Methods: Rats were given a single intravenous dose of 75, 100 or 125 mg/kg puromycin aminonucleoside (PAN) (n=8/group) to induce renal injury. Six days after PAN administration the rats received an intravenous dose of the exogenous fluorescent marker FITC sinistrin (4 mg/100g body weight). A miniature (Non-Invasive Clearance (NIC), Mannheim Pharma and Diagnostics, Mannheim, Germany) device that excites FITC sinistrin and detects the emitted light through the skin was mounted on the back of the freely moving rats. Digitalized records of the elimination kinetics of FITC sinistrin was analysed using a NIC computer software (1).

Results: There was a dose-dependent decline in GFR (0.73, 0.52 and 0.34 ml/min/100g body weight) whereas the urine albumin/creatinine ratio increased with the dose of puromycin (3.0, 3.9 and 6.3 mg/mg) compared with normal rats (1.2 ml/min/100g body weight and 0.07 mg/mg respectively).

Conclusions: Transcutaneous GFR measurements resulted in highly reproducible GFR values in line with previously published data using the invasive Cr-EDTA method (2). This new technique is well in accordance with the 3R principle for refinement, replacement and reduction in experimental animal usage and allows serial measurements longitudinally. References 1. Visualization the Calcium Dynamics of Ischemia-Reperfusion Injury in Rat Proximal Tubules by a Genetically Encoded Indicator Protein Rozsa Csohany,[1] Kornélia Szebényi,[2] András Füredi,[2] Orsolya Kolacsek,[2] Agnes Prokai,[1] Katalin Kis-Petik,[3] Attila J. Szabo,[4] Tamás I. Orbán,[2] Ágota Apáti,[2] Balazs Sarkadi.[2,5] *[1]1st Dept of Pediatrics, Semmelweis Univ, Budapest, Hungary; [2]Inst of Enzymology, Research Centre for Natural Sciences, Hungarian Academy of Sciences, Budapest, Hungary; [3]Dept of Biophysics and Radiation Biology, Semmelweis Univ, Budapest, Hungary; [4]MTA-SE, Pediatrics and Nephrology Research Group, Budapest, Hungary; [5]MTA-SE Molecular Biophysics Research Group, and National Blood Center, Budapest, Hungary.*

Background: Cytoplasmic calcium changes in the kidney have a crucial role in determining pathological and pharmacological responses in major renal diseases. The epithelial cells of the proximal tubule (PT) play a key role in renal physiology. Because of their high energy demand these cells are especially sensitive for ischemia-reperfusion injury. We have established a transgenic rat strain stably expressing the GCaMP2 calcium indicator protein in the kidney PT.

Methods: The transposon-based method allowed the generation of homozygous transgenic rats, containing one transgene copy per haploid genome with a defined insertion pattern, and showing no genetic or phenotypic alterations. We performed *in vitro* confocal and *in vivo* two-photon microscopy to examine ischemia-reperfusion injury-induced alterations in PT epithelial cell calcium levels.

Results: The pathologically important renal ischemia caused a rapid and transient increase in PT cellular calcium level, while reperfusion induced again a rapid and significant secondary calcium load, significantly decreased by specific blockers of the angiotensin receptor and the Na-Ca exchanger.

Conclusions: Applying this new animal model with the combination of new imaging approach opens new possibilities for physiological and pharmacological investigations; particularly we provide valuable information about the changes in PT cellular calcium levels in ischemia-reperfusion disease model. FR-PO093

Long-Term Risk of Chronic Kidney Disease and Mortality in Children after Acute Kidney Injury: A Systematic Review Jason Henry Greenberg,[1,3] Steven G. Coca,[2,3,4] Chirag R. Parikh.[2,3,4] *[1]Dept of Pediatrics, Section of Nephrology, Yale Univ School of Medicine, New Haven, CT; [2]Dept of Internal Medicine, Section of Nephrology, Yale Univ School of Medicine, New Haven, CT; [3]Program of Applied Translational Research, Yale Univ School of Medicine, New Haven, CT; [4]Dept of Internal Medicine, Section of Nephrology, VA Medical Center, West Haven, CT.*

Background: Acute kidney injury (AKI) is associated with significant short-term morbidity and mortality in children. However, the risk for long-term outcomes after AKI is largely unknown.

Methods: We performed a systematic review and meta-analysis to determine the cumulative risk of proteinuria, hypertension, decline in glomerular filtration rate (GFR), and mortality after an episode of AKI. After screening 1934 published articles from 1985-2013, we included 10 cohort studies that reported long-term outcomes after AKI in children.

Results: A total of 346 patients were included in these studies with a mean follow-up of 6.5 years (range 2-16) after AKI.The studies were of variable quality and had differing definitions of AKI with five studies only including patients who required dialysis during the AKI episode.There was a substantial discrepancy in the outcomes of the primary studies due to study size and methodological differences. In addition, there was no non-AKI comparator group in any of the published studies. The cumulative rates for proteinuria, hypertension, abnormal GFR (< 90 ml/min/1.73m^2), GFR<60 ml/min/1.73m^2, end stage renal disease, and mortality per 100 patient-years were 2.9 (95% CI 1.2-4.6), 1.4 (0.2-2.7), 6.2 (3.1-9.3), 0.8 (0 -1.6), 0.9 (0.4-1.4), and 3.5 (1.7-5.3) respectively. The mortality rate after AKI appears to be higher when compared with population mortality rates in children and the long term follow-up of other hospitalized cohorts.

Conclusions: AKI appears to be associated with a higher risk of long-term renal outcomes in children. Future prospective studies with appropriate non-AKI comparator groups will be required to confirm these results.

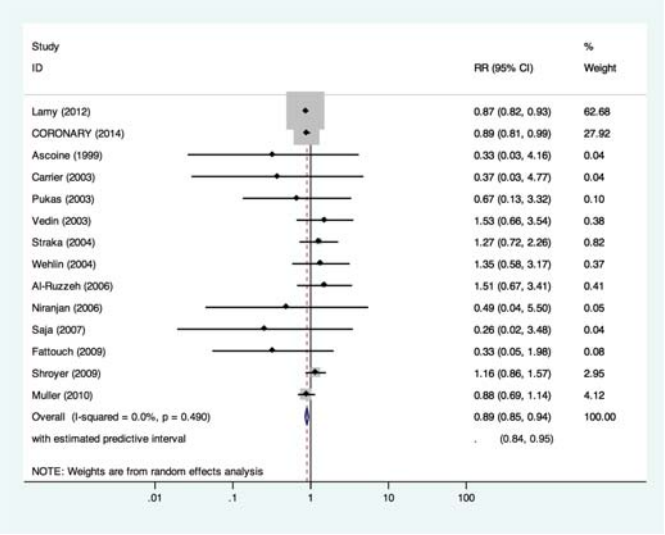
Off-Pump or On-Pump Coronary Artery Bypass Sugery for Better Kidney Risk Profile - A Systematic Review and Meta-Analysis

Taomin Huang,[1,2,3] Vincent Wu,[3] Guang-Huar Young.[3] *[1]Internal Medicine and Critical Care Center, National Taiwan Univ Hospital Yun-Lin Branch, Dou-Liu, Taiwan; [2]Institue of Epidemiology and Preventive Medicine, National Taiwan Univ, Taipei, Taiwan; [3]National Taiwan Univ Hospital and College of Medicine, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: Coronary artery bypass and grafting (CABG) surgery is a prevalent technique for coronary disease. Acute kidney injury (AKI) is a complication post CABG and leads to worse outcomes. Cardiopulmonary bypass (CPB) may protect the mocardium from injury, but may also exposes the patients in risk for AKI. The roles of CPB on renal outcomes are not determined. The aim of current study is to determine the role of off-pump technique on incident AKI from available literature.

Methods: The primary end-point was defined with serum creatinine-based definition for AKI. A systematic review and meta-analysis was carried out with random effect models, for presumed heterogeneity among studies. Only RCTs addressing the issue were included. We excluded studies done in pediatric patients (Age<18 years old). Studies with no events in both arms will be excluded. The heterogeneity among studies was assessed using tau-square, which will be judged high, moderate, or low, if >50%, 25%-50%, or <25%. A P-value less than 0.05 will be judged statistically significant.

Results: A total of 14 RCTs were left in final analyses, which was composed of 15,982 patients. AKI developed in 2051 (12.8%) of all patients. The tau-square was 0%. The summarized risk ratio of off-pump versus on-pump technique for incident acute kidney injury was 0.89 (95%CI=0.85-0.94). We detected no publication bias based on Egger's test (p = 0.235).



Conclusions: We demonstrated that Off-pump technique provide better kidney risk profiles than on-pump technique. The conclusion is robust based on low heterogeneiety detected.

FR-PO095

Relation of Radiographic Contrast to In-Hospital Acute Kidney Injury

Harlan Sparrow,[1] Nelda P. Wray,[1,2,3] Carol M. Ashton,[1,2,3] David Putney,[1] Linda W. Moore,[1,2] Wadi N. Suki,[1,3,4] A. Osama Gaber.[1,2,3] *[1]Houston Methodist Hospital; [2]Houston Methodist Research Inst; [3]Weill Cornell Medical College; [4]Baylor College of Medicine.*

Background: Administration of radiographic contrast (CON) is believed to increase Acute Kidney Injury (AKI) in hospitalized patients. However, most studies have neglected to include a control group when assessing CON-related AKI (CR-AKI).

Methods: In-hospital AKI was defined as an increase in serum creatinine (SCr) by >=0.3 mg/dL or >=50% or a decrease in estimated Glomerular Filtration Rate by >=25% over any 72h interval during the hospitalization. CRAKI was similarly defined based on comparing SCr baseline values to SCr changes within 72h post CON. The first hospitalization of patients admitted in 2012 to a tertiary academic medical center were included. Patients <18 years, those with preexisting AKI, stage 5 CKD, dialysis on admission, a maximum serum creatinine (SCr) <=0.4 mg/dL or AKI prior to CON were excluded as were, patients lacking SCr values for the ascertainment of AKI or CRAKI. Doses administered within 60min or less of each other were considered a single-dose.

Results: Demographic and hospital data of 13,406 unique patients included in the study were as follows: AKI 17%, 31% had one or more ICU days, 52% were female, and 64% were Caucasian. Patients with AKI were older (66 versus 61 yrs p<0.001) and more likely black (19% p=0.008). Approximately 30% of patients received CON of some type.

CON Exposure	% Total Population	% CR-AKI	% AKI any time post-CON
No CON	70		17
Oral Iodinated	0.01	4	6
IV Gadolinium	5	6	10
IV Iodinated Multi-Dose Same Day	0.01	7	14
IV Iodinated – Single Dose	21	7	15
IV Iodinated Multi-Dose Different Day	4	16	29

The great majority of AKI occurred more than 72 hours after CON administration. Further, the overall incidence of AKI after CON was lower than the AKI rate in patients who did not receive CON except for patients receiving multi-dose different day CON. All p values<0.001.

Conclusions: This retrospective analysis of nearly 14,000 patients provides no evidence that the use of radiographic CON in a single procedure increases the incidence of AKI compared to non-CON patients. However, multi-dose CON is associated with more AKI.

FR-PO096

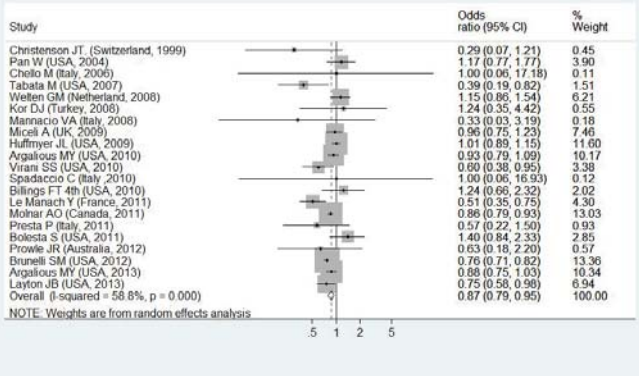
The Effect of Preoperative Statin Therapy on Postoperative Acute Kidney Injury in Patients Undergoing Major Surgery: Systemic Review and Meta-Analysis

Szu Yu Pan,[1] Taomin Huang,[1] Vincent Wu.[2] *[1]National Taiwan Univ Hospital, Yun-Lin branch; [2]National Taiwan Univ Hospital.*

Background: The effect of preoperative statin therapy on postoperative acute kidney injury (AKI) is contraversial. We performed a systemic review and meta-analysis to exam the association.

Methods: MEDLINE and EMBASE, from inception to April 2013, and the reference lists of relevant articles were searched. Trials comparing preoperative statin therapy with no preoperative statin in patients undergoing major surgery were included. Outcome measures of interest were the risk of cumulative postoperative AKI and postoperative AKI requiring renal replacement therapy (RRT). No language restrictions were applied. Authorship, country, year of publication, study population, study exposure, study outcome, crude and adjusted effect size, and confidence interval (CI) were extracted. Fixed or random effect meta-analysis was performed to derive summary effect estimates.

Results: In 5 randomized studies and 19 observational studies, comprising a total of 983,173 patients undergoing major surgery, 112,840 patients (11.4%) received preoperative statin therapy. Preoperative statin therapy was associated with a significant risk reduction for cumulative postoperative AKI (weighted summary odds ratio 0.87, 95% CI 0.79-0.95). (Figure 1) The effect of risk reduction was also significant when considering postoperative AKI requiring RRT (odds ratio 0.80, 95% CI 0.72-0.90). Various sources of heterogeneity existed among included studies. The types of surgery varied in each study. The specific type, dosage, and duration of statin therapy were not available in most studies. The definition of AKI was not uniform. The definition of AKI requiring RRT was based on clinical grounds.



Conclusions: In patients undergoing major surgery, preoperative statin therapy may be associated with a reduced risk for postoperative AKI.

FR-PO097

Iatrogenic Hospital Acute Kidney Injury: Results of the Implementation of a Prevention Protocol Anna Saurina,[1] Monica Pou,[1] Miquel Fulquet,[1] Ramon Roca-Tey,[2] Vicents Esteve,[1] Veronica Duarte,[1] Manel Ramírez de Arellano.[1] *[1]Nephrology, Consorci Sanitari de Terrassa, Terrassa, Barcelona, Spain; [2]Nephrology, Hospital de Mollet, Mollet del Vallés, Barcelona, Spain.*

Background: Analysis of Iatrogenic Hospital Acute Kidney Injury (HAKI) in a Hospital 162000 referred people. Elaboration and implementation of Prevention Protocol for HAKI.

Methods: Prospective single centre study in two phases. Definition HAKI: Acute increase of plasmatic creatinine up to 2 mg/dL in hospitalized patients with previous normal creatinine value, or its increase of more than 50% from baseline in patients with CKD-I-II-III. Patients with CKD IV or V, paediatric, ICU or palliative patients were excluded. First: identification and analysis of the HAKI during a 1st period of 9 months. Inclusion criteria for HAKI were detected automatically by the laboratory tests. Once detected, the clinic histories were revised by 2 physicians, collected a database and analysed the results. A Prevention Preventive Protocol of HAKI were developed, with participation of medical staff and nursing, laboratory and pharmacy. Second: new study of HAKI after the implementation of the Protocol for a 2nd period of 9 months.

Results: 394 HAKI episodes detected (167/227).Average age:75, 61.4% males, 36.3% diabetic and 75.4% with previous history of hypertension. Hemodynamic instability in 65.5% and infection in 36.3%. A 29.3% had a previous episode of HAKI. Prerrenal aetiology in 93% and 3.3% required dialysis. No differences between phases in terms of age, sex, grade of CKD, aetiology of HAKI and dialysis. After the implementation of the Protocol: reduction in the time of detection of HAKI: 4.95 versus 3.92 days (p=ns), Length of Stay 18.18 versus 13.74 days (p=0.087) and significantly decrease in its duration (8.99 versus 5.83, p=0.0000001). We detected a better monitoring on the collection of diuresis (74.4 versus 83.3% %, p = 0.012) and a decrease of iatrogenic HAKI (52.1% versus 37%, p= 0.0002) mainly due to a better correction of the hemodynamic instability (68.9 versus80.2%, p=ns).

Conclusions: The elaboration of a multidisciplinary prevention protocol for HAKI and its wide application, has allowed a significant reduction of the iatrogenic HAKI and all its consequences.

FR-PO098

Marked Improvent in Outcome of Acute Kidney Injury over the Past 20 Years Þórir E. Long,[1] Martin I. Sigurdsson,[2,3] Gisli H. Sigurdsson,[1,2] Olafur S. Indridason.[4] *[1]Faculty of Medicine, Univ of Iceland, Reykjavik, Iceland; [2]Dept of Anesthesia, Perioperative and Pain Medicine, Brigam and Women´s Hospital / Harward Medical School, Boston, MA; [3]Dept of Anesthesia and Intensive Care; [4]Div of Nephrology, Lanspitali - The National Univ of Iceland, Reykjavik, Iceland.*

Background: Acute kidney injury (AKI) is a serious condition associated with poor prognosis but it is unclear whether advances in medical management have resulted in improved outcome. The purpose of this study was to examine time trends in outcome of AKI with regard to kidney function and patient survival.

Methods: This was retrospective study that included all adult patients with AKI at Landspitali – The National University Hospital of Iceland from June 1st 1993 to May 31st 2013. AKI was diagnosed based on serum creatinine (SCr) values found in the electronic database of the clinical laboratory. The highest SCr value for each person was identified and a baseline value within the 6 preceding months used to categorize patients into stage 1, 2 and 3 of AKI based on the RIFLE criteria. Renal recovery was defined as the average of the last three available SCr measurements <1.5 x baseline SCr. Survival status was verified at Statistics Iceland. The 20 years time interval was divided into 4 equal periods and the periods compared with regard to outcomes of interest using Chi-squared, Kaplan-Meier and Cox proportional hazards analyses.

Results: In the 20 years period we identified 14,841 patients with AKI. Of those 7,524 (51%), 3,684 (25%) and 3,633 (24%) had stage 1, 2 and 3 AKI, respectively. The mean age was 69.1±16.9 years and 51% were female. The 90 day mortality was 40.3% in the first 5 year period, 39.7% in the second, 31.7% in the third and 25.9% in the last five year period (p<0.0001). Cox analysis showed a hazard ratio of 0.75 (95% CI:0.74-0.76) per 5 years. Improvements were seen for all stages of AKI. A total of 69%, 67%, 72% and 72% of patients achieved renal recovery in time periods one, two, three and four, respectively (p<0.0001).

Conclusions: Over the past two decades there have been significant improvements in survival and renal outcome for patients with AKI, probably as a result of improved medical care.

Funding: Government Support - Non-U.S.

FR-PO099

Acute Kidney Injury and Its Impact on Clinical Outcomes in Octogenarians following Cardiac Valve Replacement Surgery Michael A. Mao, Charat Thongprayoon, Qi Qian. *Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: The goal of this study is to investigate the occurrence, severity and outcomes of acute kidney injury (AKI) in octogenarians following cardiac valve replacement surgery.

Methods: Consecutive patients, age ≥80 years, undergoing cardiac valve replacement surgery at Mayo Clinic Rochester in 2002-2003 were enrolled. Dialysis patients were excluded. AKI was diagnosed based on AKIN criteria (abrupt s.Cr increase ≥0.3 mg/dL). AKI severity was determined using the RIFLE criteria.

Results: 209 consecutive patients undergoing valve replacement surgery with (58.4%) and without CABG were studied. Mean follow-up duration was 3.94±0.28 years (range: seven days, 12 years). 180 (85.7%) of the 209 patients underwent aortic valve replacement (AVR), 6.19% MVR, 0.9% TVR and 8.1% multivalve replacement. 34 (16.3%) had baseline CKD (s.Cr 1.7±0.04 mg/dL). Post-surgery, 98 of the 209 (47%) developed AKI. 79.8% (n=75) of the AKI was in stage R (risk), 9.3% in stage I (injury) and 14.4% in stage F (failure). 79.4% CKD patients developed AKI (ACKI). Of ACKI, 63% were in R and 25.9% in F. 14 of the 98 AKI patients required dialysis. 20% of them were ACKI versus 3.4% AKI without CKD, p<0.001. Length of hospital stay (LOS) was longer for AKI/ACKI patients, 14.4 versus 9.9 days in non-AKI, p=0.002. At hospital discharge, patients with AKI/ACKI had a higher sCr 1.42±0.49 mg/dL, compared to the non-AKI patients, 1.09±0.25 mg/dL, p<0.001. Patient survival at 30 days and 1 year for AKI/ACKI versus non-AKI were 89.8 versus 99.1% (p=0.003) and 76.5 versus 89.3% (p=0.03), respectively. Long-term survival also was reduced for AKI/ACKI patients by Kaplan-Meier analysis, p<0.001. Elevated Charlson Comorbidity Index was a risk factor for AKI, OR 1.19, 95% CI 1.02-1.40, p=0.03. Other adjusted AKI risk factors include CKD and surgical duration (ORs >1.0, CI >1-49, p<0.05).

Conclusions: Almost half of the octogenarians developed AKI following cardiac valve replacement surgery. AKI is associated with a worsening residual kidney function, longer LOS and reduced short-term and long-term patient survival. Comorbidity, preoperative CKD and surgery duration are independent risk factors for post-surgery AKI.

FR-PO100

Diabetes Mellitus Type 1 and Type 2 and Risk of Acute Kidney Injury following Coronary Artery Bypass Grafting Daniel P. Olsson,[1] Ulrik Sartipy,[3,4] Martin Holzmann.[1,2] *[1]Dept of Medicine, Karolinska Instt, Stockholm, Sweden; [2]Dept of Emergency Medicine, Karolinska Univ Hospital, Stockholm, Sweden; [3]Dept of Cardiothoracic Surgery and Anesthesiology, Karolinska Univ Hospital, Stockholm, Sweden; [4]Dept of Molecular Medicine and Surgery, Karolinska Instt, Stockholm, Sweden.*

Background: The objective was to investigate the risk for acute kidney injury (AKI) in patients with diabetes mellitus type 1 (DM1) and type 2 (DM2) undergoing coronary artery bypass grafting (CABG).

Methods: We included all patients (n=34 784) who underwent primary isolated CABG in Sweden during 2003 to 2013 from the Swedish national heart surgery register SWEDEHEART. Type of diabetes was retrieved from the Swedish National Diabetes Register. Acute kidney injury was defined according to the Acute Kidney Injury Network (AKIN) classification as an increase in postoperative compared to preoperative serum creatinine values: Stage 1, absolute increase by 0.3 mg/dL (26 mmol/L) or a relative increase by 50% to 100%; stage 2, 100% to 200% increase; and stage 3, ≥ 200% increase. The relative risk of AKI according to DM1 and DM2 compared to no diabetes diagnosis was calculated using logistic regression. Multivariable adjusted odds ratios with 95% confidence intervals (CI) were reported.

Results: In total 1.7% (n=605) of the study population had DM1 and 21% (n=7275) had DM2. Among patients with DM1 26%, 4.6% and 1.0% developed AKI stage 1, 2 and 3 respectively. Among patients with DM2 15%, 2.2% and 0.5% developed AKI stage 1, 2 and 3 respectively. In patients with DM1 the odds ratio for AKI stage 1 or higher was 4.38 (95% CI: 3.58-5.35) compared to patients with no diabetes diagnosis. In patients with DM2 the odds ratio for AKI stage 1 or higher was 1.32 (95% CI: 1.22-1.42) compared to patients with no diabetes diagnosis. The analysis was adjusted for age, sex, preoperative estimated glomerular filtration rate, left ventricular ejection fraction, chronic obstructive pulmonary disease, peripheral vascular disease and body mass index.

Conclusions: We found a strong and significant association between diabetes and AKI after CABG. The risk for AKI was markedly higher in patients with DM1.

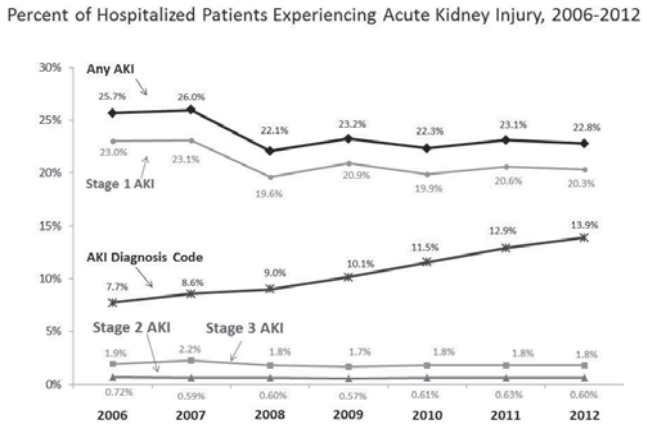
FR-PO101

Trends in Acute Kidney Injury Hospitalizations among U.S. Veterans: A Comparison between Clinical and Administrative Data Michael Heung,[1] Diane Steffick,[1] Chi-Yuan Hsu,[2] Neil R. Powe,[2] Nilka Rios Burrows,[3] Meda E. Pavkov,[3] Vahakn B. Shahinian,[1] Kara Zivin.[1] *[1]Univ of Michigan, Ann Arbor; [2]Univ of California San Francisco; [3]Centers for Disease Control & Prevention, Atlanta, GA.*

Background: Recent studies have suggested rising incidence of severe acute kidney injury (AKI). Most epidemiologic studies have relied on administrative data, while consensus AKI definitions emphasize use of clinical data. We examined recent trends in AKI hospitalizations using both administrative and clinical data.

Methods: Using national Veterans Administration data (5% sample:2006-2009; 100%:2010-2012), we identified patients with 1+ hospitalization. Patients with outpatient dialysis were excluded. The primary outcome was the proportion of hospitalized patients with an episode of AKI each year. We used a modified Poisson model to examine the effect of year on the likelihood of having AKI, adjusting for age, gender, ethnicity, diabetes and hypertension. Analyses were conducted separately for creatinine-defined (sCR) AKI and diagnosis code AKI.

Results: Over 360,000 patients were hospitalized in the VA annually. 23.6% of hospitalized patients met sCR criteria for AKI, decreasing from 25.7% in 2006 to 22.8% in 2012 (p<0.001). In the adjusted model, each increase in year was associated with a modest decreased risk for AKI (RR 0.99, 95% CI 0.99-1.00). Over the same period, the proportion of patients with a diagnosis code for AKI rose from 7.7% to 13.9% (p<0.001). After adjustment, each increase in year conferred a 10% increased risk for diagnosed AKI compared (RR 1.10, 95% CI 1.10-1.11).



Conclusions: Between 2006 and 2012, in the U.S. veteran population, diagnosed AKI rose markedly while the fraction of hospitalized patients with sCR-defined AKI decreased slightly. These findings highlight an important difference between clinical and administrative data for epidemiologic studies of AKI.

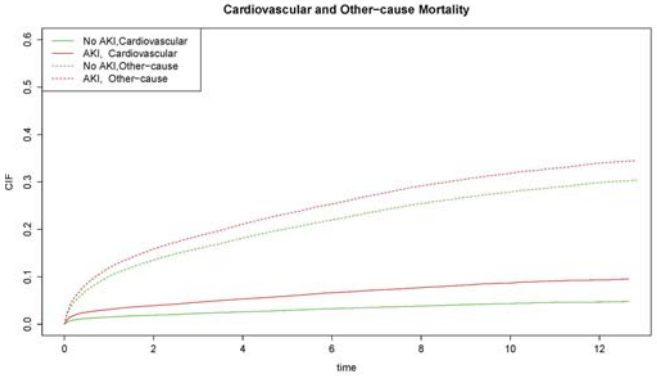
FR-PO102

Effect of Acute Kidney Disease on Competing Risks for Survival After Major Surgery Azra Bihorac,[1] Tezcan Ozrazgat-Baslanti,[1] Paul Thottakkara,[1] Wan Xu,[1] Shuo Zhang,[1] Matthew P. Huber,[1] Charles E. Hobson.[2] *[1]Anesthesiology, Univ of Florida, Gainesville, FL; [2]Surgery, Malcom Randall VA Medical Center, Gainesville, FL.*

Background: Acute kidney injury (AKI) affects up to 40% of surgical patients and is associated with increase in all-cause mortality. We determined the effect of acute and chronic kidney disease, age and comorbidity on cardiovascular–specific mortality in patients undergoing major surgery.

Methods: We performed survival analyses that accounted for competing risks in a single-center cohort of 51,457 adult surgical patients. We defined AKI using KDIGO (Kidney Disease: Improving Global Outcomes) criteria. We determined the presence of chronic kidney disease (CKD) prior to surgery and adjusted all analyses for age, comorbid conditions and type of surgery using multivariable subdistributional hazards model.

Results: Ten-year cumulative cardiovascular-specific mortality rates were significantly higher for AKI (10.2%), CKD with no AKI (10.3%), and ESRD (10.2%) patients compared to patients with no kidney disease (2.7%) whereas no significant difference was observed for cumulative cancer-specific mortality. Adjusted HR of cardiovascular-specific mortality for patients with AKI, CKD and ESRD were 2.1 (95% CI, 1.9-2.3), 1.8 (95% CI, 1.5- 2.2), and 3.2 (95% CI, 2.7-3.8), respectively, compared with those that had none. Hazards of cardiovascular-specific mortality were highest for patients with older age (HR 1.04, 95% CI 1.04-1.05), male gender (HR 1.2, 95% CI 1.1-1.3), Charlson comorbidity index score of at least 3 (HR 2.1, 95% CI 1.9-2.4), emergent surgery (HR 1.5, 95% CI 1.4-1.7), cardiothoracic surgery (HR 3.1, 95% CI 2.8-3.4) and hemoglobin of 8 to 10 (HR 1.3, 95% CI 1.1-1.5) compared to those with level ≥12.



Conclusions: Patients with acute kidney injury after major surgery are at high risk for cardiovascular-specific mortality within 10 years of diagnosis.

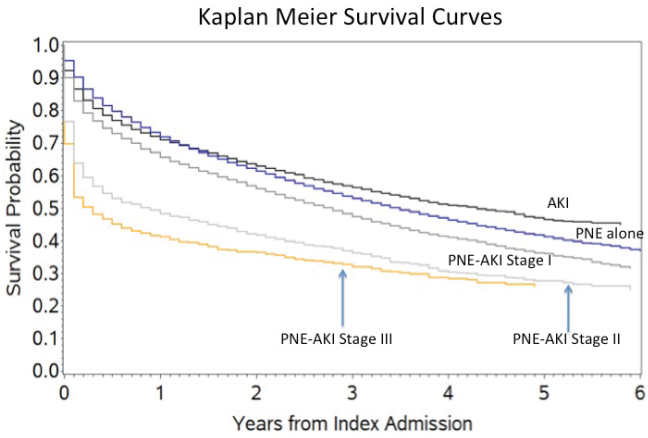
FR-PO103

Impact of Acute Kidney Injury on Patients Admitted to the Hospital with Pneumonia Ping Li,[1] Richard Amdur,[1] Carlos E. Palant,[1] Charles Faselis,[1] Paul L. Kimmel,[2] Lakhmir S. Chawla.[1] *[1]Medical and Research Service, DC VAMC, Washington, DC; [2]NIDDK, NIH, Bethesda, MD.*

Background: Acute Kidney Injury (AKI) is associated with major adverse kidney events-MAKE (death, dialysis, and durable loss of renal function[CKD]). CKD is associated with an increased risk of major adverse cardio-vascular events-MACE (MI, CVA, and CHF). We sought to determine incidence and impact of AKI on major adverse reno-cardiovascular events or MARCE (a combination of MACE and MAKE).

Methods: Patients in VA database with discharge diagnosis of ICD-9 code 584.xx (AKI), or 486.xx (PNE) were selected for analysis. Three groups were created, based on the index admission diagnosis and serum creatinine (SC) values: 1) AKI; 2) Pneumonia (PNE); 3) PNE with AKI. Patients with mean baseline estimated glomerular filtration rate (eGFR) < 45 ml/min per 1.73 m^2 were excluded.

Results: 55,088 subjects were analyzed. Mean age: 68.1 ± 12.0 yrs. Median follow-up:1.3 years following index admission (IQR = 0.4 to 2.9). At 5 years, death occurred most often for patients in the PNE+AKI group (64%), and least often (53%) for those with AKI admission. When AKI complicated an admission for PNE, mortality was increased OR 1.38 (1.34-1.42, p < 0.0001) in a Cox hazards model adjusted for age, baseline eGFR, gender, race, DM, and HTN. The severity of AKI was also linked to outcomes in a stepwise fashion. Patients with PNE and AKI-Stage III had worst outcomes as compared to patients with PNE-AKI-II, PNE-AKI-I, and AKI alone (mortality: 72.3%, 69.8%, 60.9%, and 49.4% [p < 0.0001], respectively



Conclusions: Hospital admission for AKI is associated with long-term outcomes comparable to hospital admission for PNE. When AKI accompanies PNE, outcomes are worse than either diagnosis alone for death, MACE, MAKE, and MARCE. The impact of AKI on PNE follows a stepwise worsening corresponding to the severity of the kidney injury.

FR-PO104

Acute Kidney Injury and Acute Myocardial Infarction: Partial Recovery of Kidney Function Is Associated with Improved Inpatient Mortality David G. Warnock,[1] T. Clark Powell,[1] John P. Donnelly,[1] Peter A. McCullough,[2] Henry E. Wang.[1] *[1]School of Medicine, Univ of Alabama at Birmingham, Birmingham, AL; [2]Baylor Heart and Vascular Inst, Dallas, TX.*

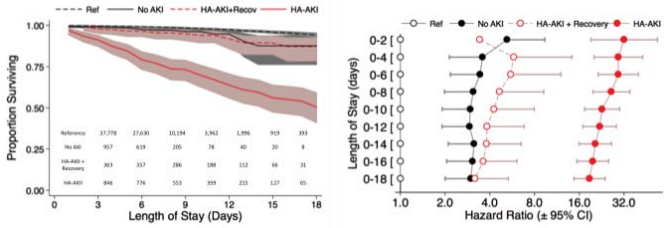
Background: Hospital-Acquired Acute Kidney Injury (HA-AKI; increase in serum creatinine (sCr) ≥0.3 mg/d), and acute ST-segment elevation myocardial infarction (STEMI) are associated with increased mortality (Newsome et al Arch Int Med 2008). We assessed mortality among patients with HA-AKI, STEMI, and partial recovery of sCr.

Methods: Hospital discharge, sCr and mortality data over 4 years (2010-2013) at UAB Hospital were analyzed for adults with >2 sCr values and no prior ESRD history, and length of stay (LOS) >1 and <22 days. STEMI events were coded with ICD9 410.*. Regression models were adjusted for demographics and baseline eGFR, with HA-AKI, STEMI and AKI_recovery (decreased sCr ≥0.3 mg/dL from peak sCr) as the effect variables.

Results: For 69,826 qualifying admissions; median LOS 4 days; mean age 56 years; 52% male, 36% black; baseline eGFRcreat, 77 ml/min/1.73 m^2. The time-averaged hazard ratio (HR; ±95% CI for inpatient mortality) was reduced from 3.43 for HA-AKI+STEMI to 1.0 with partial recovery of sCr, equal to cases with No AKI – STEMI (HR 1.00).

	No AKI		HA_AKI			
	–STEMI	+STEMI	–STEMI–Rec	–STEMI+Rec	+STEMI–Rec	+STEMI+Rec
Cases	37,379	980	6,544	6,326	414	420
Deaths (5)	358 (1%)	36 (3.7)	711 (11%)	388 (6.1%)	122 (30%)	67 (16%)
HR (±95% CI)	1.00 (Reference)	3.66 (2.60–5.17)	5.18 (4.55–5.91)	1.60 (1.38–1.87)	3.43 (2.34–5.04)	1.00 (0.65–1.54)

More striking were effects seen with shorter LOS.



Conclusions: HA-AKI and STEMI independently associate with inpatient mortality. Partial recovery of sCr is associated with decreased mortality among those with HA-AKI, and HA-AKI with STEMI. This finding could improve risk prediction for future intervention studies.

FR-PO105

Long Term Evolution from Acute Kidney Injury: A Prospective Study in Critical Ill Patients Carmen Bernis,[1] Laura Salanova,[1] Marta Chicot,[2] Diego Anibal Rodriguez-Serrano,[2] Ana Diaz,[3] Enrique Cereijo,[2] Jose-Antonio Sanchez-Tomero.[1] *[1]Nephrology, H.U Princesa CIFRA -CM, Madrid, Spain; [2]ICU, HU Princesa, Madrid, Spain; [3]Biochemistry, HU Princesa, Madrid, Spain.*

Background: In the past years there has been a great interest regarding the impact of an AKI episode on development of incident CKD and the value of markers of tubular injury as NGAL to predict long term outcomes. We study these questions in a group of ICU survivors.

Methods: A Prospective study of 415 patients admitted to a general ICU was initiated 2011. Patients (APACHE, SAPS, RRT, urinary NGAL, AKI defined by AKIN) were follow up until their discharge and a group of 108 survivors during 24 months. AKI developed in 99/415 patients and 29 died. No AKI patients were 316 and 25 died during hospitalization. We were able to follow up 54 AKI patients discharged alive (all of them in the geographical area of our hospital) and a control group of 54 no AKI survivors (similar charasteristics, age, sex).

Results: In 34/54 AKI patients renal function at 24 months was clearly worse (cr increment from discharge 1.1±1.8) versus only in a small increment in 14 /54 controls (cr increment 0,29± 0,15) p<0,001. CRD stage 5 needing dialysis was required in 7 AKI patients during follow up and in none controls. The no AKI group has a homogenous cr evolution with stable or small increase being the medium cr increment 0, 21± 0, 48. In the AKI group there were two patterns, (although the discharge creatinine was similar) one subgroup (34) get clearly worse and other subgroup (20) get better with a 24 months creatinine decrement of 0,61 ± 0,07. NGAL was higher in AKI group (772 +200 versus 84+ 42 controls p<0, 0001) but NGAL in AKI with good evolution was 809± 226 versus 525± 301 in AKI with bad evolution (pns). Mortality was 12/54 in AKI group versus 9/54 in controls (p.n.s).

Conclusions: In our prospective control trail of critical ill patients, AKI patients are clearly more likely to suffer accelerated loss of kidney function than controls. It is remarkable that AKI patients have two evolution patterns: 61% to worse and 29% to improvement. In our experience NGAL levels during AKI hospitalization cannot predict in the future progressive chronic kidney disease.

Chronic Kidney Disease and Mortality in Long-Term Survivors of an Episode of Acute Renal Injury Carlos Enrique Arias, Eva Rodriguez, Adriana Sierra, Sheila Bermejo, Alejandra Prada, Carla Burballa, Ali Berrada, Julio Pascual. *Nephrology, Hospital del Mar, Barcelona, Spain.*

Background: Several population studies have shown an association between acute kidney injury (AKI) and subsequent development of chronic kidney disease (CKD). However, there are few studies in our population that analyze this association. OBJECTIVES: The aim of this study is to evaluate the impact of AKI episode in the subsequent development of CKD, mortality and morbidity in the midterm follow-up (12 months) and long term follow-up (24 months).

Methods: Retrospective study of patients diagnosed with AKI (ICD- 9) as ADQI criteria definition, with full renal recovery at discharge. We included demographic, clinical and laboratory data at 12 months and 4 years follow-up.

Results: 498 patients were included, 61.8 % men, mean age 66.2 ± 19 years. At discharge, 386 patients (78.6 %) recovered renal function. Follow-up at 12 months showed that 122 (22.1 %) patients developed CKD and after 4 years follow-up, CKD was diagnosed in 106 patients (40.8%). Multivariate analysis showed that history of hypertension (OR: 1.62, 95% CI 1.2-2.6, p < 0.05) and serum creatinine > 2.6 mg / dl during the AKI episode (OR: 1.7, 95% CI 1.2-3.7, p < 0.05) are risk factors for CKD at 12 months, while at 4 years, the risk of CKD is associated with age (p < 0.05), hypertension (p < 0.05) and peripheral vascular disease (p < 0.05). Mortality was higher in patients who developed CKD at 12 months n = 38) (OR: 2.68 95% CI 1.26 -5.7, p < 0.05) and 4 years (n = 106) (OR: 4.13 95% CI 1.13 to 4.90, p < 0.05). Multivariate analysis showed that associated factors with mortality at 12 months were age and creat > 2.6 mg / dl; while 4 years mortality was significantly associated with male sex, age, ischemic heart disease, peripheral vascular disease and variables related to the severity of the episode of AKI (creatinine > 2.6 mg / dl, dialysis treatment and Failure and Loss RIFLE-staging).

Conclusions: Our data showed, that development of CKD after an AKI episode, is related, in the medium term, with severity of the AKI while in the long term is related with classical cardiovascular disease risk factors.

FR-PO107

Relationship between Recurrences of Acute Kidney Injury and Development of Chronic Kidney Disease, Cardiovascular Events and Mortality Carlos Enrique Arias, Eva Rodriguez, Sheila Bermejo, Adriana Sierra, Alejandra Prada, Carla Burballa, Ali Berrada, Julio Pascual. *Nephrology, Hospital del Mar, Barcelona, Spain.*

Background: Observational studies have shown that acute kidney injury (AKI) can be considered as a risk factor for later development of chronic kidney disease (CKD). However, there are few studies that evaluate the effect of AKI recurrences and the development of CKD, mortality or cardiovascular events. OBJECTIVE The aim of this study is to evaluate if the presence of various episodes of AKI, are related to the subsequent development of CKD and mortality and morbidity in these patients.

Methods: A retrospective study in 498 patients was conducted with a diagnosis of AKI (ICD-9) with full recovery of renal function. We reviewed medical records and we recorded the presence or abscense or new episodes of AKI, cardiovascular events and mortality. We also recorded clinical and laboratory variables.

Results: From an initial sample of 498 patients we had follow-up data at 4 years of 241, of these 147 (61 %) had ≥ 1 episode of AKI during follow-up Multivariate analysis showed that risk factors for new episodes of AKI were: previous type 2 diabetes mellitus (OR: 2.89 95% CI 1.33 to 1.67 p < 0.05), previous ischemic heart disease (OR: 2.62 95% CI 1.07 to 6.45 p < 0.05) and age > 67 years (OR: 1.02 95% CI 1.04 to 1.01 p < 0.05). Patients with ≥ 1 AKI episodes showed a higher risk of 4 years follow-up CKD (OR 2.43, 95% CI 1.16 to 5 p < 0.05), increased frequency of cardiovascular events (OR 4.25, 95% CI 2.05 to 8.81 p < 0.05) and higher mortality from all-cause (OR 3.12 95% CI 1.31 to 7.6 p < 0.05 comparing with 1 AKI episode survivors patients.

Conclusions: Previous hypertension, type 2 diabetes mellitus and ischemic heart disease are risk factors for AKI recurrence after an episode of AKI, also the fact for recurrence confers an increases the risk of developing CKD, cardiovascular events and higher mortality from all causes at 4 years.

FR-PO108

Acute Kidney Injury following Elective Total Joint Arthroplasty Rowan G. Walker,[1,2] Lara A. Kimmel,[1,2] Jyotsna Dinesh Janardan,[1] Susan Liew.[1,2] *[1]Alfred Hospital, Victoria, Australia; [2]Monash Univ, Victoria, Australia.*

Background: Total joint arthroplasty (TJA) is a frequently performed procedure shown to improve function and quality of life in patients with osteoarthritis. Incidence of acute kidney injury following TJA is generally low, with most studies reporting an incidence <2%, in the elective population, increasing to 9% when emergency orthopedic cases are included.

Methods: Retrospective medical record review of consecutive primary, elective TJA procedures was undertaken at a large tertiary hospital in Melbourne, Australia. Demographic, peri- operative and post-operative data were recorded. Multiple logistic regression was used to determine factors (clinical, biochemical and drug related) associated with AKI (RIFLE criteria).

Results: Of 429 patients undergoing TJA between January 2011 and June 2013; [254 total knee replacements (TKR) and 175 total hip replacements], 67 (15.6%) developed AKI, including 51 TKR. Increasing body mass index (AOR 1.12 95%CI: 1.06, 1.19), older age (AOR 1.06 95% CI 1.01, 1.11) and lower pre operative glomerular filtration rate (AOR 0.98 95%CI 0.96, 0.99) were associated with the development of AKI. Of drug related factors, taking angiotensin converting enzyme inhibitors (AOR 2.73 95%CI 1.18, 6.31) and angiotensin-II receptor blockers (AOR 2.49 95% CI 1.14, 5.43) were factors associated with worsening RIFLE criteria (after accounting for known confounders) whereas NSAIDs appeared protective (AOR 0.22 95%CI: 0.08, 0.64). AKI resolved by discharge in most cases although only 50% of the total population had renal function tests after discharge, rendering long term analysis difficult.

Conclusions: Although the incidence of AKI (>15%) in our TJA population is higher than previously reported, most associated factors were similar to other studies. The apparent protective nature of the NSIADs was surprising. Given AKI is associated with increased length of stay and long term complications, prospective research is needed to further understand the number and interrelationship of factors that might assist with prediction of AKI risk. Opportunities to maximise the pre-operative medical management and mitigate risk should be considered in this elective orthopedic population.

FR-PO109

Baseline Characteristics Associated with AKI after Hospitalization for Serious Infection T. Clark Powell,[5] Orlando M. Gutierrez,[2] Russell Griffin,[3] John P. Donnelly,[5] Monika M. Safford,[4] Henry E. Wang.[5] *[1]Div of Nephrology, Univ of Alabama School of Medicine; [2]Dept of Epidemiology, Univ of Alabama School of Medicine; [3]Div of Preventive Medicine, Univ of Alabama School of Medicine; [4]Dept of Emergency Medicine, Univ of Alabama School of Medicine, Birmingham, AL.*

Background: While ample data describe AKI, only limited data describe the risk of future AKI in healthy individuals. We sought to identify baseline characteristics of community dwelling adults associated with long-term risk of AKI after hospitalization for serious infection.

Methods: We used 8 years of data on 30,239 adults ≥45 years old from the REasons for Geographic and Racial Differences in Stroke (REGARDS) cohort. Using medical records, we identified serious infection hospitalizations. We defined AKI as a serum creatinine (sCr) increase ≥0.3 mg/dL from first inpatient measurement. We excluded individuals with prior renal transplant or ESRD, as well as hospitalizations with <2 sCr measurements (n=878). Examined baseline characteristics included sociodemographics, health behaviors, chronic medical conditions, and biomarkers. We identified associations with hospitalizations with AKI events using Generalized Estimating Equations.

Results: Over median follow-up of 4.5 years (IQR 2.4-6.3) we identified 2,074 serious infection hospitalizations among 1,547 individuals. Infection types included: lung 45.2%, kidney 16.2%, abdominal 18.0%, skin 10.8%, other 9.8%. AKI occurred in 312 hospitalizations (15.0%) (sCr rise 0.3-0.69 mg/dL - 8.7%; 0.7-1.19 - 2.7%, ≥1.20 or acute dialysis - 3.7%). Baseline characteristics independently associated with AKI after serious infection included male sex (adjusted OR 1.51; 95% CI: 1.11-2.05), history of diabetes (1.54; 1.13-2.08), Cystatin-C [CysC] ≥1.11 mg/dL (1.95; 1.37-2.78) and Albumin-to-Creatinine Ratio [ACR] ≥30 mg/g (1.69; 1.23-2.32). eGFR<60 was not associated with future AKI.

Conclusions: Male sex, history of diabetes, and elevated baseline CysC and ACR are independently associated with future AKI after serious infection. These findings highlight baseline characteristics that may be useful for risk-stratification and awareness of increased future AKI risk.

FR-PO110

Severity of Anemia Is Associated with AKI Recovery During ICU Stay Etienne Macedo,[1] Josee Bouchard,[2] Glenn M. Chertow,[3] Jonathan Himmelfarb,[4] T. Alp Ikizler,[5] Ravindra L. Mehta.[6] *[1]Univ of Sao Paulo; [2]Hospital du Sacre-Coeur de Montreal; [3]Stanford Univ; [4]Univ Washington; [5]Vanderbilt Univ; [6]Univ of California San Diego.*

Background: Anemia is a risk factor for development of AKI but has not been evaluated for renal recovery following AKI. We hypothesized that the severity of anemia would contribute for non-recovery from AKI in the ICU setting.

Methods: We included ICU survivors whose sCr increased consecutively for>3 days before recovery or dialysis. We stratified patients in quartiles according to the lowest Hb during ICU stay before dialysis. Recovery was defined as complete when ICU discharge sCr was within 20% of the reference sCr, and partial for sCr values >20% and not on dialysis. Non-recovery was defined as dialysis-dependence at ICU discharge. The likelihood of recovery was assessed in a logistic regression in reference to the lowest Hb quartile.

Results: Of the 212 ICU survivors, 40 (18%) were dialysis dependent at ICU discharge; and 64 (30%) had complete recovery. Median (IQR) Hb were (10.7G/dL (9.7-12.5) at ICU admission and the lowest during ICU stay were 8.6 G/dL (7.9-9.5). 25% of patients had Hb<8G/dL during ICU stay. Patients in the highest Hb quartile were less likely to be dialysis dependent and more likely to have complete recovery than those in the lowest quartile.

Hb quartiles during ICU stay	<7.9	8-8.5	8.6-9.5	>9.5
Complete recovery - ALL (212)	17 (32)	16 (28)	11 (19)	20 (42)
CKD (68)	3 (21)	5 (22)	3 (20)	8 (47)
Partial recovery - ALL	24 (45)	27 (48)	35 (62)	22 (46)
CKD	5 (35)	10 (45)	10 (66)	7 (41)
Dialysis dependency - ALL	12 (22)	13 (23)	10 (18)	5 (11)
CKD	6 (42)	7 (31)	2 (13)	2 (12)
OR for any recovery - ALL	1	3.30* (1.7-6.1)	4.6* (2.3-9.1)	8.4* (3.3-21)
CKD	1	2.14 (0.8-5.2)	6.5* (1.4-2.8)	7.5* (1.7-32)

*P<0.05

CKD patients in the highest Hb quartile had significantly higher recovery rates (88% versus 57%) and lower dialysis dependency those on the lowest quartile (43% versus 12%;p=0.024). The highest Hb quartile was associated with an 8.4 times higher likelihood of recovery.

Conclusions: Anemia is frequent in AKI patients during ICU and is associated with higher risk of RRT dependence at ICU discharge. Future studies should evaluate if prevention or attenuation of anemia could improve AKI recovery.

FR-PO111

Medication Usage and Survival After Acute Kidney Injury Sandeep Brar,[1] Neesh I. Pannu.[2] *[1]General Internal Medicine, Univ of Alberta, Edmonton, AB, Canada; [2]Nephrology, Univ of Alberta, Edmonton, AB, Canada.*

Background: The incidence of acute kidney injury (AKI) is continuing to rise, and there are currently no effective therapies for the treatment of AKI. Recent studies suggest that nephrology follow-up reduces the risk of mortality in AKI survivors and this may be due to the receipt of beneficial medications.

Methods: Retrospective cohort study of adults greater than 65 years of age, residing in Alberta, who were admitted to hospital between 2002 and 2008 and developed AKI during the index hospitalization, with progression to chronic kidney disease (CKD) within 120 days post discharge. Angiotensin-converting enzyme inhibitor (ACEi) or angiotensin II–receptor blocker (ARB), beta-blocker and statin use was assessed within 120 days post discharge.All participants had a minimum of two years of follow up.

Results: n= 14,921 mean age 78.8 years. Within 120 days of discharge, 59.4% of the participants were on an ACEi or ARB, 36.7% were on a beta-blocker and 28.5% were on a statin. The adjusted hazard ratio of mortality for participants on an ACEi or ARB was 0.931 (95% confidence interval [95% CI], 0.868, 0.999), 0.931 for participants on a beta-blocker (95% confidence interval [95% CI], 0.868, 0.999) and 0.74 for participants on a statin (95% CI, 0.69, 0.80). Participants on an ACEi or ARB had a higher risk for all cause re-hospitalization (adjusted HR, 1.16; 95% CI, 1.1, 1.22). Participants on a beta-blocker also had a higher risk for all cause (adjusted HR, 1.07; 95% CI, 1.02, 1.13) and renal cause re-hospitalization (adjusted HR, 1.25; 95% CI, 1, 1.56). There was no significant difference in the rate of ESRD with any of the medications.

Conclusions: In AKI survivors, ACEi, ARB, beta-blockers and statins are associated with a decreased risk of mortality. However, ACEi or ARB and beta-blockers are associated with a higher incidence of re-hospitalizations.

Funding: Government Support - Non-U.S.

FR-PO112

Effect of Angiotensin-Converting Enzyme Inhibitor or Angiotensin-Receptor Blocker Use on the Progression of Acute Kidney Injury in Heart Failure Patients Ke Wang, Mayank Sardana, Payel Jhoom Roy, Youssef Rahban, Bailey Y. Chang, Ashish Upadhyay. *Nephrology, Boston Medical Center, Boston, MA.*

Background: Angiotensin-converting-enzyme inhibitors (ACEI) and angiotensin-receptor blockers (ARB) are widely used in patients with heart failure. ACEI/ARB lower intra-glomerular pressure and may impair renal auto-regulation during hemodynamic stress. We examined if early discontinuation of ACEI/ARB during in-hospital acute kidney injury (AKI) affected AKI progression in patients with heart failure.

Methods: We reviewed charts of patients admitted to Boston Medical Center's heart failure service from 2/2007 to 6/2013. Patients who developed in-hospital AKI while taking ACEI/ARB were included. Exact timing of ACEI/ARB discontinuation after onset of AKI was noted. We used regression analyses to assess the impact of the timing of ACEI/ARB discontinuation on doubling of serum creatinine (Cr), absolute change in Cr, length of hospital stay (LOS), and time to peak Cr. Results were adjusted for demographic characteristics and co-morbidities.

Results: 202 patients met the inclusion criteria. Group 1 included 27 patients with ACEI/ARB discontinuation within 24 hours after AKI, group 2 included 36 patients with ACEI/ARB discontinuation more than 24 hours after AKI, and group 3 included 139 patients whose ACE-I/ARB was continued during AKI. When comparing group 1 to groups 2 + 3, there was no difference in doubling of Cr (25.9% versus 22.8%, p=0.39), absolute change in Cr (0.99 mg/dL versus 0.80 mg/dL, p=0.07), LOS (10.5 days versus 8.7 days, p=0.11) and time to peak Cr (3.1 days versus 2.4 days, p=0.33). When comparing group 1 to group 2, group 1 had lower rates of doubling of Cr (25.9% versus 58.3%, p=0.01) and less absolute change in Cr (0.97 mg/dL versus 1.37 mg/dL, p=0.048). There was no statistically significant difference in LOS (10.1 days versus 12.2 days, p=0.27) and time to peak Cr (3.1 days versus 4.0 days, p=0.42).

Conclusions: Our results suggest that early discontinuation of ACEI/ARB after AKI may not affect AKI progression in heart failure patients. Among patients who had ACEI/ARB discontinuation, however, there was a trend towards better kidney outcomes in the group with early discontinuation.

FR-PO113

Acute Kidney Injury Complications in Critically Ill Patients: Implications on Mortality Rate and on the Efficacy of Renal Replacement Therapy Alexandre Braga Liborio,[1] Evandro Faria,[2] Eder Pinheiro Arantes,[1] Renata Almeida Leitao.[3] *[1]Clinical Medicine, Univ Federal of Ceara, Fortaleza, Ceara, Brazil; [2]Pronefron, Fresenius Medical Care, Fortaleza, Ceara, Brazil; [3]UNIFOR.*

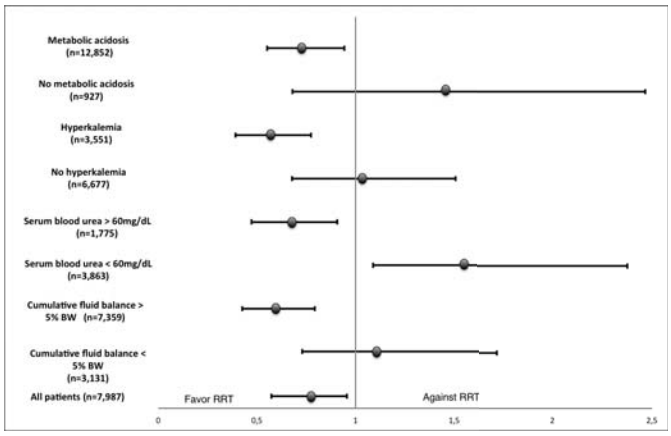
Background: it is unknown the contribution of AKI complications to AKI-related mortality and if renal replacement therapy (RRT) has any beneficial effect in critically ill patients mortality.

Methods: Retrospective study using data from MIMIC-II project comprising 23,529 patients.

Results: 10,245patients developed AKI.After adjustment for confounders (model 1), OR for hospital mortality are demonstrated.

	Model 1	Model 1+ hyperkalemia	Model 1+ hyperkalemia+ metabolic acidosis	Model 1+ hyperkalemia+ metabolic acidosis+ cumulative fluid balance
No-AKI	ref.	ref.	ref.	ref.
AKI stage 1	1.976 (1.737-2.247)	1.892 (1.661-2.154)	1.702 (1.492-1.942)	1.651 (1.446-1.885)
AKI stage 2	2.209 (1.858-2.626)	2.023 (1.696-2.413)	1.708 (1.428-2.044)	1.493 (1.243-1.794)
AKI stage 3	3.090 (2.529-3.775)	2.745 (2.235-3.371)	2.096 (1.637-2.589)	1.583 (1.268-1.996)

After including each AKI complication (hyperkalemia, metabolic acidosis and cumulative fluid balance), the excess of mortality rate was explained by 33% in AKI stage 1, 59 % in stage 2 and 72% in stage 3. The main burden of AKI-excess mortality was explained by metabolic acidosis and cumulative fluid balance. Long-term mortality was not explained by any of AKI complications.Subsequently,we used two different approaches to explore the association between RRT, AKI complications and hospital mortality: multivariate analysis and propensity-score matching. In both approaches, RRT was associated with better survival only in AKI-related complications subgroups



Conclusions: Majority of AKI excess risk of mortality can be explained by its complications, mainly in severe AKI.Also, for the first time we demonstrated RRT was associated with a better outcome only in those patients with AKI-related complications.

FR-PO114

Discordant Trends in Sepsis and Its Associated Acute Kidney Injury, 2004-2008 Jean-Sebastien Rachoin,[1] Andrew Moore,[2] Lawrence S. Weisberg.[1] *[1]Medicine, Cooper Univ Hospital, Cooper Medical School of Rowan Univ, Camden, NJ; [2]Medicine, Cambridge Health Alliance, Cambridge, MA.*

Background: Concerted efforts recently have been made to reduce the high mortality rate associated with sepsis in critically-ill patients. The impact of such efforts on the development of acute kidney injury (AKI) is unknown. We hypothesized that the incidence of AKI requiring renal replacement therapy (AKI / RRT) among patients with sepsis has not changed in recent years.

Methods: We performed a retrospective observational study of all patients in the U.S. and Canada admitted to a, ICU from 2000 through 2008 and entered in the Project Impact® database. We analyzed 28,238 records from21 hospitals deemed to have a sufficiently accurate time series without major gaps in the data. We constructed a cross sectional auto-regressive integrated moving average model (ARIMA) to smooth out seasonal variations in the data and examine trends more closely.

Results: There were 2,304 cases of sepsis in 2004, which increased to 2,496 in 2008. The number of cases of AKI / RRT was 218 in 2004 and 219 in 2008. After analyzing monthly variations and adjusting for confounding variables with our ARIMA model, we found that the temporally adjusted trend in sepsis cases showed a significant increase over time (p=0.0121), whereas that for AKI / RRT did not (p=0.4296.

Conclusions: Cases of sepsis increased significantly over time in our hospital ICU series from 2004 through 2008, without a corresponding significant increase in AKI / RRT. The factors associated with this discordance, including demographics, quality of care and goals of care, remain to be investigated.

FR-PO115

Acute Kidney Injury and Long-Term Outcomes after Major Abdominal Surgery: A Retrospective Cohort Analysis Joana Gameiro,[1] Catarina Bekerman,[1] Maria Ornelas,[1] Marta Pereira,[1] Sofia C.A. Jorge,[1] Rosario Rosa,[2] António Gomes da Costa,[1] Jose António Lopes.[1] *[1]Dept of Medicine, Centro Hospitalar Lisboa Norte, EPE, Lisboa, Portugal; [2]Dept of Surgery, Centro Hospitalar Lisboa Norte, EPE, Lisboa, Portugal.*

Background: Data regarding the influence of acute kidney injury (AKI) on long-term outcomes of patients submitted to major abdominal surgery are still lacking. We analyzed the impact of AKI on long-term renal outcome and mortality in a cohort of patients undergoing major abdominal surgery.

Methods: Patients who underwent major abdominal surgery in Centro Hospitalar Lisboa Norte, EPE, (Lisbon, Portugal) between January 2010 and February 2011 and were discharged alive from the hospital were retrospectively studied. AKI was defined by an increase in absolute serum creatinine (SCr) ≥0.3 mg/dl or by a percentual increase in SCr≥50%, and/or by a decrease in urine output to <0.5 ml/kg/hour for more than 6 hours, in the first 48 hours after surgery. Renal outcome was defined as the requirement for long-term dialysis and/or a 25% decrease in estimated glomerular filtration rate after hospital discharge. Cumulative survival curves were determined by the Kaplan-Meier method, and log-rank test was employed to analyze statistically significant differences between curves. Multivariate analysis was used to determine predictors of renal outcome and mortality. A two-tailed P value<0.05 was considered significant.

Results: Out of the 390 patients analyzed, 72 (18.5%) had postoperative AKI. Median follow-up was 38 months. Patients with AKI had worse renal outcome (47.2 versus 21.4%, P<.0001; unadjusted OR 3.2, 95%CI 1.9-5.4, P<.0001). In multivariate analysis, AKI still emerged as a risk factor for renal outcome (adjusted OR 2.2, 95%CI 1.2-4, P=0.013). At 1, 2 and 3 years of follow-up, the cumulative probability of survival of patients with AKI was 83.3, 68.4 and 56.8%, respectively, compared with 96.2, 93.4 and 90.9% in patients without AKI (log-rank, P<.0001). In multivariate analysis AKI was associated with increased mortality (adjusted HR 1.7, 95% CI 1.1-2.6; P = 0.016).

Conclusions: Postoperative AKI was associated with poor long-term renal outcome and mortality in patients undergoing major abdominal surgery.

FR-PO116

Acute Kidney Injury (AKI) Requiring Dialysis: Long Term Follow Up Survival and Effect on Kidney Function Paula A. Duran, Luis A. Concepcion. *Medicine Div Nephrology, Scott&White Hospital Texas A&M Health Science Center, Temple, TX.*

Background: Data on long term follow up after AKI requiring dialysis is scarce. Objective: Describe and Identify factors associated with survival, recovery of kidney function at discharge and long term follow up of renal function in AKI patients requiring hemodialysis (HD).

Methods: All AKI patients requiring HD (conventional and daily shift CVVHD (2000-2013) included. Data:mean (SD).

Results: 499patients 60.9%male33.8%diabetic75%w/dipstick proteinuria on admission.345discharged alive (mortality 30.6%).68died after discharge50% in the first 162 d,mortality at the end of study 41.7%.F/U (1-86 m).At discharge 273 recovered kidney function (51.8%).Of those who died in the hospital 88.1%did no recover kidney function (dialysis dependent).Baseline creatinine 1.5mg/dl (0.9) eGFR60.8ml/min (30.7),Peak creatinine6.0 (2.9) BUN85.4mg/dl (39.0).Discharge creatinine3.6 (4.0) eGFR 30.4 (28.0) 6months creatinine 1.8 (1.4) eGFR60.7 (44.7),at all f/u times creatinine was higher eGFR was lower than the baseline values (p<0.05).Non survivors were older 62.4y (15.2) versus 58.9 (16.9) had a lower peak creatinine 4.9 (2.3) mg/dl versus 6.5 (3) had lower eGFr at discharge 24.9 (16.4) versus 32.7 (31.5) ml/min.Mean survival time 39.9m.The survival of the patients who recover kidney function at discharge was longer than ones who did not recover (59.4 versus 13.2m p<0.05).Cox regression the factors significant for survival were peak creatinine and status at discharge (recovery versus nonrecovery) eGFR at baseline and days on HD. During follow up (up to 54 months) the percentage of patients with eGFR<60decreased from discharge88.5%to60.3% at 6months then increased to 75% at 36 months and longer.The percent with eGFR<30 decreased from67.1% at discharge to11% at 24 months to increase at a later date (30-36%).The percentage of patients with eGFR<15decreased from discharge (31.3%) to 10%at 18m of follow up to increase to 22% at later dates.

Conclusions: AKI requiring dialysis has a significant effect on GFR with almost 80% of the surviving having CKD stage 3 or less (GFR<60). Progression was observed on the long term follow up. Factors affecting the survival included peak creatinine and recovery of kidney function at discharge.

Acute Kidney Injury in Critically Ill Patients with Severe Acute Pancreatitis: Clinical Characteristics and Outcomes Jiaojiao Zhou, Yi Tang, Fang Liu, Yuliang Zhao, Ping Fu. *Div of Nephrology, Dept of Medicine, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

Background: Severe acute pancreatitis (SAP) is believed to be a frequent cause of acute kidney injury (AKI) in critical illness, but there is little information on SAP-induced AKI. We therefore studied the incidence of AKI defined by the Acute Kidney Injury Network (AKIN) criteria and the risk factors associated with outcomes in patients with AKI following SAP.

Methods: A multicenter retrospective study of critically ill patients with AKI due to SAP was performed from August 2009 to June 2013. Univariate and multivariate analysis were performed to investigate the risk factors on outcomes in the study population.

Results: In a total of 414 patients with SAP, 287 (69.3%) had AKI during intensive care units (ICU) stay by AKIN criteria and 16.7% was classified as AKI stage 1, 18.4% as AKI stage 2, and 34.3% as AKI stage 3. SAP patients with AKI was associated with a significantly higher ICU mortality (20.5% versus 44.9%, p<0.001) when compared without AKI. AKI was associated with older age and greater proportion of heart failure, chronic kidney disease, abdominal compartment syndrome (ACS), and operation than without AKI. In those patients, independent risk factors for ICU mortality included ACS (OR10.58; 95% CI: 5.98–18.72), renal replacement treatment (RRT) (OR 3.31; 95% CI: 1.77–6.19), sepsis (OR 2.46; 95% CI:1.10–4.01), Computed Tomography Severity Index (CTSI) (OR 3.01; 95% CI: 1.78–5.32), APACHE II score (OR 1.82; 95% CI: 1.23–2.72), AKI stage 3 (OR 1.38; 95% CI:1.19–1.77), duration of ICU stay (OR 1.04; 95% CI: 1.01–1.07), and multi-organ failure.

Conclusions: For the first time we have investigated the epidemiology of AKI due to SAP with the AKIN criteria in critically ill patients. We found that independent factors including ACS, RRT, sepsis, CTSI, APACHE II score, AKI stage 3, duration of ICU stay, and multi-organ failure were significantly related with ICU mortality.More effect should be taken to strengthen the management of AKI following SAP and improve the outcomes.

FR-PO118

Early Acute Kidney Injury in Critically Ill Combat Casualties Ian J. Stewart,[1] Jonathan Sosnov,[1] David Zonies,[2] Benjamin D. Morrow,[1] James D. Oliver,[3] Kevin Chung.[4] *[1]San Antonio Military Medical Center; [2]Oregon Health & Science Univ; [3]Walter Reed National Military Medical Center; [4]U. S. Army Inst of Surgical Research.*

Background: While acute kidney injury (AKI) has been studied in a variety of populations, there is a paucity of data in members of the U.S. Military injured in the wars in Iraq and Afghanistan. We sought to evaluate risk factors for the development of early AKI in this population and to determine factors associated with mortality.

Methods: We queried a military research database for subjects with combat injury that required ICU level care and survived to be evacuated from theater between 1 Feb 2002 and 1 Feb 2011. Data on creatinine, age, Injury Severity Score (ISS), Glasgow Coma Scale (GCS), race, in hospital mortality and presence of burn injury were extracted. Patients with at least one creatinine level within 2 calendar days of the date of injury were included for analysis. AKI was determined by KDIGO criteria. Univariate and stepwise multivariate logistic regression was performed to determine variables associated with AKI and mortality.

Results: A total of 1642 subjects were included for analysis. They had an average age of 25.7±6.0, median ISS of 18 (IQR 12, 27), median GCS of 15 (IQR 12, 15). The majority (98.4%) were male and 7.8% were African American. Burn injury was present in 13.9%. The in hospital mortality rate was 2.4%. AKI occurred in 13.9% of patients (12.1%, 1.2%, and 0.7% for KDIGO stages 1, 2 and 3, respectively). On univariate logistic regression, age (OR 1.02, 95% CI 1.00-1.05), ISS (OR 1.04, 95% CI 1.03-1.05) and GCS (OR 0.96, 95% CI 0.93-0.98) were associated with AKI. On multivariate analysis, only age (OR 1.03, 95% CI 1.00-1.05) and ISS (OR 1.04, 95% CI 1.03-1.05) were significantly associated with AKI. In the multivariate analyses for mortality, ISS (OR 1.07, 95% CI 1.04-1.09), GCS (OR 0.82, 95% CI 0.77-0.88) and AKI (OR 3.22, 95% CI 1.59-6.52) were significant. The c statistic of the model was 0.89.

Conclusions: Early AKI is common among combat trauma patients admitted to the ICU, occurring in 13.9%. Furthermore, the development of AKI is independently associated with a more than 3 fold rise in the odds of death in this population.

FR-PO119

Renal Outcomes Post Orthoptic Heart Transplant in the Era of Left Ventricular Assist Device Siddiq Anwar, Pooja Koolwal, Mansumeet Singh, Jerrica Shuster, Timothy A. Horwedel, Justin Vader, Daniel C. Brennan. *Div of Medicine, Washington Univ School of Medicine, St. Louis, MO.*

Background: Hemodynamic support with a continuous-flow left ventricular assist device (LVAD) prior to orthotopic heart transplant (OHT) is increasingly common and introduces surgical complexity, but the incidence and extent of acute kidney injury (AKI) following OHT in these patients is not well-described.

Methods: Retrospective analysis of 190 consecutive OHT recipients from 2007-13 at a single center.

Results: Results are shown in Table 1.Of 190 OHT recipients, 86 (45%) had an LVAD pre-OHT and they were more likely to be male, white, obese, and to have a past history of hypertension. There was no statistical difference in the frequency or duration of renal replacement therapy (RRT) between VAD and non LVAD OHT patients. In the LVAD group there is no difference in LVAD duration (mean days ±SD) support pre- OHT between in those who did (374 ± 301.7) or did not die (355.1 ± 205.3) by 1 year (p=0.80) and also in those who needed RRT post OHT surgery (395.8 ± 427.2) and those who did not (365.4 ± 245.4) (p=0.70). In the LVAD group patients became RRT independent even up to 3 months after OHT. Creatinine clearance in the two groups was similar up to 60 months post OHT. Any need for RRT was associated with death by 1 year (23% RRT patients dead at 1 year versus 8% non-RRT dead at 1 year. p=0.02), but this was not different between VADs and non-VADs

Figure Legend: LVAD- Left venticular assist device, RRT: renal replacement therapy, BMI: body mass Index, OHT: Orthoptic Heart Transplant, N/A: Not applicable

Conclusions: Despite greater baseline risk factors for AKI, greater surgical complexity, and a trend to more frequent short term post-operative renal replacement therapy, OHT patients bridged with LVAD experience long term renal outcomes similar to OHT patients who were not bridged with LVAD.

FR-PO120

Long-Term Clinical and Renal Outcomes in Critically Ill Patients with Acute Kidney Injury Paul Hamilton Purvis,[1] Robert I. Docking,[2] Patrick B. Mark.[3] *[1]Univ of Glasgow, Glasgow, United Kingdom; [2]Glasgow Royal Infirmary, Glasgow, United Kingdom; [3]Inst of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom.*

Background: Critical illness is frequently complicated by acute kidney injury (AKI). The long-term outcomes of this patient group are poorly understood, with conflicting evidence regarding benefits of continuous versus intermittent renal replacement therapy (RRT). We studied short and long-term patient and renal outcomes in patients started on RRT in the intensive care unit (ICU).

Methods: Patient records were interrogated for all patients undergoing RRT in ICU at Glasgow Royal Infirmary between August 2010 and May 2013. Demographic, laboratory and clinical outcome data were retrieved, including creatinine and estimated glomerular filtration rate (eGFR) predating ICU admission (median 73 days pre-admission). Patients with pre-existing end-stage renal disease and ICU readmissions were excluded. Data were analysed for predictors of long-term renal outcome in hospital survivors, and comparison made between modality of RRT.

Results: 209 patients were studied. Modality of RRT was intermittent haemodialysis (IHD) in 88% and continuous veno-veno haemofiltration (CVVH) in 12%. Inpatient hospital mortality was 54%. Compared to hospital survivors, patients who died had higher APACHE score (26 versus 24, p=0.029) and non-significantly higher preadmission creatinine (1.23 versus 0.98mg/dL (p=0.09); other variables did not differ significantly. Baseline characteristics (age, sex, severity of acute illness, comorbidities) did not differ between modality of RRT. Those receiving CVVH did not differ in outcomes of renal function, survival or comorbidity. Hospital survivors had a non-significant decrease in renal function (pre/post hospital eGFR, 82.4/77.7 mL/min/1.73m^2). The only significant predictor of long-term eGFR or change in eGFR was baseline eGFR in a linear regression model.

Conclusions: Patients requiring ICU admission with AKI have a high mortality. We have shown a modest reduction in renal function following ICU admission, which is predicted by baseline eGFR; this may impact on long-term renal outcomes. Neither RRT modality showed superiority regarding long-term renal function.

FR-PO121

Acute Kidney Injury in Hospitalized Stroke Patients: Incidence, Risk Factors and Its Influence on the Outcomes Yang Luo. *Dept of Nephrology, Beijing Tiantan Hospital, Capital Medical Univ, Beijing, China.*

Background: Acute kidney injury (AKI) is a common and serious problem in hospitalized patients, however, there is a paucity of data describing clinical epidemiological characteristics of AKI among stroke patient. We therefore evaluate the incidence and risk factors of AKI and its impact on the outcomes in a group of hospitalized stroke patients.

Methods: We retrospectively analysed 647 consecutive patients with computer tomography confirmed stroke in neurological ICU between 2012 and 2013. Data were retrieved from electronic database of our hospital. AKI was identified and staged according to the 2012 KDIGO criteria. The incidence, risk factors of AKI and its influence of clinical outcomes of stroke were analysed. Stroke severity was assessed by the National Institutes of Health Stroke Scale (NIHSS) score.

Results: The mean age was 58.1±13.6 years old and 54.1% were males. AKI occurred in 135 (20.9%) patients with 84 (62.2%), 26 (19.3%), and 25 (18.5%) of AKI stage 1, 2, and 3, respectively. Patients with AKI appeared to be older, male, higher NIHSS score, and lower baseline eGFR than non-AKI patients (P<0.05 for all). Moreover, the rate of atrial fibrillation, hypertension, diabetes mellitus, sepsis, iodinated contrast media, ACEI/ARBs, antibiotics and diuretics administration were significantly higher in AKI patients (P<0.05 for all). A multi-logistic regression analysis showed that the independent risk factors of AKI in these patients were NIHSS score, baseline eGFR, hypertension, and sepsis [ORs (95%CI) were 1.027 (1.003-1.051), 0.985 (0.977-0.993), 1.592 (1.002-2.528), 3.385 (1.976-5.799), respectively; P<0.05 for all]. Patients with AKI had a significantly higher rate of all-cause mortality (36.3% versus 3.1%, P<0.01), and length of stay in hospital (15±6 days versus 6±2 days, P<0.01).

Conclusions: AKI is not rare among the stroke patients. Prevention and management of AKI is one of important measures among the stroke patients who are exposed to many risk factors of AKI.

FR-PO122

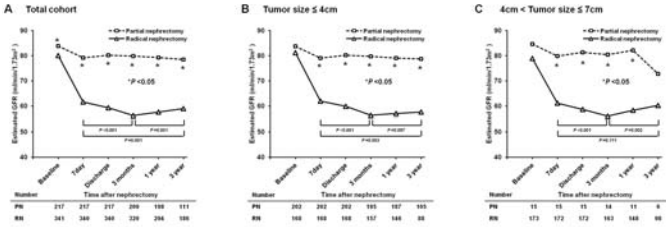
Impact of Partial Nephrectomy on Kidney Function in Patients with Renal Cell Carcinoma Chang Seong Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Dept of Internal Medicine, Chonnam National Univ Hospital, Gwangju, Korea.*

Background: The development of chronic kidney disease (CKD) is higher in patients with a small sized renal cell carcinoma (RCC) after radical nephrectomy (RN) than partial nephrectomy (PN). However, the renal outcomes between RN and PN are not well-

understood in a moderate sized RCC patients. This study aimed to compare the changes in kidney function and the association of tumor size and renal outcomes between patients with RCC who underwent RN and those who underwent PN.

Methods: A retrospective cohort study was conducted for 557 patients with an RCC ≤7 cm in diameter and normal contralateral kidney function who underwent PN or RN. PN was performed for 218 (39%) patients. Renal outcomes included the incidence of acute kidney injury (AKI), new-onset CKD and a ≥25% decline in eGFR 1 year after surgery.

Results: Serial changes in eGFR were compared during the 3 years of follow-up. Postoperative eGFR was significantly lower in patients undergoing RN than in those undergoing PN. The incidence of AKI and new-onset CKD was significantly higher in patients after RN (70.1% versus 24.3%, respectively; P < 0.001) than after PN (55.7% versus 6.2%, respectively; P < 0.001). According to the multivariable logistic regression analysis, RN was an independent risk factor for a ≥25% decline in kidney function after 1 year regardless of the tumor size, even after adjusting for various covariates.



Conclusions: Compared to PN, RN for even a moderate sized RCC leads to an increased incidence of AKI and new-onset CKD, and is a significant risk factor for kidney function decline. Therefore, PN should be considered as the choice of surgical treatment for RCCs that are ≤7 cm in diameter in order to preserve renal function postoperatively.

FR-PO123

The Effect of Renal Consults on Mortality in Patients with Acute Kidney Injury Iram Aqeel, Matthew J. Triano, Yevgeniy Gitelman, Yuliya Borovskiy, Michael G. Shashaty, Barry D. Fuchs, Francis Perry Wilson. *Univ of Pennsylvania.*

Background: Identifying which patients with acute kidney injury benefit most from renal consultation would increase the efficiency of care delivery and potentially improve outcomes.

Methods: We performed direct chart review of patients enrolled in a randomized trial of an electronic alert system for acute kidney injury (clinicaltrials.gov #NCT01862419). Renal consults were identified and abstracted by trained reviewers. We developed a propensity score for renal consultation based on demographics, time-varying laboratory parameters, and other clinical factors. Each patient who received a renal consult was propensity score matched with one patient who did not receive a renal consult in a greedy, nearest-neighbor fashion. Our primary outcome was inpatient mortality. Factors associated with consult benefit were evaluated by including interaction terms in a logistic regression model.

Results: Of 817 patients reviewed, 115 (14.1%) received a renal consult and were matched to 115 patients who did not receive a consult. The groups were similar with regard to age, sex, race, and all covariates used in propensity matching including serum creatinine, bicarbonate, potassium, blood urea nitrogen, lactic acid, and medical versus surgical status (all p>0.05). In the matched cohort, renal consult was not associated with a mortality benefit with inpatient mortality 17% among those who received a consult and 23% among those who did not (p=0.25). Renal consult was associated with a mortality benefit among those on the general floor as compared to the ICU (p=0.04), and among older patients (p=0.02). There was no detectable benefit to consultation among those with a shorter duration of AKI or among medical versus surgical patients. After exclusion of patients who went on to receive dialysis, consultation was associated with a reduced risk of inpatient mortality with OR 0.29 (0.11 – 0.78, p=0.01).

Conclusions: Renal consult for acute kidney injury may be associated with a survival benefit, particularly among those who are not yet receiving ICU care and those of older age. Randomized trials of renal consultation in AKI may be warranted to further elucidate this relationship.

FR-PO124

Outcome of Dialysis-Dependant Patients with Cast Nephropathy Treated or Not By Bortezomib: A Retrospective Monocentric Study Including 59 Consecutive Patients Levy Benedicte, Chadia H. Beaini, Denis Viglietti, Fabien Metivier, Denis Glotz, Marie-Noelle Peraldi. *Hopital Saint-Louis, Univ Paris 7, Paris, France.*

Background: Dialysis-dependant renal failure (DDRF) is associated with a poor outcome in multiple myeloma (MM), although some studies have shown improved overall survival in patients treated with novel agents such as bortezomib (borte).

Methods: This retrospective monocentric study included 59 consecutive patients with MM and DDRF for more than two weeks hospitalized in our unit between january 2004 and december 2010. Only patients with cast nephropathy were included. The aim of the study was to analyze the effects of borte on both patient and renal survivals. Statistical analysis were performed using the Mann-Whitney U test, Cox proportional hazard regression analysis and the Kaplan-Meier method for survival analysis.

Results: Median follow-up was 20.7 months (2-39). Median age of the patients was 60.7 years. In 22 cases (37%), DDRF occurred at diagnosis of MM. Thirty-nine patients were treated by Borte (66%). Borte treatment was associated with overall patients'survival improvment (P=0.03) with a median survival of 22 months in the Borte group *versus* 10 months in the other group. Multivariate analysis showed that only age <60 years (P=0.027), Borte treatment (P=0.033) and the occurrence of DDRF at diagnosis of myeloma (P=0.016) were factors associated with patient survival. In 16 patients (27%), dialysis could be withdrawn after 3.5 +/- 1.2 months. The use of either polysulfone or PMMA membranes did not influence the renal outcome. The single parameter significantly associated with dialysis withdrawal was the decrease of serum free light chain (P=0.001).

Conclusions: In DDRF patients with cast nephropathy included in this study, borte treatment was associated with improved survival, but not with the weaning of dialysis. The decrease of serum free light chain levels was the single parameter associated with dialysis withdrawal.

FR-PO125

Acute Kidney Injury in Crohn's Disease: Incidence, Risk Factors and Outcome Sarah Margaret Moran,[1] Michael Clarkson,[1] Carthage Patrick Moran.[2] *[1]Renal Medicine, Cork Univ Hospital, Ireland; [2]Gastroenterology, Univ College Cork, Ireland.*

Background: The association between interstitial nephritis and glomerulonephritides in Crohns disease (CD) is well described. However, the incidence of AKI and CKD is not known. Our aim was to assess the incidence and risk factors for AKI in patients with CD.

Methods: We retrospectively examined laboratory records of all patients with CD from a tertiary referral centre over a 7 year period. Patients who had more than 3 serum creatinine measurements were included. Episodes of AKI and CKD were classified using the KDIGO guidelines.

Results: 416 patients with Crohns disease were identified. 55.4% (232) were female. Mean age was 45.1 years (range 17-88 years, SD 14.2 years). Mean baseline creatinine was 70.8umol/L (range 32-227; SD 21.68). Mean baseline eGFR was 103.3 mls/min (range 19-232, SD 27.5). 3.8% (16) of patients had CKD with an eGFR less than 60mls/min. 3.3% (14) CKD stage 3 and 0.5% (2) had CKD stage 4 (none had CKD 5). Overall 20.2% (85) of patients with CD experienced an episode of AKI during the time period of evaluation. 23.5% (20) of affected patients had more than one episode of AKI: 17.6% (15) had 2 episodes, 2.3% (2) had 3 episodes, 1.1% (1) had 4, 5 and 6 episodes respectively. 77.3% (85) had AKIN stage I, 11.8% (13) had AKIN stage II and 10.9% (12) had AKIN stage III. No patients required renal replacement therapy. Peak creatinine values ranged from 72-955umol/L (mean of 178; SD of 146). 12.7% (14) of patients did not recover their renal function to baseline level. Episodes of AKI correlated with lower baseline GFR, higher CKD stage and increasing age (p<0.001). Increasing age correlated with higher AKI stage and baseline CKD. There was a 3.3% annualized risk of AKI in patients with CD. Recurrent episodes of AKI were associated with increasing severity of AKI (p=0.039), higher baseline creatinine and CKD (p<0.001).

Conclusions: We report the first study of the incidence and outcome of AKI in patients with Crohns disease. AKI is a common event in the natural history of this illness with an annual incidence of 3.3%. This data suggests the need for targeted strategies to prevent AKI and progressive CKD in this population.

Superimposed Community-Acquired Acute Kidney Injury in Patients with Chronic Kidney Disease: A Prospective Observational Study Patrick Saudan,[1] Belen Ponte,[1] Cyrielle Alves,[2] Fabien Stucker,[3] Pierre-Yves F. Martin.[1] *[1]Nephrology Unit, Dept of Medical Specialties, Geneva Univ Hospitals, Geneva, Switzerland; [2]Dept of General Internal Medicine, Geneva Univ Hospitals, Geneva, Switzerland; [3]Nephrology Unit, Hôpital de la Providence, Neuchatel, Switzerland.*

Background: Patients with CKD are prone to superimposed AKI. We aimed to better define characteristics, prognosis of community-acquired (CA-AKI) and use of potentially nephrotoxic drugs in CKD patients.

Methods: Prospective observational study within the Emergency Department of a University Hospital, screening for any patient > 16 years admitted with an eGFR < 60 ml/mn. Patients with CKD (previously known for a eGFR < 60 ml/mn) were included in this analysis and superimposed AKI was defined as a decline in eGFR compared to previous values according to KDIGO AKI criteria.

Results: From May 1st up to June 21st 2013, there were 8464 admissions and 664 patients (8%) had a eGFR < 60 ml/mn of whom 439 (66%) were known to have previous CKD. Mean age was 79 (12) yrs and 22% were diabetics. Use of ACEIs/ARBs, diuretics, NSAIDs and antibiotics was 47, 40, 3 and 3 % respectively. AKI was superimposed in 102 (23%) CKD patients. Etiology of superimposed AKI was prerenal (73%), renal (17%) and postrenal (9%).Stage I/II/III AKI were 8, 5 and 8% respectively. Multiple logistic analysis showed that occurrence of AKI was associated with male gender (OR 2.24; 95%CI:139-3.64, p=0.001) and diuretic use (OR 1.61; 95%CI:1-2.60, p=0.05).10 % of these patients went to ICU, and 4 % needed RRT. Length of stay (median+IQR) was increased in CKD patients with superimposed CA-AKI (11; 4-24 versus 8;8-17 days, p=0.01) Three month survivals were 93 % in patients with CKD and 90 % in CKD patients with superimposed CA-AKI.

Conclusions: These preliminary results show that community-acquired superimposed AKI in elderly CKD patients is more frequently encountered in male patients and those treated with diuretics may be at higher risk of CA-AKI. Some cases of CA-AKI may be avoided in CKD patients with clear education as to management of diuretics in case of disease-induced hypovolemia.

FR-PO127

Contrast Induced Nephropathy: Assessing the True Incidence of AKI Related to CT Scans with and without Contrast Juliya Hemmett,[1] Lee Er,[2] Chris Cheung,[1] Sean West,[3] Helen Chiu,[2] Ognjenka Djurdjev,[2] Adeera Levin.[1] *[1]Nephrology, St. Paul's Hospital and Univ of British Columbia, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, St. Paul's Hospital, Vancouver, BC, Canada; [3]Vancouver Coastal Health Authority, Vancouver, BC, Canada.*

Background: Contrast-induced nephropathy (CIN) is the acute decline in renal function 48-72 hours after contrast media administration. Incidence rates vary in the literature. Since 100,000 CT scans are performed annually within one health authority (HA) in Canada, there is interest in implementing a standardized CIN prevention protocol (CIN-PP), to decrease risk of CIN.

Methods: We evaluated the efficacy of a pilot CIN-PP by measuring the incidence of CIN within the HA at baseline and after PP implementation. During two time periods, pre and 3 mo post CIN-PP implementation, all hospitalized patients who had 2 serum creatinine (sCr) values within a 7 day period pre and post CT scan, with and without contrast were included in the sample. Data included: patient (pt) demographics, type of CT scan, and sCr values. CT scans were excluded if they involved an extremity or if a pt received more than one scan within a 7 day period. Of 4919 scans done, there were 325 CT scans from the pre-protocol phase in Dec. 2012, and 518 CT scans from the post-protocol phase in Oct. 2013 meeting inclusion criteria. The primary outcome was the incidence of CIN, defined as a sCr increase of >26.5 mmol/L within 7 days post-CT scan.

Results: The mean age of the population was 70y, mean eGFR at baseline =70. Baseline and post-protocol implementation CIN incidence was similar (10.9 versus 10.0%;p=0.64). We evaluated the proportion of pts who received IV contrast in both time periods who had 2 sCr values; more pts post CIN-PP had 2 sCr values (73.6 versus 79.8%;p=0.14). The incidence of CIN did not vary between those who did and did not receive contrast in either time period.

Conclusions: The application of robust research methodology to the CIN-PP quality improvement initiative raises questions as to the value proposition of CIN-PP. Further understanding of factors contributing to AKI in those receiving CT scans, irrespective of contrast may guide future targeted interventions.

FR-PO128

Mortality and Hospital Re-Admission Rates for Patients with Stage III AKI Compared to all General Medical Admissions Pritpal Singh Virdee, Ben Talbot, Janet Campbell, Debasish Banerjee. *Renal Unit, St. Georges NHS Trust, London, United Kingdom.*

Background: Increased morbidity associated with acute kidney injury may precipitate further medical intervention or consultation following initial discharge. This has cost and resource implications which may be preventable. We compared mortality and re-admission rates for patients with Acute Kidney Injury stage III against all other patients admitted under General Medicine in a large tertiary referral hospital based in London.

Methods: A retrospective audit was performed to identify patients admitted to St Georges Hospital NHS Trust between July 2013 and March 2014. The hospital database was interrogated using information submitted via Electronic Patient Records (EPR) and iClip to create two patient groups with 30 day mortality and re-admission rates for each. Patients who were admitted under a treating general medical team following blood tests were identified. Patients admitted with AKI stage III were identified via AKI stage calculation performed by iSOFT pathology software and these patients formed the second group. All patients receiving acute or chronic dialysis were excluded from both groups prior to analysis.

Results: The average age amongst general medical patients and patients with AKI III were 64.51+/- 21.10 (1SD) and 67.17+/- 17.29 (1SD) respectively. 458 patients were admitted with AKI stage III not requiring dialysis. Amongst this group there were 141 deaths within 30 days (30.79%) and 30 re-admissions to hospital (6.55%). In the General medicine group there were 5458 admissions, 253 deaths (4.64%) and 418 readmissions (7.66%). There was statistical significance in mortality (P <0.0001) but not re-admission rates (P = 0.4418) between the groups.

Conclusions: 30 day mortality is significantly increased when patients are admitted with AKI stage III not requiring dialysis with a relative risk of death of 6.64 but risk of re-admission is not found to be increased. One factor may be increased mortality in patients with AKI stage III resulting in a smaller discharged patient cohort. Further investigation is required to determine what prompts re-admission to hospital amongst these patients and what the long term outcome is.

FR-PO129

Acute Renal Replacement in Critical Care: Short and Long-Term Prognosis Fernando Saldanha Thome,[1,2] Antonio Balbinotto,[1] Cássia M. Morsch,[1] Verônica Verleine Hörbe Antunes,[1] Aline Castello Branco Mancuso,[1] Pâmela Dalla Vecchia.[1] *[1]Nephrology, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [2]Internal Medicine, FAMED-UFRGS, Porto Alegre, Brazil.*

Background: Our objective is to identify short and long term prognostic factors for acute kidney injury (AKI) with renal replacement therapy (RRT) in critical care patients.

Methods: A cohort of critical care patients needing RRT for stage 3 AKI was prospectively followed from 2006 to 2013. Chronic kidney disease stage 5 and renal transplants were excluded. RRT was intermittent hemodialysis-IHD (Fresenius™) for hemodinamically stable or continuous RRT-CRRT (Prisma™ or Diapact™) for unstable patients. Independent variables were: demographics, baseline creatinine, type of AKI, co-morbidities, APACHE II score, variables related to the treatments. Outcomes were mortality and dependence on dialysis during and after hospitalization. Statistics: univariate and mutivariate Poisson regression with robust variance analysis, SPSS 18.

Results: We followed 1828 patients, age 58.4±16.8years, 57%male, 86%white, 23%having baseline creatinine ≥ 1.5 mg/dl, 69%with clinical AKI, 77%septic, 93%with mechanical ventilation, 88%with vasopressors,APACHE II score 27.2±8.8. IHD (5.1±5.7 sessions) was used in 46% and CRRT (5.5±5.7 days) in 86%patients. Citrate was the anticoagulant in 71% of CRRTs. Time in the ICU was 14.7±16.7 days. Case-fatality rates were 65% in ICU and 72% in the hospital; 30% of patients became independent of dialysis in the hospital. Hospital survivors (n=489) were reached in a median of 24.1 months after discharge, seventy of them (14.3%) on chronic dialysis and 69%still alive. Factors associated with hospital mortality were sepsis, APACHE II score, use of mechanical ventilation or vasopressors, severe hepatic disease and age. Factors associated with mortality after discharge were baseline creatinine≥1.5 mg/dl, diabetes and cancer. The main factor related to dependence on chronic dialysis was baseline creatinine.

Conclusions: The high morbidity and mortality of critical care patients needing RRT because of AKI stage 3 remains beyond hospital discharge, but prognostic factors determining outcomes in the hospital or after discharge are different.

FR-PO130

The Impact of Serum Creatinine Adjustment for Fluid Balance on Diagnosis of Acute Kidney Injury in Critically Ill Patients Wisit Cheungpasitporn, Charat Thongprayoon, Kianoush Banaei-Kashani. *Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Fluid accumulation may delay recognition of acute kidney injury (AKI) in ICU patients commonly developing volume overload. This study aims to evaluate the impact of fluid balance on the diagnosis of AKI and associated outcomes in critically ill patients.

Methods: This is a single-center retrospective observational study conducted at a tertiary referral hospital. All adult ICU patients between January and March 2010 with at least one serum creatinine (SCr) measured in ICU were included. Patients with end stage renal disease or on dialysis before the ICU admission were excluded. AKI was defined as an absolute increase in SCr in ICU of ≥ 0.3 mg/dl or relative change of ≥ 50% from baseline. AKI was identified before and after serum creatinine adjustment for fluid balance. We used the following formula for the correction factor [admission body weight (kg) * 0.6 + cumulative fluid balance (L)]/ [admission body weight * 0.6].

Results: A total of 563 patients were enrolled in the final analysis. AKI was detected in 126 (22.4%) before adjustment and 148 (26.3%) after adjustment for fluid balance (P < 0.001). Among 124 patients who had AKI regardless of SCr adjustment SCr adjustment did not change the time of AKI diagnosis in most patients. Risk of 90 mortality in patients with AKI both before and after SCr adjustment for fluid balance showed significant increase compared to patients without AKI (RR = 2.33; 95% CI 1.59-3.42). In patients who met AKI criteria after but not before SCr adjustment for fluid balance, risk for 90-day mortality was not higher than patients without AKI both before and after adjustment (RR = 1.38; 95% CI 0.54-3.49), although there was a non-significant trend toward increased mortality in the former group.

Conclusions: Fluid management in ICU influences SCr and therefore diagnosis of AKI using SCr-based definition. SCr adjustment for fluid balance could detect earlier and more AKI cases. We would suggest using fluid balance adjustment for screening purposes as a highly sensitive definition. On the other hand when specificity is important AKI definition without fluid balance adjustment could be used.

FR-PO131

Renal Dysfunction and Fluid Overload in *Clostridium difficile* Infections Ravindra L. Mehta, Romana Turanovicova, Sareen Kaila Sandhu, Yu-Ting Christi Kao, Saima Aslam. *Univ of California, San Diego.*

Background: Clostridium difficile infection (CDI) is a devastating complication in hospitalized patients that increases morbidity, mortality and resource utilization. We sought to elucidate the role of fluid overload as a contributing factor to the link between renal disease and poor outcomes in CDI.

Methods: We retrospectively collected data from the electronic medical record of patients diagnosed with their first episode of CDI at an academic medical center during 2012. Data abstracted: demographics, clinical characteristics, daily fluid balance, body weight, laboratory values including creatinine, severity of CDI, treatment outcome, recurrence, readmission, and mortality in 90 days.

Results: Among 359 patients with CDI, 22.8% had AKI in the 2 weeks prior to CDI diagnosis and 8.4% were on hemodialysis; these were independent predictors of severe CDI in a multivariate model (p=<0.05). Dialyzed patients had a lower treatment success rate versus non-dialyzed patients (50% versus 69.5%, p=0.049); ≥5% fluid overload in the 48 hours following CDI diagnosis was as an independent predictor of treatment failure in this group. Additionally, cumulative fluid balance ≥ 10% in the first week prior to CDI diagnosis was associated with significantly longer length of stay (mean 29.1 versus 16.2 days, p=0.0007). Once CDI was diagnosed, fluid overload ≥ 5% in the following 48 hours was associated with diarrhea duration ≥ 5 days, accounting for severe diarrhea (≥10 stools/day) as well as severe CDI as confounders (OR 2.35, p=0.027). 13% of patients developed AKI in the 2 weeks following CDI diagnosis; this was associated with increased mortality independent of fluid overload (36% versus 8.9%, p=0.001). Patients that had severe CDI at the time of diagnosis were more likely to develop AKI in the following 2 weeks (p=0.001), independent of diarrhea severity.

Conclusions: Patients with renal disease have a higher rate of severe CDI, and development of AKI following CDI diagnosis is associated with increased 90-day mortality.

Fluid accumulation in dialyzed patients plays a role in the poor treatment outcomes of these patients. Fluid overload in general is also associated with prolonged diarrhea in CDI patients.

Funding: NIDDK Support

FR-PO132

Effect of Fluid Overload on Survival Rate in Critically Ill Patients with Acute Kidney Injury Receiving Continuous Renal Replacement Therapy

Min-Jee Han, Chae Rim Kim, Do Hyoung Kim, Su Hyun Kim. *Dept of Internal Medicine, Chung Ang Univ Hospital, Seoul, Republic of Korea.*

Background: Extensive fluid overload (FO) leads to acute physiological changes such as metabolic imbalances of water and electrolytes, pulmonary edema, and respiratory failure. Thus we investigated whether FO is associated with mortality in critically ill patients with acute kidney injury (AKI) receiving continuous renal replacement therapy (CRRT).

Methods: We retrospectively reviewed 140 patients with AKI treated with CRRT between April 2005 and August 2011. We calculated fluid balance for each day using the sum of daily fluid intake (L) from which we subtracted total output (L) before initiation of CRRT. Patients were divided into three groups according to the tertile of FO: mild (FO1), moderate (FO2), and severe (FO3).

Results: Of the 140 enrolled patients, the mean follow-up period was 37.0 ± 77.8 days and the median duration of renal replacement therapy was 8 (1-594) days. Mean cumulative fluid balance was 9.0 ± 9.3 L (FO1, 1.1 ± 3.4L; FO2 6.8 ± 1.7L; FO3, 19.2 ± 8.5L). The FO1 group showed a significantly lower incidence of mechanical ventilation (63.8% versus 88.2%, *P*=0.001) and a lower use of inotropics (68.1% versus 91.4%, *P*=0.001) compared to the FO2 and FO3 groups. Survival rate was significantly higher in the FO1 group than in the FO2 and FO3 groups (P=0.003). In multivariate Cox analysis, patient survival was significantly higher in the FO1 group than in the FO2 and FO3 groups (hazard ratio 1.79, 95% confidence interval 1.15–2.80, P=0.011).

Conclusions: In critically ill patients with AKI, fluid overload was independently associated with mortality.

FR-PO133

Extracelular Hypervolemia and Prognosis in Acute Kidney Injury. Bioimpedance Analysis Aplication to Prevent Volemic Hyperexpansion

Francisco Javier Lavilla, Nuria Garcia-Fernandez, Paloma L. Martin Moreno, Jose Maria Mora Gutierrez, Maria Jose Molina Higueras, Diana Lopez Espinosa, Pelayo Moiron Fdez-Felechosa, Pedro Errasti. *Nephrology, Clínica Univ de Navarra, Pamplona, Navarra, Spain.*

Background: The aim of this study is to evaluate corporal hypervolemia by bioelectrical impedance analysis (BIA) as a marker of poor prognosis in acute kidney injury (AKI). Hypervolemia in AKI have consequences (cardiac failure, pulmonary edema, ICU and renal replacement theraphy). Another aim is evaluate application of cardiothoracic bioimpedance to prevent volemic hyperexpansion.

Methods: In a cohort of 122 patients (62 years-old SD 0.33, 72% male) with a diagnosis of AKI, a corporal bioimpedance analysis was made. Volemic bioelectricals parameters extracellular/intracellular water ratio (EC/IC), acute clinical index (individual severity index –ISI-), analytical parameters (C-reactive protein –CRP-, prealbumin –PRALB-) and mortality were evaluated. In a preliminary study we use hemodynamic bioimpedance analysis to evaluate Corporal Thoracic Fluid (CFT) and CFT index (CFTI). SPSS version 20.0 software was used.

Results: Exitus 10.4%. Extracelular hypervolemia was associated with poor prognosis in AKI. EC/IC showed a statistical significance correlationship with ISI (r = 0.286, p=0.001) andCRP (r = 0.323, p=0.001); as well as an inverse correlationship with PRALB (r = -0.405, p=0.010). EC/IC was associated with mortality risk (p= 0.008, OR 2.218 CI 95% 1.23-3.98) showing an AUC cut-off 0.776 (p=0.001;CI 95% 0.667-0.885). In a preliminary study with oliguric AKI we evaluated CFT and CFTI in 15 patients, showing higher CFT (> 37 l/kOhm) and CFTI (> 21 l/kOhm/m2) in 8/15 (53%). Patients with higher CFT and CFTI the intravenous hydration was stopped. No cardiorespiratory complications were found after adjustment of fluidotherapy during AKI.

Conclusions: Hypervolemia was associated with poor prognosis in AKI. Inflammatory status and hypoproteinemia were associated with hypervolemia. In oliguric AKI it may be possible to prevent complications of hyperexpansion by bioelectrical impedance (corporal and cardiothoracic). Bioimpedance is an useful tool in the evaluation and management of patient with AKI.

FR-PO134

Prognosis in Acute Kidney Injury. Unicentric Prospective Observational Study. Clinical Parameters Associated with Mortality and Renal Replacement Therapy

Francisco Javier Lavilla,[1] Siru Hu,[2] Nuria Garcia-Fernandez,[1] Paloma L. Martin Moreno,[1] Diana Lopez Espinosa,[1] Jose Maria Mora Gutierrez,[1] Maria Jose Molina Higueras,[1] Pelayo Moiron Fdez-Felechosa,[1] Pedro Errasti.[1] *[1]Nephrology, Clínica Univ de Navarra, Pamplona, Navarra, Spain; [2]School of Medicine, Univ de Navarra, Pamplona, Navarra, Spain.*

Background: The aim of this prospective study is to evaluate clinical parameters associated with mortality and renal replacement therapy (RRT) in acute kidney injury (AKI).

Methods: In a cohort of 2559 patients (62 years-old SD 0.31, 71.4% male) with a diagnosis of AKI (creatinine increase > 20%) between march1996 and march2014 in a tertiary hospital center, we evaluated acute clinical index (individual severity –ISI-) ISI formula=0.032* (age decade)-0.086* (male)-0.109* (nephrotoxic) +0.109* (oliguria) +0.116* (hypotension) +0.122* (jaundice) +0.150* (coma)-0.154* (consciousness) + 0.182* (assisted respiration) +0.210.), mortality and renal replacement therapy requirement (RRT). In 674 patients we analyzed analytical parameters during AKI (peak creatinine –C-, peak C-reactive protein –CRP-, peak brain natriuretic factor -pro BNP-, minimal albumin –ALB-, basal prealbumin –PRALB-, minimal haemoglobin –Hb-) to correlate its relationship. An univariant analysis with logistic regression was made to analyzed ISI with mortality and RRT. Multivariant analysis was performed to study analitical parameters and its relationship with oliguria. SPSS version 20.0 software was used for statistical analysis.

Results: The mortality rate was 17.7% with RRT required in 26.1% of the patients. Multivariant analysis with clinical parameters included in ISI showed a relationship between mortality and coma (p=.000, OR=8.186, CI 95% 5.993-11.18), as well as oliguria (p=.000, OR=6.592, CI 95% 5.140-8.453); while RRT was associated with oliguria (p=.000, OR=17.816, CI 95% 14.27-22.32). Oliguria showed an association in Multivariant analysis (including analytical parameters) only with PRALB (p=.004, OR=.911, CI 95% 0.855-.970).

Conclusions: Protein status was associated with oliguria risk. Oliguria was associated with RRT and mortality in AKI.

FR-PO135

Association between Phase Angle and Mortality Risk in Acute Renal Failure Patients

Francisco Javier Lavilla,[1] Jorge M. Nunez-Cordoba,[2] Maria Jose Molina Higueras,[1] Nuria Garcia-Fernandez,[1] Paloma L. Martin Moreno,[1] Jose Maria Mora Gutierrez,[1] Diana Lopez Espinosa,[1] Pelayo Moiron Fdez-Felechosa,[1] Pedro Errasti.[1] *[1]Nefrologia, Clinica Univ Navarra, Pamplona, Navarra, Spain; [2]Preventive Medicine and Public Health, Clinica Univ Navarra, Pamplona, Navarra, Spain.*

Background: The phase angle (PA) is defined as the relation between the 2 vector components measured by bioelectrical impedance analysis (BIA): resistance and reactance. A low PA has been suggested to be an adverse prognostic marker of survival, although no study has evaluated their prognostic influence on Acute Renal Failure (ARF) patients. The individual severity index (ISI) estimates the probability of death. We evaluated the association between PA and ISI, and between PA and death in AKI patients.

Methods: Clinical factors, PA, and death were prospectively registered in 69 AKI patients. ISI formula=0.032* (age decade)-0.086* (male)-0.109* (nephrotoxic) +0.109* (oliguria) +0.116* (hypotension) +0.122* (jaundice) +0.150* (coma)-0.154* (consciousness) + 0.182* (assisted respiration) +0.210. Each variable is evaluated when the nephrologist sees the patient the first time, and takes a value of 1 (presence) or 0 (absence), except for the age.

Results: Patients´ characteristics: Mean age, 65.5±15.2 years; men (72.5%); mean ISI, 0.25±0.11; and mean PA, 3.95±1.47. Deaths: 10 (14.49%). The association between PA and ISI index is showed in figure 1, and the relationship between PA and predicted mortality is shown in figure 2.

Figure 1

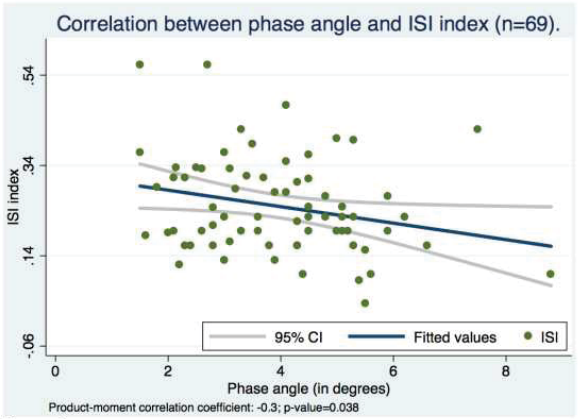

Figure 2

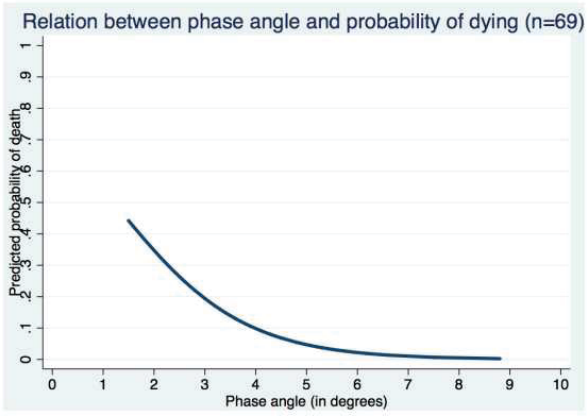

Conclusions: These findings suggest a statistically significant, moderate, and negative association between PA and ISI index. The PA appears to be a prognosis index of mortality in AKI patients.

FR-PO136

Obstetric Nephrology - Acute Kidney Injury in the Third Trimester of the Pregnancy and in the Puerperium Aline Gibson Notaro,[1] Luisa Queiroga Ferreira,[1] Ana Paula Gueiros,[1,2] Rafaella Barros da Paixão,[1] Raquel Leal de Alcantara Belfort,[1] Rodrigo Amblard Wanderley,[1] Ruben Andrade Filho,[1] Denise Maria do Nascimento Costa.[1,2] *[1]Nephrology Dept, Inst de Medicina Integral Prof. Fernando Figueira - IMIP, Recife, Pernambuco, Brazil; [2]Nephrology Div, UFPE, Recife, PE, Brazil.*

Background: Acute kidney injury in pregnancy (P-AKI) remains a cause of significant fetomaternal mortality. P-AKI occurs mainly during the late third trimester and around delivery. Hypertensive complications of pregnancy (HCP) are currently the leading cause of P-AKI. The aim of this study was to evaluate the factors responsible for P-AKI and its relation with outcomes.

Methods: Ninety-four women in the third trimester of pregnancy or in the immediate puerperium were included in this retrospective study. Demographic data, urine output (UO), HCP [preeclampsia (PE) /eclampsia (E) or hemolysis, elevated liver enzymes, and thrombocytopenia syndrome (HELLP)], sepsis and maternal mortality were noted and need for dialysis (HD) was considered. Biochemical tests were evaluated: creatinine on admission (Cr A), on arrival of nephrology (Cr N), 24-hour urinary protein (UP), hemoglobin (Hb), platelets (PT) and lactate dehydrogenase (LDH).

Results: The mean age of the patients was 26.2 ± 6.7 years and 72 (76.6%) were in immediate puerperium. The mean gestacional age was 30.4 ± 3.98 weeks. Twelve (12.8%) patients had CKD. The main causes of AKI were: Ischemic acute tubular necrosis (29.8%), PE + HEELP (25.5%), Sepsis (17%), PE (14.9%). Anuria or oliguria was observed in 29.7% cases and 35.1% required dialysis. Fourteen (15%) patients died, complete recovery was observed in 68 (72.3%), 4 patients (3 with CKD) remained on dialysis and 8 CKD patients returned to the basal creatinine or were not dependent on dialysis. Factors associated with HD were: Hb (p=0.028), Cr N (p<0.001), LDH (p<0.001) and UO (p<0.001). Maternal mortality was associated with HD (p<0.001), UO (p<0.001), sepsis (p<0.001) and LDH (p=0.01). Regarding fetal outcomes, 43.8% were preterm.

Conclusions: P-AKI is associated with a high risk for fetomaternal mortality and morbidity. HCP, notably HEELP syndrome, are the leading cause of P-AKI. LDH and UO are markers of worse outcome in pregnancy.y.

FR-PO137

Outcomes in Acute Kidney Injury-Dialysis Dependent Population Rabeeh I. El-Refadi, Tadesse Beyene, Jerry Yee, Lenar T. Yessayan. *Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Background: Acute kidney injury (AKI) is an increasingly common complication of hospitalization affecting approximately 20% of all hospitalized patients and up to 67% of patients in the ICU. Approximately 4% of critically ill patients require renal replacement therapy (RRT). As a result of AKI, patients will have longer hospital stays and may require dialysis as outpatients. However, outcomes of renal recovery of dialysis-dependent AKI remain poorly described. **Aim:** The aim of this study is to examine the renal recovery rates of patients discharged on hemodialysis.

Methods: We prospectively enrolled 40 patients who developed dialysis-dependent AKI at a single center from January 1, 2013 to December 31, 2013. AKI causes, comorbid conditions and potential contributors to AKI as well as indications for RRT were recorded by time of initiation of dialysis. Dialysis dependence and mortality were assessed at 30, 60 and 90 days. For patients who eventually transferred to outside dialysis facilities, outcome data were collected by contacting dialysis units and patients or their surrogates.

Results: 40 patients initiated on RRT in intensive care units and were subsequently discharged on dialysis. Their mean age was 59 years. 9 (23%) had sepsis as a cause of AKI. 23 (58%) had underlying CKD; 28 (70%) had hypertension; 19 (48 %) had diabetes; and 12 (30%) had underlying liver disease. A total of 4 patients were lost to follow-up. The 90-day mortality rate was 4/36 (11%). Data at successive 30-day time intervals for renal recovery, death, loss to follow-up and cumulative probability of dialysis dependency are shown in the Classical Life TIME Table.

Days	0	30	60	90
No. at risk, n	40	30	23	14
Died, n	0	2	0	2
Lost to follow-up, n	0	1	2	1
Renal recovery, n (%)	0	7 (19%)	5 (18%)	6 (30%)
Probability of dialysis dependency	100%	82%	69%	51%

Conclusions: Prospective studies examining rates of recovery from dialysis-dependent AKI are lacking. Nearly one-fifth of hospitalized AKI patients who require RRT recover by 30 days and one-third by 60 days. Of those remaining dialysis-dependent after 60 days, nearly one-third recover.

FR-PO138

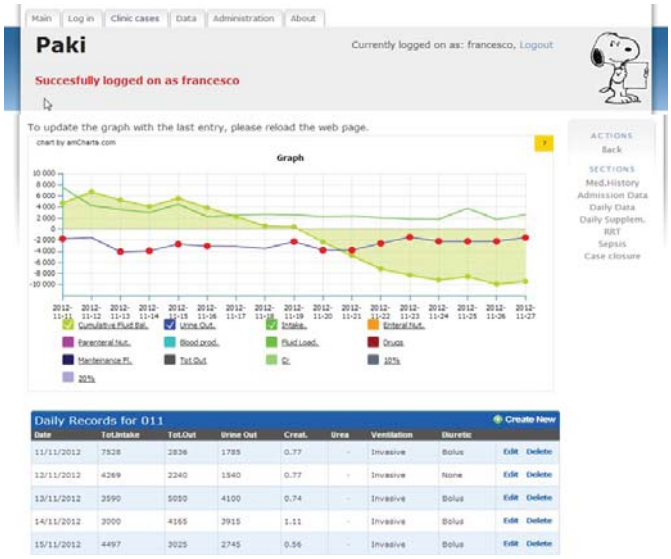
Development of a New Pediatric Acute Kidney Injury Registry Francesco Garzotto, Monica Zanella, Anna Lorenzin, Claudio Ronco. *Nephrology and IRRIV, St. Bortolo Hospital, Vicenza, Italy.*

Background: Advancements and improvements in care for critically ill pediatric population has led to fast changes in pediatric acute kidney injury AKI epidemiology. Prevalent causes leading to pediatric AKI are actually from single center's data. There is also a lack of information concerning AKI patients who did not require CRRT. The aim of the study is to: describe pediatric AKI patients, identify risk factor for AKI progression, evaluate the influence of fluid overload and type of fluids administrated (colloids, versus crystalloids versus nutrition) on clinical outcomes in AKI (w and w/o RRT) patients, describe current practices of RRT.

Methods: We developed a web-based password protected registry, dedicated to pediatric patients to support an observational and prospective international multicenter study in pediatric intensive care units pICU. Inclusion criteria: all patients admitted to pICU for almost 48h. We daily collect the amount of fluids (intake and output), diuretics, drugs, vasopressors and inotropes as well as scores and type of ventilation. Sepsis has also a dedicated section. RRT page includes dose calculation, circuit type and life, anticoagulants, type and location of catheter. Treatments done with the new carpediem machine also find their location in this section.

Results: After usability test, the registry has been designed on an open source based framework. Automated data verification system, pRIFLE calculation and alert, fluid management graph result as valid supports for fast data analysis helping in daily clinical activities.

Conclusions: The PAKI registry could represent a step forward in the description of the AKI epidemiology in pediatric patients and contribute to the resolution of the controversies regarding CRRT like initiation, dose, technique, anticoagulation.



Funding: Private Foundation Support

FR-PO139

Acute Kidney Injury among 234 In-Hospital Elderly Patients: A Single Center Retrospective Cohort Ederson Vidal Moura, Cintia Germana Mergulhão da Costa, Hugo Pinheiro, Têg Marcos Veiga, Luis H.B.C. Sette, Gisele Vajgel Fernandes, Geraldo José de Amorim, Lucila Maria Valente. *Nephrology, UFPE, Recife, PE, Brazil.*

Background: Acute kidney injury (AKI) occurs in 2-7% of all hospital admissions and at a higher rate in elderly patients (EP). However data about epidemiological profile and outcomes are poorly known in this population.

Methods: We analyzed nephrologist referral (NR) medical records from January 2011 to December 2013. AKI was evaluated at the first day of NR based on AKIN Scr criteria and CKD was defined based on prior baseline Scr >1.3 mg/dL. EP were defined as patients older than 60 years-old.

Results: Among 778 medical records analysed, 319 of them were EP, with median age of 70y and 59% were male patients. AKI was found in 154 EP (48%), acute on CKD (A-CKD) was found in 80 patients (25%), ESRD in 66 patients (21%) and in the remainder (6%) renal injury could not be classified (missing data). Sepsis was found in 37% of in-hospital EP and it was the major cause of hospital entrance (20%) and mortality (65%). Ischemic etiology of AKI, including ATN and sepsis, was the most frequent mechanism of renal injury, followed by nephrotoxic and hypovolemic etiologies. Mean Charlson Comorbity Index (CCI) was 6.59 (95% IC: 6.18 - 7.01) in AKI patients and 5.98 (95% IC: 5.49-6.46) in A-CKD patients, without significant difference. AKI patients had higher rates of mechanical ventilatory assistance and need for vasoactive agents than A-CKD patients (P=0.001). Our overall mortality rate was 31% and univariated analysis showed higher mortality in AKI group when compared to A-CKD group (P= 0.001). Interestingly,

there was no difference in mortality rate relative to dialysis requirement in AKI patients (P=0.12) and A-CKD patients (P=1.0). NR occured in earlier stages of AKIN criteria in A-CKD group compared to AKI group (P=0.0001), but there was no diference in dialysis requirement between AKI and A-CKD groups (P= 0.32).

Conclusions: Among EP, AKI was associated with worse outcomes related to A-CKD, probably due higher rates of renal dysfunction at the NR and the high rates of cardiovascular and respiratory failure in the AKI group.

Blood Oxygen Level Dependent (BOLD) Imaging to Assess Disease Severity in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Maria V. Irazabal, Timothy L. Kline, Behzad Ebrahimi, Katharina Hopp, Slobodan Macura, Lilach O. Lerman, Peter C. Harris, Bernard F. King, Vicente E. Torres, Bradley J. Erickson. *Mayo Clinic, Rochester, MN.*

Background: MRI is the gold standard imaging technique to measure kidney volumes (KV) in ADPKD patients. However, KV does not provide information on non-cystic tissue. BOLD-MRI is sensitive to the blood concentration of paramagnetic deoxyhemoglobin, which acts as an MR contrast agent. Hypoxic regions present high R_2* (BOLD index), while fluid filled spaces (urine or cysts) have low R_2* values. We evaluated the use of BOLD-MRI for fast quantification of cystic and non-cystic tissue in a mouse model *Pkd1*R3277C (RC) of human ADPKD.

Methods: Fourteen *Pkd1*$^{RC/RC}$ mice; 9 and 12 mo old, and 4 wild type (WT) controls were scanned *in vivo* using a ultra-high field (16.4T) MRI system. R_2* was calculated for the entire kidney, and its distribution in all WT was averaged and fitted to a Gaussian distribution curve. Values within 95% C.I. were considered renal parenchyma. A threshold was then set to the lower limit, and the %cystic and non-cystic tissue calculated in the *Pkd1*$^{RC/RC}$. All mice were euthanized after imaging; blood was collected for BUN and kidneys harvested for histology. Cystic index (CIx) was determined from histological sections.

Results: Fig 1A shows BOLD maps and T2 images in 2 representative *Pkd1*$^{RC/RC}$ and a WT mouse. Fig 1B shows the histograms generated from BOLD maps in all mice. Average WT R_2* was 138 1/s (95% C.I.: 58-218 1/s), lines indicating the limits. CIx correlated well with BOLD-defined % of cystic-tissue (R^2=0.89) and BUN inversely with % non-cystic tissue (R^2=0.73).

Conclusions: The percentage of cystic and non-cystic tissue derived from BOLD-MRI correlate well with histological and functional parameters in *Pkd1*$^{RC/RC}$ mice. BOLD-MRI may be a marker of disease severity and useful for following disease progression in ADPKD

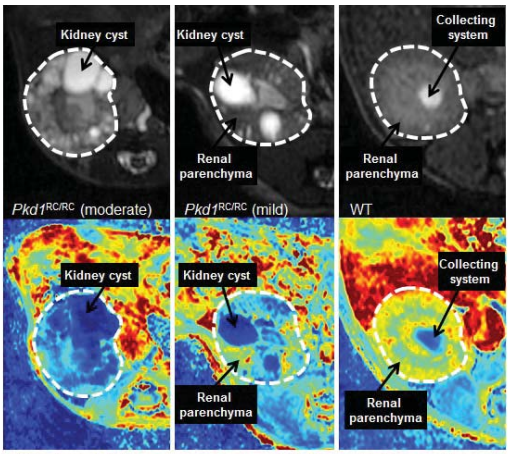

Figure 1A. T2 weighted MRI images (top row) and BOLD maps (bottom row) in 2 representative (moderate and mild disease) *Pkd1*$^{RC/RC}$ and a WT mouse.

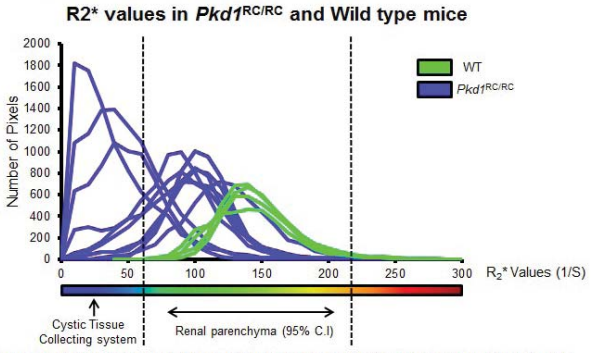

Figure 1B. Histograms generated from BOLD maps in *Pkd1*$^{RC/RC}$ (blue) and WT (green) mice.

Gender Is a Disease Modifier in an Adult-Onset *Pkd1*-Mouse Model of Autosomal Dominant Polycystic Kidney

Luis F. Menezes, Fang Zhou, Gregory G. Germino. *NIDDK, National Insts of Health, Bethesda, MD.*

Background: The NIH has recently called for greater study of the effects of gender in preclinical research. In this study, we have examined the relationship between gender and disease severity in a *Pkd1* mouse model in which conditional inactivation of Pkd1 in 40-days-old (P40) mice results in delayed-onset kidney cystogenesis starting 60 days post induction.

Methods: We injected tamoxifen in 135 P40 mice with floxed *Pkd1* alleles to delete *Pkd1* in 72 Cre-recombinase + mice (Mut: 39 males and 33 females) and 63 control mice (Cre-: 32 males and 31 females). We collected samples between P87 and P210 (Median: 160) and measured kidney/body weight (KBW; n=135), liver/body weight (LBW; n=49) and gene expression by microarray (n= 80).

Results: In mice <P100, the difference in KBW between mutant and control is not significant (n=6, p=0.6); in contrast, at P200, it is (n=6, p<0.02), consistent with the observation that kidneys look macroscopically normal ~60 days post-induction and get progressively larger and cystic with time. Analysis of covariance in cre+ mice fitting KBW to age and using gender as a categorical factor confirmed that age correlates with increased KBW (p<0.001), and showed that gender is a modifier of the rate of cyst growth (p<0.001; 2.5% to 97.5% confidence interval: 0.0072 to 0.0181), which corresponds roughly to an increase of 66% to 167% in mutant male KBW (compared to mutant females). In contrast, the liver disease shows the opposite trend: males have significantly better liver disease (p<0.05; 2.5% to 97.5% confidence interval: -0.0273 to -0.003), a LBW reduction of approximately 4% to 37%.

Conclusions: These data are consistent with reports of human studies and recapitulate an important and underappreciated aspect of ADPKD, suggesting that the model can be used to study the underlying mechanisms. The data also indicate that gender effects should be taken into account in ADPKD mouse studies. Furthermore, the magnitude of the effect is comparable to treatments tried in *Pkd1* mouse models, suggesting that understanding this phenomenon could provide novel therapeutic targets. Gene expression studies are being performed towards this goal.

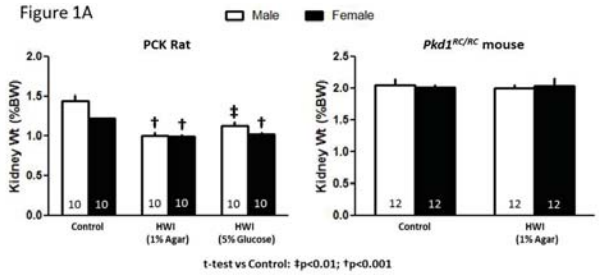
Effects of Hydration in Rodent Models of Polycystic Kidney Disease: Differences Between Rats and Mice

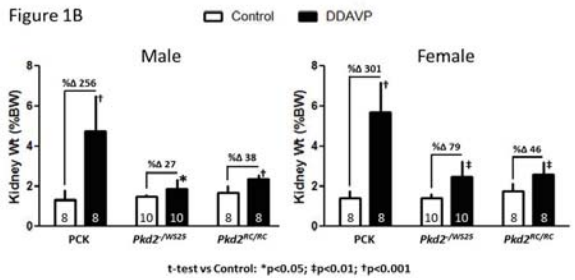
Katharina Hopp, Xiaofang Wang, Hong Ye, Maria V. Irazabal, Peter C. Harris, Vicente E. Torres. *Mayo Clinic.*

Background: Evidence that vasopressin and V2 receptor signaling promotes the progression of polycystic kidney disease (PKD) has raised the question of whether suppressing vasopressin release through enhanced hydration can delay disease progression. Enhanced hydration by adding 5% glucose to the drinking water is protective in a rat model orthologous to ARPKD. We wanted to explore the effect of enhanced hydration in a murine model orthologous to ADPKD and exclude an effect of glucose unrelated to enhanced hydration.

Methods: PCK rats were randomly assigned to control normal water intake (NWI) or to one of two high water intake groups achieved by adding 5% glucose to the drinking water (HWI-glucose) or by feeding a hydrated agar diet (HWI-agar). *Pkd1*$^{RC/RC}$ mice were assigned to NWI and HWI-agar groups. The cystogenic effect of 1-deamino-8-D-arginine vasopressin (DDAVP) was assessed in PCK rats and in *Pkd1*$^{RC/RC}$ and *Pkd2*$^{WS25/-}$ mice. Urine vasopressin, renal cAMP levels and phosphodiesterase activities were measured and histomorphometry used to assess disease severity.

Results: HWI-agar, like HWI-glucose, reduced renal cAMP levels and PKD severity in PCK rats, but not in *Pkd1*$^{RC/RC}$ mice (Fig1A). Compared to rat kidneys, murine kidneys had higher phosphodiesterase activity and lower cAMP levels and were less sensitive to the cystogenic effect of DDAVP (Fig1B).





Conclusions: The effect of enhanced hydration on PKD differs in rats and mice. A more powerful suppression of V2 receptor mediated signaling than that achievable by enhanced hydration alone may be necessary to affect the development of PKD in murine models.

Blockage of Receptor for Advanced Glycation End Products Inhibits Cyst Growth in Polycystic Kidney Disease Jong Hoon Park, Eun Young Park, Eunji Lee, Eun Sun Chang. *Dept of Life Systems, Sookmyung Women's Univ, Seoul, Republic of Korea.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited renal disorder, which is characterized by abnormal epithelial cell growth, fluid-filled cystformation, and interstitial fibrosis. Many studies have attempted to identify a new therapeutic target or striking biomarker for ADPKD,no drug has worked well in clinical trials. In this study, we focused on the receptor for advanced glycation end products (RAGE) gene as a novel target for ADPKD.

Methods: *In vitro* tests including viral infection, cell proliferation assay were performed with WT9-12 cell line, renal epithelial cells isolated from human patients with ADPKD. In addition, to examine the effect of RAGE on cyst enlargement *in vivo*, an adenovirus containing anti-RAGE shRNA was injected intravenously into PC2R mice, a severe ADPKD mouse model that we generated.

Results: We observed that RAGE gene knockdown resulted in loss of kidney weight and volume. Additionally, the cystic area that originated from different nephron segments decreased in size because of down-regulation of the RAGE gene. Blood urea nitrogen and creatinine values tended to be lower after inhibiting RAGE.

Conclusions: In conclusion, suppresion of RAGE using an adenoviral delivery system decreased cyst growth via inhibition of cell proliferation signals and improved renal function in PKD mouse. We propose that RAGE may play a role in cystogenesis and could be a new therapeutic target for PKD.

FR-PO144

Correlation of Expression of Ras-GTPase Isoforms in Rodent and Human Polycystic Kidney Disease Ayesha Irtiza-Ali,[1] Richard N. Sandford,[2] Patricia D. Wilson,[3] Bruce M. Hendry.[1] *[1]Renal Medicine, King's College London, United Kingdom; [2]Medical Genetics, Cambridge Univ, United Kingdom; [3]Nephrology, Univ College London, United Kingdom.*

Background: Small Ras GTPases act as central mediators for numerous effector cascades and are crucial in the control of cell proliferation, differentiation and apoptosis. Ras-GTPase signalling has been implicated in the pathogenesis of polycystic kidney disease (PKD), however the role of the 3 isoforms, Kirsten (Ki)-, Neural (N)- and Harvey (Ha)-Ras, in PKD are unknown. Our previous work has shown upregulation of Ki- and N-Ras isoforms across the proliferative and fibrotic phases of disease progression in an orthologous ADPKD mouse model. Here we extend our studies to examine Ras isoform expression in human polycystic kidneys, and a mouse model of recessive polycystic kidney disease.

Methods: Immunohistochemistry (IHC), qPCR and immunoblotting were used to characterize Ras isoform expression in normal and human polycystic kidney tissue, and in *pcy* mice.

Results: Similar to our findings in the *PKD1*$^{nl/nl}$ hypomorphic mice model, 2-3 fold rises in N- and Ki- Ras mRNA expression occur in pcy mice compared to wt between weeks 10 to 20, crossing both proliferative and fibrotic stages of disease ($p=<0.05$). Interestingly, in this model Ha-Ras mRNA is also elevated 2-fold during the early phase of cystic development ($p=<0.05$), declining after week 10. In human disease, Ras expression strongly localises to the epithelia of early and later stage cysts, as well as tubules in both the medulla and cortex of pre-dialysis stage polycystic kidneys (E-PKD), detected to a weaker degree in end-stage polycystic kidneys (ES-PKD), on IHC. Phospho-ERK similarly localises to these cells in human E- and ES-PKD. Furthermore, Ki-, N- and Ha- Ras isoform mRNA is detected in all stages of human PKD tissues.

Conclusions: These results show a close correlation in the cellular localisation of Ras and p-ERK expression between human ADPKD and PKD mouse models. In addition, a clear pattern of Ki- and N- Ras upregulation associated with different phases of disease progression occurs in 2 distinct models of polycystic kidney disease. These data further support a role for Ras-isoforms in PKD pathogenesis.

2'-O-Methoxyethyl Gapmer Antisense Oligonucleotides Are Efficacious for Selective Gene Targeting in Polycystic Kidney Disease Ayesha Irtiza-Ali,[1] Richard N. Sandford,[2] Dorien J.M. Peters,[3] Adam E. Mullick,[4] Bruce M. Hendry.[1] *[1]Renal Medicine, King's College London; [2]Medical Genetics, Univ of Cambridge; [3]Leiden Univ Medical Center; [4]Isis Pharmaceuticals.*

Background: Generation 2'-O-methoxyethyl (2'MOE) gapmer antisense oligonucleotides (ASOs) concentrate in the kidney as they are freely filtered through the glomerulus and efficiently re-absorbed by proximal tubular epithelial cells. Their use in PKD, where cysts can arise from all nephron segments, has not previously been extensively examined. Here, we demonstrate in several detailed studies the efficacy of 2'MOE gapmer ASOs in PKD.

Methods: 5 ASOs targeting different Kirsten-Ras sequences were investigated in normal mice, and 2 active ASOs selected for study in two murine PKD models, an ADPKD orthologous mouse, PKD1$^{nl/nl}$, and the Pcy mouse. Doses between 50-150mg/kg/week given subcutaneously for durations of 1, 2, 4 and 17 weeks were compared. Renal ASO activity and localization was analysed with qPCR and immunohistochemistry, and extra-renal effects assessed.

Results: Distribution of ASOs in normal kidney after 1 week at a dose of 60mg/kg was predominantly cortical, with uptake in the proximal and distal tubules, and collecting ducts. A striking shift in distribution occurred in the *PKD1*$^{nl/nl}$ and *Pcy* kidneys with uniform uptake across the medulla and cortex, localizing to the tubular and cystic epithelia, as well as the peri-cystic vascular endothelium, that was consistent irrespective of the dose or duration of ASO administered. Specific Ki-Ras knockdown of 60-85% was achieved in both *Pcy* and *PKD1*$^{nl/nl}$ kidneys at similar doses given for varying durations between 2 to 17 weeks. No significant differences in body weight gain, liver function tests, and spleen weights between vehicle and ASO treated groups, and no increase in renal expression of inflammatory markers MCP-1, IL1b, NFkB, and TNFa, were found.

Conclusions: 2'MOE gapmer ASOs reliably localize to target cells in cystic kidneys in two different PKD models, and achieve effective gene knockdown without significant adverse effects. We propose this as a strategy for selective gene silencing in the investigation and potential modulation of polycystic kidney disease.

Kidney-Selective AMPK Activator NT1021 Inhibits Cyst-Like Tubule Expansion in Pkd1 Mutant Kidneys Brenda S. Magenheimer,[1] Gail Reif,[1] Archana Raman,[1] James P. Calvet,[1] Ken W. Batchelor,[2] Darren P. Wallace.[1] *[1]Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS; [2]NovaTarg Therapeutics, Research Triangle Center Park, NC.*

Background: In autosomal dominant polycystic kidney disease (ADPKD), aberrant cell proliferation and transepithelial fluid secretion are responsible for cyst enlargement. Inappropriate activation of mTOR promotes cyst epithelial cell proliferation, indicating that mTOR is potential therapeutic target for slowing cyst growth. Stimulation of AMP-activated protein kinase (AMPK), an energy sensor, inhibits mTOR mediated cell proliferation and CFTR-dependent Cl^- secretion. NT1021, a novel kidney selective biguanide that is selectively transported by organic cation transporter (OCT)-2 over OCT-1, is 38 times more potent than metformin, a clinically approved AMPK activator. Previously, NT1021 decreased levels of phosphorylated S6 kinase, a downstream mediator of mTOR signaling, cell proliferation and Cl^- secretion by human ADPKD cells. Here, we determined the effect of NT1021 on cAMP-dependent cyst expansion in Pkd1 mutant kidneys.

Methods: Embryonic kidneys (E15.5) were harvested from wildtype and Pkd1 mutant (Pkd1$^{+/-}$ and Pkd1$^{-/-}$) mice and placed on permeable cell culture inserts. The kidneys were bathed in media containing 100 mM cAMP ± NT1021 (concentrations ranging from 1 to 100 mM) or 1 mM metformin. Images of kidneys were captured using a digital camera connected to a dissecting microscope and cystic area was monitored for 5 days. For each experiment, cyst area of the treated kidney was compared to that of the contralateral control-treated kidney.

Results: cAMP stimulated cyst-like tubule expansion in Pkd1$^{+/-}$ and Pkd1$^{-/-}$ kidneys to a great extent than Pkd1$^{+/+}$ kidneys. Cystic area was decreased 1.7%, 23.7% and 96.7% in Pkd1$^{+/-}$ kidneys treated with 1, 10 and 100 mM NT1021, respectively, demonstrating a concentration dependent inhibition of cyst enlargement. In Pkd1$^{-/-}$ kidneys, cystic area was decreased 95% by 100 mM NT1021, compared to 50% with 1 mM metformin. The effect of NT1021 was reversible.

Conclusions: We conclude that NT1021, a kidney-selective AMPK activator, inhibits cyst-like tubule expansion in Pkd1 mutant kidneys.

FR-PO147

Role of NKCC1/CFTR-Dependent Fluid Secretion in Postnatal Cyst Formation in Mouse Pkd1 Kidneys Brenda S. Magenheimer,[1] Xia Zhou,[1] Gunda I. Georg,[2] Joseph S. Tash,[1] Xiaogang Li,[1] James P. Calvet.[1] *[1]Univ of Kansas Medical Center, Kansas City, KS; [2]Univ of Minnesota, Minneapolis, MN.*

Background: Cyst initiation in autosomal dominant polycystic kidney disease is thought to involve focal dilation of the renal tubule followed by expansion of the dilated area until a cyst pinches off from the tubule and becomes an isolated, self-contained structure. As the cyst continues to enlarge, it fills by secretion of fluid into the cyst lumen. Cysts would not enlarge to their enormous size if it were not for this fluid secretion. We previously showed using genetic models that polycystin-1 deficient kidneys in metanephric organ culture developed cyst-like expansions that depended on NKCC1/CFTR-mediated fluid secretion. The current study investigated the requirement for NKCC1/CFTR-mediated fluid secretion in postnatal cyst development in the mouse.

Methods: H2-gamendazole (H2-GMZ) treatment was carried out on Pkd1 floxed, Pkhd1-Cre mice using daily IP injections of 10 mg/kg H2-GMZ from postnatal day 8 to 24. H2-GMZ inhibits NKCC1 and CFTR and targets a number of other pathways in cystic kidneys. Pkd1 floxed, Hoxb7-Cre mice were crossed with Nkcc1 +/- mice and with Cftr +/- mice to test the effect of homozygous Nkcc1 or Cftr deletion on postnatal cyst growth.

Results: H2-GMZ targets Hsp90 and causes decreases in NKCC1 and CFTR, both being Hsp90 client proteins. H2-GMZ also acts as an open channel inhibitor of CFTR, and thus through a combination of activities it should effectively inhibit cyst-filling fluid secretion. Pkd1 floxed, Pkhd1-Cre mice treated with H2-GMZ had significantly ($P<0.001$) decreased kidney weight/body weight ratios and blood urea nitrogen, although the kidneys remained quite cystic. Interestingly, knockout of either Nkcc1 or Cftr had a minimal effect on cystic disease in Pkd1 floxed, Hoxb7-Cre mice examined at postnatal days 7-10.

Conclusions: Rapid postnatal cyst formation in Pkd1 conditional mouse models does not appear to depend significantly on NKCC1 and CFTR, possibly because at this stage rapid cystic dilation depends on glomerular filtration more than secretion. The effects of H2-GMZ on ameliorating PKD may be due to targeting pathways other than NKCC1 and CFTR.

Funding: NIDDK Support, Private Foundation Support

FR-PO148

Effect of Sodium-Glucose Cotransport (SGLT) Inhibition on Cystic Disease Progression in PCK Rats with Autosomal Recessive Polycystic Kidney Disease (ARPKD) Sarika Kapoor,[1] Daniel Rodriguez,[1] Meliana Riwanto,[1] Ilka Edenhofer,[1] Stephan Segerer,[2] Rudolf P. Wuthrich.[2] *[1]Univ of Zurich, Switzerland; [2]Univ Hospital Zurich, Switzerland.*

Background: The SGLT inhibitors Dapagliflozin (DAPA; SGLT-2 selective) and Phlorizin (PHLO; SGLT non-selective) induce profound renal glycosuria. The role of SGLTs and the therapeutic effect of these drugs in ARPKD have not been studied.

Methods: We examined the effect of DAPA (10 mg/kg/day po) or PHLO (400 mg/kg/day sc) in PCK rats, an orthologous animal model of ARPKD. Drugs or vehicle (CON) were administered to 6 week old male PCK rats (n=8 per group) for a total of 6 weeks. Blood and urine were collected at baseline and after 3 and 6 weeks of treatment to assess parameters of renal function. Rats were sacrificed after 6 weeks, and kidneys were excised for analysis of cyst growth.

Results: DAPA significantly increased urine output (DAPA 57.3±19.2, CON 19.3±2.3 ml/day at week 6) and resulted in higher osmolar excretion (DAPA 62.5±15.8, CON 23.9±2.8 mosm/day) and higher glucose excretion (DAPA 23.4±12.0, CON 0.3±0.3 mmol/day). After 3 weeks of treatment, DAPA-treated PCK rats displayed higher clearances for creatinine (DAPA 3.06±0.40, CON 2.56±0.54 ml/min) and BUN (DAPA 1.71±0.34, CON 1.23±0.31 ml/min) whereas after 6 weeks there was no difference between DAPA and CON. Furthermore, DAPA-treated PCK rats displayed a 3.5-fold increase in albumin excretion after 6 weeks of treatment. Surprisingly, there was a 23% higher total kidney weight after 6 weeks of treatment with DAPA. *In vivo* ultrasound imaging and histological analysis also showed an increase in the cyst growth, although there was no change in the level of renal cAMP content between both groups. Likewise, PHLO-treated rats displayed enhanced medullary cyst growth by ultrasound imaging.

Conclusions: Inhibition of glucose reabsorption with SGLT inhibitors caused significant glycuresis, hyperfiltration and albuminuria in PCK rats. Unexpectedly, the cyst growth was enhanced, suggesting that the factors which regulate cyst growth act independently from the factors which control GFR. The mechanisms which link glycosuria and hyperfiltration to distal cyst growth remain to be elucidated.

FR-PO149

Ischemia-Reperfusion Injury Causes Renal Cystogenesis with Long-Term Enhanced Expression of Polycystin-1 and Polycystin-2 Marie Trudel, Almira Kurbegovic. *Institut de Recherches Cliniques de Montréal, Montreal, QC, Canada.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by multiple cysts in both kidneys leading to renal insufficiency. ADPKD is associated with mutations mainly in *PKD1* (encoding polycystin-1/PC1) and less frequently in *PKD2* gene (encoding polycystin-2/PC2). We generated several Pkd1 mouse models that support gene dosage increase in PKD pathophysiology. Dosage-increased models with mild overexpression of full-length native Pkd1 gene ($Pkd1_{TAG}$) or of extracellular domain ($Pkd1_{extra}$) mimicking natural human *PKD1* mutations develop slow progressive PKDand renal failure at >1 year of age. Since ischemia-reperfusion injury (IRI) was reported to promote earlier cyst formation in Pkd1 dosage-reduced mouse models, we questioned whether cystogenesis could be accelerated in Pkd1 dosage increase mouse models via a similar cellular and molecular mechanism.

Methods: Mice from $Pkd1_{TAG}$ and $Pkd1_{extra}$ transgenic lines were subjected to unilateral renal IRI including control littermates at 3-months of age (90 ±3.0days) and sacrificed at different time points following reperfusion.

Results: From 23 to 120 days post-IRI, all mice showed hypoplasia of the IRI kidney and a compensatory hypertrophy of the non-IRI kidney independently of the genotype. Interestingly, all transgenic (n=22) and non-transgenic (n=36) mice develop 3 months after IRI moderate to severe renal cysts with epithelial hyperplasia, immune interstitial infiltrates and fibrosis. We then questioned the molecular and signaling mechanism leading to cystogenesis in these mice. Noticeably, stimulation of Hif1a expression was detected over time. Our data also showed significantly increased expression of Pc1, Pc2 and Tsc2 (~3-to 5-fold) in the IRI kidneys of non-transgenic and transgenic mice relative to non-IRI kidneys and to mice without exposure to IRI. Such overexpression in IRI non-transgenic kidneys is consistent with cystogenesis and with dosage increase PKD pathogenesis.

Conclusions: Our results provide evidence for a combinatorial role of increase Pc1 and Pc2 in renal injury and repair and insight into IRI progressive cellular pathophysiologic mechanism.

FR-PO150

Autocrine Macrophage IL-10 Signaling Is Required for Macrophage-Promoted Polycystic Kidney Disease Cyst Cell Proliferation Jacqueline D. Peda, Sally M. Salah, Darren P. Wallace, Timothy A. Fields, Katherine Swenson-Fields. *The Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS.*

Background: We have previously shown that ADPKD cyst cells secrete factor (s) that promote M2-like macrophage differentiation and that this macrophage phenotype is pathogenic, promoting cyst cell proliferation and cyst growth. We have also shown that these M2-like macrophages secrete IL-10. Here we examined the role of IL-10 in expression of the pathogenic macrophage phenotype.

Methods: Murine macrophage-like cells [RAW 264.7 (RAW macrophages)] were cultured with primary ADPKD cyst cells in the presence/absence of IL-10 neutralizing antibody and effects on PKD cell proliferation measured by direct cell counting. Similarly, primary, mouse bone marrow-derived macrophages (BMDM) from both wild type and IL-10 knockout mice (IL10KO) were co-cultured with primary ADPKD cells. Signaling was assessed using phospho-specific Western blot analysis.

Results: Neutralization of macrophage-derived IL-10 blocked the ability of RAW macrophages to stimulate ADPKD cell proliferation. Also, primary BMDM from wild type but not IL10KO mice stimulated ADPKD cell proliferation. Moreover, the pro-proliferative macrophage phenotype could be rescued by addition of exogenous, mouse-derived IL-10 to IL10KO BMDM during co-culture, while IL-10 alone had no effect on the PKD cells.

Conclusions: Macrophages in ADPKD kidneys can be programmed by PKD cyst cells to take on a pathogenic, pro-proliferative phenotype. While the signal that initiates this differentiation process is unknown, these data suggest that an autocrine IL-10 signaling loop in macrophages is required for expression of the pathogenic phenotype.

FR-PO151

Role for the Primary Cilium in Inflammatory Responses and Cystogenesis During Kidney Maturation and Injury Cheng 'Jack' Song,[1] Bradley K. Yoder,[1] Michal Mrug.[2] *[1]Cell, Developmental, and Integrative Biology, Univ of Alabama at Birmingham, Birmingham, AL; [2]General Clinical Research Center, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Studies utilizing conditional IFT mutations suggest that the rate of cyst formation is dependent upon the timing of cilia loss. Induction of cilia loss in juvenile mice (before postnatal day 12) results in rapid cyst development while induction of cilia loss after P12 (critical switch point) or in adult mice causes a much slower progressing form of cystic disease. Interestingly, rapid cyst formation can be initiated in the adult-induced IFT mutants by ischemic reperfusion (IR) injury suggesting a possible role for inflammation in cyst development. This was recently confirmed by liposome clodronate (LC) mediated depletion of phagocytic macrophages that reduced cystic disease severity and improved renal function. The mechanism connecting an injury response, cilia dysfunction, and cyst formation remains poorly defined and it is not understood why cystogenic rates are markedly different in juvenile versus adult-induced cilia mutants. Here we investigate potential connections between primary cilia associated cystogenesis and an altered inflammatory response.

Methods: We used Immunofluorescence staining and flow cytometry to characterize different macrophage populations. qRT-PCR will be used to access the cytokine expression in these different macrophage populations.

Results: Our preliminary data show there is a similar kidney macrophage populations that accumulates in juvenile-induced as well as in adult-induced cilia mutants following IR injury. Importantly, this population of macrophages rapidly dissipates after the critical switch point and is not present in the adult-induced non-injured kidney.

Conclusions: We are testing the hypothesis that these are pathogenic macrophages capable of promoting cystogenesis. This would help explain the large differences in the rate of cyst progression observed in cilia mutant mice. This work will shed new light on mechanisms contributing to the rate of cyst formation associated with cilia dysfunction and provide possible targets for therapeutic intervention.

Vasopressin V2 Receptor Independent Anti-Inflammatory Effect of Tolvaptan in Kidney Cells Osamu Takase, Masaomi Nangaku, Keiichi Hishikawa. *Dept of Advanced Nephrology and ReGenerative Medicine, Div of Nephrology and Endocrinology, Graduate School of Medicine, Univ of Tokyo, Tokyo, Japan.*

Background: Tolvaptan is a highly selective vasopressin V2 receptor antagonist, and is useful for the treatment of congestive heart failure. Lots of studies demonstrated renoprotective effects of long-term tolvaptan therapy, and tolvaptan is also expected to be a candidate for treatment of autosomal dominant polycystic kidney disease. However, the renoprotective effect of tolvaptan and its underlying mechanisms remain unknown. In this study, we investigated the vasopressin V2 receptor independent renoprotective effect of tolvaptan, especially on NF-kappaB activation, *in vitro.*

Methods: We studied the effect of tolvaptan related to inflammation and apoptosis in human renal tubular injury stimulated by LPS. NF-kappaB activity, NF-kappaB-associated inflammatory factors, and apoptosis were examined by EMSA, western blot, ELISA, and

Hoechst staining. Also we knocked down the NF-kappaB or IkBa activity using siRNA treatment in order to explore the effect on the NF-kappaB as a nuclear transcription factor, which plays a central role of inflammation.

Results: Tolvaptan inhibited the NF-kappaB activity and the expression of NF-kappaB-associated inflammatory factors in LPS-stimulated cultured human renal tubular cells. Pre-treatment with siRNA for IkBa significantly diminished inhibitory effect of tolvaptan on NF-kappaB activity. Interestingly, tolvaptan increased the expression of clusterin which stabilizes IkBa. These results showed that tolvaptan inhibited NF-kappaB activity by stabilizing IkBa or clusterin, independent of vasopressin V2 receptor. Tolvaptan also augmented LPS-induced apoptosis by NF-kappaB-AP-1 related extrinsic pathway, but not intrinsic pathway.

Conclusions: Our results for the first time demonstrated the direct inhibitory effect of tolvaptan on LPS-induced NF-kappaB activity independent of vasopressin V2 receptor in human renal tubular cells. Our results suggest the new anti-inflammatory renoprotective roles of tolvaptan beyond diuresis.

FR-PO153

Regulation of Fluid Secretion by Ouabain in Autosomal Dominant Polycystic Kidney Disease Gustavo Blanco,[1,4] Kyle Jansson,[1,4] Brenda S. Magenheimer,[3,4] James P. Calvet,[3,4] Darren P. Wallace.[2,4] *[1]Molecular and Integrative Physiology, Univ of Kansas Medical Center, Kansas City, KS; [2]Medicine, Univ of Kansas Medical Center, Kansas City, KS; [3]Biochemistry and Molecular Biology, Univ of Kansas Medical Center, Kansas City, KS; [4]The Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS.*

Background: Enlargement of renal cysts in autosomal dominant polycystic kidney disease (ADPKD) requires the transepithelial secretion of fluid into the cyst lumen. We had previously shown that physiological levels of the hormone ouabain enhance cAMP-dependent fluid secretion in epithelial cells derived from renal cysts of patients with ADPKD (ADPKD cells) and cyst expansions in metanephric organs from ADPKD mice. In contrast, ouabain only slightly affects normal human kidney cells and metanephroi. Here, we have investigated the mechanisms by which ouabain stimulates ADPKD fluid secretion and cystogenesis.

Methods: The effects of physiologic amounts of ouabain (3nM) on ADPKD ion/fluid movement was studied in mouse metanephric organ cultures and in ADPKD cell cultures, using different transport assays.

Results: Ouabain, synergistically with cAMP, induced cystic dilations in embryonic kidneys from $Pkd1^{m1Bei}$ mice, but had no effect on $Pkd1^{m1Bei}$ mouse metanephroi that also lacked the cystic fibrosis transmembrane conductance regulator (CFTR). Similarly, in ADPKD cells, ouabain stimulation of cAMP-induced fluid secretion and microcyst growth required the activity of CFTR. Ouabain enhanced forskolin-dependent and CFTR mediated Cl^- efflux in ADPKD monolayers by increasing plasma membrane levels of CFTR and expression of the CFTR activator PDZK1. In addition, ouabain decreased ADPKD cell basolateral Na^+ transport by partially reducing Na,K-ATPase plasma membrane amounts and activity.

Conclusions: Ouabain enhances fluid secretion in ADPKD by both increasing the apical efflux of Cl^- via activation of CFTR, and by decreasing basolateral fluid reabsorption through down-regulation of the Na,K-ATPase. These mechanisms further highlight the importance of ouabain as a non-genetic factor capable of stimulating ADPKD cystogenesis.

ADAM17 Regulates Cellular Bioenergetics in Polycystic Kidney Disease (PKD) Monika Beck Gooz,[1] Eduardo Maldonado,[1] Yujing Dang,[1] Hanna E. Abboud,[2] John J. Lemasters,[1] P. Darwin Bell.[1,3] *[1]Medical Univ of South Carolina, Charleston, SC; [2]Univ of Texas Health Science Center, San Antonio, TX; [3]R.H. Johnson VA Medical Center, Charleston, SC.*

Background: Recently, we found that the disintegrin metalloenzyme ADAM17 promotes proliferation of collecting duct kidney epithelial cells originating from the *Ift88*^{orpk} mice model of PKD through extracellular signal-regulated kinase (ERK) activation and increased glycolysis. In this study we investigated the effect of increased ADAM17 activation on mitochondrial bioenergetics in PKD cells.

Methods: We used immortalized control and PKD collecting duct cells. We assessed ERK activation and ADAM17 expression by Western blotting and ADAM17 activity by a fluorogenic substrate. We measured ROS production by the ROS substrate CM-H_2DCFDA, determined mitochondrial respiration by a Seahorse XF Analyzer, and measured nicotinamide adenine dinucleotide (NADH) autofluorescence by confocal multiphoton microscopy. We assessed mitochondrial membrane potential (DY) by tetramethyl rhodamine methyl ester fluorescence and expression of the mitochondrial uncoupling protein-2 (UCP2) by Western blotting.

Results: Expression and enzyme activity of ADAM17, and the level of phosphorylated ERK were higher (2-fold, 2-fold and 4-fold, respectively) in PKD cells compared to the less proliferative control cells. PKD cells also had higher basal respiration and ROS production than control cells: 440±31 versus 278±39 pmol O_2/min/10,000 cells and 0.41±0.04 versus 0.26±0.01 arbitrary units, respectively. NADH levels were 36±15% higher in PKD cells compared to control cells. Expression of UCP2 was 1.7-fold higher and DY was 50% lower in PKD cells compared to control cells. Chemical inhibition of ADAM17 (10 µM TMI-005, Pfizer) inhibited ERK activation, decreased ROS production, decreased both basal respiration (365±9 pmoles/min) and NADH levels and increased DY in PKD cells to the level of control cells.

Conclusions: Our data suggest that upregulation of the pro-proliferative ADAM17 activates an ADAM17/ERK/mitochondrial ROS loop, causing increased mitochondrial metabolism and aerobic glycolysis (incomplete Warburg effect) possibly due to UCP2 activation to promote cell proliferation in PKD.

Exosome Based Biomarkers for Polycystic Kidney Disease Christopher James Ward,[1] Marie C. Hogan.[2] *[1]Div of Nephrology and Hypertension, KUMC, Kansas City, KS; [2]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a common cause of ESRD. Affected individuals inherit a defective copy of either the *PKD1* or *PKD2* gene, encoding the proteins polycystin–1 (PC1) or polycystin–2 (PC2) respectively. PC1 and PC2 are secreted on urinary exosome–like vesicles (ELVs) (100nm diameter vesicles), where PC1 is present in a cleaved form and may be complexed with PC2. Label free quantitative proteomic studies of urine ELVs in an initial discovery cohort (13 PKD1 and 18 Normals), revealed that of 2008 ELV proteins, nine (0.32%) showed a statistically significant difference between PKD1 and normals at a $p<0.025$.PC1 was reduced to 54% of the normal level ($p=0.011$) and PC2 reduced to 53% ($p=0.0004$).TMEM2, a protein with homology to fibrocystin, the product of the polycystic hepatic and kidney disease (*PKHD1*) gene, is increased 2.1 fold ($p=0.022$). The PC1/TMEM2 ratio correlated inversely with height adjusted total kidney volume (HtTKV) in the discovery cohort and the ratio of PC1/TMEM2 or PC2/TMEM2 could be used to distinguish PKD1 from normals in a confirmation cohort.

Methods: We have developed a novel high throughput western assay to measure the ratio of PC1 to TMEM2 or PDCD6IP (ALIX), a protein that is not altered in level. The assay uses 100ml of raw urine thus avoiding the use of an ultracentrifuge.

Results: We are able to detect PC1, TMEM2 and PDCD6IP in normal urine and measure the ratios of PC1/TMEM2 and PC1/PDCD6IP in normal and ADPKD urines.

Conclusions: Our high throughput western blotting technique offers the possibility of monitoring the PC1/TMEM2 ratio in ADPKD patients. We believe this ratio may correlate with disease status and might be useful in monitoring the disease state in individuals undergoing treatment for the disease.

Polycystin-1 Regulates the Bioactivities of Exosomes Derived From Kidney Epithelial Cells Gang Yao, Hansong Xu, Yanan Chen, Maria Rasmussen, Maoqing Wu, Xuefeng Su, Jing Zhou. *Renal Div, Dept of Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: Polycystin-1 (PC1) is an integral membrane protein essential for tubule morphogenesis, and its disruption causes autosomal dominant polycystic kidney disease (ADPKD). Exosomes are small membrane vesicles with a diameter of 40-100 nm that originate as internal vesicles of multivesicular bodies (MVBs). They are secreted by various cell types and are involved in multiple biological processes. Exosomes are abundant in human urine and PC1 is abundant in these human urinary exosomes. However, the function of the PC1-containing exosome is unknown.

Methods: We isolated exosomes from the wild-type and *Pkd1*-knockout mouse kidney epithelial cells using a well established differential centrifugation protocol. By utilizing immunoelectron microscopy, biochemistry, cell biology, and live cell imaging, we investigated the functions of PC1-containing and PC1-free exosomes in several biological assays known to contribute to cytogenesis in human ADPKD patients and mouse ADPKD models.

Results: We show by immunoelectron microscopy that PC1 colocalized with exosomal marker CD63 and an FCH Bin–Amphiphysin–Rvs (F-BAR) protein important for vesicle trafficking in exosomes derived from cultured kidney epithelial cells. Depletion of the F-BAR protein significantly reduced the abundance of exosomal PC1. Comparative analysis of the effects of exosomes isolated from wild-type and *Pkd1*-knockout mouse kidney epithelial cells revealed that the PC1-containing exosomes were bioactive, promoted cell migration and cell signaling, yet inhibited cell proliferation. PC1-null exosomes were defective in these activities. We established a cilium-knockout kidney epithelial cell line and investigated the roles of primary cilium in the secretion of PC1-containing exosomes and bioactivities mediated by exosomes.

Conclusions: Our data demonstrates, for the first time, that PC1-containing exosomes are bioactive and regulate multiple cell behaviors in kidney epithelial cells. The abundance of PC1-containing exosomes is regulated by an F-Bar protein. This work also represents the first functional study of exosomes derived from cilium-deficient cells.

The Role of Polycystin 1 GPS Cleavage in Vascular Development Patricia Outeda, Kathleen Mcavoy, Feng Qian, Terry J. Watnick. *Dept of Medicine, Div of Nephrology, Univ of Maryland, School of Medicine, Baltimore, MD.*

Background: Polycystin-1 (PC1) plays an important role during development. $Pkd1^{-/-}$ embryos die at mid-gestation with a variety of phenotypes including cystic kidneys and profound edema due to aberrant lymphatic vessel development. It was previously shown

that PC1 undergoes incomplete cleavage at the GPS domain (GPCR proteolytic site). Mice with disrupted PC1 GPS cleavage (*Pkd1*$^{v/v}$) appear normal at birth but develop polycystic kidneys during the postnatal period.

Results: To examine the role of GPS cleavage in the vasculature during development we harvested *Pkd1*$^{-/-}$, *Pkd1*$^{v/v}$ and controls (WT) embryos at E14.5. While severe polyhydramnios and edema were observed in *Pkd1*$^{-/-}$ embryos, no obvious phenotype was observed in *Pkd1*$^{v/v}$ embryos. We performed whole mount staining of skin with Lyve1 or Nrp2 (lymphatic endothelial cell (LEC) markers) and we found that *Pkd1*$^{-/-}$ embryos exhibited a dilated and disorganized lymphatic network with decreased branching compared to controls. In contrast, there was no difference in the lymphatic network between *Pkd1*$^{v/v}$ embryos and controls. Next, we focused on the placental vasculature that was previously shown to be abnormal in *Pkd1*$^{-/-}$ embryos. Paraffin sections were stained with Isolectin B4 (embryonic endothelial cell marker), and Laminin. Although *Pkd1*$^{-/-}$ embryos exhibited a decrease in fetal vessels with reduced branching, the placental vasculature appeared normal in the *Pkd1*$^{v/v}$ animals. We cultured MEF cells from *Pkd1*$^{-/-}$, *Pkd1*$^{v/v}$ and control embryos. We found that *Pkd1*$^{-/-}$ cells have an intrinsic defect in directed migration but *Pkd1*$^{v/v}$ cells behave normally.

Conclusions: Our results suggests that uncleaved PC1 is fully sufficient for proper vascular development.

RNA-Guided Editing of Mouse *Pkhd1* in Kidney Epithelial Cells Using CRISPR-Cas9 system Maoqing Wu, Benjamin S. Freedman, Xuefeng Su, Jing Zhou. *Harvard Center for Polycystic Kidney Disease Research and Renal Div, Dept of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Progress on research of autosomal recessive polycystic kidney disease (ARPKD) is hindered by the scarcity of human tissue samples, and the lack of a satisfactory mouse model that mimics the phenotypes in human ARPKD. The establishment of cell models by small hairpin RNA has been challenged by the large size of the *PKDH1* gene, the complexity of the splicing patterns.Mouse *Pkhd1* contains 67 exons and likely produces multiple isoforms. The clustered regularly interspaced short palindromic repeats (CRISPR) /Cas9 system is a newly developed technique and has become a powerful tool to mediate genome editing with high precision, which allows the one-step generation of animals and cell lines carrying mutations in multiple genes as well as distinct mutations in a single gene. It is particularly useful to edit genes encoding multiple alternatively spliced isoforms that may cause functional redundancy.

Methods: We searched for the CRISPR/Cas9 binding site conforming to the sequence G (N) $_{19}$NGG in the most commonly used exon (present in most of splicing variants) of *Pkhd1* as previously reported. We designed the guide (g) RNA and cloned it into pX330, a gRNA vector. The gRNA plasmids were then co-transfected with pCas9-GFP into mIMCD-3 cells. pCas9-GFP positive cells were selected by flow cytometry.

Results: Twelve lines derived from single GFP-positive cells were screened by PCR of the mutated region. Mutations in *Pkhd1* were identified in all lines by direct sequencing of PCR products. One homozygous line with deletion of the most commonly used exon was identified. Results on the characterization of these cell lines will be presented.

Conclusions: We have successfully established a *Pkhd1* deletion mutant cell line using CRISPR/Cas9 system. This is the first report of using the CRISPR/Cas9 system for functional studies of a PKD gene. We believe genomic editing is a powerful alternative to small hairpin RNA-mediated knockdown of complex genes such as *PKHD1*.

Genome Editing-Mediated Deletion of *Pkd2* in mIMCD3 Cells Disrupts Epithelial Morphogenesis Alexis Hofherr, Michael Kottgen. *Renal Div - Dept of Medicine, Univ Medical Center Freiburg, Freiburg im Breisgau, Baden-Württemberg, Germany.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most prevalent inherited cause for end-stage renal disease in the United States. It is defined by the age-dependent massive enlargement of both kidneys, which is characterized by dilated or cystic renal tubular segments. The two causative genes *PKD1* and *PKD2* encode together for a sensory receptor-channel complex that is required for renal tubular morphogenesis. Yet, the molecular function of the Polycystin-1/TRPP2 signaling module has remained elusive. To investigate the polycystin complex on a biochemical level, the establishment of suitable orthologous *in vitro* model systems is essential. Loss of function cell lines from knockout mice or RNAi-mediated depletion of PKD-genes have provided valuable insights, but are compromised by technical challenges including lack of cellular differentiation *in vitro*, poor scalability, incomplete knockdown, and putative RNAi off-target effects.

Methods: Here we present the site-specific genome engineering-mediated deletion of *Pkd2* in mouse inner medullary collecting duct (mIMCD3) cells using Transcription Activator-Like Effector Nucleases (TALENs). Wildtype mIMCD3 cells retain core differentiation characteristics of the collecting duct, e.g. apico-basolateral polarization, epithelial transport, and tight junctions.

Results: In contrast to the distinctive *in vivo* phenotype of loss of *Pkd2*, the epithelial morphology of these *Pkd2*$^{-/-}$ cells is not impaired in 2D cell culture. This is in line with previously described *Pkd2* depletion experiments. However, in a complex extracellular matrix environment *mIMCD3 PKD2*$^{-/-}$ cells show a marked defect of proper epithelial organization, with break down of the epithelial monolayer and cytoskeletal aberrations. In 3D culture these cells present with a prominent and easy to score phenotype, which may serve as a readout for impaired tubular morphogenesis *in vivo*.

Conclusions: In this proof of concept study we establish that *PKD2* is required for epithelial morphogenesis *in vitro*; and that the directed manipulation of PKD genes provides novel opportunities to model polycystin protein function.

An E3 Ligase Complex Is Critical for Polycystin-2 Ciliary Trafficking in *Drosophila* Weizhe Li, Stacey Cook, Terry J. Watnick. *Univ of Maryland Baltimore, Baltimore, MD.*

Background: Ciliary dysfunction can cause a variety of severe human diseases including Autosomal Dominant Polycystic Kidney Disease (ADPKD). Ciliary localization of Polycystin-1 and Polycystin-2, the protein products of ADPKD genes, is critical for their function, but how these proteins traffic to cilia remains largely unknown.

Methods: We have been using Drosophila as a model to address this question. The homologue of polycystin-2 in Drosophila (dPKD2) is localized at the tip of sperm tails, which can be regarded as specialized cilia. We used a collection of EMS mutant flies to screen for proteins that might be required for dPKD2 to reach the tip of the sperm tail.

Results: We identified one line, Z2-5905, that showed absent sperm staining for dPKD2, while the overall expression level in the testis was similar to wild type. We found that Z2-5905 harbors a truncating mutation in a gene, that we named zuba, which contains a UBA (ubiquitin associated) domain. We used homologous recombination to generate a knock-out allele and showed that it had the same phenotype as Z2-5905. We were able to rescue dPKD2 sperm localization in both zuba alleles using a genomic rescue construct. We developed an antibody against Zuba and found that the protein was almost exclusively expressed in the testis and mature sperm. In addition, we found that Zuba isolated from mature sperm is monoubiquitinated. We also identified an E3-ligase that we speculated might interact with Zuba. We used shRNA to knock down this E3 ligase and found that male flies show the same phenotype as Z2-5905, including male sterility and dPKD2 mislocalization at the tip of sperm tails. In addition, knock down of this E3 ligase resulted in the specific absence of the monoubiquitinated form of Zuba in mature sperm while keeping the unmodified form in testis intact. We are currently testing whether these proteins physically interact.

Conclusions: In conclusion, we found an E3 ligase complex that is required for polycystin-2 ciliary localization in flies. The E3 ligase and Zuba show 34% and 28% identity with their corresponding mammalian homologues. Future experiments will explore the role of vertebrate homologues in ciliary trafficking.

FR-PO162

Cilia Trafficking Defective Mutation in PC2 Results in Complete Loss of Function *In Vivo* Xin Tian, Yiqiang Cai, Seung H. Lee, Stefan Somlo. *Internal Medicine/Section of Nephrology, Yale Univ School of Medicine, New Haven, CT.*

Background: Polycystin-2 (PC2) is expressed in cilia of kidney tubule epithelia and it has been demonstrated in LLC-PK1 cells that an N-terminal motif, R_6VxP is required for cilia localization of PC2.

Methods: To elucidate the function R_6VxP motif in vivo, we developed a BAC (Bacterial Artificial Chromosome) transgenic mouse model, *Pkd2*^{GAxA} -BAC expressing a substitution mutant R_6VxP motif, G_6AxA, that abrogates cilia trafficking *in vitro. Three founder lines (#17, 45 and 71) with germ line transmission had Pkd2*^{GAxA} -BAC transgene copy numbers of 2, 4 and 5, respectively.

Results: *Mice expressing Pkd2*^{GAxA} -BAC are viable, fertile and do not develop polycystic disease up to 12 months. We generated *Pkd2*^{GAxA} -BAC transgenic mice on the *Pkd2*$^{-/-}$ background to determine whether PC2 deficient in cilia trafficking can rescue any part of the embryonically lethal null phenotype. We documented expression of the transgenic PC2 and found that *Pkd2*^{GAxA} -BAC;*Pkd2*$^{-/-}$ mice are *embryonically lethal* by E15.5, comparable to *Pkd2*$^{-/-}$mice. *The left-right axis defect in Pkd2*$^{-/-}$ *was not affected by the Pkd2*^{GAxA} -BAC transgene. We also crossed the *Pkd2*^{GAxA} -BAC transgene with *Pkd2*^{flox};*Pkhd1-Cre* mouse line, in which *Pkd2* is inactivated exclusively in collecting duct. Histological and functional examination of kidneys from *Pkd2*$^{flox/flox}$;*Pkhd1-Cre;Pkd2*[/italic]^{GAxA} -BAC mice at P24 showed no significant change in kidney weight, cystic index and serum BUN when compared with *Pkd2*$^{flox/flox}$;*Pkhd1-Cre* mice. There was no significant difference in cyst lining cell proliferation (BrdU incorporation) and apoptotic activity (TUNEL) between two groups. Cilia in cyst lining epithelium appeared normal by immunofluorescence microscopy, and immunostaining with anti-PC2 antibody indicated that the PC2 cytosolic expression pattern was well maintained, but cilia expression was absent.

Conclusions: These results indicate that mutation in R_6VxP motif can prevent PC2 trafficking to cilia and result in complete loss of PC2 function *in vivo.*

FR-PO163

The Net Effect of Actin Binding Protein Filamin-A on Regulating Polycystin-2 Qian Wang,[1] Horacio Cantiello,[2] Xing-Zhen Chen.[1] *[1]Physiology, Univ of Alberta, Edmonton, AB, Canada; [2]Cátedra de Biofísica, Facultad de Odontología, Univ de Buenos Aires, Buenos Aires, Argentina.*

Background: Polycystin-2 (PC2), encoded by the PKD2 gene, is a Ca-permeable cation channel mutated in ~15% of autosomal dominant polycystic kidney disease (ADPKD). PC2 is mainly localized on the endoplasmic reticulum (ER) membrane, and is also present on the plasma membrane and primary cilium.

Methods: Lipid bilayer is used to study PC2 channel function in vitro by reconstituting purified PC2 protein; Live cell Ca imaging is to measure ER-localized PC2 function in vivo.

Results: Previously we reported that cytoskeletal actin-binding protein filamin-A (FLNA) reduces PC2 channel activity in a lipid bilayer system through direct binding with both the N- and C-termini of PC2. On the other hand, our data submitted for publication showed that FLNA stabilizes PC2 protein expression by anchoring it to the actin cytoskeleton. The apparent contradiction was solved by the observations that FLNA did not exhibit an inhibitory effect on PC2 channel activity in the absence of Ca in lipid bilayer system, and that Ca chelation by EGTA dramatically weakened the PC2-FLNA interaction. Thus, the inhibition of PC2 channel function by FLNA may be Ca-dependent in living cells. Next, we employed live cell Ca imaging technique to study the net effect of FLNA on PC2 (expression and function) in vivo. We found that PC2 silencing by siRNA increases ER Ca content, which is consistent with previous publication proposing that PC2 is an ER Ca leak channel. With FLNA silencing, a decreased ER Ca content was observed, indicating a high PC2 channel activity.

Conclusions: Thus, we think that the net effect of FLNA is to inhibit PC2 channel activity.

FR-PO164

The Effect of Polycystin-2 Disruption on the Osmotic Response of Renal Epithelial Cells Brian J. Siroky,[1] Nancy Kleene,[2] Raven Gail Comer,[1] Steven Kleene,[2] Bradley P. Dixon.[1] *[1]Div of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Dept of Molecular and Cellular Physiology, Univ of Cincinnati College of Medicine, Cincinnati, OH.*

Background: Renal epithelial cells exposed to hyperosmolality in the inner medulla withstand these conditions by activating the osmotic stress response. Primary cilia detect mechanical and chemical stimuli including osmolality. We have previously shown that renal epithelial cells with loss of cilia formation due to *Kif3a* deletion have an attenuated osmotic response, and that TRPM3 is involved in cilia-dependent osmosensation. It is unknown whether the osmotic response is compromised in cells that harbor functional, rather than structural, defects in cilia. We characterized the osmotic response of renal epithelial cells deficient in polycystin-2 (PC2), a protein expressed in primary cilia that is defective in some patients with autosomal dominant polycystic kidney disease (ADPKD).

Methods: Murine inner medullary collecting duct (mIMCD3) cells were transduced with an shRNA construct targeting *Pkd2*, or a non-target control sequence. PC2 expression was reduced by 90% by the *Pkd2* shRNA construct as determined by immunoblotting, and cilia structure was normal in both cell lines as observed by immunofluorescence. Both cell lines were exposed to hyperosmolal culture conditions with NaCl (500 mOsm/kg), or maintained under isoosmolal conditions (300 mOsm/kg) in the presence of pregnenolone, an agonist for TRPM3, or DMSO vehicle. Western blotting for aldose reductase (AR), an osmotic response protein, was performed on whole cell lysates.

Results: Induction of AR expression by hyperosmolality was markedly reduced in PC2 knockdown cells compared to non-target controls. Pregnenolone attenuated the AR induction in non-target control cells only.

Conclusions: We demonstrate a novel finding of diminished osmotic response in mIMCD3 cells with reduced PC2 expression, but intact cilia structure, suggesting that impaired osmoregulation may play a role in ADPKD pathogenesis. Further, the impaired osmotic response in PC2-deficient cells may result from altered TRPM3 activity.

FR-PO165

Osteoblast-Specific Deletion of *Pkd2* Leads to Low-Turnover Osteopenia and Reduced Bone Marrow Adiposity Zhousheng Xiao, Leigh Darryl Quarles. *Univ of Tennessee Health Science Center, Memphis, TN.*

Background: Polycystin-1 (Pkd1) and polycystin-2 (Pkd2) are implicated in skeletal development. Selective deletion of Pkd1 the osteoblasts lineage in mice inhibits osteoblast differentiation and stimulates adipogenesis through the reciprocal regulation of Runx2 and PPARg. The osteoblast specific functions of Pkd2 have not been defined.

Methods: We conditionally inactivated Pkd2 in postnatal mature osteoblasts by crossing Osteocalcin (Oc)-Cre;$Pkd2^{/+}$ mice with floxed Pkd2 ($Pkd2^{flox/flox}$) mice to generate conditional heterozygous (Oc-Cre;$Pkd2^{flox/+}$) and homozygous (Oc-Cre;$Pkd2^{flox/null}$) Pkd2-deficient mice.

Results: Pkd2 expression was reduced by ~75% in bone of Oc-Cre;$Pkd2^{flox/null}$ mice. Oc-Cre;$Pkd2^{flox/null}$, and Oc-Cre;$Pkd2^{flox/+}$ demonstrated no cyst formation in the kidney. Compared to $Pkd2^{flox/+}$ control mice, Pkd2-deficiency resulted in a reduction in bone mineral density, trabecular bone volume, cortical thickness and mineral apposition rate that were associated with significant alterations in biomechanical properties, including a reduction in maximum force and stiffness. Similar to Pkd1 deficiency, loss of Pkd2 in osteoblasts resulted in diminished Runx2 expression in bone and impaired osteoblast differentiation of osteoblast cultures ex vivo. Expression of osteoblast-related genes, including, Osteocalcin, Osteopontin, Bone Sialoprotein, Phex, Dmp1, and Sost, were reduced proportionate to the reduction of Pkd2 gene dose in bone of Oc-Cre;$Pkd2^{flox/+}$ and Oc-Cre;$Pkd2^{flox/null}$ mice. Significant reductions in both serum concentrations and bone mRNA expression of FGF23, RankL and TRAP were also observed in Oc-Cre;$Pkd2^{flox/null}$ mice compared to controls. In contrast to Pkd1 deficient mice, loss of Pkd2 in bone resulted in diminished PPARg expression and reduced bone marrow fat in vivo and reduced adipogenesis in osteoblast culture ex vivo.

Conclusions: The selective loss-of-Pkd2 in osteoblasts inhibits both osteoblast differentiation and adipogenesis. Thus, Pkd1 and Pkd2 have concordant effects on osteoblast differentiation, but opposite effects on skeletal adipogenesis through signaling mechanisms that remain to be elucidated.

Phenotype Rescue in the *cpk* Mouse Model By a Conditional, Inducible Transgene Targeted to the ROSA26 Locus Chaozhe Yang, Amber K. O'connor, Jacob A. Watts, Lisa M. Guay-Woodford. *Children's National Medical Center.*

Background: Mouse models have been instrumental in the characterization of polycystic kidney disease (PKD). Unfortunately, gene-targeting of *Pkhd1*, the mouse ortholog of the autosomal recessive PKD gene, results in minimal or no kidney disease. However, the *cpk* mouse renal lesion phenocopies human ARPKD. We previously identified *Cys1* as the disease-causing gene in this model. Interestingly, initial efforts to rescue the renal phenotype via standard, random-insertion, transgenic approaches were unsuccessful, despite *Cys1 re*-expression.

Methods: A *Cys1-GFP* fusion gene was cloned into a ROSA26 targeting construct to create a knock-in line (ROSA26-$Cys1^{GFP}$). $B6^{cpk/+}$ mice were then crossed with ROSA26-$Cys1^{GFP}$ mice to generate the ROSA26-$Cys1^{GFP}$;$Cys1^{cpk/+}$ line. In this model, gene activation requires the deletion of a stop-lox cassette using a Cre recombinase. Therefore, we mated this line to Ksp-Cre mice to express *Cys1-GFP* in the renal collecting ducts, the major nephron segment involved in ARPKD.

Results: At 6-weeks of age, kidneys harvested from putative rescue mice (ROSA26-$Cys1^{GFP}$;$Cys1^{cpk/cpk}$;Ksp-Cre) and control mice (ROSA26-$Cys1^{GFP}$;$Cys1^{+/+}$;Ksp-Cre and ROSA26-$Cys1^{GFP}$;$Cys1^{cpk/cpk}$) were comparatively evaluated by H&E staining, immunoblotting, and immunofluorescent analysis. In rescued kidneys, fluorescence was detected in collecting duct structures, confirming nephron-specific, Ksp-driven expression of the *Cys1-GFP* transgene. The renal phenotype in the rescue mice was comparable to normal kidneys, save for a few scattered cysts that were of proximal tubular origin.

Conclusions: Using a conditional, inducible *Cys1-GFP* transgene targeted to the ROSA26 locus, we have rescued the *cpk* phenotype by re-expressing *Cys1* within the collecting ducts. Our data suggest that a "set point" of *Cys1* expression is required for renal tubular homeostasis and significant alterations in gene expression are not tolerated, as has been observed for other cystoproteins.

Tandem Affinity Purification (TAP) Identifies Arl3 as an Interacting Partner of Cystin, the Ciliary Protein Disrupted in the *cpk* Mouse Model of Polycystic Kidney Disease Jacob A. Watts,[1,2] Landon Shay Wilson,[3] Lisa M. Guay-Woodford.[1] *[1]Center for Translational Science, Children's National Med Center, Washington, DC; [2]Dept of Genetics, Univ of Alabama at Birmingham, Birmingham, AL; [3]Targeted Metabolomics and Proteomics Laboratory, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is a major cause of pediatric morbidity and mortality caused by mutations in *PKHD1*. Animal models are the mainstay for studies of human diseases, however, gene-targeting of *Pkhd1* results in mutants with little or no kidney disease. In contrast, disruption of the *Cys1* gene in the *cpk* mouse model closely phenocopies human ARPKD. We speculate that this phenotypic similarity suggests the protein products of *Pkhd1* and *Cys1*, FPC and cystin, respectively, belong to a common molecular pathway. The current study was designed to identify cystin-binding partners and the pathways that regulate the intracellular trafficking and nuclear function of cystin.

Methods: To identify cystin interacting partners we employed TAP using mIMCD-3 cells expressing a cystin-TAP construct. The SF-TAP vector contains a 4.6 kDa tag comprised two Strep and one FLAG domain on the N-terminus of a mutant form of cystin that lacks the myristoylation site, is unable to stably associate with the membrane and has enhanced trafficking to the nucleus.

Results: Mass spectrometry identified interacting partners, including the vesicular transport proteins Importin a1, a2, b1, b2, Rab5c, 7a, and 11a, as well as IFT74, and the GTP-binding protein, Arl3. Of note, Arl3-/- mice exhibit an ARPKD-like phenotype.

Conclusions: Based on our data, we propose that Arl3 may direct the localization of cystin via-IFT-mediated processes to the distal cilium. We have previously shown that cystin cilia localization is mediated in part by a myristoyl-electrostatic switch and that when released from the ciliary membrane, cystin traffics to the nucleus where it regulates c-myc expression. We speculate that loss of either cystin or Arl3 causes c-myc upregulation, a cardinal feature of proliferating cystic epithelia. Current knockdown studies are directed to address this proposed mechanism.

Accelerated Epithelial Cell Cycle Causes Cyst Growth in the *Kif3a* Non-orthologous Mouse Model of Polycystic Kidney Disease Dongmei Lu,[1] Alysha Rauhauser,[1] Binghua Li,[1] Kayla McEnery,[1] Chongyu Ren,[1] Moumita Chaki,[1] Komal Vadnagara,[1] Anton M. Jetten,[2] Peter Igarashi,[1] Massimo Attanasio.[1,3] *[1]Internal Medicine, Univ of Texas Southwestern Medical Center, Dallas, TX; [2]Cell Biology Section, Div of Intramural Research, National Inst of Environmental Health Sciences, National Insts of Health, Research Triangle Park, NC; [3]Eugene McDermott Center, Univ of Texas Southwestern Medical Center, Dallas, TX.*

Background: The progressive growth of tubules is the hallmark of several genetic forms of polycystic kidney disease (PKD) that inexorably leads to nephron loss, but the molecular causes that sustain uncontrolled growth are largely unknown. Unlike autosomal dominant polycycstic kidney disease (ADPKD), kidneys in nephronophthisis (NPHP) are smaller in volume, suggesting that differences in proliferation rates may underlie the different phenotype.

Methods: Using the *Kif3a* knockout as non-orthologous mouse model of polycystic kidney disease and the *Glis2$^{mut/mut}$ mouse model of NPHP, we have found that genetic inactivation of Glis2* in *Kif3a* null mice results in decreased tubular proliferation and apoptosis, delayed cyst progression and preserved renal function. [/italic]

Results: *In vitro* studies on immortalized tubular cells indicate that *Kif3a* null cells fail to activate the G1/S checkpoint and have accelerated G1-to-S transition that leads to accumulation of spontaneous DNA damage and cell death. Inactivation of *Glis2* in *Kif3a* null tubular cells restores the G1/S checkpoint, reduces cell proliferation rates and DNA damage by activation of checkpoint kinase 1.

Conclusions: Our data indicate that accelerated cell cycle paired with compromised DNA damage-induced cell cycle arrest are primary causes of cyst growt in the *Kif3a* non-orthologous mouse model of polycystic kidney disease. These results further substantiate the emerging link between DNA damage and cystic kidney disease and shed light on the biological bases of the different kidney phenotype of PKD and NPHP.

Deficiency of Tuba, a cdc42 GEF, Disrupts Normal Zebrafish Ciliogenesis and Kidney Development Jeong-In Baek, Soo Young Choi, Xiaofeng Zuo, Joshua H. Lipschutz. *Renal Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia, PA.*

Background: Dysfunction of renal primary cilia leads to polycystic kidney disease (PKD). The exocyst, a highly-conserved eight-protein membrane trafficking complex, is essential for ciliogenesis, and is regulated by Rho and Rab family GTPases, such as cdc42. We previously showed that cdc42 deficiency disrupts renal ciliogenesis and causes PKD in zebrafish and mice, and that Tuba, a cdc42-specific GEF, is necessary for ciliogenesis in cultured renal tubular MDCK cells.

Methods: To determine how tuba affects ciliogenesis and kidney function *in vivo*, tuba knock-down was performed in zebrafish by microinjection of a translation blocking morpholino (MO). The phenotypic and histological defects caused by tuba deficiency were analyzed using whole-mount *in situ* hybridization, H and E staining and immunofluorescence.

Results: Tuba was expressed in several tissues containing primary cilia, including the brain, neuromast cells, and renal tubules. We found that tuba morphants phenocopied cdc42 morphants, with ciliary mutant phenotypes including: a curly tail, hydrocephalus, and abdominal fluid accumulation. These defects were rescued by human tuba mRNA, which was resistant to the morpholino due to a difference in primary base pair structure, indicating that the phenotype was due to tuba deficiency, and not off-target effects. In the tuba morphant kidney, pronephric cilia were short and disordered, and the glomeruli were also disorganized. Because tuba is a known GEF of cdc42, and tuba and cdc42 morphants shared the same phenotype, we next performed a genetic synergy experiment in which we knocked down both tuba and cdc42. Co-injection of tuba and cdc42 morpholinos at low concentrations, which individually resulted in no phenotype, caused a severe phenotype, suggesting that tuba and cdc42 act in the same pathway.

Conclusions: Our study showed that tuba deficiency causes an abnormal renal ciliary phenotype in zebrafish, demonstrating that tuba plays a critical role in ciliogenesis and kidney development in zebrafish. We are currently generating kidney-specific tuba knockout mice to confirm these results in metanephrogenesis.

Greb1, a Gene Responsible for the Development of Renal Cysts Originating in the Distal Tubules in DBA/2 Mice Osamu Ichii,[1] Saori Otsuka,[1] Akira Yabuki,[2] Taro Horino,[3] Teppei Nakamura,[1,4] Yasuhiro Kon.[1] *[1]Laboratory of Anatomy, Dept of Biomedical Sciences, Graduate School of Veterinary Medicine, Hokkaido Univ, Sapporo, Japan; [2]Laboratory of Veterinary Clinical Pathology, Joint Faculty of Veterinary Medicine, Kagoshima Univ, Kagoshima, Japan; [3]Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi Univ, Nankoku, Japan; [4]Section of Biological Safety Research, Chitose Laboratory, Japan Food Research Laboratories, Chitose, Japan.*

Background: In cystic kidney disease, the localization of cysts depends on expression of the gene responsible. In this study, we found the development of renal cysts in DBA/2 mice, clarified their pathological features, and identified a responsible gene.

Methods: The histopathology of renal cysts was analyzed in C57BL/6 and DBA/2 of 10–32 weeks of age. In these strains, diabetes and acute kidney injures were induced by streptozotocin and folic acid, respectively. Genetic analysis of cyst formation was performed using F1, F2, and N2 progenies from C57BL/6 and DBA/2.

Results: With aging, DBA/2 but not C57BL/6 developed renal cysts characterized by columnar change, deciduation, and increased intercellular spaces of tubular epithelial cells. These epithelial cells expressed uromodulin and calbindin D-28K, markers for distal tubules. Some epithelial cells also expressed IL-1F6, a marker of injury of distal tubules, and showed BrdU incorporation. In diabetes and acute kidney injuries, DBA/2 showed severe distal tubular damage compared with C57BL/6. Genetic analysis revealed that cyst formation in DBA/2 is a monogenic autosomal recessive trait. Cyst formation was found to be significantly associated ($P < 0.01$) with the *D12Mit169–282* locus on chromosome 12, and we named this locus DBA/2-type renal cyst (*drecy*). Of the 26 genes encoded on *drecy*, mRNA expression of gene regulated by estrogen in breast cancer protein (*Greb1*) was significantly higher in the kidneys of DBA/2 compared to C57BL/6 (12-fold, $P < 0.0004$). The Greb1 protein primarily localized to the distal tubular epithelium in mouse kidneys.

Conclusions: *Greb1* is a strong candidate gene for *drecy* and shows promise as a novel molecular target for development of cystic kidney disease.

Loss of *Zeb2* Causes Glomerulocystic Kidney Disease in Mice Hila Milo Rasouly,[1] Stefanie Chan,[1] Anna Pisarek-Horowitz,[1] Yuriko Nishizaki,[2] Yujiro Higashi,[2] Weining Lu.[1] *[1]Renal Section, Boston Univ Medical Center, Boston, MA; [2]Inst for Developmental Research, Aichi Human Service Center, Kasugai, Aichi, Japan.*

Background: ZEB2 is a zinc finger E-box binding homeobox transcription factor. Mutations in *ZEB2* cause the Mowat-Wilson syndrome, an autosomal dominant disorder characterized by multiple congenital anomalies including kidney malformations. However, the role of ZEB2 in kidney development is unknown.

Methods: ZEB2 expression was analyzed in developing embryonic kidneys by immunostaining of a ZEB2-EGFP reporter knock-in mouse. Kidney specific *Zeb2* conditional knockout mice were generated by crossing the *Zeb2* floxed allele (*Zeb2$^{flox/flox}$*) with the *Pax2*-cre and *Six2*-cre alleles. The conditional knockout mice were analyzed from embryonic stage E14.5 to postnatal 8 weeks old. The mouse kidneys were analyzed by H&E staining for histological changes and immunostaining for apoptosis. Gene expression analysis was performed by TaqMan assays. Kidney function was assessed by measuring urine protein levels, serum creatinine and blood urea nitrogen.

Results: ZEB2 is highly expressed at E13.5 and E16.5 in the developing mouse kidney. Both *Zeb2$^{flox/flox}$*;*Pax2*-cre and *Zeb2$^{flox/flox}$*;*Six2*-cre conditional knockout mice developed kidney glomerular cysts starting at E16.5 dpc. *Zeb2$^{flox/flox}$*;*Pax2*-cre mice died at birth and *Zeb2$^{flox/flox}$*;*Six2*-cre mice developed abnormal kidney function at 5 weeks old. The cysts originate from the glomeruli with dilated Bowman's capsule and collapse of glomerular tufts. Reduced apoptosis was detected in the S-shaped and C-shaped bodies of *Zeb2* knockout embryonic kidneys compared to the wild type controls. Gene expression analysis revealed that both *Zeb2* conditional knockout mice had higher levels of *Pkd1* mRNA in the developing kidney than their wild-type littermates. Interestingly, overexpression of *Pkd1* has been reported to cause glomerular cysts in mice.

Conclusions: Loss of *Zeb2* causes glomerulocystic kidney disease in mice with increased expression of the *Pkd1* transcript.

FR-PO172

Elongated Ciliary Length of Proximal Tubules in a PKD Model AQP11 Knockout Mouse Yuichi Inoue,[1] Eisei Sohara,[1] Katsuki Kobayashi,[2] Tatemitsu Rai,[1] Kenichi Ishibashi,[3] Shigeo Horie,[4] Xuefeng Su,[5] Jing Zhou,[5] Sei Sasaki,[1] Shinichi Uchida.[1] *[1]Dept of Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan; [2]Div of Molecular Genetics, Chiba-East National Hospital, Chiba, Japan; [3]Dept of Medical Physiology, Meiji Pharmaceutical Univ, Kiyose, Tokyo, Japan; [4]Dept of Urology, Juntendo Univ, Tokyo, Tokyo, Japan; [5]Renal Div, Dept of Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: It is well known that PKD gene products localize to the primary cilia. In addition, abnormal ciliary length has been reported in many renal cystic diseases, although molecular mechanisms regulating ciliary length remain unknown. AQP11 is a membrane-channel protein at endoplasmic reticulum (ER) and reported to be permeable to the water. The disruption of AQP11 gene in mice resulted in renal cystogenesis. We recently reported that aberrant glycosylation and localization of polycystin-1 (PC-1) could be key mechanisms of cystogenesis in AQP11 (-/-) mice. However, the involvement of primary cilia in the mechanism of cystogenesis in AQP11 (-/-) mice remains unknown. In this study, we examined whether AQP11 regulates length of primary cilia.

Methods: We performed immunofluorescence with anti-a-acetylated tubulin antibody in wild-type, AQP11 (-/-), and Tg^{AQP11}AQP11 (-/-) mice kidneys.

Results: Interestingly, elongated primary cilia of proximal tubules in AQP11 (-/-) mice were observed, compared to wild-type mice. In addition, in Tg^{AQP11}AQP11 (-/-) mice, AQP11 transgene expression normalized the ciliary length in AQP11 (-/-) mice, indicating that AQP11 may play a role in controlling ciliary length. Since we recently reported that Pkd1 (+/-) background resulted in increased severity of PKD in AQP11 (-/-) mice, we further examined whether Pkd1 affects elongated ciliary length in AQP11 (-/-) mice. However, the Pkd1 (+/-) background did not change the ciliary length in AQP11 (-/-) mice, indicating that elongation of cilia in AQP11 (-/-) mice might not be solely dependent on PC-1.

Conclusions: Our data demonstrated that AQP11 may regulate ciliary length. To the best of our knowledge, this case is the first in which ER protein regulates the ciliary length of kidney tubules.

FR-PO173

Metabolic Reprogramming Results in the Production of an Oncometabolite, 2-Hydroxyglutarate (2HG), in Polycystic Kidney Disease Robert H. Weiss,[1] Vicki Hwang,[1] Chaozhe Yang,[2] Hiromi Inoue Wettersten,[1] Lisa M. Guay-Woodford.[2] *[1]Internal Medicine/Nephrology, UC Davis, Davis, CA; [2]Center for Translational Science, Children's National Health System, Washington, DC.*

Background: Polycystic Kidney Disease (PKD) and cancer share many of the same characteristics including defects in cell growth control, altered metabolism, etc. Recently, the oncometabolite, 2-Hydroxyglutarate (2-HG), has been found to be increased in certain cancers due to mutated Isocitrate Dehydrogenase (IDH) 1 and/or 2 enzymes. Similarly, 2-HG was elevated in human cells proliferating in hypoxia in the absence of IDH mutations. 2-HG has been known to increase HIF1-alpha levels resulting in unregulated cell growth.

Methods: Human ARPKD tissues and normal tissue (adjacent to kidney cancer) were obtained under approved IRBs. Non-targeted metabolomics was performed in wt and *cpk* kidneys as well as human tissues using gas chromatography-mass spectrometry (GC-MS) based methods. Wild type IDH2 expression was analyzed in mouse cells and tissues from the *cpk* and *jck* mouse PKD models by western blot and immunohistochemistry.

Results: Using non-targeted metabolomics in the cpk mouse model of ARPKD, we identified 2-HG as being significantly increased in *cpk* over wt kidneys ($p<0.038$); this data was confirmed in two human ARPKD tissues ($p<0.001$). Correspondingly, a significant increase was found in citrate ($p<0.001$), and significant decreases were found in downstream metabolites of the TCA cycle, fumarate ($p<0.001$) and malate ($p<0.001$). An increase in IDH2 expression was found by IHC in the cyst epithelial cells in both *jck* and *cpk* kidney tissues.

Conclusions: Our results in two PKD mouse models and in a small number of human tissues suggest increased presence of 2-HG in cystic tissue which correlates with increased expression of wild type IDH2, possibly as a result of local hypoxia. This dysregulated expression of metabolites suggests a shift in the TCA cycle and metabolism, further supporting the parallels between oncogenesis and PKD. Such connections will allow us to tap into the vast resources of cancer basic research and cancer clinical trials to bring new treatment paradigms to PKD.

FR-PO174

p21-Activating Kinase 4 (PAK4) Inhibition as a Novel Treatment for Autosomal Dominant Polycystic Kidney Disease Robert H. Weiss,[1] Arzu Ulu,[1] Hiromi Inoue Wettersten,[1] William T. Senapedis,[2] Erkan Baloglu,[2] Yosef Landesman.[2] *[1]Internal Medicine/Nephrology, UC Davis, Davis, CA; [2]Karyopharm Therapeutics, Natick, MA.*

Background: Due to its mechanistic similarities with cancer, the repurposing of cancer drugs is a largely untapped area of polycystic kidney disease (PKD) research. p21-activated kinase 4 (PAK4) is a mediator of filopodia formation and stabilizes β-Catenin which lies in a pathway which is integral to both nephrogenesis and cancer. In light of abundant evidence that defective ciliary signaling leads to renal tubular epithelial (RTE) cell proliferation, and because PAK4 is upregulated in most cancer cell lines, we asked whether specific inhibition of PAK4 inhibits activation of β-Catenin and thereby attenuates RTE cell proliferation.

Methods: Immortalized human autosomal dominant PKD (ADPKD) cells (WT9-12; WT9-7), human primary normal RTE cells (NHK) were incubated with a specific PAK4 inhibitor, KPT-8752, and cell viability assay and immunoblotting were performed.

Results: The PAK4 inhibitor, KPT-8752, decreases cell viability in both WT9-12 and WT9-7 as well as several renal cell carcinoma (RCC) cell lines (786-0 and ACHN). NHK cells were less sensitive to KPT-8752 when compared to ADPKD or RCC cell lines, which suggests the likelihood of decreased adverse effects when given in vivo. The cytotoxic effect of KPT-8752 was time- and dose-dependent in both ADPKD and RCC cell lines. KPT-8752 decreases protein levels of the activated form of PAK4 (phospho-PAK4) as well as phospho-β-Catenin at 48 and 72 hours.

Conclusions: A novel PAK4 inhibitor, KPT-8752, decreases cell viability in ADPKD cell lines. The mechanism of PAK4 inhibition appears to be driven by the changes in the β-Catenin/Wnt pathway which plays key roles in ciliary signaling and is deranged in the ciliopathies including PKD. Thus, once confirmed in vivo, PAK4 inhibition could be a new targeted therapy for human ADPKD.

FR-PO175

Restoring Multidrug-Resistance Associated Protein 3 Suppresses Cell Proliferation in Polycystic Kidney Jong Hoon Park, Eun Sun Chang, Eun Young Park, Yu Mi Woo. *Biological Science, Sookmyung Women's Univ, Seoul, Korea.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by abnormal proliferation of renal tubular epithelial cells resulting in loss of renal function. Despite identification of the genes responsible for ADPKD, few effective drugs are currently available for the disease. Only few drugs such as tolvaptan or octreotide have shown powerful therapeutic potential in clinical trials. Thus, finding additional effective drug targets is necessary. The functions of multidrug-resistance associated protein 3 **(**MRP3) have been reported only in the field of drug-resistance, and the renal functions of MRP3 are mostly unknown.

Methods: Basal expression of MRP3 was measured in the kidneys of human patients with ADPKD and mouse PKD models. *Abcc3* RNAi or *ABCC3* clone was transfected respectively into MDCK cells to regulate MRP3 expression. To examine the effects of MRP3 on cell proliferation, we performed XTT (WST-1) assay and observed PCNA-positive cells by immunocytochemistry-florescence. *In vitro* cyst formation assay was performed with ABCC3 overexpression. Content of intracellular cyclic AMP was measured in WT9-12 cells and the activation of signaling molecules involved in B-Raf/MEK/ERK pathway were detected using Western blotting analysis. $p < 0.05$ was considered significant.

Results: MRP3 was significantly downregulated in polycystic kidneys compared with normal kidney tissues, particularly in the cystic epithelial lining cells. The RNAi-mediated downregulation of MRP3 induced cell proliferation through activating B-Raf/MEK/ERK signaling pathway. In contrast, restorating MRP3 suppressed cell proliferation and in vitro cystogenesis in MDCK cells. The level of cyclic AMP was reduced by MRP3 restoration and resulted in inhibition of PKA and Rap-1 which known as upstream of B-Raf in WT9-12 cells.

Conclusions: Significant decreases of MRP3 were observed in polycystic kidney tissues. In this context, MRP3 restoring could be one of therapeutic approaches through targeting cAMP/PKA-dependent signaling pathway.

FR-PO176

Cyclic AMP Regulates Glycogen Synthase Kinase-3b by a Feed Forward Mechanism in Polycystic Kidney Disease Vijayakumar R. Kakade, Shixin Tao, Reena Rao. *The Kidney Inst, Dept of Internal Medicine, Univ of Kansas Medical Center, Kansas City, KS.*

Background: Glycogen synthase kinase 3b (GSK3b), a protein kinase is crucial for vasopressin mediated renal cAMP generation. Cyclic AMP levels are elevated in polycystic kidney disease (PKD) and stimulate cyst expansion. Earlier we found that GSK3b protein levels are increased and associated with cyst lining epithelia in human and rodent models of PKD and its inhibition can reduce cyst expansion in PKD by reducing cAMP. The increase in GSK3b protein levels in PKD was an unexpected finding, as GSK3b is known to be regulated at the level of its activity rather than expression. Hence the current studies examined if cAMP mediated cell signaling can regulate GSK3b expression in a feed forward loop.

Methods: M1-cortical collecting duct cells and PKD-1 knockout or heterozygous cells were used.

Results: In M1 cells, forskolin treatment increased GSK3b protein and mRNA levels, and kinase activity. To examine if GSK3b is a cAMP responsive gene, we examined its promoter region and found five conserved potential cAMP-response element (CRE) binding sites. Forskolin treatment increased activated CRE-binding protein (pCREB) and GSK3b, while H-89, a Protein kinase-A (PKA) inhibitor reduced pCREB and GSK3b. This suggested that CREB could be involved in cAMP induced GSK3b expression. Hence we made GSK3b-promoter luciferase constructs to examine the effect of cAMP on CREB dependent GSK3b transcriptional activity. Luciferase activity was increased by forskolin or 8-Br-cAMP treatment and reduced by CREB inhibitor treatment. CREB inhibitor also reduced forskolin induced GSK3b protein levels. In PKD1 knockout cells, GSK3b expression as well as pCREB levels were significantly higher than control cells and CREB inhibitor treatment significantly reduced GSK3b expression.

Conclusions: Thus a unique feed-forward relation exists between cAMP and GSK3b, whereby increased cAMP levels can activate PKA and CREB mediated GSK3b expression, which in turn is essential for cAMP generation. Use of a GSK3 inhibitor can break this destructive cycle and may be therapeutically useful to reduce cyst expansion and preserve renal function in PKD.

MitoQ Modulates Hypoxia-Inducible Factor-1a 1n ADPKD Cells
Wei Wang, Berenice Y. Gitomer, Kristen L. Jablonski, Robert W. Schrier, Michel Chonchol. *Univ of Colorado Anschutz Medical Campus.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a common genetic disease that leads to end-stage kidney disease. So far there is no effective treatment other than dialysis or transplant. The pathophysiology of the disease is still unclear. One hypothesis is that cyst expansion results in pericystic hypoxia which leads to up-regulation of HIF-1a. Expression of HIF-1a is increased in the cyst epithelium in human and animal models of ADPKD. HIF-1a has many target genes including those involved in angiogenesis, cell proliferation and apoptosis which are involved in cyst growth and thus disease progression. Therefore agents that have an inhibitory effect on HIF-1a may have a beneficial effect in slowing progression of ADPKD. MitoQ, a mitochondrial-targeted antioxidant, was previously shown to ablate the hypoxic induction of reactive oxygen species and destabilize HIF-1a protein in various cancer cells. We hypothesized that HIF-1a is induced in ADPKD cells and that mitoQ may have an inhibitory effect on oxidative stress.

Methods: An immortalized human epithelial cell line derived from a single cyst from an ADPKD patient and normal renal tubular epithelial cells were used. A proteome profiler human cell stress array from R&D systems was used. Both cells were treated with 1μM mitoQ for 24hr.

Results: HIF-1a expression in ADPKD cells was increased by 60% as compared to normal tubular cells. MitoQ decreased the expression of HIF-1a in ADPKD cells by 51% as compared to untreated ADPKD cells.

Conclusions: The induction of HIF-a in PKD cells *in vitro* indicates that polycystin deficiency itself may have direct influence on HIF-1a regulation. The inhibitory effect of mitoQ on HIF-1a may imply a beneficial effect on ADPKD disease progression. *In vivo* studies are needed to confirm this observation.

FR-PO178

Statin Effect on Human ADPKD Tubular Epithelial Cell Proliferation
Wei Wang, Melissa A. Cadnapaphornchai, Michel Chonchol, Godela M. Brosnahan, Robert W. Schrier, Berenice Y. Gitomer. *Univ of Colorado Anschutz Medical Campus.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a common genetic disease with no treatment. In our recently published study, pravastatin was shown to slow progression of structural kidney disease in children and young adults with ADPKD. However, the underlying mechanisms of statin's action are unclear. Statins have been shown to inhibit proliferation of cancer cells by inducing apoptosis. Cyst growth in ADPKD in some ways resembles characteristics of benign tumors. We thus hypothesized that statin may have an inhibitory effect on ADPKD cell proliferation through regulation of apoptosis.

Methods: An immortalized human epithelial cell line derived from a single cyst from an ADPKD patient and normal renal tubular epithelial cells were used. Both simvastatin (1 μM and 10μM) and pravastatin (1 μM and 10μM) were used. Cell viability was examined with trypan blue and cell proliferation by BrdU incorporation. Cell apoptosis markers were examined using proteome profiler human apoptosis arrays from R&D systems.

Results: Both simvastatin and pravastatin have a dose dependent inhibition of proliferation in ADPKD cells. Expression of the cell cycle regulator p21 increased more than two fold in simvastatin treated ADPKD cells. Similar results were observed by Western blot where pravastatin significantly increased the expression of p21.

Conclusions: P21 is a cyclin kinase inhibitor which has pleiotropic effects on the cell cycle. It is up-regulated by polycustin-1 and its expression is decreased in humans and animals with ADPKD. Thus the clinical benefit of pravastatin in ADPKD patients may well be related to its inhibitory effect on tubular cell proliferation through the regulation of p21. P21 in ADPKD merits further investigation as a target for future therapies.

FR-PO179

High Rates of Cellular Extrusion, Primary Cilia Defects, and Increased Apoptotic Sensitivity in Renal Epithelia with Inactivated Exocyst Sec10
Noemi Polgar, Amanda J. Lee, Vanessa H. Lui, Ben Fogelgren. *Univ of Hawaii.*

Background: The establishment and maintenance of epithelial barrier function are fundamental aspects of epithelial morphogenesis, and polarized exocytosis plays a key role in these processes. The eight-protein exocyst complex is responsible for the targeted trafficking of certain exocytic vesicles to specific subcellular locales. In Madin-Darby canine kidney epithelial (MDCK) cells grown on transwells, the exocyst has been reported to contribute to trafficking to primary cilia. Also, knockdown of exocyst subunit Sec10 (Sec10-KD) in MDCK cells prevented normal cyst formation when grown in 3D matrix.

Methods: We utilized the well-characterized MDCK cell line grown in 3D gel matrices to perform a detailed analysis of the consequences of loss of Sec10 and the exocyst complex on epithelial morphogenesis and primary cilia assembly. We also utilized our newly generated kidney-specific Sec10 knockout mouse strain to analyze primary cilia and epithelial characteristics *in vivo*.

Results: When grown in 3D collagen gels, late-stage Sec10-KD cysts (day 12) displayed high rates of apoptotic cells extruded from the basal surface of the cysts' epithelial layer. The early formation of these collagen-grown Sec10-KD cysts were marked by normal lumenogenesis (<8 days), however we observed significant defects in primary cilia assembly in Sec10-KD cysts beginning at day 8. As cell extrusion can be triggered by signals from dying cells, we found Sec10-KD MDCK cells demonstrated an increased sensitivity to apoptotic signals, and further analysis revealed defects in planar cell polarity and re-establishment of apical-basal polarity. Renal epithelia in mice with targeted inactivation of the Sec10 gene also displayed primary cilia defects and signs of cellular extrusion not observed in control littermates.

Conclusions: Based on these results, silencing exocyst component Sec10 in renal epithelial cells leads to defective primary cilia assembly, with an increased sensitivity to apoptotic signals and defective planar cell polarity. These factors lead to high rates of apoptotic cell extrusion from the epithelial monolayer in Sec10-silenced MDCK cysts and mouse tissues.

Aquaporin-1 Retards Renal Cyst Development in Polycystic Kidney Disease by Inhibition of Wnt Signaling
Weiling Wang,[1] Yin Xia,[2] Baoxue Yang.[1] *[1]Dept of Pharmacology, Peking Univ, Beijing, China; [2]School of Biomedical Sciences, The Chinese Univ of Hong Kong, Hong Kong, China.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common human monogenic diseases for which there is no effective treatment at present. Water channel aquaporin-1 (AQP1) is expressed at epithelial cell plasma membranes in renal proximal tubules and thin descending limb of Henle, as well as in epithelial cells lining the cyst wall in a subset of renal cysts in ADPKD kidneys.Our aim was to study the role of AQP1 in ADPKD development.

Methods: Postulating that AQP1 may enhance renal cytogenesis because its water transporting role, we investigated the role of AQP1 in ADPKD using *Aqp1* / *Pkd1* double knockout mice, embryonic kidney organ cultures, and matrix-grown MDCK cells.

Results: Contrary to expectations, kidney size and cyst number were significantly greater in AQP1 null PKD mice than in AQP1-expressing PKD mice, with the difference due mainly to a greater number proximal tubule cysts. In embryonic kidney cultures, AQP1 deletion increased cyst development by up to ~40%. Biochemical analysis revealed decreased β-Catenin phosphorylation and increased β-Catenin expression, suggesting enhanced Wnt signaling in AQP1 null PKD mice. In matrix-grown MDCK cells, AQP1 transfection inhibited cyst development and promoted tubulogenesis, and decreased β-Catenin and cyclinD1 expression, suggesting down-regulation of Wnt signaling. Co-immunoprecipitation showed AQP1 interaction with β-Catenin, GSK3b and LRP6.

Conclusions: These results implicate AQP1 as a novel determinant in renal cyst development that may involve inhibition of Wnt signaling by an AQP1-macromolecular signaling complex.

Funding: Government Support - Non-U.S.

Epithelial Morphogenesis Can Be Rescued by Modulation of Actomyosin Contractility in Fibrocystin-Deficient MDCK Cells
Wolfgang H. Ziegler, Birga Soetje, Lisa Burrer, Romina Gutsch, Dieter Haffner. *Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany.*

Background: Fibrocystin (FPC), a type I transmembrane protein of largely unknown function, is encoded by the *Pkhd1* gene, mutations of which cause autosomal recessive polycystic kidney disease (ARPKD). Among other potential functions, FPC appears to affects adhesion signaling of cells involving the FAK/Src axis. Contributions of epithelial cell adhesion and contractility to the disease process of ARPKD remain to be defined. The aim of this study is (i) to establish the link between FPC function and the capacity of renal collecting duct epithelial cells to generate normal epithelia, and (ii) to determine consequences of altered cell adhesion / contractility.

Methods: We analyze FPC function in Madin-Darby canine renal collecting duct epithelial cells (MDCK). In this cell line, formation of 3D spheroids can be employed to study establishment of polarity, lumen formation and ciliogenesis. A micro-pattered surface is used to confine (initial) adhesion / spreading of cells and induce spheroid formation. In this setup, establishment of polarity and lumen depend on the capacity of cells to properly control cell adhesion and actomyosin contractility. The impact of altered cell behavior is being addressed using modulators of actomyosin contractility e.g. blebbistatin and adhesion signaling.

Results: Pkhd1 siRNA-treated MDCK cells and controls were employed to analyze formation of spheroids (within three days), using specific markers for polarity, cell junctions and cilia. Knockdown of FPC strongly affects polarity and lumen formation in MDCK spheroids suggesting critical involvement of FPC protein in cellular control of adhesion signals and establishment of polarity. Furthermore, transient inhibition of actomyosin contractility using blebbistatin during the first day of spheroid formation restores 70% of (correct) epithelial morphogenesis in FPC-deficient cells.

Conclusions: FPC knock down in MDCK cells disturbs adhesion signaling, cell-cell interaction, and control of cell tension resulting in impaired epithelial morphogenesis, which can be rescued by transient reduction of cell contractility.

Disruption of TRPV4 Reduces Survival of Renal Epithelial Cells in a Hyperosmolal Environment Charles D. Varnell,[1] Brian J. Siroky,[1] Nancy Kleene,[2] Bradley P. Dixon.[1] *[1]Div of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Dept of Molecular and Cellular Physiology, Univ of Cincinnati College of Medicine, Cincinnati, OH.*

Background: TRPV4 localizes to primary cilia of renal epithelial cells, and is vital to cilia-mediated mechanosensation. Renal epithelial cells in the inner medulla are exposed to hyperosmolality, and survive such conditions through the osmotic response. We previously demonstrated attenuation of the osmotic response of renal epithelial cells by pharmacological modulation of TRPV4. To explore these findings further, we characterized the osmotic response and survival of ciliated and non-ciliated renal epithelial cells with disrupted TRPV4 expression.

Methods: Both renal epithelial cells lacking cilia due to an *Ift88* mutation and cells in which *Ift88* was re-expressed, rescuing cilia expression, were transduced with an shRNA construct targeting TRPV4 and compared to cells without this construct. TRPV4 expression was assessed by immunoblotting. Cells were exposed to basal osmolality or hyperosmolality induced with NaCl. Cell quantitation was assessed by crystal violet assay, and expression of *Akr1b3* and *Bgt1*, important in osmolyte accumulation in response to osmotic stress, was measured by qPCR.

Results: Cells lacking cilia had reduced *Akr1b3* and *Bgt1* expression and decreased survival in hyperosmolality compared to cells with intact cilia. Ciliated cells with reduced TRPV4 expression had reduced survival in hyperosmolal conditions compared to those with normal TRPV4 expression, whereas in non-ciliated cells, reduced TRPV4 expression did not diminish survival. Disruption of TRPV4 did not significantly alter *Akr1b3* and *Bgt1* expression in either ciliated or non-ciliated cells under hyperosmolal conditions.

Conclusions: We demonstrate a novel finding of reduced survival of ciliated renal epithelial cells with disrupted TRPV4 expression in hyperosmolal conditions. As disruption of TRPV4 expression did not alter expression of genes that regulate osmolyte accumulation, the reduced survival observed may be independent of this process but mediated by other components of the osmotic stress response.

Periostin Activation of Integrin-Linked Kinase Stimulates Akt/mTOR and GSK3b/β-Catenin Mediated Proliferation of Human ADPKD Cells Archana Raman, Gail Reif, Lindsay A. Astleford, Darren P. Wallace. *Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS.*

Background: Periostin, a matricellular protein, is highly overexpressed in ADPKD, ARPKD and several rodent models of PKD. Periostin binding to a_v-integrins (a_vb_3, a_vb_5) stimulates the proliferation of ADPKD cyst epithelial cells, suggesting that it is an important autocrine factor that promotes cyst growth. Genetic knockout of periostin in *pcy* mice, a slowly progressive model of PKD, reduced the number of proliferating cells in the kidney, cyst growth and interstitial fibrosis, and significantly improved renal function and survival of the mice. We **hypothesize** that periostin promotes the proliferation of cystic cells through integrin-linked kinase (ILK) activation of Akt/ mTOR and/or GSK3b/ β-Catenin signaling pathways.

Methods: ADPKD and normal human kidney (NHK) cells were grown for 4 days and ILK activity was determined using an immunocomplex kinase assay. ADPKD cells were treated with human recombinant periostin and levels of phosphorylated Akt and S6 kinase (S6K), a downstream target of mTOR, were evaluated by immunoblot analysis. To determine if β-Catenin signaling was altered, levels of phosphorylated GSK3b at Ser-9, an inhibitory site, and nuclear accumulation and transcriptional activity of β-Catenin were measured. ADPKD cells were treated with periostin ± CPD22, an ILK inhibitor, and then ILK activity and phosphorylated Akt, S6K and GSK3b were determined.

Results: Basal ILK activity was significantly elevated in ADPKD cells compared to NHK cells. Incubation of ADPKD cells with periostin increased ILK activity 1.5-fold and increased phosphorylated levels of Akt and S6K. Periostin also increased phosphorylated GSK3b and both the level and transcriptional activity of β-Catenin. Treatment with CPD22 blocked periostin-mediated phosphorylation of Akt, S6K and GSK3b and cell proliferation.

Conclusions: These data demonstrate that ILK is a key intermediate in periostin activation of signaling pathways involved in the proliferation of ADPKD cells and suggests that ILK may be a potential therapeutic target to slow cyst growth.

TNFa and RANKL Regulates the Expression and Nuclear Translocation of Id2 in Renal Epithelial Cells Xia Zhou, Lucy Fan, Xiaoyan Li, Xiaogang Li. *Dept of Internal Medicine and Kidney Inst, Univ of Kansas Medical Center.*

Background: TNFa presents in the cyst fluid and promotes cyst growth in autosomal dominant polycystic kidney disease (ADPKD). The inhibitor of DNA binding 2 (Id2) regulates cystic renal epithelial cell proliferation through Id2-p21-Cdk2 axis. However, the cross-talk between TNFa and Id2 in ADPKD is unknown. It has been reported that receptor activator of NF-KB ligand (RANKL), a member of the TNFa cytokine family, is able to induce nuclear translocation of Id2 in mammary epithelial cells.

Methods: To test our hypothesis that TNFa or RANKL regulates the expression and nuclear translocation of Id2 in renal epithelial cells, we treated *Pkd1* wild type and mutant renal epithelial cells with either TNFa or RANKL alone, or plus different inhibitors of TNFa or RANKL mediated signaling molecules.

Results: We found that RANKL treatment increased the expression level of TNFa mRNA in renal epithelial cells. TNFa or RANKL stimulation increased 1) the expression of Id2 protein but not mRNA in *Pkd1* wild type and mutant renal epithelial cells; 2) the activation of mTOR in renal epithelial cells, whereas inhibition of mTOR with rapamycin decreased TNFa or RANKL induced upregulation of Id2; 3) the nuclear translocation of Id2 in *Pkd1* wild type renal epithelial cells; 4) the activation of PI3K, MAPK and CDK2, whereas inhibition of PI3K, MAPK and CDK2 with Ly294002, SB202190 and roscovitine, respectively, blocked TNFa or RANKL induced Id2 nuclear translocation. These results suggested that TNFa or RANKL induces Id2 expression via mTOR signaling pathway and regulates Id2 nuclear translocation via PI3K-MAPK-CDK2 pathway. In addition, we found that treatment with TNFa or RANKL significantly decreased the mRNA and protein levels of p21 in renal epithelial cells, which is an inhibitor of CDKs and the target of Id2.

Conclusions: TNFa or RANKL regulates 1) the expression and nuclear translocation of Id2 via mTOR and PI3K-MAPK-CDK2 pathways, respectively, in the renal epithelial cells, and 2) the expression of p21 and renal epithelial cell proliferation via Id2, which elucidates a novel mechanism for TNFa signaling in promoting cyst growth in ADPKD.

Label-Free Quantitative Analysis of the YAP/TAZ Interactome Priyanka Kohli, Thomas Benzing, Bernhard Schermer, Markus M. Rinschen. *Univ Hospital Cologne, Dept of Internal Medicine, Cologne, Germany.*

Background: The Hippo signaling pathway is a potent regulator of cell proliferation and tissue growth. It has a significant effect on tumor development and progression, in addition to regulating organ size. Altered Hippo signaling has been suggested as a mechanism for cyst growth in autosomal-dominant polycystic kidney disease (ADPKD) and nephronophthisis (NPHP). YAP and TAZ are the downstream mediators of Hippo signaling in mammals.

Methods: To identify the interactomes of YAP and TAZ we expressed YAP and TAZ in a Flp-in single-copy cellular integration system. We performed single-step affinity purification with single-shot quantitative mass spectrometry analysis.

Results: Our study provides both comprehensive and comprehensive interactomes for both YAP and TAZ and does not only confirm the majority of previously described interactors but, strikingly, revealed uncharacterized interaction partners. Some of these interaction partners modulate YAP/TAZ TEAD-dependent transcription: YAP/TAZ TEAD-dependent transcription was inhibited by the transcription factor C/EBP and activated by Rassf8, a known modulator of Wnt signaling. In addition, our data allowed insights into complex stoichiometry and uncovered discrepancies between the YAP and TAZ interactomes.

Conclusions: Further studies will now characterize these novel interactors and unravel their dynamic role in regulating proliferation and ciliary signaling in ADPKD.

Hedgehog Defects in a Cep290 Model of Nephronophthisis John Andrew Sayer,[1] Ann Marie Hynes,[1] Rachel H. Giles,[2] Shalabh Srivastava,[1] Lorraine Eley,[1] Henry Ajzenberg,[2] Colin Miles.[1] *[1]Inst of Genetic Medicine, Newcastle Univ, Newcastle upon Tyne, United Kingdom; [2]Dept of Nephrology and Hypertension, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: Nephronophthisis (NPHP) is the major cause of paediatric renal failure, yet the disease remains poorly understood, partly due to the lack of appropriate animal models. Joubert Syndrome (JBTS) is an inherited ciliopathy giving rise to NPHP and mutations in *CEP290* (*NPHP6*) are a common genetic lesion.

Methods: We have generated a Cep290 gene trap mouse model of JBTS that displays the kidney, eye and brain abnormalities and use isolated collecting duct epithelial cells in 3D culture as a model for assessing the response to Hedgehog signalling agonists.

Results: Mutant mice present with cystic kidney disease as neonates. Newborn kidneys contain normal amounts of Lef1 and Tcf1 protein, indicating normal function of the Wnt signalling pathway, however, an increase in Gli3 repressor reveals abnormal Hedgehog (Hh) signalling evident in newborn kidneys. Collecting duct cells from mutant mice have abnormal primary cilia and are unable to form spheroid structures *in vitro*. Treatment of mutant cells with the Hh agonist purmorphamine restores normal spheroid formation.

Conclusions: These data implicate abnormal Hh signalling as the cause of NPHP and suggest that Hh agonists may be exploited therapeutically.

FR-PO187

Mapping Genetic Modifiers of Autosomal Recessive Polycystic Kidney Disease (ARPKD) Michael Flister,[1] Bradley T. Endres,[1] William E. Sweeney,[2] Howard J. Jacob,[1,2] Ellis D. Avner,[2] Carol Patricia Moreno Quinn.[3] *[1]Physiology, Medical College of Wisconsin, Milwaukee, WI; [2]Pediatrics, Medical College of Wisconsin, Milwaukee, WI; [3]MedImmune, Cambridge, United Kingdom.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is caused by mutations in PKHD1 in humans and the orthologous PCK rat model. Although ARPKD results solely from PKHD1 mutations, the disease onset and severity are highly variable, indicating that other unknown genetic risk factor (s) modify ARPKD-associated phenotypes. Here we performed genome-wide analysis of the PCK rat and two genetically distinct Pkhd1 congenic rat strains on the Fawn-Hooded Hypertensive (FHH) and the Dahl S (SS) rat backgrounds (denoted FHH.Pkhd1 and SS.Pkhd1, respectively) to identify genetic modifiers of ARPKD severity.

Methods: The PCK, FHH.Pkhd1, and SS.Pkhd1 rat strains were phenotyped for renal and hepatic cystogenesis, followed by genome-wide expression and sequence analysis.

Results: The FHH.Pkhd1 and SS.Pkhd1 strains had lower renal cyst formation at 30 days-of-age (5±2% and 8±2% cystic, respectively; P<0.001) compared to the PCK kidneys (26±4% cystic), which coincided with significantly reduced kidney weights in the FHH. Pkhd1 and SS.Pkhd1. In contrast, hepatic cystogenesis did not differ between PCK, FHH. Pkhd1, and SS.Pkhd1. These data indicated that the PCK genome harbors kidney-specific genetic modifier (s) of ARPKD severity that are not present in the FHH and SS genomes. Using high density SNP array genotyping and microarray expression analysis, we identified 50 potential modifiers of ARPKD severity in the PCK rat. Of these candidates, a damaging nonsynonymous variant in Nphp4 stood out as the most likely candidate based on variant segregation, protein modeling, network analysis, and gene ontology. Nphp4 mutations cause type 4 autosomal recessive nephronopthisis, but had not been previously implicated in the molecular or cellular pathophysiology of ARPKD.

Conclusions: These data provide genetic evidence of disease modifier (s) in the PCK model of ARPKD and prioritized multiple candidates, including NPHP4, for further investigation in ARPKD pathogenesis.

FR-PO188

Smad3 Gene Deletion Ameliorates Cyst Formation and Interstitial Fibrosis in cpk Mouce, a Model of ARPKD Taketsugu Hama,[1] Koichi Nakanishi,[1] Hironobu Mukaiyama,[1] Hiroko Togawa,[1] Masashi Sato,[1] Yuko Shima,[1] Masayasu Miyajima,[2] Kandai Nozu,[3] Shizuko Nagao,[4] Hisahide Takahashi,[4] Kazumoto Iijima,[3] Norishige Yoshikawa.[1] *[1]Pediatrics, Wakayama Medical Univ, Wakayama, Japan; [2]Laboratory Animal Center, Wakayama Medical Univ, Wakayama, Japan; [3]Pediatrics, Kobe Univ, Kobe, Japan; [4]Education and Research Center of Animal Model for Human Disease, Fujita Health Univ, Aichi, Japan.*

Background: Cystic epithelia acquire mesenchymal features in response to cyst enlargement, showing proliferative activity and interstitial fibrosis in PKD. In the context of this phenotypic alteration, we previously demonstrated that Smad3 phosphorylated at both linker regions and COOH terminal regions (pSmad3L/C) upregulated c-Myc through JNK/CDK4 dependent pathway. Therefore, pSmad3L/C may be a disease specific target. The aim of this study is to examine the effect of Smad3 gene deletion in *cpk* mice.

Methods: Mice with Smad3 gene deletion (EMBO J 1999;18:1280) were crossed with *cpk* mice to generate double-mutant (DM) mice (*cpk;smad3*$^{-/-}$).

Results: The ratio of kidney to body weight is significantly lower in DM mice than *cpk* (N=10 each, 0.13 ± 0.04 versus 0.22 ± 0.03, P<0.01). Western blot analysis revealed that protein expressions of nuclear pJNK, pCDK4 and c-Myc significantly decreased by 78% (P<0.05), 66% (P<0.05) and 63% (P<0.01), respectively, in DM mice kidneys compared to *cpk*. Compared with *cpk*, Ki-67 positive cells in cyst lining epithelia were significantly fewer in DM mice (50.7 ± 20.8 versus 35.8 ± 13.4%, P<0.01). Matrix deposition by Masson's trichrome staining in the peritubular interstitum and mRNA levels of collagen type I were significantly decreased in DM mice kidneys compared to *cpk* (9.4 ± 4.4 versus 14.4 ± 6.4, P<0.01 [% blue area]; 2.6 ± 0.6 versus 4.3 ± 1.3, P<0.01 [collagen type I mRNA/GAPDH mRNA]).

Conclusions: Study results suggest that Smad3 gene deletion inhibits deregulated cellular proliferation in cystic epithelia by suppressing the pSmad3L/C-JNK-CDK4-c-Myc cascade, and also reduces the interstitial fibrosis by suppressing TGF-β/Smad3 pathway. In conclusion, the modulation of Smad3 may offer a therapeutic strategy in PKD.

Temporal Profile of the Renal Transcriptome of HIV-1 Transgenic Mice during Disease Progression Ying Fan,[1] Chengguo Wei,[2] Wenzhen Xiao,[2] Niansong Wang,[2] Peter Y. Chuang,[2] John C. He.[2] *[1]Dept of Nephrology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China; [2]Dept of Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Profiling of temporal changes of gene expression in the same kidney over the course of renal disease progression is challenging because repeat renal biopsies are rarely indicated in clinical practice.

Methods: Here, we profiled the temporal change in renal transcriptome of HIV-1 transgenic mice (Tg26), an animal model for human HIV-associated nephropathy (HIVAN), and their littermates at three different time points (4, 8, and 12 weeks of age) representing early, middle, and late stages of renal disease by serial kidney biopsy. We analyzed both static levels of gene expression at three stages of disease and dynamic changes in gene expression between different stages.

Results: Analysis of static and dynamic changes in gene expression revealed that up-regulated genes at the early and middle stages are mostly involved in immune response and inflammation, whereas down-regulated genes mostly related to fatty acid and retinoid metabolisms. We validated the expression of a selected panel of genes that are up-regulated at the early stage (CCL2, CCL5, CXCL11, Ubd, Anxa1, and Spon1) by real-time PCR. Among these up-regulated genes, Spon1, which is a previously identified candidate gene for hypertension, was found to be up-regulated in kidney of human with diabetic nephropathy. Immunostaining of human biopsy samples demonstrated that protein expression of Spon1 was also markedly increased in kidneys of patients with both early and late HIVAN and diabetic nephropathy.

Conclusions: Our studies suggest that analysis of both static and dynamic changes of gene expression profiles in disease progression avails another layer of information that could be utilized to gain a more comprehensive understanding of disease progression and identify potential biomarkers and drug targets.

FR-PO190

Linking Plasma Changes in ApoL1 Variants Causal for Nephropathy to Chronic Kidney Disease Maarten Hoek,[1] Julia Kozlitina,[2] Haihong Zhou,[1] Patricia Brown,[1] Rory Rohm,[1] Gulesi Ayanoglu,[1] Xiaoyan Du,[1] Eric Rimmer,[1] Dermot Reilly,[1] Thomas P. Roddy,[1] Doris F. Cully,[1] Thomas F. Vogt,[1] Daniel Blom.[1] *[1]MRL, Merck & Co., Kenilworth, NJ; [2]McDermott Center for Human Growth and Development, UT Southwestern Medical Center, Dallas, TX.*

Background: Two common missense variants in ApoL1 (G1 and G2) have been definitively linked to CKD in African Americans. However, not all individuals with the renal-risk genotype (RRG) go on to develop CKD and little is known about how ApoL1 variants drive disease. Because HDL is cleared by the kidney, it has been suggested that differences in the level or quality of mutant ApoL1-HDL particles could be causal and might serve as useful risk stratification markers.

Methods: Levels of G0 (low-risk variant), G1 and G2 ApoL1 were measured in plasma from 3552 individuals in the Dallas Heart Study using an LC-MS method that enabled the quantitation of the different variants. Additionally, native ApoL1-HDL from donors with no or two ApoL1 risk alleles was characterized by size exclusion chromatography and further analysis of immunopurified ApoL1-HDL particles.

Results: Though an association between APOL1 variant status and renal function in non-diabetic individuals was replicated ($p=7.1 \times 10^{-6}$ for microalbuminuria, 2.7×10^{-5} for GFR<60 ml/min per 1.73 m^2), there was no association between circulating ApoL1 levels and microalbuminuria or GFR after adjusting for genotype. This was true even when analysis was restricted only to subgroups such as G0 homozygotes, single risk allele carriers or double risk allele carriers. ApoL1 in the circulation existed in a heterogeneous high MW HDL pool, but no consistent size differences were observed between ApoL1-HDL from G0 and RRG donors. There were no differences in the relative amounts of Hpr and IgM in ApoL1-HDL purified from G0 and RRG individuals, though a potential change in ApoA1/ApoL1 stoichiometry was noted.

Conclusions: These data demonstrate that plasma levels of ApoL1 (G0, G1 or G2) are not useful to stratify risk of renal disease in ApoL1 RRG individuals and suggest that mechanisms underlying ApoL1-nephropathy cannot be easily attributed to obvious differences in the amount or quality of G0 or G1/G2 ApoL1 in the circulation.

FR-PO191

Impact of Genetically Determined Ancestry Informative Markers on GFR Estimates and Kidney Disease Risk Girish N. Nadkarni, Miriam S. Udler, Gillian Belbin, Vaneet Lotay, Christina M. Wyatt, Omri Gottesman, Eimear Kenny, Inga Peter, Erwin P. Bottinger. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Self-reported race, genetic ancestry, and Apolipoprotein L1 (APOL1) polymorphisms contribute to variation in kidney function and related disease risk, yet it remains unclear what their relative contributions are.

Methods: We estimated global proportion of African ancestry (using genome-wide genotype data) and *APOL1* risk status for 9,048 unrelated individuals (self-reported as 3,189 African Americans, 1,721 European Americans, and 4,138 Hispanic/Latino Americans). We extracted CKD-EPI estimated glomerular filtration rate (eGFR), clinical and demographic characteristics from the electronic medical record. We assessed relationships between continuous variables and racial groups or *APOL1* variants using multivariable linear regression.

Results: In both the admixed African Americans and Hispanic/Latino Americans, there was significant trend of increasing creatinine as percent African ancestry increased (per 10% increase in African ancestry, 0.01 mg/dl increase in creatinine in African Americans, P=1x10^{-7} and 0.009 mg/dl in Hispanic/Latino Americans, P=1x10^{-8}).Estimated GFR was likewise significantly associated with African genetic ancestry in both populations. *APOL1* risk haplotypes were not associated with normal-range creatinine and eGFR, but were significantly associated with CKD, eGFR<45 mL/min/1.73m2, and ESRD, with effects of *APOL1* increasing with worsening disease states and the contribution of genetic African ancestry decreasing in parallel. Using genetic ancestry to reclassify patients as "Black" based on >50% African ancestry resulted in higher eGFR for 14.7% of Hispanic/Latino Americans and lower eGFR in 4.1% of African Americans, impacting CKD staging in 4.3% of Hispanic/Latino Americans and 1% of African Americans.

Conclusions: In summary,proportion African ancestry was significantly associated with normal-range creatinine and eGFR, while *APOL1* risk haplotypes drove associations with CKD states. Recalculation of eGFR based on genetic ancestry impacted CKD staging and warrants further investigation including correlation with measured GFR particularly in Hispanic/Latinos.

FR-PO192

APOL1 Risk Variants Are Strongly Associated with HIV-Associated Nephropathy in Black South Africans Alex Nganga Kasembeli,[1] Raquel Duarte,[1] Michele Ramsay,[1,2] Pulane Mosiane,[2] Caroline Dickens,[1] Therese Dix-Peek,[1] Sophie Limou,[3] Efe Sezgin,[3,4] George W. Nelson,[3] Jeffrey B. Kopp,[5] Cheryl Ann Winkler,[3] Saraladevi Naicker.[1] *[1]Univ of the Witwatersrand, Johannesburg, South Africa; [2]National Health Laboratory Service, Johannesburg, South Africa; [3]NCI, Frederick National Laboratory, Frederick, MD; [4]Johns Hopkins Bloomberg SPH, Baltimore, MD; [5]NIDDK, Bethesda, MD.*

Background: APOL1 variants are strongly associated with HIVAN and FSGS in African Americans; however, their impact and prevalence on chronic kidney disease (CKD) in a setting of HIV-1 subtype C infection was not previously investigated. This study aims to determine the role of *APOL1* variants on HIVAN and CKD in a South African black population.

Methods: Archived kidney biopsies (N=124) were selected according to their histological diagnosis and DNA was extracted. The control groups comprised HIV positive individuals without CKD (N=54) and population controls (N=54). Genotypes were determined for APOL1 G1 (rs73885319 and rs60910145), G2 (rs71785313) and global ancestry informative markers. Association of APOL1 alleles with HIVAN and CKD was tested by Fisher's exact test (FET) and by logistic regression adjusting for age, sex, and genetic ancestry.

Results: Genotypes were determined for 38 HIVAN, 41 HIV positive CKD, and 41 HIV negative CKD cases (N=120) and 54 HIV positive controls and 54 population controls. 79% of HIVAN cases and 2% of the population controls carried two APOL1 risk alleles. In a recessive model, individuals carrying any combination of two *APOL1* risk alleles had 89-fold higher odds (95% CI 17.7-911.7; $p=1.2x10^{-14}$) of developing HIVAN. Population allele frequencies were 7.3% for G1 and 11.1% for G2. APOL1 risk variants were not significantly associated with other forms of CKD, including FSGS.

Conclusions: This is the first African study to report the impact of APOL1 risk variants on HIVAN in patients infected with HIV-1 subtype C. HIV positive, anti-retroviral therapy naïve South African blacks with two APOL1 risk alleles are at very high risk for developing HIVAN. Further studies are required to determine the impact of APOL1 risk variants on kidney disease in other regions of sub-Saharan Africa.

FR-PO193

Copy Number Variation in APOL1 Gene in African American Individuals and Its Role in Kidney Disease Rupam Ruchi,[1] Giulio Genovese, Jessica Lee,[1] Victoria Charoonratana,[1] David J. Friedman,[1] Martin R. Pollak.[1,2] *[1]Nephrology, Beth Israel Deaconess Medical Center/Harvard Univ; [2]Broad Inst of MIT and Harvard.*

Background: APOL1 associated kidney disease is largely autosomal recessive. However, in some studies, G1 heterozygotes develop kidney disease more frequently or have earlier onset of disease than individuals with two normal alleles. We hypothesize that structural variation in the APOL1 gene determines at least some of the phenotype seen in heterozygous individuals.

Methods: Sequence coverage analysis of 1000 genome project (KGP) phase 3 samples and exome sequencing data from our lab were screened for copy number variation by assessing read depth in the APOL1 region. A PCR-based assay was designed to confirm a putative APOL1 duplication. The frequency of this duplication was compared among heterozygous African American (AA) cases (n=123) and controls (n=255) by an allelic discrimination assay. A 314 bp region on the last exon of APOL1 (including the site of G1 SNP) was amplified, cloned and sequenced for haplotype identification.

Results: Analysis of data from 8 samples (including 5 heterozygous for G1) sequenced in KGP showed increased coverage over ~ 100kb region, including APOL2, APOL1 and part of MYH9, suggesting the presence of APOL1 copy number > 2. The qualitative PCR assay confirmed the presence of a duplication, which we subsequently observed in additional samples from heterozygous AA individuals with kidney disease. Sanger sequencing revealed identical sequences at the junction, indicating that the duplication likely occurred once and was co-inherited by all the subjects with the duplication. Bioinformatic analysis combined with cloning and Sanger sequencing revealed that most carriers of extra APOL1 copies were G0G0G1, but that G0G1G1 genotypes also existed. Taqman-based copy number assay confirmed the presence of multiple copies in these individuals. Comparison of cases and controls showed the presence of the APOL1 duplication in 4.06% of cases and 0.78% controls (p=0.03).

Conclusions: Copy number variation exists in APOL1 gene, and may be a genetic determinant of kidney disease in AA individuals who are heterozygous for the risk alleles by traditional genotyping techniques.

Association between Apolipoprotein L1 Gene Variants with Prevalent Kidney and Cardiovascular Disease: Systolic Blood Pressure Intervention Trial (SPRINT) Carl D. Langefeld,[1] Jasmin Divers,[1] Nicholas M. Pajewski,[1] Amret T. Hawfield,[1] David Reboussin,[1] D. Bild,[2] George A. Kaysen,[3] Paul L. Kimmel,[4] Dominic S. Raj,[5] Ana C. Ricardo,[6] Jackson T. Wright,[7] John R. Sedor,[7] Michael V. Rocco,[1] Barry I. Freedman.[1] *[1]Wake Forest Sch Med; [2]Patient-Centered Outcomes Research Inst; [3]Univ of California Davis Healthcare Sys; [4]NIDDK; [5]George Washington Univ Sch Med; [6]Univ of Illinois Coll Med at Chicago; [7]Case Western Reserve Univ.*

Background: Apolipoprotein L1 gene (APOL1) G1 and G2 coding variants are strongly associated with chronic kidney disease (CKD) in African Americans (AAs). APOL1 association was tested with baseline estimated glomerular filtration rate (eGFR), urine albumin:creatinine ratio (UACR), and prevalent cardiovascular disease (CVD) in 2,571 AAs from the Systolic Blood Pressure Intervention Trial (SPRINT). SPRINT is assessing effects of systolic blood pressure reduction on renal and CVD outcomes.

Methods: Logistic regression models adjusting for potentially important confounders were computed to test for association between APOL1 risk variants and baseline clinical CVD (defined as myocardial infarction, surgical or percutaneous coronary artery or carotid artery revascularization) and with CKD (eGFR<60 ml/min/1.73m^2 and/or UACR >30 mg/g).

Results: AA SPRINT participants were 45.3% female with mean+SD (median) age 64.3+9.3 (63) years, mean arterial pressure 100.7+12.2 (100) mmHg, eGFR 76.3+22.9 (77.1) ml/min/1.73m^2, UACR 49.9+188.6 (9.2) mg/g, and 8.2% had clinical CVD. APOL1 (recessive inheritance) was positively associated with CKD (p=0.0095, odds ratio (OR) 1.37, 95% confidence interval (CI) 1.08-1.73) and log UACR ($p=7.7x10^{-6}$,estimated slope [b] 0.33) and negatively associated with eGFR (p=0.0029, b -3.58). APOL1 risk variants were not associated with prevalent CVD (p=0.86, OR 1.02, 95% CI 0.82-1.27).

Conclusions: SPRINT data reveals that APOL1 nephropathy risk variants are associated with kidney disease in AA subjects with a UACR <1 gm/gm, but are not associated with clinical CVD. [Support: NIH HHSN268200900040C (SPRINT); RO1 DK084149 and RO1 DK070941 (BIF)].

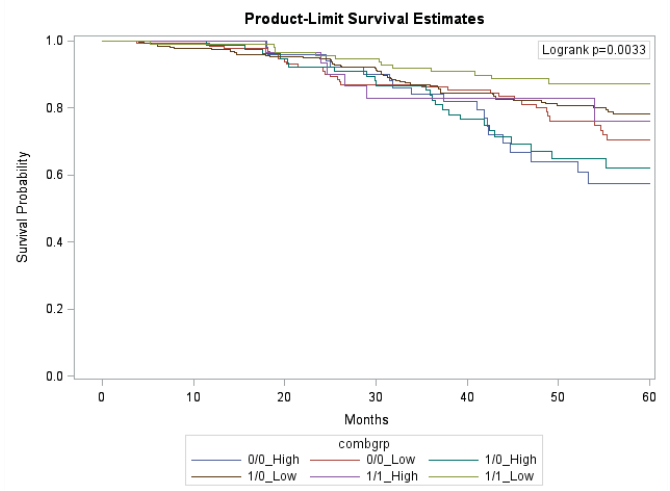
Additive Effect of the *GSTM1 (0)* Null and *APOL1* High Risk Alleles in the African American Study of Kidney Disease (AASK) Trial Gabor Bodonyi-Kovacs,[1] Jennie Z. Ma,[2] Michael S. Lipkowitz,[3] Jeffrey B. Kopp,[4] Cheryl Ann Winkler,[5] Thu H. Le.[1] *[1]Renal Div., UVA, Charlottesville, VA; [2]Biostat. Sect., UVA, Charlottesville, VA; [3]Renal Div., Georgetown Univ, Washington, DC; [4]Kidney Diseases Branch, NIH, Bethesda, MD; [5]Center for Cancer Research, NIH, Frederick, MD.*

Background: Apolipoprotein L-1 (*APOL1*) G1 and G2 alleles are associated with chronic kidney disease (CKD) in African American (AA) patients. Glutathione-S-transferase Mu 1 (*GSTM1*) null allele, *GSTM1 (0),* is also associated with accelerated progression of CKD in hypertensive AA patients. We hypothesized that the *GSTM1 (0)* and *APOL1* high risk alleles interact to influence the clinical outcomes in the AASK Trial participants.

Methods: A total of 682 patients were classified into the combination of homozygous null for *GSTM1 (0/0),* heterozygous *(1/0),* and homozygous active *(1/1)* and *APOL1* high (*High*) and low (*Low*) risk genotypes. The survival differences among the six groups were assessed by log-rank test and in the Cox regression for time to the event of glomerular filtration rate (GFR, 50% or 25ml/min/1.73m^2 decline), dialysis, or death, or their composite events. Regression analyses were adjusted for age, gender, proteinuria, baseline GFR, MAP, CVD, drug class, and population admixture.

Results: The 6 groups differed significantly in the time to composite events of GFR, or dialysis or death (log-rank p=0.0033) (Fig.1).



Compared to *(1/1) _Low* group, the hazard ratios (HR) for the composite events were 2.6 (p=0.009) and 2.4 (p= 0.019) for the *(0/0) _*Low and the *(1/0) _High* groups, respectively. The HRs for the other groups did not reach statistical significance [*(1/1) _High* (HR 1.2, p = 0.73), *(1/0) _Low* (HR 1.78, p = 0.079), and *(0/0) _High* (HR 1.91, p = 0.097)].

Conclusions: *GSTM1 (0)* and *APOL1* high risk alleles have additive deleterious effects on CKD progression among hypertensive AAs.

FR-PO196

The Apolipoprotein L1 gene G3 Haplotype Is Not Associated with End-Stage Kidney Disease (ESKD) in African Americans Nicholette D. Palmer,[1] Maggie Ng,[1] Carl D. Langefeld,[2] Jasmin Divers,[2] Janice P. Lea,[4] Mark D. Okusa,[5] Robert P. Kimberly,[6] Donald W. Bowden,[1] Barry I. Freedman.[3] *[1]Biochemistry, Wake Forest; [2]Biostatistical Sciences, Wake Forest; [3]Nephrology, Wake Forest; [4]Renal Medicine, Emory; [5]Nephrology, Univ VA; [6]Rheumatology, Univ AL Birmingham.*

Background: Apolipoprotein L1 gene (APOL1) G1 and G2 nephropathy risk variants are strongly associated with progressive non-diabetic etiologies of kidney disease in populations with recent African ancestry. Selection for these variants likely occurred due to protection from human African trypanosomiasis (HAT). Resequencing of this region in ten genetically and geographically distinct African populations residing in HAT endemic regions identified 8 single nucleotide polymorphisms (SNPs) in strong linkage disequilibrium and comprising a novel G3 haplotype. The G3 haplotype could confer protection from HAT and/or risk for kidney disease (Ko WY et al, Am J Hum Genet 93:54-66, 2013).

Methods: To determine whether the APOL1 G3 haplotype was associated with nephropathy, G1, G2, and G3 SNPs and 70 ancestry informative markers spanning the genome were genotyped in 937 African Americans with non-diabetic ESKD, 965 with type 2 diabetes associated (T2D)-ESKD, and 1,029 non-nephropathy controls.

Results: Cases with non-diabetic ESKD and T2D-ESKD initiated renal replacement therapy at mean±SD 48.7±15.5 and 58.0±10.9 years, respectively. Controls were recruited at 50.0±11.9 years. Overall African ancestry was 80.0±11.6%, 79.9±11.4%, and 78.2±10.9% in non-diabetic ESKD cases, T2D-ESKD cases, and controls, respectively. In analyses adjusting for age, sex, APOL1 G1/G2 risk (recessive model), and global African ancestry, the APOL1 G3 haplotype was not significantly associated with ESKD (p=0.14 for non-diabetic ESKD; p=0.57 for type 2 diabetes-associated ESKD; p=0.38 for combined all-cause ESKD). Only one of eight G3 SNPs, rs136170, was significantly associated with non-diabetic ESKD and all-cause ESKD in the adjusted model ($P=3.9x10^{-4}$ and 0.017, respectively).

Conclusions: Variation in APOL1 G3 makes nominal, if any, contribution to ESKD susceptibility in African Americans. G1 and G2 variants explain the vast majority of nephropathy susceptibility.

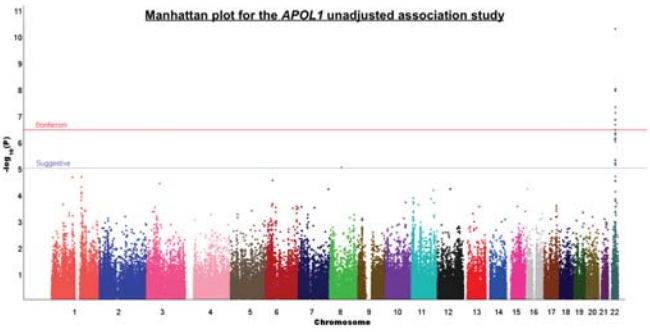
Large-Scale Gene-Centric Exploration of FSGS Risk in African Americans Sophie Limou,[1] George W. Nelson,[1] Jeffrey B. Kopp,[2] Cheryl Ann Winkler.[1] *[1]Frederick National Laboratory, NCI, Leidos Biomedical Research, Inc., Frederick, MD; [2]NIDDK, NIH, Bethesda, MD.*

Background: Much of the increased burden of chronic kidney disease in people of African ancestry has been attributed to two *APOL1* alleles, termed G1 and G2. Approximately 10% of African Americans (AA) with focal segmental glomerulosclerosis (FSGS) or HIV-associated nephropathy (HIVAN) do not carry an *APOL1* renal risk allele, raising the possibility that other genetic variants may contribute to kidney disease.

