KIDNEYWEEK 2014
Philadelphia, PA | Nov 11 - 16

JASN Abstract Supplement

Abstract Publication
More than 4,500 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date*, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined. For the poster sessions, the publication numbers and poster board numbers are the same.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 25, 2014: Page(s).

Abstract Experts
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The *Onsite Program* lists all abstract experts.

Abstract Disclaimer and Copyright
The Abstract Issue of JASN® contains proprietary information belonging to the American Society of Nephrology (ASN). It is published as a service for the personal, noncommercial, and informational use only of its members and Kidney Week participants. Any commercial use is strictly prohibited. ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such material within Kidney Week and other ASN publications, or online postings does not constitute an endorsement by ASN.

ASN General Information

Kidney Week Program and Presentations
The Kidney Week 2014 program, which can be found in the *Onsite Program*, includes:

- Early Programs' content
- Plenary Sessions
- Basic and Clinical Science Symposia
- Clinical Nephrology Conferences
- Special Sessions
- Educational Symposia
- Oral Abstract Sessions
- Poster Sessions

Disclosure Statement
ASN requires all individuals in a position to control content for Kidney Week 2014 to complete a disclosure form. Responses are listed on the ASN website (www.asn-online.org/kidneyweek/faculty) and on the Kidney Week 2014 mobile app.

Program Builder
All abstracts and the complete Kidney Week 2014 program are viewable online through the Program Builder at www.asn-online.org/KidneyWeek with features including keyword search and PDA download.

Support provided by OPKO Health Renal Division.

Posters On-Demand™
Fully paid participants can access electronic versions of the Kidney Week 2014 posters at no additional cost. Search and locate posters easily by authors, categories, or keywords during and after the meeting. Posters can be accessed online at www.asn-online.org/KidneyWeek.

Support provided by OPKO Health Renal Division.

Cardiac Dysfunction in *Pkd1*-Deficient Mice and Phenotype Rescue by Galectin-3 Knockout Bruno E. Balbo,[1] Andressa Godoy Amaral,[1] Jonathan Mackowiak Fonseca,[1] Isac De Castro,[1] Vera Mc Salemi,[1] Leandro Eziquiel Souza,[1] Fernando Santos,[1] Maria Irigoyen,[1] Feng Qian,[2] Roger Chammas,[1] Luiz F. Onuchic.[1] *[1]Univ of São Paulo, Brazil; [2]Univ of Maryland.*

Background: Myocardial abnormalities stand out among ADPKD cardiovascular manifestations.

Methods: To elucidate their pathogenesis, we analyzed the cardiac phenotype in distinct models of *Pkd1*-deficiency. We evaluated *Pkd1*$^{cond/cond}$:*Nestin*^{cre} (CY) cystic, hypertensive mice at 20-24 weeks of age, and *Pkd1*$^{+/-}$ (HT) noncystic mice at 10-13 weeks, a model of haploinsufficiency.

Results: Echocardiographic analyses in CY and HT mice revealed decreased left ventricle ejection fraction (LVEF), indicating systolic dysfunction, as well as E/A ratios and deceleration times consistent with diastolic dysfunction in CYs and a similar trend in HTs, when compared to *Pkd1*$^{cond/cond}$ (noncystic; NC) and *Pkd1*$^{+/+}$ (wild type, WT) controls. Speckle-tracking echocardiography showed reduced cardiac deformability in both models. CY and HT hearts presented higher apoptotic rates (TUNEL) and mild fibrosis (Sirius red), without TGFß1 increased expression. In this scenario, we investigated galectin-3 (Gal-3) as a potential modifier of the ADPKD cardiac phenotype. Double mutants *Pkd1*$^{cond/cond}$:*Nestin*^{cre};*Lgals3*$^{-/-}$ (CYG-) and *Pkd1*$^{+/-}$;*Lgals3*$^{-/-}$ (HTG-) displayed improved systolic and deformability parameters compared to single mutants, while such values did not differ from NCs and WTs. HTG-s presented a trend of improvement in diastolic function. CYG- and HTG- hearts showed decreased apoptosis and fibrosis, reaching NC and WT baselines. Western blot analyses revealed higher Gal-3 expression in CY than NC hearts. CYG- and HTG- animals showed no difference in BUN compared to CYs and HTs, but displayed trends of increased fractional excretion of Na^+, Cl^- and K^+. We also employed a more severe cystic model, homozygous for an allele that hinders polycystin-1 cleavage (*Pkd1*$^{V/V}$; VV), to show that *Pkd1*$^{V/V}$;*Lgals3*$^{-/-}$ mice present longer survival than VVs.

Conclusions: Our findings demonstrate myocardial dysfunction in different *Pkd1*-deficient models, reproducing human ADPKD, and reveals that absence of Gal-3 expression significantly rescues this phenotype.

Deletion of Heart *Pkd1* Promotes Cardiac Remodeling via Smyd2 and NF-κB Cross-Talk Changlin Li, Lucy Fan, James P. Calvet, Xiaogang Li. *Medicine, The Univ of Kansas Medical Center, Kansas City, KS.*

Background: ADPKD associated cardiovascular complications have been suggested to result from renal cyst growth induced cardiovascular hypertension, which occurs in patients at an earlier age than in the general population. However, the fact that cardiac hypertrophy also occurs in young ADPKD patients with normal blood pressure and normal renalfunction suggests that cardiac dysfunction in ADPKD does not develop solely in response to hypertension and renal failure, and additional genetic or environmental factors may be required. In this study, we investigated the direct involvement of heart *Pkd1* in regulating cardiac complications.

Methods: To understand the role of *Pkd1* in the heart, we generated a heart specific Pkd1 conditional knockout (*Pkd1-hCKO*) mouse via the deletion of heart *Pkd1* in cardiomyocytes in six-week-old *Pkd1*$^{flox/flox}$:αMHC-MerCreMer mice induced by tamoxifen for five days. The *Pkd1*-hCKO mice were further analyzed at 6, 12, and 18 weeks after tamoxifen induction.

Results: We found that heart specific knockout of *Pkd1* resulted in heart hypertrophy as early as 6 weeks after tamoxifen treatment characterized by increase of 1) the heart weight (HW)/body weight (BW) ratios; as well as the expression of 2) the hypertrophic markers, atrial natriuretic factor (ANF) and β-myosin heavy chain (β-MHC); 3) the cardiac hypertrophy related cytokines, TNF-α, MCP-1, and IL-6; and 4) Smyd2, a histone methyltransferase in *Pkd1*-hCKO cardiomyocytes. Deletion of heart Smyd2 blunted cardiac hypertrophy induced by knockout of heart *Pkd1* as shown by decreased HW/BW ratios in those mice and decreased expression of ANP and β-MHC as well as TNF-α, MCP-1, and IL-6 in *Pkd1* and Smyd2 double knockout cardiomyocytes. In addition, we found that Smyd2 interacted with the NF-κB p65 subunit in *Pkd1*-hCKO cardiomyocytes but not in *Pkd1* wild type cardiomyocytes and that this interaction resulted in the methylation of p65 and activation of NF-κB leading to increased cardiac hypertrophic cytokine expression in *Pkd1*-hCKO cardiomyocytes.

Conclusions: Heart specific deletion of polycystin-1 directly promotes cardiac hypertrophy mediated by cross-talk between the Smyd2 and NF-κB signaling pathways.

TH-OR003

mTORC1 Regulates Polycystin-1 Expression Levels Possibly Explaining Renal Cystogenesis in *Tsc1* Mutant Mice Monika Pema, Marco Chiaravalli, Luca Drusian, Alessandra Boletta. *Div of Genetics and Cell Biology, DIBIT-San Raffaele Scientific Inst, Milan, Italy.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a common genetic disorder characterized by massive bilateral renal cyst formation. ADPKD results from mutation in the *PKD1* or *PKD2* genes, encoding the Polycystin-1 (PC-1) and 2 (PC-2) proteins respectively. Several studies have implicated a crosstalk between the *PKD* genes and the genes mutated in a genetic disorder called Tuberous Sclerosis Complex (TSC). mTOR is upregulated in PKD and rapamycin slows cyst expansion, PC-1 can inhibit mTORC1 and finally renal inactivation of the *Tsc* genes causes cysts. Thus upregulation of mTORC1 downstream of *PKD1* mutations is viewed as an important driver of cystogenesis. Here we show that this model should be revisited.

Methods: Inactivation of *Pkd1* and *Tsc1* genes in the kidney using the same KspCre recombinase results in different phenotypes.

Results: Whereas both *Pkd1* and *Tsc1* inactivation result in mTORC1 upregulation in the kidneys, *Pkd1* mutant mice develop a more aggressive cystic phenotype leading to death by P12, while *Tsc1* mutants display a milder and delayed phenotype with cysts arising at P20 and death by P80. Interestingly, we found a strong downregulation of PC-1 in *Tsc1*-/- MEFs compared to wild type controls, which was reverted by rapamycin. Thus, our data indicate that mTORC1 can regulate the expression levels of PC-1. This process does not act on the rate of protein degradation, but it requires protein neo-synthesis. Lowering PC-1 to 50% exacerbates cystogenesis in *Tsc1* mutants, while a brief pulse of rapamycin overcomes a critical time-window in which PC-1 is essential leading to a long-lasting rescue.

Conclusions: Thus, we show that mTORC1 upregulation *per se* is not sufficient to drive cystogenesis, but that this is due to downregulation of PC-1 in *Tsc* mutants. Our data might provide a mechanistic explanation for the severe renal cystogenesis observed in the *PKD/TSC* contiguous genes syndrome opening new perspectives for the use of rapamycin analogues in this syndrome or in ADPKD caused by hypomorohic or mild *PKD1* mutations.

Ciliary Polycystin Complex Traffics Through the Golgi *Via* a Rabep1/GGA1/Arl3-Dependent Mechanism Feng Qian,[1] Hyunho Kim,[1] Hangxue Xu,[1] Qin None Yao,[1] Weizhe Li,[1] Qiong Huang,[1] Patricia Outeda,[1] Marco Chiaravalli,[2] Alessandra Boletta,[2] Gregory G. Germino,[3] Terry J. Watnick.[1] *[1]Medicine, Univ of Maryland School of Medicine, Baltimore, MD; [2]San Raffaele Scientific Inst, Milano, Italy; [3]NIDDK, Bethesda, MD.*

Background: Primary cilia play a critical role in autosomal dominant polycystic kidney disease. We have previously presented that their gene products polycystin-1 and -2 must interact and form a complex (the polycystin complex) to traffic through the Golgi for subsequent ciliary targeting. The purpose of the study is to identify the molecules that mediate ciliary trafficking of the polycystin complex.

Methods: We performed a yeast two-hybrid screen for polycystin-1 interacting proteins with the C-terminal tail as bait and examined their role in mediating polycystin complex ciliary trafficking in renal epithelial cells.

Results: Thirteen unique cDNA clones were identified that specifically interact with the polycystin-1 C-terminus. One of these clones corresponded to amino acids 465 to 799 of Rabep1, an effector of multiple Rab GTPases involved in various steps of intracellular vesicular trafficking. The Rabep1 binding requires the intact coiled-coil domain of polycystin-1, which is outside of the previously reported ciliary targeting sequence. Rabep1 recruits the polycystin complex to GGA1 and Arl3 at TGN for ciliary trafficking. We find that GGA1, previously shown to be important for protein sorting and vesicle budding for endosomal proteins, can function as an Arl3 effector and mediate sorting and targeting of the polycystin complex to the cilium. We find that GGA1/Arl3 recruitment and ciliary trafficking of the polycystin complex require GPS cleavage of polycystin-1 *in vivo*, and are disrupted by the *PKD1* mutation in the REJ domain that impairs the GPS cleavage. Importantly, GGA1/Arl3 recruitment and ciliary trafficking of the mutant polycystin complex can be restored upon rescuing GPS cleavage.

Conclusions: We show that ciliary polycystin complex traffics through the Golgi *via* a Rabep1/GGA1/Arl3-dependent mechanism. Our study provides novel insights into the ciliary trafficking mechanism of transmembrane proteins and has important implications for ADPKD.

Arl13b and the Exocyst Are Necessary for Ciliogenesis and Interact Synergistically Soo Young Choi,[1] Cecília Seixas,[2] Nicole L. Umberger,[3] Xiaofeng Zuo,[1] Tamara Caspary,[3] Duarte C. Barral,[2] Joshua H. Lipschutz.[1,4] *[1]Depts of Medicine, Univ of Pennsylvania, Philadelphia, PA; [2]CEDOC, Univ Nova de Lisboa, Lisboa, Portugal; [3]Human Genetics, Emory Univ, Atlanta, GA; [4]Depts of Medicine, Philadelphia VAMC, Philadelphia, PA.*

Background: Arl13b belongs to the ADP-ribosylation factor family of small GTPases of the RAS superfamily, and is important for primary ciliogenesis. We previously showed that the eight-protein exocyst complex is necessary for ciliogenesis, and most likely acts by targeting and docking vesicles carrying ciliary proteins. Notably, mutations in Arl13b and exocyst subunit Exo84 were found in patients with Joubert Syndrome, a nephronophthisis form of polycystic kidney disease (PKD).

Methods: To investigate an interaction between Arl13b and the exocyst *in vitro*, we performed immunoprecipitation, immunoblotting, and *in vitro* transcription and translation. To investigate if arl13b and the exocyst interact *in vivo*, we used two different model systems, antisense morpholinos to knock down *arl13b* and exocyst subunit *sec10* in zebrafish, and Cre-Lox to knock out Arl13b in mice.

Results: Arl13b interacts directly with the exocyst subunit Sec8. Sec8 is a *bona fide* effector of Arl13b, as it binds only to the active form of Arl13b. Kidneys from Arl13b deficient mice demonstrated cysts in all segments of the nephron, along with decreased ciliogenesis. The observed MAPK activation suggests that excessive cell proliferation is involved in the cystic phenotype. We previously showed that depletion of *sec10* in zebrafish phenocopies *arl13b* (aka *scorpion*) knockdown with ciliary mutant phenotypes, including: curly tail up and left-right patterning defects. We show here a synergistic genetic interaction between *arl13b* and s*ec10* in zebrafish, suggesting that *arl13b* and the exocyst function in the same pathway.

Conclusions: Our study demonstrates that the exocyst is a novel effector of Arl13b, that these proteins likely function in the same pathway, that both are required for ciliogenesis, and that this may have important implications for PKD patients.

TH-OR006

Ciliary Trafficking of Polycystin-1 Is Regulated by Polycystin-2 and Other Factors Xuefeng Su, Gang Yao, Maoqing Wu, Azadeh Tabari, Jing Zhou.

Background: Polycystin-1 (PC1) is the product of the *PKD1* gene that is mutated in over 85% cases of autosomal dominant polycystic kidney disease (ADPKD). Multiple lines of evidence suggests an essential role of ciliary PC1 in the disease process. About one third of the *PKD1* mutations are missense mutations which likely produce full-length proteins that fail to be targeted to their normal functional sites, yet the regulation of PC1 trafficking remains poorly understood. We have recently shown that the Bardet-Biedl Syndrome (BBS) gene products BBS1 and BBS3 regulates the ciliary localization of PC1 and that the C-terminal cytoplasmic domain of PC1 is essential for its targeting to the primary cilia (Hum Mol Genet 2014).

Methods: A set of deletion/mutation in PC1 and chimeric constructs with different PC1 C-terminal motifs were made. They were transfected alone or together with other molecules into IMCD3 cells, and the ciliary trafficking ability of these constructs was evaluated by immunostaining. The role of other genes in this process was also evaluated by depletion of respective proteins by lentiviral shRNAs. Western blot and co-immunoprecipitation were performed to analyze the PC1 protein complex forming ability and GPS cleavage.

Results: Here we report a systemic investigation of cis elements modulating the ciliary trafficking of PC1. We show that a coiled-coil (CC) motif in the cytoplasmic tail (CTT) of PC1 is required for efficient targeting of full-length polycstin-1 to cilia, while the previously identified ciliary targeting VxPx motif critical for several ciliary proteins is dispensable. Besides the CC motif, we also identified the presence of other motif/sequences in CTT that is required for PC1 ciliary trafficking. Knockdown of small GTPases previously shown important for the ciliary localization of rhodopsin has no effect on the full-length PC1 trafficking to cilia. While PC1 remains to traffic to the primary cilia in cells depleted of PC2, expression of PC2 promoted the ciliary trafficking of PC1 and several PC1 mutants. Co-expression of PC1 and PC2 lead to the increased ciliary expression of both proteins. The presence of intact PC2 C-tail but not its channel activity or ciliary targeting sequence is required for this process. The effect of PC2 on the ciliary trafficking of PC1 correlates with its ability to form a complex with PC1. GPS cleavage mutants may or may not affect PC1 trafficking to the primary cilia.

Conclusions: The ciliary trafficking of PC1 is highly regulated by motifs in its primary structure, interactions with PC2, but not cleavage at its GPS site.

Funding: NIDDK Support

Pkd2 Is Essential for Intraciliary Calcium Signaling In Vivo Zhaoxia Sun,[1] Shiaulou Yuan,[2] Lu Zhao,[1] Martina Brueckner.[2] *[1]Genetics, Yale Univ School of Medicine, New Haven, CT; [2]Pediatrics, Yale Univ School of Medicine, New Haven, CT.*

Background: Mutations in *PKD1* or *PKD2* are responsible for autosomal dominant polycystic kidney disease. PKD2 is a six transmembrane protein that can complex with PKD1 to form a voltage-sensitive, non-selective cation channel. In cultured renal epithelial cells, mechanical stress on the cilium results in a rise in cytosolic calcium that depends on both PKD1 and PKD2. PKD2 is also essential for vertebrate left-right development, which is initiated in the left-right organizer (LRO) by cilia-driven directional fluid flow. However, the exact role of polycystins in ciliary and cellular signaling remains unclear.

Methods: In this study, we utilized multiple compartment-targeted genetically encoded calcium indicators (GECIs) to measure calcium dynamics in the cilium and cytosol in cultured renal epithelial cells and at the LRO in developing zebrafish embryos.

Results: In cultured renal epithelial cells at resting state, the concentration of free calcium in the cilium is slightly higher than that in the cytosol. Strikingly, intra-ciliary calcium levels increase in response to triptolide, a small molecule agonist of Pkd2. Further, this response is dependent on extracellular calcium and there is a temporal delay between intra-ciliary and cytosolic calcium elevations. Our study in intact zebrafish embryos show that (1) Dynamic asymmetric intraciliary calcium waves at the LRO begin with the onset of cilia motility, preceding all other known molecular LR asymmetries; (2) Pkd2 initiates intraciliary calcium waves to direct LR development; and (3) intraciliary calcium signaling is specifically required for establishing LR asymmetry.

Conclusions: Our results suggest that the cilium can be an initiating source for intracellular calcium signaling and that triptolide activates the Polycystin channel on cilia in differentiated renal epithelial cells. Results from zebrafish place Pkd2 directly at mechanosensation at cilia in the LRO to initiate intraciliary calcium oscillations and further cytosolic calcium. Together, these results suggest that the cilium is a distinct calcium signaling compartment that are functionally significant in vivo.

TH-OR008

Pharmacology of a Novel, Highly Selective Aldosterone Synthase Inhibitor in Non-Human Primates Steven M. Weldon,[1] Nicholas F. Brown,[1] Jeremy G. Richman,[1] Matthew A. Cerny,[1] Derek Cogan,[1] Xin Guo,[1] Glenn A. Reinhart.[1] *[1]CardioMetabolic Diseases; [2]Medicinal Chemistry, Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT.*

Background: Aldosterone (ALDO) signaling modulates pathology in metabolic diseases including diabetic nephropathy (DN). An ideal, selective aldosterone synthase (CYP11B2) inhibitor (ASI) will reduce ALDO levels in patients and minimize deleterious effects mediated via MR- and non-MR pathways without altering cortisol (CORT). However, discovery of selective ASI molecules is challenging due to 93% identity of AS with cortisol synthase (CYP11B1) and the utility of preclinical rodent models that are limited by low homology. Therefore we developed an acute conscious cynomolgus (CYNO) monkey model to define the in vivo selectivity of ASI molecules including the novel molecule, BI689648.

Methods: Conscious, non-chaired CYNOs received vehicle (n=23), FAD286 (n=9), LCI699 (n=36) or BI 689648 (n=26) at doses of (0.003-10 mg/kg) via NG gavage (po) or iv (lightly ketamine sedated) prior to ACTH-challenge. Maximal ACTH-induced ALDO and CORT production occurred within 15 min at which time blood was collected for plasma concentration of ALDO, CORT and compound. Steroid levels for individual ASI-treated CYNOs were expressed relative to mean values for the vehicle-treated group and plotted against plasma [compound]. This allowed aggregation of data from multiple studies to derive in vivo EC_{50} values for ALDO and CORT by curve-fitting. CYNOs were used for multiple experiments allowing 2 week washouts.

Results: Baseline ALDO was 139±17 pg/ml and CORT was 50±2 ng/ml (n=82; complete study cohort). Both ALDO and CORT increased ~4-fold at 15 min post-ACTH. Calculated EC_{50} ALDO/CORT were: FAD286=13/140 nM (~11-fold selective), LCI699=3.5/920 nM (~260-fold), BI 689648=1.5/>11000 (>7000-fold).

Conclusions: The cyno ACTH-challenge model differentiates highly selective inhibitors from those with moderate (LCI699) or low (FAD) selectivity. BI 689648 was identified as the first example of a potent ASI in CYNO with high selectivity versus CORT representing a major improvement toward the discovery of safe and effective ASIs for clinical use including DN.

TH-OR009

Heparanase-2 Is an Inhibitor of Heparanase-1, Stabilizes Endothelial Glycocalyx, and Prevents Albuminuria in Zebrafish and Diabetic Mice Hermann G. Haller,[1,2] Anna Bertram,[1] Putri Andina Agustian,[1] Torsten Kirsch,[1] Mario Schiffer,[1,2] Jan Menne.[1] *[1]Department of Nephrology, Medizinische Hochschule Hannover, Hannover, Germany; [2]Mount Desert Biological Laboratory, Bar Harbor, ME.*

Background: Heparanase-1 activity is implicated in endothelial dysfunction. Heparanase-2, a homologue of heparanase-1, associates physically with heparanase-1 and inhibits heparanase enzymatic activity. Using a zebrafish model of glomerular albuminuria we have tested the hypothesis that heparanase-2 is in equilibrium with heparanase-1 and prevents heparanase-1 induced downregulation of glycocalyx and endothelial cell dysfunction.

Methods: Heparanase-2 was down-regulated by morpholino in transgenic zebrafish Tg(l-fabp:DBP:EGFP) and proteinuria asessed by the Fabp-eye-assay. Glomerular barrier was analyzed by immunohistochemistry and electron microscopy. STZ -treated mice received either sham or rivaroxaban. Urinary albumin was measured by ELISA. Immunohistochemistry was performed on cryostat or on paraffin sections. Gene and protein expression was analyzed by real-time qPCR and western blot analysis.

Results: Downregulation of heparanase-2 induced edema, endothelial cell swelling and massive proteinuria in the zebrafish. Concomitant inhibition of both heparanases abolished this effect. Rivaroxaban prevented diabetes-induced albuminuria in the mosue and increased heparanase-2 expression in the glomeruli. Overexpression of heparanase-2 in diabetic mice prevented the development of proteinuria.

Conclusions: Heparanse-2 stabilizes the endothelial glycocalyx and prevents heparanase-1 induced endothelial damage and dysfunction. Both enzymes seem to be necessary for balanced regulation of the endothelial glycocalyx. Induction of heparanase-2 may be a therapeutic strategy in diabetic nephropathy and other glomerulopathies.

Activation of Aryl Hydrocarbon Receptor by Indoxyl Sulfate, a Uremic Toxin, Is Critically Involved in Vascular Inflammation Shunsuke Ito,[1,2] Takeo Edamatsu,[2] Yoshiharu Itoh,[2] Masayuki Yoshida.[1] *[1]Life Science and Bioethics, Tokyo Medical and Dental Univ, Tokyo, Japan; [2]Kureha Corporation, Tokyo, Japan.*

Background: Indoxyl sulfate is associated with cardiovascular disease in patients with chronic kidney disease (CKD). Aryl hydrocarbon receptor (AhR) is a ligand-inducible transcription factor known to mediate the toxic effects of dioxins and uremic toxin such as indoxyl sulfate. Here, we investigated potential roles of AhR in indoxyl sulfate-induced leukocyte-endothelial interaction.

Methods: Endothelial cell-specific AhR deletion (eAhR KO) mice were generated utilizing the Cre-LoxP conditional knockout strategy. Indoxyl sulfate was administrated subcutaneously by osmotic pump for 2 weeks, followed by intraperitoneal injection of 2

μg of tumor necrosis factor-α (TNF-α). Leukocyte recruitment in the femoral artery was evaluated by intravital microscopy system. Human umbilical vein endothelial cells were transfected with siRNA of AhR (siAhR) and treated with indoxyl sulfate for 20 hours, followed by stimulation with TNF-α.

Results: Intravital microscopic analysis in control mice revealed that indoxyl sulfate dramatically enhanced TNF-α-induced leukocyte adhesion to the vascular wall, however, in eAhR KO mice, indoxyl sulfate did not increase the number of adherent leukocytes. *In vitro* studies demonstrated that AhR mediated indoxyl sulfate-enhanced leukocyte adhesion and expression of adhesion molecule such as E-selectin. Though indoxyl sulfate enhanced activation of JNK and NF-κB, siAhR did not suppress their induction. Luciferase assay revealed that the promoter region of E-selectin, corresponding to -153 to -146 bps, was essential for the effect of indoxyl sulfate mediated by AhR. Because the indoxyl sulfate response region is similar to AP-1 response element and cAMP response element (CRE), we investigated which transcription factors were involved in indoxyl sulfate. AP-1 but not CRE was activated by indoxyl sulfate, which is suppressed by siAhR.

Conclusions: AhR mediates indoxyl sulfate-enhanced vascular inflammation through activation of AP-1 transcriptional factor. These results provide a novel mechanistic insight into the CKD-related vascular inflammation.

TH-OR011

Low-Energy Shockwave Treatment Preserves the Kidney Microvasculature in Swine Renovascular Disease

Xin Zhang,[1] James D. Krier,[1] Carolina Amador Carrascal,[3] James F. Greenleaf,[3] Behzad Ebrahimi,[1] Amir Lerman,[2] Lilach O. Lerman.[1,2] *[1]Divs of Nephrology and Hypertension, Mayo Clinic; [2]Div of Cardiovascular Diseases, Mayo Clinic; [3]Dept of Physiology and Biomedical Engineering, Mayo Clinic.*

Background: Atherosclerotic renal artery stenosis (ARAS), an increasing cause of renal dysfunction, is characterized by micro-vascular rarefaction. Low-energy shockwave (SW) therapy is noninvasive, stimulates angiogenesis, and has been shown to improve cardiac function in coronary artery disease. We hypothesized that low-energy SW would alleviate renal dysfunction in ARAS by restoring angiogenesis.

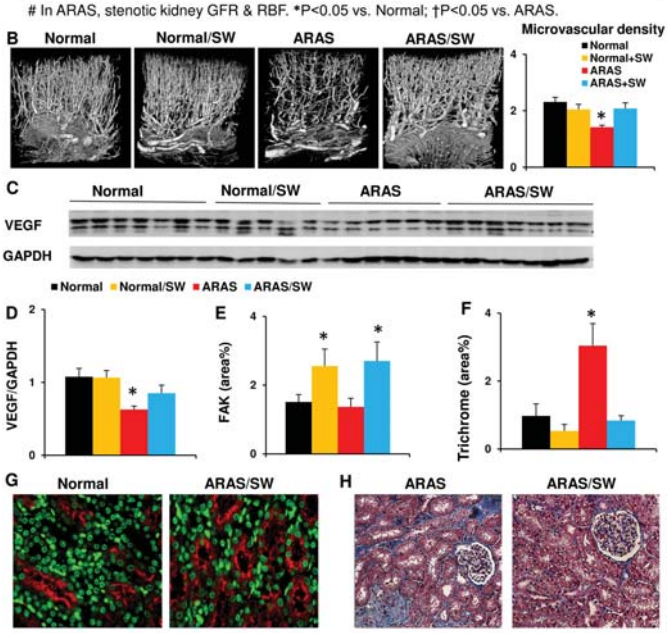
Methods: Domestic pigs were randomized to control or unilateral ARAS, treated with low-energy SW or sham (n=7 each group), bi-weekly for 3 consecutive weeks, starting after 3 weeks ARAS. Blood pressure, urinary protein, single kidney renal blood flow (RBF), glomerular filtration rate (GFR), and microvascular structure were assessed 4 weeks after completion of treatment. The expression of vascular endothelial growth factor (VEGF) and the mechanotransducer focal adhesion kinase (FAK) were determined by western blotting and staining, respectively.

Results: SW attenuated (albeit not normalized) blood pressure in ARAS, alleviated urinary protein excretion, improved stenotic kidney RBF and GFR, and blunted fibrosis (trichrome). This was associated with restored VEGF and elevated proximal tubular FAK expression, as well as normalized microvascular density.

A

	Normal	Normal/SW	ARAS	ARAS/SW
Mean arterial pressure (mmHg)	95.9±5.4	94.1±7.9	142.2±16.5*	119.0±12.8 *†
Urinary protein (mg/dl)	18.6±2.4	23.6±4.3	31.6±6.4 *	24.5±4.7*†
Single-kidney GFR# (ml/min)	70.7±6.1	73.2±7.0	51.2±3.9 *	71.5±10.1*†
Single-kidney RBF# (ml/min)	494.3±53.2	545.8±79.0	335.0±49.9 *	426.8±74.9*†

In ARAS, stenotic kidney GFR & RBF. *P<0.05 vs. Normal; †P<0.05 vs. ARAS.



B: Representative micro-CT images of kidney microcirculation and quantification. C and D: VEGF expression. E, G: FAK expression (red FAK, green nuclei). F, H: Fibrosis. * P<0.05 vs. Normal.

Conclusions: Low-energy SW protects the kidney by preserving its microcirculation, and may attenuate renovascular hypertension. SW may thus serve as a novel therapeutic intervention in the management of renovascular disease, and possibly in other forms of renal dysfunction.

TH-OR012

Glomerular Filtration Rate in the Contralateral Kidney Falls After Successful Revascularization of Stenotic Kidney

Sandra Herrmann, Ahmed Saad, Lilach O. Lerman, Stephen C. Textor. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Overall glomerular filtration rate(GFR) in patients with atherosclerotic renal artery stenosis(ARAS) rarely increases after stenting despite technical success. Occlusive vascular disease is known to cause atrophy of the stenotic kidney(STK) and leads to increased volume of the contralateral kidney(CLK). We sought to examine changes in individual kidney blood flow, oxygenation and GFR before and after unilateral renal revascularization focusing on changes in the CLK.

Methods: Inpatient studies during fixed Na+ intake and ACE/ARB Rx were performed in unilateral ARAS with more than 60% occlusion(US velocities >250cm/s) before and 3 months after stent revascularization(n=10) or medical therapy alone(n=20). Renal blood flow was measured with multidetector CT and GFR by iothalamate clearance, individual kidney GFR was assigned by its percentage of renal blood flow(RBF). Tissue deoxyhemoglobin levels(R2*) were measured by blood oxygen level-dependent MRI at 3T.

Results: Baseline, RBF, GFR and tissue oxygenation(R2*) were reduced in the STK compared to the CLK. Total iothalamate GFR did not change in ARAS patients 3 months after either revascularization or medical therapy alone. STK RBF and tissue oxygenation increased 3 months after stenting, and STK GFR remained unchanged, whereas CLK GFR decreased(p=0.03).No such changes were evident in the medically treated group, in which at 3 months STK RBF and GFR were lower than in the stented group STK(p=0.01 and p=0.03 respectively).

Table : BOLD MRI and Multidetector CT Measurements of Renal Parameters before and after Revascularization or Medical Therapy Alone

Single Kidney	Baseline		3 months	
	Stent STK (N=10)	Stent CLK (N=10)	Stent STK (N=10)	Stent CLK (N=10)
Single Kidney R2*, 1/sec	24.7±6.2	20.7±2.1§	22.4±4.1*	21.5±2
Single kidney blood flow, mL/min	253±123.3	377.9±158.9§	320.8±175.5*	327±206.6
Single kidney GFR, mL/min	30.5±17.7	43.4±19.7§	34.3±15.8	36.6±19.5*
Patient Total Iothalamate Cl, mL/min	74±34.8		70.9±32.1	

- Data are mean and ± SD. STK indicates Stenotic Kidney; CLK, contra-lateral kidney; BOLD, blood oxygen level-depended; CT, computed tomography; GFR, glomerular filtration rate.
- §P<0.05 CLK vs STK within the same group
- *P<0.05 at 3 months vs baseline

Conclusions: Stenting increased RBF and reduced hypoxia in the STK, but failed to change GFR. Our results demonstrate that decreased compensatory GFR from the CLK contributes to the lack of improvement in total GFR after stenting. These data suggest that hypoxia within the STK may participate in crosstalk leading to the compensatory hypertrophy in the CLK.

Serum FGF21 Is a Novel Biomarker Associated with Endothelial Dysfunction and Aortic Calcification in Chronic Kidney Disease

Masashi Kitagawa, Hitoshi Sugiyama, Hiroshi Morinaga, Ayu Akiyama, Toshio Yamanari, Akifumi Onishi, Keiko Tanaka, Yoko Kikumoto, Tatsuyuki Inoue, Yohei Maeshima, Jun Wada. *Medicine and Clinical Science, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Insulin resistance is present even in the earliest stage of renal dysfunction in patients with chronic kidney diseases (CKD). Fibroblast growth factor (FGF) 21 is a member of the endocrine FGF subfamily and a hepatic hormone involved in the regulation of glucose and lipid metabolism. The purpose of this study was to identify the relationship between the serum FGF21 levels and the vascular disorders in CKD patients.

Methods: We assessed the relationships between the serum FGF21 levels measured by ELISA and vascular parameters, including the flow-mediated dilatation (FMD), intima-media thickness (IMT), ankle-brachial pulse wave velocity (baPWV) and aortic calcification index (ACI) in 200 CKD patients (median age, 56 years; 62% male; 55% had glomerulonephritis).

Results: The serum FGF21 level in the CKD patients with hypertension, diabetes and dyslipidemia was significantly higher than that in the patients without such conditions. The FGF21 level gradually increased along with the CKD stage ($p < 0.0001$). Regarding vascular parameters, the FGF21 level was positively correlated with the baPWV, maxIMT and ACI, and was negatively correlated with the FMD. There were significant increases in the FGF21 level in the patients with a FMD < 6 %, baPWV ≥ 1400 cm/sec, maxIMT ≥ 1.1 mm and ACI > 0%. In a multivariate analysis, the FGF21 level was a significant determinant of endothelial dysfunction, as assessed by a FMD < 6 %, and vascular calcification, indicated

by a value of ACI> 0%, even after adjustment for age, gender, body mass index, smoking, blood pressure, the lipid and glucose profile, the estimated GFR, proteinuria, the phosphate and FGF23 (phosphatonin).

Conclusions: The data indicate that the serum FGF21 level is significantly associated with vascular disorders, including endothelial dysfunction and vascular calcification, independent of the glucose and lipid profiles. The serum FGF21 level may serve as a novel biomarker of vascular dysfunction in CKD patients.

Enhancing Akt Signaling in the Endothelium Restores Defective Angiogenesis in Kidney After Injury Takahide Aburatani,[1] Giovanni Ligresti,[1,2] Ying Zheng,[1] Alfred Aplin,[1] Roberto F. Nicosia,[1,3] Jeremy Stuart Duffield.[1,2] *[1]Depts of Medicine & Pathology & Bioengineering, Univ of Washington, Seattle, WA; [2]Biogen Idec, Cambridge, MA; [3]VAPSHCS, Seattle, WA.*

Background: Acute kidney injury and CKD are characterized by progressive loss of kidney peritubular capillaries, which leads to deterioration of renal function. While many vascular beds can regenerate following tissue injury, the renal microvasculature fails to regenerate. This distinctive property of the kidney microvasculature justifies investigation of organ-specific regulatory mechanisms that can be selectively targeted to promote kidney stable neoangiogenesis. Functional characterization of kidney microvascular endothelial cells (KMVEC) will shed light on the unique properties of this vascular bed and may lead to new therapies to ameliorate renal function in pathologic conditions.

Results: Isolated KMVEC failed to form angiogenic sprouts in collagen invasion assays. Protein analysis of KMVEC showed that in response to VEGF stimulation, downstream signaling via Akt phosphorylation was severely attenuated. Similarly, kidney explants cultured in collagen failed to generate new vessels whereas control cultures of aortic, venous, lung or adipose tissue explants produced angiogenic outgrowths. Akt signaling plays a critical role during angiogenesis and is inhibited by the phosphatase PTEN. Pharmacologic inhibition of PTEN promoted angiogenic sprouting in cultures of KMVEC. PTEN inhibition also enhanced kidney revascularization *in vivo* following ischemia re-perfusion injury; diseased mice treated with the PTEN inhibitor showed higher vessel density in kidney compared to control mice.

Conclusions: KMVEC have limited angiogenic potential in part due to impaired Akt activation following VEGF stimulation. The PTEN inhibitor bpV restored the in vitro sprouting properties of isolated KMVEC and the angiogenic response of the kidney microvasculature in an ischemia re-perfusion injury model. These findings suggest pharmacologic targeting of Akt function may be beneficial for the treatment of kidney diseases associated with inadequate neovascularization.

TH-OR015

Effects of Linagliptin on Early Alterations of Renal Endothelial Function in Patients with Type-2 Diabetes Roland E. Schmieder, Christian Ott, Iris Kistner, Stefanie Friedrich. *Nephrology and Hypertension, Friedrich-Alexander-Univ Erlangen-Nürnberg, Univ Hospital, Erlangen, Germany.*

Background: Animal experiments and human studies indicate an increased nitric oxide (NO) activity and endothelial NO synthase (NOS) expression in type-2 diabetes. The exaggerated NO production, compensatory to the increased oxidative stress in diabetes, lead to early hemodynamic changes characterized by hyperfiltration, hyperperfusion and increased vascular permeability.

Methods: In this randomized, double-blind, investigator-initiated trial, 62 patients (57±9.3 years) with type-2 diabetes were randomly assigned to linagliptin 10mg (n=30) or placebo (n=32) for a 6 weeks treatment period. Endothelial function of the renal vasculature was assessed by constant-infusion input-clearance technique with p-aminohippurate and inulin, as well as urinary albumin creatinine ratio (UACR), both assessed before and after blockade of NOS with systemic infusion of N^G*-monomethyl-L-arginine (L-NMMA*).

Results: Treatment with linagliptin for 6 weeks reduced fasting (137±26 versus 129±30 mg/ml, p=0.072), postprandial (171±44 versus 160±45 mg/ml, p=0.076) blood glucose and HbA1c (6.98±0.7 versus 6.86±0.8 %, p=0.089), whereas not change occurred in placebo. Renal plasma flow (RPF) and glomerular filtration rate (GFR) did not change after linagliptin and placebo, without any difference between the groups. After 6 weeks of treatment the absolute [percental] change in RPF due to L-NMMA (primary objective), was lower (-46.8±34 [-7.61±5.3] ml/min [%] than in the placebo group (-65.1±36 [-10.4±5.6] ml/min [%], p=0.045 (0.046)), indicating a lower basal NO activity after treatment with linagliptin.Consistently, after 6 weeks of treatment UACR due to L-NMMA did not clearly change in linagliptin group (22.2 (11.6–40.3) versus 28.2 (16.5–50.3) mg/g, p=0.061), but increased significantly in the placebo group (13.5 (8.6–25.9) versus 20.9 (15.9–33.5) mg/g, p<0.001), pointing to upregulation of NO activity in the untreated placebo group.

Conclusions: Thus, our data suggest that linagliptin normalizes increased renal endothelial function, and hence NOS-dependency of vascular tone, in patients with type-2 diabetes.

Extracorporeal Removal of sFlt1 in Preeclampsia: A Pilot Trial Ravi I. Thadhani,[1] Henning Hagmann,[2] Wiebke Schaarschmidt,[4] Tuelay Kisner,[2] S. Ananth Karumanchi,[3] Tom H. Lindner,[4] Alexander Fridman,[2] Bernhard Roth,[2] Peter Mallmann,[2] Holger Stepan,[4] Thomas Benzing.[2] *[1]MGH Nephrology, Boston, MA; [2]Univ of Cologne, Cologne, Germany; [3]BIDMC, Boston, MA; [4]Univ of Leipzig, Leipzig, Germany.*

Background: Soluble Flt1 is a potential therapeutic target to treat severe preterm preeclampsia. We previously reported that therapeutic apheresis with a whole blood dextran sulfate column reduces blood levels of sFlt1 and proteinuria in 8 women with severe preterm preeclampsia, and may prolong pregnancy (Circulation 2011). We now report treatment of 10 patients using a plasma specific dextran sulfate (PSDS) column.

Methods: Six patients with severe preterm preeclampsia (mean gestational age 30 weeks) underwent one PSDS apheresis treatment (duration 45-120 minutes), three were treated twice, and one was treated three times.

Results: Mean starting sFlt1 concentration was 17,447 pg/mL (range 7,546-35,301pg/ml), and the mean reduction within ~4 hours following apheresis was 18.6% (range 7.5-31.8%). Mean starting Protein:Creatinine (P/C) ratio was 6.2 g/g (range 0.4-19.3g/g), and the mean reduction within 12 hours following apheresis was 42.4% (range 87.9% reduction-19.2 increase). Among women treated 2-3 times, pregnancy continued for 10 days (range 7-18 days). Changes in sFlt1 and P/C ratio for the patient treated three times (dashed lines represent treatment days) is shown (Figure). The most common side effect during treatment was a reduction in blood pressure (10-20 mmHg), which was managed by withholding anti-hypertensive therapies, saline prehydration, and a reduction blood flow. There were no adverse effects to the fetus, and in women treated 2-3 times, fetal growth occured in-utero.

Conclusions: Therapeutic apheresis reduces sFlt1 and proteinuria in severe preterm preeclampsia, and may prolong pregnancy. A randomized phase III trial is now warranted.

Sphingosine-1-Phosphate Regulates Kidney Vascular Development Yan Hu,[1,2] Maria Luisa S. Sequeira Lopez.[1] *[1]Dept of Pediatrics, Univ of Virginia, Charlottesville, VA; [2]Dept of Biology, Univ of Virginia, Charlottesville, VA.*

Background: Sphingosine 1-phosphate receptor 1 (S1P1) is one of the five G-protein coupled receptors activated by Sphingosine 1-phosphate (S1P), which is a crucial sphingolipid in many biological processes, including vascular development. Deletion of S1P1 in mice results in embryonic (E) lethality at E12.5-14.5 due to failure of migration and/or differentiation of vascular smooth muscle cells (vSMCs) and pericytes and S1P1 functions autonomously in endothelial cells (ECs) as an inhibitor of angiogenesis. However, due to the early lethality, the role of S1P and S1P1 in kidney vascular development has not been determined. This study was designed to test the hypothesis that S1P and S1P1 regulate the development of the renal vasculature.

Methods: 1.Using *EC-SCL-Cre^{ERT}* mice that specifically express tamoxifen inducible Cre in EC progenitors crossed to *S1P1$^{fl/fl}$* and Rosa-LacZ reporter mice, we generated mice with timed deletion of *S1P1* in ECs during kidney development (*EC-S1P1KO*). 2.Histological stainings, including X-gal reaction and immunohistochemistry for markers of ECs and mural cells. 3.Cross-transplantation of E12.5 kidneys from *EC-S1P1KO* and control mice under the kidney capsule of adult WT mice. 4. Embryonic kidney cultures treated with S1P and S1P1 antagonists.

Results: 1. *EC-S1P1KO* embryos develop severe edema, hemorrhages or die around E14.5 to E16.5. 2. *EC-S1P1KO* embryos show kidney vascular abnormalities including dilation of arteries, veins and glomerular capillaries, disruption of vSMC coating of arteries and arterioles and absence of lymphatic endothelium. 3. The transplanted kidneys of *EC-S1P1KO* mice also develop vascular alterations revealing the intrinsic requirement of S1P1 for renal vascular development. 4. The embryonic kidney culture experiments show improved capillary development when exposed to S1P.

Conclusions: These studies strongly suggest that the S1P-S1P1 signaling pathway is an essential regulator of kidney vascular development.

Prior Ultrasound Reduces Murine Acute Kidney Injury by Modulating Splenocyte Function Joseph C. Gigliotti,[1] Liping Huang,[1] Amandeep Bajwa,[1] Eric Mace,[1] Hong Ye,[1] Diane L. Rosin,[2] Kambiz Kalantari,[1] John Hossack,[3] Mark D. Okusa.[1] *[1]Nephrology & CIIR, Univ of Virginia; [2]Pharmacology, Univ of Virginia; [3]Biomedical Engineering, Univ of Virginia, Charlottesville, VA.*

Background: We have shown that prior (24-48hr) exposure to a modified ultrasound (US) regimen prevents kidney ischemia-reperfusion injury (IRI). Our data suggest that US modulates IRI via the splenic cholinergic anti-inflammatory pathway (CAP) and the α7 nicotinic acetylcholine receptor (α7nAChR). However, it is unclear how US stimulates the splenic CAP and whether it is efficacious in other forms of acute kidney injury (AKI).

Methods: Male C57BL/6 mice were lightly anesthetized and exposed to our modified US regimen (f=14MHz, MI=1.2) 24 hr prior to IRI or cecal ligation and puncture-induced sepsis (CLP). Chemical splenic sympathectomy was performed via splenic injections of 6-hydroxydopamine (6OHDA) 14d prior to US/IRI. Chimeric mice were generated via transfer of wild-type or $\alpha7nAChR^{-/-}$ bone marrow (BM) into irradiated mice 10wks prior to US/IRI. Splenocytes were isolated from US- or sham-treated mice 24hrs after US and then stimulated *ex vivo* with LPS or injected (i.v.) into naïve mice undergoing IRI 24hrs later.

Results: Similar to IRI, prior US reduced septic AKI as compared to sham+CLP (plasma creatinine 0.4±0.08 versus 0.8±0.12mg/dL, P=0.03). Splenic 6OHDA removed US protection from IRI, with reduced function (1.7±0.05mg/dL) and acute tubular necrosis compared to vehicle-injected mice (0.3±0.06, P<0.001). US treatment was protective only in chimeric mice with WT BM regardless of the parenchymal genotype (P<0.001). LPS-induced IL-6 release was greater in splenocytes from US-treated mice than controls (P<0.05); however IRI was significantly reduced when US-treated splenocytes (but not sham treated) were transferred to naïve mice 24hrs prior to surgery (0.4±0.2 versus 1.6±0.2mg/dL, P<0.001).

Conclusions: US reduces AKI in different animal models and is dependent upon the splenic nerve and hematopoietic α7nAChRs. US-treated splenocytes are more responsive to inflammatory stimuli and are capable of modulating IRI in vivo, supporting our ongoing hypothesis that US has therapeutic potential for AKI and other inflammatory conditions.

Coupling Pulsed Focused Ultrasound with Mesenchymal Stem Cells Prevents and Rescues Established Acute Kidney Injury Scott R. Burks,[1] Saejeong Kim,[1] Jonathan Street,[2] Peter S.T. Yuen,[2] Robert A. Star,[2] Joseph Frank.[1] *[1]Radiology and Imaging Sciences, NIH, Bethesda, MD; [2]NIDDK, Bethesda, MD.*

Background: Pulsed focused ultrasound (pFUS) creates a "molecular zip code" that enhances homing of i.v. infused mesenchymal stem cells (MSC) to murine kidneys. We examined pFUS to enhance homing to kidneys during cisplatin-induced acute kidney injury (AKI). We investigated pFUS-enhanced MSC homing during early AKI; and delayed administration of pFUS and MSC until injury was clinically obvious to attempt rescue of renal function.

Methods: C3H mice received cisplatin (15 mg/kg ip), kidney pFUS (8 MPa; 5% duty cycle) and/or MSC (10^6 cells iv). The study included groups that had cisplatin only, cisplatin+pFUS, cisplatin+MSC, cisplatin+pFUS+MSC, and normal mice. For early treatment, mice received cisplatin at 0 hr and pFUS/MSC at 24hr. Renal function (BUN; SCr), apoptosis, and Ki67 expression were measured at 96 hr. For established disease, mice received cisplatin at 0 hr and MSC/pFUS at 72 hr. BUN/SCr were measured at 4 and 6 d, and 7-day survival was measured.

Results: pFUS enhanced MSC homing 2-3 fold at 24 or 96 hr. MSC alone at 24 hr modestly protected against AKI (reduced BUN ~40%). pFUS alone had no effect on AKI, but pFUS+MSC better protected than MSC alone (reduced BUN ~65%, SCr ~80%, apoptosis ~60%, and increased Ki67). To examine potential intervention during established AKI, treatment was delayed until 72 hr. Only pFUS+MSC improved BUN at day 4 and 6. MSC alone (no pFUS) significantly improved survival through 7 days (57% compared to 14%), but pFUS-enhanced MSC homing yielded additional significant increases in the survival (93%).

Conclusions: pFUS+MSC during early AKI further improves MSC protection against AKI. MSC alone improved survival when administered during clinically-obvious AKI (day 3) but survival further improved with pFUS+MSC. Therapies have largely failed for established AKI that requires treatment after renal function declines. Therefore, MSC with pFUS represent a novel potential therapeutic option to treat established AKI.

Glycogen Synthase Kinase 3β (GSK 3β) Inhibition Promotes Macrophage Polarization and Reduces Inflammation and Acute and Chronic Damage following Acute Kidney Injury (AKI) Chunming Jiang,[1,2] Evelyn Tolbert, Weiwei Xu,[1] Hui Bao,[1] Rujun Gong,[1] Lance D. Dworkin.[1] *[1]Nephrology, Medicine, Brown Univ, Rhode Island Hospital, Providence, RI; [2]Nephrology, Drum Tower Hospital, Nanjing Univ, Nanjing, Jiangsu, China.*

Background: Different macrophage (Mø) phenotypes play distinct roles during kidney injury and recovery. Classically activated Mø (M1) promote inflammation and injury, while alternatively activated Mø (M2) help resolve inflammation and facilitate recovery. Although inhibition of GSK 3β has been shown to protect the kidney and promote recovery from AKI, the underlining mechanisms are not fully explored. We hypothesized that specific inhibition of GSK 3β by TDZD-8 might reduce kidney inflammation and injury in AKI by regulating Mø recruitment and polarization.

Methods: C57BL/6 mice were randomly divided into four groups; sham, FA, TDZD-PRE (30 minutes prior to FA), and TDZD-POST (36 hours after FA). Blood and kidney tissue were examined at multiple time points after FA.

Results: Kidney function was improved and morphologic evidence of injury decreased in both treated groups. Mechanistically in mice given FA, TDZD reduced Mø infiltration into the kidney (FA 25.1 ±2.2: TDZD-PRE 9.7±2.1: TDZD-POST 15.4±2.7; # per × 200 field), and markedly shifted Mø phenotype. The ratio of M1/M2 was in FA 2.5±0.6, TDZD-PRE 1.1±0.13, and TDZD-POST 0.2 ±0.1. *In vitro*, mouse bone marrow derived Mø stimulated with LPS underwent a similar shift from M1 to M2 with GSK 3β inhibition, as determined by increased expression of CD206 and arginase I, decreased the expression of iNOS and IL-1 β, and confirmed by flow cytometry. That the phenotypic change resulted from inhibition of GSK was confirmed by specific knockdown of GSK 3β, which also shifted cultured Mø from M1to M2.

Conclusions: Systemic administration of a small molecule GSK 3β inhibitor given both before and 36 hours after onset of AKI attenuated renal inflammation. Kidney Mø infiltration was reduced and Mø switching from pro-inflammatory M1 to anti-inflammatory M2 phenotype was promoted. This was associated with preserved and more rapid recover of renal function, reduced morphologic evidence of acute injury, and less eventual fibrosis.

TH-OR021

KIM-1 Interacts with p85 and Modulates the Proximal Tubule Cell Inflammatory Response through Regulation of NFκB Craig R. Brooks,[1] Li Yang,[1,2] Venkata Sabbisetti,[1] Takaharu Ichimura,[1] Li-Li Hsiao,[1] Joseph V. Bonventre.[1] *[1]Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Peking Univ First Hospital, Beijing, China.*

Background: Kidney injury molecule 1 (KIM-1) is a type 1 transmembrane protein which we identified as the most upregulated proximal tubule cell (PTC) protein during acute kidney injury (AKI) and is expressed in chronic kidney disease. Functionally, KIM-1 acts as a phosphatidylserine and scavenger receptor and is the first non-myeloid receptor identified that transforms epithelial cells into phagocytes.

Methods: The function of KIM-1-mediated phagocytosis in AKI was studied *in vivo* by inducing ischemia reperfusion injury in mice expressing wild-type KIM-1 or mutant KIM-1 lacking the mucin domain, $KIM\text{-}1^{\Delta mucin}$, where phagocytosis is markedly impaired. The role of KIM-1-mediated phagocytosis in inflammation was examined *in vitro* by analysis of cytokine secretion by ELISA and activation of NFκB using a luciferase reporter. RNA microarray and Ingenuity pathway analysis were performed to identify potential immuno-modulators regulated by KIM-1. KIM-1 phosphorylation and interaction with p85 was analyzed by immunoprecipitation.

Results: Ablation of the KIM-1 mucin domain significantly reduced PTC phagocytosis *in vivo* and *in vitro*. Decreased KIM-1-mediated phagocytosis *in vivo* led to accumulation of apoptotic cells, increased immune cell infiltration and a secondary worsening of kidney injury. Primary PTCs from $KIM\text{-}1^{\Delta mucin}$ mice released more pro-inflammatory cytokines when stimulated with LPS or TNFα, when compared to wild-type PTCs. Pathway analysis of microarray data revealed that NFκB transcriptional targets were modulated by KIM-1 expression. Wild-type, but not mutant, KIM-1 expression reduced p-NFκB levels and NFκB activity, which was further decreased with phagocytosis. Mechanistically, wild-type KIM-1 co-precipitated with p85 in a tyrosine-phosphorylation dependent manner. Inhibition of the p85/PI3K pathway negated the effects of KIM-1 expression on NFκB phosphorylation.

Conclusions: We have linked the process of KIM-1-mediated phagocytosis to modulation of PTC inflammatory response through KIM-1 interaction with p85 and regulation of NFκB.

Fibroblast-Specific β-Catenin Signaling Dictates Tubular Injury and Repair After Acute Kidney Injury Dong Zhou,[1] Roderick J. Tan,[2] Haiyan Fu,[1] Youhua Liu.[1] *[1]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Wnt/β-catenin signaling plays a crucial role in regulating kidney development and tissue homeostasis. We previously demonstrated that tubule-specific ablation of β-catenin aggravates acute kidney injury (AKI) after either ischemic or toxic insults, suggesting a beneficial, cyto-protective activity of Wnt/β-catenin. However, whether β-catenin activation in interstitial fibroblasts plays any role in kidney injury/repair after AKI remains ambiguous.

Methods: To address this issue, we generated conditional knockout mice in which β-catenin was specifically ablated in interstitial fibroblasts by mating β-catenin-floxed mice with $Gli1\text{-}CreER^{T2}$ mice. Mice with fibroblast-specific deletion of β-catenin were subjected to renal ischemia/reperfusion injury (IRI).

Results: Surprisingly, we found that specific ablation of β-catenin in interstitial fibroblasts significantly preserved renal function after IRI at 1 day, comparing with control littermates. Both serum creatinine level and morphologic injury were significantly ameliorated in mice with fibroblast-specific deletion of β-catenin. Consistently, apoptosis was markedly reduced in the kidneys of the knockout mice, which was accompanied by decreased expression of p53, FasL, Bax, and upregulation of phosphorylated Akt. Furthermore, NF-κB signaling was significantly suppressed in β-catenin-knockout mice. Interestingly, fibroblast-specific ablation of β-catenin resulted in an increased expression of hepatocyte growth factor (HGF) after AKI. Accordingly, HGF receptor, c-met, was activated

with increased tyrosine phosphorylation in renal tubules of fibroblast-specific β-catenin knockout mice. Consistently, kidneys with fibroblast-specific deletion of β-catenin displayed reduced myofibroblasts activation and renal fibrosis at 10 days after IRI.

Conclusions: Taken together, these results suggest that in sharp contrast to tubular β-catenin, fibroblast β-catenin activation after AKI is detrimental by attenuating HGF/c-met signaling.

mTOR Mediates Autophagy Impairment in Telomerase Deficient Mice and Leads to Delayed Renal Recovery after Ischemia Reperfusion (I/R) Injury

Huifang Cheng, Raymond C. Harris. *Nephrology/Medicine, Vanderbilt Univ Medical School, Nashville, TN.*

Background: mTOR is a ubiquitous kinase that controls many different cellular processes and may play important roles in renal disease and aging.

Methods: To understand the role of mTOR in the increased susceptibility to AKI seen with aging, we induced renal I/R in fourth generation telomerase deficient mice (either TerC or TerT deletion), using wild type (Wt) mice as controls. mTOR activation was monitored at day 0, 1, 3, 5, 7 and 14 post I/R. We also investigated the effect of mTORC1 inhibition on hypoxia-induced injury in primary cultured renal tubular epithelial cells (TECs).

Results: Telomerase deficient mice had delayed recovery from I/R injury. Compared to Wt, following I/R injury both TerC / TerT KO mice had greater increases in phosphorylation of mTOR and its downstream signaling targets (4E-BP1 and p70 S6 Kinase) as well as P16, a cell-cycle regulator. I/R-induced markers of epithelial dedifferentiation (CD133, Vimentin, Pax2) and proliferation (Ki67) were markedly blunted in TerC/TerT KO mice.TerC/TerT KO mice also demonstrated impaired autophagy in response to I/R, as indicated by reduced and delayed autophagosome formation and conversion of LC3 I to II, along with prolonged accumulation of P62. Increased mTOR expression and impaired autophagy in response to transient hypoxia was further confirmed in primary cultures of TECs with TerC deletion. The mTOC1 inhibitor, rapamycin, restored the autophagic response in TECs with TerC deletion to that of Wt. However, rapamycin did not significantly alter either upregulation of p16 or impaired proliferation in TerC deficient TECs in response to the hypoxic insult.

Conclusions: These studies indicate that mice with telomerase deficiency have delayed recovery from I/R due both to impairment of autophagy mediated by increased mTOR signaling and activation of the p16 senescence pathway.

Hepcidin Mediates Protection in Renal Ischemia Reperfusion Injury Through Modulation of Systemic Iron Homeostasis

Yogesh M. Scindia,[1] Cindy N. Roy,[2] Mark D. Okusa,[1] Sundararaman Swaminathan.[1] *[1]Nephrology, Univ of Virginia Health System, Charlottesville, VA; [2]Geriatric Medicine and Gerontology, Johns Hopkins School of Medicine, Baltimore, MD.*

Background: Iron-mediated oxidative stress has been implicated in the pathogenesis of renal ischemia reperfusion injury (IRI). Hepcidin exerts a precise control over systemic iron status by inducing ferroportin degradation, which results in reticuloendothelial iron sequestration and hypoferremia. We hypothesized that hepcidin treatment would mitigate IRI by decreasing iron availability and ROS-mediated cell death.

Methods: Mice (C57Bl/6 (WT) and hepcidin knock out (*Hamp*^{KO}) were treated with saline or 50 μg of hepcidin i.p, 24 hours prior to bilateral renal IRI (24 min in *Hamp*^{KO} and 26 min in WT). Outcomes (renal function, injury markers, histopathology and inflammation) were examined after 24 hours of reperfusion.

Results: In WT mice, IRI induced a significant increase in serum (100.19±19.8 μg/dl) and kidney non-heme iron levels (109.3±27.7 μg/g). In comparison, hepcidin treatment induced sequestration of iron in the spleen and liver and prevented IRI-associated increase in serum (50.91±13.39 μg/dl; p=0.0017 versus WT-IRI) and kidney non-heme iron (48.2±32.3 μg/g; p=0.018 versus WT-IRI). Kidney function was significantly better (p=0.001) in hepcidin-treated (P_{Cr} 0.9 ± 0.50) than saline-treated WT mice (P_{Cr} 3.1± 0.2) and this was accompanied by less acute tubular necrosis and reduced infiltration of immune cells. Hepcidin treatment decreased kidney ferroportin expression and induced the expression of cytoprotectant, H-ferritin. This was associated with less ROS and tubular epithelial apoptosis, as measured by 4-hydoxynonenal and TUNEL reactivity respectively. Hepcidin deficiency increased susceptibility to IRI as mild IRI (24 min) induced severe renal injury in *Hamp*^{KO} mice compared to WT controls (P_{Cr} 2.7± 0.6 versus WT 0.3± 0.07, p=0.001). Hepcidin supplementation restored a near complete protection in the *Hamp*^{KO} mice (P_{Cr} 0.5±0.2), with striking preservation of kidney architecture.

Conclusions: Our results demonstrate a protective role of hepcidin in IRI achieved through its effects on iron metabolism in the kidney as well as in distinct organs.

TH-OR025

Tubular Repair following Acute Kidney Injury Occurs through Clonal Expansion of a Preexisting Population of Tubular Progenitors in Mouse

Anna Julie Peired, Elena Lazzeri, Duccio Lombardi, Elisa Ronconi, Maria Lucia Angelotti, Sara Nardi, Laura Lasagni, Paola Romagnani. *Excellence Centre DENOTHE, Univ of Florence, Florence, Italy.*

Background: Although renal progenitors (RPC) are well characterized in human, their role in kidney regeneration is still debated due to the lack of a suitable model of RPC lineage tracing in mouse. We propose to use Pax2 as a marker to perform RPC fate mapping and demonstrate RPC involvement in tubular regeneration following acute kidney injury (AKI).

Methods: To track RPC, we used Pax2-rtTA/tetO-cre/ROSA26-Confetti (Pax2/Confetti) inducible mice in which YFP, RFP or CYP is randomly expressed under Pax2 promoter. Pax8-rtTA/tetO-cre/ROSA26-Confetti (Pax8/Confetti) mice were used to track all tubular cells. To visualize cell-cycle progression, we used Pax2- or Pax8-rtTA/tetO-cre/ROSA26-FUCCI2 (Pax2/FUCCI2 and Pax8/FUCCI2) mice in which the promoter drives expression of mCherry or mVenus in cells in G1 or S/G2/M phase, respectively. To induce AKI, mice underwent unilateral ischemia for 35 minutes, followed by a 30 day reperfusion period (ischemia/reperfusion injury, IRI).

Results: In healthy Pax2/Confetti mice, Pax2+ cells form a subset of parietal epithelial cells of the Bowman's capsule and scattered cells in tubular structures. We observed a slow expansion of Pax2+ cells over time in physiologic conditions. After IRI, the percentage of Pax2+ cells increased in the ischemic versus contralateral kidney, suggesting that this population was amplified after IRI Indeed, the Pax2+ cells formed series of 3 to 11 cells labeled with an identical fluorochrome, indicating the clonal origin of the series. Observations of Pax2/FUCCI2 mice following IRI confirm that the RPC proliferate. Moreover, analysis of Pax8/Confetti mice after IRI excludes involvement of fully-differentiated tubular cells in the regeneration process and Pax8-FUCCI2 mice show that only a small population of cells undergo cell division while the rest of the tubular cells undergo hypertrophy as shown by their arrest in S/G2/M phase.

Conclusions: Pax2+ cells correspond to a preexisting population of tubular progenitors that clonally expands following AKI and represent the driver of tubular regeneration after IRI.

Activated CD47 Contributes to Renal Ischemia Reperfusion Injury by Simultaneously Limiting Self-Renewal Genes and Autophagy

Natasha M. Rogers,[1,2] Jeffrey S. Isenberg.[1,2] *[1]Vascular Medicine Inst, Univ of Pittsburgh, Pittsburgh, PA; [2]Starzl Transplant Inst, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Renal ischemia reperfusion injury (IRI) is a frequent cause of acute kidney injury and promotes the development of chronic kidney disease. The basis for faulty repair following IRI remains unclear. Recently we reported that the matricellular protein thrombospondin-1 (TSP1), and its high affinity receptor CD47 are induced in renal IRI. However, the role of this receptor-ligand pair in regulating renal recovery is unknown.

Methods: Age matched male wild type (WT) and CD47$^{-/-}$ mice were challenged with 20 minutes bilateral renal ischemia and variable reperfusion time points (1, 3 and 7 days). All animals underwent assessment of renal function and biomolecular analysis. Human, and murine WT and CD47$^{-/-}$ rTEC were studied *in vitro.*

Results: Mice lacking CD47 were resistant to renal IRI with decreased urea and creatinine, and ameliorated histological changes at 1, 3 and 7 days following reperfusion compared to WT animals. CD47$^{-/-}$ mice subjected to renal IRI demonstrated return of renal function compared to ongoing impairment in renal function in WT controls after 7 days. CD47$^{-/-}$ mice, at both baseline and post-IRI, displayed upregulation of key self-renewal genes including cellular homolog of the v-myconcogene (cMyc), Klf4, Oct4, and Sox2, as well as autophagy markers Atg5, Atg7, Beclin-1. In contrast, WT mice demonstrated a negligible self-renewal gene expression and autophagic signaling at all time points post-IRI. RTEC from CD47$^{-/-}$ mice displayed basal and hypoxic upregulation of self-renewal genes and autophagy markers that correlated with enhanced proliferative capacity. siRNA suppression of cMyc down-regulated autophagy markers in RTEC. Conversely, treatment with a CD47 antagonist antibody, to block TSP1-CD47 signaling, or morpholino oligonucleotide increased cMyc expression and promoted cell proliferation.

Conclusions: CD47 is a proximate promoter of renal IRI and inhibits rTEC recovery through inhibition of self-renewal and cMyc-mediated inhibition of autophagy. Functional studies suggest that CD47 is a clinical target to restore renal function following injury.

ADAM17 Promotes Kidney Fibrosis after Severe Ischemia-Reperfusion Injury

Eirini Kefalogianni, Jakob R. Kaeppler, Muthu Lakshmi Muthu, Benjamin D. Humphreys, Joseph V. Bonventre, Andreas Herrlich. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

Background: ADAM17 expression has been found upregulated in ischemia induced fibrotic kidney lesions in humans and in kidneys of an angiotensin II-induced CKD mouse model. Its substrates, including EGFR ligands and TNFα, have been linked to maladaptive repair. We hypothesize that ADAM17 promotes injury and fibrosis in AKI and CKD.

Methods: We used ADAM17 hypomorph mice (A17ex/ex, very low ADAM17 expression in all cells) and a mouse model with tamoxifen-inducible proximal tubular-specific ADAM17 knockout (SLC34a1-Cre-ERt2/ADAM17flox/flox). Mice were subjected to severe bilateral ischemia reperfusion injury.

Results: ADAM17ex/ex mice show similar initial tubular damage on day 1 after injury but significantly less damage on day 5 after injury, as compared with wt mice. Kidney mRNA expression of ADAM17, EGFRs, EGF ligands and TNFα is significantly increased by injury over days 1-21 in wt mice. ADAM17 protein is strongly upregulated in wt mice as compared to sham controls, but ADAM17ex/ex mice lack detectable upregulation of ADAM17 protein after injury. Thus, ADAM17ex/ex mice show reduced TNFα and EGF ligand cleavage in vivo after injury, reduced activation of EGFR on days 2 and 3 after injury and a delay in proliferation of tubular cells after AKI, as compared to wt mice. ADAM17ex/ex mice show also reduced ingress of macrophages 5 pays post-injury. Interestingly, at later time points ADAM17ex/ex mice are strongly protected against fibrosis. As compared to wt, ADAM17ex/ex mice have lower mRNA induction of fibrosis markers (Tgfb, Pdgfr2, Acta2) 21 days after injury. On the protein level, they show significantly decreased production of the profibrotic markers fibronectin and αSMA at day 21 after injury, resulting in less interstitial fibrosis as detected by Masson stain. SLC34a1-Cre-ERt2/ADAM17flox/flox mice show similar acute injury, but significantly less induction of TGFα and reduced production of profibrotic myofibroblast markers αSMA and fibronectin, as compared to control littermates.

Conclusions: The above results reveal that ADAM17 has a critical role, in particular in proximal tubule, in kidney injury and repair and is a potential drug target in AKI and fibrosis.

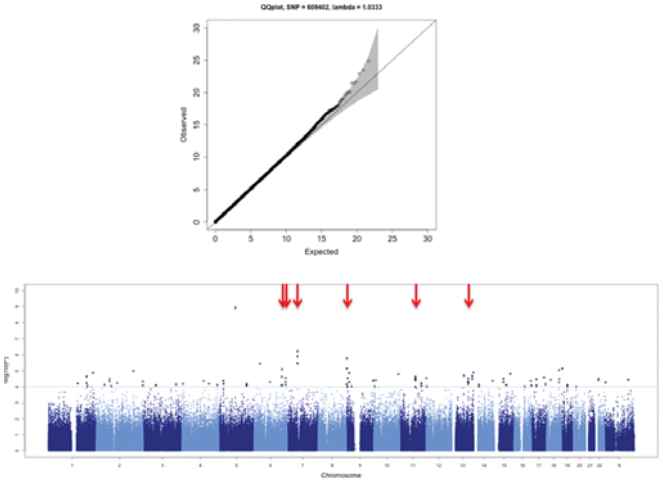
A Genome-Wide Association Study to Identify Single Nucleotide Polymorphisms Conferring Risk for Acute Kidney Injury

Bixiao Zhao,[1] Justin Miles Belcher,[1] Edward D. Siew,[2] T. Alp Ikizler,[2] Amit X. Garg,[3] Richard P. Lifton,[1] Chirag R. Parikh.[1] *[1]Yale Univ; [2]Vanderbilt Univ; [3]Univ of Western Ontario.*

Background: Acute kidney injury (AKI) is a common and severe complication of multiple hospital settings. Identifying patients at heightened genetic risk for AKI may uncover novel pathways for therapeutic interventions. We performed a genome-wide association study (GWAS) in patients at risk for AKI to evaluate for single nucleotide polymorphisms (SNP) associated with the development of AKI.

Methods: 833 adult cases, defined by a rise in creatinine of 0.3mg/dL or 50% from baseline for at least 2 days, and 730 controls were selected from surgical (TRIBE-AKI) and medical (VALID ICU) ICU cohorts. Genotyping was performed with Illumina BeadChips with a total of 992,895 SNPs.

Results: After quality control, 773 (93%) cases and 684 (94%) controls were genotyped for 609,402 (61%) SNPs. 112 SNPs differed between cases and control with a p-value below a pre-specified cut-off of 10^{-4}. Six SNP clusters were identified containing at least 3 positive SNPs, on chromosomes 6 (2 clusters), 7, 9, 11 and 13 (**Figure 1**, red arrows).



While one cluster on chromosome 6 and that on 13 conferred an increased risk (OR range 1.35-1.73), the others were protective (OR range 0.27-0.67). On ontology analysis, significant SNPs were enriched in pathways for intracellular signaling, phosphate metabolism and amino acid phosphorylation. Further analysis on pre-specified sub-groups including patients with CKD and those with mild or severe AKI identified clusters for multiple sub-groups on chromosomes 4 and 14.

Conclusions: GWAS analysis of patients at risk for AKI undergoing cardiac surgery or admitted to the ICU identified multiple clusters of SNPs significantly associated with AKI. Further research is required to confirm these findings, identify candidate genes and characterize their function and role in AKI.

The Effect of Early Intervention with Renal Replacement Therapy Guiding by Plasma Neutrophil Gelatinase Associated Lipocalin and the Outcome of Acute Kidney Injury (the EARLYRRT Trial): A Randomized Controlled Trial

Nattachai Srisawat, Khajohn Tiranathanagul, Paweena Susantitaphong, Kearkiat Praditpornsilpa, Somchai Eiam-Ong, Kriang Tungsanga. *Div of Nephrology, Dept of Internal Medicine, Facutly of Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

Background: Acute Kidney Injury (AKI) is a major complication of patients admitted to the intensive care unit (ICU). Unfortunately, there have been no successful intervention trials. Early initiation of renal replacement therapy (RRT) might provide the benefit to AKI patients in various aspects including controlling fluid balance, prevention of acid-base disorder, and finally improvement in patient survival.

Methods: This prospective RCT was conducted at ICU from 2013 to 2014. The study comprised an intervention trial and a triage trial running serially. Initially, we used novel AKI biomarker, plasma NGAL (pNGAL) to triage between severe AKI group (pNGAL ≥ 400 ng/ml) and less severe AKI group (pNGAL < 400 ng/ml). Only patients who had severe AKI (pNGAL ≥ 400 ng/ml) were randomized into two groups: *Early RRT group* and *Standard RRT group*. While patients who had pNGAL lower than 400 ng/ml were constituted as the *control group*. The primary outcome was mortality and the secondary outcome was ventilator-free days, ICU-free days and dialysis dependence on day 28.

Results: Of the 60 enrolled patients, 40 were randomly assigned to *Early RRT group*, and *Standard RRT group*. The baseline characteristics were comparable. At day 28, 10(50%) deaths had occurred in the *Early RRT group* and 9(45%) deaths in the *Standard RRT group* (P=0.96). While ventilator-free day and ICU-free day for the *Early RRT group* and the *Standard RRT group* were 21.0(8.9) versus 9.0(11.6) days, P=0.03 and 19.0(7.7) versus 10.4(11.4) days, P=0.38, respectively. No patient in the *Early RRT group* was dialysis dependence while 54.6% in the *Standard RRT group* were dialysis dependence, P=0.01.

Conclusions: EARLYRRT was the first RCT to test the role of pNGAL in guiding of RRT intervention and to proof the benefit of early RRT in severe AKI. The preliminary result showed that early RRT did not reduce mortality rate but could increase ventilator-free day and dialysis independence at 28 days.

A Multi-Center, Randomized, Control Trial to Assess the Safety and Efficacy of a Selective Cytopheretic Device (SCD) in Patients with Acute Kidney Injury (AKI)

James A. Tumlin,[1] Alexander S. Yevzlin,[2] H.D. Humes.[3] *[1]Nephrology, Nephrology Associates, Chattanooga, TN; [2]Internal Medicine; Nephrology, Univ of Wisconsin Medical Center, Madison, WI; [3]Internal Medicine, Univ of Michigan Medical School, Ann Arbor, MI.*

Background: Acute kidney injury (AKI) is a highly lethal condition in critically ill patients. Previous clinical studies have demonstrated the safety and efficacy of the Selective Cytopheretic Device (SCD) in the treatment of AKI requiring continuous renal replacement therapy in the intensive care unit (ICU).

Methods: We performed a randomized, controlled, multi-center trial of 134 ICU patients with AKI, 69 of whom received continuous renal replacement therapy (CRRT) alone and 65 of whom received SCD therapy.

Results: No significant difference in 60-day mortality was observed between the treated (27/69; 39%) and control patients (21/59; 36%, with 6 patients lost to follow up). Of the 19 SCD subjects (CRRT+SCD) and 31 control subjects (CRRT alone) who maintained a post-filter ionized calcium level in the protocol's recommended range (riCa), ≤ 0.4mmol/L for greater or equal to 90% of the therapy time, 60-day mortality was 16% (3/19) in the SCD group compared to 41% (11/27) in the CRRT alone group (p = 0.07). In the subset of patients who received the prescribed level of iCa, the secondary endpoint of dialysis dependency showed a statistically significant difference between the SCD group versus control with 0% (0/16) and 25 %(4/16), respectively (p=0.03). When the riCa treated subgroups were compared for a composite index of 60 day mortality and dialysis dependency, the percentage of SCD treated subjects was 19% versus 58% in the control subjects (p<.007). The incidence of serious adverse events did not differ between the treated (45/69; 65%) and control groups (40/65; 63%; p=0.86).

Conclusions: Attenuating the inflammatory response to AKI with SCD therapy may improve mortality in a tightly controlled regional hypocalcemic environment.

Remote Ischemic Preconditioning May Reduce Acute Kidney and Myocardial Injury in Children Undergoing Cardiac Surgery

Christine W. Hsu,[1] Matthew Toma,[1] Ronit Katz,[1] Cassianne Robinson-Cohen,[1] Bryan R. Kestenbaum,[1] Yuk M. Law,[2] Jonathan Himmelfarb.[1] *[1]Medicine/Nephrology, Univ of Washington, Seattle, WA; [2]Pediatrics/Cardiology, Seattle Children's Hospital, Seattle, WA.*

Background: Remote ischemic preconditioning (RPC) is a noninvasive intervention that protects remote organs from subsequent ischemia-reperfusion injury and may reduce the risk of clinical acute kidney injury (AKI) and acute myocardial injury (AMI).

Methods: We conducted a double-blind randomized clinical trial of RPC versus no treatment among 84 children undergoing cardiac surgery with cardiopulmonary bypass for congenital heart disease (ClinicalTrials.gov Identifier NCT01260259). We elicited

RPC by inflating a blood pressure cuff to 15 mmHg above systolic blood pressure over a lower extremity for 5 minutes and then deflated it for 5 minutes; this procedure was repeated up to 4 times before the start of surgery. Control children had a non-inflated cuff placed over a lower extremity for the same time period. We collected plasma biosamples at baseline and then 6, 12, 24, 48, and 72 hours postoperatively. Our primary aims were to determine whether RPC reduced AKI and AMI. We defined AKI by a 50% increase in plasma creatinine concentration and examined AMI by comparing mean troponin I (TnI) after RPC versus control.

Results: A total of 84 children underwent randomization (mean age 3.7 years; range 3 days-18 years). The incidences of postoperative AKI in the RPC and control groups were 35.6% and 51.3%, respectively; relative risk 0.69; 95% confidence interval (CI) 0.42, 1.14, p=0.15. Mean TnI was 27.3% lower after RPC compared to control (CI -72.5%, 17.9%, p=0.24).

Conclusions: This study demonstrates proof of concept that RPC may lower rates of AKI and AMI in children undergoing cardiac surgery, although results cannot exclude the null hypothesis. While previous groups studying RPC in children undergoing cardiac surgery have demonstrated RPC decreases AMI, only one group has studied AKI and concluded RPC does not decrease AKI. Our study is the first to demonstrate a potentially large protective effect of RPC on kidney injury in children and large clinical trials will be required to confirm or refute the findings.

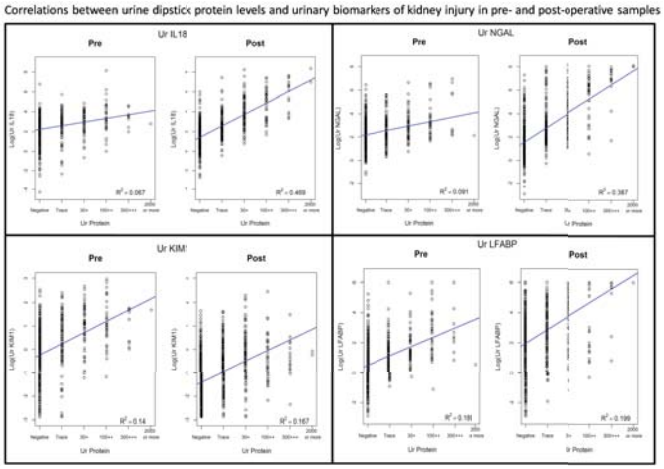
TH-OR032

Association between Urinary Kidney Injury Biomarker Concentrations and Urine Dipstick Findings Steven G. Coca, Allison Meisner, Uptal D. Patel, Jay L. Koyner, Amit X. Garg, Charles L. Edelstein, Michael Shlipak, Chirag R. Parikh. *TRIBE-AKI Consortium.*

Background: Concentrations of urinary biomarkers of kidney injury may be influenced by other factors besides renal tubular damage, such as hematuria or pyuria. We investigated urine dipstick factors that are associated with urinary biomarker levels.

Methods: We examined 714 adults who underwent cardiac surgery who did not experience post-op clinical AKI (peak serum creatinine change of ≥20% were excluded). We examined the association between urinalysis findings and the concentrations of 4 urinary biomarkers: NGAL, IL-18, KIM-1, and L-FABP at two time points- before surgery and immediately after surgery.

Results: Age, sex, and storage time had minimal associations with urinary biomarker concentrations. The presence of leukocyte esterase and nitrites on urinalyses were modestly associated with increased urinary NGAL (R^2 0.16, p<0.001 and 0.07, p<0.001, respectively) in pre-op urine samples. Hematuria weakly associated with increased levels of all 4 biomarkers on pre-op samples (R^2 0.02 to 0.04, p <0.001 for all), but was more strongly associated with IL-18, NGAL and L-FABP in post-operative samples (R^2 0.13, 0.21, and 0.13, respectively). Dipstick proteinuria concentrations correlated with levels of all 4 urinary biomarkers in pre-and post-operative samples



(R^2 between 0.05 and 0.14 in pre-op and between 0.10 and 0.34 in post-op samples).

Conclusions: Several findings from urine dipstick testing are positively associated with urinary biomarker concentrations in patients who underwent cardiac surgery. These associations were seen on both pre-operative and post-operative samples in patients without clinical AKI, which suggests the associations are not fully explained by clinical kidney injury. Future studies should consider these factors when assessing the independent prognostic and diagnostic performance of the biomarkers.

TH-OR033

Furosemide Stress Test Is Better Than Biochemical Biomarkers for the Prediction of AKI Severity, Progression and Mortality Jay L. Koyner, Danielle Davison, Ermira Brasha-Mitchell, Divya M. Chalikonda, John M. Arthur, Andrew Shaw, James A. Tumlin, Sharon A. Trevino, Michael R. Bennett, Paul L. Kimmel, Michael Seneff, Lakhmir S. Chawla. *Furosemide Stress Test Investigators.*

Background: A furosemide stress test (FST)(1.0 or 1.5 mg/kg based on prior diuretic exposure) in the setting of early AKI has been previously demonstrated to predict progression to Stage 3 AKI.

Methods: We measured several biomarkers of AKI in 77 subjects with at least AKIN Stage 1 who received a FST. We compared the ability of FST and biomarkers to predict progression to Stage 3 AKI(n=25, 32.4%), receipt of renal replacement therapy (RRT) (n=11, 14.2%) and inpatient mortality (n=16, 20.7%). We compared the area under the ROC (AUC) of FST to biomarkers alone.

Results:

Biomarker	AUC(SE) Progression to Stage 3 AKI	AUC(SE) Inpatient Mortality	AUC(SE) Receipt of RRT
FST	0.87(0.09)†	0.70(0.09)†	0.86(0.08)†
U NGAL	0.65(0.06)†‡	0.66(0.08)	0.50(0.08)‡
U IL-18	0.65(0.07)†‡	0.57(0.09)	0.61(0.07)‡
U KIM-1	0.63(0.06)‡	0.68(0.07)†	0.61(0.10)‡
Uromodulin	0.54(0.07)‡	0.52(0.08)	0.55(0.11)
U TIMP2 *IGFBP7	0.69(0.08)†‡	0.64(0.11)	0.62(0.13)
U ACR	0.56(0.07)‡	0.47(0.09)	0.67(0.09)
Fractional Excretion of Sodium	0.51(0.07)‡	0.41(0.08)‡	0.64(0.09)
Plasma NGAL	0.75(0.08)†‡	0.43(0.11)	0.52(0.13)
† p<0.05 biomarker to predict endpoint ‡p<0.05 for ΔAUC FST vs. biomarker; U=Urine			

Combining FST with individual biomarkers using logistic regression did not significantly improve its risk stratification (ΔAUC) for progression to Stage 3, receipt of RRT or inpatient mortality (p>0.10 for all). When FST was assessed in patients with increased pre-FST biomarker levels, the performance improved; AUC 0.91(0.06),p<0.001 for receipt of RRT (n=44; urine NGAL>150ng/ml) and 0.90(0.06),p<0.001 (n=32; TIMP2*IGFBP7 >0.3) for Stage 3 progression.

Conclusions: FST, a functional biomarker of AKI, outperformed biochemical biomarkers for the prediction of AKI progression, RRT and mortality. Using FST in patients with increased biomarker levels improved risk stratification. The utility of FST and biomarkers must be tested in randomized trials.

Funding: NIDDK Support

TH-OR034

Transient Tissue Hypoxia without Acute Kidney Injury Immediately and 3 Months after Complex CT Imaging and Renal Revascularization for Atherosclerotic Renovascular Disease Ahmed Saad, Sandra Herrmann, James Glockner, Michael A. Mckusick, Lilach O. Lerman, Stephen C. Textor. *Mayo Clinic.*

Background: Renal angiography and contrast-induced nephrotoxicity (CIN) are thought to pose a risk for older subjects with atherosclerotic renovascular disease (ARVD), particularly during renin-angiotensin system (RAAS) blockade, although specific pathways and degree of injury are poorly understood. We aimed to study the evolution of tissue oxygenation and markers of acute kidney injury (AKI) during early and subsequent months after renal imaging (CT angiography followed immediately by intra-arterial angiography and renal artery stenting).

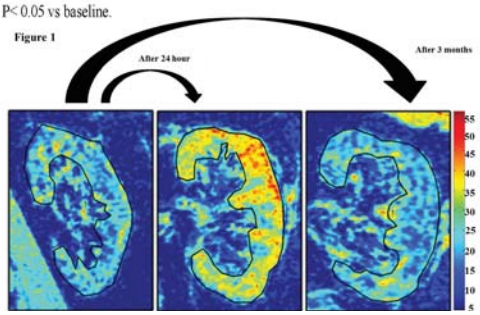
Methods: Inpatient studies were performed in patients with severe ARVD (Doppler Peak Systolic velocity = 318±100cm/sec), during 150 mEq Na+ intake and ACE/ARB Rx. Tissue deoxyhemoglobin levels (R2*) and fractional kidney hypoxia (% of Coronal area with R2*>20/s) of both kidneys were measured by BOLD-MRI at 3T. Blood samples of NGAL, KIM-1, TNF α and creatinine (Cr) were obtained before, 24 hour after and 3 months after imaging with contrast (Iohexol and iodixanol) (500mgI/kg).

Results: BOLD imaging 24 hours after CT imaging/stenting demonstrated substantial cortical hypoxia and elevated fractional kidney hypoxia (p < 0.05)Table. These changes were reversed to baseline after 3 months. Despite early changes in BOLD, no clinical episodes of CIN / AKI were identified and blood levels of NGAL, KIM-1, TNF α and Cr did not change; Serum Cr fell after 3 months for the group (p< 0.05)

Table. N=12	Baseline	After 24 hour	After 3 months
Age		72.3 ± 6.2	
Creatinine mg/dl	1.83 ± 0.49	1.7 ± 0.45	1.47 ± 0.4*
eGFR mL/min/1.73 m²	34.7 ± 11.8	36.9 ± 13.3*	45 ± 13.1 *
Total RBF (ml/min)	219.9 ± 103.8		255.4 ± 122.9
Cortical perfusion (ml/min/mL tissue)	2.5 ± 0.8		2.8 ± 1.1
Cortical R2* (1/s)	20.4 ± 4.3	24.6 ± 6.8*	18.4 ± 6.7
Fractional hypoxia(R2*> 20/s)	53.3 ± 22.1	69.4 ± 26.1*	42.4 ± 17.5
KIM-1 (ng/ml)	0.26 ± 0.2	0.25 0.2	0.24 ± 0.19
NGAL (ng/ml)	264.7 ± 77.4	243.1 ± 65.4	269.6 ± 86.1
TNF-α (pg/ml)	16.6 ± 7.3	16.7 ± 7.2	15.2 ± 13.2

(Mean ± SD) * P< 0.05 vs baseline.

Figure 1



Conclusions: Our results demonstrate widespread tissue hypoxia 24 hours after contrast imaging and renal stenting in patients with ARVD, under standardized conditions. Importantly, these changes were not associated with AKI based on circulating injury markers suggesting renal adaptation to transient hypoxia. These events were followed by improved blood flow and GFR 3 months later.

TH-OR035

Association between In-Hospital Furosemide Exposure and the Incidence of In-Hospital Acute Kidney Injury Joshua Taylor Swan,[1,2,3] Harlan Sparrow,[1] Beverly A. Shirkey,[2] Carol M. Ashton,[1,2,4] Wadi N. Suki,[1,4,5] David Putney,[1] Nelda P. Wray,[1,2,4] A. Osama Gaber.[1,2,4] *[1]Houston Methodist Hospital; [2]Houston Methodist Research Inst; [3]Texas Southern Univ; [4]Weil Cornell Medical College; [5]Baylor College of Medicine.*

Background: Furosemide (FUR) is commonly used in hospitalized patients who have a high risk of developing acute kidney injury (AKI) and may cause AKI through a hemodynamic-mediated mechanism. This study describes the association between FUR and incident AKI in hospitalized patients.

Methods: All first hospital admissions to a tertiary academic medical center in 2012 were included. Patients <18 years, those with preexisting AKI, stage V CKD, or dialysis on admission, and those with a maximum serum creatinine (SCr) <=0.4 mg/dL were excluded. Also, patients lacking 2 SCr values within a 72-hour period were excluded. In-hospital AKI was defined as an increase in SCr by >=0.3 mg/dL or >=50% or a decrease in eGFR by >=25% over a 72-hour interval. Billing claims and ICD9 codes were used to determine FUR use and comorbidities, respectively. We tested the association between FUR and AKI with chi-squared.

Results: This study included 13,951 unique patients, of whom 52% were female, 64% were Caucasian, and 2,568 (18%) developed AKI. FUR was used in 3,599 (26%) patients during the period for AKI determination and was associated with AKI (% AKI, 29.7% with FUR versus 14.5% without FUR, relative risk [RR]=2.1, P<0.001). This association was modified by comorbidity status.

Comorbidity	No. (%) with comorbidity	Comorbidity present				Comorbidity absent			
		% AKI with FUR	% AKI without FUR	RR	P	% AKI with FUR	% AKI without FUR	RR	P
CHF	2345 (17%)	37	38	1.0	NS	24	13	1.9	<.001
CKD	1305 (9%)	52	42	1.2	<.001	25	13	2.0	<.001
Cirrhosis	725 (5%)	32	24	1.3	<0.05	30	14	2.1	<.001
ASCVD	2462 (18%)	37	24	1.6	<.001	27	13	2.1	<.001
HTN	7706 (55%)	27	15	1.8	<.001	34	14	2.5	<.001
Diabetes	3664 (26%)	36	21	1.8	<.001	26	13	2.1	<.001

Conclusions: FUR was commonly used in hospitalized patients and was associated with an increased risk of in-hospital AKI in all subgroups analyzed, both with and without comorbidities, except for patients with CHF. Further research is needed to determine if this association is causal or induced by confounders.

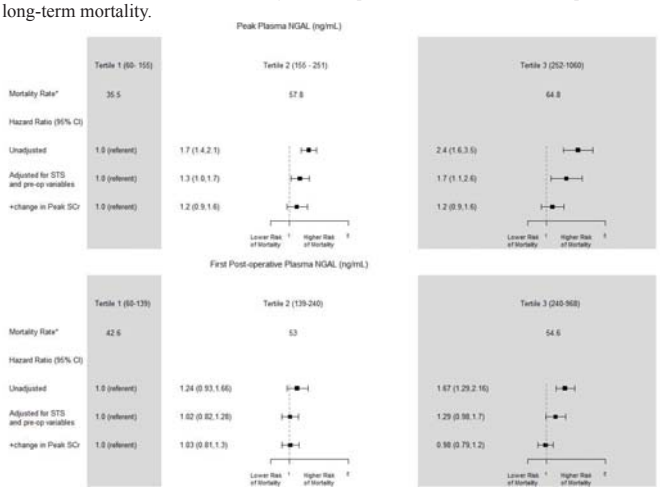
TH-OR036

Peri-Cardiac Surgery Levels of Plasma Neutrophil Gelatinase-Associated Lipocalin Are Not Associated with Long-Term Mortality Independent of Serum Creatinine Levels Dennis Moledina, Chirag R. Parikh, Amit X. Garg, Heather Thiessen Philbrook, Jay L. Koyner, Uptal D. Patel, Prasad Devarajan, Michael Shlipak, Steven G. Coca. *TRIBE-AKI Consortium.*

Background: Higher levels of plasma neutrophil gelatinase-associated lipocalin (pNGAL) are an early marker of acute kidney injury and are associated with increased risk of short-term adverse outcomes. The independent association between pNGAL and long-term mortality is unknown.

Methods: We examined the association between perioperative pNGAL concentrations and 3-year all-cause mortality in a six center, prospective long-term follow-up study of 1191 adults who underwent cardiac surgery between 2007 and 2009. We measured pNGAL both before surgery and on each of the three days after surgery.

Results: During a median follow-up of 3.0 years, 139 participants died (50/1000 person-years). After adjustment for pre- and intra-operative variables, including pre-operative NGAL levels, the first post-operative and peak post-operative NGAL were independently associated with 3-year mortality risk (adjusted HR 1.3, 95% CI 1.0-1.7 and adjusted HR 1.8, 95% CI 1.2-2.7, respectively). However, after adjustment for peri-operative changes in serum creatinine, there was no longer an independent association between pNGAL and long-term mortality.



Conclusions: Peri-operative pNGAL levels are associated with long-term mortality, but not independent of changes in the peri-operative serum creatinine concentration. The findings suggest plasma NGAL measurements may not be clinically useful or cost effective for prognostication beyond testing available in routine care to assess peri-operative kidney injury.

TH-OR037

Intermittent Hemodialysis in Acute Kidney Injury: Results from the VA/NIH ATN Trial Rowena B. Delos Santos,[1] Tingting Li,[1] Paul M. Palevsky,[2] Anitha Vijayan.[1] *[1]Renal Div, Washington Univ in St. Louis, St. Louis, MO; [2]Renal Section, VA Pittsburgh Healthcare System, Pittsburgh, PA.*

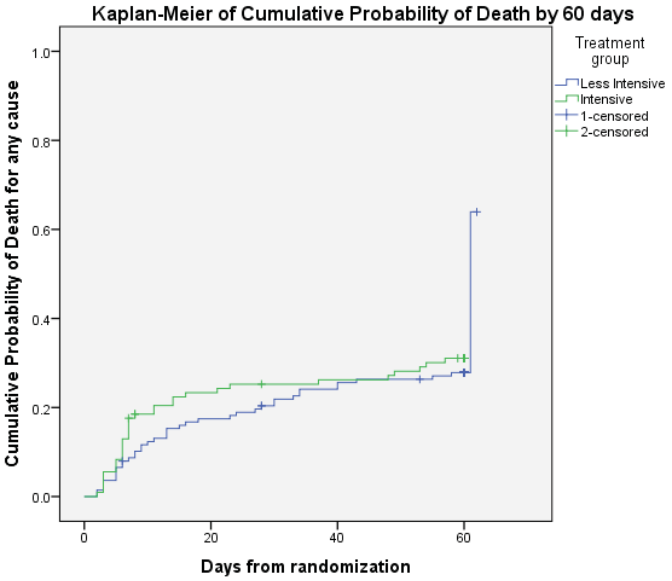
Background: Critically ill patients with AKI were randomized to receive intensive (I) or less-intensive (L-I) renal replacement therapy (RRT) in the VA/NIH Acute Renal Failure Trial Network (ATN) study. Modality of RRT was determined by CV-SOFA score. Hemodynamically stable subjects (CV-SOFA 0-2) received IHD 6X/wk (I) or 3X/wk (L-I). In this *post-hoc* analysis we assessed renal recovery (RR) and 60-day mortality in the 246 subjects who only received intermittent HD (IHD).

Methods: Categorical variables were expressed as proportions and continuous variables as mean±SD. Kaplan-Meier method was used to evaluate survival.

Results: Baseline data including age, sex, race, SCr, cause of AKI and APACHEII scores were not statistically different between the groups. Table 1 shows additional results.

	I IHD (N=108)	L-I IHD (N=138)	P Value
Mean pre-tx BUN(mg/dL)	44.4±27	68.1±31	<0.001
Initial Kt/Vurea	1.31±0.4	1.29±0.3	NS
Subsequent Kt/Vurea	1.33±0.4	1.32±0.3	NS
Mean pre-tx MAP(mmHg)	87.4±17	75.8±35	<0.001
Mean change in MAP during HD(mmHg)	-10.46±11.5	-9.89±13.1	NS
Net fluid removal per HD(L)	1.7±1.3	2.1±1.4	<0.001
Renal recovery	32%	43%	NS
Mortality	31%	29%	NS

Overall mortality was 29.5% and was not different between the 2 groups.



Conclusions: This is the largest study evaluating role of IHD in ICU patients with AKI. IHD 3Xwk required higher UF. Intradialytic hypotension (change in MAP) was not different. There was no difference in 60-day mortality and RR. Overall mortality was lower than typically observed in a critically ill population with AKI, most likely as a result of the selection criteria used in our analysis. There is no benefit to providing IHD more frequently than 3X/wk in hemodynamically stable critically ill AKI patients.

Recellularization of Vascular and Tubular Compartments of Rat Kidney Scaffolds with Embryonic Stem Cells Andrea Remuzzi,[3] Barbara Bonandrini,[1] Marina Figliuzzi,[1] Sara Silvani,[1] Ariela Benigni,[1] Giuseppe Remuzzi.[1,2] *[1]IRCCS Mario Negri Inst, Bergamo; [2]Ospedale Giovanni XXIII, Bergamo; [3]Univ of Bergamo, Dalmine, Italy.*

Background: The recontruction of the kidney is more challenging than regeneration of other tissues because of the complexity of kidney structures. We previusly showed that infusion of embryonic stem (mES) cells in the renal artery of acellular kidney scaffolds allowed repopulation of vascular tree and glomerular capillaries. This study aimed to develop experimental techniques to repopulate the tubular component.

Methods: As previously reported (Bonandrini et al. 2014) a complete decellularization of rat kidneys was achieved to produce extracellular matrix (ECM) scaffolds. There we seeded Kidney rat scaffolds with 15x10^6 mES cells through renal artery at 1 ml/min for 9 min. Then, 15x10^6 mES cells were infused through the ureter at 1 ml/min for 9 min while negative pressure of -50 mmHg was applied, in the perfusion chamber, outside of the scaffold. Scaffolds were then maintained in perfusion culture at 0.4 ml/min for 3 days.

Results: Immunofluorescence and H&E staining showed that mES cells infused in renal artery were uniformly distributed in the vascular network and in glomerular capillaries and expressed endothelial markers, while cells infused in the ureter reached tubular compartment (Figure 1). Cell delivery at proximal tubular level improved when scaffolds were maintained in seeding chamber under a vacuum to generate a pressure gradient across ECM.

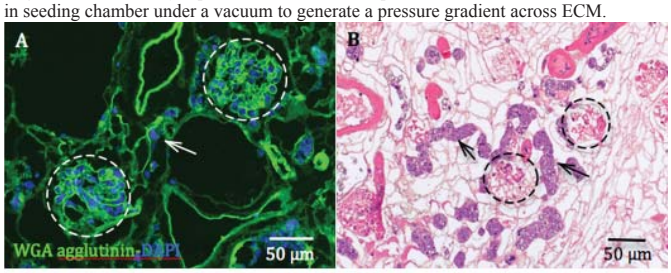

Figure 1. Immunofluorescence (A) and H&E (B) staining of recellularized kidney showing recellularized glomeruli (circle) and tubuli (arrows).

Conclusions: Our results demostrate that acellular kidney scaffolds can be cellularized not only at vascular level but also in the tubular compartment up to proximal tubules. Future studies to obtain more uniform and complete cellularization may open the way to recreate whole kidney in laboratory. *ERC grant RESET-268632 from EU supported this research.*

Long-Term Water Transport and Barrier Function of Proximal Tubule Cells Cultured Under Apical Shear Flow Conditions Paul R. Brakeman,[1] Peter Soler,[4] Nicholas J. Ferrell,[3] William Fissell,[3] Shuvo Roy.[2] *[1]Pediatrics, UCSF, San Francisco, CA; [2]Bioengineering & Therapeutic Sciences, UCSF, San Francisco, CA; [3]Medicine, Vanderbilt Univ School of Medicine, Nashville, TN; [4]Dept of Chemical & Biomolecular Engineering, UC Berkeley, Berkeley, CA.*

Background: Development of a bioartificial kidney (BAK) comprising a hemofilter and a proximal tubule cell bioreactor for treatment of chronic kidney disease requires long-term survival of proximal tubule cells under shear flow conditions. Previous work has only characterized transport properties of proximal tubules cells for 2-3 weeks in perfusion culture. We investigated fluid transport characteristics of proximal tubule cells in a shear flow bioreactor in long-term culture for >60 days.

Methods: LLC-PK1 cells were cultured on polycarbonate filter supports for 14 days and then exposed to apical shear stress. Cells were perfused with media containing urea (40 mg/dL) and creatinine (10 mg/dL) on the apical side and media alone was used on the basal side. The change in volume of the compartments and concentrations of sodium, potassium, phosphorus, urea and creatinine were measured.

Results: Water transport for proximal tubule cells under shear flow conditions increased significantly from 34+/-10 ul/cm^2/day on day 7 of low shear flow (0.2 dyn/cm^2) to 119+/-12 ul/cm^2/day on day 63 (p=.002) with high shear flow (2 dyn/cm^2) and was stable for 14 days at high shear flow from days 49 to 63. We characterized the barrier function of the cells by looking at the leakage of creatinine. On day 63, the leakage of creatinine was 0.012+/-0.009 mg/cm^2/day and did not differ significantly from the leakage of creatinine on day 7.

Conclusions: Proximal tubule cells can maintain barrier function and water transport under shear flow conditions for >60 days. Water transport increased with increased shear flow and time in culture.

Functional Organic Cation Transporters in Human Proximal Tubule Epithelial Cells Cultured on Hollow Fiber Membranes Jitske Jansen,[1,2,3] Ilaria Ester De Napoli,[4] Carolien M.S. Schophuizen,[1,2,3] Martijn J. Wilmer,[1] Jack F. Wetzels,[5] Lambertus P.W.J. Van den Heuvel,[3,6] Joost Hoenderop,[2] Dimitrios Stamatialis,[4] Rosalinde Masereeuw.[1] *[1]Pharmacology and Toxicology, RadboudUMC, Nijmegen, Netherlands; [2]Physiology, RadboudUMC, Nijmegen, Netherlands; [3]Pediatrics, RadboudUMC, Nijmegen, Netherlands; [4]Biomaterials Science and Technology, Biomedical Technology and Technical Medicine Faculty of Science and Technology, Enschede, Netherlands; [5]Nephrology, RadboudUMC, Nijmegen, Netherlands; [6]Pediatrics, Catholic Univ Leuven, Leuven, Belgium.*

Background: The bioartificial kidney (BAK) aims at developing living membranes for human renal epithelial cells-aided removal of protein-bound uremic toxins. Here, human conditionally immortalized proximal tubule epithelial cell (ciPTEC) monolayer functionality when cultured on polyethersulfone hollow fiber membranes (HFM) was evaluated.

Methods: Cell-free permeability of H_2O, IgG and albumin was studied in HFM coated with L-DOPA (2 mg/ml) and collagen IV (25 µg/ml). The the tight junction protein zonula occludens-1 (ZO-1) was examined by immunostaining in matured ciPTEC on HFM. Monolayer functionality was determined by real-time ASP^+ uptake (10 µM), a known substrate of Organic Cation Transporter 2 (OCT2), in the presence or absence of cimetidine (100 µM). Uptake was measured under a constant flow of 6 ml.h^{-1} by confocal microscopy.

Results: The H_2O permeability was not significantly different in coated HFM (17.1 ± 1.1 L.m^2.h^{-1}.mbar^{-1} *versus* uncoated 17.1 ± 0.4 L.m^2.h^{-1}.mbar^{-1}, n=6). The sievingcoefficient for IgG (0.91 ± 0.02, n=3) and albumin (0.94 ± 0.05, n=3) close to 1.00 indicated free passage of both compounds. After 7 days of culturing at 37°C, ciPTEC developed a tight monolayer with abundant ZO-1 expression along the tight junctions. Intracellular ASP^+ uptake was detectable within 1 min of perfusion, which was significantly inhibited for 61 ± 10% by cimetidine, as measured over 13 min (n=4; p<0.05).

Conclusions: This study reports, for the first time, active OCT2 transport in proximal tubule cell monolayers on HFM. We expect that this living membrane may positively contribute to the excretion of uremic toxins by ciPTEC in BAK.

A Microphysiological 3D Model of the Renal Proximal Tubule Demonstrates Reabsorptive Function Else M. Frohlich,[1] Hyoungshin Park,[1] Jose L. Alonso,[2] M. Amin Arnaout,[2] Joseph L. Charest.[1] *[1]Biomedical Engineering, Draper Laboratory, Cambridge, MA; [2]Div of Nephrology, Massachusetts General Hospital, Charlestown, MA.*

Background: Re-absorption occurs in the proximal tubule as solutes and water are transported from the tubule lumen to the blood stream. Since the re-absorption of fluids and solutes in the kidney constitutes transport through epithelial and vascular components, models of reabsorptive barriers, such as the proximal tubule, should provide both phenotypes to more accurately replicate the physiological barrier architecture.

Methods: In this work we demonstrate a co-culture orientation of primary human renal proximal tubule epithelial cells (hRPTEC) and human microvascular endothelial cells (hMVEC) in a microfluidic model. hRPTEC tissue layers were characterized by

immunofluorescent protein labeling, gene expression, and barrier function quantification techniques. Re-absorptive function was investigated by quantifying molecular uptake and sodium transport across the tissue.

Results: hRPTEC tissue layers were found to have enhanced tissue structure, extended viability, higher proliferation rates, and increased levels of mitochondrial activity in co-culture conditions of the model. hRPTEC tissue also expressed transport proteins and barrier characteristics, demonstrated glucose uptake, and showed decreased sodium re-absorption in response to a drug.

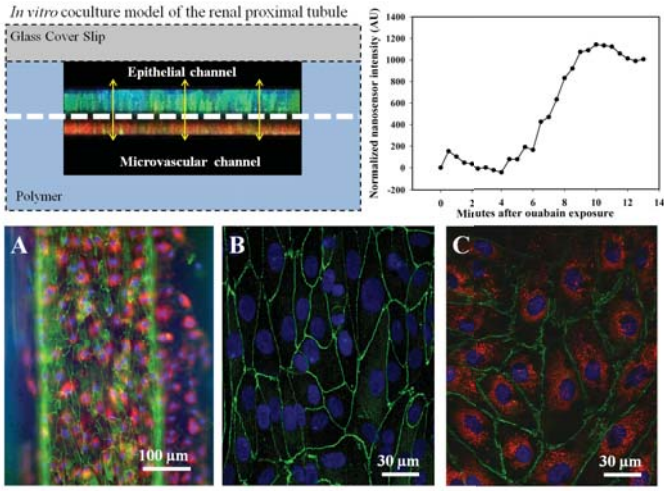

Figure 1. hRPTEC and hMVEC tissue layers are cultured on either side of a membrane in our microfluidic model to mimic the *in vivo* architecture of the renal re-absorption barrier. hRPTEC TJs are labeled (green) and hMVEC tissue layers are labeled for Von Willebrand factor (red). Epifluorescent microscopy shows the coculture of tissue layers in the model (A) and confocal images show well-developed hRTPEC (B) and hMVEC (C) tissue in each channel. The re-absorption of water and solutes can be studied across the tissue layers. Sodium re-absorption decreases across the tissue layers in response to a Na^+/K^+ ATP-ase pump inhibitor drug, evidenced by an increase of sodium-sensitive nanosensor signal in our model (graph).

Conclusions: The physiological microenvironment of our model enhanced tissue structure formation *in vitro* and mimicked *in vivo* architecture and function of the proximal tubule. Our model allows observation of tissue structure development, direct quantification of kidney-specific transport mechanisms and a method to quantify functional change to kidney tissue due to injury, kidney active compounds, or toxic insult.

TH-OR042

Development of a Bioengineered Human Kidney Microphysiological System for Assessment of Drug Transport and Toxicity Alenka Jaklic,[1] Elijah Weber,[1] Danny D. Shen,[1] Jonathan Himmelfarb,[2] Edward J. Kelly.[1] *[1]Pharmaceutics, Univ of Washington, Seattle, WA; [2]Kidney Research Inst, Univ of Washington, Seattle, WA.*

Background: There is a critical need to model the human kidney in order to improve our understanding of drug efficacy and toxicity, especially during drug development. The proximal tubular epithelial cells (PTEC) play a central role in the renal excretion of endogenous toxins and drugs, but to date conventional cultures of human PTECs fail to fully recapitulate their physiological functions in vivo.

Methods: We have developed and assessed the functionality of a 3D culture model of human PTECs in a microfluidic device (microphysiological system or MPS) from Nortis Inc., which allows luminal or basolateral perfusion.

Results: Human PTECs in the Nortis MPS platform expressed sodium-glucose transporter 2 (SGLT2) and did not express kidney injury marker (KIM-1). The exact opposite was observed in 2D culture, which confirms that in the MPS, PTECs are able to maintain its constitutive phenotype. In response to lowering of perfusate pH (7.4 to 6.9), PTECs in 3D culture increased production and secretion of ammonia, i.e., ammoniagenesis. Trans-epithelial transport of organic solutes by PTECs was assessed by measuring secretion of markers for OCT2 (creatinine) and OAT1/3 (p-aminohippurate, PAH). The appearance of markers in the lumenal effluent was reduced in the presence of their respective transport inhibitor. In addition, PAH secretion is reduced in the presence of indoxyl sulfate, confirming competition for the same OAT-mediated transport across PTECs. In ongoing studies with cisplatin and gentamicin, human PTECs in 3D culture showed altered morphology after timed exposure to these prototypical nephrotoxic compounds.

Conclusions: It is possible to recapitulate a functional proximal tubular epithelium ex vivo in an MPS. This system more accurately reflects renal physiology, and demonstrates renal handling of xenobiotics as well as biological response to renal toxins.

Nine-Day Filtration by an Implantable Hemofilter Clark David Kensinger,[1] Seth J. Karp,[1] Joseph J. Groszek,[2] Mark S. Goodin,[3] Rishi Kant,[4] Torin Yeager,[4] Shuvo Roy,[4] William Fissell.[2] *[1]Surgical Sciences, Vanderbilt Univ, Nashville, TN; [2]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; [3]Simutech Group, Hudson, OH; [4]Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, CA.*

Background: Patients with end-stage renal disease (ESRD) have high mortality and morbidity on dialysis. ESRD patients could experience better quality of life if implanted with an artificial kidney. A new ultrathin membrane with highly controlled pores made by sacrificial silicon oxide techniques allows size selective sieving in vivo. In a canine model, we have demonstrated protein permselectivity through an implanted high-efficiency hemofiltration membrane over 9 days.

Methods: The device comprised a single channel blood conduit with parallel-plate hemofiltration membranes. *In vivo,* the device blood conduit was connected via PTFE grafts to the common iliac artery and vein. Filtrate was collected in two implanted reservoirs. The animal was housed without restriction and received thromboembolic prophylactic doses of enoxaparin (0.5mg/kg) once a day. After 9 days, filtrate was sampled from the reservoirs. Albumin concentration in filtrate was measured by colorimetric assay. Filtration rates were estimated by indicator dilution.

Results: Effluent sampled on day 9 had low albumin sieving coefficients (bag 1: 0.13, and bag 2: 0.24). Ficoll sieving coefficients at equivalent Stokes radius were 0.14 and 0.19 respectively. *In vivo* hydraulic permeability was consistent with *in vitro* measurements after correction for plasma oncotic pressure.

Conclusions: A high efficiency hemofiltration device is capable of filtration over 9 days in a canine surgical model. Albumin sieving coefficients and hydraulic permeability *in vivo* match preoperative in vitro values. This demonstrates sustained in vivo filtration by silicon nanopore membranes without fouling or thrombosis.

TH-OR044

Evaluation of Next-Generation Silicon Nanopore Membranes Optimized for Diffusive Clearance Steven Kim,[1,2] Charles Blaha,[2] Zohora Iqbal,[2] Clarence Chow,[2] Rishi Kant,[2] Benjamin Chui,[3] Jaehyun Park,[2] Ken Goldman,[4] Eun Jung Kim,[2] William Fissell,[5] Shuvo Roy.[2] *[1]Nephrology, UCSF; [2]Bioengineering, UCSF; [3]Ben Chui Consulting; [4]H-Cubed; [5]Nephrology, Vanderbilt Univ.*

Background: Silicon nanopore membranes (HF-SNM) designed for hemofiltration have demonstrated remarkable permeability and selectivity. However, diffusive clearance was hindered by their thickness. Here we report hemodialysis-SNM (HD-SNM) with enhanced diffusive clearance.

Methods: A new MEMS (microelectromechanical systems) fabrication protocol utilizing nested etch-back techniques was used to decrease the effective SNM thickness (HD-SNM 100 µm versus HF-SNM 400 µm). Diffusive clearances of polyethylene glycol coated HD-SNM and HF-SNM with sub-10 nm pore sizes were tested in a parallel plate flow cell. PBS with Cr 10 mg/dL, BUN 90 mg/dL, and albumin 3 g/dL was recirculated (45ml), while dialysate (160 mEq NaCl) was recirculated in a counter-current fashion. At Q_d=Q_b=10 ml/min and zero transmembrane pressure (TMP) clearance was independent of flow rate. Solute clearance (K) was calculated by fitting concentrations measured at 0, 2, 4 hrs (n=3) to an exponential decay function: $C(t)=C_i e^{-Kt/V}$. C(t): conc at time t ,C_i: initial conc, V: volume. Filtration was tested in water and fetal bovine serum at various TMP (1, 2, 4 psi) using cross flow velocities at 0.1, 0.5 and 3 ml/min. Platelet adhesion and activation were evaluated by immunohistochemistry (IHC) and scanning electron microscopy (SEM) after flowing human blood for 2 hrs at 2 ml/min.

Results: HD-SNM had an ~3 fold improvement in K, consistent with mathematical models. Creatinine, BUN and phosphorus clearances were 280.8±20.8, 380.0±18.3, 231.1±7.6ml/min/m^2 (HD-SNM) and 85.5±10.6, 135.3±22.9, 75.5±12.8 ml/min/m^2 (HF-SNM), respectively. HD-SNM maintained mechanical integrity at over 200mmHg. The HD-SNM also showed comparable filtration rates (71.5 ± 21.3 ml/hr/mmHg/m^2) and selectivity to HF-SNM. IHC for CD62 and SEM images showed similar levels of platelet activation and adhesion.

Conclusions: These preliminary studies demonstrate significant improvement in diffusive clearance with the HD-SNM while still maintaining mechanical robustness, selectivity, permeability and hemocompatibility.

TH-OR045

Slit Nanotopography on Silicon Nanopore Membranes Resists Protein Deposition and Cell Attachment Eun Jung Kim,[1] William Fissell,[2] Tejal Ashwin Desai,[1] Shuvo Roy.[1] *[1]Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, San Francisco, CA; [2]Nephrology and Hypertension, Vanderbilt Univ and Medical Center, Nashville, TN.*

Background: Silicon Nanopore Membranes (SNM) with compact geometry and uniform pore size distribution are under development for the hemofiltration unit in an implantable bioartificial kidney.[1] Key concerns for long-term membrane function are centered on protein deposition and cell attachment that can result in surface fouling and thrombotic occlusion.[2] In this study, weinvestigated the influence of surface coatings and nanotopography on protein deposition and cell growth on SNM substrates.

Methods: SNM substrates consisting a 6 x 6 mm slit-array patterned hemofiltration region areain the center surrounded by a 2 mm unpatterned, smoothborder, were modified by physically adsorbing either collagen type I (Col I-SNM) or covalently immobilizing RGD peptide (RGD-SNM).Atomic forcemicroscopy (AFM)was used to characterize the roughness of modified SNM surfaces.The propensity of protein adsorption onSNM surfaceswas evaluated using fluorescein isothiocyanate labeled bovine serum albumin (*FITC-BSA)*. Human umbilical vein endothelial cells growth on both modified and unmodified (Control) SNM were analyzed using immunohistochemistry.

Results: The surface roughness (RMS) of RGD-SNM (12.5nm) wasgreater than that of Col I-SNM (7.8 nm)and Control(6 nm). In unpatterned regions, FITC-BSA adsorbed strongly to the Col I as well as RGD, and RGD-SNM was found to significantly enhance cell growth (1500 % on day 7) compared to Col I-SNM (120%) and Control (100 %). In patterned area of all modified SNMs, however, FITC-BSA protein adsorption and cell growth are strongly attenuated (below 10 % on day 7). In addition, significant actin impairmentand cell detachment were observed on the patterned regions.

Conclusions: These results suggest that RGD is superior to Col I coatings for cell attachment. However, protein deposition and cell attachment on the slit-array region was significantly attenuated despite favorable coatings. This work will inform the development of SNM-based hemofiltration unit.

TH-OR046

Water Permeable Nanoporous Membrane Device for Implantable Artificial Kidney Yoshihiko Kanno,[3] Naoya To,[1] Shinya Morita,[2] Ippei Sanada,[1] Norihisa Miki,[1] Hikaru Itoh.[1] *[1]Faculty of Science and Technology, Keio Univ; [2]Dept of Urology, Keio Univ; [3]Dept of Nephrology, Tokyo Medical Univ.*

Background: In the previous meeting, we have reported a microdialyzer containing nanoporous polyethersulfone (PES) membranes, which could remove urea nitrogen and electrolytes from the dissolved solution and cattle blood. Implantable dialysis system will improve patients' quality of life, which requires a sufficiently small and no-dialysate dialysis device. As a second step for future clinical use, we investigated whether this membrane device had water permeability in vitro and in vivo.

Methods: We developed water-permeable and robust nanoporous membrane from a casting solution of polyether sulfone (PES), polyethylene glycol (PEG), and Dimethylacetamide (DMAc) using a wet phase inversion method. The newly developed composition achieved high water permeability even with a high ratio of PES in in vitro experiments using a cow whole blood. The 24x24x16 cubic dialysis device that stacked 11 micro-channel titan layers and 10 membranes (14.1% PES, 11.8%PEG, 74.1% DMAc) was connected to SD rats. The rat artery and vein are connected to the inlet and outlet of the device. The blood pressure was monitored during the experiment. Then rat kidneys were removed and saline was infused.

Results: After the overload of saline, aqueous filtrate was successfully collected which was affected by blood pressure. Low-molecular-weight electrolytes in the blood was removed with the filtrate while proteins, such as albumin, was maintained in the blood. No leakage was observed and the filtrate was successfully collected. The filtrate was found to increase after the addition of saline, which implies that the filtrate amount depend on the blood pressure. We also investigated the composition of blood before and after the device. The concentration of urea nitrogen and potassium were decreased (31 to 27 mg/dl, 5.1 to 4.6 mEq/L) while that of albumin was maintained (2.4 to 2.3 g/dl).

Conclusions: Our water permeable nanoporous membrane device allowed water and low-molecular-weight molecules to permeate through, which may satisfy the requirements for the dialysis membranes for the future implantable artificial kidney.

TH-OR047

Extracorporeal Mesenchymal Stromal Cell Therapy for Acute Kidney Injury Biju Parekkadan. *Surgery (Bioengineering), Harvard Medical School, Massachusetts General Hospital, Boston, MA.*

Background: Human mesenchymal stromal cells (MSCs) metabolize and secrete anti-inflammatory and regenerative factors that can be of systemic benefit in the setting of injury to the kidney. When transplanted, MSCs are limited in dose and rapidly cleared by the body, therefore prohibiting controlled exposure to this cell therapy. We have developed a bioreactor technology to maintain MSC viability at high fidelity and continuously delivers secreted factors into the blood stream in a clinical setting. MSCs were integrated into hollow-fiber bioreactor devices whereby the cells, separated by a permeable membrane, can directly and dynamically provide systemic therapy without entering the body. We present a human scale prototype of the technology that has shown sustained cell viability and function throughout clinical-grade manufacturing and large animal efficacy testing in preparation for a Phase I human trial set to begin in 2015.

Methods: A canine study of unilateral nephrectomy and a 90 minute, warm ischemic clamp of the remaining kidney was used to induce acute kidney injury (AKI). The bioreactor or control arms were tested 24 hours after ischemia and used in continuous operation for a 12 hour dose. Animals were monitored for survival with daily sampling of serum and urine with a 7-day study endpoint.

Results: This presentation will report encouraging results from in vivo therapeutic trials in a large animal (canine) model of ischemic acute kidney injury (AKI) whereby 91% of animals survived with extracorporeal MSC therapy compared to 50-60% in control arms. The biological response of extracorporeal MSC therapy in serum and tissue analysis revealed an anti-inflammatory effect at the prescribed dose. Pharmacological analysis of this bioreactor technology in vivo allowed for an unprecedented look at MSC function during product use and verified potency that is unattainable by conventional intravascular delivery of MSCs.

Conclusions: We expect that a combined approach ach to optimize MSC therapy that employs this novel approach to optimize the pharmacological influence of MSCs will enable the translation of this stem cell product to humans for AKI and other critical organ dysfunction syndromes.

TH-OR048

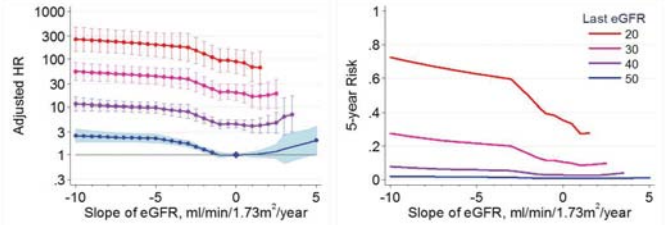
eGFR Level and Its Past Trajectory for Risk of Progression to End-Stage Renal Disease: Meta-Analysis of 22 Cohorts in the CKD Prognosis Consortium Csaba P. Kovesdy, Josef Coresh, Shoshana Ballew, Mark Woodward, David M. Naimark, Joseph V. Nally, Adeera Levin, Dietrich Rothenbacher, Benedicte Stengel, Kunitoshi Iseki, Kunihiro Matsushita, Andrew S. Levey. *CKD Prognosis Consortium.*

Background: The level of eGFR is a potent predictor of risk for progression to end-stage renal disease (ESRD). In practice, rate of progression is inferred from the past trajectory (slope) of eGFR decline. It is unclear how much prognostic information is provided by the current eGFR versus the past slope.

Methods: Slopes were estimated from all eGFR values in a 3-year baseline period of 13 CKD and 9 general/high-risk cohorts. We modeled the hazard ratios (HRs) of subsequent ESRD as a spline function of eGFR slopes after adjusting for age, sex, race, last eGFR, and co-morbid conditions compared to no eGFR decline. We used random effects meta-analyses to combine results across studies, stratified by type of cohort. We calculated the absolute risk of ESRD at 5 years after the last eGFR period using the weighted average baseline risk.

Results: 1,080,221participants experienced 5,159 ESRD events during a mean follow-up period of 2.0 years after the baseline period. In CKD cohorts the last eGFR was associated with a stronger HR than past decline (Figure, left panel), but both contributed substantially to the absolute risk of ESRD (Figure, right panel). Similar results were observed in the general/high risk cohorts. Results were similar when using different baseline periods for slope assessment and when adjusting for last albuminuria.

Figure. Adjusted hazard ratio and absolute risk of ESRD, vs. slope of eGFR



Conclusions: Risk of progression to ESRD is primarily associated with the current eGFR, but past slopes of eGFR decline can add further detail to risk assessment.

TH-OR049

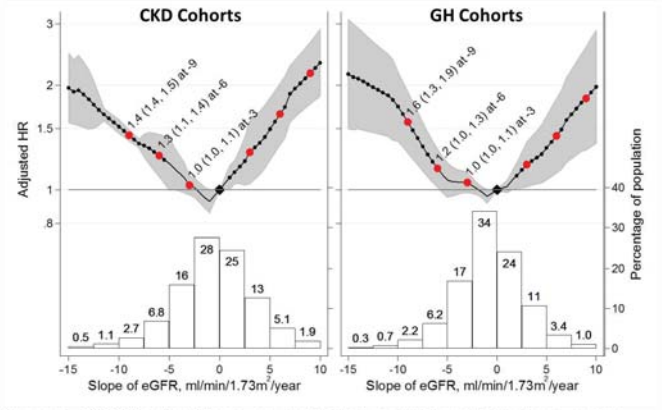
Prior Change in Estimated Glomerular Filtration Rate and the Subsequent Risk of All-Cause Mortality David M. Naimark, M. Grams, Kunihiro Matsushita, Corri Black, Lesley Inker, Areef Ishani, Sun Ha Jee, Akihiko Kitamura, Janice P. Lea, Joseph V. Nally, Carmen A. Peralta, Dietrich Rothenbacher, Seungho Ryu, Marcello Tonelli, Hiroshi Yatsuya, Ron T. Gansevoort, David G. Warnock, Mark Woodward. *CKD Prognosis Consortium.*

Background: A single determination of the estimated glomerular filtration rate (eGFR) is a strong predictor of subsequent all-cause mortality (ACM) risk. Whether an antecedent change in eGFR adds additional prognostic information regarding ACM risk is uncertain.

Methods: We conducted a meta-analysis of 22 general population and cardiovascular high-risk (GH) and 12 chronic kidney disease (CKD) cohorts in which eGFR slope could be determined during a 3-year antecedent period. Hazard ratios (HRs) for ACM associated with eGFR slope, after adjustment for various factors including last recorded eGFR, were estimated in a subsequent observation period.

Results: Among 1,277,202 subjects, 102,484 (8%) died over a mean observation time of 3.2 years after the initial 3-year antecedent period. A U-shaped relationship between ACM risk and eGFR slope was observed (Figure). For example, compared to stable eGFR, a decline of 9 ml/min/1.73m^2/year over the baseline period was associated with a subsequent adjusted hazard ratio of 1.6 (CI: 1.3-2.0) among GH and 1.4 (CI: 1.4 -1.5) among CKD cohorts, respectively. Sensitivity analyses, within strata of eGFR variability (root mean square error), after exclusion of subjects who lost weight during the baseline period, and after restriction to cardiovascular mortality, yielded qualitatively similar results.

Conclusions: Prior slope of the estimated glomerular filtration rate, whether positive or negative, provides additional prognostic information beyond that which can be obtained from a single measurement.



Top panels – ACM HRs adjusted for age, sex, race (black *vs.* non-black), systolic blood pressure, total cholesterol, diabetes, history of CVD, and baseline (last) eGFR. Bottom panels – distributions of antecedent eGFR slope frequencies among the GH and CKD cohorts.

TH-OR050

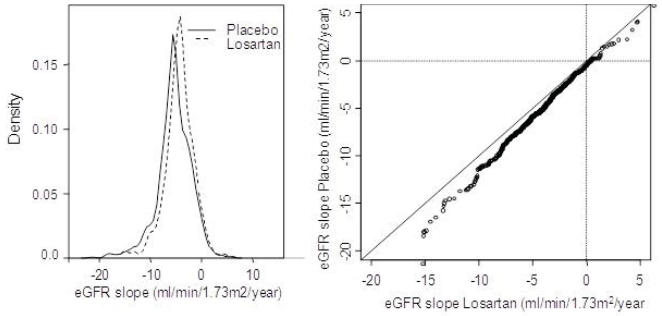
Slope of Glomerular Filtration Rate Decline as Clinical Trial Endpoint Misghina Tekeste Weldegiorgis,[1] Dick de Zeeuw,[1] Jamie P. Dwyer,[2] Tom Greene,[3] Hiddo Jan Lambers Heerspink.[1] *[1]Univ Medical Center Groningen, Netherlands; [2]Vanderbilt Univ School of Medicine; [3]Univ of Utah.*

Background: In some trials of chronic kidney disease (MDRD, AASK, DETAIL), the slope of GFR decline is used as efficacy endpoint. This endpoint provides great statistical power but only if the treatment effect does not depend on the underlying rate of GFR decline. In the MDRD trial it was shown that if this assumption is violated, statistical power is compromised as the lack of treatment effect in a subgroup (e.g. slow progressors) dilutes the overall treatment effect (*Greene Biometrics 2001*). We tested whether this also holds true for a trial testing a drug intervention, Angiotensin Receptor Blockers (ARB).

Methods: We used RENAAL and IDNT data testing the effect of losartan (RENAAL) and irbesartan (IDNT). We used linear mixed models to calculate the eGFR slope from baseline to month 3, and from month 3 until month 48 to exclude the acute effects of ARBs.

Results: In RENAAL, the decline in eGFR at 3 months was larger in the losartan versus placebo group (2.4 versus 1.3 ml/min/1.73m^2; p<0.01). After 3 months, the mean eGFR slope was smaller with losartan versus placebo (-4.4 versus -5.3 ml/min/1.73m^2/year; p<0.01). The variability in eGFR decline was also smaller with losartan (variance 8.5 versus 11.0; p<0.05). The attenuation of both the mean and variability of the slope suggests larger treatment effects in those with higher eGFR decline (Figure 1). Results were similar in IDNT.

Conclusions: The treatment effects of ARBs are larger in those with a faster rate of eGFR decline. The absence of treatment effect in slow progressors dilutes the greater treatment effect in fast progressors if eGFR slope is used as endpoint. These findings should be taken into account when considering eGFR slope as trial endpoint. Figure 1: Distribution of eGFR slopes (left) and QQ plot of eGFR slopes (right)



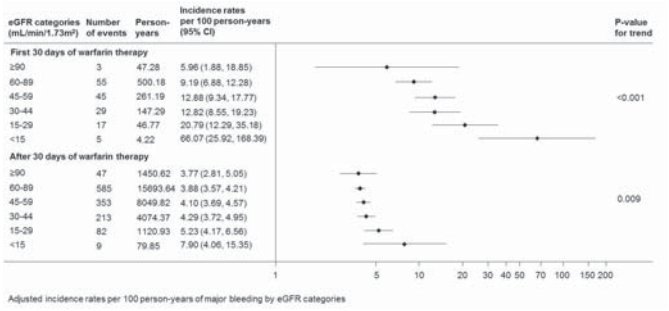
TH-OR051

The Association between Kidney Function and Major Bleeding in People with Atrial Fibrillation Initiating Warfarin Therapy Min Jun,[1] Matthew T. James,[1] Braden J. Manns,[1] Robert R. Quinn,[1] Pietro Ravani,[1] Marcello Tonelli,[2] Vlado Perkovic,[3] Wolfgang C. Winkelmayer,[4] Zhihai Ma,[1] Brenda Hemmelgarn.[1] *[1]U of Calgary, Canada; [2]U of Alberta, Canada; [3]George Inst, Australia; [4]Stanford Uni.*

Background: Limited safety data exist on warfarin in people with atrial fibrillation (AF) and reduced kidney function. The objective was to determine rates of major bleeding by level of kidney function in people with AF initiating warfarin.

Methods: We identified adults aged≥66years in Alberta, Canada, with AF who started warfarin therapy between 2003-2010. Patients were grouped into 6 eGFR categories:≥90, 60-89, 45-59, 30-44, 15-29, <15ml/min/1.73m^2; those with ESRD(dialysis or renal transplant) at baseline were excluded. The outcome assessed was a hospitalization or emergency department visit for major bleeding(intracerebral, upper or lower gastrointestinal, or other).

Results: Of 12403 patients, 45% had an eGFR<60mL/min/1.73m^2. Overall, 1443(11.6%) experienced a major bleeding episode over a median follow-up of 2.1(IQR:1.0-3.8) years. During the first 30 days of warfarin, adjusted rates of major bleeding were higher at lower eGFR(p for trend<0.001;).



eGFR categories (mL/min/1.73m²)	Number of events	Person-years	Incidence rates per 100 person-years (95% CI)	P-value for trend
First 30 days of warfarin therapy				
≥90	3	47.28	5.96 (1.88, 18.85)	
60-89	55	500.18	9.19 (6.88, 12.28)	
45-59	45	261.19	12.88 (9.34, 17.77)	<0.001
30-44	29	147.29	12.82 (8.55, 19.23)	
15-29	17	46.77	20.79 (12.29, 35.18)	
<15	5	4.22	66.07 (25.92, 168.39)	
After 30 days of warfarin therapy				
≥90	47	1450.62	3.77 (2.81, 5.05)	
60-89	585	15693.64	3.88 (3.57, 4.21)	
45-59	353	8049.82	4.10 (3.69, 4.57)	0.009
30-44	213	4074.37	4.29 (3.72, 4.95)	
15-29	82	1120.93	5.23 (4.17, 6.56)	
<15	9	79.85	7.90 (4.06, 15.35)	

Adjusted incidence rates per 100 person-years of major bleeding by eGFR categories

Adjusted bleeding rates per 100 person-years were 66.0 (95%CI:25.9-168.3) in patients with eGFR<15ml/min/1.73m^2 compared to 5.9 (95%CI:1.8-18.8) among those with eGFR>90ml/min/1.73m^2 (IRR 11.0, 95%CI:2.5-48.9). Across all eGFR categories, adjusted bleeding rates were consistently higher in the first 30 days of warfarin therapy than the remainder of follow-up.

Conclusions: Reduced kidney function was strongly associated with the risk of major bleeding in older adults with AF initiating warfarin, with excess risks from reduced eGFR most pronounced in the first 30 days. Our results support the need for careful assessment of bleeding risk in people with CKD and AF being considered for warfarin therapy, especially in the first 30 days of treatment.

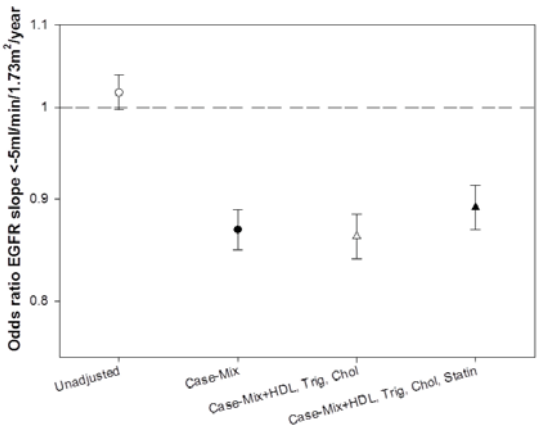
TH-OR052

Association of Baseline Use of Niacin with Progression of Chronic Kidney Disease in over 3 Million U.S. Veterans Elani Streja,[1] Kamyar Kalantar-Zadeh,[1] Hamid Moradi,[1] Miklos Zsolt Molnar,[2] Jun Ling Lu,[2] Csaba P. Kovesdy.[2] *[1]Harold Simmons UC Irvine MC, Orange, CA; [2]Memphis VAMC, Memphis, TN.*

Background: It has been suggested that dyslipidemia can contribute to deterioration of kidney function. Niacin has been used to manage elevated triglycerides and low HDL levels. We hypothesize that niacin also reduces the progression of renal function decline in a cohort of U.S. Veterans.

Methods: In a cohort of 3.3 million U.S. Veterans with normal baseline eGFR in 2005-2006 we examined the association of baseline use of niacin with slopes of eGFR over median follow up of 7.7 years (6.0, 8.4). The referent group was patients who never used niacin throughout the cohort period. Associations were examined in crude and adjusted logistic regression models (for slopes <-5ml/min/1.73m^2/year), with adjustments for demographics, comorbidities, HDL, triglycerides, total cholesterol, and use of statins.

Results: Patients were 60±14 years old, 6% female, 17% African-American, and 23% diabetic with a mean baseline eGFR 84±15 mL/min/1.73m^2. In the total cohort, 9.3% of patients had a rapid kidney function decline with an eGFR slope of <-5 mL/min/1.73m^2/year. In logistic regression models after adjustment for case-mix covariates including BMI and cardiovascular and other comorbidities, baseline use of niacin was associated with lower odds of rapid kidney function. Associations remained significant after further adjustments for HDL, triglycerides total cholesterol, and use of statins.



Conclusions: Baseline use of niacin is associated with slower progression of CKD. Clinical trials evaluating the effect of niacin on progression of CKD are warranted.

25-Year Kidney Function Trajectories Associated with *APOL1* High-Risk Variants: The ARIC Study

M. Grams, Adrienne Tin, C. Rebholz, Yuan Chen, Wen Hong Linda Kao, Josef Coresh. *Johns Hopkins Univ.*

Background: In populations with preexisting CKD, *APOL1* high-risk status associates with faster eGFR decline. Kidney function trajectories associated with *APOL1* high-risk status in populations without kidney disease have not been characterized.

Methods: Participants from the ARIC study, a community-based prospective cohort followed from 1987-1989 (baseline) until 2011-2013, were followed for yearly change in eGFR, based on study visit-measured creatinine (visit 1, 2, 4, and 5) and an imputed value of 15 ml/min/1.73 m^2 at incident ESRD (via linkage with USRDS). Mixed models with random intercept and slope were adjusted for race/*APOL1* high-risk status, age, sex, as well as baseline hypertension, diabetes, coronary heart disease, HDL cholesterol, and BMI.

Results: Among 12,902 participants (75.3% Caucasian, 21.5% African-American (AA) *APOL1* low-risk, and 3.2% AA *APOL1* high-risk), African Americans in both risk groups were younger, more often female, and had a higher prevalence of hypertension and diabetes at baseline. The annual change in eGFR differed by race/*APOL1* group: median, 75th, and 90th percentiles were -1.5, -1.7, and -2.2 ml/min/1.73 m^2 per year in Caucasians, -2.0, -2.5, and -3.1 ml/min/1.73 m^2 per year in AA *APOL1* low risk, and -2.2, -2.8, and -3.5 ml/min/1.73 m^2 in AA *APOL1* high risk. Applying the full distribution of slopes to the study population, the 25-year probabilities of eGFR <45 ml/min/1.73 m^2 among Caucasian, AA *APOL1* low-risk, and AA *APOL1* high-risk populations were 18.5%, 20.3%, and 30.5%, respectively.

Conclusions: In this population-based cohort, the 25-year slopes of eGFR varied by race and *APOL1* status, with a greater skew toward faster decline in African Americans, particularly those with *APOL1* high-risk status. All race/*APOL1* risk groups showed a wide heterogeneity in eGFR slopes, suggesting caution when making individualized predictions.

TH-OR054

Different Biomarker Profiles Identify Chronic Kidney Disease Patients of Different Etiologies at the Highest Risk of Mortality before Progression to Dialysis Dependence

David Langsford,[1] Ognjenka Djurdjev,[2,3] Mila Tang,[1,3] Adeera Levin.[1,3] *[1]Div of Nephrology, Univ of British Columbia; [2]BC Renal Agency; [3]On Behalf of CAN PREDDICT Steering Committee.*

Background: No model exists for predicting mortality in chronic kidney disease (CKD) patients despite the high risk for mortality in later stages of CKD. Competing risks for death and dialysis dependence vary according to CKD etiology. Newer biomarkers (BM) associated with specific pathological processes could identify CKD patients at risk of death before dialysis (DBD).

Methods: A subset of a pan-Canadian prospective cohort of 2544 referred CKD patients from 25 diversely located nephrology centers were examined for predictive utility of different panels of BM: troponin I, pro-brain natriuretic peptide (NT-proBNP), fibroblast growth factor 23 (FGF23), high sensitivity C-reactive protein (hsCRP) and asymmetric dimethylarginine (ADMA). We assessed all cause mortality before reaching dialysis and dialysis dependence at 3 yrs in 3 groups of CKD patients: those with diabetes (DM) n=672, glomerulonephritis (GN) n=275 and polycystic kidney/tubulointerstitial disease (PCKD/PI) n=222.

Results: The mean age (yrs) DM, GN, PCKD/PI was: 68, 58, 63. The mean eGFR (ml/min/1.73m^2) DM, GN, PCKD/PI was: 27.6, 27.3, 27.1. Overall 173 (14.8%) died: most in DM n=124 (18.3%), then PCKD/PI=28 (12.6%) and GN=21 (7.6%). Different panels of BM were associated with DBD in each group: DM with NT-proBNP and ADMA, GN with FGF23 and troponin and PCKD/PI with ADMA and hsCRP.

Parameter	Diabetic Nephropathy HR	95% C.I.		P value	GN HR	95% C.I.		P value	PCKD/PI HR	95% C.I.		P value
Age, per 5 yrs	1.321	1.188	1.469	<.0001	1.214	1.006	1.464	0.0434	1.672	1.292	2.163	<.0001
CVD history (Reference=No CVD)												
Ischemic	1.977	1.110	3.522	0.0207					3.769	1.360	10.446	0.0108
CHF	3.267	1.708	6.248	0.0003					0.897	0.115	7.022	0.9179
Ischemic+CHF	3.209	1.853	5.559	<.0001					3.197	1.036	9.869	0.0432
Albumin per 1 g/L	0.915	0.878	0.952	<.0001								
Hemoglobin per 1 g/L									0.961	0.936	0.988	0.0042
Cystatin C per 100 ng/mL	1.059	1.025	1.095	0.0006								
ADMA per 0.1 µM	1.300	1.098	1.540	0.0024					1.328	1.187	1.485	<.0001
logProBNP pg/mL	1.396	1.178	1.654	0.0001								
Troponin I (> LDL)					3.562	1.334	9.513	0.0113				
log TGFβ1 pg/mL					0.271	0.080	0.923	0.0368				
log FGF-23 RU/mL					2.065	1.100	3.878	0.0241				
log CRP mg/L									1.864	1.284	2.705	0.001

Conclusions: The risk of DBD is high, particularly in DM. BM can be used to identify patients at higher risk of DBD. BM profile differs between distinct CKD etiologies consistent with different pathological processes which may underlie DBD. Future studies should validate these findings in other cohorts and then test interventions aimed at addressing pathological processes.

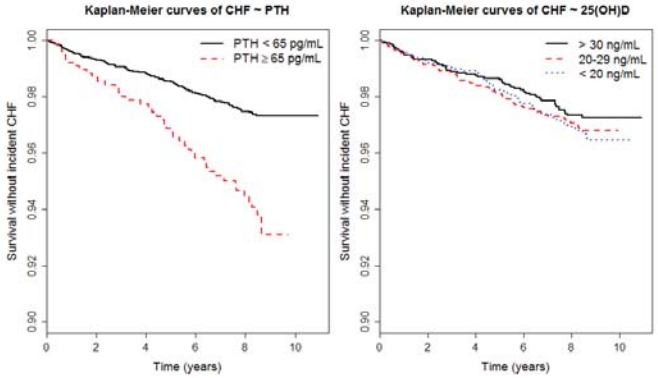
Parathyroid Hormone and 25-Hydroxyvitamin D Concentrations and Risk of Incident Heart Failure: The MESA Study

Leila R. Zelnick,[1] Ian H. de Boer,[1] Cassianne Robinson-Cohen,[1] Andrew N. Hoofnagle,[1] Joachim H. Ix,[2] Abigail Shoben,[4] Carmen A. Peralta,[5] David Siscovick,[1] Bryan R. Kestenbaum,[1] Nisha Bansal.[1] *[1]Univ of Washington; [2]Univ of California, San Diego; [3]Johns Hopkins Univ; [4]Ohio State Univ; [5]Univ of California, San Francisco.*

Background: Heart failure (HF) is common and associated with high mortality. Parathyroid hormone (PTH) and insufficient 25-hydroxyvitamin D (25[OH]D) may promote increased left ventricular mass (LVM) and clinical HF.

Methods: We tested associations of baseline PTH and mean annual 25(OH)D concentrations with incident HF events among 6,459 participants, and with LVM among 4,763 participants without prevalent cardiovascular disease in the Multi-Ethnic Study of Atherosclerosis (MESA). HF events were physician-adjudicated. LVM was measured by cardiac MRI at baseline, concurrent with PTH and 25(OH)D. Cox proportional hazard and linear regression models were used to test associations of PTH and 25(OH)D with incident HF and LVM, respectively.

Results: Mean age was 62 years and 53% were female. There were 180 incident HF events over a median (IQR) follow-up time of 8.5 (7.7-8.6) years. Participants with higher PTH and lower 25(OH)D had higher unadjusted rates of incident HF.



Compared with participants with PTH<65 pg/mL, PTH>65 pg/mL was associated with a 50% greater risk of incident HF (95% CI: 3-219%) and a 5.3 gram higher left ventricular mass (95% CI: 2.6,7.9) in models adjusted for demographics, physical exam measures, comorbidity, kidney function and other mineral metabolism markers. In contrast, there was no association of 25(OH)D with risk of incident HF or elevated LVM.

Conclusions: In a racially/ethnically diverse population without prevalent cardiovascular disease, higher serum PTH concentration was associated with increased LVM and increased risk of incident HF. PTH excess may be a modifiable risk factor for HF.

TH-OR056

Diet and Major Renal Outcomes: The NIH-AARP Diet and Health Study

Andrew Smyth,[1,2,3] Michelle Canavan,[1] Matthew D. Griffin,[2] Martin O'donnell.[1] *[1]HRB Clinical Research Facility Galway, National Univ of Ireland Galway, Galway, Ireland; [2]Nephrology, Galway Univ Hospitals, Galway, Ireland; [3]Nephrology, McMaster Univ, Hamilton, ON, Canada.*

Background: Chronic kidney disease (CKD) affects 14% of the U.S. population and >400,000 people require dialysis. These patients are at increased risk of morbidity and mortality. Diet modification may be a low-cost, simple intervention that could reduce the burden of CKD. To evaluate the association between diet quality, sodium and potassium intake and major renal outcomes (death from renal cause or dialysis).

Methods: Participants from the National Institutes of Health-AARP Diet and Health Study completed a food frequency questionnaire, used to assess diet quality (Healthy Eating

Index (HEI), Alternate Healthy Eating Index (AHEI), Mediterranean Diet Score (MDS) and Recommended Food Score (RFS)), sodium and potassium intake. Participants on dialysis at baseline were excluded. Multivariable adjusted competing risks regression was used to calculate sub-hazard ratios (sHR) for a composite outcome of renal death (based on ICD coding) and self-reported dialysis, with non-renal death as the competing event.

Results: Of 544,635 included participants, 1,879 died from renal disease, 963 reported dialysis and the composite occurred in 2,757. Compared to the lowest quality diet (quintile 1), the highest quintile of HEI (sHR 0.83 (95% CI 0.72-0.98)), AHEI (sHR 0.77 (95% CI 0.68-0.88)) and MDS (sHR 0.84 (95% CI 0.71-0.99)) were associated with a reduced hazard of the composite. There was no significant association with RFS. The highest quintile of sodium:potassium ratio (sHR 1.19 (95% CI 1.05-1.36 versus lowest quintile)) was associated with an increased hazard.

Conclusions: Our findings support an association between healthy dietary patterns, including a diet lower in sodium and higher in potassium intake, and reduced risk of major renal outcomes.

Sickle Cell Trait and Chronic Kidney Disease and Albuminuria in African-Americans V. K. Derebail,[1,5] R. Naik,[2,5] M. Grams,[2,5] Nora Franceschini,[1,5] Bessie A. Young,[3,5] A. V. Kshirsagar,[1,5] James G. Wilson,[4,5] Alex Reiner.[3,5] *[1]UNC; [2]Johns Hopkins; [3]Univ of Washington; [4]Univ of Mississippi; [5]On Behalf of SCT-CKD Working Group.*

Background: Renal abnormalities are common among individuals with sickle cell trait (SCT) but historically considered benign. Large studies in well-characterized population-based cohorts investigating the relationship between SCT and chronic kidney disease (CKD) have not yet been performed.

Methods: We examined the association of SCT and CKD among self-identified African-Americans from five large population cohorts: the Atherosclerosis Risk in Communities Study (ARIC), Jackson Heart Study (JHS), Coronary Artery Risk Development in Young Adults (CARDIA), Multi-Ethnic Study of Atherosclerosis (MESA), and Women's Health Initiative (WHI). Exposure status was determined by custom genotyping, whole exome sequencing or genetic imputation. Primary outcomes were prevalent and incident CKD (eGFR<60ml/min/1.73m^2), prevalent albuminuria (spot urine albumin-creatinine ratio >30mg/g or albumin excretion rate >30mg/24 hours), and rapid decline in eGFR (decrease of >3ml/min/1.73m^2 per year). Effect sizes were calculated separately for each cohort and subsequently meta-analyzed using a random effects model.

Results: A total of 15,959 African-Americans (7.9% with SCT) were included from the five cohorts. Final regression models adjusted for age, sex, clinic/region, African genetic ancestry, diabetes and hypertension. In pooled meta-analysis, individuals with SCT had increased risk of prevalent CKD (odds ratio 1.56, p<0.001), incident CKD (odds ratio 1.78, p<0.001), and rapid decline in eGFR (odds ratio 1.30, p=0.013) compared to non-carriers. SCT was also associated with albuminuria (odds ratio 1.85, p<0.001). Similar associations were noted in each individual cohort. No interaction between SCT and diabetes or hypertension was noted. *APOL1* status (available in ARIC and JHS) did not influence the association between SCT and CKD or albuminuria.

Conclusions: Sickle cell trait is consistently and strongly associated with an increased risk of CKD, rapid eGFR decline, and albuminuria. Our findings demonstrate that sickle cell trait may contribute to the higher risk of kidney disease in African-Americans.

TH-OR058

The *UMOD* Locus Shows Signature of Pathogen Adaptation through Human Evolution Olivier Devuyst,[1] Linda Pattini,[2] Guido Barbujani,[3] Luca Rampoldi.[4] *[1]Physiology, UZH, Zurich, Switzerland; [2]Politecnico di Milano, Milan, Italy; [3]Univ of Ferrara, Ferrara, Italy; [4]San Raffaele Scientific Inst, Milan, Italy.*

Background: Variants in the *UMOD* gene encoding uromodulin have been associated with the risk of developing hypertension and CKD in the general population. Lead variants from association studies map in the same linkage disequilibrium block in the *UMOD* promoter. The *UMOD* risk variants directly increase uromodulin expression *in vitro* and *in vivo*, causing salt-sensitive hypertension and renal lesions. The unusually high frequency of *UMOD* risk variants (about 80% in Europeans), combined with strong biological activity, suggested the action of some sort of selective pressure.

Methods: In order to test this hypothesis, we investigated the frequency of the allelic variants of the lead SNP rs4293393 of *UMOD* in modern and ancient human genomes and in available non-human primate genomes.

Results: The risk T allele had high allelic frequency in nearly all the populations present in Human Genome Diversity Project (HGDP), with few exceptions in populations from equatorial Africa and South America. The major, T allele was the one present in macaque, gorilla, orang-utan and gibbon genomes, suggesting that it is the ancestral one. Noteworthy, the rare, protective C variant was identified in the high-coverage genomes of Denisovans and Neandertals, from whom present-day humans diverged 550,000 to 750,000 years ago. We also correlated patterns of allele frequencies of a large sample of SNPs from the 52 human populations in HGDP to a set of environmental variables including climate, diet regimen and pathogens. Interestingly, the *UMOD* locus was significantly correlated with pathogen diversity (bacteria and helminths), but not with diet nor climatic conditions.

Conclusions: These data suggest pathogen-driven selection in the *UMOD* locus. Since uromodulin is known to interact with uropathogen bacteria and to modulate innate immunity, we speculate that *UMOD* variants associated with increased uromodulin expression and urinary excretion would confer selective advantage by enhancing antimicrobial and immunoregulatory activity. In turn, that might account for the current high frequencies of the *UMOD* risk allele.

TH-OR059

A Novel Locus for Blood Pressure Identified in GWAS of U.S. Hispanics Nora Franceschini,[1] Mariaelisa Graff,[1] Christina Wassel,[2] Myriam Fornage,[3] Ran Tao,[1] Cara Carty,[4] Stephanie Rosse,[4] Girish N. Nadkarni,[5] Eli A. Stahl,[5] Erwin P. Bottinger,[5] Charles Kooperberg.[4] *[1]Univ of North Carolina, Chapel Hill, NC; [2]Univ of Pittsburgh, Pittsburgh, PA; [3]Univ of Texas Health Sciences Center, Houston, TX; [4]Fred Hutchison Research Cancer Center, Seattle, WA; [5]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Genome wide association studies identified over 55 loci for blood pressure (BP) and hypertension risk in populations. These studies did not include Hispanics, the fastest growing U.S minority who also has low rates of hypertension control. By leveraging the population admixture in Hispanics, we sought to identify novel loci for BP traits.

Methods: We tested the association of 161,098 metabochip array single nucleotide polymorphism (SNPs) with BP traits using genotyped or 1000 Genomes imputed data from three Hispanic studies (19,744 participants, aged 18 or older). We added 10 and 5 mmHg to systolic and diastolic BP for individuals using BP medications. Each study performed linear regression or mixed models assuming an additive genetic model, adjusted for age, sex, body mass index and population stratification. Results were combined using meta-analysis. A p-value <2.8 x 10^{-7} was considered significant based on multiple testing.

Results: We identified associations of SNPs with BP traits in three loci, including one novel region. An intronic variant at the *KCNK3* gene (rs2586886, minor allele frequency=0.32) was significantly associated with increased diastolic BP (p=5.8 x 10^{-9}). The encoded protein is a potassium channel associated with primary aldosteronism in double knockout mice of the *kcnk3/kcnk9* genes. Additional significantly associated SNPs were located at *FGF5* (systolic and diastolic BPs, p=1.8 x 10^{-10}) and *SHB2B3* (diastolic BP, p=1.2 x 10^{-8}), both known BP loci. At the *FGF5* locus, there was evidence for two independent signals.

Conclusions: We identified a novel locus for BP in Hispanics which has strong biological support, replicated two known BP loci and provided evidence for independent signals at *FGF5*. Our findings support the advantages of using diverse ancestry for gene discovery of BP traits.

TH-OR060

Functional Annotation of SNPs Associated with Chronic Kidney Disease Yi-An Ko, Nora Ledo, Pazit Beckerman, Katalin Susztak. *Renal Electrolyte and Hypertension Div, Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA.*

Background: Genetic variants associated with chronic kidney disease (CKD) are localized to the non-coding regions of the genome. We hypothesize CKD associated SNPs localize to kidney specific gene regulatory regions (promoters, enhancers), alter transcription factor binding sites (TFBSs), and influence target transcript expression. Cell type specific gene regulatory regions can be identified by specific histone tail modifications. In addition, these regions show increased interspecies sequence conservation.

Methods: 1. To identify regulatory elements in human kidney, we performed chromatin immunoprecipitation and whole genome sequencing using histone tail modification antibodies (including H3K4me1, H3K4me3, H3K36me3, H3K27ac, and H3K27me3). 2. We develop an algorithm, HST-rank, to rank sequences by histone tail aided regulatory region annotation, sequence conservation, and TFBSs. 3. To validate regulatory elements, we perform lineage tracing by cloning regulatory sequences to zebrafish with EGFP tagged pronephos. 4. To identify genes regulated by specific genetic variation, we generate an atlas of kidney expression quantitative trait loci. We correlate genetic polymorphism with gene expression based on RNAseq of human kidneys.

Results: 1. We generated the first human kidney gene regulatory maps. These maps identify promoters, enhancers and transcribed regions, and can predict outcome after transcription factor binding. 2. Using HST-rank, we found targets including rs1010117, which is located near the cystatin gene family cluster on chromosome 20. It locates at kidney specific enhancers, shows open chromatin structure properties, and displays sequence conservation. 3. We identified target genes regulated by genetic variation using *cis*-eQTL. Target sequences and genes are validated in zebrafish.

Conclusions: CKD SNPs are enriched in the kidney specific regulatory regions, especially in the enhancers. We develop HST-rank to prioritize variants found in GWAS and examine predicted regions in a living organism. We identified and tested kidney specific gene targets in zebrafish kidney reporter lines.

TH-OR061

Rare Mutations Associating with Serum Creatinine and Chronic Kidney Disease Runolfur Palsson,[1,2] Olafur S. Indridason,[1] Gardar Sveinbjornsson,[3] Evgenia K. Mikaelsdottir,[3] Hilma Hólm,[3] Daniel Gudbjartsson.[3] *[1]Div of Nephrology, Landspitali - The National Univ Hospital of Iceland; [2]Faculty of Medicine, Univ of Iceland; [3]DeCODE genetics, Reykjavik, Iceland.*

Background: Chronic kidney disease (CKD) is a complex disorder with a strong genetic component. While a number of common sequence variants have been found to associate with serum creatinine (SCr), estimated glomerular filtration rate (eGFR) and/or CKD, these variants explain less than 1% of the variation in SCr and CKD. The objective of this study was to find rare sequence variants that associate with SCr and CKD.

Methods: Sequence variants identified by whole-genome sequencing of 2,230 Icelanders were imputed into 81,656 chip-typed individuals and 112,630 relatives of genotyped subjects. The subjects were older than 18 years and had a median of 4 (range, 1-645) SCr measurements available. A genome-wide association study was conducted on this sample of 194,286 subjects, testing 24 million single nucleotide polymorphisms (SNPs) and insertions/deletions (indels) for association with SCr. Novel variants associating with SCr were tested for association with CKD defined as eGFR <60 mL/min/1.73 m^2 for more than 3 months duration.

Results: In addition to replicating 15 established loci, we discovered missense and loss of function variants associating with SCr in 3 solute carriers (SLC25A45, SLC47A1, SLC6A19) and 2 E3 ubiquitin ligases (RNF128, RNF186). All these 5 variants are coding variants, 4 of which are rare (minor allele frequency <2%). We tested the 5 variants for association with CKD in a sample of 15,594 cases and 291,428 controls from Iceland. Three of the variants also associated with CKD (P <0.05/5 = 0.01). These rare variants have a greater impact on SCr than previously reported common variants, with a maximum effect of 0.069 SD.

Conclusions: Our findings have revealed novel rare sequence variants that associate with SCr and CKD. All of the variants are predicted to alter an encoded protein, potentially affecting kidney function or creatinine synthesis and excretion.

GWAS Results in the PediGFR Consortium Identifies Six Genomic Loci Associated with GFR and Proteinuria Matthias Wuttke,[1] Craig S. Wong,[2] Elke Wuehl,[3] Bradley A. Warady,[2] Anke Doyon,[3] Betul B.S. Sozeri,[4] Daniela Kracht,[5] Anette Melk,[5] Uwe Querfeld,[6] Tom D. Blydt-Hansen,[7] Susan L. Furth,[2] Franz S. Schaefer,[3] Anna Kottgen.[1] *[1]Univ Medical Center, Freiburg, Germany; [2]Univ of New Mexico Children's Hospital, Albuquerque; [3]Univ Medical Center, Heidelberg, Germany; [4]Ege Univ Faculty of Medicine, Izmir, Turkey; [5]Medizinische Hochschule, Hannover, Germany; [6]Charite Univ Hospital, Berlin, Germany; [7]Univ of Manitoba, Canada.*

Background: The international PediGFR Consortium is aimed at the identification of genetic factors associated with kidney function decline in children with chronic kidney disease (CKD). We performed genome-wide association studies (GWAS) to find genetic variants associated with eGFR and proteinuria in children with CKD using cross-sectional data at the PediGFR enrollment visit.

Methods: The Illumina Omni2.5 chip was used to genotype ~2.5 million SNP markers among 1450 participants of the CKiD, ESCAPE and 4C studies. The data was cleaned and divided by parent study and ancestry into six separate study populations, followed by imputation using 1000 Genomes Project reference data, resulting in ~10 million high-quality SNPs per patient. We performed GWAS for GFR estimated from serum creatinine, as well as an analysis of the presence of proteinuria (defined as UACR <0.3 g/g or UPCR <0.5 g/g) among children with CKD. A fixed-effects inverse-variants weighted meta-analysis was used to combine the association results.

Results: After filtering for minor allele frequency >5%, one SNP was associated with eGFR with $p<10^{-6}$ near *NYAP2* and 5 SNPs associated with proteinuria at $p<10^{-5}$ in or near *ARSB*, *FAM151B*, *SAMD3*, *MIR4493* and *RSL24D1*. Findings were consistent in the individual subgroups and for association with alternative measures of GFR. In addition, we detected association signals at previously published kidney disease risk loci from population-based studies such as for *SHROOM3* (p-value=$4.0*10^{-5}$ for the best SNP in the PediGFR data).

Conclusions: We identified 6 potential new loci associated with eGFR and proteinuria in children with CKD. Because of the lack of suitable replication cohorts, external experimental validation of our findings is currently sought.

TH-OR063

Characterization of *HLA-DQA1* and *PLA2R1* Risk Alleles across the Spectrum of Chronic Kidney Disease Etiologies Peggy Sekula,[1] Yong Li,[1] Matthias Wuttke,[1] Robert Kleta,[3] Florian Kronenberg,[4] Kai-Uwe Eckardt,[2] Anna Kottgen.[1] *[1]Univ of Freiburg, Germany; [2]Univ of Erlangen, Germany; [3]Univ College London, United Kingdom; [4]Innsbruck Medical Univ, Austria.*

Background: Genetic variants in *HLA-DQA1* and *PLA2R1* show strong and reproducible associations with membranous nephropathy (MN). We aimed to investigate if the conferred risk extends to additional etiologies of chronic kidney disease (CKD).

Methods: We genotyped rs17830558 in *PLA2R1* and rs9272729 in *HLA-DQA1* in 4,960 patients with CKD from different etiologies enrolled in the German Chronic Kidney Disease (GCKD) study. These patients of European ancestry had estimated glomerular filtration rate (GFR) of 30-60 ml/min/1.73m^2 or eGFR >60 and albumin to creatinine ratio >300 mg/g. Genotypes of 379 European ancestry samples from the 1000 Genomes project were used for comparison.

Results: After correction for multiple testing, both variants were significantly (p<2.8E-03) associated with biopsy-proven MN; odds ratios were comparable to previous estimates. While the association between rs17830558 in *PLA2R1* was specific to MN among 18 CKD etiologies studied, rs9272729 in *HLA-DQA1* conferred susceptibility to additional CKD etiologies, including nephropathy in type I diabetes, FSGS, and lupus nephritis, but not type II diabetes or IgA nephropathy.

odds ratio (95% confidence interval, p-value [*significant])	rs17830558 (*PLA2R1*) coded allele frequency T: 0.46	rs9272729 (*HLA-DQA1*) coded allele frequency A: 0.12
MN, n=137	1.63 (1.23-2.15, 5E-04)*	6.86 (4.55-10.3, 6E-24)*
type I diabetic nephropathy, n=89	0.76 (0.55-1.05, 9E-02)	2.69 (1.67-4.34, 7E-05)*
type II diabetic nephropathy, n=649	0.89 (0.74-1.07, 2E-01)	1.38 (1.02-1.87, 3E-02)
focal-segmental glomerulosclerosis, n=141	0.86 (0.66-1.13, 3E-01)	2.39 (1.58-3.60, 4E-05)*
lupus nephritis, n=125	1.14 (0.87-1.49, 3E-01)	3.23 (2.13-4.89, 3E-08)*
IgA nephropathy, n=362	1.03 (0.84-1.25, 8E-01)	1.17 (0.83-1.64, 4E-01)

Conclusions: MN risk variants in *HLA-DQA1* also show associations with additional CKD etiologies, particularly autoimmune diseases, while variants in *PLA2R1* are specific to MN. Our results strengthen the concept of a shared genetic component of some but not all autoimmune kidney diseases.

TH-OR064

Genome Wide Exome Array Analysis Identifies *HLA-DQA1* and *PLCG2* as Risk Loci for Childhood Onset Steroid Sensitive Nephrotic Syndrome Rasheed A. Gbadegesin, Adebowale A. Adeyemo, Nicholas J. Webb, Larry A. Greenbaum, Asiri S. Abeyagunawardena, Shenal Thalgahagoda, Debbie S. Gipson, Arundhati S. Kale, Tarak Srivastava, Jen-Jar Lin, Deepa H. Chand, Tracy E. Hunley, Patrick D. Brophy, Arvind Bagga, Michelle N. Rheault, Elizabeth C. Abraham, Halima S. Janjua, Abiodun A. Omoloja, Gina-Marie Barletta, William E. Smoyer, Gentzon Hall, Shashi K. Nagaraj, Delbert R. Wigfall, John W. Foreman, Michelle P. Winn. *Pediatrics, Medicine and DIMP, Duke Univ, Durham, NC.*

Background: Steroid sensitive nephrotic syndrome (SSNS) accounts for over 80% of cases of nephrotic syndrome in childhood. However, its etiology and pathogenesis remain obscure. Hypothesizing that coding variation may underlie SSNS risk; we have conducted an exome array based genome wide association study of SSNS.

Methods: We enrolled a discovery set of 363 subjects (214 South Asian children with SSNS and 149 controls) and genotyped them using the Illumina HumanExome Beadchip. SNPs at or near genome wide significance ($p < 2.5 X10^{-6}$, the Bonferroni adjusted p value for the number of genes in the human genome) were genotyped in subjects of White European ancestry.

Results: Four common SNPs in *HLA-DQA1 and HLA-DQB1* (rs1129740, rs9273349, rs1071630, rs1140343) were associated with SSNS with genome wide significance: OR 2.11 (SE 0.16), $p=1.19 X 10^{-6}$. Two of these SNPs, the missense variants C34Y (rs1129740) and F41S (rs1071630) in *HLA-DQA1*, were replicated in an independent cohort of children with SSNS of White European ancestry (100 cases and up to 589 controls) with a $p= 1.83 X10^{-17}$. Rare variant gene set based analysis demonstrated that missense variants in PLCG2 were most strongly associated with SSNS ($p=7.825X10^{-5}$).The protein encoded by *PLCG2* is involved in adaptive immunity, and is involved in B cell receptor signaling and T cell receptor signal transduction.

Conclusions: This is the first genome-wide study to identify *HLA-DQA1* and *PLCG2* missense coding variants as risk factors for SSNS. The finding of a MHC class II locus underlying SSNS risk points to a major role for immune response in the pathogenesis of SSNS.

Targeted Sequencing of MHC Region and Immune Related Genes in Han Chinese Identifies Independent Variants Associated with Lupus Nephritis Ricong Xu,[1,2] Qibin Li,[3] Yingrui Li,[3] Zhijian Li,[1,2] Peiran Yin,[1,2] Xueqing Yu.[1,2] *[1]Dept of Nephrology, The First Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Guangdong Provincial Key Laboratory of Nephrology, Ministry of Health, Guangzhou, Guangdong, China; [3]BGI-Shenzhen, Shenzhen, China.*

Background: Lupus nephritis (LN) is a common complication (15-55%) and fatal target-organ damage of SLE. Previous genetic studies had identified numerous variants for SLE, however, the genetic background of LN is less well known. In this study, we aim to

identify novel variants especially low frequency and functional variants in MHC region and immune related genes that contribute to the pathogenesis of LN using targeted sequencing.

Methods: We employed targeted capture and next generation sequencing (NGS) of the whole MHC region and the protein-coding sequence of 697 known immune related genes for 1331 patients with biopsy-proven LN and 1296 controls. Read mapping, SNP detection, genotype calling, and SNP annotation were performed using public software and database. The canonical HLA alleles were typed using sequencing data. After stringent quality control, we performed single marker association tests for common variants, alleles and amino acid of HLA genes and various burden tests for rare variants. Top associations will be validated in an independent cohort comprised of 2000 samples by amplicon sequencing (Warfergene).

Results: 24 SNPs (5 missense, 3 low frequency) within 20 immune related genes in non-MHC region showed significant associations with LN, including 7 SLE GWAS genes (TNFAIP3, BANK1, STAT4, GTF2IRD1, SLC15A4, SELE, NFKBIA) and 13 newly identified candidate genes, most of them were involved in the IFN-α signaling pathway, cell apoptosis, lymphocytes proliferation and adhesion. We also found 9 independent signals in MHC region showed significant associations, including one low frequency missense variant within a newly identified gene.

Conclusions: The results of study show that targeted sequencing is an efficient approach to identify gene mutations, including low frequency and novel variants for LN. Previously reported variants in SLE are also successfully verified in this study.

TH-OR066

Identification and Validation of New Risk Genes in European-American Population by Exome-Sequencing and RNAi-Based Mouse Model for Focal Segmental Glomerulosclerosis Haiyang Yu,[1] Cheryl Ann Winkler,[2] Jeffrey B. Kopp,[3] Andrey S. Shaw.[1] *[1]Pathology and Immunology, HHMI, Washington Univ School of Medicine, St. Louis, MO; [2]Molecular Genetic Epidemiology Studies Section, National Cancer Inst, Frederick, MD; [3]Kidney Disease Section, NIDDK, National Inst of Health, Bethesda, MD.*

Background: The evidence that Focal Segmental Glomerulosclerosis (FSGS) is a genetic disease has been accumulated in the past decade. However, the genetic causes of sporadic FSGS are still unknown. We identified rare variants that may contribute to the pathogenesis of FSGS by exome-sequencing in European American population. The top candidate genes were further validated by an RNAi-based FSGS mouse model.

Methods: We sequenced 3000 genes in 178 FSGS patients and 384 controls. Common variants were analyzed by Fisher's exact test. Rare variants were analyzed by burden test, varable threshold test and C-alpha test. The top 4 candidate genes were knocked down in podocytes in vivo by a doxycycline-inducible RNAi mouse model. The Albumin/creatinine ratio was calculated for each urine samples to examine the proteinuria. High Albumin/creatinine ratio is used as an early sign of FSGS. The kidneys of proteinuric mice were subjected to histological and electron microscopic analysis.

Results: We identified rare variants in WNK4, ARHGEF17, DLG5, and several other genes that were significantly enriched in the patient population. Inducible podocyte specific RNAi mice were generated to validate whether the loss of function of these genes contribute to FSGS. We observed a proteinuric phenotype and foot process effacement in WNK4 and ARHGEF17 RNAi mice, but not DLG5 RNAi mice. We also identified a SNP in APOL1 gene in EA, rs73885319 (p. S342G) (OR=23.8, P<0.003), which belongs to the G1 allele.

Conclusions: Using exome-sequencing technology, we identified new risk genes and alleles for FSGS. We have validated that Arhgef17 and Wnk4 could contribute to the pathogenesis of FSGS by an inducible RNAi mouse model.

TH-OR067

Missense Mutation of the RhoGTPase Regulator FSGS11 Is a Cause of Autosomal Dominant FSGS Gentzon Hall,[1,2] Rasheed A. Gbadegesin,[1,2] Andrew F. Malone,[1,2] Paul J. Phelan,[1,2] Alison Homstad,[2] Guanghong Wu,[2] Thomas Lindsey,[4] Michelle P. Winn.[1,2] *[1]Nephrology, Duke Univ, Durham, NC; [2]Duke Molecular Physiology Inst, Duke Univ, Durham, NC.*

Background: FSGS is a disorder characterized by focal scarring of the glomerular capillary tuft, podocyte injury, nephrotic syndrome and rapid progression to ESKD. While idiopathic forms of the disorder predominate, insights into the molecular and genetic causes of inherited forms of FSGS have greatly enhanced our understanding of the pathogenic mechanisms of FSGS. We report the discovery of a novel heterozygous missense mutation of the RhoGTPase regulatory protein FSGS11 as the cause of autosomal dominant (AD) FSGS in a Northern European kindred from Canada (Family DUK6516).

Methods: We performed whole-exome sequencing (WES) on two affected members of Family DUK6516. All identified novel variants were confirmed by Sanger sequencing. Complimentary molecular genetic analyses were performed in conditionally immortalized human podocytes (CIHP) to evaluate the effects of gene knockdown on podocyte cytoskeletal dynamics and motility.

Results: We identified a novel heterozygous missense mutation (T369I) within a critical N-terminal protein:protein interaction domain of FSGS11 as the cause of AD FSGS in Family DUK6516. The mutation segregates with the disease in the family and was not found in 1600 control chromosomes. The change is conserved in evolution and is considered damaging by *in silico* simulation. We confirm the expression of FSGS11 in whole kidney and podocytes by RT-PCR and immunoblot analyses. We hypothesize that the T369I is a loss-of-function mutation and may cause FSGS by dysregulation of podocyte motility. To confirm this, we performed targeted gene knockdown of FSGS11 in CIHPs and demonstrated significantly impaired podocyte motility.

Conclusions: In summary, we report the identification of a novel heterozygous missense variant of the RhoGTPase regulatory protein FSGS11 as a new cause of AD FSGS in a Northern European kindred. FSGS11 is expressed in the kidney and podocytes and targeted gene knockdown significantly impaired basal podocyte motility *in vitro*.

Complement Activation Patterns in Atypical Hemolytic Uremic Syndrome (aHUS) During Acute Phase and in Remission Lambertus P.W.J. Van den Heuvel,[1,6,7] Elena Volokhina,[1] Thea J. Van der Velden,[1] Dineke Westra,[1] Nicole Van de Kar,[1] Tom Eirik Mollnes.[2,3,4,5] *[1]Dept of Pediatric Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Dept of Immunology, Oslo Univ Hospital, Norway; [3]K.G. Jebsen IRC, Univ of Oslo, Norway; [4]Research Laboratory, Nordland Hospital, Bodø, Norway; [5]Faculty of Health Sciences, Univ of Tromsø, Norway; [6]Dept of Laboratory Medicine, Radboud Univ Medical Center, Nijmegen, Netherlands; [7]Dept of Pediatrics, Univ Hospitals Leuven, Belgium.*

Background: Pathogenesis of aHUS is associated with (genetic) defects in the alternative complement pathway. Nevertheless, comprehensive evidence that the complement system in aHUS patients is more prone to activation is still lacking. Therefore, we performed a thorough analysis of complement activation both during the acute phase and in remission of this disease.

Methods: Complement activation patterns of the aHUS patients in acute phase (n=6) and in remission (n=11) were compared to those of healthy controls (n=19). Background levels of complement activation products C3b/c, C3bBbP and TCC were measured in EDTA plasma using ELISA. Efficiencies of the C3b/c, C3bBbP and TCC generation in serum during spontaneous activation in the fluid phase, as well as after triggering by zymosan, were analyzed using the same assays.

Results: Patients with acute aHUS showed elevated levels of C3b/c (P<0.01), C3bBbP (P<0.0001) and TCC (P<0.0001) in EDTA plasma, while values of patients in remission were normal. In a single aHUS patient with CFB mutation we showed normalization of complement activation during aHUS recovery. Serum samples from patients in remission showed normal *in vitro* patterns of complement activation both spontaneously and triggered by zymosan, and the kinetics of complement activation in the fluid phase were similar as for the healthy controls.

Conclusions: Our data indicate that aHUS patients showed significantly increased complement activation during acute phase of the disease but not in remission. The data have implications for interpretation of the complement analyses in aHUS patients and may have an impact on monitoring of these patients, particularly when using complement inhibition therapy.

TH-OR069

Identification of Distinct Dominant and Subdominant Humoral Epitopes within PLA2R1 in Primary Membranous Nephropathy Laurence H. Beck, Dana Sandor, Hong Ma, David J. Salant. *Medicine, Renal Section, Boston Univ Medical Center, Boston, MA.*

Background: Autoantibodies to the M-type phospholipase A2 receptor 1 (PLA2R1) are found in up to 80% of patients with primary membranous nephropathy (MN). PLA2R1 is a large transmembrane glycoprotein, consisting of an N-terminal cysteine-rich domain (CysR), a fibronectin-like type II domain, and eight C-type lectin-like domains (CTLD1-8) in its extracellular region. We sought to determine which domains contained epitopes reactive with autoantibodies in primary MN.

Methods: The following tagged constructs derived from human PLA2R1 were expressed in HEK293 cells: CysR, CTLD1, CTLD2, CTLD3, CTLD1-3, CTLD4-8, CysR-CTLD3, and CysR-CTLD8. Reactivity was assessed by Western blotting with human MN and control sera. Domain-specific antibodies were affinity purified and their specificity demonstrated by Western blotting.

Results: All constructs could be expressed in HEK293 cells, although the individual CTLD1, 2 and 3 domains were less efficiently expressed. 100% of MN sera (35/35) reacted with CysR alone, as well as with CysR-CTLD8 and with the full-length molecule. Approximately half the sera (17/35 and 19/35) reacted with CTLD1 or CTLD1-3, respectively. There was no reactivity detected with CTLD3 alone, and only 3% (1/35) reacted with CTLD2. 29/35 (83%) demonstrated reactivity with epitopes in the more C-terminal (CTLD4-8) region of the molecule. For an individual patient, reactivities to specific PLA2R1 domains appeared to disappear and reappear in unison during remission and relapse, respectively. There was no correlation noted between duration of disease and number of humoral epitopes recognized. Autoantibodies affinity purified on either a CysR or a CTLD1 column specifically recognized the domain against which they were purified.

Conclusions: There appears to be a dominant humoral epitope located in the CysR domain of human PLA2R1 that is recognized by 100% of patient samples. Additional (subdominant) epitopes exist within the CTLD4-8 region, in CTLD1, and in CTLD2. There was no evidence for progressive epitope spreading found in these samples collected after patients had presented to clinical attention.

Funding: NIDDK Support

TH-OR070

Phospholipase A_2 Receptor Autoantibodies and Renal Function in Patients with Primary Membranous Nephropathy Elion Hoxha,[1] Sigrid Harendza,[1] Hans O. Pinnschmidt,[2] Ulf Panzer,[1] Rolf A. Stahl.[1] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Institut für Medizinische Biometrie & Epidemiologie, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: Loss of renal function in patients with membranous nephropathy (MN) cannot be reliably predicted by laboratory or clinical markers at the time of diagnosis. Phospholipase A_2 receptor autoantibodies (PLA_2R-Ab) have been shown to be associated with changes in proteinuria. Their role in the development of renal function, however, is unclear.

Methods: In this prospective study we analysed the role of PLA_2R-Ab in predicting the decline of renal function in 118 consecutive PLA_2R-Ab positive patients with biopsy proven MN. The clinical endpoint was defined as increase of serum creatinine (Scr) by ≥25% and reaching a Scr ≥1.3 mg/dl.

Results: Patientswere divided in tertiles according to their PLA_2R-Ab at the time of inclusion in the study, which was 1.0±1.4 months after diagnosis of MN by renal biopsy. PLA_2R-Ab of patients in tertile 1 (low) ranged between 20-86 U/ml; in tertile 2 (medium) between 87-201 U/ml, and in tertile 3 (high) above 202 U/ml. At study start, serum creatinine levels and histologic changes (interstitial fibrosis, glomerular lesions, nephrosclerosis) were not different between patients of all three tertiles. Patients in tertile 3 had higher proteinuria than patients of tertile 1 (9.2±5.5g/24h versus 7.4±5.2g/24h; p=0.14). The clinical endpoint was reached in 69% of patients with high PLA_2R-Ab (tertile 3) but only 25% of patients with low PLA_2R-Ab (tertile 1). Patients with high PLA_2R-Ab reached the endpoint significantly faster than patients with low PLA_2R-Ab (17.7 months versus 30.9 months; p<0.001). A multivariate cox regression analysis using age, sex, total IgG PLA_2R-Ab, IgG4 PLA_2R-Ab, proteinuria, serum albumin, Scr, time between renal biopsy and measurement of PLA_2R-Ab, morphologic glomerular lesions, blood pressure and use of immunosuppressive treatment as explanatory variables showed that high PLA_2R-Ab are an independent predictor for progressive loss of renal function.

Conclusions: High PLA_2R-Ab are associated with progressive loss of renal function in patients with primary MN.

TH-OR071

Identification of Thrombospondin Type 1 Domain Containing 7A as a Novel Antigen in Idiopathic Membranous Nephropathy Nicola M. Tomas,[1] Laurence H. Beck,[2] Catherine Meyer-Schwesinger,[1] Barbara Seitz-Polski,[3] Hong Ma,[2] Gunther Zahner,[1] Guillaume Dolla,[3] Elion Hoxha,[1] Udo Martin Helmchen,[1] Michael Merchant,[4] Jon B. Klein,[4] David J. Salant,[2] Rolf A. Stahl,[1] Gerard J. Lambeau.[3] *[1]Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Boston Univ School of Medicine, Boston; [3]Inst of Molecular and Cellular Pharmacology, Valbonne, France; [4]Univ of Louisville, Louisville.*

Background: Idiopathic membranous nephropathy (iMN) is an autoimmune disease associated with autoantibodies against the phospholipase A2 receptor (PLA2R1) in approximately 70% of cases. Antigenic targets in the remaining cases have remained unidentified.

Methods: We screened sera from patients with iMN, other glomerular diseases, and healthy donors for antibodies against native glomerular proteins by Western blotting. We partially purified a potential new antigen, identified this protein via mass spectrometry, and validated the results with recombinant protein expression, immunoprecipitation and immunohistochemistry.

Results: Sera from 5 out of 35 patients with anti-PLA2R1 negative iMN recognized a glomerular protein of 250 kDa. None of the sera from iMN patients seropositive for anti-PLA2R1 (n=60), from patients with other glomerular diseases (n=76), and from healthy donors (n=44) were reactive against this antigen. While clearly different from PLA2R1, this novel antigen was found to share similar biochemical features, i.e. N-glycosylation, membranous location, and reactivity with sera only under non-reducing conditions. Mass spectrometry identified this new antigen as thrombospondin type 1 domain containing 7A (THSD7A). All reactive sera recognized recombinant THSD7A and immunoprecipitated THSD7A from glomerular lysates. Moreover, immunohistologic analyses of patient biopsies localized THSD7A to podocytes and IgG eluted from one of these biopsies was specific for THSD7A.

Conclusions: We have identified THSD7A as a novel target antigen in iMN, with 5 out of 95 iMN patients having circulating autoantibodies to THSD7A and not PLA2R1. This suggests that anti-THSD7A positive patients represent a distinct subgroup of iMN and that anti-THSD7A could be an additional biomarker for diagnosis and monitoring.

TH-OR072

Renal PLA_2R in Hepatitis B Virus-Associated Membranous Nephropathy Qionghong Xie, Yan Li, Chuanming Hao. *Div of Nephrology, Huashan Hospital, Fudan Univ.*

Background: Circulating anti-phospholipase A2 receptor antibody (PLA_2R-Ab) is reported to be a valuable biomarker for idiopathic membranous nephropathy (iMN). Patients with PLA_2R-antibody also exhibit strong positive staining for renal PLA_2R. The present study examined renal PLA2R expression in idiopathic and secondary MNs.

Methods: Patients with biopsy-proven MN, including iMN, hepatitis B virus-associated MN (HBV-MN) and type V lupus nephritis, were enrolled in the study. Circulating PLA_2R-Ab was detected by indirect immunofluorescence (IF), and renal PLA_2R was examined using a specific anti-PLA_2R antibody. For IF staining of paraffin-embedded sections, two antigen retrieval methods were used: autoclave heating at 120°C or microwave heating. Renal PLA_2R positivity was determined according to the microwave heating method.

Results: PLA_2R was detected along the capillary loop in 84% (86/102) of renal biopsies from patients with iMN but not in patients with any other primary glomerular diseases (n=40); In contrast, only 1 out of 38 (2.6%) of type V lupus nephritis patients showed renal PLA2R(+). Interestingly, in HBV-MN, 64% (25/39) showed PLA_2R(+). In PLA_2R(+) HBV-MN, renal PLA_2R staining overlaps with HBsAg and IgG_4 along the capillary loop. Importantly, in 6 HBV-MN patients with serum available, all (6/6) showed serum PLA2R-Ab(+). In the PLA_2R(-) kidneys, renal PLA_2R became detectable after antigen retrieval by autoclave heating, but exhibited a different pattern consistent with whole cell body expression in the podocyte. Serum PLA_2R-Ab was closely associated with renal PLA_2R positivity. Of the 41 iMN cases with both serum PLA_2R-Ab and renal biopsy PLA_2R data available, 24 were serum-positive for PLA_2R-Ab (59%). All of the serum PLA_2R-Ab(+) cases showed renal PLA_2R(+), while 9 of the 17 serum PLA_2R-Ab(-) cases also exhibited renal PLA_2R(+). However, all of the renal PLA_2R(-) patients were also negative for serum PLA_2R-Ab.

Conclusions: Renal PLA_2R(+) was common in iMN and HBV-MN, but rare in lupus-associated MN. Further studies examining the implication of this association of PLA_2R positivity and HBV-MN may shed light on mechanism underlying the pathogenesis of iMN or HBV-MN.

TH-OR073

Reassessment of suPAR in Kidney Disease Joann M. Spinale,[1] Laura H. Mariani,[2,3] Robert J. Weyant,[2] Peter X.K. Song,[4] Deepak Nihalani,[5] Lawrence B. Holzman.[5] *[1]Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA; [2]Arbor Research for Collaborative for Health, Ann Arbor, MI; [3]Nephrology, Univ of Michigan School of Medicine, Ann Arbor, MI; [4]Biostatistics, Univ of Michigan School of Medicine, Ann Arbor, MI; [5]Renal-Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia, PA.*

Background: Soluble urokinase receptor (suPAR) might be a causative circulating factor for FSGS and it might serve as an FSGS biomarker. We undertook validation of these conclusions in both mouse models and in human subjects.

Methods: In wild type mice, we performed intravenous injection of recombinant suPAR and observed mice for 24 h. We also created an inducible transgenic mouse model that maintained serum suPAR concentration at least four-fold above baseline for 6 weeks. Further, we studied 241 glomerular disease patients from the prospective, longitudinal multi-center observational NEPTUNE cohort: 95 patients had FSGS, 62 had minimal change disease (MCD), 52 had membranous nephropathy (MN) and 32 had IgA nephropathy (IGAN).

Results: Mice treated acutely or with prolonged exposure to suPAR did not develop proteinuria. In NEPTUNE cohorts, serum suPAR concentration at baseline was inversely correlated with eGFR (ρ = -0.57, P≤0.01) and urine suPAR/creatinine ratio was positively correlated with urine protein to creatinine ratio (ρ = -0.38, P ≤0.01). After adjusting for eGFR and urine protein, neither serum nor urine suPAR level were independent predictors of FSGS histopathology. Using longitudinal data, a multivariable mixed-effects model was fit to evaluate the association of change in serum suPAR concentration from baseline with eGFR. After adjusting for baseline suPAR concentration, age, sex, proteinuria and time, change in suPAR from baseline was associated with eGFR (p= 0.004), but this association was not different for FSGS patients as compared to those with MCD, MN or IgAN (interaction p-values 0.62, 0.81 and 0.30, respectively).

Conclusions: These results do not support a pathological role for suPAR in FSGS or suPAR's value as a biomarker of FSGS.

B7-1/CD80 Is Not a Reliable Immunophenotypical Marker of Focal Segmental Glomerulosclerosis, Membranous Glomerulonephritis, and Diabetic Nephropathy Zoltan G. Laszik,[1] Dejan Dobi,[1] Flavio Vincenti.[2] *[1]Dept of Pathology, Univ of California San Francisco, San Francisco, CA; [2]Transplant Service, Univ of California San Francisco, San Francisco, CA.*

Background: Induced expression of B7-1/CD80 in the podocytes has been recently reported in various glomerular diseases, including focal segmental glomerulosclerosis (FSGS), recurrent FSGS, membranous glomerulonephritis (MN), and diabetic nephropathy (DNP). To survey the potential of B7-1/CD80 podocyte expression as a diagnostic marker and possible therapeutic target we evaluated the immunohistochemical expression of B7-1/CD80 in native and transplant kidney biopsies with FSGS, MN, DNP, and new onset diabetes after transplantation (NODAT).

Methods: Consecutive renal biopsies were selected for the following study groups: FSGS (n=10), early post-transplant recurrent FSGS (n=10), MN (phospholipase A2 [PLA2] positive, n=5), MN (PLA2 negative, n=5), DNP (classes 1, 2b, and 3) (n=15), NODAT (6 month post-transplant protocol biopsies with normal morphology, n=10), and controls (6

month post-transplant protocol biopsies with normal morphology from patients with no diabetes [n=10], and minimal change disease [MCD] [n=5]). Double immunostains were performed for B7-1/CD80 and the podocyte marker synaptopodin on formalin-fixed paraffin-embedded and frozen tissues with standard immunoperoxidase and immunofluorescent methodology, respectively. Cutaneous T cell lymphoma served as method control for the B7-1/CD80 stain.

Results: One native FSGS biopsy showed weak focal podocyte staining with B7-1/CD80; all of the MN biopsies revealed strong B7-1/CD80 granular staining along the periphery of the glomerular capillary loops, however, the signal did not show apparent co-expression with synaptopodin. The rest of the biopsies showed no detectable B7-1/CD80 glomerular signal.

Conclusions: B7-1/CD80 immunostain has a limited value as an immunophenotypical marker in routine biopsy specimens with FSGS, recurrent FSGS, DNP, and NODAT. The B7-1/CD80 signal in MN might be attributed to nonspecific cross reactivity of the B7-1/CD80 antibody with immune complexes; alternatively, the signal can also reflect B7-1/CD80 accumulation in the immune deposits.

Biomarkers of Disease Pathobiology in Patients with Glomerulonephritis in the NEPTUNE Cohort Heather N. Reich,[1,6] Viji Nair,[2] Wenjun Ju,[2] David Cherney,[1] Marie C. Hogan,[3,6] John C. Lieske,[3,6] Sharon G. Adler,[4,6] Daniel C. Cattran,[1,6] Michelle A. Hladunewich,[1,6] James W. Scholey,[1] Peter J. Nelson,[5,6] Matthias Kretzler.[2,6] *[1]UHN, Univ of Toronto; [2]Univ of Michigan; [3]Mayo Clinic; [4]UCLA; [5]Univ Washington; [6]NEPTUNE Consortium.*

Background: Cytokines/chemokines (CC) contribute to disease immunopathogenesis and to local modulation of tissue injury and extracellular matrix (ECM) turnover in GN. Associations between urine and tissue expression of these mediators in patients with GN could identify non-invasive biomarkers of molecular and clinical response and facilitate development of novel personalized treatment strategies. The NEPTUNE cohort integrates multidimensional molecular and clinical data in patients with proteinuric GN, including biosamples obtained at the time of diagnostic kidney biopsy. We evaluated if urine expression of CC and mediators of ECM turnover reflects renal mRNA expression.

Methods: We used a multiplex platform to measure CC and MMP/TIMPs in serum and urine of 74 patients undergoing kidney biopsy. Results were correlated with microdissected renal biopsy microarray mRNA expression profiles. Serum and urine measures were performed in duplicate; analytes with <40% within-individual variation in >70% of samples were included. Urine analytes were adjusted for creatinine. Spearman correlation coefficients were calculated and FDR-adjusted pvalue <0.05 was considered significant.

Results: The urine expression of 10 CC/ECM proteins was highly correlated with tubulo-interstitial mRNA expression. These included inflammatory cytokines IL8 and MCP1, and mediators of ECM turnover MMP2 and TIMP1 (pvalue <0.05). Serum expression of most of the CC did not correlate with tissue expression, while expression of serum ECM turnover mediators paralleled tissue mRNA levels.

Conclusions: Non-invasive measures of a urine CC/ECM protein panel can be used to evaluate tissue molecular responses in GN. The source of these proteins –systemic or renal– requires further study. Use of a CC/ECM protein panel could allow design of targeted molecular therapies for proteinuric GN. Serial measurement of the analytes in the NEPTUNE cohort will permit longitudinal evaluation and correlation with clinical outcomes.

TNFSF13 Has a Key Role in Both the Susceptibility and Progression of IgA Nephropathy Seung Seok Han,[1] Nara Shin,[1] Seung Hee Yang,[2] Hajeong Lee,[1] Jung Pyo Lee,[3] Jae Hyun Chang,[4] Kwon Wook Joo,[1] Yon Su Kim,[1] Dong Ki Kim.[1] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Kidney Research Inst, Seoul National Univ, Seoul, Korea; [3]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea; [4]Internal Medicine, Gachon Univ of Medicine and Science, Incheon, Korea.*

Background: Tumor necrosis factor superfamily 13 (TNFSF13, also known as APRIL) has been found as a susceptibility gene in the genome-wide association study of IgA nephropathy. However, this issue is not fully established at least in Korean subjects, and the role of TNFSF13 in the progression of IgA nephropathy remains unresolved.

Methods: 634 patients with IgA nephropathy were recruited from major 4 hospitals. Two SNPs of TNFSF13 gene (rs3803800 and rs11552708) were evaluated and compared with the data on 1068 healthy controls. Furthermore, plasma TNFSF13 level at the time of diagnosis was measured using ELISA and compared with the data on 66 healthy volunteers. The times to end-stage renal disease or doubling serum creatinine were used as primary outcomes and the odds ratios (ORs) for outcomes were calculated according to the genetic polymorphisms or the quartiles of plasma TNFSF13 level.

Results: For rs3803800, the susceptibility of IgA nephropathy increased in AA homozygotes [OR, 1.4 (1.03–1.94)]. The serum IgA levels in patients with AA homozygotes were significantly higher than patients with AG or GG genotypes (Ps<0.05). For rs11552708, there was neither correlation with disease susceptibility nor the difference in serum IgA levels. Neither of two SNPs was associated with the risk of end-stage renal disease or doubling creatinine. However, plasma TNFSF13 levels had significant correlations with both outcomes: the 4th quartile had greater ORs for end-stage renal disease [8.9 (1.08–74.32)] and doubling of serum creatinine [4.6 (1.20–17.44)] compared with the 1st quartile. Patients with IgA nephropathy had greater plasma TNFSF13 levels compared with healthy volunteers (P<0.001).

Conclusions: The present study first demonstrates the relationships of TNFSF13 with both the susceptibility and progression of IgA nephropathy.

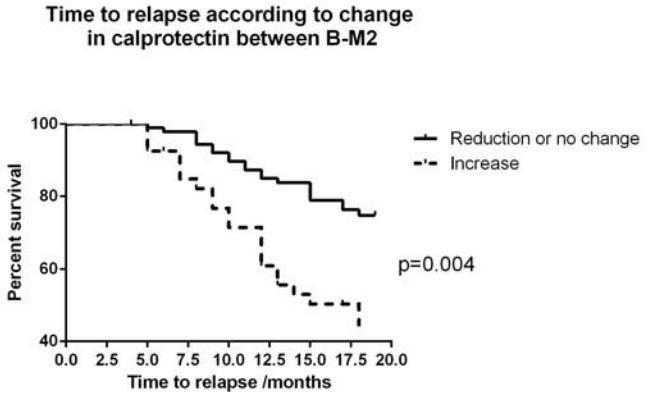
TH-OR077

Serum Calprotectin and Disease Relapse in ANCA-Associated Vasculitis Alan D. Salama,[1] Ruth J. Pepper,[1] Peter A. Merkel,[2,3] Juliana Bordignon Draibe.[1] *[1]Centre for Nephrology, UCL, United Kingdom; [2]Rheumatology, Univ Pennsylvania; [3]RAVE Investigators, RAVE-ITN Research Group.*

Background: In ANCA-associated vasculitis (AAV) disease relapses remain common but there are no reliable means to predict them. We previously showed serum calprotectin was elevated during active AAV and patients in the NORAM trial on treatment who relapsed had higher levels than non relapsers. We set out to validate calprotectin as a biomarker of relapse using samples from the Rituximab in ANCA-associated Vasculitis (RAVE) study.

Methods: Serum was obtained from 182 subjects from the RAVE trial at baseline (B), 1 month (m1), and 2 months (m2) following entry and evaluated by ELISA. Absolute calprotectin levels and changes from B to m1 and m2 were calculated and stratified according to disease relapse at 18 months.

Results: Serum levels of calprotectin were similar between relapsers (R) and non-relapsers (NR) at B and m1, but at m2, levels were significantly higher in relapsers (R median 4750 ng/ml, range 1364-26071 versus NR 3769 ng/ml, 1020-9964; p=0.04). There was no correlation between calprotectin and ANCA titer or CRP, and only weak correlation with white cell count (r=0.27, 0.3, 0.38, at B, m1, and m2 respectively, all p<0.0003). The percentage reduction in levels between m1 and m2 were significantly lower in R patients compared to NR patients (R +9.7% versus NR -9.8%; p=0.035) confirming that R patients failed to suppress calprotectin to the same extent as NR. Time to relapse was significantly faster in those patients with an increase in calprotectin between B and m2 or between m1 and m2, when compared to those in whom levels showed no change or reduction(p=0.0004 and p=0.04 respectively)



Conclusions: Failure to suppress calprotectin following induction AAV treatment is associated with greater and faster rates of disease relapse, now confirmed in two independent cohorts.

Timing of Arrhythmias with Dialysis Schedule: Preliminary Results of the Monitoring in Dialysis (MiD) Study Prabir Roy-Chaudhury,[1] Alexandru Ionel Costea,[1] James A. Tumlin,[2] Amber S. Podoll,[3] Don E. Williamson,[4] Suresh Chandra Tiwari,[5] Vikranth Reddy,[6] David M. Charytan.[7] *[1]U of Cincinnati and VAMC, Cincinnati; [2]U of Tennessee; [3]U of Texas; [4]Nephrology Associates, Augusta, GA; [5]Fortis Inst, New Delhi, India; [6]Care Hospital, Hyderabad, India; [7]Harvard U.*

Background: ESRD patients are at increased risk of arrhythmias and sudden cardiac death, but little is known about arrhythmia type, prevalence or relationship to dialysis schedule.

Methods: MiD is a prospective, multi-center study to characterize arrhythmias in 3x weekly hemodialysis (HD) patients over a 6-month period using an implantable cardiac monitoring device, Medtronic Reveal® XT. Recorded ECGs were centrally adjudicated, and the time of arrhythmia onset relative to each HD session was determined. Clinically significant arrhythmias (CSA) were defined as bradycardia ≤40 bpm for ≥6 seconds (s), asystole ≥3 s, sustained ventricular tachycardia ≥130 bpm for ≥30 s, and symptomatic arrhythmias.

Results: 45 implanted subjects were followed for a mean of 4.9 months [46% with prior history of arrhythmias]. 605 CSA occurred in 26 subjects (57.8%), a rate of 2.8 events per patient-month (ppm). 6,532 confirmed arrhythmias occurred in 39 subjects (86.7%), a rate of 27.2 events ppm. Arrhythmic risk (Figure) peaks during the 12 hour interval beginning with each HD session (especially after the end of dialysis), decreases for the next 12 hours, and then gradually increases over the remainder of the interdialytic interval; this pattern holds for sinus tachycardia, atrial and ventricular arrhythmias, but not for bradycardia.

Conclusions: Arrhythmias are frequent during HD and strongly associated with the HD schedule. Identification of HD session parameters that result in the CSA in particular, could potentially allow us to modify HD induced stressors and so reduce arrhythmias and improve patient safety in ESRD patients.

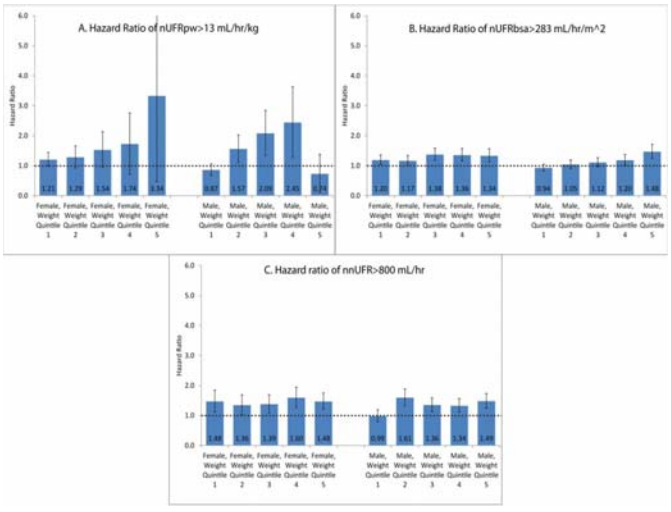
Body Size and Gender Dependent Differences in Mortality Risks Associated with Ultrafiltration Rates John W. Larkin,[1] Sheetal Chaudhuri,[1] Len A. Usvyat,[1] Paul Balter,[1] Peter Kotanko,[2] Franklin W. Maddux,[1] Eduardo K. Lacson.[1] *[1]Fresenius Medical Care North America (FMCNA); [2]Renal Research Inst.*

Background: Hemodialysis (HD) ultrafiltration rates (UFR)s normalized by body weight ($nUFR_{pw}$) >13mL/kg/hr have been suggested to be associated with poor survival by the CMS TEP, yet it is not known if $nUFR_{pw}$ is a one-size fits all quality metric in a population that varies in body size. We studied whether using $nUFR_{pw}$, UFR normalized by body surface area ($nUFR_{bsa}$), or non-normalized UFR (nnUFR) is associated with differing relative risks of death for gender and body size strata.

Methods: From Jan 1, 2010 to Jan 31, 2013, we studied all incident HD (iHD) Pts at FMCNA clinics. Mortality was tracked until May 1, 2013. Inclusion criteria were: 1) survived the first 90 days of HD and 2) no residual renal function (Kru<0.1mL/min) upon starting HD. Pts were dichotomized into groups of average UFR in the first 90 days as nnUFR >800mL/hr, $nUFR_{pw}$ >13mL/kg/hr and $nUFR_{bsa}$ >283mL/hr/m^2 versus groups below those thresholds. Pts were stratified by gender and quintiles of post HD weights. Cox proportional hazard models were used to assess survival after the first 90 days of HD.

Results: The cohort of 49,617 iHD Pts had mean age of 62.8±15.0 years, 54% male, 64% white, 16% Hispanic, 63% diabetic, mean albumin 3.56±0.45g/dL, and median survival follow-up of 304 (range 1-1,126) days. Risks for mortality varied greatly across different genders and weight quintiles in Pts above pre-defined thresholds of nnUFR, $nUFR_{pw}$, and $nUFR_{bsa}$.



Conclusions: Normalized and non-normalized UFRs are not one-size fits all metrics that uniformly predict survival irrespective of body size or gender. Recommendations to use UFR metrics as performance measures are premature and clinically inappropriate. More studies are needed to define and refine its utility as a population measure; individualized Pt management is prudent at this time.

Serum Filtration Markers to Estimate Native Kidney Urea Clearance (KrU) in Hemodialysis Patients Tariq Shafi,[1] Andrew S. Levey,[2] Friedo W. Dekker,[3] Lesley Inker,[2] Raymond T. Krediet,[4] Wieneke Michels,[4] Tiny Hoekstra,[3] Josef Coresh.[1] *[1]Johns Hopkins Univ; [2]Tufts Medical Center; [3]Leiden Univ Medical Center; [4]Academic Medical Center.*

Background: Residual kidney function can contribute substantially to solute clearance in hemodialysis patients but cannot be assessed without urine collection limiting its incorporation in dialysis dose. We hypothesized that serum filtration markers that are either not removed by dialysis [serum β-trace protein (BTP)] or partially removed [cystatin C (CYS), β2-microglobulin (B2M)], might allow estimation of KrU (eKrU) without urine collection.

Methods: We measured serum markers in the hemodialysis participants of the Netherlands Cooperative Study on the Adequacy of Dialysis (N=722) where KrU was measured (mKrU) by 24-hour inter-dialytic urine collection. We developed eKrU equations using linear regression in a training sub-sample (N=469) and then validated them in the remaining participants (N=253). We assessed the equations' performance by calculating median bias (mKrU-eKrU), precision (interquartile range of bias) and accuracy (eKrU within ±2ml/minof mKrU).

Results: Mean age of the participants was 61 years, 60% were male and 88% were white. mKrU was 2.8±2.1 ml/min. All eKrU models included sex and urine volume categorized at 250 ml/day (p<0.01 for both). In the validation dataset, all equations had a low bias. Precision and accuracy were higher with equations including BTP and B2M. Equation containing both BTP and B2M had the best performance.

Performance of eKrU Equations in the Validation Data						
	Urea	**Creatinine**	**BTP**	**B2M**	**CYS**	**BTP B2M**
Bias, ml/min	0.2 (0, 0.3)	0.1 (0, 0.2)	0.1 (0, 0.2)**	0.1 (-0.1, 0.2)**	0.1 (-0.1, 0.2)	0 (-0.1, 0.1)**
Precision, ml/min	1.7 (1.3 2.1)	1.6 (1.1, 2.1)	1.4 (1.2, 1.7)	1.2 (1.0, 1.5)	1.6 (1.2, 2.0)	1.1 (0.9, 1.3)
Accuracy, %	83 (78, 87)	81 (76, 86)	90 (86, 94)***	90 (86, 94)***	86 (81, 90)**	91 (87, 94)***
Compared with creatinine: *p<0.05; **p<0.01; ***p<0.001						

Conclusions: Serum filtration markers have the potential to allow estimation of eKrU in dialysis patients without urine collection.

Funding: NIDDK Support

TH-OR081

Low Predialysis Serum Sodium Modifies the Effect of Hemodialysis (HD) Frequency on Left Ventricular Mass: The Frequent Hemodialysis Network (FHN) Trial Jochen G. Raimann,[1] Christopher T. Chan,[2] John T. Daugirdas,[3] Thomas A. Depner,[4] Frank A. Gotch,[1] Tom Greene,[5] George A. Kaysen,[6] Alan S. Kliger,[7] Peter Kotanko,[1] Robert M. Lindsay,[8] Michael V. Rocco,[9] Glenn M. Chertow,[10] Nathan W. Levin,[1] The FHN Trial Group.[11] *[1]Renal Research Inst; [2]Univ Health Network Toronto; [3]Univ of Illinois College of Medicine; [4]Univ of California Davis; [5]Univ of Utah; [6]UC Davis, Nephrology; [7]Yale New Haven Health System; [8]London Health Sciences Centre; [9]Wake Forest School of Medicine; [10]Stanford Univ School of Medicine; [11]NIDDK, NIH.*

Background: The FHN Trials were designed to compare HD six versus three times per week. More frequent in-center HD significantly reduced left ventricular mass (LVM), an effect that was more pronounced in subjects with low baseline urine volumes. More frequent HD also reduced measures of interdialytic extracellular fluid volume and fluid overload. Patients receiving HD with low predialysis serum sodium concentrations (SNa) are at increased risk of mortality and cardiovascular events. We hypothesized that patients with lower SNa would have a more pronounced benefit of more frequent HD on LVM compared to patients with higher SNa.

Methods: The randomized treatment effect of frequency on LVM was compared in subgroups with baseline SNa≤138 versus >138 mEq/L. The interaction of treatment effect with SNa was tested using a mixed model adjusted for age, diabetes, facility and baseline LVM. Data presented as mean and corresponding 95% CI.

Results: In the in-center Daily Trial, the effect of frequent HD on LVM reduction was more pronounced in patients with lower baseline SNa (**Table**; Interaction P=0.03). In the at home Nocturnal Trial, change in LVM was nominally higher in patients with lower predialysis SNa, but the interaction was not statistically significant (**Table**; Interaction P=0.49).

Conclusions: The effect of frequent HD on LVM is more pronounced in patients with lower pre-dialysis SNa.

	Serum Sodium Concentration (SNa^+) [mEq/L]	LVM reduction (Month 12 – Baseline value)
Daily	≤ 138 mEq/L	**-27.98 (-40.54 to -15.41)**
	> 138 mEq/L	-1.97 (-15.45 to 11.50)
Nocturnal	≤ 138 mEq/L	-14.70 (-32.92 to 3.52)
	> 138 mEq/L	-7.54 (-24.77 to 9.68)

FSP-1/ROCK1 Signaling Contributes to Diabetes-Induced Neointima Formation in Arteriovenous Graft Jinlong Luo,[1] Ming Liang,[1] Farhad R. Danesh,[2] William E. Mitch,[1] Jizhong Cheng.[1] *[1]Nephrology Div, Baylor College of Medicine, Houston, TX; [2]Emergency Medicine, Univ of Texas MD Anderson Cancer Center, Houston, TX.*

Background: Diabetes-induced endothelial damage could be the initial event leading to arteriovenous graft (AVG) failure. We hypothesized that increased expression of fibroblast specific protein 1 (FSP-1) or ROCk1 in endothelial cells (ECs) triggers diabetes-induced AVG failure.

Methods: Diabetes was induced with streptozotocin (STZ). AVGs were created in wild type (WT), ROCK1 KO, and FSP-1 KO mice with or without diabetes. The underlying mechanism of endothelial damage in diabetes was investigated.

Results: We found that diabetes induces neointima formation in AVGs and this was accompanied by impaired endothelial barrier function and and increased inflammatory cells accumulation. Diabetes also led to significantly increased FSP-1 and ROCK1 expression in AVGs of diabetic mice compared to the expression in control mice. ECs treated with FSP-1 led to ROCK1 activation. FSP-1 treatment or expression of constitutive active ROCK1 decreased expression of junction molecules. Increased FSP-1 expression also induced endothelial permeability and trans-endothelial migration of inflammatory cells. These responses were suppressed by treatment of the ROCK1 inhibitor or by expression of dominant negative ROCK1 vector. Thus, FSP-1-induced endothelial dysfunction can be mediated through ROCK1 activation. To evaluate the function of ROCK1 or FSP-1 *in vivo*, AVGs were created in ROCK1 KO or FSP-1 KO mice. We found that a deficiency of FSP-1 decreased diabetes-induced ROCK1 expression and activation in the endothelium of AVGs. Indeed, FSP-1 KO exhibited decreased infiltration of inflammatory cells and suppressed neointima formation despite diabetes. Finally, ROCK1 KO improved endothelial barrier function and decreased neointima formation in AVGs.

Conclusions: Thus, diabetes induces endothelial dysfunction through activation of FSP-1/ROCK1 signaling. This response increases endothelial permeability which enhances infiltration of inflammatory cells, triggering neointima formation and AVG failure. Blocking FSP-1/ROCK1 could become a therapeutic target for suppressing AVG failure.

TH-OR083

In Vivo Nanoparticle Imaging of Dysfunctional Endothelium Predicts the Development of Inflow Stenosis Jie Cui,[1,2] Chase Kessinger,[2] Jason McCarthy,[3] David E. Sosnovik,[2] Ravi I. Thadhani,[1] Farouc Amin Jaffer.[2] *[1]Nephrology Dept, MGH; [2]Div of Cardiology, MGH; [3]Center for System Biology, Massachusetts General Hospital.*

Background: Inflow stenosis is one of the most common causes of arteriovenous fistula (AVF) failure and is driven by inflammatory endothelium dysfunction after AVF creation. *In vivo* assessment of dysfunctional endothelium following AVF creation could provide new insights into subsequent neointimal hyperplasia (NH) and inflow stenosis.

Methods: AVF were created in C57Bl/6 mice by carotid artery and jugular vein anastomosis. On day 13 post-AVF creation, mice were injected with 10mg/kg of the fluorescent-magnetic nanosensor CLIO-VT680, which targets inflamed endothelial cells. On day 14, *en face* confocal microscopy (n=3), intravital microscopy (IVM) (n=5), *ex vivo* magnetic resonance imaging (MRI) and transmission electron microscopy (TEM) were performed. A subgroup of mice was kept alive after day 14 IVM imaging and then sacrificed on day 42 post-AVF creation. Image analysis was performed using Image J software.

Results: Confocal microscopy imaging demonstrated the deposition of CLIO-VT680 in day 14 AVF. *In vivo* arterial inflammation signals of day 14 AVF by IVM correlated negatively with the distance from the anastomosis (r=-0.98, p<0.0001). TEM of day 14 AVF revealed that most of the CLIO-VT680 deposited in the endothelium and the space between endothelium and internal elastin. The degree of day 14 endothelial dysfunction imaged by CLIO-V680 predicted day 42 arterial NH.

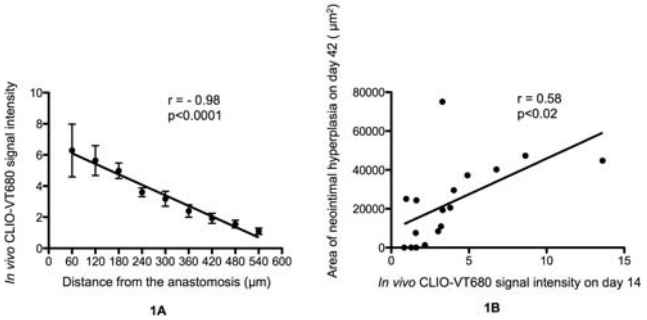

Figure 1:A. On day 14, *in vivo* CLIO-VT680 signal intensity measured by IVM showed a strong negative correlation with the distance away from the anastomosis. B. Day 14 *in vivo* CLIO-VT680 signal intensity can predict the area of neointimal hyperplasia on day 42.

CLIO-VT680 signal of day 14 AVF was detectable by *ex vivo* MRI.

Conclusions: Endothelial dysfunction post-AVF creation can be detected and quantified *in vivo* using high-resolution nanoparticle imaging, and the *in vivo* endothelial signal predicts subsequent inflow neointimal formation. This imaging strategy could be used to test different therapeutic interventions aiming to decrease inflow stenosis.

TH-OR084

Validation of Criteria Diagnosing Catheter-Related Bloodstream Infections in Hemodialysis Patients Friederike S. Quittnat Pelletier,[1,3] Mohammad Z.H. Joarder,[1] Alyssa Loughborough,[1,2] Susan Poutanen,[1,2,3] Charmaine E. Lok.[1,3] *[1]Univ Health Network; [2]Mount Sinai Hospital; [3]Univ of Toronto, ON, Canada.*

Background: Most hemodialysis (HD) units diagnose HD catheter-related bloodstream infections (CRBSI) by obtaining blood cultures (BC) from the HD bloodline (circuit) concurrent with clinical exclusion of other sources of infections. Guidelines from the Infectious Diseases Society of America (IDSA, 2009) recommend making the diagnosis of CRBSI by cultivating the same organism from a peripheral vein and from the catheter hub, meeting criteria for differential time to positivity (DTTP) >120 minutes. These criteria for CRBSI were derived from patient data reflecting practices with indwelling catheters used for drug administration; they have not been validated in HD patients who develop symptoms suspicious for CRBSI during hemodialysis.

Methods: Four sets of BC (peripheral vein, both catheter hubs and HD bloodline) were obtained from adult patients who were suspected of having a CRBSI. CRBSI was determined by an independent hemodialysis infection control committee. Sensitivity, specificity and accuracy of each BC type were calculated. DTTP of peripheral vein BC and HD bloodline BC compared to catheter hub BC was determined.

Results: 100 blood sample sets from patients with suspected CRBSI were obtained. Bacteremia was found in 27% of these patients and these BC consistently grew the same bacteria from all culture sites. Highest sensitivity, specificity and accuracy of BC results were found in samples from the dialysis bloodline and the venous catheter hub (93%, 98%, 96%, respectively), while BC from the peripheral vein combined with the arterial hub were the least sensitive, specific or accurate (88%, 89%, 88%, respectively). DTTP <120 minutes was found in 65-76% of samples.

Conclusions: BC results are more sensitive, specific and accurate if taken from the dialysis bloodline and a catheter hub, rather than from a peripheral vein. DTTP >120 minutes usually used to diagnose CRBSI is seen in less than one third of the compared BC and does not add to the accuracy of CRBSI diagnosis.

