes in the autopsy report. Tissue specimens had to be non-autolytic and at least 100 glomeruli had to be available for evaluation. Patients with renal and or pancreas transplantation were excluded. New tissue slides were cut and new stainings were performed (HE, PAS, silver). All specimens were evaluated by 2 observers and the histopathological classification for DN was scored as well as interstitial and vascular parameters. GBM width was measured by electron microscopy if no light microscopic changes were found consistent with DN. Clinical parameters included: age at death, cause of death, proteinuria and renal function (eGFR measured with MDRD formula) when available in a period of at least 6 months before death.

Results: A cohort of 150 patients was included (average age 69, sd=12.1). No light microscopic changes compatible with DN were found in 76 patients. Of these cases, we have currently measured the GBM width of 40 cases, resulting in the diagnosis of class I DN in 12. Of those patients with LM changes compatible with DN (N=74; 49.3%), 18 (12%) had class IIA, 10 (6.7%) had class IIB, 41 (27.3%) had class III and 5 (3.3%) had class IV. We found a trend for severity of DN being related to cardiovascular death (p=0.059). Also DM duration showed a trend for being related to the severity of DN (p=0.07). No significant correlation with proteinuria and class (p=0.112) was found. There was a significant difference (p<0.05) in eGFR over the classes.

Conclusions: This study shows that the incidence of DN (49.3%) in patients with diabetes is much higher than currently assumed. The clinical relevance of silent DN should be further investigated.

SA-PO274

Control of dGlucose Is Fundamental to Renal Preservation in Diabetes Anil K. Mandal,[1] Linda M. Hiebert.[2] *[1]Medicine, Univ of Florida, Gainesville, FL; [2]Veterinary Biomedical Sciences, Univ of Saskatchewan, Saskatoon, SK, Canada.*

Background: We previously reported that dglucose predicts renal function change in diabetes (Diab Res Clin Prac 2011;91:190). This study is an expansion of a previous study but with longer duration.

Methods: 85 diabetic patients (M:F,34:51;60.8±13.8[SD] yrs) were treated with a combination of glargine or detemir and regular insulin for 26.3±24.6(SD) months. Blood pressure was controlled by beta blockers, calcium channel blockers, sympathetic inhibitors or a combination and chlorthalidone in resistant cases. Treatment with angiotensin converting enzyme inhibitors (ACEIs) or receptor blockers (ARBs) was excluded. Objectives were to determine if this paradigm of treatment prevented progression of diabetic nephropathy into end stage renal disease(ESRD). Fasting(F) and 2-hour postprandial(2hPP) glucose, serum creatinine(Scr) and estimated glomerular filtration rate(eGFR); hemoglobin $A1_C$($HbA1_C$); sitting and standing systolic and diastolic blood pressures(SBP,DBP) were recorded for first and last visits. Mean blood pressure (MBP) and differences (d, 2hPP-F) were calculated for glucose, Scr and eGFR. Parameters between first and last visits were compared using a paired t-test adjusted for age, gender and duration of treatment. P<0.05 was considered significant.

Results: Differences were not significant between first and last treatments for F and 2hPPglucose (175.2±83.6[SD] versus 166.2±87.9 mg/dL, n=59, P=0.5243; 244.0±98.2 versus 217.2±94.8 mg/dL, n=57, P=0.1119, respectively), F and 2hPPScr (1.11±0.44 versus 1.11±0.45 mg/dL, n=60, P=0.9364; 1.22±0.53 versus 1.27±0.60 mg/dL, n=50, P=0.5186, respectively), F and 2hPPeGFR (68.2 ±26.3 versus 65.8±26.3 ml/min, n=60, P=0.1419; 61.0±24.3 versus 58.5± 23.0 ml/min, n=50, P=0.2475,respectively) and $HbA1_C$ (8.2±2.0 versus 8.2±1.8%, n=29, P=0.9643, respectively). Dglucose, sitting SBP and MBP were significantly reduced at the last versus first visit (36.6±65.6 versus 63.5±68.1 mg/dL, n=41, P=0.0449; 128.4±13.9 versus 133.1±17.1 mmHg, n=74, P=0.0319; 95.4±10.9 versus 98.9±11.3 mmHg, n=74, P=0.0151 respectively).

Conclusions: This study reinforces the importance of control of dglucose (2hPP-F) with insulin and exclusion of ACEI/ARB in the prevention of ESRD in diabetes.

SA-PO275

Effect of Metformin Compared to Insulin in Renal Preservation of Adults with Diabetes Aswini Prasad Patnaik,[1] Anil K. Mandal,[2] Linda M. Hiebert.[3] *[1]Medicine and Nephrology, South Eastern Railway Hospital, Kolkata, West Bengal, India; [2]Medicine, Univ of Florida, Gainesville, FL; [3]Veterinary Biomedical Sciences, Univ of Saskatchewan, Saskatoon, SK, Canada.*

Background: It was reported that oral antidiabetic agents, including metformin, have a variable risk for decline in renal function including end stage renal disease or death (Kidney Int 2012; 81: 698). This prospective study compares the effect of biguanide monotherapy (metformin) versus insulin treatment, in controlling postprandial hyperglycemia and maintaining renal function.

Methods: Seventy-eight adults with diabetes (M:F,38:40; 55.7±11.1[SD] yrs [range 32–85]) were treated with metformin alone for mean 13.3±11.4 months and were compared with 64 diabetic patients (M:F,24:40, 58.8±14.4 yrs, [range 24-87]) treated with a combination of glargine or detemir and regular insulin for 23.6±30.5 months. The 2-hour postprandial (2hPP) glucose, 2hPP serum creatinine (Scr), and hemoglobin $A1_C$ ($HbA1_C$) were determined for the first and last visit. Efficacy of metformin and insulin were compared using multiple regression analyses adjusting for age, gender, duration of diabetes and treatment. P<0.05 was considered significant.

Results: In the metformin treated patients, when values for first versus last visit were compared, no difference in 2hPP glucose (231±19[SD] versus 215.5±48.1 mg/dL, P=0.0565), an increase in Scr (1.37±1.22 versus 1.47±1.22 mg/dL, P=0.0002) and no difference in $HbA1_C$ (7.2±0.9 versus 6.9±0.6 %, P=0.0555) were found. In the insulin treated patients, a significant decrease in 2hPP glucose (281.6±129.1 versus 241.0±77.8 mg/dl, P=0.0466), no change in Scr (1.15±0.38 versus 1.32±0.73 mg/dl, P=0.8503) or $HbA1_C$ (8.9±2.0 versus 9.0±1.8 %, P=0.2387) were found. When the difference in change between first and last visits in the metformin and insulin treated groups were compared a significantly greater decrease in 2hPP glucose with insulin treatment (50.6±19.5 mg/dL, P=0.0109), a significantly greater increase in Scr with metformin treatment (0.17±0.06 mg/dL, P=0.0075) but no difference in change in $HbA1_C$ (-0.4 %, P=0.3781) between the treatments were noted.

Conclusions: Thus this study indicates that insulin but not metformin preserves renal function in diabetes.

Funding: Clinical Revenue Support

SA-PO276

Personalized Podocyte Biology for the Prediction of Diabetic Kidney Disease Mayrin Correa-Medina,[1] Evadnie Rampersaud,[1] Christopher E. Pedigo,[1] Viji Nair,[2] Matthias Kretzler,[2] Robert G. Nelson,[3] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]Univ of Miami; [2]Univ of Michigan; [3]National Inst of Diabetes and Digestive and Kidney Diseases, Phoenix, Arizona.*

Background: Diabetic kidney disease (DKD) is the leading cause of end-stage kidney disease in the U.S, and podocyte injury correlates with DKD progression in type 2 diabetes. In order to identify key signalling pathways that are induced in podocytes in early DKD, we utilized a cell-based assay where normal human podocytes are cultured for 24 hours with sera of DKD patients.

Methods: We used sera obtained from a total of 31 patients enrolled in the "*Renoprotection in Early Diabetic Nephropathy in Pima Indians trial*" and collected on average 7 years after enrolment. We studied two groups of patients with extreme phenotypes based on the rate of decline in glomerular filtration rate (GFR) between enrollment and last examination (mean time of 10±1.7 years). The two groups were defined as progressors (delta GFR of -97.39±8.2, n=15) and non progressors (delta GFR of 40.62±8.6, n=16). mRNAs obtained from podocytes were utilized to generate microarray data and for validation of gene expression by real-time PCR.

Results: We identified 397 genes differentially expressed in podocytes exposed to progressor sera. Using selection criteria (p<0.05 and 2 ≥ fold-change in expression), we found 26 down and 28 up regulated genes in progressor group. Selected genes were validated by real-time PCR where we found reduction by ~60%, p<0.05 of the ABCA1

gene in podocytes treated with progressor sera. A significant negative correlation between ABCA1 gene expression and GBM thickening was identified. BODIPY staining showed 3 fold, $p<0.05$ increases in cholesterol accumulation in podocytes treated with DKD sera when compared with cells treated with healthy control sera. Exposure of podocytes to progressor sera also induced apoptosis ($p<0.05$).

Conclusions: In summary, we propose a novel method to identify podocyte molecular fingerprint in DKD. Once validated in different cohorts, this method may serve as a non-invasive approach to predict DKD progression and as a tool to identify new podocyte-specific targets in DKD.

Effects of Febuxostat Rx on Adipokines and Markers of Kidney Fibrosis in Asymptomatic Hyperuricemic Patients with Diabetic Nephropathy: A RCT Srini Beddhu,[1,2] R. Filipowicz,[2] Bin Wang,[2] G. Wei,[2] Xiaorui Chen,[2] E. Constantz,[2] Abinash C. Roy,[2] A. N. Habib,[2] Donald E. Kohan,[1,2] Mark Munger,[2] Tom Greene,[2] Yufeng Huang.[2] *[1]SLC VA; [2]Univ of UT.*

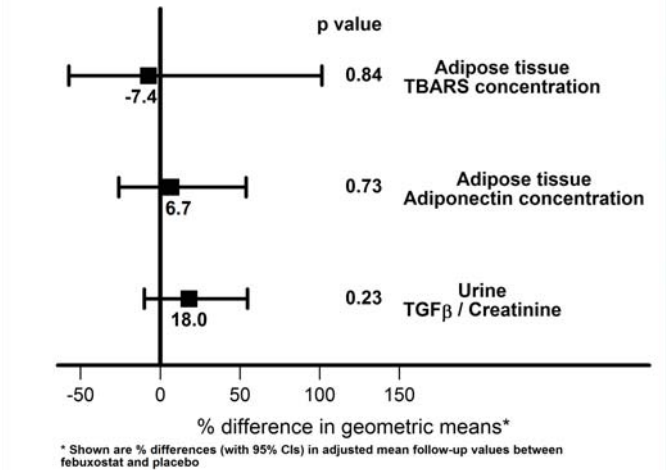
Background: Experimental data suggest that decreasing uric acid(UA) impacts adipokines and kidney disease. Therefore, we hypothesized febuxostat(FBX) Rx in humans with diabetic nephropathy(DN) will ↓ hyperuricemia and thereby, impact adipose tissue(AT) oxidative stress (OS) and adipokines; ↓ plasma markers of inflammation and OS; and ↓ urinary markers of kidney fibrosis.

Methods: Overweight or obese adults with hyperuricemia and type 2 DN were randomized to FBX(n= 40) or placebo(n=40) for 24 wks. Abdominal subcutaneous fat biopsy was performed at baseline and 24 wks. Blood and urine samples were collected at baseline, 12 and 24 wks. Mixed effects models were used to examine the impact of FBX on primary (AT thiobarbituric acid reducing substances(TBARS), AT adiponectin and urinary TGF-β) and secondary endpoints.

Results: Baseline characteristics are summarized in the table.

	FBX	Placebo
	N=40	N=40
Age(year)	67±10	68±11
Male(%)	60.0	70.0
Black(%)	2.5	5.0
CAD(%)	20.0	17.5
CHF(%)	10.0	10.0
PVD(%)	2.5	5.0
Stroke(%)	5.0	2.5
BMI(kg/m^2)	36.2±7.0	30.1±6.2
Plasma UA (mg/dl)	7.2±1.5	7.1±1.2
eGFR(ml/min/1.73m^2)	52.2±15.3	54.8±19.0
Urine ACR<30mg/g(%)	64.1	65.0

92% in FBX and 97.5% in placebo groups completed the study. FBX ↓ plasma UA by 50%($p<0.001$).



No detectable differences with FBX Rx were observed for the primary endpoints [fig) or the secondary endpoints of plasma levels of high molecular weight adiponectin(14.6%, 95% CI -3.7 to 36.3, p=0.12), TNF-α(-2.8%, 95% CI -31.8 to 38.7, p=0.87), MCP-1(4.9%, 95% CI -21.1% to 39.5%, p=0.34) or IL-6(-16.6%, 95% CI -33.0 to 5.2, p=0.13).

Conclusions: FBX Rx affected plasma UA levels in DN. However, no significant effects on the primary or secondary endpoints were observed.

Elevated Neutrophil Gelatinase-Associated Lipocalin (NGAL) Level in Chronic Kidney Disease (CKD) Is Function of Both Reduced Glomerular Filtration Rate (GFR) and Circulating Neutrophil Count Shweta Bansal,[1,2] Chakradhar Velagapudi,[1,2] William E. Friedrichs,[1] Perla R. Zarate-Abbott,[1,2] Sue Cunningham,[1,2] Paolo Fanti.[1,2] *[1]Medicine/Renal, Univ of Texas Health Sciences Center at San Antonio, San Antonio, TX; [2]Medicine/Renal, South Texas Veterans Healthcare System, San Antonio, San Antonio, TX.*

Background: Serum neutrophil gelatinase-associated lipocalin NGAL levels increase progressively with chronic kidney disease (CKD) and predict worse outcome. However, the source of serum NGAL, whether it is injured renal tubular cells or other tissues or both, remains unclear.

Methods: NGAL and other parameters were assessed on two occasions with 3-month interval in stored blood samples of 51 diabetic nephropathy patients with stage III and IV CKD, who participated in a clinical study evaluating the effect of N-acetyl cysteine and silymarin on albuminuria.

Results: The study population was 61.6±7.5 year old, 85% male, 71% Hispanic white, 53% with stage III and 47% with stage IV CKD, and with body mass index 35.3±8.8 kg/m^2. In Pearson's correlation, $\log_{10}$-NGAL levels were correlated negatively with eGFR ($r=-0.71$, $p<0.001$), plasma hemoglobin ($r=-0.37$, $p=0.008$) and serum albumin ($r=-0.28$, $p=0.04$); and positively with total leucocyte count ($r=0.5$, $p<0.001$), absolute neutrophil count (ANC) ($r=0.58$, $p<0.001$) and serum phosphorus ($r=0.58$, $p<0.001$). In a standard multivariate regression model, the same parameters explained 75% of NGAL variation ($p<0.001$), with partial F-test analysis showing significance for only eGFR ($\beta=-0.47$, $p<0.001$) and ANC ($\beta=0.40$, $p<0.001$). Very similar results were obtained at the 3-month follow up.

Conclusions: The results of our study suggest that elevated serum NGAL is a function of both decreased kidney function and circulating neutrophils in CKD patients. Further studies are needed to evaluate the cause(s) of increased NGAL production in circulating neutrophils.

Crosstalk between Hippo and EGFR Signaling Pathway in Development of Diabetic Nephropathy Jianchun Chen, Raymond C. Harris. *Nephrology/ Medcine, Vanderbilt Univ, Nashville, TN.*

Background: The Hippo signaling pathway in mammalian cells controls cell proliferation, apoptosis and differentiation. In mammalian cells, this pathway is a kinase cascade in which Mst1/2 kinases and Sav1 form a complex to phosphorylate and activate LATS1/2, which phosphorylate and inhibit two major downstream effectors YAP and TAZ. Our recent studies have demonstrated that EGFR is activated in renal proximal tubule injury during diabetic nephropathy (DN) development, and EGFR activation plays an important role in DN progression.

Methods: We induced type I diabetes in our proximal tubule EGFR deletion mice(*EGFR^{ptKO}*) and their wild type littermates (WT) by daily low dose streptozotocin injections for 5 consecutive days. Cell signaling studies were performed in a proximal tubule epithelial-like cell (LLCPKCl4).

Results: STZ injection induced similar levels of hyperglycemia in *EGFR^{ptKO}* and their *WT* mice. Both total and phosphorylated YAP (at Ser127) increased in diabetic *WT* mice, and these increases were inhibited in *EGFR^{ptKO}* mice compared with *WT* mice. In LLCPKCl4cells, 24 hour exposure to high glucose (25 mM) induced EGFR and YAP phosphorylation. These effects were inhibited by treatment with the EGFR tyrosine kinase inhibitor erlotinib or transfection with EGFR siRNA. Akt phosphorylation was also upregulated in response to high glucose treatment, and the PI3K inhibitors LY29004 or wortmannin inhibited both Akt and YAP phosphorylation. Further studies revealed that knockdown of YAP expression by siRNA transfection inhibited cell proliferation in response to EGF and also abrogated proliferative responses to high glucose.

Conclusions: This study indicated that the hippo signaling pathway activation mediated by EGFR activation may play a role in diabetic nephropathy.

The Interaction Between DPP-4 and Integrin β1 Regulates the Signaling that Is Responsible for the Induction of Endothelial to Mesenchymal Transition in Diabetic Kdiney Keizo Kanasaki, Shi Sen, Megumi Kanasaki, Swayam Prakash Srivastava, Daisuke Koya. *Dept of Diabetology and Endocrinology, Kanazawa Medical Univ, Kahoku, Ishikawa, Japan.*

Background: Endothelial-to-mesenchymal transition (EndMT) is an important source of matrix-producing mesenchymal cells. Dipeptidyl peptidase-4 (DPP-4) plays a crucial role in transforming growth factor (TGF)-β2-induced EndMT. Vascular endothelial growth factor (VEGF)-A signaling antagonizes EndMT through VEGF-receptor (R)2, but VEGF-R1 has been shown to promote EndMT via reducing the bioavailability of VEGF-A.

Methods: In vivo, streptozotocin-induced diabetes in CD-1 mice were used. The functional interaction between DPP-4 and integrin β1 was analysed double labeled immunofluorescence in vivo, western blot, and siRNA knockdown in endothelial cells. The proximity of two proteins was analysed by Duolink in situ kit.

Results: Here, we found that the interaction between DPP-4 and integrin β1 plays a crucial role in regulating the intracellular signaling responsible for EndMT. In STZ-induced diabetic kidneys of CD1 mice, the endothelial DPP-4, integrin β1 and phospho-integrin β1 levels were increased compared to control kidneys; linagliptin suppressed the elevation

of these proteins in diabetic kidneys. In cultured endothelial cells, TGF-β2 increased/linagliptin suppressed proximity of DPP-4 and integrin β1. DPP-4 suppression by siRNA was associated with suppressed levels of integrin β1, and vice versa. Knockdown of either integrin β1 or DPP-4 inhibited TGF-β2-induced TGF-β receptors heterodimer formation, smad3 phosphorylation, and EndMT. When we analyzed the VEGF-A-mediated signal transduction in endothelial cells, we found that DPP-4 negatively regulates endothelial viability signaling via VEGF-R2 suppression and VEGF-R1 induction.

Conclusions: These data suggest that the interaction between DPP-4 and integrin β1 regulates key endothelial cell signal transduction in both physiological and pathological conditions, and abnormal over activation of these proteins would induce EndMT. Therefore, inhibiting DPP-4 is a reasonable therapeutic target for the vascular complications associated with EndMT, such as diabetic nephropathy.

Renal Complement in Ischemia and Diabetes Katherine J. Kelly,[1] Jesus H. Dominguez.[1,2] *[1]Medicine/Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; [2]Medicine/Nephrology, Roudebush VA Medical Center, Indianapolis, IN.*

Background: ZS obese-diabetic rats (D) develop diabetic nephropathy (DN) as early as 12 weeks of age. The DN is accelerated by a single episode of bilateral renal ischemia at 8 weeks of age (DI). Sham operated D rats (DS) develop a less aggressive form of DN when compared to DI. DI, and to a lesser extent DS, develop renal capillary loss, inflammation and fibrosis. We hypothesized that renal ischemia activates the renal complement system which causes chronic inflammation.

Methods: We studied primary renal tubular cells and normal SD rats subjected to 30 minutes of ischemia. Also, ZS obese/diabetic and lean (L) rats were operated at 10 weeks of age and terminated at 28 weeks of age (DI, n = 11; DS, n 7; LS; n = 7). Whole renal transcriptomes were analyzed by RNAseq.

Results: First, we tested if ischemia activated renal complement directly. As little as 8 hours of ischemia in a hypoxic chamber activated renal C5 (3.3 fold, $p< 0.05$) and C3 (2.9 fold $p< 0.05$) expression in renal tubular cells. Second, in SD rats, renal C3 and C5 were upregulated after 30 minutes of bilateral ischemia and 24 hours of reperfusion. Third, DN was accompanied by activation of the renal complement system, manifested by 5.2, 8.8, 18.1, and up to 81.2 fold increases, over lean normal controls of C3, C6, C8 and C9 mRNAs. Moreover, mRNA for the receptor for C3a is increased 2.4 fold, and mRNA for the complement receptor 2 is increased 42 fold ($p < 0.05$). Furthermore, critical regulators of the complement system were significantly attenuated in DN. These include mRNAs encoding CD55, decay accelerating factor, down 65 % and CD59, which inhibits the membrane attack complex, also down by 65 %. We found C3, C4 and C9 proteins in renal tubules and glomeruli.

Conclusions: Activation of the intrinsic renal complement system participates in renal inflammation in renal ischemia and in DN, a condition characterized in part by ischemia. The self-sustained and chronic complement activation is likely to participate in diabetic and ischemic nephropathies.

SA-PO282

Increased B-Oxidation and Fatty Acid Flux Characterizes Diabetic Nephropathy Kelli M. Sas, Pradeep Kayampilly, Viji Nair, Hongyu Zhang, Jaeman Byun, Matthias Kretzler, Frank C. Brosius, Subramaniam Pennathur. *Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease in the United States. While it is well-recognized that diabetes leads to altered fatty acid metabolism, the utilization and flux of fatty acids *in vivo* has not been systematically studied.

Methods: To obtain a global systems view of fatty acid metabolism we utilized gene expression studies in parallel with targeted metabolomics approaches. We developed a metabolomics platform for simultaneous quantitative analysis of glycolytic, tricarboxylic acid (TCA) and fatty acid oxidation intermediates by liquid chromatography tandem mass spectrometry (LC/MS/MS). Animals which exhibit characteristic pathological features of DN (BKS db/db) were used as a model system to examine the dynamic changes in fatty acid utilization at 12-weeks (early DN) and 24-weeks (established DN).

Results: Transcriptomics analysis identified significant upregulation of pathways involved in fatty acid metabolism and B-oxidation. Consistent with the murine transcriptomics data, steady state levels of acylcarnitines were statistically significantly elevated in the mouse diabetic renal cortex (1.5-5-fold) and mitochondria (2.9-6.7-fold). *In vivo* LC/MS metabolic flux analysis (MFA) was performed to study the dynamic changes in fatty acid metabolism following administration of 0.5 g/kg U-$^{13}C_{16}$ palmitate by gavage. MFA revealed statistically significant increases in cortical palmitate uptake and an elevation of labeled long-chain acylcarnitines and TCA cycle intermediates in the diabetic mouse cortex, consistent with increased fatty acid flux. Acetylation of enoyl-CoA-hydratase/3-hydroxyacyl-CoA dehydrogenase (EHHADH) in the diabetic renal cortex was increased, showing activation of a primary enzyme in B-oxidation. Diabetic renal cortical mitochondria exhibited reduced ATP production, impaired complex 2 activity and increased proton leak indicating diminished activity.

Conclusions: Taken together, these results highlight a previously unrecognized role for altered fatty acid metabolism and flux in the pathogenesis of DN and raise the possibility of a novel therapeutic target of DN.

Insulin Signaling in Exfoliated Kidney Tubule Cells Mollie E. Jacobs,[1] Alan C. Pao.[1,2] *[1]Medicine, Stanford Univ, Stanford, CA; [2]Veterans Affairs Palo Alto Health Care System, Palo Alto, CA.*

Background: One significant barrier to defining insulin resistance in the kidney is obtaining sufficient kidney tissue for metabolic and molecular characterization. Current methods for detecting activation of insulin signaling proteins in clinical specimens require large quantities of tissue, which must be procured by invasive needle biopsies.

Methods: We have developed a protocol to overcome this technical barrier by using the following approaches: 1) isolation and expansion of exfoliated renal tubular epithelial cells from human urine in culture; and 2) detection of insulin signaling phospho-proteins through application of nano-immunoassay (NIA) technology. NIA technology, which utilizes isoelectric focusing of proteins followed by antibody detection, has the capability to detect changes in the phosphorylation profile of low abundance proteins in nanoliter volumes.

Results: Using gene expression studies, we found that exfoliated cells in human urine contained a mixture of renal proximal tubule and collecting duct cells, as well as fibroblasts. Preliminary NIA assays examining key components of the insulin signaling pathway demonstrated that the exfoliated cells in human urine robustly express activated/phosphorylated components of the insulin signaling network (PI3K subunits, Akt1-3, and Erk1/2).

Conclusions: The ability to isolate viable exfoliated tubule cells from urine samples overcomes a significant technical barrier to defining insulin resistance in the kidney. We next propose to identify defects in insulin signaling pathways in insulin resistant individuals who have hypertension or uric acid kidney stones. This information could be used to diagnose insulin resistance in the kidney and suggest novel strategies for the prevention and treatment of obesity-related hypertension or kidney stones.

SA-PO284

Atrasentan, a Selective Endothelin A Receptor Antagonist, Treatment of Diabetic db-db Mice Prevents the Progression of Diabetic Nephropathy Xiaoxin Wang, Yuhuan Luo, Cherelle Parker, Moshe Levi. *Univ of Colorado Denver.*

Background: Diabetes is the leading cause of renal disease and new treatment modalities are needed to slow the burden and progression of diabetic nephropathy.

Methods: The purpose of the present study was to determine if treatment of hyperglycemic and proteinuric db-db mice with Atrasentan (A) can prevent the progression of diabetic nephropathy.

Results: Treatment resulted in significant decreases in urinary albumin (337±54 mg/g in db-db versus 189±23 mg/g in db-db+A, $p<0.05$), mesangial index (4±0.5 in db-db versus 2.4±0.2 in db-db+A, $p<0.05$), prevented decrease in synaptopodin immunofluorescence (podocyte marker, 3.8±0.4 in db-db versus 4.4±0.3 in db-db+A, $p<0.05$) and fibrillary collagen accumulation as determined by two photon excitation-second harmonic generation (TPE-SHG) microscopy. These beneficial effects of Atrasentan were associated with significant decrease in the expression of the profibrotic growth factor TGF-β (1.59±0.19 in db-db versus 1.08±0.03 in db-db+A, $p<0.05$) as well as CTGF and PAI-1. In addition Atrasentan induced increased expression of Nrf-2 (1.55±0.06 in db-db versus 1.88±0.04 in db-db+A, $p<0.05$) and HO-1 (2.62±0.17 in db-db versus 5.16±1.09 in db-db+A, $p<0.05$). Furthermore Atrasentan also prevented increased expression of the lipogenic enzymes SCD-1 (4.76±0.18 in db-db versus 3.05±0.16 in db-db+A, $p<0.05$) and LPK (52.0±4.73 in db-db versus 24.2±6.19 in db-db+A, $p<0.001$).

Conclusions: In summary treatment of diabetic db-db mice with the selective endothelin A receptor antagonist Atrasentan prevents the progression of diabetic nephropathy at least in part by inhibiting the increased expression of profibrotic growth factors, enhancing the Nrf2 antioxidant stress response, and inhibiting increased expression of fatty acid synthesis pathways.

Human Mesenchymal Stem Cells Promote Alternative Activation of Monocytes Isolated from Healthy and Type 2 Diabetic Subjects Andrea F. Wise,[1] Timothy M. Williams,[1] Stephen Rudd,[2] Christine A. Wells,[3,4] Peter G. Kerr,[5] Sharon D. Ricardo.[1] *[1]Anatomy and Developmental Biology, Monash Univ, Melbourne, VIC, Australia; [2]QFAB Bioinformatics, Univ of Queensland, Brisbane, QLD, Australia; [3]The Australian Inst of Bioengineering and Nanotechnology, Univ of Queensland, Brisbane, QLD, Australia; [4]Inst of Infection, Immunity and Inflammation, College of Medical, Veterinary and Life Sciences, Univ of Glasgow, Scotland, United Kingdom; [5]Dept of Medicine, Monash Univ, Melbourne, VIC, Australia.*

Background: Pro-inflammatory monocytes and macrophages are the main immune cells that infiltrate the damaged kidney in type 2 diabetes, where they contribute to disease progression. Mesenchymal stem cells (MSCs) possess unique immunomodulatory properties, however, their effect on monocytes is unclear. This study investigated whether MSCs could modulate the phenotype of monocytes isolated from control subjects and type 2 diabetic patients with end-stage renal disease (ESRD).

Methods: Monocytes from control subjects (n=4) and type 2 diabetic patients with ESRD (n=5) were compared by flow cytometry for the expression of CD14, CD16 and

HLA-DR. Microarray gene expression profiling was used to analyze the gene expression profile of the monocytes following 48 hours of co-culture with MSCs using an *in vitro* transwell system.

Results: Control subjects had a greater proportion of $CD14^{++}CD16^{-}$ classical monocytes compared to diabetic patients (73.9%versus56.3%; $P<0.05$). In contrast, the diabetic patients had a higher proportion of intermediate ($CD14^{++}CD16^{+}$; 32.2%versus19.2%; $P<0.05$) and non-classical ($CD14^{+}CD16^{++}$; 7.5%versus2.8%; $P<0.05$) monocytes compared to control subjects. Following co-culture with MSCs, CD14 and CD16 expression was significantly up-regulated on diabetic blood monocytes, while HLA-DR expression was down-regulated. Principal component analysis revealed that MSC-treated monocytes clustered separately from the untreated monocytes. Genomic profiling revealed MSCs up-regulated several 'M2' macrophage associated genes such as *IL10*, *IGF1*, *MRC1*, *CD163* and *MMP9*.

Conclusions: MSC-derived factors can alter the phenotype of human monocytes isolated from healthy and diabetic subjects towards an M2 phenotype.

Potential Impact of IV versus Oral Route of Iron Administration on Pancreatic Beta Cell Viability and Function in Rats with CKD

Nosratola D. Vaziri,[1] Chie Takasu,[2] Shiri Li,[2] Lourdes Y. Robles,[2] Sohrab Nazertehrani,[1] Mahyar Khazaeli,[1] Wei Ling Lau,[1] Shuman Liu,[1] Hirohito Ichii.[2] *[1]Medicine, UC Irvine, Orange, CA; [2]Surgery, UC Irvine, Orange, CA.*

Background: Type-2 diabetes is a common cause of ESRD and residual pancreatic b-cell s is critical for wellbeing of these patients. ESRD patients routinely receive IV iron for anemia treatment. Via divalent metal transporters beta cells which are exquisitely vulnerable to oxidative stress take up non-transferrin-bound iron. By catalyzing Fenton reaction, labile iron within the b-cell triggers oxidative stress and cell damage. We compared the effect of IV iron which bypasses body's natural safeguards for iron transport with oral iron in CKD rats and examined the effect of an IV iron product on isolated pancreatic islets in vitro.

Methods: CKD (5/6 Nx) rats were treated with either IV ferric sucrose (10 mg/kg/week) or an iron sulfate-fortified diet (400 ppm) for 2 weeks. CKD rats fed regular diet served as controls. Intra-peritoneal glucose tolerance test (IPGTT) was performed and pancreatic tissues were harvested and assessed for islet yield, islet viability, cellular composition, apoptosis, and 8'OH-guanosine (marker of DNA oxidation) content by FACS and IHC. Also normal rats' islets were studied after incubation in media containing pharmacologically-relevant concentrations of ferric sucrose or vehicle for 24 hr.

Results: Compared to CKD rats fed regular diet IV iron-treated CKD rats showed significant impairment of IPGTT. The islet isolation yield, islet viability, and b/acell ratio were lower and DNA oxidation and cell necrosis were higher in islets from IV- than oral-iron treated CKD rats. Incubation of islets from normal animals in media containing pharmacologically-relevant concentrations of iron sucrose resulted in significant concentration-dependent rise in DNA oxidation and islet cell necrosis, and a significant fall in cell viability and b/a cell ratio.

Conclusions: Use of clinically relevant doses of IV iron products adversely affected beta cell viability and function in CKD animals. Future studies are needed to examine the impact of these compounds on pancreatic endocrine function in ESRD patients.

SA-PO287

Hyperglycemia Induces Downregulation of Podocyte-Associated Proteins in the Albuminuric $GIPR^{dn}$ Mouse Model of Diabetic Nephropathy and in Cultured Glomerular Epithelial Cells

Sebastian Stefan Roeder,[1] Christoph Daniel,[1] Alexandra Rieger,[2] Andreas Blutke,[2] Ruediger Wanke,[2] Kerstin U. Amann.[1] *[1]Nephropathology, FAU Erlangen-Nuremberg, Germany; [2]Animal Pathology, LMU Munich, Germany.*

Background: Proteinuria, as a consequence of podocyte damage, is a common clinical feature of diabetic nephropathy (DN). The exact pathogenesis of glomerular damage, however, remains unclear. We hypothesized that downregulation of key podocyte proteins is induced directly by high levels of glucose and triggers albuminuria in a murine model of DN.

Methods: Kidney samples and glomerular preparations of 21-week old transgenic $GIPR^{dn}$ mice (n=6) and wild-type littermates (n=7) were analyzed by immunohistochemistry, immunofluorescence and real-time qPCR. As a proof of concept, differentiated cultured podocytes were supplemented with low and high glucose and mannitol as osmotic control. After 48 hours mRNA expression was assessed by real-time qPCR.

Results: In the $GIPR^{dn}$ model of early-onset diabetes, transgenic mice displayed decreased number of podocytes (podocyte number: 12.8±1.6 versus 10.8±1.0; $p<0.05$) and pronounced albuminuria with markedly elevated urinary albumin/creatinine-ratio (ACR; 5.7±1.4 mg/ml versus 0.04±0.01 mg/ml, $p<0.01$). Semiquantitative glomerulosclerosis index was substantially higher in $GIPR^{dn}$ animals (GSI; 1.13±0.3 versus 0.29±0.1, $p<0.001$) and correlated significantly with ACR ($r=0.791$, $p=0.001$). mRNA levels of podocyte-associated proteins were significantly downregulated up to 60% in diabetic animals and also correlated with ACR: Synaptopodin ($r=0.670$, $p=0.012$), Podoplanin ($r=0.648$, $p=0.017$), WT-1 ($r=0.588$, $p=0.035$), Nephrin ($r=0.533$, $p=0.061$). Similarly, specific staining revealed reduction of these proteins. Stimulation of cultured podocytes with high glucose confirmed hyperglycemia induced downregulation of Synaptopodin, Podoplanin, WT-1 and Nephrin.

Conclusions: Our data suggest a direct action of high glucose condition on downregulation of proteins essential for podocyte structure and slit-diaphragm integrity. Decrease of these proteins is paralleled by a loss of podocytes and subsequent albuminuria *in vivo*.

SA-PO288

Wnt5a/SFRP5 Axis in Macrophages: Potential Role in Diabetic Nephropathy

Liwei Huang,[1] Andrea B. Wecker,[2] An Xiao,[1] Quan'e Kan,[1] Jerry L. Nadler,[1] Michael J. Solhaug,[2] Anca Dobrian.[2] *[1]Medicine, Eastern Virginia Medical School, Norfolk, VA; [2]Physiological Sciences, Eastern Virginia Medical School, Norfolk, VA.*

Background: Macrophage recruitment correlates strongly with the progression of renal dysfunction in diabetic nephropathy (DN). Wnt5a, a non-canonical Wnt protein, is expressed in macrophages and has recently been implicated in chronic inflammation. Secreted frizzled related protein 5 (SFRP5) suppresses Wnt5a signaling and is a regulator of Wnt5a resulting in reduction of chronic inflammation. We begun to test the hypothesis that Wnt5/SFRP5 axes is involved in the development of DN, and related to macrophage infiltration and polarization.

Methods: To test our hypothesis, we used db/db mice, a model of type 2 diabetes mellitus, with functional and morphologic DN, and control heterozygotes (n=6/group). At 4 months of age, when the mice are severely hyperglycemic and have mild DN, whole kidneys were harvested and macrophages were isolated by immunoseparation. Gene expression of Wnt5a and SFRP5 was analyzed by real-time PCR.

Results: Our results showed no significant difference in Wnt5a expression in control and db/db mouse kidneys, however SFRP5 expression was elevated in db/db mouse kidneys compared to controls ($p<0.05$). Wnt5a expression was elevated in the kidney macrophages of db/db mice. We also examined the macrophage phenotype by measuring the expression of macrophage inhibitory cytokine-1 (MIC-1), a marker of the M2 macrophage phenotype, and arginase II, a marker of the pro-inflammatory M1 phenotype. We found increased MIC-1 and decreased arginase II expression levels in renal macrophages of db/db mice compared to controls, indicating a predominant M2 macrophage population in db/db mouse kidneys. Wnt5a secretion/protein expression is mainly associated with the M2 phenotype in the atherosclerotic lesions. Renal M2-like macrophages have critical roles in tissue repair and fibrosis.

Conclusions: Our findings suggest that Wnt5a and SFPR5 may play a role in the pathological tissue repair during development of DN in db/db mice. Our next step is to investigate the detailed mechanisms of Wnt5a/ SFRP5 axis in macrophages related to the progression of DN.

SA-PO289

Gonadectomy Prevents Mesangial Expansion and Podocyte Loss in Angiotensin Converting Enzyme 2 Knockout Diabetic Male Mice

Sergi Clotet-Freixas,[1] Maria Jose Soler,[1] Marta Rebull,[1] Javier Gimeno,[2] Julio Pascual,[1] Marta Riera.[1] *[1]Dept of Nephrology, Hospital del Mar Research Inst (IMIM), Barcelona, Spain; [2]Dept of Pathology, Hospital del Mar Research Inst (IMIM), Barcelona, Spain.*

Background: Whereas ACE2 deletion worsens kidney injury, its amplification ameliorates diabetic nephropathy.The effect of gonadectomy(Gdx) in diabetic ACE2KO male mice has not been previously studied.

Methods: We studied the effect of ACE2 deletion and Gdx on systolic blood pressure(SBP), glomerular filtration rate(GFR), glomerular tuft area(GTA), mesangial index(MI), podocyte number(%POD), glomerular cellularity, and serum(s) and kidney(k) ACE expression in c57bl/6 streptozotocin(STZ)-induced male mice and their controls. Mice were followed-up for 19 weeks after induction of diabetes with STZ injection. Study groups:Wild-type(WT)-CONT,ACE2KO-CONT,ACE2KO-CONT+Gdx,WT-DB,ACE2KO-DB,ACE2KO-DB+Gdx.

Results: ACE2KO-DB mice had increased SBP, GFR, and MI as well as decreased %POD compared to diabetic WT. ACE2KO-DB + Gdx group showed lower values of these measured parameters excepted for augmented %POD.sACE was increased in WT and ACE2KO DB mice.Gdx decreased sACE in both CONT and DB ACEKO mice.kACE was reduced by diabetes in terms of enzymatic activity, protein and mRNA. kACE was also decreased in ACE2KO-CONT mice as compared to WT-CONT.kACE activity positively correlated with protein($r=0.7$;$p<0.001$) and gene expression($r=0.481$, $p=0.005$).

*$P<0.05$ vs CONT; †$P<0.05$ vs WT; §$P<0.05$ vs non-Gdx	WT-CONT (n=12)	ACE2KO-CONT (n=12)	ACE2KO-CONT + Gdx (n=9)	WT-DB (n=10)	ACE2KO-DB (n=10)	ACE2KO-DB + Gdx (n=10)

Conclusions: Diabetic ACE2KO showed increased blood pressure and accentuated glomerular injury as compared to diabetic WT.These alterations were prevented by gonadectomy.Diabetes and *ace2* deletion supposed increased circulating ACE but decreased renal ACE expression.Thus, the alterations observed in this model of diabetes may be related to a modulation of ACE at serum and kidney level.This regulation may be mediated,at least in part,by AngII accumulation.

SA-PO290

ACE2 Amplification by Minicircle Gene Delivery in Diabetic Mice
Jan A. Wysocki,[1] Minghao Ye,[1] Ahmed Mohamed Khattab,[1] Mark Osborn,[2] Yashpal S. Kanwar,[1] Daniel Batlle.[1] *[1]Div. Nephrology and Hypertension, Northwestern Univ, Chicago; [2]Univ of Minnesota.*

Background: Angiotensin-Converting Enzyme-2 (ACE2) enhances the degradation of Ang II. We used minicircle delivery for chronic ACE2 amplification *in vivo*.

Methods: The cDNA of soluble mouse ACE2 was cloned into a circular expression cassette and the resulting ACE2 minicircle (MC) was injected to *FVB* mice in which STZ diabetes was induced.

Results: At 3-7d after MC administration, serum ACE2 activity in mice that received 10ug ACE2MC (n=9) was over 100-fold higher than in controls (n=9) (138±48 versus 0.7±0.2 RFU/uL/hr) and with a larger dose (30ug) (n=8) increased even further (480±153 RFU/uL/hr). The marked increase in serum ACE2 activity was sustained for several months but did not result in a detectable increase in either kidney ACE2 activity or immunostaining. We reasoned that ACE2MC could be used to examine if chronic amplification of circulating ACE2 affects the development of glomerular lesions in diabetic mice. Control or ACE2MC(10-30ug)-treated mice were either injected with vehicle or STZ. Urinary ACR measured over the entire 20 wks after the injection was significantly increased in STZ (n=16) and in STZ-MCACE2 mice (n=14) as compared to vehicle controls(n=9). Glomerular mesangial score, cellularity, glomerular area and GFR were all similarly increased in STZ and STZ-ACE2MC mice.

Parameter	Veh	STZ	STZ-ACE2MC
Serum ACE2 act (RFU/ul/hr)	1.4±0.3	2.4±0.3*	497±135*#
ACR (ug/mg)	19±2	118±18*	91±14*
Mesangial Score	1.0±0	2.33±0.15*	2.15±0.15*
Glom. Cellularity	1.0±0	2.14±0.17*	2.05±0.11*
Glom. Area(um^2)	4173±67	5738±197*	5427±267*
GFR (uL/min/g)	3.6±0.7	10.8±1.3*	10.3±0.5*

*p<0.05 or p<0.01 vs. veh; #p<0.01 vs. STZ

Conclusions: Mini-circle delivery of ACE2 results in a dose-dependent and sustained long-term increase in serum but not kidney ACE2 activity. A profound augmentation of ACE2 activity confined to circulation is not sufficient to prevent glomerular pathology and hyperfiltration in diabetic mice. Strategies to achieve kidney over-expression of ACE2 are needed to examine its postulated beneficial effect in diabetic kidney disease.

Calcitriol and Its Analogue BXL-628 Attenuate High Glucose-Induced Epithelial-Mesenchymal Transition of HK-2 Cells By Suppressing RhoA/ROCK Signaling Pathway
Hao Zhang, Wei Zhang, Jing Huang, Wei Li, Bin Yi. *Dept of Nephrology, The Third Xiangya Hospital of Central South Univ, Changsha, Hunan, China.*

Background: Vitamin D has been shown to be renoprotective in diabetic nephropathy recently, of which the exact mechanism still remains much unknown. In order to investigate the protective role of vitamin D in high glucose-induced epithelial-mesenchymal transition (EMT) in human renal proximal tubular cell, we detected the effect of calcitriol and its analogue BXL-628 in high glucose induced activation of RhoA in HK-2 cells.

Methods: HK-2 cells were divided into five groups: Normal control group (glucose, 5.6 mmol/L); High glucose group (glucose, 30 mmol/L); Calcitriol group (high glucose + calcitriol, the active form of vitamin D); BXL-628 group (high glucose + BXL-628, a selective vitamin D receptor agonist); Positive control group (high glucose + Y-27632, a RhoA inhibitor). Active RhoA protein were assessed by Western Blot and immunofluorescence. The expression of α-SMA, E-Cadherin were determined by Western Blot analysis and qPCR. Collagen-I and Fibronectin were observed by ELISA and qPCR.

Results: Active RhoA protein were significantly increased by high glucose treatment for 2 h. Moreover, the expression of α-SMA, Collagen-I and Fibronectin were significantly up-regulated at 48 h treatment of high glucose. Compared with high glucose group, both calcitriol and BXL-628 treatments reduced the expression of active RhoA protein thus consequently decrease the level of α-SMA Coll1 and Fibronectin while increased E-cadherin expression at both protein and mRNA levels.

Conclusions: High glucose activates RhoA/Rock pathway in HK-2 cells, leading to EMT and up-regulation of ECM. Vitamin D receptor agonist calcitriol and its analogue BXL-628 attenuate high glucose-induced EMT and ECM accumulation in HK-2 cells by suppressing the activation of RhoA/Rock pathway.

Reduced Nuclear Translocation of DNMT3a Contributes to CTGF Hypo-Methylation in Human Mesangial Cells
Hao Zhang, Bin Yi, Jing Huang, Wei Li, Wei Zhang. *Dept of Nephrology, The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: Connective tissue growth factor (CTGF) plays an essential role in the pathogenesis and development of diabetic nephropathy. We have previously identified that high glucose induces the expression of CTGF by decreasing DNA methylation. The aim of the present study was to investigate the underlying mechanisms that contribute to the hypo-methylation of CTGF in diabetic nephropathy.

Methods: Human mesangial cells (HMCs) were treated with normal glucose (5mM), mannitol (30mM) or high glucose (30mM). Immnofluorescence staining was used to determine the cellular distribution, and real-time PCR or western blotting were performed to measure the mRNA or protein expression levels of CTGF, DNMT1, DNMT3a, and DNMT3b, respectively. ChIP assay was applied to investigate the capacity of DNMTs to bind the putative CpG island on CTGF promoter.

Results: High glucose induced both the mRNA and protein expression levels of CTGF in human mesangial cells. Although the protein expression of total DNMT1, DNMT3a, or DNMT3b was not altered by high glucose, both immunofluorescence staining and western blotting of nuclear/cytosol fractionation showed that the nuclear translocation of DNMT3a was significantly reduced in high glucose group compared to normal glucose or mannitol group. In addition, DNMT3a was bound to the putative CpG island of CTGF promoter and high glucose promoted this binding potential.

Conclusions: High glucose attenuates the nuclear translocation of DNMT3a, which is responsible for the methylation of CTGF, and possibly contributes to CTGF hypo-methylation in diabetic nephropathy.

Hydrogen Sulfide (H2S) Inhibits High Glucose-Induced NOX4 Expression By Activating Nitric Oxide (NO)-AMPK Axis in Proximal Tubular Epithelial (MCT) Cells
Hak Joo Lee,[1] Doug Yoon Lee,[1] Meenalakshmi M. Mariappan,[1] Denis Feliers,[1] Goutam Ghosh-Choudhury,[1,2] Hanna E. Abboud,[1,2] Yves C. Gorin,[1] Balakuntalam S. Kasinath.[1,2] *[1]Univ of Texas Health Science Center, San Antonio, TX; [2]South Texas Veterans Healthcare System, San Antonio, TX.*

Background: Renal cells constitutively generate gasotransmitters, H2S and NO; their interaction is not understood. High glucose increases NOX4 expression, ROS generation and matrix synthesis by inhibiting AMPK in renal cells. Since H2S inhibits high glucose-induced matrix increment by activating AMPK, we examined if H2S inhibits high glucose–induced NOX4 and matrix protein expression and if H2S-NO pathways are integrated.

Methods: MCT culture, immunoblotting, confocal microscopy.

Results: High glucose (30 mM) increased NOX4 expression at 1 hr and 24 hrs. that was inhibited by H2S at both time points. H2S inhibited high glucose-induced ROS generation and matrix protein laminin γ1 expression at 24 hrs. High glucose decreased activating AMPK phosphorylation on Thr172 that was restored to baseline by H2S. Compound C, an AMPK inhibitor, prevented H2S inhibition of high glucose-induced NOX4 expression at both 1 hr and 24 hrs. H2S inhibition of high glucose-induced NOX4 expression was abrogated by L-NAME, an inhibitor of NO synthase (NOS), at 24 hrs, but not at 1 hr. L-NAME tended to abolish the inhibitory effect of H2S on high glucose-induced laminin γ1 expression. H2S increased the expression of iNOS at 4 hrs; but had no effect on eNOS content. ODQ, a selective inhibitor of soluble guanylyl cyclase, did not affect H2S inhibition of high glucose-induced NOX4 expression at 24 hr.

Conclusions: H2S inhibits high glucose-induced NOX4 expression at both 1 hr and 24 hrs. by activating AMPK in MCT cells. This effect depends on NO generation at the late time point. Interestingly, iNOS, but not eNOS, appears to be involved in the ameliorative effect of H2S on high glucose-induced NOX4 expression; however, guanylyl cyclase seems not to be involved. Thus, H2S recruits NO to inhibit high glucose-induced NOX4 expression which plays a role in matrix protein accumulation; this is an example of integration of actions of two gasotransmitters in the renal cells.

Ursolic Acid Attenuates HG-Induced Podocyte and Mesangial Injury By Inhibiting PI3K/Akt/mTOR and Wnt/β-Catenin Pathways
Qiuling Fan. *Dept of Nephrology, China Medical Univ, Shenyang, Liaoning, China.*

Background: Autophagy and podocyte epithelial-mesenchymal transition (EMT) implicated with HG-induced renal injury. Ursolic acid (UA) has been identified to inhibit early lesions of diabetic nephropathy. We investigate the effects of Ursolic acid on autophagy, EMT, PI3K/AKT/mTOR and Wnt/β-catenin pathways in podocyteand mesangial cellscultured by highglucose (HG).

Methods: Podocyte andglomerularmesangial cells were cultured in normalglucose, HG and HG with Ursolic acid. The cell proliferation and intracellular ROS were detected by MTT and DCF-DA respectively. Cell cycle and apoptosis were investigated by flow cytometry.The PI3K/Akt signaling signatures,apoptosis, autophagy, EMT and fibrosis associated proteins were detected by immunofluorescence, real-time RT-PCR, western blotting andelectron microscope.

Results: Ursolic acid inhibited HG-induced mesangial cell proliferation and decreased ROS generation and TGF-β, fibronectin expression. Ursolic acid induced mesangial cell apoptosis by increased Bcl-xl, Bax and Survivin expression. The expression of podocin, ZO-1 was down-regulated and the expression of α-SMA was up-regulated in podocyte cultured by high glucose and inhibited by ursolic acid. The cells exposed to HG for 48h showed up-regulated pAkt, pmTOR, pβ-catenin and down-regulated Wnt5a, GSK3β, LC3BII expression. Ursolic acid down-regulatedpAkt, pmTOR andpβ-catenin expression and up-regulated Wnt5a, GSK3β, LC3BII expression in mesangial cell and podocyte cultured by HG. Mass abnormal mitochondrion and decreasedautophagosomeswere observed by electron microscopy in cells cultured by HG for 48h and Ursolic acid decreasedautophagosomes expression.

Conclusions: Ursolic acid can regulate autophagy and EMT and ameliorate high glucose induced podocyte and mesangial cell injury by inhibiting PI3K/AKT/mTOR and Wnt/β-catenin pathways.

SA-PO295

Paricalcitol Has the Renoprotective Effect Related to Catalase Pathway in Kidney Injury Young Sun Kang,[1] Sung Jin Kim,[1] Jung Eun Kim,[1] Jungyeon Ghee,[1] Hye Kyung Song,[1] Hye Sook Min,[1] Mi Jin Lee,[1] Jin Joo Cha,[1] Dae R. Cha,[1] Ji Eun Lee,[2] Hyunwook Kim,[2] Mihwa Lee,[1] Jee-Young Han.[3] *[1]Nephrology, Korea Univ, Ansan, Korea; [2]Nephrology, Wonkwang Univ, Gunpo, Korea; [3]Pathology, Inha Univ, Incheon, Korea.*

Background: Paricalcitol (Pari), vitamin D receptor agonist, is known to have an antioxidative effect on tissue injury, where catalase activity is involved. However, there is no data for the role of Pari on catalase pathway of kidney. The aim of this study is to investigate it in catalase knock-out (CKO) diabetic and non-diabetic mice.

Methods: 8-week-old CKO C57/BL6 and wild-type (WT) mice were treated by i.p. streptozotocin (STZ) (50mg/kg/day) injection for 7days and followed by i.p. Pari injection for two months into 7 groups; I) WT 2) CKO 3) CKO+Pari 4) WT+STZ 5) WT+STZ+Pari 6) CKO+STZ 7) CKO+STZ+Pari.

Results: CKO mice showed lower body weight and more urinary volume than WT, without any changes by Pari treatment. Blood pressure, heart rate, and organ weights were similar among groups. However, FBG level, HbA1c, glucose tolerance test, and insulin tolerance test were of significantly improved by Pari treatment in CKO mice. In addition, urinary albumin excretion was increased in CKO and reduced significantly by Pari treatment. As expected, CKO mice presented lower catalase activity in kidney. However, the catalase deficiency was recovered by Pari treatment, interestingly, only in diabetic mice, not in non-diabetic mice. Consistently, expressions of MCP-1, IL-10, TGFb and type IV collagen were inhibited by Pari treatment in diabetic CKO mice using RT-PCR, western blot analysis, and immunohistochemistry. The lipid contents and liperoxidase of kidney were not changed by Pari, although they were increased more in CKO than WT mice. In addition, urinary 8-isoprostane level did not show any difference among groups. On the other hand, Pari suppressed the PI3K/Akt pathway and urinary nephrin excretion.

Conclusions: These results suggest that the catalase deficiency might be recovered by Pari treatment in kidney injury. However, that renoprotective effect of Pari may occur through the nephrin/PI3K/Akt pathway, independent of the antioxidative effect of catalase.

SA-PO296

Calcitriol Prevents Podocyte Injury via Regulation of Macrophage M1/M2 Phenotype in STZ-Induced DN Rats Yinfeng Guo, Zhixia Song, Min Zhou, Xiaoliang Zhang. *Nephrology, Zhongda Hospital, Southeast Univ, Nanjing, Jiangsu, China.*

Background: Increasing evidences suggest that the heterogeneity of macrophage phenotype and function ultimately determines the outcome of diabetic nephropathy (DN). Therefore, finding method of regulating macrophage phenotype and function is a strategic point of preventing podocyte impairment in DN. In this study, we investigated the effect of calcitriol on macrophage M1/M2 phenotype and its role in protecting podocyte impairment in DN rats.

Methods: DN model rats were established by intraperitoneal injection with streptozocin (STZ). The rats were subsequently receiving either calcitriol (0.1μg/kg/d) or vehicle by gavage. Rats were sacrificed at three time points (8, 14 and 18w) for histological and molecular analysis. In addition, we performed *in virto* study using U937 cells cultured with either high glucose or high glucose followed by 1,25-dihydroxyvitamin D3 medium to assess macrophage phenotype.

Results: Calcitriol decreased proteinuria and attenuated podocyte damage with up-regulating expressions of nephrin and podocin. DN rats showed increased $CD68^+$ macrophages infiltration in glomeruli and interstitium with enhanced protein expressions of M1 markers, including iNOS and TNF-α. Calcitriol significantly decreased the infiltrating macrophages and suppressed M1 macrophage activation. Interestingly, calcitriol improved M2 macrophage activation with elevated protein expressions of M2 markers, including CD163, Arg-1 and MR at 18w but not 8w or 14w. The ratio of CD163/CD68 considered as the proportion of M2 macrophage was about 2.9 fold highly after calcitriol treatment. Moreover, the protein expression of M1 marker iNOS was negatively correlated with expression of either nephrin or podocin, while M2 marker CD163 was positively correlated. *In vitro*, 1,25-dihydroxyvitamin D3 also switched high glucose-induced M1 macrophage toward an M2 phenotype.

Conclusions: Calcitriol regulates macrophage phenotype, via inhibiting M1 macrophage activation as well as enhancing M2 macrophage activation to prevent podocyte impairment in STZ-induced DN rats.

Funding: Government Support - Non-U.S.

1,25-Dihydroxyvitamin D3 Upregulates the PI3K/p-Akt Signal Pathway via Inhabition of TRPC6 Expression to Ameliorate High Glucose Induced Podocyte Injury *In Vivo and In Vitro* Zhixia Song, Yinfeng Guo, Min Zhou, Xiaoliang Zhang. *Nephrology, Zhongda Hospital, Southeast Univ, Nanjing, Jiangsu, China.*

Background: Podocytes injury plays a critical role in the development and progression of diabetic nephropathy(DN).Growing evidenceshave demonstrated PI3K/p-Akt signal pathway in the protection of podocytes. Besides, TRPC6 on the podocytes has been revealed to cause podocyte injury. Recent investigations demonstrated that vitamin D3 reduced albuminuria and prevented podocyte injury. The aim of this study is to investigate whether 1,25-dihydroxyvitamin D3 (VD) upregulates the PI3K/p-Akt signal pathway via inhabition of TRPC6 expression to ameliorate injury of podocyte *in vivo and in vitro* high glucose induced podocyte injury.

Methods: DN model rats were established by intraperitoneal injections of streptozocin. The rats were subsequently receiving either calcitriol (0.1μg/kg/d) or vehicle by gavage and then sacrificed after 18 weeks treatment. In addition, we performed in virto study using MPC5 cells (conditionally immortalized mouse podocyte clonal cells) cultured with either high glucose or high glucose followed by VDmedium orhigh glucose followed by VD and SKF-96365(a generic blocker of TRPC6 channels) medium.

Results: DN rats exhibited increased proteinuria accompanied by elevated TRPC6 expression. Treatment with calcitriol not only reduced proteinuria, but also normalized TRPC6 expression. Meanwhile, the expression of podocyte specific markers, including nephrin and podocin, together with PI3K/p-Akt were significantly decreased in DN rats, whereas calcitriol reversed these above changes. *In vitro*, podocyte injury induced by high glucose exposure in cultured MPC5 increased TRPC6 expression and decreased PI3K/p-Akt expression. Expectedly, VD reversed the increased TRPC6 as well as decreased PI3K/p-Akt expression in a does dependent manner, which were abolished by SKF-96365, a blocker of TRPC6.

Conclusions: 1,25-dihydroxyvitamin D3 upregulates the PI3K/p-Akt signaling pathway via inhabition of TRPC6 expression to ameliorate *in vivo and in vitro* high glucose induced podocyte injury.

The Circulating Inactive Form of Matrix Gla Protein (MGP) Is Associated with Diabetic Nephropathy but Not with Artery Intima-Media Thickness (cIMT) Stefanos K. Roumeliotis, Athanasios K. Roumeliotis, Anna Tavridou, Marios Theodoridis, Stelios A. Panagoutsos, Elias Dimitrios Thodis, Ploumis Stavros Passadakis. *Medical School, Democritus Univ of Thrace, Alexandroupolis, Greece.*

Background: Vitamin K-dependent MGP acts as a calcification inhibitor *in vitro* and *in vivo*and needs modification by γ-carboxylation to become biologically active. Vitamin K deficiency leads to accumulation of high levels of inactive uncarboxylated MGP (dpucMGP) in calcified vessels. The vitamin K oxidoreductase (VKOR) reduces vitamin K to support the γ-carboxylation and consequent activation of MGP. Single nucleotide polymorphism (SNP) *VKORC1 -1639 G>A*results in lower activity of VKOR complex subunit 1 in subjects with the AA genotype and probably higher levels of dpucMGP. We sought to determine the association between dpucMGP levels in the five progressive stages of diabetic nephropathy with *VKORC1 -1639 G>A* polymorphism and cIMT.

Methods: Measurements of cIMT were performed in 124 patients (mean age 68.1±8.6 years) in different stages of diabetic nephropathy, using a high resolution, real-time B-mode ultrasonograph. *VKORC1 -1639 G>A* polymorphism was determined using PCR-RFLP. Plasma dpucMGP levels were measured in a subgroup of 71 patients using ELISA.

Results: Plasma dpucMGP levels increased significantly ($p<0.001$) with disease severity (stage 1: 345±211 pM, stage 2: 513±488 pM, stage 3 and 4: 958±532 pM, stage 5: 1175±428 pM) but were not associated with cIMT. Moreover, no significant difference in dpucMGP levels was observed between *VKORC1* GG/GA and AA genotypes. Multiple linear regression analysis revealed gender (b=-0.139, p=0.001), BMI (b=0.009, p=0.032), and stage of diabetic nephropathy (b=0.063, p=0.001) as independent predictors of cIMT.

Conclusions: Plasma dpucMGP levels were significantly elevated as the stage of diabetic nephropathy progressed but not associated with *VKORC1* genotype and cIMT. Male gender, increased BMI and advanced stage of diabetic nephropathy are independent predictors of cIMT in diabetic nephropathy.

SA-PO299

Contrast-Induced Nephropathy in Hyperglycemic Kidney Cells and Elderly Diabetic Mice Altaf-M. Khan,[1] Federico Teran,[1] Kristina Angela Rathmell,[1] Madlin Alzoubi,[1] Kathleen S. Hering-Smith,[1] Eric E. Simon,[1,2] Vecihi Batuman.[1,2] *[1]Medicine, Section of Nephrology and Hypertension, Tulane Univ School of Medicine; [2]Veterans Affairs, SLVHCS, New Orleans, LA.*

Background: We studied the toxicity of contrast media (CM) on human kidney epithelial (HK-2) cells in high-glucose medium and in aged db/db (diabetic obese) mice to evaluate the effect of diabetes on the vulnerability to contrast-induced nephropathy (CIN).

Methods: HK-2 cells were exposed to nonionic (iohexol or iodixanol) CM, 25 to 100 mg iodine/ml, for 6–24 h. HK-2 cells were studied in high-glucose medium (25 mM glucose, or mannitol as osmolal control) for 6–24 h. For studies *in vivo*, 24-wk-old diabetic db/db and non-diabetic control mice (n = 5 in each group) were dehydrated for 24 h and nonionic low osmolal (iohexol) or isosmolal (iodixanol) CM at a dose of 3 g of iodine/kg bw was injected via a jugular vein catheter. All mice were sacrificed at 24 h after CM injection.

Results: Both CM caused significant cytotoxicity at 50 mg iodine/ml in HK-2 cells. Cells treated with glucose or mannitol combined with iodixanol showed a significant ($p < 0.01$) decrease in cell proliferation compared to cells treated only with iodixanol. The 24-wk old db/db mice gained significant weight, had increased urine volume, GFR, NGAL, and blood and urine glucose levels compared to non-diabetic mice. 24 h after CM (iohexol) injection, db/db mice had a significant decrease in GFR and a significant increase in serum creatinine, urine and kidney KIM-1 levels, and showed kidney damage histologically compared to control db/db mice. The mRNA level of TLR2 (Toll-like receptor 2) was significantly upregulated by iohexol in db/db mouse kidney. Iohexol also caused acidosis in diabetic mice evidenced by decreasing levels of serum pH and HCO_3 levels.

Conclusions: HK-2 cells in high-glucose medium exhibited more severe contrast-induced toxicity than normoglycemic HK-2 cells. Iohexol is more nephrotoxic than

iodixanol both *in vitro* and *in vivo*. At age ≥ 24 wk, db/db mice are prone to CIN and innate immunity mediated by TLR2 may play a role in its pathophysiology. This diabetic mouse model could be useful for in depth studies of mechanisms involved in CIN.

SA-PO300

The Role of the Intestinal Microbiota in the Development of Pre-Diabetes and Diabetes in BTBR and BTBRob/ob Mice Kelly D. Smith, Tomasz A. Wietecha, Xiaodan Zhao, Charles E. Alpers. *Pathology, Univ of Washington, Seattle, WA.*

Background: Obesity and diabetes are associated with an altered gut microbiota that may aggravate metabolic syndrome, and promote inflammation and diabetic complications. The BTBR mouse is insulin resistant due to mutations in 3 loci and develops pre-diabetes; the BTBR$^{ob/ob}$ mouse is leptin-deficient, resulting in progressive obesity and severe type II diabetes. BTBR$^{ob/ob}$ mice also develop features that closely mimic diabetic nephropathy in humans. In this study we analyzed the role of the microbiome in modulating pre-diabetes in BTBR and type II diabetes in BTBR$^{ob/ob}$ mice.

Methods: Starting at 4 weeks, BTBR and BTBR$^{ob/ob}$ mice were fed normal mouse chow, with or without an antibiotic cocktail. Mice were analyzed for weight, blood glucose, glucose tolerance, urine protein, and histopathology. Fecal bacteria were analyzed by culture and 16S rDNA sequencing.

Results: Antibiotic treatment suppressed intestinal microbiota in BTBR mice and significantly improved glucose levels, glucose tolerance and cardiac hypertrophy. In contrast, antibiotic treatment significantly decreased survival (50% at 16 wk, log rank test P=0.0016), increased proteinuria and did not alter glomerular histopathology. Analysis of the microbiome revealed modest, non-significant changes in gut bacterial composition between BTBR and BTBR$^{ob/ob}$ mice. Antibiotic treatment dramatically altered microbiota, but did not completely suppress microbiota in BTBR$^{ob/ob}$ mice, which had an outgrowth of fungi and antibiotic resistant bacteria.

Conclusions: Antibiotic-mediated suppression of the intestinal microbiota improved pre-diabetes in non-obese BTBR mice, suggesting that gut microbiota contribute to the development of pre-diabetes in this genetic model of insulin-resistance. In contrast, antibiotics did not alter the course of severe type II diabetes in BTBR$^{ob/ob}$ mice and significantly increased mortality. Thus the contribution of gut microbiota to severe diabetes is complex and may not be adequately assessed with broad spectrum antibiotic treatment. Future studies in germ-free mice may help clarify the role of gut microbiota in diabetes and diabetic nephropathy.

Moderate Exercise Training Improves Renal and Cardiac Parameters in Diabetic Rats. Is It Enough to Change the Progression of Hypertrophy? Luciana Jorge,[1] Kleiton Augusto Santos Silva,[1] Rafael Luiz,[1] Rodolfo Rosseto Rampaso,[1] Tatiana Sousa Cunha,[2] Nestor Schor.[1] *[1]Medicine/Nephrology, Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]Science and Technology Inst, Federal Univ of Sao Paulo, Sao Jose dos Campos, SP, Brazil.*

Background: Diabetes mellitus (DM) causes damage in both heart and kidneys, leading to the cardiorenal syndrome that is associated with increased complications and mortality. Moreover, DM induces cardiac and renal hypertrophy. The aim was to verify if moderate exercise training (MET) improves renal and cardiac parameters and whether it is able to prevent cardiac and kidney hypertrophy.

Methods: Male Wistar rats were divided into 4 groups: control (C=8), control trained (CT=8), diabetic (D=8) and diabetic trained (DT=8). DM was induced by STZ. Trained groups were submitted to a MET protocol on a treadmill (8 wk). We measured SBP, HR, proteinuria and microalbuminuria in all groups. The cardiac and kidney hypertrophy index was assessed using weight/body weight ratio. By western blot were assessed p-Akt, p-TSC2, p-AMPK. TGF-β1 was evaluated by multiplex.

Results: MET improved renal parameters in the DT group showing a decreased urinary volume (DS:153; DT:106; CS:10 and CT:13ml), proteinuria (DS:46; DT:29; CS:18; CT:7mg/24h) and the microalbuminuria (DS:8.7; DT:4.7; CS:1.5; CT:2.3mg/24h). The SBP was similar between groups (CS:124, CT:128; DS:122; DT:130 mmHg), however, the HR decreased in the DS (323bpm), while the DT (342bpm) was increased. Diabetes resulted an increased cardiac and renal weight, surprisingly, the MET not prevented it. The cardiac expression of p-TSC2 and p-AMPK were reduced in DS group and MET normalized this expression. Moreover, the cardiac expression of p-AKT was increased in the DM and MET did not change it. The cardiac TGF-β1 was elevated in DM and the MET normalized this variable.

Conclusions: MET attenuated the progression of diabetic nephropathy and cardiac dysfunction; those improvements could be a result of the increased expression of p-TSC2, an important protein in the inhibition of the mTOR pathway, a hypertrophic signaling. Ours findings demonstrated that MET is an important approach to prevent complications caused by diabetes.

SA-PO302

High Glucose Upregulates ADAM17 through HIF-1α in Mesangial Cells Renzhong Li,[1] Lalita Uttarwar,[1] Claire M. Dubois,[2] Martine Charbonneau,[2] Bo Gao,[1] Joan C. Krepinsky.[1] *[1]Medicine, McMaster Univ, Hamilton, ON, Canada; [2]Pediatrics, Univ de Sherbrooke, Sherbrooke, PQ, Canada.*

Background: We previously showed that ADAM17 mediates high glucose (HG)-induced matrix production by mesangial cells (MC). ADAM17 expression is increased in diabetic kidneys, suggesting that its upregulation may augment the HG profibrogenic response. We thus studied the effects of HG on ADAM17 gene regulation.

Methods: Primary rat MC were treated with HG (30mM) or mannitol as osmotic control. ADAM17 regulation was assessed by real-time PCR, immunoblotting and activation of a promoter luciferase (-2304 to -1bp) construct.

Results: ADAM17 transcript and protein levels and promoter activity were dose-dependently increased by 24h of HG, but not mannitol. This correlated with increased ADAM17 activity at 24h versus 1h of HG. We tested the involvement of transcription factors shown in other settings to regulate ADAM17 transcription. Promoter activation by HG was not affected by inhibitors of NF-κB or Sp1, but was blocked by inhibition of HIF-1α which also prevented the increase in protein and transcript levels. HIF-1α siRNA also decreased HG-induced promoter activation. HIF-1α activation by HG was confirmed by its increased nuclear translocation and activation of the HIF-responsive plasmid HRE-luciferase. A series of ADAM17 promoter deletion constructs identified decreased promoter activation by HG upon deletion of -2304 to -1567 and complete abolition of activation upon deletion of -903 to -410. These contain two potential HIF-1α regulatory binding sites, termed H1 and H4 respectively. Only mutation of H4 prevented HG-induced promoter activation. HG-induced HIF-1α binding to this region was confirmed by ChIP studies. Finally, inhibitors of EGFR or ADAM17 itself prevented HG-induced ADAM17 promoter activation and protein upregulation and HIF-1α activation.

Conclusions: Thus, HG induces ADAM17 upregulation in MC which is associated with augmentation of its activity. This is mediated by HIF-1α and requires EGFR/ADAM17 signaling, demonstrating the potentiation by ADAM17 of its own upregulation. ADAM17 inhibition thus provides a potential novel therapeutic target for the treatment of diabetic nephropathy, which will be evaluated in further studies.

SA-PO303

Mitochondrial Targeting of Superoxide by MitoQ Improves Metabolic Renal Dysfunction Micheal S. Ward,[1,2] Josephine M. Forbes.[1,2] *[1]Glycation and Diabetic Complications, Mater Research Inst - The Univ of Queensland, Brisbane, Queensland, Australia; [2]School of Medicine, The Univ of Queensland, Brisbane, Queensland, Australia.*

Background: Pathological progression of renal disease (RD) in diabetes is associated with mitochondrial dysfunction attributed in part to excess reactive oxygen species (ROS) generation. Progression of ~30% of diabetic individuals to RD highlights possible underlying susceptibility.

Methods: Groups (n=10/group; 8W of age) of randomised male db/db and db/m mice to (i) Vehicle (H_2O), (ii) MitoQ (MQ), (iii) Ramipril (Ram) or (iv) Co-therapy (MQRam) were followed for 12 weeks. Human immortalized podocytes and primary proximal tubular cells (PTC) were also studied using a Seahorse XF24 analyser to define mitochondrial respiratory function after normal (NORM; 5mM glucose and 100pM insulin), diabetic-like (DIA; 15mM and 500pM) and modulating (MOD; 2 hour alternating treatments) conditions in the presence and absence of MQ.

Results: *In vivo* pharmacological interventions each improved renal function (Sinistrin GFR and UAER) in db/db mice. Oral glucose tolerance testing suggested improvements in renal function with MQ were independent of improved glycaemic control. Analysis of freshly isolated renal mitochondria showed improved function with MQ treatments. *In vitro*, human PTCs had greater maximal respiratory capacity (MRC) and ATP content than podocytes in NORM. Under DIA, MRC and ATP content were reduced in both cell types, significantly in podocytes. However, mimicking glucose excursions, via MOD, podocytes and PTCs elevated MRC and ATP content, significantly in podocytes, compared with NORM. MQ targeting of podocytes attenuated significant decreases presenting under DIA.

Conclusions: Targeting of mitochondrial ROS by MQ has efficacy in experimental models of type 2 diabetes and mechanistically improves mitochondrial function both in vivo in renal cortical mitochondria and in cultured human cells.

Metallothionein (MT)-3 Is a Novel Direct Target of Hypoxia Inducible Factor-1 Alpha (HIF-1α) Yumi Takiyama, Manami Kobayashi, Kuralay Atageldiyeva, Tsuyoshi Yanagimachi, Jun Honjo, Yukihiro Fujita, Masakazu Haneda. *Dept of Medicine, Asahikawa Medical Univ, Asahikawa, Hokkaido, Japan.*

Background: Diabetic nephropathy (DN) represents excessive production of reactive oxygen species (ROS) and renal hypoxia, leading to cellular dysfunction accompanied with subjugated antioxidant mechanisms.Metallothionein (MT) is a cysteine-rich protein with low molecular weight, and act as an antioxdant against the toxicity of metals, ischemia, and ROS. To investigate the pathophysiological role of MT in DN, we studied MT expression in human renal proximal tubular epithelial cells (HRPTECs) and in human kidney tissue derived from subjects with type 2 diabetes.

Methods: The regulation of MT expression was evaluated using HRPTECs by RT-qPCR. Transfection of HRPTECs was carried out by electroporation using the Nucleofection system. Expression of MT3 in human kidney was tested by immunohistochemistry.

Results: HRPTECs constitutively expressed the mRNAs of MT 1-3. Hypoxia (1% O_2) induced a remarkable increase in MT3 mRNA (~300-fold) and a moderate increase in MT2 mRNA (~5-fold), but not in MT1 mRNA in HRPTEC. The genetic inhibition of HIF-1α by siRNAs abolished the stimulatory effect of hypoxia on MT3 mRNA expression, indicating that hypoxia induced MT3 mRNA dependent on HIF-1α. We also found four putative hypoxia response elements (HREs) containing the consensus sequence (A/G) CGTG within the human MT3 gene. In addition, for investigation of which molecules are regulated by MT3, we analyzed microarray data using Affymetrix GeneChip (Human Gene 1.0 ST Array) with siRNA-mediated knockdown of MT3 under hypoxia in HRPTECs. A total of 28,869 transcripts were analyzed, among them, the crucial players in iron or hemoglobin metabolism, ceruloplasmin (-2.333-fold) or cytochrome b reductase 1 (-2.019-fold), were downregulated. Finally, MT3 protein expression in tubular cells in DN was increased compared with those in minimal change nephrotic syndrome (MCNS).

Conclusions: Our study, for the first time, suggests that MT3 is a novel direct target of HIF-1α-mediated signaling during hypoxia-induced renal injury in DN.

SA-PO305

Interaction of RhoA/ROCK Signaling and Renal Angiotensin System in Macrophages Infiltration of Diabetic Nephropathy Jialing Rao, Zengchun Ye, Tan-Qi Lou. *Dept of Nephrology, The Third Affiliated Hospital of Sun Yet-sen Univ, Guangzhou, Guangdong, China.*

Background: Recent studies suggests activation of RhoA/ROCK signaling and renal angiotensin system(RAS) may play an important role in the development of diabetic nephrophathy(DN). The macrophages infiltration is found in diabetic kidneys and macrophage-mediated inflammation may be critical in the early stage of DN. However, whether the interaction of RhoA/ROCK and RAS affect the infiltration of macrophages has not been determined. Therefore, a comprehensive understanding of the macrophages infiltration in the presence and absence of RhoA/ROCK signaling and RAS can contribute to provide more and safer therapies.

Methods: The effect of interaction of RhoA/ROCK signaling and RAS was investigated in the cultured rat glomerular endothelial cells(RGECs). RGECs were incubated with advanced glycation end products(AGEs). Y27632, an inhibition of ROCK and RAS inhibitor losartan were cultured with these cells. RT-PCR, immunofluorescence and Western blots were used to detected the expression of ICAM-1, MCP-1, PECAM-1, AT-1, AGT and renin in cell lysate and culture medium. Using a transwell system, we evaluated the effect of blockage of ROCK and RAS on migration of macrophages.

Results: The experiments showed that, incubated with an increasing dose and time of AGEs, the expression of ICAM-1, MCP-1, PECAM-1, AT1, AGT and rennin in RGECs was gradually enhanced. Either Y27632 or losartan could depress the increased expression of these cytokines. When AGEs-incubated cells cultured with both inhibitors, significant reducing expression of these cytokines could be observed. Using a transwell system, we demonstrated that RGECs grown with AGEs were associated with significant increase in macrophages migration. This effect was completely blocked by the addition of Y27632 and losartan.

Conclusions: These findings suggest that RhoA/ROCK and RAS play a critical role in macrophages' adhesion and migration to endothelial cells. Blocking both signalings can mitigate the expression of adhesion molecule and infiltration of macrophages. This effect can offer protection for the kidney on early stage of DN.

The Persisting Pro-Inflammatory Effects of Transient Glucose Exposure in the Kidney Are Equivalent to That Observed in Chronic Hyperglycemia with Diabetes Chris Tikellis, Raelene J. Pickering, Andrew Murphy, Merlin C. Thomas. *Diabetic Complications, Baker IDI Heart and Diabetes Inst, Melbourne, Victoria, Australia.*

Background: It is now clear that even transient hyperglycemia can have long-lasting effects on the development and progression of diabetic complications, including diabetic nephropathy. This '*metabolic karma*' may explain why many patients with pre-diabetes manifest albuminuria and other diabetic complications, and why even brief periods of poor control in patients with diabetes may have a sustained adverse legacy for the development and progression of renal damage in diabetes.

Methods: Male C57Bl6 mice (n=10/group) were randomised to receive 4 sequential injections of D-glucose (3g/kg IP) or an equivalent volume of saline or L-glucose delivered 2 hours apart. This protocol produces a sustained elevation in plasma glucose levels (15-25mM) for 8 hours, after which time no difference in plasma glucose levels is detectable between treated and control mice. Mice were then followed for 7 days at which time they were killed and glomeruli were isolated by differential sieving. To explore the long term effects mice were injected with glucose or saline weekly using the same protocol for 10 weeks.

Results: Glomeruli isolated from mice 1 week after transient glucose exposure showed persistent up-regulation of ICAM-1, VCAM-1, MCP-1 and NFKB expression when compared to mice that received saline alone. Glomerular leukocyte recruitment was also increased as indicated by the expression of CD11b and FACS analysis. Aortae taken 1 week after glucose exposure also demonstrated up-regulation of adhesion molecules and increased adhesiveness when exposed to labelled human leucocytes *ex vivo*. Repetition of the transient hyperglycaemia protocol every week for 10 weeks in complications-prone apolipoprotein E KO mice led to the development of atherosclerosis, renal damage and albuminuria comparable to that observed in streptozotocin induced diabetic mice.

Conclusions: These experimental data support the hypothesis that transient glucose excursions have adverse proinflammatory effects in the kidney and vasculature potentially contributing to the development of diabetic complications before the onset of diabetes.

The Role of Renal Lipid Metabolism and Lipotoxicity in Human Obesity-Related Glomerulopathy Michal Herman-Edelstein,[1] Amalia Getsztain Bakshi,[1] Talia R. Weinstein,[1] Pnina Scherzer,[1] Uzi Gafter,[1] Vivette D. D'Agati,[3] Moshe Levi.[2] *[1]Nephrology, Rabin Medical Center-Felsenstein, Tel Aviv Univ, Petah-Tikva, Israel; [2]Nephrology, Univ of Colorado, Denver; [3]Renal Pathology, Columbia Univ.*

Background: Obesity-related glomerulopathy(ORG) is an emerging complication of the obesity epidemic. The pathophysiological mechanism ofglomerular injury in ORG is incompletely understood. There is growing evidence that ectopic lipid accumulation pathways (fatty kidney) may cause renal disease.The aim of this project was to study the mechanisms of kidney injury in ORG.

Methods: To identify metabolic pathways involved in the pathogenesis of obesity-related renal disease, we studied by qtPCR the expression of candidate genes involved in cholesterol and fatty acid metabolism, using RNA isolated from formalin-fixed, paraffin-embedded (FFPE) renal biopsies from patients with established ORG (n=33) versus normal kidneys (n=15). We also studied differential expression of these genes in glomeruli versus tubulescollected using laser-capture microdissection(LCMD) method.

Results: Glomerular surface area was markedly enlarged in ORGand was accompanied by significant decreases in the podocyte marker genes, including nephrin and podocin. There was marked lipid accumulation in both glomeruli and tubules by EM and adipophilin staining which was mediated in part by decreased expression of PPARα andfatty acid β oxidation which would favor accumulation of fatty acids and triglycerides.

Conclusions: lipotoxicity may contribute to obesity induced kidney injury.

SA-PO308

Cholecystokinin Activates AMPK and Protects against Progression of Diabetic Kidney Disease in db/db Mice Satoshi Miyamoto,[1,2] Maggie K. Diamond-Stanic,[1,2] Manjula Darshi,[1,2] Tammy Quach,[1,2] Larkin B. Slater,[1,2] Kumar Sharma.[1,2] *[1]Center for Renal Translational Medicine, Univ of California, San Diego, La Jolla, CA; [2]Veterans Administration San Diego HealthCare System, La Jolla, CA.*

Background: We have previously shown that cholecystokinin (CCK) is expressed in the rodent kidney, and that administration of CCK-octapeptide (CCK-8S) confers protection against renal inflammation in early stage of type 1 diabetic kidney disease via an unclear mechanism. We investigated whether interventional CCK arrests diabetic kidney disease (DKD) in a model of type 2 diabetic kidney disease and to determine if AMPK may play a role.

Methods: Sixteen weeks-aged male diabetic db/db (D) mice (BKS.Cg-Dock7^{m} +/+ Lepr^{db}/J strain) were randomly assigned to three groups: db/db treated with vehicle (D+V), db/db treated with low-dose CCK-8S (D+LC) and db/db treated with high-dose CCK-8S (D+HC), n=12/group. Nondiabetic db/m mice were used as control. Vehicle or CCK-8S was infused subcutaneously via osmotic pumps over a 4 weeks period. Glomerular size and mesangial matrix area were assessed by morphometric analysis. AMPK was measured via immunostaining and immunoblotting.

Results: Urinary albumin/creatinine ratio was elevated in D+V (273 ± 47, $P<0.001$) versus control db/m mice (49 ± 4), and reduced in both D+LC (135 ± 16, $p<0.05$) and D+HC (128 ± 29, $p<0.05$), whereas there were no significant differences in body weight, food intake and HbA1c among diabetic groups. There was no significant difference in glomerular size between D+V and D+LC or D+HC, but mesangial matrix was increased by 32 % in D+V and reduced to 88% and 84% of D+V levels by low and high dose CCK treatment, respectively ($p<0.001$). Interestingly, both AMPKα phosphorylation in the renal cortex and average number of pAMPKα positive cells in glomeruli was significantly increased in the D+HC group compared with D+V ($p<0.01$).

Conclusions: We found that a cholecystokinin agonist can improve features of established DKD with type 2 diabetes and may be renoprotective via activation of AMPK. Regulation of gut-kidney axis by CCK may be a novel therapeutic approach for the treatment of established DKD.

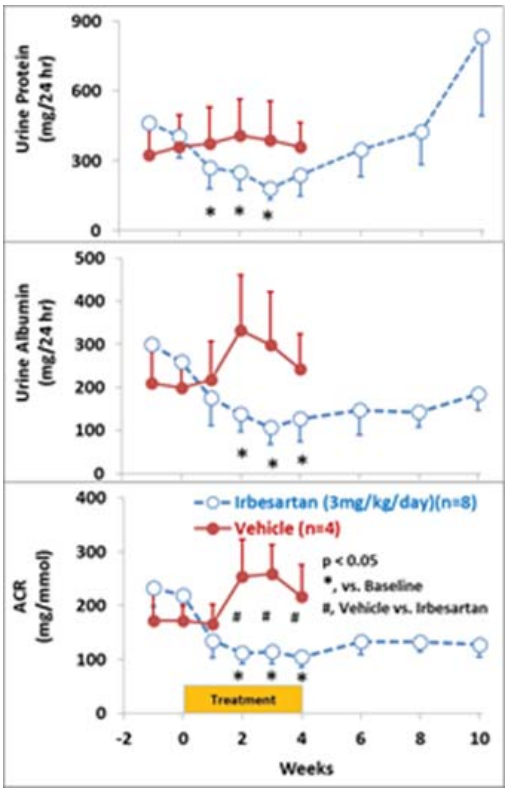
Angiotensin II Receptor Blockers (ARB) Reduce Proteinuria in Diabetic Monkeys Zhonghua Qi,[2] Yixin (Jim) Wang,[1] Xiaoli Wang,[1] Yupeng Fang,[1] Yong-Fu Xiao,[1] Yongqiang Liu,[1] Jing Wu,[1] Guofeng Sun,[1] Bingdi Wang,[1] Mark Kowala,[2] Matthew D. Breyer.[2] *[1]Pharmacology, Crown Bioscience Inc, Taicang, China; [2]Lilly Research Labs, Eli Lilly & Co., Indianapolis, IN.*

Background: Diabetic Nephropathy (DN) is a grave microvascular complication of diabetes. DN initially presents as microalbuminuria, however as it progresses, glomerular damage and proteinuria increase and ultimately renal failure ensues. Efficacy of monoclonal antibody (mAb) therapies for human disease can often only be tested in monkeys but not other species due to lack of mAb cross-reactivity.

Methods: To determine whether DN in monkeys is similar to human DN this study tested whether ARBs reduce proteinuria in spontaneously diabetic cynomolgus monkeys. Two groups of diabetic monkeys were compared: Vehicle (n=4) versus Irbersartan treated (n=8).

Results: Oral administration of Irbesartan (3mg/kg/day), achieved a plasma concentration at 70±17 ng/mL at 24h and significantly reduced urinary protein and albumin excretion as well as ACR. After termination of a 4 week treatment, both gradually returned towards baseline .



There were no significant changes in urinary protein or albumin excretion, in the vehicle group, nor were there significant changes in blood pressure, serum creatinine concentrations or glomerular filtration rate (GFR) measured by creatinine clearance in either group. In a separate experiment in the same model, daily treatment with losartan (1mg/kg) resulted in a similar reduction of proteinuria.

Conclusions: These data demonstrate, to our knowledge, for the first time, that blockade of Ang-II receptors reduces proteinuria in monkeys with DN, and is consistent with the clinical observations in patients with DN. This supports the feasibility of testing therapeutics in the monkeys with DN and their use as a translational model for studying pathophysiological mechanism(s) of DN.

Glomerular Parietal Epithelial Cell Activation Induces Collagen Secretion and Thickening of Bowman's Capsule in Diabetes Alexander Holderied,[2] Simone Romoli,[2] Jonathan Nicodemos Eberhard,[2] Lukas A. Konrad,[2] Satish Kumar Devarapu,[2] Julian A. Marschner,[2] Susanna Mueller,[1] Hans J. Anders.[2] *[1]Ludwig-Maximilians-Univ, Pathologisches Institut, München, Germany; [2]Klinikum der Ludwig-Maximilians-Univ, Nephrologisches Zentrum, Medizinische Klinik und Poliklinik IV, München, Germany.*

Background: The metabolic and hemodynamic alterations in diabetes activate podocytes to increase extracellular matrix production leading to thickening of the glomerular basement membrane, i.e. an early sign of diabetic nephropathy (DN). We hypothesized that diabetes would activate parietal epithelial cells (PEC) and cause thickening of Bowman's capsules.

Methods: Human kidney biopsies and in vitro experiments with human PECs were used to address this issue.

Results: Periodic Acid Schiff staining of human kidney biopsies of 30 patients with DN revealed a significantly thicker Bowman's capsule as compared to 20 non-diabetic controls. The average thickness was 4.55 +/- 0.21 µm in the group of patients with DN compared to 2.92 +/- 0.21 µm in the group of non-diabetic controls ($p<0.001$). Transmission electron microscopy confirmed this finding. In vitro, exposure of human PECs to hyperglycemic conditions, advanced glycation end-products or tumor growth factor-β1 increased the mRNA expression of collagen Iα1, collagen IV, bamcan, nidogen, laminin 1 and perlecan. Western-blot and colorimetric collagen assays confirmed these results for collagen IV on a protein level. To validate these findings in vivo, activation of the PECs was assessed by immunohistochemical staining for CD44 of twelve human biopsy cases with DN. Thickening of the Bowman's capsule showed strong association to CD44 positive PECs.

Conclusions: In summary, metabolic alterations in diabetes activate PECs to increase the expression and secretion of Bowman's capsule proteins. This process should contribute to the thickening of the Bowman's capsule similar to the thickening of the glomerular basement membrane that is driven by activated podocytes. These data may also imply that activated PECs contribute to extracellular matrix production once they migrate to the glomerular tuft, a process resulting in glomerular scaring, e.g. in diabetic glomerulosclerosis.

SA-PO311

Paricalcitol Modulates Plasma ACE2 Activity and Renal ADAM17 Content in Type1 Diabetic Mice Marta Riera, Lidia Anguiano, Marta Rebull, Sergi Clotet-Freixas, Julio Pascual, Maria Jose Soler. *Nephrology, Hospital del Mar Medical Research Inst (IMIM), Barcelona, Spain.*

Background: We demonstrated that circulating and renal ACE2 activity is increased in the NOD DB mice. We studied the role of Paricalcitol in modulating ACE2 in these mice and the renal ADAM-17, implied in ACE2 shedding. Also, the effect of Paricalcitol on tubular epithelial cells was studied.

Methods: Diabetic NOD females age-matched with non-DB controls were studied for 21 days after DB onset. Treatments (n=10,each): Diabetic (DB) animals given vehicle **NOD_pe**; DB treated with Paricalcitol 0.4µg/kg; **NOD+PARI_L**; DB treated with Paricalcitol 0.8µg/kg; **NOD+PARI_H**; DB treated with Aliskiren **NOD+ALSK**; DB with the combination **NOD+PARI_L+ALSK**. Non-obese Resistant mice were controls **NOR**. Mouse tubular epithelial cells were incubated for 24h with Paricalcitol (0.04, 0.4, 4 ng/ml) and high concentration of glucose(25mM).

Results: PARI alone or in combination with ALSK significantly reduced cACE2 activity in DB NOD mice without variations in UAE. Serum renin activity significantly decreased in ALSK-receiving groups but no effect was found with Paricalcitol. Renal content of ADAM17 significantly decreased in NOD+PARI_H. Oxidative stress evaluated by means of renal Nitrotyrosine IHQ and H_2O_2 content in blood. Oxidative stress was reduced in NOD+PARI_H as compared to NOD_pe. In MTC cells, HG increased ACE2 protein expression as compared to cells in low glucose. Paricalcitol significanlty increased the ACE2 expression as compared to HG non-treated cells.

	Blood Glucose t=21d (mg/dL)	UAE (µgAlb/mgCrea)	Circulating ACE2 activity (RFU/µl/hr)	Renal cortex ACE2 expression (ACE2/βactin)	Serum Renin Activity (RFU/µl/hr)	Renal TACE/ADAM17 (pg/µg prot)
NOR	156.5 ± 7.1*	22.17 ± 7.50	111.4 ± 5.0*	0.41 ± 0.07*	1293.1 ± 124.9*	37.56 ± 3.53*
NOD pe	582.3 ± 11.6	482.93 ± 275.41	403.1 ± 42.6	0.66 ± 0.07	1941.5 ± 117.1	75.01 ± 7.00
NOD+PARI_L	525.3 ± 32.8	419.68 ± 209.93	316.2 ± 23.6$	0.81 ± 0.06$	1931.4 ± 80.0	67.34 ± 6.36
NOD+PARI_H	581.6 ± 17.6	311.93 ± 57.63	301.4 ± 12.4$	0.87 ± 0.09$	2034.1 ± 126.3	40.57 ± 4.42$
NOD+ALSK	582.4 ± 9.3	234.41 ± 54.04	357.7 ± 43.6	0.70 ± 0.10	1623.5 ± 130.3$	61.68 ± 6.05
NOD+PARI+ALSK	538.5 ± 23.7	433.10 ± 202.60	263.6 ± 32.5$	0.77 ± 0.09	1507.3 ± 111.0$	64.86 ± 6.56
P	*p<0.05 vs. NOD groups; $p<0.05 vs. NOD_pe					

Conclusions: In NOD diabetic mice, with type 1 diabetis, Paricalcitol modulates ACE2 activity, ADAM17 and oxidative stress renal content independently from the glycemic profile and UAE. In tubular cells, Paricalcitol may modulate ACE2 by blocking its shedding. In the early DN stage, Paricalcitol treatment counterbalances the effect of diabetes on circulating ACE2 activity.

Meprin Alpha Modulates the Immune Response in Mice with Diabetic Nephropathy Kasheena Burris,[1] Jean-Marie V. Niyitegeka,[1] Radiah Minor,[2] Dawn Conklin,[2] Elimelda Moige Ongeri.[1] *[1]Biology; [2]Animal Sciences, North Carolina A&T State Univ, Greensboro, NC.*

Background: Pre-existing chronic kidney disease increases the mortality rate in sepsis. Meprins, metalloproteases that are abundantly expressed in the brush border membranes of kidney proximal tubules, have been implicated in the pathology of diabetic nephropathy (DN). The mechanisms by which meprins modulate kidney injury in DN are not fully understood. Recent studies have shown that meprins are also expressed in leukocytes and play a role in the inflammatory response. The objective of the current study was to determine whether meprin α modulates the immune response associated with sepsis in mice with pre-existing DN.

Methods: Streptozotocin (STZ) was used to induce type 1 diabetes in 8-week old wild-type (WT) and meprin α knockout (αKO) male mice on a C57BL/6 background. At 5 weeks post-STZ injection, the mice were subjected to cecal-ligation and puncture (CLP)-induced sepsis, sacrificed 18h later, and kidney tissue processed for proteomic analysis. Blood samples were collected pre-and post-CLP, and flow cytometry used to evaluate blood leukocyte profiles. The levels of blood urea nitrogen (BUN) and serum creatinine were also measured.

Results: The mortality rate associated with CLP was significantly lower in meprin αKO mice with DN when compared to WT counterparts. BUN levels significantly increased at 18h post-CLP, but were comparable in both genotypes. There was no significant change in the serum creatinine levels at 18h post-CLP. Flow cytometric data showed a 1.5 fold increase in B-cell numbers in WT mice with DN when compared to meprin αKO counterparts at 5 weeks post-STZ injection. However, there were no significant changes in B-cell numbers at 18h post-CLP for either genotype. The levels of neutrophils were 4 times higher in meprin αKO mice at 5-weeks post STZ-injection when compared to WT mice. There was a 3.3 fold increase in neutrophil levels in diabetic WT mice after CLP, an increase that was not observed in diabetic meprin αKO mice.

Conclusions: The data suggest that meprin α deficiency protected mice with DN from injury associated with CLP-induced sepsis. The impact appears to be in part via modulation of neutrophil levels.

Deletion of Aminopeptidase-N Ameliorates Kidney Function in Diabetic Mice Denis Feliers, Robert T. Day, Rita de Cassia Cavaglieri, Balakuntalam S. Kasinath, Hanna E. Abboud. *Medicine/Nephrology, UTHSCSA, San Antonio, TX.*

Background: Aminopeptidase N (AP-N), which degrades angiotensin III (Ang III), is upregulated in diabetic nephropathy, and renal content of Ang III is decreased. Renal levels of Ang III show a strong inverse correlation with kidney hypertrophy, extracellular matrix expansion and albuminuria. We hypothesized that deletion of AP-N will increase renal levels of Ang III and reduce indices of kidney injury in mice with type 1 diabetes.

Methods: Type 1 diabetes was induced with streptozotocin in APN knockout mice (APN-KO) and their wildtype counterparts (APN-wt). Renal levels of Ang II and Ang III, expression of AP-N and indices of kidney injury were assessed after 2 weeks of diabetes.

Results: In Ove26 mice with type 1 diabetes, renal cortical levels of Ang III were decreased, and inversely correlated with albuminuria ($r = -0.67$, $p = 0.01$), kidney hypertrophy ($r = -0.79$, $p < 0.0001$) and fibronectin expression ($r = -0.77$, $p = 0.0001$). AP-N deletion had no effect on glycemia of control or diabetic mice, and slightly reduced blood pressure in diabetic mice. Renal cortical Ang III expression was significantly increased in control and diabetic APN-KO mice but Ang II levels were unchanged. There was a ~ 50% reduction in urinary albumin excretion and kidney hypertrophy in diabetic APN-KO mice compared to diabetic APN-wt mice. Superoxide production as well as expression of NAD(P)H-oxidase Nox4 and fibronectin were significantly reduced in diabetic APN-KO mice. Expression of pro-inflammatory molecules VCAM1 and MCP1 was significantly increased by diabetes in wild type mice but not in APN-KO mice.

Conclusions: Our data show for the first time that deletion of aminopeptidase-N increases renal levels of Ang III without affecting the levels of Ang II, reduces albumin excretion, kidney hypertrophy, oxidative stress and expression of pro-fibrotic and pro-inflammatory molecules. Our results suggest combination of blockade of Ang II synthesis and increase in renal Ang III may contribute to amelioration of kidney injury in diabetes.

miR-21 Contributes to Proximal Tubule Cell Dysfunction in Diabetic Nephropathy Through Augmentation of TGFβ-Induced Changes in Mitochondrial Morphology and Metabolism Aaron D. McClelland, Phillip Kantharidis, Karin Jandeleit-Dahm, Mark E. Cooper. *JDRF Danielle Alberti Memorial Centre for Diabetes Complications, BakerIDI Heart and Diabetes Inst, Melbourne, Victoria, Australia.*

Background: miR-21 is strongly upregulated by TGFβ and known to directly play roles in the development of tissue fibrosis and cancer metastasis. These major roles have encompassed a small number of the predicted targets of miR-21 and therefore likely represent an equally minute understanding of the pathophysiology of miR-21. To further this understanding, miR-21 was studied in context of mitochondrial dysfunction in PTCs, a major contributor to the oxidative stress induced in the diabetic kidney.

Methods: PTCs were grown in high glucose conditions with or without 10ng/μl TGFβ. miR-21 was over-expressed and knocked-down using miRNA mimics and locked-nucleic-acids (LNAs) respectively. The effect of miR-21 on mitochondrial morphology and metabolism were analysed by an array of biochemical and imaging based techniques.

Results: Mitochondria underwent increased fission characteristic of TGFβ treatment. This was accompanied by changes in levels and localisation of mitochondrial dynamics proteins. TGFβ-induced changes in mitochondrial basal and maximal respiration in addition to spare respiratory capacity were all increased by miR-21 overexpression by ~2-fold. TGFβ-induced mitochondrial reactive oxygen species production was increased 50% above baseline. This was further increased by miR-21 over-expression to 2-fold above baseline. This was partially overcome by the addition of glutathione. Reduction of oxidative stress was accompanied by downregulation of a number of genes important to PTC DN pathophysiology including Collagen1 and Fibronectin.

Conclusions: These data provide further insight into the role of miR-21 in DN and how it mediates the pathogenic gene expression changes associated with its dysregulation. Undoubtedly, these findings add support to the notion of targeting miR-21 in a clinical setting with the aim of attenuating the progression of diabetic nephropathy.

Macrophage TNF-α Mediates Diabetic Renal Injury Hanning You,[1] Ting Gao,[1] Timothy K. Cooper,[2] Jean Vacher,[3] Francis Xavier Farrell,[4] William Brian Reeves,[1] Alaa S. Awad.[1] *[1]Medicine, Penn State Univ College of Medicine, Hershey, PA; [2]Comparative Medicine, Penn State Univ College of Medicine, Hershey, PA; [3]Clinical Research Inst of Montreal, Univ de Montréal, Canada; [4]Immunology Research, Centocor Research and Development.*

Background: Monocyte/macrophage recruitment correlates strongly with the progression of diabetic nephropathy (DN). Tumor necrosis factor-alpha (TNF-α) is produced by monocytes/macrophages. However, the direct role of TNF-α and/or macrophage-TNF-α in the progression of DN remains unclear. We hypothesize that deficiency or blockade of TNF-α confers kidney protection in DN via macrophage-TNF-α dependent pathway.

Methods: Experiments were conducted in TNF-α deficient mice ($TNF\text{-}\alpha^{-/-}$), macrophage-specific TNF-α deficient mice ($CD11b^{cre}/TNF\text{-}\alpha^{flox}$) and their wild type littermates following STZ induced diabetes and $Ins2^{Akita}$ mice treated with a TNF-α blocking antibody.

Results: Pharmacologic blockade of TNF-α using a TNF-α blocking antibody conferred kidney protection in $Ins2^{Akita}$ mice as indicated by reductions in albuminuria ($p<0.0001$), plasma creatinine ($p<0.05$), histopathologic changes ($p<0.05$), kidney macrophage recruitment ($p<0.001$) and plasma inflammatory cytokine levels (GM-CSF; $p<0.001$, KC; $p<0.01$, TNF-α; $p<0.05$ and MCP-1; $p<0.05$) compared to vehicle-treated $Ins2^{Akita}$ mice at 18 weeks of age. Likewise, diabetic $TNF\text{-}\alpha^{-/-}$ mice had reduced albuminuria ($p<0.05$) after 20 weeks of STZ-induced diabetes compared to diabetic $TNF\text{-}\alpha^{+/+}$ mice. To assess the direct role of macrophage-TNF-α in DN, we generated a macrophage specific TNF-α deficient mouse ($CD11b^{cre}/TNF\text{-}\alpha^{flox}$). Our results show that conditional ablation of TNF-α in macrophages significantly reduced albuminuria ($p<0.01$), the increase in plasma creatinine ($p<0.05$), histopathologic changes ($p<0.01$) and kidney macrophage recruitment ($p<0.05$) compared to diabetic $TNF\text{-}\alpha^{flox}$ control mice after 12 weeks of STZ-induced diabetes.

Conclusions: These findings indicate that production of TNF-α by macrophages plays a major role in diabetic renal injury and that blocking TNF-α could be a novel therapeutic approach for treatment of DN.

SA-PO316

Aerobic Exercise Training (AET) Improves Proteinuria in Rats with Diabetic Nephropathy Rodolfo Rosseto Rampaso, Rafael Luiz, Kleiton Augusto Santos Silva, Luciana Jorge, Edson Andrade Pessoa, Mario Luis Ribeiro Cesaretti, Nestor Schor. *Nephrology Div, UNIFESP-EPM, Sao Paulo, Brazil.*

Background: Moderate AET is an important tool for the treatment of diabetic patients. Several studies show that EXE decreases blood glucose, the incidence of CKD and contributes to a better control on hypertension and obesity among other effects. The aim of this study was to evaluate the effects of AET in controlling the progression of diabetic nephropathy, and its possible renoprotective effects.

Methods: Wistar rats divided into 4 groups: Sedentary controls (C-SED), Diabetes/Sedentary (DM-SED), Diabetes/Exercise(DM-EXE) and Exercise Controls (C-EXE). DM was induced with streptozotocin,50mg/kg i.v. The AET were done on treadmill 60 min/day, 5 days a week for 8 weeks. Weekly determined Maximal Exercise Test (set at 65-70% of MEtest). Glycemia after 24h post training (24h glycemiapt), creatinine clearance/BW (CrCl/BW), arterial pressure(AP), proteinuria(uProt) were measured. Data in Mean±ED.

Results:

	C-SED	DM-SED	DM-EXE	C-EXE

$p<0.05$:* VS C-SED. # VS DM EXE. & VS C- EXE

Conclusions: Reductions in glycemia and AP (~11%) were observed when comparing the groups DM-EXE versus DM-SED. The DM-EXE group showed a reduction in the

progression of weight loss (~40%) compared to DM-SED, but did not prevent alteration in the CrCl/BW with this protocol. However, the effect of the EXE was strikingly observed in the reduction of mean uProt excretion (~60%) comparing DM-SED versus DM-EXE. Therefore, preliminary data suggest that moderate aerobic exercise can reduce proteinuria in diabetic animals and consequently diminish the potential effects caused by diabetic nephropathy and could reduce the progression of renal failure.

SA-PO317

AMPK Regulates Fibronectin in Renal Cells and in Kidney of Diabetic Mouse Samy L. Habib,[1,2] Adam Kosti,[2] Sitai Liang.[2] *[1]Geriatric Research, Education, and, Clinical Center, South Texas Veterans Healthcare System, San Antonio, TX; [2]Cellular and Structural Biology, Univ of Texas Health Science Center, San Antonio, TX.*

Background: Tubular cells are a primary target of hyperglycemia contribute to the tubulointerstitial in diabetic nephropathy. The rate of deterioration of kidney function is highly correlated with the degree of tubular fibrosis and accumulation of cell matrix proteins. The mechanisms by which hyperglycemia contributes to matrix expansion and fibrosis are not known.

Methods: Mouse proximal tubular (MPT) cells were grown in normal glucose (NG) or treated with high glucose (HG) or pretreated with AICAR or compound C. MPT cells were transfected with DN-AMPK before exposure to HG to measure AMPK activity, protein expression and promoter activity of fibronectin. Db/db mice were treated with AICAR for 1 month, physiological and kidney parameters as well as p-AMPK/fibronectin expression were measured.

Results: HG significantly reduced AMPK activity and increased fibronectin expression in MPT cells while pretreatment with AICAR reversed these changes. Downregulation of AMPK by DN-AMPK or by compound C significantly increased protein expression and promoter activity of fibronectin. Further, HG significantly increased the promoter activity of fibronectin while pretreatment with AICAR reversed HG effects to NG levels. In addition, HG decreases YY1 expression and activates of mTORC1 while pretreatment the cells with AICAR reversed these changes. Moreover, kidney cortex of diabetic mice showed significant decrease in YY1 and AMPK and increase in mTOR activity that resulted in significant increase in fibornectin expression. While, mice treated with AICAR showed decrease in proteinuria and decrease in fibronectin protein expression compared to non-treated mice.

Conclusions: Our data showed that AICAR activates AMPK to block mTOR and prevent binding YY1 to mTORC1 that led to decrease accumulation of fibornectin in renal cells. In addition, AICAR treatment improves kidney parameters as well as blocks cell matrix protein accumulation in kidney of diabetic animals. These data shed the light on AMPK as potential therapeutic kinase target for treatment of renal complications in diabetes.