Methods: We conducted a large-scale gene-centric association study on 181 AA with FSGS or HIVAN and 273 AA controls using the customized Illumina Human CardioMetaboloKidney Beadchips enriched in markers for kidney genes and 22q13.1 locus (198K). After quality control, 146,794 SNPs were tested for association with FSGS/HIVAN by logistic regressions adjusted for gender, HIV status, and the first two eigenvectors from the population stratification analysis.

Results: Thirteen chromosome 22 genetic variants were significantly associated with FSGS/HIVAN ($P<3.4x10^{-7}$).



After adjusting for the strong recessive *APOL1* G1/G2 effect ($P=8.4x10^{-17}$, OR=9.8), no SNP reached the study-wide significance level. However, two chromosome 1 variants met the suggestive significance threshold ($P<10^{-5}$, OR=2.7). Both are located in an estrogen-inducible gene whose encoded protein is localized in late endosome and lysosome, and plays a role in autophagy and cell survival under stress.

Conclusions: Our study confirmed the importance of *APOL1* association with FSGS/HIVAN in AA, and revealed a new candidate gene involved in autophagy as intracellular ApoL1 is thought to be. This new result warrants replication in a larger sample size and functional exploration in kidney cells.

FR-PO198

Common and Rare Codon-Altering Variants in the Functional Domains of APOL1 Sophie Limou,[1] George W. Nelson,[1] Jeffrey B. Kopp,[2] Cheryl Ann Winkler.[1] *[1]Frederick National Laboratory, NCI, Leidos Biomedical Research, Inc., Frederick, MD; [2]NIDDK, NIH, Bethesda, MD.*

Background: Much of the increased burden of chronic kidney disease in people of African ancestry has been attributed to two alleles, termed G1 and G2, in the *APOL1* gene, which encodes a component of the trypanosome lytic factor (TLF). Approximately 10% of African Americans (AA) with focal segmental glomerulosclerosis (FSGS) or HIV-associated nephropathy (HIVAN) do not carry an *APOL1* renal risk allele, raising the possibility that other *APOL1* variants may contribute to kidney disease. A recent report identified an additional *APOL1* haplotype, termed G3, which may be under selection by trypanosomes and might cause renal injury.

Methods: To determine the extent of variation in the terminal exon of *APOL1* encoding the functional domains, we resequenced 2,549 individuals: 1,112 individuals from 53 global populations from the Human Genome Diversity Project and International HapMap Project; 241 AA and 169 European Americans (EA) with FSGS; 54 AA with HIVAN; and 651 AA and 322 EA controls. To test for association of common and rare variants with FSGS and HIVAN, logistic regression, burden, and SKAT tests were performed. We computed the F_{ST} estimates to quantify the population divergence, and the EHH and iHS statistics to assess for signatures of recent selection. Plasma containing variant ApoL1 protein isoforms was tested for TLF-mediated lysis of *T.b. rhodesiense* and *gambiense*.

Results: None of the common or rare *APOL1* variants, including the G3 missense variants, were associated with FSGS or HIVAN beyond the strong association of G1 and G2 alleles ($P=3.31x10^{-58}$, OR=18). The selection analysis revealed signatures of recent selection only for G1, and to a lesser extent for G2, in West Africa. With the exception of plasma containing ApoL1 G1 or G2 isoforms, none of the human plasma containing other ApoL1 isoforms lysed trypanosomes.

Conclusions: Only *APOL1* G1 and G2 alleles are strongly associated with increased risk of FSGS and HIVAN, suggesting that sequencing *APOL1* would bring no additional benefit for prevention or clinical management of kidney disease compared to genotyping *APOL1* G1 and G2 risk alleles only.

FR-PO199

Fine Mapping of the HIVAN1 Susceptibility Locus on Chr. 3A1-A3 via Generation of Subcongenic Strains Natalia Papeta,[1] Ami Patel,[1] Travis Stanley Crevecoeur,[1] Vivette D. D'Agati,[2] Ali G. Gharavi.[1] *[1]Medicine, Columbia Univ, New York, NY; [2]Pathology, Columbia Univ, New York, NY.*

Background: HIV-1 transgenic mice on the FVB/NJ background (TgFVB) represent a validated model of HIV- associated nephropathy (HIVAN). A major susceptibility locus (*HIVAN1*), with CAST alleles associated with increased risk of disease, was previously identified on chromosome 3A1-A3 in a mapping study between TgFVB and CAST/EiJ (CAST) strains. Previously reported TgFVB-HIVAN1^{CAST}congenic strain, carrying a 50 Mb CAST interval (encompassing the *HIVAN1* locus), introgressed into the TgFVB genome, showed accelerated development of HIVAN compared to TgFVB strain.

Methods: We generated three subcongenic strains, which encompass proximal (SubII 4.2-38.55 Mb) or distal (SubIII 38.45-54.8Mb and SubIV 48.7-54.8Mb) regions of the reported FVB-HIVAN1^{CAST} locus (build 38.1). These strains were crossed with TgFVB strain and HIVAN pathology traits were analyzed to refine the *HIVAN1* locus.

Results: At 5-10 weeks of age renal injury parameters in Tg-SubII-FVB-HIVAN1^{CAST} mice were not different from those of TgFVB. In contrast, HIV transgenic SubIII and SubIV mice displayed significantly more severe kidney disease compared to Tg-SubII-FVB-HIVAN1^{CAST} mice (glomerulosclerosis 64.1+ 6.5% and 64.8 + 5.3% and versus 25.8 +3.5%, tubulointerstitial injury 38.5 +5.7% and 36.6+3.6% versus 14.2+ 1.9%, inflammation 28.1+5% and 28.4+3% versus 11.2+2.2%, P<0.01 for each comparison). The severity of disease correlated with the number of SubIV CAST alleles, indicating an additive effect. The identified *SubIV-HIVAN1* locus spans 7.3 Mb and encodes 31 genes, of which 4 have non-synonymous coding SNPs that differentiate CAST from FVB and 9 genes show expression levels, significantly different between these strains, according to our transcriptome data. High priority candidate genes include Pcdh18, Mgarp, Setd7, Exosc8 and Frem2.

Conclusions: These data further confirm that a gene on chr3A1-A3 increases susceptibility to HIVAN and reduce the *HIVAN1* locus to a maximal 7.5Mb interval with 5 high priority candidate genes based on sequence and transcriptome data.

A Bioinformatics Approach to Understanding a Common Pathogenesis for Chronic Kidney Disease: Perspectives from Mendelian Genes and Proteome Analysis Chen-Han Wilfred Wu,[1] Jingtao Guo,[3] Robert H. Yenchek,[2] Jo Abraham,[2] Alfred K. Cheung,[2] Lynn B. Jorde.[1] *[1]Dept of Human Genetics, Univ of Utah, Salt Lake City, UT; [2]Div of Nephrology, Dept of Internal Medicine, Univ of Utah, Salt Lake City, UT; [3]Dept of Oncological Sciences, Univ of Utah, Salt Lake City, UT.*

Background: Chronic kidney disease (CKD) affects more than 13% of people in the United States, and is one of the leading causes of death. Genetics studies have provided molecular insights into CKD. However, genes identified so far showed locus heterogeneity across different functions. Yet the clinical manifestations of CKD are often shared across various etiologies. Is there a common pathogenesis that may explain these heterogeneous diseases? Here we employed a bioinformatics approach to identify one or a few common groups for CKD pathogenesis.

Methods: We first identified known causative genes associated with CKD curated by the Online Mendelian Inheritance in Man (OMIM). We explored their evidence of protein-protein interactions in the Database of Interacting Proteins (DIP). After parsing the genes and interactions, more candidate genes and interaction networks were discovered. A statistical hypothesis test was performed to see if these interactions are more abundant compared to the proteome. The extended candidate genes and networks are further analyzed for grouping for possible common pathogenesis.

Results: From OMIM, we identified 84 causative genes for CKD, and 16 of them have experimentally determined interactions in DIP. These resulted in 56 protein-protein interactions which is statistically more abundant than the interactions proteome-wide (p=0.0069). Through these interaction networks, 49 candidate genes were discovered, and 12 independent groups of possible pathogenesis pathways can be distinguished.

Conclusions: CKD causative genes have significantly more protein-protein interactions than that of the proteome. We identified 49 new candidate genes for CKD awaiting further verification. The networks form 12 independent groups. Although this model is still heterogeneous, further study may show additional reduction in heterogeneity towards shared common pathogenesis.

GWAS-Derived Renal Genetic Risk Score and Renal Function in a Prospective Cohort of Type 2 Diabetic Patients – SURDIAGENE Study Philippe Zaoui,[1] Pauline Barbieux,[2] Samy Hadjadj.[2] *[1]Nephrology, CHU Michallon, Grenoble, France; [2]Endocrinology, CHU Poitiers, Poitiers, France.*

Background: Renal disease is a complex condition with ill-defined genetic components. Recent GWAS-identified loci seem associated with renal failure and/or function (see appendix). These genetic findings have not been yet tested for their clinical utility in prospective studies or in specified populations.

Methods: We used 16 SNPs identified by CKD consortium as associated with renal function or End-Stage Renal Failure (ESRF) to build a renal genetic risk score (RGRS): for a given SNP, homozygotes for a protective allele were given 0 point, heterozygotes 1 point and homozygotes for the risk allele 2 points. We tested the genetic risk score on 1420 type 2 diabetic patients of European origin from the real-life SURDIAGENE cohort, with 1136 patients of European ethnicity having the whole set of genetic determinations. Study endpoints were incidence of ESRF and/or sustained doubling of serum creatinine and trajectory of eGFR (CKD EPI) using a total of 20,898 determinations.

Results: The median (range) of RGRS was 17 (min=9, max=25). Follow-up duration was 70 months. RGRS was not different between CKD stage at baseline: CKD 1-2 versus CKD 3 versus CKD 4-5 (p=0.109). RSGS was not associated with occurence of renal events (72 events i.e. 1.1 % person-year). When analyzing eGFR trajectory with a mixed-linear model, RSGS was not associated with renal function decline (p=0.7115). In addition, none of the SNPs was individually associated with renal event or renal function decline.

Conclusions: The RGRS derived from 16 SNPs identified by the CKD consortium proved to add no major prognostic value for renal outcomes in type 2 diabetes patients. **Appendix:** gene (s) or putative gene (s) and corresponding rs NAT8_S143F rs13538; STC1 rs10109414; DAB2, C9 rs11959928; SLC7A9, CCDC123, ECAT8 rs12460876; GCKR, IFT172, FNDC4 rs1260326; UMOD, ACSM5, GP2, PDILT rs12917707; UBE2Q2, FBXO22 rs1394125; SHROOM3, CCDC158 rs17319721; ANXA9, FAM63A, PRUNE, BNIPL, LASS2, SETDB1 rs267734; TFDP2 rs347685; PIP5K1B, FAM122A rs4744712; DACH1 rs626277; SLC34A1, GRK6, RGS14, LMAN2, PRR7, F12, PFN3 rs6420094; ATXN2 rs653178; PRKAG2 rs7805747; VEGFA rs881858.

miRNome Expression Profiling in Plasma From Type 1 Diabetic Patients with Impaired Renal Function and an Increased Risk of Rapid Progression to End-Stage Renal Disease Eiichiro Satake, Marcus G. Pezzolesi, Kevin P. Mcdonnell, Adam Smiles, Andrzej S. Krolewski. *Genetics and Epidemiology, Joslin Diabetes Center, Boston, MA.*

Background: MicroRNAs (miRNAs) are short endogenous, non-coding RNA molecules that have recently been shown to be expressed in a variety of human biofluids. These molecules are involved in gene regulation and play important roles in the pathogenesis of various renal diseases. The objective of this study was to determine the miRNA signature that is associated with impaired renal function in Type 1 diabetes (T1D) patients with nephropathy.

Methods: The expression levels of 1,811 miRNAs from the human miRNA genome (miRNome) were measured in baseline plasma samples from 78 proteinuric T1D patients who lost renal function at a rate of >3.3ml/min/year before reaching end-stage renal disease during 7-20 years of follow up.

Results: A total of 390 miRNAs were detectable in plasma samples from these study participants. To identify miRNAs associated with impaired function, miRNome expression profiles among individuals with normal (estimated glomerular filtration rates (eGFR) > 60 ml/min/1.73m^2) and impaired (eGFR= 30-59 ml/min/1.73m^2) renal function at baseline were compared. In total, 39 miRNAs (2.2%) with <0.5 or >2.0 fold changes were identified between individuals with normal and impaired renal function. Among 86 highly-expressed miRNAs, we identified 7 miRNAs with <0.5 or >2.0 fold change between the groups.

Conclusions: These data suggest that miRNAs are associated with eGFR difference in diabetic nephropathy. Furthermore, these differentially expressed miRNAs can be potential marker for renal function or therapeutic targets for diabetic nephropathy in T1D.

FR-PO203

Pro-Arrhythmic Genotypes and Sudden Cardiac Arrest Risk in Chronic Kidney Disease Patients Patrick H. Pun, Carol Haynes, Damian M. Craig, Megan Chryst-Ladd, John Paul Middleton, Laura P. Svetkey, Svati H. Shah. *Medicine, Duke Univ, Durham, NC.*

Background: CKD patients are at increased risk of sudden cardiac death (SCD); unfortunately, traditional risk factors have low utility in risk prediction in this population. The influence of genetic factors on SCD risk among CKD patients is unknown but could improve risk prediction. Genes encoding ion channels are intriguing candidates for SCD risk, since they underlie the majority of inherited arrhythmias, and subclinical mutations may promote arrhythmias when combined with CKD-related environmental stressors. We examined the SCD risk associated with common variants in the *KCNH2*, *SCN5A* and *NOS1AP* genes in CKD patients with coronary heart disease.

Methods: Using a biorepository of patients undergoing cardiac catheterization at our institution from 2001-2011, we genotyped candidate single nucleotide polymorphisms (SNPs). The primary outcome was a composite of SCD and clinically significant ventricular arrhythmias, as adjudicated from chart review. Analyses stratified by race and Cox proportional hazards models adjusted for covariates were used to compare the relationships among single SNPs (dominant model) and outcome in CKD patients (eGFR<60) and non-CKD patients (eGFR≥60).

Results: Of 9206 total subjects included, 26% had eGFR<60. There were a total of 832 composite events over a mean follow up of 5.5 yrs. All SNPs were in Hardy-Weinberg Equilibrium and met quality control metrics. SNPs in *SCN5A* and *KCNH2* were not associated with the composite outcome in the CKD population. There was a significant interaction between CKD and RS16847548 in *NOS1AP* (minor C allele frequency=0.2 in CKD population), with an association between genotype and outcome only in those with CKD (HR=0.65, 95%CI 0.50-0.83, p=0.0008). Stratification by race and adjustment for covariates did not alter the association (aHR=0.71, 95% CI 0.54-0.94, p=0.015).

Conclusions: A common SNP in the *NOS1AP* locus was associated with a ventricular arrhythmias and SCD in CKD patients. In contrast to prior studies, the SNP was associated with a diminished rather than augmented risk. This observation should encourage investigation into unique mechanisms of risk protection in the CKD population.

Genomic Changes of Cardiovascular Disease in Patients with Chronic Kidney Disease Tzongshi Lu,[1,2] Li-Lun Ho,[3] Guerman Molostvov,[4] Lingsheng Dong,[2] Thomas F. Hiemstra,[5] Daniel Zehnder,[4,6] Li-Li Hsiao.[1,2] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Chemical Engineering, Massachusetts Insts of Technology, MA; [4]Warwick Medical School, Univ of Warwick, Coventry, United Kingdom; [5]School of Clinical Medicine, Univ of Cambridge, Cambridge, United Kingdom; [6]Univ Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom.*

Background: Over 20 million U.S. adults have chronic kidney disease (CKD). Cardiovascular disease (CVD) is the major cause of death among ESRD patients. The prevalence of acute myocardial infarction and congestive heart failure in patients with CKD is much higher than those without CKD. In this study, we explored the direct genomic effects of CKD on CVD.

Methods: Arteries were collected from patients with CVD with or without CKD in the absence of diabetes, hypertension or smoking history. RNA sequencing technology (RNAseq) was used to identify molecular markers. Gene selections are based on log 2 ratio using folds changes. Data analysis was using Kyoto Encyclopedia of Genes and Genomes (KEGG), and Database for Annotation, Visualization and Integrated Discovery (DAVID).

Results: When comparing arteries from CVD with CKD to those without CKD, 13 genes were up-regulated and nine genes were down-regulated. Pathway analysis among the up-regulated genes revealed that these genes are mainly involved in cardiomyopathy processes, such as NR1D1 (nuclear receptor subfamily 1, group D, member 1), a regulatory function gene in metabolic and inflammatory process; SGCG (gamma-sarcoglycan), a gene associated with hypertrophic/dilated cardiomyopathy or arrhythmogenic ventricular cardiomyopathy. Among the down-regulated genes, they were found to play roles in cell cycle regulation, apoptosis, oxidative stress and stress resistance. In addition, these genes also involve in HIF-1, which regulates the VEGF signaling pathway.

Conclusions: We have identified a group of genes of which expression is uniquely altered in the presence of CKD. This gene set may have pathophysiological significance and may serve to inform rational development of therapeutic strategies to prevent CVD adverse effects in CKD patients.

Uromodulin (UMOD) Gene Polymorphism Shows Different Associations with Chronic Kidney Disease in Euro-American versus African-American Individuals with Diabetes Mellitus

Anthony J. Bleyer,[1] Stanislav Kmoch,[2] Carl D. Langefeld,[1] Laura M. Raffield,[1] Lingyi Lu,[1] Donald W. Bowden,[1] Barry I. Freedman.[1] *[1]Wake Forest School of Medicine, Winston-Salem, NC; [2]Charles Univ 1st School of Medicine and General Faculty Hospital, Prague, Czech Republic.*

Background: Single nucleotide polymorphisms (SNPs) in the *UMOD* gene encoding uromodulin (Tamm Horsfall protein) are associated with eGFR and BP in non-diabetic populations of European ancestry. Relationships between *UMOD* and HTN, CKD and subclinical cardiovascular disease are not as well characterized in T2D.

Methods: Associations between *UMOD* SNP rs4293393 and CKD, HTN and coronary artery calcified plaque (CAC) were assessed in 1117 European Americans (EAs) enriched for T2D from the Diabetes Heart Study (DHS), of whom 936 (83.6%) had T2D, and in 479 African Americans (AAs) with T2D from the AA-DHS. eGFR was calculated with the modified MDRD formula. Association analyses with eGFR and urine albumin creatinine ratio (UACR) were adjusted for age, sex, ACE inhibitor/angiotensin receptor blocker use, T2D and hypertension. Analyses with CAC were adjusted for age, sex, BMI, statin use, T2D, and smoking. Analyses with hypertension were adjusted for age, sex, and T2D.

Results: As shown in the Table below, rs4293393 was associated with higher eGFR (but not UACR) in EAs from the DHS; with a trend toward positive association with CAC. Conversely, rs4293393 was significantly associated with increased UACR in AAs with T2D, but not with eGFR or CAC.

Study Sample	Ancestry	N	Trait	P-value	Estimate (β)
Full DHS (T2D+non-T2D)	EA	1117	Hypertension	0.949	-0.008
Full DHS (T2D+non-T2D)	EA	1058	CAC	0.075	0.222
Full DHS (T2D+non-T2D)	EA	1117	eGFR	0.047	0.028
Full DHS (T2D+non-T2D)	EA	1092	UACR	0.725	0.028
T2D-affected DHS	EA	936	eGFR	0.056	0.030
T2D-affected AA-DHS	AA	479	UACR	0.043	0.27
T2D-affected AA-DHS	AA	479	eGFR	0.650	-0.05
T2D-affected AA-DHS	AA	479	CAC	0.290	0.37

Conclusions: We conclude that *UMOD* SNP rs4293393 associates with higher eGFR in EA populations enriched for T2D, but not in AAs with T2D. Rs4293393 was significantly associated with proteinuria in AAs. Differences in effects based on population ancestry require additional investigation.

FR-PO206

Overexpression of Uromodulin Induces Age-Dependent Renal Damage

Matteo Trudu,[1] Alessandro Corbelli,[2] Maria Pia Rastaldi,[2] Olivier Devuyst,[3] Luca Rampoldi.[1] *[1]San Raffaele Scientific Inst, Milan, Italy; [2]IRCCS Ospedale Maggiore Policlinico, Milan, Italy; [3]Univ of Zurich, Zurich, Switzerland.*

Background: Variants in the *UMOD* gene encoding uromodulin have been consistently associated with an increased risk for chronic kidney disease (CKD) in the general population. The *UMOD* risk variants, which are located in the promoter region in a LD, directly increase *UMOD* expression *in vitro* and *in vivo*. To gain insight into the role of uromodulin as a risk factor for CKD, we investigated renal function parameters and kidney pathology and structure in transgenic mice overexpressing *Umod*.

Methods: Renal function of transgenic and control mice (n= 6-8/group, age-, sex-matched) was monitored over time at 12, 16 and 20 months of age by sinistrin and creatinine clearance. We obtained urine by using individual metabolic cages and blood samples at time of sacrifice. Kidney samples were collected for mRNA and protein extraction, and for optical and electronic microscopy (EM).

Results: Transgenic uromodulin is specifically expressed in TAL segments. Increased uromodulin expression in transgenic mice (+80%) is comparable to the one observed in subjects homozygous for *UMOD* risk variants, relative to homozygous carriers of protective alleles. Baseline diuresis and urine parameters (creatinine, electrolytes, osmolarity) were within normal range and similar between strains up to 20 months of age. Renal function was also similar between groups. Increased microalbuminuria was observed in transgenic mice, starting at 16 months and present in about 50% transgenic mice by the age of 20 months. Renal damage in the kidneys of transgenic mice was evidenced by increased expression of lipocalin-2 (NGAL) and KIM-1, paralleled by segmental dilations and tubular casts, mainly affecting distal segments. There were no significant changes in the glomerular ultrastructure (EM) or in podocin and nephrin expression.

Conclusions: These results substantiate the causal link between *UMOD* variants, increased uromodulin expression and age-dependent renal damage. The preserved GFR/renal function in aged transgenic mice suggests that the effect of uromodulin as a risk factor for CKD may be dependent on additional conditions harming the kidney.

FR-PO207

Common *UMOD* Variants Influence Transcription, Urinary Excretion and Biochemical Properties of Uromodulin

Celine Schaeffer,[1] Sonia Youhanna,[2] Stephan Troyanov,[3] Francois Madore,[3] Cinzia Magagnotti,[1] Luca Rampoldi,[1] Olivier Devuyst.[2] *[1]San Raffaele Scientific Inst, Milan, Italy; [2]Physiology UZH, Zurich, Switzerland; [3]Hopital du Sacre-Coeur, Montreal, Canada.*

Background: Uromodulin is exclusively expressed in the kidney and is the most abundant protein in urine. Common variants in the promoter of the *UMOD gene* encoding uromodulin are associated with renal function and blood pressure. We recently demonstrated that such variants affect gene transcription but their impact on uromodulin excretion and biochemical properties remains unknown.

Methods: We analyzed urinary uromodulin (ELISA) in 14,404 Europeans from three genetic isolates and five urban cohorts. We measured plasma values in cases with low (2.0 ± 0.18 mg/g creat) and high urinary uromodulin (69.19 ± 2.84 mg/g creat) (N=53 pairs). Uromodulin qualitative analysis was carried out by immunoblotting and 2D-gel electrophoresis on urine samples from age- and sex-matched homozygous carriers of protective or risk *UMOD* variants (N=10 pairs).

Results: The lead *UMOD* SNPs rs12917707 and rs4293393, associated with increased risk for CKD and hypertension, are located in the gene promoter in a linkage disequilibrium block that extends to exon 6 in the coding sequence. In all cohorts, the common G allele of rs12917707 was associated with higher uromodulin levels in an additive fashion (geometric means 10.24, 14.05 and 17.67 mg/g creat for zero, one, or two copies respectively, $p<1x10^{-8}$). By contrast, plasma levels of uromodulin were not influenced by genotype. Similar plasma levels were also observed in subjects with extreme urinary values. The *UMOD* genotype was associated with a systematic difference in uromodulin immunoreactivity, independently of protein denaturation and glycosylation patterns. Individual differences were also observed within each genotype and were confirmed by 2D-gel electrophoresis.

Conclusions: These data indicate that common variants in the *UMOD* promoter region exert a strong influence on urinary uromodulin levels and are associated with significant modifications in uromodulin immunoreactivity. They provide insights into uromodulin biology and its association with renal function.

Combination of Linkage Analysis and Whole Exome Sequencing for the Identification of Risk Variants in IgA Nephropathy

Sharon N. Cox,[1] Francesco Pesce,[1,2] Julia Sarah El-Sayed Moustafa,[2] Fabio Sallustio,[1] Grazia Serino,[1] Annalisa Giampetruzzi,[3] Nicola Ancona,[4] Mario Falchi,[2] Francesco Paolo Schena.[1,5] *[1]D.E.T.O., Univ of Bari, Italy; [2]Genomics of Common Disease, Imperial College, United Kingdom; [3]IPSP, Cnr, Italy; [4]ISSIA, Cnr, Italy; [5]C.A.R.S.O. Consortium, Bari, Italy.*

Background: The pathogenesis IgA nephropathy (IgAN) is still not clear but familial clustering demonstrates a strong genetic involvement. Aim of our study was to find rare, high penetrant risk variants, combining family-based linkage analysis with full exome sequencing.

Methods: Genotyping and linkage analyses have been performed on 25 families of South Italian ancestry. Eight IgAN families that gave the strongest linkage signals were selected for exome sequencing. Variant calling and annotation were performed with standard procedures. High priority variants were chosen based on call quality, MAF, impact, co-segregation in affected family members and their presence within linked areas. Follow-up on these variants was performed using Sanger sequencing and TaqMan Assays on familial and sporadic IgAN patients and in-house population controls.

Results: We confirmed and refined our previously published identified regions on chromosome 4q26, 6q22-23 and17q21 linked with IgAN. Moreover, we detected additional regions on chromosome 1p and 3p, 8p. Our exome study identified a total of 150913 variants in at least one of the 24 samples. Sanger sequencing validated variants within different genes. Taqman assays showed that a missense variant segregated in affected individuals in five independent families and it was also detected in sporadic IgAN cases. Another coding variant showed a higher frequency than expected in both cases and controls, but a statistically significant difference was found.

Conclusions: Gene variants common to all affected IgAN patients have not been detected in our study confirming the already documented genetic heterogeneity of the disease. Sanger sequencing and taqman validation is still being performed on other selected variants and the most promising variants will be selected for functional studies.

Exome Array Analysis Identifies Rare Coding Variants Associated with IgA Nephropathy in Han Chinese

Ming Li,[1,2] Hui Qi Low,[3] Jia Nee Foo,[3] Peiran Yin,[1,2] Jianjun Liu,[3] Xueqing Yu.[1,2] *[1]Dept of Nephrology, The First Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Key Laboratory of Nephrology, Ministry of Health, Guangzhou, Guangdong, China; [3]Human Genetics, Genome Inst of Singapore, Singapore, Singapore.*

Background: IgA nephropathy (IgAN) is one of the most common glomerulonephritis throughout the world and the major cause of ESRD in China. Our previous genome wide association study (GWAS) has identified several susceptibility loci, which are mainly

common variants in the non-coding regions. In order to identify rare and low-frequency non-synonymous variants associated with IgAN, we performed a comprehensive analysis of rare and common coding variants using an exome chip.

Methods: We performed the discovery analysis in 2378 cases and 15642 controls of Chinese Han population by using the Illumina HumanExome Beadchip. Genome-wide efficient mixed-model association (GEMMA) was used for SNP-based association study, and burden test and SKAT-O were used for the gene-based analysis. The replication analysis of top SNPs from the discovery analysis was done in an additional 4270 cases and 6017 controls by using the Sequenom iPLEX system and TaqMan assays.

Results: After sample and SNP quality control, 60676 SNPs, including 43977 non-polymorphic coding ones, were subjected association test. The validation analysis of top SNPs discovered two novel low-frequent risk variants for IgAN.

Conclusions: This study demonstrates that the genome-wide association analysis using exome array is a valuable approach in identifying low-frequency and rare coding variants that contribute to complex human traits. By identifying novel susceptibility variants, our study provides new insights into the biological variability in the development of IgAN.

Genetic Association Study of Alpha-Defensin Gene DEFA1A3 Copy Number Polymorphism in Chinese Han Patients with IgA Nephropathy

Zhen Ai,[1,2] John A.L. Armour,[3] Jianjun Liu,[4] Xueqing Yu.[1,2] *[1]Dept of Nephrology, The First Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Guangdong Provincial Key Laboratory of Nephrology, Ministry of Health, Guangzhou, Guangdong, China; [3]School of Biology, Univ of Nottingham, Queen's Medical Centre, Nottingham, United Kingdom; [4]Human Genetics, Genome Inst of Singapore, Singapore.*

Background: Our recent GWAS study has confirmed a novel susceptibility locus, 8p23.1 (rs2738048) in Chinese Han patients with IgA nephropathy (IgAN). The association is within an LD block where several members of the DEFA family reside, including the DEFA1A3 gene which has extensive copy number variations. In this study, we aim to investigate the role of DEFA1A3 gene copy number polymorphism in Chinese Han IgAN patients.

Methods: 2400 Han Chinese subjects (1200 cases/1200 controls) were enrolled in the study. We combined two paralogue ratio tests (PRT) and four allelic ratio measurements to provide accurate measurements of DEFA1A3 gene number. Besides, we performed SNP genotyping of rs2738048 in all selected subjects. Then we did the association analysis using the trend test.

Results: The total copy numbers of the DEFA1A3 gene ranged from 2 to 16 copies and 6 copies was the most common in Chinese Han. DEFA1A3 copy number variants were significantly different between IgAN cases and controls. According to the association analysis, the total copy numbers of DEFA1A3, DEFA1, and DEFA3 were all strongly associated with IgAN susceptibility. SNP rs2738048 also showed significant association. But the significance of rs2738048 disappeared when conditioned on total DEFA1A3 or DEFA1,while it remained when conditioned on DEFA3. Lower copy numbers of total DEFA1A3, DEFA1 and DEFA3 were all more frequent in IgAN patients.

Conclusions: The case-control association study performed finds some evidence for an influence of variation in genes coding for alpha defensins in susceptibility to IgAN in Chinese Han. Previous significance found for SNP rs2738048 probably lies in the gene DEFA1A3. Lower copy numbers of DEFA1A3 are significantly associated with high risk of IgAN.

FR-PO211

Differential Expression of MicroRNA in Peripheral B Lymphocytesin Patients with IgA Nephropathy

Guisen Li, Li Wang. *Renal Dept, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: IgA nephropathy (IgAN) is one of the most common causes of end stage renal disease (ESRD). The pathogenesis of IgAN is still unclear. Epigenetic alterations may play an important role in the pathogenesis of IgAN, but previous studies didn't focus on B lymphocytes that produce IgA1 molecules. In this study, our aim is to detecte the microRNAs expression profiles fromperipheral blood B lymphocytes, to find out significantly differential expressed microRNAs between IgAN patients andhealthy controls, and to explore the possible mechanism of microRNA in the pathogenesis of IgAN.

Methods: Five microliters peripheral blood was collected from 7 IgAN patients and 4 healthy controls. We selected B lymphocytes with magnetic Beads, and then isolated RNA from those lymphocytes. After hybridized on the miRCURY™ LNA Array (v.18.0), we compared the differential expression of microRNAs.

Results: Compared with healthy controls, there were 115 discriminating microRNAs with more than 2-fold change,85 of which were upregulated and 30 were downregulated in IgAN patients. Five significantly different microRNAs were picked out, four upregulated microRNAs, miR-3189-5p, let-7g-5p, miR-4258, miR-4695-3p and one downregulated microRNAs miR-99b-5p.

Conclusions: The expression profile of microRNAs from peripheral blood B lymphocytes in IgAN patients is different from healthy controls.

FR-PO212

Collagen Type IV Alpha Defect May Be Susceptibility Factor to IgAN

Yifu Li,[1] Sindhuri Prakash,[1] Simone Sanna-Cherchi,[1] Krzysztof Kiryluk,[1] Hussein H. Karnib,[2] Gianluca Caridi,[3] Gian Marco Ghiggeri,[3] Ali G. Gharavi.[1] *[1]Div. of Nephrology, Columbia Univ, New York; [2]American Univ of Beirut, Lebanon; [3]G. Gaslini Inst., Italy.*

Background: Increasing evidence have demonstrated that extracellular matrix components may play important roles in pathogenesis of glomerulonephritis. Familial IgA Nephropathy (IgAN), thin basement membrane nephropathy (TBMN) and Alport syndrome (AS) are primary glomerular disorders which all present with micro- or macroscopic hematuria, proteinuria and variable progression to ESRD. A previous genome-wide scan reported linkage of familial IgAN to chromosomes 2q36, which encompasses the collagen type IV gene COL4A3/A4 locus. Suggesting that collagen type IV alpha defects may be a susceptibility factor for IgAN.

Methods: We report five multigenerational kindreds referred for evaluation of familial IgAN. All kindreds were ascertained via an index case with renal failure, and a kidney biopsy demonstrating mesangial proliferation and dominant IgA deposition; each kindred featured multiple individuals with dominant transmission of hematuria/proteinuria with/without chronic renal failure, and absence of hearing or ocular defects. We performed mutational screening of all exons of the COL4A3, COL4A4 and COL4A5 genes in all affected members in these 5 [A1] pedigrees because we detected linkage peaks on 2q36 or rare coding mutations in one of the COL4A genes by exome sequencing the index case.

Results: Linkage analysis demonstrated linkage to the COL4A3/A4 or the COL4A5 loci in five families (LOD = 1.186, 2.1 and 2.2 at 2q35-37, and LOD = 3.6, 0.534 at Xq22-25). Mutational screening revealed a single segregating pathogenic mutation in five families (COL4A3 G291E, COL4A4 G852D, G1624V, and COL4A5 G174C, G1357V). These novel mutations occurred on conserved glycine residues, and segregated in all affected individuals without classic TBMN features. Additionally, these novel mutations were not present in at least 200 ethnically-matched controls.

Conclusions: The present case series suggest collagen type IV alpha may not be simply a coincidental finding and may represent a susceptiblilty factor for IgAN, motivating systematic investigation of rare coding mutations in COL4A genes in IgAN patients.

FR-PO213

Mannose-Binding Lectin Gene Polymorphism Is Closely Associated with Clinical Manifestation and Renal Prognosis in Lupus Nephritis

Xinbei Chang, Shan Mou, Zhaohui Ni, Qin Wang. *Nephrology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong Univ, Shanghai, China.*

Background: Lupus nephritis (LN) is one of the most serious SLE complications since it is the major predictor of poor prognosis.Complement system may play an important role in the pathogenesis of LN, such as mannose-binding lectin (MBL).

Methods: 140 LN patientswho received renal biopsy at our hospital from January 1, 2003 to December 31, 2012 were enrolled, and 150 healthy subjects were enrolled. Primary and secondary end-point was defined as entering ESRD or death, and Scr level increased >50% of baseline, respectively. ELISA was used to detect serum MBL level.Integrated capillary electrophoresis was used to detect gene polymorphism of MBL.

Results: The mean age of LN patients was 39.79±13.46 years old (129 females). During the following-up of 44.30±30.91 months, 40 patients entered end-point, and 7 patients entered ESRD. Compared with control group, LN patients with -550 GC gene type, -221 GG gene type, -435 GG gene type, +4 CC gene type and 54 codon GG gene type had lower serum MBL. LN patients had lower GG genotype frequencies at 54 codon compared with control group[124 (82.12%) versus 104 (74.29%),p=0.019]. Patients with SNP in -550 had higher systolic blood pressure, higher ds-DNA antibody level, higher serum creatinine, more proterinuria, higher SLEDAI score, and higher AI, but lower C3 and eGFR. Patients with SNP in +4 had higher ds-DNA antibody level, higher serum creatinine, more proterinuria, higher AI and CI, but also had lower eGFR. LN patients who progressed to end point events had less frequencies of GG, CC wild type at promoter -550 and +4 respectively compared with those LN patients without end point events. Kaplan-Meier analysis showed that patients with SNPs of -550, +4 were more likely to develope into ESRD. Cox regression analysis further showed that male (HR=5.654), SNP of +4 site (HR=5.142) and baseline serum creatinine (HR=1.012) were all independent risk factors of poor renal prognosis in LN patients.

Conclusions: Single nucleotide polymorphisms of MBL gene were related to clinical manifestation and renal prognosis of LN, and SNP of +4 site may predict progression of lupus nephritis.

Genetic Variants in ANCA-Associated Vasculitis: A Meta-Analysis

Chinar Rahmattulla, Antien Mooyaart, Daphne Van Hooven, Jan A. Bruijn, Ingeborg M. Bajema. *Pathology, Leiden Univ Medical Center, Netherlands.*

Background: ANCA-associated vasculitis (AAV) is a systemic autoimmune disease of unknown etiology. Both genetic and environmental factors are believed to be involved in the pathogenesis of AAV. Evidence of a genetic component has been growing. This meta-analysis assessed the pooled effect of each genetic variant that is reproducibly associated with AAV.

Methods: Studies that assessed the association between genes and AAV were searched in PubMed, Embase, and Web of Science. All genetic variants that were significantly associated with AAV in an initial study and were subsequently independently reproduced

in at least one additional study were selected. All studies that assessed these reproduced genetic variants were subsequently included in the meta-analysis. Associations were calculated at the allele level, and the main measure of effect was a pooled odds ratio in a random-effects model.

Results: The literature search yielded 5020 articles. Genetic associations in AAV were investigated in 85 of these articles. We identified 16 replicated genetic variants, of which 13 remained significantly associated with AAV following meta-analysis. These variants were in or near the following genes: ARHGAP18, CD226, FCAR (CD89), COL11A2, CTLA-4, HLA, HSD17B8, LEPR, PTPN22, RING1, RXRB, and SERPINA1.

Conclusions: This meta-analysis identified 13 genetic variants associated with AAV. The contribution of the identified genetic variants in the pathogenesis of AAV should be the focus of future studies.

FR-PO215

Sequence Variants of PLA2R1 and HLA Loci in Caucasians and Asians with Idiopathic Membranous Nephropathy Gyungah Jun,[1] John Farrell,[1] Wei-Song Qin,[2] Zhihong Liu,[2] David J. Salant,[1] Laurence H. Beck.[1] *[1]Medicine, Boston Univ, Boston, MA; [2]Jinling Hospital, Nanjing, China.*

Background: Primary membranous nephropathy (MN) is associated with variants in *PLA2R1* and the MHC II region but it is unclear which sequence variants explain the association.

Methods: We conducted targeted resequencing of PLA2R1 and MHC II regions in 76 subjects from Caucasian (EA: 49 cases and 6 controls) and Asian (ASN: 12 cases and 2 controls) populations. Ninety-five percent of MN cases were anti-PLA_2R positive. All exonic variants and nominally significant ($p<0.05$) intronic variants were followed up by genotyping in independent (n=274) and the sequenced (n=73) samples. Two HLA genes (DRB1 and DQA1) from 109 subjects (total: EA=42 and ASN=66) including 8 cases that had been sequenced (total: EA=4, ASN=4) were typed in an independent HLA laboratory. With ethnic specific controls from the 1000 Genomes Project, a total of 581 EA (195 cases and 386 controls) and 442 ASN (83 cases and 359 controls) subjects were available for analysis. Association was conducted separately in each population and then meta-analyzed.

Results: No novel exonic variants in PLA2R1 were observed in MN cases. Minor alleles of six known variants in PLA2R1 were nominally significant with increased risk for MN in both EA and ASN (best variant, rs4664308, meta-analysis p value [meta-p]=$1x10^{-12}$, odds ratio [OR]=2.7, 95% confidence interval [CI]=1.7-2.9). Association of rs35771982 and rs3749117 in PLA2R1 was also confirmed (meta-analysis p~10^{-9}). Highly linked HLA subtypes, DRB1.03.01 and DQA1.05.01, were associated with similar effect sizes for MN (meta-p=$2x10^{-16}$, OR=5.6, CI=3.7-8.4). A novel independent HLA subtype, DRB1.11.04, was nominally significant in both populations (meta-p=0.006, OR=3.12, CI=1.39-6.98). Four additional DRB1 subtypes (07.01, 08.01, 15.01, and 16.02) were nominally significant only in the EA population.

Conclusions: Comprehensive resequencing of *PLA2R1* and MHC II suggests that MN risk is attributable to multiple HLA-D subtypes along with previously known *PLA2R1* risk variants. Further examination of additive effects of HLA subtypes and interactive effects between PLA2R1 variants and HLA subtypes is warranted.

FR-PO216

Role of Mutations of Inverted Formin 2 in Pathogenesis of Familial Focal Segmental Glomerulosclerosis Xu Hao, Jingyuan Xie, Jun Ma, Weiming Wang, Hong Ren, Zhaohui Wang, Nan Chen. *Dept of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ, School of Medicine, Shanghai, China.*

Background: In our previous study, we identified two mutations of inverted formin 2 among seventy independent FSGS families by linkage analysis and Sanger sequencing methods. The aim of this study is to further investigate the effects of these two mutations on podocyte function.

Methods: Site mutagenesis was carried out to create S85W and S129_Q130insVRQLS mutant. Podocytes were transfected with plasmids. Quantitative PCR, western blot, immunofluorescence were performed to detect expression and localization of INF2, a-actinin4, Cdc42 and serum response factor (SRF). Immunoprecipitations were conducted to study the interaction of INF2 and Cdc-42. Adhesion assay, wound scratch assay and hoechst staining were performed to detect the effect of two mutations on adhesion ability and cell apoptosis.

Results: We found that protein and mRNA level of S85W decreased compared with wide type (WT) type podocyte. In addition, in WT podocyte, INF2 distribution was diffuse throughout the cell in WT podocytes; In S85W podocytes, INF2 had a perinuclear localization or aggregation in cytoplasm, whereas in S129_Q130ins VRQLS podocytes, the localization of INF2 was similar compared with WT pococytes. In addition, the expression of a-actinin4 was decreased compared with WT podocyte protein in levels of protein and mRNA. The phosphorylation of SRF decreased compared with WT podocyte and the localization of SRF in the podocyte changed in p.S85Wpodocyte, which indicated the activation of SRF decreased compared with WT podocyte. The result of Co-IP and inflorescence indicated that the interaction of INF2 and Cdc42 decreased in p.S85W podocyte. Adhesion assay and wound scratch assay revealed the decreased cell adhesion of both p.S85W and p.S129_Q130ins VRQLS. Hoechst staining demonstrated more apoptosis of p.S85W and p.S129_Q130ins VRQLS.

Conclusions: S85W could damage podocytes by affecting the cytoskeleton, and p.S129_Q130ins VRQLS has no effect on the cytoskeleton. Both p.S85W and p.S129_Q130ins VRQLS could decrease the adhesion ability and induce cell apoptosis.

FR-PO217

Reciprocal Regulation Between ANLN and AKT Influence Podocyte Motility in Podocytes Gentzon Hall,[1,2] Andrew F. Malone,[1,2] Paul J. Phelan,[1,2] Alison Homstad,[2] Guanghong Wu,[2] Thomas Lindsey,[2] Michelle P. Winn.[1,2] *[1]Nephrology, Duke Univ, Durham, NC; [2]Duke Molecular Physiology Inst, Duke Univ, Durham, NC.*

Background: Mutations of the F-actin binding protein anillin (ANLN) have been shown to cause FSGS. ANLN is a complex, multidomain protein that is known to play a role in cytokinesis and cell motility through interactions with phosphoinositol-3-kinase (PI-3K) signaling intermediates such as AKT. In prior studies, we demonstrated that ANLN modulates AKT activation in podocytes. In subsequent *in silico* analyses of the ANLN peptide sequence, we identified a candidate AKT consensus phosphorylation site within the ANLN F-actin binding domain (Ser659). Therefore, we hypothesize that ANLN and AKT modulate podocyte motility and cytoskeletal dynamics via reciprocal regulation.

Methods: Immunoblot and immunoprecipitation studies, siRNA-mediated gene knockdown studies and scratch wound healing assays were performed by standard methods in conditionally immortalized human podocytes (CIHP). Immunoprecipitation studies and scratch wound healing assays were performed in CIHPs stably overexpressing tGFP empty vector, tGFP-$ANLN_{WT}$, tGFP-$ANLN_{S659A}$, or tGFP-$ANLN_{S659E}$. Immunoblot and scratch wound healing studies were also performed in CIHPs with siRNA-mediated *ANLN* knockdown (KD).

Results: *ANLN* KD significantly reduced AKT and GSK-3b activation and basal motility in podocytes. ANLN phosphorylation and basal podocyte motility are significantly reduced in the presence of a highly selective pharmacologic antagonist of AKT. Finally, basal podocyte motility in phospho-null ANLN-overexpressing podocytes ($ANLN_{S659A}$) is significantly impaired relative to $ANLN_{WT}$ and $ANLN_{S659E}$-overexpressing cells.

Conclusions: ANLN is a critical modulator of podocyte cytoskeletal dynamics likely via the modulation of AKT activity. AKT is a modulator of ANLN activity via the direct phosphorylation of Ser659. Taken together, these novel findings elucidate the cellular effects of the dynamic interplay between ANLN and AKT and highlight a potential role for pharmacologic antagonism of AKT signaling in the treatment of FSGS.

FR-PO218

Genetic Loss of Function Mutations in Zebrafish and Human *CRB2*, a Regulator of Epithelial Polarity, Are Associated with Podocyte Foot Process Effacement and Focal Segmental Glomerulosclerosis Arindam Majumdar,[1] Lwaki Ebarasi,[1] Shazia Ashraf,[2] Agnieszka Bierzynska,[3] Hugh J. McCarthy,[3] Svjetlana Lovric,[2] Moin Saleem,[3] Friedhelm Hildebrandt.[2] *[1]Immunology, Genetics, and Pathology, Uppsala Univ, Uppsala, Sweden; [2]Div of Nephrology, Harvard Medical School, Boston Children's Hospital, Boston, MA; [3]Paediatric Renal Medicine, Univ of Britstol, Bristol Royal Hospital for Children, Bristol, United Kingdom.*

Background: Podocytes are epithelial cells, central to the glomerular filtration barrier, and a pathological target in glomerular diseases. In published work, we identified a requirement for zebrafish *crb2b*, an evolutionarily conserved regulator of epithelial apical basal polarity, in podocyte morphogenesis. The Crb proteins are transmembrane proteins which lie at the intersection of epithelial polarity, cell signaling, and membrane biogenesis.

Methods: We studied *crb2b* function in podocytes using a genetically heritable, loss of function mutation in zebrafish. Using homozygosity mapping in combination with exome sequencing and next generation sequencing, we then translated our findings into humans by determining whether the *CRB2* locus may be mutated in nephrotic syndrome patients.

Results: Homozygous *crb2b*$^{-/-}$ zebrafish podocytes show loss of foot process architecture and slit diaphragms and apical mis-localization of Nephrin protein. We identified recessive mutations in the *CRB2* in four different families with steroid resistant nephrotic syndrome (SRNS) and one family with congential nephrosis. All together, we present five new human mutations, including a putative null allele, which together constitute the first reported allelic series in human CRB2. By complementation rescue experiments of zebrafish *crb2b*$^{-/-}$ *embryos*, we show that three of these *CRB2* mutations resulted in loss of protein function. We show that Crb2 and Nephrin proteins molecularly interact.

Conclusions: Based on genetic analysis of CRB2 in zebrafish and humans we conclude that *CRB2* is required for proper podocyte morphological differentiation. Furthermore, our human genetic studies suggest that *CRB2* loss of function mutations may be causative to some forms of inherited nephrotic syndrome.

FR-PO219

The Genomic Landscape of Congenital Malformations of the Kidney and Urinary Tract Miguel Verbitsky,[1] David Fasel,[1] M. Sampson,[2] John M. Darlow,[3] Prem Puri,[3] Rik Westland,[1,4] Francesco Scolari,[5] Monica Bodria,[6,7] Landino Allegri,[7] Joanna Van Wijk,[4] Krzysztof Kiryluk,[1] Marijan Saraga,[8] Velibor Tasic,[9] Friedhelm Hildebrandt,[10] Cecile Jeanpierre,[11] Craig S. Wong,[12] David E. Barton,[3] Gian Marco Ghiggeri,[6] Ali G. Gharavi,[1] Simone Sanna-Cherchi.[1] *[1]Div of Nephrology, Columbia University, NY; [2]Dept of Pediatrics, University of Michigan, Ann Arbor, MI; [3]National Children's Research Centre, Dublin, Ireland; [4]Pediatric Nephrology, VUMC, Amsterdam, Netherlands; [5]Div of Nephrology, Hospital of Montichiari, Italy; [6]Pediatric Nephrology, G. Gaslini Hospital, Genoa, Italy; [7]Div of Nephrology, University of Parma, Italy; [8]Pediatric Nephrology, University of Split, Croatia; [9]Pediatric Nephrology, University of Skopje, Macedonia, The Former Yugoslav Republic of; [10]Div of Nephrology, Boston Children's Hospital, MA; [11]Lab des Maladies Rénales Héréditaires, Inserm U1163, France; [12]Dept of Pediatrics, University of New Mexico, Albuquerque.*

Background: Copy number variations (CNVs) predispose to multiple developmental phenotypes. We demonstrated that ~17% of cases affected by renal hypodysplasia (RHD) are caused by rare CNVs. We performed a CNV study across the clinical spectrum of congenital malformations of the kidney and urinary tract (CAKUT) from >2,000 affected individuals.

Methods: The study comprised 2,063 CAKUT cases and 23,362 controls, all genotyped with high-density SNP arrays. QC was performed using PLINK, CNV calls were determined using PennCNV.

Results: After QC, CNV analysis in 1,989 patients identified 2,851 large (>100 kb), high-quality, and rare (<1:1,000) CNVs. 337 cases carried a CNV with an overlap with a known genomic disorder, and 180 patients carried a novel large (>500 kb) CNV of potential pathogenic relevance. CNV burden was higher in patients with RHD compared to patients with obstructive uropathy or VUR. Besides the common 17q12 RCAD deletion, we identified multiple recurrent CNVs that can represent genomic disorder specific for urinary tract developmental phenotypes, such as the 1q21 deletion, 1p36 duplication, 16p11.2 deletion, 22q11 deletion.

Conclusions: This study describes the genomic landscape across the entire phenotype spectrum of CAKUT and identifies recurrent CNVs for urinary tract developmental phenotypes.

FR-PO220

Genome-Wide Joint Linkage and Association Analyses Confirm *SLC2A9* and *CNTN4 as C*andidate Genes for Serum Uric Acid Levels in Mexican Americans Geetha Chittoor,[1] Jack W. Kent,[2] Marcio Almeida,[2] Sobha Puppala,[2] Vidya S. Farook,[2] Shelley A. Cole,[2] Karin Haack,[2] Jean W. Maccluer,[2] Joanne E. Curran,[2] Melanie Carless,[2] Matthew Johnson,[2] Ravindranath Duggirala,[2] Michael C. Mahaney,[2] Anthony Comuzzie,[2] John Blangero,[2] V. Saroja Voruganti.[1] *[1]Nutrition, Univ of North Carolina at Chapel Hill, Kannapolis, NC; [2]Genetics, Texas Biomedical Research Inst, San Antonio, TX.*

Background: The variation in serum uric acid (SUA) levels is under significant genetic influence. Studies from our group and others have shown strong association of SUA levels with solute carrier family 2, member 9 (*SLC2A9*), a uric acid transporter gene. Our previous linkage study identified a novel QTL on chromosome 3p26 affecting SUA.

Methods: As a follow up, we examined genome-wide SNP data in an expanded cohort of 1281 Mexican Americans from the San Antonio Family Studies. We used a joint linkage/association (JLA) approach for each SNP, implemented in SOLAR, that tested each saturated model (including linkage and the fixed effect of the SNP) against a null model in which both effects were constrained to zero.

Results: JLA results showed a strong association of *SLC2A9* SNPs with SUA ($p<8x10^{-8}$), with the top three SNPs (rs10016075, rs6818672, rs12644047; MAF between 30 and 39%) showing association with lower SUA levels. Results also confirmed our previous linkage findings for SUA on 3p26 (LOD=4.9, $p=1x10^{-6}$) where we observe a strong association with SNPs in contactin 4 [*CNTN4*] (rs1153535, rs4685494, rs11720157; MAF between 17 and 44%; $p<3x10^{-6}$). Furthermore, association analysis of 2920 SNPS in *SLC2A9* in a subset of participants (n=447) confirmed our previous associations and identified novel SNPs (chr_pos: 4_9952938 and 4_9972304; MAF=9 and 32%, respectively) at $p<2.7x10^{-5}$ after accounting for multiple testing.

Conclusions: Our JLA results are especially interesting given the recent attention on the relative importance of common and rare genetic variants for risk of common complex diseases. These findings provide further confirmation of important roles for *SLC2A9* and *CNTN4* in the regulation of SUA levels in Mexican Americans.

CFH-Mutation Related Atypical Hemolytic Uremic Syndrome May Be Modulated by Coagulation Factor X Fengxiao Bu,[1] Nicolo Ghiringhelli Borsa,[1] William T.A. Tollefson,[2] Michael J. Schnieders,[2] Hela Azaiez,[1] Kai Wang,[3] Christie P. Thomas,[1] Carla M. Nester,[1] Richard J. Smith.[1] *[1]Molecular Otolaryngology and Renal Research Labs, Univ of Iowa; [2]Dept of Biochemistry, Univ of Iowa; [3]Dept of Biostatistics, Univ of Iowa.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a complement-related rare renal disorder characterized by microangiopathic hemolytic anemia, thrombocytopenia and acute renal failure. Mutations in *CFH* account for approximately 22% of aHUS cases. In familial cases, *CFH*-mutation penetrance ranges from 12.5% to 100% suggesting the involvement of other genetic factors/modifiers in the etiology of this disorder.

Methods: Five families carrying the same disease mutation c.3644G>A (p.Arg1215Gln) in *CFH* were included in this study. Using targeted genomic enrichment and massively parallel sequencing, all coding exons of genes in complement and coagulation cascades were screened for coding variants. Data were analyzed using a customized Galaxy pipeline. After filtering for quality and frequency, novel and rare variants were annotated based on computational algorithms and reported studies. For selected variants the predicted functional impact was confirmed *in vitro*.

Results: A known factor X deficiency variant (*F10* c.424G>A, p.Glu142Lys) was identified in a three-generation pedigree. No carriers of both the *F10* p.Glu142Lys and the *CFH* p.Arg1215Gln variant developed aHUS, although two persons carrying only the *CFH* p.Arg1215Gln variant developed disease in early childhood. Protein modeling shows that wild-type Glu142 hydrogen bonds with Cys129, while mutated Lys142 hydrogen bonds with Ser146, a shift that destabilizes an important intra-light-chain interaction between a two-stranded beta-sheet and a small alpha-helical secondary structure element. Consistent with this prediction, recombinant mutant factor X secretion was altered in HEK293 cells and its activity was reduced by 30%.

Conclusions: We have identified a variant in *F10*, p.Glu142Lys, that may modify *CFH*-related aHUS perhaps protecting *CFH*-mutation carriers from developing the phenotype. This finding may explain some instances of incomplete penetrance and offer new therapeutic targets to treat this life-threating disease.

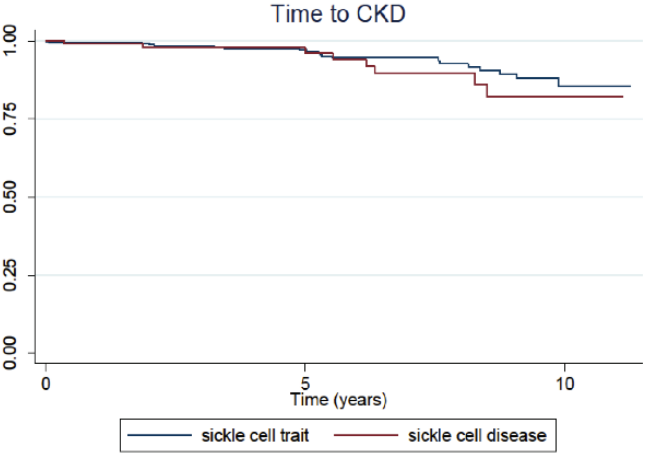
FR-PO222

Sickle Cell Trait a Possible Risk Factor for CKD Maulin Shah,[1] Iris C. De Castro,[2] Danielle Guffey,[1] Charles G. Minard,[1] Biruh Workeneh.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Univ of Washington, Seattle, WA.*

Background: Patients heterozygous for sickle hemoglobin have a phenotypic spectrum including hyposthenuria, hematuria and papillary necrosis, but traditionally sickle cell trait (SCT) has been considered a generally benign state that does not result in progressive CKD and ESRD. However, given recent reports raised in the literature possibly implicated SCT in progressive CKD, we sought to determine whether this was the case in our region.

Methods: We performed database query at a large county hospital in Houston, TX. A total of 972 cases were identified, 790 with SCT and 134 that were confirmed by hemoglobin electrophoresis. We did not include a similarly matched control arm in our initial analysis, and hypothesized that patients with SCD would have significantly higher rates of CKD.

Results: There was no statistically significant difference in the risk for CKD between patients with SCT and SCD (P=0.40). The Kaplan-Meir plot (figure) shows the time to CKD by phenotype group.



After adjusting for age, HTN, diabetes and smoking status in a Cox Proportional Hazards model, the hazards ratio for CKD was 2.30 (95% CI: 0.96, 5.55; P=0.063) for those with sickle cell disease compared to SCT. When we included the interaction between HTN and diabetes (p=0.002 however, the hazards ratio was 2.61 (95% CI:1.11, 6.15; p=0.029).

Conclusions: The risk of CKD among those with trait appears to be more significant than originally thought in our population. We suspect that a prospectively designed study controlling for these other risk factors would more clearly determine whether patients with SCT have just as much risk for CKD as patients with CKD in our population. Further corroborative studies that also control for emerging genetic markers for CKD are required.

Effects of Renal Transplantation on Telomere Attrition Karin Luttropp,[1] Louise Nordfors,[2] Dagmara Mcguinness,[3] Abdul Rashid Tony Qureshi,[2] Peter F. Barany,[2] Paul G. Shiels,[3] Peter Stenvinkel.[2] *[1]Dept of Molecular Medicine and Surgery, Karolinska Instt, Stockholm, Sweden; [2]Dept of Clinical Science, Intervention and Technology, Karolinska Univ Hospital, Stockholm, Sweden; [3]Wolfson Wohl Translational Research Centre, Inst of Cancer Sciences, Univ of Glasgow, Glasgow, United Kingdom.*

Background: Telomere attrition is a feature of the process of aging and renal disease accelerates the attrition rate. It is unknown what effect a successful renal transplantation (RTx) has on telomere attrition. In this study, we investigated dynamic changes in telomere length following RTx its relation to age, CMV serology, homocysteine levels and biomarkers of oxidative stress and inflammation.

Methods: Telomere length was measured in whole blood DNA collected from 47 ESRD patients immediately prior to RTx and again 1 year after RTx. Telomere length determination was performed by qPCR using a Roche Light Cycler LC480.The relative T/S ratio (repeat copy number to single copy gene number) for each experimental sample was determined in relation to the control DNA sample. For comparison of data, Spearman's rank correlation (r) or linear regression was used, as appropriate.

Results: Baseline telomere length ($[T/S]_{base}$) was significantly correlated to telomere length at 1 year ($[T/S]_{1y}$) ($p < 0.0001$; adjusted $R^2 = 0.41$). Telomere length decreased one year after RTx (mean $[T/S]_{base} = 0.986$ versus mean $[T/S]_{1y} = 0.83$; $p<0.001$). $[T/S]_{base}$ was significantly associated to age ($p = 0.04$), IL-6 ($p = 0.01$), TNF ($p = 0.04$), PTX3 ($p = 0.01$) and homocysteine levels ($p = 0.0139$). An inverse association between changes in telomere attrition following RTx and baseline homocysteine levels ($p = 0.007$) was observed. No associations were found between $[T/S]_{base}$ and BMI, gender, fetuin-A, 8-OHdG, hsCRP, cardiovascular disease, folic acid, CMV serology or dialysis vintage.

Conclusions: Age and levels of IL-6, TNF and PTX3 were associated with shorter telomere length before RTx. One year after RTx, a significant decrease in telomere length was observed, which was inversely associated to levels of homocysteine before RTx.

Clinical Diagnostic Testing amongst Australians with Genetic Renal Diseases Using a Targeted Exomic Approach Andrew John Mallett,[1,2] Gladys Ho,[6] Hugh J. McCarthy,[3,6] Melissa H. Little,[4] Bruce Bennetts,[6] Stephen I. Alexander.[3,5,6] *[1]Dept of Renal Medicine, Royal Brisbane and Womens Hospital, Brisbane, Queensland, Australia; [2]CKD.QLD and School of Medicine, The Univ of Queensland, The Univ of Queensland, Brisbane, Queensland, Australia; [3]Dept of Paediatric Nephrology, The Children's Hospital at Westmead, Sydney, New South Wales, Australia; [4]Inst for Molecular Bioscience, The Univ of Queensland, Brisbane, Queensland, Australia; [5]Discipline of Paediatrics and Child Health, Univ of Sydney, Sydney, New South Wales, Australia; [6]Dept of Molecular Genetics, The Children's Hospital at Westmead, Sydney, New South Wales, Australia.*

Background: Massive parallel sequencing shows promise in enabling diagnostic interrogation of the protein-encoding exome that is enriched for mutations causing Mendelian disease. Genetic causes of kidney disease continue to rapidly expand representing a ripe target for such translational application.

Methods: Consecutive patients in an Australian adult and paediatric cohort with clinically identified likely genetic causes for kidney disease had DNA referred for disease-targeted exomic sequencing (AUSCam V3 Renal Panel, Illumina TruSight One). 458 genes were potentially analysed per patient according to phenotype with an average read depth of 200 (98% coverage).

Results: 22 patients with renal disease of likely genetic aetiology had DNA referred. Pathogenic mutations were detected in 8 patients with a further 3 detected requiring further family investigation. Causative genes included HNF1B, CEP290, ATP6V1B1, CFH, PKD1, PKD2, SALL1, ACTN4, DLX6, COL4A5 and LMX1B. Several variants of uncertain significance were detected amongst additional patients, including in COL4A4 and CR1.

Conclusions: An early national cohort of variable genetic renal disease has identified a number of clear mutations in diseases with significant genetic heterogeneity. Continued evolution and refinement of the local disease-targeted approach (AUSCam) continues and may result in a valuable tool for genetic diagnosis with implications for future treatment and management options.

FR-PO225

Comprehensive Diagnosis of Hereditary Kidney Diseases By a Customized Diagnostic Panel of Targeted Exome Sequencing Takayasu Mori,[1] Kazuyoshi Hosomichi,[2] Eisei Sohara,[1] Tatemitsu Rai,[1] Sei Sasaki,[1] Ituro Inoue,[2] Shinichi Uchida.[1] *[1]Dept of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental Univ, Bunkyo, Tokyo, Japan; [2]Div of Human Genetics, National Inst of Genetics, Mishima, Shizuoka, Japan.*

Background: Gene identification of hereditary diseases by DNA sequencing is very important for precise diagnosis, following treatment, and genetic consulting. However, recent increases of causative genes of multiple diseases or even in a single hereditary disease make it difficult to perform DNA sequencing using conventional Sanger sequencing. Targeted multiple genome resequencing using next-generation sequencing (NGS) enables rapid and precise DNA diagnosis at a large scale, which may be helpful for the efficient diagnosis of hereditary kidney diseases.

Methods: With reference to Human Gene Mutation Database (HGMD^R), articles, opinion of experts, we created a customized capture RNA probe library (SureSelect Custom, Agilent Technologies) for about 70 hereditary renal diseases, including previously reported over 100 of disease-causing genes and their related genes. Using this newly developed DNA diagnosis panel, we performed genetic diagnosis for a total of 16 subjects including two healthy controls and 14 subjects who were clinically suspected hereditary renal diseases, such as Gitelman syndrome, nephrogenic diabetes insipidus, pseudohypoaldosteronism type II, Alport syndrome, etc. Captured genomic DNA libraries of target regions were analyzed with MiSeq (Illumina).

Results: The average coverage depth was 349.5 x with 96.3 % mapped rate and 99.7 % of the target bases covered by at least 10 reads. On-target rate was 65.1 %. Causative mutations were found in four subjects in the expected genes. These mutations were confirmed by Sanger sequence (accuracy of diagnosis by using this panel was 100%, 4 of 4). In other 10 subjects, several exonic non-synonymous mutations not reported as causative so far were also identified.

Conclusions: We succeeded in developing a customized DNA diagnostic panel for more than 70 hereditary kidney diseases using NGS, which provided us fast and accurate DNA diagnosis and may contribute to the improved managements of diseases.

FR-PO226

Survey of the Performance of Protein Prediction Methods with Locus Specific Insights for Steroid Resistant Nephrotic Syndrome Denis Andrew Baird,[1] Agnieszka Bierzynska,[2] Ian N. Day,[1] Moin Saleem.[2] *[1]School of Social and Community Medicine, Univ of Bristol, Bristol, United Kingdom; [2]Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom.*

Background: Protein prediction tools are often used as a guide for determining pathogenic mutations from a background of many neutral variants. Mutational prediction is challenging and a wide range of tools using a variety of computational approaches exist. Although SRNS is genetically heterogeneous, single mutations in NPHS1 and NPHS2 account for the majority of Steroid Resistant Nephrotic Syndrome (SRNS) cases in childhood. This study compares the performance of 10 recent, commonly used web-based prediction tools on mutations within NPHS1 and NPHS2, as well as performing a leave one out validation to determine potentially important biological features contributing towards tool performance.

Methods: Two benchmark datasets were formed from pathogenic mutations in Human Gene Mutation Database (HGMD) and ClinVar and neutral mutations in dbsnp138, and submitted to 10 different protein prediction tools. Performance statistics (accuracy, specificity, sensitivity and Matthews Correlation Coefficient) and ROC curves were calculated. A leave one out analysis was carried out by removing mutations with specific biological features and comparing the change in performance statistics. The features investigated were mutations within a certain domain and allele frequency band (rare, intermediate, common), and mutations with certain physicochemical properties.

Results: All prediction tools performed well on NPHS1 (N=129), and most performed well on NPHS2 (N=82). Mutation Assessor 2 and PolyPhen2 performed best for NPHS1, and SIFT and PolyPhen2 performed best on NPHS2. The next step will involve annotating mutations within NPHS1 and NPHS2 to carry out the leave one out analysis.

Conclusions: Performance comparisons are usually performed on genome-wide benchmarks, with little attention given to performance of tools at a gene level. This study suggests that researchers interested specifically in NPHS1 and NPHS2 may wish to select Mutation Assessor 2, PolyPhen2 or SIFT.

FR-PO227

Understanding Cell Identity in the Kidney Using Novel Cell Type Specific Epigenome Mapping Pazit Beckerman, Yi-An Ko, Katalin Susztak. *Renal, Electrolyte and Hypertension Dept, Univ of Pennsylvania, Philadelphia, PA.*

Background: A single genome gives rise to over 200 cell types in the human body. The epigenome determines the unique gene expression program in each cell type through its effect on chromosomal architecture and transcription factor accessibility to DNA. Histone modifications serve both activating and silencing roles in transcription e.g H3K27ac is found at active promoters/enhancers, H3K36me3 at actively transcribed gene bodies and H3K27me3 marks repressed regions. Determining genome-wide distribution of histone marks in different cells can decipher their role in cell type specific transcriptional regulation and identify cell specific regulatory regions. Such maps are lacking in the kidney research. The aim of this study is to construct the first epigenome maps of the human kidney and of different kidney cell types.

Methods: Human kidney cortical tissue samples were processed to single cell using manual homogenizing. Human renal proximal tubule (HKC8) and podocyte cell lines were cultured. Chromatin was cross-linked, lysed and sonicated to generate fragments ~200bp. ChIP (chromatin immunoprecipitation) was preformed using antibodies for H3K4me3, H3K36me3, H3K4me1, H3K27me3 and H3K27ac. Libraries of ChIP-enriched DNA and control were prepared and sequenced. ChIP-Seq was validated using ChIP-PCR.

Results: Sequences obtained from human kidney tissue, proximal tubule and podocyte ChIP-seq were aligned to the human genome and histone modification maps were constructed. Using computational approaches, we integrated the chromatin datasets to build the first annotated epigenome maps of human kidney, proximal tubular cells and podocytes, defining cell specific enhancers, promoters and other regulatory regions.

Conclusions: We have constructed novel kidney-specific epigenomic regulatory maps. Their crucial significance lies in our ability to define kidney cell-specific critical genes and regulatory networks. Comparing epigenomic maps of different kidney cells will help us better understand cell identity in the kidney. We will be able to identify key transcription factors that take critical part in kidney cells regulation and in the pathogenesis of kidney disease.

Broadening the Differential of Cystic Kidney Disease: Disease

Kristin M. Corapi,[1] Martina M. McGrath,[2] Anthony J. Bleyer,[3] Anna Greka.[2] *[1]Nephrology, Massachusetts General Hospital, Boston, MA; [2]Nephrology, Brigham and Women's Hospital, Boston, MA; [3]Nephrology, Wake Forest Univ School of Medicine, Winston Salem, NC.*

Introduction: Patients with bilateral renal cysts are often presumed to have polycystic kidney disease (PKD). In this case report we describe a patient who presented for a second opinion with a strong family history of chronic kidney disease (CKD).

Case Description: Our patient is a 41 year old male with a history of CKD (eGFR 24ml/min/m^2), dyslipidemia, and gout. His maternal grandfather passed away at age 55, with end stage kidney disease (ESKD). His mother passed away at age 65 after being treated with hemodialysis for 5 years. A renal biopsy was inconclusive in her case. His bother also has CKD and gout. A maternal aunt and two cousins have been diagnosed with presumed PKD. Recent workup includes a renal US, which confirmed normal sized kidneys (11.1cm on right, 11.5cm on left) and numerous cortical cysts bilaterally. Previous urinalyses have been negative for blood and albumin to creatinine ratio is 241. His blood pressure is controlled with an angiotensin receptor blocker and calcium channel blocker. He is on allopurinol for recurrent gout. Given the atypical appearance on ultrasound, strong family history of CKD and gout disproportionate to the level of renal impairment, there was a clinical suspicion for uromodulin associated kidney disease. DNA testing was done and a previously unreported mutation leading to a single amino acid substitution of an Asparagine to a Serine (N128S) was found in the uromodulin gene, confirming the diagnosis of uromodulin associated kidney disease.

Discussion: Uromodulin associated kidney disease is sometimes associated with corticomedullary cysts, and gout may be a prominent feature. This case could be differentiated from PKD because the cysts did not have characteristic features and the kidney size was preserved. Since genetic diagnosis of even rare kidney disorders is now readily available, this case serves as a reminder that multiple renal cysts are not necessarily diagnostic of PKD, and that recurrent gout and significant kidney dysfunction should raise suspicion for uromodulin-associated disease.

FR-PO229

An Unusually Severe Case of Polycystic Kidney Disease

Farshid Yazdi,[1] Derek E. Moore,[2] Ricardo B. Fonseca,[3] Rachel B. Fissell.[1] *[1]Nephrology, Vanderbilt Univ, Nashville, TN; [2]Surgery, Vanderbilt Univ, Nashville, TN; [3]Radiology, Vanderbilt Univ, Nashville, TN.*

Introduction: Patients with polycystic kidney disease (PKD) can have extrarenal cysts. We present a severe case of PKD with extensive liver and renal involvement.

Case Description: The patient is a 43yo old woman with a known history of PKD, who was referred to renal clinic for evaluation of Stage IV chronic kidney disease. Her history was notable for a central nervous system aneurysm, as well as significant flank and back pain and severe shortness of breath. The patient reported she could only eat small amounts of food at one time, and was subsisting on 10-12 small meals a day. Subsequent abdominal CT scan revealed cystic disease involving a significant proportion of her abdominal space, including the majority of the liver parenchyma with shifting of the liver across the midline, and notable lung, gastric, and splenic compression. Remarkably, labs were all in the normal range, with the exception of creatinine of 2.3 mg/dL. Because of the extent of the cystic disease, surgical resection was not an option, and the patient was listed for a combined kidney/liver transplant. She underwent dual organ transplantation and her native liver and both kidneys were removed and sent to pathology. Her liver was noted to weigh 12,986 grams and measured 45x36x19 cm and contained cysts measuring up to 7 cm; her kidney was noted to be 22 x 14 x 8 cm and weighed 668 grams, containing cysts up to 3 cm in size.

Discussion: Although PKD is relatively common, this case is unusual because of the large extent of the extrarenal cysts, making a combined kidney/liver transplant clinically necessary.

FR-PO230

An Unusual Case of Familial Cystic Kidney Disease

Seerapani Gopaluni, Mobin Mohteshamzadeh. *Renal Unit, Royal Berkshire Hospital, Reading, Berkshire, United Kingdom.*

Introduction: We report an unusual case of bilateral renal lymphangiomatosis in a woman who was mistakenly believed to have autosomal dominant polycystic kidney disease (ADPKD). Given the familial and cystic nature of this disease it can be easily confused with ADPKD on ultrasound scanning (USS) unless there is a high degree of clinical suspicion or the typical imaging features are recognised.

Case Description: A 46-year-old woman with a prior diagnosis of ADPKD was referred to us with abdominal fullness. She was diagnosed with ADPKD by USS 10 years previously at a different renal unit and was lost to follow up. Her father at the age of 74 and her younger sister were diagnosed with ADPKD after her initial diagnosis. A repeat USS of the abdomen showed bilateral polycystic kidneys and a small amount of free fluid within the pelvis. A CT of the abdomen and pelvis was done to investigate pelvic free fluid. This showed bilateral perinephric fluid collections and a trace of free fluid. The appearances on CT were felt to be typical of renal lympangiomatosis rather than ADPKD.

Discussion: It is a rare disease characterised by cystic masses in the renal parenchyma, renal sinuses or perinephric spaces. It can be congenital or acquired and is caused by malformation of renal lymphatic drainage to retroperitoneal lymph ducts. It can run in families. The patients may be completely asymptomatic and diagnosed incidentally. Flank pain, abdominal distension, ascites, haematuria, fatigue, weight loss, hypertension and polycythemia have been described. The condition can be difficult to differentiate clinically, radiologically and surgically from ADPKD. Asymptomatic patients do not need treatment. When the pressure effects of enlarged kidneys give rise to significant symptoms treatments such as percutaneous drainage and repeated sclerotherapy have been reported to be safe, minimally invasive and effective techniques in comparison to surgery.

FR-PO231

Gitelman-Like Syndrome in a Patient with Primary Sjögren Syndrome

Taha Ayach, Imtiaz M. Ather, Hem P. Chataut, Yuvaraj Thangaraj. *Univ of Florida, Gainesville, FL.*

Introduction: Sjögren syndrome is associated with different renal manifestations including tubulopathy, usually in the form of distal renal tubular acidosis. Here, we report a case Gitelman-like syndrome associated with primary Sjögren syndrome.

Case Description: Case Presentation: A 67 y o Caucasian female with a longstanding history of Sjögren syndrome on treatment with Cevimeline, presented with 6 weeks history of fatigue and generalized weakness. She denied any history of diarrhea or diuretic use. Physical examination revealed a BP of 117/60 mmHg and remarkable for dry eyes and oral mucosa. Laboratory studies showed hyponatremia, hypokalemic metabolic alkalosis and mild hypomagnesemia with high plasma renin activity and aldosterone level.

		Normal Value
Plasma Biochemistry		
Na^+	121	136 - 145 mmol/L
K^+	2.8	3.3 - 5.1 mmol/L
Cl^-	78	98 - 107 mmol/L
HCO_3^-	29	22 – 28 mmol/L
Arterial PH	7.51	7.35 - 7.45
Arterial PCO_2	39	35 - 45 mm Hg
Urea Nitrogen	19	6 - 20 mg/dL
Creatinine	0.84	0.40 - 0.90 mg/dL
Ca^{2+}	9.4	8.0 - 10.6 mg/dL
Mg^{2+}	1.6	1.5 - 2.8 mg/dL
Renin	3.2	0.2-1.6 ng/mL/hr
Aldosterone	40.9	≤ 16.0 ng/dL
24h Urine biochemistry		
Urine amount (mL)	2950	
Na^+	83	40 - 220 mmol/24h
K+	63	< 40 mmol/24h (in hypokalemic patients)
Cl^-	65	110-250 mmol/24h
Ca^{2+}	94	100 - 300 mg/24 h

Trans-Tubular potassium gradient (TTKG) was high at 13.6% indicating renal potassium wasting. 24h urine studies showed increased potassium excretion in the settings of hypokalemia along with mild hypocalciuria. These features are suggestive of Gitelman

syndrome. Her hyponatremia improved with isotonic volume expansion. She was started on Amiloride and potassium replacement. 1 month follow up revealed improvement in hypokalemia and metabolic alkalosis.

Discussion: While tubulointerstitial disease and distal tubular acidosis have been commonly associated with Sjögren syndrome, Gitelman syndrome has been exceptionally reported. Some reports suggested the presence of circulating autoantibodies to the sodium-chloride cotransporter (NCCT) in the distal convoluted tubules. Interestingly, the renal manifestations can be the presenting symptoms of the Sjögren syndrome and clinicians need to be aware of this possible association.

FR-PO232

Gitelman versus Bartter Syndrome Complicated by Diuretic Abuse
Ghulam Akbar,[1] Muhammad Ameen,[1] Nancy A. Finnigan.[1,2] *[1]Dept of Nephrology, Lankenau Medical Center, Wynnewood, PA; [2]Dept of Nephrology, Mercy Suburban Hospital, PA.*

Introduction: Bartter (BS) and Gitelman syndromes (GS) are autosomal recessive conditions that share common clinical features: hypokalemic metabolic alkalosis, hypomagnesemia, hyperreninemic hyperaldosteronism with normal or low blood pressure. BS usually has hypercalciuria as opposed to hypocalciuria in GS. We present a puzzling case with positive genetic mutation for BS and GS in addition to diuretic use.

Case Description: A 32 years old female had multiple admissions for refractory hypokalemic metabolic alkalosis. Pertinent positive data revealed K+ 1.9mEq/L, Ca++ 9.7mEq/L, Mg++ 1.7mEq/l, chloride 93mEq/L, bircabonate 34mEq/l, creatinine 1.01 mg/dl, phosphate 3.4, renin 130, and aldosterone 26.8. 24 hour collection revealed 6400ml urine with high potassium 158mmols/24hours (reference 25-125 mmol/24hours), hypercalciuria 378 mg/24 hour (reference 42-300 mg/24hour) and creatinine of 1.125g/24hour. Initial diuretic screen was negative on multiple occasions but was found positive 1 year later for hydrochlorathiazide and furosemide. Genetic analysis showed: (1) a duplication of CLCNKB gene with unknown duplication break points (2) a variant of unknown significance in SLC12A3. Diuretic abuse made the diagnosis and management difficult.

Discussion: CLCNKB gene mutation can be related to BS III causing an abnormal Na+-K+-2Cl- transporter in the thick ascending limb but its duplication has not been reported previously. SLC12A3 gene mutation is classically associated with GS that leads to an abnormal thiazide sensitive sodium-chloride symporter in the distal convoluted tubule. Interestingly, she had hypercalciuria intially but subsequent urine collection revealed hypocalciuria. Persistent profound hypokalemia under close inpatient supervision and genotype suggests GS, while a mutation in both CLCNKB and SLC12A3 may have contributed to mix picture. In CLCNKB mutations high, normal or even low urinary calcium levels have been reported.Diuretic abuse likely complicated the laboratory evaluation. This case demonstrates the importance of repeated evaluation of urine electrolytes and diuretic screens with understanding of genotype-phenotype variability.

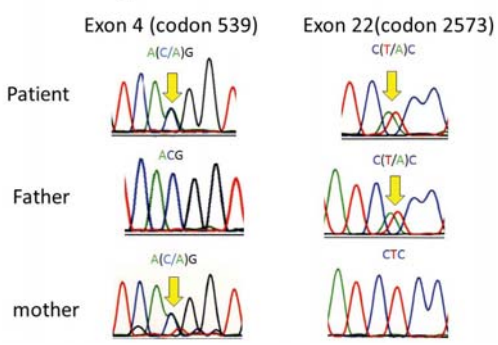
FR-PO233

A Case of Compound Heterozygous Mutation of Gitelman Syndrome, Diagnosed During Preoperative Examination of Kidney Transplantation as a Donor
Akiko Soda, Sahoko Yamamura, Yudo Tanno, Ichiro Ohkido, Nanae Matsuo, Takashi Yokoo. *Dept of Internal Medicine, Div of Nephrology and Hypertension, Jikei Univ School of Medicine, Tokyo, Japan.*

Introduction: Gitelman syndrome is an autosomal recessive disorder, which is caused by mutations in the solute carrier family 12, member 3 (SLC12A3) gene that encodes the thiazide-sensitive Na-Cl co-transporter (NCCT) in distal convoluted tubules (DCT).

Case Description: A 44-year old woman was admitted to our hospital for a preoperative assessment as a kidney transplant donor to her husband who was undergoing dialysis. During her preoperative examination, she presented with hypokalemia, hypomagnesemia, hypocalciuria, metabolic alkalosis and hyperreninemic hyperaldosteronism. The thiazide loading test did not affect chloride reabsorption. Hence, a diagnosis of Gitelman Syndrome was made. In this case, gene-sequencing analysis revealed compound heterozygous mutations of c.539C>A and c.2573T>A in SLC12A3 (ref. Figure). Family analysis of the patient confirmed an autosomal recessive inheritance. Her kidney tissue from the biopsy obtained during the transplant operation was stained with immunostaining anti-SLC12A3 antibody. The expression of SLC12A3 protein was detected in the apical membrane of DCT. This result suggests that the transporter mutation of this case does not cause the functional abnormality of the trafficking procedure to the cell membrane.

Figure: Genetic mutations of this case



Discussion: We found a rare case of Gitelman Syndrome with compound heterozygous mutations in SLC12A3.

FR-PO234

Two Cases of Successful Pregnancy in Patients with Gitelman's Syndrome
Dia Rose Waguespack,[1] Riyaj A. Kasekar,[2] Khaled Abdel-Kader,[1] Rachel B. Fissell.[1] *[1]Nephrology, Vanderbilt Univ; [2]Nephrology, Univ of Pittsburgh.*

Introduction: Gitelman's syndrome is characterized by hypokalemic metabolic alkalosis. Pregnancy in women with Gitelman's syndrome often results in severe hypomagnesemia and hypokalemia. We report two cases of successful pregnancies in patient's with Gitelman's syndrome, managed with aggressive oral and intravenous (IV) electrolyte repletion.

Case Description: The first case is a 25yo woman who presented at 6 weeks gestation with asymptomatic hypokalemia and hypomagnesemia. Patient had a history of 4 previous unsuccessful pregnancies, and was being managed as an outpatient with both oral and intermittent IV potassium and magnesium supplementation. Nephrology was consulted, and continuous IV electrolyte supplementation was initiated. The patient had labs monitored initially twice a week and then once a week, with continuously increased doses of electrolyte solutions to maintain a serum potassium of 2.5-3.3 mEq/L, and a serum magnesium of 1.7-2.5mg/dL. Her maximum repletion requirements were 120meq of IV potassium and 19g of IV magnesium per day. At 27 weeks gestation she was hospitalized and delivered a healthy infant. The second case is a 34yo woman on oral potassium and magnesium replacement. Her first pregnancy was lost in the first trimester. During her second pregnancy, one year later, she was maintained on an increased oral replacement from her prior pre pregnancy state. She had labs monitored at three-week intervals. Her electrolyte replacement was increased to a maximum daily dose of 200 meq oral potassium chloride and 768 mg oral magnesium chloride. This maintained serum potassium levels greater than 3.2meq/L and serum magnesium levels of 1.0-1.1mg/dl. She delivered a healthy infant at 32 weeks gestation.

Discussion: These cases are notable because of the high doses of electrolyte repletion required and the increased requirements over the course of the pregnancies. These cases also demonstrate that successful pregnancy outcomes are possible in Gitelman's syndrome with frequent laboratory monitoring and aggressive titration of oral and/or IV electrolyte replacement, even after previous miscarriages.

FR-PO235

Clinical and Molecular Genetic Correlations in Families with UMOD Variants
Michael James Kelly,[1] Bodo B. Beck,[2] Matthias Wolf,[3] John Andrew Sayer.[1,4] *[1]Renal Medicine, Freeman Hospital, Newcastle-Upon-Tyne, United Kingdom; [2]Inst of Human Genetics, Univ of Cologne, Köln, Germany; [3]Div of Pediatric Nephrology, Univ of Texas Southwestern Medical Center, Dallas, TX; [4]Inst of Genetic Medicine, Newcastle Univ, Central Parkway, Newcastle-Upon-Tyne, United Kingdom.*

Introduction: Mutations in *UMOD* underlie medullary cystic kidney disease type 2. The purpose of this investigation was to analyze the clinical and molecular genetic characteristics of families and individuals with *UMOD* mutations and sequence variants.

Case Description: Families with suspected autosomal dominant interstitial kidney disease were investigated including renal USS, biochemical data and genotyping of *UMOD*. Clinical characteristics including gout and progression of chronic kidney disease were retrospectively evaluated.

12 families were identified with *UMOD* mutations and sequence variants of uncertain significance. Individuals with *UMOD* mutations/variants suffered from chronic kidney disease with a variable age of onset of end stage kidney disease ranging from 36 to 68 years. Urinalyses revealed minimal protein and no blood. Ultrasounds of 22 individuals showed atrophic/cortical thinning in 6 cases and renal cysts in 4 cases. 9 families had a history of gout. One individual from a consanguineous family had a homozygous *UMOD* variant. The remaining sequence changes were all heterozygous. A deletion/insertion mutation affecting exon 4 was seen in 4 families. The T62P variant of uncertain significance was seen in 3 families.

Discussion: *UMOD* mutation results in progressive chronic kidney failure, gout occasional renal cysts and a bland urinary sediment. The age of onset of end stage kidney disease is highly variable. Mutations and variants may be throughout the *UMOD* gene, but are most commonly seen in exon 4.

FR-PO236

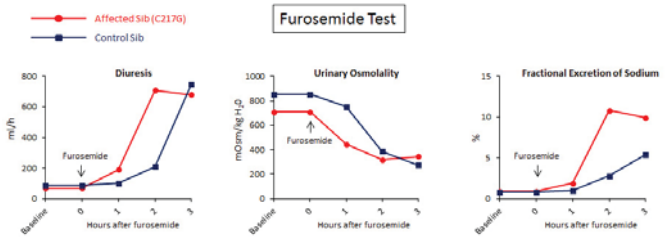
Paradoxical Response to Furosemide in Uromodulin-Associated Kidney Disease
Eric Olinger,[1] Laura Labriola,[2] Karin Dahan,[3] Olivier Devuyst.[1,2] *[1]Physiology, Univ of Zurich, Zurich, Switzerland; [2]UCL Nephrology, Brussels, Belgium; [3]Inst of Pathology and Genetics, Gosselies, Belgium.*

Introduction: Mutations in the *UMOD* gene encoding uromodulin (UMOD) cause autosomal dominant tubulointerstitial nephropathy. UMOD has been shown to regulate the Na^+-K^+-$2Cl^-$ cotransporter NKCC2 in thick ascending limb (TAL) cells. Whether these mutations induce functional alterations in the TAL in the early phase of the disease is unknown.

Case Description: The function of the TAL was tested by comparing the response to a single dose (80 mg) of furosemide and to a water deprivation test with desmopressin

perfusion in a 32-year-old female patient carrying the pathogenic *UMOD* mutation p.C217G and her unaffected 31-year-old sister. The affected sib had a lower GFR compared to her sister's (60 versus 99 ml/min/1.73m^2, respectively).

After furosemide, the affected sib presented intense headache with exaggerated decrease in blood pressure (D syst: 30 versus 20mmHg; D diast: 18 versus 5mmHg) and body weight (D2.6kg versus D0.1kg over 3h). The expected increase in diuresis with concomitant fall in urine osmolality (U_{osm}) was more important and detected earlier in the affected sib (Fig. 1.). Water deprivation was well tolerated and led to an increase in plasma osmolality (P_{osm}) and urine concentration in both subjects. In the healthy sib, desmopressin perfusion lowered P_{osm} by further increasing U_{osm}, whereas no changes in U_{osm} nor diuresis were observed in the affected sib, despite a continued increase in P_{osm} (from 298 to 305 mOsm/L).



Discussion: Despite a significantly lower GFR, the proband harbouring a pathogenic mutation of *UMOD* showed an exaggerated response to furosemide and a failure to maximally concentrate urine after water deprivation/desmopressin perfusion. These results confirm that mutations of *UMOD* cause specific transport defects in the TAL in the early phase of the disease.

Phenotypic Variability Associated with Combined Podocin Pathogenic Mutation and Variant R229Q Paul J. Phelan,[1,2] Delbert R. Wigfall,[3] Shashi K. Nagaraj,[3] John W. Foreman,[3] Andrew F. Malone,[1,2] Gentzon Hall,[1,2] David Howell,[4] Michelle P. Winn,[1,2] Rasheed A. Gbadegesin.[1,3] *[1]Duke Molecular Physiology Inst, Duke Univ, Durham, NC; [2]Dept of Medicine, Div of Nephrology, Duke Univ Medical Center, Durham, NC; [3]Dept of Pediatrics, Duke Univ Medical Center, Durham, NC; [4]Dept of Pathology, Duke Univ Medical Center, Durham, NC.*

Introduction: Mutations in podocin (NPHS2) are the most common cause of childhood onset autosomal recessive steroid-resistant nephrotic syndrome (SRNS). The disease is characterized by early onset proteinuria, resistance to immunosuppressive therapy and rapid progression to end stage renal disease. Compound heterozygous mutations involving the podocin variant R229Q and another pathogenic mutation have been associated with a milder phenotype. Disease onset is often considered only to occur in adolescence or early adulthood.

Case Description: We screened our entire cohort with childhood onset SRNS for mutations in *NPHS 1* (nephrin), *NPHS2* and *WT1* (Wilm's Tumor 1) genes, using Sanger sequencing.

We identified 2 families with 3 individuals presenting in childhood who are compound heterozygous for R229Q and one other pathogenic *NPHS2* mutation, either L327F or A291V. One child presented at age 4 years and the other two at age 13, one with steadily deteriorating renal function. Renal biopsy in the four year old child showed minimal change disease and focal segmental glomerulosclerosis in the other two children.

Discussion: These cases highlight the phenotypic variability associated with the NPHS2 R229Q + pathogenic mutation. Individuals may present with early aggressive disease suggesting that R229Q + pathogenic mutation should be screened not only in adults with familial FSGS but also in children.

FR-PO238

Renal Involvement in the Systemic Variant of Retinal Vasculopathy and Cerebral Leukodystrophy (RCVL) Associated with Novel TREX1 Gene Mutation Tiziana Stellato,[1] Andrea Stella.[2] *[1]Clinica Nefrologica, AO San Gerardo, Monza, Italy; [2]Dipartimento di Scienza della Salute, Univ degli studi di Milano Bicocca, Milano, Italy.*

Introduction: Retinal Vasculopathy and Cerebral Leukodystrophy (RCVL) is a rare autosomal dominant inherited disease linked with mutation TREX1 gene. It is characterized by retinal and cerebral progressive vascular lesions and in a systemic variant it compromises renal involvement. We describe a case of a 30 years old man who presented with malignant hypertension and renal dysfunction. Histological features at renal biopsy were consistent with thrombotic microangiopathy. A genetic screening identifield a novel T270fs heterozygous C-terminal frameshift mutations of TREX1 gene.

Case Description: In 2005 the patient presented to emergency department with severe hypertension (250/150 mmHg) and decreased visual acuity. Fundoscopy was consistent with severe hypertensive retinopathy. Brain CT scan did not show significant abnormalities. Laboratory tests showed serum creatinine 2.5 mg/dL, urinary protein excretion of 2.6 gr/24h, unremarkable autoimmunity tests. No mutation was found in CFH, CFI, MCP genes. Factor H level and enzymatic activity of ADAMS-13 were normal. In 2010 the patient developed a bilateral necrosis of hip's heads and few months later he developed left hemiparesis and dysarthria. Brain CT and MRI showed a right fronto-parietal lesion and multiple bilateral calcifications in the white matter. Later patient presented severe dysphagia necessitating a gastrostomy for enteral nutrition. Now renal function is stable (serum creatinine 2 mg/dl), levels of cholestasis indices (gammaGT 252 UI/ml, alkaline phosphatases 314 UI/ml) are increased, blood pressure is well controlled (120/80 mmHg) with ACE inhibitor.

Discussion: The systemic variant of RCVL should be suspected in patient presenting with features of malignant hypertension and renal microangiopathy. Genetic testing including TREX1 gene should be carried out whenever a progressive systemic disorder characterized by an occlusive vasculopathy arise in middle-age people.

FR-PO239

Identification of a Novel Mutation in SLC2A2 Leading to the Fanconi-Bickel Syndrome in an Adult with Associated Erythrocytosis Francesco Trepiccione,[1] Giovanna Capolongo,[1] Giovambattista Capasso,[1] Robert J. Unwin.[2] *[1]Dpt of Cardio-Thoracic and Respiratory Science, Second Univ of Naples, Naples, Italy; [2]UCL Centre for Nephrology, Univ College London, London, United Kingdom.*

Introduction: We described here the case of an adult male diagnosed with the Fanconi-Bickel syndrome associated with erythrocytosis.

Case Description: Clinical signs were first detected at two months of age with failure to thrive, hepatomegaly, glycosuria and fasting hypoglycaemia with ketonuria. No liver or renal dysfunction was reported in other family members (parents and two sisters). At five months of age he had a liver biopsy that was reported to show a 'glycogen storage disease'. He grew normally thereafter with no renal or other clinical problems. At age 25, he developed a JAK2 negative erythrocytosis with no elevation in erythropoietin concentration, which was treated by regular venesections. At this point he was referred to our clinical service and a clinical diagnosis of Fanconi-Bickel syndrome was made based on the history and evidence of a proximal tubulopathy.

Gene analysis of SLC2A2, which encodes the glucose transporter GLUT2, showed him to be a compound heterozygote for a nonsense mutation, p.R301*, and a splice site mutation, c.1068+1G>A. Each parent was heterozygous for one of these mutations and did not have any signs of disease. The nonsense mutation p.R301* has been described previously in homozygous patients with the Fanconi-Bickel syndrome, but not the splice site mutation, which is novel.

Discussion: Fanconi-Bickel syndrome has been described with erythrocytosis, although this may be a feature in other forms of the renal Fanconi syndrome, such as Dent's disease, and also in some forms of chronic liver disease, but usually with raised erythropoietin levels. Thus, we describe an adult patient with Fanconi-Bickel syndrome associated with non-erythropoietin-dependent polycythemia and a novel splice site compound heterozygote mutation in SLC2A2.

FR-PO240

Fanconi Syndrome Induced by Clofarabine: Evidence for Multiple Tubular Defects due to a Nucleoside Analogue Abdulmawla Albirini, Joe Ghata, Benjamin D. Cowley, Kai Lau. *Nephrology, Univ of Oklahoma, OKC, OK.*

Introduction: A 78-year-old 59-kg woman with newly diagnosed AML received 5 daily doses of clofarabine (Clofa) 40 mg/m^2/d. eGFR was 55 ml/min. In < 2 d, she developed several new lab findings [K <3.0 mM, Phos (P) <2.5 mg%, urate <1.5 mg% and glycosuria] despite no diuretics and frequent, robust replacement.

Case Description: Past medical history, ongoing issues and lab data were reviewed to examine potential etiology: low intake, GI, renal losses. Review of systems revealed anorexia but no vomiting/diarrhea. Serial exams showed mild volume depletion but no fever/hypotension. To test a renal tubular leak hypothesis, clearance and fractional excretion (FE) of solutes were repeatedly measured during hypophosphatemia, hypokalemia, hypouricemia and normoglycemia.

There was no glycosuria pre-Clofa but 3+ glycosuria on 3 separate days despite serum (S) glucose <150 mg%. Renal P wastage was repeatedly shown by high FEP (40, 55, and 56% in 3 spot urine) despite concurrent S-P <2.9 mg%. Off P therapy, 24 h urine had 1.35 g P and FEP of 67% despite S-P of 2.6 mg%. Renal K leakage was shown by FEK of 65, 67, and 66% in 3 spot urine despite concurrent S-K <2.8 mM. Renal urate wastage was supported by S-urate of 1.5 mg%, normal 24 h urine urate of 532 mg and FEurate of 80%. Renal tubular acidosis was suggested by urine anion gap of 50 mM and urine pH of 7 at S-HO3 of 21 mM. Proximal leakage of these solutes persisted >4 weeks. Measured creatinine clearance (56 ml/min) was stable.

Discussion: Our data showing marked tubular wastage of glucose, P, K, urate and HCO3 support the hypothesis of clofarabine-induced Fanconi syndrome. To our knowledge, this is the first documented case of tubular complications from a nucleoside analogue. We propose a pathophysiologic mechanism of proximal tubular injury similar to that caused by tenofovir, given their similarity in structure, proximal tubular handling, and ability to also impair GFR. Since Clofa is renally excreted but potentially nephrotoxic, we recommend initial and subsequent dosing based on GFR and checking serial creatinine during its infusion. Her persistent tubular defects beyond 4 weeks may reflect dose excess relative to intrinsically low GFR due to age and petite mass.

FR-PO241

Olanzapine-Induced SIADH: Correction of a Serum Na of 99 mEq/L Abdulmawla Albirini, Joe Ghata, Lukas Haragsim. *Nephrology, OUHSC, Oklahoma City, OK.*

Introduction: Hyponatraemia (serum (S) Na<136 mEq/L) is a dangerous medical comorbidity in psychiatric patients. Hyponatremia occurs as a rare adverse reaction to treatment with different psychotropic drugs. In these patients, it is important to rule out psychogenic polydipsia, characterised also by polyuria, as it is seen also in schizophrenia. In our patient, diagnosis of hyponatremia secondary to SIADH was established per consistent biochemical blood and urine test results/analyses.

Case Description: A 50 years old Caucasian obese male, smoker with schizophrenia (paranoia type) and hypertension who presented to ER with a chief complaint of weakness. Prior to labs, he was alert, following commands and answering questions appropriately. Labs and imaging were performed, which revealed a Na of 99 mg/dL, a S osm of 221 M, urine osm of 707 M and FENA of 0.2%. TSH was 0.81. CXR demonstrated no focal opacity. His baseline S Na was 137 mg/dL 3 months prior. Review of systems revealed no polydipsia/polyuria. Physical exam revealed no edema. He reported only Olanzapine use. The patient was soon intubated and transferred to the ICU after a protracted generalised tonic clonic seizure leading to an aspiration episode and subsequent intubation in the ER. CT Head, soon after, revealed cerebral edema.

Secondary causes of hyponatremia were sought, and none were found. Olanzapine was stopped. The patient was restricted from free water and given hypertonic saline (3%) x 5 days with an average serum Na increase of 6-8 mEq/L over 24 hour, until a serum Na of 124 on hospitalization day 5, whereupon the patient was free water restricted in addition to antibiotics in norma saline. Upon day 8, patient was extubated and transferred to the floor with a serum Na of 137 mg/dL. Prior to discharge, a repeat CT Head scan demonstrated no sequalae.

Discussion: SIADH is suspected in any patient with hyponatraemia, hypoosmolality, and a urine osmolality >100 mOsm/kg. Four cases of hyponatremia and concommitant severe SIADH have been attributed to Olanzapine, but never less than serum Na < 100. In our patient, the correction of hyponatremia, combined with the discontinuation of his Olanzapine, resulted in resolution of hyponatremia, without any further recurrence.

FR-PO242

Glomerular Nephropathy due to Lipids Deposition in a Woman with Niemann-Pick Type B Disease: First Reported Case in South America Hugo Pinheiro, Gisele Vajgel Fernandes, Luis H.B.C. Sette, Cintia Germana Mergulhão da Costa, Ederson Vidal Moura, Maria Alina G.M. Cavalcante, Geraldo José de Amorim, Nathalia K.N. Alecrim, André Luiz De Andrade Araújo. *UFPE.*

Introduction: Niemann-Pick (NP) type B disease is a rare pathology classified as a storage disease resulting from enzymatic deficiency of sphingomyelinase which leads to lysossomal accumulation of sphingomyelin. It affects many organs, including liver, spleen, lungs and bone marrow with progressive fibrosis due to inflammation around the deposit of lipids. Renal involvement is rare and nephropathy has been previously reported in association with NP once in an American girl.

Case Description: A 47y woman reported progressive edema, oliguria and episodic gross hematuria for the past six months. She was underwent splenectomy 25y later for thrombocytopenia. Liver biopsy showed structural changes suggestive of lipidosis. Intra-abdominal lymphadenopathy associated with anemia and lymphocytosis justified bone marrow biopsy where numerous filled macrophages were visualized by bluish inclusions (lipid accumulation). Tests showed proteinuria and hematuria and 24h urine protein 3.1g, SAlb 1.4mg/dL, SCr 2.7mg/dL; negative ANA, normal complement, no monoclonal spike on serum protein electrophoresis, serology for HBV, HCV and HIV were negative. Sphingomyelinaseactivity was 0.2nmol/h/mg protein (0.74-4.9) and quitotriosidase was 6nmol/h/mL (8.8-132). Kidney biopsy revealed 17 glomeruli with hypercellular proliferation of own cells, particularly endothelial cells (microvesicles in cytoplasm). Podocytes exhibit moderate diffuse degenerative changes. The capillary loops exhibit regular external contours, some with widening of subendothelial spaces and images in "double contour". Tubules had atrophy and mild interstitial fibrosis. Immunofluorescence staining was negative. Electron microscopy showed capillary loops occluded by cells with prominent vacuolization in cytoplasmic, podocytesdegeneration andretractionofpedicels.

Discussion: NP type B usually causes liver, spleen, bone marrow and pulmonary involvement and although proteinuria has been described in these patients, this is the second reported case of glomerular deposition of lipids.

FR-PO243

A Case of Multicentric Castleman's Disease with IgG4 Related Disease Like Multiorgan Lesions Including Tubulointerstitial Nephritis Takeshi Zoshima, Kazunori Yamada, Mitsuhiro Kawano. *Div of Rheumatology, Kanazawa Univ Hospital, Kanazawa, Japan.*

Introduction: Renal involvement in Multicentric Castleman's disease (MCD) is uncommon, but various types of renal disease have been reported. Some cases of MCD occur with infiltration of many IgG4-positive (IgG4+) plasma cells (PC) and elevated serum IgG4 levels. We report a case of MCD with IgG4 related disease (IgG4RD) like lesions, such as tubulointerstitial nephritis (TIN) with IgG4+ PCs, retroperitoneal fibrosis (RF), and periaortitis.

Case Description: A 64-year-old woman with a 2-month history of fever and night sweats was referred. Blood tests revealed severe inflammation (CRP 16.9 mg/dl, IL-6 113 pg/ml), anemia (Hb 8.5 g/dl), hyper IgG (IgG 4807 mg/dl, IgG4 235 mg/dl). PET-CT showed systemic lymphadenopathy, RF, hydronephrosis, and periaortitis. After admission, decreased renal function (Cr 0.99 mg/dl, eGFR 44 mL/min/1.73m^2, u-b2MG 18358 ng/ml, u-NAG 52.4 IU/l) was detected. Renal biopsy revealed TIN with clear margin, and IgG4+ PCs (54 /hpf, IgG4+/CD138+ PC ratio 32%). Supraclavicular lymph node (LN) biopsy showed hyperplasia of germinal centers and a few IgG4+ PCs, but no monoclonality. We diagnosed MCD, and prescribed prednisolone (PSL) 30 mg/day with little efficacy. Additional tocilizumab (TCZ) therapy improved her symptoms and laboratory data, and the lesions of LN, retroperitoneum and periaorta regressed transiently. But, the disease flared after PSL tapering, and severe anemia with cachexia developed. Although lymphoma was suspected, paraaortic LN biopsy revealed histological findings consistent with MCD but not those of lymphoma. Rituximab and cyclophosphamide therapy followed by restart of TCZ achieved a marked response.

Discussion: The present case showed IgG4RD-like lesions, but differed from typical IgG4RD in that marked inflammation and resistance to PSL were seen. Though a case of MCD with TIN and RF had been reported, the present case is the first one of MCD with IgG4RD-like TIN detected by renal biopsy, to our knowledge. Some MCD with IgG4+ PCs in LN, skin, and lung have been reported. The present case suggested that similar findings may also be detected in the kidney of MCD.

FR-PO244

Lack of Genotype-Phenotype Correlation in Two Brothers with Identical Mutations in Nephronophthisis 3 Gene Charu Gupta, Asha Moudgil. *Nephrology, Children's National Medical Center, Washington, DC.*

Introduction: Nephronophthisis (NPHP)-related ciliopathies are autosomal-recessive cystic kidney diseases. Phenotypic heterogeneity has been linked to more than 13 genes implicated in its pathogenesis. The cases presented here highlight the lack of genotype-phenotype correlation in two brothers with identical genetic mutations in the NPHP3 gene.

Case Description: Fifteen-year-old boy presented with fatigue and elevated serum creatinine (2.5 mg/dl, Schwartz eGFR 40 ml/min/1.73m^2). Lab evaluation revealed anemia (Hemoglobin 10.7 g/dl), metabolic acidosis (serum bicarbonate 18 mmol/l), glucosuria and mild proteinuria of tubular origin (UPC 0.41, b2 microglobulin 16,749 mcg/gm). His birth, past and family histories were unremarkable. There was no history of chronic medication intake, substance abuse or use of herbal supplements. His physical exam was normal with no extra-renal or skeletal abnormalities. Renal sonogram revealed bilateral echogenic and small kidneys (bilateral renal size two standard deviation below mean). Renal biopsy showed severe chronic tubulointerstitial fibrosis, tubular atrophy and dilatation with global glomerulosclerosis in 4 of 9 glomeruli, immunofluorescence was negative and focal foot process fusion was noted on electron microscopy. Whole exome sequencing showed that he was compound heterozygous for the novel c.958-2 A>G mutation (of paternal origin) and Q696P variant (of maternal origin) in the NPHP3 gene which encodes for nephrocystin 3. His 18 year old asymptomatic brother was noted to have serum creatinine 1.2 mg/dl (MDRD eGFR 79 ml/min/1.73m^2), his urinalysis showed no proteinuria or glucosuria and he had normal sized kidneys with mild increase in echogenicity. He was noted to have the same exact genetic mutations as his brother.

Discussion: NPHP is a common childhood ciliopathy which progresses to end stage renal disease. While phenotypic variability has been attributed to different genetic mutations, these cases highlight the lack of genotype-phenotype correlation with the same genetic mutations suggesting that other factors like genetic load, oligo-genetic inheritance, modifier-effect of other genes and other unknown modifiers may affect the phenotype.

FR-PO245

Acute Kidney Injury in Von Hippel-Lindau Disease Sunggeun Lee, Roger F. Carbajal Mendoza, Ashok P. Chaudhari, Donald I. Baumstein. *Nephrology, Metropolitan Medical Center, New York Medical College, New York, NY.*

Introduction: Von Hippel-Lindau disease (VHLD) is a autosomal dominant syndrome, usually complicated with renal cell carcinoma (RCC), Hemangioblastoma and Pheochromocytoma. For renal manifestation of NHLD, not only patients develops RCC and multiple renal cysts, also they seem to carry a higher risk for acute kidney injury (AKI). Here we describe a case of AKI in VHLD.

Case Description: 41 year-old male with medical history of VHLD and hypertension was consulted for AKI and hyperkalemia. He had right side nephrectomy for RCC one year ago, also had ventriculoperitoneal (VP) shunting for cervicomedullry hemangioblastoma with hydrocephalous. He did not have any complaints. The physical examination was normal. The laboratory tests showed BUN of 25mg/dL Cr of 2.0mg/dL (estimated GFR 37 L/min), K of 5.5mmol/L. FeNa of 0.5%.The renal sonogram revealed only left side kidney, size of 18.8cm,two hypoechoic masses, urinary retention. We concluded that AKI was from the hypovolemia with obstructive uropathy. Cr was improved to 1.3mg/dL and hyperkalemia was resolved with fluid and foley catheter insertion.

Discussion: There are several factors that VHLD patient are more prone to AKI. First of all, he was not able to function without assistance since the VP shunt procedure, which easily leads to poor oral intake and makes him prone to hypovolemia. He also has risk factors to have urinary retention, such as neurologic deficit and multiple pain medications. VHLD patients get frequent urinary tract infection, which also can contribute to AKI. The partial recovery from AKI might exacerbate the worsening of renal function, VHLD patients should be followed up closely to limit the risk factors for AKI. The bigger concern was that he had another new mass in his only remaining kidney. He will be on dialysis if he gets nephrectomy of his left kidney. The 69% of VHLD patients develop RCC by the age of 60. Most of them develop bilateral RCC eventually, partial nephrectomy is preferred

than radical nephrectomy. The nephron-sparing approaches, such as cryoablation and radiofrequency ablation also can be considered. The proper screening for RCC and nephron sparing surgery are the cornerstone of VHLD management.

FR-PO246

Sunitinib-Induced Persistent Hypomagnesemia with Hypocalcemia

Sunggeun Lee, Montish Singla, Roger F. Carbajal Mendoza, Ashok P. Chaudhari, Donald I. Baumstein. *Nephrology, Metropolitan Medical Center, New York Medical College, New York, NY.*

Introduction: Sunitinib is the FDA-approved treatment for renal cell carcinoma (RCC), known to cause hypomagnesemia and hypocalcemia. It acts by blocking vascular endothelial growth factor receptors (EGFR) to inhibit tumor growth. Because of abundance of EGFR and its ligands in renal tubular epithelial cells, renal toxicity mainly manifests as tubular dysfunction. Recently it was discovered that EGFR also play a role in renal magnesium regulation directly though transient receptor potential melastatin. Here we describe a case of persistent hypomagnesemia and hypocalcemia caused by Sumitinib.

Case Description: 58 year-old male with medical history of CKD stage III, renal cell carcinoma (RCC) with bone metastasis, hypertension, diabetes was admitted for severe hypocalcemia, complaining of jerky movements and constipation. Home medication includes calcium carbonate plus vitamin D,magnesium gluconate. The physical exam did not show chvostek's and trousseaus sign. The lab findings showed creatinine of 3.3mg/dl, BUN of 34mg/dl, calcium of 4.2mg/dl, albumin of 1.8g/dl, PTH of 207pg/ml, phosphate of 2.8mg/dl, Magnesium of 1.2mg/dl, vit D,25-OH of 14 ng/ml, vitD 1,25OH of 61 pg/ml. Electrocardiogram showed QTc prolongation (524 ms). Patient was treated with calcium gluconate IV, Calcium carbonate, rocaltrol, IV and oral magnesium sulfate. The main cause of hypocalcemia would be magnesium-wasting nephropathy in this case. 24-hour urinary magnesium excretion was 118mg, severe hypomagnesemia has been persistent since patient received Sunitinib 6 months ago. Sunitinib had to be switched to Temisirolimus because of the other complications, such as bleeding, pancytopenia and hand-foot syndrome. Despite discontinuation of Sunitinib, the hypomagnesiumia persisted and the patient continued to require IV magnesium. That further supports the permanent damage of the tubule by Sunitinib. Even though he also received radiation therapy for RCC later which also can damage the tubules, hypomagnesemia was started even before the radiation.

Discussion: It is important to aware hypomagnesemia as a possible adverse effect when using Sunitinib. The tubular damage can be permanent.

FR-PO247

Management of Hypernatremia in New-Onset Reversible Diabetes Insipidus

Ekamol Tantisattamo,[1] Michael J. Connor,[2] John Doran.[1] *[1]Renal Div; [2]Div of Pulmonary, Allergy, and Critical Care Medicine, Emory Univ.*

Introduction: Hypernatremia is common in acutely ill patients with altered mental status. Diagnosis and treatment can be difficult especially if the cause is new-onset diabetes insipidus (DI).

Case Description: Case description: A 62 year-old man was admitted after fall with altered mental status, hypotension, and hypothermia. He had urosepsis, AKI (BUN/serum creatinine (SCr) of 86/1.9 mg/dL), and hypernatremia with serum sodium (SNa) of 156 mmol/L. In ED, a 4 L bolus of IV NS was given. Maintenance D5W was started, but SNa ranged from 147–159 mmol/L. Urine output (UOP) was up to 4.7 L/day. Serum and urine osmolality (Uosm) were 338 and 226 mOsm/kg, respectively (Figure1). Electrolyte-free water clearance (EFWC) was >61% of UOP. An initial diagnosis of partial nephrogenic DI from azotemia was made, but high SNa and UOP (4 L/day) persisted despite improved BUN/SCr of 18/1.2 mg/dL. DDAVP 2 mcg IV was started (hospital day 8). Urine osmolality increased to 534 mOsm/kg, indicating partial central DI and DDAVP 1 mcg SC twice a day was continued. D5W was restarted for a 2 day period when SNa increased again but as mental status improved PO fluids were substituted for D5W. On hospital day 27, SNa dropped to 133 mmol/L. DDAVP was stopped and SNa remained normal. He was discharged on hospital day 32 with SCr of 0.9 mg/dL and SNa of 139 mmol/L. A cause for the CDI was not found.

Discussion: Although water depletion is the most common cause of hypernatremia, some patients may have components of both nephrogenic and central DI that complicates treatment and delays the correction of the SNa. In this case both water and DDAVP were used to correct the hypernatremia. Over a hospitalization, the origin, and therefore treatment, of the DI may change. Careful monitoring of the UOP, Uosm, EFWC, and SNa, are important in the diagnosis and treatment of DI and hypernatremia.

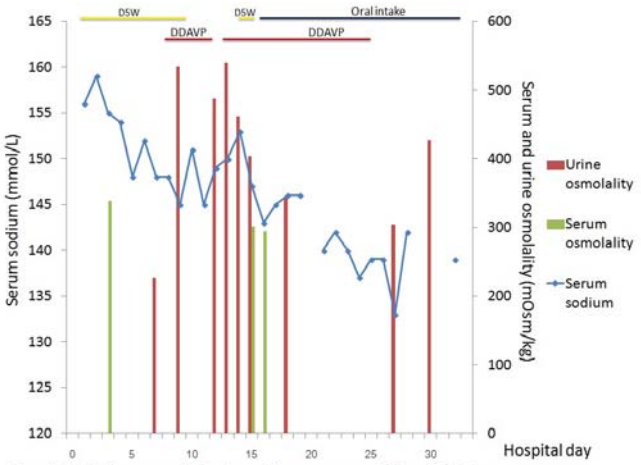

Figure1: *Clinical course and laboratory data over one month hospitalization.*

FR-PO248

Hypokalemia Induced Nephrogenic Diabetes Insipidus from Ifosfamide Use

Richa A. Pandey, Arvind K. Garg, Will R. Ross. *Nephrology and Hypertension, Washington Univ School of Medicine, St. Louis, MO.*

Introduction: Ifosfamide (IFO) is used as an anticancer drug for sarcomas and lymphomas. It causes nephrotoxicity in form of decline in GFR, tubular damage presenting as fanconi's syndrome, and albuminuria. Higher cumulative dose (>40-60 gm/m2), younger age of treatment, previous nephrectomy, previous use of cisplatin are risk factors for IFO induced nephritoxicity. Nephrogenic Diabetes Insipidus (NDI) is a rare toxicity of this drug, and only 4 cases have been reported in adults. We report a case of IFO induced Fanconi's syndrome and NDI in a patient with uterine sarcoma.

Case Description: 52 year old lady came with vomiting. Past medical history of uterine sarcoma and diabetes mellitus. She was treated with 29.5 gm IFO and 120 mg Adriamycin over a 4 week period, last dose being 2 weeks ago. Admission laboratory values revealed (meq/dl) hypernatremia (157), hypokalemia (2), hypophosphatemia (0.8) and metabolic acidosis (serum bicarbonate 19 meq/dl), along with glycosuria. She was diagnosed with Fanconi's syndrome, likely from IFO use. She had significant polyuria, daily urine output of upto 6-9 liters. Her serum osmolality (moms/dl) was high (314) and urine osmolality was low (196) suggestive of DI. She was given 2 doses of 15 mcg intranasal desmopressin with mild increment in her urine osmolality. She was diagnosed with hypokalemia driven partial NDI in the setting of IFO use. Potassium was repleted and Hydrochlorothiazide was initiated for continued improvement of her urine osmolality.

Discussion: Ifosfamide related fanconi's syndrome is rare in adult population. The mechanism is likely accumulation of IFO metabolite chloracetaldehyde which causes tubular toxicity. There have been 4 reported cases of NDI related to IFO use, all had coexistent fanconi's syndrome. Mechanism for this could be related to distal tubular damage done by IFO. More importantly, this process is likely driven by severe persistent hypokalemia, which causes downregulation of aquaporin2 channel expression. There was mild improvement of urine osmolality with desmopressin suggestive of partial down regulation of arginine vasopressin receptors. This is the second reported case of desmopressin responsive NDI with IFO use.

FR-PO249

Hypothermia Associated Hypokalemia: A Cautionary Note for an Increasingly Popular Treatment after Cardiac Resuscitation

Tanya Tocharoen Tang, Daniel Batlle, Robert M. Rosa. *Nephrology, Feinberg School of Medicine Northwestern Univ, Chicago, IL.*

Introduction: Induced hypothermia is a widely recommended intervention to improve neurological outcome in patients who have survived prolonged cardiac resuscitation. Hypothermia, however, can produce hypokalemia by a mechanism that has not been defined.

Case Description: We present a 60-year-old Caucasian male admitted after an out of hospital ventricular fibrillation cardiac arrest with prolonged CPR with intubation. Therapeutic hypothermia was implemented with intent to achieve a core temperature of 91.4 degrees over 24 hours. Serum potassium concentrations declined during induced hypothermia (Table). Ventricular ectopy recurred during hypothermia and K+ was replaced (a total of 400 mEq) without correction of hypokalemia. Upon rewarming, K+ rose to 6.8 with occurrence of sine waves and cardiac arrest (Table). Blood pH was in the range of 7.01-7.33 and bicarbonate was 13-24 throughout the entire episode. Patient had normal renal function throughout and urine output remained consistently between 100-200 cc/hr.

K^+	4.1	2.7	2.9	3.1	5.7	6.8	6.7
		------Ventricular Ectopy------ ------ 400 mEq KCl given----- INDUCED HYPOTHERMIA			-Cardiac Arrest, EKG sinus wave- REWARMING		

Discussion: This case illustrates the adverse effect of hypokalemia during induced hypothermia as well as the complication of hyperkalemia while rewarming. The mechanism of hypothermia-induced hypokalemia has been attributed to a shift of K^+ from extracellular space to the cellular space. Rather, we propose that extreme low body temperature is more likely to suppress the activity of skeletal muscle K channel (s) thereby decreasing the efflux of K^+ out of the cell. Physicians should be aware of this phenomenon and limit K replacement during rewarming.

FR-PO250

Adipsic Central Diabetes Insipidus Secondary to Gunshot Head Injury - A Case Report Chintan Shah, Roveena N. Goveas, Inder Patel, Wihib A. Gebregeorgis. *Nephrology, Wayne State Univ/DMC, Detroit, MI.*

Introduction: Trauma to the hypothalamus and posterior pituitary region is known to cause central diabetes insipidus (DI) leading to polyuria, hyperosmolality and in the alert patient, excessive thirst. Central DI with deficient thirst (Adipsic DI) as a complication of head trauma is extremely rare. We report a 39 year old man who was admitted for musculoskeletal shoulder pain and was incidentally found to have hypernatremia. Patient reported polyuria and nocturia but denied any history of excessive thirst. He estimated his habitual 24hr fluid intake to be 2-3 Liters. He was not on any medications. He has no history of psychiatric illness and has never been on lithium. Relevant past history included gunshot injury to the head at age 11. On examination, he was euvolemic with normal BP and PR. He was alert and oriented to time, place and person. Neurological examination was normal. Hypernatremia persisted throughout his hospitalization with a serum Na ranging 150-153mmol/L. Glucose level was normal. He denied feeling thirsty on several occasions when his serum Na was 150-153mmol/L despite being fully alert with free access to water. At a serum Na of 153mmol/L, his urine osmolality was 234mOsm/Kg but increased to 605mOsm/Kg after administration of DDAVP 5mcg SQ, consistent with central DI. Given the lack of thirst at serum Na of >150mmol/L despite intact sensorium, a diagnosis of adipsic DI was made. Head CT showed a bullet in the suprasellar/dorsum sella region with severe streak artifact related to the bullet limiting detailed evaluation of the sella turcica. There was no mass, pathologic enhancement, ischemia or hemorrhage. Treatment with DDAVP and scheduled water intake corrected his sodium to normal. In conclusion, we describe a rare case of gunshot injury to the pituitary/hypothalamic area resulting in combined deficits in ADH secretion and thirst sensation, a condition called adipsic DI. Adipsic DI has been previously reported with septo-optic dysplasia, tumors, aneurysms and sarcoidosis. On extensive literature review, we found two previous reports of head trauma causing adipsic DI. However bullet injury to the head as a cause of adipsic DI has not been reported.

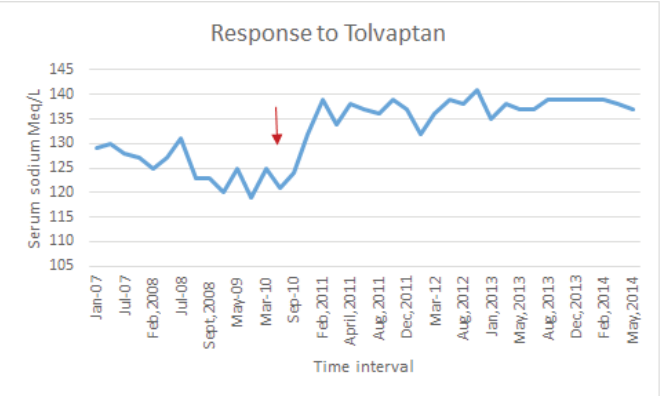
FR-PO251

Low Dose Tolvaptan for Chronic Outpatient Hyponatremia Sumedha Dhar, Daniel Batlle. *Nephrology and Hypertension, Feinberg School of Medicine, Northwestern Univ, Chicago, IL.*

Introduction: The use of vasopressin antagonists such as Tolvaptan, a selective V2 blocker, has greatly facilitated the therapy of hyponatremia in the hospital setting and obviated the need for fluid restriction that is often difficult to implement. However, long-term outpatient use has recently been limited to only a month because of concerns with potential liver injury.

Case Description: A 59 year old male patient with past medical history of C5-C6 injury during a motor vehicle injury resulting in quadriplegia, deep venous thrombosis, pulmonary embolism, neurogenic bladder with indwelling catheter and frequent urinary tract infections was referred to the nephrology clinic in 2010 for low plasma sodium. A diagnosis of syndrome of inappropriate antidiuretic hormone (SIADH) was made and attributed to central nervous system pathology. His lowest plasma sodium was 118 meq/L. Fluid restriction was not only difficult to follow but relatively contraindicated since the frequency of recurrent urinary tract infection could be worsened by reducing urine output during fluid restriction.

Tolvaptan 15 mg was started initially and then decreased to 7.5 mg for the last 3 years. The graph shows the fluctuation of plasma sodium before and after Tolvaptan over time. During the prolonged follow up, liver enzymes have always been in the normal range.



Discussion: This case illustrates that sustained correction of hyponatremia can be accomplished by low dose of Tolvaptan (half the lowest dose in the U.S. market) while fluid intake can be liberalized. The reported increases in liver enzymes have been observed in clinical trials for Adult Polycystic Kidney Disease (about 4%) for a different indication (to reduce cyst volume) where higher doses of Tolvaptan may be needed. Low dose Tolvaptan should be a logical option for treatment of hyponatremia in the outpatient setting.

FR-PO252

Hypokalemia, Rhabdomyolysis, and Nephrogenic Diabetes Insipidus from Excessive Soda Consumption Sharidan Parr, Jamie P. Dwyer. *Nephrology and Hypertension, Vanderbilt Univ Medical Center, Nashville, TN.*

Introduction: Excessive soda intake is a rare but important cause of severe hypokalemia. Under-recognized complications of hypokalemia include rhabdomyolysis and nephrogenic diabetes insipidus.

Case Description: A 37 year-old woman presented with a 4-day history of generalized weakness, myalgias, and paresthesias. She reported polyuria in the 2 months prior to admission. She denied vomiting or diarrhea. She consumes 24 cans (8.5L) of regular soda daily for several years. Past medical history includes lumbago, migraine, seizure disorder, hypokalemia, and remote history of cocaine use. She has no history of thyroid or autoimmune disease, and does not drink alcohol. Initial examination included BP 106/57 and HR 100. Neurologic examination revealed markedly diminished strength and sensation to light touch and pinprick in all extremities. The remainder of the physical exam was normal. Plasma laboratory values: sodium 142mEq/L, potassium 1.9mEq/L, chloride 107mEq/L, bicarbonate 31mmol/L, BUN <1 mg/dL, creatinine 0.5mg/dL, calcium 7.4mEq/dL, magnesium 1.6mEq/dL, phosphorus 3.8mg/dL, albumin 2.7g/dL, TSH 1.19µU/mL, and CPK 3029 Units/L. Urine laboratory values: specific gravity <1.005, sodium 73mEq/L, potassium 11mEq/L, chloride 72mEq/L, calcium-creatinine ratio 0.1, TTKG 3, osmolality 197mosm/kg. Urine output was >6L/day. Urine drug screen was positive for opiates. Plasma aldosterone and renin activity were <2.5ng/dL and <0.2ng/mL/hr, respectively. Her symptoms resolved with administration of potassium and magnesium, limitation of soda intake, and improved dietary solute intake.

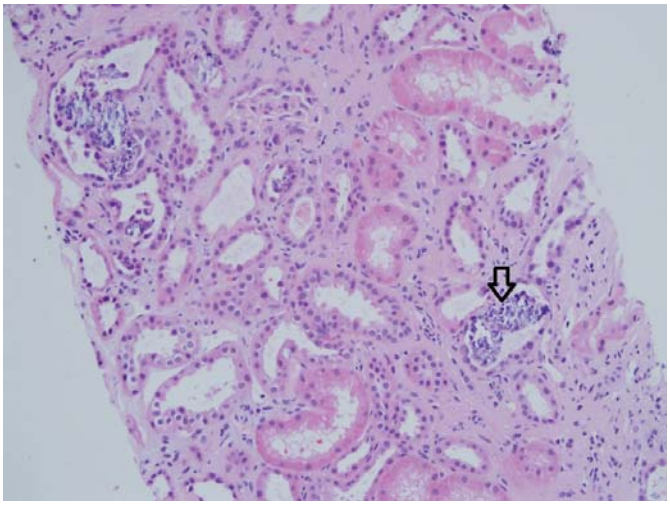
Discussion: In this case, while urinary potassium excretion was appropriately reduced, the obligatory potassium loss due to polyuria exceeded the dietary intake, causing severe hypokalemia. Elevated b-adrenergic activity from caffeine can cause intracellular shifts of potassium and further exacerbate hypokalemia. Skeletal muscle ischemia and rhabdomyolysis resulted from impaired vasodilation due to severe hypokalemia. Nephrogenic diabetes insipidus was likely due to both low medullary urea concentration from low protein intake, and hypokalemia-induced reduction of collecting tubule sensitivity to ADH.

FR-PO253

An Usual Case of Hypercalcemia: The Resurgence of the Human Adjuvant Disease Owolabi Ogunneye, Jo Abraham, Alfred K. Cheung. *Nephrology, Univ of Utah.*

Introduction: Oils have been injected by laymen into various parts of their bodies for cosmetic reasons. Various side-effects have emerged following the injections of these substances. Human adjuvant disease is associated with exposure to foreign substances.

Case Description: A 47 year old Hispanic male-to-female transgender presented to our Nephrology Clinic with several-year history of severely itchy bilateral thigh lichenification. Fifteen years prior, she had a transgender surgery that includes silicone-breast implantation and mineral-oil injection into the hips and buttocks. Five years preceding this presentation, she was hospitalized for AKI with serum creatinine of 4.0 mg/dl and calcium of 12.5 mg/dl. Renal biopsy at that time revealed calcium crystals in tubules.



One year prior to this visit, she had surgical excision of a granulomatous mass in the gluteal region. Her medical history was also notable for CKD stage IV secondary to nephrocalcinosis and hypertension. Chest x-ray was normal. Abdomen CT showed two 1-mm non-obstructing opaque calculi in the right kidney. She was maintained on

hydroxychloroquine 200 mg BID and ketoconazole 400 mg QD for the treatment of granulomatous hypercalcemia and calcium remained within normal level at 9.6 mg/dl.

Discussion: Exposure to adjuvants elicits both innate and adaptive immune responses. Extra-renal 1-alpha-hydroxylation of 25 (OH)-vitamin D by activated macrophages is likely responsible for the hypercalcemia in granulomatous disease. Ketoconazole that inhibits the 1-alpha-hydroxylation of 25 (OH)-vitamin, as well as hydroxychloroquine are effective in the treatment of hypercalcemia. While most patients who receive adjuvant injections for cosmetic reasons in general do not suffer from significant adverse events for a number of years, they should be followed carefully because granulomatous hypercalcemia may develop leading to chronic kidney disease.

FR-PO254

Persisting Hypocalcemia after Surgical Parathyroidectomy on Proton-Pump Inhibitor: The Differential Effectiveness of Calcium-Citrate versus Calcium-Carbonate

Abdeen Rihan Farah Musa,[1] Tibor Fulop,[1] Vonda Echols,[1] Bela Alex Kosztaczky,[2] Eva Csongradi.[1,2,3] *[1]Medicine, Univ of Mississippi, Jackson, MS; [2]Danvile VAMC, Danville, IL; [3]Medicine, Medical and Health Science Center, Univ of Debrecen, Debrecen, Hungary.*

Introduction: Successful surgical parathyroidectomy (PTX) elicits "hungry bone syndrome" with massive calcium-influx into the bones and potential for symptomatic hypocalcemia. The effectiveness of oral calcium may be contingent on patient's factors beyond compliance, such as PPI use and choice of calcium supplements.

Case Description: A 32 year-old Hispanic male with end-stage renal disease on peritoneal dialysis (PD) underwent successful surgical parathyroidectomy (initial parathyroid hormone level: 2,328 pg/mL; post-PTX: 287-69 pg/mL) but his post-operative course has been complicated by recurring hypocalcemia in the outpatient setting. At that point, the severe and recurrent hypocalcemia (corrected Ca: 4.8-5.6 mg/dL; nadir ionized Ca: 0.57-0.69 mM/L) was attributed solely non-adherence. During admissions, normocalcemia has been repeatedly restored on IV calcium (Ca)-gluconate infusion, but he has failed outpatient therapy, while on high-Ca PD dialysate fluid (1.5 mM/L), large doses of oral Ca-carbonate (3750 mg, x3/day) and calcitriol (2-4 mcg/day). During a subsequent admission, however, additional inquiry revealed that he was also taking a proton-pump inhibitors (PPI) for severe esophageal reflux and dysmotility, a therapy he could not abandon. Subsequently, oral Ca-supplement he was changed to calcium-citrate (3 gm x3/day), with prompt resolution of hypo-Ca (corrected Ca 8.1-8.3 mg/dL) and no further readmission necessary.

Discussion: Gastric acid contains hydrochloric acid, which reacts with calcium-carbonate to form calcium-chloride, easily bioavailable for absorption form the GI tract. Additionally, this chemical interaction results in net loss of acid and effectively converts the gastric mucosa and parietal cells into net bicarbonate secreting organ. In large epidemiologic studies, PPI have been associated with reduced bone mineral density. This current case emphasizes the disproportionate effectiveness of Ca-citrate under circumstances of achlorhydria.

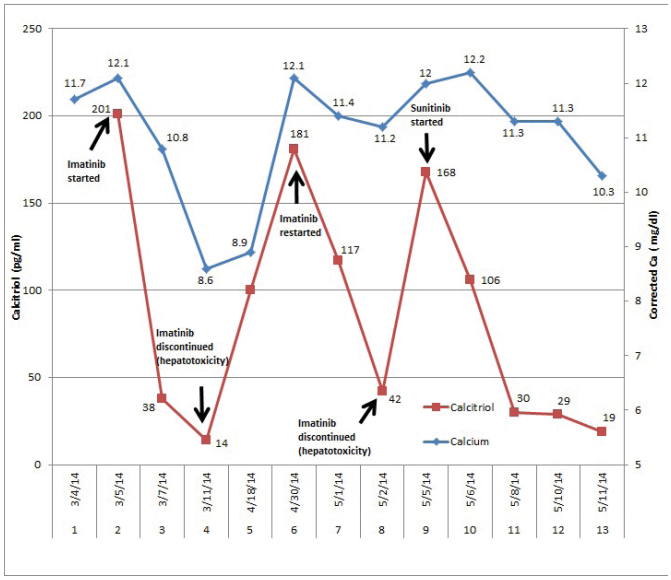
FR-PO255

A Dramatic Response to Imatinib in Calcitriol-Mediated Hypercalcemia

Surabhi B. Thakar, Milind Y. Junghare, Keith E. Eidman. *Nephrology, Univ of Minnesota.*

Introduction: Hypercalcemia is rarely reported in gastrointestinal stromal tumors (GIST) and is predominately parathyroid hormone-related protein (PTHrP) mediated. Calcitriol-mediated hypercalcemia is uncommon and described mostly in lymphomas and granulomatous disease. We report a case, only second in the literature, that demonstrates calcitriol-mediated hypercalcemia in GIST. This case is novel in showing a dramatic response to tumor suppression by tyrosine kinase inhibitors (TKIs) with rapid lowering of calcitriol and resolution of hypercalcemia.

Case Description: A 44 year-old man with recently diagnosed GIST developed refractory hypercalcemia. He had suppressed parathyroid hormone (PTH), undetectable PTHrP, no paraproteins but markedly elevated serum calcitriol. He remained hypercalcemic despite bisphosphonates and high dose steroids. Positron emission tomography (PET) showed marked tumor activity. On initiating imatinib, calcitriol declined rapidly with immediate resolution of hypercalcemia and PET activity. After developing ascites, imatinib was held and he had rebound hypercalcemia and elevated calcitriol. A rechallenge with imatinib again demonstrated an impressive response but with hepatotoxicity. Sunitinib therapy resulted in similar reduction in calcium and calcitriol.



Discussion: GIST are the most common mesenchymal tumors of the digestive tract, characterized by expression of receptor tyrosine kinase gene mutations. PTH and PTHrP are present in 90% of GIST and associate with tumor growth and differentiation. This case illustrates calcitriol-mediated hypercalcemia, independent of PTH and PTHrP. Plausible mechanisms are tumor production of humoral factors that increase 1-a hydroxylase activity or decrease metabolic inactivation of calcitriol. TKIs decreased calcitriol within 24 hours. In such cases, serum calcitriol could be used as a tumor marker indicating adequate and sustained response to therapy.

FR-PO256

Management of Severe Hyponatremia in Patients Requiring Continuous Renal Replacement Therapy

Roger Keshav, Mohamad El Kassem, Bernice Acevedo, Ivonne Hernandez Schulman, Marco A. LadinoAvellaneda. *Medicine, Univ of Miami, Miami, FL.*

Introduction: Severe hyponatremia, defined as a serum sodium of less than <125meq/L, is an electrolyte disorder that is frequently seen in the critical care setting. Continuous renal replacement therapy (CRRT) dialysate solutions contain a sodium concentration of 140 meq/L. This significant concentration gradient between the patient's serum and dialysate solution poses a risk for rapid sodium correction that can lead to an osmotic demyelination syndrome. Several case studies have demonstrated altering the dialysate solution in order to achieve a gradual correction, but this is not feasible in many hospital settings and other reviews propose complicated formulas for dialysis delivery. We propose a practical solution that involves using a lower CRRT dose, serial monitoring of sodium levels with titration of the CRRT dose.

Case Description: Case series of seven patients with severe hyponatremia and AKI stage III (severe) that required RRT. All the patients required vasopressors in the ICU. Nephrology was consulted due to the severe electrolyte/metabolic abnormalities and low-dose CRRT was started in the setting of severe hyponatremia. All the patients had serum sodium checked every hour and then every 2 hours once sodium of 125 mmol/L was reached.

Patient	Reason for admission to ICU	CRRT dose	Sodium before CRRT was started	Sodium 1 hour on CRRT	Sodium 6 hours on CRRT	Sodium 24 hours on CRRT
1	Septic shock	20 ml/kg/ hour	118	119	121	125
2	Septic shock	20 ml/kg/ hour	117	118	119	122
3	Liver failure and shock	15 ml/kg/ hour	120	120	122	124
4	Septic shock	20 ml/kg/ hour	115	116	118	120
5	Congestive heart failure/ pulmonary edema	20 ml/kg/ hour	116	116	120	126
6	Septic shock	20 ml/kg/ hour	115	116	118	123
7	Septic shock	20 ml/kg/ hour	117	117	119	125

Table 1. Patients, CRRT dose and changes in sodium over 24 hours.

With a CRRT dose of 15 – 20 ml/kg/hour we were able to correct the hyponatremia safely at a correction rate of 10 mmol/day, with close serum sodium monitoring.

Discussion: This study shows that severe hyponatremia in patients with kidney dysfunction can be managed safely and effectively with CRRT despite a set sodium concentration in the dialysate solution. We propose that instead of altering dialysate solution, lowering CRRT dose with close serum sodium monitoring is safe and practical in order to properly manage hyponatremia in the critically ill patient.

FR-PO257

Hyponatremia, It's All in the Head Zahra Deen,[1] Mahveen Sohail,[1] Muhammad Deen,[2] Sreedhar A. Mandayam.[1] *[1]Nephrology, Baylor College of Medicine, Houston, TX; [2]Medicine, Ziauddin Univ, Karachi, Pakistan.*

Case 1: 79 y/o female presented with 3 day h/o nausea, vomiting and decreased po intake. Serum Na was 111 mmol/L and nephrology was consulted. She had h/o hypothyroidism and was on thyroxine.

PE: Elderly lady with pallor, awake, lethargic and delayed deep tendon reflex relaxation but hemodynamically stable and euvolemic.

Labs: Urine osmolality 698 mOsm/kg >serum osmolality 236 mOsm/kg (suggesting elevated ADH) and urine sodium 51 mmol/L. Cortisol 0.8ug/dL (low) and TSH 0.15 uIU/mL (low).

As work up for hypoaldosteronism we checked pituitary hormone level and MRI of brain which showed low TSH, low FSH, low GH and pituitary macroadenoma. Hyponatremia, a consequence of secondary adrenal insufficiency due to panhypopituitarism normalized after starting on hydrocortisone. Case 2: 62 y/o Vietnamese female presented to ER with 5 day h/o epigastric pain, nausea and vomiting. PMH included HTN and recently diagnosed hypothyroidism. Serum Na was 120 mmol/L and nephrology was consulted.

PE: Middle age woman, awake, alert and oriented, hemodynamically stable and euvolemic.

Labs: urine osmolality 465 mOsm/kg > serum osmolality 236 mOsm/kg (high ADH), Urine sodium 56 mmol/L and a low uric acid 1.7 mg/dL. Low TSH 1.96 uIU/mL and cortisol 3.1ug/dL.

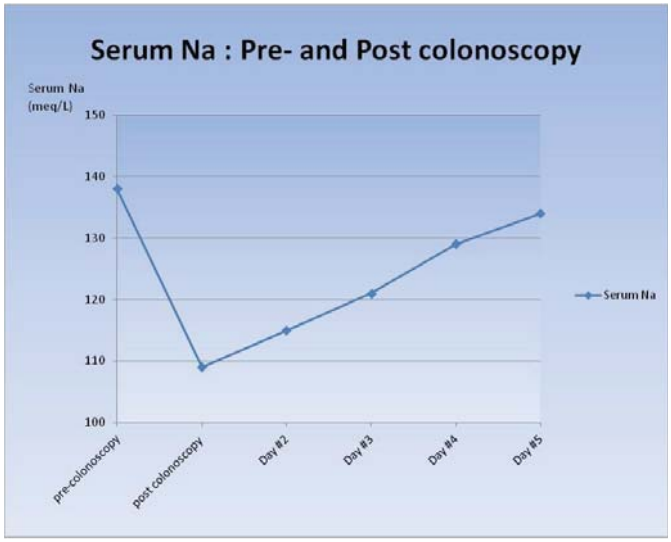
Work up for hypoaldosteronism showed low FSH, LH and IGF-1 and MRI showed intra and suprasellar cystic mass. As her hyponatremia resolved with hydrocortisone, we concluded that she had secondary adrenal insufficiency due to hypopituitarism. Discussion: Severe hyponatremia due to secondary adrenal insufficiency from panhypopituitarism is rare and usually overlooked. This is included in the category of "normovolemic hyponatremia". It present with nausea, vomiting, confusion, disorientation, somnolence or coma. On exam they have scanty pubic and axillary hair, pale and doughy skin and usually small testicles in male. In most patients with hyponatremic hypopituitarism, plasma ADH levels are inappropriately high, probably due to a failure of endogenous cortisol to suppress the hormone in a stressful situation. All patients show recovery soon after starting low-dose hydrocortisone due to normalization of ADH levels.

FR-PO258

Hyponatremia following the Administration of Bowel Prep Products for Colonoscopy Thet N. Zaw, Neil W. Lyman. *Dept of Nephrology, Saint Barnabas Medical Center, Livingston, NJ.*

Introduction: Polyethylene glycol (PEG) solution bowel prep agent induced hypernatremia is well recognized. Hyponatremia following the administration of PEG products is rarely seen. In our published literature search over the past 14 years, we encountered only 7 isolated case reports of PEG induced hyponatremia in patients over the age of 60.

Case Description: We report a case of an 84 year old Caucasian male who received PEG bowel prep for a screening colonoscopy. He had a normal sodium of 138 meq/L a month prior to the presentation. His daily medications include amlodipine and lisinopril for hypertension, synthroid for hypothyroidism, and flomax for benign prostatic hyperplasia. After the colonoscopy, the patient felt nauseous and had an episode of vomiting. He tried to hydrate himself at home by drinking 4 liters of water which was his usual habit. A day after the colonoscopy, the patient presented to the emergency department with gradually worsening lower abdominal pain. His basic metabolic panel showed a sodium level of 109 meq/L. Subsequently, he seized. The patient was treated with 3% saline and seizure terminated. He was then fluid restricted and his sodium slowly normalized over several days. Our workup confirmed the diagnosis of non-osmotic secretion of antidiuretic hormone (ADH).



Discussion: In this report, the advanced age (>75 years), nausea, and crampy abdominal pain which followed the bowel preparation may have led to inappropriate ADH secretion. The patient's vomiting and pure water ingestion were additional factors which ultimately resulted in his severe hyponatremia and seizures. We conclude that physicians should become thoroughly familiar with a patient's medical history and current medications before prescribing a bowel cleansing regimen. Furthermore, serum electrolytes should be checked if there are any changes in mental status after a colonoscopy procedure.

FR-PO259

A Heterozygous Female with Fabry Disease due to a Novel a-Galactosidase A Mutation (Pro210Ser) Exhibits a Unique Synaptopodin Distribution in Vacuolated Podocytes Mamiko Imada,[1] Naoki Takahashi,[1] Seiji Yokoi,[1] Kenji Kasuno,[1] Yoshinari Yokoyama,[1] Daisuke Mikami,[1] Hideki Kimura,[1] Masanori Hara,[2] Masayuki Iwano.[1] *[1]Div of Nephrology, Fukui Univ, Yoshida Gun, Japan; [2]Dept of Pediatrics, Yoshida Hospital, Tsubame, Japan.*

Introduction: Fabry disease (FD) is an X-linked ailment resulting from a deficiency in lysosomal enzyme a-galactosidase A (GLA) activity, which disrupts glycosphingolipid metabolism. As the clinical manifestation in heterozygous females is much more variable compared to homozygous males, it is difficult to diagnose FD in a heterozygous female with a novel mutation. In addition, there are no reports showing immunohistologically colocalization of deposited globotriaocylceramide (Gb-3) and podocyte markers in FD.

Case Description: A 42-year-old woman was referred to our hospital with moderate proteinuria (2.7 g/24 h), and a renal biopsy was performed. Light microscopic examination of the specimen revealed diffuse global enlargement of podocytes, which also showed foamy changes. Electron microscopy revealed abundant myeloid bodies in podocytes and focal mitochondrial abnormalities within the tubules. The patient exhibited none of the characteristic symptoms of FD except hypohidrosis and had no obvious family history. Genetic analysis revealed a novel missense mutation (Pro210Ser) in the GLA gene. She was ultimately diagnosed as FD by immunohistochemical staining indicating large amounts of accumulated Gb-3 in her podocytes, detection of urinary Gb-3 secretion using high-performance thin-layer chromatography, and structural modeling of the mutated GLA. Immunostaining the foamy podocytes using podocyte-associated antibodies (against podocalyxin, WT-1, vimentin and synaptopodin) revealed a unique distribution of cytoplasmic synaptopodin surrounded by Gb-3. Enzyme replacement therapy (agalsidase alfa) was started in January 2013 and her renal function has been stable for 16 months.

Discussion: To our knowledge, this is the first report of a patient with FD showing the augmented synaptopodin expression in foamy podocytes. The combined findings of vacuolated podocytes and cytoplasmic synaptopodin upregulation may be one of the helpful tools to suspect FD.

FR-PO260

A Novel Mechanism of Hyponatremia in HIV Disease Hector Madariaga, Apurv Khanna. *Div of Nephrology, SUNY Upstate Medical Univ Hospital, Syracuse, NY.*

Case Description: This is 22-year-old Black male prisoner who presents with exertional dyspnea, chest pain, relieved by resting, productive cough of clear sputum, weight loss. Pertinent physical examination demonstrated respiratory distress, tachycardia and decreased air entry at bases. A chest CT scan was obtained revealing ground glass opacities. His HIV 1 antibody was positive. In light of his pulmonary findings, treatment for Pneumocystis pneumonia with prednisone and Trimethoprim/sulfamethoxazole was started. His kidney function remained at baseline (0.5-0.8 mg/dL). Serum sodium on admission ranged from 129-135 mmol/L. Urine Na was 46 mEq/L. Serum bicarbonate ranged 20-21 mmol/L and measured osmolality, 258 mOsm/L. Serum potassium remained elevated ranging 4.8-5.8 mmol/L. Normal TSH and cortisol level. Given the suspicion for volume depletion, the patient received intravenous normal saline, but his urinary output increased. He had increased thirst and his fluid balance became negative since admission. His serum sodium decreased to 120 mmol/L and at this point we suspected a possible Glucocorticoid Resistance for which we initiated treatment with fludrocortisone. His serum sodium improved to 131-133 mol/L as well as his serum potassium. We monitored fludrocortisone dosage with plasma renin activity.

Discussion: Cortisol acts as a negative feedback mechanism on both corticotropin-releasing hormone and vasopressin. It has been reported that patients with hypopituitarism who have developed severe hyponatremia, ADH levels are high and get normalized after treatment with cortisone. Our Patient's cortisol level was normal, but he had an Adrenal Insufficiency picture, since he appeared to have sodium wasting in his urine, even though he was volume depleted. This is unique to HIV in which it has been reported that there is likely tubular dysfunction and impaired water handling that is independent of anti retroviral therapy and glomerular filtration rate. There is evidence in vitro and in vivo that there is direct invasion of tubular epithelial cells by HIV virus, even in the absence of viremia. More studies need to done on acquired Glucocorticoid Resistance and its physiopathology should be examined with more detailed.

FR-PO261

Adderall-Associated Severe Hyponatremia with Seizures

Robenson Jean Marie, Maria Saleem Khan, Ganesh B. Shidham. *Nephrology, OSUMC, Columbus, OH.*

Introduction: Adderall (Amphetamine stereoisomer Mixed Salts) is used in Attention deficit disorder (ADD) and works by increasing norepinephrine and dopamine neurotransmitters in brain. Antidiuretic Hormone (ADH) is regulated by osmotic and non-osmotic stimuli. In addition to Catecholamine, other biogenic amines (serotonin, dopamine), polypeptides and even cytokines are implicated in ADH release. Adderall increases thirst and also likely stimulates ADH secretion via non-osmotic pathways, predisposing to hyponatremia. We describe a young female with severe hyponatremia and seizures, on Adderall.

Case Description: 23-year-old female with ADD on Adderall, admitted with altered mental status. On admission day she was vomiting and three hours later experienced a witnessed seizure-like episode. She denied substance abuse or taking more than her usual dose of Adderall. Two months prior, in clinic, her sodium was 131 mEq/L. In the ED she was still lethargic and was intubated. Cardio-vascular examination was unremarkable. She was euvolemic. Sodium was 111 mEq/L and osmolality 229 mOsm/L. Urine sodium was 50 and urine osmolality 143. CT head showed brain edema. She was given 100 ml of 3% saline, switched later to normal saline. In about 5 hours her sodium overcorrected to 125 mEq/L. Saline was stopped and IV D5W was started. She woke up the following day and was extubated. EEG revealed no new seizure. Her sodium increased over 5 days to 135 mEq/L and she was discharged. During the hospital stay she was polyuric with 4-7 liters per day of dilute urine. Once awake she reported being always thirsty and drinking a lot of water at baseline.

Discussion: There has been no report of hyponatremia with Adderall. One can find blogs online where people on Adderall share experience with increased thirst. Our patient had all the risk factors for hyponatremia in the form of thirst and possible stimulation of ADH secretion by Adderall via non-osmotic stimuli. Her GI malaise, which triggered a surge of ADH, led to acute hyponatremia. SIADH is only reported with Ecstasy as amphetamines. Adderall is believed to be safe, however we think fluid intake and urine output should be monitored carefully in conditions of high ADH state like vomiting, pain, and volume depletion.

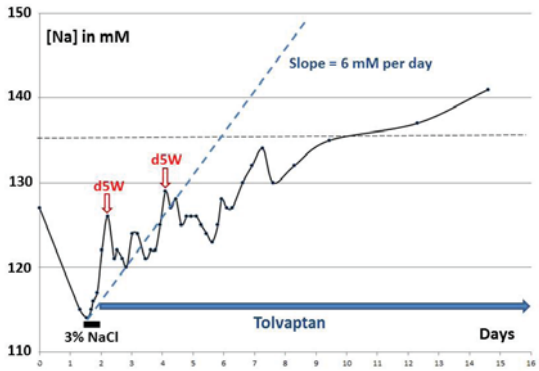
FR-PO262

Severe Symptomatic Chronic Hyponatremia in Guillain-Barré Syndrome Treated with Tolvaptan

Mohamad Adel Abdessamad, Stewart A. Weber, Alan Segal. *Medicine, Univ of Vermont/Fletcher Allen Health Care, Burlington, VT.*

Introduction: Guillain-Barré Syndrome (GBS) is an autoimmune disease characterized by progressive ascending muscle weakness and autonomic dysfunction. Hyponatremia can occur in GBS and may be due to the syndrome of inappropriate antidiuresis (SIAD). Here, we report a case of a patient with symptomatic SIAD treated with Tolvaptan (TVP) —a selective V2 receptor blocker—rather than with hypertonic saline.

Case Description: A 65 year old man experienced muscular pain while mowing his lawn. He progressed to an unsteady gait and paresthesias. Physical examination showed a clinical euvolemia, diminished reflexes, muscle weakness, and limb ataxia suggestive of GBS, confirmed by LP and MRI. Upon admission, his [Na] was 127 mM, but 30 h later dropped to 114 mM. Initially, he was given 200-ml of IV 3% NaCl over 4 h, and then converted to oral TVP (15-mg) when [Na] was 114 mM and urine ([Na]+[K]) was 206 mM, indicating an inability to excrete free water. The course of serum [Na] is shown below, with the goal to increase [Na] by no more than 6 mM per 24 h, and to use free water to re-lower [Na] in case of overcorrection.



By day 4, his impaired short-term memory and impulsiveness had resolved. After 2 weeks on TVP, his [Na] was 141 mM and he was discharged home without fluid restriction on TVP 15-mg M-F, then restarted on Monday if serum [Na] < 136 mM and urine ([Na]+[K]) > serum [Na]. TVP was required for 11 weeks and [Na] was 138-141 mM, and remained in this range off TVP.

Discussion: This case of SIAD in the setting GBS illustrates that TVP can be used to safely treat inpatients with symptomatic chronic euvolemic hyponatremia. Growing data support the safety and efficacy of Vaptans in a dose-dependent fashion. In contrast to 3% NaCl, TVP can be easily continued after discharge without the need for fluid restriction as long as the patient is properly monitored.

Funding: Private Foundation Support

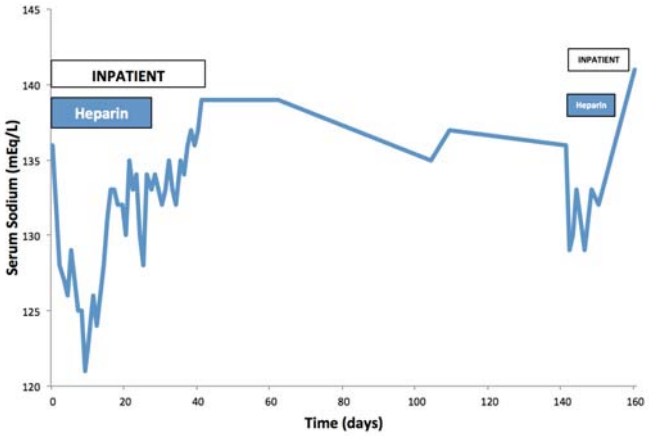
FR-PO263

Recurrent Hyponatremia Secondary to Subcutaneous Heparin Exposure

Yelena Rekhtman Drexler, Sumit Mohan. *Nephrology, Columbia Univ, New York.*

Introduction: Heparin-induced aldosterone suppression is well-described and thought to be secondary to reversible suppression of aldosterone synthase resulting in hyperkalemia commonly (8% of cases) and hyponatremia that is reported less frequently.

Case Description: We present the case of a 38-year-old man with no known medical history who was admitted with S. agalactiae-associated mitral valve endocarditis complicated by septic emboli to the brain and spleen, requiring a mitral valve replacement. Post-operatively, his serum sodium (sNa) decreased gradually to a nadir of 121 mEq/L by post-operative day (POD) #8 with stable renal function (sCr 0.9 mg/dL) and normal serum potassium (3.6–4.6 mEq/L). He developed orthostatic hypotension and had a urinary Na of 148 mEq/L for which free water restriction and sodium chloride tablets were started (then uptitrated to 12 g/d), resulting in a rise in serum sodium to 130 mEq/L but persistent orthostatic hypotension. On POD #20, he had an undetectable aldosterone level of <1.6 ng/dL (normal 4–31), plasma renin activity of 0.87 ng/mL/h (normal 0.25–5.82), and cortisol level of 27.8 ug/dL (normal 5–25), suggesting aldosterone suppression rather than insufficiency. Subcutaneous (SQ) heparin for DVT prophylaxis was stopped, with a resulting rise in sNa to 136 mEq/L and aldosterone to 4 ng/dL over 8 days with no further hyponatremia for the remainder of his hospitalization or subsequent outpatient followup. The patient was readmitted 4 months later for management of gangrene related to prior emboli and again developed hyponatremia (sNa 129 mEq/L) while on SQ heparin, which resolved with cessation of SQ heparin therapy.



Discussion: This case represents the first report of recurrent heparin-induced hyponatremia without concomitant hyperkalemia. Given the widespread use of SQ heparin, this should be considered as an often overlooked cause of hyponatremia with salt wasting.

FR-PO264

Severe Hypernatremia Causing Osmotic Demyelination Syndrome

Sandesh Joshi, Ali Javed, William DiFilippo. *Nephrology, Geisinger Medical Center, Danville, PA.*

Introduction: Rapid correction of hyponatremia is a known risk factor for osmotic demyelination syndrome, but severe hypernatremia can also cause this syndrome, which we should be aware of.

Case Description: A 54 years old women, with history of bipolar disorder on chronic Lithium therapy, chronic kidney disease, esophageal cancer treated with resection and gastrectomy, failure to thrive with protein calorie malnutrition on chronic tube feeds via J tube presented to outside hospital due to nausea, poor oral intake with diarrhea and confusion for few days. Blood work showed severe hypernatremia, sodium of 186 mmol/L prompting transfer to our center. On arrival, she was lethargic, looked very dry and delirious. Was tachycardic as well was hypotensive. A repeat sodium was 192 mmol/L with a fluid deficit of 10L. She was started on intravenous free water (5% Dextrose in water) with rate adjusted as necessary, with an aim to correct not more than 8 mmol/L of sodium in 24 hours. The rate of correction was challenging as she had high urine output. Given her long standing history of lithium use and low urine specific gravity, a diagnosis of nephrogenic diabetes insipidus was made and Hydrochlorothiazide was started. Rate of correction of sodium was appropriate and her sodium level remained stable at approximately 145 mmol/L after 10 days of admission. However, her mental status did not improve, and even after appropriate correction of hypernatremia, she remained very lethargic and slow to respond. An MRI of brain was done which was consistent with osmotic demyelination syndrome.

Discussion: Rapid correction of hyponatremia is a known risk factor for osmotic demyelination syndrome. However, this syndrome can also be found in correction of severe hypernatremia. Awareness of this phenomenon should always be considered in correction of sodium abnormalities.

FR-PO265

Factitious Hyponatremia: A Case Study Talal A. Khan, Purna Bindu Nandigam, Muhammad Awais Arif, Azka Arif, Bette Seamonds, Sandeep Aggarwal. *Drexel Univ College of Medicine, Philadelphia.*

Introduction: Hyponatremia is associated with significant morbidity and mortality. It is important to understand pathophysiology associated with hyponatremia.Clinicians should be aware of factitious Hyponatremia which can trigger un-necessary interventions. Here-in we report an interesting case of spurious hyponatremia secondary to severe triglyceridimia.

Case Description: 40-year-old white male with history of non-insulin dependent diabetes mellitus presented to the hospital with 2 days history of severe abdominal pain. On evaluation his vitals were stable. Initial serum chemistry showed sodium of 122 meq/L and serum triglycerides were 2629 mg/dL. Urine sodium and osmolality were 57mmol/L and 703 mOsm/Kg respectively.Serum glucose was 226mg/dL and total proteins were 6.6g/dL.We suspected falsely low serum sodium as his serum osmolality was 297 mosm/Kg. We sent an arterial sample that's analyzed by direct potentiometric assay, which revealed sodium of 137meq/L.

Upon confirmation it was concluded that this patient had spurious hyponatremia. He was diagnosed with acute pancreatitis which improved over the course of few days.He was started on subcutaneous insulin and oral omega-3 fish oil and as his serum triglycerides came down, his pseudo-hyponatremia improved, confirming our diagnosis.

Discussion: The mechanism underlying psuedohyponatremia is secondary to high serum triglycerides, which markedly reduce the fraction of serum water content. In normal subjects plasma water makes 93 percent of total volume while fats and proteins make rest of the 7%. However in cases of severe hyperlipidemia or hyperproteinemia, this percentage of plasma water falls below 80 percent. In such conditions plasma sodium concentration and plasma osmolality will be unchanged. But commonly used indirect potentiometric methods of serum sodium measurement will show falsely low serum sodium. To eliminate this erroneous laboratory abnormality, direct potentiometric assay (ion-specific) should be used. In our case we used the rapid blood gas analyzer that has direct potentiometric assay capability.Clinicians may find it useful to familiarize themselves with certain methodologoies used by the laboratory and their limitations.

FR-PO266

Manganese Toxicity as a Cause of Altered Mentation in a Chronic Dialysis Patient Karandeep Shergill, Richard E. Wing, Shkendie Velia. *Nephrology, Univ of Rochester, Rochester, NY.*

Case Description: A 60 years old woman with ESRD on hemodialysis for two years suffered a progressive decline in cognitive ability over several months prior to presentation. She presented acutely to the hospital with a 'few days' of confusion, lethargy, slurred speech and worsened tremor. Her past medical history also included hypertension, congestive heart failure, diabetes mellitus, and 'familial' essential tremor for six years. Medications included omeprazole, multivitamin, clonidine, melatonin, erythromycin, citalopram, gabapentin, and ondasetron. Social history was notable for use of well water. On presentation, the patient exhibited lethargy, slurred speech, and disorientation. Vitals: BP 104/56; pulse 56; R.R. 26; temp. 35.2 °C. Her physical exam was also notable for edema and a functional AVF. Her symptoms improved after holding sedatives; however, 1 week into her hospital stay she developed a profound agitation and delirium. EEG was suggestive of a moderate, diffuse encephalopathy. MRI brain showed symmetrical T1 hyper intensity within the bilateral globi pallidi and nigrostriatal tracts. Her Manganese (Mn) level was found to be elevated at 26.5 (Normal 4.2-16.5 mcg/L).On hospital day 23, a 10-day course of Calcium Disodium EDTA, 2 gram i.v. daily chelation therapy was administered. By the end of treatment, the patient's mentation had improved dramatically, coinciding with decreasing Mn levels.

Discussion: Manganese (Mn) circulates in the blood as Mn3+ bound tightly to transferrin or Mn2. High levels of Mn can be neurotoxic, with symptoms similar to those of Parkinson's disease, and include dis-coordination, loss of balance, and confusion. ESRD is significantly associated with an increased risk of Parkinson's disease but Mn toxicity is rarely diagnosed in patients with ESRD. In this case the Mn toxicity was thought to be due to a combination of hepatic cholestasis, Iron deficiency and the increased Mn content in the patient's drinking well water. In the right clinical setting, it may be prudent to check a Mn level on ESRD patients diagnosed with Parkinson Disease or other movement disorder.

FR-PO267

Succinylcholine-Induced Hyperkalemic Cardiovascular Collapse – Therapeutic Challenges Deepak Jasuja, Tarek M. El-Achkar. *Nephrology, Indiana Univ and Indianapolis VA Medical Center, Indianapolis, IN.*

Introduction: Succinylcholine is a depolarizing neuromuscular paralytic agent used for rapid sequence intubation for emergent airway management. It acts through the Acetylcholine receptors (AChRs) located in the junctional region. In certain pathological conditions including upper and lower motor neuron defects, immobilization, muscle atrophy, burns, severe infections, prolonged chemical denervation, muscle trauma, tumor or inflammation, patients are predisposed to a lethal hyperkalemic response. Succinylcholine induced hyperkalemia (SIH) can be initially missed, in predisposed patients who require rapid sequence intubation and develop cardiac arrest.

Case Description: We present the case of 70 kg 45 year old African American male patient with significant neurological history including multiple strokes, secondary right hemispheric encephalomalacia, thalamic dysfunction, seizure disorders and generalized debility. He was sent from a nursing facility with respiratory failure requiring emergent intubation; 120 mg succinylcholine was used as a paralytic prior to intubation. 5 to 10 minutes after intubation, he developed bradycardia followed by ventricular fibrillation and cardiac arrest. His potassium (K) during code was 8.3 meq/L; he was treated twice with calcium gluconate, Dextrose, insulin, and bicarbonate injections. He also received epinephrine pushes and defibrillation; repeat k after 5 minutes was 9.3; He was transferred to ICU and nephrology was urgently consulted for his hyperkalemia. His kidney function was normal. An emergent dialysis access was placed but a repeat k (measured 3 hrs after the code) came back as 3.1, and SIH was diagnosed.

Discussion: SIH typically lasts around 10-15 minutes but may last longer depending on the degree of upregulation in AChRs. Acute dialysis with low K bath to treat this self-resolving hyperkalemia could be detrimental. Cardiovascular instability, hyperkalemia with EKG changes that occurs within 2-5 minutes after intubation should alert providers to a potential diagnosis of SIH. It is imperative to follow up on potassium levels frequently to establish the diagnosis and avert additional complications.

FR-PO268

Normocalcemic Hyperparathyroidism and Calcium Phosphate Crystals during Pregnancy Ed Gould, Julia Lewis. *Div of Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

Introduction: The hormonal alterations seen both during pregnancy and lactation invoke a variety of clinically significant physiologic changes. Here we present the case of a woman who developed hematuria after beginning lactation secondary to calcium phosphate crystal precipitation with CaP crystals on renal biopsy.

Case Description: The patient was a 26 year old G1P0 female with no significant PMHx presenting with unremitting gross hematuria at the 36th week of pregnancy. Lactation began during her 34th week of pregnancy. Her hematuria was initially thought to be vaginal spotting and was induced during her 37th week. After delivery, she was referred to urology who did cystoscopy and ureteroscopy without identifying a lower GU source. At the time of Nephrology referral she was five months post-partum and continued to breast feed; her urine remained grossly bloody with every void. Further review found no culpable medications, no history of nephrolithiasis, no TB risk factors or trauma. Physical examwas unremarkable. She had normal renal imaging by sonography. Laboratory evaluation showed a Cr of 0.75, normal electrolytes including a calcium of 8.4, normal CBC, and no coagulopathy. Urinalysis with pH of 6.0, large blood, >200 RBCs, and +1 protein. No dysmorphic red cells or casts were identified and no crystals on urine microscopy. Limited serologic workup was negative. Serum phosphorous was 3.2, iPTH was measured at 131. After discussion, decision was made to proceed to renal biopsy. Biopsy showed intratubular calcium phosphate crystal deposition. A twenty-four hour urine collection revealed hyperphosphaturia and hypercalciuria. One year after delivery she stopped breast feeding. Within one month, her iPTH returned to normal and her hematuria resolved.

Discussion: Both nephrolithiasis and primary hyperparathyroidism are recognized clinical problems in pregnancy. In our patient, the temporal association of her symptoms with lactation – which can begin as early at the second trimester – and the development of normocalcemic hyperparathyroidism with calcium phosphate deposition without frank renal stones is interesting and has not been previously reported.

FR-PO269

Refractory Hypercalcemia in a Patient with Adult T Cell Leukemia/Lymphoma Laith Farah Al-Rabadi, Abdul Qadir, Abraham Cohen-Bucay, Amanda Rubenstein, Craig E. Gordon. *Nephrology, Boston Univ Medical Center.*

Introduction: Adult T cell leukemia/lymphoma (ATLL) is a rare malignancy of the peripheral T lymphocytes, caused by infection with human T cell lymphotropic virus -1 (HTLV-1). Hypercalcemia occurs commonly with ATLL. However, few cases of hypercalcemic crisis are reported.

Case Description: We present a 35 year old male patient presenting with abdominal pain, confusion and acute kidney injury. Serum calcium was 21.5 mg/dl, Creatinine 2.9 mg/dl, phosphate 5.5 mg/dl. He was resuscitated with 4 liters of isotonic saline and IV calcitonin was administered without immediate response. In light of a QT interval of 326 msec and the extreme hypercalcemia, urgent hemodialysis was performed using low-calcium dialysate (2[thinsp]mmol/L) to avoid large changes in calcium concentration leading to potential hemodynamic instability or cardiac arrhythmia. Dialysis was well tolerated with a decline in serum calcium to 13 mg/dl. However, the calcium level repeatedly rebounded to above 20 mg/dl mandating frequent sessions of dialysis. In the interim, denosumab, a human IgG2 monoclonal antibody that binds to human RANKL, was initiated with eventual improvement in serum calcium to normal values and dialysis was discontinued. Workup showed that PTH was suppressed at 8 pg/ml. AlP and LDH were significantly elevated at 432 U/L and 840 U/L, respectively. CT scan and MRI abdomen showed no lymphadenopathy. Skeletal survey showed no lytic lesions. MRI and PET scan showed increased bone activity. Ultimately, HTLV serology returned positive and a bone marrow biopsy showing abnormal T cell population. CHOP chemotherapy was initiated. Unfortunately, the patient ultimately succumbed to the illness within 6 months of diagnosis.

Discussion: Hemodialysis can be used in extreme hypercalcemia, with caution to avoid excessive lowering of serum calcium, while awaiting more definitive treatments. No guidelines are available about the indications for or timing of dialysis for extreme hypercalcemia, or the role and safety of calcium-free or low-calcium dialysate for extreme hypercalcemia. HTLV-associated ATLL is increasingly recognized as a cause of extreme hypercalcemia and should be investigated for in patients at risk.

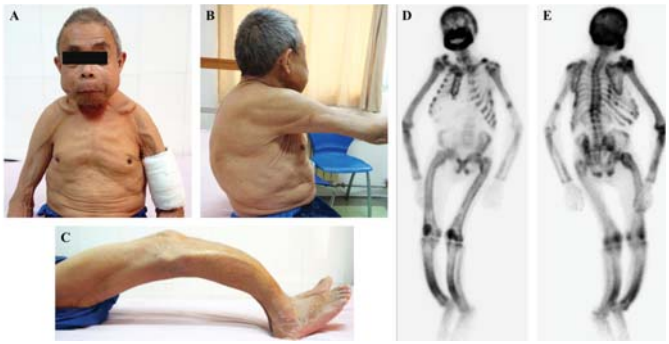
FR-PO270

Advanced Uremic Leontiasis Ossea Ameliorated by Total Parathyroidectomy
Ningning Wang, Jingjing Zhang. *Nephrology, First Affiliated Hospital of Nanjing Medical Univ, China.*

Introduction: Leontiasis ossea (LO) describes a lion-like face bone disease with overgrowth of maxilla and mandible. Uremic leontiasis ossea (ULO) is a rare systemic disease in patients suffered from chronic renal insufficiency and secondary hyperparathyroidism (SHPT). Here we report a 62-year-old male patient diagnosed of ULO.

Case Description: Global severe bone deformity of the patient was determined by technetium-99m (99mTc)-MDP bone scintigraphy. The lower limb and craniofacial bones was determined by radiographs and computed tomography respectively. Ultrasonography (US) and emission computed tomography (ECT) were used for preoperative localization to exclude ectopic and supernumerary parathyroid glands.

The main clinical features include advanced craniofacial disfigurement, dysarthria, pectus carinatum, kyphosis, left humerus fracture and severe bowing of lower extremities. The patient was shortened from 170cm to 150cm.Technetium-99m (99mTc)-MDP bone scintigraphy indicated: a) Increased activity in bones, especially in the axial skeleton, calvaria, mandible, costochondral junctions, long bones and a "tie" sternum;b) Increased bone-to-soft tissue ratio's; c) Higher radionuclide uptake in left humerus dues to prior fracture; d) Spinal kyphosis deformity owing to multiple thoracic and lumbar vertebra compression fracture; e) Severe bowing of legs.



The patient was under successful total parathyroidectomy (TPTX) with a remove of five parathyroid glands. Postoperative improvement tendency of craniofacial disfigurement, dysarthria, itching, osteodynia and blood biochemical indexes was observed within a 10-month follow-up.

	Serum Ca (mg/dl)	Serum P (mg/dl)	Serum ALP (U/L)	Serum iPTH (pg/ml)
Before PTX	11.12	5.13	1138.7	2183.2
After PTX	9.32	2.16	141	4.8

Discussion: ULO is a rare systemic disease in chronic kidney disease. Parathyroidectomy is critical to prevent the progression of clinical complications in these patients.

Neonatal Nephrolithiasis in an SLC7A9 Heterozygote with Cystinuria
Watfa S. Al-Dhaheri, Paul R. Goodyer. *Pediatric Nephrology, Montreal Children Hospital McGill Univ, Montreal, QC, Canada.*

Introduction: Cystinuria is a hereditary form of nephrolithiasis accounting for 1% of urinary tract stones. In Quebec, a newborn urine screening program identifies newborns with cystinuria. In previous publications we described a form of "transient neonatal cystinuria" in which babies with heterozygous null SLC7A9 mutations initially excrete cystine in the homozygous range, but urine cystine levels gradually fall below the stone-forming range as the renal proximal tubular undergoes functional maturation over the first 1-3 years of life.

Case Description: Here we present a girl identified by the newborn screening program whose urine cystine was confirmed to be 2370 mmol/g creat at 3 months of age. Her father's urine cystine 81 was within the normal range (<100 mmol/g creat) whereas her mother's urine cystine was 1069 mmol/g creat, suggesting that the baby was an SLC7A9 heterozygote with transient neonatal cystinuria. At the time of baseline renal ultrasonography (8 months), she was found to have two large non-obstructive stones in the left kidney (measuring 1.5 and 1.7 mm) and she was started on intensive potassium citrate therapy to alkalinize the urine and dissolve the stones. By 18 months, urine cystine had fallen to 1600 mmol/g creat and repeat ultrasonography showed that both stones had resolved. Molecular testing showed that the child had inherited a heterozygous mutant SLC7A9 allele bearing a deletion of Exon 12. No coding sequence mutations, deletions or rearrangements of the SLC3A1 gene were identified.

Discussion: To our knowledge this is the first known example of nephrolithiasis in transient neonatal cystinuria. Our case is important since it indicates the importance of baseline ultrasonographic screening in affected asymptomatic infants and demonstrates that the presence of one normal SLC7A9 gene does not protect against stone formation during the period of transient neonatal cystinuria.

FR-PO272

Association of Trimethylamine-N-Oxide (TMAO) with Nutrition, Inflammation, and Outcomes among Incident Dialysis Patients
George A. Kaysen,[1] Kirsten L. Johansen,[2] Glenn M. Chertow,[3] Lorien S. Dalrymple,[1] John Kornak,[4] Barbara A. Grimes,[4] Oliver Fiehn.[5] *[1]Medicine, UC Davis, Davis, CA; [2]Medicine, UCSF, San Francisco, CA; [3]Medicine, Stanford, Palo Alto, CA; [4]Epidemiology and Biostatistics, UCSF, San Francisco, CA; [5]Molecular and Cellular Biology, UC Davis, Davis, CA.*

Background: Trimethylamine-N-oxide (TMAO) is a product of metabolism of phosphatidylcholine (lecithin) and carnitine by the intestinal microbiome that has been strongly associated with all-cause and cardiovascular (CV) mortality and CV hospitalizations in the general population.

Methods: We examined 235 participants in the Comprehensive Dialysis Study (CDS), measuring albumin, prealbumin, C reactive protein (CRP) and TMAO concentrations. TMAO was measured by liquid chromatography and online tandem mass spectrometry in CDS participants and in 3 pooled samples of serum from healthy controls. Data on creatinine, co-morbidities, hospitalization and death were obtained through the USRDS, and patients were followed for a median of 6 years (P25:3.9, P75:6.6). We used Cox proportional hazards modeling to examine the association of log TMAO with all-cause mortality and with time to CV death or CV hospitalization.

Results: TMAO was elevated compared to control (mean 48.4 ± 30.9 versus 1.41 ± 0.49 μM) and was directly correlated with albumin (Spearman rank correlation 0.24, [95% CI 0.12, 0.35]; p < 0.001), prealbumin (0.19 [0.07, 0.31]; p = 0.003), and creatinine (0.21[0.08, 0.33]; p = 0.002), and inversely with log CRP (-0.18 [-0.30, 0.06]; p = 0.005). For mortality, the multivariable HR for log TMAO was 0.84, 95% CI: 0.65-1.09; p =0.19. For the combined CV outcomes, the univariate HR for log TMAO was 0.95, 95% CI: 0.62-1.46; p=0.81.

Conclusions: TMAO levels were markedly elevated in patients new to HD and correlated directly with biochemical markers of nutrition and inversely with markers of inflammation. The hazard ratios for (log) TMAO predicting all-cause mortality or CV death or hospitalization were considerably smaller in our cohort than in the general population, suggesting that adverse vascular effects of TMAO may be counterbalanced by its association with better nutritional status in HD.

FR-PO273

Comparison of Angiotensin Receptor Blocker (ARB) versus ACE Inhibitor (ACEI) Administration on High Density Lipoprotein (HDL) Functionality in Patients on Maintenance Hemodialysis (MHD)
Ryohei Kaseda, T. Alp Ikizler, Nancy J. Brown, Valentina Kon. *Vanderbilt.*

Background: ACEI and ARB reduce cardiovascular events (CVE) in the general population. Although MHD are at high CVE risk, few studies have directly addressed their efficacy and recent findings suggest differences. Since CKD disrupts the normally protective HDL functions, we compared ACEI and ARB treatment on HDL functions in MHD.

Methods: After 3 week washout, we randomly assigned 40 MHD to placebo, ramipril or valsartan. HDL was isolated from blood at the start and 3-6 months later (pre/post). Cell cholesterol and efflux were assessed by gas chromatography and inflammatory markers (TNF-a, MCP-1, IL-1b) and cellular transporters (ABCA1/ABCG1) by RT-PCR in HDL-exposed human THP-1 cells and mouse macrophages.* P<0.05 **P<0.01.

Results:

	Placebo (pre/post)	ARB (pre/post)	ACEI (pre/post)
Efflux-THP-1	24.1±1.0/17.0±1.9**	24.2±1.0/22.4±2.2	23.3±1.6/22.2±1.2
Efflux-mouse cells	37.1±1.3/29.3±1.9**	35.6±5.6/42.7±3.6	34.5±0.9/33.2±2.0
ABCA1	0.84±0.06/0.95±0.05	0.94±0.09/0.95±0.06	1.13±0.07/1.41±0.09*
ABCG1	0.87±0.08/0.77±0.03	0.70±0.08/1.19±0.18*	0.70±0.04/0.85±0.04*
TNF-α	1.00±0.09/1.20±0.07	1.32±0.10/1.43±0.12	1.37±0.07/2.01±0.18*
MCP-1	0.97±0.13/1.15±0.10	1.25±0.17/1.28±0.13	1.44±0.11/1.89±0.13
IL-1β	1.63±0.07/1.97±0.13	1.93±0.10/1.97±0.12	1.73±0.11/2.78±0.23**

Pre/post in placebo found HDL becomes significantly less effective in facilitating efflux. ACEI or ARB abrogated this deterioration and increased cholesterol transporters. Neither ARB nor ACEI quelled HDL inflammatory response and ACEI potentiated TNF-a, IL-1b compared to placebo or ARB.

Conclusions: HDL cholesterol acceptor function in MHD deteriorates over time, but can be stabilized by ACEI and ARB, which stimulate transporters. By contrast, inflammatory effects of uremic HDL do not respond to the interventions and are amplified by ACEI. The findings reveal utility of antagonizing angiotensin in MDH and suggest a mechanism for superiority of ARB versus ACEI.

FR-PO274

Lower C-reactive Protein and Better Hemodialysis Survival Are Associated with Regular Exercise Activity: Longitudinal Outcomes from the ACTIVE USRDS Special Study Nancy G. Kutner,[1] Rebecca H. Zhang,[1] Yijian Huang,[1] Jeanie Park.[2] *[1]USRDS Rehabilitation/Quality of Life Special Studies Center, Emory Univ, Atlanta, GA; [2]Medicine, Renal Div, Emory Univ, Atlanta, GA.*

Background: Inflammation markers are powerful predictors of hemodialysis (HD) patient mortality, and a sedentary lifestyle is a risk for the inflammatory syndrome, but the association of regular exercise activity with inflammation over time in an HD cohort has not been studied.

Methods: Longitudinal measures of physical activity and C-reactive protein (CRP) were obtained 2009-2013 for a multi-center cohort of 716 prevalent HD patients in a USRDS special study. Activity energy expenditure (kcal/week) was estimated from Minnesota Leisure Time Activity responses at baseline, 12-months, and 24-months; <500 kcal/week expenditure defined sedentary status (Dergance et al. 2003). Baseline CRP concentrations were right skewed. For inference testing CRP values were natural log transformed. The association of kcal/week with CRP at the three time points was examined in generalized estimating equations, and baseline activity status, CRP and mortality over a median follow-up of 718 days were investigated in a Cox proportional hazards model.

Results: After adjustment for demographic, clinical and HD treatment variables (including BMI, comorbid conditions, smoking, catheter use, HD hours/week, and vintage), sedentary patients on average were 0.21 higher than non-sedentary patients in CRP value on the log scale, (ß = 0.21, 95% confidence internal [CI] 0.04-0.39; P=0.02), and they had a more than 50% greater mortality risk (hazard ratio 1.58; 95% CI 1.03-2.42; P = 0.04). Among 360 patients who had baseline and 12-month activity and CRP data, sedentary patients' median CRP was 3.70 mg/L at baseline and 4.33 mg/L at 12-months, while active patients' values were 3.38 mg/L at baseline and 3.27 mg/L at 12-months.

Conclusions: Observed associations of HD patients' regular exercise activity with CRP and survival are consistent with the hypothesis that lower inflammation is one plausible biologic pathway by which greater physical activity may be associated with lower mortality risk.

FR-PO275

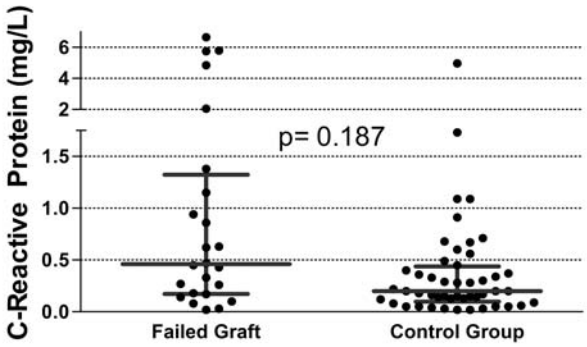
The Failed Kidney Allografts Are Not Associated with Increase in Ultrasensitive C-Reactive Protein Roxana Villca Gonzales, Raquel Aracely Vazquez, Josefina Alberú, Luis E. Morales-Buenrostro. *Nephrology, National Inst of Medical Sciences and Nutrition Salvador Zubiran, Mexico City, DF, Mexico.*

Background: A non-functional graft is associated with lower hemoglobin levels, erythropoietin resistance, and increased morbidity and mortality. Therefore, some experts advocate graft nephrectomy to improve their prognosis. **OBJECTIVE**: To establish if there is any difference in inflammatory status between patients on dialysis with non-functional graft versus non-transplanted patients.

Methods: Case-control study. Case were patient with retained non-functional graft, without surgical procedures or infections during previous 2 months. Control cases were defined as dialysis patients with similar characteristics but without previous transplant, paired 2:1 by age, gender, ESRD etiology, and time on dialysis. Ultrasensitive C-reactive protein was determinate by ELISA. Chi Square test, Student T test, and Mann-Whitney U test were used.

Results: A total of 24 cases and 48 controls were included. The relevant characteristics are showed in table. Levels of C-reactive protein in both study groups are depicted in Figure.

Variable	Failed Graft (N=24)	Controls (N=48)	p
Age	36.07±10.64	35.84±12.41	0.938
Male Gender n (%)	15 (62.5%)	30 (62.5%)	1.000
Hemoglobin (g/dL)	9.10±2.11	11.18±2.70	0.002
PTHi (pg/mL)	487.96±492.94	677.62±558.37	0.207
Albumin (mg/dL)	3.98±0.58	4.29±0.51	0.028
EPO dose (UI/w)	8333.33±4350.57	5666.66±5756.41	0.035
Ferritin (ng/mL)	323.10 (76.70 - 911.70)	248.00 (51.97 - 451.25)	0.291
Procalcitonin (ng/mL)	0.45 (0.19 - 0.63)	0.34 (0.16 - 0.68)	0.742



Conclusions: This study shows that having a non-functional graft NO necessarily results in an inflammatory status. Any case with suspected chronic inflammation should be studied comprehensively to exclude other causes before assigning it to the failed kidney allografts and propose nephrectomy.

Funding: Government Support - Non-U.S.

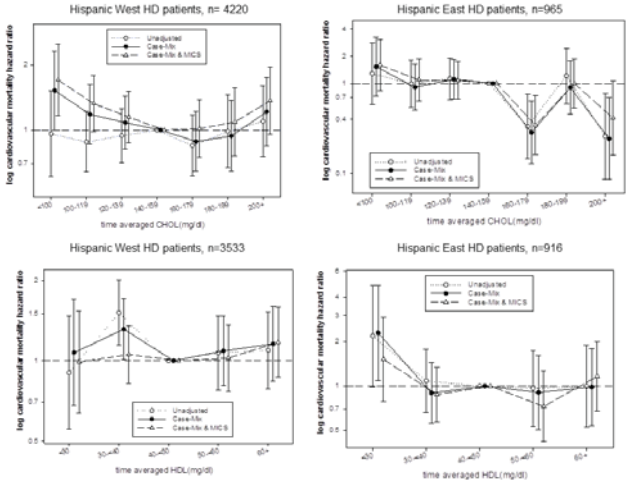
FR-PO276

Association of Lipid Profile with Cardiovascular Mortality in Dialysis Patients of Hispanic Origin in the East versus West Coast Is Significantly Different Pouya Abhari,[1] Hamid Moradi,[1] Madeleine V. Pahl,[1] Elani Streja,[1] Nosratola D. Vaziri,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons UC Irvine MC, Orange, CA; [2]Memphis VA MC, Memphis, TN.*

Background: Previous studies have shown paradoxic associations between serum lipid levels and cardiovascular (CV) mortality in hemodialysis (HD) patients. Subgroup analyses have confirmed these findings in patients of Hispanic origin. However, significant racial-ethnic differences exist in patients of "Hispanic" background. For example, the Hispanic population of the West Coast consists mainly of those from Mexico and Central America, while on the East Coast there is a large Afro-Caribbean contingency. We hypothesized that major differences exist in association of dyslipidemia and cardiovascular survival in Hispanic HD patients on the West versus East Coast.

Methods: We examined the CV survival impact of serum lipids in a 2-year (6/2005-6/2007) cohort of 5,185 HD patients of Hispanic origin being treated in clinics of a large dialysis organization (in California, Texas, New York, New Jersey and Florida) using Cox models adjusted for demographics and case-mix and markers of malnutrition-inflammation complex (MICS) variables.

Results: In this cohort there were 4,220 West and 965 East Coast Hispanic patients. In fully adjusted models, significant differences were noted in the association of lipid markers and CV mortality between these 2 groups.



Conclusions: Significant differences exist in association of serum lipids with CV mortality in MHD patients of Hispanic background depending on whether they live on the West or East Coast of the United States. These geographical differences most likely reflect ethnic and racial differences which usually go unnoticed. Future studies should take into account these critical variations in a population of patients who will make up a majority of our society in the future.

Protein Energy Wasting Is a Risk Factor for Infectious Complications in Both Hemodialysis and Peritoneal Dialysis Patients Raymond T. Krediet,[1] Anouk Van Diepen,[1] Tiny Hoekstra,[2] Joris I. Rotmans,[3] Marit M. Suttorp,[2] Dirk Gijsbert Struijk,[1] Friedo W. Dekker.[2] *[1]Nephrology, Academic Medical Centre, Amsterdam, Netherlands; [2]Clinical Epidemiology, Leiden Univ Medical Centre, Leiden, Netherlands; [3]Nephrology, Leiden Univ Medical Centre, Leiden, Netherlands.*

Background: Protein-energy wasting (PEW) has been linked to impaired immunity in both peritoneal dialysis (PD) and hemodialysis (HD) patients. The objective of our study was to investigate the association between protein-energy wasting and the risk for infections in both HD and PD patients.

Methods: In a prospective multi-center cohort study of incident dialysis patients (NECOSAD), the 7-point Subjective Global Assessment of nutritional status (SGA) was assessed every six months. Information about infections of all patients from 5 participating hospitals was retrospectively collected from the start of dialysis until censoring or 3 years of follow up. PEW was defined as SGA 1-5. Incidence rate ratios (IRR) were calculated with (Time-dependent) Poisson regression considering all infections in 3 years of follow-up. Models were adjusted for age, sex, ethnicity, primary kidney disease, smoking and comorbidity.

Results: This study included 400 patients, of whom 240 initially started on HD and 160 on PD. Thirty-two percent of HD patients and 18% of PD patients suffered from PEW

at dialysis start. In 3 years of follow up the incidence rate of infection was 0.46/HD year and 0.68/PD year. Both HD (Adjusted IRR: 1.42; 95%CI: 1.06, 1.92) and PD patients (1.37; 0.98, 1.92) suffering from PEW showed an increased risk for infection compared with patients with a normal nutritional status. Compared with HD patients with a normal nutritional status (reference group), 6-months adjusted IRRs for infection were 2.06 (95%CI: 1.60, 2.65) for PD patients with a normal nutritional status, 2.24 (1.65, 3.04) for HD patients with PEW, and 3.37 (2.27, 5.03) for PD patients with PEW.

Conclusions: Protein-energy wasting was associated with an increased risk for infection in both HD and PD patients. Routine screening of nutritional status is important in all dialysis patients.

FR-PO278

High Serum Hemojuvelin Levels in Hemodialysis Patients with Acute Infection Chia-Yu Wang, Kristin M. Corapi, Ishir Bhan, Jodie L. Babitt, Herbert Y. Lin. *Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Hemojuvelin (HJV), encoded by the *HFE2* gene, functions as a BMP co-receptor to activate hepcidin expression through the BMP/SMAD signaling pathway. Humans with *HFE2* mutations develop juvenile hereditary hemochromatosis. HJV can be cleaved and secreted as soluble hemojuvelin (sHJV), which can selectively bind to BMP ligands to inhibit hepcidin expression. Studies using cell culture and animal models suggest that HJV expression is regulated by inflammation and that sHJV levels increase in iron deficiency, conditions found in patients with chronic kidney disease and on hemodialysis (HD). In this study, we examined whether sHJV levels are altered in HD patients with acute infection.

Methods: After IRB approval, HD patients with (N=30) or without (N=28) acute infection were enrolled at the time of hospital admission and blood was collected at the start of the first inpatient HD session. sHJV levels were measured using a novel validated two-site enzyme linked immunosorbent assay (ELISA). Demographics, routine laboratory parameters, and dialysis details were compared using univariate analyses. Multivariable linear regression was used to adjust for possible confounders.

Results: Infected and non-infected HD patients were similar with respect to gender, race, dialysis vintage, and vascular access type. Infected HD patients were at 7.3 higher odds of having a detectable sHJV level (95% confidence interval 1.8 - 29.4, p=0.003). Patients with a detectable sHJV level were younger (median 57 versus 70 years, p=0.045), had lower iron levels (33 versus 50 mg/dL, p=0.001) and a smaller proportion had diabetes (29.4% versus 65.9%, p=0.01). Lower transferrin saturation and ferritin were noted, but not significantly different (p=0.08, and p=0.06 respectively). After adjusting for potential confounders, only age and iron level remained significant predictors of having a detectable sHJV level.

Conclusions: sHJV may be a new biomarker for acute infection in HD patients. Detailed mechanisms of how sHJV is regulated by inflammation and iron status need to be investigated.

Serum Procalcitonin as a Predictive Test for Bacteremia in Acute Pyelonephritis Sihyung Park, Bongsoo Park, Kyubok Jin, Yang Wook Kim. *Dept of Internal Medicine, Inje Univ Haeundae Paik Hospital, Busan, Republic of Korea.*

Background: Serum procalcitonin is a specific biomarker for bacterial infection, which rises rapidly after bacterial infection. It is known that levels of procalcitonin are correlated with the severity of disease and the mortality of patients with pneumonia and sepsis. However, the effectiveness of procalcitonin in acute pyelonephritis is yet to be known. This study was aimed to evaluate the effectiveness of procalcitonin as a predictive test for bacteremia in acute pyelonephritis.

Methods: During the period of January 2012 to June 2013, a total of 140 patients admitted to Haeunade Paik Hospital of Inje University due to acute pyelonephritis and had a positive urine culture results finally. Serum procalcitonin, CRP, and white cell count at pre (D1) and post (D3-7) treatment were measured and blood and urine culture test were conducted in all patients. In order to access the ability to predict bacteremia of procalcitonin, the levels of procalcitonin between blood culture positive group and negative group were analyzed.

Results: Pre-treatment procalcitonin (D1) level was 0.77 ng/mL (95% CI: 0.42-1.60) in blood culture negative group, the level was 4.89 ng/mL (95% CI: 2.88-9.04) in blood culture positive group respectively. The level of procalcitonin in blood culture positive group increased to a statistically significant degree. Also, the CRP was increased significantly in blood culture positive group than that of the negative group (Table 1). Based on positive correlation between procalcitonin, CRP and bacteremia, receiver operating characteristic (ROC) curve analysis was performed. Area under the ROC curve (AUC) was 0.728 for procalcitonin while AUC was 0.614 for CRP. Thus procalcitonin level demonstrated more effectively to predict bacteremia, compared with CRP (Figure 1).

Conclusions: Serum procalcitonin is a useful predictive test for bacteremia in acute pyelonephritis. Through the early detection of bactermia, serum procalcitonin can help toestimate the prognosis and thecomplications such as multiple organ failure or sepsis.

Immune Changes Associated with Home Hemodialysis Todd Fairhead,[1,2] Andreea Slatculescu.[1,2] [1]*Kidney Research Inst, Ottawa Hospital Research Inst, Ottawa, Canada;* [2]*Dept of Medicine, Univ of Ottawa, Ottawa, Canada.*

Background: Infection is a leading cause of death in patients with end-stage renal disease (ESRD). This is partly due to dysfunctional immunity, leading to poor immunization success, increased chronic or latent infections, and elevated levels of serum inflammatory markers. Frequent dialysis therapy improves patient outcomes and quality of life; but, it is currently unknown if this correlates with enhanced immunity.

Methods: We recruited 12 patients from the Ottawa Hospital currently on extended-home hemodialysis (EHHD) plus 18 healthy volunteers (HV) as controls for optimal immune function. We are now enrolling a matching-cohort of conventional in-center hemodialysis (CHD) patients. For this study, we used serum biomarkers of inflammation as predictors of overall immune status and we evaluated cellular immunity based on monocyte-derived dendritic cell (MDDC) maturation phenotype, dextran endocytosis, and T-cell activation capacity in an allogeneic mixed lymphocyte reaction using flow cytometric analysis. Intrinsic T-cell function was further measured by CFSE proliferation and cytokine production.

Results: Serum IL-6 and IL-10 levels were significantly higher in EHHD patients compared to HVs. However, our preliminary CHD cohort data showed that IL-6, CRP, and IL-10 levels were further elevated in CHD versus EHHD patients. MDDCs from EHHD patients exhibited a mature phenotype when stimulated with LPS and, compared to HVs. A significantly larger percentage of cells expressed co-stimulatory molecules (CD83 and CD40), adhesion molecules (CD11c), and endocytic receptors (CD206). We also observed robust T-cell proliferation and allogeneic activation in EHHD patients, although this did not differ statistically from HVs.

Conclusions: Serum pro- and anti- inflammatory markers are elevated in EHHD patients compared to HVs. This disrupted cytokine balance appears to increase the maturation status of MDDCs in individuals with renal failure, which possibly contributes to the chronic inflammation syndrome. Although EHHD therapy does not restore the healthy physiologic environment, it appears to be associated with decreased inflammation and cellular maturation/activation compared to CHD.

Probiotic *Bifidobacterium animalis* subsp. *lactis* Bi-07 Restores Epithelial Tight Junction Proteins and Ameliorates Microinflammation in Experimental Uremia Meng Wei, Hongli Jiang. *Dialysis Dept of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi'an Jiaotong Univ, Xi'an, Shaanxi, China.*

Background: Uremia is characterized by intestinal bacterial translocation, which contributes to the development of microinflammation. Probiotic *Bifidobacterium animalis* subsp. *lactis* Bi-07 alleviates bacterial translocation and ameliorates microinflammation inexperimental uremia in previous study. This study investigated whether the probiotic *Bifidobacterium animalis* subsp. *lactis* Bi-07 enhance the intestinal barrier by restoring epithelial tight junction proteins.

Methods: Thirty Sprague–Dawley rats were divided into 3 groups of 10 rats each: the sham group, which underwent only laparotomy; the uremia group, which underwent 5/6 nephrectomy; and the uremia + probiotic group, which underwent 5/6 nephrectomy and daily intragastric administration of B. animalis subsp. lactis Bi-07 for 4 weeks. The animals were then euthanized and their ileum were removed. Ultrastructure of intestinal epithelial tight junction (TJ) complex was observed by scanning electron microscopes (SEM). The expression of the key constituents of TJ were evaluated by realtime polymerase chain reaction and western blot analysis.

Results: The uremic rats showed significant microinflammation. Administration of B. animalis subsp. lactis Bi-07, resulted in marked amelioration of microinflammation. Realtime polymerase chain reaction and western blot showed that constituent of TJ (ZO-1,occludin) in uremia + probiotic group were restored compared with uremia group. Ultrastructural observations by SEM reveal that probiotic B. animalis subsp. lactis Bi-07 treatment marked restored the epithelial intercellular space and microvilli, suggesting a benefit for TJ ultrastructural intergrity.

Conclusions: This study demonstrates the probiotic B. animalis subsp. lactis Bi-07 restores epithelial tight junction proteins, thereby, ameliorates microinflammation in uremia.

FR-PO282

Targeting Microbiota Derived Uremic Retention Solutes with Antibiotics Ruben Poesen,[1] Bert Bammens,[1] Patrick Augustijns,[2] Pieter Evenepoel,[1] Bjorn Meijers.[1] [1]*Nephrology, Univ Hospitals Leuven, Belgium;* [2]*Drug Delivery and Disposition, Univ of Leuven, Belgium.*

Background: The gut microbiota contributes substantially to uremic retention solutes accumulating in CKD. p-Cresyl sulfate and indoxyl sulfate are representatives of this group of solutes and associate with adverse outcome in patients with renal dysfunction. Whether antimicrobial therapy has a direct and sustained effect on generation of these solutes in CKD patients has not been studied to date.

Methods: Serum levels and generation rates of p-cresyl sulfate and indoxyl sulfate were prospectively measured in CKD patients receiving antibiotics. To minimize the effect of systemic infection, we studied a homogenous population of peritoneal dialysis patients receiving flucloxacillin for exit site infection. We collected serum, urine and peritoneal

dialysate at baseline, as well as immediately and 6 weeks after treatment. Total removal rate, a surrogate of intestinal generation, was calculated using 24h urinary collection and dialysate. Differences were compared using the Wilcoxon signed rank test.

Results: In this ongoing trial, 11 peritoneal dialysis patients (mean age 55y, dialysis duration 11.8 months, weekly Kt/V 2.32) have already been included. Serum levels of p-cresyl sulfate significantly decreased during antimicrobial therapy (median decrease 46%, P 0.03), also accompanied by a trend of lower total removal rates (-60%, P 0.08). For indoxyl sulfate, we observed a trend of lower serum levels (-33%, P 0.12), and concomitant significant decreases in total removal rate (-21%, P 0.04) following antimicrobial therapy. However, there were no significant changes when comparing baseline serum levels and total removal rates of both solutes with those obtained 6 weeks after treatment.

Conclusions: Antibiotics decrease intestinal generation of microbiota derived uremic retention solutes in CKD patients. Therefore, antimicrobial therapy should be taken into account when interpreting solute levels in observational and intervention trials. Although single and short-term antibiotic exposure had no sustained solute-decreasing effect, probably due to recovery of gut microbiota, the long-term effects of frequent antimicrobial treatment remains unknown.

Relationship between Geriatric Nutritional Risk Index and Subpopulation Lymphocyte Counts in Hemodialysis and Peritoneal Dialysis Patients

Ho Sik Shin,[1] Gyung-Hoon Kang,[1] Ye Na Kim,[1] Yeonsoon Jung,[1] Hark Rim,[1] Hyun Yul Rhew.[2] *[1]Internal Medicine, Kosin Univ College of Medicine, Gospel Hospital, Busan, Korea; [2]Urology, Kosin Univ College of Medicine, Gospel Hospital, Busan, Korea.*

Background: No standard method for assessing the nutritional status in dialysis patients. In the present study, we undertook an evaluation to determine whether estimation of geriatric nutritional risk index (GNRI) and lymphocyte subset counts can be helpful in diagnosis of malnutrition in hemodialysis (HD) and continuous ambulatory peritoneal dialysis (CAPD) patients.

Methods: We examined the GNRI and lymphocyte subset counts of 50 HD patients (55.8 ± 12.7 years; 28 men and 22 women) and 16 CAPD patients (49.8 ± 14.5 years; 10 men and 6 women). The GNRI is calculated based on the serum albumin level and total lymphocyte count and uses the following equation: GNRI= [14.89 C albumin (g/dL)]+[41.7 C (weight/ideal body weight)]. Logistic regression analysis was performed for predicting malnutrition in dialysis patients.

Results: The average GNRI value was 100.1 ± 8.4 in HD patients and 99.2 ± 8.1, and GNRI values were normally distributed. lymphocyte subset counts were not different between HD patients and CAPD patients. Lymphocyte subset counts were lower in patients with higher GNRI (GNRI ≥ 100).

Table 4. Clinical characteristics of 66 dialysis patients according to CD19 count at start of the study

Variables	CD19 ≥ 100 (n=41)	CD19 < 100 (n=25)	P value
Age	55.1 ± 13.7	53.1 ± 12.7	0.565
Sex (Male/Female)	21/20	17/8	0.208
DM	15 (36.6%)	10 (40%)	0.799
HD/PD	32/9	18/7	0.768
Duration of dialysis (months)	50.6 ± 37.7	78.8 ± 59.6	0.022
Body Mass Index	21.4 ± 2.9	22.3 ± 3.5	0.511
GNRI	101.2 ± 8.0	97.9 ± 8.4	0.121
Systolic blood pressure (mmHg)	131.8 ± 30.6	145.4 ± 26.5	0.062
Diastolic blood pressure (mmHg)	78.2 ± 17.6	84.7 ± 10.2	0.065
Kt/V	1.74 ± 0.29	1.70 ± 0.22	0.504
Neutrophil Lymphocyte Ratio	0.42 ± 0.15	0.41 ± 0.15	0.931
Total Lymphocyte Count (/mm^3)	1525 ± 586	1537 ± 513	0.933
CD3 count (/mm^3)	1129 ± 406	796 ± 256	0.001
CD4 count (/mm^3)	701 ± 262	488 ± 169	0.001
CD8 count (/mm^3)	426 ± 177	302 ± 127	0.002
CD19 count (/mm^3)	176 ± 74	57 ± 26	0.001
CD4/CD8 ratio	1.7 ± 0.7	1.7 ± 0.7	0.905
Hemoglobin (g/dL)	11.1 ± 0.7	10.8 ± 0.9	0.145
Iron (ug/dL)	96.9 ± 35.9	83.7 ± 38.0	0.173
TIBC (ug/dL)	247.2 ± 38.2	249.7 ± 40.6	0.805
TSAT (%)	40.5 ± 17.5	33.5 ± 15.6	0.111
Ferritin (ng/mL)	366.4 ± 241.3	337.5 ± 295.4	0.672
BUN (mg/dL)	63.1 ± 17.1	66.1 ± 21.0	0.534
Cr (mg/dL)	9.9 ± 2.6	10.3 ± 2.2	0.472
Sodium (mEq/L)	137.8 ± 2.1	137.3 ± 4.0	0.487
Potassim (mEq/L)	5.1 ± 0.8	5.1 ± 0.8	0.987
Calcium (mg/dL)	8.9 ± 0.5	8.8 ± 0.5	0.656
Phosphorus (mg/dL)	5.1 ± 1.3	5.4 ± 1.5	0.282
Parathyroid hormone (pg/mL)	277.6 ± 251.4	171.6 ± 216.6	0.077
Albumin (g/dL)	3.9 ± 0.3	3.6 ± 0.4	0.022
Total cholesterol (mg/dL)	154.8 ± 37.0	176.1 ± 54.0	0.071
High density Lipid (mg/dL)	44.4 ± 19.0	50.7 ± 14.6	0.163
Low density Lipid (mg/dL)	67.8 ± 24.8	81.7 ± 33.1	0.064
Uric acid (mg/dL)	7.6 ± 1.6	7.4 ± 1.4	0.748

According to logistic regression for predicting malnutrition according to GNRI, age, female and CD 19 count predicted malnutrition in hemodialysis and peritoneal dialysis patients.

Conclusions: These results suggest that GNRI and lymphocyte subset counts (especially CD 19 count) may be a significant nutritional marker in HD and CAPD patients.

FR-PO284

Development of a Novel Index of Nutritional Status Based on Hemodialysis Patients' Mortality in Dialysis Outcomes and Practice Patterns Study (DOPPS)

Eiichiro Kanda,[1] Brian Bieber,[2] Ronald L. Pisoni,[2] Bruce M. Robinson,[2] Douglas S. Fuller.[2] *[1]Tokyo Kyosai Hospital, Japan; [2]Arbor Research of Collaborative for Health.*

Background: For hemodialysis (HD) patients, their nutritional status strongly affects their quality of life and mortality. However, there is no single index that can be used for malnutrition diagnosis of HD patients. We developed a novel nutritional risk index for U.S. HD patients from the Dialysis Outcomes and Practice Patterns Study (DOPPS) database: the DOPPS nutritional risk index (DNRI).

Methods: We analyzed data from 5765 patients for DNRI development and those from 5610 patients for DNRI validation. To predict death within one year, DNRI was developed using logistic regression models.

Results: The final DNRI model included serum creatinine, albumin, and phosphorus levels, body mass index and its square, white blood cell count above 9000/ml, and age. DNRI showed higher accuracy in predicting death (area under curve [AUC] 0.714) than geriatric nutritional risk index (AUC 0.637).

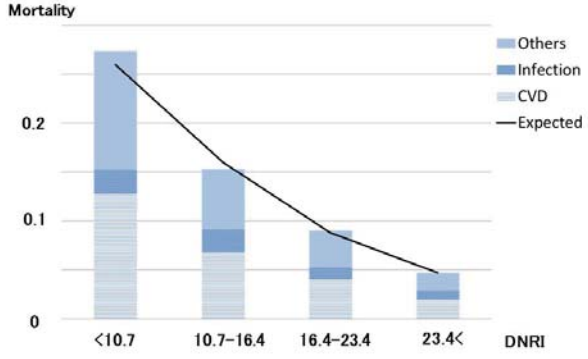

Fig.1 Probability of death expected on the basis of DNRI coincided with the observed incidence of deaths in US hemodialysis patients

Cox proportional hazard models for time-dependent DNRI showed that a 1 unit increase in DNRI decreased the risk of death (adjusted hazard ratio [aHR]: 0.83; 95% confidence interval [CI]: 0.80, 0.87), and that patients with a low DNRI (<12.9) showed a higher risk of death than patients with a high DNRI (aHR, 3.48; 95% CI, 2.27, 5.33).

Conclusions: DNRI may be a useful index to identify HD patients at higher mortality risk due to poor nutritional status.

FR-PO285

A Common microRNAs Pattern Expression Related to Malnutrition and Inflammation in Chronic Kidney Disease Mice Model

Carmen Josefina Mora,[1] Marcela Avila,[1] Teresa Renata Romero,[1] Carmen María del Prado,[1] Diego Julio Arenas,[2] Ramon Paniagua-Sierra.[1] *[1]Unidad De Investigacion Medica En Enferm, Edades Nefrologicas, Inst Mexicano del Seguro Social, Mexico, DF, Mexico; [2]Unidad De Investigacion Medica En Genetica Humana, Inst Mexicano del Seguro Social, Mexico, DF, Mexico.*

Background: Malnutrition and inflammation are risk factors for ESRD; its relationship with the molecular regulators like miRNas is unknown. Our aim was to investigate the differential expression of miRNas in a Chronic kidney disease (CKD) mice model and its relationship with malnutrition and inflammation.

Methods: Three mice groups were performed: CKD group (Nx 5/6), I group (Inflammation induced with *E. coli LPS*) and C group (Control). We determined food intake in CKD group and was created a four group: FR (food restriction). Animals were sacrificed after eight weeks of treatment; plasma creatinine, albumin, and total proteins tests were measured, liver was extracted, and weighted. Total RNA was extracted from liver; miRNAs were obtained for miRNAs microarrays. Gene target prediction was made with "miRANDA" database.

Results: Food intake in CKD group was 59.2% less than control group (4.8±1.22 versus 8.1±1.47 g/day, p <0.005), in I group was 46.9% less than C (3.8±0.94 versus 8.1±1.47 g/day, p<0.005). Groups were confirmed with creatinine and albumin. Body and liver weight in CKD and FR groups were lower than control p<0.05. The mir-409, mir-29b, mir-206, and mir-30a showed common differential expression in CKD, I and FR groups; mir-212 expression is common in CKD and FR groups, mir-376 expression is common in I and FR groups; mir-376, mir-30b and mir-195, have common expression pattern in CKD and I groups.

Conclusions: A common microRNAs pattern expression was found in CKD, Inflammation and Food Restriction mice models, their predicted gene targets are cellular cycle, transcription and inflammation factors mRNAs. These results suggest that nutrition signaling is similar in CKD, inflammation and food restriction models.

FR-PO286

A Pharmaco-Metabolomic Study of Chronic Aristolochic Acid Nephropathy
Ying-Yong Zhao,[1,2] Shuman Liu,[2] Hua Chen,[1] Ya-Long Feng,[1] Ruichao Lin,[1] Wei Ling Lau,[2] Nosratola D. Vaziri.[2] *[1]Dept of Traditional Chinese Medicine, Northwest Univ, Xi'an, Shaanxi, China; [2]Div of Nephrology and Hypertension, Univ of California, Irvine, Irvine, CA.*

Background: Aristolochic acids (AA) belong to a family of carcinogenic, mutagenic, and nephrotoxic compounds that are found in the Aristolochiaceae plants which are commonly used in Chinese herbal medicine. AA are thought to be involved in pathogenesis of Balkan nephropathy, Chinese herbal nephropathy and urothelial cancer. CAAN is a rapidly progressive interstitial nephritis that can lead to ESRD and urothelial malignancy and is frequently associated with the long-term consumption of AA-containing herbs.

Methods: Serum metabolomics based on the ultra-performance liquid chromatography/ SYNAPT high-definition mass spectrometry was undertaken to explore the pattern of low molecular mass metabolites in the rat model of CAAN. Sixty-four rats were randomized into AA and control groups. The AA group was fed 20 mg/kgbody weight/day of AA for 12 weeks. Blood biochemistry, and Masson's trichrome staining and Western blot analysis of kidney tissues were performed. Data were analyzed using principal component analysis, orthogonal partial least squares-discriminant analysis, heatmap analysis and metabolic pathways analysis.

Results: As expected the CAAN rats exhibited progressive deterioration of renal function and renal histology, and up-regulation of TGF-β1, CTGF, PAI-1 and TIMP-1 during the observation period. This was coupled with a significant change in the global serum metabolites from CAAN compared to control rats at weeks 4, 8, and 12. These included bile acids, phospholipids, uremic toxins and eicosanoids. The changes in these metabolites correlated with progressive renal injury and upregulation of the TGF-β pathway in the CAAN rats.

Conclusions: This study provides longitudinal data on the metabolic profile across a wide range of biochemical pathways in response to AA-induced chronic renal injury. The observed changes highlight perturbations in the metabolism of bile acids, phospholipids, uremic toxins and fatty acids, in tandem with upregulation of inflammatory, oxidative stress and fibrosis pathways.

FR-PO287

Circulating Irisin Levels Are Associated with Sarcopenia and Carotid Atherosclerosis in Peritoneal Dialysis Patients
Mi Jung Lee,[1] Seonghun Kim,[2] Young Su Joo,[1] Seung Hyeok Han,[1] Shin-Wook Kang,[1,2] Tae-Hyun Yoo.[1] *[1]Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea; [2]Brain Korea 21 PLUS, Severance Biomedical Science Inst, Yonsei Univ, Seoul, Korea.*

Background: Sarcopenia is an important cardiovascular risk factor in patients with end-stage renal disease. Recent studies have indicated that skeletal muscles mediate their protective effect by secreting myokines. However, to date, the pathophysiologic role of irisin, a novel myokine, has not been evaluated in peritoneal dialysis (PD) patients. In this study, therefore, we investigated the association of irisin with sarcopenia and carotid atherosclerosis in these patients.

Methods: Serum irisin levels were assessed by enzyme-linked immunosorbent assay in 102 prevalent PD patients. To determine sarcopenia and carotid atherosclerosis, anthropometric indices including mid-arm muscle circumference (MAMC) and carotid intima-media thickness (cIMT) were measured. Linear and logistic regression analyses were performed to ascertain the independent association of irisin with sarcopenia and carotid atherosclerosis.

Results: The mean serum irisin levels were 184.2 ± 88.0 ng/mL. Thirty-seven patients (36.3%) had carotid atherosclerosis. In univariate linear regression analysis, serum irisin concentrations were positively correlated with MAMC, thigh circumference, and serum creatinine levels, whereas negatively correlated with residual renal function and cIMT. Multivariate analysis revealed that MAMC [b = 0.31, 95% confidence interval (CI) = 1.89 to 17.85, P = 0.02] and cIMT (b = -0.29, 95% CI = -92.53 to -17.11, P = 0.005) had independent association with serum irisin levels. In addition, serum irisin concentration was a significant independent risk factor for carotid atherosclerosis after adjustment for confouding variables (per 1 ng/mL increase, odds ratio = 0.987, 95% CI = 0.979 to 0.996, P = 0.004).

Conclusions: This study demonstrated for the first time that circulating irisin levels were significantly associated with sarcopenia and carotid atherosclerosis in PD patients, suggesting that irisin could mediate the detrimental effect of sarcopenia on cardiovascular disease.

FR-PO288

Angiotensin II Induces Lipid Accumulation in Hepatic Cells via the Disruption of Low Density Lipoprotein Receptor Pathway
Kun Ling Ma, Wu Yu, Jing Liu, Yang Zhang, Zebo Hu, Bi-Cheng Liu. *Inst of Nephrology, Southeast Univ, Nanjing City, Jiangsu Province, China.*

Background: Our previous studies demonstrated that activation of renin-angiotensin system (RAS) contributes to the progression of chronic kidney disease via the disruption of low density lipoprotein receptor (LDLr) pathway. This study aimed to investigate the effects of angiotensin II (Ang II) on lipid homeostasis in Human hepatoblastoma cell line (HepG2) cells and its underlying mechanisms.

Methods: HepG2 cells were cultured and divided into the control group (incubated with serum-free medium) and Ang II group (treated by 10^{-7} mol/L of Ang II for 24 hours). The effects of Ang II on lipid accumulation were examined by Oil red O staining and a quantitative assay of intracellular cholesterol. The expression of LDLr, sterol regulatory element–binding protein (SREBP) cleavage activating protein (SCAP) and SREBP-2 mRNA and protein were examined by Real-time polymerase chain reaction (PCR) and Western Blot. The colocalization of SCAP and Golgi in HepG2 cells was examined immunofluorescent staining using confocal microscopy.

Results: Ang II treatment increased intracellular lipid accumulation in HepG2 cells, which was correlated with increased mRNA and protein expression of LDLr, SCAP, and SREBP-2 in HepG2 induced by Ang II. Furthermore, results from confocal microscopy observation demonstrated that Ang II increased the translocation of SCAP/ SREBP-2 complex from endoplasmic reticulum to Golgi, thereby upregulating LDLr gene transcription.

Conclusions: Ang IIdisrupts LDLr feed-back regulation to increase cholesterol uptake and induce intracellular lipid accumulation. It suggests that local RAS activation in livers may contribute to the progression of non-alcoholic fatty liver disease via the disruption of LDLr pathway.

FR-PO289

Activation of the Renin-Angiotensin System Is Involved in Hyperlipidemia-Mediated Liver Injuries in Apolipoprotein Knockout Mice and HepG2 Cells
Kun Ling Ma, Wu Yu, Jing Liu, Yang Zhang, Zebo Hu, Bi-Cheng Liu. *Inst of Nephrology, Southeast Univ, Nanjing City, Jiangsu Province, China.*

Background: Our previous studies demonstrated thatdyslipidemia and activation of renin-angiotensin system (RAS) contribute to the progression of chronic kidney disease. This study aimed to investigate possible synergistic effects of intrahepatic RAS activation with hyperlipidemia in liver injuries of non-alcoholic fatty liver disease (NAFLD).

Methods: Apolipoprotein knockout mice were fed with normal chow diet (control) or high fat diet (HF group) for 8 weeks. Human hepatoblastoma cell line (HepG2) cells was treated without (control) or with 30 mg/ml cholesterol (lipid group) for 24 hours. The plasma lipid profile and RAS components were determined by clinical biochemistry assay and radiommunoassay, respectively. The gene and protein expressions of molecules involved in RAS components and biomarkers of epithelial mesenchymal transition (EMT) were examined by real-time PCR, immunochemical staining, and Western blot.

Results: The mice fed with high-fat diet showed significant hyperlipidemia with collagen deposition in livers compared to the controls. The plasma levels of renin, angiotensin I, and angiotensin II were no difference in two groups. However, the livers of HF group showed up-regulated RAS components, which were positively associated with increased plasma levels of triglyceride, total cholesterol, and LDL. These effects were further confirmed by *in vitro* studies. Lipid loading induced HepG2 cells underwent EMT, which was closely associated with the increased expressions of intracellular RAS components.

Conclusions: Local RAS activation was involved in hyperlipidemia-mediated liver injuries, suggesting that there are synergistic effects resulting from RAS activation with hyperlipidemia that accelerates the progression of NAFLD.

FR-PO290

Increased Expression of ADAM17 and Soluble TAM Receptor in Patients with Chronic Renal Failure
Iris J. Lee,[1] Brendan A. Hilliard,[2] Chandan Vangala,[3] Jean Lee,[1] Crystal A. Gadegbeku,[1] Philip L. Cohen.[2] *[1]Nephrology, Temple Univ; [2]Rheumatology, Temple Univ; [3]School of Medicine, Temple Univ.*

Background: The receptor tyrosine kinases Mer and Axl (TAM receptors) are expressed on mononuclear cells and are important regulators of cytokine and toll-like receptor signaling. Mer is crucial for clearance of apoptotic bodies and resolution of vascular inflammation, and plays an anti-inflammatory role in lipopolysaccharide induced inflammation and autoimmunity. Preservation of membrane bound Mer is necessary for these functions. Proteolytic cleavage of membrane bound Mer by metalloproteinase (MMP) ADAM17 to its soluble form (sMer) causes its inactivation. Reactive oxygen species and toll like receptor signals, likely operative in inflammatory states such as chronic renal failure (CRF), are known inducers of ADAM17.

Methods: We measured levels of (sMer), soluble Axl (sAxl), ADAM17 and ADAM10 in the plasma and peripheral blood mononuclear cells of non-dialysis (CKD) and dialysis (HD) patients by real time PCR, ELISA and FACS.

Results: TAM receptors sAxl and sMer, were significantly increased by ELISA in the plasma of patients with CRF compared to controls. sMer was (Mean ± SD, ng/ml) 1.26±.65 in CKD, 1.16±.65 in HD and.54±.20 in controls. sAxl was 39 ± 14.3 in CKD, 60 ± 18.2 in HD and 27 ± 9.8 in controls, (p<.0001). Both sAxl and sMer were positively associated (r=.30, and r=.50 respectively, p<.0001) with levels of the TAM ligand Gas6 known to be elevated in patients with systemic inflammation and CRF. Only sAxl was inversely associated with eGFR, (-.32, P=.004). Given increased levels of soluble TAM receptor, expression of ADAM10 (cleaves Axl) and ADAM17 (cleaves Mer) was examined by PCR. We found HD monocytes expressed significantly more ADAM17 (6-fold) than controls. No difference was found for ADAM10.

Conclusions: The inflammation induced MMP ADAM17 cleaves membrane bound Mer, limiting Mer receptor ligation and subsequent regulation of inflammation in basic studies. In line with this, our data show increased expression of ADAM17 and high levels of sMer and sAxl in CRF. These findings suggest a new mechanism underlying chronic inflammation in patients with CRF.

Insulin Secretory Defect in a Mouse Model of Chronic Kidney Disease
Koppe Laetitia, Moulle Valentine, Nyam Elsa, Bergeron Valerie, Vincent Poitout. *Montreal Diabetes Research Center, Univ of Montreal, Montreal, QC, Canada.*

Background: Disorders of glucose homeostasis are common in chronic kidney disease (CKD), but the presence of impaired insulin secretion are unclear. Recent data show that elevated levels of urea increase O-GlcNAc–modified insulin signaling molecules and cause insulin resistance. The aim of this study was 1- to examine whether insulin secretion is altered in a CKD mice; and 2- to ascertain whether urea has a direct negative impact on insulin secretion by increasing protein O-GlcNacylation in islets.

Methods: C57BL/6N mice underwent a 5/6 nephrectomy. At 3 weeks post-surgery,b-cell mass, insulin content and insulin secretion were measured. *In vivo,* insulin secretion was assessed by intraperitoneal glucose tolerance tests and hyperglycemic clamps. Isolated mouse islets were exposed to pathological concentrations of urea (20 mM) for 24 h and insulin secretion was measured. Total O-GlcNacylated proteins and O-GlcNAc transferase (OGT) levels were evaluated by Western blot.

Results: CKD mice were glucose intolerant compared to sham-operated controls (AUC glucose during the IPGTT: 315±31 versus 414±29 mmol/l*h, n=10, $p<0.05$). Hyperglycemic clamp revealed a decrease in both glucose- and arginine-induced insulin secretion in CKD mice. Thus, insulin levels during the steady-state phase of the clamp were 1.2±0.1 ng/ml versus 2.2±0.3 ng/ml in sham mice (n=7, $p<0.01$). Accordingly, isolated islets from CKD mice showed reduced insulin secretion in response to 16.7 mM glucose (-41±19 %, n=5-7, $p<0.05$) and 35 mM KCl (-55±12%, n=5, $p<0.05$). b-cell mass and islet insulin content were similar in both group. A similar reduction in insulin secretion was observed in normal mouse islets exposed to 20 mM urea for 24h (-46±17 % versus control islets exposed to 20 mM mannitol, n=4, $p<0.05$), without changes in insulin content. In addition, exposure of islets to urea led to an increase in total O-GlcNAcylated proteins and expression of OGT (+137±18 % versus control, n=3, $p<0.05$).

Conclusions: CKD is associated with an insulin secretory defect which likely lies at the level of exocytosis. This defect is recapitulated by prolonged exposure of islets to urea and is associated with an increase in protein O-glycosylation.

Urinary Nephrin Is an Early Biomarker for CKD in Maternal Caloric Restricted Rats
Natalie S. Uy,[1] Hye J. Heo.[2] *[1]Children's Hospital at Montefiore, Albert Einstein College of Medicine; [2]Montefiore Medical Center, Albert Einstein College of Medicine.*

Background: Inadequate nutrition during pregnancy is a major cause of low birth weight (LBW) and impaired fetal growth. LBW may lead to low nephron endowment and increased risk of CKD. Despite large numbers of infants with LBW, clinical guidelines for monitoring of infants at risk for CKD do not currently exist. Urinary biomarkers of renal injury would be helpful in identifying those individuals at greatest risk for CKD. We previously characterized a model of CKD, induced by nutritional deprivation, in which caloric- restricted offspring had low nephron number, and developed hypertension and albuminuria by adulthood. We hypothesized that urinary biomarkers of renal injury, cystatin C and/or nephrin, could be detected prior to the onset of disease, and help predict the development of CKD in maternal caloric-restricted rats with low nephron number.

Methods: Sprague Dawley rats were fed standard chow (control) or 50% caloric restricted diet (CR) starting at 11 days of gestation until weaning. All litters culled (8/lit). Both groups were fed standard chow postweaning. Urine was collected at 2 months from CR (n=6) and controls (n=11) and at 6 mos (control,n=8;CR,n=9). Spot urine albumin, cystatin C and nephrin were quantified by ELISA and normalized to urine creatinine.

Results: CR had similar albumin to creatinine ratios (ACR) compared to controls at 2 mos. At 6 mos, CR had a 3-fold increase in ACR compared to controls (290.2mg/mg ± 44.5 versus 94.3mg/mg ± 15.3, $p=0.002$). Urinary nephrin doubled in CR compared to controls at 2 mos (271.9mg/mg ± 38.6 versus 123.5mg/mg ± 25.4, $p=0.003$). At 6 mos, urinary nephrin increased by 3-fold in CR compared to controls (392.1mg/mg ± 63.5 versus 108.9mg/mg ± 16.4, $p=0.001$). Urinary cystatin c was not significantly different between groups.

Conclusions: Urine nephrin is significantly increased prior to the onset of albuminuria in caloric-restricted offspring, and may be an early biomarker for CKD. Cystatin C may not be a useful marker to detect increased risk of CKD. Longitudinal studies in humans will be necessary to determine if urinary nephrin is useful in identifying LBW infants at increased risk for kidney disease in adulthood.

FR-PO293

Sustained Beneficial Effects of a Soluble Guanylate Cyclase Activator on Diabetic Nephropathy
Hongxing Chen,[1] Paul Harrison,[1] Kathleen A. Lincoln,[1] Susan Goldrick,[1] Nicholas F. Brown,[1] Kristina Gueneva-Boucheva,[2] Hu Sheng Qian,[1] Steven S. Pullen,[1] Glenn A. Reinhart,[1] Carine Boustany.[1] *[1]CMDR, Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT; [2]Medicinal Chemistry, Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT.*

Background: We hypothesized that a soluble guanylate cyclase (sGC) activator would result in a reduction in renal damage that would be maintained following discontinuation of treatment in the ZSF1 rat model of diabetic nephropathy.

Methods: Male ZSF1 rats implanted with telemetry devices were treated for 10 weeks with either BAY 58-2667 (sGC activator) in combination with enalapril, amlodipine in combination with enalapril, enalapril alone, or vehicle. Mean arterial pressure (MAP), heart rate (HR) and proteinuria were recorded. Following 10 weeks of treatment (Treatment phase), the compounds were discontinued and similar endpoints as above were measured for 5 weeks (Reversibility phase). Histopathological assessment of glomerulosclerosis and tubulointerstitial damage was performed at study termination.

Results: In the treatment phase, MAP reduction was greater in the amlodipidine + enalapril group, versus BAY 58-2667 + enalapril (-27.4 ± 3.9 mmHg versus -19.8 ± 3.0 mmHg, $p<0.05$). In contrast, reductions in proteinuria were similar between the 2 groups (-108.1 ± 63.4 mg/day versus -115.6 ± 41.3 mg/day). Upon discontinuation of treatment, MAP in both combination groups rebounded to a similar level. However, proteinuria appeared to rise to a greater extent in the amlodipine + enalapril group versus BAY 58-2667 + enalapril (224.6 ± 47.1 versus 190.8 ± 31.1 mg/day, $p<0.05$). Importantly, glomerulosclerosis and tubulointerstitial lesions were only significantly reduced in the BAY 58-2667 + enalapril group versus vehicle (-35.4% and -45% respectively, $p<0.05$); thereby indicating a persistent improvement in renal damage despite treatment discontinuation. Such an effect was not observed in the amlodipine + enalapril group, thus demonstrating its dissociation from MAP lowering.

Conclusions: An sGC activator resulted in disease modification in the ZSF1 rat model of diabetic nephropathy, as evident by beneficial effects maintained weeks after treatment discontinuation.

FR-PO294

A Receptor Fusion Protein (mIL-6-RFP-Fc) for the Inhibition of IL-6 in Preclinical Disease Models
Gerald S. Braun,[1] Dieter Görtz,[2] Yuichi Maruta,[1] Tammo Ostendorf,[1] Jürgen Floege,[1] Gerhard Müller-Newen.[2] *[1]Nephrology, RWTH Univ, Aachen, Germany; [2]Biochemistry and Molecular Biology, RWTH Univ, Aachen, Germany.*

Background: IL-6 is a central regulator of inflammatory processes and has been shown to be markedly increased during glomerulonephritis, chronic inflammation, fibrosis, and acute kidney injury. Targeting of this cytokine during these states is highly desirable to develop potential therapeutic strategies. Fusion proteins derived from the extracellular parts of heteromeric cytokine receptors have turned out to be promising cytokine inhibitors.

Methods: We constructed an improved receptor fusion protein, mIL-6-RFP-Fc, consisting of the ligand binding domains of murine signal transducer gp130 and the murine IL-6Ra-subunit connected by a flexible polypeptide linker. The gene sequence was optimized for expression in mammalian cells. An engineered Fc fragment from murine IgG2a was added to increase half-life and to allow for purification through affinity chromatography. Further tagging with V5 and HA allowed for the reliable quantification of the fusion protein by ELISA during expression and purification.

Results: Codon optimization led to a 10-fold increase in protein yield from transfected HEK cells. mIL-6-RFP-Fc was a highly specific and highly potent inhibitor of murine, rat and human IL-6 *in vitro* as evidenced by downstream signaling and cell proliferation. Pharmacokinetics of mIL-6-RFP-Fc in mice was assessed following intravenous, intraperitoneal and subcutaneous application in mice showing availability for at least 8 hours after a single administration. Transient hydrodynamic expression in mice using a kidney and liver-specific promoter (PEPCK) resulted in organ expression and significant plasma levels (up to 0.5 µg/ml) of mIL-6-RFP-Fc. The inhibitory *in vivo* activity of mIL6-RFP-Fc was confirmed in murine models of IL-6-induced signaling responses.

Conclusions: mIL-6-RFP-Fc is ready for use in research and preclinical models. Encoded by a single gene, it is also well suited for organ-specific or inducible expression in transgenic mice.

Therapeutic Targeting of JAK/STAT/SOCS Pathway Reduces Diabetic Nephropathy in Mice
Carlota Recio, Ainhoa Oguiza, Iolanda Lazaro Lopez, Benat Mallavia, Jesus Egido, Carmen Gomez Guerrero. *Renal and Vascular Pathology, IIS-Fundacion Jimenez Diaz, Autonoma Univ of Madrid, Madrid, Spain.*

Background: JAK/STAT pathway regulates a broad range of mediators implicated in cell proliferation, inflammation and fibrosis and is an important mechanism whereby hyperglycemia and dyslipemia contribute to the progression of diabetic complications. SOCS proteins negatively regulate JAK/STAT signaling and have emerged as a promising target for novel anti-inflammatory therapies. We investigate whether a cell-permeable peptide inhibitor of JAK/STAT pathway could decrease inflammation, fibrosis and renal injury in experimental diabetic nephropathy.

Methods: Type I diabetes was induced in apolipoprotein E KO mice by streptozotocin injection. Diabetic animals were treated with a peptide containing the SOCS1 kinase-inhibitory region (65 µg/day, i.p., 8 weeks, n=9) or vehicle (n=9). Kidney samples were analyzed for morphology (PAS), leukocyte infiltration (F4/80 and CD3) and collagen content (Picrosirius red). In vitro studies were performed in mesangial and tubular cells stimulated with cytokines (IFNg/IL-6) in the presence of inhibitory (SOCS1) and control mutant peptides. Cell migration was determined by wound-healing assay. STAT activation was evaluated by detection with phospho-specific antibodies. Expression of inflammatory and fibrotic genes was analyzed by real-time PCR.

Results: *In vivo*, SOCS1 peptide improved renal function and reduced the pathologic changes associated with diabetes, without impact on hyperglycemia and hyperlipidemia. Kidneys from SOCS1-treated mice exhibited a decreased infiltration of leukocytes and collagen content. SOCS1 peptide prevented STAT1/STAT3 activation and the expression of CCL2, CCL5,TNFa, TGFb and fibronectin. In cultured renal cells, SOCS1 peptide, but not control mutant peptide, inhibited cytokine-induced STAT1/STAT3 activation, target gene expression and cell migration.

Conclusions: SOCS1-based targeting JAK/STAT reduces renal inflammation and fibrosis and ameliorates renal dysfunction in experimental diabetic nephropathy. Mimicking SOCS1 functions may have a therapeutic potential to retard the progression of diabetic complications.

Funding: Government Support - Non-U.S.

FR-PO296

Peptide-Based Modulation of NF-kB in a Mouse Model of Diabetes-Driven Nephropathy and Atherosclerosis Ainhoa Oguiza, Carlota Recio, Iolanda Lazaro Lopez, Benat Mallavia, Jesus Egido, Carmen Gomez Guerrero. *Renal and vascular pathology, IIS-Fundacion Jimenez Diaz, Autonoma Univ of Madrid, Madrid, Spain.*

Background: Hyperglycemia, dyslipidemia and inflammation participate in the progression of diabetes complications. Transcription factor NF-kB regulates the gene expression of many inflammatory factors involved in these pathologies. The NBD peptide selectively blocks the interaction of NEMO with IkB kinase complex and is proven to be effective in experimental models of acute inflammation but not in diabetes complications. Our aim is to inhibit NF-kB activation in an experimental model that combines hyperglycemia and hypercholesterolemia.

Methods: Type I diabetes was induced in apolipoprotein E deficient mice by streptozotocin injection. Diabetic animals were given i.p. injections of cell-permeable NBD peptide (40µg/day and 200µg/day) or vehicle for 8 weeks. Rhodamine-labeled NBD peptide was used for tissue distribution analysis. Tissues were analyzed for changes in morphology (PAS and ORO), cellularity (leukocytes and a-actin), collagen content (picrosirius red), gene expression (RT-PCR) and NF-kB activity (Southwestern). In vitro effects were studied in mesangial and tubular cells under hyperglycemic and inflammatory conditions.

Results: NBD peptide accumulated in kidneys and aorta of diabetic mice and suppressed NF-kB activation. NBD therapy improved renal function of diabetic mice and reduced glomerular and tubulointerstitial lesions without affecting metabolic parameters. Kidneys from treated mice exhibited less infiltrating cells and inflammatory molecules (MCP-1, RANTES and TNF-a), and reduced expression of pro-fibrotic genes (collagen, fibronectin and TGFb). In aorta, NBD peptide ameliorates atheroma plaques by reducing leukocyte content and inflammatory markers and increasing plaque stability. In cultured renal cells, NBD peptide disrupted the interaction of IkB kinase subunits, inhibiting NF-kB activation and pro-inflammatory gene expression.

Conclusions: Peptide-based modulation of NF-kB restrains the progression of renal and vascular damage in experimental diabetes and may be of potential interest in the treatment of diabetes complications.

Funding: Government Support - Non-U.S.

A Novel Integrin Agonist Reduces Inflammation and Protects against Diabetic Nephropathy Mohd Hafeez Faridi,[1] Hatem A. Elshabrawy,[1] Johanna Guzman,[2] Alessia Fornoni,[2] Vineet Gupta.[1] *[1]Internal Medicine, Rush Univ Medical Center, Chicago, IL; [2]Medicine, Univ of Miami, Miami, FL.*

Background: Diabetic nephropathy (DN) is one of the major complications of diabetes mellitus leading to deterioration of kidney ultrastructure often culminating in end stage renal disease. Clinically, DN results in complex pathologic changes in the glomeruli, including basement membrane thickening, glomerular mesangial expansion, glomerulosclerosis and a significant loss of podocytes. Inflammation, often accompanied by leukocyte infiltration, has been shown to play a significant role in the development and progression of DN, suggesting that reducing leukocyte infiltration may be a promising therapeutic strategy. We recently identified a class of novel compounds (termed leukadherins) that exhibit a unique mechanism for reducing leukocytes infiltration into inflamed tissue. We report the therapeutic effect of leukadherins on DN progression in a murine type 2 diabetes model.

Methods: We used the BTBR ob/ob murine model of DN, in which the disease resembles human DN. At the onset of DN in these mice (4 wks of age), they were injected i.p. with our novel compound (Leukadherin 1 i.e. LA1) daily for eight weeks. Animals were monitored for blood glucose level, body weight, and renal function and for glomerular defects using histopathology at different time points.

Results: Daily administration of LA1 significantly reduced the number of infiltrating leukocytes in the glomeruli and preserved the kidney function in diabetic animals. We observed no effect of our interventions on hyperglycemia. Histopathological studies showed a significant reduction in glomerular mesangial sclerosis in LA1-treated animals.

Conclusions: Our results suggest that LA1 significantly preserves the kidney function in DN and provides a novel approach to delay the onset of DN.

FR-PO298

Urine Cell Quantitative RT-PCR for Analysis of Renal Inflammation in Diabetic Nephropathy Bairbre A. McNicholas,[1,2] Malgorzata Zurawska,[1] David Lappin,[2] Matthew D. Griffin.[1,2] *[1]ReGenerative Medicine Inst, School of Medicine, National Univ of Ireland, Galway, Ireland; [2]Nephrology Services, Galway Univ Hospitals, Ireland.*

Background: Urine cell analysis is a non-invasive approach to study and diagnose human kidney disease. We investigated technical feasibility and results of urine cell quantitative (q) RT-PCR for selected inflammatory mediators (IL-6, IL-6R, IL-17) in fresh urine samples from adults with type 2 diabetes (T2DM) and nephropathy of varying severity and from healthy adults.

Methods: Urine pellet mRNA from 160 T2DM outpatients with varying urine albumin creatinine ratio (ACR) and 20 healthy adults was extracted by modified Trizol® protocol and analysed for quantity and quality by NanoDrop and Bioanalyzer. Relative abundance of IL-6, IL-6R and IL-17 mRNA was quantified on a StepOne Plus® Real-Time PCR System by standard curve method normalized to b-actin and in relation to a calibrator sample. Samples with 260/280 ratio <1.7 and/or amplification threshold for b-actin >24 were deemed unsuitable. Transcript levels were correlated with HbA1c, BMI, MDRD-eGFR, ACR and systolic blood pressure (SBP).

Results: Only 72 (40%) cell pellets had adequate mRNA for qRT-PCR. Subjects with adequate compared to inadequate mRNA had similar age, ACR, BMI and HbA1c but lower eGFR (66±20 v 73±18 ml/min/SA, p=0.02). Among the 61 T2DM subjects with adequate urine cell mRNA, albuminuria grade was normal in 25, mild to moderate in 26 and severe in 10. Quantifiable mRNA for IL-6, IL-6R and IL-17 was present in 100%, 100% and 72% respectively of all adequate samples. Contrary to expectations, mean urine cell mRNA levels of IL-6, IL-6R and IL-17 were no different in T2DM compared to healthy adults. Furthermore, urine cell mRNA levels did not correlate with albuminuria grade, eGFR, BMI or SBP. Subjects with detectable urine cell IL-17 mRNA had higher albuminuria (11±18 v 41±85 mg/mmol, p=0.01).

Conclusions: 1. Even with optimized methodology, sample inadequacy significantly limits urine cell qRT-PCR for investigation of mild to moderate diabetic kidney disease. 2. For T2DM subjects with mild to moderate nephropathy and adequate urine cell RNA the results provided evidence against overt renal inflammation.

FR-PO299

Reduced Connexin 43 Expression Protects against the Progression of Experimental Glomerulonephritis in Mice Ahmed Abed,[1] Panagiotis Kavvadas,[1] Carlo M. Alfieri,[2] Jean-Jacques Boffa,[3] Christos Chatziantoniou,[1] Christos E. Chadjichristos.[1] *[1]UMR-S1155, INSERM, Paris, France; [2]Unit of Nephrology Dialysis and Kidney Transplantation, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico di Milano, Milano, Italy; [3]Nephrology Dpt, Tenon Hospital, Paris, France.*

Background: Glomerulonephritis (GN) includes a variety of renal pathologies which may progress to end-stage renal disease. We have recently observed an increased expression of the gap junctional protein connexin 43 (Cx43) in injured glomeruli of mice treated with nephrotoxic serum (NTS). The aim of our work was to study the role of Cx43 in this model of GN.

Methods: We compared the progression of the NTS-induced GN between two different groups of mice, one normally expressing Cx43 (WT) and a second in which Cx43 expression was genetically reduced by half (Cx43+/-) (n=10 mice per group). Mice were sacrificed at day 15. After sacrifice kidneys were assessed for morphometry, inflammation and interstitial fibrosis.

Results: Renal function was improved in Cx43+/- mice two weeks after NTS administration. Indeed, proteinuria (11.1±1.1g/mol for Cx43+/- versus 16±0.5g/mol for WT, p<0.05), blood urea nitrogen (35±5.3mmol/l for Cx43+/- versus 55±9.mmol/l for WT, p<0.05) and serum creatinine (25±4.4mmol/l for Cx43+/- versus 56±9mmol/l for WT, p<0.01) were significantly decreased. Consequently, renal structure was preserved as crescent-like formation (30±3.3% of crescentic glomeruli in Cx43+/- versus 45±4.5% in WT, p<0.05), tubular dilation (1.8±0.4 index for Cx43+/- versus 2.5±0.3 for WT, p<0.05), monocyte infiltration (cortex surface of F4-80 immunostaining 3±0.5% for Cx43+/- versus 7±1.5 for WT, p<0.05) and interstitial renal fibrosis (2±0.45% and 4.5±0.9% of cortex surface for Cx43+/- and WT respectively, p<0.001) were blunted in these mice. Colocalization experiments with nestin indicated that Cx43 was mainly induced in damaged podocytes. Interestingly, western blotting demonstrated that neprhin expression was preserved in Cx43+/- mice confirming the beneficial effect of Cx43 deletion for the integrity of glomerular podocytes.

Conclusions: Our study demonstrates the deleterious role of Cx43 in NTS-induced GN and suggests that targeting Cx43 may protect against the progression of the disease.

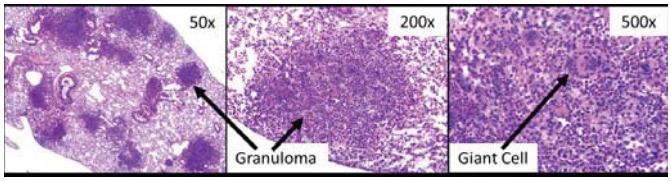
FR-PO300

Induction of Pulmonary Granulomatosis in Mice By Anti-MPO IgG: An Animal Model of ANCA Granulomatosis Peiqi Hu, Hong Xiao, Hua Su, Kemper Ramsey, Ronald J. Falk, J. Charles Jennette. *Pathology and Laboratory Medicine, Univ of North Carolina, Chapel Hill, NC.*

Background: Extravascular granulomatosis is a major pathological feature of some variants of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis. Understanding the pathogenic mechanism for granulomatosis has been hampered by the lack of animal models. Here we show a mouse model of lung granulomatosis induced by anti-MPO IgG that closely mimics the early acute pulmonary lesions of ANCA granulomatosis.

Methods: 9-10 weeks old B6, 129S6 wild type (WT), 129S6 rag2-/-, 129S6 Fc gamma RIIb-/- mice were injected i.v. at day 0 and day 1 with 75ug/g body weight of anti-MPO IgG. Mice were sacrificed at day 6 and kidney, lung and other tissue collected for pathologic assessment.

Results: Six days after two dose i.v. injections of anti-MPO IgG on consecutive days, lung granulomatous lesions and necrotizing glomerulonephritis (GN) developed in all mouse strains with the least severe disease in B6 mice and the most severe in 129S6 Fc gamma RIIb-/- mice lacking inhibitory Fc receptor. The nodular lung lesions contained neutrophils, monocyte and macrophages, including prominent multinucleated giant cells.



Conclusions: 1) The same batch of anti-MPO IgG that induces only renal limited GN when given as a single dose causes pulmonary granulomatosis when administered in two sequential doses. The first dose positions primed neutrophil and monocytes in the lung for activation by the second dose. 2) Induction of granulomatosis by anti-MPO IgG in Rag2-/- with no functioning T cells mice documents that the granulomatosis is not T cell-mediated. 3) Absence of the inhibitory Fc gamm R IIb results in more severe pulmonary granulomatosis.

FR-PO301

Altered Phenotypeof Anti-GBM Glomerulonephritis following Conditional and Kidney-Specific Knockdown of Stanniocalcin-1 Luping Huang, Luan D. Truong, Huiming Ju, David Sheikh-Hamad. *Medicine/Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Inflammation is the hallmark of anti-GBM GN. We have shown stanniocalcin-1 (STC1) inhibits macrophages, stabilizes endothelial barrier function, and diminishes trans-endothelial migration of leukocytes; consistently, transgenic (Tg) overexpression of STC1 protects from anti-GBM glomerulonephritis (GN). In the following experiments, we sought to determine the phenotype of anti-GBM GN following conditional and kidney-specific knockdown of STC1.

Methods: We generated STC1 shRNA Tg and scrambled shRNA Tg mice that express STC1 shRNA or scrambled shRNA, respectively, upon removal of floxed reporter (PGK-EGFP); delivery of pTie2-Cre to the kidney using ultrasound microbubbles, initiates expression of the shRNA, in kidney endothelial cells. STC1 shRNA expression provides global kidney knockdown of STC1 protein (70%) within 4 days, persisting through day 14. We observe no change in STC1 expression in similarly treated scrambled shRNA Tg mice. Sheep anti-mouse GBM antibody was administered at day 4, mice were killed at day 14 and the following were determined: blood pressure; urine output; proteinuria; serum creatinine; kidney morphology, fibrosis, T-cells and macrophages infiltration, C_3 and mouse IgG deposition, and cytokine array.

Results: The increase in serum creatinine and proteinuria, and decline in urine output, were similar in STC1 shRNA and scrambled shRNA Tg mice after anti-GBM GN; however, STC1 shRNA Tg mice displayed: higher blood pressure; greater tubulointerstitial expansion; marked tubular epithelial vacuolization and sloughing; massive cast formation and severe tubular dilatation; 7-fold higher glomerular necrosis/hyalinosis; 5-fold greater glomeruli with crescents. STC1 shRNA Tg kidneys had fewer T-cells and macrophages, less C_3 and mouse IgG deposition, and reduced cytokine expression.

Conclusions: Anti-GBM following kidney-specific knockdown of STC1 is characterized by: severe tubular and glomerular necrosis; massive cast formation. Surprisingly, inflammation is not a dominant feature, and we speculate that absent cytokine release from necrotic tubules may account for the paucity of inflammatory cells within the kidney.

The Growth Factor Midkine Reflect the Disease Activity in Lupus Nephritis Tomohiro Masuda,[1] Kayaho Maeda,[1] Waichi Sato,[2] Tomoki Kosugi,[1] Yuka Sato,[1] Takuji Ishimoto,[1] Seiichi Matsuo,[1] Shoichi Maruyama.[1] *[1]Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [2]Nephrology, Fujita Health Univ School of Medicine, Toyoake, Japan.*

Background: Midkine (MK), a heparin-binding growth factor regulates cell growth, cell survival and migration in nephrogenesis and development. Its pathophysiological roles are diverse, ranging from the occurrence of acute kidney injury to progression of chronic kidney disease, often accompanied by hypertension and diabetes. In autoimmune diseases, however, molecular mechanism involving MK is unknown. We so far examined the association of MK in regulatory T cell population *in vitro.* In current study, we elucidated the role of MK in lupus nephritis (LN).

Methods: *In vivo* study: LN was induced in MK-deficient ($Mdk^{-/-}$) or wild-type mice ($Mdk^{+/+}$) with an intraperitoneal injection of pristane.Mice were sacrificed at 6 months later. Kidney, spleen and lipogranulomas were analyzed. Clinical study: Plasma and spot urine samples were collected from LN patients (N=42), who underwent renal biopsy in our affiliated hospitals, and healthy volunteer (N=33). MK values were measured by ELISA. MK expression in tissue samples from LN patients was assessed by immunostaining.

Results: *In vivo* study, glomerular injury in $Mdk^{+/+}$mice was severer than that of $Mdk^{-/-}$ mice. Particularly, mesangial and endothelial cells proliferations, component C3 deposition, $CD68^+$ macrophages, neutrophils and $CD4^+$ T cells infiltration were prominent in glomeruli of $Mdk^{+/+}$mice, consistent with the profiles of albuminuria and renal function. In addition, MK expression was increased in LN kidneys of $Mdk^{+/+}$ mice and positively correlated with pathological severity. In patients with LN, the close relationship between urine MK and LN disease activity was also observed. Interaction between immune complex (IC) and Fcg receptor (FcgR) is an important factor for LN progression. Interestingly, FcgR-dependent activation and cytokine production in ICs-regulated leukocytes was found in MK dose-dependent manner *in vitro.*

Conclusions: Lack of MK ameliorates glomerular injury of LN through the suppression of cytokine production in ICs-regulated leukocytes.

FR-PO303

Decay Accelerating Factor (DAF) Induction and Attenuation of Complement Activation in the Rat Glomerulus By Heme Oxygenase (HO)-1 Maria Detsika,[1] Pu Duann,[2] Elias A. Lianos.[2] *[1]Medicine, Univ of Athens, Greece; [2]Medicine, Rutgers Biomedical and Health Sciences, NJ.*

Background: Rat glomeruli express DAF exclusively in glomerular epithelial cells (GEC) thus attenuating complement (C)-mediated injury. HO-1 attenuates C-mediated injury via heme degradation products. An alternative mechanism may involve DAF upregulation. This was explored in normal rat glomeruli.