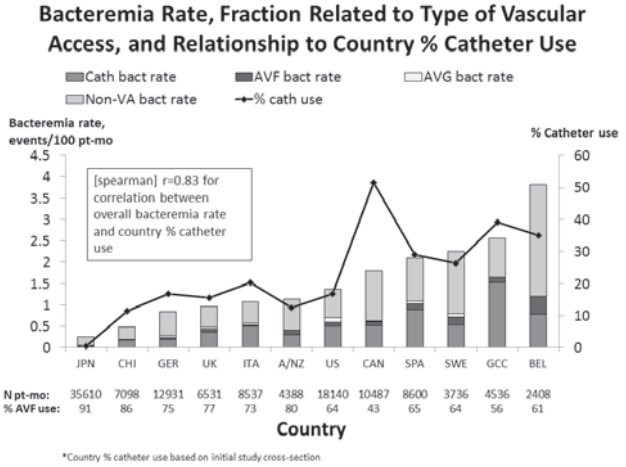
International Differences in Bacteremia Rates in Hemodialysis Patients in the DOPPS: Strong Relationship with Catheter Use Hugh C. Rayner,[1] Lindsay Zepel,[2] Michel Y. Jadoul,[3] Charmaine E. Lok,[4] David C. Mendelssohn,[5] Jeffrey Perl,[6] Richard J. Fluck,[7] Lawrence M. Spergel,[8] Brenda W. Gillespie,[2,9] Ayman Karkar,[11] Hideki Kawanishi,[10] Brian Bieber,[2] Friedrich K. Port,[2] Bruce M. Robinson,[2,9] Ronald L. Pisoni.[2] *[1]Heart of En. NHS Found.Trust; [2]ARCH; [3]Cliniques U. St. Luc; [4]Toronto Gen. Hos.; [5]Humber River Reg. Hos.; [6]St. Michael's Hos.; [7]Derby Hos. NHS Found.Trust; [8]Dial. Mgmt. Med. Group; [9]UM; [10]Tsuchiya Gen. Hos.; [11]Kanoo Kid. Cent.*

Background: To inform efforts to reduce infection in HD patients (pts), we compared bacteremia (BA) rates in 18 DOPPS countries.

Methods: Monthly prospective data from 2012-2014 for infections for which blood cultures were consistent with bacteremia (BA). Relation of BA to pt's vascular access (VA) was locally attributed. Data were from representative random samples of HD pts in A/NZ, JPN, EUR, CHI, Gulf Cooperation Council (GCC), CAN, and the U.S. Calculation of BA events was not feasible with data from U.S. LDOs. BA rates were **not** calculated according to the time using a particular VA.

Results: Total BA rates varied >10 fold from 0.25/100 pt-months in JPN to 3.8 in BEL. Non-VA-BA rates were higher than VA-BA in most countries. Total BA rates strongly correlated with country % catheters (CATH) at baseline (r=0.83). Total BA attributed to CATH-BA varied from 11% in JPN to 59% in GCC (median ~36%). Even though AV fistula (AVF) use was greater than CATH use in nearly all countries, CATH-BA rates were considerably greater than AVF-BA rates in all countries. Similar results were seen when restricted to only the first 4 months of the baseline period for all pts. Restricting to CAN, ITA, SPA, GER, UK, and U.S., CATH-BA rates were considerably higher than AVF-BA rates in both pts 18-74 yrs and >74 yrs.



Conclusions: Total BA rates are strongly correlated with country % CATH use. The variation in BA rates not attributed to VA requires further investigation.

Preoperative and Postoperative Vascular Ultrasound in the Hemodialysis Fistula Maturation (HFM) Cohort Study

Michelle L. Robbin, Tom Greene, The HFM Study Group. *NIDDK, NIH.*

Background: Vascular changes resulting from arteriovenous fistula (AVF) creation for hemodialysis access have not been well characterized, in part due to the lack of use of standardized imaging.

Methods: Preoperative (preop) mapping ultrasound (US) and postoperative (postop) AVF USs were performed by centrally trained sonographers at 7 HFM Study sites using a standardized protocol. AVF diameters and blood flow rates were assessed at ~1 day, 2 weeks and 6 weeks after AVF creation. Images were read by HFM Core radiologists blinded to clinical information, using standardized criteria. This report summarizes findings in the first 582 subjects out of a total 602 enrolled.

Results: There were 444 subjects (76%) with upper arm (UA) AVFs and 138 (24%) with forearm (FA) AVFs. Median (25^{th}-75^{th} percentile) preop artery and vein, and postop AVF diameters are shown in the table. The figure shows deaths, thromboses, and postop AVF blood flow. Individual trajectories were highly diverse. KDOQI physiologic maturation criteria of flow ≥ 600 ml/min and vein diameter ≥ 0.6 cm were met at 1 day, 2 and 6 weeks postop by 16.3%, 42.1%, and 53.9% of UA fistulas and by 0%, 8.9%, and 17.5% of FA fistulas, respectively. Logistic models predicting joint satisfaction of both KDOQI criteria at 6 weeks from AVF diameters and flows, measured respectively at 1 day or 2 weeks postop, had C statistics of 0.84 and 0.89.

	Preop Diameter (cm)		Postop AVF Diameter (cm)		
Location	Artery	Vein	1 day	2 weeks	6 weeks
Upper Arm	0.42 (0.36-0.48)	0.31 (0.24-0.38)	0.50 (0.43-0.57)	0.58 (0.51-0.68)	0.63 (0.52-0.75)
Forearm	0.23 (0.20-0.26)	0.26 (0.18-0.32)	0.39 (0.32-0.44)	0.46 (0.38-0.52)	0.50 (0.40-0.56)

Conclusions: The extent and timing of AVF diameter and flow increases in the first six weeks are highly heterogeneous. US diameter and flow measurement at 1 day and 2 weeks is highly predictive of 6 week values and may have clinical utility.

Demographic, Clinical, and Anatomic Factors Correlate with Physiologic Adaptation following Fistula Placement: The Hemodialysis Fistula Maturation (HFM) Cohort Study

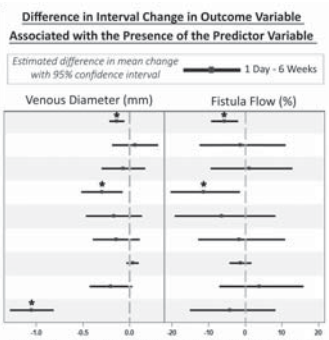
Scott A. Berceli, Tom Greene, The HFM Study Group. *NIDDK, NIH.*

Background: Demographic variables associated with AVF maturation are well established but the physiologic mechanisms that lead to this maturation success or failure are unknown.

Methods: Using a standardized protocol, duplex ultrasound was performed at 1 day, 2 weeks, and 6 weeks to map the temporal changes in flow rate and vein diameter following AVF creation (n=582 subjects). Mixed effects regression analyses with random surgeon effects, controlled for fistula location, were performed to examine the relationships between patient demographic/clinical/anatomic factors and both absolute and interval adaptation differences in diameter and flow.

Results: Greater age, female sex, black race, diabetes, history of coronary artery disease, and AVF transposition were associated with reduced vein diameter at 6 weeks, versus those without these characteristics (Table). Older age, female sex, black race, diabetes, peripheral and coronary artery disease, and smaller anastomotic lengths were associated with reduced AVF flow at 6 weeks. Examining the temporal changes in these parameters between 1 day and 6 weeks (Figure) also revealed differences in vein adaptation between patient subgroups. Patients with increasing age, diabetes, and AVF transposition demonstrated compromised venous dilation. Diabetes and increasing age were associated with progressively diminished flow augmentation over that period.

	6 Week Outcome Variable			
	Venous Diameter (mm)		Fistula Flow (%)	
Predictor Variable	*Diff. in Outcome*	*P Value*	*Diff. in Outcome*	*P Value*
Age (10 years)	-0.16	**.002**	-9.22	**.000**
Female	-0.13	.423	-14.9	**.011**
Black	-0.55	**.000**	-8.01	.126
Diabetes	-0.42	**.002**	-19.0	**.000**
PAD	-0.07	.716	-18.6	**.005**
CAD	-0.30	**.049**	-16.3	**.003**
Length Anastomosis (mm)	0.07	.106	4.17	**.028**
Dialysis Dependent	-0.05	.744	1.01	.851
Transposed Vein	-0.58	**.000**	-4.05	.492



Conclusions: AVF diameter and flow are associated with multiple demographic and clinical factors. Impaired vein dilation and reduced capacity for flow augmentation contributed to moderated diameters and flows among older and diabetic patients, and to smaller diameters among patients with transposed vein fistulas. This understanding of the physiologic mechanisms that are associated with maladaptive remodeling provides needed granularity to clinical maturation failure.

Effect of Dietary Sodium Restriction on Human Urinary Metabolomic Profiles

Kristen L. Jablonski,[1,2] Jelena Klawitter,[2] Michel Chonchol,[2] Candace Bassett,[1] Matt Racine,[1] Douglas R. Seals.[1] *[1]Univ of Colorado Boulder, Boulder, CO; [2]Univ of Colorado Denver, Aurora, CO.*

Background: Metabolomics is a relatively new field of "-omics" research, focusing on high-throughput identification of small molecular weight metabolites. Diet has both acute and chronic effects on metabolic profiles; however, alterations in response to dietary sodium restriction (DSR) are completely unknown. The goal of this study was to explore changes in urine metabolites in response to DSR, as well as their association with previously reported improvements in vascular function with DSR.

Methods: Using stored urine samples from a 10 week randomized, placebo-controlled cross-over study of DSR in 17 middle-aged/older adults (6M/11F; 62±2 yrs, mean±s.e.) with moderately elevated SBP (130-159 mmHg) and otherwise healthy, we performed a liquid chromatography–mass spectrometry (LC/MS)-based analysis of 289 metabolites. We identified metabolites that were significantly altered between the normal (153±7 mmol/day) and low sodium condition (70±7 mmol/day), as well as their association with responsiveness to previously reported improvements in vascular endothelial function (brachial artery flow-mediated dilation [FMD_{BA}]) and large elastic artery stiffness (aortic pulse-wave velocity [aPWV]).

Results: 13 metabolites were significantly altered (12 up- and 1 down-regulated) during the low sodium condition, and 10 of these exceeded our pre-specified threshold of a clinically significant change of >40%. These metabolites were involved in biological pathways broadly related to cardiovascular risk, nitric oxide production, oxidative stress, osmotic regulation, and metabolism. Furthermore, 2 of these metabolites (serine and D-gluconate) were independently associated with previously reported improvements in the primary vascular outcomes of FMD_{BA} and/or aPWV.

Conclusions: This proof of concept study provides the first evidence that DSR is a stimulus that induces significant changes in urinary metabolomic profiles, some of which are related to improved vascular function with reduced dietary sodium. Larger follow-up studies will be required to confirm and further elucidate pathways that are altered in response to DSR.

A Plasma Proteomic Classifier to Predict Transition of Albuminuria Stage in Subjects with Hypertension Michelle Pena,[1] Georg Heinze,[3] Peter Rossing,[4] Dick de Zeeuw,[1] Hiddo Jan Lambers Heerspink,[1] Joachim Jankowski.[2] *[1]Univ Medical Center Groningen, Groningen, Netherlands; [2]Univ Hospital RWTH, Inst for Cardiovascular Research, Aachen, Germany; [3]Medical Univ of Vienna, Vienna, Austria; [4]Steno Diabetes Center, Gentofte, Denmark.*

Background: Development of micro- or macroalbuminuria is a hallmark of progression of nephropathy in various diseases including hypertension. Early detection of patients with hypertension at risk for micro- or macroalbuminuria may facilitate prevention and treatment of renal diseases. We aimed to develop a plasma proteomic classifier specific to hypertension that could predict the development of micro- or macroalbuminuria.

Methods: Patients with hypertension (n=125) were selected for this case-control study from the PREVEND cohort. Cases transitioned in albuminuria stage from normo- to microalbuminuria or micro- to macroalbuminuria during 2.7-years. Controls, matched for age, gender, and baseline albuminuria stage, did not transition. Plasma proteomic profiles were measured by LC-electrospray-trap mass-spectrometry and a classifier was developed and cross-validated for prediction of transition to micro- or macroalbuminuria. Improvement in risk prediction was tested on top of a baseline model of albuminuria, eGFR, and renin-angiotensin-system intervention (RASi) use. The external validity of the classifier was tested in a type 2 diabetes cohort (n=82).

Results: The proteomic classifier was independently associated with transition in albuminuria (Odds ratio 1.26, 95% CI=1.11-1.42, p<0.01). The classifier improved risk prediction for transition in albuminuria on top of the baseline model (C-index from 0.68 to 0.78; p<0.01; IDI 0.061 p=0.034). The association was similar in case-control pairs with RASi use (C-index from 0.71 to 0.78) or without RASi use (C-index from 0.69 to 0.81). The peptides included in the classifier could not be detected in a type 2 diabetes cohort suggesting disease specific peptides.

Conclusions: A hypertension-specific plasma proteomic classifiers was developed and validated that could predict the transition of albuminuria stage beyond established renal risk markers. These results have to be validated in a prospective cohort.

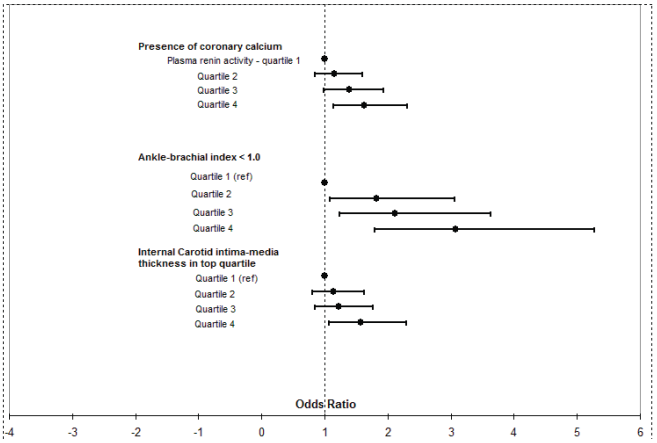
TH-OR090

Association of Plasma Renin with Subclinical Cardiovascular Disease in a Population-Based Cohort: The Multi-Ethnic Study of Atherosclerosis Dena E. Rifkin,[1,2] Joseph A. Abdelmalek,[1,2] Nancy Jenny,[3] Robyn L. Mcclelland,[4] Matthew Jay Budoff,[5] Joachim H. Ix,[1,2] Matthew Allison.[1,2] *[1]UC San Diego; [2]VA San Diego; [3]Univ of Vermont; [4]Univ of Washington, Seattle; [5]UCLA.*

Background: Several studies have demonstrated an association with renin and cardiovascular disease. Many experimental studies support a link between RAAS activation and atherosclerosis, as both renin and aldosterone are known to be profibrotic. We hypothesized that plasma renin activity (PRA) and aldosterone would be associated with markers of subclinical CVD, independent of traditional cardiovascular risk factors in a multi-ethnic population without clinical CVD.

Methods: A cross sectional analysis of 1800 individuals from the Multi-Ethnic Study of Atherosclerosis (MESA) study was performed. PRA and aldosterone were measured, in addition to quantification of coronary artery calcification (CAC), internal carotid artery intima-media thickness (IMT), and ankle-brachial index (ABI).

Results: The mean age was 64.5 years, and 50.3% were male. Twenty percent of the study population was African American, 26% Hispanic, 13.1% Asian and 40.8% White. After multivariable adjustment including demographic, cardiovascular, and kidney markers, increasing quartiles of PRA were associated with a more than 50% higher odds of CAC presence or high cIMT and a tripling of the odds of having a low ABI in the highest renin quartile.



Race did not modify associations of PRA with either CAC or IMT. Aldosterone was not independently associated with subclinical atherosclerosis, and adjustment for aldosterone did not affect these estimates.

Conclusions: In a large multi-ethnic cohort, renin was independently associated with greater prevalence of subclinical atherosclerosis in multiple vascular beds. This finding was independent of demographic factors as well as aldosterone levels.

TH-OR091

Association of Body Fluid Composition with Resistant Hypertension in Patients with Chronic Kidney Disease Toshiyuki Aoki,[1] Yasushi Ohashi,[1] Reibin Tai,[1] Sonoo Mizuiri,[2] Yoshihide Tanaka,[1] Atsushi Aikawa,[1] Ken Sakai.[1] *[1]Nephrology, School of Medicine, Faculty of Medicine, Ohta-ku, Tokyo, Japan; [2]Nephrology, Ichiyokai Harada Hospital, Hiroshima-shi, Japan.*

Background: Treatment-resistant hypertension remains a common clinical issue in patients with chronic kidney disease (CKD). Our objective is to investigate the association of body fluid composition with treatment-resistant hypertension in patient with CKD.

Methods: Using bioimpedance analysis (BIA), body fluid composition was measured in 149 patients with CKD from 2005 to 2009, who were followed until August 2013. The ratio of extracellular water measured by BIA (ECW_{BIA}) to total body water calculated using the Watson formula (TBW_{Watson}) was used as an indicator of volume excess. Treatment-resistant hypertension was defined as an office BP of ≥130/80 mmHg, despite receiving ≥3 antihypertensives including diuretics, or ≥4 drugs usage. Main outcomes were adverse renal outcomes, as defined by a decline of 50% or more from baseline glomerular filtration rate or initiation of renal replacement therapy and cardiovascular events.

Results: Treatment-resistant hypertension was present in 37 patients (24.8%). Patients with treatment-resistant hypertension were more likely to be older and male and have diabetes mellitus, higher body mass index (BMI), lower eGFR and serum albumin, higher triglyceride and UPCR levels, and volume excess ($p < 0.05$). Compared with patients with no treatment-resistant hypertension during a median 4.9-year follow-up, those with treatment-resistant hypertension had worse adverse renal outcomes (21.3 versus 6.1 per 100 patient-years, $P < 0.001$) and cardiovascular events (5.0 versus 1.5 per 100 patient-years, $P = 0.009$) by Kaplan–Meier survival analysis. In multivariate analysis, body mass index and volume excess remained independently associated with treatment-resistant hypertension. The best cut-off value of ECW_{BIA}/TBW_{Watson} ratios for Treatment-resistant hypertension was 39.9%.

Conclusions: Treatment-resistant hypertension is associated with fat content and volume excess, which exhibits adverse renal outcomes and cardiovascular events. These findings emphasize the importance of adequate weight and volume status.

TH-OR092

Elevated Endogenous Ouabain and Reduced Excretion of Uric Acid after Acute Salt Load in Hypertensive Patients Chiara Lanzani,[1] Lorena Citterio,[1] Elena Brioni,[1] Marco Simonini,[1] Chiara Maggioni,[1] Elisabetta Messaggio,[1] John Hamlyn,[2] Paolo Manunta.[1] *[1]San Raffaele Scientific Inst, Milan, Italy; [2]Univ of Maryland, Baltimore.*

Background: The independent functional role of serum uric acid (UA) in enhancing cardio-renal risk is controversial. The permeability glycoprotein (PGP) encoded by the ATP-binding cassette B1 gene (ABCB1), extrudes UA in the kidney, and is associated with chronic kidney disease. Endogenous ouabain (EO), an adrenal steroid hormone, and UA are increased among hypertensives and both are associated with increased cardiovascular risk. The present study examined the relationship between baseline EO and the renal excretion of UA in hypertensives after an acute Na load.

Methods: Plasma EO, and the fractional excretion of Na+ and UA were determined in 222 naïve hypertensives (age 52.3±10.6 years, BMI 25.7±2.99 Kg/m^2) after 2 hour of 0.9% NaCl infusion.

Results: Elevated plasma EO was associated with higher systolic and diastolic BP**.** Genotype analysis for EO levels and UA were significant for the ABCB1 rs1045642, with the minor allele tracking with higher EO (T/T 184.7 (147–272) versus C/C+C/T 211.1 (193–366) pmol/l, p=0.033). FEUA after the NaCl load was lower in T/T carriers (7.21±0.34) versus the CC+CT variants (8.4±3.95 p=0.046). A direct (b=3.57) linear relationship (p=0.0004) was present between baseline plasma EO and FEUA after salt loading.

Conclusions: EO and urinary UA excretion are strictly related, likely via the same (PGP) tubular transporter. Our results imply that UA is a marker for high EO and that EO is the functional effector of UA risk.

TH-OR093

Effect of Arteriolar Hyalinosis on the Blood Pressure-Dependent Proteinuria in Non-Nephrotic Chronic Kidney Disease Ryo Zamami,[1] Kentaro Kohagura,[1] Yusuke Ohya,[1] Kunitoshi Iseki.[2] *[1]Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus, Nishihara-cho, Okinawa, Japan; [2]Dialysis Unit, Univ Hospital of the Ryukyus, Nishihara-cho, Okinawa, Japan.*

Background: It has been suggested that afferent arteriolar hyalinosis was associated with disturbed autoregulation of glomerular hemodyanamics. However, effect of afferent arteriolar hyalinosis on a relationship between blood pressure (BP) and proteinuria is unknown in chronic kidney disease (CKD) patients.

Methods: A total of 208 consecutive patients who underwent renal biopsy at our department between 2003 and 2007 were considered for the study. We excluded patients receiving renin angiotensin inhibitors, or steroids or calcineurin inhibitors, and those with diseases such as vasculitis, which cause morphological changes to renal arterioles. We then selected non-nephrotic CKD patients defined as serum albumin equal or more than 3 g/gCr, leaving us with 103 patients (48 men and 55 women) for analysis.Arteriolar hyalinosis

were assessed by semi quantitative grading for arterioles. We compared the relationship between systolic BP category (<120, 120-140, >140) and urine protein (g/gCr) the patients with or without arteriolar hyalinosis.

Results: The mean ± standard deviation values for patients' age, BP, estimated glomerular filtration rate (eGFR), and urine protein were as follows: 39± 18 years, 126 ± 20/75 ± 12 mmHg, and 86 ± 38 ml/min/1.73 m^2, and 1.2±1.1 g/gCr, respectively. Either, systolic BP or mean arteriolar hyalinosis index was significantly correlated with log-transformed urine protein (r=0.27, p=0.006; r=0.35, P=0.0003), respectively. In the patients with hyalinosis (n=53), proteinuria (g/gCr) was significantly increased as systolic BP category was increasing (1.0, 1.2, 2.1, ANOVA p=0.03). In contrast, there was no significant association between systolic BP category and urine protein in the patients without hyalinosis (n=50).

Conclusions: These results indicated that renal arteriolar hyalinosis might potentiate the susceptibility of glomerular damage by BP in non-nephrotic CKD patients. Dysregulation of afferent arteriolar resistance via arteriolar sclerosis may be involved in hypertensive renal damage.

TH-OR094

Long-Term Intake of Animal Flesh and Risk of Developing Hypertension in Three Prospective Cohorts

Lea Borgi, John P. Forman. *Nephrology, Brigham and Women's Hospital, Boston, MA.*

Background: Prospective data are scarce on the relation of red meat, seafood, and poultry consumption with hypertension risk. Although red and processed meats are generally considered to have adverse cardiovascular consequences, seafood is believed to be protective and poultry's effect is controversial.

Methods: We prospectively examined the independent association of animal flesh intake with incident hypertension in three large longitudinal cohort studies of originally non-hypertensive individuals: Nurses' Health Study I (NHS1, n=62,273, aged 38-63 years in 1984), Nurses' Health Study II (NHS2, n=88,831, aged 27-44 years in 1991), and Health Professionals Follow-up Study (HPFS, n =37,414, aged 40-75 years in 1986). Information about diet (using a validated food frequency questionnaire), behaviors, and health status was updated biennially. We used multivariable Cox proportional hazards regression to study the associations of different types of flesh (red meat, processed meat, seafood, and poultry) with the risk of developing hypertension while controlling for numerous other hypertension risk factors. We then used random effects meta-analysis to derive pooled estimates of effect.

Results: Compared with participants whose consumption was <1 serving/month, the pooled hazard ratios (HR) among those whose intake was ≥1 serving/day were 1.31 (95% CI: 1.23-1.39) for total meat (a combination of processed and red meat), 1.06 (0.98-1.14) for seafood, and 1.22(1.11-1.33) for poultry. Seafood was associated with an increased risk of hypertension in NHS2 (HR= 1.15, p-trend<0.001) and HPFS (HR= 1.18, p-trend<0.001), but not in NHS1. In substitution analyses, replacing one type of flesh with another (eg, replacing red meat with seafood) did not increase or decrease risk of hypertension. Consumption of any animal flesh ≥1 serving/day was associated with an important increase in the risk of hypertension (pooled HR= 1.29[1.15-1.45]).

Conclusions: Our results suggest that long-term intake of animal flesh is prospectively and independently associated with an increased risk of developing hypertension. Furthermore, in addition to meat, poultry intake was associated with increased risk, and seafood was not found to be protective.

TH-OR095

Elevated Blood Pressure Index and Decreased Nocturnal Dip Are Risk Factors for Cognitive Dysfunction in Children and Young Adults

Nina Laney,[1] Stephen R. Hooper,[2] Jerilynn Radcliffe,[1] Ji Young Kim,[1] Rebecca Ruebner,[1] Erum A. Hartung,[1] Divya Ganeshmurthy Moodalbail,[3] Susan L. Furth.[1] *[1]Children's Hospital of Philadelphia; [2]Univ of North Carolina; [3]Nemours/A.I. duPont Hospital for Children.*

Background: Hypertension (HTN) is a known risk factor for cognitive dysfunction in adults, yet there are few studies examining the same in children and young adults. Thus, we aim to elucidate the relationship between HTN and cognitive function in a younger population.

Methods: Cross-sectional study of 104 subjects, ages 8-25, including 65 with chronic kidney disease (CKD) [mean(SD) age 15.7(3.9) yrs, eGFR 48.6(23.7) mL/min/1.73 m^2, 16 with transplant, 2 on dialysis] and 39 healthy controls [mean(SD) age 15.1(3.7) yrs, eGFR 103.1(20.3) mL/min/1.73 m^2]. Each completed 24 hour ambulatory blood pressure measurement (ABPM) and a neurocognitive battery consisting of measures of Language, Attention, Inhibitory Control, Problem Solving, Set Shifting, Visuospatial, Memory (Verbal and Visual), Working Memory (Verbal and Visual), and Executive Function. Neurocognitive results were converted to z-scores based on published norms. ABPM data yielded measures of systolic and diastolic means, percent dipping, load, and index, using 95th percentile limits based on age, height, and gender.

Results: After controlling for CKD versus control, race, and maternal education, multiple regression analysis showed significant associations with ABPM measures in Verbal Memory and Set Shifting. Systolic and diastolic index were negatively associated with performance in the Verbal Memory domain, with a decrease of 0.66 (P=0.002) and 0.53 (P=0.006) in z-scores for every 0.1 point increase in systolic and diastolic index, respectively. Systolic dipping was negatively associated with Set Shifting, with a decrease of 0.03 in z-score (P = 0.04) for every 1% decrease in systolic dipping.

Conclusions: Children and young adults with increased systolic and diastolic indices and decreased systolic dipping on ABPM show clinically significant deficits in Verbal Memory and Set Shifting, regardless of disease, race, and maternal education. Early identification and treatment of HTN may be effective in preserving cognitive function.

TH-OR096

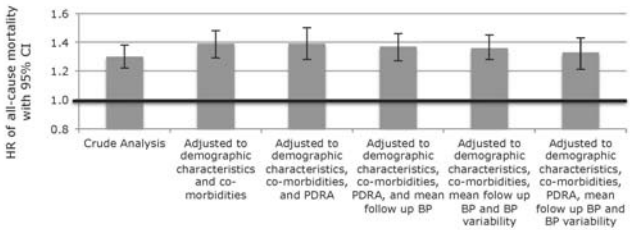
Examining Association of Medical Non-Adherence with All-Cause Mortality in Incident Hypertensive U.S. Veterans

Elvira Gosmanova,[1] Jun Ling Lu,[1] Elani Streja,[2] William C. Cushman,[3] Miklos Zsolt Molnar,[1] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[3,1] *[1]Univ of Tennessee; [2]Univ of California Irvine; [3]Memphis VAMC.*

Background: Non-adherence to antihypertensive drugs (AHD) is associated with adverse outcomes, but mediators of this relationship are poorly understood. We examined the effect of ICD-9 code for medical treatment non-adherence (V15.81) on survival in a cohort of hypertensive U.S. veterans and explored possible mediators of this association.

Methods: Historical prospective cohort study involving 311,622 newly treated hypertensive individuals (mean age 53.8 years, 90.9% males, 20.3% black, 7.1% with V15.81). Associations between V15.81 assigned prior to treatment with AHDs, and all-cause mortality were examined in Cox models adjusted for demographics and co-morbidities. Effect mediation was examined by additional adjustment for follow-up adherence to AHD through pharmacy dispensation records analysis (PDRA), mean follow-up BP, and follow-up BP variability (measured as the median absolute deviation from the mean).

Results: 27,384 patients (8.9%) died (mortality rate 23.1 [22.8-23.4]/1000 patient-years) during a median follow up of 3.8 years. Patients with V15.81 had higher all-cause mortality and this association remained unchanged after serial adjustments (Figure), even though PDRA, mean BP, and BP variability were independently associated with higher mortality.



Conclusions: Assignment of V15.81 prior to AHD therapy was associated with increased all-cause mortality in incident hypertensive U.S. veterans, independent of AHD adherence or follow up BP. Non-pharmacologic aspects of adherence may explain these associations. Non-adherence is a complex condition and further research is needed to understand what modifiable patient characteristics are prone to interventions that could improve outcomes in hypertensive individuals.

Funding: NIDDK Support, Veterans Affairs Support

Renal and Heart Function in Essential Hypertension

Vanessa E. Tzamou,[1] Panagiota E. Giannou,[2] Eva Karpanou,[3] Dimitrios Petras,[2] Gregory Vyssoulis.[1] *[1]Hypertension Unit, 1st Cardiology Clinic Athens Univ Hippokration Hospital, Athens, Greece; [2]Nephrology, Hippokration Hospital, Athens, Greece; [3]Hypertensive Center, Onassis Cardiosurgery Center, Athens, Greece.*

Background: The relationship between heart and renal function is a precarious matter that has been investigated through the years. Lately many studies suggest that renal injury is associated with early stage heart dysfunction. The aim of the present study is to investigate the grade of renal deterioration according to heart function in non diabetic essential, never treated, hypertensive patients.

Methods: We studied 7970 consecutive patients (4419 males, mean age 53 years) with uncomplicated essential hypertension and the correlation between cardiac function using the Tei index (defined as the sum of the isovolumetric relaxation and contraction time divided by the ejection time), transmitral blood flow velocities ratio (E/A), ejection fraction (EF) and kidney injury [eGFR(ml/min), ACR (urine albumin-creatinine ratio)]. Patients were grouped by ACR (ACR>30 and ACR<30) and eGFR (eGFR>90, eGFR 90-60, eGFR<60).

Results: The model was adjusted for age, gender, blood pressure, lipid profile and smoking habit. EF was decreased with renal function deterioration as did the E/A ratio, while the Tei index increased (Table 1). Furthermore EF has higher normal levels in patients with ACR <30 as did the E/A ratio while Tei index present lower levels (Table 1).

	eGFR >90 n: 1926	eGFR 90-60 n: 4693	eGFR <60 n: 1351				F value	p-value
EF	67.3±4.6	66.1±5.2	63.6±5.2				199.5	<0.0001
E/A	1.094±0.207	0.978±0.167	0.859±0.148				723.9	<0.0001
Tei index	0.561±0.063	0.584±0.068	0.627±0.080				363.3	<0.0001

		ACR >30 n:2210	ACR <30 n:5760	t-test		p-value
	EF	63.1±5.9	67.0±4.8	30.1	-	<0.0001
	E/A	0.880±0.159	1.027±0.185	32.8		<0.0001
	Tei index	0.623±0.029	0.571±0.064	29.9		<0.0001

Conclusions: We found that the Tei index and E/A was correlated with eGFR, and ACR. It seems that systolic and diastolic heart function indices can be used not only for the evaluation of the global myocardial performance of hypertensive patients but also for the assessment of the risk of kidney damage.

TH-OR098

Long Term Cholecalciferol Supplementation in Hemodialysis Patients: Effects on Mineral Metabolism, Inflammation, and Cardiac Parameters Patrícia Matias,[1,2,3] Cristina Jorge,[1,2,3] Ana Azevedo,[2,3] Ivo Laranjinha,[2,3] David Navarro,[1,3] Ana Carina Ferreira,[2,3] Tiago Amaral,[2,3] Marco Mendes,[1,3] Ines Aires,[1,2,3] Célia Gil,[1,2,3] Manuel A. Ferreira.[1,2,3] *[1]Dialysis Clinic, Nephrocare - Vila Franca de Xira, Vila Franca de Xira, Portugal; [2]Dialysis Clinic, Dialverca, Forte da Casa, Portugal; [3]NIDAN, Lisboa, Portugal.*

Background: Vitamin D deficiency is highly prevalent in chronic kidney disease. The aim of this 5-year prospective study was to evaluate the effects of long term oral cholecalciferol supplementation on mineral metabolism, inflammation and cardiac parameters in chronic hemodialysis (HD) patients.

Methods: Serum levels of 25-hydroxyvitamin D [25(OH)D], circulating bone metabolism, inflammation parameters, pulse pressure (PP) and left ventricular mass index (LVMI) were evaluated before and after supplementation. Baseline 25(OH)D levels were measured twice (end of winter and of summer, respectively). Therapy with active vitamin D and darbepoietin was evaluated. The study included 97 HD patients that completed 60 months of supplementation, 40.6% female, with a mean age of 63.19±14.14 and with a median HD time, at baseline, of 25 months. Cholecalciferol was given after dialysis according to 25(OH)D levels in the first 6 months (mean dose of 21.000 IU/week) and afterwards 8.000 IU/week.

Results: There was a significant increase in serum 25(OH)D levels after supplementation (23.13±13.16 *versus* 44.13±11.92; p<0.001). On the opposite, serum calcium (p=0.02), phosphorus (p=0.018) and iPTH (p=0.03) were decreased. A reduction in the dose and number of patients treated with active vitamin D (p<0.001) and darbepoietin was also observed (p=0.02), with no modification of hemoglobin values. Serum albumin increased (p<0.001) and C-reactive protein decreased (p=0.01) during the study. PP (p=0.007) and LVMI (p=0.02) were significantly reduced at the end of supplementation.

Conclusions: Long term oral cholecalciferol supplementation in HD patients appears to be an easy and cost-effective therapeutic measure. It allows correction of vitamin D deficiency, better control of mineral metabolism with less use of active vitamin D, attenuation of inflammation, reduced dosing of erythropoiesis stimulating agents, and possibly, improvement of cardiac dysfunction.

TH-OR099

Proteinuria Increases Phosphatemia By Altering Tubular Handling of Phosphate Pierre-Yves F. Martin,[1] Sophie M. De Seigneux,[1] Marie Courbebaisse,[2] Joseph M. Rutkowski,[4] Alexandra Wilhelm-Bals,[1] Marie Metzger,[2] Dominique Prie,[2] Carsten A. Wagner,[3] Benedicte Stengel,[2] Philipp Scherer,[4] Eric Feraille,[1] Pascal Houillier,[2] *[1]Univ Hospital of Geneva, Switzerland; [2]Hopital Européen Georges Pompidou, France; [3]Univ of Zurich, Switzerland; [4]UT Southwestern Medical Center.*

Background: Proteinuria and elevated phosphatemia are cardiovascular risk factors independent of glomerular filtration rate (GFR). We hypothesized that proteinuria modifies tubular handling of phosphate.

Methods: We studied phosphate handling in nephrotic children and in a cohort of 1738 CKD patients. To understand the molecular mechanisms, we induced glomerular proteinuria in two animal models: a toxic and a genetic model of glomerular lesions. OK and mDCT cells were used for in vitro studies.

Results: Plasma FGF23 and phosphate levels increased whereas fractional excretion of phosphate decreased during proteinuric phase as compared to remission phase in nephrotic children. Cross-sectional analysis of a cohort of 1738 CKD patients showed that 300mg/24h albuminuria or higher is predictive of higher phosphate levels, independent of GFR and other factors. Albuminuric patients also displayed higher plasma FGF23 and PTH levels. Rats with puromycin aminonucleoside induced proteinuria displayed elevated FGF23, but higher renal NaPi-IIa and lower Klotho proteins expression associated with decreased phosphorylation of FRS2α, a major FGF23 receptor substrate. In phosphate loaded rats, proteinuria impaired NaPi-IIa apical retrieval in proximal tubular cells. These findings were confirmed in transgenic mice that develop proteinuria resulting from podocyte depletion. In vitro, albumin did not directly alter phosphate uptake in proximal OK cells, whereas it downregulated Klotho in distal tubular cells.

Conclusions: We show that proteinuria increases phosphatemia independent of GFR and despite elevated FGF23 in children and adults CKD patients. Experimentally, we observed that proteinuria increased proximal tubule NaPi-IIa expression and is associated with downregulation of Klotho which confers FGF23 resistance. Proteinuria thus induced elevation of both FGF23 and phosphate, potentially contributing to cardiovascular disease.

PAI-1 Regulates FGF-23 Metabolism in Plasma Aaron T. Place,[1,2] Mesut Eren,[1] Toshio Miyata,[3] Douglas E. Vaughan.[1,2] *[1]Dept of Medicine, Northwestern Univ, Chicago, IL; [2]Feinberg Cardiovascular Research Inst, Northwestern Univ, Chicago, IL; [3]United Centers for Advanced Research and Translational Medicine, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.*

Background: Elevated blood levels of fibroblast growth factor-23 (FGF-23) are present in a variety of human diseases and conditions including chronic kidney disease, autosomal dominant hypophosphatemic rickets, and tumor-induced osteomalacia. Furthermore, increased levels of FGF-23 are independently associated with mortality in patients undergoing dialysis. Clearly, methods to reduce the elevated FGF-23 levels in these settings offer novel therapeutic potential.

Methods: We investigated the effects of plasminogen activator inhibitor type-1 (PAI-1) activity on plasma levels of FGF-23 in transgenic mice that overexpress a stable form of human PAI-1 and in *klotho* mice that were treated with a novel small molecule PAI-1 inhibitor, TM5441. We also investigated how plasminogen activators (PAs) affect FGF-23 using recombinant human FGF-23, tissue-type (t-PA) and urokinase (uPA) PAs and PAI-1.

Results: We observed that the PAI-1 transgenic mice exhibit 3.5-fold elevated plasma levels of FGF-23 compared to littermate controls. Additionally, pharmacologic inhibition of PAI-1 activity with TM5441 reduced plasma levels of FGF-23 by over 60% (p<0.01) in *klotho* mice, which also display elevated PAI-1 levels compared to WT littermates. The mechanism through which PAI-1 contributes to increased FGF-23 levels appears to involve PA-dependent proteolysis, as both t-PA and uPA were observed to cleave FGF-23 *in vitro*. Furthermore, inhibition of t-PA or uPA by PAI-1 prevented the proteolysis of FGF-23, which was then restored by pretreatment of PAI-1 with TM5441.

Conclusions: Taken together, these results suggest that t-PA and uPA play a critical role in the proteolytic clearance of circulating FGF-23. PAI-1, the primary inhibitor of PAs in plasma, is a key regulator of this process. Furthermore, selective inhibition of PAI-1 offers a novel and direct therapeutic approach to reduce the high levels of FGF-23 seen in many human diseases and conditions.

Rapid Minute-to-Minute Regulation of Plasma Fibroblast Growth Factor 23 – A Key Role of the Kidney Maria Lerche Mace,[1] Eva Gravesen,[2] Jacob Hofman-Bang,[2] Klaus Olgaard,[2] Ewa Lewin.[1,2] *[1]Nephrology, Herlev Hospital, Univ of Copenhagen, Denmark; [2]Nephrology, Rigshospitalet, Univ of Copenhagen, Denmark.*

Background: Chronic uremia is characterized by high circulating levels of fibroblast growth factor 23 (FGF23), yet the mechanisms behind are not completely clarified. Recently, studies reported a rise in FGF23 during acute kidney failure. The aim of the present study was to examine the impact of the kidney on the very early minute-to-minute regulation of FGF23, along with the importance of PTH and the FGF receptor 1 (FGFR1) signaling pathway.

Methods: Adult male Wistar rats were randomized to either acute bilateral or unilateral nephrectomy (NX, UNX), parathyroidectomy (PTX) or sham surgery. The FGFR1 signaling pathway was blocked by pharmacological inhibitor of FGFR1 (PD173074) prior surgery. Furthermore, to examine FGF23 kinetics an iv bolus of 0.1 µg of recombinant human FGF23 (LC lab) was administered after suppression of endogenous FGF23 by PD173074. Intact FGF23 levels were measured using the intact FGF23 Kainos assay.

Results: NX resulted in an immediate, within 15 minutes, increase in FGF23 levels from 112±18 to 267±26 pg/ml (p< 0.001), and then the following levels remained stable. UNX generated as well a prompt rise in FGF23 to 147±20 pg/ml, reaching a level in between NX and sham group, the latter demonstrating stable FGF23 levels. NX and PTX+NX showed same FGF23 levels. PD173074 suppressed FGF23 levels to 36±8 pg/ml, which similarly increased by 134±34% in PD173074 and 155±30% in vehicle groups after NX (ns). The half-life of rhFGF23 was significantly prolonged from 5.4 to 14.5 min in anephric rats (p<0.01) independently of FGFR1 inhibition.

Conclusions: The present results clearly demonstrate the importance of the kidney in the very rapid regulation of FGF23, as acute total nephrectomy immediately, within minutes, resulted in a more than 200% rise in FGF23 levels. This effect was independent of PTH and a similar increase was demonstrated, too, after inhibition of the FGFR1 signaling pathway. The half-life of FGF23 was significantly prolonged in anephric rats. A principal role of the kidney in the rapid regulation and rapid clearance of FGF23 is shown.

Inflammation and Iron Deficiency Stimulate FGF23 Production
Valentin David,[1] Aline Martin,[1] Kimberly Zumbrennen-Bullough,[3] Chia Chi Sun,[3] Herbert Y. Lin,[3] Tamara Isakova,[2] Jodie L. Babitt,[3] Myles S. Wolf.[2] *[1]Univ of Miami; [2]Northwestern Univ; [3]Massachusetts General Hospital.*

Background: Iron deficiency and inflammation are common in CKD, and associated with elevated circulating levels of fibroblast growth factor-23 (FGF23). We tested the hypothesis that iron deficiency and inflammation regulate FGF23 production.

Methods: To investigate the effects of inflammation on FGF23 production, wild-type (WT) mice received a single injection of heat-killed Brucella abortus (BA), interleukin-1B (IL1B) or saline (Ctr). To test the effects of iron deficiency, WT mice were fed low-iron or normal diets for 3 weeks.

Results: Inflammation decreased serum iron levels 6 hours after injection of both BA and IL1B mice compared to Ctr mice. In BA mice, inflammation was accompanied by increased FGF23 mRNA expression in bone and a 9-fold increase in serum C-terminal FGF23 levels (cFGF23, which detects both intact FGF23 and its inactive C-terminal cleavage fragments). IL1B-injected mice demonstrated a comparable 3.5-fold and 8-fold increase in cFGF23 at 3 and 6 hours post-injection, respectively. No acute changes in intact FGF23 (iFGF23) levels were observed during the early post-injection period in either model, suggesting that FGF23 production and cleavage initially increase in parallel in response to inflammation. By 4 days post-injection, serum iFGF23 levels increased by 1.4-fold in IL1B mice compared to Ctr. Consistent with increased bioactive FGF23, mRNA expression of renal Cyp24a1 increased 4–fold, Cyp27b1 decreased 3-fold, and Npt2a decreased 2-fold, resulting in increased phosphate excretion. Sustained iron deficiency induced by a low iron diet mimicked the effects of inflammation and resulted in a 2.5-fold increase in cFGF23, a 3-fold increase in osseous FGF23 mRNA expression, and a 2-fold increase in iFGF23.

Conclusions: Inflammation and iron deficiency stimulate FGF23 production but secretion of the intact protein is overridden initially by a simultaneous increase in proteolytic cleavage of FGF23. Chronic inflammation and sustained iron deficiency, however, lead to increased intact FGF23. These data suggest that iron deficiency and inflammation may contribute to elevated FGF23 levels in CKD.

TH-OR103

FGF23 Targets the Heart by Activating FGFR4
Ansel P. Amaral,[1] Alexander Grabner,[1] Saurav Singh,[1] Karla J. Schramm,[1] Alexis J. Sloan,[1] Myles S. Wolf,[2] Christian Faul.[1] *[1]Univ of Miami Miller School of Medicine, Miami, FL; [2]Northwestern Univ Feinberg School of Medicine, Chicago, IL.*

Background: Serum FGF23 levels are elevated in patients with chronic kidney disease (CKD) and are independently associated with increased rates of left ventricular hypertrophy (LVH). A recent translational study from our group demonstrated that FGF23 is a causal factor in the pathogenesis of LVH: we reported that FGF23 induces hypertrophy of cardiac myocytes via FGF receptor (FGFR)-dependent signaling and independent of klotho, which is the FGF23 co-receptor in the kidney. Different from klotho expressing cell types, FGF23 does not stimulate Ras/MAPK signaling in cardiac myocytes, but activates the PLCγ/calcineurin/NFAT axis, a potent pro-hypertrophic signaling pathway in the heart. Mammals express four different FGFR isoforms (FGFR1-4), and we currently focus on the identification of the FGFR isoform that mediates FGF23's cardiac effects. Our preliminary work in HEK293 cells that lack klotho indicates that of the four ectopically expressed FGFR isoforms, only FGFR4 can bind and activate PLCγ upon FGF23 stimulation.

Methods: To determine if FGFR4 activation in cardiac myocytes is required for FGF23-induced hypertrophy, we studied constitutive FGFR4 knockout (-/-) mice. Cardiac myocytes were isolated from newborn mice, treated with recombinant FGF23 for 48 hours and analyzed for hypertrophic cell growth. Serum FGF23 levels were elevated in adult FGFR4-/- mice and wild type littermates via administration of a high phosphate (2%) diet for 3 months followed by histological and serological analyses.

Results: Isolated cardiac myocytes from FGFR4-/- mice are protected from FGF23-induced hypertrophic growth. High phosphate diet causes a significant increase in serum phosphate and FGF23 in wild type and FGFR4-/- mice, without inducing kidney injury. However, only wild type but not FGFR4-/- mice develop LVH.

Conclusions: The FGF23-induced hypertrophic growth of cardiac myocytes requires FGFR4 and mice with elevated FGF23 lacking FGFR4 are protected from LVH. Pharmacologically blocking FGF23-mediated FGFR4 activation in the heart could represent a novel approach to reduce cardiac damage in CKD.

Pharmacologic FGFR4 Blockade Attenuates LVH in a Rodent Model of CKD
Alexander Grabner,[1] Ansel P. Amaral,[1] Saurav Singh,[1] Karla J. Schramm,[1] Alexis J. Sloan,[1] Dominik Kentrup,[2] Stefan Reuter,[2] Hermann Pavenstaedt,[2] Giovana Seno Di Marco,[2] Myles S. Wolf,[3] Marcus Brand,[2] Christian Faul.[1] *[1]Dept of Medicine, Univ of Miami Miller School of Medicine, Miami; [2]Dept of Internal Medicine D, Univ Hospital Muenster, Muenster, Germany; [3]Northwestern Univ Feinberg School of Medicine, Chicago.*

Background: Left ventricular hypertrophy (LVH) is an important mechanism of cardiovascular disease in chronic kidney disease (CKD) and affects up to 90% of patients by the time they reach dialysis. Serum levels of fibroblast growth factor (FGF) 23 continuously rise as patients progress to renal failure. Human studies demonstrated a dose-dependent association between FGF23 levels, increased prevalence of LVH and greater risk of mortality among CKD patients. In a recent study we showed that increased FGF23 induces LVH thereby repositioning FGF23 from biomarker of risk to mechanism of disease.This cardiac effect is mediated by FGF receptors (FGFR) but does not require klotho, the co-receptor in "classic" FGF23 target organs like the kidney. Our preliminary analyses indicate that of the four FGFR isoforms, FGF23 can directly activate FGFR4 in the absence of klotho.

Methods: To determine if FGFR4 activation in cardiac myocytes is required for FGF23-induced LVH, we used an isoform-specific anti-FGFR4 blocking antibody that is currently in clinical cancer trials. Neonatal rat ventricular myocytes were co-treated with recombinant FGF23 and anti-FGFR4 and analyzed for hypertrophic growth. Anti-FGFR4 was administered intraperitoneally to the 5/6 nephrectomy rat model of CKD every three days for two weeks, starting one hour after surgery, and serum, heart and kidney were isolated for molecular and histological analyses.

Results: Anti-FGFR4 treatment inhibits FGF23-induced hypertrophic growth of cardiac myocytes in vitro, and protects 5/6 nephrectomized rats from developing LVH without reducing the animals' elevated blood pressure and FGF23 levels or improving kidney function.

Conclusions: The development of LVH in the 5/6 nephrectomy rat model with elevated serum FGF23 requires FGFR4 activation. FGFR4 blockade might serve as a novel pharmacological intervention for LVH in patients with CKD.

Association of Bioavailable Vitamin D, Bone Mineral Density and Markers of Mineral Metabolism in Adults with Nephrotic Syndrome
Ashok Kumar Yadav,[1] Abhinav Aggarwal,[2] Vinod Sharma,[1] Raja Ramachandran,[1] Vivekanand Jha.[1] *[1]Nephrology, Post Graduate Inst of Medical Education and Research, Chandigarh, India; [2]Internal Medicine, Post Graduate Inst of Medical Education and Research, Chandigarh, India.*

Background: Blood levels of 25-hydroxyvitamin D [25(OH) D] are reduced in patients with nephrotic syndrome (NS). The relationship between reduction in vitamin D and bone health and abnormalities in mineral metabolism in NS is unclear. We hypothesized that alterations in bioavailable vitamin D levels might be linked to these abnormalities in NS.

Methods: We measured ciculating levels of total 25(OH)D, vitamin D binding protein (DBP), serum albumin, iPTH and fibroblast growth factor-23 (FGF-23) in 43 adults with sporadic idiopathic NS and 40 healthy controls. Free and bioavailable 25(OH)D were calculated from previously validated formulae. Bone mineral density (BMD) was measured at left neck of femur by DEXA.

Results: Compared to healthy controls, total, free and bioavailable 25(OH)D levels were significantly reduced in patients with NS. Among the nephrotic patients, bioavailable 25(OH)D was positively correlated with BMD ($r = 0.345$; $p = 0.024$), whereas total 25(OH) D ($r = 0.072$; $p = 0.65$) and free 25(OH)D levels ($r = 0.18$; $p = 0.25$) were not. Bioavailable 25(OH)D levels showed a strong inverse correlation with iPTH on univariate ($r = -0.428$; $p = 0.004$) and multivariate ($b = 0.42$, $p<0.001$) analyses. FGF -23 correlated with iPTH but not with calcium and phosphorus or vitamin D.

Conclusions: We conclude that bioavailable 25(OH)D is a better measure of vitamin D status with respect of BMD and mineral metabolism in patients of nephrotic syndrome.

Funding: Government Support - Non-U.S.

TH-OR106

Association of Bone Turnover with Oxidized PTH, but Not 'Intact' PTH or Non-Oxidized PTH, in Patients Undergoing Hemodialysis (HD) Treatment
Berthold Hocher,[3] Janaina Silva Martins,[4] Tilman B. Drueke,[1] Vanda Jorgetti.[2] *[1]Inserm U1088, UPJV, Amiens, France; [2]Nephrology, USP, Sao Paulo, Brazil; [3]Nutr Sciences, Univ Potsdam, Germany; [4]Univ Maranga, Parana.*

Background: Oxidized PTH (oxPTH) does not stimulate the PTH/PTHrp receptor, in contrast to non-oxidized PTH (n-oxPTH). PTH oxidation has been ignored in the development of PTH assays: the current intact PTH (iPTH) assays recognize both n-oxPTH and oxPTH. Our recently developed assay separately measures oxPTH and n-oxPTH. Here we analyze the relation of iPTH, oxPTH and n-oxPTH with bone morphology parameters in HD patients.

Methods: Bone histomorphometry data and blood samples for serum biochemistry were available from 51 HD patients. Mean (± SD) patients' age was 55±14 yr, and dialysis vintage 66±51 mo.

Results: Mean serum iPTH was 695±717, n-oxPTH 97±100, and oxPTH 598±628 pg/mL. Mean serum Ca was 8.4±2.7 mg/dL, phosphorus 6.0±2.1 mg/dL, 25OH vitD 54±28 ng/mL, and FGF23 9578±16483 pg/mL. Using Pearson's correlation analyses there was a strong relationship between iPTH and oxPTH ($r=0.998$; $p<0.0001$). The relationship was much weaker between iPTH and n-oxPTH ($r=0.861$; $p<0.0020$). Multivariate linear regression analysis revealed a positive correlation of mineral apposition rate with oxPTH ($\beta=0.725$, $p=0.006$) but a negative correlation with n-oxPTH ($\beta=-0.661$, $p=0.020$), and no correlation with iPTH (p=NS). Similarly, there was a positive correlation of bone formation rate with oxPTH ($\beta=0.816$, $p=0.002$), a negative correlation with n-oxPTH ($\beta=-0.714$, $p=0.010$), and no correlation with iPTH (p=NS). In addition to these dynamic parameters, there were similar negative and positive correlations of oxPTH and n-oxPTH, respectively, with the static parameters osteoblast surface and osteoclast surface. None of the 3 PTH species was associated with mineralization lag time, bone volume, or fibrosis volume.

Conclusions: Our study in HD patients unexpectedly showed positive correlations of dynamic and static bone activity parameters with oxPTH, but not with n-oxPTH. These findings either could indicate a direct stimulation of bone turnover by oxPTH under conditions of secondary hyperparathyroidism or be merely a reflection of enhanced bone turnover by oxidative stress.

TH-OR107

Increased Bone Density in Mice Lacking the Proton Receptor OGR1 Is due to Increased Osteoblast Activity Nancy S. Krieger, Min Ho Kim, David A. Bushinsky. *Medicine, Univ of Rochester, Rochester, NY.*

Background: Chronic metabolic acidosis (MET) stimulates net calcium (Ca) efflux from bone by decreasing osteoblastic (OB) bone formation and increasing osteoclastic (OC) bone resorption. OBs express the H^+-sensing G-protein coupled receptor, OGR1, which appears necessary for MET-induced bone resorption. Mice with a genetic null mutation in OGR1 (KO) have increased bone density compared to wild type (WT) which may be due to increased OB bone formation and/or decreased OC bone resorption. Here we test the hypothesis that the increased bone density in KO is caused by increased OB activity due to an inability of these KO to respond to the large endogenous H^+ production generated during rapid growth of the mice.

Methods: Femurs were dissected from 8 wk old KO and WT mice and RNA isolated for real time PCR (QPCR). OBs were isolated from neonatal KO and WT calvariae. RNA was obtained at confluence for baseline gene expression by QPCR and then after culture for 2 wks in mineralization medium. RNA expression was normalized to RPL13a.

Results: There is no difference in gross phenotype of KO compared to WT; however, both μCT and histology demonstrate an increase in bone volume, trabecular number and trabecular thickness in KO compared to WT (all $p<0.05$). Bone formation rate and OC number are also increased (both $p<0.05$). Femur mRNA from 8 wk old KO mice have increased OB runx2 expression compared to WT (3.0±0.9 versus 1.8±0.3, $p<0.05$), with no difference in OC TRAP (3.2±0.6 versus 2.5±0.5, p=ns) or cathepsin K (2.5±0.6 versus 3.3±0.7, p=ns) levels. Primary KO calvarial OBs have increased expression of runx2 (1.6±0.2 versus 1.1±0.2), osteocalcin (1.8±0.3 versus 1.0±0.1), collagen 1a1 (3.0±0.7 versus 1.2±0.2) and alkaline phosphatase (6.7±2.2 versus 2.0±0.6) at baseline compared to WT (all $p<0.05$). After 2 weeks in mineralization medium, KO OBs have elevated runx2 (5.2±1.3 versus 1.1±0.4), collagen 1a1 (4.3±0.9 versus 0.7±0.2) and osterix (2.5±1.2 versus 0.4±0.2) compared to WT (all $p<0.05$).

Conclusions: OGR1 KO mice have a consistent increase in markers of OB activity. Lack of OGR1 in KO mice results in OBs unable to respond to the large amount of H^+ generated by these rapidly growing mice and may account for their increased bone density.

Calcineurin Homologous Protein 1 Regulates the Renal Na-K-2Cl-Cotransporter Kerim Mutig,[1] Christin Dathe,[1] Alexander Paliege,[1] Vera Jankowski,[2] Shigeo Wakabayashi,[3] Takashi Hisamitsu,[3] Sebastian Bachmann.[1] *[1]Dept of Anatomy, Charité Universitaetsmedizin Berlin, Germany; [2]Dept of Nephrology, Charité Universitaetsmedizin Berlin, Germany; [3]Dept of Molecular Physiology, National Cerebral and Cardiovascular Center Research Inst, Osaka, Japan.*

Background: Activity of the thick ascending limb (TAL) Na-K-2Cl-cotransporter (NKCC2) is facilitated by phosphorylation. Our recent data suggest that calcineurin is involved in dephosphorylation and deactivation of NKCC2. The activity of the phosphatase can be modulated by members of the calcineurin homologous protein family (CHP). CHP1 has been implicated in the regulation of several membrane proteins either through direct interactions or via inhibition of calcineurin. This study focuses on the role of CHP1 in the regulation of NKCC2.

Methods: CHP1 was localized along the nephron using immunofluorescence. Protein-protein interactions were studied by co-immunoprecipitation (co-IP) and GST pulldown assay. Effects of CHP1 on NKCC2 phosphorylation have been evaluated in cell culture. To evaluate the role of CHP1 during vasopressin (AVP)-induced NKCC2 activation the AVP analogue desmopressin (dDAVP) has been acutely administered to AVP-deficient rats.

Results: CHP1 and NKCC2 were closely co-localized in the apical compartment of TAL cells and interacted by co-IP. GST pull down assay with recombinant NKCC2 C-terminus and N-terminal NKCC2 mutants mimicking its (de)phosphorylation at functionally relevant residues (T96, T101, T114, and S126) suggested that CHP1 preferentially interacts with the phosphorylated N-terminal tail of NKCC2. Overexpression of CHP1 substantially increased phosphorylation of endogenous NKCC2. The role of CHP1 during vasopressin (AVP)-induced NKCC2 activation was studied in AVP-deficient Brattleboro rats. Short-term stimulation of the AVP/V2 receptor axis in these rats resulted in a marked increase of NKCC2 phosphorylation which was paralleled by stronger interaction of the transporter with CHP1 and concomitant, weaker association between NKCC2 and calcineurin.

Conclusions: In sum, our data provide evidence for a permissive role of CHP1 in NKCC2 phosphorylation at baseline and during AVP-induced activation of the transporter.

TH-OR109

Identification of DNPEP, a Cytosolic Aminopeptidase That Cleaves SPAK in the Kidney Nicolas Markadieu,[1] Paul A. Welling,[2] Eric J. Delpire.[1] *[1]Dept of Anesthesiology, Vanderbilt Univ, Nashville, TN; [2]Dept of Physiology, Univ of Maryland, Baltimore, MD.*

Background: In the kidney, SPAK and OSR1 phosphorylate and activate the sodium chloride cotransporters NKCC2 and NCC. Although SPAK and OSR1 share high sequence homology, the molecular size of SPAK is larger than the size of OSR1, due to the presence of an N-terminal proline-alanine rich domain. In the mouse kidney, SPAK fragments have been detected and shown to be inhibitory to the activity of NKCC2. It has been hypothesized that those fragments originate from alternative translation start sites, but their precise origin is unknown. Here, we demonstrate that kidney possesses a protease cleaving SPAK but not OSR1.

Methods: Recombinant fusion proteins were purified from bacteria. Proteolytic cleavage was monitored by Western blotting. Protease was identified by ion exchange and size exclusion chromatography combined with mass spectrometry (MS). Identification of sites of cleavage was done by MS. Inhibitory effect of SPAK fragments was studied in *Xenopus laevis* oocytes.

Results: Lysates prepared from mouse kidney possess protease activity that leads to the cleavage of SPAK into multiple fragments. Cleavage was not prevented by widely used protease-, proteasome-, aminopeptidases (bestatin)-inhibitors. Proteolytic activity was inhibited by 1-10 mM DTT, 5-20 mM EDTA and by 5 mM phenanthroline. These results point to the action of a Zn^{2+} metalloprotease. Active fractions collected from gel filtration indicated that the protease molecular weight was as large as thyroglobulin. Cation exchange chromatography combined with MS provided a list of 44 proteases, including seven Zn^{2+} metalloproteases. Among those, DNPEP caught our attention as it has a molecular weight of 624 kDa and is sensitive to DTT, EDTA, phenanthroline, but not bestatin. DNPEP was cloned from mouse kidney and recombinant DNPEP produced the same pattern of degradation. By mass spectrometry, we identified the cleavage sites within SPAK. Corresponding SPAK fragments were constructed and demonstrated to be inhibitory to NKCC2.

Conclusions: Our data indicate that DNPEP specifically cleaves SPAK in kidney to give rise to fragments which are inhibitory to NKCC2.

TH-OR110

Functional Characterization of an Alternative Splice Variant of the Thiazide-Sensitive NaCl Cotransporter Sabina K. Jelen, Omar Tutakhel, Marco Valdez Flores, Joost Hoenderop, René J. Bindels. *Dept of Physiology, Radboud Univ Medical Centre, Nijmegen, Netherlands.*

Background: The importance of the thiazide-sensitive Na^+-Cl^- cotransporter (NCC) in renal electrolyte transport and blood pressure regulation has been well documented. Recently, a new phosphorylation site at serine 811 (pS811) in the carboxyl (C)-terminal domain of NCC was identified. This phosphorylation site is present only in the longest NCC splice variant (NCC-Sv), up to now an isoform poorly characterized. The aim of the present study was to establish localization of NCC-Sv in the human kidney as well as to determine its functional properties.

Methods: Immunohistological analysis was performed on kidney biopsies of healthy human subjects. Urinary exosomes were isolated and probed for protein abundance in Western blot analysis. Functional properties of NCC-Sv was evaluated by $^{22}Na^+$ influx measurements using the *Xenopus laevis* expression system.

Results: Immunohistological analysis of NCC-Sv in the human kidney showed a robust expression at the apical site of the distal convoluted tubule. Similarly, the NCC-Sv protein was detected in human urinary exosomes. We also demonstrated that acute water loading in human subjects significantly reduces abundance of NCC-Sv in urinary exosomes. Thiazide-sensitive $^{22}Na^+$ transport of NCC-Sv was significantly increased in comparison to the wild type NCC (NCC-Wt). The mutant mimicking a constitutively active phosphorylation site at the residue 811 (S811D) presented an additional increase of Na^+ transport in comparison to unmutated NCC-Sv. Consequently, inactive mutant (S811A) prevented the enhanced response.

Conclusions: The present study for the first time demonstrates a vast abundance and dynamic regulation of the alternative isoform of NCC protein in the human kidney, potentially controlled by additional phosphorylation pathway. Previously underrepresented NCC-Sv may constitute a unique route of Na^+ reabsorption and could play an important role in blood pressure regulation. Analysis of samples from different human pathological states as well as various *in vitro* models could aid in determining the precise regulation and function of NCC-Sv.

KCNJ10 (Kir4.1) Determines the Apical Na-Cl Expression in the Distal Convoluted Tubule (DCT) WenHui Wang. *Pharmacology, New York Medical College, Valhalla, NY.*

Background: The renal phenotype induced by loss-of-function mutations of Kcnj10 is characterized by salt wasting, hypomagnesemia, metabolic alkalosis and hypokalemia. However, the mechanism by which Kir.4.1 mutations cause the tubulopathy is not completely understood.

Methods: Because homozygous *Kcnj10*-/- mice were not able to survive more than two weeks after birth, it prevents studying renal phenotype of adult Kcnj10 knockout mice. Thus, the present study was carried out in p7-p10 neonatal littermates to explore the role of Kcnj10 in regulating the membrane transport in DCT.

Results: Immunostaining demonstrated Kcnj10 and Kcnj16 were expressed in the basolateral membrane of DCT. The patch-clamp study detected a 40 pS K channel, a heterotetramer of Kcnj10 and 16, in the basolateral membrane of the early DCT (DCT1) of p8-p10 wild type *Kcnj*10+/+ mice (WT). The probability of finding the 40 pS K channel was decreased in Heterozygous *Kcnj10*+/- (het) and was zero in homozygous *Kcnj*10-/- (knockout) mice. Moreover, the disruption of Kcnj10 almost completely eliminated the basolateral K conductance and decreased the negativity of the cell membrane potential in DCT1. Moreover, the lack of Kcnj10 also decreased the basolateral Cl conductance and inhibited the expression of Ste20-prorin-alanine-rich protein kinase (SPAK). Immunostaining image showed that NCC was highly expressed in the apical membrane

of DCT of WT but the staining of NCC was fait in the apical membrane and diffused into the intracellular space of knockout mice. Western blot further demonstrated that NCC expression was low in het mice but it was the lowest in knockout mice.

Conclusions: We conclude that Kcnj10 plays a dominant role in determining the basolateral K conductance and membrane potential of DCT1 and that the basolateral K channel activity in the DCT determines the apical NCC expression possibly through SPAK-dependent mechanism.

Increased Calcium-Binding Protein 39 (Cab39) Expression in Renal Tubule Recuses the Gitelman-Like Phenotype in Wnk4 Knockout Mice

Sung-Sen Yang, Shih-Hua P. Lin, Chih-Jen Cheng. *Div of Nephrology, Tri-Service General Hospital, Naional Defense Medical Center, Taipei, Taiwan.*

Background: Recently, it was shown that an ubiquitously expressed Cab39 protein could also stimulate Na-(K)-(2)Cl cotransporter [N(K)CC] through activating SPAK/OSR1 kinases mimicking WNK1/4 kinases *in vitro study.*To uncover the physiological role of Cab39 on the regulation of SPAK/OSR1 and N(K)CC *in vivo*, especially in the renal tubules.

Methods: We generated and analyzed both the kidney tubule-specific cadherin gene promoter driven flag-tagged mouse Cab39 (KSP-Flag-mCab39) transgenic (Tg) and WNK4 knockout mice. At age of 10-12 weeks fed with normal rodent chaw, phenotype including blood pressure as well as serum and urine electrolytes was measured in WT, Cab39 Tg, Wnk4 knockout and Cab39 TgxWnk4 knockout transgenic mice. The expression of WNK1/4, Cab39, SPAK/OSR1 and N(K)CC was evaluated by western blotting and immunofluorescence stain.

Results: Offspring from Cab39 Tg mice with mildly overexpressed abundance of flag-Cab39 (25% ±6%) were phenotypically normal but a slightly increased p-SPAK/OSR1, p-NKCC2 and p-NCC in the kidneys was found. A significantly elevated blood pressure ($p<0.05$) and slightly hyperkalemia ($p=0.16$) but a resistance of p-SPAK/OSR1, p-NKCC2 and p-NCC suppression were observed in the Cab39 Tg mice with high NaCl intake. Wnk4 knockout mice manifested Gitelman-like syndrome (with hypotensionm hypokalemia, hypomagnesemia and hypocalciuria) with significantly reduced abundance of phosphorylated Spak, Osr1 and Ncc ($p<0.05$). The phenotype and abundance of the p-SPAK/OSR1 and p-NCC in WNK4 knockout mice was partially corrected after crossing with Cab39 Tg mice.

Conclusions: Augmented Cab39 expression in renal tubule may lead to salt-sensitive hypertension through activating SPAK/OSR1-N(K)CC signaling. Reduced WNK4 stimulation of SPAK/OSR1-NCC phosphorylation signaling could be rescued by Cab39 overexpression.

Renal Epithelial-Specific Disruption of Cullin 3 Causes Salt-Wasting, Polyuria, and Renal Fibrosis

Hae Jean Park, James A. McCormick. *Medicine (Nephrology and Hypertension), Oregon Health and Science Univ, Portland, OR.*

Background: Familial Hyperkalemic Hypertension (FHHt) is caused by mutations in genes that regulate activity of the renal sodium chloride cotransporter (NCC), including the kinases WNK1 and WNK4, and Cullin3 (Cul3) and KLHL3, members of a ring ubiquitin ligase complex.

Methods: To examine the physiological roles of Cul3 and gain insight as to how Cul3 mutations might cause FHHt, we generated doxycycline-inducible kidney-specific $Cul3^{-/-}$ mice using the Pax8-LC1 system.

Results: Western blots showed nearly complete absence of Cul3 in $Cul3^{-/-}$ kidneys. Expression levels of WNK4 were dramatically elevated in $Cul3^{-/-}$ mice, while expression of total and phospho-NCC, KLHL3, WNK1, and WNK3 were only modestly elevated. Surprisingly the effects of Cul3 disruption on renal function were the opposite of those predicted by western blotting. $Cul3^{-/-}$ mice displayed volume contraction, hypochloremia, metabolic alkalosis, elevated plasma aldosterone, and a trend toward hypokalemia. Blood pressure, measured by radiotelemetry, was similar in wild type and $Cul3^{-/-}$ mice on normal NaCl diet, but during NaCl restriction, $Cul3^{-/-}$ mice displayed a progressive reduction in blood pressure; at 9 days, their 24h mean blood pressure was 18 mmHg lower. $Cul3^{-/-}$ mice displayed profound polyuria (5-fold higher urine volume than wild type), and salt, potassium and calcium wasting. Expression levels of p-NKCC2 were reduced in the medulla, while AQP2 expression was almost absent in $Cul3^{-/-}$ mice, providing mechanisms for the observed salt, potassium and calcium wasting, and for the polyuria. Histological analysis revealed the rapid onset of tubulointerstitial inflammation and fibrosis, with signs of inflammation including neutrophil and white cell casts. $Cul3^{-/-}$ mice also displayed elevated plasma creatinine and BUN, and proteinuria. Expression levels of the cell cycle regulator Cyclin E, a target of Cul3 that plays a role in the development of fibrosis, were also elevated.

Conclusions: In conclusion, these data suggest that loss of Cul3 activity along the nephron does not mimic FHHt, but leads to salt wasting and polyuria via effects on NKCC2 and AQP2, and also causes kidney injury.

Distal Nephron Remodeling Occurs in Response to a Loss of Thiazide-Sensitive Sodium-Chloride Channel Phosphorylation

P. Richard Grimm,[1] Susan M. Wall,[2] Eric J. Delpire,[3] Paul A. Welling.[1] *[1]Physiology, Univ of Maryland SOM, Baltimore, MD; [2]Renal Divison, Emory Univ SOM, Atlanta, GA; [3]Anesthesiology, Vanderbilt SOM, Nashville, TN.*

Background: Salt balance is maintained in the absence of the renal thiazide-sensitive sodium-chloride cotransporter (NCC) by poorly defined adaptive mechanisms, which may limit diuretic efficacy. Here, we identify nephron remodeling processes in SPAK null mice, which are unable to phospho-activate NCC and exhibit a salt-wasting nephropathy similar to Gitelman Syndrome.

Methods: Global transcriptional profiling, combined with biochemical and physiological phenotyping, identified the gene expression signature of the adaptive response in the SPAK KO mice, and revealed how it establishes a new adaptive physiology.

Results: We found salt reabsorption pathways are created by the coordinated induction of a multi-gene transport system in Pendrin(+)-intercalated cells (PPIC), involving solute carriers (pendrin, *Slc26a4*; NDCBE, *Slc4a8*; AE4, *Slc4a9*), carbonic anhydrase 2 and 15, and V-type H^+-ATPase subunits, and activation of ENaC in principal cells (PC). The gene profile was also enriched in Notch signaling factors that contribute to nephrogensis in the developing kidney, prompting us to examine morphogenesis of the adult distal nephron. Analytical confocal microscopy and morphometric measurements revealed that activation of the transport pathways coincides with a remodeling process, which replaces acid-secreting α-intercalated cells with PPIC, and expands the CNT with an increased number of PC to replace the dystrophic DCT. Up-regulation of the Notch receptor ligand, Jagged 1 (Jag-1), and down-regulation of Jag-2 was accompanied by an increase in a key Notch-activated transcriptional factor, Hes1, in PC of the CNT, suggesting that Notch signaling is activated to drive a program of PC differentiation and proliferation.

Conclusions: Nephrogenic cell fate determinants are reactivated in the adult kidney to remodel the distal nephron in response to NCC inhibition. Activation of adaptive salt reabsorption pathways are explained by the CNT remodeling processes that replaces α-IC with PPIC and increases the number of PC.

MicroRNA-27 Is Upregulated by Aldosterone in the Kidney Distal Nephron Where It Facilitates the Regulation of ENaC-Mediated Sodium Transport

Michael Butterworth,[1] Christine Anne Klemens,[1] Yu Leng Phua,[2] Jacqueline Ho.[2] *[1]Dept of Cell Biology, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Pediatrics, Div of Nephrology, Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA.*

Background: The epithelial sodium channel (ENaC) is a major determinant of sodium (Na^+) reabsorption in the kidney. We recently reported that aldosterone (aldo) modifies expression of microRNAs (miRs) to alter target gene expression and regulate Na^+ transport in principal cells of the cortical collecting duct (CCD) (JASN, in press). Here we investigated two miR clusters that are significantly upregulated by aldo, and are members of the miR-23~24~27 family.

Methods: Experiments were carried out in cultured mCCD-cl1 cells or from CCD cells isolated from mouse kidney using a magnetic bead/lectin conjugation procedure.

Results: Aldo stimulation (50nM, 24hr) of mCCD cells resulted in >1.7 fold increase in miR-23~24~27 family members as determined by microarray and qRT-PCR. In isolated ex-vivo CCD cells from aldosterone stimulated mouse kidneys these miRs were significantly increased (1.6-3.5 fold). Overexpression of the miRs, using mimics, increased ENaC-mediated Na^+ transport in the mCCD cell line (44±5.9%, n=8, $p<0.002$), without aldo stimulation. Inhibition of miR family members using locked nucleic acid inhibitors, blunted aldosterone stimulation. Of the family members a change in miR-27 expression was the most effective in altering ENaC-mediated Na^+ transport. To establish the role of miR-27 in aldo regulation, we depleted the expression of the miR processing enzyme Dicer1 in mCCD cells. As we recently reported, Dicer1 depletion prevented stimulation of mCCD cells by aldo (7±20% stimulation compared to 96±15% in controls n=6). We next overexpressed miR-27 in the Dicer1 KD cells, so that only mature miR-27 was present. MiR-27 overexpression partially restored the aldo stimulation (74±30%, n=5), comapred to control KD cells.

Conclusions: The results support our recent findings that miRs are essential components of the aldo signaling cascade that regulate Na^+ homeostasis, and further implicate miR-27 as an essential miR in this new signaling pathway.

TH-OR116

The PIM-3 Kinase as a New Player in the Aldosterone-Regulated Renal Salt Handling

Alessia Spirli, Caroline Ronzaud, Olivier Staub. *Dept of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland.*

Background: The kidneys play a central role in blood pressure regulation as defaults in maintaining salt balance can result in the development of hypertension, the most common disease in the human population. The renin-angiotensin-aldosterone system (RAAS) plays a crucial role in salt handling. Aldosterone is the key hormone in the control of sodium balance, blood volume and blood pressure, acting in the aldosterone-sensitive distal nephron (ASDN) and stimulating a complex transcriptional, translational and cellular program.

Methods: We have carried out a gene expression profiling in a mouse cortical collecting duct cell model (mpkCCD), stimulated or not by aldosterone, and identified the PIM-3 Ser/Thr kinase as a novel aldosterone-induced protein. PIM kinases (PIM-1, -2 and -3), and

in particular PIM-3, are overexpressed in different tumors. PIM-3, the only PIM kinase family member expressed in the kidney, has similar substrate specificities to other Ser/Thr kinases (e.g. SGK1, PKB) but its role in the kidney is largely unknown. Here we studied a possible new role of PIM-3 in the regulation of renal salt handling, both *in vitro* ($mCCD_{cl1}$ cells) and *in vivo* (PIM-3 KO mice).

Results: In $mCCD_{cl1}$ cells, we confirmed that PIM-3 expression is stimulated by aldosterone and observed that shRNA-based suppression of PIM-3 reduces basal and aldosterone-induced sodium currents as well as the activation of the aldosterone-mineralocorticoid receptor pathway. In PIM-3 KO mice, we found increased circulating renin activity and elevated plasma aldosterone levels compared to control littermates. Moreover, preliminary measurements of metabolic parameters indicate that sodium handling is impaired in PIM-3 KO mice.

Conclusions: In conclusion, our data suggest a possible novel function of the PIM-3 kinase and its potentially important role in the control of sodium homeostasis and blood pressure.

TH-OR117

The BKα/β1 Channel Localizes to Cilia of Principal Cells (PC) in Cortical Collecting Duct (CCD) Rolando Carrisoza-Gaytan,[1] Carlos Schreck,[1] Lijun Wang,[2] WenHui Wang,[2] Lisa M. Satlin.[1] *[1]Pediatrics, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Pharmacology, New York Medical College, Valhalla, NY.*

Background: Conducting BK channels, present in PC and intercalated cells (IC) of the CCD, mediate Ca^{2+}-dependent iberiotoxin (IbTX)-sensitive flow-induced K secretion (FIKS). PC, which possess a single apical cilium which responds to manipulation with an increase in cell Ca^{2+} concentration, are considered to mediate transepithelial Na absorption and K secretion. However, immunodetectable BKα has been consistently identified along the apical membrane of acid-base transporting IC, which are decorated with apical microvilli and microplicae, and not PC, raising uncertainty as to the identity of the cells that mediate FIKS. Based on the localization of mechanosensitive Ca^{2+} channels (polycystin-2) to cilia, we hypothesized that BKα localizes to the cilia of PC and thus mediates FIKS.

Methods: Microperfused CCDs from NZW rabbits fed control, low, or high K (HK) diet x 5 d were fixed for immunolabeling for BKα, β1 or β4 subunits, α-tubulin, or AQP2, and visualized by confocal microscopy. Net transport (Jx) of Na and K was measured in microperfused control or deciliated (with 1 mM dibucaine) CCDs. Single channel recordings were obtained from cell-attached patches of cilia or apical membrane of mpkCCD cells stably-transfected with Ssr3::GFP.

Results: Immunodetectable BKα colocalizes with β1 in cilia and apical membrane of PC and microvilli of IC, but not β4, which is distributed diffusely throughout the cytoplasm of all CCD cells. A HK diet enhances BKα labeling in apical membrane of IC but not cilia in AQP2 positive cells. Pharmacological deciliation of CCD leads to no apparent change in FIKS but tends to reduce JNa (77.8+2.6 to 11.6+29.1 pmol/min.mm; n=3, p=0.07). K channels with conductance and kinetics typical for the BK channel are present in cilia.

Conclusions: Immunodetectable BKα/β1 is present on cilia of PC and may represent the functional channel detected by patch clamp analysis. Given that deciliation of CCD PC does not affect FIKS, we speculate that the cilia BK channel participates in maintaining a favorable membrane potential for sustained Ca^{2+} entry into cilia.

In Vivo Measurement of Albumin Concentration Gradients within the Glomerular Capillary Wall Bingshu Wang,[1] Ruben M. Sandoval,[2] Bruce A. Molitoris,[2] Don Mitchell Wilkes,[1] William Fissell.[3] *[1]Electrical Engineering, Vanderbilt Univ, Nashville, TN; [2]Div of Nephrology, Indiana Univ, Indianapolis, IN; [3]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN.*

Background: Proteinuria is the single strongest risk factor predicting end stage renal disease and is mechanistically important in tubulointerstitial scarring. There is still significant uncertainty regarding the mechanism by which the glomerular capillary wall (GCW) retains proteins. Imaging studies of frozen tissue as well as transport theory do not support a role for the podocyte as molecular sieve, yet foot process effacement invariably accompanies significant proteinuria. We present the first measurements of solute concentration profiles within the GCW in living animals.

Methods: Glomeruli of 20 week old Fromter strain and 11 week old Simonsen strain Munich-Wistar rats were imaged using two-photon intravital microscopy with FITC-labelled low molecular weight dextran (LMWD) and Texas Red labeled albumin. Lateral resolving power for the confocal microscope is estimated to be 220 nm sampled at a spatial frequency of 62 nm. Regions of interest with capillary lumen, Bowman's space and podocyte foot processes were identified. A computer algorithm selected a contour corresponding to the glomerular basement membrane (GBM) based on the locations of the foot processes in the LMWD image. The algorithm then selected transects perpendicular to the GBM contour and recorded the brightness of the albumin signal along each transect from lumen to Bowman's space. For each region of interest, transect solute profiles were aligned to the GBM contour and averaged.

Results: Both LMWD and albumin concentrations decrease monotonically from capillary lumen to Bowman's space. There is no evidence for a concentration polarization of albumin within the GBM as would be expected if the podocyte slit diaphragm were the most stringent filter in the GCW.

Conclusions: This finding is consistent with inferences from multiple other studies that suggest a significant role for the basement membrane in protein retention. Further mechanistic insight regarding protein retention by the GCW is needed.

TH-OR119

Genetic Deletion of Endothelial Hyaluronan Synthase 2 Results in Glomerular Injury and Albuminuria Bernard van den Berg,[1,3] Margien G.S. Boels,[1] Cristina Avramut,[1,2] Erik Jansen,[3] Sascha Meldner,[4] Martijn Dane,[1] Johan Van der Vlag,[5] Hans Vink,[6] Abraham J. Koster,[2] Anton Jan Van Zonneveld,[1] Hermann-Josef Groene,[4] Eelco de Koning,[1,3] Ton J. Rabelink.[1] *[1]Nephrology, LUMC, Leiden, Netherlands; [2]Molecular Cell Biology, LUMC, Leiden, Netherlands; [3]De Koning Group, Hubrecht Inst for Developmental Biology and Stem Cell Research, Utrecht, Netherlands; [4]Cellular and Molecular Pathology, DKFZ, Heidelberg, Germany; [5]Nephrology, RUNMC, Nijmegen, Netherlands; [6]Physiology, MUMC, Maastricht, Netherlands.*

Background: We tested the hypothesis that the glomerular endothelial glycocalyx constitutes a primary barrier against albumin filtration and development of renal injury. To this end we constructed mice that have an inducible deletion of endothelial hyaluronan synthase 2 (has2). This enzyme produces the polysaccharide hyaluronan, a major constituent of the glycocalyx, in particular with respect to its physical dimensions and structure.

Methods: 8-Week old B6.cdh5-creERT2.has2$^{f/f}$.R26R-tdTom (has2-cKO) mice were injected i.p., 5x with 2mg/0.2mL tamoxifen (ctrl, B6.cdh5-creERT2.R26R-tdTom). Tail-cuff DBP and SBP measurements, 24hrs urine and organs were collected at 2-, 4- and 8wks after induction for analysis.

Results: Over the 8 week period following induction, has2-cKO mice developed systemic edema and increased urinary albumin excretion (ACR of 58±8 versus ctrl 36±2, p=0.036). DBP and SBP did not change. At 4 weeks the histology showed glomerular capillary hypertrophy (1194±77 versus 795±55μm^2, p<0.01) and diffuse mesangial expansion (2200±75 versus 888±77μm^2, p<0.01). This was associated with focal mesangiolysis and the formation of micro aneurisms. At 8 weeks these lesions progressed to diffuse glomerular capillary rarefaction (capillary area 531±26 versus 834±47μm^2, p<0.01) and was accompanied by focal loss of podocyte foot processes, without signs of tubular damage.

Conclusions: Loss of hyaluronan from the glomerular endothelial glycocalyx results in destabilization of glomerular capillary structure and albuminuria. Financial Support by the Dutch Kidney Foundation (grants C08.2265 and C09.03).

TH-OR120

The Absence of Albumin Improves Kidney Disease in Alport Mice George Jarad, Jeffrey H. Miner. *Medicine/Renal, Washington Univ School of Medicine, St. Louis, MO.*

Background: Alport syndrome is an inherited glomerular disease that leads to ESRD. Alport syndrome is the result of the absence of normal collagen IV in the glomerular basement membrane (GBM). Previous investigations in Alport mice suggested that increased albumin permeability is an early phenomenon preceding the development of severe GBM, podocyte, and tubulointerstitial abnormalities. Whether filtered albumin contributes to kidney disease progression and whether reducing albuminuria can improve outcomes are still open questions.

Methods: To investigate the role albuminuria plays in Alport syndrome, we generated an albumin null (*Alb-/-*) mouse, then generated a mouse model of Alport syndrome that lacks any circulating or filtered albumin (*Col4a3-/-;Alb-/- mice*). *Alb-/-* mice are viable and fertile. Despite the lack albumin, reduced total serum protein and associated dyslipidemia, *Alb-/-* mice do not develop edema or ascites and their blood pressures are within normal range. *Alb-/-* mice have normal kidneys and BUN and creatinine. *Alb+/-* mice show significant reduction in serum albumin (~50%) and the same level of dyslipidemia as *Alb-/-* mice.

Results: *Col4a3-/-;Alb-/-* mice are viable and indistinguishable from their *Col4a3-/-; Alb+/-* littermates at birth. Although they do eventually succumb to kidney disease, their survival is improved compared to Alport mice with albumin (>1 year compared to 6.5-8.5 months). In the absence of albumin, there is some improvement in tubulointerstitial injury, but more significantly, there is also significant improvement in the glomerular phenotype. The improvement includes reductions in glomerulosclerosis, GBM thickening, podocyte foot process effacement, deposition of laminin alpha2 in the GBM, and better preservation of slit diaphragm components. These improvements are not secondary to lower blood pressure in the double mutant mice or to lipid abnormalities.

Conclusions: These early results lead us to conclude that the absence of albumin attenuates kidney injury in Alport syndrome, however, contrary to current dogma, the primary site of albumin-induced injury appears to be the glomerulus, especially podocytes, not tubular cells. The mechanism for this improvement is under further investigation.

TH-OR121

Tubule-Specific ß-Catenin Signaling Contributes to Glomerular Injuries Roderick J. Tan,[1] Dong Zhou,[2] Liangxiang Xiao,[2] Robert Powers,[3] Youhua Liu.[2] *[1]Medicine, Univ of Pittsburgh, Pittsburgh, PA; [2]Pathology, Univ of Pittsburgh, Pittsburgh, PA; [3]Obstetrics, Gynecology and Reproductive Sciences, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Wnt/ß-catenin is an evolutionarily conserved signaling pathway important in kidney development. Although quiescent in adults, this pathway is re-activated in disease and contributes to kidney pathology. Previous evidence has shown that activation of glomerular ß-catenin expression causes glomerular injury and proteinuria, but whether tubule-specific ß-catenin activation contributes to these injuries was unknown.

Methods: We crossed ß-catenin floxed mice with mice expressing Cre under the tubule-specific Ksp promoter, resulting in tubule-specific knockouts for ß-catenin (Ksp-ß-catenin). To induce proteinuria, we exposed these mice to angiotensin II (1.5 mg/kg/day), or to adriamycin (14 mg/kg). Urinary albumin-to-creatinine ratios were determined. Wilms tumor 1 (WT1) was detected with western blot and immunofluorescence. Blood pressure was measured with tail volume-pressure recordings.

Results: All mice developed albuminuria, but Ksp-ß-catenin mice had significantly less albuminuria compared to control littermates. We obtained similar results with adriamycin, demonstrating that this effect was generalizable to proteinuric diseases. The albuminuria was not accompanied by increases in low-molecular weight proteins, suggesting that excretion originated from glomeruli rather than the tubules. In support of this, we found that angiotensin-treated control littermates expressed less WT1 compared with Ksp-ß-catenin mice. As WT1 is critical for maintenance of podocyte differentiation and function, this suggests that tubule-derived ß-catenin adversely affects podocytes during disease. Another interesting finding was that Ksp-ß-catenin mice were protected from angiotensin-induced increases in blood pressure.

Conclusions: Tubule-specific ß-catenin activation plays a key role in the development of glomerular injuries, primarily through a reduction in WT1 expression and an increase in systemic blood pressure. Our studies suggest a novel ß-catenin-mediated tubular-glomerular crosstalk in the pathogenesis of proteinuric kidney diseases.

TH-OR122

Endoplasmic Reticulum Stress Is a New Therapeutic Target in Proteinuric Chronic Kidney Diseases Khalil El Karoui,[1] Amandine Viau,[1] Clement Nguyen,[1] Martine Burtin,[1] Laurence Heidet,[2] Geraldine Mollet,[2] Frank Bienaime,[1] Morgan Gallazzini,[1] Fabiola Terzi.[1] *[1]INSERM U1151 - Hôpital Necker Enfants Malades, Paris, France; [2]INSERM U1163 - Hôpital Necker Enfants Malades, Paris, France.*

Background: Proteinuria is a critical player of CKD progression. Proteinuria may accelerate the development of tubulo-interstitial lesions by favoring the production of several molecules, such as endothelin-1, MCP-1, RANTES or complement components, in tubular cells. However, none of these pathways has led so far to new treatments in humans. Our aim was to identify a new therapeutic strategy to slow down proteinuric CKD progression.

Methods: We combined genetic and pharmacologic models of proteinuria with in vitro studies in which tubular cells were exposed to albumin or ER stress inductors. Pharmacological inhibitors were used. Human biopsies from CKD patients were studied.

Results: We demonstrated that ER stress and unfolded protein response (UPR) activation in tubular cells is a hallmark of proteinuric diseases. Mechanistically, we showed that extracellular albumin directly induced UPR in tubular cells in a calcium-dependent manner. We also identified a novel pathway in which proteinuria-induced UPR regulates the expression Lipocalin2 (Lcn2), a known mediator of CKD progression, via the activating transcription factor 4. These results were not restricted to mice, as we identified Lcn2 activation in proteinuric patients. Notably, we demonstrated Lcn2 is involved in the deleterious effect of proteinuria. In fact, Lcn2 gene invalidation protected proteinuric mice from CKD progression and mortality by decreasing ER-induced apoptosis. More importantly, we demonstrated that this pathway can be pharmacologically inhibited by phenylbutyrate, a drug already used in humans, which has a chaperone activity: inhibition of ER stress reduced tubular lesions, renal dysfunction, and Lcn2 activation in proteinuric mice. Interestingly, a pilot study revealed that phenylbutyrate might decrease urinary Lcn2 in proteinuric patients.

Conclusions: In conclusions, our study uncovers a novel molecular pathway of proteinuria and identified ER stress inhibitors as a novel therapeutic strategy for the maintenance of tubular structures in proteinuric CKD.

Injury to Glomerular Permeability Barrier by Cardiotrophin-Like Cytokine Factor 1 (CLCF1) or Focal Segmental Glomerulosclerosis (FSGS) Serum Is Mediated by JAK2 and STAT3 Activation Mukut Sharma,[1] Jianping Zhou,[1] Tarak Srivastava,[2] Ellen T. McCarthy,[3] Ram Sharma,[1] Virginia J. Savin,[1] Jean-Francois Gauchat.[4] *[1]Nephrology Research, Kansas City VAMC, Kansas City, MO; [2]Pedicatric Nephrology, Children's Mercy Hospital, Kansas City, MO; [3]Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS, United States Minor Outlying Islands; [4]Pharmacology, Univ of Montreal, Montreal, Canada.*

Background: We have shown that CLCF1 is present in plasma from patients with recurrent FSGS. CLCF1 is an IL6 family cytokine that activates the JAK/STAT pathway and is believed to be secreted as a heterodimer with cytokine receptor-like factor 1 (CRLF1). Recombinant CLCF1 increases albumin permeability (P_{alb}) while the heterodimer CLCF1-CLF1 or CRLF1 alone blocks this effect. JAK2 and STAT3 are dominant isoforms in glomeruli and podocytes. We hypothesized that inhibitors of JAK/STAT pathway would also block the effect of CLCF1 on P_{alb}.

Methods: We incubated isolated rat glomeruli with rCLCF1 (10 ng/mL) or FSGS sera (n=6, 2% vol/vol). We included anti-CLCF1 mAb (0.5-50 mkg/mL) in some conditions. In separate experiments, we pre-treated glomeruli with JAK2 inhibitor BMS911543 (5nM) or STAT3 inhibitor STATTIC (0.001-10 mkM) followed by addition of rCLCF1 or FSGS serum. Change in albumin permeability (P_{alb}) was detemined using an in vitro assay.

Results: BMS911543 blocked the effect of both rCLCF1 and the effect of each FSGS serum ($p<0.001$). STATTIC also blocked the effect of both CLCF1 and of FSGS serum. This effect was dose dependent with maximal effect at 100nM ($p<0.001$ in each case). Anti-CLCF1 antibody blocked the CLCF1 or FSGS serum-induced increase in P_{alb} in a dose-dependent manner ($p<0.001$ at 5 mkg/mL antibody).

Conclusions: We conclude that activation of JAK2/STAT3 by CLCF1 or FSGS sera is required for the observed loss of glomerular permeability barrier. Small molecule JAK2 and STAT3 inhibitors have recently become available and are being tested in clinical trials to treat other diseases. Repurposing orally available JAK2 and STAT3 inhibitors may provide effective intervention to treat glomerular dysfunction and proteinuria in FSGS as well as other diseases.

TH-OR124

Neutrophil and Macrophage Extracellular Traps and Extracellular Myeloperoxidase Are Prominent in Human Anti-Neutrophil Cytoplasmic Antibody Associated Vasculitis Kim M. O'Sullivan,[1] Shaun A. Summers,[1,2] Poh-Yi Gan,[1] Sharon Lee Ford,[1,2] A. Richard Kitching,[1,2] Peter G. Kerr,[1,2] Stephen R. Holdsworth.[1,2] *[1]Dept of Medicine, Monash Univ, Melbourne, Victoria, Australia; [2]Dept of Nephrology, Monash Health, Melbourne, Victoria, Australia.*

Background: Myeloperoxidase (MPO) is the major autoantigenic target in MPO ANCA associated Vasculitis (AAV) but is potentially also a mediator of glomerular injury.

Methods: To assess the participation of MPO in the glomerular lesions of glomerulonephritis (GN) in MPO AAV patients, 48 renal biopsies were examined by confocal microscopy for MPO positive infiltrating cells, the extent of extracellular MPO and its association with either neutrophil extracellular traps (NETs) or macrophage extracellular traps (METs). These were correlated with clinical and histological parameters. Control biopsies included 10 patients within minimal renal disease (MRD) and 11 with anti PR3 AAV.

Results: MPO was rarely detected in MRD controls but was prominent in all cases of MPO AAV. The most abundant MPO positive cells were a sub population (31.7%) of CD68+ macrophages then MPO+CD15+ neutrophils. The total number of glomerular MPO+ cells correlated with decreased eGFR at the time of biopsy, ($r=-0.3$, $P=0.04$) as did the interstitial presence of MPO+ macrophages and neutrophils ($r=-0.34$, $P=0.02$, and $r=-0.39$, $P=0.01$). Extracellular MPO comprised 24.7% of total renal MPO. NETs were found in the glomeruli and interstitium of 63% of patient biopsies and patients with NETS had significantly more total and extracellular MPO. Seventy five percent of NET+ biopsies had NETs present in over 50% of their glomeruli. Co-localisation studies suggest neutrophils are the major source of extracellular MPO ($P=0.0006$). MPO+CD68 macrophages also demonstrated MPO in extracellular traps (METs). Control PR3 AAV biopsies showed similar extent and cell associations of MPO as seen in MPO AAV biopsies.

Conclusions: This study demonstrates the prominent participation of MPO in AAV. In MPO-AAV, most renal MPO is contained in macrophages the predominant leukocyte in this disease. MPO is also prominent extracellularly, alone and as NETS. We now report MPO containing METs contribute to MPO participation in this disease.

Neutrophil-Extracellular Traps Cause ANCA-Induced Glomerulonephritis in a Complement-Dependent Mannor Adrian Schreiber,[1,2] Ralph Kettritz,[1,2] Astrid Bergmann.[1] *[1]Experimental and Clinical Research Center (ECRC) at the MDC Berlin, Charité, Berlin, Germany; [2]Dept of Nephrology and Intensive Care Medicine, Campus Virchow Clinic, Medical Faculty of the Charité, Berlin, Germany.*

Background: ANCA are found in patients with necrotizing crescentic glomerulonephritis (NCGN). Numerous experiments showed that ANCA activate several neutrophil functions in vitro, including respiratory burst, degranulation, complement activation, and neutrophil

extracellular trap (NET) formation. Using an ANCA mouse model, we established neutrophil serine proteases and the alternative complement pathway as a disease inducer, whereas NADPH oxidase-dependent ROS were protective. We now hypothesized that NETs are a mediator of ANCA-induced NCGN.

Results: By immunofluorescence, primed human neutrophils challenged with control IgG generated small NET amounts after 3 h (9.0 ± 1.1% NET-positive cells), which was upregulated in response to MPO-ANCA IgG (21.4 ± 3.4%) and PR3-ANCA IgG (28.4 ± 6.7%, n=5, $p<0.05$), respectively. Monoclonal Abs to PR3 and MPO recapitulated NET formation (not shown). The highly specific PI3Kγ inhibitor AS505240 (0.5 μM) significantly reduced anti-MPO mAb induced NET formation indicating PI3Kγ as an important signaling pathway in this process (34.0 ± 2.4 % versus 11.0 ± 1.2%). When ANCA-induced NETs were harvested and incubated with normal human plasma, complement activation occurred as demonstrated by NET staining for C3d and ELISA (data not shown). To assess the role of NETs in vivo, we used a murine model where anti-MPO IgG, generated in murine MPO-immunized MPO-deficient mice, was transferred to LPS-challenged wild-type mice. Mice received either buffer or rec DNAse I (twice daily 10mg/g BW iv, n=6 in each group). After 6 days, disease was less severe in DNAse I-treated animals as assessed by urine pathology (not shown) and renal histology (22.3 ± 3.3 % crescents in controls 5.7 ± 2.9 % with DNAse I).

Conclusions: Our findings indicate that PI3Kγ-mediated NET generation by neutrophils contributed to ANCA-induced NCGN. Complement activation could provide a mechanistic link between NETs and tissue damage. In addition, PI3Kγ, NET formation and complement are treatment targets to abrogate disease.

Fanconi Syndrome Associated Light Chains Trigger Aberrations of Endolysosomal Compartments and Apical Dedifferentiation in Proximal Tubule Cells Alessandro Luciani,[1] Claudia Raggi,[2] Jenny A. Kuerth,[1] Vincent Javaugue,[3] Christophe Sirac,[3] Olivier Devuyst.[1] *[1]Physiology, UZH, Zurich, Switzerland; [2]UCL Nephrology, Brussels, Belgium; [3]CNRS UMR 6101, Limoges, France; [4]CHU Jean Bernard, Poitiers, France.*

Background: Generalized dysfunction of the proximal tubule (renal Fanconi syndrome) can occur when specific monoclonal immunoglobulin light chains (LCs) accumulate within the endolysosomal system of tubular cells and form intracellular crystals. The early molecular events involved in proximal tubule (PT) dysfunction remain poorly understood.

Methods: We characterized transgenic mice expressing human k-LC associated Fanconi syndrome (k-CHEB) and analyzed endocytic uptake, lysosome function, and differentiation and proliferation markers using primary cultures of PT cells derived from these transgenic and control mice.

Results: Metabolic studies revealed that k-CHEB mice show progressive manifestations of renal Fanconi syndrome, before structural damage and renal failure. These changes are related to decreased expression of specific apical transporters and receptors (megalin/cubilin) and to increased dedifferentiation (ZONAB transcription factor) and proliferation (PCNA and CyclinD1) rates. Exposure of PT cells to low concentration (25μg/mL) of k-CHEB-LC resulted in perinuclear positioning of enlarged and dysfunctional lysosomes with impaired clearance of autophagosomes containing ubiquitinated proteins and damaged mitochondria. These changes led to excessive production of reactive oxygen species (ROS) and increased tyrosine phosphorylation of ZO-1, disrupting the integrity of tight junctions and promoting the nuclear translocation of ZONAB responsible for proliferation and dedifferentiation of the cells. These changes were dramatically reduced in PT cells exposed to LCs lacking crystal formation in lysosomes.

Conclusions: These findings reveal that accumulation of specific LCs within PT cells impairs the autophagy-lysosome pathway and activates a chain of event promoting dedifferentiation and dysfunction of the cells. The characterization of these early events opens new perspectives to prevent the progression of LC-induced renal Fanconi syndrome.

TH-OR127

Genetic Activation of Hypoxia-Signaling Restores Erythropoietin Synthesis in Renal Myofibroblasts Tomokazu Souma,[1,2,3] Masahiro Nezu,[1,2] Sadayoshi Ito,[2] Norio Suzuki,[1] Masayuki Yamamoto.[1] *[1]Medical Biochemistry, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan; [2]Medicine, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan; [3]Medicine, Nephrology, Northwestern Univ, Chicago, IL; [4]United Centers for Advanced Research and Translational Medicine, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.*

Background: The conversion of renal erythropoietin (Epo)-producing cells (REPs) to myofibroblasts is a major cause of fibrosis and anemia. It is characterized that prolyl-hydroxylase domain–containing proteins (PHDs) directly sense oxygen tension and regulate Hypoxia-inducible factor (HIF)-mediated Epo synthesis in REPs. However, the role of PHD-HIF pathways in renal myofibroblasts and Epo insufficiency has remained elusive.

Methods: To analyze PHD-HIF pathway in REPs, we generated single and combinational deletions of 3 isoforms of PHDs (PHD1-3) selectively in Epo-producing cells using Cre-lox approach in mice. We utilized unilateral ureteral obstruction (UUO) as a model for the myofibroblast conversion of REPs.

Results: Deletions of PHD2 alone or in combination with PHD1 and/or PHD3 induced polythythemia by HIF-2α-dependent Epo production from REPs. Epo production from injured kidneys in these conditional knockout mice were significantly higher than control littermates after UUO (% Epo repression [deleted alleles]; 93% [control littermates], 54% [Phd2], 51% [Phd2 and Phd3], 50% [Phd1and Phd2], 31% [Phd1, Phd2, and Phd3]). Intriguingly, combined deletions of PHD1 and PHD3 did not result in polythythemia in normal but prevented the loss of Epo-production in UUO (% repression; 69%). Furthermore, PHD-deficient REPs showed resistance to lipopolysaccharide-induced Epo repression, suggesting augmented HIF signal counterbalanced the NFκB signaling.

Conclusions: Our findings demonstrate that attenuated HIF signaling in myofibroblast-transformed REPs is a major cause of renal anemia and augmenting HIF signaling by inhibiting PHDs is an attractive therapeutic strategy for renal anemia by re-activating Epo synthesis from damaged and transformed REPs.

TH-OR128

Pathogenic Form of suPAR in FSGS Sanja Sever,[1] Jochen Reiser.[2] *[1]Nephrology, MGH, Boston, MA; [2]Medicine, Rush Univ, Chicago, IL.*

Background: Soluble urokinase plasminogen receptor (suPAR) has been implicated in the pathogenesis of focal segmental glomerulosclerosis (FSGS) through activation of a_vb_3 integrin on podocytes. suPAR exists in different forms with different degree of glycosylation. Total suPAR serum levels as measured by commercial ELISA can be elevated through reduced GFR or in some other disease conditions including inflammation and certain cancers.

Methods: To identify pathologic effects of various suPAR forms on podocytes, we employed a novel, high throughput cellular assay whereby we quantitatively assessed a_vb_3 integrin activation on podocytes in response to different suPAR levels in serums of patients suffering from FSGS, sepsis and end-stage renal disease (ESRD).

Results: suPAR containing FSGS patient sera but not sepsis or general ESRD sera strongly activated podocyte a_vb_3 integrin. We next wondered if specific fragments of suPAR are particularly strong transmitters of podocyte injury. Biochemical analysis revealed a soluble D2-D3 fragment of suPAR in the blood and urine of FSGS patients but not in healthy individuals. Functionally, low concentration of this fragment potently activates a_vb_3 integrin in cultured human podocytes and also produced nephrinuria and albuminuria in mice. Additional cellular studies revealed a circulating suPAR feed-forward loop in which activation of a_vb_3 integrin on podocytes lead to proteolysis of uPAR from the podocyte membrane thereby generating high local concentration of D2-D3 fragment.

Conclusions: Our study unravels a pathological fragment of suPAR in human FSGS and describes a cooperative injury pathway between systemic and podocyte-proteolyzed suPAR as potent disease mediators.

Podocyte Autophagy Is Down Regulated by Cardiotrophin-Like Cytokine Factor-1 (CLCF1), a Permeability Factor in Focal Segmental Glomerulosclerosis (FSGS) Mukut Sharma,[1] Jianping Zhou,[1] Alok De,[1] Tarak Srivastava,[3] Ellen T. McCarthy,[2] Ram Sharma,[1] Jean-Francois Gauchat,[4] Virginia J. Savin.[1] *[1]Nephrology, Kansas City VAMC, Kansas City, Mo; [2]Kidney Inst, Univ of Kansas Medical Center, Kkansas City, KS; [3]Nephrology, Children's Mercy Hospital, Kansas City, MO; [4]Pharmacology, Univ of Montreal, Montreal, Canada.*

Background: We have detected CLCF1 in FSGS plasma and proposed that it is a FSGS permeability factor. CLCF1, a member of the IL6 family, activates the JAK/STAT pathway but its role in maintaining podocyte integrity is unknown. Podocyte autophagy is required for cellular repair and survival. Disruption of constitutive autophagy is associated with proteinuria, loss of podocytes, and glomerular sclerosis. We hypothesized that CLCF1 modulates podocyte autophagy and adversely affects cell survival.

Methods: We treated immortalized mouse podocytes with recombinant human CLCF1 (rhCLCF1) for up to 24 hours. We added rapamycin, an inducer of autophagy, to some incubations. We used Western blotting to analyze cell lysates for elements of autophagy pathway (microtubule-associated protein 1 light chain (LC3 aka Atg8), beclin, Atg3, Atg5 and Atg7), and measured phosphorylation of Akt and ERK1/ERK2 to define signaling pathways. We also observed effects of CLCF1 on podocyte morphology and LC3 expression and intracellular distribution using microscopy.

Results: Podocytes express LC3-A and LC3-B with different intracellular distribution. Incubation of podocytes with CLCF1 (10 ng/mL) decreased the expression of LC3A and B with maximal effect at 4-6 hours ($P<0.001$). CLCF1 also attenuated rapamycin-induced up-regulation of autophagy as indicated by decreased LC3 expression. CLCF1 did not down-regulate beclin, Atg3, Atg5 or Atg7 appreciably. Additionally, CLCF1 also down-regulated the phosphorylation of Akt and ERK1/ERK2 and decreased the number of vacuolar structures.

Conclusions: We interpret these novel findings as evidence that CLCF1 down-regulates autophagy by a STAT3-mediated effect on LC3. Thus, CLCF1 may impair autophagy putting podocytes at risk. We propose that small STAT3 blocker(s) may be valuable in protecting podocyte function and structure in diseases such as FSGS.

Identification of Novel Gene Products that Regulate Glomerular Filtration Barrier Function Davide Pietro Cina,[1,2] Chengjin Li,[3] Jason Moffat,[4] Susan E. Quaggin.[1,2] *[1]Feinberg Cardiovascular Research Inst, Northwestern Univ, Chicago, IL; [2]Div of Nephrology, Northwestern Univ, Chicago, IL; [3]Lunenfeld-Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, ON, Canada; [4]Donnelly Centre for Cellular and Biomedical Research, Univ of Toronto, Toronto, ON, Canada.*

Background: Podocyte function is linked to the complex organization of its cytoskeleton and adhesion to the glomerular basement membrane. Disruption of genes involved in these processes results in proteinuria and glomerular injury. To identify novel genes that regulate podocyte function, we designed a genome-wide screen for genes involved in podocyte adhesion to both fibronectin, an integrin mediated pathway, and sFLT1/Fc, a novel heparin sensitive pathway, using a pooled shRNA library.

Methods: A pool of shRNA knock-down podocytes was generated using this library and plated on both substrates for one hour followed by separation of adherent and non-adherent fractions, and deconvolution of the hairpins present in each fraction by sequencing. Following deconvolution, we developed a highly stringent method for statistical analysis and 'hit' determination, and performed a small-scale validation of several top candidates.

Results: We identified 214 hairpins that increased podocyte adhesion to fibronectin and 237 hairpins that increased adhesion to sFLT1/Fc. We also identified 183 hairpins that decreased adhesion to fibronectin and 243 hairpins that decreased adhesion to sFLT1/Fc. Hairpins against *DPH1*, *DPH2*, *DPH3* and *DPH4* were in the top hits for increased adhesion to both substrates. Stable cell lines for these hairpins showed knock-down of gene expression by qPCR and a statistically significant increase in adhesion to both substrates. Stable overexpression of *DPH2* in human podocytes resulted in decreased adhesion to both substrates.

Conclusions: We have developed a novel screen for identifying candidate genes involved in regulating podocyte adhesion. Future work will include a large-scale validation of hits, and follow-up of select candidates. This approach will yield a list of genes that broadens our understanding of podocyte biology and conditions that perturb this system resulting in kidney disease.

TH-OR131

Regulation of Fluid-Phase Uptake in Podocytes by Albumin-Associated Lipids Jun-Jae Chung,[1] Tobias B. Huber,[1] George Jarad,[2] Bjorn Hartleben,[1] Jeffrey H. Miner,[2] Andrey S. Shaw.[1,3] *[1]Pathology and Immunology, Washington Univ School of Medicine, Saint Louis, MO; [2]Medicine, Renal Div, Washington Univ School of Medicine, Saint Louis, MO; [3]Howard Hughes Medical Inst, Washington Univ School of Medicine, Saint Louis, MO.*

Background: The mechanisms by which the glomerular filter is maintained and prevented from clogging is unclear. We postulated that fluid-phase uptake by podocytes might play a role in maintaining the permeability of the filtration barrier.

Methods: Using fluorescently labeled fluid-phase tracers, we examined whether podocytes are capable of fluid-phase uptake in vivo or in culture. Podocytes were treated with serum albumin and various lipids to determine the regulation of fluid-phase uptake. Finally, shRNA-mediated knockdown and chemical inhibition of lipid-binding receptors and downstream signalling molecules were used to elucidate the signaling pathway mediating fluid-phase uptake in podocytes.

Results: Using fluid-phase tracers, we showed that podocytes actively internalize fluid from the serum and that the rate of internalization is enhanced when the filtration barrier is disrupted. In vitro experiments demonstrated that lipids associated with serum albumin stimulated macropinocytosis in podocytes. This process was specific to podocytes as known stimuli that induce macropinocytosis in other cells had no effect on podocytes, while serum lipids did not stimulate macropinocytosis in other cells. A candidate lipid approach showed that free fatty acids stimulate macropinocytosis through G protein-coupled receptors, FFAR1, FFAR2, and FFAR3 and the Gbeta/Ggamma complex.

Conclusions: Our observations suggest that podocytes sense the disruption of the filtration barrier via free fatty acids bound to albumin and respond to the increased protein by enhancing fluid-phase uptake. Dysregulation of this process could play and important role in the development of podocyte disease.

TH-OR132

MiR-193a Regulates the Transdifferentiation of Human Parietal Epithelial Cells Toward a Podocyte Phenotype Catherine Meyer-Schwesinger,[1] Sebastian Guhr,[1] Tobias N. Meyer,[3] Marlies Sachs,[1] Rolf A. Stahl,[1] Moin Saleem,[4] Dontscho Kerjaschki.[2] *[1]Dept of Internal Medicine, Nephrology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Dept of Clinical Pathology, Medical Univ of Vienna, Vienna, Austria; [3]Dept of Internal Medicine, Nephrology, Univ Affiliated Asklepios Clinic Hamburg Barmbek, Hamburg, Germany; [4]Childrens Renal Unit, Bristol Royal Hospital for Children, Bristol, United Kingdom.*

Background: Overexpression of microRNA-193a (miR-193a) in mice induces FSGS through down-regulation of WT1, a transcription factor and master regulator of podocyte differentiation. In in situ hybridizations of normal human renal biopsies miR-193a was detected in parietal epithelial cells (PEC), but not in podocytes. Here we investigated, whether knockdown of miR-193a induced the differentiation of PECs towards a podocyte phenotype in vitro and in vivo.

Methods: We established an immortalized human PEC (hPEC) line from naïve Bowman's capsule cells isolated by mechanical micro-dissection. MiR-193a was stably knocked down in culture. In mice, miR193a was inhibited or over expressed. The expression of PEC and podocyte markers was investigated by qPCR, IF and WB.

Results: Cultured hPECs expressed high levels of PEC proteins such as Claudin-1, UCH-L1 and Pax-8 and of miR-193a, whereas they expressed low levels of podocyte markers. Following knock-down of miR-193a, hPECs adopted a podocyte-like morphology and expressed high levels of the podocyte proteins WT1, Podocalyxin, Synaptopodin, Nephrin and a-Actinin-4. We could also observe an upregulation of the podocyte marker Synaptopodin and WT1 upon inhibition of miR-193a in mice indicating at least a partial transdifferentiation *in vivo*. On the other hand, overexpression of miR-193a *in vivo* resulted in the upregulation of PEC and the loss of podocyte markers in isolated glomeruli.

Conclusions: Taken together, we successfully established a human PEC line and demonstrate that miR-193a acts as a master switch in regulating the expression of PEC and podocyte markers. Glomerular epithelial cells with high levels of miR-193a adopt a PEC phenotype whereas glomerular epithelial cells with low levels of miR-193a adopt a podocyte phenotype.

TH-OR133

The Role of Mesangial Cell-Derived CTGF in Anti-Glomerular Basement Membrane Nephritis Naohiro Toda,[1] Hideki Yokoi,[1] Masato Kasahara,[2] Kiyoshi Mori,[3] Takashige Kuwabara,[1] Hirotaka Imamaki,[1] Akira Sugawara,[4] Taiji Matsusaka,[5] Kazuwa Nakao,[3] Motoko Yanagita,[1] Masashi Mukoyama.[1,6] *[1]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [2]Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan; [3]Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [4]Div of Nephrology, Osaka Red Cross Hospital, Osaka, Japan; [5]Dept of Internal Medicine, Tokai Univ School of Medicine, Kanagawa, Japan; [6]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: Connective tissue growth factor (CTGF/CCN2) regulates signaling of other growth factors and promotes fibrosis. We previously showed that systemic deletion of CTGF ameliorates proteinuria and glomerular injury in anti-glomerular basement membrane (GBM) nephritis. To explore which glomerular cells producing CTGF are most important, we generate podocyte-specific CTGF knockout mice (Pod-CTGF cKO) and mesangial cell-CTGF knockout mice (Mes-CTGF cKO).

Methods: CTGF floxed mice were crossed with Nephrin-Cre mice to create Pod-CTGF cKO or PDGFRα-Cre mice for Mes-CTGF cKO. We evoked anti-GBM nephritis at 8 wksof age and investigated glomerular injury after 28 days. *In vitro*, Mes13 cells were used to examine the effects of CTGF deletion by siRNA transfection on MCP-1 expression.

Results: Pod-CTGF cKO and Mes-CTGF cKO showed normal renal structure. After induction of anti-GBM nephritis, severe proteinuria and glomerular injury were developed in control mice. Pod-CTGF cKO showed no improvement of glomerular injury or proteinuria. In contrast, Mes-CTGF cKO exhibited reduced proteinuria by 30% with ameliorated histological changes. The number of Mac2-positive cells (7 versus 2.4 cells/glomeruli) and expressions of TGF-β1 and F4/80 in glomeruli were reduced in Mes-CTGF cKO by 70% but not in Pod-CTGF cKO. TGF-β1-stimulated MCP1 expression was downregulated by reduction of CTGF in MES13 cells.

Conclusions: These results indicate that CTGF produced by mesangial cells plays a role in macrophage infiltration, suggesting that inhibition of CTGF/MCP1 axis could be a therapeutic target for anti-GBM nephritis.

TH-OR134

Crosstalk of mTOR Signaling and Autophagy Tillmann Bork,[1] Philipp Lee,[1] Bjorn Hartleben,[1,2] Tobias B. Huber.[1] *[1]Renal Div, Univ Hospital Freiburg, Freiburg, Germany; [2]Inst of Pathology, Univ Hospital Hamburg-Eppendorf, Hamburg, Germany.*

Background: Autophagy emerged as a key mechanism to eliminate unwanted cytoplasmic materials, thereby preventing cellular damage and stress to safeguard long-lived podocytes. The serine/threonine kinase mTOR (mammalian target of rapamycin) is a central regulator of cell growth and metabolism and usually inhibits autophagy. Podocytes however show high levels of basal autophagy in the presence of mTOR activation suggesting and unexpected uncoupling of mTOR and autophagy in podocytes. We did set up complementary mouse models to study the functional interplay of mTOR signaling and autophagy in podocytes.

Methods: Autophagy levels were monitored *in vivo* by crossing *GPF-LC3* reporter mice to models of mTOR hyperactivation (*Tsc1* PcKO) and mTOR loss of function (*Raptor* PcKO). In addition, podocyte-specific *Raptor* and *Tsc1* KO mice were crossed to a *Tomato/eGFP* reporter line to efficiently isolate podocytes for primary cell culture studies.

Results: In contrast to other known cellular systems podocytes did exhibit high basal autophagy rates independently of the mTOR activation status. Strikingly, there was no difference in LC3 conversion in vivo and no difference of the GFP-LC3 signal between *Raptor* and *Tsc1* PcKO mice. Unexpectedly, Beclin 1 expression was inversely regulated by mTOR activation. Isolated primary podocytes showed typical features of mTOR activation (proliferation, hypertrophy) and mTOR suppression, respectively, but autophagy

remained unaffected even in case of starvation suggesting that mTOR signaling influences the repertoire of expressed autophagy-related proteins but did not regulate the autophagy-response towards metabolic stimuli.

Conclusions: mTOR and autophagy are key regulators of podocyte function and maintenance. Our data highlight a specific mTOR-autophagy regulatory cascade, which allows to operate mTOR activity and high basal autophagy rates simultaneously in podocytes.

TH-OR135

Investigating a Role for the ShcA Adaptor Protein in Kidney Podocytes Claire E. Martin,[1] Kelly A. Petersen,[1] Vera Eremina,[2] Susan E. Quaggin,[2,3] Tomoko Takano,[4] Nina Jones.[1] *[1]Univ of Guelph, Guelph, ON, Canada; [2]The Lunenfeld-Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, ON, Canada; [3]Feinberg Cardiovascular Research Inst and Div of Nephrology and Hypertension, Northwestern Univ, Chicago, IL; [4]McGill Univ, Montreal, QC, Canada.*

Background: The transmembrane protein nephrin is a key component of the kidney glomerular slit diaphragm that is required for normal morphology and permselectivity of podocytes. It has recently been reported that tyrosine phosphorylation of the cytoplasmic tail of nephrin facilitates recruitment of several signaling proteins that regulate podocyte function. The ShcA adaptor protein's importance within a broad range of cell types is well established and has been attributed to its ability to bind and mediate signaling between a diverse group of membrane receptors and cytoplasmic proteins. However, its role within the podocyte to this point remains under-investigated.

Methods: Multiple approaches were used to identify ShcA as a nephrin binding partner, to map this interaction and to evaluate ShcA's effect on nephrin signaling. Cre-loxP technology was used to generate podocyte-specific knockout of ShcA in mice.

Results: We demonstrate that the adaptor protein ShcA is differentially expressed in podocytes and binds phosphorylated nephrin via its SH2 domain. This interaction can be mapped to three conserved phosphotyrosine-based docking sites on nephrin. Loss of ShcA expression specifically within developing mouse podocytes leads to reduced barrier function and disruption of podocyte ultrastructure by 6-8 weeks of age. Furthermore, in mature kidneys and cultured podocytes, response to PAN-induced injury is associated with increased expression of ShcA, which correlates with activation of the stress-activated p38 and JNK MAP kinases. Interestingly, we found that transactivation of AP-1, which occurs downstream of nephrin as well as p38 and JNK, is attenuated by ShcA, and this effect is reversed by mutation of the ShcA SH2 domain.

Conclusions: Together these findings suggest a protective effect of ShcA in nephrin-dependent signalling, that is required during both podocyte maturation and response to injury.

TH-OR136

Genetic Deletion of Myo1c in Podocytes Protects Them From Glomerular Injury Inducing Agents Ehtesham Arif, Yogendra Singh Rathore, Lawrence B. Holzman, Deepak Nihalani. *Medicine, Univ of Pennsylvania, Philadelphia, PA.*

Background: Glomerular diseases including FSGS and nephrotic syndrome that induce podocyte effacement are leading causes of kidney failure. Podocyte proteins Nephrin and Neph1 are major components of the slit diaphragm and it is now well documented that the organization of Nephrin and Neph1 at the membrane is lost in various glomerular disorders, which may contribute towards the development of disease pathology. Our recent observations suggest that Myo1c is directly involved in turnover of these proteins at the podocyte cell membrane.

Methods: To further understand the function of Myo1c in podocytes, we generated podocyte specific Myo1c knockout mice in different genetic backgrounds.

Results: Myo1c variants on all genetic backgrounds tested were born with normal Mendelian frequency and when aged to at least 6 months showed no evidence of proteinuria. However, podocyte-specific Myo1c null mice bred to an adriamycin-sensitive (C57BL/6**N**) background showed remarkable resistance to adriamycin-induced glomerular injury; they did not develop proteinuria as compared to the control mice. To gain insight into the mechanism of this protection the kidney sections were analyzed for change in expression levels of Neph1 and Nephrin in response to injury. Remarkably, Nephrin and Neph1 were maintained at the podocyte intercellular junction following injury, indicating that loss of Myo1c prevented loss of these proteins in response to injury. Additionally, adriamycin-induced expression of autophagy marker LC3 was diminished in Myo1c depleted glomeruli suggesting that loss of Myo1c prevents autophagy induction in response to injury.

Conclusions: Several published studies indicate that Myo1c is involved in cellular trafficking ranging from compensatory endocytosis to recycling. Therefore, we hypothesize that loss of Myo1c in podocytes affects cellular trafficking events including autophagy that may prevent injury-induced loss of Nephrin and Neph1. Under these conditions podocytes fail to generate an appropriate injury response, and are thus protected from injury.

The Glomerular Filter as an Electrical Powerhouse: How Much Voltage Is Required to Prevent Proteinuria? Turgay Saritas,[1] Sandra Uhlig,[1] Ralf Hausmann,[2] Jürgen Floege,[1] Marcus J. Moeller.[1] *[1]Nephrology and Clinical Immunology, Univ Hospital RWTH Aachen, Aachen, North Rhine-Westphalia, Germany; [2]Molecular Pharmacology, Univ Hospital RWTH Aachen, Aachen, North Rhine-Westphalia, Germany.*

Background: It is still incompletely understood how the glomerular filter functions and why it never clogs. Recently, the electrokinetic model for glomerular filtration has been proposed: Streaming potentials generate an electrical field across the filtering capillaries, which in turn repel the negatively charged plasma proteins from entering the glomerular filter. From mathematical considerations, it was argued against this concept was that an electrical field of approx. 1600 Volts/m (as measured by micropuncture in Necturus *in vivo*) may not be sufficient to prevent albumin from passing the across the glomerular filter. Therefore, we have determined the electrophoretic mobility of albumin experimentally in isolated perfused kidney (IPK) of a mammalian (rat) kidney in this study.

Methods: IPK were fixed with glutaraldehyde to block tubular or other cellular artifacts while preserving the electrical characteristics of the glomerular filter. An electrical field was applied externally to IPK via electrodes. The electrokinetic model requires that already relatively weak electrical fields (3.5 Volts, i.e. approximately 700 Volts/m) interfere with the endogenous electrical field of the glomerular filter resulting in significant increases of the albumin sieving coefficient. In contrast, mathematical modeling of the traditional pore model predicts that 100x more voltage is needed. As control, no current or 3.5 Volts high frequency alternating current (AC, 41 kHz) were used.

Results: Albumin sieving coefficient increased significantly when applying 3.5 Volts DC but not when applying AC or no current.

Conclusions: The results show that already relatively weak extracellular streaming potentials influence the passage of albumin across the glomerular filter supporting the electrokinetic model.

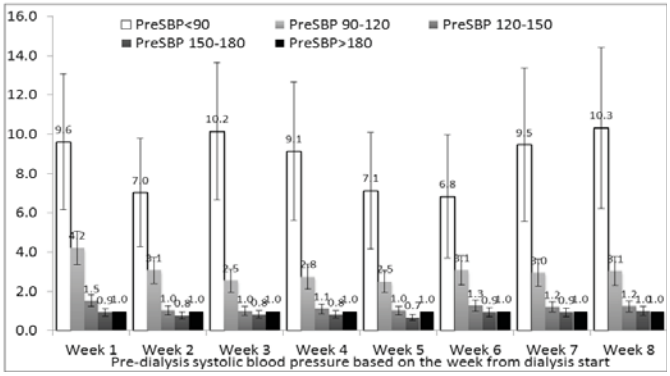
Lower Systolic Blood Pressures Are Consistently Associated with Poorer Outcomes in Incident Hemodialysis Patients in the First 8 Weeks of Treatment Dugan Maddux,[1] Len A. Usvyat,[1,3] Jeroen Kooman,[2] Frank van der Sande,[2] Kevin Chan,[1] Peter Kotanko,[3] Franklin W. Maddux,[1] John W. Larkin.[1] *[1]FMCNA, Waltham, MA; [2]Dept of Internal Medicine, Univ Hospital Maastricht, Maastricht, Netherlands; [3]RRI, NY, NY.*

Background: Hypertension management is recommended in CKD to reduce cardiovascular risk; however, low pre-dialysis systolic BP (preSBP) has been paradoxically reported to associate with poor outcomes among prevalent hemodialysis (HD) patients. We investigated if this association also exists among incident dialysis patients.

Methods: Incident HD patients in FMCNA who initiated dialysis between Jan 1, 2004 and Dec 31, 2010 and had >=1 preSBP measurement were included. We computed mean preSBP weekly in patients up to week 8 from the start of dialysis. The primary outcome was 120 day survival from the start of each of the 8 weeks. Patients were stratified into 5 groups by preSBP and analyzed by <90, 90-120, 120-150, 150-180, and >180mmHg. Cox models adjusted for age, gender, and race were used to relate preSBP level to outcomes.

Results: 47,315 patients were included in the analysis (mean age 62.3+/-12.2, 57% male, 66% White, 28% Black, 60% diabetic). Mean preSBP was 149.1 in week 1 and 150.0 mmHg in week 8. 88% of patients were alive and dialyzing in week 8 (N=41,546). Mortality risk was consistently high in preSBP<90mmHg group ranging from HR=6.8 [CI 4.0-10.0] (week 6) to 10.3 [6.0 -14.0] (week 8). Groups with preSBP 90-120 and 120-150 mmHg were also higher than the reference group of preSBP>180 mmHg. The hazard ratios did not change significantly between weeks.



Conclusions: PreSBP <90-120 mmHg in the first months of dialysis was associated with high mortality. At any point during the first 2 months of HD a mean preSBP <90 mmHg was associated with increased mortality risk. Moderately low preSBP between 90 and 120 mmHg was also associated with increased mortality risk.

TH-OR139

The Safety and Efficacy of Mineralocorticoid Receptor Antagonists in Patients Who Require Dialysis: A Systematic Review and Meta-Analysis Kevin Quach, Lyubov O. Lytvyn, Colin Baigent, Joe A. Bueti, Amit X. Garg, Carmel M. Hawley, Richard Haynes, Braden J. Manns, Vlado Perkovic, Christian G. Rabbat, Ron Wald, Michael Walsh. *McMaster Univ/Population Health Research Inst.*

Background: Mineralocorticoid receptor antagonists (MRAs) prevent cardiovascular events in patients with heart failure who do not require dialysis. Whether MRAs are effective and safe in dialysis patients is uncertain. We conducted a systematic review and meta-analysis of randomized controlled trials testing the effect of MRAs in dialysis patients.

Methods: We identified relevant randomized controlled trials from electronic databases, bibliographies, trial registries, and by contacting experts. Eligible trials randomized patients on chronic dialysis between a MRA (spironolactone or eplerenone) and control and reported at least one outcome of interest: cardiovascular death, all cause death, hyperkalemia, or blood pressure. Data was abstracted in parallel by two reviewers and analyzed using random effects models.

Results: Of 1006 screened citations, seven relevant trials including 729 patients were included. The relative risk (RR) of cardiovascular death (MRA versus control) was 0.34 (95% confidence interval [CI] 0.15 to 0.75]) and the RR of all-cause death was 0.40 (95% CI 0.23 to 0.69). However, mortality benefits were not observed in sensitivity analyses that explored assumptions about losses to follow-up. Additionally, the RR of hyperkalemia was 3.14 (95% CI 1.08 to 9.17) suggesting potential harm. Sensitivity analyses suggested the risk of hyperkalemia may be underestimated. Overall, there were insufficient data to robustly estimate any of the effects of MRA treatment in dialysis patients.

Conclusions: Treatment of dialysis patients with MRAs is promising but further large, high quality trials are required to definitively assess the benefit-risk balance.

Comparative Effectiveness of Renin-Angiotensin System Antagonists in Chronic Dialysis Patients Theresa I. Shireman,[1] James B. Wetmore,[2] Edward F. Ellerbeck,[1] Jonathan D. Mahnken,[1] Milind A. Phadnis.[1] *[1]Univ of Kansas School of Medicine, Kansas City, KS; [2]Hennepin County Medical Center, Minneapolis, MN.*

Background: Renin-angiotensin system antagonists are known to significantly reduce cardiovascular events and mortality in the ESRD setting, but their inherent characteristics suggest they may have different within class pharmacodynamic effects. The purpose of this study was to compare outcomes between chronic dialysis patients with hypertension who were treated singularly with either ACEs or ARBs.

Methods: We linked Medicaid pharmacy claims, United States Renal Data System (USRDS) core files, and Medicare inpatient and outpatient claims. The cohort included hypertensive Medicare-Medicaid eligible ESRD patients initiating dialysis. We followed the new user cohorts from their 1st day on either an ACE or an ARB until they incurred an outcome event (all-cause mortality (ACM) and combined cardiovascular hospitalization or death (CV-endpoint)) or were no longer observable. Patients who changed from an ACE to ARB or vice versa were excluded. Covariate adjustments included demographics, vintage, functional measures, and comorbidity. We used Cox proportion hazards models to compare the effect of ACE versus ARB use on outcomes.

Results: ACM models were based on 8,246 ACE and 3,012 ARB new users: CV-endpoint models included 6,560 ACE and 2,609 ARB new users. After adjustment for several small but significant differences in baseline characteristics between groups, ACE users had higher hazard ratios for ACM (AHR = 1.21, 99% CI 1.10-1.34) and CV-endpoints (AHR = 1.11, 99% CI 1.02-1.22). When new users were limited to persons with drug initiation early in the observation window (first 3 months), findings were comparable for ACM (AHR = 1.22, 99% CI 1.05-1.42) but the association with CV-endpoint was no longer significant (AHR = 1.12, 99% CI 0.99-1.27).

Conclusions: In this observational study, we demonstrated that ACE versus ARB users face an increased risk for mortality and possibly an increased risk for CV-endpoints. Validation of these results in a rigorous clinical trial is warranted given their widespread use in the ESRD community.

Comparative Effectiveness of Cardioselective and Non-Selective β-Adrenergic Blockers in Chronic Dialysis Patients Theresa I. Shireman,[1] James B. Wetmore,[2] Edward F. Ellerbeck,[1] Milind A. Phadnis,[1] Jonathan D. Mahnken.[1] *[1]Univ of Kansas School of Medicine, Kansas City, KS; [2]Hennepin County Medical Center, Minneapolis, MN.*

Background: Although β-adrenergic blockers reduce cardiovascular events and mortality in ESRD patients, it is unknown if there significant within class cardiovascular outcomes between agents with β_1 or cardio-selectivity and differential alpha blockade and vasodilatory effects (cardioselective and non-cardioselective agents).

Methods: We linked Medicaid pharmacy claims, United States Renal Data System (USRDS) core files, and Medicare Parts A and B claims to create a cohort of hypertensive Medicare-Medicaid eligible patients initiating dialysis from 2000-05. We followed new users of either a cardioselective (metoprolol or atenolol) or non-selective (carvedilol or labetolol) β- blocker from their 1st day on medication until they incurred an outcome event (all-cause mortality (ACM) and combined cardiovascular hospitalization or death (CV-endpoint)) or were censored. We used Cox proportion hazards models to compare the effect of cardioselective or non-selective β-blockers use on ACM and CV-endpoint, adjusting demographics, vintage, functional measures, and comorbidities.

Results: ACM models were based on 9,196 cardioselective and 2,650 non-selective β-blocker new users: CV-endpoint models included 7,386 cardioselective and 1,978 non-selective β-blocker new users. After adjustment for differences in baseline characteristics between groups, cardioselective β-blocker users had lower hazard ratios for ACM (AHR = 0.79, 99% CI 0.72-0.87) and CV-endpoint (AHR = 0.80, 99% CI 0.73-0.89). When new users were limited to persons with drug initiation in the first 3 months, findings were comparable: ACM (AHR = 0.84, 99% CI 0.72-0.97) and CV-endpoint (AHR = 0.86, 99% CI 0.75-0.99). Results also did not vary when heart failure was included in an interaction term with drug selection.

Conclusions: Chronic dialysis patients who received cardioselective β-blocker had a lower risk for mortality and CV-endpoints when compared to their peers who received non-selective β-blockers. Validation of these results in a rigorous clinical trial is warranted given their widespread use in dialysis patients.

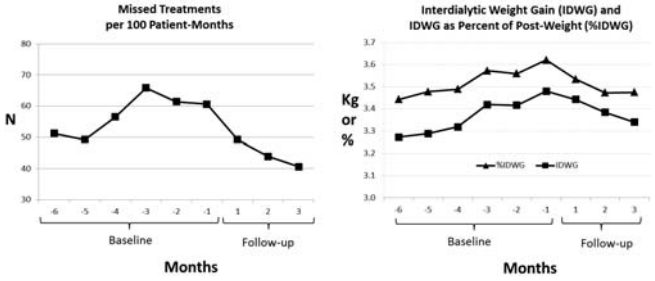
A Social Worker Initiated Program to Reduce Fluid Overload in Hemodialysis Patients Stephanie Johnstone, Nien-Chen Li, Franklin W. Maddux, Amy R. Weissman-Hunt, Jessica Demaline, Eduardo K. Lacson. *Fresenius Medical Care, North America, Waltham, MA.*

Background: A social worker (SW) initiated intensive program was implemented as a quality improvement (QI) initiative to address problematic hemodialysis (HD) patient compliance. We report preliminary results of the intervention for patients with worsening fluid overload.

Methods: The cohort included 246 patients completing ≥6 of the 8 session intervention (1 session every 1-2 weeks) from 167 FMCNA centers between 2/1/13 and 01/31/14, with at least a 6-month baseline and 3-month follow-up period. The intervention included patient-empowerment education and cognitive/behavioral counseling designed to address potential root causes of fluid non-compliance. Baseline versus follow-up interdialytic weight gain (IDWG; also as %IDWG of post-weight), rates of missed treatments, and hospitalization for fluid overload were tracked.

Results: The patients' mean age was 54 years, with 56% males; 69% white, 29% black; 67% had DM, 23% CAD, and 47% CHF. During baseline, at least 1 missed treatment was noted in 46%. While all-cause hospitalization rates were unchanged, baseline versus follow-up hospitalizations due to fluid overload decreased from 1.7 to 0.8 episodes per 100 patient-months. Missed treatment rate was 57 versus 45 per 100 patient-months while period mean %IDWG was unchanged at ~3.5%. However, slopes for both were increasing at baseline then slopes declined during follow-up.



Conclusions: Preliminary results indicated that the intensive SW-initiated program reduced fluid overload-related hospitalizations in the short term (3 months). Furthermore, trends for contributory non-adherent behavior such as %IDWG and missed treatments improved, which may help sustain the favorable results over the long term. This QI study is ongoing and updated outcomes will subsequently be reported.

TH-OR143

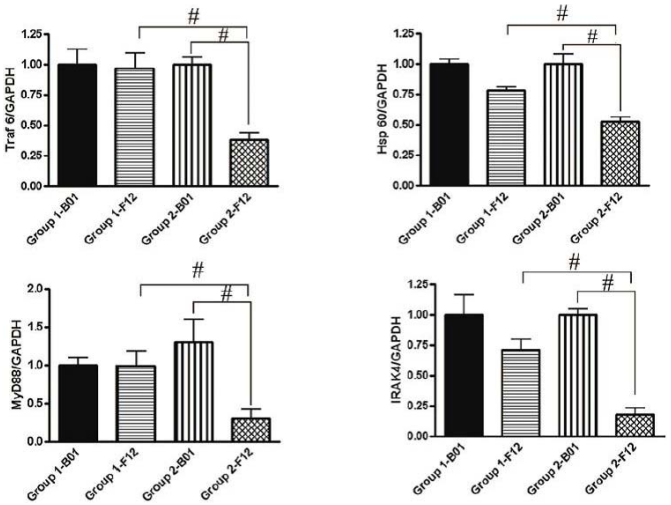
The Role of Cardiomyocyte Apoptosis in the Pathogenesis of Left Ventricular Hypertrophy (LVH): Results from the Frequent Hemodialysis Network (FHN) Christopher T. Chan, Michael V. Rocco, Glenn M. Chertow, George A. Kaysen, Nathan W. Levin, Brett Larive, Gerald J. Beck, Alan S. Kliger. *NIDDK - FHN Cardiac Biomarker Group.*

Background: Cardiomyocyte apoptosis (CA) is a novel cardiac biomarker. We hypothesize that extent of CA is responsible in part for the response of LV mass (LVM) with frequent hemodialysis in end-stage renal disease (ESRD) and that this effect is transmitted by a factor found in plasma.

Methods: Neonatal cardiomyoytes were cultured with plasma from responders (LVM reduced by a min of 10%) and progressors (LVM increased by a min of 10%) among randomized patients in FHN trials. The primary aim was to ascertain the effect of plasma on CA.

Results: Among the 332 patients randomized, there were 105 responders and 63 progressors. Selected baseline and clinical variables are shown in Table. LVM changed by -33.9 (-37.9,-29.8) g in responders and +24.1 (19.0,29.2) g in progressors, p<0.0001. CA (Anexin V) was similar at baseline but significantly higher at 12 months after exposure

to plasma from progressors versus responders (1.15 ± 0.19 versus 0.73 ± 0.09, p=0.02). Expressions of Innate immunity pathway remained elevated in progressors (group1) and fell in responders (group2) (Figure).



Variables	Responders (N=105) (69M)	Progressors (N=63) (34M)
Age (yrs)	51.2±14.0	50.5±11.6
ESRD vintage (yrs) (10^{th},90^{th}%tile)	3.3 (0.3,16.7)	2.8 (0.2,12.6)
Change in weekly volume removal rate (ml/kg/h)	-1054±356	-529±452
Change in pre-dialysis systolic BP (mmHg)	-11.4±1.8	4.1±2.3*
Change in pre-dialysis phosphate (mmol/L)	-0.72±0.17	-0.23±0.21*

*p<0.05

Conclusions: CA was associated with progression of LVM in ESRD. Cardiomyocyte death and remodelling with fibroblast-like cells may play a pivotal role in LVH progression. Both may be affected by a factor found in plasma at concentrations that vary depending on the frequency of HD.

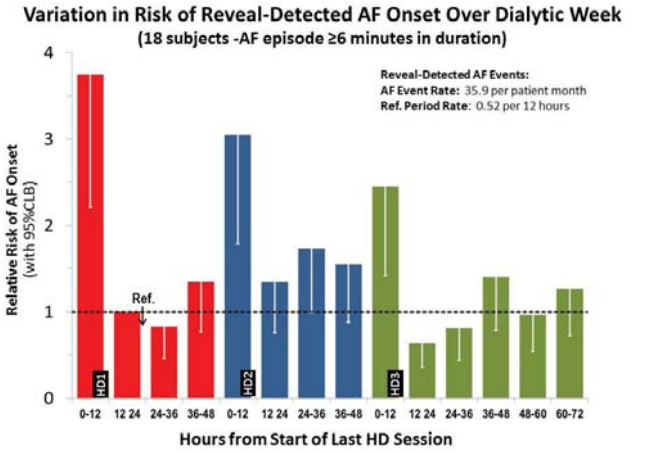
Frequency and Distribution of Dialysis-Associated Atrial Fibrillation: Results of MiD Study James A. Tumlin,[1] David M. Charytan,[2] Don E. Williamson,[3] Amber S. Podoll,[4] Suresh Chandra Tiwari,[5] Prabir Roy-Chaudhury,[6] Vikranth Reddy.[7] *[1]Internal Medicine Renal Div, Univ of Tennessee College of Medicine, Chattanooga, TN; [2]Internal Medicine Renal Div, Harvard Brigham and Women's Hospital, Boston, MA; [3]Nephrology Associates, Augusta, GA; [4]Internal Medicine Renal Div, Univ of Texas Houston, Houston, TX; [5]Transplantation, Fortis Inst of Renal Sciences and Transplantation, Vasant Kunj, New Delhi, India; [6]Internal Medicine Renal Div, Univ of Cincinnati, Cincinnati, OH; [7]Care Hospital, Hyderabad, India.*

Background: End-stage renal disease (ESRD) patients are at increased risk for atrial arrhythmias. While previous studies report atrial fibrillation (AF) rates of up to 40%, the link between the hemodialysis (HD) cycle and AF is unknown. Therefore, we conducted a prospective, multi-center, 6-month observational study characterizing the incidence of AF in ESRD patients.

Methods: MiD is a prospective multi-center study designed to characterize the frequency of AF in 45 ESRD patients implanted with the Medtronic Reveal® XT device. The Reveal device detects AF events based on incoherence in adjacent R-R intervals. Reveal device data was centrally adjudicated weekly for 6 months of follow up.

Results: 45 subjects were implanted and followed for a mean of 4.9 months. A total of 1231 AF episodes with ≥6 min duration were detected in 18 of 45 (40.0%) subjects. This corresponds to an overall AF rate of 5.6 events per patient month (ppm), while patients with AF > 6 minutes duration had 14.1 ppm.



The rate of AF events was 3.5 fold higher in the 12 hours following dialysis (Figure). Only 1 of 18 had any prior history of AF.

Conclusions: Atrial fibrillation is seen in up to 40% of ESRD patients. The dialysis procedure may enhance AF rates with the greatest incidence occurring during the first 12 hours after the initiation of dialysis.

Greater Frequency of Clinically Significant Bradycardia Than Ventricular Tachycardia in Hemodialysis Patients: Preliminary Results of the Monitoring in Dialysis (MiD) Study David M. Charytan,[1] Bruce A. Koplan,[1] Amber S. Podoll,[2] Vikranth Reddy,[3] Prabir Roy-Chaudhury,[4] Suresh Chandra Tiwari,[5] James A. Tumlin,[6] Don E. Williamson.[7] *[1]Harvard U; [2]U of Texas; [3]Care Hospital, Hyderabad, India; [4]U of Cincinnati; [5]Fortis Inst, New Delhi, India; [6]U of Tennessee; [7]Nephrology Associates, Augusta, GA.*

Background: End-stage renal disease patients are at increased risk of arrhythmias and sudden cardiac death (SCD), but little is known about arrhythmia type, prevalence or relationship to dialysis schedule.

Methods: MiD is a prospective, multi-center study to characterize arrhythmias occurring in 3x weekly hemodialysis (HD) patients using an implantable cardiac monitoring device, Medtronic Reveal® XT. ECGs recorded during the first 6 months of monitoring were centrally adjudicated. Reveal-detected arrhythmic event data were collected for an additional 6 months thereafter without adjudication. Clinically significant arrhythmias (CSA) include bradycardia ≤40 bpm for ≥6 seconds (s), asystole ≥3 s, or sustained ventricular tachycardia (SVT) ≥130 bpm for ≥30 s are limited to the main 6-month study period.

Results: 45 implanted subjects were followed for a mean of 6.4 months (0.6-12.0) [mean age: 56 (27-76) years; male: 64%; history of cardiac arrhythmias: 46%]. The overall rate of bradycardia was 10.2 [95% CI: 3.1-34.1] events per patient month (ppm) for all subjects, and 28.7 [95% CI: 10.1-81.7] events ppm for 16 subjects with ≥1 bradycardia episode. Average time to first episode of bradycardia or asystole was 62 days after Reveal XT implant. There was no apparent association of bradycardia with the timing of dialysis. Among 605 CSA, 74.9% were bradycardia or asystole events. In contrast, only 1 episode was SVT (0.2%). To date, 4 subjects received a pacemaker; 3 subjects had no prior history bradycardia, and 1 subject had a prior history.

Conclusions: Clinically significant bradycardia is common in previously asymptomatic HD patients and occurs at a much higher frequency than VT. Our data suggests that bradycardia converting to asystole may be the dominant terminal arrhythmia compared to VT in HD patients. This finding has important implications for the prevention of SCD in HD patients.

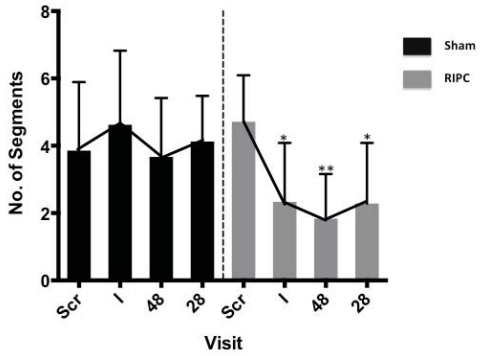
Remote Ischaemic Preconditioning in Haemodialysis: An Initial Randomised Controlled Trial Lisa E. Crowley,[1] Aghogho Odudu,[3] Chris W. McIntyre.[2] *[1]Royal Derby Hospital, United Kingdom; [2]Univ of Nottingham, United Kingdom; [3]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom.*

Background: Haemodialysis results in a recurrent segmental ischaemic cardiac injury which helps to drive the excess cardiovascular morbidity in HD patients.Previous exposure to an ischemic insult (even if delivered remotely) has been shown to be cardioprotective in numerous experimental and clinical studies.We investigated if application of Remote Ischaemic Preconditioning (RIPC) prior to HD provided protection against dialysis induced cardiac injury.

Methods: 20 patients receiving hospital HD were recruited.Presence of dialysis induced myocardial stunning was confirmed with echocardiography before randomisation into 2 groups.One group received a single RIPC stimulus administered via a BP cuff inflated to 200mmHg in the lower limb.The other received Sham-RIPC with the cuff inflated to

40mmHg.All patients were studied at intervention,48 hours and 28 days post RIPC.Stunning was identified using pre and peak stress echo analysed using 2D speckle tracking.A stunned segment was defined as undergoing a 30% reduction in longitudinal strain.

Results: At baseline the number of stunned segments was 4.7±1.3 versus 3.8±2.0 (RIPC and sham respectively).Following administration of RIPC the number of affected segments fell significantly in the intervention arm.This reduction was sustained at both 48hrs and 28 days.No change was observed in the sham group.The largest reduction was at 48hrs in comparison with screening (1.83±1.3 versus 4.70±1.3 p=0.002).The difference in pre and peak global longitudinal strain present in the RIPC group at screening (15.98±3 versus 13.04±3.4) was abolished at subsequent visits.Levels of HD induced circulatory stress were lower in the sham group (as judged by UF volume or intradialytic reduction in BP).



Conclusions: A single RIPC stimulus administered prior to conventional HD provides relative protection against HD induced cardiac injury for up to 28 days.

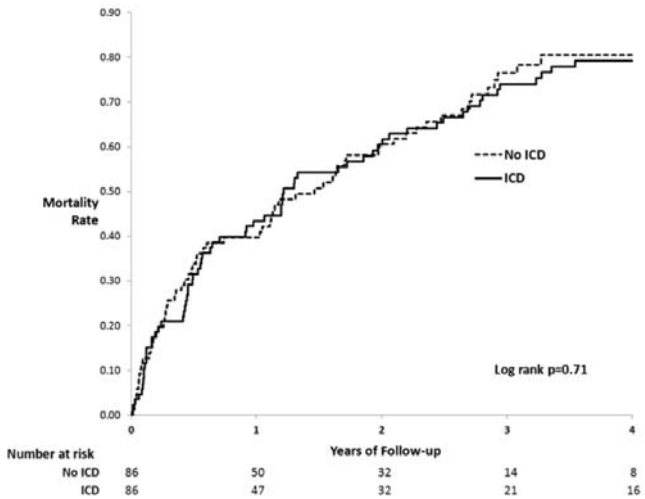
Primary Prevention Implantable Cardioverter Defibrillators in Dialysis Patients: A Matched Cohort Study Patrick H. Pun,[1] Anne Hellkamp,[1] Gillian Sanders,[1] John Paul Middleton,[1] Stephen Hammill,[3] Hussein Al-Khalidi,[1] Lesley H. Curtis,[1] Gregg C. Fonarow,[2] Sana M. Al-Khatib.[1] *[1]Duke Univ Medical Center, Durham, NC; [2]UCLA Medical Center, Los Angeles, CA; [3]Mayo Clinic, Rochester, MN.*

Background: Sudden cardiac death is the leading cause of death among dialysis patients, but the benefit of primary prevention implantable cardioverter defibrillators (ICD) in this population is uncertain. We conducted this investigation to compare the mortality of dialysis patients receiving a primary prevention ICD with matched controls.

Methods: We used data from National Cardiovascular Data Registry's ICD Registry to select dialysis patients who received a primary prevention ICD, and the Get With The Guidelines-Heart Failure Registry to select a comparator cohort. We matched ICD recipients and no-ICD patients using propensity score techniques to reduce confounding, and survival was compared between groups.

Results: We identified 108 dialysis patients receiving primary prevention ICDs and 195 comparable dialysis patients without ICDs. One year (3-year) mortality was 42%(69%) in the ICD registry cohort compared to 38%(76%) in controls. There was no significant survival advantage associated with ICD (HR=0.87, 95%CI 0.66-1.13, p=0.29). After propensity matching, our analysis included 86 ICD patients and 86 matched controls. Comparing the propensity-matched cohorts, 1 year(3 years) mortality was 43% (74%) in the ICD cohort and 40% (77%) in controls; there was no significant difference in mortality outcome between groups (HR=0.94, 95% CI 0.67-1.31, p=0.71).



Conclusions: We did not observe a significant association between primary prevention ICDs and reduced mortality among ESKD patients receiving dialysis. Consideration of the potential risks and benefits of ICD implantation in these patients should be undertaken while awaiting the results of definitive clinical trials.

Effect of Maternal Obesity in Offspring Predisposition to Chronic Kidney Disease in Rats Sarah J. Glastras,[1] Hui Chen,[2] Carol A. Pollock,[1] Sonia Saad.[1] *[1]Renal Medicine, Kolling Inst, Univ of Sydney, NSW, Australia; [2]School of Biomedical Sciences, Univ of Technology, Sydney, NSW, Australia.*

Background: Exposure to excess nutrition *in utero* and in early postnatal life is associated with adverse consequences for the offspring including diabetes, hypertension, dyslipidemia, cardiovascular disease and CKD. We aimed to determine whether maternal obesity predisposes the offspring to CKD.

Methods: Dams were fed normal or high-fat diet (HFD; 20 kJ/g)) 6 weeks before gestation until pups weaned, and their offspring's kidneys examined at Day 20 (weaning), Week 9 (adolescence) or Week 13 (adulthood). Animals were exposed to a normal or HFD from weaning. The pups' anthropometric measures and hormonal levels were recorded. Renal structure was assessed using PAS and Masson's trichrome staining. Gene expression of profibrotic factors (TGF-β, CTGF), proinflammatory cytokines (TNF, IL-6 and MCP-1), and metabolic markers (FAS, PPARα, SREBP) was measured by RT-PCR. Western blotting and immunohistochemistry was utilized to confirm these changes.

Results: Offspring from obese dams displayed increased fat mass, body weight, blood triglycerides levels, and glucose intolerance compared with those from lean rats in adolescence (week 9). Hormonal levels of leptin, ghrelin, GLP-1, and glucagon were increased in the offspring of obese mothers compared to control animals at Week 9 and Week 13. This is associated with increased renal inflammatory markers (MCP1 and TGFβ), increased fibrotic markers (fibronectin and collagen) and increased oxidative stress markers (iNOS and SOD activity). In addition the obese offspring have lipid droplets in their kidneys, and signs of tubulointerstitial injury which foreshadow the development of CKD. Interestingly, those markers were largely normalized when examined in adulthood when they were glucose intolerant at week 13.

Conclusions: Maternal HFD causes metabolic and hormonal derangement associated with altered fibrotic, inflammatory and oxidative stress markers within the kidneys of rat offspring at adolescence but not sustained to adult life. This suggests that maternal obesity may predispose the offspring to further renal damage in the setting of other insults such as diabetes.

Tubular Dysfunction Results in Altered Nucleoside Metabolism in Diabetic Nephropathy Anna V. Mathew, Farsad Afshinnia, Jaeman Byun, Pradeep Kayampilly, Frank C. Brosius, Subramaniam Pennathur. *Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: Our recent work demonstrated that plasma nucleosides pseudouridine (PU) and dimethyl guanosine (DMG) predict type 2 diabetic nephropathy (DN) progression, but the mechanism underlying this increase is not well-understood.

Methods: In order to study the metabolism and flux of the nucleosides *in vivo* systematically, we developed a targeted quantitative analysis of nucleosides by liquid chromatography/ tandem mass spectrometry (LC/MS). Mice which exhibit characteristic pathological features of DN (BKS db/db) and control (BKS db+) were used to examine the static and dynamic changes in nucleoside metabolism in DN. We performed *in vivo* metabolic flux analysis (MFA) by LC/MS following intraperitoneal administration of isotopically labeled substrates ^{13}C Uracil (precursor of PU) and ^{13}C hypoxanthine (precursor of DMG and allantoin) to 24-week old mice.

Results: MFA revealed statistically significant elevations in label incorporation into PU and hypoxanthine (HX) in plasma with corresponding decrease in urinary labeling in diabetic mice compared with controls. In contrast, label incorporation of uracil, HX, PU, DMG and allantoin were unchanged in diabetic renal cortex, liver and muscle suggesting that renal and tissue metabolism were not the source of the altered nucleosides. The elevated plasma levels and diminished urinary excretion strongly implicate altered tubular handling of nucleosides in DN. In order to determine if the altered nucleoside handling was specific to DN, we measured nucleosides in baseline samples of subjects with stages 3 and 4 chronic kidney disease (CKD) from the CPROBE cohort (16 DN and 24 non-diabetic subjects). After adjusting for serum creatinine, plasma PU, DMG and allantoin, and urinary allantoin and HX were significantly associated with DN. Levels of plasma PU and DMG predicted renal progression in one year (defined as 20% decrease in eGFR or 1.5 fold increase in proteinuria) only in DN, but not in non-diabetic CKD.

Conclusions: Taken together, these results highlight previously unrecognized unique role for altered nucleoside metabolism and handling in the pathogenesis of DN.

G Protein Coupled Receptor TGR5 Agonist Prevents Kidney Disease in Mice with Diet Induced Obesity Xiaoxin Wang,[1] Yuhuan Luo,[1] Cherelle Parker,[1] Luciano Adorini,[3] Michal Herman-Edelstein,[2] Moshe Levi.[1] *[1]Medicine, Univ of Colorado Denver; [2]Univ of Tel Aviv; [3]Intercept Pharmaceuticals.*

Background: Obesity-related glomerulopathy (ORG) is becoming one of the leading causes of kidney disease. In addition to life style changes and/or bariatric surgery additional treatment modalities are needed to prevent ORG.

Methods: In recent studies in kidney biopsies from subjects with ORG we have determined that there is decreased expression of the G Protein Coupled Receptor TGR5. In the present study we therefore determined the role of the G Protein Coupled Receptor TGR5 in modulation of kidney disease in a mouse model of diet induced obesity and insulin resistance.

Results: Treatment of mice with the selective TGR5 agonist INT-777 decreased urinary albumin (73±8 in HF versus 26±9 in HF+INT-777, $p<0.05$), podocyte injury, mesangial expansion, tubulointerstitial fibrosis, and CD68 macrophages in the kidney. These beneficial effects of INT-777 were associated with significant increases in p-AMPK (12±1.2 in HF versus 19±1.3 in HF+INT-777, $p<0.01$), PGC-1α (37±0.8 in HF versus 50±4.1 in HF+INT-777, $p<0.05$), and Sirt3 (85±2.1 in HF versus 142±15 in HF+INT-777, $p<0.01$) protein abundance. At the same time there was an increase in MnSOD (94±3.4 in HF versus 105±2.4 in HF+INT-777, $p<0.05$) protein abundance. We also performed studies in cultured human podocytes to determine direct renal specific effects of TGR5 activation. Treatment with INT-777 prevented glucose induced podocyte apoptosis and increased podocyte SIRT1, p-AMPK, and PGC-1α protein abundance. These effects were associated with increased mitochondrial number, decreased mitochondrial ROS production, and increased SOD2 gene expression. In addition, INT-777 decreased SREBP-1 protein and increased PPARα, LCAD, and CPT-1b expression, resulting in decreased lipid accumulation in podocytes.

Conclusions: These studies indicate a novel role for TGR5 in inducing energy metabolism, mitochondrial biogenesis, and fatty acid oxidation which result in prevention of oxidative stress and lipid accumulation and firmly establish an important role for the GPCR TGR5 in preventing kidney disease in obesity.

TH-OR151

Glomerular microRNA-26a Expression Correlates with eGFR in Diabetic Nephropathy and Its Regulation in Podocytes Kenichi Koga,[1] Hideki Yokoi,[1] Kiyoshi Mori,[2] Masato Kasahara,[3] Takashige Kuwabara,[1] Moin Saleem,[6] Akira Sugawara,[4] Kazuwa Nakao,[2] Motoko Yanagita,[1] Masashi Mukoyama.[5] *[1]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [2]Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [3]Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan; [4]Dept of Nephrology, Osaka Red Cross Hospital, Osaka, Japan; [5]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [6]Academic and Children's Renal Unit, Univ of Bristol, United Kingdom.*

Background: microRNAs are small non-coding RNAs which negatively regulate target genes. We reported that microRNA-26a (miR-26a) directly inhibits connective tissue growth factor (CTGF/CCN2) expression and attenuates TGF-β/SMAD signaling in cultured human podocytes. The aim of this study is to investigate the relation between glomerular miR-26a expression in human diabetic nephropathy (DN) and renal function, and to evaluate its regulation in podocytes.

Methods: We analyzed miR-26a expression in microdissected glomeruli from human biopsy samples of 11 subjects with DN. We transfectedmiR-26a mimic and inhibitor into cultured human podocytes and analyzed expression of the host genes of miR-26a, small C-terminal domain phosphatases 2 and 3 (SCP2/3). We also examined miR-26a and SCP2/3 expressions in glomeruli of streptozotocin (STZ)-induced diabetic mice at 3 weeks after induction of diabetes.

Results: Glomerular miR-26a expression in human DN correlated positively with eGFR ($p < 0.05$, $r = 0.659$). SCP2/3 expressionswere downregulated by miR-26a mimic and upregulated by its inhibitor. SCP2/3 siRNA attenuated TGFβ1-induced ECM accumulation. STZ mice exhibited lower miR-26a and higher CTGF and SCP2/3 expressions in glomeruli than control mice.

Conclusions: We showed that miR-26a expression was lower in glomeruli of both the advanced phase of human DN and the early phase of a mouse model of DN, suggesting that downregulated miR-26a expression together with upregulated SCP2/3 can be involved in the pathophysiology of DN through the dysregulation of CTGF and TGF-β/SMAD signaling.

Overexpression of Transcription Factor FOXC2 Induces Dedifferentiation and Increased Motility of Cultured Human Podocytes Sanna H. Lehtonen,[1] Naoyuki Miura,[2] Moin Saleem,[3] Neeta Datta.[1] *[1]Haartman Inst, Dept of Pathology, Univ of Helsinki, Helsinki, Finland; [2]Dept of Biochemistry, Hamamatsu Univ School of Medicine, Hamamatsu, Japan; [3]Academic and Children's Renal Unit, Univ of Bristol, Bristol, United Kingdom.*

Background: The molecular mechanisms leading to the development of diabetic nephropathy remain poorly understood, but podocyte injury is known to be involved. We hypothesized that transcription factor FOXC2, known to associate with obesity, insulin resistance and type 2 diabetes mellitus, could play a role in the pathophysiology of diabetic nephropathy.

Methods: We analyzed by immunostaining the localization of FoxC2 in the glomeruli of obese Zucker rats, and overexpressed FOXC2 in cultured human podocytes by lentiviral transduction. The effects on podocytes were studied by immunostaining and quantitative Western blotting, and the motility of podocytes was assessed by the wound healing (scratch) assay.

Results: We observed increased expression and nuclear concentration of FoxC2 in podocytes of obese Zucker rats that are insulin resistant and proteinuric. Overexpression of FOXC2 in differentiated human podocytes *in vitro* led to increased nuclear expression of FOXC2 and dedifferentiation of podocytes associated with a change of cellular morphology. This was accompanied by upregulation of key mesenchymal markers including vimentin, alpha-smooth muscle actin and active beta-catenin, re-organization of the actin cytoskeleton and disrupted localization of the tight junction protein ZO1. FOXC2 overexpressing podocytes also showed increased motility.

Conclusions: The data indicate that the expression and localization of FOXC2 in podocytes needs to be tightly regulated, and that its overexpression induces a chain of cellular events leading to podocyte dysfunction. These changes may lead to podocyte detachment and depletion ultimately contributing to albuminuria and diabetic nephropathy.

Attenuated Cholesterol Efflux Causes Podocyte Cholesterol Accumulation and Apoptosis in Diabetic Kidney Disease Christopher E. Pedigo,[1,5] Farah Leclercq,[1,5] Mayrin Correa-Medina,[1,5] Alla Mitrofanova,[1,4,5] Armando Mendez,[3] Robert G. Nelson,[2] George William Burke,[4] Alessia Fornoni,[1,3,5] Sandra M. Merscher.[1,3,5] *[1]Div of Nephrology and Hypertension, Univ of Miami, Miami, FL; [2]NIDDK, Phoenix, AZ; [3]Diabetes Research Inst, Univ of Miami, Miami, FL; [4]Dept of Surgery, Univ of Miami, Miami, FL; [5]Katz Family Drug Discovery Center, Univ of Miami, Miami, FL.*

Background: Diabetic Kidney Disease (DKD) is the most common cause of ESRD and serum Tumor Necrosis Factor alpha (TNFα) levels correlate with the development and progression of DKD. In DKD decreased podocyte number and glomerular cholesterol accumulation are associated with albuminuria. We hypothesized that TNFα causes lipid dependent podocyte apoptosis in DKD.

Methods: Caspase 3 activity was determined in human podocytes. ^{3}H-cholesterol was used for efflux experiments and cyclodextrin to deplete cells of cholesterol. TNFα inhibition was achieved using Infliximab.

Results: Human podocytes cultured in the presence of sera from patients with T2D and progressive DKD (ΔGFR of -97.39±8.2, n=15) revealed significant reduction in ABCA1 (ATP Binding Cassette A1) mRNA expression compared to podocytes cultured in sera from patients with non-progressive DKD (ΔGFR of 40.62±8.6, n=16). TNFα treatment reduced ABCA1 mRNA and protein expression ($p<0.05$) but did not affect mRNA expression of other cholesterol metabolism genes (HMGCR, LDLR and SOAT1). TNFα treatment reduced ABCA1 mediated cholesterol efflux ($p<0.01$) in association with increased cholesterol content ($p<0.05$), reduced esterified cholesterol($p<0.05$) and reduced SOAT1 activity ($p<0.05$). TNFα treatment also increased caspase 3 activity ($p<0.05$) that was prevented by ABCA1 overexpression or cholesterol depletion ($p<0.05$). TNFα inhibition with Infliximab decreased albuminuria in BTBR*ob*/ob mice (T2D and DKD).

Conclusions: ABCA1 expression is reduced in DKD sera treated podocytes. TNFα attenuates ABCA1 mediated reverse cholesterol transport in podocytes leading to cholesterol accumulation and apoptosis. Our data suggest that treatments targeting the TNFα-ABCA1 axis in podocytes may inhibit the development of DKD.

TH-OR154

Podocyte-Specific Nox4 Deletion Attenuates Albuminuria in Diabetic Nephropathy Jay Chandra Jha,[1,2] Stephen P. Gray,[1] Mark E. Cooper,[1,2] Harald H. Schmidt,[3] Karin Jandeleit-Dahm.[1,2] *[1]Diabetic Complication Div (Diabetes and Kidney Disease Laboratory), Baker IDI Heart and Diabetes Inst, Melbourne, VIC, Australia; [2]Medicine, Monash Univ, Melbourne, VIC, Australia; [3]Dept of Pharmacology Cardiovascular Research Inst, Faculty of Medicine Health & Life Sciences Maastricht Univ, Maastricht, Netherlands.*

Background: Chronic kidney disease is a major microvascular complication of diabetes; however the underlying causes remain unclear. NADPH oxidase and in particular Nox4 derived reactive oxygen species (ROS) in the kidney play a crucial role in the development and progression of diabetic nephropathy. Albuminuria is a key feature of

diabetic nephropathy and podocyte injury leads to the development of albuminuria in diabetes. We examined the effect of podocyte specific NADPH oxidase Nox4 deletion in diabetic nephropathy (DN) using a podocyte specific Nox4 deficient mice.

Methods: Podocyte-specific Nox4 KO (podNox4KO) and floxedNox4 mice were rendered diabetic via streptozotocin injection and followed for 10 and 20 weeks. Urine samples were collected for the assessment of renal function. After 10 and 20 weeks of diabetes animals were culled and kidneys were removed for assessment of structural damage, as well as for the assessment of gene and protein expression of extracellular matrix (ECM), pro-fibrotic and pro-inflammatory markers.

Results: Podocyte-specific Nox4 KO mice were generated. Podocyte specific Nox4 deletion in diabetic podNox4KO mice significantly attenuated the diabetes induced increase in albuminuria compared to the diabetic floxedNox4 mice. However, no significant changes in renal structure as well as glomerular gene expression of profibrotic and proinflammatory markers were observed in diabetic podNox4KO when compared with diabetic floxedNox4 mice. In contrast, the gene expression of nephrin was down regulated in diabetic floxedNox4 mice and was restored to normal in diabetic podNox4KO mice.

Conclusions: Collectively, these results identify Nox4 is a key source of ROS in podocytes and may mediate podocyte injury in diabetes leading to the development of albuminuria.

TH-OR155

Unraveling the Mechanism of Action of Glucocorticoids in Glomerulonephritis Christoph Kuppe,[1] Claudia R.C. van Roeyen,[1] Antonio Sechi,[2] Tammo Ostendorf,[1] Bart Smeets,[1] Jürgen Floege,[1] Hermann-Josef Groene,[3] Marcus J. Moeller.[1] *[1]Dep. of Internal Medicine II, Div. of Nephrology and Clinical Immunology, RWTH Aachen, Aachen, Germany; [2]Dep. of Cell Biology, RWTH Aachen Univ, Aachen, Germany; [3]Dep. of Cellular and Molecular Pathology, German Cancer Research Center, Heidelberg, Heidelberg, Germany.*

Background: Glucocorticoids are commonly used for the treatment of glomerulonephritis. Particularly in the most severe form, crescentic glomerulonephritis (CGN), high-dose steroids are first-line therapy. To date, the mechanisms or target cells of glucocorticoid actions remain incompletely understood. The present study investigated whether glucocorticoids – beside their immunosuppressive effects - directly act on intrinsic glomerular epithelial cells in CGN.

Methods: For this purpose, the glucocorticoid receptor was inactivated specifically in all kidney epithelial cells in Pax8-Cre/GR$^{fl/fl}$ mice, including podocytes and parietal epithelial cells (PECs).

Results: GR inactivation did not impair renal development or function up to 12 months of age. Next, the nephrotoxic serum nephritis model (NTS) was induced in knockout and wild-type control mice. CGN was attenuated by high-dose prednisolone, as expected. Surprisingly, disease activity was also attenuated in renal epithelial GR knockout animals. To verify this, animals were treated with the GR antagonist mifepristone alone. CGN was attenuated more potently than when using prednisolone without obvious effects on the immune system. These findings were verified in a second, non-immunological model (Alport-mouse), where again progression of glomerulosclerosis by activated PECs was attenuated more efficiently by mifepristone than by high-dose prednisolone treatment. Direct actions of steroids on intrinsic renal cells were also verified *in vitro* using primary parietal epithelial cells.

Conclusions: In summary, glucocorticoids exert direct effects on activated epithelial cells in CGN, which appear to be therapeutically more important than immunosuppressive effects. Strikingly, genetic or pharmacological GR inactivation in glomerular epithelial cells is at least as effective as GR stimulation using high-dose steroids. Thus, we propose GR antagonism as novel therapeutic concept.

The Kidney Regulates Granulopoiesis and Neutrophil Homeostasis via Tamm-Horsfall Protein–Dependent Epithelial Activation of the IL-23/IL-17 Axis Radmila Micanovic,[1] Edward F. Srour,[1] Pierre C. Dagher,[1] Brahmananda Reddy Chitteti,[1] Shehnaz Khan,[1] Takashi Hato,[1] Tarek M. El-Achkar.[1,2] *[1]Indiana Univ School of Medicine; [2]Indianapolis VA Medical Center.*

Background: Tamm-Horsfall Protein (THP) is a glycoprotein uniquely expressed in the kidney and excreted as one of the most abundant proteins in the urine. We recently showed that THP is also targeted to the interstitium, and plays a role in tubular cross-talk during kidney injury. In this study, we investigate the modulatory role of THP on the immune system.

Methods: We used THP knockout mice and wild type background strains as previously described. Various experimental methodologies and interventions were used as described in results.

Results: Using immuno-histochemistry and flow cytometry in THP-/- and THP+/+ mice, we show that THP deficiency caused significant depletion of resident macrophages in the kidney but not in other organs such as the liver. This was associated with systemic neutrophelia, and stimulation of granulopoesis in the bone marrow. By means of an ELISA multiplex assay, we confirm that THP-/- kidneys are a unique source of myeolopoeitic growth factors, and differentially activate the IL-23/IL-17 axis, which is known to stimulate granulopoiesis. Indeed, neutralization of IL-17 in THP-/-mice reversed the neutrophelia. To determine the source of IL-23, we used real-time PCR on RNA extracted from S3 segments, thick ascending limbs, macrophages and lymphocytes (isolated with laser micro-dissection and FACS, respectively). Surprisingly, S3 segments were the major source of IL-23 in THP-/- kidneys. Furthermore, macrophage depletion in WT mice using clodronate did not increase the levels of IL-23 in the kidneys, suggesting that the effect of THP deficiency on IL-23 is independent from macrophage depletion.

Conclusions: In conclusion, we show that THP is essential to maintaining resident renal macrophages, and that THP deficiency stimulates proximal epithelial activation of the IL-23/IL-17 axis and systemic neutrophelia. Our findings provide novel insights on the immune-modulatory role of THP and its importance in defining how the kidney can regulate granulopoiesis and systemic neutrophil homeostasis.

The Lymphotoxin β Receptor Is a Therapeutic Target in Renal Inflammation Stephan Segerer,[2] Gitta Seleznik,[1] Harald Seeger,[2] Kai Fu,[3] Maja Lindenmeyer,[2] Marcus J. Moeller,[4] Judith Bauer,[5] Mathias Heikenwaelder,[5] Jeffrey L. Browning.[6,3] *[1]Div of Visceral Surgery, Univ Hospital, Zurich, Switzerland; [2]Div of Nephrology, Univ Hospital, Zurich, Switzerland; [3]Dept of Immunobiology, Biogen Idec, Cambridge, MA; [4]Dept of Nephrology and Clinical Immunology, Rheinisch-Westfälische Technische Hochschule (RWTH) Univ Hospital Aachen, Aachen, Germany; [5]Inst of Virology, TUM, Munich, Germany; [6]Dept of Microbiology and Section of Rheumatology, Boston Univ School of Medicine, Boston, MA.*

Background: Accumulation of inflammatory cells in the tubulointerstitium, at times with a defined microarchitecture, is a hallmark of chronic glomerulonephritis (GN). Lymphotoxin β receptor (LTβR) is important for the formation of lymphoid tissue. We hypothesized that LTβR signaling plays a role in chronic renal inflammation.

Methods: LTs, LTβR, and regulated genes were evaluated by microarray analysis and confirmed by real-time RT-PCR in renal biopsies (n=53). LTβ protein was localized by immunohistochemistry in 48 biopsies from patients with the most common forms of GN. Regulation of LTs and response to LTβR signaling was tested in human mesangial cells, tubular epithelial cells and mouse parietal epithelial cells in-vitro. LTβR signaling was blocked in two mouse models of GN.

Results: Renal biopsies with GN displayed increased levels of LTβ mRNA and protein. LTβ was localized to interstitial lymphocytes, and tubular epithelial cells. Human mesangial and tubular epithelial cells expressed both LTα and LTβ RNA upon stimulation with TNF-α in vitro, and expressed chemokines in response to LTβR signaling. In an anti-glomerular basement membrane antibody induced model of GN, the blockade of LTβR signaling reduced crescent formation and parietal epithelial cells responded to LTβR signaling with CCL2 induction. In a lupus model, LTβR blockade improved renal function without reduction in glomerular immune complex deposition.

Conclusions: Preclinical mouse models and human data strongly suggest that LTβR signaling is involved in renal injury and is a new therapeutic target in renal diseases, mediating a novel pathway in parietal epithelial cell activation with crescent formation.

Milk Fat Globule-Epidermal Growth Factor-8 Limits Tissue Damage Through Inflammasome Inhibition in Renal Obstruction Jean-Francois Cailhier, Marie-Joelle Brissette, Patrick Laplante. *Medicine, CRCHUM, Univ de Montreal, Montreal, QC, Canada.*

Background: Renal diseases are characterized by tubulointerstitial fibrosis due to the loss of renal parenchymal cells. During renal inflammation, macrophages induced apoptosis of resident cells leading to renal fibrosis. We described that milk fat globule-epidermal growth factor 8 (MFG-E8) released by apoptotic renal cells can modulate the renal microenvironment and reprogram macrophages. In this study, we investigated the role of MFG-E8 on the modulation of inflammasome activation, tissue damage and fibrosis in a renal obstruction model.

Methods: C57BL/6 WT or MFG-E8 KO mice underwent unilateral ureteral ligation for 3, 7 and 14 days. MFG-E8 (30μg/kg) was administered intra-peritoneally 1 day before and every 3 days subsequently. In order to evaluate the role of MFG-E8 on macrophage reprogramming, inflammasome activation and renal damage, we adoptively transferred MFG-E8-treated macrophages to MFG-E8 KO mice prior to the renal obstruction. At the end of experiments, kidneys were harvested and were stained for PAS and Sirius Red to evaluate renal damage and fibrosis. Kidneys were also harvested for immunoblotting against inflammasome components (NLRP3, ASC, Caspase-1, IL-1β and IL-17).

Results: MFG-E8 reduced kidney damage and fibrosis compared to control, whereas its absence in the MFG-E8 KO mice was associated with worse disease. Moreover, MFG-E8 administration was associated with a decreased activation of inflammasome in the kidney. Furthermore, administration of ex vivo MFG-E8-stimulated macrophages prior to obstruction conferred renal protection against kidney damage by reducing inflammasome activation and renal injury.

Conclusions: MFG-E8 reduced renal damage through decreased activation of inflammasome. Moreover, administration of ex vivo MFG-E8-stimulated macrophages was sufficient to attenuate renal inflammasome and renal damage suggesting that MFG-E8 present in the renal microenvironment is crucial for macrophage reprogramming. These data identified MFG-E8 as a novel target for the regulation of renal inflammation and chronic kidney disease progression.

Myeloid-Derived tPA Promotes Macrophage Motility through FAK, Rac1, and NF-κB Pathway Ling Lin, Kebin Hu. *Medicine, Penn State Univ College of Medicine, Hershey, PA.*

Background: Macrophage accumulation is one of the hallmarks of progressive kidney disease. Tissue-type plasminogen activator (tPA) is known to promote macrophage infiltration and renal inflammation during chronic kidney injury. However, the underlying mechanism remains largely unknown.

Methods: We examined the role of tPA in macrophage motility in vivo by tracking fluorescence-labeled bone marrow-derived macrophages, generated bone marrow chimeric mice to determine the source of endogenous tPA that promotes renal inflammation and macrophage infiltration, and investigated the underlying signaling mechanisms.

Results: We found that tPA-deficient mice had markedly fewer infiltrating fluorescence-labeled macrophages than the wild-type mice. Experiments in bone marrow chimeric mice further demonstrated that myeloid cells are the main source of endogenous tPA that promotes macrophage migration. In vitro studies showed that tPA promoted macrophage motility through its CD11b-mediated protease-independent function; and FAK, Rac-1 and NF-κB were indispensable to tPA-induced macrophage migration as either infection of FAK dominant-negative adenovirus or treatment with a Rac-1-specific inhibitor or NF-κB inhibitor abolished the effect of tPA. Moreover, ectopic FAK mimicked tPA and induced macrophage motility. tPA also activated migratory signaling in vivo. The accumulation of phospho-FAK-positive CD11b-macrophages in the obstructed kidneys from wild-type mice was clearly attenuated in tPA knockout mice, which also displayed lower Rac-1 activity than their wild-type counterparts.

Conclusions: Therefore, our results indicate that myeloid-derived tPA promotes macrophage migration through a novel signaling cascade involving FAK, Rac-1 and NF-κB.

TH-OR160

Lysosomal Transporter Cystinosin Alters Macrophage Activation and Promotes Renal Fibrosis Daryl M. Okamura, Nadia Bahrami. *Center for Developmental Biology & ReGenerative Medicine, Seattle Children's Research Inst, Seattle, WA.*

Background: Nephropathic cystinosis has traditionally been considered a primary disease of renal tubules induced by the toxic effects of lysosomal cystine accumulation, which leads to renal Fanconi syndrome and eventual tubular apoptosis. However, recent studies demonstrate that the cystinosin-deficient (CTNS-/-) macrophage (mphi) plays a critical role in progressive nephron loss.

Methods: The present study was designed to investigate the role of Ctns in mphi function in nephropathic cystinosis and during kidney injury.

Results: In order to investigate Ctns-/- mphi behavior, we performed FACS analysis on mphi subpopulations in nephropathic cystinotic kidneys at mild (6m) to moderate-severe fibrosis (12m). We found that the number of M1-type mphi ($Ly6c^{med/hi}$) almost doubled between 4 to 6 months and suggests that these cells may initiate an early pro-inflammatory response. During the progression from mild to moderate-severe fibrosis (12m) there was a significant increase in the M1 subset by 120% and is the predominant subpopulation within the cystinotic kidney. These results suggest that M1 mphi and phagocytic dendritic cells are important in the progression of injury in nephropathic cystinosis. We examined proinflammatory and fibrogenic gene expression with M1/M2 activation in bone marrow derived macrophages (BMDM). At baseline, Ctns-/- BMDM have a 43-fold increase in iNOS expression (P=0.03) and with M1 activation, there is a 6.3-fold increase in IL6 expression (P=0.001) compared to Ctns+/+ BMDM. With M2 activation, there was a nearly 6-fold reduction in IL4 receptor and a 2.2-fold reduction in IL10 expression. We further examined the role of Ctns in mphi phagocytosis and chemotaxis. We found that Ctns-/- mphi are hyperphagocytic and do not respond appropriately to chemotactic stimuli. Using a model of chronic kidney injury, we found a significant increase (63%) in Ctns-/- mphi with more severe fibrosis (increased 19%) in UUO kidneys compared to wild-type mice.

Conclusions: These data suggest that the lysosomal transporter cystinosin may play an important role not only in nephropathic cystinosis but in chronic kidney disease progression as well.

TH-OR161

A Small Molecule Inhibitor of Apoptosis Signal-Regulating Kinase 1 (ASK1) Reduces Key Pathological Processes Related to CKD John T. Liles,[1] Haichun Yang,[2] Agnes B. Fogo,[2] David G. Breckenridge.[1] *[1]Gilead Sciences, Inc; [2]Dept of Pathology, Microbiology and Immunology, Vanderbilt Univ Medical Center.*

Background: Oxidative stress (OS) is elevated in patients with chronic kidney disease (CKD) and is a major driver of disease progression. ASK1 is a critical signaling node through which OS promotes inflammation, apoptosis and fibrosis via downstream activation of the MAPK kinases p38 and JNK.

Methods: To validate ASK1 as a therapeutic target in CKD, we evaluated the effects of a potent and selective small molecule inhibitor of ASK1 (GS-444217) in rodent models of acute and chronic kidney disease.

Results: In an acute renal I/R rat model (30 min of ischemia followed by 24 hr reperfusion), prophylactic treatment with GS-444217 (30 mg/kg, p.o.) significantly reduced elevations in serum creatinine (1.76 ±0.4 [SEM] versus 0.85 ±0.2 mg/dl) and BUN (100 ±12 versus 58 ±8 mg/dl), and decreased renal apoptosis (61 ±8 versus 39 ±8; # TUNEL cells) and tubular necrosis (pathology score of 3.7 ±0.3 versus 2.7 ±0.2). Unilateral ureteral obstruction (UUO) for 7 days in rats caused significant increases in renal ASK1 activation, fibrosis, and apoptosis compared to sham animals. GS-444217 (30 mg/kg b.i.d., p.o, 7 days) blocked activation of ASK1 pathway, reduced fibrosis by 88% as measured by picrosirius red staining, and reduced apoptosis by 79% as measured by TUNEL. Rats given deoxycorticosterone acetate (DOCA)-salt for 2 weeks had progressive increases in blood pressure and urinary albumin-to-creatinine ratio (ACR). GS-444217 reduced ACR (2.4 ±0.5 versus 0.3 ±0.1 mg/mg)and decreased both urinary KIM-1 and 8-OH-dG by 50% without impacting systemic blood pressure. 5/6 nephrectomized (5/6 Nx) rats treated orally with GS-444217 for 4 weeks (starting 8 weeks after 5/6 Nx) had decreased glomerulosclerosis (pathology score 1.21 ± 0.12 versus 0.7 ± 0.1) and ACR (152±21 versus 52 ±9mg/mg) compared to vehicle-treated 5/6 Nx.

Conclusions: Results from several *in vivo* studies demonstrate that selective inhibition of ASK1 decreases renal injury, tubulointerstitial fibrosis, glomerulosclerosis, and proteinuria, and improves renal function. The data provide compelling evidence for ASK1 as a therapeutic target in kidney disease.

TH-OR162

Loss of *Sec63* and *Xbp1* Caused Renal Interstitial Inflammation and Fibrosis Yasunobu Ishikawa,[1] Sorin V. Fedeles,[1] Ming Ma,[1] Rachel Gallagher,[1] Stefan Somlo.[1,2] *[1]Internal Medicine, Yale Univ School of Medicine, New Haven, CT; [2]Genetics, Yale Univ School of Medicine, New Haven, CT.*

Background: *SEC63* is one of genes linked with the occurrence of autosomal dominant polycystic liver disease. The product of *SEC63*, SEC63p is a protein associated with the SEC61 translocon and involved in co-translational protein translocation and folding. In the presence of endoplasmic reticulum (ER) stress, a housekeeping mechanism called the unfolded protein response (UPR) is turned on in order to mitigate stress. The UPR is mediated by three major stress sensors, IRE1α, PERK and ATF6. Phosphorylation of IRE1α leads to spliced XBP1 which is a transcription factor that activates transcription of chaperones and proteins involved in ER-associated degradation. In the current study we investigated the effect of Xbp1 inactivation in the kidney in the presence and absence of Sec63.

Methods: We used combinatorial genetics to generate WT, SKO (*$Sec63^{fl/fl}$;$Pax8^{rtta}$;TetOcre*) and DKO (*$Sec63^{fl/fl}$;$Xbp1^{fl/fl}$;$Pax8^{rtta}$;TetOcre*) mice. All mice were induced with 2 mg/mL doxycycline (DOX) in drinking water for 2 weeks beginning at P28. We investigated the kidney phenotype and UPR activation pathways 1, 2, 3 and 6 weeks kidney after the start of DOX induction.

Results: Kidney weight to body weight ratio of DKO mice 1 and 2 weeks after the start of induction was higher than those of WT and SKO mice due to the accumulation of inflammatory cells, while the WT and SKO kidneys were normal by histology. The interstitial inflammatory infiltrate in the DKO kidneys included lymphocytes, plasma cells, macrophages and fibroblasts. Few cysts were also observed. Gene expressions of Mcp-1, F4/80 and Pai-1 were elevated 1 week after the start of induction, while Tgf-β and Fsp-1 were increased 2 weeks after the start of induction. Notably, dual loss of *Sec63* and *Xbp1* lead to a complete activation of the Ire1α pathway while Perk and Atf6 did not exhibit signs of activation compared to WT and SKO kidneys.

Conclusions: Activated IRE1α is an important driver of renal interstitial inflammation and fibrosis like chronic kidney disease (CKD) in the absence of *Sec63*/*Xbp1*. The *Sec63*/*Xbp1* DKO mice may represent a useful genetic model of CKD.

De Novo Synthesis of Acetylcholine by Podocytes Is a Key Mechanism for Kidney Self-Defense against Progressive Kidney Injury Gabriela E. Garcia,[1] Luan D. Truong,[2] Jessica Helen Trostel,[1] Richard J. Johnson,[1] Lili Feng.[3] *[1]Medicine, Univ of Colorado Denver, Aurora, CO; [2]Pathology, The Methodist Hospital, Houston, TX; [3]Medicine, Baylor Collage of Medicine, Houston, TX.*

Background: There is a communication between the immune and neuroendocrine systems. Acetylcholine (ACh), the principal vagal neurotransmitter, is expressed in non-neuronal cells and inhibits proinflammatory cytokines production.

Methods: Using ChAT(BAC)-EGFP transgenic mice, which express enhanced green fluorescent protein (EGFP) under the control of transcriptional regulatory elements for choline acetyltransferase (ChAT), the sole enzyme that produces ACh, we investigated the role of kidney derived ACh in kidney injury in the cytokine-dependent anti-glomerular basement membrane glomerulonephritis (anti-GBM GN).

Results: ChAT is expressed in the kidney, during GN ChAT expression is induced in the glomeruli, mainly in podocytes. Mice with less kidney injury expressed less podocytes ChAT. In contrast, higher podocytes ChAT expression was observed in mice with more kidney injury, suggesting that increased ChAT is a counter-regulatory response to inflammation. Importantly, nephritic kidneys from ChAT mice showed less kidney damage compared to WT mice. Glomerular proliferation, fibrinoid necrosis, crescent formation, tubulointerstitial injury and macrophages (MΦ) infiltration were significantly lower in ChAT mice. Similarly, collagen (Col) III and Col IV deposition were decreased in nephritic kidneys from ChAT mice compared with WT mice. To investigate if ACh could arrest established GN, anti-GBM GN was induced in WKY rats to generate a progressive model of kidney injury. Treatment with donepezil (DPZ), that increases ChAT promoter activity and ChAT protein amount and inhibits acetylcholinesterase, was delayed until day

3 or day 6 after the induction of GN and rats were euthanized at day 25. In rats treated with DPZ, glomerular proliferation, necrotizing lesion, MΦ infiltration and Col deposition were significantly reduced compared with the control group.

Conclusions: These findings suggest that de novo synthesis of podocytes ACh protects from excessive inflammation preventing progressive kidney fibrosis.

Transcriptome-Based Cluster Analysis Identifies TNF-Subgroup in Focal and Segmental Glomerulosclerosis Sebastian Martini,[1] Viji Nair,[1] Felix H. Eichinger,[1] Heather N. Reich,[2] Matthias Kretzler.[1] *[1]Internal Medicine, Div of Nephrology, Univ of Michigan, Ann Arbor, MI; [2]Div of Nephrology, Univ Health Network, Toronto General Hospital, Toronto, ON, Canada.*

Background: The histopathology-based taxonomy of FSGS and MCD fails to capture the molecular basis of these diseases and does not adequately predict response to therapy. Novel treatment strategies like anti-TNF-alpha drugs (FONT trial, Trachtman, *Am J Kidney Dis. 2010*) led to remission induction in only ~25% of participating FSGS patients. We here describe a strategy that could potentially predict treatment response using transcriptomic profiling.

Methods: Transcriptomic profiles from microdissected clinically indicated renal biopsies were generated from 49 study participants with FSGS or MCD of the NEPTUNE study using the Affymetrix 2.1 ST platform. Gene expression levels were analyzed by hierarchical clustering via Arraytrack. The functional context was defined using Ingenuity pathway analysis tools and the Connectivity Map project (CMAP) database that comprises transcriptomic profiling data from >6,100 treatment control pairs and >1,300 pertubagens.

Results: Unsupervised hierarchical clustering grouped subjects into 3 distinct molecular subgroups with significant differences in the clinical outcomes: proteinuria remission (25 remission cases in cluster 1+2 versus none in cluster 3) and eGFR at baseline (cluster 1/2/3: 108/79/42 mL/min/m^2). Functional analysis of the transcripts differentially regulated between subgroups identified a transcriptional network centered on TNF-alpha whose transcripts were upregulated in cluster 3 compared to clusters 1+2. This upregulation of TNF-associated genes was confirmed in an independent cohort of 31 patients with FSGS or MCD and was concordant with the CMAP findings that predicted a reversal of expression signatures in cluster 3 with therapeutics targeted against TNF alpha.

Conclusions: Developing a molecular taxonomy for primary proteinuric kidney disease should rationalize clinical trial design and identify patients most likely to benefit from intervention for enrollment. Supported by NIH grant to NEPTUNE: U-54-DK-083912.

Funding: Other NIH Support - Supported by NIH grant to NEPTUNE: U-54-DK-083912

Apolipoprotein L1 Gene Variants in Deceased Organ Donors Are Associated with Renal Allograft Failure Barry I. Freedman,[1] Bruce A. Julian,[2] Stephen O. Pastan,[3] Ajay K. Israni,[4] Allan D. Kirk,[5] Robert S. Gaston,[2] Robert J. Stratta,[1] Sumit Mohan,[6] Patricia L. Adams,[1] Amudha Palanisamy,[1] Amber M. Reeves-Daniel,[1] Jasmin Divers.[1] *[1]Wake Forest School of Medicine; [2]Univ of Alabama at Birmingham School of Medicine; [3]Emory Univ School of Medicine; [4]Hennepin County Medical Center, Univ of Minnesota; [5]Duke Univ School of Medicine; [6]Columbia Univ College of Phaysicians and Surgeons.*

Background: Apolipoprotein L1 gene (APOL1) nephropathy variants in African American deceased kidney donors were associated with shorter renal allograft survival in a single-center report from North Carolina. Replication analyses were performed in a larger cohort.

Methods: APOL1 G1 and G2 nephropathy variants were genotyped in newly accrued DNA samples from African American deceased donors of kidneys recovered and/or transplanted in Alabama and North Carolina. Data from the Scientific Registry of Transplant Recipients (SRTR) was utilized to link allograft outcomes and APOL1 genotypes (recessive model) in subsequent kidney transplants performed at 55 centers across the country, adjusting for age, sex and ancestry of recipients, HLA match, cold ischemia time, panel reactive antibody levels, and standard-criteria versus expanded-criteria donor.

Results: For 221 transplantations from kidneys recovered in Alabama, allograft failure was significantly associated with APOL1 genotype (odds ratio [OR] 2.87; p=0.04). For the 675 kidneys transplanted from donors at both centers, APOL1 genotype (OR 1.83; p=0.03), African American recipient ancestry (OR 1.72; p=0.01), and expanded-criteria donation (OR 1.79; p=0.04) were associated with allograft failure. Allograft survival was significantly shorter in recipients of two-APOL1-nephropathy-variant kidneys (hazard ratio 2.26; p=0.001).

Conclusions: Kidneys from African American deceased donors with two APOL1 nephropathy variants are reproducibly associated with a higher risk for allograft failure after transplantation. These findings warrant consideration of rapid genotyping of deceased African American kidney donors for APOL1 G1 and G2 variants at the time of organ recovery and incorporation of the results into allocation and informed-consent processes.

Variation in the Multidrug Resistance Protein 1 Gene (*ABCB1*) in African American Deceased Organ Donors Is Associated with Renal Allograft Failure Jun Ma,[1] Jasmin Divers,[1] Nicholette D. Palmer,[1] Bruce A. Julian,[2] Stephen O. Pastan,[3] Ajay K. Israni,[4] Robert S. Gaston,[2] Lijun Ma,[1] Robert J. Stratta,[1] Amudha Palanisamy,[1] Amber M. Reeves-Daniel,[1] Barry I. Freedman.[1] *[1]Wake Forest Sch Med; [2]Univ of Alabama at Birmingham Sch Med; [3]Emory Univ Sch Med; [4]Hennepin County Med Cen, Univ of Minnesota.*

Background: ABCB1 and caveolin 1 (CAV1) gene variants in deceased organ donors of European ancestry are associated with allograft failure after kidney transplantation.

Methods: To further analyze this effect in African Americans (AAs), 39 haplotype-tagging single nucleotide polymorphisms (SNPs) spanning ABCB1 and 15 tag SNPs spanning CAV1 were genotyped in 368 AA deceased organ donors; 679 resultant kidney transplants were assessed. Tests for genetic association were performed with time to allograft failure in the Scientific Registry of Transplant Recipients (SRTR) adjusting for recipient age, sex and ethnicity, cold ischemia time (CIT), panel reactive antibodies (PRA), HLA mismatch, standard- versus expanded-criteria donation, and apolipoprotein L1 gene variants.

Results: AA deceased kidney donors were 60.3% male and 82.3% standard-criteria donors, with mean±SD (median) age 34.9±16.8 (36) years, terminal serum creatinine 1.25±0.7 (1.1) mg/dl, CIT 23.5±11.2 (22) hours, HLA mismatch 4.3±1.4 (5), and recipient PRA 23.9±32.7 (5.5)%. In fully adjusted models, four ABCB1 SNPs were significantly associated with time to renal allograft failure: rs1055302 (hazard ratio±SE 1.32±0.08; p=0.0007, additive model), rs17064 (HR±SE 2.51±0.25; p=0.0002 recessive), rs17209837 (HR±SE 1.29±0.08; p=0.0021 additive), and rs3789246 (HR±SE 0.54±0.22; p=0.005 recessive); two ABCB1 SNPs were weakly associated: rs6949448 and rs956825 (both p<0.03, recessive). In contrast, CAV1 SNPs were not significantly associated with renal allograft failure.

Conclusions: Genetic variation in ABCB1 in deceased organ donors of European and African ancestry is reproducibly associated with allograft failure after kidney transplantation. Because ABCB1 mediates cellular transport of calcineurin inhibitors, alterations in drug metabolism may be involved. Pharmaco-genetic profiling based on ABCB1 should be evaluated to improve outcomes in kidney transplantation.

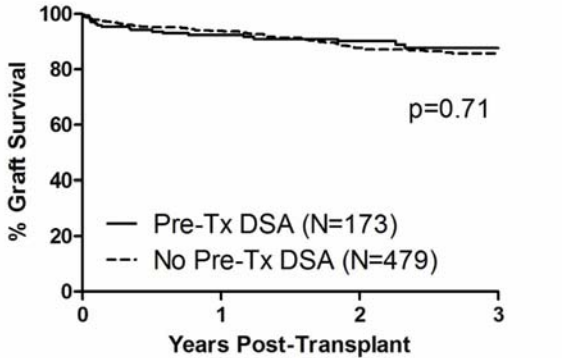
Impact of Pre Transplant Donor Specific Antibodies in the Setting of a Negative Cell Based Flow Cytometry Cross Match on Graft Outcomes Oluwafisayo O. Adebiyi, Jane Gralla, Alexander C. Wiseman, James E. Cooper. *Div of Renal Disease and Hypertension, Univ of Colorado, Aurora, CO.*

Background: Presence of antibodies to donor specific HLA antigens (DSA) detected by single antigen bead (SAB) analysis prior to kidney transplant(Tx) has been associated with inferior graft outcomes. However, it is unclear if low-level DSA leads to a higher risk of rejection or late graft dysfunction. Most studies, limited by small sample size, have not considered flow cytometry cross match(FCXM) results or desensitization therapy in the analysis.

Methods: 652 recipients of a kidney or kidney/pancreas Tx with a negative pre-Tx FCXM(-FCXM) between September 2007 and August 2012 at our center without desensitization therapy were analyzed. All patients underwent cell-based FCXM and SAB analysis on current and historic sera prior to transplantation. Patients were placed on triple immunosuppression. Graft outcomes were compared for patients with (DSA+) and without (DSA-) pre-Tx DSA.

Results: Of 652 patients with -FCXM, 173 had DSA (MFI ≥ 500) detected prior to Tx by SAB analysis. Acute rejection (AR) rates at one year were similar in DSA+ versus DSA- groups, (14.2% versus 11.6% respectively, p=0.349) With a median follow up period of 2.3 years, mean GFR, mean proteinuria, 3 year graft survival by Kaplan-Meier estimate were similar in DSA+ and DSA-patients (p= 0.71) and remained similar irrespective of the strength of DSA. Effect of pre-Tx DSA on graft outcome remained non-significant with multivariate analysis.



Conclusions: To our knowledge, this is the largest series characterizing graft outcomes of patients with pre-Tx +DSA/-FCXM. Presence of pre-Tx DSA in the setting of -FCXM was not associated with poorer graft outcomes. These data suggest that DSA detected by SAB alone may confer minimal immunologic risk and does not require preemptive B-cell/antibody-targeted therapies.

Persistence or De Novo Occurrence of C1q-Binding Donor Specific Antibodies Strongly Predict Future Graft Loss in Presensitized High-Risk Kidney Transplant Recipients

Sebastian Markus Schaefer,[1] Caner Süsal,[2] Gerhard Opelz,[2] Luis Eduardo Becker,[1] Stefanie Sickmüller,[1] Ruediger Waldherr,[3] Stephan Macher-Goeppinger,[3] Martin G. Zeier,[1] Christian Morath.[1]
[1]Nephrology, Univ of Heidelberg, Heidelberg, Germany; [2]Transplantation Immunology, Univ of Heidelberg, Heidelberg, Germany; [3]Pathology, Univ of Heidelberg, Heidelberg, Germany.

Background: Certain subgroups of presensitized patients are at a higher risk for early adverse events post transplant (tx).

Methods: We studied the impact of pre- and post-tx presence of HLA antibodies on subsequent occurrence of antibody-mediated rejection (AMR) episodes and graft loss in a unique cohort of 80 presensitized high-risk kidney tx recipients. All patients received desensitization by apheresis and anti-CD20 therapy, and were transplanted until December 2011. Follow-up was until September 2013. Single Antigen Bead (SAB) assay-detected DSA with or without C1q-binding capability were measured a) pre-tx, and b) post-tx, either before the occurrence of an AMR episode, before graft loss, or at year one.

Results: The rates of AMRs and graft loss were not significantly different in patients with or without C1q-binding capability of their pre-tx DSA. This was attributable to the post-tx loss of pre-tx C1q-DSA in 11 of 13 patients who showed only one graft loss during the further course. In contrast, post-tx presence of C1q-DSA was associated with a significantly higher rate of AMRs (compared to the absence of C1q-DSA or the overall absence of DSA: 86% versus 33% versus 0%, p<0.001) and graft loss from rejection (86% versus 3% versus 3%, p<0.001). Patients with post-tx C1q-DSA had either persistent (N=1), de novo (N=6) or persistent and de novo (N=1) C1q-DSA. Patients with persistent C1q-DSA (N=2) had higher pre-tx SAB IgG-DSA mean fluorescence intensity (MFI) values as compared to C1q-DSA that were lost post-tx (24.867-28.435 MFI versus 1.098-13.317 MFI). De novo DSA (N=6) occurred primarily in patients with insufficient immunosuppression in the early post-tx phase.

Conclusions: In this unique cohort of presensitized kidney tx recipients we found that persistent and de novo C1q-DSA in the early post-tx phase were strongly associated with AMR episodes and consecutive graft loss.

A Novel Multiplex Approach to Define Peripheral Blood HLA-Specific B-Cell Subsets in Clinical Transplantation

Ahmed Akl, Anat R. Tambur, Mohammed Javeed Ansari. *CTC, Northwestern Univ, Chicago, IL.*

Background: Naïve B cells have been associated with long term allograft survival. Memory B cells have been linked to poor allograft survival. Role of HLA-specific B cells in chronic allograft rejection is still unknown. Quantifying HLA-specific B cells (donor specific or not) might be of importance for better understanding of the mechanisms of graft lesions, for an earlier diagnosis of chronic rejection, and eventually to guide specific B cell-targeted therapy. In here, we describe our method to quantify, characterize and correlate the phenotype of HLA-specific B cells (HSB) in kidney transplant recipients (TR).

Methods: PBMC from TR [n=8; 4 patients with good graft outcome (GO), the others with poor outcome (PO)] and healthy volunteers (HV) [n=10] were incubated with HLA single antigen beads (SAB) for class I and II. HLA Bead-B-cell Rosette (BBR) frequency and specificity were analyzed by flow cytometry. HSB polyreactivity was defined by the percentage of total SAB forming BBR. TR serum was tested for HLA antibodies using SAB. Phenotype of total B cells and HSB was determined by CD27, CD38 and IgD expression.

Results: Significantly higher frequency of HSB were identified in TR compared to HV. HSB were in higher frequency (HLA class I: 1.86% versus 0.47%; class II: 8% versus 0.7% ; p<0.05), had a wide breadth of polyreactivity (HLA class I: 76.97% versus 13.1%; class II: 91.9% versus 13.69%; p<0.05) among PO compared with GO. Not all HSB were associated with IgG HLA antibodies. Majority of HSB and total B cells were in the naive compartment in the GO while in the PO HSB were among the memory, pregerminal and centroblasts phenotypes.

Conclusions: Our novel approach enables identification and characterization of HLA-class I and II specific B cells. HSB memory phenotype correlated with poor graft outcome. Further functional and gene expression analysis of HSB will be done.

Figure 1: A) Significant difference between the frequency of B cell rosettes identified in transplant recipients compared with healthy volunteers (HLA class I p=0.024; class II P<0.05). Anti-HLA class II B cell recognition pattern differences at 12 months PT between transplant recipient with good (B) and in contrast poor (C) graft outcome 2 years later (3 years PT). dark dots represent the HSB, orange dots represent the HLA beads.

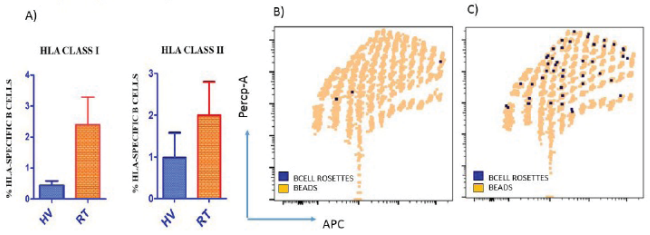

Figure2: A) CD27/IgD classification of B cells shows HSB (in dark dots) expansion and deviation toward unswitched, switched and exhausted memory phenotypes within total B cells (in orange dots). B) CD38/IgD classification of B cells shows HSB (in dark dots) expansion and distribution among active naïve, pregerminal, centroblasts, early memory phenotypes within total B (in orange dots).

Urine Kidney Injury Biomarkers and Risk of Cardiovascular Events, Death and End-Stage Renal Disease among Prevalent Kidney Transplant Recipients: The FAVORIT Trial

Nisha Bansal,[1] Daniel E. Weiner,[2] Myra A. Carpenter,[3] Andrew S. Levey,[2] Marc A. Pfeffer,[4] Meyeon Park,[5] Kathleen D. Liu,[5] John W. Kusek,[6] Chi-Yuan Hsu.[5] *[1]UW; [2]Tufts; [3]UNC; [4]BWH; [5]UCSF; [6]NIH.*

Background: Kidney transplant recipients (KTR) are at high risk for cardiovascular (CVD) and kidney failure. Urine injury biomarkers are associated with poor outcomes in native kidney disease. It is unknown whether the same associations are true among KTR.

Methods: We conducted a post hoc analysis of FAVORIT, a multicenter, trial of KTR examining the effect of B-vitamin therapy on CVD and death. We used a case-cohort design, selecting 737 participants with adjudicated CVD events, ESRD or death and a random sub-cohort of 489 participants. CVD was defined by CVD death, myocardial infarction, and stroke. Urine neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule (KIM)-1, interleukin (IL)-18 and liver-type fatty acid binding protein (L-FABP) were measured in spot urine samples at baseline and standardized to urine creatinine concentration. Weighted Cox models were used to examine the association of each biomarker with each outcome.

Results: Among the 489 participants in the random sub-cohort, mean age was 51.4(±9) years, 39% were women, 18% were Black and median graft vintage was 3.8(1.7, 7.0)years. Mean systolic blood pressure was 136(±20)mm Hg, 37% had diabetes, mean eGFR was 46(±18)ml/min/1.73 m2 and median ACR was 24.5(9.5, 104.7)mg/g. 281 adjudicated CVD events, 359 deaths and 257 cases of ESRD were identified. Higher NGAL was associated with greater risk of CVD, death and ESRD (Table). Higher KIM-1 and IL-18 were associated with greater risk of death (Table).

Conclusions: Among KTR, elevations in urine NGAL, KIM-1 and IL-18 are associated with death and elevation in NGAL is associated with CVD and ESRD, even with adjustment for ACR. Urine biomarkers may help identify KTR at high-risk for poor outcomes.

Urine biomarker / urine creatinine	Median (IQR) level in random cohort	Cardiovascular Events HR (95%) CI (per log increase)*	All-cause Death HR (95%) CI (per log increase)*	ESRD HR (95%) CI (per log increase)*
NGAL	0.2 (0.1, 0.5) mg/dL	1.24 (1.06-1.45)**	1.44 (1.26-1.65)**	1.40 (1.16-1.68)**
KIM-1	7.3 (3.8, 12.8) mg/dL	1.14 (0.91-1.43)	1.29 (1.03-1.61)**	0.93 (0.71-1.22)
IL-18	0.3 (0.1, 0.7) mg/dL	1.03 (0.86-1.23)	1.25 (1.04-1.49)**	1.15 (0.93-1.43)
L-FABP	0.1 (0.0, 0.2) mg/dL	1.00 (0.83-1.20)	1.12 (0.94-1.35)	1.07 (0.85-1.35)

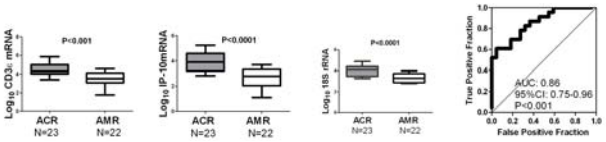
Distinguishing Acute Antibody-Mediated Rejection (AMR) From T Cell-Mediated Acute Cellular Rejection (ACR) with the 3-Gene Urinary Cell Signature Thangamani Muthukumar, Darshana Dadhania, Ruchuang Ding, Catherine Snopkowski, Carol Y. Li, John R. Lee, Hua Yang, Vijay K. Sharma, Manikkam Suthanthiran. *Cornell Univ.*

Background: Noninvasive diagnosis of ACR and AMR would represent a major clinical progress. We recently reported that a 3-gene signature of 18S rRNA normalized measures of CD3ε mRNA, IP-10 mRNA and 18S rRNA in urinary cells discriminates between biopsies showing ACR and those not showing rejection (Suthanthiran M et al. N Engl J Med 2013). Despite mRNA profiling of 4300 urine specimens from 485 kidney graft recipients prospectively enrolled in the CTOT-4 study, there were insufficient cases of AMR (9 patients) to determine whether the signature distinguishes ACR from AMR. We have addressed this issue by profiling 45 urine specimens collected from 45 kidney allograft recipients from an independent study cohort.

Methods: Biopsy-matched urine samples were collected from 22 patients with AMR and 23 patients with ACR prior to any anti-rejection therapy. We measured absolute mRNA copies from the urinary cells by RT-PCR assay.

Results: CD3ε mRNA, IP-10 mRNA and 18S rRNA (Fig.1A-C) were higher in patients with ACR compared to patients with AMR. The 3-gene signature accurately discriminated ACR from AMR (Fig.1D).



Additionally, we found that the 3-gene signature distinguishes not only ACR from biopsies showing acute tissue injury (ATI, n=29 patients) due to non-immunological causes, but also AMR from the ATI biopsies (AUC 0.97 [95%CI 0.93-1.00] P<0.0001 and 0.72 [95%CI 0.56-0.87] P<0.01, respectively).

Conclusions: Our findings that the 3-gene signature of 18S rRNA normalized measures of CD3ε mRNA, IP-10 mRNA and 18S rRNA in urinary cells accurately discriminates ACR from AMR, ACR from acute graft injury and AMR from acute graft injury demonstrate the feasibility of noninvasive diagnosis of ACR, AMR or acute graft injury due to non-immunological causes.

Soluble CASK, a New Factor Implicated in the Recurrence of FSGS After Renal Transplantation Séverine Beaudreuil,[12] Xiaomeng Zhang,[2] Ye Fan,[2] H. Francois,[12] L. Lecru,[2] Jean Jacques Candelier,[2] Bernard Charpentier,[12] Aime Vazquez,[2] Hans Kristian Lorenzo,[12] A. Durrbach.[12] *[1]Nephrology Dialysis Transplantation IFRNT, Univ Hospital Paris Sud, Le Kremlin Bicetre, France; [2]INSERM U1014, Villejuif, France.*

Background: Focal segmental glomerulosclerosis (FSGS) account for 20% of all cases of nephrotic syndrome, both in children and adults. Its recurrence after renal transplantation has suggested the presence of a soluble factor of permeability (sFP) which has not be clearly characterized. In case of recurrent FSGS, the reduction of proteinuria with immunoadsorption on protein A columns (IA) suggest that the sFP can bind to this columns and cad be eluted from them. In order to characterize the sFP, we have analyze the elute from these columns.

Methods: Elutes of IA used for the treatment of recurrent FSGS have been compared to elutes of IA used for the treatment of antibody mediated autoimmune disease on SDS page and different proteins (bands) have been analyze by mass spectrometry. We have identified one molecule cask (calcium/calmodulin-dependent serine-threonine kinase). Recombinant CASK has been produced in E.coli (recCASK) to test its effect in vitro on podocyte culture and in vivo in mice.

Results: We have observed a protein of 85kDa which has been identifed as a serine Threonine Kinase, CASK to be eluted from IA of patients with recurrent FSGS. CASK can be immunoprecipited in sera of those patients but not in healthy donor or patients having a diabetes nephropathy. recCASK impairs the morphology of podocytes in vitro with a redistribution of actin stress fibers, ZO-1, synaptopodin, vinculin and induces albumin permeability of a podocyte monolayer in a transwell assay. The intravenous injection of cask induces proteinuria in mice and electron microscopy analysis of kidneys shows podocyte foot process effacement in treated animal with CASK.

Conclusions: A new soluble form of CASK has been detected in sera from patients with recurrent FSGS. Our preliminary data suggest that CASK would be implicated in the pathogenesis of recurrent FSGS after renal transplantation.

TH-OR173

The Double-Edged Sword of Therapeutic Tacrolimus Levels in African-American Kidney Transplant Recipients David J. Taber,[1] Titte Srinivas,[2] Mulugeta Gebregziabher,[3] Kenneth Chavin,[1] Prabhakar Baliga,[1] Leonard Egede.[4] *[1]Transplant Surgery, MUSC; [2]Transplant Nephrology, MUSC; [3]Public Health Sciences, MUSC; [4]Center for Health Disparities Research, MUSC, Charleston, SC.*

Background: African-Americans (AA) may require higher doses of tacrolimus (FK) to achieve therapeutic levels. We examined racial differences in the concentration effect relationships with FK as a potential contributor to disparities in outcomes.

Methods: Retrospective longitudinal cohort study of solitary adult kidney transplant (KTX) with >3 mo graft survival transplanted between 2005-13 with the aim of determining the influence of therapeutic FK levels (≥8 ng/mL) on clinical outcomes across recipient race (AA versus non-AA). We included only those that received FK/MMF-based therapy.

Results: 1,083 patients were included (570 AA, 513 non-AA). Mean FK levels are displayed in Figure 1. AAs were 1.7 times less likely to achieve a mean therapeutic FK level (≥8 ng/mL) during the 1st year post-KTX (35% versus 21%, p<0.001). AAs that did not achieve FK ≥8 ng/mL were twice as likely to have acute rejection (19% versus 8%, p=0.016, Figure 2) and 10 times more likely to have antibody mediated rejection ([AMR] 8.6% versus 0.9%, p=0.007) compared to non-AAs. Rejection (10% versus 7%, p=0.122) and AMR (3.8% versus 2.0%, p=0.131) rates were similar between AAs and non-AAs that had FK levels ≥8 ng/mL. AAs that achieved therapeutic levels had significantly higher rates of de novo IF/TA (18% versus 11%, p=0.006, Figure 3); conversly, AA and non-AAs with low FK levels had similar rates of IF/TA (26% versus 22%, p=0.344).

Conclusions: In contrast to non-AAs, AAs that achieve therapeutic FK levels have substantially lower rejection rates. AAs achieving therapeutic FK levels are prone to developing IF/TA, unlike non-AAs. These findings may reflect modifiable time dependent racial differences in the concentration effect relationship with FK in KTX recipients.

Epithelial to Mesenchymal Transition Markers in Kidney Transplantation Recipients: The CERTITEM Trial Alexandre Hertig,[1] Lionel Rostaing,[2] Dany Anglicheau,[2] Pierre Merville,[2] Bruno Moulin,[2] Marc Hazzan,[2] Guy Touchard,[2] Fabienne Di Giambattista,[3] Eric Rondeau.[2] *[1]Urgences Nephrologiques et Transplantation Renale, APHP, Hopital Tenon, Paris, France; [2]For the Certitem Study Group; [3]Novartis Pharma SAS.*

Background: We conducted a randomized trial to determine whether epithelial to mesenchymal transition (EMT) markers would help to identify kidney transplant (tx) recipients at such a high risk of graft fibrogenesis that they would benefit from an early withdrawal of calcineurin inhibitor (CNI).

Methods: Initial treatment consisted in CsA, mycophenolate sodium (MPS), corticosteroids and basiliximab. We measured by immunohistochemistry expression of vimentin and beta-catenin translocation in tubular cells, on a first biopsy performed at 3 months post-tx. A biopsy in which ≥10% of tubules expressed mesenchymal markers defined EMT+ patients (pts). We randomly assigned both EMT+ (n=75) and EMT- (n=119) pts to either continue CsA+full dose MPS (n=98), or to withdraw CsA and to start on everolimus+low dose MPS (EVL/CNI-free) (n=96).

Results: Study objective was to evaluate if the progression of interstitial fibrosis (IF) between the first and a second surveillance biopsy performed at 12 months post-Tx would be attenuated in EMT+ pts converted to a CNI-free regimen, when compared to those maintained on CsA. The primary endpoint (PE) was the progression of IF and tubular atrophy (TA) Banff score from M3 to M12 (ΔIF/TA>1). In the intent-to-treat analysis the PE occurred in 16 of the 31 EMT+ pts maintained on CsA and in 12 of the 26 EMT+ pts converted to EVL (p=0.68). Biopsy proven acute rejection (BPAR) occurred more frequently in the EVL group (25.0 *versus* 5.1%, p<0.001). Of these, subclinical BPAR was diagnosed on M12 biopsy in 10.4% of the EVL/CNI-free pts and 2.0% of the CsA pts (p=0.015). Independent associated factors of BPAR was a MPS dose inferior to the recommended one during >28 consecutive days, and a trough level of EVL < 7.0 ng/mL.

Conclusions: An early CNI withdrawal with a switch from CsA to EVL does not prevent IF progression in patients at high fibrogenic risk and carries out a significant risk of rejection.

TH-OR175

Anti CD40 Autoantibodies Functionally Interact with suPAR to Predict and Cause FSGS Recurrence in Kidney Transplantation Minnie Sarwal,[1] Tara Sigdel,[1] Changli Wei,[2] Alessia Fornoni,[3] Dany Anglicheau,[4] Nada Alachkar,[5] Jochen Reiser.[2] *[1]CPMC, Research Inst, San Francisco, CA; [2]Medicine, Rush Univ, Chicago, IL; [3]Nephrology, Univ of Miami, Miami, FL; [4]Necker Hospital, Paris, France; [5]Medicine, Johns Hopkins, Baltimore, MD.*

Background: Recurrence of focal segmental glomerulosclerosis (rFSGS) after kidney transplantation is a significant cause of early and accelerated graft loss that likely involves circulating factor. Immuneadsorption can alleviate renal dysfunction and suggests that circulating antibodies (Ab) are likely implicated in disease pathogenesis as well.