Thioredoxin Interacting Protein Mediates Dysfunction of Tubular Autophagy in Diabetic Renal Interstitial Fibrosis Chunling Huang,[1] Yuan Zhang,[2] Darren J. Kelly,[2] Christina Yan Ru Tan,[2] Xinming Chen,[1] Carol A. Pollock.[1] *[1]Renal Lab, Kolling Inst of Medical Research, Univ of Sydney, Sydney, NSW, Australia; [2]Dept of Medicine, St. Vincent's Hospital, Univ of Melbourne, Fitzroy, VIC, Australia.*

Background: Autophagy is a major pathway that delivers damaged proteins and organelles to lysosomes in order to maintain cellular homeostasis. Thioredoxin interacting protein (Txnip) expression is induced by a variety of cellular stresses including high intracellular glucose, which is associated with activation of oxidative stress and tubulointerstitial fibrosis in diabetic nephropathy. The aim of the study is to define the role of Txnip on dysfunctional tubular autophagy in the development of diabetic renal interstitial fibrosis.

Methods: Transgenic (mRen-2) 27 rats with streptozotocin-induced diabetes were randomly assigned to receive Txnip DNAzyme or control (scrambled DNAzyme) delivered by implanted minipump. Using immunofluorescence staining, the formation of autophagosomes was measured with LC3, and the effectiveness of autophagic clearance was determined by p62 expression in human kidney biopsy specimens from patients with diabetic nephropathy as well as experimental rat kidney tissues. The expression of Txnip and fibrotic marker collagen I was assessed with immunohistochemical staining. The activation of oxidative stress was measured by nitrotyrosine using immunohistochemical staining.

Results: Immunofluorescence staining results showed increased LC3 and P62 in renal tubular cells of human diabetic kidneys compared to non-diabetic kidneys, which indicated tubular accumulated autophagosomes and suppressed autophagic clearance. Similarly, increased LC3 and P62 were also found in renal tubular cells of experimental rat model of diabetic nephropathy compared to non-diabetic kidneys, which were reversed by Txnip DNAzyme treatment. Diabetic induced upregulation of Txnip, collagen I and nitrotyrosine were dramatically attenuated in the animals treated with Txnip DNAzyme.

Conclusions: Hyperglycemia induced overexpression of Txnip may contribute to the dysfunction of tubular autophagy in diabetic renal interstitial fibrosis through oxidative stress.

SA-PO319

Blockade of Smad3 Signalling Reduces Podocyte Injury in High Fat Diet-Induced Obesity Jinhua Li, Yu Bo Yang Sun, Xinli Qu. *Anatomy and Developmental Biology, Monash Univ, Melbourne, Vic, Australia.*

Background: Central obesity poses an increased risk for the development of renal-cardiovascular diseases and type 2 diabetes. TGF-β/Smad signalling plays a key role in renal fibrosis with the majority of the biological effects mediated via Smad3. Smad3-null mice are protected from high fat diet (HFD)-inducedobesity and exhibit reduced adiposity. We hypothesize that Smad3 deficiency may reduce obesity-related kidney injury.

Methods: Smad3 wild type and knockout mice were given HFD or normal diet (ND). Mice were killed 1, 4, 8 or 16 weeks after HFD or ND treatment.

Results: In response to a HFD, we have observed activation of Smad3, a significant increase of albuminuria and the incipience of insulin resistance occur at 1, 4 and 8 week(s) respectively. This suggests a temporal pattern of Smad3 signalling activation leading to kidney injury and subsequent insulin resistance in the aetiology of obesity-related kidney disease. With prolonged HFD exposure (16 weeks), there is a progressive increase of renal fibrosis with associated with loss of synaptopodin expression. Smad3 deficiency attenuated HFD-induced proteinuria and glomerulosclerosis, reduced alternatively activated M2 macrophages, and prevented down-regulation of synaptopodin. Confocal microscopy also demonstrated that mitochondrial marker significantly decreased in podocytes in HFD-treated group compared with that in ND-treated group. Smad3 deficiency rescued the loss of mitochondrial markers in podocytes. In a vitro model, palmitate acid addition to cultured podocytes induced a similar rapid activation of Smad3 and loss of synaptopodin after 5 days treatment. Addition of the specific Smad3 inhibitor, SIS3, prevented palmitate-induced down-regulation of synaptopodin expression and loss of mitochondrial marker.

Conclusions: Our studies provide the first evidence that high fat diet may directly cause kidney injury and Smad3 plays essential roles in HFD-induced podocyte damage by down-regulation of synaptopodin. Smad3 may be a novel therapeutic target in obesity-related kidney disease.

Effect of Bilirubin on Triglyceride Synthesis in Streptozotocin-Induced Diabetic Nephropathy Ho Jun Chin, Seong Woo Lee, Seon Ha Baek, Ki Young Na, Youn-Su Park. *Internal Medicine, Seoul National Univ Bundang Hospital, Seong nam, Kyeongkido, Republic of Korea.*

Background: Recent studies have indicated that bilirubin, in modest levels, acts as a major physiologic cytoprotectant for diabetes, diabetic complications, cardiovascular diseases, and renal diseases, mainly through anti-oxidative and anti-inflammatory properties. We investigated the other effects of bilirubin on diabetic nephropathy and probable mechanisms of them in rats with type I diabetes induced by streptozotocin (STZ).

Methods: Sprague–Dawleyrats were grouped into control, DM, and DM with bilirubin treatment (Bil) groups.Bil group was treated with bilirubin (60 mg/kg IP x 3/week). Hepatoma cells were also cultured withbilirubin(0.3 mg/dL).

Results: In SD rats of Bil group, serum creatinine level was preserved at 5 weeks after diabetes and decreased mesangial matrix with lower expression of renal collagen VI and TGF-β1, lower level of apoptosis determined by TUNEL staining in the kidney compared to DM group. That finding accompanied by decreased tissue level of hydrogen superoxide and protein expressions of subunits of NADPH oxidase. Bilirubin decreased serum total cholesterol, HDL cholesterol, free fatty acid, and triglyceride, and the content of triglyceride in liver tissue, also. The protein expression of genes involved in triglyceride synthesis, LXRα, SREBP-1, SCD-1, and FAS,was suppressed by bilirubin, which was enhanced in liver of DM rats or hepatoma cells in HG condition.

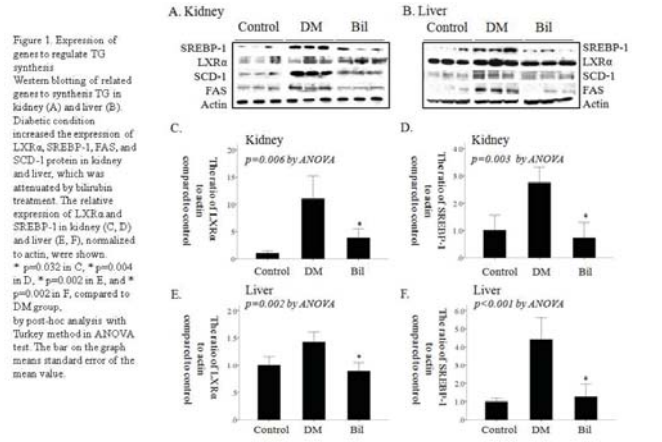

Figure 1. Expression of genes to regulate TG synthesis
Western blotting of related genes to synthesis TG in kidney (A) and liver (B). Diabetic condition increased the expression of LXRα, SREBP-1, FAS, and SCD-1 protein in kidney and liver, which was attenuated by bilirubin treatment. The relative expression of LXRα and SREBP-1 in kidney (C, D) and liver (E, F), normalized to actin, were shown. * p=0.032 in C, * p=0.004 in D, * p=0.002 in E, and * p=0.002 in F, compared to DM group, by post-hoc analysis with Turkey method in ANOVA test. The bar on the graph means standard error of the mean value.

Bilirubin suppressed the SREBP-1 gene, indirectly, via downregulation of LXRα, and through direct pathway, also.

Conclusions: Bilirubin attenuated diabetic renal dysfunction, and dyslipidemia in diabtes through suppression of LXRα and SREBP-1 genes.

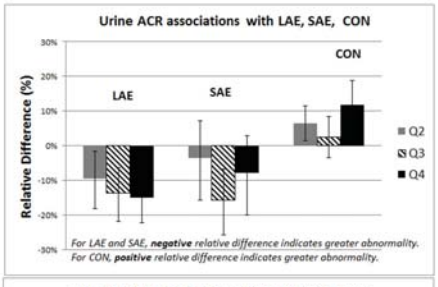
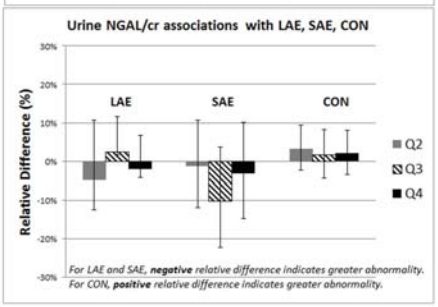
Urine ACR, NGAL, and KIM-1 and Subclinical Cardiovascular Disease: The Multi-Ethnic Study of Atherosclerosis (MESA) Meyeon Park,[1] Michael Shlipak,[1] Ronit Katz,[2] David Siscovick,[2] Mark J. Sarnak,[3] Chi-Yuan Hsu,[1] Carmen A. Peralta.[1] *[1]UCSF; [2]UW; [3]Tufts.*

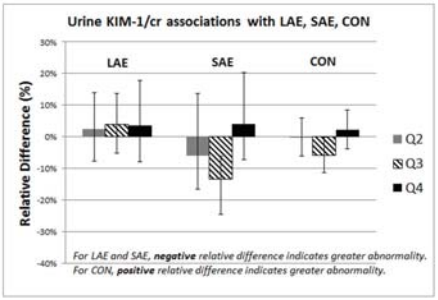
Background: Elevated levels of urine markers of glomerular and tubular injury are associated with heart failure and death. Whether or not these biomarkers are associated with subclinical abnormalities in vascular function or cardiac structure is not established.

Methods: In a nested case-control study of MESA, we investigated cross-sectional associations of urine markers and 3 subclinical measures predictive of later cardiac events in MESA: large (LAE) and small artery elasticity indices (SAE), measured by arterial tonometry; and left ventricular mass to end-diastolic volume ratio (concentricity (CON)), measured by cardiac MRI. Urine albumin (ACR), neutrophil gelatinase-associated lipocalin (NGAL/cr), and kidney injury molecule-1 (KIM/cr), normalized to creatinine, were measured at baseline. We used inverse probability weighting to account for the study design. Using linear regression, we evaluated associations of quartiles of urine markers with log-transformed outcomes of LAE, SAE, and CON, adjusting for age, race/ethnicity, sex, height, pulse, blood pressure, smoking, medications.

Results: All 686 participants (37% white, 30% black, 26% Hispanic, 6% Asian) were free of cardiovascular disease at baseline. Mean (SD) age was 67 (8.7) years; median (IQR) baseline eGFR was 75.7 (69.8-82.4) ml/min/1.73m². Compared to the lowest quartile, higher quartiles of ACR were associated with worse LAE (Q4 v. Q1 relative difference 15%, 95% CI 7.7-21.8) and more severe CON (11.7%, 95% CI 4.5-19.3), but not with SAE. NGAL/cr and KIM/cr were not significantly associated with LAE, SAE, or CON.







Conclusions: Higher levels of urine ACR, but not NGAL or KIM-1, are associated with subclinical vascular and cardiac abnormalities. Arterial elasticity and cardiac remodeling do not readily explain the association between kidney injury and elevated cardiac risk.

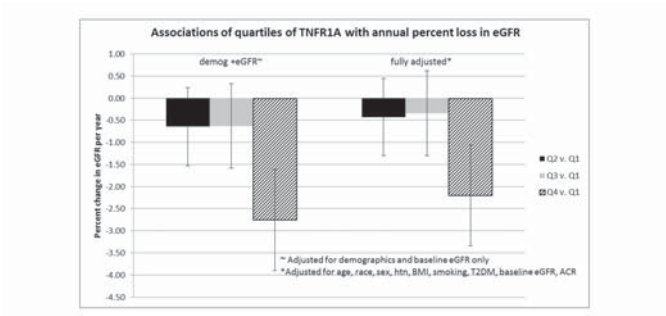
TNF-Alpha Receptor 1 Is Associated with Kidney Function Decline in Persons with Coronary Artery Disease Meyeon Park, Eric Vittinghoff, Mary Whooley, Michael Shlipak. *UCSF.*

Background: Inflammation is a possible mechanism to explain the association between atherosclerosis and kidney disease. This study evaluated circulating tumor necrosis factor alpha receptor type 1 (TNFR1A), a marker of inflammation, as a risk factor for kidney function decline and albuminuria.

Methods: In the Heart and Soul Study, a cohort with established coronary artery disease (CAD), we measured TNFR1A from baseline serum samples and defined elevated levels of TNFR1A by the highest quartile (Q4, > 3.3 ng/ml). We calculated estimated glomerular filtration rate (eGFR) at baseline and after 5 years of follow-up using the CKD-EPI equation. We evaluated the associations of high TNFR1A with annual percent loss in eGFR, rise in urine albumin:creatinine ratio, rapid eGFR loss (>3% per year), and incident CKD (change from eGFR>60 to <60). We adjusted for age, race, sex, hypertension, smoking, diabetes, HDL, and medications.

Results: Among 629 participants who had TNFR1A measurements at baseline and follow-up measures of kidney function, median TNFR1A was 2.33 ng/ml (1.8-3.1). Higher levels of TNFR1A (Q4 v. Q1) were associated with a 1.94% (95% CI 1.03-2.86%) annual percent loss in eGFR (Figure) and rise in ACR (β=41.45, 95% CI 0.28-82.62, p=0.0016) in adjusted analyses. The highest TNFR1A quartile had similar associations with rapid kidney function loss (OR 3.66, 95% CI 2.03-6.6, p<0.001) and incident CKD (OR 1.89, 95% CI 0.89-4.02), although the latter outcome was non-significant after adjustment.



Conclusions: TNFR1A is independently associated with increased albuminuria and greater loss of kidney function longitudinally. These findings implicate inflammation as a potential contributor to the elevated kidney disease risk in persons with CAD.

Validation of Molecular Signatures Linked to Asymmetric Dimethylarginine Dysregulation in Chronic Kidney Disease Varsha Pathak,[1] Wenjun Ju,[2] Viji Nair,[2] Matthias Kretzler,[2] Crystal A. Gadegbeku.[1] *[1]Temple Univ School of Medicine; [2]Univ of Michigan.*

Background: Asymmetric dimethylarginine (ADMA), an endogenous competitive inhibitor of nitric oxide synthase, is implicated in endothelial dysfunction and accelerated atherosclerosis in patients with chronic kidney disease (CKD). Here, we validate and extend data on gene expression profiles from renal biopsy samples in a large CKD cohort, European Renal c-DNA Bank (ERCB).

Methods: Gene expression analysis was performed using Affymetrix 133 plus GeneChips on renal biopsy tissue obtained from consented individuals in ERCB. Steady state gene expression levels of PRMT 1, DDAH and oxidative stress markers (gp91-phox, p67-phox, mitochondrial [Mn] superoxide dismutase) were measured from the microdissected tubulo-interstitial (n=162) and glomerular (n= 143) compartments from renal cortical samples. Pearson correlations were used to compare enzyme profiles and eGFR (CKD-Epi equation) with adjustment for multiple comparisons.

Results: In the tubulo-interstitial compartment, PRMT1 was significantly inversely correlated with DDAH1 and positively correlated with the oxidative stress markers gp91-phox, p67-phox and Mn-SOD. These oxidative stress markers were inversely correlated with DDAH1. Further, eGFR correlated positively with DDAH1 and negatively with PRMT1 and oxidative stress markers. In the glomerular tissue, only the oxidative stress markers demonstrated significant associations and were inversely correlated with eGFR. Also, we observed a negative co-relation with DDAH1 and not DDAH2 (known to be expressed predominantly in vascular endothelium).

Compartment	Enzyme	gp91-phox	p67-phox	Mn-SOD	eGFR
Interstitium	PRMT1	0.40**	0.45**	0.44**	-0.37**
	DDAH1	-0.43**	-0.50**	-0.30**	0.29**
	eGFR	-0.43**	-0.45**	-0.43**	--
Glomerulus	PRMT1	0.4**	-0.42**	-0.39**	0.07
	DDAH1	-0.25**	-0.29**	-0.01	0.02
	DDAH2	-0.03	0.13	-0.16	-0.06
	eGFR	-0.4**	-0.42**	-0.4**	--
*p≤0.05, **p≤0.001					

Conclusions: Here, we confirm the relationships between renal tissue gene expression profiles of ADMA-related enzymes and renal function and provide further molecular evidence of the kidney's role in ADMA dysregulation.

Funding: NIDDK Support

SA-PO324

Endocan as a Biomarker of Endothelial Function in End Stage Renal Disease Vinod K. Bansal,[1] Debra Hoppensteadt,[2] Daneyal Syed,[2] Jawed Fareed.[2] *[1]Nephrology, Loyola Univ Medical Center; [2]Pathology, Loyola Univ Medical Center.*

Background: Endocan also described as endothelial cell specific molecule (ESM1) is a proteoglycan of 50kda which is highly upregulated in various vascular diseases. Endocan binds CD11a / CD18 integrin on human leukocyte. Pro-inflammatory mediators such as TNFalpha and proantiogenic molecules such as VEGF or FGF 2 stimulate the formation of this mediator. Elevated blood levels of endocan have been reported in patients with cancer (lung, kidney, blood), severe sepsis, and post-transplantation veno-occlusive disease. The purpose of this study is to measure endocan in ESRD patients to demonstrate its relevance to this disease.

Methods: Citrated plasma samples were collected from 85 patients who were on maintenance hemodialysis in the dialysis clinic at Loyola University Chicago Hospital. The control group represents 50 normal, drug free individuals. Endocan levels were measured in these plasma samples using a commercially available ELISA method (Lunginnov,Paris, France). VEGF and FGF 2 levels were also measured using commercially available ELISA methods (R&D, Minneapolis, Minnesota).

Results: Endocan levels were found to be significantly higher (p=<0.05) in the ESRD patients (2.6 + 1.3ng/ml) with a wide range (0.9 + 14.7 ng/ml) in contrast to normal (1.8 + 0.6ng/ml) with a narrower range of (1.3 + 3.4ng/ml). Of the 85 patients, 10 showed greater than 5 ng/ml of this biomarker. Both the VEGF level and FGF 2 levels were also elevated (2-5 folds) in the ESRD group in comparison to the normal. There was a poor correlation (r=<0.3) between the elevation of endocan with either VEGF and FGF 2.

Conclusions: Consistent with earlier reports endocan is elevated in various diseases with endothelial dysfunction. These studies suggest that this biomarker may be a useful prognostic indicator for ESRD. Contrary to the earlier reports the observed poor correlation between endocan and VEGF / FGF 2 may suggest independent regulation of endocan through other mechanisms. This data warrants additional studies to validate the relevance of this marker with the pathogenesis of ESRD.

SA-PO325

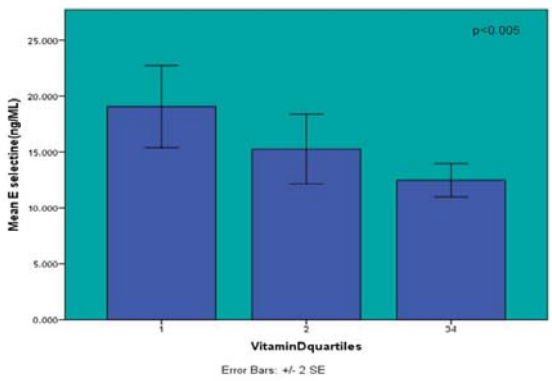
Vitamin D Deficiency and Biomarkers of Endothelial Function in Kidney Transplant Recipients Ashok Kumar Yadav,[1] Matthew Steel,[2] Raja Ramachandran,[1] Juan Carlos Kaski,[2] Vivekanand Jha,[1] Debasish Banerjee.[2] *[1]PGIMER, Chandigarh; [2]St. Georges, Univ of London.*

Background: Vitamin D deficiency is common in kidney transplant (KTx) recipients and associated with adverse outcomes. We have previously demonstrated abnormal endothelial function in KTx patients and worse endothelial cell biomarker profile in vitamin D deficient CKD patients, which improves with vitamin D supplementation without a change in FGF23 concentration. However the relationship between vitamin D deficiency and biomarkers of endothelial dysfunction in KTx recipients is unknown which the present study investigated.

Methods: We assessed 93 non-diabetic, stable KTx patients from Chandigarh, India, none on vitamin D therapy. Data on demographics, anthropometrics, and treatment were collected. Blood samples were stored at -70^{0}C until analysis for bone and endothelial cell biomarkers including FGF 23, iPTH and E-Selectin using standard ELISA techniques.

Results: Clinical characteristics were: age 37±10 years, 80% men, 23% past smokers, SBP 125±15 mmHg, DBP 78±10 mmHg, cholesterol 172±47 mg/dL, haemoglobin 13±2 g/dL, calcium 9.4±0.6 mg/d and iPTH 58±33 ng/mL and Vitamin D 36±39 nmol/L. Patients with Vitamin D <37.5 nmol/L (66%) had similar age, creatinine, phosphate, iPTH, BP but lower calcium (9.3±0.7 versus 9.6±0.5 mg/dL, p<0.05), lower FGF23 (59±73 versus 107±97 pg/mL, p<0.05) and higher E Selectin (16±8 versus 13±5 ng/mL, p<0.05). With increasing quartiles of Vitamin D concentration the levels of E Selectin decreased (p<0.005) and this was associated with rising levels of FGF23 (p<0.05).

Figure 1: Showing relationship of quartiles of Vitamin D and concentration of E Selectin



Legend: The concentration of E Selectin rises with decreasing Vitamin D, quartiles 3 and 4 are combined

Conclusions: This study demonstrates that Vitamin D deficiency is common in KTx recipients in North India, associated with low calcium, low FGF23 and high E Selectin. These findings set up the basis for further studies to assess whether vitamin D deficiency associated endothelial dysfunction play a role in CV complications in KTx recipients.

SA-PO326

Vitamin D Supplementation Improves Central Arterial Stiffness and Inflammatory Biomarkers in Patient with Chronic Kidney Disease Ashok Kumar Yadav,[1] Vivek Kumar,[1] Anupam Lal,[2] Manphool Singhal,[2] Vivekanand Jha.[1] *[1]Nephrology, Post Graduate Inst of Medical Education and Research, Chandigarh, India; [2]Radio-Diagnosis and imaging, Post Graduate Inst of Medical Education and Research, Chandigarh, India.*

Background: Cardiovascular abnormality is a significant cause of morbidity and mortality in patients with Chronic Kidney Disease (CKD). Vitamin D deficiency is common and associated with mortality in CKD patients. Vitamin D supplementation might mitigate the cardiovascular risk of CKD by favourably influencing endothelial and vascular function.We investigated the effect of vitamin D supplementation on arterial stiffness, and inflammatory and endothelial dysfunction biomarkers in patients with stage 3 and 4 CKD.

Methods: In this prospective randomized, placebo-controlled trial, 38 vitamin D deficient (<20ng/ml) CKD patients were randomized to placebo (n=16) and vitamin D (n=22) group. Subjects received 2 directly observed oral doses of 300,000 IU cholecalciferol at 0 and 8 weeks or matching placebo. Circulating vitamin D3, interleukin-6 (IL-6), highly sensitive C-reactive protein (hsCRP), Von Willebrand factor (VWF), e-selectin, fibroblast growth factor-23(FGF-23), pulse wave velocity (PWV) and augmentation index (AI) were analysed at baseline and week 16.

Results: Baseline characteristics of the two groups were similar. Two patients (one from each group) dropped out. Serum level of vitamin D3 increased in vitamin D group (17.04±5.4 versus 46.22±14.91, p<0.0001) whereas in placebo group no difference was noted (17.66±5.03 versus 17.47±10.37, p=0.95). There was significant decrease in IL-6 (p=0.05), FGF-23 (p<0.0001) and PWV (p=0.005) in vitamin D group. No difference in these parameters was noted in placebo group except FGF23 which showed increased level at follow-up (p=0.03).

Conclusions: Achievement of vitamin D sufficiency (>30ng/ml) by supplementation of oral vitamin D leads to improvement in markers of inflammation, FGF-23 and arterial stiffness.

Funding: Government Support - Non-U.S.

Calcitriol Pretreatment Blunts the Permeability Inducing Effect of Vascular Endothelial Growth Factor Through Reducing the Expression and Protein Level of Caveolae- and Fenestrae Associated PV-1 Protein Adrienn Németh,[1] Csaba Bodor,[1] Sharokh Mirza Hosseini,[1] Laszlo Kohidai,[2] Laszlo Rosivall.[1] *[1]Dept of Pathophysiology, MTA-SE Pediatrics and Nephrology Research Group, Semmelweis Univ, Budapest, European Union, Hungary; [2]Dept of Genetics Cell and Immunobiology, Semmelweis Univ, Budapest, European Union, Hungary.*

Background: Vascular endothelium provides a semipermeable barrier that plays a pivotal role in both physiological and pathophysiological processes involving several endothelial structures including fenestrae and caveolae. VEGF was initially described as a potent endothelial permeability-increasing factor involved in tumor development, hypertension and diabetic nephropathy. Hence VEGF is known to induce endothelial fenestration and the expression of plasmalemma vesicle associated protein (PV-1), which is the key structural component in fenestrae and caveolae formation. While calcitriol, the most active form of vitamin D, is an anti-angiogenic and anti-inflammatory agent, it has beneficial effects on glomerulosclerosis and hypertension. We hypothesized that pretreatment with calcitriol may modulate the VEGF-induced increase in permeability of human umbilical vein-derived endothelial cells(HUVEC).

Methods: Cells were pretreated with 0,1 nM calcitriol for 30 min and/or with 100 ng/ml VEGF for 48hours. Permeability of endothelial monolayers was determined by using 40 kDa FITC-dextrane. The mRNA expression and protein levels of PV-1 were measured by real-time PCR and western blot. The activation (phosphorylation) of VEGFR-2 at tyrosine 1175 was detected by western blot.

Results: Pretreatment with calcitriol reduced the VEGF-induced increase in permeability, moreover, calcitriol lowered PV-1 protein and mRNA levels. Calcitriol prevented the VEGF-induced activation of VEGFR-2 by inhibiting the phosphorylation of tyrosine 1175.

Conclusions: We assume that the VEGF-induced increase in permeability of HUVEC is the consequence of increased PV-1 expression. Reduction in PV-1 protein expression and endothelial permeability by calcitriol pretreatment may ameliorate endothelial function in hypertension and glomerulosclerosis.

SA-PO328

VDR Deficiency Aggravates Atherosclerosis: A Possible Role for Endothelial NF-kB Activation Governing the Onset of an Early Leukocyte-Endothelium Interplay Milica Bozic,[1] Carmen de Pablo Bernal,[2] Angeles Alvarez Ribelles,[2] Maria D. Sanchez-Niño,[3] Alberto Ortiz,[3] Elvira Fernandez,[1] Jose M. Valdivielso.[1] *[1]IRBLleida; [2]Univ de Valencia; [3]Fundacion Jimenez-Diaz.*

Background: Cardiovascular mortality is very high among CKD patients. Endothelial cell activation plays an essential role in atherosclerosis. Vitamin D has been proposed to have an important role in cardioprotection. The aim of this study was to evaluate the effect of vitamin D receptor (VDR) deficiency on atherogenesis and the possible mechanisms.

Methods: ApoE-VDRdouble-knockout (DKO) mice were generated and fed an atherogenic diet. Atherosclerotic burden was quantified. Cellular composition of the atherosclerotic lesions was assessed. Expression of VCAM-1, ICAM-1 and IL-6 mRNA in the aorta was analyzed. Knockdown of VDR in human endothelial cells was performed by shRNA. Interactions between peripheral blood mononuclear (PBMC) cells and endothelial cells *in vitro* were evaluated.

Results: Serum total cholesterol, HDL, LDL and triglycerides were significantly lower in DKO than in apoE-/-. However, DKOs showed larger plaques. DKO plaques had fewer smooth muscle cells and more macrophages, as well as higher immunoreactivity for MCP-1 and F4/80. Serum levels of IL-6 were significantly higher in DKOs compared with apoE-/-. Furthermore, DKOs showed significantly higher expressions of VCAM-1 and ICAM-1 and IL-6 in the arteries. Knockdown of VDR in endothelial cells led to a decrease in PBMC rolling velocity and an increase in PBMC rolling flux and adhesion to the endothelium, together with an upregulation of VCAM-1 and ICAM-1. The levels of κB inhibitor (IκB) α were decreased in sh-VDR cells compared with controls. Level of p65 in the nuclear extracts was higher in sh-VDR cells than in controls. The IκB kinase inhibitor, PS-1145, prevented upregulation of VCAM-1 and ICAM-1 in endothelial cells carrying shRNA targeting VDR.

Conclusions: Endothelial NF-kB activation in cells lacking VDR leads to endothelial dysfunction with pronounced leukocyte-endothelial interactions, which may lead to bigger plaques in DKOs. Data reveal an important role for basal levels of endothelial VDR in limiting endothelial cell dysfunction and atherosclerosis.

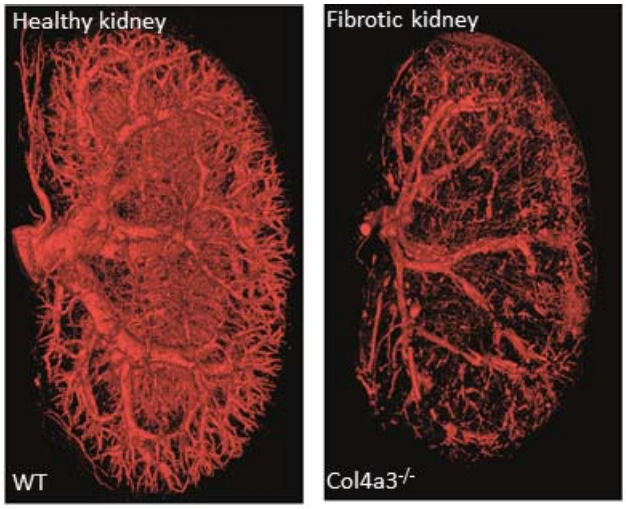
Imaging of Renal Vasculature in Murine Kidney Fibrosis Peter Boor, Josef Ehling, Janka Babickova, Barbara Mara Klinkhammer, Felix Gremse, Fabian Kiessling, Jürgen Floege, Twan Lammers. *RWTH Univ, Aachen, Germany.*

Background: Renal fibrosis is associated with rarefaction of the renal vasculature and this might contribute to fibrosis progression. The aim of this study was to establish anatomical, functional and molecular imaging of renal vessels in fibrosis.

Methods: We analyzed three murine fibrosis models: unilateral ureteral obstruction (days 1-10), unilateral ischemia-reperfusion (days 1-56) and Alport mice (6 and 8 weeks old). We assessed renal blood volume using *in vivo* contrast-enhanced micro-computed tomography (μCT), analyzed vasculature using *ex vivo* high-resolution μCT after perfusion with a polymerizing cast agent, and used an elastin-specific contrast agent and magnetic resonance imaging (MRI) for molecular imaging of vessels and fibrosis.

Results: Functional *in vivo* μCT showed an early, significant, and progressive reduction of renal blood volume in all models. These findings correlated with peritubular capillary rarefaction. In 3D rendered renal vasculature obtained by high-resolution μCT we found in all three models a significant reduction in the number and diameter of renal vessels, vascular branching, and a significantly increased vessel tortuosity (fig. 1). *In vivo* a stronger MRI signal was found in fibrotic kidneys of mice with UUO compared to healthy kidneys using the elastin-specific probe. The up-regulation of elastin in fibrotic kidneys was confirmed on mRNA and protein level.



Conclusions: Using new methods to assess the murine renal vasculature, we observed a significant vascular rarefaction and pathological alteration in different models of fibrosis. Increased MRI signals using an elastin-specific probe suggests this to be a potential molecular imaging approach in renal fibrosis. These methods lay the basis for better understanding of renal fibrosis and may become novel outcome parameters in intervention studies targeting progressive renal disease.

Alterations of Peritubular Capillaries in Experimental Renal Fibrosis Peter Boor, Janka Babickova, Eva Miriam Buhl, Sonja Djudjaj, Barbara Mara Klinkhammer, Jürgen Floege. *RWTH Univ, Aachen, Germany.*

Background: Renal fibrosis is associated with rarefaction of peritubular capillaries (PTCs). However, functional and ultrastructural alterations of the renal microvasculature in renal fibrosis are not well described.

Methods: We studied three murine models of fibrosis with distinct mechanisms of injury, i.e. unilateral ureteral obstruction (UUO, day 1, 3 and 5), unilateral ischemia-reperfusion injury (IR, day 14 and 21) and Col4A3 deficient (Alport) mice. In all models we quantified PTC to tubule ratios using immunohistochemistry, analyzed vascular leakage using Evans Blue dye and fibrinogen extravasation and ultrastructure by electron microscopy.

Results: Compared to healthy kidneys, we found significantly lower numbers of PTC in UUO day 3 (-11%) and day 5 (-16%), but not day 1. Capillary rarefaction was also observed after IR injury on both days 14 (-12%) and 21 (-17%). Compared to healthy kidneys, we observed significantly higher extravasation of Evans blue in UUO day 3 (+250%) and day 5 (+167%), but not day 1, as well as in IR injury day 14 (+460%) and day 21 (+157%) and in Alport mice (+100%). Compared to healthy kidneys, we found significantly more interstitial deposition of fibrinogen in the fibrotic kidneys in all three models (+109 to +459%). In fibrotic kidneys, ultrastructural studies revealed loss of fenestrations, increased thickness of endothelial cell soma and of lamina densa of the PTC basal membrane.

Conclusions: Independent of the underlying mechanism, all fibrosis models were characterized by progressive loss of renal microvasculature, a significant increase in vascular leakage and substantial alterations of the endothelial ultrastructure. These data show that renal fibrosis not only involves loss of PTC but also significant functional alterations of remaining capillaries.

Platelet-Derived Growth Factor CC and Capillary Rarefaction in Experimental Renal Fibrosis Peter Boor,[1] Janka Babickova,[1] Ina V. Martin,[1] Claudia R.C. van Roeyen,[1] Frank Eitner,[3] Jürgen Floege,[1] Carine Peutz-Kootstra,[2] Tammo Ostendorf.[1] *[1]RWTH Univ, Aachen, Germany; [2]Maastricht Univ, Netherlands; [3]Bayer Pharma AG, Germany.*

Background: Renal fibrosis is associated with progressive capillary rarefaction. Neutralization of platelet-derived growth factor (PDGF)-CC potently reduced kidney fibrosis. However, PDGF-CC has also been shown to be a potent proangiogenic factor in experimental glomerular diseases. Here we asked, whether PDGF-CC neutralization might have potentially deleterious anti-angiogenic effects during renal fibrosis, i.e. promote capillary rarefaction.

Methods: We analyzed capillary rarefaction in a model of renal fibrosis, unilateral ureteral obstruction (UUO) in genetically PDGF-C-deficient mice or by using neutralizing PDGF-CC antibodies.

Results: Lack or antagonism of PDGF-CC significantly reduced renal fibrosis. In contrast, extensive quantification yielded in a similar number of peritubular capillaries in control mice compared to mice with PDGF-CC-deficiency or -neutralization in both healthy and fibrotic kidneys (apart from significantly preserved peritubular capillaries in PDGF-CC knock-out mice in UUO day 5). Similarly, no difference in microvascular leakage (assessed by extravasation of Evans Blue) was found between the WT and PDGF-CC knock-out mice in UUO day 5. Expression of angiogenic molecules, such as VEGF, VEGF receptors 1 and 2 and angiopoietins 1 and 2 was similar in these mice, whereas FGF-2 was significantly reduced in mice with PDGF-CC deficiency or neutralization. In healthy mice or the contralateral non-obstructed kidneys the antagonism or deficiency of PDGF-CC had no effect on the number or functionality of the tubulointerstitial microvasculature.

Conclusions: Despite a significant reduction of renal fibrosis, PDGF-CC deficiency was not associated with an accelerated loss of peritubular capillaries, suggesting that in the fibrotic renal tubulointerstitium, proangiogenic effects of PDGF-CC are much less potent than its pro-fibrotic properties. Thus PDGF-CC's proangiogenic effects do not limit its therapeutic antagonism in renal fibrosis.

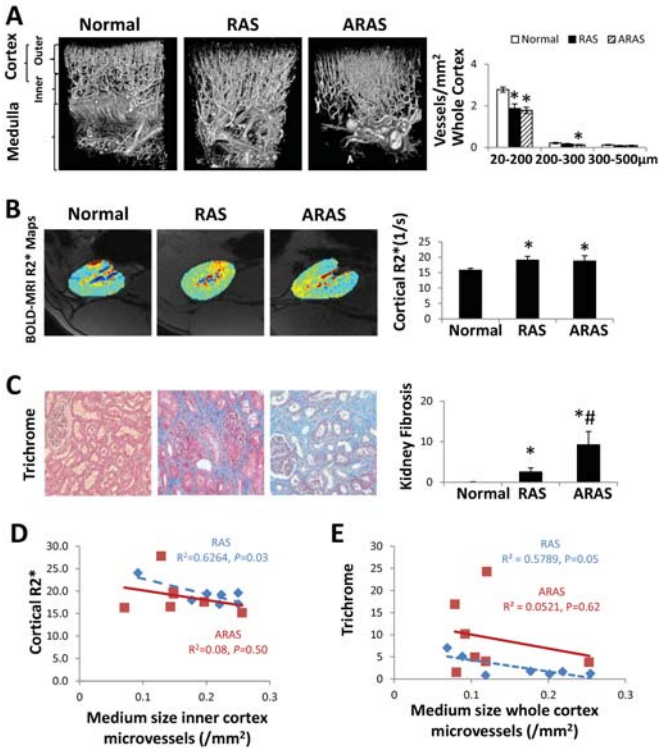
Atherosclerosis Aggravates Renal Microvascular Loss and Fibrosis in Swine Renal Artery Stenosis Dong Sun, Behzad Ebrahimi, Alfonso Eirin, Stephen C. Textor, Amir Lerman, Lilach O. Lerman. *Mayo Clinic.*

Background: Renal function in patients with combined atherosclerosis and renal artery stenosis (RAS) deteriorates more than in non-atherosclerotic RAS. Whether microvascular loss is a comparable determinant of renal dysfunction in RAS and atherosclerotic RAS (ARAS) remains unclear. We hypothesized that ARAS aggravates stenotic kidney loss of microvessels and fibrosis compared to RAS.

Methods: Domestic pigs were randomized to Normal, RAS, and ARAS groups (n=7 each). Stenotic kidney oxygenation was determined 10 wks later using blood oxygen-level dependent (BOLD) magnetic resonance imaging (MRI). Single-kidney renal blood flow (RBF) and glomerular filtration rate (GFR) were evaluated using multidetector CT (MDCT), and microvascular density by Micro-CT.

Results: Mean blood pressure in RAS and ARAS groups was elevated compared with normal (117.5±10.7 and 127.4±10.9 versus 98.4±1.6 mmHg, respectively, $P<0.05$), and RBF and GFR were similarly decreased in their stenotic kidneys. RAS decreased the

density of small-size cortical microvessels (diameter <200 μm), while ARAS extended the decrease to medium-sized microvessels (200-300 μm) (Fig. A). Cortical R2* (BOLD-MRI hypoxia index) increased in both RAS and ARAS (Fig. B), but correlated inversely with microvascular density only in RAS (Fig. D). Interstitial fibrosis was higher in ARAS than in both Normal and RAS cortex (Fig. C), but correlated inversely with microvascular density only in RAS (Fig. E).



A-Micro-CT images of Microvascular Architecture; **B**-Measurement of Kidney Oxygenation by MRI; **C**-Trichrome staining for renal fibrosis; **D** and **E**-Correlation analysis.
*P<0.05 compared with Normal; #P<0.05 compared with RAS.

Conclusions: Atherosclerosis aggravates loss of stenotic-kidney cortical microvessels, yet unlike RAS, additional determinants may contribute to cortical hypoxia and fibrosis in swine ARAS.

A Novel Role for Renal NMDA Receptors: Regulation of the Renal Microcirculation Kadeshia N. Dunn,[1] Edward W. Inscho,[2] Scott S.P. Wildman,[1] Claire M. Peppiatt-Wildman.[1] *[1]Medway School of Pharmacy, The Univs of Kent and Greenwich at Medway, United Kingdom; [2]Physiology, Georgia Regents Univ.*

Background: Glutamate and GABA receptors have been detected throughout the kidney, although the precise role(s) these play in the kidney remain unclear. Previously we have reported that glutamate and its substrate, GABA, are involved in the regulation of the renal microcirculation [1]. Specifically, we observed that GABA and glutamate induce vasoconstriction of afferent arterioles in the renal cortex, whereas in the medulla, glutamate evokes vasodilation and GABA evokes vasoconstriction of vasa recta capillaries via their actions at contractile pericytes.

Methods: It is well established that pericytes regulate vasa recta diameter and thus medullary blood flow. We have utilised a rat live kidney slice model to investigate glutamate-evoked vasodilation of vasa recta capillaries [2].

Results: We tested a panel of glutamate receptor antagonists (MK-801, GYKI, MSOP, LY341495, UBP302) and found that only the NMDA receptor antagonist, MK-801 (300 uM, n=11), significantly attenuated glutamate-evoked vasodilation mediated via pericytes. Accordingly, NMDA alone evoked a pericyte-mediated vasodilation of vasa recta via pericytes, similar to that seen with glutamate. In addition, glycine (1 mM), a co-agonist for glutamate NMDA receptors, evoked a pericyte-mediated vasodilation of vasa recta (16.5 ± 1.1%, n=6). Interestingly, MK-801 (300 uM, n=6) significantly attenuated glycine-evoked vasodilation of vasa recta via pericytes. In parallel experiments in the cortex, glycine (100 nM – 1 mM) evoked vasodilation of afferent arterioles, which was disparate to the glutamate mediated-constriction previously reported.

Conclusions: In conclusion, we provide evidence to suggest that glutamate-mediated vasodilation of vasa recta occurs via NMDA receptors, presumably expressed on pericytes. Moreover, we provide novel observations regarding the differential roles of glutamate and glycine in the regulation of afferent arteriole diameter. The mechanisms underlying these observations require further delineation. References [1] Dunn et al, 2013 FASEB J. 27, 1110.13. [2] Crawford et al, 2012 Nephron Physiol. 120, 17-31.

SA-PO334

The Effect of L-Arginine on Cutaneous Microvascular Function Is Inversely Related to Blood Urea Nitrogen in Patients with Stage 3-4 Chronic Kidney Disease Meghan G. Ramick,[1] Jennifer DuPont,[1] William B. Farquhar,[1] Raymond R. Townsend,[2] David G. Edwards.[1] *[1]Dept of Kinesiology and Applied Physiology, Univ of Delaware, Newark, DE; [2]Clinical and Translational Research Center, Univ of Pennsylvania, Philadelphia, PA.*

Background: Either a relative or absolute deficit of the nitric oxide (NO) precursor L-arginine likely contributes to reduced NO synthesis in chronic kidney disease (CKD) however the effectiveness of L-arginine in studies of endothelial dysfunction in CKD has been mixed. This may be due to inhibition of L-arginine uptake by urea and other uremic toxins as demonstrated in cell studies. The purpose of this study was to determine the effect of local L-arginine delivery on cutaneous microvascular function in patients with CKD. Further, we investigated whether the effect of L-arginine in CKD was related to blood urea nitrogen (BUN) levels.

Methods: Ten patients with stage 3-4 CKD (62±4 years; 4M/6F; eGFR: 38±5 ml·min^{-1}·1.73m^{-2}) and 10 healthy controls (HC; 55±2 years; 4M/6F; eGFR: 90±6 ml·min^{-1}·1.73m^{-2}) were instrumented with 2 intradermal microdialysis fibers for the local delivery of Ringer's solution and 10 mM L-arginine. Red blood cell (RBC) flux was measured via laser Doppler flowmetry. A standardized non-painful local heating protocol (42°C) was used. Cutaneous vascular conductance (CVC) was calculated as RBC flux/MAP and all data were expressed as a percentage of the maximum CVC at each site (28 mM sodium nitroprusside, 43°C).

Results: The plateau %CVCmax, which is largely mediated by NO, was attenuated in CKD (CKD: 80±3 versus HC: 89±1 %CVCmax; $p<0.05$) and augmented with local L-arginine delivery (L-arg: 88±2 versus Ringer's: 80±3 %CVCmax; $p<0.05$) such that it did not differ from HC ($p>0.05$). The difference in plateau %CVCmax between L-arginine and Ringer's sites was variable in CKD (range: -8.5 to 20.3) and was related to eGFR ($r=0.46$, $p<0.05$) and inversely related to BUN ($r=0.63$, $p<0.01$).

Conclusions: These data suggest that the effectiveness of L-arginine in restoring vascular function in patients with CKD may be dependent on the level of BUN and other uremic toxins, which may explain why L-arginine is ineffective in some patients with CKD.

Nicorandil Prevents Endothelial Dysfunction, Renal Dysfunction, and Anemia in Dahl Salt-Sensitive Hypertensive Rats Ken-Ichi Serizawa, Kenji Yogo, Yoshihito Tashiro, Ken Aizawa, Koichi Endo. *Product Research Dept, Chugai Pharmaceutical Co., Ltd., Gotemba, Japan.*

Background: Cardiorenal anemia syndrome (CRAS) is closely associated with extremely poor outcomes in patients with heart failure, and chronic kidney disease is an important factor in its development. Dahl salt-sensitive (DS) hypertensive rats incurs heart failure, renal failure, and anemia by salt loading. Nicorandil, used to treat angina and acute heart failure, is reported to improve the prognosis of patients with ischemic heart disease. This study examined the beneficial effects of nicorandil on multiple disorders in salt-loaded DS rats.

Methods: Male DS rats (6 wks old) were divided into 3 groups: DS-NS (fed normal-salt diet), DS-HS (fed high-salt diet containing 8% NaCl), and DS-HS+nicorandil. Nicorandil (15 mg/kg/day) was administered concurrently with salt loading. After 7 wks of treatment, urine was collected from individual metabolic cages and jugular vein blood was sampled to evaluate renal function and anemia. Then, as a marker of cardiovascular risk, endothelial function was assessed by ultrasound measurement of flow-mediated dilation (FMD) in femoral arteries.

Results: FMD was lower in DS-HS rats than in DS-NS rats (DS-NS, 24.0±2.7%; DS-HS, 9.4±1.6%; n=6–7). Renal function as evaluated by urinary protein excretion (DS-NS, 16.0±1.9 mg/day; DS-HS, 342.0±38.1 mg/day; n=8–10) and creatinine clearance (46.5±5.7%, % of DS-NS, n=8) was also reduced in DS-HS rats. Furthermore, DS-HS rats developed anemia (hemoglobin: DS-NS, 15.4±0.1 g/dL; DS-HS, 11.1±1.4 g/dL; n=9–10). Nicorandil prevented the reduced FMD (16.8±1.6%, n=9), the increased urinary protein excretion (165.6±20.7 mg/day, n=10), the decreased creatinine clearance (80.8±7.9%, % of DS-NS, n=10), and anemia (hemoglobin: 15.2±0.4 g/dL, n=8). Systolic blood pressure was increased in DS-HS rats, and nicorandil showed no influence on systolic blood pressure (DS-NS, 133.4±2.8 mmHg; DS-HS, 215.9±8.3mmHg; DS-HS+nicorandil, 218.5±4.8 mmHg; n=6–9).

Conclusions: These results suggest that nicorandil prevented endothelial dysfunction, renal dysfunction, and anemia in salt-loaded DS rats, and are expected to clarify how nicorandil will affect the prognoses of patients with CRAS.

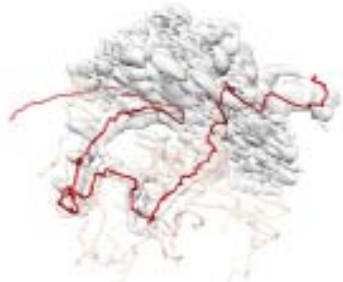
3D Modeling and Analysis of the Human Glomerular Capillary Network
Arjun Dayal,[1] Landon Clarke Stout, jr,[2] Kammi J. Henriksen,[3] Anthony Chang.[3] *[1]Pritzker School of Medicine, Univ of Chicago, Chicago, IL; [2]Dept of Pathology, The Univ of Texas Medical Branch, Galveston, TX; [3]Dept of Pathology, Univ of Chicago, Chicago, IL.*

Background: 3D modeling of the glomerulus can provide information about the physiology of glomerular filtration and perfusion and reveal deviations from the normal renal vasculature that occur with glomerular diseases. We developed a technique that enables 3D reconstruction of the glomerular capillary lumen structure. The models generated using this technique allow analysis of network topology and provide detailed renderings of the interior of the glomerulus, which is information that cannot be obtained by scanning electron microscopy.

Methods: Digital photomicrographs of serial one-micron thick tissue sections that were stained with Toluidine blue of an entire normal human glomerulus were obtained by light microscopy. The serial images were registered using MIDAS (Boulder, CO) and segmented semi-automatically using TrakEM2 and ImageJ (Bethesda, MD) using a Fast-Marching algorithm and binary thresholding. 3D renderings of the model were created using UCSF Chimera.

Results: Topological analysis shows that there are numerous parallel paths that red blood cells can travel from the afferent to the efferent arteriole and one possible path (red pipe) is shown.



The transparent surface models glomerular capillary lumina. The orange pipes represent the skeleton of the capillary network. There are also numerous anastomoses along these parallel paths. We found no path that bypassed the glomerular filtration system.

Conclusions: Modeling of additional normal glomeruli will help establish the conserved and variable architecture of the capillary structure. 3D modeling of diseased glomeruli can provide important insights into the pathophysiologic alterations that may occur in a variety of glomerular diseases.

FIR-Induced Autophagy in Vascular Endothelia Cells Protects Vascular Endothelium From Advanced Glycation End Products-Induced Injury
Yung-Ho Hsu,[1] Tso Hsiao Chen,[2] Cheng-Hsien Chen.[3] *[1]Div of Nephrology, Dept of Internal Medicine, Shuang Ho Hospital, Taipei Medical Univ, New Taipei City, Taiwan; [2]Div of Nephrology, Dept of Internal Medicine, Wan Fang Hospital, Taipei Medical Univ, Taipei, Taiwan; [3]Div of Nephrology, Dept of Internal Medicine, Shuang Ho Hospital, Taipei Medical Univ, New Taipei City, Taiwan.*

The accumulation of advanced glycation end products (AGEs) in diabetic patients can trigger apoptotic changes in vascular endothelial cells and contribute to the pathogenesis of diabetes mellitus and atherosclerosis. Far-infrared radiation (FIR) therapy has been proved to be effective in increasing patency of dialysis vascular access. In this study, we investigate the protective effects of FIR on AGEs-induced injury in vein endothelial cells in vitro and in vivo. We found that FIR irradiation induced autophagy in human umbilical vein endothelial cells (HUVECs). FIR irradiation induced the expression of autophagic markers, such as Beclin-1 and LC3-II. FIR irradiation also induced nuclear translocation of promyelocytic leukaemia zinc finger (PLZF) and the expression of phosphatidylinositol-3 kinase (PI3K) class III, an important kinase in autophagic signaling pathway. PLZF siRNA transfection inhibited FIR-induced autophagy. Immunofluorescence staining showed that AGE-bovine serum albumin (BSA) was engulfed by HUVECs and presented at lysosomes. FIR irradiation promoted AGE-BSA degradation in HUVECs, which was inhibited by autophagy inhibitor 3-methyladenine. In streptozotocin-induced type 2 diabetic mice, blood AGEs and MCP-1 significantly increased. FIR therapy dose-dependently reduced blood AGEs and MCP-1. FIR therapy also reduced AGE deposition, inducible nitric oxide synthase expression and leukocyte infiltration in the intestinal vascular endothelium. Aorta ring relaxation analysis revealed that FIR therapy improved vascular endothelia function in diabetic mice. However, we can't found these protective effects of FIR therapy in PLZF-knockout mice. Our data suggest that FIR-induced autophagy in vascular endothelia cells protects vascular endothelium from AGE-induced inflammation in diabetic mice.

PPAR-β Agonist Protects the Tight Juntions of Glomerular Endothelial Cells Through RhoA/ROCK1 Pathway
Zengchun Ye, Wei-Yan Lai, Canming Li, Tan-Qi Lou. *Dept of Nephrology, The Third Affiliated Hospital of Sun Yat-sun Univ, Guangzhou, Guangdong, China.*

Background: The destruction of junctions between adjacent glomerular endothelial cells (GEnCs) can lead to increased glomerular permeability, which may be one of the most important mechanisms of early proteinuria in diabetic kidney disease. In our previous study, we found that treatment of GEnCs with advanced glycation end products(AGEs) can reduce the expression of occludin and JAM-A, while increased rGEnCs permeability. The present study is to investigate whether the agonist of peroxisome proliferator activated receptor β(PPAR-β) L165041 can reverse the damage of tight junctions of rGEnCs caused by AGEs, and the role of RhoA/ROCK1 pathway.

Methods: The rGEnCs were pretreated with inhibitor of ROCK and PPAR-β agonist before AGEs treanment. RNAi of PPAR-β or ROCK-1 was also used to study the role of PPAR-β and ROCK-1. JAM-A, Occludin, ROCK1, PPAR-β and phosphorylation of MYPT1 were detected by western blotting. The endothelial permeability was investigated by transendothelial electrical resistance and the flux of FITC-conjugated bovine serum albumin. The activity of RhoA was evaluated by pull-down assay. Immunofluorescence was used to demonstrate the distribution of the tight junction proteins.

Results: AGEs reduced the expression of occludin and JAM-A, and increased the rGEnC monolayer permeability. Inhibition of PPAR-β by siRNA can promote the destruction of the tight junctions cause by AGEs. Treatment of GEnCs with AGEs activated RhoA/ROCK1 pathway and increased the phosphorylation of MYPT1 in rGEnCs, while PPAR-β agonist L165041 pre-treatment can block these effects and protect the tight junction and endothelial permeability.

Conclusions: The agonist of PPAR-β can protect the tight juntions of glomerular endothelial cells from the damage of AGEs partly through RhoA/ROCK1 pathway. * Zengchun Ye and Weiyan Lai contributed equally to this work.

Targeting CKD-Associated High-Density Lipoproteins-microRNA Intercellular Communication to Treat Atherosclerosis
Valentina Kon, Carrie B. Wiese, Jianyong Zhong, T. Alp Ikizler, Kasey C. Vickers. *Vanderbilt.*

Background: In addition to cholesterol, high density lipoproteins (HDL) transport other cargo, including proteins and nucleic acids. Recently, we found that HDL transport and deliver functional microRNAs (miRNAs) to recipient cells where they regulate gene expression through post-transcriptional regulatory modules. We also showed that HDL's anti-inflammatory capacity is mediated by HDL-miRNA suppression of adhesion molecules. We now compare HDL-miRNA signatures and transfer ability in patients with ESRD on hemodialysis (ESRD) and matched controls (C). We also use a subtotal nephrectomy mouse model (5/6Nx) to assess HDL delivery to endothelial cells and the impact of blocking miRNAs on atherosclerosis.

Methods: Real-time PCR-based OpenArrays were used to profile HDL-miRNAs of ESRD (n=12) and C (n=12). Human coronary artery endothelial cells (HCAEC) were used as recipient cells in HDL-miRNA transfer studies. Apolipoprotein E-deficient mice (n=14) underwent 5/6Nx and 7 wks later were injected with HDL alone or complexed with locked-nucleic acid (LNA) miR-92a inhibitors (20/mg/kg) followed by gene expression studies and phenotypic characterizations of plaques 1 wk later.

Results: Compared to C, HDL of ESRD have 8.5-fold increase in miR-92a levels ($p=0.001$), a pro-atherogenic miRNA in endothelial cells. Further, uremic HDL increased HCAEC miR-92a ($p<0.05$) with concomitant down-regulation of 18 putative miR-92a targets. Likewise, HDL of 5/6Nx have >20-fold increase in miR-92a ($p<0.05$), versus controls. *In vivo*, HDL complexed with LNA-92a, but not HDL alone, did not affect blood pressure but decreased miR-92a levels in aortic endothelium and decreased Oil Red O staining for atherosclerosis by 21% ($p<0.05$) along with greater macrophage (MOMA) and collagen content (Masson).

Conclusions: HDL intercellular communication is significantly altered in ESRD, which results in increased pro-atherogenic miR-92a levels in arterial endothelial cells. Inhibition of HDL-miR-92a transfer and activity in CKD-induced atherosclerosis decreased atherosclerotic burden. Thus, nucleic-acid based therapies may be a viable approach to attenuate cardiovascular disease in ESRD.

The Renal Microvasculature Is a Primary Target for Blood Pressure Regulation by Inorganic Nitrate and Nitrite
Xiang Gao,[1] Ting Yang,[2] Eddie Weitzberg,[2] Jon Lundberg,[2] Erik G. Persson,[1] Mattias Carlstrom.[2] *[1]Dept Medical Cell Biology, Uppsala Univ, Uppsala, Sweden; [2]Dept Physiology and Pharmacology, Karolinska Instt, Stockholm, Sweden.*

Background: Oxidative stress and nitric oxide (NO) deficiency in kidney are key events in development of hypertension. Stimulation of a nitrate-nitrite-NO pathway reduces blood pressure, but the mechanism(s) are not clear. We investigated the hypothesis that inorganic nitrate and nitrite attenuates reactivity of renal microcirculation and blood pressure responses to angiotensin II (ANG II) by modulating NADPH oxidase activity and NO bioavailability.

Methods: Isolated and perfused mice renal afferent arterioles were performed, then arteriolar diameters changes were measured to estimate the effect of vasoactive substances.

Fluorescent detection of NO production in afferent arterioles, renal NADPH oxidase activity analysis, renal NADPH oxidase expression analysis, plasma analysis, telemetric study for blood pressure response to long-term Ang II infusion were also taken.

Results: Nitrite dilated afferent arterioles in the physiological concentration range (0.1-10 μM), and this dilatation was associated with increased NO formation. Contractions to ANG II alone and during inhibition of NO synthase were attenuated by nitrite. Abnormal ANG II responses in arterioles from SOD-1 deficient mice were normalized by simultaneous nitrite administration. The effect of nitrite was abolished by NO scavenger (cPTIO) and by xanthine oxidase inhibitor (oxypurinol). In the presence of NADPH oxidase inhibitor apocynin, no effect of nitrite on ANG II-induced contractility was observed, suggesting this enzyme as a possible target. In preglomerular vascular smooth muscle cells and in kidney cortex, nitrite dose-dependently reduced both basal and ANG II-induced NADPH oxidase activity. Supplementation with dietary nitrate (10 mM, 7 days) reduced renal NADPH oxidase activity and attenuated ANG II-mediated arteriolar contractions. Finally, dietary nitrate markedly attenuated gradual hypertension induced by chronic ANG II infusion in rats.

Conclusions: All findings position NADPH oxidase in renal microvasculature as a prime target for blood pressure-lowering effects of inorganic nitrate and nitrite.

SA-PO341

Metabolomics of Renal Venous Plasma from Individuals with Unilateral Renal Artery Stenosis and Essential Hypertension Eugene P. Rhee,[1,2] Clary B. Clish,[2] Kerry A. Pierce,[2] Ahmed Saad,[3] Lilach O. Lerman,[3] Stephen C. Textor.[3] *[1]Nephrology Div, Massachusetts General Hospital, Boston, MA; [2]Metabolite Profiling, Broad Inst, Cambridge, MA; [3]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Comparing venous effluent from both kidneys of individuals with unilateral atherosclerotic renal artery stenosis (ARAS) provides an opportunity to directly examine how impaired renal blood flow impacts renal metabolic function in humans.

Methods: We applied liquid chromatography-mass spectrometry based metabolite profiling to venous plasma obtained from the stenotic (STK) and contralateral (CLK) kidneys of ARAS patients (n=16) and both kidneys of essential hypertensive (EH) controls. Study samples were acquired during a 3-day protocol that included radiographic kidney phenotyping (Duplex ultrasound, multidetector CT, and blood oxygen-level dependent MRI) and controlled sodium and caloric intake and anti-hypertensive treatment.

Results: Partial least squares-discriminant analysis demonstrated clear separation of EH kidney metabolite profiles versus STK and CLK metabolite profiles, but no separation between metabolite profiles of STK and CLK samples. All of the discriminating metabolites were similarly elevated in the STK and CLK samples, likely reflecting the lower GFR in the ARAS versus EH subjects (mean 66.1versus 89.2 mL/min/1.73m^2). In a paired analysis within the ARAS group, no metabolite was significantly altered in STK compared to CLK samples; notably, creatinine was the same in STK and CLK samples (STK/CLK ratio = 1.0, P=0.9). Results were unchanged in an examination of ARAS subjects in the bottom half of renal tissue perfusion or oxygenation.

Conclusions: Metabolite profiling does not differentiate venous effluent from STKs or CLKs in individuals with unilateral ARAS, despite measurable loss of kidney volume and blood flow on the affected side. These findings are consistent with the kidney's ability to adapt to ARAS to maintain a range of metabolic functions.

Albuminuria Is Associated with the Loss of Endothelial Glycocalyx in Diabetic Mice – A Quantitative Electron Microscopy Analysis Using Cationic Hydrous Thorium Dioxide Colloids ($cThO_2$) Jan Hegermann,[1] Putri Andina Agustian,[2] Anna Bertram,[2] Nelly Shushakova,[2] Joon-Keun Park,[2] Torsten Kirsch,[2] Jan Menne,[2] Hermann G. Haller.[2] *[1]Hannover Medical School, Dept of Anatomy, Hannover, Germany; [2]Hannover Medical School, Clinic of Nephrology and Hypertension, Hannover, Germany.*

Background: The endothelium is covered by the glycocalyx. Damage of the glycocalyx enhances inflammation and permeability in diabetes. The analysis of the glycocalyx is difficult because of (1) its complex structure and (2) its instability ex-vivo. We have therefore established novel electron microscopy techniques to test the hypothesis that hyperglycemia damages the endothelial glycocalyx and that this damage is associated with albuminuria.

Methods: StSTZ-treated mice and control animals were analyzed after 4 and 8 weeks of hyperglycemia. Urinary albumin was measured by ELISA. Immunohistochemistry was performed on cryostat or on paraffin sections. Glycocalyx was assessed by (1) quantitative electron microscopy using cationic hydrous thorium dioxide colloids ($cThO_2$), (2) staining for alcian-blue, and (3)perfusion-fixation with lectins.

Results: Lectin-staining and alcian-blue showed a continuous linear lining of the capillary endothelium. In contrast, the EM analysis revealed a bushel-like structure of the glycocalyx with a spacing varying between 30 and 100 nm. These structures were regularly aligned. Hyperglycemia induced a rapid loss (4 weeks) of lectin staining. Both, the size and the number of glycocalyx "bushels" were significantly reduced by hyperglycemia.

Conclusions: We show here for the first time the use of $cThO_2$ to visualise the endothelial glycocalyx in glomerular capillaries in the mouse. Within weeks a reduction of glycocalyx structures both in size and number were observed. We suggest that the loss of glycocalyx molecules changes the functional properties of the endothelium with enhanced permeability, inflammation and coagulation.

SA-PO343

Inhibition of Endothelial TGF-β Signaling Reduces Fibrosis and Endothelial-Mesenchymal Transition (EndoMT) in CKD Sandhya Xavier, Radovan Vasko, Kei Matsumoto, Joseph A. Zullo, Robert Chen, Julien Maizel, Praveen N. Chander, Michael S. Goligorsky. *New York Medical College, NY.*

Background: Recently, endothelial cells undergoing EndoMT have been shown to contribute significantly to fibrotic process. While several studies focused on the ablation of epithelial or fibroblast TGF-β signaling on development of fibrosis, there is lack of information on its ablation in the endothelium due to embryonic lethality. We previously used TbRII$^{endo+/-}$ mice and reported that curtailed TGFb signaling in the endothelium modifies nephrosclerosis. Here we extend our findings to the UUO model and also study tissue hypoxia.

Methods: Unilateral ureteral obstruction (UUO) surgery was performed on TbRII$^{endo+/+}$ and TbRII$^{endo+/-}$ mice. Renal blood flow was evaluated 14 days post UUO. To analyze the degree of renal hypoxia in UUO mice, before sacrifice mice were i.p. injected with pimonidazole HCL and kidneys collected.

Results: TbRII$^{endo+/-}$ mice exhibited less tubulointerstitial fibrosis and less alpha-smooth muscle actin staining as compared to TbRII$^{endo+/+}$ mice. While renal blood flow was impaired in TbRII$^{endo+/+}$ mice, flow was significantly preserved in TbRII$^{endo+/-}$ mice, associated with lesser tissue hypoxia and much better preserved the patency (intravital lectin labeling), than its TβRII$^{endo+/+}$ counterpart. These findings shed light on the mechanisms underlying loss of patency of microvessels observed in injured kidneys. Partial deletion of TbRII in the endothelium also significantly reduced endothelial-to-mesenchymal transition (EndoMT). In vitro, TGF-β-induced canonical Smad2 signaling was reduced in TbRII$^{+/-}$ EC's, however, ALK1 mediated Smad1/5 phosphorylation in TbRII$^{+/-}$ EC's remained unaffected. Endoglin S/L mRNA expression ratio was significantly lower in TbRII$^{+/-}$ EC's as compared to TbRII$^{+/+}$ EC's.

Conclusions: Our data collectively document that partial ablation of TbRII in the endothelium reduces fibrosis during chronic kidney injury. Our results indicate the critical role of excessive endothelial TGF-β signaling in enhanced EndoMT and development of fibrosis. EndoMT may represent a proximal cause of the loss of vessels' patency, even when microvascular density is minimally impaired.

Estrogen Augments while Progesterone Inhibits Arginine Transport in Human Endothelial Cells, through Modulation of Cationic Amino Acid Transporter-1 Ohad S. Bentur, Doron Schwartz, Gil Chernin, Idit F. Schwartz. *Nephrology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel.*

Background: Decreased generation of nitric oxide (NO) by endothelial nitric oxide synthase (eNOS) has emerged as a primary factor provoking endothelial dysfunction (ECD). Delivery of L- arginine to membrane bound eNOS, by the cationic amino acid transporter-1 (CAT-1) has been shown to modulate eNOS activity. We have found in female rats, as oppose to males, that CAT-1 activity is preserved in aging and in chronic renal failure, two established experimental models of ECD. In contrast, during pregnancy CAT-1 is inhibited. The current experiments were designed to explore the role of female sex hormones on arginine transport.

Methods: Using radio-labeled arginine {[^{3}H] L-arginine} uptake was determined in HUVEC following incubation with progesterone, 17β estradiol, and both. Subsequently, western blotting for CAT-1, PKCα, ERK 1/2, JNK, and their phosphorylated forms were performed.

Results: Exposing HUVEC to 17ß estradiol (50 and 100nM) for 30 minutes resulted in a significant increase in arginine transport and in diminished phosphorylated CAT-1(the inactive form) protein content. The aforementioned findings were associated with a decrease in phosphorylated ERK1/2 abundance while PKCα and JNK proteins were unchanged. Incubating HUVEC with UO 126 (ERK 1/2inhibitor) or SP600125 (JNK inhibitor) augmented arginine uptake while tocopherol (PKC inhibitor) had no effect. Progesterone (1 and 100 pM) for 30 minutes attenuated arginine uptake, increased phosphorylated CAT-1 and phosphorylated PKCα protein content while JNK and ERK protein expression remained unchanged. Tocopherol prevented the decrease in arginine transport by progesterone. Co-incubation with both progesterone and estrogen for 30 minutes resulted in attenuated arginine transport.

Conclusions: While estrogen increases arginine transport and CAT-1 activity through modulation of constitutive cellular signaling transduction pathways involving ERK 1/2, progesterone inhibits arginine transport and CAT-1 via PKC phosphrolyation, an effect which predominates over that of estrogen.

Astragaloside IV Synergizes with Ferulic Acid to Reduce Endothelial Cell Microparticles Release in 5/6 Nephrectomized Rats Liqiang Meng, Jiawei Tang, Lei Qu, Xiaomei Li. *Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.*

Background: Astragaloside IV (AS-IV) and ferulic acid (FA) were demonstrated to possess a renoprotective effect partly via endothelial cell protection. Here, the mechanisms of AS-IV and FA in improvement of endothelial cell function were studied.

Methods: Male SD rats were divided randomly into 5 groups: sham, 5/6 nphrectomy (Nx), Nx+AS-IV-treated, Nx+FA-treated and Nx+AS-IV+FA (AF)-treated group. Blood endothelial microparticle (EMP), platelet microparticle (PMP) were evaluated using flow

cytometry. Cultured human umbilical vein endothelial cells (HUVEC) were divided into 5 groups: CON, TNF-α stimulated, TNF-α+FA-treated, TNF-α+AS-IV treated, TNF-α+AF treated (AF). Flow cytometry was used to analysis the type and concentration of EMP release from endothelial cells. Amino phospholipid translocase (APLT) activity, Caspase 3, Caspase 9, calpain, ROCK-I, II expression in the supernatant fluid were detected.

Results: Compared with sham group, EMP was increased significantly in Nx group. In AS-IV and AF group EMP was lower than that in Nx group. PMP was increased significantly in Nx group than that of sham group, but it was significantly decreased in the treatment groups. Compared with CON group, EMP release from endothelial cells was increased significantly in TNF-α group. While in AF group, the concentration of EMP was lower than that of TNF-α group, but there were no difference in FA or AS-IV group. Compared with CON group, endothelial cell APLT activity was decreased, whereas the expression of Caspase 3, Caspase 9, ROCK-II increased in TNF-α group. In AF group, the activity of APLT was significantly decreased and the expression of Caspase 3, Caspase 9 increased than that of TNF-α group, but no significant difference in FA and AS-IV group. The expression of calpain, ROCK-I was shown no change between each group.

Conclusions: In chronic renal failure, the apoptosis of endothelial cell is increased and release EMP that might be associated with reducing APLT activity. AF could protect endothelial cell and reduce EMP release, which might relate to APLT activity enhancement by inhibiting the expression of Caspase 3 and Caspase 9.

Atherosclerotic Plaque Characterization in Chronic Kidney Disease (CKD)

Kristien El Daenen,[1] Eric Verbeken,[3] Inge Fourneau,[2] Marc Hoylaerts,[4] Bert Bammens.[1] *[1]Nephrology, Univ Hospitals, Leuven, Belgium; [2]Vascular Surgery, Univ Hospitals, Leuven, Belgium; [3]Translational Cell and Tissue Research, Univ Hospitals, Leuven, Belgium; [4]Molecular and Vascular Biology, KU Leuven, Leuven, Belgium.*

Background: CKD is characterized by accelerated atherosclerosis as compared to the general population. MCP1, ICAM, VCAM, CD36 and MMP2 are pro-atherogenic enzymes involved in plaque progression and plaque (in)stability, characterized by inflammation and Neoangiogenesis (nAng). Heme oxygenase-1 (HO-1) is a well-known anti-atherogenic enzyme.

Methods: Peripheral-artery biopsies retrieved during vascular surgery of 27 CKD stages 3-5D patients were compared with those of 43 nonCKD patients. Atherosclerotic plaques were scored blindly for lesion type, nAng, cap characteristics, inflammation and/or plaque complications. Immunostainings for HO-1, CD36, MMP2, MCP1, ICAM1, VCAM and Activated Caspase-3 (aCasp3) were judged semi-quantatively (0-3) and means were calculated. Patients were further phenotyped by clinical and lab evaluation.

Results: Atherosclerotic plaques of CKD patients showed more inflammatory activity (foam cells 2.2 versus 1.5 (p=0.004) and MCP1 (2.2 versus 1.6 p=0.04)), nAng (1.5 versus 1.0 p=0.04) and complicated plaques (68 versus 27 % p=0.002) than clinically well-matched nonCKD patients. In univariate analyses nAng correlated positively with CD36, aCasp3, ICAM1, HO-1, BMI and plaque inflammation, and negatively with eGFR and HDL-cholesterol level (HDL). Main predictors for nAng in multivariate linear regression analysis were plaque inflammation, ICAM, CD36, MMP2, HDL and eGFR ($R^2 = 0.5791$). Univariate correlation analyses in CKD versus nonCKD including HDL, HO-1, MCP1, CD36, ICAM, VCAM and nAng reveal the loss of the classical protective associations for HDL and HO-1 in atherosclerosis in CKD.

Conclusions: Atherosclerosis in CKD is characterized by a vulnerable plaque phenotype, with more inflammation, nAng and plaque complications. Besides the classical pathological cardiovascular markers and plaque inflammation, lower eGFR is associated with more nAng. The loss of the correlations for HO-1 and HDL with atherosclerosis-specific markers such as MCP1, ICAM, VCAM, CD36 and nAng in CKD requires further elucidation.

SA-PO347

Higher Plasma Level of Carnitine Contributes to Preventing Arteriosclerosis via the Reduction of Advanced Glycation End Products in Hemodialysis Patients

Yumi Kamada,[1,2] Takashi Masuda,[2] Yoko Itoh,[1] Ibuki Moriguchi,[1] Naoyuki Kobayashi,[1] Michihito Okubo,[1] Yasuo Takeuchi,[3] Kouju Kamata.[3] *[1]Sohbudai Nieren Clinic, Zama, Japan; [2]Kitasato Univ Graduate School of Medical Sciences, Sagamihara, Japan; [3]Kitasato Univ School of Medicine, Sagamihara, Japan.*

Background: Hyperglycemia or aggravated oxidative stress is well known to promote production of advanced glycation end products (AGEs). There is accumulating evidence that AGEs play an important role in cardiovascular disease in patients with maintenance hemodialysis (HD). It has been known that carnitine, derived from diet or synthesized in liver or kidney, improves insulin resistance and reduces oxidative stress. We hypothesized that higher plasma carnitine leads to prevention of arteriosclerosis via reduction of AGEs. The aim of this study was to investigate the relationships among carnitine, AGEs and arteriosclerosis in HD patients.

Methods: We recruited 79 patients (43 men and 36 women, 60.9 ± 13.2 years) undergoing HD thrice a week. Patients with diabetes or those regularly taking carnitine drug were excluded. We measured pre-HD plasma free carnitine and pentosidine as a parameter of plasma AGEs at the first weekly session. Skin AGEs level was quantitatively evaluated by measuring skin autofluorescence with an AGE-reader. Arteriosclerosis was evaluated by measuring post-HD cardio-ankle vascular index (CAVI). Correlations among carnitine, AGEs and arteriosclerosis were analyzed using Pearson's correlation coefficient.

Results: Free carnitine ranged from 14.9 to 53.3 μmol/L, and was negatively correlated with pentosidine (r=-0.32, P<0.01), skin AGEs level (r=-0.26, P<0.05) and CAVI (r=-0.30, P<0.05). Skin AGEs level was positively correlated with CAVI (r=0.42, P<0.01).

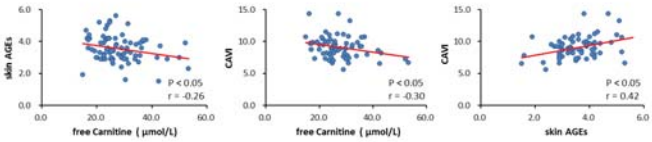

Figure1 Relationships among carnitine, AGEs and arteriosclerosis

Conclusions: Higher plasma level of carnitine contributed to preventing arteriosclerosis via reduction of AGEs in HD patients.

SA-PO348

Carotid Intimal Medial Thickness and Kidney Dysfunction in Rheumatoid Arthritis

Suad Ma Hannawi,[1] Issa A.L. Salmi.[2] *[1]Dept of Medicine, MOH Hospital, Dubai, United Arab Emirates; [2]Dept of Medicine, MOH Hospital, Muscat, Oman.*

Background: Both glomerular and tubular damage contribute to kidney damage(KD) in Rheumatoid arthritis(RA) patients. Cardiovascular disease(CVD) reported to play a pivotal role in the increased KD in RA patients. With significant increase inKD with duration and severity of RA. KD in RA however is usually asymptomatic and is detected only on laboratory investigations. Despite the presence of number of parameters that reflect KD, these cannot be applied to day to day practice and still remain research tools.

Methods: KD was assessed in 37 RA patients(mean age 44.7) by estimated Glomerular Filtration Rate(GFR) using MDRD equation. Risk factor for KD and CVD were recorded or measured in all participants. Linear regression used to test the independence of the association between GFR and each of KD and CVD risk factors.

Results: Univariable analysis revealed significant associations between GFR and age of the participants (p<0.001), age at RA onset(p=0.001), number of cigarettes consumed per day(p=0.036), smoking duration(p=0.031), pack year history of smoking(p=0.024), systolic blood pressure(p=0.002), cIMT(p=0.026), uric acid(UA) level(p<0.001), urine microalbumin level(p=0.029) and urine microalbumin creatinine ratio(0.035). Of traditional CVD risk factors, age had the most powerful association with KD(r=0.42), followed by age at RA onset(r=0.265), and systolic blood pressure(r=0.241). Pack year of smoking and cIMT had almost a same power(r=0.137 and 0.134, respectively). A baseline model was created, incorporating all of the above parameters along with ESR and CRP values. Factors that maintain a significant association with GFR were age, uric acid and cIMT.

Conclusions: This is the first study to report that cIMT is a correlate of KD in RA, in addition to age and UA. CVD-associated factors appear to play a role in reduced KD development. The presence of RA disease with reduced KD may lead to an increase of CVD risk as manifested by a progression of cIMT. Based on these findings: kidney function monitoring; by uric acid and cIMT may be used to pick up early KD and minimize the risk of KD deterioration and subsequent CVD complications in RA population.

Improved Arterial Stiffness Is Associated with Blood Pressure But Not Inflammation, Dialysis Modality or Bioimpedance in Incident Dialysis Patients

Kenneth Yong,[1,2] Gursharan K. Dogra,[1] Neil Boudville,[1,2] Wai Hon Lim.[1] *[1]Dept of Renal Medicine, Sir Charles Gairdner Hospital, Perth, Western Australia, Australia; [2]School of Medicine and Pharmacology, Univ of Western Australia, Perth, Western Australia, Australia.*

Background: A recent ANZDATA study suggests commencing PD has superior survival at 90-days compared to HD in ESKD patients. This could be explained by preserved residual renal function and induction of a lesser inflammatory response with PD.

Methods: We assessed the effects of conventional haemodialysis (HD) or continuous ambulatory peritoneal dialysis (PD) on surrogate markers of cardiovascular disease in incident end-stage kidney disease (ESKD) patients. We conducted a prospective study of 75 ESKD patients commencing HD or PD between January 2009 to December 2012. We measured inflammatory markers (IL-18, hs-CRP), SBP, bioimpedance and arterial stiffness (PWV) 0-3 months prior to dialysis initiation and 3-6months following commencement of HD or PD. Dialysis modality was chosen independent of this study.

Results: Baseline patient characteristics, inflammatory markers, bioimpedance and arterial stiffness were similar between HD and PD patients. Compared with pre-dialysis values, commencing any dialysis significantly lowered PWV (10.2±1.3 versus 8.9±1.0m/s;p<0.001), SBP (156±2.9 versus 136±3.0mmHg;p<0.001), and IL-18 [568(439-711) versus 494(343-578); p=0.004) but not ECW:ICW ratio (0.91±0.02 versus 0.88±0.02;p=0.08). While hs-CRP increased in HD compared with PD [rCRP 0.5±1.6 versus -1.2±1.9 g/L, p=0.02], changes in PWV, SBP, ECW:ICW ratio or IL18 were not significantly different between HD or PD. In multivariate analysis, after adjusting for age, and time on dialysis, only ΔSBP, but not ΔIL-18, ΔCRP, ΔECW:ICW ratio or dialysis modality, was an independent predictor of improved PWV (B=0.03;p=0.005).

Conclusions: Commencement of conventional dialysis in the short-term improves SBP and arterial stiffness, and lowers IL-18 levels. Improvement in arterial stiffness is mediated by changes in SBP rather than pro-inflammatory cytokines, volume status or specific dialysis modality per se. The beneficial effect of PD over HD on 90-day mortality is not supported by our data.

Abstract Withdrawn

SA-PO351

Peripheral Monocytes Are Constitutively Primed for Scavenger Receptor in Hemodialysis Patients, which Likely Facilitates the Development of Atherosclerosis Miki Nishida,[1] Minoru Ando,[2] Yusuke Iwamoto,[3] Ken Tsuchiya,[1] Kosaku Nitta.[1] *[1]Dept of Medicine kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan; [2]Renal Div, Dept of Medicine, Tokyo Metropolitan Komagome Hospital, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [3]Dialysis Center, Saito Memorial Hospital, Tokyo, Japan.*

Background: Atherosclerosis is closely associated with morbidity and mortality in hemodialysis (HD) patients. Scavenger receptor (SR) plays a pivotal role in the initial stage of atherosclerosis by ingesting oxidized low-density lipoprotein (ox-LDL) in monocyte lineage cells.

Methods: Subjects included 61 HD patients and 29 healthy controls. Peripheral monocytes were isolated using magnetically labeled Whole Blood $CD14^+$ micro-beads. Transcriptional levels of SR class A and class B (CD36) were simultaneously measured in peripheral monocytes by quantitative real-time RT-PCR, using the comparative threshold (Ct) method. The gene expressions were compared between HD patients and controls, and between HD patients who had cardiovascular disease (CVD) and those who did not. Additionally,CD36 protein expression was analyzed by a flow cytometry.

Results: Both SR-A and CD36 gene expressions were significantly higher in monocytes from HD patients than in those from controls (mean [95% CI of the mean]: 2.35 [1.97-2.74] versus 1.24 [0.91-1.56], P=0.0001; and 1.52 [1.30-1.74] versus 1.30 [0.92-1.69], P=0.0351). Both SR receptor expressions were significantly higher in HD patients with CVD than in those without (SR-A, 2.78 [2.28-3.29] versus 1.64 [1.16-2.13], P=0.0023; and CD36, 1.72 [1.43-2.00] versus 1.20 [0.89-1.50], P=0.0056).

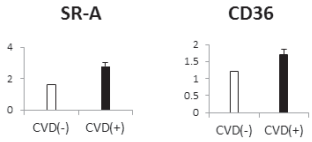

Figure1. Gene expression of SR-A and CD36 in HD patients with and without CVD

The proportion of $CD14^+CD36^+$ cells was 1.3-fold higher in the HD patients than in the controls (35.65% versus 27.65%).

Conclusions: Peripheral monocytes in HD patients may be primed for SR expressions, suggesting that they are predisposed to uptake of atherogenic ox-LDL.

The Interaction between C5a and Sphingosine-1-Phosphate in Neutrophils for ANCA-Mediated Activation Min Chen,[1,3,4,5] Jian Hao,[1,2] Yimin Huang,[1,3,4,5] Minghui Zhao.[1,3,4,5] *[1]Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China; [2]Renal Div, Dept of Medicine, The Affiliated Hospital of Inner Mongolia Medical Univ, Huhehot, Inner Mongolia, China; [3]Key Laboratory of Renal Disease, Ministry of Health of China, Beijing, China; [4]Key Laboratory of Chronic Kidney Disease Prevention and Treatment (Peking Univ), Ministry of Education, Beijing, China; [5]Peking-Tsinghua Center for Life Sciences, Beijing, China.*

Background: C5a plays an crucial role in antineutrophil cytoplasmic antibody (ANCA)-mediated neutrophil recruitment and activation. The current study further investigated the interaction between C5a and sphingosine-1-phosphate (S1P) in neutrophils for ANCA-mediated activation.

Methods: The plasma levels of S1P from 29 patients with ANCA-associated vasculitis (AAV) in active stage and in remission were tested by ELISA. The generation of S1P was tested in C5a-triggered neutrophils. The effect S1P receptor antagonistwas tested on respiratory burst and degranulation of C5a-primed neutrophils activated with ANCA.

Results: The plasma level of circulating S1P was significantly higher in patients with AAV with active disease comparedwith patients in remission (2034.2±438.5 versus 1489.3±547.4 nmol/L, *P*<0.001). S1P can prime neutrophils for ANCA-induced respiratory burst and degranulation. Compared with non-triggered neutrophils, the MFI value for CD88 expression up-regulated significantly in S1P-triggered neutrophils. S1P receptor antagonist decreased oxygen radical production in C5a primed neutrophils induced by ANCA-positive IgG from patients.Blocking S1P inhibited C5a-primed neutrophils migration.

Conclusions: S1P triggered by C5a-primed neutrophils could further activate neutrophils. Blocking S1P could attenuate C5a-induced activation of neutrophils by ANCA. The interaction between S1P and C5a plays an important role in neutrophils for ANCA-mediated activation.

SA-PO353

Analysis of Mitochondrial DAMPs in ANCA Vasculitis Lovisa Odén,[1,2] Eóin O'Brien,[1] Alice M. Coughlan,[1] Paul O'Hara,[1] Mark Alan Little,[1] Fionnuala B. Hickey.[1] *[1]Trinity Health Kidney Centre, Trinity College Dublin, Dublin, Ireland; [2]Karolinska Instt, Solna, Sweden.*

Background: Anti-neutrophil cytoplasmic autoantibody (ANCA) vasculitis is an autoimmune condition characterised by inflammation and necrosis of blood vessels. In its most severe form it manifests with rapidly progressive glomerulonephritis and vasculitis of the respiratory tract. Danger-associated molecular patterns (DAMPs) are cellular components released from injured tissues that activate the innate immune system. As mitochondria are considered endosymbionts that evolved from bacteria, components of these organelles including mitochondrial DNA (mtDNA) can act as DAMPs. This study examined mtDNA copy number in serum of patients with ANCA vasculitis compared to healthy controls, and analysed the ability of mtDNA to prime neutrophils and monocytes for activation by ANCA, thus exacerbating the course of the disease.

Methods: Samples derived from the Irish Rare Kidney Disease Registry and Biobank. DNA was extracted from the serum of 173 patients and 53 controls. Mitochondrial and nuclear genes (MTND3 and UCP2) were quantified by real time-PCR. Neutrophils and monocytes isolated from whole blood were stimulated with mtDNA (extracted from HeLa cells) and/or ANCA. Cell activation was measured by DHR123 assay and secretion of IL-1β.

Results: Serum mtDNA levels were significantly higher in patients with active disease (n=74) versus those in remission (n=99) (p<0.05). Analysis of UCP2 indicated that nuclear DNA was significantly elevated in patients versus healthy controls (p<0.0001) and also significantly higher in patients with active disease versus remission (p<0.0001). Treatment of neutrophils with mtDNA primes them for activation by ANCA, as measured by oxidative burst. Similarly, treatment of monocytes with mtDNA results in enhanced activation and IL-1β secretion in response to ANCA.

Conclusions: Increased levels of serum mtDNA are seen in patients with active disease compared to remission. mtDNA enhances the activation of both neutrophils and monocytes by ANCA and as such may propagate the autoimmune response in ANCA vasculitis, although it remains unclear whether the elevated level is a driver of inflammation or a consequence of tissue damage.

Cyclosporine Enhances Macrophage Lipid Accumulation via the TLR Pathway Joseph Mattana, Nobuyuki (Bill) Miyawaki, Laura Kaplan, Iryna Voloshyna, Allison B. Reiss. *Dept of Medicine, Winthrop Univ Hospital, Mineola, NY.*

Background: Cyclosporine A (CsA), an immunosuppressive used in renal transplantation, is associated with nephrotoxicity, atherosclerosis and dyslipidemia. Chronic CsA use may be pro-atherosclerotic and nephrotoxic due to mechanisms involving endothelial injury and macrophage infiltration. Modified low density lipoproteins (LDL), particularly carbamylated (c)LDL, are elevated in renal disease and can promote atherosclerosis through vascular endothelial dysfunction or foam cell formation. Toll-like receptors (TLRs) play a key role in inflammation and atherosclerosis. TLR2 is activated by CsA. Here we determined that CsA enhances lipid accumulation in cultured THP-1 human macrophages through the TLR pathway.

Methods: THP-1 macrophages (10^6/ml) were incubated 24h and 48h in media alone (control), oxidized (ox)LDL or cLDL (50 μg/ml) ± CsA (1 μg/ml). Cholesterol influx analysis and foam cell detection were performed under these conditions ± 5μg/ml 1,1'-dioctadecyl 3,3,3',3'-tetramethylin docarbocyaninet (Dil)-oxLDL. Message levels of the scavenger receptors CD36, LOX1, SRA1 and CXCL16 were evaluated by real-time PCR. Inflammatory response was analyzed by expression of TLR2 and TLR4. The TLR pathway was inhibited with BAY 11-7082. Protein levels were confirmed by Western blot. Cellular dil-oxLDL was quantified by fluorescent intensity using confocal microscopy.

Results: CsA doubled expression of the scavenger receptors CD36, SRA1 and CXCL16 in THP-1 macrophages exposed to oxLDL or cLDL, but not in control cells (set at 100%) (n=3, P<0.05). CsA doubled TLR2 under all 3 conditions (control, oxLDL, cLDL) (n=3, P<0.05), while TLR4 was unchanged. In THP-1 macrophages exposed to oxLDL or cLDL + CsA, enhanced cholesterol influx was accompanied by acceleration of oxLDL uptake (by 46% and 56%, respectively versus no CsA). Blockade of the TLR-2 signaling pathway reduced lipid influx and accumulation to the level of control cells.

Conclusions: CsA acts synergistically with modified LDL to induce an atherogenic macrophage phenotype. CsA-induced activation of innate immunity provides a link to accelerated lipid accumulation and pro-atherogenic changes in renal disease states.

Serum YKL-40 Level Is Associated with Vascular Injury and Predicts Proteinuria in Nephrotic Syndrome Patients Ismail Kocyigit,[1] Ozkan Gungor,[2] Ender Dogan,[3] Serhat Karadavut,[4] Cigdem Karakukcu,[5] Eray Eroglu,[3] Ozcan Orscelik,[4] Aydin Unal,[1] Murat H. Sipahioglu,[1] Bulent Tokgoz,[1] Oktay Oymak.[1] *[1]Dept of Nephrology, Erciyes Univ Medical Faculty, Kayseri, Turkey; [2]Nephrology Clinic, Kahramanmaras Education and Research Hospital, Kahramanmaras, Turkey; [3]Dept of Internal Medicine, Erciyes Univ Medical Faculty, Kayseri, Turkey; [4]Dept of Cardiology, Erciyes Univ Medical Faculty, Kayseri, Turkey; [5]Biochemistry Laboratory, Kayseri Education and Research Hospital, Kayseri, Turkey.*

Background: Nephrotic syndrome (NS) is associated with increases in cardiovascular events. YKL-40 levels are associated with atherosclerosis, endothelial dysfunction and proteinuria in renal and non-renal populations. The aim of this study was to investigate the relationship between YKL-40 levels with vascular injury and proteinuria in NS patients.

Methods: Sixty-nine NS patients and 20 healthy subjects were enrolled in the study. Endothelial function was measured by flow mediated dilatation (FMD) and arterial stiffness by pulse wave velocity (PWV). Serum YKL-40 levels were measured by ELISA.

Results: YKL-40 level and PWV were higher and FMD was lower in NS patients compared with healthy controls. However, CA-IMT and LVEF levels were not statistically significant between the two groups. Patients were divided into three groups in terms of proteinuria levels: the normoproteinuria group (n:18), non-nephrotic proteinuria group (n:33) and nephrotic proteinuria group (n:18). YKL-40 levels and PWV were significantly increased and FMD was decreased in the nephrotic proteinuria group compared to both the non-nephrotic proteinuria and normoproteinuria groups. The YKL-40 level correlated with FMD and PWV in NS patients. In patients with NS, proteinuria correlated with YKL-40, FMD, PWV, eGFR and fasting LDL cholesterol. Multivariate linear regression analyses showed that YKL-40 and eGFR were effective in predicting proteinuria in NS patients.

Conclusions: Serum YKL-40 level in NS patients is associated with endothelial dysfunction and increased arterial stiffness, and YKL-40 level is an indicator of the amount of proteinuria seen in these patients.

Hyperuricemia Is a Risk for Coronary Artery Calcification in Asymptomatic Subjects Undergoing General Health Examination Ah Ran Choi, Miok Cho, Tae Hoon Kim, Sung Chang Bae, Hoon Young Choi, Sung-Kyu Ha, Hyeong Cheon Park. *Yonsei Univ College of Medicine, Gangnam Severance Hospital, Seoul, Republic of Korea.*

Background: Recent studies suggest that hyperuricemia may be a potential risk factor for atherosclerosis even in healthy subjects. Quantity of coronary artery calcium (CAC) correlates with atherosclerotic plaque burden and increased coronary artery calcium score (CACS) predict future coronary heart disease (CHD) events. We aimed to assess the relationship between CACS and serum uric acid (sUA) as well as other cardiovascular risk factors in asymptomatic subjects undergoing general health examination.

Methods: We consecutively enrolled 5,491 asymptomatic subjects without history of CHD who underwent coronary CT angiography as part of a general health examination. Patients with gout orthose taking uric acid lowering medications were excluded.

Results: Mean age of enrolled subject was 52.97 ± 9.5 years, 61 % of the study participants were male, mean CACS was 36.13 ± 148.9. Overall, 8.5% of subjects had an Agatston score greater than 100. The proportion of subject with serum uric acid of greater than 6.8 mg/dL in male were 24.6 %, and sUA greater than 6.0 mg/dL in female were 6.2 %. Compared to subjects with CACS less than 100, subjects with CACS > 100 had significantly higher sUA and higher fasting blood sugar (FBS), old age, and hypertension. CACS was positively associated with age, male gender, diabetes, body mass index, FBS, calcium-phosphate product (CPP), and sUA in CACS > 100 group according to multivariate logistic regression. Odds ratios (OR) of CACS for CPP and sUA was 1.021 (P <0.001) and 1.126 (P <0.012), respectively, after adjusting for other variables. In multivariate linear regression analysis, male, old age, hypertension, diabetes, smoking, increased CPP, serum uric acid, and fasting blood glucose were significantly associated with log transformed CACS.

Conclusions: Our data suggest that in addition to other known traditional risk factors, high sUA and CPP are independent risk factors for high CACS in asymptomatic subjects undergoing general health examination.

Endothelial RIG-I Signaling: A Crucial Pathway for Endotoxin-Induced Inflammatory Activation and Leukocyte Recruitment Jill Moser,[1,2] Peter Heeringa,[2] Rianne Jongman,[2] Jan G. Zijlstra,[1] Grietje Molema,[2] Matijs Van Meurs.[1,2] *[1]Dept Critical Care, UMCG, Groningen, Netherlands; [2]Dept Medical Biology, UMCG, Groningen, Netherlands.*

Background: Sepsis is a well-known risk factor for the development of AKI. RIG-I-like receptors have been suggested to play a role in the pathophysiology of sepsis yet very few studies have investigated this in detail. The aim of the current study was to investigate the role of RIG-I signaling in the development of endothelial dysfunction contributing to sepsis-induced kidney failure.

Methods: In this study, we investigated the mRNA levels of RIG-I and endothelial inflammatory markers in sepsis mouse models, LPS administration and CLP. Moreover, using laser microdissection/qRT-PCR analysis we investigated RIG-I expression in the renal microvascular compartments. In vitro studies using siRNA technology were adopted to ascertain whether there was a functional role for RIG-I in the regulation of endothelial cell (EC) responses to LPS.

Results: EC responses to LPS lead to the upregulation of RIG-I mRNA levels which followed the expression kinetics of the endothelial adhesion and inflammatory cytokine genes. We found that NFκB-mediated endothelial adhesion molecule and inflammatory cytokine expression was markedly inhibited in response to LPS in RIG-I and MAVS deficient ECs. Accordingly, less leukocyte adherence to the endothelium was observed in RIG-I and MAVS deficient ECs treated with LPS. We also identified RIG-I to regulate LPS-induced IRF1 transcriptional responses in ECs which we show specifically regulates VCAM-1 expression. In our mouse sepsis models we found renal RIG-I mRNA was upregulated which was paralleled by endothelial inflammatory activation. Moreover, endothelial-specific RIG-I was upregulated by LPS in all microvascular beds of the kidney despite variations in their basal levels.

Conclusions: Here we describe the identification of two unanticipated factors, RIG-I and MAVS, as essential core components required for LPS-induced activation and inflammatory responses which promote leukocyte adhesion to the endothelium. In vivo models of sepsis-induced AKI furthermore provide evidence of RIG-I involvement in the microvascular pathogenesis associated with septic shock.

Mechanisms and Prevention of Low Birth Weight Associated Acute and Chronic Renal and Vascular Impairment May M. Rabadi, Joseph A. Zullo, Wasan Abdulmahdi, Ashvary Parth Dwivedi, Michael S. Shen, Kavneet Kaur, Brian B. Ratliff. *New York Medical College, NY.*

Background: In the United States, 8.1% of annual live births result in low birth weight (LBW) infants, contributing up to 80% of all neonatal deaths, and is the major cause of childhood morbidity. These babies are also predisposed to chronic illness later in life.

Methods: We used a maternal malnourished mouse model to examine the effects of LBW on kidney and vascular development and short/long-term function. Circulating cyto-/chemokines, nephron development, renal blood flow, renal developmental gene expression, autophagy, renal function and systemic blood pressure were examined in the LBW offspring. The therapeutic potential of glutamine, methionine and calendula treatment was examined in these animals.

Results: LBW male offspring birth weight and kidney size were reduced by 50%. During the first week after birth of the LBW neonate, BUN levels were elevated by 66%, renal blood perfusion was attenuated by 50%, and circulating proinflammatory cyto-/chemokines including IL-1β, IL-5, IL-12, IFNγ and GM-CSF were elevated. During mid to late nephrogenesis, the LBW fetus/neonate demonstrated a 25-50% reduction of pre-glomerular structures (renal vesicles, comma and s-shaped bodies) and glomeruli, a blunting of autophagy, and altered expression of critical developmental genes including elevated Wnt9b, Bmp7 and FoxD1, but reduced Eya1 and Sall1. Supplementation of methionine and glutamine during nephrogenesis normalized kidney development and function in the LBW neonate. At 2 months post-birth, LBW mice had 30% fewer glomeruli, showed early tubular damage and glomerular abnormalities. At 5 months post-birth, LBW animals had 10% elevated blood pressure, elevated serum creatinine and proteinuria, and enhanced circulating proinflammatory cyto-/chemokines. Treatment with calendula improved blood pressure and renal function in the older animals.

Conclusions: LBW compromises the kidney and vascular system, enhances circulating proinflammatory cyto-/chemokines, interferes with normal nephron/glomeruli development and predisposes mice to acute and chronic illness. Effects are improved upon treatment with glutamine, methionine or calendula.

Loss of Endothelial Surface Glycocalyx (ESG) in Early Sepsis (S) Jie Fan,[1] Wan-Yi Yen,[1] Min Zeng,[1] Jun Chen,[2] Brian B. Ratliff,[2] Jungol Song,[2,3] John Tarbell,[1] Bingmei M. Fu,[1] Michael S. Goligorsky.[2] *[1]City College, CUNY; [2]NY Medical College, NY; [3]Ulsan Medical College, Seoul, Korea.*

Background: ESG is a surface layer consisting of glycoproteins, proteoglycans and glycosaminoglycans; heparan sulfate (HS) is the most abundant. ESG provides a barrier to water and solute transport, sensing of mechanical forces, and shielding receptors from hyper-activation. S disorganizes ESG, but the mechanism is nebulous. Among the earliest responses of activated endothelial cells to LPS are exocytosis of Weibel-Palade bodies (WPB) and lysosomes. We hypothesized that those responses result in the focal degradation of ESG unleashing the cascade of events culminating in multiorgan failure.

Methods: bEnd3 endothelial cells and HUVEC were treated with LPS (5ug/ml) and stained with mAb against HS or vWF; intravital microscopy of lysosomal motility was performed using LysoTracker. C57BL/6 mice were injected with LPS IP. After 1h or 6h treatment, the cremaster microvessels were in vivo stained with FITC-anti-HS; in another group, the aorta was similarly stained en face. Zeiss LSM 710 confocal microscopy and 3-D multi-color ultra-high resolution Nikon-STORM (Stochastic Optical Reconstruction Microscopy) were used to detect ESG, vWF/WPB and lysosomes.

Results: At 10 min after LPS treatment of bEnd3, we observed a significant loss of ESG and exocytosis of vWF/WPB (Fig. 1). At 30 min, ESG was degraded by ~90%, 30% more lysosomes and 4-fold vWF/WPB externalized compared to the control. 1h and 6h LPS treatment removed ESG by ~50% and more than 90%, respectively, in microvessels; by ~60% and ~90%, respectively, in aorta of mice.

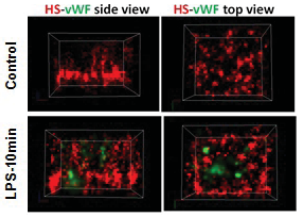

Fig.1.Representative STORM-acquired images of anti-HS labeled ESG (red) and vWF (green) distribution in control and 10min post-LPS (side and top views) in bEnd3 cells. In control ESG is richly represented, whereas it is sparse and vWF density hightened in LPS group. HS-vWF-*side view* images depict the relative distribution of ESG and vWF (note that ESG is impregnated with vWF and is fragmented in LPS series); *top view* illustrates the formation of ESG "halo" around vWF-labeled WPB. Bar = 1 um.

Conclusions: Patchy loss of ESG is detectable after 10-30 min of LPS treatment, coinciding with exocytosis of WPB and lysosomes in cultured cells. Loss of ESG is a very early event in S. and may serve as a therapeutic target in preventing the complications of S.

The Kidney Enriched Proteome Defined by Transcriptomics and Antibody Based Profiling Masato Habuka,[1,2] Ichiei Narita,[3] Tadashi Yamamoto.[1] *[1]Dept of Structural Pathology, Inst of Nephrology, Medical and Dental School, Niigata Univ, Niigata City, Japan; [2]Affinity Proteomics, Science for Life Laboratory, KTH - Royal Inst of Technology, Stockholm, Sweden; [3]Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental School, Niigata City, Japan.*

Background: The kidney is a specialized tissue and plays a vital role in maintaining body homeostasis.To understand renal biology and disease, it is important to define the molecular constituents of the various subcompartments of the kidney, including glomerulus and tubule.

Methods: we have used an integrated omics approach involving genome wide transcriptomics analysis using deep RNA sequencing across 27 different human tissue types combined with antibody-based immunohistochemistry in 48 different tissues to identify the genes overrepresented in the kidney and to further map the localization of the corresponding protein. All human genes were classified into categories of expression patterns with regards to expression pattern in the kidney as compared to the other anlyzed tissues.

Results: Altogether 387 genes were found to be elevated in kidney as compared to the other analyzed tissues and 64 genes were found to have a significant higher expression in kidney and these genes are designated as highly and moderately enriched. In-depth analysis of all the elevated genes using antibody-based allowed us to create a nephron and collecting duct segment-specific map, including 149 proteins with a unique localization, including 12 proteins in glomeruli, 120 in proximal tubule, 9 in distal tubule and 8 in collecting duct. An analysis of the identified genes supports their role in the function of each segment. Among the gene products identified as kidney-enriched, we found several proteins not previously described in the context of the kidney.

Conclusions: In summary, we have identified and mapped proteins with elevated expression in kidney through an integrated omics approach and these proteins are important starting points for further functional studies. The identified protein targets can also serve as the vantage point for identification of early kidney specific biomarkers of disease and injury before clinical symptoms arise.

SA-PO361

Tracking the Fate of Renal Mesenchymal Stem Cells with In Vivo Multiphoton Imaging James L. Burford, Janos Peti-Peterdi. *Physiology and Biophysics and Medicine, Univ of Southern California, Los Angeles, CA.*

Background: Currently there is no cure for chronic kidney disease (CKD) other than non-specific drugs that only slow down progression. The unmet medical need and inadequacy of current treatments have led to great interest in regenerative stem cell approaches. We aimed to track the localization, migration, and fate of resident mesenchymal stem/progenitor cells in the renal cortex in intact mouse kidneys.

Methods: Tamoxifen-inducible chondroitin sulfate proteoglycan NG2-Tomato reporter mice were subjected to multiple surviving surgeries to exteriorize and image the same region and glomeruli of the left kidney by in vivo serial multiphoton microscopy (MPM). Blood vessels were labeled green by 500 kDa dextran. Specific renal cortical regions and glomeruli were z-scanned to visualize changes in tissue morphology and cell dynamics.

Results: Compared to baseline, the density of cells that belong to the NG2 lineage (red) was increased 3-fold and observed in a scattered pattern throughout the renal interstitium, along the afferent arteriole towards the MD tubular segment, within the glomerulus (including mesangial and parietal epithelial cells, and podocytes), and in the early proximal tubule 1-2 weeks after UUO (a common model of CKD and tubulointerstitial fibrosis) or low salt diet+captopril treatment. Spherical or stellate-shaped cells of the NG2 lineage were observed in the Bowman's space and in the proximal tubule lumen suggesting cell migration.

Conclusions: In summary, these in vivo MPM imaging data suggest the dynamic cellular remodeling of the renal interstitium, juxtaglomerular vasculature, mesangium, the Bowman's capsule, and the proximal tubule by renal progenitor cells in these conditions. The more precise mechanistic understanding of this novel NG2 cell function needs further study.

Analysis of Renal Tubular Function by ^{99m}Tc-MAG3 Secretion Requires MRP2 Transporter with Interference from Morphine as a Co-Ligand Samriti Dogra,[1] Kang Cheng,[2] Pravin C. Singhal,[2] Chris Palestro,[2] Sanjeev Gupta,[3] Kuldeep Bhargava.[2] *[1]Pediatric Nephrology, Montefiore Medical Center, Bronx, NY; [2]North Shore-Long Island Jewish Health System, Manhasset and New Hyde Park, NY; [3]Pathology and Medicine, Albert Einstein College of Medicine, Bronx, NY.*

Background: The widespread use of ^{99m}Tc-MAG3 complex in evaluation of renal proximal tubule function requires molecular details of tracer biology. Recent studies established that ^{99m}Tc is a ligand for the bile canalicular apical MRP2 transporter, which is also expressed in renal tubules, with specificity for ^{99m}Tc-MAG3 due to the small size of MAG3. As glucuronidated metabolites of morphine are also transported by MRP2 and individuals undergoing renal imaging may have received this drug, we investigated the effect of morphine on renal ^{99m}Tc-MAG3 excretion.

Methods: The study used 9 mice in 3 groups: untreated controls, morphine given continuously for 72 h via s.c. 75 mg pellet, and morphine for 72 h via s.c. pellet of 75 mg followed by morphine withdrawal for 72 h. Administration of 3.7 MBq ^{99m}Tc-MAG3 via tail vein was followed by acquisition of 60 1-second images and 29 1-minute images by gamma camera. Regions of interest were drawn around kidneys for time–activity curves to illustrate split renal function and time-to-peak activity (Tpeak). Immunostaining and westerns were used for MRP2 expression.