Methods: $hmox1^{+/-}$ and $hmox1^{-/-}$ rats were obtained by Zinc Finger Nuclease (ZFN)-mediated HO-1 gene disruption. Rats with GEC targeted HO-1 overexpression (GEC^{HO-1}) were generated by Sleeping Beauty Transposon mediated transgenesis using a nephrin promoter. Glomeruli from wild type (WT) or $hmox1^{+/-}$, $hmox1^{-/-}$ or GEC^{HO-1} rats were treated for 18h with Metalloporphyrins (MPs): Heme (Hemin) or Cobalt Protoporphyrin (CoPP) (HO inducers), Zinc (ZnPP) or Tin (SnPP) (HO inhibitors), and effect on glycosyl-phosphatidyl-inositol (gpi)-anchored DAF was assessed. Verification of gpi-DAF expression was confirmed by phosphatidylinositol specific phospholipase C (PI-PLC) treatment. Glomerular C3b deposition was triggered by incubation with 10% rat serum (spontaneous C-activation). DAF, HO-1 and C3b protein levels were assessed by western blot analysis.

Results: PI-PLC treatment resulted in ≥90% reduction in glomerular DAF. Constitutive gpi-DAF levels decreased by 2-fold and 4-fold in $hmox1^{+/-}$ and $hmox1^{-/-}$ glomeruli, respectively. All MPs dose-dependently induced gpi-DAF in WT glomeruli. In co-incubations with Hemin, ZnPP and SnPP had an additive effect on DAF induction. Hemin-mediated DAF induction in $hmox1^{+/-}$ and $hmox1^{-/-}$ glomeruli was attenuated in comparison to WT. In GEC^{HO-1}glomeruli, constitutive DAF expression was increased and Hemin-mediated DAF induction was augmented. C3b deposition was decreased by 40% at Hemin concentrations that induced gpi-DAF.

Conclusions: Glomerular gpi-DAF expression is HO-1 dependent. MPs induce gpi-DAF in a metal and HO-activity independent manner. In spontaneous C-activation Hemin-mediated gpi-DAF induction attenuates C3b deposition. MP-mediated DAF induction may point towards novel therapeutic strategies in C-dependent glomerulopathies.

Modulation of Heparan Sulfate in the Glomerular Endothelial Glycocalyx Decreases Leukocyte Influx during Experimental Glomerulonephritis Angelique Rops,[1] Markus A. Loeven,[1] Jasper J. Van Gemst,[1] Xander Van Wijk,[2] Henry Dijkman,[3] Toin Van Kuppevelt,[4] Jo H.M. Berden,[1] Ton J. Rabelink,[5] Jeffrey D. Esko,[2] Johan Van der Vlag.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Cellular & Molecular Medicine, Univ of California, San Diego; [3]Pathology, Radboud Univ Medical Center, Nijmegen, Netherlands; [4]Biochemistry, Radboud Univ Medical Center, Nijmegen, Netherlands; [5]Nephrology, Leiden Univ Medical Center, Leiden, Netherlands.*

Background: The glomerular endothelial glycocalyx is postulated to be an important modulator of permeability and inflammation. The glycocalyx consists of complex polysaccharides, the main functional constituent of which, heparan sulfate (HS), is

synthesized and modified by multiple enzymes. The N-deacetylase-N-sulfotransferase (Ndst) enzymes initiate and dictate the modification process. Here we evaluated the effects of modulation of HS in the endothelial glycocalyx on albuminuria and glomerular leukocyte influx using mice deficient in endothelial and leukocyte Ndst1 ($TEKCre^{+}/Ndst1^{flox/flox}$).

Methods: Albuminuria, blood urea nitrogen, glomerular leukocyte influx, histology, electron microscopy, and glomerular HS expression were determined before and after anti-GBM nephritis induction. Leukocyte adhesion was evaluated i*n vitro* using mouse glomerular endothelial cells (mGEnC) with reduced Ndst1 expression and Ndst1-deficient granulocytes.

Results: In Ndst1-deficient mice, glomerular expression of a specific HS domain was significantly decreased, whereas the expression of other HS domains was normal. In the endothelial glycocalyx, this specific HS structure was not associated with albuminuria or with changes in renal function. However, glomerular leukocyte influx was significantly reduced during anti-GBM nephritis, which was associated with less glomerular injury and better renal function. *In vitro* decreased adhesion of wild-type and Ndst1-deficient granulocytes to Ndst1-silenced mGEnC was found, accompanied by a decreased binding of chemokines and L-selectin.

Conclusions: Modulation of heparan sulfate in the glomerular endothelial glycocalyx significantly reduces the inflammatory response in anti-GBM nephritis.

Identification of Activin A as a Novel Urinary Biomarker for Lupus Nephritis in MRL/lpr Mice Anastasie Kadiombo Tshilela, Akito Maeshima, Noriyuki Sakurai, Hidekazu Ikeuchi, Toru Sakairi, Yoriaki Kaneko, Keiju Hiromura, Yoshihisa Nojima. *Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: Activin A, a member of TGF-beta superfamily, is known to regulate cell growth and differentiation in various tissues. It has been reported that activin A modulates ureteric bud branching in kidney development, inhibits tubular regeneration after renal ischemia, and acts as a potent inducer of renal fibrosis in a rat unilateral ureteral obstruction model. However, the precise role of activin A in the progression of kidney diseases is not totally understood. To address this issue, we used female lupus-prone MRL/lpr mice in this study.

Methods: The expression and localization of activin A in the kidneys of MRL/lpr mice at 12, 16, 19 weeks of age was analyzed by real-time PCR, western blot analysis, and immunostaining. Histological changes of the kidneys (PAS, HE, and EVG staining), urinary protein level, renal functions (BUN, creatinine), infiltration of inflammatory cells (CD3, CD19, and CD68) and urinary activin A concentration (ELISA) were examined. C57BL/6 mice were used as control.

Results: No expression of activin A was observed in the kidneys of normal C57BL/6 mice. In contrast, activin A was detectable in periglomerular or perivascular CD68-positive cells in the kidneys of MRL/lpr mice at 12 weeks and thereafter. Urinary activin A was not detected in normal C57BL/6 mice or in MRL/lpr mice at 14 weeks or less, but became detectable in MRL/lpr mice at 16 weeks and thereafter. Urinary activin A level was statistically correlated with the number of infiltrating CD68-positive cells, the number of crescentic glomeruli, EVG-positive fibrotic area, and urinary protein level, but not with renal functions.

Conclusions: These data suggest that urinary activin A is a new biomarker reflecting renal inflammation in MRL/lpr mice. Activin A produced by infiltrating CD68-positive cells might be involved in crescent formation and interstitial fibrosis in these mice.

Complement Activation on Vascular Endothelial Cells Results in Polymorphonuclear Leukocyte Adhesion Magdalena Riedl,[1,2] Damien Gerard Noone,[1,3] Meraj Alam Khan,[1] Fred G. Pluthero,[1] Walter H. Kahr,[1] Nades Palaniyar,[1] Christoph Licht.[1,3] *[1]Research Inst, The Hospital for Sick Children, Toronto, ON, Canada; [2]Dept of Pediatrics I, Innsbruck Medical Univ, Innsbruck, Austria; [3]Div of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a devastating disease caused by defective complement (C) regulation on vascular endothelial cells (EC) resulting in microvascular thromboembolism and organ failure. EC are protected from C attack via C regulators (e.g. CD46, CD55 and CD59).The clinical observation of infections often preceding aHUS events has suggested a key role for the inflammatory system. Combining these insights, we hypothesized that adhesion of polymorphonuclear leukocytes (PMN) will be enhanced following EC C challenge.

Methods: Calcein-labeled PMN were introduced at 1 dyne/cm^2 into a microfluidic system (Bioflux), seeded with blood outgrowth endothelial cells (BOEC). These EC were pretreated with a) GB24 (blocking CD46), b) GB24 and BRIC216 (blocking CD55) and BRIC229 (blocking CD59) or c) TNFa 20ng/ml as positive control (PC). 50% normal human serum (NHS), used as source for C, or heat-inactivated serum (HIS) as control were either introduced simultaneously or for 1h prior to PMN. PMN adhesion was quantified in static conditions using a fluorescent plate reader assay.

Results: In fluidic conditions significant PMN adhesion was observed 5min after PMN/50%NHS introduction, only when CD46, CD55 and CD59 were blocked. ($p<0.05$). This effect was abandoned with HIS. The same effect was seen after 1h incubation of serum, indicating an independent effect of direct C activation on PMN. C-induced EC activation upon blockade of all three C regulators was confirmed by immunofluorescence for C5b-9 and flowcytometry for C3c. In static conditions, significantly ($p<0.025$) increased PMN adhesion was observed upon blockade of CD59, CD59 in combination with CD46 or CD55, and triple block.

Conclusions: C challenge of EC results in significant increase of PMN adhesion in static and fluidic conditions. This finding supports a precipitating role of inflammatory events for aHUS pathogenesis and has the potential to guide ways towards novel treatment targets.

CXCL1, CXCL2 and CCL2 Binding to Mouse Glomerular Endothelial Cell Glycocalyx Is Differentially Mediated by Specific Heparan Sulfate Domains Jasper J. Van Gemst,[1] Angelique Rops,[1] Markus A. Loeven,[1] Toin Van Kuppevelt,[2] Jo H.M. Berden,[1] Ton J. Rabelink,[3] Johan Van der Vlag.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Matrix Biochemistry, Radboud Univ Medical Center, Nijmegen, Netherlands; [3]Nephrology, Leiden Univ Medical Center, Leiden, Netherlands.*

Background: Heparan sulfate in endothelial glycocalyces is an important co-factor for binding of chemokines, cytokines, and is involved in leukocyte adhesion to activated endothelium. In glomerulonephritis, heparan sulfate (HS) in the glomerular endothelial glycocalyx could play a role in chemokine presentation and oligomerization, and in binding of selectins and integrins expressed by leukocytes.

Methods: We evaluated binding of three pro-inflammatory chemokines (CXCL1, CXCL2 and CCL2) to mouse glomerular endothelial cells (mGEnC-1) in ELISA in competition with GAG preparations and anti-HS single chain variable fragment (ScFv) antibodies.

Results: We showed a different affinity of CXCL1, CXCL2 and CCL2 to HS, chondroitin sulfate and dermatan sulfate in a competition ELISA with mouse glomerular endothelial cells (mGEnC-1) as a substrate. HS appeared to be the main contributor in the glomerular endothelial glycocalyx mediating endothelium-chemokine interactions. Blocking of specific HS domains with anti-HS ScFv antibodies revealed a domain-specific interaction of the tested chemokines to HS.

Conclusions: From these findings it can be concluded that CXCL1, CXCL2 and CCL2 binding to the glomerular endothelial glycocalyx is differentially mediated by specific HS domains. Our findings may lead to the development of specific GAG-based drugs specifically targeting chemokine-endothelium interactions.

FR-PO308

Concomitant Inhibition of Renin Angiotensin System and Toll-Like Receptor 2 Attenuates Renal Injury in Unilateral Ureteral Obstructed Mice Sarah Chung,[1] Jin Young Jeong,[1] Ye Jin Kim,[1] Dae Eun Choi,[1] Yoon-Kyung Chang,[2] Ki Ryang Na,[1] Kang Wook Lee.[1] *[1]Internal Medicine, ChungNam National Univ Hospital, Daejeon, Korea; [2]Internal Medicine, Saint Mary Hospital, Catholic Univ, Daejeon, Korea.*

Background: There has been controversy about the role of toll-like receptor (TLR) 2 in renal injury following ureteric obstruction. Although inhibition of the renin angiotensin system (RAS) reduces TLR2 expression in mice, the exact relationship between TLR2 and RAS is not known. The aim of this study was to determine whether the RAS modulates TLR2.

Methods: We used 8-week-old male wild type and TLR2-knock out (KO) mice on a C57Bl/6 background. Unilateral ureteral obstruction (UUO) was induced by complete ligation of the left ureter. Angiotensin (Ang) II (1,000 ng/kg/min) and the direct renin inhibitor aliskiren (25 mg/kg/day) were administrated to mice using an osmotic minipump. Molecular and histologic evaluations were performed.

Results: Ang II infusion increased mRNA expression of TLR2 in wild type mouse kidneys ($p < 0.05$). The expression of renin mRNA in TLR2-KO UUO kidneys was significantly higher than that in wild type UUO kidneys ($p < 0.05$). There were no differences in tissue injury score or mRNA expression of monocyte chemotactic protein-1 (MCP-1), osteopontin (OPN), or transforming growth factor-b (TGF-β) between TLR2-KO UUO and wild type UUO kidneys. However, aliskiren decreased the tissue injury score and mRNA expression of TLR2, MCP-1, OPN, and TGF-β in wild type UUO kidneys ($p < 0.05$). Aliskiren-treated TLR2-KO UUO kidneys showed less kidney injury than aliskiren-treated wild type UUO kidneys.

Conclusions: TLR2 deletion induced activation of the RAS in UUO kidneys. Moreover, inhibition of both RAS and TLR2 had an additive ameliorative effect on UUO injury of the kidney.

FR-PO309

The Axis Gremlin/VEGFR2 in Renal Damage Carolina Lavoz,[1] Matilde Alique Aguilar,[1] Raquel Rodrigues-Diez,[1] Janos Pato,[4] Gyorgy Keri,[5] Jesus Egido,[2] Sergio A. Mezzano,[3] Marta Ruiz-Ortega.[1] *[1]Cellular Biology in Renal Diseases Laboratory, IIS-Fundación Jiménez Díaz. Univ Autónoma, Madrid, Spain; [2]Nephrology, IIS-Fundación Jiménez Díaz. Univ Autónoma, Madrid, Spain; [3]Nephrology, School of Medicine, Univ Austral, Valdivia, Chile; [4]Vichem Chemie Ltd., Budapest, Hungary; [5]Pathobiochemistry, Semmelweis Univ, Budapest, Hungary.*

Background: Gremlin is a developmental gene up regulated in human chronic kidney diseases and proposed as a mediator of renal damage. Gremlin binds to bone morphogenetic proteins (BMPs) acting as an antagonist regulating, among other process, nephrogenesis and fibrosis. In cultured endothelial cells Gremlin binds to vascular endothelial growth factor receptor-2 (VEGFR2) to induce angiogenesis. Our aim was to investigate the direct effects of Gremlin in the kidney, evaluating the receptor subtype and mechanisms involved.

Methods: Gremlin was administered into C57BL/6 mice (renal parenchymal injection, 50 ng/g BW). Some mice were treated with the VEGFR2 inhibitor SU5416 (i.p; 0.1 mg/mice/day). In vitro studies were done in cultured tubular epithelial cells (HK2 cell line).

Results: Gremlin administration caused a rapid and sustained activation of VEGFR2 signalling in the kidney, mainly located in tubular epithelial cells. One of the earliest downstream mechanism activated was the nuclear factor-kB pathway (observed at 15 min). Gremlin via nuclear factor-kB pathway caused renal inflammation, characterized by up-regulation of pro-inflammatory factors (chemokines, adhesion molecules and cytokines) and infiltration of inflammatory cells, observed after 48 hours. VEGFR2 kinase inhibition diminished Gremlin-induced renal inflammation. In vitro, Gremlin activated VEGFR2 pathway independently of BMPs. VEGFR2 kinase inhibition or gene silencing inhibited Gremlin-mediated NF-kB activation and pro-inflammatory genes upregulation. In the model of renal damage by unilateral ureteral obstruction, Gremlin overexpression was associated to VEGFR2 pathway activation, and VEGFR2 kinase inhibition diminished renal inflammation.

Conclusions: These data demonstrate that Gremlin binds to and activates the VEGFR2 signalling pathway in the kidney linked to renal inflammation.

PEDF Protects Tubular Epithelial Cells and Ameliorates Renal Fibrosis via Inhibition of the Wnt/β-Catenin Pathway Xuemin He, Rui Cheng, Jian-Xing Ma. *Dept of Physiology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Our previous studies revealed that pigment epithelium-derived factor (PEDF) confers reno-protective effects in diabetic nephropathy. The purpose of the present study was to evaluate the protective effect of PEDF on tubular epithelial cells in obstructive nephropathy and explore its molecular mechanism.

Methods: Two months-old PEDF$^{-/-}$ mice and wild-type (WT) mice received sham or unilateral ureteral obstruction (UUO) operation. Five and ten days after the surgery, renal fibrotic markers, inflammatory factors and the Wnt/β-Catenin pathway were evaluated by quantitative real-time PCR, Western blot analysis, immunohistochemistry and X-gal staining. In proximal tubular epithelial cell line (HKC-8), 4-HNE-induced cell death was determined by TUNEL and Trypan blue exclusion assay. Primary tubular epithelial cells (PTECs) were isolated from WT mice and PEDF$^{-/-}$ mice.

Results:: Renal levels of PEDF were significantly down-regulated at day 5 after UUO. Loss of PEDF led to aggravated UUO-induced renal tubular epithelial cell death compared with WT/UUO controls. Recombinant human PEDF (rhPEDF) or over-expression of PEDF using adenovirus significantly decreased 4-HNE-induced tubular epithelial cell death. Compared with WT/UUO controls, PEDF$^{-/-}$/UUO mice showed higher levels of p-LRP6, non-β-Catenin and β-Catenin activities in the kidney compared to WT/UUO mice. Further, PEDF$^{-/-}$/UUO kidneys exhibited more severe renal fibrosis and renal inflammation, including elevated levels of collagens, TGF-β1, TGF-β receptor type I and type II, fibronectin, ICAM-1, TNF-a, IL-6 and M-CSF, most of which were regulated by the Wnt/β-Catenin pathway. In PEDF$^{-/-}$ PTECs, Wnt3A conditioned medium (WCM) induced more prominent increases of p-LRP6, non-β-Catenin, fibronectin and TGF-β1levels relative to that in WT PTECs. In addition, rhPEDF suppressed WCM-induced Wnt/β-Catenin signaling and downstream genes in a dose-dependent manner in PTECs.

Conclusions: PEDF protects tubular epithelial cells against obstructive nephropathy. This effect may be ascribed to its anti-oxidant and anti-inflammatory activities through regulation of the Wnt/β-Catenin pathway.

FR-PO311

The Involvement of Histone Acetylation in the Progression of Nephrosclerosis Kumiko Muta,[1] Yoko Obata,[1] Takehiko Koji,[2] Tomoya Nishino,[1] Shigeru Kohno.[1] *[1]Second Dept of Internal Medicine, Nagasaki Univ School of Medicine, Nagasaki City, Nagasaki Prefecture, Japan; [2]Dept of Histology and Cell Biology, Nagasaki Univ School of Medicine, Nagasaki City, Nagasaki Prefecture.*

Background: Although histone acetylation, one of epigenetic modification, has been reported to be related to the progression of various diseases, its involvement in the progression of nephrosclerosis is unclear.

Methods: 6 week-old Dahl salt-sensitive rats were divided into 3 groups: (i) normal salt diet (NS) group, (ii) high salt diet (HS) group, (iii) HS group administered daily curcumin, a histone acetyltransferase (HAT) inhibitor, (HS+C group). At 6 week after salt load, the kidneys were dissected out. Morphologic changes were assessed by Masson's trichrome staining. The number of macrophages and fibroblasts, and histone acetylation—positive cells were assessed by immunohistochemistry. HAT and histone deacetylase (HDAC) activity were measured by Enzyme-linked immunosorbent assay. The genes affected to their expression by histone acetylation were examined by chromatin immunoprecipitation.

Results: Both HS and HS+C groups showed marked increase of systolic blood pressure since 2 week of salt load. At 6 week, serum creatinine was increased markedly in HS group, whereas it was suppressed in HS+C group. In HS group, interstitial fibrosis and glomerular sclerosis were observed, and the each number of macrophages and fibroblasts was increased more than those in NS group. HS+C group showed the inhibition of these inflammation and fibrosis. The level of histone acetylation was enhanced in HS group compared to NS group, whereas the curcumin administration suppressed histone acetylation. HAT/HDAC activity ratio was elevated in HS group and tended to be lower in HS+C group than that in HS group. In HS group, interleukin 6 (IL-6) gene and protein expression were increased by histone acetylation.

Conclusions: Our results suggested that increased IL-6 gene expression induced by the enhancement of histone acetylation might be involved in the progression of nephrosclerosis, independently of hypertension.

FR-PO312

Progressive Activation of Innate Immunity and Inflammasome Components in the 5/6 Renal Ablation Model Camilla Fanelli, Jessica K. Okuma, Fernanda F.F. Zambom, Simone C.A. Arias, Flavia G. Machado, Victor F. Avila, Viviane D. Faustino, Gizely C.S. Moreira, Orestes Foresto-Neto, Lisienny C.T. Rempel, Claudia R. Sena, Vivian L. Viana, Ricardo P. Mazzonetto, Denise M.A.C. Malheiros, Niels O.S. Camara, Clarice K. Fujihara, Roberto Zatz. *Univ of Sao Paulo, Brazil.*

Background: Innate immunity activation may play a key role in the development of chronic kidney disease (CKD). We showed previously that NFkB inhibition attenuates renal injury in the 5/6 nephrectomy model (NX). Here we examine whether activation of the inflammasome/IL-1b pathway occurs as renal injury associated with NX progresses.

Methods: Adult male Munich-Wistar rats underwent NX (N=20) or sham operation (S, N=10). Tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/24h), serum creatinine (S_{cr}, mg/dL), glomerulosclerosis index (GSI), % interstitial expansion (INT), macrophage infiltration (MF, cells/mm^2), % TLR4+ tubules (%TLR4+tub) and the gene expression of Casp1, Nrlp3, Tlr4, and Il1b were assessed 7, 30, 60 and 120 days after ablation.

Results:

	S	NX 7d	NX 30d	NX 60d	NX 120d
TCP	137±2	171±5^{a}	206±7^{ab}	211±9^{ab}	218±5^{ab}
ALB	5±1	55±16^{a}	88±15^{ab}	94±11^{ab}	175±14^{abcd}
S_{cr}	0.6±0.1	1.2±0.1^{a}	1.2±0.1^{a}	1.1±0.1^{a}	1.3±0.1^{a}
GSI	0±0	0±0	15±4	38±9^{ab}	108±20^{abcd}
INT	0.2±0.1	0.5±0.1	2.9±0.4^{ab}	4.7±0.8^{abc}	5.0±0.2^{abc}
МΦ	21±2	47±10	135±35^{ab}	153±29^{ab}	216±25^{abcd}
TLR4+tub	7±1	11±2^{a}	18±1^{ab}	20±1^{ab}	20±2^{ab}

Results are mean±SE: $^{a}p<0.05$ vs C, $^{b}p<0.05$ vs NX7, $^{c}p<0.05$ vs NX30, $^{d}p<0.05$ vs NX60.

Innate immunity activation followed closely the progression of renal injury and inflammation. At 7 days after NX, mRNA and protein expression of Tlr4 were statistically increased when compared to S group. By the end of the study, the expressions of Casp1, Nlrp3, Tlr4 and Il1b were 3-, 8-, 5- and 4-fold, respectively, those observed in S.

Conclusions: Activation of innate immunity/inflammasome tends to parallel, since early stages, the development of renal injury in NX, suggesting that these events may constitute early pathogenic factors and may offer novel targets for treatment of CKD.

Funding: Government Support - Non-U.S.

FR-PO313

Genetic Background Dictates the Incidence of Renal Fibrosis following Experimental Pyelonephritis Babitha Haridas,[1] Birong Li,[1] Hanna H. Cortado,[1] Robert Easterling,[1] David S. Hains,[2] John David Spencer,[1] Santiago Partida-Sanchez,[1] Brian Becknell.[1] *[1]Nationwide Children's Hospital, Columbus, OH; [2]Le Bonheur Children's Hospital, Columbus, OH.*

Background: Risk factors for post-pyelonephritis renal scarring are incompletely elucidated. We induced experimental pyelonephritis in inbred mice to test the hypothesis that renal fibrosis is genetically determined.

Methods: Six week old C3H/HeOuJ or C3H/HeN females were transurethrally inoculated with 10^8 CFU uropathogenic Escherichia coli (UPEC). Mice were sacrificed 1, 3, 7, 14, and 28 days post infection (dpi) to measure bacterial burden, gene expression, inflammation and fibrosis.

Results: UPEC challenged C3H/HeOuJ and C3H/HeN mice developed pyelonephritis with comparable frequency and bacterial burden 1 and 3 dpi. UPEC induced renal transcripts associated with response to bacterial lipopolysaccharide and renal injury in both strains, including Il6 and Lcn2 ($p < 0.05$). Beginning 14 dpi, UPEC burden was increased in C3H/HeOuJ compared to C3H/HeN kidneys ($p < 0.05$). UPEC clearance occurred in 57% of C3H/HeN kidneys by 14 dpi, whereas 100% of C3H/HeOuJ kidneys remained infected ($p < 0.001$). C3H/HeOuJ kidneys displayed cortical inflammation (25%) and scarring (17%) by

7 dpi, but these features were absent in C3H/HeN kidneys. Inflammation grade correlated with myofibroblast activation and interstitial fibrosis in C3H/HeOuJ kidneys (Spearman coefficients 0.85 and 0.69, respectively, $p = 0.01$). Flow cytometry identified increased absolute number of macrophages and neutrophils in C3H/HeOuJ kidneys 7 dpi compared to uninfected controls ($p < 0.005$).

Conclusions: C3H/HeOuJ kidneys demonstrate increased bacterial burden, prolonged infection, increased inflammation, and higher grades of fibrosis, compared to C3H/HeN following UPEC infection. C3H/HeOuJ serves as a preclinical model for the development of anti-inflammatory and antifibrotic therapies for pyelonephritis. Our study supports the hypothesis that host genetic determinants dictate susceptibility to inflammation driven renal fibrosis in pyelonephritis.

FR-PO314

HIP-PAP / RegIIIg Is a Urothelium Derived Antimicrobial Peptide Induced by Bacterial Infection in Humans and Mice Birong Li,[1] Martin S. Vonau,[3] Ashley R. Carpenter,[1] Kirk M. McHugh,[2] John David Spencer,[1] Brian Becknell.[1] *[1]Nephrology, Nationwide Children's Hospital, Columbus, OH; [2]Anatomy, Ohio State Univ School of Medicine, Columbus, OH; [3]College of Medicine, Ohio State Univ, Columbus, OH.*

Background: Antimicrobial peptides (AMPs) serve proposed roles in shielding the urinary tract from invading microbes. We hypothesized that global transcriptome profiling following experimental urinary tract infection (UTI) would identify key AMPs that serve this function *in vivo*.

Methods: We analyzed the bladder transcriptomes of C57BL/6 female mice transurethrally inoculated with 10^8 uropathogenic Escherichia coli (UPEC) 2 and 6 hours post-infection (hpi), using oligonucleotide microarrays. Human and mouse AMP mRNA was measured by QRT-PCR, and AMP protein was detected by immunoblotting, immunohistochemistry, and ELISA. AMP knockout or wild type female mice were inoculated with 10^7 UPEC and evaluated for bacterial burden 16, 24, 48, and 72 hpi.

Results: *RegIIIg* is the most upregulated AMP mRNA in UPEC infected bladders, with a 300-fold induction peaking 16 hpi ($p = 4 \times 10^{-5}$). RegIIIg protein localizes to the apical surface of infected bladder and renal urothelium. Bladder and urine RegIIIg protein levels increase with infection. In humans, the orthologous HIP/PAP protein localizes to urothelium and renal tubules. Kidney HIP/PAP protein levels increase in pyelonephritis. HIP/PAP is absent from sterile human urine and significantly increases in urine from patients with UPEC cystitis and pyelonephritis ($p = 0.009$). We next evaluated the functional consequences of *RegIIIg* deletion on bacterial clearance following experimental UTI. *RegIIIg* deficiency did not significantly affect UPEC bladder clearance 16, 24, 48 and 72 hpi.

Conclusions: Murine RegIIIg and human HIP/PAP are urothelial derived peptides enriched in infected urine. While *RegIIIg* is the most induced AMP mRNA in experimental cystitis, it is dispensable for UPEC clearance from the murine bladder. The function of RegIIIg and HIP/PAP during UTI and mechanism of their induction by UPEC require further study.

FR-PO315

Renal Effects of Dipeptidyl Peptidase-4 Inhibition in Rats with Doxorubicin Nephropathy Gheun-Ho Kim, Eun Young Choi, Sua Kim, Chor Ho Jo, Joon-Sung Park. *Internal Medicine, Hanyang Univ College of Medicine, Seoul, Republic of Korea.*

Background: Dipeptidyl peptidase-4 (DPP-4) inhibitors were known to have a protective effect on the diabetic kidney disease, possibly via reduction of oxidative stress and inflammation in the kidney. However, whether these potential mechanisms may exert in non-diabetic kidney diseases is not clear. We tested if DPP4 inhibitors may have beneficial effects on rat kidneys in doxorubicin nephropathy.

Methods: Two different animal experiments were carried out using sitagliptin (10 mg/kg/d) and linagliptin (3 mg/kg/d) for DPP-4 inhibition. In each experiment, male Sprague-Dawley rats were uninephrectomized and randomly divided into vehicle-treated controls and doxorubicin-treated (a single iv bolus 5 mg/kg BW) rats. A half of the doxorubicin-treated rats were then treated with a DPP-4 inhibitor given by daily oral gavage over 6 weeks. Systolic blood pressure, proteinuria, and serum creatinine were determined at 4 and 6 weeks, and then kidneys were harvested for histopathologic examination, immunoblot analysis, and quantitative PCR analysis.

Results: In doxorubicin-treated rats, remarkable hypertension and proteinuria were noted. Although systolic blood pressure was significantly reduced by linagliptin treatment (180 ± 5 versus 155 ± 4 mmHg, $P<0.05$), heavy proteinuria was not affected by DPP-4 inhibition. Increases in serum creatinine in doxorubicin-treated rats were insignificantly decreased by DPP-4 inhibition, but tubulointerstitial injury and interstitial fibrosis were significantly relieved by treatment with sitagliptin or linagliptin. The increase in renal protein expression of monocyte chemotactic protein 1 in doxorubicin-treated rats was significantly decreased by linagliptin treatment (205 ± 9 versus $114 \pm 24\%$, $P<0.05$). The increases in renal mRNA expression of gp91phox (175 ± 13 versus $104 \pm 13\%$, $P<0.05$) and RANTES (811 ± 39 versus $459 \pm 41\%$, $P<0.05$) were significantly reduced by sitagliptin treatment.

Conclusions: In rats with doxorubicin nephropathy, hypertension and renal injury may be attenuated by DPP-4 inhibition. Inflammatory responses associated with NADPH-oxidase 2 upregulation in doxorubicin nephropathy seem to be suppressed by treatment with DPP-4 inhibitors.

FR-PO316

Mild Acidic Milieu Alters Action Potential Threshold in Renal Neurons Wolfgang Freisinger,[1] Nadja Tzinis,[2] Tilmann Ditting,[2] Sonja Heinlein,[2] Jens Lutz,[1] Roland E. Schmieder,[2] Karl F. Hilgers,[2] Roland Veelken.[2] *[1]Med. Clinic, Nephrology, Universitätsmedizin Mainz, Mainz, Germany; [2]Med. Clinic 4, Nephrology and Hypertension, Univ Erlangen-Nürnberg, Erlangen, Germany.*

Background: Renal innervation has been shown to play an important role under pathologic conditions, e.g. renal inflammation. Recently, we found that afferent renal neurons exhibit predominantly a sustained firing upon current injection due to specific sodium channel expression. Additionally, we had hints that these particular neurons show inward currents mediated by acid sensitive channels, e.g. TRPV1 and ASIC. Therefore, we hypothesized that mild changes in pH, could alter the firing activity of renal afferent neurons.

Methods: Dorsal root ganglion (DRG) neurons (n=94) from Th_{11}-L_2, harvested from SD-rats were investigated. Retrograde labelling (DiI) identified renal afferent neurons. Current clamp was used to characterize neurons as "tonic", i.e. sustained action potential (AP) firing or "phasic", i.e. <5 APs upon electrical stimulation. Current injections (40pA-12000pA) were performed under physiologic (pH 7,4) and mild acidic (pH6,9) conditions. Acid channel blocker (Capsazepine, CPZ 10µmol/l and Amiloride, 10µmol/l) were added to investigate the respective channels.

Results: 73 renal (DiI-positive) and 21 non-renal neurons (DiI neg) were investigated. Non-renal neurons were exclusively "phasic" and unaffected by pH-change, also "phasic" renal neurons. In "tonic" renal neurons (47/73), exposure to pH 6,9 did alter the threshold of action potential activation (-17.4 ± 7.5 versus -13.5 ± 7.3*) and reduced firing frequency (22.3 ± 9.5 versus 15.9 ± 10.1/600ms, *$p<0.05$), other electrophysiological parameters (resistances, capacity) remained equal. Blockers did not reverse this effect.

Conclusions: We found that exposition to protons significantly decreased the firing rate of renal "tonic", more active neurons. On the other hand this was accompanied by a less negative threshold putatively facilitating activation of tonic neurons with reduced maximum firing rate. This effect seems to be independent of acid sensitive channels such as the ASIC and TRPV1.

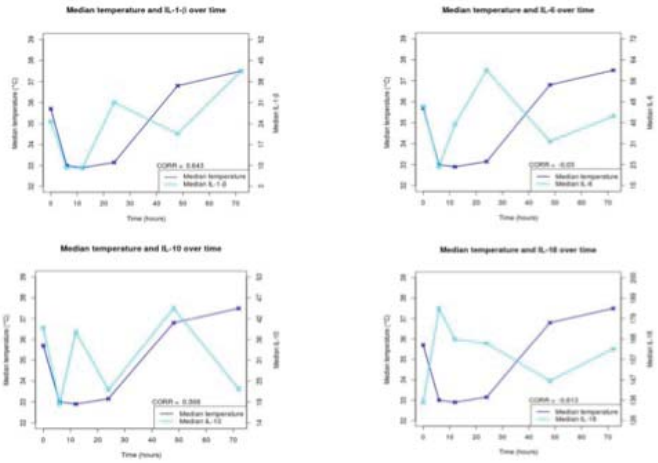
FR-PO317

Cytokines Response following Induced Hypothermia Silvia De Rosa,[1,2] Alessandra Brocca,[1] Massimo de Cal,[1] Stefano Marcante,[1] Silvia Pastori,[1] Massimo Antonelli,[2] Claudio Ronco.[1] *[1]Nephrology and Dialysis, International Renal Research Inst (IRRIV), San Bortolo Hospital, Vicenza, VI, Italy; [2]Intensive Care and Anaesthesiology, Univ Cattolica del Sacro Cuore, Rome, RM, Italy.*

Background: The impairment of cardiac contractility during endotoxemia causes overexpression of proinflammatory cytokines that can significantly alter metabolic response. In vitro studies suggest that proximal tubular cells are vulnerable to proinflammatory cytokines (i.e.IL6 and IL1b) mediated injury.Therapeutic hypothermia (TH) has been used to prevent damage connected with ischemia and hypoperfusion.The purpose of the study is to analyze the influence of hypothermia state (33°C) during TH on renal infiammatory response in patients after cardiac arrest with restoration of spontaneous circulation.

Methods: We performed a prospective observational study of 8 comatose patients resuscitated from out-of-hospital cardiac arrest and treated with TH.On Admission time and at 6,12,24,48,and72hrs after the start of TTTH,blood samples were collected.Plasma cytokines were measured by ELISA.

Results: At the beginning of TH and at 6,12,24,48,72 hrs,mean T were respectively 35 (±0.5),33 (±0.4),33 (±0.4),33.5 (±1.6),36 (±0.8),37 (±0.6).Correlations were calculated between temperature (T) and cytokines.



During the induction phase,we observed a decrease of IL6,IL1b and IL10 levels,and an increase of infiammatory during the maintenance phase.A similar initial effect is showed for IL18,but with an earlier proinfiammatory effect during induction phase.Furthermore,we assist an increase of IL10 and ILb during the rewarming phase.

Conclusions: In conclusion,data indicate that,during induction and rewarming phases there is a modification of infiammatory balance.It is important to define a real time window during which TH could provide a therapeutic effect on these mechanisms.Additional clinical studies are needed for an optimal maintenance period and strategy.

FR-PO318

NLRP3 Inflammasome Mediates Albumin-Induced Renal Tubular Injury through Impaired Mitochondrial Function Aihua Zhang, Songming Huang, Zhanjun Jia. *Nephrology, Nanjing Children's Hospital, Nanjing Medical Univ, China.*

Background: Proteinuria serves as a direct causative factor of renal tubular cell injury and is highly associated with the progression of chronic kidney disease (CKD) via uncertain mechanisms. The present study was undertaken to examine the role of NLRP3 inflammasome/mitochondria axis in albumin-induced renal tubular injury.

Methods: A total of 18 renal biopsy samples obtained from patients undergoing diagnostic evaluation at our department were selected. Nlrp3$^{-/-}$ and caspase1$^{-/-}$ mice on a C57BL/6J-129 background were used to examine the roles of NLRP3 and caspase-1 in albumin overload-induced renal tubular injury. Mouse proximal tubular cells (mPTCs), an immortalized cell line, were cultured. NLRP3, caspase-1, IL-1b, and IL-18 were examined by immuohistochemistry, immunoblotting, real time RT-PCR. Mitochondrial function including ROS production, mitochondrial membrane poteintial (MMP), and ATP content was evualuated.

Results: In patients with proteinuria, NLRP3 was significantly upregulated in tubular epithelial cells and was positively correlated with the severity of proteinuria. In agreement with these results, albumin remarkably activated NLRP3 inflammasome in both in vitro renal tubular cells and in vivo kidneys in parallel with significant epithelial cell phenotypic alteration and cell apoptosis. Genetic disruption of NLRP3 inflammasome remarkably attenuated albumin-induced cell apoptosis and phenotypic changes under both in vitro and in vivo conditions. In addition, albumin treatment resulted in a significant mitochondrial abnormality as evidenced by the impaired function and morphology, which was markedly reversed by invalidation of NLRP3/caspase-1 signaling pathway. Interestingly, protection of mitochondria function by MnTBAP or CsA robustly attenuated albumin-induced injury in mPTCs.

Conclusions: These findings demonstrated a pathogenic role of NLRP3 inflammasome/caspase-1/mitochondria axis in mediating albumin-induced renal tubular injury. The discovery of this novel axis provides some potential targets for the treatment of proteinuria-associated renal injury.

FR-PO319

IL13-Induced Hepatic Cholesterol Transport Defect in Rat Model of Minimal Change Nephrotic Syndrome (MCNS) Lauretta Danwei Low,[1] Chang Yien Chan,[1] Jinmiao Chen,[2] Henry He Yang,[1] Caroline G.L. Lee,[1] Hanry Yu,[1] Markus R. Wenk,[1] Hui Kim Yap.[1] *[1]Pediatrics, Biochemistry, Cancer Science Inst, Physiology, National Univ of Singapore, Singapore; [2]SIgN, A*STAR, Singapore.*

Background: Hypercholesterolemia in nephrotic syndrome is thought to be secondary to marked proteinuria. However, in our *IL13*-overexpression rat model of MCNS, hypercholesterolemia preceded development of proteinuria suggesting the role of a cytokine. This study aimed to investigate the mechanism of IL13-induced cholesterol dysregulation in our rat model of MCNS.

Methods: Plasmid containing rat *IL13* gene was transfected into Wistar rats. Liver RNA was used for microarray and qPCR. The direct effect of IL13 (100ng/ml) on rat primary hepatocyte cell culture was studied after 24-hour incubation using qPCR to evaluate gene expression, while cholesterol efflux via Abcg5 was measured using taurocholate as a cholesterol acceptor.

Results: *IL13*-transfected rats became nephrotic by Week 10 and both liver microarray analysis and qPCR showed 6-fold downregulation in *Abcg5*, with no change in *Lxra*. Moreover, compared to controls, we demonstrated downregulation in gene expressions of *Abcg5* (0.033±0.011 versus 0.091±0.022, p=0.021), *Abca1* (0.072±0.005 versus 0.094±0.007, p=0.025), and their transcriptional regulator, *Lxra* (0.21±0.01 versus 0.29±0.03, p=0.03), early on in *IL13*-transfected rats with hypercholesterolemia prior to onset of proteinuria. Similarly, IL13-stimulated rat primary hepatocyte cells showed downregulation in gene expressions of *Lxra* (0.010±0.002 versus 0.024±0.009, p=0.012) and *Abca1* (0.016±0.002 versus 0.027±0.004, p=0.012), as well as decreased cholesterol efflux (10.77±1.13% versus 13.31±1.24%, p=0.012) compared to unstimulated cells, consistent with the early events in the rat model.

Conclusions: In conclusion, our study demonstrated that IL13 was able to downregulate the Lxra-Abca1/Abcg5 pathway of hepatic cholesterol elimination, with resultant hypercholesterolemia in the *IL13*-transfected rats prior to development of proteinuria. Subsequent sustained severe hypercholesterolemia as seen in the nephrotic rats could result in normalization of *Lxra* expression due to the positive feedback stimulus possibly via oxysterols, which are natural agonists for Lxra.

FR-PO320

HIV Enhances Kidney Cell Inflammasome Formation Both *In Vivo* and *In Vitro* Shabirul Haque, Partab Rai, Kartikeya Kashyap, Rivka Lederman, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Inflammasome activates an inflammatory cascade by binding to pro-caspase-1 via ASC (apoptosis-associated speck-like protein containing CARD [caspase recruitment domain]) and cleaving caspase-1, the later, converts pro-interleukin (IL)-1ß to IL-1ß. Deregulated inflammasome activity has been linked to variety of inflammatory diseases. HIV-1 has been reported to stimulate NLRP3 expressing inflammasomes in immune cells. However, the effect of HIV on kidney cell inflammasome formation has not been studied. In the present study, we evaluated the effect of HIV on kidney cell inflammasome formation both *in vitro* and *in vivo*.

Methods: Renal cortices of four week old control (FVB/N, n=4) and HIV-transgenic (Tg26, n=4) mice were immunolabeled for molecular markers of inflammasomes including NLRP3, ASC1, pro-caspase-1, and pro-IL-1ß (n=4). cDNA and protein blots of renal tissues of control and Tg26 mice were probed for above mentioned markers. Serum levels of IL-1ß in control and Tg26 mice were measured. Human podocytes-transduced with either empty vector (EV) or HIV were treated with either caspase-1 inhibitor or buffer for 24 H, followed by Western blot analysis for ASC and IL-1ß. Since inflammasome formation is associated with pyroptosis (condensed nuclei with leaky cell wall), EV/HPS and HIV/HPs in the presence or absence were evaluated for induction of pyroptosis.

Results: Renal tissues of Tg26 mice displayed enhanced mRNA as well as protein expression of NLRP3, ASC, caspase-1 and IL-1ß. Renal cortices of Tg 26 mice also displayed enhanced kidney cell expression NLRP3, ASC, caspase-1 and IL-1ß. Serum of Tg26 mice displayed 4-fold higher levels of IL-1ß versus FVB/N mice. *In vitro* studies, protein blots of HIV/HPs displayed 2-fold increase in ASC and IL-1ß expressions. Whereas, caspase-1 inhibitor down regulated the effect of HIV on podocyte ASC and IL-1ß expressions**.** HIV/HPs displayed greater number of pyroptosed cells versus EV/HPs. Whereas, caspase-1 inhibitor-treated HIV/HPs displayed attenuated number of pyroptosed cells.

Conclusions: HIV enhances kidney cell inflammasome formation both in vivo and in vitro. HIV induces pyroptosis in podocytes.

Mitigation of CD40 Dependent Renal Inflammation via CD40 Antisense Oligonucleotides Adam E. Mullick, Aaron Donner, Steve T. Yeh, Huimin Li, Mark Graham, Rosanne M. Crooke. *Antisense Drug Discovery, Isis Pharmaceuticals, Carlsbad, CA.*

Background: Experiments were conducted to test the hypothesis that renal CD40 is primed in kidney disease and that CD40 dependent renal inflammation would be mitigated by CD40 antisense oligonucleotide (ASO) treatment.

Methods: Activation of CD40 dependent renal inflammation was performed by IV administration of an activating CD40 mAb. ASO treatments consisted of SQ administrations of Gen 2.5 CD40 or control ASOs. Studies were conducted in two models of kidney disease. In the first, mice were given adriamycin and then 2 weeks later divided into groups with low or high adriamycin nephropathy (AN) based on proteinuria and urine NGAL. ASO treatments were started 30 days after initiation of AN. In a second model, ASO treatments were initiated in mice after unilateral ureter obstruction (UUO). In both studies, the CD40 mAb was administered after 10 days of ASO treatments and tissues harvested 24 hours afterward.

Results: In AN mice, CD40 mAb resulted in larger increases in kidney CD40, CCL5 and IL12 in mice with high AN versus low AN. E.g., CD40 mAb increased renal CCL5 by 38-fold in high AN mice but only 6-fold in low AN mice. CD40 ASO treatments strongly mitigated or prevented CD40 mAb-dependent inflammation in both subgroups of AN mice. In UUO mice, renal inflammation following the CD40 mAb was larger in the obstructed kidney versus the unobstructed kidney. E.g., following CD40 mAb renal CCL5 increased 120-fold in the obstructed kidney versus 10-fold in the unobstructed kidney. In both kidneys, CD40 ASO treatments reduced renal CD40, CCL5 and IL12 by up to 90% relative to control. This level of activity was comparable to that observed in vehicle treated UUO mice not given the CD40 mAb as well as CD40 knockout mice receiving UUO and the CD40 mAb.

Conclusions: These data demonstrate CD40 activation results in renal inflammation, with the extent of preexisting injury or inflammation priming the CD40 response. CD40 ASO treatments sharply attenuated or prevented CD40 dependent inflammatory responses and were equally efficacious in kidneys with either low or high preexisting injury. Such treatments could be beneficial in patients with aberrant or excessive renal CD40 activation.

Inflammasome Activation in Renal Failure Is Exaggerated by High Fat Diet (HFD): Role of Lipopolysaccharides (LPS) Sam Righi, Siddhartha S. Ghosh, Daniel E. Carl, Richard Krieg, Todd W. Gehr. *Nephrology, VCU, Richmond, VA.*

Background: Inflammasome activation is shown to play a major role in various inflammatory disorders. Activation of inflammasome is generally mediated by two triggers (i) Activation of NFkB by LPS and (ii) membrane perturbation and K^+ efflux which can be mediated by iPLA2. We have seen increased iPLA2 and NFkB activation in renal failure (RF) and in animals on high fat diet (HFD). In this study we observe an increase in circulatory LPS in RF mice and mice on HFD therefore, we postulate that LPS activates inflammasome in RF which is aggravated by HFD. We use LPS binder Polymyxin (PM) to prove our hypothesis.

Methods: We used LDLR-/- mice since they are susceptible to inflammation following HFD. RF was induced in LDLR-/- mice by 5/8 nephrectomy. 24 Mice were divided into sham surgery (C) and C+HFD (HF), 5/8 nephrectomy with normal chow (Nx), Nx with 4 months of high fat diet (NxHF). Two NxHF groups received PM; 15 mg/l in drinking water; n=5.

Results: Creatinine, BUN,ACR of Nx and NxHF ($p<0.01$) were significantly higher than C and HF. HF was similar to C, suggesting no renal impairment in HF. Compared to Nx, creatinine, BUN and ACR of NxHF were significantly higher ($p<0.05$). Circulatory LPS levels of the groups were as follows: Nx>HF ($p<0.05$) and HF> C ($p<0.05$). LPS of NxHF was 2 fold higher than Nx ($p<0.05$) indicating HFD increased LPS. Inflammasome markers, pNFkB/NFkB, Caspase 1, IL-1b and ASC in the kidney were highest in NxHF

(p<0.05), followed by Nx>HF (p<0.05) HF>C (p<0.05). Since Nx+HF had highest levels of LPS and renal dysfunction we chose to treat this group with PM. PM reduced BUN and ACR 30% and 40% respectively (P<0.05) but not creatinine. PM also decreased the levels LPS by 55% (p<0.01). All the inflammasome markers were significantly reduced by PM.

Conclusions: This study show that in RF circulatory LPS is increased possibly due to increased permeability from the gut.This increase is further exaggerated by HFD. PM is a non-absorbable antibiotic with LPS binding properties hence its beneficial effect can only be imparted by modulating LPS permeability from the gut. By reducing circulatory LPS, PM significantly reduces inflammation and ameliorates RF.

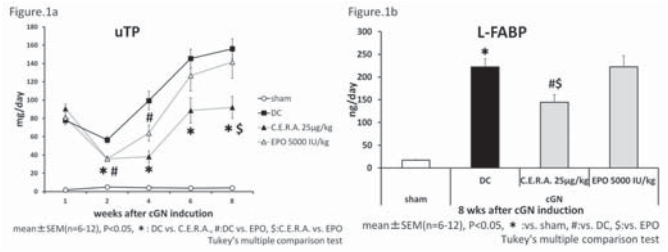
Single Treatment of Epoetin Beta Pegol Halts Chronic Kidney Disease Progression in Chronic Glomerulonephritis Rats: Comparison with Epoetin Beta Ryohei Kawasaki, Ken Aizawa, Michinori Hirata, Yoshihito Tashiro, Kenji Yogo, Mika Yagoto, Koichi Endo. *Product Research Dept, Chugai Pharmaceutical Co., Ltd., Gotemba, Shizuoka, Japan.*

Background: Erythropoietin-stimulating agents (ESAs) show renoprotection in several acute kidney disease models, such as puromycin aminonucleoside and Thy1-induced nephritis models. However, the renoprotective effects of ESAs in progressive chronic kidney disease (CKD) models have not been fully studied. We reported previously at ASN 2012 that epoetin beta pegol (continuous erythropoietin receptor activator, C.E.R.A.), which has a longer half-life than any other ESAs, showed renoprotection in rats with chronic glomerulonephritis (cGN). The aim of the current study was to compare the renoprotective effect of C.E.R.A. with that of epoetin beta (EPO) in cGN.

Methods: The cGN model was established by injection of anti-Thy1.1-antibody (OX-7, 0.6 mg/kg, i.v.) to uninephrectomized rats (F344, 7 wks old, male). Vehicle (disease control: DC), C.E.R.A. (25 mg/kg), or EPO (5000 IU/kg) was intravenously administered 24 h after the operation. We then evaluated urinary total protein (uTP) at 1, 2, 4, 6 and 8 wks after induction of cGN, and liver-fatty acid-binding protein (L-FABP) at 2 wks and 8 wks.

Results: uTP excretion was higher than sham-operated rats at 1 wk after induction of cGN, and it gradually increased from 2 wks to 8 wks. C.E.R.A. and EPO showed almost the same level of renoprotection (decreased uTP and L-FABP compared with DC) at 2 wks after treatment. C.E.R.A. showed continuous suppression of uTP and L-FABP until 8 wks, whereas EPO did not.



Conclusions: Although both C.E.R.A. and EPO showed a renoprotective effect in the early phase of cGN, only C.E.R.A. suppressed CKD progression in the late phase. This is the first evidence that the long half-life of ESA might be one of the beneficial features in suppressing the progression of CKD.

FR-PO324

The Increases in Glomerular Permeability due to IL-1ß, TNF-a and IL-6 in Rats Are Inhibited By the Superoxide-Scavenger Tempol Bengt Rippe, Kristinn Sverrisson, Josefin Axelsson, Anna Rippe. *Dept of Nephrology, Lund Univ, Lund, Sweden.*

Background: This study was performed in order to investigate the actions of some common proinflammatory cytokines, interleukin-1 beta (IL-1ß), tumor necrosis factor alpha (TNF-a) and IL-6, on glomerular permeability in rats and to test whether these actions depend upon the release of reactive oxygen species (ROS), particularly superoxide.

Methods: In anaesthetized Wistar rats (~250 g) blood access was achieved and the left ureter was cannulated for urine collection. Rats were continuously infused i.v. with either IL-1ß (2 micro-g/kg/h), TNF-a (2 micro-g/kg/h) or IL-6 (4 micro-g/kg/h), with 1/4 of the dose given as an initial bolus, together with polydisperse fluorescein isothiocyanate (FITC)-Ficoll-70/400, Inulin and ^{51}Cr-EDTA for 1h. Plasma and urine samples were taken simultaneously at different time points and analyzed by high performance size exclusion chromatography (HPSEC) for determination of glomerular sieving coefficients (q) for Ficoll. The glomerular filtration rate (GFR) was assessed using ^{51}Cr-EDTA. In separate experiments the superoxide scavenger, tempol (15 mg/kg/h), was given before and during the cytokine infusions.

Results: IL-1ß and TNF-a caused rapid, partly reversible increases in glomerular permeability to large Ficoll molecules ($Ficoll_{50-80Å}$), peaking at 5-15 min, while IL-6 caused a more gradual increase in glomerular permeability, leveling off at 30 and 60 min. For TNF-a, q for $Ficoll_{70Å}$ increased from $2.7 \times 10^{-5} \pm 0.7 \times 10^{-5}$ to $2.1 \times 10^{-4} \pm 1.2 \times 10^{-5}$ at 15 min, while GFR and systemic arterial blood pressure remained largely unchanged. Co-infusion of tempol almost completely abrogated the permeability effects of the cytokines infused.

Conclusions: IL-1ß, TNF-a and IL-6, when infused systemically, can cause marked and partly reversible increases in glomerular permeability, which can be inhibited by the superoxide scavenger, tempol. Our data suggest that, like angiotensin II, the proinflammatory cytokines, IL-1ß, TNF-a and IL-6, all induce increases in glomerular permeability mediated via the release of ROS.

FR-PO325

Inhibition of Dipeptidyl Peptidase-4 Suppresses Macrophage Infiltration via Glucagon-Like Peptide-1 Dependent Signaling in the Rat Thy-1 Nephritis Model Yoshiki Higashijima, Tetsuhiro Tanaka, Junna Yamaguchi, Shinji Tanaka, Masaomi Nangaku. *Div of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Bunkyo-ku, Tokyo, Japan.*

Background: Dipeptidyl peptidase-4 (DPP-4) is an enzyme that inactivates incretin hormones such as glucagon-like peptide-1 (GLP-1) and gastric inhibitory peptide (GIP). DPP4 inhibitors are now widely used for the treatment of type 2 diabetes. In contrast, widespread expression of the receptor for GLP-1 has called for alternative actions of incretins in extrapancreatic tissues. In the kidney, DPP4 inhibitors exhibited reno-protective effects against various models of diabetic kidney disease. However, little is known in the non-diabetic models. Thus, we examined the effect of DPP4 inhibitors in the rat Thy-1 nephritis model.

Methods: Rats were injected with OX-7 (1.2 mg/kg, iv) and treated with alogliptin (20 mg/kg/day, orally by gavage) or vehicle for 7 days.

Results: DPP4 inhibitors did not ameliorate glomerular injury and resulted in a non-significant trend toward a reduction in proteinuria. Instead, immunohistological analysis revealed that DPP4 inhibitors significantly reduced the number of CD68 positive inflammatory macrophages in the kidney. An additional DPP4 inhibitor, anagliptin, (300mg/kg/day, mixed with food) and a GLP-1 receptor agonist, exendin-4 (10 mg/kg, sc), similarly reduced CD68 positive macrophage infiltration to the kidney, raising a possibility that this is a class effect and that the anti-inflammatory effect was mediated by the GLP-1 receptor signaling. The reduction in macrophages was not associated with changes in the mRNA levels of chemokines such as MCP-1 and RNATES, but was further corroborated in ex-vivo studies. Boyden chamber assays using peritoneal macrophages revealed that exendin-4, but not the DPP4 inhibitor, dose-dependently reduced MCP-1-stimulated macrophage infiltration.

Conclusions: These data suggest that DPP4 inhibitors reduced macrophage infiltration directly via GLP-1 dependent signaling in the rat Thy-1 nephritis model, and offer a promising view that the control of inflammation by anti-diabetic drugs may be of use in models of non-diabetic kidney diseases.

FR-PO326

Activated Macrophages Trigger Mesangial Cells to Produce Inflammasome Siddhartha S. Ghosh, Hiba Sheikh, Sam Righi, Daniel E. Carl, Todd W. Gehr. *Nephrology, VCU, Richmond, VA.*

Background: Renal injury is an inflammatory disorder and activation of inflammasome may play a role in renal failure (RF). Lipopolysaccharide (LPS) seen in the circulation of RF patients activates inflammasome which often require two triggers. We have observed an increase in circulatory LPS in mice with RF following 5/8th nephrectomy. We postulated that LPS activates inflammation/inflammasome in the kidney. However, it is not clear whether inflammasome activation detected in RF originates from the macrophages infiltrating the kidney and/or directly originates from the kidney cells. This study was undertaken to delineate the source of inflammasome activation.

Methods: 200 pg/ml LPS was used to simulate low levels LPS seen in the circulating plasma of RF animals. Mouse mesangial cells (MC) and macrophages (MO) were incubated separately with LPS for 4 hours (hrs). In separate experiment MO were incubated with LPS for 4 hrs washed and incubated with normal MO media. This MO media is conditioned media. MC were treated with 4 hrs LPS washed and MO conditioned media was added for 24 hrs. Western blot measurements of caspase 1, IL-1b and ASC were carried out to assess inflammasome activation. Ratios of phosphorylated NFkB and NFkB (pNFkB/NFkB) were also measured by immunoblot.

Results: The table shows low levels of LPS can activate MO but not MC however, conditioned media from activated MO can stimulate MC.

	MC treated with 200 pg/ml LPS	MO treated with 200 pg/ml LPS	MC treated with 200 pg/ml LPS washed and treated with MO Conditioned Media
Caspase 1	1.5 (NS)	1.7 fold; p<0.05	2.2 fold; p<0.05
IL-1β	1.7 (NS)	2.5 fold; P<0.05	3.5 fold; P<0.01
ASC	1.8 (NS)	2.8 fold; P<0.05	3.8 fold; P<0.01
pNFkB/NFkB	2.0 (p<0.05)	2.4 fold; P<0.05	3.5 fold; P<0.01

The values are fold increase from their respective controls. NS= non significant

Conclusions: NFkB activation in MC suggest low levels of LPS can cause inflammation but not inflmmasome activation. MO conditioned media activates inflammasome in the MC suggesting that substances released from MO produces second trigger to activate inflammasome in the MC. We conclude inflammasome activation seen in the kidneys of RF animals may be influenced by infiltrating MO.

Regulation of the Anti-Inflammatory Glucocorticoid Target Annexin A1 during the Course of Acute Anti-Thy-1.1 Nephritis Robert Labes,[1] Frank Stephan Hohberger,[1] Tanja Loof,[2] Harm Peters,[2] Sebastian Bachmann,[1] Alexander Paliege.[1,2] *[1]Anatomy, Charité - Universitätsmedizin Berlin, Berlin, Germany; [2]Nephrology, Charité - Universitätsmedizin Berlin, Berlin, Germany.*

Background: Glucocorticoids are an essential component of immunosuppressive therapeutic strategies in the treatment of inflammatory renal disease. Annexin A1 (AnxA1) has been identified as a central mediator of anti-inflammatory glucocorticoid actions but its regulation during the course of nephritic disease is unknown.

Methods: We used the anti-Thy-1.1 rat model of human mesangioproliferative glomerulonephritis to study the expression of AnxA1 in a time- and cell-specific manner. Adult Wistar rats were injected with anti-Thy-1.1 antibody and examined after 24h, 5d, and 15d. Regulation of AnxA1 was studied by qPCR, immunohistochemistry and double-labelling immunofluorescence using markers for endothelial cells (rat endothelial cell antigen), fibroblasts (CD73), macrophages (CD68), and lymphocytes (CD4, CD8, CD20).

Results: Under control conditions, AnxA1 was expressed in the podocytes, Bowman's capsule, macula densa, thick ascending limb, medullary collecting duct, and in cortical fibroblasts. Rapid and sustained increases in renal AnxA1 mRNA abundance were recorded at d1 (+92±16%), d5 (+128±19%), and d15 (+78±33%) after the induction of anti-Thy-1.1 nephritis (compared to vehicle-treated controls; $p<.05$ for each time point). AnxA1 immunoreactive signal was enhanced selectively in cells of the cortical renal interstitium at d5 and d15 whereas in the epithelia, signal intensities were unchanged. Double staining immunofluorescence identified infiltrating macrophages as the major source for the interstitial signals (+150±40% on d5 and +378±43% on d15; $p<.05$). The number of AnxA1 immunoreactive cortical fibroblasts was increased as well in these stages. Lymphocytes and endothelial cells of the renal microvasculature were negative for AnxA1.

Conclusions: We have shown that AnxA1 gene expression and protein abundance are significantly increased during the course of anti-Thy-1.1 nephritis. Abundant expression of AnxA1 in macrophages and fibroblasts suggests an important role for these cells during the resolution of renal inflammation.

FR-PO328

Activation of Innate Immunity Parallels the Progression of Renal Injury in Adriamycin Nephropathy Viviane D. Faustino, Simone C.A. Arias, Flavia P. Albuquerque, Camilla Fanelli, Victor F. Avila, Lisienny C.T. Rempel, Orestes Foresto-Neto, Gizely C.S. Moreira, Claudia R. Sena, Vivian L. Viana, Ricardo P. Mazzonetto, Denise M.A.C. Malheiros, Niels O.S. Camara, Roberto Zatz, Clarice K. Fujihara. *Univ of Sao Paulo, Brazil.*

Background: Excess filtered protein can promote the release of inflammatory mediators by tubular cells. The mechanisms underlying this effect are unclear. We investigated whether innate immunity/inflammasome assembly is activated in this setting.

Methods: Albuminuria (ALB) was induced in 15 male Munich-Wistar rats by adriamycin (AD), 5 mg/kg iv. Control rats (C, N=5) received saline only. ALB, mg/d, tail-cuff pressure (TCP, mmHg), serum creatinine (S_{Cr}, mg/dL), NGAL, mg/day, % Glomerulosclerosis (%GS), % cortical interstitium (%INT) and INT macrophages (MF, cells/mm^2) were assessed at Weeks 2 (AD_{2wk}), 4 (AD_{4wk}) and 20 (AD_{20wk}) after AD. Renal innate immunity was assessed by gene expression (IL-1ß, TLR4, NLRP3) and protein abundance (IL-1ß, TLR4).

Results:

	C	AD_{2wk}	AD_{4wk}	AD_{20wk}
ALB	7±2	336±34^{a}	356±49^{a}	505±34^{abc}
TCP	142±2	149±3	156±2^{a}	169±4^{abc}
S_{Cr}	0.7±0.1	0.7±0.1	0.7±0.1	1.6±0.2^{abc}

MeanSE, $^{a}p<0.05$ vs C, $^{b}p<0.05$ vs AN_{2wk}, $^{c}p<0.05$ vs. AN_{4wk}.
In addition, the mRNA levels of IL-1b, TLR4 and NLRP3 were significantly increased at Weeks 4 (68%, 106% and 177%, respectively) and 20 (127%, 215% and 74%).

Conclusions: AD was followed by massive albuminuria, early tubular injury (indicated by NGAL excretion), and MF infiltration; GS and INT expansion developed from Week 4 on. The expression and/or abundance of IL-1b and TLR4 were approximately parallel to the extent of renal injury. Innate immunity activation/inflammasome assembly may represent one important pathogenic link between tubular exposure to excess protein and renal injury. FAPESP/CNPq.

Gadolinium–Based Magnetic Resonance Imaging Contrast–Induced Systemic Fibrosis Is Attenuated in Chemokine Receptor–Deficient Mice Brent Wagner. *Medical Service, South Texas Veterans Health Care System, San Antonio, TX.*

Background: Almost nothing is known about the pathobiology of nephrogenic systemic fibrosis. We have found that the monocyte chemoattractant protein–1 (MCP–1) /chemokine (C–C motif) ligand 2 (CCL2) is increased in the serum from contrast–treated animals. CCR2 was detected in the dermis of magnetic resonance imaging contrast–treated rats. Studies were conducted to demonstrate whether an association of gadolinium deposition correlated with tissue fibrosis and the fibrocyte receptor for MCP–1/CCL2, chemokine receptor 2 (CCR2).

Methods: C57 black mice, and CCR2–deficient mice (kindly provided by Seema Ahuja) were treated with magnetic resonance imaging contrast (2.5 mmol/kg), 20 doses over a 4–week period. Fixed, paraffin–embedded tissues were stained and examined by light microscopy. Frozen sections of tissue were homogenized in RIPA buffer, protein quantitated by immunoblot. Relative amounts of gadolinium were assessed by scanning electron microscopy equipped with energy–dispersive x–ray spectroscopy. Inductively–coupled plasma mass spectroscopy was employed to quantify gadolinium in a sample of contrast–treated mice (Jaqueline Ranger, Department of Analytical and Environmental Chemistry, Southwest Research Institute, San Antonio, TX).

Results: With respect to the control animals, there was an increase in dermal cellularity only in the wild–type contrast–treated mice. In parallel, there was an increase in skin fibronectin and a smooth muscle actin in the contrast–treated mice which was attenuated in the CCR2–deficient mice. Liver from contrast–treated animals invariably demonstrated a greater gadolinium signal (both from the Ma and La electron shell regions). Gadolinium was detected in skin, liver, and kidney from contrast–treated mice using inductively–coupled plasma mass spectroscopy.

Conclusions: That CCR2 is increased in contrast–treated animals, and that mice deficient in CCR2 have abrogated skin fibrosis supports the fibrocyte theory of nephrogenic systemic fibrosis. Gadolinium deposition in tissues may trigger the release of MCP–1/CCL2 that mediates the recruitment of CCR2–expressing fibrocytes to affected lesions.

Indole Derivatives Enhance Epo Production through AhR-XRE Pathway and Induces Cell Protectvie Gene NQO1 Yuki Oba,[1] Shun Watanabe,[1] Akihiro Matsuo,[1] Hisato Shima,[1] Yoichi Takeuchi,[1] Eikan Mishima,[1] Yasutoshi Akiyama,[1] Chitose Suzuki,[1] Takehiro Suzuki,[2] Ken-Ichiro Hayashi,[3] Sadayoshi Ito,[1] Takaaki Abe.[1] *[1]Tohoku Univ Graduate School of Medicine; [2]Brigham and Women's Hospital, Harvard Medical School; [3]Okayama Univ of Science.*

Background: In CKD patients, the accumulation of uremic toxins causes renal inflammation and the inflammatory cytokines (IL-1b, TNF-a) suppress erythropoietin (Epo). Recently, we have identified and reported that certain indole compounds potently enhance Epo production. 41 indole derivatives were further synthesized and shown to be in the same range as FG4592, a potent PHD nhibitor (ASN2013). The aim of this study is to identify the mechanisms underlying the effect of the compound on Epo-production and cell protection.

Methods: 1, An Epo-producing hepatoma cell line (Hep3B) was incubated under both 20% (normoxia) and 1% conditions. 2, a mouse erythropoietin promoter luciferase reporter vector and 4X XRE vector were used for transcriptional assay. 3. Signal transduction pathways were analyzed with a Cignal Transduction 45 Pathway Arrays reporter assay kit™ (Qiagen). 4. *siRNA* knockdown of AhR and NQO1 and QT-PCR was performed.

Results: Epo mRNA was markedly increased by 60 times that of control after the administration of Compound #5 in Hep3B cells under a normoxic condition, although FG4592-mediated upregulation was only two fold. Compound #5 also enhanced Epo protein by 3 fold under a normoxic condition. By signal pathway analysis, Compounds #5 was shown to be linked with the AhR-XRE pathway. The AhR inhibitor CH233191 blocked the Compound #5-induced Epo protein, but K7174 (a GATA inhibitor) and YC-1 (an HIF inhibitor) did not. The Epo mRNA increased by compound #5 was completely abrogated by AhR knock down. These data suggest the involvement of the AXR-EXR pathway in Epo production as well as known GATA and HIF pathways. We also found that NQO1, ananti-odxidant stress gene, was up-regulated by compound #5 and this increment was blocked by AhR knockdown.

Conclusions: This data suggests that indole compounds enhance Epo production by the AhR-XRE pathway as well as GATA and HIF, and the induction of NQO1 may be involved in its cell protective activity.

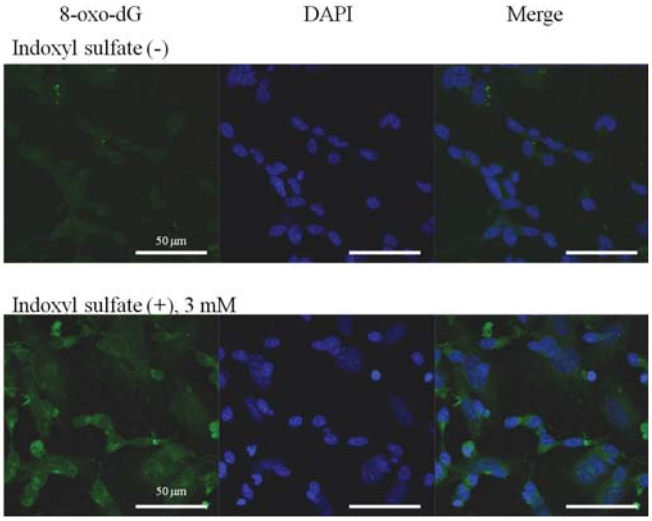
Indoxyl Sulfate, a Potential Uremic Neurotoxin, Causes Accumulation of 8-Oxoguanine in Mitochondrial DNA in Differentiated SH-SY5Y Cells
Naoki Haruyama,[1] Kumiko Torisu,[1] Kiichiro Fujisaki,[1] Kazuhiko Tsuruya,[1,3] Takanari Kitazono,[1] Yusaku Nakabeppu.[2] *[1]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Div of Neurofunctional Genomics, Medical Inst of Bioregulation, Kyushu Univ, Fukuoka, Japan; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Several reports suggested that indoxyl sulfate (IS) is elevated in the brain of uremia, hence it is implicated as a putative toxin in uremic encephalopathy. Recent experimental studies revealed that mitochondrial dysfunction and oxidative mitochondrial DNA damage are involved in many neurodegenerative disorders (i.e. Alzheimer's disease). We thus explored whether IS causes oxidative DNA damage in neuronal cells.

Methods: Human SH-SY5Y neuroblastoma cell line was treated with retinoic acid to induce neuronal differentiation, then the cells were exposed to 3 mM of IS. After assessment of cell viability, IS-induced production of reactive oxygen species (ROS) was visualized by dihydroethidium. To detect 8-oxo-2'-deoxyguanosine (8-oxo-dG), we performed immunofluorescence laser scanning confocal microscopy.

Results: Ninety six hours after exposure to IS, the number of live cells was significantly decreased (50.9±1.4 %; P <0.01, versus control cells).The level of intracellular ROS in IS-exposed cells was increased in a time dependent manner. In addition, we performed immunofluorescence microscopy for 8-oxo-dG 96 hours after exposure to IS. The nuclear levels of 8-oxo-dG in IS-exposed cells were not increased, but those in mitochondrial DNA were significantly increased after exposure to IS (Figure).



Conclusions: Exposure to IS increased accumulation of 8-oxo-dG in mitochondrial DNA in differentiated SH-SY5Y cells.

FR-PO332

A New Mosaic Mouse Model of Segmental Podocyte Ablation
Masahiro Okabe,[1,2] Masaru Motojima,[1] Yoichi Miyazaki,[2] Takashi Yokoo,[2] Masafumi Fukagawa,[1] Iekuni Ichikawa,[1,3] Taiji Matsusaka.[1] *[1]Tokai Univ School of Medicine, Isehara, Japan; [2]Jikei Univ School of Medicine, Tokyo, Japan; [3]Vanderbilt Univ Medical Center, Nashville.*

Background: Our recent study using chimeric mice demonstrated that injury of a fraction of podocytes can be spread to other initially intact podocytes, which may underlie the progressive expansion of glomerulosclerosis. Each chimeric mouse needs to be de novo generated by aggregating embryos, hindering a further study.

Methods: We aimed to establish a new mosaic mouse model in which a fraction of podocytes express hCD25 and can be injured by an hCD25-targeted immunotoxin, LMB2. For this purpose, lox2272 - loxP - stop - lox2272 - EGFP - polyA - loxP - hCD25 - IRES - tdTomato - polyA were inserted into the first intron of the ROSA26 locus. Upon mating with Nephrin-Cre mice, podocytes are designed to randomly and alternatively express either hCD25 + tdTomato, or EGFP.

Results: Analysis in frozen sections confirmed that glomeruli of this line showed mosaic patterns containing both EGFP-positive and -negative podocytes. Flow cytometry analysis of glomerular cells showed that 51.3±4.3% of podocin-positive podocytes were tdTomato-positive and 30.3±2.4% were EGFP-positive. RT-PCR analysis confirmed that hCD25 mRNA was expressed in tdTomato-positive cells, but not in EGFP-positive or double-negative cells. The mosaic mice showed no abnormal renal phenotype before LMB2 injection, with normal urinary albumin/creatinine ratio (ACR), 0.347±0.81 mg/mg. Nine mosaic mice were subjected to heminephrectomy and injected with LMB2. These mice showed moderate proteinuria with ACR 40.1±20 mg/mg, and focal segmental glomerular sclerosis two weeks after the injection. Of note, EGFP-positive, i.e. hCD25-negative, podocytes were also injured as evidenced by desmin staining and diminished nephrin staining.

Conclusions: While the subtotal nephrectomy model reproduces the spreading of damage from nephron to nephron in a late phase of renal failure, this new model reproduces the spreading of damage from podocyte to podocyte in all phases. This model will be useful for exploring the common therapeutic measure to block the progression of kidney diseases.

Podocyte Injury-Driven Endocapillary PAI-1 Promotes a Vicious Cycle of Podocyte Loss *via* beta-1 Integrin Endocytosis
Namiko Kobayashi,[1] Toshiharu Ueno,[1] Satoshi Hara,[1] Shun Manabe,[1] Yukina Takahashi,[1] Kazuo Sakamoto,[1] Tomo Suzuki,[1] Yasutoshi Takashima,[1] Taiji Matsusaka,[2] Toshio Miyata,[3] Michio Nagata.[1] *[1]Renal Nephrology, Univ of Tsukuba, Tsukuba, Japan; [2]Internal Medicine, Tokai Univ School of Medicine, Japan; [3]United Centers, Tohoku Univ.*

Background: We reported transgenic mice with podocyte-specific injury (NEP mice) showed up-regulation of the capillary plasminogen activator inhibitor-1 (PAI-1) in glomeruli, prior to thrombosis and proteinuria. PAI-1 is expressed from endothelial cells or platelets in damaged tissue. Both PAI-1 and uPA bind to uPAR, and make a complex with integrin on the cell membrane. Internalization of the complex induces cell detachment as a result of reducing integrin. The present study was aimed to show PAI-1 was involved in podocyte detachment through this novel mechanism.

Methods: Podocyte injury was induced in NEP mice with PAI-1 inhibitor (PI), anti-platelet antibody (PLab), heparin sodium (Hep) or with PBS as a control, by LMB2 injection. Histological and clinical parameters were analyzed on Day 12. We treated cultured podocytes either with uPA (control), PAI-1, PAI-1/uPA complex (P/U), or an antibody for blocking uPAR before P/U. After incubation, we analyzed the localization of b1 integrin and uPAR by immunofluorescence (IF) and immunolabeling electron microscopy (IEM), and western blot.

Results: The NEP mice with PI ameliorated podocyte number, thrombosis and proteinuria compared to the control. b1 integrin translocation to podocyte cytoplasm was inhibited. The NEP mice with PLab reduced PAI-1 expression and preserved podocyte number, whereas Hep loading showed no effect on proteinuria and podocyte number, despite a thrombi decrease. In vitro, attached cells in P/U were reduced compared to the other groups (p <0.01). IF showed cell membrane-localized b1 integrin translocation to cytoplasm in P/U. It was confirmed by b1 integrin western blotting of a biotinylated experiment and cytoplasmic fraction. IEM revealed co-localization of b1 integrin and uPAR in podocyte endocytotic vesicles in P/U.

Conclusions: PAI-1/uPA complex-mediated uPAR-dependent podocyte b1 integrin endocytosis is a novel mechanism of glomerular injury leading to progressive podocytopenia.

FR-PO334

Pharmacological Targeting of GSK3b Confers Protection against Podocytopathy and Proteinuria via Desensitizing Mitochondrial Permeability Transition
Zhen Wang,[1,2] Yan Ge,[1] Ai Peng,[2] Rujun Gong.[1] *[1]Div of Nephrology, Brown Medical School, Providence; [2]Div of Nephrology, Shanghai Tenth People's Hospital, Tongji Univ, Shanghai, China.*

Background: Mitochondria dysfunction, triggered by mitochondria permeability transition (MPT), has been centrally implicated in the pathogenesis of podocytopathy and involves a multitude of cell signaling mechanisms, among which, glycogen synthase kinase (GSK) 3b has emerged as the integration point and plays a crucial role. This study aimed to examine the role of GSK3b in podocyte MPT and mitochondria dysfunction.

Methods: The regulatory effect of GSK3b on MPT was examined in differentiated podocytes in culture and in a murine model of adriamycin induced podocytopathy by using 4-Benzyl-2-methyl-1,2,4-thiadiazolidine- 3,5-dione (TDZD-8), a highly selective small molecule inhibitor of GSK3b.

Results: TDZD-8 therapy prominently ameliorated proteinuria and glomerular sclerosis in mice with adriamycin nephropathy, associated with a correction of GSK3b overactivity in glomerulus and attenuated podocyte injuries, including foot process effacement and podocyte apoptosis. Consistently, in adriamycin injured podocytes, TDZD-8 treatment overrode GSK3b overactivity, improved cell viability and prevented apoptosis, concomitant with diminished oxidative stress, improved mitochondrial dysfunction and desensitized MPT. Mechanistically, a discrete pool of GSK3b was detected in podocyte mitochondria and colocalized with clyclophilin F, a key structural component of MPT pore, as revealed by dual color immunocytochemistry staining and confocal microscopy. Co-immunoprecipitation assay confirmed that GSK3b interacts with and phosphorylates clyclophilin F, which possesses multiple GSK3b phosphorylation consensus motifs, suggesting that GSK3b has a direct control of MPT. TDZD-8 treatment intercepted the GSK3b controlled phosphorylation and activation of cyclophilin F, desensitized MPT and alleviated mitochondria damages in podocytes upon adriamycin injury *in vivo* and *in vitro*.

Conclusions: Pharmacological targeting of GSK3b might represent a promising and feasible therapeutic strategy to protect podocytes against mitochondrial dysfunction induced by oxidative injuries.

Overexpression of microRNAs May Be Key to Decreased Autophagy and PRR in the Pathogenesis of Focal Segmental Glomerulosclerosis

Nuket Bavbek,[1] Derya Akdeniz,[1] Hakki Yilmaz,[1] Umran Yildirim,[2] Onur Bender,[4] Zehra Firat,[3] Muradiye Acar,[4] Omer Faruk Hatipoglu,[4] Ayse Mukadder Bilgic,[1] Esra Gunduz,[4] Ali Akcay.[1] *[1]Internal Medicine, Section of Nephrology, Turgut Ozal Univ, School of Medicine, Ankara, Turkey; [2]Pathology, Turgut Ozal Univ, School of Medicine, Turkey; [3]Ankara Univ, Biotecnology Institue, Turkey; [4]Medical Genetics, Turgut Ozal Univ, School of Medicine, Turkey.*

Background: Focal segmental glomerulosclerosis (FSGS) is one of the most common glomerular causes of end-stage renal disease (ESRD). In this study, we aimed to explore the role of autophagy in the pathogenesis of podocyte injury, which is the key point in disease progression, and the roles of intrarenal microRNAs and the prorenin receptor (PRR) in the 5/6 nephrectomy and adriamycin nephropathy models of FSGS.

Methods: Using microarray technology, we assayed microRNA expression in kidney tissues from 5/6 nephrectomy rats, adriamycin nephropathy rats, and control rats. microRNAs were then validated using quantitative polymerase chain reaction (PCR). Beclin-1, microtubule-associated protein 1 light chain-3B (LC3B), Autophagy Protein 5 *(*ATG5), Autophagy Protein 7 (ATG7) and PRR expression were detected by western blotting, immunohistochemistry and ELISA.

Results: Beclin, LC3B, ATG5, ATG7 and also PRR were strongly expressed in podocytes of normal kidneys. In contrast, the expression of these autophagy markers were significantly decreased in the 5/6 nephrectomy group than the adriamycin nephropathy group ($p<0.05$), and both were lower than controls ($p<0,05$). These tended to correlate with the extent of global and segmental sclerosis ($rs<0.01$). miR212 (2.18 fold increase, $p<0.05$), miR132 (10.85 fold increase, $p<0.01$), miR146b (8.19 fold increase, $p<0.01$), miR34c (11.87 fold increase, $p<0.01$) and miR21 (5.44 fold increase, $p<0.01$) expression were significantly higher in the patients than in the controls.

Conclusions: These results suggest that increased level of microRNAs may be related to reduced expression of autophagy proteins and PRR, that may contribute to the development of FSGS. We speculate that the induction of autophagy and the overexpression of PRR may protect against the development of FSGS.

FR-PO336

Deficient Autophagy Results in Endoplasmic Reticulum and Mitochondrial Dysfunction and the Development of Focal and Segmental Glomerulosclerosis of the Kidney

Ivan G. Gomez,[1,2] Allie M. Roach,[1,2] Shuyu Ren,[1,2] Charles E. Alpers,[1] Stuart J. Shankland,[1] Vivette D. D'Agati,[3] Jeremy Stuart Duffield.[1,2] *[1]Univ of Washington, Seattle, WA; [2]Biogen Idec, Cambridge, MA; [3]Columbia Univ, New York, NY.*

Background: FSGS is a heterogeneous fibrotic disease recognized as a component of other kidney diseases, whose etiology remains poorly understood. Autophagy is the process by which cells degrade damaged organelles, cell membranes and proteins. Deficient autophagy may contribute to the accumulation of cell damage and disturbance of cell homeostasis.

Methods: We explored autophagic deficiency in the kidney epithelium by mutating critical autophagy gene *ATG5* or *ATG7* during nephrogenesis only in kidney epithelium using Cre-Lox recombination.

Results: Mice with *ATG5* mutations develop foot process effacement, mild tubular cell dysfunction and albuminuria within 2 mths. By 4 mths they exhibit profound glomerular, tubular and interstitial disease, which bear remarkable similarity to the FSGS in humans, as well as severe albuminuria, hypoalbuminemia. They developing advanced renal failure sufficient to cause death by 6 mths. *ATG7* mutants develop a similar disease with slower progression. In addition to the characteristic features of FSGS, podocytes and tubular cells show vacuolization, enlarged damaged mitochondria, and changes to the endoplasmic reticulum. At 2 mths, ATG5 KO tubules and podocytes show ER and mitochondrial distress and produce high levels of ROS, the result of impaired autophagic organelle turnover in podocytes. FSGS biopsies also show mitochondrial morphometric abnormalities consistent with mitochondrial dysfunction in human disease.

Conclusions: We conclude deficient autophagy in the Nephron is sufficient to cause all the manifestations of FSGS.

FR-PO337

Vitamin D Attenuates Proteinuria by Inhibition of Heparanase Expression in the Podocyte

Marjolein Garsen,[1] Angelique Rops,[1] Suzanne Huntink,[1] Toin Van Kuppevelt,[2] Joost Hoenderop,[3] Jo H.M. Berden,[1] Tom Nijenhuis,[1] Johan Van der Vlag.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Matrix Biochemistry, Radboud Univ Medical Center, Nijmegen, Netherlands; [3]Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Heparan sulfate (HS) is a negatively charged polysaccharide that is abundantly expressed in the glomerular filtration barrier. HS expression is reduced in patients with proteinuria, which is associated with an increased expression of the HS-degrading enzyme heparanase. Heparanase is essential for the development of proteinuria in diabetic nephropathy. Several studies showed that proteinuria and podocyte loss could be reduced by treatment with activated vitamin D ($1,25\text{-}D_3$).

Methods: We evaluated the effects of vitamin D on heparanase expression in vivo and in vitro.

Results: In vivo, 1a-hydroxylase knockout (1a-OHase KO) mice, which are unable to hydrolyze 25-hydroxy vitamin D to $1,25\text{-}D_3$, developed proteinuria, which could be corrected by treatment with $1,25\text{-}D_3$. Heparanase expression and activity were increased in the 1a-OHase KO mice and normalized by $1,25\text{-}D_3$ treatment. In addition, adriamycin-exposed (AN) rats developed proteinuria, which could be ameliorated by $1,25\text{-}D_3$ treatment. Glomerular heparanase expression and activity were increased in AN, which was reduced by $1,25\text{-}D_3$ treatment. Furthermore, glomerular HS expression was reduced by induction of AN, and normalized by $1,25\text{-}D_3$ treatment. In vitro, adriamycin stimulation increased heparanase mRNA expression in the podocyte, which could be corrected by $1,25\text{-}D_3$ treatment. $1,25\text{-}D_3$ treatment alone also reduced heparanase mRNA expression. In line with these results, $1,25\text{-}D_3$ treatment dose-dependently reduced heparanase promoter activity. By chromatin immunoprecipitation we showed that the vitamin D receptor binds directly to the heparanase promoter. Finally, we showed that $1,25\text{-}D_3$ treatment reduced transendothelial albumin passage after adriamycin stimulation.

Conclusions: Our data suggest that the protective effect of vitamin D on the development of proteinuria in AN is mediated by reduction of the increased heparanase expression in the podocyte.

FR-PO338

Inhibitory Effects of Acthar® Gel in the Passive Heymann Nephritis Model

Paul Higgins, David Young. *Questcor Pharmaceuticals, Ellicott City, MD.*

Background: H.P. Acthar Gel, a purified preparation of ACTH derived from porcine pituitary gland, is an FDA approved therapy to induce a remission of proteinuria in the nephrotic syndrome without uremia of the idiopathic type or that due to lupus erythematosus. Membranous nephropathy (MN) is a common cause of idiopathic nephrotic syndrome, accounting for about one-third of the cases in adults. ACTH has been shown to be effective in alleviating proteinuria in patients with MN. However, the effects of Acthar have not been tested in an animal model of MN. We therefore tested the efficacy of Acthar in passive Heymann nephritis, an animal model which resembles MN in several clinical and histopathologic aspects.

Methods: Disease was induced in male Sprague-Dawley rats by i.v. injection of anti-Fx1A antibody (5 ml/kg). Ten days after disease induction, after proteinuria was well-established, Acthar was dosed at 40, 160, and 400 U/kg s.c. every other day for 4 weeks. Placebo gel (the vehicle for Acthar, not containing the active ingredient) was administered as a negative control. Urine was sampled weekly for determination of urinary protein and creatinine. After 4 weeks of drug administration, rats were sacrificed and kidneys harvested for semi-quantitative histologic analysis to assess inflammation, glomerular sclerosis, mesangial proliferation and tubular nephrosis.

Results: The results showed a progressive increase in urinary protein/creatinine ratio in animals treated with Placebo gel. Rats treated with all doses of Acthar exhibited significantly reduced protein/creatinine ratios compared to Placebo gel at week 3 (37-44% decrease, $p < 0.05$) and week 4 (58-67%, $p < 0.001$) of drug treatment. Histologically, reductions in kidney histology scores for inflammation (50-88% decrease, $p < 0.01$), glomerular sclerosis (46-65%, $p < 0.001$), mesangial proliferation (35-62%, $p < 0.0001$), tubular nephrosis (67-87%, $p < 0.01$) as well as total score (59-63%, $p < 0.01$) were all induced by Acthar treatment.

Conclusions: The present results demonstrate the in vivo efficacy of Acthar in the Heymann nephritis model and provide evidence to support the use of Acthar in the treatment of proteinuria in patients with idiopathic membranous nephropathy.

Fingolimod (FTY720), an Analog of Sphingosine Inhibited the Reduced Expression of the Slit Diaphragm Molecules and Ameliorated Proteinuria in PAN Nephropathy

Eriko Hasegawa,[1] Yoshiyasu Fukusumi,[1] Ayako Wakamatsu,[1] Natsumi Takashima,[1] Ichiei Narita,[2] Hiroshi Kawachi.[1] *[1]Cell Biology, Inst Nephrol, Niigata Univ Medicine, Niigata, Japan; [2]Medicine II, Niigata Univ Medicine, Niigata, Japan.*

Background: Fingolimod has a structural similarity to a sphingosine 1-phosphate (S1P), and acts as a functional antagonist. Fingolimod is used an immunosuppressant, because it can sequester lymphocytes to lymph tissues by binding to S1P receptor (S1PR) on lymphocytes. It is also reported that S1P-S1PR signaling regulates a variety of cell functions including survival, cytoskeletal rearrangement, and cell-to-cell barrier. In this study, we examined the effect of fingolimod in puromycin aminonucleoside (PAN) nephropathy, a mimic of MCNS.

Methods: First, the expressions of S1PRs and metabolic enzymes of S1P were analyzed in cultured mouse podocytes, and normal and PAN nephropathy rat glomeruli. Next, the effects of fingolimod on proteinuria and the expression of slit diaphragm molecules in PAN nephropathy were analyzed.

Results: mRNA expressions of sphingosine kinase (SK) 1,2, S1P phosphatase1, 2, S1P lyase, and S1PR1, 2, 3, 4, 5 were detected in normal rat glomeruli. In mouse cultured podocytes S1PR5 was not detected, although other S1P related molecules were detected. The treatment of fingolimod reduced the mRNA expressions of S1PR3, 4. mRNA expressions of S1PR3, 4, and SK1 were upregulated in cultured podocytes treated with PAN. In PAN nephropathy rat glomeruli, mRNA expressions of S1PR3, 4 and SK1 were clearly upregulated (S1PR3 488% to normal: S1PR4 208% SK1 162%). Daily administration of fingolimod (1mg/kg BW) reduced proteinuria in PAN nephropathy (day8, 103.4mg/day versus 5.3 $p<0.05$: day10, 152.3 versus 11.2 $p<0.05$), and prevented the reduced expressions of nephrin (IF score 1.78 versus 2.86 $p<0.05$) and podocin (1.62 versus2.62 $p<0.05$), but not ZO-1.

Conclusions: Increased S1P-S1PR signaling may contribute to the development of podocyte injury. Fingolimod ameliorated PAN nephropathy by suppressing the S1P-S1PR signaling in podocyte.

FR-PO340

Production of Congenic Mouse Strains with Mutated or Wild-Typed Tensin 2 Gene in Multiple Inbred Mouse Genetic Backgrounds to Elucidate the Mechanism for Renal Failure due to Tensin 2 Deficiency Hayato Sasaki,[1] Kiyoma Marusugi,[2] Junpei Kimura,[3] Hiroshi Kitamura,[4] Ken-Ichi Nagasaki,[5] Yasuhiro Kon,[3] Daisuke Torigoe,[1] Takashi Agui,[1] Nobuya Sasaki.[2] *[1]Laboratory of Laboratory Animal Science and Medicine, Graduate School of Veterinary Medicine, Hokkaido Univ, Sapporo, Japan; [2]Laboratory of Laboratory Animal Science and Medicine, Faculty of Veterinary Medicine, Kitasato Univ, Towada, Japan; [3]Laboratory of Anatomy, Graduate School of Veterinary Medicine, Hokkaido Univ, Sapporo, Japan; [4]Dept of Veterinary Physiology, School of Veterinary Medicine, Rakuno Gakuen Univ, Ebetsu, Japan; [5]Chitose Laboratory, Japan Food Research Laboratories, Chitose, Japan.*

Background: Tensin 2 (Tns2) is thought to be a component of the actin cytoskeletal structures linking actin filaments with focal adhesions and play a role as an intracellular signal transduction mediator through integrin in podocytes, and how it functions is unclear. *Tns2*-null mutation (*Tns2*^{nph}) leads to massive albuminuria following podocyte foot process effacement in ICR-derived glomerulonephritis (ICGN) mice, which is the origin of the mutation, and DBA/2J (D2) mice, but not in C57BL/6J (B6) mice and 129X1/SvJ (129) mice. Elucidating the reasons for these differences in diverse genetic backgrounds could help unraveling *Tns2* function in podocyte.

Methods: We produced the congenic mouse in which *Tns2*^{nph} is introgressed into FVB/NJ (FVB) background (FVB-*Tns2*^{nph}), and evaluated the progression of kidney disease. We also produced the congenic strain carrying wild-type *Tns2* on an ICGN background (ICGN-*Tns2* (+/+)).

Results: FVB-*Tns2*^{nph} mice developed albuminuria, renal fibrosis and renal anemia, like ICGN mice, whereas ICGN-*Tns2* (+/+) mice did not. In FVB-*Tns2*^{nph} mice, podocyte foot process effacement was observed with an electron microscope at as early as 4 weeks age.

Conclusions: Our mice reveal that FVB mice are susceptible to *Tns2* deficiency, and provide bona fide controls for ICGN mice that derived from ICR outbred mice. Now, we can provide the two resistant strains (B6 and 129) and the three susceptible strains (D2, FVB and ICGN-*Tns2* (+/+)) for comparative analyses to elucidate the mechanism for renal failure due to *Tns2* deficiency.

FR-PO341

Podocyte Nox5 Induces a RAS-Independent Systolic Blood Pressure Increase in Mice Chet E. Holterman, Chris R. Kennedy. *Ottawa Hospital Research Inst, Ottawa, ON, Canada.*

Background: Mice with podocyte Nox5 expression (Nox5^{pod+}) develop pathology reminiscent of diabetic nephropathy coupled with elevated systolic blood pressure (SBP). While the mechanisms underlying such effects are unresolved, the AngII/AT1R pathway is known to both activate and be regulated by Nox members, including Nox5. We therefore investigated whether activation of the renin-angiotensin system (RAS) is linked to Nox5-driven renal injury and SBP elevation.

Methods: We queried renal expression of RAS pathway family members in Nox5^{pod+} mice by qPCR. We employed a tetracycline-inducible mouse line to express Nox5 in podocytes (Nox5^{podInd}) and investigated potential interactions between AngII and Nox5. Nox5 expression was induced with doxycycline in Nox5^{podInd} mice and osmotic minipumps loaded with either AngII or Losartan were implanted. SBP was measured by tail cuff and albuminuria was determined via spot urine collection/albumin ELISA. Glomerular filtration rate (GFR) was measured via FITC-inulin clearance.

Results: Nox5^{pod+} transgenic mice displayed increased renal cortex expression of endogenous RAS pathway members, renin, AT1R, ACE2, as well as cyclooxygenase-2. Similar to Nox5^{pod+} animals, Nox5^{podInd} mice developed albuminuria and increased SBP following Nox5 induction. Exogenous AngII infusion in Nox5^{podInd} mice increased SBP and albuminuria to a greater extent than in non-transgenic mice ($P<0.05$). Interestingly, Losartan attenuated neither albuminuria nor SBP yet reduced GFR in Nox5^{podind} mice.

Conclusions: Our data reveal that podocyte-specific Nox5 expression renders mice more sensitive to the effects of exogenous AngII infusion including SBP elevation and albuminuria. In contrast, and despite AT1R blockade, Nox5-driven filtration barrier damage and SBP elevation remain unchallenged in mice without AngII infusion, thereby negating endogenous RAS involvement in such injury. However, activation of the endogenous RAS pathway may nevertheless compensate to maintain GFR in response to altered arteriolar tone brought about by oxidative stress in podocyte-specific Nox5 mice. These findings highlight the complex interplay between Nox5-driven oxidative stress and the renin angiotensin system.

Podocyte Injury Promotes Glomerular Lipid Peroxidation and Foam Cell Infiltration Under Hypercholesterolemia Satoshi Hara,[1,2] Namiko Kobayashi,[1] Shun Manabe,[1] Tomo Suzuki,[1] Kazuo Sakamoto,[1] Yasutoshi Takashima,[1] Toshiharu Ueno,[1] Juri Hamada,[3] Taiji Matsusaka,[4] Michio Nagata.[1] *[1]Kidney and Vascular Pathology, Univ of Tsukuba, Tsukuba, Japan; [2]Rheumatology, Kanazawa Graduate School of Medicine, Kanazawa, Japan; [3]Tsukuba Advanced Research Alliance, Univ of Tsukuba, Tsukuba, Japan; [4]Internal Medicine, Tokai Univ School of Medicine, Isehara, Japan.*

Background: Glomerular macrophage (Mj)-derived foam cells (FCs) infiltration is frequently observed in various nephrotic diseases and it is associated with podocyte injury. We have reported that acute podocyte injury under hypercholesterolemia (NEP25/LDLRKO mice) accelerated glomerular lipid deposition. The present study analyzed the effect of acute podocyte injury on lipid peroxidation and chronic effect on glomerular Mj-derived FCs infiltration.

Methods: Matrix-assisted laser desorption/deionization imaging mass spectrometry (MALDI-IMS) was performed to examine oxidized LDL (oxLDL) in NEP25/LDLRKO mice as compared with NEP25 mice and LDLRKO mice. Then, uninephrectomized LDLRKO mice were induced of adriamycin (ADR) nephropathy. ADR + high fat diet (HFD) group was compared with ADR + normal diet and vehicle + HFD group in histology. Finally, using rat mesangial cell (MC) and glomerular endothelial cell (GEnC) line, the effect of oxLDL on cytokine signaling about Mj adhesion and migration was analyzed by quantitative RT-PCR.

Results: MALDI-IMS showed that lysophosphatidylcholine (LPC) 16:0 and 18:0 were accumulated only in the kidney of NEP25/LDLRKO mice. The amount of glomerular LPC16:0 and 18:0 was significantly high in NEP25/LDLRKO mice compared with control ($P < 0.05$). In ADR + HFD group, glomerular Mj and a LPC precursor oxidized phospholipid (oxPL) increased ($P < 0.05$) and Mj-derived FCs contained oxPL ($P < 0.05$) as compared with control. In vitro, LPC16:0 induced MCP-1, VCAM-1, ICAM-1 and Mj migration inhibitory factor (MIF) mRNA up-regulation in MC. LPC18:0 induced VCAM-1, P-selectin and MIF mRNA up-regulation in GEnC and MCP-1 mRNA up-regulation in MC.

Conclusions: Podocyte injury promotes LPC formation within the glomeruli, leading to glomerular Mj-derived FCs infiltration through chemokines and adhesion molecules expression in GEnC and MC.

FR-PO343

sPLA2 IB Induces Human Podocyte Apoptosis via the M-Type Phospholipase A2 Receptor Yangbin Pan,[1] Jian-Xin Wan,[2] Huiming Wang,[1] Yipeng Liu,[1] Qian Yang,[1] Wei Liang,[1] Guohua Ding.[1] *[1]Div of Nephrology, Renmin Hospital of Wuhan Univ, Wuhan, Hubei, China; [2]Div of Nephrology, First Affiliated Hospital of Fujian Medical Univ, Fuzhou, Fujian, China.*

Background: The M-type phospholipase A2 receptor (PLA2R) is expressed by human podocytes. Group IB secretory phospholipase A2 (sPLA2 IB), one of the ligands of PLA2R, has been found to be at a high level in patients with chronic renal failure than in normal controls. However, little is known about the role of sPLA2 IB in the pathogenesis of glomerular diseases. In the present study, we evaluated the effects of sPLA2-IB /PLA2R on human podocyte (HPC) injury and explored the underlying signaling pathway.

Methods: Western blotting, real-time polymerase chain reaction (PCR) analyses and immunofluorescence assays were performed to evaluate PLA2R, cPLA2a, ERK1/2 and p53 expressions. High-performance liquid chromatography (HPLC) was used to evaluate arachidonic acid (AA) content. Podocyte apoptosis was assessed by flow cytometry and Hoechst-33342 staining.

Results: PLA2R was expressed in the membrane of HPCs and medicated internalization of sPLA2 in HPC cytoplasm. sPLA2 IB was able to induce podocyte apoptosis in a PLA2R-dependent manner. Moreover, sPLA2 IB exposure promoted expression of PLA2R and phophorylation of cPLA2a and ERK1/2. HPLC analysis demonstrated that elevated levels of AA were found in the culture medium of sPLA2-exposed HPC in a dose-dependent manner. In addition, exogenous AA was able to provoke apoptosis and p53 pathway was involved in AA-induced apoptosis in HPC.

Conclusions: sPLA2 IB has a potential ability to combine PLA2R of human podocyte and induce podocyte apoptosis through activation of ERK1/2 and cPLA2a and release of AA.

FR-PO344

Heterozygous Actn4 Mutant Mice Are Susceptible to Glomerulopathy when Subjected to Hemodynamic Stress Mostafa Belghasem, Mei Cao, Joel M. Henderson. *Pathology & Laboratory Medicine, Boston Univ, Boston, MA.*

Background: a-Actinins are actin-binding and cross-linking proteins. Mutations in ACTN4, the gene encoding the actin binding protein a–actinin-4, can cause familial focal segmental glomerulosclerosis (FSGS) in humans. Previous studies showed that Actn4 knockout mice are prone to develop spontaneous glomerular disease. However, heterozygous Actn4 mutant mice carrying a human disease-associated mutation, K255E, do not. In this study heterozygous Actn4 mutant mice are challenged with systemic hypertension using the deoxycorticosterone acetate (DOCA)-salt uninephrectomy model, to determine if their kidneys are especially vulnerable to hemodynamic stress.

Methods: Heterozygous Actn4 mutant mice (n=4) and wild type (n=4) controls were subjected to uninephrectomy and DOCA-salt treatment for 6 weeks. During treatment, systemic blood pressure was measured by the tail cuff method, and kidney function was assessed with urine and serum biomarkers. At the end of the treatment period, kidney tissue was harvested for histological analysis.

Results: Both groups displayed a remarkable increase in systolic blood pressure in response to DOCA-salt uninephrectomy, with minimal difference between the groups. Survival was markedly reduced (25%) in heterozygous Actn4 mutant mice compared to controls (75%) prior to the end of the observation period (6 weeks). The heterozygous mouse that survived to the end of observation period showed severe glomerular injury, more extensive than that seen in controls. Glomerulosclerosis involved 27% and 10% of glomeruli in the heterozygous mouse and wild type controls, respectively. The glomerular lesions almost exclusively affected the juxtamedullary glomeruli in both groups.

Conclusions: Overt glomerular disease does not develop spontaneously in heterozygous Actn4 mutant mice. However, our findings suggest that additional modifying factors, such as hemodynamic stress, play a role in the development of glomerular disease in these mice. Furthermore, these mice display a remarkable decrease in survival in response to hemodynamic stress induced by DOCA-salt uninephrectomy.

Podocyte-Preserving Strategies for Preventing Hypertrophy-Driven Progression Ryuzoh Nishizono, Masao Kikuchi, Su Qing Wang, Mahboob A. Chowdhury, Yan Yang, Larysa T. Wickman, Roger C. Wiggins. *Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: Uni-nephrectomy (to a lesser extent than 5/6 nephrectomy) can trigger accelerated podocytes detachment leading in susceptible individuals to ESKD over time. Model systems show that this process which is driven by compensatory hypertrophy is podocyte-dependent. We hypothesize that this mechanism common to all nephronopenic progression is also analogous to kidney transplantation ("reverse nephrectomy") where post-implantation hypertrophic events cause podocyte stress leading to accelerated podocyte detachment and progressive loss of renal function.

Methods: To investigate how to mitigate these events we used the AA-4EBP1 transgenic rat model where expression of the dominant AA-4EBP1 transgene is driven by the human podocin promoter. Homozygous AA-4EBP1 rats maintained on an ad lib diet developed proteinuria, podocyturia, progressive podocyte depletion, glomerulosclerosis, hypertension and progressed to ESKD by 12 weeks after nephrectomy. Three potentially mitigating strategies were tested: (i) reduced food intake by 40% or 20%, (ii) ACE inhibitor (enalapril) to inhibit angiotensin II, and (iii) rapamycin to slow growth.

Results: Each of these approaches was largely effective when started immediately after nephrectomy, although protection occurred by different mechanisms. Both food restriction and rapamycin prevented glomerular enlargement so podocytes did not become stressed and detach. In contrast ACE inhibitors did not prevent glomerular enlargement but prevented podocyte detachment thereby preventing proteinuria and progression. These strategies were also tested for their efficacy starting 3 weeks after nephrectomy when the urine protein:creatinine ratio was already elevated to 10 but prior to loss of podocytes from glomeruli to simulate treatment of already established glomerular disease. None of the strategies was completely effective if started late. However combinations were more effective than individual strategies alone.

Conclusions: These data provide a guide towards mitigating all forms of growth-dependent glomerular progression in the clinic.

FR-PO346

Podocyte Density Decreases with Age in Man Roger C. Wiggins, Su Qing Wang, Jeffrey B. Hodgin, Yan Yang, Larysa T. Wickman, Farsad Afshinnia, Mahboob A. Chowdhury, Ryuzoh Nishizono, Jocelyn E. Wiggins, Markus Bitzer. *Univ of Michigan, Ann Arbor, MI.*

Background: Human aging is associated with sclerosed glomeruli, decreasing eGFR and increasing ESKD prevalence. Podocytes are long-lived post-mitotic cells with limited capacity for renewal. Model systems show that podocyte depletion below a density of about 100 per 10^6 um^3 causes glomerosclerosis, and can occur because (i) podocyte number per glomerulus can decrease and/or (ii) glomerular volume can increase. We therefore tested the hypothesis that glomerular aging is associated with reduced podocyte density.

Methods: Podocyte density was estimated from archival tissue sections with recently developed technology (Venkatareddy et al. JASN 2014) using kidney donor biopsies (n=59 age 4-71) and normal nephrectomy samples (n=30, age 31-85).

Results: Podocyte nuclear density decreased linearly with age with a slope of -0.8% per year (R^2=0.43, P<0.001) corresponding to the approximate rate of decrease of eGFR with age, and reaching a podocyte density beyond which glomerulosclerosis is increasingly prevalent by 80 years of age. Decreased podocyte nuclear density with age was due to a combination of decreased podocyte number per tuft (-0.4% per year, R^2=0.15, P<0.01) and increased glomerular volume (+0.4% per year, R^2=0.19, P<0.01). As podocyte density decreased with age podocyte cell volume increased (measured by Glepp1 area density) (R^2=0.44, P<0.001) in parallel to podocyte nuclear volume (R^2=0.53, P<0.001) reflecting the well-established karyplasmic ratio relationship of cell size to nuclear size (R^2=0.64).

Conclusions: These observational data provide a logical explanation for kidney aging as a dynamic process whose variables can be understood and potentially modulated by pharmacologic and dietary factors. In successful glomerular aging increased podocyte cell size (estimated by two independent methods) compensates for decreasing podocyte density. Diabetes, hypertension and other glomerular disease can be seen as superimposed accelerators of age-associated reduction in podocyte density. Podocyte reserve is much reduced in older than in younger individuals.

MiR-21 in Renal Aging Christopher Lund O'Connor, Jinghui Luo, Harkamal Singh Jhajj, Jennifer Yi-Chun Lai, Markus Bitzer. *Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: Loss of podocytes is sufficient to cause progressive glomerulosclerosis (podocyte depletion hypothesis). Increased age, reduction in nephron number and hypertension are associated with development of glomerulosclerosis. We had previously shown that miR-21, a small regulatory RNA, antagonizes loss of podocytes. Therefore we investigated changes in glomerular pathology associated with increased age and after nephron mass reduction plus hypertension in miR-21-mutant mice.

Methods: Mature miR-21 expression was determined using qrt-PCR. Ubiquitously miR-21-deficient mice and wildtype littermates were aged to 24 months on ad-libitum diet (n=5 in each genotype) or underwent uninephrectomy + s.c. implantation of a DOCA tablet + saline drinking water (1% NaCl, 0.2% KCl) (UN/DOCA salt) at 3 months of age (n=5 in each genotype). Computer-assisted morphometric image analysis of immunohistochemistry for WT-1 for podocyte enumeration and PAS staining to measure mesangial matrix area.

Results: miR-21 expression was increased significantly in kidney cortex of 22 months compared to 3 months old wildtype mice (3.1-fold, n=5 per age-group, p<0.001) but not after UN/DOCA-salt (n=5). At 3 months of age miR-21-deficent mice did not exhibit differences in blood pressure, proteinuria, podocyte density or mesangial matrix area compared to wildtype littermates. Unchallenged 24 months old miR-21-deficient mice exhibit a significantly decreased podocytes density (p=0.0189) and higher glomerular volume per podocytes (p=0.045). Genotype had no significant effect on kidney weight, kidney-to-body weight ratio and mesangial matrix area. In UN/DOCA salt mice blood pressure increased after two weeks in all mice independent of genotype. miR-21-deficient UN/DOCA salt mice exhibited increased proteinuria (p=0.043), decreased podocyte density (p=0.004) but no difference in mesangial matrix area.

Conclusions: miR-21 antagonizes loss of podocytes associated with aging and after nephron mass reduction plus hypertension in mice consistent with our previous findings. Studies examining the underlying signaling events and molecular mechanisms and the effect of loss of miR-21 in specific renal cell-types are ongoing in the lab.

Podocyte Depletion in Kidney Allografts Yan Yang, Jeffrey B. Hodgin, Su Qing Wang, Farsad Afshinnia, Larysa T. Wickman, Ryuzoh Nishizono, Mahboob A. Chowdhury, Milagros D. Samaniego-Picota, Roger C. Wiggins. *Univ of Michigan, Ann Arbor, MI.*

Background: Kidney allografts half-life is unexpectedly short in spite of improved immunosuppression. Podocytes are long-lived post-mitotic cells with limited capacity for renewal. Model systems show that podocyte depletion beyond a threshold density (about 100 per 10^6 um^3 glomerular volume) due to (i) decreased podocyte number per glomerular tuft and/or (ii) glomerular enlargement causes glomerulosclerosis. We therefore tested the hypothesis that allografts develop decreased podocyte density.

Methods: Podocyte density was estimated from archival histologic sections using recently developed technology (Venkatareddy et al, JASN 2014).

Results: Protocol kidney biopsy 3 months post-implantation shows 21% decrease in podocyte density from 214±73 to 173±45 per 10^6 um^3 (P<0.01) due to glomerular enlargement (compensatory kidney hypertrophy) without podocyte loss. By 12 months post-implantation podocyte density was not further decreased (157±53 per 10^6 um^3, P=0.37 versus 3 month biopsy). In contrast biopsies with glomerulopathy (excluding recurrent glomerular diseases) within 2 years post-implantation (mean 0.9±0.7 years) podocyte nuclear density had decreased to 92±32 per 10^6 um^3 (P<0.001) due primarily to reduced podocyte number per tuft from 463±85 to 305±55, P<0.001) and associated with >10-fold accelerated podocyte detachment rate estimated using a non-invasive urine pellet podocin mRNA assay (Wickman et al, JASN 2013). Grafts that survived longer term (mean 10.2±4.3 years post-implantation) biopsied for abnormal kidney function and with a pathologic diagnosis of transplant glomerulopathy had markedly reduced podocyte nuclear density at 70±33 per 10^6 um^3 (P<0.0001 versus control) due to a combination of glomerular enlargement and reduced podocyte number per tuft. Allograft eGFR correlates with podocyte density (R^2=0.42, P<0.001).

Conclusions: Podocyte depletion is a common phenomenon in allografts likely to be contributing to failure in both the short and long term.

FR-PO349

Podocyte-Specific TRPC6 Overexpression-Induced FSGS in Mice Is Exacerbated by a Novel TRPC6 Mutation Zijin Sun,[1] Yaochun Zhang,[1] Kar Hui Ng,[1] Zakir Hossain,[2] Jun Li Ng,[1] Chang Yien Chan,[1] Isaac Liu,[1] Hui Kim Yap.[1] *[1]Dept of Paediatrics, National Univ of Singapore, Singapore; [2]Cancer Science Inst of Singapore, National Univ of Singapore, Singapore.*

Background: Mutations in the Transient Receptor Potential Cation Channel 6 *(TRPC6)* gene have been associated with familial focal segmental glomerulosclerosis (FSGS). We found one Chinese family with autosomal dominant FSGS carrying a novel *TRPC6* p.R68W missense mutation which increases *TRPC6* current amplitudes, suggesting gain of function. This study aimed to compare the phenotypes of transgenic mice with podocyte-specific overexpression (OE) of wild type (OE^{WT}) and p.R68W mutant (OE^{Mut}) *TRPC6* to ascertain the in-vivo function of p.R68W.

Methods: cDNAs of WT and p.R68W EGFP-*TRPC6* were subcloned independently downstream of the pNPHS2 podocin-specific promoter. Founders with the transgene were obtained by pronuclear microinjection. These were crossed with FVB/N WT mice to establish mouse lines with varying transgene copy numbers. Transgene expression was verified by reverse-transcription PCR and western blot analysis, while transgene copy number was estimated by qPCR. The phenotypes of OE^{WT} (n=5) and OE^{Mut} (n=6) mice with comparable transgene copy numbers were studied and compared with control mice (n=8) carrying only native *TRPC6*. Urine albumin:creatinine ratios were obtained monthly. The mice were euthanized at 6 months of age. Statistical analysis was performed using Mann-Whitney *U* test.

Results: At 5 months' of age, both OE^{WT} (36.5±5.7 ng/µg) and OE^{Mut} (48.3±19.6 ng/µg) mice had higher mean urine albumin:creatinine ratios compared to controls (25.3±7.8 ng/µg) ($P<0.01$). Moreover, OE^{Mut} had higher mean urine albumin:creatinine ratios compared to OE^{WT} mice ($P<0.05$). Histologically, both OE^{WT} and OE^{Mut} mice had FSGS and extensive podocyte foot process effacement. Immunogold studies with anti-EGFP antibody showed more extensive deposition on the podocyte foot processes of OE^{Mut} compared to OE^{WT} mice.

Conclusions: Podocyte-specific overexpression of both WT and p.R68W *TRPC6* in mice results in albuminuria and FSGS, with a more severe phenotype in p.R68W, suggesting an important role of p.R68W mutation in the pathogenesis of familial FSGS.

FR-PO350

Podocyte Injury and Segmental Glomerulosclerosis in Heme Oxygenase (HO)-1 Knock Out Rats Harikleia Gakiopoulou,[1] Vasileios Atsaves,[2] Maria Detsika,[2] Elpida Poulaki,[1] Pu Duann,[3] Elias A. Lianos.[3] *[1]Pathology, Univ of Athens, Greece; [2]Medicine, Univ of Athens, Greece; [3]Medicine, Rutgers Biomedical and Health Sciences, Greece.*

Background: In the kidney,the inducible isoform of Heme Oxygenase (HO-1) protects against oxidative injury. It is unknown whether HO-1 is also important for preservation of renal structural/functional integrity. The aim of this study was to assess structural/functional consequences of HO-1 depletion in the rat kidney.

Methods: HO-1 depletion was achieved in Sprague-Dawley rats using Zinc Finger Nuclease technology to disrupt the HO-1 sequence 5'-GGT GGC CCA CGC ATA tac ccg cTA CCT GGG TGA CCT CTC AG-3' within Exon 3, and was documented in isolated glomeruli by western blot analysis. Urine albumin and creatinine excretion were measured at defined time points in sex and age-matched Heterozygotes (HO-1 depletion), homozygotes (HO-1 absence) and wild-type controls. Pathologic lesions were examined by routine histolology and immunohistochemistry techniques.

Results: Both heterozygotes and homozygotes developed albuminuria. Podocytes were hypertrophied with copious cytoplasm, enlarged nuclei, prominent nucleoli and presence of WT1 antigen in glomerular filtrate. There was also increased mesangial matrix and segmental sclerosis with synechial adhesions to Bowman's capsule or to the origin of the proximal convoluted tubule. Tubules displayed microcystic dilatation with proteinaceous casts and there was interstitial infiltration by inflammatory cells, more prominent in homozygotes.

Conclusions: HO-1 is important in preserving glomerular, particularly podocytic, and interstitial integrity. HO-1 depletion or absence results in FSGC.

FR-PO351

Dual Role of SDF-1 in Podocyte Injury and Regeneration Simone Romoli,[1] Santhosh Kumar Vr,[1] Shrikant R. Mulay,[1] Dirk Eulberg,[2] Hans J. Anders.[1] *[1]Nephrologisches Zentrum, Klinikum der Univ Muenchen, Germany; [2]NOXXON Pharma AG, Germany.*

Background: Stromal Derived Factor-SDF1 is a homeostatic chemokine, which promotes homing and activation status of stem cells. We speculated that SDF-1 regulates glomerular injury and regeneration.

Methods: Glomerular injury was induced by single intravenous injection of Adriamycin 13.4mpk (ADR) in male Balb/c mice that received either the SDF-1 inhibitor NOX-A12 (50mpk *s.c*) After 2 weeks all mice were sacrificed for analysis: ELISA, Histology. Human parietal epithelial cells (PECs) with renal progenitor cell properties were used for *in-vitro* cell culture studies, q-RT-PCR.

Results: ADR injection induced proteinuria with a peak at 7 days (injury phase), which subsequently declined without returning to baseline and was associated with FSGS lesions at the end of week 2. SDF-1 blockade significantly aggravated the injury phase at day 7. Despite this effect, at day 14 SDF-1 blockade had improved proteinuria and markers of glomerular disease versus control mice. SDF-1 inhibition only from day 7 to 14 displayed the same beneficial effect on the regeneration phase of ADR. To unravel these oppositional effects we focused on the Notch signaling pathway. Notch ligand and receptor mRNA expression profiling revealed their suppression during ADR, which was recovered by SDF-1 blockade. In vitro, we found SDF-1 to suppress PECs proliferation. The same results were obtained when podocyte progenitors where exposed to supernatants of necrotic podocytes, which implies that necrotic cells provide Notch ligands and SDF-1 to podocyte progenitors. SDF-1 also reduced the induced differentiation of PECs into podocytes by VRAD medium. In contrast, SDF-1 increased the viability of podocytes in vitro after Adriamycin stimulation.

Conclusions: These data unravel a bivalent role of podocyte-derived SDF-1 in glomerular injury. SDF-1 protects podocytes during injury phase, which may relate to its suppression of Notch and Notch-driven mitotic catastrophe of podocytes. However, SDF-1 also acts as a negative regulator of Notch-mediated podocyte regeneration; therefore, SDF-1 inhibition may be a suitable therapeutic strategy to enhance the regenerative capacity of the glomerulus after podocyte loss.

FR-PO352

Thymosin b4 Plays a Critical Role in the Progression of Glomerular Disease Elisa Vasilopoulou,[1] Maria K. Joannou,[1] Kathryn E. White,[2] Michael G. Robson,[3] Paul Winyard,[1] David A. Long.[1] *[1]Developmental Biology and Cancer, UCL Inst of Child Health, United Kingdom; [2]EM Research Services, Univ of Newcastle, United Kingdom; [3]MRC Centre for Transplantation, King's College London, United Kingdom.*

Background: Podocyte shape is essential to maintain the structure and function of the glomerular filtration barrier; hence molecules which alter this process may contribute to the progression of kidney disease. Based on this premise, we hypothesised that the actin-sequestering protein, thymosin-ß4 may have a critical role in the glomerular filtration barrier.

Methods: We assessed thymosin-ß4 expression in developing and adult kidneys by qRT-PCR, in-situ hybridisation and immunohistochemistry. To determine the role of thymosin-ß4 in healthy glomeruli we examined renal function and glomerular morphology in wild-type and thymosin-ß4 knockout (Tß4ko) mice. Glomerular disease was also induced in wild-type and Tß4ko mice by administration of nephrotoxic serum. In-vitro, thymosin-ß4 was downregulated by siRNA in differentiated immortalised mouse podocytes. Cell migration and podocyte process number and length were assessed.

Results: Thymosin-ß4 mRNA and protein were highly expressed in developing and adult mouse glomeruli, both in podocytes and endothelial cells. The kidneys of Tß4ko mice had normal renal function and glomerular morphology. Renal thymosin-ß4 expression was upregulated in mice following glomerular injury. Lack of thymosin-ß4 accelerated glomerular disease in mice administered nephrotoxic serum compared with wild-type littermates as demonstrated by significantly increased albuminuria, plasma creatinine, blood urea nitrogen and decreased creatinine clearance. Tß4ko mice also had increased glomerular histological damage, inflammation and fibrosis. In vitro, thymosin-ß4 downregulation increased podocyte migration and average process length.

Conclusions: Our results suggest that although thymosin-ß4 is not essential for glomerular function in healthy mice, it may be critical in glomerular disease. Modulation of thymosin-ß4 may be a novel treatment strategy for renal disease in the future.

FR-PO353

$P2X_7$ Promotes Podocyte Injury in the Experimental Model of Anti-Podocyte Nephritis Catherine Meyer-Schwesinger,[1] Marlies Sachs,[1] Björn Rissiek.[2] *[1]Dept of Internal Medicine, Nephrology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Inst of Immunology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: The $P2X_7$ receptor is a ligand-gated cation channel that is expressed by a variety of immune cells, including macrophages and lymphocytes. Activation of $P2X_7$ leads to an influx of Ca^{2+} ions and to an efflux of K^+ ions. Moreover, $P2X_7$ activation induces the assembly of the NALP3 inflammasome complex resulting in the release of IL-1b. Sustained activation of $P2X_7$ leads to cell death by pore formation. Increased expression of both $P2X_7$ mRNA and protein was reported in mesangial cells and macrophages infiltrating the glomeruli in animal models of antibody-mediated glomerulonephritis. Cultured podocytes were demonstrated to express mRNA of $P2X_7$ and to react to benzoyl ATP, a selective agonist of $P2X_7$. $P2X_7$ could therefore mediate injury in podocytes and could be a potential therapeutic target for podocyte disease.

Methods: $P2X_7$ expression was investigated by WB and by IP in cultured murine podocytes and functional assays were performed to search for effects of a $P2X_7$ activation in podocytes. Additionally, the experimental model of anti-podocyte nephritis was induced in $P2X_7$-deficient mice and $P2X_7$-specific nanobodies were used in wild-type mice to modulate $P2X_7$ function in the course of disease.

Results: $P2X_7$ expression was demonstrated by WB and IP in murine podocytes. Functional assays in cultured podocytes demonstrated that ATP-induced activation of $P2X_7$ increased the intracellular Ca^{2+} concentration and the phosphorylation of Erk1/2 of the MAP-kinase pathway. The course of anti-podocyte nephritis was attenuated in $P2X_7$ deficient mice and in mice treated with $P2X_7$-blocking nanobodies. Disease parameters were aggravated in mice treated with $P2X_7$-enhancing nanobodies. Moreover, histology and Western blot analyses indicated enhanced levels of $P2X_7$ in glomeruli during active APN.

Conclusions: Our results support a pro-inflammatory role for $P2X_7$ in podocyte injury and suggest that the $P2X_7$ receptor is a potential therapeutic target in podocyte damage.

FR-PO354

Studying the Mechanism of Apolipoprotein L1 Nephropathy through Transgenic Zebrafish Opeyemi A. Olabisi,[1,2] Khaldoun Al-Romaih,[2,5] Joel M. Henderson,[4] Ritu Tomar,[1] Iain A. Drummond,[1] Callum MacRae,[3] Martin R. Pollak.[2] *[1]Medicine, Massachusetts General Hospital, Boston, MA; [2]Medicine, Beth Israel Deaconess Medical Center, Boston, MA; [3]Medicine, Brigham and Women's Hospital, Boston, MA; [4]Pathology and Lab Medicine, Boston Univ School of Medicine, Boston, MA; [5]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia.*

Background: Risk variant APOL1 (G1/G2) are strongly associated with a spectrum of kidney disease in people of recent African descent. Mechanism of APOL1 nephropathy is unknown. Podocytes and/or endothelial cells are presumed mediators. Given the close homology between zebrafish (ZF) pronephros and human nephron, we study the effect of podocyte-or endothelium-specific expression of G0, G1, or G2 on the structure and function of ZF pronephros.

Methods: Podocyte-specific and endothelium-specific expression of APOL1 was driven by by podocin and Flk promoters, respectively, using Gal4-UAS system. Structural pronephric changes were studied with light and electron microscopy (EM). Proteinuria was assayed by measuring renal excretion of GFP -vitamin D binding protein. Puromycin aminonucleoside (PAN) was used as inducer of podocyte injury.

Results: Vivo-morpholino knock-down of APOL1-like sequence in ZF (~20% similarity to Hu-APOL1) showed no toxicity when splice blocking morpholino was used at concentrations of up to 0.5mM. Toxicity of translation blocking morpholino was seen, however it was similar to that caused by control-morpholino. Endothelial-specific transgenic expression of G1/G2 is associated with condensed appearing glomeruli on H&E and electron dense subendothelial deposits on EM. Podocyte specific expression of G1 is associated with segmental podocyte foot process effacement and irregularities relative to G0. Expression of G1/G2 alone in podocyte or endothelium is not associated edema or gross whole fish phenotype. Moreover, PAN produced equal pericardial edema in all transgenic fish as well as non-transgenic control.

Conclusions: Transgenic expression of risk variant APOL1 is associated with moderate structural changes in the ZF glomerulus, however, expression alone is insufficient to cause quantifiable functional dysfunction.

Funding: NIDDK Support

BH3 Domain-Independent Apolipoprotein L1 Toxicity Rescued by Bcl2 Pro-Survival Proteins John F. Heneghan, Seth L. Alper, Martin R. Pollak. *Nephrology, Beth Israel Deaconess Med Ctr, Harvard Med School, Boston, MA.*

Background: The APOL1 gene encodes Apolipoprotein L1 (APOL1), an HDL3 component which lyses many pathogenic trypanosomes. However, "serum resistance-associated" protein (SRA) of *T. Brucei rhodesiense* neutralizes APOL1 to foster progression of trypanosomiasis. Expression of APOL1 variant G1 or G2 confers resistance against SRA but elevates kidney disease risk through mechanisms unknown, but previously suggested to include ionophore toxicity or BH3 domain-dependent autophagy.

Methods: We expressed APOL1 in *Xenopus laevis* oocytes from cRNA and noted rapid oocyte degeneration (toxicity). Partial replacement of extracellular Na^+ with K^+ substantially reduced APOL1-associated oocyte toxicity, allowing further investigation. Since APOL1, a BH3-only protein, might be modulated by Bcl2 family members, we expressed APOL1 in oocytes co-injected with cRNA encoding a Bcl2 family member, and documented morphology at 24, 48 and 72 hrs post-cRNA-injection. We measured influxes of $^{45}Ca^{2+}$ and $^{36}Cl^-$, and measured trans-membrane currents by two-electrode voltage clamp.

Results: Co-expression of a Bcl2 family member decreased APOL1-associated oocyte toxicity in the order Mcl1~BclW>BclXL~Bfl1A1>Bcl2. Deletion of 9 core codons from the APOL1 BH3 domain abolished toxicity (as previously reported in HEK-293 cells), but Ala substitution of the same 9 core BH3 codons abolished neither APOL1-associated oocyte toxicity nor its rescue by co-expressed Mcl1. Oocyte influxes of $^{36}Cl^-$ (blocked by DIDS) and of $^{45}Ca^{2+}$ (DIDS-insensitive, blocked by Gd^{3+}, inhibited by Na^+) paralleled in magnitude the severity of APOL1-associated oocyte toxicity, and were accompanied by increased Gd^{3+}-sensitive non-selective currents. Mcl1 coexpression with APOL1 reduced $^{45}Ca^{2+}$ flux and ion current, paralleling morphological rescue of APOL1-associated toxicity.

Conclusions: We propose the BH3-independent toxicity of APOL1 is rescued by Mcl1 and other Bcl2 prosurvival proteins either by an indirect mechanism, or directly via interaction (s) distinct from or only partially overlapping the BH3-binding groove of Bcl2 proteins.

FR-PO356

Cre-Recombinase Toxicity in Podocytes – A New Model for FSGS Kevin Schulte,[1] Madeleine Angela Frahsek,[1] Herdit M. Schüler,[2] Katja Berger,[1] Bart Smeets,[1] Jürgen Floege,[1] Marcus J. Moeller.[1] *[1]Div of Nephrology and Clinical Immunology, Univ Hospital of the RWTH Aachen Univ, Aachen, Germany; [2]Inst of Human Genetics, Univ Hospital of the RWTH Aachen Univ, Aachen, Germany.*

Background: The tetracycline inducible system has become a widely used tool to control gene expression in specific cell populations *in vivo*. Here, we show that inducible expression of Cre-recombinase in podocytes of newborn mice results in cellular toxicity and subsequent focal and segmental glomerulosclerosis (FSGS).

Methods: Transgenic Pod-rtTA/LC1 and PEC-rtTA/LC1 mice overexpress Cre-recombinase in a doxycycline inducible fashion specifically either in podocytes (Pod) or parietal epithelial cells (PEC). Transgenic mice were treated once with doxycyclin shortly after birth (p3) or after completion of nephrogenesis (p10). Kidneys were analysed after 1, 3, 6 and 13 weeks. Karyogram analyses were performed in primary cultures.

Results: In newborn Pod-rtTA/LC1 mice, overexpression of Cre-recombinase induced by administration of doxycyclin resulted in podocyte loss and progressive FSGS in 100% of transgenic Pod-rtTA/LC1 mice. At high doses of doxycycline, FSGS progressed rapidly resulting in premature lethality at the age of 6-8 weeks. Induction at a later time point (p10), or at any time in PEC-rtTA/LC1 or in mice lacking the LC1 transgene had no effect on renal function or histology. Numerous chromosomal aberrations were found in podocytes isolated from Pod-rtTA/LC1 mice treated with doxycyclin on p3, but not in controls.

Conclusions: The Pod-rtTA/LC1 transgenes mediate aberrant Cre-recombination exclusively in newborn mice – most likely because of the increased transcriptional activity of the podocin promoter in early developing podocytes. When induced at birth, the Pod-rtTA transgenic mouse represents a novel and highly reliable model for FSGS in mice.

Common Responses of Glomerular Epithelial Cells in Human Secondary FSGS Lesions Christoph Kuppe,[1] Hermann-Josef Groene,[2] Jürgen Floege,[1] Bart Smeets,[1] Marcus J. Moeller.[1] *[1]Dep. of Internal Medicine II, Div. of Nephrology and Clinical Immunology, RWTH Aachen, Aachen, Germany; [2]Dep. of Cellular and Molecular Pathology, German Cancer Research Center, DKFZ, Heidelberg, Germany.*

Background: Recently, it has been shown that parietal epithelial cells (PECs) are involved in the development of sclerotic lesions in focal and segmental glomerulosclerosis (FSGS). In FSGS, PECs become activated, proliferate, migrate onto the glomerular tuft and deposit extracellular matrix. Here, the role of PECs was investigated in secondary FSGS lesions in different primary glomerular diseases in human biopsies.

Methods: A total of 55 renal biopsies diagnosed as "secondary FSGS" were selected with an average of 13.4 glomeruli (11 systemic lupus erythematosus, 12 diabetic nephropathy, 7 membranous nephropathy, 7 membranoproliferative glomerulonephritis, 11 transplant glomerulonephritis, 2 amyloidosis, 2 Alport, 3 HIV-associated FSGS). One section each per biopsy was quadruple stained by immunofluorescence for: activated PECs (CD44 and CK19), PEC matrix (LKIV69) and nuclei (Hoechst); a second slide was stained for PECs (ANXA-3); podocytes (synaptopodin); PEC matrix (LKIV69) and Hoechst.

Results: Three major response patterns of PEC involvement in FSGS lesions were observed in all disease entities: 1. Early FSGS lesions (cellular adhesions between Bowman's capsule and tuft) were formed by podocytes and/or PECs. 2. PECs were always detected in more advanced FSGS lesions independent of the primary glomerular disease. 3. Proliferative (crescentic) lesions were also observed in all glomerular diseases and consisted of activated PECs. Several early FSGS lesions, which could not be identified on PAS sections yet, were detectable already by IF staining. Podocytes or PECs were absent in globally sclerotic lesions.

Conclusions: PECs are involved in the formation of secondary FSGS lesions independent of the primary glomerular disease.

FR-PO358

Parietal Epithelial Cell Reactions Follow Podocyte Loss in a Spectrum of Glomerular Lesions Astrid Weins,[1] Minna D. Balbas,[5] Marcel Tuecking,[2] Kirk N. Campbell,[3] Charles Sawyers,[4] Peter H. Mundel.[2] *[1]Pathology, BWH, Boston, MA; [2]Medicine, MGH, Boston, MA; [3]Medicine, MSSM, New York, NY; [4]MSKCC, New York, NY; [5]UCSF, San Francisco, CA.*

Background: Parietal epithelial cells (PECs) play an elementary part in the evolution of glomerular lesions in Adriamycin (ADR) nephropathy. We sought to address the question if PEC activation represents a ubiquitous response to podocyte loss independent of the cause of podocyte injury. We examined 2 mouse models of primary podocyte injury: 1) Mice deficient in the podocyte protein CD2AP, an established model of progressive proteinuria and focal segmental glomerulosclerosis (FSGS), and 2) Mice deficient in the scaffolding protein MAGI-2, characterized by slit diaphragm disruption, severe early podocyte loss and nephrotic proteinuria.

Methods: Kidney tissue from CD2AP and MAGI-2 knock out (KO) mice and age-matched controls was analyzed by light and electron microscopy. Glomeruli were studied by immunohistochemistry using antibodies against the podocyte marker synaptopodin (synpo), the PEC marker PAX2, and the proliferation marker KI67.

Results: Analysis of both models revealed a spectrum of distinct non-inflammatory glomerulopathies. The CD2AP KO showed FSGS and rare collapsing lesions by 5 weeks as described. As in the ADR model, KI67- and PAX2-positive, synpo-negative PECs populated the tuft in FSGS and in collapsing lesions. The MAGI-2 KO demonstrated a diffuse collapsing glomerulopathy (CG) at 5.5 weeks, including many glomeruli with extensive cellular crescents. Interestingly, proliferating cells within the crescents were diffusely PAX2 and KI67 positive, indicating they also represented activated PECs. In addition, podocyte loss preceded the formation of all light microscopic glomerular lesions, with the most severe loss seen in the MAGI-2 KO at 4-5 weeks.

Conclusions: Our findings suggest that PECs are activated in response to podocyte loss irrespective of the cause of primary injury, leading to distinct light microscopic patterns. We conclude that the severity or rate of podocyte loss governs the PEC response, resulting in the wide range of glomerular lesions currently included in the podocytopathy spectrum.

FR-PO359

The Glomerular Parietal Epithelial Cell Phenotype Depends on SM22 Alpha Levels Shokichi Naito,[1,2] Jeffrey W. Pippin,[1] Kouju Kamata,[2] Stuart J. Shankland.[1] *[1]Nephrology, Univ of Washington, Seattle, WA; [2]Nephrology, Kitasato Univ School of Medical Sciences, Sagamihara, Kanagawa, Japan.*

Background: Reduced podocyte number underlies proteinuria and glomerulosclerosis. Studies suggest glomerular parietal epithelial cells (PECs) are podocyte progenitors. Others show PEC epithelial-to-mesenchymal transition (EMT) associated with crescent formation, and a proliferative phenotype. We have shown that SM22a, an actin-binding protein considered a marker of smooth muscle differentiation, is upregulated in PECs in experimental glomerular models of podocyte injury. The purpose of this study was to investigate the role of SM22a in PECs transition and EMT.

Methods: Experimental glomerular disease was induced in SM22a +/+ and -/- mice by intraperitoneal injection of sheep anti-rabbit glomeruli antibody, and studies on days 7 and 14. Immunohistochemistry was used to determine PEC transition, defined as cells lining

Bowman's capsule co-expressing a podocyte (synaptopodin) and PEC (PAX2) protein, or NCAM (progenitor cells marker). Vimentin and a-smooth muscle actin were used as EMT markers. Podocyte number (WT-1) and proliferation (Ki-67) were also measured.

Results: The number of podocyte progenitors, defined as cells expressing both a PECs protein and a podocyte protein, and NCAM+ progenitor cells was significantly increased in diseased SM22a -/- mice lining Bowman's capsule (P<0.01 versus SM22a +/+) and in the tuft (P<0.01 versus SM22a +/+). Conversely, immunostaining for the EMT markers vimentin and a-smooth muscle actin were reduced in PECs in diseased SM22a -/- mice (P<0.05 versus SM22a +/+).

Conclusions: These data suggested that SM22a may inhibit PECs transition and augment EMT.

ARB, But Not Nonspecific Antihypertensive Drugs, Promotes Survival and Parietal Epithelial Cell to Podocyte Transition in 5/6 Nephrectomy Rats

Xuejing Zhu,[1,2] Haichun Yang,[2] Agnes B. Fogo.[2] *[1]Nephrology, Second Xiangya Hospital, Central South Univ, Changsha, Hunan, China; [2]Pathology, Microbiology and Immunology, Vanderbilt Univ, Nashville, TN.*

Background: We previously found that angiotensin receptor blocker (ARB) could regress existing sclerosis in short term, but not in long term follow-up in 5/6 nephrectomy (Nx) rats. ARB also prolonged the survival time in this model. We now further investigated whether ARB effects are blood pressure-dependent and effects on parietal epithelial cell (PECs)-podocyte transition.

Methods: Adult male Sprague Dawley rats underwent 5/6 Nx. Glomerular sclerosis index (SI, 0-4 scale) was assessed by renal biopsy (Bx) at 8 weeks. Rats were then divided into three groups with equal average systolic blood pressure (SBP), 24-h urinary protein (Uprot) and SI, and treated with high dose losartan (ARB, n=20), triple-therapy (hydralazine, reserpine, HCTZ, TRX, n=20) or no treatment (CONT, n=21) till 30 wks after 5/6 Nx.

Results: Both ARB and triple-therapy lowered SBP, but only ARB reduced proteinuria and increased survival rate when compared with control (median survival time ARB 27.1, TRX 25.0 and CONT 19.7 wks). Serum creatinine levels and glomerulosclerosis were similarly improved with ARB and TRX versus control (SI: ARB 2.37±0.19, TRX 2.28±0.11 versus CONT 2.88±0.15, p<0.05). ARB maintained density of WT1-positive podocytes, while TRX did not preserve podocytes (ARB 311.39±31.18, versus TRX 145.23±20.07 and CONT 139.28±18 N/mm^2, p<0.05). In parallel, there were more double CD44 and synaptopodin positive cells in the tuft area after ARB treatment than TRX and control (ARB 0.44±0.01, versus TRX 0.17±0.01 and CONT 0.13±0.01/glomeruli, p<0.05).

Conclusions: We conclude that both ARB and triple-therapy reduce glomerulosclerosis. However, ARB, but not triple-therapy, has survival benefit and podocyte protection. We further speculate that ARB has beneficial effects on permeability functions to enhance survival in the uremic environment.

FR-PO361

Soluble Urokinase Receptor and HIV-Associated Podocyte Dysfunction

Shikha Wadhwani,[1] Mehmet M. Altintas,[1] Audrey French,[1,2] Jochen Reiser.[1] *[1]Internal Medicine, Rush Univ Medical Center, Chicago, IL; [2]Infectious Diseases, CORE Center/Stroger Hospital of Cook County, Chicago, IL.*

Background: Soluble urokinase receptor (suPAR) is a circulating factor that can become pathological when serum or urine levels increase, or if particular subtypes are present. In some patients, this leads to heightened podocyte avb3 integrin activation—causing foot process effacement, proteinuria, and initiation of early FSGS pathology. Because commercial ELISAs do not recognize all suPAR types, we developed cellular assays to decipher which suPAR-containing samples specifically lead to podocyte dysfunction. This comprehensive suPAR testing method was used to study suPAR's role in HIV-associated podocyte dysfunction, given its resemblance to FSGS.

Methods: suPAR was measured in urine and serum samples from 202 women (eGFR>30) enrolled in the Chicago Women's Interagency HIV Study. Selected HIV+ samples with elevated suPAR were then tested for podocyte avb3 integrin activation (detected by AP5 antibody). Differentiated human podocytes were treated with patient serum or urine, and IF staining was used to test for avb3 activation. High-throughput fluorescence microscopy (Opera LX) provided a novel, quantitative measurement of AP5/Paxillin intensity.

Results: Mean serum suPAR was 4872 pg/ml and 3775 pg/ml in HIV+ (n=172) and HIV- (n=30) patients respectively (p =0.005). Mean urinary suPAR/Cr was 4572 pg/mg and 2520 pg/mg for HIV+ and HIV- patients respectively (p <0.001). Significantly higher suPAR levels were seen in HIV+ patients even after adjusting for age, race, eGFR, and urine ACR. In the subset of serum and urine samples tested for avb3 integrin activation, significantly higher AP5/Paxillin intensities were noted in HIV+ patients, with activity localized to focal adhesions.

Conclusions: Serum and urine suPAR levels are significantly higher in HIV+ compared to HIV- individuals. Elevated suPAR levels coupled with podocyte integrin activation suggest functional similarity between FSGS and podocyte dysfunction in HIV. Since suPAR can partly be removed by plasmapheresis, there may be an avenue for improved therapies for early HIV-podocytopathy owing to this activated suPAR-avb3 integrin axis.

FR-PO362

HIV Genes-Induced Disparate Effects during the Initiation and Progression of HIV-Associated Nephropathy (HIVAN) Are Mediated through Vitamin D Receptor

Xiqian Lan,[1] Guohua Ding,[2] Ashwani Malhotra,[1] Praveen N. Chander,[3] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Gret Neck, NY; [2]Medicine, Renmin Hospital of Wuhan Univ, Wuhan, China; [3]Pathology, New York Medical College, Valhalla, NY.*

Background: Since angiotensinogen (Agt) is the substrate for renin, we hypothesized that mice with enhanced expression of Agt would display accelerated progression of HIVAN. We evaluated the effect of different copies of Agt in the initiation and progression of HIVAN in genetically engineered HIVAN mice (Tg26).

Methods: Control and Tg26 mice with 2 (Tg26/Agt-2) and 4 (Tg26/Agt-4) copies of Agt were evaluated for severity of renal lesions, arteriosclerosis and hypertension at 8 weeks and 16 weeks. Renal cortical sections were stained with sirus red and PAS. RNA was extracted from renal tissues and probed for AT1, AT2, PAI-1, VDR and molecules involved in Tert and epithelial mesenchymal transition (EMT) pathways.

Results: Tg26/Agt-4/8wks showed lower blood pressure (P<0.01) versus Tg26/Agt-2/8 wks. While Tg26/Agt-4/16wks displayed higher blood pressure versus Tg26/Agt-2/16wks. Tg26/Agt-4/8wks displayed attenuated expression of PAI-1 versus Tg26/Agt-2/8wks; however, Tg26/Agt-4/16wks showed 3-fold greater PAI-1 expression than to Tg26/Agt-2/16wks. Tg26/Agt-2/8wks displayed attenuated expression VDR and enhanced production of Ang II versus Tg26/Agt-4/8wks, however this pattern reversed at 16 wks. Tg26/Agt-4/8wks displayed attenuated expression of AT1 and AT2 and down regulation of Tert, TGF-β, Snail, and vimentin when compared to Tg26/Agt-2/8wks. However, all these markers were comparable between these groups at 16 wks of age. Tg26/Agt-2/8wks developed renal lesions which were more advanced than Tg26/Agt-4/8wks. Conversely, Tg26/Agt-4/16wks displayed more advanced renal lesions versus Tg26/Agt-2/16wks.

Conclusions: Tg26/Agt-4 displayed slowed progression of HIVAN at early time periods associated with enhanced renal tissue VDR expression and attenuated expression of AT1, TGB-b, PAI-1, Tert and EMT markers. However, Tg26/Agt-4 at 16 wks displayed accelerated growth possibly due to attenuated VDR expression, high blood pressure and upregulation of EMT and profibrotic molecules with ageing.

HIV-Induced Kidney Cell Renin Generation Enhances Kidney Cell HIV Gene Expression

Mohammad Husain,[1] Partab Rai,[1] Rivka Lederman,[1] Nirupama Chandel,[1] Guohua Ding,[2] Ashwani Malhotra,[1] Praveen N. Chander,[3] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Renmin Hospital of Wuhan Univ, Wuhan, China; [3]Pathology, New York Medical College, Valhalla, NY.*

Background: The activation of renin -angiotensin system has been demonstrated to play an important role for the development and the progression of HIV-associated nephropathy (HIVAN). However, the involved mechanism is far from clear. Recently, HIV has been demonstrated to stimulate renin generation by kidney cells *in vitro* studies. Moreover, we observed that renin directly enhances HIV replication in T cells (another **submisstion** to ASN). We hypothesized that HIV-induced kidney cell renin production might also be enhancing kidney cell HIV gene expression.

Methods: Immortalized differentiated human podocytes (IDHP) were trandudced with either empty vector (EV/IDHP) or HIV (NL4-3, HIV/IDHP). To increase endogenous renin production, EV/IDHPs and HIV/IDHPs were transfected with siRNA vitamin D receptor (siRNAVDR/HIV/IDHPs) or scrambled (Scr-siRNA/HIV/IDHP) siRNA. Protein blots were probed for renin and actin. To evaluate the effect of renin *in vivo*, mRNA expressions of HIV genes from renal tissues of HIVAN mice with high endogenous renin (genetically engineered Tg26 mice either with 2, 3 and 4 copies of angiotensinogen [Agt] or lacking VDR) were quantified by qPCR. To downregulate renal tissue renin expression, Tg26 mice were treated with either vehicle or a VDR agonist (VDA) for 2 weeks and then renal tissues were evaluated for HIV gene expression.

Results: HIV enhanced renin expression in human podocytes. Silencing of VDR in HIV/IDHPs further enhanced expression of Nef, Tat, and Vif. On the other hand, treatment of HIV/IDHPs with VDA downregulated HIV gene expression. Renal tissues of Tg26-Agt-4 displayed 2-4 fold increase in mRNA expression of gp120, Vpr, Tat, Nef and Vpu versus Tg26-Agt-2. Similarly, Tg26 mice lacking VDR displayed greater HIV gene expression when compared with wild type Tg26 mice. Moreover, VDA treatment of Tg26 downregulated renal tissue expression of HIV genes.

Conclusions: HIV-induced kidney cell renin generation enhances HIV gene transcription both *in vitro* and *in vivo*.

FR-PO364

Metformin Slows Down the Progression of HIV-Associated Nephropathy (HIVAN) through Down Regulation of Mammalian Target of Rapamycin (mTOR) Pathway

Mohammad Husain, Xiqian Lan, Partab Rai, Kartikeya Kashyap, Rivka Lederman, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: The mTOR pathway has been reported to play an important role in the development of renal lesions in patients with HIV infection. Since patients with HIV infection are now living almost a normal life style including the development of metabolic

syndrome. we hypothesized that use of metformin in this population would not only control insulin resistance but would also slow down the progression of kidney lesions related to HIV-associated nephropathy. To test our hypothesis, we studied the effect of meformin on the progression of renal lesions in a mouse model of HIVAN (doxycycline-inducible Vpr [podocyte specific] transgenic mice).

Methods: Vpr mice in groups of eight were fed either doxycycline with or without metformin for six weeks followed by evaluation for renal biomarkers (Blood urea nitrogen, urine protein:creatinine ratio, grading of severity of renal lesions and immunoblotting for phospho-mTOR and down stream molecular markers). In *in vitro* studies, mouse proximal tubular epithelial cells (MPTECs) were transduced with either empty vector (EV) or NL4-3 without *gag* and *pol* (HIV). EV/MPTECs or HIV/MPTECs were incubated in media containing either buffer or metfromin (0.5mM) for 48h. Protein blots of EV/MPTECs and HIV/MPTECs were probed for phospho-mTOR, phospho-p70S6 kinase, phospho-eEF2, p-eIF4B, and p-4EBP-1. The same blots were stripped and reprobed for actin.

Results: Vpr mice displayed sclerotic glomerular lesions, microcyst formation, proteinuria and activation of mTOR pathway; metformin not only attenuated proteinuria but also decreased severity of renal lesions. Moreover, metformin downregualed activation of the mTOR pathway. In vitro studies, protein blots of HIV/MPTEC displayed 2-fold increase in phospho-mTOR, 2.5-fold increase in phospho-p70S6K, and 2-fold increase both in p-eIF4B and p-4EBP-1when compared to EV/MPTECs. On the other hand, metformin inhibited HIV-induced mTOR phosphorylation and associated down stream signaling.

Conclusions: Metformin slows down the progression of HIVAN through down regulation of mTOR pathway.

FR-PO365

Transmembrane Protein 14A Is Involved in the Development of Proteinuria

Ramzi Khalil,[1] Reshma Lalai,[1] Rosalie Bor,[1] Reinhold Kreutz,[2] Emile De Heer,[1] Jan A. Bruijn,[1] Hans J. Baelde.[1] *[1]Pathology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Inst of Clinical Pharmacology and Toxicology, Charité - Univ Medicine, Berlin, Germany.*

Background: Proteinuria is an independent risk factor for cardiovascular mortality and progression of renal disease. To understand the underlying mechanism and find potential targets for treatment, identifying and investigating genes suspected of playing a role in the proteinuric pathway is required. Our group has previously performed a microarray experiment in spontaneously proteinuric Dahl SS rats. In this experiment, transmembrane protein 14A (TMEM14A) mRNA was found to be differentially expressed. Little is known of this gene and the protein it encodes. In this study, we have investigated whether blocking TMEM14A mRNA translation results in proteinuria.

Methods: Zebrafish (Danio rerio, ABTL strain) embryos were injected with a morpholino targeting zgc:163080, the zebrafish homologue of TMEM14A, during the one- to four-cell stage of embryonic development. Proteinuria was measured by intravenously injecting a mixture of dextran tracers at 4 days past fertilization (dpf). After fixing, embedding and sectioning, fluorescent microscopy was used to investigate tubular reabsorption of the dextran tracers that have passed the glomerular filtration barrier. Results were quantified by comparing the mean amount of 70kD droplets with an independent samples t-test.

Results: TMEM14A mRNA was significantly downregulated in Dahl SS rats. Morpholino injected zebrafish showed developmental defects and displayed a significantly ($p<0.05$) higher amount of 70kD droplets in the tubular epithelial cells compared to wildtype zebrafish embryos.

Conclusions: The higher amount of 70kD droplets in the tubular epithelial cells of the morpholino injected zebrafish indicates that their glomerular filtration barrier is more permeable to 70kD particles than in the control group. This indicates that blocking translation of zgc:163080 results in proteinuria. These results, taken together with our previous results from the microarray experiment in spontaneously proteinuric rats, strongly imply a role for TMEM14A in the development of proteinuria and warrant further research into its function.

FR-PO366

Intracellular Transcytosis and Exocytosis of Albumin in Human Glomerular Endothelial Cells

Takahito Moriyama, Keiko Uchida, Ken Tsuchiya, Kosaku Nitta. *Dept of Medicine, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: We have been reported the albumin endocytosis through caveolae into human glomerular endothelial cells (HRGEC) as a new pathway of albumin through HRGEC in addition to fenestrae, and its pathway may be recognized as the new mechanism of albuminuria. This study is the next step to show intracellular trafficking pathway and exocytosis of albumin in HRGEC after caveolar endocytosis.

Methods: HRGEC were incubated with Alexa Fluor 488 labeled bovine serum albumin (BSA) for 0.25, 0.5, 1, 2, 4, and 6 hours. Then immunofluorescence study was performed by using golgi zone as the Golgi apparatus marker, LANP2 as the lysosome marker, PDI as the endoplasmic reticulum (ER) marker, AE-8 as the microtubules marker, and anti actin antibody. HRGEC were also incubated with the immune gold labeled BSA for 15 and 30 minutes, and ultrastructural pathological study by electron microscope was performed.

Results: Alexa Fluor 488 labeled BSA were not co-localized with any marker of organelle, such as golgi body, lysosome and ER. Labeled BSA were also not co-localized with cytoskeletons, such as actin and microtubules. The intensity of colocalized BSA with any organelle and cytoskeletons were significantly lower than that with Caveolin-1, which was a main component of caveolae. In ultrastructual pathological study, gold labeled BSA were clearly observed to enter into HRGEC through caveolae. Caveolae were pinched off and detached from cell membrane. BSA particles coated with cavelae were transported through HRGEC without dropping on any organelle and cytoskeletons, and finally excreted to the other side of HRGEC.

Conclusions: We have shown transcytosis and exocytosis of albumin coated with caveolae through HRGEC was independent from the Golgi apparatus, lysosome, ER, actin and microtubules. Albumin was entered into HRGEC through caveolae form capillary lumen, caveolae coated pits include albumin were transported through HRGEC to the other side of cells and excreted to sub-endothelial space. This is the new caveolae dependent pathway of albumin through HRGEC and may become new pathogenesis of albuminuria independent from fenestrae.

FR-PO367

Ubiquitin-Specific Protease 2-69 Antagonizes Glomerulonephritis by Stabilizing Decorin

Huijuan Wu, Xing Mao, Weili Luo, Jianyong Sun, Zhigang Zhang. *Pathology, School of Basic Medical Sciences, Shanghai, China.*

Background: Decorin (DCN) is a well-known anti-sclerosis factor in kidney diseases because it inhibits mesangial cell (MC) proliferation and neutralizes the effect of TGF-β1. Our previous studies have shown that DCN is degraded by ubiquitin-proteasome pathway which can be reversed by deubiquitinases. However, no deubiquitinase related to DCN was reported. USP2-69, a recently found deubiquitinase, is implicated in the regulation of cell proliferation in cancer and highly expresses in kidney, but its deubiquitinated effect on DCN and role in glomerulonephritis (GN) have not yet been explored.

Methods: Firstly, we detected the interaction between USP2-69 and DCN. After overexpressed or silenced USP2-69 in rat MCs, ubiquitination of DCN, half-life of DCN and expression of collagen IV and TGF-β1 were examined. Then we examined USP2-69 and DCN in MCs treated with TGF-β1, TNF-a or PDGF-BB for 3h to 36h and in human GN such as MCD, IgA (type MsPGN) and LN (type IV). In addition, we transfected USP2-69-HA plasmid into the left kidney of rat anti-thy1.1 GN by using electroporation-mediated gene transfer via renal artery, and then the renal morphology was examined by H&E and PAS, expressions of PCNA, collagen IV, fibronectin and TGF-β1 were detected in both left and right kidneys.

Results: A novel physical interaction between USP2-69 and DCN was found. Overexpression of USP2-69 resulted in decreased ubiquitination and prolonged half-life of DCN and decreased collagen IV and TGF-β1, which was opposite after USP2-69 interference. Stimulation of TGF-β1, TNF-a or PDGF-BB led to a same decreased trend of USP2-69 and DCN. Both of USP2-69 and DCN expression increased in human IgA and LN compared to MCD. In anti-thy1.1 model transfected with USP2-69-HA plasmid, HA positive staining was detected in glomeruli, less cell proliferation and matrix was observed and decreased PCNA, collegen IV, fibronectin and TGF-β1 was examined in the left kidney compared to the right one.

Conclusions: This study showed that USP2-69 deubiquininated DCN specifically and antagonized GN in anti-thy1.1 model, indicating that USP2-69 is an effective approach targeting DCN for against glomerular sclerosis.

FR-PO368

Nuclear Translocation of Dendrin in IgA Nephropathy

Julia Wijkström,[1] Jenny Hulkko,[1] Liqun He,[2] Anna Levin,[1] Peter F. Barany,[1] Jaakko Patrakka,[3] Kjell R. Hultenby,[4] Annika Wernerson.[1] *[1]CLINTEC, Karolinska Instt; [2]IGP, Uppsala Univ; [3]MBB, Karolinska Instt; [4]LABMED, Karolinska Instt.*

Background: Dendrin is an 81-kD protein localized in the podocyte slit diaphragm. Recent studies have focused on the proteins pro-apoptotic signaling properties, and its accumulation in the podocyte nucleus in response to glomerular injury. With recent findings of an increased occurrence of dendrin-positive podocyte nuclei in IgA nephropathy (IgAN), we analyzed glomerular gene and protein expression of dendrin in renal biopsies from patients with IgAN and membranous nephropathy (MN).

Methods: Microarray was performed on the glomerular fraction of kidney biopsies from patients with IgAN (n=30), MN (n=5) and normal renal tissue (n=20). Podocytic dendrin expression was studied by iEM, on kidney biopsies from patients with IgAN with or without nephrosis (n=4 and n=5, respectively), MN (n=3) and normal renal tissue (n=5). The primary antibody was detected by gold-conjugated protein A and semi-quantification was performed.

Results: Gene expression analysis revealed a 2.01 fold significant up regulation of dendrin expression in IgAN compared to controls. In MN, gene expression of dendrin was not significantly changed. Dendrin was significantly increased in the podocytes nuclei in both IgAN, with and without nephrosis (0.9 ± 0.0 and 0.9 ± 0.2, respectively) compared to controls (0.4 ± 0.1). The increase of dendrin was also seen in the podocytes cytoplasm of IgAN with nephrosis (3.0 ± 0.6) compared to controls (1.5 ± 0.6). The amount of dendrin in MN was unchanged both in the podocytes nuclei (0.2 ± 0.1) and the cytoplasm (1.1 ± 0.3).

Conclusions: Our data demonstrates a two fold up regulation of dendrin gene expression in IgAN and a corresponding increase in podocytic protein expression. The increase in nuclear protein expression was not correlated to the degree of proteinuria. In MN, on the other hand both gene- and protein expression were unchanged. Our results supports the hypothesis that dendrin is translocated into the podocytic nuclei in IgAN. This may induce apoptosis and chronic glomerular injury, e.g. capsular adherences.

C4d Deposits Are Associated with Thrombotic Microangiopathy in IgA Nephropathy and Mark a Poor Renal Function Jamie S. Chua,[1] Malu Zandbergen,[1] Johan W. De Fijter,[2] Ron Wolterbeek,[3] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, LUMC, Leiden, Netherlands; [2]Nephrology, LUMC, Leiden, Netherlands; [3]Medical Statistics and Bio-Informatics, LUMC, Leiden, Netherlands.*

Background: Complement deposits such as C4d and MBL can be found in 25% of patients with IgA nephropathy (IgAN), the most prevalent primary chronic glomerular disease worldwide (Wyatt et al, NEJM 2013). We previously demonstrated that C4d marks thrombotic microangiopathy (TMA) in native biopsies with lupus nephritis. We hypothesized that C4d marks TMA in native biopsies with IgAN and that both C4d and TMA are clinically significant markers of poor renal function.

Methods: In this single center study, 132 native renal biopsies diagnosed with IgAN from 2003-2013 were included, of which 108 were previously diagnosed with IgAN and 24 with Henoch-Schönlein nephritis (HSN). Biopsies were re-evaluated according to the Oxford Classification for IgAN. Additional scored histologic parameters were: arterial intimal sclerosis, arteriolar hyalinosis and TMA (presence, localization and chronicity). C4d was scored in glomeruli (<25% or >25% of all glomeruli), in peritubular capillaries (Banff '07 criteria) and in arterioles (absent or present). Demographics and clinical data were collected retrospectively from medical records, and included blood pressure, history of hypertension and renal function.

Results: TMA was present in 27 biopsies (21%). TMA lesions were mainly chronic (67%) and mainly present in arterioles (85%). C4d staining was available for 126 biopsies and was associated with TMA ($p<0.001$). Glomerular and arteriolar C4d deposits were present in 15% and 13% of all biopsies respectively. C4d was absent in the peritubular capillaries of all biopsies. Biopsies with both TMA and C4d had significantly more E1 and higher T scores ($p<0.05$), whereas biopsies without TMA and without C4d had significantly less S1 scores ($p<0.05$). Patients with both C4d and TMA had significantly more frequently hypertension ($p<0.05$) and a significantly lower eGFR (30.6 ml/min/1.73m2) compared to TMA only (59.8), C4d only (48.2) or neither (74.9 $p<0.05$).

Conclusions: C4d is associated with TMA in IgAN and both C4d and TMA are clinically significant markers of a poor renal function.

FR-PO370

Gene Expression Analysis of the Renal Lesions in IgA Nephropathy. A Multicenter Study Claudia Curci,[1] Fabio Sallustio,[1] Grazia Serino,[1] Mirko Trpevski,[1] Francesco Pesce,[1] M. Rossini,[2] Mario Bonomini,[3] Vittorio Sirolli,[3] Paolo Felaco,[3] Giuseppe Lattanzio,[3] Gianluigi Zaza,[4] Antonio Lupo,[4] Isabella Squarzoni,[4] Patrizia Bernich,[4] Concetta Gangemi,[4] Francesco Paolo Schena.[1] *[1]C.A.R.S.O. Consortium; [2]Univ of Bari; [3]Univ of Chieti; [4]Univ of Verona.*

Background: The diagnosis of idiopathic IgA Neprhopathy (IgAN) may be based on two type of histomorphological classification. The "lumped system" (Schena classification, 2005) identify three grades (G) of severity. The "split system" (Oxford MEST classification, 2009) is based on 4 types of lesions: Mesangial hypercellularity (M 0-1), Endocapillary hypercellularity (E 0-1), Segmental glomerulosclerosis (S 0-1) and Tubular atrophy/interstitial fibrosis (T 0-2). Aim of our study was to elucidate the molecular changes that happen in the renal lesions at the time of biopsy.

Methods: We obtained total RNA from archival FFPE renal tissue samples of 34 IgAN, 24 non-IgAN patients (MCD 12, MGN 12) and 6 kidney living donors (KLD, as normal controls). Genome-wide expression profiles were generated by Illumina platform. Real Time PCR was used for validation of the identified transcripts.

Results: The principal component analysis showed that 152 transcripts partially separated IgAN renal biopsies from non-IgAN, while 107 transcripts clearly separated IgAN from KLD. We identified 28 genes exclusively modulated in IgAN biopsies. These genes belonged to apoptotic processes, renal cellular damage and immune system regulatory pathways. We identified genes were differentially modulatedthe different degrees of severity (G1-3). Finally, we differentiated the gene expression profiles of the 4 MEST lesions and identified specific gene clusters for each lesion. We have validated the candidate transcripts by qRT-PCR in anothere independent cohort of 35 IgAN biopsies.

Conclusions: Transcriptomics on FFPE renal biopsies offer the possibility to integrate genomics and histomorphologic renal lesions. Our study the involvement of specific gene pathways that are responsible for the development of MEST lesions in IgAN. This novel type of information has identify some gene classifiers that may be considered for target therapy.

Enhanced Glomerular Neutrophil Chemoattractants Expression in Experimental ANCA Associated Vasculitis Go Kanzaki, Shinya Nagasaka, Seiichiro Higo, Yusuke Kajimoto, Kiyotaka Nagahama, Yukinari Masuda, Akira Shimizu. *Analytic Human Pathology, Nippon Medical School, Tokyo, Japan.*

Background: ANCA-neutrophil and neutrophil-endothelial cell interactions play an important role in the pathogenesis of ANCA-associated vasculitis (AAV). However, the mechanisms underlying the pathogenesis of crescent formation in AAV have not been completely elucidated. To unveil an involvement of these interactions in necrotizing crescentic glomerulonephritis (NCGN), we used an AAV rat model and investigated the effects of MPO, TNF-a, G-CSF, or subnephritogenic anti-GBM antibodies (Ab), as a pro-inflammatory stimulus.

Methods: NCGN was induced in WKY rat by immunization with human MPO (hMPO; 1600 μg/kg). Blood and urine samples were obtained at 8 weeks. NCGN was evaluated by renal histopathology. Furthermore, we examined whether the pro-inflammatory stimulus induced NETs in crescent formation in AAV rat model. At 8 weeks after NCGN induction, the expression of cytokines and adhesion molecules in isolated glomeruli were analysed by quantitative RT-PCR.

Results: Hematuria were noted from 4 weeks. The hMPO-immunized rats had serum anti-hMPO antibody titers of 1:10000 by ELISA. We demonstrated that the induced anti-hMPO antibodies cross-reacted with TNF-a or G-CSF primed rat neutrophils inducing IL-1b in vitro. Crescent formation with NETs in the AAV rat model is dramatically enhanced by the subnephritogenic anti-GBM Ab, whereas not significantly enhanced by the administration of TNF-a or G-CSF. AAV rats injected with the subnephritogenic anti-GBM Ab elevated serum TNF-a and IL-1b level with mild renal failure. TNF-a, CXCL-1, and CXCL-2, which are mainly involved in neutrophil-endothelial interactions, were induced or up-regulated in NCGN.

Conclusions: Although neutrophil stimulation by ANCA can trigger pro-inflammatory cytokines, neutrophil migration into glomerulus by the proinflammatory chemokines after exposure to ANCA might be necessary to develop NCGN with NETs in AAV.

FR-PO372

Structural Analysis of a New Epitope Causing Experimental Autoimmune Glomerulonephritis (EAG) in Rats Jitendra K. Gautam,[1] Palak D. Shah,[2] Kline Bolton.[1] *[1]Dept of Medicine, Div. of Nephrology/CIIR, Univ of Virginia (UVA) HS; [2]College of Arts and Science, UVA, Charlottesville, VA.*

Background: The a_3 (IV) NC1 domain causes Goodpasture's syndrome (GPS) in humans and similar disease in rats, EAG. We have shown that an immunodominant pure T cell epitope, p13, that induces EAG, is frequently associated with intra-and-intermolecular antibody (Ab) B cell epitope spreading along the a_3 (IV) NC1 and the a_4 (IV) NC1chains. Several other peptides can induce EAG, and EAG can be transferred by T cells. In our reported screen of 22 overlapping peptides, each 20 amino acids long, one peptide Col_131-150, induced severe EAG (JASN 24, 2013 FR-PO563). Cathepsin D cleavage sites are present within this region of a_3 (IV) NC1 and normal humans harbor autoreactive T cells reacting to the same region (JASN 19:396-404, 2008). This region has also been shown to be important for EAG in a humanized mouse model (JASN 24: 419-431, 2013).

Methods: In this study we used a structural biologic approach to visualize the 22 overlapping peptides in the 3D structure of a3 (IV) NC1 in reference to Cathepsin D cleavage sites. We used SWISS-MODEL (http://swissmodel.expasy.org/) to model human a3 (IV) NC1 based on related PDB 1T60 (JBC 279 (43):44723-30, 2004). Web Lab Viewer Pro was used for surface visualization.

Results: We assessed each peptide surface within the a3 (IV) NC1 structure for overall exposure and accessibility for Cathepsin D cleavage. Peptides varied in their surface accessibility of Cathepsin D sites. Peptide Col_131-150 partially overlapped with the well described surface exposed EB Ab epitope. The rest of the peptide was found to be buried inside rendering it inaccessible from the surface. The cryptic region also includes the reported Cathepsin D sites. Exposure of this cryptic site could play a role not only in the development of EAG and GPS, but also in augmentation of the disease phenotype.

Conclusions: A better understanding of the structural basis of this molecular epitope exposure and release, and its correlation with clinical and immunological data of GPS could enhance our understanding of disease pathogenesis. It may also help us design antigen specific therapeutic interventions.

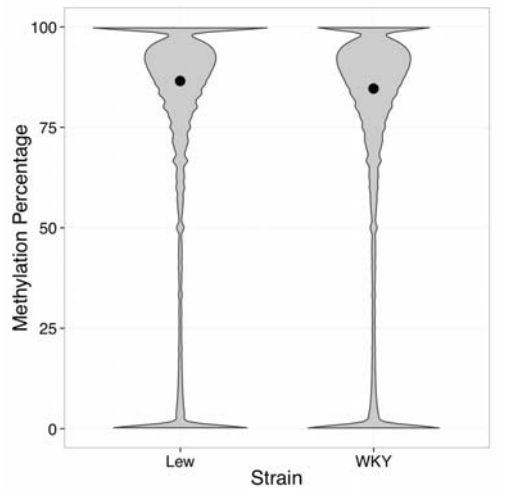
The Role of DNA Methylation in a Rat Model of Crescentic Glomerulonephritis Thomas M. Oates,[1] Michael Mueller,[2] Charles D. Pusey,[2] H. Terence Cook,[2] Enrico Petretto.[1] *[1]MRC Clinical Sciences Centre, London, United Kingdom; [2]Imperial College London, London, United Kingdom.*

Background: The Wistar-Kyoto (WKY) rat is susceptible to crescentic glomerulonephritis (CRGN), whilst the Lewis (LEW) rat is resistant, making this a useful model to study underlying disease mechanisms. Previous work has implicated macrophages in CRGN and defined some of the genetic determinants underlying CRGN susceptibility. Recent data has linked epigenetic modifications to macrophage activation and autoimmune disease. Therefore, we hypothesized that variation in DNA methylation in macrophages could contribute to susceptibility to glomerulonephritis in the WKY rat.

Methods: Fragmented DNA libraries from WKY and LEW bone marrow-derived macrophages (BMDMs; 4 biological replicates/strain) were subject to whole genome shotgun bisulfite sequencing using an Illumina HiSeq 2000. Multiplexed PCR sequencing was used to verify whole genome methylation signatures at CpG dinucleotides. Bioinformatic analysis of bisulfite sequencing, histone and transcription factor binding site data was used to explore the interaction of methylation and gene regulatory sequences.

Results: Approximately 15 million CpG dinucleotides were analyzed. WKY BMDMs were generally less methylated than LEW ($P<2.2x10^{-16}$; Wilcoxon rank sum test).



More than 13,000 CpG dinucleotides were differentially methylated between the two strains and 70.5% of these were >5 kilobases from genes. As a result, we investigated the relationship to distant gene regulatory sequences. Our analyses suggested that differentially methylated CpGs were enriched at gene enhancer elements and at binding sites of transcription factors of functional importance in macrophage biology.

Conclusions: These data reveal an association between DNA methylation and susceptibility to CRGN and highlight macrophage genes and gene regulatory elements that could underlie this association.

Toll-Like Receptor 8 Contributes to Podocyte Injury in Murine Autoimmune Glomerulonephritis Junpei Kimura,[1] Osamu Ichii,[1] Teppei Nakamura,[1,2] Taro Horino,[3] Saori Otsuka,[1] Yasuhiro Kon.[1] *[1]Laboratory of Anatomy, Dept of Biomedical Sciences, Graduate School of Veterinary Medicine, Hokkaido Univ, Sapporo, Japan; [2]Chitose Laboratory, Japan Food Research Laboratories, Chitose, Japan; [3]Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi Univ, Nankoku, Japan.*

Background: Glomerulonephritis (GN) is a major cause of chronic kidney disease. Recent studies have revealed that the Toll-like receptor (TLR) family plays a central role in local autoimmune response as well as pathogen sensing; however, the contribution of TLRs to GN progression remains unknown. In the present study, we investigated glomerular injury and expression of TLRs and their downstream factors using a murine model for autoimmune GN.

Methods: BXSB/MpJ-*Yaa* (BXSB-*Yaa*) and BXSB/MpJ mice were used as models of autoimmune GN and healthy controls, respectively. Glomerular histopathology and urinary albumin creatinine ratio (uACR) were evaluated. Glomerular expression levels of the TLR family, downstream factors, and glomerular functional factors were determined using isolated glomeruli. TLR8 protein and mRNA were localized using immunohistochemistry (IHC) and in situ hybridization (ISH), respectively. The serum and glomerular levels of miR-21, a candidate ligand of TLR8, were determined.

Results: BXSB-*Yaa* developed membranoproliferative GN and increased uACRs compared to controls. The glomerular expression levels of TLR-family genes (*Tlr1*, *2*, *7*, *8*, *9*, and *13*) and downstream factors (*Il1b*, *Il6*, and *Tnfa*) were significantly higher in BXSB-*Yaa* mice than in controls; *Tlr8* expression was particularly increased (107-fold), and both TLR8 protein and mRNA were localized to podocytes. The glomerular expression levels of podocyte functional markers (*Actn4*, *Cd2ap*, *Myh9*, *Nphs1*, *Nphs2*, *Podxl*, and *Synpo*) were significantly lower in BXSB-*Yaa* mice than in controls. The glomerular expression levels of *Tlr8* were significantly correlated with both those of podocyte functional markers and uACRs. The serum and glomerular mi-R21 expression levels were significantly higher in BXSB-*Yaa* than in controls.

Conclusions: These findings suggest that activation of the TLR8-mediated pathway contributes to podocyte injury in murine autoimmune GN.

FR-PO375

Renal Iron Accumulation Precedes Albuminuria in the (NZBxNZW) F1 Model of Lupus Nephritis Erika I. Boesen. *Univ of Nebraska Medical Center.*

Background: Poorly-liganded iron damages tissue via several mechanisms. Lupus patients may be at risk of increased exposure to iron via hemolytic anemia or iron supplements to treat anemia of chronic disease. Several iron homeostasis proteins have been proposed as urinary biomarkers of lupus nephritis, but whether renal iron homeostasis is altered in lupus nephritis is unknown. Accordingly, we compared renal non-heme iron concentrations between the (NZBxNZW) F1 (NZBWF1) mouse model of lupus and age-matched NZW control mice.

Methods: Female mice fed normal chow were studied at 8 weeks, 20 weeks or 7-8 months (n=4-6 per group). Urine was collected for 24h by metabolic cage. Albuminuria was tested by dipstick, protein excretion by Bradford assay, lipocalin-2 excretion and plasma anti-dsDNA IgG by ELISA. Non-heme iron was measured in renal cortex by acid extraction and colorimetric assay.

Results: Renal cortical non-heme iron concentration was similar in NZBWF1 and NZW mice at 8 weeks (60±3 versus 56±53μM, P>0.05). At this age, 3 out of 4 NZBWF1 mice were negative for anti-dsDNA IgG. At 20 weeks, cortical iron was significantly higher in NZBWF1 mice than age-matched NZW mice (86±4 versus 69±53μM, P<0.05). Anti-dsDNA IgG were not yet significantly elevated in NZBWF1 versus age-matched NZW (19±5 versus 10±3kU/ml, P=0.2). Dipstick revealed only trace amounts of albumin in both groups, and 24h urinary protein excretion (1.8±0.3 versus 1.9±0.1mg/day, P>0.05) and lipocalin-2 excretion (69±5 versus 123+/-56ng/day, P>0.05) did not differ between NZBWF1 and NZW mice, suggesting that increased iron accumulation in NZBWF1 mice preceded overt renal injury. At the onset of albuminuria (≥2+ or 100mg/dL) at 7-8 months, cortical iron levels remained higher in NZBWF1 mice (109±11 versus 81±3μM in NZW, P<0.05), and anti-dsDNA IgG were markedly elevated in NZBWF1 versus NZW mice (332±60 versus 19±5kU/ml, P<0.01).

Conclusions: Our data show that renal iron accumulation is increased in the NZBWF1 model of lupus nephritis and precedes overt renal injury. This enhanced iron accumulation, which occurred without iron supplementation, may contribute to the development and progression of lupus nephritis. As a clinical perspective, our data suggest that lupus patients may be at increased risk of iron-mediated renal damage.

Application of Proteomics to Glomerular Diseases Tadashi Yamamoto,[1] Hidehiko Fujinaka,[1] Shigeru Miyazaki.[2] *[1]Structural Pathology, Inst of Nephrology, Niigata Univ, Niigata, Japan; [2]Internal Medicine, Shinrakuen Hospital, Niigata, Japan.*

Background: Proteomics approaches are now applicabletoclinical nephrology. To understand systems biology/pathology of the kidney and also to discover biomarkers for kidney diseases in urine, an international collaboration project, Human Kidney and Urine Proteome Project (HKUPP) was established as an initiative in Human Proteome Organization (HUPO). In this presentation is introduced an application of proteomics to kidney tissue analysis and urine biomarker discovery.

Methods: By LC-mass spectrometry (MS) and immunohistochemistry (IHC), proteomes of normal human kidney tissues (cortex, medulla, glomerulus and other several compartments), CKD disease glomerulus (IgA normal volunteers are examined.Thousands of proteins with high confidence were identified by LC-MS, quantified by non-labeled quantitaion, normalized spectral index, of MS data and localized by IHC.

Results: Thousands of proteins with high confidence were identified by LC-MS, quantified by non-labeled quantitaion, normalized spectral index, of MS data and localized by IHC. Bioinformatics tools for network and pathway analysis of the glomerulus proteomes depicted interesting networks and pathways; networks of oxidative stress, immune response, fibrosis, and hypertension and pathways of GRAB2, snRNP, g-secretase, angiogenin and glutathione are demonstrated as enhanced ones in membranous nephropathy glomerulus. Proteins identified in healthy volunteer urine are annotated with their sources, cells or plasma, for construction of urinary proteome database.

Conclusions: Proteomics and bioinformatics analysis of kidney biopsy specimen provided new insights intomolecular mechanisms of glomerular diseases and may promote efficient personalized medicine in the near future. New biomarkers for earlier detection, pathologic diagnosis, or prognosis of CKD may be introduced by urine proteomic analysis.

FR-PO377

Tubuloglomerular Crosstalk Is Affected by Type of Tubulointerstitial Injury Jae Won Yang,[1] Beom Jin Lim,[1] Ming-Zhi Zhang,[2] Raymond C. Harris,[2] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Pathology, Microbiology, and Immunology, Vanderbilt Univ, Nashville, TN; [2]Nephrology, Vanderbilt Univ, Nashville, TN.*

Background: Glomerular injury can cause subsequent tubulointerstitial ischemia and fibrosis. However, little is known about how tubulointerstitial injury causes glomerular injury. In this study, we evaluated the effect of different types of preexisting tubulointerstitial injury on glomerular function and sclerosis.

Methods: Nep25 transgenic mice express human CD25 receptor on podocytes, and develop glomerulosclerosis when immunotoxin (LMB2) is administered. To assess toxic tubulointerstitial injury, we mated DT/gGT transgenic mice with diphtheria toxin (DT) receptor in proximal tubular epithelial cells with Nep25 mice, to generate $Nep25^{+}/DT^{+}$ and $Nep25^{+}/DT^{-}$ mice and treated with DT. To assess crystal-induced tubulointerstitial injury, we mated Col I-luciferase mice, which have luciferase inserted in the collagen I promoter, with Nep25 mice to generate Nep25/Col I-luciferase mice, and treated with folic acid or vehicle. All mice underwent uninephrectomy (UNx) at day 42 to assess type and extent of tubulointerstitial fibrosis, and LMB2 injection 3 days later, and were sacrificed one week after LMB2.

Results: The kidneys from UNx showed diffuse interstitial fibrosis in $Nep25^{+}/DT^{+}$ but not $Nep25^{+}/DT^{-}$ mice. Although bioluminescence imaging showed higher score for collagen I in folic acid group, Masson staining of the UNx kidney showed only patchy and mild interstitial fibrosis along medullary rays. After UNx, but before LMB2 injection, all mice showed normal range albuminuria. After LMB2 injection, proteinuria increased 2.8 fold in $Nep25^{+}/DT^{+}$ mice versus 1.4 fold in $Nep25^{+}/DT^{-}$. Glomerulosclerosis at sacrifice was more widespread in $Nep25^{+}/DT^{+}$ versus $Nep25^{+}/DT^{-}$. In contrast, proteinuria and synaptopodin expression at sacrifice were similar in folic acid and vehicle groups.

Conclusions: We conclude that different types and severity of tubulointerstitial injury have varied effects on development of glomerular injury. Thus, crystal induced mild tubulointerstitial injury may not adversely impact glomerulosclerosis in the short term, in contrast to the deleterious effects of severe ischemic injury.

FR-PO378

Development of Atubular Glomeruli in Cisplatin-Induced Chronic Kidney Disease Robert L. Safirstein,[1,2] Heino Velazquez,[1,2] Richard Torres,[1,2] John J. Chang,[1,2] Gilbert W. Moeckel,[1] Gary V. Desir.[1] *[1]Nephrology Div, Yale Univ, New Haven, CT; [2]Nephrology, VACT HealthCare System, West Haven, CT.*

Background: Chronic Kidney Disease (CKD) develops in humans after repeated doses of cisplatin (CP). Here we report on a new model to investigate the mechanism of CP-induced CKD.

Methods: 8-week old C57Bl6 mice received a single or double doses (2 weeks apart) of CP (15 mg/kg) and were studied 2,4,6,9 and 16-25 weeks after the first dose. Glomerular filtration rate (GFR) was measured by inulin clearance. Renal tissue was prepared for quantitative 3-D multiphoton microscopy (MM) using a novel tissue clearing method that allowed for the collection of high resolution images at more than 1 mm depth.

Results: Cisplatin caused profound functional and morphologic changes. GFR dropped progressively to 50% of age-matched controls by 9 weeks without hypertension or loss of glomeruli. Kidney weight fell mainly by loss of cortical tissue. Extensive fibrosis developed, as measured by Sirius Red staining and confirmed by MM, first appearing 6 weeks after the first dose. Glomerulosclerosis failed to develop even as late as 25 weeks. After fibrosis, widespread peritubular vascular rarefaction appeared (by CD34 staining). An influx of macrophages, F4/80 staining, also was noted in the backdrop of an increase in both cell cycle activity (Ki67) and apoptosis (TUNEL). The earliest morphologic changes seen on MM involved the glomerulotubular (GT) junction and were characterized 1) by the loss of parietal cuboidal cells from Bowman's capsule and 2) by the loss of connection between the glomerulus and its proximal tubule resulting in an atubular glomerulus. Notably, these abnormalities developed before fibrosis and correlated well with the development of progressive renal insufficiency.

Conclusions: Using MM on a new murine model of CP-induced CKD, we identified the morphologic changes at the GT junction that occur earlier than fibrosis and that herald the development of CKD. Thus, this segment of the nephron may be integral to the onset and progression of CKD. Understanding the mechanisms that determine the development of the cellular changes at the GT junction is likely to yield new information on ways to prevent CKD.

FR-PO379

Proteinuria That Develops with Aging in the MWF Rats Results From Both Glomerular and Tubular Alterations Mark C. Wagner,[1,5] Silvia B. Campos-Bilderback,[1,5] Brittany N. Flores,[1] Sudhanshu Kumar,[1,5] Xianyin Lai,[2] Jered Myslinski,[1,5] Ruben M. Sandoval,[1,5] Sarah E. Wean,[1,5] Frank Witzmann,[3] Bruce A. Molitoris.[1,4,5] *[1]Medicine, Indiana Univ School of Medicine, Indianapolis, IN; [2]Biochemistry & Molecular Biology, Indiana Univ, Indianapolis, IN; [3]Celluar & Integrative Physiology, Indiana Univ, Indianapolis, IN; [4]Roudebush VAMC, Indianapolis, IN; [5]Indiana Center for Biological Microscopy, Indiana Univ School of Medicine, Indianapolis, IN.*

Background: While the clinical relevance of albuminuria is well documented, the role of glomerular and tubule contributions remains of considerable interest. Understanding protein handling in the PT cells requires a better understanding of their function and regulation under physiological and disease conditions.

Methods: Glomerular sieving coefficient (GSC) and PT uptake was measured in young (7-9wks) and old (32-46wks) MWF rats. Two-photon intravital microscopy was used to study handling of Texas Red RSA. Analysis of cortical protein changes identified proteins and pathways altered by age which may contribute to proteinuria.

Results: MWF female and male GSC increased from 0.0075 to 0.0117 and from 0.0052 to 0.0134, respectively. 24hr urine total protein increased from 49mg to 900mg in the females and from 126mg to 3000mg in the males. The increased urine protein does not directly correlate with the GSC changes. PT TRRSA uptake in males was reduced by 50%. To address cortical proteome changes in young and old MWF male rats, proteins were analyzed by LC-MS/MS. 1485 unique cortical proteins, splice variants or isoforms were identified, and compared. 255 proteins detected in both groups were differentially expressed ($p<0.05$). 32 proteins were detected only in the 32 wk group and 7 in the 7wk group. Prominent up-regulated proteins included ribosomal proteins Rps28 and Rps20, Filamin C, serum albumin, Vps29, and Lims. The largest down-regulations included proteasome proteins Rpn6 and Rpn11; mitochondrial proteins Dmgdh,Ckmt2, and Diablo homolog; ABC transporter G family member 2; GPI-anchor transamidase; and Rab-5c.

Conclusions: These data support a model in which the tubular epithelia play a greater role in albuminuria.

FR-PO380

Apoptosis Is the Primary Cause of Renal Albumin Toxicity and Can Be Rescued By a Na,K-ATPase Triggered Cytosolic/Mitochondrial Calcium Signal Ievgeniia Burlaka,[1] Jacopo Maria Fontana,[1] Lena Scott,[1] Hjalmar Brismar,[1,2] Anita Aperia.[1] *[1]Karolinska Instt, Sweden; [2]Royal Inst of Technology, Sweden.*

Background: There is a great need for treatment that arrests progression of chronic proteinuric kidney disease (CKD). Increased levels of albumin in the primary urine lead to fibrosis and apoptosis of podocytes and proximal tubule cells. There have been many attempts to target fibrosis but few to target apoptosis, because of lack of appropriate therapeutic agents. The interrelationship between fibrosis and apoptosis is not well understood.

Results: Here we show with time-sequence imaging that excessive albumin uptake into primary rat proximal tubule cells (RPTC) promptly triggers the mitochondrial apoptotic pathway, while increased production of pro-fibrotic factors lag behind. Incubation of RPTC with delipidated, endotoxin-free albumin 2.5 -10 mg/ml results within an hour in reduction of the anti-apoptotic factor Bcl-xL, mitochondrial accumulation of the apoptotic factor Bax and depolarization of the mitochondrial membrane. We previously reported that the Na,K-ATPase ligand ouabain triggers an anti-apoptotic signal mediated via cytosolic calcium oscillations. Here we show that ouabain, in concentrations that do not inhibit Na,K-ATPase pumping function, attenuates albumin triggered mitochondrial membrane depolarization, lowers mitochondrial accumulation of apoptotic factor Bax, increases abundance of anti-apoptotic factor Bcl-xL and rescues from apoptosis. Using genetic Ca^{2+} indicators targeted to cytosol and mitochondria, we show that each cytosolic calcium wave triggered by ouabain is followed by a delayed mitochondrial calcium transient, which is similar in amplitude, but slower in recovery than the cytosolic wave.

Conclusions: We have shown that renal albumin toxicity is primarily due to mitochondrial dysfunction, that the Na,K-ATPase ligand ouabain rescues from mitochondrial dysfunction and that Na,K-ATPase may exert a feedback control on mitochondrial function and control of life and death.

Deletion of the mTORC1 and -2 Induced Signalling Pathways Reduce Renal Proximal Tubular Endocytosis Franziska Theilig,[1] Florian Grahammer,[2] Mélanie Bousquenaud,[1] Alexey Larionov,[1] Suresh K. Ramakrishnan,[1] Tobias B. Huber.[2] *[1]Medicine, Anatomy, Fribourg, Switzerland; [2]Nephrology, Freiburg, Germany.*

Background: Receptor-mediated endocytosis is a pivotal function of the renal proximal tubule (PT) to reabsorb proteins from the ultrafiltrate to maintain body homeostasis. The signaling pathways involved in the regulation of endocytosis and their point of action remain uncertain. We aimed to elucidate the role of mTORC1 and -2-induced signaling pathways in clathrin-mediated endocytosis.

Methods: Therefore Raptor $^{fl/fl}$ and Rictor $^{fl/fl}$ Pax8rtTA*TetOCre as well as double mutants were analyzed.

Results: Renal function analysis of double mutants revealed a low molecular weight proteinuria, reduced FITC-inulin-GFR (4.3 versus 6.7 µl/min/g bw in double mutants versus controls, $p<0.01$) and increased plasma urea concentration (88 versus 37 mg/dl in double mutants versus controls, $p<0.001$). Single mutants did not differ from their respective controls. Raptor fl/fl and Rictor fl/fl Pax8rtTA*TetOCre and more pronounced the double mutants demonstrated a reduced proximal tubular HRP-uptake. Morphological analysis showed reduced BBM microvilli length and endocytic vesicle formation in single mutants and most pronounced in double mutants. Vacuoles formation and cystic dilation with loss of proximal tubular phenotype were observed in double mutants and to lesser extent in single mutants. Western blot and immunohistochemical analysis of endocytic parameters revealed in double mutants reduced clathrin vesicles, recycling endosome formation and ClC-5 expression whereas the early endosomes were increased. Megalin expression remained unaltered. Viral knockdown of S6K1 and rictor in opossum kidney cells demonstrated reduced albumin uptake and vesicle formation in ligand-induced endocytosis.

Conclusions: In conclusion, mTORC1 and -2 are important regulators of PT endocytic functions by altering vesicle formation and therefore intracellular endocytic transport mechanisms.

Graft Reconditioning with Mesenchymal Stromal Cells in Non Hearth Beating Donors Experimental Model Valeria Corradetti,[1] Eleonora Francesca Pattonieri,[1] Marilena Gregorini,[1] Chiara Rocca,[1] Samantha Milanesi,[1] Teresa Valsania,[1] Carolina Bianco,[2] Ilaria Benzoni,[2] Manuela Cannone,[1] Maria Antonietta Avanzini,[3] Melissa Mantelli,[3] Marcello Maestri,[2] Teresa Rampino,[1] Antonio Dal Canton.[1] *[1]Nephrology, IRCCS Policlinico San Matteo, Italy; [2]Chirurgia Generale, IRCCS Policlinico San Matteo, Italy; [3]Oncoematologia Pediatrica, IRCCS Policlinico San Matteo, Italy.*

Background: Grafts from non hearth beating donors (NHBD) have high risk for primary non and delayed-graft-function.Viability of NHBD kidneys is improved by perfusing them with hypothermic machine perfusion (HMP),but the outcome of NHBD grafts remains worse in spite of HMP.Mesenchymal stromal cells (MSC) are multipotent

cells and in a rat model of renal transplantation they have anti inflammatory effects.We evaluated whether perfusing the isolated kidney with MSC in HMP,NHBD graft is protected by ischemia/reperfusion injury.

Methods: Fisher rats (F) were used as kidney donors,Lewis rats (L) as MSC donors and Transgenic Sprague-Dawely rats expressing enhanced green fluorescence protein as MSC donors to track MSC.After 20' of warm ischemia,bilateral nephrectomy from F was performed and kidneys perfused with BelzerUW solution (A) or BelzerUW solution plus $3*10^6$ MSC (B) for 4 h, at 4°C.8 kidneys for each group were studied after 4 h perfusion. Proliferating cell nuclear antigen (PCNA) expression was evaluated by immunochemistry. Renal damage was graded according to semiquantitative score in 15 non-consecutive microscopic fields (0-4) (0:0%tubular casts/microscopic field;4:<75% tubular cast/microscopic field).Tubular mitotic index was measured as tubules with mitotic cells/total tubules number in 15 microscopic fields.Malondialdeide (MDA) was measured on perfusion liquid effluent.

Results: We found MSC in tubules,glomeruli,interstitium and no MSC capillary margination.PCNA positive cells were increased significantly in B compared with A (A 27.9±12.1;B 35.0 ±15.7,p<0.0001) Damage score was significantly lower in MSC perfused kidneys (A:3.4±1;B1.6±1.2,p<0.0001) Mitotic index was higher in B than in A (p<0.005). MDA levels were lower in B than in A (p<0.001).

Conclusions: Our results demonstrate that pre-transplant graft reconditioning with MSC protects from ischemia/reperfusion injury.

FR-PO383

Possible New Biomarkers for Transplanted Kidneys: The Indoleamine 2,3-Dioxygenase (IDO) and the Switch from Proteasome to Immuneproteasome (PS/iPS) Licia Peruzzi,[1] Andrea Ranghino,[2] Elisa Loiacono,[1] Alessandro Amore,[1] Alberto A.B. Boido,[2] Luca Vergano,[1] Giulio Mengozzi,[3] Paola Puccinelli,[3] Inna Lastauka,[4] Rosanna Coppo.[1] *[1]Nephrology Dialysis Transplantation, Città della Salute e della Scienza, Regina Margherita Hospital, Turin, Italy; [2]Nephrology Dialysis Transplantation, Città della Salute e della Scienza, Turin, Italy; [3]Laboratory Medicine, Città della Salute e della Scienza, Turin, Italy; [4]Belarusian Medical Academy of Postgraduate Education, Belarus.*

Background: There is a growing interest in biomarkers of immune system activation in transplanted subjects. Indoleamine 2,3 dioxygenase (IDO), an interferon-g induced enzyme degrading tryptophan (Trp) to kynurenine (Kyn) expressed in dendritic cells is triggered in acute rejection and downregulated by immunesuppressive drugs. Interferons regulate also the switch from proteasome (Ps) to immuneproteasome (iPs) favouring optimal antigen presentation.

Methods: We prospectively detected in 25 transplanted patients (T0, T15, T30, T60, T180 D) and 30 controls (HC) IDO activity (Kyn/Trp) (HPLC), mRNAs for IDO and 3 catalytic PS and iPS units (Taqman). T regulatory cells were investigated by forkhead box P3 (FoxP3), Th17-related factors (IL-17) and TGF-β1 mRNAs.

Results: At T0 IDO activity was significantly higher than in HC (Kyn 4.16±0.26 versus 2.05±0.07, p<0.0001; Trp 29.58±2.89 versus 54.02±1.63, p<0.0001; Kyn/Trp: 16.02±1.61 versus 3.83±0.15,p<0.0001) as well as IDO mRNA (p=0.004). TGF-β1 mRNA was also increased (2.13±0.2 versus 1.37±0.1,p=0.004) while IL-17 (1.49± 0.42 versus 0.81±0.10) as well as FoxP3 mRNA (1.16±0.23 versus 1.21±0.11) were similar to HC. A significant PS/iPS switch was detected at T0 (LMP2/b1,p=0.011 versus HC). A significant correlation was found between Kyn/Trp and TFG-b1 mRNA (p=0.005). Kyn was significantly correlated with LMP2/b1 (p=0.005). A significant reduction in IDO activity and IDO mRNA expression were found over the first month after transplantation (T15 and T1), with decrease in Kyn/Trp parallel to a decrease in PS/iPS switch (LMP2/b1mRNA). IDO activity progressively increased over T3-T6.

Conclusions: IDO and the proteasome/immunoproteasome switch represent possible biomarkers for monitorning the immune system activation after kidney transplantation.

Transcriptome Analyses of Zero Kidney Graft Biopsies Reveal Metallothioneins as Candidate Markers of Biological Age Johannes Leierer, Gert J. Mayer. *Dept of Internal Medicine IV, Nephrology and Hypertensin, Medical Univ Innsbruck, Innsbruck, Austria.*

Background: Structure and function of the kidney deteriorate with age and age-related diseases contribute to this process, leading to the high frequency of end-stage renal disease in the elderly. Despite some similarities the aging kidney and CKD differ but it is difficult to distinguish these two conditions. Thus biological markers for age might be useful tools to dissect the specific pathologies and gene expression analysis of healthy aged kidneys might be a reasonable approach to avoid confounding by disease.

Methods: Age-regulated gene expression changes in zero hour donor kidney biopsies were determined using microarray technology followed by ANOVA and SAM analysis. Expression changes of selected genes were confirmed by quantitative real-time PCR. *In situ* hybridization and immunohistochmistry was used to localize mRNA and protein expression in zero hour biopsies. Functional aspects were examined *in vitro* in RPTEC/TERT1 cells.

Results: Donors were classified into 3 age groups (<40, 40-59, >60 years). In the given Microarray data age-associated transcriptional changes were identified: 16 transcripts were found to be significantly upregulated in age group 3 as compared to age group 1. 8 of these transcripts encoded for metallothionein (MT) isoforms. *In situ* hybridization demonstrated localization of MT mRNA in renal proximal tubular cells.RPTEC/TERT1 cells overexpressing MT2a were less susceptible towards CdCl2 induced cytotoxicity.

Conclusions: Metallothionein (MT) expression might serve as a marker for biological age in zero hour biopsies. As MTs contribute to detoxification of heavy metals and homeostasis of essential metals, protect from ROS mediated oxidative stress and prevent apoptosis their upregulation with ageing might represent an intrinsic protective mechanism.

FR-PO385

Decreased Kidney Oxygenation due to Mitochondrial Uncoupling in Renal Transplantation Diana A. Papazova,[1] Malou Friederich-Persson,[2] Jaap A. Joles,[1] Marianne C. Verhaar.[1] *[1]Nephrology & Hypertension, UMC Utrecht, Netherlands; [2]Medical Cell Biology, Uppsala Univ, Sweden.*

Background: Ischemia/reperfusion (IR) is a common cause for chronic allograft dysfunction. Lower renal oxygenation (pO_2) is observed after IR. We hypothesize that mitochondrial uncoupling via uncoupling proteins (UCP) increases oxygen consumption and leads to decreased pO_2. Furthermore, we examined whether mitochondrial-targeted antioxidant therapy can improve mitochondrial uncoupling and graft oxygenation after renal Tx.

Methods: Male Lewis rats were left untreated as 2K-controls, uninephrectomized as 1K-controls, or underwent syngenic renal Tx (Tx). Two weeks after Tx, we measured renal function glomerular filtration rate (GFR: inulin), renal plasma flow (RPF: PAH), renal blood flow (RBF: PAH clearance/1-HCT) and pO_2. Mitochondrial uncoupling was evaluated as decreased consumption after UCP-2 blockade with guanosine diphosphate. In a follow-up experiment, donors were treated with mitoTempo (200 ug/kg, TxT) or vehicle (0.9% NaCl, TxV) daily for 5 days prior to Tx. Recipients were followed for two weeks and renal function (GFR, RPF, RBF) and pO_2 and mitochondrial uncoupling were measured.

Results: Tx resulted in increased GFR (0.65±0.07 versus 0.47±0.05 ml/min/kidney/100g, P<0.001), RPF (2.6±0.2 versus 1.8±0.2 ml/min/kidney/100g, P<0.001), RBF (3.9±0.4 versus 3.0±0.3 ml/min/kidney/100g,p<0.01) in comparison to 2K-controls. Similar changes were observed in 1K-controls. However, Tx also decreased pO_2 (30.3±12.6 versus 58.3±15.8 μM, P<0.01) in comparison to 2K-controls, changes not observed in in 1K-controls (47.1±4.2 μM, NS). Tx resulted in mitochondrial uncoupling (-15.8±5.6 versus -1.9±2.1 pmol O_2/s,p<0.05), but not in 1K-controls (-2.3±1.4 pmol O_2/s,ns). MitoTempo pretreatment did not improve any of the measured in vivo parameters (GFR, RPF or pO2) in comparison to vehicle but resulted in less mitochondrial uncoupling (-7.20±1.02 versus -13.12±2.51 pmol O_2/s, P<0.01).

Conclusions: The present study demonstrates that mitochondrial uncoupling occurs early after Tx and is associated with decreased kidney pO_2 despite similiar oxygen delivery as compared to 1K-controls. This early hypoxia may contribute to progressive chronic damage in transplanted kidneys.

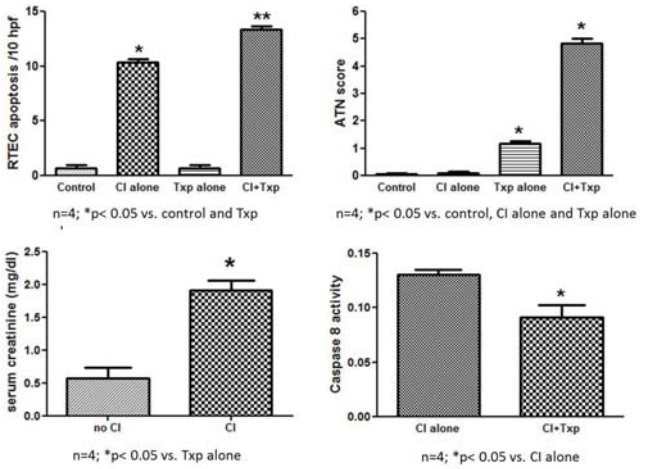
FR-PO386

The Changing Phenotype of Tubular Cell Death during Delayed Graft Function Swati Jain, Danica Ljubanovic, Charles L. Edelstein, Alkesh Jani. *Renal, Univ of Colorado, Aurora, CO.*

Background: Delayed graft function (DGF) independently predicts reduced 5 yr kidney transplant survival. Treatments of DGF are lacking. Cold ischemia (CI) is a significant risk factor for DGF but the mechanism by which CI leads to DGF is unknown. The effect of CI alone versus CI + warm reperfusion (WR) on renal tubular cell (RTEC) death are not well defined. The aim of this study was to determine the relative effects of CI versus CI+WR on donor kidneys in a kidney transplant model of DGF. We hypothesized that CI alone would produce a different injury phenotype to CI+WR.

Methods: Male C57BL6 mice aged 12 weeks were subjected to mouse kidney transplant. Donor kidneys subjected to 3 hours CI at 4°C in UW solution, were either processed immediately or subjected to syngeneic mouse kidney transplant. Renal function was assessed by serum creatinine (SCr). RTEC apoptosis and necrosis were assessed by a nephropathologist in a blinded fashion.

Results: CI alone significantly increased RTEC apoptosis but did not result in necrosis. In contrast, CI+WR after transplant caused RTEC apoptosis and necrosis. SCr was significantly increased in transplants subjected to CI versus no CI. Since caspase-8 is known to trigger apoptosis and also serves as a negative regulator of programmed necrosis, we examined caspase-8 protein expression and activity. Caspase-8 activity and protein expression were significantly decreased in CI+WR versus CI alone.



Conclusions: We have shown that CI alone results in RTEC apoptosis whereas CI+WR after mouse kidney transplant results in a different injury phenotype with the development of RTEC necrosis. A potential mechanism by which these differing phenotypes may occur is via decreased caspase-8 after CI+WR, thus removing negative regulation of programmed necrosis. These studies suggest that while inhibition of capsase-8 may prevent RTEC apoptosis, a consequence might be increased RTEC necrosis.

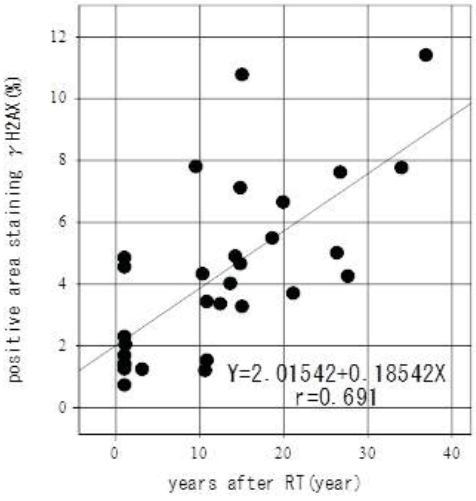
FR-PO387

DNA Double Strand Brakes Induced Intractable Glomerular Fibrosis in Renal Allografts Yuki Matsui, Hirokatsu Atsumi, Junko Imura, Keiji Fujimoto, Hiroki Adachi, Hiroshi Okuyama, Hideki Yamaya, Hitoshi Yokoyama. *Kanazawa Medical Univ, Kanazawa, Japan.*

Background: DNA injury in renal allografts has been reported in a few studies of cyclosporine nephrotoxicity, chronic renal allograft rejection, and renal reperfusion injury. However, the relationship between DNA injury and glomerular fibrosis was still unclear. In this study, we investigated DNA injury and glomerular fibrosis in renal allografts.

Methods: We evaluated 30 patients who underwent renal graft biopsy from 1.0 to 36.9 years after transplantation. We detected DNA double strand brakes by immunostaining using an anti-phospho-Histone H2A.X (Ser139; gH2AX) monoclonal antibody, and analyzed positive area by an image analyzing system. Subsequently, we identified glomerular fibrosis in renal allografts by collagen (COL) type III, IV, and VI accumulation.

Results: gH2AX staining area was positively correlated with years after renal transplantation (RT) (r=0.691 p<0.01). Similarly, type VI COL, which accumulated mainly in the subendothelial and mesangial area, was also positively correlated with years after RT (r=0.760, p<0.01). In multiple regression analysis, years after RT was selected as a significant factor for the accumulation of type VI COL in glomerular capillaries (b value=0.699, p<0.001), type III COL on vascular pole (b value=0.441, p=0.027), and gH2AX (b value=0.700, p<0.001). In addition, gH2AX staining area was also selected as a predictor of the accumulation of type VI COL in glomerular capillaries (b value=0.439, p=0.028). On the other hand, donor age at renal biopsy was a significant factor for type IV COL accumulation in glomeruli (b value=0.505, p=0.01).



Conclusions: These findings suggested that long-term RT induced DNA double strand brakes and accumulation of type VI COL in glomerular capillaries, which may progress to intractable glomerular fibrosis.

FR-PO388

CDKN2A Expression in Uremic Artery and Muscle - A Biological Marker of Ageing in Renal Disease Karin Luttropp,[1] Abdul Rashid Tony Qureshi,[2] Dagmara Mcguinness,[3] Peter F. Barany,[2] Louise Nordfors,[2] Peter Stenvinkel,[2] Paul G. Shiels.[3] *[1]Dept of Molecular Medicine and Surgery, Karolinska Instt, Stockholm, Sweden; [2]Dept of Clinical Science, Intervention and Technology, Karolinska Univ Hospital, Stockholm, Sweden; [3]Wolfson Wohl Translational Research Centre, Inst of Cancer Sciences, Univ of Glasgow, Glasgow, United Kingdom.*

Background: Using chronic kidney disease (CKD) patients as a clinical model of accelerated ageing, we investigated the expression of cyclin-dependent kinase inhibitor 2A (CDKN2A) in artery and muscle biopsies taken from CKD patients undergoing renal transplantation (RTx) and examined its applicability as a marker of ageing and cardiovascular disease (CVD).

Methods: 43 biopsies from epigastric artery and 81 biopsies from muscle were obtained at RTx and RNA was prepared using Trizol (see Table 1). CDKN2A gene expression was measured by qRT-PCR with reference to the HPRT gene on an ABI Prism® 7700 Sequence Detection System. TaqMan™ Primer/Probe sets were designed by Primer Express algorithm (Applied Biosystems, Austin, TX, U.S.A.). For comparison of data, Spearman's rank correlation (r) or linear regression was used, as appropriate.

	Artery	Muscle
Men, %	70	62
Age, median	42	46
DM, %	16	21
CVD, %	12	20
RQ CDKN2A, median	0.96	0.59

Results: CDKN2A expression was significantly higher in artery than in muscle (p = 0.01). In arteries, CDKN2A expression was significantly associated with CVD (p = 0.001), medial calcification (p = 0.04), and diabetes mellitus (DM) (p = 0.05). In muscle, CDKN2A expression was significantly associated to age (p = 0.003) and DM (p = 0.04). After correction for age, the association between arterial CDKN2A and CVD and DM remained significant whereas the relation to medial calcification was lost.

Conclusions: CDKN2A expression in muscle increases with age, demonstrating its validity as a biomarker of ageing. The age-independent association with CVD confirms previous genotype studies that have shown associations between this DNA locus and various forms of CVD. The finding that CDKN2A expression is higher in artery than in muscle indicates that vessels are prone to a more rapid ageing process than other organs/tissues in the uremic milieu.

FR-PO389

Role of Complement in the Regulation of Anti-Senescence Protein Klotho (KL) in Kidney Transplantation Giuseppe Castellano,[1] Angelica Intini,[1] Alessandra Stasi,[1] C. Divella,[1] Margherita Gigante,[1] Paola Pontrelli,[1] Fabio Sallustio,[2] Anna Zito,[1] Marco Fiorentino,[1] Giovanni B. Pertosa,[1] Loreto Gesualdo,[1] G. Grandaliano.[3] *[1]Dept of Emergency and Organ Transplantation, Univ of Bari, Italy; [2]C.A.R.S.O. Consortium, Valenzano, Bari, Italy; [3]Dept of Medical and Surgical Sciences, Univ of Foggia, Italy.*

Background: The transmembrane KL protein is mainly produced at renal level and is released into blood as an endocrine anti-aging factor. Recent studies demonstrated a reduction of KL in acute kidney injury. Aim of the study was to investigate the modulation of KL in a swine model of Ischemia /Reperfusion (I/R) injury and in Delayed Graft Function (DGF) patients.

Methods: In an experimental model of I/R injury, 10 pigs underwent to 30 min of renal warm I followed by 24h of R. Five pigs (C1-Inh) were treated with recombinant C1-Inh. KL level was investigated by immunohistochemistry in renal biopsies from animal model and patients and by ELISA assay in patients serum. We evaluated KL *in vitro* in renal tubular cells (HK-2) stimulated with C5a by qPCR and Western Blot.

Results: We found a significant reduction in tissue KL in I/R pigs (Ctr) at 24h from R compared to basal condition (30.4%±1.2% versus T0:72.5%±2.1%,p<0.05). Complement inhibition preserved KL expression in vivo (T24C1-Inh:70.7%±1.9% versus T24Ctr,p<0.05). In accordance, Complement anaphylotoxin C5a led to a downregulation of KL gene (p<0,01) and protein (p<0,05) expression in vitro in HK-2 cells. Moreover, KL was not expressed in adult renal progenitor cells compared to primary tubular cells in vitro. In transplant patients, we found a significant reduction of tubular KL in DGF compared to pre-transplant (pre-Tx) biopsies (DGF:10.8%±0.6% versus pre-Tx:73.1%±2.5%,p<0.05). Moreover DGF patients showed low levels of serum KL at 2 years after transplantation compared to EGF patients with similar renal function (DGF:412pg/ml±106 versus EGF:900.25pg/ml±153.9,p=0.03).

Conclusions: Our study demonstrated that the Complement activation during renal I/R injury plays an important role in KL modulation. Considering the renoprotective functions of KL, its reduction in DGF patients might promote the senescence of kidney allograft.

FR-PO390

Fibroblast Growth Factor 23/Klotho Axis Is a Risk Factor for Kidney Transplant Loss Siren Sezer,[1] Ayse Zeynep Bal,[1] Mehtap Erkmen Uyar,[1] Handan Ozdemir,[2] Orhan Guliyev,[1] Saliha Yildirim,[3] Mehmet Haberal.[4] *[1]Nephrology, Baskent Univ Faculty of Medicine, Ankara, Turkey; [2]Pathology, Baskent Univ Faculty of Medicine, Ankara, Turkey; [3]Internal Medicine, Baskent Univ Faculty of Medicine, Ankara, Turkey; [4]General Surgery, Baskent Univ Faculty of Medicine, Ankara, Turkey.*

Background: Chronic allograft nephropathy (CAN) is a major cause of late kidney allograft loss. Increased circulating level of fibroblast growth factor 23 (FGF23) is an independent risk factor for cardiovascular disease. The aim of this study is to evaluate the relationship between FGF-23 and allograft loss and to identify risk factors for progression to ESRD.

Methods: We performed a study of 80 maintenance kidney recipients with stable allograft function who had received their transplant at least 36 months previously. All acute cellular and humoral rejections were excluded. According to renal biopsy patients divided four groups: Group CAD (n:38) was the patients diagnosed as chronic allograft dysfunction; group TED (n:18) was included the patients with tubular epithelium damage and group CON (n:24) was defined as control group. Samples for FGF-23 and Klotho were taken on the biopsy day and patients were followed at least 36 months after renal biopsy.

Results: FGF23 and parathyroid hormone (PTH) values were higher in CAD group, while the calcium levels and Klotho were significantly lower compared to other groups. A significant inverse correlation was found between FGF23 and MDRD, Klotho, serum calcium level and albumin level. FGF-23 levels were positively correlated with duration after transplantation, serum uric acid level, serum creatinine level, interstitial fibrosis score, glomerulosclerosis rate and proteinuria. Multivariable analysis showed that serum albumin, interstitial fibrosis score and percentage of glomerulosclerosis were associated with high FGF23 levels.

Conclusions: We conclude that elevated FGF23 and decreased Klotho were associated with chronic allograft dysfunction and an independent risk factor allograft loss in kidney transplant recipients. We suggest that FGF-23/Klotho axis could play a role as triggering factor and could be a prognostic marker in case of progressive renal injury.

FR-PO391

FGF23 Induced Vascular Endothelial Activation and Proliferation via the mTOR Pathway Eileen W. Tsai,[1] Yiping Jin,[2] Katherine Wesseling-Perry,[1] Isidro B. Salusky,[1] Robert B. Ettenger,[1] Elaine F. Reed.[2] *[1]Pediatrics, UCLA, Los Angeles, CA; [2]Pathology, UCLA, Los Angeles, CA.*

Background: Fibroblast growth factor 23 (FGF23) has been associated with allograft rejection, chronic kidney disease (CKD) progression, cardiovascular mortality and poor graft survival in renal transplantation. We recently discovered that FGF23 induces endothelial cell (EC) functional changes, including EC phosphorylation and proliferation, which we postulate contribute to transplant vasculopathy (TV). We, therefore, aimed to determine the intracellular signaling pathway mediating FGF23-induced EC signal transduction and proliferation.

Methods: Primary human aortic EC, passages 2-8, were treated with FGF23 100 ng/ml with and without mTOR inhibitors, rapamycin 30 nM (RAP) and everolimus 10 nM (RAD). Untreated EC were used as control. Phosphorylation of S6kinase389 and Akt Ser473 was measured by Western blot. EC proliferation was assessed by flow cytometry using CSFE labeling.

Results: Both RAP and RAD reduced FGF23 phosphorylation of S6KinaseThr369 and Akt Ser473 which are downstream targets of mTOR (Fig 1A). These phosphoproteins have been associated with EC proliferation. Moreover, RAP also directly reduced FGF23 stimulated EC proliferation (Fig 1B).

Conclusions: We show for the first time that mTOR inhibition reduced FGF23-induced EC signal transduction and proliferation, suggesting that FGF23 uses the mTOR pathway to exert functional changes on the endothelium. This could have important clinical and therapeutic implications, delaying chronic kidney disease progression and potentially TV.

(Non-) Anticoagulant Heparinoids Alter Proteoglycan Mediated In- and Efflux of Interstitial Leukocytes in Experimental Renal Transplantation Ditmer Talsma,[1] Kirankumar Katta,[1] Saritha Adepu,[1] Miriam Boersema,[2] Saleh Yazdani,[1] Gerjan Navis,[1] Harry Van Goor,[2] Jan-Luuk Hillebrands,[2] Jacob van den Born.[1] *[1]Nephrology, UMCG, Groningen, Netherlands; [2]Pathology & Medical Biology, UMCG, Groningen, Netherlands; [3]Ronzoni, Milano, Italy.*

Background: Chronic renal transplant dysfunction (CTD) is characterized by loss of renal function and extensive tissue remodeling, including chronic inflammation and lymph vessel formation. Previously, we showed upregulation of matrix proteoglycans in CTD. We hypothesize that proteoglycans, via their glycosaminoglycan side chains act as docking platforms for L-selectin and chemokines, orchestrate in- and efflux of interstitial leukocytes, and could be target of intervention.

Methods: In a rat renal CTD model, collagens, chemokines and matrix proteoglycans were profiled by qRT-PCR in microdissected tubulo-interstitium. Heparinoid effectivity to dampen inflammation was tested in vitro and in the rat CTD model. Interstitial leukocytes were quantified by CD45 staining, whereas the in- and efflux of leukocytes was assessed by counting leukocyte numbers within vanWillebrand factor positive bloodvessels and podoplanin-positive renal lymphatics.

Results: qRT-PCR profiling revealed upregulation of Collagen I and IV, TGF-beta, chemokines CCL2, CCL5, and matrix proteoglycans perlecan and versican in CTD allografts compared to isografted and control kidneys (all $p<0.05$). In vitro (non-anticoagulant) heparin (oids) showed dose-dependent inhibition of both L-selectin and CCL2 binding to perlecan. In the rat CTD model daily treatment with non-anticoagulant heparinoid reduced tubulo-interstitial leukocyte numbers two-fold ($p<0.02$). Moreover, heparin (oid) treatment resulted in a decreased leukocyte adhesion to endothelium ($p<0,05$) but an increased leukocyte efflux into renal lymphatics ($p<0,001$).

Conclusions: We conclude that in renal CTD matrix proteoglycans via their glycosaminoglycan side chains stabilize chemokine gradients and interaction with L-selectin, thus promoting inflammation. Heparinoid treatment blocks these interactions and reduces interstitial leukocyte number both by reducing influx from blood vessels and by increasing leukocyte efflux into renal lymphatics.

FR-PO393

Nanoparticle Delivery of Donor Antigens for Transplant Tolerance Induction Jane Bryant, Xiaomin Zhang, Lei Zhang, Xun-Rong Luo. *Medicine, Northwestern Univ Feinberg School of Medicine.*

Background: Human islet cell transplantation is a promising treatment for type 1 diabetes; however, long-term donor-specific tolerance to islet allografts remains a clinically unmet goal. We have previously shown that recipient infusions of apoptotic donor splenocytes chemically treated with 1-ethyl-3- (3'-dimethylaminopropyl)-carbodiimide (donor ECDI-SP) can mediate long-term acceptance of full major histocompatibility complex (MHC)-mismatched murine islet allografts without the use of immunosuppression.

Methods: In this report, we investigated the use of poly (lactide-co-glycolide) (PLG) particles in lieu of donor ECDI-SP as a synthetic, cell-free carrier for delivery of donor antigens for the induction of transplant tolerance in full MHC-mismatched murine allogeneic islet transplantation.

Results: Infusions of donor antigen-coupled PLG particles (PLG-dAg) mediated tolerance in ~20% of recipient mice, and the distribution of cellular uptake of PLG-dAg within the spleen was similar to that of donor ECDI-SP. PLG-dAg mediated the contraction of indirectly activated T cells but did not modulate the direct pathway of allorecognition. Combination of PLG-dAg with a short course of low dose immunosuppressant rapamycin at

the time of transplant significantly improved the tolerance efficacy to ~60%. Furthermore, altering the timing of PLG-dAg administration to a schedule that is more feasible for clinical transplantation resulted in equal tolerance efficacy.

Conclusions: Thus, the combination therapy of PLG-dAg infusions with peritransplant rapamycin represents a clinically attractive, biomaterials-based and cell-free method for inducing long-term donor-specific tolerance for allogeneic cell transplantation, such as for allogeneic islet transplantation.

Interleukin-5 Therapy Prevents Chronic Allograft Rejection By Induction of T Regulatory Cells Bruce M. Hall,[1] Rachael Hall,[1] Giang Tran,[1] Catherine Robinson,[1] Chuanmin Wang,[2] Alexandra Sharland,[2] Suzanne Jean Hodgkinson.[1] *[1]Immune Tolerance Group, UNSW Australia, Sydney, NSW, Australia; [2]Collaborative Transplant Research Group, Univ of Sydney, Sydney, NSW, Australia.*

Background: Chronic rejection of allografts remains a major problem that may be controlled by promotion of alloantigen specific Treg cells. Naïve $CD4^+CD25^+Foxp3^+$ Treg activated by specific alloantigen (alloAg) in the presence of IL-4, not IL-2, express the specific receptor of IL-5 (IL-5Ra) and are more potent alloAg specific Treg than nTreg. IL-5 therapy (IL-5Rx) promotes expansion of Ag specific Treg to prevent autoimmunity.

Methods: We examined if IL-5Rx prevented chronic rejection of Lewis heterotopic cardiac allografts in F344 rats. rIL-5 was given ip daily at 5000 units for 10d, from 7d post-transplant. IL-5Rx was delayed to allow alloactivation to produce the IL-4 required to activate Ts2 cells. Grafts were monitored by palpation and scored as ++++ full function to 0 as fully rejected.

Results: Sham Rx rats developed rejection at 18d and by 28d all grafts were fully rejected (n=5). IL-5Rx prevented rejection, with all grafts ++++-+++ until cessation of IL-5 treatment at day 18 ($p<0.01$ compared to sham Rx). After 18d, there was rejection with a mean score of ++ until 50d (n=5) ($p<0.01$). Another group (n=5) had a transient rejection episode after changing on d18 to IL-5Rx 3x/wk, but by 30d the grafts recovered, so at 60d, 3 of 5 heart grafts were ++++, one +++, and one ++ ($p<0.05$ v short IL-5Rx; $p<0.01$ v sham Rx). Depleting $CD25^+$ cells or blocking IL-4 with mAb therapy abolished the effects of IL-5, all grafts rejected in <28d. IL-5Rx increased $CD4^+CD25^+$T cells at 6-8% versus 3-4% in controls. After IL-5Rx, $CD4^+CD25^+$T cells proliferated in MLC to Lewis, but not F344 alloAg, and this was enhanced by presence of IL-5.

Conclusions: In a model of chronic rejection, ongoing IL-5Rx reduced rejection and restored good graft function. IL-5Rx promoted growth of Ag specific $CD4^+CD25^+$Treg that were activated by host IL-4 and alloAg. In vitro, these cells had enhanced proliferation to donor Lewis that was further enhanced by IL-5. IL-5 therapy controlled chronic allograft rejection by the expansion of host Ag specific Treg.

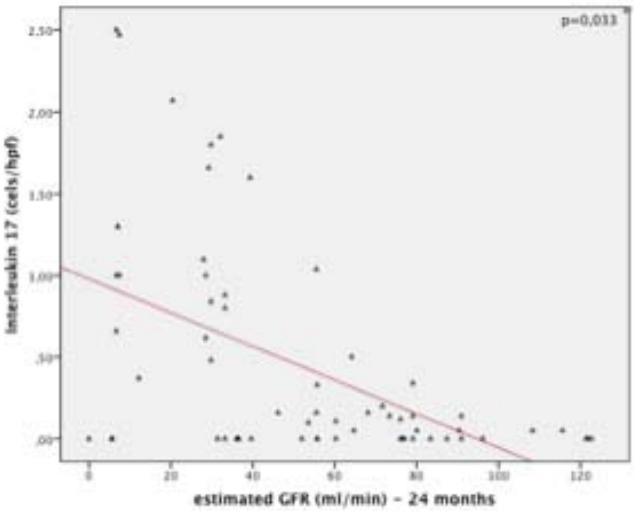
FR-PO395

Interleukin-17 Expression Is Associated with Worse Long-Term Kidney Graft Function Luciana Mello,[1,2] Lucio Roberto Requiao-Moura,[1,2] Denise M.A.C. Malheiros,[3] Alvaro Pacheco-Silva.[2] *[1]Kidney Transplant Unit, Hospital Israelita Albert Einstein, Sao Paulo, Brazil; [2]Nephrology Dept, Univ Federal de Sao Paulo, Sao Paulo, Brazil; [3]Pathology Dept, Univ de Sao Paulo, Sao Paulo, Brazil.*

Background: The identification of the family of interleukin-17 (IL-17) cytokines, defined a new cellular type called Th17 cells. Some studies point to the involvement of this new inflammatory pathway and others proinflammatory cytokines such as interleukin 6 and presence of B cells in acute rejection and graft loss. The aim of this study was to evaluate the presence of producing IL-17 cells in kidney transplant allograft tissue and correlate with long-term graft function.

Methods: Immunohistochemical staining for IL17, IL6, and CD20 was performed in 65 biopsy samples from patients who underwent kidney transplantation between 2007 and 2010 in Hospital IsraelitaAlbert Einstein, São Paulo, Brazil, and correlated with the presence of rejection and long-term graft function.

Results: We observed that the higher IL17+ cell count, the worse graft function found after one or two years was detected ($p<0,05$) regardless of the presence of rejection.



Neither interleukin-6 nor CD20 rich infiltrates were related to poor graft outcome. No significant difference was observed between Il17+ cell count in rejection and non-rejection groups. Instead, CD20 and IL-6 positive cellular infiltrates were more common in the rejection group ($p<0.001$) and ($p<0.005$), respectively.

Conclusions: The presence of IL-17 in renal transplant tissue is associated with a worse long-term kidney function regardless of whether associated with acute rejection. This finding makes room for a possible role of this interleukin in the immune component of chronic renal allograft dysfunction.

FR-PO396

Gene Expression Profiles in CD4+ T Cells Suggest an Interferon Alpha Signature in Chronic Antibody-Mediated Rejection (CAMR) of Kidney Transplantation Paola Pontrelli,[1] Annarita Oranger,[1] Matteo Accetturo,[1] F. Rascio,[2] Margherita Gigante,[1] Giuseppe Castellano,[1] Marco Fiorentino,[1] Anna Zito,[1] Gianluigi Zaza,[3] Giovanni Stallone,[2] Loreto Gesualdo,[1] G. Grandaliano.[2] *[1]Dept of Emergency and Organ Transplantation, Univ of Bari, Italy; [2]Dept of Medical and Surgical Sciences, Univ of Foggia, Italy; [3]Dept of Medicine, Univ of Verona, Italy.*

Background: CAMR is the main cause of graft loss, but its pathogenesis is still unclear. The aim of the present study was to investigate the molecular mechanisms underlying CAMR by the analysis of gene expression profiles of both total peripheral lymphomonocytes (PLM) and isolated CD4+ and CD8+ T cells.

Methods: We enrolled 14 patients with biopsy-proven CAMR and 12 stable transplant recipients with normal graft (control group). Gene expression profiles of PLM and CD4+ and CD8+T cells were assessed using Agilent microarrays. Results were evaluated by statistical (unpaired t tests, moderated t test, Benjamini-Hochberg correction, Storey q-value) and functional pathway analysis (Ingenuity Pathway Analysis) and then validated by q PCR in an independent set of patients. To analyze the genome-wide expression of CD4+ and CD8+T cells, we enrolled an independent cohort of 8 CAMR patients and 8 control subjects.

Results: Gene expression profiles of PLM identified a characteristic activation of the interferon (IFN)-alpha pathway in CAMR patients. Interestingly, the gene expression profiles of CD4+ and CD8+ T cells resulted completely distinct: only one gene (TNFSF10) was commonly expressed in CAMR patients versus control. CD4+T cells showed a specific IFNalpha feature ($p=5.06*10-11$), confirming the differential expression of genes such as IFIT1 (Fold change:+9.5) and IFIT3 (Fold change:+16.6). CD8+ T cell response resulted instead less unambiguous, as several pathways were involved (Tryacylglicerol biosynthesis $p=1.45*10-3$; TREM1 signaling $p=5.8*10-2$; Toll like receptor signaling $p=5.2*10-2$) except type I IFNs signaling.

Conclusions: Our data suggest a key role for IFN-alpha in modulating the immune response during CAMR, mainly influencing CD4+T cells response. This observation may open new perspectives for non-invasive diagnosis and to define new therapeutic targets.

FR-PO397

The Onset of Post-Transplant Malignancies Is Related to a Change in Gene Expression Profiles in Peripheral Blood Mononuclear Cells Giovanni Stallone,[1] F. Rascio,[1] Paola Pontrelli,[2] Matteo Accetturo,[2] Annarita Oranger,[2] Margherita Gigante,[2] Giuseppe Castellano,[2] Marco Fiorentino,[2] Barbara Infante,[1] Loreto Gesualdo,[2] G. Grandaliano.[1] *[1]Dept of Medical and Surgical Sciences, Univ of Foggia, Italy; [2]Dept of Emergency and Organ Transplantation, Univ of Bari, Italy.*

Background: Malignancies are the third leading cause of death in renal transplant recipients and their incidence is increasing. Although the role of the immune system in malignancies development is known, mechanisms of tumor escape remain an unsolved problem.

Methods: We enrolled 8 patients with post-transplant neoplasia (PTN: 2 kidney graft, 3 native kidney, 2 prostate, 1 stomach), 8 transplanted patients without neoplasia (Tx-control) and 8 non-transplanted patients with cancer (neoplasm control: 4 kidney, 3 prostate,1 bladder). All groups were comparable for the main clinical characteristics/ demographics. Transplant patients were all receiving immunosuppressive therapy with calcineurin inhibitors, mycophenolate, steroids. The transcriptomic profiles of peripheral blood mononuclear cells were assessed by microarray. Results were analyzed statistically and functionally (Ingenuity Pathway Analysis).

Results: 4345 genes were differentially expressed between PTN and Tx-control. The most significantly represented pathway was linked to the mechanisms of cancer ($1.71*10^{-5}$, 87 genes). The first 6 network (score = 34) included regulation of cell cycle and gene expression, reparative mechanisms of RNA/DNA, the pathogenesis of immunological and metabolic disorders. The 29 differentially expressed genes between PTN and neoplasm control were included in two networks. The first (score = 56) consisted of 21 genes related to TGF-beta. Among the most activated pathway there was coagulation. In particular, the tissue factor was significantly increased in the PTN group (fold-change: +2.93).

Conclusions: Our data, using an "omic" approach, may allow us to identify the immunological mechanisms underlying the development of post-transplant malignancies and suggest new markers useful in the monitoring of transplanted patients.

FR-PO398

The Histopathological Investigation of Kidney in Acute Graft-versus-Host Disease After Allogeneic Rat Bone Marrow Transplantation

Seiichiro Higo,[1,2] Akira Shimizu,[1] Yukinari Masuda,[1] Shinya Nagasaka,[1] Yusuke Kajimoto,[1] Go Kanzaki,[1] Megumi Fukui,[2] Kiyotaka Nagahama,[1] Akiko Mii,[2] Shuichi Tsuruoka.[2] *[1]Dep. of Analytic Human Pathology, Nippon Medical School, Tokyo, Japan; [2]Dep. of Nephrology, Nippon Medical School, Tokyo, Japan.*

Background: Allogeneic hematopoietic and bone marrow cell transplantation are responsible for acute and chronic graft-versus-host disease (GVHD). Liver, gut, and skin are known to primary target sites of GVHD. However, the disorder of kidney in acute GVHD is not well-understood. We examined the clinical and histopathological characterizations of the kidney in acute GVHD in Dark Agouti (DA)-to-Lewis rat bone marrow transplantation (BMT) model.

Methods: Acute GVHD was induced in Lewis rats ($RT1^l$) by transplantation of DA rat ($RT1^a$) bone marrow cells (6.0×10^7 cells) after irradiation (10Gy) without immunosuppression. We examined the impact of acute GVHD on the kidney in allogeneic BMT rats and compared them with those in Lewis-to-Lewis syngeneic BMT and non-BMT control rats.

Results: In peripheral blood, almost white blood cells were constituted with DA phenotype. Between 21 and 40 days after BMT, severe acute GVHD was developed with decreased body weight (>20%), skin rush with alopecia, and diarrhea. Liver and kidney dysfunction was detected: asparate aminotransferase (AST: 271.8 ± 104.2 U/L), alanine aminotransferase (ALT: 82.8 ± 19.9 U/L), blood urea nitrogen (BUN: 33.9 ± 4.68 mg/dL) and urinry N-acetyl-b-D-glucosaminidase (NAG: 31.5 ± 15.5 U/L). In kidney, many numbers of CD3+ T-cells, CD8+ T-cells, and ED1+ macrophages infiltrated the interstitial inflammation around small arteries that expanded into peritubular interstitium with peritubular capillaritis. CD4+ T-cells also infiltrated the kidney. Acute glomerulitis and endarteritis in small arterioles were evident. Acute tubulitis with $CD3^+$ T-cells were also noted. No obvious IgG, IgM, and C3 deposition was detected in the kidney.

Conclusions: Kidney was one of the target organs of acute GVHD. The pathology of acute GVHD in the kidney was characterized by T cell-mediated injury for the microvascular endothelium and renal tubules, and these findings were very similar of acute T cell-mediated rejection in transplanted kidney grafts.

FR-PO399

Contractile Pericytes May Contribute to Calcineurin Inhibitor-Mediated Nephrotoxicity

Mark C. Kelly, Carol Crawford, Scott S.P. Wildman, Claire M. Peppiatt-Wildman. *Urinary Physiology, Medway School of Pharmacy, Kent, United Kingdom.*

Background: Cyclosporine A (CsA) and Tacrolimus (FK-506) are immunosuppressant calcinerium inhibtors (CNI's) prescribed to prevent allograft rejection post kidney transplant. Both agents are however nephrotoxic, which significantly impacts upon long-term kidney graft/patient survival. The precise mechanism of the CNI-induced toxicity is unknown, although impairment of endothelial cell function and reduced production of endogenous renal vasodilators has been noted with concomitant release of vasoconstrictors resulting in net vasoconstriction and exacerbated ischemia.Rapamycin is macrocyclic antibiotic that shows similar immunosuppression to CNI's, albeit through a different pathway, but more importantly, a reduced nephrotoxicity associated with its use, potentially offering an alternative immunosuppression regime for allograft transplantation without risk of acute rejection.

Methods: We have utilized a live kidney slice model, developed by our group [1], to investigate the mechanism (s) of CNI-induced nephrotoxicity in the renal medulla; a region of the kidney that is particularly sensitive to ischemia.

Results: Data presented here demonstrates both CsA (600 ng/ml) and FK506 (800 ng/ml) caused vasoconstriction (9.9%±0.88% and 9.2%±0.63%, n=7, respectively) of vasa recta via their specific action at contractile pericytes, whereas Rapamycin (44ng/ml) failed to evoke pericyte constriction. Application of CsA with Rapamycin produced a significantly enhanced contractile response compared to CsA alone (13.2% versus 9.9% respectively). The thiazide diuretic, hydrochlrothiazide, was shown to significantly reduce FK506-induced vaosconstriction (3.15% versus 11.35%, respectively) while the calcium channel antagonist, Diltiazem, significantly inhibited CsA-induced vasoconstriction (4.04% versus 8.98%, respectively). Medullary tubule diameter was unaffected by bath application of CsA, FK506 and Rapamycin.

Conclusions: Data suggesting that CNI-induced constriction of vasa recta by pericytes may contribute to the nephrotoxicity and exacerbated ischemia that can result in allograft dysfunction in renal transplant patients.

Human Cytomegalovirus Infection Induces Viral Chemokine Receptor US28 Expression in Renal Allografts and Dedifferentiation of Infected Cells

Wouter Lollinga,[1] Raymond H. De Wit,[3] Afsar Rahbar,[2] Annelies Riezebos-Brilman,[1] Cecilia Söderberg-Naucler,[2] Willem Van Son,[1] Johannes S. Sanders,[1] Martine J. Smit,[3] Jacob van den Born.[1] *[1]Nephrology and Medical Microbiology, UMCG, Groningen, Netherlands; [2]Medicine, Karolinska, Stockholm, Sweden; [3]Medicinal Chemistry, VU Univ, Amsterdam, Netherlands.*

Background: Human cytomegalovirus (HCMV) infection is associated with decreased renal graft function and survival. HCMV expresses US28, a chemokine receptor that might alter cell phenotype by modifying intracellular signaling. We investigated US28 expression in renal biopsies and its effect on cell phenotype in vitro.

Methods: US28 immunohistochemistry was semi-quantitatively scored in recipient renal transplant biopsies (n=49) from HCMV-seropositive donors. Cultured primary vascular smooth muscle cells (VSMCs) and tubular epithelial cells (TECs) were infected with wild type HCMV and stimulated with PDGF-BB and TGF-β1. Expression of viral antigens and phenotypic markers was detected using qRT-PCR, and infection efficiency and dissemination using HCMV carrying a GFP-tag.

Results: US28 was expressed in all renal compartments, but was most prevalent (Kruskal-Wallis; $P<0.001$) in VSMCs (42% of cells positive) and TECs (30%). Cultured VSMCs were permissive to HCMV, underwent lytic infection and IEA, US28 and HCMVpol displayed distinct kinetics. Infection resulted in a phenotype transition characterized by loss of a-SMA and SM22a along with induction of Klf4 (27-, 13 and 2-fold). Infection of TECs reduced E-cadherin and induced vimentin. HCMV infection followed by PDGF-BB and TGF-β1 resulted in more extreme phenotypic marker changes.

Conclusions: HCMV induced US28 in renal allografts and dedifferentiation of cultured cells. Long-term renal graft survival remains poor after transplantation and US28 could link HCMV to transplant dysfunction. Phenotype transition can enable HCMV to initiate or instigate IF/TA and transplant vasculopathy; two major features of transplant dysfunction. The implication of US28 for transplant histopathology and recipient clinical outcome are now investigated. Further studies will elucidate the role of US28 and its potential for therapeutic intervention, so to prevent HCMV-induced transplant dysfunction.

Adherence to Immunosuppression in Kidney Transplant Patients Treated in a Federal Universal Healthcare System

Dustin J. Little,[1] Robert Nee,[1] Deepti S. Moon,[1] Matthew Ward,[2] Christina M. Yuan,[1] Kevin C. Abbott,[1] Rahul Jindal.[3] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]Uniformed Services Univ, Bethesda, MD; [3]Organ Transplant Surgery, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Medication non-adherence following organ transplantation is common, and associated with increased risk of graft loss. Immunosuppression (IS) medication cost may be an important contributor to non-adherence, and leading nephrology organizations continue to advocate for changes to U.S. public policy to decrease patient out-of-pocket IS costs. To our knowledge, however, medication adherence has not been reported in U.S. patients who receive IS medications at no out-of-pocket cost. We therefore designed a study to evaluate medication adherence in organ transplant recipients treated in the military health system (MHS).

Methods: Study subjects reported medication adherence and depressive symptoms via the Medication Therapy Adherence Scale (ITAS-M) and Beck Depression Inventory (BDI), respectively. Subjects also completed the Immunosuppressant Therapy Barrier Scale (ITBS), which includes a question rating level of agreement with the following statement, "I skip doses of my immunosuppressant medication (s) when I am short of money."

Results: Nineteen of 21 (90%) subjects approached about the study provided consent and completed the study instruments. The median age and time from transplant to study participation were 52 years and 12 months, respectively. Twelve of 19 (63%) subjects were male. The mean ITAS-M was 11.5 ± 0.99, with 12, 5, and 1 subject reporting perfect (12/12 ITAS-M score), nearly perfect (11/12), and less than perfect (≤ 10/12) adherence, respectively. Fifteen, 1, and 3 patients reported minimal, mild, and moderate depressive symptoms, respectively. Thirteen patients strongly disagreed with the ITBS statement about skipping IS medications when short of money;2 subjects disagreed, 1 strongly agreed, and 2 did not answer the question.

Conclusions: Our preliminary results suggest that MHS transplant patients who receive free IS medications have low levels of medication non-adherence and depressive symptoms, and do not miss IS medications due to financial concerns.

FR-PO402

Utilization of Smart Phones and Medication Adherence in Adolescents with Kidney Disorders Oleh M. Akchurin, Alexandra P. Hollman, Dionne Sears, Rebecca Hashim, Frederick J. Kaskel, Paula Marcus, Marcela Del Rio. *Montefiore Medical Center / Albert Einstein College of Medicine.*

Background: Medication non-adherence is widespread in adolescents with chronic conditions; however, little is known about the utilization of available smart phone-based technologies in community-based settings.

Methods: Study was approved by the IRB of Montefiore Medical Center and powered for 70 participants. Patients at pediatric nephrology clinic were surveyed about cell phone access and its utilization for medication adherence management. Medication adherence was assessed by self reports (objective assessment based on the drug blood levels is ongoing). Standardized adolescent medication barriers scale was used to identify obstacles for medication use in three domains (frustration, adaptation, and ingestion).

Results: The majority (77%) of teens continue to utilize such traditional techniques of improving medication adherence as pillboxes and incorporating medications into daily routines. While 93% of surveyed teens have a smart phone in their personal possession, only 29% are aware about medical mobile apps, although 50% reported that they utilized cell phones for some kind of reminders to take medications. Only 30% of patients use an electronic device to maintain their medication list / schedule. Boys were more likely to use cell phones to remember to take medications than girls (71% versus 17%) and the prevalence of 100% self-reported medication adherence was higher in teens who utilized cell phones for reminders (70% versus 14%). Patients who used cell phone reminders reported significantly fewer barriers for taking medications within the adaptation domain ($p<0.03$) and had a trend towards having fewer barriers on the frustration domain ($p=0.05$), while ingestion domain was not different ($p=0.2$).

Conclusions: A substantial number of teenagers with kidney disorders and transplants reported cell phone use for managing their medications; however, significant opportunity for utilizing smart phone-based technology to improve medication adherence remains. Utilization of cell phones was associated with beneficial self-reported outcomes in this study. Data collection and analysis on this project is currently ongoing.

FR-PO403

Peers4PATH: Feasibility of Medication Adherence Measures in Adolescent Transplant Recipients Sandra Amaral, Nina Foster, Hannah S. Dashefsky, Christopher S. Paterno, Susan L. Furth. *Pediatrics, Children's Hosp Phila, Phila, PA.*

Background: Adolescents with solid organ transplants face difficulties adhering to prescribed medication regimens. Although screening for nonadherence is tremendously important, nonadherence is challenging to identify and quantify, and there is no one "gold standard" for measurement.

Methods: Peers4PATH is an NIDDK-sponsored clinical trial to test the efficacy of peer mentoring to improve medication adherence in adolescent solid organ transplant recipients ages 14-23 years. Subjects are randomized to a peer mentor versus standard of care. Peer mentors interact with mentees over a one-year study intervention by phone, text, email or Facebook weekly and have in-person meetings at time 0, 6 months and 12 months. The primary outcome is medication adherence, captured in four different ways: pharmacy refill data, pill counts, self-report (by the modified Medication Adherence Measure-Medication Module) and coefficient of variation of immunosuppressive drug levels.

Results: To date, 46 subjects (of an anticipated 60) have completed their first visit and have baseline adherence data available. Pill counts were successfully obtained for only 30 subjects (65.2%) due to patients stockpiling medications and using bottles from prior time periods. Pharmacy refill records were successfully obtained for 32 subjects (69.6%) and were difficult to obtain for patients who use multiple pharmacies or mail orders and for those with frequent dose changes. 45 subjects (97.8%) completed the self-report measure and 45 (97.8%) had ≥ 2 drug levels to calculate coefficient of variation.

Conclusions: Though multiple measures of adherence are thought to provide a more complete picture of true adherence behavior, our initial findings suggest that the feasibility and interpretability of pharmacy refill data and pill counts is poor for adolescent solid organ transplant recipients. Although imperfect, self-report and immunosuppressive drug levels appear preliminarily more feasible to obtain for this population. With longer follow up, we will examine these four adherence measures as time-dependent covariates and consider the intra- and inter-individual variation between intervention and control groups.

FR-PO404

Generic Immunosuppression in Kidney Transplantation: A Systematic Review and Meta-Analysis Amber O. Molnar,[1,2] Anne K. Tsampalieros,[3,2] Dean Fergusson,[2] Alexandria Bennett,[2] Greg A. Knoll.[1,2] *[1]Nephrology, Univ of Ottawa, Ottawa, ON, Canada; [2]Epidemiology, Ottawa Hospital Research Inst, Ottawa, ON, Canada; [3]Nephrology, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada.*

Background: The use of generic immunosuppressants in the kidney transplant population has the potential for huge cost savings. However, there is growing concern that generic and trade name immunosuppressants are not bioequivalent and differ in terms of clinical efficacy.

Methods: We performed a systematic search of the literature using MEDLINE and EMBASE from 1980 to 2014. Studies comparing a trade name to a generic immunosuppressant in kidney transplant recipients were included. The main outcomes were bioequivalence and acute rejection. If appropriate, data was meta-analyzed.

Results: We screened 1,542 citations of which 159 were selected for full text review. 39 studies met eligibility criteria (14 trials, 14 non-randomized interventional studies and 11 observational studies). 3 studies compared Cellcept to a generic, 9 studies compared Prograf to a generic, and 27 studies compared Neoral to a generic. A total of 10 studies (Cellcept n=0; Prograf n=1; and Neoral n=9) reported and met the standard criteria for bioequivalence (90% confidence intervals [CI] for the relative means of the AUC and Cmax 0.80 to 1.25). In terms of clinical equivalence, the risk of acute rejection was similar for trade name versus generic immunosuppressants (Peto odds ratio [OR] 0.71, 95% CI 0.16-3.1 for Cellcept; Peto OR 1.06, 95% CI 0.50-2.27 for Prograf; Peto OR 0.93, 95% CI 0.61-1.41 for Neoral).

Conclusions: Few studies reported the criteria needed to determine bioequivalence. While acute rejection rates were similar, analyzed studies were primarily non-randomized, underpowered and had short follow up times.

FR-PO405

Post Hoc Subgroup Analysis of ZEUS: Outcome on Renal Function, Efficacy and Safety in Living-Donor Kidney Transplant Recipients after Conversion from a Calcineurin Inhibitor to an Everolimus Based Regimen Claudia Sommerer,[1] Klemens Budde,[1] Martin G. Zeier,[1] Rudolf P. Wuthrich,[3] Petra Reinke,[1] Ute Eisenberger,[1] Anja Susanne Muehlfeld,[1] Wolfgang Arns,[1] Rolf A. Stahl,[1] Katharina M. Heller,[1] Oliver Witzke,[1] Heiner H. Wolters,[1] Barbara M. Suwelack,[1] Ingeborg A. Hauser,[1] Martina Porstner,[2] Frank Lehner.[1] *[1]ZEUS, Study Group, Germany; [2]Novartis, Pharma, Germany; [3]ZEUS, Study Group, Switzerland.*

Background: To study renal function and patient outcome in living donation subgroup of kidney de novo transplant recipients after conversion to an everolimus (EVR) based regimen and withdrawal of calcineurin inhibitor (CNI) therapy.

Methods: Post hoc subgroup analysis from the prospective, open-label, controlled, multi-center study ZEUS. 300 renal transplant (Tx) patients were randomized at month 4.5 post Tx to either receive EVR plus enteric coated-mycophenolate sodium (EC-MPS) or cyclosporine (CsA) plus EC-MPS regimen, among them were 80 living donor recipients (EVR n=42; CsA n=38).

Results: In this subpopulation of living donation recipients, adjusted estimated GFR (Nankivell) at month 12 (the primary endpoint) was 74.3 (95%CI [70.7, 77.9]) mL/min/1.73m2 with EVR versus 63.8 (95%CI [60.0, 67.7]) mL/min/1.73m2) with CsA, a difference of 10.5mL/min/1.73m2 in favor of EVR ($p<0.001$). From randomization to month 12, adjusted estimated GFR increased by a mean of 9.8 (95%CI [6.2, 13.4]) mL/min/1.73m2 in the EVR subgroup, versus -0.7 (95%CI [-4.6, 3.1]) mL/min/1.73m2) ($p<0.001$) within the CsA group. Of six biopsy-proven acute rejection episodes in the EVR group, five were Banff grade I. Overall safety profile was similar between treatment groups. Discontinuation due to adverse events occurred in three EVR-treated patients (7.1%) and five CsA-treated patients (13.2%) between randomization and month 12.

Conclusions: EVR-based regimen with early elimination of CNI therapy in living donor kidney transplant recipients is associated with a significant renal benefit at 12 months post Tx without compromising safety and efficacy.

FR-PO406

HERAKLES Trial after 36 Month: Follow-Up Results on Efficacy and Safety of Three Different Treatment Regimens in De Novo Renal Transplant Patients Claudia Sommerer,[1] Klemens Budde,[1] Wolfgang Arns,[1] Petra Reinke,[1] Thomas Rath,[1] Ingeborg A. Hauser,[1] Hans-Hellmut Neumayer,[1] Frank Lehner,[1] Peter Weithofer,[1] Johannes Jacobi,[1] Martina Porstner,[2] Daniel Baeumer,[2] Martin G. Zeier,[1] Oliver Witzke.[1] *[1]HERAKLES Study Group, Germany; [2]Novartis Pharma, Germany.*

Background: To compare safety and efficacy of 3 immunosuppressive regimen 3 years after renal Tx.

Methods: A prospective, open-label, randomized (rdz), controlled, multi-center study where all pts received induction with basiliximab, cyclosporine A (CsA), enteric-coated mycophenolate sodium (EC-MPS) and steroids. 3 months (Mo) post Tx 499pts were rdz 1:1:1 to either a) continue standard CsA (100-180ng/ml) +EC-MPS (n=166) (STD) or convert b) to calcineurin inhibitor (CNI)-free regimen with everolimus (EVR) (5-10ng/ml) and EC-MPS (n=171) or c) to a CNI-low regimen with EVR (3-8ng/ml) and low CsA (50-75ng/ml) (n=162). Steroids were continued. Mo36 FU visit was performed by 123 (89%) STD, 130 (95%) CNI-free, 123 (94%) CNI-low treated pts of the FU population.

Results: Since rdz to Mo36 BPAR was reported in 19/151 (13%) STD, 22/149 (15%) CNI-free and in 21/146 (14%) CNI-low pts (ITT). 3 deaths (2%) occurred in STD, 2 (1%) in CNI-free and 5 (3%) in the CNI-low group. 6 (4%) graft losses were observed in the STD, 5 (3%) in the CNI-free and 1 (1%) in the CNI-low group. Composite failure (BPAR,death,graft loss,loss to FU): 27 (19%) in STD, 28 (20%) CNI-free and 33 (23%) in CNI-low group; premature discontinuation due to AEs: 4/154 (3%) in STD, 4/150 (3%) in CNI-free and 1/147 (1%) in CNI-low group (safety set) from Mo12 to 36.