Methods: To evaluate novel, correlative, pathogenic Ab in rFSGS, we processed 141 unique serum samples from patients with and without primary rFSGS (n=64) and 34 non-FSGS control, transplanted at five (U.S. and EU) hospitals. 9000 antigens were screened in pre-transplant sera by protein arrays and 10 Ab targeting glomerular antigens were selected for ELISA validation.

Results: A panel of 7 Ab (CD40, PTPRO, CGB-5, FAS, P2RY11, SNRPB2 and APOL2) could predict post-transplant FSGS recurrence with 92% accuracy. Pre- transplant elevation of anti-CD40 Ab levels alone had maximal impact (78% accuracy) on the identification of rFSGS risk after transplantation. Epitope mapping of CD40 with customized peptide arrays and rFSGS sera demonstrated altered immunogenicity of the extracellular CD40 domain in rFSGS. Anti-CD40 Ab purified from rFSGS patients were uniquely pathogenic in human podocyte cultures; injection of patient-derived anti-CD40 Ab resulted in proteinuria in a rodent mode but not when blocking CD40 using a monoclonal blocking Ab. The kidney pathogenic effects were further enhanced in combination with suPAR.

Conclusions: In conclusion, a novel panel of 7 Ab can identify primary FSGS patients at high risk of recurrence prior to transplantation. In particular, anti-CD40 Ab together with suPAR were most pathogenic in mice., allowing for customized therapies and improved patient selection for transplant. Intra-renal CD40 is an important axis of disease pathogenesis, and human trials of anti-CD40 therapies are warranted to evaluate their efficacy in preventing rFSGS and improving graft survival.

TH-OR176

Salt Reduces Regulatory T Cells and Accelerates Allograft Rejection Kassem Safa,[1,2] Shunsuke Ohori,[1] Ciara N. Magee,[1] Anil K. Chandraker,[1] Leonardo V. Riella.[1] *[1]Renal Div/Transplantation Research Center, Brigham and Women's Hospital, Boston, MA; [2]Renal Div, Massachusetts General Hospital, Boston, MA.*

Background: Recent reports suggest that high-salt diet (HSD) might exacerbate autoimmunity in mice. Whether HSD is deleterious in transplantation is unknown. Herein, we examined the effect of NaCl in the alloimmune response, using mixed-lymphocyte cultures and a murine model of solid organ transplantation.

Methods: *In vitro*, B6.Foxp3.GFP mice were sensitized with BALB/c skin grafts. 2 weeks later, $CD4^+Foxp3.FGP^-$ cells were isolated and stimulated with irradiated BALB/c $CD3^-$ cells in the presence of increments of NaCl concentrations ([NaCl] 0-40 mM). Proliferation was then measured by thymidine incorporation. *In vivo*, B6 mice were fed either HSD or normal diet (NSD) and received bm12 heart transplants (single MHC II mismatch).

Results: *In vitro*, proliferation of $CD4^+Foxp3^-$ cells augmented with [NaCl] increase from 0 to 40 mM (7355 versus 18588 CPM, p=0.004). *In* vivo, feeding mice HSD accelerated allograft rejection compared with NSD (median survival time 43 versus >56 days, p=0.04). Serum sodium and mean blood pressure were similar between groups (Na 149.5 versus 150.4 mEq/L, p=0.8 and MBP 63.43 versus 65.42 mmHg, p=0.57). At 25 days after transplantation, HSD fed mice had decreased draining Lymph nodes (LN) Tregs ($CD4^+Foxp3^+$) versus NSD (6.1 versus 15.4%, p=0.01); also Treg proliferation (measured by $\%Ki67^+$) was reduced in LN and spleens of mice fed HSD versus NSD (14.44 versus 20.17%, p=0.04 and 21.32 versus 44.97%, p=0.02, respectively). In addition, HSD resulted in higher $CD4^+$ eff/Treg ratio versus NSD (2.57 versus 1.54, p=0.02). As sodium has been shown to activate the SGK1 kinase in immune cells, we performed the *in vitro* and *in vivo* experiments using $CD4^{Cre}SGK1^{fl/fl}$ B6 mice. Indeed, the increased proliferation and reduced Tregs were abrogated in the absence of SGK1 on CD4 cells, implicating SGK1 as a mediator of the observed effects.

Conclusions: In summary, we show for the first time a deleterious effect of NaCl in transplantation by affecting the regulatory balance of T cells and precipitating rejection. This effect seems to be partially mediated by SGK-1 activation.

TH-OR177

Small Molecule Agonists of CD11b/CD18 Reduce Leukocyte Activation and Recruitment to Promote Kidney Allograft Survival Samia Khan,[1] Mohd Hafeez Faridi,[1] Hatem A. Elshabrawy,[1] James George,[2] Anupam Agarwal,[2] Vineet Gupta.[1] *[1]Internal Medicine, Rush Medical Center, Chicago, IL; [2]George M. O'Brien Kidney Research Center, The Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Allograft rejection in kidney transplantation is associated with leukocyte infiltration, including myeloid cells expressing β2 integrin CD11b/CD18. Previously, we reported that activation of CD11b/CD18 by a small molecule compound, leukadherin-1 (LA1), increases leukocyte cell adhesion to the inflamed endothelium, prevents transmigration and inhibits leukocyte tissue recruitment resulting in improved kidney function in a murine nephritis model.

Methods: Here, we test whether LA1 mediated activation of CD11b/CD18 enhances kidney allograft survival in a mouse model of fully MHC-mismatched orthotopic kidney transplant, where C57BL/6J (H-2b) recipients received a kidney allograft from Balb/c mice (H-2d). Isograft control recipients received a kidney from a littermate. Control isograft and allograft recipients were treated daily with cyclosporine (CsA) only for 2 weeks, while the test group received standard CsA therapy and daily LA1 injections during week 1 and alternate days during weeks 2-8. Renal allograft rejection was considered when mice displayed signs of ill health and high serum creatinine levels.

Results: LA1 treatment reduced interstitial leukocyte infiltration in the allograft, neointimal hyperplasia and glomerular damage and prolonged graft survival from 48.5% (CsA only) to 100% (CsA and LA1) on day 60. At week 8, CsA treated controls had serum creatinine values of 0.5 mg/dL while LA1 and CsA treated mice had baseline values of 0.2 mg/dL. Furthermore, combination therapy reduced macrophage infiltration and increased the frequency of FoxP3+ Tregs in the allograft.

Conclusions: LA1 treatment enhances the survival and the function of the allograft by reducing inflammatory cell infiltration and increasing the number of Tregs resulting in an overall immunosuppresive effect of LA1 administration. These findings indicate a role for CD11b/CD18 in the control of leukocyte migration to the transplanted kidney and identify leukadherins as therapeutic agents for renal transplantation.

MCMV Infection and Reactivation in Transplantation Tolerance Lei Zhang,[1] Xiaomin Zhang,[2] Zheng Jenny Zhang,[2] Mary Hummel,[2] Xun-Rong Luo.[1,2] *[1]Medicine, Northwestern Univ Feinberg School of Medicine; [2]Surgery, Northwestern Univ Feinberg School of Medicine.*

Background: Experimental tolerance is meeting initial success in clinical transplantation. CMV is a ubiquitous virus that presents risks for reactivation or de novo infection in recipients. Limited information is available on how CMV infection may affect transplant tolerance, or how donor-specific tolerance may influence CMV reactivation.

Methods: To determine the effect of MCMV infection on transplant tolerance, we used a BALB/c to B6 islet transplant model. Transplant tolerance was induced using infusions of donor splenocytes (SPs) chemically fixed with ethylene carbodiimide (ECDI). MCMV infection was given to B6 mice by injection of 10^9 PFU of Δm157 MCMV.

Results: We found that acute Δm157 infection impaired tolerance induction, leading to 80% of recipients acutely rejecting the islet grafts. Anergy of donor-specific T cells induced by ECDI-SP tolerance therapy was reverted by acute Δm157 infection. Similarly, acute Δm157 infection during tolerance maintenance led to reversal of tolerance and precipitation of graft rejection in 30% tolerant recipients. Surprisingly, recipients latently infected with MCMV were also less susceptible to tolerance induction, with 50% recipients rejecting the islet grafts. To examine the effect of donor-specific transplant tolerance on MCMV reactivation, BALB/c kidneys latently infected with MCMV were generated by infecting 3-5 wk old mice with of $5x10^5$ PFU of MCMV and transplanted in B6 recipients 90 days later. Transplanting in non-tolerant recipients led to significant up-regulation of the IE-3 gene from the latently infected kidneys, whereas transplanting in tolerant recipients significantly suppressed this up-regulation.

Conclusions: In conclusion, CMV infection significantly impairs tolerance efficacy, and the presence of donor-specific tolerance effectively suppresses IE gene expression and possibly CMV reactivation. The interaction between CMV infection and tolerance thus warrants future studies, and will likely provide critical information for adequately approaching CMV infections in clinical tolerance protocols.

Molecular and Immunological Phenotype of CNI Minimization Strategies Using an Investigational Proteasome Inhibitor, Ixazomib Citrate

Nancy A. Wilson,[1] Shannon Reese,[1] Gengwen Huang,[2] Arjang Djamali.[1,2]
[1]Medicine, Div of Nephrology, Univ of Wisconsin, Madison, WI; [2]Surgery, Univ of Wisconsin, Madison, WI.

Background: CNI nephrotoxicity is a frequent complication kidney transplantation. We sought to determine whether ixazomib (IX), an investigational proteasome inhibitor, can mitigate antibody mediated rejection (ABMR) while minimizing CNI toxicity in a sensitized rat model.

Methods: ABMR was induced in Lewis (RT1[l]) recipients sensitized with donor-specific blood transfusion from Brown Norway (RT1[n]) rats 3 weeks prior to kidney allograft transplantation. Treatment groups included:control, no treatment (NoRx), Standard of Care (SOC, 10 mg/kg/d CsA) ixazomib alone (IX) or CNI minimization (CNImin, IX + 5mg/kg/d CsA).

Results: Comparing CNImin to SOC by microarray using kidney RNA isolated at 1wk post transplant, highly significant pathways included antigen processing, T and B signaling and the retinoic acid pathway in macrophages. Treatment was associated with up regulation of MHC class I, IL-1A, LBP and MSR1, with down regulation of MHC class II, CD79 and TLRs, Figure 1A. Transcript lists of differentially expressed genes (DEG) for B cell/plasma cells, NK cells and macrophages were developed for the rat model. Median log2 fold expression differences for NoRx were up regulated, Figure1B. Ixazomib treatment alone reduced median DEG, comparison of SOC to CNImin had a median of 0, indicating these treatments have comparable reductions in molecular signature of ABMR. Compared to SOC, BAFF levels measured by ELISA in IX and CNImin groups were significantly reduced, Figure 1C, indicating ixazomib improved the immunological phenotype.

Conclusions: A CNI minimization strategy using ixazomib has an immunological signature similar to full dose CNI SOC, while reducing serum BAFF, suggesting that the protease inhibitor ixazomib may have a role in preventing ABMR.

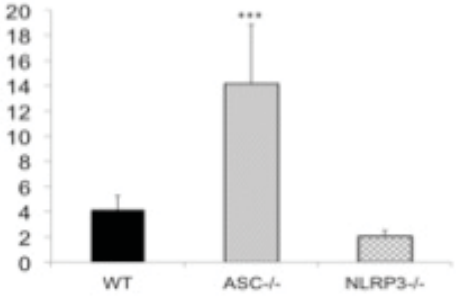
Enhanced Engraftment of Hematopoietic Stem Cells for Solid Organ Transplant Tolerance

Reza Elahimehr, Sashi Kasimsetty, Alana Shigeoka, Dianne B. McKay. *UC San Diego.*

Background: Engraftment of donor-derived hematopoietic stem cells (HSCs) is essential for successful bone marrow transplantation, and ground breaking clinical trials demonstrated that successful HSC engraftment also allows for induction of tolerance to solid organ allografts. Experimental evidence suggests that inducing chimerism promotes central T cell tolerance and allows for acceptance of an allograft without need for immunosuppression. A logical approach to enhance HSC engraftment and differentiation into tolerogenic APCs involves blockade of primitive receptors that are the triggers of cellular activation and stress pattern recognition receptors (PRRs). The NLRP3 inflammasome family of these receptors is highly expressed in HSCs, and HSCs are activated by specific signals delivered through these PRRs, resulting in their expansion and migration in inflammatory states.

Methods: BALB/c mice were preconditioned (sublethal irradiation, anti-CD8 and anti-MR-1Ab) and reconstituted with HSCs isolated from either WT (C57BL/6) mice or from mice deficient in key inflammasome proteins, ASC-/- or NLRP3-/- mice (all on B6 background). Engraftment of HSCs in BALB/c recipient mice was detected by FACS (staining for H-2b+ cells) six weeks after transplantation.

Results: Disruption of ASC, resulted in significantly enhanced HSC engraftment ($p<0.005$). Interestingly, deletion of NLRP3 had no effect on HSC engraftment, suggesting important differences in the role of these inflammasome proteins in HSC function.



Conclusions: Possible conclusion of our data is the absence of ASC confers enhanced HSC engraftment due to a direct effect on DC maturation and antigen presentation, essentially inducing a tolerizing DC phenotype. Ongoing studies in our laboratory are now focused on the mechanisms by which a deficiency in this central inflammasome component enhances engraftment of HSCs and promotes allograft tolerance.

TH-OR181

Potent Beneficial Effects of HDAC11 Targeting on Foxp3+ Treg-Dependent Allograft Survival

Jianbing Huang, Liqing Wang, Rongxiang Han, Wayne W. Hancock. *Children's Hospital of Philadelphia.*

Background: There is now intense interest in harnessing Foxp3+ Treg cells in transplantation. The most pedestrian approach being proposed is to harvest Tregs from a potential recipient, expand them in vitro, and infuse them soon after transplantation. This approach is ultra-expensive, has risks of the infused cells becoming pathogenic given their limited purity, and is likely only a one-off shot of cells that survive 7-10 days. By contrast, pharmacologic modulation of Treg function has the advantages of being able be titrated and given as desired, including potentially long-term. Some but not other HDAC inhibitors can promote Treg production and suppressive functions, depending upon the isoforms being targeted. Hence, there is considerable interest in isoform-selective targeting strategies.

Methods: Histone/protein deacetylase-11 (HDAC11) is the sole class IV HDAC enzyme and was first described in 2002. We report data from mice with constitutive HDAC11 deletion, as well as from mice with conditional deletion of HDAC11 just within Foxp3+ Treg cells.

Results: HDAC11 deletion had no effect on overall health or development, including that of host immune cells. Compared to WT controls, Foxp3+ Tregs lacking HDAC11 showed increased suppressive function in vitro, along with increased expression of Foxp3 ($p<0.05$) and TGF-beta ($p<0.0005$), but not of IL-10 or CTLA-4 (both $p>0.05$). HDAC11-/- Likewise, compared to WT recipients, C57BL/6 recipients of fully MHC-mismatched BALB/c cardiac allografts showed prolonged allograft survival ($p<0.01$), and this effect was matched by longterm allograft survival in mice with conditional deletion of HDAC11 just within Treg cells ($p<0.01$).

Conclusions: Very little is known of the functions of HDAC11. A sole previous report linked HDAC11 with regulation of IL-10 expression in antigen-presenting cells. However, the current data indicate that HDAC11 has more complex, IL-10-independent roles in regulation of adaptive immune responses, especially with regard to functions of Foxp3+ Treg cells. These data are powerful stimuli for our development and testing of selective HDAC11 small molecule inhibitors, and may provide new approaches post-transplantation or for therapy of autoimmune diseases.

TH-OR182

Inducible Knockdown of SHROOM3 Reduces Renal Fibrosis in Mice

Madhav C. Menon, Chengguo Wei, Ilana Greene, Ruijie Liu, Peter Y. Chuang, John C. He, Barbara T. Murphy. *Nephrology-Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: From the Genomics of Chronic Allograft Rejection (GoCAR) cohort, we previously identified SHROOM3 as a candidate gene whose expression in the allograft precedes and correlates with the histological development of renal fibrosis and GFR-decline by 12-months post-transplant.

Methods: To study the mechanism of facilitation of renal fibrosis by SHROOM3, we developed a murine model of inducible shRNA-mediated SHROOM3 knockdown. Here, RTTA-elements were linked to the universal ROSAm26 promoter for RTTA expression in all cell-types. After invitro selection, a shRNA hairpin on a mir30 backbone was linked to doxycycline-RTTA-responsive elements and positioned 3' to the Collagen-1 gene. Doxycycline (DOX) feeding of these animals confirmed SHROOM3 knockdown (~75%) at 3-weeks by RT-PCR and western blot (WB). We performed unilateral ureteric obstruction

surgery (UUO) on 8-10 week old animals after 3-weeks of DOX-feeding (n=5). Mice were sacrificed at 10-days post UUO. Littermates that were not fed with DOX were used as controls. Results were analyzed quantitatively by the unpaired t-test.

Results: We observed an increased SHROOM3 expression in UUO-kidneys compared to controls by RT-PCR in DOX-fed and non-DOX animals; however knockdown was still demonstrable. Among UUO-kidneys, COL1A1 expression was significantly inhibited in DOX-fed animals compared to controls. Kidney lysates of UUO-kidneys showed reduction in phosphorylated-SMAD3 in DOX-fed animals compared to controls by WB. Interstitial fibrosis (by picrosirius red staining) was significantly reduced in DOX-fed UUO kidneys. Type-I Collagen staining was also significantly reduced in UUO-kidneys of DOX-fed animals by immunofluorescence.

Conclusions: In summary, we demonstrate in a murine model that knockdown of SHROOM3 inhibits canonical TGFB1 signaling, COL1A1-production, and ameliorates renal interstitial fibrosis. This further validates our translational finding that SHROOM3 may be a therapeutic target in chronic allograft nephropathy and chronic kidney disease.

The H_2S System during Cooling and Rewarming in the Kidney of Hibernators: From Hibernation to Kidney Transplantation

George Johnson Dugbartey, Leo E. Deelman. *Dept of Clinical Pharmacy and Pharmacology, Univ Medical Center Groningen, Groningen, Netherlands.*

Background: Hypothermic preservation is widely used to protect kidney and other solid organs during transplantation. However, hypothermic storage induces cold ischemic injury and is aggravated during reperfusion. Interestingly, hibernating animals have shown to possess a natural protection against kidney injury induced by cooling-rewarming (torpor-arousal). Unlike cold ischemic and reperfusion injury in human kidneys during transplantation, the repetitive stress of cooling-rewarming in hibernators does not seem to cause irreversible kidney injury. Therefore, this study aimed at unraveling possible mechanisms that confer tolerance and protection of the kidney during the physiological extremes in hibernating animals.

Methods: Syrian hamsters (*Mesocricetus auratus*) were housed in cages in a climate controlled chamber at 5°C under dim red light to induce torpor. Movement of all animals was continuously monitored with passive infrared detectors. Periods with >24h of inactivity were considered to be torpid phases. Arousal occurred naturally without outside stimuli or changes in ambient temperature. Subsequently, animals were sacrificed 24h after torpor entrance (torpor early; $n = 5$), ≥72h after torpor entrance (torpor late; $n = 5$), 2h after the onset of arousal (early arousal; $n = 8$) and ≥9h after the onset of arousal (late arousal; $n = 8$). Blood samples were taken and kidney of the hamsters were obtained. Summer euthermic hamsters ($n = 7$) served as controls.

Results: Levels of endogenous H_2S were significantly increased during torpor and restored to euthermic level during arousal. Also, CBS expression was upregulated during torpor and normalized upon arousal. Further, there was no significant difference in ROS production during torpor and arousal phases.

Conclusions: The tight regulation of renal H_2S, CBS and HSP-70 during hibernation suggests an important role of the H_2S system in normalizing renal ROS production during cooling and rewarming. Therefore, understanding the mechanisms of hibernation may lead to development of pharmacological strategies which will protect kidneys during hypothermic storage and reperfusion in transplantation.

TH-OR184

Environment and Graft Interaction on Renocardiac Injury in Renal Transplantation

Diana A. Papazova, Jaap A. Joles, Marianne C. Verhaar. *Nephrology & Hypertension, UMC Utrecht, Netherlands.*

Background: Renal transplantation from expanded–criteria donors increases mortality and graft failure. Preemptive transplantation has been associated with an allograft survival advantage. Uremic state in CKD patients receiving a kidney allograft could also influence transplantation outcome.The aim of our study was to investigate the interaction between graft and environment on renocardiac injury in renal transplantation.

Methods: CKD and proteinuria developed in male Lewis rats after bilateral ablation of 2/3 of kidney mass. When proteinuria exceeded 200 mg/d, L-NNA (20 mg/L water) and 6% salt diet were switched to normal water and chow. Control rats were age-matched. Orthotopic transplantations (TX, 30 min cold- and 40 min warm ischemia time) were performed: healthy kidney to healthy rat (HH); CKD kidney to healthy rat (CH); healthy kidney to CKD rat (HC); CKD kidney to CKD rat (CC). Contralateral kidney was removed 10-14 days after transplantation. Proteinuria (UpV) was measured 3 and 5 wk after TX. At wk 6, we evaluated glomerular filtration rate (GFR: inulin); renal plasma flow (RPF: PAH), mean arterial pressure (MAP) and left ventricular mass (LVM) of every recipient.

Results: Diseased kidneys performed better in a healthy environment (CH) shown as reduced UpV at wk 3 (25±5 versus 60±17 mg/24h, P<0.01) and wk 5 (51±30 versus 102±32, P<0.01) in comparison to CC. At 6 wk after TX, MAP and LVM were increased in CH versus HH (162±25 versus 110±4 mmHg, P<0.01 and 0.32±0.04 versus 0.24±0.01 mg/100g,P<0.01). In HC MAP was normalized but LVM remained unchanged compared to CC (111±7 versus 147±13 mmHg, P<0.01 and 0.28±0.07 versus 0.32±0.06 mg/100g, NS). Plasma creatinine, GFR and RPF of healthy (HH versus HC) and CKD (CH versus CC) kidneys were not influenced by environment.

Conclusions: Healthy environment improved proteinuria of diseased kidneys. Diseased renal grafts increased MAP and LVM, but pre-existent left ventricular hypertrophy was not reversed by a healthy renal graft. In conclusion, our results demonstrate that as expected blood pressure follows the kidney. Moreover, a healthy environment can reduce proteinuria, but transplantation of a healthy kidney is not able to reverse cardiac hypertrophy despite normalization of hypertension.

Heme Oxygenase-1 (HO-1) Expression Regulates Trafficking of Myeloid Cells in Acute Kidney Injury (AKI)

Ahmed I. Kamal,[1,2] Travis D. Hull,[1,3] Ravindra Boddu,[1] Subhashini Bolisetty,[1] Sunil Rangarajan,[1] Lingling Guo,[3] Lisa M. Curtis,[1] James George,[3] Anupam Agarwal.[1] *[1]Medicine, UAB, Birmingham, AL; [2]Nephrology, Urology and Nephrology Center, Mansoura Univ, Mansoura, Dakahliya, Egypt; [3]Surgery, UAB, Birmingham, AL.*

Background: Ischemia reperfusion injury (IRI), a major cause of AKI, is mediated by a complex cascade of immunological events secondary to oxidative injury to renal epithelial cells. Induction of HO-1 expression is a protective response to IRI. We tested the hypothesis that HO-1 ameliorates renal IRI by regulating the recruitment, infiltration and phenotypic differentiation of myeloid-derived immune cells.

Methods: Age-matched male wild-type (WT), HO-1 knockout (HO-1$^{-/-}$), and HO-1$^{-/-}$ mice expressing the human HO-1 gene (HBAC) underwent bilateral renal ischemia for 10 minutes. Kidneys were harvested after 1 or 7 days of reperfusion.

Results: Consistent with previous findings,IRI resulted in significantly elevated mortality (50% in HO-1$^{-/-}$ versus 0% in WT or HBAC) and serum creatinine (1.0±0.3 mg/dL in HO-1$^{-/-}$ versus 0.16±0.05 mg/dL in WT, n=4-8/group, P<0.05, day 1) only in HO-1$^{-/-}$ mice. Relative to sham controls, cast formation and brush border loss were only observed in HO-1$^{-/-}$ kidneys. FACS analysis revealed significantly increased inflammatory macrophages (P<0.01) and neutrophils (P<0.05) in HO-1$^{-/-}$ mice subjected to IRI, while resident renal mononuclear cells (RMNC) were proportionally decreased in HO-1$^{-/-}$ mice. Using FACS analysis, RMNCs were confirmed to phenotypically resemble dendritic cells (CD11b^{int} F4/80^{hi}). Syngeneic kidney transplant experiments utilizing GFP^{+} donor kidneys (25 minutes ischemia) and WT GFP^{-} recipients confirmed increased migration of the RMNC population from HO-1$^{-/-}$ donor kidneys to the primary lymphoid organs compared to controls with WT grafts. This effect on RMNC migration was corroborated in Mye-HO-1$^{-/-}$ mice (myeloid-specific HO-1 deficiency) subjected to 25 minutes of ischemia, confirming the importance of HO-1 expression in myeloid cells.

Conclusions: These results highlight an important role for HO-1 in modulating the trafficking of myeloid cells in acute kidney injury, which may represent a key pathway for therapeutic intervention.

FR-OR002

Retinoic Acid Signaling Promotes Repair by Altering Renal Macrophage Responses after Acute Kidney Injury

Mark P. De Caestecker,[1] Nataliya Skrypnyk,[1] Lauren Brilli,[2] Ming-Zhi Zhang,[1] Raymond C. Harris,[1] Neil A. Hukriede,[2] Takuto Chiba.[1] *[1]Depts of Medicine, Cell and Developmental Biology, Vanderbilt Univ Medical Center, Nashville, TN; [2]Dept of Developmental Biology, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Retinoic acid (RA) signaling is activated in proximal tubular epithelial cells (PTECs) after gentamicin-induced acute kidney injury (AKI) in zebrafish larvae and inhibition of RA signaling impairs normal repair in this model. However the regulation and role of RA signaling in mammalian kidneys after AKI is unknown. In addition, while renal mononuclear phagocyte (MNP) polarization towards a pro-regenerative M2 phenotype plays an important role in tissue repair after AKI, the signals regulating MNP phenotypes post-AKI are unclear.

Methods: We used ischemia/reperfusion AKI (IR-AKI) in mice with the RARE-Hsp68-LacZ transgenic reporter to assess the regulation of RA signaling post AKI. FACS and MACS sorting were used to isolate PTECs and renal MNPs, respectively. The RA antagonist BMS493 and agonist all-trans RA (ATRA) were used to evaluate functional effects of RA signaling, as well *PEPCK CRE; R26-LSL-RARa430X* mice (PTEC DN-RAR) to inhibit RA signaling in PTECs.

Results: RA signaling is activated 12-72 hours after IR-AKI in injured PTECs. Inhibition of RA signaling increases PTEC injury and long-term fibrosis, and decreases renal MNP M2 polarization 3 days after IR-AKI. Conversely, activation of RA signaling with ATRA reduces PTEC injury and fibrosis, and reduces M1 MNP polarization post AKI. To study the role of PTEC RA signaling in mediating these effects, we evaluated IR-AKI in PTEC DN-RAR mice. These mice have increased PTEC injury and decreased repair as well as decreased M2 renal MNP polarization post IR-AKI.

Conclusions: These studies suggest that activation of RA signaling in PTECs enhances post-AKI repair by promoting renal MNP polarization towards a pro-regenerative M2 phenotype. This demonstrates a novel mechanism whereby reactivation of an embryonic signaling pathway that is conserved in zebrafish and mouse kidneys drives repair post AKI, and suggests that RA-dependent signaling in PTECs regulates renal MNP phenotypes post-AKI.

FR-OR003

The Sentinel Role of Renal Dendritic Cells in Systemic Infection Karim Yatim, Martin H. Oberbarnscheidt. *T.E. Starzl Transplantation Inst, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Dendritic cells (DC) in barrier organs such as the lung and intestine have been shown to sample intraluminal compartments by extending cellular processes across epithelial layers. The kidney is a non-barrier, highly vascularized organ with an extensive interstitial DC network that can take up intravascular, non-filterable antigen (Ag). Here, we hypothesized that renal DCs sense Ag by extending cellular processes into the blood vessel lumen, playing a sentinel role in sensing intravascular pathogens in systemic infection.

Methods: Native kidneys of WT or fluorescent reporter mice were analyzed by flow cytometry and two photon intravital microscopy (2PIM) using an E. coli systemic infection model.

Results: Flow cytometric analysis of renal DC revealed that the majority of the DC (lineage$^-$(CD19, CD90, NK1.1, Ly-6G) CD11c$^+$MHCII$^+$) were monocyte-derived DC (mono-DCs:CD11b$^+$), with less than 15% displaying a classical DC phenotype (CD11b$^-$). Monocyte-derived DC are comprised of two subsets, F4/80$^+$ (60%) and F4/80$^-$ (40%).2PIM performed on double reporter mouse kidneys (CX3CR1-GFP = monocytic-lineage cells; CD11c-YFP = DCs), where mono-DCs express GFP and YFP, revealed a cellular network of mono-DCs. This network encased renal post-capillary venules with 30% of the cells extending processes into the venular lumina. 2PIM of mouse kidneys demonstrated that mono-DC processes caused intravascular filling defects and captured intravascularly retained, anti-CD11c-coated beads. Anti-CD11b antibody injected i.v. labeled 80% of renal mono-DCs (flow cytometry). Systemic administration of antigen-coated beads or fluorescent E. coli was followed by mono-DC uptake of beads or bacteria from the intravascular space within 2 hours (2PIM and flow cytometry).

Conclusions: We identified mono-DC as the major renal DC subset. Our data demonstrate access of renal mono-DC to the intravascular compartment via cellular processes that allow sampling and uptake of blood borne antigen. These findings could have important implications for the initiation of adaptive immunity as well as local regulation of kidney function in the setting of systemic infection. Further studies will investigate the consequences of Ag-uptake by mono-DC.

FR-OR004

Transcriptional Regulation of Th17 Cell Differentiation in Ischemia-Reperfusion Injury Hajeong Lee, Seung Hee Yang, Ji In Park, Kyung Don Yoo, Seung Seok Han, Dong Ki Kim, Yon Su Kim. *Seoul National Univ Hospital, Seoul, Korea.*

Background: Although Th17 cells are crucial for the pathogenesis of acute kidney injury (AKI), the precise molecular pathways involved are unknown. STAT3 is essential for the initiation of the transcription that mediates Th17 differentiation. Cln three requiring 9 (Ctr9) is a negative regulator of STAT3. However, crosstalk between STAT3 and Ctr9 in AKI has not been investigated.

Methods: We evaluated the role of STAT3/Th17 pathway focusing on Ctr9 in bilateral renal ischemia/reperfusion injury (IRI) model. Mice with a STAT3 deletion in T cells (STAT3 knock-out [KO]) were generated by crossing mice with the floxed STAT3 allele with mice expressing Cre under the control of the Lck promoter 17. We used caffeic acid 3,4-dihydroxy-phenethyl ester (CADPE) as JAK2/STAT3 blockade.

Results: The renal injury with macrophage, neutrophil and T-cell infiltrations were improved in both STAT3 KO and CADPE-treated wild type (WT), compared to WT mice at day 2. Intra-renal mRNA expressions of Th17 related cytokines were up-regulated in WT, however, suppressed in STAT3-KO and CADPE-treated WT mice. In contrast, Ctr9 expression was attenuated in WT and accentuated in STAT3-KO and CADPE-treated WT mice. These findings were reproducible in the intra-renal lymphocyte, which monocyte and macrophage frequency was increased in WT and decreased in STAT3-KO and CADPE-treated WT mice. In vitro study using human tubular epithelial cell (TEC) cultured on hypoxic condition showed that STAT3, RORγt, and IL-17R mRNA expressions were increased, and decreased by CADPE. When rIL-17 was applied, STAT3 dependent Th17 pathway was activated with increase of IL-6 and IL-18 secretion, however CADPE inhibited these activations. To regulate STAT3/Th17 pathway transcriptionally, we suppressed Ctr9 expression in intrarenal lymphocytes, and STAT3, RORγt and IL-17 expressions were increased in co-cultured mouse TECs, resulting in IL-17 production, which coincided with an increase in CD4$^+$IL-17$^+$ T cells.

Conclusions: In conclusion, STAT3/Th17 pathway plays a critical role in IRI model. As a negative regulator of the STAT3-dependent Th17 pathway, Ctr9 might be a novel therapeutic target for the treatment of IRI.

FR-OR005

Th-17 Cell Activation in Response to High Salt following Acute Kidney Injury Is Associated with Progressive Fibrosis and Attenuated By AT-1 Antagonism Purvi Mehrotra, David P. Basile, Jaymin B. Patel, Carlie M. Ivancic. *Cellular and Intergrative physiology, Indiana School of Medicine, Indianapolis, IN.*

Background: Exposure of rats to elevated dietary sodium (4% NaCl) following recovery renal ischemia reperfusion accelerates the transition of AKI to CKD. Lymphocyte inhibition with mycophenolate mofetil attenuated the development of hypertension, fibrosis and proteinuria of injury post-AKI provided a high salt diet (Pechman et al Am J Physiol 294:R1234, 2008). We hypothesized that high salt diet will trigger lymphocyte activity in post-ischemic rat kidneys to exacerbate renal inflammation and fibrosis.

Methods: Male SD rats on 0.4% NaCl diet were subjected to left unilateral I/R for 40 minutes and allowed to recover for 5 weeks, which resulted in recovery of renal structure with minimal secondary damage and a mild elevation of CD4+ T-cells relative to sham. Surgical removal of the contralateral kidney at 5 weeks and exposure to 4% dietary NaCl for an additional 4 weeks induced chronic kidney disease as indicated by rapid proteinuria and significant interstitial fibrosis.

Results: Activated T cells were increased in kidney by 3 fold after 4 weeks of 4% dietary salt exposure relative to kidneys from post AKI rats on standard salt diet. Further analysis determined that the T-cells were positive for TNF-α and IL-17, indicative of Th-17 cells, while a small percentage was positive Th-1 or Th-2 cells. Because progression following AKI is associated with enhanced sensitivity to Ang II activity (Am J Physiol 302:F1494, 2012) and Ang II activity may influence lymphocyte activation, injured rats were given Losartan (30 mg•kg^{-1}•day^{-1} in drinking water) during the high salt phase. Losartan treatment reduced the number of renal Th-17 cells by 75 % ($P<0.05$) attenuated the development of interstitial fibrosis (80%, $P< 0.05$) and reduced level of proteinuria. In vitro studies in AKI primed CD4+ T cells indicated Ang II stimulation enhanced, and Losartan inhibited IL-17 secretion.

Conclusions: Taken together, these data suggest that dietary sodium modulates immune cell activity in post ischemic recovered kidneys, due in part to the activity of the local RAS, and participating in the AKI to CKD transition.

Funding: NIDDK Support

T Lymphocyte Specific Nuclear Factor Erythroid-Derived 2-Like 2 (Nrf2) Activation Protects from Acute Kidney Injury in Mice Sanjeev Noel,[1] Maria Noel Martina Lingua,[2] Samatha Bandapalle,[1] Sekhar P. Reddy,[3] Lorraine C. Racusen,[2] Abdel Hamad,[2] Hamid Rabb.[1] *[1]Dept of Medicine; [2]Dept of Pathology, Johns Hopkins Univ, Baltimore, MD; [3]Dept of Pediatrics, Univ of Illinois, Chicago, IL.*

Background: T lymphocytes play an important role in ischemic acute kidney injury (AKI), as does the transcription factor Nrf2 that regulates antioxidant and stress genes. Nrf2 is thought to work in kidney resident epithelial cells, however, it could be important in T cell function. We therefore hypothesized that T cell Nrf2 activation mediates AKI.

Methods: T cell specific Keap1-deficient (T cell-Keap1-KO) mice were generated using Cre-LoxP mechanism and its effect on Nrf2 activity was assessed by measuring Nqo1 and HO-1 mRNA levels. AKI was induced by bilateral ischemia reperfusion and serum creatinine (SCr) measured to assess kidney function. Post-ischemic kidneys were assessed for histologic changes, pro-inflammatory cytokines, infiltrating immune cells and intracellular cytokine production. Adoptive transfer of T cells from T cell-Keap1-KO mice into WT mice was also performed.

Results: T cell specific augmentation of Nrf2 resulted in significant increase in baseline Nqo1 ($p\leq0.01$) and HO-1 ($p=0.05$) expression in T cell-Keap1-KO mice. T cell-Keap1-KO mice had significantly lower SCr (0.53±0.20 versus 1.6±0.26 mg/dL, $p=0.01$) and fewer necrotic tubules in cortex ($p=0.001$) and outer medulla ($p=0.05$) 24h post ischemia as compared to Keap1 floxed control mice. T cell-Keap1-KO mice kidneys revealed a high frequency of CD25+Foxp3+ Treg (4.1%±0.4 versus 2.8%±0.7, $p=0.01$) and decreased frequency of CD11bCD11c (14.4%±2.2 versus 21.2%±3.5, $p=0.01$) and F4/80 (9.8%±2.6 versus 17.2%±2.8, $p=0.01$) positive cells among CD45+ cells at baseline. Intracellular TNFα, IFNγ and IL17 were significantly lower in CD4, CD8 and double negative T cells in KO mice. Adoptive transfer of T cells from T cell-Keap1-KO mice significantly improved kidney function ($p=0.02$) and survival ($\chi2\leq0.01$) in WT mice.

Conclusions: These data demonstrate that T cell specific Nrf2 augmentation protects from IR induced AKI. This provides novel converging mechanistic information on T cells and Nrf2 function in AKI.

Funding: NIDDK Support

FR-OR007

Role of IKK2 Mediated NF-Kappa B Activation in CD4 Positive Lymphocytes in Ischemia Reperfusion Injury Model Linlin Guo, Hannah Heejung Lee, Hans-Joachim Paust, Gunther Zahner, Friedrich Thaiss. *MED III, Univ Hospital, Hamburg, Germany.*

Background: We and others have previously shown a causal relation between the leukocyte activation and infiltration into kidney as well as NFκB activation after ischemia reperfusion injury (IRI). Therefore, we hypothesized that T cell specific NFκB inhibition may have effects on IRI and tested this idea by ablating IKK2 expression in CD4+ lymphocytes in IRI model.

Methods: Briefly, IRI was induced in 8 to 10 weeks old male CD4Cre and CD4-Cre x IKK2-fL/fL [CD4IKK2] mice by placing atraumatic microvascular clamp on both renal pedicles for 75 minutes. Tissue was collected at 12h and 7d. Renal function, kidney morphology, RT-PCR and FACS were examined.

Results: The results demonstrated improved renal function after IRI in CD4IKK2 mice at 12h (BUN 12: 85±6 versus 115±5 mg/dL; $p< 0.05$), while no significant change at 7d (BUN 7d: 35±3 versus 38±5 mg/dL).CD4+ T cells infiltration in kidney after IRI was significantly increased in CD4IKK2 mice at 7d while not at early point when compared with CD4Cre mice (12h: 41±5 versus 39±3 %CD3cells and 7d: 55±7 versus 41±3 %CD3cells; $p< 0.05$). More remarkably Tregs in kidney were significantly reduced in CD4IKK2 when compared with CD4Cre mice (12h: 6±2 versus 11±3 %CD4 cells; $p< 0.05$ and 7d: 7±1 versus 15±2 %CD4cells; $p< 0.05$). Spleen Tregs were unchanged in CD4Cre mice after

IRI when compared with sham operated animals (9±2 versus11±3 %CD4cells), however, significantly increased in CD4IKK2 mice from 12h to 7d after IRI (1±2 versus 13±3 %CD4 cells; p<0.01).The inflammatory mediator IL6 and chemokines CCL2 and CCL20 were significantly increased (p<0.05) after renal IRI in CD4IKK2 when compared with CD4Cre mice.

Conclusions: It has been proven that T cells play a central role in mediating IRI. Our results extend recent findings (Kim et al. JASN, 2013) that expansion of Tregs in kidney after IRI is critically dependent on IKK2 and Tregs in spleen and kidney are differentially regulated. The pathway of IL6 driven CCL20 expression in the recruitment of CCR6-positive Th17 cells in CD4IKK2 mice after IRI will be further evaluated. Our findings caution against the therapeutic use of systemic application of IKK2 inhibitors in the inflammatory kidney injury.

IL-233 Fusion Cytokine - A Novel Therapeutic Approach for Acute Kidney Injury Marta Stremska,[1] Liping Huang,[1] Amandeep Bajwa,[1] Diane L. Rosin,[1,2] Mark D. Okusa,[1] Rahul Sharma.[1] *[1]Div of Nephrology, Univ of Virginia, Charlottesville, VA; [2]Dept of Pharmacology, Univ of Virginia.*

Background: The Foxp3$^+$ regulatory T cells (Tregs) are important for suppressing inflammation, which is a common mechanism in acute kidney injury (AKI). Based on the dependence of Tregs on IL-2 and our finding that Tregs constitutively express IL-33 receptor (ST2), we designed a novel fusion cytokine IL-233, comprised of two pleiotropic interleukins: IL-2 and IL-33. ST2 is also expressed on T helper 2 (Th2) cells, mast cells and innate lymphoid type 2 cells (ILC2).

Methods: The cytokines were expressed in *E.coli* and purified. We pretreated 6-8 week old C57BL/6 male mice with different doses of cytokines (ip) administered 48 hrs prior to 26 min of bilateral ischemia and 24 hours of reperfusion. Adoptive transfers of purified Tregs (iv) were performed. Plasma creatinine and kidney morphology in H&E stained sections were assessed. Flow cytometry and immunofluorescent microscopy were used to phenotype the immune cells.

Results: Pretreatment with low dose IL-233 protected kidneys from ischemia reperfusion injury (IRI). Acute tubular necrosis score, plasma creatinine and infiltrating neutrophils numbers were significantly lower in the IL-233-treated kidneys, as compared to IL-2 or IL-33 injected separately or in combination. Our findings show that IL-233 treatment first increases the splenic reservoir of Tregs, of which especially the ST2$^+$ proportion, is then mobilized into the blood. Additionally, we observed an increase in Th2 cytokine production in the spleen and decreased inflammatory cytokines IFN-γ and TNF-α, indicating a shift towards a protective Th2 response. Adoptive transfer studies revealed that recipient mice injected with Tregs isolated from IL-233 pre-treated mice had significantly higher proportion of ST2$^+$ Tregs in the kidney and had better protection from AKI compared to those injected with either saline or Tregs from saline-treated mice.

Conclusions: Pretreatment with IL-233 protects against AKI. The putative mechanism of action is through targeting Treg homeostasis and stimulating the anti-inflammatory response of Th2 and the ILC2 cells. Thus, our novel fusion cytokine bears therapeutic potential.

Kidney Derived Endothelial Progenitors Play a Critical Role during Development and Kidney Injury Sunder Sims-Lucas, Natasha M. Rogers, Christopher Cain Rymer. *Univ of Pittsburgh, Pittsburgh, PA.*

Background: Acute kidney injury leads to the increased risk of morbidity and mortality in hospitalized patients. Acute kidney failure is particularly prevalent amongst subpopulations that are already susceptible, including patients with chronic kidney disease, and kidney transplant recipients. The microvasculature of the kidney is an important vascular network that is critical for maintaining normal tissue homestasis during baseline conditions. We have recently determined that the endothelium of the peritubular capillaries (critical for normal homeostasis) is derived from inherent kidney progenitors. Thus, we hypothesize that abnormal formation of the renal microvasculature leaves kidneys susceptible to ischemic injury.

Methods: To specifically target the kidney-derived peritubular capillary endothelium, we conditionally deleted Flk1 (critical for endothelial development) with the Foxd1EGFPcre line (kidney specific). We utilized sophisticated 3D reconstruction to determine the effects upon vascular growth. We interrogated the location and initiation of embryonic blood flow using in utero intracardiac microinjection. To test postnatal vessel phenotypes, we performed fluorescent microangiography. Furthermore, post-natal mice were subjected to ischemic-reperfusion injury, and pre- and post- kidney perfusion was monitored using laser Doppler imaging.

Results: Deletion of the kidney-derived endothelium produced mutant kidneys with severe kidney medullary hypoplasia, and dilated remnant Flk1-positive peritubular capillaries with normal appearing glomerular capillaries. There also appears to be less blood flow into the developing kidney of the mutants compared to the controls. Our microangiography reveals that the mutant post-natal vessels also appear dilated, suggesting they are susceptible to injury. Further to this, the ischemic injury model revealed that there was reduced reperfusion 24 hours after the ischemic episode, and increased kidney tubular damage in the mutants compared to controls.

Conclusions: In conclusion, kidney derived endothelial cells are critical for normal kidney and vascular development, and deletion of these progenitors leaves kidneys susceptible to ischemic injury.

Human Endothelial Progenitor Cells Protect against Acute Kidney Injury: Role of Exosomes and miR-486 Jose L. Vinas, Dylan Burger, Alex Gutsol, Pearl Ann Campbell, David Allan, Kevin D. Burns. *Nephrology, Medicine, Kidney Research Centre, OHRI, Univ of Ottawa, Ottawa, ON, Canada.*

Background: In preliminary data, we have shown that human cord blood endothelial-colony forming cells (ECFCs) are protective in a mouse model of ischemia-reperfusion (I/R) acute kidney injury (AKI). Extracellular vesicles (EVs) diminish apoptosis by horizontal miRNA transfer. Since two main classes of EVs exist with distinct properties (exosomes and microparticles), we determined the miRNA profile of ECFC-derived EVs and their role in ischemic injury.

Methods: Mice subjected to kidney I/R were injected with ECFCs at reperfusion. Cultured human umbilical vein endothelial cells (HUVECs) were treated with EVs and rendered hypoxic for 24 hr, followed by reoxygenation (H/R). In both models, apoptosis was assessed by expression of caspase-3, PTEN and AKT phosphorylation. The expression profiles of miRNAs isolated from exosomes and microparticles were determined by next-generation sequencing, followed by bioinformatic pathway analyses.

Results: In mice with I/R AKI, ECFCs blocked increases in renal caspase-3 activity and expression (P<0.05 versus I/R alone, n=6). In the cell model, H/R increased caspase-3 activity and expression, effects that were inhibited by incubation with ECFC-conditioned medium (CM) or ECFC-derived exosomes (P<0.001 versus H/R alone, n=3). By contrast, treatment with CM without EVs or microparticles had no effect on apoptosis. ECFC exosomes were highly enriched in miR-486 (288-fold increase versus microparticles, 30-fold increase versus ECFC lysate). In mice with I/R AKI, ECFCs significantly increased kidney miR-486 levels, associated with decreases in PTEN expression and increased AKT phosphorylation (P<0.05 versus I/R alone; n=6). In HUVECs subjected to H/R, ECFC exosomes decreased PTEN expression, associated with an increase in AKT phosphorylation (P<0.001 versus H/R alone; n=3).

Conclusions: These data show that the protective effects of ECFCs are mediated by exosomes activating the pro-survival AKT pathway, possibly due to horizontal transfer of antiapoptotic miR-486 and subsequent PTEN inhibition. The results suggest that exosomes enriched in miR-486 could represent a therapeutic tool in human I/R AKI.

Exploring the Pathophysiological Functions of Resident Fibroblasts in the Kidney Jin Nakamura, Akiko Oguchi, Ryo Yamada, Motoko Yanagita. *Nephrology, Kyoto Univ, Kyoto, Japan.*

Background: We previously reported that resident fibroblasts in the kidney cortex and outer medulla are myelin protein zero-Cre (*P0-Cre*) lineage-labeled cells of extra-renal origin, and that some of them are erythropoietin (EPO) producing cells in the healthy kidney. In UUO kidney, *P0-Cre* lineage-labeled fibroblasts transdifferentiate into myofibroblasts and predominantly contribute to fibrosis, with concomitant loss of EPO production. In this study, we further investigated the pathophysiological function of fibroblasts and the crosstalk between the fibroblasts and tubular epithelial cells.

Methods: To analyze the function of fibroblasts in the kidney, we utilized *P0-Cre* inducible simian diphtheria toxin receptor (DTR) transgenic mice (*P0-Cre:iDTR* mice) in which Cre-mediated excision of a STOP cassette renders *P0-Cre* linage-labeled fibroblasts sensitive to diphtheria toxin (DT). The binding of DT to DTR halts protein synthesis within the cells.

Results: First we confirmed that DT administration ablated the expression of fibroblast markers in the kidney, indicating the effective cessation of protein synthesis in *P0-Cre* linage-labeled fibroblasts. Simultaneously, the expression of tubular injury markers, as well as the proliferation of proximal tubule cells was observed. In UUO kidney, DT administration enhanced the expression of tubular injury markers. Unlike the results of healthy kidney, DT administration significantly attenuated tubular proliferation, mainly in proximal tubules. To search for the fibroblasts-derived molecules supporting tubular epithelial cells in healthy condition, we performed microarray analysis and identified several signaling pathways down-regulated in DT-administered kidney, suggesting resident fibroblasts triggering corresponding signals in tubular epithelial cells.

Conclusions: Our results indicate that resident fibroblasts inhibit tubular proliferation and injury in healthy kidney, while support the repair of injured tubule by promoting tubular proliferation in diseased kidney. These results indicate the possible interactions between the fibroblasts and tubular epithelial cells, and the signaling pahtways responsible for the interaction may be of therapeutic implication.

FR-OR012

Cell Autonomous and Non-Cell Autonomous Responses Mediated By Angiogenin During Kidney Injury Nicolas Pallet, Iadh Mami, Eric Thervet. *Hopital Europeen Georges Pompidou.*

Background: Endoplasmic Reticulum (ER) stress contributes to kidney disease and aging. The Unfolded Protein Response (UPR) helps to adapt to the changing environment and reestablish normal ER function. Angiogenin (ANG) is a stress-activated ribonuclease that cleaves tRNA and produces stress-induced tRNA fragments (tiRNA), which inhibit translation. Whether ANG is integrated in the UPR is currently unknown.

Methods: We combined in vitro, in vivo and human models of kidney injury to explore the molecular basis whereby ANG is regulated by the UPR, and to characterize how it promotes cellular adaptation during ER stress.

Results: In mice models of ischemic injury and cyclosporine nephrotoxicity, and in human kidney biopsies, ANG expression was upregulated in the tubules, and this expression occured with ER stress. In human renal epithelial cells in culture (HREC), IRE1a, and the transcription factors sXBP1 and p65 induced ANG expression, and also IL6. We showed that ANG, like IL6, was conventionnally secreted. Secreted ANG primed non-stressed HREC to activate the UPR, but without apoptosis, indicating that ANG may induce non-stressed HREC precontionning. In addition, ANG activated macrophages to produce IL6, IL8 and TNFa. Looking at cell intrinsic properties of ANG during early ER stress, we have found that the inhibition of expression of ANG increased HREC apoptosis, and these adaptive effects of ANG were mediated by a reduction in protein synthesis, which alleviated ER stress. The inhibitory effects of ANG on protein translation were mediated by the production of tiRNA, which interfere with translation initiation. Validation of these findings in mice knocked-out for ANG are ongoing. Finally, we measured the urinary concentrations of ANG in 110 consecutive patients referred for a kidney biopsy, and we demonstrated that the urinary concentrations of ANG were positively correlated with renal function and the intensity of tissue injury.

Conclusions: ANG is a regulator of the stress response integrated to the UPR during kidney injury, which acts in a cell intrinsic mode by inhibiting translation, and in a cell extrinsic mode by inducing pre-emptive responses in neighbouring cells. ANG is a non invasive marker of kidney tissue injury.

Podocytes Proliferation Is Detected in Rat and Human Nephoritis

Zhigang Zhang, Ruimin Hu, Xing Mao, Huijuan Wu. *Dept of Pathology, Shanghai Medical College, Fudan Univ, Shanghai, China.*

Background: Podocyte depletion is a pivotal pathogenesis for many types of glomerulonephritis. It has been found recently that podocytes is able to replicate in certain glomerular diseases, such as idiopathic collapsing glomerulopathy and HIV-associated nephropathy. But in most immune complex mediating glomerulonephritis, the question whether podocytes can proliferate and replenish its lost after injury is still undefined. In this study, we used a retrovirus- enhanced green fluorescent protein (pMSCV-EGFP) tracing technology to observe direct evidence of podocyte proliferation in two type rat nephropathy models, cytotoxic nephrosis induced by adriamycin and immune-mediated injury of passive Heymann nephritis (PHN) and anti-Thy1.1 nephritis.

Methods: It is a new technology developed recently to investigate cells proliferation by infecting of retrovirus in animal experiment. Retrovirus is positive-strand RNA viruses which can integrate into the host DNA only during the host cells division. The proliferated podocytes in rat glomeruli were captured by detecting EGFP as well as BrdU via immunohistochemistry staining.Moreover, PCNA immunohistochemistry staining was used in human renal biopsy tissue and Western blot was used in cultured mice podocytes to detect cell cyclin kinase as well as Wnt/β-catenin molecules.

Results: The clear evidence of positive for EGFP and BrdU were found in glomeruli of rat nephropathy. It confirmed that podocytes do proliferate in animal cytotoxic nephropathy and in immune complex mediating glomerulonephritis. Meanwhile, podocytes positive for PCNA and WT1 double staining were detected by immunohistochemistry in human renal biopsy tissue of diverse nephritis. In vitro studies showed that the up-regulation of cyclinB1, cdc2, and PCNA were observed in cultured podocytes after treatment of inflammatory stimulation, and these effects were mediated via the activation of Wnt/β-catenin.

Conclusions: These results indicate that podocytes have a capability of proliferation in rat and human common immune mediating glomerulonephritis, which was regulated by activation of cyclin kinases via the mediating of Wnt signaling.

Krüppel-Like Factor 6 Protects the Podocyte from Mitochondrial Injury under Cell Stress

Sandeep K. Mallipattu,[1] Sylvia Horne,[1] John C. He.[2] *[1]Medicine, Stony Brook Univ; [2]Medicine, Icahn School of Medicine at Mount Sinai.*

Background: Krüppel-like factors (KLFs) play a critical role in podocyte biology. As compared to other KLFs, Krüppel-like factor 6 (KLF6), a zinc-finger DNA-binding transcription factor, expression was reduced in HIV-1 infected podocytes, HIV-1 transgenic mice, and in human biopsies with HIVAN. Podocyte-specific loss of *Klf6* (*Cre*$^{+}$ *podocin Klf6*$^{flox/flox}$) in mice resulted in significant albuminuria, podocyte effacement, and FSGS with adriamycin (ADR) treatment. ADR-treated *Cre*$^{+}$ *podocin Klf6*$^{flox/flox}$mice exhibited dysmorphic mitochondria with a reduction in mitochondrial transcripts in the podocytes. Promoter analysis also showed putative binding sites for KLF6 exist on cytochrome c oxidase assembly gene (*SCO2*).

Methods: Cultured human podocytes (HP) were treated with and without ADR (0.4μg/μl) for 6, 12, 18, and 24 hours. Stable knockdown for *KLF6* and *SCO2* (shRNA) was performed in HP and mitochondrial injury and apoptosis was determined.

Results: KLF6 expression increased within 6 hours of ADR treatment and shRNA-*KLF6* reduced the mitochondrial membrane potential as compared to shRNA-EV (control). In ADR-treated HP, shRNA-*KLF6* increased mitochondrial fragmentation with reduced SCO2 expression and ATP levels. Also, ADR-treated shRNA-*KLF6* increased cleaved-caspase 3, 9, and cytosolic cytochrome c expression and decreased pro-caspase 3 expression. KLF6 regulation of mitochondrial function was determined by identifying KLF6 transcriptional binding sites on *SCO2* using ChIP assay. ADR-treated *Podocin-Cre Klf6*$^{flox/flox}$ mice exhibited a podocyte-specific reduction in *Sco2* expression as compared to ADR-treated *Podocin-Cre Klf6*$^{+/+}$ mice. *Sco2* expression was also reduced in HIV-1 transgenic mice as compared to wild-type mice. Also, shRNA-*SCO2* increased cytosolic cytochrome c, cleaved-caspase 3 and 9 levels. Finally, immunostaining revealed a reduction in podocyte-specific KLF6 expression in human biopsies with FSGS as compared to healthy donor nephrectomies.

Conclusions: These findings suggest that *KLF6* is an early inducible injury response gene, critical to the maintenance of mitochondrial function and preventing the activation of the intrinsic apoptotic pathway upon stress to the podocyte.

Suppression of Acetyl-CoA Carboxylase 2 Rescues Kidney Proximal Tubule Epithelial Cells from Palmitic Acid-Induced Lipotoxicity via Autophagy

Wei Xin, Xu Zhao, Liyong Chen, Lei Liu, Ying Xu, Qiang Wan. *Shandong Provincial Hospital Affiliated to Shandong Univ.*

Background: Acetyl-CoA carboxylase b (ACC2) enzyme plays a crucial role in the fatty acid (FA) metabolism. Autophagy is known to control the cellular energy balance. In the present study we aim to investigate the effects of ACC2 downregulation on palmitic acid (PA) induced lipotoxicity in human proximal tubular cells and the putative role on autophagy in this process.

Methods: ACC2 expression was suppressed by shRNA transfecion. The lipid deposition was accessed by oil-red O staining. The cell viability was analyzed by MTT. Immunoblot and immunostaining were used to characterize autophagic proteins expression. The autophagy level in vivo was characterized by immunohistochemistry.

Results: Autophagy level was dramatically higher in high fat fed rats compared to controls. PA induced autophagy in HK-2 cells evidenced by decreased P62 expression. More interestingly, the knockdown of ACC2, representing an accelerated b-oxidation rate, reduced autophagy. Further, the ACC2 knockdown ameliorated the PA-induced lipid accumulation (not shown) and cell viability defects.

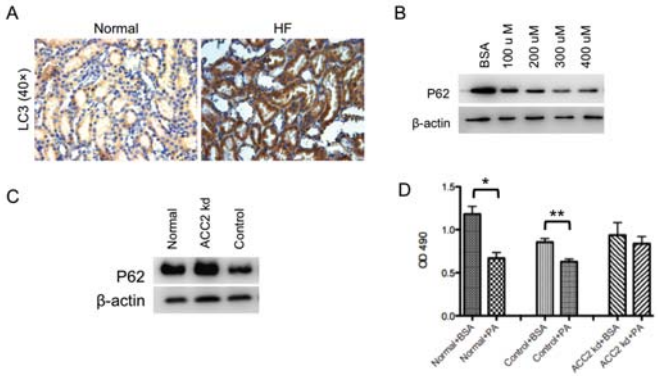

Fig.1 Role of ACC2 knockdown on autophagy in PA stimulated HK-2 cells. A) Autophagy level was dramatically increased in high fat fed rats (HF) compared to normal rats. B) Autophagy was induced in HK-2 cells after stimulated by PA for 2h. C) ACC2 knockdown decreased autophagy level in HK-2 cells. D) ACC2 knockdown attenuated PA induced proliferation defects of HK-2 cells.

Conclusions: Taking together, it was proved that PA was able to induce autophagic flux both in vivo and in vitro and the knockdown of ACC2 reduced PA-induced autophagy and thus protects cells from PA-induced lipotoxicity with attenuated lipid accumulation and rescued cell viability. Thus we proposed a novel autophagy-involved mechanism of PA-induced renal lipotoxicity and provided potential therapeutic strategy by modulating lipid b-oxidation for DN.

Long-Chain Saturated Fatty Acid-Induced Endoplasmic Reticulum Stress Suppresses Erythropoietin Production in Kidney

Thitinun Anusornvongchai,[1,2] Chih-Kang Chiang,[3] Yu Ishimoto,[1] Norio Suzuki,[4] Masayuki Yamamoto,[4] Masaomi Nangaku,[1] Reiko Inagi.[5] *[1]Divs of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]Lerdsin General Hospital, Bangkok, Thailand; [3]National Taiwan Univ, Taiwan; [4]Tohoku Univ School of Medicine, Japan; [5]CKD Pathophysiology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan.*

Background: Renal anemia is caused by derangement of EPO production in renal EPO-producing (REP) cells. Long-chain saturated fatty acid (palmitate) induces endoplasmic reticulum (ER) stress, which contributes to kidney cell damages. Thus, we evaluated the effect of palmitate on EPO production via the ER stress pathway.

Methods: C57/BL6 or inherited super-anemic mice (ISAM), in which the renal EPO gene was replaced with GFP, were daily injected with palmitate (BSA-conjugated) or vehicle for 11 days. Free fatty acids, expression of EPO and other hypoxia inducible factor (HIF) target genes (VEGF and Glut-1), or ER stress state in kidney were measured. Alteration of EPO production in REP cells was estimated by GFP detection in ISAM mice. We also stimulated cultured EPO-producing cells (HepG2) with palmitate in various doses and durations and/or under hypoxic condition (1%O_2 or chemical inducer of HIF-1 [$CoCl_2$]).

Results: Palmitate suppressed EPO mRNA and protein in HepG2 and the kidney of C57/BL6 mice ($p<0.05$). Particularly in hypoxic condition, the EPO suppression by

palmitate was conversely associated with activation of ER stress signal (ATF4 and XBP-1). Interestingly, we identified a novel ATF4 binding site (TGACCTCT) near HIF binding site at the 3'-enhancer region of EPO gene. ATF4 upregulation selectively suppressed the HIF-dependent-enhancer activity of EPO gene but not the other HIF target genes. In ISAM mice, palmitate significantly reduced renal EPO production and REP cell number at cortico-medullary junction as compared with the control, respectively.

Conclusions: EPO production by REP cells was suppressed by palmitate especially under hypoxic condition via the ER stress pathway. The link between ER stress, dyslipidemia and hypoxia in CKD may contribute to development and progression of anemia.

FR-OR017

Altered Autophagy Flux Contributes to Kidney Aging via Mitochondrial Dysfunction Takeshi Yamamoto,[1] Yoshitsugu Takabatake,[1] Tomonori Kimura,[1] Atsushi Takahashi,[1] Tomoko Namba,[1] Jun Matsuda,[1] Fumio Niimura,[2] Taiji Matsusaka,[3] Motoko Yanagita,[4] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Dept of Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Dept of Pediatrics, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan; [3]Inst of Medical Science and Dept of Internal Medicine, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan; [4]Dept of Nephrology, Graduate School of Medicine, Kyoto Univ, Kyoto, Japan.*

Background: Autophagy is essential for cellar homeostasis through the quality control of proteins and organelles. Controversy exists whether the decline of autophagic activity is involved in aging process. We have previously demonstrated that autophagy maintains proximal tubule cell homeostasis and protects against ischemic and nephrotoxic injury.

Methods: We extended this prior study to longer observation period to elucidate the association of autophagy and kidney aging.

Results: Temporal cessation of autophagy in recently generated tamoxifen-inducible proximal tubule-specific Atg5-knockout mice exhibited increased accumulation of p62/SQSTM1- and ubiquitin-positive aggregates in the aged kidneys, but not in younger kidney, indicating that basal autophagic activity is high in aged kidney. Younger GFP-MAP1LC3 transgenic mice showed a drastic increase of GFP-positive puncta in proximal tubules in response to starvation, whereas aged GFP-MAP1LC3 mice did not, suggesting that autophagic flux is blunted with aging. Proximal tubule-specific Atg5-knockout mice at 24 months of age exhibited a significant deterioration in kidney function and fibrosis. Furthermore they revealed deformation and dysfunction of mitochondria and mitochondrial DNA abnormalities in the proximal tubules.

Conclusions: These results suggest that age-dependent high basal autophagy plays a crucial role in counteracting kidney aging through mitochondrial quality control but that lack of upregulation of autophagy flux in response to metabolic stress with age may be associated with age-related kidney diseases.

Funding: Government Support - Non-U.S.

FR-OR018

A Lifetime Health Outcomes Model in Moderate to Severe Chronic Kidney Disease Based on the Study of Heart and Renal Protection (SHARP) Borislava N. Mihaylova, Iryna Schlackow. *On Behalf of the SHARP Collaborative Group, Nuffield Dept of Population Health, Univ of Oxford, Oxford, United Kingdom.*

Background: Chronic kidney disease (CKD) increases the risk of cardiovascular disease (CVD) and CVD may contribute to kidney disease progression. A model taking into account this interdependence is developed to evaluate lifetime health outcomes of patients with moderate-to-severe CKD.

Methods: The individual participant data of SHARP (9,270 participants, 5 years' mean follow-up) were used to develop CKD risk equations predicting progression through CKD stages, and CVD risk equations predicting major vascular events and vascular mortality. These were combined into a lifetime Markov SHARP CKD-CVD model. A range of socioeconomic, CKD and CVD risk factors together with annually updated age, CKD duration, CKD stage and nonfatal vascular events were used to estimate disease risks. The model was validated within subgroups of participants in SHARP as well as using external clinical trial and observational CKD patient data.

Results: Cardiovascular events, CKD stage and age were the major determinants of CVD risks and CKD progression and, consequently, of patient survival (Table). Model predictions of rates of cardiovascular events and progression of CKD corresponded well to observed rates in different subgroups of SHARP participants and in the external CKD cohorts.

CKD stage at baseline	Age at baseline (years)				
	<50	50-59	60-69	70-79	≥80
	Predicted survival (years), in the absence of any lipid-lowering therapy				
Stage 1-3 (predomintantly 3B)	23.8	18.3	13.5	9.6	6.7
Stage 4	22.3	16.2	11.8	8.4	5.7
Stage 5, not on renal replacement therapy	20.6	13.3	9.2	6.4	4.6
On dialysis	19.4	13.1	8.7	6.1	4.3
	Rediction in survival (years) associated with a nonfatal major atherosclerotic event				
Stage 1-3 (predominantly 3B)	2.7	2.3	1.6	1.0	0.5
Stage 4	2.5	2.2	1.8	1.1	0.6
Stage 5, not on renal replacement therapy	2.0	1.6	1.4	0.9	0.5
On dialysis	1.5	1.1	0.9	0.6	0.5

Conclusions: The SHARP CKD-CVD model performs well and will be made available for simulating lifetime health outcomes in moderate-to-severe CKD.

Funding: Pharmaceutical Company Support - The SHARP study was funded mainly by Merck/Schering-Plough Pharmaceuticals (North Wales, PA, USA), Government Support - Non-U.S.

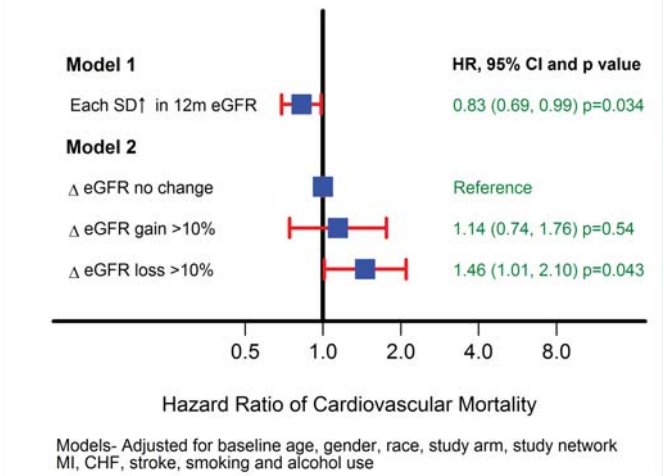
FR-OR019

Early GFR Decline as a Predictor of Cardiovascular Mortality in Non-CKD Diabetics Srini Beddhu,[1,2] G. Wei,[2] E. Constantz,[2] Xiaorui Chen,[2] R. Boucher,[2] Ajay Giri,[2] Debra Lynn Simmons,[2] Molly B. Conroy,[3] Jane J. Lee,[3] Tom Greene.[2] *[1]SLC VAMC; [2]Univ Utah; [3]Univ of Pitt.*

Background: Early GFR decline in non-CKD diabetics might reflect systemic microvascular disease and predict cardiovascular mortality (CVM).

Methods: We examined this hypothesis in a secondary analysis of the ACCORD study (a RCT conducted by NHLBI to examine the effects of glycemic control, BP control and fibrates on CV outcomes in type 2 DM). The cohort for this analysis consisted of those with a). baseline and 12 m CKD-EPI eGFR and b). 12 m eGFR ≥ 60 ml/min/1.73 m^2. Based on the baseline and 12m eGFR, ΔeGFR groups (no change: -10% to +10%, >10% loss: ΔeGFR <-10% and >10% gain: ΔeGFR>+10%) were defined. Separate Cox regression models were used to relate ΔeGFR groups and 12 m eGFR with CVM.

Results: 7574 diabetics without CKD at 12m were included. The mean age was 62.8 ± 6.2 yrs, 62.6% were men, 61.9% were Caucasian. The mean ± SD 12m eGFR was 86.3 ± 14.2 ml/min/1.73 m2. The mean ΔeGFR in the no change, ΔeGFR loss and ΔeGFR gain groups were -1.2 ±3.8, -17.7±7.5, 15.7±7.8 ml/min/1.73 m2, respectively. There were 159 CVM events over 30070 patient-yrs of follow-up.



Each SD ↑ in 12m eGFR was strongly associated with lower hazard of CVM (Fig). Compared to the group ΔeGFR no change group, ΔeGFR loss > 10% group had higher hazard of CVM (Fig). ΔeGFR and 12 m eGFR were strongly correlated (r =0.53, p <0.001) and when both were included in the same model, neither had significant association with CVM.

Conclusions: Both current eGFR and loss of eGFR in the preceding 12 m in non-CKD diabetics predict CVM. Early decline in eGFR might be a marker of cardiovascular disease in diabetics without CKD.

Funding: NIDDK Support

Risk of Complications in Hospitalized Patients with Chronic Kidney Disease

Babak Bohlouli,[1] Terri Jurgens Jackson,[2] Marcello Tonelli,[1] Scott Klarenbach.[1]
[1]Medicine, Univ of Alberta, Edmonton, AB, Canada; [2]Northen Hospital, Univ of Melbourne, Australia.

Background: Complications that arise during hospitalization are associated with prolonged stay, increased disability, death; many of these complications are preventable. Patients with CKD may be at high risk of in-hospital complications. Objective: Determine the association of CKD and the risk of in-hospital complications.

Methods: All adults (age >= 18) in Alberta, Canada with a hospital admission between March 31, 2003 to April 1, 2008 were included. CKD was defined using outpatient proteinuria and eGFR (CKD-EPI). Other comorbid conditions were identified using validated algorithms. In-hospital complications were identified and categorized by the type 2 flag (Hospital Acquired Diagnoses; ICD-10 CA). Multiple logistic regression assessed the independent association between CKD and the risk of developing any in-hospital complication.

Results: Of 536,549 hospitalization, 8.5% involved patients with CKD. Subjects with CKD were older (72, SD: 15) and more likely to be female than those without CKD. Disease of circulatory system was the most common reason for admission (20.8%), diabetes was the most common co-morbid condition (23.6%), and the unadjusted proportion of patients with >=1 HAD was 7.3% and 13% for those without and with CKD, respectively. In a fully adjusted analysis the OR of HAD in patients with CKD (reference: no CKD) was 1.22(95% CI: 1.18 – 1.26). A graded association with severity of CKD was observed

		Adjusted OR	95% CI
CKD (Ref: no CKD)		1.22	1.18 – 1.26
eGFR (ml/min/1.73/m^2)	> 60	Ref	
	45 - 59	1.14	1.09 – 1.19
	30 - 44	1.25	1.18 – 1.33
	15 - 29	1.48	1.35 – 1.62
Proteinuria None	None	Ref	
	Moderate	1.22	1.14 – 1.30
	Heavy	1.37	1.27 – 1.49

Conclusions: CKD and its severity are associated with an increased risk of in-hospital complications. Our findings can be used to guide preventive strategies aimed at reducing complications in vulnerable hospitalized patients.

FR-OR021

Infection Is a Risk Factor for Faster Progression to Renal Replacement Therapy and Death in Chronic Kidney Disease

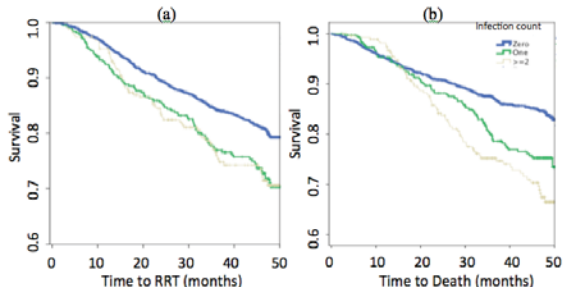
Hicham I. Cheikh Hassan,[1,2] Mila Tang,[1] Ognjenka Djurdjev,[3] Adeera Levin.[4,5] *[1]St. Pauls Hospital, Vancouver, BC, Canada; [2]UNSW, Sydney, NSW, Australia; [3]British Columbia Provincial Renal Agency, Vancouver, BC, Canada; [4]Univ of British Columbia, Vancouver, BC, Canada; [5]CanPREDDICT Investigators.*

Background: Chronic Kidney Disease (CKD) affects 10% of adults and is associated with increased risk of infection (Inf). In patients undergoing renal replacement therapy (RRT), Inf is an established and increasing cause of death. However, the role of Inf in non dialysis CKD patients remains understudied. We aim to establish if Inf is a risk factor for faster progression to RRT and mortality in CKD patients.

Methods: CanPREDDICT is an observational pan-Canadian cohort of prospectively followed up CKD outpatients. Baselines characteristics were recorded at initial visit and patients followed up six monthly. Inf were defined by use of antibiotics, categorised by anatomical location and counted for each six monthly interval. Endpoints were death and commencing RRT.

Results: The analysis cohort consisted of 2529 patients (mean follow up 35.3 months); median age was 70.6 years, males (62.5%) and Caucasians (88.7%). 399 patients (15%) died and RRT was started in 464 patients (18%). 30% had an Inf. Those with Infs were more likely to be male (p<0.001), have diabetes (p= 0.01) and cardiovascular disease (p< 0.001), lower eGFR (p=0.019) and higher albumin (p< 0.001) and C reactive protein (p= 0.003) as compared to those with no Inf; no statistical difference in age (p=0.71) or urine albumin/creatinine (p=0.89) were seen. Patients with Inf were more likely to die (No Inf= 13.2%, 1 Inf= 20.8%, ≥2 Inf= 26.4%, p< 0.001) and undergo RRT (No Inf= 16.2%, 1 Inf= 24.5%, ≥2 Inf=24.3%, p< 0.001).

Kaplan-Meier curves a) time to RRT and b) time to mortality based on number of infections.
p< 0.001 by Log Rank for both curves



Conclusions: We demonstrate that the presence of any Inf in this CKD cohort is a risk factor for increased mortality and faster RRT progression. Reasons for this association is the focus of future study.

Incident Atrial Fibrillation and Risk of End-Stage Renal Disease in Chronic Kidney Disease: The CRIC Study

Nisha Bansal,[1] Dawei Xie,[2] Elsayed Z. Soliman,[3] Kelvin Tao,[2] Jing Chen,[4] Rajat Deo,[2] Edward J. Horwitz,[5] Chi-Yuan Hsu,[6] Claudia M. Lora,[7] Dominic S. Raj,[8] Myles S. Wolf,[9] Alan S. Go.[10] *[1]UW; [2]UPenn; [3]WF; [4]Tulane; [5]CWRU; [6]UCSF; [7]UIC; [8]GWU; [9]NWU; [10]KPNC.*

Background: Atrial fibrillation (AF) frequently occurs in patients with chronic kidney disease (CKD) and may be associated with adverse kidney outcomes. We examined the association of incident AF with the risk of end-stage renal disease (ESRD) among adults with CKD.

Methods: We studied participants in the prospective Chronic Renal Insufficiency Cohort (CRIC) Study between 2003-2008 without AF at baseline. Incident AF was identified by study visit ECGs, self-report and hospital discharge diagnostic codes, with confirmation by physician adjudication of medical records. ESRD through 2012 was ascertained by self-report, medical records and linkage to the U.S. Renal Data System. Multivariable Cox regression models were used to study the association of time-updated incident AF with subsequent risk of ESRD.

Results: Among 3,091 participants, 172 (5.6%) developed confirmed incident AF. Participants who developed incident AF were more likely to be older, white, have a history of hypertension, cardiovascular disease and have more advanced CKD at baseline. During a mean follow-up of 5.9 years, 43 cases of ESRD occurred after development of incident AF (4.23 per 100 p-y) compared with 581 cases in those without incident AF (3.54 per 100 p-y). After adjustment for potential confounders, incident AF was associated with a threefold increase in rate of ESRD (**Table**) and this association was consistently strong across important subgroups (**Table**).

Conclusions: Incident AF independently increases the risk of developing ESRD in adults with CKD. Further study is needed to identify potentially modifiable pathways through which AF leads to a higher risk of progression to ESRD.

Table. Association between incident atrial fibrillation and progression to ESRD in the CRIC study (N=3,091)

Chronic Kidney Disease and 10-Year Risk of Cardiovascular Death: An Evaluation of European Cardiovascular Prevention Guidelines in a Community-Based Cohort

Martin Holzmann,[1] Axel C. Carlsson,[1] Per Erik Wändell,[1] Johan Arnlov.[2] *[1]Karolinska Instt, Stockholm, Sweden; [2]Uppsala Univ.*

Background: The updated European Society of Cardiology prevention guidelines recommend that subjects with chronic kidney disease should be considered at high or very high 10-year risk of future cardiovascular death regardless of age, sex, or other risk factors. As data is limited to support this recommendation we aimed to investigate if moderate, or severe chronic kidney disease is associated with a high, or very high 10-year risk of cardiovascular death, respectively.

Methods: We included 295 191 [46% women] individuals between the age of 40 and 65 years in accordance with current European Society of Cardiology guidelines who underwent health check-ups in primary health care in Stockholm, Sweden between 1985 and 1996. Moderate and severe chronic kidney disease was defined as an estimated glomerular filtration rate 30 to 60 ml/min/1.73 m^2, and 15 to 30 ml/min/1.73 m^2, respectively; high risk, or very high risk of cardiovascular death was defined as 5 to 10%, or > 10% absolute 10-year risk of cardiovascular death, respectively, in accordance with guidelines.

Results: In total there were 4290 cardiovascular deaths within 10 years. Individuals with moderate chronic kidney disease had a 3.91 % absolute 10-year risk of cardiovascular death (95% confidende interval (CI) 3.46-4.36), while participants with severe chronic kidney disease had 14.0% risk (95% CI 7.86-20.2). Women had substantially lower

absolute risks than men, and the absolute risks were substantially lower in younger than in older age groups. Severe chronic kidney disease was associated with a very high risk of cardiovascular death in both men and women older than 50 years.

Conclusions: Our data suggest that risk estimation of future cardiovascular death solely based on the European Society of Cardiology risk categories overestimate the true absolute risk in individuals with moderate chronic kidney disease, particularly in women or in individuals < 60 years of age.

FR-OR024

Weight Loss after Bariatric Surgery Is Associated with Increased eGFR and Decreased Albuminuria Alex R. Chang,[1] Robert M. Perkins,[1] G. Craig Wood,[2] M. Grams.[3] *[1]Nephrology, Geisinger Health System, Danville, PA; [2]Geisinger Obesity Inst, Geisinger Health System, Danville, PA; [3]Nephrology, Johns Hopkins Univ, Baltimore, MD.*

Background: Bariatric surgery is highly effective at inducing rapid weight loss in patients with morbid obesity, who are at markedly increased risk for end-stage renal disease. The effect of bariatric surgery-induced weight loss on kidney function is unknown.

Methods: Using the Geisinger Clinic Bariatric Surgery Research cohort, we examined the association between weight loss after bariatric surgery and estimated glomerular filtration rate (eGFR) calculated by the CKD-EPI equation. The association between weight loss and resolution of albuminuria was examined in the subset of patients with baseline albuminuria (albumin/creatinine ratio >=30mg/g) and subsequent ACR quantification. Mixed effects models were used, adjusted for time and baseline weight, allowing intercepts and slopes to vary for each individual.

Results: A total of 3134 participants were followed for a median of 2.4 years (interquartile range 0.9 to 4.2). Mean age was 47.2, 36.6% had diabetes, and 6.4% had eGFR <60 ml/min/1.73m^2. One year after bariatric surgery, mean weight decreased from 130.1 to 90.9 kg, mean BMI decreased from 46.8 to 32.6 kg/m^2, and mean eGFR increased from 94.8 to 99.1 ml/min/1.73m^2. Every 5 kg of weight loss was associated with a 0.50 ml/min/1.73m^2 (95% CI: 0.42 to 0.57; p<0.001) increase in eGFR. The association between weight loss and increased eGFR was stronger in patients with eGFR <60ml/min/1.73m^2: 0.89 ml/min/1.73m^2 per 5kg decrease (95% CI: 0.63 to 1.15; p<0.001) compared to 0.46 (0.39 to 0.54; p<0.001) for those with eGFR ≥60 ml/min/1.73m^2 (p<0.001 for interaction). In the subset of 108 patients with baseline albuminuria, weight loss was associated with resolution of albuminuria (odds ratio 2.03 per 5kg weight loss, 95% CI: 1.06 to 3.87; p=0.03).

Conclusions: Weight loss after bariatric surgery is associated with increased eGFR and resolution of albuminuria. While these findings suggest potential benefits to the kidney, additional studies using measured GFR or alternative filtration markers to confirm these findings are needed.

FR-OR025

Uromodulin Excretion Predicts Renal Disease Progression in Children with Chronic Kidney Disease Elke Wuehl,[1,2] Anke Doyon,[1,2] Aysun Karabay Bayazit,[2] Nur Canpolat,[2] Ali Duzova,[2] Daniela Kracht,[2] Betul B.S. Sozeri,[2] Mieczyslaw Litwin,[2] Matthias Wuttke,[2] Anna Kottgen,[2] Marietta Kirchner,[2] Olivier Devuyst,[2] Franz S. Schaefer.[1] *[1]Center for Pediatrics and Adolescent Medicine, Heidelberg Univ, Germany; [2]ESCAPE/4C Study Consortium.*

Background: Uromodulin (Tamm-Horsfall protein) has recently received attention as a potential biomarker of CKD progression. A common *UMOD* gene variant is linked to GFR and CKD in the general population. Here, we sought to explore the determinants of uromodulin excretion in children with CKD and its predictive value for renal disease progression.

Methods: Uromodulin concentration was measured in spot urine samples of 770 children with CKD from the 4C Study and ESCAPE Trial cohorts (age 12.4 (4-20) years, eGFR 33 (10-75) ml/min/1.73 m^2). The single nucleotide polymorphism rs4293393 was assessed as part of a genome-wide SNP screening (Illumina Omni 2.5M chips). Mixed linear modeling was performed to identify predictors of uromodulin concentrations, and extended proportional hazard analysis to identify factors affecting the risk of CKD progression. Renal 'death' was defined by eGFR loss >50% from baseline, eGFR <10 or start of renal replacement therapy.

Results: Uromodulin excretion indexed for eGFR was higher in girls (p<0.0001), and decreased with declining eGFR (p<0.0001) and with each copy of the minor *UMOD* allele (median (IQR) TT: 0.25 (0.23); CT: 0.21 (0.22), CC: 0.19 (0.22); p<0.05). Moreover, uromodulin excretion differed significantly among renal diagnosis groups (p<0.005), with highest levels in children with tubulointerstitial nephropathies (0.35 (0.34)) and lowest levels in glomerulopathies (0.18 (0.20)). The renal endpoint was reached by 31.9% of patients with uromodulin excretion in the lower, as compared to 66.5% in the upper distribution quartile (p<0.0001). The risk of renal 'death' increased by 5.3% per 0.1 increase of the uromodulin index (HR 1.053, 95%CI 1.021-1.1086, p=0.001) independently of gender, age, proteinuria, genotype, and renal diagnosis.

Conclusions: In children with CKD uromodulin excretion is independently affected by genotype, gender, renal disease type and renal function. Uromodulin excretion is an independent predictor of renal disease progression.

Children and Young Adults with Chronic Kidney Disease Have Neurocognitive Deficits Compared to Healthy Controls Rebecca Ruebner,[1] Nina Laney,[1] Ji Young Kim,[1] Stephen R. Hooper,[3] Jerilynn Radcliffe,[2] Susan L. Furth.[1] *[1]Pediatrics, Children's Hosp of Phila; [2]Psychology, Children's Hosp of Phila; [3]Psychiatry, Univ North Carolina.*

Background: Neurocognitive deficits have been reported in children and adults with CKD.

Methods: As part of the Neurocognitive Assessment and Magnetic Resonance Imaging Analysis of Children and Young Adults with Chronic Kidney Disease (NiCK) Study, we assessed neurocognitive (NC) function in subjects aged 8-25 yrs with CKD Stages 2-5, compared to age matched healthy controls. A battery of NC measures was administered. Relevant tests were grouped into 11 NC domains. Results of NC tests were converted to age-normalized Z-scores. For domains defined by multiple tests, median Z-score of tests in that domain was used. Each NC domain was analyzed in linear regression with test Z-score as the dependent variable and CKD versus control as the main explanatory variable, adjusted for age, race, and maternal education level.

Results: There were 76 CKD subjects (median eGFR 49.3) and 50 controls (median eGFR 95.7 ml/min/1.73 m2). 20 CKD subjects had a transplant; 16 were previously or currently on dialysis. Significantly poorer performance was seen in CKD subjects versus controls in language, visual spatial, short-term memory, working memory, and inhibitory control; no differences were seen in attention regulation, set-shifting, or global ratings of executive functions.

Cognitive domain	Group difference in Z-score (control vs CKD)*	p value
Language	0.355	<0.001
Visual spatial	0.529	<0.001
Verbal short-term memory	0.882	<0.001
Visual short-term memory	0.414	0.036
Verbal working memory	0.711	<0.001
Visual working memory	0.377	0.05
Inhibitory control	0.239	0.039
Attention regulation	0.216	0.09
Set-shift	0.194	0.23
Problem solving	0.136	0.25
Global executive composite	0.383	0.099

*adjusted for age, race, maternal education

Conclusions: Children and young adults with CKD have significantly lower NC abilities, particularly in verbal memory, verbal working memory, and visual spatial domains. Recognition of these areas could influence how health information is delivered to patients with CKD. Future analyses will focus on correlating structural and functional brain imaging studies with NC performance in CKD.

Funding: Other U.S. Government Support

FR-OR027

Association between Body Mass Index and ESRD Outcomes in U.S. Children Elaine Ku, David V. Glidden, Barbara A. Grimes, Chi-Yuan Hsu, Anthony A. Portale, Kirsten L. Johansen. *UCSF.*

Background: Obesity in adult hemodialysis patients associates with decreased mortality, but in children with ESRD, the association of obesity with survival and transplantation has not been examined in large contemporary cohorts. Obesity may lower the probability of receiving a living-donor transplant, as potential related donors may also be obese and therefore excluded from donation. We examined the association between BMI at initiation of RRT and all-cause mortality and odds of receiving a living-donor transplant.

Methods: We analyzed USRDS data on 11,123 children ages 2-18 who developed ESRD between 1995 and 2011 followed through June 2012. BMI at incident ESRD was expressed as age-standardized z-scores and categorized as underweight (z-score < -2), normal weight (z-score -2 to 2), or overweight (z-score >2). We used Cox models to determine the association between BMI category and death, and logistic regression to determine the association between BMI category and odds of receiving any living versus deceased donor transplant in those who received a transplant within 18 months of ESRD onset (adequate time frame for transplant workup and waitlist time accrual). Models were adjusted for demographic factors, cause of ESRD, initial treatment modality (dialysis versus transplant), and calendar year.

Results: Prevalence of overweight was 10.9% and underweight 6.6% at incident ESRD. There were 1350 deaths over 81,141 person-years of follow-up, with median follow-up of 7.0 years. In multivariable analysis, risk of death was higher in overweight (hazard ratio [HR] 1.48 [95% CI 1.26-1.73]) and underweight children (HR 1.42 [95% CI 1.18-1.71]) relative to normal weight children. 5,953 patients received a kidney transplant within 18 months of ESRD onset, of which 55.6% were from living donors. Those who were overweight were less likely to receive a living versus deceased-donor transplant (odds ratio 0.72 [95% CI 0.60-0.87], p=0.001).

Conclusions: Both extremes of BMI were associated with higher risk of death in children, which differs from observations in adult hemodialysis patients. Being overweight may be a barrier to living-donor transplantation in children and its association with higher mortality warrants further investigation.

FR-OR028

Does Tubular Secretion of Creatinine Increase Proportionally as Renal Function Declines? Xuehan Zhang,[1,2] Yen Chung Lin,[3] Charles E. McCulloch,[2] Isabel Elaine Allen,[2] Nisha Bansal,[4] Alan S. Go,[2,5] Chi-Yuan Hsu.[2,5] *[1]Peking Union Medical College Hospital; [2]Univ of California-San Francisco; [3]Taipei Medical Univ Hospital; [4]Univ of Washington; [5]Kaiser Permanente Northern California.*

Background: Numerous textbooks and review articles state that as renal function declines, the proportion of creatinine that is cleared by tubular secretion increases. This is identified as a major weakness of using creatinine clearance(CrCl) to estimate renal function. However, this is based on the assumption that measured glomerular filtration rate (GFR) equals true renal function and does not take into consideration errors in measured GFR (and CrCl) due to short-term biological variability or test imprecisions.

Methods: We analyzed cross-sectional data from 1342 Chronic Renal Insufficiency Cohort (CRIC) Study participants who underwent measurement of glomerular filtration rate by iothalamate clearance (iGFR) and of CrCl by 24-hour urine collection. We examined the CrCl/iGFR ratio classified by categories of iGFR and also by categories of CrCl.

Results: Overall, mean CrCl to iGFR ratio was 1.13. CrCl/iGFR ratio was higher at lower iGFR levels(Table). However, in the same patients, the ratio of CrCl/iGFR was *lower* at lower CrCl levels(Table).

iGFR (ml/min/1.73m²)	<30 (n=250)	30-45 (n=400)	45-60 (n=362)	≥60 (n=330)
median CrCl/iGFR ratio	1.27	1.13	1.07	0.99
CrCl (ml/min/1.73m²)	<30 (n=244)	30-45 (n=341)	45-60 (n=333)	≥60 (n=424)
median CrCl/iGFR ratio	0.78	1.04	1.12	1.21

We were able to replicate these trends in a simulation exercise in which there was no variation in the ratio of CrCl/iGFR with true renal function. Our simulation generated realistic true renal function values with measured iGFR differing from true renal function by only measurement error and CrCl differing from true renal function by a factor of 1.13 and measurement error.

Conclusions: Observations that the CrCl/iGFR ratio increases with lower iGFR can be entirely explained by measurement errors (in both CrCl and iGFR) without the need to postulate that progression of chronic kidney disease leads to actual physiological increase in tubular secretion of creatinine.

FR-OR029

Serum Filtration Markers to Estimate Residual Kidney Function (RKF) without Urine Collection in Dialysis Patients Tariq Shafi,[1] Andrew S. Levey,[2] Friedo W. Dekker,[4] Lesley Inker,[2] Raymond T. Krediet,[5] George J. Schwartz,[3] Wieneke Michels,[5] Tiny Hoekstra,[4] Josef Coresh.[1] *[1]Johns Hopkins Univ; [2]Tufts Medical Center; [3]Univ of Rochester; [4]Leiden Univ Medical Center; [5]Academic Medical Center.*

Background: RKF is a significant contributor to solute clearance but cannot be assessed without urine collection. We hypothesized that filtration markers that are either not removed by dialysis [β-trace protein (BTP)] or partially removed [cystatin C (CYS), β2-microglobulin (B2M)], might allow RKF estimation (eRKF) without urine collection.

Methods: We developed eRKF equations in a derivation cohort (N=74) of dialysis patients in Baltimore with glomerular filtration rate measured by iohexol clearance (mRKF). We validated the equations in the Netherlands Cooperative Study on the Adequacy of Dialysis (NEOCSAD; N=994; mRKF=24-hour urine urea+creatinine clearance). We assessed equations' performance by calculating median bias (mRKF-eRKF), precision (bias' interquartile range) and accuracy (eRKF within ±2ml/min/1.73m² of mRKF).

Results: In the derivation and validation cohorts, mean age was 53 and 61 years; 62 and 60% were male; 51 and 88% were white; and mRKF was 3.0±3.2 and 3.7±2.7 ml/min/1.73m², respectively. Age, sex and race were not included in eRKF models (p≥0.01). Bias was lower in HD compared with PD patients whereas precision was similar. BTP, B2M, CYS and combination improved RKF estimation compared with urea or creatinine.

Performance (95% CI) in NECOSAD						
HD(N=723)	**Urea**	**Creatinine**	**BTP**	**B2M**	**CYS**	**BTP B2M CYS**
Bias, ml/min	1.2 (0.9, 1.4)	0.6 (0.5, 0.8)	0.5 (0.4, 0.7)*	0.9 (0.8, 1)	0.5 (0.3, 0.6)***	0.6 (0.5, 0.7)***
Precision, ml/min	3.1 (2.9, 3.4)	2.5 (2.3, 2.8)	2.1 (1.9, 2.3)	1.9 (1.8, 2)	2.3 (2.1, 2.5)	1.8 (1.7, 2)

FR-OR030

Independent Predictors of Uromodulin Excretion in a Large Population Survey: The CARTaGENE Study Catherine Delmas-Frenette,[1] Stephan Troyanov,[1] Philip Awadalla,[2] Olivier Devuyst,[3] Francois Madore.[1] *[1]Dept of Nephrology, Hopital du Sacre-Cœur de Montreal, Montreal, QC, Canada; [2]Medical and Population Genomics Laboratory, Univ of Montreal, Montreal, Qc, Canada; [3]Inst of Physiology, Univ of Zurich, Zurich, Switzerland.*

Background: Single nucleotide polymorphisms near the *UMOD* gene have been associated with uromodulin excretion and CKD risk. However, the impact of non-genetic factors on uromodulin excretion remains ill-defined.

Methods: A sample of 946 participants from the CARTaGENE survey was genotyped for rs4293393. Urinary uromodulin levels were measured using an ELISA method and expressed as a creatinine ratio. We tested associations between uromodulin and several determinants (gender, BMI, smoking status, diabetes status, mean arterial pressure, GFR [using the CKD-EPI equation], serum HDL cholesterol levels and the fractional excretion [FE] of sodium and uric acid) using univariate and multivariate linear regression after log transformation of uromodulin measurements.

Results: The population studied was 54±9 years old, composed of 51% women and had a mean GFR of 90±14 ml/min/1.73m². The CC/CT genotypes (rs4293393) were present in 32% of participants and were associated with lower urinary uromodulin levels (CT/CC: 21, IQR 10-34 *versus* TT: 27, IQR 12-44 mg/g creatinine, p<0.001). **Table 1** shows predictors of urinary uromodulin:

Variable	Univariate		Multivariate	
	Standardized B	p-value	Standardized B	p-value
Gender (men)	-0.122	<0.001	-0.018	0.621
Current smoking	0.003	0.067	0.055	0.098
BMI (body mass index)	-0.085	0.009	-0.012	0.737
HDL-Cholesterol	0.139	<0.001	0.035	0.354
Diabetes mellitus	0.085	0.009	0.048	0.134
Mean arterial pressure	-0.072	0.026	-0.013	0.713
GFR (CKD-EPI)	0.108	0.001	0.126	<0.001
rs4293393 CT/CC	-0.100	0.002	-0.107	0.001
Fe Na	0.158	<0.001	0.097	0.005
Fe Uric acid	0.038	0.223	0.263	<0.001

Conclusions: This study shows that several factors impact uromodulin excretion. In addition to genetic polymorphism (CT/CC at rs4293393), a lower GFR and lower fractional excretion of sodium and uric acid were independently associated with lower uromodulin excretion. Further studies are warranted to elucidate the mechanisms underlying these associations.

Funding: Private Foundation Support, Government Support - Non-U.S.

FR-OR031

Precise Estimation of Glomerular Filtration Rate from Multiple Blood Biomarkers Josef Coresh,[1] Lesley Inker,[2] Andrew S. Levey.[2] *[1]Epidemiology, Johns Hopkins Univ, Baltimore, MD; [2]Biomedical, Tufts Univ, Boston, MA; [3]Medicine, Tufts Univ, Boston, MA.*

Background: Precisionof estimated GFR (eGFR) is improved by adding serum cystatin C (Scys) to serum creatinine (Scr) and demographics (Inker et al. NEJM 2012). It is unclear if adding other markers in a panel (peGFR) can improve precision to a level comparable to direct measurement of GFR (mGFR).

Methods: Study Population: 200 individuals with mGFR by urinary clearance of I-125 Iothalamate at the AASK F48 (48 month follow-up visit) with mGFRs at F42 and F54 visits within 25% of mGFR at F48. **Laboratory Methods:** Untargeted, GCMS and LCMS-based metabolomic quantification of serum (Metabolon, Inc.). **Data Analysis Methods:** On the log scale, metabolites were ranked by correlation with average mGFR (at F42, F48 and F54). peGFR constructed by stepwise regression excluding creatinine. Precision of eGFR estimate evaluated using root-mean square error (RMSE) and the percent of errors greater than 30%, 20% and 10% from average mGFR (e.g. 1-P30).

Results: Average mGFR was highly correlated with many metabolites (195 negative and 61 positive at $p<10^{-3}$; 12 better than Scr r<-0.7, $p<10^{-16}$; n=188 with data on 780 analytes). peGFR based on the top 5 (excluding creatinine) showed excellent precision and low error rates. Jaffe assay was superior to metabolite discovery assay (M513 1-P30 16.0% versus 28.5%) but both required demographics for good performance while peGFR using the top 5 or 10 metabolites did not.

Table: Precision (RMSE) and Proportion with Errors (1-**P30** = >**30**% between eGFR and mGFR)				
	eGFR without age & sex		eGFR with age & sex	
Analytes in the estimate:	RMSE	1-P30	RMSE	1-P30
Creatinine (M513)	0.29	29.8%	0.26	23.9%
Creatinine (Jaffe)	0.23	17.0%	0.19	8.5%
Top 5 Metabolites (excl. creatinine)	**0.14**	**3.2%**	**0.14**	**2.1%**
Creatinine + Cystatin C	0.16	5.8%	0.14	4.3%
Creatinine + Cystatin C +top5 Metabolites	0.14	1.6%	0.13	1.1%

Conclusions: A panel of markers from a single blood draw can yield precision comparable or better than a single mGFR (RMSE ~0.14, 1-P30~6.9%; Kwong et al. 2010 in AASK). Targeted assays and further validation are ongoing to study clinical implications. [Patents pending by the authors and Metabolon].

Estimated GFR Is Biased by Non-Traditional Cardiovascular Risk Factors

Toralf Melsom,[1,3] Jørgen Schei,[1,3] Trond G. Jenssen,[3] Harald Strand,[2] Bjorn Odvar Eriksen.[1,3] *[1]Nephrology, UNN, Norway; [2]Laboratory Medicine, UNN, Norway; [3]Metabolic and Renal Research Group, UIT.*

Background: Estimated GFR (eGFR) based on cystatin C or creatinine performs equally well in estimating measured GFR, but associates differently with CVD and mortality. Non-GFR related components associated with creatinine or cystatin C may explain this paradox. We investigated the non-GFR related associations between eGFR and two groups of non-traditional CVD risk factors; the L-arginine/dimethylarginine metabolism and insulin resistance (IR).

Methods: GFR was measured with iohexol-clearance in a cross-sectional study of 1627 persons from the general population without CVD or chronic kidney disease.

Results: ADMA, SDMA, the L-arginine/ADMA ratio and IR were associated with eGFRcre after accounting for mGFR. eGFRcys had a similar residual association with SDMA, a borderline significant association with ADMA in the opposite direction, and a stronger residual association with IR compared to eGFRcre.

Generalized estimating equations showing associations between risk factors and eGFR after accounting for mGFR[a]

		Adjusted[d]	
Dependent variable	**Independent (per SD increase)**	**Estimate[b] (ml/min/1.73m)**	**P[c]**
eGFRcre	L-arginine	-0.7	0.03
	ADMA	1.6	<0.001
	L-arg/ADMA ratio	-1.8	<0.001
	SDMA	2.1	<0.001
	Insulin	-0.1	0.8
	HOMA-IR	-0.8	0.04
eGFRcys			
	L-arginine	-0.4	0.1
	ADMA	-0.6	0.06
	L-arg/ADMA ratio	0.0	1.0
	SDMA	1.3	<0.001
	Insulin	-1.0	0.01
	HOMA-IR	-1.4	<0.001

[a]GEE with eGFR and mGFR as stacked dependent variables regressed on each independent variable to compare the difference in eGFR and mGFR regression coefficients. [b]Difference between eGFR and mGFR estimates. [c]Significance determined by the interaction between each risk factor and eGFR relative to mGFR. [d]adjusted for age, sex, ACE-i, ARB, BMI, BP, chol., gluc.,smoking and ACR.

Conclusions: Non-traditional CVD risk factors are usually not measured in epidemiological studies of eGFR. Thus, adjustment cannot be performed to reduce non-GFR related bias of these risk factors. Our findings indicate that both eGFRcre and eGFRcys are influenced by non-traditional risk factors, and this may bias risk prediction in longitudinal studies.

Change in Measured GFR Does Not Outperform Change in Estimated GFR in Predicting Adverse Outcomes in CKD: Results from the CRIC Study

Elaine Ku, Dawei Xie, Michael Shlipak, Amanda Hyre Anderson, Jing Chen, Alan S. Go, Jiang He, Edward J. Horwitz, Mahboob Rahman, Ana C. Ricardo, James H. Sondheimer, Raymond R. Townsend, Chi-Yuan Hsu. *CRIC Study Group.*

Background: Measured GFR has long been considered the "gold standard" measure of kidney function, but recent studies have shown that measured GFR is not consistently superior to estimated GFR in explaining CKD-related comorbidities. The association between longitudinal changes in measured or estimated GFR and adverse outcomes has not been previously examined.

Methods: We studied 942 CKD patients who had at least 2 of the following determined concurrently: iothalamate GFR (iGFR), estimated GFR by creatinine (eGFRcre, MDRD equation), and estimated GFR by cystatin C (eGFRcys, Stevens 2008). 839 of these patients also had 24-hour urine creatinine clearance (CrCl) measures. We examined the associations between changes in these parameters and risk of ESRD, cardiovascular (CVD) events (MI, HF, CVA, and PAD), and all-cause mortality using univariate Cox models.

Results: Declines in iGFR (as a continuous and dichotomized predictor) were not consistently more strongly associated than declines in eGFR with risk of ESRD or CVD events.

Decline in kidney function measured by	**ESRD** Hazard ratio [HR] (95% CI) for every 5 mL/min/1.73 m^2 decrease over 2 years	C-statistic	**ESRD** HR comparing most negative slope tertile versus all others	C-statistic
iGFR	1.28 (1.20, 1.36)	0.72	2.85 (2.01, 4.03)	0.65
$eGFR_{cre}$	1.54 (1.44, 1.66)	0.76	4.54 (3.16, 6.52)	0.70
$eGFR_{cys}$	1.31 (1.23, 1.40)	0.70	2.09 (1.48, 2.96)	0.61
CrCl	1.03 (1.00, 1.05)	0.60	1.51 (1.06, 2.14)	0.56
	CVD event		**CVD event**	
iGFR	1.12 (1.03, 1.20)	0.59	1.62 (1.10, 2.40)	0.55
$eGFR_{cre}$	1.22 (1.11, 1.36)	0.60	1.91 (1.30, 2.80)	0.59
$eGFR_{cys}$	1.10 (1.02, 1.20)	0.57	1.13 (0.76, 1.70)	0.54
CrCl	1.00 (0.97, 1.03)	0.50	0.90 (0.60, 1.36)	0.51

There was no association between death and change in any of the kidney function measures.

Conclusions: Decline in iGFR is not consistently superior in predicting adverse outcomes in CKD than decline in eGFR (even when earlier generations of estimating equations were used). These results question continued acceptance of iGFR as the "gold standard" measure of kidney function.

The Association of Maternal Obesity with Infant Congenital Abnormalities of the Kidney and Urinary Tract in Washington State

Ian R. Macumber,[1] Nicolae Leca.[2] *[1]Seattle Children's Hospital; [2]Univ of Washington Medical Center.*

Background: Congenital abnormalities of the kidney and urinary tract (CAKUT) are diagnosed in up to 1% of pregnancies and account for 20-30% of the abnormalities identified in the prenatal period. In previous studies, maternal obesity has been associated with congenital malformations in offspring. Our aim was to evaluate the association between maternal obesity and CAKUT in offspring.

Methods: We conducted a population-based, case control study using linked birth-hospital discharge records from Washington State, 2003-2012. We identified 3,221 cases using ICD-9 codes. Controls were defined as births without any classifying ICD-9 codes, matched to cases by year of birth in a 4:1 ratio.

Results: We found no parental factors that altered the OR estimate substantially; thus we reported the crude OR. Compared to controls, mothers giving birth to infants with CUTA were more likely to be obese (OR=1.26, 95% CI=1.14-1.40). We found a significant positive trend between odds of CAKUT in offspring and higher categories of obesity (score test for trend of odds p<0.0001). This association remained significant in offspring with isolated CAKUT (OR=1.20, 95% CI 1.07-1.35). Maternal overweight was not associated with CAKUT in offspring.

Association Between Maternal Weight Category and CAKUT in WA State 2003-2012

	Controls		**Overall CAKUT**		**OR**	**95% CI**	**Renal Anomalies**		**OR**	**95% CI**
	No.	**%**	**No.**	**%**			**No.**	**%**		
Normal BMI	5608	49.8	1271	46.6	1.00	Ref	981	46.1	1.00	Ref
Overweight	3044	27.0	712	26.1	1.03	0.93-1.14	561	26.4	1.05	0.94-1.18
Obese	2603	23.1	745	27.3	1.26	1.14-1.40	583	27.4	1.28	1.14-1.43
Obese Cat I	1493	57.4	419	56.2	1.24	1.09-1.40	327	56.1	1.25	1.09-1.44
Obese Cat II	680	26.1	187	25.1	1.21	1.02-1.44	149	25.6	1.25	1.04-1.51
Obese Cat III	430	16.5	139	18.7	1.43	1.17-1.74	107	18.3	1.42	1.14-1.78

Conclusions: Our results show a robust positive association between maternal obesity and CAKUT in offspring. In addition, we show for the first time an obesity severity effect on the association with CAKUT in offspring. This research provides additional evidence for the public health importance of obesity, particularly as a modifiable risk factor.

Payer Impact of Anemia Management Among Medicare Insured Dialysis Patients During the Implementation of the ESRD Prospective Payment System (PPS)

James B. Wetmore,[1] Craig Solid,[1] Spyridon Tzivelekis.[2] *[1]Chronic Disease Research Group, Hennepin County Medical Center, Minneapolis, MN; [2]Amgen, Inc., Thousand Oaks, CA.*

Background: Since the 2011 implementation of the ESRD PPS and the FDA label changes for erythropoietin stimulating agents (ESAs), hemoglobin (Hb) concentrations have declined while red blood cell (RBC) transfusion rates have risen. CMS intended to reduce outpatient dialysis costs; however, whether these reforms reduced anemia management costs or merely shifted them to other payers is uncertain.

Methods: Using 2009-2011 U.S. Medicare ESRD data, including Parts A and B claims, we identified maintenance hemodialysis patients from facilities that initially enrolled 100% into the ESRD PPS. Outpatient (OP) transfusion- and dialysis-related costs were identified and summed at the facility level, with a per patient per month (PPPM) cost calculated. Patterns of ESA and IV iron use, Hb concentrations, and transfusion rates were also analyzed.

Results: Approximately 4,200 facilities were included over the study period; the number of eligible patients per facility, as well as the basic demographics of those included, remained relatively stable, except time on dialysis, which increased slightly. From 2009-2011, the distribution of the median % of patients per facility with Hb < 10 g/dL in a given month shifted upwards (from 9.4% to 18.2%). While the OP transfusion rates remained relatively stable, dialysis facilities saw the mean number of inpatient (IP) transfusions for patients dialyzing at their facility increase by > 20%; the mean PPPM OP transfusion-related ($5-$6) and dialysis-related (~$2,300) costs per facility remained relatively stable over the same time period.

Conclusions: Although on a PPPM basis OP transfusion-related costs to Medicare did not significantly change from 2009 to 2011, the marked increase in IP transfusions, the most common (~80%) site of transfusions, suggests that part of the cost burden of anemia management in dialysis patients has been shifted from dialysis facilities to the hospital IP setting. Further exploration to determine the economic burden to payers when maintenance dialysis patients receive IP RBC transfusions is warranted.

FR-OR036

Evaluation of the Annual Red Blood Cell Transfusion Rate in Patients on Dialysis before and after the Implementation of the New Prospective Payment System (PPS) Allan J. Collins,[1] Scott Jackson,[1] Yi Peng,[1] Anne C. Beaubrun,[2] Keri Monda,[2] Brian D. Bradbury,[2] David T. Gilbertson.[1] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]Amgen, Inc., Thousand Oaks, CA.*

Background: On January 1, 2011, the Centers for Medicare and Medicaid Services implemented a new PPS, bundling payment for injectable drugs for dialysis patients. This change, along with clinical trial-based FDA changes to ESA labeling to increase safety, led to a decline in ESA doses and Hb levels. This study evaluated transfusion event rates before and after PPS implementation.

Methods: We used Medicare ESRD yearly standard analytical files, which allow for the most complete identification of transfusion events, to create yearly cohorts, 2008-2011. Each cohort comprised patients who were dialyzing as of January 1 of the year. Each patient was followed for transfusion events from January 1 until death, kidney transplant, loss to follow-up, or December 31 of the year.

Results: Between 2008 and 2010, annual transfusion rates were 337.3 to 340.5 per 1000 patient-years (PY). Rates increased to 411.0 transfusions per 1000 PY in 2011 (21.8% increase between 2008 and 2011). Rates were consistently higher in PD versus HD and also varied consistently over time within groups defined by age, sex, race, and dialysis vintage.

Conclusions: Concomitant with lower ESA doses and Hb levels, transfusion rates increased after implementation of the ESRD PPS and the label change. Balancing higher risk of adverse events due to high hemoglobin levels against the consequences of increased transfusion rates will be important.

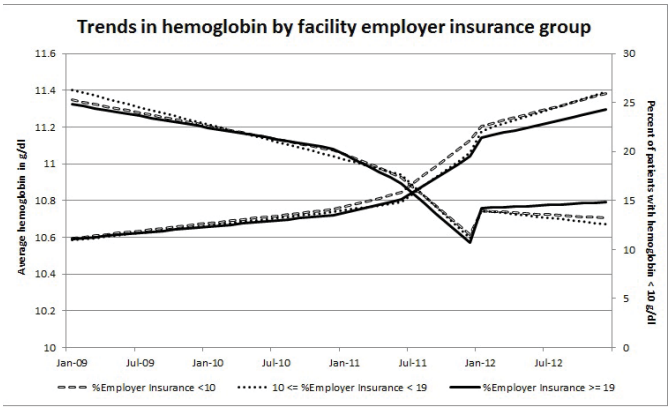
FR-OR037

Changes in Hemoglobin under the Dialysis Prospective Payment System (PPS) by Facility Payer Mix Marc Turenne,[1] Purna Mukhopadhyay,[1] Jeffrey Pearson,[1] Elizabeth L. Cope,[1] Chad M. Cogan,[1] Brenda W. Gillespie.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor; [2]Univ of Michigan, Ann Arbor.*

Background: The Medicare ESRD PPS set fixed payment rates for outpatient dialysis-related services, which increased risk to facilities that payments may not cover the cost of caring for some patients. These financial risks are likely to be greater for independent dialysis facilities, especially those with relatively few privately insured patients for whom payment rates may be higher.

Methods: We used Medicare dialysis claims to examine trends in Hgb values from 77,000+ Medicare dialysis patients in over 530 independent dialysis facilities each month from 2009-2012. We fitted mixed models of average Hgb and the percent of patients with Hgb<10 by facility month, with spline points corresponding to key payment and regulatory changes and adjustment for repeated facility observations, to compare three groups of facilities: low, moderate, or higher levels of employer insurance (EI) among incident patients.

Results: Similar initial trends for all three facility groups in 2009-10 were followed by a greater decline in predicted average Hgb and a greater increase in predicted Hgb<10 in the post-PPS period for facilities with low/moderate EI (p<0.0001).



Similar trends by facility EI group were observed for black and non-black patients. Facilities with low/moderate EI were more likely to be in rural areas (24% and 19%, respectively) than those in the high EI group (10%).

Conclusions: There appear to be emerging differences in Hgb levels in independent facilities based on facility payer mix, which may have a disparate impact on rural populations. In addition to evaluating the overall impact of the PPS and other recent policy and regulatory changes, it is important to consider the role of potential mediating factors such as facility payer mix that could have implications for health disparities.

FR-OR038

Decreasing the Cost of Anemia Treatment, in Hemodialysis Patients, Through Splitting of Iron and Darbepoetin Doses Marco Oliveira Mendes,[1] David Navarro,[1] Ana Azevedo,[2] Cristina Jorge,[1] Patrícia Matias,[1] Ana Carina Ferreira,[2] Bruno Costa Pinto,[1] Fernanda Gomes,[1] Célia Gil,[1] Manuel A. Ferreira,[1] Ines Aires.[1] *[1]Nefrologia, Nephrocare de Vila Franca de Xira, Vila Franca de Xira, Lisboa, Portugal; [2]Nefrologia, Dialverca, Alverca, Lisboa, Portugal.*

Background: As erythropoiesis is a continuous process, we hypothesized that smaller doses of darbepoetin alpha (EPO) administered more regularly, could result is less variations of its seric levels and be more "physiologic" and effective. In a prevalent HD population already exposed to iron splitting, we evaluated the hypothetical additive effects of the EPO splitting in "mini-doses".

Methods: A 34-month prospective study was performed in a cohort of 110 pts, with mean age of 67.9±14.2 years, 50.9% female, 36.3% diabetics, with mean HD time of 85.3±49.4 months. In the first 12 months of the study (T1), the usual dose regime for EPO (weekly, every other week or monthly) was unchanged. In the following 22 months (T2), EPO doses were divided into multiples of 10 µg and distributed among the maximum possible of HD sessions. The same membrane (FMC-Cordiax) and dialysis method (on-line hemodiafiltration) was used throughout the study. Paired T-student and Wilcoxon analysis were performed.

Results: After EPO splitting we verified a slight decrease in hemoglobin levels (T1: 11,45±0,61 g/dl versus T2: 11,31±0,62 g/dl; $p < 0.01$), but with a remarkable decrease in EPO consumption (T1: 1,34±1,83 µg/Kg versus T2: 0,8±1,48 µg/Kg; $p < 0.001$) and in the erythropoietin resistance index (ERI) (T1: 5,87±8,90 IU/Kg/week versus T2: 3,5±7,53 IU/Kg/week; $p < 0.001$). We also observed an increase in ferritin (T1: 490±138 µg/L versus T2: 560±149 µg/L;$p < 0.001$) and in CRP levels (T1: 8,91±8,27 mg/L versus T2: 10,87±9,53 mg/L; $p < 0.001$), with the same consumption of iron (T1: 1,62±1,71 mg versus T2: 1,82±1,52 mg; $p = 0.172$). No correlation between ferritin and CRP levels was found.

Conclusions: From these results, we conclude that the splitting of iron and EPO in "mini-doses" is highly effective and allows a significant decrease in the costs of anemia treatment. Larger and randomized studies are needed to exclude that this new strategy further induces inflammation.

FR-OR039

Understanding the Recent Increase in Ferritin Levels in U.S. Dialysis Patients Angelo Karaboyas,[1] Hal Morgenstern,[1,2] Jacqueline G. Nolen,[3] Raymond M. Hakim,[4] Kamyar Kalantar-Zadeh,[5] Philip Zager,[6] Ronald L. Pisoni,[1] Friedrich K. Port,[1] Bruce M. Robinson.[1,2] *[1]Arbor Research Collaborative for Health; [2]U of Michigan; [3]Vifor Pharma; [4]Vanderbilt U; [5]U of Cal-Irvine; [6]U of New Mexico.*

Background: Ferritin levels in U.S. hemodialysis (HD) patients rose dramatically from 2010 to 2012, coincident with changes to reimbursement and ESA prescribing info in 2011. Over this time, ESA dose and hemoglobin (Hgb) decreased; case-mix changed minimally. Clear explanation for the ferritin rise is lacking; here we evaluate possible causes.

Methods: Quarterly trends (2009-13) in Hgb, ESA dose, ferritin, and IV iron dose were summarized from treatment-level data in 8961 Dialysis Outcomes and Practice Patterns Study (DOPPS) patients in 91 U.S. HD facilities.

Results: ESA dose and Hgb declined from 2010 to 2012 (Fig A). IV iron dose rose sharply in Q4 2010, stayed elevated for 1 yr, then returned to 2009-10 levels (Fig B). Ferritin began to rise in 2010 before IV iron dose increased, rose dramatically during 2011, and remained high >1 yr after reduction in IV iron dose. Other findings: (1) Ferritin was not higher due to timing of measurement with respect to IV iron dosing: mean dose over 3 wks before ferritin measurement was 157 versus 137 mg in 2010 versus 2012. (2) DOPPS Practice Monitor data did not show greater iron blocking (e.g., inflammation/infection): mean TSAT and albumin were stable.

Conclusions: The large rise in ferritin after ESA bundling in 2011, sustained into 2013, has received considerable attention because the levels (>800 ng/mL) exceed KDIGO recs and clinical consequences are unclear. Contrary to expectation, rise in IV iron dose was curtailed after 2011 so does not readily explain the persistently high ferritin. High ferritin may reflect retained excess iron due to lower erythropoietic requirements (lower Hgb and ESA dose). To evaluate further, analyses of within-patient changes over time are planned.

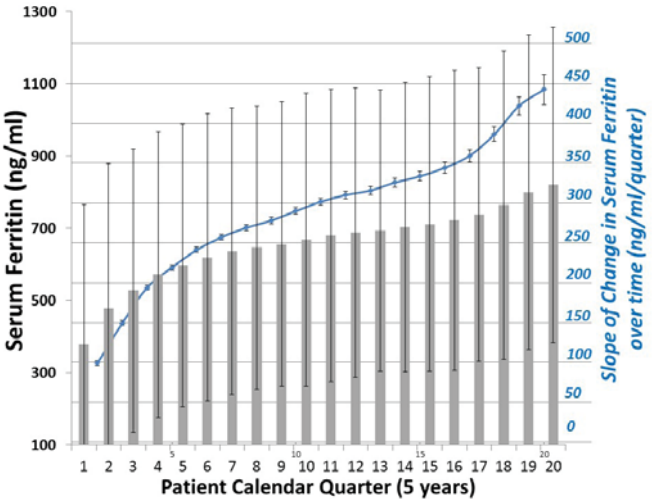
Longitudinal Changes in Serum Ferritin over 5 Years in 134,090 Incident Dialysis Patients

Sepideh Rezakhani,[1] Elani Streja,[1] Vanessa A. Ravel,[1] Connie Rhee,[1] Miklos Zsolt Molnar,[2] Csaba P. Kovesdy,[2] Rajnish Mehrotra,[3] Kamyar Kalantar-Zadeh.[1] *[1]Univ California Irvine, Harold Simmons Center, Orange, CA; [2]Univ Tennsessee, Renal, Memphis, TN; [3]Univ Washington, Renal, Seattle, WA.*

Background: Recent rise in averaged serum ferritin in prevalent dialysis patients in the U.S.A. have been attributed to changes in practice pattern including higher doses of IV iron and/or lower use of ESA. We hypothesized that maintenance dialysis therapy per se may have a bearing on the upward trend of ferritin over time independent of secular trend.

Methods: We examined changes in serum ferritin over up to 5 yrs in 134,090 incident dialysis patients (124,395 HD and 9,527 PD) who initiated dialysis therapy bewteen 2007-2011 in one of the clinics of a large dialysis organization in the U.S.A. We examined mean serum ferritin in each patient quarter (91 days) up to 20 quarters and calculated the rate of change in ferritin from first quarter to the n^{th} quarter using time-varying mixed models.

Results: The 134,090 incident dialysis patients were 61±15 yrs old and included 43% women, 30% African Americans, 14% Hispanics, and 57% diabetics. Mean serum ferritin (±SD) at the start of dialysis (Quarter 1) was 377±388 ng/ml, increasing to 597±391, 655±394, 693±389, and 737±407 ng/ml at the start of Year 2, Year 3, Year 4, and Year 5 of dialysis therapy, respectively. The slope of change in the rate of ferritin change over time continued to show upward trends.



Conclusions: Notwithstanding the current limitation related to medication and their doses, we observed a consistent rise in serum ferritin over time from the start of maintenance dialysis therapy, and this upward movement exhibits no evidence of slowing tendency at any point in time for up to 5 years. Whether the rise in serum ferritin is inherent to dialysis therapy independent of changes in practice pattern warrants additional studies.

FR-OR041

Association between Intravenous Iron Receipt during Infection-Related Hospitalization and Clinical Outcomes among Hemodialysis Patients

Julie H. Ishida,[1] Ben Marafino,[1] Charles E. McCulloch,[1] Lorien S. Dalrymple,[2] R. Adams Dudley,[1] Barbara A. Grimes,[1] Kirsten L. Johansen.[1] *[1]UCSF; [2]UC Davis.*

Background: Guidelines for the treatment of anemia of chronic kidney disease have recommended withholding intravenous (IV) iron in the setting of active infection. However, no data specifically supports this recommendation, and there is a critical need for investigation of how clinical outcomes differ according to receipt of IV iron in the setting of infection among hemodialysis patients.

Methods: From the USRDS, we identified 23,306 Medicare-covered adults on in-center hemodialysis who had received IV iron within 14 days of their first hospitalization for bacterial infection in 2010. Using logistic, Cox, and linear regression models in which we adjusted for demographics, comorbidities and the infected organ system, we evaluated the association between continued receipt of IV iron (any dose or duration) versus no receipt of IV iron during the infection-related hospitalization (IRH) and all-cause mortality (within 30 days of admission and in 2010), need for ICU/CCU care, readmission for IRH within 30 days of discharge, and length of hospital stay (log-transformed).

Results: There were 2,518 patients who continued to receive IV iron during their first IRH in 2010. Continued receipt of IV iron was not associated with age, dialysis vintage or comorbidities. There were 2,684 deaths within 30 days of admission and 7,059 deaths in 2010 with a median follow-up time of 173 days (25-75^{th} percentiles: 78-271 days). Continued receipt of IV iron during an IRH was not associated with adverse outcomes in hemodialysis patients (Table).

Outcome	Estimated IV iron association	95% CI
All-cause 30-day mortality	OR 0.91	0.76-1.08
All-cause mortality (2010)	HR 0.94	0.86-1.03
ICU/CCU care	OR 0.92	0.83-1.03
30-day IRH readmission	OR 1.06	0.89-1.25
Length of stay	1.9% fewer median days with continued IV iron receipt	-5.3 to +1.7%

OR = odds ratio, HR = hazard ratio, CI = confidence interval

Conclusions: Our analysis does not support a guideline recommendation to withhold IV iron in the setting of active infection among hemodialysis patients.

Robust Treatment for Renal Anemia Increase Frataxin Level in Parallel with the Improved Mitochondria Metabolism and Oxidative Stress in ESA-Hyporesponsive Anemic Patients on Maintenance Hemodialysis (MHD)

Yukiko Hasuike,[1] Wataru Fukao,[2] Kazuhiro Toyoda,[2] Satoko Masachika,[2] Yuki Morikami,[1] Tomoko Kimura,[1] Kiyoko Yamamoto,[1] Sayuri Kawada,[1] Kosuke Mizusaki,[1] Soshi Yorifuji,[1] Mai Oue,[1] Shoji Kaibe,[1] Mana Yahiro,[1] Aritoshi Kida,[1] Masayoshi Nanami,[1] Takeshi Nakanishi.[1] *[1]Div of Kidney and Dialysis, Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan; [2]Kidney and Dialysis, Meiwa Hospital, Nishinomiya, Japan.*

Background: In MHD, the disturbance of iron regulation for erythropoiesis could cause hyporesponsiveness to erythropoiesis stimulating agents (ESA). We previously reported the decrease in frataxin, an iron regulator, and a significant association between frataxin and oxidative stress in MHD *[Clin Exp Nephrol 2012]*. The effects of robust treatment using longer-acting ESA on hepcidin level, iron regulation, and redox status were investigated.

Methods: The ESA-hyporesponsive anemic HD patients without iron deficiency (serum ferritin ›250 ng/ml) were recruited (N=20) and administrated darbepoetin-α weekly whose dose was adjusted to increase hemoglobin up to 11.0 g/dl. Factors related to iron regulation (ferritin, frataxin, hepcidin) and markers of oxidative stress (advanced oxidation protein products (AOPP), pentosidine, GSH/GSSG ratio) were investigated during the 6 months period.

Results: During the 6 months period, hepcidin levels were significantly decreased by 25.3% (137.3±19.1 ng/ml to 102.5±9.5 ng/ml, p=0.0061) with a significant reduction of ferritin (median 510 ng/ml to 415 ng/ml, p=0.0032).Frataxin protein were significantly increased compared with that at start (202.9±7.1 ng/gHb, versus 155.5±4.7 ng/gHb, p<0.0001). GSH/GSSG ratio tended to increase (p=0.0825) and both AOPP and pentosidine tended to decrease (p=0.0872, 0.0978).

Conclusions: The robust treatment of renal anemia may increase frataxin and improve mitochondrial iron metabolism in MHD, which could subsequently parallel with the improvement of iron metabolism and oxidative stress. Further studies may be necessary to better elucidate the biological usefulness of ESA.

FR-OR043

Is Erythropoietin Resistance Index (ERI) Merely a Proxy for Inflammation?

Anirudh Rao,[1] Julie A. Gilg,[1] Fergus J. Caskey.[1,2] *[1]UK Renal Registry, Bristol, United Kingdom; [2]Univ of Bristol, Bristol, United Kingdom.*

Background: Inflammation contributes to EPO resistance with ERI being increasingly used to measure EPO resistance and as a predictor for adverse outcomes. **Aim:** To describe the prevalence of high ERI, to identify factors associated with high ERI and 1 year survival.

Methods: Prevalent dialysis patients submitted to UK Renal Registry (UKRR) on 31st December 2011 were included. ERI was calculated as the weekly weight-adjusted dose of ESA divided by the hemoglobin level. Patients were stratified into 3 groups ERI <5; ERI=5–15, ERI>15 IU/kg/week/g per dl. Statistical analysis was by logistic models and Cox proportional hazards models as appropriate.

Results: Analysis included 6,144 patients from 30 centres for hemodialysis (HD) and 343 patients from 17 centres for peritoneal dialysis (PD) equating to 31% and 11% of prevalent HD and PD patients in UK. In the univariate analysis, dialysis vintage (OR 1.03,p=0.0004) for HD and (OR 1.24,p=0.0007) for PD; ferritin >800 µg/L (OR 1.47,p<.0001) for HD and (OR 4.5,p=.009) for PD; lower albumin (OR 0.92,p=.0001) for HD and (OR 0.90,p=0.002) for PD to name a few were identified as predictors of high ERI.

Table 2 Unadjusted and adjusted 1 year survival, HR and (p-value), for HD & PD patients

	HD (N=5073)			PD(N=343)	
ERI Group	Unadjusted	Adj for age & sex	+ URR, dialysis vintage, ferritin & albumin	Unadjusted	Adj for age & sex
<5	-	-	-	-	-
5-15	1.2 (0.02)	1.3(0.01)	1.2(0.06)	1.2(0.57)	1.7(0.15)
>15	2.4(<.0001)	2.7(<.0001)	2.2(<.0001)	1.9(0.16)	2.6(0.05)

Adjusted stratified analyses, in HD patients to evaluate whether it is the high EPO component of ERI that contributed to the worse outcome, showed that, in patients with an Hb in the 10-12 g/dL range, there was an increasing hazard with increasing EPO dose with nearly three times the risk (HR 2.8, p=0.02) in patients requiring >450 IU/Kg/week versus <50 IU/kg/week.

Conclusions: Despite controlling for ferritin and albumin, high ERI portended mortal outcomes suggesting either residual confounding or as yet unidentified deleterious effect of EPO resistance. Completely disentangling the effect of low Hb and high ESA on mortality is complex. Statistical techniques such as marginal structural modelling might help to better understand cause and effect.

FR-OR044

ESA Hyporesponsiveness Is Associated with Adverse Event in Maintenance Hemodialysis (MHD) Patients, but Not with Iron Storage

Takahiro Kuragano, Takeshi Nakanishi. *Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan.*

Background: It has been reported that hyporesponsiveness to erythropoiesis-stimulating agent (ESA) is associated with adverse events in the maintenance hemodialysis (MHD) patients. However, it has not been well determined whether higher iron storage is associated with the improved response to ESA or better survival.

Methods: In 1086 MHD patients, we measured serum ferritin, Hb, and transferrin saturation (TSAT) levels every 3 month during 2 years. The weekly dose of ESA /Hb (ESA/Hb) level was also calculated as an index of ESA responsiveness index. The associations between ESA/Hb and several adverse events were investigated with the cox proportional hazards model for time-dependent variables.

Results: There was no significant difference in ERI and Hb levels among the patients with serum ferritin levels (< 50, 50 ≤ ferritin < 100, 100 ≤ ferritin < 300, ≥ 300 ng/mL). A significant correlation (p<0.001, R=0.89) between ferritin and Hb was found only in the patients with ferritin levels <50. In LASSO regression analysis, high dose (>50mg/week) of intravenous iron administration, female, low serum albumin, and use of ACE-I were selected as significant predictors of higher ESA/Hb (>280), but serum ferritin and TSAT were not. Patients were divided into 4 groups according to their ESA/Hb and ferritin levels. In time dependent Cox hazard model, the risk for CCVD (p=0.029, HR: 5.28) and hospitalization (p=0.087, 1.98) were significantly higher in patients with high ESA/Hb (>280) and high ferritin (≥100 ng/mL) than those high ESA/Hb (>280) and low ferritin (<100 ng/mL).

Conclusions: In patients with ferritin < 50, Hb was dependent on ferritin, but not in those with ferritin ≥ 50. Although the patients with the hypo-responsiveness to ESA had higher risk for CCVD and hospitalization, ESA/Hb were not related to the iron storage. Among patients with hyporesponsiveness to ESA, higher serum ferritin levels bears higher risk for CCVD and hospitalization. We concluded that excessive iron storage did not necessarily lead to the improvement of the responsiveness to ESA in MHD patients.

FR-OR045

Phosphorus Binding with Ferric Citrate Is Associated with Reduced Hospitalizations and Costs for Cardiac, Gastrointestinal, and Infection-Related Causes

Roger A. Rodby,[1] Robert M. Niecestro,[2] T. Christopher Bond,[3] Mohammed Sika,[4] Jamie P. Dwyer,[4] Julia Lewis,[4] Kausik Umanath.[5] *[1]Rush Univ Medical Center, Chicago, IL; [2]Independent Consultant, Pocono Pines, PA; [3]Covance Market Access Services, Inc, Gaithersburg, MD; [4]Vanderbilt Univ, Nashville, TN; [5]Henry Ford Hospital, Detroit, MI.*

Background: In a Phase III study of 441 ESRD subjects, the iron-based phosphate binder ferric citrate (FC) provided equivalent phosphorus control while increasing and maintaining iron stores compared to an active control (AC) group of sevelamer carbonate and/or calcium acetate. Due to the effect of FC on iron stores, subjects also received significantly less intravenous (IV) iron and erythropoiesis-stimulating agents (ESAs).

Methods: Two blinded physicians (Covance Market Access) examined the records of serious adverse events (SAEs) from the active control period of the trial and mapped the hospitalizations to diagnosis-related groups (DRGs) based on standard billing practices. Medicare 2011 payment rates were applied to these DRG designated admissions, and inflated to 2013 dollars. Costs were cumulated and expressed as mean cost per patient year. This analysis focuses on three areas of morbidity potentially related to use of IV iron and ESAs in this patient population.

Results: FC-treated subjects had lower hospitalization rates than AC-treated subjects in all three system-organ classifications (considered independent categories). Per-patient per-year (PPPY) cost savings were also substantial in each of the three categories: from $896 to $1033 per category.

	Cardiac		Gastrointestinal		Infection	
	AC (n=149)	FC (n=289)	AC (n=149)	FC (n=289)	AC (n=149)	FC (n=289)
Subject-years	140.8	242.2	140.8	242.2	140.8	242.2
Events/100 subject-yrs	9.95	6.19	18.47	10.32	20.60	17.75
Total cost	$257,960	$193,602	$288,607	$249,294	$442,051	$543,608
Cost/subject-yr	$1832	$799	$2050	$1029	$3140	$2244
Savings with FC	$1033 PPPY		$1021 PPPY		$896 PPPY	

Conclusions: FC-treated subjects experienced substantially lower hospitalization rates and costs related to cardiac, gastrointestinal, and infection-related events compared to AC-treated subjects.

FR-OR046

Reduced Hemodialysis Patient Hospital Admissions and Readmissions Associated with Right TraC (RT) Transitions of Care Program

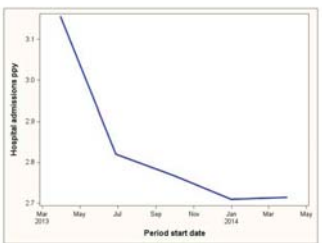
Andrew D. Howard,[2] Rebecca L. Wingard,[1] Kathryn A. McDougall,[1] Billie Axley,[1] Cathleen Okeefe,[1] Janice B. Sitzlar,[1] Sharon Deluca,[1] Fern Parlier,[1] John W. Larkin,[1] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Fresenius, Waltham, MA; [2]Metropolitan Nephrology Associates, Clinton, MD.*

Background: The 30-day readmission rate for hemodialysis (HD) patients (pts) is high at 36%. The Right TraC™ Program was designed to address multiple factors aimed at reducing readmissions.

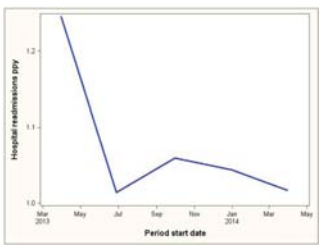
Methods: 28 HD clinics participated in RT. Phase I (began Apr 2013): Staff used admit- and post-hospital checklists including enhanced exchange of pt information, rapid anemia management, oral nutritional supplements, target weight assessment, medication review, and pt counseling for "red flag" symptoms. Phase II (Feb 2014): telephonic case management for 30 days post-discharge. Phase III (Mar 2014): Dialysis Link centralized transitional care information exchange in 9 clinics. Hospital admission and readmission rates per pt year (ppy) for each quarter from April 1, 2013 to March 31, 2014 were computed. Comparisons were made using Poisson regression with log of exposure days as offset.

Results: For the 2542 pts in RT, hospital admissions ppy decreased from 3.2 in Q2 of 2013 to 2.71 in Q1 of 2014, while hospital readmissions ppy decreased from 1.25 to 1.02 during this time. Poisson regression between Q2 of 2013 and Q1 of 2014 showed significant differences between periods (p<0.01). Crude comparison between these periods suggests 75 admissions were avoided. Analysis of matched control clinics based on clinic size, urban/rural setting, and baseline hospital admission and readmission rates showed that RT clinics had a larger decline in admissions (results not shown).

Panel 1. Hospital Admission Rate



Panel 2. Hospital Readmission Rate



Conclusions: The RT Program in its early stages has demonstrated reduced hospital admission and readmission rates. More time and further analysis are needed to demonstrate which components of RT have the most significant impacts on outcomes.

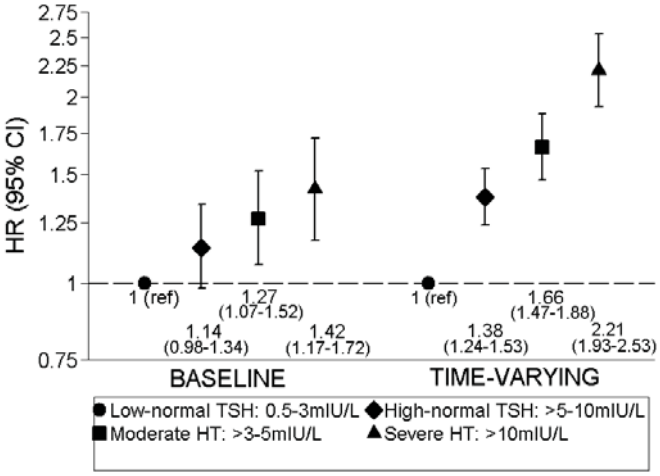
FR-OR047

Hyperthyrotropinemia and Mortality in a National Incident Hemodialysis Cohort Connie Rhee,[1] Steven B. Kim,[1] Bahattin T. Oztan,[1] Jiaxi Wang,[1] Daniel L. Gillen,[1] Rajnish Mehrotra,[2] Steven M. Brunelli,[3] Csaba P. Kovesdy,[4] Gregory Brent,[5] Kamyar Kalantar-Zadeh.[1] *[1]UCI, Irvine, CA; [2]Univ of Washington, Seattle, WA; [3]DaVita Clinical Research, Minneapolis, MN; [4]Memphis VAMC, Memphis, TN; [5]UCLA, Los Angeles, CA.*

Background: Hemodialysis (HD) patients have a higher risk of both hypothyroidism (HT), defined by elevated thyrotropin (TSH), and cardiovascular (CV) mortality. In the general population HT is a CV risk factor, but data examining the HT-mortality association in HD patients are inconsistent.

Methods: We studied a 5-year cohort (1/2007-12/2011) of adult incident HD patients from a large national dialysis organization with ≥1 serum TSH level(s) during their baseline HD quarter. We examined the association between baseline HT versus euthyroidism (TSH >5 versus 0.5-5mIU/L, respectively) with all-cause mortality using case-mix adjusted traditional Cox models. To address variations in thyroid function over time, we examined the association between time-dependent HT versus euthyroidism with mortality using time-dependent Cox models. In parallel analyses, we examined granular categories of thyroid function (low-normal TSH, high-normal TSH, moderate HT, severe HT).

Results: Among 8840 patients, 22% had HT at study entry. In analyses of baseline and time-dependent thyroid function, HT was associated with higher death risk: HR (95%CI) 1.29 (1.12-1.48) and 1.72 (1.57-1.89), respectively. Baseline moderate and severe HT were associated with higher mortality versus low-normal TSH; high-normal TSH trended to higher risk but was not statistically significant (Figure). However, in time-dependent analyses, high-normal TSH, moderate HT, and severe HT were incrementally associated with higher mortality.



Conclusions: HD patients with incrementally higher TSH levels have heightened mortality. Further studies are warranted to determine if the HT-mortality association is ameliorated by thyroid hormone replacement.

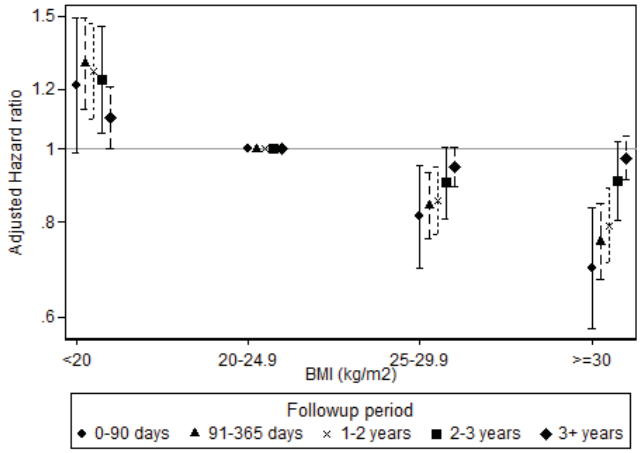
FR-OR048

The BMI/Survival "Paradox" among HD Patients Is Explained By Differential Followup Stephen P. McDonald,[1,2] Mark R. Marshall,[4,5] Kevan Polkinghorne.[1,3] *[1]ANZDATA Registry, Adelaide, SA, Australia; [2]School of Medicine, Univ of Adelaide, Adelaide, SA, Australia; [3]Monash Univ, Melbourne, VIC, Australia; [4]Renal Unit, Middlemore Hospital, Auckland, New Zealand; [5]Baxter Healthcare, Auckland, New Zealand.*

Background: In the general population, BMI in the overweight and obese categories is associated with increased mortality, but reports from the haemodialysis population have shown a survival advantage for haemodialysis patients in these groups. Reports have, however, assumed a constant relationship of BMI with early and with late mortality.

Methods: Using the ANZDATA registry, we examined the relationship of BMI at the start of dialysis with mortality in early and later time periods. Cox models were used to account for confounding by demographic factors and comorbidity. Shared frailty was used to account for "centre effects", and patients were censored at transplantation. Patients who began haemodialysis between 1991 and 2012 (n=33,559) were included.

Results: BMI has progressively increased over the period, with the prevalence of overweght and obesity among those starting HD rising from 25 and 14% respectively in 1991 to 31 and 39% respectively in 2012. In univiariate and multivairiate analyses, there was a substantial survival advantage in the first year among overweight and obese HD patients, but this advantage waned over longer followup periods. Underweight is associated with an increased risk of deaths at all time points of followup.



Interactions were examined with age, comorbidities, year of dialysis start and late referral.

Conclusions: The "paradoxical" association of higher BMI with better survival among HD patient wanes over time, although there is no clear disadvantage seen among this group. These trends in fact are similar to the general population, where the adverse associations of high BMI are mediated by processes such as diabetes and hypertension that take years to become manifest.

FR-OR049

A Personalized, Low-Intensity, Easy to Implement, Home Exercise Program Improves Physical Performance in Dialysis Patients: The Exercise Introduction to Enhance Performance in Dialysis (EXCITE) Trial Francesca Mallamaci,[1] Fabio Manfredini,[2] Davide Bolignano,[1] Silvio Bertoli,[2] Piergiorgio Messa,[2] Alessandro Zuccalà,[2] Pasquale Fatuzzo,[2] Francesco Rapisarda,[2] Luigi Lombardi,[2] Adamasco Cupisti,[2] Giorgio Fuiano,[2] Claudia Torino,[1] Rossella Baggetta,[1] Giovanni Tripepi,[1] Luigi Catizone,[2] Carmine Zoccali.[1,2] *[1]CNR-IFC/IBIM & Nephrology and Transplantation Unit, Reggio Calabria, Italy; [2]On Behalf of the EXCITE Working Group (Renal Research and Academic Units in Ferrara, CNR-IFC Reggio Cal, Milan, Imola, Catania, Catanzaro, Pisa ITALY).*

Background: EXCITE (ClinicalTrials.gov NCT01255969) is a multicenter, randomized, controlled clinical trial testing the effectiveness of a low-intensity, easy to implement, home exercise program on physical performance in dialysis patients.

Methods: From a dialysis population of 648 patients, 297 eligible patients were randomized to the exercise group (n=151) or to the control group (n=146).To set and maintain the target walking cadence patients in the active group were instructed to follow the cadence of an inexpensive metronome (Seiko DM50, Seiko LTD, Japan). Patients in the control group maintained their habitual physical activity.Physical performance was assessed by the 6 Minute Walking Test (6 MWT) and the Sit- to- Stand test at baseline and after 6 months. The primary outcome was the change in physical performance at 6 months.

Results: At baseline the two groups were comparable for demographic and clinical characteristics as well as for physical performance. The 6 MWT improved in the exercise group (baseline: 328±96 m versus 6 months: 369±113 m), but remained unmodified in the control group (baseline: 320 ± 107 m, 6 months 324±116 m) and the between groups difference was highly significant (P <0.001). Similarly, the Sit to Stand test improved in the exercise group (from 20.5±5.0 seconds to 18.3±5.1 seconds), while no change was observed in the control group (20.8±6.1 seconds versus 19.7±6.7 seconds) (P between groups = 0.009).

Conclusions: A personalized, low-intensity home exercise program improves physical performance in dialysis patients. The simplicity and adaptability of the program make it suitable to the needs of a high-risk population such as the dialysis population.

FR-OR050

Upper Urinary Tract Cancer, but Not Kidney Cancer, Is Significantly Associated with Chinese Herbal Medicines Containing Aristolochic Acid in Dialysis ESRD Patient Sheng-Wen Niu,[1,2] Ming-Yen Lin,[2,3] Huei-Lan Lee,[4] Shu-An Yang,[2] Li-Tzong Chen,[5] Shang-Jyh Hwang.[2,4] *[1]Graduate Inst of Medicine, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan; [2]Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung Medical Univ, Kaohsiung, Taiwan; [3]Instrument Technology Research Center, National Applied Research Laboratories, Hsinchu, Taiwan; [4]Faculty of Renal Care, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan; [5]National Inst of Cancer Research, National Health Research Insts, Tainan, Taiwan.*

Background: Popular uses of Chinese herbs containing aristolochic acid (AA) were noted in Taiwan. It had been reported increasing risk of renal disease and urinary tract cancer. However, there is no data on the development risk of renal cancer. The study is

aimed to identify the possibility of Chinese herbs associated with the risk of renal cancer and upper urinary tract cancer (UTUC) in dialysis patient, through Taiwan National Health Insurance Research Database.

Methods: The study population included incident dialysis patients from 1997 to 2008. Patient who was newly diagnosed renal cancer or UTUC during the period was considered as potential case, and a 1:5 matching with ESRD patient without these two cancers. Chinese herb drugs, including 15 brand names for Mu-Tong, and 15 for Xi-Xin, were identified and traced up to the second year before cancer diagnosis. Conditional logistic regression was used and p-value less than 0.05 was consider as statistical significance.

Results: Totally, there were 159 dialysis patients with renal cancer, 493 with UTUC and corresponding to their age- and sex- matched dialysis control subjects for final analyses. After adjusting demographic factors, comorbidities, use of any Chinese herbal medicine containing Mu-Tong (OR:2.3, 95%CI:1.5-3.5) or Xi-Xin (OR: 1.9, 95%CI:1.3-2.8) was associated with the risk of UTUC only, but no association with renal cancer.

Conclusions: The findings indicate that upper urinary tract had a higher risk to develop malignant lesion by herbal medicines containing Mu-Tong and Xi-Xin, but it has no association with renal cancer in dialysis patient.

Funding: Government Support - Non-U.S.

FR-OR051

Influenza Vaccination Reduced Pneumococcal Disease in Incident Dialysis Patients Jordan T. Powner,[1] Thomas Ryan Gallaher,[1] Rhonda E. Colombo,[1] Stephanie L. Baer,[1,2] Lulu Huber,[1] Mufaddal F. Kheda,[1] N. Stanley Nahman,[1,2] Kristina Weis Kintziger.[1] *[1]Dept of Medicine, Georgia Regents Univ, Augusta, GA; [2]Dept of Medicine, Norwood VAMC, Augusta, GA.*

Background: Pneumococcal disease (PnD) may manifest as local or systemic infection and may be fatal, yet there is limited data on PnD in dialysis patients. Because vaccines against PnD are readily available, we queried the UDRDS to further define the incidence and clinical scope of PnD in ESRD patients.

Methods: All incident dialysis cases from 2005-2008 were included. PnD and the administration of pneumococcal (PnV) or influenza (IFV) vaccines were defined using ICD-9 diagnosis or CPT procedure codes. Pneumococcal septicemia and meningitis were categorized as invasive pneumococcal disease (IPD). Additional demographic and clinical data was obtained from form 2728. Individuals were classified by risk category for PnD according to the CDC's Advisory Committee on Immunization Practices (ACIP) guidelines. Data were analyzed using bivariate analysis.

Results: 355,084 dialysis patients met criteria for analysis. There were 10,188 (2.4%) cases of PnD, including pneumonia (N=9,067), septicemia (N=930), pneumococcal infection not otherwise specified (N=154), and meningitis (N=37). Demographics showed: 55% male, 71% white and 65% > age 65 years. Clinical co-variates conferring the greatest adjusted relative risk (aRR) of PnD included ACIP at-risk category (medium risk: aRR 8.86, 95% CI 7.78-10.08; high risk: aRR 8.83, CI 7.71-10.11), age > 65 (aRR 1.62, CI 1.53-1.72), and starting dialysis with a catheter (RR 1.40, CI 1.27, 1.54). IPD was associated with black race (p=0.003). IFV was documented in 35% of patients, PnV in 13%. IFV was associated with a lower risk of PnD (aRR 0.43, CI 0.40, 0.46), but not IPD (p=0.071). An effect of PnV on the development of PnD was not detected.

Conclusions: PnD occurs in ESRD patients and the ACIP guidelines are predictive. Prior IFV may have benefit in preventing PnD. The lack of detectable impact of PnV in preventing infection in this cohort may be attributable to low vaccination rates. These data suggest that improving both IFV and PnV administration may be of therapeutic benefit in preventing PnD.

FR-OR052

Perceived Facilitators of and Barriers to Home Dialysis Use: A Canadian National Survey of Nephrologists Gihad E. Nesrallah,[1] Lianne Barnieh,[2] Braden J. Manns,[2] Andreas Pierratos,[1] David C. Mendelssohn,[1] Catherine M. Clase,[3] Gordon Guyatt.[3] *[1]Nephrology Program, Humber River Hospital, Toronto, ON, Canada; [2]Nephrology, Foothills Medical Centre, Calgary, AB, Canada; [3]McMaster Univ, Hamilton, Canada.*

Background: Barriers to and facilitators of home dialysis (peritoneal dialysis and hemodialysis) are numerous and complex. In order to better understand these factors in the Canadian context, we developed a de novo survey to measure nephrologists' attitudes and perceptions.

Methods: We used in-depth interviews and rigorous qualitative methods to develop a theoretical framework, which led to an initial item (N=60) pool. We used preference ratings and a Delphi process to reduce and refine candidate items into a 47-item survey, which we administered to all Canadian nephrologists providing dialysis and predialysis care to adult (>18 years) patients.

Results: We received 199 complete and 6 partial responses (response rate 41%). We examined item-level responses and used factor analysis to reduce items into domains. An 11-factor solution explained 67% of the variance across 41 item scores, denoting excellent construct validity. Test-retest reliability was 0.70; Crohnbach's α was 0.60-0.95. Domain-level median scores for barriers were low (12-19; possible range 0 to 100), indicating that respondents were unconcerned about most barriers. The highest median domain scores were for facilitators related to nephrologist training (75), funding for personnel and infrastructure (64), physician reimbursement (42), and offering home dialysis to most patients (38). The highest-ranked items included: nurse and lay caregiver-assisted home dialysis, PD in long-term care facilities, pre-dialysis nurse case-managers, multi-disciplinary modality rounds, public funding of water and electricity for home HD, and mandatory fellowship training in home HD. There was little support for home dialysis targets or a mandatory "PD first" policy.

Conclusions: We identified several potential target interventions to promote appropriate use of home dialysis. We also established the reliability and validity of a barrier assessment tool for potential use in other jurisdictions.

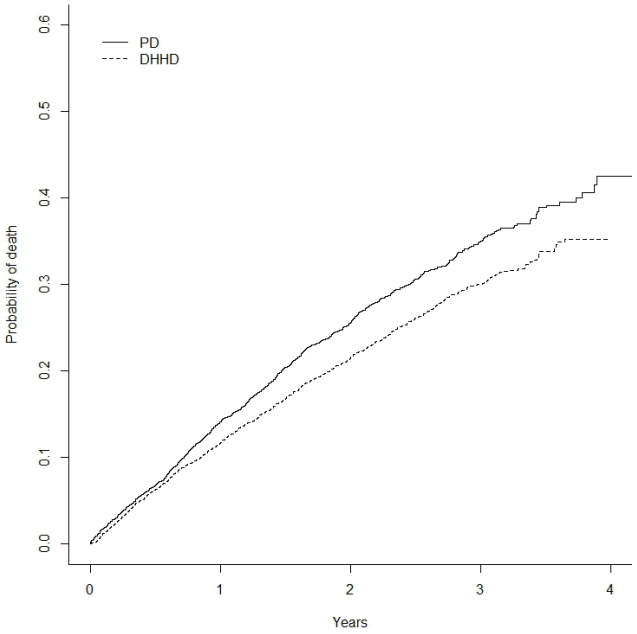
FR-OR053

Lower Risk of Death in Daily Home Hemodialysis versus Peritoneal Dialysis Patients Eric D. Weinhandl,[1] David T. Gilbertson,[1] Allan J. Collins.[1,2] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]School of Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: Daily home hemodialysis (DHHD) and peritoneal dialysis (PD) have grown in popularity, but direct comparisons between these modalities are lacking. We aimed to compare the risk of death in U.S. patients initiating DHHD or PD.

Methods: We identified new DHHD patients, Jan 1, 2007-Jun 30, 2010, from a registry of NxStage System One users and linked them to United States Renal Data System (USRDS) records. We identified new PD patients from USRDS records. For each DHHD patient, we selected 1 matched PD patient according to the date of home dialysis initiation and a 33-factor propensity score of DHHD initiation. We followed patients from home dialysis initiation to the earlier of death or Dec 31, 2010.

Results: We identified 4460 DHHD and 4460 matched PD patients. Cumulative incidence of death for DHHD versus PD was 11.6% versus 14.0% at 1 yr, 21.4% versus 25.5% at 2 yr, and 30.0 versus 34.9% at 3 yr (figure). From Cox regression, the morality hazard ratio (HR) for DHHD versus PD was 0.84 (95% CI, 0.77-0.91); cause-specific mortality HRs were 0.87 (0.76-1.00) for cardiovascular disease and 0.80 (0.62-1.02) for infection. In patients (n = 3092 per group) initiating home dialysis after >6 mo following ESRD onset, the mortality HR was 0.80 (0.72-0.88). In patients (n = 1368 per group) initiating home dialysis within 6 mo following ESRD onset, the mortality HR was 0.95 (0.80-1.13), but HRs varied during the follow-up interval: 1.05 in year 1, 0.89 in year 2, and 0.80 in years 3-4.



Conclusions: DHHD was associated with lower risk of death than PD. The association was most pronounced in patients initiating home dialysis after >6 mo following ESRD onset and after the first year of follow-up in patients initiating home dialysis within 6 mo following ESRD onset.

FR-OR054

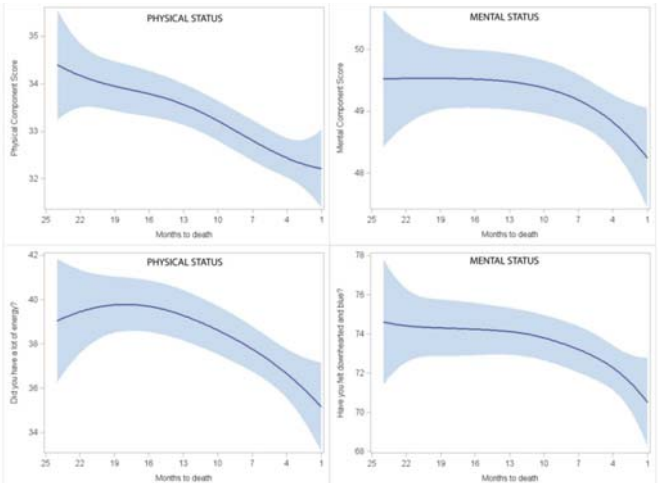
Declines in Hemodialysis Patients' Physical and Mental Component Scores before Death Stephanie Johnstone,[1] Lisa Dombro,[1] Greg S. Garza,[1] Krister Cromm,[1] John W. Larkin,[1] Len A. Usvyat,[1] Eduardo K. Lacson,[1] Peter Kotanko,[2] Jeffrey L. Hymes,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America (FMCNA); [2]Renal Research Inst.*

Background: Prior studies indicate that patients (Pts) experience a decline in several biomarkers such as blood pressure, body weight, and albumin before their demise (Usvyat, KI). We sought to understand whether hemodialysis (HD) Pts' self-assessment of their Health Related Quality of Life (HRQOL) also declines before death.

Methods: All Pts in FMCNA clinics are invited to complete KDQOL surveys annually. Between Jan 1, 2009 and Dec 31, 2012, we analyzed data on all in-center HD Pts treated up to 24 months before and within 30 days preceding death with at least one KDQOL survey. Cubic spline models were constructed to demonstrate trajectory of key KDQOL parameters prior to death. KDQOL areas studied were: 1) the measure relating to physical

status (physical component score and question 10, "Did you have a lot of energy?") and 2) the measure relating to mental status (mental component score and question 11, "Have you felt downhearted and blue?").

Results: We studied 4,227 Pts who died and completed KDQOL surveys; only a range of 105-314 surveys were performed 30 days before death. Both the physical component and mental component scores declined in Pts before death. While the decline in the physical status score appears more linear, the decline in the mental status score is more pronounced approximately 6 months before death.



Conclusions: Our analysis suggests that HD Pts' self-assessment of their physical and mental status deteriorates before death. More frequent measurements with the KDQOL may be needed to properly assess the decline in physical and mental status of HD Pts before death. Outcome studies are needed to identify the impact of behavioral health interventions on Pt perceived HRQOL status and utilization of care during this end of life period.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America

Skeletal Muscle Cytokine Gene Expression after Resistance Exercise in Chronic Kidney Disease Joao L. Viana,[1] Emma L. Watson,[2] Neil J. Greening,[2] Jonathan Barratt,[2] Alice C. Smith.[2] *[1]School of Sport, Exercise and Health Sciences, Loughborough Univ, United Kingdom; [2]Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom.*

Background: Pro-inflammatory genes are up-regulated in the skeletal muscle of chronic kidney disease (CKD) patients contributing to local and systemic inflammation and facilitating muscle atrophy through reduced protein synthesis and increased protein degradation. In healthy individuals, acute resistance exercise (RE) induces a transient inflammatory response that is required for appropriate muscle regeneration and adaptation, but its effects in CKD are unknown. Therefore, we investigated skeletal muscle cytokine gene expression in response to acute RE before and after 8 weeks of RE training in pre-dialysis CKD.

Methods: 18 patients with CKD3b-4 (mean eGFR 23, range 16-36ml/min/1.73m^2; mean age 63, range 45-77 years) were randomised to RE (3 sets of 10-12 leg extensions at 70% maximum, 3/week for 8 weeks; n=11), or control (usual activity; n=7). Quadriceps muscle volume was measured by ultrasonography at baseline and 8 weeks. Muscle biopsies were obtained at baseline and 8 weeks in controls, and baseline, 24h post first training session and 24h post final training session in exercisers. Interleukin-6 (IL-6), monocyte chemoattractant protein-1 (MCP-1) and tumour necrosis factor-alpha (TNF-α) mRNA expression were analysed by RT-PCR.

Results: No changes were seen in the controls. In exercisers, 8 weeks of RE training significantly increased quadriceps muscle volume (baseline 153±9 to 8 weeks 168±11cm^3; P=0.009). 24h after the first RE training session IL-6, MCP-1 and TNF-α mRNA expression were all up-regulated from baseline by medians of 22-fold (P<0.001), 20-fold (P<0.001) and 4-fold (P=0.002), respectively. However, no changes from baseline were observed 24h after the last RE training session.

Conclusions: These data reveal a previously unknown heightened and prolonged inflammatory response to unaccustomed RE in the skeletal muscle of CKD patients, which likely contributes to its impaired regenerative capacity. Fortunately, regular RE training appears to normalize this inflammatory response, which probably contributes to the significant muscle hypertrophy observed.

Muscle Mass and Function following Renal Transplantation Thomas Dienemann, Shaun Bender, Francis Perry Wilson, Peter P. Reese, Jin Long, Mary B. Leonard. *Perelman School of Medicine at the Univ of Pennsylvania, Philadelphia, PA.*

Background: Advanced CKD is associated with sarcopenia and impaired physical function. These deficits are associated with increased morbidity and mortality. Changes in body composition and muscle function in kidney transplant recipients (KTRs) have not been well characterized.

Methods: 60 incident KTRs (48% male, 44% black race, ages 19 – 60 years) were enrolled and DXA measures of body composition [appendicular lean mass index (ALMI, kg/m^2), fat mass index (FMI, kg/m^2)], quantitative CT measures of calf muscle density (mg/cm^3) and dynamometric measures of calf muscle strength (ft-lbs) were obtained at the time of transplantation, and 6, 12, and 24 months. Results were expressed as sex- and race- specific Z-scores relative to age based on 500 healthy controls. KTRs were treated with glucocorticoids rapidly tapered to 5 mg daily.

Results: At baseline, ALMI, muscle density and muscle strength Z-scores were significantly lower in KTRs (all p<0.001) compared with controls. The baseline strength deficit was minimally attenuated to -0.71 (95% CI -0.98, -0.45, p<0.001) with adjustment for ALMI Z-score; muscle density was not associated with strength. ALMI Z-scores recovered rapidly; however, strength deficits persisted at 24 months. FMI increased progressively over 24 months; the prevalence of obesity increased from 18 to 45%. The low muscle density Z-score at 24 months was partially explained by the greater FMI Z-score [adjusted muscle density Z-score = -0.49 (95% CI -0.77, -0.22, p<0.001)].

Z-Score	Baseline Mean±SD	6 Months Mean±SD	12 Months Mean±SD	24 Months Mean±SD	Change between Baseline & 6 Months	Change between 6 & 24 Months
ALMI	-0.52±1.02***	-0.09±1.00	0.01±1.01	0.02±1.01	p<0.001	p=0.06
Muscle density	-0.94±1.07***	-0.64±1.04***	-0.72±1.05***	-0.71±1.04***	p<0.001	p=0.61
Muscle strength	-0.85±1.02***	-0.43±1.01*	-0.32±1.02*	-0.32±1.01*	p<0.01	p=0.34
FMI	0.02±1.03	0.42±1.03**	0.62±1.04***	0.69±1.05***	p<0.001	p<0.001
* p<0.05; ** p<0.01; *** p<0.001 compared w controls						

Conclusions: Renal transplantation is associated with excess adiposity, increased intramuscular fat, and incomplete recovery of muscle function despite improvements in lean mass.

FR-OR057

N-Terminal pro-B-Type Natriuretic Peptide as a Biomarker for Sarcopenia in Prevalent Hemodialysis Patients Misa Ikeda,[1] Hirokazu Honda,[2] Hiroaki Ogata,[3] Fumihiko Koiwa,[4] Eriko Kinugasa,[3] Kanji Shishido,[5] Takanori Shibata.[1] *[1]Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine, Tokyo, Japan; [2]Div of Nephrology, Dept of Medicine, Showa Univ Koto Toyosu Hospital, Tokyo, Japan; [3]Depts of Internal Medicine, Showa Univ Northern Yokohama Hospital, Yokohama, Japan; [4]Div of Nephrology, Dept of Medicine, Showa Univ Fujigaoka Hospital, Yokohama, Japan; [5]Dialysis Center, Kawasaki Clinic, Kawasaki, Japan.*

Background: N-terminal pro-B-type natriuretic (NT-proBNP) was demonstrated as a risk factor for protein-energy wasting (PEW) in prevalent hemodialysis (HD) patients. The aim of this study was to assess an association between NT-proBNP and loss of muscles mass, sarcopenia, as an important element of PEW in HD patients.

Methods: Two hundred and twenty-six prevalent HD patients (mean age 64 year, men 63%, diabetes mellitus state 30%) were recruited for this prospective study. Blood samples were obtained at baseline measuring high-sensitive (hs) CRP, interleukin (IL)-6, adiponectin (ADN) and NT-proBNP. Cardiac function was estimated by ultrasound cardiography. Nutritional state was assessed by subjective global assessment (SGA), body mass index (BMI), normalized protein catabolic rate, and geriatric nutritional risk index. Dual-energy X-ray absorptiometry was performed at baseline and 1 year later and change in total fat mass (TFM) and total lean body mass (TLBM) were estimated.

Results: NT-proBNP was positively correlated with age, hsCRP, IL-6, ADN, LVDd and inversely correlated with BMI, ejection fraction, TFM and TLBM. NT-proBNP level in SGA-positive patients (median 7,195, range 1,340-63,500 pg/mL) was significantly increased as compared with SGA-negative patients (median 2,535, range 508-78,400 pg/mL). NT-proBNP was independently associated with decreased changes in TLBM, but not with changes in TFM, by the multivariate regression model adjusted with confounders (adjusted r^2 0.16, p=0.0003).

Conclusions: NT-proBNP may be a reliable biomarker for PEW in prevalent HD patients, especially those with sarcopenia.

FR-OR058

Association between Fibroblast Growth Factor-23 and Frailty in Elderly Community-Living Adults: The Cardiovascular Health Study
Tomasz Beben,[1,2] Michel Chonchol,[3] Linda F. Fried,[4] Bryan R. Kestenbaum,[5] Mark J. Sarnak,[6] Michael Shlipak,[7] Ian H. de Boer,[4] Joachim H. Ix,[1,2] Dena E. Rifkin.[1,2] *[1]UCSD; [2]VA San Diego; [3]Univ of Colorado; [4]VA Pittsburgh; [5]Univ of Washington; [6]Tufts Medical Center; [7]UCSF.*

Background: Frailty has been previously associated with low 25-OH vitamin D and high parathyroid hormone (PTH) levels. Fibroblast Growth Factor 23 (FGF23) is related to phosphate and vitamin D metabolism and has been associated with cardiovascular and kidney disease. Whether FGF23 is related to frailty is unknown.

Methods: 2970 individuals from the Cardiovascular Health Study (CHS) at the year 9 (1996/1997) study visit had FGF23 levels measured and were assessed for frailty using previously described criteria of weight loss, weakness, exhaustion, slowness, and decreased physical activity. Frailty was defined as ≥3 and prefrailty as 1 or 2 criteria present. Logistic regression was performed with multivariate adjustment for demographics, CVD risk factors, C reactive protein, and kidney function.

Results: The mean age was 78 years; 40% were male, 83% were Caucasian and 16% were African American. The median FGF23 value was 70.8 RU/mL [IQR 53.6-100.4]. 52% were prefrail and 13% were frail. After multivariate adjustment, a doubling of FGF23 level was associated with 33% higher odds of frailty versus nonfrailty and 15% higher odds of prefrailty (Figure). Sensitivity analysis in 1208 subjects who had phosphorus, PTH, and vitamin D measurements showed that these did not meaningfully alter the FGF23-frailty association.

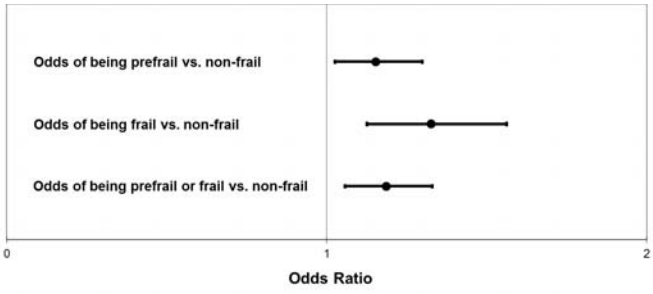

Figure: Odds ratios of prefrailty, frailty, and prefrailty or frailty relative to nonfrailty are presented adusted for age, race, gender, BMI, HTN, diabetes, CHF, CHD, stroke, claudication, CRP, eGFR (cystatin C), and albumin to creatinine ratio.

Conclusions: In a large elderly cohort, higher FGF23 was independently associated with higher odds of frailty and pre-frailty. In the context of previous findings, it is becoming increasingly clear that FGF23 is not only a marker for CVD and mortality, but also for functional outcomes of relevance for geriatric populations.

FR-OR059

Insulin Resistance in CKD-A New Role for the Ubiquitin System in Muscle
Molly Colleen Tokaz, Yanlan Dong, Liping Zhang, William E. Mitch. *Medicine/Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Mechanisms of insulin resistance in chronic kidney disease (CKD) are poorly understood. We reported that CKD activates the signal transducer and activator of transcription 3 (Stat3) in muscle and suppresses phosphatidylinositol 3-kinase/p-Akt activities leading to activation of protein degradation by the ubiquitin-proteasome system (UPS; Cell Metab., 2013 and JASN, 2006). Now we find that CKD increases expression of Fbxo40, a muscle-specific, E3 ubiquitin ligase, in mouse muscles. Since Fbxo40 mediates ubiquitination/degradation of IRS1 (Dev Cell., 2011), we examined if p-Stat3 stimulates Fbxo40 to degrade IRS1 in muscles of mice with CKD or fed a high-fat diet (HFD, 58% kcal from fat).

Methods: We created CKD in mice or fed mice a HFD to create diabetes. We studied muscle-specific Stat3 KO mice or mice treated with a Stat3 inhibitor (C188-9; 12.5mg/kg/d). Insulin (ITT) and glucose tolerance (GTT) tests were measured in both groups and in muscles, p-Stat3, Stat3, p-Akt, Fbxo40, IRS1 and GAPDH were measured. Adenovirus expressing constitutively active Stat3 was transfected into C2C12 myotubes to evaluate signaling pathways. We found Stat3 binding sites in the Fbxo40 gene promoter and performed CHIP assays to examine if activated Stat3 can increase Fbxo40.

Results: In muscles of mice with CKD or HFD-induced diabetes, Fbxo40 and p-Stat3 were increased, p-Akt was decreased; ITT and GTT were both lower. Both Stat3 KO in muscles or C188-9 Stat3 inhibition in CKD or HFD fed mice had lower fasting glucose, improved ITT and GTT and decreased Fbxo40 with higher IRS-1 and p-Akt in muscles versus control mice. C2C12 myotubes overexpressing constitutively active Stat3 had increases in p-Stat3 and Fbxo40 but reduced levels of IRS1 and p-Akt; infection of C2C12 myotubes with lentivirus expressing Stat3-shRNA had suppressed Fbxo40 mRNA and protein. CHIP assay revealed Stat3 associated with Fbxo40.

Conclusions: Activation of p-Stat3 stimulated expression of Fbxo40 to degrade IRS1, suppressing p-Akt in muscle. These results provide a new mechanism for the insulin resistance in CKD and diabetes as both disorders cause degradation of IRS1.

Prevalence, Body Composition and Mortality Associations of Protein-Energy Wasting in Non-CKD and CKD in the U.S.
Srini Beddhu,[1,2] G. Wei,[2] R. Boucher,[2] E. Constantz,[2] Xiaorui Chen,[2] Tom Greene.[2] *[1]SLC VAMC; [2]Univ of Utah SOM.*

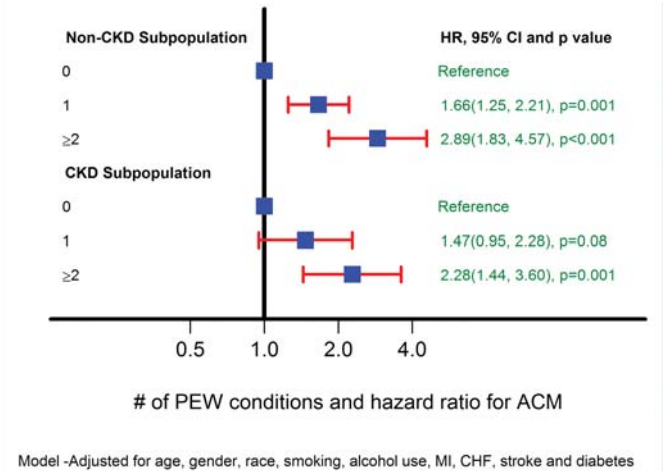
Background: The prevalence and clinical significance of protein-energy wasting (PEW) defined by the International Society of Renal Nutrition and Metabolism (ISRNM) criteria in non-CKD and moderate CKD populations have not been well established.

Methods: 7987 participants in the 1999-2002 NHANES were included. CKD-EPI eGFR < 60 was defined as CKD. Serum chemistry (serum alb < 3.8 g/dl or cholesterol < 100 mg/dl), body weight (BMI < 20 kg/m^2, unintentional wt loss > 10% over 1 yr or body fat% < 10%), muscle mass (mid-arm muscle circumference (MAMC) < 10% of age and gender specific 50th percentile) and dietary protein intake (< 0.6 g/kg/d based on 24h diet recall) were the 4 PEW criteria. Mortality data was through 12/31/2006. The associations of the # of PEW criteria with MAMC were examined in linear regression models and mortality in Cox regression models using survey weights. There were very few with ≥ 3 PEW conditions; hence, these were merged with those with ≥ 2 PEW conditions.

Results: 6.3% had CKD. The mean eGFR were 98 ± 14 and 47 ± 11 in non-CKD and CKD, respectively. Prevalence of the number of PEW conditions and the associations with FFM in non-CKD and CKD are summarized in the table.

#PEW Conditions	Prevelence(%)		β,95% CI for MAMC(cm)*	
	Non-CKD	CKD	Non-CKD	CKD
0	58	48	Ref	Ref
1	32	36	-1.3(-1.6,-1.1), p<0.001	-0.5(-1.1,0.1)
≥2	10	17	-3.7(-4.1, -3.3), p<0.001	-1.5(-2.5,-0.4)

There were 391 and 232 deaths over 41929 and 3527 years of follow-up in non-CKD and CKD, respectively. The associations of # of PEW conditions with mortality in non-CKD and CKD are summarized in the figure.



Model -Adjusted for age, gender, race, smoking, alcohol use, MI, CHF, stroke and diabetes

Conclusions: PEW conditions are highly prevalent and associated with ↓ muscle mass and ↑ mortality in non-CKD and CKD populations in the U.S. Further studies are warranted to determine the etiology and Rx of PEW in the non-CKD and CKD populations.

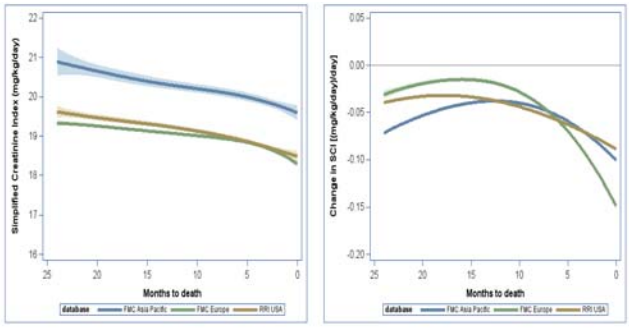
Creatinine Index Dynamics before Death in Chronic Hemodialysis Patients – Results of an International Study
Daniele Marcelli,[1] Len A. Usvyat,[1] Peter Kotanko,[2] Michael Etter,[1] Gero D. von Gersdorff,[3] Aileen Grassmann,[1] Cristina Marelli,[1] Adrian M. Guinsburg,[1] Laura Scatizzi,[1] Inga Bayh,[1] Yuedong Wang,[4] Frank van der Sande,[5] Jeroen Kooman,[5] Bernard J. Canaud.[1] *[1]Fresenius Medical Care; [2]Renal Research Inst; [3]Univ Hospital Cologne; [4]Univ of California; [5]Maastricht Univ Medical Centre.*

Background: Lean tissue mass (LTM) is predictive of survival in HD patients. In health, LTM estimations are based on creatinine excretion. For anuric patients, Canaud [PLoS One, 2014] derived the Creatinine Index (CI): $CI(mg/kg/day)=16.21+1.12x[1\ if\ male;0\ if\ female]-0.06xage\ (years)-0.08xspKt/V_{urea}+0.009xCr_{preHD}(\mu mol/L)$. Here, CI dynamics in the months prior to death and CI survival predictive value were investigated.

Methods: CI was calculated from the MONitoring Dialysis Outcomes (MONDO) initiative database [Usvyat et al, Blood Purif 2013]. Dynamics for 2 years before death were investigated using partially conditional means E(Y(u) | T>u), fitted using quintic splines, and trajectories of first derivatives [Usvyat et al, Kidney Int 2013]. The relationship to all-cause mortality was studied by adjusted multivariate Cox proportional-hazard models.

Results: CI levels for 13,620 HD patients (22 countries) fell by ~1 mg/kg/day in the 2 years before death.



Trend of CI (left) and of CI first derivative (right) in male HD patients (two years preceding death

CI levels were higher for males, and generally highest in Asia. CI decline accelerated ~10-12 months before death and was virtually identical in all regions (except females in Asia). A CI increase of 1 mg/kg BW/day was associated with a 16.5% lower risk of death (HR=0.835; 95% CI:0.812-0.859, p<0.001).

Conclusions: CI, a surrogate of muscle mass, declines as early as 10-12 months before death in an accelerated fashion. The predictive value of CI was demonstrated by regression analysis. This supports the need for following CI. Future trials should address outcome and physical activity and nutritional intervention effects on CI.

FR-OR062

Histologic versus Clinical Remission in Lupus Nephritis (LN) Ana Malvar,[1] Valeria Gabriela Alberton,[2] Cecilia Recalde,[1] Bernarda Fazzini,[1] Bruno Jorge Lococo,[1] Paola Pirruccio,[1] Brad H. Rovin.[3] *[1]Nephrology, Hospital Fernandez, Buenos Aires, Argentina; [2]Pathology, Hospital Fernandez, Buenos Aires, Argentina; [3]Nephrology, State Univ, Columbus, OH.*

Background: Treatment response in LN is defined as resolution of proteinuria and improvement of GFR. Histology is not considered in LN response. Several studies show discordance between long-term clinical and histologic findings, but only a few have systematically examined the histologic response to induction.To examine this question we reviewed protocol kidney biopsies done after LN induction.

Methods: SLE patients(n=69)were biopsied at first presentation of kidney involvement(Bx1)and again after induction treatment(Bx2,mean intra-biopsy interval 8±2 months).All patients had Class III or IV LN, and were induced with steroids plus mycophenolate or cyclophosphamide. NIH activity(AI)and chronicity(CI)indices were calculated.

Results: Clinical and histologic data are shown in the Table.After induction AI decreased and CI increased (P<0.0001for both). At Bx2, 13 patients (19%) had an AI of 0, but 6(46%)of these still had proteinuria ≥500 mg/d (0.75-2.63g/d).In contrast, of the 30(43%)patients who had proteinuria ≤500 m/d, 15(22%) patients had an AI ≥ 4, 8 (11.6%) had an AI ≥ 5, and 2(3%) had an AI ≥ 6. Of the 30 patients who had proteinuria ≤500 mg/d, 19(63%) had a CI≥4 at Bx2.Ten patients(14%)had a CI of 0 or 1 on Bx1 and developed a CI of≥4 at Bx2.

PATIENTS	Bx1			Bx2		
	AI	CI	PROT(g/d)	AI	CI	PROT(g/d)
All	8,5	2,6	2,9	3,5	4	1,1
responders(prot≤500 mg/d,n:32)	7,9	2,6	2,1	3,1	3,7	0,2
non responders(n:37)	8,9	2,5	3,5	3,8	4,1	1,8

Conclusions: After induction 9% of this cohort achieved histologic remission but still had significant proteinuria, while 22% achieved clinical remission, but still had significant histologic activity(AI≥4). Despite intense therapy several patients rapidly developed histologic chronic kidney disease(CKD)with a Bx2 CI≥4. These data suggest that: 1) a repeat kidney biopsy after induction could stratify patients who need typical prolonged maintenance immunosuppression from those who may do well with a shortened maintenance phase; and 2)early use of anti-fibrotic therapies may be necessary to prevent CKD.

FR-OR063

Repeat Renal Biopsies Help to Tailor Immunosuppression in Lupus Nephritis Angela Pakozdi,[1] Dev Pyne,[1] Michael Sheaff,[3] Ravindra Rajakariar.[2] *[1]Rheumatology, Barts Health NHS Trust, London, United Kingdom; [2]Renal Medicine, Barts Health NHS Trust, London, United Kingdom; [3]Histopathology, Barts Health NHS Trust, London, United Kingdom.*

Background: Lupus nephritis (LN) is the major cause of morbidity and mortality in patients with SLE. The role of repeat kidney biopsies (RB) to guide treatment or to predict outcome and prognosis has been controversial. In this retrospective study we focused on histological characteristics of RBs and aimed to identify any clinical variables useful to predict histological changes.

Methods: In a large single-centre cohort of 257 patients from 1988-2014 with biopsy proven LN, 58 (23%) had two or more biopsies (a total of 68 RBs). LN classes based on glomerular pathology were defined according to the ISN/RPS classification. Clinical and laboratory data were obtained from electronic records of patients.

Results: The median time between initial and RB was 33 months [IQR, 15-84]. Caucasians (n=8) had a lower RB rate of 16% compared to blacks (n=37, 33%; p=0.010). Indication for RB was worsening proteinuria (n=38, 71%; of which 23 had associated rising creatinine, 61%), rise in serum creatinine alone (n=6, 11%) and lack of treatment response (n=9, 17%) defined as <50% reduction in proteinuria. At time of RB, 25 (78%) had raised dsDNA, 33 (73%) had low complements. LN class transition occurred in 31 (48%), most commonly from class II or V to III or IV (n=11, 36%). 6 RB (6.8%) showed inactive lesions either due to FSGS or advanced sclerosing LN. 42 (65%) had a change in their treatment regime. Immunosuppression was more likely to be escalated in case of a class switch (87% versus 38%, p=0.002). The histological transition could not be predicted by any serological or biochemical variables.

Conclusions: Over a 1/3 of our LN patients showed histological transition to a more aggressive class, based on which the majority (87%) had treatment escalation. Histological transition could not be predicted by clinical values. Hence, we conclude that RB remains an important tool to guide management of LN, particularly in those with initial class II or V who flare.

FR-OR064

Outcomes of Maintenance Therapy in Patients with Less Severe Lupus Nephritis Previously Randomized to Receive Either Low Dose Cyclophosphamide versus Oral Mycophenolate Mofetil Manish Rathi,[1] Krishan L. Gupta,[1] Ajay Jaryal,[1] Aman Sharma.[2] *[1]Nephrology; [2]Rheumatology, Postgraduate Inst of Medical Education and Research, Chandigarh, India.*

Background: Management of lupus nephritis is always challenging. No trial has compared induction by oral mycophenolate mofetil (MMF) and low dose intravenous cyclophosphamide (CYC) followed by maintenance with azathioprine (AZA).

Methods: This study followed the previous open label, ongoing prospective, randomized trial comparing the efficacy and safety of low dose CYC (Euro-lupus regimen) and oral MMF in subjects with class III, IV, V, III+V, or IV+V LN. Subjects with crescentic LN, serum creatinine >3mg/dl, neurological or pulmonary lupus, ongoing infection, pregnancy and prior CYC or MMF use were excluded. The dose of MMF was 2–3 gm/day for 6 months, while CYC was administered as six fortnightly infusions of 500 mg each. All subjects also received three intravenous methylprednisolone injections initially followed by oral steroids at 1mg/kg up to 2 months and then tapered to a dose of 5-7.5 mg/day. After completion of induction treatment, all subjects were prescribed AZA (2 mg/kg) with low dose steroid.

Results: A total of 55 subjects completed one year of maintenance treatment with AZA after receiving either MMF (n=28) or CYC (n=27) as induction agent. Baseline characteristics were similar except for a higher 24 hour protein excretion in the CYC group. Forty one of total subjects, 74.54%, (n=22 in CYC and n =19 in MMF, p=ns) achieved remission within mean duration 21.81 weeks in CYC arm was and 19.47 weeks in MMF arm. Five patients had resistant disease (MMF =4, CYC=1), six deaths (MMF=5, CYC=1), four lost to follow up (MMF=1, CYC=4) and one patient deviated from protocol. Four subjects, 3 in MMF and 1 in CYC arm had proteinuric flare during follow up and none had nephritic flare. Main adverse events during maintenance phase were cytopenia, herpes zoster and avascular necrosis of femoral head in one patient each. The treatment cost of MMF was ten times more than the CYC therapy.

Conclusions: One year outcome of maintenance phase with azathioprine were similar in low dose intravenous CYC and oral MMF arm in treatment of less severe lupus nephritis.

FR-OR065

Long Term Follow Up of the Rituxilup Steroid Sparing Regimen in Lupus Nephritis Andrew Porter, Marie B. Condon, Anne Frances Doyle, Megan Griffith, H. Terence Cook, Tom Cairns, Liz Lightstone. *Imperial Lupus Centre, Hammersmith Hospital, London, United Kingdom.*

Background: Lupus nephritis is a relapsing/remitting condition and much of the long term damage relates to oral steroid use. In a single centre cohort study, the Rituxilup regimen (2 doses Methyl-prednisolone 500mg and Rituximab 1g, 2 weeks apart, followed by maintenance Mycophenolate Mofetil alone) was safe, effective treatment for ISN/RPS class II/IV/V lupus nephritis (Ann Rheum Dis 2013) over 1 year follow-up. We now report outcomes over ≥ 5 years.

Methods: Renal outcomes in the 50 patient cohort were assessed. Definitions: Complete Remission (CR)– urine PCR<50mg protein/mmol creatinine + creatinine no > than 15% above baseline; Partial Remission (PR)– uPCR <300mg/mmol + >50% fall from baseline + creatinine no > than 15% above baseline. Renal flare: uPCR>100mg/mmol on 2 consecutive visits + >50% above remission value +/ or creatinine rise >30% above baseline OR biopsy proven relapse. Non Response (NR)– failure to achieve CR or PR.

Results: Out of 50 patients, 1, in CR, lost to f/up early. By May 2014, 49 had median f/up of 78 mths (median range 50-90). There were 4 NR (8%). Of the 45 achieving CR/PR: 22/45 (48.9%) patients never flared. Mean time to flare in the rest was 54 mths (+/- 4.81). At 5 years and latest f/up respectively, 2 (5.1%) and 4(10.1%) had doubled creatinine. At latest f/u, there were 4 (8%) deaths (median age 72yrs (61-76) of whom 2 in ESRF) and 3 (6%) were alive with ESRF; those who died were much older at presentation (median 67yrs (59-73)) versus those who survived (39yrs (18-74)). Importantly, over this long f/up, of 40 patients in whom data available, 29 (72.5%) never required oral steroids, 4 (10%) had courses <4 weeks and just 6 (15%) required long term use, usually as a switch to Eurolupus regimen for flare.

Conclusions: These data suggest the Rituxilup regimen leads to sustained remission and minimal steroid use in a significant proportion of patients. Relapses often related to non-adherence, and usually responded to retreatment, again with no oral steroids. The deaths were in older patients. The planned Rituxilup trial (NCT01773616) will address efficacy and safety in an international multicentre randomised controlled trial.

FR-OR066

Tacrolimus Combined with Corticosteroids versus Modified Ponticelli Regimen in Treatment of Idiopathic Membranous Nephropathy: Randomized Control Trial Raja Ramachandran, Harsha Kumar Hn, Vinod Sharma, Ashwani Kumar, Ashok Kumar Yadav, Ritambhra Nada, Harbir Singh Kohli, Vivekanand Jha, Krishan L. Gupta. *PGIMER, Chandigarh, India.*

Background: Very few studies have evaluated the effectiveness and safety of Tacrolimus (TAC) versus the standard Cyclophosphamide (CYC) based regimen in IMN. So the present study was aimed at comparing the efficacy and safety of TAC with CYC in patients with IMN.

Methods: The study was Randomized, Parallel Group, Active Controlled Trial. Adult IMN patients with persisting nephrotic syndrome after 6 months of ACEi or ARBs or with complications of nephrotic syndrome were randomized to receive Modified Ponticelli (MP) regimen (6-month course of alternating prednisolone and cyclophosphamide) or Tacrolimus (0.1 mg/kg/day for 12 months; trough level 5-10 ng/ml in 1st 6 months and 4-8 ng/ml for next 6 months) with oral prednisolone (0.5 mg/kg/day) for 6 months. Tissue staining for phospholipase A2 receptor (PLA2R) at baseline and serum anti PLA2R antibodies (ELISA, EUROIMMUN, Germany) was done at baseline, 6 and 12 months. Primary end point was achievement of remission (complete and partial) and secondary end points was adverse effects and eGFR in both the study groups.

Results: Study included 61 patients (32 in the CYC arm and 31 in TAC arm). There was no difference in the baseline parameters, PLA2R in the glomeruli and anti PLA2R antibody. Intention-to-treat analysis suggested that remission at the end of 12 months were comparable in both the groups (75% with CYC versus 67% with TAC; p=0.58). Complete and partial remission was seen in 56% and 19% in CYC and 35% and 32% in TAC group respectively. There were no significant differences in the anti PLA2R titers at 6 and 12 months in both groups. CYC treated patients had significantly higher risk of leucopenia and azoospermia/ amenorrhea and those on TAC had significantly higher incidence of reversible nephrotoxicity, gastrointestinal side effects and tremors. There were no significant differences in the incidence of Diabetes mellitus, eGFR and infection in both the groups.

Conclusions: In the management of IMN, both TAC with steroids and CYC regimen have similar efficacy, but with different adverse effect profile.

FR-OR067

The Risk of Cardiovascular Events (CVE) Is Greater in Membranous Nephropathy (MN) Than Focal Segmental Glomerulosclerosis (FSGS) Taewoo Lee,[1] V. K. Derebail,[1] A. V. Kshirsagar,[1] Caroline J. Poulton,[1] Susan L. Hogan,[1] Sophia Lionaki,[2] Ronald J. Falk,[1] Heather N. Reich,[3] Patrick H. Nachman.[1] *[1]Univ of North Carolina; [2]Laiko Hospital, Athens, Greece; [3]Univ of Toronto, Canada.*

Background: Patients with MN have a greater risk of venous thromboembolism than patients with FSGS. We hypothesized that the risk of CVE in MN exceeds that in FSGS. We compared the risk of CVE between MN and FSGS adjusting for other risk factors.

Methods: We investigated the incidence of ESKD, all-cause mortality and CVE (defined as acute coronary syndrome, stroke or peripheral artery thrombosis) in inception cohorts of MN and FSGS. Cumulative incidence rates of CVE before reaching ESKD were estimated using competing risk analysis. To determine risk factors, competing risk regression analysis was performed with relevant covariates at baseline, including underlying disease (MN versus FSGS). Severe nephrotic syndrome was defined as proteinuria ≥3.5 g/day and/or hypoalbuminemia <2.5 g/dL and used as a time-dependent variable.

Results: We identified 404 patients with MN [median follow-up 23 m (IQR 9 -50)] and 387 with FSGS [median follow-up 24 m (IQR 10 -37)]. The cohorts were similar with respect to age, sex, diabetes, smoking, previous CVE and baseline eGFR, proteinuria and cholesterol. The FSGS cohort had a higher proportion of blacks and patients with eGFR<45 ml/min/1.73m2, but fewer patients with severe nephrotic syndrome. The estimated cumulative incidence rates of CVE was significantly higher in the MN than FSGS cohort (6.5% versus 3.5% at 3 yrs). Whereas the incidence of CVE and ESKD were similar during the first 2 yrs among MN patients, ESKD was far more frequent than CVE in the FSGS cohort. The table summarizes the multivariable analysis of risk factors of CVE adjusting for demographics, eGFR, diabetes and smoking.

Variables (reference)	Hazard ratio	95% C.I.	*P*-value
MN (vs. FSGS)	2.1	1.1-4.2	0.026
Severe nephrotic syndrome (time-varying)	1.7	1.0-2.9	0.043
Age decades at biopsy (<30 years old)	1.6	1.2-2.0	<0.001
Previous history of CVE	2.6	1.3-5.2	0.005

Conclusions: MN is associated with a disease-specific increased risk for CVE compared to FSGS, independent of severity of nephrotic syndrome, CKD and traditional risk factors.

FR-OR068

Extended NIH Cyclophosphamide Regime Is Associated with Improved Patient Outcomes in ANCA Associated Vasculitis Valeed Ghafoor,[1] Laura Chadwick,[2] Ajay Prabhakar Dhaygude,[1] Michael Venning.[2] *[1]Renal Medicine, Royal Preston Hospital, Preston, United Kingdom; [2]Renal Medicine, Manchester Royal Infirmary, Manchester, United Kingdom.*

Background: Despite vigorous induction immunotherapy, ANCA Associated Vasculitis (AAV) still carries a 50% 5- year relapse rate. Morbidity/mortality are closely linked with immunosuppression exposure; infection being the greatest problem after treatment. Current European League Against Rheumatism recommendation is to treat organ/life-threatening disease with cyclophosphamide by CYCLOPS protocol, 10 doses over 26 weeks. The NIH regime extending Cyp after 6 months with quarterly doses to 30 months total reduces relapses in lupus nephritis[1] and AAV[2]. In this study we compared the outcomes of AAV pts treated with CYCLOPS and extended NIH regimes in NW of England.

Methods: A retrospective study was performed of 90 sequential AAV patients treated with the 2 Cyp regimens. Prospectively collected demographic, and outcomes data were analysed.

Results: Results are presented in Table-1.

	NIH regime	CYCLOPS regime	p value
Patients	33	57	
Average Age	58 (30-82)	60 (18-80)	
Average Follow up months (pt*months)	56(1848)	50(2850)	
PR3 +Ve	63%	52%	
Cumulative Cyp dose (mili-grams)	8807	6951	
Dialysis dependant at diagnosis	30%	33%	
Dialysis dependant at last F/U	12%	14%	0.6
Relapses (relapse/pt*months)	7(0.003)	27(0.009)	0.01
Infections (inf/pt*months)	6(0.003)	12(0.004)	0.44
Deaths	15%	14%	

Use of methyl prednisolone, plasma exchange and maintenance immunotherapy did not differ between groups.

Conclusions: These data appear to support the previous findings that a more intensive Cyp regime may be associated with lower relapse rates with no increase in treatment related complications. A large RCT is required to confirm these findings: addressing the question of whether a more intensive induction regime than CYCLOPS might carry benefit.

FR-OR069

Can Autologous Stem Cell Transplantation Improve the Prognosis of Primary AL Amyloidosis via Cardiac Effects? Masahiro Kawada, Yoshifumi Ubara, Junichi Hoshino, Koki Mise, Kenmei Takaichi. *Nephrology, Toranomon Hospital, Minato-ku, Tokyo, Japan.*

Background: AL amyloidosis shows a wide spectrum of organ involvement and is known to have a poor long-term prognosis, with cardiac disorders being an adverse prognostic factor. High-dose melphalan combined with autologous stem cell transplantation (HDM/ASCT) has been expected to prolong the survival of these patients, but long-term efficacy has not been demonstrated.

Methods: Between 2004 and 2012, HDM/ASCT was carried out in 18 patients with AL amyloidosis after one or two courses of VAD therapy (vincristine, doxorubicin, and dexamethasone) according to the criteria and regimen of Gono. The long-term outcome and organ responses were investigated in this study according to the classification of Gertz (Am J Hematol, 2005).

Results: The mean follow-up time after HDM/ASCT was 65.8 months. At treatment, these patients had a mean age of 51 years (6 women), mean serum Cre of 0.86 mg/dL, proteinuria of 7.11 g daily, BNP of 181 pg/mL, ejection fraction of 68 %, and left ventricular mass (LVM) of 169.2 g on echocardiography. After treatment, four patients died (3 of amyloid-related causes and 1 of infection), and 14 patients are alive. There was no treatment-related mortality. A renal response occurred in 12 patients (66.7%) and a cardiac response was seen in 77.8%. Hematological complete remission (HCR) was achieved in 14 patients (77.8%), and overall survival (OS) was 83.3% at 5 years. OS was good (100 %) in 14 patients with HCR at 37 months after treatment, while OS was poor (0 %) in 4 patients without HCR. LVM was reduced from 207.1 g to 188.0 g after 2 years in 6 HCR patients with left ventricular hypertrophy (LVH), while LVM was increased from 204.3 g to 231.3 g in 3 patients who had LVH without HCR.

Conclusions: When HCR is achieved after VAD + HDM/ASCT in patients with AL amyloidosis, a good prognosis can be expected due to cardiac improvement.

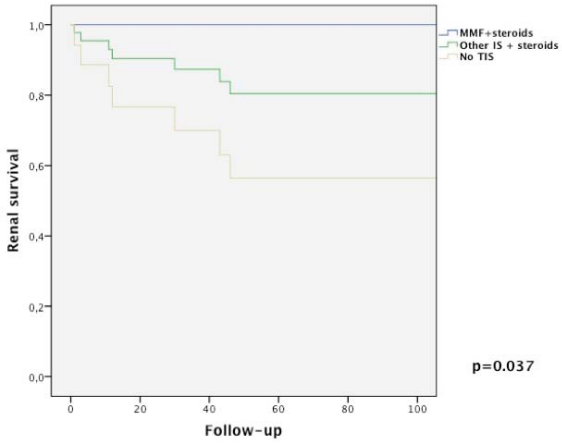
FR-OR071

Mycophenolate Mofetil in C3 Glomerulonephritis Cristina Rabasco, Manuel Praga. *Nephrology, Spanish Nephrology Society's Glomerular Diseases Study Group (GLOSEN), Spain.*

Background: C3 Glomerulonephritis (C3GN) is a recently recognized clinicopathologic entity defined by the finding of dominant deposits of C3 on immunofluorescence. Some patients have treated with eculizumab with variable results, but information about the efficacy of immunosuppresssion is very scarce. We aimed to investigate if immunosuppressive therapy (IST) can influence long-term outcomes in C3GN.

Methods: A multi-center study of the GLOSEN that collected patients with biopsy-proven C3GN. Demographic data, clinical presentation, histological findings, and response to IST were analysed. Outcomes of the study were: response, doubling of serum creatinine or progression to end stage renal disease (ESRD).

Results: Sixty patients were identified (57% male, median age 37yr). Clinical presentations were nephrotic syndrome (50%), nephritic syndrome (33%) and asymptomatic urinary abnormalities (17%). Membranoproliferative GN was found in 74%, the remaining patients showing other histological patterns. Most patients (90%) received ACEI/ARB. 66% patients received IST: corticosteroids (CS) plus mycophenolate mofetil (MMF) in 55%, CS plus immunossupressants other than MMF in 22% and CS only in 22%. There were no differences at baseline between treated and untreated patients. Median follow-up was 48 months. Rate of response was higher among treated patients (70% versus 25%;p=0,001) and the number of patients reaching ESRD was significantly higher in nontreated patients (35% versus 7%;p=0,007). When analyzing the different types of IST, patients who had received MMF had an almost significantly higher rate of responses than patients who received other types of IST and their probability of renal survival was significantly higher than that patients treated with other IST: 100% versus 78% at 50 months(P=0,034)



Conclusions: IST, particularly CS + MMF, is effective in C3GN, improving outcomes in comparison with nontreated patients.

FR-OR072

Ablation of Dendritic Cells Prevents Hypertension in Mice Infused with Angiotensin II plus High Salt Diet Daniel E. Hevia,[1] Carolina E. Prado,[2] Eugenia L. Fuentes,[1] Rodrigo Pacheco,[2] Luis F. Michea.[1] *[1]Centro de Estudios Moleculares de la Célula, Inst Milenio de Inmunología e Inmunoterapia, ICBM, Facultad de Medicina, Univ de Chile, Santiago, Chile; [2]Laboratorio de Neuroinmunología, Fundación Ciencia y Vida, Santiago, Chile.*

Background: High levels of Angiotensin II (AngII) cause hypertension (HT), inflammation, fibrosis and hypertrophy in heart and kidney. Inflammation implies the immunogenic response of Dendritic Cells (DC). Previous studies showed that AngII promoted DCs maturation and proinflamatory cytokine production *in vitro*. Moreover, blocking of DC-T Lymphocyte interaction *in vivo* partially prevented AngII-induced HT. We tested the hypothesis that DCs are necessary for blood pressure increase and tissue damage caused by AngII infusion and high salt diet (AngII+HS).

Methods: WT andCD11c.DOG mice (with selective loss of DCs, $CD11c^{Hi}$ cells) after Diphteria Toxin (DT) administration received AngII+HS treatment during 14 days. Arterial blood pressure and physiological parameters were measured, and at day 14 we characterized markers for: oxidative stress, inflammation, fibrosis and hypertrophy.

Results: Ablation of $CD11c^{Hi}$ cells in CD11c.DOG mice prevented HT and cardiac hypertrophy, as compared to vehicle-treated group (101.2±3.8 mmHg). DT administration to CD11c.DOG mice depleted $CD11c^{Hi}$ cells in ~91.6% from spleen and ~83.7% from kidney. WT mice receiving AngII+HS developed HT irrespective to DT infusion (166.2±5.3 mmHg). qRT-PCR studies in kidney tissues of both strains showed that AngII+HS without DT administration increased expression of NOX2, NOX4, TNF-α, IL-1β, MCP-1, CTGF, TGF-β, Collagen and Fibronectin ($p<0.05$; n=5-7 *versus* vehicle). AngII+HS increased $CD8^{+}IFN\text{-}\gamma^{+}$ and $CD4^{+}IFN\text{-}\gamma^{+}$ and reduced $CD4^{+}Foxp3^{+}$ and $CD4^{+}IL\text{-}10^{+}$ populations in in renal lymph nodes. DCs ablation prevented changes mentioned above.

Conclusions: These results show for the first time that DCs ($CD11c^{Hi}$ cells) are necessary for HT development and tissue damage in response to AngII+HS. The potential role of DCs in the activation of the intrarenal RAAS and/or the modulation of the expression of sodium transporters in nephron is under investigation. FR-OR073

IL-1 Potentiates Sodium Retention in Angiotensin II-Dependent Hypertension Through Nitric-Oxide-Mediated Regulation of Na^{+}-K^{+}-2Cl^{-} Cotransporter Jiandong Zhang, Matthew A. Sparks, Steven D. Crowley. *Div of Nephrology, Duke Univ, Durham, NC.*

Background: The macrophage cytokine interleukin 1 (IL-1) is a key regulator of innate immunity, and chronic angiotensin (Ang) II infusion raises IL-1 levels in the kidney.

Methods: To study the role of IL-1 receptor (IL-1R) activation in Ang II-dependent hypertension, we chronically infused uni-nephrectomized IL-1R-deficient (KO) and wild-type (WT) mice with Ang II for 4 wks.

Results: Baseline mean arterial pressures (MAPs) were similar between groups. By contrast, after the 1st wk of Ang II, KOs had blunted MAP elevations versus WTs (169±6 versus184±3 mm Hg; $p<0.05$). At 4 wks of Ang II, KO kidneys contained more F4/80+ macrophages than WTs (18±1 versus 14±2 per HPF; p=0.03). Among these macrophages, monocytic myeloid-derived suppressor cells (Mo-MDSC) that produce nitric oxide (NO) showed 60% greater accumulation in KO kidneys than in WTs by FACS (p=0.05). In turn, KOs had enhanced renal expression of iNOS mRNA (1.7±0.3 versus 1.0±0.2 au; $p<0.05$) and higher excretion of NO metabolites versus WTs (152±46 versus 60±15 nmol/mg Cr; p=0.05). NO inhibits renal sodium reabsorption, and during the 2nd wk of Ang II when WT and KO BPs separated, only the KOs entered negative Na balance (-16.8±16.8 versus WT 34.8±7.5 µmol/day, p=0.01). To confirm that preserved NO bioavailability in the Ang II-infused KOs led to their lower BP versus WTs, we blocked NO generation in the groups with L-NAME starting on day 7 of Ang II when the WT and KO BPs were 179±3 versus 165±6 mm Hg ($p<0.01$). By day 14, BPs converged (186±5 versus 185±8; p=NS). As NO is known to inhibit NKCC2, we measured NKCC2 activity at day 10 of Ang II by quantitating UNa/UCr 3 hours after an IP injection of saline with or without furosemide. After saline alone, the KOs had a higher UNa/UCr than the WTs (237±38 versus120±14 mmol/mmol; p=0.01) whereas the UNa/UCr converged in response to furosemide (481±103 versus453±60; p=NS). Thus, reduced NKCC2 activity in the KOs protects them from Ang II-induced sodium retention.

Conclusions: In sum, our studies define a novel immune-mediated hypertension mechanism in which stimulation of IL-1 signaling by Ang II promotes renal sodium retention through NO-dependent regulation of NKCC2 activity.

FR-OR074

Kidney Specific FKBP12 Knockout Mice Are Protected From Tacrolimus Induced Hypomagnesemia and Hypercalciuria Rebecca A. Lazelle,[1] Belinda H. McCully,[2] Chao-Ling Yang,[1] David H. Ellison.[1] *[1]Div of Nephrology and Hypertension, Oregon Health and Sciences Univ, Portland, OR; [2]Div of Trauma, Critical Care & Acute Care Surgery, Oregon Health and Sciences Univ, Portland, OR.*

Background: The calcineurin inhibitor tacrolimus (FK-506) is widely used to prevent organ transplant rejection, but also causes side effects, including hypomagnesemia and hypercalciuria. Although tacrolimus alters renal calcium and magnesium transport proteins, contributing to these effects, the cellular mechanisms have not been established. Tacrolimus inhibits calcineurin by binding FKBP12. In T-cells this results in immunosuppression. FKBP12 is an endogenous immunophillin, and global FKBP12 knockout is lethal. Thus, we developed an inducible kidney tubule-specific FKBP12 knockout mouse to test whether magnesium and calcium wasting result from disruption of FKBP12 itself or from disruption of calcineurin signaling.

Methods: Using a Doxycycline inducible CRE/LOX system, we deleted FKBP12 from the kidney tubules of adult mice (FKBP12-KO). We characterized these mice at baseline, and after tacrolimus treatment (3 mg/kg tac/veh intraperitoneally for 3 weeks on a high K^{+} diet), using metabolic cages, colorimetric assays and Western blotting.

Results: Doxycycline treatment reduced FKBP12 by >90% in kidney. At baseline, FKBP12-KO mice appeared normal, without signs of magnesium or calcium imbalance. While tacrolimus caused significant hypomagnesemia (veh 1.67 ± 0.01 v tac 1.07 ± 0.01 mg/dL) and hypercalciuria (veh 0.09 ± 0.01 v tac 0.37 ± 0.01 mg/g BW/24 hours) in FKBP12-WT mice, these effects were absent in FKBP12-KO mice (veh 1.57 ± 0.03 v tac 1.73 ± 0.08 mg/dL) and (veh 0.11 ± 0.03 v tac 0.13 ± 0.01 mg/g BW/24 hours)(Data:mean± SEM).

Conclusions: Loss of renal FKBP12 itself does not cause kidney dysfunction. Loss of renal FKBP12, however, protects kidneys from tacrolimus effects on renal magnesium and calcium transport. These data suggest that tacrolimus causes electrolyte imbalance by inhibiting calcineurin in kidney epithelial cells. Since the toxic and therapeutic effects both result from calcineurin inhibition, safer immunosuppressive drugs will likely require tissue specificity.

Increased Susceptibility to Angiotensin II-Induced Renal Injury and Glomerular Filtration Rate Reduction in Mice with Vascular-Specific EP4 Receptor Deletion Jean-Francois Thibodeau,[1,2] Chet E. Holterman,[2] Chris R. Kennedy.[2] *[1]Dept of Cellular and Molecular Medicine, Univ of Ottawa, Ottawa, ON, Canada; [2]Kidney Research Center, Ottawa Hospital Research Inst, Ottawa, ON, Canada.*

Background: Cyclooxygenase (COX)-inhibition by NSAIDs is contraindicated in CKD patients as it reduces GFR by diminishing renal blood flow. Prostaglandin E2 (PGE2) is vasodilatory and counteracts pressor hormones such as angiotensin II (AngII). PGE2 responsiveness in the renal microcirculation is governed primarily by pre-glomerular E-Prostanoid 4 (EP4) receptors in vascular smooth muscle cells.

Methods: Using a Cre/LoxP approach, we generated mice with inducible vascular smooth muscle cell EP4 receptor deletion ($EP4^{VSMC-/-}$) and subjected them to AngII-induced hypertension by implantation of osmotic mini-pumps (1000ng/kg/min, s.c.).

Results: After 4 weeks of AngII administration, systolic blood pressures were significantly yet similarly elevated in both wild type (WT) and $EP4^{VSMC-/-}$groups (WT, 104±1; AngII, 169±5; $EP4^{VSMC-/-}$, 106±7; $EP4^{VSMC-/-}$ + AngII, 178±5 mmHg) while albuminuria was significantly exacerbated in $EP4^{VSMC-/-}$ mice versus WT mice (WT, 430±70; AngII, 917±284; $EP4^{VSMC-/-}$, 354±54; $EP4^{VSMC-/-}$ + AngII, 2907±420 µg albumin/mg creatinine). AngII-treated $EP4^{VSMC-/-}$ mice but not WT mice exhibited severe renal structural damage characterized by glomerulosclerosis (WT, 28.6±1.2; AngII, 32.0±1.2; $EP4^{VSMC-/-}$, 31.0±1.3; $EP4^{VSMC-/-}$ + AngII, 44.0±2.0 % glomerular area), tubulointerstitial fibrosis and tubular proteinaceous casts. GFR decreased significantly in AngII-treated $EP4^{VSMC-/-}$ mice, but was unaffected in AngII-treated WT mice (WT, 0.26±0.04; AngII, 0.24±0.07; $EP4^{VSMC-/-}$, 0.16±0.05; $EP4^{VSMC-/-}$ + AngII, 0.07±0.02 ml/min). In addition, renal medullary COX-2 mRNA induction in AngII-treated mice was impaired in $EP4^{VSMC-/-}$ mice compared with WT counterparts (WT, 0.9±0.2; AngII, 2.8±0.7; $EP4^{VSMC-/-}$, 1.7±0.7; $EP4^{VSMC-/-}$ + AngII, 0.6±0.2 a.u.).

Conclusions: These results indicate that vascular EP4 receptor activation in a hypertensive context is critical as it buffers AngII's effect on GFR and protects against associated renal structural injury.

FR-OR076

Cardiac Hypertrophy in Angiotensin II-Dependent Hypertension: Dominant Effect of Blood Pressure Matthew A. Sparks,[1] Johannes Stegbauer,[2] Steven D. Crowley,[1] Subramaniam Pennathur,[3] Susan B. Gurley,[1] Thomas M. Coffman.[1] *[1]Duke Univ; [2]Heinrich-Heine-Univ Düsseldorf; [3]Univ of Michigan.*

Background: LVH is a common result of end-organ injury in HTN, leading to higher CV risk. ACEi's and ARBs attenuate LVH through actions suggested to depend on direct interruption of AngII signaling via AT_1R in cardiac myocytes, rather than effects to lower BP.

Methods: In order to define the contribution of AT_1R in myocytes to LVH, we generated 2 mouse lines with cell-specific deletion of $AT_{1A}R$ from the heart using a floxed Agtr1a allele. In the 1st line, elimination of $AT_{1A}R$ was achieved with a Cre transgene under control of the Sm22 promoter(Tagln-Cre), which expresses Cre in smooth muscle and myocyte cells.

Results: In Tagln-KO mice, there was loss of $AT_{1A}R$ from cardiac myocytes and VSMCs in aorta, but not in smaller vessels. With chronic AngII infusion, Tagln-KOs develop HTN similar to controls(MAP:157±6 versus 153±6 mmHg, P=NS). In AngII-infused controls, there was oxidative stress in the heart with enhanced nitrated tyrosine, but this was reduced by ~75% in Tagln-KOs($P<0.005$). Despite the loss of $AT_{1A}R$ in myocytes and differences in free radicals, the extent of cardiac hypertrophy was similar in Tagln-KOs and controls(6.9±0.2 versus 6.7±0.2 mg/gm; P=NS). Heart BNP mRNA and cardiac injury were not reduced in Tagln-KOs compared to controls. The phenotype and molecular signature of LVH were not affected by the absence of cardiac $AT_{1A}R$ in Tagln-KOs. The 2nd line in which the $AT_{1A}R$ floxed allele was excised by a Cre cassette "knocked-in" to the Sm22 locus(KISm22-KOs). The KISm22-KOs showed loss of $AT_{1A}R$ from myocytes and VSMCs in large arteries, but in this case $AT_{1A}R$ were also deleted from VSMCs in resistance vessels. Accordingly, AngII-induced HTN was attenuated in KISm22-KOs(MAP: 122±3 versus 145±4 mmHg; P=0.004). Unlike the Tagln-KOs, cardiac hypertrophy was lower(5.5±0.2 versus 7.4±0.6 mg/gm; p=0.01) and BNP mRNA levels was reduced(1.0±0.2 versus 2.6±0.8; $p<0.05$).

Conclusions: In 2 models lacking AT_{1AR} in the heart, the extent of cardiac hypertrophy in AngII HTN followed the BP, rather than $AT_{1A}R$ in myocytes. Suggesting that the magnitude of BP elevation is of primary importance in driving cardiac hypertrophy.

FR-OR077

Kidney Androgen Regulated Protein Controls Baseline Blood Pressure Kamyar A. Zahedi,[1,2] Saeed Alshahrani,[3] Marybeth Brooks,[1,2] Sharon L. Barone,[1,2] Jie Xu,[1,2] Manoocher Soleimani.[1,2,3] *[1]Internal Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Affairs Medical Center, Cincinnati, OH; [3]Pharmacology and Cell Biophysics, Univ of Cincinnati, Cincinnati, OH.*

Background: The kidney androgen-regulated protein (KAP) is abundantly and exclusively expressed in the proximal tubule. KAP function in proximal tubule remains unknown. KAP interacts with the Na-K-ATPase B subunit through binding with cyclophiline and its over-expression in the proximal tubules of transgenic mice leads to increased 20-HETE generation, resulting in vasoconstriction and systemic hypertension (Circ. 2009). In order to investigate its role in blood pressure (BP) regulation, kidney specific KAP KO mice were generated.

Methods: Proximal tubule specific KAP knockout (KAP-KO) mice were generated by cross breeding of floxed-KAP (CONT) and villin cre mice. Animals were subjected to systemic BP measurement by tail cuff method, and kidney RNA from KO and CONT mice were examined by RNA-SEQ. Northerns and immunofluorescence labeling were performed.

Results: Compared to CONT, KAP-KO mice display significantly reduced systolic BP (145+/-2 versus 108+/-3, $p<0.01$). Placing the animals on high salt diet for 5 days led to rapid normalization of BP in KAP-KO mice without significantly affecting CONT mice. RNA-SEQ analysis revealed that the expression of Cyp4a12a, the main kidney 20-HETE-generating enzyme was hugely up-regulated whereas the Na-K-ATPase B subunit was down-regulated in KAP-KO mice. Northern blot analyses confirmed RNA-SEQ results. Immunofluorescent studies indicated that the expression of NBCe1, the basolateral sodium/bicarbonate cotransporter, is upregulated in KAP-KO mice. The latter suggests the presence of a sodium reabsorption mechanism that may compensate for reduced activity of Na-K-ATPase in the proximal tubules of KAP-KO mice.

Conclusions: Our results suggest that KAP plays an important role in systemic blood pressure homeostasis, likely through regulation of sodium reabsorption in the proximal tubule. Further, the up-regulation of Cyp4a12a, the main 20-HETE-generating enzyme, points to a compensatory vaso-constricting response aimed at keeping the BP within physiologic range.

FR-OR078

Role of the Natriuretic Peptide GC-A Receptor on Podocytes in Aldosterone-Induced Glomerular Injury Yukiko Kato,[1] Hideki Yokoi,[1] Kiyoshi Mori,[2] Masato Kasahara,[3] Yoshihisa Ogawa,[4] Takashige Kuwabara,[1] Takeshi Tokudome,[5] Ichiro Kishimoto,[6] Akira Sugawara,[4] Taiji Matsusaka,[7] Kazuwa Nakao,[2] Motoko Yanagita,[1] Masashi Mukoyama.[1,8] *[1]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [2]Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [3]Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan; [4]Div of Nephrology, Osaka Red Cross Hospital, Osaka, Japan; [5]Dept of Biochemistry, Research Inst Index, National Cerebral and Cardiovascular Center, Osaka, Japan; [6]Dept of Atherosclerosis and Diabetes, National Cerebral and Cardiovascular Center, Osaka, Japan; [7]Dept of Internal Medicine, Tokai Univ School of Medicine, Kanagawa, Japan; [8]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: Aldosterone is a key molecule in glomerular injury. The natriuretic peptide receptor guanylyl cyclase-A (GC-A) signaling exerts renoprotective effects by eliciting natriuresis and reducing blood pressure. We demonstrated that systemic GC-A knockout (KO) mice with aldosterone and sodium overload exhibited accelerated hypertension with massive proteinuria. In this model, inhibition of p38 MAP kinase reduced blood pressure and ameliorated renal injury. Local function of the GC-A receptor in podocytes, however, remains unknown.