Results: We observed differences in Tpeak for ^{99m}Tc-MAG3 activity, which was 6, 27 and 10 min in untreated controls, morphine-treated mice and morphine-treatment-withdrawal mice, respectively, $p<0.05$, ANOVA. No urinary excretion of activity was noted during imaging study in morphine-treated mice. MRP2 was expressed equally by westerns in kidneys of animals in all groups. Similar localization by immunostaining of MRP2 in tubular cells of controls and morphine-treatment excluded dysregulation of transporter expression.

Conclusions: Morphine blocked renal ^{99m}Tc-MAG3 excretion, which was in agreement with preferential MRP2-binding of morphine. These findings have clinical implications because presence of morphine may confound results of ^{99m}Tc-MAG3 imaging.

CD36: A New Therapeutic Target for Chronic Kidney Disease Progression Ana C. Souza,[1] Alexander V. Bocharov,[2] Irina Baranova,[2] Tatyana Vishnyakova,[2] Yuning George Huang,[1] Kenneth J. Wilkins,[1] Xuzhen Hu,[1] Adam E. Mullick,[4] Alan Remaley,[3] Thomas Eggerman,[1] Peter S.T. Yuen,[1] Robert A. Star.[1] *[1]NIDDK; [2]CC; [3]NIHLBI, NIH; [4]ISIS.*

Background: CD36 is a scavenger receptor important for lipid metabolism and inflammation. To test for a direct role of CD36 in CKD, we compared wild type (WT) versus CD36 knockout (KO) versus WT mice treated with 5A-37pA (5A), a CD36 antagonist peptide, in a CKD model.

Methods: 16wk old male C57BL6 WT and KO mice were subjected to 5/6 nephrectomy (5/6Nx) with AngII infusion (0.75 µg/Kg/min) through osmotic minipump. Some mice got 5A (5mg/kg/day) in a second minipump. WT mice with 5/6Nx without AngII served as controls. All groups (WT5/6Nx, WT 5/6Nx+AngII, KO 5/6Nx+AngII, WT 5/6Nx+AngII+5A, N=11-19/group) were followed for 4wk, and telemetry blood pressure monitored in WT and KO 5/6Nx+AngII (N=6/group). Serum creatinine was measured by HPLC; albuminuria, serum amyloid A (SAA), and FGF-23 by ELISA. Kidney sections were stained for histology. We measured renal cytokines and NLRP3 by RT-PCR (N=4-6/group). Fluorescent 5A was injected IV and kidneys analyzed after 3h by 2 photon microscopy. Statistical analyses primarily involved ANOVA; repeated measures data were analyzed by mixed models.

Results: Non-treated WT 5/6Nx+AngII mice developed albuminuria, substantial decline in kidney function, histological damage, and a metabolic profile typical of CKD with increased FGF-23 and SAA. Kidney function was improved by ~ 40% in the KO 5/6Nx+AngII and 5A-treated WT 5/6Nx+AngII groups, with decreased albuminuria (~ 50%), improved histology and metabolic profile. There was no difference in blood pressure between WT 5/6Nx+AngII and KO 5/6Nx+AngII. 5A decreased mRNA expression of renal cytokines and inflammasome NLRP3 and IL-1ß genes. Fluorescent 5A localized in proximal convoluted tubules (PCT) after IV injection, coinciding with the most prominent CD36 staining by IHC.

Conclusions: CD36KO and 5A-treated WT mice are protected from CKD progression. This protection occurs without changes in blood pressure. 5A decreases inflammation and inflammasome activation in the kidney. Both 5A and CD36 localized in PCT. CD36 is a new therapeutic target for CKD, and 5A is a promising protective agent.

5A-37pA, a CD36 Antagonistic, Decreases Kidney Interstitial Fibrosis in Mice Subjected to Unilateral Uretheral Obstruction Ana C. Souza,[1] Alexander V. Bocharov,[2] Irina Baranova,[2] Xuzhen Hu,[1] Jonathan Street,[1] Alan Remaley,[3] Thomas Eggerman,[1] Peter S.T. Yuen,[1] Robert A. Star.[1] *[1]NIDDK; [2]CC; [3]NIHLBI, NIH.*

Background: Inhibiting CD36 receptor with 5A-37pA (5A) slows CKD progression after 5/6 nephrectomy with Ang II infusion in C57BL6 mice (ASN 2014). To test the efficacy of 5A in a outbred strain in a fibrosis model that is not Ang II- dependent, we evaluated 5A in CD-1 mice subjected to unilateral uretheral obstruction (UUO).

Methods: CD-1 mice (male, 9wk, n=8/group) were divided as follows: 1) Sham operated; 2) UUO; 3) UUO + 5A, 5mg/kg/day (5A5); 4) UUO + 5A, 15mg/kg/day (5A15). 5A or vehicle (water) was infused through subcutaneous osmotic minipump that was implanted 24h before sham surgery or UUO. After 10 days, mice were euthanized. A biochemistry serum panel was analyzed by automated analyzer. Kidney sections were stained with Masson's trichrome for interstitial fibrosis and morphometric analysis. IHC for F4/80$^+$ cells and RT-PCR analysis of cytokines and NLRP3 expression in the kidney was performed (n=4/group). Statistical analyses were performed by ANOVA.

Results: Mice subjected to UUO had significant kidney histological damage with substantial interstitial fibrosis, which was less prominent in mice receiving 5A15: (a) interstitial fibrosis scores- sham 1.1; UUO 4.8 $p<0.0001$ versus sham; 5A5 4.3; 5A15 3.9 $p<0.05$ versus UUO (b) cortex thickness- sham 1000 pixels; UUO 469.7 $p<0.0001$ versus sham; 5A5 664.9; 5A15 771.4 $p<0.001$ versus UUO). F4/80$^+$ cells infiltration was significantly elevated after UUO ($p<0.001$ versus sham), and decreased in both 5A-treated groups to levels similar to sham. mRNA expression of TGF-ß and 1L-1ß were decreased in the kidney in the 5A15 group in comparison to untreated UUO ($p<0.05$ and $p<0.01$, respectively). mRNA expression of other inflammatory cytokines trended toward decreased levels in the 5A15 group. Biochemistry panel did not show any drug toxicity at either dose.

Conclusions: 5A treatment protected mice subjected to UUO from kidney interstitial fibrosis in a dose-dependent manner, potentially through anti-inflammatory actions. 5A did not cause toxicity at the doses and route of administration used.

Blockade of Mitochondrial Complex-1 Remarkably Attenuates Fibrosis via Inhibition of Oxidative Stress and Inflammation in Chronic Obstructive Nephropathy Ying Sun,[2] Yue Zhang,[1] Guixia Ding,[1] Aihua Zhang,[1] Songming Huang,[1] Zhanjun Jia.[2] *[1]Nephrology, Nanjing Children Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China; [2]Nanjing Key Laboratory of Pediatrics, Nanjing, Jiangsu, China.*

Background: Mitochondrial abnormality has been shown in many kidney disease models. However, its role in the pathogenesis of chronic kidney diseases (CKDs) is still uncertain. In present study, a mitochondrial complex-I inhibitor rotenone was applied to the mice subjected to unilateral ureteral obstruction (UUO) to evaluate its effect on the tubular injury, fibrosis, as well as the oxidative stress and inflammation.

Methods: Following the UUO surgery, mice were treated with rotenone at a dose of 500 ppm in diet for 7 days. Then the mice were sacrificed and the kidney tissues were harvested for analysis.

Results: By PAS staining, a remarkable attenuation of tubular injury was observed after rotenone administration. In line with the improvement of kidney morphology, we found that rotenone markedly suppressed expressions of FN (-80%), PAI-1(-71%), collegen-1(-66%), collagen-3 (-72%), and α-SMA (-70%) at protein and mRNA levels as determined by Western Blotting and qRT-PCR. Meanwhile, the protein and mRNA expressions of TGF-β1 were reduced by 71% and 62%, respectively. To investigate the potential mechanisms, we examined the oxidative stress and inflammatory response. Importantly, the oxidative stress level in obstructed kidney was robustly inhibited by rotenone as evidenced by the significant blockade of renal TBARs content (-62%)and HO-1 protein expression (-75%). Similarly, the inflammatory markers of TNF-α, IL-1β, and ICAM-1 were also markedly ameliorated by 60-80% as determined by ELISA and qRT-PCR.

Conclusions: Mitochondria complex I inhibitor rotenone effectively attenuated obstructive kidney injury and fibrosis, possibly via the inhibition of mitochondrial oxidative stress and the subsequent inflammatory response, suggesting an important role of mitochondrial dysfunction in mediating the pathogenesis of obstructive kidney disease. These results also suggested that mitochondria might be a potential target for the treatment of chronic kidney disease.

SA-PO366

Pro-Inflammatory and Pro-Fibrotic Action of the Protease-Activated Receptor-2 (PAR-2) in the Rodent Unilateral Ureter-Obstraction-Model (UUO) Christoph Daniel,[1] Iris Scheitacker,[1] Marko Bertog,[2] Christoph Korbmacher,[2] Kerstin U. Amann.[1] *[1]FAU Erlangen-Nuremberg; Nephropathology, Germany; [2]FAU Erlangen-Nuremberg; Physiology, Germany.*

Background: Protease activated receptor-2 (PAR-2) is a G-protein coupled receptor, that can be activated by a panel of serine proteases being secreted in response to injury. In different disease models it has been shown that pro-inflammatory as well as pro-fibrotic signal transducing cascades were activated by PAR-2. At present it is unknown whether PAR-2 mediated processes also play a role in kidney injury following unilateral ureter obstruction (UUO).

Methods: To investigate this, the UUO model was induced in wildtype (wt, n=16) and PAR-2-/- mice (n=26). Seven days later non-treated and ureter ligated kidneys were collected and analyzed for morphologic changes, fibrosis and inflammatory response using immunohistochemistry (n=9/20); real-time PCR (n=6/6) and flow cytometry analysis (n=6/6).

Results: UUO kidneys from wt mice showed pronounced tubular injury including tubular dilatation and atrophy. These changes were significantly lower in PAR-2-/- mice (38.8%±7.2 versus 23.4%±8.9 of tubular damage, p<0,001). The milder tubular damage was accompanied with a slightly lower degree of fibrosis (Sirius red semiquantitative score 2.9±0.3 versus 2.2±0.5, $p<0.001$) and lower CTGF mRNA expression (rel. expr.: 1.04±0.5 versus 0.48±0.2, p<0,05) in the obstructed kidney of PAR-2-/- mice. In addition, a non-significant trend was observed that in PAR-2-/- mice the expression of TGF-ß and of the myofibroblast markers α-smooth muscle actin and collagen-I was lower than in wt mice. Furthermore, inflammatory response in PAR-2-/- kidneys after UUO was also attenuated compared to injured wt controls. In PAR-2-/- mice MCP-1 expression was significantly lower (rel. expr.: 31.2±12.7 versus 15.7±7.5; $p<0.05$) with a non-signficant trend to lower TNF-α und IL-6 mRNA expression. Influx of F4/80 positive macrophages and CD3 positive T-cells in diseased kidneys from PAR-2-/- mice also showed a tendency to lower numbers as assessed by immunohistochemistry and flow cytometry compared to wt animals.

Conclusions: Thus, PAR-2 might be a potential new target for the therapy of inflammatory and fibrotic kidney disease.

SA-PO367

The Fate of Nephrons in Congenital Obstructive Nephropathy: Adult Recovery Is Limited by Nephron Number Maria Sergio, Carolina I. Galarreta, Barbara A. Thornhill, Michael S. Forbes, Robert L. Chevalier. *Dept of Pediatrics, Univ of Virginia, Charlottesville, VA.*

Background: Pediatric chronic kidney disease (CKD) is most often due to congenital anomalies of the kidneys and urinary tract (CAKUT), and obstructive nephropathy is the leading cause. Progression to renal failure, however, is more likely to develop in adulthood than childhood (Wuhl, CJASN 8: 67–74, 2013). Frequently associated with CAKUT, reduced nephron number (NN) at birth is an independent risk factor for adult CKD.

Methods: To determine the role of NN in progression of congenital obstructive nephropathy, wild-type (WT) and reduced NN mice (Os/+) were subjected to sham operation or partial unilateral ureteral obstruction (UUO) in the first 2 days of life (prior to completion of nephrogenesis). To assess the impact of NN on recovery, additional WT and Os/+ mice underwent release of UUO at 7 days. All kidneys were harvested at 3 weeks (weaning) or 6 weeks (adulthood). Glomerular number and area, glomerulotubular junction integrity, proximal tubular volume fraction, and interstitial fibrosis were measured by histomorphometry.

Results: *In the obstructed kidney*, UUO caused additional nephron loss in Os/+ but not WT mice. Glomerular growth from 3 to 6 weeks was impaired by ipsilateral UUO and was not preserved by release in WT or Os/+. Proximal tubular growth was impaired and interstitial collagen was increased by ipsilateral UUO in all mice. These were attenuated by release of UUO in WT mice but were not restored in Os/+ mice. *In the contralateral kidney* of Os/+ mice, UUO decreased proximal tubular growth and increased interstitial collagen which were not prevented by release of obstruction.

Conclusions: Congenital partial UUO impairs glomerular and proximal tubular growth, and causes additional nephron loss in mice with reduced NN. Release of UUO does not restore glomerular growth and does not preserve tubular mass when NN is reduced. Because tubular injury and fibrosis develop in *both* kidneys of adult Os/+ mice with UUO, the concept of "renal reserve" should include tubular as well as glomerular components. Children with CAKUT should be followed throughout adulthood regardless of earlier surgical intervention.

In Unilateral Ureteral Obstruction Rat Model Mesenchymal Stromal Cells Downregulate Renin-Angiotensin System Inhibiting HuR Chiara Rocca,[1] Marilena Gregorini,[1] Samantha Milanesi,[1] Valeria Corradetti,[1] Eleonora Francesca Pattonieri,[1] Teresa Valsania,[1] Manuela Cannone,[1] Pasquale Esposito,[1] Carolina Bianco,[2] Ilaria Benzoni,[2] Marcello Maestri,[2] Maria Antonietta Avanzini,[3] Ingo Daniela,[3] Teresa Rampino,[1] Antonio Dal Canton.[1] *[1]Nephrology, IRCCS Policlinico San Matteo, Italy; [2]Chirurgia Generale, IRCCS Policlinico San Matteo, Italy; [3]Oncoematologia Pediatrica, IRCCS Policlinico San Matteo, Italy.*

Background: Mesenchymal Stromal Cells(MSC) prevent inflammation and renal scarring in Unilateral Ureteral Obstruction model in rats(UUO) suppressing renin-angiotensin system(RAS),but mechanisms by which MSC exert their effect is unknown. Renin synthesis is critically dependent on renin mRNA(RENmRNA) stability.HuR is a protein that target a cis-element 3'UTR of RENmRNA and regulate renin production.We investigated the mechanisms by which MSC suppress RAS.

Methods: *In vivo*:We studied 3 groups of SpragueDawley rats.MSC were isolated by bone marrow.A:5 sham operated.B:8 UUO received saline at day 0.C:8 UUO received MSC at day 0 via tail vein.Rats were sacrified at days 1 and 7.*In vitro*:HK-2 cell line were cultured in high glucose medium(HK2HG) to induce upregulation of RENmRNA and incubated in presence and absence of MSC,in presence of IL10,and MSC+anti IL10 antibody.Macrophages(M) derived from circulating monocytes(Mo) were isolated by Ficoll density gradient centrifugation and adhesion for 24h.Mo to M shifting phenotype was assessed by FACS flow cytometer.M and MSC were cocultured for 4 days.RENmRNA and HuRmRNA expression were evaluated on renal tissue and on cell lysate by RT PCR.

Results: MSC reduced RENmRNA in C,compared with A and B.At day 1 HuRmRNA expression was significantly higher in rats MSC untreated compared to sham operated rats($p<=0.05$).MSC treatment in C suppressed HuRmRNA expression compared with B($p<0.005$).*In vitro* MSC suppressed RENmRNA expression in HK2HG($p< 0.005$). RENmRNA expression was lower in presence than in absence of IL10($p<0.001$) and increased whether in MSC HK2HG cocultures was added antibody blocking IL10($p<0.001$). MSC suppressed RENmRNA in M.

Conclusions: MSC in UUO model suppress HuR transcription via IL-10.The inhibition of HuR transcription may decrease RENmRNA stability and suppress RAS in UUO.

Phosphodieterase-4 Inhibitor Roflumilast Attenuates Renal Fibrosis in a Rat Model of Chronic Kidney Disease Xianzhong Lau,[1] Yuan Zhang,[1] David Stapleton,[2] Robyn G. Langham,[1] Darren J. Kelly.[1] *[1]Dept of Medicine (St Vincent's), Univ of Melbourne, Fitzroy, Victoria, Australia; [2]Howard Florey Inst, Parkville, Victoria, Australia.*

Background: The prevalence of chronic kidney disease (CKD) is increasing globally. There has been recent interest in the role of Phosphodiesterase (PDE) enzymes in mediating inflammation and fibrosis in acute kidney injury. Given the predominance of cAMP-signaling regulation by PDE4 isoforms in the kidney, we sought to examine the potential efficacy of a selective PDE4 inhibitor, roflumilast (RFL) in abrogating progressive fibrosis of the remnant kidney. Having demonstrated *in vitro* efficacy of RFL, in reducing inflammatory and fibrotic responses to injury in renal cells, the question of potential efficacy of RFL as an effective therapy in *in vivo* renal fibrosis was raised.

Methods: Sprague-Dawley rats underwent either STNx or sham surgery, further randomised after 2 weeks to receive an oral dose of either RFL (1 mg/kg/day) or vehicle, and sacrificed at 12 weeks. Renal function was assessed via glomerular filtration rate (GFR) and urinary protein. Glomerulosclerosis and tubulointerstitial fibrosis were evaluated histologically. Macrophage infiltration was measured with CD68 immunohistochemistry. Gene expression for MCP-1 was evaluated via PCR.

Results: RFL significantly attenuated GFR decline (treated:2.32±0.20 VS untreated:0.96±0.34 ml/min/kg, P<0.05) and proteinuria (treated:199±21 VS untreated:277±27 mg/day, P<0.05) in STNx rats. Histologically, RFL treatment significantly reduced glomerulosclerosis (treated:0.97±0.11 VS untreated:1.59±0.22 AU, P<0.05) and macrophage infiltration (treated:123±9 VS untreated:214±12 count/field, P<0.001), and though a trend towards reduced tubulointerstitial fibrosis was seen, this did not reach statistical significance. MCP-1 gene expression was also significantly lower in the treated group (treated:2.19±0.28 VS untreated:3.10±0.38 AU, P<0.05).

Conclusions: RFL attenuated the functional and structural deterioration in a rat CKD model, at least in part, by reducing inflammation. Therefore, PDE4 inhibition may represent a potential therapeutic target for the treatment of CKD.

Erythropoietin Protects Integrity of Tubular Basement Membrane by Up-Regulating miR-144 Level in Serum Microvesicles Yang Zhou, Jing Niu, Junwei Yang. *Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Chronic kidney disease is characterized by tubulointerstitial fibrosis. Disruption of the integrity of tubular basement membrane (TBM) contributes to renal fibrosis. Tissue plasminogen activator (tPA) is one of the major components in the matrix proteolytic network by activating matrix metalloproteinase (MMP)-9. tPA is the predicted target of miRNA (miR)-144. It was reported by anti-doping researchers that serum miR-144 was up-regulated by erythropoietin (EPO), which was reported to attenuate renal fibrosis. Serum miRNAs are probably encapsulated in microvesicles. Here, we investigated whether EPO protected the integrity of TBM to attenuate renal fibrosis by up-regulating miR-144 in serum microvesicles, which then targeted fibroblasts' tPA expression and inhibited MMP-9 activation.

Methods: Renal tubulointerstitial fibrosis mouse model was induced by unilateral ureteral obstruction (UUO). EPO was administered intraperitoneally at a dose of 1000U/kg body weight every other day. Serum microvesicles were isolated by ultracentrifugation and administered through tail vein injection. Q-PCR, western blot and zymography were applied to evaluate expression of miR-144 and tPA and activity of MMP-9, respectively.

Results: In obstructed kidney, EPO attenuated disruption of TBM, relieved up-regulation of tPA and activation of MMP-9. MiR-144 level in serum microvesicles was up-regulated by EPO. The miR-144-containing microvesicles attenuated TGF-β1-induced up-regulation of tPA and activation of MMP-9 in renal fibroblasts. Moreover, administration of miR-144-containing microvesicles attenuated disruption of TBM and relieved up-regulation of tPA and activation of MMP-9 in obstructed kidney. MiR-144 negatively regulated tPA expression and therefore interfered MMP-9 activation of fibroblasts. Ectopic expression of miR-144 alleviated, while inhibition of miR-144 facilitated TGF-β1-induced up-regulation of tPA and activation of MMP-9 of renal fibroblasts.

Conclusions: These results suggest that EPO protects the integrity of TBM in obstructed kidney by up-regulating miR-144 level in serum microvesicles, which then inhibits the expression of tPA and activity of MMP-9 of fibroblast.

Autophagy Is the Predominant Mediator of TGF-β1-Induced Profibrotic Dedifferentiation in Tubular Epithelial Cells Hailong Wang,[1,2] Min Pang,[1,3] Ye Zhao,[1] Yun Zhang,[1,3] Qi Cao,[1] Yiping Wang,[1] Yuan Min Wang,[4] Stephen I. Alexander,[4] Guoping Zheng,[1] David C. Harris.[1] *[1]Centre for Transplant and Renal Research, Westmead Millennium Inst, Univ of Sydney, Sydney, NSW, Australia; [2]Biochem and Mol Biol, Shanxi Medical Univ, Taiyuan, Shanxi, China; [3]1st Hospital of Shanxi Medical Univ, Shanxi Medical Univ, Taiyuan, Shanxi, China; [4]Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia.*

Background: Autophagy and tubular cell profibrotic dedifferentiation are both increased in kidney fibrosis, but the role of autophagy in kidney fibrosis is controversial, and details of cross-talk between autophagy and profibrotic dedifferentiation are unclear.

Methods: Mouse tubular epithelial C1.1 cells were treated with TGF-β1 in presence or absence of Rapamycin or 3-methyladenine (3-MA) to augment or inhibit autophagy respectively, and to examine the role of autophagy in tubular cell profibrotic dedifferentiation. MG132 and chloroquine or NH_4Cl were used to inhibit proteosomal or lysosomal protein degradation respectively. Smad7 and β-catenin degradation chimera F-TrCP-Ecad plasmids were used to inhibit TGF-β1/Smad and β-catenin signalling.

Results: TGF-β1-induced both autophagy and profibrotic dedifferentiation in C1.1 cells, as demonstrated by increased levels of autophagy markers (beclin 1 and LC3) and vimentin and integrin linked kinase (ILK) with reduction of E-cadherin. Serum rescue or inhibition of autophagy reduced (by more than 90%) while augmentation increased (about 2 fold) TGF-β1-induced profibrotic dedifferentiation. Inhibition of lysosomal but not proteosomal degradation prevented reduction of E-cadherin. Autophagy increased Src kinase, Src kinase-mediatedphosphorylation of Y654-β-catenin (pY654-β-catenin) and pY654-β-catenin/pSmad2 complex formation, while pY654-β-catenin/pSmad2 mediated upregulation of ILK, a known inducer of tubular cell dedifferentiation and fibrosis.

Conclusions: Autophagy accounts for the majority of TGF-β1-induced tubular cell profibrotic dedifferentiation, through pSmad2/pY654-β-catenin-mediated upregulation of ILK. Autophagy is a key target to limit fibrosis.

Targeting Tubulointerstitial Remodeling By Lymphangiogenesis Blockage and Macrophage Depletion in Rat Proteinuric Nephropathy Saleh Yazdani,[1] Ryanne S. Hijmans,[1] Gerjan Navis,[1] Harry Van Goor,[2] Jacob van den Born.[1] *[1]Nephrology, UMCG, Groningen, Netherlands; [2]Pathology, UMCG, Groningen, Netherlands.*

Background: Proteinuria is an important cause of progressive tubulointerstitial damage. We previously showed that proteinuria can trigger renal lymphangiogenesis (LA) before the onset of interstitial inflammation and fibrosis. However, the interrelationship of these tubulointerstitial events is not clear yet. Also, macrophages (MΦs) have shown to be involved in tubulointerstitial remodelling and promoting LA. Therefore, in a proteinuria model we targeted LA (anti-VEGFR3 antibody (IMC-3C5)) and inflammation (deplete monocytes/ MΦs by Clodronate liposomes (CL)) and evaluated interstitial pathology and renal function.

Methods: Proteinuria was induced in 3 month-old male Wistar rats by adriamycin injection (1.8 mg/kg). After 6 weeks, when proteinuria was developed (~200 mg/ml /24hrs), the treatment by IMC-3C5 (Imclone, U.S.A., i.p. 40mg/kg, 3 times/week) and CL (i.p. twice weekly 1 ml) started for another 6 consecutive weeks. At week 12, rats were sacrificed and blood, urine and organs were collected.

Results: : In proteinuric rats, LA (podoplanin+ vessels), inflammation (ED1+ MΦs), and fibrosis (Collagen III, and α-SMA for myofibroblasts) significantly increased at week 12 versus week 6 (all p<0.05). IMC-3C5 completely blocked LA (p<0.0001), diminished interstitialMΦs, and improved plasma creatinine (p<0.05) and urea levels in proteinuric rats. However, LA blocking did not prevent α-SMA expression, collagen III deposition and progression of proteinuria. Additionally, CL significantly reduced MΦ influx into kidney (p<0.05), partly reduced α-SMA expression, however, neither prevented LA, fibrosis and proteinuria, nor improved renal function.

Conclusions: This study showed the dissociation of renal LA from inflammation (MΦ), and to some extent from profibrotic/fibrotic response (α-SMA and Collagen III), at least in this proteinuric model. It seems that, opposite to several earlier reports both in renal diseases and other organs, MΦs are not the main player in inducing LA in proteinuric kidneys. Moreover, blocking LA evidently reduced plasma creatinine/urea which might be therapeutically relevant in proteinuric conditions.

SA-PO373

Macrophage Phenotypes in Acute and Chronic Kidney Disease Magnus Soderberg,[1] Alan Sabirsh,[1] Johan C. Molne.[2] *[1]AstraZeneca R&D, Sweden; [2]AstraZeneca R&D, Sweden; [3]Sahlgrenska Univ Hospital, Sweden.*

Background: Macrophages (MØ) play an important role in the progress of kidney disease. In animal models, modifications of MØ phenotype (M1/M2) have been described that retard disease progression, leading to the assumption that steering MØ response from a "pro-inflammatory" M1 type towards a "pro-reparative" M2 type is a target for therapeutic intervention. However, there is currently a lack of scientific data on the phenotypic profiles of MØ subsets in human kidney disease.

Methods: Renal biopsies from healthy renal transplant donors and from patients with renal disorders have been used, including 5 patients each with diabetic nephropathy (DN), IgA nephropathy (IgAN), acute transplant rejection and chronic transplant rejection. Immunohistochemistry was done using CD68 as a pan-MØ marker. MØ subtype phenotyping was performed using: M1: CD80; M2a: CD206; M2b: IL10; M2c: CD163. Dendritic cells were identified using CD1a and CD83. Positive cells were counted manually using light microscopy or automated using image analysis.

Results: A limited number of MØ were found in healthy controls. All disease groups showed increased MØ infiltration revealed by CD68 stain; the increase was 4-fold in IgAN, 5-fold in DN and 6-fold in rejection. M1 MØ were few (<2% of total MØ in controls), with no clear increase in any disease. M2a was the dominating MØ subtype (>90% of all MØ in all groups). M2a increased 1.5-fold in IgAN and 2.5-fold in DN and rejection. M2b and M2c were few (<1 % each of total MØ in controls). M2b increased 10-fold in IgAN, 20-fold in rejection and 25-fold in DN. M2c doubled in rejection, but did not change in DN or IgAN. M2b and M2c varied considerable between individuals within disease groups. Dendritic cell presence was minimal, except in chronic disease when positive cells appeared in intrarenal lymphoid follicles.

Conclusions: Proper interpretation of MØ response in human kidney must take both type of disorder and stage of disease development into account. The observations of M2a domination both in acute and chronic renal disease and the limited contribution and response of the M1 phenotype in disease challenge the current paradigm of the M2 response being the more benign.

RNA-seq Profiling of S1 Proximal Tubules Microdissected from the Uninephrectomized Rats

Jae Wook Lee, Mark A. Knepper. *Systems Biology Center, NHLBI, NIH, Bethesda, MD.*

Background: Nephron hypertrophy occurs as a compensatory response to reduction in nephron mass. To identify early gene expression changes in nephron hypertrophy, we measured global gene expression in microdissected S1 proximal tubules of the contralateral kidney of uninephrectomized rats using next-generation sequencing of RNAs (RNA-seq).

Methods: 5-week-old male Sprague-Dawley rats received uninephrectomy (U, n=4) or sham surgery (S, n=4). 48 hours after surgery, S1 proximal tubules (8 mm per each animal) were microdissected under a stereomicroscope. Poly(A)'-tailed mRNAs were reverse-transcribed and the adapter-ligated cDNA libraries were sequenced using an Illumina HiSeq2000 platform. FASTQ sequences obtained were mapped to rat reference genome. Expression levels are calculated for RefSeq transcripts in terms of reads per kilobase exons per million mapped reads (RPKMs).

Results: The contralateral kidneys in uninephrectomized rats were heavier than their sham counterparts (0.87±0.11 g/100 g BW in U versus 0.76±0.09 in S). Each library had 35-42 million reads and more than 80% of reads were uniquely aligned to the reference genome. There were 6093-7995 RefSeq transcripts detected in individual samples with RPKM > 1. Using dual statistical criteria (U/S ratios outside of 95% confidence interval for S/S ratios and $p<0.05$ for t-test, "volcano plot") giving a conservative criterion for changes, more transcripts were downregulated (41) than upregulated (8). Among these were *Zfp36*, an immediate early gene induced by growth factors as well as a secreted growth factor (*Ctgf*) and several modulators of growth-factor signaling (*Errfi1*, *Igfbp1*, and *Igfbp3*). Also downregulated were three regulators of cell cycle (*Pim3*, *Plk3* and *Rgcc*), a scaffold/ubiquitin E3 ligase (*Sh3rf1*, also known as 'plenty of SH3 (POSH)'), and two glucocorticoid-regulated genes (*Sgk1* and *Tsc22d3*). Upregulated transcripts included a transcription factor (*Hnf1b*).

Conclusions: The RNA-seq method is applicable at the level of single microdissected tubules and that the overall method is sufficiently facile to allow us to map transcriptional responses over a full set of time points after uninephrectomy in S1 proximal tubules and other relevant structures.

Kidney Angiotensin and Bradykinin Levels Are Decreased in Captopril-Treated Uninephrectomized Fawn-Hooded Hypertensive Rats

Michael G. Janech,[1] Wayne R. Fitzgibbon,[1] John M. Arthur,[1,2] Juan Carlos Q. Velez.[1,2] *[1]Medicine/Nephrology, Medical Univ of South Carolina, Charleston, SC; [2]Dept of Veterans' Affairs Medical Center, Charleston, SC.*

Background: The intrarenal renin-angiotensin system is a therapeutic target of glomerular disease. We previously reported the effect of chronic intravenous infusion of angiotensin (Ang) 1-7 and Ang2-10 in comparison to captopril on severity of kidney damage in uninephrectomized fawn-hooded hypertensive rats (Unx-FHH). Here we report on the intrarenal concentrations of Ang peptides, bradykinin (BK) 1-9, and their relationship with hemodynamic/renal outcomes.

Methods: AngI, AngII, Ang2-10, Ang1-7 and BK1-9 levels were determined using liquid chromatography tandem mass spectrometry.

Results: Vehicle-treated rats developed hypertension and lesions of FSGS. Both hypertension and renal disease were markedly attenuated by captopril treatment. Tissue AngII levels were 1.4 fold lower in the captopril- versus vehicle-treated groups (3.3+/-0.8 versus 5.5+/-1.6 fmol/mg, respectively, $p<0.05$), which is consistent with Ang converting enzyme inhibition. Paradoxically, although we predicted a rise in BK1-9 in captopril–treated rats due to inhibition of BK degradation, tissue BK1-9 levels were 2.2 fold lower in animals treated with captopril versus control (12.8+/-4.3 versus 28.4+/-11.1 fmol/mg, respectively, $p=0.006$). Correlation analysis of all Ang and BK peptide levels at 30 weeks showed positive correlations between BK1-9 levels and urine volume ($R=0.46$, $p<0.01$), blood pressure ($R=0.63$, $p<0.001$), and Ang1-7 ($R=0.48$, $p<0.01$). In contrast, AngII levels were only significantly correlated with kidney weight normalized to body weight ($R=0.38$, $p<0.05$), Ang2-10 ($R=0.55$, $p<0.001$), and Ang1-7 ($R=0.45$, $P<0.001$). Ang1-7 levels were correlated to urine volume ($R=0.46$, $p<0.01$). No peptide correlated to proteinuria.

Conclusions: The counterintuitive finding that BK1-9 levels are reduced in response to captopril suggests downregulation of the renal bradykinin system under conditions of reduced levels of AngII. Further, intra-renal BK1-9 may contribute to the regulation of renal function in Unx-FHH.

Combination Treatment with ACE Inhibitor and Nicorandil in the Rat Remnant Kidney Model

Takeshi Shiraishi,[1] Yoshifuru Tamura,[1] Shigeru Shibata,[1] Richard J. Johnson,[2] Shunya Uchida.[1] *[1]Teikyo Univ School of Medicine, Tokyo, Japan; [2]Univ of Colorado Denver, Aurora, CO.*

Background: An inhibition in the renin-angiotensin system is one of the most widely used therapies to treat chronic kidney disease. However, its effect is not sufficient and in such cases, additional treatment is required. Recently, we reported that nicorandil exhibited renoprotective effects in a mouse model of diabetic nephropathy. Here we examined if nicorandil can provide an additive protection on enalapril in chronic kidney disease.

Methods: RK rats were divided into five groups: Sham operated rats (n = 6), remnant kidney (RK) rats without treatment (n = 6), RK rats treated with enalapril 2 mg/kg/day (Ena, n = 6), RK rats treated with nicorandil 15 mg/kg/day (Nico, n = 6), RK rats treated with Ena + Nico (Ena + Nico, n = 6). Twelve weeks later, the rats were sacrificed.

Results: Single treatment with either enalapril or nicorandil significantly ameliorated Ccr, proteinuria and histological injury in the kidney of RK model whereas the combination of these two compounds provided additive effects (Table). In addiiton, an increase in oxidative stress was also blocked by either enalapril or nicorandil while the combination of the drugs was more potent. A mechanism was likely due for nicorandil to preventing MnSOD and sirtuin-3 from being reduced in injured kidneys.

	Ccr	Proteinuria	Glomeruli	Tubulointerstitium
	ml/min/100g	mg/day	CollagenIV (+) area (%)	CollagenIII (+) area (%)
Sham	0.72±0.08**††	4.2±2.3**	11.9±1.8**	5.4±1.1**
RK	0.13±0.07††	98.5±42.0††	34.5±8.9††	24.7±0.3††
Ena	0.23±0.02*†	55.3±38.0**††	23.2±2.7**††	14.6±0.8**††
Nico	0.30±0.07**	69.6±26.0*††	22.1±2.7**†	14.5±1.4**††
Ena+NIco	0.34±0.04**	19.0±6.8**	13.8±2.2**	7.1±1.5**

**p<0.01, *p<0.05 vs RK, ††p<0.01, †p<0.05 vs Ena+Nico

Conclusions: Nicorandil can be added on enalapril to obtain further protection in the patients with chronic kidney disease.

Chronic Angiotensin II Infusion Causes Kidney Angiotensin II Accumulation and Aggravated Glomerular Injury in Aminopeptidase A-Deficient Mice

Juan Carlos Q. Velez, Michael G. Janech, John M. Arthur, Wayne R. Fitzgibbon. *Div of Nephrology, Dept of Medicine, Medical Univ of South Carolina, Charleston, SC.*

Background: The intrarenal renin-angiotensin system is a therapeutic target in progressive proteinuric glomerular diseases. Aminopeptidase A (APA) is abundantly expressed in the kidney and metabolizes angiotensin (Ang) peptides at the amino terminus. However, it is not known whether APA is renoprotective in Ang II-mediated hypertensive kidney disease.

Methods: We tested the effect of a 3-week subcutaneous administration of Ang II (400 ng/kg/min) via osmotic mini-pumps in BALB/c APA-deficient (APA-KO) and wild-type (WT) mice. Systolic blood pressure (SBP) was measured by tail-cuff, urine albumin-to-creatinine ratio (UACR) was determined by ELISA, and intrarenal Ang peptide content was measured by liquid chromatography/tandem mass spectrometry.

Results: Baseline SBP was not different between APA-KO and WT mice (104 ± 3 versus 103 ± 2 mmHg). Although no significant difference was found in SBP after chronic infusion of Ang II between the strains (220 ± 4 versus 216 ± 6 mmHg), APA-KO mice developed a significant rise in UACR that was not observed in WT controls (245 ± 106 versus 28 ± 10 μg/mg, for APA-KO and WT, respectively; $p=0.009$). Under baseline conditions, the intrarenal concentration of Ang II was similar between groups. Following chronic Ang II infusion, the intrarenal concentration of Ang II in APA-KO mouse kidneys was significantly greater than that observed in WT controls (16 ± 4 versus 7 ± 3 fmol/mg, for APA-KO and WT, respectively; $p=0.005$). On histology, arterial wall thickening was noted in renal vessels in both groups. Furthermore, focal areas of glomeruli with near total collapse and markedly dilated tubules filled with proteinaceous material were found in kidneys of APA-KO mice, while those abnormalities were absent in WT mouse kidneys.

Conclusions: These data demonstrate that deficiency of APA increases Ang II-mediated hypertensive kidney injury, supporting a protective role for APA in Ang II-mediated kidney disease, likely explained by APA-mediated degradation of Ang II to Ang III and diversion of Ang I conversion to Ang 2-10.

SA-PO378

Renin Angiotensin System (RAS) Blockade Attenuates Growth and Metastasis Formation of Renal Cell Carcinoma in Mice Wedson Araujo,[1] Juliana N. Ravanini,[2] Josne Carla Paterno,[1] Marcelo Andery Naves,[1] Nestor Schor,[1] Vicente De Paulo Castro Teixeira.[1] *[1]Medicine / Nephrology Div, Univ Federal de Sao Paulo/EPM, Sao Paulo, Brazil; [2]Pathology, USP, Sao Paulo, Brazil.*

Background: Renal cell carcinoma (RCC) is the most frequent cancer among renal neoplasms in adults and poor responsive to radio-, chemo- and immunotherapy There is increasing evidence that blockade of RAS has antineoplasic effects. Objective: Investigate the effects of RAS blockade on renal cell carcinoma (RCC) in a murine model.

Methods: Murine renal cancer cells (RENCA) were cultivated and injected ($1x10^5$) into subcapsular space of the left kidney of BALB/c mice (8 weeks). The animals were divided into 4 groups : control group (no treatment), Losartan (100 mg / kg / day), Captopril group (10 mg / kg / day) and Losartan + Captopril group (100 mg / kg / day + 10 mg / kg / day). The animals received the drugs by gavage 2 days before tumor induction and continued until euthanasia (21 days after inoculation). After sacrifice, kidneys and lungs were removed, weighed and processed for histopathological. Angiogenesis and vascular microvessel were determined by immunohistochemical evaluation for VEGF and CD34. The statistical significance of the results was evaluated by ANOVA followed by Tukey test.

Results: All inoculated animals developed renal tumor. Treated animals presented smaller tumors, regardless the therapeutic regimen and far fewer lung metastases in both quantity and dimension in relation to controls. The expressions of VEGF and CD34 were significantly decreased in renal tumors of animals treated when compared with controls.

Conclusions: Our findings suggest that blockade of RAS decrease the tumor proliferation capacity and metastatic potential of renal cell carcinoma in this experimental model.

SA-PO379

Blockade of Wnt/β-Catenin Signaling Ameliorates Hypertension and Kidney Injury By Targeting Renin-Angiotensin System Liangxiang Xiao,[1] Lili Zhou,[1] Fan Fan Hou,[1] Youhua Liu.[2] *[1]State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical Univ, Guangzhou, Guangdong, China; [2]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Local activation of the intra-renal renin-angiotensin system (RAS) plays a critical role in mediating hypertension and chronic kidney diseases. As Wnt/β-catenin regulates multiple RAS genes in the kidneys, we speculated that this developmental signaling might be linked to blood pressure regulation and kidney pathology after injury.

Methods: To test this hypothesis, we investigated the role of β-catenin in regulating RAS activation, hypertension and kidney injury in rat remnant kidney model induced by 5/6 nephroectomy (5/6NX).

Results: At 12 weeks after 5/6NX, renal β-catenin was markedly up-regulated predominantly in renal tubular epithelium. Delayed administration of a small molecule β-catenin inhibitor (ICG-001), starting at 6 weeks after 5/6NX, substantially reduced albuminuira, serum creatinine and blood urea nitrogen. Interestingly, ICG-001 blunted blood pressure elevation in 5/6NX rats, and markedly alleviated renal fibrotic lesions. Renal expression of fibronectin, collagen I, collagen III and plasminogen activator inhibitor 1 was reduced. ICG-001 also inhibited renal infiltration of $CD3^+$ T cells and $CD68^+$ monocytes/macrophages. Subtotal renal ablation by 5/6NX induced multiple RAS components such as agiotensinogen, renin and angiotensin type I receptor in the kidneys. However, inhibition of β-catenin signaling by ICG-001 dramatically blocked their induction. In vitro, incubation with losartan, an angiotensin type I receptor blocker, prevented Wnt/β-catenin-mediated fibronectin, α-smooth muscle actin and Snail1 expression, suggesting that the fibrogenic action of Wnt/β-catenin is dependent on RAS activation.

Conclusions: These results illustrate that hyperactive Wnt/β-catenin signaling drives hypertension and kidney damage via RAS activation after subtotal renal ablation.

Sustained Activation of Wnt/β-Catenin Signaling Drives AKI to CKD Progression Liangxiang Xiao,[1] Dong Zhou,[1] Roderick J. Tan,[2] Haiyan Fu,[1] Lili Zhou,[3] Fan Fan Hou,[3] Youhua Liu.[1] *[1]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA; [3]State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical Univ, Guangzhou, Guangdong, China.*

Background: Acute kidney injury (AKI) is increasingly recognized as a major risk factor leading to subsequent progression to chronic kidney disease (CKD). However, what factors govern AKI to CKD progression remains poorly understood.

Methods: In this study, we investigated this issue by using both moderate (20 min) and severe (30 min) ischemia/reperfusion injury (IRI) in mice.

Results: Moderate IRI led to acute kidney failure and transient Wnt/β-catenin activation, which was followed by the restoration of kidney morphology and function. However, severe IRI resulted in sustained Wnt/β-catenin activation, which was accompanied by development of renal fibrotic lesions characterized by interstitial myofibroblast activation and excessive extracellular matrix deposition. To ascertain the role of sustained Wnt/β-catenin in AKI to CKD progression, we manipulated this signaling by either over-expression of Wnt ligand or pharmacologic inhibition of β-catenin. At 5 days after IRI, over-expression of Wnt1 in vivo induced β-catenin activation and accelerated AKI to CKD progression. Conversely, blockade of Wnt/β-catenin by small molecule ICG-001 prevented AKI to CKD progression. In vitro, Wnt ligands induced myofibroblastic activation of fibroblasts. However, activated myofibroblasts readily returned to quiescent fibroblast phenotype after Wnts were removed.

Conclusions: These results indicate that sustained, but not transient, activation of Wnt/β-catenin signaling plays a decisive role in AKI to CKD progression.

Lubiprostone Ameliorates the Progression of Chronic Kidney Disease By Altering the Intestinal Environment Eikan Mishima,[1] Shinji Fukuda,[2] Yasutoshi Akiyama,[1] Hisato Shima,[1] Sadayoshi Ito,[1] Takaaki Abe.[1] *[1]Tohoku Univ, Sendai, Japan; [2]Keio Univ, Japan.*

Background: The accumulation of uremic toxins is involved in CKD progression. It is well known that various uremic toxins are derived from gut microbiota and that an imbalance of gut microbiota is related to renal failure. In CKD, the intestinal environment is reported to be adversely altered. However, the pathophysiological mechanisms underlying the relationship between the gut microbiota and renal failure are still obscure.

Methods: Using an adenine-induced renal failure mouse model, we evaluated the potentially beneficial effects of the ClC-2 chloride channel activator lubiprostone, commonly used for constipation treatment, on CKD. Intestinal and fecal properties were evaluated. Renal fibrosis and inflammation were evaluated with histology, IHC and quantitative PCR. Gut microbiome was analyzed at the genus level by pyrosequencing of microbial 16S rRNA genes with the next generation sequencer.The plasma concentration of various uremic solutes was measured by capillary electreophoresis-masss pectrometry (CE-MS)-based metabolome analysis.

Results: Oral administration of lubiprostone (500 μg/kg/day) changed the fecal properties and reduced the collagen deposition in the colon of the renal failure mice. Lubiprostone treatment also reduced the elevated blood urea nitrogen and protected against tubulointerstitial damage, renal fibrosis and inflammation. Gut microbiome analysis in the renal failure mice showed that lubiprostone treatment altered their microbial composition, especially the recovery of the level of the *Lactobacillaceae* family and *Prevotella* genus, which were significantly reduced in the renal failure mice. Furthermore, CE-MS-based metabolome analysis showed that lubiprostone treatment decreased the plasma level of uremic toxins, such as 3-indoxyl sulfate and hippurate, which are derived from gut microbiota as well as newly identified uremic toxin, trans-aconitate.

Conclusions: This suggests that lubiprostone ameliorates CKD progression and uremic toxin accumulation through an improvement of the gut microbiota and intestinal environment.These findings provide supporting evidence to recent reports on the gut-kidney axis.

Differential Roles of C5a Receptors C5aR and C5L2 in Kidney and Liver Fibrosis Ina V. Martin,[1] Annika Bohner,[2] Peter Boor,[1] Frank Lammert,[2] Jürgen Floege,[1] Tammo Ostendorf,[1] Susanne N. Weber.[2] *[1]Nephrology, Univ Hospital, RWTH, Aachen, Germany; [2]Gastroenterology, Saarland Univ Hospital, Homburg, Germany.*

Background: Complement factor C5a has two known receptors, C5aR and C5L2. C5aR is involved in transduction of the proinflammatory effects of C5a, whereas C5L2 has been suggested as a decoy receptor. We previously demonstrated a pro-fibrotic role of C5a and C5aR in kidney and liver, but nothing is known concerning the potential involvement of C5L2 in organ fibrosis.

Methods: $C5L2^{-/-}$-, $C5aR^{-/-}$- and wildtype (WT) control mice were subjected to 5 days of unilateral ureteral obstruction (UUO), a model of renal fibrosis, or liver fibrosis by CCl_4-treatment for 6 weeks. Extracellular matrix (ECM) deposition, the inflammatory status and injury markers were analyzed by gene expression analyses and immunohistochemistry.

Results: During progression of kidney fibrosis both C5a receptors are overexpressed. Compared to WT, C5aR deficiency led to a significant reduction of renal collagen I and IV, fibronectin, αSMA and vimentin mRNA. At the protein level similar changes were observed. Renal infiltration of macrophages and CCL2, CCL5 and TNFα expression did not change in $C5aR^{-/-}$-mice versus WT. In contrast, C5L2 deficiency in renal fibrosis resulted in only mild reduction of ECM compared to WT, whereas CCL2, CCL5, IL6 and TNFα expression increased. Accordingly, there was a trend towards increased renal infiltration of macrophages in $C5L2^{-/-}$-mice. Transcripts of TGFβ and KIM1 were markedly reduced in both, $C5aR^{-/-}$- and $C5L2^{-/-}$-mice versus WT. In liver fibrosis, collagen contents were significantly lower in $C5aR^{-/-}$- but unchanged in $C5L2^{-/-}$-mice. Transcript analyses of cytokines in the chronic fibrosis model (TGFβ, TNFα, IL6, IL10, IL12, IL23, IL27) showed a prominent reduction in both receptor-deficient mice versus WT. One day after an acute single CCl_4-challenge, these cytokines were highly upregulated specifically in $C5L2^{-/-}$-mice versus WT and $C5aR^{-/-}$-mice.

Conclusions: In conclusion, C5aR is involved in chronic fibrogenesis in both liver and, albeit less potently, also in the kidney. In the liver, C5L2 provides protection from early inflammatory insults, and in kidney fibrosis C5L2 might also play an anti-inflammatory role.

SA-PO383

Loss of Expression of the SMAD2/3 Phosphatase, PPM1a during Kidney Fibrosis Promotes a Maladaptive Repair Response Rohan Samarakoon,[1] Nidah S. Khakoo,[1] Amy D. Dobberfuhl,[2] Sevann Helo,[2] Lucas Falke,[3] Jessica Overstreet,[1] Roel Goldschmeding,[3] Paul J. Higgins.[1] *[1]Center for Cell Biology and Cancer Research, Albany Medical Center, Albany, NY; [2]Div of Urology, Albany Medical Center, Albany, NY; [3]Dept of Pathology, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: Deregulation of negative regulators of TGF-βeta1 pathway (e.g., BMP-6/7, Ski, SMAD7) are documented in the progression of kidney disease. PPM1a is a recently identified c-terminal SMAD2/3 phosphatase that inhibits TGF-βeta signaling. The role of PPM1a in renal fibrosis, however, is unknown.

Methods: Ureteral unilateral obstruction (UUO) and Aristololic acid nephropathy (AAN) mouse models and genetic manipulation in HK-2 tubular epithelial cells and NRK-49F renal fibroblasts were utilized to investigate role of PPM1a in fibrosis.

Results: PPM1a expression is dramatically decreased in UUO and AAN-injured kidneys both in the tubular and interstitial regions, correlating with increased pSMAD3 and fibrosis marker expression. Stable gene silencing of PPM1a in HK-2 cells further enhanced TGF-βeta1 induced pSMAD3 activity and PAI-1, fibronectin and CTGF target gene expression. Conversely, transient PPM1a overexpression suppressed this response. Prolonged loss of PPM1a by stable RNA interference initiates pSMAD3 activation as well as PAI-1, CTGF and fibronectin, vimentin and alpha-SMA induction while transient PPM1a gene depletion in NRK-49Fs promotes a fibro-proliferative response. Nuclear levels of PPM1a are dramatically reduced by PTEN knockdown, enhancing SMAD3 activation and PAI-1 induction. These responses are reversed by ectopic PPM1a expression in PTEN depleted HK-2 cells.

Conclusions: A negative regulator of the SMAD2/3 pathway, prolonged PPM1a gene silencing initiated renal mesenchymal gene induction and proliferative arrest in tubular epithelial cells. PTEN is an upstream regulator of PPM1a as loss of PTEN promotes PPM1a mislocalization and a SMAD3-dependent renal fibrotic phenotype.

Increased Expression of Par1a/1b in Proximal Tubular Injury in Murine Kidneys Natalie S. Uy,[1] Samriti Dogra,[1] Jennifer R. Charlton,[2] Michael S. Forbes,[2] Robert L. Chevalier,[2] Sanjeev Gupta,[3] Kimberly J. Reidy.[1] *[1]Pediatric Nephrology, Children's Hospital at Montefiore, Bronx, NY; [2]Pediatric Nephrology, Univ of Virginia, Chralottsesville, VA; [3]Dept of Gastroenterology, Albert Einstein College of Medicine, Bronx, NY.*

Background: Apico-basal polarity is required for directional transport by renal epithelial cells. Defects in apico-basal polarity occur in kidney diseases such as acute kidney injury (AKI) and obstructive nephropathy. Partitioning defective Par1 is a serine-threonine kinase that localizes to the basolateral aspect of cells and establish apico-basal polarity in vitro. Mammlian homologues Par1a and 1b are functionally redundant on kinase assays and appear to compensate for one another in vivo. We have recently examined the role of Par1a/b in vivo and identified a role for Par1a/b in establishing proximal tubular polarity in developing mouse kidneys. Par1a/b proteins are highly expressed in developing kidneys and down-regulated in the adult. We hypothesized that Par1a/b would be re-expressed in the setting of kidney injury and sought to define Par1a/b expression in the setting of tubular injury.

Methods: We examined expression of Par1a and 1b using immunofluorescence with homologue specific antibodies in two models of renal tubular injury as compared to adult controls. Adult mice underwent unilateral ureteral obstruction (UUO) by complete ligation of the left kidney ureter. Kidneys were examined 14 days after obstruction. To examine the effect of proximal tubular toxin, we examined Par1a/b expression in kidneys from cisplatin treated mice (20 mg/kg).

Results: In controls, Par1a/b expression was almost completely absent in adult proximal tubules. Increased expression of both Par1a and 1b was identified in both UUO injury and cisplatin-induced AKI. Par1a/1b expression localized predominantly at the basolateral aspect of proximal tubules.

Conclusions: Par-1a are 1b are required for normal kidney development, but are downregulated in the adult. We identified up-regulation of Par1a/b in the setting of two mouse models of tubular injury, suggesting the possibility that re-expression of Par1a/1b and apico-basal polarity signaling may contribute to tubular repair.

SA-PO385

L-Carnitine Reverses the Effect of Maternal Smoking on Renal Oxidative Stress and Mitochondrial Dysfunction Stefanie Stangenberg,[1] Long The Nguyen,[2] Ibrahim Al-Odat,[2] Hui Chen,[2] Martin Edward Gosnell,[3] Carol A. Pollock,[1] Sonia Saad.[1] *[1]Kolling Inst of Medical Research, Univ of Sydney, Australia; [2]School of Medical and Molecular Sciences, Univ of Technology, Sydney, Australia; [3]Macquarie Univ, Sydney, Australia.*

Background: Maternal smoking has been associated with underdevelopment of fetal/neonatal organs and low birth weight, which is closely linked to a susceptibility to chronic kidney disease (CKD) in later life. Evidence suggests that oxidative stress and mitochondrial dysfunction may play a role. L-carnitine is a nutritional supplement that was shown to benefit both antioxidant defense and mitochondrial performance in different disorders, however its role in the kidney is not known.

Methods: Balb/c mice were sham exposed to air or exposed to cigarette smoke from 2 cigarettes twice daily for 6 weeks before mating, throughout gestation and lactation. A subgroup of smoke exposed (SE) mice received L-carnitine in drinking water. Offspring's kidneys were harvested at birth, weaning and adulthood. Mitochondrial function was examined by levels of oxidative phosphorylation (OXPHOS) enzymes, mitochondrial protein (TOM20) and antioxidant levels of Manganese Superoxide Dismutase (MnSOD) and Glutathione Peroxidase (GPX-1).Oxidative stress was evaluated by determining total and mitochondrial reactive oxygen species (ROS). Body and kidney weight and and glucose tolerance were also measured.

Results: L-carnitine reversed low birth weight, glucose intolerance and high levels of ROS in the SE offspring. Maternal smoke exposure caused a significant reduction in most of the OXPHOS complexes, TOM20, MnSOD and GPX-1 at birth and adulthood, which were normalized under L-carnitine supplementation.

Conclusions: L-carnitine significantly reduces renal oxidative stress and mitochondrial dysfunction in offspring of smoke exposed mothers. This suggests a potential role for L-carnitine in preventing CKD.

SA-PO386

The Effect of Maternal Smoking on Mitochondrial Structure and Function in Offspring Kidneys Stefanie Stangenberg,[1] Long The Nguyen,[2] Ibrahim Al-Odat,[2] Hui Chen,[2] Martin Edward Gosnell,[3] Carol A. Pollock,[1] Sonia Saad.[1] *[1]Kolling Inst of Medical Research, Univ of Sydney, Sydney, Australia; [2]School of Medical and Molecular Sciences, Univ of Technology, Sydney, Australia; [3]Macquarie Univ, Sydney, Australia.*

Background: The role of an adverse in-utero environment on programming of chronic adulthood diseases is emerging. Maternal smoking during gestation is associated with low birth weight and increased oxidative stress in mothers and newborns. The association between low birth weight and chronic kidney disease in later life is well described, however the mechanisms underlying such susceptibility remain unknown.

Methods: Female Balb/c mice were sham or cigarette smoke exposed (SE) for 6 weeks before mating, throughout gestation and lactation. Male offspring were sacrificed at day 1, day 20 (weaning) and week 13 (adulthood). Blood and urine were collected, kidneys were harvested to determine oxidative stress and mitochondrial function. Oxidative stress was assessed by CellROX® and localized by Mitotracker® co-stain. Mitochondrial structure was examined by electron microscopy. Mitochondrial copy number was determined by real-time PCR. The activity of mitochondrial superoxide dismutase (MnSOD) and levels of the oxidative phosphorylation (OXPHOS) complexes I-V and translocase of outer mitochondrial membrane (TOM20) protein were determined.

Results: Offspring from SE mothers had low birth weight and increased albumin/creatinine ratio at adulthood. Kidneys of SE offspring had fewer and enlarged mitochondria at adulthood while oxidative stress was increased and localized to mitochondria. OXPHOS enzyme levels, TOM20 and MnSOD level and activity were significantly reduced at birth and adult age but not at weaning.

Conclusions: Maternal smoking leads to oxidative stress, structural mitochondrial changes and mitochondrial dysfunction as well as adult onset albuminuria in the offspring kidney. The mitochondrial dysfunction and reduced antioxidant capacity may predispose to further renal damage in the setting of other insults.

SA-PO387

Mitigation of Radiation Injury by Low Anti-Oxidant Diet Eric P. Cohen,[1] Brian L. Fish,[1] Meetha Medhora,[1] Jessica Flowers,[2] John E. Moulder.[1] *[1]Radiation Oncology, Medical College of Wisconsin, Milwaukee, WI; [2]Nutrition, Harlan Laboratories, Madison, WI.*

Background: Oxidative stress may be a significant mechanism of renal injuries. Radiation causes prompt oxidative stress (OS) and has been hypothesized to cause chronic OS, with fibrosis and organ failure. We tested the chronic OS hypothesis by using low anti-oxidant diets.

Methods: Radiation nephropathy (rad np) was created by 11 Gy single fraction total body irradiation (rads) with one leg shielded to avoid early hematologic death. Rad np and renal failure determine survival in this model. Low antioxidant diets (modified AIN-76A) were started 2 weeks before or 1 week after rads to test the effect of low antioxidant status on development and progression of rad np. Starting one week after injury is mitigation; the modifying agent starts after the initiating injury but before its expression. The standard diet was Teklad 8904, which has complex ingredients: corn, wheat, and soybean meal. The AIN-76A diets (casein or soy versions) have refined ingredients and reduced antioxidants compared to 8904. All 3 diets have typical levels of protein (18-24%), sodium (0.1-0.3%), and polyunsaturated fat (2-2.9%). Body weight, survival and renal function were monitored. Results are medians for weight, BUN and survival. ANOVA was used for statistical comparisons, * is $p < 0.05$ versus standard diet.

Results:

Diet	8904	AIN pre	AIN mitig-casein	AIN mitig-soy
weight, grams, 17 weeks	200	214	228*	233*
BUN, mg%, 21 weeks	180	300	40*	60*
Survival, days	152	126	228*	192*

The low anti-oxidant diet started before rads does not protect but instead exacerbates injury as expected, but when started 1 week after irradiation it mitigates rad np. The protein source did not change this unexpected mitigation benefit.

Conclusions: 1) These data do not support a major role for chronic oxidative stress in rad np, consistent with genomic and biochemical evidence. 2) The low anti-oxidant diet mitigation benefit compares favorably to past studies of captopril in this model. 3) Low anti-oxidant diets could be used to test the role of chronic OS in non-radiation models of renal injury. 4) Diets may exert unsuspected effects: diet must be taken into account in any renal injury model.

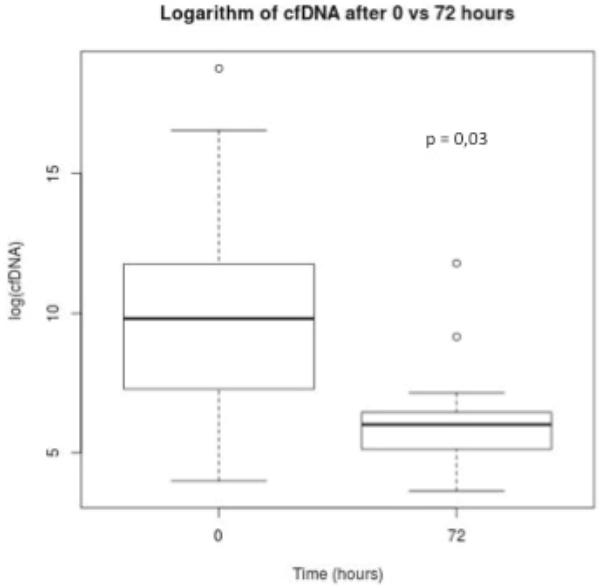
Impact of Mild Therapeutic Hypothermia on Cell-Free DNA

Grazia Maria Virzì,[1] Silvia De Rosa,[1,2] Massimo de Cal,[1] Stefano Marcante,[1] Alessandra Brocca,[1] Silvia Pastori,[1] Enrico Tonini,[1] Massimo Antonelli,[2] Claudio Ronco.[1] *[1]Nephrology and Dialysis, International Renal Research Inst (IRRIV), San Bortolo Hospital, Vicenza, VI, Italy; [2]Intensive Care and Anaesthesiology, Univ Cattolica del Sacro Cuore, Rome, RM, Italy.*

Background: There is growing interest in using hypothermia to prevent hypoxic damage in experimental models, although the mechanisms regulated by hypothermia are still unclear.Cell-free DNA (cfDNA)is a circulating extracellularDNA fragment that originates from necrotic and apoptotic cells derived from infiammation and tissue damage.The study examined the effect of Mild Therapeutic Hypothermia (MTH) on plasma cfDNA levels to evaluate the antiapoptotic effects of MTH.

Methods: We performed a observational study of 19 patients resuscitated from out-of-hospital cardiac arrest.On Admission time and at 72 hours after the start of MTH, we collected EDTA blood samples.The cfDNA was extracted from plasma and quantified by Real time PCR in Genome Equivalent (GE)/ml for β-globin gene.We applied a linear trasformation of cfDNA in log cfDNA to manage the data better.

Results: Mean age was 66 ± 11, 16(84%)males, 14(80%)experienced ventricular dysrhythmia as the primary rhythm of arrest,14(74%) survived, and 12(63%)GCS 15 at discharge.The concentration range of cfDNA in plasma at time 0 was 15566 GE/ml(IQR 15686 – 132985).The median concentration of cfDNA at 72 hours was 410 GE/ml(IQR166 - 630);We observed an significantly descease in cfDNA levels after 72 hrs of MTH(p<.05)



Conclusions: In conclusion,we observed from our data that the MHT induced a decrease of cfDNA levels.Thus,it could be associated with an antiapoptotic and antinecrotic effect of this treatment.Our results provide new evidence concerning the protective mechanism of hypothermia in vivo.

NEFA Induces Tubular Damage via CPT-1 Inhibition and Energy Depletion and Could Be Reversed By Malonyl-CoA Modulation

Sebastian Mas,[1,2] Enrique Bosch,[1,2] Esther Civantos,[1,2] Olha Zhenyukh,[1,2] Jesus Egido.[1,2] *[1]Renal, Vascular and Diabetes Research Laboratory, IIS-FJD. Univ Autonoma Madrid, Spain; [2]Spanish Biomedical Research Centre in Diabetes and Associated Metabolic Disorders (CIBERDEM), Spain.*

Background: Diabetic nephropathy has become the major single cause of end-stage renal disease and its prevalence is dramatically increasing. In DN tubulointerstitial damage has a better correlation with impaired renal function than the degree of glomerular damage. Among the most relevant mediators involved are the circulating non-esterified fatty acids (NEFA), a characteristic feature of type 2 diabetes and obesity, that are able to induce tubular damage.

Methods: We use functional assays (apoptosis, CPT-1 activity, ATP) and protein quantitation to assess NEFA lipotoxicity in proximal tubular epithelial call (PTEC). A NEFA lipotoxicity model, by intraperitoneal injection in mouse, was employed to confirm tubular damage and test therapeutical intervention by AICAR/carnitine or metformin.

Results: Palmitic and linoleic acids are capable to inhibit carnitine-palmitoyl transferase 1 (CPT-1) in PTEC. CPT-1 inhibition, depletes ATP and depolarizes mitochondrial membranes, causing a mitochondrial dysfunction that leads to cytochrome c release and triggers apoptotic intrinsic mechanisms. NEFA inhibition of CPT-1 is mediated by an increase on malonyl-CoA level. The inhibition of its synthesis, reverted the observed effects. We additionally examined apoptotic damage and mitochondrial dysfunction in a protein-overload nephropathy in mice, and tested if the modulation of CPT-1 inhibition, using AICAR or Metformin, could attenuate tubulointerstitial lesions in proteinuric kidney diseases.

Conclusions: High NEFA-content albumin elicits CPT-1 inhibition and mitochondrial dysfunction both in vitro and in vivo. Mechanisms capable to overcome CPT-1 inhibition may improve cell energy status and ameliorate tubular damage in DN.

SA-PO390

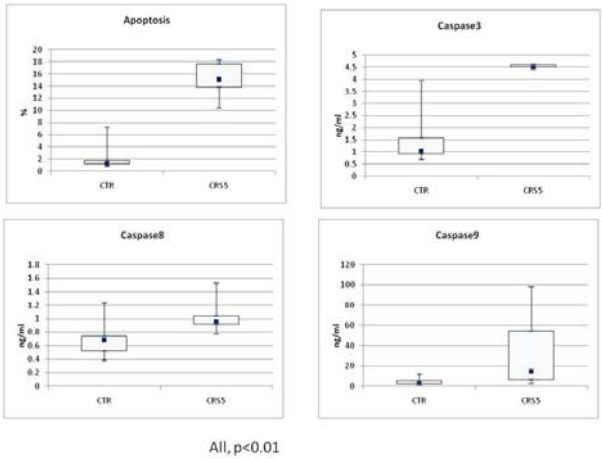
Apoptotic Pathways in Cardiorenal Syndrome Type 5

Alessandra Brocca,[1] Grazia Maria Virzì,[1] Massimo de Cal,[1] Stefano Marcante,[2] Enrico Tonini,[1] Silvia Pastori,[1] Chiara Pasqualin,[1] Claudio Ronco.[1] *[1]Nephrology-IRRIV S Bortolo Hosp; [2]ICU S Bortolo Hosp.*

Background: Cardiorenal Syndrome Type 5 (CRS5) is characterized by the presence of combined cardiac and renal dysfunction and damage due to systemic disorder. CRS5 mechanism is not well-known, although specific cellular and molecular changes with time-specific pattern are reported as a potential mechanisms involved in CRS5. We examined the effect of plasma from patients with CRS5 on Renal Tubular Epithelial Cells (RTCs) apoptosis as a pathogenic mechanism in this syndrome. In particular, we investigated the Caspase pathway involved in this induced apoptosis.

Methods: We enrolled 11 patients with CRS5 (68.4±10.8yrs), and 16 controls (CTR) (52.0±7.7yrs). Plasma from different groups were incubated with RTCs for 24h and, subsequently, cell apoptosis was evaluated by Flow Cytometer. Renal Tubular cells were assayed for activation of Caspase3, 8 and 9.

Results: Quantitative analysis of apoptosis by Annexin-V/Propidium Iodide (PI) showed significantly higher apoptosis rates in CRS5 compare to CTR (p<.01).This increasing apoptosis was confirmed by Caspase3 levels with a strong correlation (rho=.71). Caspase8 and 9 were significantly higher in CRS5 compare CTR (p<.01)



Furthermore, Caspase3 levels showed a significantly positive correlation with Caspas8 (rho=.72) and 9(rho=.49).

Conclusions: This pilot study demonstrates the significantly heightened presence of dual apoptotic disequilibrium with high upregulation of Caspase8 and with mild activation of Caspase9 in RTCs treated in vitro with CRS5 plasma.We observed the activation of 2 distinct apoptotic pathways in CRS5.These apoptotic pathways could be proved an important contribution of the development of CRS5 and may play a role in the mechanism of this syndromeand may be essential for the damage of distant organs. Our findings indicate that apoptosis could be a potential therapeutic target.

Congestive Heart Failure in the Rat Induces Subtle Renal Damage via Neurogenic Pathways Tilmann Ditting,[1] Peter Linz,[1] Martin Hindermann,[1] Kristina Rodionova,[1] Christian Ott,[1] Sonja Heinlein,[1] Roland E. Schmieder,[1] Karl F. Hilgers,[1] Kerstin U. Amann,[2] Roland Veelken.[1] *[1]Medical Clinic 4, Nephrology and Hypertension, Friedrich-Alexander Univ Erlangen Nürnberg, Erlangen, Germany; [2]Pathology, Friedrich-Alexander Univ Erlangen Nürnberg, Erlangen, Germany.*

Background: Cardiomyopathy in experimental renal insufficiency is putatively influenced by neurogenic pathways of renal origin. We wondered if neurogenic effects in congestive heart failure could likewise harm the kidney. We hypothesized that increased renal sympathetic nerve activity (RSNA) in rats after myocardial infarction (CHF) induces renal structural damage.

Methods: 21 day after induction of CHF renal morphology was evaluated by immunohistology (interstitial and glomerular mononuclear cell infiltration (ED1), cell proliferation (PCNA), collagen I,III,IV,V,VI, laminin und fibronectin). RSNA was assessed by volume challenge (VE) to decrease RSNA. CHF and control rats were investigated with and without renal denervation (DNX). Blood pressure (BP), heart rate (HR) and RSNA were recorded. Nodose ganglion neurons (NGN) with vagal cardiac afferents were cultured for 1 day. Whole cell recordings were obtained and current-voltage relationships established. Cells were characterized by osmomechanical stress with a mannitol solution.

Results: In CHF rats with intact renal nerves (nonDNX) formation of collagen I occurred, that was reduced after DNX (12.2+0.7 %area versus 9.1+1.1 %area*, n=6, * p<0.05).VE-induced RSNA decreases were impaired in CHF versus controls suggesting increased RSNA (-D 34+8% versus -D 54+6% *, n=6, * p<0.05). NGN from CHF exhibited altered conductance in response to mechanical stress as compared to controls (change in holding current at -80 mV: control_normoosmotic: -144±30 pA; control_hypoos.: -282±34 pA versus CHF_normosmotic: - 230±55 pA; CHF_hypos.: -540±100* pA; *p<0.05 CHF versus control).

Conclusions: CHF induced subtle renal structural damage due to increased renal sympathetic tone which was likely due to altered NGN mechanosensitivity.

Human Kidneys with Diabetes and Stage 3 CKD Are Ischemic and Hypoxic as Evaluated by MRI Jon Thacker,[1] Huan Tan,[2] Luping Li,[3] Stuart M. Sprague,[4] Orly F. Kohn,[5] Ivana Lazich,[5] Pottumarthi V. Prasad.[1,3,5] *[1]Biomedical Engineering, Northwestern Univ; [2]Dept of Surgery, Univ of Chicago; [3]Dept of Radiology, Northshore Univ HealthSystem; [4]Div of Nephrology, Northshore Univ HealthSystem; [5]Pritzer School of Medicine, Univ of Chicago.*

Background: Renal ischemia and hypoxia are key contributors to CKD progression according to chronic hypoxia theory [PMID: 9551436]. Identification of suitable markers to predict risk of progression remains as an unmet need. In this study, we evaluated both renal cortical oxygenation and perfusion using blood oxygenation level dependent (BOLD) and arterial spin labeling (ASL) MRI in subjects with diabetes and moderate CKD, known to be risk of progression.

Methods: Coronal acquisitions of ASL [PMID: 23447145] and BOLD MRI were acquired in healthy and CKD (N=10 per group) on a 3T scanner. *Parameters* BOLD: mGRE, TR 62ms, TE 3.09 - 30.53ms, 8 echoes; ASL: FAIR, post labeling delay=1.5s (healthy) or 2.0s (CKD); other: resolution 1.48x1.48mm, slice 8mm (ASL) and 5mm (BOLD). Regions of interest were defined in the cortex and medulla.

Results: Both perfusion and oxygenation were reduced (i.e. R2*) in CKD compared to healthy (see table). BOLD MRI data is consistent with previous report [PMID: 21757771]. However, other studies reported no difference between groups [e.g. PMID: 24760031]. We report for the first time a combined study of ASL and BOLD MRI, and show consistent trends with both measurements. An inverse correlation between R2* and perfusion was observed, suggesting that decreased perfusion may be responsible for increased hypoxia (r=-0.55; p<0.05; CI 95% [-0.71,-0.27]; n=19).

Cortical Measurements	Stage 3 CKD with diabetes	Healthy	T-Test
Perfusion (ml/100g/min)	111±28	207±65	p<0.01; t=4.20
R2* (s-1)	26.7±3.4	20.2±2.1	p<0.01; t=-5.13

Conclusions: The reductions in renal perfusion and oxygenation in subjects with diabetes and moderate CKD are consistent with chronic hypoxia theory. It is important to note that the reported differences may actually be lower compared to those in progressors because only 1 in 3 with CKD stage 3 are estimated to progress toward ESRD [PMID: 19176795].

SA-PO393

Evidence for Thalidomide Treatment Blocking the Development of Diabetic Nephropathy in Mice Xiaojie Shen,[1] Zhaoyong Hu,[2] Jing Xu.[1] *[1]Nephrology Div, Changhai Hospital, Shanghai, China; [2]Nephrology Div, Baylor College of Medicine, Houston, TX.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease (ESRD), however, the effective treatments for DN is lack. Down-regulation of Phosphatase and tensin homolog (**PTEN**) had linked to mesangium expedition and renal interstitial fibrosis. While thalidomide, an anti-inflammatory and anti-angiogenesis drug, reportedly up-regulates PTEN by inhibiting its degradation. Therefore, we investigated if thalidomide administration can block the progression of DN.

Methods: In human mesangial cells, we examined if thalidomide addition blocks TGF-β1 stimulated the expressions of fibronectin (FN), Collagen IV (Col IV), alpha-smooth muscle actin (α-SMA). In C57/BL6 wild-type mice (32, male), and db/db mice (32 male, C57BL / 6 background, 6-month age), we assessed whether thalidomide administration (100mg/kg, three days/week by gavage) suppresses proteinuria and the expression of α-SMA, FN and Col IV. Furthermore, we examined PTEN expression and pathologic changes in kidneys of Wt and db/db mice treated with or without thalidomide.

Results: Thalidomide addition blocked the expressions of α-SMA, FN, ColIV in mesangial cell cultures. Without thalidomide treatment, db/db mice developed DN characterized by a marked increase in proteinuria and histological changes including mesangial cell proliferation and mesangium expansion. Electron microscopy revealed that the GBM thickness and foot processes enfacement. In contrast, thalidomide treatment significantly reduced proteinuria and suppressed the expressions of fibrotic proteins followed by improved pathological changes in glomeruli of db/db mice. Western blot also indicated that PTEN expression was decreased in glomeruli of db/db mice, but thalidomide treatment effectively blocked this response.

Conclusions: our results demonstrated that thalidomide blocks or slows-down the progression of DN, this benefic effect might be due to the up-regulation of PTEN in glomeruli of db/db mice. These findings could provide a therapeutical strategy to combat the development of DN.

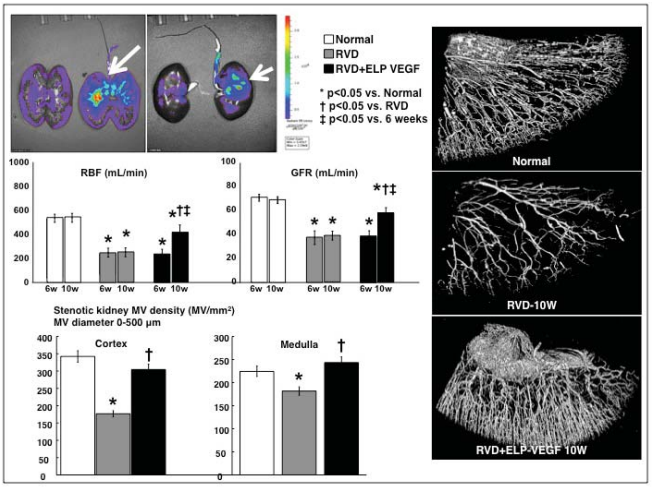
SA-PO394

Administration of Elastin-Like Polypeptide-VEGF in the Stenotic Kidney to Recover Renal Function Alejandro Chade,[1] Gene Lee Bidwell.[2] *[1]Physiology and Biophysics, Medicine, Radiology, Univ of Mississippi Medical Center, Jackson, MS; [2]Neurology, Biochemistry, Univ of Mississippi Medical Center, Jackson, MS.*

Background: Elastin-like polypeptides (ELP) are drug delivery vectors with high affinity for kidney tissue. ELPs can be fused to peptides to increase their tissue binding and half-life. We designed a novel fusion of ELP and vascular endothelial growth factor (VEGF). We showed that intra-renal administration of *free* VEGF in renovascular disease (RVD) improved but not fully recovered the kidney, possibly due to its short half-life and/or rapid wash-out by the renal circulation. We tested the therapeutic feasibility of ELP-VEGF fusion and hypothesized that by augmenting binding of VEGF to renal tissue, intra-renal infusion of ELP-VEGF will recover renal function.

Methods: Unilateral renovascular disease (RVD) was induced in 8 pigs by renal artery stenosis. After 6 weeks, stenotic kidney blood flow (RBF) and filtration (GFR) was quantified *in vivo* using multi-detector computed tomography. Then, pigs were randomized in placebo (RVD) or treated with a single stenotic kidney infusion of ELP-VEGF (RVD+ELP-VEGF, 100 ug/kg, n=4 each). Pigs were observed for 4 weeks, *in vivo* studies repeated and then euthanized for *ex vivo* studies.

Results: Placebo and ELP-VEGF treated pigs showed similar stenosis. Notably, ELP-VEGF fusion significantly bound to stenotic kidney parenchyma and improved RBF, GFR, and cortical and medullary microvascular (MV) density compared to placebo.



Conclusions: Our results support the feasibility of a novel therapeutic intervention. A single intra-renal administration of an ELP-VEGF fusion largely recovered the function and expanded the MV architecture of the stenotic kidney. Our data constitutes a solid first step for a novel therapeutic application of an existing compound never tested before to protect the kidney.

SA-PO395

Nrf2 Is Activated and Has a Protective Role in Cyclosporine Nephrotoxicity

Fumio Niimura,[1] Eisuke Suganuma,[1] Shojiro Okamoto,[1] Masayuki Yamamoto,[3] Taiji Matsusaka.[2] *[1]Pediatrics, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan; [2]Nephrology, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan; [3]Medical Biochemistry, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.*

Background: Oxidative stress-causing agents interact with cytosolic Keap1 complex, leading to stabilization of Nrf2, an active form of a transcriptional factor, which readily induces the expression of antioxidant genes including heme oxygenase-1 (HO-1). This study aimed to clarify the role of Keap1-Nrf2 system in the pathogenesis of cyclosporine A (CyA) nephrotoxicity.

Methods: Nrf2 knockout (NKO) and wild type (WT) mice were injected with CyA (50mg/kg/day, i.p.)(n=9 and 6, respectively) or vehicle (both n=7) for 3 weeks. Separately, similar experiment was done using Keap1 knockdown (KKD) (n=10 and 8, respectively) and WT mice (both n= 6). Renal mRNA expression of Nrf2-regulated genes (HO-1, GSTM1, and NQO1) and those related to kidney damage (TGFß1 and Kim1), and malondialdehyde(MDA) content in the kidney reflecting oxidative stress were quantified.

Results: CyA upregulated HO-1 (6.71±5.20 versus 1.00±0.27, p=0.007) in WT mice. This was blunted in NKO+CyA (2.44±1.19). GSTM1 and NQO1 were downregulated in NKO, but not upregulated in response to CyA. Renal MDA content was higher in NKO+CyA than WT+CyA (0.14±0.01 versus 0.07±0.02 nmol/mg•prot, p=0.041). Renal TGFß1 mRNA was more abundant in NKO+CyA than WT+CyA (1.77±0.62 versus 1.00±0.47). In addition, Kim1 was significantly upregulated by CyA in WT (24.8±16.7 versus 1.00±0.88), and further exaggerated in NKO+CyA (103.2±133.9). As expected from the Nrf2-regulatory role of Keap1, HO-1 mRNA was more abundant in KKD+CyA than WT+CyA (7.16±3.58 versus 2.14±1.57, p=0.016). However, renal TGFß1 and Kim1 were not suppressed in KKD+CyA compared to WT+CyA.

Conclusions: CyA induces oxidative stress in the kidney, and also induces HO-1 expression mediated by Nrf2, leading to amelioration of the oxidative stress and renal injury. However, constitutive Nrf2 activation does not contribute to further prevention of CyA nephrotoxicity, suggesting that CyA itself sufficiently activates Nrf2 to maximally ameliorate oxidative stress-related renal injury induced by CyA.

Funding: Government Support - Non-U.S.

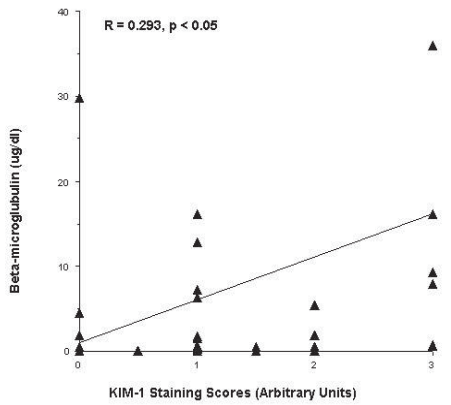
Correlation of Urinary β2-Microglobulin with Kidney Injury Molecule-1 Staining in Renal Biopsy

Xu Zeng,[1] David G. Bostwick,[2] Joseph V. Bonventre,[4] Guillermo A. Herrera,[3] Ping L. Zhang.[5] *[1]Dept of pathology and laboratory Medicine, Temple Univ Hospital, Phialadelphia, PA; [2]Bostwick Laboratories, Orlando, FL; [3]Pathology, Louisiana State Univ Health Sciences Center, Shreveport, LA; [4]Pathology, William Beaumont Hospital, Royal Oak, MI; [5]Renal Div, Brigham and Women's Hospital, Boston, MA.*

Background: After filtration through glomeruli, β2-microglobulin (β2-MG) is reabsorbed by proximal tubules. Increase in urine β2-MG indicates proximal tubular injury and measurement of β2-MG in urine is useful to determine the source of kidney injury. Kidney injury molecule-1 (KIM-1) has been characterized as a injury marker for proximal tubules. This study was designed to evaluate the correlation of urinary β2-MG with KIM-1 staining, i.e. proximal tubular injury.

Methods: During 2009-2012, 46 patients had urine β2-MG (RenalVysion™) and renal biopsies with various diagnoses including minimal change disease, IgA nephropathy, lupus nephritis and crescentic glomerulonephritis. Immunohistochemical staining for KIM-1 was performed. The intensity was graded from 0 to 3+ (0, no staining; 0.5 to 1+, focal to diffuse weak fine granular staining; 2 to 3+, moderate to strong granular staining). Linear regression was used to correlate urinary β2-MG and KIM-1 staining.

Results: 30 patients had elevated urinary β2-MG.KIM-1 staining. KIM-1 was positive in 36 cases. There was a significant correlation between urinary β2-MG and KIM-1 staining (R value = 0.293, p < 0.05). Odds ratio was 7.229, so for every unit increase in KIM-1 staining level, β2-MG increased by 7.229. Confidence interval at the 95% range was 2.868 to 12.01.



Conclusions: Increase in urine level of β2-MG is significantly correlated with KIM-1 up-regulation in injured proximal tubules. Measurement of urine β2-MG is a reliable assay for proximal tubular injury.

SA-PO397

DNA Hypermethylation Contributes to Mouse Kidney Fibrosis and the Hypermethylation of Homeobox A5 Promotes the Expression of Smad1

Xiao Xiao,[1,2] Qingqing Wei,[1,2] Man J. Livingston,[1,2] Zheng Dong.[1,2] *[1]Dept of Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA; [2]Dept of Research, Charlie Norwood VA Medical Center, Augusta, GA.*

Background: Renal fibrosis is a common, pathogenic process in chronic kidney diseases. Emerging evidence has implicated epigenetic regulation in renal fibrosis. However, the underlying epigenetic mechanisms, including DNA methylation, remain largely unclear.

Methods: In this study, we analyzed the genome-wide DNA methylation in mouse kidney tissues following unilateral urethral obstruction (UUO) by using the Next Generation Sequencing (NGS). We also examined the effect of 5-aza-2'-deoxycytidine(5-aza), a DNA methylation inhibitor, on UUO-induced renal fibrosis. Further studies verified the methylation changes of genes such as HoxA5 and suggested the regulation of important renal fibrosis regulators, including Smad1.

Results: The global methylation analysis demonstrated an overall DNA hypermethylation following UUO, which was attenuated by 5-aza. 5-aza also suppressed the expression of fibrosis markers (eg. a-SMA, collagens, fibronectin) as well as DNA methylation enzymes including DNMT1, DNMT3A, and DNMT3B in UUO. To identify the key hypermethylated genes involved in renal fibrosis, we analyzed the global sequencing data and showed hypermethylation in the promoter CpG islands of Homeobox A5 (HoxA5) gene. The hypermethylation was associated by a marked decrease of HoxA5 expression in UUO kidney tissues. In cultured mouse proximal tubule cells, overexpression of HoxA5 inhibited the expression of Smad1.

Conclusions: The results reveal DNA hypermethylation in UUO and support a critical role of DNA methylation in renal fibrosis. Moreover, the results highlight the involvement of HoxA5 methylation in the regulation of fibrosis-related signaling pathways.

Mechanisms of Gremlin1 Signalling and BMP Antagonism In Vivo and In Vitro

Arjun Krishnakumar,[1] Derek P. Brazil,[1] Rachel H. Church,[1] Imran H.A. Ali,[1] Ellen Kok,[2] Roel Goldschmeding,[2] Finian Martin.[3] *[1]Centre for Experimental Medicine, Queen's Univ, Belfast; [2]Univ Medical Centre Utrecht; [3]Univ College Dublin.*

Background: Gremlin (Grem1) is a secreted glycoprotein antagonist of bone morphogenetic proteins (BMPs) that plays a critical role in development and disease. Grem1 is implicated in fibrotic diseases of the kidney, lung and other tissues. Increased levels of Grem1 are detected in the kidney tubules of diabetic nephropathy patients, and correlate with progressive renal disease. The specific BMP targets of Grem1 in development and disease have not yet been identified.

Results: Levels of Grem1 were highest in colon, brain and spleen with lower levels detected in kidney, liver, lung, stomach and skin. In contrast, levels of Grem2 were highest in kidney, followed by colon, brain and liver. Mating *grem1*+/- mice on a C57Bl/6:FVB background produced viable *grem1*-/- offspring that displayed the previously described limb deformities. Approximately 95 % of the *grem*-/- offspring died at P2 due to the absence of kidneys with less than 5 % surviving into adulthood. The surviving *grem1*-/- mice were, on an average, 33 % smaller in size and weight compared to controls. Consistently, the right kidney was absent in *grem1*-/- mice of both genders, with an enlarged left kidney evident. Average kidney:body weight ratios were 6.07 g/kg for wild-type versus 8.52 g/kg for grem1-/- at 4 wk and 6.54 g/kg versus 13.96 g/kg at 4 months of age. The glomerular density of *grem1*-/- mice was significantly lower than wild-type (5.41 glomeruli/mm^2 versus 9.26 glomeruli/mm^2, p<0.001). However, the total number of glomeruli was comparable between wild-type and *grem1*-/- mice when normalised to body weight, suggesting that the increase in kidney size was due to expansion of the tubular area. Interestingly, levels of Grem2 mRNA were increased 4-fold in *grem1*-/- kidney compared to wild-type, suggesting compensatory changes may be occurring here.

Conclusions: We are currently using these mice to identify exact mechanisms of BMP signalling in kidney and Grem1-mediated pathophysiology in acute and chronic fibrosis models.

SA-PO399

A Module IV-Defective CCN2 Mutant and Module IV-Derived Decoy Peptides Attenuate Renal Fibrogenesis

Tsutomu Inoue,[1] Takeru Kusano,[2] Hiroaki Amano,[1] Kei Sugiyama,[1] Hiromichi Suzuki,[1] Hirokazu Okada.[1] *[1]Nephrology, Saitama Medical Univ, Iruma-gun, Saitama, Japan; [2]General Internal Medicine, Saitama Medical Univ, Iruma-gun, Saitama, Japan.*

Background: CCN2 is a TGF-β-induced profibrogenic mediator. It consists of four different functional modules, although the most profibrogenic module remains to be clarified.

Methods: Using mutant cDNAs, each of which lacked one of Exon 2~5 corresponding to module I~IV, we found that a module IV-defective CCN2 expressed in tubular epithelial cells didn't induce fibronectin (FN) synthesis in fibroblasts in the co-culture system. We next generated Exon 5-deleted CCN2 gene knock-in mice (Ex5-/-). By using unilateral ureter obstruction (UUO) model of these mice, we evaluated the levels of mRNAs encoding the

profibrogenic molecules and the area of interstitial fibrosis. Western blot analysis was also used to measure intracellular signaling molecules. Decoy peptides corresponding to partial amino acid sequences of module IV were administered to Ex5+/+ with UUO to examine the profibrogenic roles of module IV. To confirm our results in another model, a subtotal nephrectomy (SNx) model was also tested.

Results: The kidneys in the UUO showed a significant reduction in the levels of mRNAs encoding FN and collagen type I (COLI) in Ex5-/- compared to those in Ex5+/+ (FN; 8.63 ± 1.87 versus 4.06 ± 0.47, COLI; 33.77 ± 11.75 versus 8.37 ± 0.59). Fibrotic area was also significantly reduced in Ex5-/- (13.2 ± 5.1 versus 9.6 ± 6.6). Additionally, the administration of some of decoy peptides significantly attenuated the expansion of the interstitial fibrotic area in the UUO model of Ex5+/+. Levels of pAkt and pGSK-3β, but not pLRP6, were significantly lower in the fibrous kidneys of Ex5-/- than in those of Ex5+/+. We also confirmed that, in the SNx model, the fibrotic area in the kidneys was significantly reduced in Ex5-/- in comparison with that in Ex5+/+.

Conclusions: The module IV-defective CCN2 mutant and module IV-derived decoy peptides attenuated renal fibrogenesis. This suggests that CCN2 promotes renal fibrogenesis via module IV, probably through the integrin/integrin-linked kinase/Akt/GSK-3β pathway, which appears to be an appropriate, anti-fibrotic therapeutic target.

SA-PO400

Total Flavone Glycosides of Flos *Abelmoschus manihot*, Ameliorates Renal Fibrosis in Diabetic Nephropathy Rats via Inhibiting Oxidative Stress and p38MAPK Signaling Activity, Compared with Alpha-Lipoic Acid

Zhimin Mao,[1] Yigang Wan.[2] *[1]Graduate School, Nanjing Univ of Chinese Medicine, Nanjing, China; [2]Dept of Traditional Chinese Medicine, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing Univ Medical School, Nanjing, China.*

Background: Total flavone glycosides of flos *Abelmoschus manihot* (TFA)has been widely used for treating renal fibrosis in patients with diabetic nephropathy (DN) in China. However, therapeutic mechanisms remain unclear. Oxidative stress (OS) is a determinant during renal fibrotic progress under hyperglycemia. As one of regulative approaches of OS, p38MAPK signaling pathway plays a pivotal role. This study thereby aimed to investigate effects and mechanisms in vivo of TFA on renal fibrosis, compared with alpha-lipoic acid (ALA) as an antioxidant in clinic, through attenuating OS-related injury and p38MAPK signaling activity.

Methods: Rats were randomly divided into 5 groups, sham-operated group, vehicle-given group, low dose of TFA-treated group, high dose of TFA-treated group and ALA-treated group. TFA, ALA and saline were daily administrated for 8 weeks after induction of DN by streptozotocin with unilateral nephrectomy. DN rats' general state, biochemical indicators, renal pathological changes, OS-related markers, as well as key protein expressions in p38MAPK signaling pathway, fibrogenic cytokines and inflammatory factors were examined, respectively.

Results: DN model rats exhibited typical renal fibrosis, OS-related features and increases in expressions of p-p38MAPK, TGF-β1 and TNF-α. UAlb, BUN, UA, Alb, TG, TC and OS-related markers including MDA, T-SOD, GSH-Px, 8-OHdG and NOX4 in serum or kidneys were ameliorated in treated groups, especially in high dose of TFA-treated group. Of note, TFA synchronously inhibited p38MAPK signaling activity and TGF-β1 and TNF-α protein overexpressions, whereas, ALA only suppressed TNF-α protein overexpression in kidneys.

Conclusions: By means of DN models, we demonstrated that OS promotes renal fibrosis and p38MAPK signaling activity. TFA, as a natural regulator in vivo, can improve OS-related renal damage via regulating protein overexpressions of p-p38MAPK, TGF-β1 and TNF-α, which is different from ALA.

SA-PO401

Alpha2A-Adrenoceptors Deficiency Protects From Renal Fibrosis and Inflammation

Henning Hoch, Ivo Quack, Lars C. Rump, Johannes Stegbauer. *Dept of Nephrology, Medical Faculty, Heinrich-Heine-Univ, Duesseldorf, Germany.*

Background: Chronic kidney disease (CKD) is one of the major health issues. Inflammatory processes play a pivotal role in the pathogenesis of CKD. Alpha2A-adrenoceptors (α2A-AR) regulate sympathetic nerve activity by controlling presynpatic norepinephrine (NE) release. Activation of SNS leads to the progression of CKD. On the other side, there is increasing evidence that α2A-ARs on non-adrenergic cells, like immune cells, modulate pro-inflammatory processes during tissue damage. Here we tested the impact of α2A-AR on the progression of renal fibrosis.

Methods: Unilateral ureteral obstruction (UUO) – a model of renal fibrosis - was performed in α2A-AR-KO mice (KO) and compared to its wild-type (WT). Renal NE tissue content was measured by HPLC. 7d after UUO immunohistochemistry and gene expression analysis by real-time PCR analyses were carried out. Murine macrophages were isolated from the peritoneal cavity, subsequently cultured and stimulated.

Results: Renal sympathetic neurotransmission and renal NE tissue content was significantly exaggerated in KO compared to WT. Despite an increased sympathetic activity, renal fibrosis, assessed by sirius red/ fast green collagen staining (p=0.0428) and renal collagen-1 expression (p=0.001), was significantly attenuated in KO compared to WT 7 days after UUO. Moreover, the expression of the pro-inflammatory and pro-fibrotic cytokines TNF-α (p<0.05) and TGF- β (p<0.05) as well as the chemokines CCL2 (p<0.05) and CCL5 (p<0.05) were significantly reduced in KO compared to WT indicating a pro-inflammatory role of α2A-AR on immune cells in the progression of renal fibrosis. To test that, we isolated macrophages from WT and stimulated them with the α2-AR-agonist UK14.304 (0.1 μM). Stimulation of α2A-AR, expressed on macrophages, induced a 1.5-fold expression of TNF-α (p<0.05).

Conclusions: Our results show, α2A-ARs appear not only to be key players in regulating renal sympathetic activity, but also promote inflammation and the progression of renal fibrosis in response to kidney injury. Activation of non-adrenergic α2A-ARs on immune cells seems to be at least partly responsible for this effect.

SA-PO402

Rho Kinase Mediates Renal Fibrosis via Nox4-Derived Reactive Oxygen Species

Mandakini Jagdish Patel,[1] Fredyne C. Springer,[1] Yves C. Gorin,[1] Jeffrey L. Barnes.[1,2] *[1]Univ of Texas Health Science Center at San Antonio, San Antonio, TX; [2]The Medical Research Service, Audie Murphy Memorial veterans Administration Hospital, South Texas Veterans Health Care System, San Antonio, TX.*

Background: We previously showed that TGF-β1-induced renal myofibroblast differentiation *in vitro* is regulated via a Rho-GTP/Rho kinase (ROCK) signaling mechanism involving NAD(P)H oxidase (Nox4)-derived reactive oxygen species (ROS) and a Nox4 enhancing protein, polymerase delta interacting protein 2 (Poldip2). Here we link the ROCK and Poldip2/Nox4 axis *in vivo* during renal fibrosis.

Methods: The effect of a ROCK inhibitor, Fasudil (2.0 mg/kg/day, i.p.) on Poldip2 and Nox4-generated ROS during renal fibrosis was examined 7 days after unilateral ureteral obstruction (UUO) and compared to vehicle treated UUO and unobstructed contralateral kidneys. Protein and RNA expression levels of ROCK substrate pMYPT1, Poldip2, Nox4, and markers of fibrosis (transforming growth factor-beta 1 (TGF-β1), alpha-smooth muscle actin (α-SMA), cellular fibronectin (Fn-EIIIA) and collagen type 1 were examined by immunoblot, RT-PCR and immunohistochemistry.

Results: Expression of pMYPT1 (ROCK activation) and NADPH oxidase activity (ROS generation) was significantly elevated in kidneys of vehicle-treated UUO rats relative to unobstructed controls. Similarly, renal expression of Poldip2, Nox4, TGF-β1, α-SMA, Fn-EIIIA and collagen type 1 were significantly increased after UUO-induced renal fibrosis. Fasudil treatment significantly inhibited renal pMYPT1 expression and NADPH oxidase activity relative to vehicle-treated UUO rats. Likewise, Fasudil reduced protein and mRNA expression of Poldip2, Nox4, TGF-β1, α-SMA and Fn-EIIIA relative to kidneys from vehicle-treated UUO rats. Moreover, Fasudil treatment reduced interstitial expression of α-SMA, Fn-EIIIA, and collagen type 1 relative to vehicle-treated UUO rats assessed by immunohistochemistry.

Conclusions: Fasudil interrupts ROCK activation and reduces Poldip2, Nox4 expression, NADPH oxidase activity, and myofibroblast activation after UUO, indicating that a Rho/ROCK-Poldip2/Nox4 axis plays an important role in ROS-mediated renal interstitial fibrosis.

Sirt1 in Kidney Fibrosis: Human, Cell Culture, and Animal Intervention Studies

Yanling Zhang,[1] Kerri Thai,[1] Suzanne L. Advani,[1] Manish M. Sood,[2] Ian W. Gibson,[3] Richard E. Gilbert.[1] *[1]St. Michael's Hospital, Toronto, Canada; [2]Univ of Ottawa, Ottawa, Canada; [3]Univ of Manitoba, Canada.*

Background: Sirt1, the mammalian ortholog of silent information regulator 2 (Sir2) has been implicated in the pathogenesis of fibrosis, in addition to its role in longevity. To explore this further, we conducted human, transgenic and interventional animal and cell culture studies.

Methods: We extracted RNA from formalin-fixed archival kidney biopsies from patients with focal and segmental glomerulosclerosis (FSGS, n=6) and thin basement membrane disease (TMN, n=10). Sirt1 mRNA levels were determined by real-time QPCR. We also investigated the effects of Sirt1 activation in the subtotal nephrectomised (SNX) rat, a rodent model of FSGS. One week after 5/6 nephrectomy, rats were randomized to receive either regular chow or chow containing the Sirt1 activator, SRT3025 (Glaxo Smith-Kline), then followed for a further 12 weeks. We next examined kidney function in aged (2 year old) sirt1-/- (129/CD1) mice and their age-matched wild-type littermates to further investigate the role of Sirt1 activity in age-associated decline in kidney function. Finally, the effects of Sirt1 activation on TGF-ß induced collagen production in renal fibroblasts was quantified by 3H-proline incorporation.

Results: When compared with TMN, Sirt1 mRNA was reduced by >70% in biopsies from patients with FSGS (p<0.05). When compared with untreated SNX rats, those that received the Sirt1 activator had less glomerulosclerosis (GSI: 1.3±0.17 v 1.9±0.26), higher GFRs (2.9±0.25 v 1.7±0.20 μl/min/g) and less proteinuria (224±41 v 363±47 mg/d), p<0.05 for all. Blood pressure was unaffected. When compared with wild-type mice, aged Sirt1-/- mice had substantially lower GFRs (7.0±0.58 v 4.2±0.22 μl/min/g). TGF-ß induced a 5-fold increase in fibroblast 3H-proline incorporation that was abrogated by Sirt1 activation (p<0.001) in association with a reduction in acetylation of the downstream TGF-ß signalling molecule, Smad2.

Conclusions: Together, these findings implicate Sirt1 in the pathogenesis of kidney fibrosis and suggest that its activation may provide a new therapeutic strategy in fibrosis-associated kidney disease.

SA-PO404

Loss of Tumor Suppressor PTEN Expression in Renal Injury Initiates SMAD3 and p53 Dependent Fibrotic Responses Rohan Samarakoon,[1] Sevann Helo,[2] Amy D. Dobberfuhl,[2] Nidah S. Khakoo,[1] Lucas Falke,[3] Jessica Overstreet,[1] Roel Goldschmeding,[3] Paul J. Higgins.[1] *[1]Center for Cell Biology and Cancer Research, Albany Medical Center, Albany, NY; [2]Div of Urology, Albany Medical Center, Albany, NY; [3]Dept of Pathology, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: Deregulation of the tumor suppressor PTEN occurs in lung and skin fibrosis, diabetic and ischemic renal injury. However, the potential role of PTEN and the associated mechanisms in the progression of kidney fibrosis remains unclear.

Methods: We utilized Ureteral unilateral obstruction (UUO) and Aristocolic acid nephropathy (AAN) mouse models and in vitro molecular approaches to investigate PTEN function in renal tubular cells and fibroblasts.

Results: Tubular and interstitial PTEN expression is dramatically decreased in the UUO and AAN-injured kidney, correlating with Akt, p53 and SMAD3 activation and fibrosis. Stable gene silencing of PTEN in HK-2 tubular epithelial cells induces CTGF, PAI-1 and fibronectin expression. Prolonged inhibition of PTEN with OHpic trihydrate in NRK-49F cells similarly initiated a profibrotic gene cascade. RNA interference or inhibition of PTEN stimulated Akt, SMAD3 and 53^{Ser15} phosphorylation with accompanying proliferative arrest in HK-2 cells. Gene depletion or pharmacological blockade of either SMAD3 or p53 partially suppressed fibrotic gene expression and relieved growth inhibition associated with either loss or inhibition of PTEN. Similarly shRNA suppression of PAI-1 induction rescued growth inhibition orchestrated by PTEN loss. Moreover, TGF-βeta1-initiated fibronectin, PAI-1 and alpha-SMA expression is further enhanced by PTEN deletion. Furthermore, combined TGF-βeta1 treatment and PTEN silencing potentiates epithelial cell death.

Conclusions: PTEN loss initiates tubular dysfunction via SMAD3 and p53 mediated PAI-1, CTGF and fibronectin induction with accompanying PAI-1 dependent proliferative arrest. Moreover, PTEN loss cooperates with TGF-βeta1 in inducing profibrotic responses and tubular cell apoptosis.

SA-PO405

Impaired Cyclooxygenase-2 Expression Leads to Aggravated Renal Fibrosis in Response to Unilateral Ureteral Obstruction in Mice Kirsten Madsen,[1,2] Signe Skou Tofteng,[1] Line Nilsson,[3] Boye Jensen,[1] Rikke Norregaard.[3] *[1]Dept of Cardiovascular and Renal Research, Inst of Molecular Medicine, Univ of Southern Denmark, Odense, Denmark; [2]Dept of Pathology, Odense Univ Hospital, Odense, Denmark; [3]Dept of Clinical Medicine, Aarhus Univ, Aarhus, Denmark.*

Background: Renal fibrosis is the final common pathway in chronic kidney diseases and is the most consistent predictor of irreversible loss of renal function. Prostaglandins have anti-fibrotic effects in several organ systems and have also been suggested to diminish the development of renal fibrosis. We tested the hypothesis that renal cyclooxygenase-2 (COX-2) expression is increased in an experimental model of renal fibrosis, and that renal COX-2 activity impairs renal fibrogenesis.

Methods: Seven days unilateral ureteral obstruction (7dUUO) was performed in adult COX-2 knock-out (KO) mice and in wild-type (WT) littermate controls on a C57BL6 genetic background.

Results: Both the obstructed and the contralateral kidney increased in size in both genotypes in response to 7dUUO with no changes in total body weight. Quantitative PCR analysis of WT kidney tissue showed significantly increased renal COX-2 expression after 7dUUO compared to baseline. Sirius red staining showed no renal fibrosis at baseline in either genotype. After 7dUUO, development of fibrosis was seen with accumulation of extracellular matrix (ECM) in the renal interstitium and tubular atrophy with kidneys from COX-2 KO mice being more severely affected than WT controls. Messenger RNA expression and protein abundance of ECM proteins fibronectin, collagen I and III increased significantly in both genotypes after 7dUUO and were significantly higher in COX-2 KO mice compared to WT controls. Expression of fibroblast markers alpha-smooth muscle actin (αSMA) and fibroblast specific protein-1 (FSP-1) increased significantly in both genotypes after 7dUUO with the level of expression being significantly higher in COX-2 KO mice compared to WT controls.

Conclusions: In conclusion, renal COX-2 expression increases in response to 7dUUO, and impairment of COX-2 activity aggravates renal fibrosis suggesting an anti-fibrotic effect of COX-2 in renal fibrogenesis.

SA-PO406

Astragaloside IV Ameliorates Renal Fibrosis via the Inhibition of MAPKs and Anti-Apoptosis *In Vivo* and *In Vitro* Weijia Xu,[1] Xinghua Shao,[1] Lei Tian,[1] Qin Wang,[1] Minfang Zhang,[1] Ling Wang,[1] Jufang Yao,[2] Xiaoping Xu,[3] Shan Mou,[1] Zhaohui Ni.[1] *[1]Dept of Nephrology, Molecular Cell Laboratory for Kidney Disease, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong Univ, Shanghai, China; [2]Animal Centre, Ren Ji Hospital, Shanghai, China; [3]Dept of the Biochemical Laboratory, Ren Ji Hospital, Shanghai, China.*

Background: Apoptosis of renal tubular cells plays a crucial role in renal fibrosis. Astragaloside IV (AS-IV) has been shown to inhibit renal tubular cell apoptosis induced by high glucose, but its role in preventing renal fibrosis and the underlying molecular mechanisms is still unknown.

Methods: As an in vivo model, mice subjected to unilateral ureteral obstruction (UUO) were administered AS-IV (20 mg/kg) by intraperitoneal injection for 7 days after operation. Bilateral kidneys were collected in postoperation days 7, 14. In vitro, human HK2 cells induced by TGF-β1 (10ng/ml) were utilised to investigate the protective role of AS-IV in anti-fibrosis. TUNEL, Western Blotting and real-time PCR were respectively used to detect apoptosis, protein and mRNA levels.