Safety Pop. n(%) *during FU (Mo12-36)	Standard	CNI-free	CNI-low
Infections	56 (36.4)	74 (49.0)	55 (37.7)
Severe infections	12 (7.8)	14 (9.3)	12 (8.2)
Infections leading to hospitalisation	40 (26.0)	47 (31.1)	41 (28.1)
CMV	4 (2.6)	6 (4.0)	6 (4.0)
BKV	1 (0.6)	2 (1.3)	2 (1.4)
Hospitalisation due to:			
Acute rejection	13 (8.4)	16 (10.6)	12 (8.2)
Cardiovascular event	7 (4.5)	4 (2.6)	2 (1.4)
GI event	7 (4.5)	6 (4.0)	7 (4.8)
Malignancy	2 (1.3)	8 (5.3)	3 (2.1)
Metabolic disorder	2 (1.3)	0	0

cGFR (Nankivell) was significantly improved at Mo36 by +7.0mL/min/1.73m2 in favor of the CNI-free group (ITT;p<0.01).

Conclusions: Mo36 results from HERAKLES show that an immuosuppression using EVR with low-dose or without CNI reflect an efficacious and safe therapeutic approach offering the opportunity for an individualized immunosuppression.

FR-PO407

5 Year Data of the APOLLO Trial: Outcome on Renal Function of an Everolimus Based Therapy after Calcineurin Inhibitor Withdrawal in Maintenance Renal Transplant Recipients

Klemens Budde,[1] Thomas Rath,[1] Barbara M. Suwelack,[1] Petra Reinke,[1] Hermann G. Haller,[1] Oliver Witzke,[1] Martina Porstner,[2] Daniel Baeumer,[2] Wolfgang Arns,[1] Claudia Sommerer.[1] *[1]APOLLO Study Group, Germany; [2]Novartis Pharma, Germany.*

Background: To study renal function, safety and efficacy of an Everolimus (EVR) based regimen after Calcineurin-Inhibitor (CNI) withdrawal in maintenance kidney allograft recipients.

Methods: In an open-label, randomized,controlled,multi-center study 93 patients (pts) on stable immunosuppressive therapy consisting of CNI (CsA or Tac), Enteric-Coated Mycophenolate Sodium (EC-MPS) with or without steroids were randomized to either continue CNI/EC-MPS or convert to an EVR/EC-MPS based regimen. After completion of the 12-months (Mo) core study patients were included in an observational 4 year follow-up.

Results: 93 maintenance kidney Tx pts with a mean time of 6.4 years since most recent transplantation (Tx) were randomized to either EVR (n=46) or CNI (n=47) treatment. 78 pts completed 12Mo core study, 67 (72%) attended the final 60Mo visit. Mean trough levels were 81±34ng/ml in CsA, 5.2±1.9ng/ml in Tac and 6.1±2.4ng/ml in EVR treated pts. Mean time post-Tx at baseline was 82.6 months and 70.5 months in the EVR and CNI groups, respectively. At Mo60, adjusted mean eGFR (Nankivell) was 63.0 (95% CI 57.8, 68.2) mL/min/1.73m2 in the EVR versus 57.9 (95% CI 52.6, 63.1) mL/min/1.73m2 in the CNI group, a difference of 5.1 (95% CI -0.6, 10.8) mL/min/1.73m2 (p=0.076). Among pts who remained on randomized study drug until Mo60, mean eGFR (Nankivell) was 71.6 (95% CI 64.2, 79.0) mL/min/1.73m2 in EVR-treated pts (n=21) versus 60.6 (95% CI 55.1, 66.1) mL/min/1.73m2 in CNI-treated pts (n=29) (mean difference 11.0; 95% CI 3.6, 18.5 mL/min/1.73m2; p=0.005). No cases of BPAR occurred from randomization to Mo60 in either group. Graft loss occurred in 3EVR-treated pts and one CNI-treated patient. Until Mo60 one death had occured in the EVR group, three deaths in the CNI group. No unexpected safety concerns were observed in either group.

Conclusions: The late conversion to an EVR/EC-MPS treatment in maintenance renal Tx pts after CNI withdrawal is safe and led to a sustained better renal function in EVR treated pts 5 years post Tx.

Renal Function Outcomes Associated with Once-Daily MeltDose Tacrolimus versus Twice-Daily Tacrolimus, a Phase 3 Randomized Trial in De Novo Kidney Transplantation

Lionel Rostaing,[1] Suphamai Bunnapradist,[2] Steven M. Steinberg.[3] *[1]Hôpital de Rangueil, Toulouse, France; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]California Inst of Renal Research, San Diego, CA.*

Background: Conversion of stable kidney transplant recipients (KTR) from twice-daily tacrolimus (tac) (Prograf) to a novel, once-daily, Meltdose® formulation of tac (Envarsus®; LCP-Tacro) showed greater bioavailability, noninferior efficacy and similar safety and with lower total daily dose (TDD) for Envarsus.

Methods: Here we report renal function results from a phase 3 double-blind, double-dummy, trial of de novo KTR randomized to Envarsus or Prograf. Renal function was assessed via the MDRD7 formula. Delayed graft function (DGF) was clinician-reported as an adverse event (AE) or a serious adverse event (SAE). eGFR at 12 months follow-up are reported; 2 year data are forthcoming.

Results: A total of N=543 (Envarsus, n=268; Prograf, n=275) KTR were included. Target trough levels were achieved earlier for Envarsus versus Prograf; within 1 day of first dose 66% of Envarsus patients versus 25% of Prograf achieved troughs of ≥6ng/mL, p<0.001. Total daily dose (TDD) and troughs were higher for Envarsus in the first 2 weeks; cumulative dose over the study was 14% lower for Envarsus. Incidence of DGF tended to be lower for Envarsus (7%) versus Prograf (11%). DGF reported as a SAE trended towards being lower for Envarsus (3%) versus Prograf (6%). Both Envarsus and Prograf were associated with good renal function over the first 12 months of the study period; 2 year data will be available by the time of the conference.

Conclusions: These results show that both tac formulations are associated with good renal function in the first year post-transplant. A higher initial Envarsus TDD was not associated with renal function decrement, either in terms of eGFR or DGF.

FR-PO409

Superior Renal Function in an Everolimus-Based Calcineurin Inhibitor Free Regimen Compared to Standard Cyclosporine/Mycophenolate and Low Cyclosporine/Everolimus: Follow-Up of the HERAKLES Study at Month 36

Wolfgang Arns,[1] Klemens Budde,[1] Claudia Sommerer,[1] Thomas Rath,[1] Volker Kliem,[1] Petra Reinke,[1] Johannes Jacobi,[1] Martina Porstner,[2] Daniel Baeumer,[2] Hans-Hellmut Neumayer,[1] Ingeborg A. Hauser,[1] Frank Lehner,[1] Oliver Witzke,[1] Martin G. Zeier.[1] *[1]HERAKLES Study Group, Germany; [2]Novartis Pharma, Germany.*

Background: To follow-up (FU) on renal function (RF) at month (Mo) 36 after kidney Tx in patients (pts) on immunosuppressive regimen with different calcineurin inhibitor (CNI) exposures.

Methods: 802 patients (pts) were included in a 1 year, prospective, open-label, randomized, multi-center study. After induction with basiliximab all pts received cyclosporine A (CsA), enteric-coated mycophenolate sodium (EC-MPS) and steroids. 3 months post Tx 499 pts were randomized (rdz) 1:1:1 to either a) continue standard (STD) CsA (100-180ng/ml) with EC-MPS (n=166), b) convert to CNI-free regimen with everolimus (EVR;5-10ng/ml) and EC-MPS (n=171) or c) convert to CNI-low regimen (CsA 50-75ng/ml +EVR 3-8ng/ml) (n=162). Mo36 FU visit was performed by 123 (89%) STD, 130 (95%) CNI-free and 123 (94%) CNI-low pts.

Results: Median trough levels were: CsA 98ng/ml in STD, 72ng/ml in CNI-low treated pts; EVR 6.0ng/ml in CNI-free and 5.4ng/ml in CNI-low pts. cGFR (Nankivell) was similar at rdz, had significantly improved at Mo12 by +5.6mL/min (95%CI:[+2.9;+8.3];p<0.001) and remained significantly improved by +7.0mL/min in favor of CNI-free group at Mo36 (p=0.009). 58% of CNI-free, 36% of CNI-low and 46% of STD treated pts had an improvement in RF at Mo36 (p=0.04 CNI-free versus STD). All groups had similar rejection rate since rdz (13%STD, 15%CNI-free, 14%CNI-low) and an overall comparable safety profile.

Conclusions: CNI-free as well as reduced CNI therapy in combination with EVR are both efficacious and safe regimen. CsA trough levels showed that in CNI-low group the CNI reduction was not fully met, hence lower effect on sparing RF should be expected compared to STD. However, CNI-free group showed better RF maintained for 3years post Tx. The results of this large trial confirm previous reports of improved RF after CsA withdrawal by an EVR-regimen in combination with EC-MPS.

FR-PO410

Efficacy of Envarsus Once-Daily MeltDose Tablets versus Twice-Daily Prograf Capsules in Black De Novo and Stable Kidney Transplant Recipients: A Pooled Analysis of Two Phase 3 Trials

Suphamai Bunnapradist,[1] Steven M. Steinberg,[2] Shamkant P. Mulgaonkar.[3] *[1]David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]California Inst of Renal Research, San Diego, CA; [3]St. Barnabas Medical Center, Livingston, NJ.*

Background: Black kidney transplant recipients (KTR) have shown increased risk for poor clinical outcomes post-transplant. Management of immunosuppression may be challenging in black KTR due to the high frequency of the CYP3A5 genetic polymorphism which increases clearance and lowers bioavailability of tacrolimus (tac). Envarsus® (LCP-Tacro), a once-daily MeltDose® formulation of tac, has shown non-inferiority, similar safety, improved bioavailability, and less peak and peak-trough fluctuations versus Prograf.

Methods: The efficacy of Envarsus in Black KTR was examined in a pooled analysis of data from two phase 3 randomized, controlled trials. Treatment failure (death, graft failure, centrally read biopsy-proven acute rejection [BPAR], or lost to follow-up) was compared between black KTR randomized to Envarsus versus Prograf. One trial included de novo KTR where initial dosing was: Envarsus: 0.17 mg/kg/day; Prograf: 0.1 mg/kg/day. In the other trial, stable black KTR were switched from Prograf to Envarsus at a conversion ratio of 0.85.

Results: N=93 black KTRs were enrolled in the two trials (Envarsus N=44; Prograf N=49; 26% were de novo KTR). Significantly more treatment failures occurred in black KTR in the Prograf group versus the Envarsus group at 12 months (18.4% versus 4.5%; difference [95% CI]: -13.82% [-27.22%, -0.31%]). Numerically, more black KTR in the Prograf group had BPAR versus the Envarsus group at 12 months (12% versus 2%; -9.97% [-22.12%, 1.57%]). In the de novo study, initial target tac troughs (6–11 ng/mL) were more rapidly achieved following first dose of Envarsus versus Prograf.

Conclusions: Envarsus appears to be efficacious in black KTR. This analysis shows that Envarsus may be associated with fewer treatment failures among black KTR. The increased bioavailability of Envarsus contributes to the rapid achievement of therapeutic tac trough levels in the de novo setting and the maintenance of target levels in the conversion setting.

FR-PO411

Mycophenolate Mofetil (MMF) Therapeutic Drug Monitoring and Dose Modification in Pediatric Kidney Transplant Patients Vimal Chadha,[1] Judith Sebestyen,[1] Chelsey Jensen,[2] Bradley A. Warady.[1] *[1]Children's Mercy Hospital; [2]Children's Hospitals and Clinics of Minnesota.*

Background: Exposure to MMF is measured by area under the time-concentration curve (AUC) of mycophenolic acid (MPA). A goal AUC of 30 – 60 mg*h/L, has been suggested. However, there is substantial inter-patient variability between standard fixed-dose MMF and exposure to MPA. Therapeutic drug monitoring (TDM) of MPA has the potential for optimization and individualization of MMF dosing and efficacy.

Methods: All patients received MMF at an initial fixed dose of 450 mg/m^2 twice daily within 2 weeks of kidney transplant. AUC was determined by obtaining plasma MPA levels at 0, 1, 2 and 4 hours post dose once the patients were receiving oral MMF. The dose was then adjusted to achieve desired AUC based on first order kinetics. The data from 47 patients who received a kidney transplant between January 2010 and December 2013 was analyzed.

Results: 42 patients with median age 10.9 yrs. (1.4 to 21.6 yrs.) had MMF kinetics at baseline. Their daily MMF dose was 866 ± 96 mg/m^2 which resulted in AUC of 40 ± 19 mg*h/L. There was poor correlation between MMF dose and AUC (r = 0.08). Less than half (48%) of the patients had an AUC in the desired range (30 – 60 mg*h/L). 36% of patients had AUC < 30 mg*h/L, and 16% had AUC > 60 mg*h/L. The patients with subtherapeutic AUC were younger (median 4.5 yrs) in comparison to those with AUC > 60 (median 17.1 yrs). To achieve the desired AUC, the daily MMF dose was increased to 1133 ± 153 mg/m^2, and decreased to 634 ± 63 mg/m^2, in the younger and older children, respectively. 22 patients had repeat MMF kinetics at median of 6 months post-transplant. While their current daily MMF dose 880 ± 284 mg/m^2 was statistically not different (p = 0.88) from their initial dose, their AUC increased from 42 ± 20 at baseline to 54 ± 20 mg*h/L at 6 months ($p < 0.05$).

Conclusions: Our data reveals that systemic exposure to MPA is unpredictable at a fixed-dose regimen in pediatric kidney transplant recipients. Age appears to be a significant influence on exposure and MPA exposure tends to increase in patient over time. Individualized MMF dosing based on TDM has the potential for improving the outcome of transplant patients.

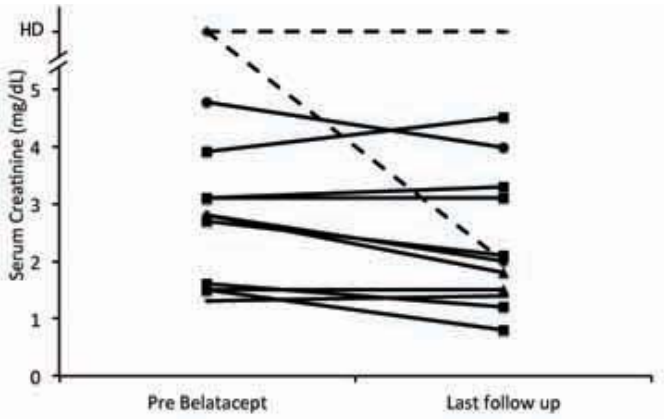
FR-PO412

Belatacept Conversion in Renal Transplant Recipients with Calcineurin Inhibitor Toxicity Russell J. Crew, Shefali Patel, Heather K. Morris, Lloyd Ratner, David J. Cohen, Sumit Mohan. *Columbia Univ Medical Center.*

Background: Although calcineurin inhibitors have improved kidney transplant and recipient survival, their use has significant nephro- and neuro-toxicities. Belatacept is a recently approved immunosuppressant for use at time of transplantation that does not share these properties. However, little is known about the safety and efficacy of conversion from a CNI based regimen to a Belatacept based regimen.

Methods: Conversion protocol: Patients received Belatacept 5mg/Kg on day 0, 14, 28, 42, 56 and then every 28 days with a 50% reduction of CNI after the second dose and cessation after the 5th dose of Belatacept.

Results: Since 2013, we have converted 13 patients from a CNI based regimen to Belatacept. for graft dysfunction (8), thrombotic microangiopathy (2), neurotoxicity (2) and bone marrow suppression (1). Patients were 54.3±15.7 years old, 54% male and were converted a median of 20 months (IQR: 12- 60) after transplant. After 8.8±7.7 months on Belatacept, mean+SD serum creatinine improved from 3.32 ±1.78 to 2.49±1.29 and includes renal recovery from dialysis dependence for one of two patients with severe TMA.



A single patient was hospitalized for pneumonia after conversion, recovered completely, but later had sudden cardiac death at home.

Conclusions: The short-term results of conversion to Belatacept show significant improvement in renal function and resolution of CNI related toxicity, but longer term follow up is needed to confirm its safety.

FR-PO413

Early Clinical Experience with Conversion from Calcineurin Inhibitors or Sirolimus to Belatacept in Renal Transplant Patients Marat Abdullin, Gregory Lee Braden, Michael J. Germain. *Baystate Medical Center, Springfield, MA.*

Background: Belatacept (Blt) demonstrated renal and metabolic benefits over a calcineurin inhibitors (CNI) based regimens in recent trials. No study has yet evaluated late conversion to Blt from CNI or mammalian target of rapamycin inhibitors (mTOR). We analyzed our experience in converting renal transplant patients from CNI or mTOR to Blt.

Methods: Patient switched to Blt from CNI or mTOR regimens with at least 4 months follow up were studied. Laboratory data including hemoglobin (Hb), serum creatinine (SCr), triglycerides (Tg), blood glucose (BG), urinary protein/creatinine ratio (PCR) before and after conversion were compared. We used three measurements before and after transition for SCr, Hb and BG, and two measurements before and after transition for Tg and PCR. Patients filled out a questionnaire to assess their experience with the conversion.

Results: 24 patients (14 male and 10 female) were switched from CNI (CNI group - 11 patients) or sirolimus (mTOR group - 13 patients) to Blt. Average age was 45.3 (17-74) years old. Average allograft age was 8 (1.5-20) years. Average follow up on Blt therapy was 13.2 (4-28) months. Indications for conversion were various side effects of CNI and mTOR, including proteinuria, pulmonary toxicity, diabetes, CNI renal toxicity, etc. SCr decreased in patients converted from CNI and remained unchanged in mTOR group. There was no change in Hb in either group. Tg and BG improved in both groups. PCR decreased in both groups.

	CNI	mTOR inhibitor	Combined
Creatinine, % change	- 9.7	- 0.9	- 4.9
Hemoglobin, % change	+ 3.1	+ 0.8	+ 1.9
Triglycerides, % change	- 23.7	-23.1	- 23.3
Fasting blood glucose, % change	- 21.1	- 7.1	- 13.3
Protein/creatinine ratio, % change	- 33.1	- 20.2	-25.7

No significant side effects with Blt were reported. No clinical rejections were noted. On a three point Lickert scale 10 out 14 patients reported feeling better after conversion.

Conclusions: Conversion to Blt from CNI and mTOR is safe, well-tolerated, associated with improved renal function in patients transitioned from CNI and stable renal function in patients transitioned from mTOR. It was associated with improved metabolic parameters and decreased proteinuria.

FR-PO414

Polyclonal and Monoclonal Antibodies for Induction Therapy in Kidney Transplant Recipients Penny E. Hill,[1] Nick Cross,[1] Nicholas Barnett,[2] Suetonia Palmer,[1] Jonathan C. Craig,[3] Angela C. Webster.[3] *[1]Christchurch Hospital; [2]Guy's and St. Thomas' NHS Foundation Trust; [3]Sydney School of Public Health.*

Background: Induction immunosuppression with antibody therapy is recommended for kidney transplant recipients but the relative benefits and harms of available agents remain uncertain.

Methods: Systematic review of randomised trials of all monoclonal or polyclonal antibodies (excluding interleukin-2 receptor antagonists) used as induction therapy in adult kidney transplant recipients. We appraised risk of bias and obtained estimates using random effects models.

Results: We identified 89 trials (8246 participants). Many study design details were incompletely reported. Compared to no induction, ATG prevented acute rejection (relative risk (RR) 0.63 95%CI 0.51-0.78) but increased CMV infection (RR1.56 95%CI 1.24-1.97). Estimates of treatment effects on mortality, graft survival, malignancy, PTLD, and NODAT were imprecise. In 6 trials (N=446) alemtuzumab, compared with ATG, had uncertain effects on acute rejection. Subgroup analysis of 4 trials with steroid withdrawal as a co-intervention

showed reduced acute rejection with alemtuzumab at 1 year (RR0.57 95%CI 0.35-0.93) compared to ATG but uncertain effects on mortality, graft loss, infection, malignancy and PTLD. Compared with triple therapy without induction antibody, alemtuzumab with steroid withdrawal increased CMV (RR2.28 95%CI 1.18-4.40) but estimates of treatment effects on mortality, graft loss, acute rejection, NODAT, PTLD and malignancy were imprecise.

Conclusions: Given a 45% acute rejection risk with no induction, 9 patients would need ATG to prevent 1 from having rejection. There would be 1 extra CMV case for every 10 patients treated with ATG. In steroid withdrawal trials 11 patients would require alemtuzumab to prevent 1 having rejection given a 21% rejection risk with ATG. Alemtuzumab and steroid withdrawal would cause 1 extra CMV case for 6 patients treated compared to no induction and triple maintenance without apparent benefits. ATG and alemtuzumab decrease acute rejection at a cost of increased CMV and patient centred outcomes of survival and reduced side effects do not appear to be improved.

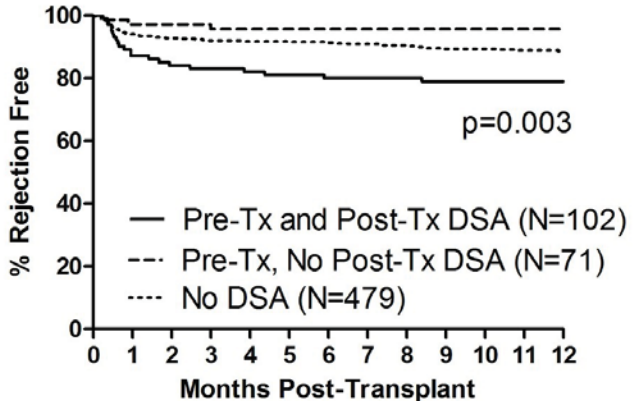
FR-PO415

Class, Timing and Persistence of Pre Transplant Donor Specific Antibodies (DSA) and Impact on Renal Allograft Outcomes Oluwafisayo O. Adebiyi, Jane Gralla, Alexander C. Wiseman, James E. Cooper. *Div of Renal Disease and Hypertension, Univ of Colorado, Aurora, CO.*

Background: Presence of low-level HLA donor specific antibodies pre-transplant (pre-tx DSA) often wanes prior to and following transplant. Specifically, few studies have evaluated the impact of DSA class, timing of pre-tx DSA detection and their persistence post-transplant on graft outcomes.

Methods: 652 consecutive recipients of a kidney or kidney/pancreas transplant with a negative pre-transplant FCXM between 09/2007 and 08/ 2012 at our center without desensitization therapy were analyzed. All patients underwent cell-based FCXM and SAB analysis on current and historic sera prior to transplantation. Patients were screened for DSA at post-transplant months 1, 6, 12, and annually thereafter. Graft outcomes were compared for patients with (DSA+) and without (DSA-) pre-transplant DSA.

Results: Of 652 patients with a negative FCXM and pre-tx DSA, 173 had DSA (DSA+, MFI $\geq$ 500) detected at any point prior to transplant by SAB analysis. Patients with pre-tx DSA that persisted post-transplant (N=102) had significantly higher acute rejection (AR) rates versus pre-tx DSA only versus no pre-tx DSA (p=0.003). With a median follow-up period of 2.3 years, presence, class type, timing of pre-tx DSA and persistence post-transplant was not associated with worse graft survival (p=0.71, p= 0.36, p=0.7 and p=0.44 respectively). Multivariate analysis of persistent pre-tx DSA impact on one year AR remains significant (p=0.05).



Conclusions: We present the first study to our knowledge evaluating the impact of timing, class type and post-transplant persistence of pre-DSA on renal allograft outcomes. Persistence of pre-tx DSA after transplant correlates with a modestly increased incidence of AR. However neither class type, timing of detection of pre-tx DSA, nor its persistence post-transplant impacts long term graft survival.

FR-PO416

Noninvasive Detection of Acute Renal Allograft Rejection by Measurement of Soluble Tim-3 in Urine Dajin Chen, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang Province, China.*

Background: The purpose of this study was to assess whether measurement of urinary soluble T cell immunoglobulin domain and mucin domain 3 (sTim-3) could be adopted as a new non-invasive diagnostic tool for acute rejection following renal transplantation.

Methods: 286 patients were enrolled between January 2001 and December 2009., including 116 with biopsy-proved acute rejection (AR), 80 patients with stable renal function and no abnormal histological findings (NO-AR), 23 patients with subclinical rejection (SCR) in protocol biopsy, 24 patients with biopsy-proven acute tubular necrosis (ATN) and 43 patients with biopsy-proven chronic allograft nephropathy (CAN). Urinary concentration of sTim-3 was determined by an enzyme-linked immunosorbent assay technique in 286 renal allograft recipients and 40 healthy controls.

Results: Patient with acute rejection (n=116) excreted urinary sTim-3 at a significantly higher level (4356±440.4ng/mmol creatine) than levels of patients with No-AR (n=80) and healthy controls (n=40) (P<0.001). Patients with acute tubular necrosis (n=24) excreted urinary sTim-3 at a significantly lower level (2060±217 ng/mmol creatine) than levels of patients with acute rejection. ROC curve was constructed to determine the discriminatory power of sTim-3 levels for diagnosis of acute rejection. The area under ROC curve was 0.874, which showed that sTim-3 was a suitable marker for the diagnosis of acute rejection. At a cut point of 1836 ng/mmol creatinine, the sensitivity was 89.4% and the specificity was 82.5% (P<0.001). Patients with steroid-resistant acute rejection (n=66) had significantly greater urinary sTim-3 concentration than patients with steroid-sensitive acute rejection (n=50) (5548±613.5ng/mmol creatinine versus 2653±391.7ng/mmol creatinine, P=0.0002).

Conclusions: This study demonstrates that the monitoring of urinary sTim-3 may be a useful non-invasive approach for the detection of acute rejection. Additionally, urinary sTim-3 levels were shown to predict the response to anti-rejection therapy.

FR-PO417

Effect of Pre-Transplant Use of Rituximab on Post-Transplant Clinical Outcome in Highly Sensitized Patients Seon Deok Hwang, Byung Ha Chung, Bum Soon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

Background: Pre-transplant sensitization is important risk factor for the development of antibody-mediated rejection and can result in inferior long-term allograft survival in kidney transplantation (KT). The aim of this study is to investigate the effect of pre-transplant Rituximab infusion on the clinical outcome in highly sensitized patients.

Methods: Between Jan. 2002 and Aug. 2013, 52 patients showed the result of panel-reactive antibody higher than 50%, but showed negative crossmatch test before transplantation. Out of them, 32 patients who took pre-transplant Rituximab at a dose of 375 mg/m^2 belonged to Rituximab group and remained 20 patients were regarded as historic control group. We compared the development of antibody mediated rejection, the change of allograft function and allograft survival rate between 2 groups after KT.

Results: Between two groups, no difference was found in baseline characteristics such as age at KT, gender, pre-transplant dialysis duration, primary renal disease. The mean value of PRA and HLA mismatching number, the type of main immunosuppressive agent did not differ as well. Deceased donor turned out to be higher in non-Rituximab group (P=0.02). After KT, the development of antibody mediated rejection was significantly lower in Rituximab group (3/32 (9.4%)) compared to historic control group (8/20 (40%, P<0.009) and total rejection rate showed lower tendency in Rituximab group as well. (P=0.056). However, development of pooled infection and infection free survival rate did not differ between 2 groups. Allograft function assessed by MDRD eGFR at 14 days after KT was significantly higher in Rituximab group compared to historic control group, but at 1, 3, 6, and 12 months from KT, it did not differ between two groups. Allograft rejection free survival was significantly higher in Rituixmab group compared to historic control group.

Conclusions: In sensitized patients with high PRA but negative crossmatch, Rituximab was effective to prevent the development of antibody mediated rejection without increased risk for infection.

FR-PO418

Differential Clinical Outcomes in Kidney Transplant Recipients with De Novo C1q+ and C1q- Donor Specific Antibodies Maria Ajaimy,[1,2] Adriana Colovai,[1] Sumeyye Calp Inal,[2] Michal L. Melamed,[2] Joel Lindower,[1] Enver Akalin.[1,2] *[1]Einstein/Montefiore Transplant Center; [2]Renal Div, Albert/Einstein College of Medicine, Bronx, NY.*

Background: Development of de novo donor-specific anti-HLA antibodies (DSA) has been associated with increased risk of antibody mediated rejection (AMR) and poor graft outcome. However, it is not clear if C1q binding capacity of DSA plays role in clinical outcomes.

Methods: The study included 301 consecutive recipients who received renal transplant between May 2009 and December 2012. We excluded patients who were transplanted with pre-transplant DSA. HLA antibody testing and C1q binding capacity was performed using the Luminex Single Antigen Bead assay. Anti-HLA antibodies were monitored after transplantation at 3, 12 months and yearly thereafter, and at the time of clinically indicated biopsies.

Results: Thirty-five of the total 301 patients (11.6%) developed DSA during a median follow-up of 28.5 months (17, 50). 23% had class I, 46% had class II, and 31% showed both class I and II DSA. DSA directed to donor HLA-DQ were most frequently observed (49%). Of the 35 DSA+ patients, 12 were C1q+ (34%). C1q+ DSA patients had significantly higher mean fluorescence intensity (MFI) values compared to C1q- DSA patients (7282+3423 versus 3898+3428, respectively, p=0.002). There was a striking difference in clinical outcomes that C1q+ DSA patients had higher AMR and transplant glomerulopathy (TG) (42% and 50%) compared to C1q- DSA (13% and 13%) and DSA- patients (1% and 4%), respectively. The graft survival was lower in the C1q+DSA group (75%) compared to the C1q-DSA (87%) and DSA- (90%) groups. Patients with C1q+ DSA had higher creatinine levels compared to C1q-DSA and DSA- groups.

Conclusions: Our results suggest that de novo C1q+ DSA patients had more AMR and TG, and lower allograft survival compared to C1q-DSA patients.

	No DSA (N=266)	De novo DSA c1q + DSA (N=12)	De novo DSA c1q - DSA (N=23)	P-value

Increased Risk of Antibody Mediated Rejection and Graft Loss in Sensitized Pregnant Kidney Transplant Recipients Maria Ajaimy, Michelle L. Lubetzky, Layla Kamal, Anjali Gupta, Graciela De Boccardo, Enver Akalin. *Einstein/ Montefiore Transplant Center, Bronx, NY.*

Background: Pregnancy and allograft outcomes in sensitized renal transplant recipients were not well documented. We aimed to examine the clinical outcomes of these immunologically high risk pregnancies.

Methods: This is a single-center retrospective cohort study of adult kidney transplant recipients who became pregnant from June 1, 2009 through December 31, 2012. Donor-specific anti-HLA antibodies (DSA) and panel reactive antibody (PRA) levels were studied by Luminex single antigen beads.

Results: There were 9 pregnant patients with a median age of 36 years (22, 38) and 33 % were African-American. Pregnancies occurred at a median of 3.1 years (1.1, 7.2) after transplantation. Patients' median serum creatinine levels and spot urine protein/creatinine ratio were 1.1 mg/dl (1.1, 2.1), and 0.55 g/day (0, 1.2) respectively. Of the total cohort, 6 patients were sensitized (PRA > 0%) and 3 had PRA of 0%. Of those sensitized patients, the median PRA level was 46% (25, 98) for class I and 0% (0, 86) for class II, and 2 had DSA. All patients were on triple drug immunosuppression with tacrolimus, mycophenolate mofetil and prednisone before pregnancy and mycophenolate mofetil was switched to azathioprine. The sensitized group had a higher incidence of adverse pregnancy outcomes; 1 stillbirth and 1 second trimester miscarriage. The remaining four high PRA patients and three 0% PRA patients delivered babies at a median of 34.5weeks (34, 36.5). During a median follow-up of 2.3 years (2, 4) after delivery, 3 high PRA patients (50%) developed AMR within one year after delivery that led to graft loss. In the low PRA group, no patients had rejection episodes and all maintained stable graft function (median creatinine level of 1.1 mg/dl (1.0, 1.2) and median proteinuria of 0.4 g/day (0.3, 0.5) without the development of new DSAs.

Conclusions: Our observational cohort suggests that there is an increased risk of AMR, graft loss and adverse pregnancy outcomes in sensitized kidney transplant recipients.These results should be assessed in a larger cohort for a better counselling of high immunologic risk patients who wish to become pregnant.

FR-PO420

C1q Binding and Humoral Rejection in Kidney Transplant Mohammad Sharif,[1] Navin Jaipaul,[2] Thanh Hoang,[1] Siegmund Teichman.[1] *[1]Loma Linda Univ Medical Center; [2]Loma Linda VA Healthcare System.*

Background: Donor specific antibodies (DSA) are associated with antibody-mediated rejection (AMR), detected by histology and C4d staining. However, the presence of DSA does not necessarily result in graft dysfunction. One way to distinguish when DSA are harmful is to determine when DSA can activate the classical complement pathway. C1q is the first step in the classical complement cascade activated by DSA. Two novel assays are available to detect this process, DSA by C1q by luminex (DSA-C1q) and C1 binding assay (which detects the presence of circulating immune complexes).

Methods: This is a single center retrospective cohort study of kidney transplanted patients above 18 years of age, who developed DSA post-transplant and subsequently underwent transplant kidney biopsy between 06/2012-07/2013. The aim was to compare the correlation of both assays with AMR and C4d staining on transplant kidney biopsy. All statistical analysis was performed using SPSS, version 17.0.

Results: Baseline characteristics were similar without significant differences between all groups. Results

		DSA-C1q		Total	C1q binding assay		Total
		Negative	**Positive**		**Negative**	**Positive**	
AMR	Positive	4	5	9	0	4	4
	Negative	3	1	4	8	0	8
Total		7	6	13	8	4	12
C4d staining	Positive	3	5	8	0	4	4
	Negative	4	1	5	8	0	8
Total		7	6	13	8	4	12

C1q binding was superior to DSA-C1q in correlation with biopsy-proven AMR: (r=1.0 versus 0.28; p <0.001 versus 0.35), sensitivity (100% versus 55.6%), specificity (100% versus 75%), positive predictive value (PPV) (100% versus 83.3%) and negative predictive value (NPV) (100% versus 42.9%) for C1q binding versus DSA-C1q, respectively. Also, C1q binding was superior to DSA- C1q in correlation with biopsy-positive C4d staining: (r= 1.0 versus 0.41; p<0.001 versus 0.16), sensitivity (100% versus 62.5%), specificity (100% versus 80%), PPV (100% versus 83.3%) and NPV (100% versus 57.1%) for C1q binding versus DSA-C1q, respectively.

Conclusions: This pilot study demonstrated that C1q binding correlated better than DSA-C1q in detecting DSA which activates the complement pathway to induce AMR. More studies are needed to confirm these results as it is a noninvasive and an inexpensive method for monitoring DSA in kidney transplant patients.

FR-PO421

Expression of IL-6 and Its Receptor IL-6Ra Is Increased in Kidney Allografts with Antibody Mediated Rejection (ABMR) Jolanta Kowalewska,[1] Hedyeh Shafi,[1] Cynthia C. Nast,[1] Arkadiusz Gertych,[1] Mark Haas,[1] Ashley Vo,[2] Mieko. Toyoda,[2] Stanley C. Jordan.[2] *[1]Pathology, Cedars-Sinai Medical Center, Los Angeles, CA; [2]Comprehensive Transplant Center, Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: IL-6 is a multifactorial cytokine regulating immune response and hematopoiesis. It has 2 receptors: IL-6R (membrane-bound and soluble) and gp130. Membrane bound IL-6R is expressed on T and B lymphocytes, and other cells. IL-6 may be involved in transplant rejection; it is elevated in allograft recipients with glomerulitis, suggesting association with ABMR.

Methods: We studied renal allograft biopsies that met Banff criteria for cell mediated rejection (CMR) and ABMR. Controls included native kidneys with thin basement membrane disease (Nk) and allograft kidneys without rejection (Tx). Biopsies were retrospectively stained for IL-6 and IL-6Ra. Slides were digitized using a whole-slide ScanScope AT Turbo scanner (Aperio), then analyzed by Tissue IA software (Leica). Negative and positive cell number and staining intensity were assessed. IL-6 was expressed as number of positive cells/area (mm^2). IL6Ra positive glomerular and tubulointerstitial cells were counted manually and expressed as mean number /glomerulus or area (mm^2).

Results: 6 cases of Nk, 9 Tx, 12 CMR and 11 ABMR were analyzed. IL-6 was expressed by leukocytes and tubular epithelial cells. Biopsies with ABMR showed greater numbers of IL-6 positive cells compared to CMR, Tx and Nk (5001 versus 2669 versus 2890 versus 3023, respectively; p=0.02). IL-6Ra was expressed in infiltrating leukocytes, and the cytoplasm of intrinsic renal cells, including podocytes, distal nephron tubular epithelium and arterial smooth muscle cells. ABMR had the most IL-6Ra positive leukocytes in glomerular [1.1 (ABMR) versus 0.4 (CMR) versus 0.5 (Tx) versus 0.2 (Nk)] and tubulointerstitial (82.3 versus 16.8 versus 15.6 versus 13.5, respectively) compartments, although these differences were not statistically significant.

Conclusions: Allograft kidneys with ABMR have significantly increased IL-6 expression and have more leukocytes with IL-6R compared to CMR, Tx without rejection and Nk. These findings suggest a role of the IL6 /IL-6R pathway in tissue injury in ABMR.

FR-PO422

Anti-Angiotensin Receptor Type I Antibody: Role in Antibody Mediated Rejection and Response to Plasmapheresis Dhiren Kumar,[1] Gaurav Gupta,[1] Anne L. King,[1] Amit Sharma,[2] Adrian Cotterell,[2] Felecia McDougan,[2] Pam Kimball.[2] *[1]Nephrology, Virginia Commonwealth Univ, Richmond, VA; [2]Transplant Surgery, Virginia Commonwealth Univ, Richmond, VA.*

Background: In kidney transplant patients sensitization to Angiotensin type I receptor auto-antibody (AT1R-Ab) has been associated with antibody-mediated rejection (AbMR) and worse graft survival. It is unknown if AT1R-Ab sensitization independently causes AbMR in the absence of donor-specific HLA antibodies (HLA DSA). This study aims to examine the association of AT1R-Ab with the incidence of AbMR and response to therapy with plasmapheresis (PP).

Methods: Forty consecutive kidney transplant patients with biopsy proven AbMR between Jan '06 and Sep '13 were included. They were treated with 6 sessions of PP followed by CMVIg 150mg/kg. Flow cytometry and solid-phase assays were used to measure HLA DSA and At1R-Ab at the time of transplant, acute AbMR and post therapy. Based on prior reports a positive AT1R-Ab concentration was set at > 10U/ml.

Results: Most patients were African-American (26/40; 65%) and sensitized with a PRA>20% (21/40; 53%). At the time of rejection a substantial proportion of patients (14/40; 35%) had no HLA DSA, of these 3 (21%) had a positive AT1R-Ab. Thus, 3/40 (7.5%) episodes could be attributable to AT1R-Ab. Seventy percent (28/40) of the patients had a decline in AT1R-Ab levels after PP from a mean of 26U/ml (median 13, range 6.5-216) to 11U/ml (median 10, range 5-21) at the end of therapy. There was a trend towards greater graft loss among patients who had an AT1R-Ab>10U/ml (14/17; 82%) compared with patients with AT1R-Ab <10U/ml (13/23; 56%; p=0.08).

Conclusions: In this single-center study, we report that 7.5% of all cases of AbMR could be attributable to non-HLA AT1R-Ab. There was a trend towards greater graft loss among patients with a positive AT1R-Ab at the time of rejection although a clear association was not evident. It is possible that this effect was blunted by the efficacy of plasmapheresis in the removal of the AT1R-Ab. Further prospective studies are needed to determine the clinical course of kidney transplant patients with detectible AT1R-Ab and its impact on graft outcomes.

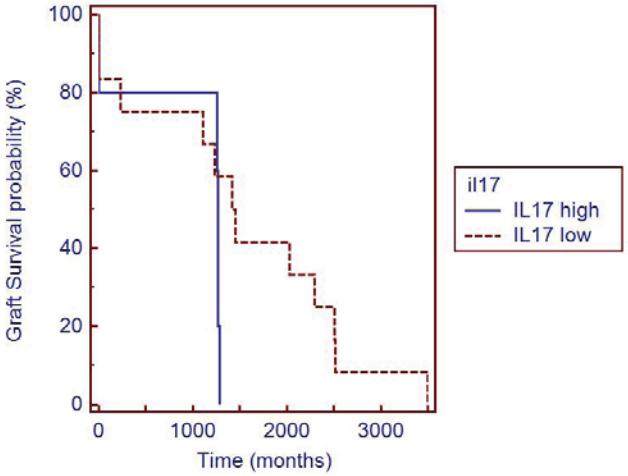
FR-PO423

T Regulators/Th17 Polarization in Cellular Rejection in Kidney Allograft
Helena Viana,[1] Isabel Mesquita,[1] Joaquim T. Calado,[2] Fernando E.B. Nolasco.[1]
[1]Serviço de Nefrologia, Hospital Curry Cabral, Lisboa, Portugal; [2]Nova Medical School.

Background: Th17 in association with Th1, Th2 and Th follicular are the effectors cells in kidney rejection. Th17 have a pro-inflammatory activity by the production of IL17 cytokine. The T regulators (Tregs), marked by FOXP3, have several inflammatory suppressor effects. Nowadays, it is known that Th17 and Tregs have a common precursor. According the cytokine milieu, the Tregs could be converted in Th17 and vice-versa. The final immune response, the tissue lesion severity depends of the balance between Tregs/th17.

Methods: Reevaluation of all consecutive biopsies (n=45), between 2000-2001 unicenter, with a histological diagnosis of borderline alterations (BA), cellular rejection (CR) or vascular rejection (VR). Identification of Il17 and FOXP3 cells by indirect immunohistochemistry in paraffin preserved tissue. Numbers of cells/mm2 are determined. Cells are counted in all the biopsies. Areas are measured using digital methods. Biopsies are divided in two groups according the median: low IL17 and high IL17.

Results: Biopsies present a mean of 16.56±17.66 FOXP3/mm2 and a mean of 6.12±14.53 Th17/mm2. Th17 cells were not present in 16 biopsies. Biopsies with BA have less FOXP3 than CR (8.49±11.32 versus 25.33±19.66; p=0.0022) with a low and similar number of Th17 (2.39±4.14 versus 2.45±4.45; p=0.015). Biopsies with VR present lower FOXP3 (6.11±5.98 versus 25.33±19.66; p=0.0002) and higher Th17 (15.74±25.17 versus 2.45±4.45; p=0.015). We demonstrates 10 years graft survival according Th17 number at biopsy time.



Conclusions: It seems that FOXP3 was "substituted" by Th17 in Vascular rejection. That probably explains the severity of inflammation/ tissue destruction observed in vascular rejection. The number of Th17 in biopsy seems influence the 10 years graft survival after the rejection.

FR-PO424

Does Renal Allograft C1q Staining Predict Outcomes?
Jones S. John, Arpit Bhargava, Mahboob Ali Khan, Imad Harmouch, Kalathil K. Sureshkumar, Katherine M. Jasnosz, Sabiha M. Hussain, Swati Arora, Richard J. Marcus, Diane J. Pidwell, Bhavna Chopra. *Nephrology, Allegheny General Hospital, Pittsburgh, PA.*

Background: Antibody mediated rejection (AMR) results from activation of the complement cascade by donor specific antibody (DSA) leading to microcirculatory injury within the renal allograft. Studies have shown association between C1q binding of DSA and inferior graft outcomes. However, the relationship between renal allograft C1q staining and outcomes is unknown. We hypothesized that the presence of C1q staining on allograft biopsy (bx) portends worse graft outcomes.

Methods: We performed a retrospective chart review of kidney transplant recipients from 2007-2013 who underwent for-cause allograft bx and a had positive DSA defined as MFI>1000. The frozen bx tissue was retrieved and stained for C1q with immunofluorescence. The light microscopy of each bx was reviewed by a single pathologist blinded to clinical data. C1q binding of DSA closest to the time of bx was performed using Luminex platform. Graft outcomes were compared for C1q positive (C1q+) versus C1q negative (C1q-) bx.

Results: The study included 28 patients with average age of 50±14 years and mean follow-up of 26±20 months of which 11 had C1q+ bx. There were no differences in the incidences of acute cellular rejection (36% versus 29%, p=0.7), AMR (27% versus 29%, p=0.9), C4d staining (18% versus 29%, p=0.5), graft failure (36% versus 29%, p=0.7) or level of serum creatinine at 1-year (1.6±0.4 versus 1.6±0.9 mg/dl, p=1.0) and 2-year (1.6±0.4 versus 1.9±1.2 mg/dl, p=0.66) for C1q+ versus C1q- groups. Transplant glomerulopathy (p=0.03) and interstitial fibrosis (p=0.01) scores were significantly higher while scores on tubulitis (p=0.5), interstitial inflammation (p=0.15), glomerulitis (p=0.13) and peritubular capillaritis (p=0.4) were similar for C1q+ versus C1q- bx groups. C1q binding DSA was observed in 4 patients of which 2 had C1q+ bx.

Conclusions: Although presence of C1q in renal allograft bx did not translate to adverse short-term graft outcomes, the observation of increased transplant glomerulopathy and interstitial fibrosis in these patients may portend worse long-term graft outcome. Larger studies are needed to verify these findings.

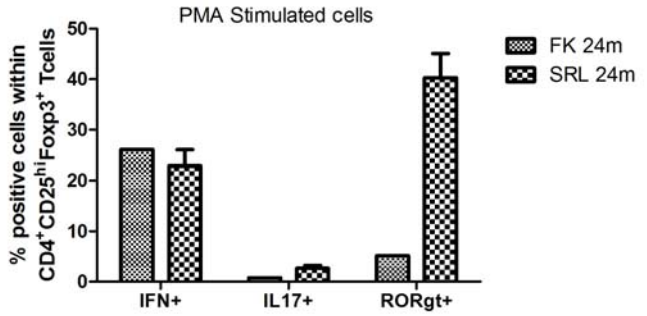
FR-PO425

Immune Activation in Kidney Transplant Recipients After Sirolimus Conversion
Opas Traitanon,[1] Antonio Alvarado,[1] Mohammed Javeed Ansari,[1] Nader Najafian,[2] Lorenzo G. Gallon.[1] *[1]Medicine-Nephrology, Northwestern Univ, Chicago, IL; [2]Nephrology, Brigham and Women's Hospital, Boston, MA.*

Background: Conversion from Tacrolimus (TAC) to Sirolimus (SRL) in kidney transplant recipients was aimed to improve calcineurin inhibitor nephrotoxicity and long term graft function. The results from multiple studies are not consistent. This study investigates the effects of SRL on immune cell functions after conversion.

Methods: The study included 30 renal transplant recipients from a randomized trial of SRL conversion (n=18) or TAC maintenance (n=12). The conversion started at 12 months post-transplant. PBMC were collected at 0, 6, 12 and 24 months post-randomization. T cell subpopulations were analyzed by flow cytometry. Cellular alloreactivity against irradiated donor cells (Direct), donor cell membrane sonicates (Indirect) and synthetic mismatched HLA peptides (Indirect) were tested by IFN-g ELISPOT assay.

Results: SRL conversion led to a significant increase in $CD4^+CD5^{hi}Foxp3^+$ T cells at 6, 12 and 24 months post conversion (1.58±0.09 (SRL group) VS 0.13±0.02 (TAC group) % of PBMC at 24 months (p<0.01). However, Intracellular cytokine and transcriptional factor staining showed that $CD4^+CD25^{hi}Foxp3^+$ T cells in SRL-converted group had more percentage of cells that co-expressed ROR-gt and IL-17 which are Th17 markers.



SRL conversion also showed an increase in indirect donor alloreactivity against both donor cell membrane sonicates and synthetic HLA peptides from 0 to 12 months post-randomization while the TAC maintenance showed a decrease alloreactivity resulted in a significant different over time between TAC and SRL group (p<0.01). No difference in direct alloreactivity was detected at 12 months.

Conclusions: Chronic immune alterations are induced after conversion from TAC to SRL. These findings have important implications for guiding the clinical use of mTOR-inhibitors.

T Cell Receptor Deep Sequencing to Track Alloreactive T Cells: Evidence for Clonal Deletion in Tolerant Patients following Combined Kidney and Bone Marrow Transplantation
Susan DeWolf,[1] Heather K. Morris,[1] Harlan Robins,[2] Ben Sprangers,[1] Samuel A. Locascio,[1] Brittany Shonts,[1] Waichi Wong,[1] Tatsuo Kawai,[3] Julien Zuber,[1] Yufeng Shen,[1] Megan Sykes.[1] *[1]Columbia Univ Medical Center, New York, NY; [2]Fred Hutchinson Cancer Research Center, Seattle, WA; [3]Massachusetts General Hospital, Boston, MA.*

Background: Alloreactive T cells recognize myriads of MHC/peptide specificities, thus far precluding the identification of those mediating graft rejection and graft-versus-host disease in HLA-mismatched transplantation. In addition, the need for new non-invasive tools to monitor rejection risk and/or operational tolerance in kidney transplant recipients is underscored by the morbidity associated with chronic immunosuppression.

Methods: We hypothesized that high-throughput deep sequencing of a transplant recipient's donor-reactive TCRb CDR3 regions expanded in one-way mixed lymphocyte reaction prior to transplantation could identify and allow tracking of donor-reactive T cells following transplantation. We tested this approach in four combined kidney and bone marrow transplantation patients in a trial aimed at achieving allograft tolerance (ITN036ST), and in two "conventional" kidney transplant recipients.

Results: We observed significant post-transplant reductions in donor-reactive CD4 and CD8 T cell clones only in the CKBMT patients who achieved allograft tolerance (3 of 4 CKBMT). In the "conventional" kidney transplant recipients, we found a significant increase in circulating anti-donor CD4 clones post-transplantation. Loss of donor-reactive TCR in the CKBMT patients identified tolerance more specifically than functional assays. In some instances, clonal reduction was specific for donor-reactive clones; in others, the reduction reflected repertoire turnover due to lymphocyte depletion during conditioning.

Conclusions: We have developed a method of tracking donor-reactive T cells and obtained evidence for clonal deletion as a mechanism of allograft tolerance in humans.

FR-PO427

Application of Flow Cytometry to Measure Anti-A/B Antibody in ABO Incompatible Kidney Transplantation Ji-Young Choi,[1,2] Ji-Eun Lee,[1,2] Jang-Hee Cho,[1,2] Hee-Yeon Jung,[1,2] Se-Hee Yoon,[3] Sun-Hee Park,[1,2] Yong-Lim Kim,[1,2] Chan-Duck Kim.[1,2] *[1]Dept of Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Korea; [2]Clinical Research Center for End Stage Renal Disease in Korea; [3]Dept of Internal Medicine, Konyang Univ, Daejeon, Korea.*

Background: Current methods of measuring anti-ABO antibody titer by hemagglutination are subjective and not reproducible. However, the flow cytometry (FCM)-based method was suggested to be reproducible and yield semi-quantitative results. The aim of this study is to compare anti-ABO antibody levels by FCM with the levels by column agglutination test (CAT) and to evaluate the clinical outcome according to the baseline mean fluorescence intensity (MFI) ratio obtained by FCM.

Methods: We reviewed 21 cases of ABO-incompatible kidney transplantation (ABO-i KT) performed from February 2012 to March 2014. In these patients, baseline IgG titers were measured using both FCM and CAT methods. We investigated the correlation between levels measured by FCM and levels measured by CAT using correlation coefficient. Patients were classified as the high MFI ratio group (≥200, n=7) or the low MFI ratio group (<200, n=14).

Results: The MFI ratio of FCM-based method was highly correlated with the titer of CAT (r=0.890, p=0.01). An equation between MFI ratio and CAT titer is as follows: Log (MFI ratio) = 0.879 x log (CAT titer) + 0.298. The number of pre-transplant plasmapheresis significantly increased with the increase of baseline MFI ratio (r=0.838, p = 0.01). The allograft function was immediately recovered and stable. The pre-transplant MFI ratios were reduced from 221.3 (baseline) to 8.0 (day of transplantation) and the highest MFI ratio at kidney transplantation was 32.6. There was no acute rejection in ether group during follow-up. The postoperative bleeding requiring reoperation immediately after KT occurred in 2 and 1 patients of the high MFI ratio and low MFI ratio groups, respectively.

Conclusions: Anti-ABO antibody levels measured by FCM-based method were highly correlated with the levels by CAT in ABO-i KT. The decreased level of anti-ABO antibody by FCM after plasmapheresis suggested its potential as effective method for assessment of anti-ABO antibody level.

FR-PO428

ABO Incompatible Kidney Transplantation Enabled by Non-Antigen Specific Immunoadsorption: A 5-Year Experience Luis Eduardo Becker,[1] Daniela Siebert,[1] Sebastian Markus Schaefer,[1] Caner Süsal,[2] Gerhard Opelz,[2] Albrecht Leo,[2] Ruediger Waldherr,[3] Stephan Macher-Goeppinger,[3] Martin G. Zeier,[1] Vedat Schwenger,[1] Christian Morath.[1] *[1]Nephrology, Univ of Heidelberg, Germany; [2]Immunology, Univ of Heidelberg, Germany; [3]Pathology, Univ of Heidelberg, Germany.*

Background: We recently proposed a protocol using non-antigen specific immunoadsorption (IA) and rituximab for the desensitization of ABO incompatible (ABOi) kidney transplant recipients. This protocol allows a high number of IA treatments at reasonable cost, and the depletion of HLA antibodies at the same time.

Methods: In the current analysis, we compared clinical outcomes from 34 ABOi kidney transplant recipients who were desensitized and transplanted by this protocol to 68 standard-risk living donor kidney transplant recipients matched for time posttransplantation. Patients with preexisting donor-specific HLA antibodies were excluded.

Results: Before desensitization, the 34 patients had a median isoagglutinin titer of 1:64 (1:2-1:1.024; Coombs technique). Patients required a median of 7 (5-12) preoperative IA treatments, and 24 patients had 1 (0-6) additional plasmapheresis treatment to reach the preoperative target isoagglutinin titer of ≤1:8. After a median postoperative follow-up of 22 (6-65) months overall allograft survival was with 94% in the ABOi group not significantly different from the 99% graft survival in standard-risk patients. Allograft function was also not significantly different between the groups after 1, 2 and 3 years, as was the incidence of cellular or antibody mediated rejection episodes (18% for both groups). ABOi patients had both a higher incidence of polyoma BK virus replication (>10*4 copies/mL plasma) and nephropathy (SV40 staining positive) compared to standard-risk patients (21% versus 6%; P=0.04 and 12% versus 0%; P=0.01, respectively). The incidence of CMV, fungal or bacterial infections was similar between the groups.

Conclusions: Outcomes of ABOi patients desensitized with a non-antigen specific IA device and rituximab do not differ from the outcomes in standard-risk patients. Special attention, however, must be given to the higher incidence of polyoma BK virus infection in the ABOi patients.

FR-PO429

The Role of Rituximab in ABO Incompatible Kidney Transplantation in Japan Kazuhide Saito,[1,2] Kota Takahashi.[1,2] *[1]Urology, Niigata Univ, Niigata, Japan; [2]Japan ABO Incompatible Kidney Transplantation Committee, Niigata, Japan.*

Background: Since the first success in January 1989, we have performed more than 2,400 ABO incompatible kidney transplantation (ABOIKT) to date. Especially after 2001, the concept of desensitization and rituximab has been introduced and patient and graft outcome dramatically improved. Purpose of this study is to confirm the benefit of rituximab for desensitization as a substitute for splenectomy and elucidate the factors affecting the patient and graft outcome in large Japanese ABOIKTx cohort.

Methods: Among 2,212 cases registered in Japan ABO incompatible kidney transplantation committee, we have selected 1,121 patients after 2001 era in whom the data for the use of rituximab and splenectomy status were available. We have categorized the patients into 4 groups according to the splenectomy (S) and Rituximab (R) status, S (-) /R (-): N=16, S (-) /R (+): N=738, S (+) /R (-): N=320 and S (+) /R (+): N=47. At first, we analyzed overall patient and graft survival, next, compared the outcome beween each group, finally analyzed the factors affecting patient and graft outcome by univariate and multivariate analysis.

Results: Overall patient survival rate at 1,3,5 and 10 years were 98.5, 97.3, 95.4 and 94.8%, and graft survival rate were 97.1, 94.5, 91.3, 59 and 84.8%, respectively. There was no statistically significant difference in patient and graft survival between 4 groups. The factors affecting the patient survival were postoperative antibody removal (PAR) (multivariate: p<0.004, HR 2.986, PI 1.419-6.283) and postoperative anticoagulation (PAC) (multivariate: p<0.020, HR 3.148, PI 1.199-8.261). The factors affecting the graft survival were PAR (multivariate: p<0.001, HR 4.238, PI 2.510-7.156) and PAC (univariate: p<0.021, HR 1.936, PI 1.107-3.385). There were no significant difference in patient and graft survival according to the preoperative anti-A/B IgG/IgM antibody titer.

Conclusions: For successful ABO-IKTx, desensitization with rituximab has become standard and the substitute of splenectomy for prevention of AMR and accommodation induction. ABOIKTx has become accepted as a therapeutic alternative treatment of choice for end-stage kidney disease.

FR-PO430

Long Term Outcome of ABO-incompatible Living Donor Kidney Transplantation, Using the Desensitization Protocol and Timely Plasmapheresis after Transplantation Eunhye Shin, Hyosang Kim, Su-Kil Park. *Internal Medicine, Asan Medical Center, Seoul, Republic of Korea.*

Background: ABO-incompatible (ABOi) kidney transplantation (KT) has gradually increased in consequence of the development of desensitization protocol for overcoming the serious organ shortage. However, there are only few long term follow-up data in Korean patients receiving ABOi KT.

Methods: A retrospective review of medical records was conducted for individuals who underwent KT in Asan Medical Center from February 2009 to January 2012.

Results: A total of 666 patients were included; the mean age was 43.4±11.7 and the median follow-up period was 39 (interquartile range 31-48) months. 83 individuals who had ABOi living donor KT were compared with 583 individuals who had ABO-compatible (ABOc) KT. Kaplan-Meier survival analysis showed that ABOi KT group had slightly lower cumulative survival rate compared to ABOc KT group (p=0.030). However, graft survival, acute rejection episode, graft function, and postoperative complications were not significantly different between two groups. Additionally, ABO incompatibility was not a significant risk factor for acute rejection (HR, 1.47; 95% CI, 0.72-2.99; p=0.294) but, donor age, mismatch of HLA, and panel-reactive antibody (PRA) ≥20% were significant risk factors (HR, 1.04; p=0.001; HR, 1.20; p=0.046; HR, 3.17; p=0.002, respectively). In the ABOi KT group, initial high isoagglutinin titer (≥1:256) was related with titer-rebound after KT (HR, 1.05; 95% CI, 1.00-1.10; p=0.037), many preoperative plasmapheresis (HR, 3.39; 95% CI, 1.69-6.79; p=0.001), and low titer reduction rate (HR, 9.56; 95% CI, 1.14-80.5; p=0.038). However, patient survival, graft survival, and graft function were similar regardless of initial isoagglutinin titer or presence of titer rebound after KT.

Conclusions: Although ABOi KT group showed significantly lower survival rate, graft survival, graft function, acute rejection, and peri- or postoperative complications were comparable with ABOc KT group. Therefore, ABOi KT could be a safe option for patients whose only available donors are ABO incompatible.

FR-PO431

Do Pre-Existing Donor Specific Anti-Human Leukocyte Antigen (HLA) Antibodies Lead to Increased Risk of Cellular Rejection Post-Transplantation A. Regmi,[1] P. Singh,[1] S. Koenig,[3] O. Myers,[2] B. Masten,[3] K. Madden,[1] A. Harford.[1] *[1]Internal Medicine, Univ of New Mexico School of Medicine, Albuquerque, NM; [2]Biostatistics, Univ of New Mexico School of Medicine, Albuquerque, NM; [3]Pathology, Univ of New Mexico School of Medicine, Albuquerque, NM.*

Background: Some studies have shown that the presence of DSA can negatively impact renal allograft survival. In this study we examined the association between pre-existing DSA and outcomes post-transplant.

Methods: We retrospectively analyzed 213 consecutive renal transplants, at a single center between 1/2007 and 9/2013, for the presence of pre-transplant DSA and its strength expressed as mean fluorescence intensity (MFI).Univariate analysis and logistic regression analyses included the following variables: race, ethnicity, gender, age at transplant, ESRD cause, prior sensitizing events, donor type, cross match results, and induction agent. Outcomes analyzed were presence of cellular and antibody mediated rejection and eGFR at 1 year using MDRD.

Results: There were 39 episodes of rejection in 213 patients with an incidence of 18.3%. Of the patients with rejection, 18% had pre-existing DSA. Of those with pre-existing DSA and rejection 85.7% had cellular rejection and 14.3% had antibody mediated rejection**.** MFI levels for DSA were not different between those patients with rejection versus those without. The incidence of rejection was decreased in recipients of expanded criteria donor kidneys: 8% versus 19.7% in recipients of standard criteria donors and 19.4% in recipients of living donors. A higher incidence of rejection was observed among non-Hispanic whites at 23.8%

versus 16.3% in Hispanics and 11.6% in Native Americans. Patients with rejection had significantly lower eGFR (47.1ml/min) at 1 year versus those with no rejection (60.2ml/min), (P=0.004).

Conclusions: DSA and the strength of pre-existing antibody as expressed as MFI, were not associated with higher rates of rejection within the first year of transplant. There was a trend towards cellular rejection in those patients who had rejection and DSA. eGFR was lower in the group who experiencedrejection.

FR-PO432

De Novo Donor-Specific Antibodies in Pediatric Renal Transplant Recipients - Risk Factors and Treatment Effectiveness Mercy Rajesh, Samhar I. Al-Akash. *Pediatrics/Pediatric Nephrology, Driscoll Children's Hospital, Corpus Christi, TX.*

Background: Development of De Novo donor-specific antibodies (DSA) in renal transplantation (RTx) has been shown to be associated with decreased graft survival (GS). There is limited data on DSA in pediatric (Ped) RTx, and on the impact of treatment on graft function (GF) and GS. In this study we examine the risk factors for development of DSA and effect of therapy on GF and GS.

Methods: This is a retrospective study on Ped RTx recipients who received RTx at our center from 2006 to 2012 and had at least 12 months (mon) of follow up. 55 transplants were included. Our immunosuppressive regimen consisted of induction with a 5-day steroid taper and Daclizumab (ZEN) or rabbit-thymoglobulin (r-ATG) or Alemtuzumab (C1H), and maintenance with tacrolimus (Tac) and mycophenolate (Myc) or azathioprine (Aza). DSA were tested periodically after the first year and the time of biopsy-proven rejection. Single-antigen luminex beads were used to identify and measure DSA.

Results: 49 (89%) received deceased donor (DD) RTx. 18 pts (32.7%) developed DSA. [table 1] shows the differences between the DSA+ and DSA- pts. Risk factors for DSA were nonadherence (p 0.003, OR 9.1), and induction with Zen versus either r-ATG (p 0.01, OR 8.7; 1.5-49.2) or C1H (p 0.02, OR 5.1; 1.2-22.7). Treatment for DSA resulted in overall reduction of DSA mean florescence intensity (MFI) from 6998 to 2900 (P<0.001). DSA reduction of 80% or more was achieved in 65% of pts with MFI < 10000 and 38% in pts with MFI > 10000; p 0.0002). GF was significantly better in DSA- pts.

	DSA+	DSA-
Mean age at Tx	13.3 (3-22)	11.7 (1.5-19)
Primary vs. re-Tx (%)	94	89
Mean followup (mon)	49 (12-78)	40 (12-81)
Mean HLA mismatches	4.5	4.1
Induction % (Zen/r-ATG/C1H)	39/17/44	49/35/16
Mean eGFR ml/min/1.73m2		
- 3 mon	67	75
- 12 mon	69	71
- 24 mon	64	68
- 36 mon	60	68
- 48 mon	57	74
- 60 mon	47	72

GS was higher in DSA- pts, but did not reach statistical significance.

Conclusions: De Novo DSA is associated with worse GF in spite of treatment and reduction in DSA. Therapies and strategies directed at improving adherence and preventing development of De Novo DSA may be beneficial and should be explored.

FR-PO433

Renal Allograft Outcomes with Alemtuzumab in Highly Sensitized Recipients. A Single Centre Experience Pradeep Vaitla,[1] Ushma Patel,[3] Ryan C. Mascarenhas,[1] Antonio G. Jimenez,[1] Abdul Moiz,[1] George E. Loss,[2] Stephanie Anders,[3] Jorge C. Garces,[1] Humberto Bohorquez.[2] *[1]Nephrology, Ochsner Clinic Foundation; [2]Transplant Surgery, Ochsner Clinic Foundation; [3]Pharmacy, Ochsner Clinic Foundation.*

Background: Pre-transplant sensitization is a well recognized risk factor for acute rejection and allograft failure. Higher dose of immunosuppressive agents is needed to minimize risk of allograft rejection.Several studies have been published with renal allograft outcomes using Alemtuzumab for antibody induction therapy but not much data are available for highly sensitized patients.We report our experience with Alemtuzumab (30 mg iv single dose) in pre-transplant sensitized patients.Our current protocol for immunosuppression includes Tacrolimus with a target trough level between 7-10 ng/ml, Mycophenolate mofetil (MMF) 500 mg oral twice daily,methylprednisolone 500 mg post opertive day (POD) 0, 250 mg POD 1 and 125 mg POD 2 with immediate steroid withdrawal.

Methods: We performed a retrospective chart review of 441 kidney transplants performed from November 2007 to December 2011 of which 311 recipients received Alemtuzumab for induction immunosuppression and we obtained demographic, laboratory and clinical data including biopsy proven acute rejection during 1 year of follow up. We stratified recipients based on Panel-reactive antibody (PRA) levels as 0%,1-50% and >50%.

Results: The overall incidence of biopsy proven acute rejection during one year follow up was 8% and graft failure of 3%. Recipients with PRA level 0% had a rejection rate of 4.2% and graft failure of 1.8%, recipients with PRA level 1-50% had a rejection rate of 14% and graft failure of 3%, recipients with PRA level >50% had a rejection rate of 19% and graft failure rate of 11%.

Conclusions: Alemtuzumab seems to be a cost-effective agent in high risk population with a 1 year rejection rate of 19% in highly sensitized recipients. It is well documented that increased pre transplant sensitization leads to reduced allograft survival. Alemtuzumab provides good rejection profile with a one year graft survival rate of 97% in recipients with PRA level 1-50% and 89% in recipients with PRA level >50%. More data are needed to address long-term follow-up with this agent.

FR-PO434

Treatment of Chronic Active Antibody-Mediated Rejection: What to Expect? Isabelle Houde, Stephanie Beland, Patrice Vallin, Real Noel, Isabelle Lapointe, Isabelle Côté, Eric Wagner, Olivier Desy, Julie Lesage, Sacha A. De Serres. *Renal Div, Dept of Medicine, CHU de Quebec Hôtel-Dieu, Laval Univ, Quebec City, QC, Canada.*

Background: Anti-rejection protocols for antibody-mediated rejection (AMR) reduce graft loss for acute AMR. However, little is known about the effect of treatment for chronic active AMR (CAAMR). Notably, it is unknown whether we should expect a return to previous baseline graft function following treatment.

Methods: This is a single center retrospective observational study of 50 patients treated for suspicious or confirmed CAABMR according to Banff criteria between June 2002 and January 2012. Patients were classified in 3 treatment groups: solumedrol only (S, n=18), solumedrol and IVIG (S+I, n=24) and solumedrol, IVIG and plasma exchange and/or rituximab (S+I±P±R, n=8). Therapeutic decision was made on clinical grounds. We studied a composite endpoint of death-censored graft failure or doubling of serum creatinine (Scr), using Chi-square, non-parametric paired and unpaired tests.

Results: Mean recipient age was 39±18yrs and 88% were recipients of a deceased donor. At biopsy, median time post transplant was 90mo and Scr was 2.2±1.0mg/dl. 30 patients (60%) reached the endpoint at a median time of 36mo. Among patients free of the endpoint, median Scr increased from 1.7mg/dl at biopsy to 1.8mg/dl at last follow-up (median 39mo), with a mean increase of 0.1±0.4mg/dl on an individual basis. Compared to patients treated with S, patients treated with S+I and S+I±P±R had similar Scr at biopsy (median 1.9 versus 1.8 versus 2.1 respectively; p=0.42). The endpoint was reached in 56%, 75% and 25% of S, S+I and S+I±P±R patients respectively (p=0.039). In patients free of the endpoint, mean Scr increased non-significantly in S and S+I groups and remained stable in the S+I±P±R (0.1±0.5, 0.2±0.6 and 0.0±0.2, p=0.16, 0.60 and 0.92 respectively, paired test).

Conclusions: The prognosis of CAAMR is dismal. A more aggressive therapy including S, I and a combination of P and/or R seems to be associated with better outcomes. Our data suggest that following successful treatment, Scr stabilizes rather than improves. These data need to be replicated in a larger cohort.

FR-PO435

Complement Inhibition in Antibody Mediated Rejection during Kidney Transplantation Michelle Elias, Erika Nnang Obada, Séverine Beaudreuil, Alyette Duquesne, Caroline Poitou, Laurentiu Iamandi, B. Charpentier, A. Durrbach, H. Francois. *Nephrology, Bicêtre Hospital, Univ Paris Sud, INSERM 1014, Le Kremlin-Bicêtre, France.*

Background: There is to date no gold standard treatment of antibody mediated rejection (AMR). Current therapeutic strategies rely on plasmapheresis combined with intraveinous globulins (IVIg). Eculizumab is a humanized monoclonal antibody that targets complement protein C5 and prevents the formation of the membrane attack complex. Therefore it could be efficient in treating complement mediated lesions during AMR. Few clinical cases describe the efficiency of Eculizumab in treating acute AMR.

Methods: We conducted a monocentric retrospective study of 15 patients (7 men and 8 women) that have been treated between October 2011 and June 2013 for severe AMR using eculizumab on top of plasmapheresis, IV Ig and a B-cell targeting agent. Patients were transplanted between January 2002 and November 2012. All AMR were documented by a graft biopsy according to the Banff 2011 criteria at diagnosis and we report patients and graft outcome after treatment. The biopsy was repeated whenever necessary.

Results: The mean follow up was 16,4 months. Complement inhibition was fullfilled in both treatment groups throughout follow up.8 patients out of 15 (53%) did not respond to the treatment and 6 lost their graft. 9 patients were diagnosed with AMR 27,2 months after their transplantation, out of which 7 (78 %) did not respond to treatment. The remaining 6 were diagnosed with AMR in the first year following transplantation and only one lost its graft (17%), p<0,05. Only one of the patients died with a functional graft and 9 patients experienced severe infections. In the responders group, the mean serum creatinine was 205 µmol/l 37,6 months after transplantation and 10,4 months after AMR diagnosis. No responding patients received eculizumab more than 3 months.

Conclusions: Eculizumab seems more efficient in early versus late AMR, which reflects a more prominent involvement of the complement cascade in early versus late AMR.

FR-PO436

Microcirculation Inflammation in Transplant Kidney Biopsies: Clinicopathological and Genomic Significance Anjali Gupta,[1] Pilib O Broin,[2] Yi Bao,[1] Aaron Golden,[2] Enver Akalin.[1] *[1]Einstein/Montefiore Transplant Program; [2]Computational Genomics, Albert Einstein College of Medicine.*

Background: We investigated the clinical and genomic significance of microcirculation inflammation (MI) score [peritubular capillarities (ptc) + glomerulitis (g)] in transplant kidney biopsies.

Methods: 345 clinically indicated kidney transplant biopsies were classified into 3 groups G1:MI=0 (n=199), G2:MI=1 or 2 (n=94), G3:MI>2 (n=52). Gene expression profiles were studied by Affymetrix HuGene 1.0 ST expression arrays in a subset of patients (n=93).

Results: G3 and G2 groups had higher median class I (23% and 17%) and class II (41% and 30%) calculated panel reactive antibody levels and Donor Specific Antibody (DSA) frequency (56% and 40%) compared to G1 group (0%, 2%, and 26%), respectively, p<0.01. Acute Antibody Mediated Rejection (AMR) were more frequent in G3 (10%) compared to G2 (3%) and G1 (0%), p<0.01. Chronic AMR and transplant glomerulopathy (TGP) were more frequent in G3 and G2 (40% and 41%) compared to G1 (13%), p<0.01. The Banff tubulitis, intimal arteritis, allograft glomerulopathy and ptc C4d staining scores were significantly higher in G3 (0.75, 0.22, 0.73 and 1.33) and G2 (0.43, 0.09, 0.61 and 0.59) compared to G1 (0.10, 0.01, 0.15 and 0.16), respectively, p<0.01. Gene expression profiles revealed increased intragraft Interferon-Gamma and Rejection Induced (GRIT), Quantitative Cytotoxic T-cell (QCAT), Natural Killer Cell (NKAT), T Regulatory (TREG) and Donor Specific Antibody Selective Transcripts (DSAST) in G3 compared to G2 and G1. QCAT and DSAST were the only increased pathogenesis based transcripts (PBT) studied in G2 samples compared to G1 samples. Endothelial cell associated transcript (ENDAT) expression was not different between the 3 groups.

PBT	G2 VS G1	G3 VS G1	G3 VS G2
GRIT	0.059	**0.01**	**0.01**
QCAT	**0.016**	**0.003**	**0.007**
TREG	0.08	**0.03**	**0.03**
BAT	0.09	**0.04**	0.10
NKAT	0.14	**0.037**	**0.02**
DSAST	**0.015**	**0.001**	**0.007**
ENDAT	0.40	0.17	0.10

Conclusions: Our results indicated that increased MI score is significantly associated with histological diagnosis of acute and chronic AMR/ TGP, positive C4d staining and increased intragraft gene transcripts related to AMR.

FR-PO437

C4d+ Endothelial Microparticles: A Highly Sensitive and Specific Noninvasive Biomarker of Acute Antibody-Mediated Rejection (AAMR) Behzad Najafian,[1] Aleksandra Kukla,[2] Nicolae Leca,[1] Niamh Kieran,[1] Kimberly A. Muczynski,[1] J. Ashley Jefferson,[1] Elizabeth A. Kendrick,[1] Christopher D. Blosser,[1] Paul Warner,[3] Krena A. Nelson.[3] *[1]Univ of Washington; [2]Univ of Minnesota; [3]Puget Sound Blood Center.*

Background: Antibody mediated rejection (AMR) is a major cause of kidney transplant (KTX) loss. Currently, AMR diagnosis depends on KTX biopsy (Bx). Injured cells release microparticles (MP). We hypothesized that since AAMR is associated with endothelial (endo) injury and endo C4d staining in Bx, AAMR is associated with increased C4d+ endo (C4d+/CD144+) MP, abbreviated EMP+.

Methods: Blood was collected prior or shortly after for cause KTX Bx from 62 patients, including 18 with AAMR and 44 with no AMR (NAMR) based on Bx and donor specific antibody (DSA). Platelet poor plasma was prepared, stained with anti-CD144 and C4d antibodies and studied for MP using flow cytometery. Results were compared with samples from 23 healthy subjects.

Results: Densities of total MP, CD144+, C4d+ and C4d+/CD144+ MP (EMP+) were greater in AAMR than NAMR and controls (P<0.00001), and greater in NAMR than controls (p=0.004). Importantly, there was no overlap between EMP+ density in AAMR and other groups. As such, a cut off of 3100 EMP+/uL had 100% sensitivity and specificity to diagnose AAMR with a perfect receiver operation characteristics curve (area under the curve =1.0) in this data set. Paired pre/post AAMR treatment samples from 10 patients with GFR improvement from 28±14 (pre) to 39±16 (post) ml/min/1.73 m^2 (p=0.006) showed reduced EMP+ density from 11,365±8,075 to 3,916± 3,031 /mL (p=0.02). EMP+ density inversely correlated with GFR in all KTX subjects (r=-0.26, p=0.045). EMP+ density was greater in Bx with Banff g2 or g3 compared to g0; ptc2 or ptc3 compared to ptc0; and cg2 or cg3 compared to cg0, confirming relationships between EMP+ and AMR Bx findings.

Conclusions: Our data identify EMP+ as a highly sensitive and specific biomarker of AAMR diagnosis with potential for treatment efficacy assessment and possible prognostic value. Further studies are needed to prepare for clinical use of EMP+ which may lead to early, non-invasive diagnosis of AMR with valuable implications for treatment and allograft outcomes.

FR-PO438

Comparison of a Bortezomib Based and a Standard Regimen in Antibody Mediated Rejection following Kidney Transplant Aneesha A. Shetty,[1] Yvonne El Kassis,[1] Stuart M. Flechner,[1] Andres G. Chiesa-Vottero,[2] Richard A. Fatica.[1] *[1]Dept of Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH; [2]Dept of Anatomic Pathology, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Antibody mediated rejection (AMR) is a cause of graft loss after kidney transplant. Despite limited evidence, bortezomib has been used in AMR. This study compares graft outcomes in kidney recipients with AMR treated with a standard regimen of intravenous methylprednisone (IVMP), intravenous immunoglobulin (IVIG) and plasmapheresis (PLEX), and those treated with bortezomib plus the standard regimen.

Methods: We studied 28 renal transplant recipients treated for biopsy proven AMR by Banff criteria and donor specific anti-HLA antibodies (DSA). 12 patients received IVMP, a 2-week cycle of bortezomib 1.3g/m^2/dose and PLEX on days 1-4-8-11, and 4 doses of 0.5g/kg of IVIG. 16 patients in the control group got the standard regimen without bortezomib. 8 patients in this group also received Thymoglobulin. Primary outcome was death censored graft loss at 18 months. Secondary outcomes were time to graft loss, serum creatinine (SCr) and protein creatinine ratio (PCR) at 1 year, and treatment related adverse effects.

Results: Mean follow up was 43±15 and 32±17 months in the bortezomib and control group. De novo class II DSA were more prevalent than class I in both groups. Patients in the bortezomib group had a more favorable histology. There was no significant difference between the 2 groups in graft loss at 18 months, time to graft loss, SCr and PCR at 1 year, and treatment related adverse effects.

	Bortezomib	Control	p
Patients (n)	12	16	
Age (years)	62±11	57±15	0.82
Males (n)	10	9	0.12
African Americans (n)	5	7	0.65
Time to AMR (months)	18 (8,35)	22 (1,70)	0.83
SCr at AMR (mg/dL)	2.2 (1.9,2.9)	4.1 (2.4,4.9)	0.02
PCR at AMR	0.3 (0.2,4.4)	0.7 (0.2,2.5)	0.64
Graft loss at 18 months (%)	69±14	56±12	0.47
SCr at 1 year (mg/dL)	2.6 (1.4,5.1)	1.8 (1.4,2.4)	0.28
PCR at 1 year	1.6 (0.2,8.3)	0.1 (0.09,2.2)	0.03

Conclusions: The bortezomib based and the standard regimen resulted in similar graft outcomes. Larger prospective studies are needed to characterize the role of bortezomib in AMR in kidney transplant recipients.

FR-PO439

Off Label Thymoglobulin Induction for Belatacept Based Calcineurin Inhibitor Sparing Regimen in Kidney Transplantation Is Associated with Lesser Risk of Acute Allograft Rejection Ashish Kataria, Barbara Bresnahan, Ehab R. Saad, Brahm S. Vasudev. *Nephrology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Belatacept, a co-stimulatory blocker of antigen-presenting cells was approved by the U.S. Food and drug administration (FDA) in 2011 for use in preventing rejection in adult kidney transplant recipients in combination with Basiliximab induction, Mycophenolate mofetil (MMF), and corticosteroids. We describe a single center experience in using Belatacept with either Basiliximab or off label Thymoglobulin induction.

Methods: Since 2006, we followed 12 kidney transplants recipients (2 cadaveric and 10 live donors) which received Belatacept as their initial (de-novo) immunosuppression medication. The decision to use Belatacept was based on the discretion of the transplant nephrologist. 7 patients received Thymoglobulin for induction therapy while 5 patients received Basiliximab. All patients also received steroids and Mycophenolate mofetil.

Results: After a maximum follow up period of up to 8 years, we encountered 4 episodes of acute cellular rejection (all within first 3 months of transplant); 3 in the basiliximab induction group (60%) and 1 in thymoglobulin induction group (14%). One patient had Banff grade IIb vascular rejection in the basiliximab group. These rejection episodes were treated with intravenous steroid with or without Thymoglobulin. All patients responded and there was no allograft loss. There was no episode of antibody mediated rejection. We encountered a low incidence of opportunistic infections; BK nephropathy in 2 patients and Cytomegalovirus (CMV) viremia in 1. There was no post-transplant lymphoproliferative disorder (PTLD) observed. Allograft and patient survival is 100% and mean eGFR after the follow up period is 70 ml/min/1.73m^2.

Conclusions: Belatacept is a novel agent in the CNI free anti- rejection regimen. It's off label use with thymoglobulin may provide a lower rate and less severe acute rejection episodes without an increased incidence of opportunistic infections or malignancies. Randomized studies in this regard are the need of present time.

FR-PO440

Single Center Experience on Comparisons of Alemtuzumab and Thymoglobulin as Induction Immunosuppressant Sandesh Parajuli, Ali Olyaei, Joshua Wiegel, Eric D. Langewisch, Douglas J. Norman. *Oregon Health & Science Univ.*

Background: Induction therapy is the standard of care at a majority of kidney transplant centers. Different induction agents are used depending on patient risks and clinician preference. The benefits of induction agents come with the risk of increased rates of infections and malignancy. In today's practice, commonly used induction therapy in immunological high risk patients are Alemtuzumab (C1H) or Thymoglobulin (rATG).

Methods: This was a prospective study of 58 immunological high risk patients transplanted between 2011 and 2013 with a minimum of six months follow up. Twenty five patients received one dose of 30 mg C1H and 33 patients received rATG, 6mg/kg in four divided doses. There was one early allograft loss due to recurrence of disease. All patients received tacrolimus, mycophenolate mofetil and prednisone for maintenance. The primary end point was biopsy-confirmed acute rejection. Secondary endpoints were BK viremia and cytomegalovirus (CMV) infections at six months.

Results: There were total of 58 patients, 25 in C1H group and 33 in rATG group. Common causes of end stage renal disease in both groups were diabetes, hypertension and chronic glomerulonephritis. Average age at transplant was 50 in C1H and 47 in rATG group (P=NS). White race was predominant among donors and recipients in both groups. Average duration on dialysis was 32.2 for C1H and 31.3 months for rATg (P=NS). 72% and 88% of transplants were deceased donors in C1H and rATG respectively (P=NS). Rejection rates within 3 months were fewer in C1H v rATG groups, 20% v 44% (p<0.005). There were no differences in serum Cr at 3 months. The mean WBC count was lower in the C1H group v in the rATG group (5.1 v 6.4) (P<0.005) at three months. The incidence of BK and CMV were slightly higher in rATG group at six months but this was not statistically significant.

Conclusions: In our single center experience, biopsy proven acute rejection was significantly lower in the C1H group. Adverse event rates were similar in both groups. Other advantages of C1H induction include single-dose administration and lower drug cost [$11,500 saving per transplant].

FR-PO441

Induction Therapy with Alemtuzumab for Deceased and Living Renal Transplant Recipients. A Single Centre Experience Pradeep Vaitla,[1] Antonio G. Jimenez,[1] Ryan C. Mascarenhas,[1] Abdul Moiz,[1] George E. Loss,[2] Stephanie Anders,[3] Jorge C. Garces,[1] Humberto Bohorquez.[2] *[1]Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [2]Transplant Surgery, Ochsner Clinic Foundation; [3]Pharmacy, Ochsner Clinic Foundation.*

Background: Antibody induction therapy has been used for induction in upto 80% kidney transplant recipients according to United Network for Organ Sharing. It has been established by multiple studies that induction therapy reduce the incidence and severity of acute rejection episodes, which may improve graft survival. Most transplant centers across the country use antibody induction with rabbit antithymocyte globulin or Alemtuzumab to minimize maintenance immunosuppression. We are presenting our experience with Alemtuzumab (30 mg iv single dose) in relation to graft survival and acute rejection rates. Our current protocol for immunosuppression includes Tacrolimus target trough level between 7-10 ng/ml, Mycophenolate mofetil (MMF) 500 mg oral twice daily, methylprednisolone 500 mg post opertive day (POD) 0, 250 mg POD 1 and 125 mg POD 2 with rapid steroid withdrawal.

Methods: We performed a retrospective chart review of of 441 kidney transplants performed from November 2007 to December 2011 of which 311 recipients received Alemtuzumab for induction immunosuppression and we obtained demographic, clinical data including biopsy proven acute rejection during one year follow up.

Results: The incidence of biopsy proven acute rejection during the one year follow up was 8% (25 of 311 patients). According to Banff classification 10 patients had type I and II rejection, 5 patients had type II alone, 4 patients had type I alone, 4 patients had type I,II and anti body mediated rejection (AMR), 2 patients had AMR alone. By the end of study period 0.3% (9) patients had graft failure requiring renal replacement therapy. Out of 311 patients induced with Alemtuzumab 0.12% (4) patients died during the study period.

Conclusions: In our experience with Alemtuzumab, using maintainance therapy of Tacrolimus, MMF and rapid steroid withdrawal (POD 2) is an effective agent with rejection rate of 8% and graft survival rate of 99% at one year post transplant.

FR-PO442

Induction with Alemtuzumab and Outcomes of Renal Allograft Transplants in African American Recipients Pradeep Vaitla,[1] Ushma Patel,[3] Antonio G. Jimenez,[1] Ryan C. Mascarenhas,[1] Abdul Moiz,[1] George E. Loss,[2] Stephanie Anders,[3] Ari J. Cohen,[2] Catherine G. Staffeld-Coit,[1] Jorge C. Garces,[1] Humberto Bohorquez.[2] *[1]Nephrology, Ochsner Clinic Foundation; [2]Transplant Surgery, Ochsner Clinic Foundation; [3]Pharmacy, Ochsner Clinic Foundation.*

Background: Induction with Almetuzumab is well documented in literature to reduce the incidence and severity of acute rejection episodes, which may improve graft survival. Not much data is available in African american population. We are presenting our experience with Alemtuzumab (30 mg iv single dose) in African american population. Our current protocol for immunosuppression includes Alemtuzumab (30 mg iv single dose),Tacrolimus target trough level between 7-10 ng/ml, Mycophenolate mofetil (MMF) 500 mg oral twice daily, methylprednisolone 500 mg post opertive day (POD) 0, 250 mg POD 1 and 125 mg POD 2 with rapid steroid withdrawal.

Methods: We performed a retrospective chart review of of 441 kidney transplants performed from November 2007 to December 2011 of which 311 recipients received Alemtuzumab for induction immunosuppression and we obtained demographic, clinical data including biopsy proven acute rejection during one year follow up.

Results: The incidence of biopsy proven acute rejection during the one year follow up was 8.8% (13 of 147) in African americans compared to 8% (25 of 311) in the study population. Incidence of graft failure by end of study period, in African american population was 0.27% (4 of 147) compared to 0.28% (9 of 311) in the study population.

Conclusions: In our experience Alemtuzumab is an effective agent with similar rejection rate and allograft survival in African American and non-African American population.

FR-PO443

A Prospective Study of Acute Clinical and Subclinical Rejection in a Rapid Steroid Withdrawal Protocol Rajil B. Mehta, Riyaj A. Kasekar, Puneet Sood, Chethan M. Puttarajappa, David Rothstein, Nirav A. Shah, Christine Wu, Sundaram Hariharan. *Medicine, Univ of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: To estimate the incidence and risk factors for acute clinical rejection (ACR) and subclinical rejection (SCR) and evaluate response to therapy in a rapid steroid withdrawal protocol.

Methods: We prospectively followed 231 adults who underwent kidney transplantation between 1/1/2013 - 2/28/2014 at our center. Patients received induction with thymoglobulin (93%), simulect (6%) or campath (1%), CNI/MPA maintenance therapy and rapid steroid withdrawal by day 7. Protocol biopsy was performed at 3 months post transplant. Eight patients were excluded from the study due to early graft failure or death. The remaining 223 patients were divided into 4 groups. Grp I (n=27) had SCR on 3 month protocol biopsy and received therapy. Grp II (n=101) had no rejection. Grp III (n=25) had ACR on for cause biopsy and Grp IV (n=70) did not undergo biopsy for various reasons. Banff classification was followed for biopsy grading and patients were treated per our center protocol. Recipient and donor demographics, transplant and post transplant variables and serum creatinine (3 and 6 months) were compared using t-test, ANOVA or chi-square test as indicated.

Results: The incidence of SCR was 17.3% (27/153) and ACR was 11.2% (25/223). The distribution of variables is as shown. The incidence of DGF and CIT were higher in Grp I (SCR). Serum creatinine was higher at 3 and 6 mths in the ACR grp.

Groups (n)	I (27)	II (101)	III (25)	IV (70)	p value
Mean age (yrs)	52	50	48	55	0.23
Gender (M/F)	17/10	57/44	11/14	28/32	0.73
Race (W/AA/O)	23/4/0	78/20/3	19/6/0	61/8/1	0.0001
Tx type (LD/DD)	7/20	54/47	11/14	14/56	0.009
Donor age (yrs)	49.4	39.4	39.8	38.2	0.82
CIT (mins)	510	353	372	504	**0.04**
HLA DR mm	1.25	1.18	1.44	1.27	0.96
PRA	9.4	18.5	10.4	18.4	0.22
DGF (Y/N)	9/18	8/93	4/21	14/56	**0.008**

Banff Gr (Bord/IA or greater)	5/22	NA	5/20	NA	NA

Conclusions: The incidence of SCR was 17.5% at 3 months in our study.CIT and DGF were higher in patients with SCR. Serum creatinine at 3 and 6 mths was higher in ACR grp.

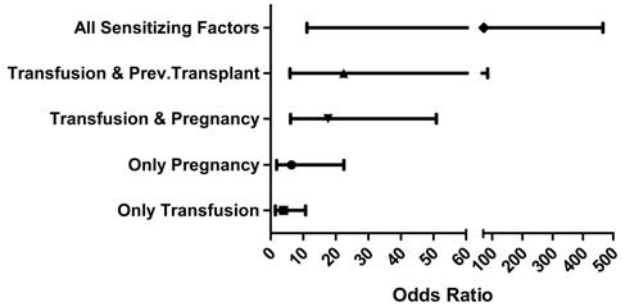
FR-PO444

Impact of Pre-Transplant Exposure to Allosensitizing Factors on the Generation of Anti-HLA Antibodies in Luminex Era Araminta Guichard, Lluvia A. Marino-Vazquez, Carlos Norman Velazquez Gutierrez, Norma O. Uribe-Uribe, Josefina Alberú, Luis E. Morales-Buenrostro. *Nephrology, Pathology & Transplantation, National Inst of Medical Sciences and Nutrition Salvador Zubiran, Mexico City, DF, Mexico.*

Background: Most studies of allosensitization were performed prior to the use of erythropoietin, new techniques of cell separation (leukoreduction) and prior to the use of Luminex to measure anti-HLA antibodies. So, the main causes of allosensitization demonstrated by these studies were transfusions, pregnancy, and transplantation of organs and tissues. OBJECTIVE: To establish the frequency of current exposure to sensitizing factors and their association with the presence of pre-transplant HLAabs measured by Luminex, a highly sensitive and specific technique.

Methods: Retrospective cohort study from January/2004 to December/2013. Variables of age, gender, %PRA and allosensitizing factors were included. Odds ratio were calculated for each sensitizing factor.

Results: In this period, 444 kidney transplants were performed and 430 (96.8%) were included. The mean age 34.7 ± 12.5 years, 56.7% males, 70.4% from living donor, and 94.4% first transplant. Of the 430 patients, 57.4% received transfusions which was associated with higher %PRA levels for both class I HLAabs ($p < 0.001$) and class II HLAabs ($p = 0.002$) compared with those negative. Only 5.6 % had a previous transplant and had higher levels of %PRA class I and II ($p < 0.001$). Of 186 women, 48.3% had one or more pregnancies, which was associated with higher %PRA levels of class I ($p < 0.001$), it showed trend for class II ($p = 0.052$). The risk to developing a %PRA greater than 20% if have been exposure to a sensitizing factor is depicted in Figure.



Conclusions: Despite use of erythropoietin and leukoreduction, the HLA sensitization is high. This study demonstrates that those recognized sensitizing factors continue to be valid in the Luminex era.

Predictors of the Response to Bortezomib in Antibody Mediated Rejection following Kidney Transplant Yvonne El Kassis, Aneesha A. Shetty, Richard A. Fatica. *Dept of Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Bortezomib has been used in the treatment of antibody mediated rejection (AMR) in kidney transplant patients. However reported treatment outcomes have been variable and inconsistent, making selection of appropriate candidates for this therapy challenging. This retrospective study evaluates the pre treatment predictors of the response to a bortezomib based regimen in AMR, in an attempt to establish its best use.

Methods: We identified 24 adult renal transplant recipients treated with bortezomib for biopsy proven AMR and donor specific antibody (DSA) between 2008 and 2013. Patients also received adjuvant intravenous methylprednisone (IVMP), plasmapheresis (PLEX) and intravenous immunoglobulin (IVIG). Response to bortezomib was defined as graft survival at 1 year.

Results: Mean age was 41±13 years. There were 15 males and 9 African American. 12 patients (50%) got basiliximab and 9 (38%) got anti thymocyte globulin for induction at time of transplant. At the time of AMR, 16 patients (67%) were on maintenance immunosuppression with tacrolimus, mycophenolate mofetil and prednisone. Median serum creatinine (SCr) and Protein creatinine ratio (PCR) at AMR were 2.4 (1.8, 3.9) mg/dl and 0.3 (0.1, 2.4) respectively. Concomitant acute cellular rejection (ACR) was present in 13 patients (54%). At 1 year, 5 patients (21%) were on dialysis. Induction with anti thymocyte globulin was associated with a higher risk of graft failure at 1 year (p 0.03), likely a reflection of high-risk patients receiving thymoglobulin induction at our center. Patients with SCr >3mg/dL (p=0.03), higher PCR (p=0.03) and concomitant ACR (p=0.02) at the time of AMR were more likely to be on dialysis at 1 year. Time from transplant to AMR, DSA class and titer, and adjuvant treatment regimen were not statistically significant predictors of the response to bortezomib.

Conclusions: Kidney transplant patients treated with a bortezomib based regimen for AMR may have worse outcomes if they have concomitant ACR and if they show clinical evidence of advanced graft damage. This may be an important consideration for clinical decision-making in selecting appropriate patients for bortezomib therapy.

FR-PO446

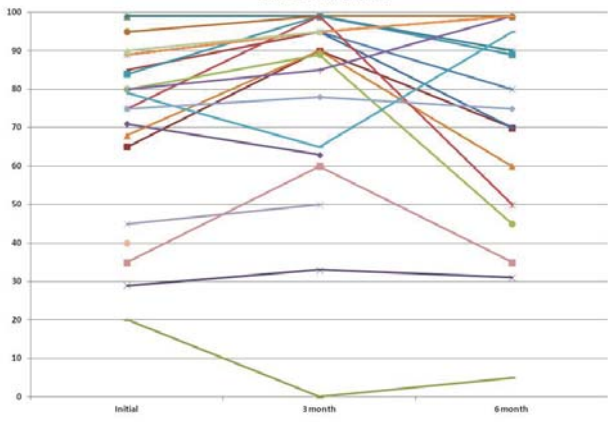
No Effect of Rituximab and IVIg on Sensitized Patients Waiting for Deceased Donor Renal Transplants Shefali Patel, Leigh-Anne Dale, Elena Rodica Vasilescu, Geoffrey K. Dube, Sumit Mohan, Lloyd Ratner, Russell J. Crew. *Columbia Univ Medical Center.*

Background: Approximately 30% of patients waiting for deceased donor renal transplant (DDRT) have anti-HLA antibodies against potential donors, leading to dramatically increased waiting times. Those sensitized patients who do receive a DDRT have higher rates of cellular (ACR) and antibody mediated rejection (AMR).

Methods: To improve access to transplantation, we attempted to desensitize 24 sensitized ESRD patients waiting for a DDRT with 2 doses of intravenous immunoglobulin (2 gm/kg in divided doses each time) separated by 4 weeks and a single dose of Rituximab 375 mg/m^2. We followed anti-HLA antibodies at 3, 6, and 12 months by cytotoxicity Panel of Reactive Antibodies (PRA) as well as by Luminex flow beads.

Results: We were unable to detect a change in PRA at any time point after desensitization.

Figure 1 - Change in PRA



However, 11/24 patients (46%) were transplanted at a mean 331 (range 26-692) days after desensitization. Transplanted patients had similar waitlist times (65.2 ± 41.6 versus 39.4 ± 30.8 months p=0.1) but lower initial PRA (63% versus 82%, p=0.038). Despite desensitization, 9/11 had donor specific antibodies (DSA) by Luminex and 6/11 had positive flow crossmatch. There was 1 allograft failure at 3 years, 1 AMR and 6 ACRs, and creatinine at 1 year=1.3 mg/dL. When compared to a contemporaneous sensitized control group matched by Luminex and flow crossmatch results, there were no differences in rejection rates, infections, or renal function.

Conclusions: We were unable to detect a decrease in PRA using IVIG and Rituximab in waitlisted patients. Nor did these patients experience a significantly different outcome compared to control sensitized patients.

FR-PO447

Clinical Outcome in Patients with Chronic Antibody-Mediated Rejection Treated with and without Rituximab and Intravenous Immunoglobulin Combination Therapy Tae Hyun Ban,[2] Byung Ha Chung,[1,2] Bum Soon Choi,[1,2] Cheol Whee Park,[1,2] Yong-Soo Kim,[1,2] Chul Woo Yang.[1,2] *[1]Transplant Research Center, Seoul St. Mary's Hospital, Seoul, Korea; [2]Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea.*

Background: We previously reported that rituximab (RTX) and intravenous immunoglobulin (IVIg) combination therapy (RIT) is effective in treating patients with chronic active antibody-mediated rejection (CAMR), and the proteinuria level can determine the response to RIT. However, the results were not compared to those of patients who did not receive RIT.

Methods: Fifty-nine patients with CAMR were divided into 2 groups: an RIT treated group (n=25) and a historic control (HC) group who had not received RIT (n=29). The RIT group was treated with RTX (375 mg/m^2) and IVIg (0.4 g/kg) for 4 days. We compared the decline in glomerular filtration rate/month (DeGFR), RIT-related complications, and allograft survival rate in both groups. We also compared the allograft survival rate between patients with high proteinuria (spot urine protein/creatinine [PC] ratio >3.5 g/g) and low proteinuria (PC ratio <3.5 g/g).

Results: DeGFR was significantly decreased in the RIT group compared with the HC group after 6 months ($P < 0.05$). No serious complications were associated with RIT, and only one case of herpes zoster infection developed. The overall allograft survival rate in the RIT group was significantly higher than in the HC group. In both groups, patients with low proteinuria survived better than patients with heavy proteinuria ($P < 0.05$). The allograft survival rate was greater in the high proteinuria RIT group than that in the HC group.

Conclusions: RIT treatment is recommended for delaying the progression of CAMR without serious complications, and is not limited by the presence of heavy proteinuria.

FR-PO448

Clinical Impact of HLA-Donor Specific Antibodies Measured By Luminex Technique in Kidney Transplant Recipients with Renal Allograft Dysfunction Ji Hyun Yu,[2] Byung Ha Chung,[1,2] Bum-Soon Choi,[1,2] Cheol Whee Park,[1,2] Yong-Soo Kim,[1,2] Chul Woo Yang.[1,2] *[1]Transplant Research Center; [2]Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: In this study, we investigated the clinical impact of donor-specific anti-HLA-antibody (HLA-DSA) measured by the Luminex single-antigen assay in patients who took indicated biopsy due to allograft dysfunction.

Methods: Between Feb. 2010 and Feb. 2013, total 210 cases of indication biopsy were performed in Seoul St. Mary's hospital. In all cases, we examined the presence of HLA-DSA using Luminex technique when allograft biopsy was done. We investigated the clinical impact of the presence of HLA-DSA and the association to the pathologic finding of biopsy specimen in those cases.

Results: Anti-HLA antibody was detected in 86 cases (41%) and 39 cases (19%) were proved as HLA-DSA. HLA-DSA-DR was most common (26%) followed by HLA-DSA-B (11%) and HLA-DSA-A (8%). In comparison between HLA-DSA positive (+) group (n=39) and HLA-DSA negative (-) group (n=171), the rate of re-transplantation and the number of HLA-mismatched antigen were significantly higher (P<0.05 for each) in HLA-DSA (+) group. The number of patients who showed sensitization before KT was higher in HLA-DSA (+) group as well (P<0.05). In comparison of histologic finding, vasculitis (v), glomerulitis (g) and peritubular capillaritis (ptc) was more severe in HLA-DSA (+) group compared to HLA-DSA (-) group, hence microvascular inflammation score (g + ptc) was also higher in HLA-DSA (+) group (P<0.05). In allograft survival rate after biopsy, HLA-DSA (+) group showed significantly worse outcome compared to HLA-DSA (-) group (P<0.05). In addition, presence of HLA-DSA was independent risk factor for allograft failure in multivariate analysis.

Conclusions: HLA-DSA detected at indication biopsy is important prognostic factor for allograft outcome independent of the result of allograft biopsy and other factors.

FR-PO449

DSA Detected by ELISA-PRA Is Associated with High Risk for Development of ABMR in Stable Kidney Transplant Recipients Dong Ryeol Lee,[1] Mi Young Jeon.[2] *[1]Medicine, Maryknoll General Hospital, Busan, Republic of Korea; [2]Pathology, Marknoll General Hospital, Busan, Republic of Korea.*

Background: Donor HLA-specific antibodies (DSAs) have been implicated in poor graft outcome and decreased survival in solid organ transplantation. The purpose of this study was to evaluate the incidence of presence of DSA and the association of DSA and development of ABMR in stable kidney transplant recipients.

Methods: We screened 208 stable kidney transplant recipients by HLA-specific ELISA-PRA (panel reactive antibody) for DSA from January to December 2013. We compared the incidence of acute rejection between Group1 (DSA positive group, n=11) and Group2 (non-DSA positive, n=11). To evaluate response after ABMR treatment, ELISA-PRA levels were monitored at day 0, month 1 (M1) and month 3 (M3).

Results: 25 (12.0%) of 208 patients were positive ELISA-PRA. 22 of them were biopsied. At the time of biopsy, median total PRA was 7.5% (2.5-47.5). In Group 1, all eleven patients with positive DSAs (5 had DSA against class I, 5 had DSA against class II, one had DSA against class I and class II) were diagnosed with subclinical ABMR. ABMR was treated with 4 (4-7)) of plasmapheresis with low dose IVIG and 100mg of rituximab.

Total median PRA levels (n=11) decreased from 13.7% at M0 to 2.5% at M1 but increased 20% at M3. Class I PRA (n=6) decreased from 12.5% to 1.8% at M1 but increased 3.6% at M3. Class II PRA (n=6) decreased from 50% to 16.7% at M1 but increased 41.7% at M3. At 3month (M3) after treatment of ABMR, Three of 6 class 1 DSA positive became negative, however, none of 5 class II DSA positive became negative. In Group 2, 3 (27.3%) of 11 non-DSA positive patients had borderline change treated with steroid pulse therapy. Time to biopsy after transplantation was 6.5 (4month-14 year). The median creatinine at the time of biopsy was 1.1 (0.6-2.2) mg/dl, FK level 5.9 (4.5-8.1) ng/ml.

Conclusions: Our study demonstrated that ELISA-DSA positive has a significantly high risk for development of subclinical ABMR in stable renal transplant recipients.ELISA-PRA is a effective screening method with subsequent allograft biopsy may be useful to recognize patients are likely to develop ABMR. Long term effect of treatment for ABMR need to be determined.

FR-PO450

Intravenous Immunoglobulin and Rituximab Based Desensitization Is Ineffective for Highly Sensitized Patients Layal Abdel Rahman,[1] Pam Kimball,[2] Anne L. King,[1] Amit Sharma,[2] Adrian Cotterell,[2] Dhiren Kumar,[1] Muhammad Raza Qureshi,[1] Felecia McDougan,[2] Gaurav Gupta.[1] *[1]Nephrology, Virginia Commonwealth Univ, Richmond, VA; [2]Surgery, Virginia Commonwealth Univ, Richmond, VA.*

Background: ESRD patients with human leukocyte antigen (HLA) sensitization can have prolonged waiting times. This can result in increased morbidity and mortality. Studies focusing on non-African Americans (AA) have suggested that desensitization with rituximab/intravenous immunoglobulin (IVIG) might be efficacious.

Methods: 15 highly sensitized patients with a median calculated panel reactive antibody (cPRA) of 99% (range=69-100%) underwent desensitization. The desensitization protocol included 2 doses of IVIG (2 g/kg) on days 0 and 30 and 1 dose of rituximab (375mg/m²) on day 15. HLA antibody profiles of sera obtained before and after treatment were characterized, and flow cytometry crossmatch (FCXM) tests were performed for all kidney offers.

Results: 87% (13/15) patients were AA and 80% (12/15) patients had previous failed transplants. Twelve (out of 15; 80%) patients had no significant decline in cPRA over a follow-up of 9 months post-treatment. There was a trend towards a decline in Class I cPRA (median 64% to 48%; p=0.1) and the number of Class I unacceptable antigens (median 11 to 8; p=0.1) after treatment. Of the 3 patients who showed a clear decline in cPRA: 2 were Caucasian and 2 had a lower cPRA (mean=70%) with pregnancy as the sensitizing event. Eight (out of 15; 53%) patients got transplanted at a median of 11.8 months post-desensitization. Among these patients, retrospective FCXM testing using pre-treatment samples showed an unchanged FCXM suggesting that all patients would have been eligible for a transplant with their respective donors even before desensitization.

Conclusions: In this small single-center study we were unable to demonstrate successful use of Rituximab/IVIG for most AA sensitized patients. It is possible that this protocol might have some efficacy in non-AA patients with a cPRA<80% and with primarily Class I sensitization. The high rate of transplantation seen in our study is likely due to an increased threshold for accepting a borderline positive FCXM.

FR-PO451

Rescue of Mutant Laminin by Combined Treatment with a Chemical Chaperone and a Proteasome Inhibitor Yeawon Kim, Jeffrey H. Miner, Ying Maggie Chen. *Renal Div, Washington Univ, St. Louis, MO.*

Background: Laminin beta2 encoded by *LAMB2* is a component of the laminin-521 trimer, an important constituent of the mature glomerular basement membrane (GBM). Utilizing our established cell and knock/transgenic mouse model resembling human nephrotic syndrome (NS) caused by the C321R-LAMB2 mutation, we demonstrated that defective secretion of the mutant protein from podocytes to the GBM and concomitant podocyte endoplasmic reticulum (ER) stress are crucial contributors to the development of proteinuria (*Chen Y et al., JASN 24: 1223-1233, 2013*). Moreover, the C321R mutant is functional. Here we investigated a novel therapeutic approach.

Methods: We generated stably transfected HEK293T cells expressing fusion proteins in which the N-terminal fragments of wild-type (WT) or mutant beta2 were fused to Gaussia luciferase (Gluc). Secretion of the fusion proteins is directed by the beta2 signal peptide, and trafficking of the fusion proteins can be analyzed by luciferase assay.

Results: The steady-state level of C321R/Gluc was increased after proteasome inhibition by MG-132 for 24h compared to that of WT/Gluc. In addition, treatment with MG-132 induced a striking accumulation of polyubiquitinated C321R mutant protein, but much less of the WT protein, indicating that a much greater fraction of the mutant protein is indeed ubiquitinated and degraded by the proteasome. These results suggest that the ubiquitin-proteasome system has been activated by ER stress induced by the C321R mutation. Previously, we showed that a chemical chaperone tauroursodeoxycholic acid (TUDCA) enhanced secretion of the C321R mutant into the medium. In the current study, when combined with MG-132, TUDCA elicited an even more robust effect on secretion of the mutant protein: a 35.2 fold increase compared to vehicle control, and a 3.6 fold increase compared to TUDCA alone.

Conclusions: Currently there is no effective treatment for genetic forms of NS. Our results suggest that therapeutic strategies aimed at modulating both protein misfolding and degradation could lead to a significant leap forward in the treatment of certain loss-of-function types of NS.

AT1R Blockade during Adverse Milieus: Role of SMRT and Co-Repressor Complexes Kamesh R. Ayasolla,[1] Nirupama Chandel,[1] Rivka Lederman,[1] Guohua Ding,[1] Praveen N. Chander,[2] Ashwani Malhotra,[1] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Pathology, New York Medical College, Valhalla, NY.*

Background: Since AT1R blockade is associated with elevated renal tissue levels of renin, use of 1, 25$[OH]_2$D (VD) in combination with AT1R blockade has been demonstrated to provide better outcome in experimental animal models of diabetic nephropathy. We hypothesized that AT1RB would provide podocyte protection through silencing mediator of retinoic acid and thyroid hormone receptor (SMRT) and VD receptor (VDR) expressions in adverse milieus (AMs) such as high glucose and HIV.

Methods: Human podocytes (HPs) were treated with losartan (AT1RB) or VDR agonist (VDA) with or without AMs (48h) and evaluated for mRNA expressions of Cytochrome P450 Family 24 (CYP24) and VDR and protein expressions of co-repressor and co-activator complexes. Protein interactions in these complexes in response to AT1RB and VDA were evaluated by immunoprecipiatation (IP) studies followed by Western blot analysis.

Results: Both AT1RB and VDA enhanced podocyte VDR expression but they exhibited disparate effects on CYP24A1 and acetylated histone (AC-H) 3 expressions. Analysis of AT1RB- induced protein interaction complexes revealed presence of VDR, SMRT, and phospho-HDAC3; whereas, VDA-induced protein interaction complexes displayed presence of VDR and CBP/p300. AT1RB induced complexes attenuated expression of AC-H3 and thus indicating their deacetylase properties. Repressive nature of AT1RB complex was also manifested by its effect on podocyte CYP24A1 expression. However, net podocyte CYP24A1 expression depended on repression by co-repressor complex and presence of VD in the media. AT1RB-induced podocyte SMRT expression inhibited pro-apoptotic gene expression through down regulation of Wip1 and phosphorylation of Chk2. Since podocyte SMRT knockdown lacked AT1RB mediated protection against DNA damage, it appears SMRT is critical for DNA repairs during AT1RB.

Conclusions: AT1RB provides podocyte protection in AMs predominantly through SMRT expression and partly through unliganded VDR expression in VD deficient states, whereas, it contributes to liganded VDR expression in VD sufficient state.

FR-PO453

Vegfa Expression by the FoxD1 Lineage Is Critical for Adequate Glomerular Development and Function Henrik Dimke,[1,2] Yoshiro Maezawa,[1] Rizaldy P. Scott,[1] Paul S. Thorner,[3] Yashpal S. Kanwar,[4] Susan E. Quaggin.[1,5] *[1]The Lunenfeld-Tanenbaum Research Inst, Mt. Sinai Hospital, Toronto, ON, Canada; [2]Dept of Cardiovascular and Renal Research, Univ of Southern Denmark, Odense, Denmark; [3]Dept of Pediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada; [4]Depts of Pathology and Medicine, Northwestern Univ, Chicago, IL; [5]Feinberg Cardiovascular Research Inst and Div of Nephrology and Hypertension, Northwestern Univ, Chicago, IL.*

Background: Intraglomerular mesangial cells (GMC) lie in close contact with the fenestrated endothelial cells that line the capillary loops. It is well established that endothelial cells communicate with GMCs by secreting platelet-derived growth factor; however, cytokines generated by GMCs may also convey signals to endothelial cells, although such signaling pathways remain poorly defined. Here we explored whether mesangial Vegfa could play a role in cross-communication between GMCs and endothelial cells.

Methods: Transgenic mice carrying forkhead box D1 (FoxD1)-driven Cre recombinase were used to excise *Vegfa* from vascular mural cells and GMCs.

Results: Elimination of Vegfa from the FoxD1 lineage ($Vegfa^{FoxD1}$) resulted in the onset of proteinuria at postnatal day (P) 14. Kidneys from $Vegfa^{FoxD1}$ appeared smaller at P0, while mild to moderate expansion of the mesangium was noted at P7. Structurally, thickening of the glomerular basement membrane was visible by electron microscopy at P7, which was confirmed by silver stains. At P14, moderate to severe expansion of the mesangium was evident, with obvious thickening of glomerular basement membranes, obliteration of capillary lumina, loss of endothelial cells and accumulation of subendothelial deposits. Progressive worsening of the phenotype was evident at P21, at which time glomeruli appeared hypocellular with collapse of capillary tufts.

Conclusions: Production of *Vegfa* from cells within the FoxD1 lineage is necessary for proper development and maintenance of the glomerular filtration barrier. The present data suggest that Vegfa produced by GMCs may play a key role in cross-communication between the GMC and endothelial compartments.

FR-PO454

Fine-Tuning of NFkB by Glycogen Synthase Kinase (GSK) 3b Dictates the Fate of Glomerular Podocytes Upon Injury Hui Bao,[1,2] Yan Ge,[1] Ai Peng,[2] Rujun Gong.[1] *[1]Nephrology, Brown Univ; [2]Nephrology, Shanghai Tenth People's Hospital, Tongji Univ, China.*

Background: NFkB acts as a double-edged sword in the pathogenesis of podocytopathy. In addition to directing the transcription of a multitude of mediators involved in podocyte injury, including proinflammatory cytokines as well as cytoskeletal remodeling molecules like lysosomal protease cathepsin L and co-stimulatory molecule B7-1, NFkB is also an

essential survival factor for cellular response to stress or injury for self-protection. The activity of NFkB is controlled by a myriad of signaling cascades and the effect of GSK3b on NFkB activation in podocytes was examined.

Methods: Podocyte injury was induced by liposaccharide (LPS) in cultured podocytes and in mice. The effect of GSK3b on NFkB activation was examined.

Results: In cultured podocytes, LPS elicited cytoskeletal disruption and hypermotility, associated with NFkB activation and induced expression of NFkB target molecules, including prosurvival Bcl-xL and podocytopathic mediators like MCP-1, cathepsin L and B7-1. Broad range inhibition of NFkB by PDTC or TPCK diminished the expression of all NFkB target genes, restored cytoskeleton integrity, but potentiated apoptosis. In contrast, inhibition of GSK3b by lithium or TDZD-8 selectively obliterated the expression of podocytopathic mediators, ameliorated podocyte injury, reinstated cytoskeleton integrity, but barely affected Bcl-xL expression or sensitized apoptosis. Mechanistically, GSK3b was sufficient and essential for phosphorylation of murine RelA/p65 specifically at serine 467 and thereby directed NFkB binding to MCP-1, cathepsin L and B7-1 genes, but not to Bcl-xL gene. *In vivo*, lithium or TDZD-8 treatment improved proteinuria and podocyte injury in LPS injured mice, concomitant with mitigated expression of MCP-1, cathepsin L and B7-1 but largely retained Bcl-xL expression. Contrarily, TPCK therapy conferred a similar but much blunted anti-proteinuric and podocyte protective effect, accompanied with marked podocyte apoptosis and suppression of glomerular expression all NFkB dependent molecules, including Bcl-xL.

Conclusions: The GSK3b dictated fine-tuning of NFkB might serve as a novel therapeutic target for podocytopathy.

FR-PO455

Shank2 Impacts Endosome Abundance and Rates in Renal Epithelial Cells

Evgenia Dobrinskikh,[1] R. Brian Doctor,[3] Kayo Okamura,[1] Linda Lewis,[1] Ryan Caldwell,[1] Jeffrey B. Kopp,[2] Judith Blaine.[1] *[1]Medicine, Univ of Colorado Denver, Aurora, CO; [2]Kidney Disease Section, NIDDK, NIH, Bethesda, MD; [3]Dept of Biology, Univ of Mississippi, Oxford, MS.*

Background: Shank2 is a scaffolding protein that has been associated with endocytic trafficking of epithelial transport proteins in proximal tubule (PT) cells. Shank2 co-migrates with NaPiIIa during endosomal trafficking to the lysosomal compartment. The present studies utilized Shank2 knockout (KO) mice to determine the significance of Shank2 in the endocytic pathways.

Methods: Electron microscopy, intensity correlation coefficient (ICQ) analysis and Western blot analysis were used to examine endocytosis in Shank2 wild type and KO renal epithelial cells.

Results: Electron microscopy analysis of renal proximal tubule cells found Shank2 KO mice have significantly decreased amounts of endocytic vesicles in the proximal tubules. Like PT cells, renal podocytes actively endocytose proteins, including albumin. Western blotting and immunofluorescence studies show that Shank2 is expressed by podocytes *in vivo* and in culture. In cultured human urine-derived podocytes, intensity correlation coefficient analysis demonstrates that Shank2 colocalizes with endocytosed FITC-albumin, early endosome compartments (EEA1) and lysosomes (LAMP1). Lentiviral shRNA knockdown of Shank2 in cultured human podocytes diminished Shank2 levels by 64±16% but failed to demonstrate a significant decrease in albumin uptake (Shank2 knockdown cells had 49±8% less FITC-albumin compare to control shRNA-infected cells at 2 hrs of uptake at 37°C, n=3, p=0.06). To evaluate the impact on albumin uptake in the complete absence of Shank2, primary podocytes were isolated from Shank2 KO mice and cultured. Primary mouse podocytes express the podocyte markers podocin and WT-1. When compared to wild type podocytes, cells from Shank2 KO mice have significantly diminished rates of albumin endocytosis.

Conclusions: Measuring changes in both endosome abundance in PT cells and endosomal uptake of albumin in podocytes, the present studies are the first to directly demonstrate a functional role for Shank2 on the endosomal pathways in epithelial cells.

FR-PO456

SIRT1 Maintains Actin Cytoskeleton by Deacetylation of Cortactin in Podocytes

Shuta Motonishi,[1] Masaomi Nangaku,[1] Takehiko Wada,[1] Yu Ishimoto,[1] Taiji Matsusaka,[2] Akira Shimizu,[3] Reiko Inagi.[4] *[1]Div of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]Dept of Internal Medicine, Tokai Univ School of Medicine, Kanagawa, Japan; [3]Dept of Analytic Human Pathology, Nippon Medical School, Tokyo, Japan; [4]Div of CKD Pathophysiology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan.*

Background: Recent studies have highlighted the renoprotective effect of SIRT1. However, its molecular mechanism in podocytes is still unclear. We therefore investigated the function of SIRT1 in podocytes.

Methods: We established podocyte-specific *Sirt1* knockout ($SIRT1^{pod-/-}$) mice and induced glomerular injury by injection of anti-GBM antibody, and histological and functional analyses were performed. The expression of podocyte specific proteins was assessed by western blot analysis or immunofluorescent study. Immortalized murine podocytes and the SIRT1 inhibitors/activator were utilized to assess the effect of SIRT1 to podocytes. Furthermore, the association between SIRT1 and cortactin was investigated *in vivo* and *in vitro*.

Results: Seven days after glomerular disease induction, u-alb/cre, BUN and the ratio of glomerular injury in $SIRT1^{pod-/-}$ mice were significantly higher compared with wild-type mice. Consistently, significant decrease in podocyte-specific molecules was shown in $SIRT1^{pod-/-}$ mice. Electron microscopy revealed the exacerbation of foot process effacement and actin cytoskeleton derangement in $SIRT1^{pod-/-}$ mice. Similarly, actin cytoskeleton derangement in H_2O_2 (mediator of anti-GBM glomerulonephritis)-treated cultured podocytes became prominent by pretreating with SIRT1 inhibitors, while it was ameliorated by a SIRT1 activator. Furthermore, we assessed the link between SIRT1 and cortactin, which acts to support actin cytoskeleton. We revealed that SIRT1 deacetylated cortactin in the nucleus in podocyte and that the deacetylated cortactin was transported to the cytoplasm for maintenance of actin cytoskeleton. We confirmed this mechanism using cortactin siRNA or leptomycinB, nuclear export inhibitor.

Conclusions: SIRT1 regulates the functional state of cortactin by deacetylation, and thereby maintains actin cytoskeleton integrity in podocytes.

Arp3 Mediated Actin Branching Controls Podocyte Cortical Tension and ECM Interaction via Modulation of the Actomyosin Machinery

Christoph Schell,[1] Dontscho Kerjaschki,[2] Tobias B. Huber.[1] *[1]Univ Medical Center Freiburg, Renal Div, Freiburg, Germany; [2]Univ Medical Center Vienna, Inst of Pathology, Vienna, Austria.*

Background: Podocyte foot processes (FP) are essentially involved in the formation of the glomerular filtration barrier and provide at the same time tight adherence of the podocyte to the underlying GBM. We´ve previously demonstrated that N-WASP mediated actin branching is involved in the stabilization and maintenance of podocyte FPs. However, it remained so far unaddressed, whether and how actin branching might influence podocyte-GBM interaction.

Methods: We generated a set of complementary conditional mouse models allowing for deletion of N-Wasp and Arp3 at decisive developmental stages of podocytes. Furthermore, a novel primary podocyte culture system with proven genetic origin was employed to investigate cellular functions of either N-WASP or ARP3.

Results: Deletion of N-Wasp at different developmental stages demonstrated only minor alterations in podocyte FP morphology at first. Interestingly, also deletion of Arp3 as an ultimate effector of N-WASP resulted in comparable phenotypes. Analysis of Arp3 deficient primary podocytes showed a decreased spreading capacity, migrational speed and altered focal adhesion morphology. Employing traction force microscopy revealed that Arp3 deficient podocytes exert higher force levels compared to control cells and display an activated actomyosin machinery. Inhibition of the actomyosin machinery reversed the inefficient protrusion formation of Arp3 deficient cells in 3D culture conditions.

Conclusions: Our observations demonstrate that the mechanism of actin-branching is not essentially required for intial podocyte FP assembly, but rather for the stabilization of FPs under mechanical stress. Furthermore, we provide evidence for a novel link between ARP2/3 dependent actin networks, the actomyosin machinery and podocyte-GBM interactions. These findings further deepen our global understanding of actin dependent podocyte FP function and plasticity.

Rac1 Protects against Podocytes Injury Induced by DNA Damage

Weibin Zhou,[1] Xiaoyang Wan,[1] Zhao-Hong Chen,[1,2] Yingbao Yang,[1] Qing Hou.[1,2] *[1]Pediatrics and Communicable Diseases, Univ of Michigan, Ann Arbor, MI; [2]National Clinical Research Center of Kidney Diseases, Nanjing Univ School of Medicine, Nanjing, China.*

Background: Podocytes are specialized epithelial cells that cover the outer surface of glomerular basement membrane and maintain the integrity of glomerular filtration barrier. Podocytes Injury in rodent models results in podocytes loss and proteinuria, and/or even focal segmental glomerulosclerosis. Rac1 is a member of small GTPase family, whose dysfunction is associated with podocytes injury and proteinuric kidney diseases. Mice with induced Rac1 expression in the podocytes develop foot process effacement and transient proteinuria.

Methods: In this study, we have generated transgenic zebrafish expressing either constitutive-active or dominant-negative Rac1 in the podocytes using Gal4-UAS system. No gross abnormality was seen either in the embryos or adults of these transgenic lines. To characterize the role of Rac1 in podocytes injury, we used an inducible podocytes injury model in which metronidazole (MTZ) is converted to a DNA damaging agent by the bacterial nitroreductase expressed specifically in podocytes of the transgenic zebrafish and DNA damage leads to podocyte apoptosis, which resembles adriamycin-induced podocyte injury in mice. Upon administration of MTZ, the transgenic zebrafish embryos developed varying degrees of peri-orbital edema and abdominal edema due to podocyte loss in a dosage-dependent manner.

Results: Inhibition of Rac1 activity by dominant-negative Rac1 significantly accelerates the onset of orbital edema while expression of constitutive-active Rac1 ameliorates the edema phenotype. This indicates that Rac1 plays a role in protecting podocytes against injury due to DNA damage. Consistently, administration of Rac1 inhibitor NSC23766 also aggravates podocytes injury in our model system. On the other hand, treatment with mineralocorticoid receptor inhibitor eplerenone does not affect the severity of MTZ-induced podocytes injury.

Conclusions: Taken together, our results unveil a distinct role of Rac1 in regulating podocytes apoptosis and suggest that modulating Rac1 pathway may be beneficial to podocytes under certain adverse or disease conditions.

Dynamin1 Regulates Actin Cytoskeleton in Podocytes in a Phosphorylation Dependent Manner Changkyu Gu,[1] Mario Schiffer,[2] Sanja Sever.[1] [1]*Nephrology, Massachusetts General Hospital, Charlestown, MA;* [2]*Nephrology, Hannover Medical School, Hannover, Germany.*

Background: Dynamin is an essential actin regulatory protein in podocytes, and loss of its function is closely connected to podocytes damage and proteinuria. Recently, our data has shown that dynamin directly regulates actin cytoskeleton via its oligomerization state. Therefore, it is important to maintain balance between dynamin assembly and disassembly. This dynamin oligomerization can be regulated through interaction with diverse cellular proteins, and it is reported that dynamin1 can differentially alter the affinity for its protein binding partners via phosphorylation by two different serine/threonine kinases, GSK3b and CDK5, in neurons. Based on these data, we hypothesize that phosphorylation-dependent dynamin1 oligomerization is an important molecular mechanism that regulates actin dynamics in podocytes.

Methods: Dynamin1 phosphorylation in podocytes was detected by western blot using phospho- dynamin1 antibodies in the presence of GSK3b or CDK5 inhibitor. Actin and paxillin in podocytes were stained to observe actin structures and focal adhesions. Cell migration and spreading assays were performed with podocytes expressing phosphor-dynamin1 mutants. For zebrafish proteinuria experiments, each phosphor-dynamin1 mutant was expressed in dynamin2^{KD} zebrafish.

Results: 1. Dynamin1 is phosphorylated by GSK3b and CDK5 in podocytes. 2. Expression of phosphor-dynamin1 mutants affects cell migration. 3. Expression of phosphor-dynamin1 mutants alters cortical actin cytoskeleton during cell spreading. 4. Expression of phosphor-dynamin1 mutants fails to rescue proteinuria in dynamin2^{KD} zebrafish.

Conclusions: The role of dynamin in actin cytoskeleton is essential to maintain the filtration barrier function of podocytes. Dynamin directly regulates actin structures via its oligomerization state. Our data suggest that dynamin1 phosphorylation is implicated in cortical actin dynamics of motile cells, possibly through regulating its oligomerization state via altering the affinity for its protein binding partners.

IQGAP1, a Downstream Effectors of Nephrin, Contributes to Actin Cytoskeleton Organization of Podocytes Yipeng Liu,[1] Wei Liang,[1] Yingjie Yang,[1] Qian Yang,[1] Xinghua Chen,[1] Huiming Wang,[1] Pravin C. Singhal,[2] Guohua Ding.[1] [1]*Div of Nephrology, Renmin Hospital of Wuhan Univ, Wuhan, Hubei, China;* [2]*Renal Molecular Research Laboratory, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: IQ domain GTPase-activating protein1 (IQGAP1) is a scaffolding protein involved in cytoskeleton regulation. Nephrin behaves as a cytoskeleton regulatory hub at slit diaphragm (SD) of podocytes. We hypothesized that IQGAP1 may be a downstream effectors of nephrin and contribute to actin cytoskeleton organization of podocytes.

Methods: Foot process (FP) fusion was observed by transmission electron microscope in puromycin aminonucleoside (PAN) –induced rats. Cytoskeletal reorganization was assessed in human podocytes. Cell migration and spreading assays were used to evaluate podocyte function. IQGAP1 plasmid and siRNA were introduced to investigate the role of IQGAP1 in actin cytoskeleton reorganization. Cytochalasin D-pretreated COS7 cells were used to evaluate the role of IQGAP1 phosphorylation in nephrin-related cytoskeletal regulation. The binding domain of IQGAP1 wtih nephrin was identified.

Results: The IQGAP1 expression and IQGAP1-nephrin colocalization in glomeruli were progressively suppressed and gradually recovered in line with the development of FP fusion and proteinuria in PAN-injected rats. In cultured human podocytes, PAN-induced disruption of F-actin and disorders of migration and spreading were aggravated by IQGAP1 siRNA, which was partially restored by IQGAP1 plasmid. Furthermore, the disorganized cytoskeleton treated by cytochalasin D in COS7 cells was recovered by cotransfection with IQGAP1 and nephrin plasmid, but not by single transfection of IQGAP1 nor by cotransfection of mutant IQGAP1[D1443 (S→A)] and nephrin. Co-immunoprecipitation assay in COS7 cells transfected with plasmids of truncated IQGAP1 and full length of nephrin demonstrated that the poly-proline binding domain (WW) and RasGAP domain in the carboxyl terminus (RGCT) of IQGAP1 were the target modules that interacted with nephrin.

Conclusions: Activated IQGAP1 is a downstream effectors of nephrin and contributes to actin cytoskeleton organization and functional regulation of podocytes.

FR-PO461

Podocyte-Specific Hyper-Activation of Rac1 Induces Glomerulosclerosis and Nephrotic Syndrome Richard Robins, Cindy Baldwin, Lamine Aoudjit, Indra R. Gupta, Tomoko Takano. *Nephrology, McGill Univ, Montreal, QC, Canada.*

Background: Rac1 is a member of the Rho-family of small GTPases that play critical roles in the regulation of actin cytoskeletal dynamics and cell motility of podocytes. Yu *et al*. have recently reported that podocyte specific activation of Rac1 results in transient proteinuria that rapidly recovers (Mol Cell Biol 2013). We hypothesize that podocyte-specific activation of Rac1 will result in sustained podocyte injury, foot process effacement and nephrotic syndrome in mice.

Methods: Transgenic mice carrying the tetracycline-inducible constitutively active mutant of Rac1 (L61, CA-Rac1, Flag-tagged) were bred with mice with the podocin-driven reverse tetracycline trans-activator to generate double transgenic mice (DTG). Mice aged 8-12 weeks were treated with doxycycline (Dox). Proteinuria was assessed by the albumin/creatinine ratio. Kidneys were evaluated histologically using light and immunofluorescence microscopy. Glomerular lysates were used for immunoblotting.

Results: After 5 days of Dox treatment, 8/12 DTG mice demonstrated heavy proteinuria which persisted for the duration of treatment (1 month), while 0/24 control mice developed proteinuria. In DTG treated with Dox for 1 month, FLAG staining was confirmed in podocytes by co-staining with WT1. 2/3 DTG mice displayed severe sclerosis, while 1 was mostly normal. Quantification of glomerulosclerosis with scores (normal=1 and global sclerosis=4) showed a significant increase of glomerulosclerosis in DTG mice (1.04 ± 0.02 for control versus 1.78 ± 0.3 for DTG; 45 glomeruli from 3 mice each, $p<0.05$). Podocyte number counted by WT1+ nuclei was significantly decreased in DTG (10.2 ± 0.21 for control versus 6.7 ± 0.4 for DTG; 30 glomeruli from 3 mice each, $p<0.001$). DTG mice showed synaptopodin and nephrin loss by immunofluorescence staining and immunobloting. In contrast, the podocyte injury marker, phospho-p38 was increased in glomerular lysates of DTG mice.

Conclusions: Podocyte-specific hyper-activation of Rac1 caused rapid and persistent proteinuria resulting in podocyte loss and glomerulosclerosis. Hyper-activation of Rac1 may contribute to the pathogenesis of primary or secondary nephrotic syndrome.

Loss of *Robo2* in Podocytes Alleviates Abnormal Kidney Phenotype in *Ilk* Knockout Mice Hila Milo Rasouly, Sudhir Kumar, Xueping Fan, Anna Pisarek-Horowitz, Stefanie Chan, Weining Lu. *Renal Section, Boston Univ Medical Center, Boston, MA.*

Background: ROBO2 is a transmembrane protein that plays an important role in kidney development. Recently we have shown that ROBO2 interacts with nephrin via adaptor protein NCK and loss of *Robo2* alleviates the abnormal podocyte phenotype in nephrin knockout mice. Integrin-linked kinase (ILK) is another important podocyte protein that interacts with NCK and nephrin. Podocyte-specific deletion of *Ilk* in mice results in proteinuria, renal failure and premature death. Therefore, we hypothesize that ROBO2 can also interact with ILK in podocytes via NCK and that loss of *Robo2* in podocytes would alleviate the abnormal kidney phenotype in *Ilk* knockout mice.

Methods: Protein complex formation was tested with yeast two-hybrid and co-immunoprecipitation assays. $Robo2^{flox/+};Ilk^{flox/+};Nphs2Cre^{+}$ podocyte-specific heterozygous knockout mice were crossed to generate $Ilk^{flox/flox};Nphs2Cre^{+}$ single and $Robo2^{flox/flox};Ilk^{flox/flox};Nphs2Cre^{+}$ double homozygotes which were followed up to one year. Urine protein levels were analyzed by Coomassie blue staining. Kidney histology was analyzed by H&E staining. Podocyte ultrastructure was analyzed by electron microscopy.

Results: Although there is no direct interaction between ROBO2 and ILK by yeast two-hybrid assay, co-immunoprecipitation analysis shows that ROBO2 and ILK form a protein complex through NCK and PINCH. At 6 weeks old, fewer *Robo2-Ilk* double homozygous mice developed proteinuria than did the *Ilk* single homozygous mice. Survival analysis of 86 mice up to one year also revealed that *Robo2-Ilk* double homozygous mice survived longer than *Ilk* single homozygous mice. Although no significant differences were observed at the histological level between the groups, electron microscopy showed that there was an improvement in podocyte ultrastructure of the *Robo2-Ilk* double homozygous mice in comparison to the *Ilk* single homozygous mice at 4 weeks of age.

Conclusions: ROBO2 and ILK form a protein complex through NCK and PINCH. Loss of *Robo2* reduces the prevalence of proteinuria and improves the survival of *Ilk* podocyte-specific knockout mice.

FR-PO463

Induced Cathepsin L Activity due to Mitochondrial Dysfunction in CD2AP-Deficient Podocytes Julia van Tuijl, Hatem A. Elshabrawy, Mehmet M. Altintas, Jochen Reiser. *Internal Medicine, Rush Univ Medical Center, Chicago, IL.*

Background: The podocytes in the kidney glomeruli play a key role in the kidney's filtration function. Their foot processes (FP) and interposed slit diaphragm form the final barrier to protein loss. The induction of cytosolic variant of the cysteine protease cathepsin L (cCatL) causes FP effacement by cleaving GTPase dynamin, synaptopodin and CD2AP. We have previously shown that acidification of cytosol during podocyte injury increases cCatL activity and glomerular disease-causing stimuli/conditions were associated with a downshift of the podocyte pH.

Methods: Conditionally immortalized podocytes were derived from wild type and CD2AP-/- mice and cultured at 33°C with interferon-g. To induce differentiation, podocytes were maintained at 37 °C for 14 days. Intracellular pH and cCatL activity were measured by using a fluorescent probe and a fluorescent substrate, respectively. Lactic acid, NADH and ATP were measured by using commercially available assay kits. Mitochondrial membrane potential was measured by FACS analysis. Mitochondrial shapes and sizes within fixed cells were analyzed by confocal microscopy.

Results: CD2AP KO podocytes had lower mitochondrial membrane potential when compared to WT podocytes. When mitochondrial function is impaired, ATP generation shifts from oxidative phosphorylation (OXPHOS) to glycolysis and generally a higher lactic acid production. We recently showed increased lactate production rates in several podocyte disease models. We also found that Complex IV, which plays a key role in the OXPHOS, was downregulated in CD2AP KO podocytes. Notably, inhibition of ATP synthase, another OXPHOS related protein, by Oligomycin increased the amounts of lactic acid in WT podocytes. We measured pHi for WT and CD2AP KO podocytes as 7.34±0.04 and 7.06±0.03, respectively. The enzyme activity versus pHi curves for both cell types indicated that the acidification of cytosol in CD2AP KO cells induced cCatL activity, which leads to podocyte damage.

Conclusions: Using an integrated approach, we have shown that the glycolytic metabolism and OXPHOS can be combined to generate a cellular profile, which explains the induced cCatL activity in diseased podocytes.

FR-PO464

Involvement of Mitochondrial Hyperactivity in Puromycin-Induced Podocytes Injury Masayo Hino,[1] Shunya Uchida,[2] Ikuroh Ohsawa.[3] *[1]Ibaraki Prefectural Central Hospital, Ibaraki, Japan; [2]Teikyo Univ School of Medicine, Tokyo, Japan; [3]Tokyo Metropolitan Inst of Gerontology, Tokyo, Japan.*

Background: Puromycin aminonucleoside (PAN)-induced nephrosis is a model of human minimal change disease. We have previously reported that PAN induces apoptosis by increasing oxidative stress in murine podocyte cell line (MPC). Increased expression of B7-1 (CD80) by PAN was suppressed by mitochondrial respiratory inhibitors, but not by NADPH oxidase inhibitor, suggesting that mitochondrial oxidative stress play pivotal role in podoyte injury. In the present study, to explore mitochondrial involvement in podocyte injury and apoptosis, we examined gene expression level of respiratory complex IV and mitochondrial membrane potential in PAN-treated MPC.

Methods: 24 hours after the addition of PAN to MPC, transcription level of complex IV subunit II (cytochrome c oxidase subunit 2; CcO-II) in total RNA was examined by quantitative PCR (qPCR). To examine mitochondrial membrane potential, PAN-treated MPC was stained with MitoTracker Red (MTR).

Results: Analysis of qPCR showed that transcription of CcO-II was markedly up-regulated by PAN, which was suppressed by the addition of mitochondrial respiratory inhibitors, rotenone and antimycin A. Fluorescent intensities of MTR were also increased by PAN, indicating that PAN could activate mitochondrial membrane potential. After the addition of PAN, we observed that localization of mitochondria was changed from uniform distribution in the cytoplasm to periphery of the nucleus, and then apoptotic nuclear cleavage was induced.

Conclusions: These results showed that PAN increased mitochondrial activity transiently, which might facilitate the production of ATP and reactive oxidative species, probably leading to podocyte apoptosis. We propose here that mitochondrial hyperactivity plays a pivotal role in PAN-induced podocyte injury.

FR-PO465

Nephrin Tyrosine Phosphorylation Is Required for Maintenance of Podocyte Foot Process Architecture and Response to Injury Nina Jones. *Molecular and Cellular Biology, Univ of Guelph, Guelph, ON, Canada.*

Background: Nephrin is a transmembrane component of the kidney slit diaphragm that plays a central role in organizing the unique morphology of actin-rich podocyte foot processes. The intracellular domain of nephrin contains several tyrosine residues that undergo phosphorylation, thereby initiating signaling events linking the slit diaphragm to the podocyte actin cytoskeleton. Human renal diseases characterized by podocyte foot process effacement and decreased filtration barrier function are associated with loss of this phosphorylation; however, it has not been clear whether phospho-nephrin signaling plays a causative or compensatory role in disease.

Methods: To explore the function of nephrin phosphorylation in vivo, we generated and analyzed knock-in mice bearing tyrosine to phenylalanine mutations at three key adaptor protein binding sites that disrupt overall nephrin tyrosine phosphorylation.

Results: Surprisingly, absence of nephrin phosphorylation does not affect the initial formation of podocyte foot processes; however, as the mice age, they develop proteinuria accompanied by structural changes in the filtration barrier, including dilated capillary loops, irregular thickening of the glomerular basement membrane and podocyte foot process effacement, all of which are influenced by genetic background. Furthermore, loss of nephrin phosphorylation enhanced the susceptibility to, and recovery from, experimental podocyte injury.

Conclusions: Our findings indicate that nephrin tyrosine phosphorylation is dispensable during development, but required for podocyte maintenance and response to stress. This is indicative of a model in which dynamic changes in phosphotyrosine-based signaling confer plasticity to the podocyte actin cytoskeleton.

FR-PO466

Integrin Dependent Nephrin Tyrosine Phosphorylation Rakesh Verma, Madhusudan Venkatareddy, Puneet Garg. *Div of Nephrology, Univ of Michigan, Ann Arbor, MI.*

Background: Events that result in Nephrin tyrosine phosphorylation have been an important gap in the field of Nephrin biology. Studies have shown that nephrin is tyrosine phosphorylated during development and following injury. Investigators have employed artificial means to phosphorylate Nephrin due to a lack of a physiological Nephrin ligand. A popular strategy involves "clustering" of transfected chimeric-Nephrin using an antibody that results in phophorylation of Nephrin cytoplamic domain. it is unlikely that this occurs *in vivo*. In fact, both *in vitro* and *in vivo* studies suggest that Nephrin phosphorylation is abrogated when ligated. Here we present data that suggests Nephrin tyrosine phosphorylation occurs following integrin activation at the basolateral aspect of the podocyte foot process. This effect is mediated via src kinase activation by integrins.

Methods: We used biochemical and cell biology techniques to demonstrate integrin dependent nephrin phosphorylation.

Results: Podocytes were plated on laminin-coated plates following suspension in serum free media. Cells were lysed at various time points and blotted for p-Nephrin and p-FAK. We observed an increase in Nephrin phosphorylation at the Y1193 and Y1217 residues within 15 minutes of plating. This observation was specific for laminin and not observed with collagen1 or plastic itself. To avoid bias from potential ligation of the N-ECD, we transfected Nephrin containing an amino terminal myristoylated sequence (membrane targeting) but lacking N-ECD. Following plating of transfected cells on laminin, Nephrin phosphorylation was observed even in the absence of N-ECD. In addition, use of a3b1 integrin- blocking antibody abrogated Nephrin phosphorylation confirming the specificity of this interaction.

Conclusions: To our knowledge, this is the first report explaining the mechanism involved in nephrin tyrosine phosphorylation that concurs with the observations made *in vivo*. Nephrin phosphorylation-dependent actin dynamics are important for foot process structural changes. Understanding mechanisms that result in nephrin phosphorylation are important to potentially abrogate or limit foot process spreading observed in various proteinuric kidney diseases.

Podocyte-Specific p53 Deletion Promotes Alport Syndrome Progression by Enhancement of Podocyte Proliferation and Migration Ryosuke Fukuda, Yukari Kai, Kohei Omachi, Mary Ann Suico, Tsuyoshi Shuto, Hirofumi Kai. *Molecular Medicine, Kumamoto Univ, Kumamoto, Japan.*

Background: p53 is thought to be as an apoptosis inducer of renal cells such as podocyte in diabetic nephropathy (DN) and several acute kidney injury (AKI) models. However the role of p53 in the development of renal disease that is caused by podocyte hyperplastic phenotype has not been investigated. Alport syndrome (AS) is a hereditary, progressive chronic kidney disease that is caused by mutation of *Col4a3,4,5* genes. AS is characterized with podocyte abnormal growth-induced glomerular crescent formation. Here we studied the role of p53 in podocyte hypercellularity using AS mouse model.

Methods: Podocyte-specific p53 deletion AS mouse (pod-p53+/+ or -/- AS) was established by crossing Podocin-CRE, p53-loxP and *Col4a5* G5X mutant mice. Renal function (U-Albumin, Proteinuria, BUN score) and histology (glomerular injury, fibrosis, PCNA staining, SEM, TEM) were compared between pod-p53+/+ AS and pod-p53-/- AS. Additionally, p53 fuction in podocyte differentiation, proliferation and migration was analysed by using primary podocyte and mouse podocyte cell line.

Results: Interestingly, pod-p53-/- AS mice showed aggravation of renal dysfunction compared to pod-p53+/+ AS mice. PCNA positive cells in glomerular region were significantly increased and foot process effacement were enhanced in pod-p53-/- AS. Furthermore, podocyte-speific p53 deletion in AS mouse induced numerous filopodia formation in podocytes. Consistent with *in vivo* data, we found that p53 regulates podocyte dedifferentiation, spreading from glomerular and migrative phenotype *in vitro*.

Conclusions: Present study showed that p53 functions as suppressor of podocyte abnormal growth and migration and loss of p53 expression in podocyte exacerbates AS mouse pathology. These results suggest that p53 is not just a malignant factor of renal dysfunction as in DN or several AKI but has the potential to maintain normal podocyte function and controls the development of podocyte hypercellularity disease such as AS.

FR-PO468

Blood Outgrowth Endothelial Cells as a Model to Study Atypical Hemolytic Uremic Syndrome Damien Gerard Noone,[1,2] Magdalena Riedl,[1,2] Lily Lu,[2] Yi (Emma) Quan,[3] Fred G. Pluthero,[2] Walter H. Kahr,[2,4,5] Christoph Licht.[1,2,5] *[1]Div of Nephrology, Hospital for Sick Children, Toronto, Canada; [2]Cell Biology Program, Hospital for Sick Children, Toronto, Canada; [3]Univ of Toronto, Toronto, ON, Canada; [4]Div of Haematology, Hospital for Sick Children, Toronto, Canada; [5]Dept of Paediatrics, Hospital for Sick Children, Toronto, Canada.*

Background: Atypical hemolytic uremic syndrome (aHUS) is due to defective regulation of the alternative complement pathway (CAP) which is constitutively active requiring a multi-layered defense system. It is unclear how this defense system functions as a whole to protect endothelial cells (EC) or why diminished function of one of these regulators can lead to aHUS. Mutations in membrane cofactor protein/CD46, a membrane-anchored CAP regulator leads to aHUS but with variable penetrance. We aimed to use blood outgrowth endothelial cells (BOEC), EC precursors that can be isolated from patients' blood, to study aHUS.

Methods: BOECs were cultured from subjects by a standard protocol. EC phenotype and presence of complement regulators was confirmed by immunofluorescence (IF), western blot, qPCR and flow cytometry. Cells were challenged with complement, with/without functional blockade of complement regulators. Adhesion of calcein-labelled platelets perfused across confluent BOEC in a microfluidic system was quantified by IF.

Results: BOECs were characterized by FACS (CD31/PECAM-1 and CD144/VE-cadherin positive; haemangioblast marker CD45 and immature endothelial progenitor cell marker CD14 negative). Surface expression of complement regulators was confirmed. A surrogate phenotype of aHUS modelled ex vivo (endothelial cell death and platelet adhesion) is not achieved with CD46 blockade alone. Complement deposition (C3) is enhanced by blocking complement regulators sequentially (four-fold increase when CD46, CD55 and CD59 are blocked;$p<0.001$) and results in cell death, apoptosis and an EC prothrombotic phenotype with platelet adhesion.

Conclusions: We have established an ex vivo method to model aHUS pathogenesis that can now be expanded to use patient-derived BOEC. Our data supports the hypothesis that an additional factor is required in order for a patient with a CD46 mutation to manifest disease.

FR-PO469

The Association of von Willebrand Factor and the Alternative Complement Pathway in Atypical Hemolytic Uremic Syndrome-Complement Amplifying or Protective? Damien Gerard Noone,[1,2] Magdalena Riedl,[2] Fred G. Pluthero,[2] Walter H. Kahr,[2,3,4] Mackenzie L. Bowman,[5] Paula James,[5] Christoph Licht.[1,2,4] *[1]Div of Nephrology, Hospital for Sick Children, Toronto, Canada; [2]Cell Biology Program, The Hospital for Sick Children, Toronto, Canada; [3]Div of Paediatric Haematology, Hospital for Sick Children, Toronto, Canada; [4]Dept of Paediatrics, Hospital for Sick Children, Toronto, Canada; [5]Clinical and Molecular Hemostasis Research Group, Queen's Univ, Kingston, Canada.*

Background: Atypical hemolytic uremic syndrome (aHUS) is due to defective regulation of the alternative complement pathway (CAP) and is associated with glomerular endothelial cell (EC) injury and platelet microthrombi. EC activated by complement release von Willebrand Factor (VWF). Recent evidence links CAP with VWF, and it has been suggested that this may amplify EC complement injury. We aimed to use blood outgrowth endothelial cells (BOEC), EC precursors that can be isolated from patients' blood, to further study this.

Methods: BOEC were cultured by standard protocol from healthy controls and patients with type 3 von Willebrand disease (VWD3 BOEC), which have no VWF secretion. EC phenotype was confirmed by immunofluorescence (IF), western blot (WB), qPCR and flow cytometry and was not different between cell lines. Cells were challenged with complement using 50% human serum, with/without functional blockade of complement regulators. EC apoptosis was quantified by IF staining for cleaved caspase 3.

Results: BOEC were characterized by FACS (CD31/PECAM-1 and CD144/VE-cadherin positive; haemangioblast marker CD45 and immature endothelial progenitor cell marker CD14 negative). VWF secretion from complement activated BOEC and a lack thereof in VWD3 BOEC was confirmed. Complement products including C5b-9 were found to associate with VWF multimers released from normal BOEC by IF and spinning disk confocal microscopy. Complement (C3) deposition however, is greater on VWD3 BOEC following complement challenge and results in an increase in cell death by apoptosis.

Conclusions: We have confirmed an association of VWF and CAP activation products, however, the finding of increased complement activation on BOEC devoid of VWF, argues for a protective effect of this association.

FR-PO470

Annexin A2 Protects the Aging Podocyte Biao Li,[1] Tuncer Onay,[2] Jessica Anne Quaggin-Smith,[1] Vera Eremina,[1] Chengjin Li,[1] Susan E. Quaggin.[1,2] *[1]Lunenfeld Tenenbaum Research Inst, Toronto, ON, Canada; [2]Nephrology, Feinberg Cardiovascular Research Inst, Chicago, IL.*

Background: Anxa2 (Annexin A2) is a calcium dependent phospholipid binding protein and one of 12 members of the Annexin family that is expressed extensively in a variety of tissues. Previously, we identified high expression of Anxa2 in lipid rafts of human podocytes and found that knockdown of Anxa2 results in dramatic changes in morphology and adhesion of podocytes in vitro. These data led us to hypothesize that Anxa2 plays a significant role in formation and maintenance of the actin cytoskeleton and foot processes in podocytes.

Methods: A floxed Anxa2 (Exon 4) mouse was generated and used to develop whole body and podocyte specific KO mice. Kidney function was evaluated by protein/creatinine ratio (P-C ratio) and histology. Northern blot was used to determine the expression of Anxa2 and other Annexin family members in glomeruli.

Results: While diffuse fibrin deposition was observed in and around glomerular capillaries of Anxa2 KO kidneys, histological analysis showed no other major differences between KO and control mice; P-C ratios were not different at 6 months of age. However, aged podocyte-specific Anxa2 KO mice (1.5 years of age) develop variable degrees of proteinuria, ranging from mild to severe (P-C ratio, 0.66-48.23ug/g). Histologic analysis of kidneys from KO mice demonstrated a spectrum of glomerular injury from focal changes to endstage sclerosis. qPCR analysis from isolated glomeruli showed increased expression of various Annexin family members at two months of age in KO mice. Northern blot analysis showed presence of new Anxa2 bands in KO mice, consistent with expression of alternative splice variants.

Conclusions: Deletion of Anxa2 from podocytes results in extensive glomerular fibrin deposition and mild changes in the podocyte cytoskeleton that appear to be well compensated by other Annexin family members in young mice. However, Anxa2 deficiency can lead to pronounced alteration of the podocyte cytoskeleton and severe proteinuria upon aging.

Micro-RNA-378 Is Upregulated in Proteinuric Kidney Diseases and Regulates Podocytic Nephronectin Expression Janina Müller-Deile,[1,3] Jan Dannenberg,[1] Jenny C. Nystrom,[2] Peidi Liu,[2] Johan M. Lorenzen,[1,4] Thomas Thum,[4] Hermann G. Haller,[1,3] Mario Schiffer.[1,3] *[1]Dept of Medicine/Nephrology, Hannover Medical School, Hannover, Germany; [2]Sahlgrenska Academy, Univ of Gothenburg, Gothenburg, Sweden; [3]Mount Desert Island Biological Laboratory, Salisbury Cove, ME; [4]Inst of Molecular and Translational Therapeutic Strategies, Hannover Medical School, Hannover, Germany.*

Background: Even though different genes and soluble factors have been previously described to cause primary glomerular disease, their clinical relevance remains elusive. Micro-RNAs (miRNAs) play an important role in gene regulation and therefore seem to be promising candidates involved in glomerular disease.

Methods: Baseline and stress-induced miRNA profiles of different human glomerular cells as well as miRNA profiles of urines from patients with different glomerular disease were used to screen for specific overlap of miRNAs. Regulation of miRNA target genes was investigated in cultured podocytes in after stimulation with TGF-beta, glucose, miRNA-mimics and -antagomirs. MiRNA-mimics and morpholinos for miRNA target genes were injected in zebrafish embryos and the resulting phenotypes and degree of proteinuria was analysed.

Results: We identified miRNA-378 specifically up-regulated in stressed human podocytes and in urines from patients with different primary glomerular disease. NPNT has been previously described as integrin interaction partner and is a confirmed target gene of miRNA-378. We detected NPNT expression in podocytes and confirmed a partial overlap with the actin cytoskeleton. NPNT expression was suppressed by miRNA-378 as well as by high glucose and TGF-beta in cultured human podocytes. Knockdown of NPNT by injection of a miRNA-378-mimic or a morpholino for NPNT in a developing zebrafish embryo resulted in a renal phenotype with edema and proteinuria.

Conclusions: Podocytic NPNT seems to play an important role for the maintenance of the in the glomerular filtration barrier. MiRNA-378 controlled NPNT expression seems to be a novel pathophysiological regulator of podocyte and basement membrane interactions. Furthermore, urinary miRNA-378 could be a novel non-invasive marker for active glomerular diseases in patients.

Tight Control of Calcium-Calcineurin Signaling by miR-30 in Podocytes Junnan Wu, Chun-Xia Zheng, Xiao Wang, Lin Liu, Yu-Ting Ye, Jing He, Changming Zhang, Wanfen Zhang, Yuqiu Lu, Hong Xia, Wei-Song Qin, Shaolin Shi, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing Univ School of Medicine, Nanjing, China.*

Background: Calcium-calcineurin signaling activation induces podocyte injury, but the mechanism underlying its regulation is largely unknown. Many components of the signaling are predicted to be miR-30 targets and they are upregulated in injured podocytes in which miR-30s are downregulated, we therefore hypothesize that miR-30s control calcium-calcineurin signaling by inhibiting the expression of its multiple components and miR-30 downregulation leads to the activation of the signaling.

Methods: Studies were performed with human podocyte cell line, podocyte-selective miR-30s sponge transgenic mice, puromycin aminonucleoside (PAN)-treated rats, miR-30a gene transferring *in vivo*, and FSGS patients' renal biopsies.

Results: We found that calcium-calcineurin signaling components, TRPC6, PPP3ca, PPP3cb, PPP3r1, and NFATc3, have abundant mRNA but not protein in normal podocytes, and that their protein but not mRNA levels are greatly elevated in the podocytes of FSGS patients. We confirmed by luciferase reporter assays that these genes are miR-30 targets and showed that. miR-30 overexpression reduced their expressions, as well as calcium influx, calcineurin activity and NFAT3c nuclear translocation in PAN-treated podocytes. *In vivo*, podocyte-selective miR-30s sponge transgenic mice displayed increased expressions of the five genes in the podocytes and the mice developed significantly higher levels of proteinuria than control mice when treated with PAN. The expressions of the five genes were also upregulated in the podocytes of PAN-treated rats, in which miR-30s were downregulated. As expected, the upregulation of these genes in the podocytes of PAN-treated rats was prevented by miR-30a gene transferring to the podocytes, accompanied by alleviation of proteinuria and podocyte injury.

Conclusions: miR-30s tightly control calcium-calcineurin signaling by inhibiting the expression of multiple components of the signaling, and miR-30 downregulation results in their upregulation and thus the signaling activation.

Optimization of TRPC5 Inhibitors for Podocyte Protective Therapy Sookyung Kim, Philip M. Castonguay, Dequan Tian, Frank Dubois, Anna Greka. *Glom-NExT, Center for Glomerular Kidney Disease and Novel Experimental Therapeutics, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

Background: Podocytes are highly specialized cells in the kidney glomerulus, whose injury and loss leads to proteinuria and progressive kidney disease. We recently showed that inhibition of Transient Receptor Potential Canonical 5 (TRPC5) channels by ML204 prevents podocyte cytoskeletal collapse, and protects mice from filter barrier damage. Here, we tested two inhibitors of TRPC5 based on the ML204 chemical backbone, to test the hypothesis that these inhibitors may better protect the podocyte actin cytoskeleton compared to ML204.

Methods: We used patch clamp electrophysiology in HEK293 cells overexpressing TRPC5 or TRPC6 to test the potency of the two inhibitors compared to ML204. For cell culture experiments, podocytes were pretreated with inhibitor 20 minutes prior to exposure to Protamine Sulfate (PS). Phalloidin staining was performed for actin stress fiber quantification. The abundance of synaptopodin was also tested by Western Blot.

Results: We confirmed that the two compounds are specific TRPC5, and not TRPC6, inhibitors by patch clamp electrophysiology. Phalloidin staining and stress fiber quantification revealed one of the two inhibitors as superior to ML204 in protecting the podocyte actin cytoskeleton from PS-induced remodeling. The abundance of synaptopodin was also preserved in a dose-dependent manner after treatment with the inhibitor compared to control PS-treated cells.

Conclusions: Our studies have validated an optimized TRPC5 inhibitor *in vitro*. This work bolsters the notion that TRPC5 inhibition is a valuable podocyte protective strategy.

Profoundly Altered TRPC6 Channel Gating Properties in Acquired FSGS Stuart E. Dryer, Hila Roshanravan, Eunyoung Kim. *Biology and Biochemistry, Univ of Houston, Houston, TX.*

Background: Gain-of-function mutations in TRPC6 channels give rise to familial FSGS[1,2]. An increase in TRPC6 protein was detected in acquired FSGS[3]. However, ion channels are regulated primarily by gating. Here we have used electrophysiology to examine the functional properties of podocyte TRPC6 channels in a rat model of acquired FSGS.

Methods: FSGS was induced in Sprague-Dawley rats by chronic treatment with puromycin aminonucleoside (PAN). PAN or saline were injected three times at 30 day intervals. Glomeruli were isolated 10 days after the third injection. Whole-cell recordings from podocytes were used to measure TRPC6 responses to chemical stimuli (OAG and ATP) and mechanical stimuli (hypoosmotic stretch). Podocytes are attached to the glomerular capillary during these recordings. Podocyte proteins were detected by immunoblot and FSGS was ascertained by PAS staining.

Results: Chronic PAN treatment resulted in segmental glomerulosclerosis and protein casts in tubules. Podocytes from PAN-treated rats showed ~10 fold larger TRPC6 currents in response to mechanical stimuli compared to controls. However, currents evoked by bath application of 50 μM ATP (P2Y agonist) or 100 μM OAG (canonical activator of TRPC6) were almost completely eliminated after PAN treatment. Podocytes from saline-treated rats exhibited modest and approximately equal sized cationic currents in response to mechanical stretch, OAG, or ATP. Podocin expression was markedly reduced, and TRPC6 was increased, in glomeruli from PAN-treated rats compared to controls.

Conclusions: Increased sensitivity to mechanical stimuli in acquired FSGS may over time lead to Ca^{2+} overload and further loss of podocytes. The change in gating properties seen here are similar to those seen after podocin knockdown[4]. Loss of TRPC6 responses to chemical stimuli suggest that Ang II signaling to podocytes is attenuated in acquired FSGS, suggesting that protective effects of RAS inhibition are exerted on other cell types. 1. FR-PO475

A STAT3 Inhibitor Alters Morphology and Migration of Podocytes and Inhibits Expression of Synaptopodin Stuart E. Dryer, Mousa Abkhezr. *Biology and Biochemistry, Univ of Houston, Houston, TX.*

Background: Previous studies have suggested that the transcription factor signal transducer and activator of transcription-3 (STAT3) plays a complex role in the progression of HIV nephropathy, collapsing glomerulopathy, and crescentic glomerulonephritis[1,2] and in podocyte cell biology. The targets of STAT3 signaling are not well understood.

Methods: Immunoblot analysis of synaptopodin (Synpo) and STAT3 tyrosine phosphorylation, RT-PCR, confocal microscopy and migration assays in immortalized mouse podocytes.

Results: Application of 5 μM Stattic, a small molecule inhibitor of STAT3 activation, caused a drastic reduction in Synpo mRNA and protein in podocytes. This effect was complete within 30 minutes after the onset of Stattic treatment. Synpo protein levels declined at a similar rate after inhibition of protein synthesis using cyclohexamide. Effects of Stattic and cycloheximide were blocked by the cathepsin-L inhibitor E-64. These observations indicate that Synpo has a very high turnover rate due to ongoing proteolytic degradation (see also ref. 3). Stattic had no effect on the time course of Synpo disappearance after inhibition of protein synthesis or cathepsin-L. This suggests that Stattic, and by implication STAT3, act primarily on Synpo biosynthesis. We also observed that treating podocytes with agents that stimulate STAT3 tyrosine phosphorylation in pododcytes, i.e. Ang II and IL-6[4], caused corresponding increases in Synpo protein. Stattic application for 24 hr caused marked changes in podocyte morphology and also caused complete inhibition of their migration as assessed by wound assays.

Conclusions: Synpo protein has high turnover rate in podocytes owing to ongoing protelolytic degradation. Synpo biosynthesis is regulated in part by signaling to STAT3, and STAT3 may therefore play a role in regulating podocyte cytoskeleton and motility. It is possible that STAT3 effects on cytoskeleton are in some way related to cell cycle control. 1. Feng et al. (2009) J Am Soc Nephrol 20 (10):2138-46. 2. Dai et al. Isolation and Characterization of Podocyte-Derived Microparticles in *In Vitro* Nephrotic Syndrome Environment Hoon Young Choi, Sung Chang Bae, Sung-Kyu Ha, Hyeong Cheon Park. *Dept of Internal Medicine, Gangnam Severance Hospital, Yonsei Univ School of Medicine, Seoul, Korea.*

Background: Microparticles (MPs) shed from cell membrane in various stimuli such as oxidative stress or hypoxia. The biological characteristics of MPs are dependent on activation stimuli or the microenvironment in which MPs are produced. Effacement of podocyte foot processes is the main pathologic features of nephrotic syndrome and FSGS. These changes could be induced by protamine sulfate experimentally. We investigated this study to perform the isolation and characteristics of podocyte-derived MPs in *in vitro* nephrotic syndrome environment.

Methods: Podocytes were cultured in serum deprived RPMI without or with protamine sulfate (300ug/mL) for 2~4 hours to mimic nephrotic syndrome condition. MPs were isolated from supernatants by differential ultrafiltration. The presence of MP was confirmed by flow cytometric analysis.

Results: Podocyte-derived MPs were mainly detected at a region below the forward scatter signal corresponding to 1μm beads, which were used as internal size standards in FACS analysis. Podocyte-derived MPs expressed nephrin, podocin, podocalyxin, which were also expressed on podocyte plasma membranes. FACS analysis showed that the expressions of podocyte specific markers and annexin V were more in MPs from podocyte treated with protamine sulfate (control versus protamine sulfate treatment: nephrin 8.6 ± 0.9 % versus 52.1 ± 7.8%, podocalyxin 15.6 ± 2.0 % versus 47.7 ± 8.9 %, podocin 9.2 ± 1.6 % versus 37.5 ± 11.7 %, $P < 0.05$).

Conclusions: This study showed that protamine sulfate mimicking *in vitro* nephrotic syndrome environment promotes more release of podocyte-derived microparticles expressing podocalyxin, podocin, and nephrin together with annexin V.

FR-PO477

Synaptic-Like-Microvesicle Regulated by SV2B in Podocyte Plays a Role in Intracellular Trafficking of Slit Diaphragm Molecules and Exocytosis of GBM Components Yoshiyasu Fukusumi, Natsumi Takashima, Ayako Wakamatsu, Eriko Hasegawa, Hiroshi Kawachi. *Dept of Cell Biology, Inst of Nephrology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: We have previously reported synaptic vesicle protein 2B (SV2B) was expressed on synaptic-like-microvesicle (SLMV) in podocyte, and SV2B knockout (KO) mice showed proteinuria. However, the function of SLMV in podocyte and the role of SV2B in SLMV are still uncertain.

Methods: The morphology and the expressions of the podocyte molecules, GBM components and synaptic vesicle molecules were analyzed in SV2B KO mice. The interactions of SV2B with podocyte molecules were analyzed. The expressions of SV2B and other synaptic vesicle molecules were analyzed with an embryonic rat kidney.

Results: SV2B KO mice showed foot process effacement and GBM thickness. The stainings of CD2AP, nephrin and NEPH1 were clearly reduced in the SV2B KO mice (IF score, KO versus WT: CD2AP, 2.6 versus 3.3, $p<0.01$; nephrin, 3.1 versus 3.4, $p<0.05$; NEPH1, 3.0 versus 3.3, $p<0.05$). However, those of other slit diaphragm (SD) molecules, podocin and ZO-1, and apical surface molecules podocalyxin and NHERF2 were not altered. The staining of lamimin was clearly reduced (3.1 versus 3.4, $p<0.05$), although other GBM components were not altered. Although mRNA expressions of SV2A, SV2C and other vesicle surface molecules, Rab3a, Rab4, and vGlut1 were not altered in the kidney cortex of SV2B KO mice, those of Munc18, synaptotagminand neurexin were clearly reduced (Munc18, 62%; synaptotagmin, 52%; neurexin, 43%). The precipitation assay showed SV2B interacted with CD2AP and nephrin, and that CD2AP interacted with neurexin. SV2B was exclusively expressed in glomeruli in embryonic rat kidney section, whereas SV2A was diffusely expressed. SV2B was first detected along the whole cell surface of podocyte in the early S-shaped body stage glomeruli, and with maturation the staining became to be concentrated to baso-lateral area.

Conclusions: SLMV plays a role in podocyte maturation and in intracellular trafficking of the SD molecules and exocytosis of GBM components. SV2B regulated the docking of SLMV to baso-lateral surface of podocyte.

Role of MAP Kinase-Activated Protein Kinase 2 (MK2)-Mediated Renal Stress Response in Adriamycin-Induced Nephropathy Shipra Agrawal,[1] Xiaojing Nie,[1] Melinda A. Chanley,[1] William E. Smoyer,[1,3] Ruma Pengal,[1] Rainer Benndorf.[1] *[1]Clinical and Translational Research, The Research Inst at Nationwide Children's Hospital, Columbus, OH; [2]Pediatrics, The Ohio State Univ, Columbus, OH; [3]Inst of Biochemistry, Hannover Medical School, Hannover, Germany.*

Background: The p38 MAPK signaling pathway plays a crucial role in glomerulopathies, whereactivation is associated with disease and inhibition is associated with disease amelioration. We have previously reported the specific role of the p38 MAPK→MK2→HSPB1 pathway in both *in vitro* models of podocyte injury and in an *in vivo* model of acute glomerulonephritis. Based on this, we hypothesized that MK2 also plays an important role in a model of chronic glomerulopathy (Adriamycin nephropathy) via its action on its downstream substrate HSPB1.

Methods: MK2 heterozygous knock-out (KO) mice (C57BL/6 background) were backcrossed with sv129 for 7 generations to obtain MK2-KO mice in an Adriamycin (Adr)-susceptible strain. At 11 weeks of age, male wild-type (WT) and MK2-KO mice were injected with 18 mg/kg Adr (N=12 per group) or PBS (N=6 per group) by tail vein injections. Serum BUN and proteinuria were measured for 21 days, when mice were sacrificed. Renal cortices were analyzed for the expression of MK2, and the stress proteins HSPB8, GRP78, HSPB1 and phospho-HSPB1.

Results: Both WT and MK2-KO mice, developed massive albuminuria and high serum BUN values after Adr. Renal cortical MK2 protein expression was completely abrogated in MK2-KO mice. HSPB1 was highly induced by Adr treatment in both WT and MK2-KO mice. While HSPB1 was highly phosphorylated in WT Adr-treated mice, its activation was greatly reduced in Adr-treated MK2-KO mice. Furthermore, HSPB8 expression was higher in Adr-treated mice compared to control mice in WT mice, but not MK2-KO mice. GRP78 expression remained unaltered.

Conclusions: Induction of Adr-nephropathy resulted in massive proteinuria and a strong renal cortical stress response via activation and increased expression of HSPB1 in a MK2-mediated manner. These studies suggest a crucial role of MK2 in regulating the renal stress response in a chronic model of glomerulopathy.

FR-PO479

CLIC5A Signaling and Hypertension-Induced Glomerular Injury

Mahtab Tavasoli, Laiji Li, Lin-Fu Zhu, Benjamin Alexander Adam, Abass Almomany, Barbara J. Ballermann. *Medicine, Surgery & Pathology, Univ of Alberta, Edmonton, AB, Canada.*

Background: Hypertension (HTN) is a major risk factor for glomerular disease progression. Glomerular capillary HTN triggers stretch-activated signals that lead to podocyte remodeling. We have shown that the podocyte-predominant protein CLIC5A stimulates PI[4,5]P2 accumulation, causing ezrin phosphorylation and ezrin coupling to actin. Rac1, a Rho GTPase activated by podocyte stretch, also stimulates ezrin phosphorylation and actin remodeling. We tested the hypothesis that HTN–induced podocyte Rac1 activation is CLIC5A-dependent.

Methods: GFP-CLIC5A or GFP were transiently expressed in COS-7 cells. Uninephrectomized CLIC5 deficient ($CLIC5^{-/-}$) and wild-type ($CLIC5^{+/+}$) mice were treated with deoxycorticosterone and 1% saline drinking water (DOCA/Salt) for 20 days. COS-7 cell and glomerular lysates were evaluated for activated Rac1-GTP, and for the Rac1 effector phospho-PAK1 (P-PAK1) and phospho-Ezrin (P-ERM).

Results: In COS-7 cells, GFP-CLIC5A, but not GFP, activated Rac1 and phosphorylation of PAK and Ezrin. GFP-CLIC5A-dependent ezrin phosphorylation was blocked by the Rac1 inhibitor NSC23766. In glomerular lysates, P-PAK1 and P-ERM levels were much lower in $CLIC5^{-/-}$ compared to $CLIC5^{+/+}$ mice. DOCA/Salt strongly stimulated podocyte-associated PAK phosphorylation in $CLIC5^{+/+}$, but not in $CLIC5^{-/-}$ mice. While the degree of DOCA/Salt-induced systemic HTN was similar in $CLIC5^{-/-}$ and $CLIC5^{+/+}$ mice, albuminuria and morphological injury were greater in $CLIC5^{-/-}$ mice.

	$CLIC5^{+/+}$	$CLIC5^{-/-}$
Systolic BP (mm Hg; baseline vs. day 20)	98±8 vs. 119±6	97±8 vs. 121±11
Urine Albumin:Creatinine Ratio (mg/g)	780±235	1,720±960*
Microaneurysms (% Glomeruli Affected)	31±17	57±18*
Foot Processes (#/µm GBM)	2.55±0.10	1.91±0.09**
Endothelial Fenestrae (#/µm GBM)	2.63±0.35	1.25±0.20**

(Mean±SEM, n=5/group, *p<0.05; **p<0.01).

Conclusions: Thus, CLIC5A-dependent Rac1 activation and downstream PAK phosphorylation are components of the podocyte response to HTN, at least in the DOCA/Salt model. The findings imply that protection from HTN-induced glomerular injury requires CLIC5/Rac1/PAK/Ezrin-dependent podocyte remodeling.

FR-PO480

Chloride Intracellular Channel 5 (CLIC5) Is Critical for Podocyte Adhesion and Regulation of Podocalyxin Stability

Alan Zhou,[1] Moin Saleem,[2] Cynthia C. Tsui.[1] *[1]Dept of Internal Medicine-Nephrology, Univ of Michigan, Ann Arbor, MI; [2]Academic and Children's Renal Unit, Univ of Bristol, Bristol, United Kingdom.*

Background: Podocytes are a common target cell of injury in the pathogenesis of many glomerular diseases that are the leading cause of end-stage renal and chronic kidney diseases. The cost of end-stage renal disease in 2009 was $25 billion, making this a major burden on our health care system. Mechanisms that promote podocyte attachment and repair are critical for podocyte survival and for the prevention of progression of glomerular disease. Chloride intracellular channel 5 (CLIC5) is a novel membrane protein that is enriched in podocytes. CLIC5 protein is decreased in the glomerulus of Minimal Change Disease compared to living donor patients. CLIC5-deficient podocytes have decreased podocalyxin (PODXL) protein expression and abnormal podocyte foot process ultrastructure. PODXL is an apical membrane protein necessary for the morphogenesis and maintenance of podocyte cytoarchitecture. We have determined the extent to which CLIC5 is critical to maintain podocyte adhesion and we measured CLIC5-mediated control of PODXL stability.

Methods: We utilized *Clic5*$^{+/+}$ and *Clic5*$^{-/-}$ differentiated podocytes to determine to what extent CLIC5 controls podocyte adhesion and migration capacity. We quantified the extent of podocyte loss into urine using qRT-PCR of podocin between *Clic5*$^{-/-}$ and *Clic5*$^{+/+}$ mice. We performed pulse-chase live-cell imaging of photoconvertable, fluorescently tagged PODXL to measure the stability of PODXL in differentiated *Clic5*$^{+/+}$ and *Clic5*$^{-/-}$ podocytes *in vitro*.

Results: *CLic5*$^{+/+}$mice shed 6-fold less urine podocytes compared with *Clic5*$^{-/-}$ mice at 10-12 months of age (N=5 *Clic5*$^{+/+}$ mice; N=7, *Clic5*$^{-/-}$ mice. P<0.01). *Clic5*$^{-/-}$ podocytes have a 3-fold decrease in adhesion and migrated 3-fold less compared to $CLIC5^{+/+}$ podocytes on fibronectin and laminin coated surfaces (P<0.05 and P<0.001, respectively). PODXL is degraded 4-fold faster in the absence of CLIC5 in podocytes (N=5 cells for each genotype, P<0.001).

Conclusions: CLIC5 is critical for podocytes to maintain their adherence to the glomerular matrix and to control PODXL stability.

Protein O-GlcNAcylation Is Essential to Maintain Normal Podocyte Function

Shinya Ono,[1] Mako Yasuda,[1] Shinji Kume,[1] Jun Nakazawa,[1] Hisazumi Araki,[1] Masami Kanasaki,[1] Shin-Ichi Araki,[1] Daisuke Koya,[2] Masakazu Haneda,[3] Takashi Uzu,[1] Hiroshi Maegawa.[1] *[1]Medicine, Shiga Univ of Medical Science, Otsu, Shiga, Japan; [2]Medicine, Kanazawa Medical Univ, Kahoku-Gun, Ishikawa, Japan; [3]Medicine, Asahikawa Medical Univ, Asahikawa, Hokkaido, Japan.*

Background: Posttranslational modification is essential for controlling cell function. It has been shown that the addition of O-linked b-N-acetylglucosamine (O-GlcNAcylation) to cytosolic and nuclear proteins serves as a nutrient/stress sensor for modulating cell functions, and is ubiquitous like phosphorylation. However, little is known about how O-GlcNAcylation affects normal podocyte function.

Methods: O-GlcNAc transferase (Ogt) is a critical enzyme for O-GlcNAcylation in mammals, and resides on the X chromosome. To examine the physiological role of O-GlcNAcylation in podocytes, we analyzed the renal phenotype of podocyte-specific Ogt-knockout mice. This mouse model was generated by crossbreeding Ogt-flox mouse with podocin-specific Cre mouse.

Results: We confirmed that O-GlcNAcylation was functionally diminished specifically in podocytes of podocyte-specific Ogt-knockout mice by immunofluorescent assay on O-GlcNAcylation. Podocyte-specific deletion of Ogt did not influence birth rate and showed a normal growth pattern until 16 weeks of age. Proteinuria began to develop at 4 weeks of age and increased with age until 16 weeks of age in podocyte-specific knockout mice. PAS and HE stains revealed little pathological alterations in the glomeruli and tubulointerstitial area of podocyte-specific Ogt-knockout mice at 16 weeks of age, compared to those of wild type mice. However, scanning and transmission electron microscopy analysis showed marked foot process effacement and enlarged cell body in podocytes of podocyte-specific Ogt-knockout mice. Also, an immunofluorescent assay on podocin revealed that the expression level of podocin significantly decreased and its expression pattern was visible as dots but not linear.

Conclusions: O-GlcNAcylation of intracellular proteins by Ogt is necessary to maintain normal foot process function in podocytes. Our results provide new insight into podocyte biology.

FR-PO482

Study in the Effect of IgA1 Glycosylation and Histone Acetylation on the Pathogenesis of IgA Nephropathy

Qin Dai,[1,2] Jian Liu,[1] Yunlei Du,[1] Xu Hao,[1] Weiming Wang,[1] Nan Chen.[1] *[1]Dept of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ, School of Medicine, Shanghai, China; [2]Dept of Nephrology, Punan Hospital, Pudong New District, Shanghai, China.*

Background: IgA nephropathy (IgAN) is the most common glomerular disease worldwide. Its pathogenesis is unclear yet. The formation of immune complexes containing Gd-IgA1 is the key factor in the pathogenesis of IgAN. Histone acetylation modification is one of the histone modification, but its role in the pathogenesis of IgAN is unclear.

Methods: 59 IgAN patients and 30 health controls were respectively collected. The plasma level of IgA and Gd-IgA1, H3/H4 acetylation and H3K4/H3K9 methylation level in PBMC were measured by ELISA. HDACs, HAT, C1GALT1 and ST6GALNAC2 mRNA in PBMC were measured by qPCR and H3/H4 acetylation level at C1GALT1 and ST6GALNAC2 gene promoter detected by ChIP. The expression of HDAC1 and H3Ac in renal tissues was observed by immunofluorescence.

Results: We found IgA and Gd-IgA1 in IgAN patients plasma were significantly increased compared with the healthy controls (P<0.0001) and Gd-IgA1 in IgAN patients was positively correlated with the total amount of 24h urine protein (r=0.479, P<0.001). Transcription of C1GALT1 and ST6GALNAC2 mRNA of IgAN patients was 0.38±0.07 (P<0.01) and 2.31±0.48 folds (P<0.05). Increased H3 acetylation (P<0.05) and H4 acetylation (P<0.01) were observed in IgAN patients. The mRNA level of HDAC1, HDAC2, HDAC3, HDAC7, HDAC8, P300 and CREBBP from IgAN patients was respectively 2.20±0.18 (P<0.001), 0.44±0.08 (P<0.05), 0.98±0.18 (P>0.05), 1.02±0.21 (P>0.05), 1.47±0.25 (P<0.05), 2.81±0.39 (P<0.01) and 2.44±0.27 folds (P<0.01). H3 and H4 acetylation at C1GALT1 and ST6GALNAC2 promoter were elevated from IgAN patients. Immunofluorescence results indicated that the HDAC1 was increased obviously, but H3Ac was significantly reduced in the renal tissue of IgAN patients.

Conclusions: This study found that IgAN patients were in an abnormal histone acetylation state; IgA1 glycosylation and Histone acetylation take part in the pathogenesis of IgAN. The results enrich the pathogenesis of IgAN and provide new insights to the treatment of IgAN.

FR-PO483

Chinese Herbal Medicine for IgA Nephropathy, ShenPing Decoction, Blocks PDGF-Induced Signaling and Proliferation in Human Mesangial Cells

Xianwen Zhang,[1,2] Zhi Qiang Huang,[2] Qi Bian,[2,3] Stacy D. Hall,[2] Lin Wang,[1] Yueyi Deng,[1] Bruce A. Julian,[2] Yiping Chen,[1] Jan Novak.[2] *[1]Longhua Hospital, Shanghai Univ of Traditional Chinese Medicine, Shanghai, China; [2]Univ of Alabama at Birmingham; [3]Changhai Hospital, China.*

Background: A prescribed Chinese herbal medicine, ShenPing Decoction (SP), has been effectively used in China to treat IgA nephropathy (IgAN) at its early stages for over 30 years. In IgAN, mesangial deposition of immune complexes, consisting of galactose-deficient IgA1 (Gd-IgA1) and auto-antibodies bound to Gd-IgA1, stimulate mesangial cell

(MC) proliferation, possibly *via* PDGF signaling. Locally produced IL-6 may be part of the pathogenic process. In this study, we investigated the effects of SP on PDGF signaling, using primary MCs.

Methods: MCs were incubated with PDGF for 24 h with or without SP. Cellular proliferation was measured with Syto60. RealTime RT-PCR was performed to determine changes in expression of IL-6. Signaling in MCs by PDGF with or without SP was evaluated by Western blotting with antibodies specific for multiple phosphorylated proteins, including ERK and p38.

Results: PDGF increased MC proliferation and SP inhibited this PDGF-induced activity in a dose-dependent manner. PDGF increased phosphorylation of multiple proteins, including ERK and of p38. SP inhibited this PDGF-enhanced phosphorylation in a dose-dependent manner, PDGF up-regulated expression of IL-6 by 5 fold; SP partially inhibited this PDGF-mediated upregulation of IL-6 gene expression in a dose-dependent manner.

Conclusions: PDGF increased MC proliferation, enhanced phosphorylation of multiple proteins, and up-regulated expression of IL-6. SP inhibited PDGF-induced MC proliferation and phosphorylation of multiple proteins, and partially inhibited expression of IL-6 mRNA. Future studies are needed to identify the active componentsof SP.

FR-PO484

Angiotensin II-Induced Podocyte Injury via the Nephrin-c-Abl-ship2-Akt Pathway Qian Yang, Yiqiong Ma, Yipeng Liu, Wei Liang, Xinghua Chen, Zhilong Ren, Huiming Wang, Guohua Ding. *Div of Nephrology, Renmin Hospital of Wuhan Univ, Wuhan, Hubei, China.*

Background: Previous studies have shown that nephrin plays an important role in podocyte injury induced by AngiotensinII. However, its specific mechanism remains unclear. C-Abl is a SH2/SH3 domain containing nonreceptor tyrosine kinase, which is involved in cell survival and cytoskeleton regulation. Phosphorylated nephrin is able to interact with molecules containing SH2/SH3 domain, which suggests that c-Abl may be a downstream molecular of nephrin signaling. In this study, we intend to study the role of c-Abl in nephrin signaling in process of podocyte injury.

Methods: Twenty-four male Wistar rats were randomly assigned to administer AngII (400 ng/kg/min) or saline with osmotic mini-pumps. In vitro, cultured murine podocytes were exposed to Ang II (10^{-6}M) for variable time. Western blotting was used for detecting expression and phosphorylation levels of nephrin, c-Abl, ship2 and Akt. The colocalization of nephrin and c-Abl was detected by laser confocal microscopy. The nephrin-c-Abl and c-Abl-ship2 interactions were assessed using co-immunoprecipitation. Cytoskeleton formation was evaluated by FITC-phalloidin staining and apoptosis was analyzed by flow cytometry.

Results: AngII-infused rats developed proteinuria and podocyte damage, which was accompanied with decreased expression of nephrin and fainter interaction between nephrin and c-Abl. *In vitro*, AngII exposure induced cytoskeleton reorganization and apoptosis in podocytes. In addition, Ang II-induced dephosphorylation of nephrin and Akt was in line with lower interaction of nephrin-c-Abl. Moreover, AngII exposure promoted phosphorylation of c-Abl and interaction of c-Abl-ship2. In contrast, c-Abl siRNA and STI571 (c-Abl inhibitor) significantly restored AngII-induced podocyte injury (cytoskeleton reorganization and apoptosis) and suppressed Ang II-induced interaction of c-Abl-ship2 and phosphorylation of ship2 without alteration of nephrin phosphorylation.

Conclusions: These findings indicate that c-Abl is a molecular chaperone of nephrin signaling and ship2-Akt pathway with released c-Abl contributes to Ang II-induced podocyte injury.

GLEPP1 Controls the Composition of the GBM in Mice Eva Koenigshausen,[1] Laura Lennartz,[1] Christian Weigel,[1] Thorsten Wiech,[2] Dontscho Kerjaschki,[3] Roger C. Wiggins,[4] Magdalena Woznowski,[1] Ivo Quack,[1] Lars C. Rump,[1] Lorenz Sellin.[1] *[1]Nephrology, Univ Hospital Duesseldorf, Germany; [2]Nephropathology, Univ Hospital Hamburg, Germany; [3]Pathology, Univ of Vienna, Austria; [4]Nephrology, Univ of Michigan.*

Background: Proteinuria is one symptom of glomerular kidney disease and evolves out of the altered glomerular filtration barrier. GLEPP1 is a receptor tyrosine phosphatase present in the podocyte foot processes. Mutations in the GLEPP1 gene were shown to be associated with MCD and FSGS. The precise function of GLEPP1 is not fully understood.

Methods: GLEPP1 -/- deficient and WT +/+ mice on a 129P3/J background were examined at the age of 4, 6 and 10 months of age. Mouse urine was analyzed. RNA was obtained from isolated glomeruli and qPCR was performed for collagen IV alpha1, 2, 3, 4, 5 as well as laminin alpha 1, 5 and beta 1, 2. Mouse kidneys were fixed. PAS staining was performed. For immunogold EM ultrathin sections of rat kidneys were labeled with a GLEPP1 antibody.

Results: GLEPP1 -/- mice display a significantly higher urinary ACR compared with age matched +/+ controls at the age of 6 and 10 months. At the age of 4 months there was no difference in proteinuria. Histologically, this correlated with focal thickening of the GBM in GLEPP1 -/- mice, resembling GBM humps. At the sights of these humps foot process effacement was observed. qPCR from glomeruli revealed significant upregulation of collagen IV alpha1 and 2 expression while alpha3 expression was significantly down regulated. qPCR also showed significant upregulation of laminin alpha1 and beta1 chains, while alpha5 and beta2 did not differ. Immunogold EM detected GLEPP1 expression mainly at the apical part of the foot processes but also in proximity to the glomerular slit.

Conclusions: GLEPP1 deficiency mediates the formation of GBM humps. With the occurence of the humps the type IV collagen alpha1 and 2 and laminin alpha1 and beta 1 is increased. There is evidence that GLEPP1 switches the GBM composition from a mature to an immature composition. This switch can only be seen in aging mice and results functionally in proteinuria. These findings stress the protective and beneficial role of GLEPP1 for podocytes.

FR-PO486

Albumin Modification Impacts Binding to the Transcytotic Receptor FcRn Mark C. Wagner,[1,2] Jered Myslinski,[1,2] Brittany N. Flores,[1,2] Bruce A. Molitoris.[1,2,3] *[1]Medicine, Indiana Univ School of Medicine, Indianapolis, IN; [2]Indiana Center for Biological Microscopy, Indianapolis, IN; [3]Roudebush VAMC, Indianapolis, IN.*

Background: Serum albumin is the most abundant carrier protein in blood and interacts with both small and large molecules. In addition, its long half-life in circulation enables more interaction with oxygen radicals, free sugars and other albumin reactive compounds present in blood. The focus of this study was to address specific *in vitro* albumin modifications and their impact on albumin-FcRn binding.

Methods: Since FcRn binds albumin strongly at acidic pH and releases it following transcytosis at physiological pH, binding at pH 6.0 and 7.4 was performed. Kd was measured using Microscale Thermophoresis (NanoTemper Technologies GmbH, Munich, Germany) which measures enzyme activities and biomolecule interactions under close-to-native conditions in immobilization-free and bioliquids of choice. The change in hydration shell of albumin is used to determine binding affinities with high accuracy and sensitivity.

Results: Purified soluble rat FcRn was incubated with normal rat albumin, human albumin and rat IgG and binding affinities agreed with previous studies. Glycated albumin results from the reaction of reducing sugars i.e. glucose, ribose which form a labile Schiff base that leads to a ketoamine adduct or Amadori product that overtime forms stable AGEs. Glucose, ribose and methylgloxal modified albumin (21day) all had reduced affinity to FcRn at pH 6.0 suggesting that these albumins would not be returned to the circulation via the transcytotic pathway. Interestingly, 7 day modified methylgloxal and glucose albumin retained pH sensitive binding suggesting that shorter exposure to reducing sugars does not alter albumin handling. Glycolaldehyde albumin had reduced binding at pH 6.0 but increased binding at pH 7.4. In CKD patients, urea leads to albumin carbamylation. Carbamylated RSA was found to have decreased FcRn binding at pH 6.0.

Conclusions: Understanding how modified albumins interact with this and other receptors i.e. Megalin/Cubilin, RAGE is critical to developing a complete picture of how the kidney handles this important protein.

FR-PO487

Differential miRNA Expression in Parietal Epithelial Cells and Cellular Crescents of IgA Glomerulonephritis Jan U. Becker,[1] Bernd Hohenstein,[2] Catherine Meyer-Schwesinger,[3] Clemens L. Bockmeyer.[4] *[1]Inst of Pathology, Univ Hospital Cologne, Cologne, Germany; [2]Medical Clinic III, Nephrology, Univ Hospital Carl Gustav Carus, Dresden, Germany; [3]Internal Medicine, Nephrology, Univ Hospital Hamburg-Eppendorf, Hamburg, Germany; [4]Inst of Pathology, Hannover Medical School, Hannover, Germany.*

Background: miRNAs are known to regulate mRNA levels and mRNA translation, thus regulating cell functions including proliferation. Parietal epithelial cells (PECs) are key players in crescent formation. We hypothesize that altered miRNA expression contributes to the proliferation of PECs involved in crescent formation.

Methods: Each 5 human renal biopsies with non-crescentic IgA glomerulonephritis (IgA-GN), IgA-GN with fresh, cellular crescents (crescIgA-GN) and minimal tubulointerstitial nephritis as controls were chosen from our archive. PECs and crescents were microdissected from paraffin sections. miRNA expression was quantified in the microdissected fractions with RT-PCR low density arrays. Relative miRNA expression levels were compared with Tukey tests. Putative target genes and pathways of differentially expressed miRNAs were determined *in silico*.

Results: miR-708-5p and miR-21-3p were higher in crescents than in PECs of IgA-GN, crescIgA-GN and and controls. Putative targets of miR-708-5p include CD44, an activation marker of PECs, miR-708-5p is known to be involved in regulation of proliferation, negatively or positively depending on the cellular context. Putative targets of miR-21-3p include cyclin-dependent kinase 6 (Cdk6) and arginine/serine-rich coiled coil 2 (RSRC2), both involved in cell cycle control and expressed in PECs.

Conclusions: We found upregulation of miR-708-5p and miR-21-3p in crescents compared to PECs. While miR-708-5p rather appears to counteract proliferation, upregulation of miR-21-3p could contribute to PECs proliferation in crescent formation. *In vitro* studies with PECs will reveal the functional role of both miRNAs regarding proliferation and inflammatory activation.

Transcriptome Analysis of Glomerular Disease Using PodNet, a Protein-Protein Interaction Network of the Podocyte Gregor Warsow,[1] Maja Lindenmeyer,[2] Nicole Endlich,[1] Matthias Kretzler,[3] Georg Fuellen,[4] Clemens D. Cohen,[2] Karlhans Endlich.[1] *[1]Anatomy and Cell Biology, Univ Medicine Greifswald, Greifswald, Germany; [2]Physiology, Univ of Zurich, Zurich, Switzerland; [3]Internal Medicine, Div. of Nephrology, Univ of Michigan, Ann Arbor, MI; [4]Biostatistics and Informatics in Medicine and Ageing Research, Univ Medicine Rostock, Rostock, Germany; [5]Genetics and Functional Genomics, Univ Medicine Greifswald, Greifswald, Germany.*

Background: Recently, we have built PodNet, a literature-based mouse network of protein-protein interactions (PPIs) in the podocyte (Warsow et al., *Kidney Int.* 2013). Mapping expression data of podocytes on PodNet, we gained valuable insight into podocyte differentiation in vivo and the loss of differentiation in culture. The aim of the present study was to analyze the glomerular transcriptome in various glomerular diseases using PodNet2, an updated and improved version of PodNet.

Methods: Recently published findings (2011-2013) were integrated into PodNet2. A mouse and a human version of PodNet2 were built and expanded to XPodNet2 by incorporation of PPIs from STRING database. The most differentially regulated interactions were identified with the Cytoscape plugin ExprEssence.

Results: After mapping glomerular transcriptomes of healthy and diseased kidney from the European Renal cDNA Bank on XPodNet2, the most differentially regulated interactions in FSGS, MCD and DN were identified. For example, small networks around collagen I and lipoprotein lipase were found to be up- and downregulated, respectively, in FSGS. Weighted gene correlation network analysis demonstrated that several modules with correlated gene expression changed in glomerular disease. As an example, FSGS modules with correlated gene expression contained frequently the gene ontology terms “cell cycle” or “mitosis”. Surprisingly, podocyte specific essential interactions (e.g. those of the slit diaphragm) exhibited a limited regulation in glomerular disease on a transcriptome level.

Conclusions: PodNet2 is a valuable tool for the comprehensive analysis of mouse and human expression data. Our analysis of human glomerular transcriptomes provides novel insight into gene expression in glomerular disease.

Inhibiting of Histone Deacetylase6 (HDAC6) Activity Alleviates Podocyte Injury in db/db Mice Yuxiong Lai, Wenjian Wang, Yuanhan Chen, Xiaofan Tan, Li Zhang, Yangyang Zuo, Lei Fu, Jianteng Xie, Jianxun Wu, Shuangxin Liu, Wei Shi. *Div of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: Podocytes are a crucial cell type in kidney and play a vital part in the pathology of diabetic nephropathy. Histone deacetylase 6 (HDAC6) gets involved in neurodegenerative disorder and several kinds of cancer, but has rarely been studied on podocyte injury in diabetic nephropathy.

Methods: To assess the function of HDAC6 on podocyte injury, we firstly examined mRNA expression and HDAC6 activity in podocytes which were treated with advanced glycation end products (AGEs). Then a further study was carried out on a type 2 diabetic nephropathy animal model (db/db mice) and their age-matched wild-type (BKS) mice. At 12 weeks of age, half of the db/db mice were randomly chosen to receive tubacin, a selective inhibitor of HDAC6 (n = 4, i.p., 0.5 $mg \cdot kg^{-1}$, one time per 2 days for 8 weeks). In control group, 4 db/db and 4 BKS mice were given the same volume of DMSO without tubacin. Relevant physiological parameters were measured on schedule.

Results: When treated with AGEs, mRNA expression and activity of HDAC6 were up-regulated in podocytes. Tubacin markedly alleviates proteinuria in db/db mice, decreases mesangial expansion and prevents podocytes losses in gulermuli. Besides, tubacin treatment exhibites better renal protection effects bases on the urinary albumin excretion ($mg \cdot mg^{-1}$ creatinine), creatinine clearance analysis in db/db mice compared to the control.

Conclusions: These data indicate that HDAC6 plays an important role in podocyte injury. Tubacin, the inhibitor of HDAC6, demonstrates a markedly renopreotection effect on podocytes exposured to hyperglycemia. However the exact mechanism under this role needs further study.

Investigation of the Role of the Inflammasome Triggering PYHIN Interferon Gene Family in Systemic Lupus Erythematosus Model BXSB Allyson Catherine Egan,[1] Michael D. Jones.[2] *[1]Dept of Medicine, Hammersmith Hospital, Imperial College London; [2]Genomics Laboratory, MRC Clinical Sciences Centre, Imperial College London.*

Background: The telomeric region of chromosome 1 (C1q21-23) in murine models and a syntenic region in humans is associated with the development of Systemic Lupus Erythematosus (SLE). This interval encodes three candidate gene families – *PYHIN*, Slam and Fcgamma Receptor. The interferon inducible PYHIN gene family includes *AIM2*, a unique cytosolic DNA sensor which instigates the formation of the inflammasome yielding cell death via IL-1b and IL-18. This project sought to develop a novel subcongenic mouse model containing the *PYHIN locus, B10. Yaa.Bxs3.Ifi* to investigate the potential role of this gene family in SLE development.

Methods: (B10 x B10.*Yaa.Bxs3*) F1 male mice were backcrossed with B10 (non-autoimmune) females. Recombinants were genotyped at six loci using polymerase chain reaction and sequenced within the*Slam* locus. ANA slides were prepared using Hep2 cells. Renal H&E sections were graded according to mesangial hypercellularity and matrix increase. Flow cytometric analyses (FACs) of splenic B and T-cells were performed.

Results: Three novel subcongenics B10.*Yaa.Bxs3.Ifi*, B10.*Yaa.Bxs3.Ifi/Slam* and B10.*Yaa.Bxs3.Fcgr* were generated. Phenotypically, in B10.*Yaa.Bxs3.Ifi* there was significant difference in the levels of ANA titres, evidence of nephritis and elevated splenic weights and lengths in comparison to the non-autoimmune strain B10.*Yaa* at twelve months. These trends reflect the autoimmune parental strain B10.*Yaa.Bxs3*. FACS analysis of B10.*Yaa, Bxs3.Ifi* at six months demonstrated expanded B-cell $CD45^{-}$ populations similar to autoimmune B10.*Yaa. Bxs3*, which was not present in the non-autoimmune B10.*Yaa*.

Conclusions: The three novel subcongenic models uniquely facilitate the opportunity to dissection the candidate gene families *HIN200*, *Slam* and *Fcgramma's* contribution to the SLE phenotype. The *PYHIN* subcongenic, identifies that phenotypic features of SLE are present in the subcongenic at 12 months, supporting the role of this interferon inducible gene family as a candidate gene for the development of SLE.

FR-PO491

Development of an In Vitro Mesangial Cell Model for Progressive Glomerulosclerosis by Disruption of the ANAPC-10 Gene in Fvb Mice Yongxin Gao, Kathleen O. Heilig, Zaid Brifkani, Charles W. Heilig. *Medicine, Univ of Florida College of Medicine - Jacksonville, Jacksonville, FL.*

Background: We previously developed Fvb Os/+ mice with disruption of the ANAPC-10 gene. These mice exhibit rapidly progressive glomerulosclerosis (GS) with heavy albuminuria, early renal failure and death at approximately 12 weeks of age. Fvb Os/+ glomeruli have enhanced glucose uptake. Here we isolated primary culture mesangial cells (MC) from Fvb Os/+ mice and Fvb +/+ wild type control mice to investigate the mechanism of GS in Fvb Os/+.

Methods: Effects of the ANAPC-10 mutation (Anaphase Promoting Complex Subunit 10) in chromosome 8 were determined by analysis of cell growth curves, and analysis of Glucose Transporter-1 (GLUT1), Mechano-Growth Factor (MGF) and extracellular matrix (ECM) proteins in Western analyses, immunofluorescence microscopy (IF), and/or immunohistochemistry (IHC). RNA/DNA ratios were determined as a marker for cell size.

Results: Fvb Os/+ MC had a 16% lower RNA/DNA ratio suggesting reduced cell size. Fvb Os/+ MC also exhibited severely slowed growth in vitro, compared to Fvb +/+ control MC. Western analyses revealed Fvb Os/+ MC had increased MGF (3.5-fold) and GLUT1 (9-fold). These are both stimuli for ECM expression. Fibronectin (FN) was increased 4-fold, and type IV collagen (Col-IV) increased 9-fold in Fvb Os/+. All of these changes were $P < .005$ versus Fvb +/+ control. This was evident even after 8 passages of the MC's in culture. IF and IHC confirmed increased FN (an expanding lattice between cells) and Col-IV in the MC.

Conclusions: 1) ANAPC-10 gene disruption slowed the growth of Fvb Os/+ MC, an expected consequence of impairing mitosis. 2) Fvb Os/+ MC produced excessive FN and Col IV, providing an explanation for the rapidly progressive glomeruloscloerisis (GS) in Fvb Os/+ mice. 3) Increased MGF and GLUT1 in Fvb Os/+ MC provide a potential mechanism for the excessive ECM production these cells, likely via enhanced glucose uptake and metabolism which both of these proteins stimulate. 4) The Fvb Os/+ and Fvb +/+ MC provide a new in vitro model for investigation of mechanisms leading to progressive GS in vivo.

FR-PO492

Mechano-Growth Factor Regulation of Mesangial Cell Growth and Extracellular Matrix Protein Expression: Implications for Diabetic Nephropathy Yongxin Gao,[1] Kathleen O. Heilig,[1] Raafat Farag Makary,[1] Zaid Brifkani,[1] Mohamed G. Atta,[2] Charles W. Heilig.[1] *[1]Medicine, Univ of Florida College of Medicine - Jacksonville, Jacksonville, FL; [2]Medicine, Johns Hopkins Univ, Baltimore, MD.*

Background: We previously identified Mechano-Growth Factor (MGF) as a glomerular mesangial and renal tubular protein expressed in normal mouse kidney, induced in glomeruli by type 1 and type 2 diabetes mellitus. MGF stimulated expression of GLUT1 and glucose uptake in mesangial cells (MC) in vitro. Here we investigated MGF effects on MC growth, fibronectin (FN) and type IV collagen (Col-IV) expression, +/- high glucose.

Methods: Primary culture mouse MC (C57BL6 background) were transduced with MGF-Sense (MGF-S cells) MGF-Antisense (MGF-AS cells), or Empty Vector (MGF-EV control cells) MoMuLV retroviral expression constructs, cloned, and studied in vitro for cell growth rate, RNA/DNA ratio (cell size), Western analyses of MGF, GLUT1, FN and Col-IV, and immunolabeling for selected proteins. MC were grown in standard 8mM glucose medium, or in 20mM high glucose medium where indicated.

Results: MGF-S MC overexpressed MGF > 10-fold, with an enhanced growth rate versus MGF-EV, and versus MGF-AS which had delayed growth. MGF-S had increased GLUT1 expression (4-fold), though MGF-AS did not have suppressed GLUT1. MGF-S have a 2 - 3-fold elevated ^{3}H2-deoxyglucose uptake rate which correlates with the increased GLUT1. MGF-S had RNA/DNA 27% higher than MGF-EV, indicating hypertrophy. In contrast, MGF-AS had 3.8% lower RNA/DNA, suggesting reduced cell size. MGF-S displayed increased extracellular matrix (ECM) protein expression: FN (1.6-fold) and Col-IV (1.7-fold), persistent after numerous cell passages. 20mM High glucose induced MGF (17-fold), GLUT1 (5.9-fold), FN (7.2-fold), and Col-IV (2.7-fold). MGF-AS was protected against 20mM high glucose induction of GLUT1 (by 31%), FN (by 11%) and Col-IV (by 56%).

Conclusions: 1.MGF, inducible by diabetes and an inducer of GLUT1, stimulated cell hypertrophy, proliferation, FN and Col-IV in vitro. 2. High glucose stimulated MGF, GLUT1, FN and Col-IV, and Antisense-MGF protected against these responses, indicating MGF involvement in mediating these effects of glucose. 3.Future studies will further delineate mechanisms by which MGF induces ECM and GS.

Funding: Pharmaceutical Company Support - Dialysis Clinics Inc.

Effect on Cultured Mesangial Cells of Chinese Herbal Medication Prescribed for IgA Nephropathy Zhi Qiang Huang,[1] Xianwen Zhang,[1,2] Lin Wang,[2] Qi Bian,[1,3] Stacy D. Hall,[1] Bruce A. Julian,[1] Yiping Chen,[2] Jan Novak.[1] *[1]Microbiology, Univ of Alabama at Birmingham, Birmingham, AL; [2]Nephrology, Shanghai Univ of Chinese Traditional Medicine, Long Hua Hospital, Shanghai, China; [3]Nephrology/Medicine, ChangHai Hospital, Shanghai, China.*

Background: IgA nephropathy (IgAN) is an autoimmune disease induced by circulating immune complexes consisting of galactose-deficient IgA1 (Gd-IgA1) and autoantibodies against Gd-IgA1. IgAN is a mesangioproliferative disease in which activation of the PDGF pathway is thought to be involved in mesangial cell proliferation and subsequent glomerular injury. A prescribed Chinese herbal mixture, ShenAn decoction (SA) has been used to treat IgAN patients with renal insufficiency in China. Its mechanism of action is unknown. In this study, we investigated the effects of SA on mesangial-cell PDGF signal transduction and proliferation.

Methods: Cultured, quiescent human primary mesangial cells were treated with PDGF, with or without SA. Protein phosphorylation was analyzed with Western blotting of cell lysates with anti-phospho-tyrosine antibody (PY20), anti-phospho-ERK antibody, and anti-phospho-p38 antibody. Cellular proliferation was assessed 24 h after PDGF treatment with or without of SA, using Syto 60.

Results: PDGF increased mesangial-cell proliferation and SA blocked the stimulatory effects of PDGF in a dose-dependent manner. PDGF enhanced phosphorylation of multiple proteins, including ERK and p38. SA inhibited this PDGF-induced phosphorylation in a dose-dependent manner.

Conclusions: SA inhibited PDGF-induced mesangial-cell phosphorylation, possibly due to the presence of inhibitors of protein kinases. Identification of the active components of SA may provide explanations of the mechanisms of action for this treatment of IgAN.

Funding: NIDDK Support, Private Foundation Support

FR-PO494

Activation of Human Mesangial Cells by PDGF: Gene Expression and Signaling Study Qi Bian,[1] Stacy D. Hall,[1] Zhi Qiang Huang,[1] Leona Raskova Kafkova,[1,2] Xianwen Zhang,[1] Bruce A. Julian,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Palacky Univ, Olomouc, Czech Republic.*

Background: Glomerular mesangial injury characterized by proliferation of mesangial cells (MCs) is an important feature in IgA nephropathy (IgAN). Platelet-derived growth factor (PDGF) is a potent stimulator of MC. Accumulating evidence indicates a critical involvement of PDGF signaling in MC in IgAN and other glomerular diseases. To better understand the effect of PDGF on MC, we studied signaling pathways and differential gene expression in PDGF-stimulated MC.

Methods: MC proliferation was measured by ^{3}H-thymidine or BrdU incorporation. Differential gene expression by PDGF after 24-h stimulation (proliferation peak) of quiescent primary human MCs was determined by high-density microarrays; genes were clustered by pathway mapping. Data were validated by RealTime RT-PCR (qPCR) and immunodetection. Signaling in MCs was evaluated by Western blotting with phospho-specific antibodies.

Results: In PDGF-treated MCs, 2,997 genes were expressed at higher levels, 2,197 genes at lower levels. Using cut off value $p<0.001$, 30 genes were significantly up-regulated and 7 genes significantly down-regulated by PDGF. By clustering analysis, 95 genes were induced and 10 genes repressed. These up-/down-regulated genes were involved in different biological processes, cellular proliferation, apoptosis, signaling, energy and lipid metabolism, ion-transport, immune regulation, and inflammation. qPCR confirmed 4.3- to 61.8-fold increased expression of PTX3, IL-8, IL-6, MCP-1, and TGF-β. Immunodetection confirmed increased protein expression of TIMP1, MMP9, and IL-8. Signaling studies revealed that PDGF increased phosphorylation of multiple proteins, including ERK1/2, p38, Akt1, and FLHRL1. MEK1/2 inhibitor reduced phosphorylation of ERK1/2 and Akt1, whereas PI3K inhibitor reduced phosphorylation of Akt1 but not of FLHRL1.

Conclusions: PDGF signaling through several pathways resulted in MC proliferation and differential gene expression. Targeting PDGF-specific pathways in MC may provide a new tool for treating mesangioproliferative diseases.

FR-PO495

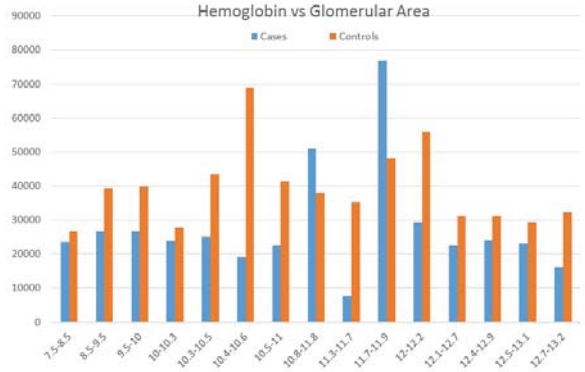
The Role of Anemia in Cardio-Renal Syndrome: Does It Impact Glomerular Size? Janice Berthe Desir,[1] Joel Neugarten,[2] Michal L. Melamed,[1] James M. Pullman,[2] Ladan Golestaneh.[2] *[1]Nephrology, Albert Einstein College of Medicine, Bronx, NY; [2]Nephrology, Montefiore Medical Center, Bronx, NY.*

Background: The presence of anemia among patients with congestive heart failure (CHF) is fairly common and found irrespective of kidney parenchymal disease. This impact on the renal histology of cardio-renal syndrome (CRS) is unclear. Patients with cyanotic heart disease are noted to have glomerulomegaly. The mechanism is purported to be polycythemia. Our recent case controlled study of anemic CHF patients showed small glomerular area. This suggests anemia may play a different role in glomerular size in patients with non-cyanotic heart disease.

Methods: We measured the total glomerular areas of 16 adult cases with end stage heart disease using the BioQuant Image Analysis program. Kidney biopsies were performed in the case patients during evaluation for heart transplant at Montefiore Medical Center between January 2007 and December 2013. Matching controls were selected from renal cell carcinoma nephrectomy samples.

Clinical Characteristcs	Cases	Controls
Gender (% male)	94 (15/16)	-
% DM	56 (9/16)	-
Mean BMI	29.8	31.8
Mean Age	59.7	60.4
Mean GFR at Biopsy	38.38	44.38

Results: 15/16 patients met the definition for anemia with hemoglobin (Hb) values less than 14 g/dL. The Hb values were 7.8-13.3 g/dL with a mean value of 11.2 g/dL among the cases and 8.2-14.8 g/dL with a mean value of 11.4 g/dL among the controls. The correlation coefficient between Hgb levels and glomerular area was 0.20 with p-value = 0.27. Hgb values were analyzed in both a continuous and dichomatous fashion and were found to have to no correlation with glomerular area.



Conclusions: This case controlled study demonstrates that patients with heart failure have smaller glomerular size that is not related to anemia. Future studies are needed to examine the histology of cardio renal syndrome.

FR-PO496

Podocytes Are a Target of Nicotine: Link to Proteinuria and Progression of Renal Disease? Leopoldo Raij,[2] Runxia Tian,[1] Bernice Acevedo,[1] Vasil Peev,[1] Sandra M. Merscher,[1] Alessia Fornoni,[1] Ming-Sheng Zhou.[1] *[1]Medicine, VAMC, Miami, FL; [2]Medicine, Univ of Miami, Miami, FL; [3]Research, SFVAFRE, Miami, FL.*

Background: Epidemiologically the link between cigarette smoking (CS), proteinuria and renal failure progression is overwhelming but the mechanisms remain obscure. We reported that Nicotine (NIC) increased superoxide anion (O_2^-) in human mesangial cells via non-neuronal nicotinic receptors (nAchRs) (AJP '07). Further, in human macrophages NIC increased O_2^-,and foam cell formation linked to increase B scavenger receptor CD36 and oxLDL uptake (AJP'13).Here we studied whether human podocytes (POD) are a target of NIC.

Methods: In immortalized human POD we determined by WB expression of 1) Synaptopodin (Synpo): key stabilizer of actin skeleton 2) Activated AMPK (pAMPK): suppresses NADPH, 3) CD36 and 4) *for the first time*: a2, a3, a4 and b3nAchRs. With lucigenin we determined O_2^- production in POD treated with NIC 100nmol/L, a plasma concentration attained with CS and E- CS. We preincubated POD with Hexametonium: blocker of nAchRs; DPI: inhibitor of NADPH; Catalase: inhibitor of H2O2 and AICAR: activator of AMPK and after 24hrs POD incubation with 50ug/ml oxLDL we measured POD cholesterol (Chol) ug/mg prot, and apoptosis (APOPT) flow.cytom. Stats.ANOVA-Bonferonni's- Scheffe's.

Results: NIC increased POD O_2^- production, max150% at 6 hrs; Synpo and active pAMPK were reduced 50% ($p< 0.05$). DPI and AICAR prevented reduction of Synpo, pAMPK and the increase in O_2^- ($p<0.05$). NIC upregulated POD CD36 40% ($p<0.05$) which was prevented by Hexametonium, DPI and Catalase. 24 hrs. oxLDL incubation increased POD Chol 28% whereas oxLDL+NIC increased Chol 54 % ($p< 0.05$) that was reduced to 17% in CD36 SiRNA pretreated POD ($p<0.05$) Only 2.8 and 2.6 % of POD incubated with NIC or oxLDL were APOPT whereas 9.4 % in oxLDL+ NIC were APOPT ($p< 0.05$ versus all); CD36-SiRNA reduced POD APOPT to baseline.

Conclusions: Concurrent $O2^-$ production, reduction in Synpo and up regulation of CD36 associated with oxLDL uptake and POD apoptosis, are sufficient to implicate nicotine as a risk factor for proteinuria and progression of renal failure linked to protracted CS and, likely, E-Cigarettes smoking.

FR-PO497

Triptolide, an Extracted Phytomedicine Attenuates Glomerularsclerosis in Diabetic Nephropathy Rats via Regulation of Akt/AMPK/mTOR and TGF-β1/Smad Signaling Activities, Compared with Rapamycin Yigang Wan, Zhimin Mao. *Dept of Traditional Chinese Medicine, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing Univ Medical School, Nanjing, China.*

Background: Triptolide (TP), a natural extract from Tripterygium wilfordii has been applied extensively for treating glomerularsclerosis (GS) in patients with early diabetic nephropathy (DN) in China. Activation of mTOR plays a critical role in pathologic forms of hypertrophy and proliferation in kidneys under hyperglycemia other than classical TGF-β1/Smad pathway. Hyperglycemia increases mTOR activity by combined actions of Akt activation and AMPK inhibition. This study thus aimed to investigate effects and mechanisms in vivo of TP on GS, compared with rapamycin (mTOR inhibitor), through regulating Akt/AMPK/mTOR or TGF-β1/Smad signaling activities.

Methods: Rats were randomly divided into 4 groups, sham-operated group, TP-treated group, vehicle-given group and rapamycin-treated group, and sacrificed at week 8 after the induction of DN by 2 consecutive intraperitoneal injections of streptozotocin (STZ) with an interval of 1 week following unilateral nephrectomy. Daily oral administration of TP, rapamycin and saline were started after the second injection of STZ until the day of sacrifice. Proteinuria, UAlb, BG, biochemical indicators, renal pathological changes, as well as key protein expressions in Akt/AMPK/mTOR and TGF-β1/Smad pathways in kidneys were examined, respectively.

Results: Akt/AMPK/mTOR and TGF-β1/Smad pathways were concurrently activated in kidneys. TP, similar to rapamycin, markedly regulated protein expressions of p-Akt, p-mTOR, p-p70S6 kinase, p-Smad2/3 and TGF-β1 in kidneys, and ameliorated proteinuria, mesangial matrix expansion, a-SMA expression and collagen deposition in glomeruli, without lowering hyperglycemia. Additionally, retardation in glomerularsclerotic development was observed.

Conclusions: Activated Akt/AMPK/mTOR and TGF-β1/Smad pathways jointly contribute to glomerular injury. TP, as a natural regulator in vivo, effectively attenuates GS by potential molecular mechanisms involving reduction of mesangial matrix and suppression of Akt and mTOR activation, as well as regulation of TGF-β1/Smad signaling activity.

Lack of Protein Fatty-Acylation Can Cause Focal Segmental Glomerulosclerosis (FSGS) Giuseppina Federico,[1] Stefan Porubsky,[1,2] Francesca Rampoldi,[1] Christoph Kuppe,[3] Hermann-Josef Groene.[1] *[1]Cellular and Molecular Pathology, German Cancer Research Center, Heidelberg, Germany; [2]Inst of Pathology, Univ Medical Center Mannheim, Germany; [3]Dept of Nephrology and Clinical Immunology, RWTH Aachen, Germany.*

Background: Protein fatty-acylation is the attachment of fatty acids to proteins. Protein N-myristoylation represents one type of protein fatty-acylation and refers to the attachment of myristic acid to the N-terminal glycine. This modification is catalyzed by N-myristoyltransferases (Nmt1 and Nmt2). Our aim was to elucidate the role of N-myristoylation for the morphology and function of podocytes.

Methods: LoxP-sites were introduced into the *Nmt1* and *Nmt2* loci by recombination in embryonic stem cells and podocyte-specific deletion was achieved by expressing Cre under the control of podocine promoter (Pod^{Cre}). At day 1, 17, 35 and 70 after birth, morphological analysis and functional tests were performed.

Results: Mice with podocyte-specific deletion of both Nmt1 and Nmt2 ($Pod^{Cre}/Nmt1^{flox/flox}/Nmt2^{flox/flox}$) did not show proteinuria at day 1 after birth. However, starting at day 17, they developed a FSGS accompanied by an increasing proteinuria. At day 35, these changes progressed to a diffuse segmental and global glomerulosclerosis with an overt nephrotic syndrome leading to death before day 70 in most of the $Pod^{Cre}/Nmt1^{flox/flox}/Nmt2^{flox/flox}$ mice. Upon electron microscopy, podocytes lacking NMT activity showed a fusion of foot processes. In contrast, the glomerular scaring and proteinuria were significantly milder or absent in mice lacking only *Nmt1* or *Nmt2* respectively. We could show that cytoskeleton-associated proteins such as MARCKS (myristoylated alanine-rich C kinase substrate) need myristoylation activity for their function.

Conclusions: These results show that protein N-myristoylation is essential for a proper localization and function of proteins in podocytes. Investigations are currently done to determine which metabolic and immunologic diseases interfere with protein N-myristoylation in podocytes. We propose that metabolic alterations may potentially initiate the most frequent form of FSGS, which is associated with degenerative and immune complex diseases.

Anti-PDGFRb Antibody Protects Col4a3-/- Mice From the Development of Alport Nephropathy Naoki Nakagawa,[1] Ivan G. Gomez,[1] Shreeram Akilesh.[1] *[1]Medicine & Pathology, Univ of Washington, Seattle, WA; [2]Medicine & Pathology, Univ of Washington, Seattle, WA; [3]Medicine & Pathology, Univ of Washington, Seattle, WA; [4]Medicine & Pathology, Univ of Washington, Seattle, WA.*

Background: The platelet-derived growth factor receptor (PDGFR) has been implicated in a number of glomerular and interstitial fibrogenic diseases in the kidney. Inhibitors of the kinase activity of PDGFRa and PDGFRb have been shown to have activity in animal models of glomerular and interstitial disease. Recently we showed that the major fibrogenic cells in the kidney express PDGFRa and PDGFRb and that blocking these receptors with soluble receptor ligand trap or monoclonal antibodies had a profound impact on fibrogenic and inflammatory responses (Chen YT, et al. Kidney Int. 2011 80:1170-81; Lin et al Am J Pathol. 2011 178:911-23). In the following studies we tested the efficacy of monoclonal antibody 1B3 (Imclone), which specifically blocks PDGF-BB binding to PDGFRb and blocks downstream signaling pathways.

Methods: Col4a3-/- mice (n=12/group) on the 129SV background were given anti-PDGFRb antibody 1B3 or isotype control antibodies (40mg/kg ip twice/week) from week 3 to week 9. Mice were evaluated for kidney function and histology at 9 weeks.

Results: No toxic or deleterious effects were observed. Mice receiving 1B3 antibody had increased body weight at 9 weeks compared to control (indicative of improved health), had a 50% reduction in BUN levels, 50% reduction in albuminuria. Mice receiving active antibody had a 50% reduction in fibrosis, and marked preservation of tubule histology and function. Glomerular histology was preserved with many fewer glomeruli showing sclerosis.

Conclusions: Antibody mediated blockade of PDGFRb signaling is a promising strategy in the treatment of Alport Nephropathy and potentially other chronic kidney diseases.

FR-PO500

APOL1 Variants Induce Pyroptosis and Formation of Inflammasomes in Human Podocytes through the Activation of Caspase-1 Shabirul Haque,[1] Xiqian Lan,[1] Hongxiu Wen,[1] Ashwani Malhotra,[1] Karl Leon Skorecki,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Rambam Health Care Campus, Haifa, Israel.*

Background: Expression of APOL1 variants (Vs) are associated with the occurrence of higher rates of FSGS in patients with Sub-Saharan African Ancestry. Since podocyte loss is a common pathway for the development of FSGS, we hypothesized that APOL1Vs may be contributing to podocyte loss through pyroptosis and the release inflammasomes, which promote the maturation of inflammatory cytokines such as interleukin (IL)-1 ß and IL-18. These interleukins participitate in multiple cellular activities, including interferon-g secretion, activation of lipid biosynthesis, and pyroptosis, a process of programmed cell death distinct from apoptosis.

Methods: To evaluate the role of APOL1Vs in the induction of podocyte injury, we overexpressed APOL1Vs (G1, G2 and G1+G2 combined) as well as APOL1WT (G0) in human podocytes (HPs). Vector/HPs, APOL1G0/HPs, APOL11 G1/HPs, APOL1G2/HPs and APOL1G1/G2/HPs were stained with H33342 and propidium iodide as a measure of pyroptosis (condensed nuclei with loss of cell wall integrity). RNA was extracted and cDNA was probed for NLRP3 expression. Protein blots were probed for podocyte caspase-1 and IL1-ß expression as markers of inflammasome formation. To test for a causal relationship, the effect of a caspase-1 inhibitor was evaluated on vector/APOL1-, APOL1G0- and and APOL1Vs-induced podocyte inflammasome formation and pyroptosis.

Results: APOL1G0/HPs and APOL1G1/HPs and G2/HPs displayed a greater ($P<0.01$) number of cells with evident pyroptosis when compared to Vector/HPs. However, strikingly, APOL1 G1/G2/HPs displayed the most significant ($P<0.01$) elevation of cells with evidence of pyroptosis. Protein blots of APOL1G0/HPs and APOL1G1/HPs and APOL1G2/HPs displayed enhanced expression of caspase-1 and IL-1ß. Since a caspase-1 inhibitor not only inhibited APOL1vs-induced IL-1ß beta production, but also attenuated induction of pyroptosis, it appears that APOL1Vs-induced pyroptosis is mediated through caspase-1 activation.

Conclusions: APOL1Vs induce pyroptosis and inflammasome formation through the activation of caspase-1.

Enhancement of Wnt/β-Catenin Signaling Promotes Renal Fibrosis by Inducing Cell Cycle Arrest at the G2/M Phase in Tubular Epithelial Cells Minoru Satoh, Hiroyuki Kadoya, Seiji Itano, Atsushi Uchida, Chieko Ihoriya, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Recent studies have indicated that renal epithelial cell cycle arrest at the G2/M phase promote renal fibrosis. However, the mechanism of cell cycle arrest at the G2/M phase on the process of renal fibrosis is not fully elucidated. The forkhead transcription factors of the O subgroup (FOXO) functions at the G2/M checkpoint to induce a delay in G2 to M progression. FOXO transcriptional activity is enhanced by β-Catenin and concomitantly with oxidative stress, both of which are increased in the process of renal fibrosis. It is possible that increased levels of β-Catenin/FOXO complex may participate

in G2/M cell cycle arrest. We hypothesized that oxidative stress-dependent β-Catenin signaling could promote renal fibrosis by leading to cell cycle arrest at the G2/M phase in tubular epithelial cells.

Methods: In vitro experiment, we examined whether the profibrotic cytokine expression at the G2/M phase is increased by Wnt3a stimulation with oxidative stress in human proximal tubule epithelial cells. Next, we examined whether renal fibrosis could be reduced by antioxidant treatment in nephritic mice (ICGN).

Results: In vitro, cell cycle arrest in G2/M phase was increased by the Wnt stimulation under the presence of hydrogen peroxide. In addition, Wnt3a with hydrogen peroxide also increased growth arrest and DNA-damage-inducible protein 45a and cyclin G2 genes with increase of β-Catenin/FOXO complex. In the G2/M phase cells, transforming growth factor (TGF)-β and connective tissue growth factor (CTGF) expressions were increased. In vivo, ICGN mice were treated with or without tempol for 6 weeks. Tempol prominently decreased the tubular expressions of phospho-Histone H3, marker of the G2/M transition. Decreased expression of TGF-β1 and CTGF were observed in the tempol-treated ICGN micecompared with non-treated control ICGN mice.

Conclusions: Oxidative stress with Wnt stimulation induces G2/M cell cycle arrest and increases profibrotic cytokine production. Reduction of the oxidative stress could ameliorate the renal fibrosis.

Kidney Fibrogenesis Is Determined by the Subcellular Localization of YB-1

Ute Raffetseder,[1] Lydia Hanßen,[1] Christina Alidousty,[1] Sonja Djudjaj,[1] Thomas Rauen,[1] Matthias A. Neusser,[2] Clemens D. Cohen,[2] Hermann-Josef Groene,[3] Jürgen Floege,[1] Tammo Ostendorf.[1] *[1]RWTH Univ of Aachen; [2]Univ Hospital Zurich; [3]German Cancer Research Center Heidelberg.*

Background: Y-box binding protein-1 (YB-1) exerts pleiotropic functions in gene transcription and translation, e.g. of fibrosis-related genes. This led us to investigate the outcome of half-maximal YB-1 depletion in two models of renal fibrosis, namely unilateral ureteral obstruction (UUO) and cyclosporine A (CsA)-induced nephropathy. Heterozygous YB-1 knockout (Yb1+/d) mice exhibit half-normal YB-1 content on mRNA and protein level. Homozygous YB-1 KO mice are not viable and die before birth due to neuronal disorders.

Methods: Parameters of renal fibrosis were determined by immunohistochemistry (IHC), qRT-PCR and Western blot (WB) analyses. We performed ex vivo chromatin immunoprecipitation and mRNA precipitation in kidney tissues obtained from Yb1+/d and wildtype (wt) mice to dissect between nuclear and cytoplasmatic YB-1 functions. Nuclear shuttling of YB-1 was induced in vivo by a small chemical compound (HSc025).

Results: Renal damage and fibrosis development were markedly aggravated in CsA-induced nephropathy in Yb1+/d compared to wt mice. In contrast, Yb1+/d animals were protected from tubular injury and renal fibrosis following UUO (mean fibrosis score: wt: 1.54 ±0.20; Yb1+/d: 0.97±0.36), with significantly reduced ECM deposition (e.g. Col1A, fibronectin), alpha-SMA expression and impaired inflammatory responses (monocyte infiltration, chemokine expression). We could localize YB-1 in the renal cytoplasm in UUO and this contributed to enhanced Col1A mRNA stabilization and to the nucleus in the CsA model, where it repressed Col1A gene expression. In line with this, in human biopsy samples of calcineurin inhibitor-treated patients, YB-1 mainly localized to the nuclei of tubular cells. Forced nuclear shuttling of YB-1 in wt mice triggered by HSc025 attenuated renal fibrosis in the UUO model (mean fibrosis score: wt: 1.54±0.2; wt/HSc025: 0.85±0.26).

Conclusions: In conclusion, intracellular localization of YB-1 decides on aggravation or improvement of renal fibrosis, and forced nuclear YB-1 shuttling may be a novel anti-fibrotic approach.

FR-PO503

ASK1/p38 Signaling in Renal Tubular Epithelial Cells Promotes Renal Fibrosis in the Mouse Obstructed Kidney

David J. Nikolic-Paterson, Gregory H. Tesch, Frank Yuanfang Ma. *Dept of Nephrology and Monash Univ Dept of Medicine, Monash Medical Centre, Clayton, Victoria, Australia.*

Background: The stress-activated kinases, p38 mitogen-activated protein kinase (MAPK) and c-Jun amino terminal kinase (JNK), promote renal fibrosis; however, the pathways by which these kinases are activated in kidney disease remain poorly defined. Apoptosis signal-regulating kinase 1 (ASK1/MAP3K5) is a member of the MAPKKK family which can induce activation of p38 and JNK. This study examined whether ASK1 induces p38/JNK activation and renal fibrosis.

Methods: Groups of 6 wild type (WT) and Ask1 deficient (Ask1-/-) mice underwent unilateral ureteric obstruction (UUO) and were killed on day 7. In separate studies, cultured renal fibroblasts were isolated from day 5 UUO kidneys, while cultured tubular cells were isolated from animals without surgery.

Results: Basal p38 and JNK activation in WT kidney was increased 3-5 fold on day 7 UUO in association with renal fibrosis. In contrast, there was no increase in p38 activation in Ask1-/- UUO, while JNK activation was only partially increased. Accumulation of a-SMA+ myofibroblasts and collagen deposition were significantly reduced in Ask1-/- UUO. However, cultured WT and Ask1-/- renal fibroblasts showed equivalent proliferation and matrix production, indicating that ASK1 acts indirectly on fibroblasts. Tubular epithelial cells are the main site of p38 activation in the obstructed kidney. Interestingly, angiotensin II but not IL-1 or LPS induced p38 activation and up-regulation of TGF-β1 and MCP-1 production was suppressed in Ask1-/- tubular epithelial cells, demonstrating that diverse stimuli can induce p38 signalling in tubular epithelial cells via different upstream MAP3K family members. In addition, macrophage accumulation was significantly inhibited in Ask1-/- UUO mice.

Conclusions: ASK1 is an important upstream activator of p38 and JNK signalling in the obstructed kidney, and ASK1 as a potential therapeutic target in renal fibrosis.

FR-PO504

Tissue Transglutaminase (TG2), a Partner of Anti-Angiogenic Peptide Endostatin, Participates in the Renal Fibrosis of Aging in Mice

Chi Hua Sarah Lin,[1] Jun Chen,[1] Kei Matsumoto,[1] Arthur J.l. Cooper,[1] Heli Ruotsalainen,[2] Taina Pihlajaniemi,[2] Michael S. Goligorsky.[1] *[1]New York Medical College, NY; [2]Univ of Oulu, Finland.*

Background: We have recently demonstrated (AJP: Heart, 2014) that accumulation of an anti-angiogenic fragment of collagen XVIII, endostatin (Endost), occurs in aging kidneys and may contribute to nephrosclerosis. TG2, a partner of endostatin, is a multifunctional protein richly expressed on the surface of vascular endothelium and in the extracellular matrix, where it cross-links fibronectin, collagen, vitronectin, osteopontin.

Methods: We used mice of different ages (from 2 mo to 24 mo on C57 background) to examine expression of TG2 in the kidneys by western blotting and immunofluorescence microscopy. Similar parameters were studied in collagen XVIII knockout (KO) mice of the same age groups and background.

Results: Endost was overexpressed in aged kidneys and suppressed ex vivo vascular sprouting. This effect was in part attributed to development of endothelial-mesenchymal transition. Immunodetection studies demonstrated upregulated expression of TG2 in aged vis-à-vis young mice, which paralleled increased nephrosclerosis. This was accompanied by enhanced TG2 activity, as judged by the extent of protein cross-linking detected using antibodies against N^{ε}-g-glutamyl-lysine residues in aging kidneys. We next examined the age-dependence of nephrosclerosis and TG2 expression and activity in Endost-deficient collagen XVIII KO mice. The kidneys from these mice showed nephrosclerosis of aging indistinguishable from wild-type mice, but the reduced levels of immunodetectable TG2 and N^{ε}-g-glutamyl-lysine cross-links. When ex vivo angiogenesis assays were performed in Matrigel supplemented with a recombinant TG2, vascular sprouting of aortic rings obtained from aSMA-GFP mice was reduced.

Conclusions: The data confirm progression of nephrosclerosis in aging mice. Data demonstrate that in vitro preconditioning of Matrigel with TG2 reduces vascular sprouting. The findings demonstrate that Endost deficiency reduces age-dependent increase in abundance and activity of TG2.

FR-PO505

STAT3 Acetylation Is Associated with Fibrotic Responses in Renal Tubular Epithelial Cells and the Obstructed Kidney

Limin Lu,[1] Jun Ni,[1] Yang Shen,[1] Zhigang Zhang.[2] *[1]Dept of Physiology and Pathophysiology, Shanghai Medical College, Fudan Univ, Shanggai, China; [2]Dept of Pathology, Shanghai Medical College, Fudan Univ, Shanghai, China.*

Background: Signal transducer and activator of transcription 3 (STAT3) is activated during the progression of renal fibrosis. Janus kinase 2 (JAK2) mediates the effects of angiotensin II (Ang II)-induced STAT3 phosphorylation, while p300 and SIRT1 are involved in regulating STAT3 acetylation. In this study, we explored the correlation between STAT3 acetylation and renal fibrosis.

Methods: Western blot was used to evaluate acteyl-STAT3 (Lys685), phospho-STAT3 (Tyr705), fibronectin, collagen IV, a-smooth muscle actin (a-SMA) and transforming growth factor-b1 (TGF-β1) in renal tubular epithelial cells and kidneys of a murine unilateral ureteral obstruction (UUO) model. Fluorescent immunocytochemistry was used to observe phospho-STAT3 (Tyr705). Transfection of a recombinant palsmid vector carrying p300 gene was used to up-regulate p300 expression. siRNA was used to knockdown p300 expression. Hematoxylin-eosin (HE) and Masson's trichrome staining were used to observe renal interstitial fibrosis.

Results: *In vitro* studies showed that Ang II increased phospho-JAK2 (Tyr1007/1008), phospho-STAT3 (Tyr705), fibronectin, collagen IV and a-SMA. Curcumin, an inhibitor of JAK2 and p300, blocked the effects of Ang II. Inhibition of acteyl-STAT3 (Lys685) by resveratrol, C646 or p300 siRNA decreased Ang II-induced up-regulation of phospho-STAT3 (Tyr705) and consequent fibrotic changes. AG490, a JAK2 inhibitor, repressed Ang II-induced phospho-STAT3 (Tyr705) and fibronectin expression. Both nicotinamide, an inhibitor of SIRTs, and p300 overexpression increased phospho-STAT3 (Tyr705) and the expression of relevant downstream proteins by up-regulation of acteyl-STAT3 (Lys685). *In vivo* studies showed that resveratrol inhibited acteyl-STAT3 (Lys685) and phospho-STAT3 (Tyr705) in obstructed kidneys, accompanied by attenuated expression of fibrotic factors and renal interstitial fibrosis in UUO mice.

Conclusions: These results suggested that STAT3 acetylation plays an important role in the activation of the STAT3 signaling pathway and consequent renal fibrosis.

Funding: Government Support - Non-U.S.

FR-PO506

Nesfatin-1 Ameliorates Unilateral Ureteral Obstruction Induced Renal Fibrosis in Rats Neslihan Tezcan,[1] Zarife Ozdemir,[2] Naziye Ozkan,[3] Dilek Ozbeyli,[2] Aysin Tulunay,[4] Sule Cetinel,[3] Berrak Yegen,[2] Mehmet Koc.[1] *[1]Depts of Nephrology; [2]Physiology; [3]Histology; [4]And Immunology, Marmara Univ, Medical Faculty, Istanbul, Turkey.*

Background: Unilateral ureteral obstruction (UUO) is a well-characterized fibrosis model exhibiting tubular injury and interstitial inflammation in the obstructed kidney. Nesfatin-1 (NS-1) is reported to have anti-inflammatory and antiapoptotic actions in several experimental models. However, the role of NS-1 in the development of fibrosis in a UUO model has not yet been elucidated.

Methods: In male Sprague-Dawley rats, UUO was performed by ligating left ureters. The rats were injected ip with either saline (SL) or NS-1 (10 μg/kg/day) for 7 or 14 days (n=8 in each group). On the 7th or 14th day, obstructed kidneys were removed for the isolation of leukocytes by flow-cytometry and for the assessment of histopathological changes and the determination of glutathione (GSH) levels and myeloperoxidase (MPO) activity.

Results: Renal MPO activity in the SL groups was significantly increased compared to sham-operated (SH) group ($p<0.05$). NS-1 treatment abolished renal MPO activity compared to corresponding SL groups ($p<0.05$). GSH levels, which were reduced in SL groups, were elevated by NS-1 treatment back to the levels observed in SH group. The percentages of lymphocytes and macrophages infiltrating the obstructed kidneys were increased in SL groups compared to SH group ($p<0.05$), while treatment with NS-1 did not prevent lymphocyte/macrophage infiltaration. Apoptosis scores were increased in SL groups compared to SH group ($p<0.05$) and NS-1 treatment for 7 days decreased the apoptosis score ($p<0.05$). The interstitial fibrosis score was increased in the SL groups compared to SH group ($p<0.05$), while treatment with NS-1 decreased the scores in both 7- and 14-day groups ($p<0.05$). a-SMA score was also significantly lower in the 7-day NS-1 treated group ($p<0.05$).

Conclusions: The present data demonstrate that UUO-induced renal fibrosis is ameliorated by NS-1, which appears to act by inhibiting the infiltration of neutrophils and preventing the oxidative stress. These data suggest that NS-1 may have a regulatory role in protecting against obstruction-induced tubular injury.

Funding: Government Support - Non-U.S.

FR-PO507

V-ATPase Promote Renal Tubulointerstitial Fibrosis By Activating (Pro) renin Receptor Qiongqiong Yang,[1,2] Yun Liu,[1,2] Xiaoyan Li,[1,2] Jinjin Fan,[1,2] Xueqing Cao,[1,2] Xueqing Yu.[1,2] *[1]Dept of Nephrology, The First Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Guangdong Provincial Key Laboratory of Nephrology, Guangzhou, Guangdong, China.*

Background: The (pro) renin receptor (P) RR activation plays an important role in the renal fibrosis. The fragment (P) RR, ATP6AP2, is associated with V-ATPase. The V-ATPase is a multi-subunit proton pump involved in diverse and fundamental cellular processes. This study is to investigate whetherV-ATPase be involved in the prorenin-induced renal tubulointerstitial fibrosis by activating (P) RR and its possible mechanism.

Methods: Prorenin, a-SMA, FN, (P) RR and V-ATPase subunits (B2, E and c) were tested on rat UUO models, and NRK-52E cells treated with prorenin in presence f Bafilomycin A1 (1nmol/L), losartan (10umol/L) or PD123319 (10umol/L). The V-ATPase activity was tested by ATPase in an ATP/NADH-coupled assay and proton transport by Na^+-independent intracellular pH recovery rate after acid load. The interaction of (P) RR and V-ATPase subunits were investigated by co-immunoprecipitates (IP), co-immunofluorescence (IF), and siRNA mediated (P) RR or B2 subunit knockdown.

Results: UUO was shown as significant upregulations of prorenin, (P) RR, V-ATPase subunits, a-SMA and FN in areas of tubulointerstitial injury, and the marked colocalization of the (P) RR and B2 subunit. Prorenin treatment resulted in upregulations of a-SMA,FN, (P) RR, and V-ATPase subunits and activity of NRK52E cells in a dose- and time-dependent manner. Furthermore, Bafilomycin A1 partially block the expression of (P) RR, FN and a-SMA, which was induced by prorenin. Co-IP and co-IF results showed that V-ATPase subunit B2 could bind to (P) RR, which was upregulated after prorenin stimulation. Si RNA (P) RR knockdown partially reduced prorenin induced FN and a-SMA expression, as well as the increase in V-ATPase activity and subunits expression. Meanwhile, siRNA B2 subunit knockdown also partially prevent FN, a-SMA and (P) RR expression induced by prorenin.

Conclusions: V-ATPase may promote renal tubulointerstitial fibrosis by activation of (P) RR and the V-ATPase B2 subunit might act as a key player in the process. (Supported by China National Natural Science Foundation 81370786).

Inhibitory Effect of the Chromatin Histone H3-Lysine 4 Methyltransferase (SET7/9) on the Tubulointerstitial Fibrosis Kensuke Sasaki, Ayumu Nakashima, Shigehiro Doi, Takao Masaki. *Nephrology, Hirohima Univ Hospital, Hiroshima, Japan.*

Background: Recent study showed that TGF-β1 increases H3K4 methyltransferase (SET domain containing lysine methyltransferase 7,SET7/9), playingan important role in production of exracellular matrix proteins (ECM). In this study, we investigated the signaling pathway of TGF-β1-induced SET7/9 expression and inhibitory effect of SET7/9 on renal fibrosis in unilateral ureteral obstruction (UUO) mice.

Methods: C57BL/6J mice underwent UUO and the gene expressions of histone modification enzymes were assessed by PCR array. In UUO mice, expressions of SET7/9, methylated H3K4, a-smooth muscle actin (aSMA), and collagen 1 were evaluated by western blotting (WB) and/or immunohistochemistry (IHC) with the administration of TGF-β1-neutralizing antibody, SET7/9 siRNA or Sinefungin (10 mg/kg/day). For *in vitro* experiment, rat renal tubular cells (NRK52E) and rat kidney fibroblasts cells (NRK49F) were used. TGF-β1-iduced expressions of SET7/9, methylated H3K4, aSMA were evaluated by WB with the pretreatment of Smad3 siRNA or Sinefungin (0.5-1.0 ng/mL). In addition, histologic analysis was performed to examine whether SET7/9 correlate with renal fibrosis on human kidney biopsy specimens.

Results: 1) PCR Array detected that SET7/9 gene expression was significantly increased at day 7 after UUO. 2) UUO-induced SET7/9 expression was inhibited by TGF-β1-neutralizing antibody. 3) TGF-β1-induced SET7/9 upregulation was inhibited by Smad3 siRNA treatment in NRK52E. 4) Administration of SET7/9 siRNA improved an increase of aSMA expression in UUO mice. 5) In human kidney biopsy specimens, SET7/9 expression was positively correlated with the degree of interstitial fibrosis ($r = 0.537$, $P < 0.05$). 6) Intraperitoneal injection of Sinefungin suppressed inductions of aSMA and collagen 1 in UUO mice. Furthermore, UUO-induced H3K4 mono-methylation was significantly suppressed by Sinefungin. 7) Sinefungin attenuated TGF-β1-induced aSMA as well as H3K4 mono-methylation in both NRK52E and NRK49F.

Conclusions: Sinefungin ameliorates renal fibrosis by inhibiting H3K4 mono-methylation.

FR-PO509

Activation of eNOS/NO Signaling Attenuates Renal Interstitial Fibrosis in Mice by the Increase of β-Catenin Degradation Hiroyuki Kadoya, Minoru Satoh, Seiji Itano, Atsushi Uchida, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Activation of the wnt/β-Catenin signaling pathway has been demonstrated to play an important role in the development of organ fibrosis. On the other hands, it is well known that systemic endothelial dysfunction is associated with chronic kidney disease. However, the role of the renal endothelium in the initiation and the progression of renal fibrosis remain largely elusive. We hypothesized that protein kinase G (PKG) activation by nitric oxide (NO) could phosphorylate β-Catenin and downregulate the β-Catenin signaling on the process of renal fibrosis.

Methods: WeusedCOS-7 cells and evaluated the effect of PKG activation on β-Catenin phosphorylation. Under the proteasome inhibition with MG132, cells were treated with 8Br-cGMP and mifepristone (Mfp) to activate PKG, and phosphorylated β-Catenin was evaluated by western blotting. We used wild type (WT) and endothelial NO synthase (eNOS)-deficient (eNOSKO) mice. GSK-3b inhibition by lithium (Li) can activate the canonical Wnt pathway by increasing β-Catenin. We administrated Li in drinking water to both WT and eNOSKO mice for 4 weeks. Some eNOSKO mice were treated with Bay41-2272 (10 mg/kg/day, i.p) as a soluble guanylate cyclase (sGC) stimulator to determine the role of the NO-sGC-PKG activation on fibrosis process.

Results: In vitro experiments, phosphorylation of β-Catenin was increased by activation of NO-PKG pathway. PKG facilitated ubiquitination of β-Catenin and promoted degradation of β-Catenin, resulting in reduced cytoplasmic β-Catenin levels. In vivo experiments, no renal fibrotic changes were observed in WT-Li compared to WT-vehi group. However, renal fibrosis was exacerbated in eNOSKO-Li compared with WT-Li group. Pro-fibrotic factors were also more prevalent in kidney from eNOSKO-Li compared with WT-Li mice. The protein expression of β-Catenin was remarkably increased in eNOSKO-Li mice. These changes were suppressed in eNOSKO-Li/Bay mice.

Conclusions: NO-PKG signaling pathway could counteract the β-Catenin accumulation by wnt activation. Activation of eNOS signaling would protect from renal interstitial fibrosis.

FR-PO510

Increased Synthesis of CD44s and Its Variants in Kidney Fibrosis of Lupus Nephritis Daniel Tak Mao Chan, Wan Wai Tse, Mel Chau, Susan Yung. *Dept of Medicine, The Univ of Hong Kong.*

Background: Lupus nephritis is characterized by immune-mediated renal injury leading to glomerular and tubulo-interstitial fibrosis. CD44 is the major cell surface receptor for hyaluronan (HA) which has been implicated in inflammatory and fibrotic processes. During pathological conditions, splice variants of CD44 may also be induced. We investigated renal expression of standard CD44 (CD44s) and its variants in patients and mice with lupus nephritis, and their role in renal fibrosis.

Methods: CD44s, CD44v3 and CD44v6 expression was determined in kidney biopsies from patients with diffuse proliferative lupus nephritis and normal kidney tissue using cytochemical staining. Expression of CD44s, CD44v3 and CD44v6 was examined in NZB/W mice during disease progression. Mesangial cells were isolated from the renal cortex of NZB/W mice to investigate the mechanisms of CD44 synthesis.

Results: There was intense staining for CD44s and its variants in the glomeruli and renal tubules in kidney biopsies from patients with lupus nephritis, compared with weak expression in controls. CD44v3, but not CD44s and CD44v6, was also noted in cells infiltrating the glomerulus, peri-glomerular area, and interstitium. Compared to mice before the development of nephritis, murine renal cortical CD44s gene expression was significantly higher during active nephritis (proteinuria >3g/l), and continued to increase during progressive glomerular and tubulo-interstitial fibrosis ($P<0.01$ and $P<0.001$ respectively). CD44s, CD44v3 and CD44v6 expression in NZB/W mice was associated with glomerular and tubulo-interstitial fibrosis. Glomerular CD44s co-localized with collagen deposition, while tubulo-interstitial CD44s expression was associated with inflammatory

cell infiltration, tubular atrophy and tubulo-interstitial fibrosis. CD44s, CD44v3 and CD44v6 were constitutive expressed in mesangial cells from NZB/W mice. Stimulation of mesangial cells with HA, IL-6, IL-1b, TNF-a, but not IFN-g, increased CD44s and CD44v3 but not CD44v6 synthesis.

Conclusions: Our data suggested a role of CD44s and its variants in renal fibrosis due to lupus nephritis, and the modulatory effect of pro-inflammatory cytokines on their expression.

GQ5 Hinders Renal Fibrosis in Obstructive Nephropathy by Selectively Inhibiting TGF-β1-Induced Smad3 Phosphorylation Jing Nie, Jun Ai, Fan Fan Hou. *Div of Nephrology, Nanfang Hospital, Guangzhou, Guangdong, China.*

Background: The TGF-β1, *via* its canonical, Smad-dependent signaling, plays a central role in the pathogenesis of renal fibrosis. This pathway has been recognized as a potential target for anti-fibrotic therapy. *Resina toxicodendri* is the dried resin secreted by *Toxicodendron vernicifluum* and has been used as an anti-inflammatory and anti-scarring agent in traditional Chinese medicine for centuries. In the previous study, we isolated and purified the major component of *Resina toxicodendri* GQ5, a small molecular phenolic compound.

Methods: We investigated the effect of GQ5 on renal interstitial fibrosis in unilateral ureteral obstruction (UUO) kidneys *in vivo* and in TGF-β1 stimulated renal proximal tubular cells (NRK52E) and renal fibroblast cells (NRK49F) *in vitro*. Western blot, immunohistochemical staining, and/or Real-time RCR were performed to detect the expression of α-smooth muscle actin (α-SMA), collagen I, fibronectin, p-Smad3, and p-Smad2. Immunoprecipitation was performed to detect the binding of Smad3 with the TGF-β type I receptor (TβRI). Immunofluorescence staining was performed to detect the nuclear translocation of Smads complex.

Results: In TGF-β1 stimulated NRK52E cells and NRK49F cells, GQ5 blocked the binding of Smad3 with the TbRI, inhibited subsequent phosphorylation of Smad3, reduced nuclear translocation of Smads complex, and suppressed the transcription of major fibrotic genes such as α-SMA, collagen I and fibronectin. Most importantly, intraperitoneal administration of GQ5 hindered the progression of renal fibrosis induced by UUO. Treatment with GQ5 selectively inhibited Smad3 phosphorylation in UUO kidneys, suppressed renal expression of α-SMA, collagen I and fibronectin, and resulted in impressive renal protection after obstructive injury. Late administration of GQ5 also effectively attenuated fibrotic lesions in obstructive nephropathy.

Conclusions: In conclusion, GQ5 hinders renal fibrosis byselectively inhibiting TGF-β1-induced Smad3 phosphorylation and might have therapeutic potential for intervention of renal fibrosis.