Methods: We generated podocyte-specific GC-A KO mice (pod-GC-A KO). Control and KO mice were uninephrectomized and then treated with high salt orally and aldosterone subcutaneously for 4 weeks.

Results: Pod-GC-A KO mice with aldosterone and high salt showed significantly increased urinary albumin excretion by 13-fold with marginal blood pressure elevation similar to control. Glomerular hypertrophy, mesangial expansion and apoptosis were aggravated in pod-GC-A KO mice. Overexpression of MKK3 in cultured podocytes induced p38 MAPK phosphorylation and BAX mRNA expression. Such increase was inhibited by ANP.

Conclusions: These results suggest that the endogenous natriuretic peptides and GC-A system on podocytes plays renoprotective and anti-apoptotic roles in aldosterone-induced glomerular injury by inhibiting phosphorylation of p38MAPK.

FR-OR079

B Cell Derived IL-4 Induces Proteinuria and Foot Process Effacement Alfred Hyoungju Kim,[1] Shreeram Akilesh,[1] Ania B. Koziell,[2] Sanjay Jain,[1] Jeffrey B. Hodgin,[3] Jeffrey H. Miner,[1] Andrey S. Shaw.[1,4] *[1]Washington Univ School of Medicine, St. Louis, MO; [2]Experimental Immunobiology, King's College, London, United Kingdom; [3]Univ of Michigan, Ann Arbor, MI; [4]Howard Hughes Medical Inst, St. Louis, MO.*

Background: Podocyte foot process effacement is a feature of proteinuria, thought to be a stereotyped response of the podocyte to injury. The stimulus for podocyte injury and foot process effacement is unknown. B cell depletion therapies have demonstrated efficacy in some patients with proteinuria including those with minimal change disease. Since pathogenic antibodies are not causative, we hypothesized that a B cell derived cytokine might be capable of directly inducing podocyte injury and foot process effacement.

Methods: B cell model antigen model hen egg lysozyme (HEL) was biotinylated, complexed to avidin and injected into mice. HEL-specific B cells were adoptively transferred and proteinuria assessed. Cultured podocyte membrane ruffling was assessed with DIC videomicroscopy. IL-4 expression in mice was achieved by hydrodynamically injecting murine IL-4 in the piggyBac vector system. Human kidney biopsies were assessed for phospho-STAT6 by immunohistochemistry.

Results: We identified IL-4 as a B cell derived cytokine capable of stimulating podocyte membrane ruffling. Using a novel model of B cell induced proteinuria, B cells polarized to secrete IL-4 upon activation induced proteinuria without antibody or complement deposition. IL-4 overexpression was sufficient to induce foot process effacement and

proteinuria in mice. Inhibition of IL-4 signaling with a JAK1/3 inhibitor markedly reduced proteinuria in these IL-4 overexpressing mice. A subset of patients with minimal change disease possessed glomerular STAT6 activation.

Conclusions: These findings suggest a potential explanation for the utility of immunosuppression and more targeted anti-B cell therapy with rituximab in the treatment of minimal change disease. These results supporting the role of IL-4 in human nephrotic syndromes and a novel therapeutic target.

Pathogenic RORγt$^+$ Regulatory T Cells Aggravate Crescentic Glomerulonephritis Malte A. Kluger,[1] Matthias C. Meyer,[1] Michael Luig,[1] Boeren Goerke,[1] Anna Nosko,[1] Claudia Wegscheid,[2] Rolf A. Stahl,[1] Ulf Panzer,[1] Oliver M. Steinmetz.[1] *[1]III. Med. Klinik, Univ Hospital Eppendorf, Hamburg, Germany; [2]Experimentelle Immunologie und Hepatologie, Univ Hospital Eppendorf, Hamburg, Germany.*

Background: Recently, cells co-expressing the regulatory T cell (Treg) transcription factor Foxp3 and the Th17 transcription factor RORγt were identified in mice and humans. It remains unclear whether these cells belong to the newly defined Th17 specific Treg17 cells, represent intermediates during Treg/Th17 transdifferentiation, or constitute a distinct cell lineage. Since nothing is known about their role in inflammatory renal disease, we studied the Nephrotoxic nephritis (NTN) model of crescentic glomerulonephritis.

Methods: Deletion of genes was achieved using Foxp3Cre x RORCfl/fl or STAT3fl/fl mice. NTN was induced and renal histology and function were assessed at day 10. Immune responses were analyzed by FACS, ELISA and Treg suppression assay. Foxp3 and RORγt stability was assessed in Foxp3 Cre x Ai9 fate reporter mice and by cell transfer from Foxp3 and RORγt activity reporters.

Results: Induction of NTN resulted in rapid expansion of RORγt+ Foxp3+ cells. A high percentage produced IL-17 and expressed the chemokine receptor CCR6. RORγt+ Foxp3+ cells were still present in Treg17 deficient Foxp3Cre x Stat3fl/fl mice showing that they are a different Treg subtype. Multiple fate reporter and cell transfer studies revealed that RORγt+ Foxp3+ cells are not Treg/Th17 transdifferentiating cells but rather represent an independent cell lineage. To study their functional role, we generated Foxp3Cre x RORCfl/fl mice lacking RORγt specifically in Foxp3+ cells. Systemic Th17 and Treg responses including in vitro suppressive activity remained unchanged. Importantly, however, NTN was significantly ameliorated in the absence of RORγt+ Foxp3+ cells, revealing a pro-inflammatory role.

Conclusions: In summary we provide evidence that RORγt+ Foxp3+ cells represent a novel and independent pro-inflammatory T-cell lineage distinct from Th17 and Treg17 cells. For the first time, we show that these pathogenic regulatory T cells act as potent mediators of crescentic glomerulonephritis and thus represent a novel therapeutic target.

Micromanging Autoimmune Nephritis: Role of miR-17 in Modulating Regulatory T Cell Activity by Targeting Foxp3 Co-Regulators Huang-Yu Yang, Chih-Wei Yang. *Kidney Inst, Dept of Nephrology, Chang Gung Memorial Hospital, Taiwan.*

Background: Regulatory T (Treg) cells play a critical role in maintaining self-tolerance and controlling the magnitude of physiologic immune response. The Treg transcription factor forkhead box P3 (Foxp3) works in concert with other co-regulator molecules including Eos to determine the transcriptional signature and characteristic suppressive phenotype of Treg. A strong correlation between systemic lupus erythematous and deficiencies of Treg has been reported. We were interested in determining whether Treg differentiation and/or suppressive activity are regulated by microRNAs (miRNAs) so that we can modulate the miRNAs to improve lupus nephritis.

Methods: We generated T cell specific miR-17-92 knockout (miR-17-92-/-) mice, followed by induction of pristane nephropathy in miR-17-92 -/- and wild type littermates. By bioinformatics study, possible targets of mir-17-92, related to Treg function was evaluated. Luciferase reporter assay was utilized for verification. Forced expression and knockdown of miRNA in Treg was performed by lentivirus.

Results: mir17-92 knockdown can mitigate pristane nephropathy in mice. Here, we showed for the first time that one miRNA of the miR17-92 cluster, miR-17, regulates the suppression function of Tregs. We identify a gene target of miR-17, Eos, which regulates Tregs through Foxp3-mediated gene suppression. Ectopic expression of miR-17 downmodulates the suppression functions of Tregs and provides Tregs with partial effector activity via de-repression of cytokine genes. In addition, mir17 knockdown improve colitis by enhancing the suppressive function of Treg.

Conclusions: Our studies suggest that miR-17 modulates Treg cell function by targeting Eos, revealing the future therapeutic potential of miR-17 manipulation in lupus nephritis or other autoimmune diseases.

Myeloperoxidase Peptide Based Nasal Tolerance as Treatment for Anti-Neutrophil Cytoplasmic Antibody Associated Glomerulonephritis Stephen R. Holdsworth, Poh-Yi Gan, A. Richard Kitching. *Medicine, Monash Univ, Melbourne, Victoria, Australia.*

Background: Myeloperoxidase (MPO)-ANCA associated glomerulonephritis (GN) is a common form of crescentic GN and current treatments are non-specific and relatively toxic. New less toxic treatments are needed. We have defined the dominant nephritogenic MPO peptide, $MPO_{409-428}$. We assessed the capacity and mechanisms of nasal insufflation of $MPO_{409-428}$ to induce immune tolerance thereby preventing and treating experimental autoimmune anti-MPO ANCA GN.

Methods: MPO autoimmunity and GN was compared between C57BL/6 mice nasally insufflated with either $MPO_{409-428}$ or control $OVA_{323-339}$. Autoimmunity was induced by MPO immunization and GN triggered using a subnephritogenic dose of anti-GBM globulin.

Results: Nasal insufflation of $MPO_{409-428}$ prior to induction of anti-MPO GN reduced renal injury (glomerular segmental necrosis (GSN); 23±13 versus 4±1% of glomeruli affected $p<0.01$) and systemic anti-MPO Tcell recall responses to MPO (ELISPOTS IFN-γ; 222±19 versus 144±19cells $p<0.05$ and IL-17A; 124±48 versus 14±1cells $p<0.05$) compared to control $OVA_{323-339}$. In mice with established MPO autoimmunity, $MPO_{409-428}$ nasal insufflation attenuated GN (GSN; 22±3 versus 9±2% $p<0.01$, reduced glomerular leukocyte accumulation and albuminuria). Both Foxp3+ and Foxp3- CD4+ Tcells from the nasal draining lymph nodes of $MPO_{409-428}$ nasally insufflated mice exhibited greater immunosuppression of anti-MPO Teff cells than Foxp3+ and Foxp3- CD4+ Tcells from nasally insufflated $OVA_{323-339}$ mice, confirming antigen specific immunosuppression. Adoptive transfer of CD4+ Tcells from mice nasally administered with $MPO_{409-428}$ to mice with established MPO autoimmunity attenuated the development of GN (GSN; 23±2 versus 9±1% $p=0.01$) with reduced glomerular leukocyte accumulation and albuminuria compared to mice that did not receive CD4+ cells.

Conclusions: Nasal insufflation with the immunodominant $MPO_{409-428}$ induces Tcell mediated immune tolerance to MPO which can prevent the induction of MPO autoimmunity and treat established disease. This provides proof of concept that peptide based nasal tolerance has therapeutic potential relevant to human MPO-ANCA associated GN.

FR-OR083

TLR9 Ligation Enhances Anti-Myeloperoxidase Autoimmunity and Glomerulonephritis Through Dendritic Cell Activation Sharon Lee Ford,[1] Irina Caminschi,[2] A. Richard Kitching,[1] Stephen R. Holdsworth.[1] *[1]Depts of Medicine & Nephrology, Monash Univ, Clayton, VIC, Australia; [2]Burnet Inst of Medical Research, Melbourne, VIC, Australia.*

Background: ANCA associated vasculitis is linked with infections. TLR9 is stimulated by a variety of pathogens and could link infections with anti-myeloperoxidase (MPO) autoimmunity and disease. We hypothesize that dendritic cell (DC) TLR9 ligation promotes anti-MPO autoimmunity and glomerulonephritis (GN).

Methods: Autoimmunity to MPO was induced either by injection of MPO in Freund's adjuvant or by subcutaneous transfer of $1x10^6$ MPO-pulsed DCs. Renal injury was triggered with a sub-nephritogenic dose of anti-glomerular basement membrane globulin, according to published protocols.

Results: After MPO/adjuvant immunisation, compared to WT mice TLR9-/- mice developed less severe glomerulonephritis (proteinuria; WT 4.2±0.3 versus TLR9-/- 1.6±0.5mg/day, $p<0.0005$; abnormal glomeruli; 35±7 versus 13±1%, $p<0.05$). The role of DC derived TLR9 was assessed by generating DCs in vitro, stimulating them with MPO and a TLR9 ligand (CpG oligodendronucleotide [ODN]) or MPO and control (GpC) ODN, then transferring DCs to WT mice and inducing anti-MPO GN. CpG ODN stimulated DCs compared to controls showed enhanced functional (serum urea; Control 12±1 versus CpG 35±9μmol/L, $p<0.05$) and histological (glomerular segmental necrosis Control 12±3 versus CpG 70±8%, $p<0.0001$) injury with increased anti-MPO Th17 responses (MPO-stimulated splenocyte IL-17A; Control 1348±156 versus CpG 677±110pg/mL, $p<0.006$). Th17 responses (IL-17A) and glomerular injury were reduced in MPO/CpG-stimulated TLR9-/- DCs, confirming the specificity of the ligand. The TLR9 ligand's effect was mediated through DEC205 dependent enhanced CD40 expression; injury was significantly reduced following transfer of both DEC205-/- and CD40-/- DCs.

Conclusions: In anti-MPO GN,DC TLR9 ligation promotes renal injury through enhanced DC activation. TLR9 inhibitors represent a potential future therapeutic option in modulating autoimmunity in ANCA associated vasculitis.

FR-OR084

CXCR3 Guides the Exit of CD4$^+$ Renal T Cells to the Draining Lymph Node in Crescentic GN Christian Franz Krebs, Tobias Koyro, Hans-Joachim Paust, Anna Kaffke, Jan-Eric Turner, Rolf A. Stahl, Ulf Panzer. *III. Medizinische Klinik, Univ Hospital Hamburg-Eppendorf, Hamburg, Germany.*

Background: Leukocyte trafficking throughout the body is essential for the defense against pathogenic infections, but also contributes to tissue damage in autoimmune disease, such as crescentic glomerulonephritis (GN). Chemokines and their receptors have been identified as key regulators of renal leukocyte infiltration under inflammatory conditions. However, hardly anything is known about the egress of leukocytes (lymphocytes) from the kidney to the renal lymph node or the involvement of this process in autoimmunity.

Methods: To address these open questions, we established an experimental system to mark intrarenal leukocytes by using transgenic mice expressing the photoconvertible fluorescent protein "Kaede".

Results: By exposing the kidney of Kaede-transgenic mice to near UV-A light (wavelength λ= 385 nm, dose 11.2 J/cm^2), 30-40% of renal leukocytes were labelled in the kidney by photoconvertion from Kaede-green to Kaede-red. Subsequently leukocyte trafficking to the renal lymph node was investigated by flow cytometry. Under homeostatic conditions renal dendritic cells (CD11b$^+$CD11c$^+$), but no CD4$^+$ T cells, entered the renal lymph node. In contrast, after induction of experimental GN (nephrotoxic nephritis) CD4$^+$ T cells migrated out of the kidney and could be detected in the draining lymph node. Maximum T cell emigration was detected 3 days after photoconversion at day 10 after GN induction. Chemokine receptor expression analysis of Kaede-red emigrating CD4+ T cells in the renal lymph node revealed an enrichment of CXCR3$^+$, but not CCR7$^+$ or CCR6$^+$ cells. In line with this the number of emigrated cells was decreased in CXCR3-deficient mice as compared to nephritic control mice (and CCR7 KO mice), indicating that the egress of T cells from the inflamed kidney to the renal lymph node is an active process that is driven by CXCR3.

Conclusions: We have established a method to study the exit of renal leukocytes out of the kidney. The expression of CXCR3 by renal CD4$^+$ T cells may control their exit, acting with recruitment mechanisms to regulate the accumulation of lymphocytes in the kidney in experimental glomerulonephritis.

Development, and Morphologic Characteriziation of a Mouse Model of Membranous Nephropathy Involving the Human Phospholipase A2 Receptor

Gunther Zahner,[1] Catherine Meyer-Schwesinger,[1] Nicola M. Tomas,[1] Elion Hoxha,[1] Thorsten Wiech,[2] Rolf A. Stahl.[1] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg Eppendorf, Hamburg, Germany; [2]Institut für Pathologie, Universitätsklinikum Hamburg Eppendorf, Hamburg, Germany.*

Background: Phospholipase A2 receptor (PLA2R) auto antibodies are associated in 70% of patients developing membranous nephropathy (MN). Since rodents do not express the PLA2R on podocytes we developed human PLA2R knock in mice that specifically express this protein on podocytes.

Methods: The extracellular part of the human PLA2R was fused with a GPI-anchor and cloned into a R26/neo-stop target vector. PLA2R positive ES-cells were injected in blastocysts and implanted in C57Bl6 females. The F1 littermates were tested for germ line transmission of the PLA2R knock in. Breeding with PodoCre mice animals were obtained that specifically express PLA2R on podocytes. These mice are called PodoCre PLA2R and compared with PodoCre-free PLA2R animals as controls. For disease induction, control and PodoCre PLA2R mice were either actively immunized with recombinant human PLA2R or received concentrated human serum from patients with high levels of serum PLA2R antibodies. Histologic assessment of the kidneys was performed after several time intervals following immunization.

Results: PLA2R expression was detected in PodoCre PLA2R but not in the appropriate control mice. PodoCre PLA2R and control mice developed PLA2R antibodies in response to the immunization. PodoCre PLA2R mice developed granular subepithelial immune deposits along the glomerular basement membrane which were positive for mouse IgG. No immune deposits could be detected in control mice. Electron microscopy showed dense deposits located in the subepithelial space exclusively in immunized PodoCre PLA2R mice. PodoCre PLA2R mice which received serum from patients with MN positive for PLA2R antibodies developed granular deposits along the glomerular capillary wall, which were positive for human IgG.

Conclusions: These studies show that the human PLA2R when expressed on mice podocytes, is a target for autoantibodies induced in mice or serves as antigen for transferred human PLA2R antibodies from patients with membranous nephropathy.

FR-OR086

The Immunodominant Epitope in PLA_2R Mediating Idiopathic Membranous Nephropathy Is Located in the CysR-FnII-CTLD1 Region

Quansheng Zhu,[1] Liyo Kao,[1] Vinson Lam,[1] Meryl A. Waldman,[2] Richard J. Glassock.[1] *[1]Medicine, UCLA, Los Angeles, CA; [2]NIDDK/Kidney Disease Section, National Insts of Health, Bethesda, MD.*

Background: Clinical studies have firmly established that over 70% of patients with idiopathic membranous nephropathy (IMN) possess high levels of circulating autoimmune antibodies targeting phospholipase A_2 receptor (PLA_2R) in the glomerular visceral epithelial cells. The level of auto-antibodies correlates with the severity of proteinuria in patients. The epitope is known to be conformational in nature and to require specific disulfide bonds. PLA_2R is a transmembrane receptor containing ten extracellular domains: an N-terminal cysteine rich domain (CysR), a fibronectin type II domain (FnII), and eight repeated C-type lectin like domains (CTLD).

Methods: To determine the location of the antigenic epitope in PLA_2R, we created various truncated extracellular domains and expressed them in HEK 293 cells. These isolated domains were analyzed on the immunoblot by probing with sera derived from IMN patients. The identified epitope region was then tested for its immunodominance using epitope competition assays in the liquid phase. Finally, the identified immunodominant epitope region was verified by comparing side by side with the full length PLA_2R for 74 IMN patient sera recognition.

Results: Our results showed that the anti-PLA_2R antibodies from patients specifically recognize a three domain structure consisting of the CysR, FnII, and the CTLD1 domains under non-reducing conditions. When the three domains were missing, none of the remaining domains were recognized. This three domain structure completely blocked the reactivity of auto-immunue antibodies with the full length PLA_2R protein on the immunoblot.

Conclusions: Our results demonstrate that the immunodominant epitope in PLA_2R mediating IMN is exclusively formed by the CysR, FnII, and CTLD1 domains in the N-terminal region of the receptor.

Alternative Pathway Amplifies Complement Activation by Human Anti-PLA2R Antibodies in Membranous Nephropathy

Dorin-Bogdan Borza,[1] Tanu Rana,[1] Florina Olaru,[1] Joshua M. Thurman,[3] Stephen Tomlinson,[4] Laurence H. Beck,[2] David J. Salant.[2] *[1]Meharry Medical College, Nashville, TN; [2]Boston Univ Medical Center, MA; [3]Univ of Colorado School of Medicine, Aurora, CO; [4]Medical Univ of South Carolina, SC.*

Background: About 70-80% of patients with primary MN have autoAbs against phospholipase A2 receptor (PLA2R), predominantly but not exclusively of IgG4 subclass. Whether and how anti-PLA2R autoAbs cause glomerular injury remains unknown. C3 and C5b-9 occur in glomerular immune deposits, implicating complement activation as a putative effector mechanism. Purified anti-PLA2R IgG4 can activate the lectin pathway (LP). Here, we investigated how unfractionated anti-PLA2R autoAbs activate complement and the role of the classical (CP) and alternative (AP) pathways.

Methods: We developed a functional assay to evaluate the complement activating ability of serum anti-PLA2R autoAbs from MN patients. Binding of complement components to complexes of human PLA2R antigen and anti-PLA2R Abs was measured after incubation with normal and complement-deficient human sera as complement source, with and without specific inhibitors.

Results: All anti-PLA2R autoAbs activated complement, with deposition of C3, C4, factors B, H and properdin (P). Binding of C3, B, H and P (but not C4) occurred under conditions where only the AP was functional. Deposition of C3 and C4 occurred under conditions where only the CP and LP were active. C3 and C4 deposition was strongly inhibited in C1q-deficient serum (lacking CP) and further reduced in C4-deficient serum (lacking CP and LP). Under physiological conditions with all pathways functional, specific AP inhibitors reduced C3 activation by 4-8 fold.

Conclusions: Anti-PLA2R autoAbs can activate complement via all three pathways. The classical pathway may be activated by anti-PLA2R IgG1/3, which were found in all MN sera. The alternative pathway likely amplifies complement activation initiated by the other pathways to pathologic levels responsible for tissue injury. We provide proof of concept that inhibiting the alternative pathway effectively limits complement activation by anti-PLA2R autoAbs. These findings are relevant for the design of interventions aimed at preventing complement-mediated injury in MN.

FR-OR088

Glomerular Deposition of Food Antigens in Adult Patients with Membranous Nephropathy

Hequn Zou. *Dept of Nephronology, Dept of Nephronology, Inst of Nephronology and Urology, The Third Affiliated Hospital of Southern Medical Univ, Guangzhou, GuangDong, China.*

Background: Cationic bovine serum albumin, a modified food-derived antigen, was reported to be related to childhood membranous nephropathy. We hypothesized that food antigen might play a role in adult membranous nephropathy, as well.

Methods: We detected food antigens, which were major allergic proteins extracted from egg, shrimp, fish, milk, hazelnuts, wheat, peanuts and soybeans in kidney biopsy specimens obtained from 67 patients with membranous nephropathy and 94 controls, through immunofluorescence technique with monoclonal antibodies to these proteins. Double-labeling confocal studies were used to analyze the location of food antigens and IgG. PLA2R1 staining was also performed in partial patients at the same time.

Results: Multiple food antigens were detected simultaneously in patients with idiopathic membranous nephropathies. Food antigens were found in 70.1% patients with IMN, while no food antigens were found in patients with other kidney diseases. Food antigens were detected in most patients with positive PLA2R1 in the biopsy. Food antigens co-localized with IgG in a fine linear and granular pattern along the glomerular capillary walls. However, there were no significant differences in clinical parameters between MN patients with or without glomerular deposition of food antigens.

Conclusions: Multiple food antigens were present in the glomeruli of patients with idiopathic membranous nephropathies. The potential role of some kinds of food antigens or curtain components of foods such as dietary lectins in the development of MN merits considering, both in exploring the pathogenesis of MN and giving a specific treatment to the patients with MN.

A Population-Based Study of the U.S. Population Shows the Majority of Persons Cannot Donate due to Preventable Diseases and Socio-Economic Conditions

Anthony J. Bleyer, Amber M. Reeves-Daniel, Anthony J. Bleyer. *Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC.*

Background: There is a shortage of living kidney donors in the U.S., but there have been no population-based studies examining the potential U.S. donor pool.

Methods: We obtained demographic data and information on potential exclusionary criteria for living donor kidney donation (LKD) from the NHANES Survey for persons 21-70 y. We defined exclusionary critera as: BMI > 35 kg2/m2, history of DM or a Hb A1c >6.5%, >4 alcoholic drinks/day, microalbuminuria >30 mg/g creatinine, eGFR < 80 ml/min/1.73m2, BP >140/90 or history of HTN, non-melanoma skin cancer, congestive heart failure, coronary artery disease, and HIV infection. Social factors included being a non-U.S. citizen and an annual family household income (FHI) <$25,000 (the U.S. poverty level).

Results: 55.2% of the population could not donate due to medical conditions: obesity (15%), hypertension (19.2%), DM (11.5%), and excessive alcohol intake (11.6%). 60.1% of individuals with FHI<$35000 could not donate due to medical conditions versus only 49.3% for FHI > $100,000 (p<0.0001). If one designates FHI below the poverty level and non-U.S. citizenship as exclusionary criteria, 68.5% could not donate. If one excludes smokers and individuals who have shortness of breath walking up an incline, 75.8% could not donate

Characteristic	White	African American	Hispanic	Asian
Obesity	13.8	24.1	15.7	2.1
Hypertension	17.9	30.3	17.6	14.9
Excess alcohol intake	10.9	8.8	18.9	3.9
Diabetes mellitus	9.5	17.6	12.8	11.5
eGFR < 80 ml/min	20.0	17.3	8.0	9.9
Microalbuminuria	5.6	12.9	9.6	8.6
Congestive heart failure	1.8	2.4	1.1	.6
Coronary artery disease	2.1	1.4	1.1	1.1
HIV infection	.2	1.2	.3	0
Total medical exclusion	54.8	63.9	54.2	37.7
Non-US citizen	2.1	5.2	42.6	37.4
Medical exclusion + non-US citizen + below poverty threshold	63.6	78.9	80.1	68.1

Conclusions: Many U.S. citizens are unable to donate a kidney due to preventable health conditions. If one includes financial and social restrictions, the proportion rises substantially. Efforts to improve the general health of the population and providing financial compensation would improve the number of possible kidney donors.

FR-OR090

Kidney Function Evaluation in Prospective Kidney Donors – Performance of Creatinine Clearance versus GFR as Measured by Iothalamate Clearance

Grace Snyder,[1] Jesse D. Schold,[1] Didier A. Mandelbrot,[2] Stuart M. Flechner,[1] Emilio D. Poggio.[1] *[1]Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH; [2]Transplant Nephrology, Univ of Wisconsin, Madison, WI.*

Background: The evaluation process of living kidney donation is dependent on the assessment of kidney function. While glomerular filtration rate(GFR) as measured by a tracer clearance is the gold standard, most institutions rely on 24-hour creatinine clearances(CrCl), and direct comparison of the two measurements in prospective living donors is limited. We therefore compared the 24-hour CrCl to ^{125}I-iothalamate GFR(iGFR) in living donors.

Methods: This is a single center, cross-sectional study of prospective living donors simultaneously undergoing both tests. We compared iGFR and 24-hour CrCl using univariate and multivariable linear regression adjusted for age, gender, body surface area(BSA), and race.

Results: 342 adults with iGFR and 24-hour CrCl measurements were included. Demographics: females:58%; Caucasians:85%; African Americans:9%; mean age 41(SD 11 range 18-72). We compare normalized iGFR and 24-hour CrCl across age groups.

			iGFR (ml/min per 1.73 m2) / 24 hr CrCl (ml/min)		
	Age subgroups (years)	n	25th percentile	Median	75th percentile
Men	18-40	76	100.1 / 95.4	108.5 / 115.0	117.9 / 135.3
	41-55	54	91.8 / 92.8	100.3 / 108.8	106.9 / 124.8
	>55	14	84.1 / 102.6	97.0 / 106.6	106.2 / 118.6
Women	18-40	94	97.8 / 91.8	111.0 / 110.5	120.0 / 122.3
	41-55	84	91.1 / 92.5	103.6 / 104.9	113.0 / 115.3
	>55	20	80.0 / 82.4	91.5 / 90.1	96.5 / 100.0

Multivariable regression showed a sigificant overestimation of GFR by 24-hour CrCl in African Americans versus others (18.5 versus 4.9, p=0.04) and men versus women (15.8 versus 7.5,p=0.01). Age and BSA were not associated with a difference in measurements.

Conclusions: 24 hour CrCl can be a useful measure of GFR in living donor evaluation, especially for women, but additional measures of GFR may be needed in men and African Americans given their significant overestimation of GFR. This issue becomes clinically relevant when assessing donors with GFRs in the lower ranges of normality.

FR-OR091

Long Term Survival in Kidney Donors with Pre Existing Hypertension

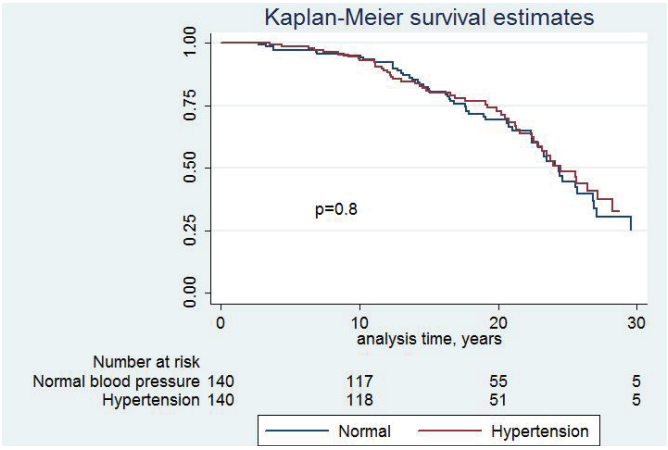
Geir Mjøen, Hallvard Holdaas. *Oslo Univ Hospital, Norway.*

Background: In the general population, even small increases in blood pressure are associated with mortality. However, in otherwise healthy kidney donors, this association is less certain. There is currently a lack of evidence whether pre-existing hypertension is associated with increased long-term mortality.

Methods: All donors in the period 1963-2007 were included. Baseline data were obtained from a national registry and patient files. Hypertension was defined retrospectively as BP> 140/90 or use of medication. Hypertensive and normotensive donors were matched 1:1 for age, gender and time of donation. As a sensitivity analysis we performed cox regression including all donors after multiple imputation adjusted for matching variables and also for BMI and smoking.

Results: Among a cohort of 2269 donors, 140 (6.2 %) had hypertension. Mean age was 57.7 years and 44.3 % were male. During a median follow-up of 16.9 years there were 51 deaths. Mean blood pressure was 147/89 mmHg in donors and 128/80 mmHg in controls. In matched analysis, there were no associations between pre existing hypertension and long-term mortality (p=0.8). Multivariate sensitivity analysis did not change results (HR 1.2, 0.9-1.7, p=0.2).

Conclusions: In otherwise healthy kidney donors, mild hypertension should not be considered a strict contraindication to kidney donation.



Funding: Government Support - Non-U.S.

FR-OR092

Gout in Living Kidney Donors

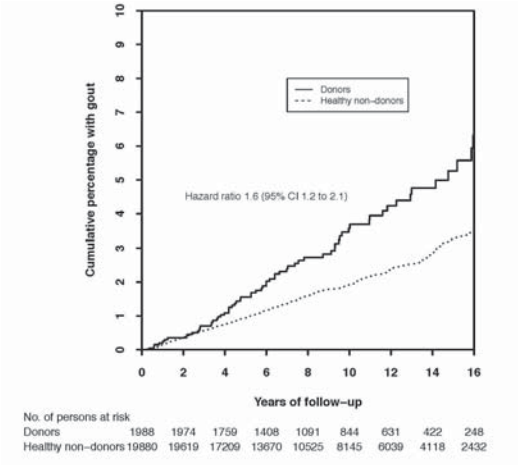
Ngan Lam,[1] Eric Mcarthur,[2] Joseph Kim,[3] G.V. Ramesh Prasad,[3] Krista L. Lentine,[4] Peter P. Reese,[5] Bertram L. Kasiske,[6] Charmaine E. Lok,[3] Amit X. Garg.[1,2] *[1]Western Univ; [2]Inst for Clinical Evaluative Sciences; [3]Univ of Toronto; [4]Saint Louis Univ; [5]Univ of Pennsylvania; [6]Univ of Minnesota.*

Background: To determine whether by donating a kidney, a person increases their risk of gout, as the serum concentration of uric acid rises in donors after nephrectomy.

Methods: We performed a retrospective matched cohort study using large healthcare databases. We included all living kidney donors in the province of Ontario, Canada who donated a kidney between 1992 and 2010. The pre-donation charts were manually reviewed and linked to provincial healthcare databases. Matched non-donors were selected from the healthiest segment of the general population. A total of 1988 donors and 19,880 matched non-donors were followed for a median of 8.4 years (maximum 20.8 years). Median age was 43 years at the time of donation (interquartile range [IQR] 35 to 51) and 52 years at time of last follow-up (IQR 45 to 60). 61% were women. The primary outcome was the time to a diagnosis of gout. The secondary outcome was receipt of medications typically used to treat gout (allopurinol, colchicine).

Results: Donors compared to non-donors were more likely to be diagnosed with gout (67/1988 [3.4%] versus 390/19,880 [2.0%]; 3.5 versus 2.1 events per 1000 person-years; hazard ratio 1.6; 95% confidence interval [CI] 1.2 to 2.1; P<0.001). Similarly, donors compared to non-donors were more likely to receive a prescription for allopurinol or colchicine (3.8% versus 1.3%; odds ratio 3.2; 95% CI 1.5 to 6.7; P=0.002). Results were consistent in multiple additional analyses.

Conclusions: The findings suggest that donating a kidney modestly increases an individual's absolute long-term risk of gout. This information should not deter living donor kidney transplantation, but it can be shared with potential donors and their recipients as part of the informed consent process.



FR-OR093

Number of Glomeruli Estimated from Renal Biopsy and CT Scan of Living Donors Aleksandar Denic,[1] Harini A. Chakkera,[1] Emilio D. Poggio,[2] Prince Singh,[1] Walter Park,[1] Mariam P. Alexander,[1] Walter K. Kremers,[1] Andrew D. Rule.[1] *[1]Mayo Clinic; [2]Cleveland Clinic, OH.*

Background: Nephron endowment is difficult to study in living humans but is thought to be an important determinant of renal health.

Methods: We studied 1281 living kidney donors at 3 different centers (Mayo Clinic in Minnesota and Arizona and Cleveland Clinic). Cortical volumes (mm^3) from both kidneys were obtained from pre-donation CT scans. At the time of surgical implantation of an allograft, a biopsy of the cortex was obtained and sections were analyzed for the numbers of non-sclerotic (NSG) and globally sclerotic (GSG) glomeruli. Weibel and Gomez models were used to calculate NSG and GSG densities (per mm^3) from the biopsy sections.

Results: We estimated the total number of NSG and GSG in each donor by multiplying cortical volume by the glomerular densities, adjusting for 30% biopsy shrinkage. There were a mean 1,378,302 NSG and 19,673 GSG per kidney in 18-19 year olds and this progressively decreased to 751,143 NSG and increased to 170,711 GSG in 70 year olds (P<0.001 for both trends). Reabsorbed glomeruli were estimated from the total number of detected glomeruli in each age group subtracted from that detected in 18-19 year olds (assumed 0 per kidney). The number of reabsorbed glomeruli increased to 481,525 in 70 year olds (P<0.001). The loss of NSG as assessed by the increase in GSG with age on biopsy fails to detect the substantial loss from reabsorbed glomeruli (Figure).

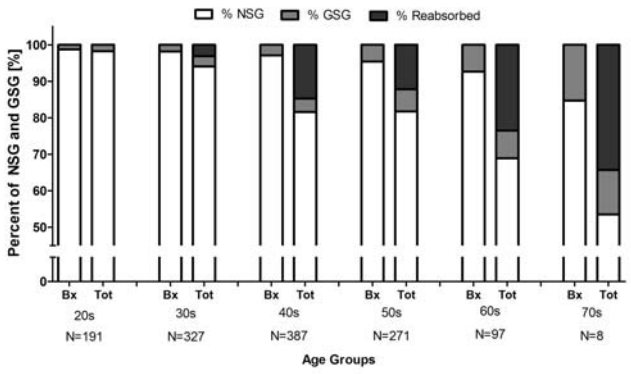


Figure. Percent of NSG and GSG on biopsy sections (Bx) and percent NSG, GSG and reabsorbed glomeruli among total glomeruli per kidney (Tot) by age group.

Analysis found that older age, shorter height, family history of ESRD, lower measured GFR and higher uric acid levels were independently associated with a decreased number of NSG (p<0.05 for all).

Conclusions: Loss of NSG with aging is much more severe than appreciated on biopsy due to the reabsorption of glomeruli. Number of NSG also associates with characteristics with congenital determinants (height and family history of ESRD).

The Effects of Recipient-Donor Gender Combinations and Body Size on Kidney Allograft Survival Valarie B. Ashby,[1] Alan B. Leichtman,[1] Michael A. Rees,[2] Peter X.K. Song,[1] Mathieu Bray,[1] Richard Eikstadt,[1] Audrey J. Goulding,[1] Wen Wang,[1] John Kalbfleisch.[1] *[1]Univ of Michigan, Ann Arbor, MI; [2]Univ of Toledo Medical Center, Toledo, OH.*

Background: Outcomes for transplants from living non biologically related donors (LNBRD) are of particular interest in kidney paired donation programs (KPDP) where exchanges are arranged among incompatible donor-recipient pairs, and chains are created from bridge, non-directed or altruistic donors. This work examines graft survival as a function of donor and recipient sex and body size.

Methods: SRTR data were used to analyze 222,443 kidney transplant recipients from 1996-2010. Rates of graft failure (HR) over 5 and 10 years were assessed using Cox models for transplants from LNBRD, living biologically related donors (LBRD), and deceased donors (DD). All models were adjusted for donor and recipient age and race/ethnicity, and recipient's primary disease, PRA, HLA mismatch, previous transplant, Hepatitis C, and years of ESRD.

Results: Males comprised 63%, 57% and 61% of LNBRD, LBD, and DD recipients; and 37%, 43% and 60% of the LNBRD, LBD, and DD groups, respectively. For each donor type, male donor to male recipient had superior graft survival compared to all other donor recipient combinations and, in particular, better than female to male. The table shows these differences persist as measured by hazard ratios after adjustment for donor and recipient body size.

Characteristic	Group	Living Not Biological Related Donor (N=28,049)		Living Biological Related Donor (N=57,102)		Deceased Donor (N=137,292)	
		N (%)	HR	N (%)	HR	N (%)	HR
Recipient-Donor Type	Female to Female	4,870 (17%)	0.97	14,729 (26%)	1.10*	22,479 (16%)	0.94*
	Female to Male	5,379 (19%)	1.04	9,577 (17%)	1.02	31,667 (23%)	0.91*
	Male to Female (Ref)	12,908 (46%)	1.00	17,682 (31%)	1.00	33,082 (24%)	1.00
	Male-Male	4,892 (17%)	0.82*	15,114 (27%)	0.88*	50,064 (37%)	0.92*
Recipient BMI	Obese (vs. Not Obese Ref)	7,001 (25%)	1.14*	11,083 (19%)	1.11*	31,576 (23%)	1.03*

	> 1.15	6,309 (23%)	1.04	14,440 (25%)	0.93*	39,530 (29%)	0.98
	Missing	5,145 (18%)	1.31*	16,444 (29%)	1.20*	15,600 (11%)	1.34*

P<0.05

Conclusions: Male recipients have significantly better graft survival outcomes with a kidney from a male donor. This difference is larger for living donors than differences due to age or HLA mismatch. These results may help guide the practice of inclusion of compatible pairs in KPDP; extensions could lead to a calculator to predict and compare donor-recipient outcomes.

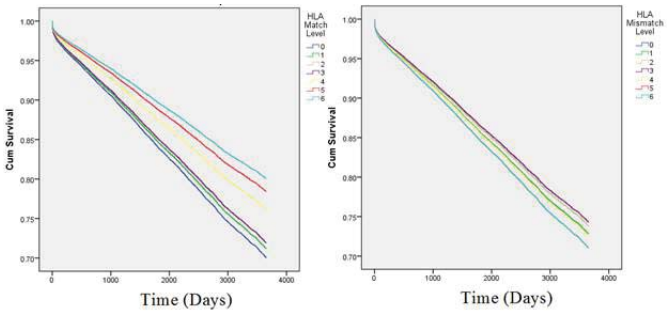
HLA Match/Mismatch Profiles and Impact on 10 Year Graft Survival: An Analysis of OPTN/UNOS Registry Data Rabi Yacoub, Madhav C. Menon, Girish N. Nadkarni, Etti Deborah Zeldis, Ioannis Konstantinidis, John C. He, Barbara T. Murphy. *Nephrology, Icahn School of Medicine at Mount Sinai.*

Background: Degree of Human Leukocyte Antigen(HLA) mismatch has known impact on allograft survival. The presence of homozygous/heterozygous HLA alleles can cause different degrees of HLA match within the same mismatch degree. There are limited data on HLA match/mismatch combinations impacting graft survival.

Methods: We utilized data from the United Network for Organ Sharing (UNOS) database from 1987-2012. We divided HLA match/mismatch profile into 22 permutations and analyzed graft survival using Cox-regression. We calculated graft loss risk using hazard ratios (HR) adjusted for: recipient demographics and comorbidities, donor demographics, terminal creatinine, ECD, DGF, CIT, and preemptive transplantation. We accounted for differences in HLA match/mismatch terminologies in the database over time by adjusting for transplantation date. Groups with <1% of the final sample size, patients with incomplete data, previous or concomitant organ transplantation were excluded.

Results: Of the 355812 recipients, we had complete data on 46048 recipients (Mean age 47.8, 60.7% male). Analysis revealed a stepwise worse 10-yr graft outcome with progressively unfavorable match/mismatch combinations (P<0.01). Both the degree of matching and mismatching had significantly independent effects on graft loss. However, when added in the same multivariable model, the degree of mismatching lost significance while HLA matches continued to be a significant predictor (P=0.579 and P=0.043, respectively).



Conclusions: Our analysis incorporating newer outcome data highlights the possible separate roles the degrees of HLA match and mismatch play in DDKT graft survival. A novel approach incorporating the HLA match/mismatch profiles in a weighted manner to stratify risk and predict graft survival may be optimal.

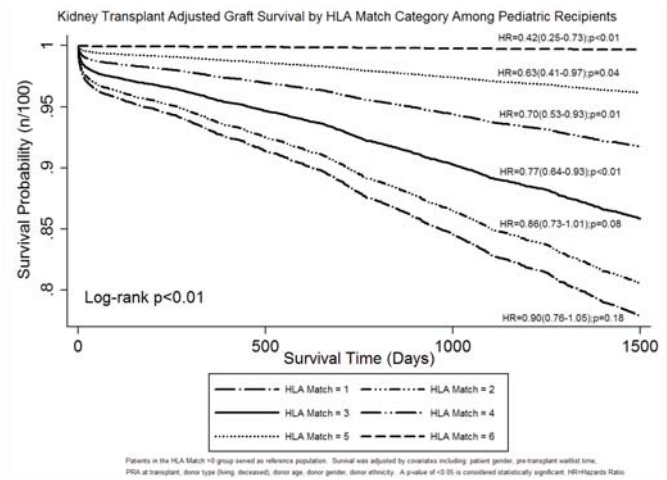
FR-OR096

Better Human Leukocyte Antigen Matching Is Associated with Graft Outcomes Among Pediatric Kidney Transplant Recipients Meera Gupta, Peter Abt, Matthew H. Levine. *Surgery, Div of Transplantation, Univ of Pennsylvania, Philadelphia, PA.*

Background: Kidney transplant(KT) graft survival is superior if received from ideal donors. Given the decline of living donor(LD) availability and the initiation of the Share35 kidney policy, we sought to determine the impact of HLA matching on graft outcomes.

Methods: A retrospective analysis of OPTN data(1988-2009) was conducted examining KT graft survival among pediatric(age<18) recipients based on HLA matching(0-6), Share35 policy status, and donor-type(LD versus Deceased Donor=DD) using Kaplan-Meier statistics and Cox regression analysis.

Results: Of 13,489 first KT pediatric recipients, there was a significant decline in LD availability post-Share35 initiation(-20.17%;p<0.01). Additionally, post-Share35 groups had poorer(0-2 HLA-antigen) matched grafts(64.88%) compared to the pre-Share35 cohort(39.69%;p<0.01). Adjusting for all factors, better HLA-matching(log-rank p<0.01), LD grafts(HR=0.63;p<0.01), and post-Share35 transplantation(HR=0.71;p<0.01) conferred better graft outcomes.



In a secondary analysis of recipients with poorly matched(0-2 antigen) grafts at first KT who underwent second KT, median wait-list time prior to second KT was longer(p<0.01), while second kidney graft survival was shorter(p=0.02). We also determined that better HLA matching at first KT correlated with lower peak PRA level at second KT(-0.14;p<0.01).

Conclusions: Among pediatric KT recipients, improved outcomes exist for better HLA-matched transplants, despite Share35 initiation and decline of LD availability. HLA matching retains its prognostic value in graft outcomes for first and subsequent KTs given its association with PRA level. Finally, patients who are better matched for previous transplants are less sensitized, have shorter waiting times, and longer graft survival times.

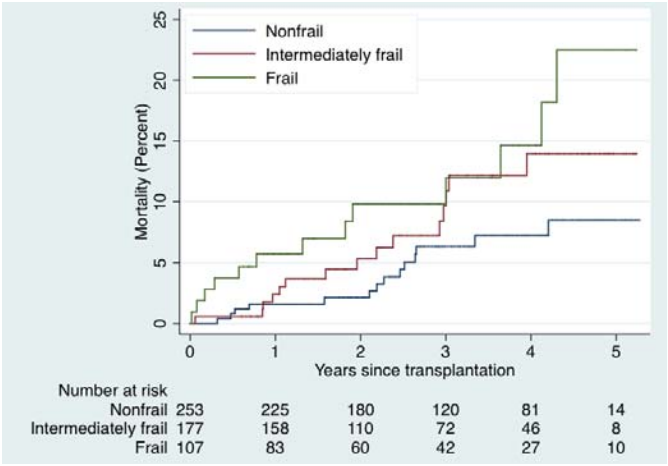
FR-OR097

Frailty as a Novel Predictor of Mortality in Kidney Transplant Recipients of All Ages Mara Mcadams-DeMarco, Andrew Law, Elizabeth King, Babak Orandi, Megan Salter, Nada Alachkar, Niraj Desai, Ravi Varadhan, Jeremy Walston, Dorry L. Segev. *Johns Hopkins.*

Background: We have described strong associations between frailty, a measure of physiologic reserve initially described and validated in geriatrics, and short-term outcomes in kidney transplantation (KT) recipients, including early hospital readmission and delayed graft function. In this study we estimated its association with mortality.

Methods: Frailty was prospectively measured in 537 KT recipients at KT (12/08-8/13). Cox proportional hazards models were adjusted for confounders using a novel approach to improve model efficiency in single-center studies. It is well-known that there are dozens of mortality predictors, but it is impossible to adjust for all of these in single centers studies with relatively small sample sizes (because of imprecision and risk of overfitting). We precisely estimated the coefficients of every confounder using the huge sample size of the SRTR (n=37,858), and fed these back into a single-center model, where frailty was the only coefficient estimated.

Results: Mean age was 53.0 years (SD=14.0), 40.0% were female, 38.9% were African American and 44.9% received live donor transplants; 19.9% were frail and 33.0% were intermediately frail at KT. At 5 years, the survivals were 91.5%, 86.0% and 77.5% for non-frail, intermediately frail and frail KT recipients, respectively. Figure: Mortality by Frailty Status



Frailty was independently associated with a 2.17-fold (95%CI:1.01-4.65, P=0.047) higher death risk with no effect difference between older and younger recipients (P for interaction=0.4).

Conclusions: KT recipients of all ages have a high frailty prevalence, >3-fold higher than community dwelling older adults. In this population, regardless of age, frailty is a strong, independent predictor of mortality, after carefully adjusting for many confounders using a novel statistical approach.

The Histologic Staging of Polyoma-BK-Virus Nephropathy: Results from a Multicenter Study Volker Nickeleit,[1] Surya V. Seshan,[2] A. Gasim,[1] Harsharan Kaur Singh.[1] *[1]Div of Nephropathology, The Univ of North Carolina, Chapel Hill, NC; [2]Dept of Pathology, Weill Cornell Medical Center, New York, NY.*

Background: Polyomavirus nephropathy (PVN) is the most important infection in renal allografts (incidence 4% in 2010)and can lead to chronic graft failure in >50% of patients reported in some series. Since PVN is not routinely classified into different disease stages, it is unclear if specific morphologic phenotypes carry prognostic significance. The **AIM** of this multicenter study is to define clinically predictive morphologic PVN disease stages in a large cohort of diverse patient populations.

Methods: 9 U.S. and European centers collected 192 diagnostic index biopsies with PVN from 192 patients; 90% transplanted between 2003-2008 (74% males, 31% blacks). Histologic changes were evaluated at time of initial diagnostic index biopsy (Banff scores; intra-renal PV load-levels (pvl)-percentage of tubular SV40-T staining). Clinical data were collected from time of transplant to 24 months post-index biopsy. Statistical analyses: hierarchical mixed models, stepwise regression, with specific emphasis on racial backgrounds.

Results: Renal function and graft survival: Strongest associations were found with intra-renal pvl and Banff ci interstitial fibrosis scores (minor: <25% and major: >25% fibrosis). Limited associations were seen with presence or absence of intra-nuclear PV-inclusion bodies. Based on these statistics, 3 PVN disease grades were defined: 1 (minimal – pvl <1% and ci <25%), grade 2 (florid – pvl and ci scores other than listed in grades 1 and 3), and grade 3 (advanced – pvl >10% and ci >25%). 24% of cases (46/192) were PVN grade 1, 64% grade 2, and 13% grade 3. PVN grades correlated significantly with: a) time of diagnosis (earliest:median 18 months in grade 1), b) peak serum creatinine level-time of index biopsy (best in grade 1 with stable function and minimal Δ change from baseline readings), 4) PVN resolution (79% in grade 1), and 5) allograft failure (grade 3 with 50%). All p <0.001.

Conclusions: The subclassification of PVN into 3 disease grades (minimal, florid, advanced) helps to predict graft function, graft survival and the resolution of PVN.

Sirtuin 7 Modulates Renal Acid-Base Homeostasis through Deacetylation of the K^+:Cl^- Cotransporter, KCC4 Zesergio Melo,[1] Armando R. Tovar,[2] Silvia Cruz-Rangel,[1] Adriana P. Mercado,[3] Dongryeol Ryu,[4] Nimbe Torres,[2] Gerardo Gamba,[1] Lilia G. Noriega.[2] *[1]Molecular Physiology Unit, INCMNSZ-IIB-UNAM; [2]Dept of Nutrition Physiology, INCMNSZ; [3]INCICH; [4]Univ of Lausanne.*

Background: Sirtuin 7 (SIRT7) is a NAD+ dependent deacetylase. Its molecular targets and physiological functions are unknown. In silico analysis of 41 recombinant inbred mouse strains kidney transcripts (GeneNetwork database) revealed a positive correlation between SIRT7 and KCC4 expression. The expression of KCC4 in the basolateral membrane of α-intercalated cells is modulated by acid-base status (Melo et al. AJP Renal 2013) and KCC4-KO mice exhibit renal tubular acidosis. We thus analyzed the effect of Sirt7 on KCC4 expression and activity.

Methods: We used *Xenopus laevis* oocytes, HEK293 cells, and a mouse model of metabolic acidosis to assess SIRT7 localization, KCC4 activity and acetylation, and the interaction between the two proteins by co-immunoprecipitation. KCC4 protein expression in kidney was assessed in Sirt7$^{-/-}$ mice. Activity of KCC4 was assessed by measuring the Cl^--dependent, $^{86}Rb^+$ uptake in control and hypotonic conditions.

Results: KCC4 is acetylated and its activity is significantly reduced when *Xenopus laevis* oocytes and HEK cells are incubated with the deacetylase-inhibitor nicotinamide (NAM). Incubation with NAM also decreases KCC4 protein levels. In contrast, KCC4 is deacetylated and its activity is enhanced in the presence of SIRT7 and its co-activator NAD^+, without affecting the protein levels. Moreover, KCC4 and SIRT7 interact and NAD^+ enhances this process in HEK cells. As occurs with KCC4, metabolic acidosis increased the expression levels of Sirt7 and its co-localization with KCC4 at the basolateral plasma membrane of α-intercalated cells. Finally, KCC4 expression levels in the kidney are significantly reduced in SIRT7$^{-/-}$ mice.

Conclusions: Our data demonstrate that SIRT7 colocalize and interacts with KCC4 and up-regulates its activity by deacetylation. This positive effect of Sirt7 is implicated in KCC4 regulation during metabolic acidosis.

The Function of ATP6AP2/PRR in Endosomal Trafficking in the Proximal Tubules of the Mouse Kidney Simon Daniel Gerber,[1,2] Florian Grahammer,[1] Tobias B. Huber,[1] Matias Simons.[1,2] *[1]Univ Medical Center Freiburg, Freiburg, Germany; [2]Imagine Inst, Paris, France.*

Background: The V-ATPase subunit, ATP6AP2 or PRR, is a highly conserved protein that has initially been reported to participate in the renin-angiotensin system. However, our recent data from *Drosophila* suggests a role in endolysosomal function, mTOR signaling and transcriptional regulation of Megalin (Gleixner et al., Cell Reports, in press). In this study, we investigate the function of PRR in endosomal trafficking in the proximal tubules of the murine kidney.

Methods: We used doxycycline-inducible *Pax8-rtTA;TetOCre* and *PRR floxed* mice to permanently delete PRR in the whole nephron except glomeruli in the mouse kidney.

Results: In the kidney, PRR is expressed in intercalated cells of the distal nephron and collecting duct. PRR is also highly expressed in the proximal tubules. The proximal tubules recover filtered proteins by endocytosis and subsequently degrade them in the lysosomes, a process that is dependent on V-ATPases. Time-specific deletion by administering doxycycline to *Pax8-rtTA;TetOCre;PRR floxed* mice ablated PRR in all proximal tubules and distal tubules and the entire collecting duct of the mouse kidney, but not in the glomeruli and interstitium. Ablation of PRR resulted in low molecular weight (LMW) proteinuria and to a high albumin to-creatinine-ratio (ACR) value. Furthermore, enrichment of lysosomal markers (Lamp-2) in proximal tubular cells was observed.

Conclusions: Collectively, these results demonstrate that deletion of PRR in the proximal tubules of the mouse kidney leads to LMW proteinuria and albuminuria as well as the upregulation of lysosomal markers. We suggest that PRR is essential for normal proximal function and may have a role in endosomal trafficking. Follow-up studies are under way to address the role of PRR and the V-ATPase in mTOR signaling and the control of Megalin-mediated endocytosis in mouse proximal cells.

FR-OR101

Renal Peroxiredoxin 6 Interacts with Anion Exchanger 1 and Plays a Novel Role in pH Homeostasis Sara Lynn Sorrell,[1] Zoe J. Golder,[1] D. B. Johnstone,[2] Fiona E. Karet.[1] *[1]Dept of Medical Genetics, Univ of Cambridge, Cambridge, United Kingdom; [2]Dept of Medicine, Section of Nephrology and Kidney Transplant, Temple Univ, Philadelphia, PA.*

Background: Peroxiredoxin 6 (PRDX6) is one of six members of the peroxiredoxin family, which have peroxidase activity and act as antioxidants. PRDX6 is a unique member because 1) it contains only one conserved cysteine residue, the others having two and 2) it has additional phospholipase A_2 activity. A yeast-two-hybrid screen elicited PRDX6 as a potential binding partner of the C-terminal tail of Anion Exchanger 1, also known as Band-3, (AE1(C)). AE1 is a Cl^-/HCO_3^- exchanger basolaterally expressed in renal intercalated cells involved in pH regulation.

Methods: Yeast mating; immunostaining; pulldown and co-IP; mass spectrometry; acid challenge testing.

Results: Human kidney immunostaining showed widespread cellular expression of PRDX6 and basolateral localization in AE1-positive cells. *In vitro and ex vivo* pulldowns and immunoprecipitation assays in human kidney confirmed specificity of the interaction between PRDX6 and AE1. Purified PRDX6 protein exhibits four oxidation states, which we verified by mass spectrometry, and which we showed can also be found in human and mouse kidney protein fractions when separated under non-reducing conditions. Site-directed mutagenesis of the conserved cysteine (47C) in PRDX6 resulted in loss of binding to AE1 and considerable loss of dimerization. We found that *Prdx6*$^{-/-}$ mice have a baseline acidosis and greater Ae1 expression than wild type animals. After acute oral acid challenge, acidosis developed transiently in +/+ animals, and worsened over a similar time period in -/- mice. Concomitantly, Prdx6 protein levels increased while Ae1 remained the same in +/+ mice, but Ae1 expression significantly decreased in *Prdx6*$^{-/-}$ animals, suggesting a requirement for Prdx6 to maintain Ae1 during acute acidosis. H+E staining of kidneys from acidified mice showed widespread cellular vacuolation (a normal response to cellular stress) in wild-type but not knockout animals.

Conclusions: These results indicate a novel role for Prdx6 in pH homeostasis.

High Mobility Group Box 1 (HMGB1) Inhibits HCO_3^- Absorption in Medullary Thick Ascending Limb (MTAL) through a Receptor for Advanced Glycation End Products (RAGE)-Dependent Pathway David W. Good, Thampi George, Bruns A. Watts. *U TX Med Branch, Galveston, TX.*

Background: HMGB1 is an endogenous damage-associated molecule that plays a role in mediating kidney dysfunction in sepsis and other inflammatory disorders. HMGB1 is a nuclear protein that is released by cells into the extracellular space in response to infection or injury, where it interacts with Toll-like receptor 4 (TLR4) and other receptors to activate immune and inflammatory responses. We have shown that bacterial LPS inhibits HCO_3^- absorption in the MTAL through activation of a basolateral TLR4-ERK pathway. Here we examined whether HMGB1 could inhibit MTAL HCO_3^- absorption through activation of the same TLR4 pathway.

Results: Adding HMGB1 (1 μg/ml) to the bath decreased HCO_3^- absorption by 25% in isolated, perfused mouse and rat MTALs. In direct contrast to inhibition by bath LPS, the inhibition of HCO_3^- absorption by HMGB1 was preserved in MTALs from TLR4$^{-/-}$ mice and was not affected by ERK inhibitors. Also, the inhibition by HMGB1 was additive to inhibition by LPS. Thus, HMGB1 receptors other than TLR4 were investigated. Immunoblot analysis showed that the cell surface HMGB1 receptor RAGE is expressed in the inner stripe of the outer medulla of mouse and rat kidney. The selective RAGE antagonist FPS-ZM1 eliminated inhibition of HCO_3^- absorption by HMGB1 but had no effect on inhibition by bath LPS. Incubation of MTALs with neutralizing anti-RAGE antibody also eliminated inhibition by HMGB1.

Conclusions: We conclude that HMGB1 inhibits HCO_3^- absorption in the MTAL through a RAGE-dependent pathway that is additive to inhibition by LPS through TLR4. These results provide the first evidence that HMGB1 acts directly to impair the function of renal tubules and that RAGE signaling modulates renal tubule transport. Our studies reveal novel pathophysiological mechanisms for sepsis-induced renal tubule dysfunction, whereby exogenous pathogen-associated molecules and endogenous damage-associated molecules function directly and independently through different receptor signaling pathways to inhibit MTAL HCO_3^- absorption. These effects could impair the ability of the kidneys to correct acidosis that contributes to sepsis pathogenesis.

FR-OR103

Furosemide Stimulates Pronounced H^+ Secretion in the Thick Ascending Limb Pauline I.A. de Bruijn,[1] Nina Himmerkus,[2] Helle A. Praetorius,[1] Markus Bleich,[2] Jens G. Leipziger.[1] *[1]Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark; [2]Inst of Physiology, Christian-Albrechst Univ, Kiel, Germany.*

Background: Furosemide is a loop diuretic that inhibits Na^+ and Cl^- reabsorption in the thick ascending limb (TAL). Besides massive diuresis, furosemide also induces a pronounced urinary acidification. This is commonly explained by the increased Na^+ delivery to the distal tubule, which is believed to stimulate H^+ secretion by the V-type H^+ ATPase in the α-intercalated cells. The direct role of the TAL on urinary acidification has never been investigated directly. We have previously reported that furosemide causes a NHE3-dependent H^+ secretion in isolated perfused medullary TAL and here we wanted to investigate if this H^+ secretion contributes to furosemide-induced urinary acidification in whole animals.

Methods: Mice were anesthetized and the bladders were catheterized. Urinary net acid excretion (NAE) and urinary pH was determined during furosemide administration with or without the NHE3 specific inhibitor #4167.

Results: In control animals, urine pH and NAE remained unaltered for the duration of the experiment. Furosemide administration caused a rapid onset of urinary acidification and reached the maximum H^+ secretion after 20 minutes (3.16 ± 0.83 μM), which was reflected by a significant increase in NAE (ΔNAE 5.05 ± 0.98 μmol/h). When #4167 was given, a reduction in H^+ secretion was observed (i.e. an alkalisation) but this did not cause a change in NAE. When both drugs were given together, the furosemide-induced H^+ secretion and NAE were much attenuated compared to furosemide alone (H^+ peak 1.17 ± 0.64 μM; ΔNAE 2.27 ± 0.84 μmol/h).

Conclusions: We show that inhibition of the apical NHE3 causes a significant drop in furosemide induced H^+ and NAE excretion. These results indicate that furosemide stimulates H^+ secretion in the TAL via the apical NHE3 and revise the current understanding of loop diuretic-induced urinary acidification.

FR-OR104

Axial Flow Stimulates Acid Secretion in the Distal Convoluted Tubule
Tong Wang,[1] Lawrence G. Palmer,[2] Alan Mark Weinstein.[2] *[1]C. & M. Physiology, Yale Univ, New Haven, CT; [2]Physiology and Biophysics, Weill Medical College of Cornell Univ, New York.*

Background: It is well documented that axial flow regulates Na^+ and HCO_3^- transport in the proximal tubule, but whether flow regulates distal tubule acid/base transport has never been directly measured. Mathematical models have examined flow-dependent transport of Na^+ and K^+ transport in the distal nephron; however, there appears to be no information about the impact of flow on the components of net acid excretion, except indirect evidence that furosemide increased urinary acid secretion.

Methods: We have examined flow-mediated changes in both Na^+ and HCO_3^- absorption along the distal tubule by *in vivo* microperfusion in rat kidney. The net fluid and HCO_3^- absorption was examined at tubular perfusion rates of 5, 10, 15 and 20 nl/min with constant luminal HCO_3^- concentration (25 mM) in the distal tubule.

Results: The fluid absorption (J_v) increased from 0.56±0.1 to 1.1±0.4 (n=8; P>0.05); 1.3± 0. 3 nl/min/mm (n=6; P<0.05) and 1.6±0.3 (n=6; p<0.05); and the HCO_3^- absorption (J_{HCO3}) increased from 26.3±12.2 to 43.4±12.7 (P>0.05); 65.3± 22.6 (p<0.05) and 160.8±16.6 pmole/min/mm (P<0.001) when flow rate increased from 5 to 10, 15 and 20 nl/min respectively. The fractional increase in J_v was 109% and 128%; fractional increase in J_{HCO3} was 65% and 148% when flow rate increased from 5 to 10 and to 15 nl/min, respectively. There is no significant difference between the increments of Jv and J_{HCO3}. However, when the flow rate increased to 20 nl/min, Jv increased 188% but J_{HCO3} increased 510%.

Conclusions: These results indicate that flow stimulates both Na^+ and HCO_3^- absorption in the distal tubule, but that HCO_3^- absorption may be driven quite a bit higher under conditions of very high flow, such as might be seen with loop diuretics. Compared to the proportional flow-induced changes in both Na^+ and HCO_3^- absorption in proximal tubule, the disassociation of flow-stimulated Na^+ and HCO_3^- absorption suggests that different mechanisms may mediate flow-dependent transport in the distal tubule.

FR-OR105

Targeted NBCe1A Deletion Causes Proximal RTA: *Whole nbce1* (*sh_nbce1*) KO versus *nbce1A* KO Mice
An-Ping Chen,[1,3] Heather L. Holmes,[1] Minhwang Chang,[1] Lena Carleton,[1] Michael F. Romero.[1,2,3] *[1]Physiology & Biomed Engineering; [2]Nephrology & Hypertension; [3]Kogod Aging Center, Mayo Clinic College of Medicine, Rochester, MN.*

Background: NBCe1 (SLC4A4) transports Na^+ and $nHCO_3^-$ out of the basolateral membrane of the renal proximal tubule. Human, recessive mutations in *SLC4A4* result in a severe proximal renal tubular acidosis (pRTA) with glaucoma and cataracts, but do not cause death. However, the NBCe1 whole-gene knockout mice (*sh_nbce1* KO; A, B and C isoforms, Gary Shull, U Cinc) die within 21d due to systemic defects gut plugging. Interestingly, one patient (Q29X) is only missing the NBCe1A-isoform but still has pRTA and glaucoma.

Methods: To distinguish the biological function of NBCe1A (only isoform in kidney), we generated mice selectively deficient in *nbce1*A using the TALEN approach. We compared non-anaesthetized, blood chemistries (cheek bleeds) of mice using a Nova pHOx Ultra analyzer.

Results: Both *sh_nbce1* and *nbce1A* KO mice are acidotic (blood pH = 7.08 and 7.10; $[HCO_3^-]$=4.9 and 7.2 mM; P_{CO2} = 16.6 and 22.7 mmHg, respectively). WT controls for both genotypes are not acidotic (blood pH = 7.44 and 7.34; $[HCO_3^-]$=17.8 and 12.9 mM; P_{CO2} = 24.7 and 23.3 mmHg, respectively). While *sh_nbce1 KO* mice die by 21d [Gawenis et al, 2007. PMID 17192275], the *nbce1*A KO mice are still alive at 9m, are not obviously runted and are fertile. Both KO mice have elevated Cl^- (131 mM for *sh_nbce1 KO and* 129 mM for *nbce1*A KO v. 114-120 mM for WT). The *nbce1*A KO mice show normal P_{CO2}, P_{O2}, hematocrit, K^+, glucose, and BUN. However, the *sh_nbce1 KO* mice show low P_{CO2}, high P_{O2}, low hematocrit, low K^+, low glucose, and high BUN.

Conclusions: Deletion of the NBCe1 protein in the renal proximal tubule results in a pRTA. If the non-renal isoforms (B,C) are also deleted (*sh_nbce1 KO*), then systemic homeostasis is further compromised. These differences in these two models should highlight which non-renal tissues play roles in systemic acid-base homeostasis. Targeted deletion of *nbce1A (nbce1A KO)*, results in a phenotype which replicates the human SLC4A4 pRTA and glaucoma, allowing aging-related investigation of the NBCe1A role in the kidney and eye. Dietary Phosphate Is a Novel Regulator of Glucose and Lipid Metabolism
Maerjianghan Abuduli, Yutaka Taketani, Hirokazu Ohminami, Haruka Ueda, Eiji Takeda. *Dept of Clinical Nutrition, Univ of Tokushima, Tokushima, Japan.*

Background: Recent epidemiological and animal studies have suggested that excess intake of phosphate would be a risk factor for progression of chronic kidney disease and cardiovascular complication. However, the effect of high phosphate (HP) diet intake on the development of metabolic disorder such as obesity and type 2diabetes is not elucidated. In this study, we investigated the effect of dietary phosphate loading on glucose and lipid metabolism in healthy rats.

Methods: Male, Sprague-Dawley rats were divided into three groups and fed experimental diets including 0.2% (LP), 0.6% (CP) or 1.2% (HP) phosphate, respectively. After 4 weeks, serum, urine, liver and brown adipose tissue (BAT) were obtained and subjected to evaluation.

Results: HP group showed the lower plasma levels of insulin and free fatty acid and significantly reduce the visceral fat accumulation than other groups. In addition, the respiratory quotient was decreased in HP group without changes in locomotive activity, which indicated preferential utilization of fat for energy production. HP group rats were also suppressed hepatic lipogenic gene expression including sterol regulatory element binding protein-1c, fatty acid synthase and acetyl-CoA carboxylase, whereas there was no difference in fat oxidation among the groups. On the other hand, uncoupling protein1(UCP1) and peroxisome proliferator-activated receptor gamma coactivator1 alpha were highly expressed in HP group than other groups due to improvement of ectopic fat deposition in BAT.BAT is known to play a critic role in energy expenditure by regulating thermogenesis, which is mediated by its characteristic UCP1 expression. It is suggested that HP diet has a potential role in the increased energy expenditure by upregulation of BAT activation.

Conclusions: Our data indicates that HP diet can negatively regulate lipid synthesis in liver and increased lipid oxidation through effective thermogenesis in BAT, thereby preventing visceral fat accumulation. Dietary phosphate is a novel regulator of glucose and lipid metabolism, although further studies are needed to elucidate the biological importance and underlying mechanisms.

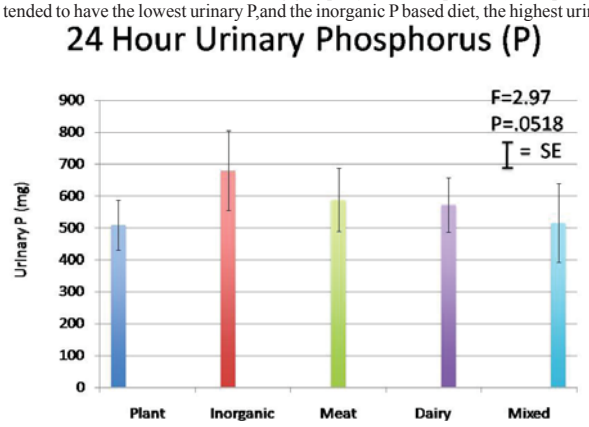
Metabolic Effects of Different Sources of Dietary Phosphorus
Anuja P. Shah,[1] Joel D. Kopple,[1] Rachelle Bross,[1] Rajnish Mehrotra.[3] *[1]Los Angles Biomedical Research Inst, Harbor-UCLA Medical Center, Torrance, CA; [2]Div of Nephrology, Univ of Washington, Seattle, WA.*

Background: Serum phosphorus (P) is associated with increase vascular calcification and endothelial cell dysfunction, and in chronic kidney disease (CKD) patients, high serum and dietary P are associated with increased mortality. Animal data and some human data suggest that different food sources of dietary P may affect intestinal P absorption. We examined in CKD patients the effect of 5 different dietary sources of P on intestinal P absorption, as determined 24 h urinary P excretion.

Methods: 24 hour urine P was measured in five stage 4 or 5 CKD patients who lived in a metabolic balance ward for a 31 hour study on five occasions separated by two week intervals each. Subject ate the same amount of P on each admission, but the source of dietary P varied in random order from P primarily from plants, inorganic P, meat, dairy foods or mixed with 25 % of P derived from each of these four food sources. For each patient, diets were isocaloric, isonitrogenous and provided about 800 mg calcium per day and 1000 mg P/day.

Results: 24 hour urine P varied among groups by ANOVA (p=.0518). The plant based diet tended to have the lowest urinary P,and the inorganic P based diet, the highest urinary P.



Conclusions: Inorganic P is the most readily intestinal absorbed source of dietary P. The preliminary data from this study suggest that to avoid or reduce high P burden, for a given P intake, dietary inorganic P should be minimized and plant sources of dietary P encouraged. This is the first study to examine the effects of five different food sources of P on intestinal P absorption in CKD patients.

Intracellular Pi Evolution in Pig Muscle during Hemodialysis: An In Vivo Phosphate MR Spectroscopy Study
Sandrine Lemoine,[1] Thomas Fournier,[1] Gabriel Kocevar,[2] Danielle Ibarrola,[2] Dominic Sappey-Marinier,[2] Laurent Juillard.[1] *[1]Nephrology, Hospices Civiles de Lyon - Hopital E. Herriot, Lyon, France; [2]CERMEP-Imagerie du Vivant, Univ Claude Bernard Lyon 1, Lyon, France.*

Background: Among the 600 to 700 mg of inorganic phosphate (Pi) removed during a 4-hour hemodialysis session, only 10% is extracted from the extracellular space (1). The origin of the other 90% of removed Pi is unknown and two hypothesis have been proposed being either the intracellular compartment or bone. Spalding et al (2) hypothesized that Pi exchanges between intra and extracellular compartments were diffusive, suggesting that the intracellular compartment could be the main source of Pi removed during hemodialysis. We tested this hypothesis during a hemodialysis session, by using Phosphorus (^{31}P)

Magnetic Resonance Spectroscopy (MRS), which is the only tool allowing in vivo and dynamic measurement of the intracellular Pi concentration as well as the other's phosphate metabolites such as Phosphocreatine (PCr) and ATP.

Methods: 3-hour hemodialysis sessions were performed in 6 pigs, after surgical bi-nephrectomy, with a Prismaflex® generator and a M100® dialyser (Hospal). The extra-corporal circulation blood flow was maintained between 100 and 150 mL/min. ^{31}P MRS exams were performed with a 1.5T Siemens Sonata system using a surface coil placed over the gluteal muscle region. ^{31}P MR spectra (TR=10s, TE=0.35ms) were acquired every 2'40" before, during and after dialysis. Blood samples were obtained during the whole examination to measure plasma Pi concentrations.

Results: During the dialysis, the mean PCr/Pi ratio decreased significantly (+6.9%, $p<0.00001$), while the PCr/βATP ratio increased (+22.2%, $p<0.00001$). Plasma Pi concentration felt rapidly within 60 min from 2.30 ± 0.18 mmol/L to 1.65 ± 0.10 mmol/L (-28,08%, p=0.003) then plateaued.

Conclusions: This study demonstrated that intracellular Pi concentration did not decrease in parallel with the extracellular Pi decrease as proposed (2). In contrast, the intracellular Pi increase may reflect a cellular stress induced by hemodialysis and/or a strong intracellular Pi production, using the mitochondrial Pi reserve, to respond to the extracellular decrease.

FR-OR109

Inorganic Phosphate Inhibits Osteoclastogenesis by Modulating miR-223. Implications for Chronic Kidney Disease-Mineral and Bone Disorder Laurent Metzinger, Eleonore Ourouda Mbaya, Loïc Louvet, Valérie Metzinger-Le Meuth, Ziad Massy. *INSERM U1088, INSERM u1088, Amiens, Na, France.*

Background: Chronic kidney disease-mineral and bone disorder (CKD-MBD) is a common complication of CKD, and uremic toxins have been shown to be instrumental in this process. We have previously shown that miR-223 is increased in smooth muscle cells subjected to the uremic toxin inorganic phosphate (Pi), and in the aorta of CKD mice. Here, we aimed to understand the role of miR-223 in osteoclastogenesis, and thus in the course of CKD-MBD.

Methods: RT-qPCR was used to measure the expression of miR-223. Up- and down-regulation of this miRNA was performed using specific pre-miR and antagomiR. We assessed differentiation of monocyte/macrophage precursors using RAW 264.7 cells and PBMC. TRAP activity and bone resorption were measured to assess osteoclast activity.

Results: As previously described, Pi induced a strong decrease of osteoclastogenesis in RAW cells. Concomitantly, miR-223 levels were decreased. An antogomiR directed against miR-223 inhibited osteoclastogenesis, while in contrast overexpression of miR-223 triggered differentiation. Similar results were found when measuring TRAP activity. We show that miR-223 affects the expression of targets Mef2 and RhoB, but also of the Akt signalling pathway, which induces osteoclastogenesis. These results were confirmed by measuring bone resorption activity in human PBMC differentiated into osteoclasts.

Conclusions: We show here an implication of miR-223 in osteoclast differentiation, with possible implications of the role of this miRNA in the course of CKD-MBD. Modulating miR-223 in CKD patients could thus be useful in the management of this complication of CKD.

Down-Regulation of Renal Type IIa Sodium-Dependent Phosphate Co-Transporter During Lipopolysaccharide-Induced Acute Inflammation Hironori Yamamoto,[1] Shoko Ikeda,[2] Otoki Nakahashi,[2] Yutaka Taketani,[2] Masayuki Iwano,[4] Ken-Ichi Miyamoto,[3] Eiji Takeda.[2] *[1]Health and Nutrition, Jin-ai Univ, Echizen, Fukui, Japan; [2]Clinical Nutrition, Univ of Tokushima, Tokushima, Japan; [3]Molecular Nutrition, Univ of Tokushima, Tokushima, Japan; [4]Nephrology, Univ of Fukui, Fukui, Japan.*

Background: The type IIa sodium-dependent phosphate cotransporter (Npt2a) plays a critical role in reabsorption of inorganic phosphate (Pi) by renal proximal tubular cells. Pi abnormalities during early stages of sepsis have been reported, but the mechanisms regulating Pi homeostasis during acute inflammation are poorly understood. We examined the regulation of Pi metabolism and renal Npt2a expression during lipopolysaccharide (LPS)-induced inflammation in mice.

Methods: C57/BL6J mice were treated with LPS in a dose-dependent manner and were sacrified after 3hrs. Wistar rats with parathyroidectomized (PTX) or sham surgery were purchased from Japan SLC Inc. Plasma Pi, intact parathyroid hormone (iPTH) and intact fibroblast growth factor 23 (iFGF23) levels were measured and renal Npt2a gene expression analysis were performed by western blotting, immunostaining, and quantitative real-time PCR.

Results: Dose-response and time-course studies with LPS showed significant increases of plasma Pi and iPTH levels and renal Pi excretion, while renal calcium excretion was significantly decreased. There was no difference in plasma 1,25-dihydroxyvitamin D levels, but the induction of plasma iFGF 23 levels peaked 3 h after LPS treatment. LPS administration significantly decreased Npt2a protein expression in the brush border membrane (BBM) 3 h after injection, but there was no change in renal Npt2a mRNA levels. Moreover, tumor necrosis factor-α injection also increased plasma iPTH and decreased renal BBM Npt2a expression. Importantly, we revealed that parathyroidectomized rats had impaired renal Pi excretion and BBM Npt2a expression in response to LPS.

Conclusions: These results suggest that the downregulation of Npt2a expression in renal BBM through induction of plasma iPTH levels alter Pi homeostasis during LPS-induced acute inflammation.

Tenapanor Inhibits Phosphorous Absorption, and Protects against Vascular Calcification in Nephrectomized Rats Dominique Charmot, Andrew G. Spencer, Marc Navre, Jason G. Lewis, Christopher Carreras, Jeffrey Jacobs, Noah Bell, Limin He, Desiree Deshpande, Kenji Kozuka, Samantha Koo-Mccoy, Ingrid Langsetmo, Edward E. Dy, Michael R. Leadbetter, Jill N. Kohler, Ziyang Zhong, Eric Daniel Labonte. *Ardelyx Inc., Fremont, CA.*

In chronic kidney disease (CKD), phosphate retention arising from diminished glomerular filtration rate (GFR) is a key early step in a pathological cascade leading to hyperparathyroidism, metabolic bone disease, vascular calcification, and cardiovascular mortality. Tenapanor, a minimally-systemic inhibitor of the intestinal sodium/proton exchanger subtype 3 (NHE3), reduces sodium absorption in humans and is currently being evaluated in patients with CKD and end-stage renal disease on hemodialysis (ESRD-HD), as well as patients with constipation predominant irritable bowel syndrome (IBS-C). We report here that tenapanor also reduces phosphorous (P) absorption from the rodent gut, despite the lack of any direct inhibition of the phosphate transporters PiT1 (SLC20A1) and NaPi2b (SLC34a2). Our studies demonstrate that intestinal NHE3 inhibitors decrease absorption of dietary P in rats as evidenced by 1) increased fecal P excretion (treated 1115 ± 61 μmol/d versus untreated 801 ± 73 μmol/d, mean ± SEM); 2) decreased urinary P excretion (treated 1321 ± 49 μmol/d versus untreated 1523 ± 33 μmol/d), and 3) reduced uptake of orally administered [^{33}P]orthophosphate (AUC reduced by 40% relative to controls). In a rodent model of vascular calcification, tenapanor reduced P absorption, and led to significant decreases in ectopic calcification (aortic P reduced 78% and Ca reduced 76%), serum creatinine levels (treated 0.85 ± 0.05 mg/dl versus untreated 1.27 ± 0.07 mg/dl), circulating phosphaturic hormone fibroblast growth factor levels (FGF)-23 (treated 84 ± 25 ng/ml versus untreated 369 ± 65 ng/ml), and heart mass (reduced by 16%). These results suggest that tenapanor may provide a new approach to P management in renal disease and associated mineral disorders.

FR-OR112

Tenapanor, a Minimally Absorbed NHE3 Inhibitor, Reduces Dietary Phosphorus Absorption in Healthy Volunteers David P. Rosenbaum,[1] Susanne Johansson,[2] Bjorn Carlsson,[2] Andrew G. Spencer,[1] Bergur V. Stefansson,[2] Mikael Knutsson,[2] Jeffrey Jacobs,[1] Dominique Charmot.[1] *[1]Ardelyx, Inc., Fremont, CA; [2]AstraZeneca R&D, Molndal, Sweden.*

Background: Tenapanor (AZD1722) is a first-in-class small-molecule inhibitor of the Na^+/H^+ exchanger isoform 3 (NHE3). Tenapanor was previously shown to reduce intestinal sodium (Na) absorption in healthy adult volunteers. Here, we report that administration of tenapanor also reduced the absorption of dietary phosphorus (P) in these individuals.

Methods: Double-blind, placebo-controlled, clinical pharmacology studies on tenapanor hydrochloride, administered orally for 7 days, were performed to evaluate multiple ascending doses (MAD) of 3, 10, 30 and 100 mg qd (RDX5791-101) and different dosing regimens (DRs) of 30 mg qd, 15, 30 and 60 mg bid, and 30 mg tid (RDX5791-102). P content of 24-hour stool samples was measured daily. Stool and urinary P levels were also evaluated daily in other clinical pharmacology studies (formulation, D5611C00002; and food-effect, D5611C00003).

Results: Tenapanor was well tolerated in all studies and no serious adverse events were reported. The placebo groups in the MAD and DR studies exhibited the same mean daily stool P levels (table). Increases in stool P with tenapanor treatment were 4.3–7.1 mmol/day in the MAD study and 6.0–12.5 mmol/day in the DR study compared with placebo. In the other clinical studies of tenapanor, decreases in urinary P excretion were observed, consistent with observed increases in stool P excretion.

Stool P excretion (mmol/day)

Multiple ascending dose (MAD) study[a]

	Placebo	3 mg qd	10 mg qd	100 mg qd
Mean	16.8	21.1	23.9	23.0
SD	3.4	4.3	4.1	4.7
n	8	8	8	8

Dosing regimen (DR) study

	Placebo	30 mg qd	15 mg bid	30 mg bid	60 mg bid	30 mg tid
Mean	16.8	28.0	29.3	25.4	22.8	27.4
SD	4.6	5.0	11.1	8.8	10.9	8.0
n	21	11	12	12	12	12

[a]30 mg qd cohort not analyzed

Conclusions: Tenapanor reduced the absorption of P from the gut, as shown by increases in stool P excretion and concomitant decreases in urinary P excretion. Tenapanor may provide a new mechanism for the treatment of hyperphosphatemia, with the potential added benefits of reducing pill burden and improving Na overload in patients with end-stage renal disease.

FR-OR113

Uromodulin Upregulates the Epithelial Magnesium Channel TRPM6 by Impairing Dynamin II-Dependent Endocytosis

Matthias Wolf,[1] Mingzhu Nie,[1] Joost Hoenderop,[2] René J. Bindels,[2] Manjot S. Bal.[1] *[1]Pediatrics, UTSW Medical Center, Dallas, TX; [2]Physiology, Radboud Univ Medical Centre, Nijmegen, Netherlands.*

Background: Uromodulin (UMOD) is the most abundant urinary protein in humans but its physiological function remains unclear. *Umod* knockout mice are characterized by urinary Mg^{2+} loss. Recently, upregulation of UMOD expression was shown in hypomagnesemic mice, suggesting a role of UMOD in renal Mg^{2+} reabsorption. We examined if UMOD regulates the epithelial Mg^{2+} channel TRPM6, which is expressed apically in the early DCT. UMOD expression has been shown in both TAL and DCT. Therefore, UMOD could act either from the urinary space or from intracellularly. We tested the hypothesis that UMOD upregulates TRPM6 from the extracellular side.

Methods: We expressed TRPM6 in HEK293 cells which were treated with purified UMOD. TRPM6 whole-cell current density was analyzed by patch-clamp recording.

Results: Coexpression of UMOD and TRPM6 resulted in higher TRPM6 current density compared to UMOD mutant C150S or control (216 ± 21 versus 56 ± 19 versus 75 ± 9 *p*A/*p*F for UMOD versus mutant versus control; $p<0.001$). UMOD also increased TRPM6 whole-cell current when applied extracellularly. The extracellular effect of UMOD towards TRPM6 was abrogated when UMOD antibody was added to UMOD-containing supernatant (260 ± 48 versus 89 ± 18 *p*A/*p*F for UMOD versus antibody; $p<0.05$). We determined a half-maximal effective concentration (EC_{50}) for purified UMOD treatment in TRPM6-expressing cells of 600 ng/ml. This is approximately 20x lower than UMOD concentration in human urine, underlining the physiological significance. Cells cotransfected with dominant-negative dynamin II (K44A), which impairs constitutive endocytosis, were resistant to the TRPM6-stimulating effect of UMOD (313 ± 34 versus 349 ± 30 *p*A/*p*F for UMOD versus control, *p*= n.s.). All three major domains of UMOD including EGF-like, D8C and zona pellucida domains but not the GPI anchor were required for TRPM6 upregulation.

Conclusions: Extracellular UMOD upregulates the activity of the TRPM6 Mg^{2+} channel by impairing dynamin II-dependent endocytosis. This suggests that UMOD may participate in Mg^{2+} homeostasis by promoting Mg^{2+} reabsorption in the DCT.

Mutations in CNNM2 Cause Hypomagnesemia and Seizures in Patients due to Impaired Renal Magnesium Handling

Joost Hoenderop,[1] Francisco J. Arjona,[1] Jeroen H.F. De Baaij,[1] Karl P. Schlingmann,[2] Martin Konrad,[2] René J. Bindels.[1] *[1]Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]General Pediatrics, Univ Children's Hospital, Munster, Germany.*

Background: Recently, we have identified mutations in the gene encoding cyclin M2 (CNNM2) in two unrelated families with dominant isolated hypomagnesemia (MIM 607803). Patients suffered from symptoms associated with low serum Mg2+ levels (0.3–0.5 mM) such as tremors, headaches and muscle weakness and also mental disability. The role of CNNM2 in the kidney for the maintenance of serum Mg2+ levels can be traced to the distal convoluted tubule (DCT). In the present study, we aim to elucidate the function of CNNM2 in the kidney.

Methods: By combining a loss-of-function approach in a zebrafish model, functional transport assays in renal cells and immunohistochemical characterisation in kidney sections we provide functional evidence for a key role of CNNM2 in renal Mg2+ handling and also brain development.

Results: Mutations in CNNM2 in five families suffering from hypomagnesemia, seizures, and mental retardation have been identified. To elucidate the physiological role of CNNM2 and explain the pathomechanisms of the disease, we studied CNNM2 function. Using stable Mg2+ isotopes, we demonstrated that CNNM2 increases cellular Mg2+ uptake in human embryonic kidney (HEK293) cells and that this process occurs through regulation of the Mg2+-permeable cation channel TRPM7. In contrast, cells expressing mutated CNNM2 proteins did not show increased Mg2+ uptake. Knockdown of cnnm2 isoforms in zebrafish resulted in disturbed brain development including neurodevelopment impairments, weak touch-evoked escape behaviour and reduced body Mg content, indicative of impaired renal Mg2+ absorption. These phenotypes were rescued by injection of mammalian wild-type Cnnm2 cRNA, whereas mammalian mutant Cnnm2 cRNA did not improve the zebrafish knockdown phenotypes.

Conclusions: CNNM2 is fundamental for renal Mg2+ homeostasis, brain development and neurological functioning. By establishing the loss-of-function zebrafish model for CNNM2 genetic disease, we provide a unique system for testing therapeutic drugs targeting CNNM2 and for monitoring their effects on the kidney phenotype.

FR-OR115

Effect of Intravenous Bisphosphonates (IVBP) on Bone Mineral Density (BMD) and Bone Turnover Markers (BTM) Is Reversible in Children

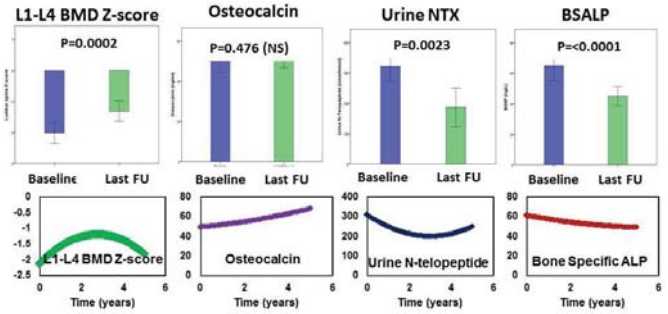
Tarak Srivastava, Naziya Tahseen, Hongying Dai, Uri S. Alon. *Children's Mercy Hospital, Kansas City, MO.*

Background: IVBPs drugs increase BMD and decrease BTM by inhibiting osteoclastic activity. IVBPs are increasingly being used in treatment of osteopenia in children. We previously reported 17 children in whom the effect of IVBP on BMD was sustained for up to 2 years [Pediatr Nephrol 2007;22:282]. The aim of the study was to evaluate if the effects of IVBPs on BMD and BTM is reversible or not in children over a period of 5 years from time of treatment.

Methods: Children treated with 2 doses of IVBP in our "Bone and Mineral Disorder Clinic" between 1997-2010 for osteopenia and had at least >3 DXA and BTM measurements were included. Data collected were age, gender, pubertal status, ambulation, parathyroid hormone (PTH), 25-Vitamin D, BTM [serum osteocalcin (OS), bone specific alkaline phosphatase (BSALP), urine N-telopeptide (NTX)], and L1-L4 BMD Z-score on DXA. Mixed Procedure Model and Quadratic Model were used to analyze the data over 4 time periods: (a) 0-5 yrs (b) 0-1 yrs (c) 1-3 yrs and (d) 3-5 yrs.

Results: 104 children met the criteria. Mean age was 11.2 ± 4.5 yrs, 59% girls, 64% pubertal and 72% ambulatory. The change in BMD and BTM over time and estimated changes/year over the 4 time periods are shown in Table (*p<0.01) and Figure. There was no significant change in PTH and Vitamin D. The effects of IVBP on BTM start to reverse in order of OS, NTX and BSALP, and on Lumbar BMD by 3 yrs.

	0-5 yrs	0-1 yrs	1-3 yrs	3-5 yrs
L1-L4 BMD Z-Score	0.19±0.04*	0.81±0.16*	0.28±0.10*	0.05±0.24
OS	3.4±0.9*	-4.9±6.5	2.7±2.8	1.2±4.2
BSALP	-2.8±0.8*	-12.5±4.5*	-8.7±2.9*	-0.4±2.6
NTX	-25.6±6.3*	-130.0±35.6*	-50.2±20.8*	5.7±30.2



Conclusions: The effects of IVBP drugs on BMD and BTM are not permanent, and start to reverse by 3 years in children; with OS heralding the process.

Funding: Clinical Revenue Support

miRNome Expression Profiling Identifies Circulating MicroRNAs That Are Differentially Expressed among Type 1 Diabetic Patients with Proteinuria and at Increased Risk of Rapid Renal Function Decline

Marcus G. Pezzolesi,[1,2] Eiichiro Satake,[1,2] Kevin P. Mcdonnell,[1] Adam Smiles,[1] Andrzej S. Krolewski.[1,2] *[1]Section on Genetics and Epidemiology, Joslin Diabetes Center, Boston, MA; [2]Dept of Medicine, Harvard Medical School, Boston, MA.*

Background: MicroRNAs (miRNAs) are key regulators of gene expression that are expressed and stable in a variety of biofluids and thus have the potential to serve as novel biomarkers for the diagnosis of a variety of human diseases. The aim of this study is to begin to understand the miRNA signature that predicts high risk of renal function decline and the progression to end-stage renal disease (ESRD) in patients with Type 1 diabetes (T1D).

Methods: We measured the expression of 1,811 miRNAs in pooled baseline plasma samples from 38 Rapid Progressors who had normal renal function at baseline and subsequently lost renal function at a rate of ≥3.3ml/min/year before reaching ESRD and 40 control subjects with normal renal function and persistent normoalbuminuria despite more than 20 years duration of T1D.

Results: A total of 425 miRNAs were detectable in plasma samples from both study groups. Among these miRNA, we identified 95 (22.4%) with <0.4 or >2.5 fold change between Rapid Progressors and controls and selected the top 20 differentially expressed miRNAs for measurement in individual samples from these two study groups. Using multivariable logistic regression analysis, 5 miRNAs were shown to be significantly increased in Rapid Progressors compared to normoalbuminuric controls. Three additional miRNAs were shown to be significantly increased in subjects with persistent normoalbuminuria relative to Rapid Progressors. Multivariable linear regression analysis revealed that 10 miRNAs were also significantly associated with longitudinal changes in estimated glomerular filtration rate.

Conclusions: These data suggest that miRNAs may be able to distinguish individuals who are at the greatest risk of losing renal function and developing ESRD from those who are protected against these complications. The differentially expressed miRNAs identified in this study represent novel therapeutic targets that may prove useful in inhibiting renal function decline in T1D.

FR-OR117

Identification of New Predictors of Declining Renal Function in Patients with Type 2 Diabetes by Metabolomics Ele Ferrannini,[1] Anna Solini,[1] Giuseppe Penno,[1] Giuseppe Pugliese,[2] Jeff E. Cobb,[3] Regis Perichon.[3] *[1]Univ of Pisa, Italy; [2]"La Sapienza" Univ, Rome, Italy; [3]Metabolon, Durham, NC.*

Background: Renal disease in type 2 diabetes (T2D) is associated with excess morbidity/mortality. While glomerular filtration rate (eGFR) and albuminuria are routine for assessing renal impairment, new biomarkers could improve risk stratification and prediction.

Methods: We performed screening metabolomics in fasting plasma and urine samples from 285 T2D pts (109 women, age 63[10] yrs, median[IQR], fasting glucose 144[47] mg/dL, HbA_{1c} 7.1[1.3]%, eGFR 93[26] ml·min^{-1}·1.73m^2, albumin/creatinine ratio (ACR) 14.3[50.2] mg/g). Non-targeted metabolomic profiling was carried out by gas chromatography or ultra-HPLC coupled with tandem mass-spec. 256 pts were seen again 3 yrs later. Biomarker identification was performed by random forest using an eGFR cutoff of ±60 or normoalbuminuria versus micro/macroalbuminuria (μMA) as endpoints for serum and urine metabolites. Data were analyzed by multivariate logistic regression and ROC Area.

Results: At follow up eGFR had declined by 4[10] ml·min^{-1}·1.73m^2 in the whole cohort ($p<0.0001$), and by 16[9]in patients in the top quartile of eGFR change; the latter was used as endpoint. Significant clinical covariates (female gender, age, fasting glucose, and baseline eGFR) predicted outcome with ROC=0.671. The 5 serum metabolites best correlated with either eGFR<60 or μMA at baseline were tested for their ability to improve clinical prediction. Sum of 3 biomarkers (C-glycosyltryptophan, pseudouridine, and N-acetylthreonine, Bio-Index) raised ROC to 0.739 ($p<0.0001$). Outcome was predicted by the top Bio-Index quartile (OR=5.48 [95%CI=2.23-14.47] versus OR's of 1.73[1.073.21], 1.59[1.09-2.40], 1.49[1.10-2.02] and 2.66[1.61-4.70] for gender, age, glucose, and baseline eGFR, respectively). In the same model, Bio-Index also predicted a change in ACR in the top quartile (+41[135] mg/g) with an OR of 2.82[1.20-7.03] and a ROC of 0.750. Top urine metabolites did not add significant predictivity.

Conclusions: A limited number of circulating intermediates of amino acid and nucleotide pathways carry clinically significant predictivity for deterioration of renal function in T2D pts.

FR-OR118

Plasma Concentrations of Midregional Pro-Atrial Natriuretic Peptide Are Associated with Cardiorenal Function and Predicts All-Cause Mortality and End Stage Renal Disease in Type 1 Diabetes Simone Theilade,[1] Tine Hansen,[1] Jens Peter Goetze,[2] Peter Rossing.[1,3,4] *[1]Steno Diabetes Center, Denmark; [2]Rigshospitalet, Denmark; [3]Aarhus Univ, Denmark; [4]Univ of Copenhagen, Denmark.*

Background: We examine associations between plasma pro-atrial natriuretic peptide (proANP) levels and diabetic complications at baseline and risk of mortality and end stage renal disease (ESRD) during follow-up.

Methods: The observational study included 665 type 1 diabetes patients from a tertiary diabetes ambulatory. Midregional (MR) proANP was measured on a Kryptor platform (Thermo-Fisher, Germany). Complications were defined as micro- (n=168) or macroalbuminuria (n=190) (urinary albumin excretion rate (UAER) 30-299 or ≥300mg/24h), history of cardiovascular disease (CVD) (n=144), cardiac autonomic dysfunction (heart rate variability <11 beats/min) (n=252) or retinopathy (n=523). Adjustments were made for gender, age, systolic blood pressure (SBP), eGFR, UAER, HbA_{1c}, total cholesterol, C-reactive protein, urinary sodium excretion, body mass index, daily insulin dose, antihypertensive treatment and smoking in linear regression and ANCOVA models. Development of ESRD (dialysis, renal transplantation or GFR/eGFR<15 ml/min/1.73m^2) and mortality was traced through national registers.

Results: Patients were (mean±SD) 55±13 years, 293(44%) female, and (median [IQR]) plasma MR-proANP concentration was 73.6[49.2-116.9]pmol/L. In adjusted models, proANP correlated positive with age, SBP, UAER, total cholesterol and CRP; and negatively with eGFR, total daily insulin dose and HbA_{1c} ($p\leq0.05$). Adjusted, MR-proANP levels increased with albuminuria degree and were higher in patients with previous CVD ($p\leq0.043$), but similar in patients with or without autonomic dysfunction or retinopathy ($p\geq0.14$). During follow-up (3.5[3.1-4.0] years), higher MR-proANP predicted ESRD and mortality combined (n=35) adjusted for gender, age, SBP and eGFR (hazard ratio per 1 SD increase in logANP: 2.2(1.4-3.6), p=0.001).

Conclusions: Higher plasma MR-proANP levels were associated with impaired renal function, increased albuminuria, and previous CVD. Moreover, higher proANP levels were associated with increased risk of ESRD and mortality combined.

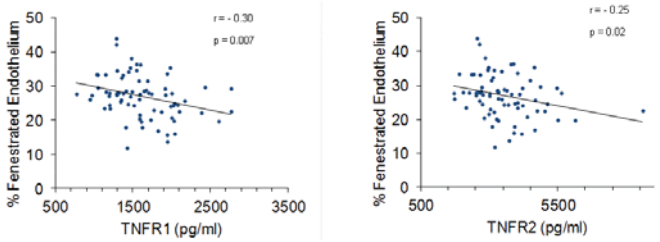
FR-OR119

Circulating Tumor Necrosis Factor Receptors 1 and 2 Correlate with Glomerular Structure in Type 2 Diabetes Gudeta D. Fufaa,[1] Robert G. Nelson,[1] E. Jennifer Weil,[1] William Knowler,[1] Monika A. Niewczas,[2] Andrzej S. Krolewski.[2] *[1]NIH; [2]Harvard.*

Background: Elevated Tumor necrosis factor receptor 1 (TNFR1) and TNF receptor 2 (TNFR2) concentrations may initiate and promote renal function decline leading to kidney failure. We examined the relationships between TNFRs and glomerular structure in American Indians with type 2 diabetes.

Methods: Serum TNFRs were measured at a research examination that included a kidney biopsy and measurement of glomerular filtration rate (GFR) by iothalamate clearance. Associations between clinical characteristics, glomerular structural variables and TNFRs were explored by Spearman correlations. Associations with glomerular structural measurements were also examined by linear regression, adjusted for age, sex, diabetes duration, HbA1c, blood pressure, GFR, and urinary albumin/creatinine ratio (ACR).

Results: Participants (n=83, mean age 46±10 years) had median GFR=130 ml/min(IQR=107-174 ml/min), median ACR=26 mg/g (IQR=12-127 mg/g), median TNFR1=1500 pg/ml (IQR=1205-1960 pg/ml), and TNFR2=3284 pg/ml (IQR=2671-4151 pg/ml). TNFR1 and TNFR2 correlated with each other (r=0.84, p<0.001), with ACR (r=0.36 and 0.37, respectively; p<0.001), and inversely with GFR (r=-0.35, p=0.001; r=-0.28, p=0.010). TNFR1 and TNFR2 correlated inversely with the percentage of endothelial capillary fenestration(r=-0.42 and -0.43; p<0.001; adjusted correlations shown in **Figure**),



filtration surface area (r=-0.27, p=0.013; r=-0.29, p=0.007), and filtration slit frequency (r=-0.24, p=0.029; r=-0.29, p=0.008). TNFRs correlated with fractional mesangial area (r=0.36; 0.38, p<0.001), basement membrane width (r=0.23, p=0.038; r=0.26, p=0.016), and podocyte foot process width (r=0.29, p=0.007; r=0.31, p=0.004). TNFR1 correlated with the number of podocytes per glomerulus (r=-0.23, p=0.04).

Conclusions: Elevated TNFR1 or TNFR2 in early diabetic nephropathy associate with glomerular structural damage.

Anti-inflammatory and Renoprotective Effects of CCL2 Inhibition with Emapticap Pegol (NOX-E36) in Type 2 Diabetic Patients with Albuminuria Hermann G. Haller,[1] Jan Menne,[1] Dirk Eulberg,[2] Matthias Baumann.[2] *[1]Clinic of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Noxxon Pharma AG, Noxxon Pharma AG, Berlin, Germany.*

Background: Inflammatory mechanisms with increased expression of chemokines such as CCL2/MCP-1 and monocyte infiltration seem to play a major role in the pathogenesis of diabetic nephropathy. Using Emapticap pegol (NOX-E36), a novel mirror-image RNA molecule (Spiegelmer®) that binds and inhibits the pro-inflammatory chemokine CCL2 (MCP-1) we tested the hypothesis that this anti-inflammatory approach exerts a renoprotective and antidiabetic effect in patients with diabetic nephropathy (DN).

Methods: A randomized, double blind, placebo-controlled multi-center phase IIa study in 5 European countries was initiated in 75 DN patients. Eligibility criteria included stable RAS blockade, ACR >100 mg/g and HbA1c from 6.0-10.5%. Emapticap was administered SC at 0.5 mg/kg twice weekly for 12 weeks, followed by a treatment-free phase of 12 weeks. Inflammatory biomarkers were evaluated. For the primary efficacy analysis, patients with major protocol violations, dual RAS blockade and concomitant hematuria and leukocyturia were excluded.

Results: Emapticap pegol was safe and well tolerated and resulted in clear beneficial effects on ACR (-32% at Day 85, P=0.014) and HbA1c (-5% at Day 85, P=0.096) which were maintained even after cessation of dosing (ACR: -39% at Day 141, P=0.010; HbA1c: -7% at Day 113, P=0.036). No change was observed for blood pressure and eGFR. Treatment with emapticap was accompanied by a rapid decrease in the number of peripheral monocytes by approx. 20% and a concomitant decrease in surface marker CCR2. Urinary sTNFR1 was elevated at baseline and decreased during treatment with emapticap.

Conclusions: Treatment with emapticap was safe and efficacious in reducing ACR and HbA1c. The sustained mode of action as well as the absence of hemodynamic changes differentiates emapticap from approved treatment strategies in diabetic nephropathy. The maintenance of beneficial effects after the treatment phase and the concomitant reduction of urinary sTNFR1 suggests that emapticap interferes with the underlying inflammatory pathophysiology in diabetic patients.

Selective Inhibition of Phosphodiesterase Type 5 Reduces Macroalbuminuria in Subjects with Type 2 Diabetes, and Overt Nephropathy Willem H. Scheele,[1] Susan Diamond,[2] Jeremy D. Gale,[3] Valerie Clerin,[1] Nihad Tamimi,[3] Vu Le,[1] Rosalind Jane Walley,[3] Fernando Grover Páez,[4] Meguid El Nahas.[5] *[1]Pfizer, Inc, Cambridge, MA; [2]San Antonio Kidney Disease Center, San Antonio, TX; [3]Pfizer, Ltd, Sandwich, United Kingdom; [4]ICLE, Guadalajara, Mexico; [5]Global Kidney Academy, Sheffield, United Kingdom.*

Background: Diabetic nephropathy (DN) is the leading cause of end stage renal disease in the Western world. Reduced availability of nitric oxide (NO) leading to decreased intracellular level of the NO pathway effector molecule cyclic guanosine monophosphate (cGMP) in the kidney has been implicated in the progression of DN. Pre-clinical studies suggest that elevation of the cGMP intracellular pool through inhibition of the cGMP-hydrolyzing enzyme phosphodiesterase type 5 (PDE5) exerts renoprotective effects in DN.

Methods: To test this hypothesis in humans, the effect on albuminuria of the novel, highly specific, and long-acting PDE5 inhibitor PF-00489791 was assessed in a multinational, multicenter, randomized, double-blind, placebo-controlled, parallel group trial of subjects with Type 2 diabetes and overt nephropathy already receiving ACE$_i$ or ARB background therapy. A total of 256 subjects with an eGFR between 25 and 60mL/min/1.73m^2 and macroalbuminuria defined by a Urinary Albumin Creatinine Ratio (UACR) > 300mg/g were randomly assigned to receive PF-00489791 20mg or placebo in a 3:1 fashion, orally, once daily for 12 weeks.

Results: A significant reduction in UACR (15.7%) was observed in response to the 12-week long treatment with PF-00489791 compared to placebo using the pre-defined primary assessment of efficacy (Bayesian analysis with informative prior). A MMRM sensitivity analysis of the results demonstrated a time-dependent reduction in UACR in subjects treated with PF-00489791 compared to placebo, reaching 21.7% reduction at Week 12 (p=0.003). PF-00489791 20mg was safe and generally well-tolerated in this population. Most common adverse events included headache and upper gastrointestinal events.

Conclusions: In summary, the safety and efficacy profile of PF-00489791 in this study supports further investigation of its potential as a novel therapeutic strategy to improve renal outcome in DN.

Efficacy and Safety of Liraglutide versus Placebo by eGFR Subgroup in Subjects with Type 2 Diabetes and Moderate Renal Impairment (LIRA-RENAL): A Randomized Trial

David Scott,[1] Guillermo Umpierrez,[2] Stephen Atkin,[3] Stephen Bain,[4] Peter Rossing,[5] Minara Shamkhalova,[6] Heidrun Bosch-Traberg,[7] Annika Syrèn,[7] Melanie Davies.[8] *[1]Diabetes, Clinical Research Development Associates, New York, NY; [2]Emory Univ, Atlanta, GA; [3]Weill Cornell Medical College Qatar, Doha, Qatar; [4]Inst of Life Science, Swansea Univ, Swansea, United Kingdom; [5]Steno Diabetes Center, Gentofte, Denmark; [6]Endocrinology Research Centre, Moscow, Russian Federation; [7]Novo Nordisk A/S, Søborg, Denmark; [8]Univ of Leicester, Leicester, United Kingdom.*

Background: To determine the effects of adding liraglutide 1.8 mg (lira) or placebo (PBO) to existing oral antidiabetic agents and/or insulin therapy to subjects with moderate renal impairment (eGFR 30-59 mL/min/1.73 m^2; MDRD), we evaluated renal function group-dependency (CKD Stages 3a and 3b) on selected efficacy and safety parameters.

Methods: In this 26-week, placebo-controlled, double-blind trial, adults with T2DM and moderate renal impairment, BMI of 20-45 kg/m^2, HbA$_{1c}$ of 7.0-10.0% and on stable diabetes medication were randomized 1:1 to receive either once-daily lira or PBO. The primary endpoint was HbA$_{1c}$ change from baseline (BL) to Week 26.

Results: 277 subjects were exposed to lira or PBO and included in the analysis. Lira exhibited a significant reduction in HbA$_{1c}$ consistent across eGFR subgroups compared to PBO (Table). More GI AEs (mostly nausea and vomiting) were reported in all eGFR lira subgroups compared to PBO. There was no significant treatment effect on UACR in any of the UACR subgroups. No difference was seen in eGFR change from BL (lira -1%; PBO +1%; p=0.3575) for the total population.

Conclusions: In subjects with T2DM and moderate renal impairment, lira showed superior HbA$_{1c}$ reduction across all eGFR subgroups compared to PBO. Overall, there was no difference in the safety profile of lira between eGFR subgroups.

Phase 3, Multicenter, Randomized, Double-Blind, Placebo-Controlled Trial of Once-Daily ZS-9 for Treatment of Hyperkalemia: Achievement and Maintenance of K$^+$ in Subgroup Analysis of Patients with Significant Renal Impairment and Diabetes

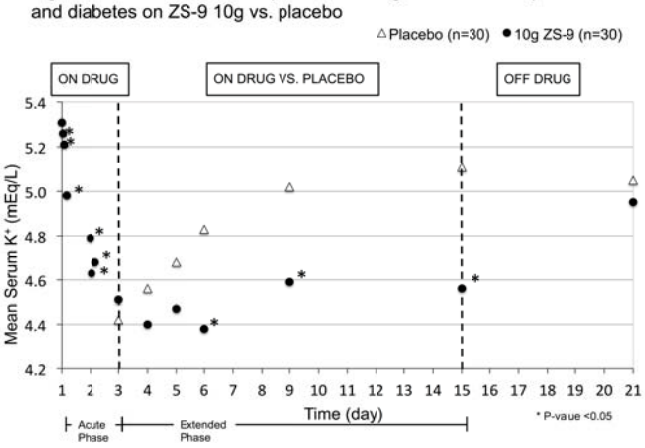
Bhupinder Singh,[1] Henrik S. Rasmussen,[2] Philip T. Lavin,[3] Alex Yang,[4] Wajeh Y. Qunibi.[5] *[1]Apex Research, Riverside, CA; [2]ZS Pharma, Inc., Coppell, TX; [3]Boston Biostatistics Research Foundation, Framingham, MA; [4]Xelay Acumen, Inc., Belmont, CA; [5]Univ of Texas Health & Science Center, San Antonio, TX.*

Background: Hyperkalemia (HK) increases risk of mortality and limits therapy with RAASi in patients (pts) with heart failure, chronic kidney disease, and diabetes mellitus (DM). ZS-9, a nonabsorbed cation exchanger designed to trap K$^+$ in the gut, was evaluated in a subgroup of hyperkalemic pts with significant renal impairment (eGFR<60) and DM from a Phase 3 trial.

Methods: Pts (N=753) with K$^+$ 5.0-6.5 mEq/L were randomized (1:1:1:1:1) to ZS-9 (1.25, 2.5, 5 or 10g) or placebo (PBO) orally 3× daily for 48hr (acute phase). Following this phase, pts with K$^+$ 3.5-5.0 mEq/L (n=542) were randomized 1:1 to the same ZS-9 acute phase dose or PBO 1× daily on Days 3-15 (extended phase). RAASi were maintained during the study. Unpaired t-tests were used to compare K$^+$ in pts treated with ZS-9 versus PBO.

Results: Of 753 pts, 366 (49%) had eGFR<60 and DM. Mean baseline K$^+$ was 5.3 mEq/L. At 48hr, K$^+$ decreased significantly with 2.5g (n=69), 5g (n=78) and 10g (n=64) ZS-9 (-0.45, -0.58, and -0.81 mEq/L, respectively) compared with PBO (n=75, 0.24 mEq/L; p=0.026, p<0.001, p<0.001, respectively). In the extended phase, baseline K$^+$ was similar in the 10g ZS-9 (n=30, 4.5 mEq/L) and PBO groups (n=30, 4.4 mEq/L). Pts on ZS-9 10g maintained normokalemia (4.6 mEq/L at Day 15; p<0.0001), versus PBO (5.1 mEq/L at Day 15). ZS-9 5g showed similar results (p<0.0001).

Figure. Mean K$^+$ over time in patients with significant renal impairment and diabetes on ZS-9 10g vs. placebo



Conclusions: ZS-9 effectively restored and maintained normokalemia and thus allows continued use of renoprotective RAASi in diabetic patients with significant renal impairment with HK.

The Risk Pattern for CV Events Differ Between Coronary Heart Disease (CHD) and Stroke in Patients with Type 2 Diabetes and Renal Impairment

Hanri Afghahi,[1] Mirnabi Pirouzi Fard,[2] Bjorn Eliasson,[3] Maria Svensson.[3] *[1]Renal Disease, Skaraborg Hospital, Skövde, Västra Götaland, Sweden; [2]Center of Registers, Region Västra Götaland, Gothenburg, Västra Götaland, Sweden; [3]Medicine, Sahlgrenska Univ Hospital, Gothenburg, Västra Götaland, Sweden.*

Background: We assessed the J-shape relationship between blood pressure (BP), risk of coronary heart disease (CHD) and stroke in patients with type 2 diabetes (T2D) and renal impairment (RI) treated and followed up in clinical practice.

Methods: 33,356 patients (47% men, age 75±9 years, BMI 29.1±4.8 kg/m^2, diabetes duration 10±8 years) with complete data on serum creatinine and blood pressure (BP) in the Swedish National Diabetes Register (NDR) were followed between 7/1/2005 and 12/31/2007 until 12/31/2011. RI was defined as estimated glomerular filtration <60ml/min/1.73m^2 according to MDRD. BP-values were the mean of all reported values during the follow-up period. The relationships between mean BPs, CV events were examined by time-dependent Cox models, to estimate hazard ratios (HR), adjusting for CV risk factors and medications.

Results: During the follow-up period (median 5.3 years) a total of 11 317 (34%) CVEs occurred, 7704 (23%) patients had CHD and 2284 (6.8%) suffered a stroke. The highest risk of CHD was found with the lowest SBP interval 80-120 mmHg (n=1211, 37%) (HR 2.6, 95% CI 2.2-3.0) and highest prevalence of stroke were found with the highest interval SBP 160-230 mm Hg (n=376, 11.3%) (HR 2.6, 95% CI 2.0-3.4). Similarly, the highest risk of CHD was found in the lowest DBP interval 40-63 mm Hg (1197, 36.1%) (HR 2.0, 95% CI 1.8-2.3) and the highest occurrence of stroke in the highest DBP interval 83-125 mm Hg (n=790, 24%) (HR 2.6, 95% CI 2.0-3.3). Adjustments for presence of albuminuria did not markedly alter the results.

Conclusions: The risk pattern for CV events differ between coronary heart disease (CHD) and stroke. The highest risk of CHD was found with the lowest BP intervals and the highest risk of stroke with the highest BP intervals. This difference in risk patterns is important to keep in mind when assessing overall risk of cardiovascular events in patient populations.

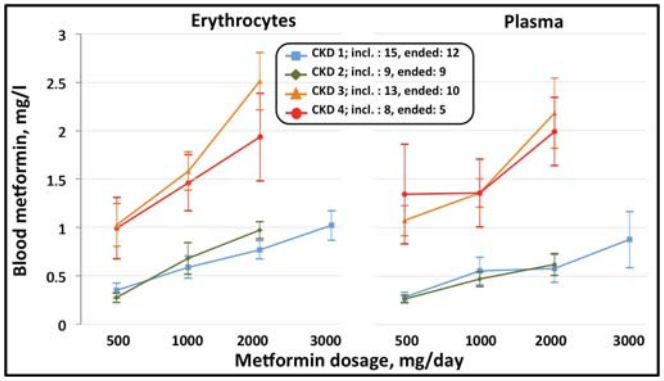
FR-OR125

Metformin Therapy at Different Stages of Chronic Kidney Disease Farshad Kajbaf,[1] Jean-Daniel Lalau,[1] Mohamed Azzoug,[1] Anne-Sophie Lemaire-Hurtel,[2] Marc E. De Broe.[3] *[1]Dept of Endocrinology-Nutrition, Univ Hospital, Amiens, France; [2]Dept of Clinical pharmacology, Univ Hospital, Amiens, France; [3]Laboratory of Pathophysiology, Univ of Antwerp, Belgium.*

Background: We are conducting an open-label pilot study in order to establish whether or not it is feasible to continue metformin therapy in diabetes patients with stable CKD 1-5 not yet in dialysis provided that the dose is adjusted. The objectives are to evaluate metformin levels in plasma and in erythrocytes (providing a better estimation of the risk of accumulation) according to metformin dosage and CKD stage and to demonstrate the absence of hyperlactatemia (≥2.5 mmol/L).

Methods: Inclusion criteria are Type 2 diabetes patients, untreated or treated with metformin and with HbA1c >6.5%, having stable renal function for at least 3 months. All patients undergo 3 one week-blocks of metformin treatment at an increasing dosage, each of which is followed by a one week-wash-out period: 500 mg/day in the evening (E) in phase 1; 1,000 mg/day (500 mg morning (M) and E) in phase 2; 2,000 mg/day (1000 mg M and E) in phase 3. Stage 1 CKD patients further complete a phase 4 with 3,000 mg/day (1000 mg M and 2000 mg E). Metformin levels are assayed in erythrocytes and in plasma 12 hours after the last metformin intake; lactate concentrations are also assayed in CKD 3-5.

Results: The available data are shown in the Fig.1.



The maximal lactate value is 2.7 mmol/L, other values are < 2.1 mmol/L.

Conclusions: 1) as CKD progresses,metformin levels did not increase more in erythrocytes (reflecting the deep-compartment) than in plasma; 2) the rather linear metformin dosage/level relationship forms a solid base to perform a pharmacokinetic study in CKD 3-5 to validate the adjustment of the metformin dosage in moderate to severe CKD; 3) in terms of blood lactate concentrations metformin therapy seems well-tolerated.

FR-OR126

Epithelial-Derived Wnt Ligand Drives Interstitial Fibrosis Through Paracrine Signaling Omar H. Maarouf,[1] Deepika Rangarajan,[2] Jeremy Welborn,[1] Benjamin D. Humphreys.[1] *[1]Medicine, Brigham and Women's Hospital, Boston, MA; [2]Biology, SRM Univ, Chennie, India.*

Background: Injured epithelial cells secrete paracrine factors that regulate interstitial fibrogenesis, but the identity of these factors is poorly defined. We have previously shown that activation of the canonical Wnt signaling pathway in pericytes cell-autonomously drives myofibroblast activation *in vivo*. Here we have investigated whether Wnt ligand derived from tubular epithelial cells is sufficient to drive interstitial fibrosis *in vivo*, and the interaction between Wnt and TGFb pathways in mediating myofibroblast activation.

Methods: We generated a novel mouse strain ($SLC34a^{GCE/+}$; $R26^{Wnt1\text{-}GFP/+}$) in which tamoxifen administration induces constitutive Wnt1 secretion by proximal tubular epithelial cells in adult kidney. We cultured NRK49F cells and primary human dermal fibroblasts (HDF) to investigate the dependence of TGFb-mediated aSMA and matrix protein expression on Wnt signaling using the Wnt pathway inhibitor XAV939, and activator CHIR99021.

Results: Tamoxifen or vehicle was administered to 8-week old $SLC34a^{GCE/+}$; $R26^{Wnt1\text{-}GFP/+}$ mice and groups were sacrificed at 16 or 20 weeks of age. Mice that received tamoxifen constitutively expressed Wnt1 in proximal tubule, and in these mice confocal microscopy demonstrated progressive interstitial aSMA+ myofibroblast accumulation in the absence of any other stimulus. Compared to vehicle-treated controls, we noted increased interstitial proliferation as well as increased aSMA and fibronectin protein levels in tamoxifen-treated mice. By contrast, neither group expressed Kidney Injury Molecule-1, indicating that epithelial damage per se was not driving renal fibrogenesis. *In vitro*, TGFb induced myofibroblast transition (aSMA and fibronectin expression) was inhibited by the canonical Wnt inhibitor XAV939. Canonical Wnt activation by CHIR99021 potentiated TGFb-induced aSMA and fibronectin expression in both NRK49F and HDF cells.

Conclusions: Epithelial-derived Wnt1 alone is sufficient to drive interstitial fibrosis *in vivo* in the absence of an injury stimulus. Wnt ligands cooperate with TGFb to drive pericyte to myofibroblast transition.

FR-OR127

Tubule-Derived Wnts Are Indispensable for Fibroblast Activation and Kidney Fibrosis Dong Zhou,[1] Roderick J. Tan,[2] Haiyan Fu,[1] Liangxiang Xiao,[1] Youhua Liu.[1] *[1]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Cell-cell communication via Wnt signals plays fundamental roles in regulating embryonic development and kidney homeostasis. Accordingly, dysregulation of Wnts expression is implicated in the development and progression of kidney diseases.

Results: We found that in kidney biopsy specimens from CKD patients with different etiologies, Wnts proteins displayed distinct expression patterns. While Wnt4 was induced in both tubular cells and interstitial fibroblasts, Wnt1 induction was limited to epithelial cells, but not fibroblasts. To investigate the potential roles of Wnts produced by different kidney cells, we generated conditional knockout mouse model in which Wntless (WLs)/Evi, a novel cargo protein specifically dedicated to the secretion of Wnt proteins, was selectively ablated in kidney tubular epithelial cells. Mice with tubule-specific deletion of Wls/Evi did not show overt abnormality. However, blockade of Wnt secretion by deleting Wls/Evi in tubular cells markedly ameliorated renal fibrosis after unilateral ureteral obstruction (UUO), comparing with controls. Consistently, renal expression of the major fibrosis-related genes including collagen, fibronectin and plasminogen activator inhibitor 1 (PAI-1) were significantly inhibited in mice with tubule-specific ablation of Wls/Evi after UUO. Tubular loss of Wls/Evi also resulted in an accelerated activation of myofibroblasts. Interestingly, tubule-specific deletion of β-catenin had no or little effect on the severity of renal fibrosis after UUO, suggesting that blockade of tubule-derived Wnt secretion mainly affects fibroblast activation by a paracrine mechanism. In vitro, incubation of normal rat kidney fibroblast (NRK-49F) with recombinant Wnt proteins promoted their proliferation and extracellular matrix expression and deposition.

Conclusions: These results illustrate that tubule-derived Wnts play an essential role in promoting fibroblast activation and kidney fibrosis via cell-cell communication.

Loss of Angiopoietin-1 Increases Kidney Fibrosis Krishnapriya Loganathan,[1] Marie Jeansson.[1] *[1]Immunology, Genetics and Pathology, Uppsala Univ, Uppsala, Sweden; [2]Feinberg School of Medicine, Northwestern Univ, Chicago, IL.*

Background: The presence of renal tubulointerstitial fibrosis is predictive of progressive decline in kidney function. It is characterized by an increase in aSMA+ fibroblasts, myofibrosblasts, that produce collagen. Identification of factors that regulate the fibrotic response are excellent candidate targets for treatment of kidney diseases. We previously showed that loss of Angiopoietin-1 (Angpt1) in adult mice predisposes to systemic fibrosis in an ear punch model. Angpt1 is expressed in pericytic lineages and acts through the Tie2 tyrosine-kinase receptor expressed on adjacent endothelium. Here, we test the hypothesis that loss of Angpt1-Tie2 signaling in renal fibrosis will result in a more aggressive fibrotic response.

Methods: To better understand the origin of fibroblast populations in renal fibrosis, we first performed lineage tagging experiments using Z/EG reporter mice that were bred to 4 independent Cre-driver strains and subjected to UUO. These Cre strains mark the tubular epithelium, renal pericytes, renal endothelium and macrophages, respectively (Pax8-rtTA/tetOCre, Pdgfrb-Cre, Tie2-Cre and LysM-Cre). Secondly, we performed UUO on Angpt1 conditional knockout mice and studied gene expression changes at different time points.

Results: Kidneys were analyzed and co-stained for the lineage tag (EGFP+) and aSMA+, 10 days post-UUO. We found that endothelial cells and pericytes each contributed to about about 15% of myofibroblast. Tubular epithelium and macrophages contributed minimally. UUO in conditional Angpt1 knockout mice show an increased expression of fibrosis markers compared to control mice subjected to UUO. For example, there is a significant upregulation of Fibronectin 3 days after UUO in Angpt1 knockout mice compared to controls.

Conclusions: Our results show that several lineages, including endothelial cells, contribute to the myofibroblast population in fibrosis. In addition, our results suggest that loss of Angpt1-Tie2 signaling increases fibrosis as seen by the increased expression of fibrosis markers. Ongoing work is designed to elucidate the mechanism(s).

FGFR2 Signaling Promotes Kidney Fibroblast Activation and Kidney Fibrosis Zhuo Xu, Weichun He, Junwei Yang, Chunsun Dai. *Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical Univ, Nanjing, China.*

Background: Fibroblast growth factors (FGFs) are heparin-bindingproteins involved in a variety of biological processes, including cell proliferation, differentiation, survival and angiogenesis. However, the role and mechanisms of FGFs/FGFR2 signaling in kidney fibroblast activation and kidney fibrosis need further investigation.

Methods: Mice with fibroblast specific FGFR2 deletion was created with Cre-LoxP system. Kidney fibrosis was induced by unilateral ureter obstruction (UUO) in mice.

Results: In this study, in the kidneys from mice with UUO nephropathy, the mRNA expression level for FGFs including FGF7, FGF10, FGF11, FGF12, FGF13, FGF16, and FGF22were significantly up-regulated. To further explore the role of FGF signaling in kidney fibroblast activation and fibrosis, a mouse model with fibroblast specific FGFR2 gene disruption was generated by using Cre-LoxP system. The knockouts were born normal and no obvious kidney dysfunction or histological abnormality was found within 2 months after birth. Kidney ischemia/reperfusion model was created in the knockouts and their control littermates and kidney tissue was harvested at 4 weeks after surgery. Kidney interstitial fibrosis was induced in the control littermates, while in the knockouts, total collagen deposition, fibronectin and a-SMA expression, interstitial inflammatory cell infiltration were all decreased compared to those in the control littermates. In addition, Ki67 positive interstitial cell number was also less in the knockout kidneys at 4 weeks after surgery. Phosphorylated Erk1, 2, a downstream signaling molecule for FGFR, was also downregulated in the knockout kidneys at 2 and 4 weeks after IRI compared to those in the control littermates.

Conclusions: Taken together, these results suggest that FGFs/FGFR2 signaling promotes the proliferation and activation of kidney fibroblasts and contributes to the development of interstitial fibrosis.

Role of Platelet-Derived Growth Factor DD in Healthy Kidneys and Renal Fibrosis Eva Miriam Buhl,[1] Sonja Djudjaj,[2] Barbara Mara Klinkhammer,[2] Janka Babickova,[1] Jürgen Floege,[1] Peter Boor.[1,2] *[1]Nephrology, RWTH Univ, Aachen, Germany; [2]Pathology, RWTH Univ, Aachen, Germany.*

Background: Platelet-Derived Growth Factors (PDGF) play a role in various renal diseases. The PDGF-DD isoform is the only specific PDGF receptor β ligand and mediates mesangial cell proliferation. Our previous data in progressive mesangioproliferative glomerulonephritis in rats also suggested a role in interstitial fibrosis.

Methods: To address the functional role of PDGF-DD we have generated PDGF-DD-/- mice, which also serve as reporter mice for PDGF-DD (using LacZ). We analysed the expression pattern of PDGF-DD in healthy and diseased kidney as well as the consequence of PDGF-DD deficiency. We compared PDGF-DD-/- mice and their wild-type (WT) littermates in models of renal fibrosis (unilateral ureteral obstruction – UUO and unilateral ischemia/reperfusion - I/R).

Results: PDGF-DD-/- mice (on both Bl6 and mixed Bl6/Sv129 backgrounds) were viable and showed no obvious spontaneous phenotype until the age of 50 weeks. Expression of PDGF-DD in healthy kidneys was observed in renal mesenchymal cells including the mesangial cells, fibroblasts and vascular smooth muscle cells. During renal fibrosis PDGF-DD and its receptor PDGFR-β were markedly upregulated in both human and murine tissues. The expanding and activated mesenchymal cells in fibrosis retained their PDGF-DD expression. In addition, PDGF-DD was expressed *de novo* in injured renal tubular cells. The PDGFR-β receptor was found on mesenchymal cells in both healthy and fibrotic kidneys and was highly upregulated during fibrosis. *In vitro,* PDGF-DD induced proliferation and expression of proinflammatory cytokines in fibroblasts. Compared to wild-type littermates, PDGF-DD-/- mice had significantly reduced indices of renal fibrosis in UUO on day 10 and following I/R on day 21.

Conclusions: PDGF-DD was strongly upregulated in kidney injury and scarring and its genetic deletion significantly attenuated renal interstitial fibrosis. PDGF-DD might represent a novel therapeutic target in kidney fibrosis.

Blocking SIRT 1/2 Inhibits Renal Interstitial Fibroblast Activation and Attenuates Renal Interstitial Fibrosis in Obstructive Nephropathy Shougang Zhuang. *Dept of Medicine, Alpert Medical School and Rhode Island Hospital, Providence, RI.*

Background: Our recent studies revealed that blocking class I/II histone deacetylases (HDACs) inhibits renal interstitial fibroblast activation and proliferation and alleviates development of renal fibrosis. However, the effect of class III HDACs, in particular, Sirtuin 1 and 2 (SIRT1 and SIRT2) inhibition on renal fibrogenesis remains elusive.

Methods: Here, we examined the effect of SIRT1/2 inhibition on the activation of renal interstitial fibroblas and development of renal fibrosis in a murine model of unilateral ureteral nephropathy.

Results: Our ressults showed that both SIRT1 and SIRT2 were expressed in cultured renal interstitial fibroblasts (NRK-49F). Exposure of NRK-49F to Sirtinol, a selective inhibitor for SIRT1/2, or EX527, an inhibitor for SIRT1, resulted in reduced expression of fibroblast activation markers (α-smooth muscle actin, fibronectin and collagen I) as well as proliferation markers (proliferating cell nuclear antigen, cyclin D1, cyclin E) in dose and time dependent manners. Treatment with a SIRT2 inhibitor, AGK2, also dose- and time-dependently inhibited renal fibroblast activation and to a less extent, proliferation. Furthermore, silencing of either SIRT1 or SIRT 2 by siRNA exhibited similar inhibitory effects. In a mouse model of obstructive nephropathy, administration of Sirtinol attenuated deposition of collagen fibrils as well as reduced expression of α-smooth muscle actin, collagen I and fibronectin in the injured kidney. SIRT1/2 inhibition-mediated anti-fibrotic effects are associated with dephosphorylation of epidermal growth factor receptor (EGFR), platelet-derived growth factor receptor-β (PDGFR-β) and STAT3.

Conclusions: Thus, SIRT1/2 activity may contribute to renal fibroblast activation and proliferation as well as renal fibrogenesis through activation of at least EGFR and PDGFRβ signaling. Blocking SIRT1/2 activation may have therapeutic potential for the treatment of chronic kidney disease.

Tenascin-C Plays an Important Role in Kidney Fibrosis Qionghong Xie, Min Zhang, Shaojun Liu, Chuanming Hao. *Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.*

Background: Tenascin-C (TNC) is a glycoprotein expressed in the extracellular matrix of various tissues during development, disease or injury repairing. The present study examined the role of tenascin C in renal fibrosis.

Methods: A renal medullary interstitial cell (RMIC) specific TNC promoter driven inducible CreER2 knock-in mouse with an EGFP reporter was generated (TNCCreER). UUO and ischemic perfusion injury (IRI) models were used to induce renal fibrosis. TNCCreER$^{+/+}$ (TNC knockout) was used to examine the role of TNC in renal fibrosis. To examine whether RMIC contribute to fibrosis, a cell linage chasing study was conducted. Recombination was induced in TNC-CreER2$^{+/-}$/Rosa-lacZ$^{+/-}$ mice by tamoxifen (1.5mg/d by ip for 7 days) at least three weeks before the fibrotic challenge.

Results: In normal kidney, TNC is expressed in RMICs. In fibrotic kidney after IRI (14 days) or UUO (7 days), the expression of TNC was markedly induced in renal cortex. The GFP (+) TNC expressing cells accounted for 42.4% of all the interstitial cells in fibrotic regions. Among these GFP (+) TNC expressing cells, 40% also expressed α-SMA, and none of the GFP(+) cells expressed macrophage marker F4/80. Among the renal interstitial cells in fibrotic regions, 25.3% were F4/80(+) cells while 32.3% were GFP(-)F4/80(-) cells. To examine whether the induced TNC contributes to the fibrosis, TNC$^{-/-}$ mice was used and TNC$^{-/-}$ kidney showed less fibrosis by Masson staining, fewer S100A4(+) cells (26.7 versus 36.3/HPF in UUO7d) and less F4/80(+) areas (5.4% versus 3.8% in UUO7d) than wild-type kidney. TNC deletion is also associated with reduced collagen Iα, PAI-1 and fibronectin mRNAs. To further examine whether the RMICs that normally express TNC contribute to TNC(+) cells in the fibrotic region, we did a cell-linage chasing study using a TNCCreER/ROSA26R mouse. The results show that the recombination reporter remained in papillary and was not observed in the fibrotic area where TNC expression was observed.

Conclusions: During fibrotic process in the kidney, tenascin C is induced in cells that may trans-differentiate to α-SMA(+) myofibroblasts. TNC plays an important role in renal fibrosis and TNC deficiency alleviates renal fibrosis induced by IRI or UUO.

FR-OR133

Role for Rictor/mTORC2 Signaling in Mediating TGFβ1-Induced Fibroblast Activation and Kidney Fibrosis Jianzhong Li, Weichun He, Junwei Yang, Chunsun Dai. *Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical Univ, Nanjing, China.*

Background: The Mammalian target of rapamycin (mTOR) is recently identified with two structurally distinct multiprotein complexes. MTORC1 has been implicated in the pathogenesis of several types of kidney disease. Our previous study demonstrated that Rictor/mTORC2 protects against cisplatin-induced tubular cell death and acute kidney injury. However, the role and mechanisms for mTORC2 in TGFβ1-induced fibroblast activation and kidney fibrosis have not been reported.

Methods: Rat kidney interstitial fibroblasts (NRK-49F) were stimulated with TGFβ1 and kidney fibrosis was induced by unilateral ureter obstruction (UUO) in mice.

Results: Here, we found that TGFβ1 could activate Rictor/mTORC2 signaling in cultured NRK-49F cells, a rat kidney fibroblast cell line, with a time-dependent manner. Blocking Rictor/mTORC2 signaling with either Rictor, Akt1 or Akt2 small interfering RNA transfection markedly inhibited TGFβ1-induced fibronection and a-SMA expression. In addition, Western blotting or immuno-staining results showed that Rictor/mTORC2 signaling was activated in kidney interstitial myofibroblasts from mice with unilateral ureter obstruction (UUO) nephropathy and from patients with various types of kidney disease including diabetic nephropathy, IgA nephropathy, lupus nephritis as well as membranous nephropathy. To further investigate the role of Rictor/mTORC2 signaling in fibroblast activation and kidney fibrosis, a mouse model with fibroblast-specific deletion of Rictor was generated with Cre/LoxP system. The knockouts were born normal and no obvious kidney dysfunction or kidney morphologic abnormality was found within 5 months after birth. However, kidney interstitial fibrosis and inflammatory cell infiltration were markedly diminished in the knockouts at 1 and 2 weeks after UUO compared to those in their control littermates.

Conclusions: Together, these results suggest that Rictor/mTORC2 signaling activation mediates TGFb1-induced fibroblast activation and contributes to the development of kidney fibrosis, possibly providing a therapeutic target for chronic kidney diseases.

GLI2 Antagonism Is a Novel Antifibrotic Strategy by Inducing Myofibroblast-Specific Cell Cycle Arrest Rafael Kramann, Susanne V. Fleig, Benjamin D. Humphreys. *Medicine, Brigham and Women´s Hospital, Boston, MA.*

Background: The Hedgehog effectors Gli1 and Gli2 are expressed in kidney pericytes as well as activated myofibroblasts during fibrosis. Whether these transcription factors might serve as therapeutic targets in chronic kidney disease (CKD) is unknown. Recently arsenic was described as an inhibitor of Hedgehog signaling, though the mechanism is unknown.

Methods: We utilized Gli1 knockout mice, in vitro drug binding, RNAi and overexpression studies to dissect the roles of Gli1 versus Gli2 in myofibroblast activation. We tested the antifibrotic efficacy of Darinaparsin, an arsenical, and GANT61, a small molecule Gli inhibitor, in two independent CKD models in mice. These drugs were given in a therapeutic protocol, ie, after the onset of fibrosis.

Results: Surprisingly, knockout of Gli1 had no effect on fibrosis compared to WT mice (n = 15 mice per group). Therefore we turned our attention to Gli2. Knockdown of Gli2 in vitro reduced Gli1 and triggered G0/G1 cell-cycle arrest, whereas knockdown of Gli1 had no effect, consistent with our in vivo results. We found that darinaparsin directly binds to Gli2, and it mimicked the effects of Gli2 knockdown. Conversely, retroviral overexpression of Gli2 increased Gli1 expression, drove cell proliferation and rescued the cell cycle effect of darinaparsin. Gli2 knockout is embryonic lethal, but when administered two days after UUO, darinaparsin potently inhibited renal Gli1 and 2 expression and reduced renal fibrosis through upregulation of p21 and induction of a myofibroblast specific G0/G1 cell-cycle arrest. There was no effect on epithelial cell cycle. Darinaparsin also improved GFR in a four week severe bilateral IRI CKD model when administered beginning one week after IRI. Importantly, the small molecule GANT61 also reduced Gli1 and Gli2 protein levels and blocked renal fibrosis following UUO in a therapeutic model.

Conclusions: Gli2 is the critical Gli effector that regulates myofibroblast cell cycle progression whereas Gli1 is dispensable. Our data provide the first conclusive evidence that targeting Gli2 is a novel and powerful antifibrotic therapeutic strategy to slow CKD progression.

Notch1, but Not Notch2, Regulates Podocyte Dedifferentiation in Glomerulosclerosis via Snail1 Mariya T. Sweetwyne, Katalin Susztak. *Renal-Electrolyte and Hypertension, Univ of Pennsylvania, Philadelphia, PA.*

Background: Expression of multiple Notch ligands and receptors has been described in different kidney injury models. During podocyte development, Notch2 is critical for differentiation whereas Notch1 is dispensable. In diabetic glomerulosclerosis, treatment with global Notch inhibitors or podocyte-specific deletion of a Notch transcriptional co-activator, Rbpj, protected glomeruli from diabetic injury; proving that podocyte Notch signaling is critical for regulating glomerulosclerosis. Here we investigated the specific role of Notch1 and 2 receptor isoforms in podocytes under pro-fibrotic stimulus.

Methods: Notch1 or 2 flox/flox and podocin Cre mice were crossed to generate animals with podocyte-specific deletion of Notch1 or 2. We cultured glomeruli and podocytes from these mice and used quantitative RT-PCR, western blots and immunohistochemistry (IHC) to examine Notch signaling.

Results: Previously we showed that podocyte-specific deletion of Notch1, but not Notch2, protects diabetic mice from podocyte loss, albuminuria and glomerular injury. To assess these responses *in vitro*, cultured primary podocytes were treated with transforming growth factor β (TGF-β) a profibrotic cytokine that is highly upregulated in injured glomeruli. In primary wildtype podocytes, TGF-β1 induced the expression of Notch ligands Jagged1 and DLL4 and the activation (cleavage) of Notch1 but not Notch2. TGF-β treatment caused podocyte dedifferentiation evident by a decrease in podocin transcript and protein levels, f-actin stress fiber formation, and upregulation of transcriptional regulator, Snail1. In Notch1 knockout podocytes TGF-β was unable to downregulate podocin and induce Snail1 expression, indicating that Notch1 mediates TGF-β-induced podocyte dedifferentiation. *In vivo,* IHC of kidneys from diabetic mice showed upregulation of Snail1 podocyte expression in wildtype, but not Notch1 knockout, animals. These findings were consistent with the *in vitro* results.

Conclusions: Podocyte Notch1 expression plays an important role in diabetic albuminuria and podocyte dysfunction. Our current experiments indicate that these changes are in part the result of Notch1 induced podocyte dedifferentiation via Snail1.

Acute Kidney Injury Progresses to Chronic Kidney Disease via Persistent Metabolic Alterations and Oxidative Stress David M. Small,[1] Washington Yamandu Sanchez,[2] Sandrine F. Roy,[3] Christudas Morais,[1] David W. Johnson,[1,4] Glenda C. Gobe.[1] *[1]Centre Kidney Disease Research; [2]Therapeutics Research Centre, Sch Medicine, Univ Queensland; [3]Diamantina Inst; [4]Dept Nephrology, PA Hospital, Brisbane, Australia.*

Background: Acute kidney injury (AKI) often progresses to chronic kidney disease (CKD). Oxidative stress and mitochondrial dysfunction exacerbate AKI but their role in progressive CKD remains unclear. The aim of this project was to determine the metabolic changes associated with oxidative stress during the progression to CKD after AKI.

Methods: Male C57Bl6 mice underwent bilateral ischemia (20min) followed by reperfusion for 21 days (21d). Intravital multiphoton microscopy (MPM) of endogenous nicotinamide adenine dinucleotide (NADH) was performed in kidneys: without ischemia-reperfusion (IR); during ischemia; immediately at reperfusion; and at 21d (n=4). Fluorescence lifetime imaging microscopy (FLIM) measured free/bound NADH (α_1/α_2 ratio), and the average weighted lifetime (τ_m) of NADH in cortex and medulla. Renal perfusion with a mitochondrial dye (TMRM) coupled with MPM assessed mitochondrial health. Molecular and histological assessments were performed in kidneys post MPM and FLIM.

Results: NADH fluorescence intensity (EFI) significantly decreased during ischemia ($p<0.05$ v control). 21d post-IR showed focal tubular atrophy and significantly increased NADH EFI in structurally normal tubules. Tubular epithelial cell uptake of TMRM decreased, the α_1/α_2 ratio increased, and theτ_m of NADH/FAD decreased in cortex ($p<0.05$). Compared with controls, biomolecular analyses showed: nuclear factor-like 2 expression increased at reperfusion ($p<0.001$) but decreased at 21d ($p<0.05$); increased apoptosis, collagen, heme-oxygenase-1, transforming growth factor-β1, proliferating cell nuclear antigen, and 8-hydroxy-2'-deoxyguanosine ($p<0.05$ at 21d); and decreased superoxide dismutase-2 ($p<0.05$ at 21d).

Conclusions: This is the first demonstration of dynamic changes in NADH utilisation by kidney tubular cells promoting oxidative stress in progressive CKD. Mitochondrial dysfunction is persistent in structurally normal tubules of the chronically-damaged kidney following AKI potentially enhancing free radical production.

Defective Fatty Acid Oxidation in Renal Tubular Epithelial Cells Plays Key Role in Kidney Fibrosis Development Hyun Mi Kang,[1] Seon-Ho Ahn,[1] Yi-An Ko,[1] Ae Seo Deok Park,[1] Jianling Tao,[1] Frank S. Chinga,[1] James M. Pullman,[2] Erwin P. Bottinger,[3] Katalin Susztak.[1] *[1]Renal Electrolyte and Hypertension Div, Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA; [2]Dept of Pathology, Montefiore Medical Center, Bronx, NY; [3]Dept of Medicine, Mount Sinai School of Medicine, New York, NY.*

Background: Fibrosis is the histological manifestation of a progressive irreversible process causing chronic and end stage kidney disease. Here we examined the role of fatty acid oxidation (FAO) in patients and mouse models of kidney fibrosis.

Methods: Here we performed gene expression analysis on a large cohort of human kidney tubule samples (n=95) with control and progressive tubulointerstitial fibrosis. In addition, we cultured renal epithelial primary cells from human and mouse to see the effect of FAO *in vitro* and also tested effect of restoring of FAO on tubulointerstitial fibrosis development.

Results: Genome-wide transcriptome studies of normal and fibrotic human kidney tubule samples identified inflammation and metabolism as the top dysregulated pathways. In particular, we found that both human and mouse models with tubulointerstitial fibrosis were characterized by decreased expression of key enzymes and regulators of FAO, loss of mitochondrial density. In vitro experiments indicated that inhibition of fatty acid oxidation in tubule epithelial cells caused ATP depletion, increased cell death, dedifferentiation and intracellular lipid deposition; a phenotype observed in fibrosis. Our results indicate that the TGFB1-induced -and Smad3- mediated repression of Ppargc1a and fatty acid oxidation were critical for the TGFB1-induced profibrotic phenotype. Restoring fatty acid metabolism by genetic or pharmacological methods protected mice from tubulointerstitial fibrosis development.

Conclusions: In summary, we identified that repressed fatty acid oxidation induces a metabolic reprogramming that is critical for the development of fibrosis in the kidney and may present novel therapeutic approaches for the cure of chronic kidney disease.

Sphingosine 1-Phosphate Receptor-1 Modulates Mitochondrial Dynamics in Proximal Tubule Cells Heather M. Perry,[1,3] Amandeep Bajwa,[1,3] Diane L. Rosin,[2,3] Mark D. Okusa.[1,3] *[1]Dept of Medicine, Univ of Virginia; [2]Pharmacology, Univ of Virginia; [3]Center for Immunity, Inflammation and ReGenerative Medicine, Univ of Virginia, Charlottesville, VA.*

Background: Sphingosine 1-phosphate receptor-1 (S1PR1) preserves tubule cells in cisplatin-induced acute kidney injury in mice by augmenting mitochondrial respiration and protecting against mitochondrial oxidative damage. Yet, it is unknown how S1PR1 improves mitochondrial function. The balance of mitochondrial fission and fusion can regulate mitochondrial function, raising the interesting hypothesis that S1PR1 may modulate mitochondrial dynamics.

Methods: Ultrastructural analysis was performed on electron micrographs to determine mitochondrial morphology in TKPTS cells stably overexpressing S1PR1 (TK-P1) or control cells (TK-ctrl). A mitochondrial gene array was performed with total RNA extracted from TK-P1 and TK-ctrl cells. Lastly, mRNA expression of PGC-1α was assessed by quantitative RT-PCR.

Results: Overexpression of S1PR1 resulted in elongated and thinner mitochondria (feret maximum: 0.675±0.027 versus 0.506±0.022, shape factor: 4.400±0.070 versus 4.036±0.036, and compactness: 0.527±0.017 versus 0.609±0.011 in 20-25 cells, 307-346 mitochondria respectively, $p < 0.001$) compared to control cells. In addition, mitochondrial fission (fis1, drp1) and fusion (opa1, mfn1/2) genes were upregulated 4- to 9-fold in TK-P1 cells compared to controls, indicating an overall increase in mitochondrial dynamics. Lastly, consistent with enhanced mitochondrial biogenesis, PGC-1α gene expression was upregulated 20-fold (n = 3) in S1PR1 overexpressing cells relative to controls.

Conclusions: Results provide evidence that S1PR1 may be a novel regulator of mitochondrial dynamics, potentially through promoting biogenesis. Therefore, increasing S1PR1 signaling in proximal tubule cells to boost mitochondrial function may be a new strategy to prevent cisplatin-mediated acute kidney injury.

Renal Tubular-Specific Lkb1 Deletion Results in Severe Kidney Damage via Altered Metabolic Reprogramming Seung Hyeok Han,[1,2] Laura Malaga-Dieguez,[3] Frank S. Chinga,[1] Katalin Susztak.[1] *[1]Renal Electrolyte and Hypertension Div, Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA; [2]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [3]Dept of Pediatrics, Div of Pediatric Nephrology, New York Univ School of Medicine, New York.*

Background: The tumor suppressor Lkb1/STK11/Par-4 is a key regulator of polarity, proliferation and cell metabolism, yet its role in kidney is poorly defined. Here, we investigated the role of Lkb1 in mice with tubule specific deletion of Lkb1.

Methods: To create tubule epithelial Lkb1 specific knock-out (KO) mice, $Lkb1^{flox/flox}$ mice were crossed to transgenic mice expressing Cre recombinase under the cadherin 16 promoter. Male mice were analyzed at 5, 14 and 27 weeks of age. In vitro we used primary cultured renal tubule epithelial cells from wild type and $Lkb1^{flox/flox}$ mice infected with cre(GFP) or empty GFP adenovirus.

Results: Mice with distal tubule specific Lkb1 deletion ($Ksp^{cre}/Lkb1^{flox/flox}$) showed no obvious histological changes at 5 weeks of age, but developed severe kidney fibrosis, including dilated tubules and interstitial matrix accumulation by 27 weeks of age. Lkb1 is an important regulator of cell polarity, however our study showed no obvious polarity defect in renal epithelial cells lacking Lkb1. We also failed to identify a significant difference in mTOR expression between wild type and Lkb1 null tubule cells, even tough Lkb1 has been shown to regulate mTOR signaling in different context. On the other hand expression of enzymes related to fatty acid oxidation was severely reduced resulting in reduced ATP content and increased apoptosis rate. We found that renal tubule epithelial metabolism exclusively depends on fatty acid oxidation. Effects of Lkb1 was mediated by Ampk and Ppara, as the Ampk agonist (A769662) and Ppara agonist fenofibrate restored fatty oxidation defect and ameliorated apoptosis induced by Lkb1 deletion.

Conclusions: In conclusion, here we show that Lkb1 deficiency in renal tubular epithelial cells, via influencing energy metabolism plays an important role in kidney fibrosis development.

Mechanisms Involved in AMPK-Regulated Tight Junction Assembly Jingshing Wu, Michael J. Caplan. *Cellular and Molecular Physiology, Yale Univ, New Haven, CT.*

Background: Epithelial tight junctions (TJ) serve as the barriers that control paracellular permeability. Formation and maintenance of TJs require calcium-dependent cell adhesion. Removing extracellular calcium leads to dissolution of TJs, while adding calcium back to cells maintained in calcium-free medium ("calcium switch") induces rapid TJ assembly. Previous studies have shown that calcium switch-induced epithelial TJ formation leads to activation of AMP-activated protein kinase (AMPK). Furthermore, activation of AMPK in cells maintained in calcium-free medium is sufficient to cause the TJ protein zonula occludens-1 (ZO-1) to relocalize to sites of junction assembly and to induce its interaction with the F-actin binding protein afadin-l. Our studies were designed to determine whether regulators of TJ assembly including Cdc42, Par3, and atypical protein kinase C (aPKC) contribute to the mechanism involved in AMPK-mediated TJ assembly.

Methods: We assessed whether AMPK regulates the GTP bound state of Cdc42 in Madin-Darby canine kidney (MDCK) cells by using an affinity binding assay and we assessed the subcellular distributions of Cdc42, Par3, and aPKC during AMPK-mediated junction assembly by immunofluorescence microscopy. We monitored the effects of aPKC inhibition on AMPK-mediated junction assembly through immunofluorescence and co-immunoprecipitation studies.

Results: AMPK-mediated junction assembly promoted by AMPK activation by AICAR (2mM) in the absence of extracellular Ca2+ increased the level of GTP-bound Cdc42 and led to Par3/aPKC localization to sites of junction assembly. Furthermore, we found that aPKC inhibition prevented ZO-1 localization to sites of AMPK-induced junction assembly while increasing the level of afadin-l/ZO-1 interaction.

Conclusions: These results demonstrate that AMPK may regulate junction assembly by stimulating nucleotide exchange to increase the size of the Cdc42 pool in the GTP bound form. Accumulation of this active form of Cdc42 may facilitate Par3/aPKC localization to sites of junction assembly, and aPKC activity may in turn regulate the level of afadin-l/ZO-1 interaction.

Transcriptome-Based Network Analysis Reveals Renal Cell Type-Specific Dysregulation of Hypoxia-Associated Transcripts Maja Lindenmeyer,[1] Natallia Shved,[1] Gregor Warsow,[2] David Hoogewijs,[1] Clemens D. Cohen.[1,3] *[1]Univ of Zurich, Zurich, Switzerland; [2]Univ Medicine Greifswald, Greifswald, Germany; [3]Klinikum Munich, Munich, Germany.*

Background: The best morphologic indicator of disease progression and development of end-stage renal disease is interstitial fibrosis and capillary rarefaction. Accumulating evidence suggests that dysregulation of hypoxia-regulated transcriptional mechanisms is involved in the loss of renal function and the development of chronic kidney disease (CKD) and hypoxia-induced transcription factors (HIFs) have relevance in the dysregulation of gene products in different renal cells.

Methods: Proximal tubular cells and conditionally immortalized podocytes with stable HIF1α and/or HIF2α suppression were generated. Gene expression profiles from cell lines and more than 160 renal biopsies from patients with different CKD stages were obtained using Affymetrix arrays. Weighted Correlation Network Analysis (WGCNA) was applied in order to identify modules of genes that showed highly correlated gene expression across cell groups (WT, HIF1α, HIF2α, HIF1α+2α) and conditions (hypoxia, normoxia). Gene sets from each module underwent GO-enrichment analysis using the topGO library for R, the Pathway System analysis as well as the transcription factor overrepresentation tool from Genomatix.

Results: Microarray analysis of hypoxia-treated renal cells revealed celltype-specific HIF1/HIF2-dependencies as well as dysregulation of several pathways in the cell lines. WGCNA analysis resulted in gene sets (modules) that were highly coregulated within the modules. Further characterization of the modules disclosed common as well as cell group- and condition-specific pathways, GO-Terms and transcription factors for each cell line. Expression of hypoxia-associated genes in genome-wide expression profiles revealed correlation with eGFR in cortical tubulointerstitial and glomerular biopsy specimens. Correlations were both positive and negative and in part compartment-specific.

Conclusions: Our gene expression analysis indicates a condition- and celltype-specific dysregulation of hypoxia-associated transcripts in renal cells.

FR-OR142

Renal Protective Effect of Proximal Tubules-Specific Ghrelin/GHSR System Through the Regulation of Oxidative Stress Levels Keiko Fujimura,[1] Shu Wakino,[1] Kazuhiro Hasegawa,[1] Koichi Hayashi,[1] Motoko Yanagita,[2] Hiroshi Itoh.[1] *[1]Dept of Medicine, Keio Univ, Tokyo, Japan; [2]Dept of Nephrology, Graduate School of Medicine Kyoto Univ, Kyoto, Japan.*

Background: Ghrelin (Ghr) discovered as an endogenous ligand for the Growth hormone secretagogue receptor (GHSR), has been reported to exert organ protective effects. We previously reported renal protective effects of Ghr against angiotensin II (AngII)-induced renal damages. We also demonstrated demonstrated anti-oxidative effects of endogenous Ghr/GHSR system by using GHSR deficient mice ($GHSR^{-/-}$) (PLoS One, 2014). In the present study, we examined the kidney-specific roles of Ghr/GHSR systems in renal function.

Methods: We first analyzed the phenotypes of $GHSR^{-/-}$ mice. We further crossed $GHSR^{-/-}$ mice with the N-Myc downstream-regulated gene 2 (NDRG2) Cre mice that harbor proximal-tubules (PT) specific Cre recombinase gene expression. With Cre recombinase, the expressions of GHSR in $GHSR^{-/-}$ mice were restored by the administration with tamoxifen (Tam) in a PT-specific manner in $GHSR^{-/-}$ mice with NDRG2-Cre gene (NDRG2 Cre^{+}-$GHSR^{-/-}$ mice). Renal senescence and oxidative stress levels were accessed by SA β-Gal and 4-HNE staining, respectively. Renal tissue damages were assayed by the urinary excretion of renal tubular marker,NAG and NGAL as well as by urinary protein excretion. The role of endogenous GHSR was evaluated by the knockdown experiment by using siRNA for GHSR in PT cell line, HK-2 cells.

Results: In $GHSR^{-/-}$ mice, tissue senescence and oxidative stress were enhanced, and renal tubular damages, urinary protein excretion and serum creatinine levels were also increased as compared to those in wild-type litter mice. The elongation of mitochondria was found in $GHSR^{-/-}$ mice in electron microscope. The renal damages in Cre^{+}-$GHSR^{-/-}$ mice with saline infusion were mitigated in Cre^{+}-$GHSR^{-/-}$ mice with Tam administration. By knockdown by siRNA for GHSR in HK-2 cells revealed the increase in mitochondria-derived oxidative stress levels.

Conclusions: Endogenous proximal-tubular Ghr/GHSR system is involved in renal senescence and renal oxidative stress. This system maintains renal function by regulating oxidative stress levels.

FR-OR143

Nox2 as a Modulator of Ischemia-Reperfusion-Induced Renal Fibrosis Aos S. Karim, Shannon Reese, Nancy A. Wilson, Arjang Djamali. *Medicine, Univ of Wisconsin SMPH, Madison, WI.*

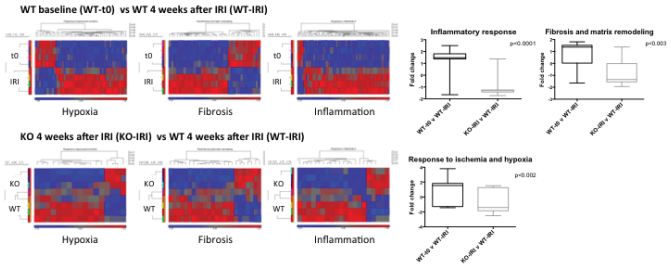
Background: Ischemia-reperfusion injury (IRI) is a significant complication of organ transplantation. Long ischemic time is associated with delayed graft function, which is mostly mediated through reactive oxygen species (ROS). We hypothesized that NADPH oxidase, specifically Nox2, plays an important role in ROS production and kidney injury in IRI.

Methods: Wild-type (WT) and Nox2 knockout (KO) mice were subjected to a right nephrectomy followed by clamping of the left renal artery for 30 min. The animals were followed for 4 weeks, when serum was collected for functional studies, and tissues were harvested for protein and genomic analyses.

Results: Kidney fibrosis (KF) was significantly reduced in tissues of KO compared to WT mice 4 weeks after IRI, as seen by the decline in picrosirius staining (collagen; $p<0.02$) and densitometry of α-smooth muscle actin immunoblots ($p<0.03$). Similarly, oxidative stress (OS; 4-hydroxynonenal and dihydroethidium) was significantly decreased ($p<0.03$ and $p< 0.02$ respectively) in KO compared to WT animals. Although BUN and creatinine levels were significantly increased in both KO and WT mice 4 weeks after IRI ($p<0.001$) compared to baseline, no significant differences were observed between the two groups, suggesting that alterations in OS and KF did not translate into functional changes.

	WT BUN	KO BUN	WT Creatinine	KO Creatinine
Baseline	26.2±0.9 mg/dL	20.4±0.5 mg/dL	0.11±0.01 mg/dL	0.11±0.01 mg/dL
4 weeks after IRI	38.7±1.3 mg/dL	39.7±1.7 mg/dL	0.19±0.01 mg/dL	0.19±0.01 mg/dL

Comparing WT to KO animals 4 weeks after IRI at the genomic level, we found that genes in pathways associated with KF, hypoxia and inflammation were significantly reduced in KO compared to WT animals.



Conclusions: Our studies suggest that Nox2 is a key contributor of oxidative stress and kidney fibrosis in this preclinical model of IRI.

Endothelial Dysfunction and Injury Control Podocyte Defects in Diabetic Nephropathy Susceptible Mice

Ilse S. Daehn, Gabriella Casalena, Liping Yu, Erwin P. Bottinger. *Medicine Nephrology, Mount Sinai.*

Background: The molecular signaling mechanisms between glomerular cell types during initiation/progression of glomerulosclerosis remain poorly understood. We demonstrated that podocyte dysfunction and depletion characteristic of various models of podocyte-initiated injury were mediated by podocyte-endothelial crosstalk and required endothelial mitochondrial oxidative stress (mtStress) and endothelial dysfunction. Oxidative stress and mitochondrial dysfunction are central mediators in the pathogenesis of diabetic complications including nephropathy (DN). We hypothesize that DN-susceptibility is characterized by glomerular endothelial mtStress-dependent endothelial dysfunction which is required for podocyte injury/loss.

Methods: Type I diabetes was induced by multiple, low-dose streptozotocin (STZ) injections in DN-susceptible DBA/2J (D2) and DN-resistant C57/Bl6 (B6). Osmotic minipumps delivering mitoTEMPO (1mg/kg/day) or vehicle were implanted s.c. prior to onset of hyperglycemia. Kidneys were harvested at 1, 3, 6, 12 weeks following hyperglycemia. Glomerular endothelial cells (mGEC) and podocytes were used in vitro.

Results: One week after hyperglycemia uncoupled oxygen consumption was significantly reduced in STZ-D2 glomeruli, but not in STZ-B6 compared to controls. STZ-D2 mice had increased mtDNA lesions, oxidative stress markers (3NT) and oxidative DNA damage (8-oxoG in mtDNA), exclusively localized to endothelial cells after 3 weeks of comparable hyperglycemia. The endothelial dysfunction and injury in turn was required for podocyte apoptosis as selective mitochondrial-targeted ROS scavenging (mitoTEMPO) prevented podocyte loss, ameliorated albuminuria, and reduced glomerulosclerosis lesions in STZ-D2 mice. In vitro treatment of mGEC cultures with mitoTEMPO prevented mtStress, fragmentation and decreased NOS activity induced by incubation with diluted STZ-D2 serum in media.

Conclusions: Our results demonstrate that mtStress and dysfunction in glomerular endothelial cells precede and mediate in part albuminuria, podocyte defects and depletion, and glomerulosclerosis in diabetic DN susceptible D2 mice. Endothelial dysfunction is not detectable in diabetic DN-resistant B6 mice.

The Polycomb Repressor Complex and Smad3 Constitute a Switch Enhancing Complex that Interprets TGF-β Signaling to Control Cell Fate in Diabetic Microvascular Complications

Letizia De Chiara, Hayley Beaton, Catherine Godson, John Crean. *UCD School of Biomolecular and Biomedical Science, Univ College Dublin, Dublin, Ireland.*

Background: Developmental cell fate decisions are controlled by the interplay of transcription factors and epigenetic modifiers which together determine cellular identity. During the initiation and progression of diabetic complications cells within affected tissues undergo a process of reprogramming, evoking gene expression profiles reminiscent of ontogenesis.

Results: We have identified a context dependent switch enhancing complex comprising Smad 3 and PRC2 that regulates cell fate during embryonic differentiation and is reactivated during fibrotic processes. Our data suggests that the H3K27 methylating polycomb repressor complex 2 regulates the silencing of TGF-β activated genes during cell differentiation and commitment. Gene expression profiles of renal cells undergoing TGF-β mediated differentiation has revealed a number of transcription factors that co-segregate with Smad3 including the Yamanaka reprogramming factors Oct4, Sox2 and Nanog, while differential expression of these factors in response to TGF-β was clearly demonstrated by western analysis of chromatin associated proteins. Analysis of H3K27 trimethylation revealed that during the process of differentiation the histone mark is turned on, suggesting PRC2 mediated remodeling of the chromatin and switching of gene expression from a permissive or "ON" state to non-permissive or "OFF". Intriguingly proteomic analysis of the EZH2 interactome revealed a number of direct associations with a transcription factor network including phosphorylated Smad 3, TEAD4, Oct 4 and Sox2, suggesting that cooperative recruitment of PRC2 regulates gene repression during TGF-β mediated differentiation. Furthermore, treatment of cells with the specific EZH2 inhibitor 3 deazaneplanocin, inhibited TGF-β mediated epitheial dedifferentiation and blocked the expression of genes associated with fibrosis.

Conclusions: This data demonstrates for the first time a functional association between Smad signaling and the polycomb repressor complex with potential for therapeutic manipulation during the progression of renal disease.

Laboratory and Biological Variation in Serum Creatinine Measurement Results in High False Positive Rate of Acute Kidney Injury

Jennie Lin, Hilda E. Fernandez, Dan Negoianu, Jeffrey S. Berns, Michael G. Shashaty, Francis Perry Wilson. *Univ of Pennsylvania, Philadelphia, PA.*

Background: Inclusion of small serum creatinine changes in the Kidney Disease: Improving Global Outcomes (KDIGO) acute kidney injury (AKI) definition may increase diagnostic false positive (FP) rates.

Methods: We created a data set of simulated non-AKI patients with true creatinine values that were constant over time. We simulated random variation in measured creatinine values using known coefficients of variation for the modified Jaffe rate reaction and a range of expected biological variation. AKI was defined when changes in measured creatinine values met KDIGO criteria. We also generated alternative criteria for AKI diagnosis and applied them to the simulated data set and a pre-existing cohort of 734 adult patients with at least stage 1 AKI (by KDIGO definition) to evaluate if these criteria capture a larger proportion of patients experiencing progression of AKI, initiation of renal replacement therapy, and inpatient mortality.

Results: After four simulated creatinine measurements, subjects with true creatinine values above 1.5 mg/dL had a FP AKI rate of 57.7% compared to 8.8% among those with lower creatinine ($p<0.001$).

AKI Definition	FP Rate at 4 Tests (%)			FP Rate at 7 Tests (%)		
	Total	Cr < 1.5	Cr ≥ 1.5	Total	Cr < 1.5	Cr ≥ 1.5
KDIGO Criteria	17.2	8.8	57.7	32.7	22.2	85.2

In contrast, our alternative approaches to AKI diagnosis had FP rates ranging from 2% to 36.2% in the higher creatinine group and from 0.7% to 4.5% in the lower creatinine group. Compared to KDIGO, our alternative criteria also captured a higher proportion of the AKI cohort that progressed to at least AKIN stage 2, required dialysis, or died ($p<0.05$ for all alternative criteria).

Conclusions: Use of small serum creatinine changes to diagnose AKI is limited by high FP rates due to inherent variability within the analyte. FP rates increase markedly at higher baseline creatinine values, potentially limiting the performance of the KDIGO AKI diagnostic criteria in the CKD population. Alternative approaches to diagnosing AKI may improve prediction of clinically relevant outcomes in an acutely ill population.

Patterns of Recovery from Acute Kidney Injury (AKI) and Risk of Kidney Disease Progression in the Irish Population

Austin G. Stack,[1,2] Els H. Gillis,[1,2] Mohamed Elsayed,[1,2] Hoang Thanh Nguyen,[2] Ailish Hannigan,[2] Patrick T. Murray,[3] Howard Johnson,[4] Liam F. Casserly,[1] John P. Ferguson.[2] *[1]Nephrology, Univ Hospital Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Ireland; [3]School of Medicine and Medical Sciences, Univ College Dublin, Ireland; [4]Health Intelligence Directorate, Health Services Executive, Dr Steevens Hospital, Dublin, Ireland.*

Background: There are limited data on the patterns of recovery from Acute Kidney Injury (AKI) and its clinical consequences in the Irish Health System. The aim of this study was to describe the patterns of recovery from AKI and risk of kidney disease progression.

Methods: We determined incidence rates and recovery rates from AKI in 207, 336 adults, age > 18 years, in the Irish Health System from 2005-2011. The diagnosis of AKI was based on standardised creatinine measurements using KDIGO classification. Recovery was defined as complete (return of function to within 1.10 times baseline creatinine); partial (1.10 and 1.50 times baseline), or failure to recover (creatinine >1.50 times baseline or dialysis) within 28-days of initial creatinine rise. We modelled time to 50% decline in eGFR among survivors of AKI who did not require immediate dialysis. Cox regression was used to explore associations of recovery status with risk of CKD progression in multivariable models with adjustment for baseline health and location of medical supervision.

Results: There were 25,744 episodes of AKI.Overall, 40.6 % (n=10, 442) of patients had

complete, 5.5 % (n=1, 409) partial, and 12.4 % (n=3, 192) non-recovery of kidney function. Median eGFR declined significantly from baseline to 12 months post AKI event by at least 3ml/min, *P<0.001]*. Compared to patients who had complete recovery (referent, Hazard Ratio =1.00), those with partial or failure to recover experienced significantly higher risks of CKD progression with hazard ratios of 1.62 (95% CI 1.37-1.89) and 6.97 (5.94-8.16) respectively. In total, 282 patients (1.1%) developed immediate ESKD and contributed to between 12 to 45 % of the incident dialysis population.

Conclusions: This is the first study to describe patterns of recovery from AKI in the Irish health system and its deleterious impact on CKD progression.

Development and Validation of a Risk Score for Predicting Acute Kidney Injury in Intensive Care Unit Patients

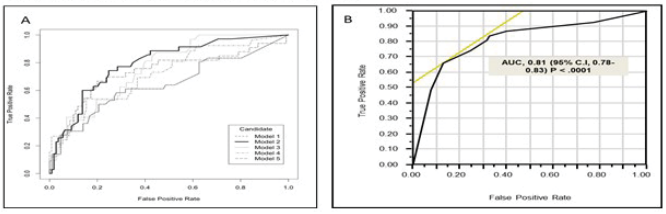
Rakesh Malhotra,[1,5] Etienne Macedo,[2] Josee Bouchard,[3] Kianoush Banaei-Kashani,[4] Ravindra L. Mehta.[5] *[1]VUMC; [2]U Sao Paulo; [3]U Montreal; [4]Mayo Clinic; [5]UCSD.*

Background: Acute kidney injury (AKI) is associated with high morbidity and mortality rates in critically ill patients. Early identification of risk factors for AKI provides an opportunity to develop strategies for prevention, early diagnosis and treatment.

Methods: We undertook multicenter prospective cohort study to develop and validate a risk score to predict AKI. Baseline risk factors were ascertained at ICU admission and additional acute factors within the first 48 hrs of ICU stay. A risk score was developed using multivariable logistic regression based on baseline and acute risk factors in the training cohort (573 patients) and the score was further evaluated in a test cohort (144 patients). Validation was performed in an independent cohort of 1280 patients. Discrimination of the scoring model was examined by the Area Under the Receiver Operating Characteristic Curve (ROC) and model calibration was evaluated by Hosmer-Lemeshow test.

Results: In the multivariate model, chronic kidney disease (CKD), chronic liver disease, congestive heart failure (CHF), hypertension (HTN), atherosclerotic coronary vascular disease (ASCVD), pH≤7.30, nephrotoxin exposure, sepsis, mechanical ventilation and anemia were identified as independent predictors of AKI and the C-statistic for the model in the test cohort was 0.79 (0.70-0.89). Validation revealed predictive accuracy of 0.81 (0.78-0.83). The risk score model demonstrated good calibration in both cohorts.

Figure 1: Area under curve of risk model for prediction of acute kidney injury in a) test cohort (n=144 patients) and b) Mayo Clinic Validation cohort (N=1280)



Conclusions: A risk scoring system based on chronic comorbidities and acute events can identify ICU patients at high risk to develop AKI and adverse outcomes within 48 hours of ICU admission. This risk assessment tool could help clinicians to stratify patients for surveillance, prevention and early therapeutic intervention.

SA-OR004

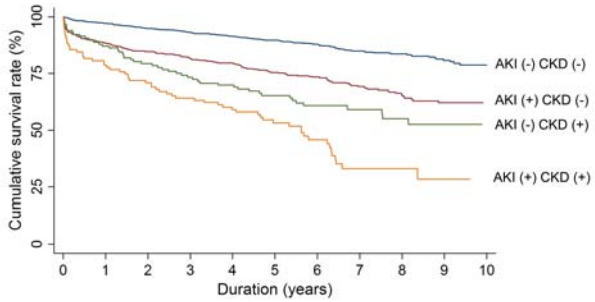
Synergistic Effects of Acute Kidney Injury and Chronic Kidney Disease on the Mortality After Coronary Artery Bypass Graft

Seung Seok Han,[1] Seon Ha Baek,[1,2] Dong Ki Kim,[1] Sejoong Kim,[1,2] Ho Jun Chin,[1,2] Dong-Wan Chae,[1,2] Ki Young Na.[1,2] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Internal Medicine, Seoul National Univ Bundang Hospital, Gyeonggi-do, Korea.*

Background: Both acute kidney injury (AKI) and chronic kidney disease (CKD) are known to predict mortality in the patients undergoing coronary artery bypass grafting (CABG). However, the synergistic effect between AKI and CKD on the long-term mortality remains unresolved.

Methods: Data on 1904 patients who underwent CABG in two major hospitals from 2004 to 2010 were collected. The hazard ratios (HRs) for all-cause mortality were calculated using Cox model after adjustment of multiple covariates. For evaluating the synergistic effect on 1-year mortality between AKI and CKD, the relative excess risk due to interaction (RERI) was used; positive results for RERI and a value greater than 1 for the synergy index means a positive interaction or more than additivity between variables. The discrimination of predicting mortality was assessed by the area under the curve (AUC) of calculating the receiver operating characteristic curve.

Results: Among the patients, 11.5% had underlying CKD and 33.4% encountered AKI after CABG. During the median follow-up period of 5 years (max. 10 years), patients with AKI or CKD had a high risk of mortality than their counterparts: HR in AKI versus non-AKI, 1.85 (1.513–2.270); HR in CKD versus non-CKD, 2.26 (1.761–2.891).



Number at risk

AKI (-) CKD (-)	1150	1116	1091	1071	974	809	620	437	283	153	40
AKI (+) CKD (-)	533	471	451	435	397	317	252	190	123	72	26
AKI (-) CKD (+)	116	101	92	85	81	65	47	32	23	14	5
AKI (+) CKD (+)	103	81	73	66	57	40	28	14	8	5	2

There was a relative excess risk of mortality when both AKI and CKD were considered together: RERI, 0.72 (-4.786 – 6.225); synergy index, 1.10 (1.962–2.242). When AUCs for predicting mortality were calculated based on the timeframe, the AUC of AKI decreased over time, but the AUC of CKD was relatively steady irrespective of the timeframe.

Conclusions: The present study first demonstrated the synergistic effects of AKI and CKD on the mortality in patients undergoing CABG.

SA-OR005

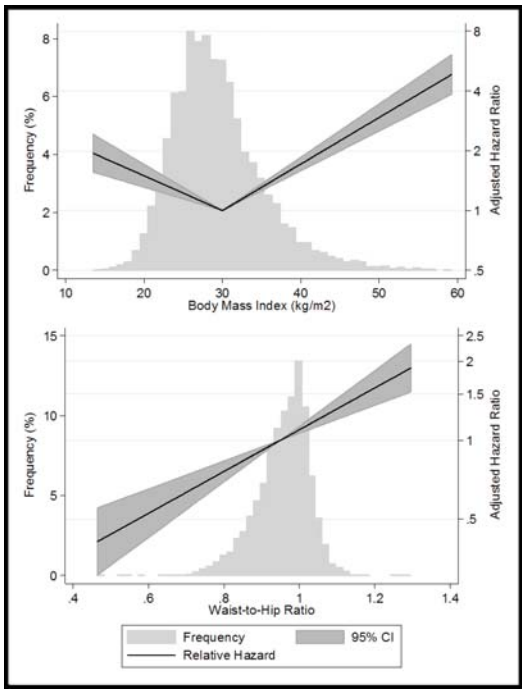
Obesity, Weight Distribution, and the Risk of Acute Kidney Injury: The Atherosclerosis Risk in Communities Study

Keiko I. Greenberg, Josef Coresh, M. Grams. *Dept of Medicine, The Johns Hopkins Univ School of Medicine, Baltimore, MD.*

Background: Elevated body mass index (BMI) at time of hospital admission has been associated with acute kidney injury (AKI) in surgical and critically ill patients. The association of BMI and measures of central obesity with AKI in the population-based setting is unknown.

Methods: Participants from the Atherosclerosis Risk in Communities (ARIC) study visit 4 (1996-8) with eGFR >15ml/min/1.73 m^2 and without a previous history of AKI were included (N=11,063). All participants were followed for subsequent hospitalizations; AKI was defined by billing code. Cox proportional hazards models were adjusted for age, sex, race, hypertension, diabetes, coronary artery disease, eGFR, albuminuria, BMI (linear spline, knot at 30 kg/m^2), waist-to-hip ratio (WHR), and time-varying number of hospitalizations, censoring at 12/31/2010, death, or ESRD.

Results: At baseline, mean age was 63.3 years, mean BMI was 28.8 kg/m^2, and mean waist-to-hip ratio was 0.95. Over 12 years of follow-up, 825 participants developed AKI. Higher BMI and higher WHR were independently associated with AKI. For BMI > 30, a 1 kg/m^2 increase was associated with a 6% increase in risk of AKI (95% CI: 1.05-1.06, p < 0.001); for BMI < 30, a 1kg/m^2 increase was associated with a 4% decrease in AKI risk (95% CI: 0.95-0.97, p < 0.001).



A 0.05 increase in WHR was associated with a 10% increase in risk of AKI (95% CI: 1.06-1.13; p < 0.001). The association of higher WHR and AKI was stronger in those with higher BMI (p for interaction < 0.001).

Conclusions: In the ARIC cohort, BMI over 30 and higher waist-to-hip ratio were independently associated with increased risk of hospitalized AKI. Prevention strategies for AKI may benefit the obese population.

Associations of eGFR and Albuminuria with Acute Kidney Injury in Individuals with and without Diabetes and Hypertension: A Collaborative Meta-Analysis

Matthew T. James, M. Grams, Mark Woodward, Carolyn Raina Elley, Jamie Alton Green, David C. Wheeler, Ron T. Gansevoort, Andrew S. Levey, David G. Warnock, Mark J. Sarnak. *CKD Prognosis Consortium.*

Background: Measures of chronic kidney disease, including reduced estimated glomerular filtration rate (eGFR) and increased albuminuria, are risk factors for subsequent acute kidney injury (AKI). Diabetes mellitus and hypertension often coexist with CKD and are risk factors for AKI; whether the associations between eGFR and urine albumin creatinine ratio (ACR) with AKI are consistent in the presence and absence of these conditions has not been established.

Methods: We performed a meta-analysis of 13 cohorts, 8 general population (1,284,751 participants) and 5 chronic kidney disease (79,496 participants) cohorts, within the Chronic Kidney Disease Prognosis Consortium, and identified AKI based on validated administrative codes. We used Cox proportional hazards models to estimate hazard ratios (HR) of AKI associated with eGFR and ACR in individuals with and without diabetes and hypertension. Random effects meta-analysis was used to pool results across cohorts.

Results: Low eGFR and high ACR were associated with higher risks of AKI in individuals with or without diabetes and with or without hypertension in both general population and chronic kidney disease cohorts. The risk gradient for AKI with lower eGFR was greater in those without diabetes than with diabetes (adjusted HR for eGFR 45 compared to 80 mL/min/1.73m^2 4.01 [3.12-5.16] versus 2.85 [2.05-3.96]), but similar with higher ACR in those without versus with diabetes (adjusted HR for ACR 300 compared to 5 mg/g 2.24 [1.89-2.80] versus 2.25 [1.71-2.96]). The risk gradients for AKI with both lower eGFR and higher ACR were greater for those without versus with hypertension (adjusted HR at eGFR 45 compared to 80 mL/min/1.73m^2 5.43 [4.79-6.16] versus 2.78 [2.06-3.76] and for ACR 300 mg/g compared to 5 mg/g 3.19 [2.24-4.56] versus 2.01 [1.69-2.38]).

Conclusions: Lower eGFR and higher albuminuria provide prognostic information about the risk of AKI in people with or without either diabetes or hypertension.

Funding: NIDDK Support

SA-OR007

The Association of Age, Sex, Race, and Kidney Measures with Acute Kidney Injury: CKD Prognosis Consortium Analysis of 1,364,568 Participants in 13 Cohorts

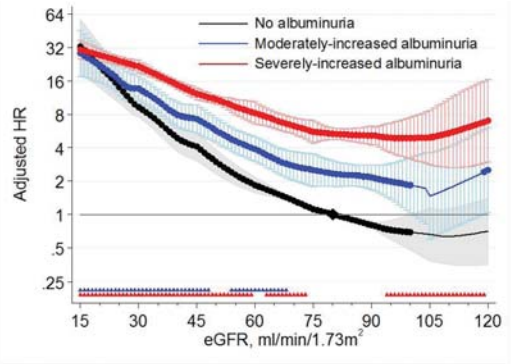
M. Grams, Yingying Sang, Shoshana Ballew, Ron T. Gansevoort, Csaba P. Kovesdy, David M. Naimark, Cecilia Montgomery Øien, David Smith, Josef Coresh, Mark J. Sarnak, Benedicte Stengel, Marcello Tonelli. *CKD Prognosis Consortium.*

Background: Acute kidney injury (AKI) is a global public health problem. The risk of AKI associated with eGFR and albuminuria (albumin to creatinine ratio, ACR) across categories of age, sex, and race has not been quantified.

Methods: Using data on 1,364,568 participants (1,285,049 in general population cohorts; 79,519 in chronic kidney disease cohorts) from 13 cohorts in 8 countries, we tested the association between eGFR, ACR and hospitalization with AKI (identified by diagnostic codes) using a two-stage meta-analysis. We also assessed how the associations of age, sex, and race with AKI vary by eGFR and ACR.

Results: Among general population cohorts, 1% of participants were hospitalized with AKI over 4 years. Lower eGFR and higher ACR were strongly associated with AKI in meta-analysis. Compared with eGFR 80 ml/min/1.73 m^2, the adjusted hazard ratio of AKI at eGFR 45 ml/min/1.73 m^2 was 3.35 (95% CI: 2.75 to 4.07). Compared with ACR 5 mg/g, the adjusted hazard ratio of AKI at ACR 300 mg/g was 2.73 (95% CI: 2.18 to 3.43). Older age was associated with higher risk of AKI than younger age in the higher range of eGFR or lower range of ACR, but this effect was attenuated in lower eGFR or higher ACR. Male sex was associated with higher risk of AKI at all levels of eGFR and ACR, with a slight attenuation in lower eGFR but not in higher ACR. In the 2 cohorts contributing to analysis by race, black race was associated with higher AKI risk than white race at higher levels of eGFR and most levels of ACR.

Conclusions: Reduced eGFR and increased ACR are consistent, strong risk factors for AKI whereas the strength of the associations between AKI, age, and sex is weaker in later stages of CKD.



Bold lines indicate statistical significance compared to the reference (black diamond) at eGFR 80 ml/min/1.73 m^2. Stars along the x-axis represent significant pointwise interactions. HRs are adjusted for sex, race, body mass index, systolic blood pressure, total cholesterol, history of cardiovascular disease, diabetes, and smoking status.

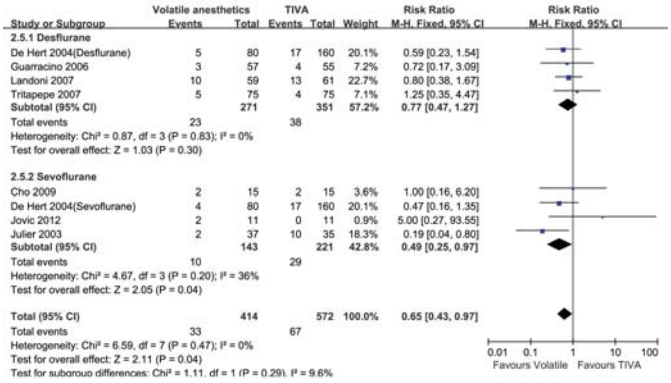
Volatile Anesthetics in Preventing Acute Kidney Injury following Cardiac Surgery

Jieru Cai,[1] Rende Xu,[2] Xiaofang Yu,[1] Yi Fang,[1] Xiaoqiang Ding.[1] *[1]Dept of Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China; [2]Dept of Cardiology, Renji Hospital, Shanghai Jiaotong Univ, Shanghai, China.*

Background: Acute kidney injury (AKI) is a common clinical complication of cardiac surgery. Volatile anesthetics have been shown to protect against AKI injury in animal experiments. However, in clinical setting, the effect of volatile anesthetics was unclear. We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) to explore whether volatile anesthetics could provide renal protection to patients undergoing cardiac surgery.

Methods: RCTs were identified in the PubMed, OVID, EMBASE, the Cochrane Library, the Current Controlled Trials Register, reviews, and reference lists of relevant articles. 10 trials with a total of 1600 participants were eligible. Data were analyzed using both fixed and random effects model.

Results: Compared with controls, volatile anesthetics significantly reduced AKI incidence [relative risk (RR): 0.65, 95% CI: 0.43 to 0.97; p=0.04)].



Although there was no significant difference between the two groups in absolute postoperative serum creatinine level and mortality, patients receiving volatile anesthetics had significantly (or borderline) lower increase in serum creatinine level from baseline on the first [weighted mean difference (WMD): -0.04 mg/dl, 95% CI: -0.07 to -0.01 mg/dl; p=0.002] and second day postoperatively (WMD: -0.07 mg/dl, 95% CI: -0.14 to -0.00 mg/dl; p=0.05), and reduced incidence of prolonged ICU stay (RR: 0.46, 95% CI: 0.34 to 0.64; p<0.001) and hospitalization (RR: 0.47, 95% CI: 0.27 to 0.83; p=0.009).

Conclusions: Current evidence showed that volatile anesthetics might provide renal protection in patients undergoing cardiac surgery, and supports further RCTs with larger sample size and high-methodological quality.

SA-OR009

Increased Risk of Elevated Blood Pressure (BP) after Acute Kidney Injury (AKI)

Chi-Yuan Hsu,[1] Raymond K. Hsu,[1] Jingrong Yang,[2] Juan Daniel Ordonez,[2] Sijie Zheng,[2] Alan S. Go.[2] *[1]Univ of California San Francisco; [2]Kaiser Permanente Northern California.*

Background: AKI leading to residual renal parenchymal injury may be a hitherto unrecognized cause of elevated BP, a major cardiovascular risk factor.

Methods: We studied adult members of Kaiser Permanente Northern California, a large integrated health care delivery system, who were hospitalized in 2008-2011. All participants had serum creatinine (Cr) and BP documented before admission and were not known to have hypertension or BP >140/90mmHg. AKI was defined using changes in inpatient serum Cr. Study outcome was BP >140/90mmHg measured during an ambulatory, non-emergency department visit within 2 years after discharge.

Results: Among 43,611 eligible patients, mean age was 56 yrs, 60% were women, and median eGFR=137 ml/min/1.73m^2. Overall, 2451 experienced AKI (71.0% AKIN stage 1, 15.3% stage 2 and 13.7% stage 3). AKI survivors were more likely to have BP >140/90mmHg during follow-up (46.1% at 730 days versus 41.2%; p<0.001). This was evident within the first 180 days (30.6% versus 23.1%, p<0.001). After adjustment for potential confounders, AKI was independently associated with a 22% (95% CI 12% to 33%) increased odds of developing elevated BP during follow-up. More severe AKI was associated with higher odds of elevated BP (Table).

Adjusted OR of BP >140/90 mmHg post discharge	**180 days (N=40,861)**	**365 days (N=42,845)**	**540 days (N=43,407)**	**730 days (N=43,611)**
Stage 1 vs no AKI	1.23 (1.10-1.37)	1.21 (1.09-1.34)	1.13 (1.02-1.26)	1.09 (0.98-1.21)
Stage 2 vs no AKI	1.66 (1.33-2.08)	1.53 (1.23-1.90)	1.51 (1.22-1.87)	1.45 (1.17-1.79)
Stage 3 vs no AKI	2.18 (1.74-2.74)	2.17 (1.73-2.71)	1.89 (1.51-2.37)	1.82 (1.45-2.29)

Results are similar in sensitivity analyses after excluding those with pre-admission chronic kidney disease or when the outcome was defined as having at least 2 BP readings >140/90mmHg.

Conclusions: AKI during hospitalization is an independent risk factor for subsequent development of elevated BP, which may be a more subtle sign of residual kidney damage than clinically evident elevations in serum Cr. Preventing the development of AKI may have clinical and public health benefits beyond the immediate hospitalization.

SA-OR010

Impact of Acute Kidney Injury on Mortality Diminishes with Greater Severity of Illness Andrew Moore,[2] Jean-Sebastien Rachoin,[1] Lawrence S. Weisberg.[1] *[1]Medicine, Cooper Univ Hospital-Rowan Medical School of Rowan Univ, Camden, NJ; [2]Medicine, Cambridge Health Alliance-Harvard Univ, Cambridge, MA.*

Background: Acute kidney injury (AKI) is independently associated with mortality. It is unclear, however, whether the impact of AKI on mortality is uniform across the range of severity of illness. We hypothesized that the odds ratio (OR) of death with AKI would be consistent across severity of illness.

Methods: We performed a retrospective observational study of all patients admitted to an ICU in the U.S. and Canada with sepsis or septic shock, from 2003 through 2009, and entered in the Project Impact® database. Patients were categorized by severity of illness using the admission APACHE II score. We defined AKI as that requiring renal replacement therapy (RRT). We analyzed mortality by APACHE II strata.

Results: 68,471 patients were initially considered for inclusion, of whom 40,332 had sepsis or septic shock. 6,773 were excluded because of a diagnosis of chronic kidney disease. 6,039 were excluded because of insufficient information leaving 27,510 records for analysis. The median [IQR] APACHE II score was 20 [10]. 2,625 (9.5%) of these septic patients developed AKI /RRT. 8,795 of the 27,510 patients died in hospital. Using logistic regression models, AKI / RRT was associated with increased mortality, with an adjusted OR 2.7. We divided the sample by APACHE II into the following strata: < 15, 15-20, 21-25, >25. As the APACHE II score increased, so did mortality (Z=-50, p<.01). In the APACHE II <15 group the mortality rate was 13.3% while in the APACHE II >25 group the mortality rate was 56.6%. After adjusting for confounding variables OR of mortality for patients with AKI / RRT declined in the higher APACHE II strata: For the APACHE II < 15 group OR 5.4 (95% CI, 4.1-7.1) and for the APACHE II > 25 OR was 1.8 (95% CI, 1.6-2.0).

Conclusions: Thus, AKI appears to be associated with a disproportionate increase in the risk of death for patients with lower severity of illness scores and its independent impact seems to diminish with higher APACHE II scores. Future studies of AKI in which mortality is an outcome of interest should take this finding into account.

SA-OR011

Association of Urine KIM-1 and NAG with CKD Progression: Results from the CRIC Study Chi-Yuan Hsu, Dawei Xie, Xiaoming Zhang, Sushrut S. Waikar, Venkata Sabbisetti, Joseph V. Bonventre, Josef Coresh, Robert G. Nelson, Clarissa Jonas Diamantidis, Claudia M. Lora, Francis Perry Wilson, Edgar R. Miller, Jiang He, Jeffrey R. Schelling, Mahboob Rahman, Akinlolu O. Ojo, Paul L. Kimmel, Harold I. Feldman, Vasan S. Ramachandran, Kathleen D. Liu. *For the NIDDK CRIC Study and CKD Biomarkers Consortium.*

Background: In chronic kidney disease (CKD), biomarkers of renal tubular injury may be elevated due to ongoing injury and therefore associated with CKD progression.

Methods: Baseline urine kidney injury molecule-1 (KIM-1) and N-acetylglucosaminidase (NAG) concentrations were determined among 2450 Chronic Renal Insufficiency Cohort (CRIC) participants. Cox models were used to examine the independent association between urine KIM-1 and NAG indexed to urinary creatinine concentration and CKD progression, defined as halving of estimated GFR or incident ESRD.

Results: Baseline mean eGFR was 43.6 ml/min/1.73m^2; median protein/Cr ratio 0.14 g/g. 581 events occurred during 5.5 median years of followup. After adjustment for baseline eGFR and proteinuria as well as age, gender, race, education, enrolling center, diabetes, cardiovascular disease, systolic BP, body mass index, and ACE inhibitor/ARB use, KIM-1/Cr was an independent risk factor for CKD progression by quintile analysis (table) or continuous analysis (Hazard Ratio [HR]1.16 per log SD increase, p=0.02). NAG/Cr was significantly associated with CKD progression in univariate analysis and in the continuous analysis (HR per log SD increase 1.13, p = 0.049).

Quintiles of KIM-1/Cr (pg/g)	Unadjusted HR (95%CI)	Adjusted HR	Quintiles of NAG/Cr (U/g)	Unadjusted HR	Adjusted HR
≤661.1	Ref	Ref	≤2.07	Ref	Ref
>661.1-1110.3	1.51 (1.04-2.19)	1.0 (0.66-1.5)	>2.07-3.03	2.2 (1.38-3.51)	1.31 (0.78-2.2)
>1110.3-1829.8	2.25 (1.59-3.19)	1.2 (0.81-1.79)	>3.03-4.97	4.5 (2.93-6.92)	1.3 (0.79-2.13)
>1829.8-2981.7	3.79 (2.73-5.26)	1.33 (0.9-1.95)	>4.97-8.37	8.19 (5.41-12.4)	1.34 (0.82-2.21)
>2981.7	7.9 (5.76-10.83)	1.55 (1.03-2.31)	>8.37	15.81 (10.54-23.72)	1.54 (0.92-2.57)

Conclusions: Higher levels of biomarkers of renal tubular injury are associated with CKD progression after adjustment for traditional risk factors, including eGFR and proteinuria.

Serum β-Trace Protein and β-2 Microglobulin as Predictors End-Stage Renal Disease in Adults with Chronic Kidney Disease Meredith C. Foster, Josef Coresh, Chi-Yuan Hsu, Andrew S. Levey, Robert G. Nelson, John H. Eckfeldt, Vasan S. Ramachandran, Paul L. Kimmel, Jeffrey R. Schelling, Michael S. Simonson, James H. Sondheimer, Amanda Hyre Anderson, Sanjeev Akkina, Harold I. Feldman, John W. Kusek, Akinlolu O. Ojo, Lesley Inker. *CKD Biomarkers Consortium and the CRIC Study.*

Background: Serum β-trace protein (BTP) and β-2 microglobulin (B2M) independently associate with ESRD and mortality in both general and high risk populations. Less is known about associations with renal outcomes in adults with moderate chronic kidney disease (CKD).

Methods: In the Chronic Renal Insufficiency Cohort (n=3479, mean age 58 yrs; 44% women), we used multivariable (MV) Cox proportional hazards models to estimate hazard ratios (HR) for ESRD by marker quintile for eGFRcr, BTP, and B2M (Referent: Q1, reflecting lowest marker level/highest filtration). We also estimated the HRs for a composite score representing a weighted linear combination of continuous1/BTP, 1/B2M, eGFRcr, and eGFRcys. BTP, B2M, and composite MV models were subsequently adjusted for eGFR creatinine-cystatin C (eGFRcr-cys).

Results: Over 6.1 years median follow-up, 725 (21%) individuals developed ESRD. Higher BTP and B2M and a composite score were associated with increased ESRD risk (**Table**). After adjustment for eGFRcr-cys, associations in the highest quintiles persisted: BTP (HR 2.3, 95% CI 1.2-4.4), B2M (HR 3.1, 95% CI 1.5-6.6), and 4-marker composite score (HR 5.5, 95% CI 2.1-14.7). Overall the composite had stronger HRs but overlapping 95% CI with other markers.

Conclusions: BTP and B2M are associated with increased risk of ESRD in adults with CKD, even with adjustment for clinically available estimates of kidney function.

Table: Adjusted° associations with ESRD

	Q2	Q3	Q4	Q5

Novel and Traditional Factors Associated with Kidney Function Decline Over Time: Findings From the Chronic Renal Insufficiency Cohort (CRIC) Study Amanda Hyre Anderson,[1] Dawei Xie,[1] Jason Roy,[1] Lawrence J. Appel,[2] Laura M. Dember,[1] Jiang He,[2] John W. Kusek,[2] James P. Lash,[2] Sankar D. Navaneethan,[2] Akinlolu O. Ojo,[2] Mahboob Rahman,[2] Julia J. Scialla,[2] James H. Sondheimer,[2] Susan P. Steigerwalt,[2] Francis Perry Wilson,[1] Myles S. Wolf,[2] Harold I. Feldman.[1] *[1]Univ of Pennsylvania; [2]The CRIC Study.*

Background: Traditional risk factors only partially explain declines in glomerular filtration rate (GFR) among those with chronic kidney disease (CKD). We examined a set of novel risk factors potentially explaining declines in GFR.

Methods: Data from participants of the CRIC Study (N=3,517; median follow-up 6 yrs) with GFR estimated using a serum creatinine and cystatin C equation were analyzed

using mixed effects models to identify traditional (demographic, clinical, behavioral, and biochemical) and novel (mineral metabolism, inflammation, cardiac strain, anthropometric, and carbohydrate metabolism (CHO)) factors associated with declines in eGFR. Prespecified stratified models were fit within diabetic and nondiabetic groups.

Results: Mean (SD) annual change in eGFR was -1.9 (4.3) mL/min/1.73m²/year overall. In multivariable-adjusted models, race/ethnicity (p<0.001), baseline eGFR (p=0.008), systolic blood pressure (p<0.001), proteinuria (p<0.001), body mass index (p=0.04), parathyroid hormone (p=0.04), serum phosphate (p=0.02), and NTproBNP (p<0.001) were all associated with eGFR decline. FGF23, high-sensitivity CRP, high-sensitivity troponin T, fat-free mass from bioelectrical impedance analysis, HOMA-IR, and HbA1c were not significantly associated with eGFR decline over time. Stratified analyses by diabetes revealed similar associations except that higher levels of baseline eGFR were associated with faster declines in eGFR among diabetics and slower declines among nondiabetics.

Conclusions: Among a large set of potentially novel risk factors, selected measures of mineral metabolism and cardiac strain, but not markers of inflammation or CHO, helped to explain eGFR decline among a large cohort with CKD after accounting for traditional factors. The relationship between baseline eGFR and decline in eGFR differed across diabetes groups.

SA-OR014

Urine Collagen Fragments Predict CKD Progression: The Cardiovascular Health Study Joachim H. Ix,[1] Mary L. Biggs,[2] Kenneth J. Mukamal,[3] David Siscovick,[4] Ronit Katz,[2] Joseph Delaney,[2] Dena E. Rifkin,[1] Jan M. Hughes-Austin,[1] Pranav S. Garimella,[5] Mark J. Sarnak,[5] Michael Shlipak,[6] Jorge R. Kizer.[7] *[1]UCSD; [2]UW; [3]BI; [4]NYAM; [5]Tufts; [6]UCSF; [7]Einstein.*

Background: Renal fibrosis on biopsy predicts ESRD and is common with aging, but is poorly captured by eGFR and ACR. Pro-collagen III N-propetide (PIIINP) is cleaved from collagen during fibrosis and urine levels correlate with fibrosis severity on biopsy. Whether urine PIIINP is associated with CKD progression is unknown.

Methods: At the 1996-97 CHS examination, we designed a case-control study to evaluate associations with CKD progression over 9 years. We selected 192 CKD progression cases (30% eGFR decline) and 231 randomly selected non-CKD progressing controls. Separately, we designed a case-cohort study to evaluate incident ESRD (958 random sub-cohort participants and 54 incident ESRD cases). PIIINP was measured in spot urine specimens by radio-immuno assay.

Results: Mean age was 78 years, eGFR was 63 ± 18 ml/min/1.73m², and median ACR was 8 (IQR 5-20) mg/g. Higher urine PIIINP associated with older age, male sex, hypertension, diabetes, lower eGFR and higher ACR. In the case-control study, there was a graded increase in odds of CKD progression across PIIINP quartiles, and each doubling associated with 23% higher odds.

Association of Urine PIIINP with CKD Progression over 9 Years and ESRD*

	Urine PIIINP quartiles				Continuous
Quartile (range [ug/L])	1 (≤ 1.39)	2 (1.40-2.58)	3 (2.59-4.22)	4 (> 4.22)	Per Doubling
CKD Progression					
# cases/controls (%)	40/65 (38%)	56/66 (46%)	45/52 (46%)	51/48 (52%)	
Odds Ratio (95% CI)	1.00 (Ref.)	1.43 (0.81, 2.52)	1.52 (0.77, 3.00)	1.77 (0.82, 3.81)	1.23 (1.02, 1.50)
Incident ESRD					
# events/PY at risk	0 / 2228	4 / 2229	13 / 2174	37 / 1975	
Hazard Ratio (95% CI)	1.00 (Ref.)		2.65 (0.67, 10.54)	3.63 (0.90, 14.70)	1.26 (0.85, 1.88)

*Adjusted for age, sex, race, education, clinical site, urine creatinine, eGFR, and urine albumin.

In the case-cohort study, there was an increasing number of ESRD events across quartiles. The association per doubling of PIIINP were similar in strength to CKD progression, albeit not statistically significant.

Conclusions: Urine PIIINP is associated with CKD progression independent of baseline eGFR and ACR in the community-living elderly. A non-significant association was observed for incident ESRD. Urine PIIINP may mark renal fibrosis and identify those at higher risk of CKD progression beyond eGFR and urine ACR.

Association of Serum Erythropoietin with Cardiovascular Events, Kidney Function Decline, and Mortality: The Health ABC Pranav S. Garimella,[1] Ronit Katz,[2] Kushang V. Patel,[2] Stephen Kritchevsky,[3] Joachim H. Ix,[4] Chirag R. Parikh,[5] Linda F. Fried,[6] Michael Shlipak,[7] Mark J. Sarnak.[1] *[1]Tufts Medical Center; [2]Univ of Washington; [3]Wake Forest Univesrity; [4]UC San Diego; [5]Yale Univ; [6]Univ of Pittsburgh; [7]UC San Francisco.*

Background: Exogenous erythropoietin has been associated with adverse outcomes in CKD and heart failure. In contrast, low erythropoietin levels may reflect kidney tubule dysfunction, which in turn is associated with adverse outcomes. We evaluated the association of endogenous erythropoietin levels with outcomes in a population of older adults.

Methods: Erythropoietin levels were measured in 2,488 women and men 70-79 years of age in the Health, Aging and Body Composition (Health ABC) cohort. Cox proportional hazards were used to evaluate adjusted associations of erythropoietin with incident heart failure, coronary artery disease (CAD), stroke, and all-cause mortality, while Poisson regression was used to evaluate the association with kidney disease progression.

Results: Mean (SD) age was 74 (3) years, 51% were women and 39% were blacks. Median (IQR) erythropoietin was 12.3 (9.0-17.2) mIU/mL. Mean follow-up time was 10.7 (SD=2.9) years. Black participants, as well as those with diabetes, hypertension and CAD had higher levels of erythropoietin (p < 0.05). Higher erythropoietin was independently associated with increased risk of heart failure but not with CAD, mortality, stroke or progression of kidney disease after adjusting for confounding factors.

Table: Association of serum erythropoietin with clinical outcomes

Erythropoietin	Risk factor adjusted* HR (95% CI)	Adjusted for kidney function† HR (95% CI)	Adjusted for hemoglobin‡ HR (95% CI)
Incident heart Failure			
Continuous (per doubling)	1.35 (1.19-.53)	1.31 (1.15-1.48)	1.26 (1.10-1.43)
Quartiles			
< 9.04	1.00 (ref)	1.00 (ref)	1.00 (ref)
9.04 – 12.29	0.99 (0.75-.31)	0.98 (0.74-1.30)	0.97 (0.73-1.29)
12.30 – 17.17	1.18 (0.90-.55)	1.11 (0.85-1.46)	1.09 (0.83-1.44)
≥ 17.7	1.55 (1.19-.01)	1.45 (1.12-1.89)	1.36 (1.04-1.78)
Total Mortality			
Continuous (per doubling)	1.13 (1.04, 1.23)	1.09 (1.00, 1.19)	1.06 (0.97, 1.15)
Incident coronary artery disease			
Continuous (per doubling)	1.08 (0.93, 1.26)	1.06 (0.91, 1.24)	1.08 (0.92, 1.26)
Incident stroke			
Continuous (per doubling)	1.04 (0.84, 1.28)	1.04 (0.84, 1.28)	1.03 (0.83, 1.29)
Incident chronic kidney disease			
Continuous (per doubling)	1.15 (1.00, 1.32)	1.08 (0.94, 1.24)	1.01 (0.87, 1.16)

* Adjusted for age, gender, race, site further adjusted for diabetes, hypertension, systolic BP, prevalent CAD, smoking, albumin, C-reactive protein
†further adjusted eGFR-cysC and urine albumin-creatinine ratio
‡further adjusted for hemoglobin

Conclusions: Higher levels of endogenous erythropoietin are associated with increased risk of heart failure independent of CVD risk factors, kidney function and hemoglobin. It remains to be determined whether this is due a causal relationship, versus a reflection of severity of other heart failure related risk factors.

Funding: NIDDK Support

SA-OR016

Fractional Phosphate Excretion Predicts CKD Progression Independently of FGF23 Carmine Zoccali,[1,2] Patrizia Pizzini,[1] Anna Pisano,[1] Daniela Leonardis,[1] Vincenzo Panuccio,[1] Giovanni Tripepi,[1] Francesca Mallamaci.[1] *[1]CNR-IFC/IBIM & Nephrology and Transplantation Unit, Reggio Calabria, Italy; [2]On Behalf of the MAURO Working Group.*

Background: Hyperphosphatemia is a predictor of accelerated renal function loss in CKD patients. This phenomenon is considered as the trade-off of a counter-regulatory response, possibly mediated by FGF23, aimed at maintaining global phosphate balance by raising phosphate excretion per functioning renal unit (fractional phosphate excretion). However, this hypothesis has never been formally tested in appropriate cohort studies.

Methods: We studied 494 incident patients with stages 2-5 CKD and the study end point was a composite renal outcome (i.e. eGFR reduction > 30%, dialysis or transplantation).

Results: Fractional phosphate excretion (median: 41%, interquartile range 27-61%) was above the upper limit of the normal range (>20%) in the majority of CKD patients (83%). In unadjusted analyses, fractional phosphate excretion was related directly to urinary protein (r=0.24, P<0.001), FGF-23 (r=0.25, P<0.001), male gender (r=0.13, P=0.003), smoking (r=0.13, P=0.004) and diastolic blood pressure (r=0.09, P=0.04) and inversely to eGFR (r=-0.44, P<0.001) and diabetes (r= -0.11, P=0.02) but was independent of serum phosphate (r=-0.03, P=0.54). Over a 2.4 (average) follow-up 165 incident renal events were registered. A 5% increase in fractional phosphate excretion predicted a 6% increase (unadjusted) in the hazard ratio of renal events (HR: 1.06, 95%: 1.03-1.09, P<0.001). In analyses adjusted for age, gender, smoking, diabetes, cholesterol, diastolic pressure, urinary protein and serum phosphate, anti-hypertensive treatment the strength of this relationship remained unmodified (HR: 1.06, 95% CI: 1.03-1.08, P<0.001). Remarkably, further adjustment for FGF23 did not modify the risk for renal events by fractional phosphate excretion (HR: 1.05, 95% CI: 1.02-1.07, P<0.001).

Conclusions: Fractional phosphate excretion is a strong, independent predictor of incident renal events. The predictive power of this parameter is largely independent of other risk factors, including serum phosphate and FGF23. Biological pathways other than FGF-23 play a dominant role in phosphate-related renal damage.

SA-OR017

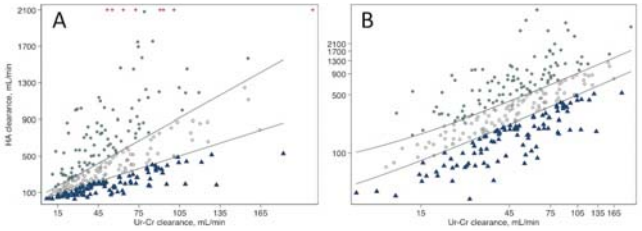
Renal Tubular Secretion in Chronic Kidney Disease Astrid Suchy-Dicey,[1] Thomas J. Laha,[1] Andrew N. Hoofnagle,[1] Cassianne Robinson-Cohen,[1] Ernest Ayers,[1] Tammy L. Sirich,[2] Timothy W. Meyer,[2] Jonathan Himmelfarb,[1] N. David Yanez,[1] Noel Weiss,[1] Bryan R. Kestenbaum.[1] *[1]Univ of Washington, Seattle, WA; [2]Stanford Univ, Stanford, CA.*

Background: The presence and severity of chronic kidney disease are currently assessed by abnormalities in glomerular filtration rate and urinary albumin excretion. Other kidney functions, such as proximal tubular secretion, are not typically quantified. Tubular secretion is capable of clearing metabolites from the blood more efficiently than filtration, suggesting important clinical consequences of secretory dysfunction. Measuring tubular secretion as an independent marker of kidney function may provide insight into kidney disease etiology and prediction of adverse outcomes.

Methods: We developed and validated mass spectrometry assays to measure hippurate and cinnamoylglycine, which are primarily cleared by tubular secretion. We estimated renal secretion function in a prospective cohort study of 299 CKD patients using timed urinary clearance of these molecules. We examined the association between renal secretion and estimated filtration (using average of creatinine and urea clearance), related clinical characteristics, and death.

Results: Tubular secretion correlated with glomerular filtration (R=0.421), but

considerable residual variability remained (Figure: Secretion over filtration, continuous (A) and log scale (B)). Tubular secretion function was significantly better among men, and tended to be lower among non-whites and smokers, although these associations were within the limits of chance. Lower secretion function was associated with increased hazard of death, independent of filtration, age, race, and sex (hazard ratio: 2.6 per halving hippurate clearance; 95% CI: 1.3-5.4).



Conclusions: Prediction of clinical outcomes of patients with CKD may be enhanced by the measurement of proximal tubular secretion.

WT1 Promotes Fgf Signaling in Nephron Progenitor Cells by Transcriptional Control of Gas1 Martin Kann, [1]Maximilian Otto Lenz,[1] Valerie A. Schumacher,[2] Bernhard Schermer,[1] Chen-Ming Fan,[3] Thomas Benzing,[1] Jordan A. Kreidberg.[2,4] *[1]Nephrolab Cologne & Center for Molecular Medicine, Univ of Cologne, Cologne, Germany; [2]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [3]Dept of Embyrology, Carnegie Inst of Washington, Baltimore, MD; [4]Harvard Stem Cell Inst, Cambridge, MA.*

Background: WT1 is a key transcription factor in nephron progenitor cells (NPC) that is required for maintenance of the NPC pool. We had previously identified Gas1 as a direct target gene of WT1, which is also required for NPC maintenance. Here we show that loss of Gas1 causes an intrinsic NPC defect in Fgf signaling and decreased NPC proliferation at an early stage in renal development at which a Gas1-related phenotype is not yet evident.

Methods: NPC proliferation was assayed by BrdU staining. An immortalized murine embryonic kidney cell line was used for assaying Fgf signaling.

Results: Proliferation of Six2 positive NPC at E15.5 was decreased by one third in Gas1 ko as compared to wildtype kidneys as by Six2 and BrdU staining in vivo. At this stage numbers of NPC per ureteric bud did not differ between Gas1 ko and control and nephrogenesis was proceeding normally as evidenced by staining and in situ hybridization for Six2, Wnt4, Jagged1 and WT1. At stage E17.5 a phenotype of a decreased NPC pool together with reduced nephrogenesis was evident in Gas1 ko kidneys. NPC proliferation at E17.5 continued to show the same defect as at E15.5. We hypothesized an intrinsic defect in Fgf signaling in NPC as this pathway is key to NPC proliferation and Gas1 is known to modulate receptor tyrosine kinase signaling. Indeed, comparing Gas1 knockdown to control conditions in a kidney cell line that expresses endogenous WT1 and Gas1, revealed decreased phosphorylation of AKT in Gas1 knockdown cells upon stimulation with Fgf9 and Fgf20. In turn, AKT has been suggested to be a key downstream mediator of Fgf signaling in NPC.

Conclusions: In summary, we describe a novel indirect effect of WT1 on Fgf signaling in NPC: WT1 directly activates transcription of Gas1, which in turn modulates the response to Fgfs in favor of AKT phosphorylation to promote NPC proliferation.

SA-OR019

Histone Deacetylases 1 and 2 Repress *Wnt4* During Kidney Development Shaowei Chen, Xiao Yao, Samir S. El-Dahr. *Pediatrics, Tulane Univ School of Medicine, New Orleans, LA.*

Background: *Wnt4*, a member of *Wnt* gene family, is a mesenchymal autocrine signal that is essential for epithelial transformation of metanephric mesenchyme. The expression of Wnt4 is tightly regulated in the cap mesenchyme (CM) cells and their derivatives during kidney development, though the underlying mechanisms remain largely unknown. Histone deacetylases (HDACs) are a superfamily of enzymes, which primarily modulate chromatin structure and thus gene transcription via removal of acetyl moieties from lysine residues of histones. We previously reported that deletion of Hdac1 and Hdac2 from the CM severely impairs nephrogenesis. Here, we examined the role of Hdac1 and Hdac2 in regulation of Wnt4 expression.

Methods: 1. To delete *Hdac1* and *Hdac2* in the CM cells, mice bearing conditional null alleles for *Hdac1* and *Hdac2* were crossed with *Six2-creEGFP* mice. 2. Quantitative real-time RT-PCR (QRT-PCR) and in situ hybridization (ISH) were performed to analyze the mRNA level of *Wnt4*. 3. Chromatin immunoprecipitation (ChIP) was performed to examine the occupancy of Hdac1, Hdac2, and acetylated histones H3 and H4 of *Wnt4* promoter in mK4 cells (immortalized mouse metanephric mesenchyme cells).

Results: 1. QRT-PCR and ISH results revealed that the mRNA level of Wnt4 is elevated in the pretubular aggregates and renal vesicles in $CM^{Hdac1, 2-/-}$ kidneys at E16.5, though no ectopic expression of Wnt4 is observed in the CM. 2. Pharmacological inhibition of HDAC activity (HDACi) or knockdown of Hdac1 and Hdac2 by morpholino oligonucleotides significantly increases the mRNA level of Wnt4 in mK4 cells, indicating a cell-autonomous role for Hdac1 and Hdac2 in regulation of Wnt4 expression. 3. ChIP assays further demonstrated that Hdac1 and Hdac2 occupy the promoter region of Wnt4 in mK4 cells, and HDACi enhances acetylation of H3 and H4 histones associated with Wnt4 promoter.

Conclusions: The *Wnt4* gene is a direct negatively regulated target of Hdac1 and Hdac2. As Hdac1 and Hdac2 themselves lack intrinsic DNA binding activity, these findings suggest that a repressive complex containing Hdac1 and Hdac2 normally represses Wnt4 expression in the pretubular aggregates and renal vesicles during kidney development.

Nephron Lumen Formation During Kidney Development Denise K. Marciano,[1] Zhufeng Yang,[1] Lei Gao,[1] Paul R. Brakeman,[4] Keith Mostov,[3] Xinchao Pan,[1] Ulrike Schnell,[1] Thomas J. Carroll,[1] Susan E. Zimmerman.[1] *[1]Dept of Medicine, Div of Nephrology, Univ of Texas Southwestern Medical Center, Dallas, TX; [2]Dept of Pediatrics, Univ of California San Francisco, San Francisco, CA; [3]Dept of Anatomy, Univ of California San Francisco, San Francisco, CA.*

Background: A fundamental question in biology is how cells polarize and undergo de novo lumen formation and elongation during tubulogenesis. To date, little is known about lumen formation and elongation in tubules of the kidney nephron. We have previously characterized several steps in nephron tubulogenesis using the mouse kidney as a model system.

Methods: Here we present preliminary studies in which we used time-lapse microscopy with genetic labeling of the nephron lumen to visualize live lumen formation in mouse kidneys. We also use a 3D cell culture model to elucidate the molecular process.