Results: AS-IV significantly alleviated renal mass loss, decreased the expression of TGF-β1 induced by UUO, and reduced the expression of α-smooth muscle actin (α-SMA), fibronectin, and collagen IV both in vitro and in vivo, suggesting that this compound functions in the inhibition of renal tubulointerstitial fibrosis. Furthermore, TUNEL assay results both in vivo and in vitro showed that AS-IV significantly attenuated both UUO and TGF-β1-induced cell apoptosis and prevented renal tubular epithelial cell injury in a dose-dependent manner. Western blotting results also revealed that the anti-apoptotic effect of AS-IV was reflected in the inhibition of caspase-3 activation, which might be mediated primarily by the downregulation of MAPK effectors phospho-p38 and phospho-JNK. SB203580 was given to inhibit p38 phosphorylation, which decreased the expression of fibronectin, α-SMA.

Conclusions: These data infer that AS-IV is effectively attenuates the progression of renal fibrosis after UUO injury and may have a promising clinical role as a potential anti-fibrosis treatment in patients with chronic kidney disease.

SA-PO407

EZH2 Blockade Inhibits Renal Interstitial Fibroblast Activation and Attenuate Renal Interstitial Fibrosis in Obstructive Nephropathy Xiaoxu Zhou,[1] Shougang Zhuang.[2] *[1]Dept of Kidney Disease and Hypertension, Alpert Medical School and Rhode Island Hospital of Brown Univ, Providence, RI; [2]Dept of Medicine, Alpert Medical School and Rhode Island Hospital of Brown Univ, Providence, RI.*

Background: Interstitial fibroblast activation and proliferation is central to the development and progression of renal fibrosis after various insults, however, the signaling mechanism regulating this process is not fully understood.

Methods: In this study, we examined the role of EZH2, the enzymatic component of the polycomb repressor complex 2 (PRC2) that is responsible for methylation at H3K27 in renal interstitial fibroblast activation and proliferation in cultured renal interstitial fibroblasts (NRK-49F) and development of renal fibrosis in a murine model of obstructive nephropathy induced by unilateral ureteral obstruction.

Results: Exposure of cultured NRK-49F cells to 3-DZNeP (3-Deazaneplanocin A) and GSK126, two EZH2 inhibitors, respectively, resulted in decreased expression of alpha-smooth muscle actin and fibronectin, two hallmarkers of fibroblast activation and type 1 collagen, a key extracellular matrix protein, in a dose and time dependent manner. Silencing EZH2 with siRNA also significantly inhibited the expression of these proteins. Moreover, inhibition of EZH2 activity with 3-DNZeP reduced cell proliferation and expression of cyclin D1, PCNA. Finally, blocking EZH2 with 3-DZNep, GSK126 or siRNA also inhibited expression of transforming growth factor-beta receptor I and phospholation of Smad2/3 and STAT3. In a murine model of obstructive nephropathy, administeration of 3-DZNep also attenuated expression of fibronectin, α-SMA and type I collagen, reduced Di/Tri-Methyl-Histone H3 expresion, and suppressed phosphorylation of Smad-3 and STAT3.

Conclusions: Collectively, our results reveal an important role of EZH2 in mediating activation and proliferation of renal interstitial fibroblasts and renal fibrogenesis, and suggest that EZH2 inhibition might be a potential therapeutic approach for treatment of chronic fibrotic kidney disease.

SA-PO408

Proteomic Analysis of Secretome of Cultured Pericytes Isolated from Unilateral Ureteral Obstruction (UUO) Mice Didier Portilla,[1,2] Shenyang Li,[1,2] Srinivas Ayyadevara,[2] Judit Megyesi,[1,2] Peter M. Price,[1,2] Jeremy Stuart Duffield.[3] *[1]Nephrology, Medicine, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Nephrology, Medicine, Central Arkansas Veterans Healthcare Systems, Little Rock, AR; [3]Biogen Idec, Cambridge, MA.*

Background: Interstitial pericytes/fibroblasts transform into myofibroblasts in kidney tissue in *in vivo* models of renal fibrosis. To understand cellular mechanisms responsible for this transformation we performed proteomic analysis of supernatants obtained from cultured pericytes isolated from sham and UUO mice.

Methods: Pericytes were isolated using magnetic beads containing anti-PDGFβ Receptor ab and grown in DMEM media. Confluent cells were incubated for 24 hrs in serum-free medium, and both cell lysates and supernatants were collected. Supernatants were concentrated and resolved in one dimension on 1% SDS acrylamide gels, stained with Coomassie, and 1-mm slices were digested in trypsin prior to LC-MS analysis of peptides using an LTQ Orbitrap-FT mass spectrometer. Proteins were identified directly with MASCOT software, matching known peptide patterns of secondary fragmentation.

Results: Pericytes isolated from 3 and 7-day UUO mice have increased cellular proliferation when compared to sham pericytes. Collagen 1 alpha (VI, VIII, XIV and XV chains) increased by 45-fold in the pericyte secretome at 3-day UUO. Collagen up regulation correlated with increased mRNA and protein expression of TGFβ-1 and αSMA in cell lysates. Thrombospondins-1 and 2 were upregulated by 47-fold at 3 day UUO. There was increased expression of phosphorylated osteopontin with increased expression of cysteine protease cathepsin S (7-fold day 3) and ADAMTS-2 (6-fold at day 3) and increased expression of ECM ligands fibrillin-1 and fibulin 2 (5-fold) both at day 3 and 7. Complement C1q subunits and Class 2 detoxification enzymes like SOD and GSTs were up regulated. DAVID analysis showed increased secretion of several glycoproteins with increased acetylation and phosphorylation.

Conclusions: Proteomic analysis of the secretome of cultured pericytes isolated from sham and UUO mice represents a novel tool to examine cellular mechanisms of kidney fibrosis.

SA-PO409

Reversal and Prevention of the Myofibroblast Phenotype through Hyaluronic Acid Internalisation and Breakdown by BMP7 Adam Midgley, Aled O. Phillips, Soma Meran. *Inst of Nephrology, Cardiff Univ School of Medicine, Cardiff, United Kingdom.*

Background: Fibrosis is mediated through myofibroblasts activity. The glycosaminoglycans hyaluronan (HA) is a key mediator of myofibroblast phenotype, with its accumulation promoting TGFβ1 driven myofibroblast differentiation. However HA can have both antifibrotic and profibrotic properties depending on its composition, size and localisation. BMP7 is an antifibrotic cytokine known to antagonise the effects of TGFβ1, however the mechanistic processes for this are not fully determined. Here we investigate whether BMP7 drives alterations in HA that then mediate prevention/reversal of TGFβ1-driven myofibroblast differentiation.

Methods: Fibroblasts were used to test two models of BMP7-driven antagonism of differentiation - a reversal model, where cells were exposed to TGFβ1 followed by BMP7, and a prevention model where cells were exposed first to BMP7, then TGFβ1. RT-QPCR, immunofluorescence, ELISA, and siRNA transfection techniques were used to delineate associated alterations in HA matrix and cell phenotype.

Results: BMP7 both prevented and reversed myofibroblast differentiation, and this was associated with removal and internalisation of cell surface HA into perinuclear endosomes. HA co-localised with the HA-degrading enzyme, Hyaluronidase-1 (Hyal1) in endosomes, and Hyaluronidase-2 (Hyal2) at the nuclear margin. This process was also associated with increased expression of the cell-surface HA receptor, CD44, and its redistribution to the perinuclear region. In addition, BMP7 markedly increased expression of the variant CD44 isoform CD44v7/8. Using siRNA techniques against Hyal2 and CD44v7/8 we identified these proteins to be essential for HA internalisation, as well as BMP7 driven prevention and reversal of myofibroblast phenotype.

Conclusions: A novel mechanism of TGFβ1 antagonism by BMP7 was identified. BMP7 prevented TGFβ1-driven pericellular HA accumulation by internalisation of HA into catalytic, perinuclear endosomes. CD44v7/8 and membrane-bound Hyal2 were critical to this process; and to the prevention and reversal of myofibroblast phenotype by BMP7, thus identifying new potential therapeutic targets for intervention in fibrosis.

SA-PO410

Role of Bone Marrow-Derived Fibroblasts in Renal Fibrosis Jun Zhou, Xiaogao Jin, Yanlin Wang. *Medicine-Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Renal fibrosis is the final common manifestation of chronic kidney disease resulting in progressive loss of kidney function. Although activated fibroblasts are responsible for the production and deposition of the extracellular matrix, the origin of activated fibroblasts mediating renal fibrosis has been controversial. Recent evidence indicates that bone marrow-derived fibroblasts contribute significantly to the pathogenesis of renal fibrosis. In this study, we characterized and examined the functional role of bone marrow-derived fibroblasts in the development of renal fibrosis.

Methods: In a well-established mouse model of renal fibrosis induced by unilateral ureteral obstruction, we characterized bone marrow-derived fibroblasts in the kidney using Col-GFP mice that express GFP driven by collagen I promoter and examined the functional role of bone marrow-derived fibroblasts in the development of renal fibrosis using Col-DTR mice that have a diphtheria toxin (DT)-induced depletion of collagen I-producing cells in the bone marrow.

Results: Bone marrow-derived fibroblasts constitute 45% of total collagen-producing fibroblasts in the obstructed kidney. The bone marrow-derived fibroblasts are of hematopoietic origin, can proliferate and differentiate into myofibroblasts in the obstructed kidney. Treatment of Col-DTR mice with DT resulted in a marked reduction of circulating fibroblasts in the peripheral blood. Col-DTR mice treated with DT accumulated significant fewer bone marrow-derived fibroblasts in the kidney in response to obstructive injury. Furthermore, Col-DTR mice treated with DT exhibited fewer myofibroblasts and expressed substantial less fibronectin, type I collagen, and a-smooth muscle actin in the obstructed kidney. Finally, Col-DTR mice treated with DT displayed significant less collagen deposition in the obstructed kidney.

Conclusions: Our results demonstrate that hematopoietic fibroblasts migrate into the kidney, proliferate and differentiate into myofibroblasts and contribute functionally to the pathogenesis of renal fibrosis.

SA-PO411

Quercetin Inhibits Fibroblast Activation and Kidney Fibrosis Involving the Inhibition of mTORC1 and β-catenin Signaling Pathways Jiafa Ren, Weichun He, Junwei Yang, Chunsun Dai. *Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical Univ, Nanjing, China.*

Background: Previous studies demonstrated that both mTORC1 and β-catenin signaling activation contribute to fibroblast activation and kidney fibrosis. Although it has been reported that Quercetin, a dietary flavonoid, is able to inhibit mTORC1 and β-catenin signaling pathways in other cell types, the role and mechanisms for it in fibroblast activation and kidney fibrosis are not fully understood.

Methods: Rat kidney interstitial fibroblasts (NRK-49F) were stimulated with TGFβ1 and kidney fibrosis was induced by unilateral ureter obstruction (UUO) in CD1 mice.

Results: Here, we show that in cultured rat renal fibroblast cells (NRK-49F), Quercetin treatment inhibited TGF-β1-induced mTORC1 and β-catenin signaling activation but not for smad3 phosphorylation. a-SMA and fibronectin expression induced by TGFb1 treatment were also remarkably inhibited by Quercetin treatment at a dose-dependent manner. In mice with UUO nephropathy, administration of Quercetin significantly diminished total collagen deposition, fibronectin and a-SMA expression in the kidneys compared to vehicle control. Macrophages infiltration and proinflammatory cytokines expression such as TNF-α and MCP-1 were also remarkably inhibited in the UUO mice treated with Quercetin. In addition, the abundance of p-4EBP1 and β-catenin nuclear translocation in kidney interstitial cells was also reduced after Quercetin treatment.

Conclusions: Take together, these results suggest that Quercetin may act as a novel therapeutic strategy for treatment of kidney fibrosis through inhibiting both mTORC1 and β-catenin signaling pathways.

Tenascin-C Is a Major Component of Fibrogenic Niche That Promotes Fibroblast Proliferation Haiyan Fu,[1] Dong Zhou,[1] Liangxiang Xiao,[1] Roderick J. Tan,[2] Youhua Liu.[1] [1]*Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA;* [2]*Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

Background: It is thought that after chronic kidney injury, fibrogenic niches are formed at various focal sites, which provide a microenvironment that favors fibroblast proliferation and activation. However, the molecular identities and compositions of such a fibrogenic niche are poorly understood. Here we report that tenascin-C (TNC), an extracellular matrix glycoprotein with both structural and cell-signaling properties, is a major component of kidney fibrogenic niche.

Results: In vivo, TNC was markedly induced in animal models of chronic kidney disease (CKD) induced by ischemia/reperfusion injury (IRI) and unilateral ureteral obstruction (UUO). Immunostaining revealed that TNC was predominantly localized at the foci rich in fibroblasts in renal interstitium. In vitro, treatment of normal rat kidney fibroblast (NRK-49F) cells with TGF-β or sonic hedgehog (Shh) dramatically induced TNC expression in a time dependent manner. TNC was also induced in human proximal tubular epithelial cells (HKC-8) after sustained incubation with TGF-β1. To investigate the potential role of increased TNC, we studied its effect on cultured interstitial fibroblasts. We found that incubation with TNC promoted NRK-49F cell proliferation, which was assessed by cell counting, MTT assay, and BrdU incorporation. Furthermore, TNC activated MEK/ERK signaling pathway and stimulated the expression of numerous proliferation-related genes in fibroblasts.

Conclusions: Taken together, these results suggest that after chronic kidney injury, TNC is induced with a unique spatial and temporal expression pattern, and forms a fibrogenic niche that ensures fibroblast proliferation and activation.

IL-4 Receptor α Deficiency Suppresses Bone Marrow-Derived Fibroblast Activation and Renal Fibrosis Jingyin Yan, William E. Mitch, Yanlin Wang. *Medicine-Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Renal fibrosis is the final common pathway for chronic kidney diseases of different causes. Recent evidence indicates that bone marrow-derived fibroblast precursors contribute significantly to the development of renal fibrosis. These cells express hematopoietic marker such as CD45 and mesenchymal marker such as platelet derived growth factor receptor-β (PDGFR-β). However, the signaling mechanisms underlying the activation of bone marrow-derived fibroblast precursors in the kidney are incompletely understood. We have recently found that Th2 cytokines - IL-4 and IL-13 are induced in the kidney during the development of renal fibrosis. In this study, we investigated the role of IL-4 receptor α in the activation of bone marrow-derived fibroblasts and the development of renal fibrosis.

Methods: IL-4 receptor α knockout (IL4Ra-KO) mice and wild-type (WT) mice were subjected to unilateral ureteral obstruction (UUO).

Results: Our results showed that the number of CD45 and PDGFR-β double positive fibroblasts was significantly increased in the injured kidneys of WT mice, whereas the number of double positive fibroblasts was significantly reduced in the injured kidneys of IL4Ra-KO mice. Furthermore, IL4Ra deficiency resulted in a significant reduction in the number of α-smooth muscle actin (α-SMA) positive myofibroblasts in the obstructed kidneys. Consistent with these findings, IL4Ra deficiency significantly reduced mRNA and protein expression of α–SMA in the injured kidneys compared with WT mice. There was also a marked increase in the mRNA and protein levels of collagen I and fibronectin in the obstructed kidneys of WT mice, while these fibrotic changes were significantly attenuated in the obstructed kidneys of IL4Ra-KO mice.

Conclusions: Our results demonstrate that IL4Ra plays an important role in the activation of bone marrow-derived fibroblast precursors in the kidney and the development of renal fibrosis. These results indicate that IL4Ra signaling may represent a novel therapeutic target for fibrotic kidney disease.

Thrombin Induces Epithelial-Mesenchymal Transition Through the Activation of PAR-1 in Tubular Epithelial Cells Wai Han Yiu, Dickson W.L. Wong, Joseph C.K. Leung, Loretta Y.Y. Chan, Kar Neng Lai, Sydney C.W. Tang. *Dept of Medicine, The Univ of Hong Kong, Queen Mary Hospital, Hong Kong.*

Background: Fibrin deposition is commonly observed in tubulointerstitial injury of chronic kidney diseases. Recent studies have suggested that local activation of thrombin contributes to renal fibrosis. However, the effect of thrombin on tubular cells is not fully understood. Since epithelial-mesenchymal transition (EMT) is an important mechanism of renal tubulointerstitial fibrosis, we investigated whether thrombin plays a role in tubular EMT and dissected the underlying mechanism.

Methods: Rat kidney tubular epithelial cells (NRK52E) were treated with thrombin (1-4U/ml) for 72 h and were examined for the expression of EMT and profibrotic markers. To determine the potential role of protease activated receptor (PAR) in tubular EMT, selective PAR antagonists, SCH7979 for PAR-1 and tcY-NH2 for PAR-4 were co-incubated with thrombin.

Results: After 72-h treatment, cells underwent a transition from an epithelial to a mesenchymal phenotype as evidenced by reduced expression of E-cadherin, and increased expression of α-smooth muscle actin in a dose-dependent manner. Expression of snail, the known inducer of EMT, was also upregulated by thrombin. Blockade of PAR-1, but not PAR-4 partially restored the altered expression of thrombin-induced EMT markers. Besides, thrombin also stimulated the expression of profibrotic growth factors (TGFβ1 and CTGF) and extracellular matrix (ECM) proteins (fibronectin and collagen IV). The induction of TGFβ1 and collagen IV were suppressed by PAR-1 antagonist; while the induction of fibronectin was inhibited by both PAR-1 and PAR-4 antagonists.

Conclusions: Our data demonstrated that thrombin promoted EMT and increased the production of profibrotic factors and ECM proteins in tubular epithelial cells. These effects were partially mediated by PAR-1 and, to a lesser extent, PAR-4. These results suggest that modulation of PAR signaling may provide a potential therapeutic strategy for the treatment of renal fibrosis. Signaling of a Receptor for Leukotriene B_4, BLT1 Plays Roles in Tubulointerstitial Fibrosis Mariko Kamata,[1,2] Kanako Hosono,[1] Tomoe Fujita,[1] Kouju Kamata,[2] Masataka Majima.[1] *[1]Pharmacology, Kitasato Univ School of Medicine, Japan; [2]Nephrology, Kitasato Univ School of Medicine, Japan.*

Background: Kidney fibrosis develops on the interaction of chemokines and cytokines secreted from migrated cells and kidney cells, and accumulates type I collagen and type III collagen in the tubulointerstitium. We investigated a role of the signaling pathway of LTB_4-BLT1 on the tubulointerstitial fibrosis of the kidney using BLT1 knockout mice ($BLT1^{-/-}$).

Methods: Ninety male C57BL/6 wild type mice (WT) and 80 male $BLT1^{-/-}$ were used. All the mice had the unilateral ureteral obstruction (UUO) at 8-wk-old. Collagen type I, III and IV, F4/80 (a macrophage marker), S100A4 (a fibroblast marker) and Gr-1 (a neutrophil marker) were stained on frozen or paraffin sections of isolated kidneys. COL1A1, COL3A1, COL4A1, S100A4, alpha-smooth muscle actin (αSMA), TGF-β, FGF-2, MCP-1, F4/80, 5-lipoxygenase (5-LOX) and BLT1 were quantitated by RT-PCR in the kidney specimens with UUO.

Results: The mRNA of BLT1 increased in UUO kidney in WT, but not in $BLT1^{-/-}$. The 5-LOX mRNA increased in both of WT and $BLT1^{-/-}$ UUO kidneys, but the increase in $BLT1^{-/-}$ was significantly blunted compared with WT UUO kidneys from day-3 to day-7. The immunoreactive type I, III and IV collagens in UUO kidneys were less deposited in $BLT1^{-/-}$ mice from day-1 to day-7 compared with those in WT. mRNA levels of COL1a1, COL3a1, and COL4a1 confirmed the above immunostaining results. The expressions of TGF-β, and FGF-2 also decreased in $BLT1^{-/-}$ from day-1 to day-7. The mRNA levels of αSMA, a marker of myofibroblast, significantly decreased in $BLT1^{-/-}$ UUO kidney from day-2 to day-7. The numbers of S100A4-positive cells also decreased in $BLT1^{-/-}$ UUO kidneys.

Conclusions: LTB_4-BLT1 signaling plays roles for tublointerstitial fibrosis of the kidney, possibly via upregulation of TGF-β, and FGF-2 together with enhanced recruitments of myofibroblasts and fibroblasts.

SA-PO416

Low-Dose Colchicine Treatment Attenuates Renal Fibrosis in Mice Unilateral Ureteral Obstruction Seiji Itano, Minoru Satoh, Atsushi Uchida, Hiroyuki Kadoya, Chieko Ihoriya, Tamaki Sasaki, Naoki Kashihara. *Dept of Nephrology and Hypertension, Kurashiki, Okayama, Japan.*

Background: Colchicine is known to exert anti-inflammatory action through inhibition of migration and chemetaxis of neutrophils by blockade of microtubule polymerization. Recently, it has been reported that colchicine treatment could prevent recurrence of pericarditis and development of atrial fibrillation after the cardiac surgery. Meanwhile, colchicine has been demonstrated to possess anti-fibrotic properties through suppression of collagen synthesis and secretion. We investigated the effects of colchicine on renal fibrosis using unilateral ureteral obstruction (UUO) model.

Methods: (1) Eight week-old male C57BL/6 mice were divided to two groups: Control group and Colchicine group. Colchicine was administrated by osmotic pump (0.5mg/kg/day). UUO operation was induced at 7 days after insertion of osmotic pump. Mice were sacrificed at 14days from UUO. (2) In vitro scratch assay were performed to evaluate the effect of colchicine on cellular migration. NRK-49F cell (rat fibroblast) were cultured with or without colchicine under TGF-β1 stimulation.

Results: (1) Any significant renal nor liver dysfunction was not observed, but slight degree of body weight loss was noted in Colchicine group. The UUO-Colchicine group showed suppression of kidney interstitial fibrosis comparing to UUO-Control group. CTGF and FN-1 mRNA expressions were elevated in UUO-Control group and decreased by colchicine administration. (2) In vitro, colchicine inhibits fibroblast migration on scratch assay. Fibrotic gene expression were ameliorated with addition of colchicine.

Conclusions: Colchicine directly affects fibroblast activity, exerts anti-fibrotic effects, and attenuates renal fibrosis in UUO mice.

Combination TGF-β and CTGF In Vivo Transfection via Minicircles: A Novel Renal Fibrosis Model Peng Sun, Scott MacDonnell, Hu Sheng Qian, Tammy Bigwarfe, Danielle M. Fowler, Chung-Wein Lee, Mark Mchugh, James W. Tanner, John Miglietta, Glenn Gibson, Glenn A. Reinhart, Steven M. Weldon. *Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT.*

Background: Transforming growth factor beta (TGF-β) and connective tissue growth factor (CTGF) have been identified as mediators of kidney fibrosis. Minicircles (MC) are DNA vectors devoid of any bacterial backbone that exhibit enhanced expression and duration compared to classic plasmids vectors. In the present study, we used MC technology to express TGF-β and CTGF transgenes to develop a novel, non-surgical model for of renal fibrosis in the mouse.

Methods: MC-DNA constructs for human TGF-β1 and CTGF were delivered by hydrodynamic injection (HI). Mice (n=6/group) received TGF-β1+CTGF transfection and antibodies, 1D11 or FG3019, to neutralize TGF-β and CTGF. Hepatocyte transfection was evaluated via MC-GFP florescence. Plasma TGF-β and CTGF levels were measured by ELISA. Renal tubulointerstitial fibrosis (TIF; cortical Sirius Red staining) and fibrotic gene transcription (Col1a1, etc.) were evaluated 10 days post-HI.

Results: GFP labeled MC transfection produced a robust GFP florescence signal in hepatocytes (10 days post HI) of a control MC injection group compared to naïve mice (523±145 GFP^+ units/area versus 0). Mice receiving TGF-β+CTGF MCs exhibited elevated plasma levels of TGF-β and CTGF by Day 4 and remained increased 10 days post-HI. TIF and col1a1 mRNA were significantly increased (54% and 40%, respectively) compared to sham MC-control. Both 1D11 and FG3019 markedly reduced TIF (~40%) in the MCs transfection groups compared to control.

Conclusions: We show for the first time in mice that co-transfection with TGF-β1+CTGF via MCs produces high levels of circulating TGF-β and CTGF and induces a significant renal fibrosis that can be attenuated by administration of neutralizing antibodies. These data support the importance of TGF-β1 and CTGF as drivers of organ fibrosis. Finally, this novel, non-surgical model of kidney fibrosis has utility for evaluation of novel anti-fibrotic agents and may be extended to organ systems.

Inhibition of EGFR Alleviates the Development and Progression of Hyperuricemia Associated Nephropathy Na Liu,[1] Shougang Zhuang.[2] *[1]Dept of Nephrology, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China; [2]Dept of Nephrology, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China.*

Background: Although mechanisms and therapeutic approaches of uric acid-associated nephropathy (UAN) have been widely studied, so far there is no any effective treatment for this disorder.

Methods: In this study, we examined the effect of epidermal growth factor factor receptor (EGFR) inhibition on the progression of UAN and the mechanism involved.

Results: In a rat model of UAN induced by feeding a mixture of adenine and potassium oxonate, severe glomerular sclerosis and renal interstitial fibrosis were observed, which was accompanied by increased expression of EGFR phosphorylation in the kidney. In paralell, serum uric acid, BUN and creatinine levels and urine micro albumin levels were increased. Adminstration of gefitinib, a specific EGFR inhibitor, prevented progressive renal injury as demonstrated by blunting the rise of serum uric acid, BUN and creatinine levels, reducing increased urine micro albumin and inhibiting expression of α-smooth muscle

actin (α-SMA), collagen I and fibronectin. Hyperuricemia resulted in downregulation of major urate transporters, OAT1 and OAT3. Gefitinib treatment preserved their expression. EGFR blockade also inhibited expression of multiple profibrogenic cytokines/chemokines including transforming growth factor-β1 (TGF-β1), MCP-1, RANTES, TNF-α, IL-1β. Furthermore, gefitinib markedly abrogated hyperuricemia-induced phosphorylation of Smad3, ERK1/2, and NF-κB(p65).

Conclusions: Taken together, blocking EGFR can alleviate the development and progression of UAN through enhancing expression of uric acid transporters, inhibit profibrotic signaling pathways and suppress proinflammatory responses. Thus, inactivation of EGFR activity may provide a novel therapeutic approach for treatment of UAN.

Podocyte Proliferation Is Associated with Loss of Contact to the Glomerular Basement Membrane (GBM) Kevin Schulte,[1] Antonio Sechi,[2] Katja Berger,[1] Bart Smeets,[1] Jürgen Floege,[1] Marcus J. Moeller.[1] *[1]Div of Nephrology and Clinical Immunology, Univ Hospital of the Aachen Univ (RWTH), Aachen, Aachen, Germany; [2]Inst of Biomedical Engineering, Div of Cell Biology, Univ Hospital of the Aachen Univ (RWTH), Aachen, Aachen, Germany.*

Background: Podocytes are thought to be postmitotic cells. Nevertheless, under specific circumstances podocytes may undergo cellular divisions. Here we investigated the role of the extracellular matrix on podocyte proliferation.

Methods: Podocytes were labeled in quadruple transgenic Pod-rtTA/LC1/R26R/eGFP-histone mice and traced in culture, as well as *in vivo* during development and in disease models. Cellular outgrowths from isolated glomeruli and podocyte proliferation were monitored in primary culture. Podocyte expression of the proliferation marker Ki67 was analysed in different models in vivo, which are characterised by (parietal) podocytes on the parietal basement membrane (PBM).

Results: *In vitro*, podocytes on isolated glomeruli did not proliferate as observed by 72 hours time-lapse video microscopy. However, outgrowing podocytes started to proliferate within 12 - 24 hours as soon as they lost contact to the GBM. In kidneys of newborn mice, expression of proliferation marker Ki67 was observed on a small fraction of "committed" podocytes on Bowman's capsule (the recently described "podocyte reserve"), but not on visceral podocytes. In a model of atubular glomeruli in adult mice, cellular proliferation was observed again exclusively in parietal podocytes located on the PBM. Visceral podocytes on the GBM did not proliferate regardless if they were filtering or not. Finally, podocytes within cellular crescents expressed Ki67 in mouse tissue.

Conclusions: Contact to the GBM is associated with an antiproliferative signal. This is consistent with histological patterns observed in glomerular diseases, where proliferation occurs in general along Bowman's capsule (e.g. cellular crescents).

SA-PO420

Precision-Cut Kidney Slices (PCKS): A Novel Model to Study Development and Treatment of Renal Fibrosis *Ex Vivo* Fariba Poosti,[1] Bao Tung Pham,[2] Klaas Poelstra,[3] Harry Van Goor,[1] Jan-Luuk Hillebrands.[1] *[1]Pathology, Univ Medical Center Groningen, Groningen, Netherlands; [2]Pharmaceutical Technology and Biopharmacy, Univ of Groningen, Groningen, Netherlands; [3]Pharmacokinetics, Toxicology and Targeting, Univ of Groningen, Groningen, Netherlands.*

Background: Renal fibrosis is a serious clinical problem forming the utmost cause of need for renal replacement therapy. As yet, no adequate preventive or curative therapy is available for clinical use to specifically target the development of renal fibrosis. The search for new efficacious treatment strategies is therefore warranted. *In vitro* models using homogeneous cell populations have contributed to the understanding of the mechanisms involved in fibrosis. However, models as such mimic the complex *in vivo* multicellular architecture poorly. Aim of this study was to evaluate the value of the precision-cut kidney slice (PCKS) model as an *ex vivo* model to study development of fibrosis, and to test the anti-fibrotic effects of IFNγ.

Methods: Precision-cut slices (250 μm thickness) were prepared from healthy mouse kidneys using a Krumdieck tissue slicer. To induce fibrosis, slices were incubated with TGFβ1 (5 ng/ml) for 48 hrs in the presence or absence of the anti-fibrotic cytokine IFNγ or a modified derivative thereof (PPB-PEG-IFNγ; *i.e.* IFNγ targeted to the PDGFR). After culture, tissue viability (ATP content) and expression of fibrotic markers (α-SMA, fibronectin, and collagen 1) using real-time PCR and immunohistochemistry were determined.

Results: Kidney slices remained viable up to 48 hrs of incubation and no significant effects of TGFβ1 and/or IFNγ on viability were observed. TGFβ1 significantly increased α-SMA, fibronectin, and collagen 1 mRNA and protein expression levels. IFNγ and PPB-PEG-IFNγ significantly reduced TGFβ1-induced fibronectin and collagen I mRNA and protein expression.

Conclusions: Fibrotic kidney slices are a promising tool to test anti-fibrotic drugs *in vitro* in a multicellular and profibrotic milieu, which cannot be achieved *in vitro* using other models. Importantly, this method provides the opportunity to study anti-fibrotic compounds not only in animal but also in human renal tissue.

SA-PO421

Nephronectin Promotes Normal Glomerular Structure and Function Denise K. Marciano,[1] Susan E. Zimmerman,[1] Zhufeng Yang.[1] *[1]Dept of Medicine, Div of Nephrology, Univ of Texas Southwestern Medical Center, Dallas, TX; [2]Dept of, Univ of California San Francisco, San Francisco, CA.*

Background: Previous studies have demonstrated that Nephronectin production by the ureteric bud is critical for the early inductive events of nephrogenesis and that Nephronectin null mice often have unilateral or bilateral renal agenesis.

Methods: In the current study, we use control and Nephronectin null mice to examine the localization and function of Nephronectin in later kidney development.

Results: We find that Nephronectin is highly produced by tubules and glomeruli. Specifically we find that Nephronectin is most highly produced by podocytes and localizes to the glomerular basement membrane. We examined glomerular structure in Nephronectin null mice that had escaped the early phenotype and found a slight expansion of the glomerular mesangium in adult mice. We subsequently conditionally deleted Nephronectin from nephron progenitors and observed significant mesangial expansion with collapse of glomerular capillary loops. The mesangial expansion was accompanied by increased mesangial matrix deposition. Furthermore, we find that in the absence of nephronectin, alpha 8 integrin produced by mesangial cells was mislocalized.

Conclusions: These results suggest that the nephronectin-alpha8 interaction is critical for normal glomerular structure.

Podocalyxin Mediates Polarized Lumenogenesis of Human Pluripotent Stem Cells in Three-Dimensional Culture Benjamin S. Freedman, Albert Q. Lam, Ryuji Morizane, Craig R. Brooks, Jing Zhou, Joseph V. Bonventre. *Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Epithelial polarization and lumenogenesis are critical to development and disease, but epithelial cell lines used to study these processes lack genetic diversity. Podocalyxin is an apical/luminal sialomucin expressed by glomerular podocytes and vascular endothelia, whose functional and mechanistic roles remain controversial and poorly understood. We investigated lumenogenesis in human pluripotent stem cells (hPSCs), which are genetically diverse and express endogenous podocalyxin.

Methods: hPSCs were cultured in three dimensions in extracellular matrix or suspension. Podocalyxin expression was disrupted using siRNA or CRISPR/Cas9 genome editing. Lumenogenesis was assayed by confocal microscopy, and tight junctions were assessed by ZO-1 immunohistochemistry and dextran dye exclusion.

Results: In 3D culture, epiblast-stage hPSCs formed expanding spheroidal cysts, comprising simple columnar epithelia surrounding hollow lumens lined with size-selective tight junctions and podocalyxin. Cysts were composed of pluripotent cells, which expressed pluripotency markers and gave rise to new cysts in serial 3D cultures. Lumenogenesis occurred via apicobasal polarization of ZO-1, ß-catenin, and podocalyxin, without requiring apoptosis, CFTR, or extracellular matrix. More primitive "naïve" hPSCs did not express podocalyxin and did not form cysts. CRISPR/Cas9 knockout of podocalyxin reduced lumen formation seven-fold, without disrupting tight junctions or pluripotency. Protamine sulfate caused podocalyxin mislocalization and collapse of cystic structures, indicating a charge-based mechanism.

Conclusions: Polarized lumenogenesis is a fundamental property of epiblast-stage human pluripotent stem cells in 3D microenvironments. Polarized, charge-repulsive interactions by podocalyxin at the apical plasma membrane are essential for expansion of the cyst lumen, independent of tight junction organization and function. hPSCs establish a new, genetically diverse model system in which to investigate the role of kidney proteins in epithelial polarity and lumenogenesis.

Anti-Inflammatory Role of miR-146a in the Pathogenesis of Diabetic Nephropathy Kirti Bhatt,[1] Linda L. Lanting,[1] Ye Jia,[1] Marpadga A. Reddy,[1] Mark Boldin,[2] Rama Natarajan.[1] *[1]Diabetes and Metabolic Diseases Research, Beckman Research Inst at City of Hope, Duarte, CA; [2]Molecular and Cellular Biology, Beckman Research Inst at City of Hope, Duarte, CA.*

Inflammation plays a pivotal role in the pathogenesis of diabetic complications including diabetic nephropathy (DN). MicroRNAs have recently emerged as critical regulators of DN. However, the role of microRNAs in the regulation of inflammation and development of DN is poorly understood. Here we show that miR-146a, a known anti-inflammatory microRNA, is up regulated in mice models of DN suggesting the involvement of inflammation/immune modulatory microRNA components in disease progression. miR-146a up regulation was consistently observed in the macrophages and kidneys of type 1 and type 2 diabetic mice by RT-PCR and in situ hybridization. Notably, miR-146a deficient mice exhibited increased diabetic kidney injury and severity in the pathogenesis of DN as compared to wild type mice. miR-146a null mice displayed a significant increase in proteinuria, macrophage infiltration, glomerular hypertrophy and fibrosis as compared to wild type mice after STZ induced diabetes. Mechanistically, the expression of pro-inflammatory mediators like MCP-1, TNF-α and pro-fibrotic genes like PAI-1, TGF-β were significantly elevated in the renal cortices of diabetic miR-146a null mice relative to wild type. Interestingly, the expression of key genes associated with anti-inflammatory M2 phenotype was significantly suppressed whereas expression of those associated with pro-inflammatory M1 phenotype

was up-regulated in macrophages from diabetic miR-146a-/- mice, suggesting a shift to more pro-inflammatory states. Furthermore, miR-146a target genes *Traf6* and *Irak1* related to NF-kB activation and inflammation were found to be up-regulated in the renal cortical tissues derived from diabetic miR-146a null mice as compared to the diabetic WT mice. These observations suggest that miR-146a plays an anti-inflammatory and anti-fibrotic role in the diabetic kidney. Approaches to overexpress miR-146a can be evaluated to confer protection from the development of DN.

SA-PO424

CXCL10 Expression Induced By Mxi1 Inactiviation Causes Mesangial Cell Apoptosis in Mice Habu Nephritis Xiang-Mei Chen, Lingling Wu, Yang Lu, Guangyan Cai. *Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center of Kidney Diseases, Beijing, China.*

Background: The Mxi1 proteins are antagonists of c-myc. It has been pointed out that Mxi1 expression decreased significantly during the proliferative period in anti-Thy1 nephritis model rats and then gradually rised as proliferation declined, thereby suggesting a possible role for Mxi1 in mesangial proliferation, while the specific mechanisms that how Mxi1 affects mesangial proliferative glomerulonephritis need to be studied further.

Methods: *In vivo*, we used Mxi1 gene knockout mice ($Mxi1^{-/-}$ mice) and wild-type mice ($Mxi1^{+/+}$ mice) to establish mesangial proliferative glomerulonephritis mice model. In vit*ro* we down-regulated mouse mesangial cell Mxi1 expression by RNAi technology.

Results: We found that $Mxi1^{-/-}$ mice exhibited more typically and more severe pathological phenotypes compared with wild-type mice, which mainly manifested as the more obvious dissolution phenotype, the higher proportion of apoptotic cells and chemokine CXCL10 expression in the early days of the model, and the higher levels of cell proliferation in late days. In vitro, we found increased expression of CXCL10 and activiation of caspase 3, and increased proportion of apoptotic cells when the expression of the Mxi1 was inhibited in mouse mesangial; while the proportion of apoptotic cells decreased after we interfered CXCL10.

Conclusions: These *in vivo* and in vit*ro* experiments demonstrate that the mouse mesangial cell apoptosis in the early age of mesangial proliferative glomerulonephritis model was related with the expression of CXCL10 induced by Mxi1 inactiviation, and this finding will provide a possible intervention target for the treatment of the mesangial proliferative glomerulonephritis.

Concomitant Inhibition of Renin Angiotensin System and Endothelin-1 Reduce Renal Fibrosis Induced By Unilateral Ureteral Obstruction in Mice Dae Eun Choi,[1] Jin Young Jeong,[1] Hyunsu Choi,[2] Ye Jin Kim,[1] Sarah Chung,[1] Yoon-Kyung Chang,[3] Ki Ryang Na,[1] Kang Wook Lee,[1] Young Tai Shin.[1] *[1]Internal Medicine, ChungNam National Univ Hospital, Daejeon, Korea; [2]Inst of Clinical Medicine, Saint Mary Hospital, Catholic Univ, Daejeon, Korea; [3]Internal Medicine, Saint Mary Hospital, Catholic Univ, Daejeon, Korea.*

Background: Both Endothelin-1(ET-1) and Renin angiotensin system (RAS) may play an important role in renal fibrosis in obstructed kidney. However, there was few study for the relationship between RAS and renal ET-1 activation in experimental unilateral ureteral obstruction (UUO). We investigated the role and relationship of renal RAS and ET-1 in UUO.

Methods: 8 weeks old male C57BL/6 mice were divided into the 6 groups; 1)Sham, 2) bosentan+Sham, 3) valsartan+Sham, 4)vehicle+UUO, 5)bosentan+UUO 6)valsartan+UUO, and 7)Valsartan + bosentan+UUO. Valsartan and bosentan were administrated via oral using NG tube (valsartan 10mg/kg/day, bosentan 100mg/kg/day for 8days). We performed realtime RT PCR and immunohistochemistry for molecular study and H&E stain and Masson trichrome (MT) stain for histologic examination of kidneys.

Results: Although angiotensinogen and angiotensin II receptor are increased in bosentan + UUO kidney compared to vehicle + UUO kidney, bosentan treatment reduced significantly renal expression of PKC-β, TGF-β, and α-SMA in UUO kidney. Also, it reduced renal tubular injury in H&E stain and blue stained area in MT stain of UUO kidney. Valsartan treatment in UUO mice showed similar results to Valsartan treated UUO mice. Co-treatment of valsartan and bosentan decrease significantly renal expression of PKC-β,TGF-β, and α-SMA compared to both valsartan+UUO and bosentan+UUO respectively. Also, they reduced significantly renal tubular injury in H&E stain and blue stained area in MT stain of UUO kidney compaired to both valsartan+UUO and bosentan+UUO respectively.

Conclusions: Concomitant inhibition of Renin Angiotensin System and Endothelin-1 reduces renal fibrosis induced by UUO in mice. It may have additive effects compare to single inhibition of RAS or ET-1.

SA-PO426

G-Protein Coupled Chemokine Receptor Cxcr4 Contributes to Kidney Fibrosis By Inducing Multiple Effectors Amy Yuan,[1] Yashang Lee,[1] Gilbert W. Moeckel,[1] Anil K. Karihaloo.[1] *[1]Medicine, Yale School of Medicine, New Haven, CT; [2]Medicine, Yale School of Medicine, New Haven, CT; [3]Pathology, Yale School of Medicine, New Haven, CT.*

Background: Kidney fibrosis is the common endpoint for every type of chronic kidney disease (CKD). G-protein coupled chemokine receptor Cxcr4 is ubiquitously expressed. The expression in an adult kidney is very low. In the present study, we hypothesized that chronically increased Cxcr4 expression will augment fibrosis.

Methods: Tubule and macrophage-specific conditional mouse knockouts of Cxcr4 were generated. Fibrosis was induced via UUO.

Results: Following UUO Cxcr4 expression in tubular cells increased by several-fold. This increased Cxcr4 expression correlated with their increased mRNA expression of PDGFα, TGFβ1 with concurrent loss of BMP7. Artificially over-expressing Cxcr4 in a human proximal tubular cell line led to almost complete loss of BMP7 mRNA. Conditional knockout of tubular Cxcr4 in-vivo was partially protective against UUO-mediated fibrotic response leading to 50% less fibrosis. This correlated with a significant reduction in PDGFα, TGFβ1 levels and the preservation of BMP7 expression after UUO. Furthermore, $Cxcr4^{+}$ immune cells infiltrated into the interstitium of the obstructed kidneys that further contributed to the increase in total Cxcr4 expression in injured kidneys. Increased Cxcr4 expression in macrophages partly correlated with increase in their pro-fibrotic markers. Selectively ablating Cxcr4 from macrophages significantly reduced UUO-mediated fibrotic response with concomitant reduction in the expression of total kidney TGFβ1 mRNA that correlated with reduced SMAD activation and αSMA levels. Finally, administering a Cxcr4 inhibitor, AMD3100, subcutaneously once every 12 hours from the time of UUO, resulted in a dose dependent significant protection from UUO-induced fibrotic response.

Conclusions: Our data demonstrate that chronic high Cxcr4 expression in multiple effector cell types contributes to the pathogenesis of renal fibrosis by altering their biological profile. We present a novel cross-talk between Cxcr4-TGFb1 and BMP7 pathways that may provide novel avenues for interrupting the progression of fibrosis and hence CKD.

Latent Transforming Growth Factor Beta Binding Protein 4 Enances Renal Fibrosis in Obstructive Nephropathy Chi-Ting Su,[1,2] Jenq-Wen Huang,[2] Chih-Kang Chiang,[2] Branka Dabovic,[3] Zsolt Urban.[1] *[1]Human Genetics, Univ of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; [2]Nephrology, Internal Medicine, National Taiwan Univ Meical College and Hospital, Taipei, Taiwan; [3]Cell Biology, New York Univ Langone School of Medicine.*

Background: Although transforming growth factor-β (TGFβ) signaling is known to play an essential role in renal fibrosis, the role of latent TGFβ binding proteins (LTBPs) remains largely unknown. LTBP4 has been recognized to regulate the secretion and deposition and activation of latent TGFβ molecules in the extracellular matrix.

Methods: To investigate the impact of Ltbp4 on renal fibrosis, we subjected *Ltbp4S*-/- mice and wild type littermates to unilateral ureteral obstruction (UUO) at 4 weeks of age. Two weeks later, the mice were euthanized. Expression of mRNA and protein markers of fibrosis and inflammation were studied by quantitative real-time PCR, immunoblotting and immunofluorescent staining of kidney samples.

Results: LTBP4 was up-regulated by UUO both at the protein and at the mRNA levels in wild type mice, and was mainly expressed around peri-glomerular cells. As expected, UUO increased the expression of both profibrotic [TGFβ1, plasminogen activator inhibitor-1 (PAI1)] and proinflammatory [interleukin1 (IL1), IL6] molecules, and increased immunoreactivity for α-smooth muscle actin (SMA) in wild type mice. *Ltbp4S* deficiency significantly attenuated TGFβ1 and PAI1 expression and SMA immunoreactivity, but did not change the expression of either IL1 or IL6 in UUO mice.

Conclusions: Ltbp4 acts downstream of inflammatory molecules to enhance fibrosis in UUO-induced renal injury. Therefore, Ltbp4 antagonism may be considered for therapeutic suppression of renal fibrosis.

Dnmt1 as a Therapy Target for *Attenuating* Diabetic Nephropathy and Podocyte Injury Li Zhang, Wei Shi, Shuangxin Liu, Xinling Liang, Ting Lin, Chunping Yu, Yuanhan Chen, Zongshun Huang, Ruizhao Li. *Dept of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: Podocyte injury plays a key role in the development of diabetic nephropathy(DN). Recent studies have suggest a potential role for epigeneticmechanisms apart from genetic predisposition in the etiology of DN. In this study, experiments were undertaken to assess the role of DNA methylation on DN, especially on podocyte injury.

Methods: Type 2 diabetic *db/db* mice received i.p. injections of DNA methylation inhibitor 5-azacytidine three times a week and were killed after 8 weeks. Immortalized mouse podocytes were cultured under different experimental conditions.

Results: Our findings indicate that the albuminuria in diabetic *db/db* mice was markedly attenuated after 5-azacytidine treatment, accompanied with alleviated glumerular hypertrophy, mesangial matrix expansion and podocyte injury. However, body weight, food and water consumption, and glucose levels remained unaffected. In addition, we also found that themethyltransferase Dnmt1, nuclear factor Sp1and NFκB-p65 expression were

markedly increased in vivo and vitro podocytes under diabetic state, and increasedDnmt1 expression was also attenuated after treatment with 5-azacytidine or 5-Aza- 2'-deoxycytidine or Dnmt1 knockdown, accompanied with improved podocyte motility and the filtration barrier function of podocyte monolayer. Further study found that increased Sp1 and NFκB-p65 are interact in the nucleus of podocytes incubated with high glucose, and Sp1 binds to Dnmt1 promoter region(-119~+102). The involvement of Sp1/NFκB-p65 in Dnmt1regulation is further demonstrated by the observation that Sp1 knockdown using mithramycin A or siRNA decreases Dnmt1 protein levels. Our results provide the first in vivo and vitro evidence that inhibition of DNA methylation ameliorate glomerular pathologies and podocyte injury in diabetic state, and thus suggest that aberrant DNA methylation is involved in DN and podocyte injury.

Conclusions: DNA methylation inhibitor might be a new therapeutic avenue for the treatment of DN. Sp1/ NFκB-p65-Dnmt1 pathway may be exploited as a therapeutic target for protecting against podocyte injury of DN.

Podocyte-Specific NFAT Activation in Mice Causes Glomerular Injury That Progresses from MCD- to FSGS-Like Features Alexis J. Sloan, Saurav Singh, Karla J. Schramm, Alexander Grabner, Ansel P. Amaral, Alessia Fornoni, Christian Faul. *Medicine, Miller School of Medicine, Miami, FL.*

Background: Aberrant elevation in cytoplasmic calcium levels in podocytes causes changes in podocyte morphology and glomerular permeability. The phosphatase calcineurin responds to elevated calcium by dephosphorylating the nuclear factor of activated T-cells (NFAT). We have shown that in podocytes NFAT is activated by proteinuric stimuli, like angiotension II or adriamycin, and that podocyte-specific activation of calcineurin or NFAT in transgenic mice is sufficient to cause proteinuria within days. We investigate the precise glomerular phenotype of NFAT transgenic mice.

Methods: Transgenic mice with the podocyte-specific, doxycyclin (Dox)-inducible expression of constitutively active NFAT (NFATc1nuc) were fed Dox chow, and urine albumin levels were monitored over time. Mice were sacrificed at different time points for histological studies of the kidney, including H&E, TEM analysis of the podocyte foot process (FP) structure and labeling for WT1 to determine podocyte numbers. In subgroups Dox was removed at different time points to study a potential reversibility of the phenotype.

Results: NFATc1nuc mice are proteinuric within three days of Dox exposure with podocyte FP effacement. NFATc1nuc induction for four months leads to sustained proteinuria with an increase in FP effacement, but without other histological changes within the kidney. Animals that are left on constant Dox treatment for 1 year develop glomerular sclerosis, extraglomerular lesions and impaired renal function. Proteinuria in mice with short-term NFATc1 activation in podocytes is reversible, whereas mice with NFATc1nuc expression for two months are unable to revert to normal podocyte morphology and kidney function.

Conclusions: Podocyte-specific NFAT activation in mice causes a two-phase renal phenotype, first MCD-like alterations that are reversible, followed irreversible FSGS-like changes. We are currently determining the precise "point of no return", and postulate that the phenotypic switch from a MCD- to an FSGS-like phenotype occurs in concert with changes in the responsiveness to pharmacological interventions like steroid resistance.

Thrombin Causes Human Podocyte Apoptosis in a Protease Activated Receptor (PAR)-3/-4 Dependent Manner Ruchika Sharma,[1] Amanda P. Waller,[1] Adam J. Guess,[1] Shipra Agrawal,[1] Berend Isermann,[3] William E. Smoyer,[1] Marvin T. Nieman,[2] Bryce Kerlin.[1] *[1]Center for Clinical and Translational Research, Nationwide Children's Research Inst, Columbus, OH; [2]Pharmacology, Case Western Reserve Univ, Cleveland, OH; [3]Clinical Chemistry and Pathobiochemistry, Otto-von-Guericke Univ, Magdeburg, Germany.*

Background: Nephrotic Syndrome (NS), one of the most common forms of glomerular disease, is associated with increased endogenous thrombin activity. *In vitro* evidence suggests that thrombin may injure podocytes and thus contribute to progressive glomerular injury. The molecular mechanisms by which thrombin induces podocyte injury are not yet known. Thrombin is known to signal through Protease Activated Receptors (PARs) in other cell types. Thus, we hypothesized that thrombin exacerbates glomerular injury by enhancing podocyte apoptosis in a PAR dependent manner.

Methods: Experiments were performed with differentiated, conditionally immortalized human podocytes. Podocyte apoptosis was determined after 36 hours of thrombin (20nM) exposure by TUNEL assay. Specific PAR antibodies and activating peptides were utilized to determine which PARs mediate thrombin-induced podocyte apoptosis.

Results: Thrombin exposure induces a significant increase in apoptosis ($p<0.05$). Blockade of PAR-3 or PAR-4 resulted in a significant decrease in apoptosis ($p<0.05$) as did inhibition of thrombin enzymatic activity with hirudin, a direct thrombin inhibitor ($p<0.05$). In comparison to a control peptide, PAR-4 activation peptide significantly increased apoptosis ($p<0.05$), while PAR-3 activation peptide did not.

Conclusions: Thrombin-induced human podocyte injury is mediated in a PAR-dependent fashion. Specifically, in this *in vitro* model, PAR-3 and PAR-4 appear to mediate thrombin induced podocyte injury. Furthermore, these data suggest that thrombin induced podocyte injury may be mediated in a manner dependent on PAR-3/-4 heterodimerization. Co-immunoprecipitation experiments are underway to evaluate for the presence of PAR-3/-4 heterodimers in human podocytes. Interrupting thrombin-mediated podocyte injury may provide a novel therapeutic approach for NS.

Disrupted ABIN1 Function Results in a Pro-Inflammatory Phenotype in Human Glomerular Cells David W. Powell, Rachel Therese G'Sell, Ryan M. Sheehan, Dawn J. Caster, Michael Merchant, Kenneth R. McLeish, Erik Korte. *Medicine/Nephrology, Univ of Louisville School of Medicine.*

Background: NF-κB activation is implicated in various types of glomerulonephritis. ABIN1 is a ubiquitin binding protein that functions as a physiological NF-κB inhibitor. We reported that mice expressing an ABIN1[D485N] mutation lacking ubiquitin binding activity develop lupus-like autoimmunity and proliferative lupus nephritis (LN) and ABIN1 polymorphisms are associated with LN. The present study tested the hypothesis that enhanced NF-kB activation in human podocytes and mesangial cells containing a loss of function ABIN1[D472N] mutation leads to local production of cytokines that amplify glomerular injury.

Methods: Expression and secretion of NF-κB target proteins were assessed in response to TNF-α and IL-1β in wild-type and ABIN1[D472N] expressing human-derived podocyte and mesangial cell lines using gene and protein arrays, RT-PCR, ELISA, and mass spectrometry. Primary human lymphocyte and leucocyte chemotaxis was measured using transwell permeable supports in response to TNF-α stimulated wild-type and ABIN1[D472N] mesangial cell supernatants.

Results: Array analysis showed that expression and secretion of NF-κB targets including interleukins (IL-6, IL-8) interferons (INF-β1, INF-γ) chemokines (CXCL1, MCP1), complement factors (CFB, C3), and colony stimulating factors (G-CSF, CSF3) were elevated in pro-inflammatory stimulated ABIN1[D472N] human glomerular cells as compared with wild-type control cells. This effect was confirmed for MCP-1, CSF3, IL-8, IL-6, and C3. Primary B/T cell and neutrophil chemotaxis was stimulated by incubation with supernatant from stimulated ABIN1[D472N] glomerular cells as compared to that of control cells.

Conclusions: Our findings suggest that dysregulation of NF-κB activation in glomerular cells containing ABIN1 polymorphisms acts to enhance glomerular inflammation in LN through production of pro-inflammatory cytokines and recruitment of immune cells, providing novel mechanistic insight for development of improved therapeutics. Our studies have focused on LN, but these finding also provide promising directions for events controlling inflammation in other types of kidney disease.

SA-PO432

Podocyte-Specific Loss of Krüppel-Like Factor 6 Accelerates Kidney Fibrosis Under Diabetic Conditions Sandeep K. Mallipattu,[1] Sylvia Horne,[1] Victoria Ly,[1] Timothy W. Miller,[1] John C. He.[2] *[1]Stony Brook Univ; [2]Icahn School of Medicine at Mount Sinai.*

Background: Krüppel-like factor 6 (KLF6) is a zinc-finger DNA-binding transcription factor, shown to play a critical role in preventing mitochondrial injury in the podocyte. Although mitochondrial injury and podocyte loss are features of diabetic kidney disease (DKD), mechanism(s) by which podocyte injury contributes to eventual interstitial fibrosis remain elusive.

Methods: Immunostaining was used to assess KLF6 expression in kidney biopsies from patients with DKD. *In vivo*: mice with podocyte-specific loss of *Klf6*, *Cre*$^{+}$ *podocin Klf6*$^{flox/flox}$, were generated and made diabetic with streptozotocin (STZ) at age 12 weeks. *In vitro*: stable knockdown (shRNA-*KLF6*) and overexpression (lentiORF-*KLF6*) of *KLF6* in human podocytes was performed under high (HG-30mM), normal glucose (NG-5mM), and mannitol (30mM) conditions for 24 hours.

Results: We observed that the glomerular expression of KLF6 was reduced in kidney biopsies from patients with DKD as compared to healthy donors. These findings were confirmed by two independent tissue arrays from Nephromine, publicly available renal gene expression database. Diabetic *Cre*$^{+}$ *podocin Klf6*$^{flox/flox}$ mice exhibited a 20-fold increase in albuminuria, kidney hypertrophy, mesangial expansion, and thickened BM with increased glomerular and interstitial collagen deposition as compared to all other groups. Immunostaining showed a significant increase in glomerular and interstitial cytochrome c, TGF-β1, and vimentin levels in the diabetic *Cre*$^{+}$ *podocin Klf6*$^{flox/flox}$ mice. Under HG conditions, shRNA-*KLF6* increased cleaved caspase 3 and 9 expression and reduced cytochrome c oxidase levels as compared to all other groups. In contrast, lentiORF-*KLF6* reduced cleaved caspase 3 expression and rescued cytochrome c oxidase levels under HG conditions, as compared to all other groups.

Conclusions: We showed that under diabetic conditions, podocyte-specific loss of *Klf6* resulted in glomerular injury, earlier activation of the intrinsic apoptotic pathway, and acceleration of interstitial fibrosis. Combined, this suggests that KLF6 may serve as the link between podocyte injury and interstitial fibrosis in DKD.

SA-PO433

Identification of Neuropilin-1 as a Target for Glomerular Disease Christina S. Bartlett,[1] Monika Lucyna Wnuk,[2] Vera Eremina,[3] Chengjin Li,[3] Yashpal S. Kanwar,[1] Jeffrey H. Miner,[4] Maria Pia Rastaldi,[5] Susan E. Quaggin.[1] *[1]Feinberg Cardiovascular Research Inst and the Div of Nephrology, Northwestern Univ, Chicago, IL; [2]Univ of Bern, Switzerland; [3]Mount Sinai Hospital, Toronto, Canada; [4]Washington Univ, St. Louis, MO; [5]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy.*

Background: Neuropilin-1 is a co-receptor for a variety of growth factors and is critical for development and patterning of the vascular and nervous systems. In the kidney NP-1 is expressed in the specialized perivascular mesangial cells, yet its role in glomerular function and disease is unknown. In biopsies from human diabetic patients, we show increased expression of NP-1. Therefore, we hypothesize NP-1 on mesangial cells, and in perivascular cells in other tissues, is required to modulate receptor tyrosine kinase activity in adjacent endothelium to maintain a quiescent vasculature.

Methods: NP-1 expression was observed in biopsy samples from diabetic and IgA nephropathy patients using IF. To further investigate the function of NP-1, mice with perivascular cell specific deletion of NP-1 were utilized.

Results: Patients with diabetic nephropathy and IgM nephropathy showed substantially increased expression of NP-1 protein within the glomerular mesangium, suggesting NP-1 may play an important role in pathogenesis of these diseases. In mice, deletion of NP-1 from mesangial cells during glomerular development results in dramatic mesangial expansion, thickening of the GBM, and tubular dilation. These mice show 10-fold higher proteinuria and an over 60% reduction in GFR at 4 weeks of age, and die within 5 weeks of age due to renal failure. Profound collagen accumulation and increased matrix protein expression was observed in mutant glomeruli, suggesting NP-1 plays a critical role in matrix production. Additionally, enhanced VEGFR2 activation and signaling was observed in mutant mice, consistent with our hypothesis.

Conclusions: These studies suggest a protective role of NP-1 in renal diseases such as diabetic nephropathy or IgA nephropathy, via regulation of matrix production and stabilization of the glomerular endothelium, and present NP-1 as an attractive target for the treatment of renal diseases.

SA-PO434

T Cells Infiltration in the Kidneys of Patients with Both Anti-Glomerular Basement Membrane Antibodies and Anti-Neutrophil Cytoplasmic Antibodies Shuiyi Hu, Zhao Cui, Ming-Hui Zhao. *Renal Div, Dept of Medicine, Peking Univ First Hospital, Inst of Nephrology, Peking Univ, Beijing, China.*

Background: Patients with anti-glomerular basement membrane (GBM) antibodies and anti-neutrophil cytoplasmic antibodies (ANCA) present severe kidney injury and poor outcomes. Cellular immunity plays important role in the pathogenesis of anti-GBM disease and ANCA associated vasculitis. In double positive patients, the participation of T cells in kidney injury is unclear.

Methods: T cells (CD3, CD4, CD8, IL-17 and foxp3) and macrophages (CD68) were examined by immunohistochemistry on renal biopsy tissues from 22 patients with anti-GBM disease, including nine patients with positive ANCA. The correlation between cell infiltration and clinical data was further analyzed.

Results: T cells and macrophages were shown in the kidneys of all patients. The distribution of cell infiltration was predominant in the peri-glomerular and interstitial areas ($p<0.001$). T cells infiltration in the kidneys of double positive patients was much severer than that of patients with anti-GBM antibodies alone (3527.6±1561.6 versus 1776.4±1209.0 cells/mm^2, $p=0.024$). This difference was much notable on CD8+ T cells and IL-17 producing cells in the peri-glomerular and interstitial areas. In double positive patients, the number of CD8+ T cell around glomeruli was positively correlated with the crescent percentage in glomeruli ($r=0.707$, $p=0.033$), and CD8+ T cells aggregated highly around the glomeruli with ruptured Bowman's capsule (13.9±6.7 versus 4.4±4.0 cells/gcs, $p=0.006$). In patients with anti-GBM antibodies alone, IL-17 producing cells showed a positive correlation with cellular crescents percentage ($r=0.968$, $p=0.007$).

Conclusions: T cell infiltration might play a crucial role in the inflammatory kidney injury of double positive patients, especially the CD8+ cytotoxic T cells around glomeruli.

SA-PO435

Zonulin, a Circulating Factor That Regulates Podocyte Function and Glomerular Permeability Karla J. Schramm,[1] Britta Sylvia Walter,[1] Alexis J. Sloan,[1] Saurav Singh,[1] Sandra M. Merscher,[1] Alessia Fornoni,[1] Cristina Zennaro,[2] Mary Artero,[2] Michele Carraro,[2] Alessio Fasano,[3] Christian Faul.[1] *[1]Dept of Medicine, Univ of Miami Miller School of Medicine, Miami, FL; [2]Dept of Medicine, Surgical and Health Sciences, Univ of Trieste, Trieste, Italy; [3]Dept of Pediatric Gastroenterology, Mass General Hospital for Children, Boston, MA.*

Background: Zonulin, a 47kDa secreted protein, stimulates protease-activated receptor (PAR) 2 on enterocytes, modifies the phosphorylation and localization of zonula occludens (ZO)-1 and alters actin dynamics. Thereby zonulin transiently disassembles tight junctions (TJ) and reversibly regulates small intestine permeability. Zonulin expression is elevated in patients with Celiac Disease (CD) and causes abnormal paracellular transport and diarrhea. It is also increased in the serum of patients with CD, indicating that zonulin could function as a circulating modifier of TJs in other tissues. Since podocytes express PAR2 and TJ proteins, zonulin might act as a regulator of the slit diaphragm (SD), and prolonged PAR2 activation may lead to irreversible podocyte injury and proteinuria.

Methods: We treated cultured podocytes (wild type and PAR2 knockdown) with AT1002, a zonulin peptide analogue, and examined its effects on the cytoskeleton and SD. We measured albumin permeability of isolated rat glomeruli treated with zonulin, and we determined urine albumin levels of zonulin knockin mice.

Results: AT1002 induced changes in the podocyte actin cytoskeleton and cell migration via PAR2, and altered ZO-1 phosphorylation and paracellular flux. Zonulin and serum from FSGS patients increased albumin permeability of isolated rat glomeruli, which was blocked in the presence of a PAR2 inhibitor. Zonulin knockin mice developed proteinuria.

Conclusions: Zonulin might act as a circulating factor that regulates the podocyte SD and paracellular permeability. It is possible that zonulin is involved in a variety of glomerular diseases and that FSGS patients would benefit from pharmacological PAR2 inhibition. Anecdotal reports suggest that a subgroup of FSGS patients show a favorable response to a gluten-free diet, which in CD has been shown to reduce serum zonulin.

SA-PO436

Rostafuroxin Protects From Podocyte Injury and Proteinuria Induced By Adducin Genetic Variants and Ouabain Mara Ferrandi,[1] Isabella Molinari,[1] Patrizia Ferrari,[3] Maria Pia Rastaldi,[2] Laura Zagato,[1] Giuseppe Bianchi,[1,3] Paolo Manunta.[1] *[1]San Raffaele Scientific Inst, Milan, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore, Italy; [3]CVie Therapeutics, Hong Kong, China.*

Background: Glomerulopathies are important causes of morbidity and mortality. Selective therapies addressed to the underlying mechanisms are still lacking. Recently, our group identified two mechanisms, mutant β-adducin and ouabain, involved in glomerular podocytopathies and proteinuria through nephrin down-regulation. Here, we proposed that rostafuroxin, a novel antihypertensive agent developed as a selective inhibitor of Src-SH2 interaction with mutant adducin and ouabain-activated Na-K ATPase, may protect podocytes from adducin and ouabain effects, thus representing a novel pharmacological approach for the therapy of podocytopathies and proteinuria caused by the above mentioned mechanisms.

Methods: To study rostafuroxin effect on podocyte protein changes and proteinuria, mice carrying mutant β-adducin and ouabain hypertensive rats, OHR, were orally treated with 100 μg/kg/day rostafuroxin. Primary podocytes from congenic rats carrying mutant α- (NA) or β-adducin (NB) from the Milan hypertensive strain, MHS, and normal rat podocytes incubated with 10^{-9} M ouabain, were cultured with 10^{-9} M rostafuroxin.

Results: We showed that mutant β-adducin and ouabain caused podocyte nephrin loss (range from -28 to -38%, $p<0.05$) and proteinuria (range from +50 to +60%, $p<0.05$) in these animal models. Such nephrin alteration was reproduced in primary podocyte cultures from NB rats (-60%, $p<0.05$ versus NA) and from normal rat incubated with ouabain (-34%, $p<0.05$ versus control). Treatment of animals, or incubation of cultured podocytes with rostafuroxin, reverted mutant β-adducin and ouabain-induced effects on nephrin protein expression (range from +25 to +35%, $p<0.05$) and proteinuria (range from -55% to -65%, $p<0.05$).

Conclusions: These findings indicate that rostafuroxin prevented podocyte lesions and proteinuria due to mutant β-adducin and ouabain in animal models. This suggests a potential therapeutic effect of rostafuroxin also in patients affected by glomerular disease progression associated with these two mechanisms.

SA-PO437

Mammalian Target of Rapamycin Complex 1 Activation in Podocytes Promotes Cellular Crescent Formation Junhua Mao, Weichun He, Junwei Yang, Chunsun Dai. *Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical Univ, Nanjing, China.*

Background: Podocytes play a key role in the formation of cellular crescents in experimental and human diseases. However, the underlying mechanisms for podocytes in promoting crescent formation need further investigation.

Results: Here we demonstrated that mammalian target of rapamycin complex 1 (mTORC1) signaling was remarkably activated and HIF1alpha expression was largely induced in cellular crescents from patients with crescentic glomerular diseases. Specific deletion of Tsc1 in podocytes led to podocyte mTORC1 activation and kidney dysfunction in mice. Interestingly, about 15% of the glomeruli developed cellular or mixed cellular and fibrous crescents in the knockouts at 7 weeks of age and the percentage was increased to about 30% at 12 weeks of age. Most notably, bridging cells between the glomerular tuft and the parietal basement membrane and cellular crescents were WT1, p-S6, HIF1alpha or Cxcr4 immunostaining positive. Furthermore, many cells within the cellular crescents were also immune-staining positive for anti-claudin 1, suggesting an involvement of parietal cells for the crescent formation in the knockouts. In addition, administration of rapamycin started at 7 weeks of age for 5 weeks abolished crescent formation as well as the induction for p-S6, HIF1alpha and Cxcr4 in the glomeruli from the knockouts.

Conclusions: It is concluded that mTORC1 activation in podocytes promotes cellular crescent formation and targeting this signaling may shed a new light for the treatment of patients with crescentic glomerular diseases.

Essential Role of iqgap2 for Maintenance of Podocyte Structure and Function in Zebrafish Yuya Sugano,[1,2,4] Ines Auberger,[1,3,4] Urs Ziegler,[5] Clemens D. Cohen,[3,4] Stephan C. Neuhauss,[2,4] Johannes Loffing.[1,4] *[1]Inst of Anatomy, Univ of Zurich, Zurich, Switzerland; [2]Inst of Molecular Life Sciences, Univ of Zurich, Zurich, Switzerland; [3]Inst of Physiology, Univ of Zurich, Zurich, Switzerland; [4]Zurich Center for Integrative Human Physiology, Univ of Zurich, Zurich, Switzerland; [5]Center for Microscopy and Image Analysis, Univ of Zurich, Zurich, Switzerland.*

Background: Podocytes are essential for the maintenance of the glomerular filtration barrier. In nephrotic syndrome (NS), podocyte dysfunction impairs the glomerular size selectivity, leading to proteinuria. In this study, we screened human and mouse mRNA datasets for genes possibly relevant to NS and tested their functional relevance in the zebrafish pronephros.

Methods: The human European renal cDNA bank, biopsies from kidneys of NS patients and isolated mouse nephron segment were screened for genes that are dysregulated in patients with NS and are also enriched in mouse glomeruli. Subsequently, the orthologues of the mammalian candidate genes were analyzed by *in situ* hybridization for expression in the pronephros and subjected to functional analyses by morpholino-based gene knockdown.

Results: One of the identified candidate genes was the IQ motif containing GTPase activating protein 2 (iqgap2), of which mRNA was found to be expressed in the zebrafish pronephros with highest expression levels in the glomerulus. Immunohistochemistry revealed that iqgap2 protein is mainly abundant in the zebrafish podocytes. Morpholino-based knockdown of *iqgap2* caused a dilation of Bowman's space that became apparent with the onset of glomerular filtration. Electron microscopy showed intact glomerular endothelial and mesangial cells. Podocytes were well developed but showed some degree of progressive foot process effacement. Consistent with an impaired glomerular filtration barrier, *iqgap2* morphants showed glomerular filtration of large fluorescent dextrans (~500 kDa), which had been i.v. injected.

Conclusions: IQGAP2 is a glomerulus-enriched gene product that is dysregulated in patients with NS, which appears to be required for normal podocyte structure and function in zebrafish larvae.

SA-PO439

Knockdown of Podocyte Foot Process Protein Klhl35 Results in Proteinuria in Zebrafish Pronephros Sonia Zambrano Sevilla, Patricia Rodriguez, Jaakko Patrakka. *Dept of Medical Biochemistry and Biophysics, Karolinska Instt, Stockholm, Sweden.*

Background: In our previous microarray study, a transcript encoding for Kelch-like family member 35 (Klhl35) was enriched in the glomerulus. As the protein is very poorly characterized, we aimed in this study to analyze the expression and function of Klhl35 in the kidney.

Methods: Expression was studied in adult and developing kidneys, as well as in cultured podocytes using RT-PCR, immunofluorescence and immune-electron microscopy. Functional studies were performed in zebrafish by inactivating the gene expression using morpholinos.

Results: Klhl35 was expressed by podocytes and it localized to foot processes. During glomerulogenesis Klhl35 was detected first at S-shaped stage glomeruli in where its expression seemed to preceed nephrin expression. In cultured podocytes, no significant expression was detected in undifferentiated cells. In differentiated podocytes the expression was induced and Klhl35 was detected in stress fibers. In zebrafish, the knockdown of Klhl35 orthologue resulted in pronephros abnormalities including foot process effacement. Functionally, pronephros was leaking as detected by the presence of of 500kD fluorescent dye in the tubular compartment.

Conclusions: Klhl35 is a novel podocyte foot process protein. It is important for the integrity of zebrafish pronephros. Based on its sequence, we speculate that Klhl35 is an actin-associated protein that regulates the organization of foot process cytoskeleton.

SA-PO440

Studying the Function of ApoL1 in the Pronephros of Zebrafish Larvae Ahmed Kotb, Elisabeth Rumpel, Ole Simon, Karlhans Endlich, Nicole Endlich. *Anatomy and Cell Biology, Univ Medicine Greifswald, Greifswald, MV, Germany.*

Background: APOL1 which encodes for a secreted high density lipoprotein (HDL) is expressed in a number of human tissues, including the kidney. Recently it was shown that genetic variants of APOL1 are associated with non-diabetic kidney diseases, kidney diseases attributed to hypertension and focal segmental glomerulosclerosis (FSGS) in African Americans. In human, ApoL1 is expressed mainly in podocytes, in extraglomerular endothelial cells and somes tubules. Since an ortholog of ApoL1 does not exist in mice, the zebrafish is an ideal model to study the function of this protein.

Results: We found that the expression of zApoL1 in zebrafish larvae is similar to the expression in human tissue. After the knockdown (KD) of zApoL1 in zebrafish larvae by the injection of specific morpholinos (zApoL1 MO) into fertilized eggs, the larvae developed severe pericardial edema accompanied by a lower number of glomerular capillaries. To determine whether the KD of zApoL1 affects also glomerular filtration we injected two different fluorescence-labeled dextran molecules (10 kDa and 500 kDa) into the vein of zebrafish larvae and studied the filtration process by measuring the fluorescence intensity in vessels and in the pronephric tubules. With this method we found that the glomerular filtration barrier was leaky for 500 kDa dextran after zApoL1 MO injection. After the injection of in vivo morpholinos into zebrafish larvae we observed a reorganization of the glomerulus directly in living zebrafish larvae by the use of two-photon micoscopy. Further, we found by immunohistochemical staining of zebrafish sections that the expression of nephrin, a slit diaphragm protein, was significantly reduced after zApoL1 KD. Interestingly, we also found a correlation between the ApoL1 and nephrin expression in biopsies of patients suffering from FSGS and membranous glomerulonephritis.

Conclusions: In summary, our data demonstrate that zApoL1 is important for the proper expression of nephrin in podocytes and necessary for an intact glomerular filtration barrier in zebrafish larvae.

Funding: Government Support - Non-U.S.

Misexpression of Mouse Nephrin in the Drosophila Developing Eye Leads to Irregular Cell Sorting Resulting in a Rough Eye Phenotype Britta George,[1] Hermann Pavenstaedt,[1] Christian Klämbt.[2] *[1]Nephrology Dept, Univ Hospital Münster, Münster, Germany; [2]Inst for Neurobiology, Westfälische-Wilhelms-Univ Münster, Münster, Germany.*

Background: Mutations in the murine NPHS1 gene which encodes the slit diaphragm protein Nephrin result in incomplete formation of podocyte cell processes and the development of proteinuria. Nephrin binds to the cell adhesion molecule Neph1 at the slit diaphragm and upon activation mediates signals to the actin cytoskeleton in a phosphotyrosine-dependent fashion. In the *D. melanogaster* developing eye Nephrin orthologs *hibris* and *sns* are expressed by ommatidial cells while Neph1 orthologs *kirre* and *roughest* are expressed by interommatidial cells and mediate cell sorting. This work aims at analyzing molecular mechanisms of Nephrin family signaling to the actin cytoskeleton.

Methods: An *in vivo* model was established which allows analyzing the signal transduction of murine Nephrin in the *Drosophila* developing eye. Wild-type as well as several mutant murine UAS Nephrin transgenes were manufactured and integrated into the genome of *Drosophila* by ΦC31-based transformation to assure equal expression strength.

Results: We expressed wild-type or one of several different mutant murine UAS Nephrin transgenes in cells of the developing eye using the GMR-Gal4 driver. Flies that express wild-type murine Nephrin in the developing eye show a characteristic rough eye phenotype which arises from defective cell sorting during the development of the compound eye. To analyze the functional role of tyrosine residues within the cytoplasmic domain of murine Nephrin, we generated a murine Nephrin mutant in which all tyrosine residues within the cytoplasmic domain were mutated to phenylalanine. Expression of this mutant Nephrin protein in the developing eye results in a weaker rough eye phenotype, compared to flies expressing the wild-type murine Nephrin.

Conclusions: SH2 domain protein-dependent Nephrin signaling as well as phosphotyrosine-independent Nephrin signaling appears to play a role in this *in vivo* model. The *Drosophila* model is a valid system to decipher Nephrin signaling.

Podocyte MicroRNA-92a Controls Glomerular Damage in Extracapillary Glomerulonephritis Carole Hénique,[1] Guillaume Bollee,[1,4] Patrick Bruneval,[1,2] Eric Thervet,[1,3] Dominique Nochy,[2] Laurent Mesnard,[5] Pierre-Louis Tharaux.[1,3] *[1]Paris Cardiovascular Centre - PARCC, INSERM, Paris, France; [2]Pathology; Hôpital Européen Georges Pompidou, Assistance Publique-Hôpitaux de Paris (AP-HP), Paris, France; [3]Nephrology; Hôpital Européen Georges Pompidou, AP-HP, Paris, France; [4]Nephrology, Centre Hospitalier de l'Univ de Montréal, Montréal, Canada; [5]UMR 702, INSERM, Paris, France.*

Background: Mature podocytes are growth-arrested because of the expression of cyclin-dependent kinase inhibitors. Under pathological conditions, podocytes may undergo mitosis, but not cell division. Exceptions to this rule is necrotizing crescentic rapidly progressive glomerulonephritis (RPGN) where podocytes differentiate and proliferate, achieving "extracapillary glomerulopathies", the most severe forms of kidney diseases. We hypothesized that break on disease tolerance with pathological dedifferentiation of glomerular cells may be elicited by microRNA (miRNA) deregulation.

Methods: RPGN was induced by injection of anti–glomerular basement membrane serum in mice with modified EGFR or STAT3 pathways. miR-92a expression was studied by in Situ Hybridization and RT-qPCR in kidney biopsies from patients diagnosed with crescentic RPGN and non-crescentic GN. We manipulated the HB-EGF/EGFR, IL-6, STAT3 and miR92a pathways in primary podocytes and in vivo in mice and evaluated functional and structural impact on RPGN.

Results: We found that microRNA-92a (miR-92a) expression in diseased glomeruli is up-regulated in experimental and clinical RPGN. An EGFR and IL-6 - STAT3 cascade induced expression of miR-92a in podocytes. The cyclin-dependent kinase inhibitor 1C/p57^{Kip2} was found to be a direct target of miR-92a. Inhibition of miR-92a upregulated expression of p57^{Kip2} and decreased podocyte proliferation and dedifferentiation. In vivo silencing of miR-92a de-repressed p57^{Kip2} expression in podocytes and prevented extracapillary proliferation, glomerular demolition and renal failure.

Conclusions: mIR-92a is the first miRNA that is found to modulate podocyte quiescence *in vivo*. A specific common miR-92a extracapillary expression pattern in murine and human RPGNs is likely to have significant pathogenic, diagnostic, and/or therapeutic implications.

SA-PO443

Differential Expressions of miRNAS in Kidney in Puromycin Aminonucleoside Nephropathy Model and Intervened Effects of Triptolide

Wei Sun,[1] Yigang Wan.[2] *[1]Jiangsu Provincial Hospital of Chinese Medicine; [2]Nanjing Drum Tower Hospital.*

Background: *Triptolide* (TP), a major active ingredient from Chinese herbal medicines, *Tripterygium wilfordii* Hook. f. (TWHF) and its extract named multi-glycoside of TWHF (GTW), has been proved effective in reducing proteinuria in China. The aim of this study is to demonstrate the mechanism in vivo of TP for reducing proteinuria and protecting podocyte in puromycin aminonucleoside (PAN) nephropathy rat.

Methods: Fifty male Wistar rats were randomly subdivided into five groups, Control (A), Model (B), TP(C), GTW (D), and Valsartan(E). Except the rats in A group, PAN nephropathy model was induced byinjection of PAN 100 mg/kg in B, C, D, and E groups. At the 2nd day after PAN nephropathy model was established, daily oral administration of the fluid of TP in C, GTW in D, valsartan in E, and physiological saline in A and B groups as a control was started respectively and lasted until sacrifice at the 10th day. Proteinuria, glomerular ultrastructure, and glomerular immunofluorescence staining of dicer enayme, nephrin, podocin and synaptopodin were examined. The differential expressional characteristics of miRNAsin renal cortex were analyzed through biochip assay. Moreover, the differential expressional volumes of no-miR-23a, rno-miR-300-3p, rno-miR-24, and rno-miR-30c were measured by real-time PCR respectively.

Results: In PAN-induced rats, proteinuria and podocyte foot processes effacement were investigated, as well as the expressions of nephrin, podocin, and synodopotodin were affected by dicer enayme. The differential expressionalmiRNAs in kidney included rno-miR-24, rno-miR-30c, rno-miR-23a, and rno-miR-300-3p. TP could improve proteinuria, alleviate podocyte foot processes effacement, reduce the expression of dicer enayme, increase the expressions of nephrin, podocin, and synodopotodin, and regulate the differential expressionalmiRNAs as well in PAN nephropathy model.

Conclusions: In PAN nephropathy rat, with the treatment of TP, proteinuria can be reduced and the expressions of nephrin, podocin, and that, synaptopodin can be regulated. The mechanism of which is probably due to intervening dicer enayme and differential expressions of miRNAs in kidney.

SA-PO444

Apolipoprotein L1 Has Diverse Isoforms and APOL1-B3 Activates the NF-kB Pathway

Hidefumi Wakashiu, Jeffrey B. Kopp. *KDS, NIDDK, NIH, Bethesda, MD.*

Background: Apolipoprotein L1 (APOL1), a trypanosomal lytic factor, is a component of the innate immune system. *APOL1* gene variants, present in individuals of recent African descent, are strongly associated with glomerular disease risk. APOL1 has RNA splice variants, summarized as A, B and C isoforms. The A isoform is encoded by exons 1 and 3-7 and has been studied most extensively. Little is known about the B isoform, encoded by exon 1-7, and the C isoform, encoded by exons 1, 3, and 5-7. The roles of distinct APOL1 isoforms in mediating renal injury are unknown.

Methods: We examined mRNA expression by TA cloning and RT-PCR and protein localization using immunofluorescence (IF) of FLAG-tagged APOL1 in stably transfected HeLa cells. Since only APOL1-B isoforms contain exon 2, we raised rabbit antiserum specific against APOL1-B peptide by immunizing rabbits with an exon 2 peptide. Mitochondrial fractions were isolated using a detergent-based method.

Results: We cloned 7 APOL1 splicing variants from cultured human podocytes. Three variants contained exon 2, which we termed APOL1-B1, B2, and B3. APOL1-B1 and B2 RNA contained exon 1-7, with B2 having an alternate spliced exon 3. APOL1 B3 lacked exon 4, which contains the signal sequence of APOL1; this isoform has not been previously reported. Using RT-PCR, we found that normal human kidney expressed four APOL1 splicing variants: APOL1-A, B1, B3 and C. In cultured human podocytes, transfected FLAG-tagged APOL1-B3 was detected by both APOL1-B and anti-FLAG antibodies (Ab). APOL1-B isoforms, detected by IF using the exon 2 Ab, localized to mitochondria in serum-starved human podocytes and were detected in mitochondrial fractions of HeLa cells by WB; further, transfected APOL1-B3 localized to mitochondria in HeLa cells. Impairment of autophagy causes NF-κB activation; when autophagy was inhibited with chloroquine, the NF-κB pathway was activated in APOL1-B3 transfected HeLa cells, compared to empty-vector transfected cells.

Conclusions: APOL1 mRNA splicing produces multiple distinct protein isoforms. APOL1-B3 over-expression activated the NF-κB pathway in HeLa cells; if this occurred in immune cells, this could promote immune response.

***APOL1* mRNA Renal Risk Variants Activate Protein Kinase R and Reduce Cell Protein Synthesis In Vitro and Increase Susceptibility to Proteinuria In Vivo**

Koji Okamoto, Jeffrey B. Kopp. *NIDDK, NIH, Bethesda, MD.*

Background: Coding variants in APOL1 (apolipoprotein L1), S342G (G1) and NYK388K (G2), compared to the ancestral allele (G0) are strongly associated with renal disease among individuals with sub-Saharan ancestry. APOL1 circulates as component of HDL and is also expressed in podocytes and vascular cells. Wiggins and colleagues have shown that in transgenic rats, suppression of protein translation via expression of a dominant-negative 4E-BP1 in podocytes leads to focal segmental glomerulosclerosis (FSGS). We asked whether *APOL1* variants might affect global protein synthesis.

Methods: For *in vitro* assay, we generated stable HEK293 cell lines bearing recombinant *APOL1* variants. For the cell free protein kinase R (PKR) activation assay, we used a synthetic mRNA T7 transcript system to generate APOL1 transcripts and we made recombinant PKR protein using E.coli. For *in vivo* studies, we generated nephrin transgenic mice in which the nephrin promoter driven drives expression of the G1 stem-loop RNA.

Results: In APOL1-overexpressing HEK293 cells, phosphorylated PKR (the active form) and inactive (phosphorylated) elongation initiation factor-2α were both increased with the G1 and G2 variants compared to G0 cells. PKR is activated by long dsRNA, which is absent in normal eukaryotic cells but is present with certain viral infections including HIV. As shown in the figure, in a cell free PKR activation assay, G1 and G2, but not G0 mRNA, generated phoshorylated PKR; poly-IC served as the positive control. Predictive software suggested that the regions near G1 and G2 have long dsRNA sequence, forming a stem-loop. When we disrupted this stem-loop with synonymous mutations, PKR activation by the risk alleles was lost. Finally, in an FSGS model involving basic fibroblast growth factor and puromycin (also a protein synthesis inhibitor), the G1 stem-loop transgenic mice had higher levels of proteinuria compared to wild-type mice.

Conclusions: These results suggest that the risk *APOL1* variant mRNAs activate PKR and thereby reduce protein synthesis. These effects appear to be mediated by dsRNA structure. Reduced protein synthesis may act as susceptibility factor which promotes podocyte injury.

Structure and Function of the Podocyte Slit Diaphragm

Florian Grahammer,[1] Christoph Schell,[1] Dontscho Kerjaschki,[2] Jeffrey H. Miner,[3] Alessia Fornoni,[4] Thomas Benzing,[5] Tobias B. Huber.[1] *[1]Medicine, Renal Div, Freiburg, Germany; [2]Pathology, Univ Vienna, Vienna, Austria; [3]Div of Biology and Biomedical Sciences, Washington Univ, St.Louis; [4]Medicine, Miller School of Medicine, Miami; [5]Medicine, Renal Div, Cologne, Germany.*

Background: The slit diaphragm is a multiprotein complex and constitutes the final component of the glomerular filtration barrier. Despite intense research its molecular ultrastructure and function of individual components have remained elusive.

Methods: We established a complimentary set of *Neph1*, *Neph2*, *Neph3* and *Nphs1* -/- mice. To compare SDs across the animal kingdom, chicken and mice kidneys were used. Detailed analysis was performed with functional assays, WB, light microscopy, STORM, TEM, Immuno-EM, HIM, as well as Cryo-Electrontomography.

Results: NEPHRIN and NEPH1 are essential to build a proper slit diaphragm. Yet in both types of constitutive -/- animals rudimentary SDs based on the remaining Super-IgG molecule could be detected. Interestingly, Neph2 and Neph3 -/- mice did not show any obvious phenotype over a 2 year observational period. Within the native cryopreserved SD ultrastructural analysis revealed that the SD is a multi-layered cell-cell contact that does not overlap in the midline, but rather forms multi-layered junctions. Individual components arch from cell membrane to cell membrane. Immuno-EM localized NEPH1 to the basal and narrower aspects of this junction, while NEPHRIN molecules form the top layer facing Bowman's space. Despite NEPHRIN's fundamental role in mammals, reptiles and birds live healthily without NEPHRIN and present with narrower and leakier NEPH1 based slit diaphragms.

Conclusions: This unique comparative approach revealed fundamentally new insights into the composition of the slit diaphragm. While NEPHRIN is essential for the formation of the slit diaphragm in mammals, it is dispensable in both reptiles and birds. NEPH1 seems to form the basal aspects of this junction in mammals and is the main component in reptiles and birds. This ultrastructural analysis challenges old views from the SD as a thin grey line linking two adjacent footprocesses but rather points towards a multi-layered cell-cell contact.

***In Vivo* Disruption of Podocyte Cytoskeletal Organization as a Result of Podocyte-Specific Deletion of NDST1**

Kevin J. McCarthy, Deborah J. McCarthy. *Pathology, LSU Health Sciences Center-Shreveport, Shreveport, LA.*

Background: Previous work from our laboratory has shown that heparan sulfate (HS) plays a key role in mediating podocyte (POD)-glomerular basement membrane (GBM) interactions by intracellular signaling mediated via the core protein of the cell surface proteoglycan, syndecan-4 (Sdc4). Recent work has shown that (Kid. Int. 85: 307-318) N-sulfation of HS is important for the proper organization of POD on the GBM. Podocytes from the Pod-Cre Ndst1$^{-/-}$ mice were shown to develop foot process effacement with an age-related increase in albuminuria. The focus of this current study was to explore the pattern of organization of Sdc4 along with known downstream components of the POD cytoskeleton.

Methods: Frozen tissue sections from 12 month and 15 month old age-matched control and mutant mice (Pod-Cre Ndst1$^{-/-}$) were double-label immunostained using antibodies directed against Sdc4 and α-actinin-4, nephrin, or synaptopodin (Synapt). The sections were examined using either wide-field fluorescence microscopy (WFM) or laser scanning confocal microscopy (LSCM).

Results: In control animals, Sdc4 immunoreactivity was present in a punctate pattern along the length of the GBM, and was colocalized with α-actinin-4 along the GBM. Synapt and Sdc4 showed a different pattern of immunostaining in WFM, having an evenly spaced, alternating punctate appearance along the GBM. In LSM sections showing the outside of the capillary, Synapt stained the 1° and 2° processes. Sdc4 staining was found on the lateral borders of the pedicels along their length. The relationship of nephrin to Sdc4 staining resembled that for Synapt. In the mutant mice, there was a complete disruption of the Sdc4/α-actinin-4 colocalization, with α-actinin-4 staining now located within the podocyte cell body. The Sdc-4 and Synapt relationship was also disrupted, with a distinct loss of

Sdc4 staining along the length of the pedicel. The pattern of nephrin staining appeared to remain the same, but its relationship to Sdc4 staining was altered, due to the change in the Sdc4 staining pattern.

Conclusions: The loss of N-sulfation on Sdc4 HS in POD causes disengagement of α-actinin-4 and Synapt but not nephrin, leading to pedicel disorganization.

SA-PO448

Clathrin Mediated Endocytosis Regulates Podocyte Migration

Agnieszka Swiatecka-Urban. *Pediatric Nephrology, Children's Hospital of Pittsburgh of UPMC, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: The cytoplasmic tail of human nephrin contains the Y-R-S-L sequence (Y^{1139}RSL) that conforms to the canonical endocytic motifs of the YxxØ type where x is any amino acid and Ø is an amino acid with a hydrophobic side chain. This sequence is conserved among several IgCAMs, including the neuronal CAM L1 where the Y-R-S-L motif directs clathrin-dependent endocytosis of L1 critical for motility of the nerve growth cone. The role of Y^{1139}RSL in human nephrin is unknown.

Methods: Phosphorylation of tyrosine residue in the YxxØ motif determines endocytic activity and comprises the information whether a protein should remain at or be removed from the cell surface. De-phosphorylation activates YxxØ as an endocytic motif and can be mimicked by substitution with phenylalanine (Y/F-Nephrin). By contrast, tyrosine substitution by alanine disables the endocytic signal (Y/A-Nephrin). The T-SV40 immortalized non-differentiated human podocytes were stably transduced with the wild type (WT)-Nephrin, Y/F-Nephrin, or Y/A-Nephrin using the lentiviral vector pLOC.

Results: The Y/F-Nephrin was less abundant at steady-state and had decreased cell surface stability compared to WT-Nephrin. By contrast, Y/A-Nephrin was more abundant at steady-state and had increased cell surface stability compared to WT-Nephrin. The difference in the cell surface abundance between the nephrin mutants further increased by stimulating nephrin endocytosis. The Y/F-Nephrin was more abundant in clathrin-coated vesicles (CCV) compared to Y/A-Nephrin, confirming the role of the Y^{1139}RSL motif in clathrin-dependent nephrin endocytosis. Podocyte migration was reduced in cells expressing WT- or Y/A-nephrin but not the Y/F-Nephrin. Finally, there was no difference in the paracellular flux of 40kDa dextran between cells expressing the Y/F- or Y/A-Nephrin.

Conclusions: The Y^{1139}RSL motif regulates cell surface abundance and stability of human nephrin by adjusting nephrin endocytosis. Clathrin-dependent endocytosis mediated by the Y^{1139}RSL motif may play a role in podocyte migration rather that the glomerular filtration barrier. The Y^{1139}RSL in human nephrin plays a similar role to the the Y-R-S-L motif in CAM L1.

SA-PO449

Acute Effects of Angiotensin II on TRPC6 Channels and Calcium Influx in the Podocytes of the Murine Glomeruli

Daria Ilatovskaya, Oleg Palygin, Alexander Staruschenko. *Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: A key role for glomerular epithelial cells (podocytes) in the pathogenesis of proteinuric renal diseases has been established since podocyte injury leads to proteinuria and foot process effacement. It was previously shown that angiotensin II (Ang II) caused depolarization and increased intracellular Ca^{2+} in podocytes. Members of the TRPC channels family, and particularly TRPC6, are proposed as proteins responsible for this calcium flux; gain-of-function mutation in the gene encoding TRPC6 channel results in the development of focal segmental glomerulosclerosis.

Methods: Changes in intracellular Ca^{2+} stimulated by Ang II in presence of various pharmacological agents were measured with live confocal microscopy in Fluo4/FuraRed loaded podocytes of the freshly isolated glomeruli; electrophysiological experiments (single channel patch clamp) were performed to assess the activity of TRPC6 channels in this preparation, as well as in transfected cells.

Results: First, we examined the effects of Ang II on intracellular Ca^{2+} in intact podocytes of freshly isolated rat glomeruli. Depletion of internal Ca^{2+} stores with thapsigargin did not affect calcium influx activated by Ang II, but SKF 96365 decreased Ang II - triggered increase in intracellular calcium concentration. Single channel patch-clamp analysis demonstrated that Ang II acutely activates native TRPC6 channels in the podocytes of rat and mouse glomeruli and in CHO cells transiently overexpressed with TRPC6 and AT_1 receptor; the effect is mediated by changes in the channel open probability. Importantly, Ang II did not activate any currents in TRPC6$^{-/-}$ mice. Further we used losartan and PD 123319, inhibitors of AT_1 and AT_2 receptors, in order to discriminate between the effects of Ang II on its specific receptors; these experiments indicated that both AT_1 and AT_2 might be involved into this signal transduction pathway.

Conclusions: Our data have provided the critical evidence of Ang II-dependent activation of TRPC6 channels and calcium influx in podocytes, which might play a significant role in the pathogenesis of kidney diseases.

SA-PO450

Up-Regulation of TRPC6 in Podocyte By Glomerular Hyperfiltration and Effect of Calcineurin Inhibition

Takatsugu Iwashita, Yosuke Tayama, Koichi Kanozawa, Ryo Yamamoto, Kunihiko Yasuda, Saeko Sato, Yoshimi Okada, Yuya Shioda, Megumi Inamura, Hitoshi Kato, Hajime Hasegawa. *Nephrology and Hypertension, Saitama Medical Center, Saitama Medical Univ, Kawagoe, Saitama, Japan.*

Background: TRPC6 in podocytes functions as a sensor of pressure load at the time of glomerular hyperfiltration (GHF). In this study, we aimed at examining the following two points: (1) in vivo changes in the expression of TRPC6 in 5/6 nephrectomized rats, which are a GHF model, and (2) effects of calcineurin inhibition, which is a downstream signal of TRPC6, on podocyte damage in GHF.

Methods: We removed 5/6 of the kidney from male SD rats and conducted histological/molecular biological examinations between a Sham group (S) and a nephrectomy group (N) six weeks later. We set up a group to which tacrolimus (T: 0.08 mg/kg) was administered subcutaneously every day in each group.

Results: The glomerular volume, urinary albumin excretion (UAE) and desmin expression score all increased in the N group. No changes were observed in the glomerular volume by the administration of T, but the UAE and desmin expression score showed a tendency for improvement. The electron microscopic images showed morphological changes of podocytes in the N group, such as loss of the foot processes and improvement in the T groups. The FGS score also increased in the N group and improved in the T groups. The mRNA expression of TRPC6 increased in the N group, and it was suppressed in the T groups. The double staining of TRPC6 with WT-1 showed the up-regulation of TRPC6 in WT-1 positive podocytes in the N group and attenuation in the T groups. The double staining of TRPC6 with synaptopodin showed a decreased staining of synaptopodin along the loop wall in the N group and improvement in the T groups. Evaluation of changes in TRPC6 mRNA by in situ hybridization showed an increased expression in the N group and suppression in the T groups.

Conclusions: The present study demonstrated the functional relationship between podocyte damage and increased expression of TRPC6 in podocytes in vivo. In addition, a direct inhibition of podocyte damage by calcineurin inhibition without suppression of GHF was evoked.

SA-PO451

TRPC5-Mediated Podocyte Calcium Toxicity Drives Progressive Glomerular Disease

Frank Dubois,[1] Philip M. Castonguay,[1] Sookyung Kim,[1] Jonas Sieber,[3] Astrid Weins,[2] Anna Greka.[1] *[1]Renal Div, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [2]Dept of Pathology, Brigham and Women's Hospital, Boston, MA; [3]Renal Div, Massachusetts General Hospital, Boston, MA.*

Background: Podocyte injury, with proteinuria as the earliest sign, is the critical step in various forms of kidney disease. Podocyte-specific expression of the human angiotensin receptor type 1 (AT1R) in rats (AT1R TG rats) causes progressive podocyte damage and loss, leading finally to kidney failure and death after 40-50 weeks. Our laboratory established that deletion or pharmacological blockade of TRPC5 channels is protective in acute models of filter barrier damage, but the role of TRPC5 in disease progression remains unknown. Previously we have also shown that AT1R activation promotes TRPC5-mediated cytoskeletal disruption in podocytes.

Methods: We investigated the influence of TRPC5 on disease progression in AT1R TG rats by 2-week treatment with the TRPC5 inhibitor ML204, starting after proteinuria had developed. For mechanistic studies, we activated TRPC5 pharmacologically in conditionally immortalized mouse podocytes after 11 days of differentiation. Annexin V/PI labeling was used as cell death assay, and mitochondrial permeability transition (MPT) was measured with Calcein/Co^{2+}. Analysis was done by flow cytometry.

Results: Treatment with the TRPC5 blocker ML204 decelerated disease progression in the AT1R TG rats. Specifically, albuminuria remitted under ML204 treatment. In vivo, podocytes showed signs of recovery following treatment. Mechanistically, we show that sustained TRPC5 activation leads to podocyte calcium toxicity via MPT and finally cell death, in a dose and time dependent manner. These effects can be blocked effectively by ML204.

Conclusions: This study reveals sustained TRPC5 activation as a driving force in progressive glomerular disease. Mitigated disease progression by ML204 treatment in AT1R TG rats is an important proof of concept study for the potential of TRPC5 blockade as a therapeutic strategy in progressive proteinuric kidney diseases.

Genetic Interactions between crb2b and moe in Podocytes

Arindam Majumdar. *Immunology, Genetics, and Pathology, Uppsala Univ, Uppsala, Sweden.*

Background: In podocytes, cell polarity is manifested in the presence of molecularly and functionally different apical and basal membrane domains, slit diaphragm cellular junctions, and well defined cellular structures like actin rich foot processes. Genetically induced derangement of apical basal polarity through gene specific mutations in polarity protein components results in loss of foot process structure and ensuing proteinuria suggesting that cell polarity is intimately coupled to podocyte function. We have used the *crb2b* gene as an entrance point into exploring the wider roles of polarity complexes

within zebrafish podocytes. *Crb* proteins directly bind to the FERM domain protein Moesin/Radixin/Ezrin/Band 4.1 through a FERM binding domain located in the Crb intracellular tail. In zebrafish, the Moesin/Radixin/Ezrin/Band 4.1 protein is mutated in the mosaic eyes (moe) mutant and moe mutants have a podocyte structural defects (Dev Biol. 2005 Sep 15;285(2):316-29). Based on studies in zebrafish and fruit flies, we hypothesize that both crb2b and moe may function antagonistically in a common protein trafficking pathway during podocyte differentiation.

Methods: The zebrafish has become a popular genetic model system for studying gene expression, gene function, and modelling kidney disases. In this study, we perform molecular genetics in the zebrafish pronphros.

Results: We present data showing the Nephrin targeting is affected in zebrafish moe mutants. We further analyze genetic interactions between crb2b and moe, through crb2b; moe double mutant using a panel of apical basal polarity markers.

Conclusions: We conclude that both crb2b and moe participate in a common pathway required for correct Nephrin localization in podocytes.

SA-PO453

Podocyte-Specific Deletion of the Planar Cell Polarity Gene Vangl2 Leads to Glomerular Abnormalities Eugenia Papakrivopoulou,[1] Sabrina Pacheco,[1] Deborah Henderson,[2] Hortensja Lucja Brzoska,[1] Adrian S. Woolf,[3] David A. Long.[1] *[1]Developmental Biology and Cancer, UCL Inst of Child Health, London, United Kingdom; [2]Inst of Genetic Medicine, Newcastle Univ, Newcastle, United Kingdom; [3]Inst of Human Development, Univ of Manchester, Manchester, United Kingdom.*

Background: The development and maintenance of podocyte architecture involves cytoskeletal re-organisation, but little is known about the pathways regulating this process. In this study, we hypothesised that the planar cell polarity (PCP) pathway, which controls cytoskeletal organisation in a variety of cell systems, may be critical in maintaining podocyte structure and the integrity of the glomerular filtration barrier.

Methods: Podocyte-specific knock-down mice of *Vangl2*, a core component of the PCP pathway, (*PodCre*$^{+/}$*Vangl2*$^{fl/fl}$) were generated by combining floxed *Vangl2* animals with *Podocin-Cre* mice (both on C57Bl/6 background); littermates without Cre were used as controls (*Vangl2*$^{flox/flox}$). Glomerular morphology, proliferation and overnight albumin excretion were assessed at 12 weeks of age. RNA was extracted from glomeruli isolated by Dynabead perfusion.

Results: *PodCre*$^{+/}$*Vangl2*$^{fl/fl}$ mice had a 40% reduction in *Vangl2* glomerular mRNA levels compared with *Vangl2*$^{flox/flox}$. Expression of other PCP genes in isolated glomeruli was unaltered. Abnormal glomerular morphology, characterised by loss of capillary loops and tuft collapse, was seen in 16.6±4.8% of glomeruli of *Vangl2*^{Dpodocyte} mice compared with 3±1.5% in control littermates. This was accompanied by increased glomerular proliferation (0.17±0.03 *versus* 0.07±0.02 cells/glomerulus, $p<0.05$) and nephrin phosphorylation. Expression of the extracellular matrix protein collagen (α_3) IV was also significantly reduced in *PodCre*$^{+/}$*Vangl2*$^{fl/fl}$mice. Despite these findings, we did not observe any changes in albuminuria or haematuria at this time-point.

Conclusions: Our data indicates that loss of *Vangl2* in the podocyte leads to subtle glomerular abnormalities including altered proliferation, matrix turnover and nephrin phosphorylation. However, this does not manifest as altered integrity of the filtration barrier.

SA-PO454

Podocyte Number in Humans: Associations with Glomerular Hypertrophy and CKD Risk Factors Victor G. Puelles,[1] Luise A. Cullen-McEwen,[1] Wendy E. Hoy,[2] John F. Bertram.[1] *[1]Anatomy and Developmental Biology, Monash Univ, Melbourne, Victoria, Australia; [2]Centre for Chronic Disease, The Univ of Queensland, Brisbane, Queensland, Australia.*

Background: Podocyte depletion can be defined as absolute (reduction in podocyte number) or relative (reduction in podocyte density), and it has been directly associated with the development of glomerulosclerosis. The aim of this study was to determine if podocyte depletion is observed in subjects without renal disease in the context of glomerular hypertrophy and in association with multiple CKD risk factors.

Methods: Tissue from 32 autopsied Caucasian American males (Jackson, Mississippi, U.S.A.), comprised of four young children (≤3 years) and 28 adults (≥18 years) without overt renal disease was used for stereological quantification of podocyte number and density by the disector/fractionator method. A total of 192 glomeruli (6 glomeruli per subject) were analyzed. Demographic variables such as age, hypertension and body mass index (BMI) were obtained from medical records and autopsy reports. Nephron number was estimated using design-based stereology.

Results: Podocyte number (podocytes per glomerulus) varied 2.1-fold in children (302-634) and 7-fold in adults (140-983). Podocyte density (podocytes per $10^6\mu m^3$ of glomerular tuft) showed a similar trend: a 2.8-fold range in children (565-1590) and an 11.4-fold range in adults (46-526). While there was a strong direct correlation between glomerular volume and podocyte number in children ($R=0.81$, $P<0.0001$), this correlation was weaker in adults ($R=0.37$, $P<0.0001$). Among adults, podocyte number was lower in subjects with older age (≥40 years; $P<0.001$), hypertension ($P<0.05$) and low nephron number (≤0.6 million nephrons; $P<0.01$), but not in subjects with overweight (BMI ≥25Kg/m^2). Podocyte density was reduced in subjects with older age, hypertension, low nephron number and overweight ($P<0.0001$).

Conclusions: The wide variation in podocyte number and density in adults may be related to a combination of podocyte loss (associated with older age, hypertension and low nephron number) and possible podocyte gain associated with glomerular hypertrophy. Further studies in controlled animal models are urgently needed.

SA-PO455

Nephrin Phosphorylation in Minimal Change Disease Gabriel M. Cara-Fuentes, Eduardo H. Garin. *Univ of Florida.*

Background: Minimal change disease (MCD) is considered a podocytopathy. Proteinuria in MCD is thought to be due to an increased CD80 podocyte expression. Experimental models of nephrotic syndrome showed that CD80 podocyte expression leads to foot processes effacement and proteinuria. Nephrin, a slit diaphragm protein, displays a structural and functional role that is critical to maintain the integrity of the filtration barrier. **Objective:** To define the pattern of nephrin phosphorylation in MCD patients during relapse and remission. This is a necessary step to our hypothesis that increased podocyte CD80 expression leads to a decrease in nephrin phosphorylation in MCD patients during relapse resulting in proteinuria.

Methods: Human cultured podocytes were incubated with serum from 11 MCD patients in relapse and 5 in remission. CD80, CTLA-4 and phosphorylated nephrin expression were measured by quantitative PCR and Western-Blot analysis. Immunofluorescence staining of CD80 and phosphorylated nephrin were performed in biopsies from MCD patients in relapse and MCD in remission.

Results: Human cultured podocytes exposed to serum from MCD patients in relapse showed a significantly increased in CD80 and decreased phosphorylation of nephrin compared to those exposed to serum from MCD patients in remission ($p=0.02$ and $p=0.03$ respectively).Expression of CD80 was decreased when podocytes were cultured with CTLA-4 ($p=0.04$). In addition, kidney biopsies of MCD patients in relapse showed a weak signal for phosphorylated nephrin by Immunofluorescence in contrast to the strong signal obtained in kidney biopsies of MCD patients in remission.

Conclusions: (1) Decreased phosphorylation of nephrin was found in podocytes exposed to serum from MCD patients in relapse along with increased CD80 expression. (2) CTLA-4 prevented the increase CD80 expression in podocytes exposed to serum from MCD patients in relapse. (3) Weak signal for phosphorylated nephrin was observed in kidney biopsies of MCD patients in relapse in contrast with those in remission. (4) We postulate that CD80 decreases nephrin phosphorylation resulting in reorganization of podocyte cytoskeleton and proteinuria.