FR-PO512

Identification and Clinical Implication of Indole Derivatives Having Anti-Inflammatory and Antifibrotic Effects Hisato Shima, Eikan Mishima, Yasutoshi Akiyama, Takehiro Suzuki, Chitose Suzuki, Sadayoshi Ito, Takaaki Abe. *Tohoku Univ, Japan.*

Background: Renal fibrosis is a common cause of ESRD. Renal inflammation is one of the known factors in the progression of renal fibrosis. Recently, we have identified certain endogenous compounds that potently ameliorate TNF-a-induced Epo suppression. The aim of this study was to investigate the effect of these compounds on renal inflammation and fibrosis.

Methods: 1. Cell viability and fibroblastic formation was analyzed using the rat renal fibroblast cell line NRK49F.

2. To examine the antifibrotic effect, Ureteral Unilateral Obstruction (UUO) was induced in Male C57BL/6 mice. Tissue fibrosis, inflammation were detected by Elastica Masson staining, Sirius red staining and F4/80 staining, respectively.

3. RNA expressin was analyzed by QT-PCR.

4. Signal transduction pathways were analyzed by a Cignal Transduction 45 Pathway Arrays reporter assay kit™ (Qiagen), STAT3 a-screening and STAT3 reporter assay.

Results: 1. In NRK49F cells, compound #35 inhibited TGF-β_1-induced fibronectin and collagen type 1 mRNA upregulation without changing cellular viability.

2. In the UUO model, the fibrotic area and F4/80 positive area were increased in the kidney. After 4 day administration of compound #35, these areas were significantly reduced (Figure 1).

3. Compound #35 significantly suppressed UUO-induced fibronectin, collagen type 1, TGF-β_1, F4/80 and TNF-a mRNA (Figure 2).

Figure 1.

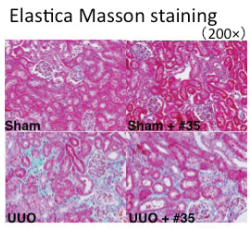

Figure 2.

4. By Signal Transduction analyses, we found that the STAT pathway was downregulated by 50% by compound #35. In addition, compound #35 inhibited STAT3 pathway in the same range as S3I-201, a representative STAT3 inhibitor.

Conclusions: These results demonstrate that compound #35 has anti-inflammatory and antifibrotic effects *in vitro* and *in vivo*. Therefore, compound #35 may be a novel tool for developing drugs that attenuate renal fibrosis and CKD.

FR-PO513

Smad Anchor for Receptor Activation (SARA) Mediates Anti-Fibrotic Activity of sKlotho Constance Runyan,[1] Tomoko Hayashida,[1] Youhua Liu,[2] Lili Zhou,[2] H. William Schnaper.[1] [1]*Pediatrics, Northwestern Univ, Chicago, IL;* [2]*Pathology, Univ of Pittsburgh, Pittsburgh, PA.*

Background: The secreted form of Klotho (sKlotho), which is downregulated in progressive kidney fibrosis, has anti-fibrotic properties that are not fully understood. Previously, we demonstrated that expression of the scaffold/adaptor protein, SARA, maintains human proximal tubular (HKC) epithelial cell phenotype, and may be protective against fibrosis. TGF-β-stimulated fibrogenesis in HKC, characterized by increased expression of type-I collagen and smooth-muscle a-actin, is prevented by overexpression of SARA. Here, we report that the antifibrotic action of sKlotho may result from its protection of SARA expression.

Methods: Kidney fibrosis in the unilateral ureteral obstruction (UUO) was assessed by pathology and qPCR. Overexpression or knockdown was performed in cultured HKC using plasmid expression constructs or lentiviral shRNA vectors.

Results: *In vivo*, kidneys from mice subjected to UUO showed >90% reduction in SARA expression. Ectopic expression of sKlotho, which greatly ameliorated renal fibrosis, was associated with partly restored SARA expression. Kidneys from Klotho hypomorph (kl/kl) mice showed a strong correlation between Klotho and SARA expression (r^2=0.892). *In vitro*, sKlotho overexpression or treatment with recombinant sKlotho increased HKC cell expression of SARA, with or without TGF-β in the culture. sKlotho inhibits TGF-β signaling at least in part by disrupting TGF-β interaction with its receptor. However, while TGF-β decreased SARA promoter activity, sKlotho did not affect the SARA promoter. Therefore it is unlikely that sKlotho increases SARA expression solely by interfering with TGF-β-stimulated SARA downregulation. While sKlotho protected against TGF-β-mediated EMT in control cells, it did not do so in SARA knockdown cells. Thus, SARA is a likely downstream antifibrotic effector of sKlotho.

Conclusions: Together, our data describe a previously unknown function of sKlotho in modulating SARA expression, and suggest that the antifibrotic action of sKlotho is mediated at least in part by SARA, both *in vitro* and *in vivo*.

FR-PO514

SARA (Smad Anchor for Receptor Activation) Inhibits Fibrosis by Suppressing β-Catenin Activity Constance Runyan, H. William Schnaper. *Pediatrics, Northwestern Univ, Chicago, IL.*

Background: TGF-β/Smad and Wnt/β-Catenin signaling are critical fibrogenic mediators in progressive CKD. Progression appears to require cross-talk between these two pathways. Recent reports suggest that association of Smad3, β-Catenin and the transcriptional activator CBP may be critical for TGF-β-induced phenotypic changes associated with tubulointerstitial fibrosis, but dispensable for its anti-inflammatory effect. How β-Catenin is distributed to different cellular pools to regulate specific fibrogenic interactions is poorly understood. Our laboratory has studied the scaffold/adaptor protein, SARA (Smad Anchor for Receptor Activation). We have reported that high SARA expression protects renal tubular epithelial cells from TGF-β-stimulated expression of smooth muscle a-actin and collagen, whereas loss of SARA promotes fibrosis without requiring TGF-β. Here, we demonstrate that SARA also regulates fibrogenic signaling by β-Catenin.

Methods: Whole-cell and fraction lysates of HKC8 cells were examined by immunoprecipitation, western blot, or promoter/reporter assay.

Results: High levels of SARA expression inhibited β-Catenin nuclear accumulation and downstream transcriptional activity, either basally or induced by TGF-β or Wnt3a. As demonstrated by co-immunoprecipitation, SARA interacts directly with β-Catenin, and overexpression of SARA enhances that interaction. One proposed mechanism of TGF-β-mediated, β-Catenin-dependent fibrogenesis is TGF-β-induced dissociation of E-cadherin/β-Catenin/a-catenin-containing adherens junctions. We detected high levels of both SARA and β-Catenin in Triton-X-100 insoluble cell lysates, which include the adherens junction membrane compartment. SARA knockdown reduced β-Catenin association with this fraction and enhanced nuclear association between Smad3 and β-Catenin. Therefore, levels of SARA may control levels of cellular β-Catenin, its availability and localization, and the localization of Smad3 to either allow or inhibit Smad3/β-Catenin complex formation.

Conclusions: Together our data suggest that by acting as a regulator of both Smad2 versus Smad3 and β-Catenin signaling, SARA has multiple inhibitory effects on TGF-β- or Wnt-induced fibrogenesis.

Inhibition of G9a Attenuated Renal Fibrosis and Retained Klotho Expression in UUO Mice Taisuke Irifuku, Shigehiro Doi, Kensuke Sasaki, Ayumu Nakashima, Takao Masaki. *Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.*

Background: Histone H3K9 modification reportedly plays an important role in the development of the epithelial mesenchymal transition and transcriptional activity of the klotho gene in cancer cells. In this study, we investigated the inhibitory effects of H3K9 methyltransferase (G9a) on renal fibrosis and klotho expression.

Methods: C57BL/6J mice underwent unilateral ureteral obstruction (UUO) and expression of G9a, methylated H3K9, a-smooth muscle actin (aSMA), collagen 1 and klotho was evaluated by Western blotting (WB) and/or immunohistochemistry with administration of TGF-β1-neutralizing antibody, G9a siRNA or BIX01294 (200mg). For in vitro experiments, rat renal tubular cells (NRK52E), rat kidney fibroblasts (NRK49F) and human renal tubular cells (HK-2) were used and TGF-β1-induced expression of G9a, methylated H3K9, aSMA and klotho was assessed by WB with pretreatment with Smad3 siRNA or BIX01294. In addition, histologic analysis was performed to examine whether G9a levels correlated with renal fibrosis or klotho expression in human kidney biopsy specimens.

Results: 1) UUO-induced G9a expression was inhibited by TGF-β1-neutralizing antibody. 2) TGF-β1-induced G9a upregulation was inhibited by Smad3 siRNA in NRK52E. 3) Administration of G9a siRNA increased aSMA and reduced klotho expression in UUO mice. 4) Intraperitoneal injection of BIX01294 not only suppressed induction of aSMA and collagen 1, but also retained klotho expression in UUO mice. Moreover, UUO-induced H3K9 mono-methylation (me1) was significantly suppressed by BIX01294. 5) BIX01294 suppressed TGF-β1-induced aSMA as well as H3K9me1 in NRK49F. 6) Pretreatment with BIX01294 reduced klotho expression and H3K9me1 by TGF-β1-stimulation of HK-2. 7) In human kidney biopsy specimens (n = 36), G9a expression was positively correlated with interstitial fibrosis ($r = 0.69$, $P < 0.05$), whereas it was inversely correlated with klotho expression ($r = -0.44$, $P < 0.05$).

Conclusions: TGF-β1-induced G9a plays an important role in the progression of renal fibrosis and reduced klotho expression through H3K9me1.

Molecular Mechanism of Hypoxia-Inducible Factor (HIF) Action in Fibrogenesis Bethany Baumann, Tomoko Hayashida, H. William Schnaper. *Pediatrics, Northwestern Univ, Chicago, IL.*

Background: Although hypoxia has been identified as a progression factor for CKD, the pro-fibrotic actions of HIF are not well understood. We have found that TGF-β increases HIF expression in normoxia, and that HIFs contribute significantly to normoxic TGF-β induction of type-I collagen, suggesting a key role for HIFs in fibrotic kidney disease regardless of oxygen tension, such as in glomerulosclerosis.

Methods: The mechanism of collagen1 transcriptional regulation by HIF-a was investigated in renal epithelial cells and primary human mesangial cells. HIF-1a and HIF-2a were manipulated by siRNA or overexpression of non-degradable (ND) HIF-a isoforms and deletion mutants. We evaluated collagen1 protein, mRNA, and COL1A2 proximal promoter reporter construct (COL1A2-luc) activity. Site-directed mutagenesis identified key sites in this promoter. HIF effects on Smad3 activity were evaluated with Smad3 responsive reporter (SBE-luc) and Smad3-Gal4 transactivation assays.

Results: HIF-a siRNA reduced TGF-β-induction of collagen1 protein, mRNA and COL1A2-luc activity. ND HIF-a expression increased COL1A2-luc activity. Site-directed mutagenesis of COL1A2-luc identified a functional hypoxia response element (HRE); binding of HIF-1a to this HRE was confirmed by DAPA assay. ND HIF-2a was much more robust in activating COL1A2-luc, and enhanced its transcription even when the HRE was mutated. ND HIF-2a, but not ND HIF-1a, significantly increased Smad3 activity in SBE-luc and Smad3-Gal4 transactivation assays. No physical interaction was detected between Smad3 and HIF-2a, and it was determined that both the transactivational and DNA-binding domains of ND HIF-2a are required for its effects on Smad3 and collagen1.

Conclusions: HIF-1a and particularly HIF-2a are likely key non-canonical mediators of the response to TGF-β, and of collagen1 deposition in CKD, regardless of oxygen tension. HIF-2a may act by inducing an additional, non-HIF, translation factor. These findings are consistent with our previous report that HIF-2 targets are upregulated in glomeruli of mice with glomerulosclerosis (AJP-Renal 305: F1312, 2013) and suggest that HIF regulation is a promising target for treating renal fibrosis.

Low-Dose Paclitaxel Ameliorates Renal Fibrosis by Suppressing Transforming Growth Factor-β1-Induced Plasminogen Activator Inhibitor-1 Signaling Cascade Eun Sook Jung,[1] Jeonghwan Lee,[2] Nam Ju Heo,[1] Sejoong Kim,[1] Kwon Wook Joo,[1] Jin Suk Han.[1] *[1]Internal Medicine, College of Medicine, Seoul National Univ, Seoul, Korea; [2]Internal Medicine, Hallym Univ Hangang Sacred Heart Hospital, Seoul, Korea.*

Background: Plasminogen activator inhibitor-1 (PAI-1), a major downstream target of transforming growth factor-b1 (TGF-β1), plays an important role in the pathogenesis of renal fibrosis. SMAD and non-SMAD pathways including mitogen-activated protein kinase and p53 are required for PAI-1 induction by TGF-β1. Previous reports have indicated that stabilizing microtubules with paclitaxel can modulate TGF-β/SMAD signaling. We investigated the effects of low-dose paclitaxel on renal fibrosis and attempted to elucidate the potential mechanism involved.

Methods: Male Spraue-Dawley rats were divided into 4 groups (n=6 per group): sham, sham/paclitaxel, UUO (unilateral ureteral obstruction) and UUO/paclitaxel. The rats received intraperitoneal injection of paclitaxel at a dose of 0.3 mg/kg twice a week and were sacrificed at day 7 after UUO or sham operation. Histological changes were examined using periodic acid-Schiff and Masson's trichrome staining. TGF-β1-induced PAI-1 signaling cascade, status of various extracellular matrix proteins and epithelial-mesenchymal transition markers in renal cortex were evaluated by western blotting.

Results: UUO injury induced tubular damage, excessive interstitial collagen deposition and increased protein expression of collagen I, fibronectin and a-smooth muscle actin. Administration of low-dose paclitaxel markedly suppressed all these fibrotic responses and enhanced E-cadherin expression levels. Low-dose paclitaxel was also effective in suppressing UUO-induced expression of PAI-1 and its E-box-binding protein, upstream stimulatory factor-2. Furthermore, the levels of TGF-β1 and the phosphorylation of SMAD2/3, p53 and ERK1/2 were substantially increased by UUO, and they were all significantly attenuated by low-dose paclitaxel.

Conclusions: Our data demonstrate that low-dose paclitaxel inhibits TGF-β1-induced PAI-1 signaling cascade and renal fibrosis. Therefore, low-dose paclitaxel may have potential as a therapeutic target for chronic kidney disease.

FR-PO518

Targeting N-Ras Reduces TGFβ1 Expression and Collagen Deposition in a Murine Model of Tubulointerstitial Fibrosis Subash Somalanka,[1] Stephen Sampson,[2] Tracy White,[2] Mysore K. Phanish,[1] Claire C. Sharpe,[3] Mark E. Dockrell.[1] *[1]South West Thames Inst for Renal Research; [2]Dept of Histopathology, Epsom & St. Helier Univ Hospital NHS Trust; [3]King's College London, United Kingdom.*

Background: Tubulointerstitial fibrosis (TIF) is a hallmark of progressive chronic kidney disease. Our group has published evidence that N-Ras is an important regulator of renal fibrosis in a human cell model. Antisense Oligonucleotides (ASO) are effective in targeting Ras GTPases in renal disease, as shown previously by Wang et al in the unilateral ureteric obstruction model. In a parallel abstract, we have demonstrated that induction of connective tissue growth factor (CTGF) and autoinduction of TGFβ1 are dependent on N-Ras in a murine renal cell culture. Hence, we extended that work to a mouse model of chronic folic acid induced nephropathy (CFAIN).

Methods: CFAIN was attained in CD1 male outbred mice by an injection of folic acid (FA, 125mg/kg) or vehicle (V) on d 1 and 21. Mice were culled at d 84. RNA extracted from kidneys was probed for Ras isoforms, CTGF, TGFβ1, fibronectin (FN), Collagen (Col) 1a2 and a-SMA. Paraffin sections were stained with Picro-Sirius Red (PSR). TIF was blindly scored by a histopathologist. 6 ASO were screened in healthy mice to assess their efficacy and toxicity with renal N-Ras knockdown assessed by qPCR and toxicity monitored by transaminases and BUN assay. Selected ASO3 and 4 were injected over 7 weeks after d 35 in CFAIN. PSR stained kidney tissue was analysed by NIS-Elements BR 3.1 software.

Results: Cortical TIF (10 – 15 %) was observed in the CD-1 mice after d 84 with increased mRNA expression of CTGF, FN, Col1a2 and TGFβ1. Renal impairment at day 84 was assessed by BUN ($p=0.056$) and Cystatin C ELISA ($p=0.02$) for V versus FA groups. ASO knockdown of N-Ras mRNA was significant ($p<0.001$). No hepatotoxicity and nephrotoxicity was seen with ASO. ASO3 inhibited Col1a2 ($p=0.024$), TGFβ1 ($p=0.006$) and collagen deposition ($p<0.01$). CTGF and FN were not affected by N-Ras ASO. No significant improvement in renal function was noted in N-Ras treated mice.

Conclusions: ASO is safe and effective in mice. Selective N-Ras knockdown with ASO3 has inhibited TGFβ1 and Col1a2 expression but interestingly did not reduce CTGF.

FR-PO519

Construction and Verification of a Chimeric Small Molecule which Induces the Degradation of Smad3 via Ubiquitin Proteasome System Xin Wang, Jinjin Fan, Xiaoyan Li, Xueqing Yu. *Nephrology, The First Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Smad3 is a key signal protein in renal fibrosis. Protein-targeting chimeric molecule (Protac) is a chimeric small molecule targeting proteins for degradation via ubiquitin proteasome system. Typically it's composed of 3 components: an E3 ligase recognition motif, known as hydroxylated pentapeptide of hypoxia-inducible factor-1a that would recruit the activity of Von–Hippel–Lindau (VHL) ubiquitin ligase (E3), linker, and ligand (protein recognition). We aimed to design a new Protac to prevent renal fibrosis by targeting Smad3 protein.

Methods: Computer aided drug design technic was utilized to find the specific ligand targeting Smad3. Surface Plasmon Resonance (SPR) was applied to choose the best fit one from screening results. The synthesized Protac structure validity was analyzed by two stage mass spectrometry. Protac' specificity to VHL (E3 ligase) was proved by 2 kinds of cell lines: 786-0 (does not express VHL) and ACHN (express VHL) *in vitro* assay. The ubiquitination and degradation of Smad3 was detected by Western blot (WB).

Results: (1).13 small molecular compounds (SMC) were got from the Enamine library by using GLIDE molecular docking program based on the active site of Smad3 (depression area where Phe247 and His248 located). (2).SPR results showed that 8# SMC (EN300-72284) had the best combination with Smad3 (K_D=4.547×10^{-5} M). (3). Protac were synthesized by Shanghai science peptide biological technology co.,ltd and Mass Spectrometry showed the synthesized Protac had the right total and seperate molecular weights of peptides. (4).WB showed Smad3 can be degraded by Protac plus whole cell lysate of ACHN but not 786-0. Only the degradation not the ubiquitination of Smad3 can be inhibited by proteasome inhibitor MG132.

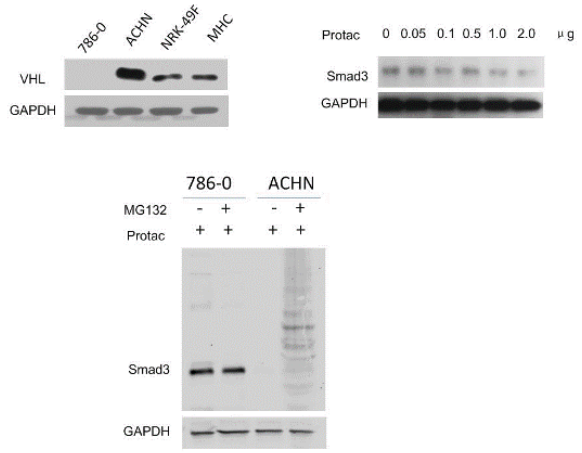

Figure 1: The ubiquitination and degradation of Smad3 (Western Blot)

Conclusions: The new Protac can target Smad3 for ubiquitination and degradation.

Funding: Government Support - Non-U.S.

Anti-microRNA21 Therapy on Top of ACE-Inhibition Enhances Nephroprotection in a COL4A3-Knockout Mouse-Model for Alport Syndrome Diana Rubel,[1] Deidre Mackenna,[2] Oliver Gross.[1] *[1]Clinic fpr Nephrology and Rheumatology, Univ Medicine Goettingen, Goettingen, Germany; [2]Regulus Therapeutics, San Diego, CA.*

Background: COL4A3 -/- Alport mice serve as animal model for progressive renal fibrosis. Testing the hypothesis of micro-RNA21 (miR21) contributing to the progression of tubulointerstitial damage we investigated the nephroprotective effects of anti-miR21 therapy in combination with ACE-inhibition in these mice.

Methods: 64 COL4A3 -/- mice were treated in 4 groups: (miR21) with anti-miR21 compound 25 mg/kg, or (PLAC) vehicle s.c. twice a week, (ACE+PLAC) with Ramipril 10 mg/kg/day p.o. plus vehicle, and (miR21+ACE) with anti-miR21 plus Ramipril. Ramipril monotherapy started preemptively in week 4, anti-miR21 monotherapy started late in week 6 in animals already showing renal damage (proteinuria >1g/l, mild renal fibrosis). In the miR21+ACE-group, Ramipril was started in week 4 and anti-miR21 was applied in 6 week old animals and lasted until death from renal failure. Six animals were sacrificed after 7.5 and 9.5 weeks, respectively, and kidneys were further investigated using histological, immunohistological and Western blot techniques. Survival until end stage renal failure was determined in the remaining animals.

Results: The combination of anti-miR21 therapy on top of ACE-inhibition MiR21+ACE significantly prolonged median lifespan by more than 30% compared to ACE-monotherapy. The effect of anti-miR21 monotherapy was restricted to tubular accumulation of extracellular matrix and renal scarring in our rather rapid progressive animal model (SvJ/129 background). Dual therapy with miR21 on top of ACE showed the best effect in immunohistochemistry.

Conclusions: In COL4A3 -/- Alport mice, the anti-miR21 therapy in combination with ACE-inhibition reduces fibrosis and prolongs survival compared to ACE-monotherapy. Despite the late onset of miR21 therapy, this nephroprotective effect is significant on top of early-on ACE-inhibition and presents a promising new therapy for patients with Alport syndrome.

FR-PO521

Inhibitory Effect of Vascular Endothelial Growth Factor-C on Renal Interstitial Inflammation and Fibrosis through Lymphangiogenesis in Mouse Unilateral Ureteral Obstruction Shoko Hasegawa,[1] Toshiaki Nakano,[1] Akihiro Tsuchimoto,[1] Kumiko Torisu,[1] Kazuhiko Tsuruya,[2] Takanari Kitazono.[1] *[1]Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: The interaction between lymphangiogenesis and renal injury has been shown in chronic kidney disease (CKD); however, the precise role of lymphangiogenesis in renal injury remains unknown. The lymphatic network is responsible for the removal of interstitial protein and fluid. In the present study, we investigated the interaction between lymphangiogenesis and renal interstitial inflammation and fibrosis using unilateral ureteral obstruction (UUO) model mice.

Methods: Seven-week-old male C57BL6 mice were divided into the 3 groups; the control mice (Con, n=5), UUO mice (UUO, n=5), and UUO mice administrated vascular endothelial growth factor-C (VEGF-C), an inducer of lymphangiogenesis (UUO+VEGF-C, n=5). VEGF-C was administered at a dose of 100 μg/kg/day using osmotic pumps for 14 days. We investigated lymphangiogenesis (anti-LYVE-1 immunostaining), interstitial fibrosis (Sirius red staining), expression levels of fibrosis-related gene [Collagen I mRNA and a-smooth muscle actin (a-SMA) protein], and macrophage infiltration (anti-F4/80 immunostaining) in each group.

Results: In UUO mice, along with progression of interstitial fibrosis, the density of lymph vessels, the levels of VEGF-receptor 3 (VEGF-R3) mRNA, Collagen I mRNA, and a-SMA protein, and macrophage infiltration increased with time in the obstructed kidney. In UUO+VEGF-C mice, the density of lymph vessels (1.21-fold, p=0.3) and the level of VEGF-R3 protein (2.18-fold, p<0.05) increased, whereas the levels of Collagen I mRNA (0.45-fold, p<0.05) and aSMA protein (0.68-fold, p<0.05), and interstitial fibrosis (0.53-fold, p<0.01) decreased compared with UUO mice.

Conclusions: In UUO mice, administration of VEGF-C suppressed renal interstitial inflammation and fibrosis through lymphangiogenesis, suggesting that lymphatic vessels might have an inhibitory effect on renal interstitial inflammation and fibrosis in the progression of CKD.

FR-PO522

A Novel Dipeptidyl Peptidase IV Inhibitor DA-1229 Ameliorates Tubulointerstitial Fibrosis in Cyclosporine A-Induced Nephrotoxicity in Mice Dae R. Cha,[1] Sung Jin Kim,[1] Jung Eun Kim,[1] Jungyeon Ghee,[1] Hye Kyung Song,[1] Hye Sook Min,[1] Mi Jin Lee,[1] Jin Joo Cha,[1] Young Sun Kang,[1] Ji Eun Lee,[2] Hyunwook Kim,[2] Mihwa Lee,[1] Jee-Young Han.[3] *[1]Nephrology, Korea Univ, Ansan, Korea; [2]Nephrology, Wonkwang Univ, Sanbon, Korea; [3]Pathology, Inha Univ, Incheon, Korea.*

Background: Dipeptidyl peptidase IV (DPPIV) is a peptidase that are involved in glucose metabolism, inflammation, cell migration, and cell differentiation. Although DPPIV is highly expressed in proximal renal tubular cells, the role of DPPIV inhibition in renal disease is not fully understood. The aim is to investigate the effects of DA-1229, a newly developed DPP IV inhibitor, on cyclosporine A-induced nephropathy model.

Methods: Male ICR mice at 6 wks were treated with a low-salt diet (0.01% Na), and mineral oil (vehicle) containing CyA at 30mg/kg/day for 4weeks. Experimental groups were divided into four groups; vehicle (n=10), CyA (n=10), DA-1229 (300mg/kg/day) (n=10) and CyA+DA-1229 (n=10).

Results: DPP-4 activities in plasma and kidney did not significantly different between control group and CyA group, but DPP-4 activity in plasma and kidney showed markedly suppressed in DA-1229 treatment group. Serum creatinine level was significantly increased in CyA group, and DA-1229 treatment restored serum creatinine level to control group. There were no significant difference in food intake, water intake, urine volume and systolic blood pressure among groups. Urinary protein and albumin excretion were significantly increased in CyA group at 4weeks, and those were markedly decreased after DA1229 treatment. DA-1229 treatment also significantly suppressed urinary levels of 8-isoprostane, an oxidative stress marker in kidney. Additionally, DA-1229 treatment improved pro-fibrotic molecule synthesis including CTGF, type I collagen and a-SMA. In addition, DA-1229 also markedly suppressed renal expression of inflammatory cytokines including IL-1b, MCP-1 and TLR4. Furthermore, DA1229 treatment decreased macrophage infiltration determined by F4/80 staining.

Conclusions: These results suggest that a novel DPP IV inhibitor, DA-1229 provide renal protective effects in animal model of CyA-induced nephrotoxicity through anti-inflammatory and anti-fibrotic mechanisms.

FR-PO523

Glucose-Regulated Protein 78 Modulates Renal Interstitial Fibrosis in the Angiotensin II/DOCA Salt Model of Chronic Kidney Disease

Zahraa Mohammed-Ali,[1,2] Chao Lu,[1,2] Edward G. Lynn,[1,2] Kjetil Ask,[1,2] Jeffrey G. Dickhout.[1,2] *[1]Medicine, McMaster Univ, Hamilton, ON, Canada; [2]St. Joseph's Healthcare, Hamilton, ON, Canada.*

Background: Endoplasmic reticulum (ER) stress is a pathophysiological condition associated with proteinuria and renal interstitial fibrosis during the development of chronic kidney disease (CKD). The ER stress regulator, Glucose-regulated protein (GRP) 78, is induced in kidneys from patients with nephrotic syndrome and glomerular nephritis as well as in animal models of CKD. Therefore, we hypothesized that modulation of GRP78 will affect CKD progression.

Methods: CKD was induced in male C57BL/6 mice by uninephrectomy and subcutaneous implantation of a slow release deoxycorticosterone acetate (DOCA) pellet and Angiotensin (Ang) II osmotic infusion pump. Mice were given 1% sodium chloride in their drinking water. To study the impact of GRP78 modulation on CKD, GRP78 heterozygous mice (~50% GRP78) were used. During the course of the study, blood pressure and 24 h total urinary protein were measured. On day 21, mice were sacrificed and renal tissue was collected and stained with PAS for intertubular casts and with a-smooth muscle actin for renal interstitial fibrosis. RNA was extracted for NanoString gene expression analysis.

Results: GRP78$^{+/-}$ animals that underwent the CKD model experienced significant increases in systolic and diastolic blood pressure, proteinuria, albuminuria and protein cast formation comparable to WT mice exposed to the model. However, NanoString analysis showed a decrease in fibrotic gene expression, Collagen Type 3, FN1, LOXL2 and a-smooth muscle actin in GRP78$^{+/-}$ mice compared to WT mice. These results were confirmed with a-smooth muscle actin staining, demonstrating renal interstitial fibrosis in WT and its inhibition in GRP78$^{+/-}$ mice.

Conclusions: The Ang II/DOCA salt model of CKD developed in the C57BL/6 mouse resembles the pathological features found in patients with late stage CKD, including proteinuria, hypertension and renal interstitial fibrosis. We have shown that GRP78 modulates renal interstitial fibrosis, an important factor in CKD progression. These findings could lead to the development of novel therapeutics to halt the progression of CKD.

Multigenerational Adaptation of the Renal Fibrogenic Response in Mice

Takeru Kusano, Tsutomu Inoue, Kei Sugiyama, Hirokazu Okada. *Nephrology, Saitama Medical Univ, Irumagun, Saitama, Japan.*

Background: Ancestral liver damage is reported to promote adaptation of the hepatic wound-healing response. (Nat Med, 18;1369-77, 2012) Therefore, we investigated whether renal fibrosis leads to heritable adaptation of the renal fibrogenic response in male mice.

Methods: Adult male 129/J mice were divided into 2 groups and underwent unilateral ureter obstruction (UUO) and sham-operation, respectively (F_0 generation), and after 2 weeks both groups was bred with females. The male offsprings from each group underwent relevant manipulation again (F_1 generation), and were bred with females. The male offsprings (n=5) from each F_1 groups underwent UUO (F_2 generation). By using the kidneys with Day 5 and 7 UUO from F_2-generation male mice with or without a family history of renal fibrosis, levels of mRNAs encoding profibrogenic molecules and area of interstitial fibrosis were measured with qRT-PCR and Sirius Red staining, respectively.

Results: In the kidneys with Day 7 UUO, levels of mRNAs encoding fibronectin EIIIA (FN), but not either transforming growth factor-b1 (TGF-β1) or a1 procollagen type I (COLI), were significantly reduced in mice with a family history of renal fibrosis (UU) compared to mice without it (NN) (UU, versus NN; 10.7 ± 1.4, versus 37.0 ± 5.3 ($p<0.05$; FN), 8.4 ± 2.3, versus 7.6 ± 2.9 (n.s.; TGF-β1), 65.7 ± 25.7, versus 52.3 ± 20.5 (n.s.; COLI)). This tendency was also observed in the kidneys with Day 5 UUO. Additionally, ancestral renal fibrosis significantly narrowed fibrotic area (%) in the kidneys with Day 5 UUO, but not Day 7 UUO (UU, versus NN; 7.3 ± 3.7, versus 10.1 ± 4.5 ($p<0.05$; Day 5), and 12.7 ± 5.4, versus 13.7 ± 4.4 (n.s.; Day 7)).

Conclusions: We found that a family history of renal fibrosis corresponds with transmission of a suppressive adaptation of the renal FN expression to the male F_2 generations. We are planning to test whether epigenetic remodeling is involved in this anti-fibrogenic adaptation of renal FN expression.

KIM-1 Regulates Fibronectin Production by Renal Epithelial Cells

Venkata Sabbisetti, Swetha Ramadesikan, Sahil Sharma, Joseph V. Bonventre. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

Background: Kidney Injury Molecule-1 (KIM-1) is upregulated in proximal tubular cells (PTC) following kidney injury. Conditional expression of KIM-1 in PTCs in mice leads to the development of renal and extra-renal complications of chronic kidney disease (CKD) similar to humans. Here, we report that KIM-1 mediates the production of fibronectin, an extracellular matrix component involved in the repair and fibrosis of the kidney.

Methods: Full-length KIM-1 or phosphotyrosine mutant (Y350) were overexpressed in LLC-PK1 and HEK cells and fibronectin levels were evaluated using RT-PCR, Western and a luminex assay. KIM-1-mediated regulation of fibronectin was investigated by treating the above cell lines with specific inhibitors for src, PI3K, JNK, MAPK, p38 MAPK and TGFb. KIM-1 expression was reduced in kidney cancer cell line (ACHN) using lentiviral shRNA. To investigate the association between KIM-1 and fibronectin *in vivo*, different animal models of renal injury were employed. Mice were subjected to either 20 and 30 min of ischemia followed by 1 or 7 days of reperfusion (I/R), unilateral urethral obstruction (UUO) or aristolochic acid (AA, 5 mg/kg) treatment.

Results: KIM-1-expressing renal epithelial cells produced increased levels of fibronectin both at mRNA and protein levels as compared to controls. The increase in fibronectin production was abrogated in Y350F mutant cells indicating that the involvement of KIM-1 phosphotyrosine-mediated signaling in fibronectin production. Blockade of PI3K-AKT, and p38 MAPK, using specific inhibitors, decreased KIM-1-mediated fibronectin production. Fibronectin levels were significantly reduced when endogenous KIM-1 expression was silenced in RCC cell lines. In mouse models, KIM-1-expressing tubular epithelial cells co-localized with high fibronectin expression in I/R, UUO and AA models of renal injury.

Conclusions: We demonstrate that KIM-1 regulates fibronectin expression and production using gain-of-function and loss-of-function approaches. Thus, chronic expression of KIM-1 may lead to deposition of excess fibronectin which contributes to fibrosis. Blocking KIM-1 signaling may be therapeutically beneficial to halt or reduce fibrosis and CKD progression.

FR-PO526

Increased Expression of miRNA in IgA Nephropathy Fibrotic Lesions

Marie-Flore Hennino,[1,3,4] Cynthia Van der Hauwaert,[3] David Buob,[2] Grégoire Savary,[3] Dominique C. Pagniez,[1] Christian Noel,[1] Christelle Cauffiez,[3] Francois Glowacki.[1,3] *[1]Nephrology, CHU of Lille; [2]Pathology, CHU of Lille; [3]EA4483, Lille 2 Univ; [4]Nephrology, Valenciennes Hospital.*

Background: Progressive IgA nephropathy (IgAN) leads to glomerular and interstitial fibrosis. Fibrosis grade is a key determinant of disease prognosis. MicroRNAs (miR), are small non coding RNA, acting as post-transcriptional gene regulators. miRNAs are implicated in various fibro-proliferative disorders. Recently, miR-21 has been suggested to be involved in the renal fibrosis process.The aim of this study was to assess the implication of miR-21 in kidney fibrosis occurring in IgAN.

Methods: A cohort of 56 patients with IgAN (biopsy proved) was selected. For each patient, the renal biopsy was scored according to Oxford classification, including mesangial proliferation (M score), endocapillary hypercellularity (E score), segmental glomerulosclerosis (S score) and interstitial fibrosis (T score). After extraction of total RNAs, the level of miR-21 was measured in renal biopsies by Q-PCR. Furthermore miR-21 expression was studied by *in situ* hybrydization (ISH).

Results: Renal expression of miR-21 was significantly higher in renal tissue of patients with IgAN and severe lesions of interstitial fibrosis (miR-21 relative quatification: for T0 score: 1.64±1.67; for T1 score: 5.38±3.8; for T2 score: 8.88±9.37; p=0.001 for T0 versus T2, or for T0 versus T1). miR-21 expression was independent of the M and E scores and was also associated with renal survival (OR for renal replacement therapy in patient with miR-21 tissue expression above the median value: 7,3, IC 95% [1,72;31,18]). Finally ISH analysis revealed that miR-21 is highly expressed in the fibrotic interstitial area.

Conclusions: Our data suggest that miR-21 is involved in renal fibrosis occurring during IgA nephropathy. In this context, miR-21 may be an interesting non invasive biomarker of fibrosis and/or an innovative therapeutic target in IgAN.

FR-PO527

Urinary and Serological Markers of Collagen Degradation Are Elevated in Three Different Rat Models of Kidney Fibrosis

Federica Genovese,[1] Marios Papasotiriou,[2] Daniel G.K. Rasmussen,[1] Diana Julie Leeming,[1] Morten Asser Karsdal,[1] Jürgen Floege,[2] Peter Boor.[2] *[1]Fibrosis Biology and Biomarkers, Nordic Bioscience, Herlev, Denmark; [2]Nephrology and Immunology, RWTH Univ of Aachen, Aachen, Germany.*

Background: In this study we explore the use of specific matrix metalloproteinase (MMP)-generated collagen degradation fragments as urinary and serological markers of fibrosis in three rat models of chronic kidney disease associated with fibrosis.

Methods: The concentration of two Protein Fingerprint markers of collagen type I and type III degradation was measured in serum (sC1M and sC3M) and urine (uC1M and uC3M) of rats after 5/6 nephrectomy (moderate disease, n=6; severe disease, n=6), chronic anti-Thy 1.1 mesangioproliferative glomerulonephritis (n=6), adenine nephropathy (n=5) and compared to healthy controls (n=6).

Results: All three models developed significant renal fibrosis shown by histology and immunohistochemistry and reduced renal function. uC1M and uC3M levels were significantly elevated in diseased animals compared to controls in all three models, and correlated with disease severity in the 5/6 nephrectomy rats. sC1M and sC3M were also significantly elevated in rats with 5/6 nephrectomy and adenine nephropathy, whereas no changes were observed in anti-Thy1.1 glomerulonephritis. The urinary markers and sC1M correlated with serum creatinine, proteinuria, and collagen type I and type III staining in kidney ($p<0.001$).

Table 1: Mean uC1M, uC3M, sC1M, sC3M concentration and collagen I and collagen III % area of staining in the different CKD models.

	Healthy	Moderate 5/6 Nx	Severe 5/6 Nx	Anti-Thy 1.1	Adenine nephropathy
uC1M/Cre (ng/µg creatinine)	0.2#	0.9	5.7***	5.7*	5.0***
uC3M/Cre (ng/µg creatinine)	0.1#	1.8	5.8***	4.3*	17.6**
sC1M (ng/ml)	58.6#	58.3	90.1**	77.3	168.2***
sC3M (ng/ml)	20.2#	45.2	74.9**	16.8	35.0*
Col I (%)	3.0	7.2	18	13.8	20.8
Col III (%)	2.4	7.6	17.3	8.8	16.4

**** p<0.0001, *** p<0.001, ** p<0.01, * p<0.05, as compared to #

Conclusions: The measurement of markers of MMP driven collagen turnover in biological fluids, in particular in the urine, may represent a non-invasive tool to determine the presence of kidney fibrosis.

FR-PO528

Nephrogenic Systemic Fibrosis: Detection of Gadolinium in and the Histologic Effect of Gadolinium–Based Magnetic Resonance Imaging Contrast in Rodents with Uninephrectomy

Catherine Do,[1] Brent Wagner.[2] *[1]Nephrology, Univ of Texas Health Sciences Center, San Antonio, TX; [2]Nephrology, South Texas Veterans Health Care System, San Antonio, TX.*

Background: Nephrogenic systemic fibrosis (NSF) can develop after intravenous exposure to gadolinium-based magnetic resonance imaging (MRI) contrast in those with renal impairment. It is characterized by diffuse skin thickening as well as internal organ fibrosis. Different formulations of contrast, each with different affinities for gadolinium ion (expressed as the thermodynamic stability, Ktherm), may carry variable risks for triggering the disease. The heart is one organ purportedly effected in NSF, therefore the effects of low– and high–Ktherm contrast agents,—gadodiamide and gadoteridol, respectively—were compared in a model of renal insufficiency.

Methods: Rats with 5/6 nephrectomy were treated with either gadodiamide or gadoteridol (2.5 mmol/kg IP) for 20 doses over a 4-week period. Immunoblot quantitated fibronectin in homogenized tissue. Gadolinium was quantified by scanning electron microscopy equipped with energy–dispersive spectroscopy (EDS).

Results: Gadodiamide induced dermal hypercellularity, fibronectin accumulation, and the recruitment of fibrocytes to a greater degree than gadoteridol. There was no evidence of fibrosis by histology or immunoblot in any of the groups. Although gadolinium was detectable in skin, liver, kidney, and spleen, cardiac tissue did not register a significant increase in gadolinium from control by EDS (see figures 1 and 2).

Conclusions: These data demonstrate that there is organ–specific accumulation of gadolinium in a rodent model of nephrogenic systemic fibrosis.

FR-PO529

Fear and Loathing in the Lanthanides: A Comparison of Gadodiamide and Gadoteridol in a Rat Model of Nephrogenic Systemic Fibrosis

Brent Wagner. *Medicine Service, South Texas Veterans Health Care System, San Antonio, TX.*

Background: It has been presupposed that the thermodynamic stability (K_{therm}) of gadolinium–based magnetic resonance imaging chelates relate to the risk of precipitating nephrogenic systemic fibrosis (NSF). This study compared low–K_{therm} gadodiamide to a high–K_{therm} gadoteridol in cultured fibroblasts and rats with uninephrectomies.

Methods: Cultured fibroblasts were serum–deprived and treated with therapeutic levels of magnetic resonance contrast. Rats with uninephrectomy were treated with magnetic resonance contrast (2.5 mmol/kg IP) for a total of 20 doses over a 4–week period. Gadolinium content was assessed using scanning electron microscopy equipped with energy–dispersive x–ray spectroscopy in paraffin–embedded tissues.

Results: Cultured human fibroblasts demonstrated dose–dependent fibronectin generation, transforming growth factor b production, and expression of the activated myofibroblast stress fiber protein a smooth muscle actin. There were negligible differences with respect to toxicity or proliferation between the two contrast agents *in vitro*. In a rodent model of chronic kidney disease (animals were status post uninephrectomy), gadodiamide treatment led to greater skin fibrosis and dermal cellularity with respect to gadoteridol. Either contrast agent induced renal proximal tubule vacuolization as well as increased fibronectin accumulation. Despite relatively large detectable gadolinium signals in spleen, skin, muscle, and liver from the gadodiamide–treated group, contrast–induced fibrosis appears to be limited to skin and kidney; skeletal muscle, liver, and spleen did not demonstrate pathology.

Conclusions: These findings 1) support the hypothesis that low thermodynamic stability chelates have a greater propensity to elicit nephrogenic systemic fibrosis, and 2) demonstrate that certain tissues are resistant to these effects. An understanding of the latter could help in finding a cure or guide in testing rational prophylactic therapies.

mTOR Component Deptor Contributes to TGFbeta-Induced Collagen I (alpha-2) Expression in Proximal Tubular Epithelial Cells (PTEC)

Falguni Das,[1] Amit Bera,[1] Nandini Ghosh-Choudhury,[2] Hanna E. Abboud,[1] Balakuntalam S. Kasinath,[1] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA, San Antonio, TX.*

Background: In progressive kidney disease, TGFbeta (TGFb)-induced collagen I (alpha-2) (collagen) expression in PTEC contributes to renal fibrosis. Along with canonical Smad 3, we have recently shown involvement of both mTOR complexes (C1 and C2) in non-canonical TGFb signaling. How TGFb maintains mTOR activity to increase collagen expression is not known. Deptor is a component of both mTORC1 and C2, and inhibits their activity.

Methods: Cultured PTECs were used. Immunoblotting, quantitative RT-PCR, chromatin immunoprecipitation assay and reporter transfection assay were used.

Results: TGFb decreased levels of deptor, resulting in increased collagen expression due to elevated Akt, mTORC1 and mTORC2 activity. Expression of deptor inhibited both mTORC1 and mTORC2 activity, resulting in reduction of expression of collagen protein, mRNA and its transcription. Conversely, shRNAs against deptor increased collagen transcription, mRNA and protein expression concomitant with enhanced mTORC1 and mTORC2 activity. As a mechanism, we identified Hif1alpha (Hif1a) responsive element in the collagen gene, which bound Hif1a in PTEC. Expression of deptor inhibited TGFb-induced Hif1a expression and its recruitment to the collagen gene. In contrast, shDeptor markedly increased Hif1a binding to the collagen gene similar to TGFb treatment. Furthermore, shDeptor-induced increase in collagen transcription and protein expression was inhibited by siRNA against Hif1a. Moreover, TGFb- and shDeptor-mediated increase in Hif1a and collagen expression was significantly inhibited by shRNA against raptor, an exclusive component of mTORC1, but not by downregulation of rictor, the required constituent of mTORC2 for its activity.

Conclusions: These results for the first time demonstrate a role for deptor in collagen expression, which contributes to renal fibrosis. We uncover a specific role of mTORC1 for collagen transcription via Hif1a in the presence of bystander activation of mTORC2.

Mycophenolate Mofetil Is Superior to Cyclophosphamide or Azathioprine Induction Therapy for Lupus Nephritis in Mexican Mestizo Population

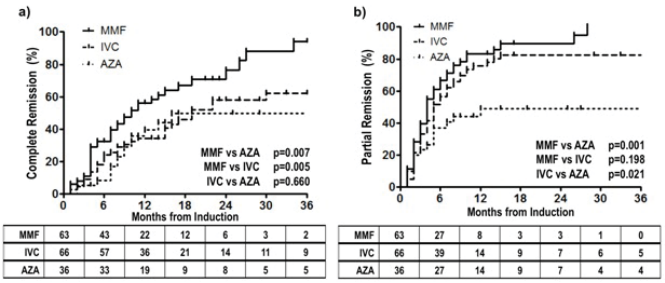
Juan M. Mejia-Vilet, Arreola Guerra Jose Manuel, Bertha Manuela Cordova Sanchez, Norma O. Uribe-Uribe, Luis E. Morales-Buenrostro, Ricardo Correa-Rotter. *Nephrology, Inst Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.*

Background: Studies comparing induction to remission strategies in lupus nephritis (LN) suggest that hispanic ethnicity and Latin America region patients may have a better response to mycophenolate mofetil (MMF) over intravenous cyclophosphamide (IVC); but these studies are frequently subanalysis with a great regional and hispanic population variability. Here, we report a comparison of MMF, IVC and azathioprine (AZA) as induction treatment regimens for active LN in a mexican one-center lupus nephritis retrospective cohort.

Methods: A total of 165 patients with ISN/RPS clases III through V LN, distributed in MMF (dosage >2g/d per 6 months), IVC (0.7g/m^{2}BSA) and AZA (dosage >1.5mg/kg/d per 6 months) groups with a median 31 +-18 months follow-up were analyzed. The primary end-point was complete remission as defined in LUNAR trial. Secondary end-points included partial remission, doubling of serum creatinine, end-stage renal disease development.

Results: Complete remission achievement was higher with MMF at 36 months (94.1%) compared to IVC (62.1%) and AZA (49.7%). Partial remission achievement was higher with MMF (100%) and IVC (85.5%) groups compared to AZA (67%). There were no differences between treatment groups in serum creatinine doubling or end-stage renal disease development. Presentation proteinuria (HR 0.91), IVC (HR 0.49) and AZA (HR 0.31) induction treatment, and absense of vascular damage (HR 2.04) were independent predictors of complete remission.

Figure 1. Complete remission (a) and Partial remission (b) at 36 months.



MMF	63	43	22	12	6	3	2
IVC	66	57	36	21	14	11	9
AZA	36	33	19	9	8	5	5

MMF	63	27	8	3	3	1	0
IVC	66	39	14	9	7	6	5
AZA	36	27	14	9	7	4	4

Conclusions: MMF induction therapy may be superior to IVC and AZA in LN patients of mexican-mestizo race.

FR-PO532

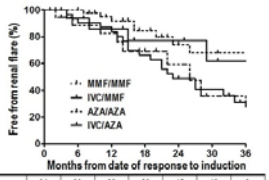
Mycophenolate Mofetil Is Superior to Azathioprine as Maintenance Therapy in Hispanic Lupus Nephritis Patients Juan M. Mejia-Vilet, Arreola Guerra Jose Manuel, Bertha Manuela Cordova Sanchez, Norma O. Uribe-Uribe, Luis E. Morales-Buenrostro, Ricardo Correa-Rotter. *Nephrology, Inst Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.*

Background: One of the goals of maintenance regimens in lupus nephritis (LN) is to prevent flares while minimizing toxicity. Renal flares have been shown to significantly impact outcome in systemic lupus erythematosus patients.

Methods: We report flare incidence in an 118 mexican-mestizo retrospective cohort of patients with proliferative lupus nephritis that had previously responded to induction therapy. We compared flare incidence by induction/maintenance groups and searched for flare and outcome predictors.

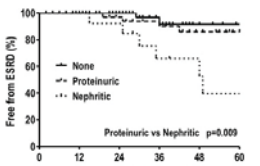
Results: Of 118 patients, 47 (39.8%) presented a renal flare at a median 17 months from time of remission achievement, 34 being classified as proteinuric and 13 as nephritic. Creatinine at initial presentation (HR 1.81 [1.22-2.88], p=0.003), ISN/RPS class IV+V histology (2.19 [1.17-4.09], p=0.014) and azathioprine maintenance therapy (HR 4.13 [1.99-8.60, p<0.001]) were significantly associated with renal flare incidence on multivariate analysis. Flare treatment regimens varied, but clinical response (complete remission 48.9%, partial remission 27.7%) was inferior to that of initial induction therapy. Twelve patients progressed to end stage renal disease (10.2%) on a median 31 months. Age (HR 0.90, [0.82-0.99], p=0.035) and nephritic flare (HR 7.29, [1.46-36.4], p=0.016) were significantly associated with ESRD development.

Figure 1. Proportion of patients with renal flare on follow-up.



IVC-AZA	34	30	28	20	15	10	6
IVC-MMF	17	15	12	9	9	5	4
MMF-MMF	47	44	34	22	14	12	9
AZA-AZA	18	16	15	10	7	3	3

Figure 2. End stage renal disease survival curves for patients with none, proteinuric or nephritic flare.



No Flare	72	60	48	21	10	4
Proteinuric	33	33	31	27	16	5
Nephritic	13	13	12	8	7	4

Conclusions: Mycophenolate mofetil may be superior to azathioprine as maintenance therapy for prevention of renal relapses in mexican-mestizo population. Age and nephritic flares constitute significant predictors of ESRD development.

FR-PO533

Glomerular Necrotizing Lesions and Long Term Outcomes among Patients with Proliferative Lupus Nephritis Abdulkareem Alsuwaida, Sufia Husain, Mohammed A. Al-Ghonaim, Saad S. Alobaili, Jamal S. Al Wakeel, Hala M. KFoury. *College of Medicine, King Saud Univ, Riyadh, Saudi Arabia.*

Background: Although necrotic lesions in lupus nephritis are common in proliferative lupus nephritis (LN), little is known about the impact of these lesions on long-term outcomes. This study was undertaken to investigate the impact of glomerular necrotic lesions on response to therapy and renal outcomes of doubling serum creatinine in patients ISN/RPS class III and IV LN and necrotic lesions.

Methods: 52 patients with ISN/RPS class III or IV LN were enrolled in this retrospective study with mean follow up of 7.4 years. Tuft necrosis was defined as fragmentation of nuclei or disruption of the glomerular basement membrane with fibrin-rich material**.** All patients underwent a repeated biopsy 12-18 months after baseline biopsy.

Results: The prevalence of necrotizing lesions was seen in 24% of those with class III versus 70.4% of class IV (*P*=0.001). The initial median serum creatinine was significantly higher at 92umol/l (Mean 154 umol/l ± 130) in those with necrotizing lesions and 76umol/l (Mean 96 ± 94 umol/l) in those with no necrosis (*P*=0.05). Proteinuria was more severe among those with glomerular necrosis (*P*=0.03). The rate of no remission was seen in 44.0% and 22.2% among those with and without necrosis, respectively. The proportion of doubling of serum creatinine was seen in 32.0% in those with necrosis and 14.8% with no necrosis (*P*=0.1).The chronicity index in the repeated biopsy was significantly worse among those with necrosis. The median chronicity index was 4 (IQR: 1–6) for the group with no necrosis and 7 (IQR: 5–8) for those with necrosis at repeated biopsy (*P*=0.0002).

Conclusions: Glomerular necrosis identifies lupus nephritis patients at greatest risk for progression to renal failure. Proactive intervention and possibly more aggressive inductions therapy in patients with necrotizing lesions may protect the kidneys from developing chronic renal impairment.

FR-PO534

Atypical Hemolytic Uremic Syndrome in Setting of Warfarin Withdrawal Neetika Garg,[1] Helmut G. Rennke,[2] Kambiz Zandi-Nejad.[1] *[1]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Pathology, BWH, Boston, MA.*

Background: Uncontrolled activation of the alternate pathway of complement system is considered central to the pathogenesis of atypical hemolytic uremic syndrome (aHUS). However, known genetic and acquired defects in the complement system account for only half of the cases. Extensive crosstalk between complement and coagulation-fibrinolysis pathways suggests potential role of the latter in pathogenesis; mutations in PLG (encoding plasminogen) have recently been implicated in some patients. Role of anticoagulation (AC) in such cases is unknown. Here, we describe 2 cases of aHUS that occurred in the setting of AC withdrawal.

Methods: Retrospective chart review of 415 patients from Harvard affiliated hospitals identified 25 cases of aHUS of which 2 developed after AC withdrawal.

Results: Case 1 (2008): 61-year-old male with history of deep venous thrombosis (DVT) on warfarin presented with a traumatic intracranial bleed. Following INR reversal with prothrombin complex concentrate, he developed hemolytic anemia, thrombocytopenia and acute kidney injury (AKI) requiring dialysis. Renal biopsy confirmed an acute thrombotic microangiopathy (TMA). C3 and C4 levels were normal. In the absence of diarrhea and ADAMTS13 activity of 63%, aHUS was diagnosed. Renal function improved with plasmapheresis and AC. No genetic testing was done. Serum creatinine 5 years later is 1.7 mg/dL. Case 2 (2005): 50-year-old male with history of recurrent DVTs and negative hypercoagulable work up on chronic AC developed TMA, confirmed with renal biopsy, in the setting of interruption of AC for a colonoscopy. C3 and C4 levels were normal. With stool negative for E. coli O157:H7, and ADAMTS 13 activity of 59%, aHUS was diagnosed. Following full recovery with AC and steroids, he suffered multiple recurrences in the setting of withholding AC for subsequent procedures/bleeding and ultimately progressed to ESRD. Genetic work up was negative for CFH, CFI and MCP.

Conclusions: Coagulation/fibrinolysis system may play a role in the pathogenesis of aHUS via its interactions with the complement system. Normal C3 level does not necessarily rule out complement activation/consumption given its upregulation as an acute phase reactant.

FR-PO535

Histological Changes of Lupus Nephritis at the Time of Flare: A Single Center Analysis in Japan Anastasie Kadiombo Tshilela, Hidekazu Ikeuchi, Keiju Hiromura, Kaori Mochizuki, Ken Kayakabe, Noriyuki Sakurai, Toru Sakairi, Yoriaki Kaneko, Akito Maeshima, Yoshihisa Nojima. *Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: Renal flares are common in lupus nephritis (LN). However, limited data are available regarding the histological changes of LN at the time of flare compared to the initial biopsy, especially by using ISN/RPS 2003 classification.

Methods: We retrospectively analyzed 18 LN patients (6 males and 12 females with mean age of 39.2±10.8 years) who received a repeat renal biopsy at the time of flare. All patients were Japanese and received both first and second biopsy at our hospital or affiliated hospitals. Renal histology was classified according to ISN/RPS 2003 classification.

Results: The mean intervals between the first and second biopsy was 6.7±2.4 years. The levels of urinary protein and eGFR were not different between the first and second biopsy: 5.2±4.0 versus 5.6±5.2 g/gCr (p=0.877), 83.1±32.9 versus 73.0±30.8 ml/min/1.73m^2 (P=0.796). In contrast, the level of serum complement activity (CH50) was significantly lower in the first biopsy: 18.4±11.3 versus 32.9±11.6 (P<0.001).The histological changes were shown in Table. Class switches were observed in 6 patients (33%). Five patients changed to mixed type (Class III/IV+V), and 1 patent with mixed type transformed to class III. In addition, chronic lesions (A/C or C by ISN/RPS) were found in 4 patients at first biopsy and in 16 patients at second biopsy.

Table Histological changes in ISN/RPS classifications at first biopsy and second biopsy at flare

Second biopsy at flare	First biopsy					
	II	III	IV	V	Mixed	Total
II	0	0	0	0	0	0
III	0	0	0	0	1	1 (6%)
IV	0	0	7	0	0	7 (39%)
V	0	0	0	1	0	1 (6%)
Mixed	1	1	4	0	4	9(50%)
Total	1 (6%)	0	11 (61%)	1 (6%)	5 (28%)	18 (100%)

Conclusions: Approximately one-third patients had class switches at the time of flare and most of them were a transition to mixed type from class IV. In addition, chronic lesions markedly progressed at flare.

FR-PO536

Remission of Proteinuria Is an Important Prognostic Factor for Mortality in Biopsy-Proven Lupus Nephritis Regardless of Recurrence Ho Jun Chin,[1] Sewon Oh.[2] *[1]Internal Medicine, Seoul National Univ Bundang Hospital, Seong nam, Kyeongkido, Republic of Korea; [2]Internal Medicine, Inje uinversity Ilsan Paik Hospital, Goyang, Kyeongkido, Republic of Moldova.*

Background: Lupus nephritis is one of the most common secondary glomerulonephritis diagnosed by renal biopsy in Korea. We investigated the importance of proteinuric remission on the outcomes in patients with lupus nephritis.

Methods: We selected patients with urine protein to creatinine ratio 0.5 g/g cr or more and biopsy-proven lupus nephritis from 1980 to 2009 in a tertiary referral hospital in Korea. Among 388 patients, we followed 280 patients during 148 ± 95 months until proteinuric remission. Remission of proteinuria was defined as 3 consecutive tests with UPCR < 0.3 g/g cr or proteinuria by dipstick test trace or less.

Results: There were 140 patients who had proteinuric remission. The differences of clinical paramaters at renal biopsy according to proteinuric remission were gender, level of anti-ds DNA antibody, and group of hemoglobin (classfied with criateria of 10.0 g/dl and 12.0 g/dl). There were 108 patients who had experienced recurrence of proteinuria after remission. If the patient would not have proteinuric recurrence until 52.6 months after remission, we could estimate no recurrence with sensitivity 80.0 % and specificity 78.1 % during follow-up period. Patients with remission had 0.169 (95% CI: 0.038-0.756, p=0.020) fold-risk for mortality and 0.476 (95% CI: 0.245-0.923, P=0.028) fold-risk for composite outcome (death or development of end stage renal disease) by Cox's hazard proportional model, however, not for ESRD. Patients with recurrence of proteinuria had similar risk for mortality and composite outcome compared with patients without recurrence.

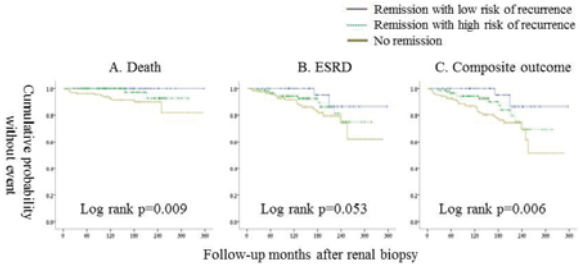

Figure 1. The outcomes of patients grouped by remission and risk of recurrence during follow-up period
Remission with low risk of recurrence: patients with proteinuric remission who did not have recurrence of proteinuria until 50 months after remission. Remission with high risk of recurrence: patients with proteinuric remission who had recurrence within 50 months after remission. ESRD: end stage renal disease, Composite: death or ESRD. Probability of event was estimated by Kaplan-Meier analysis.
P-value was estimated by Log-rank test.

Conclusions: Proteinuric remission in lupus nephritis was an important good prognostic marker for mortality regardless of recurrence after remission of proteinuria.

FR-PO537

Outcome of Lupus Glomerulonephritis with Impaired Kidney Function at Presentation Jorge L. Castaneda, Juan Carlos Q. Velez, Sally Self. *Medicine, Medical Univ of South Carolina, Charleston, SC; Medicine, Medical Univ of South Carolina, Charleston, SC; Medicine, Medical Univ of South Carolina, Charleston, SC.*

Background: There is paucity of data regarding the rate of response to therapy in patients with lupus glomerulonephritis (LN) who present with impaired kidney function (IKF) at the time of diagnosis. This population is of particular interest due to its highest risk of progression to End Stage Renal Disease (ESRD). Our goal was to report the clinical outcomes of patients with LN + IKF in our institution.

Methods: Medical records of patients (n=51) with biopsy-proven LN, ISN/RPS class III, IV and V and serum creatinine (sCr) ≥ 2 mg/dL at the time of the biopsy were reviewed retrospectively. Response to treatment was defined as decrease in urine protein-creatinine ratio (Up/c) > 50% and < 3 g/day and stabilization of sCr within 25% of baseline.

Results: The mean follow up was 18.2 months. The population was predominantly African-American (86%) female (82%). Baseline mean sCr was 3.5 ± 0.5 mg/dL, mean eGFR was 22.6 ± 2.6 ml/min and mean proteinuria was 5.7 ± 1.2 g/24h. Most patients (68%) received cyclophosphamide for induction therapy. All but 3 subjects (94%) had a proliferative lesion in the biopsy. The mean activity index was 8.2 ± 1.3 and the mean chronicity index was 5.9 ± 0.7. Crescents were seen in 64.7% of the patients. The rate of response to treatment in the first 24 weeks was 13.7%. No patient with sCr ≥ 4 mg/dL responded to treatment (relative risk for failure to respond for those with sCr ≥ 4 mg/dL: 1.21 (95% CI 1.00–1.45, p=0.047). ESRD within 3 years occurred in 51% of the patients. The mortality rate was 15.6% and severe infection requiring hospitalization occurred in 27.5% of the subjects. Among 17 patients who required dialysis at presentation, 5 (29%) were able to discontinue dialysis.

Conclusions: Patients with LN + IKF represent a subgroup with high rate of no response to therapy and progression to ESRD. Higher sCr is associated with worse prognosis. About a third of the patients who require dialysis at presentation may be able to discontinue it even after 20 weeks of treatment.

FR-PO538

Short and Long Term Outcomes of Pure Membranous Lupus Nephritis and the Relevance of Nephrotic Range Proteinuria Jorge L. Castaneda, Juan Carlos Q. Velez, Sally Self. *Medicine, Medical Univ of South Carolina, Charleston, SC.*

Background: Membranous Lupus Nephritis (MLN) represents around 15-20% of clinically significant renal disease in Lupus. MLN has distinct histologic features, clinical manifestations and more favorable outcomes than proliferative forms of lupus Nephritis (LN). Since there is conflicting data regarding the degree of proteinuria than can affect the outcomes, the goal of this study was to describe the rate of response to treatment and to determine the significance of nephrotic range proteinuria.

Methods: The medical records of patients (n=30) with biopsy-proven MLN, ISN/RPS class V were reviewed retrospectively.

Results: The mean follow up was 21.7 months (6-36 months). The population was predominantly African-American (83.3%), female (80%).The mean creatinine was 1.26 (± 0.3) mg/dl. The mean proteinuria was 3.4 g/24h (± 1.4). 20 % of the population presented with hematuria at the time of the biopsy. 97% of the entire population received any form of immunosuppression.Low activity and chronicity index were seen in the entire population 1.3 (± 0.5) and 2.5 (± 1) respectively. The rate of response to treatment at 24 weeks was 43.3%. 8 patients (26.6%) worsened eGFR over the last 3 years and only 1 patient died. Patient and renal survival at 3 years were 96% and 90% respectively. The population was divided into non-nephrotic (n=20) and nephrotic range proteinuria (n=10) at the time of the kidney biopsy. 70% of the population was treated with MMF initially. Patients with nephrotic range proteinuria are at 2.25 times increased risk of non-response to treatment in the first 24 weeks (95% CI 1.3-4,p=0.006). Among non-responders in the first 24 weeks, the rate of CKD progression and development of ESRD/transplantation in the next 36 months were 35.3% and 23.5% respectively. The rate of severe infections that required hospitalization was 23.7%.

Conclusions: MLN represents a condition with a relatively benign course however the development of Nephrotic range proteinuria may represent a risk factor for non-response and worse long-term renal survival. The institution of earlier immunosuppression may change the long-term outcomes in this population.

FR-PO539

Diagnosis, Monitoring and Treatment of Lupus Nephritis: Systematic Review of Clinical Practice Guidelines David J. Tunnicliffe,[1,2] Siah Kim,[1,2] Davinder Singh-Grewal,[3,4,6] Richard K.S Phoon,[5,6] Jonathan C. Craig,[1,2] Allison Tong.[1,2] *[1]School of Public Health, The Univ of Sydney; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Sydney; [3]The Sydney Children's Hospital Network, Sydney; [4]Faculty of Medicine, The Univ of New South Wales, Sydney; [5]Westmead Hospital, Sydney; [6]Sydney Medical School, The Univ of Sydney.*

Background: Lupus nephritis is considered the most serious manifestation of systemic lupus erythematosus. Patients with lupus nephritis experience poor quality of life and are at risk for developing end stage kidney disease. Clinical management is complex and guidelines have recently been developed on the diagnosis, monitoring and treatment of lupus nephritis.This study aimed to compare the quality, scope and consistency of clinical practice guidelines on lupus nephritis.

Methods: MEDLINE, Embase, PsycINFO and CINAHL, guideline organizations and websites of nephrology and rheumatology societies were searched up to April 2014. The Appraisal of Guidelines for Research and Evaluation (AGREE) II instrument and textual synthesis was used to appraise and compare recommendations.

Results: Six clinical practice guidelines and five consensus statements were identified and included. The methodological quality of the guidelines was variable, with the overall mean AGREE II scores ranging from 31% to 75%. Scores were consistently low for applicability with only one guideline scoring above 50%. The guidelines covered five areas: indications for renal biopsy, monitoring, treatment, treatment of difficult disease, reproductive health, and pediatric lupus nephritis. There were inconsistencies in recommendations: class II and V lupus nephritis recommendations were separated by proteinuria range by some, not all guidelines, class III/IV lupus nephritis maintenance therapy duration (1 to 3 years) and variability in recommended doses for induction and maintenance therapy.

Conclusions: International guidelines on lupus nephritis are variable in methodological quality, scope and recommendations. Collaborative and multidisciplinary efforts to develop comprehensive, high-quality evidence-based guidelines are needed to promote best treatment and health outcomes for patients with lupus nephritis.

FR-PO540

Experiences and Perspectives of Adolescents and Young Adults Living with Systemic Lupus Erythematosus David J. Tunnicliffe,[1,2] Davinder Singh-Grewal,[3,4,5] Richard K.S Phoon,[3,6] Jeffrey Chaitow,[4] Fiona Mackie,[4,5] Nicholas Manolios,[3,6] H. Patrick McNeil,[5,7] Ming-Wei Lin,[3,6] Sean G. O'Neill,[5,7] Graeme Stewart,[3,6] Angelique F. Ralph,[1,2] Jonathan C. Craig,[1,2] Allison Tong.[1,2] *[1]School of Public Health, The Univ of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, NSW, Australia; [3]Sydney Medical School, The Univ of Sydney, Sydney, NSW, Australia; [4]The Sydney Children's Hospital Network, Sydney, NSW, Australia; [5]Faculty of Medicine, The Univ of New South Wales, Sydney, NSW, Australia; [6]Westmead Hospital, Sydney, NSW, Australia; [7]Liverpool Hospital, Sydney, NSW, Australia.*

Background: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease with potential renal, cardiovascular and musculoskeletal involvement. Disease activity and the treatment burden significantly impair quality of life. We aimed to describe the experiences and perspectives of adolescents and young adults diagnosed with SLE before the age of 18 years.

Methods: Focus groups and face-to-face semi-structured interviews were conducted with 26 patients' aged 14 to 26 years, and thematically analyzed.

Results: Six themes were identified: marring identity (misrepresented self, heightened self-consciousness, sense of alienation); restricted lifestyle and goals (physical limitation, narrowed career options, threat to parenthood); confusion and uncertainty (frustration of delayed or misdiagnosis, ambiguity about cause of symptoms, prognostic uncertainty, exasperation about lack of understanding); resentment of chronic treatment (constant reminder of illness, paradoxical requirement for treatment, debilitating side-effects); gaining resilience (desire for independence, self-reliance); and appreciating personal gains (strengthening of relationships, fortunate in having milder disease).

Conclusions: Young patients with SLE perceive they have limited physical and social capacities and restricted personal and career goals. Psychosocial and educational strategies targeted at improving confidence, self-efficacy, disease-related knowledge, social support, and resolving insecurities may improve treatment and health outcomes of adolescent and young adults with SLE.

FR-PO541

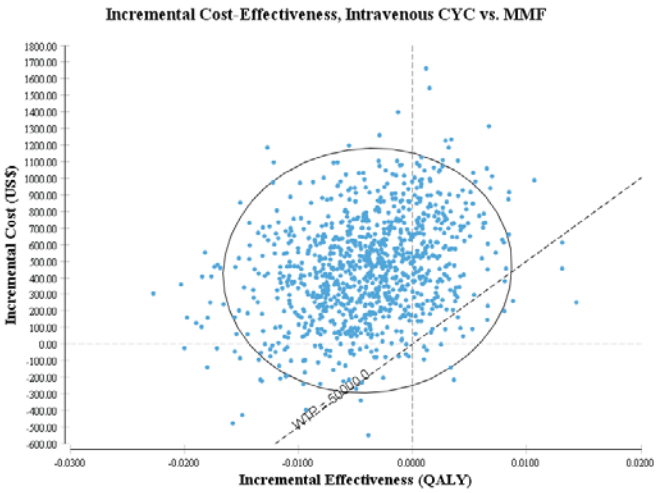
Cost-Utility Analysis of Mycophenolate Mofetil versus Intravenous Cyclophosphamide as Induction Therapy for Proliferative Lupus Nephritis

Robert Nee, Ryan J. Altenburg, Dustin J. Little, Maura A. Watson, Christina M. Yuan, Kevin C. Abbott. *Nephrology, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Practice guidelines recommend either mycophenolate mofetil (MMF) or cyclophosphamide (CYC) as initial therapy for patients with Class III and Class IV lupus nephritis (LN). However, the cost-effectiveness of these two induction strategies from a United States perspective has not been reported.

Methods: We constructed a Markov model with a 6-month time horizon to compare the cost-utility of MMF (2gm/day) and intravenous CYC (0.75gm/m2/month) from a societal perspective. We conducted Monte Carlo probabilistic sensitivity analysis to assess parameter uncertainties. We factored in drug adverse events to include ovarian failure and diarrhea. Probabilities of clinical events were drawn mainly from a Cochrane meta-analysis. Utility weights, direct and indirect costs of treatment were based upon published studies. Model outcomes were costs, quality-adjusted life-years (QALY), incremental cost-effectiveness ratios and net monetary benefit. We evaluated model validity according to established guidelines.

Results: MMF (2gm/day) was the dominant strategy compared to CYC ($13,732 versus $16,327 and 0.310 QALY versus 0.306 QALY, MMF and CYC, respectively).



Sensitivity analyses demonstrated that a higher MMF dose (3gm/day) remained dominant and that CYC would be the favored strategy only if its probability of complete remission was 3.9 times higher than MMF at a willingness-to-pay $50,000/QALY.

Conclusions: Our state-transition model over a 6-month time frame suggests that an MMF-based strategy is more effective at a lower cost compared to intravenous CYC as induction therapy for proliferative LN. *The views expressed in this abstract are those of the authors and do not necessarily reflect the official policy of the Department of the Defense, Army, Navy or the U.S. government.*

Serum Hepcidin in Lupus

Anthony Alvarado,[1] Divya Indrakanti,[1] Xiaolan Zhang,[1] Alice Hinton,[2] Daniel J. Birmingham,[1] Brad H. Rovin.[1] *[1]Nephrology Div, Dept of Internal Medicine, The Ohio State Univ, Columbus, OH; [2]Div of Biostatistics, College of Public Health, The Ohio State Univ, Columbus, OH.*

Background: Hepcidin (Hep) is an inflammation-sensitive iron regulatory protein that mediates the anemia of chronic inflammatory diseases, including chronic kidney disease (CKD). We postulated that Hep increases when systemic lupus erythematosus (SLE) becomes active, and serum hemoglobin (Hg) falls. This was tested by measuring Hep and Hg in serum collected from SLE patients who were undergoing renal flares (RF) and non-renal flares (NRF).

Methods: Serum Hep-25 was measured by ELISA in 38 RF and 25 NRF from 37 SLE patients. For each RF and NRF cycle Hep was measured at baseline (> 6 months from flare), 4 and 2 months before flare, at flare, and 2 and 4 months after flare. Covariates examined were: age, race, and serum creatinine (SCr). Hep levels were normalized by log transformation. Univariate differences were evaluated with t-tests. Mixed models were fit with a random effect for flare and a fixed effect of time. Tukey's HSD was used for multiple comparisons.

Results: We found that at baseline and flare Hg was lower in patients with RF than NRF (11.6±1.2 versus 12.6±0.96 g/dl, P=0.008; 11.4±1.4 versus 12.2±1.2 g/dl, P=0.016, respectively), but there were no differences at baseline or any flare time point in Hep between RF and NRF. Univariate analysis showed that Hep did not increase at RF or NRF compared to baseline or any time point. Between baseline and 4 months pre-flare hep tended to fall in RF (P=0.065). By multivariate analysis race and SCr were significant covariates for Hep in RF, as was SCr in NRF. Multivariate analysis did not show any change in serum hep over the course of RF or NRF. Hg did not change during RF cycles, but in NRF did show a (non-significant) trend to fall relative to baseline in the interval between 2 months pre- and post-flare.

Conclusions: Unexpectedly, these data show that serum hep is not induced, and Hg does not fall, in SLE patients with active disease. The systemic inflammation of active renal or non-renal lupus does not appear sufficient to up-regulate hep, suggesting differences in the nature of the inflammation in SLE and CKD.

Streptococcus Mutans Strains with Collagen-Binding Protein Are Associated with IgA Nephropathy

Taro Misaki,[1] Shuhei Naka,[2] Keiko Kuroda,[2] Ryota Nomura,[2] Tempei Shiooka,[1] Yoshitaka Naito,[1] Yumiko Suzuki,[1] Hideo Yasuda,[3] Taisuke Isozaki,[1] Kazuhiko Nakano.[2] *[1]Div of Nephrology, Seirei Hamamatsu General Hospital, Hamamatsu, Shizuoka, Japan; [2]Dept of Pediatric Dentistry, Graduate School of Dentistry, Osaka Univ, Suita, Osaka, Japan; [3]First Dept of Medicine, Hamamatsu Univ School of Medicine, Hmamatsu, Shizuoka, Japan.*

Background: IgA nephropathy (IgAN) is the most common primary chronic glomerulonephritis worldwide, however, its precise pathological mechanisms remain unclear. *Streptococcus mutans*,a gram-positive oral streptococcal species, is a known pathogen in dental caries. The association between *S. mutans* strains with the *cnm* gene encoding Cnm, a collagen-binding protein, and infective endocarditis is widely accepted. Recent studies have also revealed an association with other systemic diseases, including ulcerative colitis, non-alcoholic steatohepatitis, and cerebral aneurysm rupture; however, the relationship with IgAN has not been reported. Objective: The aim of this study was to investigate the relationship between *cnm*-positive *S. mutans* strains and IgAN.

Methods: Saliva samples from IgAN patients (n=53) and control subjects (n=32) were collected, and *S. mutans* strains were isolated. Genomic DNA was then extracted from each strain, and PCR was performed to detect *cnm*-positive strains. Collagen-binding assay was also performed for *cnm*-positive strains, with the relative activity of *S. mutans* TW871 set at 100. Renal biopsies from *cnm*-positive and -negative IgAN patients were also compared.

Results: The rates of *S. mutans* isolation in IgAN and control groups were each approximately 84%. In contrast, *cnm*-positive strains were significantly more prevalent in the IgAN group than in controls (32.1% versus 12.5%, $p<0.05$). With regard to collagen-binding assay, the binding rate of *cnm*-positive strains was significantly higher in the IgAN group than in controls (97.0 versus 6.2, $p<0.05$). In addition, segmental glomerulosclerosis score was significantly higher in the *cnm*-positive group than in *cnm*-negative group (0.94 versus 0.57, $p<0.05$).

Conclusions: *S. mutans* strains with collagen-binding protein may be associated with the pathogenesis of IgAN.

FR-PO544

Effects of 1a,25-Dihydroxyvitamin D3 on Memory CD4$^+$T Cells of Focal Proliferative IgA Nephropathy

Hui Guo,[1] Jing Luo.[2] *[1]Div of Nephrology of Dept of Internal Medicine, 2nd Affiliated Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China; [2]Dept of Internal Medicine, 2nd Affiliated Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China.*

Background: To explore the effects of 1a, 25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$) on memory $CD4^+$ T-lymphocytes in peripheral blood of focal proliferative IgA nephropathy (IgAN) patients.

Methods: Total of twenty incipient focal proliferative IgAN patients (Lee classification: III level) were used as IgAN group and 20 healthy volunteers were used as healthy control group. IgAN group can be divided into two subgroups (proteinuria<1g/d subgroup, proteinuria ≥1g/d subgroup). The serum $1,25(OH)_2D_3$ level was measured by radioimmunoassay (RIA). Peripheral blood mononuclear cells (PBMCs) were stimulated with anti-CD3/anti-CD28 in the absence or presence of various concentrations of $1,25(OH)_2D_3$, Dexamethasone (DEX), and $1,25(OH)_2D_3$ and DEX combined. PBMCs were cultured for 72 hours and the levels of IFN-g, IL-4, IL-17A, Foxp3 were measured by flow cytometry (FCM).

Results: Compared with healthy control group, serum $1,25(OH)_2D_3$ level of IgAN group was significantly lower ($P<0.05$). The levels of IFN-g and IL-17A and the ratios of IFN-g/IL-4 and IL-17A/Foxp3 in IgAN group increased significantly compared with healthy control group, and the level of Foxp3 decreased significantly. The levels of IFN-g and IL-17A and the ratio of IL-17A/Foxp3 in proteinuria ≥1g/d subgroup increased significantly, and the level of Foxp3 decreased significantly, compared with proteinuria <1g/d subgroup and healthy control group. The ratio of IFN-g/IL-4 in proteinuria ≥1g/d subgroup increased

significantly, compared with healthy control group. After treatment with $1,25(OH)_2D_3$, the levels of IFN-g and IL-17A and the ratios of IFN-g/IL-4 and IL-17A/Foxp3 decreased significantly, and the level of Foxp3 increased significantly.

Conclusions: There was a certain extent of vitamin D deficiency in focal proliferative IgAN patients, which may be associated with the severity of proteinuria. $1,25(OH)_2D_3$ had beneficial effects on the immunoregulation of memory $CD4^+$ T-lymphocytes of focal proliferative IgAN patients.

FR-PO545

The Significance of Mesangial C4c Deposition in IgA Nephropathy

Kazuo Torikoshi, Eri Muso, Hiroyuki Suzuki. *Nephrology and dialysis, Tazuke Kofukai Foundation, Medical Research Inst, Kitano Hospital, Osaka, Osaka, Japan.*

Background: In IgA nephropathy (IgAN), activation of the lectin pathway (LP) is associated with more severe renal damage. Mesangial C4d deposition is a marker of activation of the LP and a prognostic factor in renal survival. C4c, the same split products of C4b as C4d, is cut off into liquid phase, while C4d is bound to cell membrane. Therefore, we tried to examine whether C4c is more sensitive prognostic factor in IgAN.

Methods: This retrospective study included total of 104 patients with IgAN who underwent renal biopsy at single center from April 2001 to March 2007, and were followed for at least five years. Patients with IgA vasculitis, systemic lupus erythematosus, liver cirrhosis, or other systemic diseases were excluded. We evaluated baseline age, sex, microscopic hematuria, hypertension, serum creatinine and glomerular filtration rate (GFR), urine protein, and histopathological fincings including mesangial C4c staining by immunofluorescence and, rate of glomerulosclerosis (global and segmental), and active crescent formation by microscopical observation.

Results: 48 patients (46.2%) were C4c positive and 56 patients (53.8%) were C4c negative. The difference of baseline age, serum creatinine, eGFR, microscopic hematuria at renal biopsy was not significant between two groups. Urine protein (g/day) and the rate of eGFR decrease per year (ml/1.73min/m2/year) were significantly higher in C4c positive group (0.63±0.68 versus 1.13±1.68 and 0.85±2.69 versus 1.6±1.8, respectively). Glomeruli showing global sclerosis (%) and segmental sclerosis (%) were also significantly higher in C4c potitive group (15.8±15.5 versus 9.5±11.8 and 10.6±11.9 versus 7.0±7.4, respectively).

Conclusions: These results suggests that mesangial C4c depositon was associated with severe renal damage in IgA nephropathy.

FR-PO546

Distribution of IgA Deposits, and Not Co-Deposition of IgG, C3 or C1q, Is Associated with Crescents or Glomerular Necrosis in IgA Nephropathy

Nicole K. Andeen,[1] Charles E. Alpers,[1] Kelly D. Smith,[1] Shreeram Akilesh,[1] Roberto F. Nicosia,[1,2] Behzad Najafian.[1] *[1]Pathology, Univ of Washington, Seattle, WA; [2]Pathology, VA Puget Sound, Seattle, WA.*

Background: Although presence of crescents and glomerular necrosis in IgA nephropathy is often interpreted as a feature of activity and has been linked to adverse outcome, factors associated with these lesions are not well elucidated. Because co-deposition of complement molecules or IgG has been associated with worse prognosis, we aimed to study if co-deposition of immunoreactants was associated with the presence of crescents and/or segmental necrosis.

Methods: Consecutive native kidney biopsies at the University of Washington with a diagnosis of IgA nephropathy and no other nephropathy were retrospectively reviewed. Oxford classification scores for mesangial hypercellularity, endocapillary proliferation, segmental sclerosis, interstitial fibrosis, presence of crescents/necrosis, and location and intensity of immunofluorescent (IF) staining of IgA, IgG, IgM, C3, C1q, kappa and lambda light chains, and clinical characteristics were recorded.

Results: Of 110 cases (age 13-77, mean 41 years) reviewed, 48 (44%) had crescents/necrosis. Among parameters examined, only E1 (Chi2=14.6, p =0.0001) and presence of IgA deposits in peripheral capillary walls in addition to mesangial regions were associated with crescents/necrosis (Chi2=4.1, p=0.04). IF intensity of IgA staining was greater in biopsies with M1 than M0 (p=0.008). IF intensities of other immunoreactants were not different in biopsies with or without crescents/necrosis, endocapillary hypercellularity, segmental sclerosis, or interstitial fibrosis. Intensity of IgA, kappa and lambda inversely correlated with age, with more deposits found in younger individuals.

Conclusions: Our results suggest that the distribution of IgA deposits, and not co-deposition of other immunoreactants, influences the progression of IgA nephropathy to crescentic lesions or segmental necrosis. Longitudinal studies are needed to show if presence of subendothelial deposits are of prognostic significance in IgA nephropathy. If so, addition of this parameter into Oxford classification may be warranted.

FR-PO547

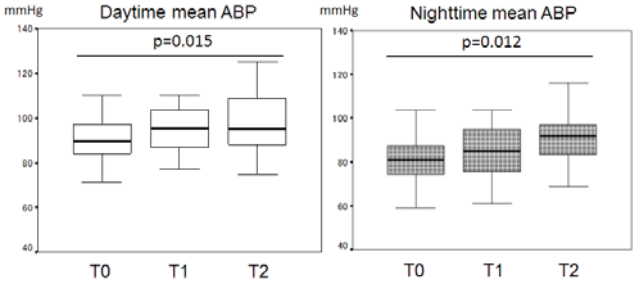
Relationship between Ambulatory Blood Pressure and Renal Histopathological Findings by the Oxford Classification in Patients with IgA Nephropathy

Kotaro Haruhara, Nobuo Tsuboi, Kentaro Koike, Masahiro Suyama, Akihiro Shimizu, Yoichi Miyazaki, Tetsuya Kawamura, Makoto Ogura, Takashi Yokoo. *The Jikei Univ School of Medicine, Div of Nephrology and Hypertension, Tokyo, Minato-ku, Japan.*

Background: Hypertension is a major risk factor for a poor renal outcome in IgA nephropathy (IgAN) patients. Further, ambulatory blood pressure (ABP) has been shown to be useful in predicting the renal function decline of IgAN. In this study, we have analyzed the relationships between ABP and renal biopsy findings by using the Oxford classification (OC), which is a recently established histopathological criteria for predicting renal outcomes of IgAN patients.

Methods: This cross-sectional study included primary IgAN patients, in whom both renal biopsy and ABP monitoring were performed during the same admission. The histopathological findings were assessed by OC, and analyzed in relation to the ABP.

Results: A total of 111 IgAN patients were analyzed. The mean values were 40 years in age, 64 mL/min/1.73m^2 in eGFR, and 1.2 g/day in urinary protein excretion (UPE), respectively. The score of interstitial fibrosis and tubular atrophy (T) was significantly associated with the mean value of daytime and nighttime ABP. In contrast, the other histopathological findings, including mesangial hypercellularity, endocapillary hypercellularity, and segmental glomerulosclerosis did not show significant association with ABP. In addition, global glomerulosclerosis, extracapillary lesions did not show significant association with ABP. T score was associated with both daytime and nighttime ABP, independent of eGFR, UPE and the use of antihypertensive medications, in multivariate analyses. Any score by OC was not associated with the ratio of nighttime to daytime ABP.



Conclusions: These results suggest that T score by OC is the most relevant renal histopathological parameter associated with ABP in IgAN patients.

FR-PO548

Long-term Impact of Immunosuppressive Therapy for IgA Nephropathy with Moderately Impaired Renal Function: A Single Center Experience in South Korea

Kyung Sun Park,[1] Jongha Park,[2] Jong Soo Lee,[2] Hyun Chul Chung.[2] *[1]Internal Medicine, Dongkang Medical Center, Ulsan, Republic of Korea; [2]Internal Medicine, Ulsan Univ Hospital, Univ of Ulsan College of Medicine, Ulsan, Republic of Korea.*

Background: A wide variety of treatment has been attempt to slow progression of IgA nephropathy (IgAN) such as renin-angiotensin system inhibitors and adding corticosteroid for patients with impaired renal function. We compared clinical outcomes of IgAN patients who received immunosuppressive therapy (IST) and who did not received IST, and identified risk factors associated with progression of renal dysfunction.

Methods: Patients with IgAN followed up for at least 36 months and with initial estimated glomerular filtration rate (eGFR) of 30-60 mL/min were retrospectively reviewed. Overall, 74 patients who diagnosed IgAN between 2001 and 2010 were included this analysis.

Results: Median follow-up was 78.5 months. Thirty-two patients received IST (Group 1) and 42 did not (Group 2). Mean age (44.4 versus 45.8 years, P=0.586), mean arterial pressure (MAP, 98 versus 93 mmHg, P=0.103), serum creatinine (1.53 versus 1.42 mg/dL, P=0.141), eGFR (48.1 versus 50.1 mL/min, P=0.269) and median proteinuria (1871 versus 1520 mg/day, P=0.111) at baseline were not significantly different. One patient of Group 1 and 4 of Group 2 progressed to end-stage renal disease (ESRD). ESRD-free survival was not different between two groups (P=0.265). In Group 2, eGFR declined significantly for 3 years (-3.16 mL/min, P=0.038), while that was not significant in Group 1 (-0.21 mL/min, P=0.937). In multivariate linear regression, age at diagnosis (coefficient, 0.546 per 1 year; P=0.015), hypertension (coefficient, -10.507; P=0.029), MAP (coefficient, -0.364 per 1 mmHg; P=0.038), baseline eGFR (coefficient, 1.251 per 1 mL/min; P<0.001) and follow-up duration (coefficient, -2.843 per 1 year; P=0.006) were independent predictors of last-visit eGFR.

Conclusions: IST may have a beneficial effect for slowing progression of IgAN with moderately impaired renal function.

FR-PO549

Mycophenolste Mofetil in IgA Nephropathy with Deteriorating Renal Function Ana Huerta,[1] Evangelina Merida,[2] Eduardo R. Hernandez,[2] Eduardo Gutierrez-Martinez,[2] Enrique Morales,[2] Manuel Praga.[2] *[1]Puerta de Hierro Hospital, Madrid, Spain; [2]12 Octubre Hospital, Madrid, Spain.*

Background: Information about treatment of IgAN showing progressive deterioration of kidney function is scarce. We designed a therapeutic protocol with corticosteroids (CS) + MMF in this type of patients (pts).

Methods: Included in the protocol were 13 pts with biopsy-proven IgAN showing a progressive decline of renal function (GFR decline of 30±9% during the previous 6 months before treatment). All were receiving RAS blockers that were maintained during immunosuppressive therapy. Treatment consisted of oral prednisone (1 mg/Kg/d-1st month, 0.5 mg/kg/d-2nd month, tapering doses during the 3rd month to maintenance therapy with 5-10 mg/d) for 9±4 months, and MMF (1-2 g/d, according to digestive tolerance) for 21±14 months. A linear regression model was used to calculate the slope of GFR, and non-parametrical tests to compare GFR and proteinuria changes after treatment.

Results: All the pts but one (Asian origin) were Caucasians; there were 8 men and 5 women. Age at baseline was 48 ±13 years, serum creatinine 1.81±0.33 mg/dl, and eGFR 40±13 ml/min (CKD-EPI). Mean 24hr urine protein excretion was 2.5±2.6 g/day and all the pts showed microhematuria. A significant change was found when comparing eGFR slope during the 6 month-period before treatment (-2.82±0.93 ml/min/m) with eGFR slope during CS+MMF treatment (+0.24 ±0.74 ml/min/m; p=001). Proteinuria showed a significant decline after treatment (2.5 ±2.6 to 0.71±0.72 g/day, p=0.002). Hematuria disappeared in 11 pts. Follow-up after CS+MMF withdrawal was 34±33 m. eGFR slope during this post-treatment period was +0.07 ±0.32 ml/min/m and proteinuria remained stable in comparison with the treatment period. CS+MMF were well tolerated. Adverse effects included herpes zoster infection in 1 patient and mild gastrointestinal disturbances in 3. No one required treatment withdrawal.

Conclusions: Combination of CS + MMF at relatively low doses for 1-2 years was effective to halt the progression of renal insufficiency in a selected group of IgAN with deteriorating renal function, and was well tolerated. Prospective controlled studies are needed to confirm our results.

FR-PO550

IgA Nephropathy and Kidney Transplantation: Recurrence Rate in the Graft and Long Term Outcomes Sophia Lionaki,[1] Konstantinos Panagiotellis,[1] Ilias Makropoulos,[1] Georgios Vlachopanos,[1] Christos Damaskos,[1] Hariklia Gakiopoulou,[2] Smaragdi Marinaki,[1] George Zavos,[1] Ioannis Boletis.[1] *[1]Nephrology & Transplantation, Laiko General Hopsital, Athens, Greece; [2]Pathology, Univ of Athens.*

Background: To estimate the recurrence rate of IgA Nephropathy (IgAN) in the graft, and also compare the long term outcomes of these patients with those of kidney transplant recipients with other primary diseases.

Methods: We studied all patients who were transplanted in our hospital between 2000 and 2013, had biopsy proven IgAN in the native kidneys, and follow up time longer than 1 year post KTx. Every patient with IgAN was matched with 2 controls, using the following criteria: primary disease, age, gender, time of KTx, and donor source. Patients with Henoch-Schonlein purpura or with a history of non-compliance were excluded. The groups were compared with respect to patient and graft survival, and renal function at the end of follow up. We also recorded the rate of IgAN in the graft and its impact in graft survival.

Results: Between 2000 and 2013, 70 patients with biopsy proven IgAN were transplanted in our center. 67 patients with IgAN and 144 matched controls were included in the study. In a mean follow up time of 65 months, 7 patients (10.4%) were diagnosed with IgAN recurrence in the graft, 39 months post KTx. None of these patients experienced graft loss due to the IgAN. Comparison of outcomes between the IgAN and the control group revealed that patient and graft survival were similar.

Parameter	IgAN, N=65	Controls, N=133	p value
Hemodialysis time (months)	46.2	49.6	0.69
PRA>50% (%)	4.8	9.8	0.22
Delayed Graft Function (%)	27	34.1	0.31
eGFR at 1st discharge (ml/min/1.73m^2)	49.6	53.5	0.17
eGFR at 1st KTx year (ml/min/1.73m^2)	56.6	55	0.59
eGFR at end of follow up (ml/min/1.73m^2)	54.5	58.9	0.21
Induction Rx, anti-CD25 (%)	93.75	91.7	0.32
Maintenance Rx, MPA+CNI+STEROIDS (%)	85.9	85.5	0.11
Incidence of Acute Rejection (%)	9.2	12.7	0.69

Conclusions: KTx in patients with IgAN who end up in ESRD results in patient and graft survival similar to the ones of patients with other primary diseases. Although recurrence of IgAN in the graft is not rare, it is not a cause of graft loss.

FR-PO551

Prognostic Impact of Serum Bilirubin Level on Long-Term Renal Survival in IgA Nephropathy Shigeru Tanaka, Toshiharu Ninomiya, Kosuke Masutani, Masaharu Nagata, Akihiro Tsuchimoto, Kazuhiko Tsuruya, Takanari Kitazono. *Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Serum bilirubin has been recognized as a novel endogenous antioxidant. The aim of our study was to evaluate the impact of serum bilirubin on kidney prognosis in IgA nephropathy (IgAN).

Methods: We followed retrospectively 694 patients with IgAN diagnosed by renal biopsy between 1982 and 2010. The risk factors for developing end-stage renal disease (ESRD) were estimated using a Cox proportional hazard model. Predictive performance between models with or without serum bilirubin was evaluated by calculating the net reclassification improvement (NRI) and integrated discrimination improvement (IDI).

Results: Seventy-seven patients developed ESRD during the median 4.9 years of follow-up. Estimated glomerular filtration rate (eGFR), proteinuria and histological severity were inversely related to bilirubin levels. In multivariate analysis, serum bilirubin was an independent risk factor for ESRD (hazard ratio for every 0.1mg/dL decrease in serum bilirubin, 1.18; 95% CI, 1.04-1.33). The incidence rate of ESRD decreased linearly with the increases in bilirubin levels (P for trend <0.01). When bilirubin was incorporated into a model with conventional ESRD risk factors, the NRI and IDI were 0.281 (P=0.017) and 0.019 (P=0.012), respectively.

Conclusions: We demonstrated that lower bilirubin levels were significantly associated with higher risk of ESRD in IgAN. In addition, bilirubin provided incremental predictive value in the risk assessment for progression of IgAN beyond that provided by standard risk factors.

FR-PO552

Total Cholesterol Is Independet Risk Factor for Progression of Kidney Disease in IgA Neprhropathy Patients Yasuyuki Nagasawa,[1] Ryohei Yamamoto,[2] Maki Shinzawa,[2] Sayuri Kawada,[1] Aritoshi Kida,[1] Mana Yahiro,[1] Takahiro Kuragano,[1] Tatsuya Shoji,[3] Terumasa Hayashi,[3] Atsushi Yamauchi,[4] Yoshitaka Isaka,[2] Takeshi Nakanishi.[1] *[1]Dept of Internal Medicine, Div of Kidney and Dialysis, Hyogo Medical College, Nishinomiya, Japan; [2]Div of Nephrology and Geriatric Medicine, Osaka Univ Graduate School of Medicine, Suita, Japan; [3]Dept of Nephrology and Hypertension, Osaka General Medical Center, Osaka, Japan; [4]Dept of Nephrology, Osaka Rousai Hospital, Sakai, Japan.*

Background: Ig A nephropathy is one of common primary glomerulonephritis. Recently, several reports indicated that the statin therapy might have favorable effect upon kidney diseases, but there was little information about the effect of hyperlipidemia itself upon progression of kidney diseases, especially in IgA nephropathy patients.

Methods: This study is retrospective cohort study. Subjects were 1205 IgA nephropathy patients who were diagnosed by renal biopsy, and over 15 years old in Osaka University Hospital, Osaka general medical center, Osaka Rosaki Hospital. Outcome was 1.5 times of serum creatinine. Explanatory variables included sex, age, BMI, blood pressure, baseline eGFR, proteinuria, smoking status.

Results: Mean age was 31[23-46] years, BMI was 22.3+-3.5, mean blood pressure was 121.67+-17.1/74.7+-13.0 mmHg, eGFR was 103.9+-33.7ml/min/1.73m2, proteinuria was 0.42[0.19-0.92] g/day. Total cholesterol was 5.03+-1.21mmol/l. Univariate analysis revealed that total cholesterol had significantly risk for progression of renal disease [Hazard Ratio 1.52[1.32-1.72],P<0.001] along with systolic BP (*10mmg), proteinuria (g/day), eGFR (*10ml/min/1.73m2). Multivariate analysis also revealed that total cholesterol was significant risk for progression of renal disease [Hazard Ratio 1.21[1.32-1.72] P<0.007] along with systolic BP (*10mmg) [HR 1.15[1.03-1.29] P=0.013], proteinuria (g/day) [HR 1.25[1.12-1.1.39],p<0.001], eGFR (*10ml/min/1.73m2) [HR 0.82[0.76-0.90],p<0.001]. After the patients were divided into four categories according to total cholesterol, IgA patients with higher cholesterol had poorer prognosis.

Conclusions: Hyper-cholesterol is independent risk for progression of kidney disease in IgA nephropathy patients.

FR-PO553

Clinicopathological Significance of Monoclonal IgA Deposition in Patients with IgA Nephropathy Hiroshi Nagae,[1] Shota Kawahara,[1] Yukiko Shimomura,[1] Akihiro Tsuchimoto,[2] Kosuke Masutani,[2] Kazuhiko Tsuruya,[2] Ritsuko Katafuchi.[1] *[1]Nephrology, National Fukuoka Higashi Medical Center, Koga, Fukuoka, Japan; [2]Medicine and Clinical Science, Kyushu Univ.*

Background: Nasr et al described proliferative glomerulonephritis with monoclonal IgG deposition (PGNMID), and serum monoclonal protein was detected in 50% of patients with PGNMID. As for IgA nephropathy (IgAN), Lai et al reported that monoclonal IgA-ldeposition was observed in 18 out of 45 patients. However, clinicopathological significance of monoclonal IgA deposition (mIgAd) in IgAN is unclear.

Methods: We retrospectively investigated the prevalence of mIgAd and its clinicopathological significance in 65 patients with IgAN. Pathological parameters included Oxford classification and histological grade proposed by Special IgAN Study Group in Japan.

Results: 38% of patients were male, median age was 40 and median observation period was 31 months. 5 patients (Group M) showed monoclonal IgA-ldeposition and one showed

monoclonal IgA-k deposition. 59 patients (Group P) showed polyclonal IgA deposition. There were no significant differences in urinary protein/creatinine ratio, urinary-RBC and eGFR between Group M and P. TP and albumin were significantly lower in Group M than in Group P. Pathologically, the % of patients with M1 was significantly higher in Group M than in Group P. Only one patient in Group P showed serum monoclonal IgG-l. No patient showed abnormal serum k/l ratio. 75% in Group M and 42% in Group P were treated with steroid. During the follow up period, proteinuria disappeared in all patients in Group M and 68% in Group P. Hematuria disappeared in 67%, and 52% in Group M and P, respectively. 3 patients in Group P progressed end-stage renal disease (ESRD). The frequency of disappearance of proteinuria or hematuria and ESRD was not different between the groups.

Conclusions: The prevalence of mIgAd was 9.2%. Although some parameters differed between the groups, renal outcome were similar in both groups. Thus, IgAN with mIgAd might not be different entity from polyclonal IgA deposition. MIgAd is not likely to be related to hematological disorder. Further investigation is required to clarify the significance of mIgAd in IgAN.

FR-PO554

The Effects of the Pathologic Evidences of Podocyte Injuries on Proteinuria in Patients with IgA Nephropathy Seon Ha Baek, Shin-Young Ahn, Seong Woo Lee, Youn-Su Park, Sejoong Kim, Ho Jun Chin, Ki Young Na, Dong-Wan Chae. *Internal Medicine, Seoul National Univ Bundang Hospital, Korea.*

Background: Although the mesangial cells are primary target of injury in IgA nephropathy (IgAN), pathologic findings suggestive of injury to podocytes (PCs) such as segmental sclerosis (SS, depletion of PCs), crescent formation (CF, activation and proliferation of PCs) and foot process effacement (FPE) are frequently observed in renal biopsies from patients with IgAN. Based on the implications of PC injuries for more widespread inflammation not confined to measangium and the essential role of PC in filtration barrier on proteinuria, we hypothesize that the existence of PC injuries in renal biopsies negatively affect the proteinuria in IgAN.

Methods: We retrospectively assessed the effect of SS, CF, and diffuse FPE on basal proteinuria (BPU) at the time of biopsy and 1 year time averaged proteinuria (TAPU) under the treatment by renin-angiotensin aldosterone system (RAAS) blockade in IgAN patients from Seoul National University Bundang Hospital in Korea.

Results: A total of 294 patients (136 men, 158 women) with biopsy-proven primary IgAN were evaluated. The mean value of eGFR and BPU were 86.8 ml/min/1.73m2 and 1.68 g/g. Diffuse or focal but marked FPE, SS, and CF at kidney biopsy were observed in 29.5%, 72.8% and 25.2% of patients respectively. The presence of FPE (r=.159, P =.007), SS (r =.186, P =.001), and CF (r=.354 P<.001) were significantly associated with the higher BPU in fully adjusted analyses. In 175 patients treated by RAAS blockade without any immunosuppressant, SS and CF were associated with higher 1 year TAPU in fully adjusted analyses. (r =.180, P=.019, r=.310, P<.001 respectively). The patients showing all three features of podocytopathy (namely FPE, SS, and CF) had higher BPU and 1 year TAPU than patients exhibiting lesser number of podocytopathy (r =.427, P<.001, r=.152, P=.047).

Conclusions: Pathologic evidences of PC injuries in IgAN are associated with higher BPU and unfavorable response of proteinuria to RAAS blockade.

FR-PO555

Comparison of Clinical Manifestations Between Henöch-Schönlein Purpura Nephritis and IgA Nephropathy: Analysis of Japan Renal Biopsy Registry (J-RBR) Hiroyuki Komatsu,[1] Shouichi Fujimoto,[1] Norishige Yoshikawa,[2] Hiroshi Kitamura,[3] Hitoshi Sugiyama,[4] Hitoshi Yokoyama.[5] *[1]Univ of Miyazaki, Miyazaki, Japan; [2]Wakayama Medical Univ; [3]Chiba-East Hospital; [4]Univ of Okayama; [5]Kanazawa Medical Univ.*

Background: The clinical presentation of Henöch-Schönlein purpura nephritis (HSPN) in an adequate sample of patients of different ages has not been studied in detail. We therefore surveyed the features of HSPN and differences between HSPN and IgA nephropathy (IgAN) based on data from the Japan Renal Biopsy Registry (J-RBR).

Methods: A cross-sectional survey of 513 patients with HSPN and 5,679 with IgAN registered in the J-RBR between 2007 and 2012 was conducted. Clinical and pathological parameters of blood pressure (BP), and blood and urine laboratory findings at diagnosis were compared between these two groups and among children (≤ 18 years), adults (19-64 years) and elderly persons (≥ 65 years). Factors affecting declining renal function in adult and elderly patients were assessed using multiple regression analysis.

Results: Age distribution considerably differed between HSPN and IgAN although the mean age was 38.6 years in both groups; HSPN had bimodal peaks at 1 - 19 and at 60 - 69 years, whereas IgAN peaked at 30 - 39 years. The clinical features of HSPN were significantly more severe than those associated with IgAN, especially proteinuria (children, 1.28 versus 0.57 g/day; adults and elderly persons, 2.16 versus 1.11 g/day), and hypoalbuminemia (children, 3.72 versus 4.13 g/dL; adults and elderly persons, 3.47 versus 3.95 g/dL). The patients with HSPN had a higher rate (%) of histological classification as endocapillary proliferative or crescentic glomerulonephritis than those with IgAN. More advanced age and increased proteinuria were independent factors associated with decreasing estimated glomerular filtration rates in patients with HSPN and high BP and hypoalbuminemia were added to these in patients with IgAN.

Conclusions: The age distribution of patients with HSPN had bimodal peaks in children and elderly persons, and the clinical features were more severe than those of IgAN across all age groups.

FR-PO556

Long Term Follow-Up of Biopsy Proven Pediatric Henoch Schönlein Purpura Nephritis Tim Ulinski,[1,4] Georges Deschenes,[3] Bilal Aoun.[1] *[1]Pediatric Nephrology, Armand Trousseau Univ Hospital, Paris, France; [2]Pediatrics, CHU Toulouse, Toulouse, France; [3]Pediatric Nephrology, Robert Debré Hospital, Paris, France; [4]Univ Pierre et Marie Curie, Paris, France.*

Background: Henoch Schönlein purpura (HSP) nephritis is responsible for progressive renal disease in 7-50% of patients. Treatment usually depends on the severity of histological lesions.

Methods: Patients from three French centres were retrospectively analysed. The aim of this study was to determine the long-term biological outcome in children with HSP nephritis who underwent a renal biopsy and to identify possible predictive markers for disease development and to examine whether treatment modalities such as intravenous steroid pulses and ACE inhibitor were correlated with a better outcome.

Results: A total of 142 patients with HSP nephritis (graded according to the ISKDC classification) were followed up from 2 to 10.5 years. Mean (± SD) age at presentation was 7.6±2.8 years. Nephrotic range proteinuria was present in 28% with grade II, 60% with grade III and 90% with grade IV histological lesions. Significant proteinuria (>0.5g/L) was found in 9/48 patients three years, in 8/25 patients five years and in 3/14 patients 10 yearspost renal biopsy. There was no correlation between risk for proteinuria at 3, 5, or 10 years with initial histological lesions or treatment modalities such as oral or pulse steroids. Treatment with angiotensin converting enzyme inhibitors/angiotensin receptor blockers (ACEi/ARB) was related with lower proteinuria mainly if started precociously.

Conclusions: Even mild forms of HSP nephritis are at risk for significant proteinuria in the long term. There is a risk for under treatment in patients with low grade lesions. Very early introduction of ACEi/ARB may improve long term outcome independent from histological lesions.

FR-PO557

High Serum IgA/C3 Ratio Is a Novel Independent Predictor of Recurrence in IgA Nephropathy After Steroid Pulse Therapy Hoichi Amano,[1] Keita Hirano,[1] Tetsuya Kawamura,[2] Nobuo Tsuboi,[2] Kazushige Hanaoka,[2] Takashi Yokoo.[2] *[1]Nephrology, Ashikaga Red Cross Hospital, Ashikaga, Tochigi, Japan; [2]Nephrology and Hypertension, Jikei Univ School of Medicine, Minato, Tokyo, Japan.*

Background: We previously reported that mesangial hypercellularity in Oxford classification (M) and high histological grades (HGs) in Japanese classification (J Nephrol 2013) predict recurrence in IgA nephropathy (IgAN) after six months-steroid therapy, and tonsillectomy (Tx) combined with the steroid therapy reduces the risk of recurrence (ASN Kidney Week 2013). Other studies have shown that serum IgA/C3 ratio is associated with renal survival in IgAN. However, its association with recurrence is obscure. Therefore, we aimed to identify the independent clinical implication of serum IgA/C3 ratio in recurrence.

Methods: Among 137 patients with IgAN who received six months-steroid pulses (Pozzi et al. J Am Soc Nephrol 2004) from 2004 to 2010 in our affiliated hospitals and whose serum IgA /C3 ratio was determined at the start of treatment, we enrolled 101 patients who achieved a reduction in the urinary protein excretion volume (UPE) to <0.4 g/day at one year following the start of treatment, employing historical cohort design. The endpoint was defined as an increase of UPE >1.0 g/day following the first one year after initiating the steroid therapy.

Results: At the start of treatment, median UPE was 0.81 g/day. Mean of eGFR and IgA/C3 ratio were 72.7ml/min and 3.28, respectively. During a median follow-up of 2.4 years after the first one year following the initiation of treatment, 27 patients (26.7%) reached the end point. The optimal cutoff for serum IgA/C3 ratio predicting recurrence was determined as 2.91 by receiver operating characteristic curve. Of note, high serum IgA/C3 ratio defined as >2.91 was a significant and independent predictor of an increased risk of recurrence in an adjusted model with M, HGs and Tx (HR: 2.58, 95%CI: 1.02-7.85, P=0.044).

Conclusions: Our data indicate that high serum IgA/C3 ratio at baseline is a novel independent predictor of recurrence in IgAN after steroid pulse therapy.

FR-PO558

Dense Deposit Disease in Ireland Carol A. Traynor, John O'regan, Limy Wong, Michelle M. O'Shaughnessy, Anthony M. Dorman, Peter J. Conlon. *Nephrology, Beaumont Hospital, Dublin, Ireland.*

Background: Dense Deposit Disease (DDD), also called membranoproliferative glomerulonephritis Type II, is a rare disease that predominantly affects children and young adults. We describe the clinical characteristics of all cases of DDD diagnosed in Ireland in the period 1976-2011.

Methods: We performed a retrospective review of all native renal biopsies performed in Ireland in the period 1976-2011. The diagnosis of DDD was based on the ultrastructural finding of a transformation of glomerular basement membranes by ribbon-like, highly electron-dense material and predominant immunofluorescence staining for C3. Patients' medical records were reviewed for demographic information, presenting clinical and laboratory findings, treatment, and outcome. Kaplan-Meier analysis was used to determine survival probabilities.

Results: There were 37 patients. Median age at diagnosis was 12.

Characteristic	All Patients (n=37)	ESKD (=20)	No ESKD (n=17)	p value
Age (median)	12.0	14.5	8.5	0.03
Gender male n (%) female n (%)	 16 (43%) 21 (57%)	 11 9	 5 12	ns
creatinine at biopsy median (IQR)	82µmol/L (68-125)	81µmol/L (71-250)	82µmol/L (60-99)	ns
Hypertension	15/33 (45%)	7/17 (41%)	8/15 (53%)	ns
protenuiria 0.5g/24hr 0.5-1g/24hr 1-3g/24hr >3g/24hr	 1/34 5/34 13/34 15/34	 0/18 1/18 8/18 9/18	 1/16 4/16 5/16 6/16	ns
nephrotic syndrome	24/29	14/16	10/13	ns
haematuria	34/35	18/19	16/16	ns
low C3	18/19	8/8	10/11	ns
low C4	2/15	1/7	1/8	ns

describes demographic characteristics. There were 21 females and 16 males affected. Twenty patients (54%) progressed to ESKD. Median time to ESKD was 8.9 years (6.2, 17.1). Patients who developed ESKD were older at presentation (median 14.5 versus 8.5). Two patients had a prior history of acquired partial lipodystrophy (APL). There were 25 transplants in 18 patients. Graft half-life was 9 years and 10 patients developed recurrence of DDD in the graft.

Conclusions: To our knowledge, this is the third largest series to date describing the clinical characteristics and transplant outcomes in patients with DDD. There was a high recurrence rate of DDD in transplanted patients although this did not universally lead to graft loss.

FR-PO559

C3 Glomerulonephritis Associated with Autoimmune Disorders: A Case Series

Mariam P. Alexander,[1] Fernando C. Fervenza,[2] Sanjeev Sethi.[1] *[1]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; [2]Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: C3 glomerulonephritis (C3GN) is a proliferative GN resulting from glomerular deposition of complement factors due to dysregulation of the alternative pathway of complement. This is due to inherited (genetic) or acquired (autoantibodies) abnormalities of the complement regulating proteins (CRP). The autoantibodies presumably cause functional impairment of CRPs. In this study, we set out to determine if C3GN was associated with an underlying autoimmune disease.

Methods: The pathology database was queried for patients (pts) with C3GN, who had serological evidence/clinical diagnosis of an underlying autoimmune disease (AI). Clinical features (fxs), laboratory values, kidney biopsy (Kbx) findings, treatment, and followup were recorded.

Results: 5 pts fulfilled the inclusion criterion. Mean age was 43 yrs, F: M ratio was 3:2, mean serum creatinine was 2.56 mg/dL and mean proteinuria was 4660 mg/day. All pts had positive serology and/or clinical evidence of AI disease. All pts had strongly positive ANA and ds-DNA. In addition, 2 had clinical evidence of AI diseases (1 with Raynauds disease; the other with skin ulcerations and fibromyalgia). C3 and C4 were normal in all, except 1 who had low C3 levels. Kbx showed membranoproliferative (2), mesangioproliferative (2), and endocapillary proliferative (1 patient) GN. IF showed bright C3 staining in all patients. There was mild (1+) staining for IgG in 1 pt and IgM in 4 pts. Tubuloreticular inclusions (TRI) were present in 2 pts. All 5 kbx's showed abundant mesangial and capillary wall electron dense deposits. Treatment included immunosuppressive therapy in 4 (prednisone-4; cyclophosphamide-2; mycophenolate mofetil-1). Follow-up in 2 pts over a mean period of 10 months, showed a mean creatinine of 1.65 mg/dL and mean proteinuria of 1674 mg/day.

Conclusions: This is the first series to show an association between C3GN and autoimmunity. The unusual fxs (positive AI panels, co-immunoglobulin deposits, and TRI's) suggest a true association of two processes. The pathogenic basis for disease might be an aberrant autoantibody directly interfering with CRP function.

FR-PO560

Ten-Year Follow-Up of Patients with Epidemic Glomerulonephritis due to Streptococcus Zooepidemicus

Ricardo Sesso,[1] Sergio Wyton.[2] *[1]Nephrology, Federal Univ of São Paulo, São Paulo, SP, Brazil; [2]Nephrology, Hospital São João de Deus, Divinópolis, MG, Brazil.*

Background: In 1998 there was a large outbreak of acute glomerulonephritis in the city of Nova Serrana, Southeastern Brazil, caused by Lancefield group C *Streptococcus zooepidemicus*. Epidemiological investigation revealed that patients had consumed a locally produced cheese prepared with contaminated unpasteurized milk. This study describes the follow-up of these patients after a mean time of 10.4 years of the acute episode.

Methods: Of 135 cases identified in 1998, 60 were reexamined and compared with a control group of community individuals (n=48) not affected during the outbreak, matched by age and gender, in a prospective study. Participants had measurements of blood pressure, glomerular filtration rate (estimated by the Modification Diet in Renal Disease equation, eGFR) and albuminuria (radioimmunoassay) expressed as albumin-to-creatinine ratio in a random untimed urine sample. Creatinine was measured using the Jaffé method on an autoanalyzer.

Results: Of the original group of 135 affected subjects, 3 died in the acute phase and 5 (3.7%) required chronic dialysis initiated during the initial disease period. Of the 60 reevaluated cases, all were adults (mean±SD age: 49±15 yr) and 40 (67%) females. Sociodemographic and baseline clinical characteristics were not significantly different between the reevaluated cases and those who were not. At the follow-up examination we found arterial hypertension (blood pressure ≥140/90 mmHg or use of anti-hypertensive drugs) in 33% (n=20) of the cases and 21% (n=10) of the controls (p>0.20), eGFR was <60ml/mim/1.73 m^2 in only 2 cases and 2 controls (3% and 5%, respectively, p=ns); albuminuria >20 mg/g was observed in a similar percentage of cases and controls (19% and 21%, respectively, p=ns); reduced eGFR or increased albuminuria was observed in a similar percentage of cases and controls (n=12 (20%) and n=11 (23%), respectively, p=ns).

Conclusions: After a mean followu-up time of 10.4 years, the prognosis of patients with epidemic poststreptococcal glomerulonephritis due to *S. zooepidemicus* was favorable; rates of abnormal renal function or hypertension were comparable with a healthy control group.

FR-PO561

Long-Term Prognosis of Postinfectious Glomerulonephritis in Adults

Carla Tenório Barros Cisne Pessoa, Camila Barbosa L. Oliveira, Alline S.A. Oliveira, Clarissa Jacob Barros Carvalho, Nathalia K.N. Alecrim, Luis H.B.C. Sette, Gisele Vajgel Fernandes, Lucila Maria Valente, Maria Alina G.M. Cavalcante. *Nephrology, Univ Federal de Pernambuco, Recife, Pernambuco, Brazil.*

Background: Postinfectious glomerulonephritis (PIGN) is uncommon in adults, with a declining incidence over the past decades, particularly in developed countries. The aim of this study is to evaluate the profile, clinical course and outcomes of adult patients with PIGN.

Methods: We conduct a retrospective single center cohort study of adult patients with PIGN diagnosed between 1997-2013. Clinical characteristics, laboratorial data and long-term follow-up were analyzed.

Results: We evaluated 40 patients, 52.5% women with a mean age of 30.7 ± 15.7 years. The most common sites of infection were upper respiratory tract (51.2%), skin (27.5%) and lower respiratory tract (6.9%). Nephritic syndrome was the main clinical presentation (82.5%), followed by rapidly progressive glomerulonephritis (10%) and hematuria and/or non-nephrotic proteinuria (5%). Hypertension was present in 65% of patients. Median serum creatinine (Cr) and Cr clearance (Cl) were 2.0 ± 1.5mg/dl and 53.4 ± 27.7 ml/min/1.73m^2, respectively, and 10% of patients required renal replacement therapy (RRT). Low serum C3 levels were detected in 78.1% and C4 in 22.2%. Biopsy was performed in 14 (35%) patients and 35% of the biopsies had crescents. Mean follow-up time was 29.6 ± 27.5 months. Outcomes are shown in table 1.

Outcome	N=38
Follow up (months)	29.6± 27.5
Serum Cr, mg/dl	0.9 ± 0.3
ClCr, ml/min/1,73m^2 (MDRD)	82.2 ± 13.4
Proteinuria > 300mg/day, %	14.8
Hematuria, %	28.9
Hypertension, %	25
Chronic Kidney Disease, %	28
Doubling Cr, %	0
RRT, %	0

Chronic kidney disease at the end of follow-up was associated with a lower baseline CrCl (36.4 ± 24.0 versus 58.3 ± 27.0ml/min/1.73m^2; p=0.015). Hypertension at the initial presentation (p=0.444), nephrotic proteinuria (p=0.626) and crescents on biopsy (p=0.587) did not increase the risk of chronic kidney disease.

Conclusions: Adult patients with PIGN can have a severe clinical manifestation, demonstrated by baseline renal dysfunction, sometimes with necessity of RRT, and a reasonable risk of chronic kidney disease.

FR-PO562

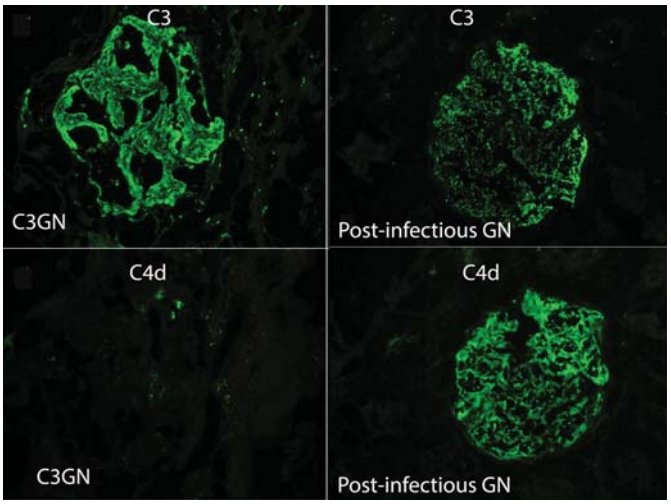
C4d as a Marker for Immune Complex-Mediated Glomerulonephritis versus C3 Glomerulopathy

Sanjeev Sethi, Samih H. Nasr, Fernando C. Fervenza. *Mayo Clinic, Rochester, MN.*

Background: Proliferative glomerulonephritis (GN) is classified as immune complex-mediated (IC-GN) and complement-mediated GN (C3 glomerulopathy). C3 glomerulopathy includes dense deposit disease (DDD) and C3 glomerulonephritis (C3GN). IC-GN results from glomerular deposition of Ig and C3; the C3 in IC-GN is derived from activation of the classical pathway of complement. On the other hand, C3 glomerulopathy results from deposition of C3 and other complement fragments; the C3 is derived from activation of alternative pathway of complement. C4d is a by-product of activation of CP of complement. Thus, we hypothesized that C4d is positive in IC-GN, while it is negative in C3 glomerulopathy.

Methods: IC-GN and C3 glomerulopathy were identified by retrospective review of kidney biopsies. We identified 18 biopsies of IC-GN and 26 biopsies of C3 glomerulopathy. IC-GN included IgA nephropathy, MPGN, membranous nephropathy, lupus nephritis, post-infectious GN, and fibrillary GN. C3 glomerulopathy included 24 cases of C3GN and 2 cases of DDD. C4d staining by IF (0-3+) was done using polyclonal FITC-conjugated antibodies.

Results: C4d was positive in all cases of IC-GN, except for IgA nephropathy. All biopsies of IC-GN showed bright glomerular C4d (2-3+) indicating on-going activation of the classical pathway. On the other hand, C4d was completely negative in 20 (77%) of 26 biopsies of C3 glomerulopathy, and showed only trace/1+ C4d staining in the remaining 6 (23%) biopsies. Importantly, none of the biopsies of C3GN showed the bright (2-3+) C4d staining seen in IC-GN.



Conclusions: IC-GN is characterized by the presence of Ig, C3 and bright C4d. On the other hand, C3 glomerulopathy is characterized by presence of bright C3, negative or weak C4d, and scant or no Ig. Thus, C4d serves a positive marker for IC-GN, while it is negative in C3 glomerulopathy. C4d is a useful ancillary study in determining the etiology of GN.

FR-PO563

Renal Disease in 95 Primary Sjögren's Syndrome with Renal Biopsy

Magali Jasiek,[1] Alexandre Karras,[2] Benjamin Terrier,[2] Rafik Mesbah,[3] Pierre M. Ronco,[4] Philippe Remy,[6] Noemie Jourde-Chiche,[7] Stanislas Faguer,[5] Raphaele Seror,[1] Xavier Mariette,[1] Eric Thervet,[2] Véronique Le Guern,[2] H. Francois.[1] *[1]Nephrology, Bicêtre Hospital, Univ Paris Sud, France; [2]Nephrology and Internal Medicine, Univ Paris Descartes, France; [3]Nephrology, Hôpital Boulogne sur Mer, France; [4]Nephrology, Tenon Hospital, France; [5]Nephrology, Ragueil Hospital, France; [6]Nephrology, Mondor Hospital, France; [7]Nephrology, Marseille Hospital, France.*

Background: Since kidney disease in Primary Sjögren's syndrome (pSS) is rare.

Methods: we conducted a French multicenter retrospective study of biopsy proven nephropathies in pSS patients. Inclusion criteria were patients diagnosed with pSS based on AECG criteria who underwent a kidney biopsy.

Results: We included 95 patients (sex ratio F/M: 9/1, mean age 49,3 years). Renal disease was diagnosed after the first symptoms of pSS in 68,4%. Renal manifestations consisted in renal failure in 86,3% of the patients, proteinuria in 26,3%, electrolyte disturbances alone in 17,9%, lithiasis in 9,5% and nephrocalcinosis in 5,3%. Renal biopsies exhibited acute or chronic tubulointerstitial nephritis in 73 (77%) patients with plasmocytes infiltrate in 69,2%. Glomerular lesions were found in 22 patients (23,2%), and mixed (intersitial and glomerular) in 19. Glomerular disease consisted in cryoglobulinemic glomerulopathy (8), focal and segmental glomerulosclerosis (5), membranous nephropathy (4), minimal change disease (2) or other lesions (3). Of note, 81 patients (85,3%) received an immunosuppressive treatment including steroids (98,8%). 21 patients received another immunosuppressant on top of steroids (mostly rituximab). After a median follow-up of 53 months (1-275), eGFR significantly improved (mean eGFR (MDRD) 39,8 ml/min/1,73m2 at presentation versus 47,3ml/min/1,73m2, p=0,001) and only 3 patients suffered from ESRD. Prognosis was correlated with age, hypergammaglobulinemia and tubulo-interstitial kidney lesions (p<0,05, multivariate analysis) although the overall renal outcome was good.

Conclusions: Tubulo-interstitial nephritis is the most common manifestation found in pSS with frequent plasmocytic infiltrate. In most cases, patients are treated with steroids which allows a good prognosis.

FR-PO564

Renal Dysfunction in Lithium-Treated Patients: A Cross-Sectional Study

Joan Doornebal,[1] Adry Diepenbroek,[2] Erwin G.T.M. Hartong,[3] Ralph W. Kupka,[4] Peter M.T. Deen,[5] Carlo A. Gaillard,[2] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Medical Centre, Nijmegen, Netherlands; [2]Nephrology, Univ Medical Centre Groningen, Groningen, Netherlands; [3]Psychiatry, Canisius Wilhelmina Hospital, Nijmegen, Netherlands; [4]Psychiatry, VU Medical Centre/ GGZ inGeest, Amsterdam, Netherlands; [5]Physiology, Radboud Univ Medical Centre, Nijmegen, Netherlands.*

Background: Lithium, the most effective drug for bipolar disorder (BD), is associated with various manifestations of renal injury. In this cross-sectional study, we examined renal concentrating ability and estimated glomerular filtration rate (eGFR) in a cohort of lithium-treated patients.

Methods: Lithium-treated patients were recruited from the outpatient clinics of a secondary and tertiary institution in the Netherlands. Participants were evaluated at the outpatient clinic. Height, weight and blood pressure were recorded and laboratory examinations were performed. Additionally, all participants filled out a comprehensive questionnaire. Moreover, a dDAVP test was performed in a subgroup of patients.

Results: A total of 201 patients – 87 (43.1%) males, median age 51 (range 19-78) yrs, 191 (95.0%) Caucasians, 180 (89.1%) with BD, 13 (6.4%) with unipolar depression and 9 (4.5%) with schizoaffective disorder – were enrolled in an observational registry. The median time on lithium was 8 (range 0-35) yrs. The prevalences of smoking, obesitas (BMI≥30 kg/m^2), hypertension, dyslipidemia, diabetes mellitus en cardiovascular disease were 68.7, 19.9, 20.5, 31.1, 6.0 and 6.4 %, respectively. CKD was present in 41 (20.3%) patients; of these, 16 (7.9%) and 25 (12.4%) patients had CKD stage G1-2 A1-3 and G3 A1-3, respectively. A dDAVP test was performed in a random subgroup of 99 patients. Renal concentrating ability was impaired (<800 mOsmol/kg) in 67 (68.4%) patients with partial NDI (<600 mOsmol/kg) in 17 (17.3%) patients.

Conclusions: This study demonstrates that the majority of lithium-treated patients show an impaired renal concentrating ability or even NDI. Moreover, CKD is present in approximately 20% of patients.

Spectrum of Histopathologic Findings on Kidney Biopsy in Individuals with Malignancy Receiving Treatment at a Large Cancer Center

Patricia M. Myers-Gurevitch,[1] Ilya Glezerman,[2] Sheron Latcha,[2] Edgar A. Jaimes,[2] Surya V. Seshan,[1] Carlos D. Flombaum.[2] *[1]Nephrology, New York Presbyterian Hospital - Weill Cornell, New York, NY; [2]Nephrology, Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: An increase in serum creatinine and/or denovo proteinuria commonly occurs in individuals with malignancy, but their basis remains poorly characterized. We undertook a systematic study of the pathology noted at kidney biopsy among individuals with malignancy.

Methods: We conducted a chart review of individuals who presented between January 2000 and 2014, and collected demographic, histopathology, treatment, and outcome data. Standard processing of biopsy specimens included light, immunofluorescence and electron microscopy.

Results: We studied 268 individuals. The majority were men, with mean: age of 60 years, serum creatinine at biopsy of 3.08 mg/dl, and urine protein excretion of 4.08 gm protein/gm creatinine. The most common histological finding was glomerular disease (132,49%), followed by tubulointerstitial disease (63,24%), vascular lesions (34,13%), and chronic kidney disease (31,12%). Thrombotic microangiopathy (TMA) was found in 34 individuals; 16 (47%) had a prior stem cell transplant. Chemotherapy was associated with 19 cases of TMA, and carflizomib was the possible etiological agent in one (new). Acute interstitial nephritis in 4 was associated with an experimental chemotherapy agent. We found association of kidney cancer with focal segmental glomerulosclerosis and IgA nephropathy. Of 268, there were 10 membranous nephropathy and 12 minimal change disease. Proliferative glomerular disease was found in 18, 9 of whom had proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) which is a recently described entity.

Conclusions: We report the only study to date of the spectrum of kidney diseases in individuals with cancer, and identified several novel associations with anti-cancer therapy. Our systematic investigation emphasizes the importance of kidney biopsy to elucidate the basis for renal dysfunction, and to guide therapeutic interventions in patients with malignancy.

FR-PO566

Glomerular and Interstitial Renal Findings in Liver Cirrhosis

Suman Nayak,[1] Sivaramakrishnan Ramanarayanan,[1] Rajendra Prasad Mathur,[1] Gyan Prakash,[1] Shiv Sarin,[1] Suresh Chandra Tiwari,[2] Archana Rastogi,[1] Chhagan Bihari,[1] Amar Mukund,[1] Chitranshu Vashishtha.[1] *[1]Nephrology, Inst of Liver and Biliary Sciences, New Delhi, Delhi, India; [2]Nephrology, Fortis vasant kunj, New Delhi, Delhi, India.*

Background: The true spectrum of kidney injury in liver disease remains speculative. Since majority of patients are very sick and coagulopathic, there is paucity of literature on renal biopsies and structural renal pathologies in cirrhotics. The pathogenesis is presumed to be the impaired hepatic clearance of immune complexes and their trapping in the kidney, causing the lesions of hepatic immunoglobulin A (IgA) nephropathy and hepatic glomerulosclerosis.

Methods: We reviewed the kidney biopsies of 27 Cirrhotic patients with the clinical suspicion of glomerular disease i.e proteinuria (>500 mg/24 hr), glomerular hematuria or renal dysfunction. Kidney biopsy was done through percutaneous route under real time ultrasound guidance in 24 patients and through transjugular method in 3 patients who were coagulopathic. Biopsy tissues were processed and subjected to light microscopy and immunofluorescence.

Results: Mean age of patients was 50.81±12.49 years. There were 22 (81.5%) male patients and 5 (18.5%) female patients. Basic liver disease was ethanol related in 40.7% patients followed by Hepatitis C (14.8%), NASH (14.8%), Cryptogenic (11.1%), Autoimmune (7.4%), EHPVO (7.4%) and Hepatitis B (3.7%).Mean bilirubin was 1.8±1.42 mg/dl. Renal dysfunction was seen in 85.2% patients. Mean urea and creatinine were 66.66±33.47 mg/dl and 2.41±1.59 mg/dl respectively. Proteinuria was present in all and glomerular haematuria was observed in 66.7% patients. Post procedure one patient had major complication in the form of perinephric hematoma, got managed successfully by coil embolisation. Most common glomerular lesion was IgA Nephropathy (40.7%) followed by CIN (14.8%), MPGN (7.4%), Diabetic Nephropathy (11.1%), FSGS (11.1%), Amyloidosis (3.7%), Nodular glomerulosclerosis (3.7%), granulomatous nephritis (3.7%) and cholemic nephrosis (3.7%).

Conclusions: IgA Nephropathy was the most common glomerular lesion in Cirrhotic patients. Child A Cirrhotics can be taken safely for renal biopsy if there is a strong suspicion of glomerular disease.

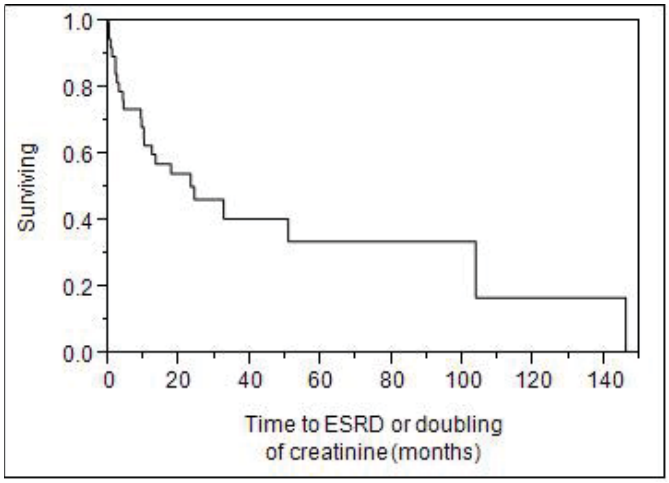
FR-PO567

Progression of Renal Disease and Treatment Outcomes in Proliferative Glomerulonephritis Associated with Non-Organized Monoclonal Immunoglobulin Deposits Gauri Bhutani,[1] Sanjeev Sethi,[2] Samih H. Nasr,[2] Fernando C. Fervenza,[1] Nelson Leung.[1] *[1]Nephrology, Mayo Clinic; [2]Anatomic Pathology, Mayo Clinic, Rochester, MN.*

Background: Prognostic and treatment data are limited for proliferative glomerulonephritis associated with non-organized monoclonal Ig deposits (PGNMID). As initially described, most cases have monoclonal IgG deposits but rare ones show IgM / IgA.

Methods: Pathology database at Mayo Clinic (R) was queried for patients with PGNMID on kidney biopsy between 1/1/2008 and 12/31/2012. A retrospective chart review was conducted in those with native kidney disease. Statistical analysis employed Kaplan-Meier curve, Log Rank test and Cox proportional hazard.

Results: Thirty-eight patients were studied including 34 with monoclonal IgG, 3 IgM and 1 IgA with a median follow-up of 1036 (608 to 1960) days. Median age was 56 (48 - 62) years. Females equaled males and majority were white (87%). Median creatinine and proteinuria at diagnosis were 1.6 (1.4 to 2.9) mg/dl and 6.2 (3-9.3) g/day respectively. Over follow up, there were no deaths and 15 (39%) reached ESRD. At 1 year point, 40% had ESRD or doubling of creatinine. Median time to this combined outcome was 24 (4 - 103) months. Most patients (87%) received treatment ranging from steroids to mycophenolate to chemotherapy agents. Higher initial creatinine was a risk factor for the combined outcome ($p<0.01$; RR 1.14 - 1.84). Normal serum C3 and C4 ($p = 0.10$); mesangioproliferative histology may be protective ($p = 0.09$). No relationship was observed between renal survival and detectability of pathologic Ig or clone, Ig isotype, IgG subtype, light chain, age or gender.



Conclusions: PGNMID has poor renal outcomes even with treatment and especially in those presenting with lower GFR. Subgroup outcome comparisons were limited by small cohort size. Evaluation of individual treatment agents and outcomes after transplant recurrence (n= 14) will be performed.

FR-PO568

Long-Term Prognosis after Kidney Biopsies in Patients with Pre-Biopsy eGFR <15 ml/min/1.73m2 Ann-Merethe Vaagane,[1] Sanjeevan Sriskandarajah,[1] Thomas Knoop,[1] Bjorn Egil Vikse,[1] Anna Reisaeter,[2] Einar Svarstad,[1] Sabine Leh,[1] Rune Bjoerneklett.[1] *[1]Inst of Clin Med, Univ of Bergen, Bergen, Norway; [2]Dept of Transplant Med, Oslo Univ Hospital, Oslo, Norway.*

Background: Kidney biopsies are sometimes performed on patients with pre-biopsy estimated glomerular filtration rate (eGFR) less than 15 ml/min/1.73m2. In this study we have analyzed overall and disease specific long-term End-Stage Renal Disease (ESRD) and mortality risk in such patients.

Methods: All patients registered in the Norwegian Kidney Biopsy Registry 1988-2012 with a specified histopathological diagnosis and a pre-biopsy eGFR <15 ml/min/1.73m2 were included in the study. Deaths and ESRD during follow-up were identified through record linkage with the Norwegian Kidney Registry (ESRD) and Population Registry (deaths). ESRD is defined as commencement of chronic renal replacement therapy (RRT). Only deaths before ESRD are included. Cumulative probability of ESRD free patient survival 1-, 5-, 10- and 20 years was calculated.

Results: 999 pts were identified, 480 progressed to ESRD and 281 died (deaths after ESRD not included).

Diagnoses	N patients	Cumulative patient survival without ESRD (%)			
		1 year	5 years	10 years	20 years
All patients	999	47	31	25	15
Sarcoidosis	8	100	73	73	0
Acute interstitial nephrithis	168	82	68	55	39
Acute endocapillary GN	17	76	76	68	58
Membranous nephropathy	4	75	50	25	25
Chronic interstitial nephrithis	47	64	41	28	10
Acute tubular necrosis	46	59	51	42	29
Trombotic microangiopathy	21	57	57	57	57
Lupus nephrithis	14	50	36	21	0
Benign nephrosclerosis	87	47	18	15	11
ANCA associated GN	166	45	30	22	5
Mesangioproliferative GN	59	42	23	15	9
Henoch Schønleins purpura	5	40	0	0	0
Membranoproliferative GN	23	35	22	22	22
FSGS	17	34	0	0	0
Malignant nephrosclerosis	48	27	17	10	5
IgA nephropathy	56	27	15	15	7
Diabetes nephropathy	44	27	9	9	9
Myeloma cast nephropathy	70	27	9	6	6
Anti GBM nephrithis	37	24	15	15	15
Amyloidosis	62	14	2	2	0

Conclusions: Long-term prognosis in biopsied patients with CKD 5 is overall poor. There is, however, substantial variation in risk of ESRD/death depending on type of renal disease. Kidney biopsies in patients with CKD 5 may therefore be useful for both diagnostic and prognostic aims.

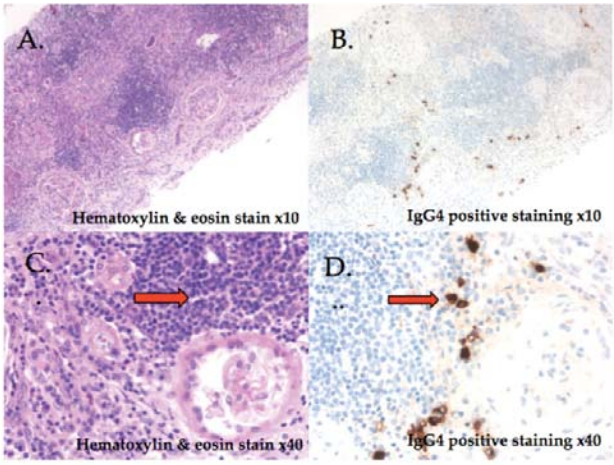
FR-PO569

The Incidence of IgG4-Related Tubulointerstitial Nephritis in Patients with Biopsy Proven Tubulointerstitial Nephritis Kathy Apy Mac, Michael G. Suranyi, Angela Makris. *Dept of Renal Medicine, Liverpool Hospital, Sydney, NSW, Australia.*

Background: Although IgG4 related disease is rare- IgG4TIN is the most common renal manifestation. The disease is usually associated with other organ involvement, renal masses, immune activation and elevated serum IgG4 levels. The incidence of IgG4TIN may be underestimated as staining for IgG4 is not routine.

Methods: We retrospectively reviewed native renal biopsies performed at our center (2002-2012). Renal biopsies with a primary diagnosis of interstitial nephritis were selected. Samples where interstitial nephritis was secondary to a glomerular disease were excluded. The renal tissue was recut and stained using a monoclonal antibody specific to IgG4. Demographic and follow up details were collected. This study was approved by the local ethics committee.

Results: 89 cases of interstitial nephritis from a total 1238 renal biopsies (2002-2012) were selected for further assessment. 12 samples demonstrated staining consistent with the criteria for IgG4-TIN, of which 3 were mildly positively stained, 7 moderately positively stained and 2 were markedly positively stained.



Example of IgG4 positive staining slide

Tubulointersitial nephritis.
x10 power field: A (H&E stain) and B (IgG4 positively stained using immunoperoxidase technique);
x40 high power field: C (H&E stain) showing cluster of lymphocytes infiltration and D (IgG4 positively stained) showing only 13 positively stained plasma cells in the heavy cluster of inflammatory cells.

There were no statistically significant differences in the baseline characteristics between the positive and the negative staining groups.

Conclusions: A clinically important number of IgG4TIN was observed in our population that had been diagnosed as undifferentitated TIN. From our study, IgG4 TIN made up of 1% of all renal biopsies performed over 10 years and 13% all biopsies demonstrating TIN not related to glomerular disease. IgG4 staining should be considered routinely in biopsies demonstrating primary tubulointerstitial nephritis.

FR-PO570

Renal Tubulointerstitial Distribution of Vasohibin-2 and Its Association with Clinicopathological Parameters in Patients with Renal Disorders Yuka Arata,[1] Hiroyuki Watatani,[1] Haruyo Omori,[1] Kana Masuda,[1] Katsuyuki Tanabe,[1] Jun Wada,[1] Hitoshi Sugiyama,[1] Naoki Kanomata,[2] Yasufumi Sato,[3] Yohei Maeshima.[1] *[1]Medicine and Clinical Science, Okayama Univ, Okayama, Japan; [2]Pathology, Kawasaki Med. School, Okayama, Japan; [3]Vascular Biology, Tohoku Univ, Sendai, Japan.*

Background: We recently reported the clinical significance of Vasohibin-1, a negative feedback regulator of angiogenesis, in predicting renal functional deterioration (PLoS ONE, 2014). Vasohibin-2, a homologue of Vasohibin-1, possesses potent pro-angiogenic effects. Study aims were to characterize renal tubulointerstitial distribution of Vasohibin-2 in patients with renal disorders and determine any potential association between the distribution and clinicopathological parameters.

Methods: Immunohistochemistry for Vasohibin-2 was performed in renal biopsy sections from 54 patients (glomerulonephritis, nephrosclerosis, diabetic nephropathy etc.) and six renal sections of healthy tissue from nephrectomized kidneys (renal cell carcinoma). Correlation between clinical/histological parameters and immunoreactivity for Vasohibin-2 in the tubules (semiquantitative score) and vasa recta (the number of vessels with immunoreactivity) was determined by the Spearman's test.

Results: Vasohibin-2 was mainly distributed in distal tubules, peritubular capillaries and vasa recta in subjects with renal disorders. Significant positive correlations were observed between 1) interstitial fibrosis and the tubular Vasohibin-2 score ($r = 0.39$, $P< 0.01$) and 2) tubular atrophy and the tubular Vasohibin-2 score ($r = 0.46$, $P< 0.01$). Significant inverse correlations were observed between 1) proteinuria and the number of Vasohibin-2$^+$ vessels in the vasa recta ($r =-0.41$, $P< 0.01$) and 2) annual reduction of proteinuria and the tubular Vasohibin-2 score ($r = -0.58$, $P< 0.01$). Renal Vasohibin-2 levels were not correlated with angiogenic factors, but were positively correlated with BMI, systolic blood pressure, LDL-C and HbA1c.

Conclusions: These results suggest that Vasohibin-2 may play a role in the progression of renal disorders including tubulointerstitial injuries, and implicates its potential to serve as a novel renal biomarker similar to its homologue, Vasohibin-1.

Funding: Government Support - Non-U.S.

FR-PO571

Clinicopathological Features of Glomerulopathy Associated with Overweight Yusuke Okabayashi, Nobuo Tsuboi, Kentaro Koike, Go Kanzaki, Kotaro Haruhara, Yoichi Miyazaki, Tetsuya Kawamura, Makoto Ogura, Takashi Yokoo. *Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Obesity-related glomerulopathy (ORG) is defined as a proteinuric renal disease found in patients with BMI of 30kg/m^2 or more, and as an absence of other known renal diseases. In the Japanese population survey, the presence of overweight (OW) with a BMI value of 25≤ BMI <30kg/m^2 was shown to have close relationships to the increased incidence of various diseases. However, little is known regarding the renal complication (s) that can occur in OW patients.

Methods: A total of 27 OW patients with proteinuria without other known renal diseases, were retrospectively analyzed. These patients were compared to the 26 ORG patients. The glomerular density (glomerular number per cortical area, GD) and the glomerular volume (GV) were measured in each patient. Biopsies of the 34 kidney transplant donors (KTD) were used for comparisons of the histological measures as healthy control. Renal outcomes were evaluated by the slope of renal function and the occurrence of progression.

Results: In the OW group, the mean age was 53 years, which was higher than that of the ORG group. Same as the ORG group, the OW group was male predominance (85%) and showed a high incidence of hypertension (80%). The serum values for creatinine or albumin, and the amount of urinary protein excretion were not different to those of the ORG group. The degrees of chronic histopathological lesions were similar to those of the ORG group. In addition, OW patients showed a typical histological characteristic of ORG; i.e., low GD with glomerulomegaly (Tsuboi N, CJASN 2012).

	KTD	OW	ORG
GD (/mm^2)	3.1±1.0	1.6±0.8	1.7±0.6
GV (x10^{6}μm^3)	2.4±0.6	6.1±2.2	6.3±1.8
BMI (kg/m^2)	24.2±3.5	27.1±1.3	32.5±2.9

Both the slope of renal function (-7.7±8.9 versus -5.8±7.1 %/year) and the rate of progression (27 versus 35%) were not different between these two groups.

Conclusions: These results suggest that a glomerulopathy similar to ORG can occur in individuals with OW, even in the absence of obesity. Renal factor (s) other than BMI value may thus underlie the susceptibility to this disease entity.

FR-PO572

The Degree of Proteinuria After Induction Therapy Was More Closely Related to Renal Functional Outcome Than the Clinicopathological Features at Diagnosis in Lupus Nephritis Yusuke Okabayashi, Nobuo Tsuboi, Kentaro Koike, Go Kanzaki, Kotaro Haruhara, Yoichi Miyazaki, Tetsuya Kawamura, Makoto Ogura, Takashi Yokoo. *Div of Nephrology and Hypertention, The Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Heavy proteinuria and renal insufficiency at biopsy are known risk factors for progression in lupus nephritis (LN). However, the significance of the degree of proteinuria achieving during follow-up period has not fully understood. This study therefore investigated whether urinary protein excretion (UPE) after induction therapy as a predictor of progression in LN.

Methods: The impact on the renal outcome was retrospectively examined as to the clinicopathological features at diagnosis and the degree of proteinuria 1 year after diagnosis. Renal biopsy findings were analyzed based on ISN/RPN classification. UPE of <1g/day at 1 year was defined as remission. Progression was defined as 50% decrease in eGFR or the development to ESKD.

Results: Of 113 LN patients in our archive, the 76 patients with follow-up period of more than 1 year were included. All patients received induction therapies, including corticosteroid and/or immunosuppressants. The average values at diagnosis were age of 38 years, eGFR of 91ml/min/1.73m^2, and UPE of 2.1g/day. Class III nephritis was most frequent finding (42%), followed by IV (40%), II (11%), and V (7%). The average value of follow-up period was 8 years and 15 patients underwent progression. Patients without remission were associated with progression in comparison to those with remission (p:0.005). Remission was identified as an independent factor associated with progression by the multivariate analysis. Of note, renal function, UPE and ISN/RPN classification at diagnosis were not associated with progression.

Predictors of progression (Cox proportional hazards model)

	Univariate			Multiivariate		
Variables	Hazard Ratio	95% CI	p-value	Hazard Ratio	95% CI	p-value
eGFR at biopsy (ml/min/1.73m^2)	1.005	(0.99, 1.02)	0.419	1.004	(0.99, 1.02)	0.541
Nephrotic range proteinuria at biopsy	1.795	(0.64, 5.01)	0.264	1.139	(0.30, 4.36)	0.850
Remission at 1year	0.257	(0.09, 0.72)	0.010	0.275	(0.08, 0.99)	0.049
Class IV nephritis	0.844	(0.30, 2.42)	0.752	1.149	(0.38, 3.52)	0.807

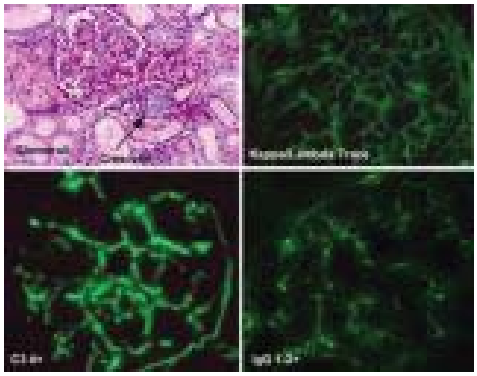
Conclusions: In LN patients, remission of proteinuria achieving 1 year after induction therapy may lead to better renal outcomes.

FR-PO573

Successful Eculizumab Treatment of Atypical Postinfectious Glomerulonephritis/C3 Nephropathy Amita Sharma, Ivy A. Rosales, Samuel V. Gorstein, Aleksandr Vasilyev, Robert B. Colvin, Rex Neal Smith. *Div of Pediatric Nephrology, Massachusetts General Hospital for Children, Boston, MA; Div of Renal Pathology, Massachusetts General Hospital, Boston, MA.*

Background: Acute post streptococcal glomerulonephritis is a common acute GN and most patients recover normal renal function if oligoanuric, with supportive care including dialysis. Patients with prolonged disease (atypical post infectious GN) often have defects in alternate complement pathway.

Methods: We report a 10 year old girl who presented clinically with post infectious glomerulonephritis ASO 683 (0-640) with rapidly progressive glomerulonephritis (peak Cr 6.4 mg/dl).Serum complement C3 was 46 mg /dL (Normal 75-175 mg/d L) with normal complement C4 (Normal 14-40 mg/dL). ANA, ds DNA, ANCA and anti GBM were negative. There was no significant preceding history. Patient continued to be oligo anuric, edematous, severely hypertensive in spite being on diuretics,antihypertensives and steroid pulses. Kidney biopsy showed atypical PIGN/C3 nephropathy with acute crescentic glomerulonephritis with complement C3 predominance but some IgG.



Rather than subjecting her to dialysis, a single dose 1200 mg of Eculizumab followed by a second dose of 900 mg 10 days later was administered, titrating with C5 functional assay.

Results: Gross hematuria cleared within 2 hours after infusion with significant increase in urine output. Serum creatinine normalized in 2 weeks and complement C3 normalized in 10 days, and both remained normal after one year. Complement Factor B stayed normal. Proteinuria and hematuria resolved by 3 months. There were no mutations detected in Complement Factor H, Complement Factor I or MCP.

Conclusions: In this case of acute and rapidly progressive atypical PIGN/C3 nephropathy a single dose of Eculizumab rather than supportive care rapidly reversed the GN and preserved renal function for one year.

Funding: Clinical Revenue Support

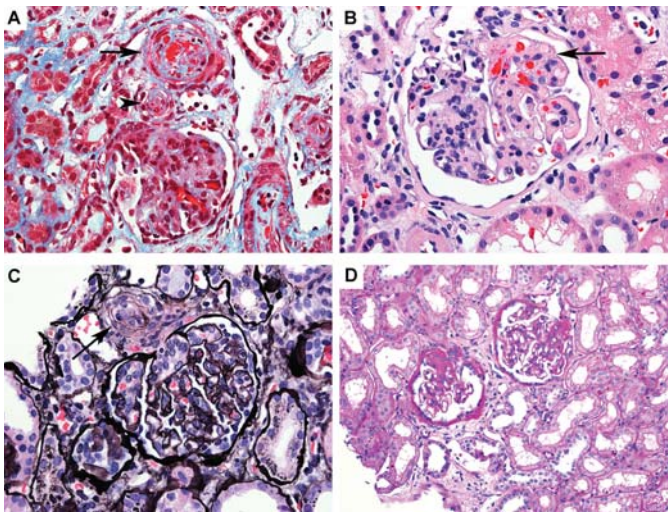
FR-PO574

Treatment with Eculizumab Reverses Thrombotic Microangiopathy Changes in Atypical Hemolytic Uremic Syndrome Carlos E. Araya,[1] Josephine M. Ambruzs,[2] Brenda S. Montane,[1] Robert S. Mathias.[1] *[1]Pediatric Nephrology, Nemours Children's Hospital, Orlando, FL; [2]Pathology, Nephropath, Little Rock, AR.*

Background: Hemolytic Uremic Syndrome (HUS) is a rare and life-threatening disorder. The majority of HUS cases are secondary to infections but 10% of HUS cases are classified as atypical and are caused by a dysregulation in the alternative pathway of the complement system. The treatment of a typical HUS (aHUS) has been challenging. Eculizumab, a humanized monoclonal anti-C5 antibody that prevents the activation of the terminal complement pathway has been found to be effective in patients with aHUS.

Methods: We present a case of a 7 year old female diagnosed with aHUS treated early after her diagnosis with eculizumab. She received one plasmapheresis treatment followed bv eculizumab.

Results: After treatment, the hemolysis decreased, LDH declined from 2345 UI/L to 847 UI/L after 2 weeks, hemoglobin stabilized and platelet count normalized. The serum creatinine normalized within 1 month and the proteinuria decreased to a ratio of 0.5 by 2 months. The findings of the kidney biopsy are shown.



Panel a, b and c- There is an interlobular-sized artery and arteriole with luminal occlusion by endothelial swelling, fibrin and red blood cell fragments consistent with TMA. Glomerular mesangiolysis and an arteriole with endothelial cell swelling and mucoid intimal change resulting in luminal narrowing. Panel d. shows glomeruli post-treatment with segmental sclerosis and hyalinosis with adhesion of the tuft to Bowman's capsule. She has continued on eculizumab for 2 years and her renal function remains normal.

Conclusions: After treatment, we noted resolution of TMA and normalization of renal function, but persistent proteinuria due to FSGS. With eculizumab, no recurrence of aHUS has occurred. This case illustrates the long term favorable outcome of aHUS with early eculizumab treatment.

FR-PO575

Is Bortezomib Useful in Plasmatic Cells Dyscrasias with Renal Affectation? Long Term Follow Up (3.5 Years) in a Reference Hospital Jose L. Lerma, Elena Ruíz, Cristina Lucas, Veronica González, Victoria Mateos. *Nephrology, Hospital Univ, Salamanca, Spain.*

Background: As Standard treatment for blood dyscrasias (BD) with renal affectation offers poor results,new treatment lines tries to improve both overall and renal survival with tolerability.Bortezomib,a proteosome inhibitor,can be useful in CKD.However,few studies evaluate stage 4CKD at diagnosis and its ongoing response to long-term therapy. Objectives:To evaluate Bortezomib's efficacy and safety in patients with BD associated with 4CKD evaluating response in renal function.

Methods: 108multiple myeloma cases were diagnosed at a reference BD Centre over a period of 41 months.Of this population, only 9.25% initially had renal affectation and the average age was 72,males (56%).Average infiltration of plasma cells was 35%.Renal biopsies were performed on 25%.GFR:19ml/min, with urinary Bence Jones (BJ) proteins of 4.5g/24hrs and severe hypercalcaemia in 44%. 100% of patients received Bortezomib as first-line therapy (Haematology porticol).

Results: Creatinine clearance improved from 19.15±12.90ml/min to 37.12±25.31ml/min (MDRD).BJ proteinuria descreased or was eliminated in 83.3%.One case did not respond to therapy.I 83% of cases, hypercalcaemia responded to treatment without requiring bisphosphonates or other measures.One case was refractory to Bortezomib and maintained parameters of myeloma activity.Three patients did not recover renal function and required haemodialysis. One case reached 3.5 year survival without hospital admission.Patients who died were principally elderly with co-morbidities.No clinically significant adverse effects were noted and Bortezomib was very well tolerated.

Conclusions: 1-83% of patients with BD and renal affectation (stage 4 CKD) responded favourably to Bortezomib with a significant reduction in urinary BJ proteins and hypercalcaemia and an improvement in glomerular filtration rate. 2-The medication provoked few side effects and was well tolerated despite the elderly population (72 years). 3-Mortality rate was 22%, particularly affecting the most elderly.78% surpassed 3.5 year survival. 4-Bortezomib can be considered a first-line therapy in the context of BD associated with severe renal involvement.

Patient Reported Outcomes in Children and Adults with Nephrotic Syndrome J. Troost,[1] David T. Selewski,[1] Patrick H. Nachman,[2] Susan F. Massengill,[3] Emily G. Herreshoff,[1] Chrysta C. Lienczewski,[1] Alexandra M. Klim,[1] Debbie S. Gipson.[1] *[1]Univ of Michigan; [2]Univ of North Carolina; [3]Carolinas Medical Center.*

Background: Proteinuric kidney diseases adversely affect children and adults beyond the traditional clinical parameters of proteinuria and kidney function.

Methods: We used data from two multisite prospective cohorts, NEPTUNE (U54DK083912-01) and PROMIS NS (U01AR05218106), to assess patient reported outcomes (PRO) over time. 185 adults and 181 children completed the Patient Reported Outcomes Measurement Information System on-line assessment over a median of 12 months. Analyses were stratified by age (8-18 versus ≥18). Distribution of PRO at study enrollment and follow-up was summarized by age, edema status, treatment, and pathology. Among those with edema at baseline we tested the hypothesis that PRO improves with resolution of edema compared to those with persistent edema adjusting for histology and disease duration. For longitudinal analyses, we used generalized estimating equations with an autoregressive correlation structure. Analyses were completed in SAS v9.2.

Results: In children baseline PRO did not differ by edema status or by pathology. Among adults, baseline edema was a strong predictor of physical functioning, fatigue, pain interference, sleep impairment, and social status (|d|=0.34-0.61). Longitudinally, PRO changed over time in response to edema status. Specifically, in children persistence of edema was associated with worse mobility, fatigue, peer relationships, and pain interference compared to those with resolution of edema (Fig). In adults, worse fatigue, pain, and physical functioning were predicted by edema, increasing number of medications and decreasing eGFR.

Conclusions: PROs are associated but not completely predicted by edema status in children and adults with proteinuric kidney diseases. Measurement of PRO may enhance clinical and research assessments.

Remission and Progression in the Nephrotic Syndrome Study Network

J. Troost,[1] Crystal A. Gadegbeku,[2] Michelle A. Hladunewich,[3] Cynthia C. Nast,[4] Howard Trachtman,[5] Frederick J. Kaskel,[6] Fernando C. Fervenza,[8] Larry A. Greenbaum,[9] Katherine M. Dell,[11] Kevin E.C. Meyers,[12] Marva M. Moxey-Mims,[13] Matthias Kretzler,[1] Debbie S. Gipson.[1] *[1]Univ Michigan; [2]Temple Univ; [3]Univ of Toronto; [4]Cedars-Sinai; [5]New York Univ; [6]Montefiore; [7]Mayo Clinic; [8]Emory Univ; [9]Case Western; [10]CHOP; [11]NIDDK.*

Background: The Nephrotic Syndrome Study Network is an observational cohort of patients with ≥0.5 g/d proteinuria, planned first renal biopsy, with collection of biosamples.

Methods: Subjects were classified into FSGS, minimal change (MCD), membranous (MN) or Other cohorts. Outcome measures, complete remission (CR, UPC <0.3 g/g) and decline in renal function (eGFR <60% baseline or ESKD), were assessed in subjects having ≥8mo observation. Time to event analyses used multivariable Extended Cox Proportional Hazard Models.

Results: 388 individuals (31% FSGS, 24% MCD, 15% MN and 30% Other) are actively enrolled. Prior to renal biopsy, 34% (19% adults) received immunosuppression. 22% of children treated prior to biopsy did not have FSGS, MCD or MN. With a median 18 mo observation period, 61% of children and 47% of adults achieved CR and 16% children and 20% adults had declining kidney function. Multivariate analysis (n=275) demonstrated that CR was least likely with UPC >3 (p<0.01) at biopsy and non-MCD pathology (p<0.01). Among the immunosuppression naïve, post biopsy steroid therapy was associated with CR in FSGS but not with other diagnoses (HR=4.2, CI: 1.3,13.7). ESKD was most likely in patients without a CR (p<0.01) and was negatively correlated with baseline eGFR (<0.05).

Conclusions: CR is common following initial kidney biopsy for nephrotic syndrome. As 22% of pre-treated children had an "Other" pathology diagnosis, earlier diagnostic kidney biopsy may be appropriate. Expansion of epidemiology with molecular profiling is planned to enrich the approach to management of glomerular diseases.

Identification and Characteristics of Population-Based Cohort of Adults with Nephrotic Syndrome: The Kaiser Permanente Nephrotic Syndrome Study

Alan S. Go,[1] Dongjie Fan,[1] Thida Tan,[1] Janet M. Wojcicki,[2] Jingrong Yang,[1] David Law,[1] Juan Daniel Ordonez,[1] Leonid V. Yankulin,[1] Kenneth K. Chen,[1] Glenn M. Chertow,[3] Sijie Zheng.[1] *[1]Kaiser Permanente Northern California; [2]Univ of California, San Francisco; [3]Stanford Univ.*

Background: Few population-based data exist about adults with primary nephrotic syndrome (NS) in the U.S. We identified and characterized a cohort of adults with primary NS within a large integrated healthcare delivery system.

Methods: Between 1996-2012, we identified non-diabetic adult members within Kaiser Permanente Northern California with nephrotic range proteinuria (urine ACR >3500 mcg/mg, PCR >3.5 mg/mg or 24-hr protein excretion >3500 mg) or diagnosed NS (ICD-9 codes 581.x). Patients with secondary causes of NS were excluded. Nephrologists reviewed electronic health records for clinical presentation and relevant lab and biopsy results to confirm primary NS.

Results: Of 5658 reviewed patients, 818 had confirmed NS due to minimal change disease (20%), focal segmental glomerulosclerosis (39%) or membranous nephropathy (41%). Mean age was 49.6 years, 43% were women, 59% were persons of color and 19% Hispanic. Additional comorbidities are shown in the Table, overall and stratified by sex.

	Overall (N=818)	Women (N=350)	Men (N=468)
Mean (SD) age, yr	49.6 (16.6)	49.2 (16.9)	49.9 (16.3)
Race/ethnicity, %			
White	41.3	38.3	43.6
Black	14.1	14.3	13.9
Asian	19.4	21.4	17.9
Other	7.8	8.3	7.5
Unknown	17.4	17.7	17.1
Hispanic	18.6	18.3	18.8
Current/former smoker, %	19.8	14.6	23.7
Baseline medical history, %			
Coronary heart disease	0.9	0.3	1.3
Stroke or TIA	0.5	0.9	0.2
Venous thromboembolism	2.6	1.7	3.2
Peripheral arterial disease	0.7	0.9	0.6
Heart failure	3.3	2.9	3.6
Hypertension	50.6	51.1	50.2
Liver disease	1.7	1.7	1.7
Lung disease	15.0	18.3	12.6
Thyroid disease	15.4	21.1	11.1
Baseline eGFR, ml/min/1.73m², %			
90-150	29.3	34.3	25.6
60-89	19.2	16.9	20.9
45-59	12.0	9.7	13.7
30-44	12.0	11.4	12.4
15-29	11.2	10.9	11.5
<15	4.3	5.1	3.6
Dialysis or transplant	0.4	0.3	0.6
Unknown	11.5	11.4	11.5

Conclusions: We identified a population-based cohort of adults with primary NS that will provide a unique platform for describing the natural history of NS and identifying predictors of adverse outcomes.

Glomerulonephritis and Morbid Nephrotic Syndrome Presenting in Pregnancy: A Case Series

Laura Pilozzi-Edmonds,[1] Kainat Shahid,[2] Mark Anthony Cabrera,[3] Michelle A. Hladunewich,[2] Amret T. Hawfield,[3] Geena Joseph,[4] Natasha Michaeloff,[2] Tiina Podymow.[1] *[1]Dept of Nephrology, McGill Univ, Montreal, QC, Canada; [2]Dept of Nephrology, Univ of Toronto, Toronto, ON, Canada; [3]Dept of Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; [4]Dept of Nephrology, McMaster Univ, Hamilton, ON, Canada.*

Background: Nephrotic syndrome due to glomerulonephritis presenting in pregnancy is a challenge to diagnose and treat.

Methods: We present a series of 20 pregnant women from 4 academic centres with glomerulonephritis and morbid nephrotic syndrome (not due to preeclampsia or diabetes), and their demographics, diagnosis, clinical and laboratory features, treatments and outcomes.

Results: 20 women average age 28.8 ± 5.2, of whom 13 were primiparas presented with nephrotic syndrome in pregnancy at gestational age 14.0 ± 6.3 weeks; 16 women presented with edema. Second trimester 24 hour proteinuria ranged from 5.3-50 g/day, serum albumin ranged from 0.9-3.7 g/dl and creatinine ranged 35-316 mean 105 ± 66 µmol/L (1.2 ± 0.8 mg/dl). Third trimester creatinine was 133 ± 80 µmol/L (1.5 ± 0.9 mg/dl). The diagnosis of glomerulonephritis predated pregnancy in 8 patients, 7 women were biopsied during pregnancy, 4 were biopsied postpartum, and 1 patient with reflux nephropathy was not biopsied. Of the 19 biopsied, 8 had FSGS, 4 had class V Lupus, 2 had class IV Lupus, 3 had IgA nephropathy and 2 had hereditary nephritis. During pregnancy, immunomodulatory treatment varied, with 14 receiving oral prednisone with doses ranging 30-120 mg daily, 3 receiving cyclosporine, 4 receiving azathioprine and 2 receiving tacrolimus. Adjunctive therapies included low molecular weight heparin (n=10), aspirin (n=12), and antihypertensives (n=12). Delivery was at gestational age 34.9 ± 3.9 weeks, 10 women had preeclampsia, birth weight at delivery was 2243.4 ± 830.5 g, and 7 infants required NICU admission.

Conclusions: Glomerulonephritis with nephrotic syndrome in pregnancy presents diagnostic, treatment and management challenges with risks to the mother and fetus including morbid edema, kidney injury, immunosuppression, hypertension, preeclampsia, prematurity and low birth weight.

FR-PO580

Mycophenolate in Refractory and Relapsing Lupus Nephritis

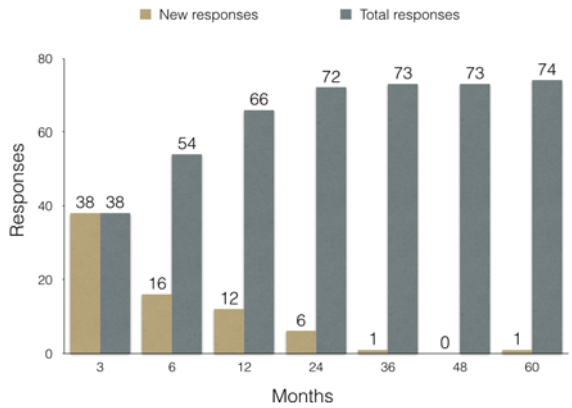
Francisco Rivera,[1] Manuel Praga.[2] *[1]Nephrology, Hospital General Univ de Ciudad Real, Ciudad Real, Spain; [2]Nephrology, Hospital Univ 12 de Octubre, Madrid, Spain.*

Background: Mycophenolate (MF) is effective as induction and maintenance treatment in patients with lupus nephritis (LN). This study evaluates the efficacy and safety of MF in patients with refractory and relapsing LN.

Methods: Data were retrospectively obtained for 85 patients (35 refractory and 50 relapsing) from 11 nephrology departments in Spain. The primary endpoints were the incidence and cumulative number of renal responses and relapses and their relationship with baseline clinical and analytical data. The secondary endpoint was the appearance of side effects.

Results: The main clinical and analytical variables were similar both in refractory and relapsing LN. Most of the patients had received cyclophosphamide, and all of them switched to MF. Seventy-four patients (87%) achieved a response (69% partial, 31% complete).

Figure 1



Age at starting MF, gender, pathological classification, body mass index, blood pressure, baseline renal function, and proteinuria were not associated with achieving response. After stopping MF, 3 of 19 patients (15.7%) relapsed, all at 6 months of follow-up. No differences were found between clinical and analytical variables and number of relapses. Side effects were unremarkable, except for 1 patient, who died of thrombocytopenia and ovarian hemorrhage.

Conclusions: Switching to MF from other immunosuppressive treatments is effective and safe in refractory and relapsing LN.

FR-PO581

Forecasting Renal Prognoses for IgA Nephropathy Using Machine Learning

Hajeong Lee,[1] Junhyug Noh,[2] Jung Pyo Lee,[1] Dong Ki Kim,[1] Yon Su Kim.[1] *[1]Internal Medicine, Seoul National Univ Hospital; [2]Computer Science and Engineering, Seoul National Univ College of Engineering.*

Background: Although various approaches have been applied to renal prognosis prediction for IgA nephropathy (IgAN), well-organized prediction methods are scarce. We aimed to develop new outcome prediction models for IgAN patients using machine learning.

Methods: Among a total of 1,585 patients, we selected IgAN patients who had a follow up ≥10-years and no missing data. The outcome was 10-year renal survival (10YRS) probability. We tested logistic regression (LR) with the Lasso method, a classification and regression tree (CART), and neural networks (NN) for predictive modeling. These results were 5-fold cross validated by random sampling.

Results: A total of 605 patients were included in the final analysis. Initial eGFR was 68.0 ml/min/1.73m^2 and proteinuria 1.63 g/day. Among them, 172 patients reached ESRD within 10-years. In the LR analysis, eGFR, age, male gender, smoking, systolic blood pressure (SBP), hemoglobin and albumin level, proportions of global sclerosis (GS) and segmental sclerosis (SS) were significant predictors for renal outcome (area under the curve [AUC] 0.867; 95% confidence interval [CI], 0.797–0.938; sensitivity [Se] 91.0%, and specificity [Sp] 61.6%). In the CART model, eGFR <48.6 was found to be the most important predictor for 10YRS. In the case of eGFR <48.6, proportion of GS ≥38.2%, serum albumin <3.15 g/dL, and SBP ≥120 mmHg sequentially determined 10YRS. In the eGFR ≥48.6 group, variables such as eGFR <68.4, proportion of SS ≥ 19.0% and age at the time of diagnosis ≥ 44.4 years showed significant relationship with 10YRS sequentially. The performance of the CART model was comparable, with AUC 0.834 (95% CI 0.750–0.918, Se 88.0%, Sp 63.3%). In the NN, 16 variables were selected including eGFR, hemoglobin, interstitial fibrosis, GS, SS, and albumin, sequentially. The model performance was also comparable with other methods (AUC 0.870, 95% CI 0.797–0.943, Se 90.5%, Sp 63.3%).

Conclusions: We have developed and validated LR with Lasso, CART and NN model with good performance to forecast 10YRS in IgAN. These stratified prediction models may be valuable in clinical application.

FR-PO582

Pregnancy in a Patient with Anti-PLA$_2$R Seropositive Membranous Nephropathy

Laith Farah Al-Rabadi, Rivka Ayalon, Ramon G. Bonegio, Jennifer E. Ballard, Alan Fujii, David J. Salant, Laurence H. Beck. *Boston Univ Medical Center, Boston, MA.*

Introduction: There is little information about pregnancy outcomes in patients with active membranous nephropathy (MN). No reports of pregnancy in patients with circulating autoantibodies to PLA$_2$R, the major autoantigen in primary MN (Beck, 2009) are available. Herein, we present the first case of a successful pregnancy in a 39-year old woman with PLA$_2$R-associated MN.

Case Description: In the year prior to pregnancy, the patient developed anasarca, hypoalbuminemia (1.3 - 2.2 g/dL) and proteinuria (29.2 g/24h). Kidney biopsy revealed MN with positive PLA$_2$R staining, and the patient was seropositive for anti-PLA$_2$R. She did not respond to conservative therapy and was treated with rituximab (2 x 1gram IV). Several weeks later, she was found to be 6 weeks pregnant and was closely followed by the maternofetal medicine service without further immunusuppressive treatment. Proteinuria remained in the 8-12 g/24h range. Circulating anti-PLA$_2$R remained positive. At 38 weeks, a healthy baby girl was born, without proteinuria at birth or at her subsequent 6 month postnatal visit. Maternal blood and cord blood was collected, as was a sample of the placental tissue. At the time of birth, the mother still was positive for circulating anti-PLA$_2$R of the IgG1, IgG3, and IgG4 subclasses, although at low titers. A very weak signal for IgG4 anti-PLA$_2$R was found in the cord blood, suggesting possible inefficient transfer across the placenta, even though IgG4 in general is known to be transferred from the maternal to the fetal circulation. IgG eluted from the placental tissue did not contain anti-PLA$_2$R, and PLA$_2$R itself was not detected in the placenta by Western blot or immuofluorescence microscopy.

Discussion: Although the outcome of pregnancy in this case was favorable, we hesitate to suggest that pregnancy is safe in women with active MN and circulating anti-PLA$_2$R because the lack of clinical disease in the baby may have been due to the very low titer of anti-PLA$_2$R in the fetal circulation. Therefore, we recommend close observation of the neonate for proteinuria in future cases.

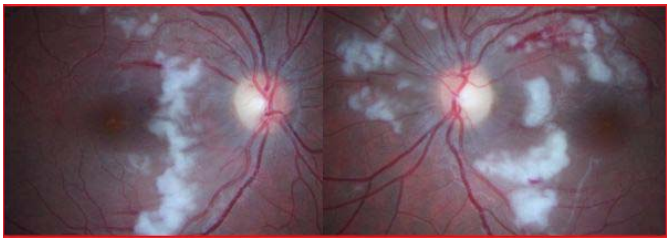
FR-PO583

Ocular Complications in a Case of Anti-Glomerular Basement Membrane Disease

Jacqueline C. Nevols,[1] Nishanthan Srikantha,[2] David Farnworth.[2] *[1]Wessex Renal and Transplant Unit, Portsmouth, United Kingdom; [2]Queen Alexandra Hospital.*

Introduction: Anti-GBM disease occurs as autoantibodies target type IV collagen in glomerular and alveolar basement membranes. This particular collagen is also found in various ocular structures, but case reports of eye pathology in this disease are rare.

Case Description: A 21 year old female presented with haematuria and acute kidney injury. Investigations revealed an anti-GBM antibody titre of 147 u/mL and a crescentic glomerulonephritis. She had no respiratory involvement. IV cyclophosphamide and methylprednisolone were commenced. She received therapeutic plasma exchange for 14 days. She then developed progressive, bilateral visual impairment. Fundoscopy revealed bilateral confluent nerve fibre layer opacities, reminiscent of infarcts, in a curvilinear distribution between the disc and macula of each eye.



Fluorescein and indocyanine green angiography showed multiple choroidal filling defects. She became dialysis dependent, and it was felt that continued immunosuppression would yield no benefit for renal function. The cyclophosphamide was changed to azathioprine, and the steroid dose reduced. On discharge 8 weeks later, visual acuity had improved and the retinal opacities were resolving. She is now starting the work up for transplantation.

Discussion: Retinal involvement in anti-GBM disease is rare and only a handful of case reports are found in the literature. Following her investigations, we postulate that the fundal appearances in our patient may result from a breakdown of the blood-ocular barrier, exposing retinal tissue to autoantibody in the peripheral blood. Treatment of ocular complications of anti-GBM disease mainly involves treatment of the underlying condition, but may require laser therapy. Although these complications are rare, clinicians should be mindful of the possibility of ocular manifestations of vasculitis whilst treating their patients.

FR-PO584

Membranous-Like Glomerulopathy with Masked IgG Kappa Deposits

Aedan Olaso,[1] Myriam C. Vela-Ortiz,[2] Sharif Ali,[1] Glen S. Markowitz,[3] James P. Reichart.[1] *[1]Nephrology, Lehigh Valley Health Network, Allentown, PA; [2]Internal Medicine, Easton Hospital, PA; [3]Renal Pathology, Columbia Univ, NY.*

Introduction: Membranous-like glomerulopathy with masked IgG kappa deposits is a novel form of glomerular immune complex deposition disease.

Case Description: A 20-year-old Cambodian woman presented with 2 weeks of fevers and flu-like symptoms. Her blood pressure was 170/90, creatinine was 3.6 mg/dl, and albumin was 2.3 g/dl. Urinalysis showed proteinuria, hematuria, and pyuria with a urine protein:creatinine ratio of 9.0. Serologic testing including ANA and sdDNA were negative. C3 and C4 were normal. Kidney biopsy showed a membranous pattern of glomerulonephritis with global basement membrane spikes and subepithelial deposits with several cellular crescents. By immunofluorescence, the deposits stained solely for C3. However, when immunofluorescence was repeated on pronase-digested tissue, the deposits stained dominantly for IgG and kappa. The patient refused immunosuppressive therapy and was treated with losartan and diuretics. Over the next 5 months, her creatinine stabilized at 1.5 mg/dl but nephrotic-range proteinuria persisted, at 6 g/d.

Discussion: MGMID is a recently described immune-complex deposition disease with unique clinical and pathologic characteristics. In the case series of 14 patients that established MGMID as a disease entity, most patients were young women with autoimmune disease or positive autoimmune serologic tests. Pathology showed membranous glomerulopathy with positive staining for IgG and kappa light chains, revealed only after pronase digestion of the paraffin embedded tissue. There is little data on the natural history and treatment of MGMID. Two of the reported cases were treated conservatively with RAAS

inhibitors, but the majority was treated with a variety of immunosuppressive agents. Among 9 cases with follow-up reported, none progressed to end stage renal disease, but most had persistent proteinuria. The long-term clinical outcome of patients managed conservatively, such as the present case, may inform prognosis and therapeutic decision-making for this disease until clinical trial data are available.

FR-PO585

A Case of Membranous-Like Glomerulopathy: What Is Behind the Mask?

Wonngarm Kittanamongkolchai, Pongsathorn Kue-A-Pai, Raquel M. Rosen. *Internal Medicine, Bassett Medical Center, Cooperstown, NY.*

Introduction: Membranous-like glomerulopathy with masked IgG kappa deposits (MGMID) is a new form of glomerular disease that has been recently described. The IgG kappa deposition is not detected by routine immunofluorescense (IF) staining and requires an antigen-retrieval step to be visualized. We present an interesting case of MGMID co-existent with antiphospholipid syndrome (APLS).

Case Description: 22-year-old female presented with hypertension and blurry vision. Physical exam showed a blood pressure of 149/109 mmHg with pitting edema. Fundoscopic examination showed left retinal artery occlusion. Laboratory work-up revealed a creatinine of 1.6 mg/dL, hypocomplementemia, 4.5 g/day of proteinuria and microscopic hematuria. Serologic work-up was negative for ANA, anti dsDNA, MPO, PR-3, ASO and anti-DNase B. There was no evidence of monoclonal gammopathy on serum and urine analysis. Antiphospholipase antibodies were positive. Renal biopsy revealed membranous glomerulopathy with thrombotic microangiopathy. IF showed non-specific low-level positivity for multiple reactants. IF was repeated on pronase digested paraffin and revealed glomerular capillary wall that stained 3+ for IgG, 1+ for C3, 3+ for kappa, and negative for lambda. PLA2R staining was negative. There was a large subepithelial and intramembranous deposition from electron microscopy (EM). These findings correlated with MGMID and APLS. The patient's MGMID was treated with an ACEI, mycophenolate mofetil, and prednisone. Her renal function improved; however, her proteinuria remained in the nephrotic range at 2-month follow up.

Discussion: MGMID is a new clinicopathologic entity of monoclonal immunoglobulin deposition disease. It occurs primarily in young women with poorly defined autoimmune disease. The mechanism of the masking of these deposits under routine IF is unclear. It was hypothesized that the abnormal glycosylation or a quaternary arrangement of IgG molecules impedes antibody blinding. The pronase digestion technique should be applied when deposits are clearly present by EM without corresponding staining by routine IF. Care must be taken when approaching patients who may have MGMID to avoid misdiagnosing them.

FR-PO586

Membranous Nephropathy Associated with Profound Hypothyroidism

Girish Singhania, Taha Ayach, William L. Clapp, Amir Kazory. *Nephrology, Univ of Florida, Gainesville, FL.*

Introduction: Thyroid disorders have been linked to alteration in kidney function and as well as glomerular injury. We report a case of secondary membranous nephropathy associated with untreated profound hypothyroidism.

Case Description: A 64 y/o man with no known past medical history presented with dyspnea, fatigue, and leg edema. Examination was unremarkable except for a BP of 166/87 mmHg and edema of the scrotum and lower extremities. Labs revealed creatinine of 3.1 mg/dL with proteinuria of 4.5 g/day, albumin of 2 g/dL, Hb of 8.9 g/dL. TSH was found to be significantly high at 99.28 mIU/L (normal 0.27-4.20 mIU/L), with low free T4 at 0.52 ng/dL (normal 0.93-1.70 ng/dL) and low total T3 at 45 ng/dL (normal 80-200 ng/dL). Complements were normal as were ANA, ANCA, anti-GBM Ab and thyroglobulin and thyroid peroxidase antibodies. Viral serologies (HIV, HCV, and HBV) were negative and Hb A1c was 5.1%. Ultrasound showed normal sized echogenic kidneys and the echocardiogram revealed dilated cardiomyopathy with EF of 20-25%. A kidney biopsy showed membranous glomerulonephritis (MGN) stage II-III with significant mesangial sclerosis.

The patient was treated with intravenous thyroid hormone replacement that was later changed into oral. ACE-inhibitors and diuretics were also started to reduce volume overload and proteinuria.

Discussion: Thyroid disease has previously been reported to have a link with glomerulonephritis. While autoimmune pathways have been proposed as potential mechanisms underlying this association, so far no precise antibody has been identified to cause simultaneous disorder in the thyroid and the kidney. Interestingly, we did not find any autoimmune cause for profound hypothyroidism in our patient while he presented with MGN. This case, coupled with previous reports, highlights the need to include thyroid studies in the workup of unexplained secondary membranous nephropathy.

FR-PO587

Does the Nephrologist Care If You Have a Cat? Bartonella Infection Associated ANCA Positive Necrotizing Glomerulonephritis

Girish Singhania, Yuvaraj Thangaraj, Shriharsha Kallahalli Jayaramu, Radhika Vemuri, Gurjit Dhatt. *Nephrology, Univ of Florida, Gainesville, FL.*

Introduction: C-ANCA positive immune complex Glomerulonephritis (GN) secondary to Bartonella infective endocarditis has been reported in literature. However, there are no reports of MPO positive immune complex GN secondary to Bartonella infection without endocarditis.

Case Description: We report a 32 y/o male with history of truncus arteriosus s/p mechanical AVR presented with fatigue, intermittent fever, worsening leg edema, non-pruritic rash for several weeks. Examination was remarkable for a petechial rash involving the lower and upper extremities and 2+ lower extremity edema. Labs: BUN 19 mg/dl, Creatinine 5.44 from 1.2 mg/dL twelve weeks ago, Na 134 mEq/L, K 4.2 mEq/L, HCO3 19 mEq/L, LFT WNL, LDH 347 U/L, Haptoglobin <10 mg/dL and pancytopenia. Urinalysis showed dysmorphic RBCs and non-nephrotic range proteinuria. C3 and C4 were low and MPO was strongly positive. Anti-GBM, ANA, HIV, CMV, EBV, Parvovirus, AFB, ASO, Hepatitis panel, SPEP, kappa/lambda, Cryoglobulin and blood cultures were negative. Kidney biopsy showed active segmental crescents and glomerular capillary wall deposition of IgG, IgM, C3, C1q, Kappa and Lamba. Electron microscopy: Glomerular, mesangial, paramesangial and subendothelial deposits suggestive of a secondary process which became more clear as the patient started talking about his cats. Later on, positive bartonella PCR confirmed bartonella infection. TTE/TEE was negative for vegetations. He was started on Rifampin and Doxycycline with clinical improvement but no renal improvement and stays on dialysis.

Discussion: It is well known to rule out infection in any case of RPGN with positive ANCA antibodies, but blood cultures are usually negative in Bartonella infection (a gram negative rod that replicates inside the RBCs). Congenital heart disease, mechanical valve replacement and history of cat scratch are recognized risk factors. It is usually associated with C-ANCA and immune complex deposition in EM. A good social history, high degree of suspicion, early diagnosis with bartonella PCR and treatment with antibiotics is needed to improve the renal prognosis.

FR-PO588

IgA Nephropathy (IgAN) and Pregnancy: The Challenge of Distinguishing between Preeclampsia and Progressive Glomerulonephritis (GN)

Baher Basta,[1] Patrick H. Nachman,[1] Harsharan Kaur Singh,[2] William Franklin Pendergraft,[1] Gerald A. Hladik,[1] Fernanda Payan Schober, Steven H. Grossman. *[1]UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC; [2]Pathology, Univ of North Carolina, Chapel Hill, NC.*

Introduction: Women with chronic GN are at increased risk for progression during pregnancy when the serum creatinine is>1.4 mg/dL. Little is known about factors that hasten progression of IgAN in pregnancy, and knowledge about optimal therapy is limited. We report a case of progressive IgAN in pregnancy.

Case Description: A 22 y.o. woman (G1P0) with a history of CKD of unknown etiology was seen for acute worsening of CKD at 36 weeks gestation.She complained of headache (HA), and had a BP of 160/90. PE showed 3+ leg edema. Serum creatinine was 3 mg/dL, increased from 2 mg/dL at 20 weeks gestation. Lab studies revealed normal C3/C4, albumin 2.0, LDH 465, AST 22, ALT 29, uric acid 8.1, Hgb 9.6, and platelets 202,000. Serologic studies were (-). UP/C ratio was 4.8. UA:3+protein, 3+blood, and glomerular hematuria.The patient underwent urgent C-section after failing induction for suspected preeclampsia (PE). Kidney biopsy 4 days postpartum showed proliferative, sclerosing, and focal necrotizing IgAN with 30% cellular to fibrocellular crescents. There was moderate tubulointerstitial scarring with mild acute tubular injury. She was treated with pulse methylprednisolone followed by an oral prednisone+IV cyclophosphamide 500 mg×1. The patent had progressive kidney dysfunction despite therapy requiring permanent hemodialysis 1 month later.

Discussion: This patient had progressive IgAN complicating pregnancy. The findings of HTN, HA, AKI, and elevated uric acid were concerning for PE meriting emergent delivery. The diagnosis of PE in chronic GN is complicated because there is considerable overlap in clinical findings. The patient had significant tubulointerstitial scarring on kidney biopsy likely explaining the failure of therapy. Earlier referral may have led to more timely diagnosis and therapy and an opportunity for counseling about risks of progressive CKD, premature delivery and PE when the serum creatinine is>1.4 mg/dL. Further research is needed to help define additional biomarkers to distinguish between preeclampsia and progressive GN.

FR-PO589

Diffuse Macrophage-Rich Mesangioproliferative Glomerulonephritis After Antibiotic Exposure Laura R. Kidd,[1] Vanessa Moreno,[1] Geetha Seerangan,[2] Ramdas N. Kumar,[2] William F. Glass.[1] *[1]Pathology and Laboratory Medicine, The Univ of Texas Health Science Center at Houston, Houston, TX; [2]Space City Associates of Nephrology, League City, TX.*

Introduction: The role of macrophages in glomerular disease has been examined in animal models, but human glomerular disease characterized by prominent mesangial infiltration by macrophages appears to largely unrecognized or undescribed.

Case Description: We report the case of a 52 year old female with a past medical history of Hepatitis C, Rheumatoid Arthritis and kidney stones, who presented to an outside hospital with complaints of severe abdominal pain, fever, and pain and tenderness of her left breast. She was found to have pneumonia and was treated with antibiotics, including Vancomycin and cefepime. In the next few days, she developed a skin rash, thrombocytopenia and nephrotic syndrome with a urine protein to creatinine ratio of up to 11 grams and a rising creatinine (up to 1.4 mg/dL). The antibiotics were stopped and she underwent a renal biopsy. Microscopic evaluation showed glomeruli with diffuse mesangial and less prominent endocapillary hypercellularity. The infiltrating cells had an unusual, very slightly foamy appearance, and electron microscopic examination revealed cells abundant phagocytic vacuoles containing cellular debris. Podocyte foot processes were irregular to segmentally effaced and segmental capillaries had mild subendothelial rarefaction and/or loss of fenestrations. Immunohistochemical studies were performed to confirm the lineage of the cells which were found to be CD68 and CD4 positive, indicative of macrophages. No evidence of immune complex deposition was identified. Serologies for a vasculitis were negative for P-ANCA, C-ANCA, and ANA.

Discussion: A search of the literature and the Web (Google) revealed no reports of human biopsy cases with similarly prominent macrophage infiltration. We speculate that the patient's nephrotic syndrome was the consequence of platelet destruction with release of cationic proteins and macrophage infiltration as a consequence of Vancomycin-induced thrombocytopenia a rare antibody mediated reaction.

FR-PO590

Focal Segmental Glomerulosclerosis Associated with Mitochondrial Cytopathy Tingli Wang, Ping Fu, Baihai Su. *Dept of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

Introduction: Mitochondrial encephalopathy, lactic acidosis and stroke-like episodes (MELAS) is a heterogeneous disorder ascribed to a defect in mitochondrial function.An A-to-G transition has been shown at 3243 in tRNALeu (UUR) in MELAS.We present an extremely rare case of mitochondrial cytopathy with focal segmental glomerulosclerosis (FSGS).

Case Description: A 18-year-old boy with mitochondrial encephalopathy, lactic acidosis and stroke-like episodes (MELAS) who was diagnosed as having focal-segmental glomerulosclerosis by renal biopsy at our hospital.He also had hypertension,hypothyroidism and non-nephrotic range proteinuria.Kidney biopsy revealed many sclerotic glomeruliand focal segmental glomerulosclerosis (FSGS). A muscle biopsy specimen of the biceps brachii, using Gomori stain, showed some ragged-red fibers,andclustered of type I muscle fiber with ATPase stain.However mitochondrial DNA from the blood didn't show an A-to-G transition at 3243 of transfer RNALeu (UUR), the common point mutation for MELAS.

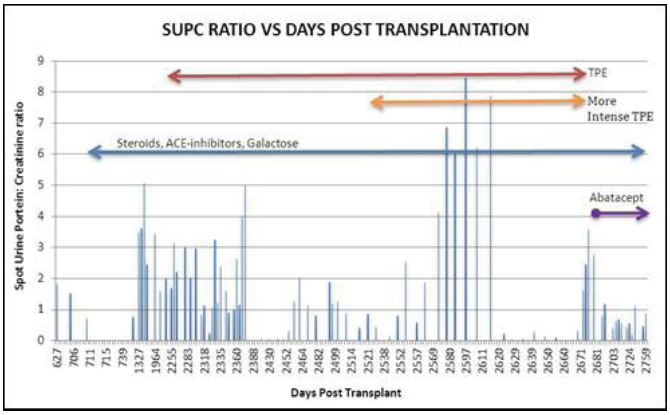
Discussion: The 3243 mutation was originally described only in patients with MELAS but about 16% of patients with MELAS don't have this mutation.Moreover,glomerulopathy is rare in patients with MELAS,and FSGS has been reported only in a fewpatients. Our case is unique in that, thecoexistence of MELAS, hypothalamic hypothyroidism,binocular vision loss, bilateral sensorineural hearing loss and FSGS has not been reported in the past. The present case of mitochondrial cytopathy was characterized by a unique clinical course and rare complications with focal-segmental glomerulosclerosis.The purpose of this report is to increase the awareness of our professionals regarding the manifestations and complications of MELAS.

FR-PO591

Successful Treatment of Proteinuria with Abatacept in Recurrent Focal Segmental Glomerulosclerosis after Transplantation Namita Singh, Marizela Savic, John P. Vella. *Div of Nephrology and Transplantation, Maine Medical Center, Portland, ME.*

Introduction: Abatacept (cytotoxic T-lymphocyte-associated antigen 4-immunoglobulin fusion protein) is a costimulatory inhibitor that targets B7-1 (CD 80). A recent report described the use of abatacept in reducing proteinuria in five patients with focal segmental glomerulosclerosis (FSGS) and B7-1 immunostaining of podocytes in renal tissue. We report the sixth case in the literature.

Case Description: A 32 year-old man with primary FSGS, status-post 2 failed renal transplants due to recurrent FSGS, had recurrence of disease in the third transplant as well. He had nephrotic range proteinuria up to 9 grams per day, that was variably responsive to 3-drug immunotherapy including high dose steroids, angiotensin converting enzyme inhibitors (ACE-inhibitors) and galactose. The patient needed aggressive therapeutic plasma exchange (TPE) treatments up to 3 times a week in order to mitigate the proteinuria. Recurrent attempts to wean either the prednisone or TPE led to prompt, marked proteinuria relapses. Based on the report by Yu et al. (NEJM 11/2013), the patient was started on a trial of abatacept. He received abatacept 10 mg/kg every 2 weeks for 3 doses and thereafter monthly. He has not required further TPE and proteinuria declined to less than 1 gram per day after 3 doses. So far the patient has received 6 doses and continues to have less than half a gram proteinuria.



Discussion: Abatacept induced clinical remission in this case of FSGS leading to discontinuation of TPE treatments and reduced prednisone dosing.

FR-PO592

Collapsing Glomerulopathy Associated with Hemophagocytic Syndrome: A Case Report Inder Patel, Roveena N. Goveas, Chintan Shah, Wihib A. Gebregeorgis. *Dept of Nephrology, Wayne State Univ, Detroit, MI.*

Introduction: Hemophagocytic syndrome (HPS) is an aggressive syndrome of excessive immune activation characterized by bone marrow and organ infiltration by activated, nonmalignant macrophages, which phagocytose blood cells. Very few data are available about the renal complications of HPS.

Case Description: We describe a 60 year old man with NK/T cell nasopharyngeal extranodal lymphoma on radiation therapy who was admitted for dysphagia, fatigue, weight loss and a decline in urine output. He was found to have acute kidney injury with a Cr of 15.2 mg/dl and BUN of 174 mg/dl. He had a baseline Cr of 1.01 mg/dl and BUN 24 mg/dl 3 weeks earlier. Renal ultrasound was unremarkable. Urinalysis showed 3+ protein. He was pancytopenic with WBC count of 1.4 k/cumm, platelet count of 36 k/cumm and hemoglobin of 6.1 gm/dl. His LDH was elevated at 1313 U/Lit and haptoglobin was < 8 mg/dl. There were < 2 schistocytes/HPF on peripheral smear examination. Serology tests for lupus and HIV were negative. ADAMTS13 activity was 55%. He remained oliguric and was initiated on hemodialysis (HD). During the hospitalization, he started having persistent fever of up to 39 °C. Extensive work up failed to disclose infectious etiology for his fever. Kidney biopsy was consistent with collapsing glomerulopathy. The persistent fever, pancytopenia and collapsing glomerulopathy in a patient with lymphoma raised suspicion for HPS and a bone marrow (BM) biopsy was pursued. BM biopsy showed increased hemophagocytic activity with many ingested RBCs, neutrophils and platelets. The presence of fever, pancytopenia, hypertriglyceridemia (triglyceride: 361mg/dl), hypofibrinogenemia (fibrinogen: 123mg/dl), hemophagocytosis on BM biopsy and elevated ferritin level of 7265 ng/ml established the diagnosis of HPS in our patient. Steroid therapy was initiated. He remains HD dependent.

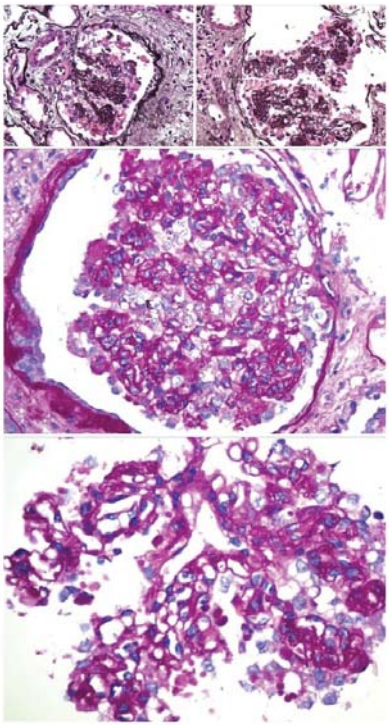
Discussion: Collapsing glomerulopathy associated with HPS is extremely rare. Hypothesized mechanism involves release of pro-inflammatory cytokines resulting in podocyte injury. The diagnosis of collapsing glomerulopathy should raise suspicion and trigger work up for HPS in the right clinical setting. In our case HPS was secondary to NK/T cell lymphoma.

FR-PO593

Collapsing FSGS in a Patient with Acute Malaria Emad Gobran,[1] Leal C. Herlitz,[2] Suzanne E. El Sayegh.[1] *[1]Nephrology, Staten Island Univ Hospital, Staten Island, NY; [2]Pathology, Columbia Univ Medical Center, NY, NY.*

Introduction: Collapsing FSGS has been associated with a various number of infectious etiologies. Here we present a case of Malaria associated FSGS.

Case Description: 72 y/o African M with PMH of HTN and gout presented to the hospital for generalized body aches, fatigue, fever and night sweats for 3 days, history of recent travel to Ghana for 2 wks, he returned to the U.S.A. 10 days prior to symptoms onset. Physical exam was significant for BP 186/99 85, T 102.9F, patient looked in acute distress and shivering. Lab. tests: elevated S. Cr 2.09 (baseline 1.5 in 2012). Hospital course was significant for rapid elevation of S.Cr to 9.5 Proteinuria (7.9 gm) and positive Plasmodium Falciparum on Bl. Smear and was treated with Coartem. He had negative ANA, Anti-dsDNA, Anti-GBM, C3, C4, Hepatitis B and C, ANCA, HIV, Free Light chain, SIF. kidney function continued to deteriorate and became oliguric, on day 7 he was started on HD. had a Lt Kidney bx which revealed 8 glomeruli, 3 of which were globally sclerosed, 4 of the remaining glomeruli displayed lesions of collapsing glomerulopathy which ranged from segmental to global. Collapse of the glomerular tufts and prominent hyperplasia of overlying epithelial cells. Interstitial fibrosis Findings consistent with severe collapsing Glomerulopathy.



Discussion: This Case illustrates a Biopsy proven Collapsing FSGS which carries the worst prognosis among all 5 types of FSGS likely 2ry to Malaria infection with rapid deterioration of kidney function to the point of requiring HD. Literature review revealed only few case reports done in Africa that suggested the possible association of Malaria to secondary form of FSGS.

FR-PO594

Glomerular Filtration Rate Restoration by ACTHAR Gel Therapy in a Patient with Focal, Segmental Glomerulosclerosis with Nephrosis and Acute Renal Failure Vishal Bharat Parekh,[1] Antonio Guasch.[2] *[1]Nephrology, Emory Univ, Atlanta, GA; [2]Nephrology, Emory Univ, Atlanta, GA.*

Introduction: Adrenocorticotropic hormone gel therapy (ACTHAR) induces remission in some patients with Focal, Segmental Glomerulosclerosis (FSGS). Hogan et al (CJASN, 2013) showed small improvement in Cr, and eGFR in FSGS responders; most of responders had relatively preserved renal function. We report a patient who presented with ARF and massive proteinuria due to FSGS that improved markedly with ACHTAR therapy.

Case Description: A 57-year-old Caucasian man with history of FSGS, on no immunosuppression, was admitted with ARF (S. Cr 7.5 mg/dL), anasarca, hypoalbuminemia (S. Alb 1.6 gm/dL), and proteinuria, urine spot protein creatinine ratio (UPCR) 8.8 g/g. He failed previous treatments with prednisone, cyclophosphamide, cyclosporine, tacrolimus and rituximab therapy. He was hypertensive, with no evidence of intravascular volume depletion. A kidney biopsy revealed 25% global and 20% segmental sclerosis and adhesions of tubular pole to proximal tubule in multiple glomerular tufts ("tip lesion"), with interstitial fibrosis. Electron microscopy showed complete foot process effacement with podocyte microvillous transformation. Patient was given pulse solumedrol and started on ACHTAR 80 units SQ thrice weekly for one year with quick improvement in renal function and anasarca. At 6 months, S. Cr 2.23 mg/dL, S. Alb 3.3 mg/dL and UPCR 3.9 g/g. At 1 year, S. Cr 2.2 mg/dL, S. Alb 3.6 g/dL and UPCR was 1.8 g/g. He is edema free.

Discussion: We previously reported (Guasch, AJP-Renal 1991) that ARF in patients with minimal change nephropathy and/or FSGS, there is marked reduction in the glomerular ultrafiltration coefficient (Kf), accounting for low GFR, which correlated with the extent of foot process effacement, suggesting that the loss in the number of filtration slits accounted for ARF. We believe that a similar mechanism resulted in ARF and massive nephrosis in our patient. We postulate that ACTHAR modulates podocyte function, restoring glomerular filtration slits, thereby improving GFR which potentially can treat ARF in patients with FSGS and warrants further evaluation.

FR-PO595

FSGS NOS (Not Otherwise Specified) in an African American Man with HbSC Disease- Sequelae of HbSC Nephropathy or Primary FSGS- A Nephrologist's Dilemma Daniel Taiwo Adeneye, Gary R. Briefel, Suchita J. Mehta. *Nephrology, Univ Hospital at Brooklyn, Suny, Brooklyn, NY.*

Introduction: Focal Segmentalglomerulosclerosis (FSGS) is a clinico-pathogic syndrome that may be idiopathic or secondary to diverse etiologies including sickle cell hemoglobinopathy. Current reports have described 2 types of FSGS in HBSS: the collapsing variant and FSGS with expansile sclerosis. HBSC and HBSS are both hemoglobinopathies, but the former is a milder variant of the disease and the histopathogical features of HBSS may not necessarily represent HBSC disease. No specific histopathogy has been described in HBSC disease and FSGS NOS, has never been reported in HBSC hemoglobinoapthy. Whether the histopathological findings of FSGS NOS; discovered in this case report represents FSGS peculiar to HBSC or primary FSGS is not clear as clearly recorded in the pathogy report of the kidney biopsy. Although a positive supra level would have been supportive of primary FSGS; it is not a sinequanon as it is present in only 70% of patients. Differentiating between the two has therapeutic and prognostic implications especially when making treatment decisions for patients presenting at the early stage of kidney disease. Is there a glomerulopathy specific to HBSC disease?

Case Description: 38 y/o African American man with lower extremity swelling,7G proteinuria; negative serologies and HIV, BUn/Cr 109/15mg.

Biopsy- FSGS NOS.

Discussion: No specific glomerulopathy has been described for HBSC disease and FSGS NOS has prognostic characteristic that is different from other variants of FSGS. 50-60% of primary FSGS respond to immunosuppressive agents including steroids, while FSGS secondary to hemoglobinopathy is best treated with agents that reduce intraglomerular pressure and periodic blood transfusion to reduce the number of sickling cells in the renal medulla. For a patient such as ours, none of this modality would apply as the patient was already end stage.The fact remains that a comprehensive kidney biopsy, more specific biomarkers and study of large sample of HBSC patients to define the specific histopathologic features of HBSC glomerulopathy will be needed to differentiate it from primary FSGS and HBSS glomerulopathy.

FR-PO596

Focal Segmental Glomerulosclerosis in a Patient with Autoimmune Pancreatitis with Elevated IgG4 Ashwin Reddy Ganta,[1] Pramod Kumar Guru.[2] *[1]Dept of Nephrology, Archbold Memorial Hospital, Thomasville, GA; [2]Dept of Nephrology, UPMC, Pittsburgh, PA.*

Introduction: A 65 y/o WF presented to the hospital with abdominal pain and melena. EGD showed esophagitis and Colonoscopy was non contributory. Her bleeding subsided but her abdominal pain continued to worsen. She had similar abdominal pain 3 months ago with elevated pancreatic enzymes that resolved with conservative management and there was no underlying cause identified. Her Scr was 0.5 and her current albumin level was 1.2 (3.3 3 months ago) which was attributed to poor nutrition. Her Amylase and Lipase were again elevated. She did not have h/o alcoholism or Gallstones and CT showed possible inflammatory mass with pancreatic duct abnormality with no e/o Gallstones. A pancreatic biopsy was not attempted given her fragile condition. Nephrology was consulted for anasarca and help with diuresis. Her Urine PCR was 5 gms with + ANA and Nucleolar ANA pattern. Other serology like c3, c4, HIV, HCV, HBV, dsDNA was negative. Ig G4 was elevated at 4x normal. A diagnosis of probable IgG4 Pancreatitis with renal involvement was made based on the Mayo-HISORt criteria and renal biopsy was done. Biopsy showed 26 glomeruli with primary FSGS pattern of injury with IgG, IgM and C3 staining with severe podocyte effacement and no e/o Tubulo-interstitial injury. She was begun on steroids and her abdominal pain improved with reduction in amylase and Ig G4 levels to normal. After 2 weeks of therapy, her Urine PCR dropped to 2.5 gms with improvement in her clinical status. She was lost for follow up and couple of months later she succumbed to sepsis.

Discussion: Discussion: AIP is a new entity that is was first described in 1961 and is more common in Asians. IgG4 related disease (IgG4-RD) refers to the spectrum of AIP with other organ involvement. The kidneys are involved with Tubulo-interstitial pattern of injury with lymphoplasmocytic infiltrate being the most common finding on biopsy. A few isolated cases of MN/MPGN have also been reported. Treatment is with high dose steroids and ours is the first known case in literature with AIP associated 1' FSGS pattern of renal involvement which was steroid responsive.

FR-PO597

Collapsing FSGS Associated with Macrophage Activation Syndrome Revekka Babayev, Shana M. Coley, Andrew S. Bomback. *Columbia Univ Medical Center.*

Introduction: Collapsing FSGS can be primary or secondary to viral infections (eg HIV), drugs (eg interferon) and rarely hemophagocytic lymphohistiocytosis (HLH). HLH can be familial or secondary to infection, malignancy or rheumatic disorders. Diagnosis of secondary HLH requires at least 5 of the following: fever; splenomegaly; cytopenias affecting at least 2 lines; hypertriglyceridemia/hypofibrinogenemia; hemophagocytosis in bone marrow, spleen or lymph nodes; decreased NK-cell activity; markedly elevated ferritin; and soluble CD25 >2400 U/mL. HLH secondary to rheumatic disease is termed macrophage activation syndrome (MAS).

Case Description: A 54 y.o. woman with no prior history presented with 2 weeks of high fevers and painful right lower extremity rash. Exam was notable for hepatosplenomegaly and right lower extremity erythema. Labs showed pancytopenia, transaminitis, and creatinine 1.5 mg/dL. Urinalysis showed 2+ blood, 3+ protein, and protein:creatinine ratio 5.3 g/g. By hospital day 5 creatinine had doubled, and a renal biopsy was performed. Light microscopy revealed collapsing FSGS with focal tubular microcysts and mild tubulointerstitial scarring. Immunofluorescence was negative. Electron microscopy showed diffuse foot process effacement. HIV and parvovirus B19 were negative by PCR. Serologies were positive for ANA, anti-SSA and anti-CCP. Serum ferritin was markedly elevated at >9000 ng/ml. Bone marrow biopsy performed for worsening cytopenias showed hemophagocytosis, supporting a diagnosis of HLH. She was started on pulse dose steroids on hospital day 6 and required 3 sessions of dialysis between hospital days 8-12. She subsequently demonstrated renal recovery and was able to discontinue dialysis.

Hospital day	1	5 (renal bx)	8 (HD initiated)	18 (discharge)
WBC (x10^9/L)	1.7	1.4	1.7	5.6
Hgb (g/dL)	11.2	11.0	11.0	8.3
Platelet count (x10^9/L)	123	105	91	321
Creatinine (mg/dL)	1.52	2.95	5.98	1.2
Albumin (g/dL)	3.1	2.2	2.3	3.5

Cyclosporine was added to oral prednisone for treatment of MAS on hospital day 18. At last follow-up, creatinine was 0.9 mg/dl.

Discussion: A diagnosis of HLH/MAS should be considered in patients with collapsing FSGS and cytopenias. Checking a serum ferritin should be part of the routine work up for such patients.

FR-PO598

A Case of Nephrotic Syndrome Associated with a Hydatidiform Mole

Aline Gibson Notaro,[1] Denise Maria do Nascimento Costa,[1,2] Ana Paula Gueiros,[1,2] Rodrigo Amblard Wanderley,[1] Rafaella Barros da Paixão,[1] Luisa Queiroga Ferreira.[1] *[1]Nephrology Dept, Inst de Medicina Integral Prof. Fernando Figueira - IMIP, Recife, Pernambuco, Brazil; [2]Nephrology Div, UFPE, Recife, PE, Brazil.*

Introduction: The precise pathogenetic relationship between the hydatidiform mole and glomerulonephritis is not clear, because the reported cases were extremely rare. The most common cause of nephrotic syndrome in pregnancy is preeclampsia. Preeclampsia may have a relation to the molar pregnancy.

Case Description: A 21-year-old woman was referred to our section of nephrology because of generalized edema, hypertension, proteinuria and hematuria. Her obstetric history was G0P0AO. During the investigation, was performed transvaginal ultrasonography that diagnosed incomplete molar pregnancy. The patient denied amenorrhea, but her serum B-HCG was 225.000UI/mL. A renal biopsy was performed. Suction and curettage was performed and a specimen evacuated from the intrauterine cavity was consistent with the diagnosis of hydatidiform mole. Light microscopy of the kidney demonstrated a narrowing the capillary lumen due to swelling of the endothelial, mesangial and epithelial cells with an expansion of the mesangial matrix. The pathologic findings suggested preeclamptic nephropathy. Two weeks later, the edema disappeared and the proteinuria was below 300mg. The patient had completely recovered from the renal manifestations.

Discussion: This is an unusual case of nephrotic syndrome in a young woman. To our knowledge, this is the fourth reported case of nephrotic syndrome associated with molar pregnancy. These several interesting cases linking the pathogenesis of the glomerulonephritis directly to the gestational trophoblastic disease provide a challenge for future research.

FR-PO599

Collapsing Focal and Segmental Glomerulosclerosis Associated with Neurofibromatosis Type I

Luisa Queiroga Ferreira,[1] Aline Gibson Notaro,[1] Denise Maria do Nascimento Costa,[1,2] Ana Paula Gueiros,[1,2] Rodrigo Amblard Wanderley,[1] Rafaella Barros da Paixão.[1] *[1]Nephrology Dept, Inst de Medicina Integral Prof. Fernando Figueira - IMIP, Recife, Pernambuco, Brazil; [2]Nephrology Div, UFPE, Recife, PE, Brazil.*

Introduction: Neurofibromatosis type 1 (NF1) is a rare autosomal-dominant genetic disorder. Renal involvement in patients with NF1 is rare. The most common manifestation appears to be renal artery stenosis. Glomerulonephritis associated with NF1 were only sporadic.

Case Description: A 21-year-old female with history of generalized edema was referred for evaluation of nephrotic range proteinuria (5.3 g/day), diagnosed 1 month earlier. She had family history of NF1 in her father. Cafe-au-lait spots and neurofibromas scattered across arms and legs. The serum creatinine was 0.8 mg/dL, albumin 1.0 g/dL and urinalysis showed proteinuria 3+ and microscopic hematuria 1+. Serological test for hepatitis B, C, syphilis, HIV were negative. Complement factors were normal; ANA and ANCA were negative. On renal biopsy, one core of renal cortex with 16 glomeruli was examined. One of 16 glomeruli showed global sclerosis and the remaining had segmental collapse associated with the adhesions to Bowman's capsule and hyperplastic and hypertrophic podocytes. There were no crescents and the mesangium was not expanded. There was diffuse and mild interstitial fibrosis and tubular atrophy. Immunofluorescence revealed no deposits. Overall these findings are consistent with collapsing focal and segmental glomerulosclerosis (FSGS). She was treated with enalapril 20 mg/day, furosemide 80 mg/day and simvastatin 40 mg/day. After 7 months she had a gradual decrease of proteinuria (down to 1.89 g/day from 5.3 g/day) and edema disappeared.

Discussion: To our knowledge, this is the first case of collapsing FSGS reported in a patient with NF1. The occurrence of collapsing FSGS with NF1 in our reported patient may also be a coincidence as we have not performed any linkage investigation.

FR-PO600

Successful Remission of Frequently Relapsing Nephrotic Syndrome due to Minimal Change Disease with Rituximab

Ruchir S. Patel, Susie L. Hu. *Div of Kidney Disease and Hypertension, Warren Alpert Medical School of Brown Univ/Rhode Island Hospital, Providence, RI.*

Introduction: MCD is known to have frequent relapses. We report a case of successful remission of frequently relapsing nephrotic syndrome (FRNS) from Minimal Change Disease (MCD) with Rituximab.

Case Description: 28 year old Caucasian female had FRNS due to MCD (biopsy proven). She was first diagnosed with MCD at age of 14. She had multiple relapses on prednisone and cyclosporine. She was treated with cyclophosphamide PO with remission for a few years. In last 7 years, she has had recurrent disease requiring various combinations of up to 3 immunosupressive agents including prednisone, azathioprine, cyclosporine, mycophenolate or tacrolimus for remission. All medications were stopped in late 2012 while in remission. She subsequently developed 4 relapses the following year. Due to concern for long term steroid exposure, future risk of calcineurin inhibitor induced nephrotoxicity and inadequate response to steroid sparing agents, Rituximab 375 mg/m^2 with 1 month of steroids and transiently overlapping triple therapy was administered. She remained disease free for 6 months. She was given a second dose of rituximab at 6 months while in remission. No further disease activity was noted for an additional 3 months thus far (total 9 months after first dose) and no infectious complications developed. We plan to monitor her disease activity without any additional Rituximab.

Discussion: Rituximab is a potential option for steroid dependent FRNS due to MCD however long term efficacy and delayed adverse effects remain unknown. Small observational studies support the use of Rituximab in FRNS due to MCD in adults however large randomized controlled trials (RCTs) are lacking. Our report also suggests that weekly Rituximab for 3 to 4 weeks may not be needed and thus exposure to Rituximab can be minimized. 2 doses of Rituximab 6 months apart are usually well tolerated. Further RCTs are needed to evaluate long-term efficacy and adverse effects.

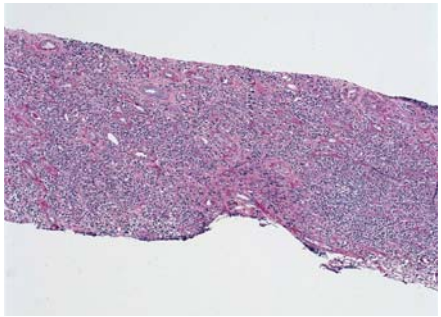
FR-PO601

IgG4 Related Tubulointerstitial Nephritis and Membranous Nephropathy Presenting as Nephrotic Syndrome and Acute Kidney Injury

Ruchir S. Patel,[1] Maroun E. Azar,[1] Kammi J. Henriksen,[2] Susie L. Hu.[1] *[1]Div of Kidney Disease, Brown Univ/Rhode Island Hospital, Providence, RI; [2]Dept of Pathology, Brown Univ/Rhode Island Hospital, RI.*

Introduction: IgG4 Related Disease (IgG4-RD) is an increasingly recognized syndrome which usually has multiorgan involvement. We report a rare case of IgG4 related renal disease.

Case Description: 48 year old Asian male with no medical history presented with 2 weeks of leg edema and an 18 lb. weight gain in setting of rare NSAID use. Review of systems is otherwise negative. Physical exam revealed a blood pressure of 141/87 and bilateral leg edema. Laboratory data were significant for creatinine 2.1 mg/dl, BUN 24 mg/dl, eosinophilia of 20%, Albumin 1.5 g/dl, cholesterol 407 mg/dl, bland urine sediment, and urine protein to creatinine ratio of 14 g/g. Serum and urine IFE were negative for monoclonal protein. ANA, HIV, Hep B and Hep C were non-reactive with normal complements. Renal biopsy showed IgG4-related tubulointerstitial nephritis (TIN) and early membranous nephropathy.



Intense lymphoplasmacytic infiltration with positive staining for 147 IgG4+ plasma cell/high power field and IgG4:IgG ratio > 90% were noted. Serum total IgG and IgG4 levels were elevated. Patient was started on prednisone 50 mg/day, lisinopril and furosemide. After 4 weeks of treatment, creatinine improved to 1.27 mg/dl and proteinuria to 7 g/g.

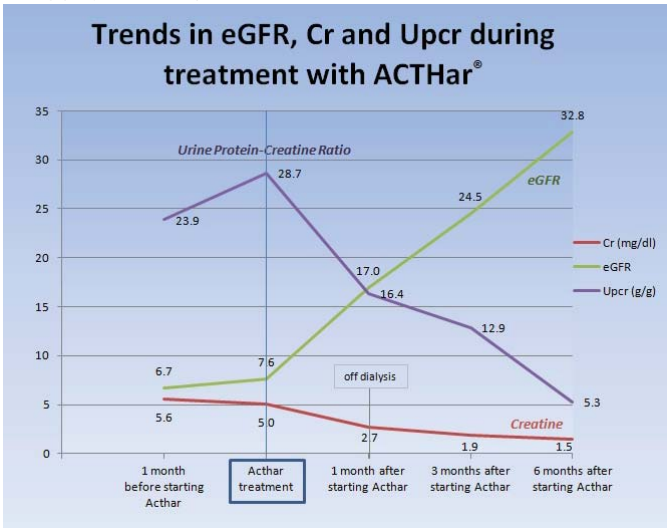
Discussion: Renal manifestations of IgG-RD are mainly in form of TIN, rarely observed with concomitant MN (or MPGN) as seen in our case. Sole kidney involvement is unique. This condition is usually steroid responsive. Long term prognosis of renal disease is not known. Our case highlights the importance of recognizing this rare but potentially treatable renal disease.

FR-PO602

Minimal Change Disease and Dialysis Dependent Acute Kidney Injury Treated with ACTHar and Low Dose Tacrolimus Thet N. Zaw, Robert D. Zenenberg. *Dept of Nephrology, Saint Barnabas Medical Center, Livingston, NJ.*

Introduction: Minimal change disease (MCD) is a major cause of nephrotic syndrome in both children and elderly. MCD may not be as responsive to treatment in elderly. This case report looks at a successful treatment approach in the setting of a resistant MCD with dialysis dependent AKI, and severe steroid side effects, using the combination of an ACTH analogue (ACTHar®) and a low dose calcineurin inhibitor (CNI).

Case Description: The patient is a 78-year-old Caucasian female with a history of borderline hypertension presents with acute onset of worsening lower extremity edema and nephrotic range proteinuria of >20 g/g day. An extensive workup was undertaken including a kidney biopsy, which showed MCD. She was started on oral steroids. Subsequently, the patient had AKI and became dialysis dependent. She had persistent repeat biopsy proven MCD, and developed a severe myopathy, which led to the discontinuation of the steroids. She was switched to a combination very low-dose Tacrolimus and ACTHar® subcutaneous injections. She eventually came off of dialysis and her creatinine stabilized at 1.1 mg/dl, after completing a 6 month course of ACTHar®. Her urine protein excretion had decreased to <6 g/g day. She is doing well on Tacrolimus.



Discussion: It is known that Melanocortin Receptor 1R subtype (MC1R) is expressed on glomerular podocytes. ACTH analogue presumptively exerts through direct MC1R activation on the podocyte, reducing the level of proteinuria by lowering oxidative stress, and improving glomerular morphology. Therefore, specific MC1R agonists such as ACTHar® may lead to fewer side effects and could be used in combination with lower doses of CNI as a new treatment option for nephrotic patients who are unresponsive to the current standard treatment of steroids, particularly in the setting of renal failure, where full dose CNI may be contraindicated.

FR-PO603

Minimal Change Disease with Thrombotic Microangiopathy during Pregnancy Louis R. Spiegel, Dron P. Bhandari, Rimda Wanchoo. *Hofstra North Shore - LIJ School of Medicine.*

Introduction: Preeclampsia is the most common cause of nephrotic range proteinuria in pregnancy and is suspected when proteinuria onset is >20 weeks of gestation. There are several case reports of new onset glomerular disease in pregnancy, mostly post-streptococcal GN and focal segmental glomerulosclerosis, but there are very few cases of minimal change disease (MCD). We describe a case of severe proteinuria, hypertension and acute kidney injury secondary to MCD with superimposed thrombotic microangiopathy during the 3rd trimester of pregnancy.

Case Description: A 21 year old G1P1 presented at 27 weeks of gestation with two weeks of sudden onset edema and anasarca. Her course during pregnancy was unremarkable including no proteinuria and no known prior history of hypertension. Her physical exam revealed a BP of 128/71, HR 71 and rest of the exam significant for bilateral lower extremity edema. Her laboratory data revealed a serum creatinine of 1.4mg/dL and spot urine protein of 20 grams. Her albumin was 1.7mg/dL and uric acid low and liver function tests normal. Based on above data, a clinical diagnosis of MCD was made. Within 24 hours of her evaluation, she became hypertensive with systolic blood pressure of 200 mm of Hg and underwent urgent C-section for atypical pre eclampsia. Several days later, she underwent a kidney biopsy which showed capillary loops with endothelial cell swelling and fibrin thrombi occlusion along with extensive foot process effacement (90%). The findings were consistent with resolving thrombotic microangiopathy (TMA) with superimposed MCD. She was started on oral steroids and discharged home once her renal function returned to normal.

Discussion: De novo MCD developing during pregnancy is very rare and we could find only two cases described in the literature (both during first or second trimester).To our knowledge, our patient is unique in that she had findings consistent with both TMA secondary to pre eclampsia as well as MCD during 3rd trimester of pregnancy, which has not been described before. The differential diagnosis for new onset proteinuria in pregnancy should include MCD. In selected cases, renal biopsy can be used to confirm diagnosis and steroid treatment might be indicated.

FR-PO604

An Unusual Case of Autoinflammatory Renal Amyloidosis Christina Chen, Jonathan S. Hausmann, Arturo Diaz, Stewart H. Lecker. *Beth Israel Deaconess Medical Center.*

Case Description: A 59 year-old man with past medical history of long standing iron deficiency anemia, splenomegaly status post splenectomy, urticarial vasculitis, and history of cocaine use in the distant past, presented to our clinic with CKD. Since 1999, he has been experiencing episodes of fevers and chills that start with extreme thirst, progress to painful hives covering the entire body, and culminate in pitting lower extremity edema. A typical episode resolves within a day. In 2006, his episodes were treated with dapsone with improvement of symptoms. When dapsone was stopped 1.5 years ago due to worsening anemia, his symptoms intensified. For the past year, he had an unintentional 40 lb weight loss due to nausea, vomiting, decreased appetite. On physical exam he was normotensive, appeared undernourished, had no rash, no edema. Labs include creatinine 1.7mg/dL (eGFR 39), potassium 5.7mEq/L, albumin 4.3g/dL, total protein 7.5g/dL, normal SPEP and UPEP, free kappa/lambda 1.79, normal C3/C4, CRP 104.2mg/L, negative ANA, albumin/creatinine 684mg/g. Urine sediment was bland. A colonoscopy with biopsies of the cecum demonstrated amyloidosis. The peptide profile of the amyloidogenic material was consistent with AA type amyloid deposition. Renal biopsy was done showing 12 glomeruli with massive amyloid deposition. Urticarial vasculitis, elevated inflammatory markers and amyloidosis were highly suggestive of an autoinflammatory disease in the cryopyrin associated periodic syndromes (CAPS) group, although subsequent genetic analysis did not allow us to establish a definitive diagnosis. He was started on human anti-IL-1b monoclonal antibody canakinumab with marked improvement in vasculitis and inflammatory markers.

Discussion: Cryopyrin is important in innate immunity and mutations cause spontaneous assembly of the inflammasome and increased production of pro-inflammatory mature IL-1b. A few case studies suggest that canakinumab may reduce proteinuria and stabilize or even improve renal function in patients with CAPS. Although our patient had improvement of his vasculitis, we are awaiting to see if there will be improvement in renal function.

FR-PO605

Spontaneous, Persistent Hypotension as a Sentinel Event for Systemic AL Primary Amyloidosis with Multiple Organ Failure Nader S. Bahri,[1] Raafat Farag Makary,[2] Leighton R. James.[1] *[1]Nephrology and Hypertension, Univ of Florida, Jacksonville, FL; [2]Pathology, Univ of Florida, Jacksonville, FL.*

Introduction: Primary Systemic amyloidosis usually presents with symptoms of cardiac or renal failure. Autonomic neuropathy involvement resulting persistent hypotension is a rare reported presentation.

Case Description: Data was abstracted from an electronic medical record data with review of medical history, examination, lab, pathology and diagnostic studies.

A 60 year-old man with a past medical history of controlled hypertension on multiple medications presented with unexplained symptomatic hypotension. He subsequently developed bilateral lower extremity edema with nephrotic range proteinuria (10 g/day) and acute kidney injury (serum creatinine 2 mg/dl). During the work-up, urine immunofixation revealed a free lambda light chain monoclonal paraprotein; all other serological analyses were negative. Kidney biopsy demonstrated prominent amorphous eosinophilic deposits in the mesangium and GBM, which were congo red positive on light microscopic examination. Fluorescent microscopic studies were negative, while electron-microscopic analysis showed large areas of mesangial and GBM deposits of relatively straight, non-branching fibrils ranging in thickness from 7.65 to 12.09 nanometers, consistent with amyloid fibrils. Bone marrow biopsy and flow cytometric analysis of the bone marrow aspirate revealed abnormal plasma cells which were positive for CD38, CD138, CD56 and lambda light chain C-region and V-region. These findings are diagnostic of plasma cell myeloma causing AL amyloidosis. Due to worsening kidney dysfunction, hemodialysis was initiated. In addition, chemotherapy with Bortezomib was initiated for management of plasma cell myeloma.

Discussion: This case highlights the presentation of systemic AL primary amyloidosis with spontaneous, sustained hypotension, associated with rapid development of multi-organ failure. Autonomic neuropathy is common in primary amyloidosis, as is vascular involvement by the disease. Amyloidosis should be included in the differential diagnosis of new onset persistent hypotension.

FR-PO606

A Case of Transthyretin-Related Familial Amyloid Polyneuropathy Incidentally Found with Abnormal Urinalysis at a General Health Checkup Yasuhiro Yoshimura,[1] Naoki Shiraishi,[1,2] Yutaka Kakizoe,[1] Kenichiro Kitamura,[1] Masashi Mukoyama.[1] *[1]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [2]Sakurajyuji Hospital, Kumamoto, Japan.*

Introduction: Familial amyloid polyneuropathy (FAP) is one of hereditary amyloidoses mostly caused by transthyretin (TTR) gene mutations. The typical form of TTR-FAP shows an autosomal dominant inheritance pattern presenting peripheral and autonomic neuropathy at a younger age. Although family pedigrees are usually identified, reports of sporadic TTR-FAP cases are increasing recently. Here, we report a case of asymptomatic TTR-FAP found with abnormality in routine urinalysis.

Case Description: A 69-year-old woman was referred to our hospital because of proteinuria (2.1g/day) and hematuria, which was pointed out at a general health checkup. She revealed asymptomatic and her serum creatinine level was normal. Renal biopsy demonstrated amorphous deposits involving glomeruli and vessels, which was positive for Congo-red stain with characteristic apple-green birefringence. No monoclonal protein was detected by serum or urine immune-electrophoresis, and immunoperoxidase staining for AA protein was negative. Subsequently, immunoperoxidase staining for TTR was performed, which revealed positive. LC-MS/MS analysis from kidney biopsy specimens detected a quantitative value of TTR, and DNA sequencing of the TTR gene showed Val30Met mutation. According to these findings, she was diagnosed as TTR-FAP.

Discussion: Although neuropathy is the principal manifestation of most TTR-associated amyloidosis, urine abnormality may precede as in this case. For AA-negative and AL-negative renal amyloidosis, TTR-FAP should be considered as a possible diagnosis.

FR-PO607

"Normo-Albuminuric" Diabetic Nephropathy: Fact or Myth? Georgi A. Kovachev, Jeffrey M. Turner. *Dept of Internal Medicine, Nephrology Section, Yale Univ, School of Medicine, New Haven, CT.*

Introduction: According to the "classic" paradigm of diabetic nephropathy (DN) the earliest functional marker of renal damage is micro-albuminuria. Since it precedes decline in GFR, it is widely used for screening and prognostication. However, some patients can reach advanced stages or renal failure and remain normo-albuminuric.

Case Description: 60 yo obese female with long-standing but controlled DM type 2 and hypertension has been followed for stable non-proteinuric CKD stage 4 presumably due to controlled hypertension. A renal biopsy obtained for unexplained decline in GFR revealed moderate diabetic nephropathy, RPC class III.

Discussion: Inaccurate GFR and albuminuria estimations, use of ACEI/ARB, non-diabetic renal disease has been used to explain data from large retrospective studies suggesting that 20-30% of diabetic patients with CKD beyond stage 3 are normoalbuminuric. Smaller studies, using isotopic GFR, supervised 24h urine collections and excluding ACEI/ARB users report prevalence of normo-albuminuria with diabetic CKD > stage 3 to be 20%. It seems to be more common in women with type 2 DM. Prospective data also suggest that some diabetics' GFR can decline to ESRD levels without ever becoming albuminuric. Limited data from biopsy studies suggest advanced glomerular lesions are not always accompanied by albuminuria. Some diabetics with CKD and normo-albuminuria may have predominantly vascular and interstitial lesions for unclear reasons. Conversely, non-diabetic renal disease often coexistent with DN, especially in DM type 2, adding to the confusion. A rat model of classic DN without albumiunria and data from human genetic studies supports the intriguing idea that susceptibility to ESRD and albuminuria are controlled by different genes. Future advances in this area may lead to better understanding of DN, improved risk stratification and developing innovative treatment targets.

FR-PO608

Secondary Amyloidosis and IgA Nephropathy in Cystic Fibrosis: A Rare Coincidence and More to Diagnose Sami Alasfar, Srinivas Ramakrishna Gottipati, Derek M. Fine. *Johns Hopkins Univ, Baltimore, MD.*

Introduction: Clinically relevant kidney involvement is rare in patients with cystic fibrosis. Secondary amyloidosis is a recognized but extremely rare complication of cystic fibrosis. IgA nephropathy in cystic fibrosis is even more uncommon and has been described only once in the literature. We report a case of a cystic fibrosis patient with nephrotic syndrome who was found to have both renal secondary (AA) amyloidosis and IgA nephropathy.

Case Description: A 36-year-old Caucasian male with cystic fibrosis presented with several weeks of lower extremity swelling. His home medications included albuterol, azithromycin, multivitamins, and pancreatic enzymes. He had mildly elevated blood pressure at 147/75 mmHg. His weight was 64.7 kg with 8 kg of recent weight gain. He had facial edema and pitting edema of lower extremities. Laboratory evaluation showed a serum albumin of 1.6 g/dL and creatinine of 2.6 mg/dL. Urine microscopic evaluation showed 17 red blood cells per high power field without casts. 24 hour urine collection revealed nephrotic range proteinuria (14.7 gm/24 hour). Other laboratory evaluations were normal including ASO, C3, C4, ANCA, HIV, SPEP, and ANA. He underwent renal biopsy which revealed renal amyloidosis (amyloid-associated protein) and minimally proliferative IgA nephropathy with focal glomerular necrosis and crescent formation. The patient was initiated on oral Prednisone 1 mg/kg/day and after about six weeks of therapy, his creatinine improved to 1.2 mg/dL and proteinuria decreased to 7 grams/24 hours.

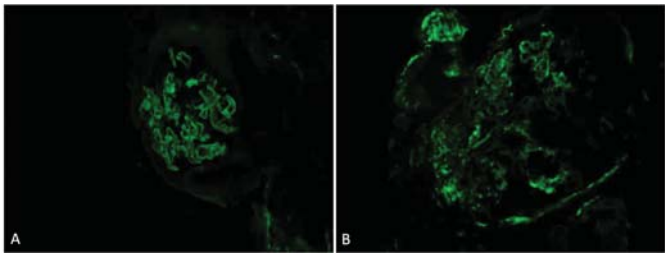
Discussion: Secondary amyloidosis occurs in patients with chronic infectious and inflammatory disease but it is surprisingly a rare complication of cystic fibrosis. Moreover, IgA nephropathy in cystic fibrosis was described only once in the past. Recent advances in the management of cystic fibrosis have led to improvement in survival. It is probable that, in the past, the short life expectancy of patients with cystic fibrosis allowed insufficient time for the development of certain renal complications. Our case suggests that some renal complications and/or manifestations of cystic fibrosis may be seen with increasing frequency in the future as life expectancy improves.

FR-PO609

Fibrillary Glomerulonephritis Masquerading as Anti Glomerular Basement Membrane Disease Juan- Carlos Aycinena,[1] Stuart C. Jennings,[1] Virgilius Cornea,[2] B. Peter Sawaya,[1] Amr Ahmed El-Husseini Mohamed.[1] *[1]Div of Nephrology, Bone and Mineral Metabolism, Univ of Kentucky; [2]Dept of Pathology, Univ of Kentucky, Lexington, KY.*

Introduction: Linear staining (LS) of immunoglobulin (Ig) by immunofluorescence (IF) is characteristic of anti-GBM disease but it has been also described in other entities. However, in patients with clinical presentation of RPGN and pathological diagnosis of crescentic GN with LS of Ig is highly suggestive of anti-GBM disease. Herein we describe a case of fibrillary GN (FGN) presenting as a crescentic RPGN (C-RPGN) with unequivocal LS of IgG and negative circulating anti-GBM antibodies (Ab).

Case Description: A 49 year-old Caucasian female with history of obesity, hypertension (HTN) and microscopic hematuria presented with headache, blurred vision, nausea and vomiting but no hemoptysis. Her blood pressure was 274/152 with no neurological deficit or skin rash. Serum creatinine was 6.4 mg/dl and urinalysis revealed 50 RBC/HPF with no cellular casts. Spot urine for protein/creatinine ratio was 10 mg/mg. The following labs were normal or negative: complement levels, hepatitis B and C profiles, HIV Ab, lupus serologies, ANCA, anti MPO, anti PR3 and anti GBM Ab. A kidney biopsy revealed crescentic GN with fibrinoid necrosis. IF revealed intense LS of GBM for IgG (Fig 1A) and coarse/short LS of C3 (Fig 1B).



The patient received high-dose steroid and plasma exchange without any benefit. Two weeks after admission, EM confirmed the presence of mesangial and intra-GBM deposition of fibrillary structure measuring 8 to 16.5 nm. The patient is currently dialysis-dependent 1 year after the original diagnosis.

Discussion: There are only 3 other reported cases of FGN presenting as C-RPGN with LS by IF. All cases presented with severe HTN and heavy proteinuria, features that are not typical of anti-GBM disease. Prompt diagnosis alters both treatment and prognosis.

Funding: Clinical Revenue Support

FR-PO610

Leukocyte Chemotactic Factor 2 (LECT2) Amyloidosis in First Nations People in British Columbia, Canada: A Case Series Holly L. Hutton,[1] Mari Demarco.[2] *[1]Dept Medicine, Monash Univ, Clayton, Victoria, Australia; [2]Dept Pathology and Laboratory Medicine, St. Paul's Hospital, Vancouver, BC, Canada.*

Introduction: Leukocyte chemotactic factor 2 (LECT2) amyloidosis was first identified in 2008, and has emerged as a frequent type of renal amyloidosis. It is typically reported as being renal limited, and, in the United States, more prevalent in Hispanic patients. We report 4 First Nations people living in Northern British Columbia who were diagnosed with renal LECT2 amyloidosis over the past 4 years.

Case Description: All patients presented with slowly progressive renal impairment and minimal proteinuria. (Table 1)

Age	Sex	Creatinine µmol/L	eGFR (ml/min)	ACR (mg/mmol)
56	F	167	37	1.9
78	M	261	21	64
68	F	223	20	48
62	F	165	27	2.4

Biopsy findings were typical of LECT2 amyloid, with intense congo red staining, and amyloid deposition in the renal interstitium and vasculature as well as glomeruli. After immunohistochemistry for common amyloidogenic proteins did not identify the pathogenic protein, laser microdissection-mass spectrometry was used to make the diagnosis. Although First Nations people comprise only about 4% of the patient population seen by our Nephrology service, all 4 cases of renal LECT2 amyloidosis, diagnosed over the past 4 years, occurred in this ethnic group.

Discussion: The pathogenesis of LECT2 amyloidosis is currently not well understood. Sequencing of the coding region of the *LECT2* gene in patients with LECT2 amyloidosis has revealed a common homozygous single nucleotide polymorphism, indicating a probable genetic component to disease pathogenesis. The fact that our centre has only identified LECT2 amyloidosis in First Nations people adds weight to the hypothesis that there is a genetic contribution to the disease. It may be that a common North American indigenous ancestry of First Nations people and Hispanics accounts for the occurrence of this condition in both populations. LECT2 amyloidosis may be an underdiagnosed cause of chronic kidney disease, as the characteristic minimal proteinuria and slow progression of renal impairment probably result in relatively few patients undergoing renal biopsy.

FR-PO611

Job's Nephropathy Salman Ahmed,[1] Luan D. Truong,[2] Biruh Workeneh.[1] *[1]Div of Nephrology, Baylor College of Medicine, Houston, TX; [2]Pathology, Houston Methodist Hospital, Houston, TX.*

Introduction: Job's syndrome or autosomal dominant hyperimmunoglobulin E syndrome (Hyper-IgE) is a result of STAT3 mutation and leads to a severe immunodeficiency and recurrent infections and what we propose is a renal pattern of injury histologically similar to lupus nephritis rather than classical lupus nephritis.

Case Description: We describe a set of fraternal sisters with autosomal dominant Hyper-IgE (loss of function mutation c.1962_1964delCAT), confirmed by genetic testing, with variable penetrance. The sister affected more aggressively developed renal manifestations as a child; she had AKI with unclear attribution requiring HD, but recovered fully. At age 18 she developed proteinuria (1 gram/day), hematuria and a SCr of 1.6mg/dL, at which time a renal biopsy was performed and revealed immune complex nephritis. Although all classical lupus serologies were negative, the patient was started on prednisone and MMF given her pattern of injury. Unfortunately, her renal disease did not abate and was declared ESRD at age 22. The younger sister who had a lower frequency of serious infections at age 21 also developed proteinuria and hematuria with a normal SCr (1.0 mg/dL) and renal biopsy showed a pattern consistent with lupus nephritis. Her serologies however, showed a positive ANA and anti-Smith and she was started cautiously on an immunosuppressive regimen.

Discussion: Because of how rare this condition is it has been difficult to characterize this association between Job's syndrome and a lupus pattern of injury in the kidneys. We speculate that as a result of recurrent, aggressive infections and tissue exposure that immune complexes form or are trapped in the kidney rather than the classical pathophysiologic pathway that occurs with lupus nephritis. It is not clear whether immunosuppression has a role in this pattern of injury associated with Job's syndrome. Research is linking to renal inflammation and injury, but more analysis is needed to elucidate a mechanism for renal injury.

FR-PO612

An Unusual Case and Treatment of Immunotactoid Glomerulonephritis and Cutaneous Leukocytoclastic Vasculitis with IgMK Monoclonal Gammopathy: A Case Report Andrea Angioi,[1] Giovanni Palladini,[2] Anna Maria Asunis,[1] Giorgio La Nasa,[3] Antonio Ledda,[3] Riccardo Cao,[1] Antonello Pani.[1] *[1]Div of Nephrology, AOBrotzu, Cagliari IT; [2]Fondazione IRCCS-Policlinico San Matteo, Pavia IT; [3]Centro Trapianti Midollo Osseo, ASL8, Cagliari IT.*

Introduction: The treatment of monoclonal gammopathies of renal significance (MGRS) is still debated. We discuss an unusual case of Immunotactoid glomerulonephritis with leukocytoclastic vasculitis (LV) and IgMK spike that we treated with rituximab (RTX), plasmaexchange (PEX), dexamethasone (DEX), cyclophosphamide (CYC) and bortezomib (BOR) despite normal bone marrow biopsy (BMB) to stabilize the renal function.

Case Description: A 50 year-old man was referred in Nov2006 because of isolated microscopic hematuria (ME). Two years earlier he had had MGUS IgMK and LV (immunofluorescence (IF) negative). The requested exams showed decreased eGFR (CKD-EPI:64ml/m/1.73m2) without proteins or Bence Jones (BJ) in urine, while BMB was normal. Cryoglobulins, autoimmunity and infections were excluded. In Nov2009, C3 73 (NV>90 ng/dl), proteinuria (300mg/24h) and BJ (K); eGFR, ME, serum free light chain K, l and K/l were within normal range. Renal biopsy was diagnostic for ITG. IF showed only IgM (3+), k (2+). In Mar2010, eGFR 36ml/m, proteinuria 0.8g/24h, BJ (K) and IgMK 1.2g. A new BMB showed no abnormal plasmacells. We started induction with PEX+DEX 40mg x4 days and CYC+DEX (200/20 mg/day) +RTX 375 mg/m2 every 21 days. After 6 courses, negative BMB**,** eGFR 40ml/m, IgMK 0.12g; maintenance therapy was started with RTX 375/m2 every 3 months. In Nov2012, CYC+RTX for a transient eGFR reduction and in Apr2013 RTX+BOR+DEX due to unexpected albuminuria (2g/24h). Now he is well with stable eGFR (49 ml/m), BJ negative.

Discussion: In this MGRS, the reduction of toxic IgMk resulted in ITG stabilization. Conceptually, our approach is opportune considering the reduced side effects of new courses and the poor renal prognosis if untreated. Supported by indirect clues (here: IF:IgM+/K+; BJ:k), treatment should be considered in selected patients to preserve eGFR. Labeling B-cell clones having mild neoplastic significance but with clear aggressive productive features as being of "undetermined significance" should be avoided.

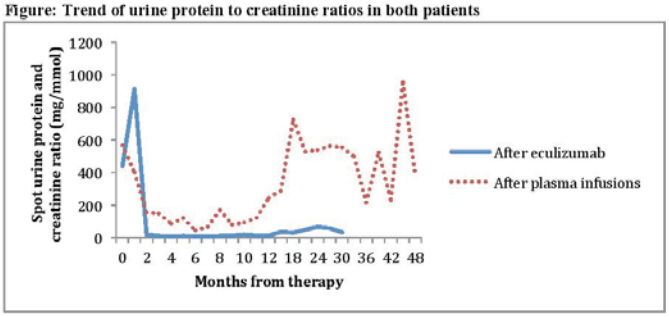
FR-PO613

Complement Targeting Therapies for Refractory C3 Glomerulopathy Rahul Chanchlani, Seetha Radhakrishnan, Diane Hebert, Valerie Langlois, Christoph Licht. *Div of Pediatric Nephrology, Hospital for Sick Children, Toronto, ON, Canada.*

Introduction: Complement targeting therapies including plasma and eculizumab have emerged as disease modifying agents for Membranoproliferative Glomerulonephritis (MPGN), which has recently been re-classified into dense-deposit disease (DDD) and C3 glomerulonephritis (C3GN) and grouped under C3 Glomerulopathy (C3G). There is very little insight on their long-term follow up and safety profile especially in children. We present more than 3 years follow up data with the use of above therapies in 2 children with refractory C3G.

Case Description: Case 1: A 16-year-old girl with MPGN secondary to CFHR1/3 deficiency was started on prednisone and MMF. Due to worsening proteinuria and renal function, hemodialysis and plasmapheresis were also initiated. Four months later, eculizumab was started (900 mg/wk x 4 wks) due to further clinical deterioration and resulted in rapid improvement in neurological status, renal and hematological parameters. Maintenance infusions of eculizumab were continued, 1200 mg q 2 wks for more than 2 years. She currently has mild proteinuria only, normal blood pressure and renal functions despite persistently low C3. **Case 2:** A 7-year-old boy with MPGN secondary to MCP/CD46 mutation continued to have proteinuria despite treatment with various combinations of prednisone, MMF, and tacrolimus over a period of 6 years. Repeat biopsy showed only mild chronic features. Plasma infusions (15 ml/kg of fresh frozen plasma 3 times a week) were started followed by transient improvement in proteinuria. However, despite chronic plasma infusions for almost 4 years (q 2 wks), he continues to have proteinuria with elevated creatinine and normal C3. (Figure)

Figure: Trend of urine protein to creatinine ratios in both patients



Discussion: Eculizumab and plasma infusions are safe and effective options for refractory C3G. Prospective studies in larger cohort are required to prove superiority of one modality over other.

FR-PO614

Chronic Inflammatory Demyelinating Polyneuropathy with Membranous Nephropathy: A Case Report Chetana Rondla, Christine Boumitri, Militza K. Kiroycheva. *Medicine/Nephrology, Staten Island Univ Hospital, Staten Island, NY.*

Introduction: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is an immune mediated disorder involving spinal nerve roots and peripheral nerves. There have been very few case reports of inflammatory demyelinating polyneuropathies occurring in association with proteinuric kidney diseases mainly membranous nephropathy and focal segmental glomerulosclerosis.

Case Description: A 66 year old Haitian male with history of Atrial fibrillation, Hypertension and Dyslipidemia was referred to the Nephrology clinic for lower extremity edema and proteinuria. Workup was significant for proteinuria of 16gms. Serologic workup was negative. Renal biopsy revealed Membranous Nephropathy with mild tubular atrophy and interstitial fibrosis. He had an extensive workup to rule out secondary causes: CT chest was normal, CT abdomen/ pelvis revealed enlarged lymph nodes with negative subsequent biopsy. PET SCAN and colonoscopy were negative. Complement level was normal. He was started on Steroids and Cyclophosphamide with partial remission of proteinuria. Soon after he was diagnosed with Membranous Nephropathy he complained of progressively worsening bilateral lower extremities weakness. He was evaluated by neurologist. The EMG/Nerve conduction studies were suggestive of demyelinating polyneuropathy with secondary axonal degeneration. Meanwhile weakness worsened and he became wheelchair bound. The rest of his workup came back as follows: CRP: 9.49, ESR: 88, normal Complements, Negative ANA, anti dsDNA, ANCA and anti Jo antibodies. These findings were consistent with inflammatory demyelinating neuropathy and a diagnosis of CIDP was made. Patient had minimal improvement with pulse steroids. He was then started on IVIG treatment following which he had significant improvement of his weakness and is currently able to ambulate with a walker. He is currently on monthly IVIG injections.

Discussion: Extra neural manifestations of chronic inflammatory demyelinating neuropathy have included association with membranous nephropathy. However there have been very few case reports in our literature search. Immunopathogenic association of these two conditions merits further investigation.

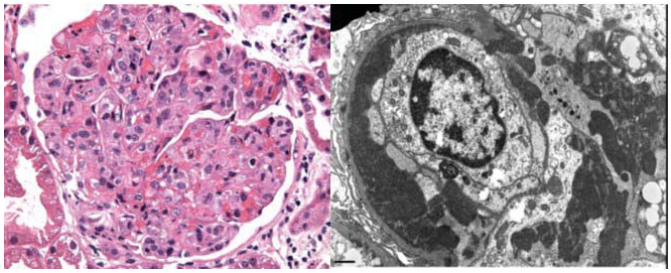
FR-PO615

A Case of Atypical Postinfectious Glomerulonephritis with Cryoglobulinemic Deposits Chetana Rondla, Christine Boumitri, Elie El-Charabaty, Suzanne E. El Sayegh. *Medicine/ Nephrology, Staten Island Univ Hospital, Staten Island, NY.*

Introduction: An increasing number of post infectious glomerulonephritis (PIGN) cases with atypical pathologic features have been reported in the last decade. Histologic features of PIGN include diffuse mesangial and endothelial cell proliferation with exudative GN. Coarse immune deposits of C3 and IgG in capillary loops are identified on IF corresponding to the subendothelial deposits on EM.

Case Description: A 55 year old male previously healthy presented for fever, cough and Rt sided pleuritic chest pain of 2 weeks that failed an outpatient course of antibiotics. CT chest revealed RLL pneumonia with loculated pleural effusion. Pleural tap revealed an exudate and patient was started on empiric antibiotics. Admission creatinine was 1.18 and UA revealed trace proteinuria and trace blood. Blood pressure was 139/85. On day 4 creatinine started to increase reaching 10.2 on day 9. 24 hour urine for protein was 1.6g. Complements- C3 and C4 were low (35 and 6 mg/dl) with negative serologies including cryoglobulin with a normal Rheumatoid Factor. All cultures were negative as patient

was already on antibiotics. On day 9 he required hemodialysis. A kidney biopsy revealed diffuse endocapillary and exudative GN with infiltrating monocytes and neutrophils, 3+ subendothelial electron dense deposits (mixed cryoglobulin) and 80% effacement of foot process. The EM findings were typical of cryoglobulinemic GN. On day 14- creatinine started to trend down and he was off dialysis. After 2 weeks of presentation the complement levels were back to normal and at last followup 1 month ago his creatinine was 1.66.