Results: Our live imaging studies revealed dynamic epithelial movements and rearrangements that occur to promote luminal extension of the nephron tubule. In addition, there were small, discrete lumens that formed at the leading edge of the extending lumen, which ultimately fused at the s-shaped body stage. Furthermore, using a 3D cell culture model, we found that multiple, small lumens often coalesced to form a larger lumen in control cells, and that this coalescence was dependent on Afadin, a Nectin adaptor and Rap1 binding protein. Afadin depletion led to a multi-lumen phenotype and loss of Nectin-3 localization at the plasma membrane. Nectin-3 depletion phenocopied the Afadin-depleted cells, giving rise to multiple lumens.

Conclusions: Together these results provide a novel model of nephron lumen extension and suggest that Afadin mediates lumen coalescence in a Nectin-3 dependent manner.

A Novel Mechanism of Glomerular Cyst Formation in Hepatocyte Nuclear Factor 1 Beta (Hnf1b)-Deficiency Armelle Jm Christophorou, Filippo Massa, Arianna Fiorentino, Serge Garbay, Evelyne Fischer, Marco Pontoglio. *Development, Reproduction and Cancer, Institut Cochin, Inserm U1016, CNRS 8104, UP5, Paris, France.*

Background: Glomerular cysts are one of the most characteristic finding in patients carrying MODY5/*HNF1B* mutations. We have previously shown that HNF1beta plays an essential role in the specification and expansion of tubules. In addition, we have shown that the lack of HNF1beta leads to cystic glomeruli connected to collecting ducts with a short and primitive tubule. The mechanisms linked to the formation of glomerular cysts is still unknown.

Methods: With a tissue specific inactivation of Hnf1b in the metanephric mesenchyme (Six2CRE) we studied the mechanism of the formation of glomerular cysts in HNF1beta-deficiency in mouse embryos.

Results: During glomerulogenesis, in S-shaped bodies, the urinary pole (UP) is initially in direct contact with podocyte precursors. Then, UP separates from the podocytes via the intercalation of Bowman's capsule cells. This process leads to the exclusion of the UP from the inner part of the glomerulus. Later on, the UP further slides along the Bowman's capsule to reach the opposite side in respect of the vascular pole (VP). When we inspected the three-dimensional configuration of glomeruli formed in the absence of HNF1beta, we discovered that the UP and VP were structured in an aberrant way. In early mutant glomeruli, the UP is inserted in the glomerular tuft leading to a situation where the tubular urinary outflow of the glomerulus is trapped inside the VP. This configuration implies the possible block of the glomerular outflow, providing the basis for glomerular cyst expansion upon the onset of glomerular filtration. During glomerulogenesis, specific cells in the lower limb of the S-shaped body are destined to remain inside and form the inner glomerular cup (podocyte precursors) whereas others (parietal cells) form the Bowman capsule. Interestingly, HNF1beta is specifically expressed in cells that are destined to be outside of the glomerulus.

Conclusions: Our results indicate that HNF1beta controls the structural architecture of glomeruli and provide the basis for a novel mechanism of glomerular cyst formation.

The Hippo Pathway Functions in Kidney Branching Morphogenesis Antoine Reginensi,[1] Masato Hoshi,[2] Marco Giovannini,[3] Sanjay Jain,[2] Helen McNeill.[1] *[1]Lunenfeld Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, ON, Canada; [2]Dept of Internal Medicine (Renal Div), Washington Univ School of Medicine, St. Louis, MO; [3]Dept of Head and Neck Surgery, House Research Inst, Los Angeles, CA.*

Background: The Hippo kinase cascade is a highly conserved signaling pathway critical for normal growth and development. Activation of Mst/Lats kinases culminates in the phosphorylation and inactivation of the Hippo targets Yap and Taz. It is still unclear if the Hippo pathway has a critical role in ureteric bud (UB) branching.

Methods: We investigated the role of *Yap, Taz* and *Nf2* in branching morphogenesis using the *Hoxb7Cre* (excision in UB lineage).

Results: We found that *Hoxb7Cre Yap$^{fl/fl}$* embryos harbored striking abnormalities of the urinary tract (92% hydroureters/hydronephrosis, 37% duplicated systems, 8% hypoplastic kidneys). Intrapelvic dye injection revealed that *Yap* deletion results in ureters ending blindly before reaching the bladder. In *Yap* mutants, apoptosis in the cloaca epithelium (E10) is dramatically reduced, preventing fusion of the nephric duct to the cloaca. Importantly, this phenotype is partially rescue by *Ret* haploinsufficency. UB tips are highly dilated in *Yap* and/or *Taz* knock-outs, indicating *Yap* may be involved in Ret signaling. We are currently investigating Yap's role in Ret signaling via regulation of downstream signaling (pERK, MAPK, p38) and target gene activation. We then investigated the function of *Nf2*/Merlin. Merlin has been shown to function as an upstream Hippo pathway regulator in *Drosophila*. *Nf2* knock-outs display severe kidney hypoplasia, due to limited UB branching. Strikingly, the *Nf2* cKO phenotype was rescued by heterozygous deletion of *Yap/Taz*, and phenocopied by Yap overexpression, suggesting that Yap and/or Taz are the major effectors of Nf2 in branching morphogenesis. No changes in *Ret, Etv5* and *Wnt11* were observed in *Nf2* cKO kidneys.

Conclusions: This work demonstrates a novel role for *Yap, Taz* and *Nf2* during branching morphogenesis. Understanding their functions might lead to identification of new players involved in kidney morphogenesis and aid in the development of new therapeutics for patients suffering from kidney diseases.

Patterning of the Renal Stroma Does Not Require Input from the Nephron Progenitors, the Ureteric Bud, or Their Derivatives Amrita Das, Thomas J. Carroll. *Internal Medicine (Nephrology) and Molecular Biology, UT Southwestern Medical Center, Dallas, TX.*

Background: Stromal/epithelial cross-talk is a fundamental event in organ development and maintenance. We have recently shown that in the developing kidney, signals emanating from the stroma play a key role in cell fate specification of the nephron progenitors. However, the regulation of the stromal cells themselves remains unclear.

Methods: All experiments are performed in genetic mouse models. RNA and protein localization using insitu hybridization and immuno histochemistry respectively are used to analyze wildtype and mutant kidneys.

Results: Stromal progenitor cells are a small population of cells within the metanephric mesenchyme, distinguished by their expression of the transcription factor Foxd1 as early as E10.5. Lineage tracing studies have shown that the derivatives of Foxd1-expressing cells populate most of the renal interstitium. These include fibroblasts, glomerular mesangial cells, pericytes and vascular smooth muscle cells. During kidney development, the Foxd1 derived stromal cells acquire a positional identity corresponding to the different nephron segments thereby forming a patterned architecture. Using marker analysis, we are able to segregate the renal interstitium into 6 domains across the cortico-medullary axis. We performed a number of embryological studies to determine if the patterning of the stroma requires signaling from other cell types within the developing kidney, such as the nephron precursor cells, the nephron, the collecting duct epithelia or the vasculature. Surprisingly, although terminal differentiation of the stroma appears to require signals from the medullary collecting ducts, the initial pattering appears to be independent of signals from any of these cell types suggesting that the stroma self-patterns.

Conclusions: Based on these findings and the close association of the distinct stromal domains with different stages of nephron formation, it is tantalizing to speculate that the stroma may affect multiple steps in the differentiation and/or patterning of the nephron.

Role of Transcription Factor Cp2l1 in Differentiation and Patterning of the Collecting Duct Max Werth,[1] Kai M. Schmidt-Ott,[2] Christian Hinze,[2] Andong Qiu,[1] Jonathan M. Barasch.[1] *[1]Columbia Univ, New York; [2]Max Delbrueck Center for Molecular Medicine, Berlin.*

Background: The collecting duct contains at least three cell types (principal, alpha- and beta-intercalated cells) that are organized in a regular pattern. Little is known about differentiation and patterning of these cells. We have identified a transcription factor, Cp2l1 that regulates both of these processes.

Methods: In vitro: Overexpression of transcription factors in rat metanephric mesenchyme. In vivo: Segment specific (Collecting Duct, Ksp-cre) and cell type specific (Intercalated Cell, V-ATPaseB1-Cre) inactivation of Cp2l1 as well as components of Notch signaling. Genome-wide DNA-binding Assay (ChiP-seq). Gene-Expression Analysis using Affymetrix Gene-Arrays and RNA-seq.

Results: Conditional deletion of Cp2l1 demonstrated the absence of alpha- and beta-intercalated Cells (IC) and their characteristic markers (Foxi1, CA2, H+ATPase, AE1 and Pendrin), leaving a homogenous, single cell type characterized by Aqp2, Krt8, Cdh1 typical of principal cells. Conversely, when Cp2l1 was overexpressed in metanephric mesenchyme, we observed upregulation of IC specific genes like CA2, H+ATPase, BSND. To determine whether Cp2l1 directly regulated IC genes, we used Cp2l1 ChiPseq. A three way comparison of ChIPseq, Cp2l1 overexpression and Cp2l1 knockout revealed that Cp2L1 directly regulated genes most typical of IC. In addition, the three way comparison demonstrated that Notch ligands were also positively regulated by Cp2l1. Notch knockouts did not completely abolish the development of cells expressing IC markers, but rather generated a large number of cells expressing both IC and PC markers. These cells were clustered in patches rather than scattered between principal cells.

Conclusions: Cp2l1 is critical for the initial differentiation of distinct cell types in the collecting duct. It does this by directly activating cell defining proteins such as the H+ ATPase and by regulating components of Notch signaling which in turn determine collecting duct patterning. In contrast, Cp2l1 had only more subtle effects on the IC cell phenotype once the H+ ATPase was expressed and the patterning of the collecting duct was established.

SA-OR025

Cell Fate Patterning along the Kidney Collecting Ducts Is Dependent on Notch/Rbpj Signaling, with Ectopic Activation of Notch1 Capable of Turning on Elf5 and the Principal Cell Program Kameswaran Surendran,[1,2] Justin J. Grassmeyer,[1] Casey Hettinger,[1] Malini Mukherjee,[1] Monica R. Bailey,[3] Satrajit Sinha.[4] *[1]Sanford Children's Health Research Center, Sanford Research, Sioux Falls, SD; [2]Dept of Pediatrics, Sanford School of Medicine, Sioux Falls, SD; [3]Augustana College, Sioux Falls, SD; [4]Dept of Biochemistry, State Univ of New York at Buffalo, Buffalo, NY.*

Background: The mechanisms by which the mammalian kidney collecting ducts are patterned along the cortico-medullary axis with a decreasing ratio of intercalated to principal cells remains unknown. Notch signaling ensures that sufficient number of renal collecting duct progenitors adopt the principal cell fate, without which mice have a reduced number of principal cells, a concomitant increase in intercalated cells and a urine concentrating defect. This study focuses on how Notch signaling regulates the progenitors of collecting ducts to select between principal versus intercalated cell fates.

Methods: We compared gene and protein expression patterns of principal and intercalated markers among others in wild type versus transgenic mice with Notch signaling deficient collecting ducts, or with ectopic Notch1 activation in developing collecting ducts. We also performed transcriptional reporter assays in newly established immature collecting duct cell lines to identify regulators of Elf5 and Avpr2.

Results: Mice with Notch signaling deficient collecting ducts have reduced renal expression of Elf5, which at embryonic day 16.5 is expressed in Foxi1$^-$, Aquaporin2$^-$ cells that surround Foxi1$^+$cells in developing collecting ducts. Consistent with Elf5 being a principal cell specific transcription factor, it is capable of activating an *Avpr2* proximal promoter. Interestingly, ectopic activation of Notch signaling in the developing collecting ducts up regulates Hes1 and Elf5 prior to down regulation of Foxi1. The Notch signaling target Hes1 can transactivate Elf5 proximal promoters.

Conclusions: In summary, Notch signaling regulates the patterning of collecting ducts with intercalated and principal cell types in part by turning on Elf5 to promote and/or to maintain the principal cell identity.

The Transcription Factor *etv5a* Is Essential for Multiciliated Cell Development During Zebrafish Nephrogenesis Amanda N. Marra, Rebecca A. Wingert. *Dept of Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: The zebrafish pronephros, or embryonic kidney, is comprised of two main types of epithelial cells: transportive and multi-ciliated cells (MCCs). Transportive cells occupy discrete tubule segments and are characterized by expression of solute transporters, while MCCs are dispersed in a "salt-and-pepper" fashion throughout the tubule and are characterized by the presence of motile cilia. The fate choice between epithelial identities is regulated by Notch signaling, in which Notch activity promotes transportive cell formation by restricting MCC fate. Recently, our lab demonstrated that the transcription factor *mecom* restricts MCC identity by promoting Notch, and that retinoic acid (RA) signaling acts upstream to regulate *mecom*. Despite this knowledge, much remains to be learned about MCC formation.

Methods: Previous research has shown that *etv5a* and its ETS family members *etv5b* and *etv4* are required for ciliogenesis in other zebrafish tissues. Here, we mapped *etv5a* expression to renal progenitors that occupy domains where MCCs later emerge. Thus, we hypothesized that *etv5a* is required for ciliogenesis of MCCs in the nephron.

Results: *etv5a* knockdown caused decreased expression of the MCC markers *odf3b, jag2a*, and *centrin*. In addition, *etv5a* knockdown led to alterations in solute transporter domains suggesting that tubule segments expanded and had more transporter cells. In epistasis studies, exogenous RA treatment expanded the *etv5a* domain, indicating that *etv5a* acts downstream of RA. Further, abrogation of Notch with DAPT treatment did not alter *etv5a* expression, suggesting Notch acts downstream of *etv5a*.

Conclusions: Ongoing studies will explore the possible redundancy between ETS factors and continue to examine the epistatic relationships between *etv5a*, RA, Notch and *mecom* to elucidate the mechanism of how these factors interact to direct MCC development during nephrogenesis.

Injury to the Developing Kidney Leads to Impaired Maturation but Not Inflammation or Fibrosis Scott R. Manson, Julio J. Geminiani, Gino J. Vricella, Qiusha Guo, Paul F. Austin. *Urology, Washington Univ, St. Louis, MO.*

Background: Inflammation and fibrosis are widely accepted as the key processes driving the progression of renal injuries to kidney disease in the mature kidney. However, congenital defects are the leading cause of pediatric kidney disease and the pathogenesis of renal injury in the developing kidney remains poorly understood. In this study, we provide the first direct comparison of injury responses during each of the critical stages of kidney development.

Methods: Disease progression was examined in chronic and reversible murine models of unilateral ureteral obstruction (UUO) at several developmental time points: (1) P1, during nephrogenesis/nephron maturation, (2) P14, during proliferative growth, and (3) P60, in the mature kidney. Renal pathology was assessed by immunostaining for molecular markers of key processes in kidney development and the pathogenesis of renal injury.

Results: UUO at either P1 or P14 in the developing kidney leads to decreased kidney growth, reduced proliferative expansion of nephrons, increased apoptosis in progenitor cells, and impaired nephron differentiation. There is also a notable absence of fibroblast and macrophage recruitment, inflammation, and fibrosis in the developing kidney. This contrasts the mature kidney where there is a marked increase in reparative proliferation, inflammation, and fibrosis. [All results are n=10, p<0.05].

	P1 (Nephrogenesis Phase)	P14 (Growth Phase)	P60 (Mature Phase)
Kidney Weight	- 35.2 %	- 26.3 %	- 11.9 %
Epithelial Proliferation	- 56.2 %	- 61.6 %	+ 538.3 %
Apoptosis	+ 9.5-fold	+ 9.3-fold	+ 6.4-fold
Inflammation	no change	no change	+ 4.3-fold
Renal Fibrosis	no change	no change	+ 6.4-fold

Conclusions: This study reveals that developmental context has a significant impact on the pathogenesis of renal injuries. In contrast to the mature kidney, injury in the developing kidney is characterized by profound developmental deficits and a distinct absence of inflammation and fibrosis. This suggests that treatment strategies for pediatric kidney disease can be optimized by stimulating proliferation and minimizing apoptosis at early stages of development while inhibiting inflammation and fibrosis at later stages.

Restoring Mitochondrial Superoxide Levels with Bendavia™ Protects against Progression of Diabetic Kidney Disease in db/db Mice Satoshi Miyamoto,[1,2] Manjula Darshi,[1,2] Larkin B. Slater,[1,2] Tai Nguyen,[1] Peter J. Oates,[3] Kumar Sharma.[1,2] *[1]Center for Renal Translational Medicine, Univ of California, San Diego, La Jolla, CA; [2]Veterans Administration San Diego HealthCare System, La Jolla, CA; [3]Stealth Peptides, Inc., Newton, MA.*

Background: We have recently demonstrated that superoxide production and mitochondria biogenesis are reduced in the kidneys of a mouse model of type 1 diabetes (DM), and that mitochondria-related urine metabolites are significantly reduced in human subjects with diabetic kidney disease (DKD) suggesting that reduced mitochondrial function plays a critical role in the progression of DKD. The aim of this study was to determine if type 2 DM is associated with reduced renal superoxide and whether Bendavia™ (B), a mitochondria-targeting peptide, protects against DKD in db/db mice.

Methods: Six weeks-aged male nondiabetic db/m mice and diabetic db/db mice (BKS. Cg-Dock7^{m} +/+ Lepr^{db}/J strain) were randomly assigned to four groups: db/m+vehicle (Control), db/m+B, db/db+vehicle (db/db) and db/db+B, n=15/group. Vehicle or B (3 mg/kg BW) were injected daily s.c. for 4 weeks and then infused subcutaneously via osmotic pumps (3mg/kg per day) over an 8 week period. Glomerular size and mesangial matrix area were assessed by morphometric analysis. Superoxide levels in kidney were measured using i.p. administration of dihydroethidium (DHE), and mounted kidney slices were imaged by confocal microscope.

Results: Urinary albumin/creat ratio, elevated in db/db (738 ± 72, P<0.001) versus Control (74 ± 6) mice, was significantly reduced with B (463 ± 75, p<0.01), whereas there were no significant differences in body weight or HbA1c between both diabetic groups. The increase in glomerular mesangial matrix area in db/db group, was significantly reduced with B (p<0.001). Superoxide levels in glomeruli were significantly reduced by 23.5% in db/db compared with Control (p<0.05) and restored to control levels in db/db+B group.

Conclusions: Our results demonstrate that DKD with type 2 DM is associated with reduced renal superoxide levels and the novel mitochondrial peptide Bendavia™ protected against DKD and restored physiologic levels of superoxide in the db/db model of DKD.

Minichromosome Maintenance Protein 3 Associates with and Regulates Nrf2 in Proximal Tubules Michelle T. Barati, Eric Poulos, Whitney L. Ward, Susan M. Isaacs, Madhavi J. Rane, Jon B. Klein, Michael Merchant. *Univ of Louisville.*

Background: Oxidative stress is a mediator of diabetic nephropathy (DN). Regulation of Nrf2, a primary oxidant-responsive transcription factor, is altered in DN. Our lab identified association of Serine-40 phosphorylated Nrf2 (pS40Nrf2), which occurs upon Nrf2 activation, with minichromosome maintenance proteins (MCM) 2-7 in renal tubule cells, by mass spectrometry (MS). MCM 2-7 proteins form a DNA helicase required for replication and not known to regulate Nrf2 or be regulated in DN. Since MCM3 was highly enriched in pS40-Nrf2 complex in MS findings, this study determined if MCM3 regulates Nrf2 activity or is regulated during DN.

Methods: MCM3/Nrf2 association determined by immunoprecipitation (IP) of pS40Nrf2 and immunobloting (IB) of precipitated proteins for MCM3. MCM3 overexpressed by transfection of a DNA plasmid or knocked down by transfection of siRNA in cultured proximal tubule cells (PTC). Cells were also cultured in media with High glucose (25mM; HG) or normal (5mM) glucose concentration for 24h, alone or after transfections. Kidney sections from 2,4,and 7 month old OVE26 diabetic and FVB control mice were immunostained for MCM3 and PCNA.

Results: IP of pS40Nrf2 from tubule extract and IB for MCM3 confirmed association in the cytosol and nuclei. Overexpression of MCM3 increased pS40Nrf2, Nrf2, and induced a Nrf2 target, NQO1. Knockdown of MCM3 reduced total Nrf2, pS40Nrf2, and NQO1. MCM3 expression increased in tubule nuclei of 4 and 7 month old diabetic mice, while PCNA was unchanged, indicating no proliferation. Culture of PTC with HG concentration increased caspase 3 cleavage, and this was augmented with MCM3 Knockdown. pS40Nrf2/MCM3 association decreased in PTC cultured in HG.

Conclusions: The results identify MCM3 as a novel positive regulator of Nrf2. Induction of MCM3 in tubules during diabetes is not associated with proliferation and a role remains to be defined. Initially, MCM3 may confer protection to tubules by preventing HG-induced apoptotic signaling through activation of Nrf2 and its anti-oxidant targets. Decreased pS40Nrf2/MCM3 association with HG may disrupt this mechanism of Nrf2 activation and increase oxidant injury in diabetes.

Funding: NIDDK Support

SA-OR030

Progression of Tubular Damage in Diabetic Nephropathy (DN) Is Linked to an Altered Ubiquitination of the Cytoskeleton Paola Pontrelli,[1] Francesca Conserva,[1] Massimo Papale,[2] Matteo Accetturo,[1] Margherita Gigante,[1] Grazia Vocino,[2] Anna Maria Di Palma,[1] G. Grandaliano,[1] Salvatore Di Paolo,[3] Loreto Gesualdo.[1] *[1]DETO, Univ of Bari, Italy; [2]Dept of Medical and Surgical Sciences, Univ of Foggia, Italy; [3]Barletta Dimiccoli Hospital, Italy.*

Background: The ubiquitin pathway is a possible key-player in the onset of DN. UBE2V1, an ubiquitin-conjugating E2 enzyme variant, mediates the formation of lysine 63 (lys63)-linked ubiquitin chains, affecting protein localization and cell signaling. Aim of our study was to evaluate the role of ubiquitination in response to hyperglycemia and its possible involvement in the progression of tubular damage in DN.

Methods: Human tubular cells (HK2) were grown in hyperglycemia(HG: 30mM). UBE2V1 expression was evaluated by qPCR and lys-63 ubiquitination by immunoblotting on cells, and immunohistochemistry on kidney biopsies of 6 DN patients and 6 controls. Lys63-ubiquitinated proteins were identified by MALDI-TOF/MS-MS. Lys63-Ubiquitination was confirmed by immunoblotting and confocal microscopy.

Results: UBE2V1 gene expression was increased in HK2 cells in HG (1.51 fold). Also UBE2V1 and Lys63-ubiquitinated proteins were increased under HG *in vitro*, and *in vivo* on DN biopsies (UBE2V1, p=0.004; Lys63: p= 0.008 DN versus control) at tubular level. To identify which proteins underwent Lysin63-ubiquitination under HG, HK2 proteins were immunoprecipitated with an anti-ubiquitin antibody and blotted with an anti-lys63-linked ubiquitin chains antibody. By MALDI-TOF/MS-MS we identified 28 lys63-linked ubiquitinated proteins under HG, involved in cellular assembly and organization (IPA score=50). Beta actin lys63 ubiquitination in HG was confirmed by immunoblotting (p=0.05), and was associated to the depolymerization of actin cytoskeleton (confocal microscopy), and the loss of vimentin (flow cytometry). UBE2V1 silencing in HK2 under HG reported actin ubiquitination in Lys63 to basal condition (immunoblotting).

Conclusions: In conclusion UBE2V1 and Lys63-ubiquitinated proteins increase under HG and persist in DN patients, mainly affecting cytoskeleton organization. Cytoskeletal ubiquitination could represent a potential therapeutic target to reduce tubular damage in the progression of DN.

SA-OR031

Proximal Tubular Activated Sirt3 and Proliferated Mitochondrial Ribosomes Compensated for Decreased Sirt1 and Mitochondrial Dysfunction at Very Early stage of Diabetic Nephropathy Kazuhiro Hasegawa, Shu Wakino, Koichi Hayashi, Hiroshi Itoh. *Keio Univ.*

Background: We demonstrated that in diabetic nephropathy (DN), the expression of NAD^{+}-dependent deacetylase, Sirt1 in proximal tubules (PT) decreased before its decrease in podocytes (Pods), which triggered DN-induced albuminuria (Hasegawa K, Nature Medicine 2013). Although previous papers have suggested that PTs are a primary site of changes in DN, it is unknown whether **morphological changes** in PT is present prior to those in Pod.

Methods: We analyzed electron microscopic findings in detail and compared the morphological changes between those in PT and those in Pods in the **early stage of DN,** i.e., in mice 8 weeks after strestozotocin (STZ) treatment or in db/db mice at 8 weeks of age when the glucose levels had already been high.

Results: Among various cellular organelle, we found that **mitochondrial ribosome (Mit-rib) number** was significantly increased in PT according to the decreased Sirt1 expression, although this increase was not observed in Pods. The number of other organelle including mitochondria or peroxisome, did not change. We next explored the relationship between Sirt1 expression and Mit-rib number by using *PT-specific Sirt1 conditional knockout (PT-CKO)* mice and *Pod-Specific Sirt1 CKO (Pod-CKO)*. Of note, the number of Mit-rib increased in PT in *PT-CKO*, but not in PT or Pod in *Pod-CKO*. Increase in Mit-rib remarkably raised the **cytochrome oxidase 18 (COX18)** expression which is a component of respiratory chain subunit and activates mitochondrial oxidative phosphorylation (OXPHOS) to maintain ATP generation. Finally, decreased Sirt1 in PT led to acetylating and activating **Foxa2** (Forkhead protein A2), a putative activator of mitochondrial Sirtuin (**Sirt3**), that is surmised to proliferate Mit-rib.

Conclusions: Recent reports showed that **Sirt3** elongates murine lifespan by increasing **Mit-rib** and activating OXPHOS. Among many cytochrome oxidases, mitochondrial DNA encodes and Mit-rib synthesizes COX18. Our data suggested that activated Foxa2/Sirt3 and proliferated Mit-rib compensated for decreased Sirt1 and mitochondrial dysfunction. These molecular links will provide a novel function for the maintenance of energy by Sirt3 in PT.

SA-OR032

Urinary Semaphorin 3A Correlates with Diabetic Proteinuria and Mediates Diabetic Nephropathy and Associated Inflammation in Mice

Riyaz Mohamed, Punithavathi Vilapakkam Ranganathan, Calpurnia Jayakumar, Ganesan Ramesh. *Vascular Biology Center, Georgia Regents Univ, Augusta, GA.*

Background: Semaphorin3A (sema3A) was recently identified as an early diagnostic biomarker of acute kidney injury. However, its role as a biomarker and/or mediator of chronic kidney disease (CKD) related to diabetic nephropathy is unknown. The aim of this study is to determine the pathogenic role of sema3A in diabetic nephropathy.

Methods: The expression and excretion of sema3A in diabetic animal models and in humans was quantified by immunostaining, RT-PCR and ELISA. To test whether sema3A plays a pathogenic role in the development of diabetic nephropathy, mice with sema3A gene mutation or pharmacological based inhibition of receptor binding or signaling was employed. Diabetes was induced by administering low dose of streptazotocin. Albuminuria was quantified at 12 weeks after induction of diabetes with/without pharmacological inhibitors.

Results: The expression of sema3A was localized to podocytes, distal tubules and collecting ducts epithelium in control animals, and its expression was increased following induction of diabetes. Urinary excretion of sema3A in three different diabetic mouse models showed that excretion was increased as early as 2 weeks after induction of diabetes and increased over time, in conjunction with the development of nephropathy. Consistent with the mouse data, increased sema3A urinary excretion was detected in diabetic patients with albuminuria, particularly in those with macro albuminuria. Genetic ablation of sema3A, or pharmacological inhibition with a novel sema3A inhibitory peptide, protected against diabetes-induced albuminuria, kidney fibrosis, inflammation, oxidative stress and renal dysfunction.

Conclusions: We conclude that sema3A is both a biomarker and a mediator of diabetic kidney disease and could be a promising therapeutic target in diabetic nephropathy.

Overexpression of Heterogeneous Nuclear Ribonucleoprotein F Attenuates Tubular Apoptosis and Tubulointerstitial Fibrosis in Type 2 Diabetic Mice

Chao-Sheng Lo,[1] Yixuan Shi,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang,[1] John S.D. Chan.[1] *[1]Research Center, CHUM-Tour Viger, Montreal, QC, Canada; [2]Research Center, Maisonneuve-Rosemont Hosp, Montreal, QC, Canada; [3]Pediatr Nephrol Unit, Mass. Gen. Hosp., Boston, MA.*

Background: We investigated whether overexpression of heterogeneous nuclear ribonucleoprotein F (hnRNP F) inhibits renal angiotensinogen and transforming growth factor-beta 1 (TGF-β1) expression and subsequently attenuate tubular apoptosis and tubulointerstitial fibrosis in type 2 diabetic db/db mice.

Methods: Db/db (BKS strain) transgenic (Tg) mice specifically overexpressing hnRNP F in their renal proximal tubular cells (RPTCs) were studied. Body weight, plasma glucose and albuminuria were monitored bi-weekly in adult male non-db/db littermates, db/db and db/db hnRNP F-Tg mice from 10 to 20 weeks of age. Kidneys were processed for histology and apoptosis studies. Gene expression in renal proximal tubular (RPT) were evaluated by respective real time-qPCR and Western blotting.Urinary Angiotensinogen (Agt), Angiotensin II (Ang II) and Angiotensin 1-7 (Ang1-7) levels were quantified by ELISA. Rat immortalized RPTCs were also studied in vitro.

Results: Db/db mice developed obesity, hyperglycemia, albuminuria and kidney hypertrophy. In contrast, overexpression of hnRNP F in RPTC attenuated the renal hypertrophy and the urinary albumin/creatinine ratio without affecting plasma glucose levels in db/db hnRNP-F Tg mice. Tubular apoptosis, RPT Agt, TGFb1, collagen IV, fibronectin, Bax and caspase-3 expression and urinary Agt and Ang II levels were significantly increased in db/db mice but normalized in db/db hnRNP F-Tg mice. In contrast, RPT Ace2 expression were decreased in db/db mice, whereas urinary Ang I-7 levels were significantly decreased in db/db mice and normalized in db/db hnRNP F-Tg mice. Finally, overexpression of hnRNP F attenuated high glucose-induced apoptosis and pro-apoptotic and fibrotic gene expression in rat RPTCs in vitro.

Conclusions: Overexpression of hnRNP F in renal proximal tubular cells attenuated tubular apoptosis and interstitial fibrosis in type 2 diabetic mice.

Deletion of UNC5B Receptor in Kidney Epithelium Exacerbates Diabetic Nephropathy in Mice

Punithavathi Vilapakkam Ranganathan, Riyaz Mohamed, Calpurnia Jayakumar, Ganesan Ramesh. *Vascular Biology Center, Georgia Regents Univ, Augusta, GA.*

Background: Diabetic nephropathy is a leading cause of end stage renal disease and a major source of morbidity, mortality and health care expenditures. Guidance cue netrin-1 was shown to have protective effects in diabetic nephropathy. However, the role of its receptor UNC5B in diabetic kidney disease is unknown. Moreover, whether netrin-1 is protective against diabetic kidney disease in a genetic model of nephropathy (Ins2Akita mice) and nephropathy prone DBA background mice are also unknown.

Methods: Using Cre-lox technology, UNC5B was specifically deleted in the proximal tubular epithelial cells or single allele whole body deletion. These tissue specific knockout mice, WT mice, and netrin-1 transgenic mice cross bred with DBA background mice were made diabetic by injecting low dose of streptozotocin 50 mg/kg in citrate buffer as multiple doses for every 24h, total of five doses. Blood glucose and urine albumin were measured at 1 week after streptozotocin injection and every four weeks thereafter. 12 week old Akita mice were treated with recombinant human netrin-1 (5μg/animal/every 48h, intraperitoneally) or vehicle (0.1% BSA) for a period of 6 weeks. Then 24h urine was collected for the determination of albumin excretion rate.

Results: WT and UNC5B receptor heterozygous knockout diabetic mice developed significant albuminuria at 8 weeks after induction of diabetes as compared to buffer treated control mice. However, albuminuria was significantly more pronounced in mice with proximal tubule specific deletion of UNC5B. Transgenic overexpression of netrin-1 in proximal tubule in DBA background and administration of recombinant netrin-1 to Ins2Akita mice also significantly reduced diabetes induced albuminuria and suppressed glomerulosclerosis. Moreover, netrin-1 administration also suppressed inflammatory cytokine production in the kidney.

Conclusions: Our data suggest that netrin-1 signaling through UNC5B in proximal tubular epithelium may play a critical role in the protection of kidney against diabetic kidney disease.

The CCR2 Antagonist CCX140 Improves Renal Function in a Human Transgenic CCR2 Diabetic Mouse Model

Zhenhua Miao, Linda Ertl, Jeffrey P. Mcmahon, Shichang Miao, James J. Campbell, Thomas J. Schall. *ChemoCentryx, Mt View, CA.*

Background: Diabetic nephropathy (DN) is a major complication of uncontrolled diabetes. CCR2 has been implicated in the renal recruitment of blood monocytes in response to hypertension and hyperglycemia. It may also be involved in activation of parenchymal renal cells under pathological conditions. CCX140 is a potent, selective, and orally bioavailable small molecule CCR2 antagonist that is currently being studied in two Phase 2 clinical trials in DN. Here we describe the effects of CCX140 on hyperglycemia and renal function in the models.

Methods: hCCR2KI mice were generated by replacing mouse CCR2 coding region with the human CCR2. Uni-nephrectomized hCCR2KI mice were placed on a high fat/high protein diet for 36 weeks to induce obesity. In an alternative model, hCCR2KI-db/db mice were obtained from breeding of hCCR2KI mouse with $lepR^{wt/db}$ mice. In both models, mice were dosed daily for a total of 6-8 weeks. Assessments included body weight, fasting plasma glucose serum clinical chemistry, and 24 hour urinary output of albumin and creatinine.

Results: CCX140 treatment significantly reduced UAER and ACR in both models. In hCCR2KI-db/db mice: Relative changes in UAER from study start to week 6 were +14% and -50% for vehicle and CCX140, respectively. Relative changes in ACR from study start to week 6 were -3% and -75% for vehicle and CCX140, respectively. In hCCR2KI-DIO mice: Relative changes in UAER from study start to week 8 were +440% and +23% for vehicle and CCX140, respectively. Relative changes in ACR from study start to week 8 were +561% and +72% for vehicle and CCX140, respectively.Treatment-related improvement in fasting blood glucose was also observed (vehicle: 190 mg/dL; CCX140: 150 mg/dL). Also observed at the end of the study were increased podocyte density and reduced interstitial macrophage infiltration in connection with CCX140 treatment.

Conclusions: Rapid and significant improvements in albuminuria and hyperglycemia were seen with CCX140 in 2 mouse models of DN. These data are highly supportive of the clinical evaluation of CCX140 in DN. Results from the two ongoing Phase 2 DN trials are expected in late 2014.

SA-OR036

Inhibition of EGFR Activity Protects against Diabetic Nephropathy in Type II Diabetes By Multiple Mechanisms Ming-Zhi Zhang, Raymond C. Harris. *Medicine, Vanderbilt Univ, Nashville, TN.*

Background: Previous studies by us and others have indicated activation of renal epidermal growth factor receptors (EGFR) in models of diabetic nephropathy (DN) and that inhibition of EGFR activity protects against progressive DN in type I diabetes. In the present studies, we examined whether treatment with erlotinib, an inhibitor of EGFR tyrosine kinase activity, affected the development of DN in a model of accelerated type II diabetes.

Methods: BKSdb/db with eNOS knockout (eNOS$^{-/-}$ db/db) mice received vehicle (water) or erlotinib (80 mg/kg/day) by daily gastric gavage beginning at 8 weeks of age. The animals were sacrificed at 20 weeks of age. A subset of mice was kept until death to achieve a survival curve.

Results: Inhibition of renal EGFR activation by erlotinib was confirmed by decreased phosphorylation of EGFR and ERK1/2. Erlotinib treatment preserved pancreas function with higher blood insulin levels at 20 wks (3.16 ± 0.31 versus 2.08 ± 0.22 ng/ml, $P < 0.05$. N=4), and increased blood levels of adiponectin, an adipocyte-derived hormone that increases insulin sensitivity (20.6 ± 0.7 versus 12.1 ± 1.2 ng/ml, $P < 0.0001$. N= 6). Erlotinib-treated mice had decreased basal blood glucose levels and increased glucose tolerance and insulin sensitivity. ACR (albumin/creatinine ratio) was markedly attenuated by erlotinib treatment (ACR at 20 wks: 588 ± 120 versus1688 ± 141 µg/mg, $P < 0.01$. N = 8). Erlotinib protection against DN was also indicated by less histological glomerular injury as well as decreased renal expression of KIM-1, a kidney injury marker, in association with deceased renal endoplasmic reticulum (ER) stress as indicated by decreased expression levels of C/EBP homologous protein (CHOP, an ER stress marker). Finally, erlotinib treatment led to markedly increased longevity (34.14 ± 1.18 versus 22.08 ± 0.56 weeks, $p<0.0001$. N = 8).

Conclusions: These studies suggest that inhibition of EGFR with erlotinib attenuates the development of DN in type II diabetes through multiple mechanisms, including preservation of pancreas function, increased insulin sensitivity due to increased adiponectin production in adipocytes and inhibition of renal ER stress.

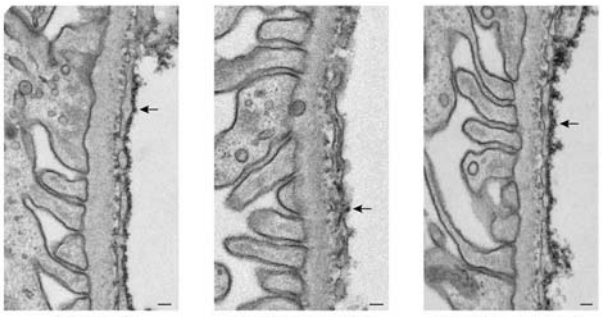
Reduction in Albuminuria in Diabetic Nephropathy by Atrasentan Is Associated with Restoration of the Glomerular Endothelial Glycocalyx Margien G.S. Boels,[1] Cristina Avramut,[1] Angela Koudijs,[1] Martijn Dane,[1] Dae Hyun Lee,[1] Johan Van der Vlag,[2] Abraham J. Koster,[1] Anton Jan Van Zonneveld,[1] Hermann-Josef Groene,[3] Bernard van den Berg,[1] Ton J. Rabelink.[1] *[1]LUMC, Netherlands; [2]RadboudUMC, Netherlands; [3]DKFZ, Germany.*

Background: Atrasentan, a selective endothelin A receptor (ETAR) blocker, has been shown to reduce albuminuria in T2DM patients. We previously showed that the glomerular endothelial glycocalyx (GEG) is crucial in preventing albuminuria. Therefore, we hypothesized that atrasentan restores the GEG.

Methods: ApoE KO mice were rendered diabetic with STZ (5x60mg/kg) and received a high-cholesterol diet for 12weeks. GEG coverage was quantified using stitches of transmission electron microscopy (TEM) images of cationic ferritin (CF, 5mg/2ml HBSS) perfused glomeruli. CF binds to the negatively charged GEG.

Results: The apoE KO diabetes model recapitulates the well-known features of human DN: mesangial expansion, mesangiolysis, glomerular hypertrophy and aneurism formation, accompanied by increased ACR. ETAR blockade, and consequently endothelial ETBR stimulation was confirmed by NO spin trapping with EPR spectroscopy, which shows almost doubled NO generation**.** 4weeks of atrasentan (7.5mg/kg/day) reduces urinary ACR (~40%, p=0.01), without changes in glomerular gross morphology. Perfusion with CF, however, reveals a clear restoration of GEG: Diabetic apoE KO mice show GEG coverage of only 40.7±3.2%, whereas atrasentan treatment increases this to 89.4±8.6%, p=0.01, comparable to non-diabetic mice, which show GEG coverage of 80.9±5.1%, (>56 capillary loops in 2-3 glomeruli/3 mice).



TEM of cationic ferritin bound to endothelial surface

Conclusions: Similar to observations in T2DM patients, atrasentan reduces albuminuria in diabetic apoE KO mice. This is accompanied by a clear restoration of the glomerular endothelial glycocalyx, confirming a role for the endothelial glycocalyx in prevention of proteinuria in diabetes induced kidney disease.

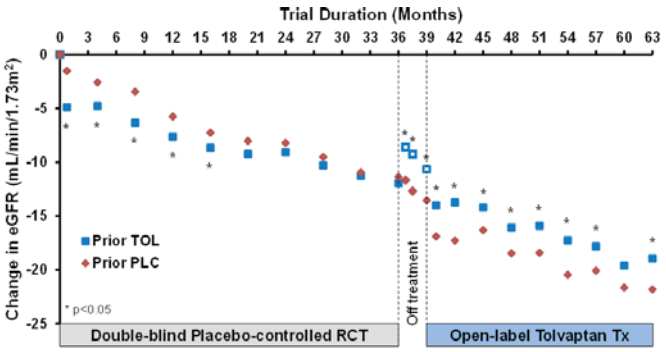
Tolvptan-Treatment of ADPKD Confers Persistent eGFR Improvement: Results from the TEMPO 4:4 Extension Trial Vicente E. Torres,[1] Arlene B. Chapman,[2] Olivier Devuyst,[3] Ron T. Gansevoort,[4] Eiji Higashihara,[5] Ronald D. Perrone,[6] John Ouyang,[7] Susan E. Shoaf,[7] Jaime Blais,[7] Frank S. Czerwiec.[7] *[1]Mayo Clinic; [2]Emory U; [3]U Zurich; [4]U Med Ctr Groningen; [5]Kyorin U; [6]Tufts; [7]Otsuka.*

Background: TEMPO 4:4 is a two-year open-label extension of the TEMPO 3:4 trial. TEMPO 3:4 showed that the V2-receptor antagonist tolvaptan slowed increase in total kidney volume (TKV) by 49% and decline in kidney function (eGFR) by 26% over 3 years in CKD 1-3 ADPKD patients. This interim analysis (data cut date 7/2013) investigated the persistence of tolvaptan's effect on eGFR.

Methods: Analyses of eGFR response to tolvaptan-treatment during TEMPO 4:4 were prespecified. Subjects outside Japan completing TEMPO 3:4 were eligible to receive 2 years open-label tolvaptan in TEMPO 4:4. Those receiving tolvaptan in TEMPO 3:4 were considered early treatment (ET) and those that received placebo delayed treatment (DT). CKD-EPI eGFR was calculated using central IDMS-traceable serum creatinine measurements taken every 3 months.

Results: Included were data from 871 ADPKD patients. An intra-subject comparison of 314 DT subjects participating in both trials showed significant improvement in eGFR slope after switching from placebo to tolvaptan (-3.59 to -2.85 mL/min/1.73m2/yr treatment effect 21% p=0.048) despite an increased proportion starting in CKD 3 at TEMPO 4:4 baseline compared to their earlier TEMPO 3:4 baseline (37 versus 15%). Analysis of the separation in eGFR between ET and DT subjects post-treatment withdrawal in TEMPO 3:4 demonstrated sustained protection of renal function during two year open label extension ($p<0.05$ for 11/12 time points).



Conclusions: This interim analysis showed deceleration in eGFR decline in placebo treated subjects after initiation of tolvaptan and sustained protection of renal function in tolvaptan treated patients during TEMPO 3:4 and TEMPO 4:4. An updated analysis will be presented.

Refining Genotype-Phenotype Correlation in Autosomal Dominant Polycystic Kidney Disease (ADPKD): The Toronto Genetic Epidemiology Study of PKD (TGESP) Young-Hwan Hwang,[1] John Conklin,[3] Ning He,[2] Kairong Wang,[2] Jamie L. Sundsbak,[4] Christina M. Heyer,[4] Masoom Haider,[3] Peter C. Harris,[4] York P. Pei.[2] *[1]Dept of Medicine, Eulji General Hospital, Eulji Unversity, Seoul, Korea; [2]Divs of Nephrology, Univ Health Network, Toronto, ON, Canada; [3]Dept of Medical Imaging, Univ Health Network, Toronto, ON, Canada; [4]Div of Nephrology, Mayo Clinic, Rochester, MN.*

Background: Renal disease variability in ADPKD is strongly influenced by both a genic and a modifier effect. Non-truncating (NT) *PKD1* mutations have been identified in ~30% of patients but their clinical significance have not been fully defined.

Methods: We recruited a prospective cohort of 220 unrelated patients and 485 of their affected family members through the PKD Clinic at Toronto General Hospital between 2005-2013. All probands had a serum [Cr] <1.4 mg/dL at presentation and underwent comprehensive *PKD1* and *PKD2* mutation screening. In-silico prediction of pathogenicity and segregation analysis was performed for all *PKD1* NT mutations. Height-adjusted total kidney volume (htTKV) was obtained in 162 patients by MRI/CT. Multivariate Cox proportional hazard analysis for renal and patient survival was performed in 646 mutation-positive subjects, adjusting for gender and clustering within the same family.

Results: Overall, 85% of our probands had an identifiable mutation in whom the prevalence of *PKD1* truncating (TR), NT (i.e. non-synonymous missense and atypical splice mutations), in-frame indels (IF indels), and *PKD2* mutations was 32.4%, 23.0%, 3.6%, and 25.7%, respectively. htTKV was smaller in patients with NT compared to TR *PKD1* mutations, but did not differ from those with *PKD2* mutations. Compared to *PKD1* TR mutations, patients with *PKD1* IF indels, *PKD1* NT, and *PKD2* mutations, respectively, had reduced risks of ESRD (hazard ratio (HR) [95%CI]: 0.35 [0.14-0.91], 0.10 [0.05-0.18], 0.03 [0.01-0.05]) and death (HR: 0.31 [0.11–0.87], 0.20 [0.11–0.38], and 0.18 [0.11– 0.31]).

Conclusions: Refining the correlation of genotype with renal disease severity, coupled with targeted exome resequencing, has the potential to advance mutation-based diagnostics to provide useful clinical prognostication in ADPKD.

SA-OR040

Enhanced Diagnostics and Gene Discovery in ARPKD-Like and Meckel Syndrome (MKS) Pedigrees Using a Next Generation Sequencing (NGS) Ciliopathy Panel Katharina Hopp, Sarah J. Koon, Christina M. Heyer, Vicente E. Torres, Peter C. Harris. *Mayo Clinic.*

Background: ARPKD and MKS are PKD associated ciliopathies, with one gene, *PKHD1*, implicated in ARPKD and >14 genes in MKS. However, many of our ARPKD-like/MKS pedigrees remain unresolved after Sanger sequencing of commonly affected genes.

Methods: We performed enrichment (Agilent HaloPlex) and NGS (Illumina HiSeq2000) of 258 genes implicated in ciliopathies or cilia biogenesis/function on 18 pedigrees, most of which were outbred, and filtered variants based on quality, population frequency, and substitution significance.

Results: Our analysis solved 50% of pedigrees (6 ARPKD-like, 3 MKS). Of these, 2 ARPKD cases had two mutations in *PKHD1,* one of which was previously missed by Sanger, and 2 MKS fetuses had mutations in *TMEM231* and *TCTN2*, recently identified MKS genes. More interestingly, 4 ARPKD-like probands had pathogenic changes in genes not previously associated with ARPKD. Case (1) presented with PKD at 24wks gestation and inherited *CEP290* p.L552fs homozygous; (2) was diagnosed with ARPKD at 8mo and inherited *TMEM67* p.T244K homozygous (scored as highly likely pathogenic); (3) was diagnosed at 3wks with failure to thrive, ARPKD and hepatic fibrosis, died at 8mo and inherited two *NPHP3* changes (p.W606* and p.D1133fs); and (4) inherited two highly likely pathogenic *IFT172* variants (p.K141E and p.R1134L), a gene recently identified in other ciliopathies. Intriguingly, proband (4) also carried a *PKHD1* mutation (p.Q1665*). We also identified a potentially novel MKS-like gene, *C2CD3*. The fetus inherited a highly likely pathogenic variant (p.V899M) and a rare synonymous change (p.C1114=), which we found to cause exon skipping by fetal tissue analysis. Interestingly, the fetus had typical MKS phenotypes (encephalocele, polydactyly) but without PKD, consistent with the null mouse model.

Conclusions: These results emphasize the suitability of candidate gene NGS for genetic testing of outbred ciliopathy patients and highlight probable additional genetic heterogeneity in unresolved ARPKD-like/MKS patients and/or potential misdiagnoses due to phenotypic overlap with other ciliopathies. Additionally, oligogenic inheritance may play a role in ARPKD-like disease.

Mutations in *DCDC2* Cause Nephronophthisis with Hepatic Fibrosis in Humans Daniela A. Braun,[1] Markus Schueler,[1] Gayathri Chandrasekar,[2] Heon Yung Gee,[1] Isabel Tapia Paez,[2] Andrea Bieder,[2] Jan Halbritter,[1] Jonathan Porath,[1] Rannar Airik,[1] Detlef Bockenhauer,[3] Tomas Honzik,[4] Richard P. Lifton,[5,6] Juha Kere,[2] Friedhelm Hildebrandt.[1,6] *[1]Div. of Nephrology, Boston Children's Hospital, Harvard Med School, Boston; [2]Dept of Biosciences and Nutrition, Karolinska Inst, Huddinge, Sweden; [3]Univ College London, London, United Kingdom; [4]Dept of Pediatrics, Charles Univ Prague, Prague, Czech Republic; [5]Dept of Genetics, Yale Univ School of Medicine, New Haven; [6]Howard Hughes Medical Inst, Chevy Chase.*

Background: Nephronophthisis-related ciliopathies (NPHP-RC) are a group of autosomal recessive diseases that cause progressive renal failure and various extrarenal manifestations like hepatic fibrosis in the first decades of life. To date, mutations in more than 80 causative genes have been identified that together explain ~70% of all cases.

Methods: To identify novel single gene causes of NHPHP-RC we performed whole exome sequencing combined with homozygosity mapping in 100 individuals. We then screened 1,064 families with NPHP-RC by barcoded multiplex PCR (Fluidigm Access Array™) and next-generation sequencing.

Results: In a consanguineous family with one affected child, we detected a homozygous truncating mutation in the gene DCDC2 (doublecortin domain containing 2). The affected child presented with liver fibrosis at age 11 months and ESRD at age 11 yrs. By screening our NPHP-RC cohort, we identified two compound heterozygous truncating alleles in DCDC2 in a second family with early-onset liver fibrosis. We show by immunofluorescence that DCDC2 localizes to the ciliary axoneme in liver and kidney, as well as to mitotic spindle fibers and the abscission structure in cycling cells. By immunoprecipitation, we show interaction of DCDC2 with Dvl1,2,3 and JIP1 via its N-terminus. Overexpression of DCDC2 inhibits canonical Wnt signaling, but interestingly all three alleles lack this inhibitory effect in vitro. Knockdown of DCDC2 in zebrafish recapitulates a ciliopathy phenotypic with ventral body axis curvature, hydrocephalus, and kidney cysts.

Conclusions: We identified mutations in DCDC2 as a novel cause of NPHP-RC with liver fibrosis in humans and link the pathogenesis to impaired Wnt signaling.

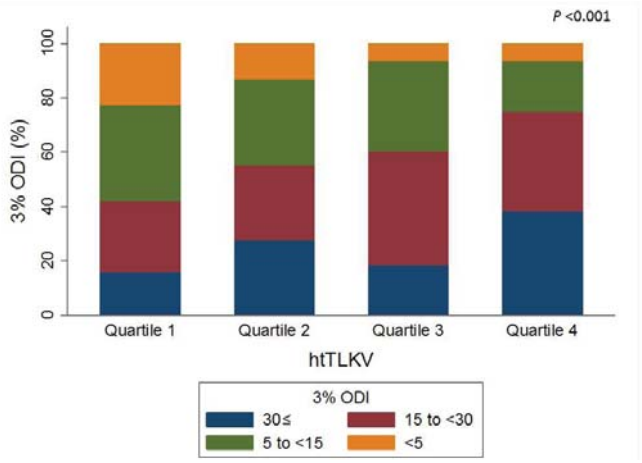
SA-OR042

High Prevalence of Sleep-Disordered Breathing and Its Association with Liver and Kidney Volume in Patients with Autosomal Dominant Polycystic Kidney Disease Keiichi Sumida, Junichi Hoshino, Tatsuya Suwabe, Koki Mise, Kenmei Takaichi, Yoshifumi Ubara. *Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Kanagawa, Japan.*

Background: Sleep-disordered breathing (SDB) is prevalent among chronic kidney disease patients, but its prevalence among patients with autosomal dominant polycystic kidney disease (ADPKD) and its association with total liver and kidney volume (TLKV) remain unclear.

Methods: We examined the association between height-adjusted TLKV (htTLKV) and SDB in a cross-sectional study of 304 adult patients with symptomatic ADPKD who were hospitalized at Toranomon Hospital for transcatheter arterial embolization and who underwent pulse oximetry between April 2008 and November 2013. SDB was defined as having a 3% oxygen desaturation index of 15 or more events per hour of sleep. We performed logistic regression with sex-specific quartiles (3,673.9, 5,262.9, and 7,087.3 cm^3/m in men and 3,526.9, 4,680.3, and 5,847.8 cm^3/m in women) of htTLKV as the main predictor, and demographic factors and comorbidities as covariates.

Results: Overall (54.6% women, mean age 56.2 ± 9.4 years, 83.5% on hemodialysis), 177 (58.2%) patients had SDB. Odds ratios (ORs) (95% confidence intervals [95% CI]) for SDB were 1 (reference), 1.73 (0.81–3.67), 2.44 (1.16–5.15), and 4.73 (2.06–10.9) for htTLKV quartiles 1–4, respectively (P for trend <0.001). Older age (OR, 1.84 [95% CI, 1.31–2.58] per increase in 10 years), male sex (OR, 3.85 [95% CI, 1.98–7.50]), receiving hemodialysis (OR, 3.54 [95% CI, 1.49–8.44]), and higher BMI (BMI ≥25 kg/m2) (OR, 4.40 [95% CI, 1.62–11.9]) were also associated with SDB.



Conclusions: SDB is highly prevalent and independently associated with increased htTLKV in patients with symptomatic ADPKD.

SA-OR043

Using Human Pluripotent Stem Cells to Model Kidney Disease Pathophysiology and Therapy Benjamin S. Freedman,[1] Albert Q. Lam,[1] Theodore I. Steinman,[1,2] Peter C. Harris,[3] Jing Zhou,[1] Joseph V. Bonventre.[1] *[1]Brigham and Women's Hospital; [2]Beth Israel Deaconess Medical Center; [3]Mayo Clinic.*

Background: Induced pluripotent stem cells (iPSCs) are adult cells that have been reprogrammed to an embryonic stem cell (ESC)-like state. We tested the ability of iPSCs to model the cellular pathophysiology of cystic kidney diseases, and to differentiate into human kidney cells.

Methods: A cohort of iPSCs was established from 14 patients representing ADPKD, ARPKD, Bardet-Biedl Syndrome, Meckel-Gruber Syndrome, and healthy controls. Pathogenic mutations were identified using next-generation sequencing. Ciliary length and protein expression were quantified in iPSCs and descendant cells. To determine their potential for kidney regeneration, iPSCs were treated with growth factors under serum-free conditions and implanted beneath the murine kidney capsule.

Results: iPSCs underwent extensive self-renewal and differentiation, elaborated primary cilia, and endogenously expressed PKD disease genes. ADPKD iPSCs and descendant cells with PC1 mutations expressed reduced ciliary PC2, which could be rescued by exogenous expression of wild-type PC1. Meckel-Gruber Syndrome iPSCs exhibited abnormally long cilia, with normal PC2 localization. Sequential treatment of ESCs/iPSCs with CHIR99021, FGF2, and retinoic acid induced markers of intermediate mesoderm (PAX2, LHX1), metanephric mesenchyme (SIX2, SALL1), and proximal tubule (KSP, LTL). When implanted in vivo, metanephric cells generated macroscopic growths expressing high levels of aquaporin-1.

Conclusions: We have established a cohort of genetically characterized PKD and ciliopathy iPSCs that recapitulate syndrome-specific ciliary phenotypes, with applicability for therapeutic screens. iPSC-derived kidney cells survive, proliferate, and differentiate in vivo, providing an expandable source of new kidney tissue which is 100 % immunocompatible with the original patient. The ability of iPSCs to provide novel

mechanistic insights into human cellular pathophysiology, together with their potential as regenerative cell therapeutics, makes them a powerful new resource for kidney disease research.

SA-OR044

miR-17~92 microRNA Cluster Promotes Disease Progression in Genetic Models of ADPKD Vishal Patel, Darren Williams, Ronak Lakhia, Sachin S. Hajarnis. *Internal Medicine, UT Southwestern Medical Center, Dallas, TX.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most frequent genetic cause of ESRD in the United States. MicroRNAs (miRNAs) are non-coding RNAs that inhibit gene expression primarily by binding to 3'-UTRs of target genes. We have recently shown that the miR-17~92 miRNA cluster inhibits *Pkd1* and *Pkd2*, and promotes kidney cyst growth. However, whether miR-17~92 can modulate the cystic phenotype in ADPKD, where *PKD1* and *PKD2* are already mutated, is not known.

Methods: qRT-PCR analysis was performed to determine miR-17~92 expression in mouse models of ADPKD. To determine whether miR-17~92 played a pathogenic role, miR-17~92 was inactivated from renal tubules of kidney-specific *Pkd1* and *Pkd2* mutant mice. Global gene expression analysis was performed to identify genes that are upregulated in *Pkd1*-miR-17~92 double knockout (KO) mice compared to *Pkd1* single KO mice, and in *Pkd2*-miR-17~92 double KO mice compared to *Pkd2* single KO mice, respectively. Bioinformatic analysis and integration of the available cross-linking and immunoprecipitation (CLIP)-seq datasets identified a common set of genes that contain binding sites and physically interact with miR-17~92 in their 3'-UTRs.

Results: The levels of miR-17~92 are increased in genetic models of ADPKD likely due to c-Myc-mediated transcriptional activation. Deletion of miR-17~92 suppressed cyst growth, decreased kidney injury, improved renal function and nearly doubled the life span of *Pkd1* and *Pkd2* mutant mice. miR-17~92 produced these effects by decreasing the proliferation of cyst epithelial cells. Gene expression analysis, 3'-UTR bioinformatic analysis and integration of CLIP-seq datasets identified a common network of miR-17~92 target genes in *Pkd1* and *Pkd2* mutant kidneys. Functional annotation of the direct targets revealed that miR-17~92 regulates glucose metabolism pathway genes in *Pkd1* and *Pkd2* mutant kidneys.

Conclusions: miR-17~92 promotes cyst growth in mouse models of ADPKD. Our results suggest a new mechanism for disease progression in ADPKD involving miRNA-mediated regulation of metabolic pathway genes.

SA-OR045

Angiotensinogen Inhibition Slows Polycystic Kidney Disease in Mice with a Targeted Mutation in Pkd2 Kameswaran Ravichandran,[1] Abdullah Ozkok,[1] Qian Wang,[1] Adam E. Mullick,[2] Charles L. Edelstein.[1] *[1]Univ of Colorado Denver; [2]Isis Pharmaceuticals.*

Background: Renal cyst enlargement is associated with the activation of both circulating and intrarenal renin-angiotensin-aldosterone (RAAS) system. The aim of the study was to determine the effect of angiotensinogen inhibition in a model of autosomal dominant polycystic kidney disease (ADPKD).

Methods: A Gen 2 angiotensinogen (AGT)antisense oligonucleotide (ASO) that selectively reducesAGT mRNA was injected at 50-100mg/kg/wk i.p. once weekly in PKD2WS25mice (WS25; an orthologous model of human ADPKD) from 4 to 16 weeks of age.

Results:

	+/+ Scr ASO (n=11)	+/+ AGT ASO (n=14)	WS25 Scr ASO (n=10)	WS25 AGT ASO (n=7)
BW (g)	28.2	29.4	27.3	29.4
2KW (g)	0.34	0.35	0.67*	0.47**
2K/TBW (%)	1.2	1.2	2.4*	1.5**
CVD (%)	0.4	0.5	34.1*	22 **
BUN (mg/dL)	32	29	47*	34**
AGT serum (ng/mL)	2489	1233	3643*	1483**
AGT kidney (ng/mL)	1.3	0.08	6.1*	0.7**
TGF-β (pg/mL)	53	40	102*	32 ± 5*
Fibrosis score	0	0	0.4± 0.1*	0.1**
CXCL1 (pg/mg)	0.4	0.3	3.4*	0.6**
IL-12	8	9	37*	9**

*P<0.001 vs. +/+; **p< 0.001 vs. WS25 Scr ASO, NS vs +/+;BW= body weight, CVD= cyst volume density. 2K/TBW (%)=two kidney weight to total body weight ratio.
AGT protein was increased in blood and kidney in PKD and the AGT ASO resulted in a significant decrease in AGT protein.The AGT ASO resulted in a significant decrease in kidney enlargement, cyst volume density and BUN without an effect on body weight. The AGT ASO resulted in a significant decrease in TGF-β and interstitial fibrosis (Sirius red staining) in the kidney. Mice treated with the AGT ASO had a significant decrease in CXCL1, a neutrophil chemokine, and IL-12, a T cell stimulating factor, in the kidney.

Conclusions: AGT inhibition decreased cystogenesis, interstitial fibrosis and pro-inflammatory chemokines/cytokines and represents a possible future therapy for ADPKD.

SA-OR046

Vascular Endothelial Growth Factor C Therapy for Polycystic Kidney Diseases Jennifer L. Huang,[1] Adrian S. Woolf,[2] Maria K. Joannou,[1] Richard N. Sandford,[4] Dorien J.M. Peters,[5] Karen Price,[1] Paul Winyard,[1] David A. Long.[1] *[1]Developmental Biology and Cancer, UCL Inst of Child Health, United Kingdom; [2]Inst of Human Development, Univ of Manchester, United Kingdom; [3]Academic Dept of Medical Genetics, Univ of Cambridge, United Kingdom; [4]Dept of Human Genetics, Leiden Univ, Netherlands.*

Background: Current therapies for polycystic kidney diseases (PKDs) have focussed on ameliorating epithelial aberrations. As an alternative strategy, we hypothesised that the niche surrounding kidney tubules, including the microvasculature, may modulate cystogenesis.

Methods: The renal capillaries and lymphatics were examined in two mouse models of PKD (*Pkd1*^{nl}and *Cys1*^{cpk}). To modulate the vasculature during PKD, mice from both models were administered vascular endothelial growth factor (VEGF)C.

Results: Normal kidney tubules were surrounded by a capillary network expressing CD31 and VEGFR3. PKD led to a significant increase in the area of CD31$^+$/VEGFR3$^+$ vessels, which were disorganised and dilated. PKD did not lead to alterations in Prox1$^+$/LYVE1$^+$ lymphatics. We targeted the aberrant vasculature in PKD using VEGFC, which enhanced the phosphorylation of VEGFR3 in the kidney and led to a normalised renal network of VEGFR3$^+$/CD31$^+$ capillaries. In addition, VEGFC led to hyperplasia of Prox1$^+$/LYVE1$^+$ lymphatics. The changes in the vasculature were associated with a 30-40% reduction in kidney/body weight ratio ($p < 0.001$); lower blood urea nitrogen ($p < 0.01$); lower creatinine concentration ($p < 0.001$); and reduced average cyst size ($p < 0.05$). VEGFC also significantly reduced numbers of M2 alternatively activated macrophages ($p < 0.05$), previously known to be cystogenic.

Conclusions: VEGFC treatment improved PKD by normalising the patterning of VEGFR3$^+$/CD31$^+$ capillaries and causing lymphatic hyperplasia; manoeuvres which would enhance the drainage of excess interstitial fluid. Our results support the contention that the niche surrounding kidney tubules modulates cystogenesis and that VEGFR3$^+$ capillaries and lymphatics are a novel and important target for PKD therapies.

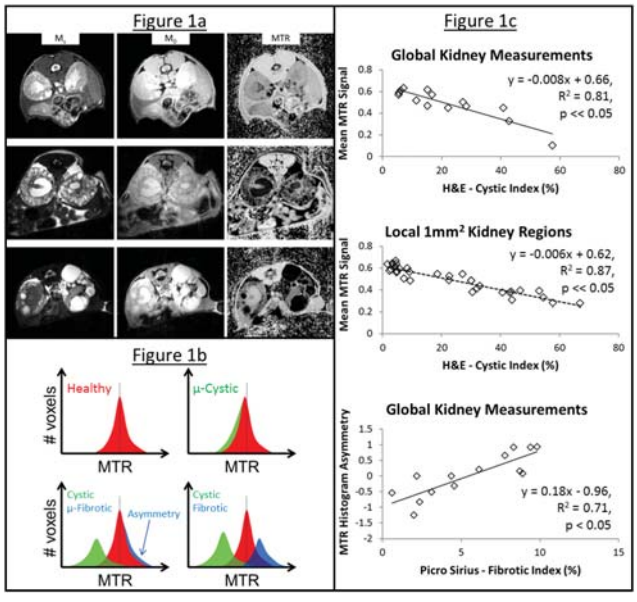
SA-OR047

Magnetization Transfer Imaging for Tissue Remodeling Analysis in a Murine Model of ADPKD Timothy L. Kline, Maria V. Irazabal, Behzad Ebrahimi, Katharina Hopp, Joshua D. Warner, Lilach O. Lerman, Peter C. Harris, Bernard F. King, Vicente E. Torres, Bradley J. Erickson. *Mayo Clinic.*

Background: Magnetization transfer (MT) imaging, a quantitative MR technique, allows the detection of macromolecules based on different magnetic characteristics of free and bound water and has been used to detect lesions and pathophysiological changes in brain, pancreas, and lungs. Early tissue changes in ADPKD may elucidate differences in phenotypically similar patients whose subsequent time-course of the disease may differ. We investigated MT as a source for new tissue remodeling biomarkers.

Methods: Homozygous *Pkd1* R3277C mice at 9 (3F;3M) and 12 months of age (4F;4M) were imaged *in vivo* with a 16.4T MR imaging system, then euthanized. Kidneys were harvested for histological measurement of cystic and fibrotic index. MT ratio (MTR) maps were computed from magnetically saturated (M_s) and unsaturated (M_0) bound proton images by computing $(M_0 - M_s)/M_0$ for each voxel. A Gaussian mixture model (GMM) quantified the presence of tissue remodeling from the MTR intensity distribution.

Results: Figure 1a displays M_s, M_o, and MTR *in vivo* images. Figure 1b conceptualizes how our GMM quantifies various PKD tissue remodeling scenarios from MTR tissue intensity distributions. Compared with normal parenchyma - cysts have decreased MTR, while fibrotic tissues have increased MTR. Figure 1c shows that MTR values correlate with cystic index, and that fibrotic remodeling of tissue is conveyed by MT.



Conclusions: We present the first use of MT imaging for use in PKD assessment. Using a murine model of the disease we found close correlations between parameters extracted from MTR maps and both cystic and fibrotic indices. This information together with traditional total kidney volume assessments will expand the number of useful quantitative measures for monitoring disease progression and predicting outcomes for PKD patients.

Podocyte Specific Expression of Mutant APOL1 Induces Albuminuria and Global Sclerosis in Mice

Ae Seo Deok Park,[1] Jeffrey B. Kopp,[2] Cheryl Ann Winkler,[3] James M. Pullman,[4] Jeffrey H. Miner,[5] Katalin Susztak.[1] *[1]Perelmen School of Medicine, UPENN; [2]NIDDK; [3]National Cancer Inst; [4]Albert Einstein College of Medicine; [5]Washington Univ in St. Louis.*

Background: Afro-Americans have 3-5 fold-increased risk of developing end stage renal disease. Recently, polymorphism (G1 and G2) in apolipoprotein L1 (APOL1) gene has been identified explaining this increased risk and presenting diverse phenotypes: focal segmental glomerulosclerosis, HIV-associated and hypertensive nephrosclerosis. The pathomechanism of APOL1 remains poorly understood.

Methods: Human kidney samples were collected from nephrectomies and genotyped for G0 (control), G1 or G2 (risk) APOL1 alleles. Gene expression analysis (GEA) was performed on microdissected tubule and glomerular samples using Affymetrix expression arrays. Primary renal epithelial cells were cultured from control and risk kidneys. Generated mice with wild type (G0) and mutant (G1 or G2) APOL1 allele under a tet inducible promoter were crossed with nephrin rtTA and induced on doxycycline diet.

Results: GEA showed that APOL1 transcript level is lower in the risk alleles than controls. APOL1 protein level in cultured renal epithelial cells was also lower in risk samples, but intermediate in G1/G0. Interferon gamma was a strong regulator of APOL1 in vitro. Chromatin immunoprecipitation showed STAT1 binding sites on the APOL1 promoter/enhancer region. IF and immunogold electron microscopy showed that APOL1 in human podocytes follows the endocytic pathway; APOL1 localized to the ER, endocytic vesicles, lysosomes and autophagosomes. Transcriptomic profiling also highlighted differences in synaptic transmission and endocytosis pathways between control and risk alleles samples. Mutant APOL1 mice developed severe albuminuria and glomerulosclerosis at 3-5 weeks after induction, while wild type mice expressing similar levels of G0 APOL1 showed minimal renal abnormalities.

Conclusions: APOL1 expression in risk allele samples was lower than in control allele samples and it could be regulated by interferon. Mutant APOL1 mice developed proteinuria and global sclerosis. APOL1 was localized to the endocytic pathway and transcriptome analysis showed differences in this pathway.

Identification of Small Molecule Integrin β1 Agonist as a Podocyte Protective Agent Using a Novel Podocyte High Content Screening Assay

Ha Won Lee, Mehmet M. Altintas, Mohd Hafeez Faridi, Hatem A. Elshabrawy, Jochen Reiser, Vineet Gupta. *Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL.*

Background: Focal segmental glomerulosclerosis (FSGS) is a leading cause of idiopathic nephrotic syndrome with limited therapeutic options. Podocytes are injured early in the disease pathogenesis and represent a crucial cellular target for therapeutic interventions in FSGS and other proteinuric glomerular diseases. However, podocyte-targeted drug discovery has been hampered due to lack of high quality screening assays. Here, we describe a high content screening (HCS) approach to discover podocyte-targetedtherapeutics using differentiated podocyte culturesand reveal that an integrin β1 agonist rescues podocyte injury.

Methods: Using a confocal microcopy based high content imaging system, we developed a high throughput screening assay to measure phenotypic changes in podocytes. Murine podocytes were treated with a podocyte-damaging agent (puromycin aminonucleoside (PAN)). We analyzed >1000 cells per assay condition to computationally and quantitatively determine changes by chemicals in podocyte morphology, cytoskeleton and focal adhesions upon injury.

Results: Our assay consistently produced a Z-prime factor > 0.5, suitable for a high-throughput screening. Subsequently, with a small chemical library of >2200 compounds identified known and novel compounds that protected podocytes from PAN-induced damage (~1% hit rate). Among the hits, we confirmed an integrin β1 agonist as a novel agent that dose-dependently protected podocytes from PAN-induced injury. It restored phenotypic (F-actin cytoskeleton, Akt phosphorylation and focal adhesions) and functional changes in PAN-treated podocytes. We are currently validating the hits using in vivo model systems.

Conclusions: We developed a high-throughput assay for unbiased quantification of changes in podocytes that has wide applicability. Using this assay, we identified novel compounds that prevent podocyte injury. Validation ofan integrin β1 agonistsupports our hypothesis that our podocyte-based HCS assay is a useful technique for the identification of therapeutics for treating proteinuric kidney diseases.

In Vivo Serial Multiphoton Imaging of the Early Changes in Glomerular Structure and Function in Nephrotic NEP25/Podocin-Confetti Mice

Kengo Kidokoro,[1,2] James L. Burford,[1] Taiji Matsusaka,[3] Naoki Kashihara,[2] Janos Peti-Peterdi.[1] *[1]Physiology & Biophysics, Univ of Southern California, Los Angeles, CA; [2]Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan; [3]Internal Medicine, Tokai Univ, Kanagawa, Japan.*

Background: The development of podocyte injury/dysfunction and albuminuria in nephrotic syndrome (NS) are still incompletely understood due to technical limitations in studying the glomerular filtration barrier (GFB) and podocytes in their intact environment *in vivo*. We aimed to directly visualize the early morphological and functional changes of GFB in vivo in the mouse kidney during the development and progression of NS.

Methods: Podocin-Confetti mice in which single podocytes were genetically labeled and identified by CFP/GFP/YFP/RFP expression were crossed with NEP25 mice, in which selective podocyte injury was induced by a single injection of the immunotoxin anti-Tac(Fv)-PE38 (LMB2). Between 0-7 days after the iv injection of 1.25-5 ng/g LMB2, NEP25/Pod-Confetti mice (4-6 weeks of age) were subjected to multiple surviving surgeries to exteriorize and image the same region and glomeruli of the left kidney by in vivo serial multiphoton microscopy (MPM). Blood vessels were labeled red by Alexa594-albumin. Specific glomeruli were z-scanned to visualize changes in podocyte morphology and dynamics.

Results: After the injection of high dose LMB2 the rapidly progressing development of NS was observed including the detection of detached podocytes and the irregular length, width, shape, and clubbing of podocyte cell processes. Multi-color podocyte clusters on visceral layer and podocyte projections to the parietal Bowman's capsule developed within 7 days. Parallel with these morphological changes, the increased GFB permeability to albumin in denuded areas of the GFB was apparent by the accumulating high level of Alexa594 fluorescence in cells of the proximal tubule and in the tubular lumen.

Conclusions: This MPM imaging study confirmed high podocyte motility, the highly dynamic glomerular remodeling in early NS, and the key role of podocytes in the development of nephrotic proteinuria.

SA-OR051

Microtubule Stabilization By Taxol Promotes Podocyte Process Elongation and Enhances Compensatory Glomerular Adaptation to Podocyte Depletion

Weiwei Xu,[1,2] Yan Ge,[1] Zhihong Liu,[2] Rujun Gong.[1] *[1]Nephrology, Brown Univ, Providence, RI; [2]Research Inst of Nephrology, Nanjing Univ, China.*

Background: Reminiscent of neuronal repair, upon podocyte depletion, remnant intact podocytes exhibit a considerable adaptive capacity to extend cellular processes and develop collateral branches to cover the denuded glomerular basement membrane. Central to the outgrowth, branching and elongation of cellular processes is remodeling of microtubule cytoskeleton, which is the principal cytoskeletal component in podocyte cell body and major processes. This study examined the role of microtubule remodeling in compensatory glomerular adaptation following podocyte loss.

Methods: The effect of manipulation of microtubule dynamics was examined in adriamycin injured conditionally immortalized mouse podocytes and in murine models with adriamycin nephropathy.

Results: Adriamycin injury induced loss of podocyte phenotypic markers, like synaptopodin and nephrin, elicited cellular shrinkage and progressively reduced cell size as measured by time lapse microscopy, concomitant with disruption of microtubule cytoskeleton integrity. These effects were mimicked by specific microtubule destabilizing agents, including colchicine and vinblastine. In contrast, delayed treatment with taxol, a quintessential microtubule stabilizing agent, abrogated the adriamycin elicited podocyte injury, promoted microtubule assembly and reinstated microtubule scaffolding, associated with a restored shape and size of podocytes and normalized podocyte phenotypes. In mice with adriamycin induced nephropathy, a single low dose taxol treatment was given 5 days after adriamycin injury, when proteinuria and podocyte injury were evident. Taxol therapy attenuated proteinuria and ameliorated progressive glomerular sclerosis despite no correction of podocytopenia. Mechanistically, taxol therapy enhanced microtubule assembly and stabilization in adriamycin injured glomeruli, associated with elongation of podocyte major processes as revealed by electron microscopy.

Conclusions: Stabilization of microtubule cytoskeleton promotes podocyte process elongation, reinforces compensatory glomerular adaptation to podocyte loss and attenuates proteinuria and glomerulosclerosis.

Protamine Sulfate-Induced Degradation of Synaptopodin and Loss of Stress Fibers Are Mediated by EGF Receptor-Dependent Activation of Src

Lisa Maria Buvall,[1] Hanna Ilse Wallentin,[1] Jonas Sieber,[1] Hoon Young Choi,[3] Anna Greka,[2] Peter H. Mundel.[1] *[1]Dept of Medicine, Massachusetts General Hospital & Harvard Medical School, Boston, MA; [2]Dept of Medicine, Brigham and Women's Hospital & Harvard Medical School, Boston, MA; [3]Dept of Medicine, Gangnam Severance Hospital, Yonsei Univ, Seoul, Korea.*

Background: Perfusion of rat or mouse kidneys with the polycation protamine sulfate (PS) causes TRPC5-dependent podocyte actin remodeling and foot process effacement. In vitro, exposure of podocytes to PS leads to loss of stress fibers and degradation of synaptopodin in a TRPC5-dependent fashion. PS has previously been show to increase

EGF receptor (EGFR) kinase activity, presumably by exposing a population of cryptic EGFRs. Therefore we hypothesized that PS induces podocyte actin remodeling through EGFR-mediated activation of Src and PI3 kinase signaling.

Methods: The effect of PS on podocytes was analyzed using biochemistry assays, lentiviral approaches and phalloidin staining to visualize the actin cytoskeleton.

Results: We found that PS-induced degradation of synaptopodin and loss of stress fibers were blocked by EGFR inhibitor AG1478, Src inhibitor-1, PI3 kinase inhibitor wortmannin, calcineurin inhibitor CsA, or Cathepsin L inhibitor E64. In a complementary genetic approach, we established that Src-resistant Synpo-Y222A, calcineurin-resistant Synpo-ED or CatL-resistant Synpo-CM1+2 protect from PS-induced loss of stress fibers. Mechanistically, the PS-induced degradation of synaptopodin initiates a signaling cascade including Vav2 activation, enhanced Rac1 signaling, RhoA inactivation and loss of actin stress fibers.

Conclusions: In summary, PS promotes Src signaling through EGFR activation to trigger the degradation of synaptopodin, which results in TRPC5 and Vav2-mediated Rac1 activation. Our results reveal EGFR as the long-sought membrane receptor responsible for PS-induced effects on actin dynamics.

SA-OR053

Identification of Podocytopathy-Associated Genes by Translational Profiling of Podocytes Ivica Grgic,[1] Andreas Hofmeister,[1] Hua Sun,[3] Omar H. Maarouf,[4] Vanesa Bijol,[5] Martin R. Pollak,[3] Benjamin D. Humphreys.[4] *[1]Internal Medicine and Nephrology, Philipps-Univ Marburg; [2]Program in Medical and Population Genetics, Broad Inst of MIT and Harvard; [3]Div of Nephrology, Beth Israel Deaconess Medical Center and Harvard Medical School; [4]Renal Div, Brigham and Women's Hospital; [5]Dept of Pathology and Laboratory Medicine, Brigham and Women's Hospital.*

Background: Research aimed at finding new biomarkers and therapeutic target structures for the management of podocytopathies such as focal segmental glomerulosclerosis (FSGS) requires a detailed analysis of transcriptional changes in podocytes over the course of disease. However, dissociating nucleic acids of specific and particularly underrepresented renal cell populations from the rest of the kidney is challenging.

Methods: Here we have used translating ribosome affinity purification (TRAP) to extract and analyze podocyte-specific mRNA during aging and in two different genetic FSGS models.

Results: We expressed an eGFP-tagged ribosomal fusion protein (eGFP-L10a) in podocytes using the Collagen-1a1 promoter, enabling podocyte-specific mRNA isolation from Col1α1-eGFP-L10a in a one-step process over the course of disease. This TRAP protocol robustly enriched known podocyte-specific mRNAs, validating the approach. We crossed Col1α1-eGFP-L10a mice with the Actn4$^{-/-}$ (severe) and Actn4$^{+/K256E}$ (mild) FSGS models and analyzed podocyte translational profiles at 2, 6 and 44 weeks. Importantly, two identified podocyte genes induced in murine FSGS (Cxcl1 and Dmpk) were also upregulated at the protein level in biopsies from patients with proteinuria and histologically proven podocyte abnormalities. There was no dilution of podocyte-specific transcripts during disease.

Conclusions: These are the first podocyte-specific RNA expression datasets during aging and in two models of FSGS. This approach identified new podocyte proteins that are upregulated in FSGS and may be useful for the discovery of novel biomarkers and therapeutic targets for human glomerular disease.

Characterization of WT1-Directed Transcription in Podocytes In Vivo by ChIPseq Martin Kann,[1] Sandrine S. Ettou,[2] Maximilian Otto Lenz,[1] Bernhard Schermer,[1] Thomas Benzing,[1] Jordan A. Kreidberg.[1] *[1]Nephrolab Cologne & Center for Molecular Medicine, Univ of Cologne, Cologne, Germany; [2]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA.*

Background: The Wilms' Tumor Suppressor protein WT1 is a key transcription factor (TF) in establishing and maintaining the podocyte pool. While it has long been known that WT1 mutations can cause FSGS, only a few targets of WT1 have been identified in podocytes. Therefore, we addressed WT1 mediated transcription by ChIPseq and mRNAseq in healthy and diseased podocytes.

Methods: ChIPseq for WT1 was carried out on wildtype kidneys. For mRNAseq, GFP was conditionally expressed in podocytes, cells were FAC-sorted from wildtype and adriamycin treated mice, and RNA was extracted.

Results: ChIPseq identified more than 14,000 WT1 peaks within the genome, located within the cis-regulatory regions (CSR) of 5,900 genes. Analysis of histone modifications found in the ENCODE database at WT1 peaks was consistent with the WT1 peaks occurring at transcription start sites (TSS), or within enhancers. While both peak clusters contained WT1 binding motifs, the enhancer cluster was enriched in motifs for TFs with known roles in podocyte speciation such as Fox-class TFs and Lmx1b, suggesting cooperation of WT1 with these TFs to establish podocyte specific gene expression. WT1 binding at TSSs resulted in higher expression levels of bound as compared to unbound genes, indicating a role of WT1 in control of podocyte specific gene expression levels. The highest expression levels were observed for a class of genes that were both, bound by WT1 at their TSS and at enhancers in their CSR. Gene ontology analysis revealed that this class of genes was enriched for hereditary podocytopathy genes, as well as genes within key components of podocytes, such as the actin cytoskeleton, slit diaphragm, and cell adhesions. Induction of podocyte damage by adriamycin resulted in differential expression of WT1 bound genes within cell adhesion pathways, identifying these pathways as novel WT1 targets in podocytes.

Conclusions: In summary, ChIPseq suggests major functions of WT1 in establishing and maintaining podocyte specific gene expression in health and disease.

Tankyrase Inhibition Reduces Elevated Total PARsylation in CD2AP Deficient Podocytes but Aggravates Kidney Injury Sanna H. Lehtonen,[1] Hong Wang,[1] Hani Suleiman,[2] Andrey S. Shaw,[2] Sara Kuusela.[1] *[1]Dept of Pathology, Univ of Helsinki, Finland; [2]Dept of Pathology & Immunology, Washington Univ School of Medicine.*

Background: Mice lacking CD2AP develop nephrotic syndrome with heavy proteinuria and effacement of podocyte foot processes.We found by yeast two-hybrid screening of a glomerular library that CD2AP interacts with tankyrase 2.Tankyrases are poly(ADPribose) polymerases that catalyze PARsylation [poly(ADP-ribosyl)ation], a post-translational modification of proteins involved in diverse cellular processes. Elevated PARsylation may be harmful for cells, as previous studies have shown increased PARsylation in the glomeruli of diabetic db/db mice. The aim of this study was to characterize the significance of tankyrase-CD2AP interaction and the PARsylation activity of tankyrases in podocyte function and injury.

Methods: The interaction of CD2AP and tankyrases was confirmed by co-immunoprecipitation and GST-pull down assays. The activity of tankyrases was blocked with a specific inhibitor, XAV-939. In zebrafish, CD2AP was knocked down with morpholino antisense oligonucleotides. Wild-type and CD2AP knockout mouse kidneys and cultured podocytes were analyzed by immunohistochemistry and colorimetric PARsylation assay. Western blotting and qRT-PCR were used for mRNA and protein expression studies.

Results: Tankyrase 1 and 2 are expressed in normal mouse and rat kidneys *in vivo*, and they form a complex with CD2AP. Tankyrase 1 is downregulated, but the posttranslational modification of both tankyrases is elevated in CD2AP-/- podocytes. Also the total PARsylation activity and the activation of beta-catenin are elevated in the absence of CD2AP, and both can be reduced by treatment with XAV-939. *Lef-1*, a mediator of Wnt/beta-catenin signaling pathway, is upregulated in CD2AP-/- podocytes, and surprisingly, XAV-939 treatment further upregulates *lef-1* and *pai-1*, known to associate with podocyte injury. In zebrafish, administration of XAV-939 to CD2AP-depleted larvae aggravated kidney injury and increased mortality.

Conclusions: The data indicate that maintaining the PARsylation activity of tankyrases in balance by CD2AP is essential for normal kidney function.

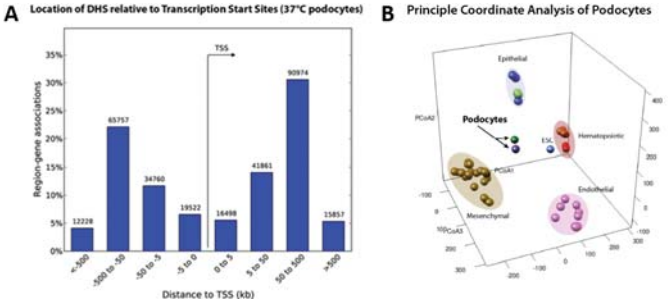
SA-OR056

Regulatory Genomics of the Glomerular Podocyte Shreeram Akilesh. *Pathology, Univ of Washington, Seattle, WA.*

Background: Understanding the genomic regulation of gene expression remains a fundamental problem in biology. As exemplified by the ENCODE project, DNaseI hypersensitivity mapping (DNaseI-seq) identifies regulatory DNA elements (e.g. promoters, enhancers, silencers) that control gene expression and thereby cell identity and their responses to external stimuli. Since these regulatory genomic maps are extremely cell-type specific, we are applying these cutting edge technologies to cultured human podocytes.

Methods: Nuclei were isolated from conditionally immortalized human podocyte cells under undifferentiated/permissive (33°C) and differentiated/non-permissive (37°C) conditions. The nuclei were digested with DNaseI and the released DNA fragments were purified and sequenced to high depth (~25 x 10^6 tags) on the Illumina HiSeq next-generation sequencing platform. The sequenced tags were mapped back to the human genome to generate per-nucleotide cleavage frequency maps across the genome. Data processing was performed using the open-source BEDOPS suite, AWK and R.

Results: DNaseI-seq on cultured podocytes identified 195027 (33°C) and 171397 (37°C) DNaseI hypersensitive sites (DHS) respectively. ~88% of these DHS map to distal regulatory DNA elements >5kb from known gene transcription start sites (TSS) (Fig. 1A). Principle coordinate analysis (PCoA) reveals that podocytes cluster in a previously unseen position between epithelial and mesenchymal cell lines, consistent with their developmental origin (Fig. 1B). Examining enrichment of transcription factor binding motifs within the regulatory DNA landscape of "differentiated" podocytes reveals significant emphasis of POU- and FOX-family transcription factors.



Conclusions: DNaseI-seq is an exceptional tool to study genome regulation. Additional experiments and analyses are in progress which are revealing novel insights into the genomic biology of podocytes and other kidney cells.

Glomerular Endothelial Cells Form a Functional Syncytium for Calcium Signals Upon Injury – A Multiphoton In Vivo Study Julia Binz, Matthias Hackl, Bernhard Schermer, Thomas Benzing. *Dept II of Internal Medicine and Center for Molecular Medicine Cologne, Univ of Cologne, Cologne, Germany.*

Background: In the renal glomerulus different cell types are located in close proximity and crosstalks, e.g. between podocytes and endothelial cells, have been reported. However the communication between neighboring endothelial cells and their crosstalk with other cell types is incompletely understood. Recently *in vivo* intra-vital imaging of mouse glomeruli has been established, which allows to study cell-cell interactions in the intact kidney.

Methods: 4 weeks old mice expressing the calcium indicator GCaMP3 specifically in endothelial cells (via Tie2:cre) were anaesthetized, an arterial catheter was placed into the right carotid artery and the left kidney was exteriorized for *in vivo* multiphoton microscopy. Blood vessels were labelled by injection of 70 kDa Texas Red dextrane. Acute endothelial injury was induced during by zooming in on a capillary loop on the outside of a glomerulus to cause a localized injury with the laser. The resulting calcium response was recorded with in a time series of the glomerulus including surrounding vessels.

Results: Upon laser induced injury of a capillary loop, a strong calcium response is rapidly propagated across the entire glomerulus extending out to endothelial cells in the afferent and efferent arterioles. At the area surrounding the point of laser damage we observed a sustained elevation of intracellular calcium levels in injured cells. From those injured cells a short calcium wave was periodically propagated towards the vascular stalk and further to the afferent/efferent arteriole.

Conclusions: Glomerular endothelial cells might act as a functional syncytium and propagate a calcium response after injury to every glomerular endothelial cell. The almost instantaneous calcium increases in neighboring cells, which quickly returned to baseline suggest the involvement of gap junctions or the existence of a short-lived local mediator. The periodical waves originating from injured areas suggest that endothelial cells can be repeatedly stimulated.

PiT-1 Signaling through ERK1/2 Promotes Smooth Muscle Cell Osteochondrogenic Phenotype Change and Calcification Nicholas W. Chavkin, Cecilia M. Giachelli. *Bioengineering, Univ of Washington, Seattle, WA.*

Background: Vascular calcification (VC) is prevalent in chronic kidney disease and elevated serum inorganic phosphate (Pi) is a recognized risk factor. Elevated Pi induces vascular smooth muscle cell (VSMC) calcification by a process that requires the Pi transporter, PiT-1. However, Pi-induced osteochondrogenic (OC) phenotype change and calcification occur at concentrations much greater than the Km of Pi transport, suggesting novel Pi transport-independent signaling functions of PiT-1. We tested this possibility using engineered phosphate uptake-deficient PiT-1 mutants.

Methods: Site-Directed mutagenesis was used to create E74K, S132A, and S623A mutations in PiT-1. VSMCs lacking PiT-1 were isolated from PiT-1 deficient mice and stably transduced with wild type (WT) or mutated PiT-1 retroviral constructs. Q-PCR confirmed mRNA expression and immunofluorescence confirmed membrane localization. Pi uptake, ERK1/2 phosphorylation, and calcification were quantitated.

Results: Sodium-dependent Pi uptake kinetic constant, Vmax, was increased in VSMCs transduced with WT PiT-1 (0.91±0.07pmol/ug*min) but not PiT-1-E74K (0.30±0.04pmol/ug*min) compared to vector control (0.41±0.04pmol/ug*min). Elevated Pi induced ERK1/2 phosphorylation in VSMCs overexpressing either WT PiT-1 (1.30±0.17-fold) or Pi uptake deficient PiT-1-E74K (1.30±0.06-fold), compared to vector control (0.83±0.06-fold). OC differentiation as measured by reduced SM22α and increased osteopontin RNA, respectively, was similar in WT PiT-1 VSMCs (0.21±0.06-fold, 14.3±5.1-fold) and PiT-1-E74K VSMCs (0.25±0.02-fold, 21.5±3.8-fold), and greater than vector control (0.98±0.18-fold, 1.9±0.6-fold). WT PiT-1 VSMCs showed higher calcification (1042±81ug Ca/mg protein) than PiT-1^{-}-E74K VSMCs (503±62ug Ca/mg protein), and both were higher than vector control VSMCs (297±30ug Ca/mg protein).

Conclusions: PiT-1 signals ERK1/2 phosphorylation and downstream phenotype change via a pathway that does not require phosphate uptake. On the other hand, Pi uptake through PiT-1 was required for maximal VSMC calcification. These data suggest that both phosphate-uptake dependent and –independent functions of PiT-1 are important for VSMC calcification.

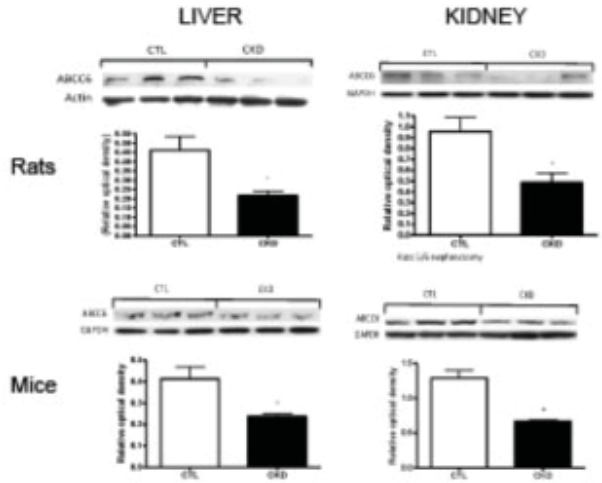
Chronic Kidney Disease Results in Deficiency of ABCC6, the Novel Inhibitor of Vascular Calcification Shuman Liu, Wei Ling Lau, Nosratola D. Vaziri. *Div of Nephrology, UC Irvine.*

Background: Chronic kidney disease (CKD) is associated with arterial medial calcification which plays a major role in the pathogenesis of cardiovascular disease in this population. Several factors are known to promote soft tissue and accelerated arterial calcification in CKD including systemic inflammation, altered calcium and phosphate homeostasis, hypertension, and deficiency of endogenous calcification inhibitors. The ABCC6 transporter(ATP-binding cassette subfamily C number 6), also known as multidrug resistance-associated protein 6 (MRP6), is highly expressed in the liver and kidney. Mutation of *ABCC6* results in pseudoxanthoma elasticum, an inherited disorder characterized by arterial and soft tissue calcification. Given the prevalence of arterial medial calcification in CKD, the present study was undertaken to test the hypothesis that CKD may lead to acquired ABCC6 deficiency.

Methods: CKD was induced via 5/6 nephrectomy in male Sprague-Dawley rats and by adenine-containing diet to cause chronic interstitial nephropathy in female DBA/2J mice. Sham-operated rats and mice fed regular diet served as controls. Liver and kidney tissues were harvested and processed for ABCC6 protein and mRNA analysis.

Results: ABCC6 protein levels were significantly reduced in the liver and kidney tissues from CKD rats and mice (* $P < 0.05$ compared to CTL). However, ABCC6 mRNA levels were unchanged, pointing to post-transcriptional or post-translational mechanisms for the observed ABCC6 deficiency. Additionally, plasma levels of the calcification inhibitor fetuin-A were significantly decreased in CKD (20.1 + 1.6 mg/L) animals compared to controls (24.8 + 1.1 mg/L, P = 0.03).



Conclusions: CKD results in acquired ABCC6 transporter deficiency. To our knowledge this abnormality has not been previously reported and may contribute to CKD-associated vascular and soft tissue calcification.

SA-OR060

Dietary Protein Restriction Induces Inflammation and Malnutrition, and Exacerbates Vascular Calcification in Uremic Rats with Hyperphosphatemia Shunsuke Yamada,[1] Masanori Tokumoto,[1] Narihito Tatsumoto,[2] Hiroaki Ooboshi,[1] Takanari Kitazono,[2] Kazuhiko Tsuruya.[3] *[1]Div of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka, Japan.*

Background: Dietary protein (Pr) restriction and use of phosphate (Pi)-binder are the two mainstay treatments for hyperphosphatemia in CKD patients. Dietary Pr restriction has the harmful potential to develop malnutrition in CKD patients. However, the differential effects between Pi-binder use and dietary Pr restriction on the inflammation, malnutrition, and vascular calcification have not been fully investigated.

Methods: To compare the effects of dietary Pi and Pr contents on inflammation, malnutrition, and vascular calcification in the uremic model, five groups of rats were fed adenine-containing diets with different combination of Pi and Pr contents for six weeks; high Pi (1.2%), low Pi (0.3%), normal Pr (19%), and low Pr (9.5%). Urine, serum, and tissue samples (aorta, muscle, and liver) were examined at 6 week. Serum biochemistries, serum inflammatory markers, and aortic calcium content were determined.

Results: Rats fed low-Pr diets reduced body weight, muscle mass and serum albumin level, with increased serum inflammatory markers, independent of the dietary Pi loading. High dietary Pi loading induced vascular calcification (increased aortic calcium content), which was enhanced by low-Pr diet. Pi-binder (lanthanum carbonate) reversed all the changes observed in rats fed high Pi and low Pr diets. However, Pr-restriction under low Pi diet did not induce vascular calcification, indicating that malnutrition and inflammation do not cause vascular calcification when high Pi loading is absent.

Conclusions: Dietary Pr restriction induces inflammation and malnutrition independent of Pi loading, and exacerbates vascular calcification under high Pi loading, suggesting that Pi-binder use is more ideal than dietary Pr restriction for the management of patients with CKD.

SA-OR061

Angiopoietin-2 Accelerates Vascular Calcification in Children with Chronic Kidney Disease Undergoing Dialysis Alexandra F. Todd,[1] Karen Price,[1] Maria K. Joannou,[1] Lesley Rees,[2] Rukshana Shroff,[2] David A. Long.[1] *[1]Developmental Biology and Cancer, UCL Inst of Child Health, London, United Kingdom; [2]Renal Unit, Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom.*

Background: Cardiovascular disease (CVD) manifested by calcification is the major cause of mortality in childhood chronic kidney disease (CKD). One of the earliest signs of CVD is disruption to the endothelium which may result from the imbalance of vascular growth factors seen in CKD. Our previous work showed that circulating levels of angiopoietin-2 (Angpt2) - a pro-inflammatory and anti-angiogenic molecule were dramatically increased in children on dialysis. However, whether Angpt2 mediates vascular calcification or is simply a marker of disturbed angiogenesis is yet to be established.

Methods: Muscular arteries were obtained from children undergoing renal transplantation and non-renal patients undergoing intra-abdominal surgery. 1-2 mm wide arterial rings were culture in high calcium and phosphate milieu with/without 25 ng/ml of Angpt2, the highest concentration of measured previously in dialysis serum.

Results: Rings from healthy controls and pre-dialysis patients did not calcify when exposed to pre-calcaemic media with/without Angpt2; in contrast, dialysis rings showed increased calcium content which was significantly enhanced in the presence of Angpt2 ($p<0.04$). Cells explanted from tunica media of dialysis patients also exhibited a significantly increased calcium load following exposure to pre-calcaemic media ($p<0.03$) which was exaggerated with the addition of Angpt2. Angpt2 exposure led to an increase in mRNA levels of the osteogenic marker bone morphogenic protein-2, and decreased levels of matrix-gla protein, a physiological calcification inhibitor. The angiopoietin receptor, Tie-2, was detected by immunohistochemistry and Western blotting on vessel rings and cultured dialysis cells respectively.

Conclusions: Angpt2 accelerated vascular calcification in vessel rings and cultured cells obtained from children with CKD undergoing dialysis, an effect which may be mediated by Tie-2. Modulation of angiopoietins may provide future therapeutic targets to slow vascular calcification in CKD patients.

Matrix Metalloproteinases Promote Uremic Vascular Calcification Uwe Querfeld,[1,2] Eva Hecht,[2] Christian Freise,[2] Karoline Websky,[2] Berthold Hocher.[3] *[1]Pediatric Nephrology, Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Center for Cardiovascular Research, Charité Universitätsmedizin Berlin, Berlin, Germany; [3]Institut für Ernährungsforschung, Potsdam, Germany.*

Background: Proteolytic matrix metalloproteinases (MMPs) degrade extracellular matrix proteins and have important physiological roles in tissue remodeling, including bone and vascular tissues. Increased MMP activity is associated with several cardiovascular diseases. We studied (1) the presence of MMP-2 and MMP-9 in aortas of uremic rats with calcitriol-induced vascular calcifications and (2) the effect of MMP-2 and MMP-9 in an ex-vivo model of calcium/phosphate induced calcifications in aortas of uremic mice.

Methods: (1) Aortas from sham-op, 5/6-nephrectomized (5/6-Nx) and 5/6-Nx + calcitriol-treated rats were immunhistologically stained for MMP-2 and MMP-9. (2) 5/6-Nx C57BL/6 mice, known to be highly calcification-resistant, were sacrificed after 8 weeks, the aortas were dissected and cultured at 37°C in a calcifying medium containing 2.7 mM calcium und 2.0 mM phosphate, with or without addition of recombinant MMP-2 or -9 or the MMP inhibitor doxycycline. Histological evaluation of the aorta sections for media calcification was performed after 21 days.

Results: An increased presence of MMP-2 was found in the media of uremic (compared to sham-operated) rat aortas, and this was significantly enhanced by calcitriol treatment. Explanted uremic mice aortas but not aortas from normal control mice were susceptible to calcifications induced by a calcifying medium. The addition of MMP-2 or MMP-9 strongly enhanced these calcifications in aortas from uremic and to a lesser extent, even normal mice. In contrast, calcifications were not found in uremic mice aortas treated with doxycycline in spite of calcifying conditions in the medium.

Conclusions: The presence of MMP-2 parallels increases in the formation of media calcifications in a rat model of calcitriol-induced vascular calcifications in uremic rats. Under calcifying conditions, addition of these proteolytic enzymes induces calcification in ex-vivo cultured aortas of mice, whereas their inhibition prevents calcification, indicating that MMP-2 -9 impact the pathophysiology of arterial calcification.

SA-OR063

Chronic Kidney Disease (CKD) Stimulates Activin and Endothelial to Mesenchymal Transition (EnMT), which Causes Vascular Calcification and Is Inhibited by an Activin Ligand Trap Keith A. Hruska,[1] Olga A. Agapova,[1] Yifu Fang,[1] Toshifumi Sugatani,[1] Michael E. Seifert,[2] Victoria Sung.[3] *[1]Pediatrics, Washington Univ School of Medicine, St. Louis, MO; [2]Pediatric Nephrology, Southern Illinois Univ, Springfield, IL; [3]Translational Development, Celgene, San Francisco, CA.*

Background: We have shown that kidney diseases cause vascular calcification by producing systemic Wnt inhibition during kidney repair. We show that the vascular effects of CKD stimulated Wnt inhibition are stimulation of vascular activin as well as induction of Smad dependent EnMT, and that an activin receptor ligand trap, inhibits EnMT and vascular calcification.

Methods: CKD with elevated Wnt inhibitors was induced in the mouse models for lineage tracing and vascular calcification. Activin, Follistatin and Inhibin levels were measured by Elisa, RT-PCR and westerns. Cell lineage tracing was performed in GNZ mice (Stoller et al, Genesis, 2008) bred to endothelial specific Tie2-Cre mice. Mice harboring knock in of GNZ express nuclear GFP and *lacZ* following Cre-mediated recombination.

Results: Activin levels were increased in the vasculature and the circulation without changes in follistatin levels in mouse models of kidney disease and CKD stimulated vascular calcification. CKD induced expression of GFP and lacZ in cells of the adventia and media of GNZ;Tie2-Cre CKD mice compared to GNZ ;Tie2-Cre mice with normal kidney function wherein the GFP and lacZ were limited to the aortic endothelium. Tie2 is an endothelial lineage specific receptor, and this demonstrates that CKD induces aortic EnMT. CKD stimulated aortic EnMT produced decreased vascular smooth muscle function, osteoblastic transition and calcification. Treatment with an activin receptor type 2A (ActR2A) ligand trap, RAP-011, inhibited Smad dependent signaling, blocked aortic osteoblastic transition, increased vascular smooth muscle function and decreased CKD stimulated vascular calcification.

Conclusions: CKD induced vascular activin and EnMT, and RAP-011 decreased activin signaling inhibiting vascular dedifferentiation, osteoblastic transition and vascular calcification.

SA-OR064

Warfarin Promotes Medial Vascular Calcification in Humans Ekamol Tantisattamo, Kum Hyun Han, W. Charles O'Neill. *Renal Div, Emory Univ.*

Background: Matrix gla-protein is a vitamin K-dependent inhibitor of vascular calcification. Genetic deficiency or inhibition with warfarin produces medial vascular calcification in animals but whether this occurs in humans is unclear. As breast arterial calcification(BAC) is exclusively medial, readily identified on screening mammograms(MG), and correlates with peripheral arterial calcification, we compared the prevalence of BAC in patients with and without warfarin therapy.

Methods: A computerized search of medical records from 2011 through 2013 yielded 16,555 patients with screening MG in whom warfarin was listed as a medication in 790. After exclusion of patients with warfarin exposure <1 month, history of ESRD, or serum creatinine ≥2.0, 453 patients were individually matched to subjects without warfarin exposure based on age and diabetes. MG were reviewed visually for BAC.

Results: Mean age was 68±0.6 and 30% had diabetes. The indication for warfarin was atrial fibrillation in 42% and venous thrombosis or embolism in 47%, and mean duration of warfarin was 4.6 yrs (range:0.1 - 39). 219 patients were on warfarin at the time of the MG and the remainder had been off warfarin for a mean of 2.7 yrs (range:0.003 - 11). Serum creatinine was slightly higher (0.91 versus 0.86,$p=0.0015$) and serum calcium was slightly lower (9.29 versus 9.39,$p=0.0005$) in the warfarin patients while serum phosphate did not differ. Prevalence of BAC was 50% greater in warfarin patients (39% versus 26%,$p<0.0001$) but not on MG performed prior to warfarin (27% versus 27%, mean 0.76 yrs), indicating that the increase was due specifically to the warfarin and not to underlying disease or other patient characteristics. The increase correlated with duration (25%, 67%, and 74% at <1, 1 to 5, and >5 yrs) and was greatest (5-fold) in patients under age 60 (12% versus 2.3 %,$p=0.006$). Among warfarin users, age ($p<0.00001$) and warfarin duration ($p=0.003$), but not warfarin indication or duration off warfarin were determinants of BAC in a logistic regression model.

Conclusions: Although limited to women, the results indicate that warfarin is strongly associated with medial arterial calcification independent of other patient characteristics. This effect is cumulative and not reversed when warfarin is discontinued.

SA-OR065

Blood Calcification Propensity and Cardiovascular Events in Hemodialysis Patients in the EVOLVE Trial Andreas Pasch,[1] Matthias Bachtler,[1] Edward Robert Smith,[2] Willi Jahnen-Dechent,[3] Spyridon Arampatzis,[1] Glenn M. Chertow,[4] Patrick S. Parfrey,[5] Yumi Kubo,[6] Jürgen Floege.[3] *[1]Univ Hospital Bern; [2]Royal Melbourne Hospital; [3]RWTH Aachen Univ Hospital; [4]Stanford Univ School of Medicine; [5]Memorial Univ; [6]Amgen Inc.*

Background: Hemodialysis (HD) patients are prone to suffer cardiovascular events. A recently developed novel blood test (T_{50}) determines the individual calcification propensity of blood, where a lower T_{50} reflects a greater tendency towards mineralisation. Whether T_{50} is associated with CV events in HD patients is not known.

Methods: T_{50} was determined in 2,785 baseline serum samples from the Evaluation of Cinacalcet Therapy to Lower Cardiovascular Events (EVOLVE) trial, a study investigating the effect of cinacalcet in HD patients with secondary hyperparathyroidism (sHPT). The associations of T_{50} with the primary composite endpoint (all-cause mortality, myocardial infarction [MI], hospitalization for unstable angina, heart failure, or peripheral vascular event) and its individual components were analyzed.

Results: The mean ± SD calcification propensity T_{50} in the EVOLVE baseline sera was 216 ± 84 min. and was closely related to serum albumin ($p<0.001$) and inversely to serum phosphorus ($p<0.001$). Using multivariate Cox regression models adjusted for patient characteristics, CV morbidities, and baseline labs, lower T_{50} was independently associated with an increased risk of the primary composite endpoint both as continuous (adjusted HR 1.09 [95% CI 1.03, 1.17], $p=0.005$ per 1 SD decrease) and categorical measures (1st tertile, HR 1.25 [1.08, 1.45], $p=0.003$; 2nd tertile, HR 1.09 [0.95, 1.26], $p=0.229$; 3rd tertile, reference). Furthermore, lower T_{50} was associated with an increased risk in MI both as continuous (adjusted HR 1.31 [95% CI 1.12-1.52], $p<0.001$ per 1 SD decrease)

and categorical measures (1st tertile, HR 1.60 [1.14, 2.24], p=0.006; 2nd tertile, HR 1.10 [0.78, 1.54], p=0.591; 3rd tertile, reference). No association was observed between T50 and the other components.

Conclusions: T_{50} was independently associated with the primary composite endpoint and with MI in the EVOLVE trial. Whether an intervention that alters T_{50} will have an impact on CV events remains to be proven.

Sodium Thiosulfate and Co-Treatments for Calcific Uremic Arteriolopathy

Sagar U. Nigwekar,[1] Ann Mooney,[2] Jeffrey L. Hymes,[1] Debra Meade,[2] Cindy A. Premo,[2] Kevin Chan,[1,2] Franklin W. Maddux,[2] Ravi I. Thadhani.[1] *[1]MGH; [2]FMCNA.*

Background: Intravenous sodium thiosulfate (STS) and a variety of co-treatments have been proposed to treat calcific uremic arteriolopathy (CUA); however, prospective phase 4 evaluation is lacking.

Methods: Our prospective cohort included 451 chronic hemodialysis patients with CUA treated with STS. Data regarding STS, co-treatments, CUA lesion status, and mortality were derived from surveys sent to treating physicians at STS initiation (baseline) and at 3-month follow-up. Demographic, clinical and laboratory data were abstracted from clinical information systems. Outcomes were CUA lesion status and mortality at follow-up. Logistic regression analyses were conducted to identify whether co-treatments predict a favorable response to STS (defined as lesion stabilization, improvement, or resolution).

Results: Mean age (± standard deviation) was 59 ± 13 years. At baseline, mean serum calcium 8.0 ± 1.7 mg/dL, phosphorous 5.3 ± 1.5 mg/dL, parathyroid hormone 464 ± 446 pg/mL, and albumin 3.3 ± 0.8 g/dL were noted. Positive response to STS was observed in 49%; 12% died and 39% had deteriorated at follow-up. Co-treatments and their association with positive response to STS are tabulated.

Co-treatment	Frequency (%)	Univariate	Multivariable
		Odds ratio (95% Confidence Intervals)	Odds ratio (95% Confidence Intervals)
Cinacalcet	51	14.35 (5.77-35.70)	4.64 (1.45-14.84)
Sevelamer hydrochloride or servelamer carbonate	45	1.10 (0.52-2.33)	1.02 (0.35-2.97)
Calcium acetate	23	2.46 (0.22-27.94)	1.70 (0.07-25.12)
Lanthanum carbonate	10	2.59 (0.61-10.94)	1.25 (0.17-9.33)
Vitamin D therapy discontinuation	42	0.64 (0.30-1.37)	0.97 (0.32-2.94)
Parathyroidectomy	12	1.02 (0.39-2.64)	1.37 (0.27-6.93)
Increased dialysis	27	1.91 (0.84-4.36)	1.53 (0.44-5.27)
Lower calcium bath	33	1.48 (0.68-3.26)	1.31 (0.44-3.94)
Wound care/debridement	68	0.76 (0.26-2.18)	0.44 (0.15-1.31)

In univariate and multivariable (adjusted for demographics, co-morbidities, and laboratory parameters) analyses, cinacalcet co-treatment was associated with a favorable response to STS.

Conclusions: Majority of CUA patients treated with STS and various co-treatments do not improve. Novel therapies and pragmatic clinical trials are needed.

Vascular Protective Effect of Spironolactone on Arterial Medial Calcification in Adenine-Induced Chronic Kidney Disease Rats

Narihito Tatsumoto,[1] Shunsuke Yamada,[1,3] Masanori Tokumoto,[3] Kazuhiko Tsuruya,[1,2] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Dept of Internal Medicine, Fukuoka Dental College Medical and Dental Hospital, Fukuoka, Japan.*

Background: Vascular calcification is highly prevalent in patients with chronic kidney disease (CKD) and is closely linked to increased cardiovascular diseases. Studies have shown that spironolactone (SPL), a mineralocorticoid receptor antagonist, has protective effects on cardiovascular systems through suppression of osteoinductive signaling and oxidative stress. However, the impact of SPL on vascular calcification in CKD remains unclear.

Methods: The present *in vivo* study determined the effect of SPL on arterial medial calcification (AMC) in CKD rats fed diets containing 0.3% adenine, 1.2% phosphate, and different concentrations of SPL of 0 mg/kg (CKD-SPL0), 25 mg/kg (CKD-SPL25), 50 mg/kg (CKD-SPL50), or 100 mg/kg (CKD-SPL100) for 8 weeks. We also examined the effect of late treatment with SPL on AMC in CKD rats using adenine-fed CKD rats treated with 100 mg/kg SPL for only the last 2 weeks of the 8-week study period (CKD-SPL100L). Blood pressure levels and urinary chemistries were determined periodically, and tissues and blood samples were collected at week 8.

Results: CKD-SPL0 rats developed hyperphosphatemia and AMC at week 8. Treatment with SPL dose-dependently decreased serum phosphate level and calcium content in the aorta in CKD-SPL50 and CKD-SPL100 rats, in parallel with SPL dose-dependent improvement in kidney function. SPL did not influence the levels of blood pressure and serum potassium. Although the degrees of kidney function and hyperphosphatemia were comparable among CKD-SPL0, CKD-SPL25, and CKD-SPL100L rats, AMC in the latter two groups were attenuated in comparison with CKD-SPL0 rats, suggesting the additional effect of SPL on AMC beyond improvement of kidney function.

Conclusions: SPL can attenuate AMC in CKD rats, by a direct vascular protective effect in addition to an indirect effect through improving kidney function.

Focal Segmental Glomerulosclerosis Exomes Reveal Candidate Variants Highly Enriched in Cell Movement and Cell Adhesion-Related Genes

Jung Hee Suh,[1] Giulio Genovese,[1,2] Victoria Charoonratana,[1] Andrea Knob,[1] Martin R. Pollak.[1,2] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Broad Inst, Cambridge, MA.*

Background: In the past two decades, the findings of focal segmental glomerulosclerosis (FSGS)-causing genes established that genetic components contribute to the development of FSGS. However, the underlying genetic cause is unknown in a majority of families, even when there is strong evidence of inheritance. We analyzed the exomes of families and sporadic cases that have not been explained by known FSGS genes in an extended effort to find the genes responsible for the development of FSGS.

Methods: We performed exome sequencing on 403 probands from 311 familial and sporadic cases of FSGS. We also sequenced 96 unaffected family members. After variant-calling, variants were filtered against common variants that were not known to cause FSGS from the 1,000 Genomes Project, dbSNP, and the Exome Sequencing Project. Novel non-synonymous or splice variants were kept.

Results: Exome analysis revealed that 30.3 percent of all cases contain known FSGS-causing variants, with these variants accounting for 47.9 percent of familial cases and 16.0 percent of sporadic cases. After excluding explained cases, we filtered genes showing more than four novel non-synonymous or splice variants, and grouped genes according to 1) their cellular component, molecular function, and biological process using AmiGO2, a gene ontology service, and 2) their protein-protein interaction using DAPPLE. GO terms of genes from unexplained cases were significantly enriched in cellular component movement and cell adhesion: both had p-values less than 0.0001. DAPPLE results consistently showed two big protein-protein interaction networks, one involving cell movement and the other involving cell adhesion.

Conclusions: Here we show that, in comparison to familial cases, sporadic FSGS cases are less explained by known FSGS-causing genes. These data show that novel non-synonymous or splice variants are highly enriched in cell movement- and cell adhesion-involved genes in the exomes of FSGS patient samples, suggesting the importance of podocyte movement and interaction with neighboring cells and the extracellular matrix.

KANK Deficiency Leads to Defective Podocyte Function

Heon Yung Gee,[1] Fujian Zhang,[2] Shazia Ashraf,[1] Stefan Kohl,[1] Carolin Sadowski,[1] Svjetlana Lovric,[1] Zhe Han,[2] Friedhelm Hildebrandt.[1,3] *[1]Div of Nephrology, Boston Children's Hospital/Harvard Medical School, Boston, MA; [2]Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI; [3]Howard Hughes Medical Inst, Chevy Chase, MD.*

Background: KANK proteins (KANK1~4) are characterized by conserved ankyrin-repeat and coiled-coil domains, and a motif (KN motif) at the N-terminus containing motifs for nucear localization and export signals. The *KANK* familly genes are highly expressed in kidney, however, their roles in kidney is not known.

Methods: To search for disease-causing mutations in more than 200 individuals with nephrotic syndrome (NS), we performed homozygosity mapping (HM) and whole exome sequening (WES). The function and localization of KANK proteins were examined in *Drosophila* cardiac nephrocytes, zebrafish, cultured podocytes and rat kidney tissues.

Results: By HM and WES in individuals with NS, we identified recessive mutations in *KANK1* (p.E454K), *KANK2* (p.S181G and p.S684F) and *KANK4* (p.Y801H). Independently, by a functional genetic screen using *Drosophila* cardiac nephrocytes, which are equivalents of mammalian podocytes, we identified *dKank* which is essential for nephrocyte function. RNAi knockdown of *dKank* in nephrocytes led to disrupted slit diaphragm structures, abnormal lacunae structures, as well as a wave-shaped plasma membrane. Intestingly, knockdown of *kank2* in zebrafish recapitulated a human NS phenotype and resulted in edema and proteinuria. Transmission electron microscopy of *kank2* morpants showed podocyte foot process effacement and disorganized slit membranes in glomeruli. In addition, KANK1, KANK2 and KANK4 localize to podocytes in rat glomeruli and KANK1 partially colocalizes with SYNAPTOPODIN. We show by coimmunoprecipitation and GST pulldown that KANK2 interacts with ARHGDIA, of which mutations cause NS and which regulates RHO GTPases in podocytes. In addition, KANK1 regulates RHOA through the interaction with 14-3-3 protein.

Conclusions: These data suggest that *KANK* muations may cause NS and the *KANK* family genes play evolutionarily conserved roles in podocyte cytoskeleton structures and function, likely through regulating RHO GTPase signaling in podocytes.

***NUP93* and *NUP205*, which Encode for Nuclear Pore Complex Proteins, Are Mutated in Individuals with Nephrotic Syndrome**

Stefan Kohl,[1] Carolin Sadowski,[1] Svjetlana Lovric,[1] Shazia Ashraf,[1] Werner Pabst,[1] Heon Yung Gee,[1] Daniela A. Braun,[1] Wolfram Antonin,[3] Friedhelm Hildebrandt.[1,4] *[1]Dept of Medicine, Boston Children's Hospital/Harvard Medical School, Boston, MA; [2]Friedrich Miescher Laboratory of the Max Planck Society, Tuebingen, BW, Germany; [3]Howard Hughes Medical Inst, Chevy Chase, MD.*

Background: Steroid resistant nephrotic syndrome (SRNS) is the 2nd most frequent cause of end-stage kidney disease (ESKD) in the first two decades of life. Identification of single-gene causes of SRNS has furthered the understanding of its pathogenesis. However, additional genes and disease mechanisms remain unknown.

Methods: We performed homozygosity mapping and whole exome sequencing (WES) in 100 individuals with SRNS. To identify additional families with mutations in potential SRNS-causing genes, we screened our cohort of ~800 individuals with SRNS by microfluidic multiplex PCR and next generation sequencing (NGS). Immunofluorescence microscopy (IF) was done using a Leica SP5X system.

Results: In 6 individuals with SRNS from 4 consanguineous families, we detected by WES homozygous missense mutations in the genes *NUP93* (3 families) and *NUP205* (1 family), which encode for directly interacting components of the nuclear pore complex. Subsequent high throughput mutation analysis of ~800 individuals with SRNS revealed 3 additional families with compound heterozygous mutations in *NUP93*. The 6 different mutations were either nonsense mutations (n=2) or conserved missense mutations (n=4). The *NUP93* p.Y629C mutation represents a Turkish founder allele, as 2 affected individuals share haplotypes in a 3.1 Mbp segment at the *NUP93* locus. *NUP93* is expressed in podocyte precursors where it localizes to the nuclear envelope and the cytoplasm in IF. All identified patients had an early age of onset of proteinuria (median of 3 years) and most of them progressed rapidly to ESKD. Microscopic hematuria was present in 5 out of 6 patients.

Conclusions: We identify mutations in *NUP93* and *NUP205* as novel causes of SRNS. Further functional studies need to shed light on the involvement of nuclear core complex proteins in the pathogenesis of nephrotic syndrome.

Addition of Genome-Wide Linkage Analysis Is Superior to Whole-Exome Sequencing Alone for Identification of Novel Genetic Causes of Hereditary Kidney Diseases

Paul J. Phelan,[1,2] Gentzon Hall,[1,2] Andrew F. Malone,[1,2] Alison Homstad,[1] Thomas Lindsey,[1] Guanghong Wu,[1] Rasheed A. Gbadegesin,[1,3] Michelle P. Winn.[1,2] *[1]Duke Molecular Physiology Inst, Duke Univ, Durham, NC; [2]Dept of Medicine, Div of Nephrology, Duke Univ, Durham, NC; [3]Dept of Pediatrics, Duke Univ, Durham, NC.*

Background: The advent of Whole-Exome Sequencing (WES) has accelerated gene discovery in familial diseases. Despite considerable advantages, a report of WES for identification of disease-causing mutations estimated a 25% success rate in a population with suspected Mendelian disease [1]. We hypothesized the addition of genome-wide linkage analysis (GWLA) to WES would increase the efficacy of identifying disease-causing variants in patients with familial kidney diseases.

Methods: We performed WES in 35 families with inherited kidney diseases, 14 with combined GWLA. The cohort included 28 families with focal segmental glomerulosclerosis, 5 with childhood-onset steroid-resistant nephrotic syndrome and 2 with vesico-ureteric reflux.

Results: Causal gene variants were identified in 9/35 families, including 3/21 (14%) in the WES alone group and 6/14 (43%) in the GWLA plus WES group. Three of the six mutations identified with GWLA plus WES group were in novel genes whereas in the WES alone group, no novel disease-causing gene was identified. African American (AA) families had more potential disease causing pathogenic variants per exome compared to other races (1 WES per family, p=0.0262; 2 WES per family, p=0.0035) [Table] and no AA families had their causal mutation identified.

Conclusions: Significant limitations remain with the use of WES and large pedigrees are still crucial for efficient identification of single gene causes of hereditary kidney diseases.Sequencing multiple individuals by WES combined with GWLA may be required for gene discovery in Mendelian kidney disease, especially in AA families. Identification of the First Gene Mutated in Galloway-Mowat Syndrome, an Association of Early-Onset Nephrotic Syndrome and Post-Natal Microcephaly

Evelyne Huynh Cong,[1,2] Estelle Colin,[3] Geraldine Mollet,[1,2] Olivier Gribouval,[1,2] Christelle Arrondel,[1,2] Olivia Boyer,[1,2,4] Laurent Daniel,[5] Marie-Claire Gubler,[1,2] Zelal Ekinci,[6] Michel Tsimaratos,[7] Anne Moncla,[8] Dominique Bonneau,[3] Corinne Antignac.[1,2] *[1]Inserm U1163, Institut Imagine, Paris, France; [2]Univ Paris Descartes, Sorbonne Paris Cité, Paris, France; [3]Biochemistry and Genetics, Univ Hospital, Angers, France; [4]Pediatry Nephrology, Necker Hospital, AP-HP, Paris, France; [5]Pathology, Timone Hospital, AP-HM, Marseille, France; [6]Pediatric Nephrology, Univ Faculty of Medicine, Kocaeli, Turkey; [7]Pediatric Nephrology, Timone Hospital, AP-HM, Marseille, France; [8]Medical Genetics, Timone Children's Hospital, Marseille, France.*

Background: Galloway-Mowat syndrome (GMS) is a rare inherited disorder, with no causal gene reported yet, characterized by nephrotic syndrome associated with neurological impairment including post-natal microcephaly.

Results: We performed whole exome sequencing combined to homozygosity mapping in a family with 2 children harboring a GMS phenotype and identified a non-sense mutation in the *GMS1* gene that encodes a WD40 repeat–containing protein of unknown function**.** Further screening revealed an additional frame-shift mutation in an unrelated patient with GMS from a consanguineous Turkish family. We demonstrated that GMS1 is expressed in the infant brain and in fetal and adult human kidneys. In human immortalized podocytes and fibroblasts, GMS1 staining presented a weak and diffused localization within the cytoplasm during interphase and then it strongly accumulated in the microtubule asters and at the midbody during mitosis. Patient fibroblasts and GMS1-depleted podocytes displayed defects in nuclear morphology, which was associated, in patient fibroblasts, to a decrease of cell survival. Furthermore, we showed that patient fibroblasts and differentiated GMS1-depleted podocytes harbored an atypical morphology resulting from disorganized microtubule network, suggesting microtubule polymerization defects.

Conclusions: Our results point to a critical function of GMS1 in the cell survival and maintenance of cellular architecture, two crucial processes in neurons and podocytes.

Integrative Genomics Identifies Novel Associations of *APOL1* Risk Genotype in African-American NEPTUNE Subjects

M. Sampson,[1] Laura H. Mariani,[1] Sebastian Martini,[1] Kevin V. Lemley,[2] C. Gillies,[1] Peter X.K. Song,[1] J. Troost,[1] Matthias Kretzler,[1] John R. Sedor.[3] *[1]U. of Michigan; [2]Children's Hosp LA-USC; [3]MetroHealth-Case Western Reserve Univ.*

Background: To gain new knowledge of *APOL1*-associated nephrotic syndrome, we co-analyzed clinical and genomic datasets from 87 African-Americans in the Nephrotic Syndrome Study Network (NEPTUNE), stratified by *APOL1* risk genotype.

Methods: Adults and children were enrolled at time of first biopsy for proteinuria, histologically classified, and followed longitudinally. We genotyped *APOL1* G1 and G2 risk alleles (RA) and sequenced 18 Mendelian FSGS genes. Analyses used a recessive model to compare those with "high-" versus "low-risk" genotype (2 versus 0/1 RA). We compared characteristics at presentation and multivariate longitudinal models of eGFR, proteinuria, and complete remission (CR). Genome-wide gene expression profiles were obtained from the research biopsy of 26 patients. Transcripts with expression highly correlated with either high- and low-risk *APOL1* mRNA levels were defined and analyzed. Glomerular density and volume and tubulointerstitial (TI) fibrosis were measured with morphometry.

Results: High-risk histologic groups were FSGS(62%), MCD(15%), MN(5%), and "Other"(18%). At baseline, risk groups did not differ in age, immunosuppression, RAS blockade, or hypertension. High-risk individuals had **3.8 higher odds of prematurity**(CI 1.0-13.5 p<0.05). Over time, independent of histologic diagnosis, they had 17ml/min lower eGFR(p<0.01), more proteinuria(p<0.05) and were **2.3x less likely to achieve CR** (CI 1.0-5.3,p<0.05). There was no monogenic NS in high-risk subjects. *APOL1* expression in each risk-genotype group was correlated with expression of distinct transcripts ("low":407 genes, "high":172, shared:7). The top functional concepts of high-risk *APOL1*-correlated genes were **leukocyte activation and migration**. High-risk patients had increased TI fibrosis(23 versus 16%, p<0.05).

Conclusions: Using integrative genomics, we show high-risk genotype subjects have increased prematurity, worse clinical outcomes, and increased interstitial scarring. Intrarenal expression analysis shows the high-risk genotype distinctly associated with inflammatory responses NEPTUNE:U54DK083912.

Mutations of the SLIT2-ROBO2 Pathway Genes SLIT2 and SRGAP1 Cause Congenital Anomalies of the Kidney and Urinary Tract Daw-Yang Hwang,[1,10] Stefan Kohl,[1] Xueping Fan,[2] Asaf Vivante,[1] Stefanie Chan,[2] Gabriel C. Dworschak,[1] Heon Yung Gee,[1] Christoph Schell,[4] Tobias B. Huber,[4] Heiko M. Reutter,[3] Neveen Soliman,[5] Radovan Bogdanovic,[6] Elijah O. Kehinde,[7] Richard P. Lifton,[8,11] Velibor Tasic,[9] Weining Lu,[2] Friedhelm Hildebrandt.[1,11] *[1]Boston Children's Hospital, Harvard Medical School; [2]Boston Univ Medical Center; [3]Univ of Bonn, Germany; [4]Univ Hospital Freiburg, Germany; [5]Kasr Al Ainy School of Medicine, Cairo Univ, Egypt; [6]Univ of Belgrade, Serbia; [7]Kuwait Univ, Kuwait; [8]Yale Univ; [9]Univ Children's Hospital, Skopje, Macedonia, The Former Yugoslav Republic of; [10]Kaohsiung Medical Univ Hospital, Taiwan; [11]Howard Hughes Medical Inst.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) account for 50% of chronic kidney disease that manifests in the first two decades of life. The wide range of structural malformations results from developmental defects of the kidneys and the urinary tract. Thus far, 31 monogenic causes of isolated CAKUT are known, explaining ~12% of cases.

Methods: To identify additional single-gene causes of CAKUT, we conducted whole exome sequencing in 20 unrelated individuals with CAKUT. In addition we performed high-throughput exon sequencing in a cohort of 749 individuals with CAKUT.

Results: We detected two heterozygous mutations in SRGAP1 in two unrelated families. We examined the candidate gene SLIT2 for mutations in cohort of 749 individuals with CAKUT and identified three unrelated individuals with heterozygous mutations. We showed that SRGAP1 is expressed in early mouse nephrogenic mesenchyme and coexpressed with ROBO2 in SIX2-positive nephron progenitor cells of the cap mesenchyme in developing rat kidney. The newly identified mutations in SRGAP1 lead to an augmented inhibition of RAC1 in HEK293T cells and the SLIT2 mutations compromise the ability of the SLIT2 ligand to inhibit cell migration.

Conclusions: We discovered two novel monogenic causes of isolated CAKUT in humans, emphasizing the importance of SLIT2-ROBO2-SRGAP1 signaling in human kidney development.

SA-OR075

Anti-miR-21 as a Potential Novel Therapy for Both Early and Late Stages of Alport Syndrome Joseph H. Boulanger,[1] Wenping Song,[1] Shweta Pandya,[2] Kelly A. Rogers,[1] Lucy A. Phillips,[1] Deidre Mackenna,[2] Rachel Yabkowitz,[1] Oxana Beskrovnaya,[1] Steven R. Ledbetter,[1] Shiguang Liu.[1] *[1]Genzyme, A Sanofi Company, Framingham, MA; [2]Regulus Therapeutics, San Diego, CA.*

Background: Alport syndrome (AS) is an inherited, progressive glomerulopathy caused by mutations in Col4A3, 4 or 5 and inevitably leads to ESRD. No disease modifying therapy for AS is currently available. An important role of miR-21 in progression of AS and kidney-protective effect of anti-miR-21 oligonucleotide treatment has been shown in Col4a3$^{-/-}$ mice. We set out to further address anti-miR-21 therapeutic effect on late stage disease and on disease progression in combination with ACEi, the current standard of care for AS.

Methods: B6;129-*Col4a3*^{tm1Dec} (F1 hybrid of C57Bl6/J and 129X1/SvJ) and 129-*Col4a3*^{tm1Dec} were used. GFR was measured by inulin clearance. Anti-miR-21 was dosed subcutaneously. Ramipril was given in drinking water. Renal function and lifespan were used as endpoints for efficacy.

Results: B6;129-*Col4a3*^{tm1Dec} mice progressively lose GFR from 20% loss at 8 weeks to 80% loss at 15 weeks of age. Anti-miR-21 had a dose-dependent protective effect on renal function when given once a week at 12.5-50 mg/kg from 5 to 15 weeks of age. Amelioration of renal pathology correlated with renal function improvement. Dose-dependent effect on lifespan and renal function were also observed in 129-*Col4a3*^{tm1Dec}mice. Renal function protection and increased lifespan were observed even when treatment started at 13 weeks of age with 70% GFR loss. A dose of 50 mg/kg/week of anti-miR-21 showed superior renal protective effect relative to 4 mg/kg of Ramipril. Additive effects of combined anti-miR-21 and Ramipril on renal function protection and lifespan extension were observed at late stages.

Conclusions: Anti-miR-21 therapy is more effective compared to Ramipril in slowing kidney disease progression in murine AS. Disease modifying effects of anti-miR-21 are evident when administered in late stage disease where there is substantial loss of renal function. Combination treatment of anti-miR-21 with ACEi may provide additional therapeutic effect. Therefore, anti-miR-21 is proposed as a new and effective therapy for AS.

SA-OR076

Endothelin A Receptor Blockade Prevents Mesangial Filopodial Invasion of Glomerular Capillaries and Delays Alport Glomerular and Interstitial Disease Onset Dominic E. Cosgrove, Brianna Johnson, Daniel T. Meehan, Linda Cheung, Duane C. Delimont. *Genetics, Boys Town National Research Hospital, Omaha, NE.*

Background: The type IV collagen network in Alport GBM is comprised of α1(IV) and α2(IV) chains which contain fewer interchain crosslinks than the networks found in normal GBM. The increase in elasticity of the Alport GBM imparts biomechanical stresses on glomerular cells. This activates Rac1 and CDC42 in mesangial cells, inducing the invasion of the capillary tufts by mesangial filopodia which deposit mesangial proteins in the GBM, activating proinflammatory cell signaling in podocytes. We explored whether endothelin receptor activation on mesangial cells might underlie stretch-mediated CDC42 activation.

Methods: 129 autosomal Alport mice were given either Bosentan (endothelin A and B receptor antagonist) or Sitaxentan (endothelin A receptor antagonist) from 2 to 7 weeks of age. Mice were analyzed longitudinally for proteinuria and BUN, glomerular RNA for gene expression of MMPs and pro-inflammatory cytokines, and tissue by histochemistry and immunohistochemistry for pathologic changes.

Results: Hypertension elevated expression of endothelin-1 in Alport endothelial cells. Endothelin blockade ameliorated mesangial filopodial invasion of glomerular capillaries, delayed disease onset, slowed progression of proteinuria, increased lifespan, and ameliorated GBM dysmorphology. Glomerulosclerosis and interstitial fibrosis were not evident in treated Alport mice when age-matched vehicle-treated Alport mice showed >30% glomerulosclerosis and fibrosis scores between III and IV. Both Bosentan and Sitaxentan were equally effective.

Conclusions: Biomechanical strain-induced activation of endothelin expression in Alport glomerular endothelial cells results in endothelin A receptor-mediated activation of CDC42 in mesangial cells, inducing the invasion of the GBM by mesangial filopodia. This appears to be an important factor contributing to the mechanism of Alport disease initiation, and presents a host of novel therapeutic targets with the potential to delay/inhibit the onset of Alport glomerular and tubulointerstitial pathogenesis.

Podocyte-Specific *Fat1* Deletion Leads to Focal Segmental Glomerulosclerosis in Mice Alda Tufro, Pardeep Kumar Aggarwal, Sherene Mason, Gilbert W. Moeckel. *Dept of Pediatrics, Yale Univ School of Medicine, New Haven, CT.*

Background: *Fat1*, a cadherin involved in planar cell polarity expressed in podocytes, is an essential slit-diaphragm component. Fat1 localizes to lamelipodia and intercellular junctions, promotes cell migration and regulates actin dynamics through beta catenin and Ena/Vasp interactions.*Fat1* null mice develop congental nephrotic syndrome (CNS), microphtalmia and holoprosencephaly, leading to perinatal lethality.

Methods: To further evaluate *Fat1* function in slit-diaphragm development and maintenance we generated podocyte-specific *Fat1* null mice (*Podocin-Cre;Fat1*$^{flox/flox}$) by Cre recombinase-mediated exon2 deletion. Podocyte *Fat1* gene dosage effect on renal structure and function was examined in neonate and adult mice. Homozygous, heterozygous and single mutant littermates were studied.

Results: Podocyte-specific *Fat1* mutants are viable, born in Mendelian ratios and survive to adulthood. Light microscopy reveals normal renal histology, and no proteinuria is detected in neonates. Adult podocyte-specific *Fat1* mutants develop progressive proteinuria inversely related to *Fat1* gene dosage. Heterozygous mutants have albuminuria ~4-fold > controls at 6 months of age, while homogygous mutants have massive albuminuria ~100-fold >controls at 4 months of age. Creatinine clearance is normal in all adult *Fat1* mutants. LM shows mesangial expansion and proteinaceous casts in podocyte-*Fat1* hets, while homogygous *Fat1* mutants have focal segmental glomerulosclerosis (FSGS). TEM in *Fat1* mutants demonstrates podocyte foot process effacement (FPE) ranging from focal to extensive FPE, microvillus transformation and collapsed F-actin. Control littermates show normal histology and TEM. Podocyte *Fat1* deletion induced nephrin downregulation in a gene dosage dependent manner.

Conclusions: We conclude that *Fat1* is required to maintain slit-diaphragm signaling and structural integrity in adult mice. In contrast with global *Fat1* KO mice, podocyte-specific *Fat1* deletion does not cause CNS or perinatal lethality. Long-term podocyte-specific *Fat1* loss-of-function causes massive proteinuria and FSGS in adult mice, suggesting that *FAT1* might be a candidate gene for human FSGS.

SA-OR078

Research Priorities in Chronic Kidney Disease: A Partnership among Patients, Caregivers, Clinicians, Researchers, and Policy Makers Allison Tong,[1,2] Sally Crowe,[3] Shingisai Alice Chando,[1,2] Jonathan C. Craig.[1,2] *[1]School of Public Health, Univ of Sydney; [2]Centre for Kidney Research, The Children's Hospital at Westmead; [3]Crowe Associates Ltd.*

Background: Research aims to improve health outcomes for patients, but research priorities are usually determined by clinicians, academics and funders, with little or no involvement by patients or their carers, and in a process which may lack transparency. This study aimed to generate and prioritize research questions in chronic kidney disease (CKD) among all relevant stakeholders at a national level and in an explicit manner.

Methods: A national priority setting partnership workshop was convened in February 2014. The 58 participants from around Australia included patients with CKD (n=23), carers (n=7), nephrologists/surgeons (n=16), nurses (n=8), and allied health professionals and researchers (n=4). In facilitated groups of 8-10, participants generated and voted on intervention questions across four CKD stages/modalities of treatment: early stage (pre-dialysis) CKD, peritoneal dialysis, hemodialysis, and kidney transplantation. Votes were summed to identify the top 20 questions across all CKD stages then ranked.

Results: Eighty-three research questions were generated. The top five research questions were: 1) How effective are lifestyle programs (diet, exercise) for preventing deteriorating kidney function in patients with early CKD? 2) What interventions can improve long-term post-transplant outcomes (drugs, lifestyle)? 3) What strategies will improve family consent for potential deceased donor kidney donation, taking different cultural groups into account? 4) What strategies help patients maintain work while on hemodialysis? 5) How

can we improve and individualize drug therapy to provide better control of side effects? There was broad agreement between patients/caregivers and health professionals in the ranking assigned to most questions.

Conclusions: Priority questions were focused on prevention, lifestyle, quality of life, and long-term impact. These prioritized research questions can inform patient/consumer organizations, researchers, policy makers, and funding agencies in developing a shared CKD research agenda that is relevant to all stakeholders.

SA-OR079

A Sustained Dietary Sodium Reduction Program Reduces Albuminuria: A Large Cluster Randomised Trial Meg J. Jardine,[1] Nicole Yan Li,[1] Toshiharu Ninomiya,[1] Xiangxian Feng,[2] Jianxin Zhang,[3] Jingpu Shi,[4] Yuhong Zhang,[5] Rui Zhang,[6] Vlado Perkovic,[1] Hiddo Jan Lambers Heerspink,[7] Yangfeng Wu,[1] Lijing Yan,[1] Bruce C. Neal.[1] *[1]The George Inst for Global Health; [2]Changzhi Medical College; [3]Hebei Province Center for Disease Prevention and Control; [4]China Medical Univ; [5]Ningxia Medical Univ; [6]Xi'an Jiaotong Univ; [7]Univ of Groningen.*

Background: Albuminuria predicts adverse clinical outcomes. Previous studies suggest dietary sodium restriction reduces albuminuria in the short term. We assessed the impact of a sustained dietary salt reduction intervention on albuminuria.

Methods: We randomised 120 rural villages in China in a 1:1 ratio to an 18 month sodium reduction program, comprising education and access to a reduced sodium, added potassium salt substitute, compared with no intervention. We further randomised intervention villages to price subsidy for salt substitute that neutralised its higher cost, or not. A stratified random sample of adults was selected from each village for outcome evaluation. The primary outcomes were urinary albumin:creatinine ratio (uACR) and albuminuria.

Results: 2,566 survey participants provided 1,903 eligible 24hr urine samples. Sodium was 0.82g/day (0.06 to 1.68g) lower in participants from intervention compared with control villages. The sodium reduction program resulted in lower mean participant uACR in intervention compared with control villages [8.84 (8.04 to 9.81)mg/g, 10.52 (9.72-11.32) mg/g respectively, p=0.008] with a corresponding odds ratio (OR) for albuminuria of 0.67 (0.46-0.99). Secondary randomisation to salt substitute price subsidy produced the lowest rates of albuminuria [respective OR: 0.59 (0.37-0.95), 0.77 (0.44-1.34), 1.00 (ref), p trend 0.02, for intervention villages with price subsidy, intervention villages without subsidy and control villages].

Conclusions: Multiple trials have showed pharmaceutical agents that reduce albuminuria protect against cardiovascular and renal events. Albuminuria reduction through a dietary intervention could potentially be achieved population-wide at low cost. Discovering whether clinical benefits will ensue from dietary sodium reduction should therefore be a global research priority.

SA-OR080

Promoting Awareness and Screening Indian Youth for CKD Risk Factors: Pilot Program Results Panduranga S. Rao,[1] Ravichandran Rajan,[2] Rachel Perlman,[1] Julie A. Wright Nunes.[1] *[1]Internal Medicine, Univ of Michigan, Ann Arbor, MI; [2]Nephrology, MIOT, Chennai, Tamil Nadu, India.*

Background: Chronic kidney disease (CKD) is a growing epidemic in India. Early detection of risk may ameliorate disease development and improve outcomes. There is little information about early screening to identify at-risk Indian youth.

Methods: Participants were enrolled from colleges throughout Chennai in a cross-sectional pilot screening program from April - May 2013. The program entailed: 1. 30-minute presentation and video on topics general to CKD with specific information on urinalysis (UA) collection techniques. 2. On-site assessment collecting age, sex, height, weight and blood pressure, led by trained study personnel. UA kits were distributed to participants at time of assessment and returned to study personnel within 48 hours. We used logistic regression to examine for associations between proteinuria and participant characteristics.

Results: 2158 students were enrolled from five centers. The mean (SD) age was 19 (1.6) years and 1451 (68%) were men. Measurements and UA kits were complete on 2035 (94%). Mean (SD) BMI was 21.9 (4) kg/m^2 and 388 (19%) had a BMI consistent with being overweight or obese (≥ 25kg/m^2). Mean systolic blood pressure (SBP) was 119 (13) mmHg with 94 (5%) participants > 140. Mean diastolic blood pressure (DBP) was 71 (12) mmHg with 119 (6%) participants > 90. 137 (6%) had glucosuria (UA ≥1+) and 120 (6%) abnormal urine protein levels (UA≥1+). In univariate analysis, sex (OR 1.6 [CI 1.06-2.56] p=0.03 men compared to women) and age (1.13 [1.01, 1.26] p=0.03 older compared to younger) were significantly associated with proteinuria. In analysis adjusted for age, sex, SBP, DBP, glucosuria, and BMI, sex and age remained independently associated with higher odds for proteinuria (1.6 [1.01, 2.56] p=0.04 men compared to women; 1.15 [1.02, 1.29] p=0.02 older compared to younger). Overall, there was active participation by the student community and wide screening of the students.

Conclusions: Early detection of CKD risk factors is important. Our novel pilot program targeting youth offers a unique opportunity to identify and intervene early. More research is needed to determine causal mechanisms.

SA-OR081

Challenges and Opportunities for Effective Chronic Kidney Disease Care Delivery: A Synthesis of Health Systems and Policies from 19 Countries Aminu K. Bello,[1] Adeera Levin,[2] Braden J. Manns,[3] Tilman B. Drueke,[4] Brenda Hemmelgarn,[3] Scott Klarenbach,[1] Giuseppe Remuzzi,[5] Marcello Tonelli.[1] *[1]Univ of Alberta, Canada; [2]Univ of British Columbia, Canada; [3]Univ of Calgary; [4]5Inserm Unit 1088, UFR Médecine/Pharmacie, Univ de Picardie, Amiens, France; [5]Mario Negri Inst, Bergamo, Italy.*

Background: Little is known about the best way to structure health systems to facilitate early chronic kidney disease (CKD) care. We evaluated CKD care programs within the context of the healthcare systems across countries to identify best practices and initiatives in care delivery.

Methods: We collated and synthesized data on existing CKD care policies and structures across 19 developed countries. These included CKD care frameworks within the context of the healthcare system providing a synthesis and comparative analysis of the information across the individual countries. Data were obtained from multiple sources, including renal registries, government reports and published literature, and a detailed survey of key stakeholders from each country(N=1226).

Results: Only three countries have a national specific CKD policy, and governments generally do not consider CKD a priority. For instance, in only three countries did the majority of respondents (>75%) believed that CKD was recognized as a priority by the government. Eleven countries have national CKD guidelines, and none has established schemes to monitor adherence. There were multi-faceted barriers to early CKD care: limited workforce capacity, absence of surveillance systems, lack of a coordinated care strategy, non-integration of CKD with other non-communicable disease (NCD) control initiatives, and low awareness of CKD among stakeholders (policymakers, primary care practitioners, and patients).

Conclusions: There are common challenges faced by diverse health systems on CKD care. Some countries are further ahead than others, but all have considerable work to do. This reflects the need for international cooperation to strengthen health systems and policies for CKD care. This data identifies opportunities for optimal care delivery, and explores potential mechanisms to capitalize on these opportunities.

SA-OR082

Patients That Utilise a Patient Facing Health Record Have Better Health Outcomes Anirudh Rao,[1] David Pitcher,[1] Richard G. Phelps.[2] *[1]UK Renal Registry, United Kingdom; [2]Univ of Edinburgh, United Kingdom.*

Background: Renal Patient View (RPV) has since 2005 been offering patients online access to their test results and information about their condition and treatment. By 2014, 30,000 patients in the UK had registered to use RPV, but how and how often patients utilise RPV varies widely. We examined selected health outcomes for any influence of the level of patient engagement with RPV.

Methods: RPV user database extant was linked with the UK Renal Registry. To assess effect of RPV use on initial RRT, patients who registered to use RPV > 90 days prior to RRT start (early-adopters), where RPV's information provision could have been influential, were compared with patients that registered after RRT start (late adopters). To assess effect of RPV on control of phosphate and URR, patients' phosphate control 6 months before registration was compared with 12 months after registration, stratifying the patients according to their utilisation of RPV inferred from the count of logons per month. Statistical analysis was by CHI sq, T test and logistic models as appropriate.

Results: Early adopters were more likely to start on a home based modality (HBM) compared to late adopters(42% versus 37%,p= .006).In adjusted models,early adopters were three times more likely to begin RRT on a HBM than the overall RRT cohort(OR 2.90,95% CI 2.52-3.34). Early adopters were more likely than late adopters to begin RRT with a living-donor transplant (63.4 versus 54.7 p= 0.03), with more persistent users twice as likely as the overall RRT population(OR 2.08, 95% CI 1.52-2.86) to begin RTT with a living-donor transplant. The greatest reduction of phosphate(0.93 mmol/L) occurred in the subgroup with most frequent login to RPV(>4/month),significantly greater than that observed in the reference group(0.49 mmol/L, p<0.001) or group of RPV registrants that never actually logged on(0.52 mmol/L,p<0.001). In contrast, there was no significant difference in URR between the groups.

Conclusions: Utilisation of RPV is associated with better patient outcomes. The stronger association where RPV utilisation might influence outcome (modality choice and phosphate control) than where influence was less likely (URR) suggests RPV supports patient engagement.

SA-OR083

Evaluating Risk of End-Stage Renal Disease in Public Health Settings Yoshio N. Hall,[1] Marlena Maziarz,[2] Glenn M. Chertow,[3] Jonathan Himmelfarb.[1] *[1]Medicine, Univ of Washington, Seattle, WA; [2]Biostatistics, Univ of Washington, Seattle, WA; [3]Medicine, Stanford Univ, Palo Alto, CA.*

Background: Models to estimate risk of end-stage renal disease (ESRD) have been mostly derived from insured cohorts of predominantly elderly, non-Hispanic white adults. We sought to evaluate the utility of several ESRD risk prediction models for public health application.

Methods: We performed a cohort study of 28,779 adults with moderate-to-advanced chronic kidney disease (CKD) who received ambulatory care in two large urban public health systems in the U.S. during 1996-2009 and who were followed for ESRD through

2011. We developed and assessed the utility of four proportional hazards models for incident ESRD using two recently proposed criteria: "proportion of cases followed" and "proportion needed to follow-up".

Results: Overall, 1,730 persons progressed to ESRD during follow-up (median follow-up=6.6 years). ESRD risk for time frames up to five years was highly concentrated among relatively few individuals. A predictive model (model 2) using five common variables (age, sex, race, eGFR, and dipstick proteinuria) performed as well as more complex models incorporating extensive sociodemographic and clinical data. Using this model, an estimated 80% of individuals who eventually developed ESRD were among the 5% of cohort members at highest estimated risk for ESRD at 1-year. Similarly, 8% and 13% of individuals at highest ESRD risk would have needed follow-up to capture 80% of those who eventually progressed to ESRD at 3- and 5-years, respectively.

Conclusions: In the healthcare safety net, a simple 5-variable model accurately predicts most cases of ESRD within five years. Applying risk prediction at the public health system level may improve CKD surveillance and management by directing resources to a relatively small sub-cohort at highest risk for progressing to ESRD.

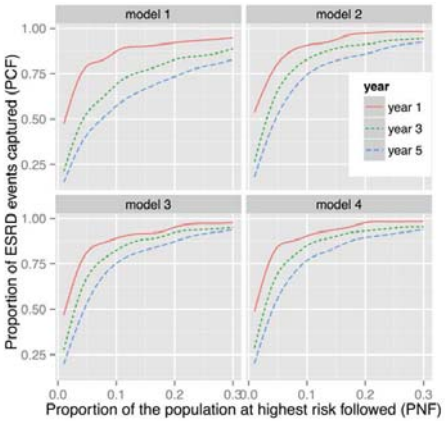

Figure 1. The estimated proportion of ESRD events captured (PCF) among a given proportion of subjects at highest estimated risk of ESRD (PNF) for models 1-4 at 1, 3 and 5-year time frames.

Model 1: adjusted for age, sex, race-ethnicity & eGFR
Model 2: model 1 covariates *plus* dipstick proteinuria & eGFR x proteinuria interaction
Model 3: model 2 covariates *plus* health insurance & comorbidities (diabetes, CVD, HTN, substance abuse and chronic viral disease)
Model 4: model 3 covariates *plus* additional laboratory variables (serum albumin, calcium, hemoglobin, cholesterol)

Funding: NIDDK Support

SA-OR084

Low Awareness and Comprehension of Chronic Kidney Disease Among Japanese Health-Check Subjects

Yoshinari Yasuda,[1] Mayumi Kamiya,[1] Yohei Maeshima,[2] Tadao Akizawa,[3] Seiichi Matsuo,[1] Shoichi Maruyama.[1] *[1]CKD Initiatives/Nephrol, Nagoya Univ, Nagoya, Japan; [2]CKD&PD, Okayama Univ, Okayama, Japan; [3]Nephrol, Showa Univ, Tokyo, Japan.*

Background: Chronic kidney disease (CKD) has been highlighted as one of serious risk factors for end stage kidney disease and cardiovascular diseases (CVD). CKD prevalence is high in Japan and it was estimated that approximately one-eighth of Japanese adults were affected with CKD. Although CKD is well understood among Japanese health professionals, CKD awareness among Japanese general population has not been fully elucidated. Thus, CKD awareness and comprehension degree was surveyed among Japanese health-check subjects in this study.

Methods: The study subjects were 7,513 health-check subjects (3,551 females) in a single center in Aichi prefecture, Japan. Questionnaire survey including CKD awareness, self-reported renal function, knowledge questions on diagnosis, risk factors, clinical symptoms and effective life-style modification of CKD was conducted from November 2010 to October 2012 and CKD awareness and comprehension degree was analyzed.

Results: CKD awareness was 15.5% and television was the major source followed by news paper. CKD awareness among subjects who were under treatment of hypertension, diabetes or dyslipidemia was slightly but significantly high at 18.2% ($p<0.001$), but only 20.6% of those knew their renal function. Regarding CKD diagnosis, proteinuria was recognized at 58.9% but eGFR was poorly recognized at 31.5%, and proper understanding for CKD diagnosis was only at 4.6% even among subjects who knew CKD. Regarding clinical symptoms of CKD, edema (69.2%) and hypertension (51.2%) were recognized sufficiently followed by CVD (47.2%), but renal anemia (33.7%) and mineral bone disorder (25.6%) were poorly recognized. CKD risk factors and effective life-style modification for CKD were not well understood.

Conclusions: This study revealed that CKD awareness and comprehension degree remained low in Japan even among health-check subjects. CKD enlightenment campaigns in collaboration with government, the mass media, health professionals and academic societies are essential to improve CKD awareness, and their effect should be adequately monitored at regular intervals.

An Oral Enzyme (ALLN-177) Reduces Dietary Hyperoxaluria

Craig B. Langman,[1] Danica Grujic,[2] Rita Pease,[2] Alexey Margolin,[2] Lee Brettman.[2] *[1]Pediatric Kidney Diseases, Feinberg School of Medicine, Northwestern Univ, Chicago, IL; [2]Allena Pharmaceuticals, Inc., Newton, MA.*

Background: Hyperoxaluria (HO) is a major cause of calcium oxalate (Ox) nephrolithiasis, resulting primarily from increased absorption of dietary Ox. The only therapy (Rx) available at present is dietary restriction which has suboptimal efficacy. ALLN-177 is a new oral recombinant enzyme with high, substrate-specific, Ox-degrading ability that may be ideal Rx for treating nephrolithiasis from HO. **Objective:** To test the efficacy and safety of ALLN-177 Rx in healthy subjects on a high Ox diet (1g/d).

Methods: Thirty healthy subjects were randomized to crossover between placebo or ALLN-177 Rx with meals (7500 u/meal tid) in a double blind, controlled study in an inpatient research unit. All subjects were placed on a 1g Ox diet alone for 3d and then treated for 7d with ALLN-177 or placebo. Subjects were crossed-over to the opposite Rx after a 7d washout. 24h urine was done daily. The 1^0 endpoint was a comparison of the mean 24h urinary Ox excretion (24hUox) while receiving ALLN-177 versus placebo Rx in the last 4d of each Rx phase. A responder analysis requiring a reduction in mean 24hUox of >5mg in favor of either Rx was done. A mixed model with random effects for crossover designs was used for analysis.

Results: A 1g Ox diet resulted in a sustained increase in 24hUox (mean±SD) similar to levels seen in patients with HO nephrolithiasis (pre-diet=27.1±11.7 to diet=82.2±27.4). ALLN-177 Rx resulted in a 24hUox reduction of 11.5±14.1 versus placebo, $p=0.0002$. There were 18/30 (60%) ALLN-177 responders and none on placebo; responder rates didn't differ by initial Rx period. The mean reduction in responders for 24hUox (23%) ranged from 8.3 to 43 mg. ALLN-177 was well tolerated, and no safety signals were noted.

Conclusions: This is the first well-controlled study of any drug demonstrating an ability to reduce urinary Ox levels of dietary origin. Further clinical studies in patients with recurrent kidney stones and HO are now warranted.

Oxalobacter Formigenes Colonization Normalizes Oxalate Excretion in a Gastric Bypass Model of Hyperoxaluria

Benjamin Canales,[1] Marguerite Hatch.[2] *[1]Urology, Univ of Florida, Gainesville, FL; [2]Pathology, Immunology and Laboratory Medicine, Univ of Florida, Gainesville, FL.*

Background: After Roux-en-Y gastric bypass (RYGB) surgery, calcium oxalate stone risk increases up to 4-fold, driven primarily by post-operative hyperoxaluria. The probiotic *Oxalobacter formigenes* (OF) can reduce urinary oxalate excretion by degrading intraluminal oxalate while promoting enteric oxalate elimination. The objective of the study was to examine the effect of OF colonization on urinary oxalate excretion and intestinal oxalate transport in an established hyperoxaluric RYGB animal model.

Methods: Obese male Sprague Dawley rats underwent sham (n=10) or RYGB (n=18) surgery and were maintained on low oxalate/fat diets. At 10 weeks post-operatively, half of the animals were randomized to OF wild rat strain (OXWR) gavage. Urine and stool were collected weekly to determine oxalate and colonization status, respectively. At 20 weeks post-operatively, [14C]-oxalate fluxes and electrical parameters were measured *in vitro* across isolated distal colon tissue mounted in Ussing chambers.

Results: All rats gavaged with OXWR were confirmed colonized at the time of flux. Urinary oxalate excretion remained low and unchanged in sham animals regardless of colonization status (mean 3.54 ± 0.59 umol/day). RYGB + OXWR had significant reductions in urinary oxalate excretion after gavage (24.94 ± 9.4 versus 6.85 ± 3.0 umol/day, $p<0.001$) while uncolonized RYGB animals remained unchanged (17.2 ± 4.2 versus 14.0 ± 3.3 umol/day, $p=0.62$). Compared to sham, the RYGB procedure increased intestinal oxalate tissue permeability by 36% and transcellular [14C]-oxalate net secretion 2-fold. When compared to non-colonized RYGB, RYGB + OXWR animals had 46% increase in net oxalate efflux with no significant changes in tissue permeability.

Conclusions: In our model, RYGB-related hyperoxaluria can be reduced to that of sham controls by OF colonization. Because intestinal permeability was similar between both RYGB groups, the mechanism for this decrease appears to be induction of distal colonic oxalate secretion by OF. This *in vivo* study suggests OF colonization may benefit RYGB patients with hyperoxaluria and warrants a clinical trial.

Urinary Hydroxy-Oxo-Glutarate (HOG) as Diagnostic Factor for Primary Hyperoxaluria Type 3

Markus Feldkötter,[1] Andrew Z. Wei,[2] Craig B. Langman,[3] Ada Ventzke,[1] Bernd Hoppe.[1] *[1]Pediatric Nephrology, Univ Hospital Bonn, Bonn, Germany; [2]Chemistry, Northwestern Univ, Evanston, IL; [3]Pediatric Kidney Diseases, Feinberg School of Medicine, Northwestern Univ, Evanston, IL.*

Background: Primary Hyperoxaluria (PH) comprises at least 3 recessive diseases characterized by endogenous overproduction of oxalate: PH1 (AGXT); PH2 (GRHPR) and PH3 (HOGA), the latter causes a defect in hydroxyproline metabolism in the mitochondria. We hypothesized that the levels of 4-hydroxy-2-oxoglutarate (HOG) in the urine of PH3-patients would discriminate among the PH diseases.

Methods: The newly created HOG assay was conducted using ion chromatography/mass spectroscopy (IC/MS). We analyzed urine specimen from 62 PH1-, 3 PH2- and of 30 PH3-patients, as well as 54 specimen of patients without a proven PH. Preparation included acidification with HCl and dilution 100x with 0.20M boric acid solution. The IC/MS system was calibrated using five standards of increasing concentrations of HOG (purchased from Santa Cruz Biotechnology). The M/S was calibrated to a span of 0.30 m/z at 161 m/z, negative polarity, dwell time of 0.5s, cone voltage of 25V and a probe temperature of 450ºC. A KOH gradient of 5mM gradually ramping to 100mM over 38 minutes was used in the IC.

Results: HOG concentration (mean 43.49 µmol/l, range 1.06-163.2) and HOG to creatinine ratio (mean 39.86 mmol/mol, range 0.60-260.0) were substantially higher in PH3-patients as compared to that of PH1/2-patients (mean 2.8 µmol/l, range 0.48-5.02

and 1.23 mmol/mol, range 0.07-1.23) or non PH patients (mean 5.18 mmol/l, range 0.08-9.97 and mean 1.45 mmol/mol, range 0.49-4.75). There was a large heterogeneity of HOG excretion in PH3-patients, as well as an overlap of values at the lower range in PH3-, with the higher range in PH1/2- and non PH-patients. However, only PH3-patient had urinary HOG concentration >9.97 µmol/l and >4.75 mmol HOG/mol creatinine. There was no correlation between urinary oxalate and HOG detected.

Conclusions: The current IC/MS assay allows the rapid identification of HOG, which can be used as a diagnostic marker of PH3. We believe that offers a way for diagnosis, and may later be helpful in providing mechanistic insights into the disease itself.

Characterization of the Urine Proteome in Calcium Oxalate Stone Formers

Jeffrey Wesson,[1,2] Ann M. Kolbach,[2] Neil S. Mandel.[1,2] *[1]Medicine/Nephrology, Zablocki VA Medical Center, Milwaukee, WI; [2]Medicine/Nephrology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Kidney stones form as aggregates of crystals (typically calcium oxalate - CaOx) with organic matrix (mainly proteins). Prior research focused on individual proteins without finding a critical protein. Of >1600 proteins identified by mass spectroscopy (proteomic) analysis in urine, >100 were found in stone matrix. Previously, urine proteins from stone formers were shown to exhibit reduced net negative charge compared to controls, and this study seeks to explain this shift in charge.

Methods: Random urine samples were collected from recurrent, idiopathic CaOx stone formers (SF, n = 25) and from healthy subjects (NU; n = 14), matched for age, sex and race. Urine macromolecules were isolated by ultradiafiltration against 10mM NaCl (10kDa cutoff, Spectrum Industries). Proteomic analysis was obtained at the MCW Innovation Center, with sequence matching to the Uniprot database (uniprot.org) and positive identification based on two unique or overlapping peptides (>85% match). Only samples with adequate signal (>1000 total scan counts and >29 proteins detected) were included.

Results: On average, each sample contained 80 unique proteins from the 409 proteins identified, with 11 proteins common to all samples, and the top 20 proteins accounting for > 70% of the protein mass. Proteins were grouped as anionic or cationic based on isoelectric points calculated from their amino acid content. Cationic proteins (pI > 6.5) were more common in SF urine (SF = 22 ± 6 % SC versus NU = 18 ± 5 %; p=0.04), consistent with a net negative charge reduction in these samples. SF urine showed significant increases in several cationic proteins from the immune response network (www.ingenuity.com), which contains most stone matrix proteins.

Conclusions: Relatively few proteins account for most of the protein signal in these urine samples. Stone formers demonstrated increased abundance of cationic proteins consistent with reduced net negative charge previously reported. This shift in composition would predispose SF urine to protein aggregate formation and loss of crystallization inhibitor properties, which would account for increased risk of stone formation.

SA-OR089

Dedifferentiation of Renal Epithelial Cells into Osteogenic Cells and Formation of Randall's Plaque

Saeed R. Khan, Sunil Joshi, Wei Wang. *Pathology, College of Medicine, Univ of Florida, Gainesville, FL.*

Background: Idiopathic calcium oxalate (CaOx) kidney stones develop by deposition of CaOx crystals on Randall's plaques (RP). Mechanisms involved are still unclear. It is our hypotheses that RP formation is similar to vascular calcification in which cells under oxidative stress (OS) acquire osteogenic characteristics. To verify our hypothesis we performed genome wide analysis of differentially expressed genes in the kidneys of hyperoxaluric rats and determine changes consistent with the dedifferentiation of epithelial cells into bone producing cells.

Methods: Male Sprague-Dawley rats received rat chow supplemented with 5% w/w hydroxyl-L-proline. After 28 days, rats were euthanized, total RNA extracted and subjected to genomic microarrays to obtain transcriptome data. Kyoto Encyclopedia of Genes and Genome (KEGG) were used to identify gene clusters. Expression of selected gene products was carried out by RT-PCR and/or immunohistochemistry.

Results: We investigated the expression of genes considered to be involved in epithelial transformation and bone morphogenesis including runt related transcription factor-1 and 2 (RUNX-1 and 2), zinc finger protein Osterix, bone morphogenetic proteins 2 and 7 (BMP2 and 7), bone morphogenetic protein receptor, Type 2 (BMPR2), cytokeratin 8, 10 and 18 (Krt 8, 10, and 18) and vimentin (VIM). Krt 10 and 18 were down regulated while VIM was upregulated and its expression increased. RUNX1 and 2 as well as Osterix were up-regulated. BMP2 and 7 as well as their receptor Bmpr2 were also upregulated.

Conclusions: Down regulation of Krt 8 and 10 and upregulation and increased expression of VIM point to phenotypic changes in epithelial cells. Upregulation of bone morphogenetic proteins and transcriptional regulators of osteogenesis are indicative of cells acquiring osteogenic characteristics. Hyperoxaluria leads to development of OS inducing dysregulated signaling and phenotypic changes. Matrix vesicles are produced and in hypercalciuric conditions, hydroxyapatite deposited on basal side of epithelium lining loops of Henle and/or collecting ducts. Such deposits are likely precursors of Randall's plaque.

Mechanism for Elevated Urine pH in Patients Who Form Calcium Phosphate Renal Stones

Kristin J. Bergsland, Elaine M. Worcester, Fredric L. Coe. *Dept of Medicine / Nephrology Section, Univ of Chicago, Chicago, IL.*

Background: Calcium phosphate (CaP) stone formers (SF) produce urine of higher pH than calcium oxalate (CaOx) SF or normal people (N). Higher pH raises CaP supersaturation (SS) and may lead to CaP stones, a more destructive kidney disease than CaOx stones. What raises urine pH is not certain.

Methods: In the General Clinical Research Center, we measured urine pH and determinants of renal acidification in 21 N, 12 female (F); 14 CaOx SF, 4 F; 14 with stones >50% CaP, 6 F. We collected 15 urines and 20 blood samples over a 15 hour day; diet was fixed.

Results: For all meal periods combined, urine pH of CaP exceeded N and CaOx (Table). SS CaP was higher in CaP than CaOx or N, but not due to higher urine calcium or phosphate excretion or lower urine volume. Urine NH_4 and citrate excretions, serum potassium and CO_2 did not differ across groups. Titratable acid (TA), net acid excretion (NAE) and fractional excretion (FE) of citrate of CaP did not differ from N. Urine SO_4 of CaP was below N despite a fixed diet, indicating lower endogenous acid production.

Conclusions: CaP SF have normal overall acid excretion, their higher urine pH being insufficient to alter NAE. Urine pH of CaP SF likely represents one end of the normal urine pH distribution rather than a disease affecting renal acidification.

Influence of Hydroxyproline Plasma Concentration on the Metabolism of Oxalate

Sonia Fargue,[1] John Knight,[1] Dawn S. Milliner,[2] W. Todd Lowther,[3] Ross P. Holmes.[1] *[1]Urology, Univ of Alabama at Birmingham, Birmingham, AL; [2]Hyperoxaluria Center, Mayo Clinic, Rochester, MN; [3]Biochemistry, Wake Forest Health Sciences, Winston-Salem, NC.*

Background: The primary hyperoxalurias (PH) are rare but severe inherited diseases characterized by an increased endogenous production of oxalate. In humans the main precursor of oxalate is glyoxylate, whose most prominent source is hydroxyproline, a collagen breakdown. In order to clarify the pathways of endogenous oxalate synthesis, the contribution of hydroxyproline turnover to oxalate and glycolate synthesis and urinary excretion is assessed in a fasted state. Such knowledge would be invaluable for a better understanding of the pathophysiology of PH and idiopathic calcium oxalate stones.

Methods: Patients with PH type 1 (n=4), and normal subjects (n=8) on a 3-days controlled diet were infused with ^{15}N-$^{13}C_5$-hydroxyproline at a constant rate (750 nmol/kg/h) for 6 h. Urine and plasma samples were collected hourly for analysis of total and ^{13}C labelled hydroxyproline and glycine by GC/MS; oxalate and glycolate by IC and IC/MS.

Results: Four PH1 patients with a mean daily excretion of oxalate of 27.3 ± 17.4 mg/1.73 m^2 (14.3 - 52.1), mean glycolate excretion of 77.9 ± 45.3 mg/1.73 m^2 (41.4 - 140.9) and 8 control subjects were analysed (Table I). The mean GFR in PH1 patients was 107 ± 11 ml/mn/1.73m^2. The total urinary oxalate was not increased and no adverse effects observed.

	total Urinary oxalate		Oxalate urine 13C2 enrichment		hydroxyproline plasma 13C2 enrichment
	(mg/h)		(% $^{13}C_2$ oxalate)		(% $^{13}C_5$ hydroxyproline)
	pre-infusion	post-infusion	post-infusion		post-infusion
control	**0.99 ± 0.3**	**0.74 ± 0.19**	**2.42 ± 0.71**	**control**	**18.2 ± 3.12**
(n=4)	(0.7 - 1.37)	(0.58 - 0.95)	(1.79 - 3.17)	(n=8)	(15.2 - 22.0)
PH1	**2.39 ± 1.15**	**2.29 ± 1.21**	**5.84 ± 1.25**	**PH1**	**32.4 ± 6.36**
(n=4)	(1.39 - 3.60)	(1.06 - 3.94)	(4.85 - 7.68)	(n=4)	(26.6 - 41.1)

Conclusions: The increased enrichment in PH1 patients suggests that hydroxyproline makes a significant contribution to oxalate synthesis in PH1 patients. Further study in other types of PH may show an even greater contribution with potential therapeutic implications.

Distinct Impact of Dabigatran and Warfarin Treatment on Bone Volume and Structure in Rats Maria Fusaro,[1] Luca Dalle Carbonare,[2] Adriana S. Dusso,[3] M. Vittoria Arcidiacono,[3] Sabina Pasho,[4] Giovanni Tripepi,[5] Claudia Torino,[5] Maurizio Gallieni.[4] *[1]CNR Padua, Italy; [2]Univ of Verona, Italy; [3]IRB Lleida, Spain; [4]Dialysis Unit Milan, Italy; [5]CNR Reggio C, Italy.*

Background: Warfarin, a commonly used anticoagulant, inhibits Vitamin K (VK) metabolism and VK-Dependent Protein (VKDP) functions that are essential for bone and vascular health. Dabigatran is a new oral anticoagulant not affecting VK. We compared the impact of warfarin and dabigatran on bone and vascular health in rats with normal renal function.

Methods: Rats received Dabigatran etexilate (0.6 mg/g of chow) or Warfarin (starting from 0.6 mg/kg and adjusted to achieve the desired INR of 2-3 for 6 weeks). Untreated Controls were fed a diet containing 8 mg of VK3 per gram of chow. Femur, tibia and vertebrae were evaluated immunohistochemically and morphometrically. Calcium deposition was examined in aorta and iliac arteries.

Results: Femur and vertebra analysis showed decreased bone volume and increased trabecular separation in rats treated with warfarin compared to control and dabigatran treated rats. vertebra, trabecular number was lower in the warfarin group. In femur, warfarin was associated with higher Activation Frequency (AcF) than in dabigatran or control rats. In vertebra, there was no difference in osteoblast activity and resorption parameters among groups, except for maximum erosion depth, which was higher in warfarin treated rats. Accordingly, warfarin treatment was associated to higher Vertebral Bone Formation Rate/ Bone Surface and AcF than in dabigatran or control rats. There was no arterial calcium deposition in any group.

Femur analysis			
	Warfarin	Dabigatran	Controls
Bone Volume/Tissue Volume (%)	27.3±8.9 (p<0.05 vs dabigatran and controls)	42.4±9.8	43.7±6.5
Trabecular Thickness (μm)	64.1±23.2 (p<0.05 vs dabigatran)	85.4±10.9	66.2±17.4

Conclusions: Warfarin treatment was associated with markedly decreased bone volume, increased trabecular separation and higher turnover than in dabigatran treated and control rats. These differences could translate into a lower incidence of fractures in dabigatran treated patients.

SA-OR093

Raloxifene, but Not Calcitriol, Improves the Structural and Mechanical Properties of Bone in an Animal Model of Chronic Kidney Disease Christopher Newman,[1] Drew M. Brown,[1] Neal X. Chen,[2] Sharon M. Moe,[2,3] Matthew R. Allen.[1] *[1]Anatomy and Cell Biology, Indiana Univ School of Medicine, Indianapolis, IN; [2]Medicine (Div of Nephrology), Indiana Univ School of Medicine, Indianapolis, IN; [3]Roudebush VA Medical Center, Indianapolis, IN.*

Background: Calcitriol (CAL) is used to control elevations in parathyroid hormone (PTH), but its fracture benefits in patients with chronic kidney disease (CKD) are largely unknown. Raloxifene (RAL) has been shown to improve bone density in these patients, but its effects on fracture resistance are likewise unclear. The goal of the current study was to examine the effects of these treatments on bone structural and mechanical properties in an animal model of CKD.

Methods: At 25 weeks of age (30% of normal kidney function), Cy/+ rats with progressive CKD (n=9-11/group) were treated with vehicle (VEH), CAL, or RAL for five weeks. Normal littermates (NL) were used as controls. Serum PTH was assessed at 30 weeks, and tibial bone structure (cortical and trabecular) was assessed using microCT. Bone mechanics were determined by four-point bending of the femur with the main outcomes being strength (bone's resistance to damage) and toughness (bone's tolerance of existing damage).

Results: CKD-VEH had higher PTH than NL (+898%). Both CKD-CAL and CKD-RAL had lower PTH than CKD-VEH (-47% and -43%) but were still higher than NL. CKD-VEH had lower trabecular bone volume compared to NL (-35%). This was normalized by RAL but not CAL. Cortical bone area and thickness were lower in CKD-VEH compared to NL (-16% and -14%). Neither CAL nor RAL eliminated these differences. Strength and toughness in CKD-VEH were both lower than NL (-26% and -25%). While neither treatment improved strength, RAL corrected toughness. Hence, the mechanical benefits of RAL were primarily due to improvements in bone quality.

Conclusions: These data show that while both CAL and RAL lowered PTH, only RAL normalized trabecular bone volume and mechanical properties in CKD animals. Whether these positive skeletal outcomes are primarily due to RAL's anti-bone remodeling effects or its suppression of PTH through a currently unknown mechanism is yet to be determined.

Identification of a Bone Defect in ADPKD Berenice Y. Gitomer,[1] Renata C. Pereira,[2] Mikaela R. Malaczewski,[1] Myles S. Wolf,[3] Isidro B. Salusky,[2] Jason W. Stoneback,[1] Michel Chonchol.[1] *[1]Univ of Colorado Anschutz Medical Campus; [2]Univ of California, Los Angeles; [3]Northwestern Univ; [4]Univ of California, Los Angeles.*

Background: Autosomal Dominant Polycystic Kidney Diease (ADPKD) is the most common potentially lethal genetic renal disease associated with aberrant expression of polycystin proteins. Polycystin-1 is highly expressed in osteoblasts and osteocytes, which are the main sources of fibroblast growth factor 23 (FGF23). A bone phenotype of reduced bone mineral density, trabecular bone volume and cortical thicknesshas been reported in mice with targeted disruption of pkd1 and normal renal function. To date there has been no systematic investigation of bone phenotype in humans with ADPKD.

Methods: Institutional review board approval was obtained and all subjects gave informed consent. Male ADPKD Caucasian patients with eGFR > 60ml/min/1.73m^2 and normal parathyroid hormone levels underwent standard tetracycline double labeling prior to transiliac crest bone biopsy. Bone samples were processed for histomorphometric analysis of static and dynamic bone parameters.

Results: Osteoid volume, thickness and surface were decreased in ADPKD bone samples compared to bone samples from healthy controls. Bone mineralization, bone formation rate and mineral apposition rate were also decreased in ADPKD bone compared to normal bone.

	PKD1	PKD2	PKD3	PKD4	PKD5	normal male
Ages (years)	35	27	28	27	21	
eGFR (ml/min/1.73m^2)	81	123	119	137.4	160.7	
Osteoid vol/bone vol (%)	0.66	0.61	0.26	0.52	0.48	2.9±2.7
Osteoid thickness (μm)	7.63	9.61	2.75	12.27	5.75	11.7±3.5
Osteoid surface/bone surface (%)	9.91	3.75	4.15	3.99	3.85	16.1±12.6
Mineralizing surface/bone surface (%)	4.43	2.47	0.73	1.55	1.59	18.0±8.0
Mineral apposition rate (μm/day)	0.45	0.42	0.38	0.71	0.48	0.65±0.12
Bone formation rate/bone surface (μm^3/μm^2/year)	7.30	37.41	1.02	40.37	2.74	47.45±25.55

Conclusions: We describe the results of the first detailed histological analysis of bone from human patients with ADPKD. The histomorphometric analyses are consistent with adynamic bone disorder in ADPKD patients despite normal renal function.

A Renal Olfactory Receptor Aids in Glucose Handling in the Proximal Tubule Blythe D. Shepard,[1] Lydie Cheval,[2] Alain Doucet,[2] Jennifer L. Pluznick.[1] *[1]Dept of Physiology, Johns Hopkins Univ School of Medicine, Baltimore, MD; [2]Centre de Recherche des Cordeliers, Paris, France.*

Background: Olfactory receptors (ORs) are seven transmembrane domain G protein-coupled chemosensors that detect odorants in the nose. We previously reported that OR signaling plays a role in the kidney, and have identified 9 renal ORs including Olfr1393.

Methods: To elucidate the role that Olfr1393 plays in the kidney, we examined nephron localization using reverse-transcribed RNA from microdissected renal segments, and subcellular distribution using stably-expressing MDCK cells. Olfr1393 ligand screening was performed using a luciferase reporter assay with Olfr1393-expressing HEK293T cells. To assay the physiological role of this OR we generated a whole-animal knockout (KO) mouse and measured plasma values by iStat, blood pressure by tail cuff, and GFR by transcutaneous decay of sinistrin in conscious, freely-moving mice.

Results: PCR on microdissected renal segments revealed that Olfr1393 is exclusively expressed in the three proximal tubule segments (S1, S2 and S3, n=3 mice). When stably expressed in polarized MDCK cells, Olfr1393 localizes to the apical PM, yet is excluded from the primary cilia. Olfr1393, like most ORs, is an "orphan receptor" with no known ligand. We comprehensively screened Olfr1393 with over 1400 chemicals and found that Olfr1393 detects preconstrained cyclic molecules containing a carbonyl or alcohol group. At baseline, Olfr1393 KO mice appear to be in homeostatic balance based on plasma electrolytes, BUN, creatinine, blood pressure and GFR. However, despite being euglycemic the KO mice exhibit glycosuria (1.6x increase in glucose/creatinine versus wild-type, WT). When challenged with a glucose bolus (glucose tolerance test, GTT), the KO mice better handled the glucose load as indicated by plasma glucose values (area under curve: WT 22.4 ± 1.9 versus KO 15.7 ± 1.1; P = 0.001).

Conclusions: These data suggest that Olfr1393 is expressed on the apical PM of the proximal tubule where it helps to regulate renal glucose reabsorption. As renal glucose handling is mediated by Sglt1 and Sglt2, we are currently examining the possibility that Olfr1393 interacts with these transporters.

SA-OR096

Nanomolar-Potency, UT-A-Selective Inhibitors of Kidney Tubule Urea Transporters Produce Salt-Sparing Diuresis in Rats Cristina Esteva-Font,[1] Onur Cil,[1] Puay Wah Phuan,[1] Tao Su,[1] Sujin Lee,[1] Marc O. Anderson,[2] Alan S. Verkman.[1] *[1]Depts of Medicine and Physiology, Univ of California San Francisco, San Francisco, CA; [2]Dept of Chemistry and Biochemistry, San Francisco State Univ, San Francisco, CA.*

Background: UT-A inhibitors have the potential to be first in their class salt-sparing diuretics with indications in volume-overload edemas and high vasopressin-associated hyponatremias. UT-A urea transporters are expressed in kidney tubule epithelial cells where they are required for urinary concentration by countercurrent multiplication.

Methods: Using a fluorescence, cell-based functional assay of UT-A1 urea transport developed by our lab (Esteva-Font et al. *Chem. Biol.* 20:1235-1244, 2013) we screened >200,000 synthetic small molecules, drugs, natural products, and urea analogs. Several classes of synthetic small molecule inhibitors were characterized and tested in rats.

Results: Screening of synthetic small molecules produced 9 classes of nanomolar-potency UT-A inhibitors, including indolethiazoles, g-sultambenzosulfonamides and aminocarbonitrilebutenes, some of which had >200-fold UT-A versus UT-B selectivity and metabolic stability *in vivo*, producing sustained therapeutic concentrations in urine. Drug / natural product screening yielded weak UT-A inhibitors (IC50 10-20 μM), including nicotine, sanguinarine and indolcarbonylchromenone; urea analog screening produced low, millimolar-potency inhibitors including dimethylthiourea, benzimidazolylurea and dichlorophenylthiourea. UT-A inhibitor administration to rats increased urine output up to 5-fold and reduced urine osmolality up to 3-fold, both under hydrated conditions with following water deprivation / DDAVP. The diuresis produced by UT-A inhibition was salt-sparing compared to that produced by furosemide.

Conclusions: UT-A1 inhibitors may be useful as diuretics in high-vasopressin, fluid-retaining conditions in which conventional salt transport-blocking diuretics have limited efficacy. Compound prioritization is in progress for efficacy testing in clinically relevant rat models of edema.

Vasopressin-Responsive miRNAs and AQP2-Targeting miRNAs in Kidney Collecting Duct Cells Jae-Eun Kim, Hyun Jun Jung, Tae-Hwan Kwon. *Dept of Biochemistry and Cell Biology, School of Medicine, Kyungpook National Univ, Daegu, Korea.*

Background: Mature microRNA (miRNA) combined with RNA-induced silencing complex acts as an important post-transcriptional regulator. However, miRNAs in the kidney collecting duct cells have not been well understood. We aimed to profile the vasopressin-responsive miRNAs in the kidney inner medullary collecting duct (IMCD) cells, and to identify the aquaporin-2 (AQP2)-targeting miRNAs.

Methods: Microarray chip assay was carried out in the IMCD tubule suspension of rat kidney in the absence or the presence of dDAVP stimulation (10^{-9} M, 2 h). To identify AQP2-targeting miRNAs, *in silico* analysis was performed. *In situ* hybridization was done for examining the expression of AQP2-targeting miRNAs in the kidney. RT-qPCR and immunoblot analysis were done to study the changes of miRNAs and AQP2 expression. Luciferase reporter assay was performed to examine the effects of AQP2-targeting miRNAs on the AQP2 translation.

Results: Microarray chip assay revealed nineteen miRNAs, including both precursor- and mature-miRNAs, as potential candidates that showed significant changes in the expression after dDAVP stimulation ($P<0.05$). Nine mature miRNAs exhibiting more than 1.3-fold changes in the expression on microarray were further examined by RT-qPCR. Four miRNAs (miR-32, miR-137, miR-216a, and miR-216b), which were also identified by microarray assay, targeted 3'UTR of rat AQP2 mRNA. Target seed regions of miR-32 and miR-137 were conserved at the 3'UTR of rat and mouse AQP2 mRNA. *In situ* hybridization demonstrated that miR-32 and miR-137 were expressed in the IMCD cells of rat kidney. Importantly, RT-qPCR and immunoblot analysis demonstrated that dDAVP-induced AQP2 mRNA and protein expression was significantly decreased in mpkCCDc14 cells transfected with miRNA-mimic of miR-32 or miR-137. Moreover, luciferase reporter assay demonstrated a significant decrease of AQP2 translation in mpkCCDc14 cells transfected with miRNA-mimic of miR-32 or miR-137.

Conclusions: We specifically identified miRNAs targeting AQP2 expression in IMCD cells to understand further the molecular mechanisms of the AQP2 regulation for AVP-regulated urine concentration and body water homeostasis.

MiR-132 Regulates Diuresis Through Vasopressin and Prostaglandin-Dependent Alteration of Aquaporin-2 Localization Roel Bijkerk,[1,3] Christiane Trimpert,[2] Ruben de Bruin,[1] Coen van Solingen,[1] Ton J. Rabelink,[1] Benjamin D. Humphreys,[3] Peter M.T. Deen,[2] Anton Jan Van Zonneveld.[1] *[1]Nephrology and Einthoven Laboratory for Experimental Vascular Medicine, LUMC, Leiden, Netherlands; [2]Physiology, Radboud Univ Nijmegen Medical Center, Nijmegen, Netherlands; [3]Renal Div, Brigham & Women's Hospital and Harvard Medical School, Boston, MA.*

Background: The collecting duct (CD) principal cells of our kidneys are critical in the maintenance of blood water levels, as binding of vasopressin (AVP) to its V2-receptor and the subsequent translocation of aquaporin-2 (AQP2) water channels to the apical membrane fine-tunes water balance. Cyclooxygenase-2 (Cox2) produces prostaglandins such as PGE2 that counteract renal AVP action by inducing internalization and lysosomal degradation of AQP2. By in silico analysis, we identified miR-132 as a potential post transcriptional regulator of Cox2 expression and subsequently investigated the role of this miRNA in diuresis.

Methods: We used miR-reporter constructs to validate Cox2 repression by miR-132 and generated antagomirs to silence miR-132 function. Synthetic AVP (ddAVP) was administered with osmotic minipumps. Mice were housed in metabolic cages and sacrificed 1 day after i.v. injection of the antagomirs or scrambled controls.

Results: We identified miR-132 to directly target Cox2, and inhibiting miR-132 in vitro increased Cox2 abundance. Silencing of miR-132 in vivo in mice caused an acute diuresis and severe weight loss, characterized by increased plasma osmolality and decreased urine osmolality. Urinary PGE2 levels were elevated and hypothalamic AVP mRNA and blood AVP levels were not increased, despite the increased blood osmolality. This resulted in less translocation of AQP2 to the apical membrane in CD cells. MiR-132 silencing combined with administration of ddAVP partially restored water reabsorption.

Conclusions: Silencing of miR-132 causes acute diuresis. Our data indicate that this is the result of a decrease in AVP synthesis/release and Cox2-mediated increase in renal PGE2 counteracting renal AVP-stimulated water reabsorption through AQP2.

Inhibition of Mitochondrial Complex-1 Restores the Downregulation of Aquaporins in Obstructed Kidney Independently of COX-2/PGE2 Pathway Zhanjun Jia,[2] Ying Sun,[1] Yue Zhang,[1] Guixia Ding,[1] Songming Huang,[1] Aihua Zhang.[1] *[1]Nephrology Dept, Nanjing Children Hospital, Nanjing Medical Univ, Nanjing, China; [2]Nanjing Key Laboratory of Pediatrics, Nanjing, China.*

Background: Downregulation of aquaporins (AQPs) in obstructed kidney has been well demonstrated with elusive mechanism. Recently, mitochondrial abnormality was shown in obstructive kidney disease. However, the role of mitochondrial abnormality in obstructed kidney is still unknown. This study was to investigate the role of mitochondrial abnormality in mediating obstruction-induced AQPs downregulation.

Methods: Following the surgery of unilateral ureteral obstruction, mice were treated with rotenone (an established mitochondrial complex 1 inhibitor) at the dose of 500 ppm in diet.

Results: Following 7 days obstruction, the levels of mitochondrial NADH dehydrogenase 1 (mtNd1), mitochondrial transcription factor (mtFAM), and the copy number of mitochondrial DNA in kidneys were strikingly reduced, suggesting a severe mitochondrial impairment. Meanwhile, AQP1, AQP2, and AQP3 were downregulated by 50-80%as determined by Western blotting and qRT-PCR. Using rotenone to block the activity of impaired mitochondria, downregulation of AQP1 and AQP2 was entirely abolished at both protein and mRNA levels. For AQP3, rotenone partially but significantly restored it by 40%. COX-2/PGE2 pathway has been reported to be associated with the downregulation of AQPs in obstructive kidney disease. Therefore, we examined this pathway in present study. As expected, kidney obstruction markedly elevated expressions of COX-2 and mPGES-1 determined by Western blotting and qRT-PCR), as well as the kidney PGE2 content determined by ELISA. In contrast, the expressions of COX-1, mPGES-2, and cPGES were not affected by ureteral obstruction. Surprisingly, rotenone treatment did not affect COX-2/mPGES-1/PGE2 signaling in present mouse model, which differs from a recent publication showing that rotenone blocked COX-2 upregualtion in obstructed rat kidney (Ostergaard M, et al, AJP-renal, 2014).

Conclusions: Our findings suggest a novel role of mitochondrial dysfunction in mediating the AQPs downregulation in obstructive kidney disease independently of COX-2/PGE2 signaling pathway.

SA-OR100

Cholesterol Depletion of mpkCCD Cells Is Associated with Increased Ubiquitylation of Aquaporin-2 Cecilie Noehr Pedersen, Robert A. Fenton, Hanne Moeller. *Biomedicine, Aarhus Univ, Aarhus, Denmark.*

Background: Arginine vasopressin (AVP) mediates the abundance of the water channel aquaporin-2 (AQP2) in the apical membrane of kidney collecting duct principal cells and thus modulates urinary concentration. AQP2 function is regulated by posttranslational modification (PTM) of its COOH-terminus. AQP2-ubiquitylation and phosphorylation (S269) occurs in the plasma membrane and promotes AQP2 internalization and membrane retention, respectively. We hypothesized that these opposing effects can occur in different domains of the plasma membrane.

Methods: We manipulated the composition of the lipid membrane of a kidney collecting duct cell model, mpkCCD cells, using the cholesterol depleting reagent methyl-β-cyclodextrin (MβCD).

Results: Treatment of mpkCCD cells using MβCD prevented dDAVP-induced phosphorylation of AQP2 at S269. Cholesterol abundance assays demonstrated that MβCD significantly reduced whole cell cholesterol levels after 40 min. MβCD had similar effects on forskolin mediated AQP2 phosphorylation, suggesting that the effects are not indirect via disturbed V2R-signaling. dDAVP washout in the presence of MβCD did not affect dephosphorylation of S269. MβCD increased ubiquitylation of AQP2 both in the presence or absence of dDAVP; which was not a result of an increased abundance of AQP2 in the membrane since MβCD treatment in itself did not increase apical abundance of AQP2. Furthermore, reducing AQP2 endocytosis following dDAVP washout using dynasore and pitstop 2 did not increase the levels of ubiquitylated AQP2.

Conclusions: Our data suggest that cholesterol is critical for modulation of AQP2 PTMs and thereby AQP2 function.

NDFIP1: The Missing Adaptor for Ubiquitination and Degradation of the Aquaporin-2 Water Channel by NEDD4 and NEDD4L

Peter M.T. Deen,[1] Christiane Trimpert,[1] Theun de Groot,[1] Martha Pimentel Rodriguez.[1] *[1]Physiology, Radboud Univ Med. Center, Nijmegen, Netherlands; [2]Biochemistry and Mol. Genetics, Univ Toronto, Toronto, Canada.*

Background: Aquaporin 2 (AQP2) is essential for renal water reabsorption and fine-tuning of its apical membrane expression is critical for reabsorption of the proper volume. This fine-tuning is the result of signals inducing exocytosis and endocytosis of AQP2. Whereas binding of arginine vasopressin (AVP) to its type-2 receptor initiates a cAMP-protein kinase A cascade and AQP2 translocation to the apical membrane, this is counteracted by protein kinase C-activating hormones, resulting in ubiquitination-dependent internalization of AQP2. The involved E3-ubiquitin ligase however is unknown.

Methods: Human embryonic kidney (HEK293) and murine cortical collecting duct (mpkCCD) cells were used to study ubiquitination and degradation of AQP2.

Results: SiRNA knockdown of NEDD4/4L ubiquitin ligases in mpkCCD cells revealed increased AQP2 abundance, but they did not directly interact with AQP2. Yeast Two-Hybrid assay with full-length AQP2 as a bait identified NEDD4 family interacting protein 2 (NDFIP2) to bind AQP2. NDFIP2 and its homologue NDFIP1 are adaptor proteins which bind NEDD4 ubiquitin ligases via their PY-motifs and bring them close to target proteins. In HEK293 cells, NDFIP1/2 bound AQP2 and were essential for NEDD4/NEDD4L-mediated ubiquitination and degradation of AQP2, an effect not observed with PY-lacking NDFIP1/2 proteins. In mpkCCD cells, downregulation of NDFIP1, NEDD4 and NEDD4L, but not NDFIP2, increased AQP2 abundance, but did not affect the extent of AQP2 internalization from the plasma membrane. In mouse kidney, NDFIP1, but not NDFIP2, co-localized and co-immuno-precipitated with AQP2.

Conclusions: Our results reveal for the first time that NDFIP1, NEDD4 and NEDD4L are involved in AQP2 ubiquitination and degradation and position NDFIP1 as a potent and rate-limiting regulator of NEDD4/NEDD4L-mediated ubiquitination and degradation of AQP2. Moreover, as NEDD4/4L also ubiquitinates ENaC in principal cells, the expression and activity of NDFIP1 may be key for principal cells to reabsorb either water or sodium, or both.

Luminal pH Affects Phosphorylation (Serine 256) and Intracellular Trafficking of AQP2 in Inner Medullary Collecting Duct Cells

Hyo-Jung Choi, Tae-Hwan Kwon. *Dept of Biochemistry and Cell Biology, School of Medicine, Kyungpook National Univ, Daegu, Republic of Korea.*

Background: Collecting duct cells are continuously exposed to the changes of luminal pH. We aimed to study the effects of altered extracellular pH (pHe) on dDAVP-induced phosphorylation (S256, p-AQP2) and apical targeting of AQP2 in rat kidney inner medullary collecting duct (IMCD) cells.

Methods: Freshly prepared IMCD tubule suspension was exposed to buffer with pH 6.4, 7.4, or 8.4 for 1 h and was treated with dDAVP (10^{-10} M, 3 min). Intracellular pH of IMCD cells were continously monitored when they were exposed to extracellular pH 6.4, 7.4, or 8.4 for 30 min, respectively. To examine whether changes of pH at the luminal side of the cells affect dDAVP-induced AQP2 phosphorylation (S256) and intracellular trafficking, cell surface biotinylation assay and laser-scanning confocal microscopy were performed. Moreover, fluorescence resonance energy transfer (FRET) technique was exploited and time-lapse changes of dDAVP- or forskolin-induced PKA activity and intracellular Ca^{2+} dynamics were monitored.

Results: Increased AQP2 phosphorylation (S256) was seen when tubule suspension was exposed to pH 7.4 and 8.4, compared to pH 6.4. When IMCD cells were exposed to 6.4, 7.4, and 8.4 for 30 min, intracellular pH became 6.1, 7.2, and 8.1, respectively. IMCD cells were exposed to transepithelial pH gradient for 1 h in the transwell chambers (apical pH 6.4, 7.4, or 8.4 versus basolateral pH 7.4). Laser scanning confocal microscopy and cell surface biotinylation assay revealed that exposure to luminal pH 6.4 for 1 h significantly decreased dDAVP (10^{-9} M, 15 min, basolateral)-induced apical targeting of AQP2. Importantly, FRET analysis revealed that dDAVP (10^{-9} M)-induced increase of PKA activity was significantly attenuated when LLC-PK1 cells were exposed to pHe 6.4, compared to pHe 7.4 and 8.4. In contrast, forskolin (10^{-7} M)-induced PKA activation was not affected. Moreover, dDAVP-induced increase of intracellular Ca^{2+} was not affected.

Conclusions: Taken together, acidotic condition is likely to decrease dDAVP-induced phosphorylation and apical targeting of AQP2 in IMCD cells, via an inhibition of V2R-G protein-cAMP-PKA action.

CaSR Signaling Prevents Forskolin-Induced pS256-AQP2 in Isolated Mouse Collecting Duct Tubules and Impairs Osmotic Water Permeability in Renal Cells

Marianna Ranieri, Grazia Tamma, Annarita Di Mise, Mariangela Centrone, Maria Svelto, Giovanna Valenti. *Dept of Biosciences, Biotechnologies and Biopharmaceutics, Univ of Bari, Bari, Italy.*

Background: We have recently provided both *in vitro* and *in vivo* evidence that high luminal calcium in the renal collecting duct attenuates short-term vasopressin-induced AQP2 trafficking via activation of the Calcium-Sensing Receptor (CaSR). Here, we evaluated AQP2 phosphorylation in response to specific activation of CaSR with the positive allosteric modulator NPS-R568 in isolated mouse collecting duct tubules and in renal HEK cells stably transfected with CaSR.

Methods: Isolated collecting duct from mouse kidney and HEK cells transfected with wt-hCaSR were exposed FK in the presence of NPS-R568 and the dynamics of pS256-AQP2 and pS261-AQP2 were evaluated. To mimic "tonic" activation of CaSR, parallel experiments were performed in HEK cells transfected with two gain of function variants of CaSR. Osmotic water permeability was analyzed in calcein-loaded cells.

Results: In transfected cells, CaSR activation with NPS-R568 drastically reduced basal pS256-AQP2 levels and increased pS261-AQP2 levels thus having an opposite effect on AQP2 phosphorylation with respect to vasopressin action. Similar, though more pronounced effects were obtained in cells expressing CaSR gain of function variants. When FK stimulation was performed in the presence of NPS-R568, the increase in pS256-AQP2 was totally prevented. In line with these data, the FK-induced increase in the osmotic water permeability was abolished in all CaSR expressing cells reaching values even lower than the basal permeability. The physiological relevance of data obtained in transfected cells was next evaluated in freshly isolated inner medullar collecting duct from mouse kidney. Stimulation with FK in the presence of NPS-R568 completely prevented FK-induced increase in pS256-AQP2. Similar results were obtained in isolated rat kidney inner medulla.

Conclusions: Our in vitro and ex vivo data demonstrate that specific activation of CaSR expressed in the collecting duct prevents FK-dependent increase in pS256-AQP2 and point to a crucial role of CaSR in counteracting short-term vasopressin response.

Glutathionylation of the Aquaporin-2 Water Channel: A Novel Post-Translational Modification Modulated By the Oxidative Stress

Grazia Tamma, Marianna Ranieri, Annarita Di Mise, Mariangela Centrone, Maria Svelto, Giovanna Valenti. *Dept of Biosciences, Biotechnologies and Biopharmaceutics, Univ of Bari, Bari, Italy.*

Background: Aquaporin-2 (AQP2) is the vasopressin regulated water channel that controls renal water reabsorption and urine concentration. AQP2 undergoes different regulated posttranslational modifications, including phosphorylation and ubiquitylation, which are fundamental for controlling AQP2 cellular localization, stability and function. The relationship between AQP2 and S-glutathionylation is of potential interest because reactive oxygen species (ROS), produced under renal failure or nephrotoxic drugs, may influence renal function as well as the expression and the activity of different transporters and channels, including aquaporins.

Methods: AQP2 S-Glutathionylation was evaluated by AQP2 immunoprecipitation followed by WB with anti-GSH in mouse kidney and HEK-293 cells stably transfected with AQP2. AQP2 S-Glutathionylation was further analyzed by using BioGEE reagent. ROS content and NADPH oxidase activity were measured with dihydrorhodamine-123 and with lucigenin-enhanced chemiluminescence assay respectively.

Results: Obtained results showed for the first time, that AQP2 is subjected to S-glutathionylation in kidney and in HEK-293 cells stably expressing AQP2. S-Glutathionylation is a redox-dependent posttranslational modification controlling several signal transduction pathways and displaying an acute effect on free cytosolic calcium concentration. Interestingly, we found that, cells expressing wild-type Calcium Sensing Receptor (hCaSR-wt) and its gain of function (hCaSRR990G hCaSRR990G; hCaSR-N124K) had a significant decrease in AQP2 S-glutathionylation secondary to reduced ROS levels and reduced basal intracellular calcium concentration compared to mock cells.

Conclusions: Identifying this novel posttranslational modification provide fundamental insight into cell biological aspects of AQP2 function and is crucial to understand renal diseases characterized by oxidative stress and AQP2-dependent water reabsorption disturbs.

Peritonitis as a Risk Factor for Long-Term Cardiovascular Mortality in Peritoneal Dialysis Patients

Roberto Pecoits-Filho, Ludimila Guedim de Campos, Thyago Proença de Moraes. *Pontifícia Univ Católica do Paraná (PUCPR), Curitiba, Paraná, Brazil.*

Background: Peritoneal dialysis(PD) related peritonitis is a major complication of the method, related to its association with infectious morbidity and mortality, and to technique failure. The impact of peritonitis on long-term mortality, particularly related to non-

infectious causes, has not been investigated until the present. The aim of this study was to analyze the impact of peritonitis on long-term cardiovascular(CV)mortality in a large cohort.

Methods: The analysis was based on BRAZPDII, a national cohort performed in Brazil from Dec2004 to Jan2011. Incident adult PDpatients with at least 90days on treatment from 122centers were included in the analysis. CVdeath occurring after a minimum of 90 after a peritonitis episode were considered the primary endpoint. Cox regression for time-dependent variables was used for the adjustments. Multivariable analysis included age,gender,educat ion,diabetes,left ventricular hypertrophy,hypertension, previous hemodialysis,pre dialysis care,hemoglobin,creatinine and blood pressure at baseline.

Results: There were 2405episodes of peritonitis in 5707patients(48%males,44%di abetes,73%hypertensive).Patients with 1 episode of peritonitis presented a 25%increase in the hazard ratio of CVmortality compared to those who never experienced peritonitis (HR1.25;CI95%1.04-1.52). Adjusted hazard for CVmortality showed an stepwise effect for patients with additional episodes of infection 2episodes(HR2.00;CI95%1.47-2.72), 3episo des(HR3.41;CI95%2.11-5.24) and 4episodes(HR4.92;CI95%2.58-9.38).

Conclusions: Peritonitis was an independent predictor of CVmortality and the frequency of peritonitis was strongly associated with a linear increase in this risk. This is the first study to demonstrate the impact of peritonitis on late CVmortality of PDpatients, suggesting a link between acute inflammation and CVoutcomes.

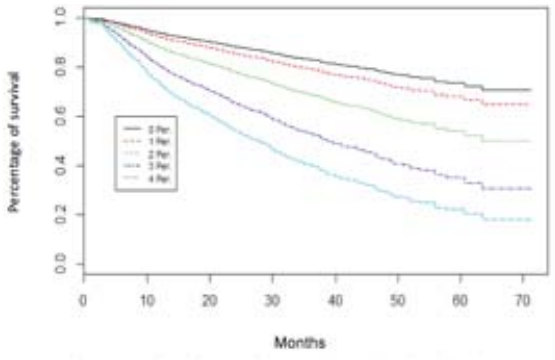

Figure 1 - Unadjusted survival curves por 0, 1, 2, 3 and 4 peritonitis events

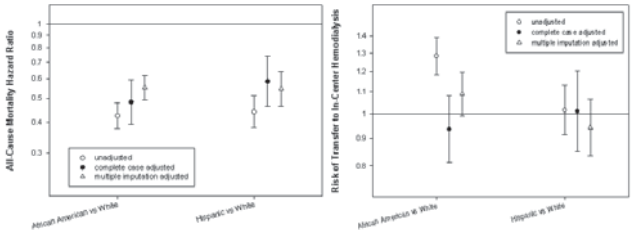
SA-OR106

Association of Race with Risk of Mortality and Transfer to In-Center Hemodialysis in Peritoneal Dialysis Patients Melissa Soohoo,[1] Vanessa A. Ravel,[1] Elani Streja,[1] Sooraj Kuttykrishnan,[2] Miklos Zsolt Molnar,[3] Kamyar Kalantar-Zadeh,[1] Rajnish Mehrotra.[2] *[1]Harold Simmons UC Irvine MC, Orange, CA; [2]Univ of Washington, Seattle, WA; [3]Univ of Toronto, Toronto, ON.*

Background: Previous studies have reported that African Americans and Hispanics undergoing hemodialysis (HD) have a lower risk for death than Whites. Peritoneal dialysis (PD) is increasingly being used for the treatment of ESRD; however, data on racial differences in survival and time on therapy for patients undergoing PD in the United States have not been well described.

Methods: We examined the probability of treatment with PD among African Americans, Hispanics, and Whites from among the 162,671 patients who started maintenance dialysis in a large dialysis organization from 2007-2011 and the risk for all-cause mortality and transfer to in-center HD for a cohort of 16,896 PD patients (4,187 African-Americans, 2,299 Hispanics, and 10,410 Whites).

Results: African Americans and Hispanics were less likely to use PD (African Americans, OR: 0.63; Hispanics, OR: 0.73) when compared to Whites. Among African Americans, Hispanics, and Whites treated with PD, the mean age (mean + SD) was 51+14, 50+16, and 59+15 years and included 53%, 44% and 40% women; and 63%, 70% and 60% diabetics, respectively. Compared to Whites, African Americans (HR: 0.55, 95% CI: 0.49-0.61) and Hispanics (HR: 0.55, 95% CI: 0.46- 0.64) have a lower risk of mortality. However, there was no significant racial differences in risk for transfer to in-center HD (African Americans, 1.09 (0.99, 1.20); Hispanics, 0.94 (0.84, 1.06)).



Conclusions: Racial-ethnic minorities are less likely to use PD for treatment. However, both African Americans and Hispanics treated with PD have a lower risk for death, compared to Whites. Furthermore, there are no racial differences in risk for transfer to in-center HD. Further studies are needed to examine these racial-ethnic differences.

Circulating Bacterial-Derived DNA Fragment Level Is a Strong Predictor of Cardiovascular Disease in Peritoneal Dialysis Patients Cheuk-Chun Szeto.[1,2] *[1]Dept of Medicine & Therapeutics, The Chinese Univ of Hong Kong, Shatin, Hong Kong; [2]Dept of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.*

Background: Circulating bacterial DNA fragment is related to systemic inflammatory state in peritoneal dialysis (PD) patients. We hypothesize that plasma bacterial DNA level predicts cardiovascular events in new PD patients.

Methods: We measured plasma bacterial DNA level in 191 new PD patients, who were then followed for at least a year for the development of cardiovascular event, hospitalization, and patient survival.

Results: The average age was 59.3 ± 11.8 years; plasma bacterial DNA level 34.9 ± 1.5 cycles; average follow up 23.2 ± 9.7 months. At 24 months, the event-free survival was 86.1%, 69.8%, 55.4% and 30.8% for plasma bacterial DNA level quartiles I, II, III and IV, respectively ($p < 0.0001$). After adjusting for confounders, plasma bacterial DNA level, baseline residual renal function and malnutrition-inflammation score were independent predictors of event-free survival. Each fold increase in plasma bacterial DNA level confers a 26.9% (95% confidence interval, 13.0 – 42.5%) excess in risk of developing the composite cardiovascular end point. Plasma bacterial DNA also correlated with the number of hospital admission ($r = -0.379$, $p < 0.0001$) and duration of hospitalization for cardiovascular reasons ($r = -0.386$, $p < 0.0001$). Plasma bacterial DNA level did not correlate with baseline arterial pulse wave velocity (PWV), but with the change in carotid-radial PWV in one year ($r = -0.238$, $p = 0.005$).

Conclusions: Circulating bacterial DNA fragment level is a strong predictor of cardiovascular event, need of hospitalization, as well as the progressive change in arterial stiffness in new PD patients.

SA-OR108

Icodextrin Reduces Insulin Resistance in Incident Non-Diabetic Patients on Peritoneal Dialysis: Results of a Randomized Controlled Trial (STARCH) Thyago Proença de Moraes,[1] Maria Eugenia F. Canziani,[2] Marcia Olandoski,[1] Jose C. Divino-Filho,[4] Roberto Pecoits-Filho.[1] *[1]Pontifícia Univ Católica do Paraná, Brazil; [2]UNIFESP, Brazil; [3]UNESP, Brazil; [4]Karolinska Instt.*

Background: No randomized clinical trial have ever assessed the impact of the substitution of glucose by icodextrin as the osmotic agent in the long dwell on insulin resistance in non-diabetic PD patients.

Methods: This is a phase IV, multicenter, open-label with balanced randomization (1:1) and with two parallel-groups study conducted in Brazil. Inclusion criteria were non-diabetic adult patients on automated PD (APD) for at least 3 months on therapy prior to randomization. Patients assigned to the intervention group were treated with 2 liters of icodextrin 7.5% and the control group with glucose 2.5% during the long dwell and, at night in the cycler, a regular prescription with glucose-based PD solutions. The primary end-point was change in insulin resistance measured by HOMA index at 90 days. Secondary outcomes were changes in fasting glucose, insulin serum levels, glycated hemoglobin and body mass index. The central laboratory was blinded for allocation group.

Results: Sixty patients were randomly assigned to the intervention (n=33) or the control (n=27) group. There was no imbalance in any covariate between groups at baseline. After adjustment for pre-intervention HOMA index levels, the group treated with icodextrin had the lowest post-intervention levels at 90 days in both Intention to Treat analysis 1.49(CI95%1.23-1.74) versus 1.89(CI95%1.62-2.17), F=4.643, p=0.036, partial η^2 =0.078; and in the As Treated analysis 1.47(CI95%1.01-1.84) versus 2.18(CI95%1.81-2.55); F=7.488, p=0.010, partial η^2 =0.195). No significant differences were observed for HbA1c and fasting glucose. Insulin levels were lower in icodextrin group in the ITT analysis (p=0.034) but not in the AT analysis (p=0.060).

Conclusions: The substitution of glucose by icodextrin for the long dwell in APD patients improved insulin resistance measured by HOMA index in non-diabetic patients.

SA-OR109

Longitudinal Effect of Biocompatible Solutions on Peritoneal Solute Transport: Results from the Global Fluid Study Emma H. Elphick,[1] Mark Lambie,[1] Lucy Riley,[1] James A. Chess,[2] Yong-Lim Kim,[3] Marc Dorval,[4] Simon J. Davies.[4] *[1]Keele Univ; [2]Morriston Hospital; [3]Kyungpook National Univ Hospital; [4]Dumont Univ Hospital Centre; [5]Univ Hospital of North Staffordshire.*

Background: Long term peritoneal dialysis (PD) is associated with adverse changes in the peritoneal membrane, such as an increased solute transport demonstrating increased vascularity. Biocompatible solutions (BCS) were developed to mitigate this damage, so we examined their effect on solute transport.

Methods: We analysed the Global Fluid Study, a multinational cohort study. Included adults had 3 or more peritoneal equilibration test measurements more than 2 months from the start of PD and remained on one solution type. Follow up was up to 7.5 years (median of 2.3) in BCS and 12.8 (median 3.2) in standard solutions (SS). A random intercept/slopes linear mixed model assessed the effect of BCS on dialysate to plasma creatinine ratio (D/P Cr) over time for each solution, adjusted for glucose exposure, baseline dialysate IL-6 levels, Icodextrin, residual renal function (RRF) and peritonitis.

Results: Of 366 patients, 71 received BCS (58 Baxter Physioneal(BP), 8 Fresenius Balance(FB) and 5 Gambrosol Trio(GT)). After 2 months of PD the BCS group had a mean

predicted D/P Cr of 0.67 compared to 0.72 for the SS group (p=0.02). The trends over time also differed (p=0.002), with the BCS group D/P Cr increasing initially, peaking at 0.749 by 2.1 years, with no further increase. SS had a continuous increase in D/P Cr. A sensitivity analysis split patients into BP and FB/GT with a difference between groups of borderline significance (p=0.06). Peritonitis correlated with an increase in D/P Cr of 0.019 per episode for SS (p=<0.001), but there was no effect in BCS (p=<0.001). Baseline dialysate IL-6, RRF, glucose exposure and Icodextrin also predicted D/P Cr.

Conclusions: The temporal course of solute transport varies between biocompatible and standard solutions, which may vary between brands. Peritonitis has long term effects on solute transport, but not with biocompatible solutions.

SA-OR110

Maintenance of Volume Status Supported by Bioimpedance Leads to Better Preservation of Cardiac Function Boon Kay Tan,[1] Zanzhe Yu,[3] Simon J. Davies,[1,2] Frauke Wilma Gisela Wenzelburger.[1] *[1]Inst for Science & Technology in Medicine, Keele Univ, Stoke on Trent, North Staffordshire, United Kingdom; [2]Nephrology, Univ Hospital of North Staffordshire, Stoke on Trent, North Staffordshire, United Kingdom; [3]Nephrology, Renji Hospital, Shanghai, China.*

Background: To determine whether optimization of fluid status supported by bioimpedance vector analysis enhances preservation of cardiac function over 12 months.

Methods: Single centre predefined subgroup analysis of non-anuric PD patients from a multicentre prospective randomised controlled trial in which clinicians were blinded to BIA measurements in control subjects. In the active group (Bioimpedance analysis) BIA vector plots were used in combination with clinical assessment (BP, oedema) to manage fluid status with capture of decision making. Full Doppler-2D-echocardiography with colour-coded tissue-Doppler (TDI) was performed at baseline and 12 months by a single blinded operator to determine left ventricular ejection fraction (LVEF). Additionally, early diastolic (E') tissue velocity and early diastolic mitral inflow velocity (E) were measured. E/E' as a surrogate parameter of end-diastolic filling pressures was calculated.

Results: 39 enrolled patients (F/M, 14/25) were non-anuric at baseline and completed the 12 months follow up. The paired t test showed a significant decrease in LVEF in controls over 12 months (56.9±6.1 versus 52.5±6.5, P=0.013), whereas change in the active group was non-significant (54.0±7.4 versus 52.3±5.2, P=0.33). E/E' worsened in control group (8.6±2.3 versus 10.8±2.8 P<0.01) and no change in active group (11.0±3.2 versus 11.5±2.6 P=0.416). On multivariate analysis LVEF and E/E' at 12 months were independently predicted by their baseline values and study randomisation group after controlling for comorbidity status, age, gender and baseline BIA. Urine volume was better maintained in the active group but no between group differences in residual renal clearance or glucose exposure. Decision to reduce target weight was more likely to be made in active group than in control group.

Conclusions: The incorporation of BIA in setting target weight leads to better preservation of cardiac function.

Anti-Fibrotic Effect of Valproic Acid in Experimental Peritoneal Fibrosis in Rats Elerson Costalonga, Deise S.J. Pimentel, Filipe M. Silva, Irene L. Noronha. *Renal Div, Univ of São Paulo, São Paulo, Brazil.*

Background: Progressive increase in the thickness of peritoneal membrane (PM) and peritoneal sclerosis are complications of long-term peritoneal dialysis. The aim of this study was to analyze the effect of valproic acid (VPA), a histone deacetylase inhibitor with anti-fibrotic properties, in an experimental model of peritoneal fibrosis induced by chlorhexidine gluconate (CG) in rats.

Methods: Peritoneal fibrosis (PF) was induced by daily intra peritoneal injections of 0.1% CG for 15 consecutive days. Male Wistar rats (250-300 g) were divided into 3 groups (n=6 per group): **CONTROL,** control rats receiving only vehicle; **PF**, peritoneal fibrosis induced in rats; **PF+VPA**, rats with PF treated with VPA (300 mg/Kg/day by gavage). At day 15, the animals were sacrificed. The thickness of PM was measured by Masson thrichrome staining. The number of macrophages (MØ) and the α-smooth muscle actin (α-SMA) expression in the PM was analyzed by immunohistochemistry. mRNA expression of TGF-β, fibronectin, fibroblast specific protein-1 (FSP-1), Smad 3, and cytokines was analyzed by qPCR.

Results: Treatment with VPA significantly reduced the thickness of the peritoneal membrane and α-SMA staining area. Reduction of TNF-α, IL-1β, TGF-β, fibronectin, fibroblast specifif protein-1 (FSP-1), and Smad 3 mRNA levels were also observed.