Nephrin Preserves Podocyte Viability and Glomerular Structure and Function in Adult Mice Xuezhu Li,[1] Peter Y. Chuang,[1] Vivette D. D'Agati,[2] Lawrence B. Holzman,[3] John C. He.[1] *[1]Dept of Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Dept of Pathology, Columbia Univ, New York, NY; [3]Renal Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia, PA.*

Background: Nephrin is required during kidney development for the maturation of podocytes and formation of slit diaphragm. As nephrin is downregulated in various acquired glomerular diseases, nephrin deficiency is considered a pathologic feature of glomerular injury. Nephrin's role in the adult kidney and in acquired glomerular diseases, however, has not been confirmed experimentally.

Methods: Mice with doxycycline inducible RNA-interference-mediated nephrin knockdown were generated. Unilateral nephrectomy (UNPX) was performed to generate a model of glomerular hyperfiltration. Adriamycin (ADR) nephropathy model was used to characterize the response of mice with nephrin knockdown to podocyte injury and glomerulosclerosis. Urinary albumin excretion, serum creatinine, renal histology, glomerular ultrastructure, glomerular gene expression, AKT phosphorylation, and podocyte apoptosis were performed.

Results: Short-term nephrin knockdown (6 weeks) has no impact on glomerular structure and function. In contrast, chronic nephrin knockdown (20 weeks) causes proteinuria, foot process fusion and effacement, filtration slit narrowing, mesangial proliferation, glomerular basement membrane thickening, sub-endothelial zone widening, and podocyte apoptosis. When subjected to UNPX and ADR, mice with short-term nephrin knockdown developed more severe glomerular injury compared to mice without knockdown. In addition, nephrin knockdown mice developed more exaggerated glomerular hypertrophy when subjected to UNPX, and more podocyte apoptosis and depletion after ADR challenge. AKT phosphorylation was markedly reduced in mice with chronic nephrin knockdown as well as short-term nephrin knockdown mice challenged with UNPX and ADR.

Conclusions: Our data established that under basal conditions as well as in acquired glomerular diseases, nephrin is required to maintain slit diaphragm-mediated signaling and podocyte viability to preserve glomerular function and podocyte viability in adult mice.

MAP-Kinase p38 – Pivotal Mediator of Slit Diaphragm Integrity

Magdalena Woznowski,[1] Sebastian Alexander Potthoff,[1] Eva Koenigshausen,[1] Thorsten Wiech,[2] Raphael Haase,[1] Clara Frosch,[1] Johannes Stegbauer,[1] Lars C. Rump,[1] Lorenz Sellin,[1] Ivo Quack.[1] *[1]Nephrology, Heinrich Heine Univ, Duesseldorf, Germany; [2]Pathology, Univ Hospital Hamburg Eppendorf, Hamburg Eppendorf, Germany.*

Background: Albuminuria is an early symptom of diabetic damage of the glomerular filter. Diabetic albuminuria has been shown to be attenuated by inhibition of MAPK p38. We could recently demonstrate that diabetic mice with albuminuria show increased nephrin endocytosis. Several other groups now confirmed that the endocytosis of slit diaphragm proteins is paramount for podocyte function. In our project we further unravel the molecular mechanism of nephrin endocytosis and identify p38 as pivotal mediator of proteinuric signaling and slit diaphragm integrity.

Methods: Diabetes was induced in C57BL/6 mice by streptozotocin. For inhibition of p38, the mice were treated with SB202190. Albuminuria was quantified as albumin/creatinin ratio. Nephrin endocytosis was analyzed by immunofluorescence staining. To quantify endocytosis in murine kidneys in vivo a special biotin-based endocytosis assay was established. Western blotting and kinase assays were performed to analyze the phosphorylation of nephrin mediated by p38 and PKCα.

Results: Hyperglycemic mice developed a significant albuminuria already four days after induction of diabetes. In vivo analysis showed a significant increase in podocytic p38 activity and nephrin endocytosis only in albuminuric animals. Pharmacologic inhibition of p38 nearly completely prevented nephrin endocytosis and albuminuria. P38 mediated phosphorylation of the nephrin c-terminus facilitates the coupling of nephrin to the endocytotic machinery via PKCα – β-arrestin2 – signaling.

Conclusions: Here we show that p38 is a pivotal mediator of hyperglycemia-induced nephrin endocytosis and albuminuria. Our in vivo endocytosis assay allowed for the first time a quantification of nephrin endocytosis in murine kidneys under diabetic conditions. Inhibition of p38 decreases nephrin phosphorylation and endocytosis, supporting the hypothesis that stabilization of the slit diaphragm prevents albuminuria. These findings suggest p38 as pivotal mediator of early diabetic damage and thus as a promising therapeutic target.

SA-PO458

Early Proteinuria in Nephrotoxic Nephritis Is Associated with p38 Activation and Nephrin Endocytosis

Magdalena Woznowski,[1] Raphael Haase,[1] Clara Frosch,[1] Eva Koenigshausen,[1] Sebastian Alexander Potthoff,[1] Thorsten Wiech,[2] Johannes Stegbauer,[1] Ulf Panzer,[3] Lars C. Rump,[1] Lorenz Sellin,[1] Ivo Quack.[1] *[1]Nephrology, Heinrich Heine Univ, Duesseldorf, Germany; [2]Pathology, Univ Hospital Hamburg Eppendorf, Hamburg Eppendorf, Germany; [3]Nephrology, Univ Hospital Hamburg Eppendorf, Hamburg Eppendorf, Germany.*

Background: Nephrotoxic nephritis is an established animal model of rapid progressive glomerulonephritis. The application of a polyvalent sheep anti-GBM serum induces two peeks of an inflammatory response and proteinuria. The first one can be detected after 24 hours, called heterologous phase. In contrast to the autologous phase which appears after 7 days and is caused by an invasion of inflammatory cells the pathomechanism of the heterologous phase is not well understood. In the following project we examined whether p38 mediated nephrin endocytosis is involved in this marked dysfunction of the glomerular filter caused by the anti-GBM serum.

Methods: C57BL/6 mice were administered intraperitoneal with 5 µl/g body weight of sheep anti-GBM serum. The animals were housed in metabolic cages for 12 h after anti-GBM serum injection for urine collection and sacrificed 24 h after injection.Albuminuria was quantified as albumin/creatinine ratio. To quantify the surface expression of nephrin murine kidneys were perfused with biotin. Afterwards glomeruli were instantly harvested and analyzed with streptavidin via Western blot and analyzed by immunofluorescence staining.

Results: Twenty-four hours after treatment with the anti-GBM-Serum the mice developed severe albuminuria. Western blot analysis of murine glomeruli revealed a strong activation of p38. Immunofluorescence studies demonstrated a translocation of nephrin from the cell surface to the cytoplasm. Quantification of nephrin endocytosis with our in vivo biotinylation assay showed a decrease of surface nephrin of about 73%.

Conclusions: The present study shows for the first time that the severe proteinuria in the heterologous phase of nephrotoxic nephritis is associated with significant nephrin endocytosis mediated by activation of p38.

SA-PO459

Combined Treatment with Pioglitazone and Glucocorticoids Enhances Protection against Nephrotic Syndrome

Shipra Agrawal,[1] Melinda A. Chanley,[1] Guillermo Hidalgo,[2] Deborah E. Westbrook,[2] Xiaojing Nie,[1] Adam J. Guess,[1] Rainer Benndorf,[1,3] William E. Smoyer.[1,3] *[1]Clinical and Translational Research, Research Inst at Nationwide Children's Hospital, Columbus, OH; [2]Div of Pediatric Nephrology, Vidant Children's Hospital, Greenville, NC; [3]Pediatrics, The Ohio State Univ, Columbus, OH.*

Background: Oral glucocorticoids (GCs) are the primary therapy for nephrotic syndrome (NS), although GCs have serious side effects and are clinically ineffective in ~20% of patients. We previously reported that like GCs, pioglitazone (Pio) also directly protects podocytes and modulates the GC receptor pathway. We thus hypothesized that Pio could enhance reduction in proteinuria seen with GCs during NS.

Methods: Proteinuria was induced in Wistar rats (N=13/group) by single PAN injections (50 mg/kg). Treatment groups received PAN+low-dose GCs (5 mg/kg), PAN+high-dose GCs (15 mg/kg), PAN+Pio (10 mg/kg), PAN+Pio+low-dose GCs, and PAN+Pio+high-dose GCs. Analyses included proteinuria, glomerular gene and protein expression 11 days after PAN injection. Translation to a childwith refractory NS included the addition of Pio to GCs and other immunosuppressive drugs at 15 mg/day for 4 weeks, followed by 30 mg/day for 20 weeks.

Results: PAN induced severe proteinuria, which was significantly reduced by high-dose (79%;P=0.005) but not low-dose (25%;P=NS) GCs. Pio alone reduced proteinuria moderately (61%;P=NS), but low-dose GCs+Pio reduced proteinuria significantly (63%;P=0.025), similar to high-dose GC alone. High-dose GCs+Pio reduced proteinuria to almost control levels (97%;P=0.001). PAN increased glomerular cycloxygenase-2 and decreased podocyte synaptopodin expression, while Pio+GCs treatment restored expression levels to control values. Analogous addition of Pio to GCs in a child with refractory NS correlated with a ~80% decrease in proteinuria.

Conclusions: Repurposing Pio as a combination therapy with GCs has the potential to notably increase the clinical efficacy of GCs in reducing proteinuria during NS, and potentially enable reduced GCs dosing and toxicity. This efficacy likely results in part from the restoration of podocyte/glomerular expression of synaptopodin and cycloxygenase-2.

The Superiority of Urinary Angiotensinogen to Proteinuria as a Marker of Podocyte Injury

Masahiro Eriguchi, Ryusuke Yotsueda, Kumiko Torisu, Kiichiro Fujisaki, Kosuke Masutani, Kazuhiko Tsuruya, Takanari Kitazono. *Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka city, Japan.*

Background: Proteinuria (PU) is widely used as a marker for renal prognosis in clinical setting, as well as urinary angiotensinogen (U-AGT). Our preliminary data confirmed that patients with focal segmental glomerulosclerosis (FSGS) represented higher U-AGT/urinary protein (UP) ratio than patients with minimal change disease (MCD) (3.1 ± 1.3 versus 0.7 ± 0.3 µg/10mg UP) and showed AGT deposition in segmental lesions of glomeruli, suggesting U-AGT is a more specific marker of podocyte injury than PU.

Methods: We tested the impacts of U-AGT and PU on two different nephrotic models induced by puromycin aminonucleoside (PAN) in Wistar rats; 15 mg/100 g·body weight (BW) of PAN administration at week 0 similar to MCD, and 5 mg/100 g·BW of PAN administration for three times at weeks 0, 1 and 2 similar to FSGS. Next, we observed renal tissue and urinary metabolism of exogenous injected human recombinant AGT (hAGT; little affinity for enzymatic cleavage by rodent renin) in FSGS and control rats. Furthermore, we tested AGT production levels in cultured mouse podocytes injured by PAN.

Results: PU levels were comparable between MCD and FSGS rats. U-AGT levels from FSGS rats were higher than MCD rats, and podocin and nephrin expressions were reduced in FSGS, but not in MCD rats. Intravenous injection of hAGT showed about 100-fold increases in urinary hAGT excretion from FSGS rats compared to undetectable levels of those from control rats. Immunostaining for rat-AGT and hAGT identified that rat-AGT was detected in injured podocytes as well as proximal tubules, but filtrated hAGT was detected only in superficial proximal tubules. Finally, we confirmed that PAN induced increases in AGT production in cultured podocytes in dose dependent manner and these were negatively associated with podocin and synaptopodin expression in podocytes.

Conclusions: U-AGT, which was affected by AGT produced from injured podocytes at least in part, in addition to exogenous filtrated AGT from glomeruli, is a reliable marker of podocyte injury.

SA-PO461

Sulfatase 2, Identified By Genome Association Analysis, Contributes to Protection against Nephrotic Syndrome

Kenjiro Honda,[1] Koji Okamoto,[2] Kent Doi,[1] Masaomi Nangaku,[1] Katsushi Tokunaga,[3] Eisei Noiri.[1] *[1]Nephrology and Endochrinology, The Univ of Tokyo, Tokyo, Japan; [2]Kidney section, NIDDK/NIH, Bethesda, MD; [3]Human Genetics, Graduate School of Medicine, The Univ of Tokyo, Tokyo, Japan.*

Background: Heparan sulfate proteoglycans (HSPGs) is major components of glomerular basement membrane (GBM) and regulating podocyte adhesion to GBM. Although Sulfatase 2 (SULF2) modulates intracellular signaling through controlling sulfation pattern on HSPGs, it is unclear whether SULF2 activity contributes to podocyte injury in nephrotic syndrome. In our previous genome-wide association study, a single nucleotide polymorphism (SNP) rs11086243 upstream of the *SULF2* gene showed a significant association with nephritic syndrome [Nat Genet. 2011;43:459-63].

Methods: We conducted a genetic association study by using 300 control samples and 201 nephrotic syndrome samples from Japanese population. High density SNP mapping was performed on the *SULF2* gene and its upstream region. As a functional study, renal Sulf2 expression was evaluated with mouse and human kidney sections. The effects of Sulf2 knockdown were examined in nephrotic syndrome model by injecting puromycin aminonucleoside and basic fibroblast growth factor.

Results: Seventeen candidate SNPs were obtained by expression-QTL analysis, transcript factor-related analysis, and imputation analysis and one haplotype was demonstrated to be significantly associated with nephrotic syndrome. Immunofluorescence staining showed intraglomerular SULF2 expression in mouse and human kidney. SULF2 was dominantly expressed in nucleus and cell surface of glomerular epithelial cells. In mouse nehprotic syndrome model, proteinuria that peaked at day 7 was significantly higher in SULF2 knockdown mice than wild-type. Blood urea nitrogen was also higher

at day 10 in knockdown mice. Segmental and global glomerular sclerosis accompanied with tubulointerstitial damage were present at day 28 only in SULF2 knockdown mice.

Conclusions: We identified a significant haplotype near SULF2 gene that was associated with nephritic syndrome. Functional analysis using knockdown mice suggested that SULF2 expressed in podocytes may have protective role in nephritic syndrome.

SA-PO462

Podocyte-Specific Deletion of Yes-Associated Protein Leads to Progressive Glomerulosclerosis Monica H. Schwartzman,[1] Antoine Reginensi,[2] Jenny Wong,[1] Vivette D. D'Agati,[3] Helen McNeill,[2] Kirk N. Campbell.[1] *[1]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Molecular Genetics, Samuel Lunenfeld Cancer Center, Mount Sinai Hospital, Toronto, Canada; [3]Pathology, Columbia Univ, New York, NY.*

Background: Podocytes and the interposed slit diaphragm form a critical component of the glomerular filtration barrier. This explains why podocyte injury is typically associated with proteinuric kidney disease. We previously identified Yes-associated protein (YAP) as a pro-survival signaling molecule whose silencing in vitro increases podocyte susceptibility to apoptotic stimuli. YAP is the key downstream effector of the Hippo signaling pathway whose role in podocyte homeostasis has not been explored. In the present study we tested the hypothesis that podocyte specific deletion of YAP would lead to proteinuric kidney disease through increased podocyte apoptosis.

Methods: A YAP flox allele was generated by inserting LoxP sites for Cre-mediated excision flanking exon 2. YAP was selectively silenced in podocytes using Cre-mediated recombination controlled by the podocin promoter.

Results: YAP loss in podocytes resulted in proteinuria at 6 weeks with subsequent development of podocyte-derived apoptotic bodies and extensive apoptosis with TUNEL staining. At 12 weeks glomeruli from podocyte-targeted YAP knockout mice displayed histologic features characteristic of focal segmental glomerulosclerosis including podocyte depletion, tubular atrophy, interstitial fibrosis and the development of tubular casts. These changes progressed in severity through 32 weeks. These animals also developed progressive renal failure as determined by an increase in serum creatinine.

Conclusions: These findings, taken together, suggest a role for YAP as a physiological antagonist of podocyte apoptosis. This could have future implications in the quest for targeted therapeutics. The results also highlight the importance of podocyte survival in maintaining the integrity of the glomerular filtration barrier.

SA-PO463

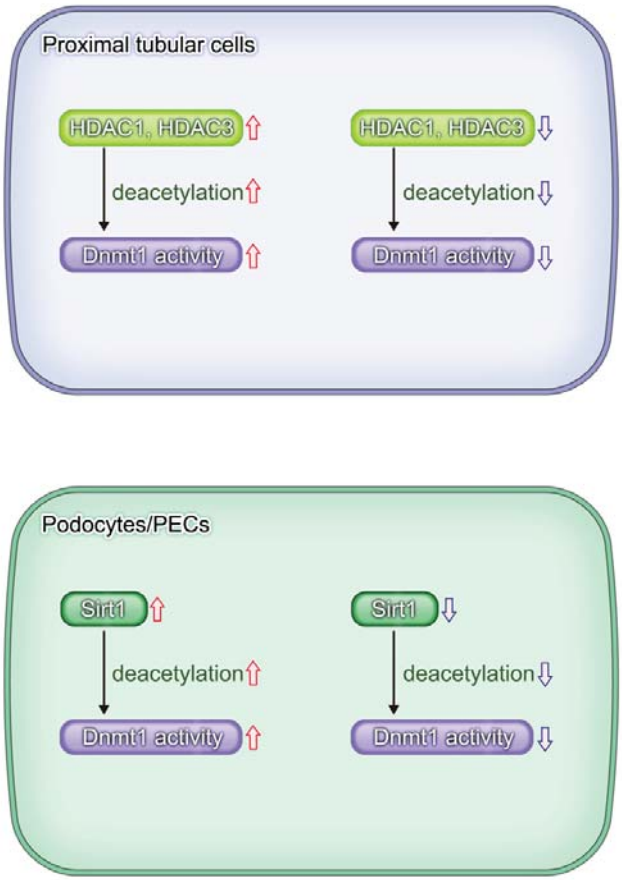
Divergent Usage of Histone Deacetylases for the Activation of DNA Methyltransferase1 in the Kidney; HDAC1, 3 (Class I HDAC) in Proximal Tubules and Sirt1 (Class III HDAC) in Podocytes De-Acetylate and Activate Dnmt1 Activity Hirokazu Muraoka, Shu Wakino, Kazuhiro Hasegawa, Koichi Hayashi, Hiroshi Itoh. *Keio Univ.*

Background: DNA Methyl Transferase 1 (Dnmt1) plays an important role in renal fibrosis and progression of CKD. We recently reported that Dnmt1 was deacetylated and activated by Class III histone deacetylase (HDAC), **Sirt1** in **podocytes (Pods)** leading to the epigenetic regulation of tight junction protein, Claudin-1. (Hasegawa K, Nature Medicine 2013). However, the regulatory mechanisms of Dnmt1 in other segments of the kidney, such as **proximal tubules (PTs)** or **parietal epithelial cells (PECs)** remains to be elucidated.

Methods: We used cultured **PT**s (HK2 and LLCPK1), **Pod**s (provided by Prof. Mundel, University of Washington), and **PEC**s (provided by Prof. Shankland, University of Washington). To determine which HDACs deacetylate Dnmt1, we transfected these cells with HA-Dnmt1, c-myc-PCAF (PCAF; P300/CBP-associated factor, which has histone acetyltransferase activity), Flag-HDAC1, V5-HDAC3 or 6×His-Sirt1.

Results: First, we confirmed that HDACs 1, 2, and 3 and Sirt1, 6, and 7 were expressed in mostly nucleus, which are more likely to colocalize with and regulate Dnmt1 in the nucleus. Since in other type of cells, HDAC1, HDAC3, and Sirt1 were reported to deacetylate Dnmt1, whereas HDAC2, SIRT6, and SIRT7 did not, we examined the effects of Sirt1, HDAC1, and HDAC3 on the activation of Dnmt1. Among the three HDACs studied, only **Sirt1** deacetylated Dnmt1 in cultured **Pod**s and **PEC**s. Conversely, in **PT**s, **HDAC1** and **HDAC3** deacetylated Dnmt1 whereas Sirt1 did not.

Conclusions: These findings demonstrated that the different types of HDACs were responsible for the activation of Dnmt1 in PTs, PECs, and Pods. Our data suggested that the divergent regulatory systems of epigenetic factor **Dnmt1** provide a novel mechanism for the functional disparity of each kidney cells or segments.



SA-PO464

FSGS-Associated Mutations in MYO1E Disrupt Intracellular Localization of Myo1e and Result in Podocyte Junctional Defects Jing Bi, Christopher D. Pellenz, Mira Krendel. *Cell Developmental Biology, SUNY Upstate Medical Univ, Syracuse, NY.*

Background: Focal segmental glomerulosclerosis (FSGS) is one of the most common primary glomerular disorders that may lead to end-stage kidney disease. The pathological features of FSGS include formation of scar tissue that obliterates glomerular capillary loops and the presence of massive proteinuria. Pathogenesis of FSGS involves impaired function of glomerular podocytes, specialized epithelial cells in renal glomeruli, which cover the surface of the capillaries. Podocytes play an essential role in maintaining proper renal filtration function. Mutations in the *MYO1E* gene (A159P and T119I) were found to be associated with childhood familial FSGS (Mele et al., NEJM, 2011; Al-Hamed et al., J. Hum. Gen., 2013). Myosin 1e (Myo1e) is a non-muscle myosin, which is expressed in kidney podocytes in humans and mice. It has been found to be a component of the slit diaphragm (specialized junction between podocytes). However, the molecular mechanism that links Myo1e and FSGS still remains unclear.

Methods: Using immortalized Myo1e-null cultured podocytes that were isolated from knockout mouse kidneys, we were able to mimic cell-cell junction assembly using calcium-switch experiments. We introduced GFP-tagged Myo1e constructs into cultured podocytes using adenoviral vectors. We utilized live-cell imaging to visualize the recruitment of junctional components during cell-cell contact assembly.

Results: We found that without functional Myo1e, cultured podocytes were unable to assemble proper junctional structures. Furthermore, FSGS-associated Myo1e mutants did not colocalize in the nascent junctions with other junctional components, such as actin and ZO-1.

Conclusions: FSGS-associated mutations in *MYO1E* result in defects in cell-cell junction assembly, which may lead to formation of "leaky" slit diaphragm complexes *in vivo*.

SA-PO465

The Role of the Scaffolding Protein Shank2 in Cytoskeletal Organization in Podocytes Evgenia Dobrinskikh,[1] Patricia M. Zerfas,[2] R. Brian Doctor,[3] Linda Lewis,[1] Kayo Okamura,[1] Jeffrey B. Kopp,[3] Judith Blaine.[1] *[1]Medicine, Univ of Colorado Denver, Aurora, CO; [2]Office of Research Services, Office of the Director, NIH, Bethesda, MD; [3]NIDDK, NIH, Bethesda, MD; [4]Dept of Biology, Univ of Mississippi, Oxford, MS.*

Background: Shank2 is a scaffolding protein that interacts with a number of cytoskeleton-associated proteins. We have found that Shank2 is expressed in podocytes both *in vitro* and *in vivo*. Shank2 knockout (KO) mice develop proteinuria by 18 weeks of age suggesting that Shank2 is involved in cytoskeletal organization in podocytes.

Methods: The present study utilized immunofluorescence and functional assays in podocytes isolated from Shank2 knockout mice to assess the impact of Shank2 on the actin and microtubule cytoskeleton. In addition, scanning electron microscopy (SEM) was used to evaluate podocyte morphology in wild type and KO mice.

Results: Podocytes isolated from wild type and Shank2 KO mice express the podocyte markers podocin and WT-1. Immunofluorescence analysis shows that in Shank2 KO podocytes actin stress-fibers are short, broken and do not run axially. In addition, some Shank2 KO cells lack actin stress-fibers entirely. In Shank2 KO podocytes, the microtubule meshwork is disorganized and in some podocytes microtubules are completely depolymerized. To examine the functional consequences of cytoskeletal disruption in Shank2 KO podocytes, *in vitro* wound closure assays were performed. The percent of the wound closed is significantly less at both 6 hrs and 24 hrs in Shank2 KO podocytes compared to wild type (WT: 31±16% and 96±3%; KO: 10±7% and 53±18% of wound area closed after 6 hrs and 24 hrs respectively) suggesting defects in podocyte migration in the KO podocytes. Scanning electron microscopy (SEM) was performed to evaluate podocyte architecture in Shank2 KO versus wild type mice. SEM demonstrates a loss of foot process complexity and foot process disorganization in the KO mouse podocytes.

Conclusions: Taken together these data suggest that Shank2 plays an important role in the cytoskeletal organization and motility of podocytes.

SA-PO466

Sphingomyelin-Phosphodiesterase-Acid-Like-3b Affects Insulin Signaling in Podocytes Alla Mitrofanova,[1,3] Ximena A. Morales,[1] Christopher E. Pedigo,[1] Rodrigo Villarreal,[1,2] Mayrin Correa-Medina,[1] George William Burke,[3] Sandra M. Merscher,[1,2] Alessia Fornoni.[1,2] *[1]Dept of Molecular and Cellular Pharmacology Peggy and Harold Katz Family Drug Discovery Center, Univ of Miami, Miami, FL; [2]Diabetes Research Inst, Univ of Miami, Miami, FL; [3]Dept of Surgery, Univ of Miami, Miami, FL.*

Background: Disruption of physiological insulin signaling in podocytes may contribute to the pathogenesis of diabetic kidney disease (DKD). Sphingomyelin-phosphodiesterase-acid-like-3b (SMPDL3b) is upregulated in DKD and may facilitate to podocyte injury. Lipid rafts and the associated protein caveolin-1 (Cav-1) modulate insulin receptor (IR) dependent signaling. We tested the hypothesis that SMPDL3b expression modulates insulin signaling in human podocytes.

Methods: Podocytes were treated with insulin (1nM/ml, 1h) or methyl-beta-cyclodextrin (5mM/ml, 1h). Plasma membranes were separated using the ultracentrifugation (100,000xg, 1h) protocol. Proteins were separated in 4-20% SDS-PAGE gels (BioRad) and transferred to nitrocellulose membranes for the Western blot analysis. All antibodies were obtained from Cell Signaling.

Results: Insulin treatment of SMPDL3b overexpressing (OE) podocytes did not result in a significant protein kinase B phosphorylation when compared to wild type (WT) podocytes. Plasma membrane localization of IR was significantly ($p<0.05$) reduced in OE podocytes (19.00±0.04%) compared to WT (99.00±0.11%). The amount of total and phosphorylated Cav-1 at the plasma membrane was not affected in OE podocytes. However, OE podocytes were more sensitive to cholesterol depletion (via cyclodextrin) causing reduced total (17.88±0.03% in OE versus 62.10±0.10% in WT cells, $p<0.01$) and phosphorylated (26.55±0.04% in OE versus 62.93±0.04% in WT cells, $p<0.01$) Cav-1. Reduction of Cav-1 was associated with increased IR plasma membrane localization in OE podocytes.

Conclusions: SMPDL3b interferes with the insulin receptor and caveolin-1 interaction. SMPDL3b overexpression could cause insulin resistance in podocytes by altering the subcellular distribution of the insulin receptor. Upregulation of SMPDL3b in podocytes may contribute to insulin sensitivity and cause podocyte damage in DKD.

Comparative Phosphoproteomic Analysis of Mammalian Glomeruli Reveals Podocin Carboxyl Terminus Phosphorylation as Determinant of Slit Diaphragm Complex Architecture Markus M. Rinschen,[1] Trairak Pisitkun,[2] Bernhard Schermer,[1] Thomas Benzing,[1] Paul T. Brinkkoetter.[1] *[1]Internal Medicine, Univ Hospital Cologne, Cologne, Germany; [2]Faculty of Medicine, Chulalongkorn Univ.*

Background: Signaling in podocytes in health and disease largely depends on phosphorylation, but technologies to understand its signaling have not been available. Recently, we performed in-depth analysis of the mouse glomerular phosphoproteome by tandem mass spectrometry and confidently identified more than 4000 phosphorylation sites. Comparisons of phosphoproteomic evidence across species is a powerful mean to functionally prioritize phosphorylation sites (Beltrao et al. Cell 2012). The purpose of this study was to use comparative phosphoproteomic analysis to prioritize phosphorylation sites for reductionist studies.

Methods: We performed an extensive phosphoproteomic analysis of glomerular fractions of bovine and rat kidneys. We performed bioinformatics analysis to determine conserved phosphorylation on homologous proteins and protein residues across mammalian species.

Results: We discovered several phosphorylation sites with potentially high biological relevance, e.g. tyrosine phosphorylation of the cytoskeletal regulator synaptopodin and the slit diaphragm protein neph-1 (Kirrel). Moreover, cross-species comparisons revealed conserved phosphorylation of the slit diaphragm protein nephrin on an acidic cluster at the intracellular terminus and conserved podocin phosphorylation on the very carboxyl terminus of the protein. Comparison of the dataset partly confirms significant cross-species conservation of signaling events in mouse, rat and cow. Given the pivotal role of podocin for glomerular biology we studied a highly conserved podocin phosphorylation site in greater detail and show that phosphorylation regulates affinity of the interaction with nephrin and CD2AP.

Conclusions: Taken together, these results suggest that species comparisons of phosphoproteomic data may reveal regulatory principles in glomerular biology.

SA-PO468

Myosin 1e Is Required for the Maintenance of the Glomerular Filtration Barrier in the Adult Kidney Mira Krendel, Sharon E. Chase. *Cell Developmental Biology, SUNY Upstate Medical Univ, Syracuse, NY.*

Background: Glomerular visceral epithelial cells (podocytes) rely on the actin cytoskeleton and actin-associated proteins in order to develop the complex system of interdigitating foot processes and to maintain their structural and functional integrity. Myosin 1e (Myo1e), an actin-dependent molecular motor protein, is one of the key components of the podocyte cytoskeleton. Mutations in the MYO1E gene are associated with childhood FSGS (Mele et al., NEJM, 2011), and mice lacking Myo1e in podocytes develop proteinuria, foot process effacement, and glomerular basement membrane defects (Chase et al., AJP Renal Physiology, 2012). These observations indicate that Myo1e is required for the normal development of the glomerular filtration barrier. We have set out to determine whether Myo1e is necessary to maintain selective glomerular filtration in the adult kidney.

Methods: To address this question, we used a transgenic mouse model with doxycycline-inducible, podocyte-specific Cre recombinase expression to remove Myo1e from the adult podocytes. Doxycycline treatment was administered to eight week old mice for two weeks.

Results: Within one to two weeks following the treatment, experimental mice developed persistent proteinuria. Control mice, not carrying the transgenes necessary for Cre expression, did not exhibit proteinuria following doxycycline administration. Transmission electron microscopy revealed foot process effacement and glomerular basement membrane abnormalities following the induction of Myo1e knockout.

Conclusions: Our findings demonstrate that Myo1e is required not only for glomerular development but also for maintaining normal glomerular filtration in the adult. Thus, changes in Myo1e expression and activity in adults could lead to podocyte dysfunction, loss of selective filtration, and progressive kidney disease.

Cyclosporine versus Tacrolimus Therapy in Steroid plus Cyclophosphamide Resistant Nephrotic Syndrome: A Prospective Long Term Follow-Up Study Narayan Prasad, Manjunath Revanasiddappa, Amit Gupta, Akhilesh Jaiswal, Raj K. Sharma. *Nephrology, SGPGIMS, Lucknow, India.*

Background: The treatment of both steroid and cyclophosphamide resistant nephrotic syndrome(CYC-SRNS) is challenging.Both calcineurin inhibitors (Cyclosporine and Tacrolimus) vary in potency and side effects. The comparative outcomes data are lacking.

Methods: Forty five CYC-SRNS patients were categorized into 2 groups to receive either CSA or TAC on1:1 distribution. Patients were followed for complete remission (CR)/ partial remission(PR), adverse effects and progression. At 6 months, patients were declared responsive/resistant to first CNIs and resistant patients were switched to another CNI. The same CNI was continued in responsive patients for 12 months and steroid was tapered.CSA and TAC dose were kept at trough level of 120-180ng/ml and 6-10 ng/ml,respectively. CNI non responsive patient at 12 months from either group were treated with MMF.

Results: At 6 months, of 23 patients on CSA,16(69.5%) achieved remission(CR13/ PR3) and of 22 patients on TAC,18 (81.8%) achieved remission(CR11/PR7)($p=0.35$). Patients who are resistant to 1st CNI, 7/23were switched to TAC and of them 4 achieved remission (3PR, 1CR), and 3 remained resistant. Of the 4 patients who were switched to CSA,1 had PR and 3 remained resistant.Mean decline in GFR from baseline in CSA and TAC was similar at 6 months.The decline at 12 months (-24.5±10.2 versus -19.4±5.6, $P=0.04$) and end of follow up (-32.7±15 versus -24.3±10,$p=0.03$) was high in CSA group as compared to TAC. Ten patients in CSA and 4 in TAC group had doubling of creatinine/ decline in GFR by 50% ($p=0.06$). Hypertrichosis, and gum hyperplasia was high in CSA group as compared to TAC($p<0.05$). On KM survival analysis with event doubling of serum creatinine, the 1,2,3,4, and 5 years renal survival in CSA group was 96%,91%,85%,54%, and 33%, and TAC group was 96%,95%,90%,89%, and 79% respectively($p=0.02$). Of the 15 patients who did not achieve CR, 14 received MMF for 12 months, and 2 had CR, 5 had PR,and7 remained resistant.

Conclusions: Though TAC and CSA have similar efficacy in inducing and maintaining remission in CYC-SRNS patients. The side effect profile and long term outcome favour use of Tacrolimus over Cyclosporine.

SA-PO470

Elimination of AT1 Receptors from Podocytes Does Not Reduce Albuminuria Stacy Alana Johnson,[1] Natalie Mattocks,[1] Momoe Maeda,[2] Susan B. Gurley,[1,3] Thomas M. Coffman.[1,3] *[1]Duke Univ; [2]Duke-NUS; [3]Durham VA Medical Center.*

Background: The renin-angiotensin system (RAS) is a key regulator of blood pressure and fluid balance. RAS blockade is the mainstay of therapy for proteinuric renal diseases and the anti-proteinuric actions of RAS inhibitors are believed to be critical to their efficacy. This suggests that angiotensin II (AngII) acting via AT_1 receptors promotes proteinuria and this may be an important pathway in the pathogenesis of glomerular diseases. The mechanism by which AngII causes proteinuria has never been clearly demonstrated. Proposed mechanisms include glomerular hypertension, mesangial cell contraction and effects on podocytes to modify the glomerular filtration barrier. To test this last possibility, we generated mice lacking expression of all AT_1 receptors in podocytes. We hypothesized that loss of AT_1 signaling in the podocyte would reduce albuminuria.

Methods: We generated mice homozygous for a conditional *Agtr1a* allele on the *Agtr1b* null background and crossed these mice with *Pod-Cre* mice expressing Cre recombinase under the control of the podocin promoter, thus eliminating all AT_1 receptors from podocytes (*PodKO*s). The resulting offspring were then crossed with mice expressing a renin transgene (*RenTg*), which expresses renin under the control of the albumin promoter. *RenTg* mice develop hypertension with albuminuria.

Results: AT_{1A} mRNA expression was significantly reduced in glomeruli isolated from *PodKO* mice compared to controls. *PodKO* and *PodKO-RenTg* mice develop normally and there were no differences in body or kidney weight compared to controls. By 12 weeks of age, *RenTg* mice developed albuminuria compared to wild-type controls (85±14 versus 18±1 µg/24h; $p<0.05$) and the extent of albuminuria is increased at 24 weeks (210±71 versus 29±7 µg/24h, $p = 0.02$). This increased level of albuminuria was similar in the *PodKO-RenTg* and *RenTg* mice at both 12 (146±36 versus 85±14 µg/24h) and 24 weeks (229±38 versus 210±71 µg /24h).

Conclusions: Elimination of AT_1 receptors from podocytes did not attenuate albuminuria, suggesting that AT_1 receptors in other cell lineages are responsible for promoting proteinuria.

SA-PO471

Day Case Renal Biopsy Is Safe Irrespective of Renal Function: Results from a Single-Center Experience Vasantha M. Muthuppalaniappan, Sheela Anpalakhan, Conor J. Byrne, Michael Sheaff, Ravindra Rajakariar, Mark Blunden. *Renal Medicine, The Royal London Hospital, United Kingdom.*

Background: Renal biopsy is a useful diagnostic test to investigate renal disease. Day case biopsies are increasing to improve efficiency in patient and hospital time. However, concerns remain about the safety of day case biopsies especially in patients with eGFR<60ml/min.

Methods: Data was collected retrospectively on 778 consecutive day-case renal biopsies performed in our short stay facility. Patients were deemed fit if; Hb >8g/dl, platelet >100 and INR and APTT <1.2 less than 1 week prior to biopsy. Patients with a creatinine >300umol/L received 20mcg of intravenous DDAVP. Anti-platelet agents were stopped 1 week prior and the blood pressure cut-off was 160/90. Patients were observed for 6 hours post biopsy and discharged if haemodinamically stable and no visible haematuria. Complications and diagnostic adequacy were identified from hospital records.

Results: Between 01.01.11-31.05.14, 778 biopsies (460 male) were performed, comprising 429 native and 349 transplant, of which 112 were 3-month protocol biopsies. The amount of biopsies performed in patients with an eGFR of; 0-19ml/min, 20-39ml/min, 40-59ml/min, were 97, 304, 181 respectively. Biopsies were diagnostic in 762 cases (97%). 6 native, 4 transplant and 6 protocol biopsies were not diagnostic due to inadequate sampling. 21 patients required overnight admission for extended observation; 12 native (1 required blood transfusion) and 5 transplant due to visible haematuria, 2 patients for pain at the biopsy site and 2 patients had non-biopsy complications. Visible haematuria occurred in 6 patients with an eGFR >60, 4 with an eGFR 0-19, 5 with a 20-39 and 2 with an eGFR 40-59 (all ml/min). The remaining admissions were haemodinamically stable with no drop in Hb. 1 patient had an accidental biopsy of spleen and kidney causing splenic haematoma and hospital admission 4 days later.

Conclusions: Day case biopsy is a safe procedure with high diagnostic yield (97%). It can be performed as an outpatient even when significant renal impairment is present. The cancellation rates were reduced when the procedure was performed as an outpatient day case as opposed to an admission for inpatient biopsy.

SA-PO472

Association of Glomerular Macrophage Phenotypes and Urinary Soluble CD163 with Disease Activity in Human Lupus Nephritis Nobuhide Endo,[1] Naotake Tsuboi,[1] Kazuhiro Furuhashi,[2] Shoichi Maruyama,[1] Seiichi Matsuo.[1] *[1]Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [2]Brigham and Women's Hospital and Harvard Medical School.*

Background: In addition to the effector roles of classically activated macrophages for tissue injury, recent studies have shown that alternatively activated (M2) macrophages are involved in resolution of inflammation in animal models of kidney disease. But, clinical relevance of M2 macrophage in human disease is largely unknown. The current study aimed to evaluate renal accumulation of macrophage phenotypes in human lupus nephritis (LN) and significance of soluble form of CD163 (sCD163), a representative marker for M2 cells, for LN disease activity.

Methods: Plasma, urine and kidney biopsy samples were obtained from 74 patients with LN. Histological features were classified according to the ISN/RPS LN criteria. Immunohistochemical analyses using anti-human CD68, CD163 or CD204 antibodies were performed for identification of macrophage phenotypes. Concentrations sCD163and MCP-1in plasma and urine were measured by ELISA.

Results: Immunohistological analysis in LN glomeluli revealed more than 70% of $CD68^+$ macrophages was merged with $CD163^+$ cells and more than 90% of $CD163^+$ cells was merged with $CD68^+$ cells. However, $CD163^+$ cells appeared to be more than $CD68^+$ cells in interstitum, indicating the different origin of glomerular and interstitial $CD163^+$ macophages. The cell counts of glomerular $CD68^+$, $CD163^+$ or $CD204^+$ macrophages were increased in association with severity of biopsy active index (BAI) score in LN. Interstitial $CD68^+$, $CD163^+$ or $CD204^+$ macrophage infiltration correlated with eGFR. Urine sCD163 level showed stronger correlation with the number of glomerular CD163 positive cell counts (r=0.501) and BAI score (r=0.644) than plasma sCD163 levels with both of the above (r=0.289 and r=0.295, respectively). Correlation of urine sCD163 with BAI was comparable to that of urine MCP-1 levels (r=0.592) in LN.

Conclusions: These results suggest that $CD163^+$ or $CD204^+$ macrophage is the dominant phenotype in kidneys of LN patients, and urine sCD163 level has a potential significance for estimation of disease activity in human LN.

SA-PO473

Urine Monocyte Chemoattractant Protein-1 (MCP-1) Associates with Interstitial Fibrosis on Implantation Biopsies of Living Kidney Donors Hisham Elsherbiny, Aleksandar Denic, Vidhu Kaushik, Prince Singh, Muthuvel Jayachandran, Mariam P. Alexander, John C. Lieske, Andrew D. Rule. *Div of Nephrology and Hypertension, Mayo Clinic, Rochester, NY.*

Background: MCP-1 plays a role in renal inflammation that leads to fibrosis and loss of kidney function in a variety of kidney diseases. We hypothesized that urinary MCP-1 associates with occult renal fibrosis in healthy adults with normal kidney function.

Methods: From 2005 to 2011, 517 living kidney donors had a pre-donation spot urine sample collected and a core needle biopsy of their donated kidney during surgery. All patients had preoperative GFR by iothalamate clearance and 24-h urine collection for albumin measurement. Mean non-sclerotic glomerular volume of periodic acid-Schiff stained biopsy sections was estimated using the Weibel and Gomez stereological method and the percentage of globally sclerosed glomeruli and interstitial fibrosis were calculated. Urinary MCP-1 was assayed by ELISA.

Results: Mean+SD age was 45+12 years, 43% were men, 14% had hypertension, 24-h urine albumin was 4+6 mg, GFR was 102+17 ml/min/1.73 m^2, MCP-1 was 187+194 pg/ml and MCP-1/ urine creatinine (UCr) was 1.6+1.3 pg/mg. Fibrosis was present in 22% with 4% having more than 5%, GSG >5% was present in 27%, and the mean glomerular volume was 0.003+0.001 mm^3. Associations of MCP-1 and MCP-1/UCr with clinical and biopsy features after adjustment for age, sex, urine albumin, and GFR are shown in the Table.

Characteristic	MCP-1	MCP-1/UCr
	% difference, p value	**% difference, p value**
Age, 10y	-1.4%, 0.79	**12%, <0.001**
Male	**58%, <0.001**	-3%, 0.67
24-h urine albumin excretion, SD	**20%, <0.001**	**9%, 0.009**
GFR, SD	1.5%, 0.80	5%, 0.16
Hypertension	-3.4%, 0.84	11%, 0.32
Any interstitial fibrosis	**44%, 0.007**	**26%, 0.005**
Interstitial fibrosis >5%	44%, 0.21	**49%, 0.028**
Percent GSG >5	23%, 0.097	12%, 0.14
NSG Volume, SD	4%, 0.44	5%, 0.20

Conclusions: Urinary MCP-1 associates with interstitial fibrosis in ostensibly healthy adults, independent of age, gender, GFR, and urine albumin excretion. Thus Urinary MCP-1 may be useful for identifying occult interstitial fibrosis that is not detected by current kidney function markers.

Pathologic Findings in Tenofovir Toxicity and Correlation with Severity of Acute Kidney Injury

Meghan E. Sise,[1] Jamie S. Hirsch,[1] Pietro A. Canetta,[1] Sumit Mohan,[1] Leal C. Herlitz.[2] *[1]Nephrology, Columbia Univ Medical Center, New York, NY; [2]Renal Pathology, Columbia Univ Medical Center, New York, NY.*

Background: Tenofovir disopril fumarate (TDF) is a nucleotide analog reverse-transcriptase inhibitor used for treatment of HIV and Hepatitis B virus infections. TDF nephrotoxicity is characterized by acute tubular necrosis (ATN) with distinctive clinical, pathological, and mitochondrial (MC) abnormalities. The pathology of TDF toxicity was first described in 2010 among a cohort of 13 patients at Columbia University Medical Center (CUMC). This study aimed to confirm the pathologic findings of TDF toxicity in a larger biopsy cohort.

Methods: Patients with biopsy proven TDF nephrotoxicity were identified from the CUMC Renal Pathology Lab database and their charts reviewed retrospectively.

Results: We identified 30 additional cases of TDF toxicity. Mean age was 55.4±8.2 years, 47% female and 44% White, 56% diabetic. The median duration of TDF therapy was 9 months (IQR 4-56mo), the earliest case was identified 2 weeks after starting therapy. The mean baseline serum creatinine (SCr) was 1.23 ±0.53 mg/dL, the mean SCr at biopsy was 4.05 mg/dL (IQR 2.2-8.3mg/dL). Biopsy indications were acute kidney injury (AKI) in 70% of patients and 30% were biopsied for chronic kidney disease (CKD) and proteinuria (1071 ±530 mg/gm). ATN was evident in 20/21 cases with AKI. Of those biopsied for CKD and proteinuria, 8 had evidence of mild, patchy tubular damage, 1 had diffuse tubular damage. A median of 8% (IQR 0-20%) of glomeruli were globally sclerotic, and mean tubular atrophy/interstitial fibrosis was 24% ±17%. Diabetic glomerular changes were seen in 11 cases, 5 had other unrelated glomerular lesions. All 30 cases showed dysmorphic MC on electron microscopy. Enlarged MC were seen in 21 cases and 12 had MC depletion. 5 showed patchy areas of both MC depletion and enlargement. MC changes were visible by light microscopy in 70% of the cases. There was minimal podocyte effacement 20%±10%.

Conclusions: Our findings add to previous series of TDF nephrotoxicity, confirming the potential for severe ATN and the presence of characteristic MC abnormalities. All cases had some element of MC damage.

SA-PO475

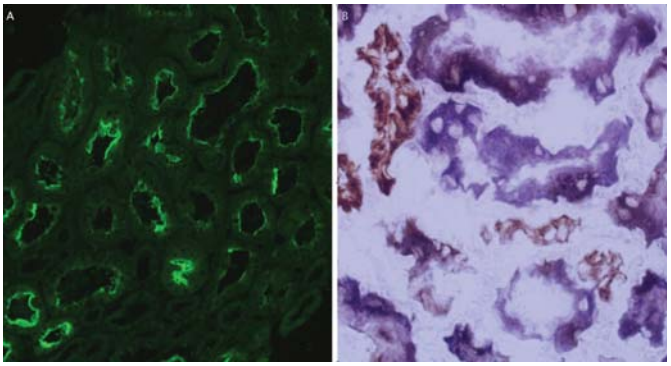
Renal Expression of the Proximal Tubular Markers Megalin and Cubulin and Mitochondrial Enzyme Activity in HIV-infected Patients with Tenofovir Nephrotoxicity

Alexandre Cez,[1,2] Isabelle Brochériou,[3] Clovis Adam,[4] Pierre M. Ronco,[1,2] Emmanuelle M. Plaisier.[1,2] *[1]Nephrology, Tenon Hospital, Paris, France; [2]Unit 1155, INSERM, Paris, France; [3]Pathology, Tenon Hospital, Paris, France; [4]Pathology, Bicêtre Hospital, Le Kremlin Bicêtre, France.*

Background: Tenofovir disoproxil fumarate (TDF) is an effective and widely used molecule for the treatment of human immunodeficiency virus (HIV) infection. TDF is infrequently associated with proximal tubular dysfunction and acute tubular necrosis (ATN).

Methods: We reviewed kidney biopsy specimen from patients presenting with TDF nephrotoxicity. Proximal tubular expression of megalin and cubulin was assessed by immunostaining. Kidney frozen sections were histochemically stained for COX and succinate dehydrogenase enzyme activity. Results were compared to kidney biopsies from control groups.

Results: Twenty HIV-infected patients with TDF nephrotoxicity were identified. Median TDF exposition duration was 36 months. At the time of kidney biopsy, median estimated glomerular filtration rate was 27,5 ml/min/1,73m^2. Histologic findings usually showed toxic ATN of various severity. Loss of megalin and cubulin expression affected more than 50% of the proximal tubules (PT) in 9 cases and 15 to 50% of PT in 10 cases, compared to less than 10% PT in control groups, that included HIV-infected patients naïve for TDF and HIV uninfected patients with ATN. Giant mitochondria were observed in only 25% of cases by light microscopy and ultrastructural mitochondrial dysmorphic changes were obvious in 4 out the 5 cases analyzed. Functional histochemistry of COX and SDH showed patchy loss of COX enzyme activity in PT.



Conclusions: Mild to severe alterations of megalin and cubulin expression characterize TDF-related proximal tubular toxicity, and may differentiate ATN unrelated to TDF exposition. Additionally, specific loss of COX activity in PT could be a strong marker of TDF nephrotoxicity.

SA-PO476

Dynamics of Renal Human L-Type Fatty Acid Binding Protein Reflects the Degree of Tubular Loss which Develops to Chronic Kidney Disease After Acute Kidney Injury

Mikako Hisamichi,[1] Atsuko Ikemori,[2] Takeshi Sugaya,[1] Yugo Shibagaki,[1] Takashi Yasuda,[1] Kenjiro Kimura.[1] *[1]Dept of Nephrology and Hypertension, St. Marianna Univ School of Medicine, Kawasaki, Japan; [2]Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Japan.*

Background: Tubular loss after acute kidney injury (AKI) is an important risk factor for onset of chronic kidney disease (CKD) and, therefore, notable detector of tubular loss is needed for prediction of renal prognosis after AKI. The aim of this study is to elucidate that dynamics of renal human L-type fatty acid binding protein (hL-FABP) is connected with the degree of tubular loss on chronic phase after AKI.

Methods: hL-FABP chromosomal transgenic (Tg) mice were subjected to ischemic reperfusion (I/R) model. The Tg mice were divided into 4 groups: short duration ischemia group (short-I/R) received procedure of renal ischemia induced by left renal artery clamping for 20 min; twice short-I/R group (2-short-I/R) received ischemia for 20 min twice with interval of 20 days; long duration ischemia group (long-I/R) received ischemia for 60 min; and the sham operated group. Kidneys were obtained 20 days after last I/R.

Results: The correlation between dynamics of renal hL-FABP and the degree of tubular loss after AKI with different frequency was revealed by comparison between short-I/R and 2-short-I/R mice. Tubulointerstitial injury and fibrosis were significantly greater in 2-short-I/R than in short-I/R mice. Under these conditions, renal gene and protein expressions of hL-FABP in 2-short-I/R increased significantly compared to short-I/R mice. Urinary hL-FABP levels were significantly higher in 2-short-I/R than in short-I/R mice. In regards to the dynamics of renal hL-FABP in tubular loss after AKI with different ischemic term, tubulointerstitial injury in long-I/R were significantly more severe than in short-I/R. Up-regulation of renal hL-FABP expression and urinary hL-FABP levels increased significantly in long-I/R more than in short-I/R.

Conclusions: In conclusion, dynamics of renal hL-FABP reflects the degree of tubular loss on chronic phase after AKI and urinary L-FABP may be useful for detection of tubular loss in clinical practice.

SA-PO477

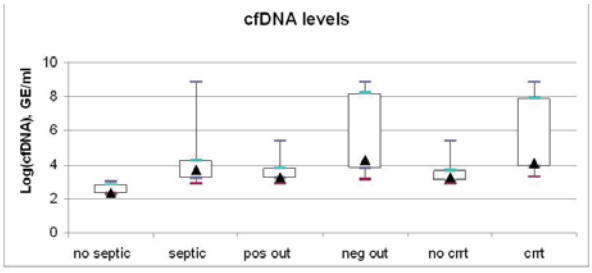
Prognostic Utility of Cell Free DNA in Critically Ill Patients

Anna Clementi,[1,2] Grazia Maria Virzì,[1] Stefano Marcante,[3] Silvia Pastori,[1] Massimo de Cal,[1] Antonio Granata,[2] Claudio Ronco.[1] *[1]Nephrology-IRRIV, S Bortolo; [2]Nephrology S Giovanni di Dio; [3]ICU S Bortolo.*

Background: Sepsis, a devastating condition characterized by systemic activation of inflammatory and coagulation pathways in response to infection, is a primary cause of morbidity and mortality in critically ill patients (pts). Recent researches suggested that cell free DNA (cfDNA), released as a result of cell necrosis and apoptosis, increases in many clinical conditions. The aim of this study was examined cfDNA levels in critically ill pts.

Methods: We enrolled 33 patients (pts) admitted in intensive care unit (ICU). 27 were septic (19 males, mean age 62±18yrs) and 7 were non septic (6 males, mean age 58±19yrs). 12/27septic pts developed acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT); 11/27 had a negative outcome during ICU stay. CfDNA was extracted from plasma and was quantified in Genome Equivalent GE/ml by Real time PCR for β-globin gene. Nonparametric variables were expressed as median and interquartile range (IQR). We applied a linear transformation of cfDNA, log(cfDNA), to manage the data better.

Results: We observed significantly higher levels of cfDNA in pts with sepsis (5331GE/ml; IQR: 1751-16113 versus 238GE/ml; IQR: 208-1001 in no septic pts) (p<.01), with no difference in its levels among pts with Gram$^{+/}$Gram$^-$ infections. Moreover, cfDNA levels resulted to be higher in septic pts who developed AKI requiring CRRT (CRRT pts: 13060; IQR: 8692-79367316 versus no CRRT: 1891; IQR: 1203-4324); and in patients with a negative outcome(negative: 18678; IQR:6175-157747 versus positive: 1891; IQR: 1497-6319)(all, p<.01).



Conclusions: cfDNA could be a potential biomarker in critically ill pts. In particular, cfDNA seems to have prognostic utility in critically ill patients with sepsis, especially if they develop AKI requiring CRRT. Moreover, it appears to be associated with negative outcomes.

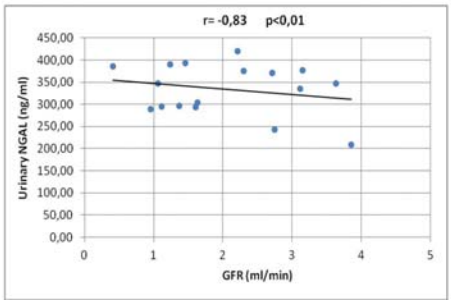
Urinary NGAL Levels in Maintenance Hemodialysis Patients
Alessandra Spinelli,[1,3] Sara Samoni,[1] Gianluca Villa,[1] Grazia Maria Virzì,[1] Massimo de Cal,[1] Alessandra Brendolan,[1,2] Federico Nalesso,[1,2] Monica Zanella,[1,2] Loreto Gesualdo,[3] Claudio Ronco.[1,2] *[1]IRRIV; [2]S. Bortolo Hospital; [3]Univ of Bari.*

Background: Urinary concentration of Neutrophil gelatinase-associated lipocalin(uNGAL) is a sensitive biomarker for acute kidney injury.Recent studies investigated its role in chronic kidney disease(CKD) and showed that uNGAL progressively increased with the reduction of Glomerular Filtration Rate(GFR).Few data are available about its behavior in maintenance hemodialysis(MHD) patients(pts).

Methods: We enrolled 17 MHD pts with residual diuresis(>200ml/die).24h diuresis(collected before the first weekly dialysis session),uNGAL,GFR(as the arithmetic mean between Creatinine and Urea Clearances) were measured.According to diuretic dose,enrolled pts were divided in a diuretic group(DG, furosemide>50mg/die) and a non-diuretic one(NDG,furosemide≤50mg/die).Results are expressed as median[I-III interquartile].The correlation between uNGAL and residual GFR was analyzed by Spearman Test.The Mann–Whitney U test was used for comparison of two groups;a p value<.05 was considered for statistical significance.

Results: We reported GFR,diuresis and uNGAL for all pts in figure1.We observed a negative correlation between GFR and uNGAL(rho=-.83,p<.01).We compared 11 DG pts versus 6 NDG pts. DG pts compared to NDG pts.However,GFR and diuresis did not differ significantly between groups.

	All subjects		
GFR (ml/min)	1.6[1.2-2.7]		
Diuresis (ml/die)	600[400-800]		
uNGAL (ng/ml)	346.8[294.5-377.0]		
	DG (11pts)	NDG (6pts)	p
Diuretic dose (mg/die)	500[250-500]	0[0-25]	
GFR (ml/min)	1.5[1.1-2.3]	1.6[1.5-2.9]	NS
Diuresis (ml/die)	500[375-650]	650[375-750]	NS
uNGAL (ng/ml)	347.4[341.2-372.98]	296.3[294-320.1]	<.01



Conclusions: In conclusion,our data have demonstrated that MHD pts have chronically increased uNGAL levels,which progressively increase with GFR reduction.uNGAL could be a new potential biomarker to evaluate renal damage severity in MHD.In particular,at similar GFR level,pts with higher levels of uNGAL need more diuretic doses to maintain the same level of diuresis.Further trials to assess the role of uNGAL in the evaluation of residual renal function and clinical outcome are necessary.

SA-PO479

The Renal Pathological Findings in Diabetic Patients with Acute Renal Failure
Steven Salvatore, Surya V. Seshan. *Weill Cornell Medical College.*

Background: Diabetic nephropathy (DN) is the most common cause of end stage renal disease in the U.S. Typically, presenting with proteinuria and progressive renal insufficiency, the diabetic patient may be managed clinically without a diagnostic kidney biopsy. However, acute renal failure in the diabetic patient tends to have many etiologies requiring a kidney biopsy for definitive diagnosis.

Methods: Of 7485 native kidney biopsies from 2000-2014, 924 (12.3%) had diabetic nephropathy and 502 of those (54.3%) presented with acute renal failure (ARF) +/- significant proteinuria and hematuria. ARF was defined by KDIGO criteria (>0.3 mg/dL increase in serum creatinine within 48 hrs or 50% in 7 days). Clinicopathologic analysis of this cohort was performed.

Results: Renal biopsy findings of DN are increasing in recent years in our cohort, found in 8.4% of cases from 2000-2004 and 16.4% from 2011-2013. The 502 patients with ARF ranged from 14-88 years old and were 63% male. The average presenting creatinine was 4.6mg/dL (1.5-22), with 9 patients on dialysis, and proteinuria was 6.6g/d (0-34). A second diagnosis in addition to DN was rendered in 343 cases (68%), most commonly patchy or diffuse active interstitial nephritis (AIN) (27%), post-infectious glomerulonephritis (PIGN) (10.5%), acute tubular injury (12%), podocytopathy (6%) [29 collapsing glomerulopathy,10 minimal change, 6 FSGS], crescentic GN (2.6%), thrombotic microangiopathy (2.2%), and occasional membranous GN (5 cases), IgA nephropathy (3), Bence Jones cast nephropathy (3), lupus nephritis (4), atheroembolic disease (3), amyloidosis (2), cryoglobulinemia (1), and membranoproliferative GN (5). The cases without a superimposed disease (32%) showed advanced diabetic disease, class III (nodular diabetic glomerulosclerosis) 38% to class IV (having >50% global GS) 37%, interstitial fibrosis (65%), and severe vascular disease (42%).

Conclusions: DN is increasingly found in the renal biopsy population. Acute renal failure, a common but important indication for kidney biopsy in diabetic patients, is frequently associated with superimposed disease but may also disclose advanced DN alone. In these patients, renal biopsy yields diagnostic and prognostic information for appropriate management.

Reproducibility of the NEPTUNE Digital Pathology Morphologic Profiling of NS
L. Barisoni,[1,2] J. Troost,[2] S. Bagnasco,[2] C. Avila-Casado,[2] M. Palmer,[2] Avi Z. Rosenberg,[2] A. Gasim,[2] Jeffrey B. Hodgin,[2] J. Charles Jennette,[2] D. B. Johnstone,[2] L. Merlino,[2] Kevin V. Lemley,[2] Catherine M. Conway,[2] Jeffrey B. Kopp,[2] Peter X.K. Song,[2] Stephen M. Hewitt,[2] Cynthia C. Nast.[2] *[1]U. Miami; [2]The Nephrotic Syndrome Study Network.*

Background: Reproducibility of conventional light microscopy analysis remains challenging. The NEPTUNE digital pathology protocol (NDPP) is a novel approach that applies a descriptor-based assessment (60 histologic (H), 10 immunofluorescence (IF) and 16 electron microscopy (EM) descriptors) to whole slide images (WSI), IF and EM digital images.

Methods: To test reproducibility, 6 pathologists and 1 trainee (P1-7) scored H descriptors in 131 glomeruli, EM podocyte descriptors (PD) (P1-5) in 178 cases, and % of interstitial fibrosis and tubular atrophy (IFTA) (P1=54, P2=38 and P4=188 cases). % IFTA was compared to IFTA morphometric measurement (64 cases). Kendal's coefficient of concordance was used to measure inter-reader reliability for glomerular H descriptors, PD and IFTA.

Results: Coefficient of concordance was *excellent* (>0.70) for PD effacement, global collapse, cellular and sclerosing tip lesion, foam cells, global spikes; *good* (<0.70 and >0.60) for PD microvillous transformation, normal glomeruli, global sclerosis with hyalinosis, global deflation, obsolescence, mid-glomerular sclerosis, hyaline droplets, global epithelial hypertrophy; *moderate* (<0.60 and >0.50) for segmental sclerosis and hyalinosis cannot determine location, perihilar hyalinosis, adhesions, segmental epithelial hypertrophy, halo, global mesangial hypercellularity. Evaluation of WSI-IFTA had excellent concordance with morphometric analysis.

Kendall's Coeff. of Concordance							
global collapse	cellular tip lesion	sclerosing tip lesion	glomerular foam cells	global spikes	IFTA %	% IFTA vs morphometric analysis	PD effacement (0-4+)
0.85	0.72	0.70	0.80	1.00	0.87-0.99	0.82-0.85	0.92

Conclusions: The NDPP has good reproducibility, independent from years of experience, enabling standardization of renal biopsy interpretation. The standardized collection of permanently recordable observational data is also suitable for correlation with clinical and molecular profiling of NS across international collaborative consortia employing the NDPP.

Morphometric Analysis of Podocyte Density and Glomerular Volume Adapted for Routine Diagnostic Biopsy Evaluation
Christopher Lund O'Connor,[1] Madhusudan Venkatareddy,[2] Su Qing Wang,[2] Laura H. Mariani,[2] Markus Bitzer,[2] Roger C. Wiggins,[2] Jeffrey B. Hodgin.[1] *[1]Pathology, Univ of Michigan, Ann Arbor, MI; [2]Nephrology, Univ of Michigan, Ann Arbor, MI.*

Background: Strong evidence from model systems and human studies support the hypothesis that podocyte density (podocyte depletion relative to glomerular volume) is the critical process driving glomerulosclerosis. We have previously reported a method estimating podocyte number and density in a single histological section (Venkatareddy et al., JASN 2014) using immunofluorescence and immunohistochemistry. Here we compare three simplified methods using immunohistochemistry for WT1, Glepp1, or routine PAS.

Methods: Human kidney tissue was obtained from 19 nephrectomies under IRB approved protocols. Slides were morphometrically analyzed according to Venkatareddy et al. Additional slides from the same cases were immunostained with WT1, Glepp1, or PAS, then scanned and analyzed morphometrically using ImageJ software for podocyte number, podocyte area, and glomerular tuft area.

Results: Podocyte density, %podocyte area, and glomerular volume were calculated (Table). All methods correlated well with Venkatareddy et al., with podocyte density from PAS sections surprisingly best. WT1 performed worst due to some nonspecific staining.

	Morphometric method	Mean (SD)	Range	R-squared*	Correlation	Relative Bias,% (SD)
Podocyte Density ($x10^6$ um^3)	**Venkatareddy et al.**	**125.2 (34.3)**	**82.0-214.0**			
	WT1 only	152.0 (49.2)	90.5-285.1	0.56	P < 0.001	20.2 (24.1)
	Glepp1 only	123.9 (22.1)	94.3-155.9	0.76	P < 0.0001	1.7 (13.9)
	PAS only	125.9 (29.3)	84.0-207.9	0.81	P < 0.0001	2.5 (14.9)
Podocyte Area (% of tuft)	**Venkatareddy et al.**	**49.5 (4.6)**	**39.5-54.5**			
	Glepp1 only	51.3 (4.8)	41.0-57.8	0.49	P < 0.001	3.9 (7.6)
Glomerular Volume ($x10^6$ um^3)	**Venkatareddy et al.**	**3.7 (1.2)**	**2.4-6.7**			
	Mean of WT1, Glepp1, PAS	3.6 (1.1)	2.3-6.7	0.87	P < 0.0001	-4.2 (11.6)
				*compared to Venkatareddy et al.		

Conclusions: Building on previous work, we demonstrate the feasibility of reporting podocyte density in standard renal pathology practice with either a single immunostain, or routine PAS, using freely available analysis software and standard imaging tools.

SA-PO482

Glycomics for Urinary Biomarker Discovery in IgA Nephropathy (IgAN) Robert H. Weiss, Renee Ruhaak, Billy T. Hour, Angela M. Zivkovic. *UC Davis, Davis, CA.*

Background: IgAN is the most common primary glomerulonephritis in the developed world, yet there are no specific biomarkers for this disease except those available on invasively obtained on biopsy tissue. Given the glycation abnormalities which are now known to be a part of this disease, we undertook a pilot study using an unbiased glycomics approach in IgAN patient urine to discover potential urinary biomarkers which, when validated, could be brought to the nephrology clinic.

Methods: After appropriate IRB approval, 11 IgAN patients and 11 age, sex, and race matched non-renal disease controls were recruited from the UCD Nephrology and Urology clinics. Unbiased glycomics analysis was undertaken after ethanol precipitation of 200 ug of urinary protein. Glycopeptide and Ig plus subtypes were analyzed using QQQ-MS and IgAN patients were compared to controls.

Results: IgAN patients had increased total urinary IgA, IgA1 and IgA2 as compared to matched controls. Total IgG as well as all the IgG subclasses were higher in the urine of IgAN patients as compared to controls. In addition, IgAN patients had a higher probability of having higher relative amounts of IgA2 in the urine. Several monofucosylated or fucosylated+sialylated IgG1 and IgG2 glycans were more likely to be found in the urine of IgAN patients than controls. IgAN patients were more likely to have several monofucosylated or fucosylated+sialylated glycans on site 205 and sialylated glycans on site 144 of IgA.

Conclusions: A glycomics analysis of IgAN urine shows promise for specific biomarkers for this disease which have the potential to obviate the need for an invasive biopsy. Further validation, including the analysis of a blinded test set, is currently underway in our laboratories and will likely lead to new and specific biofluid markers for IgAN.

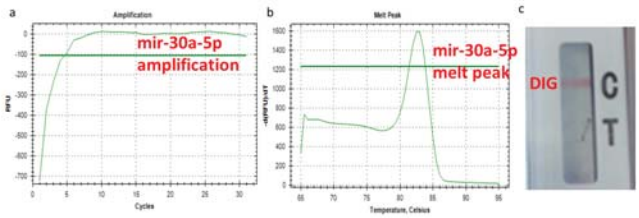
CHAMP: Novel Isothermal Amplification Assay for the Detection of microRNAs in Urine as a Biomarkers for Kidney Diseases Kathrin Gassei, Ishwad Chandra, Andrew J. Bodnar, Jacqueline Ho, Abhay N. Vats. *Pediatrics, Children's Hospital of UPMC, Pittsburgh, PA.*

Background: MicroRNAs are being explored as biomarkers for several diseases including nephrotic syndrome (NS). Lately miRNA-30a-5p has been shown to be upregulated in urine of NS patients. However, miRNA detection assays can be expensive and time consuming. We aimed to develop a fast and reliable assay for microRNAs in urine and report a novel isothermal amplification method for miR-30a-5p detection called cross hybridization amplification (CHAMP).

Methods: We designed 20-25 nt isothermal primers (F-Chip, B-Chip) and a probe specific for miR-30a-5p. The primers had a binding site for mature miR-30a-5p via a 6 nt sequence at the 5'-end, and were labeled with either Biotin or Digoxigenin on the 3'-end. Amplification required the binding of the primers to the probe, Bst DNA polymerase enzyme, and incubation at 65°C for 30-60 min. Assay optimization was performed on fresh urine samples spiked with synthetic miR-30a-5p target.

Results:



Amplification and melting curves for miR-30a were obtained within 1 hr (<20 min in Fig. 1a and b). Amplicons were also detected by UV transillumination and on agarose gels. The incorporation of Biotin and Digoxigenin in primers allowed the detection of amplicons on lateral flow strips also (Fig. 1c). The presence of urine did not inhibit the reaction, and unprocessed urine spiked with synthetic miR-30a could be used in the reactions, without the need for RNA isolation.

Conclusions: CHAMP allowed a rapid, sensitive, highly specific and cost efficient alternative to current miRNA detection methods like qPCR or microarray. CHAMP could detect miR-30a-5p, with sensitivity approaching qPCR, in unprocessed urine without the need for RNA isolation or any other sample prep. Further comparative evaluation of this method will prove its utility in developing diagnostic miRNA assays.

SA-PO484

Urinary Exosomal mRNA Analysis for Non-Invasive Diagnostics of Kidney Diseases and Damages Mizue Kawai,[1] Hideki Mochida,[1] Masashi Nishio,[1] Keisuke Fujitaka,[1] Rikako Yamauchi-Kohno,[1] Taku Murakami,[2] Masato Mitsuhashi.[2] *[1]Mitsubishi Tanabe Pharma Corporation, Saitama, Japan; [2]Hitachi Chemical Research Center, Inc., Irvine, CA.*

Background: Urinary exosomes and microvesicles (EMV) are a potential biomarker source for kidney diseases. EMV are released into the urinary space from all the areas of the nephrons by encapsulating cytoplasmic molecules of the cell of origin. Therefore, we hypothesized that mRNA profile of urinary EMV may reflect status of kidney, and be useful for non-invasive diagnosis of kidney diseases and damages. To address our hypothesis, various kidney disease models were prepared and mRNA profile of urinary EMV was examined.

Methods: Three different rat kidney disease models (drug-induced glomerulus damage (N=8), type 2 diabetes (N=10), and metabolic syndrome (N=10)) and corresponding healthy controls (N=4-5 in each group) were prepared (N=42 in total). Kidney damages were confirmed by urinalysis and kidney pathology scores. Urinary EMV was isolated from 24-hour urine by a differential centrifugation protocol. The mRNA isolation, cDNA synthesis, and quantification from the EMV fraction were conducted using oligo(dT)-immobilized microplate (Hitachi Chemical Research Center, Inc.) and real time polymerase chain reaction (PCR). The raw PCR data were normalized by the values of reference genes, and compared with the disease model types and pathology scores.

Results: Among 27 kidney specific and reference mRNA we tested, glomerulus specific Synpo mRNA was down-regulated in all the disease models compared with corresponding control groups, indicating that Synpo may be used as a marker of general kidney damages. Other kidney-specific mRNA such as Nphs1, Nphs2, Cubn, Lrp2, Aqp2, Spp1, Ppargc1, were also differentially expressed but their expression patterns were different among the disease models and pathology scores. Logistic regression analysis demonstrated that the combinations of 2 to 5 genes were capable of identifying 3 disease models as well as pathology scores with more than 95% sensitivity and specificity.

Conclusions: Urinary EMV mRNA analysis is a promising diagnostic tool for kidney diseases and damages.

SA-PO485

Improving Urine Biomarker Discovery Using Filter Assisted Sample Preparation- U-FASP James A. Hribar, Daniel Wade Wilkey, Walter Blake Kusiak, Michael Merchant. *Medicine, Univ of Louisville, Louisville, KY.*

Background: Urine can be collected using non-invasive techniques, in large quantities, and is a rich source of biomarkers of human diseases. Quantitative LCMS (qLCMS) methods are being developed to enable simultaneous quantification of multiple urine disease biomarkers. Unfortunately qLCMS analysis of urine is problematic. Our hypothesis is the irreproducible chromatographic retention times and loss of sensitivity stem from the effects of peptidoglycans found in urine tryptic digests. To address this hypothesis we adapted the Filter-Aided Sample Preparation method to the analysis of urine samples (U-FASP) with the goal of depleting high molecular weight proteoglycans to ensure a consistent urine matrix injected onto the nanoLC column.

Methods: Spot urine samples (n=3, healthy normal males) were pooled, trypsinized and then processed with or without filtration by the FASP protocol to fractionate HMW tryptic peptides from LMW peptides (<10K). A portion of the HMW tryptic peptides were deglycoslyated using PNGase F and analyzed by nanoflow-UHPLC-MS analysis using a Thermo EZ-nLC-TSQ Quantum to develop MRM methods for urinary biomarkers. UHPLC-MS performance comparing stable isotope labeled peptides (IS) retention time, sensitivity for detection and calibration curve linearity was determined. Confirmation of peptide deglycoslyation experiments was achieved using an EZ-nLC-LTQ-Orbitrap Elite and PD1.4.

Results: Application of U-FASP improved UHPLC performance by (a) extending column lifetime by approx. 50-100-fold, (b) reduced retention time drift by 25-fold, and (c) a gain of detection sensitivity for the IS of 6-10 fold. U-FASP method identified 625 proteins in 100ng urine protein; including 47 proteins only identified with the U-FASP/ PNGaseF protocol.

Conclusions: Our data shows the U-FASP method improves the reproducibility of peptide chromatography, increases the sensitivity for analyte detection by improved peak characteristics, and additionally isolates a unique urinary proteomglyome such as suPAR and SPARCL1, both markers implicated in podocentric diseases such as FSGS.

Development of Assays for Quantification of Angiotensin II Signature Proteins in Human Urine

Ana Konvalinka,[1] Andrei Drabovich,[3] James W. Scholey,[1] Eleftherios P. Diamandis.[2] *[1]Div of Nephrology, Univ of Toronto, Toronto, ON, Canada; [2]Dept of Pathology, Univ of Toronto, Toronto, ON, Canada; [3]Lunenfeld-Tanenbaum Research Inst, Univ of Toronto, Toronto, Canada.*

Background: Angiotensin II (AngII), the main effector of the renin-angiotensin system (RAS), mediates kidney disease progression. However, there are no specific markers of renal AngII activity. We previously identified 83 AngII-regulated proteins in proximal tubular cells *in vitro*, which reflected renal AngII activity in animal models of kidney disease *in vivo*. We now examine whether these proteins measured in urine represent markers of renal AngII activity in patients with CKD.

Methods: Mass spectrometry-based selected reaction monitoring (SRM) assays were developed for 37 peptides corresponding to 10 AngII-regulated proteins previously detected in urine, and 8 AngII-regulated proteins previously quantified in human kidney cells. Methods were developed in normal urine samples from 100ug of total protein. To assess reproducibility, we spiked in bovine serum albumin (BSA) and chicken ovalbumin (OVA) at known concentrations. Urine was concentrated utilizing 3kDa filter or precipitated with acetonitrile. We compared protein digestion with lys-C/trypsin to trypsin alone. After digestion, peptide fractions were analyzed on triple quadrupole mass spectrometer. We then measured peptides in 10 urine samples from patients with CKD.

Results: We repeated the optimization procedure 4 times with 2 biological and 2 technical replicates. Biological replicate analysis demonstrated excellent coefficients of variation <11% for both BSA and OVA peptides. In addition to control peptides, we detected the most peptides (16 of 37) in urine samples precipitated with acetonitrile, and digested with lys-C/trypsin. CKD urine samples contained 14 of 37 AngII-regulated peptides.

Conclusions: We optimized the procedure for SRM monitoring of peptides in urine. Acetonitrile precipitation and lys-C/trypsin digestion appeared most effective at detecting AngII-regulated peptides. We will next quantify these peptides in urine of 40 CKD patients before and after RAS blockade, and determine whether AngII-regulated proteins reflect renal AngII activity.

SA-PO487

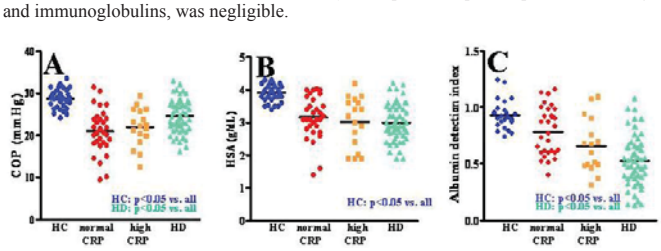
A New Player in the Evaluation of Oncotic Pressure – Oxidative Stress

Regina Michelis,[2] Shifra Sela,[2,3] Teuta Zeitun,[1] Ronit Geron,[1,3] Batya Kristal.[1,3] *[1]Nephrology, Galilee Medical Center, Nahariya; [2]Eliachar Research Laboratory, Galilee MC, Nahariya; [3]Faculty of Medicine, Bar Ilan Univ, Israel.*

Background: Hypoalbuminemia, oxidative stress (OS) and inflammation are common in patients with chronic kidney disease (CKD). Oxidative modifications of serum albumin impair its quantification by clinical assays such as bromocresol-green (BCG), affecting albumin read-out in CKD patients. As maintenance of oncotic pressure/ colloid osmotic pressure (COP) is the main albumin function, the study aim was to examine the impact of albumin oxidation on the oncotic pressure in CKD patients.

Methods: Blood samples were collected from 134 subjects including healthy controls (HC, n=32), CKD patients with (n=17) or without (n=31) systemic inflammation (evaluated by CRP levels) and patients on chronic hemodialysis (HD, n=54).

Results: COP values in HD were significantly higher than in CKD (fig.A), although the albumin levels, measured by BCG, were statistically similar (fig.B). The decreased quantification of modified albumin by BCG was assessed using the "albumin detection index", that represents the ratio between BCG read-out (albumin-specific) to total albumin (assessed by an oxidation-insensitive assay, OD at 280nm). This index was significantly lower in the HD group compared with all other groups (fig.C). In-vitro oxidized albumin and HD-albumin showed significantly higher COP values than HC-albumin and non-modified albumin. The contribution to COP by other prevalent plasma proteins, fibrinogen and immunoglobulins, was negligible.



Conclusions: Altogether, these data demonstrate that actual albumin concentration in plasma of CKD patients, and especially in HD patients, is higher than measured and contributes to the relatively higher oncotic pressure. The physiological and clinical implications of these findings, especially in edema associated states accompanied by OS and inflammation, should be addressed.

SA-PO488

Biological Variation and Analytical Stability of Serum Soluble α-Klotho in Healthy Volunteers

Sven-Jean Tan,[1,2] Edward Robert Smith,[1,3] Timothy Hewitson,[1,2] Stephen G. Holt,[1,2] Nigel David Toussaint.[1,2] *[1]Dept of Nephrology, The Royal Melbourne Hospital, Parkville, Victoria, Australia; [2]Dept of Medicine (RMH), The Univ of Melbourne, Melbourne, Victoria, Australia; [3]Monash Univ, Clayton, Victoria, Australia.*

Background: Recent evidence suggests that the cleaved extracellular domain of the α-klotho receptor, soluble α-klotho (sKl), has effects on phosphate homeostasis, ion channel regulation and anti-fibrotic/anti-oxidant pathways. However, measurements of serum sKl in healthy individuals and in cohorts of patients with renal disease have yielded inconsistent results when related to renal function, other markers of mineral metabolism and patient outcome. Pre-analytical factors such as biological variation and analyte stability may affect the interpretation of sKl results but have yet to be formally assessed.

Methods: For assessment of biological variability,serum samples were collected from 10 healthy volunteers at 3 time-points during the day (morning, midday and afternoon). For assessment of analytical stability, separate aliquots from morning samples were allowed to stand at room temperature for 30, 60 and 120 minutes, prior to centrifugation and processing. All samples were stored at -80°C until batched analysis. sKl was measured using a commercial ELISA kit (Immuno-Biological Laboratories Co., Gunma, Japan) according to the manufacturer's protocol. Differences between the groups were analyzed using non-parametric tests.

Results: Delayed separation of samples yielded median (IQR) sKl levels of 271 (204-359)pg/mL, 271 (155-358)pg/mL and 253 (152-328) g/mL, at 30, 60 and 120 minutes, respectively. A trend towards analyte degradation over time was statistically significant between 30 minutes and 60 minutes (p=0.038) as well as between 30 minutes and 120 minutes (p=0.008). Median (IQR) sKl levels were 271 (204-359) pg/mL, 276 (196-503) pg/mL and 263 (221-461) pg/mL at morning, midday and afternoon time-points respectively, showing no evidence of significant diurnal change.

Conclusions: Prompt processing of serum samples for sKlmeasurement is advisable, although the magnitude of analyte degradation over 2 hours is small. In health, sKl displays minimal variation throughout the day.

SA-PO489

Profiling the Renal Transcriptome in the North Dublin Renal Biobank: Preliminary Results

Caitriona M. McEvoy,[1,2] Eoin P. Brennan,[1] Finbarr S. Tarrant,[1] Barbara T. Murphy,[4] Peter J. Conlon,[3] Finian Martin,[1] Catherine Godson,[1] Denise Mary Sadlier.[1,2] *[1]UCD Conway Inst of Biomolecular and Biomedical Research, UCD, Dublin, Ireland; [2]Renal Medicine, MMUH, Dublin, Ireland; [3]Renal Medicine, Beaumont Hospital and RCSI, Dublin, Ireland; [4]Renal Transplantation Medicine, Mt Sinai School of Medicine, NY.*

Background: Chronic Kidney Disease (CKD) is a progressive disorder with poor outcomes. Progressive tubulointerstital fibrosis (TIF) represents the final common pathway of CKD and is a major predictor of disease progression. Elucidation of the initiation and progression of TIF will aid identification of novel targets for therapeutic intervention in CKD.

Methods: The North Dublin Renal Biobank (NDRBB) recruited patients undergoing a clinically indicated renal biopsy. Blood, urine, clinical and demographic data were collected. A dedicated sample of renal biopsy tissue was retained, and the ultimate histological diagnosis recorded. RNA was extracted from renal biopsies of individuals with CKD of diverse aetiologies and TIF severity. cDNA libraries were generated. Ultimately,44 CKD biopsies, together with 3 controls,were selected for transcriptome profiling by RNAseq analysis (IlluminaTruSeq). The sequencing reads were aligned to the Genome (TopHat) and gene expression quantified using HTseq (Ensembl70).

Results: RNAseq analysis revealed ~98% reads aligned to the reference genome GrCh37.75% genome aligned reads mapped uniquely and unambiguously to exons. Gene expression clustering analysis for the 200 most variable expressed genes shows two distinct clusters. Analysis is ongoing to determine if correlates with clinical parameters exist. Unbiased clustering of mitochondrial matrix gene expression also indicated two clusters,one of which was clearly enriched for high fibrosis cases ($p < 0.01$). Correlation analysis confirmed that the degree of fibrosis negatively correlated with the expression of transcripts associated with the human mitochondrial matrix.

Conclusions: This expression dataset shows intriguing preliminary results. Work is ongoing (GO and GSEA analysis) to determine if the observed variability in gene expression can be ascribed to sub-categories of mitochondrial function.

SA-PO490

Effect of Gender when Estimating Glomerular Filtration Rate with Beta-Trace Protein in Children Samantha Witzel,[1] Shih-Han S. Huang,[1,2] Branko Braam,[4] Guido Filler.[1,2,3] *[1]Dept of Pediatrics, Div of Pediatric Nephrology, Children's Hospital, London Health Sciences Centre, Schulich School of Medicine and Dentistry, Univ of Western Ontario, London, ON, Canada; [2]Dept of Medicine, Div of Nephrology, London Health Sciences Centre, Schulich School of Medicine and Dentistry, Univ of Western Ontario, London, ON, Canada; [3]Dept of Pathology and Laboratory Medicine, London Health Sciences Centre, Schulich School of Medicine and Dentistry, Univ of Western Ontario, London, ON, Canada; [4]Dept of Medicine, Div of Nephroloy, Univ of Alberta, Edmonton, AB, Canada.*

Background: Gender may affect the performance of small molecular weight proteins as markers of glomerular filtration rate (GFR) because of differences in fat mass between the two sexes. We hypothesized that the diagnostic performance of beta-trace protein (BTP), a marker of GFR, would be significantly better in boys than in girls.

Methods: GFR, height, serum creatinine, and BTP were measured in 755 children and adolescents undergoing ^{99}technetium diethylenetriamine penta-acetic acid (^{99}Tc DTPA) renal scans. Boys and girls were separated into formula-generation cohorts (284 boys and 220 girls) and formula-validation cohorts (140 boys and 111 girls). GFR-estimating formulae were derived using stepwise linear regression analysis of log-transformed data. Bland-Altman analysis was used for testing agreement between ^{99}Tc DTPA GFR and calculated GFR.

Results: In the stepwise regression analysis, BTP (R^2 of 0.734 for boys and 0.651 for girls) was more important than creatinine (which increased R^2 to 0.814 for boys and 0.752 for girls) and height (which increased R^2 to 0.876 for boys and 0.800 for girls). GFR can be calculated using the following formulae: GFR_{boys}=10^(2.824-0.461*log(BTP[mg/L])-0.679*log(creat[umol/L])+0.00259*height[cm]) GFR_{girls}=10^(2.772-0.433*log(BTP[mg/L])-0.661*log(creat[umol/L])+0.00256*height[cm]) Bland-Altman analysis showed better performance in boys. The new formulae performed significantly better than the previous Benlamri and White formulae.

Conclusions: We present improved and gender-specific formulae for the estimation of GFR in children based on BTP, serum creatinine, and height.

SA-PO491

Urine-Derived Human Renal Progenitors for Modeling of Genetic Renal Diseases Elena Lazzeri, Elisa Ronconi, Maria Lucia Angelotti, Anna Julie Peired, Francesca Becherucci, Paola Romagnani. *Excellence Centre DENOTHE, Univ of Florence, Florence, Italy.*

Background: Up to 20 % of adults progressing to end stage renal disease suffer from genetic kidney diseases. The current diagnostic and therapeutic management of these diseases is in most cases still insufficient. The identification of suitable disease models, that recapitulate human kidney disorders in a personalized manner, could improve diagnosis and treatment of genetic kidney disorders. Renal progenitor cells (RPC) obtained from the affected patient may represent an ideal alternative for personalized disease modeling. Since loss of renal cells in urine naturally occurs in patients, urine may represent a potential RPC source for in vitro studies of disease.

Methods: Urine samples were centrifuged and cells were plated. Cultures were analyzed by FACS and TaqMan low density array and differentiated in tubular and in podocyte after exposure to specific media. Electronic microscopy, RT-PCR, confocal microscopy and western blot were performed.

Results: In this study we describe a cheap and reliable method to amplify u-RPC from patients with renal disorders, that exhibit identical phenotype and functional properties to those purified from kidney tissue, including the capacity to differentiate into tubular cells as well as podocytes. To evaluate the possibility to use these cells for modeling of genetic kidney disorders, u-RPC were obtained from patients with genetic forms of steroid-resistant nephrotic syndrome, carrying putative pathogenic mutations in genes encoding for podocyte cytoskeleton proteins, as well as from patients without genetic alterations. U-RPC obtained from patients carrying pathogenic mutations generated podocytes that exhibited altered synthesis of mutated proteins, abnormal cytoskeleton structure and functional abnormalities. By contrast, podocytes obtained from u-RPC of patients without genetic mutations showed normal phenotype, structure and function.

Conclusions: This study demonstrate that u-RPC represent an innovative personalized tool for modeling of genetic kidney disorders providing a rapid test of putative pathogenic mutations and an essential support for the clinical diagnosis.

SA-PO492

Circulating miR-148b and let-7b in Serum as Potential Markers for Detecting Primary IgA Nephropathy: A Multicenter Study Grazia Serino,[1,2] Francesco Pesce,[2,3] Fabio Sallustio,[1] Giuseppe De Palma,[1] Sharon N. Cox,[1,2] Kar Neng Lai,[4] Joseph C.K. Leung,[4] Aikaterini A. Papagianni,[5] Maria Stangou,[5] Dimitrios S. Goumenos,[6] Miltiadis Gerolymos,[6] Kazuo Takahashi,[7] Yukio Yuzawa,[7] Shoichi Maruyama,[8] Enyu Imai,[8] Francesco Paolo Schena.[1,2] *[1]C.A.R.S.O. Consortium, Univ of Bari, Italy; [2]Dept of Emergency and Organ Transplantation, Univ of Bari, Italy; [3]Imperial College, United Kingdom; [4]Dept of Medicine, Queen Mary Hospital, Hong Kong; [5]Dept of Nephrology, Univ of Thessaloniki, Greece; [6]Dept of Nephrology, Univ Hospital Patras, Greece; [7]Dept of Nephrology, Fujita Health Univ School of Medicine, Japan; [8]Dept of Nephrology, Nagoya Univ Graduate School of Medicine, Japan.*

Background: IgA Nephropathy (IgAN) is a worldwide disease characterized by the presence of galactose-deficient IgA1 deposits in the glomeruli. A kidney biopsy for the diagnosis is required. Aim of our study was to develop and validate a new biomarker for IgAN.

Methods: We measured two miRNAs (let-7b and miR-148b), previously identified by our group as regulators of the *O*–glycosylation process of IgA1, by Real–Time PCR in serum samples of biopsy–proven IgAN patients and healthy blood donors (HBD) recruited from the international multicenter study. Logistic regression was performed to develop a predictive model based on these two miRNAs. Diagnostic accuracy of the combined biomarker was assessed by the area under the receiver-operating-characteristic curve (AUC).

Results: Training study. The combined miRNAs biomarker was able to discriminate between 88 Caucasian IgAN patients and 102 HBD from Italy and Greece (AUC, 0.849; 95% confidence interval [CI], 0.794-0.905; p <0.0001). Validation study. The biomarker was validated in another cohort of 88 Asian IgAN patients and 97 HBD from Hong–Kong and Japan. The AUC was 0.852; 95% CI, 0.793-0.910. (p<0.0001) Test study. The diagnostic biomarker discriminated each cohort of IgAN patients from 58 Caucasian and Asian individuals affected by other primary glomerulonephritides, supporting its specificity.

Conclusions: A combined miRNA biomarker, based on let-7b and miR-148b serum levels, appears to be a novel biomarker to predict the probability of IgAN and support the clinicians in the diagnosis.

Identification of Tissue Biomarkers Differentiating Primary IgA Nephropathy from Staphylococcus Infection Related Glomerulonephritis Anjali A. Satoskar,[1] Samir Parikh,[1] Paul L. Kimmel,[2] John W. Kusek,[2] Jianying Zhang,[1] Lianbo Yu,[1] Tibor Nadasdy,[1] Michael Merchant,[3] Jon B. Klein,[3] Brad H. Rovin.[1] *[1]Ohio State Univ Wexner Medical Center, Columbus, OH; [2]NIDDK, Bethesda, MD; [3]Univ of Louisville, Louisville, KY.*

Background: Staphylococcus infection-associated glomerulonephritis (SAAGN) can manifest as proliferative GN with IgA and C3-containing immune complexes, thus mimicking idiopathic IgA Nephropathy (IgAN). We addressed the hypothesis that SAAGN and IgAN could be differentiated by characterizing the glomerular and interstitial proteomes of their kidney biopsies.

Methods: Laser capture micro-dissection was used to isolate the glomerular and tubulointerstitial (TI) compartments from SAAGN (n=4), IgAN (n=4), and normal renal tissue (n=5). Proteins were extracted, digested, and analyzed by tandem mass spectrometry. Spectral counts were modeled as negative binomial distribution and compared using Wald test.

Results: 798 proteins were identified in the glomerular compartment and 1177 proteins in the TI compartment. Normal, IgAN, and SAAGN clustered separately. Glomerular proteomes of SAAGN and IgAN showed many similarities. Coagulation and complement systems were the top canonical pathways activated in both SAAGN and IgAN relative to normal. Gluconeogenesis and glycolytic pathways were down-regulated in both. TI proteomes of IgAN and normals were similar, but SAAGN differed considerably. SAAGN showed upregulation of TGFβ, RhoGDI, inflammatory pathways (TNF, IL6, and NF-κB) and lipopolysaccharide signaling. Mitochondrial functions such as fatty acid oxidation, oxidative ethanol degradation, putrescine degradation, and lipid metabolism were downregulated.

Conclusions: The most striking feature of this proteomic analysis was the perturbation of tubular metabolism in SAAGN relative to IgAN. These data suggest that proteomic and metabolomic analysis of TI may be useful to identify specific biomarkers of SAAGN and IgAN.

SA-PO494

Pro-Inflammatory CD11c+CD68+ Mononuclear Phagocytes Promote Glomerular Injury in Lupus Nephritis Yohei Ikezumi,[1] Utako Kaneko,[1] Takeshi Yamada,[1] Hiroya Hasegawa,[1] David J. Nikolic-Paterson,[2] Akihiko Saitoh.[1] *[1]Dept of Pediatrics, Niigata Univ Medical and Dental Hospital, Niigata, Japan; [2]Monash Univ Dept of Medicine, Monash Medical Centre, Clayton, Victoria, Australia.*

Background: Recent studies have shown a pro-inflammatory phenotype of mononuclear phagocytic cells (MPC) in the mouse kidney which co-express high levels of macrophage (CD11b) and dendritic cell (CD11c) markers. In this study, we examined the presence and potential role of CD68+CD11c+ MPC in biopsies of childhood lupus nephritis (LN).

Methods: Biopsies taken from 16 cases of childhood LN (12.8±1.8 years, M:F=4:12) were examined for histologic changes and by immunofluorescence staining for pan macrophages (MQ) (CD68+ cells), CD11c+ cells, M2-type MQ (CD163+ cells), CD3+ T lymphocytes, and glomerular expression of TNF-α. Nine biopsies from children with thin basement membrane disease (TBMD) were used as control.

Results: Significant accumulation of CD68+ MQ and CD3+ T lymphocytes was evident in LN. Most glomerular CD68+ MQ co-expressed CD11c (75%) but few co-expressed CD163. By contrast, most interstitial CD68+ MQ co-expressed CD163 (91%) but few expressed CD11c. Glomerular CD11c+ cells correlated with endocapillary proliferation ($p=0.002$), extracapillary change ($p=0.013$), the degree of hematuria ($p<0.01$) and proteinuria ($p<0.001$). Increased CD11c+ cells were seen in glomeruli with severe damage (ISN/RPS grade IV; n=5) compared to mild damage (grades II and III) (9.4 versus 5.4 CD11c+ cells/gcs, $p<0.01$). In addition, some glomerular CD11c+ cells expressed TNF-α. In contrast, glomerular CD163+ MQ failed to correlate with glomerular damage. However, interstitial CD163+ MQ correlated with interstitial fibrosis ($p<0.001$).

Conclusions: We have identified a pro-inflammatory population of CD68+CD11c+ MPC in childhood LN which contrasts with the pro-fibrotic CD163+ MQ population. CD68+CD11c+ MPC appear to be involved in the development of acute lesions (endocapillary proliferation and cellular crescents), which are important factors in evaluating disease severity in LN. Thus, CD68+CD11c+ MPC may represent an important therapeutic target in LN.

CNV Analysis of the CFHR Region by MLPA in aHUS Patients Michael Jones, Nicole Meyer, Yuzhou Zhang, Dingwu Shao, Erika Takanami, Carla M. Nester, Richard J. Smith. *MORL, Univ of Iowa, Iowa City, IA.*

Background: Atypical hemolytic uremic syndrome (aHUS) is an ultra-rare renal disease caused by uncontrolled activation of the alternative complement pathway at the cell surface level. Mutations in several complement genes have been implicated in its pathogenesis. Copy number variation (CNV) and complex genomic rearrangements of the complement factor H related (CFHR) region have also been causally linked to aHUS. Duplications, deletions and novel hybrid gene formation in the CFHR region reflect the frequent occurrence of non-allelic homologous recombination (NAHR). In this study, we sought to characterize the frequency and type of CFHR rearrangements.

Methods: Multiplex ligation-dependent probe amplification (MLPA) was used to characterize the genomic architecture of the CFHR region in 355 patients diagnosed with aHUS and 315 controls. Forty-three probes were used to cover this genomic region. Additional probes were used to delineate complex rearrangements.

Results: The most common finding was a common CNV, the deletion of *CFHR3-CFHR1*, del(*CFHR3-CFHR1*). Present in homozygosity in ~3.2% of a control European-American population, we found homozygosity for del*(CFHR3-CFHR1*) in 8.7% of aHUS patients. Of patients found to be homozygous del(*CFHR3-CFHR1*), 25.8% were positive for CFH autoantibody and another 25.8% were found to have variants in other complement genes. 28.7% of aHUS patients were heterozygous for del(*CFHR3-CFHR1*). 1.9% of aHUS patients had complex rearrangements of the CFHR region, which included rearrangements between homologous blocks containing CFH and CFHR1 as well as those containing CFHR3 and CFHR4. These rearrangements result in putative fusion proteins composed of SCRs from the two corresponding genes. Complex rearrangements were occasionally associated with familial aHUS but also represented *de novo* NAHR events.

Conclusions: The genetic evaluation of aHUS patients must include defining the genomic architecture of the CFHR region. The most frequent finding will be homozygous deletion of *CFHR3-CFHR1*. Complex rearrangements resulting in the formation of novel fusion genes are also quite common. Most of these fusion events appear to involve a portion of *CFHR1*.

The Clinical Application of aPLA2R Antibodies Measured By Commercial ELISA Kit in Korean Patients with Idiopathic Membranous Nephropathy (iMN) Yang Gyun Kim,[1] Jiyun Park,[1] Ju-Young Moon,[1] Kyung-Hwan Jeong,[1] Tae Won Lee,[1] Chun-Gyoo Ihm,[1] Yon Su Kim,[2] Sang Ho Lee.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Kyung Hee Univ College of Medicine, Seoul, Korea; [2]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea.*

Background: aPLA2R antibody has not been measured widely in clinical field because immunofluorescence test as an only commercially available assay could be inaccurate and western blot(WB) is too complex to be applied. Though a few studies presented aPLA2R antibodies using home-made ELISA could be useful in western population, it has never been tried against Asian patients. Therefore, we investigated the suitability of commercial aPLA2R antibody ELISA test in Korean patients with iMN through comparison with the results of WB test.

Methods: We measured aPLA2R antibodies with ELISA kit(Euroimmun, Lübeck) in 124 serum samples from patients with iMN(n=93), secondary MN(n=6), IgAN(n=5), MCD(n=8) and healthy controls(n=12) in three hospitals using serums gathering at time of renal biopsy. Serums of several patients(n=43) with iMN were also analyzed with WB method. ELISA titers of aPLA2R antibody from 8 patients were followed after immunosuppressant therapies.

Results: aPLA2R antibodies were positive in 44.1% and 69.8% of patients with iMN using ELISA and WB test, respectively, in contrast the patients with other diseases and healthy controls had negative results. The concordance rate between two tests was 69.8% and the results from both tests showed positive correlation. aPLA2R antibody-positive patients presented severe disease activity and low remission rate. The titer of aPLA2R antibody was positively correlated with proteinuria and negatively associated with eGFR and serum albumin. The patients with high titer(>80U/mL) of ELISA revealed significantly low remission rate(30% versus 71%). Following reactivity of aPLA2R antibody after treatment was reversely paralleled with the existence of remission.

Conclusions: Therefore, the assessment of aPLA2R antibody with commercial EILSA kit is thought an easy and reliable method for not only diagnosis but also guidance of therapeutic plans for Korean patients with iMN.

SA-PO497

Idiopathic Membraonous Glomerulonephritis versus Class V Lupus Nephritis: Clinical-Pathologic Features and Outcomes Alcino Pires Gama, Simone C. Lo, Cristiane B. Dias, Luis Yu, Lectícia Jorge, Viktoria Woronik. *Nephrology, Univ of Sao Paulo, Sao Paulo, SP, Brazil.*

Background: Overall renal prognosis in both Idiopathic Membranous Glomerulonephritis (IMGN) and Class V Lupus Nephritis (LNV) is worse than general population, but there is no data comparing prognosis between them. The aim of this study was to compare clinical-pathologic profile and outcomes between the two entities.

Methods: A retrospective analysis was carried out on all patients with biopsy-proven IMGN (n=195) or LNV (n=164) between 1999-2011. 86 patients with IMGN and 83 patients with LNV met inclusion criteria (age>18y and follow-up longer than 3y). The clinical endpoint was rate of loss of glomerular filtration rate(eGFR) per year(ΔeGFR/y = difference between final and initial eGFR adjusted by follow-up time).

Results:

	LNV(n=83)	IMGN(n=86)	p
Follow-up(y)	8.0±2.8	6.9±3.5	ns
Age(y)	33±10	42±13	<0.0001
%male	10	60	<0.0001
eGFR(ml/min)	87.7±41	85±44	0.67
Hb(mg/dl)	11.8±1.8	12.8±1.9	0.0001
Ptn(g/day)	4.4±4.2	7.9±7.8	0.0005
Ptn_1y(g/day)	1.4±2.4	3.3±3.8	0.0003
% Hematuria	38	24	0.06
Progression rate(ml/min/y)	4.2±4.5	5.6±5.6	0.2
Final eGFR(ml/min)	81±38	71±39	0.08
Pathologic features			
%Crescents	10	5	0.13
% IgG deposit predominance on IF	15	91	<0.0001*
% Mesangial Ig deposits on IF	57	17	<0.0001**
% Interstitial fibrosis (>10%)	26	24	0.7

Table 1. Clinical and pathological features on LNV and IMGN groups. *OR 56 CI 21-149. **OR 6.6 CI 3.2-13.7

There was no statistically difference between renal prognoses in both diseases, although CKD progression tends to occur faster in IMGN group (4.2 versus 5.6, $p=0.2$).

Conclusions: The rate of loss of renal function did not differ between the groups, but both are higher than general population (about 1ml/min/y). The persistent proteinuria, a known prognosis factor for both diseases, is more evident in IMGN. On the other hand, LNV occurs in the scenario of systemic inflammation (lower levels of hemoglobin). These factors may confer for both diseases worse renal prognosis than general population (even though the rate of progression to chronic kidney disease did not differ between the two groups).

SA-PO498

Using Urine Adiponectin as a Biomarker of Inflammatory Kidney Lesions in Lupus Nephritis (LN) Xiaolan Zhang,[1] Anthony Alvarado,[1] Hermine Brunner,[2] Brad H. Rovin.[1] *[1]Nephrology, Ohio State Univ, Columbus, OH; [2]Rheumatology, Univ of Cincinnati, Cincinnati, OH.*

Background: Adiponectin (AD) is an adipokine that regulates metabolism, but also has pro- and anti-inflammatory properties. We previously showed that urine AD levels increase significantly at LN flare. The relationship of AD to renal histology in LN has never been studied, and forms the basis for this report.

Methods: Urine was collected at the time of kidney biopsy from 78 LN patients. Urine high molecular weight (HMW) AD was measured by ELISA, normalized to urine creatinine, log-transformed, and tested as a biomarker of specific histologic lesions. A threshold AD level for each lesion was identified by visual inspection of the cohort data. Based on the threshold level, sensitivity (sens), specificity (spec) and likelihood ratios (LR) for each lesion were calculated. Post-test probabilities of having a specific lesion were determined using Bayes Theorem plus the probability of the lesion in this biopsy cohort.

Results: The characteristics of AD as a diagnostic test for cellular crescents in >25% of glomeruli, the presence or absence of glomerular necrosis, and interstitial inflammation or fibrosis in >25% of the cortex are shown in the Table. AD did not discriminate between levels of global glomerulosclerosis. There was no association between AD and serum creatinine, proteinuria, or complement levels at biopsy.

	>25% Cellular Crescents	Presence of Glomerular Necrosis	>25% Interstitial Inflammation	>25% Interstitial Inflammation
Threshold AD (ng/mg Cr)	>20	>7.4	>7.4	>7.4
Sens	1	0.96	0.89	0.93
Spec	0.5	0.34	0.27	0.19
Positive LR	2	1.45	1.21	1.14
Probability of Lesion if AD > Threshold (%)	20	41	27	36
Negative LR	0	0.12	0.42	0.40
Probability of Lesion if AD < Threshold (%)	0	5	11	17

Conclusions: A urine HMW-AD level < 20 ng/mg Cr excludes the presence of more than 25% cellular crescents in LN biopsies. Similarly, a urine AD level < 7.4 ng/mg Cr excludes the presence of glomerular necrosis and moderate-severe interstitial inflammation and fibrosis. It is conceivable that urine AD levels could be followed post-biopsy in LN patients to non-invasively assess the resolution of active inflammatory lesions.

Serum Anti-PLA2R Antibodies May Be Initially Absent in Idiopathic Membranous Nephropathy: Seroconversion after Prolonged Follow-Up Anne-Els van de Logt, Julia M. Hofstra, Jack F. Wetzels. *Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Antibodies against PLA2R (aPLA2R) are present in 70% of patients with idiopathic membranous nephropathy (iMN). In seronegative patients, iMN may be caused by other antibodies. However, in some seronegative patients PLA2R was detected in the glomerular immune deposits, suggesting that also in these patients iMN was related to PLA2R (*NEJM 2011, Ronco and Debiec).* It was suggested that the discrepancy occurred in patients who had remitting disease. Alternatively, the kidney could function as a "sink", antibodies becoming detectable only after the buffer capacity of the kidney is exceeded. We present data to support the latter hypothesis. **Case-description:** A 47-year-old patient was diagnosed with idiopathic membranous nephropathy in 2004. Treatment with prednisone and cyclophosphamide resulted in a complete remission. In June 2013 he developed a relapse. Initially aPLA2R was not detected in the immunofluorescence test (IIFT), however they became clearly positive during follow-up.

Date	IIFT	creatinine (mg/dl)	albumin (g/dl)	Protein creatinine ratio (g/g)
05-06-2013	inconclusive	0.92	2.4	2.40
25-09-2013	negative	0.96	2.4	5.82
09-10-2013	inconclusive	0.90	2.3	4.41
20-11-2013	positive	1.00	2.1	4.84
19-02-2014	positive	0.95	1.8	4.04
19-03-2014	positive	0.94	2.2	7.28

Methods: We next evaluated if seroconversion could occur more often. We identified 21 patients with a negative IIFT at first presentation or relapse and a serum sample stored during follow-up.

Results: Three patients with an initial negative IIFT became seropositive during follow-up. Mean proteinuria at presentation was 6.8 g/g creatinine and at follow-up 6.0 g/g creatinine and the interval between the baseline sample and the follow-up sample was 4.3 months.

Conclusions: Our data indicate that " seroconversion" can occur in patients with iMN and initially absent aPLA2R in serum. Our findings support the "kidney functions as a sink" hypothesis. We suggest that in aPLA2R negative patients PLA2R related disease must be excluded by either analysis of PLA2R in kidney biopsy or renewed evaluation of serum after 6 months follow-up.

Incidence of Thromboembolism and Use of Antithrombotic Primary Prophylaxis in Nephrotic Syndrome Patients Leslie N. Smith,[1] Heather Snyder,[1,2] Joanna Hudson,[1,2] Jennifer Twilla.[1,2] *[1]Pharmacy, Methodist Univ Hospital, Memphis, TN; [2]Clinical Pharmacy, Univ of Tennessee, Memphis, TN.*

Background: Compared to the general population, patients with nephrotic syndrome (NS) have a higher incidence of venous thromboembolism (VTE) ranging from 3% to 19%. Established risk factors include proteinuria, hypoalbuminemia, disease etiology, and time from diagnosis. However, there are no randomized trials to guide optimal management of hypercoagulability. The purpose of this study was to evaluate the incidence of VTE relative to bleeding events in NS patients receiving prophylactic antithrombotic therapy.