Discussion: Over the last decade pathologically atypical cases of PIGN have been increasingly reported, however PIGN with cryoglobulinemic EM features and negative cryoglobulin is an unusual presentation and to our knowledge has not been reported.

FR-PO616

HIV Associated Membranoproliferative Glomerulonephritis (MPGN) Immune Complex Disease: A Histopathologic Evolution of Kappa Light Chain Monoclonal Gammopathy to a "Lupus Like" Immune Complex Disease

Piangwarin Phaosawasdi, Jose A. Morfin. *Internal Medicine - Div of Nephrology, Univ of California, Davis, Sacramento, CA.*

Introduction: HIV has been associated with different glomerular diseases. Proliferative Glomerulonephritis with Monoclonal IgG Gammopathy (PGNMID) is a distinct glomerular injury without the presence of paraproteinemia. Lupus Like immune complex disease has been linked to HIV. We describe a perplexing case of an HIV patient who demonstrated an evolution and potential link between these two rare entities.

Case Description: A 40 y/o Latino woman with HIV with CD4 counts of 400-600 cells/mm, DM2 and HTN who presented with an episode of fluid overload, serum creatinine of 2.1 mg/dl (baseline 1.1 mg/dl) with nephrotic range proteinuria (3.5 gm/day) and albumin 1 g/l. She had negative serologic studies including normal complement levels, serum and urine electrophoresis, ANA 1:80, negative DS-DNA, RF 27 IU/ml, ANCA, MPO and PR3. Negative Hepatitis panel. Cryoglobulin was non-detected. She underwent kidney biopsy (#1) which showed immune complex-mediated MPGN with glomerular hypercellularity with kappa light chain dominant consistent with PGNMID. A bone marrow biopsy showed no increase in plasma cells. She was started on ACEI. 4 months later, she represented with worsening fluid overload and serum creatinine of 4.5 mg/dl. Repeat serology remained negative. Kidney biopsy (#2) was performed which again showed Immune complex-mediated MPGN, however, there was "full house" immune deposits (lupus like) without kappa restriction and with a focal crescentric formation. She was started on hemodialysis due to anuria with fluid overload.

Discussion: To our knowledge, this is the first case that describes a potential evolution of these two rare and distinct histological glomerular processes, PGNMID and Lupus Like immune complex MPGN. HIV infection is a major risk factor and plausible link leading to derangement and mimicry in the immune system, specifically in CD20 B cell population. Treatment options are challenging given the paucity of data in these entities, but the findings are intriguing to further understand mimicry associated with HIV infection.

FR-PO617

Fibrillary Glomerulonephritis Presenting as Rapidly Progressive Glomerulonephritis with Linear IgA Staining of the Glomerular Capillary Walls

Akiko Endo, Shinya Kaname, Yoshihiro Arimura. *First Dept of Internal Medicine, Kyorin Univ School of Medicine, Tokyo, Japan.*

Introduction: Fibrillary gromerulonephritis (FGN) is a rare glomerular disease characterized by the deposition of randomly arranged fibrils 12 to 30 nm thick in the mesangium and the glomerular basement membranes. On immunofluorescence (IF), the deposits typically stain for polyclonal IgG and complements. The light microscopic features vary, but cellular crescent formation is uncommon in FGN. Here we reported the first case of FGN accompanied by cellular crescent formation with predominantly linear IgA staining of the glomerular capillary wall.

Case Description: A 30-year-old woman was admitted for rapid progressive renal failure (Cr 1.7 mg/dl). Urinalysis showed 50-99 RBC/HPF and proteinuria 3g/day. ANA, MPO-ANCA, PR3-ANCA, anti-GBM antibody, serum and urine immunoelectrophoresis were all negative. Renal biopsy showed crescentic gromerulonephritis (5/37 gromeruli: cellular crescent, 1/37 gromeruli: fibro-cellular crescent). Congo Red staining was negative. IF revealed global linear deposition of IgG (2+), IgA (3+), segmental deposition of IgM (+) and C3 (+) along the glomerular capillary walls. Electron microscopy showed variable thickening of glomerular capillary walls with randomly oriented fibrils measured 21-26 nm in diameters in the capillary walls and the mesangium. She received methylprednisolone pulse, oral predonisone and cyclosporin. Over the follow-up course of 9 months, proteinuria decreased to 0.4g/day and creatinine level remained around 1.5 mg/dl. Re-biopsy showed 1/30 gromeruli with cellular crecentic formation, the same features of IF and partial improvement of thickening of the capillary walls on electron microscopy as compared to those in the first biopsy.

Discussion: In previously reports, 28% cases of FGN were positive for IgA, but glomerular staining for IgA was weaker than IgG. The light microscopic features are heterogeneous, most cases exhibit mesangial expansion and hypercellularity. Crescentic glomerulonephritis was less commonly reported. This is the first case of FGN accompanied by cellular crescent formation with predominantly linear IgA staining of the glomerular capillary walls.

An Uncommon Presentation of a Rare Disease: Mesangial Proliferative Glomerulonephritis with Monoclonal IgG Deposits ("Nasr Disease") in a Young Woman

Tanjim Sultana, Maria V. DeVita, Michael F. Michelis, Joshua A. Schwimmer. *Nephrology, Lenox Hill Hospital, NY, NY.*

Introduction: Proliferative glomerulonephritis with monoclonal IgG Deposits (PGNMID) is a rare dysproteinemia-related renal disease first described by Nasr et al. in 2004. It is often characterized by proteinuria, hematuria, and renal insufficiency. There are 4 pathologic patterns, of which the rarest is the mesangial proliferative form (< 3%). We present the 3rd case of this uncommon variant of PGNMID.

Case Description: A 24-year-old African American female was referred for new onset hypertension, increased creatinine (1.4 mg/dL), and albuminuria (924 mg/d) without hematuria. Labs revealed an ANA of 1:160 and a negative serum and urine immunofixation. She was subsequently found to have a positive anticardiolipin IgG, B2 glycoprotein IgG, and lupus anticoagulant. A renal biopsy was performed to exclude anti-phospholipid antibody syndrome involving the kidney or lupus nephritis. Light microscopy revealed 20/41 globally sclerotic glomeruli with old fibrous crescents. The remaining glomeruli had mesangial cell proliferation with glassy eosinophilic deposits. IF revealed diffuse granular mesangial staining for IgG1 only. EM revealed abundant granular, mesangial electron dense deposits without an organized substructure. She was treated with losartan 50 mg daily and no other agents. A bone marrow biopsy showed no evidence of malignancy. Three months later her albuminuria had decreased to 60 mg/d and her creatinine decreased to 1.2 mg/dL.

Discussion: PGNMID is a rare form of glomerulonephritis found in 0.17% of renal biopsies. It presents with proteinuria (100%), hematuria (77%), renal insufficiency (68%), nephrotic syndrome (49%), and a detectable serum or urine paraprotein (30%). There are 4 pathologic variants of PGNMID: membranoproliferative, endocapillary proliferative, membranous, and mesangial proliferative. After a mean of 30 months of followup, 37% of patients with PGNMID developed end stage renal disease or died. After treatment with losartan, our patient with mesangial proliferative PGNMID had microalbuminuria and improved renal function. Optimal therapy for PGNMID is uncertain and further studies are needed.

FR-PO619

IgA-Dominant Postinfectious Glomerulonephritis Mimicking Henoch-Schönlein Purpura in a Child

Ryan C. Mascarenhas,[1] Agnes B. Fogo,[2] Radhakrishna Baliga.[1] *[1]Ochsner Med Ctr, NO, LA; [2]Vanderbilt Univ, Nashville, TN.*

Introduction: IgA-dominant acute post infectious glomerulonephritis (APIGN) is an increasingly recognized morphologic entity typically seen in elderly and diabetics. Henoch-Schönlein purpura (HSP) predominantly occurs in children and is characterized by sudden onset of symmetric purpuric rash of the lower extremities. We report a child with typical initial presentation of HSP whose clinical course, biopsy and outcome were suggestive of IgA-dominant APIGN.

Case Description: A 6-year old AA male was admitted for progressive facial swelling, decreased urine output and difficulty breathing for 3 days. Two weeks prior he had left knee swelling and a purpuric rash over the shins. On exam he was afebrile with facial swelling,nasal flaring and grunting, with a gallop rhythm, and a diffuse excoriated rash on the lower extremity. Lab data:UA 3+ protein,3+ blood with 50RBCs, 13WBCs/hpf, 1.5G protein/24h, BUN/SCr 35/0.8mg/dl, serum cholesterol 104mg/dl, albumin 1.8G/dl, Streptozyme positive, ANA negative and C3 68 (50-180) mg/dl. Echocardiogram (ECHO) indicated decreased function. Viral and bacterial cultures were negative. Kidney biopsy:diffuse endocapillary proliferation with IgA-dominant 3+ mesangial and irregular granular capillary wall staining with lesser IgG and C3;lambda more than kappa. EM:frequent mesangial and subendothelial deposits and subepithelial hump-type deposits. Biopsy was suggestive of IgA-dominant APIGN. Skin biopsy revealed perivascular granular IgA with mild C3. He was discharged on diuretics and ACE inhibitor but returned a month later with acute cardiac decompensation. He received inotropes, IVIG, IV penicillin and steroids. Four months later he is on no medications, with normal ECHO, BUN/SCr 9/0.6mg/dl, C3 104mg/dl, albumin 3.8G/dl, UA 1+ protein, 2+ blood, 28RBCs/hpf, and 142mg protein/24h.

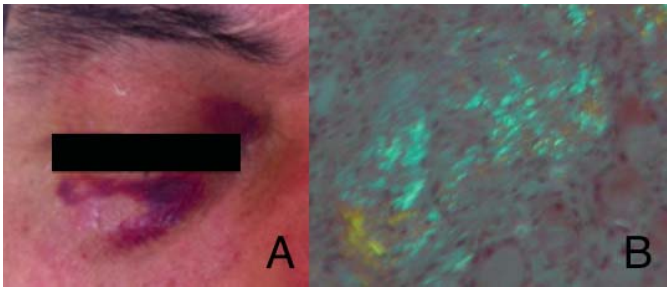
Discussion: The initial clinical presentation including the skin and kidney biopsy findings in IgA-dominant APIGN are typically indistinguishable from HSP. Even though IgA-dominant APIGN mimicking HSP is commonly seen in the adult population it does occur in children. The diagnosis should be made with a high degree of clinical suspicion looking diligently for any underlying infection.

FR-PO620

Renal Amyloidosis Associated with IgA Nephropathy in a Patient with Cirrhosis and Hepatitis B Eduardo Jorge Duque de Sa Carneiro Filho, Lectícia Jorge, Lucia Andrade, Viktoria Woronik. *Univ of São Paulo, São Paulo, SP, Brazil.*

Introduction: We present a cirrhotic patient with an unusual association of IgA nephropaty (IgAN) and renal amyloidosis.

Case Description: A 47-year-old Asian male with cirrhosis diagnosed 10 years ago caused by hepatitis B, treated with lamivudine and tenofovir, was admitted with lower extremity edema and hypotension for last 6 months. Upon physical examination: blood pressure of 76/42 and anasarca. Laboratory results demonstrated normal liver function, positive anti-Hbc, negative HbsAg and anti-Hbs, hemoglobin 11,9 g/dL, rheumatoid fator 11,1 IU/mL, C3 71 mg/dL, C4 16,6 mg/dL, IgA 476 mg/dL, twenty-four-hour urine protein collection with proteinuria of 5.84 g, creatinine 3.4 mg/dL, albumin 2.1 g/dL. Urinalysis showed proteinuria (1 g/L), 3 leukocytes per field and no red cells. During hospitalization, developed bipalpebral atraumatic ecchymoses (figure 1A). Protein electrophoresis, serum and urine immunofixation and bone marrow were normal. Renal biopsy: amyloidosis with nodular and diffuse deposition in glomeruli arteries and arterioles (positive congo-red, figure1B). Immunofluorescence: IgA (3+), C3 (+) in the mesangium and negative for k/l.



Discussion: Viral infections have been uncommonly reported with amyloidosis. Lannergard et al have shown that viral infections, including hepatitis B, result in elevated serum A amyloid protein levels that eventually could precipitate as amyloid. Mesangial IgA deposition observed in our patient is a frequent finding in chronic liver disease with minor glomerular symptoms and non progressive renal disease. It is thought to be a consequence of impaired clearance of IgA by the Kupffer cells and hepatocytes. To summarize, we report a case of nephrotic syndrome due to probably AA renal amyloidosis in a cirrhotic patient with Hepatitis B associated with IgAN probably secondary to cirrhosis.

FR-PO621

Membranous Nephritis with Full House Effect in a Patient with Negative Lupus Serologies Pradeep Vaitla, Ryan C. Mascarenhas, Antonio G. Jimenez, Jorge C. Garces. *Nephrology, Ochsner Clinic Foundation.*

Introduction: Patients with lupus nephritis usually have systemic lupus erythematosus (SLE) diagnosed by clinical and immunological criteria. American college of Rheumatology requires the presence of at least 4 of 11 clinical or laboratory criteria to diagnose SLE and Systemic lupus International Collaborating Clinics (SLICC) requires at least 4 of 11 clinical or laboratory criteria Or biopsy proven lupus nephritis with positive anti nuclear antibody (ANA) or anti deoxyribonucleic acid (DNA) antibody. We report a case of immune complex disease with sub epithelial and intra membranous deposits with IgG, IgA, IgM, C3 and C1q deposition in a patient with nephrotic range proteinuria and negative ANA. The patient had 0 of 4 criteria for ACR lupus criteria and 0 of 11 of SLICC criteria and would not qualify for diagnosis based on the criteria.

Case Description: 33 year old white male with asthma was being evaluated for elevated serum creatinine of 1.3. He did not report skin rash, arthritis,joint stiffness, photosensitivity, use of non steroidal anti inflammatory drugs or recreational drugs. On examination blood pressure was 128/82 mm Hg, rest of examination was unremarkable. Urinalysis showed +3 protein, 9 RBC's/hpf, urine protein to creatinine ratio of 9.5. Investigations were negative for HIV, Hepatitis, ANA, anti DNA and smith antibody, lupus anti coagulant and normal serum complement levels. Kidney biopsy revealed thickened basement membrane with subepithelial and intramembranous deposits, extensive foot process effacement. Immunofluorescence microscopy showed diffuse granular capillary loop staining for IgG (3+), IgA (1+), IgM (2+), C3 (2+) and C1q (1+), stains for phospho-lipase A2 receptor antibody were negative. Tubuloreticular inclusions were not identified.

Discussion: Diagnosis in this patient highlight the deficiencies in diagnostic criteria for SLE as he has no clinical or immunological criteria. Lupus nephritis still presents a challenge in clinical practice and the absence of better serologic markers to predict development of disease may delay appropriate diagnosis and treatment. Kidney biopsy remains the gold standard.

FR-PO622

***Campylobacter* Associated Glomerulonephritis** Kevin C. Roe. *Nephrology, Penn State College of Medicine, Hershey, PA.*

Introduction: *Campylobacter* bacteremia is a rare condition predominately seen in elderly patients, those with liver disease or malignancy. *Campylobacter* infection has been implicated in various inflammatory diseases including Guillain-Barre syndrome, reactive arthritis and myocarditis. We report a case of immune complex mediated glomerulonephritis (GN) in the setting of recurrent *C. fetus* bacteremia.

Case Description: A 78-year-old female was treated for prosthetic valve endocarditis following an ERCP for choledocholithiasis. Treatment required removal of her aortic prosthesis and placement of a new valve. Blood cultures grew *C. fetus* that cleared with ciprofloxacin. Six months later, she presented with generalized weakness, palpable purpura, GI bleeding and rapidly progressive acute renal failure. Urine microscopy was consistent with GN. Blood cultures again grew *C. fetus*. An upper endoscopy revealed a gastric ulcer and poorly differentiated adenocarcinoma on biopsy. Cultures cleared on treatment with meropenem. Echocardiography did not show objective findings of endocarditis. Serologic workup revealed positive ANA (1:80, homogenous pattern), anti-native DNA <20 IU/ml, ANCA directed to proteinase 3, C3 55mg/dL, C4 21mg/dL, serum cryoglobulins were negative and hepatitis serologies were negative. Renal biopsy revealed immune complex mediated GN with IgM and C3 granular glomerular staining on immunofluorescence, subendothelial and subepithelial deposits on electron microscopy.

Discussion: The epidemiology of infection-related GN has changed in the past few years. A significant percentage of cases now target adults (particularly the elderly and immunocompromised) and tend to be associated with nonstreptococcal organisms. *Campylobacter* infection is a potential trigger for immune mediated GN. Case reports of enteric *C. jejuni* infection have been implicated in GN. Molecular mimicry and immune complex activation have been suggested to contribute to *Campylobacter* related disease. Compared with other species, *C. fetus* is the most common isolate to cause bacteremia; however, this is the first reported case of GN associated with *C. fetus* that we are aware of. Our case of *Campylobacter fetus bacteremia* demonstrates notable features of the infection and potential for ensuing GN.

FR-PO623

Membranoproliferative Glomerulonephritis with "Full-House" Immunofluorescence in a Patient with IgG4-Related Disease Yuta Matsukuma,[1] Kosuke Masutani,[1] Kenji Ueki,[1] Akihiro Tsuchimoto,[1] Kiichiro Fujisaki,[1] Kumiko Torisu,[1] Kazuhiko Tsuruya,[1,2] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka, Japan.*

Introduction: Typical renal histopathological finding in immunoglobulin G4 related disease (IgG4-RD) is lymphoplasmacytic infiltrate rich in IgG4-positive plasma cells with fibrosis. Some glomerular lesions such as membranous nephropathy are sometimes evident. We hereby present an unusual glomerulonephritis in a patient with IgG4-RD.

Case Description: A 70-year-old woman was transferred to our hospital because of the microhematuria and proteinuria. The patient showed anemia on conjunctiva and leg edema. Laboratory findings revealed 3+ proteinuria, 2+ hematuria, pancytopenia, hypoproteinemia, and kidney dysfunction. Decreased levels of C3 and C4 were noted, but anti-double strand DNA antibody, anti-nuclear antibody, and cryoglobulin were negative. Serum IgG level was 1,916 mg/dL, and IgG4 1,110 mg/dL. Percutaneous kidney biopsy revealed membranoproliferative glomerulonephritis with subendothelial deposits. On immunofluorescence study, "full-house" depositions of immunoglobulins and complements were found in mesangial area and capillary loop. Electron microscopy revealed endocapillary hypercellularity, mesangial interposition, and electron dense deposits in mesangial and subendothelial area. The lip biopsy revealed diffuse infiltration of IgG4-positive plasma cells in glandular tissue. However, kidney tissue showed focal lymphoplasmacytic interstitial infiltrate with occasional eosinophils, and interstitial fibrosis was mild. In addition, the IgG subclasses in glomeruli were predominant IgG2 and IgG3. We treated this patient with oral prednisolone 30 mg/day. The patient showed decreased urinary protein excretion, gradual improvement of pancytopenia and hypocomplementemia.

Discussion: In this case, we identified IgG4+ plasma cell infiltrate on lip biopsy as well as increased level of serum IgG4, compatible with IgG4-RD. But, IgG subclasses in the glomeruli were predominant IgG2 and IgG3, suggesting the overlapped glomerulonephritis with different pathophysiology.

FR-PO624

IgA-Dominant Post Infectious Glomerulonephritis Presenting as a Fatal Pulmonary-Renal Syndrome Marc M. Saad, Magda Daoud, Patricia Nasr, Elie El-Charabaty, Suzanne E. El Sayegh. *Nephrology, Staten island Univ Hospital, Staten island, NY.*

Introduction: Postinfectious glomerulonephritis has been having over the last decades a major change in its epidemiology, pathophysiology, clinical characteristics and outcomes. We are reporting a case of IgA-dominant post infectious glomerulonephritis presenting as a fatal renal-pulmonary syndrome.

Case Description: An 86 year old Filipino man presented to the Emergency room for worsening dyspnea, hemoptysis, dull chest pain, with lower extremity edema and decrease in urine output over the last two weeks. PMH is significant for HTN, CKD stage III, gout, COPD, and a recent hospitalization 3 weeks ago for pneumonia and treated with IV cefazolin for 2 weeks for MSSA bacteremia. Physical examination was remarkable for HR of 109 bpm and RR of 25/min. There were bibasilar rales in the lungs and bilateral ankle edema. A chest

radiograph showed bibasilar opacifications. Blood work was significant for hemoglobin of 8.3 (baseline 9.7), creatinine of 9.2 (baseline of 1.67). The patient was hypoxic requiring mechanical ventilation. Urinalysis reported RBC casts. Ultrasonography revealed bilateral renal echogenicity compatible with renal disease. On day 2, Patient was started on HD for hypervolemia and on pulse solumedrol 1 g for 3 days, patient's condition precluding kidney biopsy. Serology workup for RPGN was negative with normal complements level. On day 7, bronchoscopy showed alveolar hemorrhage and plasmapheresis was initiated. Renal biopsy revealed Ig A – dominant acute post-infectious glomerulonephritis with endocapillary and focal extracapillary proliferative and exudative features.

Discussion: Previous reports showed that IgA dominant PIGN occurs in elderly with mean age of 60, after time frame of (0-16) weeks, mainly in caucasian (53%) and asian (26%). Staphyloccous was the main infectious agent and diabetes favoring the disease. However, this non diabetic patient had pulmonary-renal syndrome, with normal complement level. Patient had fatal outcome despite steroid pulse and plasmapheresis. Understanding the phathogenesis and identifying the nephrotoxic species of bacteria and the aberrant IgA molecule will open new insights toward prevention and treatment.

FR-PO625

A Case of Infection-Related Glomerulonephritis After Total Knee Arthroplasty Rushi K. Nayak, Germaine Z. Chan, Steven D. Smith. *Nephrology, Mt. Sinai-St. Luke's, New York City, NY.*

Introduction: Infection-related glomerulonephritis (IRGN) is an immune-complex mediated entity that develops in the setting of active infection, commonly due to Staphylococcus or Streptococcus species. In adults, the site of infection can be heterogeneous. We present a case of IRGN due to an infected prosthetic knee joint.

Case Description: A 62 year-old male with hepatitis C presented to the hospital with worsening knee pain at the site of total knee arthroplasty done six years previously. Blood and joint fluid cultures two weeks prior to presentation were positive for methycillin-sensitive Staphyloccus aureus and he was scheduled for knee surgery, but was lost to follow-up. Renal function was normal at that time. Upon return to the hosptial he was afebrile, hypertensive and tachycardic. Right knee was swollen and tender. Lab work revealed acute kidney injury (Cr 4.1 mg/dL), anemia, and urinalysis significant for hematuria and nephrotic-range proteinuria, with evidence of acanthocytes. Serologic testing for HIV and HBV were negative. Complement C3 and C4 levels were normal. Cryoglobulin and rheumatoid factor were absent. He was started on parenteral antibiotics but his renal function continued to deteriorate. Kidney biopsy revealed diffuse mesangial proliferative and focal endocapillary proliferative glomerulonephritis, with focal cellular and fibrous crescents. Immunofluorescence showed granular global mesangial and segmental capillary wall positivity for C3 and IgG, suggestive of IRGN. He underwent revision of his knee arthroplasty with placement of an antibiotic impregnated spacer. He required intermittent hemodialysis which was discontinued two weeks after surgery. Three months after discharge his creatinine was stable at 2.0 mg/dL.

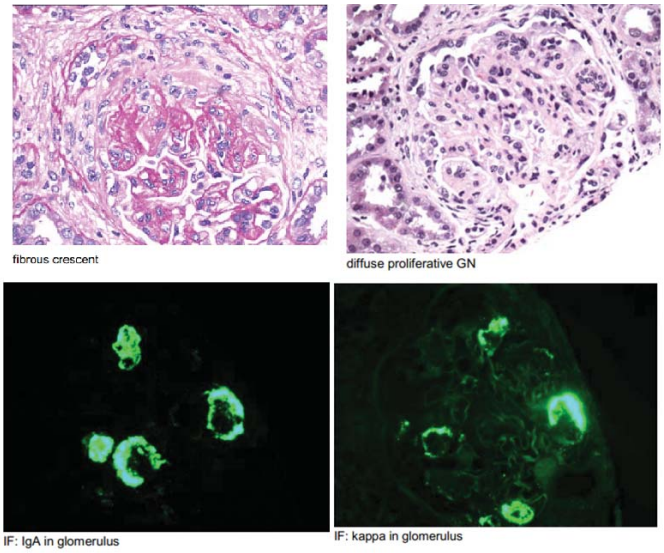
Discussion: This case illustrates a typical presentation of IRGN. HCV-related and C3 GN should be considered, but are less likely in face of ongoing bacterial infection. Hypocomplementemia, absent in this patient, is seen in 35-80% of cases. Treatment considerations include the use of steroids, which were not used given ongoing active infection. The patient experienced a permanent loss of renal function, seen in up to 54% of adult cases of IRGN.

FR-PO626

Chronic Lymphocytic Leukemia (CLL)-Associated Cryoglobulinemic Glomerulonephritis (GN) Sairah Sharif, Farah Daccueil, Naveed N. Masani. *Winthrop Univ Hospital, Mineola, NY.*

Introduction: Glomerular lesions are rare in CLL but when they occur the course may run parallel to CLL suggesting causality. We report a case of patient with CLL who was found to have cryoglobulinemic GN with monoclonal IgA deposits.

Case Description: A 74 year old female with past history of CLL, idiopathic thrombocytopenia and chronic, left hydronephrosis, presented to the emergency complaining of shortness of breath and leg swelling despite an increase in diuretics. Physical exam revealed hypertension 194/84, decreased breath sounds and +3 bilateral lower extremity edema. Workup revealed serum creatinine (SCr) of 3.2 mg/dL (baseline SCr 1.6 mg/dL), a protein:creatinine ratio of 7.9 gm/gm creatinine, and a kappa:lamda ratio of 8.6. A bone marrow biopsy showed normocellular marrow with scattered plasma cells (<10%). Subsequently, a right renal biopsy was done which demonstrated a light microscopic (LM) pattern of diffuse, endocapillary proliferation, active crescents, with membranoproliferative features; immunofluorescence staining was significant for IgA, kappa and C3.



Renal biopsy images courtesy Dr Glen Markowitz, Department of Pathology, Columbia Presbyterian Hospital, New York, USA

Therapy with pulse solumedrol/oral prednisone and ibrutinib was initiated, targeting the underlying CLL, which was ultimately felt to be responsible for the glomerular disease. While the proteinuria remains in the nephrotic range, the SCr has improved to 1.6 mg/dL.

Discussion: Kidney infiltration is seen in CLL up to 90%, but generally subclinical. GN is rare in CLL; where described, LM pattern of membranoproliferative GN is the most common. Most cases get nephrotic syndrome and one third get renal failure. Renal disease maybe related to immune complexes, cryoglobulins or monoclonal protein deposition. This case is significant as chemotherapy lead to improvement of kidney disease and supports use of chemotherapy in CLL-associated glomerulonephritis despite low grade hematological disease.

FR-PO627

Immune Complex Mediated Glomerulonephritis as a Possible Complication of Polycythemia Vera and Myelofibrosis Lisa Aimee Hechanova, Thanh Hoang. *Loma Linda Univ Medical Center, Loma Linda, CA.*

Introduction: Polycythemia vera is a chronic myeloproliferative neoplasm associated with a mutation in the JAK2 V617F domain. This mutation causes activation of the erythropoietin and thrombopoietin receptors, leading to uncontrolled hematopoietic cell growth. Over time, polycythemia vera can progress to myelofibrosis. There have been several published studies which demonstrate an association between myelofibrosis and circulating immune complex formation. Herein we present a case of a patient with polycythemia vera, who was found to have progression to myelofibrosis and immune complex glomerulonephritis.

Case Description: A 50-year-old female with a ten year history of polycythemia vera presented with new onset ascites and peripheral edema. Her polycythemia vera had initially been treated with phlebotomy and low dose aspirin, then splenic radiation for splenomegaly, and more recently ruxolitinib (an oral JAK1/JAK2 inhibitor). She was found to have nephrotic range proteinuria, portal hypertension, leukocytosis, anemia, and thrombocytopenia. She underwent extensive serologic workup, abdominal imaging, bone marrow biopsy, liver biopsy, and renal biopsy. She had creatinine of 1.5mg/dL, proteinuria of 3.5 grams, equivocal ANA, but negative complements, anti-double stranded DNA, anti-Smith antibody, SSA/SSB, hepatitis panel, HIV, SPEP/UPEP, rheumatoid factor and ANCA. Cold agglutinin was positive. She did not have any clinical signs of lupus. Abdominal imaging revealed marked hepatosplenomegaly. Bone marrow biopsy revealed myeloid hyperplasia and marrow fibrosis; liver biopsy showed extramedullary hematopoiesis with centrilobular and sinusoidal obstruction; and kidney biopsy revealed chronic immune complex mediated glomerulonephritis with both subepithelial and subendothelial electron dense deposits, a few tubuloreticular inclusions, as well as positive immunoflurescence staining for IgG, IgM, C3, C1q, fibrinogen, kappa, and lambda.

Discussion: Circulating immune complexes associated with polycythemia vera, particularly after progression to myelofibrosis, may be a rare cause of immune complex glomerulonephritis. We feel, due to the lack of other factors, that this is the most probable etiology in our case.

FR-PO628

First Reported Case of Fibronectin Glomerulopathy in a Hispanic Female Keerti K. Bhanushali,[1] Geeta Kutty,[2] Jane Vernik.[3] *[1]Nephrology, Univ of Florida, Gainesville, FL; [2]Medicine, John Stroger Jr. Hospital of Cook County, Chicago, IL; [3]Nephrology, John Stroger Jr. Hospital of Cook County, Chicago, IL.*

Introduction: Fibronectin glomerulopathy (FNG) is a rare, usually hereditary disease with autosomal dominant inheritance. It is characterized by massive deposition of fibronectin and is Congo-red negative.

Case Description: A 37 yr old Hispanic female with history of hypertension, nephrotic syndrome secondary to membranoproliferative glomerulonephritis diagnosed 8 yrs ago presented with progression of nephrotic syndrome while on optimal medical therapy. No known family history of renal disease. Physical examination was unremarkable except pedal edema. Pertinent laboratory values included normal serum creatinine, serum albumin 2.6gm/dl, serum cholesterol 396mg/dl, 24hr urine protein 15 gm. Viral hepatitis profile, HIV and immunologic panel was negative. Renal biopsy revealed mesangial expansion with PAS positive, Congo red negative homogenous material, minimal cellular proliferation and areas of interstitial fibrosis. Electron microscopy showed massive subendothelial and mesangial electron dense deposits arranged in a fine granular pattern with focal short fibrillary structure (10-16 nm). Immunoflorecence revealed scant reactivity for immunoglobulins and complements. Immunostaining with fibronectin was positive within the mesangial matrix.

Discussion: To our knowledge, no cases of FNG have yet been reported in Hispanic patients. FNG is a hereditary disease that may lead to end-stage renal failure in the second to sixth decade of life. In 40% of families, the disease is caused by heterozygous mutations in the FN1 gene (2q34) encoding fibronectin. However genetic heterogeneity is suspected. Whole genome linkage analysis in a large pedigree showed another disease locus on 1q32, with no specific candidate genes identified so far. Reported experience with treatment using steroids, cytotoxic agents and plasmapheresis is limited and anecdotal. ACE inhibitors or ARBs, diuretics and antihypertensives are used in the management.

FR-PO629

Successful Treatment of IgM Nephropathy with Rituximab

Faheemuddin A. Ahmed,[1] Abdul Mubeen Mohammed,[2] Ashraf El-Meanawy.[3] *[1]Geriatric Medicine, Loyola Univ Medical Center, Maywood, IL; [2]Nephrology, Swedish Covenant Hospital, Chicago, IL; [3]Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Immunoglobin M Nephropathy (IgMN) is a form of primary glomerulonephritis with unclear etiology and pathogenesis. There is no specific treatment, however, corticosteroids have been tried and are frequently ineffective. We present a case seen for significant proteinuria, diagnosed as IgMN and successfully treated with Rituximab.

Case Description: A 59 year-old man with history of HTN, prostate cancer, COPD, GERD was seen for proteinuria. His medications included amlodipine, metoprolol, ASA, omeprazole and meloxicam. Physical examination was positive for obesity and edema. BMP and CBC were normal. Urine microscopy showed no RBC casts. His urine P/C ratio was 2800 mg/g. ANA, ANCA, C3, C4, ASO titers, HIV, hepatitis, Anti-GBM antibodies were uremarkable. SPEP showed IgM and IgG-lambda and UPEP showed IgG-lambda and free lambda with K/L ratio 0.41. Renal biopsy was performed. LM showed increased mesangial cellularity and matrix and mild interstitial fibrosis. Immunofluorescence (IF) was positive for diffuse global mesangial staining with IgM. EM showed severe foot process effacement with normal basement membrane. He was diagnosed as IgMN with minimal FSGS. Patient received 2 doses of 1 g rituximab, 2 months apart, and started on lisinopril. After the treatment, urine P/C ratio declined and remained less than 0.2 mg/g.

Discussion: The epidemiology of IgMN is deducted retrospectively from renal biopsies due to lack of well-established population based studies. Clinical picture ranges from asymptomatic urine abnormalities to nephrotic range proteinuria. Diagnosis is primarily based on pathology. In LM, morphological changes are seen in different areas. IF is critical in the diagnosis with the characteristic pattern of diffuse and global mesangial IgM positivity. EM shows variable degree of foot process effacement. There are no RCT to date addressing its treatment. Success rate of corticosteroids vary from 0 to 50%. There is limited data on efficacy of immunosuppressive agents. The reported complications of IgMN are renal insufficiency and hypertension. More systematic studies are needed to establish the role of Rituximab in the treatment of IgMN.

FR-PO630

Case Report of a Rare Finding of Sarcoid Granulomatous Glomeruli Nephritis

Sharica Brookins,[1] Claudia Ormenisan,[2] Raafat Farag Makary,[2] Carmela B. Monteiro,[2] Leighton R. James.[3] *[1]Internal Medicine, Univ of Florida, Jacksonville, FL; [2]Pathology, Univ of Florida, Jacksonville, FL; [3]Nephrology, Univ of Florida, Jacksonville, FL.*

Introduction: Renal sarcoidosis commonly presents with acute kidney injury but rarely glomerular disease. The classic findings on biopsy are multinucleated giant cells, normal glomeruli and noncaseating granulomas involving renal interstitium surrounding tubules. We present the first case of glomerular disease from direct glomeruli effacement by renal noncaseating granulomas.

Case Description: This is a case of a 44 year old African-American male with a history of Dermatomyositis referred to Nephrology for acute kidney injury and hyperproteinemia. His studies showed creatinine (Cr) 1.76 mg/dL and gamma globulins without an M spike on serum and urine protein electrophoresis. He returned with increased urinary frequency and thirst, fatigue, Cr 3.42 mg/dL, calcium 12.1 mg/dL, and proteinuria. Any malignant, infectious, drug-induced and auto-immune etiologies were ruled out. CT chest revealed bilateral reticulonodular pulmonary opacities. A renal biopsy revealed near total effacement of renal tubules and glomeruli by numerous small noncaseating granulomas with multinucleated giant cells and extensive fibrosis with patchy chronic inflammation. He was diagnosed with Granulomatous Glomerular and Tubulo-Interstitial Nephritis due to Renal Sarcoidosis and Pulmonary Sarcoidosis stage 3. Therapeutic intervention included Prednisone with improvement.

Discussion: The classic findings on biopsy are noncaseating granulomas involving interstitium. Granulomas are the leading cause of hypercalcemia which adversely causes acute kidney injury but not glomerulopathy. First line therapy is oral prednisone 1mg/kg daily. The patient in this case report had an improvement in both renal function and proteinuria after steroids. Stehle et al. reported lesions of glomerular disease in the setting of sarcoidosis but none with granuloma involvement of glomeruli. Our case was unusual because, in addition to the classic tubulo-interstitial granulomas, there was also direct glomerular involvement and effacement by the granulomas.

FR-PO631

Treatment of Recurrent Mixed Cryoglobulinemia Syndrome

Manoj Bhattarai, Shan Shan Chen, John P. Johnson. *Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

Introduction: We report a case of recurrent mixed cryoglobulinemia type II in the absence of HCV that responded minimally to cyclophosphamide and plasmapheresis but impressively well to rituximab and plasmapheresis.

Case Description: A 60 year-old Argentinian-American male with history of essential mixed cryoglobulinemia 12 years ago treated successfully with six months of cyclophosphamide and prednisone presented with similar complaint of lower extremities skin rash and swelling. Physical exam was notable for purpuric skin rashes over bilateral legs. He was found to have proteinuria (1.5 gm/day), hematuria, RBC casts, low C3 (35 mg/dL) and C4 (<10 mg/dL), and a creatinine of 2 mg/dL (baseline 1 mg/dL). With the suspicion of recurrent disease, he was started on intravenous solumedrol 1gm daily for 3 days. Before the scheduled biopsy, he developed respiratory failure from diffuse alveolar hemorrhage and combination therapy with oral cyclophosphamide 100 mg/day (total four doses) and daily plasmapheresis was initiated. Labs revealed positive type II cryoglobulins, C3 at 35 mg/dL, C4 at <10 mg/dL, RF at 115 IU/mL, free Kappa/Lambda at 3.53, UPEP with minimal urine protein, SPEP with marked hypogammaglobulinemia; and negative for HIV, HCV, ANA, and ANCA tests. Because of recurrent mixed cryoglobulinemia involving lungs, kidneys, and skin with light chain abnormalities deteriorating rapidly, he was switched to more aggressive therapy with daily plasmapheresis and rituximab 375 mg/m2/week. He was extubated in a week of the first dose of Rituximab and subsequent doses of rituximab (total of 4 doses) were completed as outpatient. Follow up lab studies revealed creatinine at 1.1 mg/dL, urinalysis with 2+ proteinuria and occasional casts, C3 at 68 mg/dL, C4 at 11 mg/dL, free Kappa/Lambda at 2.31 and absent cryoglobulin. His prednisone therapy is tapered and he claims being normal now.

Discussion: Our patient with recurrent type 2 mixed cryoglobulinemia after 12 years of complete remission developed life threatening pulmonary hemorrhage (infrequent complication with worse prognosis) responding extraordinarily well to the rituximab and plasmapheresis suggesting rituximab as superior therapy to cyclophosphamide in such cases.

FR-PO632

Treatment of Recurrent Cryoglobulinemic Nephritis

Eoin D. O Sullivan, Brenda B. Griffin. *Dept of Renal Medicine, Cork Univ Hospital, Cork, Ireland.*

Introduction: Type 1 cryoglobulemia is a rare entity in multiple myeloma[1]. We describe a challenging case of cryoglobulinemic nephritis secondary to multiple myeloma, and the difficulties in treating relapse of renal disease.

Case Description: A 65 year old female with a background of resected ductal carcinoma in situ of breast was referred with a rising creatinine of 550mmol/l. Renal biopsy revealed subendothelial and mesangial immunotactoid deposits suggestive of a cryoglobulemic nephritis. Further investigation revealed IgG of 33 g/l, a paraprotein level of 13.1g/l, and circulating cryoglobulins. A marrow biopsy demonstrated 20% mature plasma cells, confirming a diagnosis of IgG CD138+ multiple myeloma. The patient's creatinine normalised following treatment with pulsed methylprednisolone and oral cyclophosphamide. The patient represented 3 years later with abrupt onset anasarca and nephritic syndrome, a creatinine of 479 mmol/l, urinary PCR of 1148, >500 RBC per HPF. C3 1.14 g/l (0.75 – 1.65), low C4 0.09g/l (0.14- 0.54), and positive cryoglobulins (3430mg/l). Treatment with cyclophosphamide IV and dexamethasone failed to improve symptoms or laboratory values, and a tunneled catheter was sited in anticipation of dialysis. Plasmapheresis was initiated in an attempt to gain control over the cryoglobulinemia.Within 3 sessions the patient's creatinine normalized to 98 mmol/l, and PCR dropped to 63. While the patient's renal function remained stable, 12 months later she represented with diffuse disease requiring radiotherapy and palliation.

Discussion: Recurrence of cryoglobulinemic nephritis can be treated effectively with plasmapheresis but may suggest worsening hematological disease. In the largest case series,presence of renal disease is associated with increased hazard ratio (8.9) [2]. Within a year of renal recurrence our patient presented with diffuse soft tissue plasmacytomas, refractory to therapy. While there is a sparse body of evidence to support plasmapheresis in mixed cryoglobulinemia[345], there are only a number of cases of type 1 cryoglobulinemia having been successfully treated with plasmapheresis, usually in combination with treatment of the underlying hematological malignancy [26].

FR-PO633

Rapidly Recurrent MPGN in a Transplant Patient with Cryoglobulinemia

Akanksha Gupta, Daniel J. Kenan, Harsharan Kaur Singh, Volker Nickeleit. *Div of Nephropathology, Dept of Pathology and Laboratory Medicine, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Cryoglobulinemic glomerulonephritis often displays features of Membranoproliferative glomerulonephritis (MPGN) related to glomerular deposition of cryoglobulins.

Case Description: A 49 year old male with hepatitis C presented in 2008 with mixed nephritic and nephrotic syndrome. His serum creatinine was 2.4 mg/dl, urinalysis was notable for 4+ hematuria and 4 gm/day proteinuria. His diagnosis was MPGN type 1

secondary to hepatitis C-related cryoglobulinemia. He developed ESRD and received a cadaveric renal transplant in November 2013. A zero hour renal allograft biopsy showed ATN with no evidence of MPGN. The patient was discharged with a creatinine of 2.95. Two weeks later, he presented with creatinine of 4.2 and was biopsied. The biopsy showed diffuse endocapillary hypercellularity consisting of monocytes and macrophages but no T-cells. There was GBM duplication and lobular accentuation of the tufts. Immunofluorescence showed similar staining of IgM and C3 as seen in native kidney biopsy, together indicating recurrent MPGN two weeks after transplantation. The creatinine gradually improved to a baseline of 1.5. Then in April 2014, he presented again with a rise in creatinine to 3.5, accompanied by hematuria, proteinuria, hypocomplementemia, with associated leukocytoclastic skin rash. Renal biopsy showed only mild acute rejection with no evidence of MPGN. However, the symptoms worsened and he was rebiopsied one week later, demonstrating features of MPGN again, accompanied by electron dense deposits in subendothelial and mesangial areas showing microtubular substructure, supporting the diagnosis of recurrent cryoglobulinemic glomerulonephritis.

Discussion: The median recurrence of MPGN reported in the literature is 4.7 years post-transplant. In this case, MPGN recurred only two weeks post transplant and then disappeared briefly, followed by another recurrence 6 months after transplantation. This case makes the points that 1) Extremely rapid recurrence may occur in cryoglobulinemia and 2) The severity of the MPGN may be related to the normal waxing and waning of the cryoglobulinemic glomerulonephritis.

FR-PO634

Henoch-Schonlein Purpura Nephritis Associated with Staphylococcal Infection Rungwasee Rattanavich, Steven M. Spiegel, Nilubon Methachittiphan Methachittiphan. *Internal Medicine, MetroWest Medical Center, Framingham, MA.*

Introduction: Renal involvement in Henoch-Schönlein purpura (HSP) is more severe in adults. Many etiologies of HSP have been described but Staphylococcal associated with HSP has been rarely reported.

Case Description: 72 year old male with hypertension who presented with rashes bilateral thighs,chills and fatique after underwent open reduction with internal fixation for left ankle fracture 2 weeks prior to presentation.Exams found purplish palpable purpura at bilateral thighs down to toes.The wound was swelling with pus drainage. Incision and drainage was performed.Pus culture revealed Methicillin Sensitive Staphylococcus infection. Blood culture negative. His renal functionwas normal with BUN-26 Cr-0.85 eGFR >60, UA was normal.He was treated empirically with Vancomycin IV before switching the antibiotic based on the sensitivities.During hospitalized his creatinine is progressively increasing to 4.33 on day 14 with present of microscopic hematuria,no proteinuria.Serum electrophoresis showed high level of IgA and IgG, but no M spike was found, C3,C4 complement-normal, P-ANCA, C- ANCA, ASO titer, ANA, DsDNA and cryoglobulin were negative.Renal biopsy was performed showing IgA Nephropathy/Henoch-schonlein purpura with a focal proliferative pattern of glomerular injury.No crescents, glomerulosclerosis. He was treated with Methylprednisolone followed by oral prednisone. His Renal function gradually improved with a creatinine of 1.4 mg/dl approximately one month after treatment was initiated.

Our patient developed Henoch-Schonlein Purpura Nephritis (HSPN) associated with an MSSA infection.There is speculation that enterotoxins from staphylococcus act as super antigens causing renal injury by cytokine burst and immune complex.Renal pathology in HSPN showed IgA-dominant glomerulonephritis as also commonly seen in Staphylococcus infection-associated nephritis.Interestingly a similar clinical presentation can be seen.It is critically important to distinguish between the two.HSPN may need to be treated with corticosteroids and other immunosuppressives while *Staphylococcus* infection-associated glomerulonephritis requires antibiotics and could be worsen from immunosuppressive treatment.

FR-PO635

Double Positive ANCA/GBM Antibody Glomerulonephritis Presenting as Appendiceal Vasculitis Rungwasee Rattanavich, Sneha Kilari, Steven M. Spiegel. *Internal Medicine, MetroWest Medical Center, Framingham, MA.*

Introduction: Anti-glomerular basement membrane antibody disease usually presents with rapidly progressive glomerulonephritis.25% of cases test positive for both anti-GBM and ANCA antibodies, known as Double positive disease.This abstract describes a rare presentation of this entity.

Case Description: 48 year old woman with hypertension who was diagnosed with acute appendicitis 6 weeks prior to admission. CT abdomen showed a thickened appendix and peri-appendiceal fat stranding. Laparoscopic appendectomy was performed; however, she continued to have refractory abdominal pain,nausea,vomiting and was readmitted, treated with antibiotics without improvement. Her renal function was normal at that time. 5 weeks later she was readmitted.Labs showed BUN-101,Cr-15.56,eGFR-3 with microscopic hematuria. Serology was positive for Anti-IgG; atypical p-ANCA. Anti-MPO,Proteinase 3 antibodies-negative. C3,C4 were normal. Blood and urine cultures-negative.Renal biopsy showed necrotizing and diffuse crescentic glomerulonephritis with linear IgG deposition along glomerular capillaries. Global glomerulosclerosis, tubular atrophy and interstitial fibrosis were absent.Immunofluorescence confirms anti-GBM deposition. Given the clinical course and renal biopsy,the appendiceal tissue was sent for reexamination and showed inflammation and necrosis of small blood vessels within the appendix consistent with vasculitis.Treatment consisted of plasmapheresis, methyprednisolone pulse followed by prednisone, cyclophosphamide.Though there was some improvement in renal function initially,she remains dialysis dependent after 4 months of follow-up.

Discussion: Anti-GBM antibody disease usually presents with glomerular involvement where the inflammation resulting in a rapidly progressive glomerulonephritis. ANCA may be positive along with anti-GBM antibodies, in which case the patient can present with symptoms depending on the site of involvement by vasculitis as we have seen in our patient. Vasculitis should therefore be considered in the differential diagnosis of patients with unusual or persistent abdominal pain and it should also be considered by the pathologist when examining post operative specimens.

Red Urine and Elusive Renal Failure Sahil Garg,[1] Nader S. Bahri,[1] Leighton R. James,[1] Raafat Farag Makary,[2] Carmela B. Monteiro.[2] *[1]Dept of Nephrology, UF Health Jacksonville; [2]Dept of Pathology, UF Health Jacksonville.*

Introduction: ANCA associated vasculitis has high morbidity and mortality. This case highlights the importance of timely renal biopsy in patients with high index of suspicion for glomerulonephritis. Immunosuppression with corticosteroids and Cyclophosphamide (Cyc) significantly improves prognosis.

Case Description: A 50 year old female with history of hypertension, chronic obstructive lunge disease, schizoaffective disorder was admitted with complaints of right knee pain and swelling. One year earlier, she developed right tibial osteomyelitis requiring proximal tibial resection but, continued to have repeated infections. On this admission, she underwent incision and drainage of the right knee. Subsequently she developed tea colored urine and acute deterioration in kidney function. Urine sedimentation revealed coarse granular casts (5-10/hpf), few dysmorphic RBC. SPEP, UPEP, ANA, ANCA, dsDNA, Rheumatoid factor was negative, C3 (124.8 mg/dL), C4 (35.5) mg/dL. Hepatitis C Ab was positive but viral particles were undetectable by PCR. 24 hr urine protein excretion was 725 mg. Renal biopsy was delayed for 3 weeks as she was unstable. During this period Hemodialysis was initiated. Subsequently, renal biopsy revealed diffuse, acute proliferative crescentic glomerular lesions with breaks in the glomerular basement membrane, tubular degenerative/regenerative changes with moderate interstitial acute and chronic inflammation. Immunofluorescence and electron microscopy studies were negative for immune complex deposits. She was administered methylprednisone (500 mg daily x 3 doses) and Cyc 0.5 gm/ m2. This was followed by maintenance prednisone 80 mg QD which was tapered by 25 % every 3-4 weeks. Subsequent to initial treatment with Prednisone and Cyc, her renal function exhibited significant improvement. Serum creatinine was 1.8 mg/dL, 2 months later. She is on prednisone and Azathioprine for maintainence immunosupression.

Discussion: Renal Biopsy was indicated because of rapidly worsening renal function and dysmorphic RBCs on urine sedimentation. Induction therapy consists of Cyc and steroids for 3-6 months. Maintenance therapy is with azathioprine or methotrexate.

FR-PO637

Rapidly Progressive Glomerulonephritis Associated with Hodgkin Lymphoma: Case Report Nathalia K.N. Alecrim, Carla Tenório Barros Cisne Pessoa, Camila Barbosa L. Oliveira, Alline S.A. Oliveira, Luis H.B.C. Sette, Maria Alina G.M. Cavalcante, Gisele Vajgel Fernandes, Lucila Maria Valente. *Nephrology, Univ Federal de Pernambuco, Recife, Pernambuco, Brazil.*

Introduction: Glomerulonephritis is a well recognized paraneoplastic manifestation of hematological disease, though it rarely occurs in Hodgkin lymphoma patients. The glomerular abnormalities generally observed are minimal change disease and amyloidosis. We report a patient with rapidly progressive glomerulonephritis associated with Hodgkin lymphoma.

Case Description: A 59 year-old man was admitted to the hospital because of rapid decline in renal function and microscopic hematuria. He had a two months history of left cervical mass, with hard texture and progressive growth. Exams showed serum creatinine of 4.0 mg/dL (baseline: 1.4 mg/dL) and nephrotic range proteinuria. Blood levels of complement (C3 and C4) were normal and testing was negative for antinuclear antibodies, hepatitis B and C and HIV. The patient received methylprednisolone 1g for three days, with partial recovery of the renal function (serum creatinine of 2.8mg/dL) at hospital discharge. Renal biopsy revealed focal and segmental sclerosis with multiples synechiae of the glomerular tuff and fibrotic crescents. Ultrasound of the cervical mass revealed a heterogeneous lymph node conglomerate suspicious of malignancy. The patient underwent excision biopsy, which revealed reactive hyperplasia and immunostaining showed that cells were positive CD30 and CD15 and negative for CD45, consistent with diagnosis of nodular sclerosing classical Hodgkin lymphoma.

Discussion: The association of crescentic glomerulonephritis with Hodgkin's disease has only been described in limited cases. Renal failure in the setting of lymphoma is usually attributed to infiltration of the kidney by malignant cells, obstruction of ureters, amyloidosis or increase in serum calcium or uric acid. Although rare, the possibility of a rapidly progressive glomerulonephritis should be considered, since renal function can be improved with specific treatment and chemotherapy.

FR-PO638

ANCA Negative Pauci Immune Crescentic Glomerulonephritis due to Multiple Myeloma Cyriacus Uzoma Anaele,[1] Weeraporn Srisung,[1] Yvette Corinne Tomacruz,[2] Melvin E. Laski.[1] *[1]Internal Medicine, Texas Tech Univ Health Sciences Center, Lubbock, TX; [2]Internal Medicine, Covenant Medical Center, Lubbock, TX.*

Introduction: Pauci-immune crescentic glomerulonephritis with rapidly progressive glomerulonephritis is most commonly associated with the presence of antineutrophil cytoplasmic antibodies (ANCA). We here report a case of ANCA negative pauci-immune crescentic glomerulonephritis discovered at the time a patient presented with multiple myeloma.

Case Description: A 56 year old Hispanic woman first presented with complaints of nausea, emesis, and fever. Initial serum chemistry showed a creatinine of 9.4 mg/dL, BUN 72 mg/dL, albumin 3.3 gm/dL, total protein 6.5 gm/dL, potassium 5.2 meq/L, and bicarbonate 19 meq/L. All other chemistry was normal. CBC showed normochromic normocytic anemia but WBC counts and platelets were normal. Initial urinalysis showed bland sediment with 100 mg/dl protein, but further studies defined the presence of high concentrations of kappa and lambda light chain in a ratio of 34.89. Subsequent bone marrow biopsy found 13% plasma cells. SPEP did not reveal a spike. ANCA, anti-GBM, ANA, hepatitis panel, and serum complements performed to evaluate the renal disease were all normal. Kidney biopsy revealed chronic sclerosing pauci-immune crescentic glomerulonephritis plus tubular necrosis, severe tubular atrophy, interstitial fibrosis, and severe arteriosclerosis. Congo red stains were negative. EM showed no intraglomerular deposits. The patient was subsequently treated for myeloma with bortezomib and dexamethasone. She was given the diagnosis of ESRD based on the clinical data and pathological findings and remains on outpatient hemodialysis.

Discussion: Renal pathologic manifestations of multiple myeloma often involve glomerular deposition disease, tubulointerstitial disease, or both. Our patient demonstrated neither of these two pathologic findings but did have chronic sclerosing pauci-immune crescentic glomerulonephritis in the absence of ANCA antibodies. Pauci-immune crescentic GN has previously been associated with multiple myeloma but the association remains extremely rare.

FR-PO639

Scleroderma with ANCA Associated Glomerulonephritis: Also a Renal "Crisis" Tauseef A. Sarguroh,[1] Olutayo T. Olabige,[1] Jeffrey D. Wallach,[1] Herman L. Anderson,[1] Leroy Herbert,[1] Vivette D. D'Agati,[2] Sudhanshu Jain.[1] *[1]Nephrology, Harlem Hospital Center, New York, NY; [2]Renal Pathology, Columbia Univ, New York, NY.*

Introduction: Scleroderma renal crisis is historically described as a vasculopathy and is an important cause of morbidity and mortality. We describe a patient with diffuse systemic sclerosis (SSc) presenting with a different renal "crisis" due to acute glomerulonephritis.

Case Description: A 51 year old Hispanic man with hypertension, scleroderma, vitiligo and Raynaud's phenomenon was hospitalized for acute kidney injury. Physical exam showed blood pressure of 155/94, scalp and perioral vitiligo, clubbing and sclerodactyly. Initial workup revealed blood urea nitrogen of 54mg/dl, creatinine of 6.4mg/dl and urine protein/creatinine of 4g/g. Urine microscopy showed dysmorphic RBCs and a RBC cast. Autoimmune workup was positive for p-ANCA (20.1:1), ANA (1: 640;homogeneous), RNP Ab (1.0), Scl-70 (>8) and SSA-Ab Ro (5.3). Other serologies including cryoglobulins, hepatitis B/C and HIV were negative. C3, C4 and CH50 were normal. He was treated with pulse IV methylprednisone for three consecutive days. Renal biopsy showed pauci-immune crescentic glomerulonephritis with 27 of 38 glomeruli showing active cellular crescents. There were no pathological findings to suggest scleroderma vasculopathy or thrombotic microangiopathy. Subsequently, he was started on cyclophosphamide and prednisone. He had partial renal recovery with creatinine down to 3.1mg/dl on discharge. Unlike most other reported cases; our patient did not require dialysis.

Discussion: SSc with ANCA related vasculitis is increasingly reported in literature. Abnormal regulation of T helper cells leading to production of cytokines including IL-1 and IL-17 play important roles in the pathogenesis of both SSc and ANCA associated vasculitis. The presence of anti-MPO (p-ANCA) defines a subset of patients with SSc who are susceptible to crescentic glomerulonephritis. These patients may present in a manner identical to scleroderma renal crisis; yet treatment requirements differ significantly. We propose that the presence of ANCA be routinely investigated in the setting of renal failure in SSc.

FR-PO640

Silica Induced Dual ANCA Positive Vasculitis Nidhi Varma,[1] Rahil Kasmani,[2] Balhinder S. Brar,[2] Deepak K. Malhotra.[1] *[1]Nephrology, Univ of Toledo Medical Centre, Toledo, OH; [2]Nephrology, St. Vincent's Medical Centre, Toledo, OH.*

Introduction: Environmental factors have been reported to trigger autoimmune diseases in genetically susceptible subjects. While case reports of Silica with either ANCA MPO or ANCA PR3 has been seen,the presence of both in one patient has not been established.

Case Description: 53-year old man first presented to the ER with testicular pain, swelling, intermittent hematuria, arthralgia and myalgia.He was diagnosed with epididymitis and treated with ciprofloxacin and later doxycycline.Two weeks later he was admitted with worsening of symptoms and Creatinine of 2.1 mg/dl. He had no past medical history and was not on any meds. He had a 20-pack year history of smoking, no illicit drug use. He had worked as a sandblaster for 30 years. Exam was significant for a BP of 155/72, crackles on auscultation, leg edema and scrotal edema. UA showed 2+ proteinuria, dysmorphic RBCs with acanthocytes. Utox was negative.Proteinuria was 2.5 gms. Hb was 8.5 g/dl. ANCA MPO titer was 283 AU/ml and PR3 titer was 243 AU/ml.ANA, Anti SSA and Anti RMP were also positive. Anti ds DNA, anti Histone, anti Sm, anti GBM ab and HIV was negative. Hepatitis C ab was positive with normal complements. CT chest showed scarring in the upper trachea. Bronchoscopy was normal. Renal usg and Echo were normal. Kidney biopsy showed pauci-immune necrotizing GN with crescents. Methylprednisone 500mg IV and cyclophosphamide 200 mg PO were started. Plasmapharesis was also commenced for a total of 7 cycles. Later oral Prednisone and prophylactic antibiotics was started. Cr continued to rise despite therapy and peaked at 5.4 mg/dl and needed hemodialysis. After about 6 weeks into the illness, the patient presented with pneumonia and septic shock. Immunosuppression was stopped. His clinical condition continued to deteriorate and he died from sepsis and multi-organ failure.

Discussion: Dual ANCA positivity in vasculitides is very rare. Cases with Levamisole (contaminant with cocaine) and infectious endocarditis has been reported.The prognosis of these patients is grim. To the best of our knowledge, this is the only reported case of dual ANCA positive vasculitis induced by exposure to silica.

FR-PO641

Guillian-Barre Syndrome and Lupus Nephritis: Simultaneous Presentation and Remission. A Case for Neuro-Renal Syndromes Sofian Jamal Al-Khatib, Antonio Guasch. *Renal Div, Emory Univ, Atlanta, GA.*

Introduction: Inflammatory demyelinating polyneuropathies (IDP), whether the acute or chronic form, have been reported in association with glomerulonephritis. The glomerular pathologies have mainly included minimal change disease (MCD), membranous nephropathy, or focal segmental glomerulosclerosis (FSGS). Our purpose is to emphasize the frequent association, potential common mechanisms and treatment in this neuro-renal syndrome.

Case Description: A 33-year-old male presented with bilateral lower extremity paralysis, anasarca, and a serum creatinine of 1.76 mg/dL. Electromyography was consistent with Guillian-Barre Syndrome (an acute IDP). Positive serology: ANA 1:160 speckled pattern, dsDNA Antibody (Ab) IgG 65 IU/mL, anti-Smith Ab IgG 77 Units (U), RNP Ab IgG 49 U, SSA/Ro Ab 49 U, Immunoglobulin IgA 509 mg/dL. 24-hour urine collection with 19.3 grams proteinuria. Kidney biopsy revealed lupus nephritis class IV and V. Five days of plasmapheresis failed to improve symptoms. Pulse dose steroids and one dose of cyclophosphamide administered. The following day patient's strength began to improve. Patient discharged with steroids and followed in clinic. Patient received a total of 5 doses of cyclophosphamide, once per month along with a steroid taper. Proteinuria and neurological symptoms resolved simultaneously, with renal function returning to baseline.

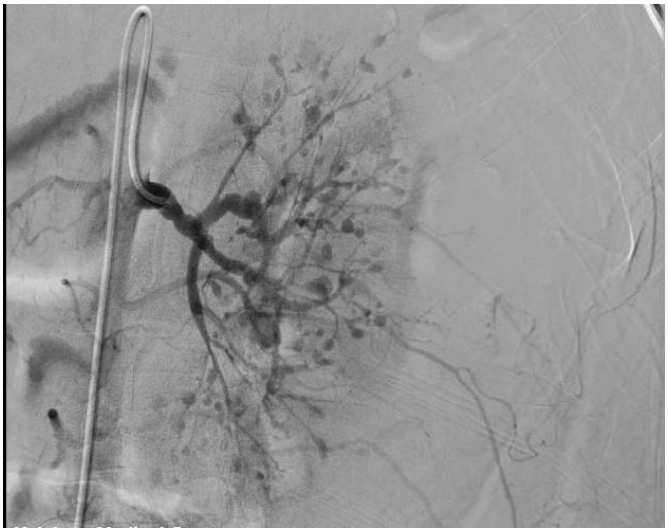
Discussion: We discuss a unique case of an IDP associated with Lupus Nephritis not before described in the literature. In previous reports, there has been an emphasis on minimal change nephropathy, FSGS and membranous nephropathy, suggesting a common etiology/pathophysiology. Experimental disease models, recent evidence proving that INF2 is responsible for cases of Charcot-Marie-Tooth neuropathy associated with FSGS by disrupting distinctly diverse Schwann cells and podocytes, and cases including this one showing a temporal existence and a positive response to immunosuppression for both the neuropathy and nephropathy in IDP's with glomerulopathies are consistent with a common mechanism or a component specific antibody causing both pathologies. This association may lead to further research in this newly described area of neuro-renal syndromes.

FR-PO642

Renal Polyarteritis Nodosa Coexisting with Lupus Nephritis Ramya Vejella, Scott McRight, Neeraj Singh. *Nephrology, LSUHSC Shreveport, Shreveport, LA.*

Introduction: We present a patient with biopsy proven lupus nephritis who presented with spontaneous perinephric hematoma and was diagnosed with polyarteritis nodosa (PAN) on renal arteriogram.

Case Description: A 30 year old African American female was referred to the Nephrology clinic for evaluation for proteinuria and microscopic hematuria. Patient had known history of thrombocytopenia requiring splenectomy, pleuritis and seizure disorder. Her current symptoms included persistent joint aches and weight loss of 15 lbs for 6 months prior to presentation. Further work-up showed serum creatinine of 1.1 mg/dl, 0.6 gm proteinuria on a 24 hour urine, microscopic hematuria, negative dsDNA, ANA > 1:640, Complement 3- 53 (normal range: 90-180), Complement 4- 17.8 (normal range 10-40), negative rheumatoid factor, and negative HIV screen. Patient underwent a left kidney biopsy which was consistent with Class III lupus nephritis. Approximately a month after her renal biopsy, she presented to the emergency room with right flank pain, anemia and hypotension. She denied any history of trauma. A CT scan of abdomen and pelvis without contrast showed a perinephric hematoma. A renal arteriogram was performed and the bleeding vessel was coiled. In addition, the angiogram showed numerous microaneurysms in the kidney consistent with polyarteritis nodosa.



Additional work-up showed a negative hepatitis B and C serologies, AST 28, ALT 10, negative ANCA with PR3 < 0.2 and negative myeloperoxidase at < 0.2. The patient is currently being treated with Cytoxan and high dose prednisone with follow up in our clinic.

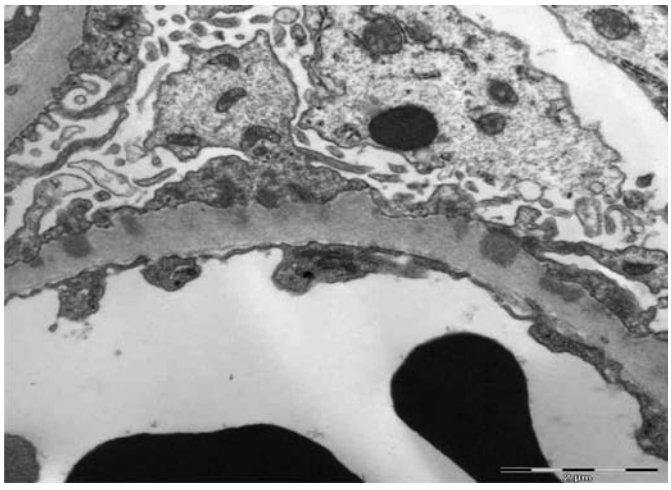
Discussion: The case of lupus nephritis and PAN coexisting in a patient has not been described in the literature before. This case highlights the probable role of lupus in the pathogenesis of medium vessel vasculitis which is typical of PAN.

FR-PO643

Biopsy Proven Lupus Nephritis in a Cocaine User with High ANCA Titers: Coincidence or Correlation? Rohini Prashar, Ginius Pradhan, Sandeep Vetteth. *Univ of Toledo Medical Center, Toledo, OH.*

Introduction: Levamisole-contaminated cocaine is now well recognized to be linked with ANCA Vasculitis. Some reports have also suggested cocaine as a causative factor for Lupus. We report an interesting case of a cocaine user with nephrotic syndrome, positive MPO and PR3 ANCA whose biopsy revealed Membranous Lupus Nephritis.

Case Description: A 37 year old female, habitual cocaine user with history of leg swelling was referred to us for nephrotic range proteinuria, quantified at 6.5 grams. She had lower extremity edema on physical examination and no skin lesions were noted. Investigations revealed normal creatinine, low complements, positive MPO (330 IU/ml) and PR3 (1265 IU/ml) ANCA. Her Anti-nuclear antibody and anti-dsDNA antibody were also positive. Kidney biopsy revealed diffuse thickening of capillary loops without evidence of vasculitis. Immunofluorescence showed diffuse IgA, IgG, kappa, lamda and C3 peripheral granular deposits. Electron Microscopy revealed electron dense deposits consistent with membranous nephropathy.



She stopped using cocaine and therapy with steroids and mycophenolate was initiated resulting in resolution of proteinuria, normalization of anti-ds DNA and reduction in ANCA titers.

Discussion: Despite widespread use of cocaine, there is still paucity of data linking it with autoimmunity and vasculitis. Illicit cocaine, adulterated with levamisole has been associated with ANCA vasculitis with both MPO and PR3 ANCA positivity. In a recent study,the presence of hypocomplementemia with anti-dsDNA antibodies raised the question of drug-induced lupus in a subset of these patients. We hypothesize that our patient might have sub-clinical extra-renal ANCA vasculitis which improved after stopping cocaine, along with the presence of lupus nephritis. Whether the co-existence of these two entities is a coincidence or correlation remains uncertain.

FR-PO644

Myeloperoxidase P-ANCA-Positive Crescentic Glomerulonephritis with Membranous Nephropathy: A Case Series Irfan K. Moinuddin, Bijin Thajudeen, Amy Nicole Sussman, Erika R. Bracamonte. *Div of Nephrology, Univ of Arizona Medical Center, Tucson, AZ.*

Introduction: Rarely, coincident PANCA GN and MN have been described. Idiopathic MN is associated 70% of the time with anti-PLA2R antibodies. The remaining 30% include ab to putative antigens such as neutral endopeptidase. Secondary MN is associated with antigens ranging from hepatitis, lupus, cancers, sphilis and schistosomiasis. Colocalization of MPO antigen and IgG deposits in capillary walls in cases of MN with PANCA vasculitis has been shown. It is postulated that the MPO antigen may promote both neutrophil chemotaxis and immune complex deposition.

Case Description: We report two cases of MN with crescentic GN due to PANCA vasculitis: Case 1 is a 50 year old female who presented for evaluation of rash and renal failure. The rash was a diffuse erythematous macular rash. Patient had a history of cocaine abuse. Patient had a nephritic urinalysis and proteinuria 1600 mg/d. Case 2 is a 30 year old male who presented with 2-3 months history of cold intolerance, weight gain and night sweats. Patient was treated for newly diagnosed Hashimoto's thyroiditis with levothyroxine and renal failure with fluid resuscitation with improvement in both. Renal failure recurred with a persistent nephritic picture, dysmorphic red blood cells and RBC casts.

Both cases had MPO and PANCA positivity. In both cases, the glomeruli showed spike formation on light microscopy and characteristic fine granular capillary loop immunofluorescence staining, predominantly for IgG. In addition, focal segmental necrotizing lesions with crescent formation were seen. Serologic testing for anti-PLA2R antibodies was negative in both cases.

Discussion: The coexistence of PANCA GN and MN supports the hypothesis that MPO may serve as an antigen for IgG deposition in glomerular capillary walls. Further studies are needed to demonstrate colocalization of IgG and anti-MPO, especially in cases of PANCA GN plus MN induced by levamisole and/or hashimoto's thyroiditis.

FR-PO645

Crescentic Glomerulonephritis Associated with Granulocytic Colony-Stimulating Factor (G-CSF): Case Report Carla Tenório Barros Cisne Pessoa, Nathalia K.N. Alecrim, Camila Barbosa L. Oliveira, Alline S.A. Oliveira, Cintia Germana Mergulhão da Costa, Daiane Silva, Luis H.B.C. Sette, Lucila Maria Valente, Gisele Vajgel Fernandes, Maria Alina G.M. Cavalcante. *Nephrology, Univ Federal de Pernambuco, Recife, Pernambuco, Brazil.*

Introduction: Granulocytic colony-stimulating factor (G-CSF) is used as adjuvant therapy in oncologic patients with neutropenia. Stimulation of certain colonies of leucocytes can induce abnormal immune reaction leading to inflammation. Neutrophils are recognized as major cells in the development of crescentic glomerulonephritis. We report a case of crescentic glomerulopathy associated with the use of G-CSF.

Case Description: A 53 year-old woman with breast cancer (ductal carcinoma in situ) received four cycles of neoadjuvant chemotherapy (docetaxel, doxorubicin and cyclophosphamide) associated with G-CSF during four months, with partial remission. After 30 days of the last cycle she was admitted at the hospital with petechiae and purpura on the lower limbs and gross hematuria. Exams showed serum creatinine of 3.9 mg/dL (baseline: 0.6 mg/dL). Blood levels of complement (C3 and C4) were normal and testing was negative for antinuclear antibodies, c-ANCA, p-ANCA, hepatitis B and C and HIV. She had no signs of infection or hypovolemia and no history of nephrotoxic drug use. Renal biopsy showed acute crescentic glomerulonephritis, tubular atrophy with multifocal hyaline casts and moderate interstitial fibrosis. Immunofluorescence was negative. She received methylprednisolone 1g for three days followed by monthly cyclophosphamide and showed improvement of skin lesions and serum creatinine decreased to 0.9 mg/dL.

Discussion: Studies demonstrate that endogenous G-CSF has a role in experimental glomerulonephritis and literature review revealed a few cases of possible association of exogenous G-CSF with acute glomerulonephritis in humans, including two case reports of crescentic glomerulopathy. The aim of this study is describe a case of crescentic glomerulonephritis developed during the use of G-CSF without another triggering factor, highlighting the importance of routine monitoring of renal function in patients using this medication.

FR-PO646

ANCA-Negative ANCA-Associated Crescentic Glomerulonephritis with Concurrent C1q Deposits Richa A. Pandey, Arvind K. Garg, Seth Goldberg, Tingting Li. *Nephrology and Hypertension, Washington Univ School for Medicine, St. Louis, MO.*

Introduction: Anti Neutrophil Cytoplasmic Antibody (ANCA) associated vasculitis (AAV) causes pauciimmune glomerulonephritis (GN), with cellular crescents. Upto 30% patients with AAV lack ANCA. There are rare reports of C1q deposits in the glomerular mesangium in patients with AAV. There is one case report of C1q nephropathy with crescentic GN. We describe a case ANCA negative AAV with strong mesangial C1q deposition.

Case Description: 68 year old caucasian man presented with tea colored urine, hemoptysis and a petechial rash for 14 days duration. Past medical history of type 2 diabetes, hypertension, aortic stenosis. Admission labs showed hemoglobin of 8.1 gm/dl, platelet count 91,000/cumm, serum creatinine 8.5 mg/dl with, potassium 7.1 meq/dl, LDH 450 units/L, reticulocyte count 3.5%, haptoglobin <10 mg/dl, red blood cell casts in the urine sediment, negative ANA and ANCA, normal serum complement C3 and

C4, anti glomerular basement membrane antibody. Bronchoscopy showed evidence of alveolar hemorrhage. He was initiated on hemodialysis for anuric renal failure. Kidney biopsy showed paucimmune crescentic glomerulonephritis, with 3+ C1q staining in the glomerular mesangium on immunofluorescence. Electron microscopy did not show any electron dense deposits. Skin biopsy showed C1q deposition around dermal capillaries. He was treated with intravenous cyclophosphamide and pulse dose steroids. Following initial therapy hematologic parameters, and hemoptysis improved, although he remained hemodialysis dependent.

Discussion: ANCA associated vasculitis is typically pauciimmune, with no evidence of immune complex deposition or complement activation. Recent studies have evaluated the role of complement in pathogenesis of AAV. In a renal biopsy study, 7 cases of AAV had evidence of C1q deposition, only 1 was quantified as 3+. Our patient presented with pulmonary renal syndrome, had negative ANCA levels and normal serum complements. C1q nephropathy is known to present with crescentic GN, but there are no cases with evidence of systemic vasculitis. To the best of our knowledge this is the first reported case of ANCA negative AAV with strong C1q deposition.

FR-PO647

Atypical P-ANCA Associated Crescentic Glomerulonephritis Presenting as Usual Interstitial Pneumonia Kelly Mazurek,[1] Gaurav Alreja,[2] Eric Loman,[1] Ruchir D. Trivedi.[2] *[1]Internal Medicine, Univ of Connecticut Health Center, Farmington, CT; [2]Nephrology, Univ of Connecticut Health Center, Farmington, CT.*

Introduction: Immunofluorescence (IF) positive anti-neutrophil cytoplasmic antibody (ANCA) patterns not fitting the typical description of cytoplasmic and perinuclear are called atypical ANCA. Sera giving rise to such IF patterns target multiple antigens (nuclear, cytosolic and various granular autoantigens) in neutrophils and lack specificity for either myeloperoxidase or proteinase 3 enzymes. Atypical ANCA, although commonly described with non-vasculitic (inflammatory bowel disease, sclerosing cholangitis, connective tissue diseases) and infectious pathologies, is rarely associated with systemic necrotizing small vessel vasculitis. An uncommon case of atypical ANCA manifesting as renal and pulmonary vasculitis is presented.

Case Description: 85-year-old woman with prolonged upper respiratory tract symptoms developed worsening cough and acute kidney injury. Medical history included hypertension, hypothyroidism and an intermittent three-month fever. CT scan of chest revealed diffuse subpleural reticulation and honeycombing of bilateral lower lung lobes consistent with Usual Interstitial Pneumonia. Laboratory data revealed leukocytosis, anemia, and Cr 3.2 mg/dL. Urinalysis showed RBC casts, dysmorphic RBCs and urine protein 1558 mg/g Cr. Autoimmune workup was negative and atypical p-ANCA 1:2560. Kidney biopsy showed segmental fibrinoid necrotizing lesions with cellular crescents and disruption of Bowman's capsule consistent with pauci-immune necrotizing crescentic glomerulonephritis. The patient received aggressive treatment of six cycles of cyclophosphamide with tapering steroids.

Discussion: Majority of ANCA associated crescentic GN and pulmonary fibrosis present with MPO-ANCA. Current literature has not identified atypical ANCA with severe forms of multisystem vasculitis. Our patient had a unique multisystem atypical p-ANCA small vessel vasculitis, with initial presentation as usual interstitial pneumonia a month before onset of renal dysfunction, and eventual renal failure. Both renal and pulmonary function improved substantially with cyclophosphamide and steroids.

FR-PO648

ANCA-Associated Vasculitis Presenting as a Unilateral Adrenal Mass Nyan W. Phyo,[1] Ghayyath Sultan,[1] Sherry L. Werner,[2] Wajeh Y. Qunibi.[1] *[1]Dept of Nephrology, UTHSCSA, San Antonio, TX; [2]Dept of Pathology, UTHSCSA, San Antonio, TX.*

Introduction: ANCA-associated vasculitis commonly presents with pulmonary-renal syndrome but can rarely present with lung or renal mass, malignancy, parotid enlargement or spinal mass. We report here the case of a patient who presented with abdominal pain and a right adrenal mass.

Case Description: A 41 year old Hispanic female was admitted to our hospital with persistent abdominal pain for one week. Laboratory data revealed microscopic hematuria, 3.7 gram proteinuria and creatinine of 4.2 mg/dl. CT scan of abdomen showed large right adrenal cystic lesion (12.3 x 11 cm) which was found nonfunctional. Cyst aspiration revealed bloody drainage with negative cytology. Further work-up showed positive anti-nuclear antibody (titer 1:160) and elevated myeloperoxidase antibody at 64 (normal 0-21 units). Hepatitis B, HCV, HIV, RPR, Anti-dsDNA, and Anti-proteinase-3 antibodies were negative. Complements levels were normal. Kidney biopsy revealed necrotizing crescentic glomerulonephritis with negative immunofluorescence staining establishing a diagnosis of ANCA- associated vasculitis. Patient was treated with plasma exchange, intravenous methyl prednisone, intravenous cyclophosphamide and initiated on hemodialysis due to hyperkalemia and worsening kidney function. She remained dialysis-dependent after 12 weeks despite continuing immunosuppressive drugs.

Discussion: ANCA associated vasculitis rarely presents as a mass lesion. The initial focus on adrenal mass in our patient resulted in delay in diagnosis of vasculitis. Given that early diagnosis and treatment are crucial for improving prognosis, vasculitis should be suspected in patients with hemorrhagic adrenal cysts.

FR-PO649

Treatment-Refractory FSGS in a Patient with Systemic Lupus Erythematosus Kristin Meliambro, Shuchita Sharma, Kirk N. Campbell. *Nephrology, Icahn School of Medicine at Mount Sinai, NY, NY.*

Introduction: Lupus podocytopathy is an increasingly recognized entity in nephrotic patients with systemic lupus erythematosus (SLE) that is distinct from classic immune-complex mediated disease. Case series have described SLE-podocytopathy as typically steroid responsive. Here we present a case of podocytopathy in a patient with SLE with the tip lesion variant of FSGS.

Case Description: This is a 60 year old female with long-standing SLE (20+ years) who presented to nephrology with proteinuria and hypertension. Her physical exam was notable for a malar rash and 1+ bilateral lower extremity edema. She had a urine protein/creatinine (P/C) ratio of 3.06 mg/mg with an eGFR of 42 cc/min and a serum albumin of 2.9 g/dl. Urinalysis revealed 11-25 RBCs/hpf. Mycophenolate Mofetil 500 mg BID had been initiated by rheumatology 4 weeks prior for extrarenal lupus manifestations including arthralgias and the malar rash. She had also been taking Captopril 12.5 mg TID. She did not tolerate hydroxychloroquine due to retinal toxicity. A kidney biopsy was performed that revealed 22 glomeruli, one with segmental sclerosis, tip variant. Electron microscopy (EM) revealed diffuse podocyte foot process effacement. There were no basement membrane or immune deposits by EM or immunofluorescence. Her urine P/C ratio peaked at 14.6, averaging 5-7 g urinary protein per day. The MMF was discontinued due to the development of herpes zoster which was treated with acyclovir. The patient completed 6 month courses of Prednisone 60 mg daily then cyclosporine 2 mg/kg/day with persistent proteinuria of 7-8 grams per day and an eGFR of 30 cc/min. Acthar gel was started at 80 units subcutaneously twice weekly. After 16 months on Acthar her nadir urine protein excretion was 1.3 g. At the time of last follow up, the patient had approximately 4 g of proteinuria and an eGFR of 25 cc/min.

Discussion: This patient's clinical course highlights the potential refractory course of non-canonical lupus-associated renal disease even in the presence of seemingly favorable histologic features. Further studies will be needed to determine the optimal treatment regimen for these patients.

FR-PO650

Unusual Presentation of Wegener's Granulomatosis with Hypercalcemia Samir A. Brahmbhatt, Robert D. Zenenberg. *Internal Medicine and Nephrology, Morristown Medical Center, Morristown, NJ.*

Introduction: Hypercalcemia has been known to be present in granulomatous diseases due to extra-renal production of 1,25-dihydroxy-vitamin D by disease-activated macrophages. It has rarely been known to occur in granulomatosis with polyangiitis (Wegener's) abbreviated as GPA. We present a case of an elderly female who presented with acute renal failure and symptomatic hypercalcemia, diagnosed as GPA. The hypercalcemia workup was non-diagnostic, but the presumption was the same mechanism, and consistent with this, it responded briskly to steroid therapy.

Case Description: 73-year-old female with coronary artery disease, controlled hypertension, ulcerative colitis and hypothyroidism was sent to the ER for hypercalcemia, unintentional 30lb weight loss, anemia and acute renal failure. Initial creatinine was 3.4mg/dl, 52mg/dl BUN, calcium 13.8mg/dl. Urinalysis showed microscopic hematuria, 3+ proteinuria, without red or white cell cast. Imaging studies of the abdomen/pelvis was unremarkable. A paraprotein mediated renal disease workup was negative. The hypercalcemia workup was inconclusive with elevated phosphorus, suppressed iPTH, negative PTHrp, high 25 $(OH)_2D$, but low 1,25 $(OH)_2D$. No signs of malignancy on imaging. No history of calcium supplement usage. Further investigation showed normal TSH, negative QuantiFERON®TB test, no signs of a fungal infection or other granulomatous diseases, but elevated ANA and myeloperoxidase ANCA. A kidney biopsy showed pauci-immune extra capillary proliferative glomerulonephritis consistent with ANCA positive disease. Patient was treated with steroids and anti-CD20 antibody with improvement in her renal insufficiency. Her calcium level normalized to 9.1 within a month.

Discussion: There are only 3 reported cases of hypercalcemia in GPA. They were associated with unregulated production of 1,25 $(OH)_2D$ by inflammatory cells. Although the comprehensive workup for hypercalcemia was largely negative, the presumption that extra-renal production of activated vitamin D was the underlying mechanism is not confirmed, but may be suggested here. This case reinforces that like other granulomatous diseases, GPA should be considered in the differential diagnosis of hypercalcemia.

FR-PO651

A Case of Systemic Lupus Erythematosus with Anti Myeloperoxidase Antibodies, Cerebral Vasculitis and Presumed Lupus Nephritis Responding to Therapeutic Plasma Exchange: A Remarkable Recovery from a Critical Illness Tamara T. Rubenzik, Umut Selamet, Amber P. Sanchez. *Nephrology and Hypertension, Univ of California San Diego, San Diego, CA.*

Introduction: MPO-ANCA antibody (Ab) in the setting of systemic lupus erythematosus (SLE) is uncommon and the significance unclear. We report the case of a patient with newly diagnosed SLE complicated by presumed lupus nephritis, antiphospholipid antibody syndrome (APLA), and persistent seizures despite cyclophosphamide and steroids, who was treated with therapeutic plasma exchange (TPE) with subsequent improvement in neurologic and renal function.

Case Description: A 20 year old male presented with altered mental status, seizures, fevers, polyarthritis, anemia, and rash. Serologic work up revealed positive ANA (>1:640), anti-dsDNA (>200), ANCA (1:1280), MPO Ab (181) and low compliments.

He was diagnosed with SLE and APLA with a cerebral vein thrombosis. The presence of proteinuria, hematuria and an elevated creatinine was consistent with lupus nephritis though the need for uninterrupted anticoagulation precluded a renal biopsy. Despite treatment with cyclophosphamide and steroids, he continued to decline with intractable seizures, renal failure, and a CT angiogram revealing cerebral vasculitis. TPE has been a useful adjunctive therapy in select cases of SLE with central nervous system involvement, as well as in ANCA-associated vasculitis, and was initiated on hospital day 25. Following five TPE treatments his seizures subsided, mental status improved, and creatinine and proteinuria began to downtrend. Treatment with cyclophosphamide and high dose prednisone continued, and he was discharged on hospital day 53. Three months after discharge he maintains normal neurologic and renal function and is independent in activities of daily living.

Discussion: The presence of an MPO-ANCA in the setting of SLE has been associated with crescentic glomerulonephritis in addition to other systemic manifestations similar to ANCA vasculitis. These patients have been reported to respond to treatment with IVIG, tacrolimus, and TPE. TPE proved to be a successful adjunctive therapy in our patient and should be considered in SLE patients with anti MPO antibodies.

FR-PO652

SLE with Fabry's Disease, Is It Too Rare? Pongsathorn Kue-A-Pai,[1] Napat Leeaphorn,[1] Wonngarm Kittanamongkolchai,[2] Raquel M. Rosen.[1] *[1]Internal Medicine, Bassett Medical Center, Cooperstown, NY; [2]Nephrology, Mayo Clinic, Rochester, MN.*

Introduction: Fabry's disease is an uncommon X-linked lysosomal storage disorder. On the other hand, SLE is a common autoimmune disease worldwide. We describe a case of a man with both SLE and Fabry's disease. The relationship between the two conditions and literature review are discussed.

Case Description: A 34-year-old man with history of chronic joints pain who presented with pleuritic-type chest pain, worsening of shortness of breath. Notable exam findings included temperature of 39 degrees Celsius, hypertension and crackles at bases on lung exam. Serum creatinine was 2.9 mg/dL. WBC was 4,800/mm^3. Hemoglobin was 8.9 mg/dL. Urinalysis showed protein 3+ and hematuria. Microscopic urine exam revealed RBC cast. ANA and double stranded DNA were positive. C3 was 70 mg/dL. C4 was 7.3 mg/dL. ESR was 100 mm/hr. Patient underwent renal biopsy which showed diffuse endocapillary proliferative glomerulonephritis with full house immune staining. Electron micrograph revealed Zebra bodies in the podocytes. Diagnosis of SLE nephritis class IV was made. IV steroid and cyclophosphamide were initiated. His condition improved. He was discharged with oral steroid. Subsequent plasma globotriaosylceramide, serum and leukocyte enzyme assay confirmed diagnosis of Fabry's disease.

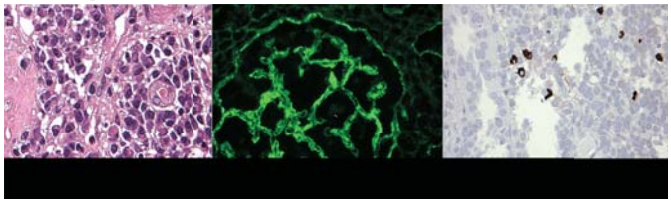
Discussion: Renal involvement of Fabry's disease almost occurs in male hemizygotes and less common in female heterozygote. Approximately 85% of patient with Fabry's disease will have proteinuria which will precedes chronic renal insufficiency but nephrotic-range proteinuria was uncommon. Review of literature revealed 2 previous case reports of lupus nephritis associated with Fabry's disease. This presenting case is the first case in literature who is a man. Although association between these two diseases is not established, recent in vivo study demonstrates lipid metabolism defects including globotriaosylceramide contribute to SLE pathogenesis and also suggest that targeting Glycosphingolipids biosynthesis restores T cell function in SLE. We propose that increase cellular and plasma globotriaosylceramide (Gb3) in Fabry's disease might facilitate in SLE pathogenesis.

FR-PO653

An Overlapping Case of Lupus Nephritis and Immunoglobulin G4-Related Kidney Disease IgG-4 RKD Ahmad Eter,[1] Suzanne E. El Sayegh,[1] Elie El-Charabaty.[1] *[1]Nephrology, Staten Island Univ Hospital, Staten Island, NY; [2]Nephrology, Staten Island Univ Hospital, Staten Island, NY; [3]Nephrology, Staten Island Univ Hospital, Staten Island, NY.*

Introduction: The renal pathology can be a dilemma especially in Lupus patients as it mimics different diseases and one of them is IgG-4 RKD, which is a recently recognized disorder defined by dense lymphoplasmacytic infiltrate rich in IgG4-positive plasma cells with frequently observed elevated antinuclear antibody ANA.

Case Description: We report a 71 year-old Philippino female with PMH of HTN and hypothyroidism who presented with abdominal pain. Physical exam indicated epigastric tenderness. Labs showed BUN100, creatinine 9.27 (baseline 1.2), albumin 1.5, urine microscopy no RBC casts, and TP/Cr 2.6 gr. CT imaging revealed multiple granulomas in rt upper lobe, and inflammatory stranding around the duodenum. Kidney function worsened in the next days and hemodialysis was initiated. Serology was positive for HBsAg, ANA, urine and serum immunofixation indicated free Lambda band and faint bands of IgG, IgG-4 sub-class was normal, total IgG was elevated, and ds-DNA was negative. Bronchoscopy was not diagnostic. Kidney biopsy showed tubulointerstitial nephritis TIN and acute tubular necrosis with abundant tubular basement membrane deposits staining for "full house" thus suggesting IgG-4 related TIN versus membranous and interstitial Lupus Nephritis. Patient did not respond to steroids but responded to mycophenolate mofetil and kidney function improved.



Discussion: This is a challenging case as pathology was inconclusive for definite diagnosis. The full house deposits, positive ANA, and normal IgG-4 levels suggest lupus nephritis, but the findings of IgG-4 positive plasma cells, negative symptoms for systemic lupus, inactive urine sediment, and the negative ds-DNA would suggest a possible diagnosis of IgG-4 related TIN.

FR-PO654

Post Infectious Glomerulonephritis with Positive C-ANCA and Anti PR3 Antibodies Ahmed Zeen Alabedeen Alrifai,[1] Barry M. Wall.[1,2] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]VAMC, Memphis, TN.*

Introduction: In the setting of acute glomerulonephritis (GN), the presence of c-ANCA (anti-PR 3) is highly suggestive of granulomatous polyangiitis (GPA). However, similar serologic findings have been described with postinfectious GN.

Case Description: 45 year old male with ulcerative colitis and primary sclerosing cholangitis presented with bloody stool for 5 days and dark colored urine for 1 wk. He had been treated 3 wk prior with clindamycin for root canal infection and 2 wk prior with ciprofloxacin for suspected epididymitis. Laboratory: serum creatinine 5.1 mg/dl (prior value, 0.8 mg/dl). Urinalysis was positive for 2+ protein, 3+ blood with >100 RBCs and WBC, and granular casts in the sediment. Urine protein creatinine ratio was 1.1. (Previous urinalyses were normal). C-ANCA titers were positive: 1:320 with positive anti-proteinase 3: 80 (high positive >30). P-ANCA titers were negative and prior ANCA studies had been negative. Screening tests for anti-nuclear antibodies, ASO titers, HIV, hepatitis B and C were negative. CH50 and C4 were normal, while C3 was low, 54 mg/dl (90- 180 mg/dl). Initial blood and urine cultures were negative. Oral prednisone therapy (1.0 mg/kg) was initiated. Kidney biopsy was suggestive of post-infectious GN; LM- acute proliferative and exudative glomerulonephritis with crescent formation, IF: positive for C3, EM showed scattered subepithelial hump like deposits. Additional blood cultures were positive for Streptococcus viridans and echocardiography was suspicious for valvular vegetation. Prednisone was discontinued and 6 weeks of antibiotics were administered for presumed endocarditis. Blood cultures became negative and renal function gradually returned to baseline without immunosuppressive therapy. During long term follow up serum creatinine is 0.8mg/dl, urinalysis is normal, and ANCA titers are negative.

Discussion: Determining whether acute GN is ANCA *mediated* (as in GPA, requiring immunosuppression) versus ANCA *associated* (as in infection- associated GN, requiring treatment of underlying infection) is crucial in determining appropriate treatment. Kidney biopsy continues to be necessary for making this distinction.

FR-PO655

ANCA Positive Necrotizing Glomerulonephritis Associated with Enterococcal Infective Endocarditis Shriharsha Kallahalli Jayaramu, Yuvaraj Thangaraj, Girish Singhania, Radhika Vemuri, Keerti K. Bhanushali, Gurjit Dhatt. *Nephrology, Univ of Florida, Gainesville, FL.*

Introduction: Crescentic glomerulonephritis secondary to enterococcal infective endocarditis is rare and mostly associated with immune complex deposition in renal biopsy. Here, we report a case of pauci immune crescentic glomerulonephritis associated with enterococcus infective endocarditis.

Case Description: 24 year old male with history of intravenous opioid abuse presented with 20 lbs weight loss, fatigue, nausea, vomiting and hematuria of three months duration. On physical exam, BP 137/91 mmHg, HR of 92/min, RR 20/min, diffuse crackles on lung exam and 2+ pitting edema in bilateral lower extremities. Labs: Serum creatinine of 11 mg/dL, BUN of 110 mg/dL, hemoglobin of 7g/dL, LDH of 204 U/L and haptoglobin of 265 mg/dL. Peripheral smear did not show any schistocytes. Urinalysis showed several dysmorhic RBC and two RBC casts. Serology: Hepatitis and HIV negative, ANA was weakly positive, P-ANCA was positive, C3 was low and C4 complement was normal. Blood cultures were positive for enterococcus 4/4. Transesophageal echocardiogram showed vegetation on posterior mitral leaflet. Ultrasound showed echogenic kidneys. Renal biopsy: Severe necrotizing and crescentic glomerulonephritis without evidence of immune deposits in immunofluorescence and electron microscopy. Infective endocarditis was successfully treated with intravenous antibiotics. He received pulse solumedrol and subsequently developed florid heart failure due to severe mitral regurgitation and underwent mitral valve replacement. At present, the patient continues to be dialysis dependent without any evidence of renal recovery.

Discussion: Diffuse crescentic necrotizing glomerulonephritis is the most common pattern of glomerular injury seen in Infection Related Glomerulonephritis (IRGN) and is often pauci immune. The major differential diagnosis of this clinical picture is ANCA vasculitis but upto 10% of IRGN can show ANCA positivity. Early recognition of IRGN and its varied histological manifestations is imperative for appropriate management.

FR-PO656

Eculizumab Induced Reversal of Dialysis Dependent Renal Failure from Crescentic C3 Glomerulonephritis Melissa Inman,[1] Ginnie Prater,[1] Anant Kharod,[1] Huma Fatima,[2] Eric L. Wallace.[1] *[1]Medicine, UAB, Birmingham, AL; [2]Path, UAB, Birmingham, AL.*

Introduction: Dysregulation of the alternative complement pathway has been implicated in thrombotic microangiopathy, atypical hemolytic uremic syndrome (aHUS), dense deposit disease, and C3 glomerulonephritis (C3GN). Eculizumab is an anti-C5 monoclonal antibody approved for treatment of paroxysmal nocturnal hemoglobinuria and aHUS. Case series have shown eculizumab's potential as a treatment for C3GN but data is limited.

Case Description: A 38 year-old woman with idiopathic urticaria and well-controlled type II diabetes mellitus was sent to the emergency room for a blood pressure of 200/100 mmHg. Laboratory evaluation revealed serum creatinine of 11.0 mg/dL (eGFR 5 mL/min per MDRD formula) up from a baseline creatinine of 1.0 mg/dL. Urinalysis showed 4+ protein and 3+ blood with protein to creatinine ratio of 6.82 g/g. Hemoglobin 6.6 g/dL and platelet count 223 K/mm^3. C3, C4, anti-dsDNA, and ANCA titers were unremarkable. Hemodialysis and empiric steroids were initiated. A kidney biopsy showed 23/49 glomeruli with crescents, immunofluorescence with diffuse mesangial staining for C3 alone, and 10% interstitial fibrosis consistent with C3 glomerulonephritis. The patient failed to improve on steroids and was transferred to University Hospital. Evaluation of the alternative pathway revealed elevated soluble MAC level (0.36 mg/L), positive complement hemolytic assay (6.17%), and two deletion mutations in the CFHR3-CFHR1 gene. Plasma exchange was initiated for 3 treatments. Due to her acute presentation and minimal fibrosis on biopsy, eculizumab was initiated at standard dosing. The patient was discharged on peritoneal dialysis and continued eculizumab. After initiation of eculizumab, the patient's renal function continued to improve. Five months after initiation of therapy, dialysis was discontinued and 24-hour urine showed a creatinine clearance of 34 ml/min.

Discussion: Eculizumab should be considered for treatment of C3GN even in patients who have acutely become dialysis dependent. Adequate time for response to therapy (3 months minimum) should be given as patients can have slow recoveries but be rendered dialysis independent after such time.

FR-PO657

Membranous Nephropathy Associated with Autoimmune Thyroiditis

Antonio G. Jimenez, Jorge C. Garces, Pradeep Vaitla, Ryan C. Mascarenhas. *Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

Introduction: Membranous nephropathy is the most common cause of nephrotic syndrome in adults and it is well known to be associated with many other conditions, including autoimmune disorders.

Case Description: 24-year-old female with history of Type I Diabetes Mellitus presented with one-month history of generalized edema associated with cold intolerance and hair loss. Her vital signs were normal. Physical exam revealed anasarca. Laboratory data showed iron deficiency anemia, normal serum creatinine, nephrotic range proteinuria, microscopic hematuria, hypoalbuminemia, Hgb was A1C 9.5%, complements were normal, autoimmune serologies were negative, Hepatitis B, Hepatitis C and HIV were negative, RPR was non reactive, TSH was 112.9 mIU/L, FreeT4 0.47 ng/dL, Free T3 was 1.6 ng/dL, Thyroperoxidase antibody (TPO) was 892 mIU/L, Thyroglobulin antibody was 35.3mIU/L, and Thyroid-stimulating IG (TSI) was normal. Renal ultrasound showed normal sized kidneys without abnormalities. Renal veins were patent bilaterally. Renal biopsy showed characteristic features of membranous glomerulopathy with segmental holes and rare spikes of the glomerular basement membrane along with eosinophilic deposits by LM, 2 to 3+ near full-house diffuse global finely granular capillary loops and segmental mesangial staining by IF and frequent small subepithelial immune complex deposits with scattered large mesangial immune complex deposits by EM. PLA2R staining was negative. She was started on thyroid hormone replacement, diuretics, and ACEi. After one month follow up, there was a mild improvement in proteinuria and hypoalbuminemia. Unfortunately, patient failed to follow up thereafter and no long-term follow up is available.

Discussion: To the best of our knowledge, only few cases of coexistent autoimmune thyroiditis with membranous nephropathy have been reported in the literature. The direct pathogenic link between these two diseases is unclear, but a same immune-mediated process affecting both organs is suspected. Optimal therapy for membranous nephropathy in the setting of autoimmune thyroiditis is not well defined. Our case shows a relationship between normalization of thyroid hormones values with decrease in proteinuria.

FR-PO658

Conditional Tissue Specific CTGF Over-Expression Results in Over-Activated Kidney Stroma

Bryce Gordon Johnson,[2] Shuyu Ren,[1] Ivan G. Gomez,[2] Jeremy Stuart Duffield.[2] *[1]Depts of Medicine & Pathology, Univ of Washington, Seattle, WA; [2]Biogen Idec, Cambridge, MA.*

Background: Connective tissue growth factor (CTGF), a member of the CCN gene family, is an extracellular matrix (ECM)-associated heparin-binding protein involved in matrix production. CTGF has been shown to contribute to progression of fibro-proliferative diseases and scarring by modifying of proliferation, migration, and adhesion of fibroblasts. CTGF has also been shown to play a role in ECM remodeling in normal physiological processes including embryogenesis, implantation, and wound healing. However recent new insights into the pathogenesis of fibrosing kidney diseases lead us to re-evaulate CTGF in this context at a cellular level. We therefore generated a mouse model which facilitates tissue specific, conditional over-expression of CTGF using homologous recombination.

Methods: A targeting vector to the ubiquitously expressed Rosa26 locus was cloned harboring a splice acceptor, chicken b-actin promoter followed by a floxed Neo-Stop cassette upstream of *CTGF*, followed by an internal-ribosomal-entry-site (IRES) and EGFP. Targeting vector was sequenced, validated in-vitro, and subsequently electroporated into mouse ES cells. Long-range PCR screens identified correctly targeted clones. Clones were injected into diploid mouse blastocysts and chimeras generated. Founder mice were bred, and offspring with transgene were expanded. To characterize this model, Foxd1 GFPCre/+ mice were utilized to over-express CTGF in kidney stromal populations. Immunostaining and WB was performed. Pericytes from Foxd1GC/+ crosses were isolated.

Results: Analysis of neonatal kidneys from mice derived via Foxd1 GC/+ X Rosa-Caggs-loxp-NeoStop-loxp-CTGF-IRES-GFP crosses displayed over-activated stroma. Kidney sections revealed hyper-cellularity in the interstitium. Immunohistochemistry showed an infiltration of leukocytes. Stromal cells isolated from CTGF over-expressing mice were more proliferative, migratory, and had a significantly higher expression of aSMA than controls.

Conclusions: CTGF over expression restricted to kidney stroma *in vivo* is sufficient to trigger cell activation and myofibroblast transition.

FR-PO659

The Role of Angiopoietin-Like Protein 2 in Renal Fibrosis

Jun Morinaga,[1,2] Yoshikazu Miyasato,[1] Miki Ueda,[1] Teruhiko Mizumoto,[1] Rika Yamazoe,[1] Manabu Hayata,[1] Kohei Uchimura,[1] Yutaka Kakizoe,[1] Taku Miyoshi,[1] Masataka Adachi,[1] Masashi Mukoyama,[1] Kenichiro Kitamura.[1] *[1]Dept of Nephrology, Kumamoto Univ, Graduate School of Medical Sciences, Japan; [2]Dept of Molecular Genetics, Kumamoto Univ, Graduate School of Medical Sciences, Japan.*

Background: Renal fibrosis is a final common pathway in the progression of CKD. Previously, we reported that abundant expression of Angiopoietin-like protein 2 (ANGPTL2) plays important pathological roles in various non-infectious inflammatory diseases. However, little has been reported about the evidence of ANGPTL2 to be involved in the progression of renal disease.

Methods: We performed Azan-Mallory staining and ANGPTL2 immunohistochemistry in exenterated kidneys from non-invasive ureteral carcinoma patients to verify the localization of ANGPTL2 expression in the pathogenesis of renal fibrosis. Next, we performed UUO to wild type (WT) mice and *ANGPTL2* knockout (KO) mice. Fourteen days after the UUO surgery, those mice were sacrificed and kidney samples were collected.

Results: The immunohistochenical analysis of human kidney showed that ANGPTL2 is marginally expressed in non-fibrotic kidney. On the other hand, in fibrotic kidney, ANGPTL2 expression was increased and was predominantly observed in renal tubule cells. In the animal study, ANGPTL2 mRNA and protein levels were markedly increased in the UUO kidney of WT mice. Histological fibrotic area, mRNA expression of extra cellular martix proteins, including fibronectin, collagen I, III and IV, and protein level of FN and collagen IV were also increased in the UUO kidney of WT mice. In addition, mRNA and protein expression of TGF-β1 and its target molecule CTGF were elevated in the UUO kidney of WT mice. However, the increase of fibrotic markers and pro-fibrotic factors were significantly ameliorated in the UUO kidney of *ANGPTL2* KO mice.

Conclusions: Our current investigation suggested that ANGPTL2 derived from renal tubule cells has a crucial role to promote renal fibrosis. In the pathogenesis of renal fibrosis, ANGPTL2 may regulate TGF-β1 expression and its signaling. These data lead us to consider that ANGPTL2 would be a new therapeutic target against renal fibrosis.

Pericyte and Myofibroblast Activation Regulated by the TWEAK/Fn14 Pathway

Ivan G. Gomez,[1,2] Naoki Nakagawa,[1] Jeremy Stuart Duffield,[1,2] Timothy Zheng,[2] Allie M. Roach,[1,2] Linda Burkly.[1] *[1]Medicine, Univ of Washington, Seattle, WA; [2]Research, Biogen Idec, Cambridge, MA.*

Background: Pericytes, mesenchymal cells that partially wrap capillary endothelium and are critical for supporting their integrity, have been shown by genetic fate-mapping to be a major progenitor pool for myofibroblasts in a number of fibrotic contexts including kidney fibrosis.In addition, pericytes provide directional cues that route the innate immune cells extravasating into injured tissue. Previously it was shown that TWEAK, a TNF family cytokine produced largely by leukocytes, promotes macrophage infiltration and fibrosis in the UUO model of renal injury. We hypothesized that TWEAK mediates its effect through its injury-inducible receptor, Fn14. In addition, since Fn14 is expressed by mesenchymal lineage cells and regulates their fate, we hypothesized that TWEAK/Fn14 might be a key molecular axis for pericyte activation in response to tissue injury.

Methods: -UUO: Unilateral Ureter Obstruction surgery -Proliferation and migration of primary cultures of pericytes. Anti-Fn14 and anti Tweak antibodies, Fn14 knockout mice. Disease model characterization-Illumina array and analysis.

Results: We now show that Fn14 deficiency ameliorates myofibroblast appearance and renal fibrosis in the UUO model, phenocopying TWEAK deficient mice. TWEAK activates primary murine cultured renal pericytes through Fn14, inducing low level proliferation, migration and production of proinflammatory mediators, as well as pericyte to myofibroblast transition measured by induction of a-smooth muscle actin expression and stress fiber formation. Differentiated myofibroblasts are also activated by TWEAK/Fn14 signaling, exhibiting higher-level proliferation, migration and cytokine production and cytoskeletal changes. Transcriptional profiling of TWEAK-stimulated pericytes and myofibroblasts supports its multifaceted role and identified TWEAK-response genes.

Conclusions: These findings suggest that targeting the TWEAK/Fn14 pathway is an approach to modulate pericyte and myofibroblast activation and a novel way to target both inflammatory and fibrotic aspects of fibrotic disease.

FR-PO661

Combination of Restoring Glomerular VEGF Expression and ARB Treatment Induces Additional Regression of Glomerulosclerosis in 5/6Nx Mice Ying Wu,[1,3] Shaojun Liu,[2,3] Ji Ma,[4] Haichun Yang,[3] Agnes B. Fogo.[3] *[1]Pediatric Nephrology, Children's Hospital, Jiaotong Univ, Shanghai, China; [2]Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China; [3]Pathology, Microbiology and Immunology, Vanderbilt Univ, Nashville, TN; [4]Pediatric Nephrology, Vanderbilt Univ, Nashville, TN.*

Background: High dose ARB induces glomerulosclerosis regression in part by decreasing matrix accumulation. Increased glomerular capillary growth, which can be stimulated by VEGF, may also contribute to regression of established glomerulosclerosis. In this study, we investigated whether combination of ARB and restoring VEGF could enhance regression of glomerulosclerosis.

Methods: Subtotal nephrectomy (5/6Nx) was performed in podocin-rtTA/TRE-human VEGF (RV) and podocin-rtTA mice (R). Glomerulosclerosis index (SI, 0-4 scale) was assessed by renal biopsy at 8 weeks. From week 8 until 12, doxycycline was added in drinking water to induce VEGF specifically in podocytes. Mice were divided into four groups with equal average SI at week 8: R group (n=11), RV group (n=10), R+ARB group (n=12), RV+ ARB group (n=9).

Results: Human VEGF was expressed on podocytes in RV and RV+ARB, but not other groups. Total glomerular VEGF level was restored to 55% of normal level. ARB significantly reduced blood pressure and proteinuria. Inducing VEGF did not increase proteinuria. There was less glomerular collagen IV accumulation in groups receiving ARB than control. SI, a measure of % tuft occupied by matrix, and thus indicating not only matrix deposition but also capillary loss, decreased from biopsy to autopsy in RV+ARB group (R 71.35±30.94, RV 89.16±36.23, R+ARB 40.73±14.62, RV+ARB -4.88±13.89%). Moreover, 4 of 9 RV+ARB mice showed regression compared to 3 of 12 R+ARB mice and 2 of 11 R mice. More DLL4 positive endothelial cells (tip cell) were detected in RV+ARB (1.07±0.12/glomerulus) and RV (0.79±0.07/glomerulus) than in R (0.48±0.03/glomerulus) and R+ARB (0.7±0.17/glomerulus).

Conclusions: We conclude that ARB induces regression of glomerulosclerosis in part by reducing matrix, and partially restoring VEGF in sclerotic glomeruli induces additional regression by new vessel branches, without deleterious increased proteinuria.

FR-PO662

PBI-4050 Reduces Pro-Fibrotic Growth Factors and Collagen Expression in Human Proximal Tubule Cells and in the Doxorubicin-Induced Nephrotoxicity Mouse Model of Acute Kidney Injury Martin Leduc, Kathy Hince, François Sarra-Bournet, Pierre Laurin, Brigitte Grouix, Lyne Gagnon. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: Many growth factors and their receptors, such as transforming growth factor (TGF)-b, platelet-derived growth factor (PDGF) and epidermal growth factor (EGF), have been implicated in the pathogenesis of renal interstitial fibrosis. These growth factors contribute to extracellular matrix production by tubular cells and fibroblasts. The aim of this study was to investigate the effect of PBI-4050, a first-in-class anti-fibrotic compound, on pro-fibrotic growth factors and collagen expression in TGF-β1-stimulated human proximal tubule (HK-2) cells and to corroborate these results *in vivo* in the doxorubicin (Dox)-induced nephropathy model of acute kidney injury.

Methods: mRNA expression was investigated on TGF-β1-stimulated HK-2 cells and in mouse kidney tissue. Nephrotoxicity was induced in BALB/c mice by an intravenous injection of Dox (10 mg/kg) on day 0. Mice were treated with PBI-4050 (100 to 200 mg/kg, oral, once daily) from day -3 to -1 and days 1 to 13. Animals were sacrificed and their kidneys were removed for histological examination (days 7 and 11) or RNA isolation (day 14).

Results: In TGF-β1-stimulated HK-2, PBI-4050 greatly reduced PDGFb, EGF, TGF-β1/2/3 and TGF-β type II receptor expression. Expression of collagens I and III was also significantly inhibited by PBI-4050. *In vivo*, Dox administration led to a significant increase of PDGFa/b, TGF-β1 and collagen I mRNA expression, which was reduced to control levels in PBI-4050-treated mice. Histological examination of renal tissue also showed a significant reduction of Dox-induced lesions (tubules distention, fluid accumulation, necrosis) in PBI-4050-treated mice.

Conclusions: Our results indicate a direct effect of PBI-4050 on human proximal tubule cells as observed by an inhibition of pro-fibrotic growth factors and collagen mRNA expression. The inhibition of the expression of these fibrotic markers was correlated in PBI-4050-treated mice in the Dox-induced nephrotoxicity model, and this was translated to significant reduction of renal histological lesions.

FR-PO663

Pentoxifylline in the Prevention of Peritoneal Fibrosis in Uremic Rats Nelly González,[1] Carmen María del Prado,[1] Virgilia Soto,[2] Marcela Avila,[1] Héctor Isaac Rocha,[3] Ramon Paniagua-Sierra.[1] *[1]Unidad de Investigación Médica en Enfermedades Nefrológicas, Inst Mexicano del Seguro Social, Ciudad de México, DF, Mexico; [2]Dept de Patología, Inst Nacional de Cardiología Dr. Ignacio Chávez, Ciudad de México, DF, Mexico; [3]Escuela Superior de Medicina, Inst Politécnico Nacional, Ciudad de México, DF, Mexico.*

Background: Uremia causes structural and morphological changes in the peritoneum. The inflammatory response in the repair process is responsible of these changes. Pentoxifylline (PTX) suppresses the production of TNF-a and interfere with the synthesis of proinflammatory cytokines.

Methods: An experimental study was performed in male Sprague-Dawley rats weighing 250-300 g. Six groups of animals with at least ten rats each were formed. Group control (C), group 5/6 nephrectomy (5/6Nx) and three groups 5/6 nephrectomy + pentoxifylline (5/6Nx + PTx) (10, 20, 40 mg / kg / day, p.o) and a group with administration of lipopolysaccharide (LPS) (1 mg / kg, i.m). At 8 weeks, were sacrificed and blood samples were taken and peritoneum. Creatinine (sCr), IL-1, IL-6, IL-10, TGF-β and TNF-a in plasma was measured. Peritoneal morphological changes were evaluated by light microscopy.

Results: Serum creatinine levels for group C was 0.41 mg / dL, and 5/6Nx groups was 1.1 mg / dL. The measurement of IL-1 showed a statistically significant difference ($p < 0.03$) between the groups that were given PTx and LPS group. For IL-6, a $p < 0.01$ was found between the groups and 5/6Nx + PTx 5/6Nx compared to group C. Light microscopy showed an increase in the morphological changes in mesothelial and LPS groups 5/6Nx regarding 5/6Nx + PTx C ($p < 0.001$) groups. Increased vascular damage was observed in the groups of LPS and 5/6Nx compared with C and 5/6Nx + PTx ($p < 0.002$) groups.

Conclusions: The data show that the administration of pentoxifylline inhibits peritoneal fibrosis in uremic rats.

Funding: Government Support - Non-U.S.

The Abnormal Expression of miRNA-21 Contributes to the Regulation of Paracrine Function in Cardiac Fibroblasts Xian Yang, Yiwen Li. *Nephrology, Zhejiang Provincial People's Hospital, Hangzhou, Zhejiang, China.*

Background: Cardiac fibroblasts are important not only to normal myocardial function, but also in the pathological cardiac remodeling such as after chronic renal failure (CRF). Cardiac fibroblasts can communicate with myocytes in autocrine, paracrine manner in response to injury. Our previous study dlucidated that a high levels of cytokines IL-1ß, IL-6, TNF-a, growth factors TGF-ß1, VEGFA, HGF and enhanced PI3/AKT, STAT5 and ERK/MAP kinase activities can be seen in CRF mouse model. Meanwhile, recent studies have found that the miRNA-21 of cardiac fibroblasts plays an important role in cardiac remodeling. However, the specific mechanism of miRNA-21 acting on cardiac fibroblasts is unknown.

Methods: Cardiac fibroblasts were separated from adult male mice. Normal medium and medium with indoxyl sulfate were used for the cardiac fibroblasts culture. Afterwards we silenced miRNA-21 level by transgecting siRNA. We observed the expression of cytokines IL-1ß, IL-6, TNF-a, growth factors TGF-ß1, VEGFA, HGF and intracellular signaling protein and miRNA-21 of cardiac fibroblasts before and after silencing miRNA-21 level separately.

Results: In cultured cardiac fibroblasts, uremia toxin indoxyl sulfate induced a higher expression of miRNA-21 accompanied with high levels of cytokines IL-1ß, IL-6, TNF-a, growth factors TGF-ß1, VEGFA, HGF. Meanwhile, it displayed enhanced PI3/AKT, STAT5 and ERK/MAP kinase activities. However, a reduced expression of IL-1ß, IL-6, TNF-a, growth factors TGF-ß1, VEGFA, HGF were observed after silencing miRNA-21. In company with it, the PI3/AKT, STAT5 and ERK/MAP kinase activities fell down.

Conclusions: The abnormal expression of miRNA-21 is involved in the pathological cardiac remodeling by regulating the paracrine manner of cardiac fibroblasts.

FR-PO665

The Inhibitive Effects of Enalapril on NLRP3 Inflammasome Activation and Tubulointerstitial Inflammation in Rats with BSA-Overload Nephropathy Lihong Ding, Dan Liu, Min Xu, Linli Lv, Kun Ling Ma, Bi-Cheng Liu. *Inst of Nephrology, Zhongda Hospital, Southeast Univ, Nanjing, Jiangsu, China.*

Background: Proteinuria is not only a common marker of renal disease, but also involved in tubulointerstitial inflammation and fibrosis. The reno-protective effects of angiotensin-converting enzyme inhibitors (ACEI) have been well demonstrated in both animal models and human being previously, which was regarded to delay the progression of renal failure. However, the exact mechanismsfor ACEI against renal failure have not been fully understood.

Methods: After unilateral right nephrectomy, Wistar rats were randomly treated with intraperitoneal injections of 0.9% saline (Control, n=8), BSA (BSA-overload, n=10), or BSA concurrently with intragastric administration of enalapril (Enalapril, n=10) for 9 weeks. The renal lesions were evaluated using histology and immunohistostaining. The NLRP3, caspase-1, IL-1b, and IL-18 expression were analyzed using immunohistostaining, RT-PCR, and Western blot.

Results: BSA-overloading resulted in marked proteinuria and interstitial inflammation with prominent macrophage and lymphocyte infiltration, particularly of B lymphocytes. We found that NLRP3, caspase-1, IL-1b and IL-18 expressed in proximal tubular epithelial cells

(TECs), and in inflammatory cells as well. Furthermore, BSA-overloading rats exhibited a significant increase in renal expression of NLRP3, caspase-1, IL-1b, and IL-18at mRNA and protein level, which was significantly attenuated in rats treated with enalapril.

Conclusions: Proteinuria induced NLRP3 inflammasomeexpression and tubulointerstitial inflammation, and enalapril exerted renoprotective effects possibly associated with thedownregulation of the NLRP3 inflammasome expression and tubulointerstitial inflammation.

FR-PO666

Prostaglandin E2 Modulates Proximal Tubule Cell (MCT) Responses via EP1 and EP4 Receptors Rania Nasrallah, Ramzi Hassouneh, Andrew J. Karam, Jean-Francois Thibodeau, Chris R. Kennedy, Richard L. Hebert. *Kidney Research Centre, Cellular and Molecular Medicine, Univ of Ottawa, Ottawa, ON, Canada.*

Background: Renal prostaglandin E_2 (PGE_2) regulates salt and water transport, and affects disease processes via four EP receptors ($EP_{1\text{-}4}$). PGE_2/EP pathways have been well studied in the glomerulus and distal nephron but very little is known about their role in the proximal tubule. We previously reported that PGE_2 inhibits growth, and increases sodium transporters, fibronectin, and ROS generation in mouse proximal tubule cells (MCT). This study characterizes the specific PGE_2/EP pathways involved.

Methods: First quantitative PCR for $EP_{1\text{-}4}$ and cyclooxygenases (COX-1, COX-2) was performed on total RNA isolated from MCT cells, fresh cultured mouse PT cells (cPT), as well as microdissected proximal tubule (PT), thick ascending limb (TAL) and cortical collecting duct (CD). Next, MCT cells were stimulated for 24 hours with 1 μM and 1 nM PGE_2 or sulprostone (SLP: $EP_{1/3}$ agonist) to study growth (H^3-thymidine and H^3-leucine incorporation), and Western blot expression of sodium potassium ATPase (NKAa1), p27, and fibronectin. To confirm the link to EP receptors, EP_1 and EP_4 were knocked down by siRNA-mediated transfection.

Results: COX-1, COX-2, EP_1 and EP_4 mRNA were detected in all preparations. EP_2 and EP_3 were undetectable in MCT cells, but were expressed in PT and cPT. PGE_2 and SLP reduced H^3-thymidine by 50% and H^3-leucine incorporation by 25-50%. Also, PGE_2 but not SLPincreased immunodetectable p27 by 2-fold, an effect attenuated by EP_4 siRNA. PGE_2 also increased NKAa1 by 2.2-fold and this response was abrogated by EP_4 siRNA. Fibronectin was increased by PGE_2 1.7-fold and EP_1 siRNA decreased the response.

Conclusions: In summary, COX-1, COX-2, and all four EP receptors are detectable in the proximal tubule, but only EP_1 and EP_4 are expressed in MCT. PGE_2 and SLP inhibit growth in MCT cells, but SLP had no effect on p27 levels or NKAa1. PGE_2 increases p27 and NKAa1 via EP_4 in MCT cells, and stimulates fibronectin in MCT cells via EP_1 receptors. EP_1 and EP_4 receptors may prove to be important targets for the management of kidney disease.

Funding: Government Support - Non-U.S.

FR-PO667

Prostaglandin E2 EP3 Receptor Regulates Glomerular Filtration Rate and Urine Output in C57BL/6 Mice Ramzi Hassouneh, Rania Nasrallah, Richard L. Hebert. *Kidney Research Centre, Cellular and Molecular Medicine, Univ of Ottawa, Ottawa, ON, Canada.*

Background: Prostaglandin E_2 exerts diverse functions within the kidney through its four receptors: $EP_{1\text{-}4}$. Renal EP_3 is present in the collecting duct (CD), thick ascending limb, and afferent arteriole. This study explores the physiological role of EP_3 in water and salt handling and glomerular filtration rate (GFR).

Methods: Global $EP_3^{-/-}$ were age (8 wks) and sex matched (male) to wild-type C57BL/6 mice (WT). GFR was estimated by FITC-inulin clearance. Blood pressure was measured using tail-cuff plethysmography. 24-hr urine was collected using metabolic cages and a urinalysis was performed. Blood was collected and plasma analytes were measured. M-1 mouse cortical CD cells were cultured to confluency and stimulated for 4 to 24 hrs in serum-free media using sulprostone (SLP) (EP_3/EP_1 agonist; 0.1nM-1mM) and/or L-798106 (EP_3 antagonist; 10nM-1mM). Protein expression of salt and water channels was quantified by Western blotting. $EP_{1\text{-}4}$ mRNA was quantified using quantitative PCR (qPCR).

Results: The *in vivo* findings are summarized in Table 1. In M-1 cells, aquaporin-2 (AQP2) and a-epithelial Na^+ channel (a-ENaC) were down-regulated by SLP up to 60% and 50%, respectively, and L-798106 reversed this effect. Na^+/K^+ ATPase-a1 was up-regulated up to 70% by SLP, however this effect was unchanged with L-798106. Na^+/K^+ ATPase-b1 and Na^+/H^+ exchanger-1 were unchanged with SLP. qPCR revealed the presence of EP_1, EP_3, and EP_4 in M-1 cells, but no EP_2.

Table 1. Physiological parameters of $EP_3^{-/-}$ and WT mice.

	WT		$EP_3^{-/-}$	
GFR (μL/min/g body wt.)	9.5 ± 0.6		5.85 ± 0.8*	
Blood Pressure (mmHg)	110.9 ± 9/ 75.8 ± 6		111.2 ± 4/ 88.1 ± 4	
Body Weight (g)	21.0 ± 0.5		24.8 ± 0.4*	
Serum Potassium (mM)	7.98 ± 0.3		5.78 ± 0.3*	
Urine Volume (μL/24hr)	429 ± 0.05		979 ± 0.08*	
Urine Osmolality (mOsm/kg)	2470 ± 200		2280 ± 100	
Urinalysis				
	mmol/24hr	*mM*	*mmol/24hr*	*mM*
Sodium	58.5 ± 8	135 ± 8	106 ± 9*	133 ± 5
Potassium	80.1 ± 10	173 ± 7	188 ± 20*	237 ± 10*
Glucose	0.99 ± 0.5	2.1 ± 0.9	3.99 ± 0.6*	5.4 ± 1

Data expressed as means ± SEM; *P< 0.01 using unpaired t-test versus WT; n ≥ 5.

Conclusions: $EP_3^{-/-}$ mice show reduced GFR, increased urine volume, and increased urine output of sodium and potassium compared to WT suggesting an *in vivo* role for EP_3 in transport responses and tubuloglomerular feedback. The data also suggest that EP_3 regulates the expression of AQP2 and a-ENaC in M-1 cells. Further work is needed to ascertain the exact mechanisms responsible for these changes.

FR-PO668

Antagonism of the Prostaglandin E_2 EP1 Receptor in MDCK Cells Increases Growth through Activation of Akt and the Epidermal Growth Factor Receptor Mary L. Taub. *Biochemistry, Univ at Buffalo, Buffalo, NY.*

Background: Prostaglandin E_2 (PGE_2) stimulates the growth of kidney epithelial cells, and for this reason has been proposed to play a role in cystogenesis in polycystic kidney disease. In this report, the involvement of the G-protein coupled E-prostanoid (EP) receptors in mediating the growth stimulatory effects of PGE_2 are examined. Included amongst the receptors are EP2 and EP4, which activate adenylate cyclase (AC), and EP1, that activates PLC.

Methods: Growth studies, Western blots and genetics were conducted to examine the role of individual EP receptors in controlling MDCK cell growth.

Results: The results indicate that EP2 and EP4 contribute to the growth stimulatory effect of PGE_2, unlike EP1, which is growth inhibitory. Indeed, the EP1 antagonists ONO-8711 and SC51089 increase, rather than inhibit MDCK cell growth. Similarly, ONO-8711 stimulates the growth of the M1 mouse collecting duct cell line, and primary rabbit kidney proximal tubule cells. Consistent with the involvement of EP1 in mediating these effects, the growth stimulatory effects of ONO-8711 and SC51089 are lost in MDCK cells with an EP1 knockdown. The growth stimulatory effects of ONO-8711 and SC51089 are observed in the absence of exogenous PGE_2. This latter effect is prevented by the cyclooxygenase inhibitor ibuprofen, indicating a dependence upon endogenous PGE_2 (and EP1 mediated growth inhibition). Consistent with the hypothesis that EP1 activation inhibits Akt signaling, is the observation that 1) ONO-8711 and SC51089 increase Akt phosphorylation, and 2) MK2206, an Akt inhibitor, prevents the increased growth caused by EP1 antagonists. In addition, 1) SC51089 increases the phosphorylation of the EGF Receptor (EGFR), and 2) AG1478, an inhibitor of the EGFR kinase, inhibits the growth stimulatory effects of ONO-8711 and SC51089.

Conclusions: These results suggest that EP1 receptor antagonism alters EGFR signaling. Consistent with this hypothesis, growth stimulation by ONO-8711 is lost following an EGFR knockdown, and the expression of a dominant negative EGFR. Conversely, EP1 receptor activation would be expected to inhibit EGFR signaling, and thus alter cystogenesis in polycystic kidney disease.

Differential Regulation of Inflammation in Human Fluids. A Pilot Study on Patients with Kidney Failure on Dialysis Liliana Monica Bivol, Carl Erik Halvorsen, Rudiger Ganss, Torbjorn Omland, Helge Rosjo. *Medical Dept, Nephrology Div, Akershus Univ Hospital, Lorenskog, Norway.*

Background: Inflammatory mediators (IM) in fluids other than blood and urine from patients ongoing dialysis have not been previously investigated. The aim was to assess inflammation in human fluids (blood, urine, saliva, dialysis fluid) from patients with stage 5 kidney failure versus healthy volunteers.

Methods: Samples from 11 patients ongoing dialysis, and 5 healthy controls were analysed for 7 IM. Multiplex-Luminex detection (MultiELISA, flowcytometry) was used. The results are given in pg/ml. Concentration in the background samples was 0.

Results: Results are shown in the table.

CONTROLS	IL1b	IL6	IL8	MCP1	TGFa	HGF	NGF
Blood	21	26	148	539	67	196	30
Urine	12	40	73	457	57	192	29
Saliva	70	150	727	1295	159	237	16
HD							
Blood	21	53 *	680 *	2648 *	233 *	2999 *	48
Urine	51 *	387 *	11049 *	12944 *	614 *	544 *	311 *
Saliva	638 *	106	15258 *	13472 *	93	472 *	207 *
Dialysis Fluid	10	20	40	226	35	13	12

Urine	21	1097 *	11330 *	22200 *	3156 *	1745 *	446 *
Saliva	51	234 *	725	14216 *	46	263 *	171 *
Dialysis Fluid	12	841 **	231 **	4708 **	72 **	302 **	38 **

Table Mean concentration (pg/ml) of Inflammation mediators in human fluids. * p<0.05 compare to controls; ** PD compare with HD fluid

Conclusions: 1. All IM were present in human fluids from volunteers, GFR>105. IL8, MCP1 and HGF were most elevated (<4% of highest detection level) and may play an essential role in renal activation of IM. 2. In dialysis patients, only IL8, MCP1, TGFa, HGF, and IL6 were raised systemic, while in urine all markers were increased, showing higher IM activation renal then systemic. Urine IL6, IL8, MCP1,TGFa and HGF from PD were much higher then in HD patients suggesting differential IM modulation. 3. All inflammation markers were raised in PD versus HD fluid, suggesting that PD activates

local IM, but also that dialysis mode could lead to different regulation pathways in these patients. 4. Almost all markers were elevated in saliva from dialysis patients suggesting that saliva is an important excretion way.

FR-PO670

Rictor-PDCD4 Interaction Controlled by microRNA-21 Contributes to Renal Cancer Cell Invasion Amit Bera,[1] Falguni Das,[1] Nandini Ghosh-Choudhury,[2] Balakuntalam S. Kasinath,[1] Hanna E. Abboud,[1] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA, San Antonio, TX.*

Background: Oncogenic forces contribute to renal cancer metastasis. Recently, we have identified miR-21 as the oncogenic driver for renal carcinogenesis. However, the mechanism by which miR-21 contributes to metastasis is not known.

Methods: VHL positive and negative renal cancer cells (RCCs) were used.

Results: Increased levels of miR-21 decreased the proapoptotic protein PDCD4 in RCCs. Inhibition of endogenous miR-21 by miR-21 Sponge abrogated RCC migration and invasion, which were restored by siRNAs against PDCD4. Expression of PDCD4 and miR-21 Sponge significantly inhibited phosphorylation of Akt and IKKbeta (IKKb), which regulates NFkappaB-dependent transcription of invasive genes. siPDCD4 prevented miR-21 Sponge-induced suppression of Akt and IKKb phosphorylation. Interestingly, PDCD4 blocked activation of the pro-metastaic kinase mTORC1, which was prevented by constitutively active (CA) IKKb. PDCD4- as well as miR-21 Sponge-induced inhibition of migration and invasion of RCCs was prevented by CA Akt, IKKb and mTORC1. These results suggest that PDCD4 regulates Akt upstream of IKKb to activate mTORC1. mTORC2 is required for full activation of Akt. Importantly, we found that rictor, the exclusive component of mTORC2, formed complex with PDCD4 and this complex formation was significantly elevated in normal proximal tubular epithelial cells than in RCCs due to increased expression of miR-21 and subsequent decrease in PDCD4 in the latter. Finally, we show that increased mTORC2 activity is necessary for mTORC1 activation in RCCs.

Conclusions: Together our results demonstrate a prometastatic function of miR-21 for RCC. We identified a previously unrecognized signaling conduit involving miR-21 to reduce PDCD4-Rictor association, resulting in activation of Akt, IKKb and mTORC1.

Functional TRPV1 and TRPV4 Channels Along Different Segments of the Renal Vasculature Lan Chen,[1] Mario Kassmann,[2] Lajos Marko, Dmitry Tsvetkov, Andreas Patzak, Wolfgang Liedtke, Martin Tepel, Maik Gollasch. *[1]Xiamen Zhongshan Hospital, Xiamen Univ; [2]Experimental and Clinical Research Center (ECRC), a joint cooperation between the Charité Medical Faculty and the Max Delbrück Center for Molecular Medicine (MDC).*

Background: Transient receptor potential vanilloid 1 (TRPV1) and vanilloid 4 (TRPV4) cation channels have been recently identified to promote endothelium-dependent relaxation of mouse mesenteric arteries. However, the role TRPV1 and TRPV4 in the renal vasculature is largely unknown. We hypothesized that TRPV1/4 play a role in endothelium-dependent vasodilation of renal blood vessels.

Methods: We studied the distribution offunctional TRPV1/4 along different segments of the renal vasculature. Mesenteric arteries were studied as control vessels.

Results: The TRPV1 agonist capsaicin relaxed mouse mesenteric arteries with an EC_{50} of 9 nM, but not large mouse renal arteries or rat descending vasa recta (EC_{50} >10 μM). This relaxation was endothelium-dependent and absent in vessels of *Trpv1* -/- mice. The TRPV4 agonist GSK1016790A relaxed large conducting renal arteries, mesenteric arteries and vasa recta with EC_{50} of 15 nM, 50 nM and ~10 nM, respectively. These effects were endothelium-dependent and inhibited by a TRPV4 antagonist, AB159908 (10 mM). Capsaicin and GSK1016790A produced vascular dilation in isolated mouse perfused kidneys with EC_{50} of 12 nM and 2 nM, respectively. The capsaicin effects were absent in perfused kidneys of *Trpv1* -/- mice, whereas the effects of GSK1016790A were absent in *Trpv4* -/- kidneys, but present in *Trpv1* -/- kidneys.

Conclusions: Our results demonstrate that two TRPV channels have unique sites of vasoregulatory function in the kidney with functional TRPV1 having a narrow, discrete distribution in the resistance vasculature and TRPV4 having more universal, widespread distribution along different vascular segments. We suggest that TRPV1/4 channels are potent therapeutic targets for site-specific vasodilation in the kidney.

Stretch–Activation of Angiotensin II Type 1a Receptors Contributes to the Myogenic Response of Mouse Mesenteric and Renal Arteries Maik Gollasch,[1] Johanna Schleifenbaum,[1] Mario Kassmann,[1] Istvan Andras Szijarto,[1] Hantz C. Hercule,[1] Michael Bader.[2] *[1]Nephrology/Intensive Care and ECRC, Charité Univ Medicine, Berlin, Germany; [2]Max Delbrück Center for Molecular Medicine, MDC, Berlin, Germany; [3]Max Delbrück Center for Molecular Medicine, MDC and FMP, Berlin, Germany.*

Background: Vascular wall stretch is the major stimulus for the myogenic response of small arteries to pressure. The molecular mechanisms are elusive, but recent findings suggest that G protein–coupled receptors can elicit a stretch response. Aims: To determine whether angiotensin II type 1 receptors (AT_1R) in vascular smooth muscle cells exert mechanosensitivity and identify the downstream ion channel mediators of myogenic vasoconstriction.

Methods: We used mice deficient in AT_1R signaling molecules and putative ion channel targets, namely AT_1R, angiotensinogen, TRPC6 channels, or several subtypes of the voltage-gated K^+ (K_v7) gene family (KCNQ3, 4, or 5).

Results: We identified a mechanosensing mechanism in isolated mesenteric arteries and in the renal circulation that relies on coupling of the AT_1R subtype a to a $G_{q/11}$ protein as a critical event to accomplish the myogenic response. Arterial mechanoactivation occurs after pharmacological block of AT_1R and in the absence of angiotensinogen or TRPC6 channels. Activation of AT_1R subtype a by osmotically induced membrane stretch suppresses an XE991-sensitive K_v channel current in patch-clamped vascular smooth muscle cells, and similar concentrations of XE991 enhance mesenteric and renal myogenic tone. Although XE991-sensitive KCNQ3, 4, and 5 channels are expressed in vascular smooth muscle cells, XE991-sensitive K^+ current and myogenic contractions persist in arteries deficient in these channels.

Conclusions: Our results provide definitive evidence that myogenic responses of mouse mesenteric and renal arteries rely on ligand-independent, mechanoactivation of AT_1R subtype a. The AT_1R subtype a signal relies on an ion channel distinct from TRPC6 or KCNQ3, 4, or 5 to enact vascular smooth muscle cell activation and elevated vascular resistance.

Para-Cresyl Sulfate Impairs Vascular Reactivity and Induces Vascular Remodeling Priscilla Gross,[1] Ziad Massy,[1,2] Lucie Henaut,[1] Cedric Boudot,[1] Tilman B. Drueke,[1] Said Kamel,[1] Isabelle Six.[1] *[1]Jules Verne Univ of Picardie, INSERM Unit 1088, Amiens, France; [2]Chief, Div of Nephrology, Ambroise Paré Hospital, Paris-Ile-de-France-Ouest Univ (UVSQ), Paris, France.*

Background: Vascular dysfunction, by contributing to vascular remodeling, is an important non-traditional cardiovascular (CV) risk factor in chronic kidney disease (CKD). Recent data suggest that uremic toxins may contribute to vascular dysfunction in CKD. Para-cresyl sulfate (PCS), a newly identified uremic toxin, has been associated with the progression of CKD and with CV mortality in this population. Based on its reported vascular pro-inflammatory effects in vitro, we aimed here to asses if PCS induces ex vivo vascular dysfunction and remodeling.

Methods: We studied the effect of PCS on vascular reactivity and remodeling using intact and endothelium-denuded thoracic aorta from C57Bl/6J mice aged 8 weeks. In parralel, we measured the effect of PCS on reactive oxygen species (ROS) production using human vascular smooth muscles cells (VSMCs) and endothelial cells (ECs). The mechanisms of action of PCS were explored using pharmacological inhibitors and western blot technics.

Results: Ex vivo, PCS significantly potentiates phenylephrine-induced contraction in both intact and endothelium-denuded thoracic aorta. Long-term exposure of aorta induces vascular remodeling characterized by a reduction of the surface area of both lumen and media, with no change in media/lumen ratio. In vitro, PCS acutely increases ROS production in both VSMCs and ECs. The pro-contacting effect of PCS is maintained in presence of dimethylthiourea, a ROS scavenger, but totally abolished by Y-27632, a rho-kinase inhibitor. MYPT-1 is a well-known target of rho-kinase. Its phosphorylation increases vascular contraction. Western blot analysis reveals that treatment of VSMCs with PCS leads to MYPT-1 phosphorylation on Threonine-853.

Conclusions: This is the first study which shows noxious effect of PCS on vascular function through rho-kinase activation, leading to vascular remodeling. The vascular effects of PCS could contribute, at least in part, to the CV changes observed in CKD.

Exploring the Nexus of Angiopoietin-Tie2 Signaling by Mass-Spectrometry for Establishing Therapeutic Strategies for Diabetic Nephropathy Tomokazu Souma, Jing Jin, Susan E. Quaggin. *Div of Nephrology, Feinberg Cardiovascular Research Inst, Feinberg School of Medicine, Northwestern Univ, Chicago, IL.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease in the U.S. It is characterized by microvascular dysfunction and endothelial instability, *i.e.*, loss of quiescence. Angiopoietin-Tie2 signaling is a major pathway for maintaining endothelial quiescence and survival. Podocytes and mesangial cells express Angiopoietin 1 (Angpt1), a major agonist of Tie2, and is vasculo-protective during diabetes. Angpt 1 binds the Tie2 tyrosine kinase receptor and induces multi-site tyrosine phosphorylation. Although the general functions of Tie2 are well-characterized, the exact phosphorylation sites in response to the various ligands have not been defined, and phosphorylation-site specific functions with regard to *in vivo* endothelial stability are still unclear.

Methods: To identify the phosphorylation sites and characterize signaling cascades for DN phenotypes, we performed phospho-mapping analysis of the Tie1 and Tie2 receptors. We generated flag-tagged full-length Tie1/2, and point mutation variants for kinase dead controls and constitutively active mutants found in vascular malformations in patients. Phosphorylation status of these proteins were analyzed by LC-tandem mass spectrometry. In parallel, we analyzed endogenously isolated Tie2 from the mouse lung to study the effects of a small molecule Tie2 activator (AKB-9785, a gift from Aerpio) on phosphorylation.

Results: We identified five phospho-tyrosine residues, which include 2 novel sites in the juxtamembrane region and the kinase domain, within the intracellular region of Tie2.

By comparison, there is very low baseline phosphorylation of Tie1. Studies to determine interdependence of Tie2 and Tie1 and a pilot study for testing effects of the Tie2 activator on a DN model are underway.

Conclusions: Our mapping results provide a roadmap for the phosphorylation status of Tie2. These data help to delineate the various *in vivo* functions of the receptor for a better understanding of Angpt-Tie signaling, which will aid in the rational design of a targeted therapy to treat microvascular manifestations of DN.

FR-PO675

Exploiting Tie2 Activation to Treat Glomerular Leak Isabel Anna Carota,[1] Chengjin Li,[2] Vera Eremina,[2] Tuncer Onay,[1] Susan E. Quaggin.[1] *[1]Feinberg Cardiovascular Research Inst, Div of Nephrology, Northwestern Univ, Chicago, IL; [2]Samuel Lunenfeld Research Inst, Mount Sinai Hospital, Toronto, Canada.*

Background: Pathologic angiogenesis and microvascular leak play a central role in the development of renal diseases. The Angiopoietin (Angpt)-Tie pathway is critical for the regulation of microvascular permeability and endothelial quiescence. Dysregulation of this pathway is associated with adverse outcomes in vascular diseases, including diabetic nephropathy. Indeed, the induction of diabetes in Angpt1-knockout mice leads to rapid glomerular scarring and renal failure. We hypothesize that loss of Tie-2 activation is a crucial step in the development of glomerular vascular leak under diabetic conditions where its activity is negatively regulated by the vascular endothelial specific tyrosine phosphatase VE-PTP. We hypothesize that restoration of Tie-2 signaling by deletion of VE-PTP is preventive.

Methods: To determine the therapeutic potential of VE-PTP we have examined its expression and function in vivo by studying a VE-PTP-lacZ reporter mouse line and by generating a conditional VE-PTP knockout mouse line.

Results: While VE-PTP is expressed in all blood endothelia, we found highest expression of VE-PTP in specialized microvascular beds including the glomerular capillaries and retinal choriocapillaris, suggesting a possible role in maintenance of fenestrated vascular beds. Additionally we have examined a conditional VE-PTP knockout mouse line, as the conventional knockout of the VE-PTP gene in mice causes embryonic lethality by E10. Mice with global excision of VE-PTP induced from E12.5 onwards are viable and grow to adulthood. By contrast, timed deletion of VE-PTP between E0 and E11.5 leads to embryonic lethality, confirming that VE-PTP is crucial for vascular development and validating our floxed line.

Conclusions: Normalizing Tie-2 activity by targeted inhibition of VE-PTP is an attractive approach to prevent glomerular microvascular leak as it occurs in diabetes. The lack of vascular defects associated with late deletion of VE-PTP suggests that VE-PTP is an ideal therapeutic target for the treatment of vascular complications in renal diseases such as diabetic nephropathy.

FR-PO676

Potential Role of Perivascular Lymphatic Vessels in Preservation of Allograft Function in Kidney Transplant Patients Akihiro Tsuchimoto,[1] Toshiaki Nakano,[1] Shoko Hasegawa,[1] Kosuke Masutani,[1] Hidehisa Kitada,[2] Kazuhiko Tsuruya,[1,3] Takanari Kitazono.[1] *[1]Medicine and Clinical Science, Graduated School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Surgery and Oncology, Graduated School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Intergrated Therapy for Chronic Kidney Disease, Graduated School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Lymphangiogenesis is often observed in both diseased native kidney and kidney allograft, and correlates with interstitial inflammation. However, there is little information about the clinical significance of lymphatic vessels in kidney transplant patients.

Methods: In this retrospective study, we reviewed 81 kidney transplant patients, who underwent both 3- and 12-month protocol biopsies (PBs). We identified lymphatic vessels by immunohistochemical staining for podoplanin and counted the number of them separately according to their location; perivascular lymphatic vessels (P-Lym) locating around interlobular arteries or veins, and interstitial lymphatic vessels (I-Lym) locating in the interstitium. We analyzed the association between the each lymph vessel density and the kidney graft function.

Results: The densities of P-lym at 3- and 12-month PBs were not different, whereas the densities of I-Lym increased with time; median (interquartile range) densities were 1.7 (0.9-3.1) /mm^2 and 2.6 (1.2-5.1) /mm^2 at 3- and 12-month PBs, respectively (P=0.003). Higher density of P-lym at 3 months was associated with milder IF/TA at 12-month PB (P for trend=0.044), lower decline rate in estimated glomerular filtration rate (eGFR) from 12 to 24 months (r=-0.26, P=0.022), and higher eGFR at 24 months (r=0.29, P=0.010).The favorable associations were still significant even after adjustment for multiple confounders.

Conclusions: Higher density of P-Lym is associated with favorable kidney graft function. Pre-existing lymphatic network may play a role in the inhibition of allograft fibrosis and stabilization of graft function.

FR-PO677

Proteinuria Severity Is Directly Correlated with *Ex Vivo* and *In Vivo* Markers of Thrombotic Capacity in Two Experimental Models of Nephrotic Syndrome Amanda P. Waller,[1] Ruchika Sharma,[1] Melinda A. Chanley,[1] Marvin T. Nieman,[2] William E. Smoyer,[1] Bryce Kerlin.[1] *[1]Clinical & Translational Research, Research Inst at Nationwide Children's, Columbus, OH; [2]Pharmacology, Case Western Reserve Univ, Cleveland, OH.*

Background: Nephrotic syndrome (NS) is characterized by glomerular injury and massive urine protein loss which leads to severe blood coagulation derangements and a high prevalence of life-threatening thrombotic complications. Proteinuria has been epidemiologically linked to thrombotic risk, thus we hypothesized that proteinuria severity is directly correlated with hypercoagulopathy.

Methods: Using puromycin aminonucleoside (PAN) and adriamycin (ADR) induced nephrosis models, we compared established markers of thrombin generation (ETP) and global hemostasis (ROTEM) in blood of male Wistar rats (6/grp) exhibiting a range of proteinuria levels (morning urine [protein:creatinine]). To further delineate the *in vivo* significance of the relationship between proteinuria severity and thrombin activation, IVC ligation was performed in NS and sham rats.

Results: A significant correlation between proteinuria severity and clinically relevant markers such as ETP (R^2=0.845, R^2=0.907; P<0.001), clot formation time (R^2=0.568, R^2=0.377; P<0.001), viscoelastic strength (R^2=0.604;P<0.001, R^2=0.390;P=0.03) and lysis at 60 min (R^2=0.738, R^2=0.638; P<0.001) was present in both the PAN and ADR rat models, respectively. Plasma thrombin/antithrombin complex [TAT] did not change with worsening proteinuria, suggesting that massive proteinuria alone is not sufficient to activate coagulation *in vivo*. In contrast, when an active thrombotic episode was induced by IVC ligation, proteinuric rats exhibited higher plasma [TAT] (P=0.022), which ultimately translated into greater thrombus formation (P=0.019).

Conclusions: These data confirm that proteinuria severity is directly proportional to hypercoagulability in two well-established animal models of NS, as assessed by ex vivo thrombin generation and global hemostasis and by an in vivo thrombosis model. The physiologic relevance of this relationship provides key evidence to further investigate proteinuria as a biomarker for thrombotic risk in persons with NS.

Sirtuin 1 Ablation in Endothelial Cells Is Associated with Impaired Angiogenesis and Diastolic Dysfunction Julien Maizel,[1,3] Sandhya Xavier,[3] Jun Chen,[3] Chi Hua Sarah Lin,[3] Radovan Vasko,[2,3] Michael S. Goligorsky.[3] *[1]Univ of Picardie, Amiens, France; [2]Univ Medical Center, Gottingen, Germany; [3]New York Medical College.*

Background: The disruption of coordinated myocardial growth and angiogenesis can explain that left ventricular hypertrophy progress toward heart failure with aging. Sirtuin 1 expression (an angiogenesis regulating factor) declines with age, therefore we explored the role played by angiogenesis and Sirtuin 1 in the development of cardiomyopathy.

Methods: We performed transthoracic echocardiographic analyses to compare the cardiac function of 10-15 weeks old (wo), 30-40 wo and 61-70 wo endothelial Sirtuin 1-deleted (Sirt1$^{endo-/-}$) mice and their corresponding knockout-controls (Sirt1$^{Flox/Flox}$).

Results: After 30-40 weeks of age, the Sirt1$^{endo-/-}$ animals presented with a diastolic dysfunction, showed a decreased mRNA expression of Serca2a in the left ventricle (LV) and a decreased capillary density compared to the controls animals, despite a similar VEGFa mRNA expression. However the LV fibrosis and the HIF1a expression were not different between Sirt1$^{endo-/-}$ and control mice. The creation of left ventricular overload - a transverse aortic constriction (TAC)- provoked a more severe diastolic dysfunction and LV fibrosis in the Sirt1$^{endo-/-}$ TAC compared to the control TAC animals. Although the VEGFa mRNA expression was not different and the protein expression of HIF1a was higher in the Sirt1$^{endo-/-}$ TAC, the capillary density remained lower in the Sirt1$^{endo-/-}$ TAC. In human umbilical vascular endothelial cells the administration of Sirtuin 1 inhibitor decreased the mRNA expression of VEGF receptors FLT 1 and FLK 1. The ex-vivo capillary sprouting from aortic explants confirmed the impaired angiogenic response to VEGF in the Sirt1$^{endo-/-}$ mice.

Conclusions: The data model demonstrates the impaired ability of endothelial cells deficient in Sirtuin 1 to create new vessels and adapt to a challenging condition, like hypertension, leading to the development of diastolic dysfunction.

Lithium Acts at Contractile Pericytes to Alter Vasa Recta Diameter: Novel Mechanism for Drug-Induced Nephrotoxicity Gary D. Mabbutt, Scott S.P. Wildman, Carol Crawford, Claire M. Peppiatt-Wildman. *Medway School of Pharmacy, Univs of Kent and Greenwich, Kent, United Kingdom.*

Background: Lithium is a widely used medication for the treatment of mental illnesses including manic depression and bipolar disorder. Its long-term use is known to have adverse effects on the kidney and can lead to acquired nephrogenic diabetes, tubular interstitial fibrosis as well as chronic kidney disease [1]. The precise cellular mechanism that precede clinical manifestations are however poorly understood. Previous studies have highlighted a key role for pericyte cells in the regulation of blood flow in the renal medulla, via control of vessel diameter [2]; and dysregulation of medullary blood flow has been shown to contribute to both acute and chronic kidney disease.

Methods: Utilizing a 'rat live kidney slice model' in combination with advanced imaging techniques [2], 'real-time' pericyte-mediated changes in vessel diameter were investigated in response to lithium compounds superfused at therapeutic concentrations.

Results: Data suggest that lithium chloride and lithium citrate [both 1 mM] caused a significantly greater constriction of vasa recta capillaries at pericyte sites (5.6±0.2% and 9.5±1.5% respectively) compared with non-pericyte sites (0.1±0.8%, n=4 and 0.6±0.2%, n=4 respectively; $p<0.01$). Similarly, lithium carbonate [0.1mM] significantly decreased vasa recta diameter by 8.2±0.8% compared with 2.0±0.7% at non-pericyte sites, (n=8, $p<0.001$).

Conclusions: These data indicate that contractile pericytes might represent a novel locus for lithium-induced nephrotoxicity, whether this is as a primary mechanism or secondary to tubular injury requires further delineation. [1] Kishore BKand Ecelbarger CM. (2013) Am J Physiol Renal Physiol 304: F1139–F1149. [2] Crawford, C., et al. (2012) Nephron Physiology, 120 (3), p17-p31.

FR-PO680

Protective Role of IGF-1R in Endothelial Cells against UUO-Induced Renal Fibrosis Ming Liang,[1] Lauren Elizabeth Woodard,[2] Jinlong Luo,[1] Matthew H. Wilson,[2] William E. Mitch,[1] Jizhong Cheng.[1] *[1]Medicine, Baylor College of Medicine, Houston, TX; [2]Medicine, Vanderbilt Univ, Nashiville, TN.*

Background: The regulation of endothelial cell contact is of central importance for the barrier function of the blood vessel wall. Activated IGF-1 receptor (IGF-1R) can regulate vascular homeostasis and endothelial function.

Methods: Unilateral ureteral obstruction (UUO) was performed in wild type (WT) and in mice with KO or overexpression of IGF-1R specifically in ECs. HUVECs were used to study the mechanisms.

Results: IGF-1R expression was decreased in obstructed kidney after UUO. To assess the role of IGF-1R in endothelial barrier function, we utilized mice with IGF-1R knockout specifically in ECs (IGF-1R EC/KO). After creating UUO in EC-specific IGF-1R KO mice, there was more severe dysfunction of the endothelial barrier by increased inflammatory cell infiltration, leakage of Evans blue dye into the renal interstitium, and increased VE-cadherin phosphorylation when compared to results of WT mice. UUO in IGF-1R EC/KO mice increased the interstitial expression of fibroblast markers and enhanced extracellular protein deposition *versus* results in WT mice. Transendothelial migration in response to hydrogen peroxide (H2O2) was impaired in cultured ECs. Exposure of HUVECs to H2O2 induced phosphorylation of VE-cadherin. In contrast, silencing IGF-1R with small interference RNA enhanced the influence of H2O2 in disrupting the VE-PTP-VE-cadherin interaction. H2O2-induced endothelial barrier dysfunction was suppressed by overexpression of IGF1R. Furthermore, using the PiggBac transposon gene transfer system, we expressed IGF1R in vascular ECs. These mice experienced amelioration of UUO-induced damage, resulting in attenuation of the interstitial expression of SMA-a and collagen I. The expression of IGF1R in ECs also suppressed the inflammatory cells infiltration and renal fibrosis induced by UUO.

Conclusions: Our results indicate that IGF-1R in the endothelium maintains the endothelial barrier function by stabilization of the VEPTP-VE-cadherin complex. Expression of the IGF-1R affects endothelial cell function and the development of chronic kidney disease.

Funding: NIDDK Support

Foxp3$^+$ Regulatory T Cells Differentiate into IL-17$^+$ T Cells, Contributing to Renal Fibrosis Ching-Yuang Lin. *Div. of Pediatric Nephrology, China Medical Univ Hospital, Taichung, Taiwan.*

Background: CD4$^+$ T cells play a key role in renal fibrosis; which subset looms critical remains unclear. Effector T cell linage shows great plasticity. CD4$^+$ FoxP3$^+$ Treg cells might convert to inflammation-associated Th17 cells that have tissue-fibrotic properties not yet clarified.This study evaluates roles of Treg and differentiation of Treg into Th17 cell contributing to chronic inflammation and renal fibrosis in unilateral ureteral obstruction (UUO) mouse model.

Methods: Study groups included control and UUO for 7, 14, or 21 days.

Results: JG hyperplasia, AT1R expression and lymphocyte infiltration arose in renal tissue after UUO. CD4$^+$FoxP3$^+$T cells increased progressively with presence of FoxP3$^+$IL17$^+$ T cells on Day 14 and then progressively decreased with increasing CD4$^+$IL17$^+$, as verified by double immunostaining in UUO kidney. Progressive renal fibrosis was associated with loss of CD4$^+$FoxP3$^+$IL17$^+$ T cells in splenic single-cell suspension. TGF-β1 mRNA expression positively correlated with IL-17 mRNA level in ligated kidney.FoxP3$^+$IL17$^+$ T cell was generated *in vitro* from CD4$^+$FoxP3$^+$Treg cells with UUO. Trichostatin A induced up-regulation of FoxP3 and down-regulation of RORgt mRNA expression.

Conclusions: Treg cells differentiate into Th17 cells in renal tissue under JG hyperplasia of UUO operation. Th17 cells positively correlate with TGF-β mRNA expression and fibrosis in UUO kidney. TSA had profound negative effect on emergence of Th17 cell from Treg. Data suggest epigenetic modification underlying this phenomenon; such a feature of Treg plasticity can facilitate anti-fibrotic strategy in chronic kidney disease.

FR-PO682

PPARg-Regulated NRF2 Expression Is Protecting from Crescentic Glomerulonephritis. Unexpected Potential Therapy Carole Hénique, Pierre-Louis Tharaux. *Paris Cardiovascular Centre - PARCC, INSERM, Paris, France.*

Background: The nuclear receptor peroxisome proliferator-activated receptor gamma (PPARg) agonists have beneficial effects on renal structure and function in models of diabetes and chronic kidney diseases. However the role of PPARg in acute or subacute model of severe glomerular diseases is unknown. Hypothesizing that podocyte ability to maintain energy supply and defense against reactive oxygen species may help cope with severe immune-mediated insult, we have explored the involvement of podocyte PPARg in crescentic rapidly progressive glomerulonephritis (RPGN).

Methods: RPGN was induced by injection of anti–glomerular basement membrane antiserum (NTS). A gain of function approach was used with administration of Pioglitazone, a PPARg agonist to nephritic mice. We generated mice with specific deletion of *Ppar-gamma* alleles in podocytes (Pod-PPARg mice) for loss of function approaches.

Results: Gain-of-function approach: Pioglitazone, a PPARg agonist, limited renal injury in RPGN. Pioglitazone ameliorated podocyte damage and reduced proteinuria. Pioglitazone administration was effective when performed from the first day of NTS injection or when started in a delayed manner (4 days after NTS injection). Pod-PPARg mice developed more severe glomerular injury and RPGN upon NTS administration. Pod-PPARg mice displayed a 2-fold increase in Albuminuria to Creatinuria ratio at day 10 (2843 +/- 329 versus 1664 +/- 207 g/mol, $p<0.001$) than wild-type mice and higher crescent incidence (35.6 +/- 5.4 versus 15.6 +/- 3.7 %, $p<0.01$). Accordingly, PPARg deletion in podocytes promoted worsening of BUN levels (119.9 +/- 11.6 versus 56.7 +/- 9.0 mg/dl, $p<0.001$). Such aggravation was not due to an effect on proliferation and migration of primary podocytes. We found that Nrf2 transcriptional activity is regulated by PPARg in cultured podocytes and in glomeruli in vivo. Furhermore, Nrf2 -/- mice were found to be prone to markedly aggravated RPGN.

Conclusions: These results suggest that the PPARg-Nrf2 pathway in podocytes is pivotal in protecting the glomerulus from severe inflammatory acute insult and may thus represent a novel therapeutic target for crescentic RPGNs.

FR-PO683

A Serine Protease Inhibitor, Camostat Mesilate, Ameliorates Podocyte Injury Through Its Antiapoptotic Effect in Metabolic Syndrome Model Rat Yoshikazu Miyasato,[1] Teruhiko Mizumoto,[1] Manabu Hayata,[1] Kohei Uchimura,[1] Yutaka Kakizoe,[1] Sakai Yoshiki,[2] Masashi Mukoyama,[1] Kenichiro Kitamura.[1] *[1]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [2]Research Headquarters, Ono Pharmaceutical Co., Ltd., Osaka, Japan.*

Background: Metabolic syndrome (MetS) frequently complicates kidney injury with proteinuria through podocyte injury, and hypertension is one of the most important components in MetS. Previously we reported that a serine protease inhibitor, camostat mesilate (CM), had beneficial effects against proteinuria and hypertension. Therefore, we investigated the renoprotective mechanism of CM in spontaneously hypertensive rat/ND (SHR/ND) mcr-cp (a rat model of MetS).

Methods: Thirteen week-old rats were divided into following four groups: 1) normal salt fed (NS) group, 2) high salt fed (HS) group, 3) high salt fed and CM treated (HS+CM) group, and 4) high salt fed and hydralazine treated (HS+Hyd) group. Blood pressure measurements and 24-hr urine collections were made during the treatment period. Rats were sacrificed following 4-week treatment period. In addition, we studied the effect of CM on apoptosis in a mouse podocyte cell line (MPC-5).

Results: Proteinuria and hypertension observed in the HS group were attenuated by both CM and Hyd. Although the reduction in BP was similar, the antiproteinuric effect of CM was much greater than that of Hyd. This result indicates that CM has a significant antiproteinuric effect independent of its antihypertensive effect. To clarify this mechanism, we explored the effect of CM on podocyte injury. CM markedly improved the reduction in podocyte specific proteins such as nephrin, podocin, and synaptopodin, and the numbers of podocyte in the HS+CM group were greater than those in the HS group and the HS+Hyd group. Furthermore, TUNEL staining and western blotting analysis demonstrated that CM ameliorated apoptosis of podocytes. In MPC-5, CM remarkably suppressed apoptosis induced by high glucose and aldosterone.

Conclusions: CM showed an antiproteinuric effect by ameliorating podocyte injury through its antiapoptotic effect. Our current results suggest the possibility that CM might be a new class of therapeutic agent against kidney injury in MetS.

Futhan Ameliorates Ischemia-Reperfusion Induced Renal Injury Dae Eun Choi,[1] Jin Young Jeong,[1] Hyunsu Choi,[2] Ye Jin Kim,[1] Sarah Chung,[1] Yoon-Kyung Chang,[3] Ki Ryang Na,[1] Kang Wook Lee.[1] *[1]Internal Medicine, ChungNam National Univ Hospital, Daejeon, Korea; [2]Inst of Clinical Medicine, Saint Mary Hospital, Catholic Univ, Daejeon, Korea; [3]Internal Medicine, Saint Mary Hospital, Catholic Univ, Daejeon, Korea.*

Background: It has been reported that futhan (nafamostat mesylate) inhibited inflammatory injury via inhibition of complementary activation in ischemic heart, liver and intestine. However, it has been little known that futhan inhibits the apoptosis in ischemia-reperfusion (IR) injured kidney. We investigated whether futhan attenuates IR renal injury and involves apoptosis inhibition.

Methods: We used HK-2 cell and male C57BL/6 mice. C57Bl/6 mice were divided into four groups; Sham, Futhan (Nafamostat mesylate, 2mg/kg) +Sham, IR injury (IR injury; reperfusion 27 minutes after clamping of both renal artery and vein), and Futhan+IR injury. Kidneys were harvested 24hr after IR injury. We performed functional and molecular study and H&E stain and Masson trichrome (MT) stain for histologic examination. For *in vitro* study, HK-2 cell were divided as into three groups; Control, IR-HK-2 (HK-2 cells were incubated for 6 hours with mineral paraffin oil for ischemic injury) and IR-HK-2+Futhan (2nM) groups. Cell survival and the magnitude of apoptosis were evaluated.

Results: BUN**,** serum creatinine level and renal tissue injury score in Futhan+IR injured mice were significantly lower than those of control IR mice (all, $p<0.01$). Futhan treatment significantly improved cell survival in ischemic HK-2 cells ($p<0.01$). Renal Bax protein and mRNA expression were significantly increased in IR injured kidneys and ischemic HK-2 cells. Futhan treatment significantly decreased renal Bax expression ($p<0.05$). Renal Bcl-2 protein and mRNA expression were significantly decreased in IR kidney and ischemic HK-2 cells compared to those of sham and control groups. Futhan treatment increased renal Bcl-2 expression in IR injured kidneys and ischemic HK-2 cells ($p<0.05$). TUNEL positive cells were significantly lower in Futhan+IR injured kidneys, comparing to control IR injured mice ($p<0.05$).

Conclusions: Futhan ameliorates ischemia-reperfusion renal injury via inhibition of apoptosis.

FR-PO685

MicroRNA-328 Inhibits Renal Tubular Cell Epithelial-to-Mesenchymal Transition by Targeting the CD44 in Pressure-Induced Renal Fibrosis Tso Hsiao Chen,[1] Cheng-Hsien Chen,[1] Yung-Ho Hsu.[2] *[1]Div of Nephrology, Dept of Internal Medicine, Wan Fang Hospital, Taipei Medical Univ, Taipei, Taiwan; [2]Div of Nephrology, Dept of Internal Medicine, Shuang Ho Hospital, Taipei Medical Univ, New Taipei City, Taiwan.*

Background: Epithelial-mesenchymal transition (EMT) occurs in stressed tubular epithelial cells, contributing to renal fibrosis. Initial mechanisms promoting EMT are unknown. Pressure force is an important mechanism contributing to the induction and progression of renal fibrogenesis in ureteric obstruction.

Methods: We establish a pressure apparatus to culture rat renal tubular cells (NRK-52E). Sixty mmHg of pressure will be applied on NRK-52E cells for different periods. The expression of EMT markers, such as transforming growth factor-b, connective tissue growth factor (CTGF), fibronectin, a-SMA and Snail will be monitored by Western blotting. Immunoprecipitation and immunofluorescence staining are used to study the interaction between CD44 and ERM.

Results: In our study of cultured rat renal tubular cells (NRK-52E) under 60 mmHg of pressure, we found that the epithelial marker E-cadherin decreased and mesenchymal markers, e.g., a-smooth muscle actin, fibronectin and Snail, increased. Pressure also induced the expression of connective tissue growth factor and transforming growth factor-b. MicroRNA array assays showed that pressure reduced miR-328 at the initial stage of pressurization. We identified a potential target sequence of miR-328 in rat CD44 3'-untranslated regions. In contrast with the miR-328 expression, CD44 expression was up-regulated at the initial pressurization stage. We also found that miR-328 expression decreased and CD44 increased in ureteric obstruction kidneys in the animal study. CD44 siRNA transfection significantly increased E-cadherin expression and inhibited pressure-induced EMT. Both hyaluronan binding peptide pep-1 and osteopontin neutralizing antibody inhibited pressure-induced EMT.

Conclusions: Our results suggest that miR-328-mediated CD44 transient upregulation is an important trigger of the pressure-induced EMT in renal fibrosis.

TRIM72 Binds Phosphatidylserine Receptor in Pre-Apoptotic PTE Cells Prevents Kim-1 Mediated Phagocytosis Pu Duann, Haichang Li, Pei-Hui Lin. *Medicine, OSU Medical School, Columbus, OH.*

Background: TRIM -72, a new member in TRIM family, is originally cloned in striated muscle, recently found with low but appreciable level in quiescent proximal tubular epithelial cells and substantial enhanced after injury. It has unique but potent membrane repair capabilities, was recruited by injured membrane and migrate to and seal membrane defects. Kidney injured molecule (Kim)-1 is a phosphatidylserin (PS) receptor which was absent in healthy but quickly unregulated in injured proximal tubules cells observed in IRI- and CDDP-AKI. PS normally only appeared in inner leaflet of cytoplasm membrane but quickly redistribute to outer surface of dead or dying cells. PS redistribution was generally considered a hallmark event in cell entering apoptosis. As a PS receptor, kim-1 was show to be scavenger receptor in apoptotic cell phagocytosis. By binding to PS-positive apoptotic cells, controversial immune consequence had been observed in different experiment setting. Kim-1 was thus proposed to contain two-faces for its immune role. The kim-1 binding to PS was suggest as harmful because it enhance the immune reaction to cause more PTE toxicity; it may be beneficial that kim-1 mediated phagocytosis helps apoptotic cell clearance therefore reduce autoimmunity.

Methods: We previously report TRIM -72 preferentially bind to synthetic PS dipped on nitrocellulous membrane. Whether TRIM -72 binding to PS suggests an important biological significance in vivo, is not yet studied. To explore whether TRIM -72 and TIM-1 are potential rivalry for competing PS binding, we conducted phargocytosis interference assay.

Results: TRIM 7 2 priming suppress Kim-1 mediated phargocytosis on dexamethasone-induced apoptotic thymocytes. Sonication induced PS-liposome, but not IP-liposome, abolished binding capability of TRIM 7 2 on PS-positive apoptotic cells. TRIM 7 2 may contain a PS binding domain, like PS-pocket in Tim family members, that saturate occupancy therefore blockade Tim-1 up regulation.

Conclusions: Our findings suggeste that TRIM -72 binding to PS-molecules of apoptotic tubule cells prevent Tim-1 expression, Tim-mediated phargocytosis, thereby attenuate ATN injury by reducing inflammatory consequence.

FR-PO687

Ablation of Proximal Tubular Autophagy Prevents Senescence and Fibrosis after Acute Kidney Injury Arpita Baisantry,[1,2] Sagar Bhayana,[1] Song Rong,[1] Hermann G. Haller,[1] Anette Melk,[2] Roland Schmitt.[1] *[1]Dept of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Dept of Pediatric Nephrology, Hannover Medical School, Hannover, Germany.*

Background: Autophagy mediates degradation and turnover of proteins and damaged organelles and is also upregulated during Ischemia-Reperfusion (I/R). Although autophagic activity has been considered a protective mechanism during acute kidney injury (AKI), the functional role of autophagy in long term renal repair and onset of tubular cellular senescence and interstitial fibrosis has not been investigated and constitutes the aim of this study.

Methods: To examine the influence of stress induced autophagy, we generated mice with Tamoxifen inducible Atg5 gene deletion in the proximal tubular S3 segment. After renal I/R GFR was longitudinally assessed and kidneys were harvested at 3 and 30 days for analyzing acute and chronic damage and the development of cellular senescence by histology, immunostaining, Western blot and RT-PCR. In vitro, Atg5 was silenced by siRNA in primary tubular epithelial cells (PTEC) that underwent stress models of cellular senescence induction.

Results: Atg5 deletion in the S3 proximal tubular segment had no significant impact on renal function or kidney histology at 3 days after I/R. However, proximal tubular Atg5-/- mice showed improved GFR recovery and kidneys displayed reduced tubular atrophy and reduced interstitial fibrosis at 30 days. Immunostaining revealed less proliferation of interstitial cells and decreased intra-renal leukocyte infiltration. These changes were paralleled by significantly fewer senescent tubular cells and reduced expression of pro-senescent cell cycle regulators p16 and p19. In vitro, inhibition of the autophagic machinery by Atg5 silencing attenuated the progression towards senescence in PTEC.

Conclusions: Our current results show that ablating autophagy in a restricted tubular compartment prevents chronic damage such as development of cellular senescence and interstitial fibrosis in response to AKI. These findings suggest caution regarding the development of therapeutic strategies for autophagy induction in AKI treatment.

Septin7 Mediates Hyperglycemia-Induced Glomerular Podocyte Apoptosis Through Activating Ca^{2+}/NFAT2 Ruizhao Li, Wei Shi, Li Zhang, Xinling Liang, Chunping Yu, Wei Dong, Yuanhan Chen, Shuangxin Liu. *Dept of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Science, Guangzhou, Guangdong, China.*

Background: Hyperglycemia promotes podocyte apoptosis and plays a key role in the pathogenesis of diabetic nephropathy (DN). However, the mechanisms that mediate hyperglycemia-induced podocyte apoptosis is still far from being fully understood. Recent studies reported that septin7, a kind of cytoskeletal protein, is expressed in podocyte, also in glioma cells. Increasing septin7 protein expression promotes glioma cells apoptosis in vitro. Here, we sought to determine if high glucose (HG) changes septin7 expression in podocyte in vivo and in vitro, whether this leads to podocyte apoptosis. Meanwhile, we also further explore the mechanisms of septin7 mediates HG-induced podocyte apoptosis in DN.

Methods: The normal kidney tissue of three patients with renal cyst surgery and the renal biopsy tissue of three patients with DN were collected. Immortalized mouse podocytes were cultured in media containing normal glucose (NG), HG, HG plus septin7-siRNA, NG plus mannitol (osmotic control), and HG plus 11R-VIVIT (a special inhibitor of NFAT2). The proportion of podocyte apoptosis in every group was observed by flow cytometer. The activation of NFAT2 in podocytes was detected by western blotting. Intracellular Ca^{2+} was monitored in podcocytes using Fluo-3/AM. Septin7 expression in human kidney was detected by immunofluorescence assay. All data were statistical analyzed using spss17.0.

Results: Septin7 protein expression was significantly increased in glomerular podocytes in DN patients than in health control.In mouse cultured podocytes, HG significantly increased septin7 expression, and promoted podocyte apoptosis. Meanwhile, the apoptosis effects induced by HG were also abrogated by silence septin7 expression.We further found that increasing septin7 expression, leading to induce $[Ca^{2+}]i$, subsequent activated NFAT2 and increased nuclear accumulation.

Conclusions: Our results identify a new finding that HG-induced podocyte apoptosis is mediated by septin7/Ca^{2+}/NFAT2 signaling pathway, which may present a promising target for therapeutic intervention.

WWC1 Promotes Podocyte Survival via Stabilizing Slit Diaphragm Protein Dendrin Ting Lin, Wei Shi, Li Zhang, Chunping Yu, Hong Zhang, Yuanhan Chen, Shuangxin Liu, Jianchao Ma, Ruizhao Li, Zhuo Li, Xiaofan Tan, Zongshun Huang, Xingchen Zhao. *Dept of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Science, Guangzhou, Guangdong, China.*

Background: Slit diaphragms (SD) of kidney podocytes form the final barrier to urinary protein loss. Loss or reorganization of SD proteins contributes to abnormalities in podocytes and proteinuria. Dendrin, a constituent of the SD complex, has been found to relocate from the SD to the nucleus in injured podocyte and promote podocyte apoptosis. However, the exact mechanism for nuclear relocation of dendrin is still unclear. WWC1, a kidney and brain associated protein, was identified as an interaction protein with dendrin by a yeast two hybrid screen. But the exact function of WWC1 and correlation with dendrin in podocyte is not well known.

Methods: In vitro, immortalized mouse podocytes were cultured and randomized into three groups: control group, lipopolysaccharide (LPS 50mg·L-1) group, Adriamycin (ADR 0.25 mg·L-1) group. The podocyte apoptosis was determined by Annexin V/PI apoptosis detection kit. WWC1 and nucleus Dendrin expression in podocytes were detected by immunofluorence method and western blotting. In vivo, BALB/c male mice were randomly divided into: normal control group (Con), LPS (10mg/kg) induced group and ADR (12mg/kg) treated group. Mouse urine albumin was tested in different time points.

Results: In this study, we found that WWC1was a key molecular component in stabilizing dendrin protein. WWC1 was significantly decreased in LPS-treated and ADR-treated podocyte. In vivo, loss of WWC1 expression was also been found in podocyte in patients of several nephritic syndromes, or in ADR and LPS mice model. Loss-function assay showed that knockdown of WWC1 promoted podocyte apoptosis and directly induced nuclear relocation of dendrin. In addition, WWC1 directly interacted with dendrin in physiological podocyte.

Conclusions: In summary, our results indicate that WWC1 is a potential anti-apoptotic property via preventing SD protein dendrin from nucleus relocation, and provide a new molecular vision to tackle proteinuric kidney diseases.

Advanced Glycation Endproducts Blocke Formation of Autophagosome in Podocytes Xiaofan Tan,[1,2] Wei Shi,[1] Yuanhan Chen,[1] Xingchen Zhao,[1,2] Yuxiong Lai,[1] Li Zhang,[1] Chunping Yu,[1] Ting Lin,[1] Shuangxin Liu,[1] Jianchao Ma,[1] Ruizhao Li,[1] Zhuo Li,[1] Hong Zhang,[1] Zongshun Huang.[1,2] *[1]Dept of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China; [2]Southern Medical Univ, Guangzhou, Guangdong, China.*

Background: Podocyte dysfunction plays a critical role in the development of diabetic nephropathy. Autophagy is vital for homestasis of podocytes. Here, we report the effect of AGEs on podocytes autophagy flux.

Methods: Conditionally immortalized mouse podocytes were cultrued in normal medium (control) or medium containing AGE-BSA, or co-BSA. Autophagy flux activity was monitored by protein expression of LC3II and P62 through western blotting, tandem Ad-mRFP-GFP-LC3 observing autophagosomes through laser scanning confocal microscope. The autophagososme generation ability was measured by a dynamic model treated with chloroquine (CQ) at different time points. To investigate the mechanism, mTOR activity and Beclin-1 expression was evaluated by western blotting. Rapamycin, the inhibitor of mTOR, were applied further to identify the effect of mTORC1 activity on autophagy in podocytes treated with AGE-BSA. Podocin detected by western blotting was used as a marker to represent podocyte injury under treatments.

Results: AGE-BSA inhibited expression of LC3II and generation of autophagsomes, while controls and co-BSA had no such an effect. There was an obviously lower accumulation of LC3IIwhen added CQ at 2h, 4h, 6h with AGE-BSA compared with controls and co-BSA. Meanwhile, P62 was accumulated in AGE-BSA treatment group, suggesting that the AGE-BSA might inhibite the formation of autophagosomes and so that block autophagy flux. We further found that mTORC1 was abnormally activated and Beclin-1 was downregulated under AGE-BSA stimulation compared with the other groups. On the basis of AGE-BSA treatment, Rapamycin could restore the LC3II protein level and rescue the podocyte injury by upregulating podocin which was downregulated under AGE-BSA treatment only.

Conclusions: AGEs inhibited podocyte autophagy flux though the blockage in the autophagosome fromation, which might be attributed to abnormal mTORC1 activity and inhibiton of Beclin-1 expression.

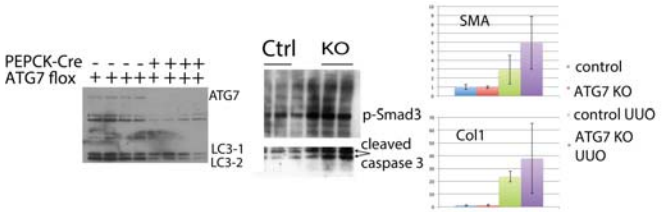
FR-PO691

Absence of Autophagy in the Proximal Tubule Increases Caspase Activation and TGF-Beta Signaling after UUO Jeremy S. Leventhal, Madhav C. Menon, John C. He, Michael J. Ross. *Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Autophagy is a ubiquitous catabolic process whereby cytoplasmic elements are digested in the lysosome after having been first sequestered within a de novo organelle called the autophagosome. Although recent evidence suggests that proximal tubular autophagy protects against acute forms of injury, its effect on chronic renal injury and fibrosis remains poorly understood.

Methods: We performed unilateral ureteral obstruction (UUO) in 8-10 week old mice with conditional knockout of autophagy protein 7 (ATG7) in the proximal tubule and evaluated autophagic capability, parenchymal injury, fibrogenic signaling and gene expression utilizing western blot, qPCR, and histological analysis.

Results: Cortical lysate from mice transgenic for both PEPCK-Cre and floxed ATG7 (ATG7 KO) demonstrated decreased ATG7 and lipidated LC3 compared to control, suggesting impaired autophagy. Three days after UUO, histology demonstrated more severe tubular damage in the cortex of obstructed ATG7 KO kidneys. Ten days after UUO, obstructed ATG7 KO kidneys demonstrated increased caspase 3 activation and Smad3 phosphorylation, suggesting increased apoptosis and TGF-beta signaling. In addition, expression of fibrosis associated genes alpha smooth muscle actin (SMA) and Collagen I (Col1), similar in the unobstructed kidneys of both control and ATG7 KO mice, were higher in the obstructed ATG7 KO kidney compared to control (5.94 versus 2.92 for SMA and 37.3 versus 23.8 for Col1).



Conclusions: In conclusion, loss of autophagy in the proximal tubule worsens injury induced by ureteral obstruction and increases renal TGF-beta activity and fibrotic gene expression, suggesting that intact proximal tubular autophagy is critical to limiting renal fibrosis after injury.

Thrombospondin1 Induces Podocyte Injury through a CD36 Dependent Pathway Shuxia Wang. *Pharmacology and Nutritional Sciences, Univ of Kentucky, Lexington, KY.*

Background: Thrombospondin1 (TSP1) is a multifunctional matricellular protein and an important player in a variety of kidney diseases. Previous studies from our lab and others demonstrated that glomerular mesangial cells produced excessive amount of TSP1 in response to diabetic stimuli, which stimulated the profibrotic factor-TGF-β activation and the development of glomerulosclerosis. In addition to regulating mesangial cell function, in the current study, we revealed a novel role of TSP1 in regulating podocyte function and contributing to proteinuric kidneydisease.

Methods: In our studies, we utilized immortalized human podocytes as well as a well-established podocyte injury and experimental focal segmental glomerulosclerosis mouse model-adriamycin (ADR) induced nephropathy model.

Results: Our results demonstrated that expression of TSP1 and its receptor-CD36 in podocytes was up-regulated in early stage during podocyte injury induced by ADR in vivo as well as in vitro. Moreover, in vitro data showed that ADR-induced podocyte apoptosis was inhibited by siRNA-mediated TSP1 knockdown. In addition, TSP1 treatment stimulated podocyte actin cytoskeletal disorganization, focal adhesion disassembly and apoptosis. TSP1-induced podocyte apoptosis was not affected by anti-TGF-β pretreatment. However, treatment of human podocytes with anti-CD36 antibody or a peptide to block TSP1/CD36 interaction significantly attenuated TSP1 induced podocyte apoptosis.

Conclusions: Taken together, these data suggest that TSP1-inducted podocyte injury is through a TGF-β independent mechanism and partially mediated by TSP1 interacting with its receptor-CD36.

Proteinuria Causes Dysfunctional Autophagy in Proximal Tubules Angela Nolin, Ramon G. Bonegio, Zhiyong Wang, Steven C. Borkan, John H. Schwartz, Andrea Havasi. *Renal Dept, Boston Univ Medical Center, Boston, MA.*

Background: Proteinuria is a major risk factor for chronic kidney disease progression. Furthermore, exposure of proximal tubular epithelial cells (PTEC) to excess albumin promotes tubular atrophy and fibrosis, key predictors of progressive organ dysfunction. The mechanism by which protein exposure causes tubular cell injury is uncertain. We hypothesize that albumin endocytosis causes tubular cell injury by inhibiting autophagy, a critical process for recycling damaged macromolecules and dysfunctional mitochondria.

Methods: The effect of proteinuria was examined both *in vivo* and *in vitro* experiments. Proteinuria was induced in mice by injection of the of sheep nephrotoxic serum that causes acute immune-complex glomerulonephritis with massive proteinuria by 24-48 hrs. To mimic nephrotic glomerular filtrate, PTECs were exposed to albumin. Autophagy was assessed in tissue samples from mice and primary PTECs. Steady state LC3-II, an autophagy marker was quantified by immunoblot and autophagosomes (APs) were visualized in cell culture and in renal cortical tissue. Autophagic flux was measured in vitro in the presence of bafilomycin, an H^+-ATPase inhibitor that prevents lysosomal LC3-II degradation. Mitochondrial oxygen consumption was measured in primary cells.

Results: Exposure to excess albumin induced defective autophagy and mitophagy *in vitro*. Albumin-exposed cells accumulated damaged mitochondria with altered mitochondrial function. In renal cortices, proteinuria decreased both the number of LC3-II positive APs and the amount of LC3-II detected in cell lysates. Exposure to either recombinant human

albumin or fatty acid free bovine albumin also decreased LC3-I to LC3-II conversion in a concentration-dependent manner and diminished autophagic flux. Albumin exposure decreased the number of APs in cells grown in normal media (basal autophagy) as well as in substrate deficient medium (induced autophagy). Finally, albumin exposure caused mitochondrial dysfunction as evidenced by decreased oxygen consumption rate from coupled ATP production.

Conclusions: Dysfunctional autophagy caused by proteinuria likely contributes to tubular cell toxicity leading to renal progression.

Angiotensin- (1–7) Attenuates Podocyte Damage Induced by Preeclamptic Serum through MAPK Pathways Jianying Niu,[1] Jimei Tian,[1] Yaping Chen,[2] Yong Gu.[1,3] *[1]Div of Nephrology, The Fifth People's Hospital of Shanghai, Shanghai, China; [2]Div of Gynecology and Obstetrics, The Fifth People's Hospital of Shanghai, Shanghai, China; [3]Div of Nephrology, Huashan Hospital, Shanghai, China.*

Background: Recent evidence indicates that the renin angiotensin system (RAS) is involved in the pathogenesis of preeclampsia. Our previous data shows that decreased Angiotensin- (1-7) [Ang- (1-7)] in the circulation and urine of patients plays an important role in this disease. In this study, we assessed effects of Ang- (1-7) on cultured podocytes incubated with preeclamptic serum and the underlying mechanisms governing the protective role of Ang- (1-7) in preeclampsia.

Methods: Conditionally immortalized human podocytes (provided by Pro.Zhihong Liu, Jinling hospital, Nanjing) were incubated with preeclamptic serum or serum from normal pregnant women (NP) for 12h. The expression levels of nephrin, podocin, WT-1 on cultured podocytes were determined by western blot analysis and Real-time PCR. The change in F-actin expression in the podocytes was assessed by immunofluorescence. The apoptosis of podocytes was determined by flow cytometry. The level of MAPK phosphorylation was evaluated by western blot analysis.

Results: The cultured podocytes incubated with preeclamptic serum undergo the down regulation of podocyte specific proteins (nephrin:0.42±0.04 VS 0.64±0.07,P<0.005; WT-1:0.28±0.05 VS 0.46±0.09, P<0.05), cytoskeletal rearrangement, and apoptosis (8.55±0.68% VS 2.36±1.05%, P<0.001) compared with the control group. Compared with the PE group, the addition of Ang- (1-7) in the PE group increased the expression of nephrin and WT-1 (nephrin:0.57±0.07 VS 0.42±0.04, P<0.05; WT-1: 0.41 ±0.04 VS 0.28±0.05, P<0.05) and decreased the number of apoptotic cells (4.47±0.73% VS 8.55±0.68%, P<0.001). Ang- (1-7) also could attenuate the cytoskeletal rearrangement induced by preeclamptic serum. In addition, Ang- (1-7) partly inhibited the phosphorylation of p38, ERK1/2 and JNK in preeclampsia group.

Conclusions: Our data indicated that Ang- (1-7) serves a protective role on podocytes in preeclampsia. The protective role of Ang- (1-7) in this condition may occur through the downregulation of MAPK phosphorylation.

FR-PO695

Smooth Muscle Cells APOL1 Risk Variants Promote Podocyte Injury in HIV Milieu Xiqian Lan,[1] Hongxiu Wen,[1] Ashwani Malhotra,[1] Karl Leon Skorecki,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Rambam Heatth Care Campus, Haifa, Israel.*

Background: APOL1 gene variants (G1 and G2) have been incriminated for higher rates of FSGS in African Americans. In human renal biopsy specimens of FSGS and HIVAN patients, the expression of APOL1 was found to be increased only in smooth muscle cells of arteries and arterioles but not in kidney cells. We recently reported that APOL1 variants induced podocyte injury. Additionally, expression of APOL1 variants enhanced podocyte vulnerability to be damaged by adverse host factors (AHFs) such as HIV. We now hypothesized that HIV enhances smooth cell production of APOL1 G1 and G2 in patients with APOL1 risk variants and enhanced release of APOL1G1 and G2 in blood enhances podocyte vulnerability for injury.

Methods: To dertermine the mediators during AHFs, the effect of IFN-g and TNF-a was evaluated on Human Artery Smooth Muscle Cell (HUASMC) expression of APOL1. Conditioned media (CM) from Vector, overexpressing APOL1 wide type (WT) and variants (Vs) was collected. Human podocytes (HPs) were incubated in serum free media containing CM-Vector, CM-WT and CM-Vs for 24 hours. Subsequently, cells were assayed for lysosomal injury by lucifer yellow and lysosomal tracker, increase in lysosomal permeability (LM) by cathepsin L leak (Magic red staining), and loss of cellular integrity (LCI) by trypan blue staining and lactic dehydrogenase assay. To determine the role of chloride influx, HPs were pretreated with DIDS (a chloride channel inhibitor) and then incubated in CM-WT and CM-Vs. APOL1 was depleted form CMs by using ELISA plates.

Results: CM-Vs enhanced (P<0.01) both lysosomal injury and LM when compared to CM-Vector and CM-WT. CM-Vs significantly increased (P<0.01) podocyte LCI both in control and AHFs. Both HIV infection, and stimulation with TNF-a or IFN-U enhanced the expression of APOL1 in HUASMCs. However, DIDS inhibited CM-Vs-induced lysosomal injury and increase in LM in HPs. APOL1 depleted CMs displayed attenuated podocyte injury.

Conclusions: Human artery smooth muscle cells APOL1 risk variants carry potential to accelerate podocyte injury in general and in HIV milieu in particular.

FR-PO696

Rhein Inhibits Starvation-induced Autophagy in NRK-52E Cells via mTOR/p70S6K and Erk/p38 Pathways Yue Tu,[1] Wei Sun,[2] Yigang Wan.[3] *[1]Nanjing Univ of Chinese Medicine; [2]Jiangsu Provincial Hospital of Chinese Medicine; [3]Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing Univ Medical School.*

Background: The injured/aged renal cells can be eliminated by autophagy, however, whether the role of autophagy is detrimental remains unclear. Under some conditions, suppressing autophagy may protect renal tubular damage. The mTOR/p70S6K pathway is considered one of the key regulatory mechanisms of autophagy. Rhein, as a major renoprotective ingredient from Rhubarb, is frequently used for treating renal tubular-interstitial fibrosis. However, the underlining mechanisms by Rhein in autophagy have not been examined.

Methods: NRK-52E cells were exposed to Rhein in the starvation induced by Hank's balanced salt solution (HBSS) and with or without bafilomycin A1 (autophagy inhibitor). The changes of LC3 conversion and the key protein expressions of mTOR/p70S6K and Erk/p38 pathways were detected. Moreover, NRK-52E cells were exposed to Rhein in HBSS with rapamycin (mTOR inhibitor) or exposed to PD098059 (Erk inhibitor) and SB203580 (p38 inhibitor) in HBSS, and the changes of LC3 conversion were detected. NRK-52E cells were further transfected with EGFP-LC3 plasmid to examine LC3 dots by fluorescence microscopy.

Results: HBSS effectively induced LC3 conversion in NRK-52E cells. This induction was markedly suppressed by Rhein in a dose-dependent manner. Rhein could suppress LC3 conversion induced by bafilomycin A1. The protein expressions of p-mTOR, p-p70S6K, p-Erk and p-p38 were reversely-regulated by Rhein in NRK-52E cells treated with HBSS, respectively. In addition, Rhein reduced LC3 conversion in NRK-52E cells incubating with rapamycin. PD098059 or SB203580 alone also reduced LC3 conversion. Under nutrient-rich conditions, EGFP-LC3 was mostly found to distribute evenly throughout cytoplasm, with few punctuate dots. After starvation, EGFP-LC3 was mostly localized to punctuate structures and these punctuate distribution can be reduced by Rhein.

Conclusions: Autophagy in NRK-52E cells induced by HBSS can be inhibited by Rhein via activating mTOR/p70S6K pathway. In addition, Rhein can abrogate Erk/p38 pathway activation, which suggests Rhein may act as the analogue of Erk and p38 inhibitors.

FR-PO697

miR-363 Induces Transdifferentiation of Human Tubular Cells to Mesenchymal Phenotype Ryuji Morizane, Toshiaki Monkawa, Shizuka Fujii, Hiroshi Itoh. *Internal Medicine, Keio Univ School of Medicine, Tokyo, Japan.*

Background: micro RNAs (miRNAs) are small non-coding RNAs that act as posttranscriptional repressors by binding to the target mRNAs. On the other hand, mesenchymal-epithelial transition (EMT) is a pathological process of kidney disease such as renal cell carcinoma or kidney fibrosis, and the relationship to miRNAs is becoming recognized as a potential target for therapies.

Methods: We used a human proximal tubule cell line (HKC-8) and a primary culture from human proximal tubule epithelial cells (RPTEC) for the experiments. First, we performed knock-down of DICER-1 which is one of enzymes required for miRNA production, and examined the markers of epithelial and mesenchymal cells. Then, we performed global gene expression analysis using microarray in three experimental models using HKC-8; a EMT model using TGF-beta, a knock-down model of miRNAs using DICER-1 siRNA, and an epithelial model by cell confluency. Based on the result of microarray, we analyzed the function of miR-363 using inhibitor and precursor of miR-363 in HKC-8 and RPTEC.

Results: Knock-down of DICER-1 showed up-regulation of both epithelial and mesenchymal cell markers, suggesting DICER-1 dependent miRNAs were involved in processes of both epithelialization and EMT. To find the miRNAs involved in EMT, we performed microarray of miRNAs using three experimental models, and the result revealed that miR-363 was mildly up-regulated by TGF-beta, and was down-regulated in DICER-1 knock-down samples and a epithelial model. Therefore, we speculated that one of DICER-1 dependent miRNAs, miR-363 has an effect to promote EMT. Over-expression of miR-363 significantly suppressed E-CADHERIN and enhanced VIMENTIN, TWIST1, TWIST2 and MMP9, but not SNAIL1, suggesting that miR-363 promoted EMT via up-regulation of TWIST pathway rather than SNAIL1 pathway.

Conclusions: DICER-1 dependent miRNA, miR-363 promotes transdifferentiation of human tubular cells to mesenchymal phenotype presumably via activation of TWIST pathway.

Funding: Government Support - Non-U.S.

FR-PO698

The Role of Epigenetic Factors and Histone Modifications in Modulation of the Pathogenesis of HIV-Associated Nephropathy (HIVAN) Vasupradha Vethantham, Noopur Goel, Nirupama Chandel, Rivka Lederman, Ashwani Malhotra, Pravin C. Singhal. *Medicine, North Shore LIJ Medical School, Great Neck, NY.*

Background: Development of HIVAN is associated with large scale of changes in expression of genes related to inflammation, fibrosis and those involved in epithelial to mesenchymal transition. Epigenetic changes such as DNA methylation and histone modifications play important roles in regulating changes in gene expression, and are attractive targets for therapeutic intervention because they are potentially reversible.

However, there have been very few studies investigating the role of chromatin modifications in disease state progression in HIVAN. The goal of this study was to investigate changes in epigenetic markers in kidney cells both *in vitro* and *in vivo* models of HIVAN to determine involvement of specific chromatin modifications and/or modifiers in its pathogenesis.

Methods: Protein blots of renal tissues of control and HIV transgenic (Tg26 and Vpr) mice were probed for Histone 4 Lysine 16 acetylation (H4K16Ac) and Histone H3 lysine 4 trimethylation (H3k4me3), pan H3 acetylation, H4 acetylation, and H3k9 trimethylation. *In vitro* studies, protein blots of human podocytes (HPs)-transduced with either empty vector (EV) or HIV were probed for H4K16Ac and H3K4me3, LC3-2 and actin. Morphologic autophagy status was assayed by acridine orange staining. To establish a causal relationship, we evaluated the effect of HIV on HPs depleted of H4K16 acetylation factor (hMof) on autophagy/apoptosis.

Results: Western blot analysis revealed increases in overall levels of H4K16Ac and H3k4me3 levels in Tg26 and Vpr mice kidney tissues versus controls. There were no significant changes in pan H3 acetylation, H4 acetylation, or H3K9 trimethylation levels. Similarly, there was an increase in levels of H4K16Ac and H3K4me3 in HIV/HPs versus EV/HPs. Western blot analysis revealed increased LC3 conversion, autophagosome formation and apoptosis in HIV/HPs. These findings suggest that hMof depletion enhanced autophagosome formation but mitigated apoptosis in HIV/HPs.

Conclusions: Acetylation of H4K16Ac is involvled in the maintenance of podocyte homeostasis in control and HIV milieus.

Lipidomic Profiling of Young and Aged Wild-Type Mouse Kidneys Reveals Lipid Groups Involved in Kidney Aging Fabian Braun,[1] Bernhard Schermer,[1] Valerie Bartels,[2] Thomas Benzing,[1] Roman-Ulrich Mueller,[1] Christine E. Kurschat.[1] *[1]Dept II of Internal Medicine - Nephrology, Univ Hospital Cologne, Cologne, NRW, Germany; [2]Dept of Cardiology, Univ Hospital Münster, Münster, NRW, Germany; [3]Univ Cologne, CECAD, Cologne, NRW, Germany.*

Background: Facing the worldwide demographic increase in the elderly population, prevention and therapy of aging-related diseases has become a major health concern. Models to study renal aging are currently lacking, although chronic kidney disease with mild to severe impairment of kidney function is common amongst old patients. In order to identify molecular mechanisms involved in kidney aging we analyzed gene expression profiles of young and aged wild-type mouse whole kidney tissue.

Methods: Wild-type C57BL/6 mice were sacrificed at 14 and 96 weeks of age and kidneys were removed. RNA was extracted, reverse transcribed and cDNA was hybridized to Affymetrix microarrays. Statistical analysis was conducted using R/Bioconductor. For GO enrichment and network analyses the DAVID server and NetBox software were used. Lipidomic profiling was done by BIOCRATES, Innsbruck. JMP was used for statistical lipid analysis.

Results: Wild-type C57BL/6 mice were sacrificed at 14 and 96 weeks of age and kidneys were removed. RNA was extracted, reverse transcribed and cDNA was hybridized to Affymetrix microarrays. Statistical analysis was conducted using R/Bioconductor. For GO enrichment and network analyses the DAVID server and NetBox software were used. Lipidomic profiling was done by BIOCRATES, Innsbruck. JMP was used for statistical lipid analysis.

Conclusions: Genes preferentially involved in lipid metabolism, immune response andinflammation were differentially expressed in aged kidney samples. The lipidomic profiling of young versus old kidney tissue confirmed significant differences in three of the investigated lipid groups. Our results will contribute to identifying novel lipid-regulating pathways involved in the process of kidney aging.

FHL2-Drived Molecular Network Mediated Septin2 Knockdown Inducing Apoptosis in Mesangial Cell Xiang-Mei Chen, Yang Lu, Fujian Zhang, Guangyan Cai. *Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center of Kidney Diseases, Beijing, China.*

Background: The apoptosis of mesangial cells (MCs) plays a critical role in the pathological progress of MesPGN. Septin2, a filamentous GTPase, is implicated in the apoptotic progress of MCs in the rat MesPGN model. However, the molecular mechanism of SEPT2 in MCs apoptosis is not clear. Here, we present the FHL2-drived molecular network as the main mechanism of SEPT2-mediated rat primary MCs apoptosis.

Methods: Hochest 33342 and TUNEL staining were applied for apoptosis determination. Label-free LC-MS was applied for proteomic research. siRNA and lentivirus transfection were used for gene function research.

Results: First, we proved that the expression of FHL2 and Septin2 were closely related with MCs apoptosis in anti-Thy1 nephritis model. Then, it was found that FHL2 was a new interaction protein of Septin2 and Septin2 knockdown could induce MC apoptosis by FHL2-mediatied signal pathways including p-ERK1, p-AKT, and NF-kappaB. We applied label-Free quantitative proteomics to identify the mechanism of Septin2/FHL2-regulated apoptosis. Bioinformatics analysis revealed that FHL2-drived molecular network composed of biological functions including glycolysis, oxidative stress, ribonucleotide metabolism, actin cytoskeleton regulation and signaling pathway, was the main mechanism of SETP2-mediated apoptosis. Furthermore, we showed that the effect of Septin2 knockdown on MC apoptosis could be alleviated by the overexpression of FHL2.

Conclusions: This study illustrated the FHL2-drived molecular network controlling SEPT2-mediated apoptosis in MCs and their potential roles in mesangial proliferative nephritis.

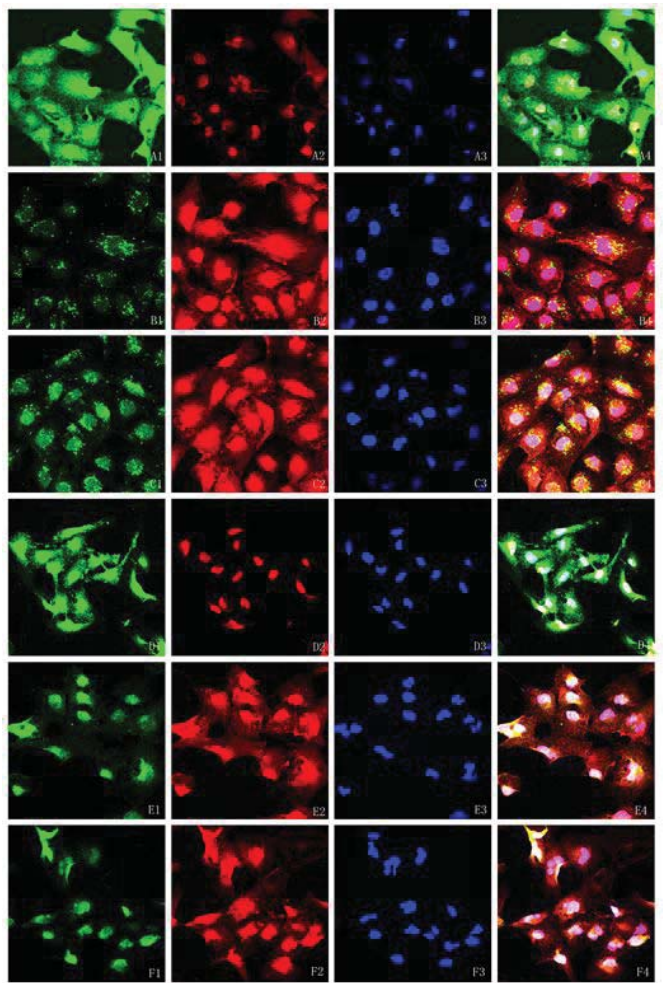
Hydronidone Suppresses TGF-β1 Induced EMT on Human Kidney Cell Line Zhongyi Zhou, Lanping Jiang, Qunsheng Yuan, Mingxi Li, Xuemei Li, Falei Zheng. *Nephrology, Peking Union Medical College Hospital&Chinese Academy of Medical Science, Beijing, China.*

Background: The analogue of pirfenidone is hydronidone, which is a new drug and the effect of hydronidone on HKC remains unclear. Our animal experiment has confirmed that hydronidone can prohibit the procedure of EMT in renal interstitial fibrosis. HKC was cultured, to observe whether hydronidone influence TGF-β1 induced EMT, and to study the possible mechanism.

Methods: 1) HKC was cultured and treated with hydronidone, TGF-β1 and 5Z-7-oxozeaenol for 48h. 2) The mRNA and protein expression levels of E-cadherin and a-SMA, TGF-β1 in each group were estimated by real time PCR, WB.4) the phosphorylated extent of TAK1 and NF-kB were evaluated by WB.

Results: 1) The double stained immunofluorescence experiment showed that:



compared with the HKC control group, TGF-β1 treated HKC group after 48h significantly expressed lower E-cadherin and higher a-SMA. Compared with the TGF-β1 treatment group, hydronidone 1mM and 2.5mM groups demonstrated higher expression of E-cadherin. 2) Compared with TGF-β1 treatment group, hydronidone 1mM and 2.5mM group displayed a higher level of E-cadherin, a lower level of a-SMA,TGF-β1 in mRNA and protein levels ($P<0.05$).3) Western blot results showed that compared with control group, the protein of p-TAK1,p-NF-kB p65 were increased in TGF-β1 treatment group ($P<0.05$). Compared with TGF-β1 treatment group, the protein of p-TAK1,p-NF-kB p65 were decreased in hydronidone 1mM and 2.5mM groups ($P<0.05$). Compared with the HKC group treated 48h by TGF-β1, the protein of p-TAK1, p-NF-kB p65 were decreased in hydronidone group contain TAK1 inhibitor ($P<0.05$).

Conclusions: 1) TGF-β1 induced HKC proliferation can be suppressed by hydronidone.2) Hydronidone can up-regulate E-cadherin, down-regulate a-SMA and TGF-β1 both in mRNA and protein levels. Besides, it also reduced TAK1 and NF-kB's phosphorylation extent.

FR-PO702

Distinct Mechanisms Involving the Cellular Toxicity to Renal Tubular Cells By Five Protein-Bound Uremic Retention Solutes Ayano Konagai, Takeo Edamatsu, Ayako Fujieda, Atsuko Ezawa, Yoshiharu Itoh. *Pharmaceuticals Div, Kureha Corporation.*

Background: Protein-bound uremic retention solutes are known to be accumulated in the serum of chronic kidney disease patients and progress the disease. Two representative molecules, indoxyl sulfate (IS) and p-cresyl sulfate (PCS), have been well studied regarding renal and vascular functions. However, effects of other solutes such as phenylsulfate (PhS), indoleacetic acid (IAA) and hippuric acid (HA) which have been detected in hemodialysis patients remain unclear. Therefore, we investigated the effects and roles of the five solutes to further understand the toxic mechanisms in renal failure.

Methods: Porcine renal tubular cells, LLC-PK1, were treated with each solute at the concentration which can decrease viable cell number by 50 percent for 2 days. Viable cell number was assessed with WST-8. After synchronization with thymidine or nocodazole, cell cycle progression was analyzed using flow cytometry. Apoptotic cells were detected by Annexin V-FITC and PI staining. Protein and gene expression were determined by western blotting and real-time PCR, respectively.

Results: All solutes reduce cell proliferation. However, treatment of N-acetyl cysteine, an anti-oxidant, reversed the toxic effect by these solutes except for HA. IAA induced apoptosis and HA showed the modest effect. Besides IAA, all the others induced cell cycle delay. IS, PCS and PhS enhanced phosphorylation of p53 and Chk1 or gene expression of ATF4 and CHOP, which are hallmarks of DNA damage or ER stress leading to cell cycle delay.

Conclusions: We clarified the effects of PhS, HA and IAA in addition to the well-known solutes, IS and PCS. Based on their mechanisms, we categorized the five solutes into three groups. First, IS, PCS and PhS induce cell cycle delay through DNA damage relating with reactive oxygen species (ROS) and ER stress. Second, HA slightly causes apoptosis and cell cycle delay through DNA damage without ROS induction. Third, IAA induces apoptosis through ROS but not cell cycle delay. IAA has completely distinct effect from others and might have previously unknown harmful impacts on renal or vascular systems.

tPA Promotes M1 Macrophage Survival through p90RSK and p38 MAPK Pathway Ling Lin, Kebin Hu. *Medicine, Penn State Univ College of Medicine, Hershey, PA.*

Background: Macrophage accumulation is one of the hallmarks of progressive kidney disease. Resting macrophages have a finite lifespan, but become resistant to apoptosis in response to pathogenic cues, whereas the underlying mechanism remains unknown. Tissue-type plasminogen activator (tPA), a protease up-regulated in the kidneys of chronic injury, has been shown to promote macrophage accumulation and renal inflammation. We hypothesized that tPA may be the endogenous factor that promotes macrophage survival and extends their lifespan that leads to their accumulation in the injured kidneys.

Methods: We examined the role of tPA in macrophage survival and the underlying signaling mechanism.

Results: We found that tPA protected macrophages from both staurosporine and H_2O_2-induced apoptosis. tPA promoted the survival of both resting and lipopolysaccharides (LPS)-induced M1 macrophages, but failed to do so in the interleukin 4 (IL4)-induced M2 macrophages. In the kidneys with unilateral ureteral obstruction (UUO), obstruction-induced M1 macrophages accumulation and M1 chemokine expression were markedly reduced in the tPA-deficient mice in comparison to their wild-type counterparts. The cytoprotective effect of tPA required its receptor, LDL receptor-related protein-1 (LRP-1). tPA induced the phosphorylation of Erk1/2, p90RSK, and p38 in a temporal order. The tPA-mediated macrophage survival was eliminated by PD98059, BI-D1870, or sc68376, the specific inhibitor for Erk1/2, p90RSK, or p38, respectively.

Conclusions: Thus, it is clear that tPA promoted M1 macrophage survival through its receptor LRP-1-mediated a novel signaling cascade involving Erk1/2, p90RSK, and p38, which leads to the accumulation of these cells in the injured kidneys.

Nicotine Induces Tubular Cell Apoptosis through the Activation of Renin Angiotensin System (RAS) via Epigenetic Factors Kamesh R. Ayasolla, Nirupama Chandel, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Cigarette smoking has been incriminated for the progression of hypertension and diabetes associated chronic kidney diseases (CKD). Firstly, kidney cells carry nicotine receptors and have been demonstrated to affect kidney cells directly; secondly, cigarette smoking is known to stimulate systemic activation of RAS and that would modulate the progression of CKD. We hypothesized that nicotine has a potential to stimulate renin generation by kidney cells and thus would activate RAS locally. We further hypothesized that this effect of nicotine is mediated through down regulation of vitamin D receptor (VDR) expression of kidney cells via epigenetic factors. Since epigenetic factors-induced gene expression are reversible, treatment strategies can be developed to reverse the smoking-induced epigenetic alterations and downsream effects.

Methods: Human proximal tubular cells (HPTC) were incubated in variable concentrations of nicotine for 24 and 48 hours and assayed for apoptosis. Protein blots of control and nicotine treated cells were probed for VDR and renin. To establish a causal relationship between nicotine-induced activation of renin angiotensin system and induction of apoptosis, HPTCs were treated with either vehicle or nicotine in the presence or absence of losartan (an angiotensin II type I receptor blocker) /EB1089 (a VDR agonist) and evaluated for apoptosis. To explore relationship between nicotine-induced down regulation of VDR and epigenetic factors, protein blots of control and nicotine-treated HPTCs were probed for DNA methyl transferases (Dnmts), histone trimethylation at K27, and hstone acetylation.

Results: Nicotine enhanced HPTC apoptosis in a dose dependent manner. Nicotine down regulated tubular cell VDR expression but upregulated renin expression. Both vitamin D receptor agonist and losartan attenuated nicotine-induced HPTC apoptosis. Nicotine enhanced tubular cell Dnmt3b and H3 trimethylated K27 but displayed a decrease in histone acetylation.

Conclusions: Nicotine enhances tubular cell apoptosis. This effect of nicotine is mediated through down regulation VDR and activation of the RAS.

Heparanase Is a Player in Renal Fibrosis by Regulating TGF-β Expression and Activity Valentina Masola,[1] Gianluigi Zaza,[1] Simona Granata,[1] Maria Francesca Secchi,[2] Maurizio Onisto,[2] Giovanni Gambaro,[3] Antonio Lupo.[1] *[1]Renal Unit, Dept of Medicine, Univ-Hospital of Verona, Italy; [2]Dept of Biomedical Sciences, Univ of Padova, Italy; [3]Div of Nephrology and Dialysis, Columbus-Gemelli Hospital, Catholic Univ, School of Medicine, Rome, Italy.*

Background: Epithelial-mesenchymal transition (EMT) of tubular cells is one of the mechanisms which contribute to renal fibrosis and transforming growth factor-b (TGFb) is one of the main triggers. Heparanase (HPSE) is a endo-b-D-glucuronidase that clives heparan-sulphate and takes part to extracellular-matrix remodeling thus regulating the bioavailability of growth factors (FGF-2, TGFb). HPSE controls FGF-2-induced EMT in tubular cells and is necessary for the development of diabetic nephropathy in mice. The aim of this study was to investigate whether HPSE can modulate the expression and the effects of TGFb.

Methods: Several biomolecular strategies (Real time-PCR, immunofluorescence, zymography and ELISA) have been used to assess EMT in WT and HPSE-silenced cells in response to TGF-β and pro-fibrotic factors.

Results: First we proved that the lack of HPSE prevents the increased synthesis of TGF-β by tubular cells in response to pro-fibrotic stimuli such as FGF-2, AGE and albumin. Second, HPSE does not prevent EMT induced by TGF-β although it slows its onset. Indeed TGF-β induces EMT in wt and in HPSE-silenced tubular cells; however in HPSE-silenced cells the acquisition of a mesenchymal phenotype does not develop as quickly as in wt cells, supporting the hypothesis that HPSE facilitates the TGF-β biological activities. Additionally, TGF-β induces an autocrine loop to sustain its signal whereas the lack of HPSE jeopardizes this autocrine loop.

Conclusions: Overall these data confirm that heparanase is a key player in renal fibrosis since it interacts with the regulation and the effects of TGF-β. HPSE is needed for the pathological TGF-β overexpression in response to pro-fibrotic factors such as albuminuria, AGE and FGF-2. Furthermore HPSE modulates TGF-β-induced EMT, the lack of HPSE delays tubular cell transdifferentiation, and impairs TGF-β autocrine loop.

Regulation of p53 Under Hyperglycemia and/or Hyperinsulinmia Conditions in Renal Cells Samy L. Habib,[1,2] Sitai Liang.[2] *[1]Geriatric Research, Education, and, Clinical Center, South Texas Veterans Healthcare System, San Antonio, TX; [2]Cellular and Structural Biology, Univ of Texas Health Science Center, San Antonio, TX.*

Background: Hyperglycemia and insulin resistance are key players in the development diabetes complication. Several evidences suggest that metabolic abnormalities cause renal dysfunction and inflammation, play a major role in precipitating diabetic kidney disease.

Methods: To determine the upstream and downstream target genes of p53, mouse renal proximal tubular cells were exposed to high glucose and/or high insulin concentrations. Several manipulations of downregulation or upregulation IRS1/p-AMPK/tuberin were performed to determine the mechanism of regulation of p53 under hyperglycemia (HG) and/or hyperinsulinmia (HI) conditions.

Results: Under HG+HI or HG exposure, IRS1, AMPK activity and tuberin expression are significantly decreased, while ppS6K expression increased that resulted in significant decrease in p-p53at Ser^{15} expression. On the other hand, insulin treatment resulted in increase expression of tuberin as well as IRS1 and decrease protein expression of p-P53 at Ser^{15}. Downregulation of tuberin by siRNA resulted in decrease AMPK activity and increase p-p53 expression under all treatment conditions. In addition, overexpression of IRS-1 leads to significant increase in AMPK activity, increase in tuberin expression and decrease p-p53. Moreover, downregulation of AMPK by DN-AMPK resulted in significant increase in p-P53 under all treatment conditions. These data suggest that p53 is mainly regulated through IRS1/tuberin/AMPK in cells under hyperglycemia and/or hyperinsulinmia conditions.

Conclusions: Taken together these signals cascade of regulation of p53 through IRS/AMPK/tuberin will be important to improve understanding the mechanism-based therapeutic strategies as a promising option to prevent renal complications in diabetes.

HPV Oncoproteins Modify DNA Damage Response (DDR) to Explain Inferior Chemotherapeutic Efficacy in Renal Cell Carcinoma
Samriti Dogra,[1] Sriram Bandi,[3] Preeti Viswanathan,[2] Sanjeev Gupta.[3] *[1]Pediatric Nephrology, Montefiore Medical Center, Bronx, NY; [2]Pediatric Gastroenterology, Montefiore Medical Center, Bronx, NY; [3]Medicine, Albert Einstein College of Medicine, Bronx, NY.*

Background: Better insights into mechanisms of chemotherapy-induced DDR will be relevant for cancer therapies. We determined whether cisplatinum (CP)-induced nephrotoxicity and DDR were recapitulated in renal cells with master switches activated by ATM and related pathways.

Methods: We studied DDR in HK-2 cells, human tubule cells immortalized by HPV16 E6/E7 genes, and HuH-7 cells from human HCC. Cells were treated with CP in IC50 doses with cell viability assays using MTT, gene expression analysis by qRT-PCR arrays, Comet assays for double-strand DNA breaks, cytostaining or westerns for ATM-related genes, ATM promoter activity using a tdT reporter, and FACS for cell cycling or Side Population (SP) assays of stem cells.

Results: In CP-treated HuH-7 cells, typical DDR was observed, including gH2AX expression, Comets, greater ATM promoter activity, fewer cells in S or G2/M and more in G0/G1, and less SP. Fewer ATM-regulated genes were expressed with more p53 expression. In CP-treated HK-2 cells, DDR was incomplete, as gH2AX was expressed and ATM promoter activity increased, but Comets were absent, p53 was expressed less, and SP was present. Next, we determined regulation of MDM2-regulated p53 expression with nutlin-3, which inhibits MDM2, or wild-type p53-induced phosphatase (WIP1) with arsenic trioxide (ATO), which decreases WIP1 expression. Nutlin-3 had no effect on cell viability and did not increase CP toxicity. In HK-2 cells, CP, ATO, or both, affected neither p53 nor WIP1 expression, in agreement with impaired DDR. However, CP and ATO synergistically enhanced cytotoxicity because ATO depolymerized tubulin and also decreased SP in HK-2 cells.

Conclusions: HPV E6/E7 oncoproteins altered DDR in HK-2 cells leading to p53-associated escape. This escape from DDR was overcome by microtubule-disrupting drug, ATO, which increased cytotoxicity and depleted cancer stem cells. Since HPV E6/E7 genes are integrated in ~20% cases of renal cell carcinoma these mechanisms will be clinically significant.

Involvement of Dysregulated Mitophagy in Albumin-Induced Apoptosis in Proximal Tubule Cells
Li Fang, Weichun He, Chunsun Dai, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Albuminuria, the universal feature of chronic kidney disease, is considered a poor prognostic factor contributes to progression of renal injury. Although it was established that ongoing albuminuria could lead to inflammation, fibrosis, tubular apoptosis and death, the underlying mechanisms remain unknown. Since recent advances in understanding molecular processes contributing to autophagy have provided insight into the relationship between autophagy and apoptosis, we show that dysregulate mitophagy might involve in albumin-induced apoptosis in cultured tubule epithelial cells (NRK-52E).

Methods: NRK-52E cells were exposed to endotoxin-free albumin. Apoptosis was detected by H-33258/PI staining; TUNEL; cleaved-caspase 3 staining; western blot and flow cytometry. Mitophagy were evaluated by western blot; immunofluorescence; GFP-LC3 staining and electron microscopy. Mitochondria function was assessed by oxygen consumption rate, reactive oxygen species, mitochondrial membrane potential and immunofluorescence.

Results: Albumin induced tubular apoptosis in a time- and dose-dependent manner. Increased caspase-3 activity was observed starting at 6 and maximally at 24 to 60 h at 5mg/ml albumin. Transient increase of autophagic flux before 24 h, happening in the early stage, seemed to mediate a compensatory protective response. GFP-LC3–tagged autophagosomes colocalized with mitochondria in tubular cells, suggesting that albumin induces mitophagy. However, sustained albumin ultimately defected mitophagy. Mitophagy-deficient tubular cells exhibit reduced mitochondrial respiratory chain activity and mitochondrial membrane potential and fragmented morphology with marked swelling. Furthermore, rapamycin, an inducer of autophagy, could increase mitochondrial respiratory chain activity and mitochondrial membrane potential and therefore alleviate albumin induced apoptosis.

Conclusions: These findings suggested that basal mitophagy played important roles in regulating apoptosis. Thus, enhancement of mitophagy might hold promise as a novel avenue for preventing albumin induced tubular cell apoptosis and ameliorating tubular injury in proteinuric kidney diseases.

FR-PO709

Hic-5 Regulates Mesangial Cell Proliferation via Altered and Coordinated Expression of Cell Cycle-Related Protein
Ariunbold Jamba,[1] Shuji Kondo,[1] Takashi Nagai,[1] Maki Urushihara,[1] Toshiaki Tamaki,[2] Shoji Kagami.[1] *[1]Dept of Pediatrics, Inst of Health Bioscience, Univ of Tokushima, Tokushima, Japan; [2]Dept of Pharmacology, Univ of Tokushima, Tokushima, Japan.*

Background: We previously reported that expression of Hic-5, a TGF-β1-inducible focal adhesion protein, was associated with glomerular cell proliferation in human and experimental glomerulonephritis (GN). In addition, we demonstrated that Hic-5 might regulate mesangial cell (MC) proliferation after glomerular injury in Habu venom-induced GN in heminephrectomized mice (Kidney Week 2014; TH-PO552).

Methods: To examine the effect of Hic-5 on the glomerular expression of growth factors, PDGF-BB or TGF-β1, or their receptors, immunohistochemistry was performed on both wild type (Hic-5+/+) and Hic-5-deficient (Hic-5-/-) GN mice. In addition, we investigated how Hic-5 regulates MC proliferation and affects cell cycle using cultured Hic-5+/+ and Hic-5-/-MCs.

Results: Glomerular expressions for PDGF-BB or TGF-β1, or their receptors, are enhanced in Hic-5+/+ and Hic-5-/- GN mice on day 7, however, their differences were not observed in both mice. Glomerular cell proliferation in Hic-5-/- GN mice was significantly greater than that in Hic-5+/+ GN mice on day 7, suggesting that Hic-5 might directly regulate MC proliferation. In vitro experiments, PDGF-BB (50 ng/ml) stimulated proliferation in Hic-5+/+ MCs, but TGF-β1 (10 ng/ml) did not. PDGF-BB and TGF-β1 enhanced proliferation of Hic-5-/- MCs compared with Hic-5+/+ MCs. Western blotting for cell cycle-related proteins revealed that PDGF-BB increased the protein levels of cyclins A and D1 in Hic-5+/+ MCs. In contrast, TGF-β1 decreased cyclin A expression in Hic-5+/+ MCs. PDGF-BB and TGF-β1 enhanced the expression of cyclins A and D1 in Hic-5-/- MCs compared to Hic-5+/+ MCs. p21 expression was increased in Hic-5+/+ MCs stimulated with PDGF-BB or TGF-β1. In contrast, p21 expression by PDGF-BB or TGF-β1 was not detected in Hic-5-/- MCs. These results suggested that Hic-5 might be involved in the regulation of MC proliferation through the altered and coordinated expression of cyclins A and D1, and p21.

Conclusions: In conclusion, Hic-5 might regulate MC proliferation by controlling cell cycle.

Funding: Government Support - Non-U.S.

Role of Calciprotein Particle-Induced Autophagy in Calcification of Human Smooth Muscle Cells
Shoko Hasegawa, Kumiko Torisu, Masahiro Eriguchi, Kazuhiko Tsuruya, Takanari Kitazono. *Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Recent studies have indicated a protective role of autophagy in calcification of vascular smooth muscle cells, but the mechanisms are poorly understood. Calciprotein particles (CPP) are cytotoxic nanoparticles composed of inorganic calcium-phosphate crystals and mineral binding proteins, such as fetuin-A. CPP circulate in the blood of patients with chronic kidney disease and may contribute to vascular calcification, chronic inflammation and a premature-aging phenotype. However, little is known about the effect of CPP on smooth muscle cells. We studied the role of autophagy in vascular calcification induced by phosphate and CPP.

Methods: We used primary human aortic smooth muscle cells (hAoSMC) to assess CPP-induced autophagy and calcification. We made CPP from Dulbecco's Modified Eagle Medium containing 10% fetal bovine serum, 5 mM phosphate, and 10 mM calcium. We also prepared CPP containing Alexa488-labeled Fetuin-A, and observed localization of CPP and LC3 in hAoSMC using confocal microscope. For high phosphate condition, we incubated cells in the presence of 4 mM phosphate. Calcification was analyzed by von Kossa staining. Induction of autophagy was detected by western blot and immunofluorescence.

Results: High phosphate obviously induced endogenous LC3 puncta in hAoSMCs. In electron microscopy, we observed calcium phosphate crystal-like substances in autophagic structures in hAoSMCs under high phosphate. CPP induced calcification of hAoSMC in concentration-dependent manner. Consistent with high phosphate condition, CPP induced autophagy in hAoSMCs. The conversion of LC3-I to LC3-II in western blot and endogenous LC3 puncta formation were induced. Furthermore, we found that a small part of CPP containing labeled fetuin-A localized in LC3-labeled autophagosome under laser confocal microscope.

Conclusions: Phosphate or CPP induce autophagy and calcification in hAoSMC. And some calcium phosphate crystal or CPP localized in autophagosome. Autophagy may regulate CPP transport or dissolution in smooth muscle cells.

FR-PO711

Pressure Applied In Vitro Increases Proliferation of Renal Proximal Tubular Cells
Diane Felsen,[1] Jie Chen,[1] Juana Gonzalez,[2] Bianca J. Diaz,[1] Dix Poppas.[1] *[1]Inst for Pediatric Urology, Weill Cornell Medical, NY, NY; [2]Ctr for Clin Translational Sci, Rockefeller U, NY, NY.*

Background: Increased renal pressure is a common finding in kidneys with obstructed ureters [UO]. In animal models of UO, increased cellular proliferation may contribute to renal damage and/or repair. We investigated the direct effect of pressure on proliferation of renal proximal tubular cells in vitro.

Methods: Human HKC-8 or rat NRK-52E proximal tubule cells were grown at either ambient pressure, or at 60 or 90 mm Hg for 24/48 hr, using a system we designed [Am J Physiol Renal 293:F1877, 2007]. Cells were grown in complete medium [CM; DMEM with

10% FBS] or in starvation media [SM; DMEM]. At 24/48 hr, cells were counted using the Cyquant assay. Western blot and PCR for proliferating cell nuclear antigen [PCNA] and Skp2 were carried out, as was cell cycle analysis by flow cytometry. Media composition was determined in an iSTAT.

Results: HKC-8 grown in CM for 48 hr at 60 mm Hg, demonstrated a 16.5 ± 5.8% increase in cell number compared to ambient pressure. After 48 hr of 60 mm Hg pressure in SM, there was a 39.2 ± 5.1 % increase in cell number. At 90 mm Hg in SM, HKC-8 demonstrated a significant increase in cell number. Similar results were found with NRK-52E. Increased expression of PCNA and Skp2 was found in pressurized cells. Cell cycle measurements demonstrated an increase in HKC-8/NRK-52E in S phase, with a corresponding decrease in cells in G1. Pressure did not significantly affect pH, PCO2 or PO2 of either CM or SM.

Conclusions: We demonstrate direct transduction of pressure into a proliferative response in HKC-8 and NRK-52E cells, measured by cell number, PCNA or increase in cells in S phase. Effects on proliferation were more pronounced in SM, suggesting that pressure may be able to [re-]activate pathways normally turned off during starvation. Increased Skp2 would accelerate degradation of the p27 cell cycle inhibitor, consistent with increased proliferation. Understanding the signaling pathways activated by pressure on epithelial and other cells in the kidney should lead to a better understanding of how pressure contributes to renal damage in UO, or in other diseases characterized by high pressure.

HIV Induces Dedifferentiation and Eithelial Mesenchymal Tansition (EMT) in Hman Pdocytes: Role of Eigenetic Fctors and ß-Ctenin Pthway

Nirupama Chandel, Kamesh R. Ayasolla, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofsta North Shore LIJ Medical School, Great Neck, NY.*

Background: Patients with HIV kidney infection develop collapsing varinat of glomeurlosclerosis. In this variant, podocytes display proliferative phenotype. This phenotype has been attributed to dedifferentiation of podocytes from its terminally differentiated state through re-entry into cell cycle. In addition, kidney cell infection by HIV has been incriminated for subversion of podocyte machinery and loss of its epithelial phenotype. We hypothesized that HIV would induce dedifferentiation phenotype through enhancing snail expression and associated epigenetic factors leading to down regulation of p-cadherin and nephrin. Additionally, HIV-induced activation of WNT receptors would activate podocyte EMT via ß-catenin pathway. Since epigenitc factors-induced alterations are reversible, thererpeutic strategies can be planned to alter HIV-induced podocyte phenotype.

Methods: cDNA and protein blots of empty vector- (EV/HPs) and NL4-3 without *gag and pol* (HIV/HPs)-transduced human podocytes (HPs) were probed for snail and markers of EMT (a-SMA, vimentin, and FSP-1) (n=3). To explore a causal relationship between hypermethylation and down regulation of p-cadherin and nephrin, EV/HP and HIV/HPs were treated with either buffer or 5-azacytidine (AZAC, a demethylating agent) for 24 hours (n=3) and evaluated for p-cadherin and nephrin expression by Western blot analysis. Binding of snail at the E-boxes was confirmed by chip assay through primers spanning E-boxes for respective genes.

Results: HIV/HPs displayed over expression of snail but down regulation of p-cadherin and nephrin. HIV/HPs displayed 2-3 fold increase in expression of a-SMA, vimentin, and FSP-1. HIV/HPs also displayed enhanced WNT7 mRNA expression and down stream molecules indicating the activation of β-Catenin pathway. AZAC inhibited HIV-induced upregulation of snail and down regulation of p-cadherin and nephrin confirms the role of epigenetics.

Conclusions: HIV induces dedifferentiation and exhibiton of markers of epithelial mesenchymal transitioin in podocytes through epigenetic factors and activation of β-Catenin pathway.

Renal Injury Suppresses Claudin-2 Expression to Induce Dedifferentiation of Renal Epithelial Cells

Rizwan Ahmad,[1] Giovanna A. Giannico,[3] Pinelopi P. Kapitsinou,[2] Volker H. Haase,[2] Roy Zent,[2] Raymond C. Harris,[2] Peter E. Clark,[4] Punita Dhawan,[1] Amar B. Singh.[1,2] *[1]Surgery, Vanderbilt Univ; [2]Medicine, Vanderbilt Univ; [3]Pathology, Microbiology and Immunology, Vanderbilt Univ; [4]Urology, Vanderbilt Univ.*

Background: Epithelial cell dedifferentiation is a feature of rapidly dividing cells under controlled growth, as in recovery of post-renal injury, or non-controlled growth, as in renal cancer. However, mechanisms regulating renal epithelial cells (REC) differentiation remain largely undefined. We have demonstrated that in MDCK cells, EGFR-activation suppresses claudin-2 expression to induce tight junction (TJ) remodeling. TJ dysregulation characterize renal injury and cancer. However, the role of claudin-2 in the regulation of REC morphogenesis remains poorly understood.

Methods: qRT-PCR, Immunoblot and immunostaining analyses were done. Hypoxia was induced in hypoxia chambers. Anti-claudin-2 shRNA was employed.

Results: In mouse kidney subjected to hypoxia, claudin-2 expression decreased significantly ($P<0.01$). Further, chronic loss of claudin-2 expression characterized dedifferentiated MDCK cells, either due to exposure to chronic hypoxia or EGFR-activation ($P<0.001$). This loss of claudin-2 expression was associated with the loss of cilia and preceded decreases in E-cadherin expression, markers of differentiated REC. Further, stable silencing of claudin-2 expression in MDCK cells inhibited markers of terminal differentiation, including dome-formation and cilia growth. By contrast, re-expression of claudin-2 in MDCK^{sol} cells, MDCK cells with constitutive EGFR-signaling and transformed phenotype, reverted the epithelial phenotype. Further studies using protein and transcriptome analyses of more than 200 renal clear cell carcinoma samples and mice renal tumors demonstrated chronic suppression of claudin-2 expression *versus* matched normal kidney ($P<0.001$).

Conclusions: Taken together, our data demonstrate a novel role of claudin-2 in the maintenance of differentiated phenotype of PTE cells. We predict that suppressed claudin-2 expression during renal injury promotes regeneration/repair however its persistent and chronic loss promotes neoplastic transformation under tumorigenic conditions.

FR-PO714

Exocyst Sec10 Regulates Kidney Tubular Epithelial Cell Wound Healing Through Modulation of Cell Proliferation and Migration

Mi Ra Noh,[1] Jee In Kim,[2] Joshua H. Lipschutz,[3] Kwon Moo Park.[1] *[1]Dept of Anatomy and BK21 Plus, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; [2]Dept of Molecular Medicine and MRC, Keimyung Univ School of Medicine, Daegu, Republic of Korea; [3]Dept of Medicine, Philadelphia Veterans Affairs Medical Center and the Univ of Pennsylvania, Philadelphia, PA.*

Background: Migration and proliferation of survived kidney tubule cells after sub-lethal kidney injury play a critical role for the kidney recovery. Exocyst component is involved in cell migration and proliferation. Here, we investigated the role of Sec10 and underlying mechanisms in the wound healing from scratch injury of cultured kidney tubule cells.

Methods: Cultured MDCK cells which over-express or lack Sec10 were scratched and further cultured for the restoration. The rate of growing and wound healing rate was determined.

Results: Sec10 over-expression delayed the wound healing and Sec 10 knock down (KD) vice versa. Mesenchymal transition and proliferation of MDCK cells were inhibited by over-expression of Sec10 and vice versa by KD of Sec10. Activation of ERK in the newly grown cells was lower in Sec 10 over-expressing MDCK cells than control and vice versa in Sec 10 KD MDCK cells. Sec10 over-expressing MDCK cells reduced ruffle formation in the growing edge of the cells, whereas Sec10 KD cells promoted ruffling, indicating that Sec10 modulates migration of tubular cells. Small GTPase Cdc42 mRNA expression was significantly increased in Sec10 KD cells compared with control.

Conclusions: Taken together, the data reveal that Sec10 delays wound healing of kidney tubule cells via inhibition of mesenchymal transition, proliferation, and migration through inhibition of ERK activation and ruffle formation likely by alteration of Cdc42 expression.

FR-PO715

The Roles of Oxidative Stress, Endoplasmic Reticulum Stress and Autophagy in Aldosterone/Mineralocorticoid Receptor-Induced Podocyte Injury

Yanggang Yuan, Changying Xing. *Dept of Nephrology, The First Affiliated Hospital of Nanjing Medical Univ, China.*

Background: Podocytes play an important role in the pathogenesis and progression of glomerulosclerosis. Recent studies indicate that aldosterone/mineralocorticoid receptor (MR) is a major contributor of chronic kidney disease (CKD) progression. aldosterone/MR induces glomerular podocyte injury, causing the disruption of the glomerular filtration barrier and proteinuria.

Methods: The expressions of well-known UPR target genes including Bip, grp94 and Chop and podocyte-specific proteins nephrin and podocin were detected by real-time PCR and immunoblotting. we confirmed the induction of autophagy using LysoTracker Red staining and accessing the ratio of LC3II/LC3I to actin. ROS generation was determined using 2,7-dichlorofluorescein diacetate (DCF-DA).

Results: We observed that aldosterone/MR induced ER stress and podocyte injury both in vivo and in vitro. Blockade of ER stress significantly reduced aldosterone/MR-induced podocyte injury. Additionally, we found that ER stress-induced podocyte injury was mediated by Chop. Interestingly, autophagy was also enhanced by aldosterone/MR. Pharmacological inhibition of autophagy resulted in increased apoptosis. Inhibition of ER stress also significantly reduced aldosterone/MR-induced autophagy. Moreover, we observed that the addition of ROS scavenger, N-acetylcystein (NAC), blocked both ER stress and autophagy by aldosterone/MR.

Conclusions: These results suggest that oxidant stress mediated aldosterone/MR-induced podocyte injury via activating ER stress which then triggers both the Chop-dependent apoptosis and autophagy to cope with the injury.

FR-PO716

P53-Mediated Upregulation of MKP-3 Contributes to the Establishment and Maintenance of Renal Tubular Cell Senescence through Inactivation of ERK1/2

Hui Zhang, Yuan Chi, Kun Gao, Jian Yao. *Dept of Molecular Signaling, Univ of Yamanashi, Chuo, Yamanashi, Japan.*

Background: Growth arrest is the essential feature of cellular senescence. At present, the mechanisms responsible for the maintenance of the arrested phenotype of senescent cells are still incompletely understood. Given that extracellular signal-regulated kinases 1 and 2 (ERK1/2) is one of the major kinases controlling cell growth and proliferation, we examined the possible involvement of ERK1/2 in tubular epithelial cell senescence.

Methods: Senescence in normal rat kidney epithelial cells (NRK) was induced by etoposide (ETO), and confirmed by morphology and b-galactosidase (b-gal) activity. Cell proliferation was evaluated by BrdU incorporation. The level of ERK1/2, MEK-1, mitogen-activated protein phosphatase-3 (MKP-3) and p53 was analyzed by Western blot, Northern blot and promoter activity assay. Suppression/downregulation of ERK1/2, p53 or MKP-3 was achieved by using inhibitors and/or siRNA. Oxidative cell injury was induced by free radical donors, and evaluated through the change of cell morphology and viability.

Results: 1) Exposure of NRK cells to ETO induced cellular senescence, as manifested by enlarged cell size, reduced cell proliferation and enhanced b-gal activity. 2) Stimulation of control cells with mitogens resulted in ERK1/2 activation and cell proliferation. Suppression of ERK1/2 significantly blunted cell proliferation. In contrast, senescent cells displayed an impaired activation of ERK1/2 and a loss of cell proliferation. 3) Senescent cells expressed a markedly increased level of p53 and MKP-3. Suppression of the transcription activity of p53 abrogated the elevation of MKP-3 and recovered cellular response to mitogen. Inhibition of MKP-3 increased the basal level of ERK1/2 phosphorylation and cell proliferation. 4) Impaired ERK activation was related to the senescence-associated resistance to oxidative cell injury.

Conclusions: The present results indicate that inactivation of ERK1/2 by p53-mediated upregulation of MKP-3 is a key molecular event implicated in the establishment and maintenance of renal tubular cellular senescence. Our finding could have implications in renal tubular cell repair and regeneration.

FR-PO717

A Western Diet Leading to Maternal Glucose Intolerance and Obesity Elevates Offspring Nephron Endowment without Adverse Effects on Adult Renal Function

Stacey Hokke,[1] James Armitage,[1,2] Victor G. Puelles,[1] John F. Bertram,[1] Luise A. Cullen-McEwen.[1] *[1]Dept of Anatomy and Developmental Biology, Monash Univ, Clayton, VIC, Australia; [2]Faculty of Medicine (Optometry), Deakin Univ, Waurn Ponds, VIC, Australia.*

Background: Consumption of a high fat 'western' diet has led to a growing number of pregnancies complicated by maternal glucose intolerance and obesity. Maternal glucose intolerance and obesity have health implications for offspring, yet little is known about their effects on offspring renal development and function. Animal studies report a nephron deficit and reduced renal function in offspring exposed to maternal diabetes, however current literature is limited to models of persistent severe hyperglycemia and fetal growth restriction which do not reflect the typical clinical condition.

Methods: Female C57Bl6 mice were fed a high fat diet (HF, 21% fat) or matched normal diet (NF, 6% fat) for 6 weeks prior to pregnancy and throughout gestation and lactation, producing overweight females with glucose intolerance. Offspring of HF and NF dams were collected prior to birth at embryonic day (E) 18.5 and at postnatal day (PN) 21 for determination of nephron number using unbiased stereology. Glomerular filtration rate (GFR) was assessed at 6 months of age by transcutaneous measurement of FITC-sinistrin clearance.

Results: HF offspring were 5% heavier at E18.5 (p=0.019) but did not differ in bodyweight at PN21 (p=0.107). Compared to offspring of NF dams, offspring of HF dams had approximately 25% more nephrons at E18.5 (p=0.009) and PN21 (p<0.0001). Nephron endowment correlated with maternal glucose tolerance (rho=0.674, p=0.0002) and maternal bodyweight (rho=0.460, p=0.011) prior to pregnancy. There was no difference in offspring bodyweight (p=0.763) or GFR (p=0.248) at 6 months of age.

Conclusions: Offspring born to mothers fed a 'western' diet associated with maternal glucose intolerance and obesity had an elevated nephron endowment, which was established early in nephrogenesis. This increase in nephron endowment was associated with larger offspring at a time of ongoing nephrogenesis. As adults, HF offspring did not show altered GFR. Further studies are required to assess nephron morphology and proteinuria.

FR-PO718

The Effect of Maternal Cigarette Smoke Exposure on Offspring Predisposition to Kidney Disease in Male and Female Mice

Ibrahim Al-Odat,[1,2] Hui Chen,[1] Yik Lung (Jeremy) Chan,[1] Amgad Sawiris,[2] Carol A. Pollock,[2] Sonia Saad.[2] *[1]School of Medical and Molecular Biosciences, Sydney, NSW, Australia; [2]Kolling Inst of Medical Research, Sydney, NSW, Australia.*

Background: Maternal smoking is associated with long term health consequences in the offspring including obesity, respiratory and cardiovascular diseases. In human, maternal smoking is closely linked to lower fetal kidney volumes during the second and third trimester and lower birth weight. However, it is still unknown whether maternal smoking increased the risk of developing chronic kidney disease in offspring and whether there is any gender difference. The study aims to investigate the effect of maternal smoking on offspring renal development and predisposition to kidney disease in both genders.

Methods: Female Balb/c breeder mice were exposed to either air or cigarette smoke for 6 weeks prior to mating, during gestation and lactation. Female and male offspring were sacrificed at postnatal day (P) 1, P20 (weaning age) and 13 weeks (mature age). Serum and urine were collected and kidneys were harvested. Kidney histological changes were examined. mRNA and proteins expression of renal development and injury markers were determined. Kidney function was assessedand intraperitoneal glucose tolerance test was performed.

Results: At W13, Males offspring from the SE group had decreased kidney/body weight compared to control (p <0.05). Glomerular number was significantly decreased only in male offspring from SE dams at P1, P20 and W13 and glomerular size was significantly increased at P20. mRNA and protein expression of renal development markers such as bone morphogenetic protein (BMP) 4, fibroblast growth factor (FGF) 2, FGF10, glial cell line-derived neurotrophic factor (GDNF) and WNT4 were only upregulated in the kidneys of male offspring from SE dams (p <0.05). Male but not female offspring had a significant increase in urinary albumin/creatinine ratio at W13 (p <0.05). Both genders had increased glucose intolerance at W13 due to maternal SE.

Conclusions: Female mice offspring are less susceptible to renal pathophysiology compared to male offspring. Both gender had metabolic disorders due to maternal SE.

FR-PO719

Furry as a Partner of the Ldb1-Lhx1 Transcriptional Complex for the Specification of the Renal Progenitor Cell Field

Maria C. Cirio,[1] Jessica Lynn Fall,[2] Jacqueline Ho,[3] Neil A. Hukriede.[2] *[1]Dept of Biodiversity and Experimental Biology, Univ of Buenos Aires, Buenos Aires, Argentina; [2]Dept of Developmental Biology, Univ of Pittsburgh, Pittsburgh, PA; [3]Dept of Pediatrics, Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA.*

Background: In the vertebrate embryo all renal progenitor cells are derived from the intermediate mesoderm. Lhx1, a LIM-class homeobox transcription factor, is initially expressed throughout the lateral and intermediate mesoderm and is one of the earliest genes to be restricted to the kidney field. We have previously shown that Lhx1 is essential for driving specification of the kidney field, but the molecular mechanism remains undefined.

Methods: By tandem affinity purification we identified the protein Furry (Fry) binding to Lhx1. In *Xenopus*, previous reports indicate that Fry acts as a transcriptional co-repressor of microRNAs preventing message degradation for Spemann organizer genes, temporally controlling their mRNA levels. We established the expression pattern of *Fry* by *in situ* hibridization and analyzed the effects of its depletion in pronephric kidney formation by using morpholinos. To investigate a possible mechanism of action for Fry and Lhx1 in the formation of the kidney field we performed MicroRNA deep sequencing on embryos depleted of the two proteins.

Results: We found that *fry* is expressed in the intermediate mesoderm and developing pronephros. We determined that embryos depleted of *fry* by morpholino injections show almost complete loss of the kidney field, resembling the *lhx1* depletion phenotype. We observed a synergistic effect of these two proteins indicating the requirement of this interaction for the specification of the kidney progenitor cells. We identified miRNAs affected by the depletion of these proteins that might be in part responsible for the phenotype.

Conclusions: These results suggest a role of Fry in the pronephric kidney development associated with the transcriptional activity of Lhx1, possibly through regulation of miRNAs expression.

Hedgehog Signaling Controls Renal Capsule Formation and Nephron Number via Cell Autonomous and Non-Autonomous Mechanisms

Norman D. Rosenblum,[1,2,3,4] Hovhannes Martirosyan,[2] Josh Blake,[3] Winny Li.[4] *[1]Div Neph, Dept Paeds, Hosp Sick Children; [2]Depts Lab Med Pathobiol, U Toronto; [3]Physiology, U Toronto; [4]Inst Med Sciences, U Toronto, Toronto.*

Background: Nephrogenesis is controlled by interactions between *Foxd1*+ cortical stromal and adjacent nephron progenitor cells. Underlying mechanisms are poorly defined. Based on expression of Hedgehog signaling effectors, Indian Hedgehog, *Gli1* and *Patched1* in cortical stromal cells, we hypothesize that Hedgehog signalling controls cortical stromal cell functions. Hedgehog ligands signal via SMO to increase levels of GLI transcriptional activators and decrease formation of GLI3 repressor (GLI3R), a processed form of GLI3 protein.

Methods: Hedgehog signalling was modulated in vivo using *Cre*-mediated recombination. Tissue ultrastructure and cell proliferation were analyzed by scanning electron microscopy and in situ BrdU-incorporation, respectively.

Results: *Foxd1-Cre;Smo^{null}* mice (E15.5) demonstrated renal hypoplasia and a discontinuous capsule of cortical stromal cells. Despite initial formation of the capsule, expression of *Gli1*, *Foxd1* and *Raldh2* was markedly decreased with a 54% decrease in capsular stromal cell proliferation by E13.5. Glomerular number was decreased by 42% by E18.5. Surprisingly, *Six2*+ positive cap mesenchyme was expanded with a 41% increase in *Six2*+ cell proliferation at E15.5. Yet, the number of nephrogenic intermediate structures was decreased by 50% starting at the stage of renal vesicle with a specific decrease in *Lhx1* expression. Introduction of conditional and obligate *Gli3R* alleles in *Foxd1*+ cells phenocopied Foxd1-Cre;*Smo^{null}* mice, while homozygous deficiency of *Gli3* rescued the mutant phenotype. Hedgehog functions in *Six2*+ nephrogenic cells were investigated in mice with *Smo* deficiency or *Cre*-mediated Gli3R expression, demonstrating decreased *Six2*+ cell number and proliferation by 70%, and a 60% decrease in nephron number.

Conclusions: We conclude that Hedgehog-Gli signalling acts via cell autonomous and non-autonomous mechanisms to control: (1) stromal cell gene expression and proliferation and nephron number, and (ii) *Six2*+ nephrogenic cell proliferation and nephron formation, in a manner that is dependent on expression of GLI3R.

Nephron Progenitor Networks in Mouse and Man: Novel Targets, Common Threads and Unexpected Differences Lori L. O'Brien,[1] Qiuyu Guo,[1,2] Joo-Seop Park,[3] Anton Valouev,[2] Andrew P. McMahon.[1] *[1]Dept of Stem Cell Biol and Regen Med, USC Keck School of Medicine, Los Angeles, CA; [2]Dept of Prev Med, USC Keck School of Medicine, Los Angeles, CA; [3]Div of Ped Urol and Dev Biol, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: All cells of the nephron are derived from a common progenitor. The nephron progenitor (NP) population of the developing kidney must maintain a balance of self-renewal and differentiation to ensure sufficient nephron endowment. While the mouse kidney generates ~14,000 nephrons over 10 days, around 1 million nephrons are generated over many weeks of human kidney development. Consequently, the lifetime of progenitor programs is quite different in each system.

Methods: Six2 is expressed within NPs where it promotes their self-renewal and prevents ectopic nephrogenesis. Pax2, Hox11 paralogs, Osr1, Sall1, Wt1, and Eya1 are expressed within the NP population and all are required for proper kidney development. Despite their integral roles, little is known about their transcriptional targets and the regulatory interplay amongst these factors. To this end, we have employed ChIP-seq to identify transcriptional targets of Six2, Hoxd11, and Osr1 in mouse and the transcriptional network regulated by SIX2 within the human fetal kidney.

Results: The binding of these three factors and human SIX2 is significantly enriched near genes associated with kidney development such as Sall1, Pax2, Wt1, Itga8, Kif26b, and the three factors themselves, in addition to unique nephrogenic targets within human. We have identified novel targets, including a component of chromatin modifying complexes that is specifically expressed within the NPs; functional analyses are underway.

Conclusions: These data suggest a regulatory circuitry that promotes self-renewal through positive feedback and supports the expression of factors essential for cellular integrity. Our studies reveal shared regulatory actions between mouse and human as well as divergent and interestingly novel regulatory interplay at other nephrogenic regulators. A better understanding here will facilitate efforts to utilize progenitor programs for regenerative strategies.

The Groucho Associated Phosphatase PPM1B Displaces PTIP to Switch Pax2 from a Transcriptional Activator to a Repressor Sanjeevkumar R. Patel,[1] Saji Abraham.[1] *[1]Internal Medicine, Univ of Michigan, Ann Arbor, MI; [2]Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: In mammals, the Gro/TLE family consists of four proteins of similar molecular weight and structure. These proteins cannot bind to DNA themselves, but modulate the process of transcription by physical interaction with DNA-binding transcription factors. These proteins can down regulate the expression of target genes of transcriptional activators, enhance the transcriptional repression effect of transcriptional repressors, or convert transcriptional activators into repressors. Grg/TLE co-repressors were shown to interact with multiple transcription factors including HES proteins, RUNX proteins and Pax proteins. Pax genes encode developmental regulatory proteins that specify cell lineages and tissues in metazoans. Upon binding to DNA through the conserved paired-domain, Pax proteins can recruit both activating and repressing complexes that imprint distinct patterns of histone methylation associated with either gene activation or silencing. Expression of the Groucho proteins is widespread during development and overlaps partially with the Pax proteins in the neural tube and the kidney. Interaction of the Groucho/TLE members and Pax proteins may repress Pax-regulated genes.

Methods: We identified Grg4 containing complexes from mammalian nuclear lysates by fractionation, immunoaffinity purification, and mass spectrometry.

Results: In this report, we identify the phosphatase PPM1B as an essential component of the Groucho4 repressor complex that is recruited by Pax2 to chromatin. PPM1B can dephosphorylated the Pax2 activation domain and displace the adaptor protein PTIP, thus inhibiting H3K4 methylation and gene activation. Loss of PPM1B, prevents Groucho mediated gene repression.

Conclusions: Thus, PPM1B helps switch Pax2 from a transcriptional activator to a repressor protein. This can have profound implications for developmental regulation by Pax proteins and suggests a model for imprinting specific epigenetic marks depending on the availability of co-factors.