	CON	PF	PF+VPA
Thickness of peritoneal membrane (mμ)	35±9	120±61*	31±15#
MØ (cells/mm^2)	133±90	826±375*	443±222*
α-SMA (%)	0.04±0.01	4.2±0.4*	0.8±0.1#
TNF-α (qPCR)	1.0±0.4	2.6±0.4*	0.9±0.3#
IL-1β (qPCR)	1.0±0.2	3.8±0.6*	2.1±0.2#
TGF-β (qPCR)	1.0±0.2	2.2±0.1*	1.1±0.2#
FSP-1 (qPCR)	1.0±0.2	3.1±0.2*	1.0±0.2#
Fibronectin (qPCR)	1.0±0.2	2.2±0.2*	1.3±0.5#
Smad 3 (qPCR)	1.0±0.2	2.3±0.5*	1.0±0.2#

*p<0.05 vs. CONTROL, #p<0.05 vs. PF

Conclusions: VPA was effective in reducing the thickness of peritoneal membrane in the experimental model of peritoneal fibrosis induced by CG developed in rats, possible due to its ani-inflamatory and anti-fibrotic effects.

SA-OR112

Inter-State Variability in Home Dialysis Utilization among Minorities in the U.S. Eric L. Wallace,[1] Janice P. Lea,[2] Eric Hammelman,[3] Joshua F. Cohen,[3] James A. Sloand.[4] *[1]Univ of Alabama at Birmingham; [2]Emory Univ; [3]Alavere; [4]Baxter Healthcare Corp.*

Background: The impact of race on dialysis modality use in the U.S. has received limited attention. Studies looking at national data in aggregate may be misleading if large inter-state variability exists. This investigation sought to examine use of home dialysis by U.S. minority populations as a whole and by individual state for Medicare beneficiaries.

Methods: 2012 Medicare 100% Outpatient Standard Analytic File was used to identify all dialysis patients using bill type "72" (outpatient dialysis). PD and HHD patients were identified using revenue and condition codes. The PD or HHD group was defined by having at least one claim during the year that met criteria for the category. Beneficiaries were counted once regardless of the number of different modalities they used that year. Medicare 100% Denominator Standard Analytic File was used to identify race and state of residence. A ratio of the percentage of patients on PD or HHD by race divided by the percentage of total patients on PD or HHD was used to determine the likelihood of being on a modality with respect to average.

Results: Nationally, 9.4% of Medicare dialysis patients received PD and 2.9% received HHD. Use of home dialysis varied across ESRD patients of different races for both PD and HHD as follows: White, 11.4% and 3.5%; Asian, 10.7% and 2.2%; Hispanic, 8.3% and 1.9%; and African American (AA) 6.6% and 2.3%; respectively. AA and Hispanic Medicare beneficiaries with ESRD were approximately 29% and 12%, and 19% and 33% less likely than average to receive PD and HHD, respectively. Significant inter-state variability existed for both total home dialysis use and across racial profile. In 95% of states where AA data was available, use of PD by prevalent AA with ESRD was less than the state's average (Exceptions: Arizona 1.04;Massachusetts 1.05). Similar findings were seen for Hispanics and for HHD use.

Conclusions: AA and Hispanics are underrepresented in the home dialysis population. Inter-state variability exists, but overall, use of PD and HHD by prevalent AA and Hispanics with ESRD was less than state averages. Reasons underlying these disparities deserve further investigation.

Time from Onset of Symptoms and Administration of Initial Antibiotic Therapy Predicts Peritonitis Outcomes and Hospitalizations Kalindu Muthucumarana,[1] Prue E. Howson,[1] Ramyasuda Swaminathan,[1] Douglas Patrick Crawford,[1] Samantha Chua,[2] Sally A. Burrows,[3] Ashley B. Irish.[1,3] *[1]Dept of Nephrology and Transplantation, Royal Perth Hospital, Perth, WA, Australia; [2]Dept of Nephrology, Sir Charles Gairdner Hospital, Perth, WA, Australia; [3]School of Medicine and Pharmacology, Univ of Western Australia, Perth, WA, Australia.*

Background: Peritoneal Dialysis (PD) peritonitis is a major cause of morbidity and mortality in PD patients. The relationship between treatment delay and outcome is not clearly defined, yet time to treatment is a critical determinant of the outcome of most infectious disorders. This study aims to define this relationship in PD peritonitis.

Methods: Multi-centreprospective study of PD peritonitis from August 2012-January 2014 in Western Australia. Patients were identified at presentation to hospital or community health facility and data pertaining to each PD peritonitis episode was analysed. SC (Symptom-to-Contact time), CT (Contact-to-Treatment time) and ST (Symptom-to-Treatment time) were recorded.

Results: 107 patients (58% Male, 13% Indigenous, 50% Diabetic, mean age 62) had 139 PD peritonitis episodes. 56% were admitted to hospital and the median SC was 5 hours, CT 2.3 hours, and ST 9 hours. 31 catheter removals and 9 deaths occurred during the study period (composite outcome PD failure). Predictors of admission were CT > 4 hours, Female sex and non-Diabetics. SC did not predict PD failure however CT > 4 hours was associated with an increased risk of PD failure by 4% for each hour over 4 hours (HR 1.04 95% CI 1-1.08 P=0.049) which persisted after adjustment for confounders (p=0.054). A ST >12 hours was also predictive of PD failure (HR 2.4 1.08-5.3 p=0.032). No other measured risk factor was found to predict PD failure in this population.

Conclusions: Each hour over 4 hours from initial antibiotic treatment after presentation, or 12 hours after symptom onset, increases the risk of PD failure or death following an episode of PD peritonitis. Delay in contact to treatment time increases hospitalizations. Targeting earlier reporting of symptoms and hospital presentation, and developing an expedited antibiotic strategy may improve outcomes from PD peritonitis.

SA-OR114

Klotho Overexpression Attenuates Peritoneal Fibrosis via Suppression of Wnt/β-Catenin Signaling Pathway in Mice Hiroyuki Kadoya, Minoru Satoh, Seiji Itano, Atsushi Uchida, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Development of peritoneal fibrosis caused by long-term exposure to bioincompatible dialysate is a major limiting factor for continuation of peritoneal dialysis (PD). However, the mechanisms underlying this process have not been fully elucidated. Activation of the wnt/β-catenin signaling pathway has been demonstrated to play an important role in the development of organ fibrosis. Moreover, klotho protein has been indicated to regulate wnt/β-catenin signaling. We investigated whether klotho protein could

reduce peritoneal fibrosis via inhibition of wnt/β-catenin signaling pathway.

Methods: Reporter mice for Wnt/ β-catenin signaling (BAT-LacZ), transgenic mice in which a-klotho is driven by human elongation factor 1 alpha promoter (KLTG), and wild type mice (WT) were used. All the strains are on C57BL/6 background. Experimental group of mice received daily intraperitoneal (i.p) injections of 4.25% glucose with lactate (PD solution) for 4 weeks. Whereas, control mice (Cont) received daily i.p injections of the same volume of saline.

Results: Enhanced Wnt/b-catenin signaling pathway was demonstrated in peritoneal mesothelium by increased β-galactosidase expression in BAT-LacZ mice after 4weeks exposure to PD solution. Concomitant expression of α-SMA, a marker of epithelial mesenchymal transition (EMT), was observed in mesothelium. Experimental group of mice also exhibited peritoneal fibrosis together with increased expressions of TGF-β and Fibronectin. On the other hand, KLTG treated with PD solution showed attenuation of of wnt/β-catenin signaling and amelioration of progression of peritoneal fibrosis.

Conclusions: Overexpression of klotho exerts protective action on peritoneal mesothelium exposed to PD solution through attenuation of wnt/β-catenin signaling.

TH-PO001

Anemia Influences Recovery from Acute Kidney Injury in Hospitalized Patients Melanie Godin,[1] Yu-Ting Christi Kao,[1] Etienne Macedo,[2] Ravindra L. Mehta.[1] *[1]UCSD, San Diego; [2]USP, San Paolo, Brazil.*

Background: Anemia (hemoglobin < 10g/L for cardiac surgery) is increasingly recognized as a modifiable risk factor for the development of AKI and correction of anemia has been associated with improved outcomes. We hypothesized that anemia is a risk factor for recovery from AKI in hospitalized patients.

Methods: 1946 patients hospitalized in the wards at an academic medical center over 24 months were included. Patients <18 years old, ICU, hospital stay <48h or >35 days, with ESRD were excluded. AKI definition was based on AKIN criteria sCr increase > 0.3 mg/dL within 48 hours. Renal recovery was classified as complete (last-ref sCr ≤0.3 g/dL or last/ref sCr ratio ≤1.2), no recovery (death or dialysis dependence at hospital discharge) or partial (meeting neither of the previous criteria). Hemoglobin (Hb) values at hospital admission, discharge (DC) and average (Av) Hb were evaluated as predictors of AKI recovery at hospital discharge.

Results: 348 (18%) patients developed AKI during hospital stay. When compared with non-AKI, the AKI group had lower Hb levels throughout hospitalization (baseline 11.1 versus 11.4; p=0.015, Av Hb 10.2 versus 10,8; p<0.001, discharge 10.1 versus 10.7; p<0.001) for AKI versus Non-AKI respectively. Worsening of anemia was more significant in AKI versus non-AKI patients from admission to DC (decline of 1.05 g/dL versus 0.69g/dL; p=0.001). Of the 348 AKI patients, 69% recovered completely, 23% had a partial recovery and 8% had no recovery. Increasing severity of anemia at baseline was associated with lower likelihood of renal recovery.

Table 1: Logistic regression of baseline Hb quintiles as predictors of renal recovery

	Baseline Hb range (g/dL)	OR of complete or partial recovery (p-value)
Q1	≤9.24	reference
Q2	9.25-10.50	2.74 (0.07)
Q3	10.51-11.60	5.02 (0.02)
Q4	11.61-12.80	4.87 (0.02)
Q5	≥12.81	5.63 (0.01)

Conclusions: AKI patients have lower Hb levels than non-AKI patients. The severity of anemia influences recovery from AKI. Further studies are needed to ascertain the cause of anemia and evaluate its effects on development of CKD post AKI.

Funding: NIDDK Support

TH-PO002

Anemia Is a Risk Factor for Development of Acute Kidney Injury in Hospitalized Patients Melanie Godin,[1] Yu-Ting Christi Kao,[1] Etienne Macedo,[2] Ravindra L. Mehta.[1] *[1]UCSD, San Diego, CA; [2]USP, San Paolo, Brazil.*

Background: Anemia (Hb< 10g/dL) is a recognized risk factor for the development of AKI in cardiac surgery. There is a lack of information on the prevalence of anemia in acute kidney injury (AKI) in other settings. We hypothesized that anemia is common and predicts AKI in hospitalized patients.

Methods: 1946 patients hospitalized at an academic medical center over 24 months who had sequential Hb and creatinine values at admission, during hospitalization and at discharge were included. Patients <18 years old, ICU, hospital stay <48h or >35 days, with ESRD or dialysis were excluded. Comorbidities and CKD status were recorded from discharge ICD-9 codes. AKI definition was based on AKIN criteria sCr increase > 0.3 mg/dL within 48 hours. Hemoglobin (Hb) values at hospital admission, discharge (DC) and average (Av) Hb were evaluated as predictors of AKI during hospital stay.

Results: At admission 26% of pts had Hb levels <10g/dL while 40.3% met this criteria during hospitalization. 348 (18%) patients developed AKI and had significantly lower levels of Hb with more patients with Av Hb <10g/dL than the non-AKI group (51.1% versus 20.7%; p<0.001). Worsening of anemia was more severe in AKI than non-AKI patients (Hb decline of 1.05 versus 0.69 g/dL between admission and DC; p=0.001). Multivariable logistic regression adjusting for co-morbidities (age, gender, BMI, diabetes, CKD and heart failure), identified Hb levels <10g/dL as an independent predictor of AKI (OR 1.82; p<0.001).

Table 1: Multivariable Logistic Regression Model for development of AKI

	OR (p-value)
Av Hb <10g/dL	1.84*
Age	1.01**
Male	1.72*
BMI	1.03**
CKD	2.19*
Diabetes	1.73*
Heart failure	3.01*
*p<0.001 ** p<0.02	

Hb levels did not correlate with the severity of AKI. Although patients with pre-existing CKD had lower levels of Hb at all time points during hospitalization, they did not experience a worsening of anemia.

Conclusions: Anemia is a risk factor for AKI in hospitalized patients. Correction of anemia could potentially modify this risk. Further studies are needed to define the cause of anemia and its relationship to AKI.

Funding: NIDDK Support

TH-PO003

Patterns of Serum Creatinine Predict Renal Recovery After Acute Kidney Injury in Critically Ill Patients Melanie Godin,[1] Etienne Macedo,[2] Yu-Ting Christi Kao,[1] Josee Bouchard,[3] Ravindra L. Mehta.[1] *[1]Neph, UCSD, San Diego, CA; [2]Neph, USP, San Paolo, Brazil; [3]Neph, HSC, Montreal, QC, Canada.*

Background: The severity and duration of AKI are important factors determining outcomes from AKI. Currently, it is difficult to determine if recovery is occurring to target interventions. We hypothesized that the patterns of sCr change would provide a method to predict the magnitude and time to renal recovery.

Methods: We studied 685 ICU patients screened for a prospective study from Jun 06 to Dec 08. AKI was defined by the AKIN Scr criteria (≥ .3mg/dL change within 48 hours). We calculated the ratio of ICU discharge/reference sCr to evaluate renal recovery with a ratio of ≤1.2 reflecting complete recovery. Duration of AKI, sCr Upslopes (US; from ref to time point) and downslopes (DS;peak to time point) at 12, 24 and 48h as well as peak, magnitude of increase or decrease were evaluated to predict renal recovery and AKI duration.

Results: 164 (23.9%) patients met AKIN criteria and 37 were treated with RRT and were not included in the ratio of sCr and DS analysis. Complete recovery was met in 36%. sCr US and DS at 48h, peak, magnitude of increase and decrease were individually correlated with the extent of renal recovery and with AKI duration.

Liner regression predictor	Ratio of Renal Recovery (DC/reference sCr)		AKI duration (h)	
	B (p-value)	r	B (p-value)	r
Peak sCr	.66(<.001)	.39	18.7181 (.002)	.34
Max–ref sCr (magnitude increase)	.01(<.001)	.64	35.7043 (<.001)	.37
US48h	1.15(.001)	.42	82.1456 (.029)	.28
Peak–last ICU sCr (Magnitude decrease)	-.58(<.001)	.28	-6.8564 (.608)	.06
DS48h	-.53(.039)	.42	-25.9102 (.084)	.10
*US=upslope; DS=downslope;				

The ratio of recovery and duration of AKI were moderately correlated (R=.459, p<0.001). RRT dependency at ICU discharge was predicted by sCr peak (OR 2.65 p=.04), magnitude increase (OR 3.13 p<.001) and US at 24 (OR 4.03 p=.002) and 48h (OR 21.39 =.003).

Conclusions: Patterns of sCr change and AKi duration are predictive of renal recovery at ICu discharge. Future prospective studies should evaluate these parameters to predict recovery and identify time points for intervention.

Risk Factors for Recurrent AKI Edward D. Siew,[1] Sharidan Parr,[1] Khaled Abdel-Kader,[1] Nisha Bansal,[3] Svetlana Eden,[1] James Fly,[2] Adriana Hung,[1] Theodore Speroff,[1,2] T. Alp Ikizler,[1] Michael Edwin Matheny.[1,2] *[1]Vanderbilt Univ Medical Center; [2]GRECC, Tennessee Valley Healthcare System (TVHS); [3]Kidney Research Inst, Univ of Washington, WA.*

Background: Recurrent AKI compounds the risk for progressive kidney disease. We examined risk factors for hospitalized recurrent AKI in U.S. Veterans.

Methods: We identified AKI survivors hospitalized within a regional VA healthcare network from 2002-2010. We excluded patients with ESRD; patients whose hospitalization involved nephrectomy, glomerulonephritis, or urinary tract obstruction; or dialysis dependence at discharge. We defined AKI as a 0.3 mg/dl or 50% increase from baseline to peak serum creatinine (SCr). Baseline SCr was defined as the most recent outpatient value 7-365 days prior to AKI (index and recurrent). Risk factors examined included demographics, comorbidities, and inpatient diagnoses and procedures. Fine and Gray Proportional Hazards regression was used to examine time to first recurrent AKI with death as a competing risk.

Results: Among 17,323 patients, 4,377(25.3%) experienced hospitalized recurrent AKI within a year, and 2,524(15%) died before experiencing recurrent AKI. Median time to recurrent AKI was 56(IQR:16-157) days. Risk factors for recurrent AKI included age, low serum albumin(SAlb), congestive heart failure(CHF), diabetes(DM), peripheral vascular disease(PVD), and advanced liver disease(ALD). Inpatient factors associated with recurrent AKI included cancer, chemotherapy, CHF, and ALD.

Risk Factor	**Adjusted Hazard Ratio aHR (95%CI)**
Age(50-80 yrs)	1.2(1.1-1.4)
SAlb(4-3 g/dl)	1.3(1.2-1.5)
Comorbidities	
CHF	1.3(1.2-1.4)
ALD	1.3(1.1-1.6)
DM	1.2(1.1-1.2)
PVD	1.2(1.1-1.2)
Inpt Dx/Proc.	
CHF	1.3(1.2-1.4)
ALD	1.6(1.3-1.9)
Cancer	1.1(1.0-1.2)
Chemotherapy	2.0(1.5-2.6)
Cardiac surgery	0.7(0.5-0.9)
Abd surgery	0.8(0.6-0.9)
Mech Ventilation	0.9(0.8-1.0)

* aHR >1 indicates a higher risk for recurrent AKI

Conclusions: Elderly patients with CHF, ALD, or receiving chemotherapy are at high risk for recurrent AKI and may benefit from risk reduction strategies. Future studies should examine how care delivery influences this risk.

Funding: NIDDK Support, Veterans Affairs Support

TH-PO005

Identification of Risk Factors of Community-Acquired Acute Kidney Injury in Outpatients Takeshi Matsubara, Tatsuo Tsukamoto, Motoko Yanagita. *Dept of Nephrology, Graduate School of Medicine, Kyoto, Japan.*

Background: Compared with hospital-acquired AKI, little is known about community-acquired AKI (CA-AKI). The definition of AKI is a small increase in Cre from baseline within 2-7 days, and extending this duration could cause an increase of false positives such as the patients with Cre fluctuation or chronic kidney disease (CKD). Therefore, the aim of study is to clarify the prevalence, risk factors, and outcome of CA-AKI in outpatients.

Methods: Firstly, we enrolled the patients whose Cre is increased by 50% or +0.3mg/dl in electric health record from baseline Cre, defined as the most recent Cre during preceding 12 months between Sep 2011 and Mar 2012 in our hospital. Next, the enrolled patients were divided into "False positive" and "CA-AKI" group. False positive group was consisted of two subgroups; one is a group of patients with Cre fluctuation, who did not fulfill the criteria when baseline Cre was redefined as the mean value of Cre obtained one year before the enrolled date, and the other is a group of patients with CKD, whose slope of the reciprocal Cre curves was constant during 6 months before and after the enrolled date. The rest of above patients were all classified into CA-AKI group. Finally, the prevalence rates of comorbidities and the outcome (AKI stage 2 and 3, or death within one year) determined from chart review were compared between CA-AKI and False positive group by multivariate analysis.

Results: Among 85172 outpatients in the analysis, 1298 patients (1.5%) were enrolled, and classified into False positive (457 patients: 0.51%), and CA-AKI (841 patients: 0.99%) group. CA-AKI group had higher prevalence of active malignancy (OR 2.98: CI 1.91-4.76), cardiovascular disease (OR 1.88: 1.36-2.62), age>65 (OR 1.71: 1.23-2.36), NSAIDs (OR 3.74: 2.22-6.63), Calcineurin Inhibitor (OR 3.08: 1.39-7.37), and ACEi/ARB (OR 1.68: 1.23-2.30) compared with False positive group. The proportion of AKI stage 2 and 3, or death within a year was higher in CA-AKI group (OR 6.81 p<0.001).

Conclusions: CA-AKI could occur in approximately 1% of outpatients, and showed poor outcome. Several comorbidities and nephrotoxic agents listed above could be candidates of the risk factors for CA-AKI.

Funding: Government Support - Non-U.S.

TH-PO006

Incidence of and Risk Factors for Acute Kidney Injury After Major Surgery M. Grams,[1] Yingying Sang,[1] Shoshana Ballew,[1] Zoltan Szabo,[4] Kunihiro Matsushita,[1] Kamyar Kalantar-Zadeh,[3] Josef Coresh,[1] Csaba P. Kovesdy.[2] *[1]Johns Hopkins Univ; [2]Memphis VA; [3]UC Irvine; [4]Linkoping Univ.*

Background: Acute kidney injury (AKI) is a frequent complication after major surgery; yet surgery-associated risk of AKI has not been well characterized, particularly for non-cardiovascular surgery. We sought to determine rates, predictors, and consequences of AKI after major surgery in a nationally representative cohort.

Methods: The study population included 3.5 million veterans with eGFR >60 ml/min/1.73 m^2 in 2004-6. The patient's first major surgical hospitalization occurring before 2011 was selected for analysis. Inpatient, post-surgical AKI was classified according to KDIGO criteria, with baseline kidney function defined as mean outpatient creatinine in the year prior to surgery.

Results: There were 167,262 veterans with eligible hospitalizations, most commonly for general (GI/abdominal procedures, 28%), orthopedic (20%), vascular (16%), and cardiac (14%) surgeries. Overall, 12% of hospitalizations were complicated by AKI (Stage 1: 75%, Stage 2: 14%, Stage 3 (No RRT): 7%, AKI-RRT: 4%). Transplant (63%), cardiac (19%), and general surgeries (13%) had the highest rates of AKI. Overall, older age, black race, lower baseline eGFR, and the presence of hypertension, diabetes, congestive heart failure, and liver disease were associated with higher risk of AKI. Diuretic and ACE-inhibition/ARB use were also associated with higher risk of AKI, whereas statin use was associated with lower risk of AKI. Higher AKI stage during surgical hospitalization was associated with longer length of stay and higher risk of end-stage renal disease and mortality.

	No AKI	AKI			
		KDIGO Stage 1	*KDIGO Stage 2*	*KDIGO Stage 3 (no RRT)*	*AKI-RRT*
N, %	147,369 (88.1%)	14,893 (8.9%)	2,837 (1.7%)	1,348 (0.8%)	815 (0.5%)
Length of stay, days	8.8	14	19	22	48
In-hospital mortality, %	1.0	4.8	15	25	31
1-year mortality, %	8.8	16	29	40	51
1-year ESRD, %	0.05	0.47	0.67	1.3	9.7

Conclusions: AKI is common after many types of surgery, in particular transplant, cardiac, and general surgeries, and it is associated with higher risk of adverse outcomes. Evaluation of preventative and treatment strategies for AKI is needed.

Funding: NIDDK Support

TH-PO007

Effect of Pre-Operative Proteinuria on Post-Operative Outcomes after Coronary Artery Bypass Grafting Lekha K. George,[1] Miklos Zsolt Molnar,[1] Santhosh K. Koshy,[2] Jun Ling Lu,[1] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,4] *[1]Univ of Tennessee; [2]Regional One Medical Center; [3]Univ of California Irvine; [4]Memphis VAMC.*

Background: Proteinuria is associated with reduced coronary flow reserve and increased microvascular resistance. We hypothesized that pre-operative albuminuria carries a poor prognosis after coronary artery bypass surgery (CABG).

Methods: Among 17,812 patients who underwent CABG during 2006-2012 in any VA hospital, we identified 5,968 with available preoperative urine microalbumin-creatinine ratio (UACR) measurements. We examined the association of UACR <30, 30-299 and >=300 mg/g with 30-day mortality and hospitalization length >10 days using logistic regression, and with acute kidney injury (AKI) (defined by K-DIGO criteria) using ordinal logistic regression. Adjustments were made for age, gender, race, baseline BP, pre- and perioperative ACEI and statin use, baseline eGFR and cholesterol, and comorbidities.

Results: Mean±SD baseline age and eGFR were 65±8 years and 77±19 ml/min/1.73m^2, respectively. 99% of patients were men, 10% were black and 88% were diabetic. 102 patients (1.71%) died within 30 days of CABG, and 26.8% patients developed AKI. Median length of hospitalization was 9 days (IQR: 6-14). Higher UACR did not confer a significant increase in 30-day mortality, but was associated with significantly longer hospitalizations and higher incidence of all stages of AKI (Table).

	UACR <30 mg/g (N=3,852)	UACR 30-299 mg/g (N=1,671)	UACR ≥300 mg/g (N=445)
30-Day Mortality (OR, 95%CI)	1.0	1.14 (0.73-1.79)	1.50 (0.75-2.97)
Length of Hospitalization >10 days (OR, 95%CI)	1.0	1.22 (1.07-1.39)*	1.73 (1.38-2.18)*
AKI (estimated incidence, %±SD)			
Stage 1	21.1±6.2	26.0±7.0***	33.0±8.0**
Stage 2	2.5±1.1	3.3±1.4***	5.0±2.3**
Stage 3	0.7±0.3	0.9±0.4***	1.4±0.7**

*p<0.001, **p<0.01, ***p<0.05, compared to UACR <30 mg/g group

Conclusions: Higher UACR is associated with significantly longer post-CABG hospitalization and AKI incidence. The effects of antiproteinuric treatments on post-CABG outcomes will need to be examined in randomized trials.

TH-PO008

Risk Factors for Progression of Acute Kidney Injury to Chronic Kidney Disease in Critically Ill Patients Jung Nam An,[1] Dong Ki Kim,[2] Hajeong Lee,[2] Yun Kyu Oh,[1] Yon Su Kim,[2] Chun Soo Lim,[1] Jung Pyo Lee.[1] *[1]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: Acute kidney injury (AKI) is an independent risk factor for progression to advanced stage chronic kidney disease (CKD). Survivors after AKI episode have also increased over time. We tried to analyze the effects of AKI episode during hospitalization on the risk for CKD.

Methods: Among 950 adult (age > 20 years old) patients who started continuous renal replacement therapy (CRRT) in intensive care units at Seoul National University Hospital and Boramae medical center from 2010 to 2013, a total of 173 surviving AKI patients at three months after initiation of CRRT were enrolled in this study. Primary outcome is composite of RRT and increased serum creatinine (sCr) level more than 50% over 3 months.

Results: The frequency of primary outcome was 33.5%. In the patients with primary outcome, sCr levels at baseline and after 3 months were 2.07 ± 1.82 mg/dL and 3.43 ± 2.76 mg/dL (p < 0.001), respectively. Compared with the others with recovered renal function, underlying diabetic nephropathy was more frequent (22.4% versus 5.2%, p = 0.001), sCr level at 72 hours after initiation of CRRT was higher (3.10 ± 1.29 mg/dL versus 1.59 ± 0.74 mg/dL, p = 0.031), and far more patients failed in RRT weaning (63.8% versus 2.6%, p < 0.001). In logistic regression analysis, old age, diabetic nephropathy, post-operative AKI, increased sCr level at 24 and 72 hours after initiation of CRRT, and RRT weaning failure increased the risk for prolonged kidney injury. After adjusting other risk factors, total duration of RRT (Odds ratio [OR] 1.25; 95% confidence interval [CI] 1.42; p < 0.001) and decreased heart rate at 72 hours after initiation of CRRT (OR 0.95; 95% CI 0.92-0.99; p = 0.014) were significantly associated with progression to CKD.

Conclusions: AKI episodes requiring CRRT are independent risk factors for CKD progression. The severity of AKI episodes is closely related to clinical outcomes, and strong predictor of advanced CKD.

TH-PO009

A Novel Risk Score of Contrast-Induced Nephropathy After Percutaneous Coronary Intervention Wei Qin, Ling Ji, Lichuan Yang. *Div of Nephrology, West china Hospital of sichuan Univ, Chengdu, Sichuan, China.*

Background: Contrast-induced nephropathy (CIN) is a major cause of acute kidney injure. Although several studies had been done to identify risk factors and score system of CIN, yet their application was limited. We aim to establish a novel risk score system could be easily used in clinical environment.

Methods: 806 PCI patients, randomly divide into analysis cohort (70%) and validation cohort (30%), were enrolled retrospectively. Risk factors of CIN were identified using univariate and multivariate logistic regression in analysis cohort. Risk score system was developed based on regression coefficients of them. Sensitivity and specificity of the new risk score system was validated and compared with previous models.

Results: Incidence of CIN was 12% in total cohort. High CIN incidence (50%) was observed in CKD patients. 62 potential risk related variables were included in univariate and multivariate analysis. Age, BMI, myoglobin, cardiac function, hypoproteinemia, CKD, IABP (intra-aortic ballon pump) and PVD (peripheral vascular disease) were identified as independent risk factors. A novel risk score system was established.

Risk factors	Weighted score in model
Age>75 years	1
BMI>26 kg/m^2	1
Myoglobin (ng/mL)	
<1000	1

The new risk score system was validated in validation cohort. Highest sensitivity and specificity (c-statistic: 0.917, 95%CI 0.877–0.957) was observed when comparing with previous models.

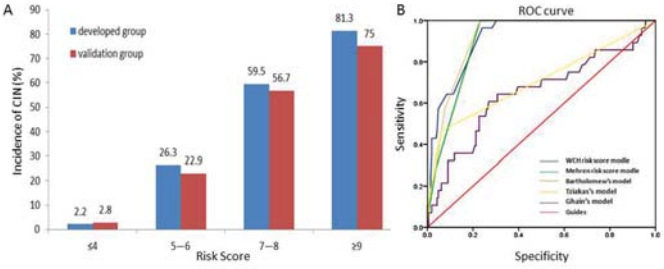

Figure 1: (A) Risk stratification of CIN according to the present risk score system. (B) Comparing of prediction accuracy among different CIN risk score models.

Conclusions: A novel CIN risk score model was developed based on a retrospective study of 805 patients undergoing PCI procedure. This model is the best score model in comparison with previous models. Application of this model might be helpful to predict CIN in patients undergoing PCI.

Prospective Observational Study of Acute Kidney Injury after Cardiac Surgery: Enrichment Strategy - on Behalf of the NephroNet Investigators James A. Tumlin, Ravindra L. Mehta, Jorge Cerda, Kevin W. Finkel, Claude Mabry Galphin, Jesse M. Goldman, Sudarshan Hebbar, Nelson P. Kopyt, Michelle W. Krause, Andreas Orfanos, Amber S. Podoll, Diane Potvin, Jon R. Von Visger, John Jason White, Lakhmir S. Chawla. *Nephronet Investigators.*

Background: To design and appropriately power clinical trials it is important to have an accurate estimation of the event rate. Typically, the rates of post-surgical AKI have been derived from national registries or epidemiologic studies. To better select the patients at increased risk of developing AKI, we conducted an observational study to determine the AKI rates in an "enriched" population. Well-defined risk factors were selected as pre-specified inclusion/exclusion criteria. The occurrence of cardiac surgery associated-AKI was determined and other clinical outcomes were collected for these patients for 90 days.

Methods: The entry criteria were patients scheduled for on-pump cardiac surgery and two or more of the following risk factors: Class III/IV CKD, IDDM, NIDDM + proteinuria, COPD, EF < 40%, anemia, or contrast exposure within 7days postoperatively (without evidence of AKI). Primary endpoint was proportion of patients with AKI. Secondary endpoints included major adverse kidney events for 90 days including the need for dialysis; or renal dysfunction as compared to baseline eGFR.

Results: 100 patients were enrolled. 97 patients were included in the Per Protocol (PP) analysis. In PP, the mean (SD) age was 65.7+ 10.0 years, 73% were male, and 86% were white. Of the 97 patients, 56 (57.7%) developed AKI within 7 days of the operation (Stage I: 71%, Stage II: 21%, Stage III: 7%). Among the patients with AKI, 34 (61%) had sustained (> 48 hours) or severe AKI (Stage II or III) within the 90 day period. 29 patients out of 34 with sustained AKI had pre-existing CKD.

Conclusions: In this prospective observation study, we demonstrate that our inclusion/exclusion study design can enrich the AKI event rate to > 50%. Pre-existing CKD appears to be a critical risk factor for sustained or severe AKI.

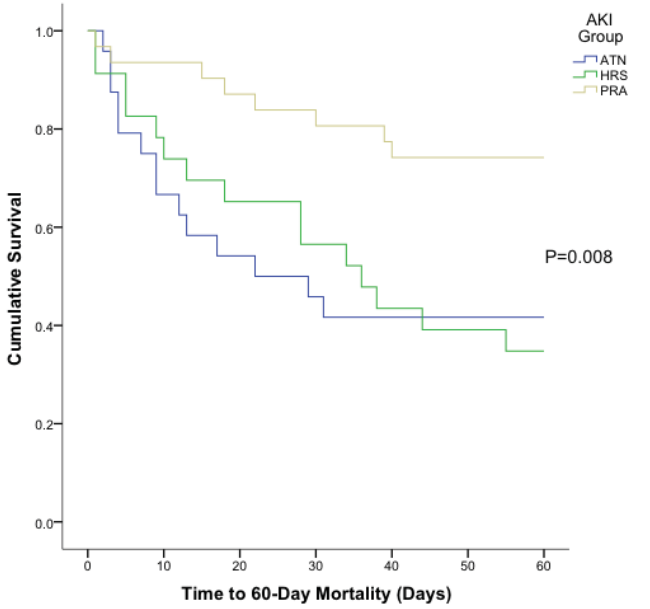
Acute Kidney Injury and Mortality in Cirrhosis – Is MELD Score Enough? Guillermo Ortiz-Sanjuan,[1] Andrew S. Allegretti,[1] Julia Beth Wenger,[1] Joseph James DeFerio,[1] Sahir Kalim,[1] Hector Tamez,[2] S. Ananth Karumanchi,[2] Ravi I. Thadhani.[1] *[1]Massachusetts General Hospital; [2]Beth Israel Deaconess Medical Center.*

Background: Acute kidney injury (AKI) increases the risk for mortality in cirrhosis. It remains uncertain whether the type of AKI increases mortality risk beyond the Model of End-Stage Liver Disease (MELD) score.

Methods: 75 hospitalized patients with cirrhosis and AKI were prospectively followed. MELD score and markers of liver and kidney function were collected on enrollment. AKI was classified as hepatorenal syndrome (HRS), acute tubular necrosis (ATN), prerenal azotemia (PRA), or other by review of records and independent physician adjudication. HRS was diagnosed using the 2006 Ascites Club Criteria. Kaplan Meier curves and log-rank tests were used to assess differences in 60-day survival by AKI group and multivariable Cox Proportional-Hazards were used to adjust for MELD score.

Results: 19 (25%) patients were diagnosed with ATN, 23 (31%) with HRS, 27 (36%) with PRA, and 6 (8%) with other etiologies. MELD scores were lower for PRA, but similar for ATN and HRS[Median (Q1,Q3): ATN 28 (21,34), HRS 28 (24,36), PRA 20 (17,26); overall p=0.002; ATN versus HRS p=0.48]; Creatinine was lower in PRA, but similar between ATN and HRS [ATN 2.1 (1.8,3.5)mg/dL, HRS 2.7 (2.1,3.0), PRA 1.3 (1.2,2.0); overall p<0.001; ATN versus HRS p=0.25]; total bilirubin (TB) and INR were similar across groups [INR: ATN 3.9 (2.5,10.4)mg/dL, HRS 5.1 (2.1,12.3), PRA 4.1 (1.5,9.1)mg/dL; overall p=0.51] [TB: ATN 1.8 (1.5,2.5), 1.8 (1.6,2.0), PRA 1.7 (1.4,2.1); overall p=0.50]. 60-day mortality was 58% for ATN, 65% for HRS, and 26% for PRA (p=0.008); after adjusting for MELD score, survival differences by AKI group were no longer significant



Conclusions: In our cohort, patients with ATN and HRS were at the highest risk for 60-day mortality. Nonetheless, the type of AKI did not add predictive value above and beyond MELD score.

TH-PO012

Postoperative Serum Chloride Levels and Acute Kidney Injury in Liver Transplant Recipients Ho Geol Ryu, Hannah Lee, Se-Hee Min. *Anesthesiology, Seoul National Univ Hospital, Seoul, Korea.*

Background: Acute kidney injury (AKI) is a common complication after liver transplantation with a reported incidence between 17 and 95%. Risk factors of AKI after liver transplantation include intraoperative blood loss and hypotension, postoperative sepsis, and calcineurin inhibitors. Chloride plays an important role in acid base balance and is regulated by the kidneys. Previous reports have suggested that metabolic acidosis caused by perioperative hyperchloremia may cause intrarenal vasoconstriction leading to decreased GFR and urine output. However, the association between AKI and perioperative chloride level is lacking in liver transplantation patients and tudy was performed to see if there was a relationship.

Methods: Patients who received liver transplantation between July 2010 and December 2012 at Seoul National University Hospital were included in the study. Patients were grouped according to their average serum chloride level for 72 hours after surgery into 3 groups (average chloride level <101, 101-110, >110 mEq/L) and the difference in the risk of AKI was analyzed.AKI was defined according to the RIFLE criteria. Risk factors for developing AKI after liver transplantation were also analyzed.

Results: A total of 363 patients had received liver transplantation during the study period and 86 (23.7%) had developed AKI. There was no difference in the incidence of AKI between the 3 groups that were divided according to the average serum chloride level (p=0.85). Preoperative serum chloride levels were also not associated with the development of postoperative AKI. Multivariate regression analysis identified high MELD scores (1.037 [1.006, 10.68], p=0.0174), deceased donor (2.746 [1.515, 4.987], p=0.0009), and preoperative renal replacement therapy (21.918 [4.459, 107.738], p=0.0001) as independent risk factors of AKI.

Conclusions: Perioperative serum chloride levels were not associated with the development of AKI after liver transplantation. Risk factors associated with postoperative AKI after liver transplantation include high MELD scores, deceased donor, and preoperative renal replacement.

TH-PO013

High and Low Level of Serum Uric Acid Is a Novel Risk Factors for Acute Kidney Injury: A Retrospective Database Analysis By Using the Integrated Medical Information System at Kochi Medical School Hospital Taro Horino,[1] Kazunori Otomo,[2] Takeo Miki,[2] Hiromi Kataoka,[3] Yutaka Hatakeyama,[3] Tatsuki Matsumoto,[1] Kazu Hamada,[1] Yoshiko Shimamura,[1] Koji Ogata,[1] Kosuke Inoue,[1] Yoshinori Taniguchi,[1] Yoshio Terada,[1] Yoshiyasu Okuhara.[3] *[1]Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi Univ, Nankoku, Japan; [2]Center for Innovative and Translational Medicine, Kochi Medical School, Kochi Univ, Nankoku, Japan; [3]Center of Medical information Science, Kochi Medical School, Kochi Univ, Nankoku, Japan.*

Background: Serum uric acid (SUA) levels before cardiovascular surgery had been reported to be independent risk factors for postoperative acute kidney injury (AKI). These studies however had some limitations. Here, we investigated the association between SUA levels and AKI by performing a retrospective database analysis using 30 years of data.

Methods: A total of 78,626 hospitalized patients aged > 18 years were enrolled. AKI was diagnosed according to AKIN criteria. Multivariate logistic regression analyses were performed to investigate the independent association between SUA levels and AKI. Kidney function and comorbidities, medication, procedures performed prior to AKI onset were taken into account as possible confounding risk factors.

Results: Adjusted odds ratios were higher in both high and low SUA strata in all sexes and age classifications. In high SUA strata, odds ratios were higher in women aged ≤50 years than in men of both age groups and women aged >50 years, and this observation was particularly remarkable in the strata corresponding to SUA levels > 7 mg/dL (OR 10.0; 95% CI, 6.43-15.58; P < 0.001). In low SUA strata, odds ratios were higher in men aged ≤50 years than in women of both age groups and men aged >50 years, and this observation was remarkable in the strata corresponding to SUA levels < 2 mg/dL (OR 9.89; 95% CI, 5.46-17.91; P < 0.001).

Conclusions: We suggest that SUA could be an independent risk factor for AKI development in hospitalized patients. Additionally, we found that patients aged ≤50 years have a greater predilection to develop AKI than those aged >50 years and the correlation between SUA levels and AKI risk are different in gender dependent manners.

TH-PO014

Risk of Acute Kidney Injury According to Each Valve Involved During Cardiac Surgery Jacqueline Villase?or, Armando Vazquez-Rangel. *Nephrology, Inst Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico, DF, Mexico.*

Background: Valve surgery is known to confer a higher risk for acute kidney injury (AKI) or renal support therapy (RST), but there is limited information dissecting the relation among the involved valves and their renal prognosis in cardiac surgery. **Aim**: To compare renal prognosis according to each valve involved or their combination during cardiac surgery.

Methods: Retrospective cohort study including patients who underwent coronary artery bypass grafting surgery (CABG) as control group or open heart valve procedures from March 1st 2009 to February 28th 2011. We excluded patients with pre-existing chronic kidney disease stage 5 or preoperative AKI. AKI was defined by serum creatinine according to KDIGO criteria.

Results: A total of 1155 patients were analyzed. AKI was present in 375 patients (32.5%) from which 72 (6.2%) required RST. There were 299 (25.9%) patients for CABG, 41 (3.5%) only tricuspid, 158 (13.7%) only mitral, 353 (30.6%) only aortic valve, 200 (17.3%) involved 2 valves, 41 (3.5%) for 3 valves, 51 (4.4%) for CABG+1 valve, and 12 (1%) for CABG+2 or 3 valves. The percentages of AKI and RST respectively were: 29.1 and 5.7% for CABG, 24.4 and 9.8% for tricuspid, 31.0 and 4.4% for mitral, 31.7 and 4.0% for aortic, 34.5 and 8.5% for 2 valves, 39.0 and 12.2% for 3 valves, 49.0 and 13.7% for CABG+1 valve, and 58.3 and 8.3% for CABG+2 or 3 valves. In multivariable analysis adjusting for pre-, trans-, and post-operative variables, only aortic valve (OR 1.81 [1.05-3.13], p=0.033) and CABG+valve (OR 2.27 [1.18-4.38], p=0.014) showed an increased risk for AKI; while for RST only tricuspid valve showed a trend (OR 3.76 [0.93-15.15], p=0.063).

Conclusions: Renal prognosis differs according to each valve involved during cardiac surgery. While aortic valve shows a higher incidence of AKI with lower requirement for RST, tricuspid valve shows less AKI with higher requirement for RST. When more than 1 valve is involved there is a higher risk for both outcomes, but they could be at least partially due to some other pre-, trans- or post-operative factors, while the single valve observations tended to be independent from them.

TH-PO015

Combining Risk Factors Improves Acute Kidney Injury Prediction in Intensive Care Unit Rakesh Malhotra,[1,5] Etienne Macedo,[2] Josee Bouchard,[3] Kianoush Banaei-Kashani,[4] Ravindra L. Mehta.[5] *[1]VUMC; [2]U Sao Paulo; [3]U Montreal; [4]Mayo Clinic; [5]UCSD.*

Background: Several individual risk factors have been reported to be associated with Acute Kidney Injury (AKI). A previous study by Chawla et al has proposed combining individual risk factors to improve predictive value for AKI. We evaluated the performance of a modified AKI risk sampling tool in a multicenter prospective cohort study of critically ill patients.

Methods: Our study included two independent cohorts: 717 patients admitted to a surgical intensive care unit (SICU) and medical intensive care unit (MICU) at UCSD from June 2006 to December 2008 and 1280 patients admitted to SICU and MICU at Mayo Clinic, Rochester from Jan 2010 to December 2010. Risk factors were classified as chronic major comorbidities (e.g., advanced age, diabetes mellitus, chronic kidney disease, or cardiovascular disease), chronic minor (e.g., hypertension, morbid obesity, cancer, chronic lung disease) and acute factors (e.g., hypotension, sepsis, high-risk surgery, mechanical ventilation or nephrotoxin exposure). Within 48 hours of ICU admission we stratified patients as no risk, baseline risk, acute risk, and enhanced risk based on their risk factor profile. The incidence of AKI, need for renal replacement therapy (RRT) and mortality were assessed among risk groups. AKI was defined by an absolute increase of 0.3mg/dL from reference sCR within 48 hours.

Results: The incidence of AKI in UCSD cohort was 22.9% (n=164) and 5.6% of patients required dialysis (n=40). In MCR cohort, 40% (n=511) developed AKI and 1.5% (8) required dialysis. Patients classified as enhanced risk in both UCSD and Mayo cohorts had a higher incidence of AKI (31.1% versus 9.1%; p < 0.001 and 56% versus 5%; p < 0.001), higher mortality (10.1% versus 0.9%; p < 0.001 and 4% versus 1%; p < 0.001) and need for RRT (8.2% versus .0%; p< 0.001 and 1.5% versus .0%) in comparison to baseline risk group.

Conclusions: The use of simple risk classification system based on chronic comorbidities and acute events can identify patients at high risk to develop AKI and adverse outcomes. Future studies should incorporate these factors to stratify patients for prevention and early therapeutic intervention.

TH-PO016

Validating a Scoring Tool to Predict Acute Kidney Injury (AKI) following Cardiac Surgery Brian L. Wong,[1] Jennifer St.Onge,[2] Bhanu Prasad Tikkisetty.[3] *[1]College of Medicine, Univ of Saskatchewan, Regina, SK, Canada; [2]Research and Performance Support, Regina Qu Apelle Health Region, Regina, SK, Canada; [3]Nephrology, Regina Qu Appelle Health Region, Regina, SK, Canada.*

Background: Acute kidney injury (AKI) after cardiac surgery is associated with increased mortality. Pre-operative risk scores may simplify identification of AKI patients to improve patient management. Current validated scoring tools are used to predict AKI requiring dialysis (AKI-D); less is known about whether these tools can predict less severe forms of AKI. The purpose of this study was to evaluate the Cleveland Clinic scoring tool in predicting both AKI-D and less severe AKI in patients in the Regina Qu'Appelle Health Region (RQHR).

Methods: Data on risk factors for AKI were collected from a retrospective chart review of 2343 cardiac surgery patients between 2007 and 2011 in the RQHR. The primary outcome was AKI as defined by KDIGO staging: Stage 1 (increase in serum creatinine 1.5-1.9 times baseline within 7 days), Stage 2 (increase in creatinine 2.0-2.9 times baseline) and Stage 3 (increase in creatinine 3.0 times baseline or more OR initiation of dialysis during hospital stay). We assessed the performance of a modified version of the Cleveland Clinic tool using all available risk factor data in predicting KDIGO Stage for AKI using receiver operating curve analyses (ROC).

Results: The incidence of AKI was 6.1% in Stage 1, 2.6% Stage 2, and 5.8% in Stage 3. Using ROC analyses, the area under the curve (AUC) for the Cleveland score was 0.61 (95% CI: .56 to .65; p<.001) for Stage 1, 0.61 (95% CI: .54 to .68; p<.01) for Stage 2 and 0.77 (95% CI: .74 to .82; p<.001) for Stage 3. Greater level of risk on the Cleveland tool was more associated Stage 3 AKI.

Conclusions: We found the Cleveland Clinic tool to be valid in identifying patients with different stages of AKI in the RQHR, particularly those that require dialysis, which could help improve patient management following cardiac surgery. Future prospective studies would further validate the use of this tool for predicting earlier stages of AKI in addition to AKI-D.

TH-PO017

Culture Positive Infection Is a Risk Factor for Acute Kidney Injury in Intensive Care Unit Patients Jamie S. Hirsch,[1,2] Andrew H. Chiang,[1] Sumit Mohan,[2] Jonathan M. Barasch,[2] Noemie Elhadad.[1] *[1]Biomedical Informatics, Columbia Univ, New York, NY; [2]Nephrology, Columbia Univ, New York, NY.*

Background: Sepsis and acute kidney injury (AKI) are frequent complications in critically ill patients admitted to the intensive care unit. While hemodynamic instability associated with septicemia can cause AKI, the impact of infections alone on the development

of AKI is unclear. We hypothesized that a culture positive infection increases the risk of developing AKI in the subsequent 48 hours even in the absence of hemodynamic instability.

Methods: Data was obtained from the Multiparameter Intelligent Monitoring in Intensive Care II database, which presents anonymized ICU patient records for 32,535 patients. All adult patients with length of stay >48 hours were included, and AKI was defined by AKI Network stage I criteria (rise in serum creatinine of ≥0.3 mg/dL). Patients with AKI on admission or preexisting end-stage renal disease were excluded. Chi-square and logistic regression analyses were conducted for AKI risk 48 hours subsequent to a culture positive infection at any site, with adjustment made for hypotension and requirement of vasopressor medications.

Results: We identified 957 unique patients with a total 1494 instances of positive cultures and 222 episodes of AKI. Among patients with positive cultures, those who developed AKI were not significantly older (65.4±21.9 versus 63.3±19.3 years, p=0.2), but were less likely to be female (48.0% versus 51.8%, p<0.001) or White (66.2% versus 71.0%, p<0.001), and had a higher number of comorbidities (2.9±1.8 versus 2.6±1.7, p=0.008). Patients with culture positive infection appear to have an increased risk of developing AKI within 48 hours (OR 1.24, p=0.005). The risk of AKI was not attenuated by adjustment for the need for vasopressor support (OR 1.28, p=0.001) or for the cardiovascular component of the SOFA score (OR 1.25, p=0.003).

Conclusions: Culture positive infection, even in the absence of hemodynamic instability, appears to be temporally associated with the development of AKI within the subsequent 48 hours. Further study is required to understand the mechanism underlying this relationship.

TH-PO018

Uncontrolled Hyperglycemia Is Associated with Greater Risk of Acute Kidney Injury in Critically Ill Patients

Jamie S. Hirsch,[1,2] Meghan E. Sise,[1] Andrew H. Chiang,[2] Noemie Elhadad,[2] Sumit Mohan.[1] *[1]Nephrology, Columbia Univ, New York, NY; [2]Biomedical Informatics, Columbia Univ, New York, NY.*

Background: Hyperglycemia is frequently associated with adverse outcomes, particularly among critically ill patients in the intensive care unit (ICU). Its influence on the subsequent development of acute kidney injury (AKI) remains unclear. We hypothesized that uncontrolled hyperglycemia during the first 24 hours of ICU admission increases the risk of developing AKI.

Methods: Data was obtained from the Multiparameter Intelligent Monitoring in Intensive Care II database, which presents anonymized ICU patient records for 32,535 patients. All adult patients with length of stay >48 hours were included, and AKI was defined by AKI Network stage I criteria (rise in serum creatinine of ≥0.3 mg/dL). Patients with AKI on admission or preexisting end-stage renal disease were excluded. Chi-square and multivariate logistic regression analyses were used to estimate the risk of AKI associated with persistent hyperglycemia (mean 24 hour glucose >160 mg/dL) on admission.

Results: We identified 5239 unique patients with 5910 ICU admissions. There were 1301 admissions with mean glucose >160 mg/dL during the first 24 hours. Patients presenting with hyperglycemia were of similar gender (female 47.1% versus 46.2%, p=0.81), but were older (66.1±18.2 versus63.7±21.7 years, p<0.001), had a higher number of comorbidities (2.5±1.7 versus 2.3±1.7, p<0.001), and higher admission simplified acute physiology score (SAPS; 14.6±5.3 versus 13.3±5.1, p<0.001) and SOFA score (6.0±3.9 versus 5.3±3.7, p <0.001). Patients with persistent hyperglycemia at the time of ICU admission were at increased risk of AKI (OR 1.41, p<0.001). This risk persisted even after adjustment for gender, age, history of peripheral vascular disease, diabetes mellitus, and chronic kidney disease, admission SOFA score, need for vasopressor support, and presence of culture-positive infection (OR 1.23, p=0.003).

Conclusions: Persistent hyperglycemia at ICU admission appears to be associated with the development of AKI. Controlled trials are required to examine if improved glucose control would ameliorate the risk of AKI.

Funding: Other NIH Support - NLM T15 LM007079-22

TH-PO019

Acute Kidney Injury Risk Prediction in Critically Ill Patients Using Fluctuating Covariates

Jamie S. Hirsch,[1,2] Andrew H. Chiang,[1] Sumit Mohan,[2] Noemie Elhadad.[1] *[1]Biomedical Informatics, Columbia Univ, New York, NY; [2]Nephrology, Columbia Univ, New York, NY.*

Background: AKI is a common complication in the ICU, and dramatically increases patient morbidity and mortality. We aimed to improve AKI risk prediction in the general critical care population by utilizing multiple covariates that vary over time.

Methods: Data was obtained from the Multiparameter Intelligent Monitoring in Intensive Care II database, which contains records for 32,535 ICU patients. Adult patients with length of stay >48 hours and without AKI or end-stage renal disease at admission were included. AKI was defined by AKI Network stage I criteria (rise in serum creatinine of ≥0.3 mg/dL). AKI risk over a subsequent 48 hour period was estimated sequentially for patients during their ICU stay. Demographics, laboratory data, medications, infection status, and illness severity were included as covariates in a multivariate logistic regression model. Forward selection using Bayesian information criterion was performed; evaluation was conducted with area under the receiver operating characteristic curve (AUC).

Results: We identified 4058 unique patients, 4464 ICU admissions, and 2787 episodes of AKI. Patients who developed AKI were of similar gender (male 56.1% versus 54.4%, p=0.27), but were older (66.6±19.7 versus61.7±21.5 years, p<0.001), had a higher number of comorbidities (2.5±1.8 versus 2.0±1.5, p<0.001), and higher admission SOFA (6.2±3.9 versus 4.9±3.4, p <0.001). 15 variables predicted the development of AKI within 48 hours, with AUC 0.73, comparing favorably against using SOFA score alone (AUC 0.65). The final feature set included age; laboratory data (hemoglobin variance, white blood cell deviance, sodium minimum, creatinine mean and maximum, blood urea nitrogen minimum, and mean anion gap, partial activated thromboplastin time, and lactate); 24 hour volume balance; medications (furosemide and vancomycin); and overall and neurologic subpart of SOFA.

Conclusions: A model incorporating covariates that vary over time provides acceptable performance in predicting temporally proximate AKI risk in ICU patients. A 48-hour fixed-window risk assessment may be valuable in the ICU, where patient status is dynamic.

Cardiac Surgery-Associated Acute Kidney Injury in Neonates and Infants: Comparison of Creatinine and Urine Output Criteria

Kathy K.Y. Lee-Son,[1] Alanna N. De Mello,[2] Sanjiv K. Gandhi,[3] Andrew I. Campbell,[3] Peter Skippen,[4] Michael Zappitelli,[5] Cherry Mammen.[2] *[1]Pediatric Nephrology, Univ of Iowa, Iowa City, IA; [2]Nephrology, BC Children's Hospital, Vancouver, BC, Canada; [3]Cardiac Surgery, BC Children's Hospital, Vancouver, BC, Canada; [4]Critical Care, BC Children's Hospital, Vancouver, BC, Canada; [5]Nephrology, Montreal Children's Hospital, Montreal, QC, Canada.*

Background: Cardiac surgery-associated acute kidney injury (AKI) in infants and neonates is common and is associated with poor outcomes. Most studies to date do not report AKI incidence with urine output (U/O) criteria. We compared AKI incidence and AKI-outcome associations using Acute Kidney Injury Network (AKIN) delta SCr (ΔSCr) and U/O to examine the effect of including U/O.

Methods: In a single centre prospective cohort study, infants and neonates requiring cardiac surgery from Mar 2013-Jan 2014 were eligible. We collected post-operative hourly U/O and ΔSCr up to 3d. Kappa statistic was used to evaluate agreement between U/O and ΔSCr staging. We defined 3 groups: No AKI, ΔSCr alone, U/O stage higher than ΔSCr stage (U/O>ΔSCr). We compared intensive care length of stay (LOS) and ventilation days (Kruskall-Wallis test) between groups.

Results: 96 infants and 34 neonates were enrolled. Mean age at surgery was 149d (infants) and 7d (neonates); 97% had post-op diuretics; dialysis incidence was 1.5%; mortality was 3.8%. AKI incidence was 39% (infants), 26% (neonates) with ΔSCr criteria alone and increased to 48% for infants and neonates when including U/O criteria. Agreement between ΔSCr and U/O stage was poor in infants (kappa 0.234) and neonates (kappa 0.121). The median (range) ventilation days in neonates with no AKI was 1.5(0-12) *versus* ΔSCr alone 7.7(6-10) *versus* U/O>ΔSCr 7.6(0-31) (p=0.003). Median LOS for infants with no AKI was 2.6(1-30) *versus* ΔSCr alone 7.7(1-78) *versus* U/O>ΔSCr 7.5(1-13) (p=0.03).

Conclusions: The incidence of cardiac surgery-associated AKI in infants and neonates rises significantly by including AKIN UO criteria. The outcomes for those diagnosed with the added U/O criteria and ΔSCr criteria are both poor compared to those without AKI, suggesting that U/O criteria may have clinical implications for AKI in this young population.

Community-Acquired Acute Kidney Injury: Incidence and Etiologic Factors

Ingibjorg Kristjansdottir,[1] Runolfur Palsson,[1,2] Olafur S. Indridason.[1] *[1]Internal Medicine Services, Div of Nephrology, Landspitali - The National Univ Hospital of Iceland; [2]Faculty of Medicine, Univ of Iceland, Reykjavik, Iceland.*

Background: Acute kidney injury (AKI) affects 5-10% of hospitalized patients and is often a complication of medical or surgical interventions. However, limited information exists on the epidemiology and causes of community-acquired AKI. The aim of this study was to examine the incidence, etiology and outcome in patients presenting with AKI to an emergency department (ED) of an urban university hospital.

Methods: In this retrospective study we used the electronic patient information system at Landspitali – The National University Hospital of Iceland, the only major hospital in the Reykjavik area, to identify all patients aged ≥18 years, who upon arrival to the ED in the year 2010 had an elevated serum creatinine (SCr) level. We used the KDIGO criteria to determine the presence of AKI by reviewing all SCr measurements of these patients available at the University Hospital. Clinical information on patients with AKI was extracted from their medical records.

Results: A total of 74,822 patients ≥18 years came to the ED, of whom 2878 had an elevated SCr. Of those, 1110 patients (1.5%) had AKI. Their median age was 78 years (range, 21-102), 55.1% were men and 29.3% had a baseline eGFR <60 ml/min/1.73 m^2. To date we have examined clinical data for 605 patients (56.2% men), of whom 360 (59.5%) had stage 1 AKI, 170 (28.1%) stage 2 and 75 (12.4%) stage 3. The AKI was of prerenal nature in 90.7% of patients, with various and often multiple underlying contributing factors, including sepsis (22.1%), volume depletion (19.8%) and exacerbation of chronic heart, lung or liver disease (16.8%). In 61.2% of these patients medications were considered a contributing factor, most frequently renin-angiotensin system blockers (52.2%) and NSAIDs (8.9 %).

Conclusions: These preliminary results show that 1.5% of patients presenting to the ED of a metropolitan hospital have AKI which is similar to previous studies. Most patients with community-acquired AKI are elderly and prerenal conditions account for the overwhelming majority of cases. Commonly used medications appear to be a dominant contributing factor.

TH-PO022

Elevated Serum Uric Acid Can Increase the Risk of Acute Kidney Injury After Cardiac Surgery in Elderly Patients Jiaqi Xu, Yuanhan Chen, Xinling Liang, Penghua Hu, Lu Cai, Wei Dong, Zhilian Li, Wei Shi. *Div of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: To investigate the effect of pre-operative serum uric acid on acute kidney injury after cardiac surgery in elderly patients.

Methods: Clinical data was collected from elderly patients(age ≥60 year)undergoing cardiac surgery with cardiopulmonary bypass in Guangdong General Hospital between January 2005 and May 2011. The baseline serum creatinine was defined as the latest before surgery, and the primary outcome was AKI according to RIFLE criteria (Risk, Injury, Failure, Loss of renal function and End-stage renal disease). Multivariate analysis by logistic regression was used to obtain the independent risk factors for AKI.

Results: Among 936 elderly patients, 576 cases (61.5%) developed AKI. Mean uric acid concentration is higher in AKI group than Non-AKI group(436.55±119.13 VS 397.98±107.21 umol/l, P<0.001). The sex-specific cutoff points for serum uric acid tertiles were: tertile 1: uric acid ≤384.65umol/l in men and ≤354umol/l in women; tertile 2: 384.66-476.99umol/l in men and 354.01-437.96umol/l in women; tertile 3:≥477umol/l in men and ≥437.97u mol/l in women. People were divided into three groups according to the cutoff points above. The incidence of AKI is highest in tertile 3(tertile 1:56.1%; tertile 2:56.3%; tertile 3:72.2%; P<0.001). The data were adjusted for age, gender, co-morbidities(hypertension, DM, cerebrovascular disease, COPD), previous cardiac surgery, eGFR<60ml/min/1.73m^2, NYHA≥Grade 3, urine protein dipstick results of ≥±,combination of CABG and valvular surgery, CPB time, aortic cross-clamping time, exposuring to ACEI/ARB and lipid-lowering drugs pre-operative, early postoperative variables (use of ACEI/ARB, diuretics and digoxin, central venous pressure during the first 24 h after surgery but before AKI). Compared with the lowest tertile, the highest had an OR for incident AKI of 1.897(95%CI 1.270-2.833) after fully adjustment.

Conclusions: Pre-operative elevated uric acid can increase the risk of AKI after cardiac surgery in elderly patients. Attention should be paid for uric acid in order to early prevention of cardiac surgery-associated AKI.

TH-PO023

Proteinuria: An Independent Risk Factor for Development of Cardiorenal Syndrome Type I and In-Hospital Mortality Lu Cai, Zhilian Li, Xinling Liang, Ruizhao Li, Lixia Xu, Wei Shi. *Dept of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Science, Guangzhou, Guangdong, China.*

Background: Proteinuria is an established risk factor for acute kidney injury (AKI), but the role of proteinuria for cardiorenal syndrome type(CRS) I is still unclear.The aim of the study is to analyse the association between proteinuria and CRS type I and in-hospital mortality.

Methods: We studied all consecutive patients hospitalized with AHF from July 2005 to July 2012 in Guangdong General Hospital and the First Affiliated Hospital of Sun Yat-sen University.Demographic and clinical data were collected retrospectively.Urinary protein in the first 48 hours after admission were recorde and AKI was defined by KDIGO criteria. Proteinuria was defined as mild (trace to 1+) or heavy (2+ to 4+) according to the results of the dipstick test. Urinary protein in the first 24 hours after admission were recorded. Baseline serum creatinine was defined as the first serum creatinine on admission. Logistic regression analysis was used to determine whether proteinuria is an independent risk factor for the occurrence of CRS type I and in-hospital mortality or not.In-hospital survival of patients with CRS type I along with proteinuria was assesed by Kaplan-Meier curves.

Results: 1058 patients were enrolled.The incidence of CRS type I with proteinuria was significantly higher than non-proteinuria group (67.9% versus 34.3%, P <0.001). Logistic regression analysis showed that proteinuria was an independent risk factor for the development of CRS type I and in-hospital mortality (OR 3.335, 95% CI 2.516 ~ 4.420; OR 1.785, 95% CI 1.164 ~ 2.737).Mild and heavy proteinuria exhibited a stepwise increased ratio for both development of CRS type I (Mild proteinuria: OR 2.801, 95%CI 2.076 ~3.778;Heavy proteinuria: OR 5.607, 95%CI 3.583 ~8.775) and in-hospital mortality (Mild proteinuria: OR1.735, 95%CI1.107~2.718;Heavy proteinuria: OR2.021, 95%CI1.169~-3.496).K-M curve indicated that in-hospital survival of CRS type I patients with proteinuria were lower than CRS type I patients without proteinuria (Long rank p <0.001).

Conclusions: Proteinuria is an independent risk factor for the development of CRS type I and in-hospital mortality.

The Incidence and Risk Factors of Acute Kidney Injury in the Very Elderly Patients with Mechanical Ventilation Qingli Cheng, Qinglin Li, Yang Liu, Guang Yang. *Dept of Geriatric Nephrology, Chinese PLA General Hospital, Beijing, China.*

Background: To investigate the incidence, pathogenetic and risk factors of acute kidney injury (AKI) in the very elderly patients with mechanical ventilation therapy.

Methods: A total of 260 elderly patients with mechanical ventilation therapy in the geriatric department of our hospital from June 2008 to December 2012 were enrolled in this study. The clinical data of all the patients were analyzed to explore the incidence and risk factors of AKI in the very elderly patients after mechanical ventilation therapy.

Results: The average age of the patients was (88.9±5) years. 125 cases (48.1%) suffered from AKI which emerged at a mean time of (1.6±0.7) days after mechanical ventilation. The incidence of the history with chronic kidney disease (66.4% versus 51.1%, *P*=0.012) and the history with diabetes (51.2% versus 38.5%, *P*=0.040) in the patients with AKI (AKI group) were higher than that in the patients without AKI (Non-AKI group). Compared with the Non-AKI group, lower level of PaO_2 (59.7±12.8 versus 63.6±14.1, *P*=0.031), lower level of oxygenation index (PaO_2/FiO_2, 122.5±42 versus 145.7±46, *P*=0.000), higher level of hemoglobin (105±23 versus 100±17, *P*=0.046) and hyperglycemic (10.2±4.1 versus 8.8±3.7, *P*=0.004) were found in AKI group. The incidence of AKI increased in the patients with mechanical ventilation if they were used higher level of positive end-expiratory pressure (PEEP≥4cmH_2O). Logistic regression analysis showed that the history of chronic kidney disease (OR=1.964), hyperglycemia (OR=1.076), the lower level of PaO_2/FiO_2 (OR=2.142) and using higher level of PEEP (≥4cmH_2O, OR=0.990) were the risk factors of the prognosis of AKI in those patients with mechanical ventilation therapy (*P*<0.05).

Conclusions: The incidence of AKI in the very elderly patients with mechanical ventilation was 48.1% in this study. The mean time of suffered from AKI in those patients was about 1~3 days after the therapy of mechanical ventilation. The history of chronic kidney disease, hyperglycemia, low level of PaO_2/FiO_2 and using higher level of PEEP (≥4cmH_2O) were the risk factors of AKI in the very elderly patients with mechanical ventilation therapy.

TH-PO025

Acute Kidney Injury After Heart Transplant in Children; Risk Factors and Outcomes Christine L. Macdonald,[2] Gwen Alton,[2] Simon Urschel,[1] Ari Joffe,[1] Gwen Rempel,[2] Colleen Norris,[2] Catherine Morgan.[2] *[1]Pediatrics, Univ of Alberta, Edmonton, AB, Canada; [2]Nursing, Univ of Alberta, Edmonton, AB, Canada.*

Background: Heart transplant is life-saving for children with end-stage congenital heart disease or acquired heart failure. Critical illness after transplant can include acute kidney injury (AKI). There is little data on the epidemiology of, risk factors for, or impact on outcomes of AKI after pediatric heart transplant.

Methods: Using secondary analysis of data from an ongoing prospective cohort study, we evaluated 72 children (0- 5 yrs) who had a heart transplant between 2001 and 2012. We evaluated: 1) postoperative AKI rate (defined by pRIFLE); 2) pre-, intra-, and early postoperative AKI risk factors (days on waitlist, inotrope use and ventilation pre-transplant, ECMO / ventricular assist device at transplant, preoperative estimated glomerular filtration rate (eGFR), ABO incompatibility, donor ischemic time, peak intraoperative lactate, tacrolimus level early postoperatively) using stepwise logistic regression; 3) effect of AKI on short-term outcomes (duration of ventilation and length of PICU stay).

Results: AKI occurred in 73% of children. Independent predictors of AKI were pre-transplant ventilation (OR 8.6, p=0.007) and higher eGFR (p=0.032). Preoperative inotrope reduced the risk of AKI (OR 0.13, p=0.016). Sixteen percent of children had a tacrolimus level >15 on day 3 post-transplant and these children had more AKI than children without (OR 7.8, p=0.086). Although not statistically significant, automated model selection retained tacrolimus level >15 as a predictor (using multiple different modeling strategies). AKI resulted in longer ventilation days and ICU stay (p=0.038 and p=0.003, respectively).

Conclusions: AKI was common after heart transplant and was associated with important outcomes. As in other pediatric cardiac surgery populations, lower preoperative GFR was protective against postoperative AKI; the role of modified immune suppressive strategies in this context needs to be further evaluated. Although not statistically significant, elevated early postoperative tacrolimus is likely biologically important in the prediction of AKI risk and needs further evaluation in a larger cohort.

TH-PO026

Postoperative Ileus Is an Important Risk Factor of Acute Kidney Injury in Patients Undergoing Colorectal Surgery Jun Yong Lee, Hyojeong Chang, Sun Chul Kim, Myung-Gyu Kim, Won-Yong Cho. *Korea Univ, Republic of Korea.*

Background: Recently, emerging evidence suggest a presence of gut-kidney crosstalk. Despite major advance in surgical techniques from open to robot assisted surgery, acute kidney injury (AKI) is still major postoperative complication. The purpose of this study is to compare the incidence of postoperative AKI according to different surgical techniques and also the risk factors, outcome of AKI in patients undergoing colorectal surgery.

Methods: This is a single center, retrospective study. A total of 199 patients who received colectomy due to colorectal cancer from 2010 to 2012 were enrolled and their clinical data were reviewed.

Results: The mean age was 66±12 years and male was 66.3%. Preoperative blood urea nitrogen and creatinine were 14.92±5.2 and 0.96±0.26 mg/dL. Stage I, II, III and IV cancer were found in 31.7%, 25.6%, 25.6% and 11.6% respectively. Open surgery was performed in 12% and laparoscopic assisted surgery or robot assisted surgery were performed in 55.7% or 32% of patients. AKI developed in 12 patients (6.0%), and 3 (25%) of them received acute hemodialysis. Postoperative ileus developed in 58 patients (29%). Incidence of AKI was not different according to surgical techniques and the presence of diabetes, hypertension, chronic kidney disease (CKD), intraoperative shock, postoperative ileus, postoperative infection were associated with the development of AKI. Interestingly, postoperative ileus was found to be the only independent risk factor of AKI in multivariate analysis (odds ratio : 14.73, p=0.004). In addition, AKI patients showed significantly longer hospital stay and higher mortality than non AKI patients.

Conclusions: Despite advances in surgical techniques, paralytic ileus is a common manifestation after colorectal surgery and it showed strong association with the development of AKI. These results suggest that enhanced bacterial translocation or increased

intraabdominal pressure possibly resulting from postoperative ileus might be partially responsible for the development of AKI following colectomy. More careful attention should be paid on the development of posoperative ileus or AKI in patients who undergo colectomy regardless of surgical techniques.

TH-PO027

Risk of Acute Kidney Injury in the General Population Arnar Jan Jonsson,[1] Bjarni Gunnarsson,[2] Hrefna Gudmundsdottir,[1,3] Margret B. Andresdottir,[3] Thor Aspelund,[1,2] Vilmundur Gudnason,[1,2] Runolfur Palsson,[1,3] Olafur S. Indridason.[3] *[1]Faculty of Medicine, Univ of Iceland, Reykjavik; [2]Icelandic Heart Association, Kopavogur; [3]Div of Nephrology, Landspitali - The National Univ Hospital of Iceland, Reykjavik, Iceland.*

Background: Acute kidney injury (AKI) is common in hospitalized patients and is associated with adverse outcomes. However, limited data exist on the epidemiology of AKI in the general population. The aim of this study was to determine the risk of AKI and associated risk factors in the general population.

Methods: We studied subjects from the Reykjavik Study, a population-based cohort study on cardiovascular disease in Iceland. The participants were recruited from 1967 to 1991 and baseline data included a measurement of serum creatinine (SCr) and assessment of cardiovascular disease (CVD) risk factors. For the 16,504 participants, we obtained all available SCr measurements at medical laboratories in the Reykjavik area from study entry until March 2012. AKI was defined according to the KDIGO criteria. Logistic regression was used to examine the relationship between AKI and baseline variables.

Results: We identified at least one follow-up SCr for 14,513 subjects, of whom 47.1% were men, 28.7% had hypertension, 2.9% had diabetes and 5.9% had eGFR <60 mL/min/1.73 m^2 at baseline. A total of 3,065 subjects (21.1%, 95%CI 20.4-21.8%), 51.1% men, developed AKI during a follow-up of 29.6 (range, 0.4-45.5) years. The frequency of a first AKI episode for different age groups is shown in the Table. Increasing age (OR 1.012, 95%CI 1.007-1.018), sex (OR 0.80, 95%CI 0.73-0.86 for women) and eGFR <60 mL/min/1.73 m^2 at baseline (OR 1.24, 95%CI 1.05-1.46), were associated with AKI. Classical CVD risk factors were not associated with future AKI.

Age group (years)	Percent men (95% CI)	Percent women (95% CI)
60-70	4.7 (4.1-5.3)	3.3 (2.8-3.8)
70-80	14.8 (13.8-15.8)	9.9 (9.2-10.7)
>80	18.5 (17.1-19.8)	15.8 (14.7-16.9)

Conclusions: Estimated lifetime risk of AKI in the general population appears quite high. Our study did not identify modifiable risk factors for AKI. Nevertheless, since many AKI episodes are known to be preventable, raised awareness among physicians may improve patient outcomes.

Funding: Government Support - Non-U.S.

TH-PO028

Urine Output Thresholds for Cardiac Surgery-Associated Acute Kidney Injury Joana Balderas Juarez, Armando Vazquez-Rangel. *Nephrology, Inst Nacional de Cardiologia Ignacio Chavez, Mexico, DF, Mexico.*

Background: In cardiac surgery there is a high incidence of short term transient oliguria, with a questionable impact on hard outcomes. Current urine output (UO) criteria for acute kidney injury (AKI) by KDIGO have not been deeply tested in terms of different thresholds and times in this population.

Methods: A retrospective cohort study ind adult patients after cardiac surgery in a third-level academic center in México City from March 1st 2010 to June 30th 2012. UO vas evaluated every 4hrs for 72hr. Progression into CKD was defined as having beyond 3 months both, an estimated glomerular filtration rate (eGFR) by CKD-EPI <60ml/min/1.73m2 and a reduction from baseline eGFR of a least 15ml/min/1.73m2.

Results: A total of 794 patients were included. RST was required in 55 (6.9%) patients, and 68 (8.6%) died during hospitalization. With a median follow-up time of 365 days, 78 (9.8%) died and 52 (6.5%) progressed into CKD. UO cut-off values obtained by ROC curves for RST at 4,8,12,16,20 and 24hr were 0.25, 0.35, 0.45, 0.5, 0.6 and 0.65ml/kg/hr respectively, with AUCs between 0.82 and 0.86 at all times. After adjusting for preoperative risk for RST (Thakar score), postoperative SOFA score and fluid balance, all cut-offs remained significant. Meeting any of these UO cut-offs showed an OR of 7.89 (3.75-16.59) (p=0.001) for RST, OR 3.99 (2.14-7.48) (p=0.001) for severe AKI by serum creatinine, OR 1.79 (1.05-3.04) (p=0.032) for in-hospital death, and HR 2.28 (1.59-3.27) (p=0.001) for follow-up death or progression into CKD.

Conclusions: While and UO cut-off of 0.5ml/kg/hr in 12hr matched the KDIGO criteria, a lower cut-off (around 0.3ml/kg/hr) should be implemented in shorter periods of time (4-8hr) and higher cut-offs (0.6ml/kg/hr) are significant for longer periods (20-24hr), with a proven impact on hard in-hospital and out-patient follow-up outcomes. This was no dependent on preoperative risk categories in contrast to renal angina criteria.

TH-PO029

A Rare Case of Acute Kidney Injury Secondary to Isoflurane Induced Malignant Hyperthermia Rohan V. Mehta,[1] Rahul Mehta,[2] John Doran.[3] *[1]Nephrology, Emory Univ School of Medicine, Atlanta, GA; [2]Internal Medicine, Univ of Virginia, Charlottesville, VA; [3]Nephrology, Emory Univ School of Medicine, Atlanta, GA.*

Introduction: Malignant hyperthermia (MH) is a rare muscular disorder provoked by exposure to halogenated anesthetics and succinylcholine. Signs of MH include increase in CO2 production and O2 consumption, acidosis, refractory hyperkalemia, hyperthermia, tachycardia, muscle rigidity, and rhabdomyolysis.

Case Description: A 58-year old male with a pancreatic mass was taken to the operating room (OR) for a Whipple's procedure. Vital signs included BP 142/73 mm Hg, HR 75 per minute, O2 saturation 100% on room air, and oral temperature of 36.5 F. In the OR, anesthesia was induced with propofol and rocuronium, and maintained with isoflurane. 6.5 hours into the procedure, sinus tachycardia ensued; BP declined to 80/40 mm Hg and minute ventilation doubled. High fever and extreme rigidity developed. ABG showed acidemia and hyperkalemia (pH 7.12, K 5.6 mmol/L). A presumed diagnosis of MH was made. All anesthetic gasses were discontinued and dantrolene was given with transient clinical improvement. However in the next 24 hours, anemia and hypotension required blood transfusions, and he developed non-oliguric acute kidney injury with persistant hyperkalemia, rhabdomyolysis and worsening metabolic acidosis for which CVVHD was initiated.

Discussion: MH is an abnormally high metabolic state of skeletal muscle in which a sudden increase in intracellular calcium caused by a defect in the RYR1 gene for the ryanodine receptor causes uncontrolled myocyte contractions. Halothane-caffeine contraction test on muscle biopsy specimen is the confirmatory test for MH. Dantrolene treats MH effectively by blocking calcium release and stopping uncontrolled muscle contractions. Discontinuation of the triggering agents, changing the breathing circuits and switching to an agent-free O2 source is recommended. In our case, CVVHD effectively treated rhabdomyolysis and hyperkalemia and helped avoid cardiac arrhythmias. In summary, we report a case of MH precipitated by isoflurane in a patient undergoing Whipple's procedure, which was successfully managed with dantrolene and CVVHD.

TH-PO030

Dialysis-Requiring Acute Kidney Injury from Pyonephrosis in Pregnancy: A Case Report Rizza Ann B. Lio, Brian Michael I. Cabral. *Section of Nephrology, Dept of Medicine, Univ of the Philippines-Philippine General Hospital, Manila, Philippines.*

Introduction: Acute Kidney Injury (AKI) during pregnancy presents a unique challenge. The medical team has to contend with the structural and physiologic changes in pregnancy and must also balance the needs of both mother and fetus. Pyonephrosis which is a life-threatening complication of ureteric obstruction is uncommon in pregnant patients because ureteral dilatation is one of the anatomic alterations of pregnancy.

Case Description: A 34-year-old G3P2 patient in her 25th week of pregnancy presented with a 3-day history of high-grade fever, right flank pain, and anuria. On admission, evaluation revealed a febrile patient with stable vital signs and a right costovertebral angle tenderness. Patient remained anuric despite foley catheter insertion. Initial laboratory findings showed leukocytosis, high anion gap metabolic acidosis, a creatinine level of 11mg/dL, and potassium of 5.7 mmol/L. Culture studies were obtained and the patient was started on Ceftriaxone as empiric therapy. An abdominal ultrasound was done which showed acute pyonephrosis and bilateral ureteropelvocaliectasia. Emergency hemodialysis was initiated to address the uremia. Subsequent dialysis sessions were done to maintain BUN <40mg/dL and to target bicarbonate of 18-22 mmol/L. On the third hospital day, a right percutaneous nephrostomy was done and 50mL of purulent discharge was drained. Culture studies revealed growth of Klebsiella sensitive to Ceftriaxone which was given for 14 days. The nephrostomy tube was removed after two weeks and patient was discharged well with a creatinine 1.2 mg/dL and BUN 8mg/dL. On subsequent out-patient consults, there was note of recovery of normal renal function. Patient then gave birth via spontaneous vaginal delivery on the 38th week of pregnancy.

Discussion: Severe cases of AKI requiring dialysis occurs in less than 20,000 pregnancies. When pyonephrosis complicates pregnancy, a multidisciplinary approach to management is necessary to balance the risks of the disease and the interventions to both mother and fetus. Timely diagnosis and urgent but safe interventions are needed because a uremic milieu is devastating for both.

TH-PO031

Supplement Associated Acute Renal Injury in Weight Athletes: A Report of 4 Cases Alaa A. Ali,[1] Safa E. Almukhtar,[2] Michael D. Hughson.[1] *[1]Shorsh General Hospital, Sulaimaniyah, Iraq; [2]Hawler Univ College of Medicine, Erbil, Iraq.*

Introduction: Athletes participating in weight lifting and body building routinely use nutritional supplements to develop and maintain a large muscle mass. This is consumed as protein powders combined with vitamins and calcium, creatine powder, and capsular forms of testosterone supplements, the later alleged to raise natural testosterone levels. Some nephrologists have expressed concern about excess protein induced glomerular hyperfiltration placing athletes at risk of developing focal segmental glomerulosclerosis (FSGS). Nevertheless, FSGS is not a demonstrated complication of weight training, and renal injury in athletes is mainly acute tubular injury complicating rhabdomyolysis during intense hot weather training.

Case Description: Case Description: In an academic Iraqi nephrology center, 4 body builders (18, 18, 23, and 24 years old) were referred who presented with renal insufficiency. All used commercial testosterone supplements, protein powders, vitamins, and creatine for periods ranging from 3-6 months. All athletic activity was indoors; none participated in endurance events. The presenting complaints were weakness and lethargy. Temperatures and blood pressures were normal. Serum creatinine levels ranged from 2.6 to 3.8 mg/dl with MDRD eGFR ranging from 22-34 mL/min/1.73m^2. Urine analyses with Labstix glucose, protein, and hemoglobin were unremarkable. Renal biopsies revealed foci of regenerating tubular epithelium, desquamated necrotic cells, hyaline casts, and intratubular calcifications. The biopsies contained 12 to 16 glomeruli in which no FSGS or pigmented casts suggesting rhabdomyolysis was found. Following the diagnoses of acute tubular injury, patients were re-evalated at 6 months and one year. None of the patients continued using supplements and serum creatinine and eGFR were in the normal range.

Discussion: Acute tubular injury was found to be the cause of renal dysfunction in weight athletes using nutritional supplements. Weight athletes should be warned about potential adverse affects, and if supplements are used, health services examinations with serum creatinine testing may be warranted even with mild symptoms.

TH-PO032

Hemodialysis for Acute Gabapentin Toxicity Abraham Cohen-Bucay, Herbert T. Cohen. *Renal Section, Boston Medical Center and Boston Univ School of Medicine, Boston, MA.*

Introduction: Gabapentin is a small molecule (171 Dalton) that is minimally protein bound, not metabolized and exclusively renally cleared. Its half-life with normal glomerular filtration rate is 5-7 hrs, but this increases up to 130 hrs in anuric patients. It is a dialyzable molecule, and its half-life on dialysis is 3.8 hrs. Serum gabapentin levels are higher in patients with chronic kidney disease (CKD), and symptoms of gabapentin toxicity are more common in those CKD patients who are elderly, have multiple comorbidities or have a pre-existing central nervous system disorder. Typically, symptoms of gabapentin toxicity appear once serum levels exceed 15 mcg/ml and include reduced consciousness, ataxia, myoclonus and asterixis. Here we present a case of acute gabapentin toxicity treated with hemodialysis.

Case Description: A 91 year-old woman with stage 4 CKD (creatinine 2.0 mg/dl) and peripheral neuropathy was admitted with chest pain and shortness of breath. Although her creatinine remained stable, on her second hospital day, she developed a change in mental status consisting of somnolence and myoclonus. Her outpatient record had indicated she was on gabapentin 800 mg three times daily, which was started on admission, although she had not been taking this recently. The altered mental status was attributed to gabapentin, as work up was otherwise negative. Because the patient had advanced CKD, and gabapentin is exclusively renally cleared, we did one session of hemodialysis for 6 hrs using a large dialyzer and high blood and dialysate flows to maximize clearance. With dialysis, her mental status improved substantially and returned to baseline in 1 day. Her serum gabapentin level decreased from 27.4 mcg/ml before dialysis to 6.9 mcg/ml 3 hrs after dialysis.

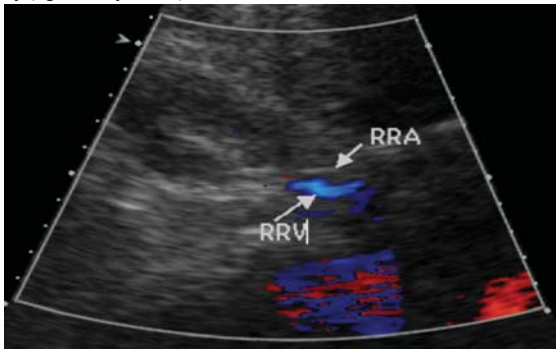
Discussion: Hemodialysis is an effective treatment for acute gabapentin toxicity. Although hemodialysis is an invasive therapy, we believe it is a safe option for patients with advanced CKD who would have no other means to excrete gabapentin in a timely manner. To our knowledge, this is the first report of the treatment of gabapentin toxicity with hemodialysis in a patient not otherwise on dialysis.

TH-PO033

Reversible Acute Kidney Injury due to Bilateral Renal Artery Thrombosis in a Patient with a Thrombophilia Mario A. Mendoza, Eddie M. Rodriguez, Emmanuel O. Gonzalez, Cristy Gianna Martinez, Carlos S. Rosado-Rodriguez, Hector R. Cordova. *Medical Service, VA Caribbean Healthcare System, San Juan, PR.*

Introduction: Hereditary thrombophilias are rare prothrombotic states, usually associated with venous thrombotic complications. We report a patient with prothrombin gene mutation who developed renal artery thrombosis after an emergency surgical procedure.

Case Description: A 46 y/o man with history of hypertension was admitted due to jaundice, choluria, acholia, and right upper quadrant pain. Imaging studies confirmed the presence of biliary tract obstruction due to choledocolithiasis. It was not possible to remove the gallstones endoscopically. Therefore, the patient underwent open cholecystectomy. The procedure was complicated by acute blood loss. The patient developed acute kidney injury post-operatively. Renal anatomy and blood flow were assessed with Doppler ultrasound due to persistent oilgo-anuria. There was evidence of absent renal artery (RA) blood flow bilaterally (right kidney shown).



Renal replacement therapy was started. Anticoagulation therapy was initially contraindicated due to the presence of a large liver subscapular hematoma. Coagulation studies revealed: INR: 1.07, PT: 14.3, PTT: 32.4, Protein S: 68%, Protein C: 104%, prothrombin gene mutation (+). The patient recovered renal function (s creat: 1.2 mg/dl) after 3 weeks of renal replacement therapy.

Discussion: Hereditary thrombophilias may predispose to venous and/or arterial thrombosis. Most reports of renal artery thrombosis are described in patients with unsuspected thrombophilias who undergo kidney transplant surgery. The renal Doppler ultrasound findings lead us to the discovery of the hereditary thrombophilia. We identified the presence of an heterozygous prothrombin gene mutation. The initiation of chronic anticoagulation therapy coincided with the slow recovery of renal function in our patient.

TH-PO034

A Rare Case of Acute Kidney Injury Caused by Mantle Cell Lymphoma Kana N. Miyata, Nazia A. Siddiqi, Lawrence P. Kiss, Nikolas B. Harbord, James F. Winchester. *Mount Sinai Beth Israel, New York.*

Introduction: Renal involvement in non-Hodgkin lymphoma, especially mantle cell lymphoma(MCL) is rare.

Case Description: A 77 year old Filipino man with hypertension, hypothyroidism, and bladder cancer developed acute kidney injury(AKI) (baseline creatinine of 2.2 mg/dL rose to 4.5 mg/dL). Two months prior he was noted to have a lung nodule on chest X ray and a PET scan showed diffuse lymphadenopathy in the neck, chest, abdomen, and pelvis. On admission, he complained of fatigue and decreased appetite. Vital signs were stable. Physical exam revealed submandibular and right axillary lymph nodes. Urinalysis showed protein 1+, large blood, eosinophils, dysmorphic RBCs, and urine protein/creatinine ratio of 2.9 g/gCr. He had low C3 49 mg/dL and C4 16 mg/dL, positive ANA of 160, negative MPO-ANCA, and positive PR-3 ANCA. Ultrasound revealed increased echogenicity with right kidney 12.4 cm and left 11.4 cm. Hospital course was complicated by pulmonary edema associated with non-ST-elevation myocardial infarction. Kidney function continued to decline requiring dialysis on hospital day 16. Biopsy revealed patchy dense monotonous lymphocytic aggregates. The lymphocytes were B cells, positive for CyclinD1, consistent with atypical CD5-negative MCL as confirmed by the detection of translocation t(11;14) by FISH. There were crescents in 3 out of 26 glomeruli, consistent with pauci-immune glomerulonephritis. Chemotherapy was started.

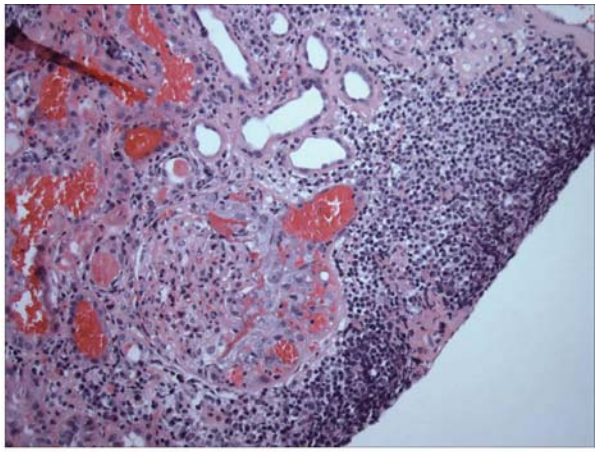

Fig.1 Crescent formation and atypical lymphoid cells infiltration.

Discussion: We present the first case of a patient with coexistence of renal MCL infiltration and pauci-immune glomerulonephritis. Renal involvement in non-Hodgkin lymphoma has been reported, including AKI, glomerulonephritis, and infiltration of renal parenchyma by lymphoma cells. Renal manifestations of MCL are especially rare and there are only 14 cases published to date. Four of them showed renal MCL infiltration and this will be the 5th case.

TH-PO035

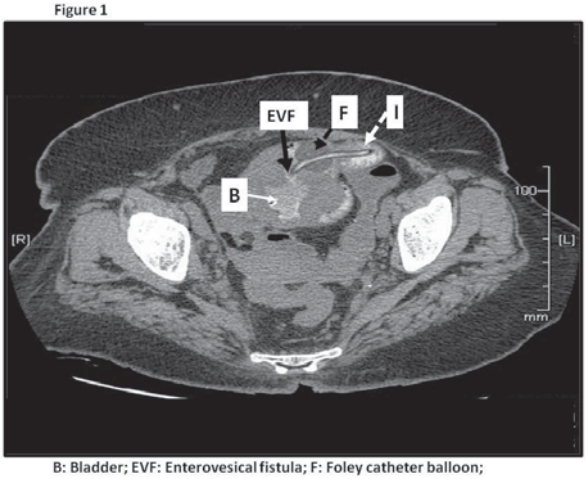
Severe Azotemia and Hyperchloremic Metabolic Acidosis in a Patient with Reverse Flow Enterovesical Fistula Ike Ezumba,[1] Elvira Gosmanova,[1] Leigh Darryl Quarles,[1] Barry M. Wall.[1,2] *[1]Nephrology, UTHSC, Memphis, TN; [2]Nephrology, VAMC, Memphis, TN.*

Introduction: Enterovesical fistula (EVF) usually has flow from intestine to the bladder and commonly manifests with recurrent urinary tract infections, fecaluria and pneumaturia. We report a rare case of EVF with reverse flow from the bladder to intestine, leading to severe azotemia and hyperchloremic metabolic acidosis.

Case Description: 55-year old female underwent transurethral resection of bladder cancer and soon developed watery diarrhea and fecal incontinence. On exam she had low BP and dry mucous membranes. Lab. findings: Na 133meq/L, K 3.6meq/L, Cl 110meq/L, HCO_3 12meq/L, BUN 100mg/dL, and Creatinine 0.7mg/dL. Urine studies could not be obtained as patient was not passing urine even after placing a Foley catheter. CT scan of the abdomen and pelvis showed a markedly contracted and nodular bladder with a large bladder

wall defect and the Foley catheter extending through the bladder wall into a small bowel loop [Figure 1]. A diagnosis of EVF with reverse flow from the bladder to intestine was made. Sodium bicarbonate infusion was started to correct volume depletion and metabolic acidosis. The patient underwent partial cystectomy with creation of an ileal conduit. These measures led to rapid resolution of azotemia and metabolic acidosis within 48 hrs.

Figure 1



B: Bladder; EVF: Enterovesical fistula; F: Foley catheter balloon; I: Intestine

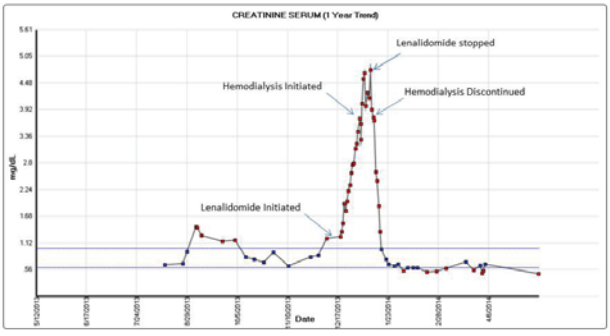
Discussion: EVF rarely can have reverse flow leading to urine excretion via GI tract in patients with diminished bladder capacity. The diverted urine stimulates HCO_3 secretion in exchange for urine Cl via Cl/HCO_3 anion exchanger located both in the ileum and the colon leading to hyperchloremic metabolic acidosis. Urinary NH_4Cl is reabsorbed in the colon and metabolized in the liver to to NH_3 and H^+. The NH_3 is metabolized to urea causing azotemia out of proportion to the kidney function. Surgical closure of EVF is required to correct these metabolic abnormalities.

TH-PO036

First Reported Case of Acute Tubular Necrosis Induced by Lenalidomide in a Patient with Follicular Lymphoma Tho M. Luong,[1] Maen Abdelrahim,[2] Ala Abudayyeh.[2] *[1]Nephrology, The Univ of Texas Medical School at Houston, TX; [2]Nephrology, The Univ of Texas MD Anderson Cancer Center, TX.*

Introduction: Lenalidomide is an immunomodulatory drug used to treat relapsed and refractory multiple myeloma, light-chain amyloidosis and certain lymphomas. Because lenalidomide is renally secreted, dose reduction is required to avoid toxic effects (pancytopenia, infections, pneumonitis, and thromboembolism). We discuss the first published case of lenalidomide-induced acute kidney injury from acute tubular necrosis.

Case Description: A 54 year old female with a history of follicular lymphoma treated with R-CHOP was evaluated for hematuria, nephrotic range proteinuria, edema, and renal failure. Renal biopsy showed membranoproliferative glomerulonephritis with C3 and IgG lambda deposition and reoccurrence of her lymphoma. Lenalidomide was initiated for further treatment and a week after initiation; the patient was hospitalized for worsening renal failure, pulmonary edema, and respiratory failure requiring intubation and hemodialysis. Urinalysis showed dense, diffuse granular casts indicative of acute tubular necrosis. After discontinuing lenalodomide the patient's renal function improved and no longer required hemodialysis



Discussion: Few associations of acute kidney injury with lenalidomide toxicity have been reported, and most have been attributed to allergic interstitial nephritis. An ongoing study at a single center is documenting the incidence of acute kidney injury after initiation of lenalidomide, but the etiology of the injury has not yet been established in this study. Lenalidomide is still recommended to treat relapsed and refractory multiple myeloma. However, our case represents a possible new complication of treatment with lenalidomide. Providers should be aware of this potential complication as the use of lenalidomide continues to rise.

TH-PO037

Two Cases of Household Product Poisoning with Hyperosmolarity Payam Shakouri, George N. Coritsidis, Ishita Rajnish, Karendip Braich, Jasjit Singh, Salwa Rhazouani, Aaron S. Stern. *Nephrology, Elmhurst Hospital Center, Elmhurst, NY.*

Introduction: In our investigation we were trying to find new etiologies for increased osmolar gap.

Case Description: Case A:43 y/o M with DM1 presented to the ICU after being found unresponsive. He presented with tachypnea, tachycardia and hypotension. He was found to be in DKA and AKI. He had a profound serum osmolar gap of 74 mOsm/kg. He was treated with IV insulin, fluids with Bicarbonate and fomepizole.Assays for toxic ingestions were later found to be negative.On hospital day 8 he admitted to spraying a common household pesticide sublingually 6-7 times daily for 7 days for its euphoric effect. Case B: 57 y/o F with multi-substance abuse and frequent overdoses presented with respiratory and renal failure after overdose of an unknown substance. She had a profound metabolic acidosis and an increased osmolar gap. Drug screen was negative for toxic ingestion.Patient underwent resuscitation, and dialysis. Upon recovery she admitted to drinking a common household cleaner (Pine Sol).

	Sodium (mEq/L)	Potassium (mEq/L)	Bicarbonate (mEq/L)	Creatnine (mmol/L)	Measured Serum Osmolality (mOsm/kg of H20)	Calculated Serum Osmolality (mOsm/kg of H20)	Osmolar Gap (mOsm/kg of H20)
Case A	112	8.8	3	3.8	372	298	74
Case B	133	3.1	6	2.6	313	288	25

Discussion: The pesticide is Case A contains imiprothrin and cypermethrin as active components. Other ingredients include: Isobutene, propane, isopropanol. There have been no reports of metabolic or serum osmolality disturbances concerning imiprothrin or cypermethrin.Increased osmolar gap is likely from other compounds present in higher concentrations and not imiprothrin or cypermethrin. We believe this is the first reported case of pesticide induced hyper osmolarity. Patient in Case B presented with AKI and anion gap metabolic acidosis.Given the patient's history of polysubstance ingestion, it was suspected that she may have also ingested ethylene glycol. On further questioning she admitted to ingesting Pine Sol. Pine Sol has two formulations, one containing Isopropanol, the other contains glycolic acid. Glycolic acid, the toxic metabolite of ethylene glycol, could account for all of the metabolic disturbances observed in this patient.

TH-PO038

Sitagliptin Associated Acute Interstitial Nephritis Julie Lesage,[1] Sebastien Savard,[1] Fabrice Mac-Way.[1] *[1]Div of Nephrology, CHU Hôtel-Dieu de Québec, Québec, QC, Canada; [2]Dept of Pathology, CHU Hôtel-Dieu de Québec, Québec, QC, Canada.*

Introduction: Inhibitors of dipeptidyl peptidase (DDP-4 inhibitors) are a new class of oral hypoglycaemic agents with increasing usage in the treatment of type II diabetes. In this paper, we describe two cases of biopsy-proven acute interstitial nephritis (AIN) attributed to treatment with sitagliptin, the first DDP-4 inhibitor to have been approved by FDA.

Case Description: Case 1 was an asymptomatic 63-year-old man that showed an elevation in creatinine, from 75 µmol/L to 225 µmol/L, twenty-two months after the introduction of a combination of sitagliptin and metformin. Renal biopsy revealed interstitial inflammation mainly composed of eosinophils. The renal function gradually improved after cessation of sitagliptin. Case 2 was a 60-year-old male with an asymptomatic increase in serum creatinine level from 103 µmol/L to 425 µmol/L over three months, which matched the introduction of sitagliptin-metformin. We could find an urinary concentration of eosinophils of 0,7% but no serologic abnormalities. Renal biopsy revealed severe tubulointerstitial inflammation composed of eosinophils, lymphocytes, plasmocytes and neutrophils, with severe fibroedema. The creatinine significantly improved with cessation of sitagliptin and an oral prednisone treatment.

Discussion: To our knowledge, this is the first report of sitagliptin-induced AIN. In both cases, the temporal association between sitagliptin initiation, renal failure and improvement of renal function after drug discontinuation supports the diagnosis of sitagliptin-induced AIN as documents by kidney biopsy. In the context of increasing popularity of this class of drugs, clinicians should be aware of this potentially adverse reaction with sitagliptan.

TH-PO039

A Case of Acute Kidney Injury from Crystal Nephropathy Secondary to Pomalidomide Use Sam Leung,[1] Phylicia Baird,[2] Olawumi O. Babalola,[2] Rimda Wanchoo,[1] Kenar D. Jhaveri.[1] *[1]Kidney Diseases and Hypertension, Hofstra North Shore LIJ School of Medicine, Manhasset, NY; [2]Internal Medicine, Hofstra North Shore LIJ School of Medicine, Manhasset, NY.*

Introduction: Pomalidomide is an analog of thalidomide indicated for treatment of refractory Myeloma. It has a reported incidence of <5% for renal failure. We report the first case of crystal nephropathy with pomalidomide use.

Case Description: A 76 year-old female with a history of refractory IgG Kappa myeloma presented with fevers, productive cough and weakness. Prior to admission, she had taken four days of a planned 21 day course of pomalidomide. Upon admission, she was noted to have a fever of 102.2F and a WBC of 2.6 K/ul with a nadir ANC of 0.3 K/ul. Respiratory

viral panel was positive for respiratory syncytial virus. In the setting of neutropenic fever, she was started on vancomycin, piperacillin/tazobactam and levofloxacin for multifocal pneumonia, seen on CT of the chest without contrast. Additionally, pamolidomide was held. On hospital day 2, her creatinine was noted to increase to 1.65 mg/dl from 1.10mg/dl on admission. Her creatinine continued to trend upwards despite adequate hydration and avoidance of nephrotoxins. Urinalysis was significant for pH of 5, and protein of 25 mg/dl with no granular casts. Microscopic analysis of urine sediment collected on second day of admission was significant for long, spindle shaped crystals. A diagnosis of pomalidomide induced crystal associated tubular damage was made. Levofloxacin was discontinued on day 2 and the other antibiotics were continued. Vancomycin levels ranged between 10-27 µg/ml. Over the following 3 weeks, her serum creatinine peaked at 3.99mg/dl, but returned to a baseline of 0.9mg/dl after three months. Due to thrombocytopenia, a kidney biopsy could not be performed.

Discussion: Given the time course of chemotherapy, urine microscopy findings and lack of use of other medications that are known to cause crystal nephropathy, pomalidomide is the most likely cause of her crystal nephropathy. This rare case of acute kidney injury due to crystal nephropathy after treatment with pomalidamide illustrates an unreported and potentially serious side effect of pomalidamide.

TH-PO040

Kinetic Estimated Glomerular Filtration Rate: Another Approach for Management of Acute Kidney Injury Ekamol Tantisattamo, Harold A. Franch, James L. Bailey. *Renal Div, Emory Univ.*

Introduction: Acute kidney injury (AKI) is common in hospitalized patients. In non-oliguric AKI, we often rely on the trend and stability of serum creatinine (SCr) to determine the onset of renal recovery. This limits an assessment of renal function when SCr is changing rapidly. Kinetic estimated glomerular filtration rate (KeGFR) is an existing simplified formula which is not widely recognized but helpful to determine renal function in AKI. We report a case of man with non-oliguric AKI requiring continuous veno-venous hemodialysis (CVVHD) and demonstrate the utility of KeGFR for management of AKI.

Case Description: Case description: A 64 year-old man with history of stage 3 CKD was admitted with urosepsis. Initial labs revealed SCr of 11.15 mg/dL from the baseline of 0.9 mg/dL. Serum K was 6.7 and HCO_3 was 5 mmol/l. ABG showed pH of 6.8, $PaCO_2$ of 19, and PaO_2 of 106 mmHg. Urine microscopy revealed muddy brown casts. He was non-oliguric. CVVHD was initiated. Forty-four hours later, acidosis was improved and CVVHD was discontinued. Around 22 hours after discontinued CVVHD, SCr was 1.6 mg/dL and had trended up to 3.06 mg/dL within 24 hours (hospital day4) when KeGFR was almost 0 ml/min (see formula in the figure1). From hospital day4-8, SCr still had trended up; however, KeGFR showed improving renal function. Therefore, dialysis catheter was removed on hospital day7. He was discharged with SCr of 1.64 mg/dL.

Discussion: SCr is not a sensitive marker and eGFR from MDRD routinely reported with SCr cannot be applied in AKI. To calculate eGFR from KeGFR formula, only SCr which is routinely monitored during AKI, is required. By using KeGFR, more accurate renal function can be confidently determined at bedside in the setting of acute change in SCr. Our case demonstrates utility of KeGFR for management in AKI especially to determine the onset of renal recovery and time to discontinue dialysis.

$$KeGFR = \frac{SSP_{Cr} \times CrCl}{MeanP_{Cr}} \times \left(1 - \frac{24 \times \Delta P_{Cr}}{\Delta Time(h) \times Max\Delta P_{Cr}/Day}\right)$$

KeGFR = Kinetic estimated glomerular filtration rate (ml/min)
SSP_{Cr} = Steady-state plasma creatinine (mg/dl)
CrCl = Corresponding creatinine clearance (mg/dl)
$MeanP_{Cr}$ = Mean maximal change in plasma creatinine /day (mg/dl)
ΔP_{Cr} = Change in plasma creatinine between 2 consecutive values (mg/dl)
ΔTime = Interval between 2 consecutive creatinines (mg/dl)
$MaxΔP_{Cr}/Day$ = Maximal change in plasma creatinine / day (use 1.5 mg/dl/day)

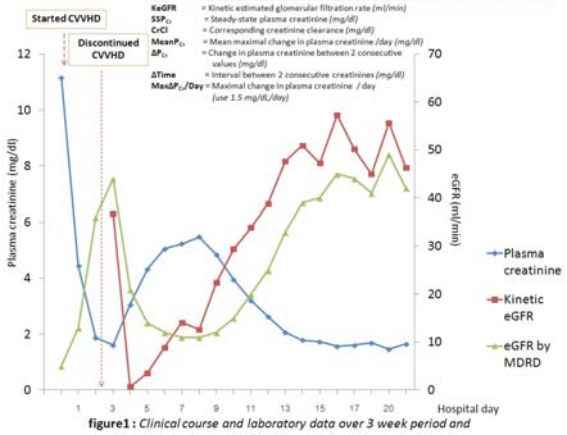


figure1 : *Clinical course and laboratory data over 3 week period and Kinetic glomerular filtration rate formula.*

TH-PO041

Fatal Rhabdomyolysis due to Massive Number of Bees' Stings Ghayyath Sultan, Gaurav Agarwal, Mohammed Ahmad, Christopher A. Dyer. *Dept of Nephrology, Univ of Texas, San Antonio, TX.*

Introduction: Rhabdomyolysis due to massive number of bee's stings with fatality has been reported in infants, elderly and debilitated patient but fatal outcomes in a previously healthy young adults has not yet been reported.

Case Description: A 30 year old athletic man with no prior history of hypersensitivity to insect stings was stung by approximately 300 bees after he accidently encountered a bee's nest. He was treated with subcutaneous epinephrine and intravenous diphenhydramine en route to the emergency department. On arrival, he was tachycardic and hypertensive and subsequently developed a progressive decline in respiratory status and required intubation. Multiple bees' stings were noted over the arms, neck, chest, face, ears and abdomen. He developed oliguric acute kidney injury accompanied by hyperkalemia, hyperuricemia, hyperphosphatemia and hypocalcemia. Laboratory findings revealed, serum creatinine 1.98[thinsp]mg/dl, AST of 1851 IU/L on admission and peaked at > 20,000 IU/L next day, uric acid of 24.9 mg/dl, phosphorus of 13.8 g/dl, myoglobin of > 1000 ng/ml and creatine phosphokinase (CPK) of 40,000[thinsp]IU/l reaching a peak of 361,200 IU/L second day of admission. He was treated with aggressive fluid resuscitation, intravenous sodium bicarbonate and emergent hemodialysis. He was converted to continuous venovenous hemofiltration (CVVH) due to persistent hyperkalemia. On the second hospital day, the patient became hypotensive and required pressor support with epinephrine. He subsequently developed ventricular fibrillation and cardiopulmonary resuscitation was attempted for over 60 minutes without success.

Discussion: Although rhabdomyolysis may be caused by multiple etiologies; it is rarely reported after bees' stings. The mechanism of myotoxicity is attributed to the direct toxicity of the venom to myocytes and fatality is a potential outcome even in otherwise young and healthy patients.

TH-PO042

High Flux Dialysis for Acute Nephrotoxicity following High Dose Methotrexate Ghayyath Sultan, Gaurav Agarwal, Nyan W. Phyo, Hanna E. Abboud. *Dept of Nephrology, Univ of Texas, San Antonio, TX.*

Introduction: High dose methotrexate (HDMTX) can be safely given to most patients with supportive care measures. Few patients, however, develop nephrotoxicity. Early recognition and treatment is essential to prevent the accumulation of toxic methotrexate (MTX) levels that can lead to significant morbidity and mortality.

Case Description: A 71 year old man with primary CNS lymphoma was started on high dose methotrexate (4g/m2). Prior to starting HDMTX he was treated with rescue leucovorin therapy and IV sodium bicarbonate to achieve urine Ph of greater than 7 for 2 consecutive days. Baseline serum creatinine on admission was 0.8 mg/dl. 24 hours after receiving HDMTX his creatinine increased to 2.3 mg/dl and peaked at 4.37 mg/dl. He continued to have adequate urine output. MTX levels were 253 µmol/L post infusion and 129 µmol/L 17 hours after the treatment. MTX levels remained in the toxic range along with worsening kidney function. High flux hemodialysis (HD) was initiated. MTX levels decreased from 32.57 µmol/L pre HD to 6.59 µmol/L after two four hours each of HD treatments. MTX levels continued to decrease gradually with ongoing treatment of sodium bicarbonate and leucovorin and reached a value of less than 1 µmol/L two weeks later. Serum creatinine also improved gradually reaching new base line of 1.2 mg/dl three weeks later. In addition to renal toxicity; patient developed thrombocytopenia with platelets count of 64000/mcl (normal 150000 - 450000/mcl) and liver toxicity with ALT of 140 IU/L (normal 10 – 40 IU/L) and AST of 62 IU/L (normal 10 – 40 IU/L). Both thrombocytopenia and liver toxicity resolved with complete clearance of methotrexate from the circulation.

Discussion: Methotrexate is a direct renal toxin that can lead to renal failure with decrease in MTX clearance and systemic toxicity. Additional treatment is required when standard measures fail to prevent MTX- induced nephrotoxicity. High flux hemodialysis is very effective in reducing MTX levels. Pharmacotherapy with glucarpidase has been used successfully to decrease MTX levels. However, the drug is prohibitively expensive and may not be available in many centers.

TH-PO043

Novel Endovascular Treatment of Supra-Renal Caval Thrombosis and Acute Kidney Injury Akshta Pai, Mohamad Alkhouli, Grayson Wheatley, Eric T. Choi, Riyaz Bashir, D. B. Johnstone. *Temple Univ Hospital, Philadelphia, PA.*

Introduction: Hospital-acquired acute kidney injury is most often seen as a result of decreased renal perfusion from any cause, including nephrotoxic medications, contrast media, surgery and sepsis. Catastrophic vascular obstruction is a relatively rare and controversial cause of acute kidney injury.

Case Description: We present a case of a morbidly obese 55-year-old male hospitalized with a large abdominal wall hematoma who suddenly became oligo-anuric for unclear reasons. Our diagnosis was renal vein thrombosis and supra-renal vena caval thrombosis. Treatment with systemic heparin unfortunately resulted in expansion of the large abdominal wall hematoma, and his obesity precluded surgical intervention. As an alternative, endovascular extraction of the thrombus using the AngioVac veno-venous filtration system was utilized, and afterwards and the patient regained normal renal function.

Discussion: To our knowledge, this is the first report of utilizing the AngioVac system in the treatment of renal vein and supra-renal vena caval thrombosis without concomitant thrombolytics.

TH-PO044

Ethylene Glycol Toxicity Masquerading as Lactic Acidosis Sami Alasfar, Mohamed G. Atta. *Johns Hopkins Univ, Baltimore, MD.*

Introduction: Ethylene glycol toxicity is manifested by gastrointestinal and nervous system involvement with metabolic acidosis. Its metabolites are structurally similar to lactate and can cause false elevation of lactate. We present a case of ethylene glycol toxicity demonstrating the substantial potential for misdiagnosis.

Case Description: A 53-year-old male with diabetes presented with confusion, nausea, and vomiting. His only home medication was Metformin with unknown dose.

On examination, pulse was 121 beats/min and blood pressure was 188/91 mmHg. He was agitated and had Kussmaul respiration. Laboratory tests on admission are shown below:

Test	Value
pH	6.3
CO2	44 mmHg
Bicarbonate	5 mEq/L
Osmolality	351 mOsm/kg
Osmolar gap	22
Sodium	142 mEq/L
Potassium	6.2 mEq/L
Cholride	97 mEq/L
Anion gap	40
Creatinine	1.6 mg/dL
Glucose	486 mg/dL
Lactate	>30 mmol/L
Ethanol and Salicylate	Undetectable
Urine drug screen	Negative
Urinalysis	Negative for ketones or crystals

He was intubated for airway protection and emergently started on sodium bicarbonate drip and continuous renal replacement therapy. After 24 hours, lactate level started to decrease and normalized by 36 hours. Three days later, admission Metformin level came back normal and admission ethylene glycol was elevated at 167 mg/L. Subsequent ethylene glycol levels normalized. Later, a friend reported that the patient purchased an online product with the intent to commit suicide. Patient developed multiple complications including strokes and septic shock. His renal function did not recover and remained on dialysis.

Discussion: Elevated lactate level suggests tissue hypoxia or, as in this case, possible metformin toxicity. However, because of misinterpretation of glycolate as lactate by analyzers that utilizes L-lactate oxidase method, ethylene glycol toxicity may be overlooked. Although lactate can be elevated in patients with ethylene glycol toxicity, such elevation is usually minimal. This case shows the potential to misdiagnose ethylene glycol toxicity as lactatic acidosis when analyzers utilizing L-lactate oxidase method are used. Thus, elevated lactate level may be the first sign of ethylene glycol toxicity in this setting and it should be considered in patients presenting with metabolic acidosis and elevated lactate level.

TH-PO045

Vancomycin Associated Interstitial Nephritis, Acute Tubular Necrosis and Leucocytoclastic Vasculitis Sherif Y. Isshak, Jiries S. Dahu, John C. Edwards. *Nephrology, Saint Louis Univ, St. Louis, MO.*

Introduction: Vancomycin (VANC) can cause leukocytoclastic vasculitis (LV), occasionally accompanied by acute kidney injury (AKI).While VANC is known to cause both acute tubular necrosis (ATN)and acute interstitial nephritis (AIN), the pathology of AKI in context of LV has not been reported.

Case Description: A 46 year old man with normal kidney function suffered a gunshot wound to the head. He had cranioplasty complicated by MRSA infection and was treated with VANC, target serum level 15-20 mg /dl. VANC level did not exceed 25 mg/dl throughout the course. On the eighth day of VANC therapy, He developed altered mental status. On day 11, serum creatinine (Scr) rose from baseline 0.8 to 1.5 mg/dl and he developed erythematous papulovesicular and petechial rash. There was no documented hypotension, urinary retention, intravenous contrast or nephrotoxic drugs exposure. Skin biopsy showed leucocytoclastic vasculitis; direct immunofluorescence stain was negative for C3, C1q, IgM, IgA, and IgG. On day 12, VANC was changed to daptomycin and rifampin. Rash improved. Five days later, VANC was restarted because of its superior CNS penetration. The rash recurred and Scr worsened to 2.9 mg/dl. Urine sediment was notable for WBC and RBC casts. Renal biopsy showed diffusely increased mesangium, interstitial mononuclear infiltrate with prominent eosinophils and tubules with focal cytoplasmic vacuolization, attenuated brush border and numerous tubular epithelial mitotic figures. Immunofluorescence was negative. VANC was changed to linezolid. The rash resolved and Scr improved to 1.6 where it stabilized.

Discussion: This patient developed manifestations of VANC toxicity, including LV and AKI that on kidney biopsy showed no evidence of vasculitis, but rather components of both AIN and ATN, both of which have been associated with VANC in the absence of vasculitis.The injury occurred without excessive VANC blood level. VANC toxicity has been associated with serum levels above 15mg/dl, daily dose 4 g or more, and concomitant drugs, particularly pipercillin and gentamicin. With stopping VANC, Scr usually improves to baseline, but may progress to CKD or ESRD.

TH-PO046

Thrombotic Thrombocytopenic Purpura with Acute Kidney Injury in a Patient with Systemic Sclerosis Bernice Kim, Dong Jun Oh, Sung Joon Shin, Kyung Soo Kim. *Div of Nephrology, Dept of Medicine, Dongguk Univ Ilsan Hospital, Go-yang, Republic of Korea.*

Introduction: Thrombotic thrombocytopenic purpura (TTP) is a rare complication of systemic sclerosis (SSc). Distinguishing TTP from scleroderma renal crisis (SRC) is difficult, because both diseases can present with thrombocytopenia, microangiopathic hemolytic anemia (MAHA), and renal impairment, but the pathogenesis and treatments are totally different. In this report, we present a case of TTP in a patient with SSc treated with plasmapheresis.

Case Description: A previous healthy 81-year-old woman was admitted because of stuporous mentality. On admission, she was afebrile with blood pressure of 141/87 mmHg. Physical examination revealed skin thickening in both hands and Raynaud's phenomenon, strongly suggestive of systemic sclerosis. Initial laboratory tests were as follows: platelet count $76x10^3$ /μL, hemoglobin 7.9 g/dL, corrected reticulocyte count 4.0%, lactate dehydrogenase (LDH) 866 IU/L, and creatinine 6.39 mg/dL. Peripheral blood smear revealed schistocytosis, indicating MAHA. Anti-Scl 70 antibody was positive, and diagnosis of systemic sclerosis was confirmed by a rheumatologist. Activity of ADAMTS13 was mildly decreased to 39%. Presumptive diagnosis of TTP was made and emergent treatment with plasmapheresis with systemic corticosteroid was initiated. After 12 sessions of plasmapheresis, she had clinical therapeutic response as evidenced by improvement of mentality to nearly alert state, and normalization of LDH and MAHA. However, thrombocytopenia persisted, but further treatments for refractory TTP were not administered, considering her age. Renal function did not improve, and she remained dialysis dependent.

Discussion: Although distinguishing TTP from SRC is difficult, urgent decision has to be made based on clinical findings, as in the presented case. Plasmapheresis should be considered when TTP cannot be ruled out, since TTP is a potentially fatal disease whereas early treatment can be lifesaving. When there is no clinical response to plasmapheresis, SRC should be reconsidered and appropriate therapy with angiotensin converting enzyme inhibitor should be taken into account.

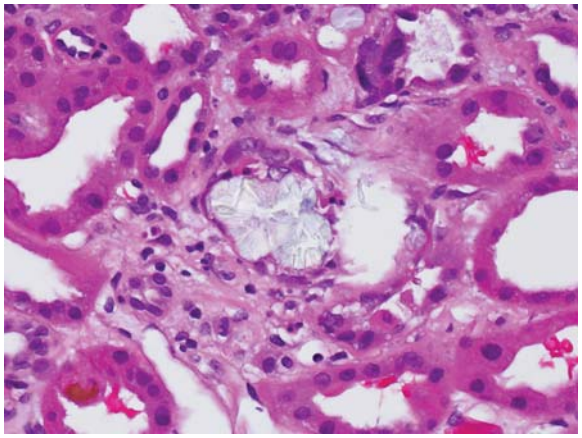
TH-PO047

Acute Kidney Injury due to Oxalosis Secondary to Pancreatic Insufficiency Irfan K. Moinuddin,[1] Machaiah M. Madhrira,[1] Amy Nicole Sussman,[2] Erika R. Bracamonte.[3] *[1]Div of Nephrology, Univ of Arizona Medical Center, Tucson, AZ; [2]Dept of Nephrology, Univ of Arizona at Tucson, Tucson, AZ; [3]Dept of Pathology, Univ of Arizona at Tucson, Tucson, AZ.*

Introduction: AKI due to pancreatic carcinoma can be the result of hypoxemia, release of pancreatic amylase from the injured pancreas with impairment of renal microcirculation, decrease in renal perfusion pressure due to abdominal compartment syndrome or hypovolemia. We describe a case of AKI due to oxalosis in a patient in whom pancreatic cancer caused severe pancreatic insufficiency.

Case Description: We report a case of a 66 year old female with past medical history of ovarian cancer, uterine cancer, colon cancer and newly diagnosed pancreatic adenocarcinoma was admitted for the evaluation of nausea, vomiting and diarrhea. She reported diarrhea of several months duration. Her admission serum creatinine was 10.4mg/dl, one month prior being 1.0mg/dl. Urinalysis showed protein 300, WBC >150, RBC 43 and no bacteria and urine protein/creatinine of 1.8gm/gm.Renal ultrasound showed no hydronephrosis. She was volume resuscitated adequately for three days with no significant improvement in her renal functions and hence a renal biopsy was pursued.

Histopathology demonstrated a tubulointerstitial process with calcium oxalate crystals in the tubules consistent with oxalosis. Patient was diagnosed with AKI due to secondary oxalosis. On enzymatic evaluation she was found to have marked pancreatic insufficiency and fat malabsorption.



Discussion: Fat malabsorption leads to saponification of calcium and absorption of free oxalate. Oxalate deposition in the kidneys can lead to nephrocalcinosis, sterile pyuria, hematuria and mild proteinuria. In a patient with pancreatic adenocarcinoma who presents with AKI associated with diarrhea, oxalosis due to fat malabsorption must be considered.

TH-PO048

Lactic Acidosis Leading to Shock: A Rare Cause and a Suggestion for Change in Guidelines Dennis Moledina, Barry R. Gorlitsky. *Nephrology, Yale, New Haven, CT.*

Introduction: Metformin is a first-line agent for treatment of type 2 DM. It has been linked to lactic acidosis in at-risk patients and current guidelines suggest avoiding Metformin if serum creatinine (mg/dl) is >1.4 in women and >1.5 in men. We describe a case of lactic acidosis with metformin use in a patient who did not meet the criteria for avoiding Metformin based on creatinine cut-off but did have a decreased eGFR. We make the case for utilizing eGFR rather than serum creatinine as a cut-off value for avoiding Metformin.

Case Description: 72-year-old woman with a baseline creatinine of 1.3 mg/dl (eGFR=41 ml/min) presents as a stroke code with severe hypotension. Her daughter provides

the history of a week of malaise and vomiting prior to presentation. Her laboratory work demonstrated a pH of 6.80, serum bicarbonate <5 mEq/L, lactic acid level of 26.0 mmol/L, and creatinine of 7.2 mg/dl. There was recovery in hemodynamics with initiation of CRRT and no source of sepsis could be identified. Due to a high level of suspicion a Metformin level was submitted from a sample drawn on admission, however discussion with patient's daughter and pharmacy regarding home medications did not reveal Metformin use. We did obtain a history of Furosemide, Lisinopril and Ibuprofen explaining the AKI. The Metformin level was found to be elevated at 33 mcg/ml (therapeutic range is 1-2) and on extubation the patient admitted to using Metformin 500 mg twice daily, which was filled from an unlisted pharmacy. She was able to achieve recovery of creatinine to her baseline.

Discussion: The FDA received 47 confirmed reports of Metformin-associated lactic acidosis in 1996–the year after its introduction in the U.S. CKD is a major risk factor for this due to renal route of elimination. While our patient clearly did not meet the defined criteria for avoiding Metformin, she did have CKD IIIb based on her eGFR. This case highlights the need for a change in the current FDA guideline to an eGFR based approach which is the case in many countries. Thus, while Metformin is a safe and effective therapy for type 2 DM, its use carries a risk of lactic acidosis in our CKD population and prescribers must consider a dose reduction or discontinuation in the at-risk patient.

TH-PO049

An Unusual Cause of Acute Kidney Injury due to Oxalate Nephropathy in Systemic Scleroderma Heather M. Mascio,[1] Michael F. Flessner,[2] Thomas P. Baker,[3] Maryann T. Ally,[4] Christie Alyce Joya,[4] Christina M. Yuan,[1] Kevin C. Abbott,[1] Robert Nee.[1] *[1]Nephrology Service, Walter Reed National Military Medical Center, Bethesda, MD; [2]NIDDK, National Insts of Health, Bethesda, MD; [3]Joint Pathology Center, Defense Health Agency, Silver Spring, MD; [4]Dept of Medicine, Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: Oxalate nephropathy is an uncommon cause of acute kidney injury. Far rarer is its association with scleroderma, with only one other published case report in the literature.

Case Description: We present a case of a 75 year-old African-American female with a history of systemic scleroderma with chronic pseudo-obstruction and small bowel bacterial overgrowth (SIBO) treated with rifaximin admitted for anorexia. The patient was normotensive. Her initial laboratory evaluation showed creatinine 4.01 mg/dL (0.65 mg/dL one week prior). Urinalysis was unremarkable. She had no serum osmolar gap. Urine microscopy revealed calcium oxalate monohydrate crystals. An extensive serologic workup was negative. Renal ultrasound was unremarkable. A renal biopsy was performed, demonstrating a diffuse tubulo-interstitial process with numerous calcium oxalate crystals consistent with oxalate nephropathy. The patient was subsequently initiated on hemodialysis.

Discussion: In this case no obvious cause for her nephropathy was found. We hypothesize that her treatment with rifaximin for SIBO may have caused decolonization of oxalate degrading bacteria in her GI tract. Also, her chronic pseudo-obstruction with delayed intestinal transit may have increased intestinal oxalate absorption. In the previous published case report of scleroderma, oxalate nephropathy was attributed to malabsorption from chronic pancreatitis and the AKI resolved without requiring renal replacement therapy. Oxalate nephropathy should be considered in the differential diagnosis for unexplained acute kidney injury in scleroderma, particularly with normotension, and subsequent evaluation should be focused on bowel function to include alterations in the gut flora due to antibiotic administration.

TH-PO050

Acute Kidney Injury and Primary Hyperoxaluria Type 1: A Case Discussion and Review of the Literature Louis R. Spiegel, Shailaja Chidella, Sam Leung, Nicole M. Ali. *Hofstra North Shore - LIJ School of Medicine.*

Introduction: Primary hyperoxaluria is characterized by an overproduction of oxalate and an increased demand on the kidneys. Oxalate is renally excreted and if the GFR decreases to less than 30-45mL/min there is a tendency towards systemic oxalate deposition in a variety of organ systems. In the setting of decreased GFR the optimal method of oxalate removal is unknown. We present a patient with primary hyperoxaluria type 1, the most common form of the three primary hyperoxalurias, who develops acute kidney injury (AKI) and subsequently requires renal replacement therapy.

Case Description: A 61 year old female with Primary Hyperoxaluria Type 1 (PH Type I), hypertension, status post deceased donor renal transplant (DDRT) in 1999, chronic kidney disease (CKD) 4, presented with vomiting, decreased oral intake, diarrhea, decreased urine output and was found to have AKI with creatinine of 12mg/dL (baseline-2.6mg/dl),severe acidosis, anemia and thrombocytopenia. She was volume resuscitated and was initiated on aggressive hemodialysis (HD) for oxalate clearance. She underwent renal biopsy which revealed severe oxalate nephropathy and tubular injury. Bone marrow biopsy showed hypocellular bone marow, renal osteodystrophy and oxalate deposition. She continued to receive HD 6 days a week for 5 hours per session. Patient has subsequently received a combined liver-kidney transplant.

Discussion: Traditional methods of obtaining clearance, such as three times per week hemodialysis and daily peritoneal dialysis are unable to clear oxalate faster than it is generated in primary hyperoxaluria. Many different approaches have been attempted with varying success. Comparisons between 4 hours of daily HD to three times per week HD to hemodiafiltration have been performed, as well as combinations of HD and peritoneal dialysis with nocturnal hemodialysis.We present a unique case of a patient with PHT Type 1 responsive to pyridoxine who received a DDRT 13 years prior. Due to hemodynamic factors she developed AKI that resulted in impaired oxalate excretion and systemic deposition. We report our experience using 6 days per week, 5 hours per session hemodialysis.

TH-PO051

Novel Features of Methylmalonic Acidemia Associated Nephropathy Jatinder K. Hothi,[1] Luan D. Truong,[2] Biruh Workeneh.[1] *[1]Div of Nephrology, Baylor College of Medicine, Houston, TX; [2]Pathology, Houston Methodist Hospital, Houston, TX.*

Introduction: Patients with methylmalonic academia have in-born errors of propionate metabolism, but given the low incidence of the disease the renal lesions associated with the disorder have not been fully characterized.

Case Description: We report a case of a 20-year-old man who presented with a slightly elevated serum creatinine and proteinuria. A biopsy of his kidney revealed mild tubulointerstitial nephritis, which has been previously described, but also 2 novel features related to the glomerulus. The glomeruli showed focal mesangial sclerosis, which has not been described at early stage. Secondly, the pathology demonstrated glomerulomegaly (enlarged glomerular volume). The glomeruli on average were 260 microns in diameter, and this in addition to the focal mesangial sclerosis indicates a previously unreported pattern of injury. In addition to starting an ARB, the patient was given a course of corticosteroids empirically to determine if it would be beneficial, but a 3-month course did not result in improved serum creatinine or proteinuria.

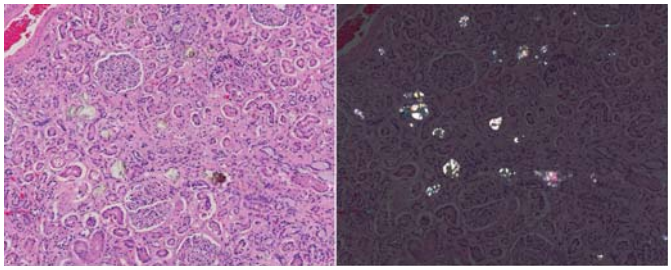
Discussion: If additional cases or review of pathologic lesions confirm the glomerulomegaly then this feature should be added to the description of pathologic injury pattern associated with MMA. Currently, there is no specific treatment for nephropathy associated with MMA and further study is necessary to determine whether specific therapy can be designed to prevent this complication in patients.

TH-PO052

Rapidly Progressive Renal Failure due to Oxalate Nephropathy in a Patient with Pancreatic Neuroendocrine Tumor Anna Malkina, Jean L. Olson, Ursula Lang, Raymond K. Hsu. *UCSF.*

Introduction: 50-year-old man with history of pancreatic neuroendocrine tumor presented with cachexia and non-oliguric acute kidney injury (AKI) with sub-nephrotic range proteinuria. Clinical history and non-invasive tests did not reveal the etiology or prognosis of AKI.

Case Description: Patient's history was notable for anorexia, 35 lbs unintentional weight loss in prior 10 months, absence of nutritional supplements use, and 14 year history of insulin-dependent diabetes mellitus. Neuroendocrine tumor was diagnosed 10 months ago with head of pancreas mass and metastases to 40% of liver parenchyma. Creatinine declined from 0.9 to 4.61 mg/dL in prior 4 months. Urine spot protein to creatinine ratio was 1.34 mg/mg. Renal ultrasound was without hydronephrosis, masses, or calculi. Urine sediment showed renal tubular epithelial cells. Patient was initiated on renal replacement therapy for treatment of severe metabolic acidosis and uremia. He sustained multi-organ failure with hypotension, hypercarbic respiratory failure, and pancytopenia; and was transitioned to comfort care. Autopsy revealed oxalate nephropathy with widespread tubular injury in the background of diabetic nephropathy.



Discussion: Oxalate deposition may lead to rapidly progressive renal failure in setting of enteric overabsorption in absence of excessive dietary oxalate intake. In this case pancreatic insufficiency due to tumor burden resulted in fat malabsorption. Accumulation of intestinal dihydroxy bile acids and fatty acids 1) increased intestinal mucosal permeability to oxalate, 2) increased amount of soluble oxalate that would otherwise complex with luminal calcium and be excreted in stool, and 3) led to inhibition of intestinal oxalate-degrading bacteria. Renal failure was due to secondary hyperoxaluria.

TH-PO053

Ibuprofen-Induced Coma and Renal Replacement Therapy Weeraporn Srisung,[1] Pavis Laengvejkal,[1] Kunut Kijsirichareanchai,[2] Sorot Phisitkul.[1] *[1]Texas Tech Univ HSC; [2]Univ of Nebraska.*

Introduction: Ibuprofen is a nonsteroidal anti-inflammatory drug that has been widely used for several years due to its relatively safe side-effect profile. Ibuprofen overdose is very common and intoxication usually occurs with ingestion exceeding 400 mg/kg. We report a case of an uncommon presentation of Ibuprofen-induced encephalopathy with severe neurological deficits mimicking brain death, which resolved with dialysis.

Case Description: A 21-year-old female presents with unresponsiveness 1 day after ingesting an unknown amount of Ibuprofen. She was intubated prior to arrival. She was hypotensive, tachycardic and afebrile. Respiration was fully supported by the ventilator. Her Glasgow Coma Scale was 2T. Pupils were 6 mm and unreactive to light. Gag, corneal and oculocephalic reflexes were absent with no muscle tone nor posturing. The remainder of the physical examination was unremarkable. Laboratory studies were notable for serum

pH 6.71, pCO2 34.4 mmHg, sodium 149 mEq/L, potassium 5 mEq/L, chloride 114 mEq/L, carbon dioxide 5 mEq/L, BUN 37 mg/dl, Creatinine 1.9 mg/dl, lactate 11 mmol/L, and no significant osmolal gap. Fractional excretion of sodium was 18.49%. She was polyuric. Renal replacement therapy was started. She became more responsive after four hours of treatment. A few hours later, she was able to follow simple commands. Her pupillary response returned and all other neurological deficits resolved. Her creatinine normalized prior to discharge.

Discussion: Ibuprofen-induced neurological deficits typically manifest as altered mentation, nystagmus, blurred vision, diplopia, and tinnitus. However, fixed dilated pupils and absent brainstem reflexes in this clinical setting are atypical. We suspect this patient's encephalopathy was secondary to Ibuprofen overdose and concomitant hypoperfusion with resultant acidosis. Dialysis does not have a clinically important effect on plasma clearance of Ibuprofen, so the patient's neurologic recovery is likely due to correction of acidosis. This case demonstrates that even in those with severely impaired neurologic status, renal replacement therapy can dramatically improve the clinical outcome in patients with ibuprofen-induced encephalopathy.

TH-PO054

Synthetic Cannabinoids and Acute Kidney Injury - A Case Series

Weeraporn Srisung, Sharma S. Prabhakar. *Internal Medicine, Texas Tech Univ HSC, Lubbock, TX.*

Introduction: Synthetic cannabinoids(SC) have been increasingly used for recreation, however, their side effects have not been well recognized. We report here 3 cases of SC-induced acute kidney injury(AKI).

Case Description: Case 1 A 31-year-old Hispanic male SC abuser presented after a physical assault. Significant soft tissue injury and fractures were excluded, but he was found to have high serum creatinine (SCr). Physical examination (PE) was unremarkable. Basal metabolic panel (BMP) showed BUN/Cr of 26/2.6. Urinalysis was negative. Fractional excretion of sodium (FENa) is 1.99%. Creatinine kinase (CK) was normal. Renal ultrasound (US) showed normal size kidneys without hydronephrosis. Soon SCr rose to 3.0 mg/dL despite intravenous fluid (IVF), however, it decreased to 1.4 mg/dL with good urine output before discharge on 6th day. **Case 2**. A 32-year-old male, drug abuser presented after amphetamine and SC overdose. PE was unremarkable. SCr was 1.1 mg/dl but rose to peak at 5.7 mg/dl despite IVF. Urine output dropped to 10-20 ml/hr. CK was 3,987 IU/L. FENa was 2.13%. Renal US showed no hydronephrosis. With dialysis and supportive care, he improved. SCr upon follow-up was 0.9 mg/dl. **Case 3.** A 31-year-old male was admitted for sensorial and behavioral problems. PE was unremarkable. Later on, he admitted to abusing SC daily. BMP showed BUN/SCr 25/3.5. FENa is 2.13%. CK was 1,137 IU/L. Urine studies and renal US were unremarkable. His SCr improved on the next day with IVF.

Discussion: SC are shown to have temporal association with AKI but the pathogenic mechanisms remain unclear. Renal biopsy showed acute tubular necrosis or acute interstitial nephritis although biopsies were done in only some of the published cases. XLR-11 or [1-(5-fluoropentyl)indol-3-yl]-(2,2,3,3-tetramethylcyclopropyl methadone) were found in products of SC used by subjects as well as clinical specimens in one case series. This raises hypothesis that XLR-11 or its metabolites might be the culprit causing AKI in this group. Potential binding of XLR-11 to renal cannabinoid receptor 1 could offer a possible pathogenic link. We conclude that AKI is a common complication of SC abuse and warrants increased awareness among medical and general communities.

TH-PO055

Correction of Acidemia and Cardiac Hemodynamics by Modified Continuous Veno-Venous Hemofilteration for Severe Lactic Acidosis

Gaurav Alreja, Joseph Palmisano, Andre A. Kaplan. *Internal Medicine, Univ of Connecticut, Farmington, CT.*

Introduction: Correction of severe lactic acidosis often results in extracellular volume expansion, hypocalcemia, hypernatremia, acceleration of lactate generation and worsening of acidemia. Previous studies failed to show improvement in hemodynamics or outcome with correction of lactic acidosis. We present a case with severe lactic acidosis that corrected with a modified replacement solution during continuous veno-venous hemofiltration (CVVH) resulting in marked improvement in cardiac hemodynamics.

Case Description: 61 year old female presented with elevated lactate level (10 mmol/L), liver damage (AST 13000 IU/L, ALT 5041 IU/L) and metabolic acidemia: HCO3 7meq/L, pH 7.094. CT scan showed cervical cancer, retroperitoneal lymphadenopathy and hepatic metastases. Despite aggressive bicarbonate administration (75 mEq/hr) and maximal minute ventilation, acidemia persisted and massive volume overload ensued. Swan Ganz catheterization showed hyperdynamic circulation with distributive shock (cardiac output 18.2 L/min, cardiac index 7.8L/min/m2, SVR 237 dyn/cm5, SvO2 82%). CVVH with predilution was initiated with a modified solution (150 mEq NaHCO3 in 1000 cc D5W) at a rate of 2000 cc/hr (delivering 300 mEq/hr NaHCO3). Although, serum lactate level increased from 10 to 30 mmol/L, both HCO3 level and pH improved to 23 meq/L and 7.42 respectively in a span of 7 hours. The patient received 14 gm of calcium gluconate during this time period through a separate infusion site. The patient's hemodynamic parameters improved significantly (Cardiac output 7L/min, SVR-800 dyn/cm5, and SvO2 63%) allowing discontinuation of vasopressors.

Time (Hours)	-11	0 (CVVH Started)	2	4	7
HCO3 (mEq/L)	7	10	14	19	23
Lactate (mmol/L)	10.7	23	27	29	30
pH	7.09	7.19	NA	NA	7.47

Discussion: Although prior studies of CVVH showed only 3% removal of generated lactic acid and difficulty in controlling acidemia (due to increased lactate generation with rising bicarbonate), the modified replacement solution utilized in this case may be valuable for correcting acidemia and improving cardiac hemodynamics. At the same time, ongoing CVVH was able to control hypervolemia, hypernatremia and hypocalcemia.

TH-PO056

Severe Tubulointerstitial Nephritis from Acute Epstein-Barr Virus Infection

Craig A. Mackaness. *Dept of Medicine, Nephrology Div, Lehigh Valley Health Network, Allentown, PA.*

Introduction: Infectious Mononucleosis from Epstein Barr Virus (EBV) is a rare etiology of severe acute renal failure.

Case Description: Our patient is a 21 year old Caucasian woman with no significant past medical history who presents to our center with complaints of a two week prodrome of nausea, vomiting, cough, sore throat, and malaise. Examination revealed a temperature of of 40 degrees C, bilateral pustular and exudative pharyngeal erythema. Tender and prominent anterior cervical lymphadenopathy with palpable hepatosplenomegaly were present. On presentation, serum creatinine was elevated at 2.24 which over the ensuing four days worsened to 7.1 mg/dL. Urinalysis demonstrated 300-600 protein with 3-5 RBC/hpf, 6-10 WBC/hpf and Granular casts of >10/lpf. A urine protein/creatinine ratio was elevated at 2.3. The patient's white blood cell count was elevated at 14,000 with 39% atypical lymphocytes. A Monospot was positive and EBV IgM was elevated at 1.68. An ASO titer was increased at 947 with a subseqently negative rapid strep and culture. Her renal function progressively worsened with oliguria. Serologic workup was otherwise negative and she underwent native kidney biopsy. The biopsy revealed patchy foci of active lymphocytic tubulitis, necrotic tubules with neutrophils, and many tubules with granular cell casts. These findings established the diagnosis of acute tubulointerstitial nephritis. EBV in situ hybridization stain (EBER) demonstrated a single small lymphocyte positive stain. She was placed on dexamethasone for her symptomatic tonsilar enlargement and concern for airway compromise. Her renal function dramatically improved over the next three days and she was discharged home without requring renal replacement therapy.

Discussion: Subclinical renal dysfunction from acute EBV is common occurring in as many as 16% of patients, (Infect Dis Clin Pract 2008; 16:127-128) but severe oliguric renal failure from acute EBV is rare. This patient had direct evidence of EBV virus in the renal parenchyma, suggesting pathogenesis. Clinicians treating patients with suspected or confirmed acute EBV should include monitoring of renal function for this rare, but serious complication.

TH-PO057

Case Report of Synthetic Cannabinoids Use Combined with Quetiapine Presenting as Rhabdomyolysis and Acute Kidney Injury

Aiyu Zhao, Maybel M. Tan, Moses A. Lee, Moro O. Salifu, Mary C. Mallappallil. *State Univ of New York at Downstate, Brooklyn, NY.*

Introduction: The use of synthetic cannabinoids (SCBs), commonly known as "Spice" or "K2", is associated with many severe adverse effects that are not observed with marijuana use. We are reporting a unique case of a patient who developed rhabdomyolysis and acute kidney injury (AKI) required dialysis after use of K2 combined with quetiapine.

Case Description: A 39 year old man with history of cannabis abuse and schizophrenia presented with generalized bodyache. He was using K2 daily for years more heavily for one week. He attempted suicide by ingesting 10 tablets of quetiapine the day before presentation. Physical exam was significant for moderate lower extremities edema and diffuse muscle tenderness without rigidity. Serum creatinine was 1md/dl one year ago which was 6.09 mg/dl on presentation and increased to 9.39 mg/dl. Peak serum Creatine Kinase (CK) level was 148,643 IU/L. Urinalysis showed muddy brown casts. Toxicity screen including urine cannabinoid was negative, which is expected with SCBs use. Fractional excretion of sodium was more than 1% compared to typical rhabdomyolysis-induced AKI when it is frequently less than 1%. All other workup for AKI was unrevealing. After trial of intravenous fluid, hemodialysis (HD) was initiated for anuria and persistent hyperkalemia. He required 10 sessions of HD after which he recovered renal function over 3 weeks. Serum creatinine was 2.25mg/dl and CK was 299 IU/L on discharge.

Discussion: Causes for the different adverse effects profile between SCBs and marijuana are not defined yet. Cases reported in literature with K2 use and AKI have been associated with reversible AKI characterized by acute tubular necrosis and interstitial nephritis. Recent studies has showed the involvement of cytochromes P450s (CYPs) in biotransformation of SCBs. The use of quetiapine which is a substrate of the CYP3A4 and is excreted 73% as urine metabolites may worsen the side effect profiles of both quetiapine and K2. SCBs use should be included in the differential diagnosis of AKI and CK level should be monitored. Further research is needed to identify the mechanism of SCBs nephrotoxicity.

TH-PO058

Renal Sarcoidosis with Vasculocentric Granulomatous Interstitial Nephritis Pattern

Swee-Ling Levea,[1] Thomas A. Golper,[1] Agnes B. Fogo.[2] *[1]Nephrology, Vanderbilt Univ Medical Center, Nashville, TN; [2]Pathology, Microbiology and Immunology, Vanderbilt Univ Medical Center, Nashville, TN.*

Introduction: Sarcoidosis is an inflammatory disorder characterized by non-caseating epitheloid cell granulomas that can involve multiple organ systems. Involvement of the kidneys is rare, most commonly showing granulomatous interstitial nephritis.

Case Description: A 69 years old white man with history of nephrolithiasis, prior pulmonary histoplasmosis, and chronic interstitial cystitis was referred by Infectious Disease for evaluation of elevated creatinine, 2.0mg/dL. He had a two month history of fever, night sweats and 20 lbs unintentional weight loss. Ground glass opacities on CT chest prompted a bronchoscopy with bronchoalveolar lavage and lung biopsy, which was negative for malignancy, granulomas or infections. Broad infectious workup was unremarkable including a tagged WBC scan. Renal biopsy was performed, which revealed a granulomatous interstitial nephritis with well-formed granulomas with epitheliod giant cells encroaching and invading vascular walls, but without necrosis. He was started on prednisone 1mg/kg/day for four months with minimal improvement in his renal function.

Discussion: Acute kidney injury with associated constitutional symptoms has a broad differential diagnosis. Renal sarcoidosis is rare and can manifest clinically as renal insufficiency, hypercalcemia, proteinuria or nephrocalcinosis. The renal lesions associated with sarcoidosis include non-caseating granulomatous interstitial nephritis, nephrolithiasis and rarely glomerular disease, including IgA nephropathy and proliferative or crescentic glomerulonephritis. The most common renal lesion is non-caseating granulomatous interstitial nephritis, and renal sarcoidosis is then a diagnosis of exclusion of other causes of granulomas. Vasculocentric granulomatous interstitial nephritis is a rare and unusual histologic variant of sarcoidosis, which carries a worse prognosis. In our patient, the biopsy finding of vasculocentric granulomatous interstitial nephritis in the absence of drug-induced, autoimmune or infectious cause is supportive of the diagnosis of renal sarcoidosis.

TH-PO059

Eight Cases of Acute Kidney Injury in Children Administered Tosufloxacin Tosilate and Non-Steroidal Anti-Inflammatory Drugs Hideki Matsumura,[1] Akira Ashida,[1] Akihiko Shirasu,[1] Hyogo Nkakura,[1] Motoshi Hattori,[2] Hiroshi Tamai.[1] *[1]Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan; [2]Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Introduction: Tosufloxacin tosilate (TFLX), a fluoroquinolone antimicrobial, and non-steroidal anti-inflammatory drugs (NSAIDs) have been widely used individually on a safe basis, but few reports have documented their association with AKI. Here, we describe eight cases of AKI that occurred after administration of TFLX and NSAIDs in children.

Case Description: The age of eight patients was ranging from 8 to 13 years. All patients visited their family physician because of fever, and were administrated drugs including TFLX and NSAIDs. Most patients suffered vomiting after drug administration. Patients visited our hospital 1 to 4 days after starting the drugs, and AKI then became apparent. Two patients received overdoses of TFLX, one received a low dose and the remaining five received appropriate doses. Their maximum levels of plasma creatinine were 0.70 – 2.90 mg/mL. Urine volumes were not decreased in all patients, and four patients had occult hematuria with isomorphic erythrocytes. Markers of AKI were not elevated. Renal functions of all patients became normalized spontaneously within five days after discontinuation of the drugs.

Discussion: As AKI resolved spontaneously and quickly, tubulointerstitial nephritis and acute tubular necrosis were unlikely. Because we did not perform biopsy, it was difficult to make an accurate diagnosis of AKI, but hematuria with isomorphic erythrocytes in some patients suggested crystal nephropathy. Our hypothesis for the mechanism of AKI is that administration of NSAIDs under conditions with insufficient oral intake results in decreased renal and urine flow. Formation of TFLX crystals is facilitated by slow urine flow, resulting in crystal nephropathy. The crystals are washed out and the AKI resolves quickly after discontinuation of TFLX and NSAIDs. Some reports have documented crystal nephropathy after long-term use of fluoroquinolones. As our patient who took NSAIDs and TFLX only once also developed AKI, we speculate that AKI due to these combined medications was not related to the dose or duration of therapy.

TH-PO060

Relapsing Interstitial Nephritis Secondary to DRESS Syndrome Abhijin Das, Elijah Stiefel, Lauren C. Hughey, Huma Fatima, Eric L. Wallace. *UAB, Birmingham, AL.*

Introduction: Allergic interstitial nephritis (AIN) is a well known cause of kidney injury and presents with eosinophiluria, rash, and can be accompanied by fever. Differentiating simple AIN from DRESS, drug reaction with eosinophilia and systemic symtpoms, is difficult but important as more aggressive management of DRESS is necessary as it carries significant morbidity and mortality.

Case Description: A 36 year old female recently treated with terbinafine for onychomycosis presented with fever, to 105^0 F and emesis prompting her to go to her local emergency room(ER). Baseline laboratory evaluation revealed a creatinine of 9.8 mg/dl. Urinalysis dipstick showed 500mg of proteinuria and trace blood and renal ultrasound showed 14cm kidneys bilaterally. Hemodialysis was initiated. Kidney biopsy revealed acute granulomatous interstitial nephritis. The drug was discontinued, and creatinine improved to 2.7mg/dl. She was discharged on prednisone. 3 days later she presented again to the ER with fever to103.8 F. Work up for infectious causes and autoimmune disorders were negative. During this hospitalization, kideny failure recurred requiring reinstitution of dialysis. Furthermore, she developed pancytopenia and erythroderma. Skin biopsy showed necrotic cells at all levels of the epidermis. The dermis contained a sparse perivascular infiltrate with occasional eosoniphils. Taken together with her relapsing course and systemic symptoms a diagnosis of DRESS was made. Due to lack of response with steroids and the desire to avoid cyclosporine,intravenous immunoglobulin and mycophenolate were administered. The patient had improvement in her rash and blood counts. Kidney function recovered to a last creatinine of 1.7mg/dl. HHV-6 viral PCR which has been associated with DRESS was negative 2 months after the episode. 5 months after discharge, she remains off dialysis and without further relapse.

Discussion: DRESS syndrome should be considered in patients with a drug history and AIN when it is associated with systemic manifestations and particularly when those manifestations have a relapsing and remitting course. Correct diagnosis is crucial as DRESS can carry significant mortality and aggressive treatment is needed to prevent subsequent relapses.

TH-PO061

Acute Kidney Injury (AKI) Caused by Synthetic Cannabinoids (SC) in 3 Teens: A Growing but Under-Recognized and Preventable Public Health Problem Saurabh Dasgupta,[1,2] Pavan Kumar Gona,[1] David A. Myers,[2] Kai Lau.[1] *[1]Medicine, Univ of Oklahoma, OKC, OK; [2]Pediatrics, Univ of Oklahoma, OKC, OK.*

Introduction: Since 2009, "herbal incenses" are increasingly popular as many contain SC escaping urine drug screen (UDS). Impaired cognition, acute coronary syndrome and seizures have been caused by these agents, besides AKI in 22 cases in U.S. as of 2013. We recently cared for 3 teens with AKI due to SC. We here share our experience on this issue.

Case Description: The clinical course, lab, therapy and follow up data were reviewed to infer insights.

Case 1, a boy aged 15, and case 2, a girl aged 15, were admitted for nausea and vomiting. Initial serum creatinine (Scr) was 7.1 and 3.0 mg%. It peaked respectively at 11.5 and 6.3 mg% 5 d later. Both admitted to using "Flame 2." The boy was hemodialysed (HD) 4 x in 9 d. Scr fell to 4.3 by d 11 and spontaneously to 2.4 mg% by d 13 and to 1 mg% 4 wk later. The girl was HD x 2. Scr fell to 2.3 on d 5, then spontaneously to 0.9 on d 9 and to 0.6 mg% 4 wk later. Case 3, a boy aged 17 admitted for altered mental status and seizures, had initial Scr of 4.6 and peak of 8.4 mg% on d 5. Fluids were given. Hyperuricemia (17.9 mg %) was treated. He admitted to using K2. Without HD, Scr fell to 1.7 mg% on d 8 and 0.9 mg% on d 15. None had oliguria or eosinophiliuria. All 3 biopsies showed acute tubular necrosis (ATN). As all known causes of AKI were excluded and the clinical course resembled published cases, SC-induced AKI was diagnosed.

Discussion: We confirm and extend published experience on the entity of SC-induced AKI. The specific nephrotoxin and exact mechanism are obscure. ATN is supported by pathology and typical clinical course, with Scr peaking ~5 d post exposure, then initial and eventually full recovery in 2-4 wk. Long-term renal impact is unknown. Legalizing marijuana expands access but also increases the incidence of SC and AKI. Our data illustrate the need for raised awareness of "herbal incenses" by all physicians, for uncovering relevant history and for recognizing various presentations. SC eludes current UDS and diagnosis needs a high index of suspicion. We urge counselors and student health staff to be familiar with SC-induced AKI and play active roles in education and prevention.

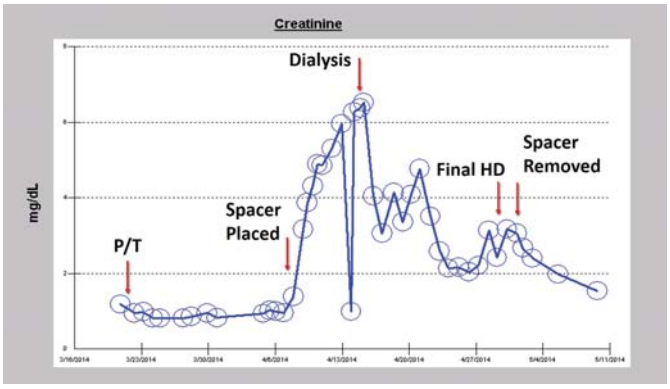
TH-PO062

Multifactorial Acute Kidney Injury and Polymethylmethacrylate Joint Spacers; Who to Blame? Sarah A. Johnson,[1] Thomas E. Rogers,[2] Frederic F. Rahbari-Oskoui.[1] *[1]Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA; [2]Dept of Pathology, Emory Univ School of Medicine, Atlanta, GA.*

Introduction: Antibiotic impregnated polymethylmethacrylate (PMMA) spacers are used for treatment of recurrent prosthetic joint infections assuring local delivery. We report a case of a patient with bilateral septic arthritis with acute tubulointerstitial nephritis (TIN) secondary to piperacillin/tazobactam (P/T), then complicated by aminoglycoside (AG) induced acute kidney injury (AKI) because of the PMMA spacer.

Case Description: Case Description: 58 yo male with melanoma on steroids post parietal mass resection presented with hip pain found to have septic arthritis with a normal serum creatinine (SC). P/T was started but caused a diffuse macular rash on day 5. P/T was changed to ceftriaxone and then levofloxacin (LFX). Recurrent sepsis on day 16 necessitated re-debridement of bilateral hips with insertion of a PMMA spacer containing 3.6 gm of tobramycin (TM) and 3 gm of vancomycin on day 18. Day 19, SC rose to 3.1 mg/dl with a peripheral eosinophilia of 940 cells/mcl. Prednisone at 40 mg daily was started. Serum TM level was 2.5 mcg/ml on Day 20 and peaked at 4.5 mcg/ml with a peak SC of 6.5 mg/ml. Daily hemodialysis was initiated for TM clearance but failed to maintain serum TM levels below 1 ug/ml. A renal biopsy showed TIN, mild tubular necrosis and tubular vacuolization consistent with TM injury. PMMA spacer was removed after which the patient's SC and TM levels rapidly improved (1.5 mg/ml and < 0.5 ug/ml respectively).



Discussion: AG-impregnated PMMA spacers may cause persistent AKI and should be removed if the serum AG levels are in the toxic range and they are not necessary for vital prognosis. Rare case reports describe renal injury secondary to PMMA spacers. The renal safety profile and kinetics of these spacers is undetermined and requires further investigation.

TH-PO063

Safety of Warfarin in Chronic Kidney Disease Patients with Solitary Kidney in the Era of Warfarin-Related Nephropathy

Ashraf M. Mohammed, Anupama Chundury, Bassim Assioun, John C. Edwards. *Nephrology, St. Louis Univ, St. Louis, MO.*

Introduction: Independent of systemic hemorrhage, warfarin coagulopathy is an emerging phenomenon in the pathogenesis of AKI especially in CKD patients. Warfarin-Related Nephropathy (WRN) was first described by Brodsky et al in 2009, as an acute kidney injury secondary to glomerular hemorrhage and renal tubular obstruction by RBC casts. We report a case of WRN in a high risk geriatric patient with stable CKD and solitary kidney.

Case Description: An 80 years old male with medical history of controlled HTN, chronic atrial fibrillation, stage 3 CKD (baseline Cr 1.8-2.2 mg/dl) and left nephrectomy due to low grade papillary urothelial carcinoma, who presented to the hospital with dyspnea, peripheral edema and decreased urine volume for a week. He has been on warfarin for many years with no history of coagulopathy. Laboratory and radiological data was pertinent for elevated Cr (15.2mg/dl), BUN (124mg/dl), INR (5.1), normal CBC, bland urine sediment and unremarkable renal US. He was diagnosed with oligouric AKI of unclear etiology after exclusion of pre-renal and post renal causes. Despite IV fluids hydration, holding ACE inhibitor and normalization of coagulopathy, his renal function did not improve. As he developed uremic symptoms, hemodialysis was initiated after which his encephalopathy, volume and acid-base status became satisfactory. A renal biopsy was then performed which revealed glomerular hemorrhage and RBC casts obstructing numerous tubules suggestive of WRN. Unfortunately, renal function did not recover and patient progressed to ESRD.

Discussion: Our case illustrates the high risk associated with warfarin therapy in CKD population even with mild degree of coagulopathy and regardless of anticoagulation therapy duration. This risk is even higher in a setting of solitary kidney due to diagnostic dilemma and fear of biopsy complications. This case may be an example of when anticoagulation monitoring should be very intense and the decision to remain on warfarin is thoughtfully reviewed.

TH-PO064

A Unique Case of Pemetrexed-Associated Renal Injury

Laith Farah Al-Rabadi,[1] Rawan Tayseer Al Odat,[2] Christopher D. Blosser.[3] *[1]Boston Medical Center; [2]Khalidi Hospital, Jordan; [3]Univ of Washington.*

Introduction: Pemetrexed is a novel antifolate chemotherapy increasingly used in treatment of metastatic non-small cell lung cancer. Acute renal injury is infrequently reported as a side effect of this agent. Vootukuru et al. discussed the association of AKI with nephrogenic diabetes Insipidus (DI) and distal renal tubular acidosis (RTA) as manifestations of drug-related renal toxicity.

Case Description: Herein, we present a 69 year-old gentleman with metastatic non-small cell lung cancer who developed acute kidney injury in association with nephrogenic DI and distal RTA following sequential treatments with Pemetrexed. Patient presented to the hospital with worsening fatigue and shortness of breath, along with 1 month of polyuria and polydipsia. Patient had been treated with pemetrexid over the last seven months and received his 7th cycle two weeks prior to presentation. Patient had also received four cycles of Carboplatin and Taxol over one year prior to initiating pemetrexid with no changes in GFR (Cr 0.8mg/dl). Patient was euvolemic on exam with stable Vitals, producing 4 liters of urine/day with intact thirst sensation. Serum creatinine was elevated (3.6mg/dl) Na 142mg/dl, Glucose 84mg/dl, HCO3 15mmol per liter, Albumin 3.5 g/dl. Venous blood gas revealed Ph 7.30, CO2 33, AG 8. This was consistent with nonanion gap metabolic acidosis. Urine analysis showed Urine PH of 6.0. Specific gravity 1.005, with urine AG 13. Urinary gap in the setting of Non-AGMA was suggestive of distal RTA. Diagnosis of RTA should be considered with caution in the setting of AKI. However, metabolic panel and VBG consistent with RTA were evident three months prior to the elevation in creatinine. Urine microscopy showed several muddy granular casts consistent with ATN. Nephrogenic DI was also diagnosed based on Urine specific gravity, polyuria and failure of improvement in SG with water deprivation. Desmopressin test was not done but brain MRI did not show any evidence to account for the DI.

Discussion: Pemetrexed-associated renal toxicity can manifest as a unique pattern of distal tubular dysfunction. Distal RTA can precede and potentially portend a decline in renal function.

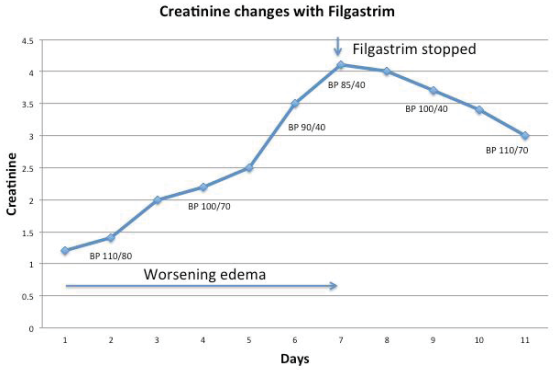
TH-PO065

Filgastrim Nephrotoxicity due to Capillary Leak Syndrome

Sheyla Zelaya, Issam Saleh Alghamdi, Ivonne Hernandez Schulman, Marco A. LadinoAvellaneda. *Medicine/Nephrology, Univ of Miami, Miami, FL.*

Introduction: Filgastrim (Neupogen) is frequently used in Hematology/Oncology. It is indicated to decrease the incidence of infection and neutropenic fever in patients with these conditions. This medication has many side effects, which include hypertension, ostealgia, nausea, leukocytosis, and capillary leak syndrome. Capillary leak syndrome presents in less than 1% of the patients and is a rare disorder that is due to endothelial dysfunction with subsequent leakage of fluid into the interstitial space and decreased organ perfusion.

Case Description: A 60-year-old man with autologous stem cell transplant due to primary Amyloidosis was admitted to the hospital due to neutropenia, he was started on Filgastrim. Two days after Filgastrim was started, the patient's renal function deteriorated. Nephrology was consulted for Acute Kidney Injury (AKI); baseline serum creatinine was 1.2 mg/dL and increased to 4.1 mg/dL



On physical exam, his systolic blood pressures were between 80-110 with notable lower extremity edema. Laboratory data showed hypoalbuminemia and renal ultrasound was normal. Creatinine peaked at 4.1 mg/dL and with the clinical findings suggestive of capillary leak syndrome, a decision was made with the Hematology service to stop the Filgastrim. The renal function improved and creatinine decrease to 1.4 mg/dL.

Discussion: Acute Kidney Injury (AKI) in patients with hemato-oncological conditions is frequent; it could be related to pre-renal, intrinsic, and/or post-renal conditions. Filgastrim rarely affects the kidney and when it happens, it is due to a described mesangioproliferative glomerulonephritis. This is the first case in the literature of AKI due to Filgastrim-induced capillary leak syndrome. This is a diagnosis of exclusion and Nephrologist and Oncologists need to be aware of this potential side effect and complication of this medication.

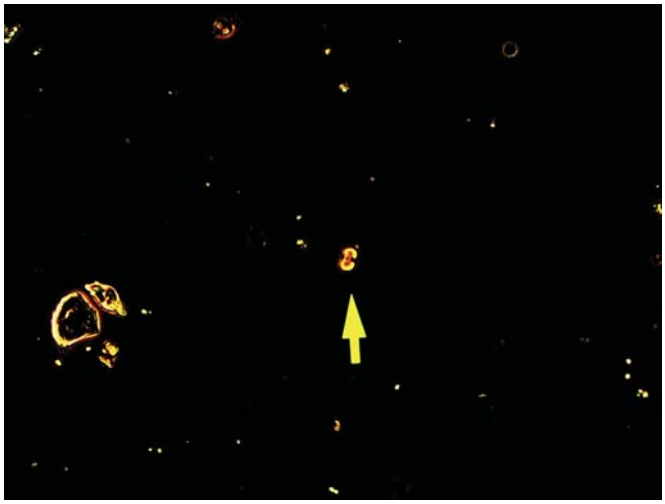
TH-PO066

Xanthine Nephropathy, a Rare Manifestation of Tumor Lysis Syndrome

Insara Jaffer Sathick, Andrea G. Kattah, Nelson Leung. *Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Introduction: Tumor lysis syndrome is an important cause of renal failure in hematological malignancies. Tumor cells lyse spontaneously or due to therapy. Renal failure results from deposition of uric acid, calcium phosphate and xanthine which are released from cells. Allopurinol used to prevent tumor lysis syndrome paradoxically causes renal failure in some patients due to xanthine crystallization. We present a case of xanthine nephropathy in a patient with T cell lymphoma.

Case Description: A 78 year old gentleman with history of chronic lymphocytic leukemia, chronic kidney disease and hypertension was admitted with pneumonia and pancytopenia. Bone marrow biopsy revealed a new diagnosis of T cell lymphoma. His baseline creatinine was 1.4 mg/dl which was elevated to 2.0 mg/dl. Chemotherapy with high dose steroid and nitrogen mustard was initiated after treatment of pneumonia. His acute renal failure progressed despite optimization of volume and discontinuation of nephrotoxic agents. Urine analysis showed ph 5.2, hyaline cases and amorphous xanthine crystals.



Serum uric acid and phosphorus levels were elevated consistent with tumor lysis. Renal biopsy was deferred due to thrombocytopenia. Urinary xanthine and hypoxanthine levels were measured due to suspicion for xanthine nephropathy and found to be very elevated. Hydration and discontinuation of allopurinol resulted in improvement of renal function.

Discussion: Xanthine nephropathy should be suspected in patients who develop acute renal failure despite tumor lysis prophylaxis. Accumulation of xanthine is due to the inhibition of xanthine oxidase by allopurinol. This paradoxically causes acute renal failure due to xanthine toxicity. Measurement of xanthine levels in the urine aids in the diagnosis. Allopurinol should be discontinued to prevent further renal injury.

TH-PO067

Mannitol-Induced Acute Renal Failure (ARF): Prompt and Full Reversal by Solute-Free Water Supports the Pathogenic Role of Hyperosmolality in Osmotic Nephrosis Joe Ghata,[1] Pavan Kumar Gona,[1] Kai Lau.[1,2] *[1]Nephrology, Univ of Oklahoma, OKC, OK; [2]Medicine, VAMC, OKC, OK.*

Introduction: Osmotic nephrosis refers to ARF following sucrose, dextrans, dye or mannitol. Morphologically there is proximal tubule cell vacuolization, swelling and collapsed lumens. The pathophysiology is unknown with theories ranging from volume depletion, tubuloglomerular feedback activated by increased distal delivery, afferent arteriolar vasoconstriction, to proximal cell swelling occluding lumen. To date, treatment is stopping mannitol and hemodialysis.

Case Description: The most proximate factor is marked hyperosmolality from excessive mannitol. We tested the therapeutic role of diluting mannitol and serum (S) Osm by solute-free fluids in a 64-year-old man with mannitol-induced ARF. He had a recent resection of recurrent glioblastoma multiforme but developed weakness and dysarthria.

For cerebral edema, he received 7 doses of 100 g of mannitol in 1 h q 6 h (total of 700 mg in 44 h). S creatinine (cre) rose from 1 to 2.5 mg% in 2 d. S Na fell from 137 to 124 mM in 2 d, measured S osmolality (Osm) rose from 293 to 333 mosm/kg whereas calculated S Osm fell from 282 to 272, yielding an osmolar gap of 62. S cre climbed to 5.9 by d 4. There were no signs of sepsis, hypotension, volume depletion or nephrotoxic drug. In response to 2 L of D5W in 36 h, S Osm fell from peak of 340 to 299 in 2 d and to 291 in 3 d as S cre fell promptly from 5.9 to 2.2 in 2 d and to the baseline of 1.1 by d 3. eGRF was inversely related to S Osm ($r=-0.92$, $p<0.001$) and to S osmolal gap ($r=-0.93$, $p<0.001$), indicating the higher the mannitol level, the worse the renal function. eGFR was negatively related to cumulative fluid balance, arguing against volume depletion. 29 cases of mannitol-induced ARF with full recovery are available for full review. 22 were successfully treated by dialysis, 7 by supportive measures (recovery in 8 d) and none by dilute fluids.

Discussion: Our patient confirms the nephrotoxic risk of mannitol infused at high dose and fast rate. The data show the utility of osmolal gap in estimating mannitol level to guide dosing. We show the efficacy of solute-free solution in reducing levels and supports the pathogenic role of hyperosmolality.

Granulomatous Interstitial Nephritis with Rare Circulating Lymphocytes Positive for Epstein-Barr Virus Encoded Small Ribonucleic Acid (EBER-1) in a Patient with Crohn's Disease Vanessa Moreno,[1] Laura R. Kidd,[1] Constance C. Foreman,[2] J. Bryan Carmody,[3] William F. Glass.[1] *[1]Pathology and Laboratory Medicine, The Univ of Texas - Health Science Center, Houston, TX; [2]Eastern Virginia Medical School, Norfolk, VA; [3]Nephrology, The Children's Hospital of the King's Daughters, Norfolk, VA.*

Introduction: Granulomatous interstitial nephritis (GIN) is an uncommon disorder found in <1% of all renal biopsies. Several cases of GIN-associated with Crohn's disease (CD) have been reported in adults, with only 3 pediatric cases described in the literature. The majority of these pediatric patients did not receive 5-ASA therapy and have occurred during the exacerbation of CD.

Case Description: We describe a case of GIN-associated CD in a 16 year old African American male who received treatment with 5-ASA for one month, followed by two months of prednisone. His baseline creatinine (Cr) was 0.8 prior to administration of 5-ASA and 1.1 mg/dl afterward. Two months after stopping 5-ASA, he developed gastrointestinal CD exacerbation, retinal vein thrombosis, and acute renal failure with elevated BUN (45 mg/dl) and Cr (2 mg/dl). Urinalysis showed trace proteinuria, 25-50 WBC/hpf and 3-5 RBC/hpf. Urine culture was negative. Protein/creatinine ratio was 0.7 mg/mg. Serology was positive for ANA and Epstein-Barr virus (EBV), which was consistent with past infection (VCA IgG+, VCA IgM-, EA-, EBNA+) and reactivation (EBV viral load by PCR of 2406 copies/ml). The kidney biopsy revealed chronic GIN, consistent with extraintestinal CD. In addition, EBER-1 in situ hybridization was positive in rare circulating lymphocytes within peritubular capillaries whereas the granulomas, infiltrating lymphocytes and plasma cells were negative, suggestive of EBV reactivation and not an EBV+ lymphoproliferative disorder.

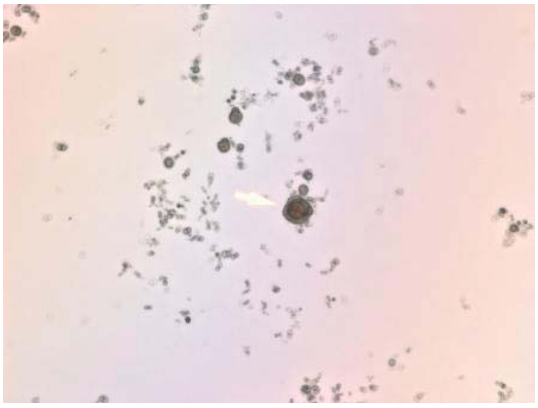
Discussion: These observations suggest the possibility that reactivation of EBV plays a role in the pathogenesis and exacerbation of this patient's CD, including involvement of extraintestinal tissues. We described the fourth case of GIN-associated CD in the pediatric population and the first known case of this entity associated with EBV reactivation and retinal vein thrombosis in a child.

TH-PO069

Xanthinuria: An Unusual Cause of Pink Diaper in an Infant Rasheda Z. Amin,[1] Loai Akram Eid,[2] Vidar O. Edvardsson,[3] Asha Moudgil.[1] *[1]Pediatric Nephrology, Children's National Medical Center, Washington, DC; [2]Pediatrics, Latifa Hospital, Dubai, United Arab Emirates; [3]Pediatric Nephrology, Landspital Univ Hospital, Reykjavik, Iceland.*

Introduction: Hereditary xanthinuria, an autosomal recessive disorder of purine metabolism, commonly presents as urolithiasis and rarely with renal failure. We report the case of an infant with pink diaper stains and failure to thrive who was found to have hereditary xanthinuria.

Case Description: A nine month old, full term, white, male infant presented with intermittent pink diaper staining and failure to thrive for five months. Past medical and family history, review of systems and physical exam were unremarkable. Urine microscopy of a first morning void showed crystals closely resembling 2,8 Dihydroxyadenine, seen in adenine phosphoribosyltransferase deficiency.



Workup showed increased urinary excretion of xanthine and hypoxanthine, low serum and urine levels of uric acid, highly suggestive of hereditary xanthinuria. Genetic testing of the proband revealed a known heterozygous mutation, T910M, in exon 25 of the XDH gene (c.2729C>T) and a second, previously unidentified, heterozygous variant, R830C, in exon 23 of the XDH gene (c.2488C>T), confirming the diagnosis. The proband's mother was heterozygous for the T910M mutation and his father was heterozygous for the R830C variant. The infant is being successfully managed with a low purine diet and high fluid intake with resolution of crystalluria and improved growth. Subsequent urine exams have not shown crystals, but pink diaper staining recurs in episodes of acute illness. His urine xanthine- and hypoxanthine-to-creatinine ratios remain elevated.

Discussion: Our case highlights the importance of manual urine microscopy for detection of crystalluria on a first morning void. It underscores hypouricemia as an important diagnostic aid. We report a new, likely pathogenic variant, R830C, in the XDH gene.

TH-PO070

Disseminated Histoplasmosis in Immunocompetent Female Presenting as Pseudoobstructive Uropathy Buthayna Dinary, Keyvan Ravakhah. *St.Vincent Medical Center, Cleveland, OH.*

Introduction: Progressive Disseminated Histoplasmosis (PDH) is a rare condition in immunocompetent host. This endemic mycosis can affect multiple systems including skin, lungs, GI, kidney, adrenal glands, blood and central nervous system. PDH characterized by variable Clinical presentation that ranges from asymptomatic infection to life-threatening illness. Here we describe a case of sudden onset of acute renal failure (ARF), hydronephrosis, in association with diffuse retroperitoneal lymphadenopathy in the context of disseminated histoplasmosis.

Case Description: A 74 year-old previously healthy female resident of Ohio presented with intermittent dyspepsia, 30- lbs weight loss and decreased appetite for 1 month duration. Upper endoscopy revealed a duodenal ulcer and biopsy was positive for H. pylori. She was treated with omeprazole, amoxicillin and clarithromycin. Her condition improved partially, but 6 weeks later she was readmitted to the hospital with dull abdominal pain, fever and decreased urine output. On physical exam she was febrile and had bilateral flank tenderness and left leg pitting edema. Her WBC was 12.6 k/ul with a neutrophil of 86%. Laboratory studies showed potassium (6.4mmol/l), creatinine (3.1 mg/dl), BUN (70 mg/dl), Hg (10.9 gm/dl) and proteinuria. US showed bilateral hydronephrosis. CT abdomen revealed retroperitoneal LAP. Duplex US of renal veins revealed left RVT. Lymph node biopsy demonstrated diffuse collections of large histiocytes with oval narrow-based budding yeast. She was found to be negative for HIV. Fungal serologies and Blood cultures were negative. She was hydrated, anticoagulated and treated with IV amphotericin for 2 weeks. Patient creatinine improved to 2.5 mg/dl. She was discharged on Lovenox and itraconazole for 6 months.

Discussion: Disseminated Histoplasmosis should be suspected in any patient presenting with unexplained ARF and enlarged kidneys, especially in the setting of widespread lymphadenopathy. Prompt diagnosis of PDH improves chances of preserving renal function. Liposomal amphotericin B are typically used to treat PDH, followed by Itraconazole. The outlook is usually good, but, if not appropriately diagnosed or treated, the disease can cause severe complications, such as ESRD.

TH-PO071

An Interesting Case of Iced Tea Nephropathy Fahd Syed,[1] Alejandra Mena-Gutierrez,[1] Neriman Gokden,[1] Sudhir V. Shah,[1,2] Umbar Ghaffar.[1,2] *[1]Div of Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Renal Section, Medicine Service, Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Introduction: Oxalate nephropathy caused by a combination of tubular toxicity, nephrocalcinosis, and obstruction from stones has been reported in the setting of primary and acquired hyperoxaluria. We present the case of a patient with kidney biopsy findings of oxalate nephropathy in which dietary history revealed excessive intake of iced tea as a potential etiology.

Case Description: A 56-year-old male presented to the hospital in 5/14 with weakness, fatigue, body aches and pains and his serum creatinine was 4.5 mg/dL. Review of his medical record indicated a creatinine level of 1.2 mg/dL in 10/13 and 2.5 mg/dL in 2/14. He had no proteinuria or hematuria. His urine sediment was remarkable for the presence of numerous calcium oxalate crystals. He did not have a past history of kidney stones or any family history of renal disease. He denied using ethylene glycol. Due to the rapidly progressive nature of renal failure and normal kidney size on ultrasound, a renal biopsy was performed which demonstrated many oxalate crystals, interstitial inflammation with eosinophils and interstitial edema consistent with a diagnosis of oxalate nephropathy. A 24-hour urinary collection revealed oxalate of 99 mg (7-44). No evidence of malabsorption or any dietary history previously associated with oxalate nephropathy was found. On further review of the patient's history, the patient admitted to drinking 16 glasses of iced tea daily. Advanced renal failure necessitated initiation of dialysis.

Discussion: Black tea has high oxalate content (1150 mg /100g) which is higher than several other foods like rhubarb, star fruit and fruit juice diets which have been reported to cause oxalate nephropathy. We are not aware of any reports of oxalate nephropathy from excessive tea ingestion. A finding of large amount calcium oxalate crystals in urine sediment in a setting of renal failure of unknown etiology led to kidney biopsy and to a detailed dietary history resulting in this interesting diagnosis of iced tea nephropathy.

TH-PO072

Primary Sjogren Syndrome with Renal Fanconi Syndrome Jing Wang, Xiaoxiao Shi, Yubing Wen, Xue-Mei Li, Limeng Chen. *Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Introduction: Proximal renal tubular acidosis (RTA) presenting as Fanconi Syndrome is rarely seen in Primary Sjogren Syndrome (pSS). We reported 4 cases of pSS with Fanconi Syndrome.

Case Description: Renal biopsy were performed in 117 pSS patients diagnosed by the 2002 American-European consensus classification criteria, in Peking Union Medical College Hospital. Clinical records were reviewed.

Remarkable tubulointerstitial lesion were observed in 55 cases (47.0%), 87.5% of them developed distal RTA. Only 4 cases were characterized by Fanconi Syndrome.

Renal biopsy revealed typical tubulointerstitial nephritis, with tubule epithelial cell degeneration, mild tubule atrophy, interstitial inflammation and fibrosis. After treating with steroid (1mg/kg/d),improvement of symptom, electrolyte disorder and Scr level(8%-65% decline)were observed.

Discussion: We reported 4 cases of pSS with Fanconi Syndrome,with coexisting acute or chronic tubulointerstitial lesion and renal function injury. Patients generally showed good response to steroid.

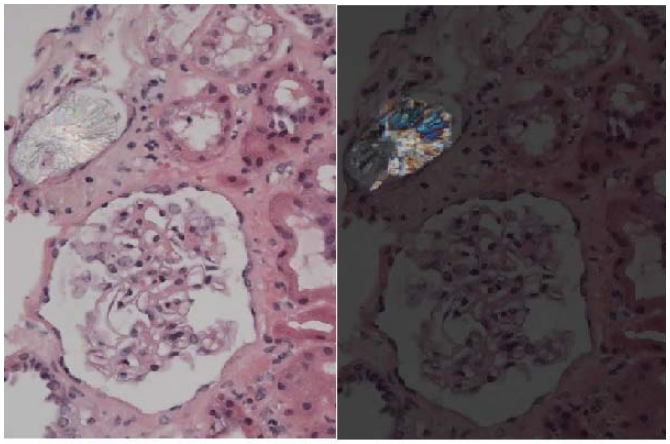
TH-PO073

Chronic Nephropathy from Dietary Hyperoxaluria: Sustained Improvement of Renal Function after Dietary Intervention Nhan Trong Luu,[1,2] B. Horowitz,[1,2] Antonios Tzamaloukas.[1,2] *[1]Nephrology, Univ of New Mexico, Albuquerque, NM; [2]Nephrology, Dept of Veteran Affairs, Albuquerque, NM.*

Introduction: Calcium oxalate may cause renal parenchymal damage by urolithiasis, nephrocalcinosis, acute kidney injury (AKI) and chronic kidney disease (CKD). Few patients with hyperoxaluric CKD have been reported. We present a case of CKD which resulted from dietary oxalate, with renal function improvement after reduction in dietary oxalate intake.

Case Description: A 56-year old man with CKD which had been stable for two years following a single episode of calcium oxalate urolithiasis developed progressive elevation of his serum creatinine with eGFR from 60 to 15 mL/min per 1.73 m2. Basic workups including urinalysis, urine microscopy, and gallium scintigraphy disclosed chronic interstitial nephritis. Culture was sterile. Despite discontinuing proton pump inhibitor and initiation of a short course of oral corticosteroids, pyuria persisted and renal function declined. Renal biopsy is shown below:



Histology showed deposition of oxalate crystals in the tubules and interstitium, pronounced tubular changes, interstitial nephritis and interstitial fibrosis.

Urinary oxalate excretion was more than 5x the upper limit of normal secondary to high dietary oxalate intake. Investigations for primary or enteric hyperoxaluria were negative. Institution of a diet low in oxalate resulted in rapid normalization of urinary oxalate excretion and improvement of renal function from eGFR of 15 to 59 mL/min/1.73 m2 after 3.5 years dietary oxalate intake change.

Discussion: CKD from dietary hyperoxaluria may be reversed by simply avoiding oxalate-rich food items even when it is diagnosed at an advanced stage. Its presentation, including the urine findings, can be indistinguishable from other types of interstitial nephritis. The diagnosis of dietary hyperoxaluria requires careful dietary history. Recognition of dietary hyperoxaluria as the cause of CKD is critical for salvage of renal function.

TH-PO074

IgG4-Related Tubulointerstitial Nephritis Associated with Only Lymphadenopathy, and without Elevated Serum IgG4 Level or Renal Imaging Abnormalities Xi Qiao, Lihua Wang. *Nephrology, Second Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China.*

Introduction: IgG4-related kidney disease (IgG4-RKD) usually presents as plasma cell–rich tubulointerstitial nephritis (TIN) associated with renal mass lesions. Serology usually demonstrates high levels of serum total IgG and IgG4. Most patients have accompanying IgG4-related extrarenal lesions. However, IgG4-TIN with only lymphadenopathy has not been well recognized. Here, we present a rare case of IgG4-TIN associated with swelling of many lymph nodes as the only extrarenal lesions, and without elevated serum total IgG or IgG4 levels or renal imaging abnormalities.

Case Description: A 61-year-old man was admitted to our hospital for renal dysfunction and swelling of many lymph nodes. He didn't have other organ involvement except for the lymphadenopathy. His renal imaging was normal radiographically. Histological findings of the kidney indicated IgG4-positive plasma cell infiltration with storiform fibrosis, which was consistent with IgG4-related TIN. Repeated lymph nodes biopsy revealed IgG4-related lymphadenopathy. However, the patient did not have elevated serum total IgG or IgG4 levels. Oral prednisolone therapy, initially 30 mg/day and gradually tapered over 10 months, improved his renal function and the swelling of his affected lymph nodes. These findings supported our final diagnosis of IgG4-TIN.

Discussion: We describe a case of IgG4-TIN associated with only lymphadenopathy and without elevated serum IgG or IgG4 levels imaging abnormalities. This case highlights

the need for renal biopsy in cases with unknown renal insufficiency. It is necessary to accumulate cases of IgG4-TIN with detailed clinical and laboratory manifestations. Early diagnosis and treatment is desirable in IgG4-TIN.

TH-PO075

Life-Threatening Metabolic Disorders Associated to Drug-Induced Hepatic and Renal Mitochondrial Dysfunction Alberto Manuel Martin Cordova, Mario A. Mendoza, Carlos Antonio Cortes Sanchez, Emmanuel O. Gonzalez, Rodolfo Estremera-Marcial, Eddie M. Rodriguez, Hector R. Cordova. *Medical Service, VA Caribbean Healthcare System, San Juan, PR.*

Introduction: Renal tubular toxicity is reported infrequently (1.5%) in patients on Tenofovir therapy. Risks factors include advanced age, low body weight, chronic kidney disease, and the use of other nephrotoxic drugs. Tenofovir can cause a rise in lactic acid levels, particularly, in patients with subjacent liver disease. We describe a case of a patient with HIV infection treated with Tenofovir who developed Fanconi syndrome and lactic acidosis simultaneously.

Case Description: A 66 y/o man with history of HIV and Hepatitis C virus infection, in treatment with Tenofovir, complained of weakness, muscle cramps, and polyuria for one week. There were no focal motor deficits. Laboratories results revealed serum creatinine of 2.7 mg/dl, mixed hyperchloremic and high anion gap metabolic acidosis (tCO2: 15 meq/L), hypokalemia (1.8 meq/L), hypophosphatemia (1.0 mg/dl), elevated lactic acid level (3.6 mmol/L), and glycosuria without hyperglycemia. Intravenous fluids and electrolyte replacement lead to improvement in symptoms and the metabolic disorder, only after discontinuation of Tenofovir. Liver enzymes were normal. However, there was evidence of liver steatosis in a previous ultrasound study. Renal function (serum creatinine: 1.5 mg/dl), serum electrolytes and lactic acid levels (1.2 mmol/L) improved.

Discussion: Accumulation of Tenofovir in the mitochondria of the proximal renal tubular cells is associated with the development of Fanconi syndrome. It can also disrupt mitochondrial function in the hepatocytes causing steatosis and a reduction in the hepatic lactate clearance. Discontinuation of Tenofovir was crucial in our case because electrolyte replacement alone failed to correct the metabolic derangements. There are few reports of Fanconi syndrome and lactic acidosis in patients receiving Tenofovir, almost all fatal. In those cases, another drug was the culprit of the lactic acidosis. Patients on Tenofovir therapy should be closely followed for the development of the Fanconi syndrome and/or lactic acidosis, particularly in the presence of liver disease.

TH-PO076

Tumor Lysis Syndrome from a Malignant Peripheral Nerve Sheath Tumor Gerald Denny, Sharidan Parr, Anna Marie Burgner. *Dept of Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

Introduction: Tumor lysis syndrome (TLS) represents a clinical entity that can lead to acute kidney injury (AKI) and prove life threatening if not treated appropriately. We report the case of a malignant peripheral nerve sheath tumor that resulted in TLS and AKI requiring renal replacement therapy.

Case Description: A 36-year-old Caucasian male presented for definitive treatment of a known malignant peripheral nerve sheath tumor of the right chest diagnosed previously following blunt force trauma to the chest. He was found at admission to have acute renal failure and hyperkalemia. He had no other previous medical problems. Plasma lab values: creatinine, 1.64 mg/dL (previously 0.92 mg/dL), potassium 6.6 mEq/L, bicarbonate 13 mmol/L, uric acid 19.2 mg/dL, phosphorus 6.7 mg/dL, LDH 3346 U/L, lactate 8 mEq/L, and creatinine kinase 85 U/L. Urine lab values: urine protein to creatinine ratio 0.17, FENa 0.1%, and eosinophils negative. Abdominal ultrasound revealed no evidence of hydronephrosis. His labs were consistent with spontaneous tumor lysis syndrome. He was transferred to the intensive care unit and hemodialysis was emergently performed. He was subsequently placed on continuous renal replacement therapy secondary to concern for ongoing tumor lysis. He further decompensated over the next 24 hours with hypoxemic respiratory failure preventing surgical intervention. The decision was made by the patient to forego intubation and resuscitation and he subsequently died due to cardiac arrest secondary to hypoxemic respiratory failure.

Discussion: Malignant peripheral nerve sheath tumors are a subset of sarcomas and to our knowledge, this is the first reported case of spontaneous TLS in the setting of not only malignant peripheral nerve sheath tumors, but also sarcomas. The rapid enlargement of this tumor likely led to outgrowth of its blood supply resulting in TLS. Recognition of characteristics such as rapid growth are important when considering the possibility of complications from novel malignancy. While acute leukemias and non-Hodgkin's lymphoma are most likely to spontaneously result in TLS, rapidly growing sarcomas must also be followed closely.

TH-PO077

Bilateral Renal Infiltration as Initial Clinical Presentation of Non-Hodgkin's Lymphoma Suellen Klein, Maria C. Piraciaba, Carlos A.T. Sampaio, Simone C. Lo, Roberto Zatz, Lectícia Jorge, Cristiane B. Dias, Leonardo Abreu Testagrossa. *Univ of Sao Paulo, Brazil.*

Introduction: Diffuse renal lymphomatous infiltration is a rare and severe condition mostly associated with aggressive non-Hodgkin's lymphomas (NHL). We report a case of a large B-cell lymphoma in which the initial clinical manifestation was bilateral renal infiltration accompanied by severe anemia and uremic syndrome.

Case Description: A 49-year-old white man was hospitalized with severe nausea, vomiting and emaciation. He had been well until 6 months earlier, when fatigue, anorexia and progressive weight loss developed. He had been diagnosed with anemia and treated with iron sulfate, but symptoms had worsened steadily. At admission, BUN was 210 mg/dL creatinine 11 mg/dL, K+ 7.0 mmol/L and HCO_3 15 mmol/L. Hemoglobin was 7.5 g/dL, and serum iron was 23 µg/dl. Urinalysis showed: protein >1g/L, WBC 15/HPF, RBC >100/HPF. Ultrasound showed markedly enlarged kidneys (19.8 and 17.3 cm), with no hydronephrosis. A percutaneous renal biopsy revealed diffuse neoplastic infiltration. Immunofluorescence detected mild mesangial C3 granular deposition. Immunohistochemistry was positive for CD 20, CD 68, Ki-67 and BCL-6, confirming the diagnosis of large B-cell NHL. A myelogram showed no abnormalities. The patient is currently on hemodialysis, and chemotherapy has been started.

Discussion: Renal involvement in NHL is common, especially among men in their late forties, but antemortem diagnosis is made in only 1% of cases, because clinical manifestations are usually nonspecific. Pathogenic mechanisms may include recruitment of lymphoid cells into renal parenchyma through preexisting inflammation; and cell migration through lymph vessels. Renal dysfunction is common at diagnosis. Clinical and radiological findings often mimic those of renal carcinoma. Diagnosis requires renal histological examination. Chemotherapy usually includes cyclophosphamide, doxorrubicin, vincristine, and prednisolone, with unsatisfactory results, which may be improved by the recent introduction of rituximab.

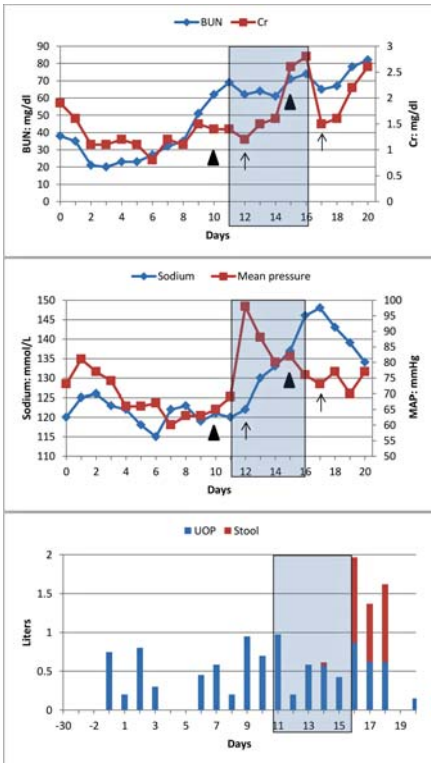
Case Report: Ileus and Severe Hepatic Encephalopathy in a Liver Cirrhosis Patient with Hepatorenal Syndrome after Starting Octreotide Mohammad G. Abu-Farsakh. *Nephrology, Baylor College of Medicine, Houston, TX.*

Introduction: Hepatorenal Syndrome (HRS) is generally associated with poor prognosis. Octreotide has been used in a combination with Midodrine and Albumin to treat Hepatorenal Syndrome. As far as we know, there was no previous reports linking Octreotide to the development of ileus, precipitating severe hepatic encephalopathy.

Case Description: Here, we report a case of a 41 year old man with alcoholic liver cirrhosis who presented with hyponatremia and refractory ascites requiring recurrent large volume paracentesis. The patient's hyponatremia did not improve with fluid restriction, and only partially and transiently corrected with Normal Saline administration. The patient was started on Octreotide, Midodrine, and Albumin for Hepatorenal syndrome but unexpectedly developed ileus which precipitated severe hepatic encephalopathy although his serum sodium corrected appropriately to normal level during therapy period. Both ileus and encephalopathy resolved after stopping Octreotide, suggesting a possible causal relationship to the event.

Discussion: In the setting of new onset ileus and hepatic encephalopathy after starting Octreotide therapy, consider stopping Octreotide as it may be the precipitating factor, especially if no other alternative explanation could be found. The attached figure below shows changes in serum BUN, Cr, Sodium, MAP, UOP and stool output in our patient before, during, and after therapy. Black arrow heads represent the onset and end of Octreotide treatment, the other two arrows represent the onset and end of encephalopathy. The shaded area represents the duration of ileus.

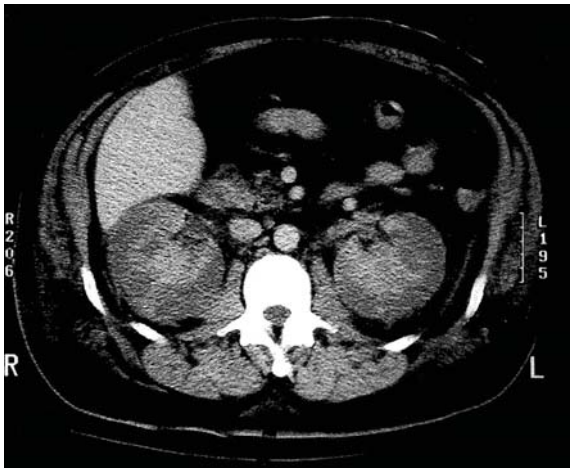


TH-PO079

Bilateral Renal Cortical Necrosis in Sepsis Mark I.C. Hong, Seyed-Ali Sadjadi. *Nephrology, Jerry L Pettis VA Medical Center, Loma Linda, CA.*

Introduction: Acute bilateral renal cortical necrosis (BRCN) is a rare cause of renal failure due to ischemia from thrombosis or vasospasm. Consequently, necrosis of the renal cortex, including Bertin columns, ensue with sparing of the medulla and a thin layer of subcapsular cortex. Etiology includes obstetric causes that account for 50 – 70% of cases and non-obstetric cases account for 20 – 30%. Herein we report a case of BRCN associated with E. Coli sepsis.

Case Description: 44 year old Caucasian male with history of diabetes and hypertension presented with upper respiratory tract infection, costovertebral angle tenderness, and anuria for 24 hours. He was admitted for urosepsis and acute kidney injury with serum blood urea nitrogen (BUN) 41 mg/dL and creatinine (Cr) 6.6 mg/dL. Contrast enhanced CT scan demonstrated bilateral renal medullary enhancement, non-enhancement of cortex and lack of contrast medium excretion in the collecting system.



Blood and urine culture were positive for E. Coli. The patient was diagnosed with BRCN due to E. Coli sepsis and started on dialysis shortly after admission.

Discussion: Acute renal cortical necrosis is a rare cause of renal failure. Though kidney biopsy is the gold standard, it may not be possible to do in critically ill patients. Contrast enhanced CT scanning is a sensitive and specific alternative modality for early diagnosis of BRCN. Recovery of kidney function depends on the extent of the renal cortical necrosis and most patients eventually become dialysis dependent with overall an mortality of 36%. Our patient remained dialysis dependent.

TH-PO080

Neurological Complications in Nephropathic Cystinosis: A Rare Case Masaaki Yamada, Aneesha A. Shetty, James F. Simon. *Cleveland Clinic, OH.*

Introduction: Nephropathic cystinosis (NC) is a rare genetic disease characterized by lysosomal cystine accumulation in cells. Early manifestations include Fanconi's syndrome, nephrolithiasis and renal failure associated with involvement of other organs if left untreated. Cysteamine therapy and renal transplantation have significantly increased the life expectancy of these patients making later manifestations of the disease important to identify. Cystinosis encephalopathy is one such late complication.

Case Description: The patient was a 23 year-old male with NC treated with cysteamine since diagnosis at age 6 months who presented with intermittent confusion and hallucinations. His renal function stayed near normal (serum creatinine 1.0 - 1.3 mg/dL) until date. Neurological examination showed no obvious cranial nerve, focal motor or sensory deficit. Initial tests including routine labs and culture, toxicology, CSF and EEG were unremarkable except presence of cerebral atrophy on CT. Brain MRI revealed chronic microvascular ischemic changes and small old infarcts. Continuous EEG showed subclinical epileptiform activity. Cystinosis encephalopathy was considered the most likely diagnosis. Cysteamine therapy was continued and subclinical seizures were treated with phenytoin and lamotrigine. His neurological symptoms improved gradually and he was discharged to a long-term care facility but subsequently developed expressive aphasia. Repeat brain MRI revealed subacute stroke involving the left frontal lobe which was managed conservatively. As of last contact, he had recovered significant neurologic functions with minimal residual deficits.

Discussion: Cystinosis encephalopathy should be considered if an adult NC patient develops unexplained neurological symptoms. Manifestations include short-term memory loss, intermittent confusion, motor and cerebellar dysfunction, cerebral ischemia and seizures. Cerebral atrophy and mineralization are typical radiographic findings. However, these are not specific and an extensive investigation into other possible causes is warranted. Cystine depleting therapy appears to slow the progression of neurological complications but the overall prognosis is poor.

TH-PO081

The Unusual Course of Severe Rhabdomyolysis in H1N1 Patient Mansumeet Singh, Ravkiran Kaur Khurana, Siddiq Anwar, Tingting Li. *Nephrology, Washington Univ School of Medicine, St. Louis, MO.*

Introduction: Rhabdomyolysis is a common and potentially lethal clinical entity that results from acute muscle necrosis with leakage of muscle constituents into circulation. A variety of causes can lead to rhabdomyolysis, including trauma, overexertion, toxins, electrolyte disorders, and infection. H1N1 influenza A infection is an under recognized cause of rhabdomyolysis. We present a case of H1N1-induced severe rhabdomyolysis leading to acute kidney injury in an adult male who recovered uneventfully.

Case Description: A 32 year old Gambian male initially presented to the outside hospital emergency room with complaints of cough, sore throat and brown streaked sputum. Rapid influenza antigen test was negative, and he was discharged on Levaquin. His symptoms persisted along with the new development of severe muscle aches which prompted a visit to our hospital. Initial labs were: creatine kinase (CK) 806,000 units/L, serum creatinine 3.96 mg/dL, Potassium (K)-4.1 mEq/L, AST 2568 units/L, and ALT 857 units/L. H1N1 influenza A was positive by RT-PCR and was thought to be the etiology of the rhabdomyolysis. He was initiated on oseltamivir and was aggressively volume repleted. Surprisingly, he remained non-oliguric (urine output consistently > 1.5 L/day) with no evidence of hyperkalemia, hyperphosphatemia, or metabolic acidosis. His creatinine peaked at 9.5 mg/dL and trended down thereafter. He did not require renal replacement therapy. His CK levels decreased slowly as did his transaminases. He was discharged to home in good condition after two weeks.

Discussion: H1N1 influenza infection should be recognized as an important cause of severe rhabdomyolysis with acute kidney injury as an expected consequence. However, the severity of rhadomyolysis does not necessarily predict severity of renal injury or need for dialysis.

TH-PO082

Diagnostic Accuracy of Neutrophil Gelatinase-Associated Lipocalin, as Marker of Acute Kidney Injury, Decreases in Chronic Kidney Disease Patients with Impaired Glomerular Filtration Rate Carlo Donadio. *Clinical and Experimental Medicine, Univ of Pisa, Pisa, Italy.*

Background: Cardio-renal syndromes are characterized by the impairment of cardiac and renal functions. Plasma and urinary Neutrophil Gelatinase-Associated Lipocalin (NGAL), and plasma B-type natriuretic peptide (BNP) are markers of acute kidney injury (AKI) and heart failure (HF), respectively. The aim of this study was to assess the effect of the reduction of GFR on plasma BNP and on plasma and urinary NGAL concentration**s** in stable chronic kidney disease (CKD) patients at different functional stages.

Methods: GFR (^{99m}Tc-DTPA), plasma BNP, and plasma and urinary concentrations of NGAL were measured in 310 clinically stable CKD patients, at functional stages from 1 to 5. Serum and urinary low-molecular-weight proteins cystatin C and β2-microglobulin, and urinary tubular enzymes were measured for comparison. Plasma BNP, NGAL, cystatin C and β2-microglobulin were measured also in 31 maintenance hemodialysis patients.

Results: Plasma NGAL increased with the reduction of GFR in CKD patients from stage 2.

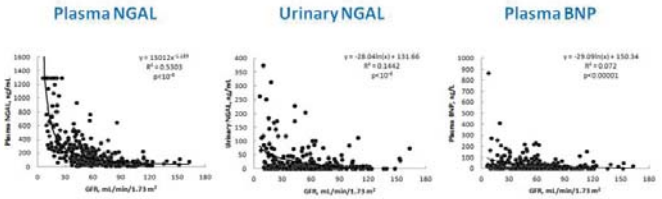


Fig 1. Correlations with GFR of plasma and urinary NGAL and plasma BNP.

In the different CKD stages modest differences were found for BNP values. Urinary NGAL increased slightly but significantly in patients at CKD stages 4 and 5, similarly to urinary cystatin C and β2-microglobulin. In maintenance hemodialysis patients, plasma NGAL and BNP were markedly increased, and high-flux hemodialysis significantly decreased their plasma concentrations.

Conclusions: Plasma NGAL increases markedly with the reduction in GFR, generating a very high number of false positive diagnoses of AKI in stable CKD patients. The grade of GFR impairment and the cause of kidney disease have a lower effect on urinary NGAL and on plasma BNP. In any case, specific reference values of NGAL and BNP should be used in chronic kidney disease patients, according to their functional stage.

TH-PO083

Association of Peak Changes in Cystatin C and Creatinine after Cardiac Surgery with 3-Year Mortality in Adults Meyeon Park,[1] Michael Shlipak,[1,2] Heather Thiessen Philbrook,[2] Amit X. Garg,[2] Jay L. Koyner,[2] Steven G. Coca,[2] Chirag R. Parikh.[2] *[1]UCSF; [2]TRIBE-AKI Investigators.*

Background: Serum creatinine (Cr) and cystatin C (CysC) have different temporal profiles in the post-operative setting. Consideration of changes in both markers may be required to capture associations of in-hospital changes in kidney function with prognosis following hospital discharge.

Methods: This is an analysis of the TRIBE-AKI (Translational Research Investigating Biomarker Endpoints for Acute Kidney Injury) multicenter prospective cohort study. We examined in-hospital peak changes of Cr and CysC for 3 days after cardiac surgery among 1199 hospital survivors, and evaluated associations with 3-year mortality, adjusting for pre-operative eGFR, elective surgery, race, gender, age, cardiopulmonary bypass time, diabetes, hypertension, heart failure, myocardial infarction, surgery type, pre-operative urinary albumin to creatinine ratio, and site.

Results: During the first 3 days of hospitalization, nearly twice as many patients had a peak rise in Cr >20% (37%) as had a >20% peak rise in CysC (20%). Patients who had elevations of >20% in both Cr and CysC were at higher adjusted risk for 3 year mortality (Table) (HR 2.4, 95% CI 1.7-3.4). However, patients who had a 20% rise in only one marker had much smaller elevations in risk.

Association of In-Hospital Changes in Cr and CysC with Mortality after Discharge		
Change in Filtration Marker	N	Adjusted HR (95% CI)
Cr<20%, CysC<20%	630	1.0 (referent)
Cr>20%, CysC<20%	273	1.32 (0.98, 1.78)
Cr<20%, CysC>20%	76	1.50 (1.05-2.12)
Cr>20%, CysC>20%	152	2.37 (1.68, 3.35)

Conclusions: In adults undergoing cardiac surgery, elevations in Cr post-operatively are twice as common as elevations in CysC. Elevations in both markers are associated with much greater increases in mortality risk at 3 years, compared with elevations of only one filtration marker.

TH-PO084

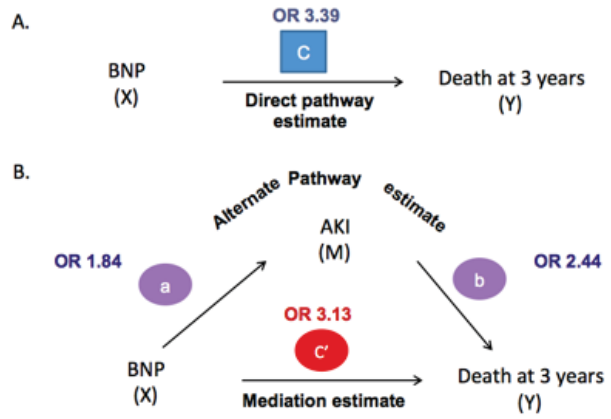
Acute Kidney Injury Mediates the Association Between Brain Natriuretic Peptide and Long-Term Mortality After Cardiac Surgery Uptal D. Patel, Heather Thiessen Philbrook, Jay L. Koyner, Steven G. Coca, Michael Shlipak, Amit X. Garg, Chirag R. Parikh. *Translational Research Investigating Biomarker Endpoint (TRIBE) in AKI Investigators.*

Background: Both brain natriuretic peptide (BNP) and AKI are associated with increased mortality after cardiac surgery. Pre-operative BNP levels are also associated with AKI, but whether post-operative AKI mediates the association between pre-operative BNP with long-term mortality is unclear.

Methods: We utilized the TRIBE AKI adult cohort (n=1121) to examine the direct association between pre-operative BNP and death at 3 years after cardiac surgery. We then examined the indirect association through post-operative AKI, defined as AKIN Stage 1 or higher. We estimated the impact of mediation by AKI with the Sobel test, which required BNP to be dichotomized (1st versus 2nd/3rd tertiles) for logistic regression models.

Results: After 3 years, there were 126 deaths. The median BNP values were significantly higher among those who died (181 mg/dL [IQR 73, 357] versus 70 [32, 165]; p<0.001) with an odds ratio (OR) for death among the highest BNP tertile of 3.4 (95% CI 2.3, 5.1; C in Fig). BNP was associated with AKI (OR 1.8; a in Fig), and AKI was associated with death (OR 2.4; b in Fig). After examining these indirect associations, the direct association between BNP and death was lower (aOR 3.1; C' in Fig). The proportion of the association mediated by at least mild AKI was found to be 30% (p=0.01).

Figure. Direct (A) and alternate pathways (B) between BNP and death.



Conclusions: We found that AKI mediates a substantial proportion of the association between BNP and mortality. These findings provide further insight into the potential pathways by which BNP is associated with mortality after cardiac surgery, and suggest that reducing the incidence of AKI may reduce the mortality risk associated with elevated BNP.

TH-PO085

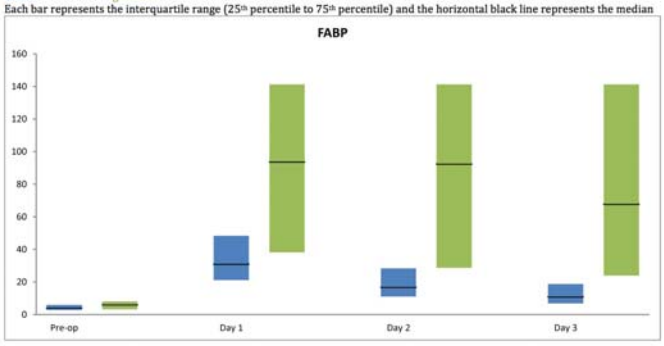
Peri-Operative Heart-Type Fatty Acid Binding Protein Predicts Acute Kidney Injury after Cardiac Surgery Jennifer A. Schaub,[1] Steven G. Coca,[1] Michael Shlipak,[2] John Eikelboom,[3] Amit X. Garg,[4] Peter Kavsak,[3] Eric Mcarthur,[4] Heather Thiessen Philbrook,[4] Richard P. Whitlock,[3] Chirag R. Parikh.[1] *[1]Yale Univ School of Medicine, New Haven, CT; [2]UCSF School of Medicine, San Francisco, CA; [3]McMaster Univ, Hamilton, ON, Canada; [4]Western Univ, London, ON, Canada.*

Background: Acute Kidney Injury (AKI) after cardiac surgery is a common and heterogenous disorder for which there is no meaningful treatment. We conducted a prospective study to evaluate if blood levels of heart FABP (hFABP) predicted incidence of AKI and helped distinguish AKI due to true tubular damage versus cardiac dysfunction.

Methods: The Translational Research Investigating Biomarker Endpoints in Acute Kidney Injury (TRIBE-AKI) cohort is a prospective cohort of 1219 patients who underwent cardiac surgery at six academic institutions across North America who were at high risk for post-operative AKI. The primary outcome was severe post-operative AKI defined as doubling of serum creatinine or requiring dialysis.

Results: On average, patients who experienced severe AKI had higher levels of hFABP both pre and post-operatively than patients who did not experience AKI.

Figure 1 – Biomarker Box Plots by Severe AKI Status
Blue = No Severe AKI green = Severe AKI Cases
Each bar represents the interquartile range (25th percentile to 75th percentile) and the horizontal black line represents the median



In analyses that adjusted for known AKI risk factors, hFABP levels within the first 6 hours post-operatively remained an independent predictor for incidence of AKI (adjusted OR 5.4 [2.9, 10.1]). Notably, this relationship persisted even after adjustment for change in serum creatinine and interleukin-18 levels (IL-18) (OR 2.9 [1.4, 5.8]).

Conclusions: Elevated hFABP levels within the first six hours post-operatively are an independent predictor for developing severe AKI. hFABP levels seem to identify a subset of patients with severe AKI whom did not sustain severe tubular injury.

TH-PO086

Increased Plasma Pro-Thrombin Fragment 1.2 (PF 1.2) Is an Independent Risk Factor for Acute Kidney Injury (AKI) in Anaemic Patients After Cardiac Surgery Simona Simone, Giuseppe Scrascia, Crescenzia Rotunno, Eustacchio Montemurno, Loreto Gesualdo, Domenico Paparella, Giovanni B. Pertosa. *DETO, Univ of Bari, Italy.*

Background: Acute Kidney Injury (AKI) following cardiac surgery is a common complication associated to short and long-term mortality. Aim of the study was to evaluate the association between coagulation system, inflammation/oxidative stress and AKI after cardiopulmonary bypass (CPB) in patients with pre-operative higher EuroSCORE points (>6) and anaemic status (Hb <12 g/dL in women, <13 g/dL in men).

Methods: Forty-one anaemic patients were prospectively enrolled. Twenty-six patients (Group A) showed a <25% postoperative Glomerular Filtration Rate (eGFR) reduction, whereas 15 patients evidenced a eGFR reduction >25% (Group B). Plasmatic Pro-thrombin Fragment 1.2 (PF 1.2, coagulation activation marker), 8-oxoDG (oxidative stress marker to DNA), IL-6 (pro-inflammatory marker), IL-10 (anti-inflammatory marker), urinary Il-18 and NGAL were evaluated.

Results: An increase in inflammatory markers (IL-6, IL10) was observed in both groups immediately after the operation compared to baseline, but no differences were found between groups. Twenty-four hours (T24) after the operation PF1.2 (999±704.1 versus 506.6±548 pmol/L; p=0.018) and 8-oxo-DG (98.8±66 versus 65.2±26 ng/mL; p=0.02) plasma levels significantly increased in group B as compared to group A. PF1.2 was independently associated with eGFR reduction in multivariate analysis. T24 PF1.2 values had an Area under the Receiving Operating Characteristic (ROC) of 0.744 for eGFR reduction. Urinary IL-18 had similar values in both groups 2 hours after the operation, but NGAL increase (2 hours versus baseline) was significantly higher in Group B patients (0.3 versus 4.4 ng/mL; p: 0.03). Five patients of Group B required renal replacement therapy (average 38.4 hours after the operation).

Conclusions: An elevated T24-postoperative plasma PF1.2 level is an independent risk factor for AKI and dialysis in anaemic patients with higher EuroSCORE points. Coagulation activation along with an increased oxidative stress may have a role in renal microcirculation impairment (ischemia-reperfusion damage) in these setting of patients.

TH-PO087

Increased Urinary Liver-Type Fatty Acid-Binding Protein (L-FABP) Linked with Incident Acute Kidney Injury and Poor Survival After Allogeneic Hematopoietic Stem Cell Transplantation Naoki Shingai,[1] Minoru Ando,[2,3] Ken Tsuchiya,[3] Kosaku Nitta.[3] *[1]Dept of Hematology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [2]Dept of Nephrology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [3]Dept of Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Hematopoietic stem cell transplantation (HCT) involves a great risk of acute kidney injury (AKI). Liver-type fatty acid-binding protein (L-FABP) is generated in renal proximal tubules and its urinary concentration is a sensitive biomarker to detect tubular injury mainly due to ischemic stress.

Methods: A one-year prospective study was conducted in 85 allogeneic HCT recipients, who had neither renal dysfunction (eGFR less than 60 ml/min/1.73 m^2) nor prior HCT at entry, to investigate the impact of baseline urinary L-FABP (uL-FABP) level on incidence of AKI and mortality after HCT. AKI was defined as one that emerges within the first 100 days after stem-cell infusion, according to the serum Cr criteria of the AKIN. The median patient age and observation period were 49 years and 710 days, respectively. The recipients were stratified into a high and a low uL-FABP group according to the reference value for healthy subjects (8.4 mg/gCr). The associations of high uL-FABP with either AKI incidence or mortality were analyzed using the Gray's method and multivariate Fine-Gray proportional hazards regression, adjusted for age, gender, disease risk, preparative regimen, and HCT-comorbidity indices.

Results: The cohort included 17 with high uL-FABP and 68 with low uL-FABP, between whom there was no significant difference in baseline eGFR. The high uL-FABP group showed significantly greater cumulative incidence of AKI (88.2% versus 59.4%, P <0.001), non-relapse mortality (NRM) at 1 year (58.8% versus 13.5%, P<0.001), and all-cause mortality (ACM) at 1 year (76.5% versus 25.5%, P<0.001), compared to the low group. The risks of high uL-FABP were statistically significant, compared to the low uL-FABP: HRs [95% CI] were 4.24 [1.7-10.6] for AKI incidence, 8.35 [3.09-22.6] for NRM, and 4.66 [2.09-10.4] for ACM, respectively.

Conclusions: Increased uL-FABP at baseline may be associated with high risk of incidence of AKI and poor survival after HCT.

TH-PO088

Endogenous Ouabain Levels Predict Survival Rate in Septic Acute Kidney Injury Marco Simonini, Simona Pozzoli, Cristina Sorlini, Andrea Duca, Chiara Lanzani, Stefano Franchini, Moreno Tresoldi, Paolo Manunta. *San Raffaele Scientific Inst, Italy.*

Background: Acute kidney injury (AKI) is a common complication of sepsis, which is associated with higher risks of adverse outcomes. Despite identification of several cellular mechanisms being thought to underlie the development of septic AKI, the pathophysiology of AKI is still poorly understood. Recently it was demonstrated that elevated levels of endogenous ouabain (EO), an adrenal stress hormone with hemodynamic and renal effects, were able to predict post-operative AKI. The aim of this work was to verify if EO dosage could be useful in the identification of subject with increased risk of AKI in severe septic state.

Methods: A group of more than 200 patients presented at Emergency Room (ER) of our hospital with severe sepsis or septic shock were studied. The incidence of AKI (stage II or III by AKIN) was 63%. Total survival rate was 41.9%. In a subgroup of subjects (40) EO was measured at the hospital admission and for the next 48h.