Methods: A retrospective chart review of patients diagnosed with NS between 10/2007 and 12/2012 was conducted. Patient admissions were classified as those with new-onset VTE (VTE group) or without VTE (no VTE group). Other pertinent data was collected including risk factors for VTE and bleeding events.

Results: A total of 532 patient admissions were reviewed with 500 that met inclusion. There were 30 admissions in the VTE group with 34 VTE events (6.8%) overall. Of these, 16 events (47%) occurred within 6 months of diagnosis. Compared to the no VTE group, patients in the VTE group had a lower serum albumin (2.2 +/- 0.7 versus 2.5 +/- 0.8 g/dl; p=0.03), higher prevalence of membranous nephropathy (23.3% versus 6.8%; p=0.005), and lower use of anticoagulant (0% versus 1%; p=NS) and antiplatelet (38% versus 43%; p=NS) primary prophylaxis. In the patient subset without prior VTE (n=449), statin use was significantly higher compared to the VTE group (45% versus 23%; p=0.04). Bleeding was reported in 12 of 500 patients (2.4%) with two patients on warfarin and four patients on antiplatelet therapy at the time of event.

Conclusions: In NS patients with VTE risk factors and a low risk of bleeding, clinicians should consider use of prophylactic anticoagulant or antiplatelet therapy. For primary prophylaxis, use of statins may be beneficial for VTE prevention. However, randomized clinical trials are needed to make a strong recommendation for statin therapy in all NS patients.

SA-PO501

The Clinical Features of PLA_2R-Related Idiopathic Membranous Nephropathy Ningxin Xu, Qionghong Xie, Yan Li, Chuanming Hao. *Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.*

Background: Idiopathic membranous nephropathy (iMN) could be categorized into PLA_2R-associated and non-PLA_2R-associated iMN, based on the presumption that different insulting auto-immune mechanisms are involved in iMN. This study aimed to examine whether the non-PLA_2R-associated iMN has any difference in clinical features compared with PLA_2R-associated iMN.

Methods: A total of 231 adult patients diagnosed as iMN during the past 5 years were recruited to this retrospective study. Renal PLA_2R was detected by immunofluorescence using a commercial available anti-PLA_2R antibody(produced in rabbit, Sigma). Among these patients, 186 (80.5%) with complete baseline clinical data were used for further study. For those patients with follow-up duration longer than 90 days, the relationship between renal PLA_2R and sensitivity to immunosuppresants were analyzed.

Results: Renal PLA_2R positive rate in the iMN patients was 81.8% (189/231).Among the 186 patients with complete baseline data, the baseline serum creatinine levels, serum albumin and 24 hours urine protein excretion were not significantly different between PLA_2R-associated (n=145) and non-PLA_2R-associated iMN patients (n=41). However, about 1/3 of the non-PLA_2R associated iMN had abnormal serological tests, significantly more common than PLA_2R-associated iMN (31.7% versus 8.3%, p=0.000). PLA_2R-associated iMN patients had higher levels of uric acid (p=0.001) and more severe hyperlipidemia (p<0.05 for total cholesterol and triglycerides), while the non-PLA_2R-associated iMN had lower C4 levels (p=0.004) and higher conjugated bilirubin (p=0.020) in serum when compared. The non-PLA_2R-associated iMN patients also showed a better response to immunosupressants (CR 37.5%; PR 12.5%) compared with PLA_2R-associated iMN (CR 2.9%; PR 48.6%, p=0.004) at 3rd month.

Conclusions: There were no significant differences in serum creatine, albumin and 24 hours urine protein excretion between PLA_2R-associated and non-PLA_2R-associated iMN, while the non-PLA_2R-associated iMN patients showed more abnormal serological tests. The non-PLA_2R-related iMN seemed to respond more quick to the immunosuppressive therapy compared with PLA_2R-associated iMN.

SA-PO502

Low Prevalence of Anti-PLA2R Antibody in Patients with Idiopathic Membranous Nephropathy in Japan Shin'ichi Akiyama,[1] Enyu Imai,[2] Seiichi Matsuo,[1] Shoichi Maruyama.[1] *[1]Nephrology, Nagoya Univ Graduate School of Medicine, Japan; [2]Nakayamadera Imai Clinic, Japan.*

Background: We previously first reported that a prevalence of circulating anti-phospholipase A2 receptor antibody (aPLA2R) in Japanese patients with idiopathic membranous nephropathy (iMN), which was measured by standard Western blot (WB) techniques, was 49.5% (n=109). Here, we validated the low prevalence in Japanese patients with iMN by enhanced WB techniques and commercial kit.

Methods: We measured autoantibodies in plasma samples obtained at the time of biopsy from a total of 115 patients with iMN who had not yet received immunosuppressive treatment. Circulating aPLA2R was analyzed by three different techniques: WB with human glomerular extract (HGE), WB with recombinant phospholipase A2 receptor (rPLA2R), commercial indirect immunofluorescence cell-based assay (IIF-CBA) from Euroimmun AG. The WB performed with diluted plasma at x1, x0.1 and x0.04. The CBA were performed according to the manufacture's instructions.

Results: The prevalence of aPLA2R in patients with iMN which was measured by WB with HGE, WB with rPLA2R and IIF-CBA were 54% (62/115), 54% (62/115) and 50% (57/115), respectively. When the analysis was limited to nephrotic patients (Urinary protein ≥3.5g/day), the prevalence were 58% (43/74), 58% (43/74) and 54% (40/74), respectively.

Conclusions: The prevalence of aPLA2R in Japanese patients with iMN varied 50% (IIF-CBA, All patients) to 58% (WB, Nephrotic patients). Our study demonstrated once again that the prevalence of iMN caused by aPLA2R is lower in Japanese iMN compared with those in Caucasian and Chinese.

SA-PO503

Association of PLA2R and HLA-DQA1 Genetic Variants with Serum Anti PLA2R Antibody and Clinical Outcome in Indian Patients with Idiopathic Membranous Nephropathy

Vinod Sharma, Raja Ramachandran, Ashwani Kumar, Ashok Kumar Yadav, Harbir Singh Kohli, Vivekanand Jha, Krishan L. Gupta. *PGIMER, Chandigarh, India.*

Background: M-type phospholipase A2 receptor (PLA2R), is the first autoantigen identified in adult patients with idiopathic membranous nephropathy (IMN). Risk alleles in PLA2R1 and HLA-DQA1 genes are associated with IMN. Whether these alleles are associated with the anti- PLA2R antibody serum level is not clear. To find the association of 5 SNPs in the PLA2R1 (1 in 5' UTR, 3-coding and 1-noncoding region) and 1 in the HLA-DQA1 gene with development of IMGN and their association with anti-PLA2R antibody levels and clinical outcome.

Methods: A total of 101 adult patients IMGN patients requiring treatment were enrolled in the study. PLA2R antibody (ELISA, EUROIMMUN) was estimated in serum samples collected before treatment, and after 6 and 12 months of therapy. Genotype analysis was done on DNA isolated from PBMCs of recruited patients and 95 healthy controls TaqMan SNP genotyping assays (ABI, Foster city, CA) for 6 SNPs (PLA2R: rs3749119, rs3749117, rs4664308 and rs 3828323; HLA-DQA1: rs2187668). Patients were followed up monthly for a period of 12 months to gauge response.

Results: Out of 101 nephrotic patients, 65 (64%) showed elevated serum anti-PLA2R antibody levels. The distribution of PLA2R rs3749119, rs3749117, rs4664308 and HLA-DQA1 SNPs was significantly associated with IMN. rs3749119 (TT+CT genotype (p=0.04) and T-allele), rs2187668 (AA+AG genotype (p=0.0025) and A-allele), rs4664308 (AA genotype (p=0.048) and A-allele) were associated with elevated PLA2R antibody levels. Of the 62 patients who have completed 12 months of follow-up, 71% achieved remission. Reduction in serum PLA2R (86%) correlated significantly with remission rate (p=0.0003). There were no significant association of the six genetic variants with clinical response to immunosuppressive therapy.

Conclusions: Presence of certain PLA2R1 and HLA-DQA1 genotypes confers risk for IMN. rs3749119, rs2187668 and rs4664308 correlate with elevated PLA2R antibody levels. However, these genotypes do not contribute in predicting response to immunosuppressive in Indian IMGN patients.

Urine Podocyte mRNA Excretion Is Predictive Biomarker of Therapeutic Efficacy in Patients with Idiopathic Membranous Nephropathy

Akihiro Fukuda,[1] Yuji Sato,[1] Takashi Iwakiri,[1] Kazuo Kitamura,[1] Shouichi Fujimoto.[2] *[1]First Dept of Internal Medicine, Univ of Miyazaki, Miyazaki, Japan; [2]Dept of Hemovascular Medicine and Artificial Organs, Univ of Miyazaki, Miyazaki, Japan.*

Background: Podocyte depletion in various glomerular diseases is considered as a major mechanism driving glomerulosclerosis. Podocyte cell lineage specific mRNAs can be recovered from urine pellets, and urine podocyte (u-pod) mRNA excretion could serve as useful glomerular disease biomarker in model system (Fukuda A et al. KI 2012). The purpose of this study was to test whether u-pod mRNA excretion is a useful biomarker in nephrotic patients with idiopathic membranous nephropathy (IMN).

Methods: From January 2009 to December 2013, early morning voided urine samples were obtained from 28 healthy volunteer and 17 patients with histology-proven IMN. We examined u-pod mRNA excretion and urine protein/creatinine ratio (u-PCR) at pre-treatment (renal biopsy), and evaluated at 6 months and a median follow-up of 38 months after treatment. We also evaluated the histological findings of podocyte depletion which was estimated by TLE4 immunoperoxidase staining of podocyte density counting methods (Venkatareddy M et al, JASN 2014).

Results: Compared with controls, u-pod mRNA excretion was significantly increased in patients with IMN at renal biopsy (P<0.01). U-pod mRNA excretion did not correlate with histological findings of podocyte depletion in patients with IMN. U-pod mRNA excretion before treatment in non-remission (NR) groups (u-PCR≥0.3) (n=11) tended to be increased compared with complete remission (CR) group (u-PCR<0.3) (n=6) at 6 months after treatment (p=0.49). This urinary biomarker before treatment in NR group (n=9) was significantly increased compared with CR group (n=8) at final follow-up (median, 38 months) (p=0.03). However, the histological findings of podocyte depletion before treatment were not different between these two groups.

Conclusions: These results suggest that u-pod mRNA excretion could be useful non-invasive biomarkers of on-going podocyte damage. On the other hand, the histological findings of podocyte depletion could indicate the accumulation of podocyte loss in patients with IMN.

SA-PO505

Presence of M-Type Phospholipase A2 Receptor Antibody in Membranous Nephropathy

Ozgur Akin Oto, Halil Yazici, Yasar Caliskan, Mehmet S. Sever. *Nephrology, Istanbul Univ, Istanbul, Fatih, Turkey.*

Background: Investigating the frequency of M-Type phospholipase A2 receptor antibody (Anti-PLAR2) seropositivity in patients with IgA and membranous nephropathy (MN).

Methods: Presence of Anti-PLA2R was investigated by using indirect immunofluorescent method in the current serum samples of the patients. Seropositivity at 1/10 dilution was accepted as significant. 108 patients with MN (97 primary, 11 secondary), 44 with IgA nephropathy and 30 healthy volunteers were included in the study irrespective of renal function.

Results: Anti-PLA2R was found to be negative in the healthy volunteers, patients with secondary MN and patients with IgA nephropathy. Anti-PLA2R was positive in 56% (n: 54) of the patients with primary MN, in 92.6% (n: 50) of the patients who were not in remission and only in 7.4% (n: 4) of the patients who were in remission. Among the Anti-PLA2R positive patients, proteinuria was >3 gr/day for 79% (n: 43) and <1 gr/day for 5.6% (n: 3). Among the Anti-PLA2R negative patients, proteinuria was <1 gr/day in 47.5% (n: 19) and >3 gr/day 30% (n: 12). (p<0,001). A positive correlation was noted between the Anti-PLA2R seropositivity and proteinuria (R=0.363, p<0.007). In a multivariable analysis, which included the patients who did not respond to the treatment, Anti-PLA2R positive patients had higher levels of proteinuria (7.2±3.7 versus 5.3±4.1 gr/day; p=0.034) and lower GFR (69.1±31.6 versus 90.8±53.1 ml/min/1.73m²; p=0.026) as compared to Anti-PLA2R negative patients.

Conclusions: In patients with primary MN, there is a correlation between Anti-PLA2R positivity and quantitative proteinuria, which can be a surrogate marker for disease progression.

Funding: Government Support - Non-U.S.

Eculizumab Reduces Terminal Complement, Complement Alternative Pathway Activation, Inflammation, Endothelial Damage, Thrombosis and Renal Injury Markers in Patients with Atypical Hemolytic Uremic Syndrome

Roxanne Cofiell, Anjli Kukreja, Krystin A. Bedard, Yan Yan, Angela P. Mickle, Masayo Ogawa, Camille L. Bedrosian, Susan Faas. *Alexion Pharmaceuticals, Inc., Cheshire, CT.*

Background: To understand how eculizumab (ECU) acts in patients (pts) with atypical hemolytic uremic syndrome (aHUS), we studied markers of complement and endothelial (EC) activation, inflammation, EC damage, thrombosis and renal injury (RI) prior to and during ECU treatment (tx).

Methods: Markers were evaluated in healthy volunteers (HV; n=9–20) and adult aHUS pts (n=26–38) at baseline and >1 year of ECU tx in a prospective clinical trial.

Results: Prior to ECU, markers were significantly elevated (Table), regardless of mutational status, in pts on plasma exchange/infusion (Figure), or with normal platelets, LDH or haptoglobin values. On ECU, C5a, sC5b-9 and RI markers rapidly fell to the HV range; sTNFR1, thrombomodulin, F1+2 and D-dimer levels decreased to 77–99%, and Ba and sVCAM-1 (complement alternative pathway [CAP] and EC activation) levels decreased (mean of 30 and 60%, respectively) but remained elevated.

Conclusions: aHUS pts not receiving ECU showed CAP and terminal complement (TC) activation and elevated markers of inflammation, coagulation, EC activation and damage, thrombosis and RI. ECU normalized TC markers, reduced EC damage markers to near-normal levels, reduced inflammatory and thrombosis markers and eliminated signs of RI; ongoing ECU sustained improvement. Elevated sVCAM-1 and plasma Ba show chronic EC and CAP activation, but tissue damage markers are decreased with ongoing ECU. These data highlight the chronic complement dysregulation and risk of TMA and organ damage in aHUS pts, and the need for continued TC blockade, even when clinical presentation and lab values have improved. An analysis correlating decreases in marker levels with clinical outcomes is under way.

Disease Process	Marker (HV range, units)	BL Median Levels (*P* Value vs HV*)	n/N (%) Elevated at BL	BL Fold Increase over HV	Median Levels, During ECU (*P* Value vs HV)
CAP activation	Plasma Ba (388.0–588.0 ng/mL)	2676.4 (<0.0001)	35/35 (100)	5.53	1451.0 (<0.0001)
TC activation	U-C5a (0.0–0.7 ng[a])	9.0 (0.0007)	26/29 (89.7)	45	0.3 (0.3694)
	U-sC5b-9 (0.0–0.6 ng[a])	30.5 (0.0025)	23/27 (85.2)	305	0.15 (0.2552)
Inflammation	sTNFR1 (407.3–1391.3 pg/mL)	17616.9 (<0.0001)	38/38 (100)	18.71	4138.2 (<0.0001)
EC activation	sVCAM-1 (159.2–444.7 ng/mL)	659.8 (<0.0001)	36/38 (94.7)	1.99	569.1 (<0.0001)
EC damage	Thrombomodulin (2.0–3.6 ng/mL)	10.0 (<0.0001)	33/34 (97.1)	3.64	3.30 (0.0220)
Coagulation	F1+2 (82.9–305.5 pmol/L)	1017.6 (<0.0001)	36/38 (94.7)	5.46	494.7 (<0.0001)
	D-dimer (157.0–395.9 µg/L)	2735.0 (0.0002)	34/36 (94.4)	9.84	510.0 (0.0070)
Renal injury	U-clusterin (5.7–437.1 ng[a])	1232.3 (<0.0001)	24/29 (82.8)	8.62	200.0 (0.305)
	U-L-FABP-1 (0.0–16.9 ng[a])	58.0 (0.0130)	22/29 (75.9)	48.33	5.55 (0.1309)
	U-β2m (0.0–2.7 µg[a])	18.4 (<0.0001)	20/28 (71.4)	46	0.25 (1.0)
	U-cystatin-C (0.3–301.3 ng[a])	1256.9 (0.0001)	18/26 (69.2)	23.85	40.5 (0.4834)

*P values were calculated from the Wilcoxon rank sum test, testing for a difference between groups and measured at weeks 49–54, with the exception of urine markers, which were measured at weeks 17–30. [a]Normalized to urinary creatinine (units per mg U-creatinine).
β2m, β2 microglobulin; BL, baseline; CAP, complement alternative pathway; EC, endothelial; ECU, eculizumab; HV, healthy volunteers; L-FABP-1, liver fatty acid binding protein-1; sTNFR1, soluble tumor necrosis factor receptor-1; sVCAM-1, soluble vascular cell adhesion molecule-1; TC, terminal complement; U, urine.

Eculizumab Safety and Efficacy in Adult Patients with aHUS, with or without Baseline Dialysis Fadi Fakhouri,[1] Camille L. Bedrosian,[2] Masayo Ogawa,[2] John Kincaid,[2] Chantal Loirat.[3] *[1]Chu Nantes, Nantes, France; [2]Alexion Pharmaceuticals, Cheshire, CT; [3]Assistance Publique-Hopitaux de Paris, Hopital Robert Debre, Paris, France.*

Background: Eculizumab (ECU) has been proven safe and effective at inhibiting terminal complement-mediated thrombotic microangiopathy (TMA), improving renal function, and eliminating the need for dialysis in many patients (pts) with atypical hemolytic uremic syndrome (aHUS). The objective of this analysis was to characterize the safety and efficacy of ECU in pts with dialysis (DIAL) and without dialysis (N-DIAL) at baseline (BL) in the largest prospective trial of adults with aHUS.

Methods: A subanalysis of an open-label, single-arm trial to evaluate safety and efficacy of ECU in pts with aHUS aged ≥18 years was performed. The primary study outcome was complete TMA response during 26 weeks (wks) of ECU therapy.

Results: BL characteristics and efficacy outcomes at Wk 26 appear in Table. ECU significantly improved plt count (x10^9/L) in both DIAL (163.2; *P*<0.0001) and N-DIAL (87.4; *P*=0.0120) pts. eGFR (mL/min/1.73 m^2) improved in DIAL (35.0; *P*<0.0001) and N-DIAL (20.0; *P*=0.0179) pts. Of BL DIAL pts, 20/24 (83%) discontinued dialysis, and all remained dialysis-free. Of N-DIAL pts, 4/17 (24%) started new dialysis and 15/17 (88%) were dialysis-free at Wk 26.

Conclusions: ECU use resulted in significant and clinically meaningful improvements in hematologic and renal parameters in BL DIAL and N-DIAL pts with aHUS at Wk 26. More than 80% of pts on dialysis at BL were able to discontinue dialysis, consistent with a prior ECU trial in adolescents and adults whereby 80% of BL DIAL pts also discontinued dialysis by Wk 26. A similar proportion of BL DIAL and N-DIAL pts were dialysis-free at Wk 26. Collectively, these data provide additional support that ECU is proven, effective, and safe in adult pts regardless of dialysis history.

Eculizumab Inhibits Thrombotic Microangiopathy, and Improves Renal Function in Adult Atypical Hemolytic Uremic Syndrome Patients: 1-Year Update Fadi Fakhouri,[1] Maryvonne Hourmant,[2] Josep Maria Campistol Plana,[3] Spero R. Cataland,[4] Mario Espinosa,[5] A. Osama Gaber,[6] Jan Menne,[7] Enrico E. Minetti,[8] Francois Provot,[9] Eric Rondeau,[10] Piero Luigi Ruggenenti,[11] Laurent E. Weekers,[12] Masayo Ogawa,[13] Camille L. Bedrosian,[13] Christophe M. Legendre.[14] *[1]Chu Nantes, Nantes, France; [2]Univ Hospital, Nantes, France; [3]Hospital Clinic, Barcelona, Spain; [4]Ohio State Univ, Columbus, OH; [5]Hospital Reina Sofia, Cordoba, Spain; [6]Methodist Hosp, Houston, TX; [7]Med School Hannover, Hannover, Germany; [8]Careggi Univ Hosp, Florence, Italy; [9]CHRU Lille, Lille, France; [10]Assistance Publique des Hôpitaux, Paris, France; [11]AO Ospedali Riuniti, Bergamo, Italy; [12]CHU ULg, Esneux, Belgium; [13]Alexion Pharmaceuticals, Inc., Cheshire, CT; [14]Hôpital Necker, Paris, France.*

Background: In the largest prospective study of adults with atypical hemolytic uremic syndrome (aHUS), eculizumab (ECU) prevented thrombotic microangiopathy (TMA), and improved renal function and hematological parameters by 26 weeks (wks). Here, we report a 1-yr update.

Methods: Single-arm, Phase 2 trial of ECU in adult aHUS patients (pts); platelets <LLN at screening; prior plasma exchange/infusion and genetic screening were not required. The primary endpoint was complete TMA response at 26 wks.

Results: 41 pts treated, 38 (93%) completed 26 wks. At 1 yr, median treatment duration was 11.9 months. At Wk 26, 30 pts (73%) achieved the primary endpoint and at 1 yr, 33 pts (81%). Respective mean eGFR increases from baseline (BL) were 29.3 and 30.0 mL/min/1.73 m^2 at Wk 26 and 1 yr. 20 of 24 pts (83%) with BL dialysis discontinued by Wk 26 and remained dialysis-free at 1 yr. 4 pts with no BL dialysis began dialysis. 2 pts had meningococcal infections in the first 26 wks–both recovered; 1 continued ECU.

Conclusions: The update confirms that ECU continues to inhibit TMA in adult aHUS pts, maintaining or improving upon clinical gains seen at 26 wks.

Time to End-Stage Renal Disease in Patients with Atypical Hemolytic Uremic Syndrome Receiving Supportive Care and Eculizumab

Gus Khursigara,[1] Scott J. Johnson,[2] Erin Harvey,[1] John Kincaid,[1] Camille L. Bedrosian.[1] *[1]Alexion Pharmaceuticals, Cheshire, CT; [2]Medicus Economics, LLC, Milton, MA.*

Background: Pre-eculizumab (ECU),up to 40% of aHUS patients (pts) died or progressed to end-stage renal disease (ESRD) within 1 year following a clinical manifestation. The overall 5-year mortality rate for all pts on chronic dialysis is 65%.[1] In clinical trials, ECU resulted in stabilization of renal function or reversal of renal damage. Thus, our objective was to compare time to ESRD in pts with aHUS receiving supportive care only (SCO) with those receiving ECU in 2 aHUS clinical trials.

Methods: We modeled time to ESRD (eGFR <15mL/min/1.73 m^2) using pts' initial eGFR with Kaplan-Meier and Cox proportional hazards analyses to determine the relationship of initial CKD stage and time to ESRD in pts with aHUS.

Results: 23 and 26 pts were included from pre-treatment and on-treatment data. In the pre-treatment period, 17%, 48%, and 35% were CKD stage 2, 3, and 4, respectively. Median time to ESRD among pts receiving SCO was 618 days, and the 25th percentile time to ESRD was 231 days. A Cox proportional hazards model showed that the risk of ESRD progression for pts on ECU was 0.11 (95% CI [0.03–0.42]; *P*=0.001), or an 89% reduction in the progression rate to ESRD compared with SCO (Figure). When stratifying by initial CKD stages 2, 3, and 4 at first eGFR measure, median time to ESRD for pts receiving SCO was 939 (*P*=0.134), 618 (*P*<0.01), and 231 (*P*<0.050) days, respectively. No pt initiating ECU in CKD stage 2 or 3 progressed to ESRD in 3 years; only 3 of 11 pts in CKD stage 4 reached ESRD over 3 years. The analysis did not assess if renal failure was acute or chronic.

Conclusions: The results suggest progression of renal impairment to ESRD is rapid in aHUS pts on SCO, and ECU eliminates or significantly reduces the rate of progression to ESRD. **Reference:** 1.U.S. Renal Data System 2011.

Characteristics of 406 Adult and Pediatric Patients in the Global aHUS Registry

Christoph Licht,[1] Gianluigi Ardissino,[2] Gema Ariceta,[3] Alexander Cole,[4] Christoph Gasteyger,[5] David J. Cohen,[6] Larry A. Greenbaum,[7] Sally A. Johnson,[8] Masayo Ogawa,[4] Franz S. Schaefer,[9] Johan Vande Walle,[10] Veronique Fremeaux-Bacchi.[11] *[1]The Hospital for Sick Children, Toronto, Canada; [2]Osp Maggiore Policlinico, Milano, Italy; [3]Hospital de Cruces, Barakaldo, Spain; [4]Alexion Pharmaceticals, Inc., Cheshire, CT; [5]Alexion Pharma, Lausanne, Switzerland; [6]Columbia Univ, NY, NY; [7]Emory Univ, Atlanta, GA; [8]Newcastle Univ, NE, United Kingdom; [9]Heidelberg Univ, Heidelberg, Germany; [10]Gent Univ Hosp, Gent, Belgium; [11]Hopitaux de Paris, Paris, France.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare, genetic, life-threatening disease of chronic complement activation leading to systemic thrombotic microangiopathy and end-organ damage. The global aHUS Registry, initiated in April 2012, prospectively collects information on patients (pts) with aHUS. Here, we report baseline demographics from pts enrolled in the aHUS Registry.

Methods: aHUS pts (regardless of treatment) are eligible for enrollment. Demographic, medical and disease histories, treatments, efficacy and safety outcomes data are collected initially and every 6 months.

Results: By March 31, 2014, 406 pts were enrolled from 13 countries. Family history of aHUS, prior kidney graft, dialysis, and PE/PI were recorded (Table). In the 6 months prior to enrollment, 52.5% reported renal symptoms, and 11% to 22% had extrarenal symptoms (GI, cardiovascular, CNS, and pulmonary). Overall, 235 pts (57.9%) received eculizumab (ECU) for a mean duration of 0.4 yrs. 46 pts discontinued ECU, with 5 of 46 pts restarting.

Conclusions: The Registry will improve understanding of aHUS and may help optimize pt care. The Registry is a successful model of partnership between industry and academia, and will provide data for additional research on multiple levels of collaboration.

SA-PO511

Safety and Efficacy of Eculizumab in Adult aHUS Patients, with or without a History of Renal Transplant

Chantal Loirat,[1] Christophe M. Legendre,[2] Masayo Ogawa,[3] Camille L. Bedrosian,[3] John Kincaid,[3] Fadi Fakhouri.[4] *[1]Assistance Publique-Hopitaux de Paris, Hopital Robert Debre, Paris, France; [2]Hopital Necker, Paris, France; [3]Alexion Pharmaceuticals, Cheshire, CT; [4]Chu Nantes, Nantes, France.*

Background: Atypical hemolytic–uremic syndrome (aHUS) is a life-threatening, chronic disease of complement-mediated thrombotic microangiopathy (TMA). In aHUS, renal transplantation (RT) has been associated with high rates of post-RT aHUS manifestations and graft loss (~50–70% 5 yrs post-RT). Eculizumab (ECU) inhibits terminal complement-mediated TMA and is safe and efficacious in aHUS regardless of RT history (hx). This analysis reports safety and efficacy of ECU in transplant (TP) and nontransplant (NTP) pts.

Methods: A retrospective subanalysis of an open-label, single-arm trial of ECU in TP and NTP pts ≥18 yrs was performed. Pts were vaccinated against *N. meningitidis*. Inclusion criteria included platelet (plt) count <150x10^9/L, LDH ≥1.5xULN, and SCr ≥ULN. Primary outcomes were evaluated at Wk 26.

Results: There were 9 (22%) TP pts (8 pts with 1 RT; 1 pt with 2 RT). ECU improved plt count (x10^9/L) in both TP (146.2; *P*<0.0810) and NTP (132.6; *P*<0.0001) pts. eGFR (mL/min/1.73 m^2) improved in TP (19.0; *P*=0.1940) and NTP (31.5; *P*<0.0001) pts. 56% and 66% of respective TP and NTP pts achieved CKD improvement ≥1 stage. Of TP and NTP pts who had BL dialysis, 2/3 (66.7%) and 18/21 (85.7%) discontinued dialysis. Treatment-emergent adverse events were similar among groups.

Conclusions: ECU produced clinically meaningful improvements in plt count and renal function in TP and NTP pts. No pt progressed to ESRD requiring RT, and most remained dialysis-free, regardless of RT hx. These results are consistent with 2 previous subanalyses in which ECU prevented progression to graft loss, and improved renal function in both TP and NTP aHUS pts.

Baseline Characteristics	TP (n=9)	NTP (n=32)	P value[a]
Age at first infusion, mean (range), years	31.1 (18–49)	37.9 (18–63)	0.03

Complement Biomarker Activity in Eculizumab Treated Patients Gilbert Van Schaeffer, Nicole Meyer, Dingwu Shao, Yuzhou Zhang, Richard J. Smith, Carla M. Nester. *Molecular Otolaryngology and Renal Research Laboratory, Univ of Iowa, Iowa City, IA.*

Background: Eculizumab is a monoclonal antibody directed against complement component C5. It has proven efficacy in aHUS. Isolated reports suggest effectiveness in C3G. The therapeutic level of >99mcg/mL is rarely used clinically. The compliment biomarker correlates of this level are sparse. No specific clinical test exists to directly assess the efficacy of eculizumab in patients.

Methods: We studied 11 patients treated with eculizumab. aHUS patients were in remission by hemolytic parameters. No C3G patient was in clinical remission. Usual dosing was the primary regimen. Two patients were on alternative dosing strategies. Eculizumab levels were compared with multiple assays: C5 (Binding Site Radial Immunodiffusion), C5a (Quidel EIA), C5 Functional (C5F Mayo Lab), Eculizumab level (Cambridge Biomedical), Alternative Pathway Functional Activity (APFA Wieslab) and a modification of the latter. The modified APFA consisted of patient sera mixed with normal human sera and then tested by standard APFA.

Results: Complement activity was reduced at 2 weeks in all patients. There was no correlation between the standard APFA or C5F with the eculizumab level. The eculizumab level was moderately correlated with the modified APFA (R = 0.600).

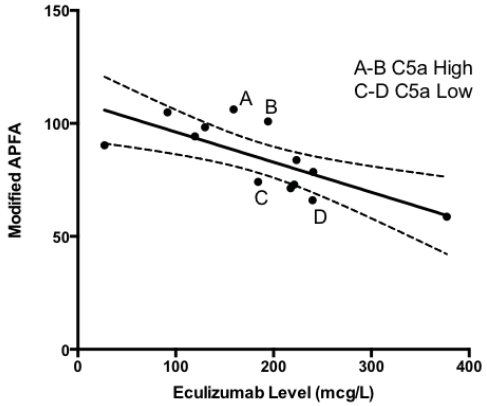

Figure 1 and values outside the 95% CI (dotted lines) correlated with the C5a level. Total C5 was significantly elevated in all patients as compared to controls and was not correlated with the eculizumab level.

Conclusions: The modified APFA had the highest correlation with eculizumab levels. C5a levels predicted non-correlation (points A-D). Assessments are ongoing to confirm the usefulness of the modified APFA as a marker of complement activity in patients treated with eculizumab. We propose this as the first step toward confirming complement blockade regardless of patient disease or dosing regimen.

Morbidity and Mortality of Shiga Toxin Associated Hemolytic Uremic Syndrome in a Contemporary Group of American Children Carla M. Nester, Larry A. Greenbaum, Myda Khalid, Stefan Kiessling, Kera E. Luckritz, John D. Mahan, Yosuke Miyashita, Michelle N. Rheault, Tarak Srivastava, Donald J. Weaver, Sharon M. Bartosh. *Midwest Pediatric Nephrology Consortium.*

Background: Shiga toxin-producing *Escherichia coli* (STEC) is the leading cause of hemolytic uremic syndrome (STEC-HUS) in the United States. There are no disease specific treatment modalities and current therapy is supportive, including fluid management, blood transfusions, and dialysis when indicated. The short-term and long-term morbidity and mortality of STEC HUS in children remains poorly defined.

Methods: A retrospective chart review was conducted within centers of the Midwest Pediatric Nephrology Consortium. Medical charts were identified using diagnosis and billing codes. Eligible patients were <18 years old. Patients with non toxin related HUS were excluded from the review. Each patient chart was quired for 145 separate data points. We present here a summary of the morbidity and mortality data.

Results: 311 patients with a clinical diagnosis of typical HUS were identified across 11 centers during the 5 year time period. The accompanying table depicts (Figure 1) the distribution of disease related events. The mortality was 1%. 44% of children required ICU care, 92% required blood transfusion and 43% required dialysis during their acute episode. Symptomatic pancreatitis was the most frequent extrarenal complication of disease with neurologic impairment being the second most likely. Many children had urine abnormalities at discharge and the majority of those patients that were followed after discharge continued to show renal dysfunction.

Morbidity and Mortality of ST-HUS in a Pediatric Population

Diagnosis	
Median of 6 days after diarrhea start	
<4 years (Median age 3.9 years)	50%
Older than 15 years	5%
Required ICU Care (Median Stay 6 Days - range 1-82)	44%
Mortality: (3 patients: Death at 6 days, 4 days and 3 days after diagnosis)	1%
Required Blood Transfusions	92%
one 17%, two 20%, three 18%, four 12%, five 8%, > 6 16% | (Median 3)	
Anuria (Median duration 5 days)	37%
Dialysis requirement during acute hospital admission (Medan duration 9 days)	43%
Renal Replacement greater than 1 week	57%
Renal Replacement greater than 2 weeks	38%
Indication: Uremia (72%), volume overload (56%), electrolyte disturbance (39%)	
CRRT 16%, HD 50%, 50% PD and 14% with more than one modality	
Complications	
Peritonitis	6%
Catheter related thrombus	5%
Blood catheter related infection	10%
Dialysis requirement at discharge	5%
Hypertension	71%
No meds 56%, 1 med 25%, 2 meds 11%, 3 meds 5%, 4 meds 3%	
Hypertension treatment significantly more likely if dialysis is required	
BP meds required at discharge	
At 1 mo 19%, at 3 mo 13%, at 6 mo 11% and 12% at both 9 & 12 months	
Urinalyses at Discharge (N= 155)	
Proteinuria of 1+ or above	82%
Hematuria	88%
Estimated GFR (intervals after discharge)	
1 month - (N = 199): < 15 in 3%, 15-30 in 2%, 30-60 in 8 %, 60-90 in 28%, > 90 in 59%	
3 months – (N = 102): < 15 in 1%, 15-30 in 5%, 30-60 in 5%, 60-90 in 16%, > 90 in 73%	
6 months – (N = 96): < 15 in 1%, 15-30 in 3%, 30-60 in 4%, 60-90 in 29%, > 90 in 63%	
12 months – (N = 90): < 15 in 1%, 15-30 in 0%, 30-60 in 7%, 60-90 in 26%, > 90 in 64%	
Complications	
ARDS	2%
Cardiac Dysfunction	1%
Pericardial Effusion	2%
Diabetes Mellitus	2%
CVA	1%
Seizure	5%
Coma	1%
Bowel Perforation	1%
Symptomatic Pancreatitis	16%
Neurologic impairment	6%

Conclusions: Of those children admitted with STEC HUS, mortality was low however morbidity was high with almost 50% requiring ICU care and/or dialysis. Thirty six percent of children were left with CKD and 12% required antihypertensive care twelve months after their episode.

Differential Alteration in Peripheral T-Regulatory and T-Effector Cells with Change in P-Glycoprotein Expression in Childhood Nephrotic Syndrome: A Longitudinal Study Narayan Prasad, Akhilesh Jaiswal, Vikas Agarwal, Brijesh Yadav, Amit Gupta, Raj K. Sharma. *Nephrology, SGPGI, Lucknow, UP, India.*

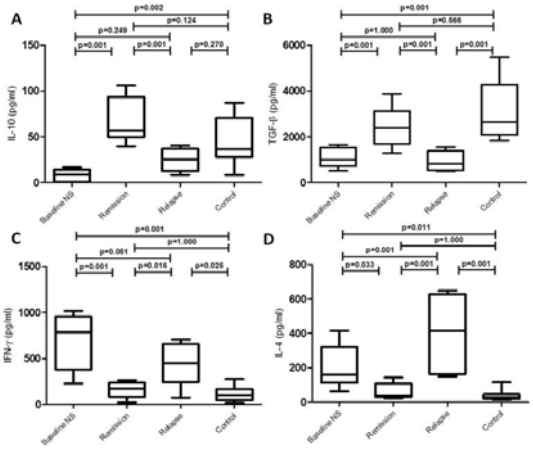
Background: We hypothesize that relapses in INS may occur due to imbalance in T-regulatory and T-effector cell and their respective cytokines and overexpression of P-gp on lymphocytes.

Methods: The frequency of peripheral blood $CD4^+CD25^+FoxP3^+$ Treg(Tregs), $CD4^+IFN\text{-}\gamma^+$ Th1(Th1) and $CD4^+IL\text{-}4^+$ Th2 (Th2) lymphocytes and their respective cytokines and P-gp expression on peripheral blood lymphocytes (PBLs) were analyzed in INS patients at baseline (n=26), during remission (n=24) and at relapse (n=15).P-gp expression was correlated with cytokine level of cultured stimulated PBMCs.

Results: Compared to baseline values(1.83±0.84),Tregs frequency was significantly increased at remission (6.82±4.12) and became similar to control(5.69±2.34) and decreased at relapse(3.03±1.18). In contrast,Th1(9.9±4.65) and Th2(4.81±1.42)frequency was significantly decreased during remission from baseline (Th116.18±7.19; Th210.5±4.66) and increased at the time of relapse(Th119.83±3.47;Th2 9.89±5.18). Similarly, expression of P-gp was high at baseline, decreased during remission and increased at relapse.

Parameters	Baseline	Remission	Relapse	Control
% P-gp positive cells	8.69±3.62	5.46±3.14	10.02±5.2	4.89±1.73
RFI	8.22±1.82	6.72±1.88	8.65±2.96	7.13±5.26
RFI×% P-gp positive cells	66.59±21.13	35.84±22.26	80.22±28.24	30.41±16.15

Cytokines Il-10 and TGF-β in supernatant of stimulated PBMCs was increased during remission and decreased at relapse. In contrast, levels of IFN-γ and IL-4 were decreased during remission and increased at relapse.



Conclusions: An increase in P-gp expression and decreased Tregs in blood at baseline and during relapse and vice versa after remission is suggestive of crucial role of T lymphocyte phenotype imbalance and P-gp overexpression in NS.

Urinary Messenger RNA of Receptor Activator of NF-kappaB Could Be Useful to Differentiate Between Minimal Change Disease and Membranous Nephropathy Shuangxin Liu, Wei Shi, Li Zhang, Sijia Li, Xinling Liang, Zhiming Ye, Bin Zhang, Lixia Xu, Jianchao Ma, Zhilian Li, Wenjian Wang, Ruizhao Li, Zhonglin Feng, Wei Dong, Yiming Tao, Yuanhan Chen, Yongzhen Liang. *Dept of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: Podocyte damage and loss play an important role in the pathogenesis and progression of glomerulonephritis. Quantification of messenger RNA (mRNA) in urine by real-time PCR is emerging as a noninvasive method of screening podocyte injury and response-associated molecule. We previously demonstratedthat RANK was upregulated in podocyte of human glomerular disease, and was marker of podocyte injury response-associated molecule. We hypothesize that expression of receptor activator of NF-kappaB (RANK) in urinary sediment may provide important clinical insight into the different type of glomerulonephritis.

Methods: Glomerulonephritis patients and healthy controls were enrolled in this study. Biochemical, clinical and experimental procedures included measurement of total urinary protein, renal biopsy, and gene expression analysis of RANK. Correlations between RANK mRNA and clinical parameters were analyzed.

Results: Between July 2012 and August 2013, 145 patients with glomerulonephritis and 22 healthy controls were included. The urinary mRNA levels of RANK were significantly higher in the glomerulonephritis group compared with controls. The urinary RANK levels of glomerular subtypes was significantly correlated with proteinuria ($r = 0.72$, $p < 0.001$ for membranous nephropathy (MN); $r = 0.63$, $p < 0.001$ for IgA nephropathy (IgAN); $r = 0.58$, $p = 0.014$ for LN; and $r = 0.80$, $p < 0.001$ for focal segmental glomerulosclerosis (FSGS)). The calculated area of RANK mRNA levels under the curve was 0.61 for MCD, 0.97 for MN, 0.65 for IgAN, 0.70 for lupus nephritis (LN), and 0.70 for FSGS.

Conclusions: The urinary mRNA of RANK may be useful to differentiate histologic subtypes of glomerulonephritis, particularly between MCD and MN.

SA-PO516

Podocyte-Associated mRNA Profile in Lupus Nephritis and Its Relation with Immunopathology Cristina Karohl,[1] Mariane Dos Santos,[1] Rafael N. Bringhenti,[2] Patrícia Garcia Rodrigues,[1] Jonathan Fraportti Do Nascimento,[1] Odirlei Andre Monticielo,[3] Andrese A. Gasparin,[3] Waldir Pedro Castro,[2] Francisco Veríssimo Veronese,[1] Rafael Zancan. *[1]Div of Nephrology, Hospital de Clínicas de Porto Alegre, Porto Alegre, RS, Brazil; [2]Div of Pathology, Univ Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, RS, Brazil; [3]Div of Rheumatology, Hospital de Clínicas de Porto Alegre, Porto Alegre, RS, Brazil.*

Background: This study aimed to quantify the expression of podocyte-associated mRNAs in patients with active lupus nephritis (LN), in correlation with the immunopathology.

Methods: Thirty-three patients with LN were included, and grouped according to the presence of mild (classes I and II) or moderate-to-severe (classes III, IV and V) immune deposits, proliferation and/or inflammation. Messenger RNA of podocyte-specific proteins, and growth (VEGF-A, TGF-β1) and regulatory (FOXP3) factors were quantified by real time PCR in the kidney tissue and urine. These mRNAs were correlated with histopathology and the intra-renal cell inflammatory infiltrate.

Results: Overall, podocyte-associated mRNAs were inhibited in the renal tissue, and substantially higher levels of podocyte products were found in the urine of the patients. Urine mRNA levels were significantly higher in patients with more severe lesions, but mRNAs in kidney tissue did not correlate with class severity. In the proliferative forms, significant alterations were found to podocin, podocalyxin, TRPC-6, and TGF-β1mRNA levels, reflecting more intense podocyte injury. Urinary nephrin, podocin, podocalyxin, TGF-β1and FOXP3 mRNA levels correlated positively with proteinuria, but the podocyte mRNAs did not correlate with renal function or anti-dsDNA titers. The density of $CD8^+$ T cells, B cells and macrophages in kidney biopsy were positively correlated with the urinary podocyte mRNAs; T cells also correlated with TGF-β1and FOXP3 in biopsy.

Conclusions: Podocyte-associated mRNAs in LN were reduced in kidney tissue, irrespective of the histological class, and substantially increased in the urine, especially in biopsies with more severe lesions. Inflammatory cells were positively associated with urine podocyte mRNAs, reflecting the ongoing immune-mediated podocyte injury in LN.

SA-PO517

Morbid Obesity, Hyperinsulinemia, and Inflammation Are Associated with Podocyte Injury in Obese Individuals Cristina Karohl,[1] Mariane Dos Santos,[1] Sane Pereira,[1] Patrícia Garcia Rodrigues,[1] Jonathan Fraportti Do Nascimento,[1] João Rodolfo Telo Timm,[1] Rafael Zancan,[1] Rogerio Friedman,[2] Francisco Veríssimo Veronese.[1] *[1]Div of Nephrology, Hospital de Clínicas de Porto Alegre, Porto Alegre, RS, Brazil; [2]Div of Endocrinology, Hospital de Clínicas de Porto Alegre, Porto Alegre, RS, Brazil.*

Background: Obesity is associated with glomerular lesions and podocyte injury. This study correlated the urinary expression of podocyte-associated messenger RNAs (mRNAs) with different degrees of obesity, metabolic syndrome and systemic inflammation.

Methods: Eighty-three obese or overweight patients and 18 controls were included. Expression of nephrin, podocin, podocalyxin, alpha-actinin-4, α3β1-integrin, vascular endothelial growth factor (VEGF-A), and transforming growth factor-beta ($TGF\beta_1$) mRNAs in urine was quantified by real-time PCR. mRNA was correlated with body mass index (BMI), metabolic syndrome, albuminuria, and inflammation.

Results: Patients had overweight (20.8%), obesity class I (11.9%), II (9.9%), or III (39.6%). Class III patients had higher serum lipids, plasma glucose, HbA1C, insulin resistance, and C-reactive protein levels ($p<0.05$), and 70% met criteria for the metabolic syndrome ($p=0.003$ versus other groups). Albuminuria >30 mg/g creatinine was observed in 14%, 8%, 10%, and 23% of patients with overweight, class I, class II, and class III obesity respectively ($p=0.548$). Expression of all podocyte-associated mRNAs varied with BMI, being significantly higher in the obese class III compared with controls and the other patients ($p<0.05$). Patients with overweight, class I or II obesity also had higher levels of mRNAs compared with controls: nephrin ($p=0.021$), alpha-actinin-4 ($p=0.014$), α3β1-integrin ($p=0.036$), and $TGF\beta_1$ ($p=0.005$). A higher degree of podocyturia was also found in hyperinsulinemic patients and in those with systemic inflammation.

Conclusions: In this study morbid obesity was associated with a higher degree of podocyturia even at normal urinary albumin excretion rates, suggesting that the presence of podocyte products in urine may reflect early podocyte injury in severe obesity. Hyperinsulinemia and systemic inflammation also correlated with higher levels of urinary podocyte-associated mRNAs.

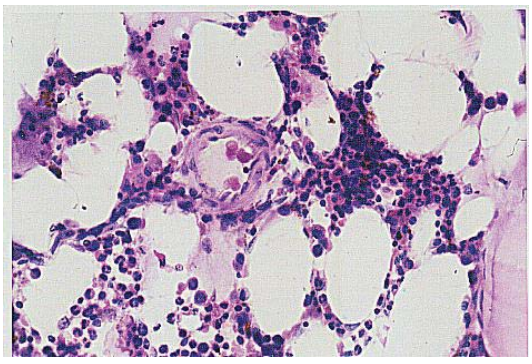
SA-PO518

Clinical and Pathological Features of Aristolochic Acid – Nephropathy Induced By Fukefenqing Pills Yanqiu Li,[1] Hua Zhou.[2] *[1]Dept of Nephrology, The First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning, China; [2]Dept of Nephrology, The First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning, China.*

Background: To dicuss the toxicity of the aristolochic acid in fukefenqing pills.

Methods: 14 patients who had eaten the pills for more than half a month were enrolled in the study in 2008-2009 at the department of nephrology of Chinese medical university.Collecting their clinical data and using prostaglandin E1(10ug/d)intravenous drop for 10-14 days.

Results: 7 patients underwent renal biopsy,all cases results with light microscopy examination showed renal interstitial infiltration of inflammatory cells, renal interstitial fibrosis, renal tubular atrophy or disappear, glomerular changed slightly, often accompanied by mild mesangial proliferation. Arteriole intima is not smooth, with inflammatory cell infiltration, visible stenosis or rigid wall, advanced muscle layer fracture and delamination. In a bone marrow biopsy case, part of the regional proliferation is extremely low, fat cells proliferate abnormal, interstitial edema, with micro vascular wall thickening and luminal stenosis.



Fukefenqing pills have guanmutong, it can cause Chronic interstitial nephritis and multiple organs lesion especially Anemia, the symptom is severity than others.According to the conventional dose, the daily amount of AA content up to 394.2mg, the equivalent of 50 grain of Guanxin Suhe pills.

Conclusions: The serum creatinine and hematoglobin before and after therapy were statistically different.

Table 1 treatment effect of AAN patients using prostaglandin E1

	Cr(umol/L)	Hb (mg/dl)
before	520.25±114.62	68.21±10.13
after	405.76±102.43	79.45±10.49
t value	2.8	2.9
p value	<0.05	<0.05

Aristolochic acid possibly causes abnormal of the system of prostaglandin or other blood vessel cytokines,so improving of microcirculation will be effect in therapy.

Decreased Tamm-Horsfall Protein Levels in Human Immunodeficiency Virus-Infected Subjects Associate with Higher Levels of Serum Tumor Necrosis Factor Alpha Receptor

Satish P. Ramachandrarao,[1] Corrilynn O. Hileman,[3] Chanthel Kokoy-Mondragon,[1] Robert T. Schooley,[1] Grace Mccomsey.[2] *[1]Medicine, UCSD, San Diego, CA; [2]Pediatrics, Case Western Reserve Univ, Cleveland, OH; [3]MetroHealth Medical Center, Case School of Medicine, Cleveland, OH.*

Background: Tamm-Horsfall Protein (THP), the most abundant protein in the urine of healthy humans, plays a regulatory role in renal function and was recently shown to influence systemic cytokine clearance. However, THP has not yet been investigated in HIV.

Methods: We performed a cross-sectional study of HIV-infected subjects on stable antiretroviral therapy (ART) with HIV-1 RNA of <1000 copies/mL and $eGFR_{cr}$ >50 mL/min per 1.73 m^2 to explore THP relationship with HIV-related factors and inflammation and immune activation markers. Creatinine (Cr) was measured by Jaffe's reaction. THP was quantified by Western blotting and normalized per unit urine protein. Univariable followed by multivariable linear regression was performed.

Results: 121 subjects were included; 82% were men and 65% African American. Median (Q1-Q3) age was 46 (40-52) years and $eGFR_{cr}$ 98.37 (84.92-115.79) ml/min per 1.73 m^2. Median known HIV duration was 141 (75-211) months, cumulative ART 65 (38-199) months, $CD4^+$ count 607 (425-823) cells/mm^3 and 76% had HIV-1 RNA ≤48 copies/ml. Median THP level was 116.16 (83.26-146.98) arbitrary absorbance units. THP levels were positively associated with $eGFR_{cr}$ inversely associated with the vascular inflammation marker Lp-PLA2 and the systemic inflammation marker sTNFR-I, but not with other parameters tested. Adjusting for $eGFR_{cr}$ and total urine protein, higher sTNFR-I were independently associated with lower THP level.

Conclusions: In HIV-infected patients on ART, lower urinary THP levels were associated with higher sTNFR-I even after adjustment for eGFRcr and urine total protein levels. This suggests that higher inflammation in HIV-infected subjects on ART may partially be due to lower THP. Cytokine clearance may be slower in individuals with lower levels of THF protein and this lower clearance rate might account, in part, for the inverse relationship between the two. A longitudinal study is required to confirm this novel observation.

SA-PO520

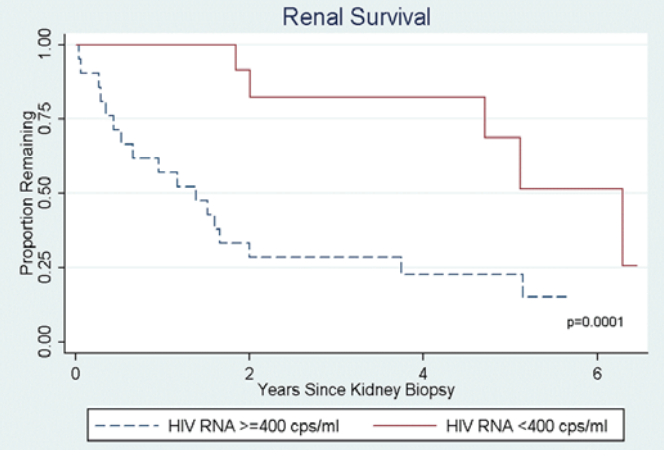
Association of HIV Suppression with Progression of Non-HIVAN FSGS

Blaithin A. Mcmahon,[1] Derek M. Fine,[1] Teresa K. Chen,[1] Mohamed G. Atta,[1] Matthew Foy,[2] Gregory Lucas,[1] Michelle M. Estrella.[1] *[1]Johns Hopkins Univ; [2]Louisiana State Univ.*

Background: In the era of potent antiretroviral therapy (ART), non-HIV associated nephropathy (non-HIVAN) FSGS is one of the most common histopathological findings in HIV+ African Americans. We aimed to examine whether HIV suppression is associated with lower ESRD risk among HIV+ African Americans with biopsy-proven non-HIVAN FSGS.

Methods: HIV+ African Americans aged ≥21 years who underwent a native kidney biopsy between 1/1996 and 6/2011 were confirmed as having non-HIVAN FSGS by the presence of FSGS without collapsing glomerulosclerosis, microcystic tubular dilatation, tubulointerstitial inflammation and tubuloreticular inclusions. Sociodemographic and clinical data were abstracted from medical records. ESRD was defined as an eGFR <15 ml/min/1.73 m^2 or dialysis initiation. Survival analyses from the time of biopsy to 1/2013 censoring for death or loss to follow-up were used to evaluate the association between viral suppression (HIV RNA<400 cps/ml at biopsy) and progression to ESRD.

Results: Among 43 HIV+ African Americans with non-HIVAN FSGS (mean age 48y, 11% women), the median CD4 count was 230 cells/μl, and 19 had suppressed viral loads at baseline. The median baseline eGFR and urine protein:creatinine ratio were 39 ml/min/1.73 m^2 and 1.3, respectively. Over a mean follow-up of 3±3 years, 22 progressed to ESRD. Those who had suppressed viral loads were less likely to progress to ESRD (Figure). Adjusting for sex and baseline CD4 count, eGFR and proteinuria, those with baseline HIV RNA levels <400 cps/ml had a 75% lower risk of progressing to ESRD (HR 0.25; 95% CI: 0.07, 0.88).



Conclusions: HIV suppression is associated with significantly lower risk of progression to ESRD among HIV+ African Americans with non-HIVAN FSGS, supporting the potential role of ART for the treatment of non-HIVAN FSGS among HIV+ African Americans.

SA-PO521

Non-Albumin Proteinuria Predominates in Biopsy-Proven Tenofovir Toxicity

Meghan E. Sise,[1] Jamie S. Hirsch,[1] Pietro A. Canetta,[1] Leal C. Herlitz,[2] Sumit Mohan.[1] *[1]Nephrology, Columbia Univ Medical Center, New York, NY; [2]Pathology, Columbia Univ Medical Center, New York, NY.*

Background: Tenofovir disoproxil fumarate (TDF) is a nucleotide analog reverse-transcriptase inhibitor that can cause mitochondrial dysfunction. TDF nephrotoxicity is characterized by proximal tubular injury and dysmorphic mitochondria resulting in proteinuria, orthoglycemic glycosuria and other markers of proximal tubular dysfunction.

Methods: Patients with biopsy-proven TDF nephrotoxicity were identified from the Columbia University Medical Center Renal Pathology Lab database and their charts reviewed retrospectively.

Results: We identified 43 cases of biopsy proven TDF toxicity; mean age 54.7± 8.4 years, 53% male, 42% white. 37 cases reported dipstick proteinuria results: (0-trace: 3, 1+: 12, 2+: 13, and ≥3+: 9). 71% had dipstick hematuria. 25 patients had total protein quantified. The median proteinuria was 1800mg per 24 hours or 1667mg/gram creatinine (IQR 900mg – 2071mg); despite this only 56% had evidence of ≥2+ proteinuria on dipstick. There was a positive correlation with serum creatinine at biopsy and proteinuria (R = 0.44 P=0.028). Urinary albuminuria was quantified simultaneously (median 236 mg/gm (IQR 136.7 -343 mg/gm) for 10 patients. When both protein and albumin excretion rates were available, only 17% (IQR 13-18%) of the total protein excreted was albumin; confirming that TDF toxicity is primarily associated with non-albumin proteinuria. Among these 10 patients, urinalysis revealed orthoglycemic glycosuria in 6, and 5 had ≥2+ proteinuria by dipstick.

Conclusions: Our results suggest that only 60% (22/37) of patients with TDF nephrotoxicity have significant proteinuria by dipstick, making this is an insensitive screening tool for TDF nephrotoxicity. The simultaneous measurement of urinary albumin and protein excretion provides clinicians an inexpensive and noninvasive means of distinguishing TDF toxicity from causes of glomerular proteinuria. A low ratio of urine albumin to protein appears to be a reliable clinical feature of tenofovir toxicity, and it's diagnostic test characteristics should be elucidated by examining a large cohort of patients taking tenofovir who undergo kidney biopsy.

SA-PO522

Circulating and Urinary MicroRNA Profile in Focal Segmental Glomerulosclerosis: A Pilot Study

Ali Ramezani,[1] Joseph M. Devaney,[1,2] Scott D. Cohen,[1] Maria R. Wing,[1] Richard Scott,[2] Rishi Singhal,[1] Jeffrey B. Kopp,[3] Dominic S. Raj.[1] *[1]Div of Renal Diseases and Hypertension, The George Washington Univ, Washington, DC; [2]Center for Genetic Medicine Research, Children's National Medical Center, Washington, DC; [3]Kidney Diseases Branch, National Inst of Diabetes and Digestive and Kidney Diseases, National Inst of Health, Bethesda, MD.*

Background: MicroRNAs (miRNAs) are non-coding RNA molecules that play important roles in the pathogenesis of various kidney diseases. We investigated whether patients with minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) have distinct circulating and urinary miRNA expression profiles that could lead to potential development of noninvasive biomarkers of the disease. To this end, we examined the urinary and serum miRNA profiles in patients with MCD and FSGS and compared them with subjects with no kidney disease.

Methods: Exosomal miRNAs were extracted from serum and urine samples of patients with FSGS (n=19) or MCD (n=5) and healthy controls (n=5). Differences in miRNA abundance were examined using Affymetrix GeneChip miRNA 3.0 arrays. QRT-PCR was used to validate the findings from the array.

Results: Comparison analysis of FSGS versus MCD revealed 72 and 81 differentially expressed miRNAs in serum and in urine, respectively. Only 38 of these miRNAs were

previously cited, whereas the remaining 115 miRNAs have not been described. Comparison analysis showed that a significant number of miRNAs were down-regulated in both serum and urine samples of FSGS patients compared to those with MCD. Serum levels of miR-30b, miR-30c, miR-34b, miR-34c, and miR-342, and urine levels of mir-1225-5p were up-regulated in MCD patients compared to FSGS patients and normal controls ($p<0.001$). Urinary levels of mir-1915 and miR-663 were down-regulated in FSGS patients compared to MCD and normal controls ($p<0.001$), whereas the urinary levels of miR-155 were up-regulated in FSGS patients when compared to MCD patients and normal controls ($p<0.005$).

Conclusions: Patients with FSGS and MCD have a unique circulating and urinary miRNA profile. The diagnostic and prognostic potential of miRNAs in FSGS and MCD warrants further studies.

SA-PO523

Focal and Segmental Glomerulosclerosis: Clinical and Kidney Biopsy Correlations

Ladan Zand,[1] Sanjeev Sethi,[2] Samih H. Nasr,[2] Richard J. Glassock,[3] Fernando C. Fervenza.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Anatomic Pathology, Mayo Clinic, Rochester, MN; [3]Nephrology and Hypertension, Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Primary focal segmental glomerulosclerosis (FSGS) can be difficult to distinguish from secondary FSGS. which can result in a number of patients with secondary FSGS undergoing unnecessary immunosuppressive therapy. We aimed to idetify clinical and histological findings that can help distinguish the two.

Methods: We reviewed the Mayo Clinic Database for patients with a diagnosis of FSGS on native renal biopsy and divided them into nephrotic syndrome(NS)-associated and non-nephrotic syndrome (NNS)-associated FSGS as a first approximation followed by dividing the lesion according to the degree of foot process effacement (FPE) on electron microscopy (EM).

Results: A total of 41 patients with an FSGS with complete evaluation were identified and divided into NS (18) and NNS (23). Baseline characteristics (age, gender, body mass index, serum creatinine) were not different between the groups. All patients with NS had diffuse FPE ranging from 80-100% (mean 96%). Conversly, of the 23 in the NNS group, 22 had segmental FPE, with all cases showing 20-70% FPE (mean of 48%).

	Nephrotic syndrome	Non Nephrotic Syndrome	P Value
n	18	23	
FPE	96 ± 5.9	48.3± 16.9	< 0.0001
FSGS Lesions (n)			
Collapsing	1	2	0.4
Tip	3	1	
Perihilar	2	7	
Cellular	2	1	
NOS	10	12	
Glomerulomegaly (Y/N)	6/12	16/7	0.02
Global glomerulosclerosis (%)	11.4 ± 13.5	30.5 ± 24.1	0.005
Tubular atrophy and interstitial fibrosis (≤25%/>25%)	18/0	18/5	0.04
Arteriosclerosis and arteriolar hylainosis (<2+/≥ 2+)	13/4	10/10	0.09

Table 1: Biopsy Characteristics

Conclusions: Adult patients presenting with NS, a FSGS lesion on LM, extensive FPE (>80%) on EM and no risk factors associated with secondary FSGS are likely to have primary FSGS. Conversely, the absence of NS, in a patient with segmental FPE on EM strongly suggests a secondary FSGS. Dividing FSGS into the presence or absence of NS together with the degree of FPE on EM examination is more helpful as it provides a more practical way to separate patients into cases of primary versus secondary FSGS.

SA-PO524

Urinary Soluble Urokinase Receptor and Alpha-1-Microglobulin Excretion in Patients with Focal Segmental Glomerulosclerosis and Chronic Kidney Disease Controls

Rutger J. Maas,[1] Ruben Poesen,[2] Ben Sprangers,[2] Jeroen Deegens,[1] Jack F. Wetzels,[1] Bjorn Meijers.[2] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Nephrology, Univ Hospital Leuven, Leuven, Belgium.*

Background: Urinary excretion of suPAR has been proposed as a marker for FSGS but little is known about factors that influence suPAR excretion. We have previously demonstrated a correlation between fractional excretion of suPAR (FEsuPAR) and other low molecular weight proteins in nephrotic patients. In the present study we compared FEsuPAR with excretion of proximal tubular marker alpha-1-microglobulin (a1m) in patients with FSGS and non-FSGS CKD.

Methods: We included 27 patients with FSGS and nephrotic syndrome and 54 controls with non-FSGS CKD. Patients were matched for eGFR, age and gender. Serum and urinary suPAR were measured by ELISA (R&D Systems, Minneapolis, MN), and urinary a1m was measured by immunonephelometry in the same samples.

Results: Patients with FSGS had higher total proteinuria and lower serum albumin compared to patients with CKD. Median urinary suPAR was 281 (range 46 - 906) pmol/μmol creatinine in patients with FSGS and 236 (range 63 - 889) pmol/μmol creatinine in CKD controls ($P = 0.37$). There was a significant correlation between FEsuPAR and urinary a1m excretion in patients with FSGS (Spearman's rho 0.41; $P=0.03$), as well as in non-FSGS CKD patients (Spearman's rho 0.56; $P<0.01$, Figure 1).

Conclusions: We did not find significant differences between urinary suPAR in patients with FSGS and non FSGS CKD. There was a significant correlation between FE suPAR and urinary a1m excretion, suggesting that there is tubular reabsorption of suPAR.

Hypercholesterolemia in Nephrotic Syndrome Is Related with Enhancing Cholesterol Absorption Dependent with Niemann-Pick C1-Like 1

Masao Kikuchi,[1] Yuji Sato,[1] Kazuo Kitamura,[1] Shouichi Fujimoto.[2] *[1]Dept of Internal Medicine, Circulatory and Body Fluid Regulation, Faculty of Medicine, Univ of Miyazaki, Miyazaki, Japan; [2]Dept of Hemovascular Medicine and Artificial Organs, Univ of Miyazaki, Miyazaki, Japan.*

Background: Although hypercholesterolemia in nephrotic syndrome is generally considered due to increased production of lipoprotein by the mechanism of compensation for hypoproteinemia, there is still no convincing evidence for this hypothesis, especially in human. We previously reported at ASN annual meeting that the serum cholestanol, a marker of cholesterol absorption, is elevated in patients with nephrotic syndrome compared to those in complete remission. Furthermore, the serum cholestanol is correlated with the severity of nephrotic syndrome. But, the relationship between nephrotic syndrome and choresterol absorption has been not fully investigated yet.

Methods: We made a comparison of lipid profile between nephrotic patients (NS) and 210 healthy subjects (CON) who were not treated with a cholesterol lowering drug and were not suffering from proteinuria. We investigated the serum cholestanol, campesterol and sitosterol, as markers of cholesterol absorption, and lathosterol as a marker of cholesterol synthesis in addition to total cholesterol, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol and triglyceride. Moreover, we examined mRNA expression of Niemann-Pick C1-like 1 (NPC1L1), that plays a pivotal role in cholesterol absorption, by using rats with puromycin aminonucleoside (PAN)-induced nephrosis.

Results: The all lipid parameters excluding high-density lipoprotein cholesterol in NS were high relative to CON. The ratio of cholesterol absorption markers (cholestanol, campesterol and sitosterol) to total cholesterol in NS were elevated compared to CON, but the ratio of cholesterol synthesis marker (lathosterol) to total cholesterol was not significantly different between NS and CON. NPC1L1 mRNA expression in the PAN-induced nephrosis approximately doubled compared to pair-fed control ($p=0.003$, $n=9$).

Conclusions: Cholesterol absorption should contribute to the mechanism of nephrotic syndrome-associated hypercholesterolemia.

SA-PO526

Effect of Metreleptin Therapy on Proteinuria in Different Forms of Human Lipodystrophy

Meryl A. Waldman,[1] John D. Christensen,[2] Xiongce Zhao,[2] Elaine K. Cochran,[2] James E. Balow,[1] Phillip Gorden,[2] Rebecca J. Brown.[2] *[1]NIDDK, Kidney Disease Branch, NIH, Bethesda, MD; [2]NIDDK, DEOB, NIH.*

Background: Acquired and congenital lipodystrophies (LD) are characterized by partial or complete absence of adipose tissue, low levels of leptin with metabolic consequences including severe insulin resistance with diabetes, severe dyslipidemia and ectopic fat accumulation. Treatment with recombinant human leptin (metreleptin) has been shown to improve metabolic disease in LD. Here we report patterns of renal pathology in LD and effects of metreleptin on renal parameters.

Methods: 64 patients (pts) with LD received metreleptin for ≥12m in an open-label trial at the NIH Clinical Center from 2000-2013. Serum creatinine (Cr), Cr clearance (CrCL), and urinary protein excretion(Prot) (24 hr collection and Prot/Cr ratio) were analyzed at baseline and follow-up. Renal biopsies (bx) were performed as clinically indicated.

Results: Median age at baseline was 17y. 60% were Caucasian, 15% African American, 25% other. Median duration of therapy was 35m (range 12-149m). At baseline, pts with

congenital generalized LD (CGL) had greater Prot (P=0.017). There were no differences in baseline A1c or lipid levels between groups. Metreleptin led to decline in proteinuria in all groups but was only significant in the CGL group.

	Baseline	Last Available	Paired Test
Acquired generalized (N=13)	1831±3192	1215±2826	0.20
Acquired partial (N=5)	1099±558	579 ±754	0.25
Congential generalized (N=30)	1875±2464	759±1194	<0.0001
Familial partial (N=16)	383±528	264±246	0.92

CrCL did not significantly change with therapy (mean baseline CrCL 180 ml/min). Of 12 renal bx performed at baseline, focal segmental glomerulosclerosis (FSGS) was seen in 7, diabetic nephropathy (DN) in 3 and membranoproliferative GN in 2.

Conclusions: Proteinuria is common in patients with different forms of LD. FSGS and DN are the predominate histologies. CGL patients tended to have greater proteinuria at baseline, and better improvement in proteinuria with metreleptin. The cause of Prot and mechanisms by which metreleptin leads to improvement is unclear, but may be related to improvements in metabolic parameters and glomerular lipotoxicity.

SA-PO527

Serum 25-Hydroxy-Vitamin-D Correlation with Serum Albumin and 24-Hour Proteinuria in Glomerulopathies Epitácio Rafael da Luz Neto, Simone C. Lo, Alcino Pires Gama, Cristiane B. Dias, Lectícia Jorge, Luis Yu, Viktoria Woronik. *Div of Nephrology, Univ of Sao Paulo, Sao Paulo, SP, Brazil.*

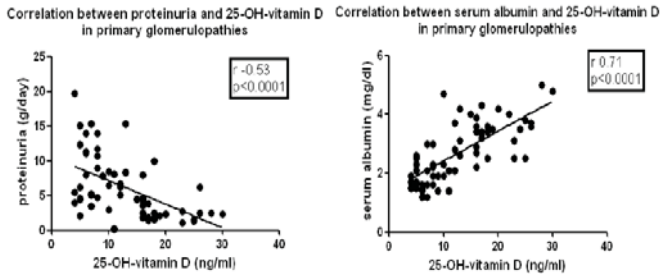
Background: Nephrotic syndrome is associated with vitamin D deficiency. Urinary losses of protein-bound intermediate metabolites of this vitamin are thought to contribute to the deficiency state as well as other factors, such as inflammatory states. The aim of this study is to evaluate possible correlations between serum 25-hydroxy-vitamin D (s25OHD) levels, 24-hour proteinuria (24PTN) and serum albumin considering nephrotic and subnephrotic states as well as inflammatory background of primary glomerulopathies (PG) in contrast to lupus nephritis (LN).

Methods: PG (n=57), LN (n=38) and others (n=22) patients medical records with proteinuria ≥ 1.5 g were reviewed. PG group was composed of FSGS (n=30), MN (n=14), IgAn (n=5), MPGN (n=4) and MCD (n=4).

Results: Subnephrotic group compared to nephrotic showed higher s25OHD levels (table 1). Considering primary glomerulopathies there was correlation between s25OHD levels and 24PTN as well as with serum albumin (fig. 1). Correlations were absent in LN group (not shown).

	Subnephrotic (n=54)	Neprotic (n=63)
Age (y)	40.9 ± 17.9	42.6 ± 16.7
Female (%)	68.5	46
24PTN (g/d)*	1.9 ± 0.8	7.5 ± 3.5
Albumin (g/dl)*	3.2 ± 0.8	2.4 ± 0.7
s25OHD (ng/ml)*	17.6 ± 8.8	12.1 ± 7.3
eGFR (ml/min/1.73 m^2)	52 ± 44	51 ± 44
Calcium (mg/dl)	4.9 ± 0.3	4.7 ± 0.3
Phosphorus (mg/dl)*	3.9 ± 1.1	4.3 ± 0.9
PTHi (pg/ml)	98 ± 85	79 ± 84

*p<0.05



Conclusions: Serum 25OHD levels in primary glomerulopathies showed negative correlation with 24PTN and positive correlation with serum albumin while in LN there was no correlation. So far, we could speculate that inflammatory state of LN is an important factor for maintaining s25OHD levels besides glomerular permeability and urinary protein loss.

SA-PO528

Role of Pituitary Adenylate Cyclase-Activating Polypeptide in the Nephrotic Kidney Benedicte Eneman,[1] Kathleen Freson,[2] Lambertus P.W.J. Van den Heuvel,[1] Chris Van Geet,[2] Henry Dijkman,[3] Elena N. Levtchenko.[1] *[1]Pediatric Nephrology, Dept of Growth and ReGeneration, Catholic Univ of Leuven, Leuven, Belgium; [2]Dept of Molecular and Vascular Biology, Catholic Univ of Leuven, Leuven, Belgium; [3]Dept of Pathology, Radboud Univ Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: Recent studies have reported a nephroprotective effect of PACAP in a variety of renal disease models. Recently, we discovered plasma PACAP deficiency in nephrotic syndrome (NS) due to urinary loss. However, renal PACAP expression in NS has never been studied. We now explored the expression of PACAP and its receptors PAC1, VPAC1 and VPAC2 in healthy and nephrotic kidney tissue and studied a potential nephroprotective role of PACAP in NS.

Methods: RT-PCR, qPCR, werstern blot and IF stainings were performed for PAC1, VPAC1 and VPAC2 in 3 renal cell lines: conditionnally immortalized (ci)proximal tubular epithelial cells (PTEC), podocytes and glomerular microvascular endothelial cells (GMVEC). IH and IF stainings for PACAP, PAC1, VPAC1 and VPAC2 were performed on kidney tissue from 4 healthy children and 2 children with congenital and 5 with acquired NS. ciPTECs were exposed to an albumin concentration range, mimicking proteinuria related damage, with and without addition of recombinant PACAP. WST-1 cell viability tests were performed.

Results: ciPTEC showed VPAC1 expression. All other cell lines did not express the 3 receptors. PACAP and VPAC1 were found in the tubular epithelial cells and VPAC1 and VPAC2 were found in the glomeruli on renal tissue of both NS patients and controls. PACAP expression was more pronounced in tubular epithelial cells of NS patients than of controls. Cell viability in ciPTECs decreased with increasing albumin concentrations. Addition of recombinant PACAP had a protective effect on cell viability.

Conclusions: Our observations provide new insights in the expression of PACAP and its receptors in the healthy and nephrotic kidney. PACAP prevents albumin induced damage of ciPTECs. The enhanced presence of PACAP in tubular epithelial cells in nephrotic kidneys is probably due to re-uptake of filtered PACAP and possibly plays a protective role in proteinuria related damage.

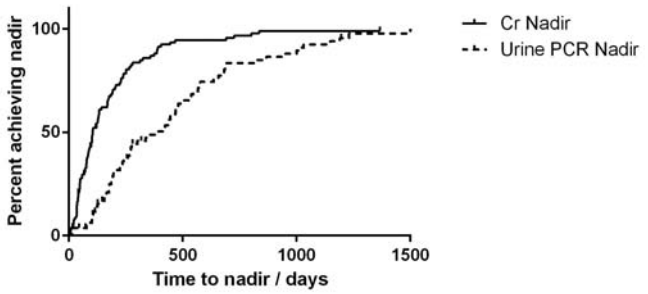
SA-PO529

Time Taken to Achieve Stable Renal Function in ANCA Vasculitis: Implications for Management and Disease Scoring Amin Oomatia,[1] Sarah Margaret Moran,[2] Claire Kennedy,[3] Sally Hamour,[1] Aine Burns,[1] Mark Alan Little,[3] Alan D. Salama.[1] *[1]Centre for Nephrology, UCL, United Kingdom; [2]Nephrology, Univ College Cork; [3]Trinity Health Kidney Centre, Ireland.*

Background: Renal involvement in ANCA associated vasculitis (AAV) is common and found in 50% of patients at presentation. Serum creatinine and proteinuria provide important information regarding renal disease activity. However, no accurate data about the time taken to achieve maximal improvement in creatinine and UPCR exist. This has implications for management and disease scoring with BVAS.

Methods: We identified the time to nadir serum creatinine and UPCR after treatment of ANCA associated glomerulonephritis (AAGN) in three seperate cohorts from UK and Ireland. Nadir was defined as a difference of < 5% between two consecutive percentage change differences in creatinine or UPCR compared to baseline. We included all patients with AAGN and renal impairment defined by eGFR<90, within 2 weeks of diagnosis. We excluded those with <3 measurements and those remaining dialysis dependent >3 months.

Results: We identified 103 patients with AAV and renal involvement, median age 64 (range 13-94) years, 50.4% male and 79.6% white British or Irish. Median presenting creatinine was 320(range 56-431) mcmol/l. MPO-ANCA was present in 55 patients, PR3-ANCA in 47 and one patient was ANCA negative. When calculating nadir for creatinine and PCR, 95(92%) and 69(67%) patients had sufficient data, respectively. Nadir creatinine was achieved at median 101 days (range 6-836), nadir PCR at 337 days (range 14-1733).



Conclusions: There is a significant delay in achieving nadirs in creatinine and proteinuria, which occur at later time points than conventionally defined clinical remission. This suggests that ongoing renal recovery is still possible for almost one year from diagnosis which should be taken into account by contemporary scoring systems.

SA-PO530

Analysis of Long-Term Morbidity in Patients with ANCA-Associated Renal Vasculitides - Data from a National Registry Vladimir Tesar, Zdenka Hruskova, Eva Jancova. *Dept of Nephrology, Charles Univ and General Univ Hospital, Prague, Czech Republic.*

Background: While long-term survival of ANCA-associated vasculitides (AAV) has been improved in the last decades, patients accumulate significant long-term disease- and treatment-related damage. The aim of this study was to describe damage in AAV patients with renal involvement included in a nationwide registry.

Methods: Clinical data from a total of 686 patients (M/F 329/357, median age at diagnosis 58 years, 89% with renal involvement) recruited from sixteen vasculitis centres participating in the Registry since 2009 were available for analysis. The damage was assessed using the Vasculitis Damage Index (VDI).

Results: VDI was available for 485/613 patients with renal involvement (biopsy-proven in 74%; 156 required dialysis anytime during the disease course and 85 were on RRT at the last visit; median S-creatinine in non-dialysed patients at the last visit 1.35 mg/dL) with median time from diagnosis 71 (range 0-480) months. The last VDI ranged between 0 and 16, with median 4; and only 42 patients (8.6%) had no items of damage. Even though the accumulation of damage increases during the long-term follow-up, it is significant in a number of patients even after the first year and seems to slow down in the subsequent years (median VDI=2.5 at 1 year, median VDI=3 at both 2 and 3 years). The most frequently scored items included those related to renal involvement: hypertension (61.2%), proteinuria (50.9%) and impaired glomerular filtration rate (48.5%). Among the other items, diabetes (17.9%), osteoporosis (17.7%), peripheral neuropathy (15.5%), cataract (14.2%) and nasal blockage/crusting (14%) were the most commonly represented.

Conclusions: In the studied population, both treatment- and disease-related damage was present, and was significant in a number of AAV patients with renal involvement. Earlier diagnosis and less toxic therapies are needed to decrease the damage burden in patients with AAV in the future.

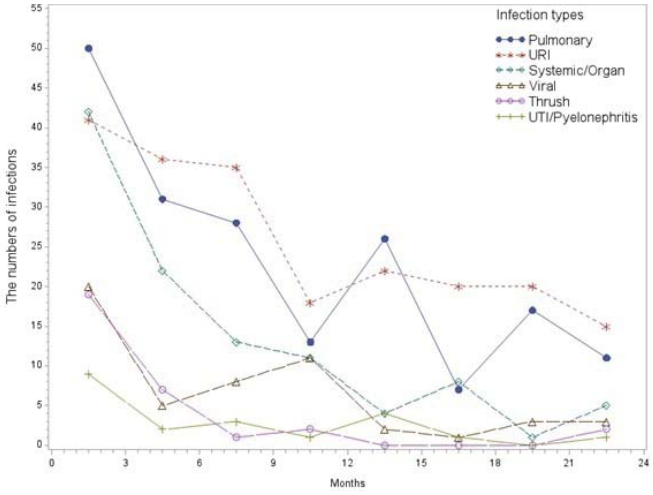
SA-PO531

Timing and Types of Infections After Diagnosis of Antineutrophil Cytoplasmic Antibody Associated Vasculitis JulieAnne G. McGregor, Caroline J. Poulton, Jason M. Kidd, Suzanne L. Katsanos, Lindsey R. Goetz, Yichun Hu, Patrick H. Nachman, Ronald J. Falk, Susan L. Hogan. *UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC.*

Background: Disease control in AAV with immunosuppression is effective but leads to serious burden of infections. Study goal was to evaluate timing and type of infections in an inception cohort with biopsy-proven AAV (1992-2011).

Methods: All patients were immunosuppressed. Infections were assessed from medical records. Severe infections were those requiring hospitalization or causing death. Induction therapy included cyclophosphamide and corticosteroids and maintenance therapy was with azathioprine, mycophenolate mofetil or rituximab. Positive cultures from all available sources were reviewed.

Results: 489 patients (median age 57 yrs; 53% male, 55% MPO-ANCA) were followed for a median of 2.8 yrs. Cumulative incidence of any infection at 1, 2 and 5 years was 51%, 58% and 65%, and of severe infections was 22%, 23% and 26%. Pulmonary and upper respiratory infections were the most common, highest in the first 3 months.



Beyond one year, there were 116 severe infections in 52 patients with 28% during relapse and 72% during maintenance therapy. In 128 patients who had cultures within 24 months, 112 patients had 192 positive cultures. Staphylococcus aureus was the most frequent organism (41%) followed by gram negatives (23%) and yeast (15%). There was one Pneumocystis carinii pneumonia 6 weeks following treatment initiation.

Conclusions: Prophylactic therapy targeted to reduce pulmonary and upper respiratory as well as S. aureus infections could be critical to decrease infectious morbidity in AAV, especially in the first 3 to 12 months. Burden of severe infections beyond 1 year is more commonly associated with maintenance therapy than relapse treatment.

SA-PO532

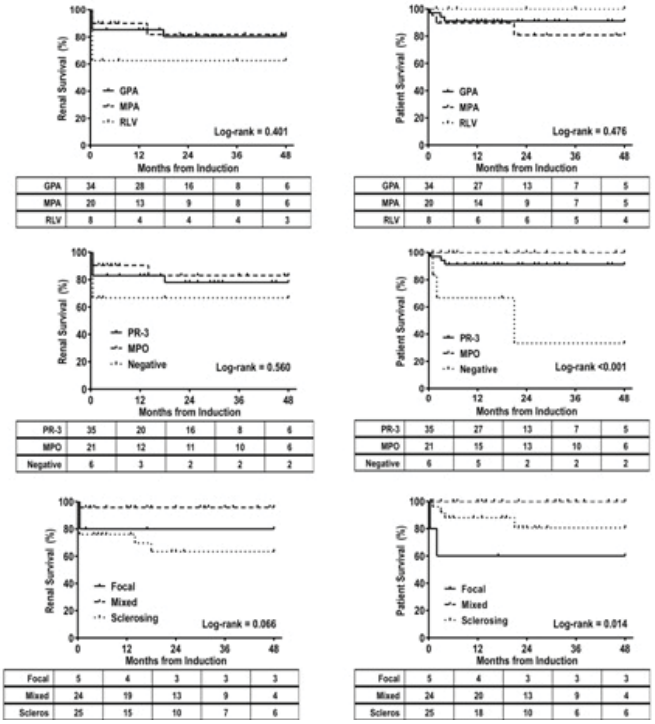
Clinical Presentation and Outcome Prediction of Clinical, Serological and Histopathological Classification Schemes in ANCA-Associated Vasculitides Juan M. Mejia-Vilet, Bertha Manuela Cordova Sanchez, Norma O. Uribe-Uribe, Luis E. Morales-Buenrostro, Ricardo Correa-Rotter. *Nefrologia y Metabolismo Mineral, Inst Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.*

Background: Various classification schemes have been developed for ANCA associated vasculitis (AAV), with actual debate focusing on their clinical and prognostic performance.

Methods: 62 renal biopsy proven AAV were retrospectively analyzed and classified in clinical (granulomatosis with polyangiitis [GPA], microscopic polyangiitis [MPA], renal limited vasculitis [RLV]), serological (PR3-ANCA, MPO-ANCA, ANCA-Negative) and histopathological (focal, crescenteric, mixed, sclerosing) groups and followed up until death, loss to follow-up or october 2013. Outcomes included remission, relapse, renal and px survival.

Results: In this mexican-mestizo population, GPA was the most frequent AAV while RLV and ANCA-negative subgroups presented with the worst renal disfunction. PR3-ANCA patients had a higher probability of relapse (HR 2.06, p=0.043). Clinical and serological classification did not predicted remission, renal or patient survival. Histopathological classification showed poorer remission and renal prognosis for sclerosing group and those with <25% normal glomeruli, and adequately separated 24 mo clinical evolution, but it did not predicted patient survival.

Figure 1. Renal survival (a,b,c) and Patient survival (d,e,f) at 48 months according to clinical (a,d), serological (b,e) and histopathological (c,f) classification.



Renal replacement therapy (RRT) requirement (HR 35.4, CI 3.84-326, p=0.003) and proteinuria (HR 1.7, CI 1.13-2.56, p=0.011) at diagnosis predicted renal survival, while age (HR 1.08, CI 1.01-1.15, p=0.044) predicted patient survival.

Conclusions: ANCA serological classification may predict AAV relapses, but neither clinical or serological categories predict renal nor patient survival. Renal function and proteinuria at presentation, age and histopathology constitute the main outcome predictors and should be considered for individualized management.

SA-PO533

Monoclonal Gammopathy Detection in ANCA-Associated Vasculitis – Attack of the Clone? Sarah Margaret Moran,[1] Mark Alan Little,[2] Michael Clarkson.[1] *[1]Renal Medicine, Cork Univ Hospital, Cork, Ireland; [2]Trinity Kidney Health, Trinity College Dublin, Ireland.*

Background: Immunoglobulin (Ig) levels are routinely used as surrogate markers of the degree of immunosuppression in patients with anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV). Incidental detection of a monoclonal immunoglobulin (MIg) band may raise concern about the presence of an underlying plasma cell dyscrasia. MIg are detected in 1 - 3.2% of the general population. While ANCA are most commonly of the IgG subtype concomitant IgM ANCA may also occur in up to 1/3 of patients with pulmonary haemorrhage.

Methods: Laboratory records of all patients attending a Regional Vasculitis Clinic were searched for MIg reported as part of their immunoglobulin profile. Detailed clinical and laboratory parameters were also recorded.

Results: 90 patients were identified. 21 (23%) had MIg bands, most commonly IgG. 17 (81%) of the patients with MIg were ANCA positive. There was an equal distribution of MPO (8) and PR3 (9) specificity.

	Monoclonal IgG	Monoclonal IgM	Total Monoclonal Ig
ANCA positive	16	1	17
ANCA negative	2	2	4
Total	18	3	21

MIgG levels in the ANCA positive patients: Range 3.04 -18.07g/L; Mean 10.42g/L; Only 3/17 had an absolute IgG value above the normal range. MIgM levels in both ANCA positive and negative patients:Range 0.93 - 5.5g/L; 2/3 patients had absolute IgM values above the normal range. ANCA titres in MIg band patients: Range 3.8-214 IU/mL; Mean 59.7IU/mL. ANCA titres in non-MIg band patients: Range 4.6-191 IU/mL; Mean 59IU/mL. No patients were developed plasma cell dyscrasias during follow up.

Conclusions: The incidence of MIg in this cohort is at least 8 times higher than the general population (23% versus 1-3%). MIg may reflect a circulating monoclonal ANCA. Further investigation needed to ascertain whether column bead extraction of ANCA leads to resolution of the MIg band.

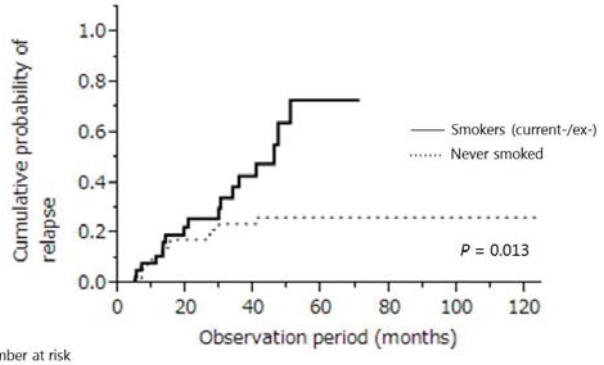
SA-PO534

Smoking Is a Risk Factor for the Relapse of Antineutrophil Cytoplasmic Antibody (ANCA)–Associated Vasculitis Makoto Yamaguchi, Sawako Kato, Takuji Ishimoto, Tomoki Kosugi, Waichi Sato, Naotake Tsuboi, Masashi Mizuno, Yasuhiko Ito, Seiichi Matsuo, Shoichi Maruyama. *Dept of Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.*

Background: Several studies have shown predictors of relapse in antineutrophil cytoplasmic antibody (ANCA)–associated small-vessel vasculitis. However, whether smoking increases the risk for the relapse is unknown.

Methods: This is a multicenter retrospective cohort study, including 123 patients with granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) from 7 nephrology centers in Japan. The dose-response relationships between cigarette smoking and the outcomes were assessed by using multivariate Cox proportional hazards models adjusted for clinically relevant factors. The primary and secondary outcomes were first relapse and first remission, respectively. A relapse was defined as clinical signs of vasculitic activity in any organ system. Remission was defined as the absence of clinical signs and symptoms of active vasculitis (BVAS.0).

Results: Throughout the observation period (median, 40 months; interquartile range, (20–67 months), 114 (92.7%) and 33 (28.9%) patients developed at least 1 remission and 1 relapse, respectively. Log-rank test showed that smokers were significantly associated with relapse ($P = 0.013$).



Multivariate Cox proportional hazards models revealed current smoking (adjusted hazard ratio [HR], 6.60 [95% confidence interval (CI), 2.39–18.4]) and cumulative smoking of ≥50 pack-years (adjusted HR, 5.05 [95% CI, 1.70–14.7]) to be associated with relapse. However, smoking was not associated with remission.

Conclusions: Smoking is a significant and dose-dependent risk factor for the relapse of ANCA–associated vasculitis. All patients with ANCA–associated vasculitis who smoke should be encouraged to quit.

SA-PO535

Long Term Damage in Patients with ANCA Associated Vasculitides Marilina Antonelou, Suceena Alexander, Anne Frances Doyle, Massimiliano Morreale, Stephen Paul McAdoo, Anisha Tanna, Charles D. Pusey, Ruth M. Tarzi. *Imperial College Kidney and Transplant Inst, London, United Kingdom.*

Background: ANCA-associated vasculitis (AAV) is associated with significant long term damage due to the disease itself and its treatments.

Methods: We collected retrospective clinical data from 265 patients with AAV between 1976-2012, and assessed the burden of disease and treatment-associated damage in our cohort over this time period.

Results: 124 patients (47%) were male. The median age at presentation was 55±16.8. Twenty six percent of patients were MPO-ANCA positive, 44% PR3-ANCA, 12% MPO- and PR3-ANCA and 20% ANCA negative. The mean follow up was 9.6±0.8 years. Forty three percent of MPO-ANCA patients and 54% PR3-ANCA patients experienced one or more relapses during follow up. During the time period management has evolved with a reduction in cyclophosphamide (CYP) exposure and increasing use of rituximab along with corticosteroids for induction. Azathioprine (AZA) or mycophenolate mofetil (MMF) were used for maintenance. The median cumulative dose of oral CYP was 5.0±50.9g, pulse CYP 3.5±4.4g and corticosteroids 12.1±47.6g. Median duration of treatment with AZA was 3.6±55.5 years and MMF 2.7±2.9 years. Long term complications occurring after the diagnosis of AAV included hypertension (31.3%), cardiovascular disease (20%), diabetes (12.9%), cataract (10.9%), venous thromboembolism (9.1%) and end-stage renal failure (14%). An association between exposure to steroids and osteoporosis was noted ($p= 0.001$). Thirty three cancers developed in 29 patients, including non-melanoma skin cancers (10), lymphoma (3), leukaemia (1), bladder cancer (1). Nine per cent of patients died during active follow up. Causes of death included cardiovascular disease (7), infection (5), active vasculitis (3). There was a higher incidence of cancer (all cause) among patients treated with oral (19/84, 22.6%) versus pulse CYP (4/70, 5.7%) ($p<0.05$). There was an association between duration of AZA use and cancer (all cause) ($p<0.05$).

Conclusions: Management of cardiovascular risk factors and bone health is an important aspect to the chronic management of AAV. There is a need to reduce the toxicity of therapies in current use.

SA-PO536

Urinary and Serum Soluble Urokinase Receptor Levels Predicts the Therapeutic Responsiveness of Nephrotic Syndrome and ANCA-Glomerulonephritis Keiji Fujimoto, Hiroki Adachi, Hiroshi Okuyama, Hideki Yamaya, Hitoshi Yokoyama. *Div of Nephrology, Kanazawa Medical Univ, Uchinada, Ishikawa, Japan.*

Background: The relationship between the therapeutic responsiveness of nephrotic syndrome (NS) and the changes of urinary (u-) and serum (s-) soluble urokinase receptor (suPAR) levels after therapy and the activation of β3 integrin is still unclear.

Methods: We investigated s- and u-suPAR levels in NS (37 cases) and ANCA-glomerulonephritis (ANCA-GN) (13 cases) and 20 healthy control subjects. We also examined the renal expression of activated β3 integrin (AP-5) by immuno-staining in primary NS, crescentic GN and normal tissues.

Results: The pretreatment s- and u-suPAR levels in NS or ANCA-GN were higher than those in the normal controls, but no differences were noted among the pathological types of NS and ANCA-GN. The pretreatment s-suPAR levels were correlated inversely with eGFR in NS and ANCA-GN, and positively with CRP in ANCA-GN. In addition, a positive correlation between pretreatment u-suPAR and proteinuria was noted in NS. By the time-course changes in the s- and u-suPAR levels over 2 months after therapy (Δ2M s- and u-suPAR), we could differentiate intractable NS from non-intractable NS (Δ2M s-/u-suPAR, $p=0.005$, $p=0.007$, respectively), and MCNS from FSGS (Δ2M s-/u-suPAR, $p=0.007$, $p=0.048$, respectively). The s-suPAR levels at 2 months were 3,373 pg/ml or higher in intractable NS (n=27, AUC=0.913, $p=0.002$). In a multiple regression analysis ($R^2=0.41$, $p=0.007$), therapeutic response was a significant predictor of Δ2M s-suPAR, whereas CRP and eGFR were not. In ANCA-GN, a positive correlation was noted between s-suPAR level before therapy and clinical severity, especially requiring hemodialysis. Activated β3 integrin was mainly detected on proximal tubular epithelium, but not glomerular capillaries in NS.

Conclusions: These findings suggested the change of s- and u-suPAR levels after therapy may serve as a clinical marker to judge the treatment response of NS and the differentiation of MCNS from FSGS. S-suPAR predicts the severity and prognosis of ANCA-GN. In addition, suPAR may activate β3 integrin on proximal tubules in human.

SA-PO537

Characteristics and Outcome of MPO-ANCA-Associated Glomerulonephritis in Patients Discharged with Seronegative for MPO-ANCA Tomohiro Saito,[1] Masayuki Iyoda,[1] Yukihiro Wada,[1] Makoto Watanabe,[2] Taihei Suzuki,[2] Ysutaka Yamamoto,[1] Ken Iseri,[1] Kei Hihara,[1] Takanori Shibata.[1] *[1]Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine, Tokyo, Japan; [2]Div of Nephrology, Makita General Hospital, Tokyo.*

Background: A role for antineutrophil cytoplasmic autoantibody (ANCA) in the management of ANCA-associated glomerulonephritis (GN) is controversial.We attempted to clarify the clinical significance of seronegative for myeloperoxidase (MPO)-ANCA at the time of discharge in patients with ANCA-GN.

Methods: We retrospectively reviewed 48 patients (29 female; average age, 69.1 years) who were diagnosed as having MPO-ANCA-GN at Showa University hospital from January 1999 to December 2012. Subjects were divided into two groups: patients discharged with seronegative for MPO-ANCA (N-group, n=18) and patients discharged with seropositive for MPO-ANCA (P-group, n=30). The study outcome was relapse, defined as the condition of strengthening immunosuppressive therapy owing to relapse from clinical remission.

Results: Baseline characteristics, including clinical findings, histological features and immunosuppressive therapy, were comparable between the two groups except for the length of hospitalization. The duration of hospitalization was significantly longer in the N-group compared to the P-group (75 ± 29 versus 58 ± 22 days, Mann–Whitney U test, $P<0.01$). During the median follow-up period of 49.0 months (range 13-131 months) in the 48 patients, we observed relapse in 2 cases of N-group (11.1%) and 16 cases (53.3%) of P-group. The cumulative incidence of relapses during the follow-up period was significantly higher in the P-group compared to the N-group (log rank test, $P = 0.010$). Cox's regression model showed that seropositive for MPO-ANCA at the time of discharge increased the hazard ratio for relapse (hazard ratio 4.98; 95 % confidenceinterval 1.84-14.77, $P = 0.001$).

Conclusions: Our results showed that seropositive for MPO-ANCA at the time of discharge is a risk factor for relapse. We suggest that the achievement of MPO-ANCA seronegativity is desirable for the initial treatment of ANCA-GN, even with extending the hospitalization or performing more intensive clinical management.

SA-PO538

CD14 Expression Is Increased on Monocytes of Patients with ANCA Vasculitis, and Correlates with the Surface Expression of ANCA Auto-Antigens Ruth M. Tarzi, Joanne Tsz Ki Liu, Nicola R. Hill, Theresa H. Page, H. Terence Cook, Charles D. Pusey, Kevin Woollard. *Dept of Renal and Vascular Inflammation, Imperial College, London, United Kingdom.*

Background: Monocyte subsets with differing functional properties have been defined by their expression of CD14 and CD16. We set out to assess these subsets in AAV compared with healthy controls, and to determine their surface expression of ANCA autoantigens.

Methods: Flow cytometry for HLA-DR, CD16 and CD16 was performed on blood from 16 patients with active AAV (7 MPO-ANCA positive, 7 PR3-ANCA positive and 2 ANCA negative), 49 patients with AAV in remission (21 MPO-ANCA, 25 PR3-ANCA and 3 ANCA negative at diagnosis), and 21 controls. The proportion of classical ($CD14^{high}CD16^{neg/low}$), intermediate ($CD14^{high}CD16^{high}$) and non-classical ($CD14^{low}CD16^{high}$) monocytes, and surface expression of PR3 and MPO on monocyte subsets was determined.

Results: There was no difference in the proportion of monocytes in each subset in patients with AAV compared with healthy controls, although the absolute number of monocytes was higher in patients with active disease compared with remission patients. However, the expression of CD14 on monocytes was increased in patients with active AAV, compared with patients in remission and healthy controls ($p<0.001$ versus controls, $p<0.01$ versus remission). Patients with PR3-ANCA disease in remission also had increased monocyte expression of CD14 compared with controls ($p<0.01$), whilst the levels were normal in MPO-ANCA disease in remission. PR3 was expressed mainly on classical and intermediate monocytes, whilst MPO was expressed mainly on intermediate and non classical monocytes. There was a correlation between CD14 and both PR3 and MPO expression on classical monocytes in AAV patients ($r=0.79$, $p<0.0001$ and $r=0.47$, $p<0.001$ respectively), but this correlation was not seen in control monocytes.

Conclusions: There were variations in the expression of PR3 and MPO on different monocyte subsets, which may impact on the ability of ANCA of different specificities to interact with these monocyte subsets. The correlation between monocyte CD14 and ANCA autoantigen expression in AAV may contribute to the pathophysiology of bacterial infection in AAV.

Ficolin-1 Is Upregulated in Leukocytes and Glomeruli from Microscopic Polyangiitis Patients Eri Muso. *Div of Nephrology and Dialysis, Center for Nephrology and Urology, Kitano Hospital, Tazuke Kofukai Medical Research Inst, Osaka, Japan.*

Background: Microscopic polyangiitis (MPA) is a systemic autoimmune disease that often has a fatal outcome. Although delineating the molecular pathogenesis is essential for its remedy, an understanding of its molecular mechanism has remained elusive.

Methods: To search for new markers of active lesions that might help better understand the molecular basis of MPA and aid in its diagnosis, DNA microarray analysis with peripheral blood mononuclear cells (PBMCs)was performed for the patients with active MPA and normal control. Ficolin 1,disease specifically upregulated mRNA was detected by immunohistochemistry in glomeruli of pateints and control, Costaining of ficolin-1 dot and CD68 was performed to investigate the cellular origin of ficolin-1 and compared those of local and peripheral cell number.

Results: Compared to normal control, several genes were up- or down-regulated in MPA patients, including up-regulation of the mRNA level of ficolin-1, an innate pattern recognition complement molecule. The amount of ficolin-1, as detected by immunohistochemistry, was higher in the glomeruli of another group of MPA patients than in the glomeruli of control patients who harbored almost normal glomeruli. Many of the ficolin-1 dots were also positive for CD68, suggesting that the ficolin-1–positive cells were monocytes, such as macrophages or dendritic cells. This is not due to the difference in the number of neutrophil or monocytes in the blood samples of MPA and control patients.

Conclusions: Increased ficolin-1 expression could serve as a new marker for the characterization of MPA, especially when it is associated with local active lesions.

Incidence of Anti-Moesin Autoantibody in Patients with Small-Vessel Vasculitis and Kidney Disease Kouju Kamata, Shokichi Naito, Tomoko Okamoto, Mariko Kamata, Chikako Okina, Togo Aoyama, Junya Murano. *Nephrology, Kitasato Univ School of Medicine, Sagamihara, Kanagawa, Japan.*

Background: Newly discovered anti-moesin autoantibody has been proposed as a novel biomarker for anti-neutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV). While, the incidence of anti-moesin autoantibody in patients with kidney disease before treatment has not been reported. This study investigated the incidence of the anti-moesin autoantibody in patients with kidney disease just before treatment.

Methods: Patients aged ≥18 years who underwent initial kidney biopsy for the diagnosis and treatment of kidney disease from 2002 to 2013 were enrolled in this study. Factors analyzed included patient age, gender, serum creatinine level, estimated glomerular filtration ratio (eGFR),urinary protein excretion, serum albumin level, MPO-ANCA level by ELISA (normal value <10 EU) and Birmingham's vasculitis activity score (BVAS) at the time of the kidney biopsy. All the sera were obtained at initial kidney biopsy. The serum anti-moesin autoantibody was semi-quantitatively analyzed by western blotting using recombinant human moesin protein generated in *Escherichia coli* BL21 as an antigen.

Results: Anti-moesin autoantibody was present in the sera of 42% (14/33) of patients with microscopic polyangiitis (MPA), 63% (5/8) of patients with anti-glomerular basement membrane (GBM) disease, 18% (2/11) of patients with IgA vasculitis and 43% (3/7) of patients with lupus nephritis, but was not detected in any of the three patients with granulomatosis with polyangiitis or the 10 with minimal change nephritic syndrome. Birmingham's vasculitis activity score was significantly higher in MPA patients with than without the anti-moesin autoantibody ($p<0.05$), and was significantly higher in MPA patients with both myeloperoxidase (MPO)-ANCA and anti-moesin autoantibody than in MPA patients with MPO-ANCA alone ($p<0.02$). The estimated glomerular filtration rate was significantly lower in MPA patients with both MPO-ANCA and anti-moesin autoantibody than in MPA patients with MPO-ANCA only ($p<0.02$).

Conclusions: Anti-moesin autoantibody is a biomarker of anti-GBM disease, lupus nephritis and IgA vasculitis as well as of AAV and MPA.

SA-PO541

Expression of Calcineurin in Podocytes Associated with Remission of Primary Nephrotic Syndrome Treated by Cyclosporine Ke Wang, Haiyun Wang, Yubing Wen, Xuemei Li, Xuewang Lee, Limeng Chen. *Dept of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China.*

Background: The expression of calcineurin in podocyte was observed in MN and FSGS patients, and associated with the injury of glomerular filtration barrier permeability.The purpose of this study is to observe the association between the expression of calcineurin in podocyte and the efficacy of NS patients treated by calcineurin inhibitor cyclosporine(CsA).

Methods: The clinical records of IMN(n=20)or FSGS(n=10) patients, who treated by CsA for at least 6ms at PUMCH, were reviewed. The expression of WT1,Calcineurin and Synaptopodin in podocytes were tested by immunohistochemical or immunofluorescence staining.

Results: The mean age of these patients was 41.8±20 years. Mean proteinuria,serum albumin and serum creatinine at baseline were (7.65±4.04) g/d, (23.9±5.9) g/L and (77.4±30.3) μmol/L. CsA was given at a dose of (3.08±0.66) mg/kg/d, combination with prednisone[(0.43±0.26) mg/kg/d] in part of patients. Complete remission and partial remission were observed in 6 and 18 patients after 6 m of treatment. Three patients with no expression of calcineurin showed no response to CsA. Compared with no remission patients, the expression of calcineurin in remission groups was significantly higher (10.96 ± 3.69% versus 3.93 ± 2.38%, $P<0.05$). But no significant difference were observed in age, gender, pathology type, proteinuria, renal function, dose and blood drug concentration of CsA. There was no correlation between calcineurin and proteinuria level. The expression of calcineurin accompanied with loss of synaptopodin was confirmed by serial section cutting.The loss of WT1 of podocyte was more obvious in FSGS patients than MN patiens.

Conclusions: The expression of calcineurin may related with the remission of NS patients treated by Cyclosporine.

SA-PO542

Clinical Value of Podocyte and Urinary CD80 in Differentiating Treatment Considerations for Minimal Change Disease and Focal Segmental Glomerulosclerosis Eduardo H. Garin,[1] Jochen Reiser,[2] Nada Alachkar,[3] Changli Wei,[2] Gabriel M. Cara-Fuentes,[1] Richard J. Johnson.[4] *[1]Univ of Florida; [2]Rush Univ Medical Center; [3]The Johns Hopkins Univ; [4]Univ of Colorado.*

Background: Minimal Change Disease (MCD) is associated with increased CD80 expression in podocytes and elevated urinary CD80 excretion during active disease, whereas focal segmental glomerulosclerosis (FSGS) is characterized by mild or absent CD80 podocyte expression and normal urinary CD80 concentration.

Methods: One patient with biopsy proven MCD, one patient with biopsy proven primary FSGS and three patients with FSGS recurrence after transplantation received CD80 blocking antibodies (Abatacept or Belatacept). Urinary CD80 and CTLA-4 were measured by ELISA. Kidney tissue samples were stained for CD80. Random urinary protein/creatinine ratio was measured.

Results: The administration of Abatacept in the MCD patient was associated with a fall in urinary CD80 excretion to an undetectable level followed by transient resolution of proteinuria. CD80-blockers (Abatacept, Belatacept) therapy did not result in any improvement in proteinuria in one patient with primary FSGS and two patients with FSGS recurrence after transplantation despite of the presence of mild CD80 glomerular expression but normal urinary CD80 excretion. One patient with recurrent FSGS after transplantation had elevated urinary CD80 excretion immediately after surgery which fell spontaneously before receiving Abatacept. His proteinuria remained unchanged for 5 days despite of a normal urinary CD80 excretion.

Conclusions: These observations provide clinical evidence that CD80 expressed in podocytes and shed into urine may play a critical role in the development of proteinuria in MCD. In contrast, it is unlikely that CD80 plays a role in FSGS recurrence since urinary CD80 is only increased transiently after surgery and normalization of urinary CD80 does not result in resolution of proteinuria.