FR-PO723

Wnt9b Directly Activates beta-Catenin Signaling in the Nephron Progenitor Cells Xinchao Pan, Thomas J. Carroll. *Internal Medicine (Nephrology), Molecular Biology, UT Southwestern Medical Center, Dallas, TX.*

Background: Wnt signals play multiple roles during kidney development. The major mediator of Wnt signaling is the transcription factor beta-catenin. Activation of the Wnt pathway leads to the translocation of β-Catenin from cytoplasm to the nucleus where it acts as a co-factor with members of the LEF/TCF family of DNA-binding transcrlption factors to drive expression of target genes. We recently hypothesized that Wnt9b promotes renewal of the nephron progenitors in a beta-catenin dependent manner. However, several "universal" beta-catenin reporter lines failed to show activity in the nephron progenitors.

Methods: To test whether Wnt9b directly activated beta-catenin activity in the progenitors, we engineered mice driving expression of Lac-z under the control of a putative enhancer element of Tafa5, a Wnt9b target gene. This enhancer element contains conserved Lef/Tcf binding sites.

Results: We found that this Tafa5-LacZ reporter is expressed in the nephron progenitor cells from E11.5 through birth. Wnt9b and β-Catenin are both necessary for expression of this reporter. Further, we have found that the transcription factors C-myc, N-myc and Six2 cooperate with beta-catenin to activate the Tafa5 reporter.

Conclusions: Our data indicate that Six2 and c-myc cooperate with a permissive Wnt9b/beta-catenin program to drive nephron progenitor renewal. We are currently testing how these interactions regulate nephron endowment in vivo.

FR-PO724

Renal Blood Flow and Oxygenation Drive Nephron Progenitor Differentiation Christopher Cain Rymer, Sunder Sims-Lucas. *Pediatric Nephrology, Rangos Research Center, Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA.*

Background: During kidney development two discrete, yet simultaneous, vascular processes take place: angiogenesis, vessel growth from a major preexisting vessel, and vasculogenesis, de novo vessel formation from residential endothelial progenitors. Little is known about renal embryonic blood flow and its interactions with renal stem cells. The nephrogenic zone contains the renal stem cells that are thought to exist and proliferate in an oxygen-depleted environments.

Methods: Here, we investigate renal blood flow ontogeny and the role of oxygen concentration on nephron progenitor differentiation. To elucidate blood flow, ultrasound-guided intracardiac microinjection of FITC-tagged tomato lectin (TL) was utilized to map perfusion throughout each embryo. Kidneys were co-stained for vasculature, ureteric epithelium, nephron progenitors, and differentiated nephron structures. Embryonic mice throughout kidney development (E11.5 to E17.5) were used. We also analyzed nephron progenitor differentiation in vitro in normoxia compared to hypoxia.

Results: At E13.5, major vascular branches were perfused, however, smaller-caliber peripheral vessels remained unperfused. By E15.5, glomeruli and peripheral vessels begin to become perfused. While interior kidney vessels were perfused, peripheral vessels within the nephrogenic zone remained unperfused. Prior to an onset of blood flow, vast populations of renal vessels (believed to be vasculogenic) form within the nephrogenic zone. Directly adjacent and internal to the nephrogenic zone, we found differentiated nephron structures surrounded and infiltrated by perfused vessels. In vitro at low oxygen concentration little nephron progenitor differentiation was observed; at higher oxygen concentrations more differentiation of nephron progenitors was induced. This is seen through a formation of Six2 derived aggregates, marking differentiated glomeruli and nephron structures. In hypoxic environments, metanephric cap mesenchyme seems to maintain a higher state of proliferation as compared to normoxia.

Conclusions: From these investigations we concluded that renal blood flow and oxygenation are critical for nephron progenitor differentiation.

FR-PO725

Metabolic Fitness in Nephron Progenitor Renewal Jiao Liu, Samir S. El-Dahr, Zubaida R. Saifudeen. *Pediatrics, Tulane Univ Health Sciences Center, New Orleans, LA.*

Background: Premature termination of self-renewal rapidly depletes the progenitor population resulting in nephron deficit. Glucose metabolism, ATP production and ROS generation are critical modulators of stem/progenitor cell self-renewal.

Methods: A conditional p53-null mouse model of the Six2+ cap mesenchyme (CM) ($Six2^{p53-/-}$) was generated and used to test the hypothesis that metabolic fitness regulates self-renewal of CM cells. Data was analyzed by immunofluorescence, transcription profiling by RNA-Seq of FACS isolated CM cells, ATP and ROS measurements.

Results: 1. $Six2^{p53-/-}$ kidneys show renal hypoplasia, nephron deficit, loss of Cited1+/Six2+ but not the Cited1-/Six2+ cells, suggesting the NPC prematurely transition to non-self-renewing Six2+/Cited1- cells. 2. While the apoptotic index is unchanged, $Six2^{p53-/-}$ cells show decreased BrdU incorporation and an extended cell cycle. 3. Top down-regulated genes in $Six2^{p53-/-}$cells belong to glucose metabolism pathways - fructose bisphosphatase 1 (*Fbp1*, -82.0), phosphoenol pyruvate carboxykinase 1 (*Pck1*, -14.3) and aldolase b (*Aldob*, -12.0). Oxphos genes are also down-regulated – including genes encoding electron transfer chain (ETC) enzymes and maintenance of mitochondrial membrane potential. 4. As a result of these metabolic derangements, $Six2^{p53-/-}$ cells showed 2.0-fold reduction in ATP levels ($p<0.005$, n=3), 33% decline in ROS levels and diminished mitochondrial immunostaining as detected with an antibody against a mitochondrial protein.

Conclusions: Our data suggest that robust metabolic fitness is required to maintain the stemness of nephron progenitors.

FR-PO726

Renal Dysplasia - unMET Needs? Satyamaanasa Polubothu, Chiara Mari, Karen Price, Paul Winyard. *Developmental Biology & Cancer, UCL Inst of Child Health, London, United Kingdom.*

Background: Renal dysplasia accounts for 50% of paediatric patients with CKD-V. A key step during nephrogenesis is mesenchymal-to-epithelial-transformation (MET), generating the entire nephron from glomerulus to distal tubule. Aberrant MET occurs in dysplasia. We tested whether there is an intrinsic defect in dysplastic mesenchyme which prevents MET or whether the cells can transform if given the right stimuli. Aims: 1) Generate novel human dysplastic mesenchymal cell lines, 2) Assess MET in response to chemical inducers, 3) Evaluate MET in 3-D reconstitution.

Methods: After ethical consent, 6 childhood dysplastic samples (6 months - 5 years) were collected, surgically diced and cultured until confluent. Cells were aliquoted and exposed to MET inducers for 7 days including: Leukaemia-Inhibitory-Factor (LIF; 20ng/ml), Lithium Chloride (LiCl; 1 or 20mM) and BIO (0.1 or 1uM). Phenotypic and molecular conversion was assessed by morphology, Q-PCR and Western blotting. In parallel, fluorescently-labeled cells were grown 1:5 in 3-D reconstitution organ culture with normal human fetal kidney progenitors.

Results: Each culture generated predominantly mesenchymal populations. These postnatal cells express key developmental markers *PAX2*, *HGF*, *GDNF*, *OSR1*, *EYA1* and stem markers *CD24* and *CD133*, but lack other critical factors including *SALL1*, *CITED1*, *SIX2*, *WT1*, *WNT4*, *WNT9b*. Each MET inducer enhanced proliferation c.f. controls, most marked with LIF and LiCl. Sparse islands of epithelial cells also developed but gene expression patterns were not consistently changed by the MET inducers. Recombined dysplastic/normal chimaeras initially re-aggregated but broke down at 48-72 hours, with no evidence of the epithelial differentiation seen in controls.

Conclusions: Our unique human postnatal dysplastic cell lines interestingly express fetal developmental markers but proliferate rather than undergoing MET with inducers, and had inhibitory effects in 3-D culture. Thus far, we cannot distinguish between intrinsic and extrinsic defects in dysplasia. Ongoing work will assess dysplastic versus normal MET. If we can identify why dysplastic cells inhibit 3-D differentiation in vitro, we may be able to target therapies to overcome this in vivo.

HoxB7.Cre-Mediated mVps34 Deletion Inhibits Nephrogenesis and Causes Nephron Hypertrophy Jinxian Xu,[1] Jianchun Chen,[2] Kaitlyn Werner,[3] Jeffrey G. Dickhout,[3] Jian-Kang Chen.[1] *[1]Cellular Biology & Anatomy and Medicine, GRU, Augusta, GA; [2]Medicine, Vanderbilt Univ, Nashville, TN; [3]Medicine, McMaster Univ, Hamilton, ON, Canada.*

Background: The mammalian homolog of yeast vacuolar protein sorting 34 (mVps34) has been implicated in nutrient sensing, but its physiological role in the renal collecting system is unknown.

Methods: We generated an mVps34-floxed (*mVps34$^{flox/flox}$*) mouse and crossed it with a HoxB7.Cre mouse to produce renal collecting system-specific mVps34 knockout (*KO*) mice and used *mVps34$^{flox/flox}$*;HoxB7.Cre $^{(-)}$ littermates as controls (*Ctrl*).We also bred *mVps34$^{flox/flox}$* mice to a membrane-targeted tomato Red/GFP reporter (mRG) mouse and then to an ImmortoMouse (Im) and established an *mVps34$^{flox/flox}$;mRG^{+};Im^{+}* inner medullary collecting duct (IMCD) cell line.

Results: By E17.5, *KO* mice began to show dilated renal collecting ducts and proximal tubules. At birth, *KO* mice had significantly smaller kidneys and lower kidney-to-body weight ratio (0.21±0.02% versus 0.42±0.18% in *Ctrl*, $P<0.0001$, $n=10$), with indistinguishable body weight but markedly reduced number of DBA- or calbindin-D28K-positive renal tubules. By 2 months of age (long after nephrogenesis is complete), *KO* mice had a 58% reduction in glomerular number (7670 ± 1530 versus 18392 ± 1333 in *Ctrl*, $P<0.001$, $n=5$-7 mice/group) and exhibited unproportionally thinner renal medulla (medulla/whole kidney volume ratios: 22.60 ± 1.84% versus 37.56 ± 3.77% in *Ctrl*, $P<0.05$, $n=4$), with marked glomerular and tubular hypertrophy. 15% of *KO* mice developed glomerulosclerosis and interstitial fibrosis, with elevated albumin/creatinine ratio (278.20 ± 67.27 versus 20.49 ± 2.36 µg/mg in *Ctrl*, $P<0.01$, $n=6$) and increased BUN levels (53.33 ± 8.43 versus 23.75 ± 7.60 mg/dl in *Ctrl*, $P<0.001$, $n=6$). Adeno.Cre-infected *mVps34$^{flox/flox}$;mRG^{+};Im^{+}* IMCD cells showed green fluorescence and mVps34 deletion, with diminished Akt phosphorylation and down-regulated cyclin D1 and cyclin E expression, leading to inhibition of cell proliferation and branching morphogenesis in 3D Matrigel culture.

Conclusions: Our study demonstrates that mVps34 plays an important role in nephrogenesis by promoting cell proliferation and branching morphogenesis of ureteric bud-derived cells.

FR-PO728

The Effect of Vitamin D Deficient Diet during Pregnancy on Nephron Endowment in Rat Offspring Cagdas Oto,[1] Mehmet Altan,[2] Mehmet Fatih Bozkurt,[3] Caner Bakici,[1] Ozan Ahlat,[4] Alexis Okoh,[5] Sim Kutlay,[5] Rifki Haziroglu,[4] Sehsuvar Erturk.[5] *[1]Anatomy, Ankara Univ, Faculty of Veterinary Medicine, Ankara, Turkey; [2]Medical Oncology, Yale School of Medicine, New Haven, CT; [3]Pathology, Afyon Kocatepe Univ, Faculty of Veterinary Medicine, Afyonkarahisar, Turkey; [4]Pathology, Ankara Univ, Faculty of Veterinary Medicine, Ankara, Turkey; [5]Nephrology, Ankara Univ School of Medicine, Ankara, Turkey.*

Background: Vitamin D deficiency has been suggested to play role in the pathogenesis of various diseases including hypertension. One of the mechanisms responsible for the development of primary hypertension is low nephron number. We hypothesized that inadequate vitamin D intake during pregnancy could influence nephron endowment in the offspring.

Methods: Sprague-Dawley female rats of 21-day old were randomly divided into three groups after weaning and fed with vitamin D-high (6,000 IU/kg), vitamin D-normal (1,500 IU/kg) and vitamin D-low (0.1 IU/kg) diets for 4 weeks. These rats were then mated with Sprague-Dawley male rats fed with vitamin D-normal diet. The offspring were euthanized after their delactation in postpartum 3 weeks and the body weight, heart weight, and kidney weight were measured. Glomerular diameters and nephron numbers were examined stereologically under light microscopy.

Results: The first two days after parturition, the numbers of living litters were 10 in vitamin D-high, 10 in vitamin D-normal, and 4 in vitamin D-low group. The body, heart, and kidney weight and nephron number were lower, while glomerular diameter was greater in the offspring of vitamin D-low group than those in the other groups.

	Vitamin D-high	Vitamin D-normal	Vitamin D-low	p
Body weight (g)	49.7±6.5	52.9±7.3	33.6±2.6	<0.001
Heart weight (mg)	239.6±17.4	224.0±26.1	192.0±18.2	0.006
Kidney weight (mg)	244.1±22.6	282.8±35.3	187.6±9.6	<0.001
Nephron number (n)	26,319±3,417	28,622±3,598	19,525±1,002	0.001
Glomerular diameter (µm)	93.5±1.4	95.0±2.2	98.6±1.4	0.035

Conclusions: Vitamin D deficiency during intrauterine life may have a negative impact on nephron endowment, which might be responsible for the development of hypertension.

FR-PO729

Redundant and Distinct Roles of Mdm2 and Mdm4 in Ureteric Bud Branching Morphogenesis Sylvia Hilliard, Samir S. El-Dahr. *Pediatrics, Tulane Univ School of Medicine, New Orleans, LA.*

Background: Murine double minute 4 (Mdm4, also called Mdmx) is a close analogue of the p53-ubiquitin ligase, Mdm2, and a negative regulator of p53 transcriptional activity. Mdm4 dimerizes with Mdm2 to regulate p53 levels and activity in some tissues while exerting functions independent of Mdm2 in others. Deletion of Mdm2 in the ureteric bud (UB) lineage causes renal cystic dysplasia in a p53-depndent manner (Hilliard et al. Dev. Biol. 2011). The role of Mdm4 in UB branching and the functional redundancy of Mdm2 and Mdm4 in kidney development are unknown.

Methods: 1. The temporal expression of *Mdm4* was determined by QRT-PCR. 2. Deletion of *Mdm4* from the UB lineage was achieved by crossing *Hoxb7*-eGFP-*Cre to Mdm4$^{F/F}$* mice. 3. The effects of Mdm4 deletion on UB branching and nephron differentiation were examined by observing GFP fluorescence in vivo, UB tip counting, and IF staining of UB and nascent nephron markers. 4. The functional overlap of Mdm4 and Mdm2 was assessed in UB$^{Mdm4/Mdm2}$ compound mutant mice.

Results: 1. Examination of UB$^{Mdm4-/-}$ kidneys revealed that Mdm4 function is dispensable until the T-stage. 2. Disruption of UB branching starts around E12.5 resulting in fewer UB tips (~42% of wild type), dilated UB ampullae, a few even oriented parallel to the cortical aspect of the kidney. 3. A marker of tip progenitors, p63, is absent from many of the mutant Calbindin^{+} UB, and expression of pan cytokeratin in the tips is less robust than in wild type. 4. The intercalated cell marker, carbonic anhydrase II, is detected in only a few of the UB$^{Mdm4-/-}$ branches. 5. Six2^{+}/Pax2^{+} cap mesenchyme clusters around the mutant UB tips are smaller and less cohesive. 6. UB$^{Mdm4-/-}$ kidneys are endowed with fewer mature glomeruli at birth and are deficient by 1-2 nephron generations. 7. The UB$^{Mdm4-/-, Mdm2+/-}$ kidneys are smaller than the UB$^{Mdm4-/-, Mdm2+/+}$ kidneys, which in turn are smaller than UB$^{Mdm4+/-, Mdm2+/-}$ kidneys.

Conclusions: 1. Mdm4 is required for normal UB branching past the T-stage. Mdm4 inactivation results in renal hypoplasia. Later in development, Mdm4 is required for collecting duct cell differentiation. 2. Mdm2 and Mdm4 cannot fully compensate for each other in UB branching morphogenesis.

Knockout of the Epithelial Splicing Regulatory Proteins Disrupts Kidney Development and Ureteric Branching Morphogenesis in Mouse
Thomas W. Bebee,[1] Sunder Sims-Lucas,[2] Daniel S. Bushnell,[2] Carlton M. Bates,[2] Russ P. Carstens.[1] *[1]Genetics/Renal and Hypertension, Univ of Pennsylvania, Philadelphia, PA; [2]Pediatrics, Children's Hospital of Pittsburgh, UPMC, Pittsburg, PA.*

Background: The Epithelial splicing regulatory proteins 1 and 2 (Esrp1 and Esrp2) coordinate a splicing regulatory network (SRN) of transcripts associated with processes necessary for epithelial function and differentiation. Esrp expression is epithelial cell-type-specific and switch-like changes of several known Esrp regulated alternative splicing (AS) targets are crucial during embryonic development. While transcriptional regulation of epithelial-mesenchymal interactions has been extensively evaluated during development, the contribution of AS to this process is limited. Esrp targets such as the Fgfr2 signaling axis have been shown to be essential for ureteric epithelium (UE) branching and kidney formation. Therefore, we propose that the Esrp SRN converges on pathways crucial for epithelial differentiation and mesenchymal interaction during UE branching and kidney formation.

Methods: To evaluate the requirement of the Esrps in these fundamental processes, we generated mouse knockout alleles for *Esrp1 and Esrp2*.

Results: Esrp1 KO mice are neonatal lethal and present with several developmental defects. Substantially more severe defects are observed in Esrp1/Esrp2 double KO (DKO) mice, some of which phenocopy those observed with disruption in FGF signaling. Evaluation of Esrp KO embryonic kidneys by 3D-reconstruction and histological analysis has revealed higher incidence of renal agenesis, reduced UE branching resulting in smaller kidneys, and dilation of ureteric tips with expanded Ret expression. Splicing analysis in Esrp KO mice indicate transcript-specific splicing susceptibility of Esrp targets, ranging from complete switches by Esrp1 KO while others require DKO.

Conclusions: These results clearly implicate AS regulated by the Esrps in kidney formation and UE branching. Using conditional KO of the Esrps in UE we will evaluate the cell autonomous nature of the UE branching defects, and RNAseq of purified UE will determine the global SRN mediated by the Esrps to guide functional evaluation of AS targets *in vivo*.

Specific Claudins Regulate Nephric Duct Elongation and Ureteric Bud Branching Morphogenesis
Indra R. Gupta,[1,2] Annie Simard,[1] Jasmine El Andalousi,[1] Halim Khairallah,[1] Jenessa Kerr,[1] Aimee K. Ryan.[1,2] *[1]Pediatrics, McGill Univ Health Center, Montreal Children's Hospital Site, Montreal, QC, Canada; [2]Human Genetics, McGill Univ, Montreal, QC, Canada.*

Background: The claudin family of tight junction proteins are important for the regulation of renal paracellular transport, but they are also expressed during kidney development. To understand their roles during nephric duct formation and ureteric bud branching morphogenesis, embryonic chick and mouse kidneys were treated with a truncated non-toxic form of the *Clostridium perfringens enterotoxin* (C-CPE) that removes Claudin-3,-4,-6,-7,-8, and -14 from tight junctions.

Methods: Chick embryos and mouse metanephric kidney explants were treated with C-CPE protein (GST fused to amino acids 184-319 of CPE) or with GST alone. CRISPR/Cas mediated gene editing was used to generate homozygous Claudin-3 knockout mice.

Results: Claudin-3 and claudin-4 are expressed in the chick nephric duct, while claudins-3,-4,-6,-7, and -8 are all expressed in the mouse nephric duct and the ureteric bud branching network by whole mount in situ hybridization (WISH). Chick nephric cords were treated with beads saturated with C-CPE protein or GST at E1.5. Adjacent to the C-CPE bead, the nephric duct failed to form as shown by histological analysis and a lack of expression of the nephric duct marker *Lim1* by WISH (15/22 embryos), while the contralateral side and controls (GST beads) showed normal nephric duct formation and elongation (10/10 embryos). Treatment of mouse E11.5 and E12.5 kidney explants from *HoxB7/GFP*$^{+/-}$ transgenic mice with C-CPE caused a marked reduction in the number of ureteric bud tips compared to GST-treated controls (n=5/group, $P<0.05$) that was not due to a defect in apoptosis or proliferation. CRISPR biallelic claudin-3 knockout mice are viable and do not appear to have a defect in kidney development.

Conclusions: Removal of a single claudin, claudin-3, does not affect kidney morphogenesis. However, the selective removal of multiple claudins impairs nephric duct formation and ureteric bud branching morphogenesis. We speculate that the C-CPE-sensitive claudins regulate changes in cell shape that are critical for tubule and branch point formation.

Lack of Glycogen Synthase Kinase 3a and b in the Ureteric Bud Leads to Renal Agenesis
Shixin Tao, Reena Rao. *The Kidney Inst, Dept of Internal Medicine, Univ of Kansas Medical Center, Kansas City, KS.*

Background: The Glycogen Synthase Kinase 3 (GSK3) family of serine/threonine protein kinase consists of two isoforms, GSK3a and GSK3b. The GSK3 isoforms regulate cell survival, proliferation, polarization and differentiation, and are critical for embryonic development of the heart and brain. GSK3b plays an important role in urine concentration by the renal collecting ducts and in cyst expansion in polycystic kidney disease. However, the role of GSK3 in renal development is unknown. The current study reports an unexpected finding that suggests that GSK3 plays a critical role in embryonic kidney development.

Methods: GSK3b knockout leads to early perinatal lethality, while global GSK3a knockout is viable. Hence, GSK3a$^{+/-}$, GSKb$^{flox/flox, HoxB7\text{-}Cre}$ mice were bred together. One fourth of the embryos were expected to lack both GSK3a and GSK3b in their ureteric bud, which gives rise to the connecting tubule, collecting ducts and ureters in the adult mouse kidney.

Results: Pups were born in the normal Mendelian ratio. Out of 158 newborn mice, 38 were GSK3a$^{-/-}$, GSKb$^{flox/flox, HoxB7\text{-}Cre}$ representing mice that lacked both GSK3a and GSK3b. However, the GSK3a$^{-/-}$, GSKb$^{flox/flox, HoxB7\text{-}Cre}$ pups died within 32 hours after birth. These mice either completely lacked kidneys or had a very small rudimentary kidney. Hematoxylin and Eosin staining in the rudimentary kidney showed very few glomeruli and tubules. Immunofluorescence staining for Dolichos biflorus agglutinin or Lotus tetragonolobus agglutinin, markers of collecting ducts and proximal tubules respectively revealed a limited number of tubules staining for either marker. The epithelial cells of some of these tubules showed staining for both markers.

Conclusions: The study thus demonstrates that gene deletion of GSK3a and GSK3b in the embryonic ureteric bud leads to renal agenesis and suggests that GSK3 may play a critical role during early development of the kidney.

FR-PO733

Lack of the Prorenin Receptor (PRR) in the Ureteric Bud (UB) Disrupts Developmental Programming of Nephrogenesis
Renfang Song, Lindsay Riedl, Ihor V. Yosypiv. *Pediatrics, Tulane Univ, New Orleans, LA.*

Background: In this study, we tested the hypothesis that decreased nephron endowment in *PRR*$^{UB-/-}$ mice which lack the PRR in the UB lineage (PLoS ONE, 2013) is due to defects in molecular pathways and cellular mechanisms that control nephrogenesis.

Methods: The number of vesicles (V), comma (C), S-shaped (S), and mature (M) nephrons was counted on P1 from H&E-stained kidney sections. Mesenchymal cell proliferation and apoptosis was assessed on kidney sections (3 sections/kidney) using anti-phosphohistone H3 (pH3) and -cleaved caspase 3 (Ca3) antibodies on embryonic (E) days E12.5 and E18.5. Data were normalized to the total number of DAPI-positive cells (Image J). Expression of key genes that control nephrogenesis was studied by real-time qRT-PCR or *in situ* hybridization (ISH) on E13.5. The intensity of Six2 immunostaining (Abcam, 1:200), normalized for the surface area of the kidney section, was quantitated by Slidebook 4.1 software.

Results: The number of V, C, S and M nephrons was reduced in mutant compared with control kidneys ($p<0.05$). The number of Ca3-positive apoptotic cells was higher (E12.5: 20.7±2.5 versus 4.0±1.4 $p<0.001$; E18.5: 10.4±3.8 versus 2.5±1.2, $p<0.05$). The number of pH3-positive cells did not differ on E12.5 (56.7±6.8 versus 61.250±9.674, $p=0.5$) and was reduced on E18.5 (18.9±2.7 versus 38.7±3.4, $p<0.001$) in the mesenchyme of mutantcompared with control kidneys. qRT-PCR demonstrated decreased ($p<0.01$): Pax2, Pax8, FGF8, Lhx1, Wnt4, Wnt9b and β-Catenin, and increased Six2, Bmp7 and Cited1 mRNA levels in mutant compared to control kidneys. Six2 immunostaining was increased in the mutant versus control kidneys ($p<0.05$). ISH showed apparent reduction in Wnt9b mRNA expression in the mutant UBs.

Conclusions: We conclude that lack of the UB *PRR* disrupts nephrogenesis *via*: 1) Induction of mesenchymal cell apoptosis, 2) Inhibition of mesenchymal cell survival and 3) Aberrant expression of key genes that direct nephrogenesis. We propose that lack of the UB *PRR* disrupts nephrogenesis through reduced Wnt9b-directed canonical Wnt/β-Catenin signaling resulting in decreased renal vesicle formation.

FR-PO734

Abnormal Urinary Tract Formation and Remodeling in the Absence of Hepatocyte Nuclear Factor 1beta
Evelyne Fischer,[1] Filippo Massa,[2] Nelly Lourenco,[1] Serge Garbay,[1] Marco Pontoglio.[1] *[1]Development Reproduction and Cancer, Cochin Inst INSERM U1016, Paris, France; [2]Centre de Biochimie - Parc Valrose, IBV-INSERM U1091/CNRS UMR7277/UNS, Nice, France.*

Background: Congenital Anomalies of Kidney and Urinary Tract (CAKUT) represent 20-30% of prenatal malformations. One of the most prevalent genetic defects responsible for CAKUT is represented by mutations in HNF1B (Hepatocyte Nuclear Factor1 beta), a transcription factor expressed since the first steps of kidney development.

Methods: Analyses of mutant embryos have shown that the absence of HNF1beta leads to renal aplasia, and that this phenotype is due to an absence of mesenchymal to epithelial transition and to abnormal branching of the ureteric bud. However, the development of the urinary tract in these embryos has not been studied.

Results: In wild type embryos, mesonephric tubules are induced in the rostral part of the nephric duct, and are spatially separated from the emergence of the ureteric bud. By contrast, embryos lacking *Hnf1b* are characterized by rudimentary ectopic budding all along the nephric duct. In wild type embryos, at E9.5, the nephric duct connects with the cloaca via the CDN, and then the CND disappears by apoptosis during the following days. In *Hnf1b* mutants, the connection between the nephric duct and the cloaca occurs normally but the CND does not regress and leads to an abnormal connection between the ureter and the bladder.

Conclusions: These observations show that, in addition to its roles during nephrogenesis, Hnf1b plays a crucial role in the formation and remodeling of the urinary tract. This suggests that children with abnormalities of the urinary tract should be tested for mutations in the HNF1B gene.

Deletion of Kelch-Like ECH-Associated Protein 1 (Keap1) in Kidney Epithelial Cells Causes Hydronephrosis in Mice Sanjeev Noel,[1] Lois J. Arend,[2] Samatha Bandapalle,[1] Sekhar P. Reddy,[3] Hamid Rabb.[1] *[1]Dept of Medicine; [2]Dept of Pathology, Johns Hopkins Univ, Baltimore, MD; [3]Dept of Pediatrics, Univ of Illinois, Chicago, MD.*

Background: The Nrf2-Keap1 pathway has an important role in both acute kidney injury (AKI) and chronic kidney disease (CKD). This pathway has a key regulatory function on many antioxidant and stress pathways, including heme oxygenase. We deleted Keap1 in tubular epithelial cells (primarily distal convoluted tubule and collecting ducts) of mouse kidney by Cre-LoxP mechanism to evaluate the specific effect of this pathway on AKI. Surprisingly, these mice had significant developmental defects in the collecting system. This could unveil a key role of this pathway in kidney development, as well as possibly in repair and regeneration.

Methods: Kidney epithelial cell specific Keap1-deficient (Ksp-Keap1-KO) mice were generated by crossing Ksp-Cre with Keap1 floxed ($Keap1^{fl/fl}$) mice. A comprehensive histological examination along with detailed hematological, biochemical and urinary analysis was performed to evaluate these mice.

Results: Kidneys from Ksp-Keap1-KO (10 weeks, male) mice had small visible dilatations on their surface and were slightly larger than $Keap1^{fl/fl}$ kidneys. More significantly, transverse sections through the middle of the kidney revealed moderate to marked renal pelvic expansion and significant compression of medullary parenchyma consistent with hydronephrosis in Ksp-Keap1-KO mice. Ksp-Keap1-KO (n=3) had a significantly higher RBC count (9±0.1 versus 9.6±0.3 M/μL, p=0.04), Hb (12.5±0.2 versus 13.9±0.6 g/dL, p=0.01), hematocrit (42.3±0.6 versus 47.3±2.0%, p=0.02), mean cell volume (46.7±0.5 versus 49±1.0 fL, p=0.02) and mean cell Hb concentration (13.8±0.1 versus 14.4±0.2 g/dL, p=0.003). There was no change in lymphocyte and platelet populations.

Conclusions: These data suggest that absence of Keap1 in renal tubular epithelial cells significantly affects normal kidney development in a fashion consistent with hydronephrosis. There is also an increased hemoglobin. This unexpected data has revealed a novel role for Keap1 mediated signaling pathway in renal development.

FR-PO736

Renal-Specific Inactivation of the Exocyst Sec10 Gene in Mice Causes Lethal Ureteropelvic Junction Obstructions due to Urothelial Defects Noemi Polgar,[1] Amanda J. Lee,[1] Vanessa H. Lui,[1] Kadee-Kalia Tamashiro,[1] Zsanett Jancso,[1] Joshua H. Lipschutz,[2] Ben Fogelgren.[1] *[1]Univ of Hawaii; [2]Univ of Pennsylvania.*

Background: Congenital obstructive nephropathy, the most common cause of pediatric chronic kidney disease and ESRD, is caused by obstruction of the urinary tract during fetal development. The most common cause of congenital obstructive nephropathy is ureteropelvic junction obstruction (UPJ obstruction), when the stenosis is localized to the upper urinary tract where the renal pelvis transitions into the ureter. Despite the high prevalence and medical burden of UPJ obstructions, we have a poor understanding of its molecular and genetic basis, with a scarcity of non-surgical genetic models.

Methods: In previous studies using cell culture models, we have shown the eight-protein exocyst trafficking complex to be critical in maintaining aspects of polarized epithelial cells. To further *in vivo* studies of polarized exocytosis in renal development and disease, we have generated a novel transgenic mouse to conditionally knockout the Sec10 gene, a central component of the exocyst. This is the first conditional mouse strain for any exocyst subunit, and should be valuable in studying the exocyst's role in various tissues and diseases.

Results: Inactivation of *Sec10* in ureteric bud-derived cells using *Ksp1.3-Cre* mice resulted in severe bilateral hydronephrosis and neonatal death. The conditional knockout $Sec10^{FL/FL}$*;Ksp-Cre* embryos developed ureteropelvic junction obstructions between E17.5 and E18.5 as a result of degeneration of the urothelial layers and subsequent overgrowth by surrounding mesenchymal cells. By E16.5, $Sec10^{FL/FL}$*;Ksp-Cre* ureter and pelvic urothelium showed decreased uroplakin-3 protein at the luminal surface of urothelial cells, and complete absence of uroplakin-3 by E17.5. Affected urothelium at the UPJ showed irregular barriers that exposed the smooth muscle layer to urine, suggesting this may trigger the surrounding mesenchymal cells to overgrow the lumen.

Conclusions: Findings from this novel mouse model show Sec10 and the exocyst are critical for maintaining the urothelial barrier in ureters, and failure of this barrier may be a cause of UPJ obstructions.

FR-PO737

Unilateral Renal Agenesis and Collecting Duct Lumen Defects in *Grainyhead-Like 2*-Deficient Mice Christian Hinze,[1,2] Janett Ruffert,[2] Annekatrin Aue,[2] Max Werth,[3] Katharina Walentin,[2] Zeliha Yesim Yurtdas,[2] Jonathan M. Barasch,[3] Kerim Mutig,[4] Sebastian Bachmann,[4] Kai M. Schmidt-Ott.[1,2] *[1]Nephrology, Charité Universitätsmedizin, Berlin, Germany; [2]Max Delbrück Center for Molecular Medicine, Berlin, Germany; [3]Nephrology, Columbia Univ College of Physicians and Surgeons, New York; [4]Anatomy, Charité Universitätsmedizin, Berlin, Germany.*

Background: Congenital defects of renal branching and luminogenesis are frequent and associated with diseases of high prevalence, including cystic kidney diseases and renal hypoplasia. The molecular and cellular mechanisms governing tubular lumen establishment and branching morphogenesis may provide critical insights into their pathogenesis.

Methods: The transcription factor grainyhead-like 2 (Grhl2) is mostly expressed in epithelial cells of the ureteric bud and the distal nephron. To investigate its role, we generated collecting duct-specific Grhl2 knockout mice (Hoxb7/Cre; $Grhl2^{flox/-}$), which exhibit a deletion of functional Grhl2 protein in most cells of the collecting duct. Littermates were used as controls. We then performed a detailed analysis of the resulting phenotype comprising 3D single cell and collecting duct reconstruction.

Results: Although Hoxb7/Cre; $Grhl2^{flox/-}$ mice were viable to adulthood and kidney function was not impaired, we found a ten-fold higher incidence of unilateral renal agenesis at P30 when compared to control littermates (6.8% versus 0.6%, P=0.0053). Additionally, knockout mice displayed kidneys with a significantly reduced kidney weight compared to control littermates (reduction related to body weight by 16 % in Hoxb7/Cre; $Grhl2^{flox/-}$ mice, P<0.001). A closer examination of the knockout collecting ducts revealed markedly reduced lumen areas in the outer medulla (mean lumen area ± SEM in control mice: 53.2 μm^2 ± 6, n=13; KO mice: 33.3 μm^2 ± 5.5, n=10; P=0.005). Reconstructing the collecting ducts up to single cell level by 3D analysis, we uncovered distinct changes in cell size and cell density constituting this lumen phenotype.

Conclusions: Our data thus indicate an impact of Grhl2 on kidney development and collecting duct lumen formation. This might be relevant for congenital diseases of the kidney, including cystic kidney diseases.

Funding: Government Support - Non-U.S.

FR-PO738

A Novel Gene Network Downstream of Grainyhead-Like 2 Regulates Lumen Expansion and Barrier Formation in Renal Epithelial Cells Annekatrin Aue,[1] Christian Hinze,[1,2] Janett Ruffert,[1] Zeliha Yesim Yurtdas,[1] Max Werth,[1] Katharina Walentin,[1] Michael Schumann,[3] Kai M. Schmidt-Ott.[1,2] *[1]Max Delbrueck Center for Molecular Medicine, Berlin, Germany; [2]Dept of Nephrology, Charite, Berlin, Germany; [3]Dept of Gastroenterology, Charite, Berlin, Germany.*

Background: The establishment of a lumen is a fundamental step during organ development. In the nephrons of the kidney, the composition and three-dimensional structure of epithelial tubules are vital to determine body fluid composition. Previous studies of our group identified transcription factor grainyhead-like 2 (Grhl2) being highly expressed in epithelia of the distal tubule and collecting duct of the kidneys, but little is known about its functional relevance in these cells.

Methods: To gain more insights into the transcriptional network downstream of Grhl2 in renal epithelia we performed gene expression analysis and chromatin immunoprecipitation followed by next generation sequencing (ChIP-seq) using antibodies against Grhl2 and histone H3 lysine 4 trimethylation (H3K4me3), a histone modification associated with active promoters.

Results: Intersections of genome-wide gene expression analysis and ChIP-seq data resulted in a set of Grhl2 core target genes. Among these genes we identified known and several novel Grhl2 targets like Ovo-like 2 (Ovol2), encoding a zinc finger transcription factor. While downregulation of Grhl2 impaired lumen formation and barrier function of inner medullary collecting duct (IMCD-3) cells, reexpression of Ovol2 induced lumen expansion as well as expression of Grhl2-dependent genes, like the small GTPase Rab25 and claudin 4 (Cldn4), in IMCD-3 Grhl2-defficient cells. Individual overexpression of Cldn4 or Rab25 did not affect the lumen phenotype, but overexpression of Cldn4 together with Rab25 rescued lumen establishment and barrier formation in Grhl2/Ovol2-depleted cells.

Conclusions: These data reveal a novel transcriptional network supporting a Grhl2/Ovol2 feed forward loop network in collecting duct epithelia, which ensures stable expression levels of critical determinants of tubular lumen expansion and barrier function.

FR-PO739

Impaired Kidney Development in Mice with a Mutation in the Planar Cell Polarity Protein Celsr1 Hortensja Lucja Brzoska,[1] Angela Maria D'esposito,[2] Mark Lythgoe,[2] Eugenia Papakrivopoulou,[1] David A. Long.[1] *[1]Developmental Biology and Cancer, UCL Inst of Child Health, London, United Kingdom; [2]UCL Centre for Advanced Biomedical Imaging, London, United Kingdom.*

Background: The planar cell polarity (PCP) pathway plays a critical role in cytoskeletal organization and cell morphology. These processes are vital for kidney development and our previous work has shown that mice with a mutation in *Vangl2*, a core PCP component, have impaired glomerular maturation and ureteric bud branching. Therefore, we hypothesised that mutations in another PCP core molecule, *Celsr1* would also have a profound effect on renal development.

Methods: Using optical projection tomography and quantitative image analysis we examined kidney branching in the *Celsr1^{Crsh}* mutant mouse model. Renal histology and gene expression of PCP genes using quantitative PCR were assessed. *Celsr1* was also knocked down using siRNA in a proximal tubular cell line (HK-2).

Results: During development, in wild-type kidneys Celsr1 was expressed in comma and S-shaped bodies, early glomeruli and in some tubular structures. In adult kidneys Celsr1 expression was detected in the brush borders of proximal tubules and the basal side of distal tubules. At embryonic day (E) 13.5 the total kidney volume of *Celsr1^{Crsh}* mutants was significantly smaller compared to wild-type littermates ($p<0.05$, n=3-5 for each genotype). The kidneys of *Celsr1^{Crsh}* mutants also contained a reduced number of ureteric bud tips ($p<0.05$) but there was no difference in the ureteric bud tip length or angle. At E17.5, some proximal tubules and Bowman's capsules were dilated in *Celsr1^{Crsh}* mice but we did not observe an overt cystic phenotype. At E17.5, there were no changes in the mRNA expression of other PCP genes (*Vangl2*, *Vangl1*, *Scrib*, *Pk1* and *Pk2*) between *Celsr1^{Crsh}* and wild-type littermates. *In vitro* experiments using knock-down of *Celsr1* in HK-2 cells showed significant up-regulation of E-cadherin, an adherens junction molecule involved in cell adhesion and maintenance of tissue structure (n=6, $p<0.0001$).

Conclusions: This data highlights that Celsr1 plays a critical role in kidney tubular branching confirming the importance of the PCP signalling pathway during kidney morphogenesis.

FR-PO740

Bicaudal-C Mutation Induces PKD-Like Phenotypes in Drosophila

Chiara Gamberi,[1,3] David Hipfner,[2] Marie Trudel.[2] [1]*Concordia Univ, Montreal, QC, Canada;* [2]*Institut de Recherches Cliniques de Montréal, Montreal, QC, Canada;* [3]*Univ de Montréal, Montreal, QC, Canada.*

Background: Renal cystogenesis can result from mutations in several genes, including *PKD1, PKD2* or *Bicaudal-C* in human and mice. The highly conserved Bicaudal-C protein was first identified in *Drosophila*. Shown to bind RNA, it down-regulates many targets mRNAs and was implicated in post-transcriptional regulation via cytoplasmic RNA polyadenylation and microRNAs. While it is known that Bicaudal-C mutation in *Drosophila* interferes with embryonic anterior-posterior polarity and development, a potential role in renal function remains to be addressed. Among all tissues, the renal (or Malpighian) tubule of *Drosophila* shows the highest degree of conservation with humans, likely because of functional constraint, making it an excellent model to identify key players in renal tubule function.

Methods: Different allelic combinations of *Bicaudal C* were tested for evidence of renal effects. Dissected Malpighian tubules were analyzed by immunofluorescence, western blot, real-time qPCR and immunoprecipitation.

Results: We found that Bicaudal C was expressed in the *Drosophila* Malpighian tubule with similar distribution to Bicaudal C in the mouse kidney. Furthermore, renal tubules with *Bicaudal C* mutation were >60% larger relative to controls, showed cyst-like structures and frequent tubular branching. *Bicaudal C* mutant flies are also sensitive to salt, indicating poor renal function. Moreover, comparable to *PKD* patients and mouse *Pkd* models, *Bicaudal C* mutant flies have shorter life span (<50%) than controls. Based on these similarities the powerful *Drosophila* model system was used to identify Bicaudal C targets contributing to the cyst-like structures. Implications for signalling pathways and interactions with *PKD* genes in vertebrate cystogenesis will be discussed.

Conclusions: Our study shows for the first time that, similar to vertebrates, *Drosophila* Bicaudal C is necessary for renal function. Moreover, the renal phenotypes of *Bicaudal C* mutants are highly reminiscent of the vertebrate renal cysts, suggesting that analyses of the underlying mechanisms in *Drosophila* may provide insights into the molecular and cellular complexities of renal cystogenesis.

FR-PO741

Atypical CNT/CD Lacking Detectable Molecular Signature of Principal Cells

Lihe Chen,[1] Qiaoling Zhou,[2] Zhou Xiao,[1] Wo Li,[1] Yujin Zhang,[1] Joseph V. Bonventre,[3] Wenzheng Zhang.[1] [1]*Graduate School of Biological Sciences, Univ of Texas Health Science Center at Houston, Houston, TX;* [2]*Internal Medicine, Central South Unversity, Changsha, Hunan, China;* [3]*Medicine, Harvard Univ, Boston, MA.*

Background: The connecting tubule and collecting duct (CNT/CD) comprise principal cells (PC) and intercalated cells (IC), which bear different molecular signatures and regulate sodium/water and acid/base balance, respectively. Recently, we reported that Aqp2-expressing cells with disrupted *Dot1l* give rise to IC. However, whether such derivation results from *Dot1l* deletion, when and how IC formation occurs, and whether atypical CNT/CD lacking PC exists, remain unaddressed.

Methods: We used loxP-Cre system to generate a new *R^{AC}* mouse model in which Aqp2 lineage is genetically traced by red fluorescence protein. Kidney sections of were subject to double and triple immunofluorescence staining with multiple PC and IC markers and examined with epifluorescence and confocal microscopy.

Results: We identified a new type of CNT/CD structure in which no cells have detectable expression of PC markers (Aqp2 and Aqp3) and some of cells express IC markers (V-ATPase B1B2, Pendrin, and AE1) in adult kidney. Like most IC and all PC in the classical CNT/CD, the cells in the atypical CNT/CD structure are derived from Aqp2$^+$-progenitors. Some of the progenitors become highly differentiated PC at E15.5. Others lose Aqp2$^+$ and sequentially gained V-ATPase B1B2 at E15.5, CAII$^+$ at E16.5, and AE1 and Pendrin at P1.

Conclusions: *R^{AC}* is a new faithful Aqp2-lineage tracing model. Mouse kidney contains a new type of CNT/CD structure that apparently contains IC but not PC. The derivation of IC as well as PC from Aqp2$^+$ progenitors occurs in normal development and progresses in a stepwise manner. The discovery of the atypical CNT/CD structure and Aqp2$^+$ progenitors may facilitate their isolation and functional evaluation.

Novel Renal Progenitor Chemical Screen Identifies Prostaglandins as Modulators of Proximo-Distal Segment Fate Choice During Nephrogenesis

Shahram Jevin Poureetezadi, Eric K. Donahue, Rebecca A. Wingert. *Dept of Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: There have been significant recent advances in our understanding of kidney ontogeny, but there are many unanswered questions concerning how different renal cell types arise. The kidney is comprised of segmented functional units called nephrons that consist of a blood filter, tubule and duct. The zebrafish embryo kidney, or pronephros, provides a model to study renal cell type formation due to its high conservation with mammals. Chemical genetics can pinpoint molecules capable of altering physiological processes in the context of the complex humoral environment.

Methods: Previously, we used small molecules to show that retinoic acid (RA) is essential for proximo-distal segment patterning by altering the balance of renal progenitors. To identify other pathways that modulate renal progenitors, we are performing an ongoing novel chemical screen. Zebrafish embryos were incubated during nephron development in each bioactive drug, then evaluated via whole mount *in situ* hybridization using a riboprobe cocktail that labeled alternating nephron segments.

Results: Thus far, a total of 78/480 compounds (16.25%) caused nephrogenesis phenotypes, including RA pathway components. Additionally, prostaglandins (Pgs) emerged as a family of compounds that consistently affected proximo-distal nephron segmentation. Following Pg treatment, the rostral domain of the proximal convoluted tubule (PCT) was diminished. Further, the proximal straight tubule (PST) dramatically expanded at the expense of the distal tubule, such that the distal early (DE) segment was unchanged but caudally shifted, while there was a preferential loss of the distal late (DL) segment.

Conclusions: These data suggest a model in which Pg exposure alters the balance of proximal versus distal nephron cell fates, such that the PCT is reduced, while the PST is promoted at the expense of the DL. Together, these data suggest that both RA and Pg have effects on kidney patterning that may have translational merit for diseases like CAKUT.

Nephron Proximal Tubule Pattern Is Regulated By the Transcription Factor *sim1a* and Retinoic Acid

Christina N. Cheng, Rebecca A. Wingert. *Dept of Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: The mechanisms that establish nephron segments are poorly understood. The zebrafish embryo kidney is a simplified yet conserved model for segmentation because its nephrons contain segments akin to mammals, including the proximal convoluted and straight tubules (PCT, PST), and are associated with the corpuscles of Stannius (CS), endocrine glands that regulate calcium.

Methods: Initial patterning of the renal progenitor field is characterized by the formation of rostral and caudal domains, which is reliant on retinoic acid (RA) signaling. Using gene expression profiling to study nephrogenesis events, we discovered that the transcription factor *single minded homologue 1 (sim1a)* is dynamic in the renal progenitors, first marking the caudal domain, then becoming restricted over time to the proximal tubule segments and finally the CS. *sim1a* knockdown expanded the PCT and abrogated the PST and CS populations. Conversely, overexpression of *sim1a* expanded the PST and CS, while reducing the PCT.

Results: These results suggest that *sim1a* activity is necessary and sufficient to induce the PST and CS fates, and that *sim1a* may negotiate the PCT/PST boundary, possibly by inhibiting PCT fate choice. In addition, *sim1a* expression is responsive to altered levels of RA, which we previously demonstrated is necessary for proximal segment formation. *sim1a* knockdowns treated with RA formed nephrons with predominant PCT segments that lacked the enlarged PST observed in RA treated wildtypes, further indicating that *sim1a* is requisite for PST formation. Alternately, when *sim1a* morphants were chemically treated with the RA synthesis inhibitor diaminobenzaldehyde, distal segments were expanded at the expense of proximal regions.

Conclusions: Taken together, our study reveals novel roles for *sim1a* during proximal tubule formation and reveal that this gene functions downstream of RA during proximo-distal nephron patterning. These findings provide valuable new insights into the genetic pathways that direct nephron development, and may have implications for understanding the causes of renal birth defects.

Interplay between the *tbx2a/b* Transcription Factors and Notch Directs Nephron Segmentation

Yue Li, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: The zebrafish embryonic pronephros is an excellent model of kidney development, as it possesses remarkable conservation with other vertebrate nephrons, including functionally distinct regions of the proximal convoluted and straight tubule (PCT,

PST), distal tubule segments, and a duct. In addition, endocrine cells called the corpuscle of Stannius (CS) are interpolated between the distal segments. How nephron pattern is established and how the CS forms remains intriguing.

Methods: Using whole mount *in situ* hybridization, we found that transcripts encoding the zebrafish orthologues *tbx2a* and *tbx2b* were spatially restricted to distal renal progenitors during nephron formation. To elucidate the function of these genes in nephrogenesis, morpholino knockdown studies were performed.

Results: *tbx2a* and *tbx2b* single and double morphants exhibited a modest expansion in the proximal segments accompanied by a reduction in the distal domains, indicating that these genes have redundant roles in segment patterning. Noticeably, *tbx2b* morphants formed significantly larger CS clusters, as shown by the elevated expression of the marker *stc1*. Further, in preliminary studies we identified expression of the Notch pathway component *her9* in the developing CS. To study the possible link between *tbx2b* and Notch, DAPT treatment was used to block Notch activity in wildtype embryos and *tbx2b* morphants. DAPT treatment resulted in moderate CS expansion in wildtypes, while DAPT induced further enlarged CS clusters in *tbx2b* morphants. Supporting this result, ectopic activation of Notch signaling in *Tg (hsp70::Gal4; UAS::NICD)* led to a reduced CS post heat-shock induction. In addition, ectopic Notch expanded proximal tubule segments at the expense of distal, reducing *tbx2* expression domains and therefore suggesting that Notch promotes proximal segments in part by inhibiting *tbx* expression.

Conclusions: Taken together, these data reveal that interplay between Notch and *tbx2a/b* mitigates nephron segmentation, and thus provide novel insights into renal genetic regulatory networks.

Compensation for Glomerular Damage by Decreasing Regression in Developing Mouse Kidney Jianyong Zhong,[1] Haichun Yang,[2] Ji Ma.[1] *[1]Pediatric Nephrology, Vanderbilt Univ, Nashville, TN; [2]Pathology, Microbiology and Immunology, Vanderbilt Univ, Nashville, TN.*

Background: We previously found a dynamic change in glomerular number in normal neonatal mice, which peaks at P7 then decreases and stabilizes after P18. This is related to regression of superficial glomeruli. In the present study, we tested the hypothesis that, injury in deep glomeruli affects normal maturation of superficial glomeruli which is preserved by podocyte-derived VEGF.

Methods: Nphs1-hCD25 transgene (NEP25) mice express human CD25 in mature podocytes, and primary podocyte injury related FSGS can be induced by immunotoxin (LMB2). By mating NEP25 with Nphs2-rtTA/tetO-hVEGF mouse, we got inducible podocyte VEGF over-expressing mouse (NEP25/rtTA/VEGF) and normal VEGF expression mouse (NEP25/rtTA) on top of NEP25, while rtTA mouse was used as control (CONT). Doxycyclinewas administratedfrom birth (P0), followed by a single LMB2 injection at P4.

Results: At P21, there were significant podocyte injury and decreasing WT1-positive cells in deep cortical glomeruli in NEP25 mouse. Although the number of WT1 positive podocytes in NEP25/rtTA/VEGF mice was not significant different from NEP25/rtTA, the glomerular volume of superficial glomeruli was enlarged (NEP25/rtTA/VEGF 6.79±0.59 $\times 10^4$ versus NEP25/rtTA 5.04±0.44 $\times 10^4$ mm^3, $P<0.05$). There was no significant difference in glomerular number at P21 or P42. To further study the mechanism of VEGF on glomerular development, some mice were studied at P10. Over-expression of podocyte VEGF significantly increased Dll4 expression, a marker of tip endothelial cell (NEP25/rtTA/VEGF 1.19±0.15 versus NEP25/rtTA 0.57±0.10, $P<0.05$). In superficial glomeruli, expression of proliferation marker (Ki67) was significantly increased by enhanced podocyte VEGF (NEP25/rtTA/VEGF 62.29±6.17 versus NEP25/rtTA 42.44±3.22%, $P<0.05$). In parallel, expression of regression marker (TSP-1) was significantly down-regulated (NEP25/rtTA/VEGF 2.63±1.00 versus NEP25/rtTA 3.47±2.00%, $P<0.05$).

Conclusions: We conclude that VEGF-mediated angiogenesis suppresses the normal maturational glomerular regression, which plays important role in the compensatory response to the damage and loss of glomeruli during development.

Genetic Analysis of Zebrafish Glomerulus Disease and Development Tomoko Obara, Rebecca Powell. *Cell Biology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: The treatment of progressive loss of function in the glomerulus filtration barrier is limited, with long-term dialysis and kidney transplantation the only options. The slit diaphragm is a highly specialized intercellular junction between podocyte foot processes that plays a crucial role in a healthy glomerulus filtration barrier. Genes, such as *WT1,* that are essential to podocyte function have been identified, but the mechanism by which mutations in these genes cause glomerular filtration barrier failure is unknown. We used zebrafish to create pathogenic genetic models not readily available in mice. The zebrafish is an important vertebrate model for studying organogenesis and the cellular pathology underlying human diseases. Zebrafish pronephric podocytes undergo dynamic morphological changes analogous to mammalian metanephros development. During the development of the zebrafish glomerulus, immature podocytes accompany the initiation of blood filtration at 40-48 hours post fertilization (hpf). At 96 hpf, the foot process and SD form to complete podocyte maturation.

Results: Due to their known roles in podocyte function, we examined Wtip, a basal body protein, and its interacting molecules (Wt1, Lats2, and Vangl2). Depletion of these resulted in accelerated podocyte maturation and led to a failure of the glomerular filtration barrier. The zebrafish and human ortholog genes rescued these phenotypes. Collectively, our data suggested for the first time that: 1) timing of podocyte maturation is important for healthy glomerulus filtration, 2) podocyte primary cilia are present in zebrafish, and 3) Wtip localizes to the basal body of podocyte cilia. In immature rat podocytes, cilia are present and gradually disappear during development, but their role is unknown. In general, it is known that cilia perform many physiological functions, including movement of fluids, signal transduction, and chemo- and mechanosensing.

Conclusions: Our ultimate goal is to understand how regulatory and signaling molecules work to establish a healthy glomerular filtration barrier, thereby providing a framework to develop interventions to restore lost kidney function.

FR-PO747

Genetic Analysis and Characterization of the Novel Zebrafish Podocyte Mutant *Zeppelin* Paul T. Kroeger, Rachel Miceli, Rebecca A. Wingert. *Dept of Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: The zebrafish pronephros is highly conserved with higher vertebrates, including mammals, thus making it an excellent model to study kidney formation. The nephron, or functional unit of the kidney, modifies the blood to excrete metabolic waste using a blood filter with specialized epithelial cells known as podocytes. Knowledge about podocyte development is highly relevant to the treatment and prevention of kidney disease, as podocyte injury leads to progressive scarring and nephron atrophy culminating with end stage renal failure, however the pathways that specify the podocyte lineage remain poorly understood. Previous work has demonstrated that expression of *wt1a* and production of retinoic acid (RA) are essential for podocyte formation in zebrafish.

Methods: Through an edema based F3 forward genetic screen, we isolated *zeppelin (zep),* which displays edema at 5 days post fertilization and forms severely reduced podocytes as assayed by *in situ* hybridization with markers such as *wt1a, wt1b, lhx1a*, and *nephrin*.

Results: *zep* mutant embryos are unaffected by RA treatment, indicating that RA acts upstream or in an unrelated pathway with that of *zep.* Interestingly, the interrenal gland of *zep* mutants is increased in size. Preliminary cell death and proliferation assays in *zep* mutants did not show any alterations from wildtypes, suggesting the possibility of a cell fate switch between the podocyte and interrenal lineages. To determine the genetic lesion responsible for *zep*, we utilized a combinatorial strategy of whole genome sequencing (WGS) and meiotic mapping. These techniques narrowed the region to a small interval on chromosome 15, and candidate genes were knocked down with morpholinos (MO). Three independent MOs designed against *breast cancer 2, early onset (brca2)* phenocopied *zep*, recapitulating both the unique late edema phenotype, as well as the vast reduction of podocytes.

Conclusions: This suggests, for the first time, that *brca2* is essential for renal development. Taken together, these findings provide novel insights into the genetic regulatory networks that control podocyte formation in the vertebrate kidney.

INF2 Regulates Rho/Dia Signaling in the Developing Glomerulus of Zebrafish Hua Sun,[1,3,4] Khaldoun Al-Romaih,[1,3,5] Callum MacRae,[2,3] Martin R. Pollak.[1,3] *[1]Nephrology, Beth-Israel Deaconess Medical Center, Boston, MA; [2]Cardiology, Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]Nephrology, Univ of Iowa Children's Hospital, Iowa City, IA; [5]King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia.*

Background: Mutations in Inverted Formin 2 (INF2), a diaphanous formin family protein that regulates actin cytoskeleton dynamics, cause focal segmental glomerulosclerosis (FSGS) and Charcot-Marie-Tooth Disease (CMT) in humans. In addition to directly remodeling actin filaments in vitro, we have shown that INF2 regulates intracellular actin dynamics and actin dependent cellular behavior by opposing Rhoa/Dia signaling.

Methods: We used a zebrafish model to investigate the in vivo role of INF2 and its interaction with Rho/Dia signaling in the pathophysiology of nephrogenesis and podocyte-mediated diseases. The integrity of the glomerular filtration barrier in zebrafish with INF2 knockdown was examined based on the expression of slit diaphragm proteins, transmission election microscopy, and the functional dextran filtration assay.

Results: Knockdown of the zebrafish homolog of INF2 leads to dysmorphic podocyte and dysfunctional glomerular filtration barrier resulting in an edematous phenotype. These changes correlate with mistrafficking of glomerular slit diaphragm proteins, defective slit-diaphragm signaling, and disinhibited diaphanous formin (Dia) activity. Wild type INF2, but not INF2 harboring human disease mutants, is able to rescue the INF2 deficient phenotype in the zebrafish. The edematous phenotype in INF2 morphants is also rescued by knockdown of RhoA or Dia2.

Conclusions: This in vivo model demonstrates that INF2 is required for normal physiologic regulation of podocyte morphology and function during embryonic development by means of its modulatory effects on Rho/Dia signaling. These data support a model in which diaphanous inhibitory domain (DID) mutants in INF2 interfere with its binding to and inhibition of Dia, leading to uncontrolled Rho/Dia signaling and perturbed actin dynamics. Targeting the uncontrolled Rho/Dia signaling might be a potential therapeutics for human diseases with INF2 deficiency.

Stroma MicroRNAs Play a Critical Role in Regulating Nephrogenesis Yu Leng Phua, Sunder Sims-Lucas, Christopher Cain Rymer, Andrew J. Bodnar, Jacqueline Ho. *Rangos Research Center, Children's Hospital of Pittsburgh of UPMC, Univ of Pittsburgh, Pittsburgh, PA.*

Background: MicroRNAs (miRNAs) are small non-coding RNAs that function to fine-tune the expression of mRNA transcripts. While multiple dysfunctional genes have been identified in developmental renal disorders, the role of miRNAs remains largely unknown. Previous studies have shown that the differentiation of nephron progenitors is in part modulated by the renal stroma. Moreover, the stroma also gives rise to various supportive cells within the kidney such as pericytes, renin-expressing cells, smooth muscle cells of the afferent arteriole and glomerular mesangium. In this study, we seek to understand the functional role of miRNAs in the renal stroma.

Methods: We generated a conditional knockout mouse model (FoxD1Cre; Dicerfl/fl) that lacks Dicer, an endoribonuclease required for mature miRNA production in the renal stroma.

Results: Mutant mice developed a multifaceted renal phenotype including an expanded nephron progenitor population and reduced nephron endowment. While differentiation of the stroma into Pdgfrb^{+} pericytes was not impacted by the loss of miRNAs, the kidneys developed fewer renin-expressing cells, less smooth muscle cells around developing arterioles, and mature glomeruli lacked a mesangium. The mesangium defect was not due to defective cellular migration since putative mesangial cells could be seen migrating into early capillary loop nephrons. Instead, increased cellular apoptosis is likely to be a contributory factor. In concordance to the phenotype observed in these transgenic mice, Taqman miRNA profiling of the renal stroma identified a panel of miRNAs that are potentially involved in perivascular development and cell survival.

Conclusions: Stromal miRNAs play an indispensable role in regulating the nephron progenitor niche. While the loss of stromal miRNAs has no overt impact on pericyte differentiation, they are required for maintenance of several perivascular supportive cells including renin-expressing cells, smooth muscle cells of developing arterioles, and the glomerular mesangium.

Fgfr2 Is Integral for Bladder Urothelial Development Kenneth A. Walker,[1] Caitlin M. Schaefer,[1] Daniel S. Bushnell,[1] Carlton M. Bates.[1,2] *[1]Pediatrics, Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]Nephrology, Univ of Pittsburgh, Pittsburgh, PA.*

Background: While embryonic bladder urothelium is critical for development of surrounding mesenchyme, little is known about molecular control of urothelial morphogenesis. Fibroblast growth factor receptor 2 (Fgfr2) is highly expressed in embryonic bladder urothelium; however its role in bladder urothelium is unclear. Our hypothesis is that Fgfr2 has critical roles in bladder urothelial development.

Methods: To addresses our hypothesis, we generated a conditional knockout mouse using the *Wnt4cre* and *Fgfr2* floxed mouse lines (termed *Fgfr2$^{Uro-/-}$*). We assessed general histology as well as immunohistochemistry for key markers and for proliferation and apoptosis. We used 3D reconstructive stereology for volumetric analyses. We also performed molecular analysis via quantitative PCR (qPCR).

Results: First, in situ hybridization showed *Fgfr2* deletion from bladder urothelium in *Fgfr2$^{Uro-/-}$* mice. At embryonic day 16.5, 3D reconstructions revealed that *Fgfr2$^{Uro-/-}$* bladders had a significant reduction in total urothelial volume when compared to controls. Furthermore, *Fgfr2$^{Uro-/-}$* bladders also exhibit decreased total muscle volume and increased lamina propria volume when compared with control bladders. Apoptosis was significantly increased in both urothelial and bladder muscle tissues in *Fgfr2$^{Uro-/-}$* bladders, with reciprocal decreases in cell proliferation versus controls. qPCR showed decreased Uroplakin3A and a-smooth muscle actin (aSMA) mRNA expression was detected confirming decreased urothelial and smooth muscle tissues volumes in *Fgfr2$^{Uro-/-}$* bladders, respectively. Increased mRNA expression of immature urothelial markers *Foxa2* and *p63* were detected in *Fgfr2$^{Uro-/-}$* bladders compared to controls. Histological analysis showed urothelial hypoplasia persists in *Fgfr2$^{Uro-/-}$* bladders at post-natal day 21.

Conclusions: In conclusion, urothelial *Fgfr2* appears integral for proper bladder urothelial morphogenesis. Moreover, absence of urothelial *Fgfr2* during development also has non-cell autonomous consequences, leading to improper lamina propria and muscle patterning. Thus, urothelial Fgfr2 is a key mediator of urothelial and overall bladder development.

FR-PO751

Stroke Outcomes and Renal Function in Diabetes: A Meta-Analysis of Randomized Controlled Trials Tomoko Usui, Frank Holtkamp, Jarno Hoekman, Dick de Zeeuw, Hiddo Jan Lambers Heerspink. *Dept of Clinical Pharmacy and Pharmacology, UMC Groningen, Netherlands.*

Background: Recent clinical trials in type 2 diabetes and nephropathy, such as ALTITUDE and TREAT, showed more cases of stroke in the active treatment versus placebo group. To test whether these were chance findings we performed a systematic review and meta-analysis to study which drugs or which type 2 diabetic patients are vulnerable.

Methods: MEDLINE database was searched for randomized controlled trials (RCTs) in type 2 diabetes between 1966 and April 2014. Included RCTs had a mean follow up of at least 1000 patient years and reported stroke outcomes. We extracted baseline characteristics, stroke and cardiovascular (CV) outcomes, and types of intervention from each publication. A multivariable meta-regression model that included age, sex, systolic blood pressure (BP), HbA1c, cholesterol, eGFR, and drug class was used to assess which characteristics modify treatment effect on stroke outcomes.

Results: The meta-analysis included 31 trials involving 18488 patients. Average age ranged from 27 to 69 years, Hba1c ranged from 5.8 to 11.5%, and eGFR from 15 to 122 ml/min/1.73m^2. Type of interventions included HbA1c, cholesterol, BP lowering interventions as well as a platelet inhibitor (aspirin), erythropoiesis stimulator (darbepoietin), and an anti-inflammatory agent (bardoxolone). Across all trials, the effect of the interventions on stroke risk was modified by baseline eGFR (p=0.01) and not by other baseline characteristics. The relative risk of stroke was 0.93 (95%CI 0.88 – 0.98) for trials with mean eGFR≥60 ml/min/1.73m^2, 1.09 (0.90 – 1.32) for eGFR 45 to 59, and 1.38 (1.14 – 1.68) for eGFR<45 (p for heterogeneity=0.009). The treatment effects on other CV outcomes did not differ between eGFR subgroups.

Conclusions: Independent of the type of intervention, patients with type 2 diabetes with a low eGFR face an increased risk for stroke, whereas patients with a higher eGFR are actually protected. These findings are very consistent across the different trials and interventions in these type 2 diabetes populations, and have major implications for trial design (stratification for eGFR!), selection of endpoints, and individual patient care.

FR-PO752

Association of Traditional and Novel Retinal Vascular Parameters with Diabetic Microvascular Complications Charumathi Sabanayagam,[1,2] Carol Y. Cheung,[1,2] Tien Yin Wong,[1,2] Ecosse L. Lamoureux.[1,2] *[1]Singapore Eye Research Inst, Singapore; [2]Duke-NUS Graduate Medical School.*

Background: To examine the association of traditional and novel retinal vascular parameters with diabetic kidney disease (DKD), nephropathy (DN) and retinopathy (DR) in a clinic-based sample of diabetic patients.

Methods: We recruited 425 diabetic patients of Chinese, Malay and Indian ethnicity aged ≥18 years from the Singapore National Eye Centre (2010-2013). Retinal vascular parameters, traditional (arteriolar and venular caliber, arteriole-to-venular ratio [AVR]), novel (fractal dimension [F_d] and branching angle [Ba]) and DR (no, yes) were assessed from fundus photographs. DKD was defined using estimated glomerular filtration rate (eGFR≥90, 60-90, <60 mL/min/1.73m^2), and DN using urinary albumin-to-creatinine ratio (ACR <30, 30-300, ≥300).

Results: The prevalence of DKD, DN, and DR were 18.6%, 42.1% and 63.9% in this clinical sample. In multivariable regression models adjusted for potential confounders, presence and severity of DKD, DN and presence of DR were significantly associated with bigger venular diameter, smaller AVR, smaller F_d and narrower retinal arteriolar Ba.

Table 1: Relationship of mean retinal parameters with DKD, DN and DR

	Mean Retinal parameters*					
eGFR	Arteriole	venule	AVR	F_d	Arteriolar Ba	Venular Ba
≥90	128.7	190.2	0.68	1.41	73.3	76.3
60-90	129.1	192.6	0.67	1.38	70.0	77.5
<60	126.2	195.8	0.65	1.39	69.8	76.9
p	0.2	0.02	0.0006	<0.0001	0.05	0.4
ACR						
<30	128.8	190.6	0.68	1.40	71.4	77.3
30-300	127.1	191.6	0.67	1.39	73.8	74.2
≥300	128.7	197.7	0.65	1.38	69.1	78.9
p	0.07	0.02	<0.0001	<0.0001	0.03	0.2
DR						
No	126.8	185.8	0.69	1.40	71.6	74.4
Yes	128.5	196.1	0.66	1.39	71.5	78.6
p	0.5	0.003	0.0001	0.0002	0.02	0.02

adjusted for age, sex, ethnicity, duration of diabetes, body mass index, smoking, education, systolic blood pressure, HbA1c, cholesterol levels and cardiovascular disease

Conclusions: Novel and traditional retinal vascular parameters were associated with diabetic microvascular complications independent of potential confounders in diabetic patients, suggesting quantification of retinal microvascular parameters might be useful in assessing microvascular damage in diabetic patients.

FR-PO753

Vascular Stiffness and Chronic Kidney Disease in Patients with Diabetes of Different Ethnic Origin Maria Karaflou,[1,2] Karima Zitouni,[1] Kenneth A. Earle.[1,2] *[1]Clinical Sciences, St. George's, Univ of London, London, United Kingdom; [2]Thomas Addison Unit, St. George's Hospital NHS trust, London, United Kingdom.*

Background: Chronic kidney disease (CKD) is a recognized cardiovascular disease (CVD) equivalent. Its progression to end-stage renal disease has a propensity for patients of African and Asian origin. Vascular stiffness is related to increased CVD risk but its association with CKD is unclear. Therefore, we assessed the relationship between vascular stiffness in type 2 diabetes patients with CKD but without CVD of Caucasian and non-Caucasian heritage.

Methods: We recruited 72 patients of Caucasian (n=28) and non-Caucasian (n=44) origin with type 2 diabetes and eGFR <90 and >45 mL/min/1.73 m^2. Body mass index (BMI) was calculated in kg/m^2. Fasting venous blood was sampled for biochemical profile and haemoglobin A1c (HbA1c). Albumin:creatinine ratio (ACR) was measured in early morning urine samples and vascular stiffness index (SI) was determined using finger plethysmography.

Results: The Caucasian (C) and Non-Caucasian (NC) patients had similar mean [SD] age, HbA1C, eGRF, ACR, systolic blood pressure, diastolic blood pressure, LDL and SI (60.2 [8.3] versus 60.2 [8.0] yrs, p=.847; 57.4 [17] versus 63.7 [18] mmol/mol, p=.067; 66 [16.6] versus 72.1 [15.9] mL/min/1.73 m^2, p=.224; 8.5 [24.9] versus 5.3 [12.5] mg/mmol, p=.214; 138 [16] versus 109[58] mmHg, p=.213; 81[7] versus 80[9] mmHg, p=.940; 1.7 [1.1] versus 1.5 [1.2], p=.658 and 8.6[5.3] versus 8.5[4.3]m/s, p=.575), respectively. The C group had a higher BMI than the NC group (32.4[5.3] versus 28.8 [8.4] kg/m^2, p=.008) and a higher percentage of smokers (80.8% versus 41.5%, chi square p=.002). In the whole population, there was a significant positive correlation between SI and BMI (r=.265, p=.036). This relationship was also found in the patients of Caucasian origin (r=.412, p=.045) and it was not confounded by smoking status, LDL or ACR.

Conclusions: In this study vascular stiffness increased with BMI in patients of Caucasian heritage at high risk of progressive renal disease. SI in this study group is independent of traditional risk factors such as smoking, LDL and ACR. This observation could be relevant in understanding the differential risk of CVD in patients with renal disease.

FR-PO754

The Intima-Media-Thickness of the Carotid Artery Wall and the Progression of Chronic Kidney Disease in Patients with Diabetes Mellitus Type 2

Stefanos K. Roumeliotis, Athanasios K. Roumeliotis, Stelios A. Panagoutsos, Marios Theodoridis, Vangelis G. Manolopoulos, Ploumis Stavros Passadakis. *Medical School, Democritus Univ of Thrace, Alexandroupolis, Greece.*

Background: The presence of albuminuria (UAL) and Chronic Kidney Disease (CKD) are traditional risk factors for cardiovascular disease (CVD) and all-cause mortality. A good predictor of the incidence of CVD is found to be carotid atherosclerosis, which is being evaluated by the Intima Media Thickness of the carotid artery wall (cIMT). The aim of the study was to examine the relationship between the cIMT and the stage of CKD as well as the presence of diabetic nephropathy graded by the UAL in patients with type 2 diabetes mellitus (DM).

Methods: In this study 151 DM type 2 patients (79 males and 72 females) were included. Traditional risk factors (Body Mass Index, blood pressure, serum lipids) as well as cIMT measurements, using B-mode ultrasonography were assessed and correlated to the stage of CKD and the presence of UAL.

Results: The median carotid IMT in stages 1, 2, 3, 4 and 5 was 0.76mm (0.55-1.61), 0.905mm (0.63-1.61), 0.93mm (0.66-1.78), 0.95mm (0.66-1.66) and 0.98mm (0.60-1.60) respectively, and in 35% of the patients the presence of a carotid plaque was revealed. The carotid IMT was significantly increased as the stage of CKD was progressing ($p<0.001$, Kruskal-Wallis test) and was correlated to the eGFR (r=-258, p=0.002) and the presence of UAL (r=301, p=0.004). However, it was not significantly correlated to the glycemic control (assessed by HbA1c). Additionally, hypertriglyceridemia was significantly negatively correlated to the deterioration of eGFR (r=-282, p=0.001) and positively correlated to the presence of UAL (r=373, $p<0.001$).

Conclusions: Increased levels of UAL and reduced eGFR are associated to atherosclerosis of the carotid artery and elevated serum triglyceride levels in type 2 DM patients. This study attenuates the importance of the carotid Intima-Media Thickness as a way of recognition and prediction of GFR's deterioration besides a classic indicator of vascular calcification.

FR-PO755

Low Magnesium Levels and FGF-23 Dysregulation Predict Mitral Valve Calcification as well as Intima Media Thickness in Pre-Dialysis Diabetic Patients

Ana Paula Silva, André Fragoso, Pedro Neves. *Serviço de Nefrologia de Faro, Centro Hospitalar do Algarve, Faro, Portugal.*

Background: Mitral valve calcification and intima media thickness (IMT) are common complications observed in chronic kidney disease (CKD) patients and have been implicated with the high cardiovascular mortality incidence observed. **Aims:** The aim of this study isto investigate the implication of serum levels of magnesium and fibroblast growth factor-23 (FGF-23) with mitral valve calcification and IMT in diabetic patients with CKD.

Methods: This is an observational, prospective study involving 150 diabetic patients with mild to moderate CKD, divided into 4 groups according to Wilkins Score' grades of mitral valve characteristics. Carotid echodoppler and transthoracic echocardiography were used to assess features of calcification. Different parameters were analyzed and compared between magnesium levels and IMT values. Statistical tests were used to establish comparisons between groups, to identify risk factors, and to establish cut-off points for prediction of mitral valve calcification.

Results: FGF-23 values continually increased with higher values for both IMT and calcification whereas the opposite trend was observed for magnesium. In addition, FGF-23 and magnesium were found to independently predict both mitral valve calcification and IMT ($p<0.05$). Using Kaplan-Meier analysis, the number of deaths was higher in patients with lower magnesium levels and with poorer Wilkins score. The mean cut-off value obtained for FGF-23 was 117 RU/mL and for magnesium 1.7 mg/dL.

Conclusions: Hypomagnesemia and high FGF-23 levels are independent predictors of mitral valve calcification and IMT and are risk factors for cardiovascular mortality in diabetics with mild to moderate CKD. Thus, FGF-23 and magnesium might be used as diagnostic or therapeutic targets in order to better manage the currently high cardiovascular risk in CKD patients.

FR-PO756

Tubular Injury Is Associated with a High Risk of Ventricular Dysfunction in Subjects with Type 2 Diabetes Mellitus

Ernesto Sabath,[1,2] Ma. Ludivina Robles-Osorio,[2] Eliodoro Castro.[2] *[1]Centro Estatal de Hemodiálisis, Servicios de Salud del Estado de Querétaro, Querétaro, Mexico; [2]Facultad de Ciencias Naturales, Univ Autónoma de Querétaro, Querétaro, Mexico.*

Background: Albuminuria has been associated with a higher risk for cardiovascular disease in patients with diabetes and it has yet to be determined whether markers of tubular injury are also associated with a higher risk for CV disease. There are no studies about this association and the aim of the current study was to determine whether markers of tubular injury are associated with a higher risk for echocardiographic abnormalities in subjects with type 2 diabetes without hypertension.

Methods: Subjects aged >20 years old were included, and those with hypertension, albuminuria, antecedent of renal and CVD were excluded. Blood samples were taken after a fasting ≥ 8hrs; the analytical measurements of the biochemical variables were done by standard technique. GFR was estimated using the CKD-EPI equation. Spot urine samples for albumin and a1-microglobulin analysis were collected and the a1M determinations were done by ELISA. Descriptive statistics were calculated and comparisons between groups were done by t-student analysis and chi-square. For variables correlated with A1M excretion a multiple linear regression analysis was used.

Results: A total of 120 subjects with T2DM were included; the mean age was 50.8 ± 7.9 yrs, median time from diagnosis was 8.6 ± 7.2 years and mean BMI was 28.1 ± 4.9. In all the subject we have determination for A1M, of them 10 (8.3%) had AIM higher than 10 µg/gCr; there was no difference in age, GFR and systolic and diastolic blood pressure between the two groups, but C reactive protein (4.45 ± 2.59 versus 2.45 ± 2.28 mg/L p=0.05), glucose (167 ± 43 versus 148 ± 39 mg/dl p= 0.04) and uric acid (6.2 ± 1.3 versus 5.3 ± 1.3 mg/dl p=0.04) were higher in those with AIM excretion ≥10 µg/gCr; 45% of patients with no LMW proteinuria has diastolic dysfunction compared with all of the patients with LMW proteinuria (p=0.002).

Conclusions: Alpha1-microglobulin urinary excretion is associated with a high prevalence of diastolic dysfunction and should be considered as a new risk factor for cardiovascular disease in T2DM patients.

Renal Health Is an Important Determinant of Cardiac and Exercise Function in Adolescents with Type 1 Diabetes

Petter Bjornstad,[1] Melanie Cree-Green,[1] Amy D. West,[1] David Cherney,[2] Laura Pyle,[1] David M. Maahs,[1] Kristen Nadeau.[1] *[1]Univ of Colorado School of Medicine / Dept of Pediatric Endocrinology; [2]Univ of Toronto / Dept of Nephrology.*

Background: Cardiovascular disease and diabetic nephropathy, the most common causes of mortality in type 1 diabetes, are strongly related in adults with type 1 diabetes, yet little is known about their relationship in youth. We have previously demonstrated that adolescents with type 1 diabetes have exercise and diastolic dysfunction compared to lean non-diabetic controls. For that reason, we hypothesized that renal health, measured by estimated glomerular filtration rate (eGFR) and albumin-to-creatinine ratio (ACR) would be associated with cardiopulmonary fitness and diastolic function in adolescents with type 1 diabetes.

Methods: This cross-sectional study at an academic hospital included 69 adolescents (15.5 ± 2.2 years) with type 1 diabetes. Cardiopulmonary fitness was measured by peak oxygen consumption (VO_2peak) and oxygen uptake kinetics (VO_2kinetics), cardiac function by doppler echocardiography and renal function by eGFR (Bouvet combined creatinine and cystatin C) and ACR.

Results: In adolescents with type 1 diabetes, eGFR by Bouvet was significantly associated with VO_2peak [r = -0.55, R^2 = 30.3%, p=0.002], early (E) mitral inflow velocity (MVE) [r = -0.42, R^2 = 17.6%, p=0.02], ratio of early (E) to late (A) mitral inflow velocities (E/A ratio) [r = -0.42, R^2 = 17.6%, p=0.02] and left ventricular posterior wall thickness in diastole (LVPWd) [r = 0.39, R^2 = 15.2%, p=0.04] univariately and after adjusting for Tanner stage. ACR was not associated with cardiopulmonary fitness or diastolic function.

Conclusions: In adolescents with type 1 diabetes and previously demonstrated exercise and diastolic dysfunction, eGFR by Bouvet but not ACR was significantly associated with markers of cardiopulmonary fitness and diastolic function.

Being at High Risk for Obstructive Sleep Apnea Is Associated with More Rapid Loss of Kidney Function in Patients with Diabetic Nephropathy

Roberto Pisoni,[1] Paul W. Sanders,[2] Susan Harding,[2] Ruth C. Campbell.[1] *[1]Medicine, Medical Univ of South Carolina, Charleston, SC; [2]Medicine, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Type 2 diabetic nephropathy (DN) is the leading cause of end-stage renal disease in Western countries. Obstructive sleep apnea (OSA) is common in subjects with diabetes. OSA is associated with glomerular hyperfiltration and proteinuria in subjects with normal renal function, raising the question if OSA may be related to chronic kidney disease (CKD) progression. The association between OSA and DN has not been fully investigated. This retrospective cohort study aimed to investigate the prevalence of being at high risk (HR) for OSA among non-dialysis CKD patients with DN and the association of being at HR for OSA with loss of estimated glomerular filtration rate (eGFR).

Methods: Data from the University of Alabama at Birmingham (UAB) CKD Database was retrospectively evaluated. The CKD Database was approved by UAB IRB. We identified 56 subjects with DN who had undergone screening for OSA using the Berlin questionnaire (BQ) during a 9-month period. These patients were divided into a HR and a low risk (LR) for OSA cohort based on the BQ score. Change in eGFR was obtained by calculating the difference between eGFR measurements at the time the BQ was done and when patients were enrolled in Clinic, divided by the total years spent in Clinic.

Results: The prevalence of a HR score for OSA was 61%. There were no significant differences in baseline gender, blood pressure (BP), BMI, use of renin-angiotensin-aldosterone blockers, eGFR, urinary protein/creatinine, and co-morbidities between the HR and LR groups. Subjects with a HR score had a significantly greater loss of eGFR than those with LR score ($P<0.02$; median loss -3.4±1.2 versus 1.5±1.5 ml/min/1.73 m^2 BSA/year for HR versus LR) despite comparable BP and proteinuria on admission to CKD Clinic and similar time spent in Clinic (1.9±0.2 versus 2.1±0.3 years for HR versus LR).

Conclusions: This study shows that a high-risk score for OSA is common in non-dialysis CKD patients with DN and is associated with more rapid loss of renal function. This simple approach identifies patients at higher risk of CKD progression.

FR-PO759

Impact of Blood Pressure and Renal Lesions on the Long-Term Outcomes of Type 2 Diabetic Patients with Biopsy-Proven Diabetic Nephropathy

Tomoaki Funamoto, Miho Shimizu, Kengo Furuichi, Takashi Wada. *Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.*

Background: Although it is important to determine whether pathological information improves the predictive power when added to clinical information, renal biopsy is not generally indicated in the management of diabetic nephropathy. We investigated the impact of blood pressure (BP) and renal lesions on the outcomes of diabetic nephropathy.

Methods: Japanese type 2 diabetic patients with biopsy-proven diabetic nephropathy (n=270) were enrolled. Blood pressure levels at the time of renal biopsy were classified into 4 categories (optimal BP (<120/<80), normal (120-129/80-84) to high-normal (130-139/85-89) BP, grade I hypertension (140-159/90-99), and grade II (160-179/100-109) to III (≥180/≥110) hypertension) according to the criteria of the Guidelines for Management of Hypertension 2014 by the Japanese Society of Hypertension. The outcomes were the first occurrence of renal events (requirement of dialysis, or a 50% decline in estimated glomerular filtration rate (eGFR) from baseline), all-cause mortality, and cardiovascular events (cardiovascular death, nonfatal myocardial infarction, coronary intervention, or nonfatal stroke).

Results: 1) The mean duration of follow-up was 7.9 years. There were a total of 121 renal events, 45 deaths, and 64 cardiovascular events. 2) Higher BP had higher cumulative incidences and the hazard ratios of renal events and all-cause mortality compared to the optimal BP among patients with albuminuria (proteinuria), low eGFR, or advanced vascular lesions. 3) The cumulative incidence of cardiovascular events in grade II to III hypertension was higher than those of other BP levels among patients with advanced vascular lesions. 4) High systolic BP was one of the clinical determinants for renal events, all-cause mortality, and cardiovascular events in multivariate analysis. Advanced arteriosclerosis was one of the pathological determinants for renal events and cardiovascular events.

Conclusions: The available data suggest that the significant impact of BP on the outcomes of type 2 diabetic patients with biopsy-proven diabetic nephropathy was present, particularly in the presence of advanced vascular lesions.

FR-PO760

Poor Glycemic Control Increases in Resistance of Efferent Arteriole and Increase in Intraglomerular Pressure, Not Affecting Resistance of Afferent Arteriole, in Human

Eiji Ishimura, Akihiro Tsuda, Mitsuru Ichii, Shinya Nakatani, Akinobu Ochi, Katsuhito Mori, Masaaki Inaba. *Osaka City Univ Graduate School of Medicine, Osaka, Japan.*

Background: Development and progression of diabetic nephropathy is associated with glomerular hypertension and glomerular hyperfiltration. However, precise glomerular hemodinamic abnormalities in hyperglycemic state have not been demonstrated in human. We examined glomerular hemodynamics in human by measuring both inulcin clearance (C_{in}) and para-aminohypuric acid clearance (C_{PHA}) simultaneously.

Methods: Thirty-one subjects (55.4 ± 14.7 years; 21 type 2 diabetics and 10 non-diabetics) were enrolled in the present study. C_{in} and C_{PAH} were measured simultaneously. C_{in} of all the subjects were more than 60 ml/min. According to Gomez formula (Guidi E, et al. Am J Hypertens 2001), afferent arteriolar resistance (R_a), efferent arteriolar resistance (R_e), glomerular hydrostatic pressure (P_{glo}) and glomerular filtration fraction (FF) were calculated. Association of these values with glycemic control indices was examined.

Results: 1) FF significantly and positively correlated with fasting plasma glucose (FPG), hemoglobin A1c (HbA1c) and glycated albumin (GA) ($r = 0.396$, $p = 0.0303$; $r = 0.587$, $p = 0.0007$; $r = 0.525$, $p = 0.0070$, respectively). 2) P_{glo} significantly and positively correlated with FPG, HbA1c and GA ($r = 0.572$, $p = 0.0008$; $r = 0.535$, $p = 0.0019$; $r = 0.540$, $p = 0.0053$, respectively). P_{glo} was significantly associated with FPG, HbA1c and GA after adjustment of age and serum albumin. 3) Although there was no significant correlation between R_a and glycemic controls of FPG, HbA1c and GA, R_e significantly and positively correlated with HbA1c and GA ($r = 0.499$, $p = 0.0043$; $r = 0.592$, $p = 0.0018$, respectively). R_e was significantly associated with HbA1c and GA after adjustment of age.

Conclusions: These results directly demonstrates, in human, that poor glycemic control is associated with increased R_e, but not with R_a. Increased R_e is suggested to cause increased P_{glo}, leading to increased FF. Thus, hemodynamic abnormalities in poor glycemic control are suggested to be related to glomerular hyperfiltration and hypertention in human.

FR-PO761

Nuclear Angiotensin-2 Expression Increased in Glomerular and Vascular Compartments of Human Diabetic Nephropathy

Ping L. Zhang,[1] Xu Zeng.[2] *[1]Dept of Anatomic Pathology, William Beaumont Hospital, Royal Oak, MI; [2]Dept of Pathology and Laboratory Medicine, Temple Univ Hospital, Philadelphia, PA.*

Background: Angiotension-2 (Ang2) is a key element involved in renal disorders associated with dysfunctional Renin-Angiotensin-aldosterone (RAA) system such as diabetic nephropathy. Although Ang2 receptors are found in the nuclei of renal cortex and adrenal glands, the nuclear localization of Ang2 in human renal biopsies has been established. In this study, we compared Ang2 expression in the nuclei of diabetic nephropathy (human biopsies) with renal biopsies without glomerular injury as negative controls.

Methods: Renal negative control biopsies (n =14) and 31 renal biopsies with diabetic nephropathy were stained for Ang2 by immunohistochemical method (using a Dako autostainer); sarcoid granulomas as positive controls. Staining intensity of Ang2 was evaluated and scored from 0 to 3+ in the nuclei of podocytes and parietal epithelium of glomeruli, mesangial cells, glomerular endothelium, arterioles and proximal tubules in the two groups. Data were compared using unpaired student t test ($p < 0.05$ was considered statistically significant).

Results: In comparison to the negative control mesengium (0.21±0.09 arbitrary units [AU]), the diabetic group exhibited significantly stronger expression of nuclear Ang2 in the mesangial cells (1.53±0.16 AU; 7 fold increase). In addition, the nuclear expression of Ang2 was significantly upregulated in parietal epithelium (0.90±0.13 AU) and podocytes (0.95±0.12 AU) of glomeruli, glomerular endothelium (1.14±0.43 AU) and arterioles (1.17±0.11 AU) of diabetic group, when compared to the controls (0.21±0.09, 0.39±0.08, 0.43±0.14 and 0.57±0.14 AU, respectively). Nuclear Ang 2 expression was similarly weak in proximal tubules in both groups.

Conclusions: Our study reveals that nuclear expression of Ang2 is present in glomeruli, arterioles and renal tubules, implying a role of nuclear translocation of Ang2 in igniting its cellular activity. Our findings showing the over-expressed nuclear Ang2 in the glomeruli (mainly mesangial cells) and arterioles from diabetic group support that upregulated Ang2 involves in the progression of diabetic nephropathy.

Effects of Angiotensin II Receptor Blockers and Calciumantagonists on Blood Pressure Variability and Carotid Artery Atherosclerosis in Patients with Type 2 Diabetic Patients with Diabetic Nephropathy

Hongyu Qiu. *Dept of Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.*

Background: This prospective, controlled study was to analyze blood pressure variability and carotid intima-media thickness (IMT) changes of ARB combinedwith CCB in the treatment of patients with type 2 diabetic patients with diabetic nephropathy.

Methods: This prospective, sigle-center, cohort study was performed. Patients who presented to the West China Hospital with type 2 diabetic nephropathy were included. This study compared treatment group (Losartan and levamlodipine) and control group (Losartan). The primary outcome was clinical blood pressure, 24-h ambulatory blood pressure (BP) monitoringand the mean of the maximum intima-media thicknesses (IMT) in far walls of common carotids. Secondary outcome measures included evaluated glomerular filtration rate (eGFR), HbA1c, electrolytes and cardiovascular events. All outcome measures were assessed at baseline, 24 weeks and 52 weeks over the 52-week study period.

Results: 80 patients with type 2 diabetic patients with diabetic nephropathy were included and analyzed.After 52 weeks of treatment, Clinic blood pressure reductions were identical with both treatments, No significant difference was found in changes of carotid IMT in both groups, Variance analysis or nonparametric analysis revealed that 24-h systolic BP variability and nighttime systolic BP variability of the control group were significantly higher than those of the combination group. No significant difference between treatments was found in eGFR, HbA1c, electrolytes and cardiovascular events.

Conclusions: Combination of ARB and calcium antagonists in the treatment of patients with type 2 diabetic patients with diabetic nephropathy can reduce 24-h systolic BP variability and nighttime systolic BP variability, carotid IMT changes have been shown to be unrelated to blood pressure reduction.

Comparison of Serum Cystatin C and Creatinine as a Marker for Detection of Microalbuminuria in Diabetic Patients

Jung-Woo Noh, Ajin Cho, Youngki Lee, Ja-Ryong Koo, Eun Jung Kim, Jang Won Seo. *Internal Medicaine, Hallym Kidney Research Inst, Hallym Univ College of Medicine, Seoul.*

Background: Serum cystatin C was introduced as an accurate endogenous glomerular filtration rate (GFR) marker. Microalbuminuria is an early signthat appears before GFR deteriorates and the correlation of cystatin C with microalbuminuria is an important factor in deciding on the usefulness of cystatin C for diabetic patients. In this study, we evaluated the effectiveness of serum cystatin C as a marker for detection of microalbuminuria.

Methods: A total of 3049 type 2 diabetic patients (785 patients with microalbuminuria and 2264 without microalbuminuria) were evaluated with serum creatinine and cystatin C in a single center from 2010 to 2013. GFR was estimated using Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation. Associations between albumin-creatinine

ratio (ACR) and two markers were examined by linear regression analysis. Receiver operating characteristics (ROC) analysis of the two filtration markers was performed to determine which marker was most effective for early detection of ACR.

Results: Serum cystatin C (0.9±0.4 versus 0.7±0.2 mg/L), creatinine (1.1±0.4 versus 0.9±0.2 mg/dl), HbA1c (7.6±1.6 versus 7.0±1.2 %) concentrations were significantly higher in patients with microalbuminuria compared those without microalbuminuria. The cut-off values for serum cystatin C and creatinine were 0.95 mg/L and 1.2 mg/dl, respectively. The proportion of abnormal values for cystatin C and creatinine were 25% and 20% in patients with microalbuminuria and 61% and 47% in patients with ACR ≥ 300mg/g. The area under the ROC curve (AUC) of the serum cystatin C curve (0.674, 95 % CI 0.651 – 0.670) was greater than those of serum creatinine (0.625, 95 % CI 0.602 – 0.649). In subgroup analysis, patients with body mass index ≥ 25 kg/m^2, age < 60 years and estimated $GFR_{cystatinC}$ ≥ 60 ml/min/1.73m2 had greater AUC of serum cystatin curve than those of serum creatinine.

Conclusions: The overall relationship between cystatin C and microalbuminuria is stronger than those between creatinine and microalbuminuria.

FR-PO764

The Glomerular Hemodynamic Profile of Normotensive, Normoalbuminuric Type 1 Diabetes Patients Compared to Healthy Controls Marko Skrtic, Yuliya Lytvyn, Ronnie Lok-Hang Har, Paul M. Yip, Melvin Silverman, David Cherney. *Univ of Toronto.*

Background: Renal hyperfiltration in experimental models of early diabetes is associated with increased intraglomerular pressure, thereby promoting the development of diabetic nephropathy. Since direct measurements of intraglomerular pressure cannot be performed in humans, our aim was to characterize the glomerular hemodynamic profile of type 1 diabetes (T1D) patients based on the presence or absence of renal hyperfiltration.

Methods: Glomerular hemodynamic parameters were evaluated in 37 healthy controls (HC) and normotensive, normoalbuminuric T1D patients with baseline hyperfiltration (n=36, T1D-H, GFR≥135 ml/min/1.73m^2) or normofiltration (n=35, T1D-N, GFR 90–134 ml/min/1.73m^2) during euglycemic conditions (4–6 mmol/L). Gomez's equations were used to derive efferent (R_E) and afferent (R_A) arteriolar resistances, glomerular hydrostatic pressure (P_{GLO}) and filtration pressure (DP_F) from inulin (glomerular filtration rate) and paraaminohippurate (renal plasma flow) clearances, plasma protein and estimated ultrafiltration coefficients (K_{FG}). Measurements were repeated during clamped hyperglycemia (9–11 mmol/L).

Results: At baseline during euglycemia, T1D-N had higher R_A (2065±597 versus 1417±740 dyne•sec•cm^{-5}, p<0.001) versus HC, while R_A was lowest in T1D-H (914.2±494 dyne•sec•cm^{-5}, p<0.01 versus HC and T1D-N). In contrast, R_E was similar in the three groups. T1D-H exhibited higher P_{GLO} versus HC and T1D-N (66±6 versus 62±5 versus 55±3 mmHg, respectively, p<0.05) and DP_F was also higest in T1D-H (p<0.05 versus other groups). Similar findings were observed during clamped hyperglycemia. As expected, clamped hyperglycemia increased GFR in T1D-N (p<0.05) compared to T1D-H, but segmental resistances did not change significantly.

Conclusions: Hyperfiltration is primarily related to alterations in R_A rather than R_E in patients with T1D, suggesting that changes in afferent arteriolar resistance related to early T1D may be clinically important. The renal protective potential of novel agents that normalize R_A by impacting tubuloglomerular feedback through increased distal tubular sodium delivery, including sodium glucose cotransport-2 inhibitors, warrants further study.

FR-PO765

Glomerular Microvascular Remodeling Cause Polar Vasculosis in Human Diabetic Nephropathy and Advanced Nephrosclerosis: with Three-Dimensional Visualization Noriko Uesugi,[1] Yoshihito Shimazu,[2] Michio Nagata.[1] [1]*Renal Vascular Pathology, Tsukuba Univ, Tsukuba, Ibaragi, Japan;* [2]*Laboratory of Food and Physiological Sciences, Azabu Univ, Sagamihara, Kanagawa, Japan.*

Background: Objects. Neovascularization of small vessels and their aggregation (polar vasculosis (PV)) are frequently found in glomerular vascular poles of diabetes (DM) with nephropathy (DN) from its early stage. Vascular remodeling of afferent arterioles is suspected to cause PV, but not yet be confirmed. To determine their origin will be clue to investigate the pathogenesis of PV. To clarify this, we investigate human DM kidney by three dimensional (D) histological image using approximately 200 serial histological sections.

Methods: We use immunohistochemical method to distinguish arteries from capillaries. Paraffin embedded sections from non-tumor parts of renal carcinoma were double-immunostained by anti-endothelial markers, CD34, and vascular medial marker, smooth muscle actin, followed by PAS staining. The sections were scanned by virtual microscopy and proceeded to reconstruct 3D microvascular structure by RATOC TRI-SRF2 software. We analyzed 11 Japanese cases including 4 DM with/without DN and 7 control cases without DM or hypertension or renal disease.

Results:: PV was observed in two DM cases, one with DN and another without DN (Non-DN) but with marked arteriolar hyalinosis. Non-DN without prominent arteriolar hyalinosis and all control revealed no PV. Glomeruli with PV revealed wide range of histological features, normal to nodular formation and occupied 100% of glomeruli in DN, or 75% in Non-DN. PV vessels often showed marked hyalinosis. 3D image proved that PV vessels were originated from several different efferent arterioles, which were directly connected to glomerular capillaries. The other ends of PV were connected to peritubular capillaries. Wide range of 3D images proved no branching of afferent arterioles after diverged from interlobular arteries and no connection to PV.

Conclusions: PV is caused by remodeling of glomerulr efferent arterioles not afferent ones. These microvascular change might be representative of alteration of diabetic glomerular circulation.

FR-PO766

NEW Magnetic Resonance Imaging Methods: Intravoxel Incoherent Motion (IVIM) in the Evaluation of Diabetic Kidney Disease (DKD) Jianxun Wu, Jianteng Xie, Lei Fu, Yangyang Zuo, Yuxiong Lai, Jing Li, Wei Shi, Wenjian Wang. *Div of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: Intravoxel incoherent motion (IVIM) is a new imaging technique for the estimation of tissue refusion by calculation of diffusivity parameters using multi-b-value diffusion-weighted MR imaging. We investigate the relationship between glomerular filtration rate (GFR) and parameters calculated using intravoxel incoherent motion (IVIM) imaging on the diabetic kidney disease (DKD).

Methods: We studied 17 patients, divided into 4 groups based on eGFR levels (mL/min/1.73m2): group 1, eGFR≥90 (n=5); group 2, eGFR 60–90 (n=3); group 3, eGFR 30–60 (n=4); and group 4, eGFR≤30 (n=5). IVIM imaging was used to acquire diffusion-weighted images at 10 b values. The diffusion coefficient of pure molecular diffusion (D), the diffusion coefficient of microcirculation or perfusion (D*), and perfusion fraction (f) were compared among the groups.

Results: In the renal cortex and medulla, f values were significantly lower in groups 2, 3, and 4 than that in group 1. The D value of renal cortex was significantly low only in group 1. Both in the renal cortex and medulla, there is a correlation between f value and eGFR.

Conclusions: As renal dysfunction of DKD progresses, renal perfusion might be reduced earlier and affected more than molecular diffusion in the renal cortex and medulla. These changes are effectively detected by IVIM MR imaging.

Funding: Government Support - Non-U.S.

FR-PO767

Correlations of BMI with CKD Prevalence in a Cross-Sectional Population Study Sharma S. Prabhakar, Katherine Kam. *Texas Tech Univ Health Sciences Center.*

Background: While the exact prevalence of CKD is unknown, studies estimated that over 10% adult population in the U.S. may have CKD. Diabetes, hypertension and obesity are believed to be major risk factors for CKD. The relationship of obesity to CKD as an independent risk factor is not well investigated. We sought to examine these correlations in a large screening study in Texas.

Methods: Using random digit dialing of an un-selected general population in Texas. a cohort of 1609 subjects was recruited to screen for CKD and its risk factors. Necessary IRB approvals and informed consents were obtained. Detailed history, physical examination, BP, weight and BMI measurements were recorded. Underweight was defined as BMI<18 Kg/m^2, overweight 25-29.9 and obesity class I, II and III were defined as 30-34.9, 35-39.9 and >40 Kg/m^2 respectively. Blood and urine samples were obtained to measure renal function parameters. Estimated GFR (eGFR) was obtained using MDRD and CKD-EPI formulae and CKD staged as per K-DOQI guidelines.

Results: A total of 1579 subjects completed the study, with 279 (17.7%) and 249 (15.8%) having CKD by MDRD and CKD-EPI formulae. Of 1579 subjects, 1255 (79.5%) were overweight and 777 (49.2%) were obese. The prevalence of hypertension and DM exponentially increased with increasing BMI. There was no correlation between the BMI classes and stages of CKD. However there was a bi-modal peaking of CKD at both ends of the BMI spectrum.

BMI class	CKD stage I% (n)	II% (n)	IIIa % (n)	IIIb% (n)	IV% (n)	V% (n)	%ge of Total
Underweight (5)	14.3 (2)	21.4 (3)	0	0	0	0	35.7*
Normal wt. (43)	5.2 (16)	2.9 (9)	3.5 (11)	1.3 (4)	0	1 (3)	13.9
Overweight (54)	2.1 (10)	1.3 (6)	5.6 (27)	2.1 (10)	0.2 (1)	0	11.3
Obesity I (64)	5.2 (19)	4.4 (16)	5.2 (19)	2.7 (10)	0.3 (1)	0	17.8
Obesity II (41)	4.5 (10)	5.0 (11)	5.5 (12)	2.7 (6)	0.5 (1)	0.5 (1)	18.6
Obesity III (41)	9.4 (18)	4.2 (8)	3.6 (7)	3.1 (6)	1 (2)	0	21.4*

p<0.01 vs. normal weight

Conclusions: Obesity is a risk factor for CKD as 59%of CKD subjects were obese. There was a linear increase in the prevalence of CKD from overweight to Class III obesity. While increased prevalence of CKD in obesity in our study confirms previous observations, high prevalence of early CKD in underweight subjects warrants further investigation.

Visceral Fat Is More Closely Associated with Microalbuminuria Than Liver Fat: The NEO Study Renée De Mutsert,[1] Martin Den Heijer,[1,4] Ton J. Rabelink,[2] Frits R. Rosendaal,[1] Hildo Lamb,[3] Aiko P.J. De Vries.[2] *[1]Dept of Clinical Epidemiology, LUMC; [2]Dept of Nephrology, LUMC; [3]Dept of Radiology, Leiden Univ Medical Center (LUMC), Leiden; [4]Dept of Medicine, VUMC, Amsterdam, Netherlands.*

Background: Obesity is a risk factor for microalbuminuria. Especially ectopic lipid accumulation in non-adipose tissue is strongly associated with metabolic disorders. Our aim was to investigate the relative contributions of liver and visceral fat with prevalent microalbuminuria (MA) in the general population.

Methods: This is a cross-sectional analysis of the Netherlands Epidemiology of Obesity study, a population-based cohort of (wo) men aged 45-65 years. MA was defined as morning spot urinary albumin excretion (UAE) of 20-200 mg/ml. Visceral adipose tissue (VAT) was assessed by MRI in combination with ^{1}H-MR spectroscopy of hepatic triglyceride content (HTGC). We estimated associations of VAT and HTGC with UAE using linear regression analyses. Using logistic regression analyses we calculated odds ratios (OR) of MA. Analyses were adjusted for age, sex, ethnicity, smoking, education, alcohol consumption, eGFR (CKD-EPI), and total body fat (%).

Results: Measurements of VAT and HTGC were available in 1911 participants with a mean (SD) age of 55 (6) years, BMI: 26 (4) kg/m², VAT: 87 (54) cm², HTGC: 5.6 (7.7) %, 56% women. Per SD of VAT, UAE increased with 8.9% (95% CI: 3.4, 14.7), and 5.4% (1.3, 9.7) per SD HTGC. In a model including both VAT and HTGC, UAE increased with 7.3% (95% CI: 1.5, 13.5) per SD VAT, and 3.9% (-0.4, 8.4) per SD HTGC. The adjusted OR (95% CI) of MA associated with VAT was 1.75 (1.11, 2.76) and associated with HTGC it was 1.31 (1.08, 1.58). In the joint model the OR (95% CI) of MA associated with VAT was 1.64 (1.03, 2.62) and with HTGC it was 1.22 (0.97, 1.53).

Conclusions: Both liver fat and visceral fat were associated with prevalent microalbuminuria. However, visceral fat was more strongly associated with MA than liver fat in joint models. Visceral fat may be more important in the etiology of MA. Prospective analyses are needed to study associations of VAT, non-alcoholic fatty liver disease and perhaps fatty kidney with microalbuminuria and the development of chronic kidney disease.

FR-PO769

Glomerular Hyperfiltration Is Associated with Obesity and Younger Age in Type 2 Diabetes Bairbre A. McNicholas,[1,2] Andrew Smyth,[1,2] Francis M. Finucane,[3] Matthew D. Griffin.[1,2,3] *[1]REMEDI, School of Medicine, National Univ of Ireland, Galway, Ireland; [2]Nephrology Services, Galway Univ Hospitals, Ireland; [3]Galway Diabetes Research Centre, School of Medicine, National Univ of Ireland, Galway, Ireland.*

Background: Glomerular hyperfiltration (GH) is the first clinical manifestation of nephropathy in type 1 diabetes and is associated with increased future risk for CKD/ESRD. In non-diabetics, severe obesity may cause GH, glomerulomegaly and glomerulosclerosis. However, the clinical significance of GH and the independent influence of obesity on renal outcomes in type 2 diabetes mellitus (T2DM) are not well understood.

Methods: Relationships between obesity (BMI), renal indices [MDRD-eGFR, urine albumin creatinine ratio (ACR), prevalence of CKD (eGFR <60ml/min/SA) and GH (eGFR >130ml/min/SA), change of eGFR over 3-5 years follow-up] and other clinical parameters were analysed in 939 adults with actively-managed T2DM. Cross-sectional analyses at an index time-point and longitudinal analyses over 3-5 yrs follow-up were performed. 87% were receiving ACEi and/or ARB. Subsequently, renal indices were compared between 76 younger (age ≤40 yr) and 500 older (age >40 yr) adults with T2DM and BMI >30 kg/m².

Results: 25/939 (2.7%) subjects had GH at baseline. Compared to all others, these were younger (47±13 v 57±12 yr, p=0.001), were more recently entered into the clinical database (37±43 v 74±85 mth, p=0.03) and had higher BMI (37±11 v 32±6, p=0.001). WHO obesity grade was associated with increased risk for GH [OR 1.07, 95% CI 1.03-1.13 adjusted for time in database, HbA1c and ACR]. The younger obese subset had higher baseline eGFR but similar ACR and HbA1c compared to the older obese subgroup. During follow-up, there was an absolute eGFR increase among the younger obese subgroup (+8.0±18.2 ml/min/SA) compared to a decline among the older obese subgroup (-1.9±18.1, ml/min/SA, p = 0.003) without significant changes in BMI and ACR.

Conclusions: 1. Adiposity increases the prevalence of GH in actively-managed T2DM independently of glycemic control, albuminuria and ACEi/ARB therapy. 2. Younger adults with obesity and T2DM manifest a pattern of increasing eGFR during mid-term follow-up that may presage future risk for CKD.

FR-PO770

The Related Study of α-Klotho and Obesity Related Glomerulonephropathy Yang Min, Guo-Qin Wang, Hong-Liang Rui, Yuan-Yuan Pei, Hong Cheng, Yi-Pu Chen. *Div of Nephrology, Beijing Anzhen Hospital, Capital Medical Univ, Beijing, China.*

Background: To investigate the relationship of α-klotho protein and obesity related glomerulonephritis.

Methods: The patient with or without ORG were diagnosed by renal biopsy. The normal and abdominal obesity people were enrolled from the physical examination center. Propensity scoring analysis was done because the four groups of people may differ in important clinical characteristics. The blood and urine samples were detected by ELISA. After the mouse were sacrificed, kidneys were redusted. mRNA expression was detected by real-time quantitative PCR, protein expression was detected by Western blotting.

Results: [circ1] The plasma α-klotho levels were lower in the ORG patients, the CKD patients and abdominal obesity people than normal people, the difference was statistically significant (P<0.05). The plasma α-klotho levels were lower in ORG patients than CKD patients and abdominal obesity people, the difference was statistically significant (P<0.05). [circ2] The urine α-klotho levels were lower in ORG patients than CKD patients, abdominal obesity people and normal people, the difference was statistically significant (P<0.05). There was no difference between CKD patients, abdominal obesity people and normal people. [circ3] Compared with the control mouse, renal tissue α-klotho mRNA and protein levels were both decreased evidently in ORG model mouse.

Conclusions: The plasma and urine α-klotho levels were lower in ORG patients than abdominal obesity people, although both this two groups have the same abdominal obesity, and this maybe owing to the reduction expression of α-klotho in ORG renal tissue.

Structured Exercise in Obese Diabetic Patients with Chronic Kidney Disease: A Randomized Controlled Trial (NCT01036490): Effect of Obesity on Peak Oxygen Consumption David J. Leehey, Eileen Collins, Holly J. Kramer, Cheryl Cooper, Jolene Butler, Conor Mcburney, Christine Jelinek, Anne Garabedian, Susan Oconnell. *Medicine and Research, Hines VA Hospital, Hines, IL.*

Background: Patients with type 2 diabetes, obesity, and chronic kidney disease (CKD) are generally physically inactive, have a high mortality rate, and may benefit from an exercise program. However, there have been no randomized controlled trials to determine the benefits of exercise training in this population.

Methods: We hypothesize that exercise training in obese diabetic patients with CKD will improve proteinuria, stabilize renal function, decrease blood pressure, improve glucose control, improve body composition, decrease inflammation, improve endothelial dysfunction, decrease oxidative stress, and improve health-related quality of life. This is a 52-week randomized controlled study. Inclusion criteria are type 2 diabetes, obesity (body mass index > 30 kg/m²), chronic kidney disease (stage 2-4) and persistent proteinuria (> 200 mg/day for at least 3 months). All subjects receive optimal medical management and dietary counselling. Subjects randomized to exercise also undergo 12 weeks of exercise training followed by 40 weeks of supervised home exercise.

Results: 46 subjects were enrolled, of whom 36 completed at least the 12 week evaluation to date. At baseline, mean values (± SD) were as follows: age 65.9 ± 7.8, body mass index (BMI) 36.7 ± 4.4 kg/m², body fat 40.5 ± 5.8%, glycated hemoglobin (HbA1c) 8.0 ± 1.8%, creatinine clearance (CCr) 57.6 ± 29.3 mL/min, and urinary albumin excretion rate (UAE) 1118 ± 1236 mg/24h. Average treadmill time was 7.8 ± 3.8 minutes and peak oxygen consumption (VO_2 peak) was 13.2 ± 3.4 mL/kg/min. There was a negative correlation between VO_2 peak and age, BMI, percent body fat, and waist circumference, and a positive correlation between VO_2 peak and hemoglobin (Hb). On multivariate regression analysis, when age, race, BMI, HbA1c, CCr, UAE, and Hb were used as covariates, only BMI was predictive of VO_2 peak (P = 0.009).

Conclusions: Obese diabetic subjects with CKD have markedly impaired physical fitness, which is particularly evident in more obese patients.

Increase of Endothelin Type A Receptor in Local Renal Tissue Correlates with the Progression of Diabetic Nephropathy Huaying Pei,[1] Limin Zhang,[1] Jianrong Wang,[1] Wangxia Yang,[1] Shuxia Fu,[1] Shaomei Li,[1] Lin Yang,[1] Anyu Zhou.[2] *[1]Div of Nephrology, The 2nd Hospital of Hebei Medical Univ, Shijiazhuang, Hebei, China; [2]Rhode Island Hospital and the Warren Alpert Medical School at Brown Univ.*

Background: Diabetic nephropathy (DN) is one of the leading causes of chronic kidney disease but its exact cause of DN is unknown. Increased endothelin-1 (ET-1) has been shown to play an important role in the pathogenesis of DN majorly through activation of one of the ET-1 receptors, ETAR. However, the relationship between the progression of DN and the expression change of the two ET-1 receptors is unknown.

Methods: To explore the role of ET-1receptors in the progression of DN, semi-quantitative analysis was conducted to investigate the expression and localization of ETAR and ETBR in kidney biopsy samples using confocal laser scanning immunofluorescence microscopy. The subjects with DN were assigned to three groups by pathology classification: DN I grade (S1), DN II grade (S2), DN III grade (S3).

Results: Both ETAR and ETBR were observed in the glomerular and proximal tubular in control and DN patients. The expression of both receptors increased significantly in DN patients compared to that of controls. The expression of ETAR was lower than that of ETBR in control subjects. More importantly, the expression of ETAR increased dramatically as the diabetic nephropathy progressing (12.5±1.7 in S3 versus 8.5±1.3 in S2, 5.5± 0.2 in S1 DN patients respectively, P<0.01). However, there was no difference for ETB expression among S3, S2 and S1 groups (P>0.05). The ratio of ETAR and ETBR increased significantly between control and DN patients (P<0.01). The expression levels of ETAR were positively correlated with proteinuria (r=0.730, P<0.01) and the rate of glomerular sclerosis (r=0.783, P<0.01).

Conclusions: Our results suggest that the increase of endothelin receptors in local renal tissue plays critical role in the development and progression of diabetic nephropathy. The increased ration of ETAR and ETBR may be responsible for the progressive damage of kidneys in diabetes patients. Selectively blocking ETA receptor may be critical for developing novel therapeutics to impede the progression of diabetic nephropathy.

Urine Metabolomic Profile Correlates with Renal Function and Changes during Atrasentan Therapy in Patients with Diabetes and Nephropathy

Hiddo Jan Lambers Heerspink,[1] Dick de Zeeuw,[1] Shoba Sharma,[2] Tom Corringham,[2] Dennis L. Andress,[3] Kumar Sharma,[2,4] The RADAR Study Group.[5] *[1]Univ Medical Center Groningen, Netherlands; [2]Clinical Metabolomics; [3]AbbVie; [4]Univ of California; [5]Multiple Affiliations.*

Background: A panel of 13 urine metabolites (reflecting mitochondrial function) has been previously identified to be reduced in diabetics with kidney disease compared to healthy controls and diabetics with no CKD (*Sharma et al, JASN 2013*). In the recently reported RADAR trial in patients with diabetes and nephropathy (de Zeeuw et al, JASN 2014), the endothelin A receptor antagonist atrasentan improved renal surrogate outcome parameters. We validated the metabolomics profile in RADAR and studied the response of the metabolomic panel to atrasentan.

Methods: RADAR is a placebo controlled double blind trial in patients with diabetes and nephropathy (urine ACR of 300-3500 mg/g and eGFR of 30 to 75 ml/min/1.73m^2) who were randomly allocated to 12 week treatment with placebo (n=50), atrasentan 0.75 mg/d (n=78) or atrasentan 1.25 mg/d (n=83) as adjunct to renin-angiotensin-system inhibition. Targeted urine metabolomics was performed with GC-MS.

Results: 4 out of the 13 metabolites of the panel were below detection. Of the remaining nine, 7 showed reduced values in patients with the reduced eGFR (all p<0.01, with Bonferroni correction for multiple testing). Interestingly, all of the 9 detectable metabolites were improved with atrasentan treatment relative to placebo at 12 weeks of treatment (p=0.0019 for probability of all 9 being elevated with treatment group versus placebo).

Conclusions: We validated and confirmed that a specific panel of urine metabolites is reduced in diabetics with decreased renal function. Treatment with atrasentan for 12 weeks increased the reduced metabolite levels, relative to the placebo group, towards non-CKD values, possibly reflecting stabilization of mitochondrial function.

Mechanism of LDL Reduction during Atrasentan Use in Patient with Diabetes and Nephropathy

Ricardo Correa-Rotter,[1] Robert D. Toto,[2] Hiddo Jan Lambers Heerspink,[3] Dick de Zeeuw,[3] The RADAR Study Group.[4] *[1]Inst Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [2]UT Southwestern Medical Center, Dallas; [3]Univ Medical Center Groningen, Groningen, Netherlands; [4]Multiple Affiliations.*

Background: We previously demonstrated that the selective endothelin A receptor antagonist atrasentan reduced albuminuria (UACR) in patients with diabetes and nephropathy (*de Zeeuw et al, JASN 2014*). We also observed a fall in total cholesterol. We therefore evaluated the effect of atrasentan on lipid profile and looked at potential mechanism (s), such as relation with UACR reduction.

Methods: 211 subjects with type 2 diabetes, macroalbuminuria, and eGFR between 30-75 ml/min/1.73 m^2, were enrolled in 2 parallel, multinational, double-blind, randomized, placebo-controlled studies. Subjects were randomized to atrasentan 0.75, 1.25 mg/d or placebo for 12 weeks. Lipid values were evaluated at baseline, after 12 weeks of treatment.

Results: Total-, LDL-, and HDL-cholesterol, triglycerides, and use of fibrates or statins were not different at baseline between groups. A significant placebo corrected reduction in LDL-cholesterol was observed of 12.5 and 14% (0.75 and 1.25 mg/d, respectively). Age, gender, baseline eGFR, serum albumin, UACR, baseline HDL and LDL-cholesterol values, and statin use did not influence the reduction of LDL cholesterol for either atrasentan dose. However, path analysis showed that the reduction of LDL was only partly explained by the reduction in albuminuria: for 37% at the 0.75 mg/d (p=0.008), and for 16% at the 1.25 mg/d dose (p=0.29). UACR responders to 0.75 mg/d atrasentan (defined as >30% albuminuria reduction) showed a significant reduction of LDL (21%) versus non-responders (6%), whereas at 1.25 mg/d LDL reductions were similar in UACR responders (14%) versus non-responders (14%).

Conclusions: Chronic administration of atrasentan reduces LDL-cholesterol significantly. This may partly be the result of altered albuminuria handling, however, at higher atrasentan dose other (undetected) effects appear to play a role.

FR-PO775

Predictors of Fluid Retention and Relation with Albuminuria Reduction During Atrasentan Treatment in Diabetics with Nephropathy

Donald E. Kohan,[1] Hiddo Jan Lambers Heerspink,[2] Dick de Zeeuw,[2] The RADAR Study Group.[3] *[1]Univ of Utah; [2]Univ Medical Center Groningen, Netherlands; [3]Multiple Affiliations.*

Background: We previously demonstrated that the selective endothelin A receptor antagonist atrasentan reduced albuminuria (UACR) in patients with diabetes and nephropathy (*de Zeeuw et al, JASN 2014*). We also observed a variable, dose dependent degree of fluid retention evidenced by weight gain and decreases in hemoglobin (Hb) and hematocrit (Hct). We thus examined whether the individual response of albuminuria and fluid retention are associated, which could be a major limiting factor in the wide spread use in this patient population. Secondly, we studied potential predictors of fluid retention.

Methods: RADAR was a randomized placebo controlled double blind trial in diabetic nephropathy patients randomly allocated to a 12 week treatment with placebo (n=50), atrasentan 0.75 mg/d (n=78) and atrasentan 1.25 mg/day (n=83) groups as adjunct to renin-angiotensin-system inhibition. For the purpose of this analysis the atrasentan 0.75 and 1.25 mg/d groups were combined. Changes in UACR, weight, Hb, and Hct were analyzed after 2 wks treatment.

Results: No correlation was observed between changes in weight and UACR response (R^2 0.032). Weight increase was similar in UACR responders (defined as >30% reduction in UACR at week 2) and nonresponders (1.1 versus 1.0 kg). Multivariate analysis showed that lower baseline eGFR, HOMA-product, and higher systolic BP, Hba1c, and atrasentan dose predicted weight gain (table). Similar results were obtained when Hb and Hct data were used as proxies for fluid retention.

Conclusions: In patients with type 2 diabetic nephropathy, atrasentan-induced fluid retention is predicted by initial eGFR, blood pressure and glucose control, but not by UACR reduction.These findings suggest potential opportunities for patient selection to optimize antialbuminuria effects and avoiding the potentially important side effect of fluid retention.

Predictors of weight gain	Coefficient	Standard error	p-value
Atrasentan dose	0.59	0.19	0.003
eGFR (10 ml/min/1.73m^2)	-0.21	0.07	0.002
HbA1c (%)	0.27	0.07	<0.001
Systolic BP (10 mmHg)	0.15	0.07	0.024
HOMA-product	-0.19	0.09	0.028

FR-PO776

Intra-Individual Variability in Multiple Parameters in Response to Angiotensin Receptor Blockers Determines Ultimate Renal Outcome

Bauke Schievink,[1] Dick de Zeeuw,[1] Hans-Henrik Parving,[2] Peter Rossing,[3] Hiddo Jan Lambers Heerspink.[1] *[1]Univ Medical Center Groningen, Groningen, Netherlands; [2]Rigshospitalet, Copenhagen, Denmark; [3]Steno Diabetes Center, Gentofte, Denmark.*

Background: Angiotensin Receptor Blockers (ARBs) are renoprotective and targeted to high blood pressure (BP). However, ARBs have multiple other (off-target) effects which may or may not affect renal outcome. It is unknown whether the on-target and off-target effects are congruent within an individual. If not, this may have major effects on individual long-term renal outcome prediction. We therefore studied intra-individual variability in multiple parameters in response to ARB in type 2 diabetes.

Methods: We used RENAAL trial data, assessing change in systolic BP (SBP) and the off-targets albuminuria, potassium, hemoglobin (Hb), cholesterol and uric acid after 6 months losartan treatment. Response was defined as the 6 months change from baseline. The improvement in predictive performance of renal outcomes (ESRD or doubling Screat) for each individual after adding ARB-induced changes in all risk markers to a renal risk score was assessed by C-index.

Results: Each parameter showed distinct response variability between patients. A response to losartan was observed in SBP (61%), albuminuria (72%), potassium (66%), hemoglobin (72%), cholesterol (61%), and uric acid (47%). The proportion of individuals with off-target responses was similar among patients with or without SBP response, suggesting that off-target responses were independent of SBP response. In addition, no correlations were seen between individual parameter responses within an individual (all r<0.3). Combining individual responses significantly improved renal outcome prediction (increase C-index 0.79 to 0.84, p<0.001). The results were validated in two independent trials with irbesartan: IDNT and IRMA-2.

Conclusions: ARBs have multiple effects which vary between individuals and vary between parameters within an individual. We found no congruency between the different parameter responses within an individual. Combining all ARB responses improves renal risk prediction, highlighting the importance of monitoring and targeting multiple risk markers.

FR-PO777

The Effect of 3 Years Insulin Pump Treatment on Albuminuria in Type 1 Diabetes

Signe Rosenlund,[1,2] Tine Hansen,[1] Steen Andersen,[2] Peter Rossing.[1,3,4] *[1]Steno Diabetes Center, Denmark; [2]Nordsjaellands Hospital, Denmark; [3]Univ of Copenhagen, Denmark; [4]Aarhus Univ, Denmark.*

Background: We investigated the effect of 3 years insulin pump (CSII) treatment on HbA_{1c}, albuminuria and kidney function compared to multiple daily injections (MDI) in a single center clinical setting.

Methods: We conducted a case-control study of all patients initiating CSII from 2004-10 and followed for at least three years: 193 patients with type 1 diabetes matched (1:2) to 386 patients treated with MDI in the same period. Matching was based on diabetes duration, sex, HbA_{1c} and normo-, micro- or macroalbuminuria at baseline. Urinary albumin creatinine ratio (UACR) was measured yearly and annual change assessed from linear regression. Unpaired t-test compared groups and multiple regression adjusted associations.

Results: At baseline, both treatment groups included 39% men with diabetes duration of (mean±SD) 23±12 years and a frequency of normoalbuminuric of 84%. Patients were (CSII *versus* MDI) 48±12 *versus* 44±11 years old, HbA_{1c} 68±11 *versus* 68±10 mmol/mol, eGFR 100±23 *versus* 101±25 mL/min/1.73m^2, UACR 9 (IQR 6-19) *versus* 9 (6-17) mg/g, and numbers on RAAS inhibition (RAASi) 40 *versus* 38%, (p>0.58 for all; except age: p<0.001). Annual change in UACR in CSII *versus* MDI treated patients was (mean (CI95%))-11.3 (-14.6;-8.0) % *versus* -1.1 (-3.3;1.1) %, (p<0.001). Reduction in UACR was significantly associated to CSII treatment after adjustment for age, sex, diabetes duration and average eGFR, UACR, MAP, HbA_{1c}, cholesterol, RAASi, antihypertensive treatment and smoking (p<0.001). In adjusted analyses of patients on stable RAASi during follow

up (n=465) CSII treatment remained significantly associated to a reduction in UACR (p<0.001). After 3 years HbA_{1c} was 62±11 *versus*69±11 mmol/mol (p<0.001) and eGFR 94±25 *versus*96±26 mL/min/1.73 m^2 (p=0.58).

Conclusions: CSII treatment over 3 years independently reduced HbA_{1c} and UACR compared to MDI, but eGFR remained unchanged. Reduced UACR may be due to less glycaemic variability as the well-known effect of CSII on HbA_{1c} could only partially explain the effect. This cannot be assessed from our data. The effect of CSII treatment on UACR needs confirmation in randomized controlled trials.

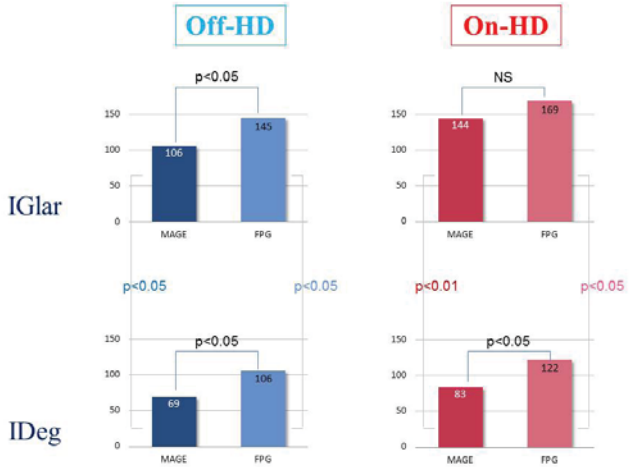
FR-PO778

Superior Glycaemic Control with Insulin Degludec (IDeg) to Insulin Glargine (IGlar) in Patients with Type-2 Diabetes (T2DM) on Hemodialysis (HD) Assessed by Continuous Glucose Monitoring (CGM) Satoshi Funakoshi,[1] Jyunichiro Hashiguchi,[1] Kenji Sawase,[1] Yoshiaki Lee,[1] Hiroshi Ichinose,[1] Osamu Sasaki,[1] Rica Etoh,[1] Masatoshi Hayashida,[1] Yoko Obata,[2] Tomoya Nishino,[2] Takashi Harada.[1] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki Univ School of Medicine, Nagasaki, Japan.*

Background: During hemodialysis session plasma glucose decreases steeply, and then increases to hyperglycemic state afterwards in diabetic hemodialysis patients. IDeg, an engineered acylated insulin, was recently reported to form a soluble depot after subcutaneous injection with a subsequent slow release of insulin and an ultralong glucose-lowering and stabilizing effect.

Methods: In this study we evaluated the efficacy of IDegin controlling glycemic variability in diabetic hemodialysis patients comparing to IGlar using CGM system. Eight relatively poor-controlled (HbA1c>8.0 %) diabetic hemodialysis outpatients treated with IGlar were enrolled in this study after appropriate IC. Subjects were then monitored overall 72-hours glycemic control, on both hemodialysis day (HD) and non- hemodialysis days (free day: FD), by CGM. Various doses of IGlarwere converted to the same dose of IDeg, and glycemic controls were compared in each patient.

Results: As shown in Figure 1, the plasma glucose curves under IGlar treatment on HD steeply declined then increased compared to FD.



On the other hand, the plasma glucose variations in IDeg -treated patients were similar between HD and FD. More importantly, the mean amplitude of glycemic excursions (MAGE) under IGlar treatment on HD was significantly higher than in IDeg -treated group (122.3±38.3 mg/dL versus 66.7+22.1 mg/dL, p<0.001).

Conclusions: In our study, IDeg, with its slow release of insulin, could be promising candidate in the treatment in diabetic hemodialysis patients.

StepAhead Program Reduces Lower Limb Amputation Rates Among Diabetic End-Stage Renal Disease Patients Stephen D. McMurray,[1] Christine Ordway,[1] Carey Colson,[2] Steven M. Brunelli.[2] *[1]DaVita VillageHealth, Vernon Hills, IL; [2]DaVita Clinical Research, Minneapolis, MN.*

Background: End-stage renal disease (ESRD) patients with diabetes are at high risk of lower limb amputations. Published data have found rates of 4.3 to 13.8 amputations per 100 persons (Eggers et al Kidney Int 1999;56:1524-33; Combe C et al, Am J Kidney Dis 2009;54:680-92). StepAhead is an integrated DM care management program designed to enhance patient self-management and reduce the likelihood of unnecessary complications among diabetic ESRD patients. We examined whether StepAhead was effective in reducing lower limb amputations among diabetic ESRD patients.

Methods: StepAhead was initiated in January 2012, and 447 diabetic ESRD patients from 11 dialysis facilities were enrolled. Patients were followed for 12 months for physician-driven DM management, eye exams, glucometer possession, and glucose education and for 18 months for foot checks. Outcomes included lower limb amputation rates.

Results: Among StepAhead enrollees the mean age was 63 years, 45% female, 45% black, 43% Hispanic, 80% had Medicare as a primary insurer, mean body mass index was 27.9 kg/m^2, and mean Charlson Comorbidity Index was 6.1. Of those who completed 18 months (n=228), 95% had at least 6 foot checks and 80% had at least 12 foot checks after 18 months. Lower limb amputation rates fell from 2.7 to 1.6 amputations per 100 patient-years between the first year and last 6 months in the program (overall rate 2.4 amputations per 100 patient-years).

Conclusions: Versus published normative data, rates of lower limb amputation among StepAhead enrollees was lower. In addition, continued improvement in amputation rates suggests that the full potential of the program in amputation avoidance may take time to be achieved and may not yet have been fully seen.

FR-PO780

Subclinical Kidney Injury before and after Bariatric Surgery in Adolescents with Severe Obesity Nianzhou Xiao, Prasad Devarajan, Michael R. Bennett, Mark Mitsnefes. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Obesity is an independent risk factor for kidney injury. We have previously shown that severely obese children have increased urinary kidney injury biomarkers (NGAL, KIM-1, IL-18). While an increasing number of obese adolescents attempt to lose weight via bariatric procedure, there are no known studies examining change in kidney status afterward.

Methods: This is a prospective study of 19 severely obese adolescents with no microalbuminuria or decreased GFR at baseline, who had bariatric procedure. Urinary NGAL, IL-18 and KIM-1 were measured at baseline, 6 and 12 months post-surgery. The levels of biomarkers were compared between obese and age-gender-matched lean controls, and between obese children at baseline and after surgery. Data are median (IQR). 95% tile were calculated from 137 healthy adolescents (age 15 to 18 years) using Cincinnati Genomic Control Cohort.

Results: Baseline BMI was 49 kg/m^2 and decreased by 32% (p<0.001) at 1 year after procedure. All urinary biomarkers were significantly increased in the obese cohort in comparison to the lean controls. The levels remained high through 1 year after bariatric surgery. Accordingly, the prevalences of abnormal urine NGAL, KIM1 and IL-18 were significantly higher in obese compared to lean controls at baseline and at 1 year after surgery.

Characteristics	Lean Controls (n = 38)	Obese (n = 19)		
		Baseline	6 m	12 m
Age, year	16 (15, 17)	16 (15,17)		
Gender (M/ F)	4/15	8/30		
BMI, kg/m^2	20 (20, 22)	49 (43, 52)	34 (29, 39)	33 (28, 38)
eGFR, mL/ min/1.73m^2	NA	114 (103, 157)	109 (97, 121)	111 (94, 169)
IL-18, pg/mL >95th tile (>139 pg/ml)	24 (16, 52) 0.02%	113 (51, 847) 43%	142 (78, 354) 50%	112 (42, 7665) 39%
NGAL, pg/mL >95th tile (>75 pg/ml)	20 (7, 39) 0.05%	32 (22,164) 43%	161 (52, 340) 57%	47 (20, 107) 29%
KIM-1, pg/mL >95th tile (>1,876 pg/ml)	430 (209, 831) 0.02%	775 (254, 1187) 20%	2798 (1008, 3294) 71%	974 (624, 2312) 33%

Conclusions: Severe obesity is associated with increased urinary biomarkers of structural and inflammatory kidney injury, despite the absence of microalbuminuria or decreased GFR. The elevation persists at 1 year after surgery, suggesting that close long-term follow up of kidney status is warranted.

FR-PO781

The Influence of Pharmaceutically Induced Weight Changes on Estimates of Renal Function Bernt Johan Illum von Scholten,[1] Frederik I. Persson,[1] Oluf Kristian Højbjerg Hansen,[2] Claus Bo Svendsen,[2] Peter Rossing.[1,3,4] *[1]Steno Diabetes Center, Denmark; [2]Novo Nordisk, Denmark; [3]Univ of Copenhagen, Denmark; [4]Aarhus Univ, Denmark.*

Background: Estimates of renal function based on serum creatinine are derived from cross-sectional studies. If body weight or body composition change over time, this could affect estimates of renal function, if plasma creatinine levels are changed as well. Whether this affects estimated renal function (eGFR) could depend on applied equations as Cockcroft-Gault (CG) which includes creatinine and body weight, whereas the 4-variable MDRD and CKD-EPI equations only include creatinine.

Methods: We compared changes in eGFR based on CG or MDRD in type 2 diabetic patients followed for 26 weeks in the seven phase 3 trials of the glucose- and body weight-lowering GLP-1 analog liraglutide (lira), with that of other glucose lowering medications with less or no weight reducing effects (insulin glargine, glimepiride, exenatide, rosiglitazone and placebo).

Results: The analysis included 5100 patients (3173 patients treated with lira and 1927 treated with comparator). Mean (SD) baseline MDRD eGFR was 88.0 (21.5) and 88.8 (22.1) ml/min/1.73m^2, for lira and comparator respectively. The reduction in body weight (BW) for lira was 1.9 (3.7) kg (with a maximum of 24.7 kg) and for comparator BW increased 0.2 (3.5) kg (maximal reduction of 14.9 kg). Creatinine was unchanged in both groups. In separate lognormal linear regression models with last observation carried forward a 10 % increase in BW corresponded to a 0.8 (-0.4;1.9) % increase in creatinine for lira and a 0.7 (-0.9;2.2) % decrease for comparator, and MDRD eGFR increased 0.24

(-1.0;1.5) % for lira, and 0.55 (-1.2;2.3) % for comparator. A 10 % increase in BW was associated with a 10.2 (9.0-11.5) % increase in CG eGFR for lira, and a 10.5 (8.9;12.2) % increase in CG eGFR for comparator.

Conclusions: In type 2 diabetic patients with normal renal function, weight reduction of 1.9 kg (maximal reduction of 24.7 kg) was not associated with change in plasma creatinine. Accordingly, there was no change in weight independent estimates of GFR (MDRD), whereas weight dependent estimates (CG) were changed.

FR-PO782

The Reno-Protective Effect of Quality Improvement Activity Targeting Better Glycemic Control Keita Hirano,[1,2,6] Sachiko Ohde,[2] Gen Shimada,[3,4] Masami Monden,[5] Yasuhiro Komatsu,[6] Gautam A. Deshpande,[2] Osamu Takahashi,[2,7] Tsuguya Fukui.[2,7] *[1]Dept of Nephrology, Kyoto Univ Graduate School of Medicine; [2]Center for Clinical Epidemiology, St. Luke's Life Science Inst; [3]Dept of General Surgery, St. Luke's International Hospital; [4]Medical information Center, St. Luke's International Hospital; [5]Dept of Endocrinology, St. Luke's International Hospital; [6]Dept of Nephrology, St. Luke's International Hospital; [7]Dept of Internal Medicine, Dept of Internal Medicine.*

Background: Although physicians acknowledge the importance of tight glycemic control to prevent complications such as chronic kidney disease for type 2 diabetes patients, the optimal methods for management are not always clear. We implemented hospital-wide QI activity (quality improvement) which includes monthly monitoring blood glucose levels and prescribing medications, and medical education by specialists. Purpose of this study is to investigate the effectiveness of QI activity by evaluating kidney function of type 2 diabetic patients between pre and post QI period.

Methods: This retrospective open cohort study included type 2 diabetic patients with baseline eGFR ≥60 ml/min/1.73m^2 at the St. Luke's International Hospital. All patients seen at least twice between 2005 and 2012 were stratified into two groups based on their first visit year: 2005-2008 year group (pre-QI period) versus 2009-2012 year group (QI period). We used linear random effects models with individual intercepts (initial eGFR level) and individual gradients (change in eGFR per year), to derive parameters describing the progression of kidney function.

Results: A total of 6,875 patients were included in the study (mean age of 62.1 years, SD 13; 66.3% male). According to the linear random effects models, eGFR decreased by 1.0 ml/min/1.73m^2 per year among the 2005-2008 year group, while decreasing by 0.2 ml/min/1.73m^2 among the 2009-2012 year group. After QI activity implementation, the prescription of metformin and DPP-4 inhibitors dramatically increased and better glycemic control was achieved.

Conclusions: According to our results, QI activity have succeded in preventing rapid decrease in kidney function in type 2 diabetic patients.

Trained Breathing-Induced Oxygenation Reverses Cardiovascular Autonomic Dysfunction in Patients with Type 2 Diabetes and Renal Disease Pasquale Esposito,[1] Teresa Rampino,[1] Per-Henrik Groop,[2] Luciano Bernardi,[3] Antonio Dal Canton.[1] *[1]Nephrology, Dialysis and Transplantation, Fondazione IRCCS, Pavia, Italy; [2]Dept of Nephrology and Folkaelsan Research Center, Univ of Helsinki, Finland; [3]Dept of Internal Medicine, Fondazione IRCCS, Pavia, Italy.*

Background: Cardiovascular autonomic neuropathy (CAN) is a risk factor for cardiovascular disease in diabetic and renal patients but its pathogenesis is obscure. This study was focused to understanding whether hypoxia is a functional determinant of CAN in diabetic patients and the extent to which hypoxia and CAN may be reversed by trained breathing blood oxygenation.

Methods: 26 type II diabetic patients (age 61±0.8 years) were enrolled. Diabetes duration was 10.5±2 years, GFR was 68.1±5.5 ml/min. 24 healthy subjects (age 58.5±1) were the controls. CAN was assessed by the measurement of arterial baroreflex sensitivity (BRS) obtained recording the RR interval and blood pressure during spontaneous, normal (15 breaths/min) or slow (6 breaths/min) controlled breathing in conditions of normoxia or hyperoxia (5 L/min oxygen).

Results: During normal controlled breathing, diabetic patients presented higher heart rate (HR) and lower BRS compared with the control participants (5.5±0.6 versus 11.8±2.0 ms/mmHg, p<0.005).Slow breathing and oxygen administration significantly reduced HR and increased BRS in both diabetic patients and the control group (9.6±1.9 and 15.3±2.3 ms/mmHg, respectively, p<0.05).

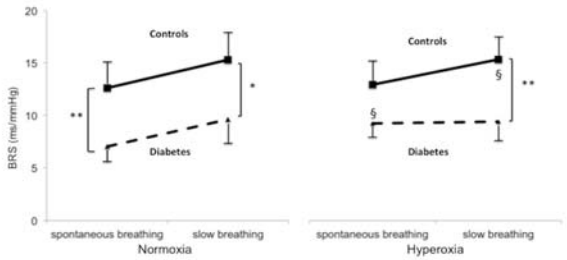

Figure 1. Effect of oxygen and slow breathing on BRS.

Data are expressed as means+SEM. In normoxia BRS was depressed in type 2 diabetes, while slow breathing increased BRS in both the groups of subjects.
In hyperoxia diabetic patients presented an improved BRS, that was unaffected by slow breathing, indicating that the two effects are probably related.
Instead, in healthy subjects hyperoxia induced a further increase in BRS during slow breathing.
* p<0.05, * * p <0.005, § p<0.05 vs spontaneous breathing

Similarly, also patients affected by chronic kidney disease, presented a significant improvement of BRS during deep breathing and hyperoxia (9.8±3.7 and 10.7±3.4 ms/mmHg, respectively, p<0.05 versus spontaneous breathing).

Conclusions: CAN affecting type II diabetic patients can be partially reversed by increasing oxygen supply through controlled breathing, thus suggesting hypoxia as a cause of cardiovascular risk potentially prevented by trained breathing.

FR-PO784

Effect of Dietary Protein Restriction and Uric Acid on Progression of Diabetic Nephropathy Sascha Pilemann-Lyberg,[1] Morten Lindhardt,[1] Frederik I. Persson,[1] Henrik Post Hansen,[2] Peter Rossing.[1,3,4] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Dept of Nephrology, Herlev Univ Hospital, Denmark; [3]Aarhus Univ, Denmark; [4]Univ of Copenhagen, Denmark.*

Background: Diabetic nephropathy (DN) is a major cause of end stage renal disease (ESRD). Evidence suggests that serum uric acid (UA) is a risk factor for development and progression of chronic kidney disease and early loss of kidney function in patients with diabetes. We aimed to investigate whether a high level of UA is associated with GFR decline, ESRD or death in patients with type 1 diabetes.

Methods: We conducted a *post hoc* analysis of 82 patients included in a prospective, randomized, controlled trial with allocation to either low versus normal protein diet for a median of 4 years. Patients were selected with progressive DN (prestudy GFR decline of ≥ 2 ml/min/year). UA was measured at baseline. The primary endpoint was a combined endpoint of death or ESRD and the secondary endpoint was decline in GFR (yearly measurement of Cr51EDTA plasma clearance). A cox regression model was built to evaluate the effect of UA on the primary endpoint. General linear model was used to evaluate association to decline in GFR. Both models were performed with and without adjustment for progression promoters (HbA1c, systolic blood pressure, cholesterol, baseline GFR, baseline urinary albumin excretion rate (UAER)) and diet allocation with backward elimination.

Results: Mean baseline UA was 6.5 mg/dL (SD±2.1), GFR 68mL/min/1.73m^2 (SD±31), geometric mean of UAER 772mg/24h (IQR, 415 to 1510). As previous shown low protein diet significant effect on the primary endpoint (log rank test, p=0.042). Level of UA was similar in patients reaching the endpoint compared to those who did not (p=0.88) and had no effect in the cox model before and after adjustment (p=0.91). Level of UA was not associated with change in GFR (r^2=0.04, p=0.11). Each doubling of baseline UAER was associated with an annual decline in GFR by 0.7mL/in (p=0.03).

Conclusions: Serum uric acid did not predict the endpoint of ESRD or death and was not associated with decline of GFR. As these results are in contrast with previous finding further evaluation of the role of UA as a progression marker is needed.

FR-PO785

Benefits of Lifestyle Modification Program in Obese Chronic Kidney Disease Patients Sankar D. Navaneethan,[1] Ciaran E. Fealy,[2,3] Amanda R. Scelsi,[2] Hazel Huang,[2] Steven K. Malin,[2] John P. Kirwan.[2] *[1]Nephrology, Cleveland Clinic; [2]Pathobiology, Lerner Research Inst; [3]Kent State Univ.*

Background: Obesity is an independent risk factor for the development and progression of chronic kidney disease (CKD). However, the feasibility and benefits of lifestyle modification on weight loss in people with CKD is less well understood. Therefore, we examined the effects of a diet and exercise intervention on body composition, exercise capacity, insulin resistance, inflammation, adipokines and kidney function in obese subjects with CKD.

Methods: Nine subjects (2M/7F, age: 57 years, median BMI 43.9 kg/m^2, iothalamate glomerular filtration rate [iGFR] 62 ml/min) underwent a 12-week lifestyle modification intervention program. This included dietary modification (500-kilocalorie deficit diet) by a registered dietitian based on measured resting energy expenditure assessment and a supervised arobic exercise (i.e. ~ 85% HR_{max}) program at our Clinical Research Unit. Body composition (iDXA), exercise capacity (VO_{2max}), insulin resistance (Matsuda Index), inflammation (hs-C-Reactive Protein), adipokines (leptin) and kidney function (iGFR) were measured before and after the intervention. Changes in parameters were compared using Wilcoxon signed rank test.

Results: After the 12-week program, there was a significant decrease in BMI and fat mass. There was also a significant increase in exercise capacity, along with improvements in insulin sensitivity and leptin. However, there was no significant change in inflammation or kidney function after the intervention.

Variable	Median (Inter-quartile range)	p-value
Change in BMI (kg/m^2)	-1.9 (-2.6, -1.4)	0.004
Change in Fat mass (kg)	-4.9 (-5.9, -3.0)	0.03
Change in Matsuda index	0.55(0.43, 1.2)	0.02
Change in Leptin	-5.1 (-14.5, -3.3)	0.008
Change in Log CRP	0.01 (-0.04, 0.14)	0.46
Change in Iothalamate GFR (ml/min)	-2.00 (-6.00, 0.10)	0.37

Conclusions: Weight loss with 12-weeks of diet and exercise is feasible in a CKD population. The effects on body weight also related to improvements in exercise capacity, insulin resistance and leptin. Whether lifestyle-induced weight loss can be sustained in CKD patients together with improvements in kidney function merits further study.

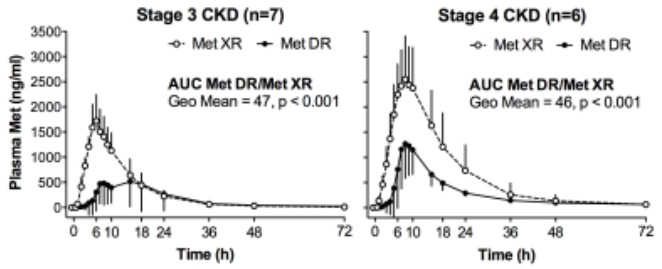
Effects of New Metformin Formulation in Stage 3 and 4 CKD: A Pilot Study

George L. Bakris,[1] Sunder Mudaliar,[2] Terri Kim,[3] Colleen Burns,[3] Sharon D. Skare,[3] Mark Fineman,[3] Alain Baron.[3] *[1]The Univ of Chicago Medical Center, Chicago, IL; [2]VA Medical Center, San Diego, CA; [3]Elcelyx Therapeutics, San Diego, CA.*

Background: Metformin (Met) is contraindicated in patients with Stage 3 or higher CKD due to increased risk of lactic acidosis. Low-dose Met is sometimes used off-label in patients with Stage 3 CKD to limit exposure. Delayed release (DR) Met targets delivery to its site of action in the lower bowel where absorption is poor, resulting in greater glucose-lowering efficacy and lower plasma Met for a given dose. We previously showed that 1000 mg Met DR produces a greater reduction in glucose and lower plasma Met levels compared to 1000 mg extended release (XR) Met in patients with normal renal function (RF). Thus, Met DR may be safer and more effective than currently available Met in patients with Stage 3 or higher CKD.

Methods: This randomized crossover study assessed the plasma PK of a single dose of Met DR, Met XR and placebo in 31 patients with T2DM and normal RF (eGFR ≥90mL/min/1.73m^2) or CKD: Stage 2 (60-89), Stage 3 (30-59) and Stage 4 (15-29).

Results: Patients were mostly white males (77%) with mean±SD BMI 32±4kg/m^2, 10±8yr duration of T2DM, fasting glucose 157±49mg/dl, and A1C 7.5±1.2%. Compared to Met XR, Met DR was associated with a 48, 26, 53 and 54% reduction in Met exposure in patients with normal RF, and Stage 2, 3 and 4 CKD. Figure 1 shows Met exposure in patients with Stage 3 and 4 CKD.



Plasma lactate and anion gap were not increased in any group. Adverse event rates were low and similar across groups.

Conclusions: In patients with T2DM and Stage 3 or higher CKD, Met DR was associated with lower Met than the same dose of currently available Met XR without increased lactate or anion gap. Together with previous efficacy data, these data support further study of Met DR in patients with T2DM and advanced CKD.

The Efficacy and Safety of Dipeptidyl Peptidase-4 Inhibitors in the Treatment of Type 2 Diabetes Mellitus in Patients with Chronic Kidney Disease: A Meta-Analysis of Randomized Clinical Trials

Suhail Khojah,[1,3] Wafa Altuwaijri,[2,4] Simon Richard Walker,[6] Brett M. Hiebert,[7] Kerry Macdonald,[5] Paul Komenda,[2,5] Claudio Rigatto,[2,5] Navdeep Tangri.[2,5] *[1]Nephrology, Univ of Western Ontario, London, ON, Canada; [2]Internal Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [3]Internal Medicine, King Abdul-Aziz Univ, Jeddah, Makkah, Saudi Arabia; [4]Internal Medicine, Univ of Dammam, Dammam, Eastern, Saudi Arabia; [5]Seven Oaks Hospital, Winnipeg, MB, Canada; [6]Faculty of Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [7]Winnipeg Regional Health Authority, Winnipeg, MB, Canada.*

Background: Glucose-lowering treatment options are limited for uncontrolled type 2 diabetes mellitus (T2DM) patients with advanced chronic kidney disease (CKD).The present meta-analysis is aimed to assess the long-term glucose-lowering efficacy, safety and tolerability of dipeptidyl peptidase-4 (DPP-4) inhibitor agents compared with placebo or other anti-diabetic medications in patients with T2DM and CKD.

Methods: We searched MEDLINE, EMBASE and Cochrane CENTRAL (2005 through Dec 2013) for relevant abstract and publications. Studies were eligible if they were randomized controlled trials (RCTs) that compared a DPP-4 inhibitor with a placebo in patients with T2DM and CKD (estimated GFR < 60 ml/min or ESRD). Included studies had information on stage of chronic kidney disease (CKD), glycemic control by HbA1C measurement, dose and type of DPP-4 inhibitor, as well as duration of T2DM and other anti diabetes medication.

Results: We screened 3,244 abstracts for inclusion in our meta-analysis. Among 151 potentially relevant studies, 6 RCTs enrolling 1082 patients with a mean follow up of 54 weeks were included in the meta-analysis. Compared to placebo or active control, treatment with a DPP 4 inhibitor was associated with a -0.53 % change in HbA1C. Rates of adverse events including hypoglycemia, death or pancreatitis were similar in placebo and treatment groups.

Conclusions: In patients with Type 2 diabetes and CKD, treatment with DPP 4 inhibitors appears to be safe and effective. Longer term follow up including post marketing surveillance studies are needed to verify the safety of these medications in the CKD populations.

FR-PO788

Systematic Literature Review of Clinical Trials of Dipeptidyl Peptidase-4 Inhibitors in Patients with Type 2 Diabetes and Renal Impairment

Merlin C. Thomas,[1] Päivi M. Paldanius,[2] Rajeev Ayyagari,[3] Siew Hwa Ong,[2] Per-Henrik Groop.[4] *[1]Baker IDI Heart and Diabetes Inst, Melbourne, Australia; [2]Novartis Pharma AG, Basel, Switzerland; [3]Analysis Group Inc., Boston, MA; [4]Helsinki Univ Central Hospital, Helsinki, Finland.*

Background: DPP-4 inhibitors (DPP-4i) have demonstrated utility in patients (pts) with normal renal function. However, more information is required on efficacy and safety of DPP-4i in pts with moderate to severe renal impairment (RI). We performed a systematic literature review of long-term efficacy and safety of DPP-4i in T2DM pts with RI.

Methods: We searched EMBASE, MEDLINE and Cochrane Central Register of Controlled Trials, from database inception to Nov 2013, to identify randomised, placebo (PB)-controlled trials (CTs) of DPP-4i in T2DM pts with RI. Eligible trials were of ≥12 weeks' (wks) duration with ≥50 pts. Change in HbA1c and incidence of hypoglycemic events (HEs) were evaluated.

Results: Four PB CTs, of vildagliptin (Vilda), saxagliptin (Saxa), linagliptin (Lina) or sitagliptin (Sita), were included; the first two had 52-wk extensions. In Vilda, Saxa and Lina trials, 74–82% pts received insulin at baseline (BL), while 10% received insulin in PB CT with Sita. After 52 wks, Vilda, Saxa and Lina all significantly reduced HbA1c by 0.4–0.7% (BL 7.7–8.7%) compared to PB. HbA1c lowering was similar at 12 and 52 wks in these studies, implying sustainable effects in this setting. In a12-wk study, a significant HbA1c reduction of 0.4% (BL 7.7%) was observed in Sita-treated pts compared to PB. Vilda-treated pts reported a similar incidence of HEs compared to PB (23% versus 17%). Similarly, rate of HEs with Saxa was comparable to PB (28% versus 29%). Lina-treated pts reported a numerically higher rate of HEs compared to PB (63% versus 49%), possibly indicating an overall higher HE rate. However, between-treatment differences in HEs were not significant for any of these molecules. No adverse effects on renal function, fluid retention or weight were observed.

Conclusions: Many pts with T2DM have RI, which makes diabetes management complicated and costly. These studies suggest DPP-4i have the potential to improve glycemic control in this setting, without increased HEs or other adverse events.

FR-PO789

Efficacy of Dipeptidyl Peptidase-4 Inhibitors in Hemodialysis Patients with Type 2 Tomomi Ishikawa,[1] Michihiro Hosojima,[2] Ryohei Kaseda,[2] Hideyuki Kabasawa,[1] Shoji Kuwahara,[3] Noriaki Iino,[1] Yoshiki Suzuki,[4] Ichiei Narita,[1] Akihiko Saito.[3] *[1]Clinical Nephrology, Niigata Univ, Japan; [2]Clinical Nutrition Science, Niigata Univ, Japan; [3]Applied Molecular Medicine, Niigata Univ, Japan; [4]Health Administration Center, Niigata Univ, Japan.*

Background: Blood glucose profile of dialysis patients remains precisely unclear. Few studies reported about the efficacy and safety of dipeptidyl peptidase-4 (DPP-4) inhibitors in diabetic dialysis patients. Our aim of this study is to monitor blood glucose levels estimated by using continuous glucose monitoring (CGM) and clarify the effect of DPP-4 inhibitors in Japanese hemodialysis (HD) patients with type 2 diabetes.

Methods: Thirty diabetic and 17 non-diabetic patients on HD underwent CGM for 48-168 h. The following parameters were measured: 1) mean 24-h glucose levels, 2) standard deviation of glucose levels (SD), 3) mean amplitude of glycemic excursion (MAGE), 4) area over the curve (AOC) for glucose levels <70 mg/dL (AOC<70) for 24 h (8am to 8am) or night time (8pm to 8am) in HD days, and 5) AOC for glucose levels under the initial levels during HD for 4h (AOC<I).

Results: CGM-estimated blood glucose levels were decreased dramatically during HD in both diabetic and non-diabetic patients. Using DPP-4 inhibitors ameliorated this decrease in diabetic patients (AOC <I: 109.8 ± 64.5 h·mg/dl versus 175.4 ± 95.3 h·mg/dl in DPP-4 inhibitors group versus non-DPP-4 inhibitor group, respectively, $p<0.05$). Asymptomatic hypoglycemia was also recorded by CGM in several diabetic patients who did not use DPP-4 inhibitors. Using DPP-4 inhibitors lessened nocturnal hypoglycemia in HD days (AOC <70: 0.9 ± 3.9 versus 14.8 ± 33.1 h·mg/dl, DPP-4 inhibitor group versus non-DPP-4 inhibitor group, respectively, $p<0.05$). Furthermore, DPP-4 inhibitors also ameliorated glucose variability (SD and MAGE) in both HD and non-HD days.

Conclusions: Our CGM study showed great glucose variability and hypoglycemic events in HD patients. We propose that using DPP-4 inhibitors is promising therapy for lowering the glucose variability and hypoglycemic events in diabetic HD patients.

FR-PO790

Effect of DPP-4 Inhibition on the Progression of Renal and Cardiovascular Disease on Type-2 Diabetic Patients María Marques Vidas, Felipe E. Zalamea, Jeanette Nora Fernandez C., Sofia Karsten, Paula López, Maria Rosario Llopez Carratala, Esther Rubio Gonzales, Jose Portoles. *Nephrology, H Puerta de Hierro Majadahonda, Madrid, Spain.*

Background: The role of the dipeptidyl peptidase-4 (DPP-4) in modulating immunity and the interaction of this system with several mechanisms that control blood pressure has risen the possibility of the existence of pleiotropic effects of the DPP4-inhibitors (DPP4i) on the cardiovascular system and renal function beyond their effect on blood glucose control. The aim of this study was to test the effect of the treatment with DPP4i on the progression of renal and cardiovascular disease.

Methods: We retrospectively analyzed the cardiovascular and renal outcomes of type-2 diabetic patients that had been on DPP-4 i (DPP4i group, n 48), other oral antidiabetic drugs (OAD, n 21) or insulin (n 51). Patients with less than one year of stable treatment, MDRD-eGFR < 10 ml/min/1.73 m² and renal disease of non-diabetic origin were excluded. All patients were on maximum dose tolerated of RAAS blockers according local practice.

Results: The median follow-up was 3.55 ± 0.71 years and there were no significant differences on demographic data nor on time of diabetes-onset between groups. We found no significant modifications from baseline on serum creatinine in any treatment group. However, eGFR MDRD was significantly reduced on DPP4i (-15,3 %) and insulin (-10,7 %) groups with respect to OAD (24,8 %), *p< 0.05*. Urinary albumin/creatinine ratio increased along time in all the groups, but the increase average was lower on the DPP-4i group compared to OAD and insulin: 47% versus 85% versus 103%, *p ns*. There were no significant differences on cardiovascular outcomes between groups: 72,5% of the DPP-4i group, 84.6% of the OAD group and 72.9% of the insuline group were free from cardiovascular events. Total and LDL-cholesterol, uric acid and HbA1 levels showed no significant modifications in any group.

Conclusions: We conclude that treatment with DPP-4i showed a beneficial effect on the progression of albuminuria on type-2 diabetic patients independently of glycemic control. The possible RAAS-blockade-like effect of these drugs on systemic and glomerular hemodynamics needs to be further elucidated.

FR-PO791

Efficacy and Safety of Liraglutide versus Placebo by Age Subgroup in Subjects with Type 2 Diabetes and Moderate Renal Impairment (LIRA-RENAL): A Randomized Trial David Scott,[1] Guillermo Umpierrez,[2] Stephen Atkin,[3] Stephen Bain,[4] Peter Rossing,[5] Minara Shamkhalova,[6] Heidrun Bosch-Traberg,[7] Annika Syrèn,[7] Melanie Davies.[8] *[1]Diabetes, Clinical Research Development Associates, New York, NY; [2]Emory Univ, Atlanta, GA; [3]Weill Cornell Medical College Qatar, Doha, Qatar; [4]Inst of Life Science, Swansea Univ, Swansea, United Kingdom; [5]Steno Diabetes Center, Gentofte, Denmark; [6]Endocrinology Research Centre, Moscow, Russian Federation; [7]Novo Nordisk A/S, Søborg, Denmark; [8]Univ of Leicester, Leicester, United Kingdom.*

Background: To determine the effects of adding liraglutide 1.8 mg (lira) or placebo (PBO) to existing oral antidiabetic agents and/or insulin therapy to subjects with moderate renal impairment (eGFR 30-59 mL/min/1.73 m²; MDRD), we evaluated age-dependency (18-64; 65-74; ≥75 yr) on selected efficacy and safety parameters.

Methods: In this 26-week, placebo-controlled, double-blind trial, adults with T2DM and moderate renal impairment, BMI of 20-45 kg/m², HbA_{1c} of 7.0-10.0% and on stable diabetes medication were randomized 1:1 to receive either once-daily lira or PBO. The primary endpoint was HbA_{1c} change from baseline (BL) to Week 26.

Results: 277 subjects were exposed to lira or PBO and included in the analysis. Lira demonstrated a significant reduction in HbA_{1c} across all age subgroups compared to PBO (Table). More GI AEs (mostly nausea and vomiting) were reported in all lira age subgroups compared to PBO. No pattern for hypoglycemic events was noted by age subgroup. No differences were seen in either systolic (p=0.2511) nor diastolic (p=0.8907) blood pressure between lira and PBO for the trial population.

Conclusions: In subjects with T2DM and moderate renal impairment, lira showed superior HbA_{1c} reduction across all age subgroups compared to PBO. Overall, there was no difference in the safety profile of lira between age subgroups over 26 weeks.

Age Subgroup	18-64 yr		65-74 yr		≥75 yr	
Treatment Group	Lira n=38	PBO n=55	Lira n=72	PBO n=66	Lira n=30	PBO n=16

Patiromer Lowers Serum K^+ and Prevents Recurrent Hyperkalemia in Patients with Diabetes and CKD on RAAS Inhibitors: Subgroup Results of a Phase 3 Trial Matthew R. Weir,[1] George L. Bakris,[2] David A. Bushinsky,[3] Martha Mayo,[4] Dahlia Garza,[4] Yuri Stasiv,[4] Yingxin Hou,[5] Heidi Christ-Schmidt,[5] Lance Berman.[4] *[1]Univ of Maryland, Baltimore, MD; [2]Univ of Chicago, Chicago, IL; [3]Univ of Rochester, Rochester, NY; [4]Relypsa, Redwood City, CA; [5]Statistics Collaborative, Washington, DC.*

Background: RAAS inhibitors (RAASi) have proven cardiorenal benefits in patients (pts) with CKD and Type 2 diabetes (T2DM), yet hyperkalemia (HK) often limits RAASi therapy. Patiromer, a nonabsorbed polymer with high K^+-binding capacity and good GI tolerability, normalized serum K^+ ($s\text{-}K^+$) and prevented HK recurrence in a large study in CKD pts with HK on RAASi. Here we present results in pts with T2DM.

Methods: Pts with BL $s\text{-}K^+$ 5.1 to <6.5 mEq/L received patiromer (4.2 or 8.4 g BID to start) in a 4-wk Initial Treatment Phase; pts with BL $s\text{-}K^+$ 5.5 to <6.5 mEq/L were eligible to continue into an 8-wk placebo (PBO)-controlled Randomized Withdrawal Phase. Primary and secondary endpoints, respectively, were: change in $s\text{-}K^+$ from BL to Wk 4 and % of pts with $s\text{-}K^+$ within target at Wk 4 [Initial Treatment Phase]; between-group difference in $s\text{-}K^+$ change over the 1st 4 wk of the phase and % of pts with recurrent HK [Randomized Withdrawal Phase].

Results: Of pts treated in the 1st and 2nd phases, respectively, 57% and 63% had T2DM. Consistent with overall results, primary endpoints were significant for pts with T2DM (Table).

Table. Primary Endpoint Results in Both Study Phases			
Primary Endpoint Results in the Initial Treatment Phase			
Population	Mean ± SE Baseline Serum K^+, mEq/L		Mean Change ± SE in Serum K^+ (95% CI), mEq/L [p value]
Overall (n=237)	5.58 ± 0.03		-1.01 ± 0.03 (-1.07, -0.95) [p < 0.001]
Diabetes (n=138)	5.61 ± 0.05		-1.00 mEq/L ± 0.04 [p < 0.001]
Primary Endpoint Results in the Randomized Withdrawal Phase			
Population	Median Change (25th, 75th Percentile) in Serum K^+ from Baseline to Week 4 of Phase, mEq/L		Between-Group Difference in Median Change in Serum K^+ (95% CI), mEq/L [p value]
	Placebo	Patiromer	
Overall (n=107)	0.72 (0.22, 1.22)	0.00 (-0.30, 0.30)	0.72 (0.46, 0.99) [p < 0.001]
Diabetes (n=67)	0.69 (0.19, 1.29)	0.03 (-0.20, 0.30)	0.66 (0.28, 1.03) [p < 0.001]

Overall and in pts with T2DM, >75% of pts had normalized s-K^+, and significantly ($p<0.001$) more PBO pts developed recurrent HK. Overall, patiromer was well tolerated; mild-to-moderate GI symptoms were the most common AEs. Rates of other AEs with patiromer were similar to, or lower than, PBO.

Conclusions: After controlling s-K^+, patiromer significantly decreased HK recurrence compared to PBO in CKD pts with T2DM on RAASi, with a tolerability profile that may allow continuous management of s-K^+ in these pts.

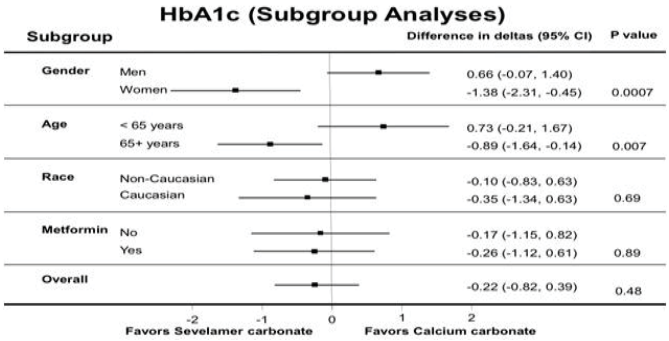
Sevelamer Carbonate Reduced Advanced Glycation Endproducts, Inflammation, and Glycated Hemoglobin in a Randomized Controlled Trial of Patients with Diabetic Kidney Disease

Nikolas B. Harbord,[1] Jaime Uribarri,[2] Elena M. Yubero-Serrano,[3] Mark Woodward,[4] Agustin Busta,[1] Leonid Poretsky,[1] Helen Vlassara,[2] Gary E. Striker.[2] *[1]Mount Sinai Beth Israel, New York, NY; [2]Mount Sinai Hospital, New York, NY; [3]Lipid & Atherosclerosis Research Unit, IMIBIC/Reina Sofia Univ Hospital/Univ of Cordoba, Cordoba, Spain; [4]The George Inst for Global Health, Camperdown, NSW, Australia.*

Background: Oxidative stress and inflammation (OS/Infl) underlie the complications of diabetics with kidney disease (DKD). Glycated hemoglobin (HbA1c) is a therapeutic target and correlates with progression of DKD. Dietary advanced glycation endproducts (AGEs) contribute to OS/infl, and sevelamer carbonate (SC) can bind and prevent their absorption. In a cross-over trial, we demonstrated reduction of AGEs, HbA1c, and OS/Infl with SC in DKD. This study further examined these effects in a larger DKD population.

Methods: In a two center, randomized, intention to treat, open label study, we enrolled 117 subjects with stage 2-4 DKD, HbA1c >6.5% and ACR >200mg/g to either SC (1600mg TID with meals) or CaCarbonate (1200mg TID with meals). Treatment continued for 6 months without changes to medications or diet.

Results: AGE intake did not change. SC reduced serum and cellular AGEs (MG and CML, p=<0.001-0.002), pro-inflammatory TNFR1 (p=0.04) and RAGE (p=0.0004); and increased anti-inflammatory adiponectin (p=0.01) and Nrf2 (p=0.0003), AGER1 (p=0.003) and SIRT1 (p<0.06) (trend). SC did not lower HbA1c in the overall population, but in women (p=0.0007) and subjects >65 years of age (p=0.007). Neither concomitant Metformin use nor race affected HbA1c response to SC.



Conclusions: SC reduces AGEs and inflammation in patients with DKD, and improves HbA1c in women and older patients. Our finding of different metabolic response among diabetic women and older patients with DKD to lowering of AGEs and OS/Infl deserves further investigation.

Alterations in a Panel of Serum Biomarkers Precede the Development of Microalbuminuria (MA) in Patients with Diabetes Mellitus Type II

Christos D. Chatzikyrkou,[1] Luis M. Ruilope,[5] Ton J. Rabelink,[3] Lars C. Rump,[6] Hermann G. Haller,[1] Jan Menne.[1] *[1]Hannover Medical School; [2]Dept of Nephrology and Hypertension, Leiden Univ Medical Center Leiden, The Netherlands;; [4]5Div of Hypertension, Univ Autonome, Madrid, Spain;; [5]Univ Hospital, Dusseldorf, Germany.*

Background: The aim of the study was to investigate if specific serum biomarkers indicative of vascular inflammation and endothelial dysfunction can predict the development of microalbuminuria in patients with diabetes mellitus type II.

Methods: Data from the ROADMAP study were used. 65 patients developed microalbuminuria after first sampling. A control group of 86 patients was generated by matching for age, sex, BMI, HbA1c, duration of diabetes, baseline urinary albumin creatinine ratio (UACR), baseline GFR, systolic blood pressure and LDL. The proinflammatory biomarkers sTNFR-I, sTNFR-II, ST2 (IL-33 receptor), VAP-1 (vascular adhesion protein-1), CXCL-16, S100A8 (calgranulin A) and Galectin-3, the anti-inflammatory mediators C1qR1 (receptor of C1q) Thrombomodulin, the endothelial stress marker Copeptin and the collagen degradation product Endostatin, were compared in baseline samples of cases and controls. Results of the univariate analysis are presented here.

Results: sTNFR1, S100A8, VAP-1, CXCL-16, Galectin-3 and Endostatin did not differ between future MA patients and controls. sTNFR-II and soluble ST2 were significantly increased in versus 1569±66 patients with future microalbuminuria (3183±145, versus 2858±90 pg/ml; p =0.047 and 14450±800 versus 12464±568 pg/ml; p=0.039). C1qR was significantly reduced in patients with future microalbuminuria (34±2.1 versus 28±2.0 ng/ml; p=0.047). Thrombomodulin and Copeptin were significantly increased in patients with future MA (4415±161 versus 4067±96 pg/ml;p=0.054 and 15±1,1 versus 11±0.48 pg/ml; p=0.003). Especially the results for copeptin were highly significant.

Conclusions: The alterations of serum inflammatory and endothelial stress markers prior to the development of microalbuminuria in patients with diabetes type II, adds to the evidence supporting its significance as a biomarker reflecting vascular inflammation and early vascular damage.

FR-PO795

A Predictive Model for All-Cause Mortality among Older Adults with Chronic Kidney Disease

Ronit Katz,[1] Nisha Bansal,[1] Ian H. de Boer,[1] Carmen A. Peralta,[2] David Siscovick,[1] Dena E. Rifkin,[3] Tamara Harris,[7] Stephen Kritchevsky,[5] Mark J. Sarnak,[4] Michael Shlipak,[2] Joachim H. Ix.[3] *[1]U Washington; [2]UCSF; [3]UCSD; [4]Tufts; [5]WFMC; [6]NIA.*

Background: Chronic kidney disease (CKD) is associated with increased mortality. Accurate prediction tools for mortality prior to ESRD may guide clinical decision making, particularly among elderly persons with CKD.

Methods: We developed a prediction equation for 5-year risk of death among participants with CKD in the Cardiovascular Health Study. Twenty-two candidate predictor variables were explored which included demographics, physical examination measures, comorbidity, medication use, kidney function (estimated glomerular filtration rate [eGFR] calculated from serum creatinine and the CKD-EPI equation; urine albumin to creatinine ratio [ACR]) and novel biomarkers (C-reactive protein, fibroblast growth factor-23, and cystatin C). Models were developed using Cox regression and evaluated using C statistics and net reclassification improvement (NRI). A final parsimonious model was externally validated in an independent cohort of community-living elders, the Health Aging, and Body Composition Study.

Results: The development cohort included 828 participants who had a mean age of 80 (±5.6) years, eGFR of 47 (±11) ml/min/1.73 m^2 and median ACR was 13 [IQR 6,51] mg/g. The best model for 5-year risk of death included age, gender, race, eGFR, urine ACR, systolic blood pressure, smoking, diabetes mellitus, heart failure, and stroke (C-statistic 0.73 p<0.0001) (**Table**). Addition of weight change, self-reported health or novel biomarkers did not significantly improve NRI. The model performed well in external validation (C-statistic 0.69).

Conclusions: A simple prediction tool using 10 readily available clinical variables can assist in predicting 5-year risk of death in elderly CKD patients, which may be useful in counseling patients and clinical decision making.

Table. Final multivariable model for 5 year risk of mortality for participants with CKD in CHS		
	Estimated β	HR (95% CI)
Age (per 5 years older)	0.427	1.53 (1.38, 1.70)
Male	0.275	1.32 (1.04, 1.68)
Black	-0.313	0.73 (0.52, 1.03)
eGFR-Cr (per SD= 11 lower)	0.104	1.11 (0.99, 1.25)
UACR (per doubling)	0.143	1.15 (1.09, 1.22)
SBP		
<110		1.00
110 – 139	-0.177	0.84 (0.55, 1.27)
≥ 140	-0.271	0.76 (0.50, 1.17)
Diabetes	0.303	1.35 (1.02, 1.80)
Current smoker	0.515	1.67 (1.08, 2.59)
Prevalent CHF	0.881	2.41 (1.86, 3.14)
Prevalent Stroke	0.297	1.35 (0.96, 1.88)
CHS equation: 5-year mortality risk prediction equation: $1-0.8637529^{\exp(\beta \cdot x - 5.4387275)}$ where β is the regression coefficient and x is the level for each risk factor.		

FR-PO796

Modelling Progression of Chronic Kidney Disease in the Irish Health System Using State Transition Probabilities Austin G. Stack,[1,2] Mohamed Elsayed,[1,2] Waleed Mohammed,[1,2] Ailish Hannigan,[2] John P. Ferguson.[2] *[1]Nephrology, Univ Hospital Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Limerick, Ireland.*

Background: Knowledge of transition probabilities from one stage of Chronic Kidney Disease (CKD) to another may be useful in deciding how to treat and monitor patients with CKD. We determined 1-year transition probabilities for patients with CKD in the Irish health system.

Methods: Demographic and laboratory data were provided from a regional laboratory database and merged with a patient information system between 2005 and 2011 (n=174,786). CKD stage for each patient was defined by median eGFR for each calendar year. Estimated glomerular filtration rates (eGFR) were determined using the CKD-EPI equations from standardised serum creatinine values, excluding episodes of acute kidney injury (AKI). Transition probabilities between CKD stages were defined as the number of patients classified as stage i in the previous year, and stage (i+1) in the current year, divided by total number of patients classified as stage i in the previous year and remained in the health system in the current year. Discrete multistate models determined transition rates across stages by demographic group and AKI presence.

Results: The multistate model found that age, gender and occurrence of AKI influenced progression to a worse stage of CKD. While the probability of transitioning from Stage 2 to Stage 3 and Stage 3 to Stage 4 CKD increased with age, the transition probability from Stage 4 to Stage 5 showed the converse

	Odds Ratios (95% Confidence Intervals) for CKD Progression in the Irish Health System				
CKD Stage Transition	# in Start Stage	# Transitions	Women (vs men)	Age (per 5 yrs)	AKI (vs no AKI)
1->2	91, 569	15, 618	1.00 (0.97-1.04)	1.35 (1.34-1.36)	1.36 (1.21-1.51)
2->3	109, 087	8, 318	1.14 (1.09-1.19)	1.41 (1.40-1.43)	2.65 (2.140-2.91)
3->4	32, 257	1,249	0.99 (0.88-1.11)	1.19 (1.15-1.23)	2.66 (2.30-3.07)
4->5	2, 733	195	0.65 (0.48-0.88)	0.88 (0.84-0.92)	1.75 (1.29 (2.37)

Conclusions: State transition models that model progression of CKD have the potential to identify patient groups with the greatest risk of disease progression and for whom intensive monitoring and treatment is required.

Advanced Chronic Kidney Disease Is a Strong Risk Factor for *Clostridium difficile* Infection Sun Chul Kim, Hyojeong Chang, Myung-Gyu Kim, Sang-Kyung Jo, Won-Yong Cho. *Div of Nephrology, Dept of Internal Medicine, Korea Univ Anam Hospital.*

Background: It has been suggested that chronic kidney disease (CKD) is a risk factor for *Clostridium difficile* infection (CDI) and is associated with increased mortality among patients infected with *C. difficile*. However, recent studies about the clinical impact of CKD on CDI in Asian countries are still controversial.

Methods: This was a single-center, retrospective case-control study. A total of 171 patients with CDI were included as cases and 342 age- and sex-matched patients without CDI were used as controls. We compared the prevalence of CKD in the study sample and identified independent risk factors that could predict the development and prognosis of CDI.

Results: Patients with CDI had a higher prevalence of ICU admission, CKD, use of any antibiotics, and gastric acid reducing drug use. The prevalence of ESRD requiring dialysis and pre-dialysis CKD stage 4, 5 was significantly higher among CDI patients than among patients without CDI. Patients with CDI had a significantly longer length of hospital stay and increased in-hospital mortality than patients without CDI. In a binary logistic regression model to identify the risk factors associated with CDI, predialysis stage 4, 5 CKD (OR, 2.87; $p = 0.039$), ESRD requiring dialysis (OR, 4.00; $p = 0.001$), ICU admission (OR, 2.54; $p < 0.001$), and use of any antibiotics (OR, 4.31; $p < 0.001$) were shown to be independent risk factors for CDI. The previous use of 2 or more antibiotics (OR, 4.48; $p = 0.007$) or vancomycin (OR, 5.02; $p = 0.060$), the presence of PMC (OR, 4.34; $p = 0.003$), and more advanced CKD (OR, 3.76; $p = 0.013$) were independent risk factors for treatment resistance to initial metronidazole therapy.

Conclusions: Advanced CKD is an independent risk factor for CDI and associated with higher in-hospital mortality and poor treatment response in CDI patients. Therefore in CKD patients, careful attention should be paid to the occurrence of CDI and its management in order to improve the outcome of CDI.

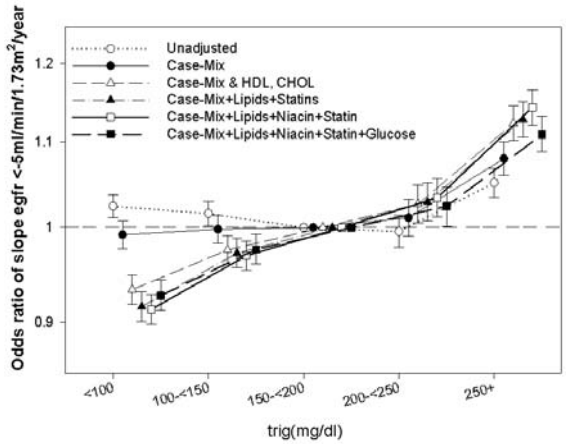
FR-PO798

Association of Baseline Triglyceride Levels with Progression of Chronic Kidney Disease in over 2 Million U.S. Veterans Elani Streja,[1] Kamyar Kalantar-Zadeh,[1] Hamid Moradi,[1] Miklos Zsolt Molnar,[2] Jun Ling Lu,[2] Csaba P. Kovesdy.[2] *[1]Harold Simmons UC Irvine MC, Orange, CA; [2]Memphis VAMC, Memphis, TN.*

Background: It has been suggested that elevated lipoproteins can contribute to deterioration of kidney function. The association of serum triglyceride levels with development of chronic kidney disease (CKD) is unclear.

Methods: In a cohort of 2.6 million U.S. veterans with normal baseline eGFR in 2005-2006 we examined the association of baseline triglyceride with slopes of eGFR over median follow up of 8.0 years (6.8, 8.4). Triglyceride (mg/dL) levels were categorized into five groups (<100, 100-<150, 150-<200, 200-<250, 250+). Associations were examined in crude and adjusted logistic regression models (for slopes <-5ml/min/1.73m^2/year), with adjustments for demographics, comorbidities including diabetes, HDL, total cholesterol, glucose and use of niacin and statins.

Results: Patients were 61±13 years old, 6% female, 16% African-American, and 26% diabetic with a mean baseline eGFR 83±13 mL/min/1.73m^2. In the total cohort, 8.9% of patients had a slope <-5 mL/min/1.73m^2/year. Higher triglycerides were linearly associated with rapid decline of kidney function independent of confounders.



Conclusions: Baseline triglyceride levels are linearly associated with faster progression of CKD. Studies evaluating the effect of treatment of hypertriglyceridemia on progression of CKD are warranted.

Funding: NIDDK Support

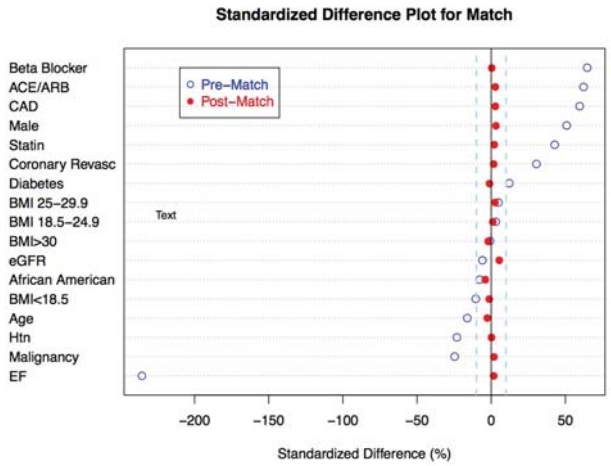
FR-PO799

Implantable Cardioverter-Defibrillators (ICD) and Mortality in Patients with Chronic Kidney Disease (CKD) Georges Nakhoul, Jesse D. Schold, Susana Arrigain, Serge Harb, Joseph V. Nally, Sankar D. Navaneethan. *Hypertension and Nephrology, Glickman Urological and Kidney Inst, Cleveland, OH.*

Background: CKD is associated with increased cardiovascular mortality, particularly from sudden cardiac death (SCD). The benefit of ICDs in prevention of SCD among the general population is proven. However, major clinical trials excluded patients with advanced CKD and thus the benefit of ICD remains unclear in this population.

Methods: We conducted a propensity-matched analysis using our pre-existing Electronic Health Record (EHR)-based CKD registry. We developed a propensity score of the likelihood of having an ICD with the following variables: age, gender, race, hypertension, diabetes, eGFR, ejection fraction, coronary artery disease, revascularization, BMI, malignancy, ACE/ARB, statin, and beta blocker. We used one-to-one greedy matching with 0.1 caliper width to match patients with ICD to those without. We used a Kaplan-Meier curve and Cox proportional hazards model to examine the survival of matched patients with and without ICD.

Results: 1,770 patients with ICD and 9,477 potential controls (CKD patients without ICD) had ECHO data.



We were able to match 983/1770 (56%) ICD patients to the control group with 1015 (51.6%) patients having eGFR of 45-59 ml/min/1.73 m^2 and 951 (48.4%) with eGFR < 45 ml/min/1.73 m^2. Kaplan-Meier survival estimates at 2 years were 80% (95% CI: 77, 82) for ICD and 69% (95% CI: 66, 72) for the control group. After adjusting for covariates

including albumin and hemoglobin, the hazards of mortality among propensity matched patients for the ICD group compared with the non ICD group was 0.78 (0.68, 0.90). There was no difference in the risk for death based on stage of kidney disease.

Conclusions: ICD therapy is associated with a survival benefit in patients with non-dialysis dependent CKD, similar to the reports in general population.

Funding: Pharmaceutical Company Support - Development of CCF CKD registry was supported by an unrestricted educational grant to the Department of Nephrology and Hypertension from Amgen

FR-PO800

Acidemia Is Associated with Decreased Physical Capacity and Activity Levels in Patients with Chronic Kidney Disease

Matthew P.M. Graham-Brown,[1] Darren Robert Churchward,[1,2] Amy L. Clarke,[1,2] Katherine Leigh Hull,[1,2] James O. Burton,[1,2] Alice C. Smith.[1,2] *[1]Leicester Kidney Exercise Team, John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom; [2]Dept of Infection, Immunity and Inflammation, Univ of Leicester, Leicester, United Kingdom.*

Background: Metabolic acidosis is often a feature of chronic kidney disease (CKD) and is integral to the pathogenesis of skeletal muscle wasting and protein catabolism, which is associated with increased morbidity and mortality. Exercise has been suggested as a way of mitigating skeletal muscle wasting but there is little data on the effects of acidosis on physical capacity and activity levels in CKD.

Methods: 916 patients with CKD not on dialysis completed Duke Activity Status Index (DASI) and Leisure Time Exercise Questionnaire (LTEQ) to assess functional capacity and activity levels respectively. Responses were correlated with haematological and biochemical data and co-morbid diseases. 49 patients were found to have venous bicarbonate <21mmol/L, and a group of 49 patients matched for age and eGFR with venous bicarbonate >21mmol/L were selected without knowing DASI or LTEQ scores.

Results: Groups were well matched for age, sex, haemoglobin, albumin, eGFR and medical co-morbidity, with no statistically significant differences between groups. Mean DASI for the group bicarb<21 was 26.4 versus 35.2 for the group with bicarb>21 (p=0.006) and median LTEQ for the group bicarb<21 was 3 versus 18 for the group with bicarb>21 (p<0.001). Using Spearman's correlation LTEQ versus bicarb: rho=0.312 (p=0.002) and DASI versus bicarb: rho=0.209 (p=0.039).

Conclusions: Our results suggest that patients with CKD and acidaemia have significantly decreased activity and functional capacity compared to patients with normal acid base balance. Whilst correction of acidemia with enteral sodium bicarbonate may improve muscle protein wasting and inflammation, exercise training is also a potentially beneficial, underused, intervention. More research is needed to define the effects of acidosis on muscle function, the effects of exercise on acidosis, and how correcting acidosis may improve exercise tolerance and quality of life.

Prevalence, Predictors and Outcomes of Pulmonary Hypertension in Chronic Kidney Disease: A Report from the Chronic Renal Insufficiency Cohort (CRIC) Study

Sankar D. Navaneethan,[1] Jason Roy,[2] Kelvin Tao,[2] Carolyn S. Brecklin,[3] Jing Chen,[4] Rajat Deo,[2] John M. Flack,[5] Akinlolu O. Ojo,[6] Ted J. Plappert,[2] Dominic S. Raj,[7] Ghulam Saydain,[5] James H. Sondheimer,[5] Susan P. Steigerwalt,[8] Raymond R. Townsend,[2] Raed A. Dweik,[1] Mahboob Rahman.[9] *[1]Cleveland Clinic; [2]Univ of Pennsylvania; [3]Univ of Illinois Chicago; [4]Tulane Univ; [5]Wayne State Univ; [6]Univ of Michigan; [7]George Washington Univ; [8]Henry Ford Hospital; [9]CWRU.*

Background: Pulmonary hypertension (PH) is generally associated with poor outcomes; however, the impact of PH in chronic kidney disease (CKD) is unknown. We evaluated the prevalence and predictors of PH and its impact on long term clinical outcomes in non-dialysis dependent CKD.

Methods: CRIC participants who had echocardiography at year 1 of the study were studied. PH was defined as estimated pulmonary artery pressure (PAP) >35 mm Hg and/or tricuspid regurgitant velocity (TRV) >2.5 m/sec. The risk factors for PH were examined using logistic regression, and its associations with cardiovascular events (adjudicated hospitalized heart failure, myocardial infarction and stroke), renal events (50% decline in eGFR and ESRD) and death were examined using Cox-proportional hazard models. We also examined these associations by considering PAP and TRV as continuous measures.

Results: Out of 2959 patients, 21% (n=623) had PH. Old age, non-hispanic blacks, lower eGFR and higher proteinuria were associated with higher risk for PH in CKD. After covariate adjustment, presence of PH, elevated PAP and TRV were associated with an increased risk for death, cardiovascular and renal events.

	All-cause mortality * (n=497)	Cardiovascular events * (n=575)	Renal events * (n=705)
	Hazard Ratio (95% CI)		
PH present	**1.38 (1.09, 1.74)**	1.11 (0.89, 1.39)	1.13 (0.92, 1.40)
PAP (each SD increase)	1.11 (0.96, 1.28)	**1.21 (1.04, 1.39)**	1.13 (0.98, 1.31)
TRV each SD increase	**1.16 (1.02, 1.32)**	**1.21 (1.06, 1.38)**	**1.14 (1.00, 1.29)**

PH: Pulmonary hypertension; PAP- Pulmonary artery pressure; TRV- tricuspid regurgitant velocity; SD- standard deviation

* Adjusted for demographics, smoking, diabetes, hypertension, previous cardiovascular disease, COPD, BMI, albumin, hemoglobin, LDL cholesterol, use of RAS blockers, diuretics, statins, beta-blockers. LVEF, diastolic dysfunction, EGFR, and proteinuria

Conclusions: This cohort of CKD patients had a higher prevalence of PH (PAP>35 mm Hg and/or (TRV) >2.5 m/sec) than that reported in the general population. Further, PH indices were independently associated with death, cardiovascular and renal events in CKD patients.

FR-PO802

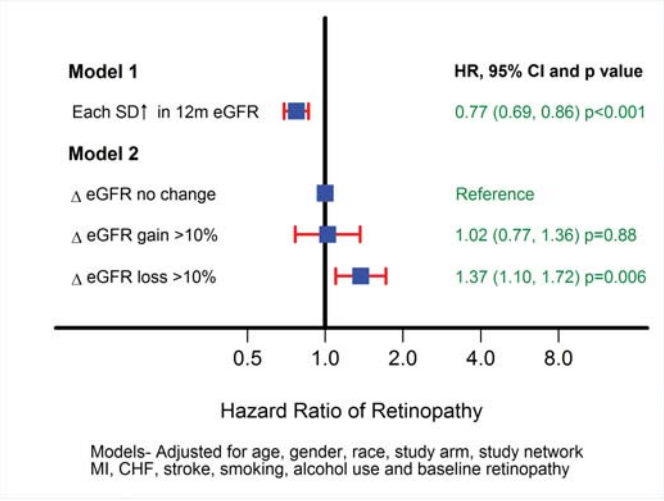
Early GFR Decline as a Predictor of Diabetic Retinopathy in Non-CKD

Srini Beddhu,[1,2] G. Wei,[2] E. Constantz,[2] Ajay Giri,[2] R. Boucher,[2] Molly B. Conroy,[3] Xiaorui Chen,[2] Debra Lynn Simmons,[2] Jane J. Lee,[3] Tom Greene.[2] *[1]VAMC SLC; [2]Univ of Utah; [3]Univ of Pitt.*

Background: Early GFR decline in the non-CKD diabetic population might reflect systemic microvascular disease and hence, predict progression of diabetic retinopathy.

Methods: We examined this hypothesis in a secondary analysis of the ACCORD study (a RCT conducted by NHLBI to examine the effects of glycemic control, BP control and fibrates on CV outcomes in type 2 DM). The cohort for this analysis consisted of those with a). baseline and 12< CKD-EPI eGFR b). 12M eGFR ≥ 60ml/min1.73m^2. Based on the baseline and 12M eGFR, DeGFR groups (no change: -10% to +10%, >10% loss: DeGFR <-10% and >10% gain: DeGFR>+10%) were defined. Separate Cox regression models were used to relate DeGFR gropus and 12M eGFR with subsequent incident retinopathy (laser Rx or vitrectomy) events.

Results: 7574 diabetics without CKD at 12M were included. The mean age was 62.8±6.2 yrs, 62.6% were men, 61.9% were Caucasian. The mean ± SD 12M eGFR was 86.3±14.2ml/min/1.73m^2. The mean DeGFR in the no change, DeGFR loss and DeGFR gain groups were -1.2±3.8, -17.7±7.5, 15.7±7.8ml/min/1.73m^2, respectively. There were 396 retinopathy events over 27495 patient-yrs of follow-up.



Each SD ↑ in 12M eGFR was strongly associated with lower hazard of retinopathy events (Fig). Compared to the group DeGFR no change group, DeGFR loss >10% group had higher hazard of retinopathy (Fig). DeGFR and 12M eGFR were strongly correlated (r=0.53, p<0.001) and when both were included in the same model, neither had significant association with subsequent retinopathy.

Conclusions: Both current eGFR and decline in eGFR in the past 12 m predict subsequent retinopathy in diabetic non-CKD population. Early decline in eGFR in the non-CKD diabetic patients might be a marker of systemic microvascular disease.

FR-PO803

Illness Perceptions, Medication Beliefs and Adherence in CKD Patients with Comorbid HIV Ioannis Konstantinidis, Jeffrey Weiss, Christina M. Wyatt. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: CKD is often accompanied by complex comorbidities that impose a significant medical and adherence burden. Patients often prioritize such conditions over CKD, but data on adherence in this setting are limited. We aimed to assess perceptions about CKD and HIV and to investigate the relationship between illness perceptions, medication beliefs, and medication adherence in patients with both CKD and HIV.

Methods: Inclusion criteria were CKD on medications to delay CKD progression or manage complications, HIV-positive on antiretroviral therapy, and planning to continue current therapy for ≥3 months. Patients on hepatitis C therapy were excluded. Participants reported adherence for each prescribed medication with a Visual Analog Scale and completed the Illness Perception Questionnaire-Revised and the Beliefs About Medicines Questionnaire for both CKD and HIV.

Results: Among 32 eligible participants, mean age was 53±8 yrs, 53% were male, and 66% were non-Hispanic black. Mean education was 12±2 yrs. Participants were prescribed a mean of 11±2 medications. Most were CKD Stage 3-5 (88%), all had undetectable HIV viral load, and mean CD4 cell count was 603±244. Patients were diagnosed with HIV (16.4 yrs) and treated for HIV (12.3 yrs) significantly longer than for CKD (5.7 and 4.2 yrs, respectively) [all p <0.001]. 56% considered CKD their primary health concern compared to 22% for HIV. Greater than 95% adherence was reported by 78%, 72% and 66% of patients for CKD, HIV, and both CKD and HIV medications, respectively. There was a trend for patients to experience more personal control over HIV than CKD (p=0.06), have more concerns about HIV medications (p=0.07), and view them as more necessary than for those for CKD (p=0.06).

Conclusions: In these patients with well-controlled HIV, CKD is a dominant health concern. Despite a perception of less personal control over CKD, self-reported adherence to CKD and HIV medications was similar. Ongoing data collection will evaluate adherence to one CKD and one HIV medication with Medication Event Monitoring System and pill counts to better elucidate the relationship between illness perceptions, medication beliefs, and adherence.

FR-PO804

Endothelial Ischaemia Reperfusion Injury Is Not Increased in Chronic Kidney Disease Kristin Vibeke Veighey,[1,2] Nichola Hawkins,[2] David C. Wheeler,[1] Raymond Macallister.[2] *[1]Centre for Nephrology, Univ College London, London, United Kingdom; [2]Centre for Clinical Pharmacology and Therapeutics, Univ College London, London, United Kingdom.*

Background: Arterial endothelial function in humans declines with advancing CKD. We have previously demonstrated a reduction in brachial artery flow mediated dilatation (FMD) following experimental IR injury in healthy volunteers. We therefore postulated that FMD would decrease and IR injury would increase with declining GFR in CKD patients.

Methods: 47 healthy volunteers (mean age 36±5) and 11 CKD patients (mean age 38±11) underwent FMD measurements before and after IR injury, induced by 20min upper arm cuff inflation to 200mmHg followed by 20min cuff deflation. Patients had CKD 4-5 but had not commenced RRT (mean eGFR 17±8), and had no known cardiovascular disease/ diabetes. All vasoactive medications (e.g beta blockers, ACE/ARBs, nitrates, nicorandil) were withheld for at least 24 hours prior to the study.

Results: There was no significant difference between mean baseline FMD in the healthy cohort compared with the CKD cohort (11.27±1.2 versus 9.75±0.8, p=0.33). There was a statistically significant correlation between decreasing eGFR and decreasing FMD (R^2=0.39 p=0.04). In healthy volunteers, there was a statistically significant decrease in FMD following IR injury (9.80±5.36 versus 5.35±0.60, p<0.0001). In CKD patients however, there was no difference (11.27±1.20 versus 10.62±1.83, p=0.64). The mean % reduction in FMD in CKD patients was significantly less than in the healthy cohort (5.23±15.91% versus 31.54±5.48%, p=0.04). Matching age, sex and BP made no difference to this observation (CKD - 11.04±3.39 versus 10.43±5.01 p=0.76, healthy - 10.30±5.19 versus 7.07±4.46 p=0.003, n=7). Cholesterol, glucose, calcium and phosphate were not significantly different between the two groups.

Conclusions: Although a reduced GFR is associated with decreased FMD, there was no corresponding increase in IR injury. This may be attributable to the effects of vasoactive medications which may protect against endothelial injury in these patients. This may also account for the failure to translate animal IR studies to patients.

FR-PO805

Placental Growth Factor as a Predictor of Cardiovascular Events in Patients with Chronic Kidney Disease from the Novel Assessment of Risk Management for Atherosclerotic Diseases in Chronic Kidney Disease (NARA-CKD) Study Masaru Matsui, Shiro Uemura, Yukiji Takeda, Katsuhiko Morimoto, Ken-Ichi Samejima, Yasuhiro Akai, Yoshihiko Saito. *First Dept of Internal Medicine, Nara Medical Univ, Kashihara, Japan.*

Background: Chronic kidney disease (CKD), of which prevalence is increasing in aged society, is a strong risk for cardiovascular events, but the risk stratification has not been well established. Placental growth factor (PlGF) plays a critical role in atherogenesis through vascular inflammation and destabilization of plaques. Whether circulating levels of PlGF are associated with mortality and cardiovascular disease in CKD is unknown.

Methods: A prospective cohort study of 1351 consecutive participants with chronic kidney disease who were enrolled in the Novel Assessment of Risk management for Atherosclerotic diseases in Chronic Kidney Disease (NARA-CKD) study between April 1, 2004 and December 31, 2011, aimed to determine the impact of PlGF on all-cause mortality and cardiovascular events in patients with CKD.

Results: During a median follow-up of 3 years, 199 participants died and 383 had cardiovascular events, defined as atherosclerotic disease or heart failure requiring hospitalization. In the adjusted analyses, mortality and cardiovascular risk were higher in each successive quartile of PlGF; hazard ratios (HRs) [95% confidence intervals (95% CIs)] were 1.59 [0.83–3.16] and 1.55 [0.92–2.66] for the second quartile, 2.97 [1.67–5.59] and 3.39 [2.20–5.41] for the third quartile, and 3.87 [2.24–7.08] and 8.42 [5.54–13.3] for the fourth quartile, respectively. The composite endpoint of mortality and cardiovascular events occurred during the study period in 76.4% of patients in the highest PlGF quartile (≥ 19.6 pg/mL) and the lowest eGFR tertile (< 30 mL/min/1.73m²). The association between PlGF and both mortality and cardiovascular events was not attenuated when participants were stratified by age, sex, traditional risk factors, and eGFR.

Conclusions: Elevated PlGF is an independent risk factor for all-cause mortality and cardiovascular events in patients with CKD.

FR-PO806

Prospective, Randomized, Controlled Trial: Comparison of Total Parathyreoidectomy without Autotransplantation and without Thymectomy versus Subtotal Parathyreoidectomy with Thymectomy for Renal Hyperparathyreoidism Sylvia Stracke,[1] Doris Henne-Bruns,[3] Peter Wuerl,[3] Frieder Keller.[2] *[1]Nephrology, Internal Medicine A, Univ Medicine Greifswald, Greifswald, Germany; [2]Nephrology, Internal Medicine 1, Univ Hospital Ulm, Ulm, Germany; [3]General Surgery, Univ Hospital Ulm, Ulm, Germany.*

Background: In patients with chronic renal failure, secondary hyperparathyroidism (sHPT) sometimes requires parathyroidectomy. Prospectively, we compared total parathyroidectomy without autotransplantation and without thymectomy (tPTX) with subtotal parathyreoidectomy with thymectomy (sPTX) for renal hyperparathyreoidism.

Methods: From 11/2004 to 11/2008, 43 consecutive patients with sHPT were prospectively randomized to receive either tPTX (22 patients) or sPTX (21 patients). Patients were followed for a median of 36 months (11-62 months). Outcome parameters were parathyroid hormone (PTH), calcium, phosphate, alkaline phosphatase (AP), vitamin D use, bone mineral density (DXA) and coronary calcification (Agatston score).

Results: tPTX reduced PTH significantly lower than sPTX (17 versus 71 pmol/L; p=0.03). 36 months (11-62) after tPTX, serum calcium was measured with 2,15±0,23 mmol/l versus 2,31±0,24 mmol/l (p=0.04) after sPTX. In the direct postoperative period, the need for active vitamin D supplementation was higher after tPTX (12,20±9,24 µg/week) compared to sPTX (6,67±6,95 µg/week). There was no difference in reduction of AP, serum phosphate, postoperative mortality, postoperative longterm dose of vitamin D, bone mineral density nor the Agatston score of the coronary arteries. Bone mineral density improved similarly in both groups. The preoperative Agatston-Score was high in both groups, but stayed unchanged throughout the whole observation period: tPTX preOP 1869±2458, postOP 2865±5865; sPTX preOP 6909±11758, postOP 6854±15414.

Conclusions: tPTX is as safe as sPTX. tPTX is more effective than sPTX in reducing PTH. Directly after PTX, serum calcium is lower after tPTX requiring a higher dose of active vitamin D. After both operations, tPTX as well as sPTX, bone mineral density increased and the otherwise expected progression of coronary calcification did not occur. Parathyroidectomy may stop vascular calcification.

FR-PO807

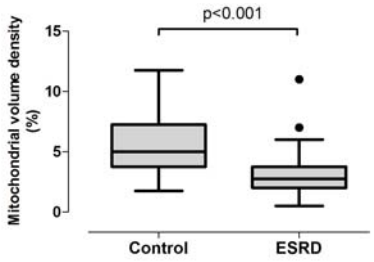
Skeletal Muscle Mitochondrial Volume Density and Morphology in Patients with End-Stage Renal Disease (ESRD) on Maintenance Hemodialysis (MHD) Jorge Gamboa, Chelsea Marie Derer, Charles D. Ellis, Edward D. Siew, T. Alp Ikizler. *Medicine, Vanderbilt Univ Medical Center.*

Background: Oxidative stress and inflammation correlate with cardiovascular events in patients with ESRD. Mitochondrial dysfunction may be the cause of oxidative stress and inflammation. Patients with ESRD on MHD exhibit mitochondrial abnormalities in peripheral blood mononuclear cells (PBMCs) and ultra-structural abnormalities in skeletal muscle. It is still unknown, however, if mitochondrial dysfunction results from a decreased number of mitochondria or from intrinsic mitochondrial impairment. Thus, we hypothesized that MHD patients will have lower mitochondrial DNA (mtDNA) copy number and lower mitochondrial volume density in skeletal muscle than healthy individuals.

Methods: We obtained PBMCs and vastus lateralis muscle biopsies from healthy individuals and patients with ESRD. mtDNA copy number was evaluated with PCR. Thin sections (~ 40) per subject were used for the calculation of mitochondrial volume density using the stereological point counting method.

Results: Patients with ESRD have lower mtDNA copy number (median 1.75, IQR 1.09-2.02) than healthy controls (2.16, IQR 1.51-3.01, p=0.041). In patients with ESRD mitochondria demonstrated signs of cristae swelling, and double-membrane structures compatible with mitophagy. Lipofuscin granules were also abundant in MHD patients, indicating oxidative damage in mitochondria and lysosomes. Mitochondrial volume density was higher in healthy controls compared to patients with ESRD **[Figure 1]**.

Figure 1.



Conclusions: The implications of these findings are that muscle quality is an important factor that might influence physical functioning in MHD patients. Further studies are required to evaluate mitochondrial function and the correlation between morphological and functional changes in patients with ESRD, especially in response to interventions such as exercise.

FR-PO808

An Increased Ultrasonographic Resistive Index Is a Risk Factor for Hypoalbuminemia in Chronic Kidney Disease, Independently of Proteinuria and Renal Function Ryuta Fujimura, Kaori Takaori, Yoko Shima, Chisako Nakano, Masafumi Yamato, Akira Wada, Takahito Ito. *Nephrology, Osaka National Hospital, Osaka, Osaka, Japan.*

Background: Lower serum albumin concentration (ALB) is a risk factor for cardiovascular disease and worsening kidney function. Inflammation, malnutrition, proteinuria, and decreased glomerular filtration rate (GFR) are associated with hypoalbuminemia in chronic kidney disease (CKD) patients. However, the role of kidney damage in hypoalbuminemia remains unknown. We studied an association of CKD and ALB by ultrasonography.

Methods: We had 199 consecutive patients who underwent a Doppler-ultrasonography from January 1th, 2013 to December 31th, 2013. We analyzed 110 patients (61.4±15.7 year-old, 83 males) after 89 patients had been excluded because of polycystic kidney disease, hepatic virus infection, single kidney, or insufficient data of blood chemistry.

Results: ALB (3.90 ± 0.73 g/dl) correlated with eGFR (43.3±23.8 ml/min/1.73m^2, r=0.248, p=0.0089), log[urinary protein (UP)] (-0.50 ± 1.83 g/gCr, r=-0.665, p<0.0001), serum cholesterol concentration (CHO) (201.9 ± 52.5 mg/dl, r=-0.295, p=0.0017), and body mass index (BMI) (23.43±4.29, r=0.275,p=0.0037), but not with age or C-reactive protein. The average of the right and left renal resistive indexes (RI) (0.706±0.079) correlated with ALB (r=-0.345, p=0.0002), Log[UP] (r=0.269, p=0.0044), eGFR (r=-0.470, p<0.0001), age (0.506, p<0.0001), and CHO (r= -0.207, p=0.0298). Age correlated with eGFR (r=-0.422, p<0.0001). On multivariate analysis with ALB as the dependent variable, we found that an increased RI was associated with hypoalbuminemia, independently of UP and GFR.

Model	R2	Dependent Variable	Standard Beta	95%CI
1	0.457	mRI	-0.176	-0.309 - -0.134
		eGFR	0.008	-0.004 - 0.005
		log[urinary protein]	-0.615	-0.302 - -0.185
2	0.487	mRI	-0.237	-3.537 - -0.816
		cholesterol	-0.189	-0.004 - 0.000
		log[urinary protein]	-0.547	-0.277 - -0.157
3	0.488	mRI	-0.208	-3.364 - -0.461
		eGFR	0.086	-0.002 - 0.007
		cholesterol	-0.218	-0.005 - 0.000
		log[urinary protein]	-0.525	-0.270 - -0.145

Conclusions: An increased ultrasonography RI accounts for hypoalbuminemia in CKD. RI might be a practical marker for renal mishandling of amino acid recycling.

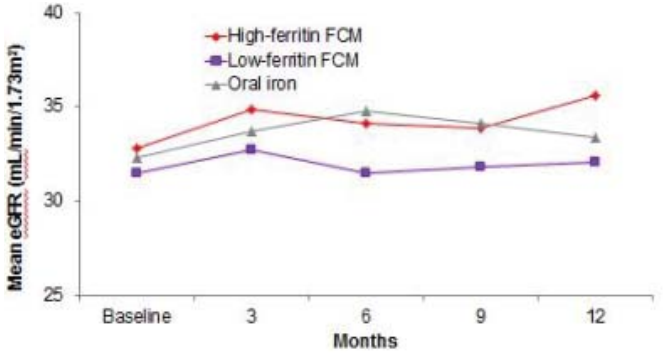
FR-PO809

Iron Administration to Non-Dialysis CKD Patients for One Year Does Not Cause Worsening of Renal Function: Results From the FIND-CKD Trial Iain C. Macdougall,[1] Andreas H. Bock,[2] Fernando Carrera,[3] Kai-Uwe Eckardt,[4] Carlo A. Gaillard,[5] David B. Van Wyck,[6] Bernard Roubert,[7] Jacqueline G. Nolen,[7] Simon D. Roger.[8] *[1]King's College Hospital, UK; [2]Kantonsspital, Switzerland; [3]Eurodial, Portugal; [4]Erlangen-Nuremberg, Germany; [5]Groningen, Netherlands; [6]Davita, US; [7]Vifor Pharma, Switzerland; [8]Gosford, Australia.*

Background: Laboratory data suggest that intravenous (IV) iron may exacerbate oxidative stress and renal tubular toxicity but robust scientific evidence that this translates into worsening renal function in non-dialysis CKD (ND-CKD) patients is lacking. One of the secondary endpoints in the FIND-CKD study was renal function measured by eGFR and this allowed further elucidation of this controversy.

Methods: 626 ND-CKD patients with iron deficiency anaemia (Hb 9–11g/dl; ferritin<100µg/l or <200µg/l and TSAT<20%; eGFR≤60ml/min were randomized to 1 of 3 strategies of iron administration (IV ferric carboxymaltose [FCM] aiming for a ferritin of 400–600µg/l, versus IV FCM aiming for a ferritin of 100–200µg/l, versus oral ferrous sulphate 200mg iron daily). Renal function (eGFR, MDRD-4) was measured every 3 months for 1 year.

Results: Over the 1-year study patients received a mean total dose of 2685 and 1040mg in the high-ferritin FCM and low-ferritin FCM groups, respectively. Mean eGFR (ml/min/1.73m^2) are shown for all 3 groups.



Conclusions: This study is the longest and largest to compare oral versus IV iron in ND-CKD patients. The results demonstrate that the administration of IV FCM in doses that maintain ferritin levels of 100-200 or 400–600µg/l over 1 year do not negatively impact renal function as measured by eGFR (MDRD-4). While this study did not directly measure true GFR, assess proteinuria or tubular damage markers, it nevertheless provides reassuring data on the absence of any overt renal toxicity following IV iron administration in ND-CKD patients over the course of 1 year.

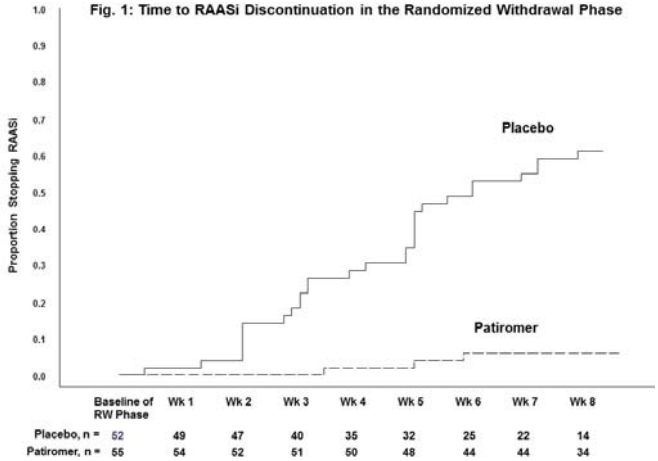
FR-PO810

Patiromer Reduced RAASi Dose Discontinuations in CKD Patients with Moderate-to-Severe Hyperkalemia Matthew R. Weir,[1] George L. Bakris,[2] David A. Bushinsky,[3] Bertram Pitt,[4] Martha Mayo,[5] Dahlia Garza,[5] Yuri Stasiv,[5] Janet Wittes,[6] Heidi Christ-Schmidt,[6] Lance Berman.[5] *[1]Univ of Maryland, Baltimore, MD; [2]Univ of Chicago, Chicago, IL; [3]Univ of Rochester, Rochester, NY; [4]Univ of Michigan, Ann Arbor, MI; [5]Relypsa, Redwood City, CA; [6]Statistics Collaborative, Washington DC.*

Background: RAAS inhibitors (RAASi) have cardiorenal benefits in patients (pts) with CKD, yet hyperkalemia (HK) often limits RAASi therapy. Patiromer, a nonabsorbed, metal-free polymer with high K^+-binding capacity, controlled serum K^+ (s-K^+) and decreased recurrent HK versus placebo (PBO) with good GI tolerability in a two-part Phase 3 trial in CKD pts with HK on RAASi. We present additional endpoints from the PBO-controlled Randomized Withdrawal Phase.

Methods: Pts with s-K^+ 5.1 to <6.5 mEq/L received patiromer (4.2 or 8.4 g BID to start) in a 4-wk Initial Treatment Phase; pts with BL s-K^+ 5.5 to <6.5 mEq/L were eligible to continue into an 8-wk PBO-controlled Randomized Withdrawal Phase. Additional endpoints included % of pts requiring an intervention for recurrent HK (RAASi dose ↓/discontinuation [PBO]; patiromer dose ↑/RAASi discontinuation[patiromer]) and time to RAASi discontinuation.

Results: Overall (n=237) after having controlled s-K^+ in the Treatment Phase (BL mean s-K^+ = 5.58 ± 0.03 mEq/L, D from BL = -1.01 ± 0.03 mEq/L; p<0.001), 55 pts were randomized to continue patiromer and 52 were switched to PBO in the 2nd phase. As a result of recurrent HK (s-K^+ ≥ 5.5 mEq/L; PBO = 60%, patiromer = 15%; p< 0.001) more PBO (62%) than patiromer (16%) pts required an intervention to manage s-K^+. By Wk 8, significantly (p<0.001) more patiromer (94%) than PBO (39%) pts were still on RAASi therapy. Figure 1 shows time to RAASi discontinuation.



Conclusions: After controlling their s-K^+ in this Phase 3 study, significantly fewer CKD pts with moderate-to-severe HK on patiromer had recurrent HK and more stayed on RAASi therapies versus PBO.

Identification of Potential New Actors Associated with Chronic Kidney Disease Complications Using Plasma Proteome Analysis

Julie Klein,[1,2] Griet Lrl Glorieux,[3] William Mullen,[4] Flore Duranton,[5] Szymon Filip,[6] Nathalie Gayrard,[5] Holger Husi,[4] Joost Schanstra,[2] Eva Schepers,[3] Antonia Vlahou,[6] Joachim Jankowski,[7] Harald Mischak,[1] Angel Argiles,[5] Raymond C. Vanholder.[3] *[1]Mosaiques Diagnostics, Hannover, Germany; [2]Inst of Metabolic and Cardiovascular Diseases, INSERM, Toulouse, France; [3]Nephrology Section, Ghent Univ Hospital, Gent, Belgium; [4]BHF Glasgow Cardiovascular Research Centre, Univ of Glasgow, Glasgow, United Kingdom; [5]RD-Nephrologie, Montpellier, France; [6]Biomedical Research Foundation, Academy of Athens, Athens, Greece; [7]Inst of Cardiovascular Research, RWTH Aachen Univ Hospital, Aachen, Germany.*

Background: Systemic complications including cardiovascular events and infections are the major cause of death in patients with chronic kidney disease (CKD). The exact mechanisms are not fully understood. In the present study, we investigated the plasma proteome changes in CKD patients in order to identify new mechanisms and factors that could be associated with CKD-related complications.

Methods: Using LC-MS/MS for discovery and ELISA for validation, we analysed the plasma proteome of patients with stage 2-3 CKD (n=14) and stage 5 CKD with hemodialysis (HD) (n=16). A validation cohort of 40 patients with different CKD stages with or without HD was also assessed.

Results: We identified 2054 proteins, of which 333 were significantly modified during progression of CKD, mainly involved in altered hemostasis and acute phase response. We identified and validated complement factor D (Cfd), lysozyme C (Lyz) and leucine-rich alpha-2-glycoprotein (Lrg1) as new potential actors of CKD-associated complications, in addition to alterations of known factors associated with the development of vascular damage and inflammation in CKD such as beta-2-microglobulin and prostaglandin-H2 D-isomerase.

Conclusions: Using plasma proteome analysis, we have identified Cfd, Lyz and Lrg1 as new potential actors in the complications of CKD. This will help to understand the mechanisms of these complications, and monitoring of plasma levels of these potential targets in CKD patients might help to prevent the occurrence of systemic complications.

FR-PO812

Association of Variants in Genes Belonging to the Angiogenesis/Wound Repair Pathway with Lower Extremity Amputation: Findings from the CRIC Study

Jayanta Gupta,[1,5] Nandita Mitra,[2,5] Raymond R. Townsend,[2] Ole Hoffstad,[2] Maryte T. Papadopoulos,[2] Michael J. Fischer,[3] Jeffrey R. Schelling,[4] Harold I. Feldman,[2] David J. Margolis.[2] *[1]TTUHSC, El Paso, TX; [2]UPenn, Philadelphia, PA; [3]UIMC, Chicago, IL; [4]CWRU, Cleveland, OH; [5]Equal contribution.*

Background: Diabetes is the major risk factor for non-traumatic lower extremity amputation (LEA). The role of genetic polymorphisms in predisposing diabetics to impaired wound healing leading to amputation has not been sufficiently explored. We investigated the association of variants in a set of genes belonging to the angiogenesis/wound repair pathway with LEA in the Chronic Renal Insufficiency Cohort (CRIC).

Methods: This study was conducted on 3772 CRIC subjects who were genotyped on the ITMAT-Broad-CARe array (IBC) chip. A total of 1017 SNPs in 22 genes belonging to the angiogenesis/would repair pathway were investigated. LEA was determined from patient self-report. The association between genetic variants and LEA status was examined using logistic regression under additive genetic models as implemented in the software PLINK. Separate analyses were performed for non-Hispanic white, non-Hispanic Black and Hispanic subjects. Further stratification was based on diabetic status. Unadjusted analyses as well as analyses adjusted for age, sex, eGFR, BMI, peripheral vascular disease, HbA1C and population stratification were conducted.

Results: In non-Hispanic white subjects with diabetes, rs11938826, an intronic SNP in the gene Basic Fibroblast Growth factor (*FGF2*),was significantly associated with LEA in covariate-adjusted analysis {OR: 2.83 (95% Confidence Intervals: 1.73, 4.62); p-value: 0.000034; Bonferroni adjusted p-value: 0.02}. In the same sub-group, another *FGF2* intronic SNP, rs1960669, had a similar effect estimate and a p-value of 0.00095, but did not withstand the Bonferroni adjustment. No other significant association could be identified in the other ethnic groups.

Conclusions: Variant/s in *FGF2* can predispose diabetics with chronic kidney disease to LEA. Dysregulation of the *FGF2* gene represents an opportunity to understand further, and possibly intervene upon, mechanisms of wound healing in diabetics with chronic kidney disease.

Acupuncture Therapy for Symptoms of Hemodialysis Patients

Hinata Sakuraba,[1] Tomomasa Moriyama,[1] Takashi Ishizu,[2] Aki Hirayama.[1] *[1]Center for Integrative Medicine, Tsukuba Univ of Technology, Tsukuba, Japan; [2]Kidney Center, Tsukuba Central Hospital, Ushiku, Japan.*

Background: Hemodialysis (HD) patients have various symptoms related to uremia, and some of them are intractable. The purpose of this study is to examine the effectiveness and safety of acupuncture for symptom management of HD patients.

Methods: Subjects were 45 patients who undergoing HD regularly, 15 males and 30 females, with a mean age of 64±9.8 years, and a mean dialysis history of 11±9.7 years. Eleven patients were complicated with diabetes mellitus (DM). The objected symptoms in this study are 1) pain caused by various reasons including uremic polyneuropathy, 2) itching, 3) muscle stiffness, 4) hypesthesia, 5) fatigue and 6) sleeplessness. Acupuncture therapies were operated at bedside by the acupuncturist during HD sessions, and at home by the self-treatment of patients under directions of the acupuncturist. Needles with guide tube (0.16×40 mm) were used for treatments by the acupuncturist, and press tack needles to stick on skin (0.2×0.6 mm) for both treatments. The number of treatments was different in each case, ranging from 4 to 43. Each symptom was evaluated before and after treatment by a visual analogue scale (VAS) and a faces pain scale (FS).

Results: Comprehensively, the acupuncture improved the VAS score significantly from 66.1±25.1 pre-treatment to 41.6±26.0 post-treatment ($P<0.05$). The improvement of itches was the most effective symptom, which VAS scale was decreased from 48.1±27.9 to 24.0±27.0 ($P<0.05$). The acupuncture therapies also significantly improved pain (VAS scale from 72.2±21.2 to 41.6±26.0), muscle stiffness (from 64.3±28.3 to 43.2±23.5) and hypesthesia (from 67.1±19.1 to 45.9±21.2), while no clear effects on fatigue and sleeplessness were observed. The effect for itching was remarkable in DM patients, while that for pain was observed in both DM and non-DM patients. The FS results improved in 17 patients, remained the same in 20, and were worse in 8. No severe complications including hemorrhage were observed.

Conclusions: Acupuncture is an effective and safe treatment for symptom managements of HD patients. Refractory itches, pains and muscle stiffness are promising therapeutic targets for acupuncture in HD patients.

Cardiac Functions Improve after Kidney Transplantation in Children with Chronic Kidney Disease

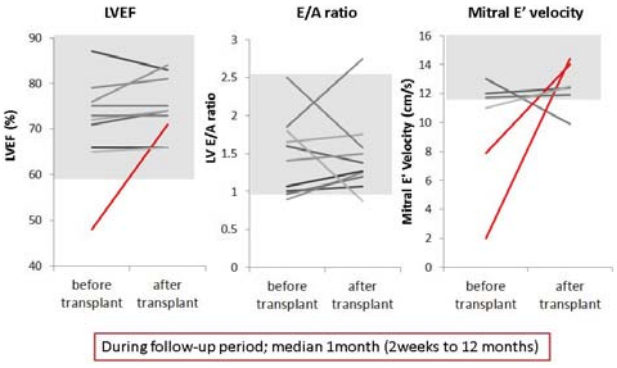
Yuko Hamasaki,[1] Seiichirou Shishido,[1] Junya Hashimoto,[1] Shinichi Takatsuki,[2] Tsutomu Saji.[2] *[1]Pediatric Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan; [2]Pediatrics, Toho Univ Faculty of Medicine, Tokyo, Japan.*

Background: Current studies indicate that cardiac function deteriorates during chronic kidney disease (CKD). Although kidney transplantation (KTx) has improved survival in children with CKD, the prevalence of cardiac dysfunction after KTx has been unknown.

Methods: This was a retrospective cohort study using clinical data from patients with CKD who underwent KTx or had scheduled the operation. Cardiac functions (left ventricular ejection fraction (LVEF), left ventricular E/A ratio, mitral E' velocity) were evaluated in patients with CKD by echocardiography comparing to age-matched healthy controls, and correlation between estimated GFR (eGFR) and echocardiographic parameters was assessed. The patients were then grouped as receiving or not receiving dialysis, and cardiac functions were analyzed. Additionally, cardiac function was evaluated before and after KTx in patients for whom follow-up echocardiographic data were available.

Results: Thirty three patients (20 boys) were included. Median age at measurement of basic cardiac function in our hospital was 10 years. E/A ratio and E' velocity in patients with CKD were significantly lower than in controls ($p<0.05$). E' velocity showed linear correlation with eGFR ($r=0.37$, $p<0.05$). Twenty patients (60%) underwent peritoneal dialysis (PD). E/A ratio in patients with PD was significantly lower than in those without PD ($p<0.05$). KTx was performed in 28 patients and 10 patients received follow-up echocardiography. Their cardiac functions improved after KTx.

Figure 1, Cardiac functions after kidney transplantation



Conclusions: This study indicated left ventricular diastolic dysfunction was prevalent in children with CKD; however, these echocardiographic abnormities may be reversible after KTx.

FR-PO815

Signaling Involved with Cbfa1 in VSMC Calcification Induced by High Phosphate

Yi Yu. *Dongfang Hospital of Fujian Province, Fuzhou, Fujian, China.*

Background: To observe the possible molecular signaling that regulates Cbfa1 on high phosphate induced vascular smooth muscle cells (VSMC) calcification.

Methods: Passage 3 to 5 of VSMC were used for experiments. VSMC were divided into two groups: normal phosphate group (Pi 1.3 mmol/L) and high phosphate group (Pi 2.6 mmol/L). Calcium deposition was visualized by Alizarin stain method at day 7. Cbfa1 and OPN mRNA levels were determined by Real-Time PCR. p-AKt (ser473), Cbfa1 and OPN protein expressions were quantified by Western Blot. Then, VSMC were treated with AKt inhibitor, Wortmannin. VSMC were divided into four groups: high phosphate group (Pi 2.6 mmol/L); high phosphate+ Wortmannin (10 nmol/L, 50 nmol/L and 100 nmol/L). After 24h, Cbfa1 and OPN mRNA levels were determined, and p-AKt (ser473), Cbfa1 and OPN protein expressions were quantified.

Results: After 7 days, compared with normal phosphate group, calcium deposition was obvious in high phosphate group;Cbfa1 and OPN mRNA expressions were significantly increased and the expressions of p-AKt, Cbfa1 and OPN protein were significantly increased in high phosphate group (P<0.05). After treated with Wortmannin 24h, compared with high phosphate group,calcium deposition was not decreased in high phosphate+ Wortmannin (10nmol/L) group. But calcium deposition was significantly decreased in high phosphate+ Wortmannin (50nmol/L, 100nmol/L) groups. Compared with high phosphate group, Cbfa1 and OPN mRNA expressions were not decreased in high phosphate+ Wortmannin (10nmol/L) group, but Cbfa1 and OPN mRNA expressions were significantly decreased in high phosphate+ Wortmannin (50nmol/L, 100nmol/L) groups (P<0.05). Compared with high phosphate group, p-AKt (ser473), Cbfa1 and OPN protein expressions were not decreased in high phosphate+ Wortmannin (10nmol/L) group, but p-AKt (ser473), Cbfa1 and OPN protein expressions were significantly decreased in high phosphate+ Wortmannin (50nmol/L, 100nmol/L) groups (P<0.05).

Conclusions: AKt inhibitor, Wortmannin may dose-dependently inhibit VSMC calcification and expressions of p-AKt (ser473), Cbfa1 and OPN. AKt is involved in VSMC calcification induced by high phosphate and AKt may work by activating Cbfa1.

Treatment of the CKD-MBD with a Ligand Trap for the Activin Receptor Type 2A

Yifu Fang,[1] Olga A. Agapova,[1] Toshifumi Sugatani,[1] Hartmut H. Malluche,[2] Keith A. Hruska.[1] *[1]Pediatrics, Nephrology, Washington Univ School of Medicine, Saint Louis, MO; [2]Medicine, Nephrology, Univ of Kentucky, Lexington, KY.*

Background: The CKD-MBD consists of vascular calcification, an osteodystrophy, and stimulation of skeletal osteocyte FGF23 secretion at its inception, and hyperphosphatemia, develops later in the course to further stimulate vascular calcification. Here we demonstrate that inhibition of activin, a member of the TGFb superfamily signaling through the activin type 2A receptor (ActR2A), induced by CKD inhibits vascular calcification and prevents cardiac hypertrophy.

Methods: CKD with hyperphosphatemia and 60% reduction in GFR (CKD-3) was induced at 14 weeks of age in our *ldlr-/-* high fat fed model vascular calcification. Some CKD mice were treated with RAP-011 (an ActR2A ligand trap), injected IP weekly beginning at 22 weeks of age and studied at 28 weeks. Aortic Ca levels, expression of osteoblastic and vascular smooth muscle proteins, skeletal histomorphometry and microCT imaging, serum chemistries and FGF23 and PTH levels were measured. Activin, Follistatin and Inhibin levels were measured by elisa, RT-PCR and westerns.

Results: Activin levels were increased in the vasculature and the circulation without changes in follistatin. CKD stimulated vascular calcification which was reduced below 22 week levels by. RAP-011 treatment, and cardiac hypertrophy was prevented. CKD induced expression of aortic Runx2, osterix, and alkaline phosphatase message and protein, and these were reversed by RAP-011 treatment. CKD reduced smooth muscle 22a (sm22a) message and protein, and RAP-011 treatment normalized sm22a expression. Bone volume was increased by RAP-011, and osteoclast pit surface was decreased, but bone formation rates and osteoblast surfaces were not affected. Hyperphosphatemia, and FGF23 levels were not changed by RAP-011.

Conclusions: Treatment with an activin receptor type 2A (ActR2A) ligand trap, RAP-011, inhibited bone resorption and increased bone volume. RAP-011 inhibited Smad dependent signaling, blocked aortic osteoblastic transition, increased vascular smooth muscle protein levels and decreased CKD stimulated vascular calcification and cardiac hypertrophy.

Effect of Valvular Calcifications on Echocardiography on Cardiovascular Outcomes in Hemodialysis Patients: A Meta-Analysis of Prospective Studies

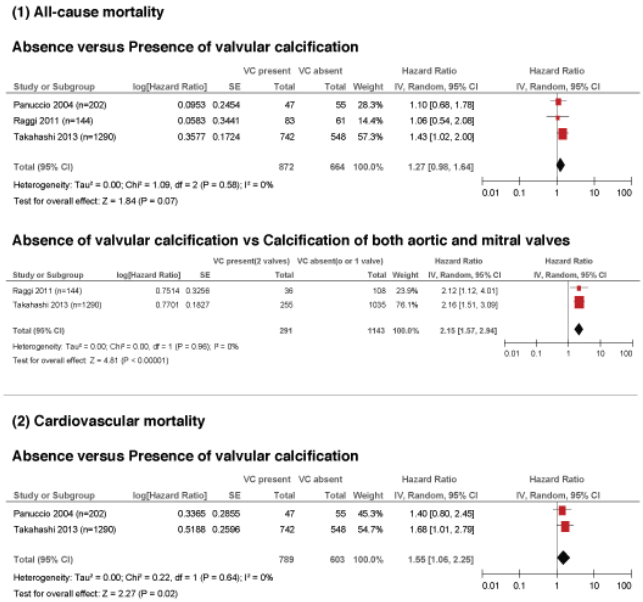
Ioannis Konstantinidis,[1] Achint Patel,[1] Spyridon N. Papageorgiou,[2] Alexandre Benjo,[3] Shiv Kumar Agarwal,[4] Narender Annapureddy,[5] Girish N. Nadkarni,[1] Joseph A. Vassalotti.[1] *[1]Icahn School of Medicine at Mount Sinai; [2]Univ of Bonn; [3]Ochsner Clinic; [4]Univ of Arkansas; [5]Rush Univ.*

Background: Valvular calcification (VC) is associated with all-cause/cardiovascular (CV) mortality in hemodialysis (HD) patients. The 2009 KDIGO guidelines suggest but do not recommend echocardiography (echo) to detect VC. We assessed the impact of VC identified by echo in HD patients, including studies after the KDIGO guidelines.

Methods: We performed a systematic review/meta-analysis of prospective studies that examined the relationship between VC on echo and all-cause/CV mortality in HD patients. MEDLINE, EMBASE, CENTRAL, CINAHL, Web of Knowledge, LILACS, and ClinicalTrials were searched until May 2014. Two authors performed study selection and data extraction. Hazard ratios (HR) were estimated with random-effects model using RevMan 5.2.

Results: Of 6,711 initially identified studies, three (n=1,636) were included; all assessed VC of the aortic and mitral valve. For all-cause mortality, three reported adjusted HRs (n=1,636) for absent versus present VC; pooled HR was 1.27 (95% CI, 0.98-1.64). Two studies reported adjusted HR (n=1,434) for absent VC versus VC presence at both aortic and mitral valve; pooled HR was 2.15 (95% CI, 1.57-2.94). For CV mortality, 2 studies reported adjusted HRs (n=1,492) for absent versus present VC; pooled HR was 1.55 (95% CI, 1.06-2.25). Range of follow-up was 44-67 mos. There was no significant heterogeneity between studies for either all-cause or CV mortality.

Figure 1: Forest plots for impact of valvular calcification on all-cause and cardiovascular mortality



Conclusions: VC of both aortic and mitral valves but not individually is associated with significantly higher all-cause and cardiovascular mortality. VC identified by echo could be used to identify high risk patients for aggressive modification of risk factors.

FR-PO818

Effect of Vascular Calcifications on Plain Radiography on Outcomes in Hemodialysis Patients: A Meta-Analysis of Prospective Studies

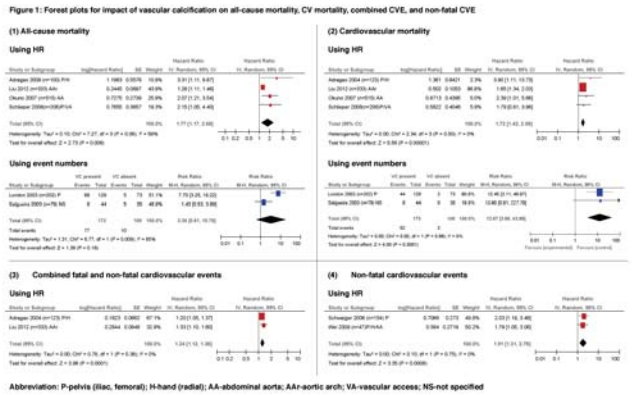
Ioannis Konstantinidis,[1] Achint Patel,[1] Spyridon N. Papageorgiou,[2] Alexandre Benjo,[3] Madhav C. Menon,[1] Rabi Yacoub,[1] Girish N. Nadkarni,[1] Joseph A. Vassalotti.[1] *[1]Icahn School of Medicine at Mount Sinai; [2]Univ of Bonn; [3]Ochsner Clinic.*

Background: Vascular calcification (VC) is associated with all-cause/cardiovascular (CV) mortality in hemodialysis (HD) patients. The KDIGO 2009 guidelines suggest but not recommend abdominal radiograph for VC based on low quality evidence. We assessed the impact of VC on plain radiography (XR) in HD patients.

Methods: This systematic review/meta-analysis of prospective studies examined the relationship between VC on XR and all-cause/CV mortality and cardiovascular events (CVE) in HD patients. MEDLINE, EMBASE, CENTRAL, CINAHL, Web of Knowledge, LILACS, and ClinicalTrials were searched until May 2014. Two authors performed study selection and data extraction. We used RevMan 5.2 to estimate hazard ratios (HR) and risk ratios (RR) with a random-effects model.

Results: Of 6,711 studies, nine (n=1,759) were included. For all-cause mortality, four reported HRs (n=1,154) and two reported events (n=281) with mean f/u 44/18 mo; pooled HR and RR were 1.77 and 3.38 (not significant). For CV mortality, four reported HRs

(n=1,177) and two reported events (n=281) with mean f/u 46/18 mo; pooled HR and RR were 1.72 and 12.67. For combined fatal/non-fatal CVE, 2 studies reported HRs (n=201; mean f/u 45 mo); pooled HR was 1.91. For non-fatal CVE, 2 studies reported HRs (n=456; mean f/u 41 mo); pooled HR was 1.24. Significant heterogeneity existed for all-cause mortality but not CV mortality/CVE.



Conclusions: VC is associated with higher all-cause/CV mortality and CVE in HD patients. VC on XR could be used to identify high risk patients for aggressive CV disease detection/management. Interpretation of pooled estimates for all-cause mortality requires caution due to heterogeneity. Assessment of interventions' impact on VC is planned.

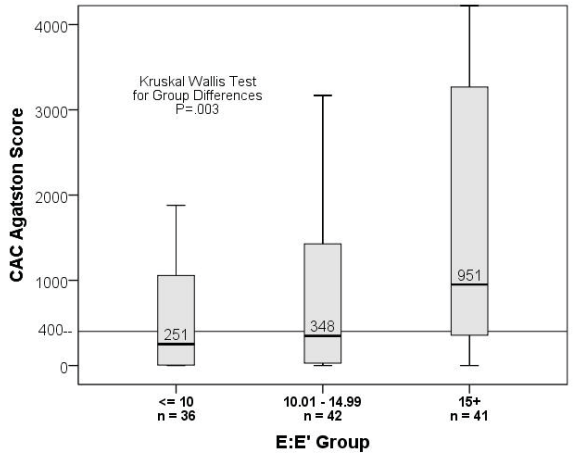
FR-PO819

Global Cardiac Function Is Negatively Affected by Coronary Artery Calcification in CKD-5D Patients Paul Anaya,[1,2] Gustav A. Blomquist,[3] Daniel Davenport,[4] Vincent L. Sorrell,[1,2] Marie-Claude M. Faugere,[5] Hartmut H. Malluche.[5] *[1]Cardiovascular Medicine, Univ of Kentucky, Lexington, KY; [2]Internal Medicine, Univ of Kentucky, Lexington, KY; [3]Radiology, Univ of Kentucky, Lexington, KY; [4]Surgery, Univ of Kentucky, Lexington, KY; [5]Nephrology, Univ of Kentucky, Lexington, KY.*

Background: Coronary artery calcification (CAC) is common in CKD-5D patients (pts). Its impact on cardiac function is not known. This study evaluates cardiac functional implications of CAC in CKD-5D.

Methods: Pts were from 37 Kentucky dialysis centers. Blood was analyzed for traditional and novel bone biomarkers. 2-D and Doppler echocardiography (ECHO) was performed and CAC was measured using 64-slice MSCT for Agatston scores (AgS). Relationships between CAC, bone markers, and ECHO results of left ventricular (LV) function were analyzed.

Results: There were138 pts: 58.6% men, 46% Caucasian. Median age 55.5 yrs (range 21-84), dialysis 49.5 mos (range 3-292). AgS > 100 in > 70% of pts with AgS > 400 in > 50%. There were relationships between CAC and LV diastolic dysfunction (DiaDf) measured by E/E' (r=0.33, p<0.01), speckle-derived global longitudinal strain (GLS) (r=0.29, p=0.03), and LV systolic velocity (r= -0.22, p=0.01). Pts with the most severe CAC had E/E' values indicating severe DiaDf. (Fig.) Multivariate regression identified CAC as an independent predictor of E/E' (r= 0.34, p< 0.001). Valvular calcification (ValvCalc), based on a visual scoring scale, varied linearly with CAC, E/E', and GLS (p<0.05), and inversely with LV systolic velocity (p<0.05). Only FGF-23 correlated linearly with GLS.



Conclusions: CAC adversely impacts LV systolic and DiaDf in CKD-5D. CAC correlates strongly with ValvCalc, suggesting that (a) the pathologic mechanism leading to CAC may also affect heart valves (b) ValvCalc identified on routine ECHO may be a marker of CAC.

FR-PO820

A Decreased Level of Serum Solubleklotho Is a Biomarker Associated with Vascular Calcification in Peritoneal Dialysis Patients Qiuling Fan. *Dept of Nephrology, China Medical Univ, Shenyang, Liaoning, China.*

Background: Low serum Klotho levels are related to the prevalence of cardiovascular diseases in community-dwelling adults. However, it is unclear whether the serum Klotho levels are associated with vascular calcification in peritoneal dialysis patients.

Methods: We determined the levels of serum solubleKlotho in 58 continuous ambulatory peritoneal dialysis (CAPD) patients using ELISA and investigated the relationship between the level of Klotho and markers of CKD-mineral and bone disorder (CKD-MBD) and the abdominal aortic calcification score (AAC), a marker of vascular calcification.

Results: Fifty CAPD patients (86.2%) had abdominal aortic calcification. The serum Klotho level significantly correlated with the 25-hydroxyvitamin D level and inversely correlated with AAC, serum phosphorus and FGF23, not correlated with the parathyroid hormone, bone-specific alkaline phosphatase (BAP), and serum calcium levels. There were significant decreases in serum Klotho in patients with abdominal aortic calcification of ACI>8. Multivariate Logistic regression analysis showed that lower serum soluble Klotho level and FGF23 were independent risk factor for abdominal aortic calcification. ROC-AUC of serum soluble Klotho for abdominal aortic calcification was 0.81 (cut-off 153.78 pg/mL, accuracy 87.5 %, specificity58.0%).

Conclusions: Decreases in the serum solubleKlotho levels are independently associated with vascular calcification in peritoneal dialysis patients. Further research exploring whether therapeutic approaches to maintain or elevate the Klotho level could improve vascular calcification in peritoneal dialysis patients is warranted.

FR-PO821

Skin Autofluorescence - A Novel Risk Marker or Risk Factor for Aortic Valve Calcification in Chronic Kidney Disease? Angela Yee Moon Wang,[1] Ck Wong,[2] Yat Y. Yau,[3] Iris Chan,[4] Christopher W. Lam.[5] *[1]Medicine, Queen Mary Hospital, Univ of Hong Kong, Hong Kong, Hong Kong; [2]Chemical Pathology, Chinese Univ of Hong Kong, Prince of Wales Hospital, Hong Kong, Hong Kong; [3]Pathology, United Christian Hospital, Hong Kong, Hong Kong; [4]Radiology, Biomedical Imaging Center, Hong Kong, Hong Kong; [5]Macau Inst for Applied Research in Medicine and Health, Macau Univ of Science and Technology, Macau, Macau.*

Background: Experimental data suggest advanced glycation endproduct (AGE) may induce vascular smooth muscle cells calcification. We hypothesized that skin autofluorescence (AF), a proxy of tissue AGE, may be associated with aortic valve calcification (AVC) in chronic kidney disease (CKD).

Methods: 300 stages 3–5 non-dialysis CKD patients (age:60±10yrs, 56%men) underwent plain multislice computed tomography to estimate aortic valve calcium score (AVCS) and had skin AF assessed using AGE Reader.

Results: Intact parathyroid hormone (iPTH) (P<0.001) displaced estimated GFR as the third most significant factor associated with skin AF after age and diabetes in multiple regression analysis. Using multinomial logistic regression, skin AF retained significance in predicting AVCS≥400 [OR, 8.80, 95% CI, 1.87–41.3, P=0.006] when adjusting for age, gender, serum calcium, phosphate, eGFR, albumin, inflammation, lipids and blood pressure. Its significance was well retained when further adjusting for iPTH [P=0.01], fasting glucose [P=0.01], glycosylated hemoglobin [p=0.01] and diabetes [OR, 11.60, P=0.02] in stepwise multinomial regression. Notably, combination of diabetes and high iPTH was associated with the highest skin AF and AVCS. Using receiver-operator characteristics curve analysis, skin AF showed highest predictive value for AVCS [area under the curve, 0.72, 95% CI, 0.65–0.80; p<0.001] compared to other biochemical parameters of mineral bone disease (MBD).

Conclusions: Skin AF showed an independent novel relationship with AVCS in CKD beyond inflammation and other biochemical parameters of CKD-MBD. These data suggest skin AF is useful in identifying CKD patients with significant AVC. Tissue AGE may represent a novel culprit linking CKD to an increased risk of heart valve calcification that warrant further investigation.

Indoxyl Sulfate Contributes to Vascular Calcification in Rats with Chronic Renal Failure Ellen Neven,[1] Rida Bashir-Dar,[1] Rita L.M. Marynissen,[1] Bjorn Meijers,[2] Pieter Evenepoel,[2] Patrick C. D'Haese.[1] *[1]Pathophysiology, Univ of Antwerp, Antwerp, Belgium; [2]Nephrology, Univ Hospitals Leuven, Belgium.*

Background: Chronic renal failure (CRF) patients develop extensive arterial calcifications, having a significant impact on mortality. Besides a disturbed mineral metabolism, protein bound uremic retention solutes, particularly indoxyl sulfate (IS) and p-cresyl sulfate (PCS), have also been associated with cardiovascular disease and mortality in these patients. To clarify the potential causal role of IS and PCS in the development of vascular calcification, the impact of both uremic toxins on arterial calcification was studied in CRF rats.

Methods: To induce CRF, all study groups were daily gavaged with 600 mg/kg adenine sulfate for 10 days and received a 1.2% P diet for 7 weeks.Two groups of CRF rats were exposed to 200 mg/kg IS (high IS) or PCS (high PCS) via the drinking water for 1 week from the start of CRF induction onwards and continued exposure to 150 mg/kg IS

or PCS from week 3 to7. Two other CRF groups were exposed to 150 mg/kg IS (low IS) or PCS (low PCS) after adenine administration was stopped, from week 3 to 7. Control CRF animals received vehicle. Calcification in the aorta, carotid and femoral arteries was measured by histomorphometric analysis on Von Kossa stained sections and by determining the calcium content of the vessels.

Results: Adenine administration led to the induction of CRF in all study groups, as evidenced by a significant decrease of the creatinine clearance, and hyperphosphatemia. No additional effect of toxin exposure on renal dysfunction was found. The calcium content of the aorta and the carotid artery was significantly increased in the CRF group exposed to the high IS dose as compared to vehicle treated CRF animals. No effect of either low or high PCS and low IS on the development of vascular calcification was observed.

Conclusions: The current experimental study shows that the uremic toxin IS accelerates the development of arterial calcification in chronic kidney disease. The potential effect of this toxin on phenotypic changes of vascular smooth muscle cells in the vessels will be further explored.

FR-PO823

Can Established Vascular Calcification Be Reversed by Pyrophosphate or Sevelamer in an Animal Model of Chronic Renal Failure? Rida Bashir-Dar,[1] Geert J. Behets,[1] Bruce L. Riser,[2,3] Patrick C. D'Haese,[1] Ellen Neven.[1] *[1]Biomedical Sciences, Univ of Antwerp, Wilrijk, Belgium; [2]Physiology and Biophysics, Rosalind Franklin Univ of Medicine and Science, Chicago, IL; [3]Medicine, Chicago Medical School, Chicago, IL.*

Background: Vascular calcification (VC) is commonly observed in CKD patients and is thought to contribute significantly to the cardiovascular morbidity and mortality in this population. In previous experimental studies, both Sevelamer (Sev) and pyrophosphate (PPi) have proven to be effective in preventing VC in chronic renal failure (CRF), the former by controlling phosphate absorption, the latter by directly interfering with the hydroxyl apatite crystal formation. However, since most patients present with established VC, it is of utmost importance to evaluate whether these compounds may also reverse established VC.

Methods: CRF was induced in all rats by subjecting them to a protein restricted high adenine diet for 4 weeks. Treatment (Tx) with PPi (30 or 120 µmol/kg/day via peritoneal infusion), Sev (1500 mg/kg/day via gavage) or vehicle was then started for 3 weeks. An additional CRF control group was sacrificed before initiation of Tx. VC was assessed by in vivo µ-CT before and after Tx, and by total calcium measurement and Von Kossa staining of the aorta at sacrifice. Static bone parameters were measured on Goldner stained slides.

Results: Hyperphoshatemia and VC had developed in all animals at the end of adenine administration (i.e prior to Tx). Whilst serum calcium was decreased in all groups inherent to CRF, the Sev group showed relative hypercalcemia. Neither doses of PPi or Sev were able to significantly reverse established VC. While PPi treatment induced no effects on static bone parameters, an increased amount of osteoid was seen in the Sev group, likely due to a relative phosphate depletion inherent to the potent phosphate binding of the compound.

Conclusions: Whilst previous experimental studies demonstrated that both PPi and Sev are able to prevent the initial development of VC, under the conditions tested, neither compound reversed established medial VC.

Funding: Pharmaceutical Company Support - Baxter Healthcare

FR-PO824

Alternative Model of Chronic Renal Failure Allowing Concomitant Evaluation of Vascular Calcification and Bone Pathology Rida Bashir-Dar, Geert Dams, Anja Verhulst, Geert J. Behets, Patrick C. D'Haese, Ellen Neven. *Pathophysiology, Univ of Antwerp, Antwerp, Belgium.*

Background: The 0.75% adenine/low protein rat model is commonly used to study chronic renal failure (CFR)-related vascular calcification (VC). However, as it shows consistent but excessive VC and chaotic and immeasurable bone mineralization due to excessive bone turnover, it is less suited to study the bone-vascular axis in one and the same animal. Moreover, with the conventional model partial restoration of the CRF after stop of adenine administration complicates evaluation of progression/reversal of established VC in intervention studies. Since VC and bone mineralization are related to each other, an animal model in which both pathologies can be studied concomitantly would be an added value.

Methods: Rats were maintained on either a low adenine/ low vitK diet to induce CRF and VC or a control diet without adenine. To follow the onset and development of VC and the evolution of bone pathology over time, rats were killed at week 4, 8, 10, 11 and 12. Static and dynamic bone parameters were measured after double tetracycline labeling. VC was evaluated by Von Kossa (VK) staining and measurement of the arterial Ca content.

Results: A severe CRF as indicated by an 8-fold increase in serum creatinine levels, hyperphosphatemia (± 18 mg/dl) and hypocalcemia was achieved after 4 weeks which remained stable until week 12. Mortality was negligible. Aortic calcification as assessed by total Ca measurement was seen in all animals from week 4 onwards, whilst Ca levels in carotid and femoral artery were significantly increased from week 8 onwards. VK staining revealed a similar pattern. Four and 8 weeks after CRF induction, both static and dynamic bone parameters were measurable in all animals, thereby presenting typical features of hyperparathyroid bone disease. However, from week 10 onwards, dynamic bone parameters were no longer measurable in about 50% of the animals due to chaotic tetracycline incorporation.

Conclusions: A low adenine/low vitK diet resulted in a stable CRF, moderate VC and quantifiable bone pathology after 8 weeks. This rat model is the first one that lends itself to study these two main complications in CRF concomitantly.

FR-PO825

Aortic Calcification Was Accelerated After Radical Nephrectomy: Clinical Impact of GFR Decline for Vascular Calcification Yoshinari Yasuda,[1] Akitaka Suzuki,[2] Ryohei Hattori,[2] Yasuhito Funahashi,[1] Shoichi Maruyama,[1] Seiichi Matsuo.[1] *[1]CKD Initiatives/Nephrology/Urology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [2]Urology, Japan Red Cross Nagoya Daiichi Hosp, Nagoya, Japan.*

Background: Chronic kidney disease (CKD) is one of serious risk factors for cardiovascular diseases (CVD) and ectopic calcification in aorta plays significant role in high mortality among CKD patients. However, chicken or egg problem remains unsolved. In this study, aortic calcifications before and after surgical GFR loss were analyzed among patients who underwent radical or partial nephrectomy, whose comorbidities associated with vascular calcification was comparable except GFR.