Results: No difference was observed in EO level in patient with or without AKI at ER admission. However patient with persistent high levels of EO (>300 pmol/L) didn't resolve AKI (prevalence at 48h from admission 60% versus 17.6%; p=0.024). Moreover patients with a more severe clinical presentation (septic shock) presented a higher EO level (411.95±202.20 versus 317.14±76.93 pmol/L). Lastly higher EO plasmatic level were associated with a lower survival rate already in the early hours of observation (p=0.013 at 72h) and with higher total in-hospital mortality of 79.6% versus 27.8% (RR 8.7 (CI95% 1.67-45.21); p<0.001). These results were statistical significant after adjustment for covariates, including clinical biomarker of sepsis severity.

Conclusions: Our data suggest that plasma EO may have a role in persistence of renal damage in evidence of severe hemodynamic alterations as presence of septic shock. Moreover EO level is able to identifies patients with more severe presentation and with an increased risk of early mortality. We believe that these preliminary findings are of great clinical impact, indeed an inhibitor of EO (rostafuroxin) has been recently developed and may help minimize AKI and improve outcomes.

TH-PO089

Storage Time and Urinary Biomarker Levels in ASSESS-AKI Kathleen D. Liu, Edward D. Siew, William Brian Reeves, Jonathan Himmelfarb, Alan S. Go, Chi-Yuan Hsu, T. Alp Ikizler, James S. Kaufman, Paul L. Kimmel, Vernon M. Chinchilli, Chirag R. Parikh. *For the NIDDK ASSESS-AKI Consortium.*

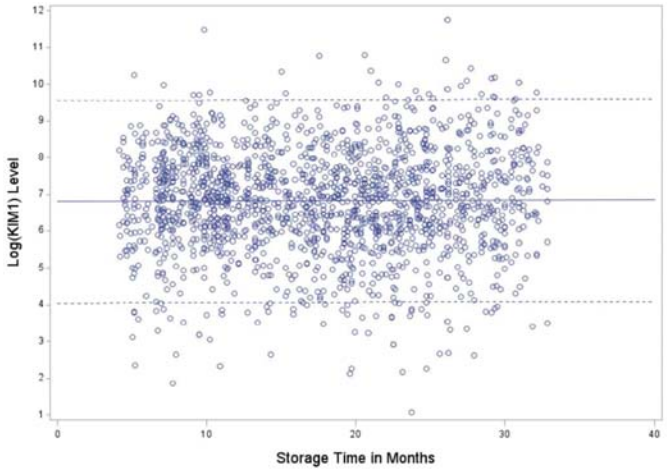
Background: Renal tubular injury biomarkers have been studied in the context of acute kidney injury (AKI). Many studies rely on banked specimens stored for months-years before biomarker measurement, but the impact of storage time on biomarker levels is not well understood.

Methods: Urine samples were obtained during initial hospitalization ("baseline") and 3 months later from 866 ASSESS-AKI participants. Samples were collected, processed and stored at -80°C per protocol until kidney injury molecule-1 (KIM-1), neutrophil-gelatinase associated iipocalin (NGAL), interleukin-18 (IL-18) and liver fatty acid binding protein (LFABP) measurements were made by ELISA at variable times after initial collection. Mixed effects models were used to determine the impact of storage time on biomarker levels. P < 0.05 was considered statistically significant.

Results: Mean age was 64 years; 39.1% were female; 34.2% had a baseline eGFR < 60 mL/min/1.73m^2. Storage time before biomarker measurement ranged from 4-34 months. There was no relationship between storage time and NGAL, IL-18 or LFABP levels after accounting for age, gender, diabetes, ICU stay, clinical center, visit, baseline and peak inpatient serum creatinine levels.

Biomarker	P value for storage time effect
NGAL	0.53
KIM-1	0.051
IL-18	0.41
LFABP	0.12

Although the p value for the overall effect of storage time on KIM-1 levels bordered on statistical significance, there was no clear relationship between time and KIM-1 levels, as shown in the Figure.



Conclusions: We found no significant association between storage time (up to 34 months) on urine NGAL, IL-18, LFABP and KIM-1 levels among urine samples collected, processed and stored under protocolized conditions. Further studies are needed to determine the impact of longer storage times on biomarker levels.

TH-PO090

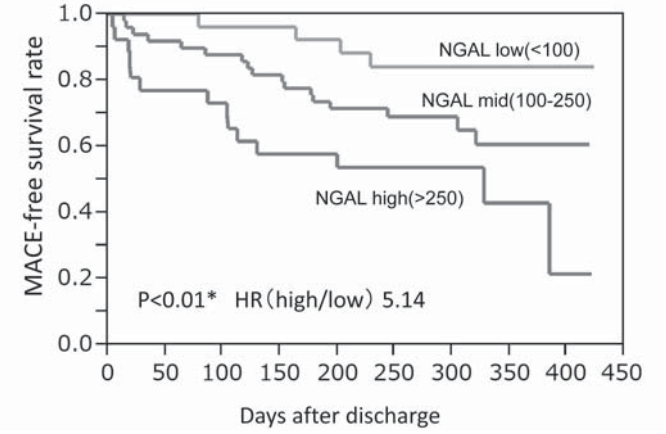
Plasma Neutrophil Gelatinase-Associated Lipocalin Predicts Major Adverse Cardiovascular Events After CCU Discharge Kent Doi,[1] Masamichi Ito,[2] Masao Takahashi,[2] Naoki Yahagi,[1] Masaomi Nangaku,[3] Eisei Noiri.[3] *[1]Emergency and Critical Care Medicine, The Univ of Tokyo; [2]Cardiovascular Medicine, The Univ of Tokyo; [3]Nephrology and Endocrinology, The Univ of Tokyo.*

Background: Acute exacerbation of renal dysfunction has a great impact on the outcomes of cardiovascular patients in critical conditions. Emerging acute kidney injury (AKI) biomarkers including neutrophil gelatinase-associated lipocalin (NGAL) have a high potential for detecting renal tissue injury better than serum creatinine. This study was aimed to evaluate whether plasma NGAL can predict the mortality and major adverse cardiovascular events after discharge from cardiac care unit (CCU).

Methods: The patients who admitted in the CCU of Tokyo University Hospital were prospectively enrolled. Blood and urinary markers including blood NGAL, brain natriuretic peptide, creatinine, and cystatin C, and urinary albumin, N-acetyl-β-D-glucosaminidase, and L-type fatty acid-binding protein were measured at their discharge from CCU. The primary outcome was major adverse cardiac event (MACE) within 6 months.

Results: Of 101 enrolled patients, 34 patients experienced MACE (34%). Among the clinical parameters and biomarkers, only plasma NGAL was significantly higher in patients with MACE than those without MACE (311.4 versus 186.3 ng/mL, p<0.01). Multivariate logistic analysis revealed plasma NGAL and complications of diabetes and heart failure were independent predicting factors for MACE. The patients with the highest NGAL at

discharge (>75th percentile) showed a significantly higher risk of MACE than those with the lowest NGAL (<25th percentile) (log-rank test, Hazard ratio 5.15 [95% confidential interval 1.84–18.20], p<0.01).



Conclusions: Plasma NGAL at CCU discharge has a significant prognostic indicator of 6 months outcomes in critically ill cardiac patients treated at CCU.

Funding: Government Support - Non-U.S.

TH-PO091

Comparative Analysis of Diagnostic and Predictive Performance of Novel Renal Biomarkers in Plasma and Urine of Acute Kidney Injury Patients Gunnar Schley, Kai-Uwe Eckardt, Carsten Willam. *Nephrology and Hypertension, Univ of Erlangen-Nuremberg, Erlangen, Germany.*

Background: Renal biomarkers represent an attractive new diagnostic tool which not only implies early diagnosis of AKI, but provides also information about patients at risk for AKI and prediction of adverse clinical outcome parameters like the need for renal replacement therapy, length of stay in ICU and mortality. This study directly compared the diagnostic and prognostic performance of biomarkers in urine and plasma.

Methods: This prospective cohort study included 110 unselected adults undergoing cardiac surgery. Plasma and/or urine concentrations of creatinine, cystatin C, neutrophil gelatinase-associated lipocalin (NGAL), liver fatty acid-binding protein (L-FABP), kidney injury molecule 1 (KIM1), and albumin and furthermore a multiplex panel of 15 biomarkers in plasma and urine were measured during the perioperative period. The primary outcome was AKI defined by AKIN criteria.

Results: Biomarkers in plasma showed markedly better predictive and diagnostic performance than their urinary counterparts. Discriminative power of urinary biomarkers improved when concentrations were related to urinary creatinine but still did not achieve AUC values of markers measured in plasma samples. Before surgery plasma IP10 (interferon-γ-induced protein 10, CXCL 10), cystatin C and MIG (monokine induced by interferon-γ, CXCL9) best predicted postoperative AKI (AUC 0.73-0.70). Best diagnostic performance 4h after surgery had NGAL (AUC 0.83), cystatin C (0.76), and MIG (0.74) in plasma. Combination with clinical scores (EuroSCORE and Cleveland Clinic Foundation Score) or combinations of several biomarkers did not significantly improve predictive or diagnostic power of either plasma or urine markers.

Conclusions: In our cohort plasma biomarkers had higher discriminative power to predict and to diagnose AKI than urine biomarkers. Plasma IP10 and NGAL performed best in predicting and diagnosing AKI respectively. Their performance could not be improved by combining with clinical scores or additional biomarkers.

TH-PO092

Higher Urinary Sediment Score Is Related to Increased Risk of AKI, and Mortality Rolando Claure-Del Granado,[1] Vania Cecilia Prudencio Ribera,[1] Susana Ledezma,[2] Ravindra L. Mehta.[3] *[1]IIBISMED, Univ Mayor de San Simon, School of Medicine, Bolivia; [2]Hospital Obrero #2, CNS, Bolivia; [3]Univ of California San Diego.*

Background: AKI diagnosis is based on changes of creatinine and diuresis, which could delay identification of AKI at earlier stages. Findings in urinary sediment have been proposed as an earlier AKI biomarker to detect kidney damage before a drop in kidney function occurs. We hypothesized that the use of urinary sediment score (Perazella et al Clin J Am Soc Nephrol 3:1615-19; 2008) in critically-ill patients could predict the development of AKI, and be related to in-hospital mortality.

Methods: We included 50 consecutive patients admitted to our Institution Medical ICU. We measured serum creatinine and collected urine every 24 hours for 7 consecutive days following ICU admission. Urine sediment was evaluated daily and assigned a score from 1 to 3 using Perazella et al criteria. We analyzed the predictive value of the urinary sediment score for the subsequent development of AKI as well to predict survival.

Results: We identified 26 (52%) patients with AKI (KDIGO guidelines sCr criteria), and 24 (48%) patients who did not develop AKI. Urinary sediment at 24 and 48 hours showed a mean score of 1.88±0.68 points in non-AKI patients versus 2.88±0.32 points in AKI patients (p=0.001); and 2.04±0.75 points in non-AKI patients versus 2.96±0.19 points in AKI patients (p=0.001); respectively. Patients with an urinary sediment score ≥ 3 at 24 and 48 hours were at higher risk of developing AKI within 7 days of follow-up (RR 5.87 95% CI 2.34 – 14.7;p < 0.001 and RR 4.31 95% CI 2.22 – 8.38;p < 0.001 respectively). The sediment score was able to predict the development of AKI (AUC 0.876 [95% CI 0.772-0.980], p < 0.0001; and AUC 0.840 (95% CI 0.720-0.959), p < 0.0001 at 24 and 48 hours; respectively). A urinary sediment score ≥2 was related to increased 28 day in-hospital mortality as compare to a score ≤1.

Conclusions: A urinary sediment score of ≥2 predicts the development of AKI before a rise in sCr occurs. This low cost tool would permit the early identification of AKI to initiate preventive and treatment strategies minimizing extension of kidney injury.

TH-PO093

Urinary α-Glutathione S-Transferase and π-Glutathione S-Transferase in Acute Kidney Injury following Cardiovascular Surgery Kai-Hsiang Shu,[1] Taomin Huang,[2] Vincent Wu.[1] *[1]Dept of Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan; [2]Dept of Internal Medicine, National Taiwan Univ Hospital Yun-Lin Branch, Dou-Liu, Taiwan.*

Background: Urinary biomarkers have been proposed to augment the diagnosis of acute kidney injury (AKI), with AKI after cardiovascular surgeries being the prototype of evaluating scenario. Glutathione S-transferse (GST), scavenging free radicals, with α-GST localized in the proximal tubule and π-GST in the distal tubule, are thus evaluated prospectively as biomarkers.

Methods: Urine samples were collected in 142 adults undergoing cardiac surgeries for analyses of urinary α-GST and π-GST using enzyme-linked immunosorbent assay (ELISA), with and without normalization to urinary creatinine concentration. AKI events were defined as AKI network (AKIN) criteria. The composite outcome of renal replacement therapy and all cause mortality were also recorded.

Results: Twenty-one (14.8%) subjects had AKIN stage 1; 4 (2.8%) patients had AKIN stage 2; 8 (5.6%) patients progressed to AKIN stage 3. Hospital mortality rate was 7.2% (9 events). Urinary π-GST concentration at 3 hours after cardiovascular surgery was able to predict all AKI (AUC = 0.61, p = 0.055), severe AKI (stage 2 or 3, AUC = 0.81, p < 0.001), stage 3 AKI (AUC = 0.78, p = 0.008), and mortality (AUC = 0.82, p = 0.001). In contrast, urinary α-GST concentration at 24 hours after cardiovascular surgery was better at predicting severe AKI (stage 2 or 3, AUC = 0.68, p = 0.04), stage 3 AKI (AUC = 0.72, p = 0.037), and mortality (AUC = 0.77, p = 0.008). Normalization of urinary π-GST and α-GST concentration to urinary creatinine concentration did not further improve the diagnostic performance.

Conclusions: Urinary π-GST predicts adverse renal outcome early and hospital mortality, while α-GST performs better at 24 hours following cardiovascular surgery. Both are more accurate at predicting advanced AKI. The differential time frame of the two biomarkers heralds further elucidation of the pathogenesis. This prospective observational study demonstrates that urinary GST can be a highly versatile marker for early detection of AKI and outcome in AKI patients.

TH-PO094

Incorporation of Urinary Biomarkers with Renal Angina Index Refines Prediction of Severe AKI in a Heterogeneous Patient Population Shina Menon,[1] Theresa A. Mottes,[2] Lin Fei,[3] Stuart Goldstein,[2] Rajit K. Basu.[2] *[1]Pediatric Nephrology, Indraprastha Apollo Hospitals, New Delhi, India; [2]Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Biostatistics and Bioepidemiology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Accurate prediction of acute kidney injury (AKI) in heterogeneous patient populations is challenging. We previously demonstrated optimized prediction of AKI via incorporation of novel biomarkers into the renal angina index (RAI) risk stratification model in children with *sepsis.*

Methods: We conducted a prospective observational study of RAI prediction of AKI in all patients admitted to a single tertiary pediatric intensive care unit. Renal angina fulfillment was determined by the RAI on the day of PICU admission (Day 0). Urinary neutrophil gelatinase associated lipocalin (NGAL), interleukin-18 (IL-18), kidney injury molecule-1 (KIM-1), and liver-fatty acid binding protein (L-FABP) were measured on Day 1. The primary outcome was KDIGO Stage II AKI (100% SCr rise from baseline) 3 days after admission (Day 3-AKI).

Results: 137 patients enrolled from September 2012 to December 2013 were included. Renal angina was present in 50 pts on Day 0 (36.4%). Day 3-AKI occurred in 33 pts (24%) with a three-fold higher incidence in patients with renal angina. RAI had high negative predictive value (NPV) for Day 3-AKI. Incorporation of NGAL and l-FABP with RAI increased predictive discrimination, measured by area under the curve (AUC) for Day 3 – AKI (0.69 to 0.77 with inclusion of either biomarker). The specificity of prediction was augmented (71% to 90% with either biomarker), increasing positive likelihood ratio (LR) (2.8 to 4.3 and 4.4, respectively) and resulting in significant net reclassification improvement (NRI) (0.39 and 0.67, respectively) and integrated discrimination improvement (IDI).

Conclusions: Incorporation of biomarkers with RAI yields refined AKI prediction, increasing specificity by reducing the rate of false positivity. We suggest renal angina risk stratification, strengthened by biomarker incorporation, identifies children at very low risk of AKI 72 hours after PICU admission with near certainty.

TH-PO095

Pattern of Urinary NGAL Elevation and Acute Kidney Injury Severity in Critically Ill Patients Fernando de Almeida Soares, Lilian Carmo, Camila Lima, Vivian Lumi Onusic, Liliany P. Repizo, Emmanuel A. Burdmann, Etienne Macedo. *Nephrology, Univ of Sao Paulo - USP, Sao Paulo, SP, Brazil.*

Background: Biomarkers are a promising tool for early Acute Kidney Injury (AKI) recognition that could lead to improvement in patients' outcomes. In clinical intensive care units (ICU), the time of insult leading to kidney injury is frequently unknown and biomarkers cutoff points are cumbersome. The purpose of this study is to evaluate if the pattern of elevation of urinary neutrophil gelatinase-associated lipocalin (NGALu) could be useful to predict AKI severity in critical ill patients.

Methods: We performed a prospective study between Jan12 and July13. We enrolled patients with high risk for AKI who were admitted in the ICU. Urinary NGAL were measured every 12h during the first 2days of ICU stay. We used the terms NGAL(+)/(-) according to study-specific NGAL cutoff for optimal AKI prediction, and the terms sCr(+)/(-) according to KDIGO criteria. Maximum delta uNGAL was defined by the greatest 12h difference between the sequential intervals. We categorized patients according to uNGAL and sCr classification.

Results: Of the 272 screened patients, 46 met the inclusion criteria. Thirty (62.5%) patients met KDIGO criteria for AKI. Four patients had AKI before ICU admission and so were excluded. In patients reaching a max KDIGO stage2/3, the delta uNGAL was 58,0 (-4,5-546,6) versus 10,8 (-3,3-50) in patients reaching max KDIGO1 (p= 0,04). There was a progressive increase in delta uNGAL with increasing biomarker positivity as shown in Table 1.

Biomarker Posivity and Maximum Delta Urinary NGAL levels

NGAL + / sCr +	152.8 (6.2- 1097)
NGAL + / sCr -	32.5 (-8.0-57.3)
NGAL - / sCr +	13.3 (1.2-31.5)
NGAL - / sCr -	6.8 (-6.0-35)

Seven (16,7%) patients needed RRT: six in the group NGAL+/sCr+ and one in the group NGAL -/sCr +. The mortality rate was higher in the NGAL+/sCr + group (23,8%), and lower in the others groups: NGAL-/sCr+ 4,7%; NGAL+/sCr– 2,3%; NGAL-/sCr– 2,3%.

Conclusions: Delta NGAL can be a predictor of AKI severity and the need for RRT. The association of groups of positive biomarkers and delta values in addition to the absolute values could improve their performance to predict AKI severity and the need for dialysis.

Identifying and Evaluating Combinations of Markers to Predict AKI Allison Meisner,[1] Kathleen F. Kerr,[1] Heather Thiessen Philbrook,[2] Steven G. Coca,[3] Chirag R. Parikh.[3] *[1]Dept of Biostatistics, Univ of Washington, Seattle, WA; [2]Div of Nephrology, Dept of Medicine, Western Univ, London, ON, Canada; [3]Section of Nephrology, Yale School of Medicine, New Haven, CT.*

Background: Urinary biomarkers of kidney injury provide modest prediction of acute kidney injury after cardiac surgery when considered individually. We developed and applied a rigorous framework to search for biomarker combinations to improve performance of AKI risk prediction models after cardiac surgery. We carefully addressed several important statistical issues, including the effect of center and the impact of optimism, when developing these combinations.

Methods: The framework involves splitting the data into training and test datasets, using logistic regression to fit models with combinations of markers and clinical covariates, and evaluating these models using center-adjusted AUC that is corrected for optimistic resubstitution bias. We applied this framework to the TRIBE-AKI study, which prospectively followed 1219 adults after cardiac surgery.

Results: Based on the training dataset, we identified 3 promising models from over 1000 models with 3 variables. The models included cardiopulmonary bypass time and change in serum creatinine plus a post-operative biomarker (urine IL-18, urine KIM-1 or urine albumin) and showed promising performance in the training dataset (Table below). The optimism-corrected AUCs for each model were higher in the training dataset than in the test dataset (Table) but still suggested good performance in the test dataset. The test dataset was limited by the small number of events.

Conclusions: Linear combination methods suggest limited improvement in accuracy for predicting AKI events. External validation of these models is required in other cardiac surgery datasets.

Center-Adjusted AUC

	Training Dataset* n=830, # severe AKI cases = 39	Test Dataset n=389, # severe AKI cases = 21
CPB Time, ΔSCr and Urine IL-18	0.858	0.751
CPB Time, ΔSCr and Urine KIM-1	0.854	0.743
CPB Time, ΔSCr and Urine Albumin	0.851	0.731

* AUC corrected for optimistic resubstitution bias

Cardiac Biomarkers in the Prediction of Postoperative Acute Kidney Injury in Children Undergoing Cardiac Surgery Emily Marie Bucholz,[1] Chirag R. Parikh.[1,2] *[1]Yale Univ School of Medicine, New Haven, CT; [2]Translational Research Investigating Biomarkers and Endpoints for Acute Kidney Injury (TRIBE-AKI) Consortium, Yale Univ, McMaster Univ.*

Background: Preliminary evidence suggests that renal biomarkers can help identify pediatric patients at risk for developing AKI after cardiac surgery; however, little is know about the prognostic utility of cardiac biomarkers.

Methods: Data from TRIBE-AKI, a prospective study of children <18 years of age undergoing cardiac surgery, were used to examine the association of cardiac biomarkers (NT pro-BNP, CK-MB, and troponins I and T (cTnI and cTnT)) with the development of postoperative AKI. Cardiac biomarkers were collected prior to and 0-6 hours after surgery. Severe AKI was defined as a doubling of creatinine or dialysis within 7 days of surgery. Logistic regression and receiver-operating characteristic curves were used to evaluate the association between cardiac biomarkers and postoperative AKI.

Results: Of the 106 patients, 23(22%) developed severe AKI after cardiac surgery. Patients who developed severe AKI had higher median levels of pre- and postoperative NT pro-BNP, CK-MB, cTnI, and cTnT compared to patients without AKI ($p<0.01$). Preoperatively, higher levels of CK-MB were associated with increased odds of developing severe AKI (OR 3.26, 95%CI:0.94-11.31). When combined with other clinical variables, preoperative CK-MB provided good discrimination of AKI status (area under the curve (AUC) 0.83, 95%CI:0.58-0.84). Among postoperative biomarkers, cTnI and cTnT were associated with increased odds of developing severe AKI (cTnI: OR 1.44, 95%CI 0.81-2.57; cTnT: OR 1.62, 95%CI:0.83-3.18) and yielded high AUCs when combined with the clinical model (cTnI: AUC 0.87, 95%CI:0.79-0.96; cTnT: AUC 0.86, 95%CI:0.78-0.95).

Conclusions: Preoperative CK-MB and postoperative cTnI and cTnT are associated with increased risk of postoperative AKI and provide good discrimination between patients who develop severe AKI and those who do not. These cardiac biomarkers may be useful for risk stratification of pediatric patients undergoing cardiac surgery; however, larger studies are needed to confirm these results.

TH-PO098

Plasma Interleukin-6 and Interleukin-10 Predict AKI and Death in Adults after Cardiac Surgery William R. Zhang, Amit X. Garg, Steven G. Coca, John Eikelboom, Peter Kavsak, Eric Mcarthur, Colleen Shortt, Heather Thiessen Philbrook, Michael Shlipak, Richard P. Whitlock, Chirag R. Parikh. *TRIBE-AKI Consortium.*

Background: Inflammation plays an integral role in the pathophysiology of acute kidney injury (AKI). We investigated the utility of plasma cytokines interleukin (IL)-6 and IL-10, two known components of inflammation in acute injury, as biomarkers of AKI and mortality in adults at high risk for AKI undergoing cardiac surgery.

Methods: Patients in the TRIBE-AKI cohort study were enrolled at six academic centers. AKI was defined as a doubling in serum creatinine concentration from baseline or receipt of acute dialysis during hospitalization. Pre- and postoperative (0-6 hours after surgery) measurements of IL-6, IL-10, and IL-6:IL-10 ratio were categorized into tertiles and evaluated for associations with outcomes of in-hospital AKI or post-discharge all-cause mortality at a median of 3 years after surgery.

Results: Elevated postoperative IL-6 was associated with increased risk of AKI (OR 6.4, 95% CI 2.2-18.7), though the association was attenuated following adjustment (OR 3.0, 95% CI 0.94-9.5). IL-6 was not associated with risk of mortality. While IL-10 was not associated with risk of AKI, elevated postoperative IL-10 was independently associated with lower risk of mortality (HR 0.72, 95% CI 0.56-0.93). There was significant interaction by neutrophil gelatinase-associated lipocalin (NGAL), an established AKI biomarker, on the association of IL-10 and mortality, such that the independent protective effect conferred by IL-10 was only observed in patients with plasma or urine NGAL levels above the median (p=0.01). Elevated IL-6:IL-10 ratio was independently associated with risk of AKI preoperatively (OR 3.2, 95% CI 1.1-9.6) and with risk of mortality pre- and postoperatively (HR 1.4, 95% CI 1.1-2.0; HR 1.4, 95% CI 1.2-1.6, respectively).

Conclusions: After cardiac surgery, elevated plasma IL-6 approached independent association with increased AKI, and elevated plasma IL-10 was independently protective against long-term mortality, suggesting that these cytokines may serve as biomarkers for perioperative outcomes.

TH-PO099

NTpro-BNP Levels Are Associated with Severe Acute Kidney Injury and 1-Year Mortality after Cardiac Surgery Emilie P. Belley-Cote,[1] Chirag R. Parikh,[3] Colleen Shortt,[1] Steven G. Coca,[3] John Eikelboom,[1,2] Amit X. Garg,[4] Peter Kavsak,[1] Eric Mcarthur,[5] Heather Thiessen Philbrook,[4] Richard P. Whitlock.[1,2] *[1]McMaster Univ, ON, Canada; [2]Population Health Research Inst, ON, Canada; [3]Yale Univ, CT; [4]Western Univ, ON, Canada; [5]Inst for Clinical Evaluative Sciences, ON, Canada.*

Background: Acute kidney injury (AKI) is a frequent complication after cardiac surgery and is associated with higher post-operative morbidity and mortality. Perioperative cardiac biomarkers levels may predict AKI.

Methods: In a prospective multicenter cohort of adults undergoing cardiac surgery, we measured the following biomarkers in pre and post-operative banked plasma samples: high-sensitivity cardiac troponin T (hs-cTnT), troponin I (TnI), CK-MB and NTpro-BNP. Our objectives were to evaluate whether these biomarkers are associated with severe AKI after surgery, defined as a doubling in serum creatinine or AKI requiring hemodialysis, and 1-year mortality.

Results: In the patients who were discharged alive, severe AKI occurred in 37/960 (3.9%) and 43/960 (4.5%) died within 1 year of follow-up. AKI occurred a median of 3 days (IQR 2-4) after surgery. NTpro-BNP was the only pre-operative biomarker that was independently associated with severe AKI (adjusted OR=1.4, 95% CI (1.0, 1.9)). Day 1 post-operative biomarkers (measured within 6 hours post-operatively) were all associated with severe AKI.

Day 1 Biomarkers and Association with Severe AKI

Biomarker	Adjusted OR (95% CI)
hs-cTnT (ng/L)	2.1 (1.3, 3.3)
TnI (ug/L)	1.6 (1.1, 2.3)
CK-MB (ug/L)	2.2 (1.3, 3.7)
NTpro-BNP (pg/mL)	1.5 (1.1, 2.0)

Pre-operative NTpro-BNP was also associated with 1-year mortality (adjusted OR=1.7, 95% CI (1.2-2.2)). Day 1 NTpro-BNP was associated with 1 year mortality independently of change in creatinine from pre-operative level (adjusted OR=1.6, 95% CI (1.2-2.2)).

Conclusions: Early increases in post-operative cardiac biomarkers are associated with severe AKI after cardiac surgery. Of the studied biomarkers, NTpro-BNP is the only pre-operative biomarker independently associated of severe AKI and 1-year mortality. Future research should focus on whether interventions that lower NTpro-BNP can impact upon post-operative outcomes.

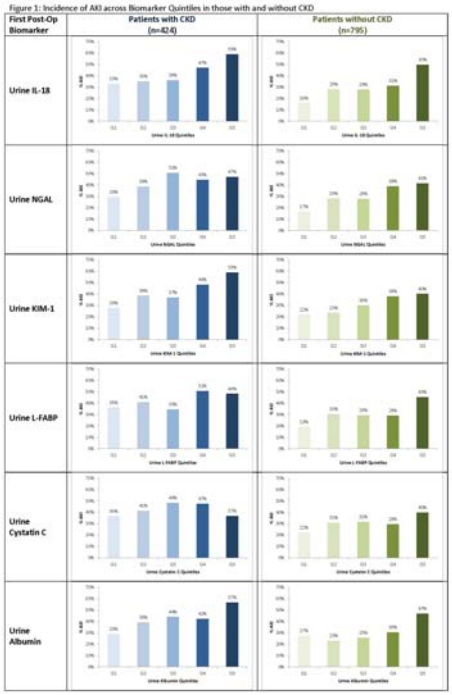
TH-PO100

Chronic Kidney Disease Does Not Impact the Utility of Urinary Acute Kidney Injury Biomarkers Jay L. Koyner, Heather Thiessen Philbrook, Steven G. Coca, Uptal D. Patel, Michael Shlipak, Amit X. Garg, Chirag R. Parikh. *Translational Research Investigating Biomarker Endpoint (TRIBE)-AKI Investigators.*

Background: The impact of underlying chronic kidney disease (CKD) on the performance of AKI biomarkers is unclear.

Methods: We stratified the TRIBE AKI adult cohort (n=1219) into those with (n=424) and without (n=795) CKD (eGFR <60ml/min), and examined the association of the first post-operative urinary concentration of 6 biomarkers (neutrophil gelatinase-associated lipocalin (NGAL), interleukin-18 (IL-18), kidney injury molecule-1 (KIM-1), and liver fatty acid binding protein (L-FABP), cystatin C and albumin) with the development of post-operative AKIN Stage 1 AKI following cardiac surgery. We categorized those with and without CKD into quintiles for each of the 6 biomarkers and determined the adjusted relative risk (aRR) of developing AKI. We also assessed the interaction with CKD using continuous log-transformed values of the biomarkers.

Results: A total of 180(42%) patients with CKD developed AKI compared to 246(31%) in the non-CKD group; p<0.001. Figure 1 displays the incidence of AKI across quintiles for each biomarker in those with and without CKD.



There was a significant difference in the incidence of AKI across quintiles for NGAL (p=0.01), L-FABP (p=0.04) and Albumin (p=0.04). For these biomarkers the aRR's were higher in those without CKD versus those with CKD. We only observed a significant interaction by CKD on the relationship between the biomarker and AKI for IL-18 using the continuous log-transformed values (non-CKD aRR [95%CI] 1.17[1.11-1.23] versus CKD 1.06[0.99-1.13]; interaction p=0.007).

Conclusions: Although interactions by CKD on the association between biomarkers and AKI may be present, they are not uniformly significant and the magnitude of the effect modifications were small. Adjusting cutoffs of urinary biomarkers for AKI in those with pre-existing CKD is not warranted.

TH-PO101

Adjudication of Etiology of Acute Kidney Injury: Experience from the TRIBE-AKI Multi-Center Study Jay L. Koyner,[1] Amit X. Garg,[1] Heather Thiessen Philbrook,[1] Steven G. Coca,[1] Lloyd G. Cantley,[2] Aldo J. Peixoto,[2] Chirag R. Parikh.[1] *[1]TRIBE-AKI Investigators; [2]Section of Nephrology, Yale Univ.*

Background: Minimal data exists on the adjudication process in the setting of Acute Kidney Injury (AKI) to confirm our ability to judge different etiologies (e.g. Acute Tubular Necrosis (ATN), Pre-renal Azotemia (PRA)) in research setting.

Methods: We enrolled 475 consecutive adults undergoing cardiac surgery at 4 sites for this sub-study of the Translational Research Investigating Biomarker Endpoints in AKI (TRIBE-AKI) study. Three expert nephrologists performed independent chart review, utilizing clinical variables and retrospective case report forms with pre, intra, and post-operative data, and then adjudicated all cases of AKI (n=67). AKI was defined as a >50% increase in serum creatinine from baseline (RIFLE "Risk"). We examined the patterns of AKI diagnoses made by the adjudication panel as well as association of these diagnoses with pre and postoperative AKI biomarkers.

Results: Based on the agreement of 2 out of 3 reviewers, ATN was the adjudicated diagnosis in 41 cases (61%) while PRA in 13 (19%) and the rest were indeterminate.

	Final Adjudication Result			Total
Etiology by Panelist Adjudication	ATN	PRA	IND	n (%)
3 ATN	11			11 (16)
3 PRA		2		2 (3)
2 ATN; 1 PRA	16			16 (24)
2 ATN; 1 IND	11			11 (16)
2 PRA; 1 ATN		4		4 (6)
2 PRA; 1 IND		6		6 (9)
2 IND; 1 ATN			2	2 (3)
2 IND; 1 PRA			5	5 (8)
1 ATN; 1 PRA; 1 IND	3	1	6	10 (15)
Total	41	13	13	67 (100)
ATN= Acute Tubular Necrosis; PRA = Pre-Renal Azotemia; IND= Indeterminate				

Neither serum creatinine nor any biomarker of AKI (urine or serum) was associated with an adjudicated diagnosis of ATN within the first 24 post-operative hours. Patients adjudicated as ATN had a longer duration of AKI and worse clinical outcomes. There was poor agreement across the panel of reviewers with adjudicated diagnoses being independent of each other (Fleiss' Kappa=0.046).

Conclusions: The etiology of AKI after cardiac surgery is multi-factorial and pure AKI etiologies, such as ATN and PRA may not exist in this setting. Biomarkers did not appear to correlate with the adjudicated etiology of AKI; however, the lack of agreement among the adjudicators impacted these results.

TH-PO102

Association of Plasma Inflammatory Biomarkers with Acute Kidney Injury after Pediatric Cardiac Surgery Jason Henry Greenberg,[1] William R. Zhang,[1] Heather Thiessen Philbrook,[2] Michael Zappitelli,[3] Prasad Devarajan,[4] Richard P. Whitlock,[5] John Eikelboom,[5] Peter Kavsak,[5] Amit X. Garg,[2] Colleen Shortt,[5] Chirag R. Parikh.[1] *[1]Yale Univ; [2]Western Univ, Canada; [3]McGill Univ, Canada; [4]Cincinnati Children's; [5]McMaster Univ, Canada.*

Background: Children undergoing cardiac surgery may exhibit a pronounced inflammatory response to cardiopulmonary bypass(CPB). Inflammation is recognized as an important pathophysiologic process leading to acute kidney injury(AKI). The aim of this study was to evaluate the association of two inflammatory cytokines interleukin(IL)-6 and IL-10 with AKI and other adverse outcomes in children after CPB surgery.

Methods: This is a sub-study of the TRIBE-AKI cohort, including 106 children from 1 month to 18 years old, undergoing CPB. Plasma IL-6 and IL-10 were measured preoperatively and postoperatively on Days 1(within 6 hours after surgery) and 3.

Results: Mild AKI, defined by a ≥50% rise of baseline serum creatinine, and severe AKI, defined by dialysis or a doubling of baseline serum creatinine, was diagnosed in 31(29%) and 24(23%) patients respectively. Preop IL-6 was significantly higher in patients with severe AKI versus without severe AKI(median 2.59(0.6-4.88) versus 1.66(0.6-3.08) p=0.03). After adjustment for age, gender, race, and study site, the highest preop IL-6 tertile was associated with an eight-fold increased risk for severe AKI compared with the lowest tertile(adjusted OR 7.9(CI: 1.7-37.3)). IL-6 and IL-10 increased significantly after

surgery, peaking on Day 1 postoperatively(Figure 1). First postoperative IL-6 and IL-10 did not significantly differ between patients with versus without severe AKI. Elevated IL-6 on day 3 was associated with longer hospital stay(p=0.0001).

Figure 1. Inflammatory Biomarker Distribution by AKI Status

A. IL-6

	Pre-op			Day 1			Day 3		
25th pct	0.6	0.6	0.6	58.73	45.57	47.33	19.08	16.7	21.61
Median	1.66	0.6	2.59	91.73	89.81	107.27	38.08	28.5	59.39
75th pct	3.08	1.44	4.88	145.36	158.85	201.15	67.15	67.9	108.7

B. IL-10

	Pre-op			Day 1			Day 3		
25th pct	0.9	0.9	0.9	49.67	54.65	79.805	0.9	0.9	0.9
Median	0.9	0.9	0.9	86.53	90.29	95	0.9	0.9	2.64
75th pct	1.95	0.9	0.9	156.2	121.6	175.2	0.9	2.39	6.33

Conclusions: Pre-operative IL-6 is associated with development of severe AKI and may be prognostic of resource utilization.

Intraabdominal Hypertension Did Not Predict Short Term Renal Recovery or in Hospital Mortality in Critically Ill Patients with AKI

Hyojeong Chang, Myung-Gyu Kim, Sang-Kyung Jo, Won-Yong Cho. *Korea Univ Anam Hospital, Seoul.*

Background: Although emerging evidence suggest that intraabdominal hypertension (IAH) is a useful predictor of the development of acute kidney injury (AKI), whether the presence of IAH could also predict renal recovery or mortality remains unclear. The purpose of this study was to determine the prevalence of IAH and also whether the presence of IAH could predict short term renal recovery or in-hospital mortality in critically patients with AKI. Prognostic value of urinary biomarkers including neutrophil gelatinase-associated lipocalin (NGAL) and liver-type fatty acid-binding protein (L-FABP) in predicting renal recovery or in-hospital mortality was also determined.

Methods: This is a prospective observational study enrolling 52 patients who admitted to intensive care unit with AKI from February 2012 and January 2014. Urine NGAL and L-FABP at the time of ICU admission were examined, and intra-abdominal pressure(IAP) was measured for initial three days and their average value was calculated. The IAH was defined as a mean IAP>12mmHg.

Results: Mean age was 69.2±14.5 years and male was 48.0%. At the time of admission, mean simplified acute physiology score (SAPS) II score was 43.5±15.2 and IAH was found in 84.6% of patients. AKI with failure grade according to RIFLE criteria developed in 65.4% and 57.7% of patients needed renal replacement therapy. In hospital mortality was 21.2% and renal recovery defined as serum creatinine level below 0.45mg/dL or within above 20% of baseline value during hospitalization was achieved in 42% of patients. Although both high urine NGAL (OR, 1.018) and L-FABP (OR, 1.032) were found to be independent predictors of renal recovery, presence of IAH did not predict renal recovery. For predicting in-hospital mortality, high SAPS II score (OR, 1.094) and high urine NGAL (OR, 1.032) were independent predictors in multivariate analysis; however IHA and urine L-FABP were not.

Conclusions: IAH is prevalent in critically ill patients with established AKI. However, it did not predict short term prognosis including renal recovery or in-hospital mortality. Urine NGAL was found to be a useful predictor of both renal recovery and in-hospital mortality.

TH-PO104

The Role of Circulating Tumor Necrosis Factor Receptor 1 and 2 in Contrast-Induced Nephropathy

Jung Nam An,[1] Dong Ki Kim,[2] Yun Kyu Oh,[1] Yon Su Kim,[2] Chun Soo Lim,[1] Jung Pyo Lee.[1] *[1]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: Contrast-induced nephropathy (CIN) is the important cause of hospital acquired acute kidney injury. Accurate understanding of the pathogenesis and the prevention and early intervention of CIN are crucial. Thus, the aim of this study was to evaluate the clinical role of circulating tumor necrosis factor receptors (cTNFRs) as predictors for CIN.

Methods: During the period of May 2013 to February 2014, a total of 262 patients who underwent coronary angiography and/or percutaneous coronary intervention in Seoul National University Boramae Medical Center, were enrolled. CIN was defined as either an increase in serum creatinine (sCr) ≥ 0.25 mg/dL or ≥ 25% within 48 hours after procedure.

Results: Male gender was 64.1%, mean age was 64.6 ± 10.9 years, and the patients with diabetes and chronic kidney disease were 27.5% and 17.6%, respectively. Overall patients had fluid therapy before and after contrast use, and 36.3% underwent percutaneous coronary intervention. CIN developed in 4.2% of patients and the levels of cTNFRs were as follows (CIN group versus non-CIN group): cTNFR1, 3223.8 ± 2899.4 pg/mL versus 1330.8 ± 841.5 pg/mL ($P = 0.026$); cTNFR2, 6535.8 ± 5353.1 pg/mL versus 3226.4 ± 2926.3 pg/mL ($P = 0.090$). The risk factors for CIN were younger age, underlying diseases as stroke and chronic kidney disease, the use of N-acetylcysteine, and higher levels of ln(cTNFRs). Increased serum levels of ln(cTNFR1) (odds ratio 16.97; 95% confidence interval 4.24-67.95; $P < 0.001$) and ln(cTNFR2) (odds ratio 4.16; 95% confidence interval 1.55-11.18; $P = 0.005$) were significantly associated with the development of CIN after adjusting other risk factors including baseline renal function and diabetes.

Conclusions: Markedly elevated circulating TNFR levels are independent predictors of decreased renal function after contrast-related procedure. Further studies, establishing the significance of cTNFRs as prognostic markers of CIN, will be needed.

Urine Vitamin D Binding Protein and Complement C 3: Novel Prognostic Biomarkers in Acute Kidney Injury

Nithin Karakala,[1] Joseph Alge,[1] Michael G. Janech,[1] James A. Tumlin,[4] Lakhmir S. Chawla,[2] Andrew Shaw,[3] John M. Arthur.[1] *[1]Medicine, Nephrology, Medical Univ of South Carolina; [2]Medicine, Nephrology, Washington DC VA Medical Center; [3]Anesthesiology, Vanderbilt Univ Medical Center; [4]Medicine, Nephrology, UTCOM.*

Background: Improved biomarkers of acute kidney injury (AKI) that can predict the prognosis of the patient early in the injury are needed. We previously identified novel AKI biomarker proteins by mass spectrometry. The aim of this study was to validate the use of two novel markers, urine vitamin D binding protein (VDBP) and complement C3, as potential prognostic biomarkers to predict outcomes in patients with AKI.

Methods: We used a cohort of 153 patients who underwent cardiovascular surgery and developed AKI stage 1 within 72 hours after the procedure. Urinary VDBP and complement C3 were measured by ELISA, urine creatinine was measured by Jaffe's method. The primary outcome was a composite of death, renal replacement therapy (RRT) and AKIN stage 3. Secondary outcomes were death, RRT, and RRT or death.

Results: There were no significant differences between the outcome groups with respect to demographics, underlying medical conditions, type of surgery or pre-op creatinine. Urine VDBP (AUC 0.67) and complement C3 (AUC 0.74) concentrations were highly discriminative for the composite primary outcome. The ability to predict primary outcome further improved when the urine biomarkers were normalized to urine creatinine (uCr), VDBP/uCr (AUC: 0.73) and complement C 3 (AUC: 0.77). The AUC values of VDBP/uCr for predicting the secondary outcomes were: death (0.71), RRT (0.68), RRT or death (0.73) The AUC values for complement C3/uCr were: death (0.77), RRT (0.70) and RRT or death (0.75).

Urine Biomarker	Primary Outcome Group (n=17) Median (IQR)	No Outcome Group (136) Median(IQR)	p Value	AUC
VDBP (ng/ml)	0.44 (0.11,1.130)	0.17 (0.06,0.34)	0.02	0.67
Comp C 3 (ng/ml)	100 (37.5, 192.5)	19.9 (5,68.8)	0.001	0.74
VDBP/uCr (ng/mg)	0.43 (0.18, 2.27)	0.14 (0.07, 0.41)	0.001	0.73
Comp C 3/uCr (ng/mg)	152.7 (48, 497)	19.9 (5.4, 77.9)	<0.001	0.77

Conclusions: Urine VDBP and complement C3 are novel biomarkers useful in predicting outcomes of death and renal replacement therapy in patients with early AKI.

Funding: NIDDK Support

Urinary Biomarkers of Acute Kidney Injury in Children after Cardiac Surgery Michael A. Ferguson,[1] Venkata Sabbisetti,[2] Satish Rajagopal,[3] Joshua Blinder,[3] Joseph V. Bonventre,[2] Sushrut S. Waikar.[2] *[1]Div of Nephrology, Boston Children's Hospital, Boston, MA; [2]Renal Div, Brigham and Women's Hospital, Boston, MA; [3]Dept of Cardiology, Boston Children's Hospital, Boston, MA.*

Background: Acute kidney injury (AKI) is common after pediatric cardiac surgery and associated with increased morbidity and mortality. Current metrics used to assess for AKI have suboptimal sensitivity and specificity. Urinary biomarkers may identify those with or at risk for AKI earlier than conventional markers.

Methods: We conducted a prospective study of children undergoing cardiac surgery to evaluate the diagnostic performance of urinary biomarkers of AKI, including kidney injury molecule 1 (KIM-1), neutrophil gelatinase-associated lipocalin (NGAL), *N*-acetyl-β-glucosaminidase (NAG), microalbumin (MAB), and total protein (TP). Urine samples were obtained at multiple time points. AKI was stratified using the pediatric modified RIFLE criteria (pRIFLE). Diagnostic performance was assessed using the area under the receiver operating characteristic curve (AUC-ROC).

Results: 16 (7%) subjects developed significant AKI (decrease in estimated GFR ≥ 50%). Those who developed AKI were younger, had longer surgical times, longer bypass times, and longer cross clamp times. Biomarker performance characteristics are detailed in Table 1. 2-hours post-operatively, no biomarker achieved an AUC-ROC > 0.70. The highest performing biomarker 8 hours post-operatively was NGAL (AUC-ROC of 0.79). The highest performing biomarker on day 1 was KIM-1 (AUC-ROC of 0.72).

Biomarker	AUC-ROC	Cutoff	Sensitivity	Specificity
2-Hour				
KIM-1 (ng/mg Cr)	0.65	0.93	88	50
MAB (mcg/g Cr)	0.65	34.3	71	63
NAG (mU/mg Cr)	0.70	64.9	77	68
NGAL (ng/mg Cr)	0.70	772	65	75
Protein (mg/mg Cr)	0.68	0.62	82	62
8-Hour				
KIM-1 (ng/mg Cr)	0.65	1.39	78	46
MAB (mcg/g Cr)	0.67	22.4	67	72
NAG (mU/mg Cr)	0.65	7.84	72	58
NGAL (ng/mg Cr)	0.79	35.7	83	79
Protein (mg/mg Cr)	0.75	0.20	72	73
Day-1				
KIM-1 (ng/mg Cr)	0.72	5.72	73	70
MAB (mcg/g Cr)	0.65	32.5	53	77
NAG (mU/mg Cr)	0.60	5.32	67	62
NGAL (ng/mg Cr)	0.67	24.3	73	57
Protein (mg/mg Cr)	0.62	0.09	87	45

Conclusions: Urinary biomarkers of kidney injury had only moderate AUC-ROCS when compared against creatinine-based definitions of AKI.

TH-PO107

Midkine Levels in Acute Kidney Injury After Cardiac Bypass - A Pilot Study Victoria K. Campbell,[1,2] Chris Anstey,[1] Sharron T. Hall,[2,4] Shay Mcguinness,[3] Rachael L. Parke.[3] *[1]Dept of Intensive Care, Sunshine Coast Hospital and Health Service, Nambour, Queensland, Australia; [2]Cellmid LTD, Sydney, New South Wales, Australia; [3]Dept of Intensive Care, Auckland City Hospital, Auckland, New Zealand; [4]Pathology North, Hunter New England, Newcastle, New South Wales, Australia.*

Background: There is great interest in biomarkers for early detection of acute kidney injury (AKI), and to identify those who will develop chronic kidney disease (CKD). Midkine (MK) is a pro-inflammatory and pro-fibrotic cytokine, implicated in both. The aim of this study was to quantify pre and post-operative MK levels in cardiac-bypass patients, and to identify any association with degree of cardiac-surgery associated acute kidney injury (CSA-AKI).

Methods: Stored samples of plasma and urine from a trial cohort of cardiac-surgery patients (Sodium Bicarbonate to reduce Cardiac Surgery Associate Acute Kidney Injury: A Phase ll Multi-centre, Double-blind, Randomized Controlled Trial.2013. Mcguiness et al. Crit Care Med 41(7) 1599), from before, immediately after, and the morning after surgery were obtained. Samples were assayed for MK levels using a commercially available validated MK-ELISA kit (Cellmid Ltd, Sydney, Australia). Plasma and urine had been stored at -70ºC. CSA-AKI was defined as an increase in plasma creatinine concentration greater than 25% from baseline to peak within 5 days of bypass.

Results: Sixty patients were selected. Plasma MK levels significantly increased in most patients immediately post-operative and fell on day 1 ($p<0.001$). Urine MK significantly increased from baseline on day 1 ($p=0.008$). Patients were evenly divided into 3 AKI groups: a <25% increase in creatinine (non-AKI controls), an increase 25-50%, and an increase of >50%. The plasma MK levels immediately post surgery and on day 1 correlated with those most severely affected (a >50% increase, $p=0.04$), but not over all degrees of AKI($p=0.14$). There was no correlation with urine MK levels and AKI.

Conclusions: The results of this study do not suggest a role of plasma and/or urine MK levels for predicting all degrees of CSA-AKI, but there is an association with the most severe CSA-AKI, and with cardiac bypass surgery itself, which warrant further exploration.

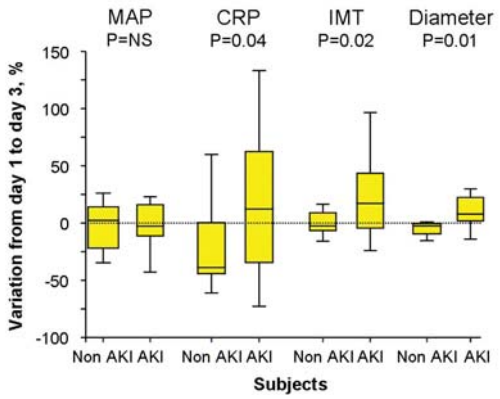
Echotracking System and Bioelectrical Impedence Analysis Parameters Link to Acute Kidney Injury in Critical Ill Patients Paolo Lentini,[1] Luca Zanoli,[2] Massimo de Cal,[1] Stefania Rastelli,[2] Anna Basso,[1] Andrea Contestabile,[1] Antonio Granata,[3] Roberto Dell'Aquila.[1] *[1]Nephrology, S. Bassiano Hospital, Bassano Del Grappa, Italy; [2]Internal Medicine, Univ of Catania, Catania, Italy; [3]Nephrology, S: Giovanni di Dio Hospital, Italy.*

Background: Acute Kidney Injury (AKI) in the Intensive Care Unit (ICU) is a risk factor for mortality. Echotracking is the reference system for the non-invasive measure of arterial parameters, including intima-medial thickness (IMT), an independent predictor for cardiovascular events, and arterial diameter. Arterial wall thickness has been widely considered a structural vascular characteristic that changes slowly over years. However, acute changes in vascular smooth muscle tone and several cytokines may theoretically alter arterial wall thickness. Little is known about these changes in AKI. Bioelectrical impedance analysis(BIA) has been used to manage volume in chronic hemodialysis patients (pts) for decades: however, the use of BIA in ICU has not been extensively studied. We aimed to assess if pts that are developing AKI have parallel alterations of arterial structure and fluid overload.

Methods: Case-control study. 17 pts with AKI and 17 without AKI (age76±13yrs, 44% males) matched for baseline C-reactive protein (CRP) were selected and followed for three consecutive days. Arterial parameters were measured with an Echotracking system device using a 13MHz probe. BIA was performed with a multifrequency device to evaluate the hydration status.

Results: Reasons for ICU admission, age, SAPS II, SOFA and APACHE II were similar between cases and controls. During follow-up CRP, IMT and carotid diameter increased significantly in AKI, suggesting that inflammation may alter acutely arterial structure in AKI. At baseline AKI pts have a significant hyperhydration.



Conclusions: Inflammation, IMT, diameter and BIA are associated with AKI in ICU pts.

TH-PO109

Urinary L-Type Fatty Acid-Binding Protein Can Predict Long-Term Renal Outcome in the ICU Patients Rei Isshiki,[1] Kent Doi,[1,2] Maki Sumida,[1] Yoshifumi Hamasaki,[1] Naoki Yahagi,[2] Masaomi Nangaku,[1] Takeshi Sugaya,[3] Eisei Noiri.[1] *[1]Nephrology and Endcrinology, Univ of Tokyo, Tokyo, Japan; [2]Emergency and Critical Care Medicine, Univ of Tokyo, Tokyo, Japan; [3]CMIC Co., Ltd., Tokyo, Japan.*

Background: Although AKI was previously considered to be reversible, recent studies have suggested that AKI will increase the risk of CKD development/progression. However, it remains unclear whether any biomarker can predict progressive CKD in AKI survivors. This study evaluated the performance of urinary biomarkers for long-term renal outcome prediction in ICU population.

Methods: We prospectively enrolled 495 adult patients who had been admitted to the ICU of the University of Tokyo Hospital. We measured three urinary biomarkers at ICU admission; L-type fatty acid-binding protein (L-FABP), neutrophil gelatinase-associated lipocalin (NGAL), and N-acetyl-β-D-glucosaminidase (NAG). Serum creatinine(sCr) values within 7 days after ICU admission were used for AKI diagnosis. Patients were followed up for three years after ICU discharge and long-term renal outcomes of halving of eGFR or incident end-stage renal disease were evaluated.

Results: Of 495 patients, 169 patients (34.1 %) could be followed up for 3 years after ICU discharge. Among them, 30 patients (17.8 %) showed progression of renal dysfunction. Compared with the non-progressors, the progressors had a significantly higher rate of AKI during ICU stay (90.0% versus 40.3%; $p<0.0001$). L-FABP and NGAL level were significantly higher in the progressors (L-FABP 110.45 versus 21.4 μg/gCre; $p=0.0014$ NGAL 215.5 versus 45.0 μg/gCre; $p=0.0017$), but NAG level was not significantly different ($p=0.62$). A step-wise multiple logistic regression analysis revealed baseline eGFR

before ICU admission, sCr increase during ICU stay, and L-FABP at ICU admission were significantly associated with progression of renal dysfunction after ICU discharge (Hazard ratio 1.53; 95% CI 1.02-2.32; p=0.038). ROC analysis demonstrated L-FABP could predict progression of renal dysfunction after ICU discharge with statistical significance (AUC-ROC 0.69 [95%CI 0.57-0.78]).

Conclusions: Measurement of urinary L-FABP at ICU admission will be useful for predicting long-term renal function after ICU discharge.

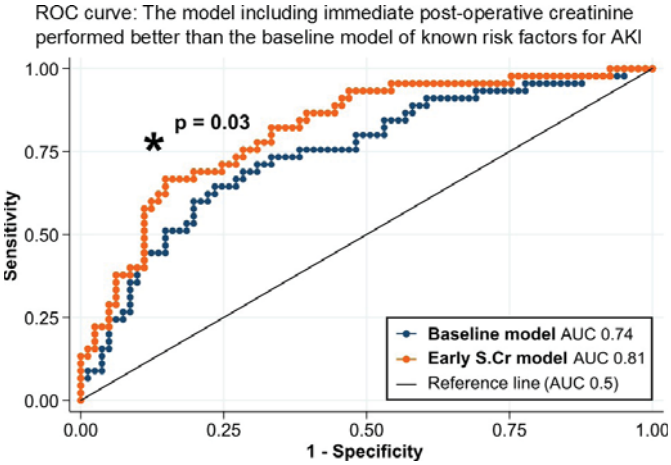
TH-PO110

Serum Creatinine Predicts Acute Kidney Injury Immediately following Cardiac Surgery Shaun Michael Hutchinson,[1] Kevan Polkinghorne,[1,2] Stephen R. Holdsworth,[1,2] Shaun A. Summers.[1,2] *[1]School of Clinical Sciences, Monash Univ, Melbourne, Victoria, Australia; [2]Dept of Nephrology, Monash Medical Centre, Melbourne, Victoria, Australia.*

Background: AKI commonly complicates cardiac surgery, affecting up to 42% of patients post-operatively. It causes significant morbidity, mortality and increased length of stay. New predictive markers are not widely available for clinical use. We aimed to investigate whether serum creatinine may predict later AKI in the early post-operative period following cardiac surgery.

Methods: We prospectively studied 127 patients who underwent cardiac surgery at Monash Medical Centre between February and July 2013. Baseline and post-operative clinical data including creatinine values were obtained. The predictor was serum creatinine taken within 15 minutes of arrival to intensive care following surgery. The primary outcome was development of AKI within 7 days of surgery.

Results:



46 patients (36.2%) developed AKI in the study. In univariate analysis, patients who developed AKI were more likely to be older (OR 1.06 per year increase, p=0.004), have higher BMI (OR 1.14 per 1kg/m^2 increase, p=0.002), poorer pre-operative renal function (OR 1.03 per 1µmol/L increase, p=0.002) and have undergone mixed procedures (coronary artery bypass plus another procedure) (OR 4.21, p=0.007). Immediate post-operative creatinine was independently associated with AKI (OR 1.2 per 5µmol/L increase, p<0.001). In multivariate logistic regression analysis, the predictive model including early creatinine was a better discriminator than the baseline model of known risk factors (AUC 0.81 versus 0.72, p=0.03).

Conclusions: Early serum creatinine is a cheap, readily available test which may help to predict AKI in patients having cardiac surgery, in combination with other known clinical risk factors. This finding could allow more accurate early risk stratification, enhancing decision-making and patient outcomes.

TH-PO111

Paraquat Induced Proteinuria Amplifies Renal Biomarker Excretion and Increases Biomarker Diagnostic Thresholds Fahim Mohamed, Nicholas Buckley, John W. Pickering, Klintean Wunnapuk, Philip Peake, Zoltan H. Endre. *Nephrology, PoW Hospital, Sydney, Australia.*

Background: Paraquat (PQ)-induced nephrotoxicity is a major problem in rural Asia. AKI biomarkers (BM) may provide early diagnosis for initiation of treatment since dialysis availability is limited. Our initial observations of significant proteinuria in this population prompted both pre-clinical and clinical studies of the effect of proteinuria on novel biomarker cut-offs for AKI diagnosis and prediction of outcome.

Methods: Male Wistar rats (6 rats per dose group) were gavaged with paraquat dichloride (dose; 15, 30, 60 and 90 mg/kg). Controls were gavaged with water. Urine and blood samples were collected at regular intervals. In an additional clinical study, all consenting patients who presented to 5 adult medical units following acute PQ self-poisoning were similarly monitored until discharge. BM concentrations were quantified using ELISA and Bio-Plex assays and correlated (Spearman rank-order correlation) with urinary albumin.

Results: A dose-dependent increase in urinary albumin excretion was observed in PQ treated rats. Increased albumin excretion was associated with increased excretion of urinary CysC (r=0.9, p<0.0001), NGAL (r=0.7, p<0.0001), β2-microglobulin (β2M) (r=0.7, p<0.001) and KIM-1 (r=0.6, p<0.01). A moderate correlation (r=0.3) was also observed between urinary osteopontin (OstP) and clusterin (Clu). Following PQ ingestion, 34 of 50 patients had albuminuria [albumin creatinine ratio (ACR) ≥30 mg/g], which increased with AKI severity. In patients with albuminuria, BM concentration was higher (p<0.001) for urinary NGAL, CysC, Clu, β2M, KIM-1 and OstP; a good correlation with ACR was observed for all BMs (r>0.6, p<0.01). BM cut-offs for prediction of death were higher in the albuminuric group.

Conclusions: Proteinuria increases excretion of most low-molecular weight protein BMs following paraquat poisoning irrespective of origin. Diagnostic cut-offs for AKI BMs and for outcome prediction must be modified in the presence of albuminuria.

Funding: Government Support - Non-U.S.

TH-PO112

Urinary Cystatin C, Clusterin and NGAL Are Early Predictors of Acute Kidney Injury (AKI) after Paraquat Poisoning Fahim Mohamed, Nicholas Buckley, John W. Pickering, Philip Peake, Zoltan H. Endre. *Nephrology, PoW Hospital, Sydney, Australia.*

Background: AKI is common following self-poisoning with the herbicide paraquat. We have observed that serum creatinine increases independently of GFR after paraquat poisoning. This study prospectively compared the diagnostic performance of serum creatinine with the panel of novel biomarkers proposed by the Predictive Safety Testing Consortium for the early diagnosis of nephrotoxic AKI (ToxAKI).

Methods: Consenting patients were recruited following paraquat ingestion. Serial blood and urine samples were collected at a regular intervals until discharge or death. The AKIN criteria were used for AKI diagnosis and staging.

Results: Of patients who provided more than two samples (n=50), 38 patients (76%) developed AKI [stage I (n=12), II (n=7) and III (n=19)] and of these most died (n=12) within 48 hours of ingestion. Urinary cystatin C (uCysC), clusterin (uClu) and NGAL levels increased many folds (p<0.01) between 16-24 hours post ingestion compared to patients who did not develop AKI and to healthy controls. Each biomarker showed good diagnostic performance [AUC-ROC for uCysC 0.79 (95% CI 0.62-0.96), uNGAL 0.79 (0.65-0.92), uClu 0.68 (0.48-0.88)], for diagnosis of AKI at 16-24 hours post ingestion. Diagnostic performance improved when biomarker levels were normalised to urinary creatinine concentration. Increases amongst these biomarkers were positively correlated with serum creatinine (r=0.6 for uCysC, 0.5 for uNGAL and uClu) and negatively correlated with creatinine clearance (r=-0.7 for uCysC, -0.3 for uNGAL, -0.6 for uClu). This study also determined the biomarker cut-off values (in ng/ml) with 70% sensitivity and 70% specificity for detecting AKI (uCysC >46, uNGAL > 25, uClu >280).

Conclusions: Many-fold increases in uCysC, uNGAL and uClu within 24 hours of poisoning confirmed paraquat induces tubular injury and can be used to detect AKI early. This could guide early intervention for reno-protection. Point-of-care biomarker analysis may accelerate early intervention in these settings.

Funding: Government Support - Non-U.S.

Impact Analysis of Prognostic Factors in Patients with Paraquat Poisoning and Discussion of the Treatment Options From One Single Center in China Jianghua Chen, Ying Xu, Jingyun Le. *The kidney Disease Center, the First Affiliated Hospital, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: To analyze the prognostic factors and discuss treatment options in order to decrease the mortality rate in paraquat poisoning patients.

Methods: 148 cases of paraquat poisoning patients from June 2010 to March 2014 in our hospital were enrolled. The general situation (gender, age), clinical data (dose of paraquat poisoning, interval from poisoning to treatment), laboratory parameters (blood oxygen, serum creatinine level, glomerular filtration rate) and treatment regimen (gastric lavage, total dose of cyclophosphamide, total dose of methylprednisolone, frequency of blood perfusion) were retrospectively analyzed.

Results: Of the 148 cases of paraquat poisoning patients, 85 cases survived and 63 cases died, the survival rate was 57.4%. All cases were divided into the survival group and the death group. There were no statistical differences in gender and age between two groups. The paraquat ingestion dose was lower in the survival group [(14.77 ± 18.9) mmHg] than the death group [(41.00 ± 36.1) mmHg] (p <0.05). The serum creatinine level and glomerular filtration rate in admission had statistically significant differences. [(85.05 ± 75.9) µmol/L and (116.80 ± 47.6) ml/min in survival group, (172.72 ± 182.8) µmol/L and (49.37 ± 52.3) ml/min in death group (p <0.05)]. The total dose of methylprednisolone therapy in the survival group (1.85 ± 1.37) g was significantly higher than the death group (1.35 ± 1.14) g (p<0.05). The gastric lavage or not, total dose of cyclophosphamide treatment and frequency of blood perfusion had no significant differences between two groups. (p> 0.05).

Conclusions: This study found that paraquat ingestion dose, renal function in admission and total dose of methylprednisolone were important factors affecting the prognosis of paraquat poisoning patients, high-dose of methylprednisolone therapy can significantly improve survival, the impact on prognosis of cyclophosphamide and hemoperfusion therapy are still pending further investigation.

Delta Neutrophil Index Is an Independent Predictor of Mortality in Patients with Septic Acute Kidney Injury Requiring Continuous Renal Replacement Therapy

Young Su Joo,[1] Seonghun Kim,[2] Mi Jung Lee,[1] Hyung Jung Oh,[1] Jung Tak Park,[1] Seung Hyeok Han,[1] Tae-Hyun Yoo,[1] Shin-Wook Kang.[1] *[1]Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea; [2]Brain Korea 21 PLUS, Severance Biomedical Science Inst, Yonsei Univ, Seoul, Korea.*

Background: Delta neutrophil index (DNI), defined as the fraction of circulating immature granulocytes, is known to increase in infectious and/or septic conditions. In this study, we investigated whether DNI had a predictive value for mortality in patients with septic acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT).

Methods: A total of 285 patients with septic AKI, who were treated with CRRT at Yonsei University Health System between August 2009 and September 2012, were included. The patients were dichotomized into 'high' and 'low' DNI groups based on the cut-off value from receiver operating characteristics curve of DNI at the time of CRRT initiation. Log-rank test and Cox proportional hazards analysis were conducted to ascertain the prognostic value of DNI for 28-day all-cause mortality.

Results: The mean age was 61.0 ± 14.7 years and 180 patients (63.2%) were male. The high DNI group (DNI > 5.6%) was composed of 149 patients (52.3%). During the study period, 192 patients (67.1%) died. 28-day mortality rates were significantly higher in the high DNI group compared to the low DNI group (79.9% versus 53.3%, P <0.01) (log-rank test, P <0.01). In multivariate Cox proportional hazard analysis, DNI at the time of CRRT initiation was found to be an independent predictor of 28-day all-cause mortality after adjustment for age, gender, mean arterial blood pressure, hemoglobin, platelet, serum albumin levels, PT, aPTT, and APACHE II and SOFA scores (per 1% increase, hazard ratio = 1.010, 95% confidence interval = 1.001-1.019, P = 0.035).

Conclusions: DNI at the time of CRRT initiation may be a useful predictor of mortality in septic AKI patients requiring CRRT.

TH-PO115

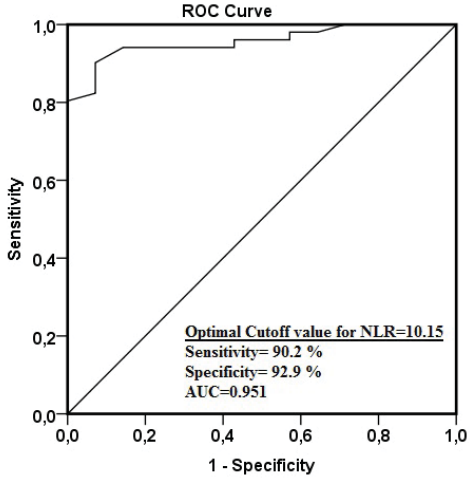
Can Neutrophil-Lymphocyte Ratio Be Independent Risk Factor for Predicting Acute Kidney Injury in Patients with Severe Sepsis?

Hakki Yilmaz,[1] Osman Inan,[2] Ayse Mukadder Bilgic,[1] Nuket Bavbek,[1] Ali Akcay.[1] *[1]Internal Medicine, Section of Nephrology, Turgut Ozal Univ, School of Medicine, Ankara, Turkey; [2]Internal Medicine, Yenimahalle State Hospital, Ankara, Turkey.*

Background: Neutrophil-Lymphocyte Ratio (NLR) is an easily calculated, sensitive, and accurate marker for prognosis and diagnosing sepsis, cardiovascular disease and cancer. As sepsis and septic shock are main causes of acute kidney injury (AKI) intensive care unit (ICU), we investigated whether NLR is an early predictor of AKI in patients with severe sepsis. We compared NLR's predictive power with that of other inflammation-related variables.

Methods: Between December 2011 and November 2013, we enrolled 118 consecutive cases with severe sepsis admitted to ICU in this retrospective study. Levels of C-reactive protein (CRP), NLR, and white blood cell count (WBC) were recorded on admission and patients' renal function was monitored for 7 consecutive days.

Results: The rate of AKI occurrence 7 days after enrollment was 57.6%. NLR levels were higher in the AKI group (Group 1) than in the non-AKI group (Group 2) on the day of ICU admission (p<0.001). AKI development was independently associated with NLR, APACHE II and duration of invasive mechanical ventilation in multivariate logistic regression analysis. The area under the receiver-operating characteristic (ROC) curve of NLR for predicting AKI was 0.951, which was superior to WBC and CRP (p<0.05). The cut-off value of 10.15 for NLR had the highest validity for predicting AKI in patients with severe sepsis. The sensitivity, specificity, negative-predictive value (NPV), positive-predictive value (PPV), for this cut-off value were 90.2%, 92.9%, 90.4%, 92.7%, respectively.



Conclusions: NLR is superior to CRP, and WBC for predicting the development of AKI in patients with severe sepsis.

TH-PO116

Diagnostic Accuracy of Urinary Neutrophil Gelatinase Associated Lipocalin (uNGAL) for the Early Detection of Contrast Induced Nephropathy – The ANTI-CIN Study

Werner Ribitsch, Gernot Schilcher, Franz Quehenberger, Stefan Pilz, Rupert H. Portugaller, Martie Truschnig-Wilders, Robert Zweiker, Marianne Brodmann, Alexander R. Rosenkranz, Joerg H. Horina. *Medical Univ of Graz, Graz, Austria.*

Background: In the ANTI-CIN Study (clinicaltrials.gov NCT01292317) we tested the diagnostic accuracy of uNGAL as an early biomarker of contrast induced nephropathy (CIN) and investigated whether patients with an early rise of NGAL benefit from an intensified volume expansion with regard to CIN incidence.

Methods: We conducted a prospective randomized trial on patients with an eGFR < 70ml/min undergoing intraarterial angiography. All subjects received 12ml/kgBW NaCl 0.9% pre-interventionally. NGAL(ARCHITECT® NGAL Test, Abbott Laboratories,U.S.) was measured the day before and 4-6hrs after angiography. In the event of a significant rise of uNGAL(uNGAL > 150ng/ml if baseline was < 75ng/ml, otherwise a doubling of uNGAL) patients were randomized into two groups. Group A received 22ml/kgBW NaCl 0.9%, Group B did not receive any i.v. fluids. Both groups had an unrestricted oral fluid intake. CIN was defined according to a ≥ 25% increase of creatinine from baseline to either 24hrs or 48hrs after angiography.

Results: We studied 617 (287 female) patients with a mean eGFR of 48.7±12.7ml/min. Ten patients(1.62%) exhibited a significant rise of uNGAL from 84ng/ml(47-226ng/ml) at day -1 to 423 ng/ml (189-1121ng/ml) 4-6hrs after angiography.The incidence of CIN was 9.4%(58 patiens) in the entire cohort and 10%(1 patient) among the subgroup with a rise of uNGAL resulting in a specificity of 0,98 and a sensitivity of 0,017 of uNGAL for the diagnosis of CIN.

	No CIN (n=559)	CIN (n=58)	p
Age (yrs)	74 (37-91)	76 (52-89)	n.s.
Creatinine d_{-1} (mg/dl)	1.38±0.42	1.19±0.27	<0.001
Creatinine d_1 (mg/dl)	1.28±0.39	1.47±0.39	<0.001
Creatinine d_2 (mg(dl)	1.32±0.40	1.58±0.53	<0.001
uNGAL d_{-1} (ng/ml)	19 (0.5-2035)	18 (2-396)	n.s.
uNGAL d_0 (ng/ml)	11 (0.5-1298)	13 (0.5-480)	n.s.

Conclusions: A significant rise of uNGAL shortly after angiography does not facilitate an early recognition of CIN in patients with impaired kidney function.

Membrane Attack Complex (MAC) Staining in Acute Kidney Injury

Eva Rodriguez,[1] Javier Gimeno,[2] Maria Jose Soler,[1] Judit Rigol,[1] Marta Riera,[1] Julio Pascual.[1] *[1]Nephrology, Parc de Salut Mar-IMIM, Barcelona, Spain; [2]Pathology, Parc de Salut Mar-IMIM, Barcelona, Spain.*

Background: There is growing evidence that the complement pathway is involved in the pathophysiology of several kidney diseases, like haemolytic-uremic syndrome, experimental models of membranous nephropaty and murine models of ischemia-reperfusion. The final component of the complement system is the membrane attack complex (MAC or C5b-C9). The role of MAC is to settle on the tubular membrane surface causing a direct cel·lular lytic effect. The aim of this study is to test if the complement system is activated in acute kidney injury (AKI), through deposition of MAC in proximal tubules (PT) and medullary collecting tubules (MCT).

Methods: Immunohistochemical staining for MAC (1:50, anti-Human terminal complement complex, Hycult Biotech©) was performed in paraffin embedded renal tissue obtained from autopsies. We evaluated the percentage of the stained tubules (0-49%, 50-100%), the perimeter of the stained tubules (0-49%, 50-100%) and the intensity of the staining (0-49%, 50-100%) in either the proximal cortical tubules (PT) and the medullary collecting tubules (MCT) per high power field (HPF),comparing between samples of patients who died presenting normal renal function and those with AKI, considering the plasmatic creatinine criteria at least 3 days before the death.

Results: 32 samples were evaluated, 21 of them (65%) had AKI and 11 of them (35%) had normal renal function. The percentage of MAC-stained PT, the perimeter stained and the intensity of their staining were significantly higher in AKI-patients when compared with those without AKI (65.6% versus 34.4%, respectively, p<0,001). In MCT we found similar results, the percentage of MAC-stained MCT, the perimeter stained and the intensity of their staining were significant higher in AKI-patients when compared with those without AKI (65.6% versus 34.4%, p< 0,001).

Conclusions: Our data showed that complement system is activated in AKI and could play a role in the physiopathology of the acute tubular injury.

TH-PO118

Alternative Complement Components as Predictors of Acute Kidney Injury Risk Michael Merchant,[1] Michael E. Brier,[1] Emily F. Anggelis,[1] Jon B. Klein,[1,2] Kenneth R. McLeish.[1,2] *[1]Medicine, Univ of Louisville, Louisville, KY; [2]Robley Rex VAMC, Louisville, KY.*

Background: Acute kidney injury (AKI) contributes to the morbidity and mortality of post-surgical and critically ill patients. The ability to intervene is limited by the availability of biomarkers that identify patients likely to develop AKI. The current study used patients undergoing cardiac surgery to test the hypothesis that the urine proteome contains surrogate biomarkers that identify patients at risk for post-surgery AKI.

Methods: Urine was obtained prior to cardiac surgery from patients at increased risk of developing AKI based on clinical criteria, and patients were followed for 48 hr post-surgery. AKI was defined as a 0.5 mg/dl increase in serum creatinine above baseline. Urine proteins were isolated from 16 patient samples (n=7 without AKI (AKI-neg) and n=9 with AKI (AKI-pos), trypsinized and analyzed by 2D-LCMS. Spectral count data were compared as an unlabeled quantitative approach using t-test examining the direction and magnitude difference in expression. Analysis of regulated proteins was performed using Ingenuity™ Pathway Analysis.

Results: Of 599 proteins identified, 15 were more abundant in the AKI-neg group and 24 were more abundant in AKI-pos group. These proteins could be sub-grouped into markers of (1) tubular injury (haptoglobin, complement components C3, C9, Factor B), (2) previously described biomarkers of established AKI (angiotensinogen, alpha1-microglobulin) and (3) novel markers (histidine rich glycoprotein, afamin, corticosteroid-binding globulin). Ingenuity™ Pathway Analysis of protein groupings identified members of the alternative complement pathway as strongly regulated in patients that later developed AKI.

Conclusions: Alternative complement pathway components are highly expressed in the urine of patients that developed AKI following cardiac surgery. The data suggest that the urine contains proteins that identify patients at risk of developing AKI.

Prognostic Value of Presepsin in Predicting Adverse Renal Outcomes and Death in Cardiosurgical Patients Maria Jimena Mucino-Bermejo, Grazia Maria Virzì, Alessandra Brocca, Davide Giavarina, Tommaso Hinna Danesi, Claudio Ronco. *IRRIV-S Bortolo Hosp.*

Background: Accurate evaluation of surgical risk is crucial to clinical decision-making in cardiosurgical (CCH) patients (pts). In a large number of clinical scenarios, biomarkers are reliable tools in stratifying morbidity and mortality risk. As a biomarker presepsin is used in acute care settings, in order to distinguish between sepsis due to bacterial infections and Systemic Inflammatory Response due to non-bacterial cause and has been reported to be useful for stratifying mortality risk among septic pts in the ICU and may also be helpful to predict infective-related morbidity and mortality in different clinical settings, including cardiosurgery. The main aim of this study is to assess the usefulness of presepsin in predicting adverse outcomes among CCH pts.

Methods: Observational single center study that includes 122 adult CCH pts (83 male, 66.4±11.2 yrs). Presepsin was dosed by the PATHFAST Immunoanalyzer system. Procalcitonin quantitative analysis was performed using BRAHMS PCT sensitive KRYPTOR.

Results: We observed that presespin is a better predictor of inhospital, 30-day and global mortality than procalcitonin. ($p<0.05$) Patients with worse renal outcome (defined as AKI, change on CKD stage or need for CRRT) have significantly higher presepsin levels. ($p<0.005$).

Conclusions: Presepsin levels correlate with the risk of death better than procalcitonin. Higher presepsin levels are associated with adverse renal outcomes. Presepsin may be a reliable biomarker for stratifying renal and mortality risk among CCH pts.

TH-PO120

Serum Cystatin C Is a Predictor of Long-Term Outcomes of Critically Ill Patines with Acute Kidney Injury Karina Soto,[1,4] Liliana Maria Goncalves Cunha,[1] Iola Pinto,[2] Alberto Ortiz,[3] Ana Luisa Papoila.[4] *[1]Hospital Fernando Fonseca; [2]ISEL; [3]Fundacion Jimez Diaz, Spain; [4]Univ Nova de Lisboa, Portugal.*

Background: Outcomes following Acute Kidney Injury (AKI) in intensive care unit (ICU) and prognostic markers are poorly known. We explored longterm kidney and patient outcomes and the prognostic value of serum Cystatin C (SCysC) following AKI.

Methods: Prospective study of 128 consecutive ICU adults. Serum creatinine (SCr) and SCysC were measured daily up to discharge. Kidney function and mortality followed up to 4y. Statistical analysis: Friedman's; Cochran's Q; Kruskal-Wallis; Chi-Square and Fisher's tests. Odds ratios by logistic regression model.

Results: 20% (26) of patients died in ICU (85% had AKI) and 2.3% at hospital discharge. Overall mortality was 44.5%, higher in AKI than in no-AKI ($p<0.001$). At 2y (92), 31.5% were AKI, 47% normal function (NF); 19% Transitory Azotemia (TAz) and 3.3 % stable CKD. 36 % of AKI patients needed RRT and 23% became RRT-dependent. During follow-up 7,6% new patients needed RRT for ESRD (86% AKI); and CKD => stage III developed in 65.5% of AKI patients; 23.5% in TAz and 11.6 % in NF groups $p<0.001$. CKD proportion increased during follow-up $p<0.001$. CKD rates were 60% at discharge; 65% at 2y; and 83% at 4y in AKI patients compared with no-AKI patients 4.0%;17.5%; 20.6%; respectively ($p<0.001$). AKI patients lost more kidney function than non-AKI patients $p<0.001$. KDIGO CKD stage =>1 was determinant of CKD progression (OR 7.3 (2.8-19.3) p=<0.001). Odds increase with severity. Daily SCysC were associated with CKD progression; OR 7.3 (2.9-17.8) p=<0.001. Variables which determined CKD were: Age (OR 1.06); CVD (OR 4.55); Shock (OR 4.9), MOF (OR 4.76), prior CKD and comorbidities (OR 17), all p<0,05. Multivariable logistic regression: prior CKD; daily SCysC and SCr desviation (baseline - discharge SCr) were predictors of CKD (OR 4.4; 3.4; and 3.5; p<0,005; HLS=0.598; ROC 0.88; $p<0.001$). Odds for mortality was 6.3 for AKI and 2.9 for SCysC $p<0.001$.

Conclusions: Patients with one episode of AKI have significantly lower long-term survival rates and higher incidence of CKD than critically ill patients with no AKI. SCysC was a determinant for CKD and death.

TH-PO121

Troponin I Serum Levels Predict the Need of Dialysis in Incident Sepsis Patients in the Intensive Care Unit Miguel Luis Graciano,[1] Daniel Almeida Thiengo,[1] Jocemir R. Lugon.[1] *[1]Clinical Medicine, Univ Federal Fluminense, Niteroi, RJ, Brazil; [2]Clinical Medicine, Univ Federal Fluminense, Niteroi, RJ, Brazil; [3]Clinical Medicine, Univ Federal Fluminense, Niteroi, RJ, Brazil.*

Background: Sepsis, an extremely prevalent condition in the intensive care unit, is usually associated with organ dysfunction, which can commonly affect the heart and the kidney. A crosstalk between these organs has already been reported in a number of circumstances.

Methods: This prospective study aimed to determine whether the cardiac dysfunction in sepsis patients predicts the occurrence of acute renal failure. Cardiac dysfunction was assessed by transthoracic echocardiography and serum troponin I levels and renal impairment by AKIN criteria and the need of dialysis. Twenty-nine patients with incident sepsis without previous cardiac or renal dysfunction were enrolled.

Results: Patients averaged 75.3±17.3 years old and 55% were male. Median APACHE II severity score at ICU admission was 16 (9.7 - 24.2) and mortality rate in 30 days was 45%. On the fifth day, 59% had ventricular dysfunction. Troponin serum levels on day 1 in the affected patients were 1.02±0.6 ng/mL compared with 0.23±0.18 ng/mL in patients without heart dysfunction (P=0.01). Eighteen out of 29 patients (62%) underwent renal replacement therapy (RRT) and the percent of patients with ventricular dysfunction who required dialysis was higher (94% versus 16%, P=0.0001). Values of troponin at day 1 were used to develop a ROC curve to determine their ability to predict the need of dialysis. The area under the curve was 0.89 and the cutoff value was 0.4 ng/mL.

Conclusions: In conclusion, we found that an elevation in serum troponin levels, while guarding a relationship with ventricular dysfunction, can be a precious tool to predict the need for dialysis in sepsis patients.

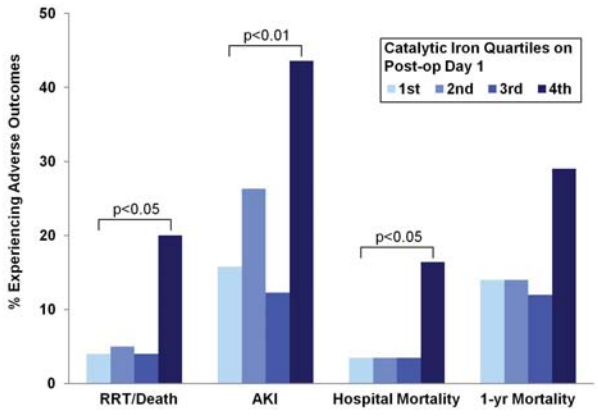
Plasma Catalytic Iron, Acute Kidney Injury, and Death following Cardiac Surgery David E. Leaf, Sushrut S. Waikar. *Div of Renal Medicine, Brigham and Women's Hospital.*

Background: Catalytic iron, the chemical form of iron capable of participating in redox cycling, has been shown to be a key mediator of AKI in multiple animal models. In humans, the role of elevated plasma catalytic iron levels in AKI has not been studied.

Methods: We performed a prospective cohort study of 250 patients who underwent cardiac surgery. Plasma catalytic iron, free hemoglobin, and other iron markers were measured at four time points (preoperatively, end of cardiopulmonary bypass, and on postoperative days 1 and 3). The primary outcome was AKI requiring renal replacement therapy or in-hospital mortality (RRT/death). Secondary outcomes included AKI, hospital mortality, postoperative myocardial injury, and postoperative vasopressor requirement.

Results: Plasma catalytic iron levels (but not other iron markers) rose significantly at the end of cardiopulmonary bypass [median (IQR) 1.1 (0.7-1.6) compared to 0.4 (0.3-0.4) µmol/L pre-operatively, $p<0.001$] and were directly associated with bypass time ($p<0.001$) and number of pRBC transfusions ($p<0.01$). In multivariate analyses adjusting for age and pre-operative renal function, patients in the highest compared to lowest quartile of catalytic iron on postoperative day 1 had a 6.71 (1.37-32.87) greater odds of RRT/death, and also had greater odds of AKI, hospital mortality, postoperative myocardial injury, and post-operative vasopressor requirement.



Conclusions: These data are consistent with and expand on the findings from animal models demonstrating a pathologic role of catalytic iron in mediating adverse renal outcomes. Interventions aimed at reducing plasma catalytic iron levels in humans as a strategy for preventing AKI are warranted.

Serum Kidney Injury Molecule-1 Levels in Acute Kidney Injury

Josee Bouchard,[1,2] Rakesh Malhotra,[2] Ashita J. Tolwani,[3] Ravindra L. Mehta.[2]
[1]Hopital du Sacre-Coeur de Montreal, Canada; [2]Univ of California San Diego; [3]Univ of Alabama at Birmingham.

Background: Urine Kidney Injury Molecule-1 (KIM-1) is a well-known marker in clinical acute kidney injury (AKI). However, there are limited data on serum KIM-1 levels in AKI. We hypothesized that serum KIM-1 levels can also predict AKI.

Methods: We conducted a prospective, multicenter observational study to evaluate the role of urine and serum KIM-1 levels as early biomarkers for AKI in critically ill patients. AKI was defined according to the AKIN serum creatinine criterion. Samples were collected every 12 hours after intensive care unit (ICU) admission for a ≥48 hours and up to 10 days.

Results: From the 80 patients enrolled, 18 developed AKI after a median of 1.0 (IQR 0 – 2.3) days after ICU admission. Mean serum KIM-1 levels were higher in AKI than in non-AKI patients over the entire ICU stay (2.47±0.42 versus 2.25±0.31,p<0.001) and similar results were obtained for urine KIM-1 (3.27±0.60 versus 2.82±0.56,p<0.001). The area under the curve (AUC) to predict AKI over 7 days using serum and urine log10 KIM-1 levels at ICU admission were 0.68 (95% CI, 0.50-0.87) and 0.75 (95%CI, 0.57-0.93), respectively. Urine KIM-1 levels at ICU admission could predict AKI (OR 4.9 95%CI, 1.2-20.1); however serum KIM-1 levels at ICU admission did not predict AKI. Neither serum nor urine KIM-1 levels at ICU admission could predict mortality and/or renal recovery.

Conclusions: Serum KIM-1 levels may help to predict AKI. Further studies are required to evaluate its role compare to urine KIM-1 in AKI.

Early Prediction of Acute Kidney Injury Severity after Liver Transplantation by Neutrophil Gelatinase-Associated Lipocalin

Camila Lima,[1] Luciana Haddad,[2] Luiz M. Malbouisson,[3] Luiz Augusto Carneiro D'Albuquerque,[2] Etienne Macedo.[1] *[1]Nephrology, Univ of Sao Paulo, Brazil; [2]Gastroinstestinal Surgery, Univ of Sao Paulo, Brazil; [3]Anesthesiology, Univ of Sao Paulo, Brazil.*

Background: In post-liver transplantation, AKI is a frequent complication associated with an increased morbid-mortality rate. We hypothesized that the pattern of NGAL elevation could provide information on the risk of progression of AKI, the need for RRT and mortality.

Methods: We analyzed 32 patients > 18 years undergoing liver transplantation from June 2013- 2014. Urine and blood samples were collected preoperatively before induction of anesthesia, after portal reperfusion, 6, 18, 24 and 48 hours after surgery. AKI diagnosis was based on the sCr KDIGO criterion.

Results: Of 32 patients, 22(69%) developed AKI during the first 7 days after transplantation and 10(31%) needed RRT during the hospital stay. AKI and no–AKI patients had similar urine biochemistry and microscopy during the sample collection period. Plasma NGAL was significantly higher in AKI patients, starting at 6h after portal reperfusion.

Eighteen hours after surgery the AUC for AKI prediction was 0,85. Urinary NGAL was higher in AKI patients starting 18h after surgery, with an AUC of 0,82 to predict AKI at 24h. Six hours after surgery non-survivors had significantly higher PNGAL.

Conclusions: NGAL is a promising biomarker for predicting AKI, the need for RRT and mortality after liver transplantation. Future studies should evaluate whether the clinical use of these biomarkers could improve patient outcomes.

TH-PO125

Utility of Fractional Excretion of Sodium and Urea in Discerning Etiology of Acute Kidney Injury in End-Stage Liver Disease

Gemlyn George,[1] Chitra Punjabi,[1] Imara Dissanayake,[2] Eyob Feyssa.[3] *[1]Internal Medicine, Albert Einstein Medical Center, Philadelphia, PA; [2]Hepatology, Albert Einstein Medical Center, Philadelphia, PA; [3]Nephrology, Albert Einstein Medical Center, Philadelphia, PA.*

Background: Acute kidney injury (AKI) is a common complication in advanced cirrhotics, seen in up to 20% of hospitalized patients. Determining the cause of renal dysfunction, whether due to pre-renal, acute tubular necrosis (ATN), or the hepatorenal syndrome (HRS) is important due to therapeutic and prognostic implications. Traditionally, fractional excretion of sodium (FeNa) <1% has been said to imply tubular integrity and thus favor a pre-renal state or HRS versus ATN. Fractional Excretion of Urea (FeUrea) <35% is used in patients on diuretics to indicate the same. However, there lacks evidence on their use in patients with ESLD. We thus aimed to see these indices were truly of value in predicting the type of AKI in ESLD patients.

Methods: We conducted a 2 year, retrospective study on ESLD patients presenting with a rise in creatinine of 0.3 mg/dL or 1.5 times baseline. AKI was defined as pre-renal, ATN (>72 hours kidney injury despite volume resuscitation with hypovolemic or septic shock preceding the AKI, +/- granular casts), or HRS, as diagnosed per guidelines of the International Ascites Club. We excluded patients with acute liver failure, MPGN or CKD. Urine indices had to be collected within 8 hours of presentation.

Results: We found 130 cases of ESLD patients with AKI, of whom 55 met inclusion criteria. 21 had ATN, the rest were equally divided between prerenal and HRS. 83% (46/55) of all AKI had FeNa<1 % and FeUrea <35%.

	Pre Renal	ATN	HRS
Mean FeNa	0.50	0.48	0.36
With Diuretics	0.49	0.45	041
W/O Diuretics	0.60	0.51	0.31
Mean FeUrea	29.4	18	22.7
With Diuretics	28.1	17.5	24.7
W/O Diuretics	18.7	19.0	20.9

FeNa and FeUrea were almost universally <1% and <35% in ESLD with AKI, even in 90% of ATN cases.

Conclusions: Our study indicates in patients with advanced ESLD, the diagnostic utility of FeNa and FeUrea is probably unreliable. A FeNa and FeUrea of <1% and <35% respectively appears to be the norm in ESLD despite tubular injury, likely secondary to chronic renal hypoperfusion.

TH-PO126

Urinary Exosomal mRNA Analysis for Non-Invasive Diagnosis of Acute Kidney Injury

Satish P. Ramachandrarao,[1] Taku Murakami,[2] Pam R. Taub,[1] Heather M. Patton,[1] Anousone Bounkhoun,[1] Masato Mitsuhashi,[2] Ravindra L. Mehta.[1] *[1]Medicine, O'Brien Center for AKI Research, UC San Diego, San Diego, CA; [2]Research Unit, Hitachi Chemical Research Center, Irvine, CA.*

Background: Acute kidney injury (AKI) is most commonly recognized through changes in serum creatinine (sCr) or urine output. Novel biomarkers such as NGAL or KIM-1 reflect underlying kidney damage in specific sites of nephron however are limited in defining underlying mechanisms of injury. Urinary exosomes and microvesicles (EMV) offer a promising biomarker source to define the underlying pathways contributing to damage as they are released throughout the nephrons by encapsulating the functional cytoplasmic molecules. To discover new AKI biomarkers, we analyzed EMV mRNA in urine of hospitalized patients in different settings.

Methods: Urine samples were obtained from healthy subjects N=6), ICU (N=6), cirrhosis (N=9), or cardiac surgery (N=9) groups. 12 patients developed AKI (based on AKIN sCr criteria; ≥0.3mg/dl in 48 hrs). After initial centrifugation, urine supernatants including ENV were applied to ENV collection tubes, followed by lysis, mRNA isolation, cDNA synthesis using oligo(dT)-immobilized microplate and quantification by real-time PCR. The mRNA data were analyzed further based on AKI diagnosis.

Results: *Among 36 mRNA, Calmodulin 1 (CALM1), Aquaporin 2 (AQP2) and Osteopontin (SPP1) were dysregulated in AKI patients.* Logistic regression analysis was conducted to select the best combinations of genes (up to 4 out of the 36) to diagnose AKI. By ROC analysis, the top formulae include the *above genes frequently and allow diagnosis of AKI among patients with more than 90% specificity and sensitivity.*

Conclusions: Urinary EMV mRNA showed differential expression in patients with AKI regardless of the setting, compared to those without AKI. These initial findings support further development of EMV biomarkers as a non-invasive tool to profile AKI and establish mechanisms of kidney injury.

AKI-Associated Mitochondrial Alterations Revealed by Urine Exosomes in Patients Undergoing Cardiac Surgery

Satish P. Ramachandrarao,[1] Pam R. Taub,[2] Chanthel Kokoy-Mondragon,[1] Minal Patel,[2] Robert K. Naviaux,[3] Ravindra L. Mehta.[1] *[1]Medicine/Nephrology, UCSD, San Diego, CA; [2]Medicine/Cardiology, UCSD, La Jolla, CA; [3]Medicine/Pathology/Pediatrics, UCSD, San Diego, CA.*

Background: Acute Kidney Injury (AKI) occurs in up to 40% of patients undergoing cardiac surgery (CS) and is currently recognized through changes in serum creatinine (sCr) or urine output (UO). Novel biomarkers of kidney damage e.g. NGAL and KIM-1 provide earlier diagnosis but are limited in identifying underlying injury mechanisms. Urinary exosomes are bioactive nanoparticles of 10-400 nm diameter released by renal tubule cells that encapsulate cellular content that can be studied to identify underlying cellular processes. We hypothesized that urinary exosomal proteins would be qualitatively and quantitatively different in patients developing AKI post CS in comparison to those without AKI.

Methods: Urine exosomes were isolated from12 subjects undergoing CS at different time points (pre surgery and at 2, 6, 12, 24 and 48 hrs after CS with normal kidney function (N=6); and cardiac surgery subjects with documented kidney dysfunction (N=6). 1-dimensional gel electrophoresis and liquid chromatography / tandem mass spec was used to identify proteins and normalized spectral abundance for semi-quantification of proteins. AKI was diagnosed in 6 subjects (AKIN sCr criteria ≥0.3 mg/dl change in 48 hrs).

Results: A total of 1176 urine exosome proteins were identified of which 401 proteins were unique to AKI patients, and 233 proteins were unique to patients that did not develop AKI. Mitochondrial proteins were more prominently expressed in AKI patients in comparison to those without AKI. Furthermore, 16 proteins had more than 10 peptide representations each, and potentially qualified as robust biomarkers tracking AKI in CS. The western blotting validation of the proteomic data is underway.

Conclusions: Urinary exosome protein analysis may be useful to identify unique molecular signatures for CS AKI. Future studies processing serial samples from the AKI and non-AKI subjects should assess the temporal sequence of mitochondrial events after CS and their role in the pathogenesis of CS AKI.

TH-PO128

Urinary Exosome Biomarkers of AKI in Patients with Liver Disease Satish P. Ramachandrarao, Michelle Pearlman, Linda Awdishu, Ravindra L. Mehta, Heather M. Patton. *Medicine, UCSD, San Diego, CA.*

Background: Acute kidney injury (AKI) occurs in 19% of patients with cirrhosis and ascites. Serum creatinine elevation is a poor measure of kidney failure or function in this population. Exosomes are membrane-bound bioactive nanoparticles of 10-400 nm diameter and released by all cell types including renal tubules, and can provide crucial cellular information on kidney health. We hypothesized that urinary exosome protein analysis distinguishes patients with AKI from those without AKI in Liver disease setting.

Methods: Urine exosomes from patients with 1) compensated cirrhosis, 2) decompensated cirrhosis without AKI 3) cirrhosis with AKI, and healthy controls (N=6 each) and their clinical data were collected. 100 micro gm protein equivalent per subject of urinary exosome proteins were resolved by 1d SDS-PAGE, Coomassie stained, in-gel trypsinized, and the trypsinized fragments were subjected to Liquid Chromatography followed by Tandem Mass Spectrometry. The proteins with at least 2 peptides were qualified for subsequent analysis.

Results: 12/16 patients had cirrhosis. Overall, 1573 proteins were identified and the number of unique proteins varied according to patient group. Normal controls had 75 (46%) proteins in common with group 1, patients with decompensated cirrhosis had 99 (63%) proteins in common with group 1, while patients with AKI had only 85 (31%) proteins in common with decompensated cirrhotics with normal kidney function, and only 52 (24%) in common with patients with compensated cirrhosis.

Variable	Group 1	Group 2	Group 3	Control Group
Age (years)	60.1 ± 9.8	57.8 ± 5.7	48.6 ± 7.4	28.7 ± 13
Gender	1 (16.7)	4 (66.7)	5 (83.3)	6 (100)
Child Pugh Turcotte Class A/B/C	6/0/0	0/5/1	0/2/4	N/A
MELD	7.8 ± 2.1	12 ±3.2	24 ± 9.1	N/A

Conclusions: Urinary exosome protein analysis in patients with various stages of cirrhosis with or without AKI identifies pathways unique to AKI in Cirrhosis setting. The quantification analysis of these unique proteins and their relationship to clinical outcomes will help clarify the potential role of this noninvasive test in assessing AKI in cirrhosis patients.

Funding: Other NIH Support - O'Brien Center for AKI Research

TH-PO129

Acute Kidney Injury following Administration of Gadolinium-Based Contrast Agents: Early Detection by Biomarkers Habib Mawad, Louis-Philippe Laurin, Jean-François Naud, François A. Leblond, Vincent Pichette, Martine Leblanc. *Nephrology, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada.*

Background: Gadolinium-based contrast agents have been traditionally used as non-nephrotoxic alternatives to iodinated contrast agents. Their well-established role in nephrogenic systemic fibrosis has limited their use in patients with moderate to severe kidney dysfunction. Recent literature has raised concern regarding their potential nephrotoxicity since cases of acute kidney injury have been reported in patients with normal renal function. The aim of our study was to determine if these agents could induce nephrotoxicity detected by early biomarkers of kidney injury.

Methods: We studied four biomarkers of acute kidney injury: interleukin-18 (IL-18), N-acetyl-glucosaminidase (NAG), neutrophil gelatinase-associated lipocalin (NGAL) and Cystatin C in 28 volunteers with normal renal function after intravenous administration of a gadolinium-based contrast agent. Urinary and serum levels of biomarkers were analyzed at 0, 3 h and 24 h following injection. All urinary biomarkers were normalized for creatinine concentration.

Results: Baseline serum creatinine was 57.8 ± 34.5 µmol/L and remained stable throughout the first 24 h. IL-18 urinary concentrations increased significantly at 3 h (10.66 versus 7.29 ng/mg creatinine; $p < 0.05$). Similarly, urinary NAG levels were significantly higher at 3 h (3.93 versus 2.19 IU/mg creatinine; $p < 0.001$). Serum Cystatin C levels decreased at 3 h from 933.72 to 897.82 ng/mL ($p = 0.0506$). For all three of these markers, the difference was no longer significant at 24 h. No difference was observed at 3 h or 24 h for urinary and serum NGAL levels.

Conclusions: Gadolinium-based contrast agents may cause transient sub-clinical kidney injury shortly after their administration as suggested by significant variations of specific urinary and serum biomarkers in patients with normal kidney function. These results provide new insight about their potential nephrotoxicity.

Peptidylarginine Deiminase-4 Exacerbates Kidney Ischemia and Reperfusion Injury May M. Rabadi, Mihwa Kim, Ahrom Ham, Kevin M. Brown, H. Thomas Lee. *Anesthesiology, Columbia Univ, New York, NY.*

Background: Peptidylarginine deiminase-4 (PAD4)-mediated post-translational conversion of arginine to citrulline is implicated in several inflammatory autoimmune diseases including rheumatoid arthritis and multiple sclerosis. Here, we tested the hypothesis that PAD4 exacerbates acute kidney injury (AKI) by promoting the inflammatory response after renal ischemia reperfusion (IR).

Methods: After IACUC approval, mice were pretreated with vehicle or with a PAD4 inhibitor (2-chloroamidine) before 30 min renal ischemia. Some mice were treated with recombinant PAD4 (rPAD4) before 20 min renal ischemia. In addition, cultured mouse kidney proximal tubule cells were treated with rPAD4 to test whether rPAD4 directly induces renal tubular inflammation. Finally, we performed PAD4 immunohistochemistry in archived kidney specimens from patients subjected to nephrectomy for tumor and from patients subjected to living-related kidney transplantation (Columbia University IRB determined this as non-human subject research).

Results: Renal IR increased PAD4 expression and activity with cytosolic translocation in mouse kidneys. In human kidneys, PAD4 is localized in the nucleus in non-ischemic kidneys whereas kidneys subjected to IR showed cytosolic PAD4 translocation. After 30 min renal IR, vehicle-treated mice developed severe AKI at 24 hr (Cr=2.9±0.2mg/dL, N=5). In contrast, mice pretreated with a PAD4 inhibitor had significantly reduced renal injury (Cr=1.9±0.2mg/dL, N=6, $P<0.05$) with decreased kidney neutrophil chemotactic cytokine (MIP-2, KC) expression and neutrophil infiltration. Furthermore, mice pretreated with rPAD4 and subjected to mild (20 min) renal IR developed exacerbated ischemic AKI (Cr=2.4±0.3mg/dL, N=6) compared to vehicle-treated mice (Cr=0.8±0.2mg/dL, N=6, $P<0.01$) with increased kidney MIP and KC induction and neutrophil infiltration. Finally, cultured mouse kidney proximal tubules treated with rPAD4 had significantly increased MIP-2 and KC mRNA expression.

Conclusions: Our studies suggest that PAD4 plays a critical role in renal IR injury by promoting neutrophil-mediated inflammation. Inhibition of renal tubular PAD4 activity may reduce the morbidity and mortality due to ischemic AKI.

Increased Kidney Injury after Ischemia-Reperfusion in G6PD Deficient Mice Zhihong Yang, Robert C. Stanton. *Vascular Cell Biology, Joslin Diabetes Center, Boston, MA.*

Background: Ischemia/reperfusion (I/R) is a common cause of acute renal failure (ARF). Diabetic patients are at greatly increased risk for I/R induced ARF. Reactive oxygen species (ROS), which are excessively produced during reperfusion, are important mediators of cell damage due to I/R. Glucose-6-phosphate dehydrogenase (G6PD) is an essential antioxidant as it is the main source of the essential reductant, NADPH. Previous work from our lab has shown that G6PD deficient mice have increased renal oxidative stress. And that diabetes leads to decreased G6PD. We hypothesized that G6PD is central to the protection against damage from I/R.

Methods: Wild type and G6PD deficient mice (about 20% of wild type function) were studied. Mice were divided into 4 groups (n=4-7 per group): wild type sham (wt+sham), wild type I/R (wt+I/R), hemi sham (hemi+sham), hemi I/R (hemi+I/R). Renal arteries and veins were clamped for 30 min. After clamp removal, kidneys were observed for a further 5 minutes to ensure blood reflow. Mice were kept at 37ºC during the procedure and allowed to recover. After 24h, mice were sacrificed.

Results: G6PD activity, mRNA and protein expression were significantly decreased in kidneys from hemi groups. The histologic kidney damage level was determined in a blinded manner. Tubules were analyzed: 0, no damage; 1, mild: rounding of epithelial cells and dilated tubular lumen; 2, moderate: flattened epithelial cells, loss of nuclear staining, dilated lumens, and congestion of lumens; 3, severe: destroyed tubules with flat epithelial cells lacking nuclear staining and congestion of lumen.10-15 fields per slide were used for counting. Hemi+I/R group had the highest damage score, 4 folds increase compared to wt+I/R group. Serum creatinine was increased 3 fold in hemi+I/R group compared to wt+I/R group. We measured neutrophil gelatinase-associated lipocalin(NGAL), a biomarker of kidney injury. Real time PCR and western blot of kidney tissues showed significant increase in NGAL in the hemi+I/R group. NGAL was also significant increased in the plasma of hemi+I/R group.

Conclusions: In conclusion, G6PD deficient mice are more sensitive to kidney I/R injury. G6PD is essential for protecting the kidney from renal injury during I/R.

TH-PO132

Kidney Injury Molecule-1 (Kim-1) Protects From Renal Ischemia-Reperfusion Injury Ola Ziyad Ismail,[1] Xizhong Zhang,[1] Junjun Wei,[1] Giulia Michela Martone,[1] Sahra Nathoo,[1] Aaron R. Haig,[1] Rita Suri,[2] Lakshman Gunaratnam.[1] *[1]Schulich School of Medicine and Dentistry, Western Univ, London, ON, Canada; [2]Univ of Montreal, Montreal, QC, Canada.*

Background: Phagocytic clearance of apoptotic cells (AC) prevents inflammation as uncleared AC undergo secondary necrosis, releasing danger associated molecular pattern proteins (DAMPs). Kidney Injury Molecule-1 (Kim-1) is a receptor for phosphatidlyserine, an "eat-me" signal on the AC surface. After acute kidney injury (AKI), Kim-1 is upregulated on surviving renal proximal tubular epithelial cells (PTECs), allowing them to become

semi-professional phagocytes for AC. We hypothesized that absence of Kim-1 expression precludes phagocytosis by PTECs, resulting in increased release of DAMPs from uncleared AC and more severe tissue damage after AKI.

Methods: We subjected previously generated Kim-1 knockout (KO) and wild-type (WT) mice to bilateral renal ischemia and measured serum creatinine and tissue injury. We exposed PTECs from WT and KO mice to fluorescently labelled AC. We assessed phagocytosis by flow cytometry and HMGB1 (a DAMP that mediates renal damage in AKI) release by Western blot.

Results: After 30 min of ischemia and 24h of reperfusion, renal function was significantly worse in KO compared to WT mice (median creat 202 versus 68 μmol/L, respectively, p=0.001, n=9/gp). After 48h of reperfusion, 7/11 KO but 0/5 WT mice had died (p=0.017). When we reduced ischemia time to 25 min, WT mice maintained near-normal renal function (median creat 13 μmol/L, n=11) while KO mice developed severe renal dysfunction (median creat 111 μmol/L, n=12) (p=0.001) after 48 h of reperfusion. KO mice exhibited worse histological renal damage compared to WT mice (median IRI score = 4 versus 2, p=0.038). The number of AC was higher in the KO compared with WT kidneys. When we exposed primary PTECs to AC, PTECs not expressing KIM-1 exhibited significantly reduced efferocytosis over 24h, compared to PTECs expressing KIM-1 (p=0.0005, n=3 x 6 time points). As expected, we detected significantly more HMGB1 in the extracellular media of PTECs from KO versus WT mice.

Conclusions: Our results suggest that Kim-1 is essential to limit renal damage after ischemic AKI in mice by enabling PTECs to clear AC.

Arginase2 Is Up-Regulated in Renal Tubules of AKI, and Inhibition of Arginase2 Ameliorates the Prognosis of AKI by Regulated NO In Vivo

Yoshiko Shimamura, Toshihiro Sano, Yu Noguchi, Yoshinori Taniguchi, Tatsuki Matsumoto, Kazu Hamada, Kosuke Inoue, Taro Horino, Shinpei Fujimoto, Yoshio Terada, Koji Ogata. *Kochi Univ, Nankoku, Kochi, Japan.*

Background: Arginase (AGase) is an enzyme that breaks down L-arginine and ornithine to urea, and was identified as NO metabolism-related factor. Because the biological role for AGase2 in AKI is poorly understood, we studied the expression/modulation mechanism and role of AGase2 axis in AKI pathogenesis, and the aging effects.

Methods: To clarify the role of AGase2 in AKI, we used a mouse ischemia/reperfusion (I/R) AKI model and cultured renal tubular cells (NRK-52E cells). S-(2-Boronoethyl)-L-cysteine (BEC), a potent arginase inhibitor was administered using a mini-osmotic pimp, then bilateral renal arteries were occluded for 28min and reperfused. Moreover, to assess aging effects, we studied AGase2 expression in aged mice (42- and 87-week-old).

Results: Western blot analysis showed that AGase2 expression was increased at 12-48 h after I/R. Immunohistological examination revealed that AGase2 expression was increased in proximal tubules. In vitro AGase2 expression was also increased in NRK-52E cells under hypoxia. Overexpression of HIF-1α increased AGase2 expression. When increased AGase2 under hypoxia was suppressed by AGase2 siRNA, phosphorylation of eNOS (Ser-177) was increased. Overexpression of AGase2 resulted in suppressed phosphorylation of eNOS. Administrarion of BEC significantly increased serum NOx levels, and ameliorates prognosis of AKI. BUN levels was reduced from 89.9 (contol) to 43.2 mg/dl (BEC), Cr levels was reduced from 0.74 (contol) to 0.17 mg/dl (BEC) at 24h. Finally, AGase2 expression was significantly increased in 42- and 87-week-old aged mice, and showed further increase after AKI, in addition to the reduction of phosphorylation of eNOS.

Conclusions: In summary, AGase2 is up-regulated in renal tubular cells under AKI and hypoxic conditions. Inhibition of AGnase2 ameliorates the prognosis of AKI. AGase2 might play a pivotal role on AKI pathogenesis via NO modulation and eNOS activity. Furthermore AGase2 might be critical for aging-related AKI pathogenesis.

TH-PO134

Activation of the Calcium-Sensing Receptor Before Renal Ischemia/Reperfusion Exacerbates Kidney Injury in Mouse

Francois Jouret,[1] Pascal De Tullio,[2] Christophe Bovy,[1] Laurence Poma,[1] Raphael Maree,[3] Jean-Olivier Defraigne,[1] Jean-Marie H. Krzesinski.[1] *[1]GIGA Cardiovascular Sciences, Univ of Liege, Liege, Belgium; [2]Center for Interdisciplinary Research on Medicines, Univ of Liege, Liege, Belgium; [3]GIGA Bioinformatics Platform and GIGA Systems and Modeling, Univ of Liege, Liege, Belgium.*

Background: The calcium-sensing receptor (CaSR) belongs to the family C of G-protein coupled receptors. In cardiomyocytes, hepatocytes and neurons, CaSR activation at the time of ischemia/reperfusion (I/R) promotes cell death. Its role in renal I/R is unknown.

Methods: We used a 12-week-old C57BL/6J mouse model of renal 30-min ischemia followed by 48-hour reperfusion. Prior to I/R, mice were administered daily with the CaSR agonist, R-568 (250μg, i.p.), or with vehicle (4% DMSO) for 48 hours.

Results: Blood analyses (serum blood urea nitrogen (BUN) levels), examination of kidney histology (using Jablonski's score) and comparative metabolomics by nuclear magnetic resonance on urine and kidney samples showed that R-568 treatment was not associated with significant nephrotoxicity in comparison to vehicle (n=2x8 mice). Still, serum Ca^{2+} level was significantly decreased in R-568-treated animals (2.37 ± 0.27 versus 2.66 ± 0.21 mmol/L, p<0.05). Following kidney I/R (n=2x8 mice), blood analyses indicated that serum BUN levels increased higher in R-568-treated animals than in controls (4.54 ± 0.82 versus 0.78 ± 0.21 g/L, p<0.05). Jablonski's score was higher in R-568-treated kidneys than in controls (3±1 versus 1±1, p<0.05). Immunodetection and quantification (www.cytomine.be) of PCNA (proliferating cell nuclear antigen) and ApopTag expression revealed that R-568-treated kidneys were characterized by a significantly higher rate of cell proliferation and apoptosis in comparison to controls (p<0.05).

Conclusions: The activation of CaSR before renal I/R increases the structural and functional damage in mouse. Modulating CaSR activity might serve as a novel pharmacological approach to prevent I/R-associated kidney injury.

Funding: Government Support - Non-U.S.

Metabolomics Study of Mouse Kidney and Urine After Renal Ischemia/Reperfusion Injury

Francois Jouret,[1] Justine Leenders,[2] Laurence Poma,[1] Jean-Olivier Defraigne,[1] Jean-Marie H. Krzesinski,[1] Pascal De Tullio.[2] *[1]GIGA Cardiovascular Sciences, Univ of Liege, Liege, Belgium; [2]Center for Interdisciplinary Research on Medicines, Univ of Liege, Liege, Belgium.*

Background: Ischemia/reperfusion (I/R) is one of the most common causes of acute kidney injury (AKI). Several cellular and tissular pathways have been implicated in renal I/R, including metabolism, ion transport, polarization, apoptosis, oxidative stress, and inflammation. Still, the pathophysiology of I/R-related AKI remains unclear, which confines the management of patients with AKI to supportive maneuvers. Metabolomics approach helps to identify the metabolites involved in physiological and pathological changes of integrated living systems, as well as their dynamic fluctuations. In kidney diseases, metabolomics demonstrated enormous potential in the research on drug-induced nephrotoxicity, diabetic nephropathy, as well as AKI.

Methods: We performed a ^{1}H Nuclear Magnetic Resonance (NMR) metabolomics analysis on urine and kidney samples from a 12-week-old C57BL/6J mouse model of renal 30-min ischemia followed by 48-hour reperfusion in order to further investigate the metabolic changes in I/R-induced AKI. The urine spectra were normalized to creatinine. Sham-operated mice were used as controls.

Results: Classical metabolomics post-treatment and non-supervised statistical analysis (i.e. Principal Component Analysis, PCA) significantly distinguished urine samples of mice with I/R-induced AKI from sham-operated animals. Additional investigations led to the identification of relevant changes in various metabolites including taurine, creatine, lactate, alanine, citrate and succinate. A similar discrimination was found after testing and processing kidney samples. Renal metabolite profile, including lactate, lipids, amino acids and taurine, was significantly affected by I/R injury.

Conclusions: In mouse, kidney I/R induces significant changes of metabolite profiles in both urine and renal parenchyma. Such investigations may help better understand the pathophysiology of I/R-related AKI, thereby leading to the identification of novel therapeutic targets.

P2X7 Receptor Inhibition Protects against Acute Kidney Injury in Mice

Yanli Yan,[1] Shougang Zhuang.[2] *[1]Dept of Medicine, Alpert Medical School and Rhode Island Hospital of Brown Univ, Providence, RI; [2]Dept of Medicine, Alpert Medical School and Rhode Island Hospital of Brown Univ, Providence.*

Background: Activation of the purinergic P2X7receptor (P2X7R) has been associated with development of experimental nephritis and diabetic and hypertensive nephropathy. However, its role in acute kidney injury (AKI) remains unknown.

Methods: In this study, we examined the effects of P2X7R inhibition in a murine model of ischemia/reperfusion (IR)-induced AKI using A438079, a selective inhibitor of p2x7R.

Results: At 24 hours after IR, mice developed renal dysfunction and renal tubular damage, which was accompanied by elevated expression of P2X7R. Administration of A438079 at the early time (immediately or 6 hours) in the onset of reperfusion protected against renal dysfunction and attenuated kidney damage whereas delayed administration of A438079 at 24 hours after onset of reflow had no protective effects. The defending actions of A438079 were associated with inhibition of renal tubule injury and apoptosis and suppression of renal expression of chemokines (monocyte chemotactic protein-1, RATES). Moreover, IR injury led to an increase in phosphorylation (activation) of extracellular signal-regulated kinases 1/2 in the kidney and early treatment with A438079 diminished this response.

Conclusions: Collectively, these results indicate that early P2X7R inhibition is effective against renal tubule injury and proinflammatory response after IR and suggest that targeting P2X7R may be a promising therapeutic strategy for clinical treatment of AKI.

Changes in Metabolic Profiles during Acute Kidney Injury and Recovery following Ischemia/Reperfusion

Qingqing Wei,[1] Xiao Xiao,[1,2] Paul W. Fogle,[3] Zheng Dong.[1,4,5] *[1]Cellular Biology and Anatomy, Medical College of Georgia, Georgia Regents Univ, Augusta, GA; [2]Wuhan Univ, Wuhan, Hubei, China; [3]Metabolon Inc, Durham, NC; [4]Charlie Norwood VA Medical Center, Augusta, GA; [5]Dept of Nephrology, The Second Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: Changes of metabolism have been implicated in renal ischemia/reperfusion injury (IRI). However, a global analysis of the metabolic changes in renal IRI is lacking and the association of the changes with ischemic kidney injury and subsequent recovery are unclear.

Methods: In this study, mice were subjected to 25 minutes of bilateral renal IRI followed by 2 hours to 7 days of reperfusion. Kidney injury and subsequent recovery was

verified by serum creatinine and blood urea nitrogen measurements. The metabolome of plasma, kidney cortex, and medulla were profiled by the newly developed global metabolomics analysis.

Results: Renal IRI induced overall changes of the metabolome in plasma and kidney tissues. The changes started in renal cortex, followed by medulla and plasma. In addition, we identified specific metabolites that may contribute to early renal injury response, perturbed energy metabolism, impacted osmotic regulation and the induction of inflammation. Some metabolites, such as 3-indoxyl sulfate, were induced at the earliest time point of renal IRI, suggesting the potential of being used as diagnostic biomarkers. There was a notable switch of energy source from glucose to lipids, implicating the importance of appropriate nutrition supply during treatment. In addition, we detected the depressed polyols for osmotic regulation which may contribute to the loss of kidney function. Several pathways involved in inflammation regulation were also induced. Finally, there was a late induction of prostaglandins, suggesting their possible involvement in kidney recovery.

Conclusions: In conclusion, this study demonstrates significant changes of metabolome kidney tissues and plasma in renal IRI. The changes in specific metabolites are associated with and may contribute to early injury, shift of energy source, inflammation, and late phase kidney recovery.

DNA Methylation in Ischemic Acute Kidney Injury Chunyuan Guo,[1,2] Xiao Xiao,[1,2] Qingqing Wei,[1,2] Zheng Dong.[1,2] *[1]Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA; [2]Research Dept, Charlie Norwood VA Medical Center, Augusta, GA.*

Background: DNA methylation is an important mechanism of epigenetic regulation, which is heritable during cell division, but does not involve the change of DNA sequence. DNA methylation plays an essential role in the regulation of gene transcription in physiological and disease conditions. However, very limited is known about DNA methylation in renal diseases, especially in acute kidney injury (AKI).

Methods: We conducted a genome-wide DNA methylation analysis in kidney cortical tissues aftrer renal ischemia-reperfusion AKI in mice using reduced representation bisulfite sequencing (RRBS) technology. The genes with differentially DNA methylated regions (DMRs) within their promoter regions were further analyzed for mRNA and protein to determine if DNA methylation changes correlates with gene transcription.

Results: Totally 1.5 and 1.4 millions of CpG sites were analyzed in the sham and ischemic injured kidney samples respectively. Comparing the methylation profiles of the sham and ischemic injured kidney, there were 235 DMRs in 425 genes. 24 genes were identified containing DMRs at 5' end regulatory regions. Several genes of interest with DMRs in the promoter region showed significantly differential expression in after ischemia-reperfusion, such as Bcl6 and Hoxc10. Hypermethylation of their promoter regions suppressed gene expression. Western blot analysis further showed a decrease in Bcl6 and Hoxc10 protein in ischemic AKI.

Conclusions: The results reveal significant changes in DNA methylation during ischemic AKI, which may contribute to gene regulation in the pathogenesis.

TH-PO139

Lipidomics Analysis of Serum from Rats with Acute Kidney Injury Reveals Increased Levels of Renally Generated N–acylphosphatidylethanolamines, which Are Precursors of Anandamide, an Inducer of Oxidative and Mitochondrial Stress Jon D. Ahlstrom,[1] Zhuma Hu,[1] Ping Zhang,[1] Landon Shay Wilson,[2] Christof Westenfelder,[1,3] Stephen Barnes,[2] Janusz Kabarowski.[2] *[1]Medicine, U of Utah and VAMC, Salt Lake City, UT; [2]Pharmacology and Toxicology, Univ of Alabama, Birmingham, AL; [3]Physiology, U of Utah, SLC, UT.*

Background: The uremic state that is induced by Acute Kidney Injury (AKI) adversely affects multiple organ systems by mechanisms that are still poorly characterized.

Methods: To further investigate the effects of exposing cells x 48 hrs (Normal Rat Kidney/tubular cells and therapeutically used Mesenchymal Stem Cells) to 10% SHAM or AKI sera obtained 24 hrs post IRI-AKI (50 min bilateral pedicle clamp) or bilateral nephrectomy (NPHX). To identify the potential mediator(s) of the oxidative and mitochondrial stress found in AKI serum, sera were subjected to comprehensive lipidomics analysis by direct infusion electrospray-mass spectrometry using SWATH Acquisition on an AB Sciex 5600 tripleTOF instrument at the UAB-UCSD O'Brien Core Center for Acute Kidney Injury Research.

Results: Incubation of both cell types to 10% IRI-AKI serum caused, compared to incubation with NPHX or SHAM rat sera, up regulation of anti-oxidant genes (catalase, HO-1), increased reactive oxygen species and mitochondrial complex I activities, and reduced mitochondrial reserve capacity. The most significantly abundant lipids in the IRI-AKI samples were N–acylphosphatidylethanolamines (NAPEs), which are precursors to the hormone anandamide, an endogeneous cannabinoid known to inhibit oxidative phosphorylation. Accordingly, these NAPEs may in part mediate systematic cellular and mitochondrial stress following AKI.

Conclusions: At comparable levels of azotemia (AKI versus NPHX), AKI serum causes distinct oxidative and mitochondrial stress in cultured cells, and it shows higher levels of NAPEs, and derivatives of these are known to impair mitochondrial function.NAPEs may represent an as yet inadequately understood "toxin" generated by the injured kidney that may adversely affect renal tissue, distant organs, and administered MSCs.

TH-PO140

Role of Chemokine Receptor 5 in Renal Ischemia-Reperfusion Injury Kyung Don Yoo,[1] Seung Seok Han,[1] Ji In Park,[1] Jung Nam An,[2] Ran-Hui Cha,[3] Hajeong Lee,[1] Dong Ki Kim,[1] Yon Su Kim,[1,4] Seung Hee Yang.[4] *[1]Internal Medicine, Seoul National Univ Hospital, Korea; [2]Internal Medicine, Seoul National Univ Boramae Hospital, Korea; [3]Internal Medicine, National Medical Center, Korea; [4]Kidney Research Inst, Seoul National Univ Hospital, Korea.*

Background: Chemokine receptor 5 (CCR5) is known for a key member of inflammatory chemokines in ischemic acute kidney injury. Signal transducer and activator of transcription 3 (STAT3) was recently revealed to play roles in CCR5 expression in human monocytes. CCR5 promoter regions contain STAT3 binding sites. In kidney disease, its role is unclarified. Therefore, we studied the interaction of STAT3 and CCR5 signals on renal ischemia-reperfusion injury (IRI).

Methods: B6 wild type and CCR5 deficient mice were performed in bilateral renal artery pedicles clamping for 30 min followed by reperfusion. After 6 hours of reperfusion, intrarenal lymphocytes were analyzed by flow cytometry.

Results: IRI produced more severe tubular damage in B6 wild type mice than in CCR5 deficient mice (BUN, 191.0 ± 2.7 versus 176.3 ± 2.3 mg/dL; creatinine, 2.37 ± 0.04 versus 1.75 ± 1.16 mg/dL, $p < 0.05$). Although inflammatory cytokines/chemokines, such as monocyte chemotactic protein-1, IFNγ,TNFα, CCL3, CCL4, and CCL5 were increased by IRI in wild type mice compared to sham mice, they were significantly attenuated in CCR5 deficient mice.Especially, CCR5 deficient mice reduced a greater number of inflammatory leukocytes and STAT3 in the kidney after IRI than wild type mice.These findings were supported by in vitro study with human tubular epithelial cells (TECs). The level of CCR5 and pSTAT3 were elevated in the hypoxia-conditioned TECs; however, those were decreased in CADPE (caffeic acid 3,4-dihydroxy-phenethyl ester, JAK2/STAT3 inhibitor) treated cells. The protective effect of the STAT3 inhibitor was achieved by suppression of proinflammatory cytokines and up-regulation of regulatory cytokines. The absence of CCR5 resulted in the protection of kidney damage via less apoptosis and tubulointerstitial inflammation.

Conclusions: These results elucidate that CCR5 regulates ischemic reperfusion injury via STAT3–dependent activation of immune system.

TH-PO141

Role of TRPV1 Channels in Ischemia/Reperfusion-Induced Acute Kidney Injury Lan Chen,[1] Lajos Marko, Mario Kassmann,[2] Kaiyin Wu, Ye Zhu, Maik Gollasch. *[1]Nephrology, Xiamen Zhongshan Hospital, Xiamen Univ, Fujian Province, China, Xiamen; [2]Nephrology, Experimental and Clinical Research Center (ECRC), a joint cooperation between the Charité Medical Faculty and the Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany.*

Background: Transient receptor potential vanilloid 1 (TRPV1) receptor-positive sensory nerves are widely distributed throughout the kidney, suggesting that TRPV1-mediated action may participate in the regulation of renal function under pathophysiological conditions. Stimulation of TRPV1 channels protects against ischemia/reperfusion (I/R)-induced acute kidney injury (AKI). However, it is unknown whether inhibition of these channels is detrimental in AKI or not. We tested the role of TRPV1 channels in I/R-induced AKI by modulating these channels with capsaicin (TRPV1 agonist), capsazepine (TRPV1 antagonist) and using *Trpv1-/-* mice.

Methods: Anesthetized C57BL/6 mice were subjected to 25 min of renal ischemia and 24 hrs of reperfusion. Mice were pretreated with capsaicin (0.3 mg/kg body weight) or capsazepine (50 mg/kg body weight).

Results: Capsaicin ameliorated the outcome of AKI, as measured by serum creatinine levels (154.35 ± 6.58 µmol/L, versus I/R control 190.84 ± 6.13 µmol/L, $p < 0.05$), tubular damage (tubular necrosis score, 2.0 ± 0.27 versus I/R control, 3.0 ± 0.0, $P < 0.05$), neutrophil gelatinase-associated lipocalin (NGAL) abundance(5.44 ± 1.13% versus I/R control, 12.78 ± 2.40%, $p < 0.05$) and Ly-6B.2 positive polymorphonuclear inflammatory cells in injured kidneys (17.95 ± 4.54 per field view versus I/R control, 41.62 ± 6.23). Neither capsazepine nor deficiency of TRPV1 did deteriorate renal function or histology after AKI.

Conclusions: Activation of TRPV1 channels ameliorates I/R-induced AKI, but inhibition of these channels does not affect the outcome of AKI. Our results may have clinical implications for long-term safety of renal denervation to treat resistant hypertension in man, with respect to the function of primary sensory nerves in the response of the kidney to ischemic stimuli.

TH-PO142

Activation of Inflammatory Mediators following Renal Ischemia-Reperfusion Injury Leads to Rapid Suppression of Mitochondrial Biogenic Signaling Ryan Whitaker, Rick G. Schnellmann. *Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.*

Background: Mitochondrial dysfunction is an important mediator of acute kidney injury (AKI) development and progression. Our group demonstrated persistent disruption of mitochondrial homeostasis and inhibition of mitochondrial biogenesis (MB) in multiple models of AKI. While the mechanism(s) of negative regulation of MB following AKI are poorly understood, there is increasing evidence for a link between inflammation and metabolism. These studies sought to examine the role of inflammatory mediators in the early suppression of MB in I/R-induced AKI.

Methods: Cell culture experiments were performed in mouse immortalized TKPTS cells. *In vivo* studies used male C57BL/6 mice subjected to bilateral clamping of the renal pedicles for 18 min to induce AKI. Mice were euthanized at 1 or 3h post-reperfusion. Blood was collected for assessment of BUN and kidneys were collected for various biochemical analyses.

Results: MB was disrupted beginning 3h post-I/R as evidenced by decreased renal cortical mRNA expression of the mitochondrial genes PGC-1α, Tfam, ATPβ, NDUFS1, NDUFB8, COX1 and ND1. Additionally, mtDNA copy number was also decreased by 50% at 3h. No changes were observed 1h after I/R. Increased renal TNF-α mRNA levels and nuclear translocation of NF kappa ß protein were observed beginning 1h after reperfusion. MicroRNA-494, a TNF-α controlled negative regulator of MB, was upregulated 2-3-fold 1h after reperfusion. To evaluate the causal role of TNF-a on the observed mitochondrial genes, TKPTS cells were treated with recombinant TNF-α (10 ng/mL) for 3h. mRNA expression of PGC-1α, NDUFS1 and COX1 were down regulated 75%, 55% and 40%, respectively.

Conclusions: These results demonstrate a potential link between renal TNF-a-mediated inflammation following AKI and the persistent suppression of MB transcriptional signaling and suggest a possible role of mir-494. Pharmacological targeting of inflammatory pathways may serve as viable therapeutic modality to promote recovery of mitochondrial and renal function following AKI.

Urinary ATP Synthase Subunit Beta Is a Novel Biomarker of Mitochondrial Dysfunction in Acute Kidney Injury

Midhun C. Korrapati,[1] Ryan Whitaker,[1] L. Jay Stallons,[1] John M. Arthur,[2,3] Rick G. Schnellmann.[1,3] *[1]Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC; [2]Medicine, Medical Univ of South Carolina, Charleston, SC; [3]Ralph H. Johnson Veterans Administration Medical Center, Medical Univ of South Carolina, Charleston, SC.*

Background: Diverse acute insults from surgery, ischemia/reperfusion (I/R), trauma, and drugs lead to mitochondrial dysfunction and acute kidney injury (AKI). Consequently, there is a great need for non-invasive biomarkers of renal mitochondrial dysfunction. We hypothesized that urinary mitochondrial ATP synthase subunit beta (ATPSβ) protein is a sensitive and specific marker of mitochondrial dysfunction in AKI.

Methods: Myoglobinuric AKI was induced by glycerol injection into rats, and mice were subjected to I/R-induced AKI.

Results: Animals in both models had persistent mitochondrial disruption and elevated serum creatinine, indicative of renal dysfunction, from 24 h through 144 h. Preliminary LC-MS/MS studies of 24 h urine samples revealed increased urinary ATPSβ protein in both AKI models. To investigate further, mice were subjected to sham or different degrees (5, 10 and 15 min ischemia times) of I/R-induced AKI. Serum creatinine, BUN and NGAL were only elevated in the 15 min I/R group at 24 h with overt histological damage. Immunoblot analysis of urinary ATPSβ revealed two bands (~52 and 25 kDa) that were confirmed to be mouse ATPSβ by LC-MS/MS. These bands increased at 24 h in the 10-and 15-min I/R groups, respectively. A time course using the 15-min I/R group revealed elevated urinary ATPSβ at 72 h that returned to control values at 144 h after reperfusion, a time when renal function was returning. LC-MS/MS analysis of urine from patients with AKI identified ATPSβ. Immunoblot analyses of patient urine samples collected 1.5 days after cardiac surgery revealed increased urinary mitochondrial ATPSβ levels in AKI patients when compared to control patients without AKI.

Conclusions: These translational studies provide evidence that ATPSβ may be a new and early urinary biomarker of renal mitochondrial dysfunction and enable evaluation of potential therapies for AKI.

Sildenafil Interferes with the Extension of the Ischemic Acute Kidney Injury

Mirian Watanabe,[1] Edson Andrade Pessoa,[2] Cassiane Dezoti Fonseca,[1] Fernanda Teixeira Borges,[2] Maria de Fatima Vattimo.[1] *[1]Experimental Laboratory of Animal Models, School of Nursing, Univ of Sao Paulo, Sao Paulo, Brazil; [2]Div of Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Ischemia is a critical event to extending renal injury. Besides, reperfusion initiates cellular injury by increasing generation of reactive oxygen species and induction of protection mechanisms such as heme oxygenase-1 (HO-1) enzyme. Sildenafil citrate (SIL) catalyzes the breakdown of cGMP nvolved in smooth muscle relaxation. This study evaluated the effect of SIL on the extension of renal damage provoked by different periods of ischemia.

Methods: Male Wistar rats weighing ±280 g were divided: **SHAM**; **Ischemia 30** (30 min renal pedicles clamping); **Ischemia 30+SIL** (0.25 mg/kg 60 min before renal ischemia); **Ischemia 45** and **Ischemia 45+SIL**. Renal function, hemodynamics, renal blood flow-RBF, oxidative injury, quantitative PCR of HO-1 and kidney histological analysis were evaluated.

Results: SIL pretreatment in Ischemia 30 and 45 ameliorated renal function by improving RBF, decreasing the oxidative metabolites with expression of HO-1 and reducing tubuleinterstitial injury.

Groups	Inulin clearance (ml/min)	RBF (ml/min)	Urinary Peroxides (nmmol/g cr)	Thiols (nmol/g protein)	Urinary TBARS (nmol/g cr)	Urinary NO (µmol/g cr)
SHAM	0.65±0.04	11.8±0.7	2±0.1	170±16	57±7	30±2
Ischemia 30	0.34±0.02α	4.2±0.3α	6±0.2α	117±10α	114±16α	76±7α
Ischemia 30+SIL	0.51±0.04αβ	7.8±1.0β	2±0.3β	111±11α	47±2β	35±3β
Ischemia 45	0.19±0.02αβ	2.3±0.1α	10±1.8αβ	129±17α	117±33α	76±14α
Ischemia 45+SIL	0.31±0.03αγ	5.8±0.4αγ	4±0.6γ	68±12αγ	45±7βγ	47±5γ

$^{\alpha}p<0.05$ vs SHAM, $^{\beta}p<0.05$ vs Ischemia 30, $^{\gamma}p<0.05$ vs ischemia 45.

Conclusions: The study concludes that the functional and histological damage induced by ischemia/reperfusion period determine the AKI extension and SIL confirms protective effect, involving mechanisms of HO and NO system.

TH-PO145

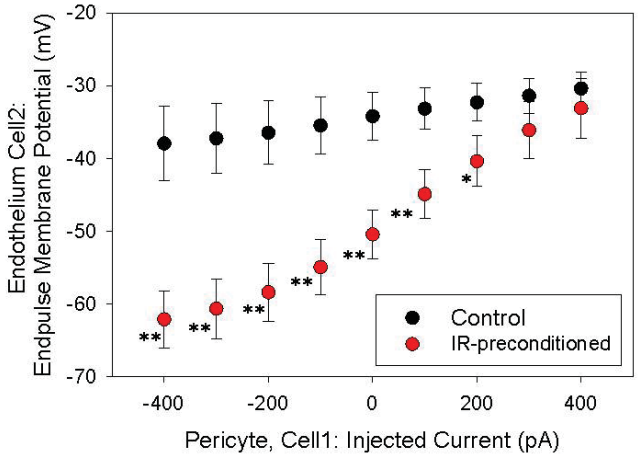
Adaptation of Rat Descending Vasa Recta to Ischemic Renal Injury

Thomas L. Pallone, Kristie Payne, Zhong Zhang. *Medicine, Nephrology, Univ of Maryland, Baltimore, MD.*

Background: Prior renal ischemia-reperfusion (IR) can protect the kidney against future insults. We tested whether cross clamp of the renal artery modifies descending vasa recta (DVR) that supply the renal medulla.

Methods: Two days after 30 minute IR, DVR were harvested from right and left, control and IR treated kidneys, respectively. NO generation, vasoactivity, pericyte and endothelial membrane potentials and mural conduction of injected currents were measured in isolated vessels.

Results: DAF fluorescence, indicating NO generation, increased over 20 minutes in IR treated DVR by 23±3% and in controls by 5±4% (P<0.01, n=7). The difference was eliminated by iNOS inhibition (1400W, 1 uM). The percent reduction of luminal diameter by AngII (10 nM) was reduced in IR pretreated DVR, 28±6% versus 54±8% (P<0.01, n=5). Membrane potentials of IR pretreated DVR were hyperpolarized; pericytes (-49±2 versus -58±4 mV, P<0.05) and endothelia (-44±3 versus -61± 4 mV, P<0.01). In dual patch clamp studies, injection of hyperpolarizing current (-400 pA) into a pericyte led to greater hyperpolarization of adjacent pericytes (-55±4 versus -77±3 mV, P<0.01 n=7) or endothelia (-38±5 versus -62±4 mV, P<0.01, n=7).



Conclusions: We conclude that IR preconditioning enhances DVR NO generation, reduces vasoconstriction, hyperpolarizes both endothelia and pericytes. It also enhances conduction of hyperpolarization, between pericytes and across myoendothelial junctions. These adaptations uniformly favor vasodilation, preservation of medullary blood flow and tissue oxygenation.

C/EBP Homologous Protein (CHOP)-Gene Deficiency Attenuates Renal Ischemia/Reperfusion Injury in Mice

Mi Ra Noh,[1] Jee In Kim,[2] Kwon Moo Park.[1] *[1]Dept of Anatomy and BK21 Plus, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; [2]Dept of Molecular Medicine and MRC, Keimyung Univ School of Medicine, Daegu, Republic of Korea.*

Background: Endoplasmic reticulum (ER) has been implicated in the pathology of renal ischemia/reperfusion (I/R). C/EBP homologous protein (CHOP) is an important mediator of ER stress-induced cell and organ injury. Here, we investigated the role of CHOP in I/R-induced kidney injury using CHOP-knockout ($CHOP^{-/-}$) and their wild-type ($CHOP^{+/+}$) mice.

Methods: Mice were subjected to either 30 minutes of bilateral renal ischemia or sham-operation in CHOP-knockout ($CHOP^{-/-}$) and their wild-type ($CHOP^{+/+}$) mice.

Renal functional and histological changes were evaluated by concentrations of plasma creatinine (PCr) and blood urea nitrogen (BUN) and the periodic acid Schiff (PAS) staining, respectively. TUNEL assay was performed to determine apoptotic cells.

Results: Twenty-four hours after ischemia, the increases of PCr and BUN concentrations were less in $CHOP^{-/-}$ than in $CHOP^{+/+}$ mice. Disruption and congestion in tubules appeared in the outer medulla in PAS-stained kidney sections of both $CHOP^{-/-}$ and $CHOP^{+/+}$ mice 24 hours after ischemia. The damage scores of kidneys after ischemia were lower in $CHOP^{-/-}$ mice than $CHOP^{+/+}$ mice. Apoptosis was evaluated with Terminal deoxynucleotidyl transfer-mediated dUTP nick end-labeling (TUNEL) assay. The number of TUNEL-positive cells were less in $CHOP^{-/-}$ mice than in $CHOP^{+/+}$ mice. The activation of caspase3 and pro-apoptotic Bax was less in $CHOP^{-/-}$ mice than in $CHOP^{+/+}$ mice. In contrast, the activation of anti-apoptotic Bcl-2 and Bcl-x_L was more in $CHOP^{-/-}$ mice than in $CHOP^{+/+}$ mice validated TUNEL results.

Conclusions: These results indicate that CHOP-deficiency attenuates susceptibility to kidney injury by inhibition of necrosis and apoptosis in tubular epithelial cells, suggesting CHOP is a potential therapeutic target protein in I/R injury.

TH-PO147

MicroRNA-34a Is Up-Regulated in Acute Kidney Injury and by Aging and Regulates PNUTS (PPP1R10) Expression and Apoptosis of Renal Tubular Cells In Vitro and In Vivo Kazu Hamada, Tatsuki Matsumoto, Yoshiko Shimamura, Koji Ogata, Kosuke Inoue, Yoshinori Taniguchi, Taro Horino, Yoshio Terada. *Endocrinology, Metabolism and Nephrology, Kochi Univ, Nankoku, Japan.*

Background: MircoRNAs(miR) have emerged as critical regulators of physiological as well as pathological conditions. PNUTS (also known as PPP1R10; protein phosphatase 1 regulatory subunits 10) has recently reported to be regulated in cardiac aging. Both ischemia and aging are risk factors of acute kidney injury (AKI). Because the biological role for miR-34a and PNUTS in AKI is poorly understood, we studied the regulation and role of miR-34a and PNUTS in AKI and aging.

Methods: We used an in vivo mice cisplatin (CDDP)-induced AKI model and cultured renal tubular cells (NRK-52E cells). To elucidate the regulation of miR-34a and PNUTS mRNA, we used RT-PCR. The protein expression of PNUTS was evaluated by western blot analysis and immunohistological examination. Moreover, to assess aging effects, we studied miRNA-34a and PNUTS in aged mice (50- and 90-week-old).

Results: Immunohistological examination revealed the reduced expression of PNUTS in the proximal tubule cells in CDDP-induced AKI. PNUTS mRNA and protein expression were down-regulated in 12–48 h and 24–48 h after CDDP injection. miR-34a was inversely up-regulated at 6–48 h. PNUTS mRNA and protein expression showed a dose-dependent reduction by H_2O_2 in NRK-52E cells. Transfection of miR-34a mimic inhibited, and miR-34a inhibitor stimulated PNUTS expression. Overexpression of PNUTS reduced H_2O_2-induced caspase3 activity and apoptotic (TUNEL positive) cell number. Finally, PNUTS expression was significantly reduced in aged mice kidney, and inversely miR-34a increased by aging.

Conclusions: We showed that PNUTS expression was reduced and miR-34a was increased during oxidative stress and CDDP-induced AKI. Expression of PNUTS was negatively regulated by miR-34a, and controlled apoptosis. These results indicate that regulation of miR-34a and PNUTS may play a key role in the pathophysiology of AKI. Furthermore miR-34a and PNUTS might be critical for age-related renal damage.

TH-PO148

Preconditioning Mice with Activators of 5'-Adenosine Monophosphate-Activated Protein Kinase Ameliorates Ischemic Acute Kidney Injury Wilfred Lieberthal,[1] Jerrold S. Levine.[2] *[1]Dept of Medicine, Stony Brook Medical Center, Stony Brook, NY; [2]Dept of Medicine, Univ of Illinois at Chicago, Chicago, IL.*

Background: We have previously shown that preconditioning cultured proximal tubular cells (PTCs) with pharmacologic activators of 5'-Adenosine Monophosphate-activated Protein Kinase (AMPK), reduces the severity of PTC injury induced by ATP depletion. We now examine the effects of preconditioning mice with the AMPK activators AICAR or A-769662 on the severity of acute kidney injury (AKI) induced by renal ischemia-reperfusion injury (IRI).

Methods: Mice were preconditioned with AICAR or A-769662 or their vehicles. The following day the mice were subjected to right nephrectomy, after which IRI was induced by clamping the pedicle of the left kidney for 30 minutes. Serum creatinine was measured before and 24 hours after IRI.

Results: In mice preconditioning with the vehicles for AICAR or A-769662, IRI increase the serum creatinine from 0.66±0.08 to 1.97±0.009 and from 0.87±0.07 to 2.08±0.06 mg/dl respectively (both $p<0.001$). In mice preconditioned with AICAR or A-769662, IRI increased the creatinine from 0.62±0.03 to 1.23±0.13 mg/dl and from 0.72±0.05 to 1.2±0.09 mg/dl respectively (both $p<0.001$). Creatinine values after IRI were lower after preconditioning mice with AICAR and A-769662 than after preconditioning with their vehicles (both $p<0.01$). However, creatinine values after IRI are comparable in mice preconditioned with AICAR and with A-769662.

Conclusions: The severity of ischemic AKI is substantially ameliorated by AICAR and A-769662. In addition, the beneficial effect of preconditioning mice with AICAR or A-769662 was comparable.

TH-PO149

Meclofenamate Elicits a Nephropreventing Effect in a Rat Model of Ischemic Acute Kidney Injury (AKI) by Suppressing Indoxyl Sulfate (IS) Production and Restoring Renal Organic Anion Transporters Yui Nomura,[1] Chika Saigo,[1] Yuko Yamamoto,[1] Hirofumi Jono,[1,2] Hideyuki Saito.[1,2] *[1]Dept of Clinical Pharmaceutical Sciences, Graduate School of Pharmaceutical Sciences, Kumamoto Univ, Kumamoto, Japan; [2]Dept of Pharmacy, Kumamoto Univ Hospital, Kumamoto, Japan.*

Background: Indoxyl sulfate (IS) is excreted in the urine under normal kidney function, but is retained in the circulation and tissues during renal dysfunction in AKI, inducing oxidative stress in the kidney and cardiovascular system. IS is enzymatically produced in the liver from indole by cytochrome P450-mediated hydroxylation to indoxyl, followed by sulfotransferase-mediated sulfate conjugation.

Methods: Meclofenamate (10 mg/kg) was adminstered intravenously to rats treated with renal ischemia/reperfusion, and examined serum and renal levels of IS, renal function and PGE2 level, and expression of organic anion transporters rOat1 and rOat3.

Results: After testing about 200 compounds, including phytochemical polyphenols, we identified meclofenamate as a potent inhibitor of IS production in both rat and human liver S9 fractions. Ischemia/reperfusion (I/R) of rat kidney caused a marked elevation in the serum IS concentration 48 hr after surgery. However, administration of meclofenamate significantly suppressed this increase in the serum IS level. Moreover, IS concentrations in both kidney and liver were dramatically elevated by renal I/R treatment, but this increase was blocked by meclofenamate. Serum creatinine and BUN were markedly elevated in rats after renal I/R treatment, but were significantly attenuated by administration of meclofenamate. Renal expression of both rOAT1 and rOAT3 was downregulated by I/R treatment. However, the expression of both transporters recovered after administration of meclofenamate, which was associated with the inhibition of I/R-evoked elevation of PGE2. These results suggested that meclofenamate inhibits hepatic production of IS, thereby suppressing serum and renal accumulation of IS. Meclofenamate also prevents the I/R-PGE2-dependent downregulation of rOAT1 and rOAT3.

Conclusions: In conclusion, meclofenamate was found to elicit a nephropreventive effect in ischemic AKI.

Mouse Kidney Resident Double Negative Alpha/Beta T Cells Have Distinct Properties From Other Lymphocytes and Can Reduce Inflammation During AKI Maria Noel Martina Lingua, Samatha Bandapalle, Sanjeev Noel, Ankit Saxena, Abdel Hamad, Hamid Rabb. *Medicine, Johns Hopkins Univ, Baltimore, MD.*

Background: TCRαβ+CD4-CD8- double negative (DN) T cells with immunoregulatory function are a significant component of T cells residing in the kidney. However, the role of DN T cells in the regulation of renal homeostasis in the steady state and during AKI is unknown. We have further explored the functional role of DNT cells in mouse kidney under normal condition and following AKI.

Methods: CD45+ lymphocytes were purified from kidney mononuclear cells isolated from normal and ischemic AKI mouse kidneys and were analyzed for activation marker and co-stimulatory molecules by flow cytometry. Microarray analysis of flow sorted DNT cells was performed to decipher unique genomic signatures distinct from CD4 and CD8 cells. Adoptive transfer experiment was performed to define the immune function of DNT cells during AKI. We also measured intracellular cytokines in the kidney-infiltrating lymphocyte.

Results: The frequency of DNT cells in the kidney was higher than other T cell subsets in normal (30% of the T cells) and 3 hours post-ischemia (>60%). DNT had a baseline activated phenotype indicated by high expression of CD40L, CD28 co-stimulatory molecules and activation marker CD69. DNT cells proliferate at an unexpectedly high rate in normal kidney (30% BrdU incorporation) with further increase in proliferation after IRI (80% BrdU incorporation). Adoptive transfer of DN T cells 3h pre-ischemia resulted in significant reduction in inflammatory response (reduced γ-IFN and granzyme) in recipient mice as compared to the control group. Microarray analysis revealed a significant up-regulation of IL-27 gene in kidney DNT cells in comparison to CD8/CD4 cells isolated from kidney.

Conclusions: Our data demonstrate that mouse kidney resident DNT cells are innate-like cells and very early responder to IRI. They have a unique molecular response compared to CD4 and CD8 cells. Understanding the role of DNT in the kidney could have important implications for new therapies for AKI as well as other immune-mediated kidney diseases including glomerulonephritis, allograft rejection and interstitial nephritis.

***In Vitro* Suppression Assays Do Not Predict *In Vivo* Functional Activity of Regulatory T Cells in Kidney Ischemia Reperfusion Injury** Gilbert R. Kinsey, Katarzyna Jobin, Joanna Ratajczak, Liping Huang, Brian K. Stevens. *Div of Nephrology and Center for Immunity, Inflammation and ReGenerative Medicine, Univ of Virginia.*

Background: Regulatory T cells (Tregs) play an important protective role in mouse models of acute kidney injury. Understanding the mechanisms used by Tregs to protect the kidney and the target cells that are influenced by Tregs would facilitate the development of therapeutic strategies based on Treg activity. Previous studies with programmed death

1 (PD-1) blocking antibodies suggest a critical role for PD-1 on Tregs in kidney ischemia reperfusion injury (IRI). $CD4^+$ T cells and natural killer T (NKT) cells promote renal injury during IRI. This study was to determine whether *in vitro* assays of Treg suppressive function are representative of Treg actions during kidney IRI.

Methods: Wild type (WT) and PD-1 KO Tregs were adoptively transferred to naïve WT mice 18 hr prior to bilateral renal IRI. Plasma creatinine and tubular necrosis were measured at 24 hr of reperfusion. *In vitro*, WT and PD-1 KO Tregs were tested for their ability to suppress $CD4^+$ T cell proliferation over 72 hrs (measured as CFSE dilution by flow cytometry) and α-galactosylceramide (α-galcer) induced-NKT cell interferon gamma (IFN-γ) production over 24 hrs (measured by ELISA).

Results: The *in vivo* experiments demonstrated that Tregs absolutely require expression of PD-1 to suppress kidney IRI. The *in vitro* experiments revealed that both WT and PD-1 KO Tregs effectively and equally suppressed the proliferation of $CD4^+$ T cells. Interestingly, whereas WT Tregs modestly inhibited α-galcer induced NKT cell IFN-γ production over 24 hr (65 ± 18% of NKT cells activated in the absence of Tregs (i.e. control)), the PD-1 KO Tregs were significantly better at inhibiting NKT cell IFN-γ production (20 ± 12% of control).

Conclusions: The lack of PD-1 expression by Tregs negates their protective function in an *in vivo* model of kidney IRI, but has no effect ($CD4^+$ T cell proliferation) or enhances (NKT cell IFN-γ production) Treg suppressive ability *in vitro*. These results suggest these *in vitro* models are not useful for determining the mechanism of action for Tregs in kidney IRI.

TH-PO152

Mice Lacking CD4 T Cells Have Worse Lung Injury After Ischemic Acute Kidney Injury (AKI) due to Reduced IL-10 Production

Ana Andres-Hernando, Kayo Okamura, Rhea Bhargava, Chris Altmann, Sarah Faubel. *Univ of Colorado Denver.*

Background: We have previously demonstrated that the spleen is an important source of the anti-inflammatory cytokine IL-10 to ameliorate AKI induced lung injury. The goal of this study was 1) to identify the splenic source of IL-10 and 2) to characterize the mechanism whereby IL-10 expression is up-regulated in AKI.

Methods: Splenic analysis of different cell populations in mice undergoing AKI revealed that IL-10 expression colocalized with molecular markers of macrophages (CD11b), T (CD4) and B-cells (B220) with little expression in neutrophils. Among these, CD4+ T cells demonstrated the highest expression of IL-10 suggesting a key role of this cell type in ameliorating lung injury post-AKI. AKI or sham operation was performed in CD4 deficient mice and lung injury was assessed 4 hours post AKI.

Results: Of interest, despite no significant changes in the degree of renal injury induced, lung injury, determined by measuring lung CXCL1 and MPO (a marker of neutrophil infiltration), was exacerbated in CD4 deficient mice compared to wild type animals. We have previously shown that circulating levels of the pro-inflammatory cytokine IL-6 are elevated in mice after AKI. In some settings, IL-6 has anti-inflammatory effects. We therefore tested the hypothesis that in splenocytes, including CD4+ T cells, IL-6 induces IL-10 expression. Addition of IL-6 to splenocytes and CD4+ T-cells increased IL-10 production in a dose-dependent manner. IL-10 production is mediated by IL-6-induced activation of STAT-3 as demonstrated by STAT-3 phosphorylation in a time-dependent manner and by the observation that IL-10 expression is reduced by the specific STAT-3 inhibitor stattic (20 μM). Consistent with this, in vivo, splenic IL-10 expression is significantly lower in IL-6 deficient mice with AKI compared to wild type.

Conclusions: In conclusion, our data indicates that in AKI, CD4+ T-cells are stimulated by IL-6 to produce IL-10 and this mechanism is important to ameliorate AKI-induced lung injury.

TH-PO153

Divergent Control of Dendritic Cell Maturation by S1P Receptors Is Critical in Modulating Acute Kidney Injury in Mice

Amandeep Bajwa,[1] Liping Huang,[1] Hong Ye,[1] Kevin Lynch,[2] Mark D. Okusa.[1] *[1]Med/CIIR, Univ of VA; [2]Pharm., UVA.*

Background: Regulation of dendritic cell (DC) maturation maybe a key therapeutic approach for the treatment of AKI. S1P, a sphingolipid is a natural ligand for family of 5 GPCRs(S1P1-5). Activation of the S1P1 reduces kidney ischemia-reperfusion injury (IRI), whereas activation of S1P3 may lead to loss of epithelial barrier and increase in IRI. $S1P3^{-/-}$ mice are protected for kidney IRI. DC maturation is necessary to initiate kidney IRI; depletion of DCs or adoptive transfer of $S1P3^{-/-}$ DCs protects kidneys from IRI.

Methods: We used WT, CD11cCre and $CD11cCreS1Pr1^{fl/fl}$ (DC deficiency of S1P1) mice and VPC01091 (S1P1 agonist and S1P3 antagonist) in kidney IRI. Injury was assessed by plasma creatinine (PCr; mg/dl), FACS, and RT-PCR.

Results: $CD11cCreS1Pr1^{fl/fl}$ mice result in more severe injury compared to CD11cCre (PCr: 0.9±0.18 versus 0.4±0.09; $p<0.01$). DCs $S1P1^{-/-}$ mice have higher number of mature kidney DCs ($CD11c^+MHCII^+$) and more neutrophil infiltration after IRI. These results suggest that in contract to the protective effect of deficiency of S1P3 in DCs, deficiency of S1P1 worsens AKI. VPC01091 (1mg/kg) treatment of WT mice led to: 1) less kidney injury after IRI compared to vehicle (1.2±0.2 versus 0.23±0.01; $p<0.001$), 2) reduced peripheral blood lymphocyte counts 3)significantly less total number of mature kidney DCs and neutrophils, and 4) less pro-inflammatory kidney cytokines (TNF-α, CXCL1 and IL-6). VPC01091 treatment led to a reduction of injury in CD11cCre mice (0.4±0.09 versus 0.2±0.01; $p<0.05$) and DC $S1P1^{-/-}$ (0.9±0.18 versus 0.44±0.09; $p<0.05$) mice.

Conclusions: S1P1 and S1P3 expression in DCs regulate maturation and have divergent effects in kidney IRI. Whereas it is known that deficiency of S1P3 inhibits DC maturation and reduces kidney IRI, deficiency of S1P1 enhances DC maturation exacerbates injury and inflammation. VPC01091 takes advantage of the protective effect of S1P1 activation and S1P3 inhibition reduces kidney IRI. Furthermore, the effect of VPC01091 is effective in mice deficient of S1P1 in DCs suggests that pharmacological activation of S1P1 extends beyond DC S1P1. VPC01091 may be useful in clinical aspects for the prevention of AKI or treatment of established AKI.

TH-PO154

Dissociation of Renal Filtration Function Failure from Leukocyte Infiltration in Proximal Tubule CD73-Deficient Mice Undergoing Ischemia-Reperfusion

Sun-Sang J. Sung, Li Li, Liping Huang, Jessica R. Lawler, Hong Ye, Diane L. Rosin, Isaah Vincent, Mark D. Okusa. *Medicine, Univ of Virginia, Charlottesville, VA.*

Background: Renal ischemia-reperfusion injury (IRI) is characterized by inflammatory cell infiltration, damages to the endothelium and tubules, and compromised renal filtration functions. CD73 is thought to protect mice from IRI by generating adenosine which inhibits leukocyte effector functions through the adenosine receptors. However, it is unclear whether a hierarchy of IRI protection efficiencies occurs with CD73 expression by various renal cell type.

Methods: Sub-threshold bilateral renal pedicle clamping (Sub-IRI) was performed in mice with global CD73 deletion or cell type-specific targeted CD73 deletion in proximal tubular cells and CD11c+ myeloid cells, as well as in bone marrow chimeras of WT and CD73 deficient mice. Creatinine measurements, confocal microscopy, and flow cytometry were used to assess kidney functions and inflammation 24 h after ischemia-reperfusion.

Results: CD73 was expressed at high levels by proximal tubule epithelial cells and mesangial cells, intermediate levels by interstitial cortical type I fibroblasts, and low levels by CD11c+ myeloid cells. Adoptive transfer experiments showed that increased IRI was found only in hosts with CD73 deletion in non-hematopoietic cells. Cell type-specific targeted CD73 expression further defined the contribution of CD73 expression on different renal cell types. Enhanced IRI was found only in PepCK-Cre-CD73fl/fl mice but not in CD11c-Cre-CD73fl/fl mice, indicating that CD73 on proximal tubular cells but not on cortical fibroblasts or myeloid cells is key to IRI protection. Interestingly more than 5-fold increases in PMN and CD11b+F4/80Low macrophages but no detectable increase in creatinine over sham-operated mice was found in wild-type and CD11c-Cre-CD73fl/fl mice undergoing sub-IRI.

Conclusions: The studies showed that CD73 expression on proximal epithelial cells and not on cortical fibroblasts and myeloid cells was critical for renal IRI protection. Furthermore, a biphasic IRI disease course with leukocyte infiltration followed by renal cell damage may occur with CD73 interfering only with the latter phase.

Double Knockout of PARP-1 and Cyclophilin D Reduces Ischemic Renal Injury in Mice

Yuan Ying, Babu J. Padanilam. *Cellular & Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE.*

Background: The key features of Ischemic renal injury (IRI) are vascular damage, inflammation and proximal tubular cell apoptosis and necrosis, particularly in the outer medulla. Poly (ADP-ribose) polymerase 1(PARP-1) and cyclophilin D play important roles in inducing necrotic cell death after various types of cell stress. Our laboratory has previously established key roles for both PARP-1 and cyclophilin D in necrosis after IRI. However, whether these molecules induce necrosis independently of each other or if their signaling pathways integrate to induce necrosis is unclear. In this study, we hypothesized that genetic deletion of both PARP-1 and cyclophilin D additively or synergistically protects mice from ischemic renal injury.

Methods: Wild type, PARP-1 knockout, cyclophilin D knockout and PARP-1/cyclophilin D double knockout mice underwent either sham surgery or clamping of the renal pedicle for 30 min followed by reperfusion for 1 and 5 days. Renal function was assessed by creatinine and blood urea nitrogen (BUN) assays, histological damage and necrosis by Periodic acid-Schiff staining, inflammation by neutrophil staining. Apoptosis was determined by TUNEL staining.

Results: Plasma levels of creatinine and BUN were significantly decreased 24 h after reperfusion in double knockout mice compared with wild type and single knockout mice for cyclophilin D and PARP-1. Double knockout mice also had less renal histological damage, necrotic proximal tubules, infiltration of neutrophils, and TUNEL positive cells.

Conclusions: Genetic deletion of both PARP-1 and cyclophilin D protects mice kidneys from functional and histological deterioration after IRI. Inhibition of both PARP-1 and cyclophilin D may provide more protective effect in IRI.

Nrf2 and HIF1α Cooperatively Regulates Heme Oxygenase 1 Expression in Renal Epithelial Cells during Hypoxia and Reoxygenation

Haranatha Reddy Potteti,[1] Sanjeev Noel,[2] Hamid Rabb,[2] Sekhar P. Reddy.[1] *[1]Pediatrics, Univ of Illinois, Chicago, IL; [2]Medicine, Johns Hopkins Univ, Baltimore, MD.*

Background: Nrf2 and HIF1α transcription factors play protective roles in ischemia reperfusion (IR)-induced acute kidney injury (AKI) *in vitro* and *in vivo* by upregulating cytoprotective enzymes that mitigate cellular stress, including heme oxygenase 1 (Hmox1).

We hypothesized that Nrf2-HIF1α crosstalk is critical for Hmox1 induction during IR-induced AKI. Indeed, we now report existence of such crosstalk in the regulation of Hmox1 expression in renal epithelial cells (RECs) following hypoxia and reoxygenation.

Methods: We have utilized human renal proximal tubular epithelial cells, HK-2, and primary cultured mouse RECs from *Nrf2*$^{-/-}$ and *Nrf2*$^{+/+}$ mice.Cells were exposed to acute (2 h) and chronic (12 h) hypoxia followed by reoxygenation (up to 6 h) with or without HIF1α inhibitor, digoxin. Cells were treated with HIF1α activator, $CoCl_2$ HIF1α, Nrf2 and Hmox1 expression levels were analyzed by qRT-PCR and immunoblot analysis.

Results: Both acute and chronic hypoxia, as expected, induced HIF1α activation, which was attenuated during reoxygenation in HK2 cells. Hmox1 expression remained significantly ($p<0.05$) elevated following acute (2-fold) and chronic (10-fold) hypoxia and during reoxygenation of chronic hypoxia (2.5-fold). Intriguingly, chronic hypoxia markedly decreased Nrf2 levels (90%), but reoxygenation restored these levels to room air controls. Digoxin inhibited hypoxia-induced HIF1α activation and Hmox1 expression, and decreased Nrf2 levels. In contrast, $CoCl_2$ increased Nrf2 expression (3-fold) but digoxin blocked this induction. We also found reduced HIF1α activation and Hmox1 expression in *Nrf2*$^{-/-}$ RECs exposed to hypoxia and reoxygenation. Consistent with this result, $CoCl_2$ markedly stimulated Hmox1 expression in *Nrf2*$^{+/+}$ (5-fold) but not in Nrf2$^{-/-}$ RECs.

Conclusions: Our results show for the first time that HIF1α and Nrf2 cooperatively modulate Hmox1 induction during hypoxia and reoxygenation in RECs, and deregulation of this HIF1α-Nrf2 crosstalk may contribute to enhanced susceptibility to RECs injury during IR-induced AKI.

Heterozygous Knockout of SerpinC1 Exacerbates Renal Ischemia/Reperfusion Injury in Rats Feng Wang,[1] Guangyuan Zhang,[2] Kristie Usa,[3] Aron M. Geurts,[4] Niansong Wang,[5] Mingyu Liang.[6] *[1]Nephrology and Rheumatology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China; [2]Physiology, Medical College of Wisconsin, Milwaukee, WI; [3]Physiology, Medical College of Wisconsin, Milwaukee, WI; [4]Physiology, Medical College of Wisconsin, Milwaukee, WI; [5]Nephrology and Rheumatology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China; [6]Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: SerpinC1-encoded antithrombin III (ATIII) is the major anti-coagulation molecule in vivo and has anti-inflammatory effects. SerpinC1 homozygous knockout is embryonically lethal. We hypothesized that partial loss of SerpinC1 would exacerbate renal ischemia/reperfusion injury.

Methods: SerpinC1 heterozygous knockout rats were established in a congenic model SS.BN-(D13Rat151-D13Rat197)/Mcwi using zinc-finger nucleases targeting exon 1, resulting in a 29 base pair deletion removing the endogenous translation initiation codon, and is therefore predicted to result in a complete null allele for SerpinC1. The left renal ischemia was induced by nontraumatic vascular clamps over the renal artery for 30 minutes after right nephroctomy and 24 hours' reperfusion followed in wild type (WT, n=6) and heterozygous knockout (Het, n=6) littermate groups. Sham operation was performed in additional groups of rats.

Results: Renal tubular injury scores were increased from 0.50±0.10 to 3.58±0.71 in the Het group and to 2.15±0.30 in the WT group after renal ischemia/reperfusion ($P<0.05$ for Het versus WT). Serum creatinine was increased from 0.21±0.04 mg/dl to 1.09±0.40 mg/dl in the Het group and from 0.20±0.02 to 0.67±0.20 in the WT group ($P<0.05$ for Het versus WT). Concomitantly, renal levels of malondialdehyde and apoptosis were 1.6±0.2 fold and 1.4±0.1 fold, respectively, greater in the Het group compared to the WT group ($P<0.05$). Significant thrombosis was not observed in the kidneys of any of the groups.

Conclusions: In summary, heterozygous knockout of SerpinC1 exacerbates renal ischemia/reperfusion injury in rats possibly via increased oxidative stress and apoptosis.

ADAMTS13-Von Willebrand Factor (vWF) Axis Is Involved in the Pathophysiology of Renal Ischemia Reperfusion Injury Myung-Gyu Kim, Sun Chul Kim, Hyojeong Chang, Sang-Kyung Jo, Won-Yong Cho. *Dept of Internal Medicine, Korea Univ Anam Hospital, Seoul, Republic of Korea.*

Background: Recent epidemiologic studies showed that impaired activity of ADAMTS13, a protease cleaving Von Willebrand factor (vWF) multimer, could predict renal complications in diabetic patients. The ADAMTS13- vWF axis has also been suggested to play a critical role in the pathophysiology of ischemia-reperfusion injury (IRI) in different organs.The purpose of this study was to investigate whether ADAMTS13-ultralarge vWF (UlvWF) multimer axis was involved in the pathophysiology of IRI induced AKI.

Methods: We performed renal IRI in ADAMTS13 knockout (KO) mice or wild type (WT) mice. Functional, histological kidney damage, inflammation were compared and the effect of recombinant human ADAMTS13 (rhADAMTS13) in ADAMTS13 KO mice was also assessed.

Results: Following IRI, the ADAMTS13 level in blood was significantly reduced and vWF was detected in both medulla and cortex of injured kidney by immunohistochemistry. Western blot analysis also showed increased expression of ULvWF-muiltimer in ischemic kidneys, and the expression was significantly higher in ADAMTS13 KO mice than WT mice. The higher level of vWF-multimer in ADAMTS13 KO mice was correlated with more functional deterioration and severe tubular injury, suggesting an important role of VWF in renal IRI. In addition, the number of Gr-1 (+) neutrophils was significantly higher in the kidney of ADAMTS13 KO mice compared to that of WT mice, whereas F4/80 macrophages were not. In ADAMTS13 KO mice, administration of rhADAMTS13 after IRI partially restored renal injury, suggesting that ADAMTS13 may be an important player that regulates IR injury associated with vWF.

Conclusions: Our data shows that ADAMTS13-vWF axis is involved in the pathophysiology in renal IRI. This is first report showing the involvement of UlvWF-multimer in renal IRI indicating that ADAMTS13 could have therapeutic value to limit renal ischemia/reperfusion injury.

Dichotomy of STAT3 Phosphorylation in Ischemic Acute Kidney Injury Istvan Arany,[1] Dustin Reed,[1] Kiran B. Chandrashekar,[2] Luis A. Juncos.[2,3] *[1]Pediatrics, Univ of Mississippi Medical Center; [2]Medicine, Univ of Mississippi Medical Center; [3]Physiology and Biophysics, Univ of Mississippi Medical Center.*

Background: Studies suggest that the transcription factor STAT3 (signal transducer and activator of transcription-3) can promote either injury or protection depending on its phosphorylation state in extrarenal organs. In the present study we tested the hypothesis that tyrosine (Y705) phosphorylation is adaptive while serine (S727) phosphorylation of STAT3 is maladaptive during renal IR-AKI.

Methods: Male wild type (w.t.), STAT3 ß k.o. (the regulatory STAT3 ß isoform is deleted) or homozygous SA/SA mice (S727A mutant, which is impaired in S727 phosphorylation) were subjected to 18 minutes of warm ischemia followed by 24 hours of reperfusion (IR). A group of w.t. mice were subjected to chronic nicotine (Ch-NIC) exposure prior to IR. Renal function (creatinine) and injury (KIM1) as well as STAT3 phosphorylation and HO-1 expression were determined. In vitro, STAT3 tyrosine/serine phosphorylation was manipulated by either mutation (Y705F or S727A, respectively) or pretreatment with LIF (↑pTyrSTAT3), ET-1 or NIC (↑pSerSTAT3) in renal proximal tubule cells (LLC-PK1) that were subjected to oxidative stress (400 μM H_2O_2). Cell injury (LDH release) as well as activity of the HO-1 promoter or a STAT3-binding element reporter (SBE; that is a part of the HO-1 promoter) was determined.

Results: IR-AKI increased pTyrSTAT3 and HO-1 but ameliorated renal dysfunction/injury in SA/SA mice while decreased pTyrSTAT3 and HO-1 and increased pSerSTAT3 and renal dysfunction/injury in STAT3 ß k.o. mice or w.t. mice exposed to Ch-NIC. In vitro, LIF (↑pTyrSTAT3) increased induction of HO-1 and SBE and attenuated oxidant injury while Y705F mutation (↓pTyrSTAT3) resulted in opposite effects. In contrast, ET-1 or Ch-NIC (↑pSerSTAT3) decreased HO-1/SBE induction and augmented injury while S727A mutation (↓pSerSTAT3) showed opposite effects.

Conclusions: Our studies suggest that pTyrSTAT3 is adaptive while pSerSTAT3 is maladaptive during IR-AKI that involves differential modulation of HO-1 transcription via the SBE. Hence, manipulation of this pathway might offer therapeutic means to ameliorate acute kidney injury.

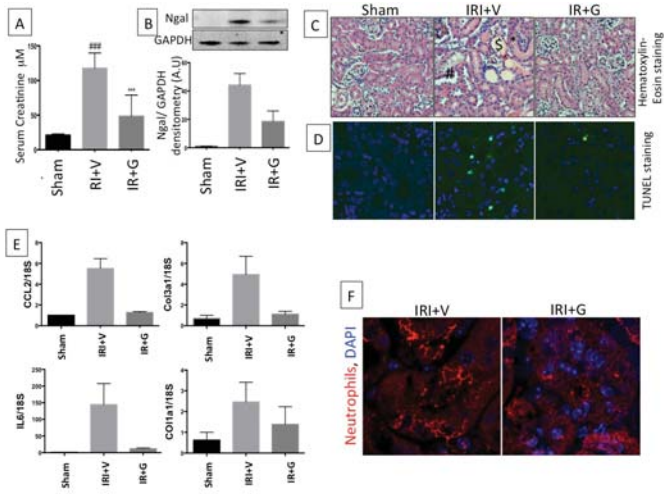
The Role of G Protein-Coupled Receptor Gβγ Signaling in Acute Kidey Injury Fadia A. Kamal, Joshua Travers, Prasad Devarajan, Burns C. Blaxall. *Cincinnati Children's Hospital Medical Center, OH.*

Background: Acute kidney injury (AKI) is a significant condition of increasing morbidity. The pathogenesis of AKI is complex and variable with renal tubular death and tubulointerstitial inflammation being two determinants of tissue damage and renal failure. G protein–coupled receptors (GPCRs) are widely expressed in the kidney and their role in AKI is understudied. Prolonged agonist stimulation of the GPCR induces pathological upregulation of its Gβγ-GRK2 signaling causing receptor phosphorylaion and internalization and activation of pathologic downstream signaling pathways.

Methods: We explored the protective effect of the small molecule Gβγ inhibitor *gallein* in a bilateral ischemia reperfusion injury (IRI) mouse model. Mice were pretreated with either vehicle (V) or galleon (G) three days pre-IRI. Twenty-four hours after IRI mice were sacrificed, urine and blood were collected before and after IRI and kidneys were harvested for histology and protein and mRNA analysis.

Results: Functionally, serum creatinine (A) and tissue Ngal (B) levels were elevated post-IRI. Histologically, tubular expansion, tubular damage and cast formation (C) and tubular apoptosis (D) revealed tissue damage post-IRI. Further, kidney inflammatory and profibrotic gene expression (CCL2, IL-6, Collagen-I and Collagen-III) (E) and neutrophil infiltration (F) were elevated post-IRI. Gallein pretreatment attenuated all these pathological changes and protected renal function post-IRI. Interestingly, renal GRK2 protein expression was upregulated post-IRI and was attenuated in gallein treated mice.



Conclusions: In conclusion, preserved renal function and structure and attenuated GRK2 upregulation twenty-four hours post-IRI by the small molecule Gβγ inhibitor gallein, indicate a direct role for Gβγ-GRK2 signaling in renal IRI and a potential protective role for gallein in AKI.

Mechanisms of the Renal Protection By Cyclosporine After an Ischemia Reperfusion Early at the Reperfusion: Role of HSP70 Sandrine Lemoine,[1,2] Bruno Pillot,[1] Lionel Augeul,[1] Michel Ovize,[1,3] Laurent Juillard.[1,2] *[1]Edouard Herriot Hospital-Nephrology, HCL, Lyon, France; [2]Carmen 1060-IHU OPERA, Univ of Lyon 1, Univ of Lyon, Lyon, France; [3]Louis Pradel Hospital-Cardiology, HCL, Lyon, France.*

Background: The aim of this study is to show that the preconditioning with CsA provides a protection against renal ischemia reperfusion (IR) by two pathways allowing together the delay of mPTP opening: the HSP70 pathways and by the direct inhibition of cyclophiline D (cypD).

Methods: We performed a right unilateral nephrectomy with a 30-minutes contralateral clamping of the left renal artery in C57BL6 male mice. First, we measured in 3 groups (a sham group, an ischemic group and a pre-conditionning group with 10 mg/kg of CsA (preCsA) injected 10 min before ischemia) the calcium overload (CRC) in order to test mPTP, the oxydative phosphorylation to test respiratory chain, the renal expression of HSP70 and GSK 3-b by western blotting at 20 min of reperfusion. Secondly, we performed the same ischemia in CyclophilineD deficient mice to evaluate the role of CypD in mPTP. Finally, we used the inhibitor of HSP70 (Quercetin, 100mg/kg, 2h before ischemia) in mice preconditioned with CsA to evaluate the possible role of HSP70 in mPTP.

Results: At 20 min of reperfusion, we showed a delay of mPTP opening in the preCsA group compared to the ischemic group. However, we found no protection in the oxidative phosphorylation that is dramatically decreased at 20 min of reperfusion in all groups, as previously reported. Renal HSP70 and GSK3 phosphorylated protein (P-GSK3b) levels were higher in the preCsA group than in the ischemic group, suggesting an enhancement of these 2 proteins by CsA. The pretreatment with Quercetin decreased HSP70 and P-GSK3b levels compared to preCsA group and eliminated the preconditionning protection with an early opening of mPTP.

Conclusions: Our study suggested that preCsA promotes two pathways of protection, the HSP70 pathways, mediated by P-GSK3B and by inhibition of cyclophilline D. These 2 pathways allow delaying the mPTP opening and protects against IR, suggesting that mPTP is the key event in the renal lesion of IR.

Small Heat Shock Protein Beta-1 (HSPB1) Is Up-Regulated and Regulates the Autophagy and Apoptosis of Renal Tubular Cells in Acute Kidney Injury In Vitro and In Vivo Tatsuki Matsumoto, Madoka Urushido, Haruna Ide, Kazu Hamada, Yoshiko Shimamura, Koji Ogata, Kosuke Inoue, Yoshinori Taniguchi, Taro Horino, Shinpei Fujimoto, Yoshio Terada. *Kochi Medical School, Kochi Univ, Japan.*

Background: Heat shock protein Beta-1 (HSPB1)(HSP27) is a small heat shock protein that is involved in many cellular processes, and it reportedly protects cells against oxidative stress. Autophagy is a mechanism that protects cells from many types of stress and is thought to play an important role in preventing stress in acute kidney injury (AKI). However, little is known about the role of HSPB1 in autophagy and apoptosis in AKI pathogenesis.

Methods: We used an in vivo rat ischemia/reperfusion AKI model and cultured renal tubular cells as an in vitro model. To elucidate the regulation of HSPB1, we evaluated the promoter activity and expression of HSPB1 in NRK-52E cells in the presence of H_2O_2. To examine the regulation of autophagy by HSPB1, we established NRK cells that were stably transfected with a fusion protein between green fluorescent protein and LC3 as a marker of autophagy.

Results: Immunohistological examination showed the expression of HSPB1 in the proximal tubule cells after AKI. RT-PCR and western blot analysis showed that HSPB1 mRNA and protein expression were upregulated 6–72 h and 12–72 h after ischemia/reperfusion. HSPB1 promoter activity, mRNA, and protein expression showed a dose-dependent induction by H_2O_2. Overexpression of HSPB1-induced autophagy in NRK cells under normoxic conditions was confirmed by confocal microscopy, which revealed the presence of LC3-positive granules. Furthermore, autophagy induced by H_2O_2 (400 µM) was inhibited by the transfection of small interfering RNAs for HSPB1. Overexpression of HSPB1 reduced Bax activation and H_2O_2-induced-apoptosis as measured by caspase 3 activity and the terminal deoxynucleotidyl transferase dUTP nick end labeling assay.

Conclusions: We showed that HSPB1 expression increased during oxidative stress in AKI. Incremental HSPB1 expression caused autophagy and inhibited apoptosis in renal tubular cells. These results indicate that up-regulated HSPB1 plays a role in the pathophysiology of AKI.

TH-PO163

Phosphoinositide 3 Kinase γ Plays a Critical Role in Acute Kidney Injury Xiaogao Jin, Yanlin Wang. *Medicine-Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Acute kidney injury (AKI) is a common clinical condition that is associated with high morbidity and mortality. Ischemia-reperfusion injury (IRI) is a common cause of AKI. There is no effective therapy for this serious clinical condition except renal replacement. Therefore, a better understanding of the pathogenic mechanisms underlying IRI is essential for ultimately developing effective therapy. Inflammation plays a critical role in the pathogenesis of IRI. However, the signaling mechanisms underlying inflammatory cell infiltration are not fully understood.

Methods: We examined the role of phosphoinositide 3 kinase γ (PI3Kγ) in inflammatory cell infiltration into the kidney in mice subjected to 30 minutes of ischemia followed by 24 hours of reperfusion.

Results: Compared with wild-type mice, PI3Kγ knockout mice protected the kidney from IRI. Tubular cell apoptosis induced by ischemia-reperfusion injury was decreased in the kidney of PI3Kγ knockout mice. Furthermore, PI3Kγ deficiency inhibited the infiltration of neutrophils, macrophages, and T cells into the kidney, which was associated with a decrease in the expression of the proinflammatory molecules in the kidney. Moreover, wild-type mice treated with AS605240, a selective PI3Kγ inhibitor displayed less tubular damage and apoptosis, accumulated fewer inflammatory cells and expressed less proinflammatory molecules in the kidney following IRI.

Conclusions: Our results demonstrate that PI3Kγ plays a critical role in the pathogenesis of acute renal ischemia-reperfusion injury, suggesting that inhibition of PI3Kγ may be a potential therapeutic strategy in acute kidney injury.

Angiotensin 1-7 (Ang1-7) Protects against Renal Ischemia Reperfusion (I/R)-Induced Acute Kidney Injury (AKI) and Its Deleterious Cardiac Effect; Possible Role of Vascular Endothelia Growth Factor (VEGF) Arnaldo F. Lopez-Ruiz,[1] Andrea P. Soljancic,[1] Kiran B. Chandrashekar,[1] Ruisheng Liu,[2] Luis A. Juncos.[1] *[1]Medicine/Nephrology, Univ of Mississippi Medical Center, Jackson, MS; [2]Physiology, Univ of Mississippi Medical Center, Jackson, MS.*

Background: Ang1-7 is a contra-regulatory peptide of the renin-angiotensin system with cytoprotective effects. AKI has been shown to induce distant deleterious effect in other organs including the heart. AKI-induced cardiac dysfunction is associated with impaired VEGF expression. We tested whether exogenous Ang1-7 protects against I/R-induced AKI and its cardiac deleterious effects. We also tested if Ang1-7 upregulates VEGF expression.

Methods: AKI was induced by clamping both renal pedicles for 40 min. SD rats were divided into 4 groups, namely; sham, AKI, AKI+Ang1-7, AKI+Ang1-7+A779 (Ang1-7 antagonist). Drugs were given 1 day before I/R and continued for for 2 extra days. During follow up, plasma creatinine, sFlt-1 (anti-angiogenic factor) and urine NGAL (tubular injury marker) were measured. 48h after I/R, kidneys (K) and heart (H) were harvested to evaluate TNFα (pro-inflammatory signal), BNP (cardiac distress) and VEGF (cytoprotective factor).

Results:

	Creat (mg/dl)	NGAL (UI/ml)	K-TNFα (pg/ml)	H-TNFα (pg/ml)	sFlt-1 (pg/ml)	K-VEGF (pg/ml)	H-VEGF (pg/ml)	H-BNP (pg/ml)
Sham	0.6±0.1	155±70	9.5±2	3.2±1	45±6	382±64	340±45	32±8
AKI	2.3±0.1*	1380±92*	155±21*	88±6*	755±35*	95±12*	88±7*	245±15
AKI+ Ang1-7	1.6±0.1#	635±115#	72±8#	38±4#	390±58#	228±25#	185±15#	115±18
AKI+ Ang1-7 +A779	2.1±0.2	1270±125	141±15	76±9	725±42	110±10	98±6	228±26

* $p<0.05$ vs Sham, # $p<0.05$ vs AKI

Conclusions: AKI leads to systemic increase of anti-angiogenic factor and impaired renal VEGF expression.AKI contributed to cardiac dysfunction by inducing pro-inflammatory signaling which also resulted in impaired cardiac VEGF expression. Ang1-7 attenuated I/R-induced AKI and ameliorated its cardiac deleterious effect perhaps by upregulating VEGF expression and reducing sFlt-1 release.

Potential Role of Asymmetric Dimethylarginine in AKI Yosuke Nakayama, Nana Obara, Seiji Ueda, Miyuki Yokoro, Seiya Okuda. *Div of Nephrology, Dept of Medicine, Kurume Univ, Kurume, Fukuoka, Japan.*

Background: Injury to the renal vasculature plays important roles in the pathogenesis of acute kidney injury (AKI). However, roles of asymmetric dimethylarginine (ADMA), an endogenous inhibitor of nitric oxide synthease, in AKI remain unclear. So, we investigated the kinetics and the roles of ADMA in ischemia/ reperfusion (IR)-injured mice and patients undergoing elective coronary angiography (CAG).

Methods: We first examined the kinetics of ADMA, and DDAH-1, a key enzyme for ADMA degradation, levels in the kidney of IR-injured mice. Further, we examined the effects of continuous infusion of ADMA on renal IR injury, and studied whether the IR injury could be attenuated in DDAH-1 transgenic (Tg) mice. Furthermore, we collected blood and urine samples of 52 patients before and after elective CAG at our institution.

Results: After the IR injury, DDAH-1 levels were decreased and renal and plasma ADMA levelswere increased in association with renal injury. Infusion of subpressor dose of ADMA exacerbated renal dysfunction,capillary loss and tubular necrosis in the kidney of IR-injured wild mice, while theseIR-induced damages were attenuated in DDAH-1 Tg mice. In contrast-induced nephropathy (CIN) study, no case of obvious AKI assessed by changes increatinine level was identified. However, levels of ADMA, high sensitivity C-reactive protein (hs-CRP), N-acetyl-β-D-glucosaminidase (NAG) and L-type fatty acid binding protein (L-FABP) were significantly increased by administration of contrast medium. Further, elevated hs-CRP levels but not ADMA, NAG and L-FABP levels were significantly associated with semiannual increased creatinine levels in these patients.

Conclusions: Our present studysuggests that IR injury may reduce DDAH-1 expression andresultantly cause ADMA accumulation, which could lead to capillary loss and tubularnecrosis in the kidney, thereby being involved in renal injury.Although, further study is needed to clarify the long term impacts of ADMA elevation in CIN patients on future of organ damage, ADMA could be a novel predictive maker for AKI.

Renoprotective Effect of Testosterone Propionate in Ischemia-Reperfusion (I/R) Induced Acute Kidney Injury (AKI) Chetan N. Patil,[1,2] Rodrigo Maranon,[1,2] Carolina Dalmasso,[1,2] Huimin Zhang,[1,2] Luis A. Juncos,[3] Jane F. Reckelhoff.[1,2] *[1]Women's Health Research Center, Univ of Mississippi Medical Center, Jackson, MS; [2]Dept of Physiology and Biophysics, Univ of Mississippi Medical Center, Jackson, MS; [3]Dept of Medicine, Div of Nephrology, Univ of Mississippi Medical Center, Jackson, MS.*

Background: Acute Kidney injury (AKI) is a leading cause of morbidity and mortality among patients, and men are more prone to AKI compared to women. Our lab has recently shown that serum testosterone levels are significantly reduced by 3 hrs post ischemia and the levels remain reduced at 24 hrs. We also found that infusion of testosterone 3 hrs post reperfusion attenuated renal injury following ischemia/reperfusion (I/R). In the present study we evaluated the dose response effect of testosterone propionate in I/R induced AKI.

Methods: Male SD rats (8-14 wks; n=3-5/grp) were subjected to sham surgery or I/R induced AKI with bilateral clamping of renal vessels for 30 min. Three hrs after reperfusion, rats were administered with vehicle (0.75%EtOH) or fixed dose of testosterone propionate (i.v. over 10 min). Rats were placed in metabolism cages for 24hrs for nitrate/nitrite excretion (UNOxV), and euthanized and blood taken for creatinine (PCr).

Results: I/R increased PCr and decreased UNOxV, compared to shams (0.58±0.05 versus 3.99±0.36 mg/dL, p<0.0001; UNOxV: 8.54±1.7 versus 1.7±0.78 µmol/day/kg BW, p<0.001). Dose response study showed that administration of low dose (10ugm/kg, PCr 4.05±0.41mg/dL) as well has very high dose of testosterone (50ugm/kg, PCr 3.89±0.23 mg/dL; 100ugm/kg, PCr 4.56±0.21 mg/dL) failed to show any improvement in renal function in I/R induced AKI rat model. But 20µgm/kg testosterone propionate attenuated the increase in PCr (2.03±0.23 mg/dL, p< 0.01) and tended to decrease UNOxV (3.79±0.91 µmol/day/kg, p=0.0596).

Conclusions: These results suggest that modest doses testosterone propionate can improve renal function in males with I/R induced AKI. Hence testosterone propionate could be a potential therapeutic agent for the treatment of AKI in men. Supported by NIH R01HL66072, P01HL05971 and AHA 14POST18640015.

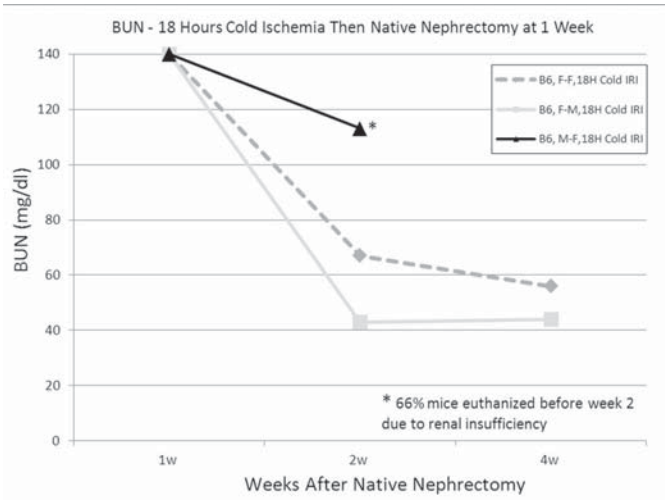
Gender Differences in Renal Ischemia Tolerance Are Mutable and Based on Reperfusion Environment Matthew H. Levine,[1] Zhonglin Wang,[1] Shayan Cheraghlou,[1] Liqing Wang,[2] Tricia Bhatti,[2] Wayne W. Hancock.[2] *[1]Surgery, Univ of Pennsylvania, Philadelphia, PA; [2]Pathology and Laboratory Medicine, Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: It is known that female mice have greater renal ischemia reperfusion injury (IRI) than males but the mutability of these differences and whether the environment at ischemia or reperfusion is unknown. We here utilize several models of transplantation to assess these factors.

Methods: A murine renal transplant model followed by native nephrectomy and subsequent 25 mins of warm IRI on the transplanted kidney was used in c57/b6 mice with readouts including daily BUN/creatinine for 4d after injury and automated Sirius Red fibrosis score at 30d after IRI. A cold ischemia model involving 18h of cold storage in UW solution followed by transplantation was used to separate donor and recipient gender effects.

Results: At baseline, B6 males tolerated approximately half the ischemic time of females to yield equivalent IRI. Female recipients of either gender kidney had superior tolerance to subsequent IRI than male recipients of either gender kidney, indicating that the IRI tolerancecan be altered by the local environment. Utilizing a cold ischemia transplant model, female donor kidneys yielded superior IRI tolerance regardless of recipient gender, compared to male donor kidneys (Fig 1).



This indicates that the gender environment at the time of ischemia is more important than at the time of reperfusion in determining IRI tolerance.

Conclusions: Syngeneic mouse gender can alter IRI tolerance significantly, indicating a role for hormonal manipulation. IRI tolerance of male kidneys can be made equal to female after transplantation to a female environment, proving mutability of the process. The cold ischemia data indicate that treatment at the time of ischemia (ie in the donor) is likely to yield maximal benefit.

Recombinant Alkaline Phosphatase Ameliorates Creatinine Clearance and Glomerular Filtration Rate in Rat Ischemia-Reperfusion-Induced Acute Kidney Injury: An Intravital Microscopy Study into the Mode-of-Action Andrea van Elsas,[1] Ruben M. Sandoval,[2] Silvia B. Campos-Bilderback,[2] Bruce A. Molitoris.[2] *[1]AM-Pharma, Bunnik, Netherlands; [2]Indiana Univ School of Medicine, Indianapolis, IN.*

Background: In two clinical studies bovine purified intestinal Alkaline Phosphatase (AP) displayed intriguing activity in sepsis-associated acute kidney injury (AKI) (Heemskerk et al., 2009. CCM 37: 417; Pickkers et al., 2012. CC 23:R14). A human recombinant AP was designed by replacing the crown domain from intestinal AP with that derived from placental AP to obtain a stable highly active chimeric enzyme called 'recAP' (Kiffer-Moreira et al., 2014. PLOS One 9:e89374).

Methods: To gain further understanding of its mode-of-action, recAP was used to treat ischemia-reperfusion (I/R)-induced AKI in rats, RecAP was dosed immediately following nephrectomy and 30' clamping of the blood supply to the remaining kidney. Kidney function was determined after 24 h by plasma creatinine (PCr) and by ratiometric GFR quantification by two-photon microscopy using rhodamine-dextran (~150 kDa) and FITC-dextran (~5 kDa). Time-lapse video recording was used to determine RBC and WBC flow and vascular endothelial adhesion in the injured kidney.

Results: A significant rise in PCr developed from ~0.4 mg/dL in control nephrectomized SD rats to 3.2 ± 0.59 mg/dL after I/R (n=6). Single dose i.v. administration of recAP (50-2000 U/kg) significantly reduced PCr (1.7 ± 0.65 mg/dl at 500 U/kg) (p<0.01). In Munich-Wistar Frömter rats, PCr was 0.38 ± 0.04 mg/dL at t=0 rising to 2.28 ± 0.64 mg/dL 24 h post-injury (control). A single dose of 1000 U/kg recAP limited PCr to 0.82 ± 0.15 mg/dL. At 24 h post injury, control AKI rats demonstrated a ratiometric GFR of 0.09 ± 0.09 ml/min, compared to 0.75± 0.29 ml/min (p<0.005) in recAP treated rats. RecAP did not appear to alter RBC and WBC flow or adherence to vascular endothelium.

Conclusions: In conclusion, recAP demonstrated significant efficacy in the treatment of rat I/R-induced AKI maintaining GFR and plasma creatinine close to normal levels. The mode-of-action of recAP in this model of AKI is under further investigation.

Human Recombinant Alkaline Phosphatase Protects against Lipopolysaccharide-Induced Renal Inflammation Esther Peters,[1,2] Norbert Gretz,[3] Peter Pickkers,[1] Rosalinde Masereeuw.[2] *[1]Intensive Care Medicine, Radboudumc, Nijmegen, Netherlands; [2]Pharmacology and Toxicology, Radboudumc, Nijmegen, Netherlands; [3]Medical Research Centre, Medical Faculty Mannheim of Univ of Heidelberg, Mannheim, Germany.*

Background: Two phase-II trials showed improved renal function in critically ill patients with sepsis-induced AKI after treatment with the enzyme alkaline phosphatase (AP). Here we investigated the protective mechanism in vitro and in vivo, possibly related to dephosphorylation of lipopolysaccharide (LPS).

Methods: Human proximal tubular epithelial cells (ciPTEC) were incubated with LPS (10µg/ml). Human recombinant AP (10U/ml) was added 2h prior to LPS and cytokine production was studied after 24h by ELISA (n=5 per group). Male SD rats were treated with placebo (n=6), LPS (n=6) or LPS+AP (n=5). At t=0, LPS (IV, 0.3mg/kg) was administered to induce AKI, followed by an AP bolus (IV, 1000U/kg) at t=2h. GFR was assessed by transcutaneous measurement of FITC-sinistrin in freely moving awake rats. Urine was collected during 16h. At t=24h animals were sacrificed followed by blood and organ sampling.

Results: In ciPTEC, AP significantly reduced LPS induced cytokine response of TNF-α (40.4±7.9%), IL-6 (47.5±3.1%) and IL-8 (39.6±2.4%). Inactive AP had no effect on LPS-induced cytokine response, confirming the relevance of dephosphorylation. *In vivo,* LPS significantly prolonged FITC-sinistrin half-life (placebo: 20.7±1.6min, LPS: 54.6±8.9min) and decreased creatinine clearance (placebo: 3.1±0.3ml/min, LPS:2.3±0.2ml/min), for which AP treated animals were protected (half-life: 37.0±5.7min; creatinine clearance: 2.7±0.2ml/min). Also, AP prevented LPS-induced increase in fractional urea and KIM-1 excretion and renal KIM-1 expression.

Conclusions: Our data show a renal protective effect of AP in LPS-induced inflammation. Cell studies showed that the dephosphorylating property of AP is responsible for this effect. The ability of AP to reduce renal inflammation may account for the observed attenuated acute kidney injury in sepsis patients.

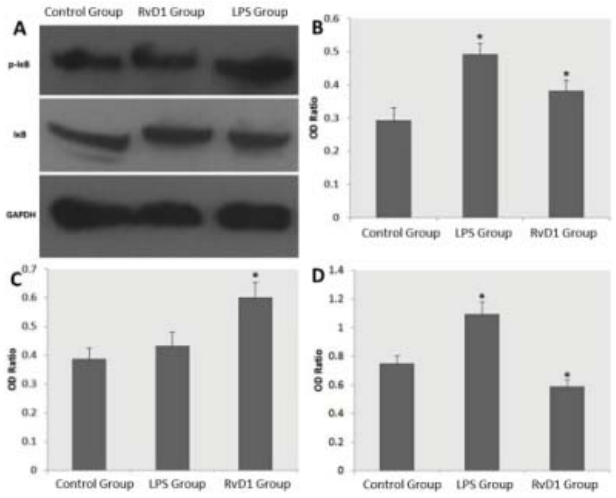
Resolvin D1 Protects Lipopolysaccharide-Related Acute Kidney Injury by Downregulating NF-κB Signaling Pathway Yuliang Zhao,[1] Ling Zhang,[2] Ping Fu.[3] *[1]Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan Province, China; [2]Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan Province, China; [3]Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan Province, China.*

Background: Resolvin D1 (RvD1), a newly found bioactive compound derived from DHA, has been described to promote inflammation resolution in various inflammatory disease models. The current study aims to explore the protection of RvD1 on lipopolysaccharide (LPS)-related AKI and its possible mechanism, so as to provide potential insights into therapeutic targets of septic AKI.

Methods: Male BALB/c mice and human proximal tubule epithelial (HK-2) cells were randomly divided into control group (saline), LPS group (LPS) and RvD1 group (RvD1+LPS). The drugs were intraperitoneally injected or added into medium. The animals' general condition were recorded. The blood, kidneys and HK-2 cells were harvested at different time points.

Results: We recorded the distribution of lipoxin A4 receptor (ALX, RvD1 receptors) on tubular epithelial. Kaplan-Meier analysis indicated that RvD1 improved 48h animal survival compared with LPS group, while RvD1 also ameliorated kidney pathological injury under HE staining and TEM scan. The blood creatinine and TNF-α level of LPS group were significantly increased, however RvD1 prohibited the trend. Quantitative PCR indicated after LPS stimulation, the mRNA expression of TLR4, MyD88 and TNF-α in both mice kidneys and HK-2 cells were all up-regulated, while RvD1 substantially inhibited the up-regulation of these genes. Western blot showed the p-IκB/IκB ratio in LPS group was significantly higher than the control group, while being inhibited in RvD1 group.



Conclusions: In LPS-related AKI, RvD1 could decrease TNF-α level, ameliorate kidney pathological injury, protect kidney function and improve animal survival by down-regulating NF-κB signaling pathway.

TH-PO171

Klotho Deficiency Aggravates Kidney Injury and Central Autonomic Modulation in Sepsis Lectícia Jorge,[1] Fernanda O. Coelho,[1] Fernando Santos,[2] Makoto Kuroo,[3] Lucia Andrade.[1] *[1]Nephrology, Univ of Sao Paulo, SP, Brazil; [2]Heart Inst, Univ of Sao Paulo, SP, Brazil; [3]Jichi Medical Univ, Tochigi, Japan.*

Background: Sepsis may be associated with a loss in cardiovascular variability and a heart sympathetic modulation impairment, suggesting that central autonomic regulatory dysfunction contributes to circulatory failure. Last year, we have demonstrated that Klotho(Kl) deficiency aggravates sepsis-related multiple organ dysfunction. The aim of this study was to evaluate the relationship among cardiovascular autonomic modulation, renal function and Kl deficiency, during sepsis.

Methods: 8-12 week old male Kl+/- and Kl+/+ mice (n=32) underwent CLP or sham operation. The mean arterial pressure (MAP) and heart rate (HR) were recorded 24 h post-surgery. Overall variability for high- and low-frequency components (HF, and LF, ms^2/Hz or mm Hg^2/Hz) from heart rate (HR) and systolic (SBP) blood pressures spectra were obtained from 60-min recordings. LF(HR)/HF(HR) and the square root of LF(HR)/LF(SBP) (alpha) were used as indices of sympathovagal interaction and baroreflex control of the heart, respectively. We also measured renal function (urea, mg/dl) at 24h after surgery.

Results: At 24h post-CLP, MAP decreased in both CLP groups compared with Sham groups (Kl+/Kl- CLP: 125±17 versus Kl+/Kl- Sham: 141±10 versus Kl+/Kl+ CLP: 116±23 versus Kl+/Kl+ Sham: 135±18, $p<0.05$). However, variability was significantly decreased in Kl+/Kl- CLP than in Kl+/Kl+ CLP (27±13 versus 77±39), as was LF power (1.8±1.5 versus 9±10), LF(HR)/HF(HR) (0.26±0.29 versus 0.57±0.5), LF(HR)/LF(SBP) (alpha) (0.6±0.38 versus 1.52±0.84). Urea was increased in Kl+/Kl- CLP group compared with Kl+/Kl+ CLP group (77±14 versus 54±4, $p<0.05$).After 24h, Kl+/Kl- CLP remained with an important impairment of autonomic control of the heart and baroreflex sensitivity, while, in Kl+/Kl+ CLP, those were recovered.

Conclusions: These results suggest that, in Kl deficiency, the decrease in central autonomic regulation contributes to circulatory failure and acute kidney injury.

TH-PO172

Nrf2 Activation Protects against Sepsis-Induced Acute Kidney Injury (AKI) Andrea P. Soljancic,[1] Arnaldo F. Lopez-Ruiz,[1] Kiran B. Chandrashekar,[1] Richard L. Ogletree,[2] Ruisheng Liu,[3] Luis A. Juncos.[1] *[1]Medicine/Nephrology, Univ of Mississippi Medical Center, Jackson, MS; [2]Pharmacology, Univ of Mississippi Medical Center, Jackson, MS; [3]Physiology, Univ of Mississippi Medical Center, Jackson, MS.*

Background: Sepsis is a systemic response to an infection that often leads to AKI. Sepsis-induced AKI is mediated by increased oxidative stress, inflammation and renal vasoconstriction. Activation of the Nrf2 pathway is an endogenous cytoprotective mechanism induced by sepsis. Nrf2 pathway upregulates antioxidant, anti-inflammatory and cytoprotective enzymes such as heme oxygenase-1 (HO-1). Bardoxolone (Bx) is a synthetic activator of Nrf2 pathway that has shown to protects against renal diseases. We tested if enhanced activation of the Nrf2 pathway using Bx protects against sepsis-induced AKI by inducing HO-1.

Methods: Sepsis was induced in SD rats by cecal-ligation-puncture (CLP). Four groups of rats were used; 1) sepsis control (CLP), 2) CLP + SnPP (HO-1 inhibitor), 3) CLP + Bx, 4) CLP + Bx + SnPP. At 24 hs plasma creatinine was measured and rats were then sacrificed. Kidneys were harvested to evaluate the expression of HO-1 and TNFα by Elisa. Urine was collected to evaluate prox. tubular injury (KIM-1).

Results:

	PL. Creatinine (mg/dl)	TNFα (pg/ml)	KIM-1 (pg/ml)	HO-1 (ng/ml)
CLP	1.97±0.1	219±7.7	390.2±15.8	11.07±0.5
CLP+SnPP	2.4±0.03*	322.5±7.4*	1079.8±47.4*	4.3±0.3*
CLP+Bx	1.3±0.1*	84.1±4.2*	224.2±9.8*	17.9±0.6*
CLP+Bx+ SnPP	1.5±0.1*	110.5±5.2*	272.6±12.8*	10.9±0.6#

Mean±SEM: *p<0.05 vs CLP; # p<0.05 vs CLP+Bx

Conclusions: CLP contributes to tubular injury (KIM-1) and activation of pro-inflammatory signals (TNFα) that are exacerbated during HO-1 inhibition. Bx further upregulates intrarenal HO-1, reduces tubular injury and improve renal function. HO-1 inhibition does not attenuate the protective effect of Bx. In conclusion, exogenous activation of Nrf2 pathway upregulates renal HO-1 and confers protection against sepsis-induced AKI; however this protective effect was not blocked by SnPP suggesting that the protective effect may not be mediated by HO-1.

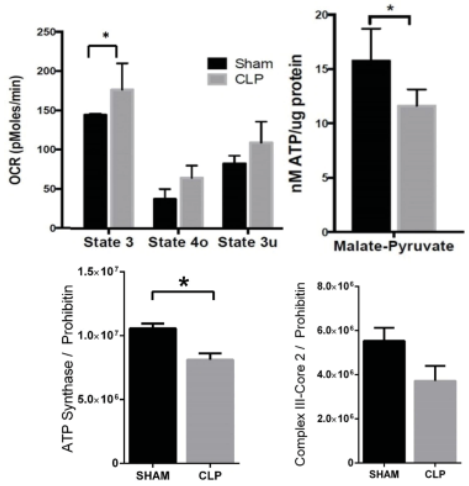
Role of AMPK in Mitochondrial Dysfunction in Sepsis-Induced AKI Noureddin D. Nourbakhsh, Joanna Thomas, Prabhleen Singh. *Medicine-Nephrology, UC San Diego and VASDHS.*

Background: Sepsis-associated AKI is frequently observed and has poor prognosis. The lack of complete understanding of its pathogenesis is a significant barrier to progress and fresh insights into its pathogenesis are critically needed.

Methods: We examined renal function, mitochondrial oxygen consumption, ATP generation and other functional and molecular analyses to examine mitochondrial dysfunction in the pathogenesis of sepsis using a model of cecal ligation and puncture (CLP) at 24 hours post-injury. We also evaluated therapies targeting mitochondrial dysfunction. Data presented as mean±sem.

Results: GFR was significantly reduced in CLP mice 345±19 versus 155±35 uL/min; p=0.004. HIF expression was significantly increased in the CLP kidneys demonstrating hypoxia. Mitochondria from CLP animals exhibited elevated rates of both coupled and uncoupled respiration, but ATP generation measured in the same samples was significantly lower, along with decreased expression of complex III and complex IV.



CLP mitochondria also demonstrated increased fission (DRP-1 expression), decreased biogenesis (PGC-1a expression) and reduced AMPK expression. AMPK activation with AICAR significantly improved GFR post CLP compared to untreated mice (267±59 versus 155±35 uL/min, p=0.02).

Conclusions: Renal mitochondria in the setting of sepsis demonstrate dissociation between oxygen consumption and ATP generation with increased fission and reduced biogenesis. Lower AMPK levels may be the primary event leading to mitochondrial dysfunction. Specific downstream pathways including biogenesis, fission-fusion balance and autophagy to explain mitochondrial dysfunction and response to AMPK activation are being examined.

Mitochondrial DNA Contributes to Sepsis Induced Acute Kidney Injury via Toll-Like Receptor 9 Naoko Tsuji,[1] Hideo Yasuda,[1] Takayuki Tsuji,[1] Naro Ohashi,[1] Akihiko Kato,[2] Yoshihide Fujigaki.[3] *[1]1st Dept of Medicine, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [3]Dept of Medicine, Teikyo Univ, Tokyo, Japan.*

Background: Inhibition of Toll-like Receptor (TLR) 9, whose ligand has been recently revealed to be not only bacterial DNA but also endogenous mitochondrial DNA (mtDNA), prevents septic acute kidney injury (AKI). We investigated roles of mtDNA for septic AKI.

Methods: Polymicrobial sepsis was induced in C57BL/6 male mice and TLR9 knockout (KO) mice by cecal ligation and puncture (CLP). The blood and kidney tissue were collected for quantitative analysis of mtDNA by PCR methods and renal injury at 2, 6 and 24 h after CLP. The intravenous mitochondrial debris (MTD) including mtDNAwas given to TLR9 KO and wild type mice. The renal expressions of neutrophil gelatinase-associated lipocalin (NGAL) by immunohistochemistry and western blot and serum creatinine (sCr) levels were assessed as renal injury and function markers respectively.

Results: The renal expressions of NGAL increased in proximal tubules at 2h and sCr levels increased at 24 h after CLP. (24h: sCr 0.41±0.05 versus 0.08±0.01 mg/dl, P<0.01). Plasma mtDNA levels increased at 2 and 6 h after CLP (2h: 4.5±1.8 versus 0.4±0.1 $\times 10^5$ copy/μl, p<0.05, 6h: 4.6±1.8 versus 0.5±0.1 $\times 10^5$ copy/μl, p<0.05, 24h: 2.0±0.9 versus 0.8±0.2 $\times 10^5$ copy/μl, p=0.20). TLR9 KO reduced renal NGAL expressions at 2h and sCr levels at 24 after CLP (sCr: 0.38±0.05 versus 0.17±0.02 mg/dl, p<0.01). MTD injection increased renal expressions of NGAL at 2 h, which was reduced by TLR9 KO.

Conclusions: Endogenous mtDNA entered into circulation of the blood at early phase after CLP and might activate TLR9 cascade, which contributed to development of AKI.

TH-PO175

TLR4-Dependent MEK/ERK Activation Suppresses Mitochondrial Biogenesis (MB) in a Mouse Model of Sepsis-Induced Acute Kidney Injury (AKI) Joshua Andrew Smith, L. Jay Stallons, Justin B. Collier, Rick G. Schnellmann. *Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.*

Background: Sepsis is the most common contributing factor to the development of AKI. Recent evidence indicates that disruption of mitochondrial homeostasis and biogenesis is an important cause of renal pathology in sepsis. We investigated the molecular mechanisms responsible for suppression of MB following endotoxin-induced AKI in mice.

Methods: AKI was induced by injecting male wild-type and TLR4-deficient mice with lipopolysaccharide (LPS; 10 mg/kg). A separate group of wild-type mice were treated with the MEK1/2 inhibitor Trametinib (1 mg/kg) 1 h prior to LPS. Serum and kidneys were harvested at 1, 3 and 18 h post-LPS. Renal function was determined by BUN. Renal mitochondrial homeostasis and biogenesis were assessed by RT-qPCR and immunoblot analysis of PGC-1α, its downstream targets, and nuclear- and mitochondrial-encoded components of the electron transport chain (ETC). Mitochondrial DNA content was measured by qPCR.

Results: Renal dysfunction was observed at 3 and 18 h post-LPS as demonstrated by increased BUN. PGC-1α transcript levels were decreased as early as 3 h after LPS exposure and remained suppressed at 18 h. mRNA expression of downstream targets of PGC-1α (NRF-1, TFAM, NDUFS1) as well as ETC components (NDUFB8, ATPSβ, and COXI) and mitochondrial DNA content was decreased at 18 h. TLR4-deficient mice were protected from LPS-induced renal dysfunction and suppression of MB. Immunoblot analysis demonstrated activation of ERK1/2 at 1 and 3 h post-LPS. Renal injury and loss of PGC-1α mRNA expression following LPS administration were attenuated by inhibition of MEK/ERK signaling.

Conclusions: Mitochondrial homeostasis is disrupted in a mouse model of sepsis-induced AKI. Our data also reveal an essential role for TLR4/MEK/ERK signaling in suppression of renal MB in this model. We propose that the TLR4/MEK/ERK signaling pathway is a novel therapeutic target to reverse mitochondrial dysfunction following AKI.

Influence of Lipopolysaccharides (LPS) on Neurogenic and Paracrine Function of Neurons with Renal Afferents Kristina Rodionova,[2] Stefan Karl,[2] Tilmann Ditting,[2] Wolfgang Freisinger,[2] Peter Linz,[2] Peter Reeh,[3] Kerstin U. Amann,[1] Roland Veelken.[2] *[1]Pathology, Universitätsklinikum Erlangen, Erlangen, Germany; [2]Nephrology, Universitätsklinikum Erlangen, Erlangen, Germany; [3]Physiology, Universitätsklinikum Erlangen, Erlangen, Germany.*

Background: Renal afferent nerves exert sympathomodulatory and paracrine effects (e.g. release of vasodilator CGRP) on kidney and cardiovascular system. Recently we demonstrated that inflammatory mediator CXCLR1 decreased the ability of cultured renal afferent neurons to generate sustained action potential (AP) firing upon electrical stimulation. Hence we tested the hypothesis that mediator of septic shock – LPS – likewise decreases number of renal neurons exhibiting sustained AP firing upon current injection.

Methods: Dorsal root ganglion neurons (Th11-L2) of rats were incubated with LPS (E.coli O127/B8, 20mg/l medium) 12 hours before patch clamp recording. Current clamp mode was used to characterize neurons as "tonic", i.e. sustained AP firing or "phasic", i.e. <5 APs in response to current injection. In voltage clamp mode, inward currents were assessed during stimulation of TRPV1 receptors with protons. In organ bath of kidney slices – incubated with or without LPS - we stimulated TRPV1 receptors with Capsaicin and measured CGRP content in organ bath supernatant (ELISA).

Results: Renal afferent neurons exhibited in 42% tonic firing pattern. Number of neurons with tonic response pattern was not altered by exposure to LPS. However, LPS exposure significantly increased inward currents due to TRPV1 receptor stimulation with protons (LPS: -3.62±0.41 pA/pF, control: -1.7±0.48 pA/pA, *p<0.05). CGRP release due to TRPV1 stimulation was also significantly increased. (LPS-incubation: 58±20 pg/ml, control: 14±2, *p<0.05).

Conclusions: LPS exposure did not decrease number of tonic afferent renal neurons as previously described for CXCL1, but increased inward currents upon TRPV1 receptor stimulation with protons. Furthermore, LPS sensitizes TRPV1 receptors to induce increased release of CGRP from afferent axons in kidney. Hence, renal afferent nerves in septic shock are rather likely to influence renal perfusion by CGRP release than sympathetic nerve activity by altered afferent nerve traffic.

Reduction of Tubular Flow Rate as a Mechanism of Oliguria in Endotoxemia Revealed by Intravital Imaging Daisuke Nakano,[1] Kent Doi,[2] Takashige Kuwabara,[3] Kiyoshi Mori,[3,4] Masashi Mukoyama,[3] Akira Nishiyama.[1] *[1]Dept of Pharmacology, Kagawa Univ, Kagawa, Japan; [2]Dept of Emergency and Critical Care Medicine, Univ Hospital, The Univ of Tokyo, Tokyo, Japan; [3]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [4]Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

Background: Urine output is widely used as a criterion for acute kidney injury (AKI) diagnosis. Although a number of investigations have identified potential mechanisms of septic AKI, regulation of urine flow post-glomerular filtration has not been evaluated. The aim of this study was to evaluate changes of urine flow in septic AKI by intravital imaging to enable real-time monitoring of intratubular urine flow rate.

Methods: Intravital imaging was performed by using 2-photon laser microscopy. Urine flow rate was estimated by the timing of the appearance of injected dyes in distal nephron segments.

Results: The tubular flow rate measured by freely filtered dye (FITC-inulin or Lucifer yellow) time-dependently declined after lipopolysaccharide (LPS) injection; it was already slower at 2 h in LPS-injected mice compared with saline-injected mice (saline: 38±3 s, LPS 2 h: 67±8 s, LPS 6 h: 125±17 s, n=5-8, p<0.05), while the blood pressure and GFR were normal. Importantly, fluorophore-conjugated LPS accumulated in the proximal tubules, selectively retaining the tubular fluid and inducing luminal obstruction owing to cell swelling. Delipidation of LPS or deletion of Toll-Like receptor 4 in mice abolished these effects (49±4 and 42±3 s, at 6 h, respectively). In contrast, neutralizing TNF-α showed little effect on LPS-induced tubular flow retention (112±20 s, at 6 h). Rapid intravenous fluid resuscitation started within 6 h could improve the tubular flow rate only when it was accompanied by the dilation of obstructed proximal tubules exhibiting LPS-accumulation.

Conclusions: The present findings suggest that LPS-induced signaling via TLR4 in the proximal tubules plays an important role in the reduction of urine flow in the early phase of endotoxemia, and that the efficacy of fluid resuscitation may depend on the response in LPS-accumulated tubules.

TH-PO178

Removal of LPS Binding Protein (LBP) Prevents Endothelial Dysfunction and Renal Fibrosis in Endotoxiemia-Induced Acute Kidney Injury Giuseppe Castellano,[1] Alessandra Stasi,[1] Angelica Intini,[1] Margherita Gigante,[1] Anna Maria Di Palma,[1] C. Divella,[1] Giuseppe Stefano Netti,[2] Clelia Prattichizzo,[2] Paola Pontrelli,[1] Enrico Fiaccadori,[3] Nicola Brienza,[1] G. Grandaliano,[2] Giovanni B. Pertosa,[1] Loreto Gesualdo.[1] *[1]Dept of Emergency and Organ Transplantation, Univ of Bari; [2]Dept of Medical and Surgical Sciences, Univ of Foggia; [3]Dept of Clinical and Experimental Medicine, Univ of Parma.*

Background: The pathophysiology of LPS-induced AKI is characterized by an intense activation of renal resident cells by endotoxin and derived pro-inflammatory products. The occurrence of renal fibrosis has been poorly investigated. Aim of the present study is to evaluate the association between endothelial dysfunction and acute fibrosis and the possible effects of coupled plasma filtration adsorption (CPFA) in this setting.