Th1 and Th2 Cytokines in Histology and Progression of Idiopathic Nephrotic Syndrome due to Focal Segmental Glomerulosclerosis and Minimal Change Nephropathy

Maria J. Stangou,[1] Christos Bantis,[1] Michael Spartalis,[1] Georgios Toulkeridis,[1] Ioanna Lampropoulou,[1] Nicoletta-Maria Kouri,[2] Aikaterini A. Papagianni,[1] George Efstratiadis.[1] *[1]Dept of Nephrology, Aristotle Univ of Thessaloniki, Hippokration Hospital, Thessaloniki, Greece; [2]Dept of Microbiology, Hippokration Hospital, Thessaloniki, Greece.*

Background: Aim of the present study was to evaluate the role of Th1 and Th2 cytokine levels in distinguishing FocalSegmentalGlomerulosclerosis (FSGS) and MinimalChangeNephropathy (MCN)and their correlation with renal histology and disease outcome.

Methods: Thirty-six patients with FSGS (Age: 41.9±17yrs, Scr=1.7±0.8mg/dl, Upr=4.7±5.5g/24hr), and 21 with MCN (Age: 41.4±15χρ, Scr=1±0.4mg/dl, Upr=7.9±9.3g/24hr) were included in the study. Th1 (IL-2, IL-12, GM-CSF, INF-γ, TNF-α) andTh2 cytokines (IL-4, IL-5, IL-10, IL-13) were measured by multiple cytokine assay, in first morning urinary sample collected at the day of renal biopsy. Levels of cytokines were correlated with renal function and degree of proteinuria.

Results: No significant differences in urinary excretion of all cytokines measured were found between FSGS and MCN patients. In FSGS however, percentage of global sclerosis had significant positive correlation with urinary levels of bothTh1, IL-2, IL-12, GM-CSF, INF-γ, TNF-α (p=0.005, p=0.01, p=0.01, p=0.005, p=0.007 respectively), andTh2 cytokines, IL-4, IL-5, IL-10, IL-13 (p=0.002, p=0.04, p=0.03, p=0.04 respectively). Degree of interstitial fibrosis was correlated with IL-12, INF-γ, TNF-α andIL-4 (p=0.04, p=0.03, p=0.04 and p=0.02 respectively). IL-12 urinary excretion was independent factor correlated with both global sclerosis (R^2=0.3, p=0.009) and interstitial fibrosis (R^2=0.3, p=0.02). Th1 cytokines (IL-2 and GM-CSF) were significantly increased in FSGS patients who did not respond to treatment (p=0.03 and p=0.007, respectively). Th2 cytokines (IL-4, IL-5, IL-10, IL-13) were significantly increased in MCN patients with frequent relapses (p=0.05, p=0.001, p=0.01, p=0.03).

Conclusions: UrinaryexcretionofTh1/Th2 cytokinescannot discriminate FSGS from MCN. Th1 may be involved in pathology and progression of FSGS, while Th2 cytokines are implicated in frequent relapses of nephrotic syndrome in MCN.

Glomerular Collapse -When It Hits, Where It Hits -Does It Matter

Krishan L. Gupta,[1] Raja Ramachandran,[1] Ritambhra Nada,[2] Ashwani Kumar,[1] Ashok Kumar Yadav,[1] Harbir Singh Kohli,[1] Vivekanand Jha.[1] *[1]Dept of Nephrology, ; [2]Pathology, Postgraduate Inst of Medical Education and Research, Chandigarh, India.*

Background: Collapsing focal segmental glomerulosclerosis (cFSGS) and other glomerulonephritis with collapsing pattern (GNcp) presents with massive proteinuria and rapid progression to end stage renal disease (ESRD). Present observational study was undertaken to study the clinicopathological spectrum of cFSGS and compare its clinical behavior to other GNcp and poorly therapy responsive non-collapsing FSGS.

Methods: Patients with a diagnosis of cFSGS and GNcp were prospectively followed. All the patients of cFSGS and GNcp were treated with oral prednisolone (1 mg/kg/day). Patients of lupus nephritis and membranous glomerulonephritis with collapse were managed with cyclophosphamide and oral prednisolone. Patients of cFSGS were compared with a cohort of prospectively followed steroid and tacrolimus (TAC) resistant non-collapsing FSGS. Loss of differentiated podocyte marker molecule (WT-1), gain of immature podocyte marker (Pax 2) and proliferation marker (Ki 67) and Parvo B19 nested PCR were performed in all the three groups. The clinical outcome and histological parameters of cFSGS, GNcp and steroid and TAC resistant FSGS were compared.

Results: The study included 32 patients (22 cFSGS and 10 GNcp). Of the 22 with cFSGS, 11 (50%) patients each presented with nephrotic syndrome and rapidly progressive renal failure. Complete remission, partial remission, steroid resistant nephrotic syndrome, progression to ESRD and death was observed in 3 (9.3%), 1 (3.1%), 7 (21.8%), 17 (53.2%) and 4 (12.5%) patients respectively. There were no differences in the clinical outcome and the histological parameters of patients with cFSGS and GNcp. Patients of cFSGS had higher serum creatinine and advanced tubulointerstitial changes compared to steroid and TAC resistant FSGS.

Conclusions: Glomerular collapse due to either cFSGS or other GNcp is poorly treatment responsive and has a high rate of progression to ESRD. cFSGS has a poorer prognosis than therapy resistant non-collapsing FSGS.

Genomic Analysis Identifies Renal Cell Carcinoma as a New Tumor Type Linked to Aristolochic Acid Exposure

Sandra Karanovic,[1] Xavier Castells,[2] Karla Tomic,[3] Maude Ardin,[2] Jiri Zavadil,[2] Bojan Jelakovic.[1] *[1]School of Medicine, Univ of Zagreb, Croatia; [2]International Agency for Research on Cancer, Lyon, France; [3]General Hospital Slavonski Brod, Croatia.*

Background: Dietary intake of nephrotoxic and carcinogenic aristolochic acid (AA) leads to endemic nephropathy (EN) marked by chronic tubulointerstitial nephropathy (CTN) and urinary tract transitional cell carcinomas (TCC). The role of AA in malignancies other than TCC is unexplored. We aimed to investigate a role of AA in the etiology of renal cell carcinomas (RCC), usually not related to EN, by conducting whole exome sequencing (WES) of tumor-enriched DNAs to detect the presence of the AA mutational signature.

Methods: Four clear cell RCC patients from EN area linked to AA exposure and 1 non-EN RCC case were studied. Of the EN patients, 3 were farmers baking bread from grain from locally grown wheat; 1 patient was diagnosed with CTN and 2 with TCC. All patients were in CKD stages≥3b.Tumor DNA was isolated by macrodissection from FFPE sections, processed for WES libraries, exome capture and sequencing on Illumina HiSeq2500 (multiplexed paired-end 50 bp run, >10x coverage/sample). Reads were aligned by BWA, variants called by GATK, annotated by ANNOVAR and genetic variants observed in normal population removed. The detection of the AA signature was performed by customized R functions.

Results: High A:T>T:A transversion rates (0.9 to 1.8 /Mb) were found in all EN RCC samples. Three cases had A:T>T:A (48.1%,38.2% and 21.6%) and 1 tumor was borderline positive (15.2% A:T>T:A). The non-EN RCC control was negative (6.4% A:T>T:A). In the positive samples the mutations occurred mainly in the C**A**G context and on the coding strand, meeting all definition criteria for the AA mutational signature.

Conclusions: Our study finds AA mutational signature in 3 EN patients with RCC, suggesting a possible causal involvement of AA in the RCC etiology, with new implications for the worldwide RCC incidence due to widespread unregulated use of AA-containing herbs. Extension of this study is underway to validate the preliminary results in a larger cohort of cases. Supported by grant 04-38 Cro Nat Foundation and IARC regular budget.

SA-PO546

Safety and Efficacy of Eculizumab in Pediatric Patients with aHUS, with or without Baseline Dialysis

Johan Vande Walle,[1] Larry A. Greenbaum,[2] Camille L. Bedrosian,[3] Masayo Ogawa,[3] John Kincaid,[3] Chantal Loirat.[4] *[1]Ghent Univ Hosp, Ghent, Belgium; [2]Emory Univ, Atlanta, Georgia; [3]Alexion Pharmaceuticals, Cheshire, CT; [4]Assistance Publique-Hopitaux de Paris, Hopital Robert Debre, Paris, France.*

Background: Atypical hemolytic uremic syndrome (aHUS) is characterized by chronic, uncontrolled complement activation and thrombotic microangiopathy (TMA). The objective of this analysis was to characterize the safety and efficacy of ECU in aHUS pediatric pts with dialysis (DIAL) and without dialysis (N-DIAL) at baseline (BL).

Methods: Subanalysis of an open-label, single-arm trial in pts with aHUS aged 1 month to <18 y and wt ≥5 kg was performed. Primary outcome was complete TMA response during 26 weeks (wks) of ECU treatment (tx). Pts were vaccinated against *N. meningitidis*. Inclusion criteria included platelet (plt) count <150x10^9/L, LDH ≥1.5xULN, and SCr ≥97th percentile for age at screening. Exclusion criteria included ADAMTS-13 activity <5% and Shiga-toxin–producing *E. coli* infection.

Results: 12 of 22 pts (55%) received ECU without first receiving plasma exchange/infusion. ECU improved plt count (x10^9/L) in both DIAL (149.8; *P*=0.0150) and N-DIAL (180.2; *P*=0.0003) pts. eGFR (mL/min/1.73 m^2) improved in DIAL (57.7; *P*=0.0568) and N-DIAL (70.3; *P*=0.0056) pts. Of BL DIAL pts, 9/11 (82%) discontinued dialysis by 26 wks. No pt began new dialysis. At Wk 26, 2 pts were on dialysis. Adverse events were similar among groups.

Conclusions: ECU led to improvements in hematologic and renal parameters in BL DIAL and N-DIAL pediatric pts with aHUS. 82% of BL DIAL pts discontinued dialysis by Wk 26, and no pt started new dialysis. Increases in eGFR were observed for both DIAL and N-DIAL pts at Wk 26. These results are consistent with data reported from a retrospective ECU trial in 19 pediatric pts (aged 2 months to 17 y), where no pt required new dialysis during ECU tx.

Baseline Characteristics	DIAL (n=11)	N-DIAL (n=11)	P-value[a]
Age at first infusion, mean (range), years	5.5 (0.0–17.0)	7.7 (1.0–17.0)	0.25
Gender, Female, n (%)	4 (36.4)	6 (54.5)	0.67
Race, n (%) Asian White Other	0 10 (91) 1 (9)	2 (18) 8 (73) 1 (9)	NE
Duration of aHUS clinical manifestation to first ECU dose, median (range), months	0.20 (0.03–1.84)	0.18 (0.03–4.26)	0.50
First clinical TMA manifestation, n (%)	10 (90.9)	6 (54.5)	0.15
Identified complement abnormalities, n (%)	5 (45.5)	5 (45.5)	1.00
Platelet count x10^9/L, mean (SD)	326.6 (94.2)	69.4 (43.3)	0.068
LDH >ULN, n (%)	8 (72.7)	11 (100)	0.45
eGFR[b] mL/min/1.73 m^2, mean (SD)	11.2 (3.9)	94.2 (30.0)	<0.0001

Efficacy Outcomes at Week 26	DIAL (n=11)	N-DIAL (n=11)	P-value[a]
Complete TMA response[c,d], n (%) [95% CI]	6 (54.5) [23–83]	8 (72.7) [39–94]	0.66
Platelet count normalization (≥150 x 10^9/L), n (%) [95% CI]	11 (100) [72–100]	10 (90.9) [59–100]	1.00
Platelet count change from baseline (x10^9/L)[e], mean (SD)	149.8 (101.0) P=0.0150[f]	180.2 (34.9) P=0.0003[f]	0.94
LDH normalization, n (%) [95% CI]	9 (81.8) [48–98]	9 (81.8) [48–98]	1.00
Hematologic normalization[g], n (%) [95% CI]	9 (81.8) [48–98]	9 (81.8) [48–98]	1.00
eGFR increase from baseline (mL/min/1.73 m^2)[e], mean (SD)	57.7 (57.3) P=0.0568[f]	70.3 (37.1) P=0.0056[f]	0.076
eGFR improvement ≥25 mL/min/1.73 m^2, n (%) [95% CI]	9 (81.8) [48–98]	10 (90.9) [59–100]	1.00
Patients on dialysis at baseline who discontinued dialysis, n/N (%)	9/11 (81.8)	N/A	NE
Patients on dialysis at 26 weeks	2	0	0.48

[a]P-values were generated by statistical comparisons between subgroups.
[b]eGFR calculated using the Schwartz formula: eGFR (mL/min/1.73 m^2) = 0.413 x height (cm) / SCr (mg/dL).
[c]Defined as (1) platelet count normalization (≥150 x 10^9/L); (2) LDH normalization (LDH≤ULN); and (3) improvement of renal function (≥25% increase in serum creatinine from baseline).
[d]Complete TMA response confirmed by 2 consecutive measurements obtained 24 weeks apart.
[e]Assessment at Week 27.
[f]P-values generated by statistical comparisons between values at 27 weeks and values at baseline.
[g]Defined by normalization of platelet count (≥ 150 x 10^9/L) and LDH (LDH≤ULN) sustained for ≥2 consecutive measurements obtained ≥4 weeks apart.
CI, confidence interval; LDH, lactate dehydrogenase; NE, not evaluated; SCr, serum creatinine; SD, standard deviation; ULN, upper limit of normal.

Management of Hepatitis-Associated Renal Autoimmunity Anke Schwarz,[1] Heiner Wedemeyer,[2] Hermann G. Haller.[1] *[1]Nephrology, Hannover Medical School, Hannover, Germany; [2]Hepatology, Hannover Medical School, Hannover, Germany.*

Background: Hepatitis-related autoimmunity with renal involvement can result in life-threatening hydropic and cachectic symptoms.

Methods: We report on 10 patients with hepatitis C (n=9) and B (1) who presented between 2010 and 2014 either with severe nephrotic syndrome caused by membrano-proliferative glomerulonephritis (MPGN; hepatitis C, 3 women, 4 men; hepatitis B, 1 man) or cachexia caused by polyarteritis of mediumsized renal vessels (hepatitis C, 2 men).

Results: Mixed cryoglobulenemia was detected in 5 and rheumatoid factor in 7 patients, hypocomplementemia in all 8 patients with MPGN (not in the 2 patients with polyarteritis). All patients had progressive renal insufficiency, and 8 had hypertension. Other organs involved were hemorrhagic alveolitis (n=1), heart involvement (1), skin vasculitis (3), and peripheral neuropathy (2). Successful antiviral treatment had been performed in 5 patients with hepatitis C and the patient with hepatitis B; four patients with hepatitis C had either not tolerated therapy (1) or had no treatment because of severe concomitant diseases (3). In spite of being virus-free after treatment, active nephrotic syndrome persisted in 3 cases with MPGN up to 24 months and relapsed after 3, 5 and 6 years after symptom-free and virus-free interval in 3 cases with MPGN. All patients were treated with rituximab (375mg/m^2) twice with one week interval; further doses were given dependent on B-cell recovery or relapsing symptoms. One patient did not lower B cells even after 4 doses of rituximab and reached end-stage renal disease after ruptured sigma diverticulitis. One other patient had remission of nephrotic syndrome but developed renal failure. Six other patients responded to treatment with reduction of proteinuria and improvement of renal function; but only one is off immunosuppressive treatment. Two other patients have just started treatment. Two patients had pneumonia, one other patient relapse of hepatitis C under rituximab (successfully retreated).

Conclusions: Rituximab is the treatment of choice in hepatitis-related autoimmunity, even in cases with continuous viral replication. Active MPGN may persist or relapse years after successful antiviral treatment.

SA-PO548

Higher Serum Uric Acid Levels Increase Resistance of Afferent Arteriole, Inducing Decreased Renal Plasma Flow (RPF) and Glomerular Filtration Rate (GFR) in Human – Inulin and Para-Aminohippurate Clearance Study Hideki Uedono, Akihiro Tsuda, Eiji Ishimura, Mari Yasumoto, Mitsuru Ichii, Katsuhito Mori, Masaaki Inaba. *Osaka City Univ Graduate School of Medicine, Osaka, Japan.*

Background: Hyperuricemia has been reported to induce decrease in GFR through endothelial cells dysfunction (Kidney Int 67:1739, 2005). Increase in resistance of renal artery and decrease in RPF is caused by hyperuricemia (Curr Hypertens Res 8:120, 2006). There are, however, no data that examined the relationship between serum uric acid levels and intrarenal hemodynamic parameters in human. The aim of the present study was to evaluate this mechanism in human, utilizing clearance of inulin (C_{in}) and paraaminohippurate (C_{PAH}).

Methods: Renal and glomerular hemodynamics were assessed by simultaneous measurements ofC_{in} (GFR) and C_{PAH} (RPF) in 50 in-patients with normal renal function (C_{in} ≥60 ml/min/1.73m^2) and without hyperuricemia (56.0±13.7 years, 23 males and 27 females, 26 diabetics and 24 non-diabetics). Renal and glomerular hemodynamics, such as resistance of afferent arteriole (R_a) and efferent arteriole (R_e), were calculated using Gomez's formulae, recently examined and reported by us (Diabetes Res Clin Pract 104:234, 2014).

Results: Serum uric acid levels in all patients were within the normal range (3.2-7.5 mg/dl). Serum uric acid levels correlated negatively with C_{in} (r=-0.381, p<0.01). Serum uric acid levels correlated positively with R_a (r = 0.308, p = 0.00293), but not significantly with R_e. In multiple regression analyses, serum uric acid levels were significantly and independently associated with C_{in} and C_{PAH} (β= -0.410, p = 0.0122; and β= -0.321, p = 0.0396, respectively) after adjustment for age, gender, body mass index, hemoglobinA1c and systolic blood pressure (R^2=0.317, p<0.01; R^2=0.365, p<0.01, respectively). Serum uric acid levels (β=0.558, p=0.0005) were significantly and independently associated with R_a after adjustment for the above confounders (R^2=0.382, p<0.01).

Conclusions: These findings suggest, for the first time in human study, that higher serum uric acid levels are significantly associated with reduced GFR and RPF. This reduction may be probably caused by increase in R_a.

SA-PO549

Plasma CD147/Basigin as a Promising Biomarker of the Kidney Diseases Kayaho Maeda, Tomoki Kosugi, Hiroshi Kojima, Tomohiro Masuda, Noritoshi Kato, Waichi Sato, Seiichi Matsuo, Shoichi Maruyama. *Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.*

Background: CD147/Basigin (Bsg), a glycosylated transmembrane protein, contributes to cell survival, migration and cancer invasion. We so far demonstrated *in vivo* that its pathophysiological roles in the kidney diseases are diverse, ranging from the occurrence of acute kidney injury frequently accompanied by ischemia, inflammation and a loss of tolerance to progression of renal fibrosis. Particularly, the biological activity of Bsg on leukocytes is indispensable for T lymphocytes differentiation and migration of leukocytes into the tubulointerstitium. Disruption a vicious chain reaction involving Bsg and its interacted molecules would be required for overcoming the kidney diseases. We therefore investigated whether Bsg could serve as a novel biomarker for disease activity and prognosis in the kidney diseases.

Methods: Plasma and spot urine samples were collected from 365 patients, who underwent renal biopsy in our affiliated hospitals between 2008 and 2012. They included healthy individuals as a pathological control (Control; n=16), rapid progressive glomerulonephritis (RPGN; n=101), lupus nephritis (LN; n=64), minimal change nephrotic syndrome (MCNS; n=45), diabetic nephropathy (DM; n=24), IgA nephropathy (IgAN; n=43), focal segmental glomerulosclerosis (FSGS; n=32), and membranous nephropathy (MN; n=40).

Results: In the normal kidneys, Bsg mainly expresses in tubules, but not glomeruli. While this expression was extremely lower in atrophic tubules of injured kidney, infiltrating leukocytes and fibroblasts, and injured glomeruli such as crescent formation showed the marked induction of Bsg. Interestingly, the close relationship between plasma Bsg and serum creatinine was found. Plasma Bsg levels were strikingly higher in RPGN, LN and DM patients with leukocytes recruitment, Furthermore, this values accurately reflected the degrees of tissue damages, leukocytes infiltration and renal dysfunction in respective diseases. Bsg on leukocytes and fibroblasts might be thus involved in inflammation in the kidney diseases.

Conclusions: Plasma Bsg may accurately reflect the disease activity in the kidney diseases.

SA-PO550

Development of a Urine Mass Spectrometry Based Test for Detection of a Mutant MUC1 Peptide in Medullary Cystic Kidney Disease Type 1 Wendy Heywood,[1] Fujun Lin,[2] Duriye Deren Oygar,[3] Thomas Michael Connor,[5] Guy H. Neild,[2] Kevin Mills,[1] Daniel P. Gale.[2] *[1]Inst of Child Health, Univ College London, London, United Kingdom; [2]Centre for Nephrology, Univ College London, London, United Kingdom; [3]Nephrology Dept, Nicosia State Hospital, Nicosia, Cyprus; [4]MRC Inst of Genetics and Molecular Medicine, Univ of Edinburgh, Edinburgh, United Kingdom; [5]West London Renal and Transplant Centre, Imperial College, London, United Kingdom.*

Background: Medullary Cystic Kidney Disease Type 1 (MCKD1) is an autosomal dominant condition that causes kidney failure in adults. The disease is clinically silent with no hypertension, haematuria, proteinuria or imaging abnormalities prior to the onset of renal impairment. Kidney biopsy in MCKD1 typically shows only tubular atrophy/fibrosis with no diagnostic histological or ultrastructural features. Only treatment is kidney transplantation. MCKD1 is caused by a single cytosine insertion mutation in an extremely (>80%) GC-rich 60-bp tandem repeat in the *MUC1* gene. The C-insertion introduces a shift in the reading frame of the protein resulting in expression of a unique peptide (MUC1fs). Reliable assays to diagnose this disease are in great demand but are not widely available.

Methods: Genome-wide SNP-based linkage, Western Blotting, MRM LC-MS.

Results: We investigated 4 families with clinical features and linkage consistent with MCKD1 with a C-insertion mutation in MUC1. Western blotting detected a protein with the MUC1fs neo-peptide protein in urine from affected individuals from each family. Using a targeted proteomic approach we have developed a 5 min peptide based multiple reaction monitoring LC-MS assay. The MUC1fs neopeptide was detected in the urine of 6 affected family members (including renal transplant recipients) and not in the urine from 10 control individuals.

Conclusions: The assay is inexpensive, requires only 2ml urine, can be automated and multiplexed with other tests and is absolutely specific for MCKD1. The assay has great potential for high throughput population screening and will make predictive and diagnostic testing available – allowing living kidney donation from unaffected relatives to patients with MCKD1 to be performed safely.

SA-PO551

Urinary Extracellular Vesicles as Potential Biomarkers for Polycystic Kidney Disease Mahdi Salih,[1] Jeroen A.A. Demmers,[2] Karel Bezstarosti,[2] Ewout J. Hoorn,[1] Robert Zietse.[1] *[1]Nephrology and Transplantation, Erasmus Medical Center Rotterdam, Rotterdam, Netherlands; [2]Proteomics Center Rotterdam, Erasmus Medical Center Rotterdam, Rotterdam, Netherlands; [3]In Collaboration with the DIPAK Consortium.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive cyst growth and often leads to renal failure. There is no good biomarker to predict disease progression. Urinary extracellular vesicles (uEVs) contain many disease-related proteins from all renal epithelial cells and form a source of biomarkers.

Methods: We collected spot urine samples of 6 ADPDK patients (confirmed PKD1 mutation) and 6 age- and sex-matched healthy volunteers. Samples were normalized for urinary creatinine, pooled and precipitated using acetone or ultracentrifuged to isolate uEVs. Proteins were trypsinized and subsequently analyzed using LC-MS/MS. uEVs were labeled with isotopomeric dimethyl labels, allowing quantitative analysis using bioinformatics. A different set of ADPKD (n = 6), CKD (n =6) and healthy control (n = 6) subjects were selected for validation of our proteomics results with immunoblotting.

Results: A total of 1048 proteins in acetone precipitated urine and 1245 proteins in uEVs were identified, of which 718 were unique for uEVs. Quantitative analysis of the uEVs revealed a ≥ 2-fold upregulation of 227 proteins and downregulation of 116 proteins. Many proteins previously implicated in the pathogenesis of ADPKD were identified. Interestingly, most of the up- or downregulated disease-related proteins were not found in acetone precipitated urine, supporting the notion that the isolation of uEVs enriches the

urinary proteome. Immunoblotting showed that several of these uEV proteins were only increased in urine from ADPKD patients, including periplakin (10-fold) and desmoplakin (3-fold), both junctional proteins known to be mislocated in ADPKD.

Conclusions: Isolation of uEVs enriched the urinary proteome and identified potential biomarkers uniquely upregulated in ADPKD, including periplakin and desmoplakin.

SA-PO552

α-Adducin Gene Polymorphism Affects eGFR Decay in ADPKD Maria Teresa Sciarrone Alibrandi,[1] Giancarlo Joli,[1] Marina Nuzzo,[1] Elena Brioni,[1] Marco Simonini,[1] L. Merlino,[1] Francesco Trevisani,[1] Rodolfo Rivera,[2] Simona Delli Carpini,[1] Lorena Citterio,[1] Donatella Spotti,[1] Paolo Manunta.[1] *[1]San Raffaele Scientific Inst, Milan, Italy; [2]San Gerardo Hospital, Monza, Italy.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common monogenic nephropathy and an important cause of ESRD, End Stage Renal Disease, accounting for about 5% of patients requiring dialysis. The number of cysts and their complications are variable among single patients as well as the renal outcome. Adducin is a heterodimeric cytoskeleton protein consisting of an alpha-subunit and either a beta- or gamma-subunit. It is involved in cohesion of renal cells. In rats and humans, mutation of the a-adducin subunit leads to the stimulation of the sodium (Na(+)), potassium (K(+))-adenosine triphosphate (ATP)-ase activity in renal tubular cells, increased renal Na(+) reabsorption, and, subsequently, hypertension.

Methods: Patients and methods: We analyzed the genetic background of a sample of 154 patients affected by ADPKD, in order to evaluate the influence of α-adducin gene polymorphism in renal outcome. ΔGFR (Glomerular Filtration Rate loss) was evaluated at the follow-up (every 6 months). Statistical analysis has been performed by Cox Regression corrected for sex, age, blood pressure, comorbid conditions, therapy and previous renal function.

Results: ADPKD patients carrying at least a mutated allele (GW and WW) present a significant loss of renal function versus wild type ones. We observed a GFR loss of 30% versus basal value in 77 months in mutated pts and in 90 months in wild type ones (p=0.03). Mean of follow up 45.5 months in the entire sample (min 6 max 169.73).

Conclusions: α-adducin genotype is associated with loss of renal function in ADPK. As mutated genotype is known to be also associated with hypertension and renal handling of sodium it could contribute to our understanding of the pathogenetic mechanisms that lead in renal failure progression for ADPKD patients.

SA-PO553

A Urine Peptidome-Based Biomarker Score Accurately Predicts the Risk of Reaching ESRD in ADPKD Patients Andreas D. Kistler,[3] Harald Mischak,[1] Arlene B. Chapman.[2] *[1]Mosaiques Diagnostiques GmbH, Hannover, Germany; [2]Renal Div, Emory Univ School of Medicine, Atlanta, GA; [3]Div of Nephrology, Univ Hospital Zurich, Zurich, Switzerland.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) accounts for about 5% of patients with end stage renal disease (ESRD). Now that specific treatment options likely become available, prediction of disease course would be of utmost importance to select high risk patients for treatment. We have previously identified ADPKD-specific patterns of urine peptide excretion that differentiate ADPKD from control patients and correlate with disease severity. Here, based on extended follow up time, we were able to identify a set of urinary peptides that predict progression to ESRD and thus allow early detection of patients at high risk for progression.

Methods: Baseline urine samples from all patients in the CRISP cohort were analyzed by capillary electrophoresis - mass spectrometry (CE-MS). All patients were followed for >7 years and the urine peptidome of patients reaching ESRD was compared to control patients with relatively slow progression (defined as an annual GFR loss of <4 ml/min/1.73m^2 during follow up). Since patients reaching ESRD had lower baseline GFR, we matched the control group by including only patients with baseline GFR <95 ml/min/1.73m^2. Two thirds of both cases and controls were used to identify a prognostic biomarker score, the remaining patients served as validation cohort.

Results: During follow up, 22 patients reached ESRD, and 46 patients matched for baseline GFR had a low progression rate. A prognostic biomarker score based on 52 urinary peptides, applied to the validation cohort, reached an AUC of 0.94 in the training cohort upon cross validation and an AUC of 0.81 in the validation cohort to identify patients reaching ESRD during follow up. This predictive value was higher than the AUC of total kidney volume (TKV) at baseline.

Conclusions: We identified a biomarker score based on the urine peptidome at a single timepoint that allows to identify ADPKD patients with high risk for progression to ESRD. This score outperforms TKV, which has by now been the best prognostic marker in ADPKD.

SA-PO554

Increased Expression of Semaphorin 7A in ADPKD Neera K. Dahl,[1] Yashang Lee,[1] Anil K. Karihaloo.[3] *[1]Section of Nephrology, Yale Univ School of Medicine, New Haven, CT; [2]Astra-Zenica, Södertälje, Sweden.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common genetic disorders in humans. It is characterized by progressive cyst growth and corresponding loss of renal function. Inflammatory cells are known to be present in the cystic kidneys of ADPKD patients. It is further validated by the presence of pro-inflammatory cytokines in cyst fluid. In ADPKD patients, high urinary monocyte chemoattractant protein-1 (MCP-1) levels correlate with high rate of cyst growth. Semaphorin 7A (Sema7A), an axonal guidance molecule, plays a critical role in lung fibrosis. Interestingly, Sema7A levels on circulating mononuclear cells are significantly higher in idiopathic pulmonary fibrosis as well as in scleroderma patient population. The Sema7A levels separate slow and fast progressing IPF patient populations. We hypothesized that the circulating mononuclear cells in ADPKD patient population will have higher Sema7A expression and will inversely correlate with renal function.

Methods: Blood samples were obtained from 80 ADPKD patients and from 20 controls with no known kidney disease. PBMCs were separated from normal (control) and ADPKD patient blood using a Ficoll gradient. RNA was isolated and analyzed for Sema7A expression. Data were analyzed using Welch's t-test (Student t-test with unequal variance).

Results: We first demonstrated that in a mouse model of unilateral ureteral obstruction there is increased level of Sema7A mRNA in peripheral blood mononuclear cells (PBMCs) derived from the buffy coat. Next, we analyzed Sema7A expression on peripheral blood CD45+, F4/80+ and CD4+ PBMCs from 80 ADPKD patients (CKD stage 1-5) and 20 healthy volunteers, using FACS analysis. Our data conclusively demonstrate that as compared to healthy volunteers Sema7a expression is highly upregulated in the circulating monocytes and CD4$^+$ T cells of ADPKD patients.

Conclusions: These data suggest a potential for Sema7A as a marker of kidney injury in ADPKD patient population.

SA-PO555

Autosomal Dominant Polycystic Kidney Disease Progression: Measuring Chronic Kidney Disease Stage Transitions Christopher M. Blanchette,[1,2] Caihua Liang,[3] Deborah Lubeck,[4] Britt B. Newsome,[5] Ben Gutierrez,[1] Nancy D. Lin.[3] *[1]Otsuka America Pharmaceuticals, Inc., Princeton, NJ; [2]Univ of North Carolina, Charlotte, NC; [3]Optum, Waltham, MA; [4]Outcomes Insights, Westlake Village, CA; [5]Denver Nephrologists, Thornton, CO.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a progressive genetic disorder characterized by bilateral cysts, leading to kidney failure. Most cases are due to a mutation in the *PKD1* gene and are associated with more rapidly progressing disease. Few studies have assessed chronic kidney disease (CKD) stage transitions of ADPKD patients.

Methods: This retrospective cohort study included patients with a claim indicating ADPKD from 1/1/2000–2/28/2013 and ≥6 months of prior continuous enrollment (baseline) within a large U.S. administrative claims database. A random sample of CKD patients served as comparators. In a subgroup of patients with linked electronic laboratory results data, the estimated glomerular filtration rate was calculated via serum creatinine values (Scr) to determine CKD stage at baseline and during follow-up. Proportions of patients transitioning to another stage and the mean age at transition were calculated. Approval from the institutional review board was obtained.

Results: Identified patients included 7617 patients with ADPKD and 22,851 with CKD. At first observation, 68% of ADPKD patients were ≥40 y (91% CKD) and 53% were female (40% CKD). Baseline Scr values were available for 1962 (26%) ADPKD patients and 7305 (32%) CKD patients. Staging at baseline for ADPKD and CKD patients, respectively, were: stage I, 627 and 934; stage II, 343 and 1658; stage III, 328 and 1937; stage IV, 166 and 577; stage V, 498 and 2199. Of ADPKD patients in stage I at baseline (n=627), 99 transitioned to stage 2 (mean age 47 y), 19 to stage III (mean age 47 y), 4 to stage IV (mean age 46 y), and 7 to stage V (mean age 45 y) during follow-up. Patterns were similar for patients in initial staging of II, III, and IV.

Conclusions: The results suggest that distributions of patients by age at transition help to identify rapid progressors. Future research should explore genetic, clinical, economic, and humanistic characteristics of ADPKD patients who rapidly progress through CKD stages.

SA-PO556

Renal Transcatheter Arterial Embolization in ADPKD Patients: Increasing Its Effectiveness Tatsuya Suwabe, Yoshifumi Ubara, Koki Mise, Keiichi Sumida, Junichi Hoshino, Masahiro Kawada, Kenmei Takaichi. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background: In patients with autosomal dominant polycystic kidney disease (ADPKD), massive renal enlargement is related to prominent abdominal distension. Renal transcatheter arterial embolization (TAE) is safe and effective for reducing renal volume, and has been performed for volume reduction before renal transplantation. The average renal volume reduction ratio (RVRR) after renal TAE was reported to be about 50%, but there is large variation and the reason is unknown.

Methods: All ADPKD patients who received renal TAE at Toranomon Hospital from 2006 to 2013 were enrolled. We calculated the RVRR as follows: (1 - renal volume 1 year after renal TAE / renal volume before renal TAE)x100. Factors affecting the RVRR were analyzed.

Results: A total of 372 patients (183 males, 189 females; 56.8±9.4 years old [mean±SD]) were enrolled. Average RVRR was 45.3±14.6% (range: 10~84%). Stepwise multiple linear regression analysis revealed that age, body mass index (BMI), blood pressure, number of microcoils used for renal TAE, renal calcification score (RCS), and cardiovascular disease significantly affected the RVRR.

Dependent variable	Explanatory variable	β	t	p value	Adjusted R^2
RVRR					0.346
	Age	-0.372	-6.18	<0.0001	
	BMI	-0.232	-4.06	<0.0001	
	BP	0.215	3.98	<0.0001	
	No. of microcoils	0.170	2.73	<0.01	
	Cardiovascular disease	-0.137	-2.52	<0.05	
	RCS	-0.138	-2.34	<0.05	

Analysis in a single age group (227 patients aged 50 to 65 years) revealed that RCS was correlated with dialysis duration (r=0.717, p<0.0001) and inversely correlated with RVRR (r=-0.206, p<0.05), while the aortic calcification index (ACI) was not. Average RVRR was significantly lower in patients with a dialysis duration > 5 years when compared among groups with different dialysis times (p<0.005).

Conclusions: Age had the greatest influence on RVRR, while calcification did not, suggesting that age-related changes like fibrosis might be the most important determinant of RVRR. RCS was correlated with dialysis duration and affected RVRR in patients from the same age group. Renal TAE might be more effective in patients with less renal calcification or patients within 5 years of starting dialysis.

SA-PO557

Phosphate Metabolism in Children with Autosomal Dominant Polycystic Kidney Disease Stéphanie De Rechter,[1,2] Justine Bacchetta,[3] Laurence Dubourg,[3] Pierre Cochat,[3] Maria Van Dyck,[1] Jean De Schepper,[4] Pieter Evenepoel,[5] Elena N. Levtchenko,[1,2] Djalila Mekahli.[1,2] *[1]Dept of Pediatric Nephrology, Univ Hospital of Leuven, Leuven, Belgium; [2]Laboratory of Pediatrics, KU Leuven, Leuven, Belgium; [3]Centre de Référence des Maladies Rénales Rares, Hôpital Femme Mère Enfant, Hospices Civils de Lyon, Bron, France; [4]Dept of Pediatric Endocrinology, Univ Hospital of Brussels, Brussels, Belgium; [5]Dept of Internal Medicine, Div of Nephrology, Univ Hospital of Leuven, Leuven, Belgium.*

Background: Clinical data have revealed in an ADPKD adult population that Fibroblast Growth Factor 23 (FGF23) increases while circulating Klotho levels decrease, with a low TmP/GFR even in patients with normal renal function. The underlying mechanisms are largely unknown. Moreover, it has been demonstrated in animal ADPKD models that the polycystic kidney produces FGF23 but is resistant to its actions. No data are available in a pediatric ADPKD population. To fill this gap, we prospectively assessed renal phosphate handling in children with ADPKD in a dual-center study.

Methods: Children with ADPKD and normal renal function were eligible for inclusion. Blood and urine samples were collected and analysed for parameters of bone mineral metabolism. Based on normal values according to age, we made percentile (P) charts for serum phosphate and TmP/GFR. Hypophosphatemia and urinary phosphate wasting were defined as values ≤ P5.

Results: We included 69 ADPKD patients (median (range) age 10.7 (2.3 – 17.5) years). Parameters of mineral metabolism (Vit D and PTH) were in the normal range. Hypophosphatemia and urinary phosphate wasting were observed in 10%, and 22% of the children respectively. Serum phosphate levels and TmP/GFR were in P5-P50 range in 70% and 77% of the patients respectively.

Conclusions: This is the first report highlighting hypophosphatemia and renal phosphate leak in ADPKD children with normal eGFR. These results confirm recent data in adult ADPKD patients and point to an abnormal FGF23 metabolism. Further studies are required to elucidate the underlying pathophysiology and to investigate potential clinical consequences.

SA-PO558

Adult Polycystic Kidney Disease Patients Show a Very Similar Cardiovascular Comorbidity Profile to CKD Patients with Other Etiologies. Most Cardiovascular and Renal Risk Factors Are Not Controlled in the Majority of Patients Jose L. Gorriz, Marco Montomoli, Cristina Castro, Belen Vizcaino, Daniel A. Molina, Angela Maria Serrato, Alberto M. Martinez-Castelao, Sandra Beltrán, Carlos Del Pozo Fernandez, Ramon Lopez-Menchero Martinez, Luis M. Pallardo. *On Behalf of the MERENA and PECERA Study Investigators, Spain.*

Background: The younger age of autosomal dominant polycystic kidney disease (ADPKD) patients compared to patients with other etiologies may cause underestimation of their cardiovascular risk. The aim of this study was to analyze renal and cardiovascular risk factors in patients with ADPKD, analyzing whether there is a difference between ADPKD and other CKD patients with different etiologies.

Methods: Cross-sectional study that included 153 patients with a diagnosis of ADPKD from two observational Spanish studies (MERENA and PECERA) and a group of ADPKD patients followed up in the Hospital Dr Peset, compared to 2,010 patients with different etiologies from these studies. CKD stages were: 16%, 66% and 17% in stages 3, 4 and 5 not on dialysis in ADPKD patients, and 23%, 61% and 16% in other etiologies respectively (p = 0.25).

Results: ADPKD patients were of a younger age (53±14 versus 68±13 years, p<0.001), male sex was 48% versus 64% (p=0.001), a lower heart failure rate (3.2% versus 19%, p=0.003) a lower prevalence of peripheral vascular disease (3.5% versus 20%, P<0.001). We did not find significant differences in prevalence of coronary heart disease (7.3% versus 11.4%, p=0.07), cerebrovascular disease (3.5% versus 12%, p=0.082) or hypertension (84% versus 92%, p=0.19). Patients with ADPKD were more likely to be smokers (14% versus 9%, p=0.03), had better, but not optimal, blood pressure control (>140 sys BP: 33% versus 59%, p=0.03) and a lower degree of proteinuria (>1g/day:18% versus 38%, p=0.008). There was no difference in the excess weight (64% versus 79%, p=0.7) nor in the degree of control of dyslipidemia (LDL>100: 56% versus 64%, p=0.18) (low HDL: 48% versus 44%, p=0.67).

Conclusions: in this epidemiological analysis, ADPKD patients have a similar comorbidity profile to other CKD patients with other etiologies. Added to this, is the fact that most of renal and cardiovascular risk factors in these patients are not controlled.

SA-PO559

Clinical Significance of Endothelin-1 in the Pathogenesis of Autosomal Dominant Polycystic Kidney Disease: A Translational Study Rupesh Raina,[1] Linda Lou,[1] Bruce E. Berger,[2] Beth A. Vogt,[1] Angelique Sao-Mai Sy Do,[1] Karin Anna Herrmann,[4] Katherine M. Dell,[3] Michael S. Simonson.[2] *[1]Dept of Pediatrics, Div of Pediatric Nephrology, Rainbow Babies and Children's Hospital, Cleveland, OH; [2]Dept of Medicine, Div of Nephrology and Hypertension, Univ Hospitals Case Medical Center, Cleveland, OH; [3]Div of Pediatric Nephrology, Cleveland Clinic Foundation, Cleveland, OH; [4]Dept of Radiology, Univ Hospitals Case Medical Center, Cleveland, OH.*

Background: The pathogenesis of progressive renal insufficiency in autosomal dominant polycystic kidney disease (ADPKD) is unclear. Evidence from experimental models of ADPKD demonstrates that elevated endothelin-1 (ET-1) drives cyst growth, renal fibrosis and loss of renal function, but whether ET-1 is elevated in humans with ADPKD is unknown.

Methods: We conducted a cross-sectional analysis of patients with ADPKD recruited from the University Hospitals Case Medical Center outpatient clinics. Urine ET-1, a well-validated surrogate for kidney ET-1, was measured in spot collections and corrected for creatinine. The volume of each kidney was measured from magnetic resonance images using stereology. The relationship of log-transformed urine ET-1 with MDRD eGFR and kidney volume was modeled by multiple linear regression with adjustment for clinical covariates in Stata 13.

Results: We recruited 21 patients with ADPKD ages 18 to 53. eGFR (mean ± SD) was 78.0 ± 47.7 ml/min/1.73m^2 and albumin/creatinine ratio (ACR) was 26.0 ± 32.3 mg/g. Urine ET-1 was negatively associated with eGFR (r = -0.395, P= 0.026) independent of age and female sex (P<0.01). In contrast, urine ET-1 was positively associated with total kidney volume (r = 0.425, P < 0.01) after adjustment for age and sex (P< 0.05).

Conclusions: In a pilot study of patients with ADPKD, urinary ET-1 was positively associated with kidney volume, a surrogate for cyst growth, and negatively with eGFR. Taken together with results from experimental models, these findings suggest that the role of ET-1 in ADPKD warrants further investigation.

SA-PO560

Arterial Stiffness in Young Non-Uremic Autosomal Dominant Polycystic Kidney Disease Patients Compared to Young Healthy Subjects Timur Selcuk Akpinar,[1] Abdullah Ozkok,[1] Fatih Tufan,[1] Murat Kose,[1] Oguz Kagan Bakkaloglu,[1] Burak Ince,[1] Elif Irem Sarihan,[1] Duygu D. Uzun,[1] Erol Bozbora,[1] Halil Yazici,[2] Yasar Caliskan,[2] Tevfik Ecder,[2] Kamil Nas,[4] Miklos Illyes.[3] *[1]Internal Medicine, Istanbul Univ, Istanbul, Turkey; [2]Nephrology, Istanbul Univ, Istanbul, Turkey; [3]Heart Inst Clinic, Univ of Pecs, Pecs, Hungary; [4]Dept of Radiology Budapest, Szent Janos Hospital, Budapest, Hungary.*

Background: Cardiovascular disease is the most important cause of mortality in autosomal-dominant polycystic kidney disease (ADPKD) patients. The ambulatory arterial stiffness index (AASI) can be used to predict cardiovascular risk in hypertensive patients. However, to our knowledge, the role of ASSI in patients with ADPKD has not been evaluated.

Methods: Age, blood pressure (BP) and GFR matched 24 normotensive and non-uremic ADPKD patients (mean age: 28±8 years, M/F: 12/12) and 18 healthy controls (31± 11 years, M/F: 12/6) were enrolled into the study. Twenty-four hour blood pressure and arterial stiffness measurements were performed non-invasively with the device Tensiomed Arteriograph24. AASI was defined as one minus the respective regression slope of diastolic BP on systolic BP.

Results: Age (p=0.36), sex (p=0.48), systolic BP (123±7 versus 124±12mmHg, p=0.85), diastolic BP (75±6 versus 76±12 mmHg, p=0.93) and GFR (104±19 versus 103±20 mL/min, p=0.72) were similar between healthy controls and ADPKD patients. However, microalbuminuria was significantly higher in ADPKD patients (106±139 versus 2.81±1.88 mg/day, p<0.001). AASI was significantly lower in patients with ADPKD (0.33±0.10 versus 0.37±0.05, p=0.03). Left ventriculer mass index was higher in ADPKD patients compared to healthy controls (93±18 versus 74±16, p=0.03). AASI was significantly correlated with microalbuminuria in patients with ADPKD (r= -0.60, p=0.03). In the linear regression analysis for predicting AASI; among age, GFR, mean BP and microalbuminuria, only microalbuminuria retained as the significant factor in the model.

Conclusions: Arterial stiffness was not found to be higher in young, normotensive and non-uremic ADPKD patients compared to young, healthy individuals. Ambulatory arterial stiffness index was significantly related to microalbuminuria in ADPKD patients.

SA-PO561

Pericardial Effusion (PE) and Autosomic Dominant Polycystic Kidney Disease (PKD) with Different Staged of Chronic Kidney Disease (CKD)

Rodolfo Rivera,[1] Luca Di Lullo,[2] Fulvio Floccari,[3] Mario Grassi,[4] Costanza Casati,[1] Andrea Stella,[1] Davide Guido.[4] *[1]Milano Bicocca Univ; [2]Colleferro H.; [3]Civitavecchi H.; [4]Pavia Univ, Italy.*

Background: PKD is a genetic disorder characterized by CKD a progression and onset of cardiovascular (CV) complications. Greater occurrence of PE has been observed in PKD. Aim: to test the effects of PE and PKD on CV and renal outcome in an Italian Cohort.

Methods: 349 CKD patients (stage I-V) were divided into two groups: A= 83 with PKD (follow up: 53.7 months) and B= 266 without PKD (50.5 months). PE was detected by echocardiography and left ventricular mass index, and systolic and diastolic volume were used to predict a latent variable score for cardiac function (CF). Primary endpoint: time to firstCV event; secondary endpoint: dialysis treatment onset. LogRank and Cox frailty random (subjects' pedigree) models were used to test central effect of PE and PKD, adjusting for age, sex, Charlson comorbidity index, renal function, hypertensive drugs and CF score. PE was more frequent in group A (34.9%) than in B (13.5%) ($p<0.001$). There were 63 CV events and 58 onset of dialysis. LogRank did not show significant evidences of PKD on both outcomes ($p>0.05$), while significant evidences of PE were observed ($p<0.001$).Cox models returned not significant for PKD effects ($p>0.05$) on both outcomes, while PE effect resulted significant for CV outcome (Hazard Ratio= 2.8, p=0.01), but not for renal outcome (HR=1.13, p= 0.8).

Results: PE was more frequent in group A (44.6%) than in B (19.0%) ($p<0.001$). There were 63 CV events and 58 onset of dialysis. LogRank did not show significant evidences of PKD on both outcomes ($p>0.05$), while significant evidences of PE were observed ($p<0.001$). Cox models returned not significant PKD effects ($p>0.05$) on both outcomes, while PE effect resulted significant for CV outcome (Hazard Ratio= 2.8, p=0.01), but not for renal outcome (HR=1.13, p= 0.8).

Conclusions: PE is more common in PKD patients. Despite of 2.8 times higher hazard for CV events in PE patients, PKD does not increase CV events and it does not anticipate dialysis therapy. PE increases the hazard for CV events but not affecting renal outcome independently from the PKD group.

SA-PO562

Patients and Kidney Graft Outcomes in Polycystic Kidney Disease (ADPKD) Transplant Recipients following Native Nephrectomy

Fouad T. Chebib,[1] Sami Safadi,[1] Mikel Prieto,[2] Patrick G. Dean,[2] Maria V. Irazabal,[1] Yeonsoon Jung,[1] Vicente E. Torres,[1] Ziad El-Zoghby.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Von Liebig Center for Transplantation, Mayo Clinic, Rochester, MN.*

Background: Native nephrectomy(NNx) is frequently needed in ADPKD patients. Timing of NNx (pre, concurrent or post) in relation to kidney transplantation (KTx) offers different challenges. We report our experience of post-transplant NNx.

Methods: Between 1977-2014, 450 ADPKD patients were transplanted in our center. 111(24.7%) underwent NNx with 80(72.1%) post-transplant and subject of this study. We reviewed the perioperative complications and compared patient and graft survival with ADPKD recipients (n=435) who did not undergo nephrectomies (NoNx).

Results: Mean age at KTx and NNx was 52.7±11.6 and 54.3±10.5 respectively, 53.3% male, 93% White, 5.4% had pretransplant diabetes, 8.3% CAD and40% were on dialysis prior to KTx for a median time of 16.8 months. NNx was done at a median of 19.9 months (IQR 8.2-71.5) post-transplant. Median follow up time was 6.4 years (IQR 3-10.3) during which 74 patients died and 117 graft failed (17.5% in NNx and 29.1% in NoNx; p=.035). Median hospital stay was 4 days after NNx. 5 patients required blood transfusions, 5 patients required admission to ICU and 2 had reversible acute graft injury. Patient survival at 1, 5 and 10 years was: 100%, 96.8% and 85.1% in the NNx group and 98.5%, 93.4% and 78.4% in the NoNx group respectively (p=.039). Graft survival at 1, 5 and 10 years was: 100%; 95.5%, and 83.9% in NNx and 95.7%, 87.9% and 67.9% in NoNx respectively (p=.022) On multivariate cox regression analysis, nephrectomy did not relate to patient or graft survival and only age at transplantation (HR= 1.1; [95% CI 1.05-1.14], p<.001) and male gender (HR=2.47[1.17-5.7]) were predictors of patient survival.

	HR	95% CI	p-value
NNx(Yes/No)	0.72	0.26-1.66	0.45
Age at Tx	1.1	1.05-1.14	<0.001
Male	2.47	1.17-5.7	0.017
Deceased donor	0.94	0.43-2.04	0.88
Diabetes	1.83	0.49-5.58	0.34
Dialysis pre-KTx	1.57	0.71-3.5	0.26

Conclusions: Native nephrectomy after kidney transplantation has low perioperative complications. Patients and grafts survival are comparable between ADPKD recipients who undergo nephrectomy and those who do not.

SA-PO563

Renal Cell Carcinoma (RCC) in Polycystic Kidney Disease (ADPKD) Transplant Recipients

Fouad T. Chebib,[1] Sami Safadi,[1] Vicente E. Torres,[1] Mikel Prieto,[2] Patrick G. Dean,[2] Maria V. Irazabal,[1] Yeonsoon Jung,[1] Ziad El-Zoghby.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Von Liebig Center for Transplantation, Mayo Clinic, Rochester, MN.*

Background: The incidence of malignancy post kidney transplantation (KTx) is higher than that in the general population. Whether the risk for development of RCC in native kidneys following KTx is higher in ADPKD patients than in patients with other renal diseases is controversial.

Methods: Between 1977-2014, 450 ADPKD patients received KTx in our center. Mean age at KTx was 50.7 years (23-70). The mean follow-up time was 6.4 years (IQR 3-10.3).111 (24.7%) underwent native nephrectomies (NNx) with 80 (72.1%) post-KTx and subject of this study. We reviewed the indications and NNx renal pathology. Univariate logistic regressions were performed to identify variables associated with RCC. We included age at NNx, gender, race, smoking status, kidney volumes, symptoms, dialysis before KTx and number of years between KTx and NNx.

Results: NNx was performed at a median of 20.6 months after KTx (IQR 8.3-73.7). All were white, 58.2% male, 40% current/previous smokers and 35% on dialysis pre KTx for a median of 20.7 months. Indications for NNx were: pain 66%, hematuria 19%, cyst infection 15%, abdominal/incisional hernias 14%, renal mass 7.5 %, GI 5%,and respiratory symptoms 5%. RCC was present in 11 patients (3 had bilateral RCC) and only 6 had a suspicious mass prior to NNx.Pathology included: 8 papillary, 4 clear, 1 chromophobe and 1 unidentified RCC. Median size of RCC on pathology was 2.4cm (IQR 1.8-3.1) for clinically suspected RCC and 1.3cm (IQR 0.95-2.4) for incidental RCC(p=.128).One patient had pancreatic metastasis.Significant variables associated with RCC were age at NNx (OR 1.98 per 10 years,p .038),and number of years between KTx and NNx (OR 1.19,p .005). The incidence of clinically suspected RCC was 1.57 per 1000 person-years. The incidence of RCC including those incidentally diagnosed at NNx was 3.7 per 1000 person-years.

Conclusions: The incidence of RCC in ADPKD transplant recipients is relatively low. Most RCCs are small and papillary type. Age and time post-transplant were associated with RCC. Further studies are needed to determine whether screening is warranted.

SA-PO564

Volume Regression of Native Polycystic Kidneys after Renal Transplantation

Yeonsoon Jung,[1,3] Maria V. Irazabal,[1] Fouad T. Chebib,[1] Patrick G. Dean,[2] Ziad El-Zoghby,[1] Vicente E. Torres.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Transplantation Surgery, Mayo Clinic, Rochester, MN; [3]Nephrology, Kosin Univ Gospel Hospital, Busan, Republic of Korea.*

Background: The natural course of native kidneys after renal transplantation or dialysis in patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD) is not well known.

Methods: We measured the volume of native kidneys (TKV) in 77 ADPKD patients who had pre (within two years) and at least one post-transplant renal CT or MRI, in 35 patients who had at least two post-transplant but no pre-transplant CT or MRI, and in 10 patients on chronic hemodialysis who had at least two CT or MRI. The last imaging was used in patients with multiple studies. Gender; age at transplantation; time on dialysis prior to transplantation; time from transplantation to post-transplant imaging; interval between pre-transplant imaging and transplantation; eGFR and diagnosis of hypertension or diabetes mellitus at last imaging; and immunosuppressive program (calcineurin, n=69, versus mTOR, n=8, inhibitors) were used in a multivariable model to identify factors associated with changes in TKV.

Results: TKV (±SD) prior to transplantation was 3218±1770 ml in the 77 patients who had imaging before and after transplantation and decreased by 20.2, 28.6, 36.5 and 45.8% after 0.5-1 (mean 0.7), 1-3 (1.8), 3-10 (5.7), and >10 (12.6) years, respectively. TKV was 3218 at baseline and 1348±1097 ml after the longest mean follow-up of 12.6 years. In the multivariable analysis, time on dialysis prior to renal transplantation (negatively) and time from transplantation (positively) associated with percent reduction in TKV. TKV decreased by 5.7±23.5% between 8.0±5.8 and 12.2±6.9 years in the 35 patients who only had imaging after transplantation. TKV increased by 15.9±32.3% in the 10 ADPKD patients on maintenance hemodialysis after a mean follow-up of 0.5±3.3 years.

Conclusions: TKV of native polycystic kidneys decreases substantially after renal transplantation, but not during chronic dialysis. The reduction occurs mainly during the first year and more slowly afterwards. Duration of dialysis prior to transplantation is associated with less reduction.

SA-PO565

Systematic and Standardized Employment of Laparoscopic Decortication to Control Pain Related to Enlarging Renal Cysts in Polycystic Kidney Disease

Neetika Garg,[1] Andrew A. Wagner,[2] Theodore I. Steinman.[1] *[1]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Urology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Severe pain that affects quality of life is reported in up to 60% of patients (pts) with Polycystic Kidney Disease (PKD). Enlarging cysts stretching the renal capsule are thought to be the cause of pain in the majority of PKD pts. This pain is most often experienced in the anterior abdomen, with only a minority having a posterior presentation. Laparoscopic cyst decortication (LCD) is reported to provide lasting pain relief in only

half the pts undergoing this procedure, but there are no uniform criteria for employing this treatment option. We describe and illustrate a systematic and uniform approach to addressing pain related to kidney cysts in PKD pts.

Methods: 1) The PKD pt must be able to provide a single finger pinpoint location of the chronic reproducible pain present for at least 6 months, especially located in the anterior abdomen. The chronic pain must be reported at least 5/10 on a Visual Analog Scale (VAS). 2) A skin marker is placed over the point of maximum tenderness prior to ultrasonography. 3) Kidney cyst(s) measuring at least 4 cm in biggest dimension must be identified directly below the marked area. 4) If the above criteria are met, our team urologist will employ the LCD technique, never unroofing more than 3 cysts.

Results: Using this detailed approach we have done 4 procedures, achieving uniform success in each pt. With a follow up of up to 32 months, pts have achieved uniform, complete and sustained improvement in their pain patterns. The VAS has fallen from an average 7/10 to 1/10. No change in serum creatinine or estimated GFR occurred in any pt.

Conclusions: Our case series suggests that targeting LCD towards cysts most likely to be responsible for pt symptoms, identified through careful history taking, physical examination and directed use of imaging, can increase the success rate of this procedure while minimizing damage to adjacent renal parenchyma. It also highlights the importance of a multi-disciplinary approach, involving nephrology, urology and radiology for management of pain attributable to enlarging cysts in PKD.

SA-PO566

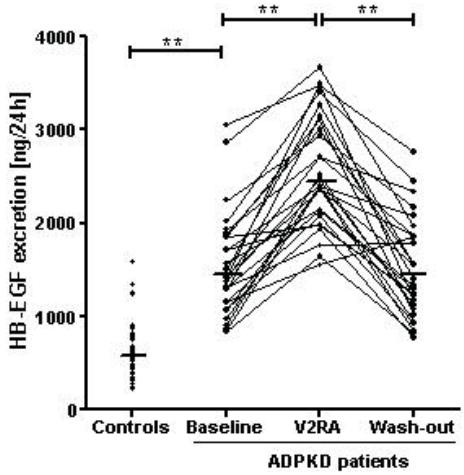
Urinary Excretion of EGF Receptor Ligands in Autosomal Dominant Polycystic Kidney Disease Patients and Response to Tolvaptan Treatment

Laura R. Harskamp, Ron T. Gansevoort, Harry Van Goor, Esther Meijer. *Nephrology, UMC Groningen, Groningen, Netherlands.*

Background: Recent animal research suggests that dysregulation of the epidermal growth factor (EGF) receptor pathway plays a role in the pathophysiology of Autosomal Dominant Polycystic Kidney Disease (ADPKD). Research on EGF receptor ligands in human ADPKD is lacking. We measured EGF receptor ligands in ADPKD patients at baseline and after treatment with the vasopressin V2 receptor antagonist (V2RA) tolvaptan, because this information could provide a rationale for future combination therapy.

Methods: Blood and urine concentrations of HB-EGF, EGF and TGF-α were measured by ELISAs in 27 ADPKD patients, 27 controls and in cyst fluid. In ADPKD patients, ligands were measured at baseline, after 3 week treatment with tolvaptan and after a 3 week wash-out period. Glomerular filtration rate (mGFR) was measured by io-thalamate infusion and total kidney volume by MRI.

Results: Urinary HB-EGF excretion as well as plasma concentration were higher in ADPKD patients compared with controls (P<0.001 and p=0.04). In contrast, both urinary EGF excretion and plasma EGF concentration were lower in ADPKD patients (both p<0.001). In cyst fluid HB-EGF was present, whereas TGF-α and EGF were not measurable. Higher HB-EGF excretion was associated with more severe disease, assessed as lower mGFR or higher TKV (both p=0.05), whereas higher EGF excretion and TGF-α excretion were negatively associated with disease severity. During tolvaptan treatment, HB-EGF excretion increased (p<0.001) and returned towards baseline after drug withdrawal.



Conclusions: Our data suggest that of the EGF receptor ligands HB-EGF may play a detrimental role in the pathophysiology of ADPKD. The V2RA induced increase in HB-EGF suggests that targeting the EGF receptor pathway during V2RA treatment may hold promise.

SA-PO567

The Feasibility of Using Urine or Plasma Osmolality as Indicator of Vasopressin Concentration and Prognosis in Patients with Autosomal Dominant Polycystic Kidney Disease

Niek F. Casteleijn, Debbie Zittema, Stephan J.L. Bakker, Wendy E. Boertien, Carlo A. Gaillard, Esther Meijer, Edwin M. Spithoven, Ron T. Gansevoort. *Univ Medical Center Groningen.*

Background: Vasopressin plays an essential role in osmoregulation, but has deleterious effects in patients with ADPKD. Increasing water intake to suppress vasopressin activity has been suggested as potential renoprotective strategy. This study investigated whether urine and plasma osmolality (Uosm; Posm) can be used as reflection of vasopressin activity in ADPKD patients in early and later stage of the disease.

Methods: We measured Uosm, Posm, plasma copeptin concentration (as surrogate for plasma vasopressin concentration), GFR using constant infusion with 125 I-iothalamate (mGFR) and total kidney volume by MR imaging (TKV). In addition, change in estimated GFR (eGFR) during follow-up was assessed.

Results: 94 patients with ADPKD were included (56 males, age 40±10 year, mGFR 77±32 ml/min*1.73m^2, TKV 1.55 (0.99 – 2.40) L. Uosm, Posm Uosm/Posm ratio and copeptin concentration were 420±195 mosmol/l, 289±7 mosmol/l, 1.4 (1.1-1.8) and 7.3 (3.2 – 14.6) pmol/l, respectively. Posm was associated with copeptin concentration, whereas Uosm and Uosm/Posm ratio were not.

Multivariate linear regression analyses investigating the cross-sectional association of baseline urine osmolality, urine to plasma osmolality ratio and plasma osmolality with baseline copeptin concentration (as dependent variable) in 94 ADPKD patients.

	Model 1		Model 2		Model 3	
	St. β	p-value	St. β	p-value	St. β	p-value
Uosm	-0.10	0.35	-0.02	0.86	+0.22	0.006
Age			+0.26	0.01	-0.12	0.14
Male sex			-0.32	0.001	-0.07	0.33
mGFR					-0.66	<0.001
TKV					+0.33	<0.001
Uosm/Posm ratio	-0.09	0.42	-0.01	0.98	+0.21	0.006
Age			-0.27	0.002	-0.13	0.13
Male sex			-0.31	0.01	-0.08	0.30
mGFR					-0.66	<0.001
TKV					+0.34	<0.001
Posm	+0.54	<0.001	+0.44	<0.001	+0.18	0.07
Age			+0.09	0.36	-0.21	0.03
Male sex			-0.15	0.13	-0.10	0.26
mGFR					-0.46	<0.001
TKV					+0.30	0.004

Abbreviations: Uosm, urine osmolality; mGFR, measured glomerular filtration rate; TKV, total kidney volume; Uosm/Posm ratio, Urine to plasma osmolality ratio; Posm, plasma osmolality.

Fifty-five patients were followed for 2.8±0.8 years. Baseline Posm and Uosm were not associated with rate of kidney function decline after adjustment for age, gender and TKV (St. β = -0.11, p= 0.6 and St. β = 0.14, p= 0.3, respectively), whereas baseline copeptin concentration did show an association with change in eGFR, in both a crude analysis (St. β= -0.41, p=0.003) and after adjustment for the aforementioned variables (St. β= -0.23, p=0.05).

Conclusions: These data suggest neither Uosm nor Posm are valid measures to identify ADPKD patients that may benefit from increasing water intake. Copeptin appears a better alternative for this purpose.

SA-PO568

Decreased Urine Concentration Ability Precede Renal Function Decline in Patients with Autosomal Dominant Polycystic Kidney Diseasewith *PKD1* Mutation

Mahiro Kurashige,[1,2] Kazushige Hanaoka,[1] Minako Imamura,[2] Takashi Udagawa,[1] Yoshindo Kawaguchi,[1,3] Toshio Hasegawa,[1,3] Tatsuo Hosoya,[1] Shiro Maeda,[2] Takashi Yokoo.[1] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ, School of Medicine, Tokyo, Japan; [2]Laboratory for Endocrinology, Metabolism and Kidney Diseases, RIKEN Center for Integrative Medical Sciences, Yokohama, Japan; [3]Dept of Medicine, Kanagawa Prefectural Shiomidai Hospital, Yokohama, Japan.*

Background: It has been shown that patients with *PKD1* mutations progressed faster than those with *PKD2* mutations in the European and Japanese patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD). However, little is known about factors or predictors for faster progression of the disease in ADPKD patients with *PKD1* mutations. To know the factors contribute to a faster decline of renal function, we evaluated clinical characteristics for 106 Japanese ADPKD patients with *PKD1* or *PKD2* mutation.

Methods: We examined the correlation between a decline of estimated glomerular filtration rate (eGFR) and clinical parameters, including urinary osmolality (Uosm), serum osmolality, plasma arginine vasopressin (AVP), using a linear regression analysis in 106 Japanese patients with ADPKD in a longitudinal study design (2.00-11.92 yrs follow-up). We further performed 15-hours fasting urinary concentration test in 41 ADPKD patients with preserved renal function (eGFR ≥60 ml/min/1.73m^2, 27 *PKD1* mutated and 14 *PKD2* mutated patients).

Results: Uosm, plasma AVP and *PKD1* mutation were independently associated with eGFR decline in 106 patients with ADPKD. In a urinary concentration test, maximum values of Uosm between 13 and 15 hours fasting were significantly lower in patients with *PKD1* mutation than in those with *PKD2* mutation (674.6 ± 119.9 versus 759.9 ± 89.4 mOsm/

kg H_2O, p = 0.007). A multiple linear regression analysis revealed that *PKD1* mutation (β = -0.460, p = 0.005), total kidney volume (β = -0.426, p = 0.004) and plasma AVP (β = -0.342, p = 0.011) were independently associated with the maximum Uosm.

Conclusions: Urinary concentration ability was decreased in ADPKD patients with *PKD1* mutation prior to decline of eGFR, and may be a good indicator for predicting eGFR decline.

SA-PO569

Accuracy of Creatinine-Based Estimating Equations for GFR in ADPKD

Stephen L. Seliger,[1] Anna T. Pham,[1] Thomas C. Dowling,[2] Charalett E. Diggs,[1] Terry J. Watnick.[1] *[1]Medicine, Nephrology, Univ of Maryland School of Medicine, Baltimore, MD; [2]Pharmacy Practice and Science, Univ of Maryland School of Pharmacy, Baltimore, MD.*

Background: The accuracy of creatinine-based estimating equations for GFR in ADPKD is uncertain. Alterations in tubular creatinine secretion early in disease progression may affect the accuracy of these equations.

Methods: Among 37 adults with ADPKD and eGFR >20 cc/min/1.73m^2,we measured GFR using iohexol plasma clearance (iGFR) and serum creatinine with an IDMS-traceable assay. We estimated GFR (eGFR) using 2 validated creatinine-based equations (CKD-Epi and MDRD). We compared the bias, precision, overall accuracy, and classification (for GFR<60 cc/min/1.73m^2) of each estimating equation.

Results: Mean age was 42.5±11.1years, 70%female, 84% Caucasian, 73% were treated with anti-hypertensives, mean iGFR was 77.6±38.7 cc/min/1.73m^2 and 41.0% had an iGFR<60 cc/min/1.73 m^2. There were strong linear correlations of each eGFR with iGFR (CKD-Epi: r=0.884; MDRD: r=0.882). The performance of $eGFR_{CKD\text{-}Epi}$ in terms of bias, precision, and accuracy was superior to that of $eGFR_{MDRD}$ (Table). However, both equations had comparable classification of patients with iGFR<60 cc/min/1.73m^2.

Performance Characteristic	Statistic	CKD-Epi Equation	MDRD Equation
Bias	Mean Difference (cc/min/1.73m^2)	-5.0 (-11.0, 1.0)	-11.7 (-18.0, -5.5)
Precision	Interquartile Range of Difference (cc/min/1.73m^2)	-10.2, +1.5	-20.8, -0.9
Accuracy	P30*	86.5%	73.0%
	Root Mean Square Error	18.34	18.52
Classification of iGFR<60 cc/min/1.73m^2	Sensitivity	93.3%	93.3%
	Specificity	90.9%	86.4%

*P30 represents proportion of GFR estimates that are within 30% of measured GFR. Negative values indicate under-estimation of true GFR (iGFR).

Conclusions: GFR estimated from CKD-Epi is superior to the MDRD estimating equation in ADPKD, but both equations underestimate iGFR and may have greater bias than when applied to the general CKD population.

Funding: NIDDK Support

SA-PO570

Glomerular Hyperfiltration Is a Common Risk Factor for Accelerated GFR Decline in Young Adults with Autosomal Polycystic Kidney Disease (ADPKD)

Giorgio Gentile,[1] Daniela Mastroluca,[2] Annalisa Perna,[1] Giuseppe Remuzzi,[1] Piero Luigi Ruggenenti.[1] *[1]IRCCS- Mario Negri Inst for Pharmacological Research, Bergamo, Italy; [2]Div of Nephrology, Univ Sapienza, Rome, Italy.*

Background: Glomerular hyperfiltration is an independent risk factor for accelerated GFR decline in ADPKD children. Here we aimed to assess whether and to what extent this finding can be extended to young (<35 years; NDT.2009.24:304-8) ADPKD adults.

Methods: Among 900 ADPKD outpatients of the "Papa Giovanni XXIII" Hospital (Bergamo, Italy), we identified all consecutive young adults with a baseline creatinine clearance (CrCl) >140 mL/min/1.73m^2, followed for at least 1 year with a minimum of 3 CrCl measurements.

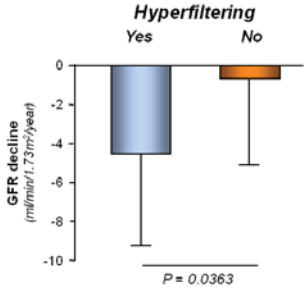
Results: We identified 91 patients (45 males, 49.5%) aged<35 years with a baseline CrCl of 110 (IQR: 86-129) mL/min/1.73 m^2. Eleven patients (12.1%) were hyperfiltering.

	Hyperfiltering (n=11)	Non-hyperfiltering (n= 80)	P
Males (%)	9 (81.1)	36 (45.0)	0.02
Age	27.2 (20.2-30.4)	29.2 (25.0-31.4)	0.17
Creatinine clearance (mL/min/1.73 m^2)	169.0 (162.0-209.0)	102.5 (84.5-122.0)	< 0.0001
Systolic BP (mmHg)	120.0 (111.0-127.0)	125.0 (112.5-136.5)	0.15
Diastolic BP (mmHg)	78.0 (63.0-81.0)	75.5 (67.5-82.0)	0.84

Over 6 (IQR:3.5-9) years, CrCl declined by 4.42 (9.35 to 0.97) and 0.50 (5.1 to -2.78) mL/min/1.73 m^2/year in hyper- and normofiltering patients at baseline, respectively (p=0.0363).

GLOMERULAR HYPERFILTRATION* AND GFR DECLINE IN 91 YOUNG ADULTS WITH ADPKD

** GFR > 140 ml/min/1.73m^2*



At final visit, median CrCl decreased by 1.5 and 57 mL/min/1.73 m^2 in normo- and hyperfiltering patients, respectively(p<0.0001). Higher baseline CrCl significantly correlated (p<0.0001,r=0.44) with faster CrCl decline on follow-up.

Conclusions: In ADPKD young adults, glomerular hyperfiltration is relatively common and associates with accelerated renal function loss. Whether hyperfiltration may be a specific target for interventions aimed at preventing disease progression merits further investigation.

SA-PO571

Serum Gamma-Glutamyl Transferase (GGT), Conjugated Bilirubin, and ^{18}F-FDG PET/CT as Potential Diagnostic Markers in Patients with Renal or Hepatic Cyst Infection

Marten A. Lantinga,[1] Tom J.G. Gevers,[1] Rudolphe De Sevaux,[2] Wim J.G. Oyen,[3] Johan W. De Fijter,[4] Darius Soonawala,[4] Mahdi Salih,[5] Robert Zietse,[5] Esther Meijer,[6] Ron T. Gansevoort,[6] Joost P.H. Drenth.[1] *[1]Hepatology, Radboudumc; [2]Nephrology, Radboudumc; [3]Nuclear Medicine, Radboudumc, Nijmegen, Netherlands; [4]Nephrology, LUMC, Leiden, Netherlands; [5]Nephrology, EMCR, Rotterdam, Netherlands; [6]Nephrology, UMCG, Groningen, Netherlands; [7]Collaboration with the DIPAK consortium.*

Background: Cyst infection is a severe complication in autosomal dominant polycystic kidney disease (ADPKD) and autosomal dominant polycystic liver disease (PCLD). Reliable, non-invasive diagnostic markers are required to reduce the need for invasive interventions. The aim was to investigate potential markers of cyst infection.

Methods: We identified ADPKD and PCLD patients with a suspected cyst infection from clinical and renal transplant registries that were monitored in four Dutch tertiary referral centers in the period 2001-2013. Patients were included if cyst aspirate culture led to pathogen isolation or diagnostic criteria indicating cyst infection (abdominal pain, fever, and serum CRP >50mg/L) were met. We retrospectively derived clinical, biochemical, and imaging data from medical records.

Results: We included 81 patients (94% ADPKD, 53% renal transplant, 11% dialysis, median age 56 years, male 51%) with renal cyst infection (RCI, 64%) or hepatic cyst infection (HCI, 36%). In patients without renal transplantation or dialysis, median eGFR (CKD-EPI) was 52ml/min/1.73m^2 [IQR 23-81] in RCI (n=19) and 74ml/min/1.73m^2 [IQR 28-89]in HCI (n=11). CKD-stage ≥4 (eGFR <30) was seen in 32% (RCI) and 27% (HCI) of patients without renal transplantation or dialysis. In patients with HCI, serum GGT and conjugated bilirubin were abnormal in 22/23 (median 94U/L, IQR 56-169) and 8/13 (median 0.5mg/dl, IQR 0.2-0.7). In contrast to computed tomography,^{18}F-FDG PET/CT was predominantly indicative for cyst infection in both RCI (12/14 versus 5/17) and HCI patients (15/16 versus 5/13).

Conclusions: Hepatic cyst infection is associated with elevated serum GGT and conjugated bilirubin. ^{18}F-FDG PET/CT is highly sensitive in detecting renal- and hepatic cyst infection.

SA-PO572

Height-Adjusted Total Liver Volume Affects Hepatic Complications and Symptoms in the Patients with Autosomal Dominant Polycystic Kidney Disease

Hyunsuk Kim,[1] Hayne C. Park,[1] Sun Ae Han,[2] Joon Young Jang,[2] Hee Jung Jeon,[2] Kook-Hwan Oh,[1] Young-Hwan Hwang,[3] Curie Ahn.[1,3] *[1]Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; [2]Transplantation Research Inst, Seoul National Univ, Seoul, Korea; [3]Internal Medicine, Eulji General Hospital, Seoul, Korea.*

Background: Polycystic liver disease (PLD) is the most frequent extra-renal manifestation of ADPKD. We investigated the relationship between hepatic complications/symptoms and the height-adjusted total liver volume (htTLV, mL/m) in a cross-sectional study with 488 Korean ADPKD patients.

Methods: PLD was defined as the presence of at least 4 liver cysts in a CT scan. Medical records were reviewed and physical examinations were undertaken to identify hepatic symptoms and complications. A questionnaire was also used to evaluate hepatic symptoms. The TLV was measured by stereotactic method and then adjusted by the height of the subject.

Results: PLD was more common among women (96.2% *versus* .86.9%, P <0.001). The common complications were ascites (16.6%), bilateral leg edema (5%), hernias (3.6%) and cyst infections (3.1%). Presence of pressure-related complications including ascites, hernia, bilateral leg edema, biliary dilatation, and IVC stenosis were associated with htTLV > 2,100 mL/m. Hepatic cyst infection or cholangitis were also related to htTLV > 2,100 mL/m (P < 0.001). The common symptoms were back pain (59.4%), flank pain (53.1%), abdominal fullness (46.5%), dyspnea or chest discomfort (44.3%). Presence of pressure-related symptoms including early satiety, dyspnea or chest discomfort, palpable mass and abdominal fullness, pain, and gastrointestinal symptoms were associated with htTLV > 1,600 mL/m (P < 0.001). Additionally, the case of pressure-related complications, hepatic cyst infection or cholangitis were also related to htTLV > 1,600 mL/m (P < 0.001).

Conclusions: Clinicians should pay more attention to symptom in case of htTLV >1,600 mL/m and complication in subjects with htTLV of 2,100 mL/m in Korea.

SA-PO573

Development and Validation of a Polycystic Liver Disease Specific Questionnaire Marie C. Hogan,[1] Tom J.G. Gevers,[2] Patrick S. Kamath,[3] Jeff Sloan,[4] Joost P.H. Drenth.[2] *[1]Nephrology, Mayo Clinic; [2]Hepatology, Radboud UMC, Nijmegen, Netherlands; [3]Hepatology, Mayo Clinic; [4]Health Sciences Research, Mayo Clinic, MN.*

Background: Symptomatic polycystic liver disease (PLD) is common in ADPKD and ADPLD and treatment focuses on improvement of symptoms. However, generic questionnaires lack sensitivity to capture PLD-related symptoms, a prerequisite to determine efficacy of therapy. The aim of this study is to develop and validate a disease specific questionnaire assessing symptoms in PLD (PLD-Q).

Methods: We identified PLD-related symptoms impacting quality of life by literature review and qualitative interviews with Dutch patients and clinicians. Subsequently, we developed questions on frequency and severity of each symptom. Individual questions scores were summarized into a total score ranging from 0-100 points. We undertook a validation study in 200 patients with mild-severe PLD from the Dutch PLD-registry. We assessed convergent validity (Spearman's correlation coefficient) of the PLD-Q score with EORTC QLQ-C30 symptoms subscale and the EQ5D-VAS score. Furthermore, we compared PLD patient scores with controls and 183 PLD; symptomatic versus asymptomatic patients and ADPKD versus ADPLD (Mann-Whitney U test) for discriminative validity. Intraclass correlation coefficient (ICC) of test-retest was calculated to assess reproducibility.

Results: In the validation survey, 167 patients (85% female, mean 55.6y, 45% ADPKD) completed the 14 item questionnaire (response rate 84%; mean score 40.1 ± 18.3, range 0-86.5 points). PLD-Q correlated well with the EORTC30 (r= 0.788,p<0.001) and EQ5D (r= -0.666,p<0.001). PLD-Q discriminated between patients and controls (40.1 ± 18.3 versus 19.3 ± 10.5, P<0.001) and between symptomatic and asymptomatic patients (44.5 ± 16.7 versus 24.9 ± 16.4, p<0.001). ADPKD patients scored higher than ADPLD patients (43.8 ± 16.6 versus 37.0 ± 19.0, p=0.016). The PLD-Q showed excellent reproducibility (ICC 0.914).

Conclusions: The PLD-specific questionnaire (PLD-Q) has good convergent and discriminative validity and reproducibility and captures symptoms in PLD patients. We have commenced validation of the translated PLD-Q in a U.S. PLD cohort, including correlation with liver/kidney volumes and comparison with ADPKD patients without PLD.

Elevated Alkaline Phosphatase Predicts Response in Polycystic Liver Disease during Somatostatin Analogue Therapy: A Multi-Center Pooled Analysis on Individual Patient Data Marie C. Hogan,[1] Tom J.G. Gevers,[2] Frederik Nevens,[3] Vicente E. Torres,[1] Joost P.H. Drenth.[1] *[1]Nephrology Div, Mayo Clinic, Rochester; [2]Dept of Gastroenterology and Hepatology, Radboud UMC, Nijmegen, Netherlands; [3]Dept of Hepatology, KU Leuven, Leuven, Belgium.*

Background: Somatostatin analogues (SA) reduce liver volumes (LVs) in patients with polycystic liver disease (PLD). However, these patients show a considerable variability in treatment responses, making it difficult to predict response to SA therapy.

Methods: Our aim was to identify specific patient, disease or treatment characteristics that predict response in PLD during SA therapy. We pooled the individual patient data of 4 trials (NCT00771888,NCT00426153, NCT01157858, NCT01354405) of long-acting SAs in PLD (120 mg lanreotide or 40 mg octreotide) for 6 or 12 months that included LV as the primary outcome. We performed uni- and multivariate linear regression analysis with 9 preselected patient, disease and drug variables to identify independent predictors of response, defined as percent change in LV. Secondary outcome was percent change in kidney volume in the ADPKD subgroup. All analyses were adjusted for baseline LV and center (random) effect.

Results: 153 PLD patients (86% female, mean age 50 years, median LV 4974 ml, 69% ADPKD) from 3 international centers were treated with octreotide (n=70) or lanreotide (n=83). Mean reduction in LV was 4.2% (range -31.7% to +9.7%). Uni- and multivariate linear regression revealed that elevated baseline alkaline phosphatase (ALP) was associated with increased response during SA therapy (-2.7%, 95% CI -5.1% to -0.2%, p = 0.037), independently of baseline LV. Duration of therapy (6 versus 12 months), SA type and eGFR did not affect response. Elevated ALP remained associated with LV response (-3.2%, 95% CI -6.0 to -0.3%, p=0.029) in ADPKD patients (n=100), but did not predict response in kidney volumes (0.1%, 95% CI -3.1 to 3.3%, p = 0.97).

Conclusions: Elevated ALP is associated with response in polycystic liver disease during SA therapy, and could possibly serve as a prognostic biomarker in this disease.

Outcomes of Liver Transplantation, Partial Hepatectomy, and Transcatheter Arterial Embolization for Massive Polycystic Liver in Autosomal Dominant Polycystic Kidney Disease Patients Hyunjin Ryu,[1] Miyeun Han,[1] Hee Jung Jeon,[2] Jong Cheol Jeong,[2] Hayne C. Park,[1] Young-Hwan Hwang,[3] Jaeseok Yang,[2] Curie Ahn.[1,2] *[1]Internal Medicine, Seoul National Univ; [2]Transplantation Center, Seoul National Univ Hospital; [3]Internal Medicine, Eulji Univ College of Medicine.*

Background: Polycystic liver disease(PLD) is the most common extra-renal manifestation in autosomal dominant polycystic kidney disease(ADPKD). Patients with PLD suffer from hepatomegaly symptoms. Interventions for symptomatic PLD include transcatheter arterial embolization(TAE), partial hepatic resection and liver transplantation(LT). We compared outcomes of each treatment modality.

Methods: We retrospectively analyzed 29 patients, undergone TAE, partial hepatectomy, or LT in ADPKD patients in a single center.

Results: Six and seven patients underwent LT and partial hepatectomy, respectively, while sixteen patients underwent TAE. Living donor LT was done for intractable hepatomegaly symptoms in 2 TAE patients, and for uncontrolled ascites in a patient. Deceased donor(DD) LT was performed in 2 patients for hepatic failure or uncontrolled ascites after TAE. Another patient underwent DDLT for hepatic failure after partial hepatectomy. The most common complications were ascites and pleural effusion. Two patients were under hemodialysis at LT, and acute kidney injury resulted in kidney failure in 1 DDLT patient. All patients had maintained good liver function at a median follow-up of 15.5 months. Causes of partial hepatectomy were recurrent cyst infection and hepatomegaly symptoms. One patient underwent partial hepatectomy, because multiple TAE had failed to control symptoms. Preoperative CTP score was lower in the partial hepatectomy group than in the LT group. A few serious infectious occurred, and antibiotic treatment cured them without mortality. Eleven patients received single TAE, and five patients underwent TAE twice. Two patients died of obstructive jaundice and cyst infection. Five patients (31.3%) in the TAE group needed LT or partial hepatectomy to relieve symptoms or rescue hepatic failure.

Conclusions: LT is more effective and tolerable treatment option for symptomatic PLD in ADPKD compared to partial hepatectomy and TAE.

SA-PO576

SIrolimus for ADPKD Patients with Massive Polycystic LiVER (SILVER): An Interim Analysis Hayne C. Park,[1] Hyunsuk Kim,[1] Hyunjin Ryu,[1] Sun Ae Han,[2] Joon Young Jang,[2] Hee Jung Jeon,[3] Kook-Hwan Oh,[1] Young-Hwan Hwang,[4] Curie Ahn.[1,2,3] *[1]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea; [2]Transplantation Research Inst, Seoul National Univ, Seoul, Republic of Korea; [3]Transplantation Center, Seoul National Univ Hospital, Seoul, Republic of Korea; [4]Dept of Internal Medicine, Eulji General Hospital, Seoul, Republic of Korea.*

Background: Polycystic liver is the most common and often fatal extrarenal manifestation to autosomal dominant polycystic kidney disease (ADPKD) patients. We aimed to assess the efficacy and safety of mTOR inhibitor, sirolimus on liver cyst growth in patients with severe polycystic liver.

Methods: Adult (18-65 years) ADPKD patients with massive (total liver volume (TLV) > 2500 mL) or symptomatic polycystic liver received sirolimus starting from 2 mg/day for 1 year and followed up with conventional treatment for another 1 year. The drug dose was titrated to the trough level of 4-10 ng/dL. The primary endpoint was TLV change in 1 year measured by CT. This study was registered with ClinicalTrials.gov, NCT01680250.

Results: Twelve patients (mean age 49, female 83%) were enrolled between Sept 2011 and Feb 2013. The TLV, TKV, and eGFR at baseline were 5641 mL, 1387 mL, and 59 mL/min/1.73m^2. Five patients (42%) dropped out due to adverse events, and therefore, 7 patients were included in the efficacy analysis. TLV was significantly increased from 6713 to 7494 mL (+11.6%) after 1 year of sirolimus treatment (p = 0.02). TKV was not significantly changed after treatment (2450 versus 2537 mL, p = 0.47), whereas eGFR was significantly decreased in spite of sirolimus treatment (59.1 versus 50.8 mL/min/1.73m^2, p = 0.02). Serious adverse events occurred in 2 subjects (1 death from biliary sepsis, 1 admission from cyst infection). Two patients intermittently reduced or stopped study medication because of adverse events (cyst infection and increased proteinuria with renal progression). The high rate of adverse events prompted us to stop further enrollment for safety reason.

Conclusions: Sirolimus did not effectively reduce TLV in ADPKD patients with massive or symptomatic polycystic liver.

SA-PO577

Identifying Genetic Modifiers for Severe Polycystic Liver Disease (PLD) by Targeted Exome Sequencing Amirreza Haghighi,[1] Young-Hwan Hwang,[2] Ning He,[1] Kairong Wang,[1] Winnie Y. Chan,[1] Xuewen Song,[1] York P. Pei.[1] *[1]Div of Nephrology, Univ Health Network and Univ of Toronto, Toronto, ON, Canada; [2]Div of Nephrology, Eulji General Hospital, Eulji Univ College of Medicine, Seoul.*

Background: Severe PLD is a rare and poorly understood phenotype associated with *PKD1* and *PKD2* mutations in ADPKD and *PRKCSK* and *SEC63* mutations in ADPLD. Mutations of *PRKCSH* or *SEC63* reduces the functional polycystin-1 (PC-1) dosage by

decreasing endoplasmic reticulum protein-processing (ER-PP) and aggrevates cystic disease severity in-vivo (Nat Genet 43: 639-647, 2011). We hypothesize that mutations of genes in the ER-PP pathway may aggrevate PLD in patients with ADPKD/ADPLD.

Methods: To identify genetic modifiers of severe PLD, we performed WES using Illumina HiSeq2000/2500 with SSV4/5 capture in 30 unrelated patients with and 3 affected relatives without severe PLD (including 4 affected sib-pairs discordant of PLD and two affected sib-pairs concordant of severe PKD) and focused analysis on 167 genes involved in ER-PP. All patients with severe PLD had a liver span >25 cm at mid-clavicular line by CT/MRI or >3x normal total liver volume. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare deleterious variants of high and moderate impact as predicted by PolyPhen-2, Sift, and Provean.

Results: Overall, 99.8% of all exomes sequenced were covered with a mean depth of 108X. We identified a total of 45 rare deleterious variants from 21 ER-PP candidate genes that affected 2-4 patients. Among them, the followings are functionally linked: SEC31B, SEC24A, SEC24D, SEC23B, MOGS, UGGT1, RPN1, OS9, EDEM3, WFS1, BAX, PARK2, ATXN3L, UBXN6, and PRKCSH.

Conclusions: If our hypothesis is correct, our preliminary results suggest extensive hetergeneity with no one single ER-PP gene accounting for a large proportion of severe PLD cases. We are currently completing exome sequencing in 50 cases of severe PKD to narrow a short list of most promising candidate ER-PP genes (i.e. each involved in >5 unrelated patients) for follow-up functional studies. Identification of genetic modifiers of PLD has the potential to improve risk prediction and treatment of this unusual complication.

SA-PO578

Genotype-Phenotype Correlations in Extra-Renal Manifestations of Autosomal Dominant Polycystic Kidney Disease (ADPKD): Insights from a Cohort of 1425 Patients Emilie Cornec-Le Gall,[1,2] Maryvonne Hourmant,[3] Cecile M. Vigneau,[4] Eric Renaudineau,[5] Christophe Charasse,[7] Philippe Gatault,[6] Marie-Pierre Audrezet,[1,2] Claude Ferec,[1,2] Yannick Le Meur.[1] *[1]CHRU Brest; [2]Inserm 1078; [3]CHU Nantes; [4]CHU Rennes; [5]CH Saint Malo; [6]CHU Tours; [7]CH Saint Brieuc.*

Background: ADPKD is marked by a high clinical variability, both in regards of the renal outcome and the occurrence of extra-renal manifestations. The aim of our study is to describe extra-renal manifestations in ADPKD and to investigate if the gene and the mutation involved predispose to specific extra-renal phenotypes such as aneurysms, diverticular disease of the colon and liver cysts.

Methods: Genkyst is an ongoing cross-sectional cohort study involving over 70 nephrologists in the western part of France. All the consenting ADPKD patients were included in 19 centers of Nephrology between 2010 and May 2014. Comprehensive clinical data were collected and a molecular analysis of *PKD1* and *PKD2* genes was undertaken.

Results: 1425 patients were included (median age 55.6 y, 659 men). The absence of liver cysts after age 45 was unusual (12% of the women and 22% of the men), irrespective of the gene and the mutation identified. 109 patients from 105 pedigrees (7.6%) had presented at least one vascular complication (86 intracranial aneurysms and 23 aortic aneurysms) at a median age of 47 y [19-71], only 26% had a familial history of vascular complication at diagnosis. Neither the gene involved, *PKD1* or *PKD2*, nor the mutation type or position (in contrast with a former study) were associated with the development of these vascular complications. Diverticular disease of the colon was reported in 10% of the patient, at a median age of 58.5 y, without any influence of the gender, or of the gene or the mutation involved. Conversely to previous publications, we did not find any evidence for infertility in ADPKD male patients.

Conclusions: Based on this large cohort, we provide insights on the exact prevalence of extra-renal manifestations in ADPKD. Despite several cases of familial clustering, there was no genic or allelic influence on the occurrence of these extra-renal features, which suggests the involvement of modifier genes.

SA-PO579

Complex Genotypes Identified Through Genetic Characterization of the HALT PKD ADPKD Cohort Christina M. Heyer,[1] Jamie L. Sundsbak,[1] Arlene B. Chapman,[2] Ronald D. Perrone,[3] Robert W. Schrier,[4] Theodore I. Steinman,[5] Vicente E. Torres,[1] Franz Winklhofer,[6] Kyongtae Ty Bae,[7] Michael F. Flessner,[8] Katharina Hopp,[1] Peter C. Harris.[1] *[1]Mayo Clinic, Rochester, MN; [2]Emory, Atlanta, GA; [3]Tufts, Boston, MA; [4]U of Colorado, Denver, CO; [5]BIDMC, Boston, MA; [6]KUMC, Kansas City, KS; [7]U of Pittsburgh, Pittsburgh, PA; [8]NIH, Bethesda, MD.*

Background: The HALT PKD study is a phase three clinical trial investigating the affects of ACE inhibitors and ARB blockers on a cohort of 1043 hypertensive ADPKD patients. We have completed genetic analysis of 970 patients who provided DNA samples from 833 families, for the *PKD1* and *PKD2* genes.

Methods: *PKD1* and *PKD2* were sequenced in all probands by direct Sanger sequencing (5 long range and 63 nested/single copy reactions), followed by bioinformatic evaluation of potential mutations. MLPA was performed in mutation negative patients to identify large deletions/duplications.

Results: Of the resolved families, 626 (75.2%) were PKD1, 121 (14.5%) PKD2, with no mutation detected (NMD) in 66 families (7.9%). Interestingly, 20 families (2.4%) exhibited evidence of complex genotypes. These included three families with one strongly predicted change along with a second significant variant in the same gene, and two families with likely significant *PKD1* and *PKD2* variants. Four other families had strong evidence of mosaicism. For example, in family 690020 the daughter had a clear frameshifting mutation, c.12442_12443insAGGA, seen as heterozygous, but the mother's sequence had a very low level of the mutant allele, detectable only by manual inspection. Disease due to the combined effect of two (or three) likely hypomorphs, in cis or trans, was suspected in nine families, include two with the previously described p.R3277C hypomorph. Finally, two families were suspected of having gene conversion events due to the large number of variants identified matching the *PKD1* pseudogenes in *PKD1* exon 23.

Conclusions: Complex haplotypes manifesting largely as typical ADPKD presentations were found in approximately 2% of the HALT cohort. These families are a particular diagnostic challenge and show the need to completely screen both genes for full genetic characterization.

SA-PO580

New Genetic Test for Prognosis and Diagnosis of All (Common, Rare and Ultra-Rare) Cystic Kidney Diseases M. Lara Besada-Cerecedo,[1] Lisbeth Silva,[1] Beatriz Sobrino,[2] Jorge Amigo,[2] Olaya Lamas-Gonzalez,[1] Helena Covelo-Molares,[1] Marina García,[1] Patricia Regueiro Casuso,[1] Ana Barcia de la Iglesia,[1] Francisco Barros Angueira,[2] Angel Carracedo,[2] Candido Diaz Rodriguez,[1] Miguel A. Garcia-Gonzalez.[1] *[1]Group of Genetics and Developmental Biology of Renal Diseases, Health Research Inst of Santiago de Compostela (IDIS). Clinical Univ Hospital (CHUS), Santiago de Compostela, Spain; [2]Galician Public Foundation of Genomic Medicine, Clinical Univ Hospital (CHUS), Santiago de Compostela, Spain.*

Background: Our group designed the first genetic and functional strategy for diagnostic and prognosis of all cystic kidney diseases using Next Generation Sequencing (NGS).

Methods: Three panels of genes were created: one of them includes the eight genes associated with PKD that are more common in the population, a second panel includes the eight genes with the replicated portion of PKD1 (exon 1-34) and finally, the other includes all the genes associated with PKD (72 genes).

Results: Here we show the validation of this three panels aiming to be use as a diagnostic tool in PKD. We have applied the test to 51 patients with PKD and we could detect 35 mutations in 25 patients.

Conclusions: Our results show that our genetic test detects mutations in all known genes associated with cystic kidney disease in a rapid, precise and cost-effective way.

Funding: Government Support - Non-U.S.

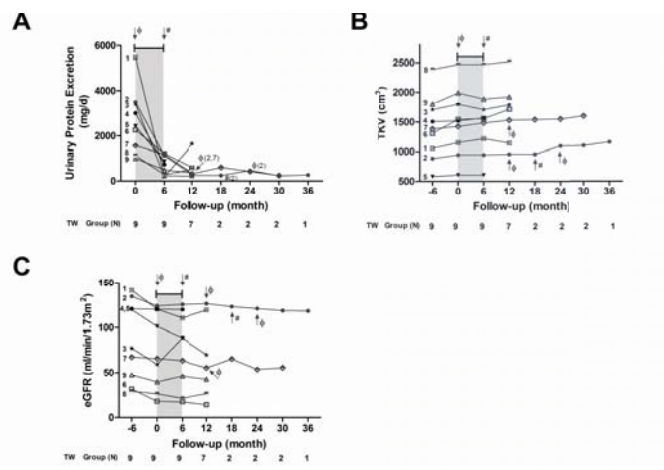
SA-PO581

Triptolide Containing Formulation in Patients with Autosomal Dominant Polycystic Kidney Disease and Proteinuria-An Uncontrolled Trial Changlin Mei, Shengqiang Yu, Dongping Chen, Yiyi Ma. *Dept of Nephrology, Shanghai Changzheng Hospital, Shanghai, China.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited cystic renal disease. Proteinuria is a risk factor for disease progression in ADPKD patients. The traditional Chinese medicine Tripterygium *wilfordii* (TW) contains triptolide and has been widely used as an effective antiproteinuric agent. Recently, triptolide was shown in experimental studies to inhibit cyst growth. The effects of TW in ADPKD patients with proteinuria are unknown.

Methods: In an uncontrolled trial, proteinuric ADPKD patients resistant to 6 months' treatment of losartan were treated with TW (1 mg/kg/d, divided into three doses per day) for 6 months. Effect of TW on 24-hour urinary protein excretion (UPE), eGFR and total kidney volume (TKV) were analyzed.

Results: Proteinuric ADPKD patients had a mean 24-hour UPE of 2,645±1,408 mg/d (range 1,004 to 5,483 mg/d) with 6-month TKV enlargement of 93±74 cm^3 and TKV growth rate of 6.8±5.1%. After 6 months of treatment with TW, the UPE decreased to 702±418 mg/d (range 189 to 1,215 mg/d) with one patient relapsed. An inhibition of the 6-month TKV enlargement (-1±61 cm^3, 0.4±3.8%) was noted. The 6-month eGFR decline was inhibited from -10±8 mL/min/1.73 m^2 to 1±12 mL/min/1.73 m^2 and the 6-month eGFR decrease rate was relieved from -14±12% to 2±20% in all the treated patients (figure1).



During treatment, 2 female patients developed menoxenia, and another 4 developed amenorrhea. The menstrual cycles normalized within 6 months after withdrawal of TW.

Conclusions: TW treatment was associated with an impressive reduction of proteinuria in ADPKD patient. It remains to be shown whether the effect of TW on proteinuria occurs independently of its possible effect on TKV enlargement and renal function protection.

SA-PO582

Feasibility of Measuring Renal Blood Flow by Magnetic Resonance Imaging without Contrast in Patients with Autosomal Dominant Polycystic Kidney Disease

Edwin M. Spithoven, Esther Meijer, Wendy E. Boertien, Carlo A. Gaillard, Priya Vart, Ron T. Gansevoort. *Dpt of Nephrology, UMCG, Groningen, Netherlands.*

Background: Renal blood flow (RBF) has been shown to predict disease progression in autosomal dominant polycystic kidney disease (ADPKD). The value of RBF measurement was, however, investigated in a single study, that included only subjects with a creatinine clearance >70ml/min. Furthermore, contrast enhanced MRI was used, which precludes RBF assessment in patients with impaired GFR. We investigated therefore the feasibility and accuracy of RBF measurement by non-contrast MRI (RBF_{MRI}) in ADPKD patients with a wide range of eGFR.

Methods: Accuracy of RBF_{MRI} measurement was assessed by gold standard for measuring flow using a phantom. In a test-set of 21 ADPKD patients repeated RBF_{MRI} measurements were performed to assess reproducibility. In addition, in a cohort of 91 patients RBF_{MRI} was compared with RBF estimated by continuous infusion of hippuran (RBF_{Hip}). Variability in RBF_{MRI} and RBF_{Hip} explained by disease characteristics in ADPKD severity was investigated using multivariate regression analyses.

Results: Concordance correlation coefficient between flow measured by fluid collection in a phantom (gold standard) and phase contrast MRI assessed flow was 0.97. Intra- and interobserver coefficients of variation (CV) in the test-set were 2.3% and 3.5%, resp. In the patient cohort technical success rate of RBF_{MRI} measurement was 76%. Technical problems that precluded RBF_{MRI} measurement occurred predominantly in ADPKD patients with lower eGFR (34 versus 16% of subjects with eGFR ≤70 and >70ml/min*1.73m^2, resp., p=0.02). In patients with lower eGFR, intra-CVs were higher compared to patients with higher eGFR (3.2 versus 1.5%) and inter-CV was 3.5%. RBF_{MRI} correlated with RBF_{Hip} (r=0.81, p<0.001). In subjects with higher eGFR variability explained by disease characteristics was similar for RBF_{MRI} and RBF_{Hip} (R^2 0.36 versus 0.51 resp., p=0.2) whereas in subjects with lower eGFR this was less for RBF_{MRI} (0.17 versus 0.72 resp., p<0.001).

Conclusions: Our study shows that RBF can be measured accurately in ADPKD patients by non-contrast MRI, but this technique may be less feasible in subjects with lower eGFR.

SA-PO583

Diagnostic Accuracy of Fluorine-18 Fluorodeoxyglucose Positron Emission Tomography with Computed Tomography for Cyst Infections in Patients with Polycystic Kidney Disease

Mickaël Bobot,[1] Bertrand Gondouin,[1] Tristan Legris,[1] Marion Sallée,[1] Stephane Burtey,[1] Philippe Souteyrand,[2] Noemie Jourde-Chiche.[1] *[1]Nephrology, Aix-Marseille Univ, Marseille, France; [2]Radiology, Aix-Marseille Univ, Marseille, France.*

Background: Renal/hepatic cyst infections are a common complication of polycystic kidney disease (PKD). CT and MRI are not always contributive for the diagnosis, which relies on an index of clinical suspicion. Objective: diagnostic accuracy of F18FDG PET-CT in cyst infection of PKD patients, and compare it with other imaging techniques.

Methods: Monocentric retrospective study on patients with PKD hospitalized in 2006-2013 for a suspicion of cyst infection, who underwent a PET-CT. Control group of patients with PKD undergoing PET-CT for other motives. Diagnosis of cyst infection retained a posteriori on index of clinical suspicion, absence of differential diagnosis and favorable response to treatment. PET-CT considered positive if focal hypermetabolism of the wall or one/several cysts. CT or MRI considered positive if thickened cyst walls (contrast enhanced if injection performed) and infiltration of adjacent fat.

Results: 32 PET-CT were performed in 24 patients with PKD for suspected cyst infection. The diagnosis was retained in 18/32. PET-CT was positive in 14/18 (true positive), negative in 4/18 (false negative). There was no false positive, even in the 9 control patients. PET-CT had a sensitivity of 77%, a specificity of 100% and a negative predictive value of 77%. PET-CT revealed a differential diagnosis in 3 patients (1 diverticulitis and 2 pulmonary lesions). In parallel, 21 CT (18 with contrast media injection) were performed in PKD patients with a suspicion of cyst infection. Diagnostic accuracy of CT was poor : sensibility 7%, negative predictive value 35% (p < 0,001 versus PET-CT). MRI was performed in 8 patients only (1 true positive, 1 false negative, 6 true negative).

Conclusions: Diagnostic accuracy of PET-CT is superior to that of CT in cyst infections of PKD, for comparable radiation exposure and without nephrotoxic contrast media injection. Prospective studies are needed to evaluate the cost-effectivness of PET-CT in this indication.

Novel Approach to Estimate Kidney Volumes Using Computer-Assisted Segmentation Tools in ADPKD

Satoru Muto,[1] Shuji Isotani,[1] Haruna Kawano,[2] Jun Masumoto,[3] Ken Kotera,[4] Kousuke Kitamura,[1] Masaki Kimura,[1] Keisuke Saito,[1] Hisamitsu Ide,[1] Raizo Yamaguchi,[1] Shigeo Horie.[2] *[1]Urology, Teilyo Univ, Tokyo, Japan; [2]Urology, Juntendo Univ, Tokyo, Japan; [3]Research and Development Management Headquarters, FUJIFILM Corporation, Tokyo, Japan; [4]Business Planning and Promotion DPET. IT Solution Business DIV, FUJIFILM Corporation, Tokyo, Japan.*

Background: Some recent data indicate that kidney growth is a critical predictor of progression to renal failure in autosomal dominant polycystic kidney disease (ADPKD) patients. Consequently, kidney volume growth is considered the best surrogate marker predicting the decline of renal function in ADPKD. It is, however, hard to measure kidney volume, easily, precisely and reproducibly. To evaluate whether kidney volumes can be accurately estimated using semi-automatic computer-assisted segmentation tools images of patients with ADPKD.

Methods: CT images of 23 ADPKD patients (9 men and 14 women, median age 48 years, age range 36–72 years), 46 kidneys were analyzed. For each transverse CT image slice, we measured kidney areas using stereology methods. The kidney volumes were calculated by summing up the area measurements of all the slices covering the kidney by using computer-assisted segmentation tools in Synapse VINCENT (FUJIFILM Corporation, Tokyo, Japan). We then compared the kidney volumes predicted from the conventional ellipsoid method and some clinical parameters.

Results: The median eGFR and cystatin C were 54.8 ml/min/1.73 m^2 and 0.97 mg/l, respectively. The median kidney volumes predicted by conventional ellipsoid method and VINCENT method are 715.4 ml (range; 369.2-8854.3), 621.4 ml (range; 283.4-2837.8), respectively. The kidney volume predicted from VINCENT method correlated extremely well with the kidney volume from ellipsoid method (R(2) = 0.812, p=0.002). In addition, the kidney volume predicted from VINCENT method correlated extremely well with s-Cr (R(2) = 0.806, p=0.003) and cystatin C (R(2) = 0.767, p=0.011), respectively.

Conclusions: Synapse VINCENT is an interactive segmentation tool for efficient, accurate, and reproducible boundary extraction. These tools helped us to reduce the time to get accurate kidney volume.

Mutations in TRAF3IP1/IFT54 in Patients with Syndromic Nephronophtisis Lead to Cilia and Cytoskeleton Defects

Albane A. Bizet,[1] Anita Becker-Heck,[2] Rebecca Ryan,[1] Kristina Weber,[3] Emilie Filhol,[1] Pauline Krug,[1] Jan Halbritter,[4] Edward James Oakeley,[2] Fan Yang,[7] Tewis Bouwmeester,[2] Lucile Pinson,[5] Elisabeth Cassuto,[6] Corinne Antignac,[1] Marie-Claire Gubler,[1] Joseph D. Szustakowski,[7] Friedhelm Hildebrandt,[4] Esben Lorentzen,[3] Andreas W. Sailer,[2] Alexandre Benmerah,[1] Pierre Saint-Mezard,[2] Sophie Saunier.[1] *[1]Inserm U1163, Imagine Inst, Paris Descartes Univ, Paris, France; [2]Novartis Insts for Biomedical Research, Basel, Switzerland; [3]Max-Planck-Inst of Biochemistry, Martinsried, Germany; [4]Boston Children's Hospital, Boston; [5]Arnaud de Villeneuve Hospital, Montpellier, France; [6]L'Archet II Hospital, Nice, France; [7]Novartis Insts for Biomedical Research, Cambridge.*

Background: Nephronophthisis (NPH), a major cause of ESRD in children, is a heterogeneous autosomal recessive renal ciliopathy, the causative genes encoding proteins being involved in ciliary function.