Methods: Study subjects were 102 and 61 consecutive patients who underwent radical (R) and partial (P) nephrectomy from 2004 to 2008 in Nagoya University and affiliated hospitals, and were followed-up more than 5 years without recurrences. As control (C), 94 consecutive gastric cancer patients underwent gastrectomy in 2008 were analyzed. Aortic calcification index (ACI) was evaluated using pre- and 5-year postoperative CT scan images, and DACI (post -pre ACI) was calculated.

Results: Patients characteristics, age, gender, HTN, DM, dyslipidemia, previous CVD, eGFR and ACI, before operation were comparable among 3 groups. Postoperative eGFR was the lowest in R and the highest in C group. DACI was significantly greater in R compared to P and C groups, and trend of higher DACI in P was shown compared to C group.

	radical nephrectomy	partial nephrectomy	gastrectomy
preoperative eGFR (ml/min/1.73m^2)	74.1±15.4	76.7±17.5	70.8±12.9
postoperative eGFR (ml/min/1.73m^2)	50.5±11.8	66.6±16.7	70.4±12.9
preoperative ACI	9.16±8.63	8.54±10.8	8.42±7.29
postoperative ACI	16.7±13.7	11.3±12.1	10.8±8.56
ΔACI	7.49±6.38	2.75±2.82	2.34±2.38

In multivariate analysis, 6-month postoperative eGFR ($p<0.001$), preoperative ACI ($p<0.001$), previous CVD ($p=0.020$) and dyslipidemia ($p=0.037$) were significantly associated with DACI.

Conclusions: Aortic calcification was accelerated after radical nephrectomy, which strongly suggested direct link between GFR loss and ectopic calcification.

FR-PO826

Wnt/β-Catenin Signaling Promotes Transdifferentiation and Calcification of Vascular Smooth Muscle Cells in a High-Phosphate Environment Danqin Sun, Ping Wen, Lei Jiang, Chunsun Dai, Junwei Yang, Weichun He. *Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical Univ, Nanjing, China.*

Background: Vascular calcification is extremely prevalent in patients with chronic kidney disease and contributes to increased risk of cardiovascular events and mortality. Osteoblastic differentiation of vascular smooth muscle cells (VSMCs) is involved in the pathogenesis of vascular calcification. Wnt/β-Catenin signaling plays a crucial role in osteogenesis and resent studies implicate it in vascular calcification.

Methods: Here, we sought to determine the role of Wnt/β-Catenin signaling in VSMCs transdifferentiation and calcification induced by high-phosphate.

Results: High-phosphate stimulated β-Catenin activation in VSMCs, along with Runx2 induction and calcium deposition. Activation of β-Catenin, through either Wnt3a or ectopic expression of stabilized β-Catenin, induced Runx2 expression in VSMCs. Upregulation of β-Catenin activity by Wnt3a also promoted calcification of VSMCs, whereas blockade of Wnt/β-Catenin signaling by Dickkopf-1 inhibited calcium deposition induced by high-phosphate. In VSMCs, a functional T cell factor/lymphoid enhancer-binding factor-binding site was identified in the promoter region of the Runx2 gene, which interacted with T cell factor upon β-Catenin activation. In rat with uremic vascular calcification, β-Catenin was dramatically accumulated in the cytoplasm and nuclei of VSMCs of aortic tunica media, meanwhile, the amount of activated β-Catenin in arterial wall was increased, accompany with Runx2 induction, followed by arterial medial calcification.

Conclusions: Collectively, these studies suggested that through direct downstream target Runx2, the activation of Wnt/β-Catenin signaling induced by high-phosphate could play a role in promoting osteoblastic differentiation and calcification of VSMCs.

FR-PO827

MicroRNAS 29b, 133b and 211 Regulate Vascular Calcification Mediated By High Phosphorus Sara Panizo,[1] Manuel Naves,[1] Natalia Carrillo-Lopez,[1] Jose L. Fernandez-Martin,[1] Maria P. Ruiz-Torres,[2] Jorge B. Cannata-Andia,[1] Isabel Rodriguez.[1] *[1]Bone and Mineral Research Unit, IRSIN, REDinREN from ISCIII, HUCA, Oviedo, Spain; [2]Dept of Systems Biology. REDinREN from ISCIII. Univ of Alcalá, Madrid, Spain.*

Background: Vascular calcification (VC) is associated with morbidity and mortality. Few recent studies have suggested that some microRNAs (miRNAs) might have a role in the transdifferentiation of vascular smooth muscle cells (VSMC) in osteoblast-like cells.

The aim of this study was to investigate *in vivo* and *in vitro*, whether several miRNAs already implicated in osteoblast differentiation and bone formation can have any regulatory role in the process of VC.

Methods: To induce VC, 7/8 nephrectomized rats were fed a high phosphorus diet, and sacrified at 12 and 20 weeks. Eight miRNAs with a known role in the osteogenic differenciation in bone (miR-29b, miR-125, miR-133b, miR-135, miR-141, miR-200a, miR-204, and miR-211) were analyzed in the aortas.

Results: Decreased levels of miR-133b and miR-211 correlated with increased RUNX2 expression, as well as increased levels of miR-29b correlated with decreased expression of several inhibitors of osteoblastic differentiation (ACVR2A, CTNNBIP1 and HDAC4). The same trend of results were observed in two *in vitro* models (VSMC cultured with uremic serum and with high calcium and phosphorus media). The results obtained with the transfection of VSMCs with antagomir to miR-29b to inhibit its expression, or with pre-miR-133b or pre-miR-211 to increase the expression of these miRNAs, confirm their role in VSMC calcification.

Conclusions: In conclusion, calcifying stimuli promoted by high phosphorus downregulated miR-133b and miR-211 and upregulate miR-29b modifying the expression of several factors involved in the phenotypic modulation and osteogenic differentiation of VSMCs. The results suggest the three miRNAs studied may play a regulatory role in the process of VC.

FR-PO828

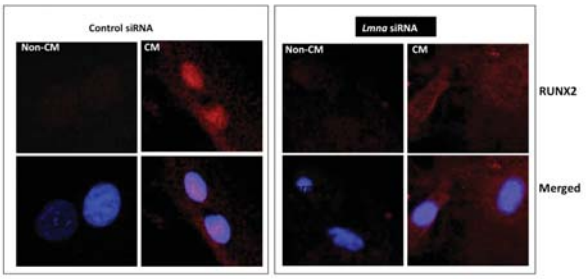
A New Role for Lamin A in the Process of Vascular Calcification

Pablo Roman-Garcia, Cristina Alonso-Montes, Isabel Quiros-Gonzalez, Sara Barrio-Vazquez, Manuel Naves, Natalia Carrillo-Lopez, Jose L. Fernandez-Martin, Jorge B. Cannata-Andia. *Bone and Mineral Research Unit, HUCA, IRSIN-FRIAT, RedInRen, Uniovi, Oviedo, Asturias, Spain.*

Background: Hyperphosphatemia, one of the main components of the CKD-MBD, and defects in the proccesing of Lamin A have been associated with vascular calcification (VC) and accelerated ageing. Thus, the aim of this "*in vivo and in vitro*" study was to investigate the role of Lamin A in the VC promoted by phosphate load.

Methods: A rat model of CKD-MBD was used. *In vivo* VC and protein expression were analized by von Kossa and 2D-DIGE, respectively. Primary rat vascular smooth muscle cells (VSMCs) were exposed to control or calcifying media (CM). In vitro VC was determined by calcium content and alizarin red. qPCR, western blot and immunoprecipitation (IP) were performed according to standard protocols. Knockdown of Lmna was performed in A7r5 VSMC line, using siRNA. Nuclear morphology and IF were assessed using FITC secondary antibodies.

Results: Rats with VC showed a 2.4-fold increase in Lamin A. VSMCs cultured in CM showed positive alizarin red staining, significant increases in calcium content (60%), Runx2 gene expression (2.3 fold), Lamin A protein levels (1.8 fold) and nuclear deformities (43%) compared to control. Knockdown of Lamin A prevented the increase of Runx2, Ostepontin, and Osteocalcin, preventing VSMC calcification. Co-IP showed that Runx2-Lamin A interaction increased in calcifying VSMCs. IF showed that the prevention in mineralization may be due to Runx2 down-regulation and impairment in its translocation to the nucleus



Conclusions: These results suggest that in VC there is an increase of Lamin A, osteogenic markers and nuclear shape abnormalities and the Runx2 recruitment to the nucleus is associated to the increase in Lamin A. Taken together, these results suggest that the nuclear envelope biology may play a role in VC, trough facilitating the role of Runx2.

FR-PO829

Characterisation of the Vitamin D Hormonal System in Healthy and CKD Artery

Thomas F. Hiemstra,[2] Maria (Maja) Anna Lubczanska,[1] Guerman Molostvov,[1] Rosemary Bland,[1] Daniel Zehnder.[1] *[1]Warwick Medical School, Univ of Warwick, United Kingdom; [2]Univ of Cambridge, United Kingdom; [3]Univ Hospital Coventry and Warwickshire, United Kingdom.*

Background: Vitamin D deficiency is associated with increased cardiovascular (CV) risk in the general population and in CKD, although the precise mechanisms remain unclear. We characterised arterial expression, activity and response to VDRa of the vitamin D signaling system in human aortic smooth muscle cells (HAoSMC), and healthy and CKD artery.

Methods: Artery biopsies were obtained from patients with normal renal function (n=9) or CKD (n=9). Gene expression for the VDR, 1a-hydroxylase (CYP27B1), 24-hydroxylase (CYP24A1), osteocytic markers RUNX2 and osteocalcin, and matrix metalloproteinases (MMPs) were explored by PCR, and protein expression by Western blot and immunohistochemistry. Artery rings were cultured with the VDRa's calcitriol or paricalcitol, and calcitriol synthesis measured by EIA.

Results: VDR, CYP27B1 and CYP24A1 were expressed in HAoSMC and healthy artery, and HAoSMC synthesized calcitriol when exposed to 25-hydroxyvitamin D. In CKD arteries, basal VDR and CYP27B1 protein expression was reduced and CYP24A1 increased by immunohistochemistry. Congruently, calcitriol synthesis was lower from tissue lysates (4 versus 8 pmol/mg/h, p=0.058) and culture supernatant (13 versus 29 pmol/mg/h, p=0.004) of cultured CKD arteries. Exposure of normal or CKD artery to 10nM calcitriol resulted in increased VDR mRNA expression without altering CYP27B1. However in CKD arteries, calcitriol induced a > 1,000 fold increase in CYP24A1 expression compared to control. Incubation with calcitriol or paricalcitol increased basal VDR and CYP24A1 expression but, in CKD arteries, VDR induction was attenuated, CYP27B1 reduced, and CYP24A1 greatly increased ($p<0.01$). Further, VDRa exposure induced RUNX2, osteocalcin and MMP2/9 in CKD arteries (calcitriol > paricalcitol) but not control.

Conclusions: Human arteries express all components of the vitamin D signaling system and synthesize calcitriol. In CKD, the normal response to VDRa is perturbed, notably with marked CYP24A1 induction and increased expression of markers of osteogenic transformation.

FR-PO830

Cholesterol Sensor SCAP Mediates Phosphate Induced Vascular Calcification via Lipid Independent Pathway

Chao Zhou,[1,3,4] Nan Ouyang,[2,3] Han Lei,[1,4] Zac Varghese,[3] Xiong Z. Ruan.[2,3,4] *[1]Dept of Cardiology, The First Affiliated Hospital of Chongqing Medical Univ, Chongqing, China; [2]Dept of Nephrology, The First Affiliated Hospital of Chongqing Medical Univ, Chongqing, China; [3]John Moorhead Research Laboratory, Centre for Nephrology, Univ College London (UCL) Medical School, Royal Free Campus, London, United Kingdom; [4]Centre for Lipid Research, Key Laboratory of Metabolism on Lipid and Glucose, Chongqing Medical Univ, Chongqing, China.*

Background: Dyslipidemia is one of the risk factors contributing to vascular calcification in CKD patients. However, the metabolism by which lipids interact with mineral metabolism remains unknown. We propose that Sterol Regulatory Element Binding Protein (SREBP) Cleavage Activating Protein (SCAP), a central controller of lipid metabolism, plays a role in vascular calcification.

Methods: Calcium deposition in human primary culture of vascular smooth muscle cells (VSMCs) was analyzed by Alizarin Red S staining and quantititive assay. The expression of the related genes and proteins were analyzed by Real-time RT-PCR, Western Blotting, Confocal microscope and Flow Cytometer. Cell proliferation, migration and apoptosis were monitored by cell cycles analysis, scratch-wound and TUNEL assay.

Results: We demonstrated that phosphate stimulated the expression of SCAP in a dose dependent manner in VSMCs. We established a VSMCs calcification model in vitro, in which SCAP expression was positively associated with the expression of osteogenic marker cbfa1. Over-expression SCAP in VSMCs led to more calcium deposition, accompanying with an increased matrix vehicle (MV) secretion, up-regulation of cbfa1, BSP and ALP while VSMCs maker a-SMA was down-regulated. These effects were blocked by knocking down SCAP using siRNA. Further, SCAP induced calcification was not affected by knocking-down SREBP2, a SCAP target gene for lipid homeostasis, suggesting that the enhanced vascular calcification by SCAP is via a lipid independent pathway.

Conclusions: Our data strongly suggest that SCAP is a novel mediator of phosphate induced vascular calcification, and its pro-calcification effect is independent of its traditional regulatory function in lipid metabolism.

Spironolactone Prevents the Upregulation of Pit1 and Vascular Calcification in Experimental CKD

Victor Manuel Barrientos,[1,2] Magdalena Gonzalez,[1,2] Luis F. Michea.[1,2] *[1]CEMC, U de Chile; [2]Millennium Inst on Immunology and Immunotherapy, ICBM, Facultad de Medicina, U of Chile, Chile.*

Background: Vascular calcification (VC) is a major risk factor for mortality in end stage renal disease and correlates with hyperphosphatemia. Phosphate-dependent mineralization of vascular smooth muscle cells (VSMC) depends on the upregulation of the Na-dependent phosphate cotransporter Pit1 and osteochondrogenic (OC) factors that mediate transdifferentiation. Mineralocorticoid receptor (MR) pharmacological blockers ameliorate experimental atherosclerosis and vascular calcification in klotho null mice. We hypothesize that vascular MR activation contributes to upregulation of Pit1, osteoblastic differentiation and calcification of VSMC.

Methods: 5/6 nephrectomy (NPX) rats under high phosphate diet (HP;1.2%) or HP plus vitamin D (VD;80ng/kg/day) or vehicle were given spironolactone (Spiro) (15mg/kg/day) in the food. Sham-operated rats in HP diet were controls. After 5 weeks, we performed biochemical analysis (blood, urine), calcification, Pit1 upregulation and OC factors in aorta. In Aortic VSMC (A7r5) we tested if Spiro prevented 2.5mM HP7-induced calcification.

Results: Aortic sections from NPX+HP rats showed granular calcification in the media and NPX+HP+VD rats presented large areas of calcification that was prevented by Spiro. Measurement of aortic tissue calcium content in all groups confirmed that Spiro treatment prevented calcification. VC was associated with upregulation of Pit1, cbfa-1 and Sox-9 transcripts. Genes potentially involved in VC were also upregulated (TNF-alpha, Nox-1 and Nox-4 (n=5;$P<0.05$;SH *versus* NPX-HP (VD)). Spiro prevented upregulation of all these genes (n=$P<0.05$;NPX+HP (VD) *versus* NPX+HP (VD) +Spiro). Finally, HP caused calcification (Alizarin Red) on VSMC, concomitant with the upregulation of Pit1, cbfa-1,

Sox-9 and Nox-1 (n=4;P<0.05). The treatment with aldosterone 100nM+HP increased the calcium deposition and the abundance of all these transcripts. Spiro (10uM) prevented calcium deposition and gene induction.

Conclusions: We conclude that vascular activation of MR contributed to upregulation of Pit1 *in vivo* and *in vitro* in CKD conditions. Supported: CONICYT/FONDECYT/Regular/ Nº1130550, IMII P09-016-F.

Warfarin Accelerates Uremic Vascular Calcification, From Clinical to Bench Szu-Yuan Li,[1] Jia-Sin Liu,[2] Chih-Cheng Hsu,[2] Der-Cherng Tarng,[1] Chih-Ching Lin,[1] Wu-Chang Yang,[1] Chi-Ting Huang.[2] *[1]Nephrology, Taipei veterans General Hospital, Taiwan; [2]Inst of Population Health Sciences, National Health Research Insts, Taiwan.*

Background: Mesenchymal stem cells differentiate to adipocytes, osteoblasts, chondrocytes and vascular smooth muscle cell (VSMC), in the setting of kidney disease, these VSMC can transform into osteocyte-like cells by upregulation of transcription factors such as RUNX-2 and MSX2. These transcription factors are critical for normal bone development and thus their upregulation in VSMC is indicative of a phenotypic switch. These osteoblast-like VSMC then become calcified in a process similar to bone formation. There are several locally expressed calcification inhibitors; including Matrix Gla protein (MGP), osteopontin, and pyrophosphate protect vascular system from calcification. (Fig 1) MGP is a Vit-K dependent protein, and its role in vascular biology is just beginning to be understood. Unlike the coagulation factors, which undergo hepatic carboxylation, MGP is carboxylated within the vasculature. This peripheral carboxylation process is distinct from hepatic carboxylation, yet both are inhibited by warfarin.

Methods: We used Taiwan National Health Insurance database to conduct a propensity score- matched cohort to analyzed the CV effects of warfarin in dialysis atrial fibrillation (Af) patients. *In vitro* experiments was used to explore mechanism; and micro-CT scan was used to follow up series vascular changes in uremic animals with or without warfarin.

Results: In dialysis-Af patients, warfarin administration was associated with a higher risk of developing CHF (HR 1.51, p<0.05) and PAOD (HR 2.43, p <0.01). Warfarin accelerates VSMC transform to osteocyte-like cells, (Fig 2) and warfarin accelerates aorta calcification in uremic animal model. (Fig 3)

Conclusions: Warfarin is able to promote uremic vascular calcification and may be harmful to dialysis population.

FR-PO833

Calcifying Matrix Vesicles (MV) Derived From Vascular Smooth Muscle Cells (VSMC) Exposed to High Phosphorus Can Induce Calcification and Upregulate Gene Expression in Neighboring VSMC Kalisha O'Neill,[1] Sharon M. Moe,[1,2] Shannon Roy,[1] Neal X. Chen.[1] *[1]Indiana Unviersity School of Medicine; [2]Roudebush VAMC, Indianapolis.*

Background: Hyperphosphatemia is associated with arterial calcification in patients with CKD and incubating VSMC with high phosphorus induces the production of calcifying MV. We tested the hypothesis that calcifying MV may play a role in cell to cell communication as a mechanism to propagate calcification.

Methods: We compared MV from VSMC incubated with high phosphorus (calcifying MV) to MV from VSMC incubated with normal phosphorus (control MV). We utilized bovine VSMC and compared VSMC from normal and CKD rats, the latter a model of CKD-MBD that spontaneously develops arterial calcification. MV were co-cultured with VSMC to assess the change in calcification and expression of osteoblast genes in VSMC determined by qPCR. MV miRNA expression was analyzed by qPCR, and MV endocytosis was examined by confocal microscopy using the fluorescent dye PKH-26.

Results: Calcifying MV induces a 3 fold increase in mineralization of a cell free collagen matrix compared to control MV, regardless of whether they were isolated from VSMC from bovine, CKD or Normal rats. The addition of rat or bovine calcifying MV to rat or bovine VSMC accelerated calcification of each VSMC compared to control MV. Compared to control MV, calcifying bovine MV induced the expression of RUNX2 and transglutaminase 2 in BVSMC when co-cultured. To determine if these differences were due to altered cellular uptake, we analyzed the uptake of both calcified and control MV in VSMC by confocal live cell imaging. Both forms of MV were similarly endocytosed, indicating that it was the content, not the uptake of MV that triggered gene expression. To understand the mechanism of triggered gene expression, we compared the miRNA content of calcifying versus control MV and found differences in multiple miRNAs thought to control expression of genes known to be involved in calcification.

Conclusions: Calcifying MV isolated from VSMC exposed to high phosphorus are endocytosed and can modify the gene expression and calcification potential of adjacent VSMC. Transfer of miRNA may be one mechanism by which this occurs.

FR-PO834

Ca Load Induces Vascular Smooth Muscle Cell Mineralization Partly Mediated by TRPV Masahide Mizobuchi,[1] Takashi Inoue,[1] Hiroaki Ogata,[2] Fumihiko Koiwa,[3] Tadao Akizawa,[1] Takanori Shibata.[1] *[1]Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine; [2]Dept of Internal Medicine, Showa Univ Northern Yokohama Hospital; [3]Div of Nephrology, Dept of Medicine, Showa Univ Fujigaoka Hospital.*

Background: Vascular calcification has been shown to be a complicated process including the transformation of vascular smooth muscle cells (VSMCs) into osteoblastic-like cells, apoptosis, elastin degradation, and loss of vascular calcification inhibitors. Although hypercalcemia, as well as hyperphosphatemia, is a risk factor for vascular calcification, little is known about the involvement of calcium (Ca) in the process of vascular calcification. We studied the effect of Ca load on VSMC mineralization.

Methods: Human aortic VSMCs were incubated in a low Ca media (0.4 mM: LCa), normal Ca media (1.8 mM: NCa), and a high Ca media (5.0 mM: HCa). All the media had normal phosphate concentration (0.8mM). VSMC mineralization, and gene expression of markers for osteogenic process and a Ca channel (transient receptor potential vanilloid-2: TRPV-2) was determined by real-time RT-PCR. RNA interference for TRPV-2 was performed to study the effect of TRPV2 on the mineralization.

Results: VSMC mineralization was induced in a dose dependent manner (P <0.05: LCa versus MCa, P<0.05: MCa versus HCa) with the induction of an osteogenic process which was confirmed by the increase in Runx2 mRNA and ALP mRNA expression (P<0.05: LCa versus HCa). In parallel with the osteogenic process, we confirmed the up-regulation of a Ca channel, TRPV-2 in the HCa (P<0.05: LCa versus HCa). When TRPV-2 mRNA in VSMC was knocked-down by RNA interference, the mineralization was significantly suppressed in the high Ca media (P<0.05).

Conclusions: These results suggest that Ca load induced VSMC mineralization which is partly mediated by TRPV2. The mineralization is induced in normal phosphate concentration. Thus in addition to phosphate, Ca load is a considerable factor for the process of VSMC mineralization. The precise mechanism by which Ca load induces VSMC mineralization is under investigation.

FR-PO835

Role of RAGE Signalling in Uremic Vascular Calcification Process Fatouma Toure,[1] Karim Belmokhtar,[1] Jeremy Ortillon,[1] Stephane Jaisson,[1] Agnes Boullier,[2] Jean-Marc Chillon,[2] Marie Daniele Diebold,[1] Guenter Fritz,[3] Philippe Gillery,[1] Ann Marie Schmidt,[4] Ziad Massy,[2] Philippe Rieu.[1] *[1]CNRS UMR URCA 7369 and CHU, Reims, France; [2]INSERM U1088, Amiens, France; [3]Univ of Frieburg, Frieburg, Germany; [4]Diabetes Research Program, NYU, New York.*

Background: ESRD is associated with increased cardiovascular morbi-mortality related to increased vascular calcification process. The receptor for advanced glycation end products (RAGE) is an ubiquitous, pro-inflammatory receptor involved in vascular remodelling during diabetes but the role of RAGE signalling in uremia induced vascular calcifications has not been extensively studied.

Methods: Uremia was induced in 8 weeks ApoE-/- mice. Control group was ApoE-/- sham operated animals. Serum and aortas were collected in both groups after 12 weeks of uremia for measurement of RAGE ligand (Carboxymethyllysine, CML) using LC/MS/MS and quantification of RAGE expression by qRT-PCR. Primary cultures of Vascular smooth muscle cells (VSMC) were established from aortas of WT or RAGE deficient mice. Inorganic Phosphate (Pi) and RAGE ligands (CML and S100A12) were used to study in vitro calcification processes including i) quantification of calcifications ii) mRNA and protein expression of cellular markers of osteodifferenciation (Runx2, BMP2, collagen1) iii) analysis of apoptosis.

Results: After 12 weeks of uremia, CML concentration was significantly increased in serum and aortas of uremic animals compared to non uremic controls. RAGE expression was also significantly increased in the aortas of uremic mice. In vitro stimulation of WT VSMC with RAGE ligands, induced the formation of calcifications, osteogenic transformation of the cells, and increased apoptosis. These processes were significantly inhibited in RAGE deficient VSMC. RAGE deletion was also protective against Pi induced vascular calcification processes. In vivo confirmation of these pathways in ApoE-/- RAGE-/- mice is in progress.

Conclusions: Uremia increases RAGE and RAGE ligands expression in the aortic wall. RAGE signalling induces VSMC dependant mineralization processes initiated not only by RAGE ligands but also by Pi. Therefore, RAGE may play a central role in the pathogenesis of uremic vasculopathy.

FR-PO836

Uremic Serum Induces Calcification in Human Aortic Smooth Muscle Cells Violeta Cazaña,[1] Teresa Giráldez,[2] Carmen Mora,[1] Mercedes Muros de Fuentes,[3] Ernesto Martín,[1] Javier Donate,[1] Juan F. Navarro-Gonzalez.[1,4] *[1]Research Unit, Univ Hospital Nuestra Señora de Candelaria (HUNSC), Tenerife, Spain; [2]Physiology, Univ of La Laguna, Tenerife, Spain; [3]Clinical Biochemistry, HUNSC, Tenerife, Spain; [4]Nephrology, HUNSC, Tenerife, Spain.*

Background: Uremic patients have a significant vascular damage characterized by artery calcification. It has been reported that uremic serum induces expression of key proteins in the osteogenic transformation of vascular smooth muscle cells. The aim of the study is to characterize the calcification process in a human *in vitro* model of smooth muscle cells of the vessel wall under conditions of uremia.

Methods: Primary human aortic smooth muscle cells (HASMC) were cultured in medium supplemented with pooled sera (20%) from either healthy or dialysis patients. Cells cultured in medium supplemented with 2.5mMP_i+2mMCa (P_i-Ca) were used as positive controls. After 2, 3, 5, 7 and 10 days, calcification was identified by Alizarin red staining, and alkaline phosphatase (ALP) activity was quantified. The expression of the phosphate transporter Pit-1, Transgelin (TAGLN), transcription factor RUNX2 and ALP was evaluated by qPCR.

Results: For each day of the assay, HASMC incubated with uremic serum showed significant calcium deposits compared to pooled control serum, with the appearance of abundant mineralized nodules. The addition of uremic serum to HASMC culture increased significantly the activity and the expression of ALP compared to cells cultured with Pi-Ca. Exposure of HASMC to growth media containing uremic serum did not cause a significant upregulation of RUNX2 compared with HASCM in medium with P_i-Ca. However, cells treated with Pi-Ca had an increased expression of Pit-1 compared to uremic serum, and a reduceed expression of TAGLN (a specific smooth muscle gene that is lost in the process of phenotypic modulation).

Conclusions: Uremic serum induces HASMC calcification and increased expression of alkaline phosphatase activity, even in the presence of lower P concentrations (<0.5 mmol/L). However, an increased expression of Pit-1 and RUNX2 was not observed, as compared to Pi-Ca-stimulated cells, suggesting a different mechanism from that of hyperphosphatemia-induced calcification.

FR-PO837

The Direct Inhibitory Effect of Etidronate Disodium Hydrate on Progression of Phosphate-Induced Calcification in Human Vascular Smooth Muscle Cells Masanori Tokumoto,[1] Shunsuke Yamada,[1,2] Tomoe Fujino,[1] Kazuhiko Tsuruya,[3] Takanari Kitazono,[2] Hiroaki Ooboshi.[1] *[1]Div of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [2]Dept of Medicine & Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Vascular calcification is a life-threatening pathophysiological abnormality, especially in chronic kidney disease (CKD). The main contribution factor for vascular calcification is phosphate (P), but it is difficult to control P retention completely in CKD. Therefore, we examined direct effects of etidronate disodium hydrate (EDH), a bisphosphonate, on P-induced calcification in vascular smooth muscle cells (VSMCs).

Methods: In experiment 1, human VSMCs were cultured in medium containing 2.9mM P with 0, 1, 5, or 10mM EDH for one or two weeks. In experiment 2, following one week incubation with 2.9mM P, human VSMCs were treated with 0, 1, 5, or 10mM EDH in medium containing 0.9 or 2.9mM P. The precipitated calcium contents were evaluated.

Results: 5 or 10mM EDH inhibited P-induced calcification completely for a week and by about 70 or 100% for two weeks, and 1mM EDH decreased by about 50% for a week ($p<0.01$), but did not for two weeks. Even after the culture with 2.9mM P medium for a week, 10mM EDH treatment completely suppressed the progression of P-induced calcification, but 5mM EDH reduced the progression by only 20% ($p<0.01$), and 1mM EDH did not. The elimination of excess P load without EDH decreased the progression of calcification by about 80% ($p<0.01$), and the addition of 1mM EDH did not have an additional effect. However, 5 or 10mM EDH administration without excess P load completely stopped further calcification ($p<0.01$).

Conclusions: The therapy with EDH, a bisphosphonate, can directly inhibit initiation as well as progression of P-induced calcification in human VSMCs.

FR-PO838

Inhibition of Matrix Metalloproteinases Attenuates the Calcification of Vascular Smooth Muscle Cells Uwe Querfeld,[1,2] Nadja Kretzschmar,[1] Eva Hecht,[1] Christian Freise.[1] *[1]Pediatric Nephrology, Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Center for Cardiovascular Research, Charité Universitätsmedizin Berlin, Berlin, Germany.*

Background: Vascular calcification involves transition of contractile vascular smooth muscle cells (VSMCs) into an osteoblast-like phenotype as part of a coordinated process of vascular remodeling resembling bone mineralization. Matrix metalloproteinases (MMPs) have important physiological roles in bone and vascular tissue remodeling. We performed in-vitro studies to characterize the individual contributions of the gelatinases MMP-2 and MMP-9 to the process of VSMC calcification.

Methods: VSMC (murine MOVAS-1) calcification was induced by incubation with a calcification medium (CM) containing elevated levels of calcium (2.7 mM) and phosphorous (2.8 mM). Calcification was quantified by calcium measurements (o-cresolphtalein method) and by alizarin-red staining. MMP activities were determined by specific substrate assays.

Results: After 9 days, CM-treated VSMC cultures exhibited distinct calcifications, which were further enhanced by the presence of recombinant MMP-2 or MMP-9 (~1.6-fold and ~2.2-fold, respectively) and accompanied by enhanced secretion of both gelatinases by VSMC. Vice versa, incubation with a specific inhibitor of MMP-2 or MMP-9 or the selective (for both gelatinases) inhibitor Ro28-2653, respectively, significantly decreased VSMC calcifications. Addition of the MMP-inhibitors decreased total gelatinolytic activity in VSMC supernatants, indicating a (negative) feedback loop for the secretion of the gelatinases under these conditions. Selective knockdown of MMP-2 and MMP-9 mRNA expression in the VSMC provoked reduced calcifications of the CM-treated cells.

Conclusions: Inhibition of enzymatic activity of MMP-2/-9 and transient knockdown of mRNA expressions prevented calcification of VSMC while addition of recombinant MMPs enhanced VSMC calcifications. Thus, both gelatinases provide extracellular calcification signals, and their effect is mainly due to their enzymatic activity, as indicated by the effect of inhibitors. Inhibition of arterial MMP-2/-9 may be a therapeutic target for the prevention of vascular calcifications (in CKD).

FR-PO839

Association between Epicardial Adipose Tissue and Vascular Calcification in Hemodialysis Patients Xoana Barros,[2] Nadine Kaesler,[1] Thilo Krueger,[1] Markus Ketteler,[3] Jürgen Floege,[1] Vincent Brandenburg.[1] *[1]Uniklinikum RWTH Aachen, Germany; [2]Hospital Clinic Barcelona, Spain; [3]Klinikum Coburg, Germany.*

Background: Epicardial adipose tisse (EAT) is associated with coronary artery calcification (CAC) and atherosclerosis in the general population. EAT is thought to trigger coronary artery disease by paracrine mechanisms. Recently it was speculated that large amounts of EAT may predict mortality in incident HD patients. Our aim was to assess the potential association of EAT with vascular calcification (VC) in chronic HD patients and compare for the first time the progression of EAT and VC over time.

Methods: Prospective study of 59 chronic HD pts (59±15 yrs; 49% male, 25% DM, HD vintage 57±55 m) who underwent non-enhanced multi-slice computed tomography (CT) at baseline; 37 pts repeated CTs after 24±5 m. Two radiologists assessed independently EAT, CAC and aortic valve calcification (AVC). EAT was presented as volume and CAC and AVC as Agatston scores. 30 healthy volunteers without VC and without CKD served as controls for EAT.

Results: Baseline EAT was 128±61 cm≥ and significantly higher than in the control group (94±46 cm≥; $p<0.05$). Median CAC was 329 (IQR 23-1181, prev 90%) and AVC was 0 (IQR 0-25.3, prev 37%). No significant differences were detected in EAT between genders or diabetics versus non-diabetics. There was a significant positive correlation between baseline EAT and age ($r=0.386$; $p=0.003$), BMI ($r=0.314$; $p=0.016$), CAC ($r=0.278$; $p=0.03$), and AVC ($r=0.282$; $p=0.03$). No correlation between EAT and biochemistry (fetuin-A, adiponectin, C-peptide, phosphate, CRP, Hb, PTH) was detected. During follow-up the amount of CAC significantly increased (annual change +19% (IQR 2-35%), Wilcoxon paired test, $p<0.005$). In contrast, the change of EAT was not significant (EAT at follow-up 133±57 cm≥, t-paired test, $p=0.066$). 35% of pts showed regression of EAT.

Conclusions: EAT correlated significantly with CAC and AVC in chronic HD patients. Rapid and homogeneous progression on CAC contrasts with EAT development over 2 years, where a third of the patients exhibited EAT regression. Larger studies need to assess a potential causality between EAT and VC as well as the EAT effects on the high cardiovascular risk in ESRD.

FR-PO840

Pulse Wave Velocity Is Superior Over Ankle Brachial Index for Screening Vascular Calcification in Hemdialysis Patients Daqing Hong, Li Wang. *Renal Dept, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Vascular calcification is prevalent in hemodialysis patients, accounting for an inevitable impact on patient survival. Pulse wave velocity (PWV) and ankle brachial index (ABI) was reported to be associated with vascular calcification, while no studies focused on the relationship between PWV or ABI and different vascular calcification. The objective of this study is to compare the difference of PWV and ABI for screening vascular calcification.

Methods: 118 hemodialysis patients were enrolled. Coronary artery CT and radiographs of lateral abdominal, pelvis, and hands were measured to evaluate vascular calcification of different arteries. PWV and ABI was measured as a screening method. ROC curves was used to analyze the relationship between PWV or ABI and vascular calcification by CT or X-ray radiographs.

Results: PWV was positively associated with coronary artery score and X-ray vascular calcification score ($P<0.05$). ROC curves showed an AUC>0.5 for PWV and an AUC<0.5 for ABI in diagnosis of different artery calcification.

Conclusions: Pulse wave velocity is superior over ankle brachial index for screening vascular calcification in different anatomical regions.

FR-PO841

Accelerated Progression of Vascular Calcification in Children with CKD Is Associated with Fetuin-A Levels and Vessel Characteristics

Rukshana Shroff,[1] John E. Deanfield,[2] Melanie Hiorns,[1] Catherine Shanahan,[3] Lesley Rees.[1] *[1]Great Ormond Street Hospital for Children, United Kingdom; [2]Vascular Physiology Unit, Inst of Child Health, United Kingdom; [3]King's College London, United Kingdom.*

Background: Vascular calcification is thought to begin early in CKD and progress rapidly on dialysis. We obtained arterial biopsy samples to determine a quantitative and histological assessment of the vessel calcium load and compared this with longitudinal changes in the vessels by imaging studies.

Methods: 48 children (13 CKD4-5, 28 dialysis and 7 failed transplants) had vascular imaging (carotid intima-media thickness [cIMT], pulse wave velocity [PWV] and coronary artery calcification [CAC] on CT scan), biomarker analyses and an arterial biopsy (at the time of renal transplantation or PD catheter insertion). The Ca load in the vessel wall was quantitated and histology for hydroxyapatite deposition, vascular smooth muscle cell apoptosis and osteogenic differentiation was performed. 41 children (20 dialysis and 21 transplants) had a second set of imaging after 14.2 ±3.9 months.

Results: The baseline vessel Ca load strongly correlated with cIMT in dialysis patients ($p=0.005$) whereas 11 of 16 pre-dialysis patients had normal cIMT. Dialysis patients had a significant annualised increase in cIMT and PWV standard deviation scores ($p<0.005$ and $p=0.03$). CAC increased in 5 children with baseline CAC and was found in 3 others. cIMT progression showed a close correlation with the vessel Ca load ($p=0.002$, $r^2=0.33$). Patients with cIMT progression had the highest apoptotic index implying vascular smooth muscle cell loss and greater osteogenic differentiation. The baseline cIMT ($r=0.31$) and Fetuin-A levels ($r=0.41$), but not FGF-23, soluble klotho or 25-hydroxyvitamin D associated with cIMT progression. Changes in PWV and CAC did not correlate with vessel Ca load.

Conclusions: In children on dialysis vascular calcification is rapidly progressive and strongly correlates with baseline vessel wall characteristics and Fetuin-A levels. No association was found between vascular measures and FGF-23 or soluble klotho levels. Fetuin-A may be a useful biomarker to predict rapid progression of vascular calcification in CKD.

FR-PO842

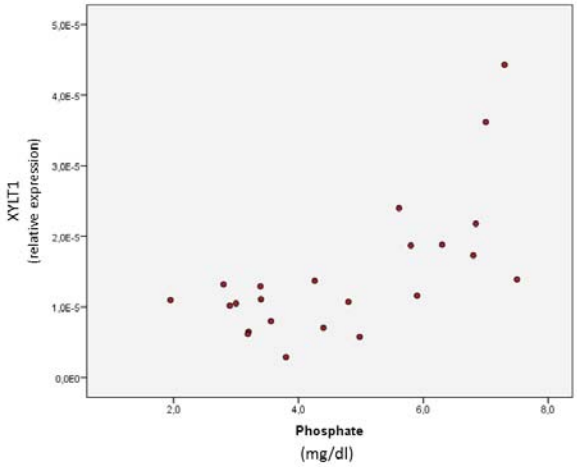
Expression of Xyloslytransferase (XYLT1) in Human Arteries Is Correlated with Serum Phosphate

Michael Fischereder,[1] Ulf Schoenermarck,[1] Antje Habicht,[3] Peter J. Nelson,[1] Manfred J. Stangl.[2] *[1]Renal Div, Medizinische Klinik IV, Klinikum der LMU, Munich, Germany; [2]Dept of Surgery - Grosshadern, Klinikum der LMU, Munich, Germany; [3]Transplant Center, Klinikum der LMU, Munich, Germany.*

Background: We have previously shown that inter-individual and highly variable tissue concentrations of sodium can be found in human arteries. There is evidence suggesting that this high variability is due to osmotically inactive sodium, bound to glycosaminoglycans. Glycosaminoglycan synthesis is initiated by XYLT1 which correlates with tissue sodium concentrations. We now sought to better characterize this regulation of XYLT1 expression in human arteries.

Methods: We studied 27 patients on dialysis. 21 live kidney donors served as healthy controls. All patients were free of clinically detectable edema. During transplant surgery, abdominal muscle and arteries were biopsied. Expression of XYLT-1 and Na-K-ATPase1 were determined in arterial tissue by real-time PCR (n=31), standardized to s18 RNA and correlated with clinical data.

Results: On univariate analysis, XYLT1 expression in human arteries was significantly correlated with serum sodium ($r = 0.456$; $p = 0.022$), calculated serum osmolality ($r = 0.558$; $p = 0.004$), serum phosphate ($r = 0.664$; $p = 0.001$), serum bicarbonate ($r = -0.523$; $p = 0.031$), and arterial Na-K-ATPase1 expression ($r = 0.459$; $p = 0.021$). On multivariate analysis, XYL1 expression was significantly correlated with serum phosphate ($p = 0.004$).



Conclusions: XYLT1 expression in human arteries is correlated with serum phosphate concentrations. This may form a pathophysiologic basis for the development of arteriolopathy in patients with hyperphosphatemia, e.g. in advanced renal failure.

A Newly Developed Chronic Kidney Disease–Mineral-Bone Disorder Rat Model

Hideki Fujii,[1] Yuriko Yonekura,[1] Kentaro Nakai,[1] Keiji Kono,[1] Shunsuke Goto,[1] Masami Shinohara,[2] Shinichi Nishi.[1] *[1]Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan; [2]Planning and Development Section, CLEA Japan, Inc., Tokyo, Japan; [3]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan.*

Background: Chronic kidney disease–mineral bone disorder (CKD-MBD) is associated with all-cause and cardiovascular mortality in CKD patients. Thus, elucidating its pathophysiological mechanism is essential for improving morbidity and mortality of these patients. In this study, we investigated CKD-MBD using a newly developed rat model.

Methods: In the present study, we used male Sprague Dawley (SD) rats and Spontaneously Diabetic Torii (SDT) rats, which are and non-obese rat models with type 2 diabetes. CKD was induced by 5/6 nephrectomy (Nx). At 10 weeks, they were classified into seven groups and were administered vehicle (V), low-dose paricalcitol (LP, 0.1 mg/kg), and high-dose paricalcitol (HP, 0.3 mg/kg) three times a week, except in the control group (the control, SD-Nx+V, SDT-Nx+V, SD-Nx+LP, SDT-Nx+LP, SD-Nx+HP, and SDT-Nx+HP group). At 20 weeks, the rats were sacrificed and urinary and blood biochemical analyses and histological analysis of the aorta were performed in all the groups.

Results: At 20 weeks, there were no significant differences in HbA1c levels, blood pressure, and renal function among the six groups, except the control group. Despite comparable doses of paricalitol, serum calcium and phosphate levels and the urinary excretion of calcium and phosphate were higher in the SDT rats compared with the SD rats. Serum PTH levels were decreased and serum FGF23 levels were elevated after administering paricalcitol in both groups of rats; however, serum PTH and FGF23 levels were higher in the SDT rats compared with the SD rats. Further histological and biochemical analyses revealed that the degree of vascular calcification of the aorta was more severe and the calcium content of the aorta was also higher in the SDT rats compared with the SD rats.

Conclusions: Our study suggested that CKD-MBD of 5/6 nephrectomized SDT rats was greatly influenced by vitamin D. Thus, this can be a suitable CKD-MBD model to examine the pathophysiology of CKD-MBD.

FR-PO844

Vitamin D Influences Drug Metabolism and Transport Pathways in Human Kidney Cells

Georgia Charkoftaki,[1] Amandla Roque Atilano,[1] Lucas Ellison,[1] Thomas D. Nolin,[2] Melanie S. Joy.[1,3] *[1]School of Pharmacy, Univ of Colorado, Aurora, CO; [2]School of Pharmacy, Univ of Pittsburgh, Pittsburgh, PA; [3]School of Medicine Nephrology, Univ of Colorado, Aurora, CO.*

Background: Despite vitamin D (VitD) deficiency and subsequent treatment in chronic kidney disease (CKD), limited information is available to inform about potential drug interactions. The goal of the current study was to determine the influence of VitD on expression and function of drug metabolism and transport pathways.

Methods: Human proximal tubular epithelial cells (hPTCs;ScienCell) were grown to confluence in 100x20 mm/well plates and seeded at 5000 cells/cm^2. hPTCs were incubated for 6 days with cholecalciferol ($VitD_3$) or calcitriol ($1,25\ (OH)_2D_3$) 100nM and 240nM in 0.1% ethanol *versus* vehicle in the presence and absence of 10% uremic serum, followed by determination of gene/protein expression of drug transporters and enzymes. P-glycoprotein (P-gp) function was assessed in transwells with [^{3}H]Digoxin+VitD (100nM) *versus* vehicle for 3 and 6 days. CYP2R1 function was assessed by evaluating metabolic ratios (MRs) of 25-OH VitD to VitD in the presence and absence of uremic serum. Gene and protein expression were determined with RT-PCR, western blots, and/or immunofluorescence.

Results: Transporter gene expression was altered with VitD: P-gp/*ABCB1* increased with all treatments (317-347%), MRP2/*ABCC2* increased 15% with 100nM VitD, and MATE1/*SLC47A1* decreased up to 220% for all treatments. *CYP3A5* and *CYP2B6* expression

increased with all treatments. With uremic serum, P-gp/*ABCB1*, MRP2/*ABCC2*, OATP4C1/*SLC04C1*, *ALDH1A1* and *CYP2B6* increased and *CYP24A1* expression decreased. Protein expression was consistent with RT-PCR data. A 10% increase in basolateral to apical transport of [^{3}H]Digoxin *versus* vehicle was seen with VitD exposure. Decreased conversion of VitD to 25-OH VitD (MRs 0.002 *versus* 23.5) in the presence and absence of uremic serum, respectively was noted.

Conclusions: Exposure of hPTCs to VitD resulted in altered expression and function of metabolism enzymes and transporters. Uremia can further modulate the influence of VitD exposures. The extension of these data to other cell types and humans with CKD requires further study.

FR-PO845

Excess of 25-Hydroxyvitamin D Exacerbates Tubulointerstitial Fibrosis in Mice Yasuo Kusunoki,[1] Isao Matsui,[1] Takayuki Hamano,[2] Akihiro Shimomura,[1] Daisuke Mori,[1] Sayoko Yonemoto,[1] Yoshitsugu Obi,[1] Yoshiharu Tsubakihara,[2] Yoshitaka Isaka,[1] Hiromi Rakugi.[1] *[1]Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Comprehensive kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

Background: In most of the observational studies, both deficiency and excess of serum 25-hydroxyvitamin D (25 (OH) D), but not active vitamin D (1,25 (OH) $_2$D), are strongly associated with poor prognosis. Those results suggest that 25 (OH) D *per se* may have some direct biological effects.

Methods: Using unilateral ureteral obstruction (UUO) model, we examined the effects of 25 (OH) D on renal fibrosis. To exclude the effects of 1,25 (OH) $_2$D hydroxylated from 25 (OH) D, we used 25 (OH) D-1a-hydroxylase systemic knockout mice (CYP27B1 KO mice). Mice were randomly divided into three groups: group vehicle, moderate-25 (OH) D (6.25ng/gBW), and high-25 (OH) D (100ng/gBW). Vehicle or 25 (OH) D was injected three times a week prior to the UUO operation. Effects of 24,25 (OH) $_2$D, another metabolite of 25 (OH) D, were also analyzed in a similar way. To explore the underlying mechanisms how 25 (OH) D exerts its own effects, we analyzed the effects of 25 (OH) D on CYP27B1/VDR double KO mice and on macrophage-depleted CYP27B1 KO mice.

Results: Serum 25 (OH) D levels in group vehicle, moderate-25 (OH) D, and high-25 (OH) D, were 7.78±0.23, 38.45±5.67, and 334.54±47.10 ng/mL, respectively. Both histological analyses and real time PCR demonstrated that high-dose 25 (OH) D exacerbated tubulointerstitial fibrosis in CYP27B1 KO mice, while moderate-dose 25 (OH) D had no effect. Oxidative stress, assessed by gH2AX-staining and Western blotting for nitrotyrosine, was aggravated in group high-25 (OH) D. Because high-dose 24,25 (OH) $_2$D did not exacerbate tubulointerstitial fibrosis, it was suggested that 25 (OH) D *per se* has direct biological effects. The profibrotic effect of high-dose 25 (OH) D was not observed in CYP27B1/VDR double KO mice or macrophage-depleted CYP27B1 KO mice.

Conclusions: Excess of 25 (OH) D exacerbated tubulointerstitial fibrosis in a VDR-dependent manner. The aggravated oxidative stress in group high-25 (OH) D might be derived from phenotypic changes in kidney-infiltrating macrophages.

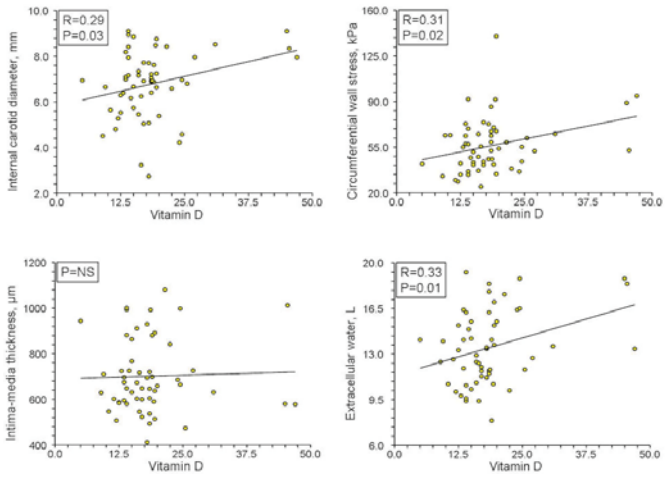
FR-PO846

Outward Vascular Remodeling and Hyperhydration Are Associated with Elevated Vitamin D Levels Paolo Lentini,[1] Luca Zanoli,[2] Massimo de Cal,[1] Stefania Rastelli,[2] Anna Basso,[1] Andrea Contestabile,[1] Antonio Granata,[3] Roberto Dell'Aquila.[1] *[1]Nephrology, S. Bassiano Hospital, Bassano Del Grappa, Italy; [2]Internal Medicine, Univ of Catania, Catania, Italy; [3]Nephrology, S.Giovanni di Dio Hospital, Agrigento, Italy.*

Background: Chronic inflammation,vascular calcification and fluid overload are common causes of cardiovascular events in hemodialysis [HD] patients [pts]. Compare to hypertensive pts, in which there is an inward remodeling (higher intima-media thickness (IMT) and higher internal carotid diameter [D]), outward carotid remodeling (unmodified IMT) is a common feature of CKD. Several studies reported that Vitamin D [VitD] might play a key role in endothelial dysfunction and in the atherosclerotic plaque structure; however, it is not clear whether in HD pts VitD levels may act the induction of vascular calcification. Echotracking system is the reference non-invasive technique to assess arterial structure and function, including IMT, an established independent predictor for future cardiovascular events, and D. Overhydration [OH] is a danger common feature among HD pts. AIM: To evaluate the link between VitD, arterial parameters and body composition in HD pts.

Methods: Arterial parameters were measured with a high-definition echotracking system paired with an high resolution (13 MHz) probe. Bioimpedance spectroscopy (BIS) was performed and overhydration (OH) and extracellular water (ECW) were used as volume indices.

Results: 60 HD pts were enrolled (age 64±16 yrs, males 55%). Elevated VitD levels were associated with outward vascular remodeling (with enlarged D but not with enlarged IMT). Consequently, higher the VitD, higher the circumferential wall stress.VitD was also positively associated with ECW and OH detected with BIS.



Conclusions: Elevated vitamin D levels may lead to outward vascular remodeling and OH: these alterations may be non-invasively detected with BIS and echotracking systems.

FR-PO847

Bioavailable 25 (OH) D Is a Better Predictor of PTH and eGFR than Total 25 (OH) D in CKD Patients Anders H. Berg,[1] Julia Beth Wenger,[2] Ishir Bhan,[2] Hector Tamez,[2] S. Ananth Karumanchi,[1] Ravi I. Thadhani.[2] *[1]BIDMC, Boston, MA; [2]MGH Nephrology, Boston, MA.*

Background: An inverse correlation between 25 (OH) D and parathyroid hormone (PTH) is reported in both the general and CKD population. However, the strength of this relationship is modest; hyperparatyhroidism is not universal among patients with low levels of total 25 (OH) D. We previously suggested that bioavailable vitamin D ($B_{av}D$) is a more appropriate measure of vitamin D status in the general population (NEJM 2013). We now examine this in patients with CKD.

Methods: From a previously completed randomized placebo controlled trial of patients with stage 3-4 CKD (PRIMO, JAMA 2012), we measured total 25 (OH) D, PTH, estimated glomerular filtration rate (eGFR), and calculated concentrations of $B_{av}D$ using genotype-specific binding affinity constants and circulating levels of vitamin D binding protein.

Results: In 64 CKD patients, median (Q1, Q3) levels of total 25 (OH) D and $B_{av}D$ were 28 ng/ml (20, 38) and 3.3 ng/ml (2.2, 5.4), respectively. $B_{av}D$ was significantly associated with PTH (r_s= -0.34, p=0.005) while total 25 (OH) D was not (r_s= -0.14, p=0.26). Similar associations were also found between $B_{av}D$, total 25 (OH) D, and eGFR ($B_{av}D$ r_s= 0.28, p=0.02; total 25 (OH) D r_s= 0.08, p=0.55). In multivariable linear regression models adjusting for age, corrected calcium, and eGFR, $B_{av}D$ remained a significant predictor of PTH (b= - 0.06, p=0.01) while total 25 (OH) D remained unrelated to PTH (b= - 0.006, p=0.23). Correlations strengthened further when the analysis was restricted to homozygous patients (in whom affinity constants could more accurately be determined).

Conclusions: Bioavailable Vitamin D may be a more appropriate measure of vitamin D status in patients with CKD. If confirmed, $B_{av}D$ measures in CKD may better direct supplemental inexpensive nutritional vitamin D to control PTH.

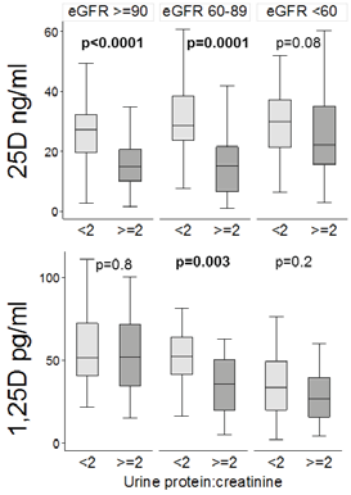
Vitamin D Metabolism in the Nephrotic Syndrome Study Network (NEPTUNE) Michelle Denburg,[1,2] Myles S. Wolf,[3] Ian H. de Boer,[4] Andrew N. Hoofnagle,[4] Samir Sayed,[1] L. Barisoni,[5] Lawrence B. Holzman,[2] Mary B. Leonard.[1,2] *[1]Children's Hospital of Philadelphia; [2]U. Pennsylvania; [3]Northwestern U.; [4]U. Washington; [5]U. Miami.*

Background: 25-hydroxy and 1,25-dihydroxyvitamin D (25D and 1,25D) circulate bound to vitamin D-binding protein (DBP) or albumin. Studies of vitamin D (VitD) in nephrotic patients are limited. We sought to determine correlates of VitD levels and the relative impact of nephrotic-range proteinuria (NRP) and GFR.

Methods: Plasma 25D, 1,25D, DBP, PTH, and FGF23 were measured in 249 NEPTUNE participants (pts): 21% minimal change, 33% FSGS, 17% membranous, 29% other. Multivariable linear regression was used to assess correlates of VitD metabolites.

Results: 43% of pts were VitD deficient (25D <20 ng/ml). NRP was associated with lower plasma DBP, independent of eGFR (p=0.001). Adjusted for albumin, DBP, and VitD supplementation, NRP was independently associated with lower 25D (Model 1). The significant impact of NRP on 25D was noted in earlier CKD stages, but not in pts with eGFR <60 ml/min/1.73m². Traditional risk factors (black race, season) and histopathology were not independently associated with 25D. Despite substantially lower 25D, NRP did not result in lower 1,25D among pts with normal eGFR. In contrast, 1,25D was lower in pts with NRP and eGFR of 60-89. 1,25D was similarly reduced in the setting of an eGFR <60 with versus without NRP. Adjusted for the reciprocal effects of PTH and FGF23, NRP was associated with lower 1,25D, but this was explained by lower substrate 25D (Model 2).



Model #1 R^2 = 0.50	25D % Difference	p
Albumin (g/dl)	45.4	<0.001
DBP (mg/dl)	1.2	0.004
Vit D supplement	63.1	<0.001
Up/c ≥2	-17.8	0.04

Also adjusted for age

Model #2 R^2 = 0.58	1,25D % Difference	p
PTH (per 10%)	2.2	<0.001
FGF23 (per 10%)	-5.0	<0.001
eGFR vs. ≥90		
60 – 89	-16.6	0.02
<60	-40.3	<0.001
25D (per 10%)	3.4	<0.001

Also adjusted for age, sex, race

Conclusions: NRP was associated with 1) lower 25D in pts with eGFR ≥60 independent of binding proteins, 2) lower DBP independent of eGFR, and 3) lower 1,25D explained by lower 25D. The impact of NRP on VitD was greatest in CKD stage 2, likely due to preserved filtration/urinary 25D loss with inadequate 1a-hydroxylation to compensate for less substrate. Supported by U54DK083912.

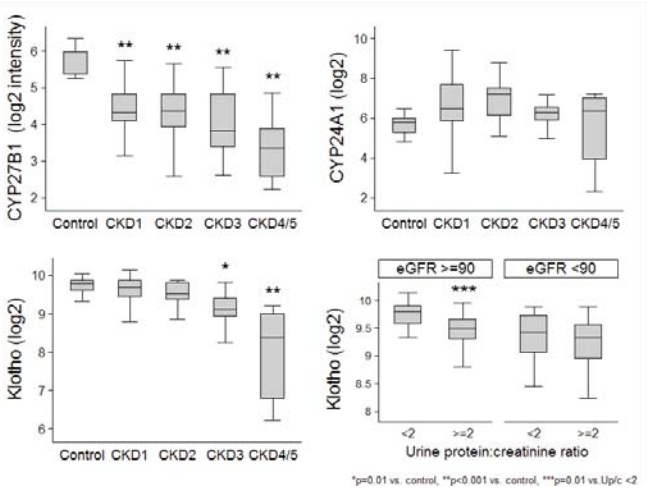
FR-PO849

Mineral Metabolism and Tubulointerstitial Gene Expression in the Nephrotic Syndrome Study Network (NEPTUNE) Michelle Denburg,[1,2] Sebastian Martini,[3] Myles S. Wolf,[4] Ian H. de Boer,[5] Andrew N. Hoofnagle,[5] L. Barisoni,[6] Lawrence B. Holzman,[2] Matthias Kretzler,[3] Mary B. Leonard.[1,2] *[1]Children's Hospital of Phila.; [2]U. Pennsylvania; [3]U. Michigan; [4]Northwestern U.; [5]U. Washington; [6]U. Miami.*

Background: The objectives were to assess tubular mRNA expression of vitamin D (VitD) hydroxylases (CYP27B1 and CYP24A1), the vitamin D-receptor (VDR), and Klotho and their relations to measures of mineral metabolism in NEPTUNE.

Methods: Transcriptomic profiles of the tubulointerstitium from microdissected renal biopsies of 94 NEPTUNE participants (pts) were generated using the Affymetrix 2.1 ST micro-array platform and compared to 5 control live donor samples (CO). Plasma VitD metabolites (25D, 1,25D, 24,25D), PTH, and FGF23 were measured in NEPTUNE pts.

Results: CYP27B1 expression was 61-82% lower in NEPTUNE pts versus CO (p<0.001) and was lower with increasing CKD severity. No differences in CYP24A1 expression were found versus CO or by CKD severity. Compared to CO, Klotho expression was lower in CKD stages 3 (39%, p=0.01) and 4/5 (70%, p<0.001). Among pts with eGFR >90, nephrotic-range proteinuria was associated with 17% lower Klotho expression (p=0.01). VDR expression was reduced in CKD stages 3 (33%, p=0.02) and 4/5 (50%, p=0.001) versus CO. Adjusted for 25D, age, race, and eGFR, CYP24A1 was negatively associated with 1,25D (p=0.001), while CYP27B1 was positively associated (p<0.001) and more so with lower eGFR (interaction p<0.001). Adjusted for 25D, age, race, and eGFR, 10% greater CYP24A1 expression was associated with 2% higher 24,25D concentrations (p=0.001). Independent of phosphate, 10% lower Klotho expression was associated with 9% higher FGF23 (p<0.001).



Conclusions: Glomerular disease is associated with substantial differences in tubular expression of genes regulating mineral metabolism, and their expression correlates with circulating VitD metabolites and FGF23. Supported by U54DK083912.

FR-PO850

Vitamin D Pathway Genes in Relation to Age at Renal Replacement Therapy Onset Alicja E. Grzegorzewska,[1] Grzegorz Ostromecki,[2] Adrianna Mostowska,[3] Anna Sowinska,[4] Pawel P. Jagodzinski.[3] *[1]Dept of Nephrology, Poznan Univ of Medical Sciences (PUMS), Poznan, Poland; [2]DaVita Dialysis Center, Piala, Poland; [3]Dept of Molecular Biology, PUMS, Poznan, Poland; [4]Dept of Statistics, PUMS, Poznan, Poland.*

Background: Vitamin D deficiency is associated with life-threatening diseases. We aimed to show a frequency distribution of vitamin D pathway genes (VDPG) and their associations with clinical-laboratory data of ESRD patients starting renal replacement therapy (RRT) at young, middle and advanced age.

Methods: Group I started RRT at age ≤40 years (n=172, 62% M), group II at 41–70 years (n=676, 59% M), and group III at >70 years (n=326, 48% M). Healthy persons aging ≤40 years (group Ia, n=180) and 41–70 years (group IIa, n=476) were controls. All subjects underwent genotyping for polymorphic variants of genes encoding vitamin D binding protein (*GC*): rs2298849 (HRM), rs7041 (RFLP), rs1155563 (HRM), vitamin D receptor (*VDR*): rs2228570 (RFLP), rs1544410 (RFLP), and retinoid X receptor A (*RXRA*): rs10776909 (HRM), rs10881578 (HRM), rs749759 (RFLP). Clinical (CAD/MI, PTX, treatment with cinacalcet) and laboratory (Ca, P, ALP, PTH, 25 (OH) D) data were related to VDPG polymorphisms shown in age categories.

Results: Groups I-Ia differed in polymorphism of rs2228570 (P_{trend} =0.031); groups II-IIa – rs2228570 (P_{trend} =0.011), rs10776909 (P_{trend} =0.027), rs749759 (P_{trend} =0.035). MAFs of these genotypes were greater in groups I-II than those in groups Ia-IIa, resp. Distribution of rs7041 polymorphic variant differed between groups I-II (P_{trend}=0.049) and II-III (P_{trend}=0.032). The younger group the higher MAF of rs7041 was observed (I - 44%, II – 43%, III – 38%; OR 1.24, 1.02-1.52 for II versus III, P=0.034). The Bonferroni corrected and gender adjusted, significant (P<0.017) VDPG associations with phenotypic features were shown in all groups: I - PTH (rs10881578), Ca (rs1155563), II - MI (rs10881578), Ca (rs10776909), III: 25 (OH) D (rs749759).

Conclusions: *VDR* and *RXRA* polymorphisms are associated with susceptibility to ESRD. The rs7041 allele T is associated with a need of RRT start at younger age. The association of VDPG with clinical/laboratory features is mediated by age at RRT onset.

FR-PO851

Genetic, Environmental and Disease-Associated Determinants of Vitamin D Status in Children with Chronic Kidney Disease: Findings from the 4C Study Anke Doyon,[1] Bettina Schmiedchen,[2] Anja Christine Sander,[3] Aysun Karabay Bayazit,[4] Anna Kottgen,[5] Matthias Wuttke,[5] Uwe Querfeld,[6] Franz S. Schaefer.[1] *[1]Univ Children's Hospital, Heidelberg, Germany; [2]German Inst of Human Nutrition, Potsdam, Germany; [3]Inst of Medical Biometry, Univ of Heidelberg, Germany; [4]Cukurova Univ, Adana, Turkey; [5]Renal Divison, Univ Hospital Freiburg, Germany; [6]Charité Children's Hospital, Berlin, Germany.*

Background: We investigated the impact of common variants in Vitamin D regulating genes, relative to environmental and disease-associated factors, on the vitamin D status of children with CKD.

Methods: Serum 25-hydroxy-vitamin-D, 1,25-dihydroxy-vitamin-D and 24,25-dihydroxy-vitamin-D were measured in 521 children (6-18 years, CKD stages III-

IV) from 12 European countries. Subjects were genotyped for SNPs in the genes encoding for 25-hydroxylase (CYP2R1), D-binding protein (GC), 7-dehydroxycholesterol-reductase (DHCR7) and 24-hydroxylase (CYP24A1). Associations of genetic status, season, local solar radiation, oral vitamin D supplementation, and disease-associated factors with vitamin D status were assessed.

Results: Serum 25 (OH) D levels were positively associated with vitamin D supplementation and summer season, and inversely with glomerulopathy diagnosis and, unexpectedly, residence in a region with higher solar exposure. When adjusting for these factors, lower serum 25 (OH) D was independently associated with genetic variations in DHCR7 (rs4945008), GC (rs7041), 25-hydroxylase (rs12794714) and 24-hydroxylase (rs3886163). The effect was strongest for patients homozygous for the SNP in DHCR7, who showed 32% lower 25 (OH) D levels than carriers of the major allele. The minor allele frequency for this SNP was significantly higher in subjects of Turkish origin (41.7% versus 26.9%). Serum 24,25 (OH) $_2$D was positively associated with 25 (OH) D, 1,25 (OH) $_2$D and FGF-23 serum levels, and decreased with declining renal function and rising serum iPTH. Minor allele homozygosity for rs7041 of GC was independently associated with higher 24,25 (OH) $_2$D levels.

Conclusions: Genetic variation significantly impacts on vitamin D turnover, adding to seasonal, geographic and disease-related factors and nutritional supplementation.

FR-PO852

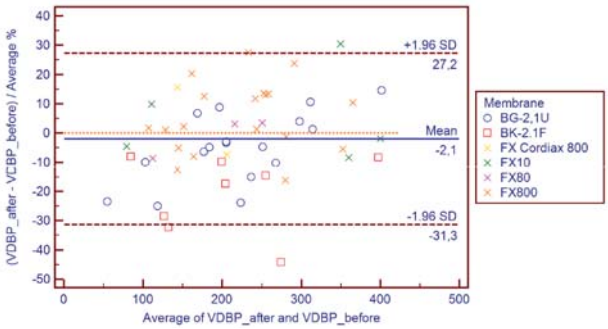
Impact of the Dialysis Membrane on the Vitamin D Metabolism Markers

Etienne Cavalier,[1] Bernard Dubois,[2] Pierre Delanaye.[2] *[1]Clinical Chemistry, Univ of Liege, CHU Sart-Tilman, Liege, Belgium; [2]Nephrology Dialisys and Transplantation, Univ of Liege, CHU Sart-Tilman, Liege, Belgium.*

Background: KDIGO guidelines recommend vitamin D supplementation in hemodialyzed patients as to monitor 25 (OH) D levels. Patient-to-patient inconsistency can however be observed in response to the treatment. In this study, we aimed to evaluate the impact of the dialysis membrane on 25 (OH) D, albumin (ALB) and vitamin D binding protein (VDBP), the major players of vitamin D transport and storage.

Methods: ALB (Roche Cobas), VDBP (Elisa R&D) and 25 (OH) D (LCMS/MS) were measured in 54 patients before and after a 4-hours dialysis session. Six dialysis membranes were used: FX Cordiax 800 (n=2), FX10 (n=5), FX80 (n=3), FX800 (n=19), BK-2.1F (BK:n= 8) and BG-2.1U (BG: n=17). Wilcoxon test was used to compare the results before/after the session, p<0.005 considered as significant.

Results: After dialysis session, ALB levels significantly increased by 9.5% (p<0.0001) with the FX membranes but not with BK or BG ones. VDBP levels significantly decreased by 13% (p=0.0078) with BK, but remain unchanged with BU or FX membranes. As expected, 25 (OH) D levels followed VDBP and decreased by 13% (close to significance level) with BK but remained unchanged with the other membranes.



Conclusions: This is the first study showing that VDBP is dialyzed by a membrane with high cut-off (BK-2.1F). This contributes to a trend in decreasing 25 (OH) D levels. Even if these results need to be confirmed in a higher number of patients, this observation can partially explain the patient-to –patient response to the same vitamin D dose.

FR-PO853

Ergocalciferol versus Cholecalciferol for Nutritional Vitamin D Replacement in CKD

Roberto Mangoo-Karim,[1] Juliana Da Silva Abreu,[1] George P. Yanev,[2] Ninfa N. Perez,[1] Jason R. Stubbs,[3] James B. Wetmore.[4] *[1]Gamma Medical Research, Edinburg, TX; [2]Mathematics, Univ of Texas Pan-American, Edinburg, TX; [3]Nephrology, Univ of Kansas Medical Center, Kansas City, KS; [4]Nephrology, Hennepin County Medical Center, Minneapolis, MN.*

Background: It is unknown whether supplementation with cholecalciferol is more effective than with ergocalciferol in chronic kidney disease (CKD) patients with nutritional vitamin D [25 (OH) D] deficiency.

Methods: A retrospective analysis of CKD patients (n = 60) was conducted to assess the relative effectiveness of ergocalciferol versus cholecalciferol on serum 25 (OH) D levels. Patients had 25 (OH) D levels assessed at baseline, after attempted repletion with ergocalciferol, and then after attempted repletion with cholecalciferol; patients served as their own controls. Absolute and dose-standardized changes were calculated. The relative paired differences of the effects of the drugs were compared using t-tests. Multiple regression modeling was used to determine the factors significantly associated with differential responsiveness to the drugs.

Results: Mean age was 66.3 years; 61.7% were female. Mean baseline 25 (OH) D level was 15.2 ng/mL, mean parathyroid hormone (PTH) was 57.3 pg/mL, and mean proteinuria was 970 mg/day. After 6 months of therapy, increase in 25 (OH) D levels was over 2-fold higher for cholecalciferol than for ergocalciferol, 2.6 ± 0.3 ng/mL per 100,000 units versus 1.1 ± 0.3 ng/mL per 100,000 units (p < 0.0001). In terms of paired differences, cholecalciferol was strongly favored over ergocalciferol in absolute (6.1 ± 1.1 ng/mL), and relative (1.5 ± 0.3 ng/mL, per 100,000 units) average differences. After multivariable adjustment, higher baseline 25 (OH) D (p = 0.01), lower baseline estimated glomerular filtration rate (p = 0.03), and lower baseline PTH (p = 0.001) were associated with significantly better response to cholecalciferol than to ergocalciferol.

Conclusions: Cholecalciferol appears to be more effective than ergocalciferol for nutritional vitamin D deficiency in CKD. Guidelines, such as those of the National Kidney Foundation, may need to be revised.

FR-PO854

Estimation of Optimal Serum Concentrations of 25-Hydroxyvitamin D for Progression and Mortality in Chronic Kidney Disease

Martinez-Castelao,[1] Del Pino Pino Maria Dolores,[1] Sandra Beltrán,[2] Belen Vizcaino,[2] Luis M. Pallardo.[2] *[1]OSERCE-2 Study Investigators, Spain; [2]Nephrology, H. U. Dr Peset, Valencia, Spain.*

Background: Based on levels of 25-hydroxyvitamin D[25 (OH) D] required to suppress parathyroid hormone,guidelines have defined optimal vitamin D status at 25 (OH) D≥30ng/ml.Aware of the weakness of this recommendation,we conducted this post-hoc analysis using data from the OSERCE-2 study to evaluate thresholds for serum 25 (OH) D concentrations in relation to hard end-points such as death,kidney progression and hospitalization.

Methods: We studied 470 subjects participating in OSERCE-2 study, a prospective,multicenter study which enrolled 742 non-dialysis 3-5 stages CKD patients. In this re-analysis we excluded patients on treatment with active vitamin D,so 25 (OH) D levels reflected the effect of the exposure to vitamin D.Subjects were classified further into 3 groups by baseline 25 (OH) Dlevel:<20,21-29 and ≥30ng/mL,considering 25 (OH) D 21-29ng/ml as reference group.Deaths,kidney progression and hospitalizations were prospectively gathered over a 3-year period.To identify 25 (OH) Dlevels at highest risk for outcomes,ROC curves were performed.

Results: Over 29±12 months of follow up 46 (10%) patients dead,156 (33%) showed kidney progression,and 126 (27%) were hospitalized. After multivariate adjustment,Cox regression analysis showed 25 (OH) D<20 as an independent predictor of all-cause mortality[HR=2.327 (95%CI:1.102-4.912);p=0.027] and kidney progression[HR=2.456 (95%CI:1.628-3.706);p<0.001],whereas the group with 25 (OH) D≥30ng/ml did not have a different hazard for outcomes from the reference group.ROC curves identified 25 (OH) D levels at highest risk for death,kidney progression and hospitalization,at 17.4,18.6 and 19.0ng/ml, respectively.

Conclusions: 25 (OH) D<20ng/ml was an independent predictor of death and progression in patients with stage 3-5 CKD, with no additional benefits when patients reached the suggested levels by CKD guidelines. In the absence of clinical trials, and in line with the Institute of Medicine recommendations, our results suggest that 25 (OH) D levels >20ng/ml could be sufficient for CKD subjects.

Vitamin D Status Determines the Dominance between FGF23 and PTH, which Affects Different Pattern of 1,25 (OH) $_2$D Decline in the Course of CKD Progression

Sayoko Yonemoto,[1] Takayuki Hamano,[2] Chikako Nakano,[1] Yoshitsugu Obi,[1] Daisuke Mori,[1] Yasuo Kusunoki,[1] Akihiro Shimomura,[1] Isao Matsui,[1] Yoshiharu Tsubakihara,[2] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Rise of FGF23 was found to precede that of PTH in the course of CKD progression, but many studies did not account for the confounding effect of vitamin D (25D) status. In this cross-sectional study, we studied the influence of 25D status on the dominance of two hormones, and consequently showed the different pattern of 1,25 (OH) $_2$D decline with the decrease in eGFR.

Methods: The study population consisted of 738 predialysis outpatients of nephrology department of two hospitals in Japan. Patients were classified as 25D insufficient (serum 25D levels <20ng/mL) and 25D replete (>=20ng/mL) groups. We utilized restricted cubic spine analysis to estimate the thresholds of eGFR at which each CKD-MBD marker increased or decreased.

Results: Most patients (87.5%) were in CKD stage 3 to 5. The median of age was 64, and the proportions of patients with diabetes mellitus and 25D insufficiency were 19.2% and 22.9%, respectively. Only 5.8% of patients received active vitamin D. In the state of 25D insufficiency, the dominant increase of PTH over FGF23 with the eGFR decline (each threshold of eGFR was about 50 and 30mL/min/1.73m$_2$, respectively) lead to stable 1,25 (OH) $_2$D levels in early CKD, while in 25D replete patients, the dominant increase in FGF23 over PTH (the slope of FGF23 was constantly positive across all CKD stages, while the threshold of eGFR of PTH elevation was about 60mL/min/1.73m^2) resulted in decrease in 1,25 (OH) $_2$D levels in early CKD. Vitamin D status did not affect 1,25 (OH) $_2$D levels in patients with eGFR<30mL/min/1.73m^2.

Conclusions: The 1,25 (OH) $_2$D level was stable in early CKD in the 25D insufficient group, while it decreased in the 25D replete group. This might be attributed to different patterns of elevation in two phosphatonins in CKD patients, and its clinical relevance remains to be elucidated.

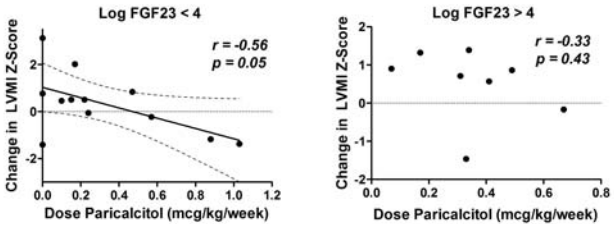
FR-PO856

Elevated FGF23 Levels Antagonize Paricalcitol Mediated Cardioprotection in Young Hemodialysis Patients Wacharee Seeherunvong,[1] Chryso P. Katsoufis,[1] Nao Sasaki,[2] Alcia D. Edwards- Richards,[1] Jayanthi Chandar,[1] Gaston E. Zilleruelo,[1] Phillip Ruiz,[3] Carolyn L. Abitbol,[1] Michael Freundlich.[1] *[1]Pediatric Nephrology, Univ of Miami/Holtz Children's Hospital, Miami, FL; [2]Pediatric Cardiology, Univ of Miami/Holtz Children's Hospital, Miami, FL; [3]Pathology, Univ of Miami, Miami, FL.*

Background: Elevated FGF23, a putative pro-hypertrophic and cardiotoxic hormone, associates strongly with left ventricular hypertrophy (LVH). Whereas administration of the calcitriol analog paricalcitol (Pc) attenuates cardiac hypertrophy, it also stimulates bone production of FGF23. We hypothesized that this paradoxical antagonism between the 2 hormones could be mediated through a therapeutic threshold depending on the degree of FGF23 elevation.

Methods: Twenty young HD patients (age 16±4yrs; dialysis vintage 30±16mos), receiving intravenous Pc, underwent sequential echocardiography (Echo) with assessment of LV mass index (LVMI) and LVH. C-terminal plasma FGF23 levels (RU/ml) were expressed as log-transformed values, and all other parameters were averaged over 6 months before each Echo (E1 and E2 time points).

Results: Between E1 and E2, log FGF23 remained unchanged (3.84 and 3.79, respectively) and correlated with serum phosphorus ($p<0.01$) and very robustly with calcium (both time points $r= 0.6$, $p<0.01$). LVH was unchanged in 50% of patients, with a 24% reduction in LVMI in 6/20 (30%) ($p<0.05$) between E1 and E2. The salutary effect of Pc in reducing LVMI was observed only when the log FGF23 levels were <4 ($r=-0.56$; $p=0.05$). This therapeutic effect was markedly blunted when FGF23 levels were >4.



Conclusions: In young HD patients, Pc treatment is cardioprotective within the therapeutic constraints of FGF23 stimulation and only when the log FGF23 level remains <4. Our findings provide a plausible explanation for this clinical paradox of hormonal antagonism.

FR-PO857

Effects of Active Vitamin D on Fibroblast Growth Factor-23 in Patients with Chronic Kidney Disease; Subgroup Analysis of the PACE Trial Seth Goldberg,[1] Daniel W. Coyne,[1] Mark D. Faber,[2] Stuart M. Sprague.[3] *[1]Washington Univ, St. Louis, MO; [2]Henry Ford Hospital, Detroit, MI; [3]NorthShore Univ HealthSystem -- Univ of Chicago, Chicago, IL.*

Background: In the development of chronic kidney disease-mineral bone disorder (CKD-MBD), dysregulated mineral metabolism with hyperphosphatemia accompanies the elevation in parathyroid hormone (PTH) concentrations. Fibroblast growth factor-23 (FGF-23) increases with progressive CKD, contributing to lower calcitriol levels and secondary hyperparathyroidism (SHPT). Low calcitriol levels, higher PTH, and higher FGF-23 are associated with increased mortality in CKD. Few human studies have compared the effect of active vitamin D analog treatment on FGF-23 levels in stage 3 and 4 CKD patients.

Methods: Data for the present study were from an open label phase 4 study of paricalcitol versus calcitriol for suppression of PTH in CKD stages 3 and 4 (Clinical Trial registry, NCT00823303). Levels of FGF-23 (Immunotopics 2nd generation C-terminal assay) were obtained at screening, 12 weeks, and 24 weeks. FGF-23 levels and their relationship to other markers of SHPT including PTH, albumin-corrected calcium, phosphorus, and urinary phosphorus, were analyzed.

Results: A total of 110 patients were randomized to receive study drug. Of these, 79 had at least one level of FGF-23 for analysis. The median (interquartile range) FGF-23 concentration increased from 240 (154, 382) RU/mL at baseline, to 392 (214, 555) RU/mL at 24 weeks ($p=0.002$). There were no significant differences in FGF-23 levels between groups at 24 weeks (366 (181, 536) RU/mL with paricalcitol, 423 (239, 566) RU/mL with calcitriol, $p=0.63$). FGF-23 levels correlated directly with the serum phosphorus ($p<0.001$) and urinary phosphorus/Cr excretion ($p<0.001$). There was no correlation between the FGF-23 levels and PTH at baseline, 12 weeks, or 24 weeks.

Conclusions: Treatment of SHPT with calcitriol and paricalcitol for 24 weeks increased FGF-23 levels similarly, with similar suppression of PTH (40-60%). As both agents treat CKD-related calcitriol deficiency and SHPT, while increasing FGF-23 and serum calcium, the effect of these agents on morbidity and mortality requires further trials.

FR-PO858

Predictors of Circulating Cathelicidin during Acute Infection in Hemodialysis Patients Kristin M. Corapi,[1] Joseph James DeFerio,[1] Julia Beth Wenger,[1] Niels Borregaard,[2] Ishir Bhan.[1] *[1]Nephrology, Massachusetts General Hospital, Boston, MA; [2]Hematology, Univ of Copenhagen, Copenhagen, Denmark.*

Background: Plasma cathelicidin is a vitamin D regulated antimicrobial peptide that predicts mortality in end-stage renal disease (ESRD). Levels correlate with 25 (OH) vitamin D (25OH D) in healthy individuals. ESRD-associated alterations in vitamin D metabolism have the potential to alter the expression of cathelicidin. We performed an observational study of hemodialysis (HD) patients with and without acute infection to determine if cathelicidin associates with 25OH D or other markers of mineral metabolism in ESRD.

Methods: Patients were enrolled upon hospital admission. Blood was collected at the start of the first inpatient HD session. Cases were patients admitted with an acute infection and controls were admitted with a non-infectious illness. Demographics, routine laboratory parameters, and dialysis details were compared using univariate analyses. Spearman correlation was used to identify correlates of cathelicidin. Multivariable linear regression was used to adjust for possible confounders.

Results: Enrollment included 30 cases and 28 controls. The majority of subjects were male (66%) with a mean age of 65 years. Analyzing the entire sample, fibroblast growth factor-23 (FGF-23; $r=0.31$, $p=0.03$), vitamin D binding protein (DBP; $r=0.35$, $p=0.008$) and bioavailable vitamin D (BioD; $r= -0.35$, $p=0.007$), but not 25OH D ($r=-0.10$, $p=0.47$), were found to have significant correlations with plasma cathelicidin. Only DBP ($r= 0.53$, $p=0.003$) and BioD ($r= -0.39$, $p=0.03$) had a significant correlation with cathelicidin amongst the 30 cases with infection. In a multivariable linear regression model, DBP, but not BioD, remained a significant predictor of cathelicidin after adjusting for white blood cell count and FGF-23 level.

Conclusions: In ESRD, plasma cathelicidin is not associated with 25OH D levels, but correlates strongly with DBP, particularly in the setting of infection. Given DBP's recognized role as a potential immunomodulator, this may represent a novel downstream effect of DBP.

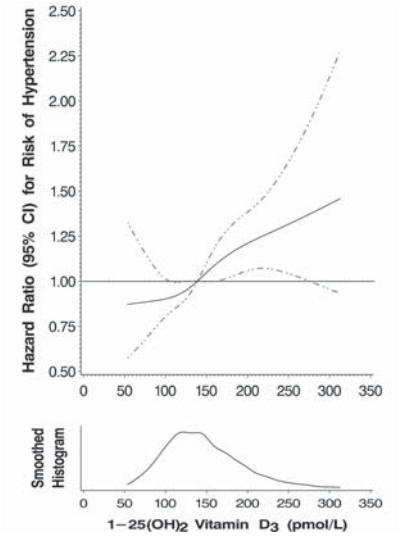
Active Vitamin D 1,25-Dihydroxyvitamin D3 Is Associated with Risk of Hypertension Adriana J. van Ballegooijen,[1] Hiddo Jan Lambers Heerspink,[2] Dick de Zeeuw,[2] Marjolein Visser,[1] Ingeborg A. Brouwer,[1] Martin H. De Borst,[4] Ron T. Gansevoort,[4] Stephan J.L. Bakker,[4,5] Michel M. Joosten,[4,5] Ido Peter Kema.[3] *[1]Health Sciences, VU Univ, Amsterdam, Netherlands; [2]Dept of Clin Pharmacol, UMC Groningen, Netherlands; [3]Dept Clin Chem, UMC Groningen, Netherlands; [4]Dept Nephrol, UMC Groningen, Netherlands; [5]Top Inst Food and Nutrition, Wageningen, Netherlands.*

Background: Previous observational studies on the vascular effects of vitamin D have predominantly relied on its precursor -25-hydroxyvitamin D- while the active metabolite 1,25-dihydroxyvitamin D (1,25D) may be of more physiological relevance.

Methods: We prospectively studied the association between 1,25D and hypertension risk (blood pressure ≥140/90 mmHg, or initiation of blood pressure-lowering drugs) in 5,066 subjects aged 28-75 years, free of hypertension at baseline from the PREVEND Study, a well-defined, general population-based cohort with serial follow-up. We measured plasma 1,25D using liquid chromatography-tandem mass spectrometry.

Results: Mean±SD plasma 1,25D levels were 145±47.0 pmol/L. Lower 1,25D levels were more prevalent during winter and associated with lower 24h urinary calcium excretion, and estimated glomerular filtration rate (eGFR). During a median follow-up of 7.4 years (range 1.7-11.2), 1,036 participants (20.5%) developed hypertension. Each 1-SD increment (47.0 pmol/L) in plasma 1,25D was associated with a 11% greater risk of hypertension (HR 1.11; 95%CI, 1.04-1.19) after adjustment for potential confounders including eGFR and 24h urinary albumin excretion.



Conclusions: In contrast to previous inverse associations between its inactive precursor and hypertension risk, plasma 1,25D was positively associated with risk of hypertension. We hypothesize that higher circulating levels of active vitamin D may promote vascular calcification, which in turn could lead to increased arterial stiffness and a greater hypertension risk.

Sucroferric Oxyhydroxide Does Not Affect Oral Vitamin D Agonists: Post Hoc Analysis of Phase 3 Data Stuart M. Sprague,[1] Jaco Botha,[2] Viatcheslav Rakov,[2] Jürgen Floege.[3] *[1]NorthShore Univ Health System; [2]Vifor Pharma, Switzerland; [3]RWTH Univ Hospital Aachen, Germany.*

Background: This analysis evaluated potential interactions of sucroferric oxyhydroxide (SFO; VELPHORO®/PA21) and oral vitamin D receptor agonists (VDRAs) during a Phase 3 study of SFO versus sevelamer carbonate (SEV) and its extension study, using intact parathyroid hormone (iPTH) as a surrogate pharmacodynamic marker of VDRA activity.

Methods: 1,059 patients were randomized to SFO (1.0–3.0 g/day) or SEV (2.4–14.4 g/day) for 24 weeks. Eligible patients enrolled in a 28-week extension study. Three populations were analyzed: patients taking concomitant oral VDRAs (Pop. 1), those not taking concomitant VDRAs, either orally or intravenous (Pop. 2), and those treated with intravenous paricalcitol (Pop. 3). Populations were compared using a mixed-effects model to obtain least squares mean change in iPTH from baseline to study endpoint (Week 52).

Results: 505 patients were included. In Pop. 1 (oral VDRA), iPTH levels decreased from baseline to Week 52 in the SFO group, but increased in the SEV group (Table). In Pop. 2 (no VDRA) iPTH levels increased to a similar extent in both treatment groups. In Pop. 3, (intravenous paricalcitol) iPTH decreased similarly in both treatment groups (n=68; data not shown). Overall (Pop. 1 and Pop. 2 combined), changes in iPTH levels were not affected to a significant extent by any of the covariates analyzed (Table).

Table: Mixed-effect model analysis of change in iPTH from baseline to endpoint (Week 52) for Pop. 1 (N=187) vs Pop. 2 (N=250).

	Least squares mean [95% CI] (pmol/L)	P-value
SFO		
Pop. 1 ΔBL	−3.3 [−9.1; 2.6]	
Pop. 2 ΔBL	5.1 [0.3; 9.9]	
Pop. 1 vs Pop. 2	8.3 [1.1; 15.6]	0.024
SEV		
Pop. 1 ΔBL	8.6 [−0.4; 17.5]	
Pop. 2 ΔBL	4.9 [2.2; 12.1]	
Pop. 1 vs Pop. 2	−3.7 [−14.8; 7.5]	0.518
SFO vs SEV (Pop. 1 [oral VDRA])	−11.8 [−22.3; −1.4]	0.027
SFO vs SEV (Pop. 2 [no oral VDRA])	0.18 [−7.9; 8.3]	0.965
Covariates		
BL iPTH		0.689
BL phosphorus		0.088
Treatment		0.084
Prior calcium-based phosphate binder		0.385
Use of oral VDRA		0.420
Interaction between treatment and use of oral VDRA		0.074

BL, baseline; CI, confidence interval.

Conclusions: In contrast to SEV, results showed no apparent interaction between SFO and oral VDRAs as indicated by changes in iPTH.

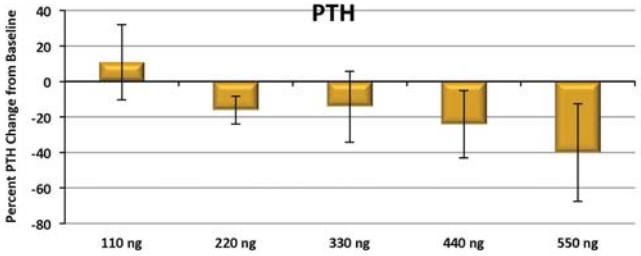
FR-PO861

2-Methylene-19-nor- (20S)-1a,25-Dihydroxyvitamin D3, a Promising New Therapeutic for Secondary Hyperparathyroidism Hector F. Deluca. *On Behalf of Phase 2 Study Sponsor and PI's, Deltanoid Pharmaceuticals, Inc., Madison, WI.*

Background: Vitamin D analogs alone or together with a calcium mimetic are used successfully to control secondary hyperparathyroidism in dialysis patients. However, both pharmaceuticals have significant side effects. Vitamin D compounds can cause unwanted hypercalcemia. Conversely, calcimimetics can produce hypocalcemia. We are developing a vitamin D analog (2-methylene-19-nor- (20S)-1a,25-dihydroxyvitamin D3 (2MD, DP001) that specifically localizes in the parathyroid glands and osteoblasts. At doses at least 10X lower than currently used vitamin D analogs, 2MD suppresses serum PTH in 5/6 nephrectomized rats and in post-menopausal women without a change in serum calcium.

Methods: A Phase 2A open label dose-finding trial was conducted in dialysis patients. Oral doses from 110 ng to 550 ng were administered after each dialysis session 3X/week for one month to 4-6 patients at each dose level. A second Phase 2B, randomized, placebo-controlled, double-blind study was conducted in 62 dialysis patients previously taking a vitamin D analog with or without calcimimetic co-therapy (Phase 2B). Each enrollee received either placebo or 2MD orally thrice weekly for 3 months. PTH, serum calcium and phosphorus levels were regularly measured throughout both studies.

Results: The Phase 2A study results showed that 2MD suppressed PTH in a dose-dependent manner at doses of 220 ng to 550 ng when given orally 3X/week at dialysis without any significant changes in serum calcium or phosphorus.



The in-life portion of the Phase 2B study has been completed and is awaiting database lock. Initial blinded results indicate no safety concerns. The results of these two trials will be reported.

Conclusions: Data to-date show 2MD is safe and will benefit dialysis patients with secondary hyperparathyroidism.

FR-PO862

A New Vitamin D Analogue VS-105 Regulates Parathyroid Hormone Secretion and Gene Expression in Human Parathyroid Cells Masafumi Fukagawa, Kaichiro Sawada, Genta Kanai, Takatoshi Kakuta. *Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.*

Background: Active vitamin D sterols are almost routinely used for the treatment of secondary hyperparathyroidism in patients with chronic kidney disease, however, development of hypercalcemia by the therapy causes serious problems such as vascular calcification. VS-105 (20R,24S-24-Methyl-2-methylene-19-nor-1a,25 (OH) 2-22-oxa-D3) is a synthetic new vitamin D analogue developed for the treatment of secondary hyperparathyroidism. We evaluated effects of VS-105 on gene expressions in cultured human parathyroid cells.

Methods: Parathyroid cells were prepared from surgically removed parathyroid glands from dialysis patients with informed consent. Mini-glands (spheroids) were formed with 10^5-10^6 cells (Kidney Int, 2009). VS-105 (10, 50 and 100 nM) and Paricalcitol (10, 50 and 100 nM) was added to wells respectively. The culture media containing reagents were exchanged every 24 hours for three days. We measured parathyroid hormone (PTH) levels secreted from the mini-glands to supernatants by ELISA. Expressions of mRNA of PTH, calcium-sensing receptor (CaR), vitamin D receptor (VDR) and CYP24A1 were analyzed by RT-PCR.

Results: VS-105 suppressed intact PTH secretion and PTH mRNA expression more effectively than Paricalcitol. The mean values and S.D. of secreted intact-PTH from cells treated with VS-105, Paricalcitol and Calcitriol were 2922.6 +- 826.6, 4218.3 +- 1484.5 and 6655.6 +- 1641.6 pg/ml/DNA microgram, respectively. Messenger RNA expression of CaR increased almost 1.8-folds by VS-105 and 1.5-folds by Paricalcitol as compared with vehicle. VS-105 did not significantly modified VDR mRNA expression, in contrast to Paricalcitol. VS-105 increased mRNA expression of CYP24A1 almost 1.9-folds, more efficiently than Paricalcitol.

Conclusions: VS-105 can be a potent therapeutic agent for severe hyperparathyroidism. Such different profiles of parathyroid gene expression may be helpful for developing more potent and safer agents for severe hyperparathyroidism in patients with chronic kidney disease.

FR-PO863

A Novel Vitamin D Receptor Modulator, VS-105, Improves Bone Mineral Density in 5/6 Nephrectomized Uremic Rats J. Ruth Wu-Wong,[1] Yung-Wu Chen,[1] Jerry Wessale,[1] Maysaa Oubaidin,[2] Phimon Atsawasuwan.[2] *[1]Vidasym, Chicago, IL; [2]Univ of Illinois, Chicago, IL.*

Background: Mineral and bone disorder (MBD) begins early in the course of chronic kidney disease (CKD). Vitamin D is essential for bone health and vitamin D receptor modulators (VDRMs) are also commonly used to manage hyperparathyroidism secondary to CKD. Previous studies on VDRMs have often attributed their bone effects to enhanced intestinal calcium absorption and parathyroid hormone (PTH) suppression. It is not well studied whether VDRMs at non-hypercalcemic doses have effects on bone mineral density (BMD).

Methods: The 5/6 nephrectomized (NX) male Sprague Dawley rat with established uremia exhibits MBD with elevated PTH and reduced BMD. Previously we have shown that after 2-weeks of treatment (i.p. or p.o.) in 5/6 NX rats, VS-105 at non-hypercalcemic doses suppressed PTH and reduced cardiac fibrosis. In this study, the effect of VS-105 on BMD was evaluated in sham-operated and 5/6 NX rats.

Results: Treatment of 5/6 NX rats by VS-105 at two doses (0.05 and 0.2 μg/kg, i.p., 3x/week, for 8 weeks) significantly improved BMD at the lumbar vertebra (sham: 347 ± 21 mg/cm^2; NX/vehicle: 318 ± 7 mg/cm^2; VS-105 at 0.05 μg/kg: 348 ± 11 mg/cm^2; VS-105 at 0.2 μg/Kg: 377 ± 9 mg/cm^2). VS-105 at both doses significantly suppressed serum PTH even after dosing for one day, and the effect was maintained throughout the treatment period. Neither dose of VS-105 affected serum calcium, which was likely due to its lack of effects on inducing the expression of intestinal calcium transporter genes such as Calb3 and

TRPV6, and on stimulating intestinal calcium transport. In a mouse calvaria bone primary organ culture system, VS-105 was ~2-fold less effective than calcitriol in stimulating net calcium release from calvaria (a measurement of osteoclast activity).

Conclusions: These results demonstrate that VS-105 is effective in suppressing PTH and improving BMD in a dose range that does not affect serum calcium in uremic rats, and the improvement in BMD is not attributable to enhanced intestinal calcium absorption. The overall preclinical profile of VS-105 supports clinical development for its use in treating MBD in CKD patients.

FR-PO864

Cardiac Effect of Vitamin D Receptor Modulators in Uremic Rats

Masahide Mizobuchi,[1] Tadao Akizawa,[1] J. Ruth Wu-Wong,[2] Hiroaki Ogata.[3] *[1]Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine, Tokyo, Japan; [2]Dept of Pharmacy Practice, Univ of Illinois at Chicago, Chicago, IL; [3]Dept of Medicine, Showa Univ Northern Yokohama Hospital, Yokohama, Japan.*

Background: Vitamin D receptor (VDR) modulators (VDRMs) are commonly used to control secondary hyperparathyroidism (SHPT) associated with chronic kidney disease, and have been associated with beneficial cardiovascular disease outcomes. In this study we compared the cardiac effect of VS-105, a novel VDRM (Br J Pharm 164: 551, 2011), with that of paricalcitol in 5/6 nephrectomized (NX) uremic rats.

Methods: Male Sprague-Dawley rats were 5/6 nephrectomized and fed a normal diet for 4 weeks to establish uremia. Rats were then treated (i.p. 3 times/ week) with vehicle (propylene glycol), paricalcitol (0.025 mg/kg and 0.15 mg/kg), or VS-105 (0.05 mg/kg and 0.3 mg/kg) for 4 weeks.

Results: In uremic groups, both VDRMs (low and high doses) did not alter- serum creatinine and phosphorus levels. Serum calcium levels were significantly higher in the high dose paricalcitol group compared to sham. PTH levels were significantly decreased in the low dose paricalcitol and VS-105 groups, and were further reduced in the high dose groups. Interestingly serum FGF23 levels were significantly higher in the high dose paricalcitol group compared to sham whereas VS-105 did not show a significant effect on FGF23 levels. Left ventricle (LV) weight, and LV mass index determined by echocardiography was significantly suppressed in the high dose group for both VDRMs. The suppression was more evident in VS-105 treated animals. Western blotting showed significant decreases in fibrosis markers (TGF-β, type 1 collagen, and fibronectin) in the high dose group for both VDRMs (versus the NX-vehicle group). Masson trichrome staining showed a significant decrease in cardiac fibrosis in the high dose group for both VDRMs.

Conclusions: These results suggest that VS-105 is less hypercalcemic than paricalcitol with favorable effects on SHPT and cardiac parameters similar to paricalcitol in uremic rats. The anti-cardiac fibrosis effect was one of the noteworthy characteristics for VS-105.

High Phosphate Induce Hyperparathyroidism through COX2-PGE2-EP2 Pathway

Shensen Li, Qian Zhang, Haiming Li, Jing Chen. *Div of Nephrology, Huashan Hospital, Shanghai Medical College, Fudan Univ, Shanghai, China.*

Background: Secondary hyperparathyroidism (SHPT) has been proved to play a central role in CKD-MBD, but its pathogenesis is still not fully understood. The purpose of current study was to elucidate whether prostaglandin E2 (PGE2) and its type 2 receptor (EP2) mediate the pathogenic role of COX2 in uremic parathyroid gland and to identify the potential therapeutic targets in SHPT.

Methods: PTG samples were obtained from parathyroidectomy surgery of uremic patients. *In vitro*, freshly excised PTG tissue were incubated in following groups: (1) normal phosphate (1mM), (2) high phosphate (HP) (2-8mM), (3) HP (4mM) with COX2 inhibitor (NS398 10^{-6}mM) or EP2 receptor antagonist (AH6809 10^{-7}mM), (4) PGE2 (10^{-5}-10^{-7}mM), (5) EP2 receptor agonist (butaprost 10^{-5}-10^{-7}mM). *In Vivo*, experiments were conducted in male SHPT Sprague-Dawley rats. By means of a small neck surgery, lentiviral carried EP2 shRNA ($1x10^{7}$ IU/ml) were implanted in the parathyroid of SHPT rats.

Results: Compared to normal PTG, the obviously enhanced immunoreactivities of COX2, mPGES1 and EP2 were detected in hyperplastic PTGs from 20 uremic patients. In cultured PTG tissues, COX2 inhibitor or EP2 antagonist significantly inhibited HP-induced iPTH secretion to 62±0.9% or 67±1.3%, and PCNA protein expression to 64±2.2% or 70±3.4%, respectively ($P<0.05$). Meanwhile, PGE2 or butaprost directly induced a dose-dependent high expression of iPTH and PCNA. In vivo study,EP2 shRNA lentivirus down-regulated EP2 gene expression by 67.7±4.5% in PTG, and significantly reduced serum iPTH levels to 21.8±5% and PTGs size to 72±4.8% ($P<0.05$). No significant differences were found in serum levels of creatinine, BUN, calcium, phosphorus or end-products of prostaglandins metabolism between each group of uremic rats.

Conclusions: Inhibition of COX2-PGE2-EP2 pathway significantly reduced the secretion of PTH and PTG cell proliferation *in vitro*, while PGE2 and EP2 agonist directly stimulated such reactions. Knocking down EP2 receptor expression in parathyroid significantly attenuated serum iPTH elevation and PTG proliferation in uremic rats. These data suggested that the COX2-PGE2-EP2 pathway promoted SHPT and parathyroid hyperplasia in ESRD.

Primary Hyperparathyroidism in Mice due to Deletion of the Gene Encoding the Transient Receptor Potential Canonical Type 1 (TRPC1) Channel: A Model of Metabolic Syndrome with Chronic Kidney Disease (CKD)

Bonnie Eby,[1] Alexander Lau,[1] Lindsay J. Barron,[1] Leonidas Tsiokas,[2] Kai Lau.[1,3] *[1]Medicine, Univ of Oklahoma Health Sciences Center, OKC, OK; [2]Cell Biology, Univ of Oklahoma Health Sciences Center, OKC, OK; [3]Medicine, VAMC, OKC, OK.*

Background: In parathyroid glands, the TRPC1 protein complexes with stromal interacting molecule 1 (STIM1) and ORAI1, the Ca release activated Ca channel modulatory protein 1, to mediate store-operated Ca entry (SOCE). We and others reported that activating mutations of STIM1 or ORAI1 produce hypocalcemia and the Stormorken syndrome. Inactivating mutations of STIM1, ORAI1, or TRPC1 could produce the opposite. We tested the hypothesis that TRPC1 deficiency impairs SOCE, reduces cell Ca, stimulates PTH and causes hypercalcemia.

Methods: In male littermates born to +/- parents, metabolic, clearance and ultrasound studies were done. Ca and lipids were measured by published methods, creatinine by HPLC, and PTH by a mouse 1-84 ELISA Kit.

Results: Nulls were 10% fatter versus +/- and wt from 4 to 30th week. Fasting triglyceride was 40% higher in null versus wt. Fasting cholesterol was 65% higher in null and +/-. From 5th-10th mon, fasting serum (S) Ca was 6-7% higher in both null and +/- ($p<0.03$ for both). At 12.5 mon, non-fasted SCa was higher in null (11.4 mg%) and +/- (11.2 mg%) versus wt (10.2 mg%) ($p<0.001$ for both). Despite hypercalcemia, [PTH] (pg/ml) was higher in null than wt (310 versus 218, $p<0.05$) and not suppressed in +/- (259). Hematocrit was lower in null (11%) and +/- (8%). SP was similar at 9 and 12 mon for all 3 groups. At 12 mon, liver density was 30% higher in null versus +/- and wt. Albuminuria was 65% heavier in null. Kidney volume was 20% lower. At 16 mon, creatinine clearance was down by 44% in null ($p<0.02$) and 40% in +/- ($p<0.05$).

Conclusions: 1.TRPC1 null mice exhibit the metabolic syndrome (obesity, fatty liver and dyslipidemia shown here and insulin resistance and glucose intolerance shown earlier). 2. Haploid deficiency produces hypercalcemia and impairs PTH suppression as diploid deficiency produces hypercalcemia and excess PTH, data in support of the stated hypothesis. 3. Renal failure emerges by 16 mon in both haploid and diploid deficiency, making them useful CKD models.

mTOR Pathway Activation Is Crucial to Parathyroid Cell Proliferation in Both Experimental Uremia and Acute Kidney Injury and Is Enhanced in the Parathyroids of CKD Patients

Oded Volovelsky, Gili Cohen, Ariel Kenig, Justin Silver, Tally Naveh-Many. *Naphrology, Hadassah Hospital, Jerusalem, Israel.*

Background: Parathyroid cell proliferation is central to secondary hyperparathyroidism (SHP). The signal transduction pathways for parathyroid cell proliferation are not defined. We have previously presented that the mTOR pathway is activated in the parathyroids of SHP rats and that the mTOR inhibitor rapamycin decreases parathyroid mTOR activation and prevents parathyroid cell proliferation. Rapamycin also decreased parathyroid cell proliferation in vitro in parathyroid organ cultures. Ribosomal protein S6 (rpS6) is a downstream target of the mTOR pathway. We now show that mTOR activation is essential for the high levels of PTH in folic acid induced acute kidney injury (AKI). We also show for the first time that mTOR is activated in human parathyroids from patients with SHP.

Methods: Knock-in mice, whose rpS6 is unphosphorylatable due to substitution of all five phosphorylatable serines to alanines ($rpS6^{P-/-}$) and wild type ($rpS6^{P+/+}$) mice were injected with folic acid to induce AKI. Archival human parathyroid sections from dialysis patients with SHP and control parathyroids removed at thyroparathyroidectomy were studied by immunofluorescence for phosphorylated rpS6 and proliferation markers, PCNA and Ki-67.

Results: rpS6 is a downstream target of the mTOR pathway. Knock-in $rpS6^{P-/-}$ and wild type mice were injected with folic acid to induce AKI. AKI led to the expected increase in serum PTH in $rpS6^{P+/+}$ wild type mice but significantly less so in the $rpS6^{P-/-}$ mice demonstrating the mTOR activation is essential for the pathogenesis of SHP. Parathyroids from CKD patients with SHP showed increased staining for phosphorylated rpS6 compared to control parathyroids. Moreover, phosphorylated rpS6 co-localized with PCNA, a marker of cell proliferation.

Conclusions: mTOR is an essential regulator of parathyroid cell proliferation and it exerts this effect through rpS6 phosphorylation. Importantly, mTOR is activated in human CKD parathyroids and co-localizes with PCNA in proliferating cells. Therefore, mTOR is central to the pathogenesis and regulation of parathyroid cell proliferation in SHP.

Characterization of the PTH-Responsive Phosphoproteome in the Proximal Tubule

Rebecca Murray,[2] Michael Merchant,[3] Syed J. Khundmiri,[2,3] Barbara Clark,[4] Eleanor D. Lederer.[1,2,3] *[1]Robley Rex VAMC, Louisville, KY; [2]Physiology & Biophysics, Univ of Louisville, Louisville, KY; [3]Medicine, Univ of Louisville, Louisville, KY; [4]Biochemistry, Univ of Louisville, Louisville, KY.*

Background: PTH is a key regulator of the expression and function of the type IIa sodium phosphate cotransporter (Npt2a), the protein responsible for regulated renal phosphate reabsorption. We have previously shown that PTH induces rapid destabilization

of Npt2a mRNA through both PKA- and PKC-dependent mechanisms. We hypothesize that PTH regulates Npt2a mRNA through phosphorylation of an RNA-binding protein (RBP), resulting in enhanced Npt2a mRNA degradation.

Methods: To address this aim, we treated opossum kidney (OK) cells, a PTH-sensitive proximal tubule cell culture model, with 100nM PTH for 30m and 2h, followed by mass spectroscopy characterization of the PTH-stimulated phosphoproteome.

Results: We identified 1083 proteins whose phosphorylation status significantly changed in response to PTH, including several RBPs. Through computational analysis, we identified two phospho-RBPs (Roquin-2 and KHSRP) with predicted binding sites for the 3'-UTR of Npt2a mRNA. Roquin-2 phosphorylation was significantly increased at both the 30m and 2h time points, whereas KHSRP phosphorylation was significantly increased only at the 2h time point. Western blot analysis confirmed expression of both proteins in OK cells and showed increased expression of both of these proteins in response to PTH, as well as decreased expression in response to treatment with low phosphate media, an upregulator of Npt2a expression. Immunoprecipitation of KHSRP from control and PTH-treated OK cell lysates, followed by RNA isolation and qRT-PCR, showed Npt2a mRNA was pulled down with KHSRP.

Conclusions: We conclude that Roquin-2 and KHSRP are potential mediators of PTH-induced changes in Npt2a expression. Funding provided by VA to EDL.

FR-PO869

An Immuno LC MS/MS Assay for Parathyroid Hormone Demonstrates Variable Oxidation of PTH Peptides: Implications for PTH Assay Li Cui,[1] Gavin E. Reid,[1,2] Fabrizio Bonelli,[3] John Wall,[3] Angela L. Podgorski,[3] Marie D. Philipneri,[4] Anjana S. Jagalur,[4] Amy L. Krieg,[4] Mustafaa S. Mahmood,[4] Kevin J. Martin.[4] *[1]Dept of Chemistry, Michigan State Univ, East Lansing, MI; [2]Dept of Biochemistry and Molecular Biology, Michigan State Univ, East Lansing, MI; [3]Diasorin Inc, Stillwater, MI; [4]Div of Nephrology, Saint Louis Univ, St. Louis, MO.*

Background: Assay of PTH has been historically problematic due to variable standardization, variable cross reactivity with PTH fragments and variable correlations with biological parameters. A recent demonstration that PTH peptides may be oxidized further complicates these issues since oxidized PTH has no biological activity.

Methods: To characterize this issue further an immuno-LC MS/MS assay was developed using stable isotope labelled PTH and oxidized synthetic peptide internal standards to analyze the nature of circulating PTH peptides and their degree of oxidation and to examine the effects of PTH oxidation on immunochemiluminescent PTH assays. Two series of samples from patients on hemodialysis were obtained and analyzed.

Results: In Set A, oxidized PTH 1-84 and oxidized PTH 7-84 were commonly observed. The oxidized peptides ranged from 0 to 80% of the total PTH peptides. Of 41 samples, 34 of 41 had more than 10% oxidized PTH peptides. In general, there was more oxidized PTH 7-84 than oxidized PTH 1-84. In contrast, in Set B, only minimal amounts of oxidized PTH peptides were observed and only 3 of 29 patient samples had more that 10% oxidized PTH peptides.

Conclusions: The marked difference in the amount of oxidized PTH peptides between Set A and Set B suggests that oxidation of PTH may be occurring ex-vivo. Further studies are required to fully define the possibility of ex-vivo oxidation and the contributing factors. The immuno-LC MS/MS results correlated extremely well with the assay of PTH 1-84 and less well with other "intact PTH" assays. The effects of oxidation of PTH peptides on the assay of PTH by currently used intact PTH assays may represent an additional factor contributing to the variability of PTH assay results and their correlation with biological parameters.

Common Genetic Variants Associate with Circulating Parathyroid Hormone Concentration Cassianne Robinson-Cohen,[1] Pamela L. Lutsey,[2] Yuri Milaneschi,[4] Carrie M. Nielson,[3] Braxton D. Mitchell,[5] Elizabeth Selvin,[6] Josef Coresh,[6] Caroline S. Fox,[7] Ian H. de Boer,[1] Bryan R. Kestenbaum.[1] *[1]Kidney Research Inst, U of Washington; [2]U of Minnesota; [3]OHSU; [4]VU Univ Medical Center/GGZ inGeest; [5]U of Maryland; [6]Johns Hopkins Univ; [7]NIH/NHLBI.*

Background: Parathyroid hormone (PTH) is commonly elevated in CKD patients and is associated with uremic bone disease. PTH is regulated by calcium, phosphate, and 1,25-dihydroxyvitamin D; however, substantial inter-individual variation in serum PTH levels remains unexplained. We conducted the first genome wide association study to investigate associations of common genetic variants with serum PTH concentrations.

Methods: We studied 22,650 participants of European ancestry from nine population-based cohort studies. We excluded participants with eGFR <30 ml/min/1.73m^2. We used a log-based model to account for differences in PTH assays across studies and we adjusted for age, sex, and principal components of ancestry.

Results: Loci from 5 independent regions reached genome-wide significance (P <5 x 10^{-8}), for associations with serum PTH, including loci near CYP24A1 (rs6127099, P=4.2E-53), SLC34A1 (P=6.6E-17), CLDN14 (P=3.5E-16), RTDR1 (P=8.7E-9) and CASR genes (P=4.8E-8). Identified loci had minor allele frequencies between 7-40%. For the top single nucleotide polymorphism near CYP24A1, each additional copy of the minor allele was associated with an estimated 7% lower serum PTH concentration. Independent replication efforts and further characterization of these loci for associations with clinical hyperparathyroidism are ongoing.

Conclusions: Common genetic variants located near vitamin D metabolism, calcium sensing, and phosphate transport genes are associated with differences in serum PTH concentrations. The functional relationship of other identified loci with PTH metabolism awaits identification.

Figure 1. Regional association plot of rs6127099 and surrounding variants with serum PTH

FR-PO871

Analysis of Hyperparathyroidism and Its Treatment in Patients with Non-Dialysis Chronic Kidney Disease Thilini Nishani Abeygunaratne, Darren Green, Diana Chiu, Philip A. Kalra. *Salford Vascular Research Group, Univ of Manchester, Manchester, United Kingdom.*

Background: Abnormalities of chronic kidney disease-mineral bone disease (CKD-MBD) occur in early stages of CKD and guidelines remain vague as to its treatment. Aim of this study was to observe the prevalence of CKD-MBD abnormalities in a non-dialysis CKD population according to the NKF- KDOQI guidelines, and to assess frequency of use of phosphate binders and vitamin D analogues in its treatment.

Methods: A sub study of a prospective longitudinal cohort study of non-dialysis patients requiring CKD management in secondary care. HPTH was defined according to NKF KDOQI guidelines (stage 3: 35-75 pg/ml:stage 4: 80-100 pg/ml: stage 5: 150-300 pg/ml). Given some patients had treated HPTH, patients within "normal PTH range" were further evaluated.

Results: The 1667 patients had a mean age of 64.6±14.3 years, eGFR 32.5 ±16ml/min/1.73 m^2,65% males. The mean PTH was 95±89.4 pg/ml and higher PTH and HPTH prevalence was observed in more advanced CKD.

	All Patients	Stage 3a	Stage 3b	Stage 4	Stage 5
N	1667	276 (17%)	485 (29%)	621 (37%)	285 (17%)
Age (yrs)	64.6±14.3	62.6±13.6	65±13.8	66.4±13.9	62.8±15.5
eGFR (ml/min/1.73^2)	32.5±16	51.1±4	36.6±4.18	21.9±3.9	11.7±4.5
PTH (pg/ml)	95±89.4	49±34.1	64±47.3	113±97.6	153±115.9
Phosphate binders: all	8.5%	5.8%	4.3%	9%	16.8%
Ca containing (%)	7.7%	5.4%	4.1%	8.2%	14.7%
Vitamin D Analogues	21.5%	8%	13.2%	27.9%	35.1%
PTH:Below Range	699 (41.9%)	120 (43.5%)	139 (28.6%)	273 (44%)	167 (58.6%)
EuPTH:within range	464 (27.8%)	105 (38%)	186 (38.4%)	85 (13.6%)	88 (30.9%)
HPTH	504 (30.3%)	51 (18.5%)	160 (33%)	263 (42.4%)	30 (10.5%)

Conclusions: This observational study of an unselected cohort of patients at different stages of CKD shows that phosphate binder use was low (<10%) except in stage 5 CKD patients (17%); vitamin D analogue use increased progressively across the stages. These results only represent a cross sectional analysis, and therefore not possible to define HPTH according to KDIGO, which depends upon a PTH above the upper limit of normal as well as a rising PTH. Further analysis with serial PTH measurements will increase the value of the study.

FR-PO872

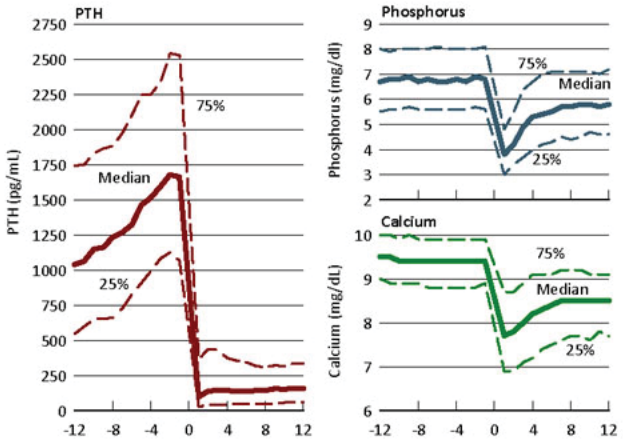
Changes in PTH, Calcium, and Phosphorus Levels after Parathyroidectomy in Patients on Hemodialysis James B. Wetmore,[1] Jiannong Liu,[1] Thy P. Do,[2] Kimberly Lowe,[2] Areef Ishani,[3] Brian D. Bradbury,[2] Geoffrey A. Block,[4] Allan J. Collins.[1] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]Center for Observational Research, Amgen, Inc., Thousand Oaks, CA; [3]Minneapolis VA Health Care System, Minneapolis, MN; [4]Denver Nephrology Clinical Research Div, Denver, CO.*

Background: Little is known about how levels of parathyroid hormone (PTH), calcium (Ca), and phosphorous (P) change after parathyroidectomy (PTX) in hemodialysis patients.

Methods: Medicare Parts A/B claims were combined with monthly lab data from DaVita, Inc., to assess PTH, Ca, and P levels in the years before and after PTX. The study cohort comprised all patients who underwent PTX in 2007-09, were aged ≥ 18 yrs, had Medicare Parts A/B as primary payer, and had been receiving HD for ≥ 1 year before PTX. PTX was identified from ICD-9 inpatient procedure codes.

Results: Among 1402 PTX patients, mean (±SD) age was 48.9 ± 13.0 years, 52.4% were male, 58.8% were African-American, and mean dialysis duration was 7.5 ± 4.6 years. PTH increased over the year before PTX from a median of 1039 pg/mL to 1661 pg/mL; levels were > 2500 pg/mL for 25% immediately prior to PTX. After PTX, PTH decreased to a median of 98 pg/mL at 1 month, but values were highly skewed, with a mean of 326 ± 535 pg/mL. Ca fell substantially after PTX, from a median of 9.4 mg/dL to 7.7 mg/dL at 1 month post-PTX; levels were ≤ 6.9 mg/dL for 25%. At 3 months, median Ca was 8.0 mg/dL; levels were ≤ 7.1 mg/dL for the lowest 25%. Median P immediately prior to PTX was 6.8 mg/dL, stabilizing at a median of 5.8 mg mg/dL one year after PTX.

Conclusions: Patients had very high PTH levels at the time of PTX. After PTX, levels fall below recommended goals for many patients, but also remain high for many. A substantial number of patients experienced strikingly low Ca levels after PTX, which can be sustained for several months.



FR-PO873

Risk Factors and Long-Term Outcome Among Dialysis Patients with Parathyroidectomy: A Population-Based Cohort Study in Taiwan Wei-Chih Kan,[1,2] Chih-Chiang Chien.[1,2] *[1]Nephrology, Chi-Mei Medical Center, Tainan, Taiwan; [2]Medical Laboratory Science and Biotechnology, Chung Hwa Univ of Medical Technology, Tainan, Taiwan.*

Background: Parathyroidectomy (PTX) is a common-used surgery in dialysis patients with severe hyperparathyroidism. Risk factors for high-risk group of PTX and their long-term outcome are inconclusive. The study aims to identify the risk factors for PTX in dialysis patients and survey for their long-term outcome after PTX.

Methods: We conducted an observational cohort study to investigate the risk factors and long-term outcome in dialysis patients with PTX, based on Taiwan's National Health Insurance claim data between 1999 and 2008, and 35,162 dialysis patients was enrolled for this study. Several risk factors possibly affecting mortality were analyzed with Cox proportional hazards models. Kaplan-Meier method was used to calculate the incidence of PTX and the survival rate after PTX.

Results: In Taiwan, The PTX rate was 8.10 per 1,000 patient-years between 1999 and 2008. Stratified on the basis of sex and diabetic mellitus (DM), the highest incidence rate of PTX was in the group of females without DM. After stratified by age and DM, the highest incidence rate of PTX was in those patients with aged 18-44 years without DM. The risk factors for PTX were younger age, female (hazard ratio (HR) 1.409, DM (HR 0.479), peritoneal dialysis (HR 1.657) and hypertension (HTN) (HR 1.317). The cumulative survival rates after PTX were 97.1%, 94.5%, 82.8% and 77.4% at the 1st, 2nd, 5th and 7th year, respectively. Only age was significantly associated with higher mortality after PTX via multivariable analysis.

Conclusions: High-risk group of PTX in dialysis patients were female, young-aged, non-DM, HTN, and patients on peritoneal dialysis. Older age was associated with a higher mortality after PTX.

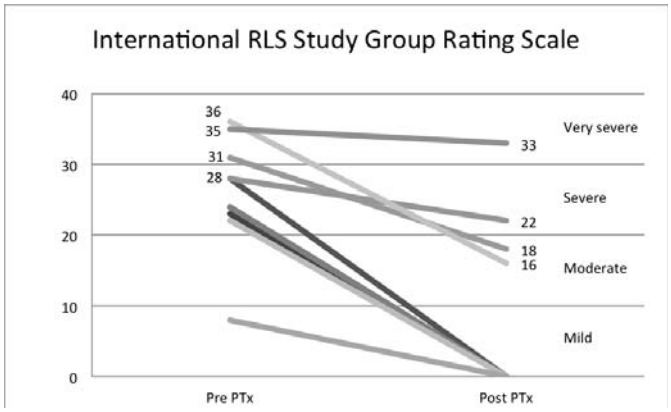
FR-PO874

Effect of Parathyroidectomy on Sleep Disorders: Is There Any Improvement? Roberto S.S. Santos,[1] Fernando Coelho,[2] Bruno C. Silva,[1] Vanda Jorgetti,[1] Rosa M.A. Moyses,[1] Rosilene M. Elias.[1] *[1]Nephrology, Univ de São Paulo, São Paulo, Brazil; [2]Neurology, Univ Federal de São Paulo, São Paulo, Brazil.*

Background: Secondary hyperparathyroidism (SHPT) is associated with complications that are not limited to the skeleton and include sleep disorders. However, there is no data based on polysomnography in these patients. In addition, little research has been made into the effects of parathyroidectomy (PTx) on sleep disorders. This prospective study was devised to investigate whether PTx can influence sleep disorders in end-stage renal disease patients on hemodialysis with SHPT.

Methods: We evaluated 18 patients (6 men, aged 48±11 years) who underwent standard PSG immediately pre and within 12 weeks post PTx. Restless Leg Syndrome (RLS) diagnosis and rating scale were accessed using the International RLS Study Group.

Results: There was a decrease in serum parathyroid hormone (PTH), calcium, phosphate, and alkaline phosphatase after PTx. Ten patients (56%) had RLS before surgery and only 4 (22.2%) remained with this diagnosis post PTX (p=0.04), accompanied by a decrease in rating scale, figure1. Patients with RLS presented higher phosphate and higher severity of periodic leg movements of sleep/h (PLMI) at baseline (p=0.008 and 0.004, respectively). PSG data are shown in table1. There was no improvement in apnea-hypopnea index (AHI) or any other sleep parameter.



PSG data	Pre PTx	Post PTX	p
Total sleep time, min	328±75	342±73	0.505
NREM, %	83 (79, 88)	83 (78, 86)	0.164
REM %	16 (12, 21)	17 (14, 22)	0.264
AHI	8.9 (2.3, 20.6)	12 (5.4, 20.4)	0.378
PLMI	6.1 (0,29)	14.7 (0,43)	0.098

Conclusions: PTx did not improve sleep architecture or sleep-disordered breathing. However, PTx provided an opportunity to improve RLS, a disabling condition for which usually only symptomatic treatment is available. Whether RLS may be improved by reduction of serum phosphorus or PTH merits further investigation.

Funding: Government Support - Non-U.S.

FR-PO875

The Calcimimetic R568 Effectively Prevents the Loss of Choroid Plexus and Parathyroid Klotho in Chronic Kidney Disease M. Vittoria Arcidiacono, Sandra De la Fuente, Petya Valcheva, Sabrina De Gaspari, Adriana S. Dusso. *IRBLleida, Spain.*

Background: Progressive loss of renal and parathyroid (PT) Klotho is a main determinant of the severity of renal and vascular lesions in chronic kidney disease (CKD). However, the impact of CKD on choroid plexus (CP) Klotho, essential for neuronal and cognitive function, is unknown. Our prior studies in mouse CKD showed that the calcimimetic R568 improved motor-neuron function by preventing CKD-induced increases in monocyte ADAM17, the cause of TNFa-driven inflammation. Since inflammation is a CKD-independent suppressor of Klotho expression and vitaminD is an inducer of the Klotho gene, this work compared R568 and vitaminD efficacy to prevent CKD-induced Klotho loss.

Methods: Two months after 75% nephron reduction (NX), mice received either R568 (s.c. 60 mg/g body weight), 25-hydroxyvitaminD (25D, i.p. 80 ng weekly) + paricalcitol (P, i.p. 16 ng thrice weekly) or the combination for 6 weeks. Tissue Klotho was measured by immunohistochemistry.

Results: Similar to renal and PT Klotho, CP Klotho was markedly reduced in untreated uremic mice. Surprisingly, R568, which had no effect on renal Klotho levels, completely prevented CKD-induced reductions in PT ($p<0.02$) and CP ($p<0.015$) Klotho at a dose ineffective to suppress PTH. Also, 25D+P, which effectively prevented CKD-induced elevations in serum PTH ($p<0.01$) and reductions in renal Klotho ($p<0.02$), had no effect on PT or CP Klotho. CKD-induced PT hyperplasia, the cause of reductions in vitaminD receptor (VDR), could partially account for vitaminD inefficacy to maintain PT Klotho. To test this possibility, we compared PT Klotho content after 14 weeks of NX in wild type mice and transgenic littermates with a PT specific EGFR-inactivation that prevents both PT gland enlargement and VDR loss. PT Klotho was similar in mice of both genotypes, supporting an abnormal vitaminD induction of PT Klotho in CKD.

Conclusions: In CKD, loss of CP Klotho may contribute to impair neuronal and cognitive function. The distinct efficacy of vitaminD and R568 treatment in preventing renal or PT/CP Klotho suggests the importance of revisiting current strategies to attenuate CKD-accelerated aging also beyond mineral bone disorders.

FR-PO876

Treatment with Cinacalcet Increases Plasma Adiponectin Concentration in Hemodialysed Patients with Chronic Kidney Disease and Secondary Hyperparathyroidism Marcin Adamczak,[1] Piotr Kuczera,[1] Grzegorz Machnik,[2] Boguslaw Okopien,[2] Andrzej Wiecek.[1] *[1]Dept of Nephrology, Endocrinology and Metabolic Diseases, Medical Univ of Silesia, Medical School in Katowice, Katowice, Poland; [2]Dept of Internal Medicine and Clinical Pharmacology, Medical Univ of Silesia, Medical School in Katowice, Katowice, Poland.*

Background: Cinacalcet increases the sensitivity of calcium receptor (CaR) to circulating serum calcium. CaR is expressed among others also in adipocytes. Adiponectin is a beneficial adipokine with antiatherogenic and insulin-sensitizing properties. The aim of this study was to assess the influence of 3-month cinacalcet therapy on plasma adiponectin concentration in hemodialysed patients with chronic kidney disease (HDP) and secondary hyperparathyroidism (sHPT).

Methods: In 65 HDP [38 males, 27 females; mean age 53.6 (50.0-57.1) years] with sHPT treated with cinacalcet (30-120 mg/day) plasma adiponectin, advanced oxidation protein products (AOPP), serum interleukin-6 (IL-6) and C-reactive protein (CRP) concentrations were assessed before the first dose of cinacalcet and after 3 months of treatment. The results are shown as means and 95% confidence index.

Results: A significant decrease in serum parathormone (PTH) concentration - from 1089 (891-1286) pg/ml to 775 (574-976) pg/ml was found after 3 months of treatment with cinacalcet ($p<0.0001$). The treatment was associated with a significant ($p=0.048$) increase in plasma adiponectin concentration from 16.9 (14.4-19.5) µg/ml to 17.8 (15.0-20.6) µg/ml. Significant ($p=0.03$) reduction of plasma AOPP concentration was observed – from 186.7 (156.7-216.7) pg/ml to 162.6 (141.2-183.9). BMI and mean concentration of serum markers of inflammation were stable during the entire treatment period.

Conclusions: 1. Three months treatment with cinacalcet in haemodialysed patients with sHPT leads to increased plasma adiponectin concentration. 2. Increased adiponectinemia may be related to the reduction of oxidative stress and may lead to reduction of cardiovascular mortality and morbidity.

FR-PO877

Cinacalcet Hydrochloride Promotes G1 Phase Transition From G0 Quiescent State and Lead to Apoptotic Pathway of Parathyroid Cells Takayo Miyakogawa, Kaichiro Sawada, Genta Kanai, Ryoko Tatsumi, Takatoshi Kakuta, Masafumi Fukagawa. *Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan.*

Background: Recent studies reported that cinacalcet promotes apoptosis of parathyroid cells. We previously reported that, compared to patients treated without cinacalcet, frequencies of both apoptosis (TUNEL positive) and proliferation (Ki-67 positive) of parathyroid cells increased significantly in parathyroid glands (PTGs) of patients treated with cinacalcet.

Methods: Paraffin sections of PTGs from patients treated with/without cinacalcet were reacted with anti-c-myc and anti-p27Kip1 antibodies. RNAs were recovered from sections and used for real time RT-PCR with primers for c-myc and $p27^{Kip1}$. Parathyroid cells were collected from PTGs and cultured with media containing 100 nM cinacalcet hydrochloride. Real time RT-PCR was performed as above with RNAs from a part of cultured cells. Remaining cells were stained with PI and DNA contents were analyzed by flow cytometry.

Results: We found that cells expressing c-myc appeared and cells expressing $p27^{Kip1}$ decreased its amount in PTGs from cinacalcet treated patients. As these genes are known to control G0-G1 phase transition in cell cycles, our findings suggested that cinacalcet treatment may activate cell cycles by accelerating the transition of cells from G0 phase into G1 phase. These changes of expressions of c-myc and $p27^{Kip1}$ were reproduced in *in vitro* parathyroid cells cultured with cinacalcet. However, the flow cytometry analysis of these cultured cells revealed only a little increase of ratios of cells in S phase (from 3.51% to 4.69%) and G2 phase (from 1.86% to 2.66%).

Conclusions: Although cinacalcet promotes transition of parathyroid cells from G0 phase (Ki-67 negative) into G1 phase (Ki-67 positive), we estimate that most of cells in G1 phase could not get over some checkpoints of cell cycles before mitosis, and they are driven to die (TUNEL positive). Transitory entry into G1 phase may be necessary for parathyroid cells in G0 phase to proceed to apoptosis pathway. Volumes of PTGs may be controlled with these mechanisms through signals from calcium-sensing receptors.

FR-PO878

Cinacalcet for Hypercalcemic Hyperparathyroidism after Renal Transplantation: A Long-Term Prospective Self-Controlled Study Ursula Thiem,[1] Kyra Borchhardt.[1,2] *[1]Nephrology, Med Univ of Vienna, Vienna; [2]Dialysis Inst Klagenfurt, Austria.*

Background: Several short-term studies demonstrated successful control of hypercalcemic hyperparathyroidism after renal transplantation with cinacalcet. As long-term studies in kidney transplant recipients (KTRs) are lacking, we herein describe our long-term experience with this drug.

Methods: In this prospective open-label self-controlled study, 44 stable KTRs with hypercalcemic hyperparathyroidism were treated with cinacalcet and its effects on biochemical parameters of mineral metabolism were assessed by comparing pre- and post-treatment periods using summary statistics. For each patient, a post-treatment median was calculated that summarizes all repeated measurements of a parameter of interest up to four years after cinacalcet initiation. This was compared to each patient's pre-treatment median that summarizes all repeated measurements obtained between the date of initial hypercalcemia following transplantation and cinacalcet initiation (median time 1.6 (IQR 0.6-3.8) years). Results are reported as mean differences (95% CI) between pre- and post-treatment periods.

Results: Cinacalcet was initiated after a median of 1.8 (0.8-4.7) years after transplantation and was maintained for 6.2 (3.9-7.6) years. Total serum calcium levels significantly decreased (-0.30 (-0.34 to -0.26) mmol/l, $p<0.001$), which was accompanied by an increase in urinary fractional calcium excretion (0.24 (0.06-0.42) %, $p<0.05$). Serum phosphate levels (sPh) and renal tubular reabsorption of phosphate corrected for glomerular filtration rate (TmP/GFR) simultaneously increased within the first year after treatment start, then reaching a plateau in the lower normal range (sPh: 0.19 (0.15-0.23) mmol/l, $p<0.001$; TmP/GFR: 0.20 (0.16-0.23) mmol/l, $p<0.001$). Intact parathyroid hormone levels significantly decreased over time (-79 (-103 to -55) pg/ml, $p<0.001$). We did not observe deterioration of graft function following treatment with cinacalcet. Side-effects included minor gastrointestinal symptoms, which were reversible after dose reduction or switch to twice-daily administration.

Conclusions: Cinacalcet effectively controlled hypercalcemic hyperparathyroidism in KTRs in the long-term.

FR-PO879

Cinacalcet (CM) versus Paricalcitol (PC) in Renal Transplant (TX) Patients with Hypercalcemic Persisting Secondary Hyperparathyroidism (HPSH). Pilot Study Marzia Pasquali,[1] Lida Tartaglione,[1] Silverio Rotondi,[1] Carlo Massimetti,[2] Sandro Mazzaferro.[1] *[1]Sapienza Univ, Rome, Italy; [2]Bel Colle Hospital, Viterbo, Italy.*

Background: Post TX HPSH results, at least partly, from decreased Ca- (CaSR) and VitD- (VDR) receptors expression on parathyroids. Receptor activators like CM or PC could increase expression of both.We hypothesized that, in post TX HPSH, after serum Ca normalization with CM, PC could maintain PTH suppression without hypercalcemia if CaSR were increased.

Methods: We prospectively enrolled 19pts with HPSH to receive CM (Phase I, 1 month), dose-titrating for normal sCa. Responders were randomized (Phase II, 3 months) to continue CM (Group A) or shift to PC (Group B). Serum Cr,Ca,Pi,PTH, BALP, 1,25D,FGF23 and Urine Ca/Cr were checked basally and monthly.

Results: 16 pts (54±7y.o.; eGFR 58±20ml/min, TX since 7±5yrs, sCa 11,1±0,6mg/dl, Pi 2,7±0,4mg/dl, PTH 133±43pg/ml, BALP 35±36U/l, FGF23 81±25pg/ml) completed the study. During Phase I, CM therapy (mean dose 35±12mg/day) reduced sCa ($p<.0001$), PTH ($p<.001$) and FGF23 ($p<.0001$) and increased sPi ($p<.0001$). During Phase II: in Group A (8 pts; CM mean dose 41±15mg/day) there was no further change; in Group B (8 pts; PC mean dose 0.8±0.3mg/day) there was: increment of sCa (back to basal, pre-treatment, values) ($p<.0001$) and FGF23 ($p<.005$); reduction of BALP ($p<.002$) and Pi (ns, $p<.06$); persistence of PTH suppression.

Conclusions: We confirm the lowering effect of CM on Ca and PTH in HPSH and report that, in TX pts, FGF23 can decrease contemporarily to sPi increments. PC maintain the reached suppression of PTH but with loss of the (hypo) calcemic effect, as if CaSR stimulation by CM were more relevant than increased CaSR expression. PC therapy increase FGF23 and this is potentially implicated with suppression of PTH and tendency to sPi reduction. BALP and FGF23 changes point to direct effects of PC on bone. In conclusion, with a short-term period of therapy, the role of receptors expression seems secondary to the direct effect of drugs. From a clinical point of view, contemporary administration of CM and PC could be advantageous to control HPSH in TX.

FR-PO880

Impact of Cinacalcet Pre-Transplant on Mineral Metabolism in Renal Transplant Recipients Ashish K. Sharma,[1,2] Sven-Jean Tan,[1,2] Stephen G. Holt,[1,2] Nigel David Toussaint.[1,2] *[1]Dept of Nephrology, The Royal Melbourne Hospital, Parkville, VIC, Australia; [2]The Univ of Melbourne, Parkville, VIC, Australia.*

Background: Cinacalcet, a calcimimetic, was approved in Australia in November 2007 for treating secondary hyperparathyroidism in dialysis patients. Reports on biochemical profiles and clinical outcomes in patients discontinuing cinacalcet at the time of renal transplantation are limited.

Methods: A single-centre retrospective analysis over 10 years was undertaken to study markers of mineral metabolism in renal transplant recipients from January 2002 to December 2011. We assessed changes in biochemical parameters with the introduction of cinacalcet, and compared patients discontinuing cinacalcet at the time of transplantation with cinacalcet-naïve patients.

Results: A total of 696 renal transplants were performed over 10yrs. Mean age of patients at transplant was 47.4yrs (64.8% male) with 29 (4.2%) deaths, 94 (13.5%) graft loss and 16 (2.3%) parathyroidectomies post-transplant (all in cinacalcet-naïve patients). Since November 2007, 377 patients received transplants, 19.9% on cinacalcet pre-transplant. No significant differences were seen in markers of mineral metabolism at 12 months post-transplant in pre and post-cinacalcet eras. At time of transplantation, parathyroid hormone (PTH) levels were higher in cinacalcet versus cinacalcet-naïve patients (61.5+/-60.5 versus 36.0+/-30.7pmol/L, $p<0.001$). Twelve months post-transplant PTH was higher (15.1+/-11.2 versus 9.6+/-8.4pmol/L, $p<0.001$) and calcium was higher (2.49+/-0.17 versus

2.44+/-0.17mmol/L, p=0.009) for those administered cinacalcet just prior to transplantation. There was no difference in renal function at 12 months (mean eGFR 53.6+/-17.4ml/min/1.73m^2) between the two groups.

Conclusions: Biochemical profiles suggest minimal changes to markers of post-transplant mineral metabolism with the introduction of cinacalcet. Renal transplant recipients discontinuing cinacalcet at the time of transplantation had statistically significant PTH and serum calcium at 12 months although this may not be clinically significant.

FR-PO881

Fibroblast Growth Factor-23 Vit D and Mineral Metabolism in Renal Transplant Recipients Raj K. Sharma, Sonia Mehrotra, Narayan Prasad, Amit Gupta, Anupama Kaul. *Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, UP, India.*

Background: Mineral bone disorder related to chronic kidney disease persists after kidney transplantation.

Methods: Fifty chronic kidney disease patients on dialysis going for transplantation were prospectively studied before and after renal transplantation for parameters like FGF23, vit D receptor (VDR), 25 (OH) D, 1,25 (OH) 2 D, PTH, serum Ca, S. Po4, alk PO4, eGFR.

Results: The prevalance of hypophosphatemia after transplantation was high 54%, hypercalemia 27.3%, elevated intact PTH levels 78.3% (at the median duration of 3 months after transplant). While before transplant 54% had hyperphosphatemia, hypercalcemia in 2.9%, elevated PTH in 97% as compared to control healthy population. FGF 23 levels were high in 82.4% before transplant (79.36+92.4 pg/ml) and decreased to normal level at 3 month post transplant (3.74+1.31 pg/m) (normal control 3.17+0.9 pg/ml), 25 (OH) D levels showed vit D deficiency in 28.6% before transplant (28.56+12.69 ng/ml), after transpalnt vit D deficiency seen in 43.9% (20.3+6.19 ng/l). 1,25 (OH) D levels before transplant were 136.36+96.14 pmol/L which was less than control (176.1+107 pmol/L) and decreased further to 45.65+34.47 pmol/ml at 3 months post transplantation. VDR activity before transplant was higher (1.91+2.73 ngm/ml) than control (1.52+0.8 ng/ml) and showed further increase to 2.25+2.19 ng/ml after transplantation. There was no difference in the eGFR in transplant patients with or without vit D deficiency (MDRD eGFR 74.4+20.6ml/ and 73.4+18.6 ml/min). Serum intact PTH levels were 316+251.8 pg/ml before transplant and came down to 91.6+58.2 at 3 months post transplantation.

Conclusions: There was high incidence of vit D deficiency or insufficiency in ESRD patients (62.9%) which increased further to 95.7% at 3 month after kidney transplant. 1,25 (OH) 2 D3 levels also decreased after transplant with concomitant increase in VDR activity. FGF 23 levels quickly came down to normal levels by 3 months post transplant. There was normalization of S.PO4 levels by 3 months post transplant. The dysregulated mineral metabolism may continue after kidney transplant despite improvement in renal function and normalization of FGF 23.

FR-PO882

Effects of Inflammation on Serum Levels of SOST in Hemodialysis Patients (HD) Silverio Rotondi, Marzia Pasquali, Lida Tartaglione, Sandro Mazzaferro. *Sapienza, Rome, Italy.*

Background: Produced by osteocytes, Sost inhibits osteoblasts Wnt pathway, thus affecting bone turnover. Recently Sost levels have been reported to be increased in HD, with a possible negative effect on bone disease. Moreover, in experimental osteoporosis, Sost have been shown to positively correlate with inflammatory cytokines. Since HD suffer with chronic inflammation, we sought to evaluate if inflammation affects Sost in HD.

Methods: 41patients (59±16y.o.) on HD since 5,9±4,8 y were sampled for parameters of inflammation (IL1,IL6,IL10,TNFa) and of mineral metabolism (Ca,P,PTH,Vit D). 30healthy subjects (34±12y.o.; eGFR95±19ml/min) as control.

Results: HD population showed a moderate degree of secondary hyperparathyroidism ((Mean values: Ca 8,9±0,9; P 4,7±1,5;PTH 343±363;vitamin D 11±6) and a significant increment of all standard inflammatory cytokines and of OPG and RANKL.

	Sost nmol/l	OPG pg/ml	RANKL mcg/ml	IL 1 pg/ml	IL 6 pg/ml	IL10 pg/ml	TNFα pg/ml
HD (41)	59±16	5±3	0.4±0.7	0.27 ±0.58	12±19	9.5±11.9	13±11
Control (30)	28 ±10	0.1±0.2	0.1±0.05	0.01 ±0,01	0.3 ±0.3	4.3±1.3	3 ±2
p<	.0001	.0001	.0001	.0001	.0001	.0001	.0001

Sost mean levels were twice times higher than normal. Sost correlated positively with age (r.503p.001),OPG (r.424p.01),IL6 (r.419p.01) and TNFa (r.329p.05) and negatively with phosphate (r.498 p.001) and PTH (r-.347 p.05).

Conclusions: Our data confirm the increment of Sost in HD in a range similar to what has been already reported. The negative correlations with P and PTH are in agreement with a role of Sost on bone:higher Sost-lower bone turnover. The positive relationship between Sost and cytokines points to a role of inflammation on bone, exerted through Sost.Inflammation, increasing Sost, could affect bone turnover, a modulatory effect already described in HD. Further,the positive correlation of Sost with age, OPG and cytokines suggest a link with artheriosclerosis. In fact, Sost have been shown to correlate with vascular calcificationsin HD. So the increase of Sost occurring in HD could be secondary, in part, to inflammation. Sost in this population can negatively affectbone turnover thus closing a circle linking inflammation andbone disease.

FR-PO883

Effects of Nephrologists Care in Late Stage CKD Patients with Anemia on Long-Term Dialysis, Cardiovascular Disease Event and Mortality Jia-Sin Liu,[1] Yu-Kang Chang,[1] Szu-Yuan Li,[2] Chih-Ching Lin,[2] Der-Cherng Tarng,[2] Wu-Chang Yang,[2] Chih-Cheng Hsu.[1] *[1]Div of Geriatrics and Gerontology, Inst of Population Health Sciences, NHRI, Miaoli, Taiwan; [2]Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: It is undetermined whether and to what extent the professional nephrologist care for late stage chronic kidney disease (CKD) patients could delay disease progression to long-term dialysis or reduce risks of cardiovascular event or mortality.

Methods: We set up a nationally representative population-based cohort of the stage 5 CKD patients with anemia using the national insurance claim database in Taiwan from 2000 to 2009. There were 53,023 subjects meeting the inclusion criteria: serum creatinine higher than 6 mg/dL, without any dialysis record and under the erythropoiesis-stimulating agent (ESA) treatment (hematocrit less than 28 %). The study cohort was followed until 2009/12/31 or death. The mean follow-up time was 3.2 years. We divided our study subjects into 3 groups: never (n=12,295), sporadic (n=15,215), and continuing (n=25,513) nephrologist care for those who had never, 1-5, and >=6 nephrologist visits, respectively, in the previous 3 years before the ESA use.

Results: Compared to the never group, the multivariable Cox proportional hazards models showed those in the continuing group were more likely to survive long enough to develop chronic dialysis (HR 1.05, 95%CI 1.02-1.08), but less likely to be hospitalized in the ICU (HR 0.86, 95%CI 0.83-0.89), and also less likely to develop heart failure (HR 0.79, 95%CI 0.71-0.88) or die including the mortality before dialysis (HR 0.58, 95%CI 0.55-0.60) and after dialysis (HR 0.78, 95%CI 0.74-0.82).

Conclusions: In conclusion, the continuity of nephrologist care for the advanced CKD patients can significantly prolong patients' survivorship, reduce cardiovascular events and prevent pre-mature death. The survival benefit in the group receiving persistent nephrologist care can sustain even after dialysis commencement. Yet, the policy makers also have to be aware that the prevalence of dialysis may temporally be increased because of the reduction of pre-mature death in the well-cared advanced CKD patients.

FR-PO884

Iron Supplementation Is Associated with Low Mortality in Pre-Dialyzed Advanced Chronic Kidney Disease Patients Receiving Erythropoiesis-Stimulating Agents – A Nationwide Database Analysis Ko-Lin Kuo,[1] Jia-Sin Liu,[2] Szu-Chun Hung,[1] Chih-Cheng Hsu,[2] Der-Cherng Tarng.[3] *[1]Taipei Tzu Chi Hospital, Taiwan; [2]National Health Research Insts, Taiwan; [3]Taipei Veterans General Hospital, Taiwan.*

Background: Iron supplementation is associated with adverse outcomes in patients undergoing hemodialysis; however, a risk/benefit analysis of iron supplementation in pre-dialysis advanced chronic kidney disease (CKD) patients has not been conducted.

Methods: To assess the effectiveness and the safety of iron supplementation in patients with CKD stage 5 who have not yet received dialysis (CKD 5 ND), a prospective cohort study was conducted based on the Taiwan National Health Insurance Research Database. From January 1, 2000, to June 30, 2009, we enrolled 31 971 adult patients who had serum creatinine levels >6 mg/dL and hematocrit levels <28% and who were treated with erythropoiesis-stimulating agents (ESAs) but not yet received renal replacement therapy. All patients were further divided into two groups with or without iron supplementation within 90 days after starting ESA therapy. Patient followed-up took place until dialysis, pre-dialysis death or December 31, 2009. The primary outcomes were pre-dialysis death, hospitalization before death or chronic dialysis.

Results: After propensity score-matching, the patients who received iron supplementation were associated with a lower risk of all-cause death (HR, 0.85; 95% CI, 0.80-0.90) compared with nonusers in a median follow-up visit of 8 months. Moreover, compared with the nonusers, the iron users were associated with a lower risk of overall hospitalizations (HR, 0.97; 95% CI, 0.94-0.99) although they exhibited a higher risk of chronic dialysis (HR, 1.05; 95% CI, 1.01-1.08).

Conclusions: Iron supplementation has a 15% decreased risk ofdeath in CKD 5 ND patients who received ESA treatment. However, physicians should be aware of an increased risk of chronic dialysis in patients who receive iron supplementation.

FR-PO885

Potential Renal Protective Effect of Telbivudine in Patients with Chronic Hepatitis B Infection Compared to Other Antivirals Vibhakorn Permpoon,[1] Krit Pongpirul,[2,3] Sira Sooparb,[4] Sinn Anuras.[1] *[1]Digestive Disease Center, Bumrungrad International Hospital, Bangkok, Thailand; [2]Preventive and Social Medicine, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand; [3]International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [4]Nephrology Center, Bumrungrad International Hospital, Bangkok, Thailand.*

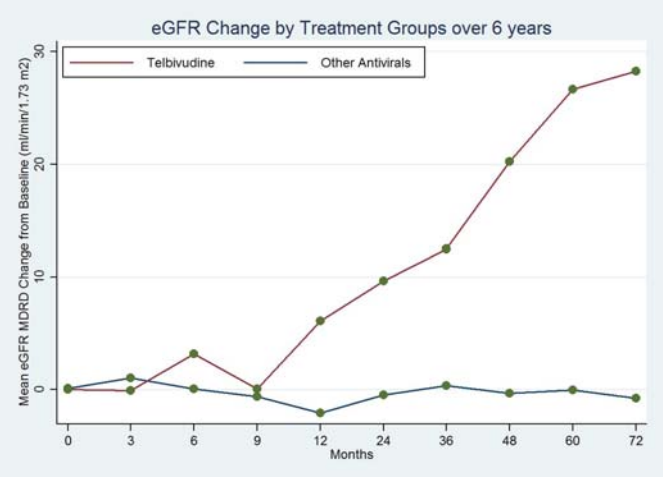
Background: This study is aimed to comparatively explore potential protective effect of Telbivudine and other antivirals on renal function.

Methods: Demographic and clinical information from medical records of 1,065 CHB patients between January 2008 and December 2013 were analyzed. Analysis of covariance model with treatment and ethnicity covariates was used to test the difference in eGFR between Telbivudine and other antivirals. Means were calculated using the least square method.

Results: Majority of the 966 patients received antivirals were Asian male with mean age of 47.57 years. Telbivudine was used in 176 cases (18.22%), of which 81 cases (46%) were combined with other antivirals. Baseline eGFR were comparable (p=0.6885). Renal function steadily improved in Telbivudine group but declined in non-Telbivudine group, with statistically significant difference shown at 12 months after treatment (p=0.0087).

Months	Telbivudine	Other Antivirals	P value*	N
Baseline	95.4244	95.6384	0.6885	577
3	101.0787	101.5174	0.8422	361
6	96.8450	94.1646	0.3383	320
9	95.0195	93.0158	0.4654	286
12	99.8380	91.1020	0.0087	295
24	105.2184	93.7611	0.0000	375
36	109.9087	95.7521	0.0000	299
48	110.0040	89.8663	0.0000	209
60	111.6309	82.3646	0.0000	145
72	113.7585	90.0600	0.1081	67

* P value was derived from analysis of covariance modelling, including treatment, ethnicity, and baseline value as covariates.



Conclusions: Potentially superior renal protective effect of Telbivudine to other antivirals for chronic hepatitis B infection exists and starts after twelve months.

FR-PO886

The Association between Renal Outcome and Use of Erythropoiesis Stimulating Agents in Patients with Advanced Chronic Kidney Disease in Taiwan

Szu Yu Pan,[1] Ping-Min Chen,[2] Tai-Shuan Lai,[2] Shuei-Liong Lin,[2] Wen-Chih Chiang.[2] *[1]National Taiwan Univ Hospital, Yun-Lin branch; [2]National Taiwan Univ Hospital.*

Background: Animal studies have shown the renoprotective effects associated with exogenous erythropoiesis stimulating agents (ESAs) at a dose as low as not to raise the hemoglobin (Hb) level. In Taiwan, the maximal ESA dose is restricted to 100mcg darbepoetin alfa or 20000U epoetin beta monthly by the National Health Insurance program. We analyzed the association between renal outcome and the use of ESAs in advanced CKD patients in Taiwan.

Methods: An observational retrospective cohort study of 455 patients with estimated glomerular filtration rate (eGFR) less than 15mL/min/1.73m^2 conducted at a single center. The patients were enrolled from 2007/1/1 to 2011/12/31 and followed until 2012/12/31. The use of ESAs was recorded every 3 months. The primary outcome was the initiation of dialysis. The secondary outcome was the annual decline rate of eGFR.

Results: The average dose of ESA received by the ESA users was around 63mcg darbepoetin alfa or 12600U epoetin beta monthly. During the first year, the Hb level of ESA non-users decreased from 10.0±1.8 to 9.7±1.8g/dL (p=0.07), while the Hb level of ESA users increased from 9.4±1.5 to 9.6±1.3g/dL (p=0.05). The factors independently associated with dialysis in the time-dependent Cox proportional hazard model were listed in table1. Of note, the use of ESA was independently associated with decreased risk for dialysis. The annual eGFR decline rates were 1.7±3.9 in ESA non-users and 2.5±3.0mL/min/1.73m^2 in ESA users (p=0.05).

Predictors	*Univariate analysis*		*Multivariate analysis*	
	HR (95% CI)	*P*	HR (95% CI)	*P*
Albumin	0.31 (0.24-0.40)	<0.001	0.31 (0.22-0.45)	<0.001
eGFR	0.83 (0.80-0.87)	<0.001	0.76 (0.73-0.80)	<0.001
ESA use	0.38 (0.29-0.50)	<0.001	0.26 (0.19-0.36)	<0.001
Log UPCR	5.60 (3.93-7.98)	<0.001	3.87 (2.41-6.22)	<0.001
Uric acid	1.14 (1.08-1.20)	<0.001	1.12 (1.05-1.20)	0.001
Male	1.40 (1.12-1.75)	0.003	1.54 (1.16-2.03)	0.002
Age	0.99 (0.98-1.00)	0.042	0.98 (0.97-0.99)	0.007
BMI	0.99 (0.97-1.02)	0.62	0.96 (0.94-0.99)	0.008

Conclusions: The use of ESAs in Taiwan was associated with delayed initiation of dialysis in patients with advanced CKD.

FR-PO887

What Are the Most Important Targets for the Management of Progression in CKD?

Marieke van Rijn,[1] Jan A.J.G. van den Brand,[1] Peter J. Blankestijn,[2] Jack F. Wetzels.[1] *[1]Radboud Univ Medical Centre; [2]Univ Medical Centre Utrecht; [3]On Behalf of the MASTERPLAN Study Group.*

Background: KDIGO guidelines for management of CKD recommend interventions on blood pressure, proteinuria, glycemic control, salt intake, lifestyle, anemia and calcium-phosphorus metabolism. We previously showed that close adherence to these guidelines reduced the risk of progression in CKD (Peeters, JASN, 2014). However, simultaneously addressing all aspects of CKD management can be challenging for doctor and patient. The purpose of this study was to identify the most important treatment factors, so that interventions may be prioritized.

Methods: The MASTERPLAN study was a RCT performed in 9 Dutch hospitals. The intervention consisted of 14 targets based on guidelines. In total 788 patients with eGFR between 20-70 ml/min per 1.73m2 were included. The outcome was a composite of death, end stage renal disease, and 50% increase in serum creatinine. The total effect of the MASTERPLAN can be split up in a direct and indirect effect. The indirect effect is defined as the proportion of the total effect explained by a change in treatment target at one year follow-up. It can be determined with mediation analysis (Imai, APSR, 2011).

Results: We were able to explain 52% of the risk reduction in the intervention arm through a reduction in blood pressure, proteinuria and LDL-cholesterol. However, a substantial proportion of risk reduction due to nurse practitioner aided care remained unexplained.

	TE	95% CI	IE	DE	Mediated (%)
Log proteinuria	-227	-468-17	-55	-171	24
LDL cholesterol	-264	-481--50	-34	-231	13
Blood pressure	-210	-425-4	-31	-181	15
Log parathyroid hormone	-266	-489--47	-1	-207	0
Total					52

The estimates for total effect (TE), indirect effect (IE) and direct effect (DE) can be interpreted as the decreased number of patients with a composite endpoint per 10.000 patients a year.

Conclusions: The reduced risk due to the MASTERPLAN intervention was mediated through lower protein creatinine ratio, LDL cholesterol and blood pressure, which may thus be priorities for a more focused intervention.

FR-PO888

Screening and Management for Chronic Kidney Disease and Risk Factors – Community-Based Program in Resource Poor Setting

Sanjib Kumar Sharma,[1] Anup Ghimire,[1] Prajjwal Pyakurel,[1] Samyog Uprety,[1] Bhawesh Koirala,[1] Sergio Carminati,[2] Giuseppe Remuzzi,[2] Norberto Perico.[2] *[1]B P Koirala Inst of Health Sciences, Nepal; [2]IRCCS - Mario Negri Inst for Pharmacological Research, Italy.*

Background: A community-based program to screen and manage hypertension, diabetes, kidney disease and its risk factors were developed in Eastern Nepal. The outcome data of such program are reported here.

Methods: A community-based screening on 20,811 people ≥20 years was performed under the coordination of BP Koirala Institute in Dharan with a collaborating network of community-based volunteers, medical students, nursing students and local leaders. Screening and intervention for chronic kidney disease, and its risk factors such as hypertension and diabetes were performed. An organization was developed to follow-up screened positive individuals in primary or equivalent health centers. Referrals were made to tertiary care centers as needed. Health status, lifestyle habit, physical examination and blood pressure were evaluated. Spot urine was examined for proteins by dipstick. Fasting blood glucose and serum creatinine were measured.

Results: Impaired kidney function (estimated GFR <60 mL/min/1.73m^2 using MDRD - 4 variables equation), dipstick proteinuria >1+, hypertension, diabetes were present in 10.6%, 5.4%, 22%, and 8%, respectively. The control of blood pressure or diabetes at baseline was 14% and 8% in respectively. 4471 participants positive at screening entered an intervention program by combining lifestyle modifications and pharmacological management with cheap drugs. At the end of three years follow up blood pressure control (<140/90 mmHg) was achieved in 53% (SBP) and 63% (DBP) of individuals, whereas glycemia target (<126 mg/dl) in 55%. Normalization of dipstick proteinuria occurred in 63% of individuals, while renal function improved in 48% of subjects during the same period.

Conclusions: The integrated care for chronic kidney disease and its risk factors is possible in low-resource settings like Nepal. The significant control of hypertension, diabetes, proteinuria and eGFR achieved in this program is expected to translate in less need of renal replacement therapy and reduced CV mortality on the long-term.

FR-PO889

Association of Drug Effects on Biochemical Endpoints (Serum Parathyroid Hormone, Calcium, and Phosphorus) with All-Cause and Cardiovascular Mortality: A Meta-Analysis

Suetonia Palmer,[1] Armando Teixeira-Pinto,[2] Jonathan C. Craig,[2] Petra Macaskill,[2] Marcello Tonelli,[3] Valeria Maria Saglimbene,[4] Giovanni F.M. Strippoli.[2,4,5] *[1]Univ of Otago Christchurch; [2]Univ of Sydney; [3]Univ of Alberta; [4]Fondazione Mario Negri Sud; [5]Amedeo Avagadro Univ of Eastern Piedmont.*

Background: Treatments to lower elevated serum parathyroid hormone and phosphorus levels are prescribed nearly universally for patients with advanced chronic kidney disease. We aimed to investigate whether drug effects on these biochemical endpoints are correlated with mortality outcomes in nephrology trials.

Methods: We did a systematic review and meta-analysis of randomized controlled trials in chronic kidney disease that reported drug effects on both biochemical endpoints (serum parathyroid hormone, calcium and phosphorus) and all-cause or cardiovascular mortality. We calculated correlated effect sizes for biochemical and mortality outcomes using bivariate random effects meta-analysis.

Results: We identified 28 studies involving 6473 participants reporting biochemical and mortality outcomes. Associations between treatment effects on surrogate endpoints and the corresponding risks of mortality were weak and imprecise. All correlation coefficients were ≤0.6 and 95% credible intervals were generally wide and overlapped with zero, consistent with the possibility of no association. The exception was an inverse correlation between drug effects on serum parathyroid hormone levels and all-cause mortality, which was nominally significant (-0.60, 95% credible interval -0.85 to -0.16), but very uncertain. Risks of bias within randomization processes, allocation concealment and loss of randomized participants from analyses were high, further reducing confidence in the summary correlations.

Conclusions: Drug effects on serum parathyroid hormone, phosphorus, and calcium are weakly and imprecisely correlated with all-cause and cardiovascular death in the setting of chronic kidney disease. Risks of mortality cannot be inferred from treatment-induced changes in serum biochemical values in nephrology trials.

Comparative Efficacy and Safety of Blood Pressure Lowering Drugs in Diabetic Kidney Disease: A Network Meta-Analysis

Suetonia Palmer,[1] Dimitris Mavridis,[2] Jonathan C. Craig,[3] Georgia Salanti,[2] Eliano Navarese,[4] Marcello Tonelli,[5] Natasha Wiebe,[5] Marinella Ruospo,[6,7] Giovanni F.M. Strippoli.[3,6,7] *[1]Univ of Otago Christchurch; [2]Univ of Ioannina; [3]Univ of Sydney; [4]Univ of Raboud; [5]Univ of Alberta; [6]Univ of Eastern Piedmont; [7]Diaverum.*

Background: The comparative efficacy of blood pressure lowering agents in diabetic kidney disease remains uncertain because few active comparator trials have been conducted.

Methods: We did a network meta-analysis, which uses both direct and indirect drug comparisons from randomized trials within a single analytical framework. We included data in adults with diabetes and kidney disease. Primary outcomes were all-cause mortality and ESKD. We also examined cardiovascular events, regression of albuminuria and doubling of serum creatinine.

Results: We identified 190 studies involving 41,598 participants. An ACE inhibitor (ACE) plus an angiotensin-receptor blocker (ARB) was the best intervention for preventing ESKD (OR 0.50; 0.31-0.79). The only other drug to significantly prevent ESKD was an ARB alone (0.77; 0.65-0.91), while point estimates suggested beneficial effects from ACE alone (0.71, 0.47-1.08) and endothelin inhibitor (0.71, 0.44-1.14) treatment. Point estimates suggested combination ACE and ARB were superior to ARB alone (0.64, 0.41-0.99) and ACE alone (0.69, 0.34-1.24) for preventing ESKD. ACE or ARB both alone or in combination with each other or another drug (CCB, diuretic) were the best interventions for inducing regression of albuminuria (mean ORs 2.25 to 9.87), whereas calcium channel blockers and diuretics were not beneficial. Endothelin inhibitors (0.32, 0.11-0.91), ACE (0.71, 0.55-0.93) and ARB (0.75, 0.64-0.88) were the best drugs for preventing doubling of serum creatinine whilst renin inhibitors and beta blockers were potentially harmful. No antihypertensive drug was significantly more effective than placebo or any other drug for reducing all-cause mortality or myocardial infarction.

Conclusions: No single blood pressure lowering strategy improved survival in diabetic kidney disease. An ACE inhibitor combined with ARB was the best intervention for preventing ESKD.

Comparative Effectiveness and Safety of Erythropoiesis-Stimulating Agents for Anemia in Adults with CKD: A Cochrane Network Meta-Analysis

Suetonia Palmer,[1] Valeria Maria Saglimbene,[2] Dimitris Mavridis,[3] Georgia Salanti,[3] Jonathan C. Craig,[4] Marcello Tonelli,[5] Natasha Wiebe,[5] Giovanni F.M. Strippoli.[2,4,6] *[1]Univ of Otago Christchurch; [2]Fondazione Mario Negri Sud; [3]Univ of Ioannina; [4]Univ of Sydney; [5]Univ of Alberta; [6]Amedeo Avagadro Univ of Eastern Piedmont.*

Background: While clinical and policy decisions about anemia management in chronic kidney disease depend on the comparative effectiveness of erythropoiesis-stimulating agents (ESAs), large head-to-head trials are lacking.

Methods: We did a network meta-analysis of 56 randomized trials involving 15,596 participants. We included trials that evaluated epoetin alfa, epoetin beta, darbepoetin alfa, methoxy polyethylene glycol-epoetin beta or a biosimilar ESA. Primary outcomes were blood transfusion and all-cause mortality.

Results: In moderate to low quality evidence, epoetin alfa, epoetin beta, darbepoetin alfa and methoxy polyethylene glycol-epoetin beta were superior to placebo for preventing blood transfusions (mean odds ratios 0·18, 0·09, 0·17, and 0·15). In very low quality evidence, biosimilar ESAs were possibly no better than placebo (95% CI, 0·05 to 1·47) for prevention of blood transfusions with considerable imprecision in the estimates. Head-to-head comparisons between ESAs were inconclusive and imprecise. Epoetin alfa, epoetin beta, darbepoetin alfa and methoxy polyethylene glycol-epoetin beta all increased the odds of hypertension (2·31, 2·57, 1·83 and 1·96, respectively) but the treatment risk for biosimilar formulations was inconclusive (1·18, 95% CI, 0·47 to 2·99) and head-to-head comparisons between all ESAs were imprecise. The comparative effects of ESAs on mortality, myocardial infarction, stroke, and vascular access thrombosis were ill-defined and network analyses for fatigue, breathlessness, major cardiovascular events and end-stage kidney disease were not possible.

Conclusions: In the setting of chronic kidney disease, there is insufficient evidence in randomized trials to show clinical differences between ESA formulations. The efficacy of biosimilar ESAs against placebo is unproven. Additional comparative data for ESAs measuring patient-important outcomes are needed to inform prescribing.

Statins for Primary or Secondary Prevention Improve Survival in Chronic Kidney Disease Stages 3-5

Beng Hock So,[12] Scott Blackwell,[1] Mario D. Hair,[1] Alan G. Jardine,[2] Mark S. MacGregor.[1] *[1]Univ Hospital Crosshouse; [2]Inst of Cardiovascular & Medical Sciences, Univ of Glasgow, United Kingdom.*

Background: We examined the relationship between statin use for primary (PP) or secondary prevention (SP) and all-cause mortality in the Ayrshire CKD Epidemiology Study (ACES) cohort.

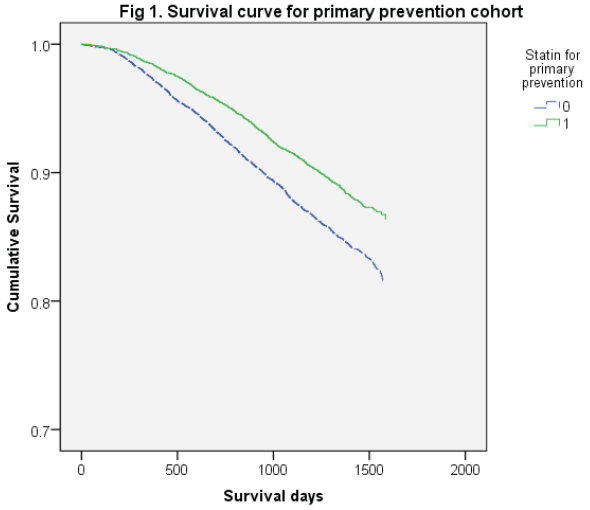
Methods: Adult population from 07/01/2009-06/30/2010 was 312,943. Using laboratory data, we identified all patients with CKD 3-5 with an algorithm to ensure chronicity. Community dispensing data, hospitalisations, and date of death for the following 4.5 years was obtained from Information Services Division Scotland. Multivariate Cox models were generated.

Results: CKD prevalence was 5.8% (n=18,113). Those with nephrotic range proteinuria, non-statin lipid therapy or renal replacement therapy were excluded (n=950). Lipid profiles were tested in 73%. LDL cholesterol was 39 (37-40) mg/dL lower in the 45% who were on statins. Table 1 details the characteristics between those on and not on statins for PP or SP.

	Primary (12,104)		Secondary (5,059)	
Statin	Yes (38%)	No (62%)	Yes (63%)	No (37%)
Age (ave±SD)	73±9	74±12	75±9	79±9
eGFR (ave±SD)	50±12	50±12	48±13	48±13
Female	64%	70%	54%	63%
Chol	165±35	205±43	155±36	187±44
HDL	52±15	54±17	49±15	51±17
LDL	82±28	121±36	75±28	107±36
TG	161±88	152±78	154±85	142±78
Coronary heart disease			86%	82%
Cerebrovascular disease			27%	28%
Hypertension	30%	28%	66%	62%
Diabetes	17%	5%	27%	13%
Peripheral Arteriosclerosis	3%	1%	9%	7%
Proteinuria	24%	15%	27%	19%

After adjustment for factors in table 1, statins was associated with HR of 0.72 (0.66,0.79) and 0.73 (0.66,0.81) for PP and SP respectively.

Fig 1. Survival curve for primary prevention cohort



Conclusions: We demonstrated a significant mortality benefit associated with statin use in CKD. Despite being an evidence-based intervention, only 45% of patients were receiving a statin.

Funding: Private Foundation Support

FR-PO893

Association between Prescription Narcotic Use and Markers of Kidney Disease in U.S. Adults

Celestina Barbosa-Leiker,[1] Sterling Mcpherson,[1] Kenn B. Daratha,[1,2,3] Radica Z. Alicic,[2] Robert Short,[1,2] John M. Roll,[1] Katherine R. Tuttle.[2,3] *[1]College of Nursing and Program of Excellence in the Addictions Research, Washington State Univ; [2]Providence Health Care; [3]School of Medicine, Univ of Washington.*

Background: Analgesic use has been associated with increased risk of chronic kidney disease (CKD). In a general population cohort, habitual *non-narcotic* analgesic use was not linked to evidence of CKD. The purpose of this study was to determine relationships between *prescription narcotics* and *non-steroidal anti-inflammatory drugs* (NSAIDs) use, as well as any analgesic use, with albuminuria and estimated glomerular filtration rate (eGFR) in a representative sample of U.S. adults.

Methods: Participants in the National Health and Nutrition Examination Survey (2009-2010) with serum creatinine, urinary albumin, and covariate data (n=3980) were included. Use of prescription narcotics, NSAIDs, and any analgesics were compared to referent groups with use of no medication or use of non-analgesic medication. Urine albumin-to-creatinine ratio (UACR) and eGFR were analyzed as continuous and binary variables (UACR ≥30 mg/g or eGFR <60 mL/min per 1.73m^2 by CKD-EPI). Regression models controlled for sex, age, poverty/income ratio, race, diabetes, hypertension, and smoking status.

Results: Frequencies of use were: prescription narcotics 4.4%; NSAIDs 5.6%; any analgesic 12.7%; non-analgesic medication 38.7%; no medication 48.6%.Narcotic use (b=0.22, p=0.01) and analgesic use (b=1.73, p=0.02) were associated with higher UACR, while NSAIDs use was not (b=0.17, p=0.11). Only narcotic use was related to risk of UACR ≥ 30 mg/g (OR=1.54, 95%CI=1.03-2.30, p=0.04), where 13.8% of those taking narcotics had high UACR compared to 8.1% of those taking non-narcotics or no medications. No type of analgesic use was related to eGFR.

Conclusions: Among U.S. adults, prescription narcotic users have increased risk of elevated albuminuria. Use of any analgesic, but not NSAIDs, was associated with albuminuria indicating that narcotics drive this relationship. Prescription narcotic use is associated with numerous adverse health consequences including albuminuria, and possibly related sequelae, such as CKD.

FR-PO894

Vitamin D Analogs Reduce the Progression of Chronic Kidney Disease: Chronic Kidney Disease Research of Outcomes in Treatment and Epidemiology Study (CKD-ROUTE Study)

Yohei Arai,[1] Eiichiro Kanda,[2] Ryoichi Ando,[3] Soichiro Iimori,[1] Sei Sasaki,[1] Eisei Sohara,[1] Tomokazu Okado,[1] Tatemitsu Rai,[1] Shinichi Uchida.[1] *[1]Nephrology, Tokyo Medical and Dental Univ, Japan; [2]Nephrology, Tokyo Kyosai Hospital, Japan; [3]Nephrology, Japanese Red Cross Musashino Hospital, Japan.*

Background: The use of vitamin D analogs has been generally recommended for the treatment of mineral and bone disorder in chronic kidney disease (CKD). However, the suppressing effect of vitamin D therapy on the progression of CKD has not yet been established.

Methods: A prospective cohort derived from one-year follow-up data of the CKD Research of Outcomes in Treatment and Epidemiology study. Participants aged over 20 years with pre-dialysis CKD stage 2-5 were eligible. The primary outcome was composite of end-stage renal disease (ESRD) or a 50% reduction in estimated glomerular filtration rate (eGFR). A Cox proportional hazards model was used to evaluate the association between the use of vitamin D analogs and the primary outcome. Furthermore, we conducted an additional analysis matched for a propensity score for the vitamin D analogs use between patients with and without the use of vitamin D analogs.

Results: We enrolled 735 patients (male 69%). The numbers of patients with and without the use of vitamin D analogs were 99 and 636, respectively. The primary outcome was observed in 108 patients (ESRD, 81; a 50% reduction in eGFR, 27) and 32 patients died. The mean age was 67±13 (SD) years; eGFR, 31±18 ml/min/1.73m^2. Multivariate Cox proportional hazard models adjusted for baseline characteristics showed that the use of vitamin D analogs independently decreased the risk of the primary outcome; hazard ratio adjusted for patients' characteristics (aHR) 0.57, 95% confidence interval (CI) (0.33, 0.97). The matched analysis also showed similar tendencies; aHR 0.43, 95% CI (0.22, 0.84).

Conclusions: Administration of vitamin D analogs for patients with pre-dialysis CKD reduces the risks for CKD progression.

FR-PO895

Association Between Serum Potassium and Discontinuation of Renin-Angiotensin Aldosterone System Blocker Medication in Patients with Chronic Kidney Disease

Jiacong Luo,[1] Steven M. Brunelli,[1] Donna E. Jensen,[1] Alex Yang.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]ZS Pharma, Inc, Menlo Park, CA.*

Background: In states of health, the kidneys maintain serum potassium (K) concentration between 3.5 and 5mEq/L. Patients with chronic kidney disease (CKD) are predisposed to hyperkalemia, which may be aggravated by drugs that increase serum K, such as RAAS blockers: angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, and mineralocorticoid receptor antagonists. While the risk/benefit threshold is unclear, RAAS blockers may be discontinued in response to hyperkalemia, which in turn denies patients potential cardio- and reno-protective benefits of these agents. We studied the association between serum K and discontinuation of RAAS blockers stratified on CKD severity.

Methods: We assembled a retrospective cohort of CKD (eGFR<60mL/min/1.73 m^2) patients with available serum K data between Jan-2009 and June-2013 (N=55,266). Serum K was considered as a time-varying exposure, updated at the time of each measurement. We considered all intervals in which the patient began on a RAAS blocker (ie, was at-risk for discontinuation) between study entry and end of study (Jun-2013), death, or loss to follow up.

Results: At baseline, 29.8% of patients were prescribed a RAAS blocker. Across all strata of eGFR, there was a U-shaped association between serum K and RAAS blocker discontinuation, which was statistically significant (p<0.001 in each stratum).

eGFR mL/min/ 1.73m^2		K <3.5 mEq/L	K 3.5 - 3.9 mEq/L	K 4.0 - 4.4 mEq/L	K 4.5 - 4.9 mEq/L	K 5.0 - 5.4 mEq/L	K 5.5 - 5.9 mEq/L	K ≥6.0 mEq/L	P value

Abbreviations: CI, confidence interval; discont, discontinued; IRR, incidence rate ratio; pt, patient; Ref, reference.
[a]Multivariable Poisson model adjusted for age, sex, race, diabetes, heart failure, coronary artery disease, cerebral vascular accident, beta blocker use, centrally acting calcium channel blocker use, loop diuretic use, and thiazide diuretic use.

The pattern of association was similar across eGFR strata (p-interaction=0.66). Compared to serum K 4.5-4.9mEq/L, K ≥6.0mEq/L was associated with a 1.7-2.2-fold greater rate of discontinuation; K 5.5-5.9mEq/L was associated with a 1.3-1.5-fold greater rate.

Conclusions: Across each cohort of CKD stage patients (stage 3, 4, 5), serum K ≥5.5mEq/L is consistently associated with greater rate of RAAS blocker discontinuation.

FR-PO896

Phase 3, Multicenter, Randomized, Double-Blind, Placebo-Controlled Trial of Once-Daily ZS-9 for Treatment of Hyperkalemia: Achievement and Maintenance of K^+ in Subgroup Analysis of Patients with Significant Renal Impairment

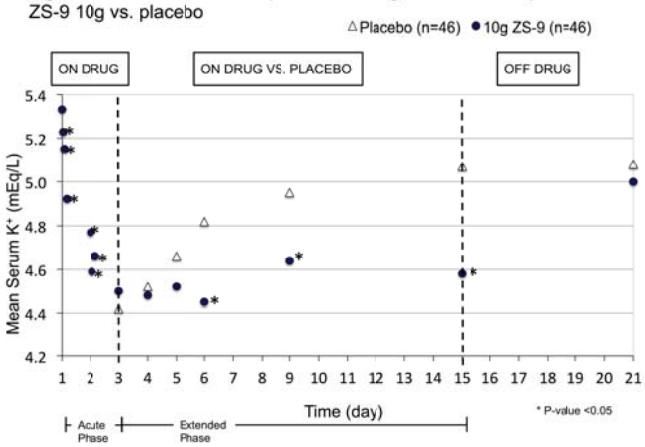
Bhupinder Singh,[1] Henrik S. Rasmussen,[2] Philip T. Lavin,[3] Alex Yang,[4] David K. Packham.[5] *[1]Apex Research, Riverside, CA; [2]ZS Pharma, Inc., Coppell, TX; [3]Boston Biostatistics Research Foundation, Framingham, MA; [4]Xelay Acumen, Inc., Belmont, CA; [5]Melbourne Renal Research Group, Reservoir, Australia.*

Background: Hyperkalemia (HK) increases risk of mortality and limits RAAS therapy in pts with heart failure and CKD. ZS-9, a nonabsorbed cation exchanger specifically designed to trap excess K^+ in the gut, was evaluated in a subgroup of HK pts with significant renal impairment (eGFR<60) from a large Phase 3 trial.

Methods: Pts (N=753) with K^+ 5.0-6.5 mEq/L were randomized (1:1:1:1:1) to ZS-9 (1.25, 2.5, 5 or 10g) or placebo (PBO) orally 3x daily for 48hr (acute phase). Following this phase, pts with K^+ 3.5-5.0 mEq/L (n=542) were randomized 1:1 to the same ZS-9 acute phase dose or PBO 1x daily on Days 3-15 (extended phase). RAASi were maintained during the study. Unpaired t-tests were used to compare serum K^+ in pts treated with ZS-9 versus PBO.

Results: Of 753 pts, 561 (75%) had baseline eGFR<60. Mean baseline K^+ was 5.4 mEq/L. At 48hr, significantly greater decreases in K^+ were seen with 2.5g (n=101), 5g (n=115) and 10g (n=102) ZS-9 (-0.43, -0.59, and -0.84 mEq/L, respectively) compared to PBO (n=120, -0.22 mEq/L; p=0.022, p<0.001, and p<0.001, respectively). In the extended phase, baseline K^+ was similar in the 10g ZS-9 (n=46, 4.5 mEq/L) and PBO groups (n=46, 4.4 mEq/L). Pts on ZS-9 10g maintained normokalemia during the extended phase (4.6 mEq/L at Day 15; p<0.0001) whereas K^+ increased with PBO (5.1 mEq/L at Day 15). Similar results were seen with 5g ZS-9 (p<0.0001).

Figure. Mean K+ over time in patients with significant renal impairment on ZS-9 10g vs. placebo



Conclusions: ZS-9 may fulfill an important clinical unmet need in hyperkalemic pts with significant renal impairment through the restoration and maintenance of normokalemia.

Reducing the Uremc Toxins Protects Kidney Function Deterioration in Patients with Chronic Kidney Disease Ran-Hui Cha,[1] Jae Hyun Chang,[2] Jung-Hwan Park,[3] Dae R. Cha,[4] Chun Soo Lim,[5] Ki Young Na,[6] Sang Youb Han,[7] Yon Su Kim.[8] *[1]Dept of Internal Medicine, National Medical Center; [2]Dept of Internal Medicine, Gachon Univ Gil Medical Center; [3]Dept of Internal Medicine, Konkuk Univ Hospital; [4]Dept of Internal Medicine, Korea Univ Ansan Medical Center; [5]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center; [6]Dept of Internal Medicine, Seoul National Univ Bundang Hospital; [7]Dept of Internal Medicine, Inje Univ Ilsan Hospital; [8]Dept of Internal Medicine, Seoul National Univ College of Medicine.*

Background: The notion that AST-120 may delay clinical outcome has not been evaluated thoroughly. In this study, we aimed to find the long-term effect of AST-120 on the renal disease progression [(doubling of serum creatinine (SCr), eGFR decrease more than 50%, or initiation of renal replacement therapy)] in patients with advanced chronic kidney disease (CKD).

Methods: We prospectively recruited 579 patients (CKD stage 3 and 4) from 11 medical centers in Korea and randomized them into AST-120 and control arm. A total of six gram of AST-120 in three divided doses was given to patients in AST-120 arm along with the standard conventional treatment. Primary analysis was done in 465 Per-Protocol participants.

Results: Initial mean SCr and eGFR levels were 248.2 μmol/l and 26.8 ml/min/1·73m^2, respectively. There was no significant difference in the occurrence of composite primary outcomes between two arms (Log-rank P=0.41). AST-120 was beneficial for the preservation of GFR in patients without composite primary outcome and with diabetic nephropathy. And the slope of 1/SCr was significantly attenuated in both two arms and the value of AST-120 arm was less than that of control arm (P=0·046). The magnitude of serum indoxyl sulfate (IS) decrement in one year by AST-120 was reversely correlated with the occurrence of composite primary outcomes (P=0.014, 0.033).

Conclusions: Long-term use of AST-120 has the potential of renal protection, and the change of serum IS level may be used as a surrogate marker for delineating the patient subgroups who would be beneficial by the use of AST-120. (Clinicaltrials.gov: NCT00860431).

FR-PO898

A Multiple Parameter Response Efficacy (PRE) Score to Predict the Effect of Atrasentan on Renal and Cardiovascular Outcomes Bauke Schievink,[1] Dick de Zeeuw,[1] Jarno Hoekman,[1] Hiddo Jan Lambers Heerspink,[1] The RADAR Study Group.[2] *[1]Univ Medical Center Groningen, Groningen, Netherlands; [2]Multiple Affiliations.*

Background: In the RADAR trial (*de Zeeuw et al,JASN 2014*), we showed that 12 weeks treatment with the selective endothelin A receptor antagonist atrasentan (0.75 and 1.25 mg/d) reduced albuminuria (UACR), blood pressure, cholesterol, hemoglobin and increased body weight in patients with diabetes and nephropathy. UACR reduction ≥30% was achieved by 51% and 55% of patients. We previously developed an algorithm (PRE score,*Smink et al,CPT 2014*) that translates the shortterm effects of a drug to longterm hard outcomes. We applied the PRE score to the RADAR data to test the potential of both atrasentan doses for longterm renal/cardiovascular protection.

Methods: PRE scores were calculated by applying a multivariable Cox model, derived from a background dataset of completed clinical trials, to the baseline and week 12 risk marker levels to calculate renal and heart failure (HF) risk change for atrasentan 0.75 or 1.25 mg/d.

Results: The PRE score indicated a renal risk change of -23% and -30% for atrasentan 0.75 and 1.25 mg/d, respectively (Table). PRE scores indicated a smaller increase in HF risk for the low atrasentan dose. We could dramatically improve the beneficial outcome (almost 50% renal risk reduction) by selecting patient that achieved ≥30% UACR reduction following atrasentan treatment (responders). The nonresponder group showed PRE scores indicating increased renal and HF risk.

Conclusions: In the overall RADAR population, the PRE score predicts that low dose atrasentan will decrease longterm renal risk without increased risk of HF. However, within this population UACR responders are actually contributing to the positive prediction, whereas nonresponders show a predicted increased risk. Patients with UACR response should be selected in a future hard outcome trial.

Population-Dose	Renal	Heart failure
Overall		
0.75mg	-23% (-47 - +1)	+2% (-16 - +20)
1.25mg	-30% (-55 - -6)	+7% (-13 - +27)
Responders		
0.75mg	-47 (-71 - -23)	-9 (-29 - +11)
1.25mg	-47 (-71 - -22)	+5 (-19 - +29)
Nonresponders		
0.75mg	+4 (-22 - +31)	+12 (-10 - +33)
1.25mg	+4 (-31 - +39)	+10 (-17 - +36)

FR-PO899

Effect of CTP-499 on Biomarkers Associated with Chronic Kidney Disease in Patients with Type 2 Diabetes Ara Aslanian, Kristine Hogan, Philip B. Graham, LuAnn A. Sabounjian, Lijun Wu. *Concert Pharmaceuticals, Lexington, MA.*

Background: The progression of CKD is intimately related to the pathophysiology of tubulointerstitial damage, as the severity of tubule injury predicts long-term clinical outcomes. Tubule cell dysfunction is mediated by pro-fibrotic and pro-inflammatory factors, thus therapeutic intervention that ameliorates these processes may be beneficial. CTP-499 is a novel, deuterium-containing, multi-subtype selective PDE inhibitor that had protective effects on renal function in patients with type 2 diabetic kidney disease in a 48-week Phase 2 clinical study. We have shown in non-clinical studies that CTP-499 has anti-fibrotic and anti-inflammatory activities consistent with inhibition of specific PDE subtypes. To investigate the mechanism of CTP-499 in diabetes-induced CKD, we examined a panel of biomarkers from this Phase 2 clinical trial patient population.

Results: At 48 weeks, biomarkers associated with the severity of tubulointerstitial damage were significantly reduced in patients receiving CTP-499 compared to placebo, including IL-18 and clusterin (25% and 42%, respectively, P < 0.05; N = 65 CTP-499, 57-58 Placebo). In general, treatment-dependent changes were more prominent in patients with a baseline UACR ≥ 850 mg/g, a group that shows more rapid decline in renal function than patients with lower baseline UACR. In this subgroup, the tubule injury markers MCP-1 and N-OPN were reduced by 34% and 55%, respectively (P < 0.05, N = 32 CTP-499, 27 Placebo) in addition to IL-18 and clusterin. Also, the extracellular matrix proteins fibronectin, collagen IV, and laminin, which undergo increased deposition in CKD, were significantly reduced in CTP-499-treated patients compared to placebo (13-68%; P < 0.05, N=65 CTP-499, 57-58 Placebo). These data are consistent with results showing that CTP-499 reduced tubule cell apoptosis and collagen deposition in the rat UUO kidney fibrosis model.

Conclusions: Collectively, these data suggest CTP-499 has protective effects on renal tubules in diabetic kidney disease, and that anti-fibrotic mechanisms may contribute to this activity. These results further support continued development of this novel agent for the treatment of CKD.

Composite Creatinine-Based Outcomes for Trials in DKD Jamie P. Dwyer,[1] Tom Greene,[2] Hiddo Jan Lambers Heerspink,[4] Nan Hu.[2] *[1]Nephrology, Vanderbilt, Nashville, TN; [2]Biostatistics, Univ of Utah, Salt Lake City, UT; [3]Nephrology, Rush Med Ctr, Chicago, IL; [4]Clin Pharm, Univ Groningen, Groningen, Netherlands.*

Background: FDA accepts doubling of creatinine (SCr) as an endpoint in trials, but it is a late event. Surrogate endpoints based on lesser SCr ↑ may reduce *N* and follow-up for trials. Lesser SCr ↑ can be affected by acute hemodynamic effects which hide the long-term treatment effect. We investigated composite endpoints based on 25% to 45% SCr ↑ at discrete time points in the IDNT and RENAAL trials, where ARB intervention led to acute increases in SCr.

Methods: We assessed the association of SCr events with ESRD using time-dependent ROC curves, and evaluated power to detect treatment effect by Z-scores indicating the ratio of the estimated treatment effect to the standard error representing the precision of the analysis, with Z-score <-1.96 indicating a statistically significant treatment benefit.

Results: In IDNT the time-dependent area under the curve for determining ESRD by month 33 based on %change in SCr to 18 mos was 0.66 without confirmation of SCr events, and was 0.76 with. Percent of pts with events (Evt%), (time-dependent sensitivity/specificity for ESRD by 33 mos), and Z-score for the composite, defined by designated confirmed changes in SCr at either 12 or 18 months are:

	%ΔSCR Over 18 Months		
%ΔSCR Over 12 Months	25%	35%	45%
25%	EVT% = 52.3 (56.5%/86.5%) Z = -0.46	EVT% = 45.7 (51.9%/88.1%) Z = -0.15	EVT% = 40.5 (51.3%/89.7%) Z = -0.49
35%	EVT%=39.6 (54.7%/88.1%) Z=-0.75	EVT% = 39.2 (44.9%/94.6%) Z= - 0.93	EVT% = 33.1 (43.7%/95.1%) Z = -1.67

The performance of the composite defined by a confirmed %DSCR of 35% at 12 months and of 50% at 18 months was externally validated using the RENAAL data base (Z = -1.29), although statistical significance of the treatment effect on the endpoint was not reached.

Conclusions: A confirmed 35%↑ in SCr by 12 months or 45% by 18 months was moderately robust to the acute effect seen in IDNT and RENAAL and predictive of long-term incidence of ESRD. This outcome would demonstrate improved performance if the intervention did not have an acute effect on SCr.

Study of Diabetic Nephropathy with AtRasentan (SONAR); a New Enrichment Study Design Dick de Zeeuw,[1] Hans-Henrik Parving,[2] Blai Coll,[3] Dennis L. Andress,[3] John J. Brennan,[3] The SONAR Steering Committee.[4] *[1]Univ Medical Center Groningen, Netherlands; [2]Univ Hospital Copenhagen, Denmark; [3]AbbVie, North Chicago; [4]Multiple.*

Background: Diabetes patients with nephropathy are at high risk for renal/CV events. Recent clinical trials of novel treatments have been negative. One reason for treatment failure may have been suboptimal patient selection. The selective endothelin A receptor antagonist, atrasentan, may be a new protective drug, since it appeared to produce a strong effect on albuminuria lowering: -35% (-24 to -45,95% CI), and in 51% of participants achieving >30% reduction (*de Zeeuw et al,JASN 2014*). To test this, we designed the SONAR study, selecting diabetic nephropathy patients with an initially favorable response to atrasentan, subsequently randomized to compare atrasentan with placebo for a primary composite renal endpoint consisting of time to doubling of serum creatinine or onset of ESRD. Secondary endpoints: CV morbidity and mortality, UACR, changes in estimated glomerular filtration rate (eGFR), and quality of life.

Methods: A prospective, randomized, double-blind, enriched-population, placebo-controlled, multinational study in 4148 subjects, with CKD stages 2-4 and macroalbuminuria on maximum tolerated dose of RAS inhibitor. After 6 weeks exposure to 0.75mg/d atrasentan (enrichment period), 3148 patients with >30% UACR decrease (responders) and no signs of major side effects (e.g. fluid retention, heart failure, and BNP<300 pg/ml) are randomized, stratified according to geographical region, baseline albuminuria and albuminuria response (30-45, 45-60 and >60% reduction). Diuretic therapy is optimized during run-in and enrichment. Study power: 425 distinct primary events; a 27% hazard reduction with 90% power,p<0.05. Additionally, 1000 nonresponders will be randomized and followed.

Conclusions: The SONAR trial will test whether we can lower the high residual renal and CV risk in type 2 diabetic nephropathy patients using atrasentan treatment on top of guideline-recommended therapies. The selection and new enrichment design will not only set the next stage for this particular population, but will also define the future role of albuminuria as a target.

Reducing Albuminuria Confers Renoprotection: A Systematic Review and Meta-Analysis of Randomized Controlled Trials Tobias Felix Kröpelin,[1] Hiddo Jan Lambers Heerspink,[1] Jarno Hoekman,[2] Dick de Zeeuw.[1] *[1]Dept Clinical Pharmacy & Pharmacology, Univ Medical Center Groningen, Netherlands; [2]Div of Pharmacoepidemiology and Clinical Pharmacology, Utrecht Univ, Netherlands.*

Background: Albuminuria has been proposed as a surrogate endpoint in randomized clinical trials (RCT's) of renal disease progression. Most evidence is based on observational analyses showing that a treatment induced short-term change in albuminuria correlates with risk change for end-stage renal disease (ESRD). However, these studies are prone to bias and residual confounding. To avoid this type of bias we performed a meta-analysis of RCT's to determine and correlate the placebo corrected drug effect on albuminuria and ESRD in order to reliably examine whether albuminuria is a valid surrogate endpoint.

Methods: MEDLINE and EMBASE were searched without language restriction for RCT's reported between 1950 and April 2014. Included RCT's had a mean follow up of at least 1000 patient years, reported ESRD outcomes, and measured albuminuria at baseline and during follow-up. Meta-regression was performed to assess the association between drug effects on albuminuria and ESRD.

Results: Twenty-one RCT's involving 78,342 patients and 4,183 ESRD events were included. Median time to first albuminuria measurement was 6 month. Fourteen trials tested the effect of renin-angiotensin-aldosterone-system inhibitors (RAASi) and 7 trials tested other interventions. We observed a wide variability across trials in the treatment effect on albuminuria (range -1.3% to -32.1%) and ESRD (range -55% to +35 relative risk change). Meta-regression revealed that the treatment effect on albuminuria significantly correlated with the treatment effects on ESRD: for each 30% reduction in albuminuria the risk of ESRD decreased by 23.7% (95%CI 11.4 to 34.2).The association was consistent regardless of RAASi drugs or non-RAASi drugs (p interaction 0.73) or other patient or trial characteristics.

Conclusions: The significant association between drug effects on albuminuria and ESRD and the consistency across drug classes and patient characteristics suggests that albuminuria is a valid substitute for ESRD in a variety of circumstances.

FR-PO903

Prognostic Utility of Estimated Albumin Excretion Rate (eAER) in Chronic Kidney Disease (CKD): Results from the Study of Heart and Renal Protection (SHARP) Marion Mafham, Natalie Staplin. *On Behalf of the SHARP Collaborative Group, Clinical Trial Service Unit and Epidemiological Studies Unit, Univ of Oxford, Oxford, United Kingdom.*

Background: eAER estimates 24-hour albuminuria more accurately than urine albumin/creatinine ratio (ACR), but whether eAER better predicts end-stage renal disease (ESRD) and vascular events (VEs) is unknown.

Methods: 5552 participants in SHARP (a randomized trial of LDL cholesterol lowering in 9270 patients with CKD) who were not on dialysis, and had estimated glomerular filtration rate (eGFR) and urine ACR measured at baseline, were included. eAER was calculated from ACR and creatinine excretion rate (CER) estimated using a formula from the MDRD study which includes age, sex and race. Relative risks (RR) of ESRD and VEs were estimated using Cox regression and improvements in risk prediction were based on the likelihood ratio test.

Results: During a median follow-up of 4.8 years, 1959 participants progressed to ESRD and 1204 had a VE. Given age, sex and eGFR, both ACR and eAER substantially improved ESRD risk prediction (both increasing the log-likelihood ratio statistic by 436) with similar adjusted RR of ESRD per 10-fold higher level of 2.10 (95% CI 1.96 to 2.26) for ACR and 2.10 (95% CI 1.95 to 2.26) for eAER. Neither ACR nor eAER provided any further predictive information over and above the other. Results were similar among individuals with eGFR <30 and ≥30 ml/min/1.73m^2 and when those with glomerulonephritis, diabetic nephropathy, cystic kidney disease or other renal diagnoses were examined separately. For the prediction of VEs, the addition of ACR (or eAER) to a model including known cardiovascular risk factors and eGFR resulted in a modest improvement in model fit (increasing the log-likelihood ratio statistic by 30), with identical adjusted RRs per 10-fold higher level of 1.26 (95% CI 1.16 to 1.37) for both ACR and eAER. Again, neither ACR nor eAER provided any further prognostic information over and above the other. Results were similar using alternative CER formulae which include weight.

Conclusions: Among individuals with moderate to severe CKD, eAER does not improve risk prediction of either ESRD or VEs beyond that provided by ACR.

FR-PO904

The Discrepancy of Clinical Significance Between Diabetic and Hypertensive Retinopathy in Patients with Chronic Kidney Disease Hyeon Seok Hwang,[1] Se Young Kim,[1] Yoon-Kyung Chang,[1] Chul Woo Yang,[2] Suk Young Kim,[1] Hye Eun Yoon.[2] *[1]Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Daejeon, Korea; [2]Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

Background: Chronic kidney disease (CKD) and retinopathy shares a common pathophysiology of microvascular dysfunction. However, the different clinical significance of diabetic retinopathy (DMR) and hypertensive retinopathy (HTNR) is undetermined in CKD patients.

Methods: We included 501 diabetic and 191 non-diabetic patients with nondialysis-dependent CKD stages 3–5. The clinical significance of DMR and HTNR was evaluated in terms of rate of renal function decline and composite of any cardiovascular event or death after the index retinopathy examination.

Results: DMR was observed in 269 (53.7%) diabetic patients with CKD, and HTNR were found in 44 (23.0%) non-diabetic patients with CKD. The rate of renal function decline was significantly steeper in diabetic patients with DMR than those without DMR (-7.4 ± 9.8 mL/min/1.73 m^2/y versus -2.4 ± 7.6 mL/min/1.73 m^2/y; P < 0.001). Patients with proliferative DMR showed more rapid renal function decline than patients with non-proliferative DMR (P = 0.015). However, HTNR was not associated with rapid decline of renal function (-3.1 ± 9.0 mL/min/1.73 m^2/y versus -2.9 ± 9.9 mL/min/1.73 m^2/y; P = 0.769). In a multivariate analysis, DMR was an independent predictor for renal function decline (b = –2.16; P = 0.014). Diabetic patients with DMR showed lower composite event-free survival rate than those without DMR (P = 0.048), while HTNR did not increase the risk for composite event. In the multivariate hazards model, retinopathy was independently associated with any cardiovascular events or death (hazard ratio, 1.59; P = 0.026) in diabetic CKD patients.

Conclusions: DMR is an independent risk factor for rapid renal function decline and composite of cardiovascular event or death in diabetic patients with CKD. However, HTNR was not associated with renal and cardiovascular outcome in non-diabetic patients with CKD.

FR-PO905

Chronic Kidney Disease of Unknown Origin and Proposed Risk Factors Prevalence in Hemodialysis Patients from Southwest Guatemala
Timothy S. Laux,[1] Joaquin Barnoya,[1] Jose Vicente Sanchez Polo,[2] Erick Fernando Herrera Escobar,[2] Ever Olivie Cipriano,[2] Marcos Rothstein.[1] *[1]Washington Univ in St. Louis; [2]Inst Guatemalteco de Seguridad Social.*

Background: An epidemic of chronic kidney disease of unknown origin (CKDu) has been documented in southwest El Salvador and Nicaragua, yet no data is available from neighboring Guatemala. Therefore, we sought to determine the CKDu and proposed risk factors prevalence in hemodialysis patients from southwest Guatemala.

Methods: The Social Security healthcare is the largest provider of hemodialysis in southwest Guatemala. All patients on hemodialysis were screened for diabetes. Non-diabetics were interviewed (and charts reviewed) asking for traditional and proposed CKD risk factors. Analyses were done in SPSS.

Results: Most patients (74%) were non-diabetic (178/242). Obesity was the most prevalent known risk factor. Many of CKDu's proposed risk factors were present in more than half the patients, including male gender and agricultural work. Almost one third were sugar cane workers. Upon dialysis initiation, only hyperuricemia was common. About 20% (45/242) possibly had CKDu. About 20% (45/242) of participants did not have a history of hypertension and overweight/obesity and could be considered possibly affected by CKDu.

Known and proposed CKD risk factor prevalence in non-diabetics from Southwest Guatemala

	n = 178 (%)
Known Risk Factors	
Hypertension	99 (55.6%)
Overweight/Obese	59 (33.1%)
Not Hypertensive or Overweight	45 (25.3%)
Family History -Renal Disease -Hypertension -Diabetes	 29 (16.3%) 51 (28.8%) 47 (26.4%)
Proposed Risk Factors	
Age < 50 years old	106 (59.6%)
Age at Diagnosis ≤ 40 years old	99 (55.6%)
Male	144 (80.9%)
≤ 6 years of schooling	127 (71.3%)
Possible Leptospirosis	15 (8.4%)
Ever Use -NSAIDs -Alternative Medicine	 154 (86.5%) 99 (55.6%)
Agricultural Occupation - > 20 years work - Age ≤ 15 when started	113 (63.5%) 51 (45.1%) 73 (64.6%)
Sugar Cane Worker	52 (29.2%)
Alcohol Consumption	128 (71.9%)
Hypokalemic (n=177) *	24 (13.6%)
Hyperuricemic (n=162) *	87 (53.7%)
* At first dialysis	

Conclusions: Several of the proposed risk factors for CKDu were highly prevalent and require additional research to establish causality.

FR-PO906

Prevalence of Glomerulonephritis in the U.S. Medicare Population
James B. Wetmore, Haifeng Guo, David T. Gilbertson. *Chronic Disease Research Group, Minneapolis, MN.*

Background: Glomerulonephritis (GN) is a serious disorder that can lead to death, end-stage renal disease, and other morbid events. However, the prevalence of GN in the Medicare population is unknown.

Methods: A retrospective observational study was conducted to ascertain the prevalence of GN using the 20% Medicare sample from 2007-11. A primary GN was established by the appearance of ≥ 2 ICD-9 codes for a GN > 30 days apart, plus ≥ 1 code for resultant renal disease occurring on or after the first GN code; a systemic immunologic disorder resulting in a GN required ≥ 3 relevant ICD-9 codes ≥ 3 days apart, plus ≥ 2 subsequent ICD-9 codes for a GN or resultant renal disease ≥ 30 days apart. We calculated the prevalence of GN's per 100,000 patients by dividing the number of GN cases by the total number of individuals in the database from 2007-11, and determined hospitalization and death rates per 1000 patient-years.

Results: A total of 8,276,664 individuals were studied. Mean ± SD age was 68.2 ± 12.9 years and 55.1% were female. Period prevalence from 2007-11 was 433 cases of primary GNs per 100,000 individuals, representing 35,870 total cases, while there were 878 cases of GN resulting from systemic diseases per 100,000 individuals, representing 72,666 total cases. Incidence rates were 86.7 and 136.1 per 100,000 patient-years, respectively. Total hospitalization rates were 2083 and 2093 hospitalizations per 1000 patient-years, respectively, while death rates were 136 and 195 per 1000 patient-years.

Conclusions: There are likely >100,000 cases of GNs in the Medicare population alone, representing a substantial burden to patients, payers, and the nation. GNs appear to be associated with high hospitalization and death rates, but further study is required.

FR-PO907

Impact of Elevated Blood Pressure on CKD Prevalence and Staging: The Texas Kidney Study
Sharma S. Prabhakar, Katherine Kam. *Internal Medicine, Texas Tech Univ Health Sciences Center.*

Background: Recent literature points to high estimates of of chronic kidney disease (CKD) in general population although true incidence and prevalence of CKD are unknown. The Texas Kidney study was designed to address the epidemiological issues of CKD in Texas and we report here the impact of uncontrolled and undetected hypertension on prevalence and stages of CKD in a random screening study of general population.

Methods: A cohort of 1606 subjects was recruited through random digit dialing of an unselected general population to participate in a study to evaluate the prevalence and risk factors for CKD. A total of 1579 subjects completed the study. IRB approvals and informed consents of all subjects were obtained. Detailed history and clinical parameters including two separate measurements of blood pressure were obtained during the screening. Subjects with elevated BP (systolic >140 and/or diastolic >90 mm/Hg) were analyzed separately. Blood and urine samples were obtained to measure the renal function. Both MDRD and CKD-EPI formulae were used separately to estimate the prevalence of CKD using K-DOQI guidelines.

Results: The overall prevalence of CKD in this cohort (n=1579) was 17.7% by MDRD and 15.8% by CKD-EPI formula while in the high BP group (n=133) it was higher at 22.6% ($p<0.05$) by both formulae. About 38% in the latter group were unaware of their hypertension. Other co-morbid conditions in this group were obesity (22%) Diabetes (20%), stroke (6%) and smoking (16%).

Group (n)	CKD prevalence MDRD CKD EPI	Males (%) with CKD	Blacks (%) with CKD	High alb/ creat ratio >100mg/G	CKD stage I-II MDRD CKD-EPI	CKD Stage III-V MDRD CKD EPI
Elevated BP Group (133)	22.6% (30) 22.6% (30)	48.9*	12.8*	8.27%*	12.8% 13.6%*	9.8% 9.1%*
Total Study Group (1579)	17.7% (279) 15.8% (249)	38.1	6.4	3.62%	7.8% 8.1%	9.9% 7.7%

*P<0.05 vs. total study group

Conclusions: We conclude that the prevalence of CKD is 16-18% (depending on the methodology) in general population in Texas which is higher than the previously reported data. However the prevalence of CKD in uncontrolled or previously undetected hypertension is much higher (22.6%) with high prevalence of heavy proteinuria, which underscores the importance of hypertension in CKD progression.

Funding: Other U.S. Government Support

FR-PO908

Association of Serum 25-Hydroxy Vitamin D Levels with Chronic Kidney Disease Progression
Dong Ho Yang,[1] So-Young Lee,[1] Hun Jeong.[2] *[1]Internal Medicine, Bundang CHA Medical Center, Seongnam-si, Gyeonggi-do, Republic of Korea; [2]Internal Medicine, Seoul Bukbu Hospital, Seoul, Republic of Korea.*

Background: Experimental studies have shown that vitamin D serves as an immune modulator and a suppressor of interstitial fibrosis. However, a relationship between vitamin D and chronic kidney disease (CKD) progression in patients is uncertain. We investigated whether 25-hydroxy vitamin D [25 (OH) D] deficiency influences the progression of CKD.

Methods: In this prospective study, serum levels of 25 (OH) D were obtained from 135 patients with chronic kidney disease in the winter of 2009. The primary composite endpoints was end stage renal disease (ESRD) or kidney transplant (KT). The secondary composite endpoint was a >50% decline from baseline in estimated glomerular filtration rate (eGFR). Data were collected over the subsequent four years.

Results: The mean age of the study population was 61.3 ± 12.4 years, and the mean eGFR was 32.6 ± 13.5 ml/min per 1.73 m^2. A total of 42.2% of patients had diabetes. Vitamin D deficiency,as defined by <15 ng/ml serum 25 (OH) D, was observed in 60% of the patients (n = 81). The mean 25 (OH) D serum level was 14.7 ± 7.8 ng/ml. During the four-year follow-up period, 27 patients reached the primary end point (21 patients with 25 (OH) D deficiency and 6 patients without 25 (OH) D deficiency, P = 0.03). Fifteen and six patients reached the secondary end point in the 25 (OH) D deficiency and no 25 (OH) D deficiency groups, respectively (P = 0.2). The annual rate of eGFR change was greater in the 25 (OH) D deficiency group (-1.6 ± 2.5 versus -0.7 ± 2.0 ml/min per 1.73 m^2. P = 0.03). Kaplan-Meier analysis revealed that the risk of ESRD or KT was significantly higher in CKD patients with 25 (OH) D deficiency (log rank test; P = 0.04). Multivariate Cox proportional hazards models also demonstrated that the risk of ESRD or KT was significantly higher in CKD patients with 25 (OH) D deficiency (hazard ratio [HR] 7.65, 95% confidence interval [CI] 2.1-27.4; P=0.02).

Conclusions: These results demonstrate that 25 (OH) D deficiency is independently associated with a higher risk of the composite outcome in patients with CKD.

FR-PO909

Renal Outcomes of Patients with Acute Renal Infarction
Jihyun Yang, Hyojeong Chang, Myung-Gyu Kim, Sang-Kyung Jo, Won-Yong Cho. *Korea Univ, Seoul, Republic of Korea.*

Background: Renal infarction (RI) is uncommon disease. Although underlying hypercoagulable state is known to be a risk factor and the consequent renal mass reduction can affect its renal outcomes, little is known about the clinical characteristics or longterm renal outcome.

Methods: This is a single center retrospective study including 86 patients with newly diagnosed acute RI between January 2002 and March 2014. Their clinical features, possible etiologies and longterm renal outcome data were reviewed.

Results: The mean age was 63.5 ± 15.5 years and the prevalence of diabetes or hypertension was 24.7 or 43.0%. Bilateral involvement was shown in 18.6%. Of the underlying diseases, cardiovascular origin including atrial fibrillation, valvular heart disease, infective endocarditis were most common (39.5%), and renal vascular injury and hypercoagulable status were found in 14% and 3.5%. Idiopathic RI comprised 20% of cases. For the treatment, anti-platelet therapy, anticoagulation or thrombolysis were used in 53.5%, 57.6% and 3.5%, respectively. At the time of diagnosis, acute kidney injury (AKI) was accompanied in 30.2% of patients. In univariate analysis, male sex, alcohol, smoking, high CRP, leukocytosis and the presence of more than two underlying causes were significant risk factors for the development of AKI. In multivariate analysis, only the presence of two or more underlying causes was a risk factor for predicting the development of AKI. During follow up (55.9±35.2 months), chronic kidney disease (CKD) with eGFR<60 mL/min/1.73m² developed in 30.2%. In univariate analysis, development of CKD was associated with old age, hypertension, smoking, leukocytosis, history of AKI and the presence of more than two underlying causes of RI. In cox-regression analysis, old age and the presence of more than two causes of RI were the independent risk factors for the development of CKD.

Conclusions: We found that idiopathic RI comprised about one fifth of overall cases and also that both AKI and CKD were relatively common complications of RI. Because old age, presence of more than two causes of RI were associated with the development of AKI and also with CKD, more careful attention should be paid for the improvement of patients outcomes.

FR-PO910

Long-Term Predictors for End-Stage Renal Disease Emanuel Zitt,[1] Constanze Pscheidt,[2,3] Reinhard Kramar,[4] Gabriele Nagel,[2,3] Karl Lhotta.[1] *[1]Nephrology and Dialysis, Academic Teaching Hospital Feldkirch, Austria; [2]Agency for Preventive and Social Medicine, Austria; [3]Inst of Epidemiology and Medical Biometry, Ulm Univ, Germany; [4]Austrian Dialysis and Transplant Registry, Austria.*

Background: Aim of this observational study was to identify anthropometric and metabolic long-term risk factors for the development of end-stage renal disease (ESRD).

Methods: The population-based surveillance/screening programme "Vorarlberg Health Monitoring and Promotion Programme" has collected information on cardiovascular risk factors in more than two-thirds of the population of Vorarlberg, the western-most part of Austria with approximately 370.000 inhabitants. From 1988 to 2005, the following data were collected prospectively during regular health examinations in 185.341 persons (M/F 85.460/99.881): age, smoking status, body-mass-index (BMI), blood glucose, systolic (BPsys) and diastolic (BPdia) blood pressure, total cholesterol (TC), triglycerides (TG) and gamma-glutamyltransferase (GGT). These data were merged with the Austrian Dialysis and Transplant Registry. To determine the long-term risk for ESRD multivariable-adjusted Cox regression models were used to estimate hazard ratios (HR), additionally stratified by renal disease and by 5-year time slots of follow up after the first health examination.

Results: Mean age at first health examination was 41.6 years. During a mean follow-up of 17.5 years 403 patients (M/F 245/158) reached dialysis dependent ESRD. Significant long-term predictors for ESRD were: age (per year) HR 1.02 (95% CI: 1.01-1.03), male sex 1.72 (1.36-2.16), smoking 1.33 (1.06-1.66), BMI (per 1 kg/m²) 1.04 (1.01-1.06), glucose (per 1 mmol/L) 1.09 (1.05-1.12), BPsys (per 5 mmHg) 1.10 (1.07-1.14), BPdia (per 5 mmHg) 1.09 (1.03-1.15), TG (per 1 mmol/L) 1.07 (1.02-1.13) and TC (per 1 mmol/L) 1.22 (1.13-1.32). Time slot analyses identified age, male sex, BMI, glucose, BPdia and GGT as long-term predictors after more than 15 years of follow-up. Stratifying by renal disease disease-specific patterns of metabolic risk factors could be determined.

Conclusions: Already at a very early stage, specific anthropometric and metabolic factors are associated with an increased risk for ESRD.

FR-PO911

Association between Smoking Habits and Urinary Excretion of Albumin in Patients with Advanced Chronic Kidney Disease. CERCA-DIABETES Study Elvira Bosch, Celia Lopez, Fatima Batista, Mar Lago, Agustin Toledo, Cesar Garcia-Canton. *Dept of Nephrology, Hospital Univ Insular de Gran Canaria, Las Palmas de Gran Canaria, Spain.*

Background: To evaluate the effects of smoking habits on the prevalence of albuminuria and proteinuria in patients with chronic kidney disease (CKD) and to assess possible modulatory effects of factors such as gender, diabetes, control of blood pressure (BP) or antyhipertensive treatment.

Methods: Transversal study with 259 patients with stage 4 and 5 CKD. Patients were classified according to their smoking habits into: smoker, non-smoker and ex-smoker. Demographic and clinical variables, as well as kidney function and proteinuria at the beginning of the study were analyzed.

Results:

	Non-smokers (n:111)	Ex-smokers (n:104)	Smolers (n:43)	p
Age (years)	68.8 ± 12.2	67.6 ± 10.9	57.6 ± 13.2	0.000
Sex (%)	♀ 77.5 /♂ 22.5	♀ 18.3/ ♂ 81.7	♀ 20.9 / ♂ 79.1	0.000
DM-2 (%)	57.7	69.2	60.5	ns
HTA (%)	97.2	95.1	97.7	ns
Ischemic c. (%)	22.5	25	19	ns
BMI (kg/m²)	34 ± 17	30.1 ± 5.3	27.9 ± 5.6	0.004
ACEinhibitor/ARAII (%)	45.9	54.8	35.7	ns
GFR (ml/min)	22.6 ± 6.7	22.5 ± 6.7	21.7 ± 4.7	ns
Proteinuria (g/24h)	0.9 ± 1.6	2.1 ± 3.6	3.5 ± 6	0.000
MAU (mg/dl)	23.3 ± 44.8	38.9 ± 61.9	81,7 ± 96.6	0.000
A/C ratio (mg/g)	422.7 ± 846.7	636.9 ± 989.4	1428 ± 1642.2	0.000

shows these variables for the three groups of patients. Smokers and ex-smokers presented higher proteinuria and albuminuria than non-smokers (p<0.005). No differences were found in the prevalence of DM-2, treatment with renin-angiotensin-aldosterone system inhibitors (RAASI) or glomerular filtration. After adjusting by age, DM, BMI, BP, glomerular filtration or RAASI treatment, smoking habit was found to be a risk factor for the development of albuminuria (HR:2.9,CI95%: 1.09-7.7;p:0.032) and proteinuria (HR:3.6,CI95%:1.09-11.8;p:0.035).

Conclusions: The prevalence of proteinuria and urinary excretion of albumin is higher in smoker and ex-smoker patients than in non-smoker ones. Differences cannot be accounted for by other variables such as gender, diabetes, BMI, BP or RAASI treatment.

FR-PO912

Measures of Carbohydrate Metabolism and Clinical Outcomes in Non-Diabetic Chronic Kidney Disease: Findings From the Chronic Renal Insufficiency Cohort (CRIC) Study Amanda Hyre Anderson,[1] Francis Perry Wilson,[1] Raymond R. Townsend,[1] Jing Chen,[2] L. Lee Hamm,[2] J. Richard Landis,[1] James P. Lash,[2] Daniel J. Rader,[1] Bruce M. Robinson,[2] Harold I. Feldman.[1] *[1]Univ of Pennsylvania; [2]The CRIC Study.*

Background: Disturbances of carbohydrate metabolism are common in chronic kidney disease (CKD), but their relationships to CKD progression, cardiovascular disease (CVD) and death in this setting remain unclear.

Methods: Data from a subset of CRIC Study participants with non-diabetic CKD (N=1,865, average follow-up 5 years) were analyzed in Cox proportional hazards models to examine the association of homeostasis model assessment-estimated insulin resistance (HOMA-IR), fasting plasma glucose, hemoglobin A1c (HbA1c), and C-peptide with risk of a renal composite endpoint (end-stage renal disease or halving of estimated glomerular filtration rate [eGFR]), atherosclerotic CVD (MI/stroke/PAD) and death with adjustment for demographics, anthropometrics, comorbidities and clinical and biochemical measures.

Results: The mean (IQR) age was 59 (49-65) years, and mean (SD) eGFR was 49 (18) mL/min/1.73m². All carbohydrate metabolism measures, whether examined continuously on the log scale or across quartiles, were not significantly associated with the renal composite, atherosclerotic CVD, or death in multivariable-adjusted models (Table). Effect modification by level of kidney function or race was not detected.

	Hazard Ratio	95% CI
Event: Renal composite		
HOMA-IR	1.04	(0.91,1.19)
Glucose	0.92	(0.80,1.04)
HbA1c	0.96	(0.85,1.08)
C-peptide	1.08	(0.94,1.24)
Event: Atherosclerotic CVD		
HOMA-IR	1.00	(0.86,1.15)
Glucose	1.11	(0.91,1.32)
HbA1c	1.09	(0.92,1.29)
C-peptide	1.03	(0.83,1.28)
Event: All-cause death		
HOMA-IR	1.10	(0.98,1.22)
Glucose	1.01	(0.86,1.17)
HbA1c	1.01	(0.86,1.17)
C-peptide	1.10	(0.92,1.30)

Conclusions: Previously reported associations of carbohydrate metabolism with clinical outcomes in the setting of kidney disease were not detectable in this study of individuals with reduced levels of kidney function.

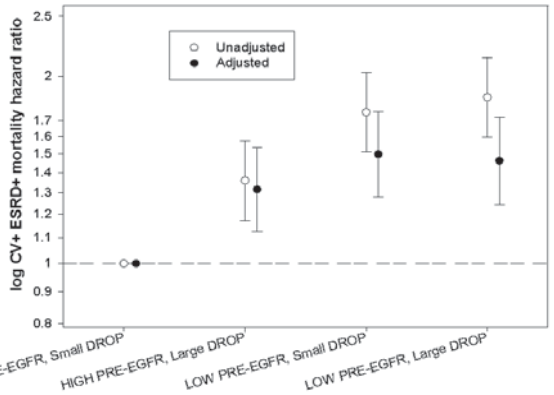
Association of Glomerular Filtration Rate and Post-Nephrectomy Outcomes in U.S. Veterans Elani Streja,[1] Kamyar Kalantar-Zadeh,[1] Lin Li,[1] Miklos Zsolt Molnar,[2] Jun Ling Lu,[2] Csaba P. Kovesdy.[2] *[1]Harold Simmons, UC Irvine MC, Orange, CA; [2]Memphis VAMC, Memphis, TN.*

Background: Radical nephrectomy has been considered the standard of care for localized renal malignancy, but results in variable loss of kidney function. It is unclear if the degree of kidney function loss is associated with the post-nephrectomy incidence of ESRD, survival, and cardiovascular events.

Methods: We identified 7,448 U.S. Veterans that had either a total or partial nephrectomy between Oct. 2004-Sept. 2012. EGFR prior to admission for nephrectomy and percentage drop in EGFR from pre-nephrectomy to 31 days post-nephrectomy were estimated from creatinine measurements using CKD-EPI equations and medians were calculated. Patients were categorized into 4 groups based on whether they were less than or greater than or equal to the median for the pre-nephrectomy EGFR and percent drop. Associations between these 4 groups with a combined risk of all-cause mortality, incident ESRD and cardiovascular event were evaluated in crude and case-mix adjusted cox models.

Results: Patients were 60±10 yrs old, 4% female, 18% African-American, and 29% diabetic. Median (p25, p75) values for pre-admission EGFR and percentage drop were 79 ml/min/1.73m^2 (65, 94) and 26% drop (8%, 39%) respectively. There were 1,631 deaths, 59 ESRD outcomes, and 310 coronary events. Using patients with combined high pre-admission EGFR, and small percent drop as the reference, patients with a combined large percent drop and high EGFR had a 32% increased risk of combined outcomes. Patients with low pre-admission EGFR had a 50% increased risk, with similar risk of outcomes for patients with small or large percent drop.



Conclusions: Loss of kidney function after nephrectomy is associated with adverse outcomes. Further studies are needed to determine if nephron-sparing surgery can improve clinical outcomes.

FR-PO914

Muscle Mass Assessed by Urinary Creatinine Excretion and Chronic Kidney Disease Outcomes Benedicte Stengel,[1] Elena Tynkevich,[1] Jean-Philippe Haymann,[2] Marie Metzger,[1] Pascal Houillier,[3] Martin Flamant.[4] *[1]Inserm Unit 1018, CESP, Villejuif, France; [2]Dept of Physiology, AP-HP, Tenon Hospital, Paris, France; [3]UMRS 775, Paris 5 Univ, Paris, France; [4]Dept of Physiology, AP-HP, Bichat Hospital, Paris, France.*

Background: Muscle wasting predicts mortality in patients with end-stage renal disease (ESRD), but its role in the progression of chronic kidney disease (CKD) is uncertain. We studied CKD outcomes associated with low muscle mass, assessed by urinary creatinine excretion.

Methods: The NephroTest cohort included 1,429 patients with CKD stages 1 to 4 and both measured (mGFR) (by ^{51}Cr-EDTA) and estimated (eGFR) (by CKD-EPI equation) glomerular filtration rates. We estimated adjusted hazard ratios (HR, 95% confidence interval) for ESRD and pre-ESRD death associated with urinary creatinine quartiles defined by gender-specific thresholds (11.3, 13.3, and 15.5 mmol/24 h in men and 7.5, 9.0, 10.5 in women).

Results: Mean urinary creatinine excretion was 13.6 ± 3.2 mmol/24 hour (0.17 ± 0.05 mmol/kg/24 h) in men and 9.2 ± 2.1 mmol/24 hour (0.14 ± 0.05) in women. Over a median follow-up of 3.6 years, 229 patients developed ESRD and 113 patients died before ESRD. Compared with patients in the highest urinary creatinine quartile, those in the lowest quartile had a higher HR for pre-ESRD mortality: 2.0 [0.98-4.1], independent of demographic variables, mGFR, cardiovascular risk factors, body mass index, and several biomarkers of nutritional status, and inflammation. In contrast, their ESRD risk was not higher either before or after adjusting for confounders including mGFR: crude HR, 0.99 [0.68-1.4] and adjusted HR, 0.69 [0.46-1.0]. Interestingly, adjustment for eGFR instead of mGFR distorted this relation by producing a significantly higher HR for ESRD in the lowest quartile: 1.6 [1.1-2.5].

Conclusions: Muscle wasting in early stage CKD, reflected by lower urinary creatinine excretion, is associated with increased mortality, but not with progression to ESRD. Previous studies showing greater ESRD risk with lower urinary creatinine excretion may have been confounded by inappropriate adjustment for creatinine-based estimated GFR.

The Association of Kidney Function with Repetitive Breath-Hold Diving Activities of Haenyeo, Korean Women Unassisted Diver Yun Jung Oh,[1] Su Mi Lee,[2] Dongyeol Lee,[2] Chungsik Lee.[1] *[1]Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea; [2]Internal Medicine, Donga Univ Hospital, Pusan, Republic of Korea.*

Background: The effects of repetitive deep breath-hold diving on cardiovascular, respiratory, and metabolic adjustments have been reported in previous studies, which include bradycardia, vasoconstriction of selected vascular beds, depressed metabolism, and decreased respiratory exchange ratio. However, renal response to high-pressure and hypoxic environment associated with diving has not investigated yet. We aimed to examine the association between kidney function and breath-hold diving activities of Korean women divers, haenyeo who traditionally harvest marine products controlling breathing without any apparatus in Jeju province.

Methods: A cross-sectional study was performed using the medical records of 1,920 women divers and 3,220 non-divers women who presented to a hospital for health check-up. Using propensity score matching, 647 women diver/non-diver were paired and the prevalence of chronic kidney disease (CKD; estimated GFR<60ml/min/1.73m^2) was investigated in both diver and non-diver groups.

Results: Women divers were older and showed higher prevalence of comorbidities (hypertension, cardiovascular disease, and diabetes) than non-divers in unmatched cohort. Women diver group showed an increased prevalence of CKD compared to non-diver group after propensity score matching (11.6% versus 7.1%; P=0.006). In multivariable analysis, women diver group remained a significant association with prevalence of CKD in unmatched cohort (OR, 1.971; 95% CI, 1.478-2.627; P<0.001). In the matched cohort, women diver group also significantly associated with a higher adjusted OR of CKD (OR, 1.898; 95% CI, 1.204-2.993; P=0.006).

Conclusions: Kidney function was more decreased in women divers compared to non-divers, suggesting that prolonged repetitive breath-hold diving may exert adverse influence on kidney function.

FR-PO916

The Association between Periodontal Disease and Kidney Function Decline in African Americans: The Jackson Heart Study Vanessa Grubbs,[1,4] Eric Vittinghoff,[1] Michael Griswold,[2] Neil R. Powe,[1,4] Kirsten Bibbins-Domingo,[1,4] James D. Beck,[5] A. V. Kshirsagar,[5] Wei Wang,[2] Adolfo Correa,[2] Bessie A. Young.[3] *[1]UCSF; [2]UMMC; [3]VA Puget Sound; [4]SFGH; [5]UNC Chapel Hill.*

Background: Chronic kidney disease (CKD) remains a prevalent public health problem that disproportionately affects African Americans, despite efforts targeting traditional risk factors. While periodontal disease (PD), a chronic bacterial infection of the oral cavity, is both common and modifiable and implicated as a novel potential risk factor for CKD in cross-sectional studies, the association between PD and longitudinal decline in kidney function has not been fully explored.

Methods: We conducted a longitudinal analysis of 699 African American participants who underwent complete dental examinations as part of the Dental-Atherosclerosis Risk in Communities study (baseline, 1996-1998) and subsequently enrolled in the Jackson Heart Study (follow-up, 2000-2004). CKD-EPI estimated glomerular filtration rate (eGFR) ml/min/1.73m^2 was calculated at baseline and follow-up. Among participants with baseline eGFR>60ml/min/1.73m^2, incident CKD was defined as incident eGFR<60ml/min/1.73m^2 accompanied by a 5% annualized eGFR decline from baseline. Multivariable Poisson regression was used to examine the association between PD status (defined by Centers for Disease Control/American Academy of Periodontology consensus criteria), and incident CKD adjusting for age, sex, diabetes, hypertension, smoking, and income.

Results: Among study participants, mean age at baseline was 60.5 years (SD 5.2), median eGFR was 95.7 (IQR 83.2, 110.3) ml/min/1.73m^2, and 114 (16.3%) had severe PD. During a mean follow-up of 4.8 years (SD 0.6), there were 21 (3.0%) incident CKD cases. Participants with severe PD had a 4.2-fold greater incidence of CKD after adjusting for covariates compared to those without severe PD [IRR 4.18, 95% CI (1.69, 10.39), p=0.002].

Conclusions: Severe periodontal disease is common among a population at high-risk for CKD and is associated with clinically significant kidney function decline. Further research is needed to determine if the association is causal and, if so, modifiable.

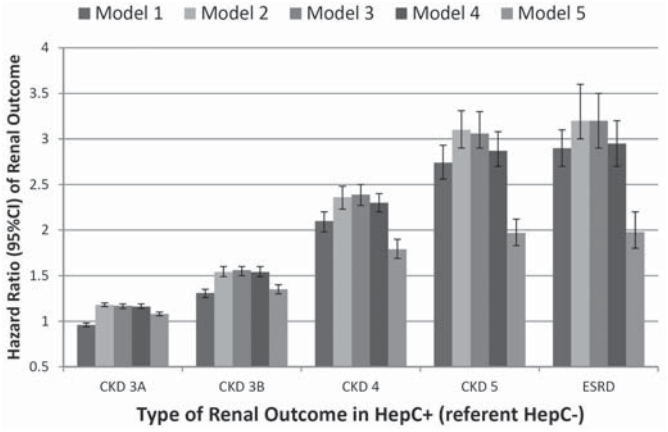
FR-PO917

Association of Hepatitis C Virus Infection with Progressive CKD and Mortality in a Large Cohort of U.S. Veterans Hazem M. Alhourani,[1] Barry M. Wall,[1,2] Miklos Zsolt Molnar,[1] Jun Ling Lu,[1] Robert B. Canada,[1] Jennie Z. Ma,[3] Elani Streja,[4] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1,2] *[1]Univ of Tennessee; [2]Memphis VAMC; [3]Univ of Virginia; [4]Univ of California Irvine.*

Background: An estimated 4 million Americans have been exposed to the hepatitis C virus (HCV). The risk of incident CKD and mortality in patients with normal kidney function infected with hepatitis C (HCV) is unclear.

Methods: In a nationally representative cohort of 1,021,049 U.S. Veterans (n=100,518 HCV+ and 920,531 HCV-) with normal baseline eGFR we examined the association of HCV infection with: (1) all-cause mortality, (2) incidence of CKD stages 3a, 3b, 4, 5 and ESRD, and (3) the slopes of eGFR. Associations were examined in crude and adjusted Cox models and logistic regression models (for slopes), with sequential adjustments for demographics (model 1), eGFR (model 2), comorbidities (model 3), BP and BMI (model 4), and markers of socioeconomic status, adherence with medical interventions and medication use (model 5).

Results: The mean (SD) age was 54.5 (13.1), 22% were black, 92% were male, and the mean (SD) baseline eGFR was 88 (16) ml/min/1.73m^2. Outcomes occurred in 116,935 (deaths); 159,872 (CKD3a); 39,518 (CKD3b); 10,578 (CKD4); 4,748 (CKD5); 3,383 (ESRD) and 70,989 patients (slopes steeper than -5 ml/min/1.73m^2/year). HCV infection was associated with higher mortality (fully adjusted HR, 95%CI: 2.17 [2.13-2.21]), with higher risk of steeper slopes (fully adjusted OR, 95%CI: 1.45 [1.41-1.48]) and with higher incidence of various CKD stages (Figure). The risk of incident CKD increased with more advanced stages of CKD end points (Figure).



Conclusions: HCV infection is associated with higher mortality and with progression of CKD. Randomized controlled trials are indicated to determine if treatment of HCV infection can prevent the development and progression of CKD and improve survival.

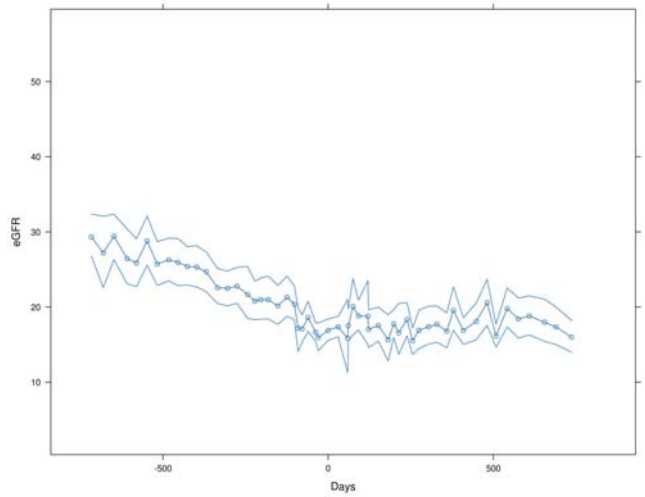
Arterio-Venous Fistula (AVF) Creation May Slow Estimated Glomerular Filtration Rate (eGFR) Trajectory

Thomas A. Golper, Phillip Matthew Hartle. *Medicine/Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: The KDOQI Vascular Access guidelines prompted a re-awareness to timely create AVFs, a policy practiced at our institution. We have often observed a slowing of the decline in kidney function (eGFR) after AVF creation, prompting the present retrospective observational analysis of the eGFR trajectory before and after the AVF creation.

Methods: We identified 123 subjects between 2005 and 2010 with at least two eGFR determinations (IDMS-traceable MDRD Study equation) for 2 years before and 2 years after AVF creation. Inclusion eligibility was that the fistula was maturing by the nephrologist's subsequent post creation exams, as noted in the medical record. Termination events were death, starting dialysis or transplantation. Each subject served as his/her own control for the before and after AVF creation eGFR measurements so size normalization was not performed.

Results: Subject characteristics are mean age of 68 years, 41% female, 56% diabetic, 97% hypertensive. The rate of change of eGFR for the two years prior to AVF creation was 5.9 mL/min/year (IQR 6.5, 5.3) and for up to 2 years after AVF creation 0.5 mL/min/year (IQR 1.1, 0.1) (p< 0.001).



Conclusions: Agreeing to timely AVF creation selects patients in an otherwise typical population. Observational studies suggest trajectory can accelerate as eGFR declines. We observed the opposite. There are biologically and physiologically plausible explanations as to how an AVF creation might alter kidney function, but this clinical observation has been attributed to improved compliance and/or divine intervention. A prospective observational study is indicated because, if the present observation is confirmed, AVF creation in and of itself may delay the initiation of dialysis, reducing morbidity and costs.

FR-PO919

Contemporary Rates and Predictors of Loss of Kidney Function and End-Stage Renal Disease in Adults with Chronic Kidney Disease

Alan S. Go,[1] Jingrong Yang,[1] Thida Tan,[1] Claudia S. Cabrera,[2] Bergur V. Stefansson,[2] Juan Daniel Ordonez.[1] *[1]Kaiser Permanente Northern California; [2]AstraZeneca.*

Background: Identifying CKD patients at high-risk for short-term adverse renal outcomes is challenging. Within a very large, diverse community-based CKD cohort, we evaluated contemporary rates and predictors of CKD progression.

Methods: Within Kaiser Permanente Northern California, we identified adult members with Stage 3/4 CKD (eGFR 15-59 min/1.73m^2 by CKD-EPI) between 2008-2012 and no prior dialysis or transplant. Through 2012, we calculated the rate and identified predictors of the composite outcome of ESRD, reaching eGFR <15 ml/min/1.73m^2, or >50% reduction from baseline eGFR. In sensitivity analyses, we used an alternative composite outcome that included >40% eGFR reduction. Demographic and clinical characteristics, plus baseline medication use were obtained from health plan databases.

Results: Among 149,487 Stage 3/4 CKD patients, mean age was 73 yr, 57% were women, 23% were persons of color and 29% were diabetic. Over mean follow-up of 3.5±1.5 years, the overall annual renal composite outcome rate was 2.14 (2.10-2.18), and higher in diabetics (3.86) versus non-diabetics (1.45). The strongest multivariable predictors of CKD progression are shown in the table.

Characteristic	Adjusted Hazard Ratio (95% CI)
eGFR (vs. 45-59 ml/min/1.73 m2)	
30-44	1.07 (1.02-1.13)
15-29	2.85 (2.69-3.02)
Proteinuria	2.63 (2.42-2.64)
Hemoglobin (vs. ≥13 g/L)	
12-12.9	2.31 (2.16-2.46)
11-11.9	3.71 (3.48-3.96)
10-10.9	6.12 (5.71-6.56)
9-9.9	8.67 (7.92-9.50)
<9	12.57 (11.23-14.08)
Male gender	1.17 (1.11-1.24)
Asian	1.25 (1.17-1.33)
Hispanic	1.13 (1.06-1.20)
Current/former smoking	1.09 (1.04-1.14)
Diabetes	1.12 (1.05-1.20)
Systolic BP (vs. ≤120 mmHg)	
121-129	1.16 (1.09-1.23)
130-139	1.29 (1.22-1.37)
140-149	1.36 (1.27-1.45)
150-159	1.70 (1.56-1.86)
160-179	2.00 (1.78-2.25)
≥180	1.36 (1.19-1.75)

When using >40% eGFR reduction in the composite outcome, the rate was 3.58 (3.53-3.63) and predictors were similar.

Conclusions: In a large, contemporary CKD population, significant progression affected 1 in 47 patients annually. A combination of readily available patient features can identify the subset of high-risk CKD patients.

Funding: Pharmaceutical Company Support - AstraZeneca

FR-PO920

Predictors of Fast Progression in a Community-Based Population with Stage 3 Chronic Kidney Disease

Alan S. Go,[1] Jingrong Yang,[1] Thida Tan,[1] Claudia S. Cabrera,[2] Bergur V. Stefansson,[2] Juan Daniel Ordonez.[1] *[1]Kaiser Permanente Northern California; [2]AstraZeneca.*

Background: Few studies have systematically evaluated a wide range of potential risk factors for accelerated progression of CKD in representative "real world" populations. We examined a large, diverse community-based CKD cohort to identify predictors of fast progression during the first two years of follow-up.

Methods: Within Kaiser Permanente Northern California, a large integrated health care delivery system, we identified adult Stage 3 CKD patients (eGFR 30-59 ml/min/1.73m^2 by CKD-EPI) between 2008-2010, no prior dialysis or transplant, had outpatient serum creatinine values spaced 10-14 months apart and did not initiate renal replacement therapy, die or disenroll during the first 2 years of follow-up. Through 2012, we calculated the annual rate of change in eGFR and classified patients as fast progressors if they lost >4 ml/min/1.73m^2 per year.

Results: We identified 30,739 eligible adults with Stage 3 CKD (mean entry eGFR 48±9, mean age 73 yr, 57% women, 35% persons of color and 28% diabetic). Annual incidence of fast progression was 14.6% (14.2-15.0) and higher in diabetics (18.2%) versus non-diabetics (12.6%). The strongest multivariable predictors of fast CKD progression are shown in the Table.

Characteristic	Adjusted Hazard Ratio (95% CI)
Age >80 (vs. 18-49 yr)	1.49 (1.15-1.92)
Heart failure	1.37 (1.20-1.55)
Dementia	1.37 (1.10-1.69)
Systolic BP (vs. <120 mmHg)	
130-139	1.21 (1.10-1.33)
140-159	1.36 (1.22-1.51)
160-179	1.97 (1.69-2.29)
≥180	2.18 (1.66-2.86)
Proteinuria	1.76 (1.60-1.94)
Hemoglobin (vs. ≥13 g/L)	
12-12.9	1.33 (1.21-1.46)
11-11.9	1.73 (1.55-1.93)
10-10.9	1.91 (1.62-2.26)
<9	1.75 (1.07-2.85)
Total cholesterol >240 (vs. <200 mg/dL)	1.34 (1.08-1.67)
HDL cholesterol (vs. ≥60 mg/dL)	
50-59	1.18 (1.06-1.31)
40-49	1.20 (1.08-1.34)
35-39	1.16 (1.02-1.32)
< 35	1.19 (1.03-1.38)

Conclusions: In a large, contemporary population of adults with Stage 3 CKD, accelerated progression of kidney dysfunction affected ~1 in 7 patients. Older age, selected morbidities, high blood pressure, proteinuria, anemia, high total cholesterol and lower HDL were the strongest predictors of rapid progression of CKD.

FR-PO921

Progression of Chronic Kidney Disease in Primary Care over 1 Year

Adam Shardlow,[1] Natasha J. Mcintyre,[1] Richard J. Fluck,[1] Chris W. McIntyre,[1,2] Maarten W. Taal.[1,2] *[1]Royal Derby Hospital, United Kingdom; [2]Nottingham Univ, United Kingdom.*

Background: Most people with CKD stage 3 are elderly and managed in primary care but much of the literature comes from studies in specialist nephrology centres. Questions remain regarding optimal frequency of follow-up and risk of progressive disease in this population. The Renal Risk in Derby (RRID) study aims to evaluate decline of renal function in a cohort of people with CKD 3 recruited from general practices in Derbyshire, UK.

Methods: Data from 1621 of 1741 participants in the RRID cohort were included in this analysis. Participants were recruited from primary care practices. All had eGFR 59-30ml/min on 2 occasions prior to inclusion. At baseline and 1 year visits, participants underwent clinical assessment, urine and serum biochemistry. Progression of CKD was defined using KDIGO criteria (25% loss of GFR and an increase in GFR category or an increase in albuminuria category).

Results: 38 participants died before the year 1 assessment. Overall, there was a small but statistically significant decline in the mean eGFR from baseline to Year 1 (52.7ml/min to 52. 3ml/min p=0.025). 140 out of 1621 participants (8.6%) demonstrated progression in either albuminuria or GFR category. Progression largely occurred separately in these two groups.

	No Albuminuria Progression n (%)	Albuminuria Progression n (%)
No GFR Progression n (%)	1481 (91.3%)	87 (5.4%)
GFR Progression n (%)	47 (2.9%)	6 (0.37%)

Significant univariate associations with progression were age (HR=1.03), diabetes (HR=2.4), haemoglobin (HR=0.72), albumin (HR=0.94), bicarbonate (HR=0.90) and GFR (HR=0.978). Multivariable logistic regression analysis identified haemoglobin (HR=0.85; 95% CI 0.73-0.99 p=0.041), albuminuria (HR 1.28; 1.11-1.47 p=0.001) and a definite or possible episode of AKI (HR 4.60; 2.75-7.90 p<0.001) as independent determinants of progression.

Conclusions: Over 1 year, a significant minority showed progression in either albuminuria or GFR category. Progression was independently associated with baseline haemoglobin, albuminuria and AKI. Our results support annual follow-up except in those with albuminuria or following AKI. Interventions to prevent AKI will likely also reduce CKD progression.

Funding: Private Foundation Support

FR-PO922

Progression to Next Stage of Chronic Kidney Disease (CKD) Using Modified KDIGO (eGFR/Proteinuria) Classification in Children

Wun Fung Hui,[1,2] Christopher B. Pierce,[2] Alison G. Abraham,[2] Bradley A. Warady,[2] Colin T. White,[2] Susan L. Furth.[1,2] *[1]Dept of Paediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA; [2]The Chronic Kidney Disease in Children (CKiD) Study Investigators.*

Background: The combination of eGFR and proteinuria in the latest KDIGO classification guideline has not been applied in children with CKD to inform the frequency of follow-up visits. Using data from the Chronic Kidney Disease in Children (CKiD) study, we assessed the percentage of individuals in a given stage who progressed to another stage within 1.5 yrs of follow up.

Methods: Accelerated failure time models were used to classify subjects into categories of eGFR and urine protein-to-creatinine ratio (uP/c) with unique risk for developing an event: either (i) 50% reduction of baseline GFR (ii) initiation of RRT or (iii) death during follow-up. Seven unique risk stages were identified. At annual follow-up visits, the proportion at each stage remained or transitioned to a different stage of CKD in 1.5 years was then assessed.

Results: 854 subjects (71.2% non-glomerular and 29% glomerular causes) with 2591 patient-years follow-up experienced 219 events (defined above). Median (IQR) age of the cohort at baseline was 11 (8, 15) yrs. Among the 1841 (82%) patient visits with original eGFR ≤60ml/min/1.73m^2, around one third of them transitioned to a higher risk stage or experienced an event within 1.5 yrs. (table). Risk of an event for individuals in stage A-D was low, while 20-56%of individuals in stages E-G experienced an event in this time frame.

		Percentage remaining or transitioning to alternate stage in 1.5 yrs							
N	Original stage	A	B	C	D	E	F	G	Event
408	A	78	14	7	0	<1	<1	0	<1
422	B	13	57	25	2	<1	1	0	2
575	C	6	15	50	15	7	5	<1	2
269	D	1	2	19	41	17	9	3	8
276	E	0	<1	7	6	54	1	13	20
177	F	1	<1	8	11	4	39	15	21
122	G	0	0	0	1	13	1	30	56

eGFR category (ml/min/1.73m^2): G1 ≥90; G2 60-90; G3a 45-60; G3b 30-45; G4 15-30
A: eGFR G1 and uP/C <2.0 or eGFR G2 and uP/C <0.5
B: eGFR G3a and uP/C <0.5
C: eGFR G2/G3a and uP/C 0.5-2.0 or eGFR 3b and uP/C <0.5
D: eGFR G3b and uP/C 0.5-2.0
E: eGFR G4 and uP/C <2.0
F: eGFR G1/G2/G3a/G3b and uP/C >2.0
G: eGFR G4 and uP/C >2.0

Conclusions: Based on observation of progression in CKiD using eGFR and uP/C, children with eGFR >30ml/min/1.73m^2 and uP/C<2.0 are at low risk of an event, despite progression over a 1.5 yr period, while children with uP/C>2.0 or eGFR≤30ml/min/1.73m^2 are at substantially higher risk and more frequent follow up is suggested.

Decline in Kidney Function with Aging: Mathematical Modeling of Serial eGFR Measurements

Runolfur Palsson,[1,2] Bjarni Gunnarsson,[3] Hrefna Gudmundsdottir,[1,2] Margret B. Andresdottir,[1] Vilmundur Gudnason,[2,3] Thor Aspelund,[2,3] Olafur S. Indridason.[1] *[1]Div of Nephrology, Landspitali - The National Univ Hospital of Iceland, Reykjavik; [2]Faculty of Medicine, Univ of Iceland, Reykjavik; [3]Icelandic Heart Association, Kopavogur, Iceland.*

Background: Decline in kidney function in the elderly is thought to be a consequence of normal aging. However, long-term prospective studies of kidney function in the general population are lacking. The purpose of this study was to characterize the changes in estimated glomerular filtration rate (eGFR) over time in a large cohort of Icelandic subjects.

Methods: For participants aged 33-75 years in the Reykjavik Study (RS), conducted between 1967 and 1995, we identified all subsequent measurements of serum creatinine (SCr) from clinical laboratories in the Reykjavik area. The MDRD Study equation was used to calculate eGFR and various statistical models for longitudinal data were applied to characterize changes in eGFR over time. The analysis was made separately for men and women.

Results: At least one SCr value was identified for 14,572 participants (85.4%), of whom 51.6% were women. Mean follow-up time was 28.4 years. Decline in eGFR with age was observed to be non-linear and best represented by the class of generalized additive mixed models. A sharper decline in eGFR after age 70 years was noted. Age, age at first entry and diabetes were significantly associated with eGFR decline in both men and women, and diastolic blood pressure and proteinuria associated with eGFR in women. At age 70 years, eGFR <60, <45 and <30 mL/min/1.73 m^2 was observed in 29.5%, 6.6% and 1.3% of subjects, and at age 80 years in 45.1%, 17.9% and 4.3% of subjects, respectively.

Conclusions: Kidney function declines with age in a non-linear fashion. Assessment of the change in eGFR over the lifespan and into older age requires flexible modeling approaches. Major cardiovascular risk factors were associated with the change in eGFR with age.

Usefulness of the CKD Classification in Targeting of HIV Individuals at High Risk of Poor Outcomes

Takeshi Tokoroyama,[1,2] Naoki Yanagisawa,[2,3] Minoru Ando,[1,2] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Dept of Nephrology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [2]Dept of Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan; [3]Dept of Infectious Disease, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan.*

Background: Chronic kidney disease (CKD) is now epidemic among HIV-infected populations and a likely determinant of their prognosis.

Methods: A total of 1,975 HIV-infected subjects (1,852 men, 124 women, mean age: 44.5 ± 11.5 years) who regularly visited one of 5 tertiary hospitals were classified into 4 risk categories, using the combination of 5 stages of eGFR and 3 grades of ACR (urinary albuminuria-creatinine-ratio) (categories 0 to 3). Among 1,975 HIV subjects, 661 were

prospectively followed-up for 4 years to determine incidence of composite outcomes, including all-cause mortality, cardiovascular disease and a decline over 25% from baseline in eGFR. The cumulative incidence of the outcomes was analyzed with Kaplan-Meier method, and hazard risk (HR) of the categories for the outcome incidence was calculated using multivariable proportional hazards regression analysis, adjusted for age, gender, infection markers, and presence or absence of comorbidities.

Results: The frequency of each CKD category was shown in Table. The Kaplan-Meier estimates were significantly increased over time in the risk categories 2 *plus* 3, compared with the categories 0 *plus* 1. The HR of risk categories 2 *plus* 3 was 2-fold greater (HR = 2.00; its 95% confidence interval, 1.08 - 3.57; P = 0.0277), as compared to risk categories 0 *plus* 1.

Conclusions: The CKD classification may serve as a new tool for highlighting HIV-infected individuals at increased risk.

Table Distribution of HIV individuals according to the CKD risk categories				
GFR stage	eGFR	ACR <30	ACR 30-300	ACR >300
G1	>90	category-0:597 (28.0%)	category-1: 41 (1.9%)	category-2: 0 (0.0%)
G2	60-90	category-0:1200 (56.2%9	category-1: 89 (4.2%)	category-2: 4 (0.2%)
G3A	45-60	category-1:135 (6.3%)	category-2: 23 (1.1%)	category-3: 3 (0.1%)