Results: Using NGS, we identified pathogenic recessive mutations in *TRAF3IP1* encoding the intraflagellar transport IFT-B component IFT54 in 5 families with renal and retinal involvement. As expected, IFT54 mutationslead to cilia defects in patients' fibroblasts and truncating mutations prevent interaction with IFT20, its partner within the IFT-B complex.We further demonstrate, using 3D structure modelling and mass spectrometry approaches, that missense mutations impair proper folding of the N-terminal domain and reduce the affinity of IFT54 for tubulin and microtubule-associated proteins. In addition,live-cell imaging in patient's fibroblasts and in knockdown mIMCD3 revealed that beside its known functions at cilia, IFT54 acts as a key regulator of cytoplasmic microtubules organization and dynamics. Consequently, epithelialization defects were observed in both 3D cultured knockdown renal cells and in the pronephros of zebrafish embryos invalidated for *TRAF3IP1*.

Conclusions: Altogether, our findings demonstrate that NPH causing mutations of *TRAF3IP1*, affect both ciliary and non-ciliary functions of IFT54, which can provide an explanation for kidney tubules morphogenesis defects.

Nephronophthisis 13: Implication of Association with Caroil Disease and Altered WDR19 Expression in the Kidney

Jiwon M. Lee,[1] Yo Han Ahn,[1] Hee Gyung Kang,[1,2] IL-Soo Ha,[1,3] Joo Hoon Lee,[4] Young Seo Park,[4] Jun-Seok Bae,[5,6] Nayoung Kim,[6] Hae Il Cheong.[1,2,3] *[1]Pediatric Nephrology, Seoul National Univ Children's Hospital, Seoul, Korea; [2]Research Coordination Center for Rare Diseases, Seoul National Univ Hospital, Seoul, Korea; [3]Kidney Research Inst, Seoul National Univ College of Medicine, Seoul, Korea; [4]Pediatric Nephrology, Asan Medical Center, Children's Hospital, Univ of Ulsan College of Medicine, Seoul, Korea; [5]Dept of Health Sciences and Technology, Samsung Advanced Inst for Health Sciences and Technology (SAIHST), Sungkyunkwan Univ, Seoul, Korea; [6]Samsung Genome Inst, Samsung Medical Center, Seoul, Korea.*

Background: Nephronophthisis 13 (NPHP13) is a rare disease with mutations in *WDR19*. We describe 6 additional cases with Caroli syndrome or disease, characterized by focal intrahepatic ductal dilatation with or without congenital hepatic fibrosis, respectively.

Methods: We performed targeted exome sequencing covering 96 ciliopathy-related-genes to 48 patients with a clinical suspicion of NPHP, and detected 3 unrelated index cases (6.3%) with *WDR19* mutations. One case had 2 siblings with the same mutation. We further detected 1 additional case by Sanger sequencing. We evaluated the expression of the WDR19 in the kidney for two patients and two controls by immunohistochemistry.

Results: All six patients progressed to chronic kidney disease and notably, all had Caroli syndrome/disease. Immunohistochemistry for WDR19 showed localized expression along the luminal borders of renal tubular epithelium in controls, while it showed diffuse cytoplasmic staining in *WDR19*-mutated patients.

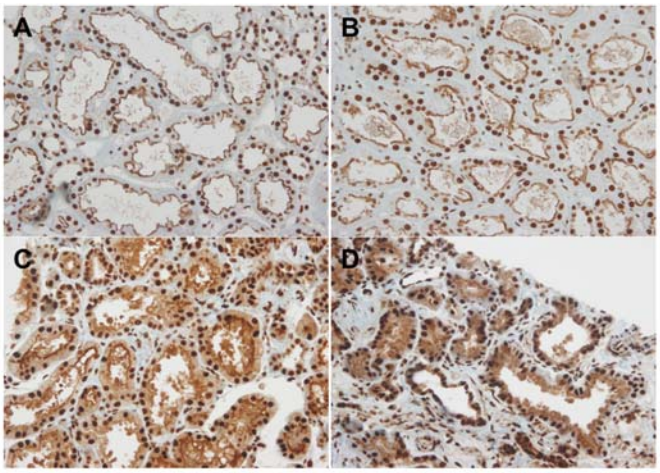

Fig.1 **Immunohistochemistry of WDR19 in kidney tissues of controls and patients.** W DR19 is expressed along the luminal border of the renal tubular epithelium without cytoplas mic staining in both normal (A) and disease controls (B). On the contrary, cytoplasmic staini ng of WDR19 is noted for Patients I-3 (C) and II-1 (D) (x400).

Conclusions: Hepatic involvement, especially Caroli syndrome/disease, may be another major extrarenal phenotype of NPHP13. We have visually validated the mutant WDR19 in NPHP13, in the human kidney using immunohistochemistry.

Studying Mechanisms Underlying NPHP6 in an Ex Vivo Murine Collecting Duct Cell Line

Shalabh Srivastava,[1,2] Ann Marie Hynes,[1] Rachel H. Giles,[2] Colin Miles,[1] John Andrew Sayer.[1] *[1]Inst of Genetic Medicine, Newcastle Univ, Newcastle upon Tyne, United Kingdom; [2]Dept of Nephrology and Hypertension, Nephrogenetics Group, Univ Medical Centre, Utrecht, Netherlands.*

Background: Nephronophthisis (NPHP) is a childhood cystic kidney disease, which invariably leads to end stage renal disease. NPHP genes encode proteins which localise to the primary cilia, basal body and centrosome. NPHP is a therefore a ciliopathy, and may be a part of a broad spectrum of clinical disease. We present an ex vivo cellular model of NPHP using Cep290 deficient collecting duct cells.

Methods: We have established immortalised wild-type and *CEP290*$^{LacZ/LacZ}$ murine cell lines. The origin of these cells was confirmed by RT-PCR using collecting duct specific molecular markers. Cells were studied to determine proliferation rates and mitotic spindle defects. Mitotic spindle defects were quantified by counting the total number of cells showing abnormal mitosis (>2 spindle poles) in the wild-type and *CEP290*$^{LacZ/LacZ}$ cells. Cells were cultured in matrigel allowing them to form 3D spheroids, develop a lumen and express primary cilia. In order to test specific disease mechanisms cells were treated with drug compounds (including purmorphamine and HPI-4) to determine effect on spheroid formation.

Results: Wild-type and *CEP290*$^{LacZ/LacZ}$ cells express the collecting duct markers epithelial sodium channel alpha subunit (E-NaC), mineralocorticoid receptor (MR), AVPR and Aquaporin-3. Proliferation rates are altered in *CEP290*$^{LacZ/LacZ}$ cells. *CEP290*$^{LacZ/LacZ}$ cells exhibit more abnormal mitotic figures as compared to wild-type cells (40% versus 8%). In 3D culture mutant cells have abnormal primary cilia and are unable to form well defined spheroid structures which is partially rescued by a hedgehog agonist purmorphamine. Wild-type cells treated with Hedghog antagonist HPI-4 mimic *CEP290*$^{LacZ/LacZ}$.

Conclusions: We have characterised a useful ex vivo model of NPHP using a *CEP290*$^{LacZ/LacZ}$ cell line. Abnormalities in cell proliferation, mitosis and hedgehog signalling have been observed. The 3D spheroid read-out has allowed us to develop a platform for drug testing and to explore pathophysiology mechanisms underlying cystogenesis.

SA-PO588

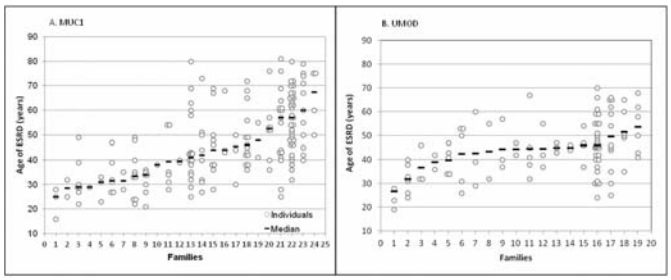
Comparison of Age of Onset of End-Stage Kidney Disease in Medullary Cystic Kidney Disease Types 1 and 2

Marwan M. Abbas,[1] Kendrah O. Kidd,[1] Stanislav Kmoch,[2] Anthony J. Bleyer.[1] *[1]Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; [2]Charles Univ 1st School of Medicine and General Faculty Hospital, Prague, Czech Republic.*

Background: Medullary cystic kidney disease (MCKD) 1 is caused by mutations in the *MUC1* gene encoding mucin-1, and MCKD2 is caused by mutations in the *UMOD* gene encoding uromodulin (Tamm Horsfall protein). Both MCKD 1 and 2 cause a similar type of autosomal dominant interstitial kidney disease. The age of onset of end-stage renal disease (ESRD) has not been compared between the two diseases. We therefore determined the age of onset of ESRD for families with each condition as a potential clue to their pathogenesis.

Methods: Families were identified with mutations in the *MUC1* and *UMOD* genes. As many family members as possible with ESRD were identified, and their ages of ESRD were compared within and between families.

Results: There were 24 families with *MUC1* mutations and 186 individuals in whom the age of onset of ESRD could be determined. The mean age of ESRD was 46.84 years ± 15.22 sd. For *UMOD* mutations, there were 114 family members with known age of ESRD in 20 families. The mean age of ESRD was 43.30 ± 12.40 sd ($p = 0.037$ for comparison between the two diseases). Figure 1 A and B show the ages of onset of ESRD for each family. There was a wide range of onset of ESRD for both types of disease.



Conclusions: While mutations in *MUC1* and *UMOD* are responsible for very distinct forms of MCKD, they have remarkably similar age ranges of onset of ESRD and variation between family members with the same mutation for the age of onset of ESRD. Modifying genes or the environment may be similar between the two disease. Identifying these factors may help slow progression of the disease.

SA-PO589

Suppressing Angiotensinogen Synthesis Attenuates Kidney Cyst Formation in a *Pkd1* Mouse Model

Takamitsu Saigusa,[1] Yujing Dang,[1] Adam E. Mullick,[2] Steve T. Yeh,[2] An Van Laer,[3] Catalin F. Baicu,[3] P. Darwin Bell.[1] *[1]Div of Nephrology, Medical Univ of South Carolina, Charleston, SC; [2]ISIS Pharmacueticals, Carlsbad, CA; [3]Div of Cardiology, Medical Univ of South Carolina, Charleston, SC.*

Background: Hypertension in Autosomal Dominant Polycystic Kidney Disease (ADPKD) is common and activation of the renin angiotensin system (RAS) is believed to play a role. However, results from clinical studies testing RAS inhibitors in slowing the progression of ADPKD are inconclusive. There is evidence that intrarenal RAS is elevated in ADPKD and therefore we hypothesize that current RAS inhibitors may not adequately block intrarenal RAS. For this study we compared a novel Gen 2 antisense oligonucleotide (ASO) that inhibits angiotensinogen (AGT) synthesis to lisinopril in adult conditional *Pkd1* systemic knockout mice, a model of ADPKD.

Methods: Adult *Pkd1*conditional floxed allele mice expressing cre were administered tamoxifen resulting in global knockout of *Pkd1*. Six weeks after tamoxifen injection, mice were treated with Agt ASO (50-100mg/kg/week), lisinopril (100mg/kg/day), PBS (control) or control ASO (50-100mg/kg/wk) for a total of 10 weeks. Tail cuff was used to measure blood pressure (BP). Kidneys, liver, heart, plasma and urine were collected at 16 weeks after tamoxifen and examined by histology and RT-PCR to assess AGT, renin and markers of fibrosis and tissue injury.

Results: Agt ASO resulted in significant reduction in liver and kidney AGT and increased kidney renin compared to control or lisinopril treatments. Additionally, kidneys from Agt ASO treated mice were not as enlarged and showed reduced cystic volume compared to lisinopril or control treatments. Although both Agt ASO and lisinopril treatments reduced BP, lisinopril was more effective. Markers of fibrosis and tissue injury in kidneys treated with Agt ASO were reduced relative to lisinopril treatment.

Conclusions: These data indicate that Agt ASO treatment is more efficacious in reducing cystogenesis and related sequelae in conditional *Pkd1* knockout mice. This

decrease in cystogenesis was not a result of effective BP lowering. Agt ASO may effectively attenuate intrarenal RAS and therefore be a novel and effective agent for treating ADPKD.

SA-PO590

Antisense Inhibition of Kirsten-Ras Slows Progression of Murine Polycystic Kidney Disease Ayesha Irtiza-Ali,[1] Richard N. Sandford,[2] Dorien J.M. Peters,[3] Adam E. Mullick,[4] Bruce M. Hendry.[1] *[1]Renal Medicine, King's College London, United Kingdom; [2]Medical Genetics, Univ of Cambridge, United Kingdom; [3]Leiden Univ Medical Center, Netherlands; [4]Isis Pharmaceuticals.*

Background: Ras-GTPase-MAPK signalling plays a crucial role in the control of cell proliferation, differentiation and survival. It is consistently activated in different PKD models but the role of the 3 Ras isoforms, Kirsten (Ki)-, Neural- and Harvey- Ras, in PKD are unknown. Our previous work has shown Ki-Ras upregulation as disease progresses across the proliferative to fibrotic phases in an ADPKD orthologous PKD1$^{nl/nl}$hypomorph and recessive Pcy mouse models. This work investigates the effects of Ki-Ras gene silencing using a generation 2 gapmer antisense oligonucleotide (ASO) in mouse models of PKD.

Methods: Study A evaluated the long-term effects of Ki-Ras inhibition in CD1-pcy mice with weekly subcutaneous injection of a Ki-Ras ASO, a control non-targeting ASO or vehicle (n=16/treatment group) from age 3 to 20 weeks. In a second smaller study(B), B6.CD1-PKD1$^{nl/nl}$mice were similarly treated with the Ki-Ras ASO or vehicle from age P21 to P49 (n=5/treatment group). Serum biochemistry assays, qPCR and immunohistochemistry (IHC) were used to assess the effects of treatment on renal function, inflammation and fibrosis.

Results: The targeting ASO specifically knocked down renal Ki-Ras mRNA expression by 65% (p=<0.0001) in Study A, and 85% (p=0.0263) in Study B compared to vehicle. In CD1-pcy mice, Ki-Ras ASO significantly improved serum creatinine levels (p=0.0298), and decreased renal αSMA IHC expression by 3 fold (p=<0.01), as well as expression of inflammatory markers MCP1 (p=0.029) and IL1β (p=0.0032), compared to vehicle. These effects were not seen in the control ASO treated group. As we have previously reported, B6.CD1- PKD1$^{nl/nl}$ develop progressive, severe fibrosis from P21 to P49, but treatment with Ki-Ras ASO over this period reduced αSMA positive area by 2.5 fold (p=0.029).

Conclusions: These results demonstrate specific antisense inhibition of Ki-Ras protects renal function with both anti-fibrotic and anti-inflammatory effects, and slows disease progression in mice with polycystic kidney disease.

SA-PO591

Inhibition of Aerobic Glycolysis with 2-Deoxyglucose Retards Polycystic Kidney Disease Progression in Han:SPRD Rats Meliana Riwanto,[1] Sarika Kapoor,[1] Daniel Rodriguez,[1] Ilka Edenhofer,[1] Stephan Segerer,[2] Rudolf P. Wuthrich.[2] *[1]Univ of Zurich, Switzerland; [2]Univ Hospital Zurich, Switzerland.*

Background: Autosomal dominant polycystic kidney disease is a common genetic disorder characterized by development of multiple renal cysts. Using microarray analysis and qPCR, we identified altered glucose metabolism in Han:SPRD rat model i.e. upregulation of genes involved in aerobic glycolysis (*Hk1, Hk2, Ldha*) and downregulation of gluconeogenesis genes (*G6pc, Lbp1*), indicating a Warburg effect.

Methods: We examined the effect of 2-deoxyglucose (2DG), a glycolytic inhibitor, on renal function loss and cyst progression in Han:SPRD rats, a PKD model with a phenotype closely resemble human ADPKD. Male heterozygous cystic (Cy/+) were administered 2DG (500 mg/kg/day) for 5 weeks.

Results: Cy/+ rats treated with 2DG (n=10) displayed significantly reduced kidney weights and kidneys/total body weight ratio and decreased renal cyst index, as compared to vehicle treatment (27%, 21% and 48% reduction, respectively). Treatment with 2DG also improved creatinine clearance (1.98±0.67 versus 1.41±0.37 ml/min, p<0.05), BUN clearance (0.69±0.26 versus 0.40±0.10 ml/min, p<0.01) and uric acid clearance (0.38±0.20 versus 0.21±0.10 ml/min, p<0.05). Interestingly, administration of 2DG led to sustained increase of urine output, suggesting renal resistance to vasopressin. Western blot analysis of kidney tissues from 2DG treated Cy/+ rats showed increased AMPK phosphorylation, a negative regulator of mTOR, and restoration of ERK signaling. Notably, 2DG treatment limited cellular proliferation as assessed by Ki67 staining, while no marked increased in apoptosis was observed with caspase-3 measurement. Moreover, in cultured epithelial cells from Cy/+ rats, 2DG dose-dependently inhibited cell growth, reduced lactate and ATP production.

Conclusions: Taken together, our results show that the kidneys of Han:SPRD rats display enhanced aerobic glycolysis which may play important role in the pathogenesis of PKD. Administration of 2DG markedly delayed the loss of renal function and retarded cyst development in Han:SPRD rats with PKD. Targeting the glycolytic pathway may therefore present a novel therapeutic strategy to control cyst growth in PKD.

SA-PO592

B-type Natriuretic Peptide Gene Therapy Improves Cardiac and Renal Functions in Autosomal Recessive Polycystic Kidney Disease Sara J. Holditch,[1] Vicente E. Torres,[2] Yasuhiro Ikedo.[1] *[1]Molecular Medicine, Mayo Graduate School, Mayo Clinic, Rochester, MN; [2]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Polycystic Kidney Disease (PKD) presents with cystic manifestations, renal enlargement, progressive renal dysfunction, and hypertension; ultimately leading to end stage renal failure. B-type natriuretic peptide (BNP) is central in controlling intravascular volume. Additionally, BNP inhibits fibroblast proliferation, prevents RAAS activation, and blocks AVP release. These properties, among others, make BNP a promising therapy for PKD.

Methods: We investigated the effects of long-term BNP overexpression in the rat model of ARPKD (PCK). 3 day old PCK littermates were administered a single intraperitoneal injection of PBS, or adeno-associated virus 9 (AAV9) vectors, expressing BNP under the control of an internal CMV promoter, at 1.0E+12 gc/kg.

Results: At three months, diastolic blood pressure was significantly (*=p<0.05) reduced (DBP: 71.2±10* versus 87.6±5 mmHg), and cardiac function was preserved, in BNP treated rats (EF tech: 74±3* versus 68±3%). Urinalysis showed reduced 24 hour urine output in treated, compared to untreated PCK (UV: 8.8±3* versus 13.2±1mL/24-hr). Creatinine clearance was also significantly higher in BNP-treatment (eGFR: 0.51±0.1* versus 0.26±0.2mL/min). BNP treated rats had significantly reduced (4.71*, and 4.01* fold) renal expression of collagen and fibronectin, respectively. Histologically, treatment preserved glomerular architecture and retarded basement membrane thickening. However, no significant effects were observed on kidney size (TKW/BW 1.27±0.14 versus 1.44±0.18) or renal cystogenesis.

Conclusions: Together, these observations indicate that long-term BNP overexpression can protect renal function and architecture, preserve renal urine-concentrating ability, and provide cardiac protection. Importantly these effects occurred despite the concurrence of renal cystogenesis. This study demonstrates the efficacy of AAV-BNP gene therapy in protecting cardio-renal organ integrity and provides a novel treatment of ARPKD-associated renal damage and hypertension, secondary to progressive renal cystogenesis.

SA-PO593

Soluble Activin Type IIB Receptor Treatment Effectively Blocks Cyst Formation in a Mouse Model for ADPKD Wouter N. Leonhard,[1] Steven J. Kunnen,[1] Fatiha Bouazzaoui,[1] Kimberley Veraar,[2] Martijn H. Breuning,[1] Emile De Heer,[2] Olli Ritvos,[3] Dorien J.M. Peters.[1] *[1]Human Genetics; [2]Pathology, Leiden Univ Medical Center, Netherlands; [3]Bacteriology and Immunology, Haartman Inst, Finland.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is caused by *PKD1* or *PKD2* mutations and is characterized by the formation of thousands of kidney cysts. TGFß and Activin signaling are known to play important roles in tissue regeneration, and this process is suggested to have substantial overlap with the process of cyst formation. Nuclear accumulation of pSMAD2/3 in cyst-lining cells suggests the involvement of these pathways in PKD. However, conditional inactivation of the TGFß receptor I (*Alk5*) in renal epithelial cells did not affect the progression of PKD. In this study, we therefore tested the therapeutic potential of an Activin type IIB receptor fusion protein (sActRIIB-Fc), which can be used as a soluble trap to sequester Activin ligands.

Methods: Activin signaling was studied in kidney samples of mice at various stages of adult PKD and in *Pkd1*-wt and *Pkd1*-KO cells by Western-blot and qPCR. Following *Pkd1*-deletion at post-natal day 10 (P10), the tamoxifen-inducible kidney-specific *Pkd1*-deletion mice were treated from P14 to P33 with bi-weekly intra-peritoneal injections with 0, 3 or 10 mg/kg sActRIIB-Fc in PBS. These kidneys were analyzed by qPCR and IHC analysis.

Results: In-vitro: Activin A and B stimulated SMAD2 and ERK1/2 phosphorylation, which was completely blocked by sActRIIB-Fc. In-vivo: The expression of both Activins increased at early and advanced stage PKD in an adult mouse model for ADPKD. Treatment with 3 or 10 mg/kg sActRIIB-Fc effectively blocked cyst formation.

Conclusions: The major findings of this study are 1) Activin signaling is increased at an early stage of PKD, 2) Activin not only stimulates phosphorylation of SMAD2 but also of ERK1/2, which is known to be involved in PKD, and 3) Activin signaling can be therapeutically targeted by sActRIIB-Fc, which effectively inhibited cyst formation in mice. Since soluble Activin receptors are currently being tested in various clinical trials for other purposes, our findings may become clinically relevant to ADPKD patients.

Funding: Government Support - Non-U.S.

SA-PO594

Beneficial Effect of Combined Treatment of Two Gi Protein Activators in PCK Rats, an Orthologous Model of Human Autosomal Recessive Polycystic Kidney Disease Masanori Kugita,[1] Daisuke Yoshihara,[1] Mai Sasaki,[1] Kazuhiro Nishii,[2] Atsushi Suzuki,[3] Yukio Yuzawa,[4] Tamio Yamaguchi,[5] Shigeo Horie,[6] Eiji Higashihara,[7] Shizuko Nagao.[1] *[1]Education and Research Center, Fujita Health Univ, Aichi, Japan; [2]Rehabilitation, Fujita Health Univ, Aichi, Japan; [3]Endocrinology and Metabolism, Fujita Health Univ, Aichi, Japan; [4]Nephrology, Fujita Health Univ, Aichi, Japan; [5]Human Nutritional Sciences, Univ of Manitoba, Winnipeg, MB, Canada; [6]Urology, Juntendo Univ, Tokyo, Japan; [7]Urology, Kyorin Univ, Tokyo, Japan.*

Background: A strategy of decreasing cAMP level by adenylyl cyclase inhibitory G protein (Gi) activators, pasireotide (PAS) and octreotide (OCT), was effective in animal models of polycystic kidney disease (PKD) (Masyuk, Hepatology, 2013). However, hyperglycemia caused by PAS treatment is concerned as an adverse effect in the clinical use (Shenouda, Am J Ther, 2012). Whereas, OCT and co-application of OCT and PAS did not increase serum glucose in rats (Schmid, J Endocrinol, 2012). Therefore, in the current study, we examined the efficacy of combined treatment of OCT and PAS in PCK rats, an autosomal recessive PKD model.

Methods: 4-week-old PCK male were treated with 8mg/kg OCT and/or PAS for additional 12 weeks. After termination, serum and renal tissue were used for analyses.

Results: In PCK rats, kidney weight, serum urea nitrogen, cyst area, Ki67 expression, and blood pressure were decreased either by PAS or combination of OCT and PAS (OCT/PAS), whereas no effect of OCT was shown. The components of mTOR pathway, serum IGF-1 and renal S6 kinase activity were significantly decreased in OCT/PAS group compared with vehicle-, OCT-, or PAS-treated groups. Serum glucose was significantly increased by PAS, whereas no difference was shown between normal rats and PCK rats with OCT/PAS, possibly because insulin/glucagon ratio was decreased by PAS, but not by OCT/PAS combination.

Conclusions: Present results show that co-administration of OCT and PAS has stronger effect on renal disease progression in PCK rats, rather than OCT or PAS alone. Further, since increased serum glucose level is concerned by the use of PAS, a co-application with OCT may reduce the risk of its adverse effect.

An mTOR Kinase Inhibitor Slows Disease Progression in a Rat Model of Polycystic Kidney Disease (PKD)

Kameswaran Ravichandran, Iram Zafar, Abdullah Ozkok, Charles L. Edelstein. *Univ of Colorado Denver.*

Background: Sirolimus and everolimus indirectly bind and inhibit mTORC1. A novel group of drugs, the mTOR kinase inhibitors, directly bind to mTOR kinase, thus inhibiting both mTORC1 and 2. The aim of the study was to determine the therapeutic effect of an mTOR kinase inhibitor, PP242, in the Han:SPRD rat (Cy/+) model of PKD.

Methods: Male rats were treated with PP242 5 mg/kg/d IP or vehicle for 5 weeks.

Results:

	+/+ Veh (n=8)	+/+ PP242 (n=6)	Cy/+ Veh (n=7)	Cy/+ PP242 (n=13)
TBW(g)	277	247	267	281
2KW	2.3	2.1	6.8*	4.7+
2K/TBW (%)	0.8	0.9	2.2*	1.6+
CVD	0.8	0.8	32*	25+
BUN (mg/dL)	23	18	56*	30+
IL-1 (pg/mg)	5.4		9.7*	10+
IL-6 (pg/mg)	2.6		5.7*	4.1
CXCL1 (pg/mg)	1.1		3.7*	3.3
TNF-α (pg/mg)	0.3		1.3 *	0.8
PCNA+ per cyst			0.9*	0.5+
PCNA + per HPF	0.58		5.6*	1.5+

***P< 0.01 vs. +/+,+P< 0.05 vs. Cy/+ Veh. BW=body weight, CVD=cyst volume density. 2K/TBW (%)=two kidney weight to total body weight ratio.**

PP242 significantly reduced the kidney enlargement, the cyst density and the BUN in Cy/+ rats (Table). On immunoblot of kidneys, PP242 resulted in a decrease in pS6, a marker of mTORC1 signaling and $pAkt^{Ser473}$, a marker of mTORC2 signaling. mTORC plays an important role in regulating cytokine production. On Meso Scale analysis, there was an increase in IL-1, IL-6, CXCL1 and TNF-α in Cy/+ rat kidneys that was unaffected by PP242. Apoptosis or proliferation are known to play a causal role in cyst growth. PP242 had no effect on caspase-3 activity, TUNEL positive or active caspase-3-positive tubular cells in Cy/+ kidneys. PP242 reduced the number of proliferating cells per cyst and per non-cystic tubule in Cy/+ rats.

Conclusions: In a rat model of ADPKD, PP242 treatment 1) decreases proliferation in cystic and non-cystic tubules; 2) inhibits renal enlargement and cystogenesis and 3) significantly reduces the loss of kidney function. Blockade of both mTORC1 and 2 has therapeutic potential in PKD.

SA-PO596

mTOR Inhibitor Rapamycin Reduces Cytogenesis in a New *Pkd2*-Mutant Mouse Model

Ao Li, Yuan Li, Haichao Liu, Wei Li, Yujie Ma, Guanqing Wu. *State Key Laboratory of Molecular Oncology, Cancer Hospital and Inst, Chinese Academy of Medical Sciences, Beijing, China.*

Background: ADPKD is caused by mutations of *Pkd1* and *Pkd2*. Recent studies showed that rapamycin treatment can improved the cystic phenotypes in mouse models of ADPKD, but clinical trials have not shown clearly benefit. Although studies have showed that rapamycin treatment could achieve therapeutic effects in both *Pkd1*- and *Pkd2*-mutant mouse models, the challenge has been arisen by a recent report that PC1 but not PC2 involves regulation of the mTOR pathway.

Methods: To validate whether rapamycin can indeed inhibit cystic phenotypes and improve renal function of a *Pkd2*-mutant mouse model, *Pkd2* conditional KO mice with *Villin*-Cre transgene (*Vil*-Cre:$Pkd2^{f3/f3}$) have been produced. *Vil*-Cre:$Pkd2^{f3/f3}$ mice exhibit full spectrum of cystic phenotypes which are closely similar to human ADPKD patients. Two groups were designed in this study: i.e. rapamycin-treated group and its solvent DMSO control group (n≥5/group). *Vil*-Cre:$Pkd2^{f3/f3}$ mice for rapamycin group received a single intraperitoneal injection of rapamycin (5 mg/kg/d) and the control group were administrated with the same amount of DMSO from postnatal days 10 (P10) to 55 (P55). The animals were sacrificed at P60.

Results: Mice with rapamycin treatment exhibit significantly prolonged lifespan (27 weeks *versus*. 17 weeks, $P<0.0001$), decreased cyst index (24.93%±4.07% *versus*. 32.25%±5.33%, $P<0.001$), kidney/body ratio (0.0162±0.003 *versus*. 0.0221±0.003, $P<0.0001$), liver/body ratio (0.0566±0.005 *versus*. 0.0605±0.003, $P<0.05$) and improved renal function (BUN) (6.11±0.98 mmol/L *versus*. 9.39±2.02 mmol/L, $P<0.0001$). *Vil*-Cre:$Pkd2^{f3/f3}$ mice with rapamycin treatment also showed significantly decreased proliferation in renal cyst-lining epithelial cells. In rapamycin group, decreased expression of phosphorylation of S6 ribosomal protein (S6Rp) which is a downstream target of mTORC1 can be seen.

Conclusions: Our results indicate that rapamycin treatment can significantly improve cystic phenotypes and prognosis in a new *Pkd2*-mutant mouse model, further validating therapeutic effects of mTOR inhibitor for *Pkd2*-mutant mice.

SA-PO597

Reduction in Cyst Volume Requires Inhibition of mTORC2 in Polycystic Kidney Disease

Kuang-Yu Jen,[1] Michael Ng,[1] Atif A. Kidwai,[2] Ron Chen,[3] Michael Martin,[3] Feng Qian,[4] David Pearce.[1] *[1]Univ of California San Francisco; [2]Beverly Hospital; [3]Takeda Pharmaceuticals; [4]Univ of Maryland.*

Background: Mammalian target of rapamycin (mTOR) is found in two multi-protein complexes, mTORC1 and mTORC2, through which it exerts a broad range of physiological effects. Rapamycin (Rapa) primarily inhibits mTORC1; however at high doses it also inhibits mTORC2. In animal models of polycystic kidney disease (PKD), Rapa administered at very high concentrations inhibited cyst progression. In contrast, in human studies, Rapa was given at much lower doses and its effects were disappointing. Here, we examined the hypothesis that mTORC2 inhibition is necessary to blunt cyst progression in PKD.

Methods: $Pkd1^{V/V}$ mice, which develop severe renal cystic disease in early postnatal period, were treated from P5 to P11 with either a potent competitive antagonist of mTOR (mTORcomp), which inhibits mTORC1 and mTORC2 equally, or with Rapa at doses that inhibit only mTORC1. At P11, the mice were sacrificed and the kidneys were harvested and subjected to computer-assisted morphometric analysis to calculate renal cyst area, which was used as a surrogate of cyst volume. The contralateral kidneys were used for Western blot analysis for markers of mTOR activity.

Results: Mice treated with mTORcomp had a 33.2% increase in cyst area during the treatment period, while mice receiving vehicle had a 39.5% increase ($p<0.01$). This difference represents 16% reduction in cyst enlargement for treated mice compared with controls. In contrast, Rapa-treated mice showed an increase in cyst area that was indistinguishable from vehicle treated controls. Western blots showed that Rapa inhibited only mTORC1 (reduced phosphorylation of S6K but not Akt), while mTORcomp inhibited both mTORC1 and mTORC2 (reduced phosphorylation of SK6 and Akt).

Conclusions: Inhibition of mTORC2 is required to blunt cyst growth in this animal model of PKD, suggesting that aberrant mTORC2 signaling is implicated in cystogenesis. Effects of Rapa or its analogues to blunt cyst growth in earlier animal studies are likely due to the high doses used, which inhibited both mTORC1 and mTORC2. These data suggest possible avenues toward more effective treatment of human PKD.

SA-PO598

Novel Means of Gene Therapy in Polycystic Kidney Disease

Katherine J. Kelly,[1] Jesus H. Dominguez.[1,2] *[1]Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; [2]Nephrology, Roudebush VA Medical Center, Indianapolis, IN.*

Background: Polycystic kidney diseases (PKD) are some of the most common life-threatening monogenic abnormalities. PKD can cause end-stage renal disease (ESRD) with immeasurable suffering, mortality and cost. While mutations for many types of PKD are known and tremendous advances in understanding the pathophysiology have been made, there is no specific therapy to repair or replace the single mutated gene. Autosomal recessive PKD (ARPKD) is truly catastrophic, causing ESRD and death in neonates and children.

Methods: The mechanisms by which renal cell transplant improves structure and function in a model of PKD were examined. Adult tubular cells from normal Sprague Dawley (SD) rats that express wild type genes were given non-invasively to PCK rats, an orthologous model of ARPKD harboring a mutation in *Pkhd1*. The effects of SD renal cells and microvesicles harvested from cultured SD renal cells and the normal rat kidney (NRK) cell line were also evaluated.

Results: Renal cell therapy resulted in expression of both mutant and wild-type Pkhd1 in treated, but not control, PCK kidneys. Marked and sustained improvements in total cyst volume, renal fibrosis, albuminuria, blood urea nitrogen and kidney weight were found in treated PCK rats. We were struck by the large effects of relatively few transplanted normal cells. In examining the mechanisms of the beneficial effects, we found that microvesicles (exosomes) shed by normal primary kidney cells and NRK cells carry *pkhd1* mRNA. PCK cells treated with exosomes from normal cells express mutant and wild type *pkhd1* mRNA. Kidneys from PCK rats treated with exosomes also express both mutant and wild type *pkhd1* mRNA. We also found that primary tubular cells from PCK rats, but not those from Sprague Dawley (SD) rats, form cysts in collagen matrices. When PCK cells were incubated with exosomes harvested from SD cells, they did not form cysts and, in some cases, formed more elongate tubular structures.

Conclusions: Renal microvesicles from normal SD rats and NRK cells can be used to transfer genetic material to mutant PKD cells. The ultimate goal is the future translation of this therapy to the clinical arena.

Heavy Chain Deposition Disease Rafia I. Chaudhry,[1] Paisit Paueksakon,[2] Rachel B. Fissell,[1] Neil S. Sanghani.[1] *[1]Nephrology, Vanderbilt Univ Medical Center; [2]Renal Pathology, Vanderbilt Univ Medical Center.*

Introduction: Heavy chain deposition disease (HCDD) is a rare cause of nephrotic range proteinurea. We report a case of HCDD associated with acquired C1q esterase inhibitor deficiency and angioedema.

Case Description: A 45 yo male presented with severe hypertension (HTN), volume overload and acute renal failure. Past history included recently diagnosed HTN, and angioedema while on lisinopril. On exam, BP was 200/129, lungs had coarse crackles bilaterally, and jugular venous distension was 10cm. Workup was notable for creatinine 1.9 mg/dL (baseline 1.5 mg/dL), BNP 5,800pg/mL, albumin 2.5 mg/dL and 24 hour urine protein of 3.6 gm. Urinalysis had 63 RBCs/hpf and 6 hyaline casts on microscopic exam. Serologies resulted HepC Ab pos, hypocomplentemia with C3 60mg/dl, C4 11.7 mg/dl, and a low C1q level at 7.2mg/dL. Transthoracic ECHO showed EF 41%, with enlarged left atrium and heavily trabeculated left ventricle suggestive of protein deposits. Renal biopsy revealed diffuse matrix expansion in a nodular pattern with mesangial and endocapillary hypercellularity with extensive eosinophilic strongly PAS positive material. There was diffuse splitting of the GBM, with 2 crescents. IF positive for IgG3 staining along glomerular and tubular BMs, without kappa or lambda staining. Congo red staining was negative. EM showed extensive punctate electron dense deposits in the GBM, Bowman's capsule, and tubular basement membrane. Final diagnosis was IgG3 heavy chain deposition disease. Interestingly he had 3 episodes of angioedema during this time, despite being off lisinopril for months, suggestive of acquired C1q esterase deficiency. He was started on aminocaproic acid and has had no angioedema since. His HCDD was treated with dexamethasone plus bortezomib, and creatinine improved to 1.5 mg/dL at 3 months.

Discussion: This patient's course was consistent with acquired C1q esterase inhibitor deficiency from hypocomplementemia caused by the HCDD. Extra renal deposition of heavy chains, also seen in this case, occurs less commonly in HCDD than in the other immunoglobulin deposition diseases, and although not proven by a cardiac biopsy, we suspect our patient also had heavy chain deposition in the left ventricle.

SA-PO600

C4 Dense Deposit Disease Associated with Monoclonal Gammopathy Radhika Vemuri,[1] Girish Singhania,[1] Sanjeev Sethi,[2] Rajesh Mohandas.[3] *[1]Nephrology, Hypertension and Transplantation, Univ of Florida, Gainesville, FL; [2]Dept of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; [3]Nephrology and Hypertension Section, Dept of Veterans Affairs Medical Center, North Florida/South Georgia Veterans Health System, Gainesville, FL.*

Introduction: C4 dense deposit disease is a recently described glomerulonephritis characterized by proliferative glomerulonephritis on light microscopy, negative Ig and C3 staining on immunofluorescence microscopy (IF) and dense capillary wall deposits on electron microscopy. The hallmark is staining of deposits for C4d. Monoclonal gammopathy has been associated with both Ig- mediated glomerulonephritis and C3 glomerulopathy, but has not been described in C4 dense deposit disease. Here we report a case of C4 dense deposit disease associated with a monoclonal gammopathy.

Case Description: A 53 year old veteran with substance abuse, HTN and CKD with a baseline Cr of 1.4-1.7 was admitted with AKI (Cr 3.0 mg/dL) and uncontrolled hypertension (BP 185/117). Urinalysis showed 50-100 RBC/HPF. Immunofixation studies showed IgG kappa. A bone marrow biopsy showed 5 % plasma cells with distinct population of immunophenotypically aberrant kappa restricted plasma cells. Patient's renal function worsened requiring dialysis. The kidney biopsy showed a proliferative glomerulonephritis with extensive focal segmental and global glomerulosclerosis, with negative staining for C3 and Ig, including light chains. Electron microscopy showed highly electron dense sausage –like deposits along the glomerular basement membranes. Complement assays including CH50, C3 nephritic factor and functional assays of alternate pathway were normal. Given dense deposits on EM and lack of C3 a stain for C4d was done which revealed dense (2-3+) staining for C4d along the glomerular capillary walls. A diagnosis of C4 dense deposit disease was made.

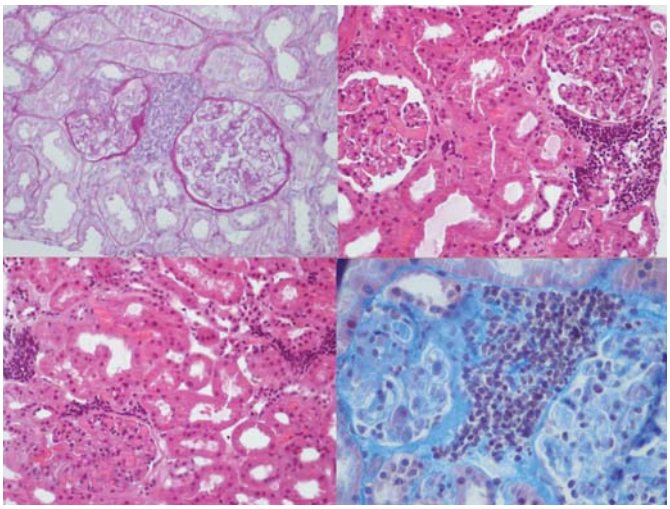
Discussion: This case highlights the association of a monoclonal gammopathy with the recently reported complement glomerulopathy that appears to be driven by over activation of the lectin pathway and deposition of C4d. Given the age of presentation we postulate that monoclonal gammopathy had a role in development of C4 dense deposit disease.

SA-PO601

Waldenström Macroglobulinemia and Minimal Change Disease: Treatment with R-CVP for a Rare Association Manuel Alfredo Podesta, David Cucchiari, Silvia Finazzi, Simona Verdesca, Rossella Valentino, Albania Calvetta, Claudio Angelini, Salvatore Badalamenti. *Nephrology and Dialysis Unit, Humanitas Clinical and Research Center, Rozzano, Milano, Italy.*

Introduction: Waldenström macroglobulinemia (WM) is defined as a lymphoplasmacytic lymphoma associated with a monoclonal IgM protein. Paraneoplastic renal manifestations of the disease are extremely rare: among them, minimal-change disease (MCD) has been reported in only 4 previous cases.

Case Description: A 54 year-old woman presented with facial and dependent edema. Physical examination was otherwise unremarkable. Laboratory investigations revealed normal renal function, microhematuria (30 RBC/HPF) and nephrotic-range proteinuria (7.8 g/day). An immune panel was negative. S-PEP showed a monoclonal peak in the gamma region, which resulted to be IgM-κ at immunofixation. Serum IgM were 1200 mg/dL, while Bence-Jones proteinuria was negative. A renal biopsy showed only focal interstitial infiltrates and 20 normal glomeruli.



IF was negative, thus confirming the diagnosis of MCD. In addition, a bone marrow biopsy revealed a $CD20^{+}/CD103^{-}$ lymphoplasmacytic infiltrate with IgM-κ monoclonal restriction, consistent with WM. The patient was treated with 6 cycles of R-CVP (Rituximab, Cyclophosphamide, Vincristine and Prednisone). After the fourth cycle, the patient underwent complete remission, with a rapid decrease of the proteinuria (0.3 g/day).

Discussion: Anecdotal reports showed that standard therapy with corticosteroids is ineffective in WM-associated MCD, probably due to specific pathogenic mechanisms underlying this condition, which may differ from idiopathic MCD. Indeed, several MCD cases have been described as paraneoplastic manifestations of Hodgkin's lymphoma. However, we report one of the few WM-associated MCD cases that required specific WM chemotherapy to obtain a remission of the nephrotic syndrome.

SA-PO602

IgG4-Related Renal Disease Presenting with Tumor-Like Masses Ghayyath Sultan, Hema Manickam, Chandandeep Takkar. *Dept of Nephrology, UTHSCSA, San Antonio, TX.*

Introduction: IgG4-related disease (IgG-4 RD) is a rare emerging entity characterized by IgG-4 - positive lymphoplasmacytic infiltration that might form tumor- like nodules and masses. We report a case of renal mass-like lesions in a patient with excellent response to steroid therapy and recurrence of the lesions when treatment was discontinued.

Case Description: A 48 year old man with no past medical history presented with weight loss, jaundice and abdominal pain for three months. He was found to have autoimmune pancreatitis, autoimmune hepatitis, sclerosing chlangitis and retroperitoneal fibrosis. Laboratories investigations revealed elevated IgG-4 level at 382 mg/dl (7-89 mg/dl). Low complement C3 level at 76 (98-162 mg/dl), normal complement C4 and negative screen for hepatitis B, hepatitis C, HIV, ANA and ANCA. CT scan of abdomen showed bilateral renal lesions concerning for malignancy. MRI of abdomen showed hypoenhancing nodular lesions (1.2–1.5 cm) in the bilateral kidneys suggesting renal involvement associated with IgG-4 related disease. He was started on prednisone 40 mg daily; azathioprine was added later on due to recurrent sclerosing cholangitis requiring biliary stenting. Renal lesions and retroperitoneal fibrosis disappeared on CT scan after steroid treatment. Numerous bilateral kidney rounded lesions (1.7 - 2.2 cm) were seen again on ultrasound, CT scan and MRI of the abdomen six months after he was taken off prednisone. Patient was restarted on prednisone and these lesions showed interval decrease in size and number on MRI six months after restarting the treatment. IgG-4 level also decreased to normal with treatment. Over three years follow up; kidney function remained normal with minimal proteinuria 200 mg/24 hour urine.

Discussion: Tubulointerstitial nephritis is the most common finding in patients with IgG4-RD; Nodular or mass lesions mimicking renal carcinoma can also bee seen. Corticosteroid is the treatment of choice and usually leads to a rapid resolution of most IgG4-RD lesions, although recurrence and relapse are frequent when corticosteroid is reduced or withdrawn.

SA-PO603

HIV – Associated Non-Hodgkin's Lymphoma Presenting with Primary Renal Involvement Seyyar A. Khan,[1] Anna T. Levy,[2] Anna Mathew.[1] *[1]Nephrology, Hofstra North Shore LIJ School of Medicine; [2]Hematology, Hofstra North Shore LIJ School of Medicine.*

Introduction: 25-40% of patients with HIV develop malignancy; 10% are Non-Hodgkin's lymphoma(NHL), commonly diffuse large B cell lymphoma (DLBLC). Common extranodal involvement includes GI tract, lung, and bone marrow. Kidney involvement is seen in 30-60%, but primary renal lymphoma is rare. Described here is an unusual case of DLBCL due to lymphomatous infiltration of the kidney, presenting as AKI.

Case Description: A 48 y/o female with HIV presented with b/l flank pain, fevers, night sweats and weightloss x 1 week. She discontinued ART, but restarted 2 weeks earlier. On exam, a 1.5 cm left axillary lymph node was palpable. On admission, Cr was 2.95, and peaked at 3.34. Pro/Cr ratio was 1.2g. CD4 count was 117 cells/uL and viral load was 1097 copies/mL. CT scan showed enlarged kidneys (right 15cm, left 13 cm). Numerous retroperitoneal and paraaortic lymph nodes measuring less than 1cm were present. A kidney biopsy was performed. Light microscopy showed <1% intact tubules and near total infiltration by a monomorphic atypical lymphoid infiltrate. Glomeruli were normal. Electron microscopy showed tubuloreticular inclusions in endothelial cell cytoplasm. Features were consistent with DLBCL. PET/CT showed uptake in b/l axillary lymph nodes and symmetric tracer activity in b/l kidneys. Bone marrow biopsy showed normal trilineage hematopoiesis. Left axillary lymph node biopsy was consistent with DLBCL. After 8 weeks of chemotherapy(DA R EPOCH) Cr decreased to 1.0 mg/dL. Six months post treatment, patient is in remission with normal renal function.

Discussion: Primary renal lymphoma accounts for 0.7% of extranodal lymphomas and < 1% of renal lesions. The low CD4 count, systemic symptoms, flank pain and kidney enlargement suggest an HIV-related lymphoma. Renal biopsy with immunohistochemical staining confirmed the diagnosis. AKI resolved and lymphoma is in remission with ART and chemotherapy. Patients with HIV-related lymphoma have numerous kidney manifestations. Hemodynamic and drug-induced mechanisms must be separated from AKI caused directly by malignancy, as therapy relies on treatment of the underlying disease.

SA-PO604

An Unusual Kidney Presentation of Multiple Myeloma in a 45-Year-Old Man Antioco Fois,[1] Daniele Derudas,[2] Emanuele Angelucci,[2] Riccardo Cao,[1] Maura Conti,[1] Alice Atzeni,[1] Antonello Pani.[1] *[1]Nephrology, Azienda Ospedaliera Brotzu, Cagliari, Italy; [2]Hematology, Ospedale Oncologico Businco, Cagliari, Italy.*

Introduction: Multiple myeloma is a plasma cell dyscrasia caused by the proliferation of a single cellular clone producing a monoclonal immunoglobulin, usually presenting with renal failure, osteolytic lesions, anemia and hypercalcemia. The most common kidney pathology is determined by light chain cast nephropathy, light chain deposition disease (LCDD or AL amyloidosis. In a small percent age of cases, renal lesions are atypical, such as interstitial nephritis and light chain proximal tubulopathy.

Case Description: Eight months before coming to our attention, a 45-year-old male had been admitted to a different hospital due to acute renal failure. Renal biopsy showed acute interstitial nephritis with chronic lesions related to NSAIDS adminstration for lower back pain. He was treated with prednisone for 7 months after which he was admitted to our unit because of fatigue, nausea and back pain. The laboratory workup showed renal insufficiency, proteinuria, hypercalcemia, hypereosinophilia and a significant increase in serum kappa free light chains with a kappa to lambda ratio of 909:1. Bone marrow biopsy revealed 70% plasma cell infiltration, and skeleton xray highlighted multiple osteolytic lesions. Kidney biopsy showed chronic interstitial nephritis with aspects of cast nephropathy and a k-restricted light chain proximal tubulopathy with crystals. Light chain multiple myeloma was diagnosed and the patient was treated with steroids, bortezomib and thalidomide. He showed no response to the therapy, and four months later he died of multi organ failure.

Discussion: Interstitial nephritis and light chain proximal tubulopathy represent an uncommon onset of multiple myeloma.We believe that the interstitial damage revealed by the first renal biopsy was due to multiple myeloma, perhaps unrecognized because of the lack of clinical suspicion. Multiple myeloma may be masked and it is fundamental to search for it depending on the clinical presentation, even if the pathologic diagnosis is atypical.

SA-PO605

T-Cell Lymphoma Presenting with Type B Lactic Acidosis Laith Farah Al-Rabadi,[1] Roberto Leon Ferre,[2] Christopher D. Blosser,[3] Mony Fraer.[4] *[1]Nephrology, Boston Univ Medical Center; [2]Internal Medicine, Univ of Iowa Hospital and Clinics; [3]Nephrology, Univ of Washington; [4]Nephrology, Univ of Iowa Hospital and Clinics.*

Introduction: Type B lactic acidosis is a rare complication of hematologic malignancies that tends to portend a poor prognosis. Although several hypotheses have been proposed, the underlying mechanisms that lead to lactic acidosis in cancer patients, mostly with hematologic malignancies, remain elusive. We report the case of a 65-year-old female who presented with lactic acidosis of unknown cause. After extensive investigations, she was diagnosed with T-Cell Lymphoma.

Case Description: Patient was in severe respiratory distress and required support with a ventilator. She was started on continuous renal replacement therapy (CVVHDF) in an attempt to correct the metabolic acidosis while definitive treatment with chemotherapy was pursued. She was started on CHOP chemotherapy regimen (cyclophosphamide, hydroxydaunorubicin, vincristine, and prednisone). lactic acid continued to rise. She had a very rapid decline with demise after 6 days.

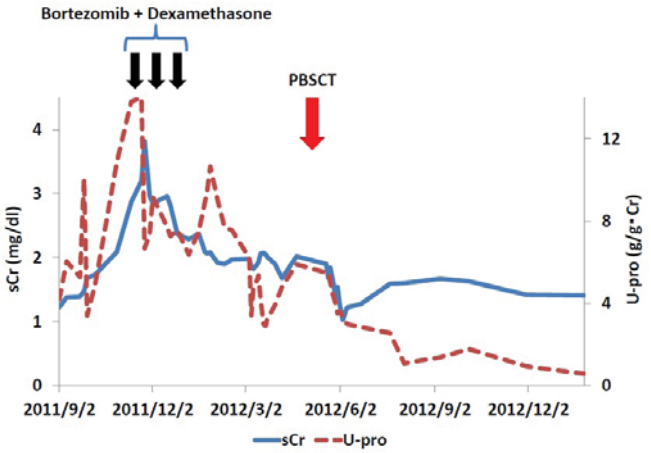
Discussion: The literature pertaining to malignancy-associated lactic acidosis and its potential treatments is scarce. Management strategies are controversial, and favorable outcomes in these patients are more often the exception than the rule. The very few patients, who survived,had received chemotherapy. Lactate clearance through continuous renal replacement therapies in order to decrease the degree of metabolic acidosis, as a temporizing measure until chemotherapy takes effect has been used but with limited results. As described by Levraut et al., the degree of lactate elimination is comparable as that of urea with an estimated excretion fraction of 25%. However, the total amount removed by dialysis is small when compared to total plasma clearance. Hence, lactate levels continue to be good reflection of the primary process without being affected much by these supportive therapies. The beneficial effect, reported in some studies, with continuous venovenous hemofiltration with dialysis on lactic acidosis likely reflects an improvement in acid-base and potentially enhanced lactate metabolism, rather than the direct removal of lactate.

SA-PO606

Light Chain Deposition Disease Successfully Treated By a Combination of Bortezomib-Based Chemotherapy and Autologous Stem Cell Transplantation Saeko Uehara, Takuya Isegawa, Masahiro Koizumi, Masafumi Fukagawa. *Nephrology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.*

Introduction: Light chain deposition disease (LCDD) is a clonal plasma cell proliferative disorder characterized by systemic tissue deposits of light chain fragments (usually kappa chain), leading to organ dysfunction including kidney. Its prognosis is very poor, especially in those with kidney involvement, and no standard therapy has been established. However, recent data indicate that bortezomib, a proteasome inhibitor, is a promising agent.

Case Description: A previously healthy 39 year-old female was referred to our department for evaluation of nephrotic-range proteinuria. In the initial test, serum creatinine was 1.2 mg/dl and urine protein was 4.2 g/g Cr. The renal biopsy showed that nodular glomerulosclerosis, linear deposits of kappa chains along tubular basement membrane by immunofluorescence. Urine immunofixation detected kappa chains, and serum kappa: lambda ratio was markedly elevated. The bone marrow exam showed slightly increase of plasma cells (6.6%). As an induction therapy, this patient received three cycles of chemotherapy composed of bortezomib and dexamethasone, and showed response in three months. After the chemotherapy, peripheral blood stem cell transplantation (PBSCT) was performed. The renal function was significantly improved, and the kappa: lambda ratio fell to within normal range.



Discussion: Bortezomib could become a preferred initial therapy for patients with LCDD, and may help improving the outcomes in patients eligible for autologous stem cell transplantation.

SA-PO607

A Case Report: Immunoglobulin D (IgD) Multiple Myeloma with Rapidly Progressing Renal Failure Jwalant R. Modi, Ahmad Eter, Suzanne E. El Sayegh, Elie El-Charabaty. *Medicine/ Nephrology, Staten Island Univ Hospital, Staten Island, NY.*

Introduction: Immunoglobulin D multiple myeloma (IgD MM) is very rare form of myeloma affecting less than 2% of all myeloma patients. It has a multiorgan involvement with renal failure being the key feature.

Case Description: We present here a case of IgD MM in a 62 year white male, smoker with past medical history of hypertension, who presented to ED with complaints of lower abdominal pain, constipation and decreased urination. Physical exam was unremarkable. Laboratory investigation showed S. Cr 5.99 mg/dL, hemoglobin 8.7 g/dL and corrected S.Ca 10.6 mg/dL. Urine dipstick showed 100 protein and TP/Cr ratio was 23. Serology was positive for Serum free lambda chain level of 8947.6 mg/L as well with free κ/λ ratio <0.01. The results of serum and urine electrophoresis and immunofixation were also supportive of diagnosis of IgD MM. IgD level was remarkably elevated (27300 mg/L) too. CT scan abd/pelvis was negative for obstructive uropathy. Skelatal survey showed a solitary lytic lesion in the iliac crest. His kidney function deteriorated next day requiring hemodialysis. The bone marrow biopsy was positive for plasma cell hypercellualrity (70-80%) and flow cytometry showed 8% monoclonal IgD lambda plasma cells. The patient was started on bortezomib and dexamethasone and he underwent bone marrow transplant 6 months later. He is doing well hematologically now but he remains dialysis dependent.

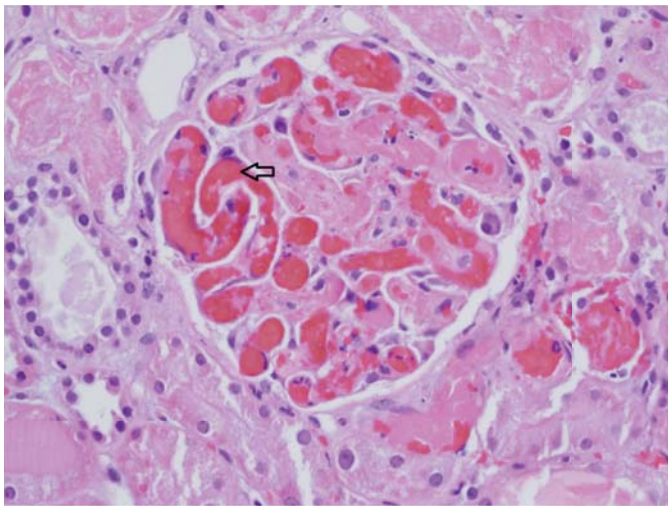
Discussion: IgD MM is very rare disease affecting younger population with poor prognosis, patients often ending up on hemodialysis despite better control of the hematological component.

SA-PO608

Renal Thrombotic Microangiopathy Associated with a Novel Chemotherapy Agent Carfilzomib Owolabi Ogunneye, Jo Abraham, Alfred K. Cheung. *Nephrology, Univ of Utah.*

Introduction: Thrombotic microangiopathy (TMA) constitutes a group of microvascular occlusive disorders characterized by systemic or intrarenal platelet aggregation, thrombocytopenia and end organ damage. Carfilzomib is a novel tyrosine-kinase inhibitor, used as a single agent for multiple myeloma. We report herein a case of TMA secondary to carfilzomib therapy, the first to our knowledge.

Case Description: A 51 year-old Caucasian male presented to the hematology clinic of our institution 12 years after he was diagnosed with smoldering myeloma. Seven years prior to his presentation, he had a recurrence of his myeloma, diagnosed as lambda-light-chain myeloma and was treated with combination chemotherapy, followed by autologous stem-cell transplantation with induction of remission. Unfortunately, he had another relapse one year before this visit. He was therefore enrolled in the Endeavour study and started on the study medication carfilzomib, a tyrosine-kinase inhibitor. On the day of presentation, while on cycle 8, the patient reported reduced urine output. He was noted to have a platelet count of 10 k/mL, a rapid elevation of serum creatinine from 1.2 mg/dl to 4.5 mg/dl in 1 week, bicarbonate of 15 mmol/l, LDH 1038 U/l, haptoglobin <10 mg/dl, ADAMSTS 13 activity >95%, and urinary FeNa 0.3%. His peripheral blood smear revealed schistocytes. Urine microscopy showed multiple dysmorphic erythrocytes and granular casts. Kidney biopsy showed TMA.



Carfilzomib was discontinued promptly and he was treated supportively with hemodialysis.

Discussion: The mainstay in the management of drug-induced TMA involves cessation of the offending agent and supportive therapies. To our knowledge, this is the first reported case of TMA that appeared to be related to carfilzomib. Clinicians should be vigilant for early signs and symptoms of TMA in patients treated with novel therapeutic agents, especially those with a prolonged course.

SA-PO609

Successful Eculizimab Withdrawal in a Patient with Pregnancy-Associated Atypical Hemolytic Uremic Syndrome Cintia Germana Mergulhão da Costa, Hugo Pinheiro, Ederson Vidal Moura, Gisele Vajgel Fernandes, Luis H.B.C. Sette, Têg Marcos Veiga, Carla Tenório Barros Cisne Pessoa, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *UFPE.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a rare and systemic disease related to dysregulation of the alternative complement system. The sporadic aHUS is related to various triggers, such as pregnancy. Eculizumab therapy was associated with a significant inhibition of complement-mediated thrombotic microangiopathy and the early infusion was associated with improvement in glomerular filtration rate and also with favorable outcome after drug withdrawal 62-64 weeks later.

Case Description: A 36y woman, in the course of 33 weeks pregnancy, was admitted with hematuria, edema and hypertension in the past 24 hours. She received magnesium sulfate and pregnancy was interrupted. After birth she developed oligoanuric AKI, hemolytic anemia (Hb 5.8g/dL), thrombocytopenia (63.000) and increased LDH (1076U/dL) with mildly increased transaminases. Schizocytes were found in peripheral blood; rate reticulocytes was 5.4%;direct Coombs was negative; haptoglobin was low (33mg/dL); anticardiolipin antibody IgG and IgM, ANA and anti-DNAds were negatives; normal C3 and C4; negative sorology for HBV, HCV and HIV; normal ADAMTS 13 (65%). She undergone daily HD after birth and one session of plasmapheresis; treatment with eculizumab was infused 72h after first session of HD. She increased diuresis (100ml/h) after drug infusion. Patient recovered renal function, not requiring HD 24h later. She underwent a 1-month induction therapy with eculizumab and maintenance up to 24 weeks. Renal biopsy was done 8 weeks after birth and was unremarkable except for mild fibrous intimal hyperplasia. After patient consent we successfully withdraw the drug and 12 weeks later she was asymptomatic with a normal Scr and controlled arterial pressure with 2 anti-hypertensives.

Discussion: Patient had an excellent response to early infusion of eculizumab which was maintained up to 24 weeks. The patient remains off dialysis and with normal renal function during a 3 months follow-up after drug withdrawal.

SA-PO610

A Rare Case of Renal Thrombotic Microangiopathy Associated with Castleman's Disease Anubha Mutneja,[1] Larry N. Cossey,[2] Helen Liapis,[1,2] Ying Maggie Chen.[1] *[1]Renal Div, Washington Univ, St. Louis, MO; [2]Nephropath, Little Rock, AR.*

Introduction: Castleman's disease (CD) is an uncommon lymphoproliferative disorder leading to high circulating levels of IL-6 and VEGF. Renal involvement in CD has only been described in single-case reports. Herein, we report a rare case of renal thrombotic microangiopathy (TMA) associated with CD.

Case Description: A 19 yo male presented with diarrhea and low-grade fever for 3 weeks with a rise of creatinine (Cr) to 1.5 mg/dl. His physical exam was notable for diffuse lymphadenopathy, splenomegaly and moderate ascites. Laboratory findings included hemoglobin 8.2, platelets 73 and normal LDH. Urinalysis showed 2+ blood and 1+ protein. Peripheral smear did not reveal schistocytes. Complement levels were normal, and ADAMTS 13 activity was decreased (10%). Shiga toxin was negative, and stool culture was negative for E coli O157:H7. Plasmapheresis was promptly initiated due to concerns for hemolytic uremic syndrome. However, his renal function kept declining. A kidney biopsy showed diffuse endothelial swelling, mesangiolysis and focal glomerular thrombi, consistent with TMA. Subsequent laboratory findings were significant for positive ANA, ENA, SS-A, SS-B and anticardiolipin antibodies. ESR 59, CRP 99.4, and serum VEGF 343 pg/ml (reference: 31-86) were high. An excisional lymph node biopsy revealed follicular hyperplasia and a diffuse intrafollicular plasma cell infiltrate. HHV-8 staining was negative. The final diagnosis was CD, plasma cell variant. After treatment with rituximab, etoposide and prednisone, his renal function, platelet count and anemia were normalized.

Discussion: Our case illustrates a rare renal histological feature of CD, although CD is known to cause endothelial injury. Other reported renal involvements include amyloidosis, acute interstitial nephritis and focal segmental glomerulosclerosis. IL-6 and VEGF are postulated to suppress glomerular VEGF expression, thereby causing renal TMA. Therapy directed against these inflammatory mediators may have important therapeutic implications.

SA-PO611

Simultaneous Infusion of Eculizumab and Intravenous Immunoglobulin Does Not Decrease the Efficacy of Eculizumab Yvonne El Kassis, Juan C. Calle. *Dept of Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH.*

Introduction: Eculizumab is approved for treatment of atypical hemolytic uremic syndrome(aHUS). Its efficacy with concomitant intravenous immunoglobulin(IVIG) infusion has not been determined yet. We describe the case of a patient with aHUS and toxic epidermal necrolysis(TEN) who got Eculizumab and IVIG simultaneously without subsequent decrease in Eculizumab activity.

Case Description: 39 year-old AAF who presented with hypertensive emergency and seizures and was found to have microangiopathic anemia, thrombocytopenia, acute kidney injury, and thrombotic microangiopathy on kidney biopsy. She was diagnosed with aHUS and underwent plasmapheresis for 1 week without improvement in her thrombocytopenia or kidney function. She was thus started on Eculizumab. She became febrile after the placement of a chest port and developed a generalized skin rash with biopsy proven TEN when she was started on Piperacillin-Tazobactam. She received IVIG for 3 days. She was due for her 2nd dose of Eculizumab but it was postponed for 24 hours after her last IVIG dose. As a surrogate marker of Eculizumab activity, we measured its level and the serum C5 functional activity when she received both infusions a day apart and, a week later, when she only got Eculizumab. In both cases, Eculizumab level was in the therapeutic range and C5 functional level was suppressed.

Discussion: This is the 1st case report of a simultaneous use of IVIG and Eculizumab in a patient with aHUS and TEN. There is only 1 study that looked at the concomitant infusion of IVIG and Eculizumab in 10 patients with motor neuropathy. In this study, Eculizumab was given before IVIG, unlike our patient who got IVIG first. This study showed no difference in complement activity between patients receiving Eculizumab only and those receiving Eculizumab and IVIG on a same day. Our results are consistent with this finding, suggesting a lack of inhibitory effect of IVIG on Eculizumab. This would be relevant in instances where IVIG and Eculizumab are needed together, particularly in the transplant field where Eculizumab appears to be an emerging drug for antibody mediated rejection and where IVIG is a cornerstone of the treatment.

SA-PO612

Vitamin B 12 Deficiency Mimicking Thrombotic Thrombocytopenic Purpura Manish Goyal, Farhanah Yousaf, Bruce S. Spinowitz, Chaim Charytan, Marilyn Galler. *New York Hospital Queens.*

Introduction: Thrombotic Thrombocytopenic Purpura (TTP) typically presents with hemolytic anemia, schistocytosis, and thrombocytopenia. We report a case of vitamin B 12 deficiency that was initially diagnosed and treated as TTP.

Case Description: A 43-year-old Hispanic male with no previous medical history was brought in to emergency department for syncope following a blood draw to investigate a 40

lbs weight loss during the past 6 months associated with decreased appetite and progressive fatigue. The patient also reported a 1 month history of jaundice. He denied any chest pain, dyspnea, fever, cough, tingling, numbness, headache, visual changes, focal weakness, abdominal pain, bleeding, leg swelling, rash, changes in urinary or bowel habits, sick contacts, or any previous history of anemia. On examination, he was hemodynamically stable, afebrile, with pallor and diffuse jaundice but without skin rash or palpable purpura. Neurological examination showed normal sensations and power in all extremities. The presence of hemolytic anemia, schistocytosis, thrombocytopenia, and elevated LDH was suggestive of TTP. Three units of packed red blood cells and one unit of platelets were transfused on Days 1-3. The response to 2 sessions of plasmapheresis on Days 2-3 was inadequate. The low WBC and low reticulocyte count were atypical for TTP and therefore an alternative etiology was sought. Testing revealed a low vitamin B 12 level and positive intrinsic factor blocking antibodies supporting a diagnosis of pernicious anemia with severe vitamin B 12 deficiency. Vitamin B12 replenishing was begun on Day 3. Additional plasmapheresis sessions were performed on Days 4-5 until a negative ADAMTS 13 test result was available. Hematological improvement was observed following vitamin B 12 supplementation. The patient was discharged markedly improved on Day 9.

Discussion: Pseudo-TTP is rare but should be considered in all adult patients especially when the laboratory data has inconsistent features of TTP. In a recent retrospective review of 7 patients with pseudo-TTP and 6 patients with TTP, the most prominent distinguishing features suggestive of pseudo-TTP versus TTP included very high LDH levels and lower reticulocyte counts.

SA-PO613

Postpartum Atypical Hemolytic Uremic Syndrome Successfully Treated with Eculizumab Ginius Pradhan, Rohini Prashar, Sandeep Vetteth. *Nephrology, Univ of toledo Medical Center, Toledo, OH.*

Introduction: Pregnancy associated atypical HUS (aHUS) is increasingly being recognized as a cause of thrombotic microangiopathy in postpartum females. We describe a case of postpartum thrombotic microangiopathy, resistant to plasmapheresis, successfully treated with Eculizumab.

Case Description: A 29-year-old female, postpartum day 3, was transferred to our center for thrombocytopenia and oliguric renal failure. Her blood pressure was 163/99 mm Hg. Her laboratory work showed a creatinine increase from 0.8mg/dl to 3 mg/dl in 3 days, hemoglobin of 8.2g/dl, with schistocytes and a platelet count of 29,000/mm3. She had elevated LDH and indirect bilirubin and low haptoglobin. There was no history of recent diarrhea. Hemodialysis had to be initiated because of worsening hyperkalemia and renal function. Immediate plasmapheresis was initiated for a presumptive diagnosis of Post partum TTP without much improvement in patient's clinical condition, hemogram or renal parameters over the next 10 days. The ADAMTS13 activity was resulted normal. With poor response to plasmapheresis and a normal ADAMTS13 activity, we had a high clinical suspicion for aHUS.

Discussion: aHUS is a disease of uncontrolled alternative complement pathway activation from mutations in complement activation inhibitors. Pregnancy associated aHUS (P- aHUS) is increasingly being recognized now and in a recent study P-aHUS occurred in 21 of the 100 adult female patients with aHUS. Eculizumab is a monoclonal antibody that targets C5 to prevent activation of the terminal membrane attack complex and thus slow down complement-mediated damage. To our knowledge, this is only the third description of successful use of eculizumab in a patient with P-aHUS. In a disease that carries a risk of significant morbidity and mortality, our case emphasizes the importance of considering this novel therapy early if there is a high index of suspicion.

SA-PO614

Hemophagocytic Lymphohistiocytosis Associated with Cytomegalovirus Infection in the Setting of Refractory Thrombotic Microangiopathy Imtiaz M. Ather, Taha Ayach, Hem P. Chataut, Yuvaraj Thangaraj, A. Ahsan Ejaz. *Medicine, Div of Nephrology, Univ of Florida, Gainesville, FL.*

Introduction: We herein report a rare case of hemophagocytic lymphohistiocytosis (HLH) associated with cytomegalovirus (CMV) infection during a prolonged course of treatment for thrombotic microangiopathy (TMA).

Case Description: A 46 year-old female with no past medical history was admitted with diarrhea, thrombocytopenia, and hemolytic anemia. Peripheral blood smear was notable for schistocytes, ADAMTS13 levels were normal, and there was no history of Shiga toxin positivity. Renal biopsy was consistent with thrombotic microangiopathy, for which the diagnosis of atypical hemolytic uremic syndrome (HUS) was made. Treatment was initiated with plasma exchange, eculizumab, and high-dose steroids, however the patient did not improve despite 8 weeks of treatment. Two weeks later she developed fevers and progressive lethargy, followed by acute liver failure. Ferritin was noted to be significantly elevated at 97,473 ng/mL, and triglycerides were elevated at 468 mg/dl. Bone marrow biopsy revealed evidence of hemophagocytosis. Infectious workup was notable for CMV infection with viral load of 28,971 copies/mL. The patient began treatment for HLH and CMV infection with etoposide and ganciclovir, respectively, but ultimately developed worsening multi-organ failure and passed away within a matter of days.

Discussion: Hemophagocytic lymphohistiocytosis (HLH) is a rare and aggressive disorder due to severe immune system activation leading to life-threatening cytokine storm. It can be triggered by viral illnesses including CMV and EBV. Our patient met diagnostic criteria consisting of fever, pancytopenia, elevated serum ferritin greater than 500 ng/ml, hypertriglyceridemia (greater than 265 mg/dl), and evidence of hemophagocytosis in bone marrow biopsy. We believe that HLH was triggered by her CMV infection, which likely arose from aggressive prolonged immunosuppressive therapy for atypical HUS. In these patients, early recognition of signs of HLH followed by rapid evaluation for possible infectious etiologies and directed treatment may prove helpful in preventing subsequent complications of this devastating disorder.

SA-PO615

Thrombotic Microangiopathy from Cannabinoids Rajat Lamba, Shantheri S. Shenoy, Savneek S. Chugh, Praveen N. Chander, David Selzer, Anita Kaul. *Nephrology, Westchester Medical Center, Valhalla, NY.*

Introduction: AKI (acute kidney injury) secondary to Synthetic Cannabinoid(SC) use was first reported to health department of Wyoming in March 2012. 16 cases have been reported since then in United States, of which 6 showed acute tubular injury and 3 showed acute interstitial nephritis on biopsy. We report a case of AKI and TMA(thrombotic microangiopathy) likely associated with synthetic cannabinoid use.

Case Description: A 35 year old female with history of smoking marijuana, Hepatitis C virus infection 10 years prior treated with peg interferon, type 2 diabetes, bipolar disorder, presented with complaints of fatigue and weight loss. On admission BP was 170/100. Labs showed hemoglobin of 11.3g/dl and platelet count of 86,000 with an elevated reticulocyte count of 10.1, LDH of 794, haptoglobin less than 8 mg/dl and uric acid of 8.5 mg/dl She was non oliguric with BUN of 46 and creatinine of 5.0. Urine had trace blood and 2 grams of protein. Ultrasound showed both kidneys were 12cm and isoechoeic. Peripheral blood smear showed 1-2 schistocytes per high power field. TTP/HUS was suspected. She denied any bloody diarrhea. Therapeutic plasma exchange was performed daily for 3 days. Further workup revealed normal ADAMTS 13 activity. ANA, anti-ds DNA, ANCA, HIV and Hepatitis B surface antigen were negative. Hepatitis C antibody was positive with negative HCV RNA, normal serum complements and negative Cryoglobulins. Urine toxicology was positive for cannabinoids. She underwent a CT guided renal biopsy that was consistent with TMA. She was started on Eculizumab, following which her serum creatinine stabilized. 3 months later, she had acute kidney injury from gram negative sepsis and eventually started on dialysis.

Discussion: Cannabinoids, particularly SCs abuse is becoming popular with young adults due to affordability and inability to be detected on routine urine toxicology screens. Although the exact mechanism of TMA in our patient is not known, we suspect that cannabinoids might have evoked an endotheliolitis and triggered a microangiopathic event. TMA from SCs should be included in the differential diagnosis of unexplained AKI, especially in young adults with marijuana use.

SA-PO616

An Unusual Case of Severe Bleeding in a Dialysis Patient Rajat Lamba, Savneek S. Chugh, Karim B. Solangi, Anita Kaul. *Nephrology, Westchester Medical Center, Valhalla, NY.*

Introduction: Bleeding in dialysis patients is multifactorial and is usually associated with vascular stenosis, anticoagulation and rarely from platelet dysfunction due to inadequate dialysis. We are reporting a rare case of life threatening bleeding in a patient on hemodialysis secondary to acquired hemophilia A due to factor VIII inhibitor.

Case Description: A 63 year old man on hemodialysis for 6 years presented to the emergency room for uncontrolled bleeding from the vascular access site, resulting in formation of a large hematoma requiring immediate surgical intervention. Surgery was complicated by severe intraoperative bleeding requiring transfusion. Admission labs showed hemoglobin of 10.5, platelet count of 88,000, BUN of 64, Cr of 11.7, significantly prolonged PTT of 69.7 with normal INR (1.04) and PT (11.4). Surprisingly, patient was not receiving any heparin on dialysis. Repeat PTT was again prolonged (63.5) and antiphospholipid antibodies were negative. Mixing study showed PTT of 33.8 after mixing with normal plasma and further investigation revealed the presence of an inhibitor against Factor VIII (low Bethesda ASSAY titer of 2.8 BU). Patient had another episode of severe bleeding which required administration of Factor VIII, DDAVP, IVIG and Steroids. Within few weeks of starting steroids, factor VIII inhibitor titer was undetectable and PTT improved (33.8). Further investigations were done to rule out any underlying malignancy and autoimmune disorders, which were all found to be negative.

Discussion: Acquired hemophilia A is a disorder characterized by the formation of an inhibitor against Factor VIII. Although about 50 percent of cases are idiopathic, associations have been made with pregnancy, malignancy, autoimmune disorder and medications. The formation of factor 8 inhibitor in this patient could be related to exposure to the dialysis membrane. Any patient receiving adequate dialysis who presents with severe bleeding warrants workup for coagulation disorders.

SA-PO617

Plasmapheresis in *Streptococcus pneumoniae* Associated TTP Kevin C. Roe, Sreedhar Devathi. *Nephrology, Penn State College of Medicine, Hershey, PA.*

Introduction: *Streptococcus pneumoniae* infection is a rare cause of Thrombotic Thrombocytopenic Purpura (TTP) via the action of circulating neuraminidase. However, within the heterogeneous disease of TTP it is unclear if plasmapheresis is an appropriate treatment for *S pneumoniae*-associated TTP. We report a case of TTP with *S pneumoniae* bacteremia effectively managed with plasmapheresis.

Case Description: A 23 year-old Puerto Rican female was admitted for ventilator dependent respiratory failure with *S pneumoniae* bacteremia and pneumonia after starting on belimumab for SLE associated arthritis. She had no previous history of renal disease or nephritis. Her hospital course was complicated by thrombocytopenia, microangiopathic hemolytic anemia and acute renal failure requiring renal replacement therapy. Renal biopsy was unrevealing. ADAMTS 13 levels were normal and testing for lupus anticoagulant was

negative. After appropriate antibiotic therapy and clearance of her blood cultures, it was not until starting on plasmapheresis that she had complete clinical recovery from thrombotic microangiopathy and associated acute renal failure.

Discussion: It has not been previously well reported but we believe that plasmapheresis should be considered in the treatment of *S pneumonia*e induced TTP.

SA-PO618

Acute Renal Artery Aneurysm Rupture with Bilateral Renal Infarction: An Unusual Case of Fibromuscular Dysplasia in a Young Male Rio Noto,[1] Hideki Yokoi,[2] Hiroyuki Ueda,[3] Makoto Kinoshita,[4] Nozomu Kamiura,[1] Motoko Yanagita,[2] Akihiro Yoshimoto.[1] *[1]Dept of Clinical Nephrology, Kobe City Medical Center General Hospital, Kobe, Hyogo, Japan; [2]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [3]Dept of Diagnostic and Interventional Radiology, Kobe City Medical Center General Hospital, Kobe, Hyogo, Japan; [4]Dept of Cardiovascular Medicine, Kobe City Medical Center General Hospital, Kobe, Hyogo, Japan.*

Introduction: Fibromuscular dysplasia (FMD) is a nonatherosclerotic and noninflammatory vascular disease that causes arterial stenosis, occlusion, dissection, and aneurysm of medium-sized arteries. Renal artery aneurysms (RAA) occur in 5.6% of patients with FMD, and rupture of RAA is uncommon. Renal failure (1.6%) and infarction (0.9%) are both rare events.

Case Description: A 26 year old male without any underlying diseases presented with progressive left flank pain. His blood pressure was 153/101 mmHg, and his heart rate was 113 bpm. Blood tests showed an elevation in white blood cell count of 19,800/μL and other laboratory findings were within normal limit. A computed tomography angiography (CTA) demonstrated a typical "string of beads" appearance of FMD with dissection of renal arteries and infarction of bilateral kidneys. He was treated with calcium blocker to reduce blood pressure. However, on day 8, he suddenly felt severe, left-sided abdominal pain. His hemoglobin decreased from 15.9 g/dl to 11.0 g/dl, and serum creatinine increased from 0.69 mg/dl to 1.52 mg/dl. A CTA showed large retroperitoneal hemorrhage from rupture of a left RAA, arising from the above-mentioned artery dissection. Receiving blood transfusion, he was treated with a coil embolization of a left RAA. Two days later, a right RAA, found by chance, was embolized with endovascular stent emplacement in the right renal artery dissection. His renal function has recovered and a subsequent CTA showed complete resolution of dissection and no appearance of new lesions.

Discussion: FMD often affects renal arteries but renal infarction and rupture are rare complications, and we will discuss the differential diagnosis of RAA. We first demonstrated rupture of RAA with dissection in a young healthy male with FMD.

SA-PO619

Reninoma a Rare Cause of Hypertension Kerri A. McGreal, Alan S.L. Yu. *Nephrology, Univ of Kansas Medical Center, Kansas City, KS.*

Introduction: Reninoma is a juxtaglomerular cell apparatus tumor that secretes renin. It is a rare cause of secondary hypertension and more specifically secondary hyperaldosteronism, with less than 100 cases ever reported.

Case Description: A 19 year old female was referred for refractory hypertension and hypokalemia. She was healthy until 4 months ago, when her blood pressure was incidentally found to be 260/150 mmHg and potassium was 2.4 mmol/L. Her blood pressure was controlled on 5 anti-hypertensive medications. She received a work-up for secondary hypertension that showed normal urine cortisol, catecholamines, and metanephrines. Her urine drug screen was negative. Ultrasound showed normal size kidneys. Plasma aldosterone was elevated at 52 ng/dL (<21). Plasma renin activity was 10 ng/mL/hr (9-24 upright is normal). 24 hr urine aldosterone was elevated at 30 mcg (<19). She had computer tomography (CT) with contrast that showed no evidence of renal artery stenosis, but an isodense mass versus cyst in the superior pole of the right kidney. Renal vein sampling showed renin level of 25 ng/ml/hr in the right upper pole vein and 49 ng/ml/hr in the right upper pole superior medial vein. The inferior vena cava, left renal, and femoral vein were all <9 ng/ml/hr. She had resection of the mass and the pathology was consistent with juxtaglomerular tumor. Her renin and aldosterone levels normalized on post-op day one. One month later she was controlled on one blood pressure medication.

Discussion: This patient had hyperaldosteronism with unsuppressed renin causing her hypertension. Non-invasive imaging showed no evidence of renal vascular hypertension, a far more common cause of secondary hyperaldosteronism, though CTA is known to have poor sensitivity for fibromuscular dysplasia. When a common cause is not found one has to go searching for the rare causes. Reninoma lesions can be difficult to identify on imaging, as they are usually small and do not enhance on CT. Renal vein renin ratios assist in localizing a renin-secreting mass. In conclusion, reninoma is a rare cause of secondary hypertension but should always be considered when a patient has refractory hypertension with hypokalemia and no other cause of hyperaldosteronism can be found.

SA-PO620

A Curious Case of Abdominal Pain: Still Related to Kidney Pramod Kumar Guru,[1] Abbasali Akhoundi,[2] Kianoush Banaei-Kashani.[3] *[1]Pulmonary and Critical Care, Mayo Clinic; [2]Nephrology, Mayo Clinic; [3]Nephrology, Mayo Clinic.*

Introduction: Spontaneous renal artery dissection is an uncommon cause of renovascular hypertension, but renal artery is the most common site for peripheral dissection. With advent of radiologic procedures renal artery dissections are increasingly recognized. This is a unique case with unexplained abdominal pain.

Case Description: 64 year old male admitted to the intensive care unit for worsening abdominal pain of the prior 12 hours associated with nausea and diarrhea. Patient had history of hypertension, atrial fibrillation and cardiomyopathy. On arrival his blood pressure was 156/96 mmHg. Review of system was negative for dysuria, fever, renal colic or prior surgery. Laboratory studies showed elevated creatinine, leukocytosis, and hematuria. CT scan of the abdomen showed bilateral renal and right external iliac artery dissection with kidney infarcts. Given the history of ablation five days prior, possibility of intervention related dissection was entertained. Work up for associated vasculitides and infections were unremarkable. The exact etiology, spontaneous or iatrogenic, of the dissection was not ascertained during hospital stay. Following IV opioids and antihypertensives his pain subsided and hypertension improved. His subsequent hospital course was uneventful, and his discharge serum creatinine was 1.4 mg/dl, higher than the baseline of 0.9-1.1 mg/dl.

Discussion: Spontaneous bilateral renal artery dissection is a rare entity and reported cases are sparse. Abnormalities of vaso-vasorum and arterial dysplasia leading to spontaneous bleeding have been proposed as the cause of dissection. However, the exact pathogenesis is unknown. Association without proof of causality has been described with fibromuscular dysplasia. Abdominal pain, hematuria and kidney injury are common presenting features. Angiography remains the diagnostic modalities of choice for most patients. Medical therapies directed to control the pain and BP is the preferred treatment. Surgical interventions (radical or endovascular) are reserved for failed medical therapy. Anticoagulation as therapeutic options remains a controversial issue. High index of suspicion is needed to diagnose renal artery dissection.

SA-PO621

Renovascular Hypertension due to an Unusual Cause of Renal Artery External Compression Prince Singh,[1] Sherry-Ann Brown,[2] Roger Shepherd,[1,2] Thomas C. Bower,[3] Suzanne M. Norby.[1,2] *[1]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Dept of Internal Medicine, Mayo Clinic, Rochester, MN; [3]Div of Vascular and Endovascular Surgery, Mayo Clinic, Rochester, MN.*

Introduction: Renal artery (RA) stenosis is a common cause of arterial hypertension (HTN). While atherosclerosis and fibromuscular dysplasia comprise the majority of cases, any structural disorder reducing renal perfusion pressure may produce renovascular HTN.

Case Description: A 20-year-old man presented for evaluation of dyspnea and was noted to have HTN. CT angiogram was negative for pulmonary embolism and incidentally noted upward displacement of the left kidney with kinking of the left RA. Blood pressure (BP) was elevated, averaging 160/110 mmHg. Lisinopril/HCTZ 20mg/12.5 mg twice daily and amlodipine 10 mg daily were initiated. He was referred for further evaluation. 6-hour ambulatory BP averaged 143/87 mmHg with pulse 69/minute. Physical examination was unremarkable; no abdominal bruit was noted. Laboratory tests included serum creatinine (SCr) 1.7 mg/dl, negative spot urinary protein, and normal urine microscopy. Duplex ultrasound (US) noted the left kidney was smaller, 9.1 cm compared to 13.2 cm for the right kidney. Before referral, selective left RA angiogram had revealed high-grade left RA stenosis; however, attempt at angioplasty and stent was unsuccessful. Surgical exploration of the left RA was performed. The left kidney parenchyma was dusky, and the RA was found to be compressed by the left crus of the diaphragm. After wide resection of the crural muscle and fibrous tissue, the RA dilated to a normal diameter. Marked improvement of RA intraoperative Doppler signals was seen. Antihypertensive medications were held after surgery. BP on postoperative day 6 was 125/72 mmHg, and SCr was 1.2 mg/dl. After 3.5 months, Doppler US revealed left RA peak systolic velocities of approximately 140 cm/sec with aortic velocity 102 cm/sec. BP remained normal on no medications.

Discussion: External compression of the left RA by the diaphragmatic crus is an atypical cause of renovascular HTN. Appropriate surgical management can result in normalization of BP.

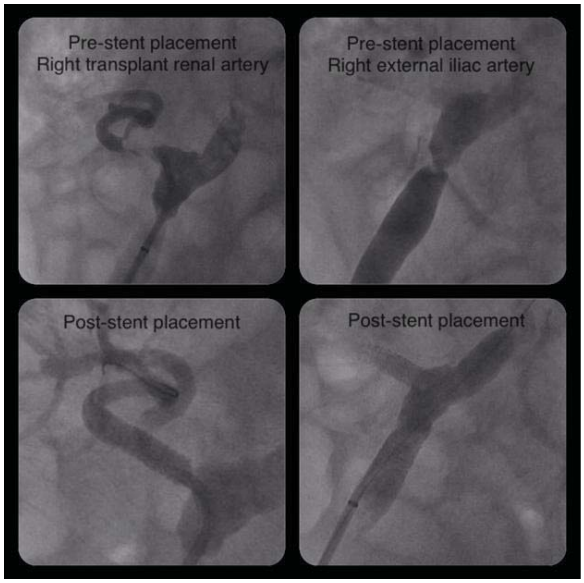
SA-PO622

A Late Presentation of Transplant Renal Artery Stenosis with a Fulminant Course Siddiq Anwar, Derek Larson, Richa A. Pandey, Daniel C. Brennan. *Renal Div, Washington Univ School of Medicine, St. Louis, MO.*

Introduction: Transplant renal artery stenosis (TRAS) is a recognized cause of renal allograft loss, hypertension (HTN) and volume overload. We report an unusual case of microangiopathic hemolytic anemia (MAHA) and malignant HTN caused by TRAS 12 years after kidney transplant (KT).

Case Description: 44yr white male with IgA nephropathy status post deceased-donor KT 12 years ago with baseline creatinine(SC) of 1.8 mg/dL was admitted with malignant HTN, MAHA (hemoglobin 6.7 g/dL platelet count, PC- 4 K/cumm),encephalopathy and anuric AKI(SC- 6.4 mg/dL). We initiated dialysis plus plasma exchange (PEX) for concern of thrombotic thrombocytopenia purpura. ADAMTS 13 activity level was subsequently 63% hence received a dose of Eculizumab for possible atypical HUS with no improvement. Donor specific antibodies,CMV, BK and HIV were negative. With HTN control PC

gradually increased and PEX was discontinued. Doppler suggested TRAS;subsequent KT renal angiogram demonstrated a 99% occlusion of the proximal KT renal artery and 80% stenosis in the external iliac artery (EIA). TRAS was treated with a bare metal Herculink-Elite stents and the EIA stenosis with an Express LD stent. He produced 7 liters of urine in the 12 hours post-stent with a marked improvement in his BP allowing the discontinuation of 4 out of 6 anti-hypertensive agents.SC remains stable at 1.6 mg/dL 18 months post-stent



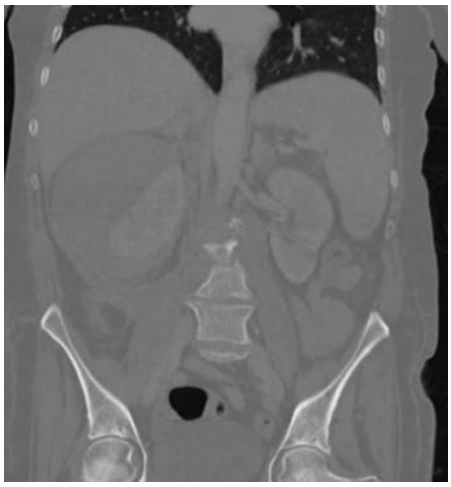
Discussion: Risk factors for development of TRAS include surgical complications,CMV,DGF and the use of older donors. This patient with anuric renal failure, thrombotic microangiopathy and malignant hypertension caused by TRAS had a complete clinical recovery after percutaneous intervention. This case highlights the need to consider TRAS in the differential diagnosis for AKI occurring late post KT and the success of percutaneous intervention if failing optimal medical therapy.

SA-PO623

Extensive Peri-Nephric Hematoma due to Ruptured Renal Artery Mycotic Psuedoaneurysm in a Patient with Bacteremia Ardavan Mashhadian,[1] Seyed-Ali Sadjadi.[2] *[1]Nephrology, Loma Linda Medical Center, Loma Linda, CA; [2]Nephrology, Loma Linda VA Medical Center, Loma Linda, CA.*

Introduction: Septic embolic from the heart can occlude the vasa vasorum of the vessel or the vessel lumen, leading to vascular wall infection and mycotic aneurysm formation. Infective endocarditis is a well-known cause of septic emboli. These emboli are commonly clinically silent and may be medically managed.

Case Description: 55-year-old female with past medical history of heroin abuse, endocarditis, osteomyelitis, and deep vein thrombosis on chronic anticoagulation with Coumadin presented with sever right-sided abdominal pain. Urine-analysis showed mild hematuria and CT scan of abdomen and pelvis showed right retroperitoneal peri-renal hemorrhage (10x8 cm), completely compressing the right kidney.



She had renal artery embolization where upper and mid portion of right renal artery was embolized. This unusual presentation of a septic embolus and its management are discussed.

Discussion: Because of their embolic nature, mycotic aneurysms tend to be multiple. Spontaneous resolution with antibiotic therapy for endocarditis has been reported. Smaller renal mycotic pseudo-aneurysms may spontaneously thrombose and require no further management. However, larger pseudoaneurysms may rupture and result in sepsis. These septic sites usually require direct surgical intervention. Hemorrhage may also occur, presenting as gross hematuria, intra-abdominal bleeding, or retroperitoneal bleeding. Renal arterial embolization is a well-accepted procedure and the treatment of choice for these lesions.

SA-PO624

Case of Renal Arteriovenous Fistula after Renal Biopsy, Accompanied with Brugada Syndrome Rie Suzuki, Asako Gondo, Kanako Jimi, Ryuji Tsujimoto, Yoshitaka Miyaoka, Toshikazu Wada, Yume Nagaoka, Yoshihiko Kanno. *Dept of Nephrology, Tokyo Medical Univ, Tokyo, Japan.*

Introduction: Renal biopsy is one of the most common causes of acquired renal arteriovenous fistula (AVF), but its incidence is rare. Also apparently very rare is the comorbidity of Brugada syndrome and chronic kidney disease (CKD) and their relationship is unclear. Here, we report the case of a CKD patient with renal AVF after renal biopsy, who also has Brugada syndrome.

Case Description: A 48-year-old Japanese woman was referred to a nephrologist for proteinuria and an elevated serum creatinine level. She had undergone 2 renal biopsies when she was a teenager. However, she had not received any special treatment. She came to our hospital because of her concern regarding her proteinuria and increased serum creatinine level, although she did not have any symptoms. Upon examination, her blood pressure was normal, but an abdominal bruit was auscultated. Her serum creatinine level was 1.02 mg/dL. Urine analysis showed no hematuria or proteinuria. Upon abdominal ultrasonography, a right renal arteriovenous malformation (AVM) was detected.

During her hospitalization for treatment of the AVM, her electrocardiogram revealed Brugada syndrome. She was diagnosed as having type 2 Brugada syndrome by a positive response in the pilsicainide test. Her renal AVF was successfully treated with coil embolization.

Discussion: Renal AVF and Brugada syndrome were found incidentally in an asymptomatic CKD patient. Our findings suggest that the results of routine examinations should be carefully followed up, even in asymptomatic cases, for the possible detection of abnormalities.

SA-PO625

Digestive Tract Bleeding due to Chronic Kidney Disease-Related Vascular Ectasia Found in Both the Upper and Lower Gastrointestinal Tract Tomomi Itoh,[1] Junichiro J. Kazama,[1] Ryohei Kaseda,[1] Michihiro Hosojima,[1] Suguru Yamamoto,[1] Ichiei Narita,[1] Sakumi Kazama.[2] *[1]Div of Clinical Nephrology and Rheumatology, Niigata Univ, Niigata, Japan; [2]Gastroenterology, Niigata Rinko Hospital, Niigata, Japan.*

Introduction: Gastric antral vascular ectasia (GAVE) is a relatively rare cause of recurrent upper gastrointestinal tract bleeding, while its etiology and pathophysiology remain obscure. Chronic kidney disease (CKD) is known as one of its background diseases, and an elevated circulating gastrin level has been assumed to be the likely cause of CKD-related GAVE.

Case Description: A 78- year- old female was transferred to our emergency room because of faintness and abdominal discomfort. She had received aortic valve replacement therapy, and anti-coagulation therapy with oral warfarin administration had been performed subsequently. She also had CKD with unproven etiology. She had no episodes of pathological bleeding or vasodilatation. She also had no past history of liver or collagen diseases. In the emergency room, she presented with pallor face and obviously anemic palpebral conjunctiva. Atypical honeycomb- like vasodilation was observed in her oral mucosa. Laboratory examinations demonstrated the followings: TP, 6.2 g/dl; Alb, 3.2 g/dl; BUN, 82 mg/dl; Cre, 3.01 mg/dl; Hb, 4.8 g/dl; Ht, 15.6 %; MCV, 94.5 fl; MCH, 29.1 pg; Fe, 142 mg/dl; UIBC, 129 mg/dl; Ferritin, 22 ng/ml and PT-INR, 1.26. A gastroduodenal endoscopic examination detected a typical watermelon-like stomach- type vasodilation in the gastric antrum. Many clots were found around the vasodilated lesion. A capsule

endoscopic and a colon fiberscopic examinations also detected vasodilatation images similar to the watermelon stomach finding along the intestinal tract, and hemodiapedesis from the vasodilated lesion was confirmed at the transverse colon. The patient's condition was improved immediately after transfusion therapy.

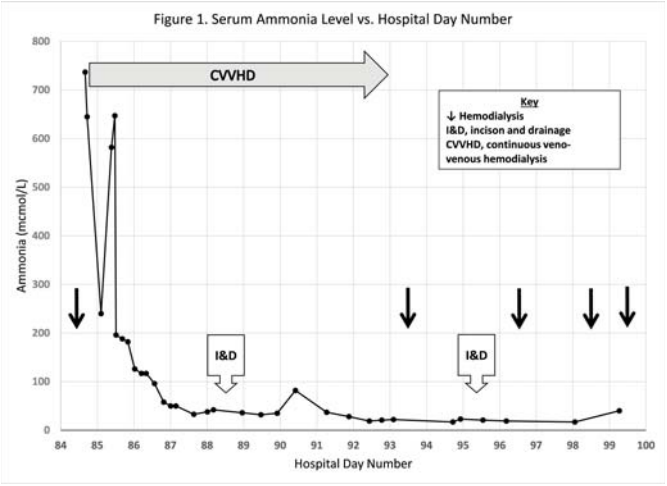
Discussion: GAVE-like vasodilation is not a stomach- specific disease, but can appear anywhere in the gastrointestinal tract in CKD patients. The role of gastrin in this disease condition must be reconsidered, because the gastrin receptors are localized predominantly in the stomach.

SA-PO626

Severe Hyperammonemia due to a *Proteus Mirabilis* Abscess in a Burn Patient without Liver Disease Treated with CRRT Sook Hyeon Park, John Doran. *Nephrology, Emory, Decatur, GA.*

Introduction: Hyperammonemia typically occurs in patients with liver disease, but can occur in normal liver function. We describe a patient with a deep tissue abscess from a urea-splitting organism that caused systemic hyperammonemia and was treated with continuous renal replacement therapy (CRRT).

Case Description: A 60 year old male with history of developmental delay and diabetes was admitted to the Grady Memorial Hospital Burn ICU for a 24% TBSA burn. Hospital course was complicated by peritonitis requiring multiple abdominal washouts, prolonged ventilatory support, atrial fibrillation and acute kidney injury from ATN due to septic shock. On hospital day 53 he began dialysis and required CRRT or intermittent hemodialysis (iHD) throughout the hospitalization to control azotemia. On hospital day 84 iHD was stopped early due to seizure-like activity. Lab tests did not indicate liver disease nor did he have cirrhosis or hepatitis, but the serum ammonia was very elevated at 737 mcmol/L (normal 11-35 mcmol/L). Urgent treatment for acute hyperammonemia was begun with high dose CVVHD (therapy fluid rate 5L/hr), hypothermia protocol, carnitine, 3% saline and holding feeds. On day 88 his thigh was noted to have fluctuance and emergent surgical exploration revealed 700 mL of foul smelling hematoma that grew *Proteus Mirabilis*. His ammonia level decreased rapidly with CVVHD and remained < 100 mcmol/L after incision and drainage.



He died of sepsis complications 2 weeks later.

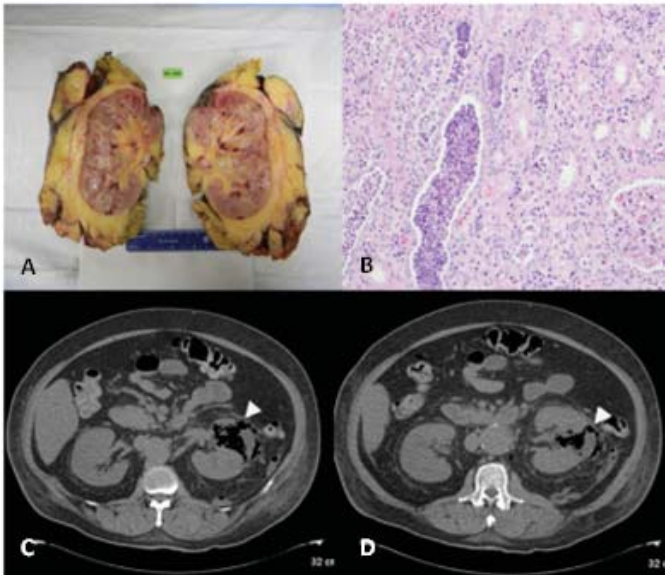
Abscesses containing urea splitting bacteria are a rare cause of systemic hyperammonemia so unexplained hyperammonemia in patients without liver disease should prompt a search for occult fluid collections. Our patient had a very large abscess that produced severe hyperammonemia that was rapidly corrected with high dose CRRT until surgical washout could be performed.

SA-PO627

Renal Emphysema – Indispensable Diagnostic Tools Isha Gupta, Eduardo J. Zouain, Germaine Z. Chan, Steven D. Smith, Ira S. Meisels. *Nephrology, Mt. Sinai St. Luke's Hospital, Icahn School of Medicine at Mt. Sinai, New York, NY.*

Introduction: Renal emphysema, popularly known as emphysematous pyelonephritis, continues to be a highly morbid condition even two centuries after Kelly and MacCullum first described it in 1898. Diabetes, especially when poorly-controlled, is a common risk factor.

Case Description: A 62-year old man presented with altered mental status. He had a history of diabetes type 2, hypertension and gout. He was hypothermic, hypotensive, tachycardic, tachypneic and hypoxemic on room air. He was started on vasopressor support and admitted to intensive care unit. On exam, he had a clouded sensorium, abdominal and left flank tenderness. Initially, blood urea nitrogen was 131 milligram per deciliter (mg/dl), creatinine level was 9.3 mg/dl and white cell count was 12.5 K/microliter. An abdominal and renal ultrasound were unremarkable but the left kidney was poorly visualized. Urine culture and blood cultures grew Escherichia Coli. Non-contrast computed tomographic (CT) scan of the abdomen and pelvis revealed intra-parenchymal air bubbles extending into the nephric space, along with infiltrative changes and small collections within the peri-nephric space diagnostic of class 3A emphysematous pyelonephritis involving the left kidney. He underwent emergent left sided nephrectomy.



A depicts the gross features of the left kidney post nephrectomy, B microscopic findings, C and D (arrowheads) depict the CT scan findings. He required hemodialysis support briefly. Over the next four months, his renal function improved to blood urea nitrogen of 20 mg/dl and creatinine of 1.8 mg/dl.

Discussion: Our case emphasizes the need for early diagnosis of this potentially fulminant disease. CT scan is the preferred imaging method for diagnosing renal emphysema. Once the diagnosis was made via CT scan, our patient underwent life-saving emergent nephrectomy.

SA-PO628

Immunoglobulin G4 Disease in Disguise Thida M. Myint, Michael G. Suranyi, Michael Lin, Ananthakrishnapuram N. Aravindan. *Dept of Renal Medicine, Nuclear Medicine, Liverpool Hospital, Sydney, NSW, Australia.*

Introduction: Immunoglobulin G4 related disease (IgG4 RD) is a rare systemic inflammatory condition of unknown aetiology characterized by lymphoplasmacytic tissue infiltration and fibrosis predominantly by IgG4-positive plasma cells and elevated serum IgG4 level. We report one such case affecting lungs and kidneys mimicking malignancy.

Case Description: A 60-year-old man was admitted for evaluation of unexplained acute kidney injury. He had been experiencing increasing thirst, polyuria, nocturia, leg cramps and 3 kg weight loss in few weeks prior to admission. He had no significant medical history except hypertension for 3 years, which was controlled well. He denied use of any analgesia, antibiotics, herbs or over-the-counter medications. There was no family history of any renal disease. Physical examination was unremarkable. Serum creatinine was 500 mmol/L. Urinalysis did not show active sediment. Chest XR showed right lower zone nodule. Non-contrast CT scan revealed multiple lung lesions, largest in right middle lobe with spiculated margins and pleural tethering suggestive of metastasis. Kidneys appeared normal on CT scan. PET scan showed intensely metabolically active lesions in the lungs, lymph nodes above and below the diaphragm, kidneys, stomach and tail of pancreas. Further investigations had ruled out lymphoma. Renal biopsy showed severe tubulointerstitial nephritis with diffuse inflammatory cells, primarily of plasma cells with positive IgG4 stain (>30/HPF). Core biopsy of the lung showed IgG4 positive plasma cells infiltration with no evidence of neoplasia. Stains for fungi and mycobacteria were negative. Serum ACE level was within range. His plasma IgG4 was high at 15.60 (0.03–2.01 g/L). A final diagnosis of IgG4 RD was made and he was started on steroids (1mg/kg/day). His renal function significantly improved to creatinine of 200 umol/L within 4 weeks. His PET scan 3 months after treatment indicated improvement of lung lesions.

Discussion: IgG4 RD is a rare systemic disease. Differentiation from malignancy changes the direction of management. Early recognition and treatment is essential to prevent extensive irreversible fibrosis. Patients usually have a good response to steroids.

Renal Lymphangiomatosis: An Uncommon Presentation Roopkiranjot K. Kahlon. *Nephrology, Boston Univ, Boston, MA.*

Introduction: Renal lymphangiomatosis is abnormal formation of perirenal,intrarenal and parapelvic lymphatic structures.I present a case of 21 yr old male presented with nausea,vomiting and abdominal pain and found to have enlarged kidneys and renal lymphangiomatosis.

Case Description: 21 yr old male presented with epigastric abdominal pain, nausea and vomiting for 6 days.He had asthma as a child.Family history of ESRD in brother and sister and were on hemodialysis. On examination he was volume depleted and had epigastric tenderness.Lab results showed S.Cr 1.16 mg/dL(baseline unknown),BUN 15 mg/dL,Na 138 mmol/L,K 3 mmol/L,HCO3 23 mmol/L,Ca 9.2 mmol/L,albumin 3.8 gm/dL, 2+ blood and 3-5RBCs in urine and sediment showed few nondysmorphic RBCs.

Ultrasound showed bilateral enlarged kidneys with heterogenous hyperechoic cortex.CT scan showed bilaterally enlarged kidneys R 16cm,L 16.3 cm,with small amount of bilateral fluid at upper poles around collecting system,no hydronephrosis seen. Upon further review with Radiology they were typical images of renal lymphangiomatosis.Patient's symptoms resolved with intravenous hydration.His sister had FSGS(biopsy proven) and cause for his brothers ESRD was unknown.

Discussion: Renal lymphangiomatosis is a rare benign disorder of renal lymphatics and can occur at any age .It occurs due to a failure of renal lymphatic drainage into the retroperitoneal lymphatics, causing dilatation of the ducts and formation of unilocular or multifocal cystic spaces in the perirenal and renal sinuses.May be asymptomatic or present with flank pain, hypertension, proteinuria and hematuria.Differentials include PKD or hydronephrosis. Diagnosis is made by the radiologic appearance.In some case aspiration of the lymphatic fluid can be done which shows chyle rich in lymphocytes.There is no definitive treament but percutaneous drainage and sclerotherapy have proven to be effective. Longterm complications include chronic pyelonephritis and hypertension.

Spontaneous Forniceal Rupture in a Pregnant Female Presenting with Acute Flank Pain Roshni Upputalla, Belinda Bun Jim. *Nephrology, Jacobi Medical Center, Bronx, Ny.*

Introduction: Spontaneous forniceal rupture usually occurs in setting of obstruction. In pregnancy, forniceal rupture is rare and may be due to increased intra-pelvic pressures.