Methods: After 3h from LPS infusion, 8 pigs were treated with CPFA for 6h; 8 control pigs receive no treatment. Renal biopsies were performed before (T0) and 9h (T9) after LPS infusion. LBP levels were quantified in sera by ELISA. Endothelial cells (EC) were cultured in presence ofswine sera for 12h and were analyzed by FACS and RT-PCR.

Results: In a swine model of LPS-induced AKI, we found that CPFA significantly prevented fibrosis in septic pigs (Masson's Thricrome, p=0.04) by preserving EC phenotype in peritubular capillaries and renal arteries (α-SMA^{pos}EC 5.58±0.52 versus T9LPS:18.10±1.58, p=0.0002). The removal of LBP from endotoxemic sera (0.21±0.03ug/ml versus LPST9:9.6±0.69, p=0.0001) was critical to abrogate the effects of LPS on EC dysfunction in vitro, by blocking LPS-induced collagen I production (normalized mRNA expression, LPS CPFA sera:1.03±0.28 versus LPS sera: 4.17±0.72, p=0.03) and preserving EC phenotype (%CD31^{pos}EC, LPS CPFA sera:94.96±3.4 versus LPS sera:49±9.05, p=0.02). The addition of exogenous LBP in LPS CPFA sera induced EC dysfunction (CD31:62.83±6.09; collagen I:3.29±0.61) like the untreated endotoxemic animals sera.

Conclusions: Selective removal of the LPS adaptor proteins LBP might represent a therapeutic option to prevent EC dysfunction and tissue fibrosis in LPS-induced AKI.

TH-PO179

Endotoxemia-Induced Decrease in GFR Is Mediated in Part by COX-1 Derived Prostanoids in Mice Klaus Höcherl. *Dept of Pharmacology and Toxicology, Friedrich-Alexander Univ Erlangen-Nürnberg (FAU), Erlangen, Germany.*

Background: Thromboxane (Tx) A_2 has been suggested to be involved in the development of sepsis-induced acute kidney injury (AKI). Therefore, we investigated the impact of cyclooxygenase (COX)-1 and COX-2 activity on lipopolysaccharide (LPS)-induced renal TxA_2 formation, and on endotoxemia-induced AKI in mice.

Methods: Male C57BL/6 mice, 8-10 wk old, were used. Endotoxemia was induced by the injection of lipopolysaccharide (LPS; 3 mg/kg; i.p.). TxA_2 levels were measured by assay kits. Glomerular filtration rate (GFR) was determined by FITC-sinistrin clearance in conscious mice. Pimonidazole (60 mg/kg) was used to investigate renal hypoxia. Renal vascular permeability was measured by using Evans blue dye.

Results: Injection of LPS (3 mg/kg; i.p.) decreased glomerular filtration rate (GFR) and the amount of thrombocytes to about 50% of basal values after four hours. Plasma and renocortical tissue levels of TxB_2 were increased about 10- and 1.7-fold in response to LPS, respectively. The COX-1 inhibitor SC-560 attenuated the LPS-induced fall in GFR and in platelet count to about 75% of basal levels. Further, SC-560 abolished the increase in plasma and renocortical tissue levels of TxB_2 in response to LPS. The COX-2 inhibitor SC-236 further enhanced the LPS-induced decrease in GFR to about 40% of basal values. SC-236 did not alter thrombocyte levels nor the LPS-induced increase in plasma and renocortical tissue levels of TxB_2. Pretreatment with Clopidogrel inhibited the LPS-induced drop in thrombocyte count, but did not attenuate the LPS-induced decrease in GFR and the increase in plasma TxB_2 levels. In addition, SC-560 reversed LPS-induced vascular leakage and renal tubular hypoxia.

Conclusions: This study demonstrates that inhibition of COX-1 improves endotoxemia-induced AKI. Our data further suggest that vascular- rather than platelet-derived thromboxane could be responsible for the fall in GFR in response to LPS.

Hydrogen Sulfide Accelerates Recovery of Kidney after Ischemia/Reperfusion Injury Sang Jun Han,[1] Jee In Kim,[2] Kwon Moo Park.[1] *[1]Dept Anatomy and BK21 Plus, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; [2]Dept Molecular Medicine and MRC, Keimyung Univ, Daegu, Republic of Korea.*

Background: Hydrogen sulfide (H_2S), a novel biological gas, plays a protective role in ischemia/reperfusion (I/R)-induced acute kidney injury. However, the role of H_2S in the repair process after kidney injury remains to be defined. Here, we investigated the role of H_2S in recovery of kidney function and tubular epithelial cells following ischemia/reperfusion (I/R) injury.

Methods: Mice were subjected to 30 min of bilateral renal ischemia. Some mice were administered with NaHS, an exogenous H_2S donor, and propargylglycine (PAG), an inhibitor of cystathionine gamma lyase (CSE) which is a H_2S producing enzyme, beginning at 2 day after ischemia until sacrifice daily.

Results: I/R resulted in severe tubular cell damage and functional loss in the kidney as evaluated by PAS staining and plasma creatinine (PCr) concentration. Eight days after ischemia, the kidney was functionally recovered with a partial restoration of damaged tubules. I/R reduced expression level and activity of CSE and cystathionine beta synthase (CBS). The reduced activity and expression levels were gradually recovered over time. Administration of NaHS accelerated return to normal level of PCr, whereas administration of PAG delayed that. Furthermore PAG treatment increased mouse mortality after I/R. Administration of NaHS accelerated proliferation of tubular epithelial cells as evaluated by 5-Bromo-2′-Deoxyuridine (BrdU) incorporation whereas PAG delayed that.

Conclusions: Our findings demonstrate that H_2S accelerated recovery of kidney tubule cells following I/R by a increase in proliferation of tubular cells, suggesting that H_2S could be a therapeutic target for recovery after acute kidney injury.

Indole Derivatives Are Renoprotective in Acute Kidney Injury Takehiro Suzuki,[1] Takaharu Ichimura,[2] Hisato Shima,[2] Yoichi Takeuchi,[1] Eikan Mishima,[1] Yasutoshi Akiyama,[2] Chitose Suzuki,[2] Sadayoshi Ito,[2] Takaaki Abe,[2] Joseph V. Bonventre.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Tohoku Univ, Sendai, Miyagi, Japan.*

Background: In patients with chronic kidney disease, the uremic toxins may promote renal damage and anemia. We analyzed the effects of uremic solutes on erythropoietin (Epo) production in Hep3B cells and identified indole compounds that enhanced Epo-production. These indoles also had protective effects on HK2 cells against cytotoxic agents. The aim of this study was to clarify the effects of the indoles in kidney injury and to identify new drugs to prevent renal disease progression.

Methods: Forty-one indole compounds were synthesized and screened by monitoring Epo-production in Hep3B cells. Cytoprotective effects were examined by cell viability in HK2 cells treated with cisplatin or aristolochic acid. The most potent compound (#5) was administrated, at 50mg/kg body weight by gavage, to mice 3 hr before they were exposed to kidney ischemia (26 min) reperfusion injury (IRI) or cisplatin (20 mg/kg body weight by intraperitoneal injection). Plasma creatinine (Cr), blood urea nitrogen (BUN), renal pathology and Epo mRNA expression in kidney were assessed.

Results: Indole compound #5 (Indole #5) was most potent in Epo-production and cytoprotection. In IRI, Cr at 48 hr after ischemia was significantly reduced in the Indole #5-treated group (0.88 + 0.38 mg/dl versus 1.60 + 0.66, control.). Indole #5 treatment resulted in reduced tubular cell injury on histological examination, reduced expression of the acute kidney injury biomarker, KIM-1, and increased numbers of Ki67 positive cells. BUN, at 96 hr after cisplatin injection, was significantly reduced in Indole #5 treated groups (70.9 + 10.1 versus 101 + 13.0 mg/dl). Tubular cell injury and KIM-1 expression were reduced in the Indole #5-treated group. Epo expression in the kidney was not significantly different between Indole #5-treated and control groups.

Conclusions: Indole #5 has renoprotective effects in both IRI and cisplatin nephrotoxicity. Indole derivatives may be effective kidney protective therapeutic agents.

Funding: Government Support - Non-U.S.

TH-PO182

Thioredoxin-Interacting Protein (TXNIP) Is Up-Regulated and Regulates the Mitochondrial Function, NOX4, and Apoptosis of Renal Tubular Cells in Acute Kidney Injury In Vitro and In Vivo Yoshio Terada, Haruna Ide, Tatsuki Matsumoto, Kazu Hamada, Yoshiko Shimamura, Koji Ogata, Kosuke Inoue, Yoshinori Taniguchi, Taro Horino, Shinpei Fujimoto. *Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Nankoku, Kochi, Japan.*

Background: Thioredoxin-interacting protein (TXNIP) has been found to regulate the cellular reduction-oxidation (redox) state by binding to and inhibiting thioredoxin in a redox-dependent fashion. However, little is known about the role of TXNIP in acute kidney injury (AKI) pathogenesis.

Methods: We used an in vivo rat ischemia/reperfusion AKI model and cultured renal tubular cells as an in vitro model. To elucidate the regulation of TXNIP, we evaluated the promoter activity and expression of TXNIP in NRK-52E cells in the presence of H_2O_2. We also evaluated mitochondrial enzymes, morphology, and apoptotic change in overexpression and siRNA of TXNIP.

Results: Immunohistological examination showed the expression of TXNIP in the proximal tubule cells after AKI. RT-PCR and western blot analysis showed that TXNIP mRNA and protein expression were up-regulated 6–48 h and 12–48 h after ischemia/reperfusion. TXNIP promoter activity, mRNA, and protein expression showed a dose-dependent induction by H_2O_2. Overexpression of TXNIP stimulated infammasome (ASC, IL-1β) and caspase3 activity, and caused apoptosis (TUNEL positive) in NRK-52E cells. Furthermore, inflammasome activation and apoptosis induced by H_2O_2 (400 μM) was inhibited by siRNAs for TXNIP. Protein and mRNA levels of ATP5a, complex(COX) IV, UCP2, PGC-1α in NRK-52E cells were significantly decreased by H_2O_2, and siRNA for TXNIP ameliorates reduction of these enzymes. NOX(NADPH oxidase)4 and oxidative stress marker (CellROX) was up-regulated by overexpression of TXNIP and down-regulated by siRNA of TXNIP.

Conclusions: We showed that TXNIP expression increased during oxidative stress in AKI. Incremental TXNIP expression induced NOX4 expression, oxidative stress, mitochondrial damage, and caused apoptosis in renal tubular cells. These results indicate that up-regulated TXNIP plays a key role in the pathophysiology of AKI.

Protective Effect of Allopurinol on Myoglobinuric Acute Kidney Injury Pedro H.F. Gois, Daniele Canale, Weverton M. Luchi, Rildo A. Volpini, Daniela Ferreira, Antonio C. Seguro, Maria H.M. Shimizu. *Univ of São Paulo.*

Background: Myoglobinuric acute kidney injury (AKI) is the most severe complication of rhabdomyolysis.**Objective:**To evaluate the efficacy of allopurinol (Allo) in protecting against glycerol-induced AKI.

Methods: Male wistar rats (258±5g) were injected intramuscularly with 5ml/Kg BW of either 50% glycerol(Gly) or 0.9% saline(SF). Five groups were studied:SF(n=5), SF+Allo(n=6), Gly(n=7), Gly+Allo(n=7), Gly+ivAllo(n=7). SF+Allo and Gly+Allo rats received Allo(300mg/L) in the drinking water 7 days prior to and for 24h after Gly/SF injection. Gly+ivAllo rats received intravenous Allo(50mg/Kg) 30 minutes after Gly/SF injection and Allo(300mg/L) in the drinking water thereafter.Analyzed data(24h after infusion):inulin clearance(GFR),blood pressure(BP),renal blood flow(RBF),tubular injury score(TIS),serum uric acid(UA),renal tissue immunoblotting for heme oxygenase(HO-1),manganese superoxide dismutase(MnSOD),cleaved caspase-3 and p21.Data are mean±SEM.

Results: Gly rats showed markedly reduced GFR associated with increased oxidative stress and apoptosis. Histopathological findings confirmed the renal dysfunction in the Gly group and myoglobin casts were observed in both Gly and Gly+Allo groups. Prophylactic Allo attenuated all of these alterations. BP and RBF did not differ among groups.

	SF	SF+Allo	Gly	Gly+Allo
GFR (ml/min/100gBW)	1.12±0.03	1.02±0.05	0.49±0.04^{ace}	0.78±0.08^{af}
UA (mg/dL)	1.7±0.1	0.3±0.1^{a}	1.4±0.3^{ce}	0.4±0.1^{a}
TIS	0.06±0.01	0.22±0.05	1.48±0.13^{ad}	0.81±0.17^{ae}
HO-1 (%)	100±6	77±8	647±40^{ace}	487±32^{ae}
MnSOD (%)	100±2	113±27	311±55^{ace}	126±25
Cleaved Caspase-3 (%)	100±8	103±6	158±18^{bce}	67±5
p21(%)	101±10	85±12	44±8^{adf}	76±9

^{a}p<0.001,^{b}p<0.01 **vs. SF**; ^{c}p<0.001,^{d}p<0.01 **vs. Gly+Allo**; ^{e}p<0.001,^{f}p<0.01 **vs. SF+Allo**

Therapeutic Allo also improved GFR(0.78±0.06ml/min/100gBW), TIS(0.89±0.17) and UA(0.3±0.1mg/dL).

Conclusions: Our data shows that Allo protects, both prophylactic and therapeutic, against renal dysfunction in a model of Gly-induced AKI by reducing oxidative stress and inhibiting apoptosis.This may represent a new therapeutic approach for myoglobinuric AKI.

Pharmacological Modulation of Wnt Signaling in a 3D Cell Culture Model Geurt Stokman, Sandrine Florquin. *Pathology, Academic Medical Center, Amsterdam, Netherlands.*

Background: Tubular morphology is tightly regulated by growth factor and morphogen signaling. Direct pharmacologic modulation of these pathways in animal models is difficult with respect to controlling adverse or off-target effects. To study the role of the morphogen Wnt in tubule formation and repair following injury we developed a 3D culture assay using proximal tubular epithelial cells.

Methods: HK-2 cells were cultured in a Matrigel-collagen matrix. Tubule formation was stimulated with Transforming Growth Factor-β1 and Hepatocyte Growth Factor resulting in formation of a branched network. Tubule morphology was analyzed by immunostaining and electron microscopy. Pharmacological activation of Wnt signaling was induced by exposure to GSK3 inhibitors or conditioned medium of L-cells expressing Wnt ligands. Inhibition of Wnt signaling was achieved by a tankyrase inhibitor. A fluorescent reporter cell assay confirmed that all Wnt signaling activators and inhibitors affected Wnt signaling in HK-2 cells. Digital image analysis was used to quantify morphological characteristics.

Results: Activation and inhibition of Wnt signaling during the full 5 day culture period significantly reduced tubule outgrowth in the culture assay and correlated to a decrease in cell proliferation. Activation of Wnt signaling in established tubules resulted in more pronounced intratubular cilia compared to controls. Inhibition of Wnt signaling led to cilia formation outside of the tubular structures and centrosome misorientation. Wnt signaling activation did not affect tubular damage by diethyl maleate-induced oxidative stress compared to controls, whereas treatment with the antioxidant N-acetyl cysteine prevented tubular damage.

Conclusions: Our results suggest that pharmacological modulation of Wnt signaling may have adverse effects on developing or regenerating tubules after injury. This model may be used to pre-screen the effect of pharmacological intervention in animal models for renal disease. In addition this model can predict the outcome on morphological alterations of tubules in the absence of biasing factors, providing a rationale for development of novel therapeutics.

Effect of Erythropoietin on Bone Marrow-Derived Mesenchymal Stem Cells Proliferation In Vitro under Acute Kidney Injury Micro-Environment and Its Mechanism Nanmei Liu. *Dept of Nephrology, Jimin Hospital of Shanghai, Shanghai, China.*

Background: Bonemarrow-derived mesenchymal stem cells (BMSC) transplantation is helpful for the repair of acute kidney injury (AKI) but with limited efficiency. Apoptosis or necrosis of the BMSC under the transplanted microenvironment is the main reason. This study investigated the effect of erythropoietin (EPO) on the proliferation of BMSC under the AKI microenvironment and the possible mechanism.

Methods: C57BL/6 mice's BMSC had been successfully isolated by the Percoll method. The AKI mouse model was prepared. Then we sacrificed the AKI mice and cut the renal cortex to make the AKI kidney homogenate supernatant. P3-BMSC was divided into the following groups:Group A: low glucose DMEM medium with the 10% FBS;Group B: low glucose DMEM medium with the 10% FBS plus the AKI kidney homogenate supernatant;Group C: low glucose DMEM medium with 10% FBS plus the AKI kidney homogenate supernatant and EPO(1, 5, 10, 50IU/ml). Each group was incubated for 1d, 3d, 5d, 7d. CCK-8 and TUNEL were used to detect proliferation and apoptosis of BMSC. Erythropoietin receptor (EPOR) and the level of the proliferation/apoptosis-related signal pathway protein were examined by the Western blot.

Results: The AKI microenvironment decreased BMSC's proliferation while the apoptotic proportion of BMSC was significantly higher than that of Group A. EPO intervention could enhanced the proliferation of BMSC, and at the same time, the apoptotic proportion of BMSC decreased significantly. Western blot showed that the EPO intervention decreased the Caspase-3 level in BMSC under the AKI microenvironment, while the protein expression of Bcl-2 in BMSC decreased significantly. The protein expressions of phosphor-Janus kinase2 (pJAK2) and phosphor-signal transducer and activator of transcription (pSTAT-5) were significantly increased by EPO intervention at the concentration of 10 IU/ml for 5d.

Conclusions: Erythropoietin can promote the proliferation of BMSC under the AKI microenvironment in vitro. EPO/EPOR and the activation of the proliferation/apoptosis-related signal pathway protein are the possible mechanisms.

Effective Treatment of Acute Kidney Injury with Mesenchymal Stem Cells Depends Critically on Their Early Administration That Is Triggered by an Early Diagnosis with SDF-1, an Injury- and Therapy-Specific Biomarker Anna Gooch,[1] Ping Zhang,[1] Zhuma Hu,[1] Jon D. Ahlstrom,[1] Florian Toegel,[2] Christof Westenfelder.[1,3] *[1]Medicine, U of Utah and VAMC, Salt Lake City, UT; [2]Medicine, Brigham and Women's Hospital, Boston, MA; [3]Physiology, U of Utah, SLC, UT.*

Background: A rise in serum creatinine (SCr) after a potential AKI in patients generally occurs only within 36 or more hours. Since it is not injury-specific, it is not suited to diagnose an actual renal insult that must be promptly treated. It is well established that

injury-specific biomarkers, such as NGAL, Kim-1, IL-18, etc., permit the diagnosis of AKI within a few hours post injury and thereby facilitate the timely institution of an effective therapy such as administration of Mesenchymal Stem Cells (MSCs). We reported previously that kidney tissue and urinary levels of the chemokine SDF-1 rise within 2-3 hrs post IRI AKI in rodents and in the urine of patients, and that this transient increase mediates the recruitment of administered, SDF-1 receptor-expressing MSCs.

Methods: To further examine the temporal relationship between induction, diagnosis and effective treatment of experimental AKI with allo-MSCs, groups (n=8) of SD rats with AKI (45 min bilateral renal pedicle clamp) were either infused with vehicle or with 2x10E6 allogeneic MSCs (Fischer344). Urinary SDF-1 and creatinine levels were monitored over 48 hrs post AKI.

Results: Urinary SDF-1/Cr ratios peaked at 2-5 hrs post insult and declined to baseline by ~ 24 hrs. The administration of MSCs post reflow and up to 6-8 hrs later was most effective in protecting and repairing renal function, while the comparative renoprotective activity declined by 24 hrs and became minimal by 36 hrs post AKI.

Conclusions: These data confirm that the early, biomarker-guided diagnosis of AKI identifies the optimal time for MSC-based, highly effective therapy of IRI AKI. Administration of MSCs at a time when injury-specific biomarker levels decline while SCr levels begin to rise appears futile because the compromised microvascular perfusion may limit the delivery of therapeutic MSCs into the kidney or may even be harmful if infused MSCs further impair renal blood flow.

Inhibition of the TGF-β Receptor 1 with SB-505124 Fails to Block the Mobilization of Mesenchymal Stem and Endothelial Progenitor Stem Cells following Remote Ischemic Pre-Conditioning Jon D. Ahlstrom,[1] Zhuma Hu,[1] Ping Zhang,[1] Christof Westenfelder.[1,2] *[1]Medicine, U of Utah and VAMC, Salt Lake City, UT; [2]Physiology, U of Utah, SLC, UT.*

Background: Acute kidney injury (AKI) is a common and serious condition for which there is currently no effective and approved treatment. Our laboratory has previously shown in animal models and in a Phase I Clinical Trial that Mesenchymal Stem Cells (MSCs) are a safe and effective therapy for AKI. Remote Ischemic Pre-Conditioning (remote IPC) has shown promise as a therapy for AKI. Remote IPC has also been shown to mobilize MSCs and endothelial progenitor cells (EPCs) into the circulation. However, the importance of MSCs and EPCs to the therapeutic effects of remote IPC for AKI is not known. To test the hypothesis that increased numbers of MSCs or EPCs from remote IPC therapy are required for the treatment of AKI with remote IPC, we evaluated the use of SB-505124 (a TGF-β R1-in inhibitor which has previously been shown to block the mobilization of MSCs) as a tool to prevent the mobilization of MSCs and EPCs in SD rats following remote IPC.

Methods: Groups (n=6) of adult, male Sprague Dawley rats were randomized into either remote IPC, remote IPC + SB-505124 (3 mg/kg I.P.), or SHAM rats. Remote IPC was performed in both hind limbs with 3 cycles of 4 min ischemia/4 min reperfusion. At 24 hrs post remote IPC, whole blood was evaluated by flow cytometry for the relative abundance of MSCs (CD45lo/CD271+), EPCs (CD45lo/CD34+), and hematopoietic stem cells (HSCs, CD45hi/CD34+).

Results: At 24 hrs following remote IPC, the numbers of circulating MSCs and EPCs were significantly increased. However, treatment with SB-505124 did not significantly block the mobilization of MSCs or EPCs following remote IPC.

Conclusions: Remote IPC significantly increased the numbers of circulating MSCs and EPCs. However, a more suitable method for blocking stem cell mobilization than SB-505124 is needed in order to test the importance of MSCs and EPCs for the treatment of AKI with remote IPC.

Effects of Human Adipose Tissue-Derived Mesenchymal Stem Cells with Expression Level Variants of HO-1 on the Cisplatin-Induced Acute Kidney Injury in Rats Hyun-Jung Kim,[1] Eun Ju Lee,[1] Hyun Seop Cho,[1] Dong Jun Park,[1] Se-Ho Chang,[1] Jin H. Kim,[2] Myeong H. Jung.[2] *[1]Internal Medicine; [2]Biomedical Research Inst Gyeongsang National Univ Hospital, Jinju, Republic of Korea.*

Background: Mesenchymal stem cells (MSCs)-based therapies are currently being investigated for the treatment of acute kidney injury (AKI), although the mechanisms involved remain controversial. Kidneys with injury were exposed to various environments such as oxidative stress, inflammation, and hypoxia. Heme oxygenase-1 (HO-1) that is induced in response to various stresses plays roles for anti-apoptotic, anti-inflammatory, and proangiogenic properties in AKI. This study designed to examine whether HO-1 plays a role in the beneficial effects of MSCs in AKI.

Methods: We isolated MSCs from human adipose tissue, found MSCs with different HO-1 expression level dependent on passages or individuals, and divided MSCs carrying the expression level variants of HO-1. Rats were divided into four groups: control, injected with cisplatin (10 mg/kg), and cisplatin followed by infusion of Ad-MSCs ($5X10^5$ cells) carrying the higher or lower HO-1 expression.

Results: Animal survival and renal function were decreased and histological damage was increased in cisplatin-treated rats at day 3. Infusion of Ad-MSCs ameliorated renal dysfunction, tissue injury, and apoptotic cell death caused by cisplatin, leading to increased survival. MSCs carrying the higher HO-1 expression are much more resistant to injury than those with the less expression of HO-1. The viability of cultured renal proximal tubular cells exposed to cisplatin was also improved by coculture with Ad-MSCs or with conditioned medium. The viability was more effective in MSCs or conditioned medium with higher HO-1 expression than less HO-1 expression. MSCs itself with higher HO-1 expression are more resistant to oxidative stimuli (and inflammatory environments) than those with the less expression of HO-1.

Conclusions: We demonstrated that Ad-MSCs with expression level variants of HO-1, naturally employed, can protect against cisplatin-induced AKI. Our results show that human Ad-MSCs exert a paracrine protective effect on cisplatin nephrotoxicity.

Human Umbilical Cord Mesenchymal Stem Cells Attenuate Kidney Injury and Endothelial Dysfunction in Sepsis Jose Manuel Condor Capcha, Camila Eleuterio Rodrigues, Daniele Canale, Maria H.M. Shimizu, Roberto De Souza Moreira, Lucia Andrade. *Nephrology, Univ of Sao Paulo, Brazil.*

Background: The pathophysiology of sepsis involves complex cytokine and inflammatory mediator networks, a mechanism to which nuclear factor kappa B (NF-κB) activation is central. Downregulation of endothelial nitric oxide synthase (eNOS) contributes to sepsis-induced endothelial dysfunction. Human umbilical cord mesenchymal stem cells (hUCB-MSCs) are known to express genes and secreted factors involved in angiogenesis, including vascular endothelial growth factor (VEGF) and e-NOS. We used a cecal ligation and puncture (CLP) model to analyze the role of hUCB-MSCs in sepsis-related organ dysfunction.

Methods: We used flow cytometry to evaluate hUCB-MSC phenotypes. We divided Wistar rats into groups: sham (sham-operated); CLP; and CLP+MSC (10^6 hUCB-MSCs, i.p., 6 h after CLP). At 24 h post-CLP, we evaluated renal function (inulin clearance, Cl_{in}); biochemical variables in serum and urine; and Klotho, eNOS, VEGF, Bax and NF-κB (immunoblotting) in kidney tissue (protein expression expressed as % of sham). Data are mean±SEM.

Results: hUCB-MSCs were negative for CD3, CD34, CD45 and HLA-DR, whereas they were positive for CD73, CD90 and CD105.

	Sham	CLP	CLP+MSC
Cl_{in}, ml/mim/100 g BW	0.84±0.02	0.26±0.031[a,b]	0.99±0.12
Klotho, %	100±3.1	43.3±5.5[a]	65.2±3.4[a,c]
eNOS, %	102.5±2.5	49.0±2.1[a,b]	97.4±2.8
VEGF, %	98.4±3.5	141.6±2.1	208.7±24.45[a,c]
NF-κB, %	98.0±4.1	164.8±3.9[a,b]	94.7±3.5
Bax, %	95.0±5.0	118.3±4.4[d]	95.2±2.3[c]

ap<0.001 vs. sham; bp<0.001 vs. CLP+MSC; cp<0.01 vs. CLP; dp< 0.05 vs. sham

Fractional excretion of sodium (FENa) was lower in CLP+MSC rats than in CLP rats (0.67±0.12 versus 2.0±0.64%, p<0.05), as was FEK (9.24±1.5 versus 18.5±4.3%), FEH_2O (1.52±0.25 versus 4.76±1.3%, p<0.002), aspartate aminotransferase (142.5±11.4 versus 217.0±25 IU, p<0.02) and alanine aminotransferase (39.6±4.2 versus 56.3±3.3 IU, p<0.02).

Conclusions: hUCB-MSCs protected renal and liver function, as well as upregulating VEGF and eNOS, and might therefore play a protective role in sepsis. (Supported by FAPESP).

TH-PO190

Human Umbilical Cord Mesenchymal Stem Cells in Acute Kidney Injury-Induced Renal Senescence Camila Eleuterio Rodrigues, Jose Manuel Condor Capcha, Ana C. de Bragança, Maria H.M. Shimizu, Barbara A. Santana-Lemos, Danilo Candido Almeida, Niels O.S. Camara, Lucia Andrade. *Univ of Sao Paulo, Brazil.*

Background: Ischemia/reperfusion-induced acute kidney injury (IR-AKI) induces kidney senescence, leading to cell-cycle arrest, telomere shortening and transient Klotho (Kl) deficiency. Although stem cells ameliorate renal injury, the effects might depend on their age. Human umbilical cord-derived mesenchymal stem cells (hUC-MSCs) might better protect against IR-AKI.

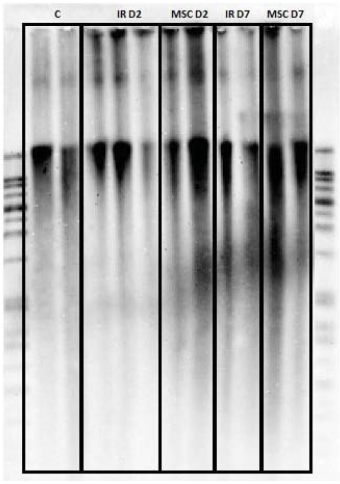
Methods: We used flow cytometry to evaluate hUC-MSC phenotype. Male rats were induced to IR-AKI by 45-min clamping of both renal arteries; some rats received 10^6 hUC-MSC i.p. 6 h later. Rats were euthanized on post-IR days 2 (D2) and 7 (D7). We studied four groups: IR-D2 (n=9); IR+MSC-D2 (n=5); IR-D7 (n=2); and IR+MSC-D7 (n=2). On D2, we measured creatinine clearance, fractional excretion of sodium (FENa) and FEK. In kidney tissue, we used Western blotting (for p21, Kl, TGFβ and ßgalactosidase) and Southern blotting (for telomere length). Data are mean±SEM.

Results: hUC-MSCs were negative for CD3, CD34, CD45 and HLA-DR, whereas they were positive for CD73, CD90 and CD105. Renal function was better in IR+MSC-D2 rats than in IR-D2 rats (0.22±0.06 versus 0.1±0.02 ml/min/100 g BW, p<0.05). FENa was lower in IR+MSC-D2 rats than in IR-D2 rats (0.73±0.25 versus 2.85±1.12%, p<0.05), as was FEK (12.41±3.96 versus 30.4±5.92%, p<0.02).

	IR-D2	IR+MSC-D2	IR-D7	IR+MSC-D7
p21, %	189.0±4.3	117.5±11.8[a]	99.5±1.5	99.5±0.5
Kl, %	42±4.0	73±8.8[a]	22.5±2.5	67.5±2.5[b]
TGFß, %	168±7.8	100±13.5[a]	99.5±1.5	98.5±0.5
ßgalactosidase, %	97.7±1.4	97.3±1.4	162±1.4	96±4.0

[a]p<0.05 vs. IR-D2
[b]p<0.05 vs. IR-D7

Telomeres length is shown.



Conclusions: hUC-MSCs improve renal function by preventing senescence. Supported by FAPESP.

TH-PO191

Exosomes (EXOs) Derived from Mesenchymal Stem Cells (MSCs) Minimized the LPS Acute Kidney Injury by Renal Pluripotent Cells Activation (rPCs) Luciana Aparecida Reis,[1] Gerson D. Keppeke,[2] Manuel De J. Simoes,[3] Nestor Schor.[1] *[1]Nephrology Div, UNIFESP/EPM, Sao Paulo, Brazil; [2]Rheumatology Div, UNIFESP/EPM, Sao Paulo, Brazil; [3]Morphology Dept, UNIFESP/EPM, Sao Paulo, Brazil.*

Background: Since acute kidney injury (AKI) has high morbidity and mortality, it is of relevance to search for alternative therapeutics. We investigated the effects of MSCs, your conditioned medium (CM) or EXOs in a LPS-induced nephrotoxicity model and the effects rPCs in this model.

Methods: Rats received *i.v.*: LPS (10 mg/B.W.) or PBS (CTL) with MSCs ($1x10^6$), CM (500 µl) or its EXOs (100 µg/ml) from MSCs incubated or not for 12 hours with cytochalasin B (CB; 1 µM) or actinomycin D (AD; 2.6 µM) and given in 1 or 3 doses and sacrificed after 72 hours. Blood and urine samples were collected for creatinine (sCr), urea (sU) and FENa. Kidneys were analyzed for HE, KI67, caspase 3, BrDU markers of RPCs as Wnt1, PAX2 and CD24. Also markers of EXOs as CD63, presence of Y chromosome, IL6, TNF-α, INF-γ and IL10 were also evaluated.

Results: As expected, it was observed increases in sCr, sU, FENa, caspase 3 marking, proinflammatory cytokines and reduction of KI67 with lesions in proximal tubules induced by LPS. However, these parameters were ameliorated with MSCs, CM or EXOs treatments. EXOs increased BrDU, Wnt1, PAX2, CD24 and CD63 expressions indicating activation of RPCs. CB and AD inhibited the protective effect of EXOs. It was impressive the effect of 3 times administration of MSCs or CM or EXOs decreasing the mortality in LPS group.

Conclusions: Therefore, results support that the MSCs and its CM and EXOs protected from AKI induced by LPS. It is reasonable to suggest that the mediation of by EXOs is, at least in part, by stimulating rPCs evaluated by PAX2, Wnt1 and CD24 positive staining. Also, suggest at least in part, participation of rPCs in this cascade of events and those EXOs alone could be employed in order to ameliorate LPS nephrotoxicity.

Granulocyte Macrophage-Colony Stimulating Factor Promotes Macrophage Alternative Activation After Renal Ischemia/Reperfusion Injury Sarah C. Huen,[1] Larry Huynh,[1] Arnaud Marlier,[1] Yashang Lee,[1] Gilbert W. Moeckel,[2] Lloyd G. Cantley.[1] *[1]Internal Medicine, Section of Nephrology, Yale Univ, New Haven, CT; [2]Pathology, Yale Univ, New Haven, CT.*

Background: Following kidney ischemia/reperfusion (I/R) injury, monocytes home to the kidney and differentiate into activated macrophages. While proinflammatory macrophages contribute to the initial kidney damage, an alternatively activated phenotype is required for normal renal repair. The microenvironment of the kidney during the repair phase mediates the transition of macrophage activation from a proinflammatory to a reparative phenotype. How signals from renal tubular cells influence these macrophage phenotypes is unknown.

Methods: Mouse proximal tubular (MPT) cells were cultured in serum free media for 48 hours to generate MPT conditioned media (CM). Bone marrow-derived macrophages (BMM) isolated from C57BL/6 mice were treated with MPT CM. Male C57BL/6 mice, 8-10 weeks old, were subjected to bilateral renal I/R for 24 minutes and given intraperitoneal neutralizing GM-CSF or isotype IgG antibody daily from day 1.5-5 after I/R. Kidney macrophages were isolated at various time points for gene expression analysis.

Results: *In vivo* kidney macrophages isolated during the tubular repair phase after I/R and *in vitro* BMM treated with MPT CM exhibit an alternative activation gene profile (induction of *Arg1*, *Cd206*, *Msr1*, but not *Dectin-1*, *Fizz1, Ym1*) that differs from macrophages induced by IL-4 (induction of *Arg1*, *Cd206*, *Dectin-1, Fizz1*, *Ym1*, but not *Msr1*). MPT CM activates STAT3 and STAT5, but not STAT6, in BMM, leading to induction of alternative activation. Using BMM from *LysM-Cre;Stat3$^{fl/fl}$* mice and pharmacologic inhibition of STAT5, we found that tubular cell mediated macrophage alternative activation is regulated by STAT5 activation. Blockade of GM-CSF, a known STAT5 activator, both *in vitro* and *in vivo* after renal I/R injury attenuated kidney macrophage alternative activation and suppressed tubular proliferation *in vivo*.

Conclusions: This data suggests that tubular cells can instruct macrophage activation by secreting GM-CSF, leading to a unique macrophage reparative phenotype and tubular proliferation after sterile ischemic injury.

Accelerated Recovery from Acute Kidney Injury through 5-Hydroxytryptamine 1F Receptor Agonism Sara M. Garrett,[1] Ryan Whitaker,[1] Rick G. Schnellmann.[1,2] *[1]Center for Cell Death, Injury, and ReGeneration, Dept of Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC; [2]Ralph H. Johnson Veterans Affairs Medical Center, Charleston, SC.*

Background: Mitochondrial dysfunction is a feature of diverse acute insults and chronic conditions (e.g., acute kidney injury (AKI), chronic kidney disease), with the greatest impact affecting tissues primarily reliant on aerobic respiration (e.g., kidney). Because pharmaceutical promotion of mitochondrial biogenesis (MB) has been shown to alleviate mitochondrial dysfunction in several model systems, we explored the role of the renal 5-hydroxytryptamine 1F receptor in MB and recovery from ischemia/reperfusion (I/R)-induced AKI.

Methods: Rabbit renal proximal tubules were isolated, cultured, treated with the selective 5-HT_{1F} receptor agonist LY344864, and tested for MB (FCCP-uncoupled oxygen consumption rate (OCR), mitochondrial protein level). Renal cortices from mice treated with LY344864 for various times and doses were analyzed for changes in MB gene expression. Mice subjected to I/R were treated daily with vehicle or LY344864, beginning 24 hr after I/R, and assessed for changes in blood urea nitrogen (BUN), kidney injury molecule-1 (KIM-1), and mitochondrial DNA (mtDNA) copy number.

Results: LY344864 (1 – 100 nM) increased FCCP-OCR and the mitochondrial proteins ATP synthase β, cytochrome c oxidase 1 (Cox1), and NADH dehydrogenase (ubiquinone) 1b subcomplex subunit 8 (NDUFB8) *in vitro*; this MB response was blocked with small interfering RNA knockdown of the 5-HT_{1F} receptor. LY344864 increased peroxisome proliferator–activated receptor coactivator 1α, Cox1, and NDUFB8 transcript levels and mtDNA copy number in renal cortex of naïve mice and accelerated recovery of renal function following I/R-AKI, as evidenced by decreased BUN and KIM-1 and increased mtDNA copy number.

Conclusions: Promotion of MB and accelerated recovery from I/R-AKI through agonism of the 5-HT_{1F} receptor represents a new approach to treat mitochondrial dysfunction in the setting of renal injury.

Nephron-Specific Kidney Injury Molecule-1 Expression Induces Tubular Damage and Kidney Failure in Transgenic Zebrafish Wenqing Yin, Dirk M. Hentschel, Joseph V. Bonventre. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

Background: Mammalian Kidney Injury Molecule-1 (KIM-1) is upregulated after kidney injury in proximal tubular cells, and also in animal models and patients with chronic kidney disease. In our murine model, sustained KIM-1 expression in renal epithelial cells causes kidney fibrosis and progression of CKD, suggesting KIM-1 could be a potential therapeutic target in chronic kidney disease. Here, we characterized zebrafish KIM-1 (zKIM-1) family members. By using the zebrafish model, we further verified the pathogenic role of KIM-1 in kidney injury and validated therapeutic screening approaches for chronic kidney disease.

Methods: We cloned zKIM-1 and compared biochemical and functional aspects with that of human KIM-1 (hKIM-1), using PCR, western blotting and immunostaining. We created two KIM-1 transgenic zebrafish models, one utilized a constitutively active promoter, the other tamoxifen-inducible. We also used the mTOR inhibitor (rapamycin) to ameliorate the KIM-1-induced phenotypes in murine and zebrafish models.

Results: As with hKIM-1, zKIM-1 was not expressed in healthy nephrons and was markedly upregulated after gentamicin-induced injury. zKIM-1 also showed a conserved phagocytic activity. Overexpression of zKIM-1 in the pronephros under control of the cdh17 promoter caused pericardial edema, reduced GFR and a higher mortality. Kidney tubular damage was present in nephrons overexpressing zKIM-1. Cre-mediated overexpression of zKIM-1 at 96 hours post fertilization caused a similar kidney maladaptive phenotype marked by tubular damage, edema and higher mortality. In KIM-1 transgenic mice and zebrafish models, rapamycin significantly protected and decreased zebrafish pericardia edema and mortality.

Conclusions: zKIM-1 has high sequence and functional similarities to hKIM-1 and is a biomarker for zebrafish kidney injury. Similar to the murine model, our zKIM-1 transgenic zebrafish also had tubular damage and renal failure, indicating that this genetic model can be used as a tool to identify potential therapeutics for KIM-1-potentiated CKD. mTOR may play an important role in maladaptive KIM-1 signaling.

Magnesium Protects against Cisplatin-Induced Kidney Injury in Tumor-Bearing Mice, without Compromising Cisplatin's Anti-Tumor Efficacy
Malvika H. Solanki, Prodyot K. Chatterjee, Xiangying Xue, Madhu Gupta, Nina Kohn, Christine N. Metz. *The Feinstein Inst for Medical Research, Manhasset, NY.*

Background: Cisplatin (CIS) is a potent chemotherapeutic drug for treating ovarian and other cancers. CIS-induced acute kidney injury (AKI) occurs in ~30% of patients with accompanying hypomagnesemia. Using an ovarian tumor xenograft model, we examined the role of magnesium (Mg) in CIS-AKI and cisplatin's anti-tumor efficacy.

Methods: Athymic nude mice (female, n=7-8/group, 7wks old) were started on normal (100%Mg) or 10%Mg (MgD) diets on day1. One group of MgD mice was switched to normal diet on day15 + $MgCl_2$ in water (7days) + $MgSO_4$ (s.c., 4days) (MgS). A2780 human ovarian cancer cells were injected (s.c., flank) on day2. Saline or CIS (10mg/kg, i.p.) were injected on days 12, 19 and 21; mice were euthanized on day22. Tumor growth was recorded, and blood urea nitrogen (BUN), renal apoptosis (TUNEL), and renal cell-death markers (by PCR array) were measured to assess renal damage.

Results: CIS-treated MgD mice had elevated BUN (P< 0.05) and renal apoptosis (P<0.05) compared to CIS alone. MgD mice treated with CIS had higher renal pro-apoptotic gene (*Apaf1, Atp6v1, Bax, Bcl2l11, Casp1/3/7, Fas, Gadd45, Tnf, Tnfrs10b,* and *Trp53*), and necrosis-related gene expression (*Ccdc103, Commd4, Dennd4a, Grb2, Mag, Mapk8, Parp2, Pvr* and *Txn14b*)compared to CIS-treated mice. Renal autophagy-related gene expression (*Akt, Atg3/5, Bax, Becn1, Casp3, Ctsb, Ctss, Map1lc3a, Mapk8, Rps6kb1, Sqstm1* and *Ulk*) was also upregulated in CIS-treated MgD mice versus CIS alone mice. MgS reversed the adverse renal effects of MgD and downregulated many of the upregulated genes (P<0.05). Tumor growth over time was inhibited by CIS and further inhibited by MgS on days 21-22. MgD did not significantly affect tumor growth regardless of CIS treatment.

Conclusions: MgS protects against CIS-induced AKI, as evidenced by improved kidney function, reduced activation of apoptosis and cell death-related pathways in the kidneys. While improving kidney function, MgS also improved CIS-induced tumor killing. These findings warrant future large scale studies assessing Mg status and aggressive Mg replacement therapy in CIS-treated patients.

CD4 T Cell Knockout Worsens Lung Cancer and Has No Effect on Cisplatin-Induced AKI in Mice
Kameswaran Ravichandran,[1] Hyun-Jung Kim,[1] Abdullah Ozkok,[1] Qian Wang,[1] Quocan Nguyen,[1] Alkesh Jani,[1] Raphael A. Nemenoff,[1] Howard Y. Li,[1] Danica Ljubanovic,[2] Charles L. Edelstein.[1] *[1]Univ of Colorado Denver; [2]Univ Of Zagreb.*

Background: We have developed a model of 4 week, low dose cisplatin (Cis)-induced AKI in mice with cancer that closely resembles the Cis dosing regimen used in humans with non small cell lung cancer. In the 4 week model of AKI, there is an increase in CD4 T cells that precedes the AKI and tubular injury suggesting that CD4 T cells may play a causative role. The aim of the study was to determine the effect of CD4 T cell depletion on AKI and the growth of lung cancer.

Methods: Wild type (WT) C57BL/6 or CD4 T cell -/- mice were injected with lung cancer cells in to the flank at day 1 subcutaneously. Ten days later, Cis (10 mg/kg/week) was given for 4 weeks.

Results:

	WT Vehicle	WT Cisplatin	CD4-/- Vehicle	CD4-/- Cisplatin
BUN (mg/dL)	20.6	128*	19	87**
SCr (mg/dL)	0.3	0.7*	0.3	0.6**
Tumor weight (g)	0.7	0.06*	1.4***	0.4**
Tumor volume week 1 (mm^3)	68	62	102	89
Tumor volume week 4 (mm^3)	682	67*	1152***	238**
Perf (n=3)	4+	4+	1+***	2+**
GrB (n=3)	5+	5+	2+***	3+**
CC3 (n=3)	1+	2+*	4+***	2+**

N=5-6 per group.* P< 0.01 vs. WT Vehicle.* P< 0.01 vs. CD4-/- Vehicle.* P< 0.05 vs. CD4-/- week 1. *P< 0.01 vs. WT vehicle.

The decrease in BUN and SCr in CD4-/- mice versus WT mice with AKI was not statistically significant. Tumor weight was double in CD4 -/- mice. Cis prevented the increase in tumor volume in WT mice but not in CD4-/- mice. Tumors in CD4-/- mice started enlarging at 1 week and were significantly larger at 4 weeks. To determine the mechanism of increased tumor growth, perforin (perf), granzymeB (grB) and cleaved caspase-3 (CC3) that decrease tumor growth by increasing apoptosis were measured by immunoblot. Perf, GrB were decreased in CD4-/- versus WT tumors. CC3 was increased by Cis in WT but not CD4-/- tumors. Despite larger tumors, CC3 was increased in CD4-/- versus WT tumors.

Conclusions: CD4-/- mice with AKI are not protected against AKI. Increased tumor growth in CD4-/- tumors is associated with decreased perf and grB. Cis increases CC3 in WT but not CD4-/- tumors (may explain less effect of Cis in -/- tumors). CC3 is increased in larger CD4-/- tumors perhaps as a compensatory response.

TH-PO197

NFKB Inhibition Protects against Cisplatin-Induced Acute Kidney Injury
Abdullah Ozkok,[1] Kameswaran Ravichandran,[1] Quocan Nguyen,[1] Qian Wang,[1] Danica Ljubanovic,[2] Charles L. Edelstein.[1] *[1]Univ of Colorado Denver; [2]Univ of Zagreb.*

Background: NFKB is a cell signaling pathway important in inflammation and cell survival. Inflammation, acute tubular necrosis (ATN) and apoptosis in the kidney are features of cisplatin-induced AKI. The role of NFKB in cisplatin-induced AKI was determined.

Methods: C57BL/6 miceinjected were with cisplatin (Cis) (25 mg/kg) get AKI on day 3. The NFKB (p65) inhibitor JSH-23 (20 mg/kg)IP was injected on day 1 and 2 after cisplatin.

Results:

	Vehicle (Veh)	Veh +JSH-23	Cisplatin	Cis+JSH-23
Creatinine (mg/dL)	0.29	0.25	1.04*	0.43 ***
BUN (mg/dL)	33	26	164 *	93 ***
ATN score	0	0	3	1.3
Apoptotic tubular cells per 10 HPF	1.5	0	8.5	5
Serum NGAL (ng/mL)	0.18	0	19.87 **	2.38 ***
IL-6 (pg/mg)	3.42	3.49	27.12 *	7.90 ***
IL-8 (pg/mg)	0.94	1.04	19.81 *	11.16 ***
TNF-alpha (pg/mg)	0.79	0.56	0.99 **	0.57 ***
MPO activity (unit/min/µg protein)	0.042	0.034	0.068 *	0.036 ***

*P<0.01 vs Veh, **P<0.05 vs. Veh, ***P<0.05 vs Cis.

Kidney function (BUN, SCr), tubular injury (ATN,serum NGAL), pro-inflammatory cytokines (IL-6, CXCL1, TNF alpha) and MPO activity (a marker of neutrophils and macrophages) were significantlyincreased in AKI and decreased by JSH. On immunoblotof kidney tissuesNFKB (p65), MEKK-1, ERK, JNK, cleaved caspase-3 were significantly increased in AKI and significantly decreased by JSH-23 (n=4 immunoblots/group. Statistical analysis of densitometry data was performed.

Conclusions: NFKB inhibition protects against Cis-induced AKI, decreases ATN but not apoptosis, decreases MAPK pathway proteins and pro-inflammatory cytokines and MPO.

TH-PO198

Paracrine Fibroblast to Epithelial Signaling Mediates Retinoic Acid-Dependent Repair after Acute Kidney Injury
Mark P. De Caestecker, Nataliya Skrypnyk, Leslie S. Gewin, Takuto Chiba. *Depts of Medicine, Cell and Developmental Biology, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Retinoic acid (RA) is a secreted ligand that activates RA signaling in neighboring cells to induce a variety of different responses. We have shown that RA signaling is activated in proximal tubular epithelial cells (PTECs) after acute kidney injury (AKI), and that inhibition of RA signaling in PTECs inhibits post-injury repair. During kidney development RA is synthesized locally from retinol by retinaldehyde dehyrogenase (Raldh) expressed in stromal mesenchyme and activates RA signaling in ureteric bud epithelium to regulate growth and branching. However the source and regulation of RA synthesis post AKI is unknown.

Methods: We used ischemia reperfusion AKI (IR-AKI) in mice to assess the regulation and localization of RA synthetic machinery post AKI. Renal cortical fibroblasts (RCFs) were isolated and treated with hypoxia and re-oxygenation, H2O2 or Antimycin A to activate oxidative stress and/or TEMOL to reduce oxidative stress. Expression of RA synthetic machinery in vivo and in vitro was assessed by QRT-PCR, Western blot and immunostaining, and RA synthesis assessed by co-culture with F9-RARE-LacZ reporter cells.

Results: Raldh3 and Raldh2 are strongly induced in SMA positive peri-tubular fibroblasts and in occasional F4/80 positive interstitial macrophages early (Raldh3: 6-12 hours) and late (Raldh2: 1-7 days) after IR-AKI. Raldh3>Raldh2 expression by cultured RCFs is increased by H2O2, hypoxia/re-oxygenation and Antimycin A, and inhibited with TEMPOL. RCFs exposed to oxidative stress secrete active RA.

Conclusions: These data suggest that RA synthesis by peri-tubular fibroblasts is induced by oxidative stress and promotes RA signaling in neighboring PTECs. Since RA signaling promotes tissue repair after AKI, these data suggest a novel paracrine-signaling pathway whereby peri-tubular fibroblasts activated by oxidative stress after AKI enhance RA-dependent regenerative repair of PTECs.

Elucidating the Mechanisms of Therapeutic Augmentation of Kidney Repair After Acute Kidney Injury
Lauren Brilli,[1] Takuto Chiba,[2] Nataliya Skrypnyk,[2] Mark P. De Caestecker,[2] Neil A. Hukriede.[1] *[1]Developmental Biology, Univ of Pittsburgh, Pittsburgh, PA; [2]Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Acute kidney injury (AKI) is a serious disorder for which there is no targeted clinical treatment. A promising approach to improve treatment options lies in developing novel post-AKI therapies that enhance innate renal regenerative processes.

Our lab has used zebrafish to identify small molecules that enhance renal tubular epithelial cell (RTEC) regeneration after AKI. Using this approach we identified methyl-4-phenylthiobutanoate (m4PTB), an HDAC inhibitor that promotes renal progenitor cell expansion in zebrafish embryos and accelerates recovery after AKI in zebrafish and mice. The ability of m4PTB to enhance RTEC proliferation post-AKI depends on intact retinoic acid (RA) signaling, suggesting that the RA pathway is critical to promote innate renal regeneration.

Methods: We utilize a nephrotoxic model of gentamicin-induced AKI in zebrafish larvae that demonstrates the same hallmarks of renal injury and regeneration post-AKI as the mammalian kidney. *Tg(12XRARE:GFP)* transgenic larvae are used to assess RA signaling, and heat shock is used to induce expression of a dominant negative RA receptor (RAR) in *Tg(hsp70:dnRARa)* larvae. Pharmacological RAR inhibitors are also used to block RA signaling.

Results: Expression of RA pathway components, including *aldh1a2* and *rarab*, is increased in the zebrafish kidney post-AKI, and RA target expression is further increased by m4PTB treatment by qRT-PCR in a mouse model of ischemia reperfusion AKI. Live imaging of *Tg(12XRARE:GFP)* zebrafish larvae after injury shows activation of RARE:GFP in RTECs that lose cadherin17 expression, suggesting that RA signaling is associated with RTEC dedifferentiation post-AKI. Finally, we show that blocking RA signaling either by heat shock in *Tg(hsp70:dnRARa)* larvae or by chemical RAR inhibition exacerbates injury and abrogates m4PTB-stimulated RTEC proliferation post-AKI.

Conclusions: This work implicates RA pathway activation as a critical response in renal regeneration post-AKI and suggests that m4PTB action is mediated by activating RA-dependent regenerative responses. Funding support: F30 DK101143.

Antagonism or Genetic Deficiency of PDGF-C Does Not Affect Renal Recovery in Two Models of Acute Kidney Injury Taizo Nakagawa,[1] Pia Paffenholz,[2] Ina V. Martin,[2] Peter Boor,[2] Stephanie Zok,[2] Sonja Djudjaj,[2] Jürgen Floege,[2] Tammo Ostendorf.[2] *[1]Toyamaken-Saiseikai Toyama Hospital, Toyama, Japan; [2]Diviision of Nephrology and Immunology, RWTH Aachen, Aachen, Germany.*

Background: Acute kidney injury (AKI) accelerates progression of chronic kidney disease. We recently identified platelet-derived growth factor C (PDGF-C) as a central pro-fibrotic factor in the kidney. Studies in AKI with non-specific PDGF/PDGF-receptor-antagonists reported an impaired tubular recovery. We therefore investigated this potential safety concern and assessed whether treating renal fibrosis with anti-PDGF-C strategies compromises renal recovery after AKI.

Methods: We compared the renal outcome following renal ischemia/reperfusion (I/R)- and cisplatin (Cis)-induced damage in wildtype- versus PDGF-C-deficient mice, and in anti-PDGF-C-antibody versus IgG-treated mice. We quantified tubular injury, apoptosis, cell proliferation, chemokine expression, leukocyte infiltration, expression of AKI markers, and expression of PDGF ligands/receptors in the cortical and outer medullary region.

Results: All mice showed severe tubular injury after induction of AKI by Cis or I/R, including overexpression of NGAL and KIM-1 and infiltration of leukocytes (day 5). mRNA expression of PDGF-A, -B and both PDGF receptors markedly increased following Cis or I/R (day5). Compared to control mice (PDGF-C WT littermates or WT mice treated with IgG) no significant differences were detected for most investigated parameters in all settings in the acute and early phase of AKI (d1 and d5 following I/R- or d3 and d5 in Cis-induced damage). In I/R (d5) infiltrating monocytes/macrophages and T cells were significantly reduced in PDGF-C$^{-/-}$-mice but not by anti-PDGF-C treatment. In the Cis model, infiltrating monocytes/macrophages (d5, 15 mg Cis, PDGF-C$^{-/-}$) and T cells (d3, 25 mg Cis, anti-PDGF-C) were rather increased.

Conclusions: In two AKI models, PDGF-C deficiency or anti-PDGF-C treatment resulted in no major difference compared to controls, suggesting, that antagonism of PDGF-C in AKI is safe at least in the short term. However, given variable effects of PDGF-C antagonism on infiltrating leukocytes, long term outcome studies in these models are ongoing.

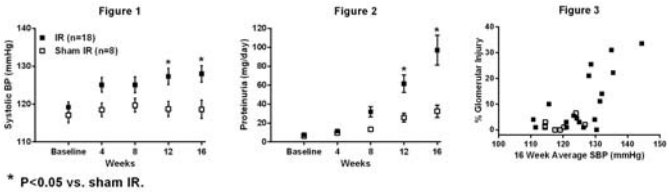
Role of Blood Pressure and Hemodynamic Factors in the Progression of CKD following AKI in Rats Aaron J. Polichnowski,[1,2] Karen A. Griffin,[1,2] Maria M. Picken,[2] Jianrui Long,[3] Geoffrey A. Williamson,[3] Rongpei Lan,[4] Manjeri A. Venkatachalam,[4] Anil K. Bidani.[1,2] *[1]Hines VA Hospital, Hines, IL; [2]Loyola Univ Medical Center, Maywood, IL; [3]Illinois Inst of Technology, Chicago, IL; [4]Univ of Texas Health Science Center, San Antonio, TX.*

Background: The mechanisms by which AKI accelerates the progression of CKD remain controversial. We have recently suggested that hemodynamic mechanisms may contribute to the accelerated rate of *de novo* glomerular injury following AKI (Polichnowski et al., *JASN* 2014); however, the quantitative relationships between radiotelemetrically measured blood pressure (BP) and renal injury have not been rigorously examined over an extended period following ischemia-reperfusion (IR) injury in rats.

Methods: Male SD rats underwent right uninephrectomy and were chronically instrumented with a BP radiotelemeter. Two weeks later, rats were subjected to 40 min IR (n=18) or sham IR (n=8). BP was assessed every 10 min, 24 hr/day and 24-hr urine collections were conducted every 4 weeks for 16 weeks following IR or sham IR. Kidneys were then perfused-fixed for blinded assessment of glomerulosclerosis (GS).

Results: Modest, but significant, increases in systolic BP (Fig. 1) and robust increases in proteinuria (Fig. 2) were observed by 12 weeks following IR versus sham IR. The % GS was significantly higher in rats with IR (11±3%) versus sham IR (2±1%). Moreover, the most robust levels of GS were observed in those rats whose average 16-week systolic BP exceeded ~128 mmHg (Fig. 3).



* P<0.05 vs. sham IR.

Conclusions: The modest hypertension that develops following IR in rats with pre-existing reduced renal mass may nevertheless lead to substantial increases in proteinuria and GS. These data suggest that further reductions of functional renal mass following IR in rats with pre-existing CKD may increase the renal BP transmission and susceptibility to additional BP-induced glomerular injury.

Id1 and 3 Expression Protects against Capillary Rarefaction and Fibrosis following Acute Kidney Injury Matthew D. Plotkin. *Dept of Nephrology, Central Arkansas Veterans Healthcare System, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Inhibitor of differentiation (Id) proteins are a family of dominant negative inhibitors of HLH transcription factors that inhibit progenitor cell differentiation and promote angiogenesis. Id1 and 3 are expressed in endothelial cells in the adult mouse kidney and are increased following injury. The aim of this study was to determine if Id1 and 3 prevent capillary rarefaction and fibrosis following acute tubular injury.

Methods: The response to folic acid (FA) induced tubular injury was examined in wild type (WT) and Id1 homozygous/Id3 heterozygous knockout (KO) mice along with the effect of oxidative stress in endothelial cells and fibroblasts isolated from these mice.

Results: Id1 and 3 levels were increased 1 day following FA injection with maximum 10-fold increased levels at day 5, returning to baseline by day 14. Elevated expression occurred in dilated collecting ducts and surrounding endothelial cells and fibroblasts. KO mice had an 8-fold increase in mortality at 2 days compared with WT mice, associated with increased collecting duct injury and nearly complete loss of medullary peritubular capillaries. At 2 weeks, KO mice had a 4-fold increase in medullary capillary rarefaction with a marked increase in fibrosis compared with WT mice. *In vitro*, cells isolated from WT mice had an immediate 5 fold increase in Id1 and 3 levels in response to H_2O_2 and a dose and time dependent increase at later time points. Compared with WT cells, KO cells displayed increased anti-oxidant and DNA repair gene expression and a 75% reduced level of apoptosis. No differences in ROS levels were detected. Surviving cells expressed αSMA, suggesting transition to a myofibroblast phenotype. Primary cultures of fibroblasts from adult WT and KO mice showed a similar response to oxidative injury and reduced αSMA expression with increased Id expression.

Conclusions: Id1 and 3 levels are increased in epithelial and mesenchymal cells following FA induced kidney injury. Id1 and 3 KO results in increased capillary rarefaction and fibrosis, a difference that may be due to endothelial-mesenchymal transition and increased fibroblast survival associated with decreased apoptosis.

H-Ras Gene Deletion in SVJ-129 Mice, Protects against Cisplatin-Induced Acute Kidney Injury Paloma Martín-Sánchez,[1] Laura Calleros,[1] Mercedes Griera,[1] Jose Luis Cano-Peñalver,[1] Manuel Rodriguez-Puyol,[1] Diego Rodriguez-Puyol.[2] *[1]Dept of Physiology, Univ de Alcalá, Alcalá de Henares, Madrid, Spain; [2]Research Unit, Hospital Univ Principe de Asturias, Alcalá de Henares, Madrid, Spain.*

Background: Arterial hypertension is one of the main causes of kidney dysfunction. Renal damage is often associated with certain drugs, as Cisplatin, a pharmacological compound used in chemotherapy that cause nephrotoxicity, altering glomerular filtration surface area. The importance of small GTP-binding protein Ras in arterial pressure regulation has been poorly studied. It has been demonstrated that H-Ras isoform genetic activation induce hypertension, and our group demonstrated that H-Ras gene deletion produces hypotension in mice. Therefore, in this work we consider the following OBJECTIVE: Check the protective effect of H-Ras deletion against Cisplatin-induced AKI.

Methods: Cisplatin was administered to SVJ-129 H-Ras lacking (H-Ras -/-) and WT mice (one single intraperitoneal 10 mg/kg dose). 72 hours after plasma and urine were collected (for creatinine determination) and kidneys were extracted to measure PKG expression. Tubular damage was analyzed in H&E stained sections. To verify that Cisplatin has a contractile effect, glomerular contraction experiments were done ex vivo.

Results: We demonstrated a significant reduction of plasma creatinine in H-Ras -/- mice, treated with Cisplatin, compared to WT group. When analyzing kidney tissue sections stained with H&E, a more important damage was observed in control samples treated with Cisplatin than in H-Ras -/- mice, showing a higher proportion of morphological alterations than in control kidneys.The increased PKG expression in H-Ras -/-, was demonstrated in

renal cortex of both animals groups (Cisplatin treated or not), suggesting the involvement of the PKG up-regulation in H-Ras deleted mice renal damage protection. Ex vivo glomerular contraction was higher in WT mice treated with Cisplatin than in H-Ras -/- mice.

Conclusions: The present results demonstrated that H-Ras gene deletion reduced acute renal damage induced by Cisplatin in mice, possibly trough a renal cortex PKG expression up-regulation mechanism that produces glomerular vasorelaxtion.

Oat1/3 Restoration Protects against Renal Damage after Ischemic AKI

Reinhard Schneider,[1] Marcus Meusel,[1] Boris Betz,[1] Christopher Held,[1] Kerstin Möller-Ehrlich,[2] Maike Julia Buettner,[3] Christoph Wanner,[1] Christoph Sauvant.[4] *[1]Div.Nephrology, Univ Hospital, Wuerzburg; [2]ZEMM, Julius-Maximilians Univ, Wuerzburg; [3]Nephropathologic Inst Univ, Erlangen; [4]Clinic for Anaesthesia, Halle/Saale, Germany.*

Background: Expression of proximal tubular organic anion transporters Oat1 and Oat3 is reduced by prostaglandin E2 (PGE2) after renal ischemia and reperfusion (I/R) injury. We hypothesized that impaired expression of Oat1/3 is decisively involved in the deterioration of renal function after I/R injury. Therefore, we administered probenecid, which blocks proximal tubular indomethacin uptake, to abolish the indomethacin mediated restoration of Oat1/3 regulation and its effect on renal functional and morphological outcome.

Methods: Ischemic AKI was induced in rats by bilateral clamping of renal arteries for 45 min with 24h follow up. Low-dose indomethacin (1mg/kg) was given i.p. at the end of ischemia. Probenecid (50mg/kg) was administered i.p. 20 min later.

Results: Indomethacin restored the expression of Oat1/3, PAH net secretion and PGE2 clearance. Additionally, indomethacin improved kidney function as measured by GFR and morphology, whereas in opposite it reduced renal cortical apoptosis and nitric oxide production. Notably, indomethacin did not affect inflammation parameters in the kidneys (e.g. MCP-1, ED1+-cells). On the other hand, probenecid blocked the indomethacin induced restoration of Oat1/3 and moreover abrogated all beneficial effects.Notably, indomethacin did not affect parameters of inflammation in the kidneys (e.g. MCP-1, ED1+-cells). On the other hand, probenecid blocked the indomethacin induced restoration of Oat1/3 and moreover abrogated all beneficial effects.

Conclusions: Our study indicates that the beneficial effect of low-dose indomethacin in iAKI is not due to its anti-inflammatory potency, but in contrast to its restoration of Oat1/3 expression and function. Inhibition of proximal tubular indomethacin uptake abrogates the beneficial effect of indomethacin by resetting the PGE2 mediated Oat1/3 impairment, thus re-establishing renal damage. This provides evidence for a mechanistic effect of Oat1/3 in a new model of the induction of renal damage following ischemic AKI.

TH-PO205

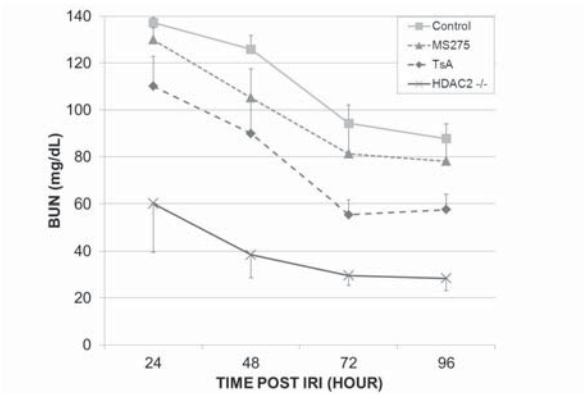
HDAC2 Deletion Leads to Substantial Increase in Tolerance of Ischemia Reperfusion Injury

Matthew H. Levine,[1] Zhonglin Wang,[1] Shayan Cheraghlou,[1] Liqing Wang,[2] Tricia Bhatti,[2] Wayne W. Hancock.[2] *[1]Surgery, Univ of Pennsylvania, Philadelphia, PA; [2]Pathology and Laboratory Medicine, Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: We have identified that pan-histone deacetylase (HDAC) and class I-HDAC specific drug inhibition leads to increased tolerance of ischemia reperfusion injury (IRI), preserving early renal function and limiting long term fibrosis. We have investigated the role of individual deletion of three of the class I HDACs (HDAC 1, 2, and 3) on IRI.

Methods: A murine model producing 28 minutes of unilateral warm renal IRI with contralateral nephrectomy was performed in mice with inducible ERT2-Cre mediated deletion on floxed HDAC 1 and 2. Pan-HDAC3 deletion led to murine death so a kidney specific deletion was produced by transplanting kidneys from floxed HDAC3:ERT2-Cre kidneys into wildtype recipients and performing renal IRI once the transplant had stabilized with equivalent wildtype controls. Renal function was assessed by BUN or creatinine measurement daily for 4 days and fibrosis scoring was by automated Sirius Red quantification at 30d after IRI.

Results: Global HDAC2 deletion led to substantial improvement in IRI tolerance by BUN and creatinine assay - greater than with pan HDAC (TSA) or class I HDAC (MS275) drug inhibitiors (Fig1). HDAC2 deletion was protective of renal fibrosis development.



HDAC1 deletion had no significant impact on renal IRI tolerance. Global HDAC3 deletion led to lethality at a mean of 17 days. HDAC3 deletion confined to the kidney was well tolerated but did not alter tolerance of renal IRI.

Conclusions: HDAC2 plays a key role in IRI tolerance with substantial improvement in renal function and fibrosis formation in HDAC2 deficient animals. The other tested class I HDAC knockouts did not alter renal IRI tolerance. Further investigation into the role of HDAC2 in IRI tolerance are ongoing.

Non-Muscle Myosin Heavy Chain Type II A Is Required for TRIM72-Mediated Proximal Tubular Cell Protection in AKI

Pu Duann,[1] Pei-Hui Lin,[2] Haichang Li.[1] *[1]Medicine, Ohio State Univ, Wexner Medical Center, DHLRI, Columbus, OH; [2]Surgery, Ohio State Univ, Wexner Medical Center, DHLRI, Columbus, OH.*

Background: Trim -72 is a TRIM family member protein essential for membrane repair. It was originally clone in striated muscle and was recently identified in proximal tubular epithelial cells after injury. We have previously demonstrated using myofibroblast cell line C2C12, it immune-colocalized with non-muscle myosin heavy chain type IIA (myh9), at early stages in myotubule differentiation. Genetic studies conducted on May-Hegglin anomaly patients, myh9 mutation is the molecular basis results victim patients highly susceptible to steroid resistant glomerulonepohropathy. In genetically ablated rodents, kidney phenotype such as glomerulopathy were observed similar to May-Hegglin patients. However, we and other groups observed that the NMIIA also abundantly expressed in tubular epithelial cells besides podocytes. We previously observed TRIM -72 are capable to protect tubular epithelial cells in acute kidney injury. And TRIM -72 null mice (mg 53-/-) are highly susceptible To IRI-AKI. It is not clear if the interaction between myh9 and TRIM -72 contributes to TRIM-72-medated PTEC protection.

Methods: We use in vitro system human proximal tubular epithelial cells (HKC8) cotransfected with TRIM -72 and various myh9 constructs (a full length, truncated or mutants: pcDNA-Myh9-wt, pcDNA-myh9-ΔTail, and pcDNA-myh9-ΔIQ2 respectively) to assess intermolecular interaction by immune coprecipitation and observe membrane repair capability.

Results: We observed the immune-coprecipitation between NMIIA and TRIM -72 was complete abolished upon tail-domain truncation (pcDNA-myh9-ΔTail) and partially altered if their light chain regulatory motif were mutated. The TRIM -72 molecules travel along the cellular tracks composed of NMIIA to seal injured membrane. The TRIM72 apparently lost its membrane repair capability with truncated (pcDNA-myh9-ΔTail) or mutant NMIIA (pcDNA-myh9-ΔIQ2).

Conclusions: NMIIA in PTEC cells may contribute to TRIM -72 mediated tubular protection in AKI. NMIIA in PTEC cells, distinct to podocyte in May-Heggin anomaly, is required for TRIM -72-mediated membrane repair at PTEC in AKI.

TH-PO207

Progranulin Protects against Renal Ischemia/Reperfusion Injury in Mice

Fan Yi. *Dept of Pharmacology, Shandong Univ School of Medicine, Jinan, Shandong, China.*

Background: Progranulin (PGRN), an autocrine growth factor, has multiple physiological functions and is widely involved in the pathogenesis of many types of diseases. However, the role of PGRN on the regulation of renal function keeps unclear. The pivotal anti-inflammatory role of PGRN in rheumatoid arthritis and other inflammatory disease models encourages us to further elucidate the function of PGRN in ischemic acute kidney injury (AKI).

Methods: Acute kidney injury was induced by renal ischemia/reperfusion (I/R) injury in PGRN knockout ($PGRN^{-/-}$) mice and age-matched C57BL/6 wild type was (WT) mice. Western blot analysis, real time RT-PCR, immunohistochemistry, TUNEL assay, and renal function and morphological examinations were used in this study.

Results: In this study, we found that PGRN was significantly reduced in the kidney from a mouse model of renal I/R injury. Furthermore, we observed that PGRN deficiency significantly aggravated renal injury as demonstrated by higher serum creatinine, more severe morphological injury, increased tubular epithelial cell apoptosis and tubulointerstitial neutrophil and macrophage infiltration in $PGRN^{-/-}$ I/R mice versus control mice. In vitro, we further found that PGRN decreased hypoxia-induced inflammatory response and apoptosis in proximal tubule epithelial cells, which was associated with NOD2-mediated immune response. To our surprise, both wild type mice pretreated with and delayed administration of recombinant PGRN (rPGRN) could effectively protect against renal I/R injury or promotes recovery from AKI.

Conclusions: Our results provide new evidence for a better understanding of the biological activities of PGRN in the kidney and suggest that PGRN may be an innovative therapeutic strategy for treating patients with ischemia and reperfusion–associated disease.

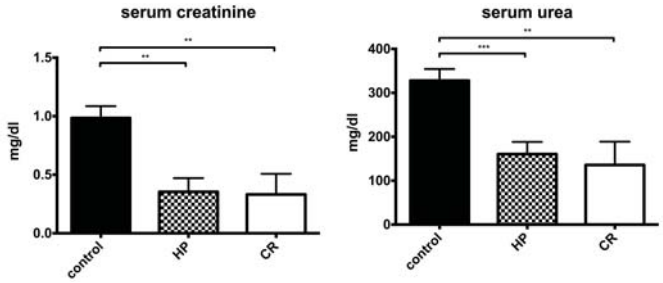
TH-PO208

Transcriptional Regulation of Renal Organ Protection Marc Johnsen,[1] Torsten Kubacki,[1] Bernhard Schermer,[1,2,3] Thomas Benzing,[1,2,3] Volker Rolf Burst,[1] Roman-Ulrich Mueller.[1,2,3] *[1]Dept 2 of Internal Medicine and Center for Molecular Medicine Cologne, Univ of Cologne, Cologne, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases, Univ of Cologne, Cologne, Germany; [3]Systems Biology of Ageing Cologne, Univ of Cologne, Cologne, Germany.*

Background: Preconditioning strategies have been used successfully to attenuate AKI but the underlying mechanisms remain largely unknown. Both, caloric restriction and exposure to hypoxia, are organ protective when applied acutely and expand lifespan when applied chronically in all species examined. We hypothesized that there are evolutionary conserved pathways which we tried to identify on the mRNA-level.

Methods: After subjecting male BL6 mice either to a 40% caloric reduction (CR) or to intermittent hypoxia treatment (HP) we performed unilateral nephrectomy and ischemic AKI in the contralateral kidney induced by clamping of the left vascular pedicle. Transcriptional analysis was performed using RNA sequencing on the unharmed kidney, which was harvested at first.

Results: There was a marked protective effect of preconditioning on serum parameters (creatinine, urea) and survival that was most prominent in the CR group.



Analysis of the RNA sequencing results revealed an overlap of a set of genes in both preconditioning groups which were confirmed by qPCR. By performing qPCR on preconditioned hearts and livers, we further reduced the number of candidate genes.

Conclusions: We were able to narrow down the group of putative candidate genes involved in a postulated, conserved, organ independent mechanism of preconditioning warranting further investigation.

microRNA Let-7C Delivery Using Engineered Mesenchymal Stem Cells to Combat Kidney Fibrosis Bo Wang, Andrea F. Wise, Brooke M. Huuskes, Sharon D. Ricardo. *Dept of Anatomy and Developmental Biology, Monash Univ, Melbourne, Victoria, Australia.*

Background: MicroRNA is highly effective at reducing renal fibrosis and reversing progression of disease. However, the advancement of miR therapies is hampered by difficulties indelivering miR in a robust and sustainable manner. The ability of MSC to transfer large molecules, and even organelles, suggests their potential usefulness as delivery vehicles for therapeutic miRtreatmentas an innovative approach.

Methods: C57BL6/J mice after unilateral ischemia/reperfusion (IR) injurywere injected with $1x10^6$ enhanced green fluorescent protein$^+$/firefly luciferase$^+$MSCs and imaged from 0-7 days using whole body bioluminescence imaging for cell tracing. miR-let7c modified MSCs were co-cultured with NRK52E, a kidney proximal tubular cell line, using a Transwell system, and the expression of fibrotic genes assessed using qPCR.

Results: Following IR, MSCs homed to the injured kidney where they remained for up to 3 days. miR-let7c was successfully engineered and expressed in MSCs. The modified miR-let7c-MSCs produced miR-let7c into the exogenous environment through exosome delivery. MSC-delivered miR-let7c was endocytosed into NRK52E cells and strongly inhibited the up-regulation of smooth muscle actin, collagen and *TGF-b* type I receptor, a specific target of miR-let7c.

Conclusions: MSCs home to the injured kidney in mice with IR injury. *In vitro* studies show that miR-let7 produced from modified MSC can be endocytosed into kidney epithelial cells leading to the inhibition of fibrotic genes induced by *TGF-b1*. This data will pave the way for the application of miR, or even siRNA, as an innovativeRNAi therapeutic strategy for renal disease therapy, but may also offer promise for other degenerative chronic disorders.

Hypoxia Inducible Factor 1 Alpha (Hif-1a) and Oxidative Stress as Triggers of Chronic Kidney Disease (CKD) Induced by an Acute Kidney Injury (AKI) Episode Roxana Rodríguez Romo,[1,2] Arturo Gómez,[1,2] Kenia Benitez,[1,2] Sara Huerta,[3] Gerardo Gamba,[1,2] Rosalba Perez-Villalva,[1,2] Norma Bobadilla.[1,2] *[1]Molecular Physiology Unit, Inst de Investigaciones Biomédicas, UNAM; [2]Nephrology, Inst Nacional de Ciencias Médicas y Nutrición; [3]Hospital Infantil Federico Gómez.*

Background: There is a lack of knowledge about the temporal influence of different potential mechanisms that trigger the progression to CKD induced by an AKI episode. This study was designed to evaluate the role of Hif-1a and oxidative stress in participating in chronic renal injury induced by ischemia/reperfusión.

Methods: Twenty three Wistar male rats underwent to renal bilateral ischemia for 45 min were studied and sacrificed after 1, 2, 3 or 4 months after ischemia. Nine sham-operated rats were studied 1, 2 and 4 months after. At the end of each experimental period, mean arterial pressure (MAP), renal blood flow (RBF), creatinine clearance (CCr), urinary protein (UProt) and urinary peroxide excretion (UH_2O_2) were measured, as well as total and nuclear Hif-1a expression assessed by tissue microarray and immunohistochemistry.

Results: Rats underwent to ischemia remained normotensive and exhibited a progressive increment in UProt that was significant since the 3rd month. In contrast oxidative stress was apparent since the 1st month. Although renal dysfunction was not observed after 4 months of ischemia, there was a significant increment in the glomerular area, which was accompanied by a significant increase in the nuclear expression of Hif-1a.

Conclusions: Our results suggest that oxidative stress plays an early role in provoking renal injury, whereas the activation of Hif-1a occurs lately, however both mechanismsare undoubtedly involved in promoting long-term functional and structural alterations in this model of renal injury induced by an AKI episode. Moreover, this study pointed out the importance of studying the effect of anti-oxidants just when ischemic insult has happened or the use of Hif-1a inhibitors to determine their impact in reducing the CKD progression.

TH-PO211

The PPAR-α Agonist Fenofibrate Ameliorates Aging-Related Progressive Renal Injury Eun Nim Kim, Ji Hee Lim, Min Young Kim, Byung Ha Chung, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Yoonsik Chang, Bumsoon Choi. *Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

Background: Aging is a multifactorial process characterized by a progressive decline in physiological function. Peroxisome proliferator-activated receptor-α (PPAR-α) is key regulators in various age-associated physiological processes related to energy metabolism and oxidative stress. We therefore examined the activation of PPAR-α by PPARa agonists fenofibrate would improve changes of aging and oxidative stress in the kidney.

Methods: Male 19-month-old C57/BL6 mice were used in this study. Fenofibrate (0.1%) was provided to old mice for 6month. We measured histological change, oxidative stress, and aging-related protein expression in the kidneys.

Results: Fenofibrate-treated old-mice displayed decreased albuminuria (59.4 ± 31 ng/24hr versus 22.7 ± 8.5 ng/24hr; $p < 0.05$ versus VH). Creatinine clearance increased with Fenofibrate-treated old-mice (0.07 ± 0.04 ml/min versus 0.16 ± 0.05 ml/min; $p < 0.05$ versus VH). Serum creatinine was decreased in Fenofibrate-treated old-mice, although this was not statistically significant (0.75 ± 0.3 mg/dL versus 0.44 ± 0.2 mg/dL). There were decreases in mesangial volume (56.1 ± 2.06% versus 42.87 ± 1.25%; $p < 0.001$ versus VH) and tubulointerstitial fibrosis (16.1 ± 4.32% versus 4.41 ± 3.61%; $p < 0.001$ versus VH) in Fenofibrate-treated old-mice. In our study, expression of PPARa (1 ± 0.2 fold versus 1.31 ± 0.11 fold; $p < 0.05$ versus VH) was increased in Fenofibrate-treated old-mice. SIRT1 expression (1 ± 0.2 fold versus 1.97 ± 0.23 fold; $p < 0.05$ versus VH) was increased in Fenofibrate-treated old-mice compared with control-old mice. Also, expression of PGC-1a (1 ± 0.07 fold versus 1.85 ± 0.13 fold; $p < 0.05$ versus VH) was increased in Fenofibrate-treated old-mice.

Conclusions: These results suggest that PPAR-α agonists may benefit aging-related renal injury by SIRT1 activation. Pharmacologically targeting PPAR-α and SIRT1 signaling molecules may reduce the pathologic changes of aging in the kidney.

TH-PO212

AMPK Activation and Angiotensin II Receptor Blockade Have Synergic Action in Reducing Angiotensin II-Induced Extracellular Matrix Accumulation in Human Mesangial Cells Jose B. Lopes de Faria, Kamila Silva, Jacqueline M. Lopes de Faria, Alexandros Papadimitriou. *Renal Pathophysiology Laboratory, Investigation on Diabetes Complications, Univ of Campinas (UNICAMP), Campinas, Sao Paulo, Brazil.*

Background: A rise in angiotensin II (ANG II) and 5' adenosine monophosphate-activated protein kinase (AMPK) reduction are both associated with progression to kidney fibrosis. However, the mechanism of interaction between ANG II and AMPK in extracellular matrix (ECM) accumulation is not known. The aims of the current study were to assess 1) the contribution and mechanism of AMPK leading to ECM accumulation in human mesangial cells (HMCs) exposed to ANG II and 2) the role of AMPK activation under a renin angiotensin system (RAS) blockade.

Methods: HMCs were exposed for 24 h under ANG II (1 μM) with or without an ANG II type I receptor blocker (losartan, LS, 10 μM); silencing NOX4 (siRNA 200 nM); AMPK

activators (AICAR, metformin (MTF), 1 mM); LS with AICAR or metformin; LS or AICAR with NOX4 siRNA; or an AMPK blocker (Compound C, CC, 10 μM). Western blot was used to evaluate the expression of NOX4, phosphorylated LKB1 (p-LKB1), phosphorylated activated AMPK (p-AMPK), phosphorylated SMAD3 (p-SMAD3), and collagen IV (C-IV).

Results: In HMCs, ANG II reduced p-AMPK and increased NOX4, p-SMAD3, and C-IV levels, all of which were reversed by LS or AICAR ($P<0.0014$). LS increased p-AMPK via a rise in p-LKB1 ($p<0.0023$). NOX4 siRNA, LS, and AICAR equally reduced an ANG II-induced rise in p-SMAD3 and C-IV levels ($p<0.0018$). Reduction in NOX4, p-SMAD3, and C-IV by LS or AICAR was reversed with CC ($P<0.0012$). AICAR or MTF with LS further increased p-AMPK and further decreased NOX4, p-SMAD3, and C-IV levels under ANG II compared to LS ($p<0.0001$).

Conclusions: HMCs under ANG II, AICAR, or MTF with LS confer an additional reduction in ECM accumulation compared to LS via a synergistic AMPK activation and hence inhibition in NOX4/TGF-β1 signaling.

Renoprotective Effects of Metformin in Response to Unilateral Ureteral Obstruction in Mice Michael Christensen, Jorgen Frokiaer, Rikke Norregaard. *Inst of Clinical Medicine, Aarhus Univ, Aarhus, Denmark.*

Background: Metformin is the first choice treatment for type-2 diabetes where it among others has glucose stabilizing effects. Besides the effects in diabetes metformin has been used as an anti-inflammatory agent preventing inflammation in several disease models, including kidney injury models. In this study, we examined the effect of metformin on the progression of tubular injury, inflammation and oxidative stress in response to unilateral ureteral obstruction (UUO).

Methods: C57bl/6 mice were treated with metformin (500mg/kg/day) 7 days prior to obstruction, as well as 3 days post obstruction. Treated and sham-operated mice were sacrificed and plasma as well as kidneys was harvested for both RNA and protein analyses as well as histological and immunohistochemical analysis.

Results: Hematoxylin and eosin staining showed lesser tubular dilation in the metformin treated UUO group (UUO-MET) compared to UUO. Kidney injury molecule-1 a specific marker for proximal tubule damage was markedly increased in the obstructed kidney of UUO mice, and this increase was partly normalized in the UUO-MET. UUO increased inflammatory markers TNFalpha and interleukin-6 which was attenuated in response to metformin administration. The M1 macrophage marker integrin alpha X was expressed to a lesser extent in the metformin treated UUO mice, indicating lesser macrophage infiltration. Besides a down regulation of inflammatory markers there was an increase in the abundance of the antioxidants protein heme oxygenase-1 and superoxide dismutase-1 in the UUO-MET mice compared to untreated UUO mice. Mice receiving metformin had elevated plasma levels of lactate both in SHAM and UUO groups, indicating that metformin was successfully administrated to the mice. Plasma creatinine and urea were unchanged after metformin administration in response to UUO.

Conclusions: In conclusion, this study indicates that metformin attenuates the progression of tubular injury, inflammation and oxidative stress in mice exposed to a 3 days UUO.

TH-PO214

PGC-1a Attenuates Reactive Oxygen Species Induced Kidney Injury By Activating Nrf2-Mediated Mitochondrial Antioxidants Hoon In Choi,[1] Jung Sun Park,[1] Eun Hui Bae,[2] Seong Kwon Ma,[2] Jong Un Lee,[1] Soo Wan Kim.[2] *[1]Physiology, Chonnam National Univ Medical School, Gwangju, Korea; [2]Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea.*

Background: The peroxisome proliferator activated receptor (PPAR) gamma co-activator 1α (PGC-1α) has been known as a transcriptional master regulator of mitochondria biogenesis and antioxidant response. Ischemia/reperfusion (I/R) triggers acute kidney injury (AKI) via aggravating oxidative stress and inflammation. Therefore we postulated PGC-1α may reduce oxidative stress and inflammation in renal tubule cells.

Methods: I/R induced AKI was developed by clamping both renal pedicles for 30 min. Mice were sacrificed 1 day later after operation. We developed stable PGC-1α over-expressing cell line in human renal proximal tubule epithelial cells (HK-2 cells). Cell viability was examined using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. Apoptosis was assessed by flow cytometry analysis after the cells were stained by fluorescein isothiocyanate-conjugated annexin V and propidium iodine. The fluorescent probe 2',7'-dichlorofluorescein diacetate and MitoTracker were used to measure intracellular and mitochondrial levels of reactive oxygen species (ROS), respectively. The expression of antioxidant related gene was measured by real time PCR and Western blot analysis. The protein expression of pro-apoptotic and pro-inflammatory proteins was determined by immunoblotting.

Results: Plasma creatinine level was increased in I/R-induced AKI compared with controls. The mRNA and protein expressions of PGC-1α were decreased in I/R-induced AKI. H_2O_2 treatment resulted in decreased expression of PGC-1α and cell viability, while increased ROS levels in HK-2 cells. These changes were counteracted by PGC-1α over expression. Over-expression of PGC-1α reduced pro-apoptotic proteins expression (Bax, P-p53, cleaved caspase3) and pro-inflammatory proteins expression (COX2 and iNOS). PGC-1a over-expression induced increased expression of NRF2 as well as induced NRF2 target genes such as Prx3, Prx5, and MnSOD.

Conclusions: PGC-1a protects ROS-mediated kidney injury by up-regulating NRF-2 dependent antioxidant enzymes.

TH-PO215

Nrf2 Mediates the Oxidative Stress-Dependent Hypertension Associated with Renal-Selective Depletion of DJ-1 Santiago Cuevas, Yu Yang, Prasad Konkalmatt, Laureano D. Asico, Jun B. Feranil, John Edward Jones, Ines Armando, Pedro A. Jose. *Div of Nephrology, Univ of Maryland School of Medicine, Baltimore, MD.*

Background: Renal dopamine D2 receptor (D2R) dysfunction is associated with increased oxidative stress and high blood pressure (BP). We have reported that the renal expression of DJ-1, an antioxidant, is regulated by D2R. Nrf2 is involved in the upregulation of several antioxidant genes. We hypothesized that Nrf2 plays a role in the antioxidant effect of DJ-1 in the kidney.

Methods: D2R and DJ-1 renal expression have been silenced in mice by renal subcapsular infusion of specific siRNA.

Results: DJ-1 and Nrf2 co-immunoprecipitate in the mouse kidney. Silencing D2R expression in mouse renal proximal tubule cells (MPTCs) decreases D2R expression (78±11%,n=4), Nrf2 promoter activity (53±2%, n=5) and increases ROS production (56±8%;n=6). Selective renal silencing of D2R in mice decreases renal expression of D2R (48±2% n=3), DJ-1 (45±2%,n=7), Nrf2 (22%±2,n=7) and GST (63±6%,n=3) and increases systolic BP (119±7%,n=3); NQO1 expression was not affected. Silencing DJ-1 expression in MPTCs decreases the expression of DJ-1 (75±15%,n=4), Nrf2 (63±11%, n=3), and its targets NQO1 (75±15%,n=4), and GST (61±8%,n=4), Nrf2 promoter activity (58±1%,n=5) and increases ROS production (182±10%,n=6). Selective renal silencing of DJ-1 in mice decreases renal expression of DJ-1 (30±6%,n=3), Nrf2 (57±6%, n=3), NQO1 (46±11%,n=3), and GST (28±7%, n=3) and increases systolic BP (115.2±3.7%, n=3). DJ-1-/- mice have decreased expression of Nrf2 (46.8±6.8%,n=5), NQO1 (19.4±2%,n=5) and GST (51±12%, n=3) and increased systolic BP (130±3%,n=5) and renal expression of nitro-tyrosine (177±31%,n=5). Immunoprecipitation experiments showed increased Nrf2 ubiquitination in DJ-1 knockout mice. Systolic BP and renal MDA expression returned to normal after treatment with both either tempol, a SOD-mimetic agent or bardoxolone, a Nrf2 inducer in DJ1-/- mice but had no effect in their wild-type littermates.

Conclusions: Our results suggest that the antioxidant effect of renal DJ-1 is, in part, mediated via decreased Nrf2 degradation. Altered DJ-1 expression results in oxidative stress-mediated hypertension.

TH-PO216

Contribution of NADPH Oxidase 4 Signaling to the Smooth Muscle Fibroproliferative Phenotype in Arteriovenous Fistulae David Jourd'heuil,[1] Roman G. Ginnan,[1] Xiaochun Long,[1] Paul B. Kreienberg,[2] David J. Conti,[2] Harold A. Singer,[1] Arif Asif.[3] *[1]Center for Cardiovascular Sciences, Albany Medical College, Albany, NY; [2]Dept of Surgery, Albany Medical College, Albany, NY; [3]Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.*

Background: Although arteriovenous fistulae (AVFs) are the preferred form of dialysis access, they suffer significant problems with high incidence of both early and late failures. NADPH oxidase (NOX) and reactive oxygen species contribute to the smooth muscle fibroproliferative phenotype during pathological vascular remodeling. However, the contribution of NOXs to the smooth muscle neoplastic response in an AVF and activation of downstream pathways are poorly characterized. We investigated the expression of NOXs during the neointimal hyperplasia associated with an AVF and analyzed their role in regulating two potential downstream targets in smooth muscle, namely the multifunctional Ca^{2+}/Calmodulin-dependent protein kinase II (CaMKII) and the cytoprotective hemoprotein cytoglobin (CYGB).

Methods: Histomorphometric, immunostaining, mRNA, and protein analysis were performed on tissue samples obtained from the venous segments of AVFs collected from patients undergoing surgical access creation or at revision. Cultured smooth muscle cells from primary placement veins were derived and the significance of NOX expression on CYGB and CaMKII expression and activation was determined.

Results: The NOX isoform NOX4 was upregulated in the revision compared to the primary placement veins. Coincidental was a differential expression of CaMKII isoforms with upregulation CaMKIIΔ, an isoform previously linked to neointimal hyperplasia. Similarly, CYGB was upregulated with significant association with both medial smooth muscle and neointimal cells. NOX4 and CYGB were upregulated through imuno-stimulation of cultured venous smooth muscle cells and CaMKII was activated by autophosphorylation and oxidation.

Conclusions: Our results identified NOX4, CaMKIIΔ, and CYGB as novel targets of inflammatory and hyperplastic conditions associated with AVF. Our results also suggest a functional link between NOX4-dependent ROS production and CaMKII and CYGB activation.

Effect of NADPH Oxidase Inhibition on the Development of Interstitial Fibrosis in Unilateral Ureter Obstruction Rats Xizi Zheng, Liqiang Meng, Yu Wang, Jiawei Tang, Lei Qu. *Inst of Nephrology, Peking Univ.*

Background: Unilateral ureteral obstruction (UUO) is a well-established model of renal interstitial fibrosis. The involvement of intra-renal oxidative stress in UUO pathogenesis has been reported. However, the source of reactive oxygen species (ROS) production remains unclear. The present study was designed to clarify the contribution of NOXs family to the ROS production and subsequent interstitial fibrosis in UUO rats.

Methods: Male Wistar rats were subjected to UUO or sham operation. Either vehicle or apocynin (100 mg/kg per day) were given by daily oral gavage for 1, 3 and 7 days after surgery, respectively. Level of 8-isoprostaglandinF2α (8-iso-PGF2α) and activity of total superoxide dismutase (T-SOD) and catalase in renal homogenates were measured by ELISA. Expressions of NOX2, NOX4, α-SMA, COL-I and pERK1/2 were measured by Western Blot. Immunohistochemistry was performed to determine the expression of α-SMA and ERK1/2 in renal tissues.

Results: Compared to the sham, UUO rats showed increased oxidative stress, as detected by increased renal tissue 8-isoPGF2α level. Meanwhile, there was an increase in NOX2 and NOX4 expression on day1, day3 and day7 in UUO rats (all $P<0.01$). There was a gradual but sustained reduction of catalase activity in UUO rats by 49%, 70% and 81% on day 1, day3 and day7, respectively(all $P<0.05$),while SOD activity increased on day 1 and day 3 ($P<0.05$) with a subsequent decrease to sham level on day 7. Furthermore, UUO rats developed interstitial fibrosis on day7 with increased COL-I and a-SMA expression, accompanied with activation of ERK1/2. Apocynin treatment significantly decreased 8-isoPGF2α level (-31.6%) and the expressions of NOX2 (-28.7%) and NOX4 (-31%) in UUO rats on day7.Significantly decreased expression of COL-I (-26.4%) and a-SMA (-80%) and activation of ERK1/2(-45%) were also observed, which were detected by IHC staining. Neither T-SOD nor catalase activity in UUO rats was affected by apocynin treatment.

Conclusions: The NOXs family contributes mainly to the production of ROS, subsequent myofibroblast activation and interstitial fibrosis after UUO. Inhibition of the NOXs family may be a choice for preventing interstitial fibrosis.

Funding: Government Support - Non-U.S.

TH-PO218

Smad2/3 and Nox4-Mediated Mitochondrial Dysfunction Is Critical in PAN-Induced Podocyte Damage and Albuminuria Development Jianming Ye,[1] Lixia Yu,[1] Yanbo Liu,[2] Qingfeng Fan.[3] *[1]First People's Hospital of Kunshan; [2]Jilin Univ First Hospital; [3]Univ of Pennsylvania.*

Background: Podocyte damage plays an important function in the initiation and progression of proteinuric glomerular diseases, whereas the underlying mechanisms are still elusive. This study investigated the potential role and proximal signaling of mitochondrial dysfunction in a PAN-induced podocyte injury model both *in vitro* and *in vivo*.

Results: In PAN-treated podocytes, cellular apoptosis and FITC-labeled albumin uptake are increased significantly in a time- and dose-dependent manner. Podocytes treated with 50 μg/ml of PAN shows a time-dependent mitochondrial DNA (mtDNA) damage, displaying as obvious decrease of mtDNA level revealed by Q-PCR, and significant reduction of mitochondrial proteins (CytC, CoxI and SDHA) revealed by immunoblotting. Dysfunction of mitochondria are accompanied with obvious decrease of oxygen consumption rate (OCR assay) and mitochondrial membrane potential (JC-1 assay), as well as significant increase of reactive oxygen species (DCF assay) and MnSOD and catalase protein level in PAN-treated podocytes. Furthermore, PAN induces obvious activation and remarkable translocation of Smad2/3 from cytoplasm to nuclei, whereas expression of Nox4 is significantly increased in mitochondria, and the translocation of CytC from mitochondria to cytoplasm is also detected in PAN-treated podocytes. Knockdown of Smad2/3 or Nox4 obviously decreases PAN-induced podocyte damage. Smad2/3 knockdown decreases mitochondrial Nox4 level, alleviates mitochondria DNA damage and improves mitochondria functions, also inhibites upregulation of cytoplasmic CytC and cleaved caspase 3 level in PAN-treated podocytes. In PAN rats, Q-PCR shows that mtDNA level decreases evidently in isolated glomerular mitochondria at day 10 following PAN injections, while expression of Nox4 and p-Smad2/3 are upregulated. Treatment with prednisone decreases albuminuria, and prevents upregulation of Nox4 and p-Smad2/3.

Conclusions: These findings provide evidences that Smad2/3 and Nox4-mediated mtDNA damage and mitochondrial dysfunction plays a crucial role in PAN-induced podocyte damage and proteinuria development.

TH-PO219

Sphingomyelinase Induces Podocyte Ferroptosis through Oxidative Stress in HIV Milieu Kamesh R. Ayasolla, Maria Sultana-Syed, Shallu Sharma, Rivka Lederman, Ashwani Malhotra, Mohammad Husain, Pravin C. Singhal. *Medicine, North Shore LIJ Medical School, Great Neck, NY.*

Background: Ferroptosis is a programmed cell death but it is distinct from apoptosis. Mechanistically it is initiated by cellular non-chelated iron and driven by altered lipid environment (reduced glutathione and lipid alterations). Since HIV-induced loss of podocytes has been incriminated in the development as well as progression of HIV-associated Nephropathy (HIVAN), we asked whether lipid alteration mediated ferroptosis is contributing to it. In the present study, we tested the role of sphingomyelinase (SMase) in induction of podocyte ferroptosis in HIV milieu, both *in vivo* and *in vitro*.

Methods: SMase activities of renal tissues of 4 wk old control (FVB/N, n=4) and HIVAN mice (Tg26, n=4) as well as empty vector (EV)- or HIV-transduced human podocytes (HPs) were measured. EV/HPs and HIV/HPs were assayed for reactive oxygen species (ROS) generation by DCFDA labeling and for ferroptosis by staining with H3342 and propidium iodide (porous cells with condensed nuclei). To establish a causal relationship between SMase activity and down stream outcomes, EV/HPs and HIV/HPs were evaluated for redox activity (superoxide dismutase[SOD], catalase, glutathione peroxidase and lipid peroxidase), NF-κB activity (gel shift assay and luciferase activity) and morphologic assay for ferroptosis in the presence or absence of GW4869 (SMase inhibitor)/TEMPOL (SOD mimetic agent).

Results: Renal tissues of Tg26 mice displayed 2-fold increase in SMase activity when compared to control mice. Similarly, HIV/HPs showed enhanced ($P<0.01$) in SMase activity when compared to EV/HPs. HIV/HPs enhanced ($P<0.01$) ROS generation and activation of NF-κB but mitigated redox activity when compared to EVs. GW4869 not only down graded HIV-induced ROS generation and NF-κB activity but also enhanced redox response in HIV milieu. In addition, GW4869 treatment markedly decreased number of ferroptosed podocytes in HIV milieu. TEMPOL also attenuated ROS generation, NF-κB activity and percentage of ferroptosed podocytes in HIV milieu.

Conclusions: HIV enhances SMase activity in kidney cells. HIV-induced activation of podocyte SMase activity contributes to ferroptosis.

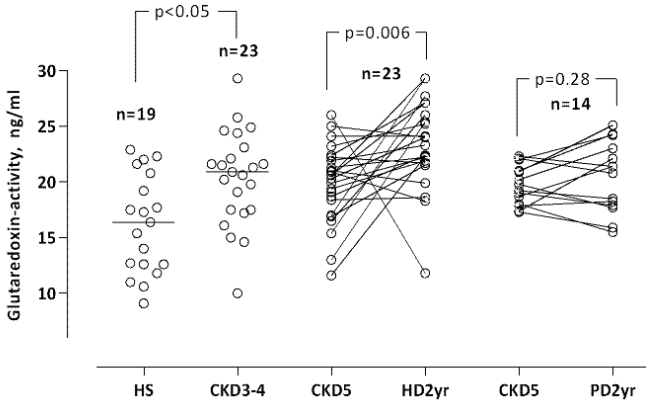
Plasma Glutaredoxin as a Marker of Oxidative Stress in Chronic Kidney Disease and Dialysis Anna Levin,[1] Annette Bruchfeld,[1] Peter F. Barany,[1] Olof Heimburger,[1] Björn Anderstam,[1] Peter Stenvinkel,[1] Johanna Ungerstedt.[2] *[1]Dept of Clinical Science, Intervention and technique, Karolinska Inst, Stockholm, Sweden; [2]Dept of Medicine, Huddinge, Karolinska Inst, Stockholm, Sweden.*

Background: Oxidative stress is known to play a major role in progression and complications of CKD. Glutaredoxin1 (Grx1) is an intracellular antioxidant, recently shown to be catalytically active also in serum. Grx1 activity levels correlate to disease severity in type 2 diabetes, and high Grx1 activity is associated with abrogated reperfusion after arterial ischemia. In the present study we investigated Grx1 activity in CKD 3-4, at dialysis start and after 2 years of dialysis.

Methods: Grx1 activity was analyzed with a novel fluorescence assay kit (Imco Corp, Stockholm, Sweden). Healthy subjects (HS, n=19), CKD 3-4 (n=23), CKD 5 starting dialysis and after two years of dialysis Hemodialysis (HD, n=23), Peritoneal Dialysis (PD, n=14) were assessed. All samples were analyzed in triplicate.

Results: Grx1 activity was significantly higher in CKD3-4 compared to healthy subjects ($p<0.05$, fig. 1), indicating an oxidized extracellular environment in CKD patients. After two years of dialysis, HD pts had a further increase in Grx1 activity ($p=0.006$, fig. 1), however a subgroup with persistently low Grx1 was identified. PD patients did not increase Grx1 at 2 years suggesting a beneficial effect of PD on extracellular oxidative state. Grx1 activity did not correlate with age (tested in both healthy subjects and CKD 3-4) norwith GFR in CKD 3-5.



Conclusions: Grx1 activity is a marker of oxidized extracellular environment. In the present study we demonstrate higher Grx1 activity in CKD than in healthy subjects. The effect on Grx1 activity seems to differ between dialysis modalities suggesting a more favorable effect in PD. Grx1 may be a useful marker of oxidative state and possibly also risk of ischemic events in CKD.

TH-PO221

Constitutive Shedding of Angiotensin-Converting Enzyme 2 from Proximal Tubular Cells Is Mediated by Protein Kinase C Isoforms Delta (Δ) and Epsilon (ε) Fengxia Xiao, Joe A. Zimpelmann, Kevin D. Burns. *Nephrology, Medicine, Kidney Research Centre, OHRI, Univ of Ottawa, Ottawa, ON, Canada.*

Background: Angiotensin-converting enzyme 2 (ACE2) degrades angiotensin (Ang) II to Ang-(1-7), and thereby protects against renal injury. Soluble ACE2 fragments are shed from the proximal tubule, and are found at higher urinary levels in humans with diabetes or

chronic kidney disease. Although high glucose-induced shedding of ACE2 from proximal tubular cells is mediated by a pathway involving a disintegrin and metalloproteinase-17 (ADAM-17), the mechanism for constitutive shedding of ACE2 is unknown.

Methods: Primary cultures of mouse proximal tubular cells were grown to near confluence, and ACE2 shedding into the media was assessed by enzyme activity assay, using an ACE2 fluorogenic substrate in the presence or absence of the ACE2 inhibitor MLN-4760. Cells were incubated with pharmacologic inhibitors, or transfected with siRNA directed at protein kinase C (PKC)-Δ or -ε.

Results: Incubation of proximal tubular cells with increasing concentrations of D-glucose stimulated ACE2 shedding, which peaked at 16 mM ($p<0.006$ versus 4 or 7.8 mM, n=5). Increasing levels of L-glucose (osmotic control) had no effect on shedding. In cells maintained in 7.8 mM D-glucose, constitutive shedding of ACE2 was significantly inhibited by the general PKC antagonist, sotrastaurin (10^{-5} M, 43.8% inhibition, $p<0.001$, n=6), but not by an inhibitor of ADAM-17 (TAPI-1). Incubation of cells with the PKC-α and -β1-specific inhibitor Go6976, the PKC β1 and β2-specific inhibitor ruboxistaurin, inhibitors of matrix metalloproteinases-2,-8, and -9, or an inhibitor of ADAM-10 (GI250423X) had no effect on basal ACE2 shedding (n=4-5). By contrast, transfection of cells with siRNA directed against PKC isoforms Δ or ε reduced ACE2 shedding by 23.2% and 24.1%, respectively, compared to transfection with scrambled siRNA.

Conclusions: These results indicate that constitutive shedding of ACE2 from proximal tubular cells is mediated by PKC isoforms Δ and ε. Targeting these PKC isoforms might maintain membrane-bound ACE2 in proximal tubule in disease states and diminish Ang II-stimulated adverse signaling.

FGF23 Enhances the Release of Nitric Oxide via Secretion of Soluble α-Klotho in Human Vascular Endothelial Cells In Vitro

Maren Leifheit-Nestler, Beatrice Richter, Jacqueline Haller, Wolfgang H. Ziegler, Dieter Haffner. *Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany.*

Background: Endothelial dysfunction is the first detectable manifestation of cardiovascular disease in CKD patients and is associated with increased degradation of secreted nitric oxide (NO) in the presence of reactive oxygen species (ROS). Elevated levels of the phosphaturic hormone fibroblast growth factor 23 (FGF23) correlate with cardiovascular mortality in CKD patients. The role of FGF23 in the pathophysiology of endothelial dysfunction is unclear. The aim of our study was to investigate the impact of FGF23 and its co-factor a-klotho on NO production, and ROS formation in vascular endothelial cells.

Methods: Human coronary artery endothelial cells (HCAEC) were stimulated with FGF23 in a time and dose-dependent manner and evaluated for proliferation, activation of downstream pathways, soluble α-klotho, the α-klotho shedding transmembrane metalloprotease ADAM17, and endothelial NO synthase (eNOS) by western blotting and immunofluorescence, respectively. FGF23-dependent NO production was assessed by the modified Griess assay, and formation of ROS was detected by fluorescence microscopy and flow cytometry.

Results: FGF23 induces proliferation of HCAEC. In HCAEC, FGF23 activates FGFR1, and increases NO production, as well as eNOS phosphorylation and dephosphorylation of S1177 and T495, respectively in a dose-dependent fashion. FGF23 stimulates the release of soluble α-klotho and enhances glycosylated ADAM17 protein expression. ADAM17 and α-klotho are co-localized in HCAEC. The NO stimulating effect of FGF23 is blunted by co-incubation of HCAEC with a klotho neutralizing antibody, and FGF23-dependent activation of eNOS is decreased after klotho inhibition. FGF23 has no impact on ROS production under physiological conditions, *in vitro*. Klotho neutralization slightly enhances ROS production. In an angiotensin induced stress model, FGF23 prevents HCAEC from oxidative stress, demonstrated by reduced ROS.

Conclusions: FGF23 stimulates NO release via secretion of soluble α-klotho, and protects HCAEC from angiotensin-induced ROS production.

TH-PO223

$1,25(OH)_2D_3$ Promotes High Glucose Induced Macrophage Activation from M1 to M2 via VDR-PPARγ Signalling Pathway in RAW264.7 Cells

Min Zhou, Yinfeng Guo, Zhixia Song, Xiaoliang Zhang. *Nephrology, Zhongda Hospital, Southeast Univ, Nanjing, Jiangsu, China.*

Background: Macrophage, especially its activation state closely relates to the progression of diabetic nephropathy. Classically activated macrophages (M1) are proinflammatory effectors, while alternatively activated macrophages (M2) exhibit anti-inflammatory properties.PPARγ, a nuclear receptor, is essential for macrophage polarization, and $1,25(OH)_2D_3$ has renoprotective roles that extend beyond the regulation of mineral metabolism. This study tries to investigate the effect of $1,25(OH)_2D_3$ on glucose induced macrophage activation and whether this is associated with VDR-PPARγ pathway.

Methods: RAW264.7 cells were used to perform cell culture, activity of intracellular iNOS was measured.VDR siRNA and PPARγ antagonist pre-treatment with macrophages were done before using 10^{-8}M $1,25(OH)_2D_3$ to intervene high glucose treated macrophages. TNF-α, IL-12 and IL-10 in supernatant, M1 marker iNOS, M2 markers including ARG-1, MRC and nuclear receptors, VDR and PPARγ were examined.

Results: The iNOS activity was increased in a glucose-dose and time dependent manner. Particularly, 25mM glucose at 24h gave the maximum response. After being treated with 25mM glucose for 24h, not only inflammatory cytokines of TNF-α, IL-12 were increased, but PCR and Western blot analysis showed iNOS was also upregulated ($P<0.05$). However, M2 markers, i.e. IL-10, ARG-1 and MRC were decreased ($P<0.05$). When in the presence of $1,25(OH)_2D_3$, the trends were reversed: the markers of M1, including TNFα, IL-12 and iNOS were reduced by 17, 39 and 77%, while the markers of M2, IL-10, ARG-1 and MRC were increased by 192, 180 and 39% respectively. In addition, VDR and PPARγ were also increased ($P<0.05$). However, the above effects of $1,25(OH)_2D_3$were abolished when inhibited the expression of VDR and PPARγ by VDRsiRNA and PPARγ antagonist. Besides, PPARγ was also decreased upon treatment with VDRsiRNA ($P<0.05$).

Conclusions: $1,25(OH)_2D_3$ can promote high glucose induced classically activated macrophages (M1) convert to alternatively activated macrophages (M2) and this is achieved through VDR-PPARγ pathway.

Vitamin D Receptor Dynamics Modulates Tubular Cell Phenotype during Low and High Expression of p53 via mdm2

Shabirul Haque, Nirupama Chandel, Kamesh R. Ayasolla, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Mdm2 induces transcriptional repression and proteosomal degradation of p53, a tumor suppressor gene. P53 plays a bimodal role in cellular injury-enhanced expression is known to stimulate apoptosis via phosphorylation of p66ShcA and attenuated expression is associated with the activation of proliferation via mTOR pathway. We hypothesized that vitamin D receptor (VDR) dynamics will not only modulate tubular cell p53 expression through alteration of mdm2 but would also alter tubular cell phenotype.

Methods: To achieve high and low expressoin of p53 in tubular cells, primary human proximal tubular epithelial cells (HPTCs) were either transfected with p53 plasmid (p53/HPTC) or p53-siRNA (si-p53/HPTC) followed by Western blot analysis for p53 expression. Control (C)/HPTCs, p53/HPTCs, and si-p53/HPTCs were evaluated for tubular cell phenotype by morphologic assays for proliferation and apoptosis. To evaluate the involved molecular mechanisms, protein blots of C/HPTCs, p53/HPTCs and si-p53/HPTCs were probed for phospho-p66ShcA, phospho-mTOR, mdm2 and reprobed for actin. To evaluate relationships amongst VDR, mDm2, and p53, protein blots of VDR agonist treated-p53/HPTCs and si-p53/HPTCs were evaluated for mdm2 and p53 expressions. C/HPTCs and VDR knockout HPTCs was probed for mdm2 expression.

Results: p53/HPTCs displayed enhanced phosphorylation of p66ShcA, associated downstream signaling and induction of tubular cell apoptosis when compared to C/HPTCs; whereas, si-p53/HPTCs displayed enhanced phosphorylation of mTOR, associated downstream signaling and increased number of PCNA +ve cells when compared to C/HPTCs. p53 expression displayed inverse relationship with tubular cell expression of mdm2 both in high and low expressing p53 cells. Treatment of p53/HPTCs and si-p53/HPTCs with a VDR agonist not only reversed the expression of p53 and mdm2 but also restored tubular cell phenotype. Since VDR knockout HPTCs displayed attenuated expression of mdm2, it appears that VDR determines the expression of mdm2.

Conclusions: VDR dynamics determines tubular cell phenotype during high and low p53 states through modulation of mdm2.

Impaired Cell-Cell Singalling via microRNA-126 Represents a Novel Pathomechanism in Asymmetric Dimethylarginin Induced Endothelial Dysfunction

Filippo Martino,[1] Claudia Bang,[1] Jan T. Kielstein,[2] Thomas Thum,[1] Johan M. Lorenzen.[1,2] *[1]Inst of Molecular and Translational Therapeutic Strategies, Hannover Medical School; [2]Div of Nephrology, Hannover Medical School.*

Background: Asymmetric Dimethylarginine (ADMA), an endogenous inhibitor of nitric oxide synthase (NOS), is elevated in patients with chronic kidney disease and is known to contribute to endothelial dysfunction. We investigated the role of microRNA-126 signalling through exosomes, which is essential for endothelial development and biology, in ADMA induced endothelial dysfunction.

Methods: We measured ADMA-Plasma levels in 39 patients with coronary artery disease (CAD) by ELISA assay and correlated them with circulating miR-126 levels assessed by qRT-PCR. We infused ADMA into healthy rats (250μMol/kg/day) and healthy human volunteers (0.1mg/kg/min, 40minutes) and quantified plasma levels of different microRNAs. Stimulating HUVECs in vitro with ADMA, we quantified extra-and intracellular levels of miR-126. Furthermore we used another eNOS-Inhibitor L-NAME. Immunefluorescence staining and confocal microscopy was performed to detect multivesicular bodies (MVB) and exosomes after ADMA/L-NAME treatment. We performed exosome isolation and characterization.

Results: Plasma levels of ADMA in patients with CAD correlated inversely with levels of circulating levels of miR-126 ($r=-0.52$; $p<0.001$). ADMA infusion reduced circulating levels of miR-126 in rats and significantly also in healthy human volunteers. Time dependent alteration of extra- (decrease) and intracellular (increase) amounts of miR-126 was detectable in vitro. Stimulation with L-NAME showed a significant reduction of extracellular levels of miR-126. Confocal microscopy of CD-63 positive MVBs and exosomes revealed an obvious change in MVB structure due to fusion and/or swelling of the vesicles. This was detectable after ADMA and L-NAME stimulation. HUVEC derived exosomes exhibited typical characteristics.

Conclusions: MiR-126 signalling via exosomos, which is known to convey alarm signals to injured endothelium and thereby contribute to repair mechanisms and cellular survival, is impaired by ADMA. This represents a novel mechanism how ADMA could contributes to endothelial function.

Podocyte Microparticles: Mechanisms of Formation and Downstream Effects on Proximal Tubular Epithelial Cells Dylan Burger, Shareef Akbari, Maddison Turner. *Kidney Research Centre, Ottawa Hospital Research Inst, Ottawa, ON, Canada.*

Background: Microparticles (MPs, also known as microvesicles) are 0.1-1.0 μm phospholipid vesicles shed from membranes of stressed/injured cells. We recently reported that podocytes produce MPs (pMPs) in response to high glucose and that pMPs may be found in the urine of diabetic mice in advance of albuminuria. In the present study we assessed the role of Rho kinase (ROCK) and ATP binding cassette A1 (ABCA1) in pMP formation and determined whether pMPs interact with proximal tubular cells and influence function.

Methods: Conditionally immortalized human podocytes (HPODs) were exposed to 25 mM glucose in the presence and absence of fasudil (ROCK inhibitor, 10 μM) or PSC833 (ABCA1 inhibitor, 5μM). Mannitol served as an osmotic control. pMPs were enumerated by flow cytometry (Annexin V labeling). pMPs were isolated from media and cultured human proximal tubular epithelial cells were exposed to pMPs (10 μg/ml). MP-cell interaction was examined by fluorescence microscopy and effects on intracellular signaling and fibronectin expression were examined by Western blot. Reactive oxygen species (ROS) production was assessed by lucigenin chemiluminescence.

Results: High glucose treatment increased pMP formation at 24 hours (~2.5-fold, $P<0.05$, n=3). Treatment with fasudil or PSC833 blocked high glucose-induced pMP formation ($P<0.001$, $P<0.05$ respectively). In proximal tubular cells, fluorescence microscopy revealed cell surface binding of pMPs, suggesting a paracrine effect. Treatment with pMPs increased p38 phosphorylation (~3 fold) after 30 minutes ($P<0.05$, n=4). By contrast, JNK and ERK phosphorylation levels were unchanged over 24 hours. Expression of fibronectin was increased following 72 hour treatment with pMPs ($p<0.05$, n=6). Proximal tubular ROS production was increased by pMP treatment at 16 and 24 hours ($P<0.05$, n=4).

Conclusions: Our results suggest that pMP formation involves activation of ROCK and ABCA1. Once formed, pMPs interact with proximal tubular epithelial cells and induce intracellular signaling, increased synthesis of matrix proteins, and ROS production. Such effects may play a role in the development of tubular injury in glomerular disease.

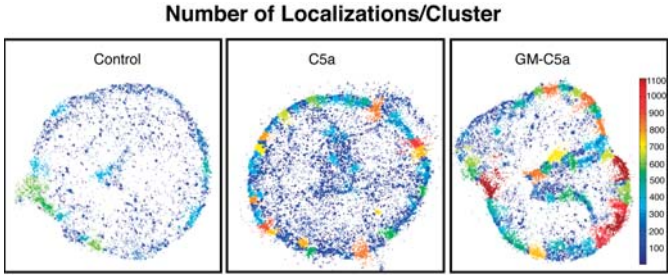
Neutrophil Activation Organizes Leukotriene Synthetic Enzymes Into Supramolecular Nanoclusters Angela Bair Schmider,[1] Hunter Elliott,[2] Roy J. Soberman.[1] *[1]Nephrology, Massachusetts General Hospital/Harvard Medical School, Boston, MA; [2]Cell Biology, Harvard Medical School, Boston, MA.*

Background: The recruitment and activation of neutrophils (PMN) is a prominent component of tissue injury in inflammatory kidney diseases. The chemotactic lipid, leukotriene (LT)B_4 plays a non-redundant role in the initial recruitment of neutrophils from the vasculature, and controls the participation of these cells in the key pathological process of swarming. We previously identified a critical structure, the LT biosynthetic complex. The core members of this structure are the enzyme 5-lipoxygenase (5-LO) and its nuclear membrane scaffold protein, 5-lipoxygenase-activating protein (FLAP). The latter presents arachidonic acid (AA) to 5-LO.

Methods: We paired single molecule superresolution microscopy (*S*tochastic *O*ptical *R*econstruction *M*icroscopy; STORM) with cluster analysis to show the reorganization of 5-LO and FLAP into supramolecular nanoclusters on the nuclear envelope of mouse PMN in response to cell "priming" by GM-CSF and activation by C5a. These processes are known to stimulate and augment LTB_4 synthesis. STORM data is generated as a "map" of intensity signals and presented as a pseudo image based on defined parameters. It does not query the relationship between individual molecules in terms of groups. To test the hypothesis that LT synthetic complexes were organized into larger groups, we developed cluster analysis algorithms to analyze primary STORM data.

Results: The activation of PMN by C5a results in reorganization of FLAP and 5-LO into supramolecular nanoclusters. Priming with GM-CSF augmented this process.



Conclusions: We have identified novel supramolecular complexes of LT synthetic enzymes that are likely to play a major regulatory role in PMN activation and have developed and employed a novel approach for analysis of single molecule fluorescence data.

Selective Proximal Tubule Injury Causes Interstitial Fibrosis, Distal Tubule Impairment, and Proteinuria Koji Takaori,[1] Jin Nakamura,[1] Tadashi Yamamoto,[2] Motoko Yanagita.[1] *[1]Nephrology, Kyoto Univ, Kyoto, Japan; [2]Structural Pathology, Niigata Univ, Niigata, Japan.*

Background: Recently we clarified that renal fibroblasts including erythropoietin (Epo) producing cells transdifferentiate into myofibroblast and predominantly contribute to fibrosis, with concomitant loss of Epo production in the diseased kidney. It remains unclear, however, what triggers the transdifferentiation of fibroblasts to myofibroblasts and how proximal tubule injury affects other segment of the nephron.

Methods: For in vitro analysis, we utilized co-culture of renal fibroblasts and tubular epithelial cells. For in vivo analysis, we utilized *N-myc downstream-regulated gene-1 (Ndrg1)CreERT2* inducible simian diphtheria toxin receptor (DTR) transgenic mice (*Ndrg1CreERT2:iDTR* mice) in which Cre-mediated excision of a STOP cassette is achieved after the administration of tamoxifen, and renders *proximal tubule*s sensitive to diphtheria toxin (DT). Furthermore, we utilized *Uterine sensitization-associated gene-1 (U.S.A.G-1) LacZ* mice in which LacZ is expressed in distal tubules for distal tubule cell sorting.

Results: First, we confirmed the expression of DTR in almost all proximal tubules in the kidney of *Ndrg1-CreERT2:iDTR* mice. A single DT injection causes proximal tubule injury, interstitial fibrosis, and distal tubule injury. While electron microscopy examinations reveal the normal glomerular structure, massive proteinuria was observed after the injection of DT. Repeated DT injections caused severer interstitial fibrosis, while most glomeruli remained intact. We also confirmed the induction of collagen expression in fibroblasts when co-cultured with damaged tubular epithelial cells.

Conclusions: Our data provide the new evidence that selective proximal tubule injury induces the transdifferentiation of fibroblast as well as distal tubule injury. Our data also demonstrates that dysfunction of proximal tubules leads to albuminuria. These results indicate the importance of protecting tubule epithelial cells to suppress kidney disease progression. Further understanding of the crosstalk between proximal tubule and other cellular components in the kidney will give us new insight into the mechanism of kidney disease progression.

TH-PO229

The Small Heterodimer Partner SHP Attenuates Renal Inflammation Through Inhibition of ROS Production in Ischemia Reperfusion Injury Jung Sun Park,[1] Hoon In Choi,[1] Eun Hui Bae,[2] Seong Kwon Ma,[2] Jong Un Lee,[1] Soo Wan Kim.[2] *[1]Physiology, Chonnam National Univ Medical School, Gwangju, Chonnam, Korea; [2]Kidney, Chonnam National Univ Hospital, Gwangju, Chonnam, Korea.*

Background: The orphan nuclear receptor, small heterodimer partner (SHP; NR0B2), appears to play a negative regulatory role in innate immune responses and contribute to various inflammatory signaling and transcriptional regulation. We investigated whether SHP attenuates renal inflammation in ischemia reperfusion (I/R) and H2O2-induced kidney injury in human proximal tubular (HK2) cells.

Methods: Mouse I/R injury was induced by clamping both renal pedicle for 30 min, and sacrificed 24 hr later. In vitro study, human proximal tubular (HK2) cells were incubated with H2O2 300 μM for 6 hr. Cell viability was examined using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay.The fluorescent probe 2',7'-dichlorofluorescein diacetate was used to measure intracellular levels of reactive oxygen species (ROS). The protein expression of NF-κB, mitogen-activated protein kinase (MAPK), iNOS, COX-2, TNFa, and IL-1β was determined by semiquantitative immunoblotting.

Results: I/R kidney injury and H2O2 treatment in HK2 cells decreased cell viability, increased production of ROS and induced expression of inflammatory proteins such as iNOS, COX-2, TNFa, and IL-1β. I/R kidney injury and H2O2 treatment in HK2 cells induced the activation of MAPK signal pathway and NF- κB signal pathway, while reduced the activation of Nrf-1 and Nrf-2. Transfection of SHP increased cell viability and prevented the IR injury and H2O2-induced ROS production as well as reduced expression of inflammatory proteins. The pretreatment of MAPK inhibitors (PD980590, SB203580) and NF-κB inhibitor (Bay11-7082) counteracted activation of the Nrf-1 and Nrf-2 signal pathway and induced SHP promoter activity. Accordingly, ROS scavenger (N-acetyl cysteine, NAC) prevented the IR injury and H2O2-induced ROS production and increased of the Nrf-1 and Nrf-2 activation and induced SHP promoter activity.

Conclusions: These findings suggest that SHP attenuates I/R and H2O2-induced kidney injury by counteracting inflammatory response through inhibition of NF-κB and MAPK signal pathway.

TH-PO230

Cytosolic Phospholipase A2 Derived Eicosanoids Regulate the Epithelial Phenotype of Human Proximal Tubular Epithelial Cells John Ross Montford, Seth B. Furgeson, Raphael A. Nemenoff. *Renal Disease and Hypertension, Univ of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Renal fibrosis represents the final common pathway in the development of progressive chronic kidney disease (CKD). Cytosolic phospholipase A2 (cPLA2) is the rate limiting enzyme in the production of eicosanoids that regulate a host of physiologic processes and have been implicated in renal fibrosis. The goal of this study was to assess the role of cPLA2 in regulating the epithelial phenotype of proximal tubule cells.

Methods: Human proximal tubular epithelial (HK-2) cells were silenced for cPLA2 using lentiviral shRNA constructs. Expression of the epithelial marker E-cadherin, and

mesenchymal markers N-cadherin, vimentin, and αSMA were measured by Western blotting for protein and by qRT-PCR for mRNA. Epithelial to mesenchymal transformation (EMT) was induced via administration of TGF-β (10ng/ml). In addition, prostaglandin E2 (PGE2) at various concentrations was administered to the non-silenced and cPLA2 silenced shRNA clones. For measurement of promoter activity cells were transfected with E-cadherin luciferase constructs and transfection efficiency normalized to b-galctosidase.

Results: cPLA2 silenced cells demonstrated altered morphology and higher expression of E-cadherin protein and mRNA with lower levels of mesenchymal markers at baseline. This effect was associated with increased E-cadherin promoter activity, suggesting transcriptional regulation. Exposure of cells to TGF-β induced EMT in control cells, characterized by suppression of E-cadherin and induction of mesenchymal markers. These effects were blunted in cells silenced for cPLA2. PGE2, an eicosanoid produced by proximal tubular epithelial cells, reversed the effects of $cPLA_2$ silencing and promoted a more mesenchymal phenotype.

Conclusions: cPLA2 derived eicosanoids regulate the epithelial phenotype of human proximal tubular epithelial cells. This effect is mediated, at least in part, by the inhibition of PGE2 expression. These data indicate that targeting eicosanoid pathways will have effects on EMT in proximal tubule cells, and provides an additional mechanism for the effects of these agents in renal fibrosis.

TH-PO231

Ste20-Like Kinase, SLK, Activates the Hsp70 Pathway Andrey V. Cybulsky, Julie Guillemette, Joan Papillon. *Medicine, McGill Univ, Montreal, QC, Canada.*

Background: Expression and activation of SLK increases during renal ischemia-reperfusion injury. When highly expressed, SLK signals via c-Jun N-terminal kinase and p38 to induce apoptosis, and it exacerbates apoptosis induced by ischemia-reperfusion injury. Overexpression of SLK in glomerular epithelial cells (GEC)/podocytes in vivo induces injury and proteinuria. In response to various stresses, cells enhance expression of chaperones or heat shock proteins (e.g. Hsp70), which are involved in the folding and maturation of newly synthesized proteins, and can refold denatured or misfolded proteins. We address the interaction of SLK with Hsp70.

Methods: cDNAs and shRNAs were expressed in GEC and COS-1 cells by transient transfection. To induce in vitro ischemia-reperfusion injury, cells were incubated with 2-deoxyglucose+antimycin A, followed by re-exposure to glucose (anoxia/recovery). Heat shock involved incubation at 42°C followed by recovery at 37°C.

Results: Increased expression of SLK (following transfection) induced Hsp70. Exposure of cells to anoxia/recovery also induced Hsp70, and this effect was amplified by SLK overexpression. Hsp70 is regulated at the transcriptional level by heat shock factor (HSF)-1. SLK stimulated HSF1-luciferase reporter activity. Moreover, HSF1-luciferase reporter activity was induced by anoxia/recovery and heat shock, and in both instances was further amplified by SLK overexpression. To address the requirement for SLK kinase activity, we employed a fusion protein consisting of the SLK catalytic domain (amino acids 1-373) and a modified FK506 binding protein, Fv (Fv-SLK 1-373). Addition of AP20187 (a FK506 analog) stimulated dimerization and kinase activity of Fv-SLK 1-373, leading to an increase in HSF1-luciferase reporter activity. Transfection of constitutively active HSF1 enhanced Hsp70 expression and inhibited SLK-induced apoptosis. Conversely, the proapoptotic action of SLK was augmented by HSF1 shRNA, or the Hsp70 inhibitor, pifithrin-μ.

Conclusions: Increased expression/activity of SLK activates the HSF1-Hsp70 pathway. Hsp70 attenuates the primary proapoptotic effect of SLK. Modulation of chaperone expression may potentially be harnessed as cytoprotective therapy in renal ischemia-reperfusion injury.

Funding: Government Support - Non-U.S.

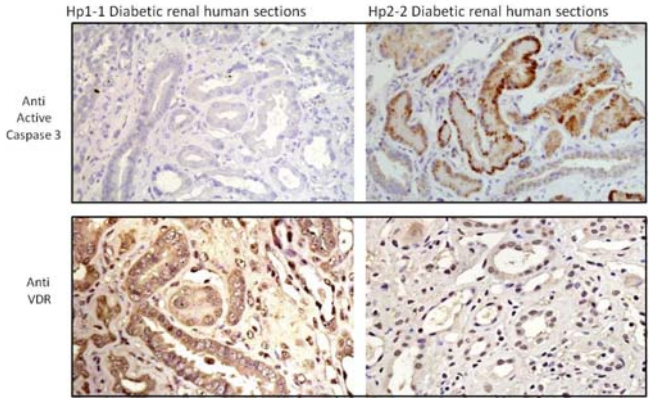
Haptoglobin 2-2 Genotype Is Associated with Decreased Levels of Active Vitamin D, Accelerated Renal Apoptosis and Injury in Diabetic Nephropathy Mice and Patients Farid M. Nakhoul,[1,2] Nadia Thawho,[2] Farber Evgeny,[1] Rabea Asleh,[3] Andy Levy,[3] Inbal Dahan.[2] *[1]Poriya Medical Center; [2]Diabetic Nephropathy Lab, Poriya Medical Center, Lower Galilee; [3]Vascular Biology lab Technion, Haifa.*

Background: Diabetic mice with different Haptoglobin (Hp) genotype (1-1, 2-2) have a different susceptibility to developed Diabetic Nephropathy (DN). Hp 2-2 diabetic mice have impaired Hb clearance and increased iron depositions in the lysosomes of kidney proximal tubules (PCT) compared with Hp 1-1diabetic mice. Patients and mice with chronic kidney disease have low levels of active vitamin D and decrease expression of the anti-oxidant- klotho. We are exploring the influence of the Hp genotype and klotho expression on active vit. D deficiency in DN mice and patients.

Methods: All patients screened for Hp genotyping. Slides from kidney biopsies of DN patients and mice with different Hp genotype (1-1, 2-2) were subjected to immunohistochemistry staining of iron, active caspase 3, vitamin D receptor (VDR) and 1-alpha hydroxylase by using specific antibodies. Blood samples subjected to laboratory evaluation and ELISA assays.

Results: 1. There were increased iron deposits in the renal lysosomal PCT of Hp 2-2 DN patients, similarly to what we have demonstrated in mice with Hp 2-2. **2.** In the PCT of Hp 2-2 mice and patients there was increase expression of active caspase-3 that was accompanied with decrease levels of klotho and decrease expression of renal VDR.



Conclusions: 1. Hp 2-2 genotype in mice and patients is associated with increased iron deposits in renal PCT, decrease levels of klotho and VDR and high levels of PCT apoptosis. **2.** The decreased levels of the anti oxidant klotho and the increase levels of PCT apoptosis, predispose to vitamin D deficieny and DN progression. **3**. Active vitamin D deficiency correlates with sever renal damage in DN patients with Hp 2-2 genotype.

TH-PO233

Pro-Fibrotic Role of Tumor Suppressor ATM Downstream of TGF-beta1 in Orchestrating Maladaptive Renal Repair Jessica Overstreet,[1] Diana Cardona-Grau,[2] Samik H. Patel,[1] Rohan Samarakoon,[1] Roel Goldschmeding,[3] Paul J. Higgins.[1] *[1]Center for Cell Biology and Cancer Research, Albany Medical College, Albany, NY; [2]Div of Urology, Albany Medical Center, Albany, NY; [3]Dept of Pathology, Univ Medical Center Utrecht, Netherlands.*

Background: Ataxia telangiectasia mutated (ATM) has been implicated in the oxidative stress response and acute ischemic renal injury. However, the mechanistic involvement of ATM in the TGF-β1 pathway related to renal fibrosis is largely unknown.

Methods: The unilateral ureteral obstruction (UUO) mouse model and genetic and pharmacological approaches were used to investigate ATM function in TGF-β1-induced pro-fibrotic responses in renal epithelial cells (HK-2) and fibroblasts (NRK-49Fs).

Results: Increased activation of ATM ($pATM^{Ser1981}$) in the tubulointerstitial region of the UUO kidney of mice correlated with SMAD3 and p53 phosphorylation and pro-fibrotic gene expression. ATM is rapidly phosphorylated at Ser^{1981} by TGF-β1 stimulation. Stable silencing and pharmacological inhibition of ATM ablated TGF-β1-induced p53 activation and PAI-1, fibronectin and p21 expression while completely relieving TGF-β1-stimulated proliferative arrest in HK-2 cells. Interestingly, stable gene depletion of the NADPH oxidase (NOX) subunits, $p22^{phox}$ and $p47^{phox}$ blocked TGF-β1-induced ATM activation and target gene induction via p53-SMAD3 dependent mechanisms. Furthermore, increased fibroblast proliferation promoted by addition of conditioned media from TGF-β1-stimulated mock transduced/control HK-2 cells were not detected by the stimulation of conditioned media derived from ATM-depleted cells treated with TGF-β1.

Conclusions: TGF-β1 promotes ATM activation via redox/NOX-dependent mechanisms leading to p53-dependent pro-fibrotic gene expression and growth inhibition in HK-2 cells. TGF-β1/ATM-initiated tubular dysfunction promotes fibroblast growth suggestive of crucial role of ATM in epithelial-mesenchymal cross-talk in fibrosis.

TH-PO234

Targeting of ROCK1 Protects Mice From Hyperlipidemia-Induced Glomerlosclerosis By Improving Podocyte Lipophagy Yangyang Zuo, Wenjian Wang, Lei Fu, Jianteng Xie, Jianxun Wu, Jing Li, Yuxiong Lai, Wei Shi. *Div of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Science, Guangzhou, Guangdong, China.*

Background: Foam cells and lipid deposits contributes to glomerulosclerosis. Intrestingly, the trapping of lipid-laden podocytes is a critical but reversible step in glomerulosclerosis. Recently, lipophagy, an alternative pathway of lipid degradation through the lysosome is observed in several cell lines. However, whether and how lipophagy is involved in the progression of lipid-induced nephropathy remains unclear.

Methods: To verify Rho kinase(ROCK) pathway plays a citical role in lipophagy, we inhibited and induced the expression of ROCK in podocytes,which were treated with oxidative low density lipoprotein in vitro. And a further study was carried out on ROCK deficient mice model.

Results: Overexpression of ROCK increase of lipid retention in oxidative low density lipoprotein treated podocytes, which consequently activates, and results in a marked increases of reactive oxygen species production. Interestingly, this process is reversed by ROCK inhibition evidenced by increased lipophagy which associated to low phosphorylated Akt and actin-related protein 2 levels. Furthermore, targeted deletion of ROCK1 in high fat diet mice exhibits a significantly ameliorated albuminuria and mesangial matrix accumulation compared to control. ROCK deficient mice with high fat diet demonstrated a marked decrease of lipid retention and improved lipophagy in the kidney.

Conclusions: Our data suggests a previously unknown contribution of ROCK to lipid-induced nephropathy. Constitutive inhibition of ROCK may be a major protective strategy to ameliorate lipid-overload in podocyte and lipid-related loss of renal function.

Inflammasomal Upregulation in a Mouse Model of Hepatorenal Syndrome Type 1 Hiba Sheikh, Sam Righi, Essa Abuhelaiqa, Siddhartha S. Ghosh, Daniel E. Carl. *Dept of Internal Medicine-Div of Nephrology, Virginia Commonwealth Univ Health System, Richmond, VA.*

Background: Hepatorenal Syndrome Type 1 (HRS-1) manifests when an acute insult leads to renal vasoconstriction and secondary impairment of glomerular filtration in the setting of liver disease. The aim of this study is to pioneer a mouse model for HRS-1 that would aid in the identification of inflammatory markers, specifically at the level of the inflammasome, which influence the pathophysiology of HRS-1 and serve as potential therapeutic targets.

Methods: C57bl mice received 1mL/kg of CCl4 biweekly for 12 weeks induce liver cirrhosis confirmed by histopathology and echocardiography. A pre-standardized dose of Lipopolysaccharide (LPS) was given intraperitoneally to control and CCl4-treated mice to induce acute kidney injury by simulating the inflammatory stressor caused by acute infection. 4 mouse populations were studied: (1)control mice (2)control mice injected with LPS (3) CCL4 treated mice (4) CCL4 treated mice with LPS (N=6 per group). Renal function was monitored by measuring urine output, urinary sodium, and serum creatinine measured at 4,6, and 12 weeks post injection. The mouse kidneys were then harvested and analyzed by western blot for the presence of inflammasomal components: xanthine oxidase, caspase 1, and ASC.

Results: The same dose of LPS in control animals had no effect on renal function. The CCl4+LPS treated mice had a significant decrease in urine volume and urinary Na ($p<0.05$) and marked increase in creatinine ($p<0.05$) compared to the other 3 mouse groups. Both xanthine oxidase and caspase 1 were significantly elevated ($p<0.05$) in the CCL4+LPS treated group compared to the CCL4 mice. ASC was significantly elevated ($P<0.05$) in CCL4+LPS mice compared to the other 3 mouse populations.

Conclusions: In the CCL4-induced cirrhotic mouse model, we found an increase in the expression of xanthine oxidase and Caspase 1 in the presence of a stressor such as LPS. This translates to an increase in downstream pro-inflammatory markers such as reactive oxygen species and IL1β. ASC was elevated in the CCL4+LPS mouse population only suggesting the activation of specific markers exclusively in HRS.

Activation of the Nlrp3 Inflammasome by Mitochondrial Reactive Oxygen Species: A Novel Mechanism of Albumin-Induced Tubulointerstitial Inflammation Dan Liu, Min Xu, Linli Lv, Bi-Cheng Liu, Kun Ling Ma. *Inst of Nephrology, Zhongda Hospital, Southeast Univ, Nanjing, Jiangsu, China.*

Background: Albuminuria is not only an important marker of chronic kidney disease, but also a crucial contributor to tubulointerstitial inflammation (TIF). Here we determine whether activation of the Nlrp3 inflammasome is involved in albuminuria induced-TIF and the underlying mechanisms of inflammasome activation by mitochondrial reactive oxygen species (mROS).

Methods: We established an albumin-overload induced rat nephropathy model. The adult male Wistar rats that were uninephrectomized or sham operated under anesthesia 5 days before starting bovine serum albumin (BSA) injection. In vitro, tubular epithelial cell line (HK-2) was cultured with or without Nlrp3 gene siRNA transfection and then stimulated with BSA for different time durations (6h, 12h, 24h) and concentrations (5, 10, 20 mg/ml). Cell lysates and supernatants were collected and determined by Western blotting and ELISA. IgA nephropathy biopsy samples were used for Nlrp3 and IL-18 detection by immunohistochemistry.

Results: The experimental rats were characterized by albuminuria, renal infiltration of inflammatory cells, tubular dilation and atrophy with albumin-overload. Renal expressions of the Nlrp3 inflammasome, IL-1β and IL-18 were significantly increased in this animal model. Invitro, albumin time- and dose-dependentlyincreased expression of the Nlrp3 inflammasome, IL-1β, and IL18. Moreover, silencing of the Nlrp3 gene or use of caspase-1 inhibitor, Z-VAD-fmk, significantly attenuated albumin induced IL-1β and IL-18 expression in HK2 cells. In addition, mROS generation was elevated by albumin stimulation, whereas the ROS scavenger, N-acetyl-L-cysteine (NAC) inhibited Nlrp3 expression and release of IL-1β andIL-18. In kidney biopsy specimens from patients with IgA nephropathy, Nlrp3 expression localized to the proximal tubular epithelial cells, which closely correlated with the extent of proteinuria and TIF.

Conclusions: This study demonstrates that albuminuria might serve as an endogenous danger associated molecular pattern (DAMP) that stimulates TIF via mROS-mediated activation of the cytoplasmic Nlrp3 inflammasome.

Indoxyl Sulfate Promotes Modulation of CD14+/CD16+ Inflammatory Monocytes and Increases ROS Generation Andrea Novais Moreno-Amaral,[1] Natalia Borges Bonan,[1] Gabriela Ferreira Dias,[1] Lia S. Nakao,[2] Fellype C. Barreto,[1] Roberto Pecoits-Filho.[1] *[1]School of Medicine, PPGCS, PUCPR, Brazil; [2]Basic Pathology Dept, UFPR, Brazil.*

Background: Circulating monocytes can be modulated into an intermediate CD14+/CD16+ inflammatory phenotype. Here we evaluate the monocyte modulation induced by the uremic toxin indoxyl sulfate (IS). In addition, we aimed to analyze the capacity of these cells to generate ROS.

Methods: Monocytes from 6 healthy controls (HC) were isolated from whole blood. Cells were incubated for 24h with N-acetyl cysteine (5mM NAC) before 24h incubation with RPMI 2% FBS, IS (0,6, 53 and 236 mg/L) or LPS+IFN-γ (25ng/ml+150U/ml). Cells were stained with anti-CD14-PE and anti-CD16-FITC or with DCFH-DA and analyzed by flow cytometry.

Results: IS induced monocytes modulation in a dose-dependent manner. The highest IS concentration (236 mg/L) promoted 46±10% of CD14+/CD16+-positive monocytes compared to 7±4.7% in control cells (RPMI 2% FBS). IS also showed high ability to induce ROS generation by inflammatory monocytes in dose-dependent manner (18±9.5% with 0.6mg/L; 37±17.5% with 53mg/L; and 81±16.9% with 236 mg/L, compared with control cells 5±1.1%). This was similar when compared to cells treated with LPS+IFN-γ (91±8.8%). Both IS effects on HC monocytes were inhibited in presence of NAC. Monocyte modulation was significantly decreased by NAC (IS 236 mg/L promoted 4±1.2% of CD14+/CD16+ positive cells) and ROS generation was decreased to 12±3.1%, 27±15.3% and 35±16.4% in an IS dose response assay.

Conclusions: Our results show that IS was able to modulate monocytes to assume an inflammatory phenotype capable of ROS generation, and that theses response was attenuated by NAC.

TH-PO238

SIRT2 Ameliorates Lipopolysaccharide-Induced Inflammation in Macrophages Won Kim, Yujin Jung, Dal Kim, Kyung Pyo Kang, Sik Lee, Sung Kwang Park, Tung Nguyen-Thanh, Aesin Lee. *Dept of Internal Medicine, Chonbuk National Univ Medical School, Jeonju, Republic of Korea.*

Background: SIRT2 is a NAD(+)-dependent deacetylases and associated with numerous processes such as infection, carcinogenesis, DNA damage and cell cycle regulation. However, the role of SIRT2 in inflammatory process in macrophage remains unclear.

Methods: In the present study, we have evaluated the regulatory effects of SIRT2 in lipopolysaccaride (LPS)-stimulated macrophages isolated from SIRT2 knockout (KO) and wild type (WT) mice or Raw264.7 macrophage cells. As inflammatory parameters, expression of inducible nitric oxide synthase (iNOS), the productions of nitric oxide, reactive oxygen species (ROS) and M1-macrophage-related factors were evaluated. We also examined the effects of SIRT2 on activation of nuclear factor-kappaB signaling.

Results: SIRT2 deficiency inhibits LPS-induced iNOS mRNA and protein expression in bone marrow derived macrophages. SIRT2-siRNA transfection also suppressed LPS-induced iNOS expression in Raw264.7 macrophage cells. Bone marrow derived macrophages isolated from SIRT2 KO mice produced lower nitric oxide and expressed lower levels of M1-macrophage related markers including iNOS and CD86 in response to LPS than WT mice. Decrease of SIRT2 reduced the LPS-induced reactive oxygen species production. The phosphorylation of p65 was significantly decreased in SIRT2-deficient macrophages after LPS stimulation.

Conclusions: Our data suggested that deficiency of SIRT2 ameliorates iNOS, NO expression and reactive oxygen species production with suppressing LPS-induced phosphorylation of p65 in macrophages.

TH-PO239

Recombinant Pentraxin-2 Directly Protects Human Proximal Tubular Epithelial Cells Tubular From Injury During Cell Stress Naoki Nakagawa,[1] Ivan G. Gomez,[1,2] Allie M. Roach,[1,2] Bryce Gordon Johnson,[1,2] Mark L. Lupher,[3] Jeremy Stuart Duffield.[1,2] *[1]Renal Div, Univ of Washington, Seattle, WA; [2]Biogen Idec, Cambridge, MA; [3]Promedior Inc., Boston, MA.*

Background: Pentraxin-2 is a naturally produced circulating plasma protein involved in innate immunity. We have previously shown that recombinant human Pentraxin-2 (rhPTX-2) therapy attenuates the progression of Alport nephropathy in Col4a3 deficient mice and rhPTX-2 is distributed not only to macrophages but also to proximal tubular epithelial cells (PTECs) in Col4a3 deficient mice. We hypothesized that rhPTX-2 would directly prevent tubular injury in human PTECs.

Methods: Human PTECs were from discarded human kidneys digested using a collagenase based method and purified by magnetic immunoaffinity separation and characterized. To induce cell-stress, PTECs were treated with TGFβ (5ng/ml) or 10% human plasma with or without rhPTX-2 (25mg/ml) for 16h or 24h and evaluated for immunostaining for mesenchymal marker (Vimentin) and epithelial marker (E-cadherin), mitochondrial Reactive oxygen species (ROS) production and qPCR for epithelial-mesenchymal-transition (EMT) markers.

Results: Immunostaining for Vimentin was increased and for epithelial marker E-cadherin was decreased in response to cell stress but those changes were dramatically attenuated by pretreatment with rhPTX-2. The mRNA expression levels of vimentin,

a-smooth muscle actin and Twist1 were increased by cell stress but significantly suppressed by pretreatment with rhPTX-2 compared to the vehicle. In response to cell stress, PTECs rapidly generated mitochondrial ROS, and lost mitochondrial function but PTECs pretreated with rhPTX-2 produced far less mitochondrial ROS accompanied by decreased caspase-3 activity. rhPTX-2 has a specific binding activity for proximal tubule cells and is internalized via a clathrin mediated pathway, suggesting an epithelial receptor.

Conclusions: rhPTX-2 protects epithelium against plasma or TGFβ mediated EMT changes, mitochondrial dysfunction and cell death. rhPTX-2 is a potential new therapy for human chronic kidney diseases.

TH-PO240

Connexin43 as a Determinant of Renal Cell Susceptibility to Nephrotoxic Drug-Induced Cell Injury Kun Gao,[1,2] Yuan Chi,[1] Hui Zhang,[1] Wei Sun,[2] Jian Yao.[1] *[1]Depts of Molecular Signaling, Univ of Yamanashi, Chuo, Yamanashi, Japan; [2]Dept of Nephrology, Affiliated Hospital of Nanjing Univ of Chinese Medicine, Nanjing, Jiangsu, China.*

Background: Drug-induced renal injury represents a frequent clinical entity. It is desirable to identify the factors that influence renal cell susceptibility to nephrotoxicity. Given that gap junctions (GJs) play a determinant role in tumor cell sensitivity to chemotherapy, we tested whether GJ affects renal cell response to nephrotoxic drugs.

Methods: Rat tubular epithelial cells and murine podocytes were exposed to nephrotoxic agents. The generation of ROS was monitored and cell injury was evaluated. The expression and function of GJ protein connexin43 (Cx43) were measured through dye transfer, IF staining and Western blot analysis. The role of Cx43 was determined through interference of its expression and function with chemical inhibitors or siRNA.

Results: 1)Exposure of renal tubular epithelial cells and podocytes to aminoglycoside or puromycin caused morphological change, cellular viability loss and caspase 3 activation, which was preceded by an elevation in ROS level and P38 activation. Treatment of cells with antioxidants (GSH and NAC) significantly prevented cell injury, suggesting a causative role of oxidative stress in cell injury. 2) The cell injury was associated with enhanced Cx43 phosphorylation, which was also preventable by antioxidants. 3) The altered Cx43 contributed to aminoglycoside- and puromycin-induced cell injury. Treatment of cells with Cx43 siRNA or GJ inhibitors enhanced cell resistance to the cytotoxicity of drugs. 4) Suppression of Cx43 expression and/or function caused a dramatic reduction in TXNIP level and an increase in AKT activation. Further analysis revealed that downregulation of TXNIP with siRNA enhanced AKT activation and augmented cell resistance to the cytotoxicity of aminoglycoside and puromycin.

Conclusions: Collectively, our results indicate that Cx43 is a determinant of cell susceptibility to nephrotoxic drugs. This effect of Cx43 is at least partially due to its regulation on TXNIP expression and AKT activation. Cx43 could be a promising therapeutic target for prevention and treatment of drug-induced renal cell injury.

Examination about Various Receptors of Sphingosine 1-Phosphate Receptor Shunji Shiohira, Miki Nishida, Kosaku Nitta, Ken Tsuchiya. *Kidney Center, Tokyo women's Medical Univ, Shinjuku, Tokyo, Japan.*

Background: In our past report, S1P induced fibrosis. In addition, there are various reports S1P has another effects besides fibrosis. The diversity of responses mediated by Sphingosine 1-phosphate receptors (S1PRs), including immunity, cell migration, angiogenesis, heart development, oxidative stress and fibrosis, depends on the pattern of receptor expression and the associated downstream effectors. To get more insight into roles for S1P and receptor subtype effects, we performed using agonists, antagonists and siRNAs knockdown of receptor subtypes. And also, in order to investigate participation with S1P in oxidative stress of acute renal injury, in vivo, we adapted ischemia-reperfusion injury model (IRI) of mice.

Methods: Normal rat kidney interstitial fibroblast (NRK-49F) cells were stimulated with exogenous S1P. And also NRK-49F cells were stimulated with S1P after the addition of S1PR agonist and antagonist, or siRNAs targeted to S1PRs were evaluated. And also, in vivo, IRI stimulated by agonists and antagonists of S1PRs were evaluated. Moreover, the SOD activity of serum was also evaluated.

Results: S1P stimulated various markers of NRK-49F cells in a dose-dependent manner. Increase in a-SMA, collagen type 1 (COL1), collagen type 4 (COL4), tissue inhibitor of matrix metalloproteinase-1 (TIMP1) and plasminogen activator inhibitor-1 (PAI1) expressions and decrease in E-cadherin expression were observed by addition of S1P. siRNA transfection to NRK-49F cells of S1PR3 attenuated the expression of markers. And, agonist of S1PR1 only attenuated the expression of COL1 and PAI1. In the presence of agonist of S1PR1, the serum BUN/Creatinine (Cre) and the activity of SOD in IRI mice were attenuated in day 1. These results suggest S1PR1 participates in the oxidant stress related to acute phase of IRI. In the presence of antagonist of S1PR3, the serum BUN/Cre in IRI mice were improved. Especially, it is remarkable in day 2. And antagonist of S1PR3 did not affect the activity of SOD. These results suggest S1PR3 affect subacute phase of organ injury rather than acute phase.

Conclusions: S1PR1 is participating in oxidant stress and S1PR3 is participating in fibrosis.

High Glucose Milieu (HGM) Induces Kidney Cell Pyroptosis and Inflammasome Formation through Activation of Caspase-1 Shabirul Haque,[1] Maria Sultana-Syed,[1] Shallu Sharma,[1] Rivka Lederman,[1] Himanshu Vashistha,[2] Ashwani Malhotra,[1] Leonard G. Meggs,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Ochsner Clinic, New Orleans, LA.*

Background: The inflammasome is a multiprotein oligomer which promotes the maturation of inflammatory cytokines such as interleukin (IL)-1 ß. The inflammasome is responsible for activation of inflammatory processes and has been shown to induce cell pyroptosis, a process of programmed cell death distinct from apoptosis. Hyperglycemia is one of the important mediators of the development and the the progression of renal lesions in diabetic nephropathy. In *in vitro* studies, HGM has been known to cause both podocyte and tubular cell injury. However, the role of inflammasomes in kidney cell injury in HGM in general and pyroptosis of kidney cells in particular, has not been investigated. We hypothesized that HGM would enhance both podocyte and tubular cell injury through induction of kidney inflammasome formation and pyroptosis.

Methods: Human podocytes (HPs) or human renal proximal tubular cells (HRPTCs) were incubated in media containing either buffer or variable concentrations of glucose (10, 25, and 35 mM) for 24 and 48 hours and assayed for pyroptosis. To determine the involved mechanisms, HPs/ HRPTCs treated with HGM (35 mM) for 48 h and then followed by RNA and protein extraction. cDNA as well as protein blots were probed for NLRP3, IL-1ß and caspase-1. To establish a causal relationship between caspase-1 activation and pyroptosis, HPs/HRPTCs were treated with HGM in the presence or absence of caspase-1 inhibitor and evaluated for occurrence of pyroptosis.

Results: HGM enhanced pyroptosis both in HPs and HRPTCs in a dose and time dependent manner. HGM enhanced transcription of NLPR3 and pro-caspase-1. HGM also enhanced protein expression of IL-1 beta and caspase-1. Since caspase-1 inhibitor not only inhibited HP/HRPTC IL-1ß expression but also reduced number of kidney cell displaying pyroptosis, it appears that this effect of HGM is mediated through caspase-1 activation.

Conclusions: High glucose enhances kidney cell pyroptosis and inflmmasome formation through the activation of caspase-1.

Bilirubin Activates Transcription of HIF-1α in Human Proximal Tubular Cells Cultured in the Physiologic Oxygen Content Ho Jun Chin, Youn-Su Park, Seon Ha Baek, Seong Woo Lee. *Internal Medicine, Seoul National Univ Bundang Hospital, Seong nam, Kyeongkido, Republic of Korea.*

Background: Hypoxia-inducible factor (HIF) is a master gene involved in the regulation of hypoxia. Hypoxic and non-hypoxic stimuli, such as oxidative stress, regulate the expression of HIF. We investigated the effect of bilirubin on HIF-1 expression under physiological oxygen concentration (approximately 5%) in the proximal tubular cells and the possible mechanism of HIF-1 regulation by bilirubin in human proximal tubular cells *in vitro*.

Methods: The human kidney (HK2) cells were cultured for 1–5 h in 5% oxygen with or without bilirubin. HIF-1α protein expression increased by bilirubin treatment at 0.01–0.2 mg/dL concentration.

Results: The messenger RNA (mRNA) expression of HIF-1α that was suppressed by actinomycin D was increased by 1.69 ± 0.05 folds in the cells cultured with 0.1 mg/dL bilirubin, compared to the control cells. The inhibitors of PI3K/mTOR, PI3K/AKT, and ERK 1/2 pathways did not attenuate increased HIF-1α expression by bilirubin. HIF-1α expression decreased by 10 μM exogenous hydrogen peroxide (H_2O_2); scavenger of ROS with or without bilirubin in the HK2 cells increased HIF-1α concentration more than that in the cells without bilirubin. Exogenous H_2O_2 decreased the phosphorylation of P70S6 kinase, which was completely reversed by bilirubin treatment. Knockdown of *NOX4* gene by small interfering RNA (siRNA) increased HIF-1α mRNA expression.

Conclusions: Bilirubin enhanced HIF-1α mRNA transcription as well as the upregulation of HIF-1α protein translation through the attenuation of ROS and subunits of NADPH oxidase in human proximal epithelial cells.

All-Trans-Retinoic Acid Prevents Oxidative Stress-Induced Loss of Renal Tight Junction Proteins in Type-1 Diabetic Model Eduardo Molina-Jijon, Rafael Rodriguez-Munoz, Maria del Carmen Namorado, Pablo Bautista-Garcia, Alejandro Perez-Lopez, Jose L. Reyes. *Physiology, Biophysics and Neurosciences, Center for Research and Advanced Studies. National Polytechnic Inst, Mexico City, DF, Mexico.*

Background: Renal complications in diabetes are severe and may lead to renal insufficiency. We previously reported that decreased expression of renal tight junction (TJ) proteins: occludin and claudin-2 and -5 in diabetic nephropathy (DN) were associated to increased oxidative stress in glomeruli and proximal tubules. Now we investigated whether all trans retinoic acid (atRA), a compound that plays a relevant role in kidney maintenance and that posses antioxidant properties, prevents loss of TJ proteins in streptozotocin (STZ)-treated rats.

Methods: atRA was administered daily by gavage (1 mg/kg) from days 3-21 after STZ administration. Renal expression of kidney injury molecule (KIM)-1, NADPH oxidase

subunits ($p47^{phox}$ and $gp91^{phox}$), endothelial nitric oxidase (eNOS), occludin, claudin-2 and -5 were analyzed by Western blot. Localization of occludin, claudin-2 and -5 were analyzed by confocal microscopy. Claudin-2 nitration and phosphorylation were analyzed by immunoprecipitation assays.

Results: atRA treatment attenuated loss of body weight and proteinuria but it did not prevented hyperglucemia. Other alterations, such as: increased KIM-1, reactive oxygen species (ROS) production, $p47^{phox}$ and $gp91^{phox}$ expressions and eNOS uncoupling were also attenuated by atRA. Decreased expressions of occludin, claudin-2 and -5 induced by diabetes were ameliorated by atRA. We also found that diabetes induces tyrosine nitration, and phosphorylation in serine residues of claudin-2 and atRA prevented these changes.

Conclusions: In conclusion, the findings described above indicated that atRA exerted nephroprotective effects by attenuating oxidative stress and in consequence loss of renal tight junction proteins was also prevented at early stages of DN. (supported by grant CONACyT 179870 to JLR).

TH-PO245

IGF-1 Receptor and E-Cadherin Form a Complex to Maintain Tubular Epithelial Cells Phenotype via β-Catenin Signaling Pathway Lei Jiang, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: In epithelial cells, intercellular adhesion is primarily mediated by E-cadherin. Previous studies have demonstrated a physical interaction between insulin-like growth factor-1 receptor (IGF-1R) and E-cadherin/catenin complex suggesting a crosstalk between the signaling pathways mediated by IGF-1R and E-cadherin. In this work, we investigated whether a crosstalk between IGF-1R, and E-cadherin was involved in the change of tubular epithelial cells phenotype.

Methods: Immunoprecipitation experiments were performed to determine the interaction of IGF-1R and E-cadherin in NRK-52E cells. Next we used IGF-1R siRNA and IGF-1R inhibitor PPP to decrease the IGF-1R expression, and detected the E-cadherin expression. We further intraperitoneal injected the CD-1 mice with PPP and observed the tubular epithelial cells phenotype by western blot and immunofluorescence assay.

Results: 1. IGF-1R and E-cadherin interact at cell–cell contact sites. 2. Inhibition of IGF-1R expression by IGF-1R siRNA transfection or PPP could reduce E-cadherin expression and change the epithelial phenotype. 3. PPP induced the change of epithelial phenotype is independent on the intracellular smad, AKT, p42/44 MAPK and p38MAPK signaling pathway, and is regulated by β-catenin/snail pathway. 4. PPP injection could decrease IGF-1R expression and change the tubular epithelial cells phenotype in CD-1 mice.

Conclusions: These results suggest that regulation of the E-cadherin/IGF-1R scaffolding is essential for maintain the phenotype of tubular epithelial cells. Its alteration could be of major importance to tubular epithelial cells injury.

TH-PO246

Connective Tissue Growth Factors Domain I and Domain IV Show Similar Capacity to Regulate Pericyte/Fibroblast Transition Shuyu Ren,[1] Bryce Gordon Johnson,[3] Scott MacDonnell,[2] Jeremy Stuart Duffield.[3] *[1]Divsion of Nephrology, Univ of Washington, Seattle, WA; [2]Boerhinger Ingelheim, New York, NY; [3]Biogen Idec, Cambridge, MA.*

Background: Connective tissue growth factor (CTGF or CCN2), is a secreted matricellular protein of the CCN family. CTGF has four domains (I to IV) with each sharing homology to different proteins (eg: IGFBP, VWC, TSP1) and lead to the interaction of CTGF with many other ligands and receptors to modulate cell function. CTGF has been shown to promote fibrosis in the kidney but its mechanism of action has been unclear. Pericytes are mesenchymal derived cells attached to peritubular capillaries which identified as a major progenitor of scar-forming myofibroblasts. However, the cellular and molecular mechanisms modulating fibrogenesis are still largely unknown. We recently showed that the canonical WNT extracellular regulator Dickkopf related protein-1 (DKK-1), potently inhibits kidney fibrosis and blocks CTGF mediated activation of pericytes and myofirboblasts (Ren et al PNAS 2013). We determined to understand how CTGF and DKK1 signal in this cell lineage to regulate fibrogenic responses.

Methods: Pericytes were purified from transgenic mice and human kidneys. Cells were assessed in migration, morphology and Western blot assays. CTGF domains I, I + II, were synthesized and purified by Boerhinger Ingelheim. Domain IV was purchased from peprotech.

Results: CTGF domain IV activates WNT/bcatenin signaling in pericytes, which is inhibited by recombinant DKK-1. CTGF Dom-IV rapidly phosphorylates the co-receptor of WNT/bcatenin signaling - LRP6. DKK-1 blocks CTGF domain IV mediated fibrotic responses in culture including fibrotic gene activation, pericyte morphology changes and migration in JNK MAP kinase dependent, WNT partially dependent pathway. CTGF Dom-I also activates pericyte migration which is also inhibited by DKK-1, JNK inhibition or Wnt ligand secretion. CTGF Dom-I or -IV induced migration and activation of human kidney pericytes.

Conclusions: Our studies suggest CTGF Dom-I may also play an important role in the regulation of human renal fibrogenesis and that DKK1 is sufficient to inhibit all the effects of CTGF on this lineage.

TH-PO247

RNA Extraction from Urinary Extracellular Vesicles isolated by Hydrostatic Dialysis Harry B. Holthofer, Dorota Ewa Tataruch, Luca Musante. *Centre for BioAnalytical Sciences, Dublin City Univ, Dublin, Ireland.*

Background: Urinary Extracellular vesicles (UEVs) carry proteins and nucleic acids characteristic for their cell of origin in the kidney (nephron) and urogenital tract. The presence of small RNAs in UEVs has gained interest as potential disease biomarkers. Although urine can be obtained in large amounts, vesicle enrichment on a large cohort of patients is still a challenging task. Differential centrifugation is considered as a "golden" standard technique in spite of its inherent problems and requirement of expensive instrumentation.

Methods: Here we report the performance of novel hydrostatic dialysis (HD) based method of urinary vesicles enrichment to yield high quality and quantity RNA from the UEVs. First, we compared RNA profile coming from above 1000kDa (HDa) fraction versus pellets 17,000g and 200,000g coming from differential centrifugation. Second, we evaluated three different RNA extraction methods with starting material from HDa fraction. These included the TRIzol, miRNeasy Micro/Mini Kit (Qiagen®) and Urine Exosome RNA Isolation Kit (Norgen Biotek®). RNA quality and yield was verified by Nanodrop Spectrophotometer ND-1000 and Agilent Bioanalyzer.

Results: RNA extracted from pellets after differential centrifugation presents closely similar results to our HDa fraction in terms of spectrophotometer data. However, qualitative analysis using Agilent Bioanalyzer showed major differences in RNA profile between these two isolation methods. Analysis of HDa derived RNA shows fully comparable profile with all three extraction techniques.

Conclusions: Use of hydrostatic dialysis method for RNA isolation is preferred for: 1) standardization of physical-chemical conditions of samples and to obtain stable RNA profiles independent of the extraction procedure; 2) extraction of RNA from UEVs coming from widely variable volume of sample instead of aliquots and to obtain high yield of nucleic acids. This high quality material can be used for further analysis like qPCR or Next Generation Sequencing. Hydrostatic dialysis appears as a superior way to process desired volumes of urine. In conjunction with optimized RNA extraction protocol this favors procurement of high quality and quantity of RNA.

Internal Proteomic Profile of Human Urinary Extracellular Vesicles Harry B. Holthofer,[1] Xinyu Liu,[1,2] Clizia Chinello,[3] Luca Musante,[1] Wenxiao Zeng,[1] Dorota Ewa Tataruch,[1] Giulio Calzaferri,[1] Fulvio Magni.[3] *[1]Centre for BioAnalytical Sciences, Dublin City Univ, Dublin, Ireland; [2]Inst of Nephrology and Urology, The Third Affiliated Hospital of Southern Medical Univ, Guangzhou, China; [3]Dept of Health Sciences, Univ of Milano-Bicocca, Monza, Italy.*

Background: Urinary extracellular vesicles (UEVs) comprise subgroups such as exosomes, microvesicles and apoptotic bodies. These membrane confined structures carry characteristic intracellular proteinsand RNA, reflecting the physio- pathological processes of their parent cell. Previous studies have identified over 3300 UEV proteins despite the presence ofTamm-Horsfall Protein (THP) which complicatesdetection of low abundant proteins. Here we established a protocol to eliminate THP to focus on the intraluminal content of UEVs.

Methods: Urine was collected from healthy volunteers and UEVs isolated by hydrostatic dialysis. UEV fraction was subjected to ***reduction*** and ***alkylation*** followed by ***trypsin***digestion. Thereafter sample was ultrafiltered by 30kDa molecular weight cut off device and theretained fraction ***solubilized*** by sodium deoxycholate (DOC) followed by yet another ***reduction***, ***alkylation*** and ***trypsin***digestion for UEV internal contents. Western-blot (WB) analysis for the exosome marker Tumor Susceptibility Gene 101 (TSG101) and podocin was carried out to estimate vesicle integrity whereas proteome mapping was performed by mass spectrometry (LC-MS).

Results: WB results showed that TSG101 was not affected by reduction-alkylation-trypsin treatment whereas signal disappeared after DOC and trypsin. Podocin was not affected by reduction-alkylation but it vanished after trypsin digestion. Notably, THP was fully digested with this treatment. LC-MS analysis identified 881 proteins 60% of which were previously found in human UEVswhile the remaining 40% were new.Gene ontology classification revealed that the unique proteins were cytoplasmic(37%), organelle specific (24%), macromolecular complexes (12%)and membrane proteins (10%).

Conclusions: Our UEV isolation and proteomic approach allows the characterization of vesicle contents, expanding the list of intraluminal UEV proteins without loss due to THP interference.

The Effect of Autologous Adipose-Derived Mesenchymal Stem Cell Transplantation on Vascular Calcification in Rats with Adenine-induced Kidney Disease Shinya Yokote,[1] Shuichiro Yamanaka,[1,2] Yuichi Jimmy Katsuoka,[2] Susumu Tajiri,[1,2] Ichiro Ohkido,[1] Makoto Ogura,[1] Takashi Yokoo.[1] *[1]Div of Nephrology and Hypertention, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan; [2]Div of ReGenerative Medicine, Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Previous studies have investigated using mesenchymal stem cells (MSC) to treat damaged kidneys. However, the effect of adipose-derived MSC (ASC) on vascular calcification in chronic kidney disease (CKD) is still poorly understood. The purpose of this work was to investigate the potential of ASC as an alternative treatment for the treatment of CKD and vascular calcification by using an adenine-induced CKD model.

Methods: CKD was induced in 13-week-old male Sprague-Dawleyrats (n=16) by feeding a diet containing 0.75% adenine for 4 weeks. Time course changes in serum inorganic phosphorus (Pi), calcium (Ca) and creatinine were measured. Rats were randomized into two groups: control (phosphate buffered saline, n=9); and MSC (intravenous transplantation of 5×10^5 autologous ASC on days 28, 35, 42, 49 and 56 following adenine-feeding, n=7).

Results: ASC transplantation significantly reduced serum Pi compared with control ($P<0.05$). Histopathology of the kidney showed greater dilation of tubular lumens and more interstitial fibrosis in the control group than the MSC group. Calcium and Pi content of the aorta in the MSC group were lower than in the control group ($P<0.05$). Von Kossa staining of the thoracic aorta media also revealed that ASC transplantaiton suppressed vascular calcification compared with the control group. There was a positive correlation between the Ca and Pi content of the thoracic aorta and the serum Pi level at the end of study, suggesting that the anti-calcification effect of ASC transplantation is due to suppression of the elevation of serum Pi levels via a suppression of kidney injury.

Conclusions: This study found that autogenic ASC transplantation improved kidney function and suppressed the progression of vascular calcification, suggesting that autogenic transplantation of ASC is a novel approach for preventing the progression of CKD and vascular calcification.

Novel Generation and Characterisation of Human Renal Progenitor/Stem Cell Lines Chiara Mari, Karen Price, Satyamaanasa Polubothu, Amnah Alharbi, Paul Winyard. *Developmental Biology and Cancer, UCL, Inst of Child Health, London, United Kingdom.*

Background: Therapy based on stem/progenitor cells ameliorates many experimental kidney diseases. CD24 and CD133 are often used as markers to identify appropriate cells, generally based on studies from adult tissues. We rationalised that fetal kidneys should contain more stem cells, with greater potential for multi-differentiation and long term efficacy. It is not certain, however, whether CD24 and CD133 are the best markers for fetal-derived stem cells. Therefore, we generated multiple early fetal human cell lines and have begun to assess expression of renal progenitor genes and differentiation potential.

Methods: Human fetal kidneys were supplied by the MRC/Wellcome-funded Human Developmental Biology Resource with full ethical permission.CD24 and CD133 expression was evaluated by immunofluorescence. Human fetal cell lines were isolated by FACS based on CD24 and CD133 expression. Real-time PCR was used to define their molecular phenotype.

Results: CD24 and CD133 were detected in developing epithelial structures from 7 weeks gestation, particularly in cells that have undergone mesenchymal-epithelial transition. We used explant culture to generate mixed cell populations from which CD24+CD133+ (double positive cells, DP) and CD24-CD133- (double negative cells, DN) were isolated. 6 DP and 6 DN lines from 8 to 13 weeks gestation were generated. DP and DN lines were clearly different morphologically: DP cells were predominantly epithelial while DN were more mesenchymal. Culture for up to 7 passages demonstrated consistent DP or DN differences. Real-time PCR showed higher expression of characteristic cap mesenchymal markers such as *SIX2*, *EYA1* and *NCAM1* in DN compared to DP lines.

Conclusions: We have generated novel human fetal kidney lines with and without CD24/CD133 co-expression. Immunostaining and PCR raises the possibility that DP cells are at a later epithelial stage of differentiation whereas the DN population may include earlier pre-epithelial progenitors. Our next steps are to assess multi-lineage differentiation, clonogenic potential and contribution to nephrogenesis *in vitro*, before comparing DN and DP efficacy in kidney diseases.

Cancer Stem/Progenitor Cells Isolated from Clear Cell Renal Cell Carcinoma Express Genes Conferring Resistance to the Cisplatin Treatment Fabio Sallustio,[1,2,3] Vanessa Galleggiante,[1] Grazia Serino,[1] Monica Rutigliano,[1] Claudia Curci,[2] G. Lucarelli,[1] P. Ditonno,[1] M. Battaglia,[1] Francesco Paolo Schena.[1,2] *[1]DETO, Univ of Bari, Bari, Italy; [2]C.A.R.S.O. Consortium, Valenzano, Bari, Italy; [3]Disteba, Univ of Salento, Lecce, Italy.*

Background: Recent studies have shown the presence of a stem-like cell population in several human cancers that is crucial for the tumor development. These "cancer stem cells" can maintain the ability to self-renew and sustain the tumor via the expression of tumor-progenitor genes. Because cancer stem cells are believed to be responsible for tumor initiation as well as resistance to chemo- and radiotherapy, their persistence may account for relapsing disease.

Methods: With the aim to study and characterize Renal Cancer Stem Cells (RCSCs) derived from clear cell renal cell carcinoma, we isolated CD133+/24+ from healthy and tumoral renal tissue of 40 patients. Cells were characterized for their mesenchymal phenotype and stemness proteomic profile. Microarray analysis was performed on 24 healthy Adult Renal Stem/Progenitor Cells (ARPCs) and 24 RCSCs. Results were validated using qRT-PCR analysis. Putative markers were evaluated by FACS.

Results: We showed that the CD133+/CD24+ tumoral cells did not express mesenchymal stem cell markers and that they were more undifferentiated than ARPCs. RCSCs were clonogenic and able to differentiate in adipocytes, epithelial and osteogenic cells. Microarray analysis identified 52 genes differently modulated between RCSCs and ARPCs. 23 genes were expressed exclusively in RCSCs but not in ARPCs and CD133- tumoral cells. Among the most significant pathways and biological processes differently modulated we identified the Cancer biological processes and in particular the proliferation of vascular endothelial cells. The gene expression profile identified NRCAM and CTR2 as putative markers for renal cancer stem cells. Moreover, we identified 2 genes (ERCC1 and CTR2) that are involved in the mechanism conferring resistance to the cisplatin treatment in patients.

Conclusions: The identification of these cancer cells in ccRCC and related markers could have a role in supporting the prognosis of patients with RCC and the improving of therapeutic strategies.

***In Situ* Cell Lineage Tracing of the Clonal Architecture of Normal Human Adult Kidney Tubules Suggests Regular Cell Turnover** Jonathan E. Zuckerman,[1] Charles Lassman,[1] Ira Kurtz.[2] *[1]Pathology and Laboratory Medicine, UCLA; [2]Nephrology Div, UCLA.*

Background: Because no clear tubule progenitor cell niche has been identified in the adult human kidney, the mechanism of tubular cell regeneration in the normal kidney and after acute injury is uncertain. We sought to use spontaneous mitochondrial DNA (mtDNA) mutations as lineage markers of progenitor cells for progenitor cell niche identification in the adult human kidney. Spontaneous mtDNA mutations in humans are common. Because of uneven partitioning of mtDNA copies (100's per cell) during cell division, a copy of mutated mtDNA can become the sole form of mtDNA within a cell that is long lived and mitotically active (e.g., a progenitor cell). This type of event, a homoplasmic transformation, can be detected in human tissues and is sufficiently rare as to mark individual cells. We hypothesized that we could identify clonal expansions of progenitor cells that have undergone this type of transformation to identify their niche within adult human kidney tubules.

Methods: Frozen sections from normal human kidney specimens were stained for both cytochrome c oxidase (COX) and succinate dehydrogenase (SDH) activity. Cell patches with deficient COX activity but normal SDH activity (indicates homoplasmic mtDNA mutations) were identified via light microscopy. Serial sections were imaged to determine 3D spatial relationships of COX deficient cell patches.

Results: Strong COX and SDH activities were observed throughout the human kidney tubules, but not in glomeruli or interstitial structures. Dual staining for COX and SDH activity allowed for easy identification of COX deficient cells. These patches were focal and evenly distributed throughout the kidney tubules in both cortex and medulla. Patches of COX deficiency spanned only short segments of tubules; often with multiple independent patches within a single nephron.

Conclusions: The presence of small clonal patches of cells distributed discontinuously throughout the nephron suggests new cells arise from locations throughout the nephron and that cell replacement occurs normally, challenging the widely held view that there is limited proliferation of normal human tubular cells in the absence of acute tubular injury.

c-Kit$^+$Cells Are Kidney-Specific Stem Cells Maintained Throughout Adult Life Erika B. Rangel,[1] Samirah A. Gomes,[2] Garrett Goss,[3] Konstantinos Chatzistergos,[3] Sabine Klein,[4] Bradley J. Goldstein,[3] Dieter Saur,[4] Joshua M. Hare,[3] Erika B. Rangel.[1] *[1]Inst Israelita de Ensino e Pesquisa, Albert Einstein Hospital, Sao Paulo, Brazil; [2]Nephrology, Univ of Sao Paulo, Sao Paulo, Brazil; [3]ISCI, Univ of Miami, Miami, FL; [4]Dept of Internal Medicine, Medizinische Klinik und Poliklinik der Technischen, Munich, Germany.*

Background: Identification of stem cell populations in mammalian tissues is important for therapeutic applications and for understanding biological processes. We recently reported that c-kit$^+$ cells isolated from developing rat kidneys exhibit stem cell properties. We hypothesize that c-kit$^+$ cells represent a tissue-specific stem cell population that contribute to kidney development and are maintained throughout adult life.

Methods: For lineage tracing, we crossed the inducible c-kit Cre reporter mice with the IRG and R26R lacZ mice. By varying the timing of tamoxifen treatment, c-kit$^+$ cells and their descendants were specifically labeled with EGFP or lacZ and their spatiotemporal distribution was followed.

Results: C-kit expression was more abundant in early post-natal (P) period (7.91 in P0.5-3.5; 10.6 in P7-14 versus 3.13 in embryonic [E]17.5-18.5, $P<0.0001$), but was maintained throughout adult life, although at lower levels (5.7 in P30 and 2.2 in P90-180). When tamoxifen was administered during E7.5-9.5, a few EGFP/LacZ$^+$ cells were observed in tubular segments from the cortex to the medulla, and at E10.5-12.5, when ureteric bud invades the metanephric mesenchyma, ribbons of c-kit-EGFP/LacZ$^+$ cells expanded to form

tubular structures and were detected in structures resembling the S-shaped bodies. In the post-natal period, the number of c-kit-EGFP/LacZ^{+} cells increased in the cortex, medulla, and papilla. No overlap between c-kit-EGFP^{+} cells and differentiation markers (AQP1, AQP2, NKCC2) was observed, suggesting that these cells correspond to undifferentiated cells. In adult mice, c-kit-LacZ^{+} cells were found in distinct tubular segments.

Conclusions: C-kit marks a stem cell population dedicated to generating different kidney tubular segments from the cortex to the medulla during kidney development and adult life, which indicates important biological and therapeutic implications.

TH-PO254

Sox9 Positive Cells Contribute Renal Epithelial Cell Regeneration and Kidney Fibrosis Development Hyun Mi Kang, Katalin Susztak. *Renal Electrolyte and Hypertension Div, Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA.*

Background: Sox9 is one of the important transcription factors controlling cell proliferation, fate and differentiation in the development of many tissues and organs. Here we examined the role of Sox9 in renal epithelial cells.

Methods: To test the role of Sox9 in renal epithelial cells, we generated mice with tubule epithelial specific Sox9 deletion, by intercrossing the PAX8 rtTA-TetO cre and Sox9^{floxed} animals. In addition, we also isolated Sox9 positive cells from the mouse kidney to examine the proliferation and differentiation capacities *in vitro.*

Results: To define the transcription factor related to progenitors in the kidney, we isolated tubule epithelial cells which showed proliferation and differentiation capacity in vitro. We performed genome wide gene expression analysis using microarrays and found cells that show high proliferation and differentiation capacity had high Sox9, Lgr4, Foxd1 and Pax8 expression. In control mouse and human kidneys, Sox9 is rarely detected in the tubules but in injury models its expression is highly increased most tubules, especially dilated proximal tubules. To test whether Sox9 contributes to kidney regeneration we generated mice with tubule specific deletion of Sox9. These animals developed more severe injury after folic acid injection than wild type animals. Fibronectin, collagen1a and 4a were significantly increased and proliferation markers, cycline A, B, D and E were remarkably decreased in Sox9 deleted kidney. Similar results were observed in different time courses, 4 weeks and 16 weeks after folic acid injection. In particular, we isolated Sox9 positive cells from mouse kidney and they showed the ability to self-renew and expressed progenitor cell markers. They also showed multi lineage differentiation potential especially renal tubule cells under the specific condition *in vitro.*

Conclusions: In summary, we demonstrated that Sox9 plays an important role in proliferating and regenerating the renal tubule epithelial cells. Deletion of Sox9 leads to decreasing proliferation and inducing fibrosis development. Sox9 positive cells may represent progenitor cells in the regenerating kidney.

TH-PO255

Isolation of Putative Podocyte Precursors and Comparison at Different Stages of Differentiation Jianxiang Xu, Patricia N. Kralik, Shirong N. Zheng, Lu Cai, Paul N. Epstein. *Pediatrics, Univ of Louisville, Louisville, KY.*

Background: Continued loss of podocytes will ultimately impair renal function. Since differentiated podocytes are unable to replicate, replacements must come from non-podocyte, precursors. However the identity of podocyte precursors in adults is uncertain.

Methods: Mice were generated with two fluorescent markers: One a red podocyte lineage marker and the other a green marker of podocyte transcription. Differential fluorescence was used to identify and purify potential podocyte precursors.

Results: FACS analysis of glomerular cells showed almost all podocytes expressed both red and green markers, but consistently 2% expressed only the green marker. Confocal microscopy demonstrated green only cells on the glomerular tuft, near the vascular pole. Structurally green only cells varied from simple ovoid cells, to complex cells with fine foot processes indistinguishable from normal podocytes. Immunostaining for podocyte proteins WT1, synaptopodin and nephrin was heterogeneous, varying from negative to strongly positive. Green only cells could be separated from normal red/green podocytes by FACS and cultured or extracted for RNA. In culture activation of the red lineage system was rare. Gene array of freshly purified cells showed differential ($P<0.05$) expression of 1392 genes in green versus red/green podocytes. The 5 most common GO processes in up-regulated RNAs of green cells were: extracellular matrix organization, axon guidance, negative regulation of cell proliferation, angiogenesis and kidney development. Surprisingly, podocyte specific RNA expression was equivalent in normal and green only podocytes.

Conclusions: Putative podocyte precursors were identified and purified using expression of a green podocyte transcription marker and absence of a red podocyte lineage marker. Green only cells were considered podocyte precursors based on robust expression of all podocyte-specific RNAs and morphology and immunostaining results showing differentiation from simple cells to nearly differentiated podocytes.

Podocytes Derived from Undifferentiated Cells of Amniotic Fluid and Urine Fanny Oliveira Arcolino,[1] Lambertus P.W.J. Van den Heuvel,[1] Silvia Zia,[1] Jaan Toelen,[1,2] Joris Vriens,[1] Patricia Murray,[3] Elena N. Levtchenko.[1,2] *[1]Dept of Development and ReGeneration, KU Leuven, Leuven, Belgium; [2]Dept of Pediatrics, UZ Leuven, Leuven, Belgium; [3]Dept of Translational Medicine, Univ of Liverpool, Liverpool, United Kingdom.*

Background: Loss of podocytes is the main cause of many glomerular diseases. Subpopulations of cells found in amniotic fluid (AF) and urine have been shown to express progenitor cell features and may have the potential to differentiate into several cell lineages. We aimed to obtain podocytes derived from kidney stem/progenitor cells (KSPC) isolated from (AF), principally composed of fetal urine, and freshly voided urine from neonates and adult donors.

Methods: Fetal progenitor cells (fPC) were isolated from AF and urine progenitor cells were isolated from neonates (nPC) and healthy adult donors (aPC). Clonal cell lines were characterized as KSPC and KSPC-derived podocytes by gene expression analyses using quantitative PCR and protein expression by flow cytometry and immunofluorescence. Podocytes differentiation was induced by incubation of KSPCs in culture medium supplemented with retinoic acid and vitamin D.

Results: KSPCs expressed mesenchymal stem cell markers, but not hematopoietic markers. While fPCs and nPCs were positive for the fetal renal markers SIX2 and PAX2, aPCs expressed the adult renal epithelial markers CD133 and CD24. KSPC-derived podocytes presented mesenchymal-to-epithelial transition and many of the cells became bi- or multi-nucleated with arborized cytoplasm comparable to conditionally immortalized podocytes. Cells presented up-regulation of podocyte-specific genes such as Lmx1b, podocalyxin, synaptopodin, CD2AP and nephrin, they presented typical podocyte cytoskeleton and focal adhesion molecules distribution.

Conclusions: Stem/progenitor cells can be isolated from amniotic fluid, neonatal and adult urine and are committed to the renal linage. These cells presenting renal phenotype can be differentiated into podocytes and may provide a novel and non-invasive source of cells for regenerative medicine aiming kidney repair.

TH-PO257

Lineage Tracing Reveals Generation of New Podocytes By Renal Progenitors of Bowman's Capsule After Injury Laura Lasagni, Elisa Ronconi, Maria Lucia Angelotti, Anna Julie Peired, Duccio Lombardi, Elena Lazzeri, Paola Romagnani. *Excellence Center Denothe, Univ of Florence, Italy.*

Background: Renal progenitor cells (RPC) are well characterized in humans, but the available data in the mouse are still limited because of the lack of appropriate models to study them. This is mostly related to the fact that the markers used to identify RPC in human cannot be applied in mouse. Based on our and others previous observation that Pax2 selectively costains CD133 in human nephron, we established a PAX2.rtTA;tetO.cre;mT/mG conditional transgenic mouse in which, following doxycyclin (dox) treatment, Pax2 promoter drives the expression of GFP specifically in RPC in Bowman's capsule and in scattered cells of tubules. With this model, we aimed to clarify the contribution of RPC to podocyte regeneration after injury and whether it could be modulated by drugs.

Methods: Following 10 days dox treatment at 5th week of age and a washout period of one week, podocyte loss has been induced in PAX2.rtTA;tetO.Cre;mT/mG mice by adriamycin administration, and animals divided on the basis of the course of proteinuria in regressing versus progressing. At day 30, the presence of GFP+ cells migrated within the tuft, expressing podocyte proteins and showing morphological characteristics of fully differentiated podocytes was evaluated by confocal and electron microscopy.

Results: In mice showing regression of proteinuria, GFP+ cells expressing podocyte markers and showing foot processes indistinguishable from resident podocytes could be detected in the glomeruli, while in mice with progressive glomerular damage, regeneration could not be detected and GFP+ cells were observed as components of glomerular lesions. To test whether podocyte regeneration could be enhanced by drug treatment, following adriamycin administration, mice were treated with a GSK3s-inhibitor or vehicle. After 15 days, the number of regenerated GFP+podocytes was significantly higher in GSK3s treated mice than in control.

Conclusions: These data support the hypothesis that podocyte regeneration is carried out by RPC after injury, is associated with regression of damage, and can be pharmacologically enhanced with important perspectives for treatment of CKD.

TH-PO258

Expression and Secretion of VEGF and SDF-1, Cytokines Essential for Mesenchymal Stem Cells' Renoprotective Effects, Vary Significantly under Different Culture Conditions Anna Gooch,[1] Ping Zhang,[1] Zhuma Hu,[1] Christof Westenfelder.[1,2] *[1]Medicine, U of Utah and VAMC, Salt Lake City, UT; [2]Physiology, U of Utah, SLC, UT.*

Background: Mesenchymal Stem Cells (MSCs) are increasingly evaluated for therapeutic applications such as AKI and CKD. Their off-the-shelf use relies on culture expansion and banking. Recent publications caution that MSC-based therapies may yield inconsistent therapeutic results due to variability in culture protocols. Using siRNA gene knock-down technology, we showed that the cytokines VEGF-A and SDF-1, as elaborated by MSCs, are critical to their renoprotective actions in rats with AKI. We investigated

whether routine cell culturing changes VEGF-A and SDF-1 expression in 7 human MSC cell lines at passages 2-6. Four lines were clinical grade and had been used at Passage (P) 2 in a successful Phase I AKI Trial.

Methods: Cells were plated at 1,000 cells/cm^2, cultured in α-MEM + 5% human platelet lysate, grown to (a) 70% or (b) full confluence, passaged up to P6, and SDF-1 and VEGF-A expression/secretion was assessed throughout and compared to P2 levels.

Results: Gene expression levels were unchanged at all passages tested. Secretion of SDF-1 was unchanged for P3 cells grown to 70% confluence, but fell by ~50% at P3 when cells were grown to confluence. Starting at P4, secretion levels became inconsistent. By contrast, VEGF-A secretion rose significantly with each passage, regardless of cell confluence.

Conclusions: MSC-expressed SDF-1 is an autocrine survival factor and does mediate survival effects in renal cells. Since a 50% reduction in SDF-1 expression diminishes MSCs' renoprotective effects in experimental AKI, a similar reduction seen here at P3 could similarly reduce their therapeutic efficacy in clinical AKI. MSC-expressed VEGF is angioprotective and pro-angiogenic in experimental AKI. It remains to be examined whether the increased VEGF expression seen with higher passaging numbers offsets the loss in the kidney protective actions of MSCs that are under-expressing SDF-1, and potentially other cytokines. Together, our data underscore the fact that it is essential that culture conditions must be stringently defined when MSCs are used therapeutically.

Transgenic Expression of Human Alkaline Phosphatase by Allogeneic Rat Mesenchymal Stem Cells Renders Them Ineffective in the Treatment of 5/6th Nephrectomy-Induced Chronic Kidney Disease

Anna Gooch,[1] Ping Zhang,[1] Zhuma Hu,[1] Christof Westenfelder.[1,2] *[1]Medicine, U of Utah and VAMC, SLC, UT; [2]Physiology, U of Utah, SLC, UT.*

Background: We showed that allogeneic rat and human Mesenchymal Stem Cells (MSCs) protect renal function post IRI AKI and appear to be renoprotective in on-pump cardiac surgery patients at risk for post-op AKI. Such paracrine effects in allogeneic settings are obtained without the elicitation of an antibody response, confirming MSCs' immune privileged properties. Here, we examined the possibility of antibody (Ab) production to allo- or xenogeneic genes and secondary loss of therapeutic efficacy as a result of multiple doses of Fischer344 allo-MSCs (F344-MSCs) or human Alkaline Phosphatase transgenic Fischer344 allo-MSCs (hPAP MSCs) given to Sprague Dawley (SD) rats with 5/6th Nephrectomy (NX)-induced CKD.

Methods: Four groups (n= 6) of SD rats underwent 5/6 NX and were treated with two, bi-weekly i.v. infusions (1x10^6 cells/kg bw) at 3 and 4 weeks post NX of (a) F344-MSCs; (b) hPAP-MSCs; (c) vehicle in Controls; (d) Sham surgery. Serum Creatinine (SCr), systolic blood pressure (BP) and urinary albumin (U Alb) excretion were assessed weekly, and at 12 weeks renal histopathology was examined, and serum samples were FACS analyzed for potential antibody production to allo- or xenogeneic genes.

Results: Rats treated with F344-MSCs showed at endpoint significantly lower SCr levels, U Alb excretion and BPs versus Controls, as well as lower scores for interstitial fibrosis and glomerulosclerosis. Serum from these animals contained no IgG to F344-MSCs, while rats treated with hPAP-MSCs showed no differences in any measured endpoints versus Controls, and their sera contained IgG to hPAP-MSCs.

Conclusions: Repeated administration of allo-MSCs in CKD appears to arrest the progressive loss of renal function and rise in albuminuria, supporting the possibility that these cells may be of use clinically in treating CKD. However, use of MSCs containing xenogeneic epitopes eliminates their protective effects, likely due to the destruction of these cells by the elicitation of antibodies to such epitopes.

Engineering Transplantable 3D Renal Tissue From a Suspension of Human Amniotic Fluid Stem Cells and Mouse Metanephric Cells

Valentina Benedetti,[1] Christodoulos Xinaris,[1] Susanna Tomasoni,[1] Paola Rizzo,[1] Rubina Novelli,[1] Daniela Corna,[1] Takashi Yokoo,[2] Marina Morigi,[1] Ariela Benigni,[1] Giuseppe Remuzzi.[1,3] *[1]IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Bergamo, Italy; [2]The Jikei Univ School of Medicine, Tokyo, Japan; [3]Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy.*

Background: Stem cell-based engineering of kidneys may offer prospects for alternatives to dialysis and transplantation. Amniotic fluid stem cells (AFSCs) have been successfully used for therapeutic applications in kidney injury models. However, the capacity of these cells to contribute to the creation of efficient kidney tissue is still unknown.

Methods: Here, we tested whether human AFSCs can be patterned by the spatial information of self-organizing metanephric cells to form a 3D tissue applicable to transplantation. Mixed suspensions of AFSCs and E11.5 mouse kidney cells were centrifuged, and pellets were cultured *in vitro* up to 5 days.

Results: Immunofluorescence analysis revealed minimal integration of labeled-AFSCs into condensing metanephric mesenchyme (MM), with the majority of AFSCs distributed between Pax-2-positive structures without acquiring renal markers. To enhance their integration in self-forming tissue, AFSCs were genetically modified to express Glial cell-derived neurotrophic factor (GDNF), a factor secreted by MM. GDNF-expressing AFSCs incorporated into Pax-2-positive structures and formed 3D chimeric tubules that were surrounded by laminin-positive membranes. Chimeric organoids were then implanted under the kidney capsule of host rats and allowed to grow *in vivo* for 7 days. Engrafted tissue became vascularized, and developed well-formed tubules and glomeruli that contained red cells. Several AFSCs were localized into developing glomeruli and expressed the podocyte marker α-actinin-4. AFSC were also found in vessels and expressed the endothelial marker CD31. Finally, only few AFSCs were found in tubules.

Conclusions: Hence, AFSCs can be effectively directed by self-organizing menatephric cells to form chimeric nephrons, which can further develop *in vivo*. This ability can assist the development of tissue-engineered kidney alternatives and facilitate more focused investigations on AFSCs biology.

Amniotic Fluid Stem Cells: Mediators of Crosstalk Between Glomerular Endothelial Cells and Podocytes

Sargis Sedrakyan,[1] Astgik Petrosyan,[1] Stefano Da Sacco,[1] Kevin V. Lemley,[2] Roger E. De Filippo,[1] Laura Perin.[1] *[1]Urology, Children's Hospital Los Angeles, Los Angeles, CA; [2]Nephrology, Children's Hospital Los Angeles, Los Angeles, CA.*

Background: Emerging evidence strongly support the notion of podocyte depletion as a major mechanism driving glomerulosclerosis. We have previously shown that stem cells derived from amniotic fluid (AFSC) significantly delay chronic kidney disease progression in Alport Syndrome mice via preservation of podocyte numbers among other mechanisms. However, exactly how stem cells mediate such protection has not been fully elucidated. Endothelial cell integrity and healthy cross-talk with the podocyte is necessary for maintenance of glomerular filtration barrier. Since injection of AFSC protect glomerular structure but do not differentiate into podocytes in vivo, we hypothesize that AFSC preserve the filtration barrier and detachment of podocytes by acting directly on endothelial cells through VEGF signaling mechanisms.

Methods: Primary glomerular endothelial cells were subjected to angiotensin II exposure for 24 hours as control and treated with AFSC in experimental groups. In vivo, Alport mice were injected with AFSC. Whole kidneys, glomeruli and glomerular cells (endothelial cells, podocytes and AFSC) derived from injected mice were harvested and analyzed.

Results: Angiotensin II stimulation resulted in endothelial cell injury after 24 hours in culture characterized by cell quiescence and necrosis with downregulation of VEGF and upregulation of necrotic markers such as Jph3, S100a7a and sycp2. In contrast, cells co-cultured with AFSC had normal morphology and proliferation with increased VEGF and decreased necrosis gene expression. The data indicate AFSC induce increased production of VEGF providing endothelial cells ample amount of the key survival signal. Injection of AFSC in Alport mice regulated VEGF expression within damaged glomeruli near normal level which in turn protects glomerular filtration barrier from subsequent deterioration.

Conclusions: Taken together our data suggest that AFSC contribute to podocyte preservation by regulating endothelial cell survival via active cytokine regulation controlling VEGF expression level both in vitro and in vivo.

TH-PO262

Adipose Tissue-Derived Mesenchymal Stem Cells in Long-Term Dialysis Patients Display Downregulation of PCAF Expression and Poor Angiogenesis Activation

Shuichiro Yamanaka,[1,2] Shinya Yokote,[1] Yuichi Jimmy Katsuoka,[1,2] Susumu Tajiri,[1,2] Hirotaka James Okano,[2] Takashi Yokoo.[1] *[1]The Jikei Univ School of Medicine, Dept of Internal Medicine, Div of Nephrology and Hypertension, Tokyo, Japan; [2]The Jikei Univ School of Medicine, Div of ReGenerative Medicine, Tokyo, Japan.*

Background: We previously demonstrated that mesenchymal stem cells (MSCs) differentiate into functional kidney cells capable of urine and erythropoietin production, indicating that they may be used for kidney regeneration. However, the viability of MSCs from dialysis patients may be affected under uremic conditions.

Methods: In this study, we isolated MSCs from the adipose tissues of end-stage kidney disease (ESKD) patients undergoing long-term dialysis (KD-MSCs; mean: 72.3 months) and from healthy controls (HC-MSCs) to compare their viability. KD-MSCs and HC-MSCs were assessed for their proliferation potential, senescence, and differentiation capacities into adipocytes, osteoblasts, and chondrocytes. Gene expression of stem cell-specific transcription factors was analyzed by PCR array and confirmed by western blot analysis at the protein level.

Results: No significant differences of proliferation potential, senescence, or differentiation capacity were observed between KD-MSCs and HC-MSCs. However, gene and protein expression of p300/CBP-associated factor (PCAF) was significantly suppressed in KD-MSCs. Because PCAF is a histone acetyltransferase that mediates regulation of hypoxia-inducible factor-1α (HIF-1α), we examined the hypoxic response in MSCs. HC-MSCs but not KD-MSCs showed upregulation of PCAF protein expression under hypoxia. Similarly, HIF-1α and vascular endothelial growth factor (VEGF) expression did not increase under hypoxia in KD-MSCs but did so in HC-MSCs. Additionally, a directed *in vivo* angiogenesis assay revealed a decrease in angiogenesis activation of KD-MSCs.

Conclusions: In conclusion, long-term uremia leads to persistent and systematic downregulation of PCAF gene and protein expression and poor angiogenesis activation of MSCs from patients with ESKD. Furthermore, PCAF, HIF-1α, and VEGF expression were not upregulated by hypoxic stimulation of KD-MSCs. These results suggest that the hypoxic response may be blunted in MSCs from ESKD patients.

***In Vitro* Culture of Human Renal Progenitors** Stefano Da Sacco, Astgik Petrosyan, Sargis Sedrakyan, Kevin V. Lemley, Roger E. De Filippo, Laura Perin. *Children's Hospital Los Angeles.*

Background: How different renal cells respond to injury may determine their survival under disease conditions. A better understanding of the developmental pathways active in these cells may shed light on their response to injury and provide insights into novel therapies. Currently, no culture system exists, without the use of genetic manipulation, that can stably propagate human nephron progenitors and differentiate them into mature renal cells. We previously showed the presence of a renal progenitor population within human amniotic fluid (hAKPC-P) that can be induced to differentiate into functional podocytes. Most importantly, hAKPC-P contain a sub-population of cells that express specific developmental renal genes, like Six2 and Cited1, suggesting their identity as nephrogenic precursors with self-renewal and nephron specification capabilities.

Methods: A live subpopulation of Six2+Cited1+ cells was isolated by FACS sorting by specifically tagging RNA with fluorescent probes. The isolated population was characterized for gene and protein expression by RT-PCR, microarrays, staining, western blot and secretome profiling. Effect of growth factors like BMP7 and Wnt9b was evaluated. Ability of Six2+Cited1+ cells to integrate into developing renal structures was also assessed by disaggregation/aggregation assays.

Results: Six2+Cited1+ cells represent 0.3-0.5% of the amniotic population as assessed by FACS analysis for both protein and RNA. Cells exhibit a fast growth rate and can be easily expanded. This subpopulation expressed nephrogenic markers including HOX genes, Eya1, and Notch. Moreover, cells respond to BMP7 and Wnt9b by losing Six2 and Cited1 expression and losing self-renewal capability. Additionally, the ability of Six2+Cited1+ cells to differentiate in vitro was assessed by culture with human fetal kidney in a disaggregation/aggregation assay.

Conclusions: Second trimester human amniotic fluid harbors a small population of renal progenitors that can be easily isolated without the use of genetic manipulation and expanded in vitro maintaining self-renewal and renal differentiation. This research could lead to important discoveries concerning renal developmental pathways in humans.

TH-PO264

Amniotic Fluid Kidney Progenitors as a Tool to Study Podocyte-Endothelial Cell Interaction In Vitro Stefano Da Sacco, Astgik Petrosyan, Sargis Sedrakyan, Kevin V. Lemley, Roger E. De Filippo, Laura Perin. *Children's Hospital Los Angeles.*

Background: The glomerular filtration barrier (GFB) is formed by three major components: the podocyte, a complex network of membranous proteins known as the glomerular basement membrane (GBM) and fenestrated endothelial cells. While podocytes are the only cells in the glomerulus to produce and assembly collagen IV, endothelial cells play a key role in the formation of a functional GFB. We have previously shown that progenitor cells from human amniotic fluid (hAKPC) differentiates into mature podocytes producing collagen IV alpha 3-4-5 chains in vitro. However, an in vitro system that can mimic the GFB is still lacking. In this study, we evaluate the ability of hAKPC to interact with glomerular endothelial cells in a 3D in vitro system to possibly resemble a GBM like-assembly.

Methods: hAKPC were differentiated for 20 days. Immunofluorescence, qPCR, SEM and TEM were performed to confirm formation of slit diaphragm on differentiated podocytes. To investigate the formation of GBM-like structures in vitro, hAKPC were co-cultured with glomerular endothelial cells in a 3D system and analyzed by PCR, Western Blotting, light and electron microscopy. In addition, response to active molecules and toxins was tested.

Results: When 3D co-cultured with endothelial cells, hAKPC are capable of forming spheroids, express podocyte specific markers including nephrin and form peculiar morphological structures when interacting with endothelial cells as confirmed by TEM and histology. These structures present deposition of collagen IV and laminin with the same spatial deposition of in vivo glomerular GBM. When stimulated with angiotensin II, spheroids showed marked contraction with modification of the structures and loss of slit diaphragm proteins.

Conclusions: hAKPC can be differentiated into mature podocytes in vitro and exhibit the ability to interact with endothelial cells to form a GBM-like structure. These preliminary results suggest that hAKPC might prove useful to understand the molecular pathways leading to formation of GBM, the most important structure in kidney ultrafiltration, as well as serve as a platform for testing specific podocyte and endothelial related drugs.

Extrarenal Progenitor Cells Do Not Contribute to Endothelial Repair in the Mouse Kidney Jan Sradnick,[1] Song Rong,[2] Anika Luedemann,[1] Vladimir T. Todorov,[1] Faikah Gueler,[2] Christian Hugo,[1] Bernd Hohenstein.[1] *[1]Div of Nephrology, Dept of Internal Medicine III, Univ Hospital Carl Gustav Carus, Dresden, Germany; [2]Div of Nephrology and Hypertension, Dept of Internal Medicine, Hannover Medical School, Germany.*

Background: The role of endothelial progenitor cells for endothelial cell (EC) regeneration unclear and we previously showed that mainly endothelial colony forming cells (ECFC) can be found in kidneys after selective EC- or ischemia/reperfusion (IR) injury. Using bone marrow (BM) transplantation (BMT), we excluded the BM origin of these cells. To clarify the role of extrarenal versus BM derived cells for EC repair, we now investigated the regenerative processes of EC-IR injury following kidney transplantation (KTx) in transgenic mice with combined BMT.

Methods: Ubiquitously tdTomato (tdt) expressing reporter mice served as recipients (R), C57/Bl6 mice were donors (D). A group of R also underwent BMT from D prior to renal injury, allowing us to differentiate the extrarenal niche. Reverse KTx served as control (D:tdt+;R:C57/Bl6). Ischemia time (25 min) was chosen to detect significant numbers of putative progenitor cells (pPC) in kidneys. On days 2 and 5, kidneys, blood and spleens were analyzed extensively using multicolor FACS-analysis and histology. pPC (CD34+,Flk-1+,CD31+,CD105+,CD146+,CD45-,CD133-,CD115-,CD14-), hematopoietic stem cells (c-kit+,Sca-1+,lin-), macrophages, dendritic-, b- and t-cells were detected by FACS and tdt co-staining by histology.

Results: On days 2 and 5, pPC were increased (+300%;$p<0.01$). Many inflammatory cells were recruited to injured kidneys, 94% of them were tdt+ (extrarenal). Following KTx, tdt+ pPC were rarely found in blood (2‰) and spleens (8‰). In contrast, no extrarenal tdt+ pPC were identified in KTx kidneys by FACS or histology at any time point. pPc makers were exclusively found on renal, tdt- cells. Only few tdt+ inflammatory cells, but no tdt- pPC, were found in KTx/BMT-chimera mice.

Conclusions: In contrast to inflammatory cells, no extrarenal pPC are recruited to the kidney during endothelial repair. Under pathophysiological conditions endothelial repair occurs exclusively via local mechanisms that need to be specified in more detail.

TH-PO266

Attenuation of Renal Fibrosis through the Combined Therapy of Mesenchymal Stem Cells and the Hormone Serelaxin Brooke M. Huuskes,[1] Andrea F. Wise,[1] Chrishan S. Samuel,[2] Sharon D. Ricardo.[1] *[1]Dept of Anatomy and Developmental Biology, Monash Univ, Clayton, Victoria, Australia; [2]Dept of Pharmacology, Monash Univ, Clayton, Victoria, Australia.*

Background: MSCs protect and repair the kidney in experimental models of acute kidney disease, however the development of fibrosis may hamper MSC-dependent repair. Here we tested the novel combination of MSCs with the antifibrotic, serelaxin to repair and protect the kidney post unilateral ureteric obstruction (UUO), when fibrosis is established.

Methods: Male C57Bl6 mice (n=4-6/group) underwent UUO surgery and received vehicle (PBS); luciferin/enhanced green fluorescent protein (eGFP)-tagged MSCs ($1x10^6$); serelaxin (0.5mg/kg/day); or the combination of MSCs and serelaxin; and were culled after 7 days. Sham-operated mice were used as a control. Bioluminescence imaging was used for live MSC cell tracing and the development of fibrosis was assessed by hydroxyproline assay, quantitative morphometry, gelatin zymography and immunostaining.

Results: *In vivo* tracing studies showed MSCs migrated to the UUO-injured kidney within 1 hour post transplantation where they remained for 36 hours, compared to sham-treated animals, confirmed by PCR for the eGFP gene. Combination therapy conferred significant protection from UUO-induced fibrosis as indicated by hydroxyproline assay ($p<0.001$ versus vehicle, $p<0.05$ versus MSC or serelaxin alone). This was accompanied by preserved structural architecture, decreased tubular epithelial injury ($p<0.01$ versus vehicle), macrophage infiltration ($p<0.01$ versus vehicle) and α-smooth muscle actin expression ($p<0.01$ versus vehicle). Gelatin zymography revealed that MMP-2 levels were significantly increased with combination therapy ($p<0.01$ versus vehicle, $p<0.05$ versus MSC or serelaxin alone). Serelaxin significantly increased MSC proliferation *in vitro* (~14%; $p<0.05$). Additionally, TNF-α stimulated MSCs showed an increased migration capacity in the presence of serelaxin (10-100ng/mL; $p<0.001$ versus negative control).

Conclusions: This study is the first to demonstrate that when used in combination, MSCs and the antifibrotic hormone serelaxin, ameliorate pathological fibrosis and improve MSC-mediated repair, in part, via through the up-regulation of MMP-2.

Nephron Regeneration After Acute Kidney Injury in the Zebrafish Kristen K. McCampbell, Kristin Springer, Rebecca A. Wingert. *Dept of Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: The zebrafish kidney is an excellent system for renal regeneration and disease studies, as it is composed of functional units known as nephrons that contain highly conserved proximal and distal tubule segments similar to other vertebrates including mammals. After zebrafish nephrons incur damage, there is robust epithelial regeneration within existing nephrons and new nephrons are produced from renal progenitors. The mechanisms responsible for these kidney regeneration phenomena remain poorly understood and a major limitation in the field has been the paucity of methods to label adult nephron cell populations.

Methods: Here, we present novel combinations of labeling methods that can be used in whole mount preparations or tissue cryosections to gage renal composition and assess nephron functionality.

Results: We demonstrate the existence of pan-proximal and pan-distal markers, as well as methods to distinguish the individual proximal tubule domains (proximal convoluted and straight tubule). We validated these markers by comparisons to the expression domains of solute transporter genes that uniquely identify each nephron segment. Next, we characterized the cellular changes resulting from acute gentamicin injury to establish the timing of renal cell death after injury, the proliferative compartments within the kidney, and the gene expression changes associated with nephron regeneration.

Conclusions: Taken together, these data have provided a greater understanding of cellular changes associated with regenerative events. This information is applicable to the future study of adult zebrafish kidney injury paradigms.

Rejuvenation of Kidney Aging By Exposure to a Young Systemic Environment Xiang-Mei Chen, Yichun Ning, Xuefeng Sun, Qi Huang, Diangeng Li, Quan Hong, Guangyan Cai. *Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center of Kidney Diseases, Beijing, China.*

Background: Kidney is a typical target organ of age-associated tissue damage, and the increased incidence of CKD and AKI in the elderly is a health problem worldwide. Our previous study found that the internal environment has an important impact on the kidney aging process. Changes of the state of the environment can accelerate or reverse the kidney aging process.

Methods: To clarify the biological mechanisms that drive kidney aging process, we tested the influence of circulating factors using heterochronic parabiosis, a surgical technique in which joining of animals of different ages leads to a shared circulation. All mice were sacrificed after parabiosis for five weeks. Blood samples were collected from angular vein of each mouse for the measurement of biochemical efficacy markers. The renal tissues from each group of mice were removed and perfused with ice-cold, isotonic phosphate-buffered saline (PBS; pH 7.4). Aging index p16, apoptotic index cleaved caspase-3, autophagy indicators LC3, p62, polyubiquitin were measured by western blot. Microarray analysis was used for filter out cytokines that had a significant difference among all groups. Cluster analysis of cytokines was to identify key factors that may affect renal aging.

Results: The survival rate of mice in heterochronic parabiosis (HP) was significantly lower than their controls. After 5 weeks of exposure to the circulation of young mice, there was no significant change in the old mice of HP on kidney morphology and function. Aging-related indicators p16 and SA-β-gal, apoptosis and autophagic activity in old mice parabiosed to young mice were all in improvement trend compared with unjoined old mice or old mice parabiosed to old mice. Using high-throughput screening methods in the blood circulatory system, we identified 6 kinds of cytokines that may be closely associated with aging; namely IGFBP-2, Eotaxin-2, Fractalkine, CD27, LIX and SCF.

Conclusions: These results suggest that kidney aging can be modulated by systemic factors that change with age.

Cross Talk between p66 and Wnt Gene Networks Regulates Stress -Induced Senescence in Mesenchymal Stem Cells and Aging Phenotypes in Diabetic Kidneys Pradeep Vaitla,[1] Ryan C. Mascarenhas,[1] Allyson E. Bradley,[1] Ashwani Malhotra,[2] Pravin C. Singhal,[2] Himanshu Vashistha,[1] Leonard G. Meggs.[1] *[1]Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [2]Medicine, Hofstra, North Shore LIJ Medical School, Great Neck, NY.*

Background: Stem cell therapy has emerged as a promising tool for the treatment of a variety of diseases. Gene based strategies that attenuate or prevent entry to senescent programs provide an innovative approach to extend the life cycle of stem cells and their regenerative potential. The p66 longevity gene plays a key role in the activation of gene programs that regulate cell entry to apoptotic and senescent phenotype(s), which are prevalent in diabetes. Here we show kidney mesenchymal stem cells (MSCs) genetically deficient in p66 exhibit enhanced canonical Wnt signaling, escape stress-induced senescent programs and participate in maintenance and repair diabetic kidneys.

Methods: We isolated lineage negative, stem cell antigen-1 positive cells from kidneys of adult wild type and p66 KO mice, that exhibit immunophenotype and differentiation characteristics of MSCs. To test whether p66 KO-MSCs delay or prevent expression of senescent phenotype(s) in diabetic kidneys, we crossed Akita diabetic ($Ins2^{+/C96Y}$) mouse with p66 KO to generate p66 KO-Akita.

Results: Microarray of cultured p66 KO-MSCs at high glucose detected differential expression of Wnt network genes that antagonize stem cell senescence. Increased accumulation of β-Catenin a key signaling molecule of the canonical Wnt pathway, was detected in p66 KO-MSCs. Expression of senescent associated proteins ($p16^{INK4a}$; p21; p53) was upregulated in WT-MSCs at high glucose and growth curves were markedly attenuated. The number of kidney nuclei staining positive for the senescent protein $p16^{INK4a}$ was substantially increased in in kidneys of Akita, as were the senescent phenotype(s) of interstitial fibrosis and tubular atrophy. By contrast, these changes were barely detectable in kidneys of p66 KO Akita.

Conclusions: These findings reveal the key role played by Wnt regulatory genes in maintaining a viable and functional population of p66 KO-MSCs under simulated HG and in diabetic kidneys.

TH-PO270

Endothelial Progenitor Cell Extract (EPC-E) Ameliorates Interstitial Fibrosis in Mice with Unilateral Ureteral Obstruction (UUO) Kei Matsumoto, Sandhya Xavier, Reina Ikeda, Michael S. Goligorsky. *New York Medical College, NY.*

Background: Accumulation of myofibroblasts leads to excessive matrix deposition, fibrotic distortion of tissue architecture and the loss of organ function. Given that a significant proportion of myofibroblasts is generated by the process of endothelial-mesenchymal transition, we inquired whether the reversal of this process is achievable. Hence, we attempted to reprogram myofibroblasts using in vitro and in vivo cell-free murine EPC-E.

Methods: Renal fibroblasts were isolated from αSMA-GFP mice and treated with TGF-b1 alone or TGF-b1 and EPC-E for 4 days. UUO surgery was performed in αSMA-GFP mice on C57BL/6J background and either EPC-E (10μl) or buffer (10μl) injected into the lower pole of UUO kidneys. Histologic, immunofluorescence staining for αSMA, CD31, and F4/80, and real-time RT-PCR for αSMA, collagen I, TIMP2 were performed.

Results: Fibroblasts derived from αSMA-GFP kidneys showed massive expression of GFP 24 h after TGF-β1 treatment. When cells were co-treated with EPC-E, their conversion to GFP-positive myofibroblasts was significantly halted. EPC-E inhibition of TGF-β1-induced phenotypic changes did not require prior cell permeabilization, raising the possibility of a similar effect in vivo setting. Indeed, when UUO, but not contralateral, kidneys were injected with Texas red dextran, 70kD, it was readily detectable in the renal parenchyma. Injection of the EPC extract was associated with the nearly 60% reduction of renal fibrosis. The number of myofibroblasts was reduced by 35% and CD31 positive area was increased by 35% compared to vehicle-treated mice. Furthermore, EPC-E-treated mice showed significantly reduced interstitial F4/80 macrophage infiltration, as well as reduced αSMA, collagen I, TIMP2 mRNA expression.

Conclusions: These studies establish 1) the possibility to prevent in vitro TGF-β1-induced fibroblast activation and acquisition of the myofibroblastic phenotype using EPC-E treatment of non-permeabilized cells; studies show that 2) EPC-E treatment ameliorates the progression of renal fibrosis in the UUO model through the suppression of myofibroblast differentiation, macrophage infiltration and preservation of vascular density.

Plasticity of Mesenchymal Stem Cells (MSCs) during Repair of Injured Mesangium Jiamin Teng, Elba Turbat-Herrera, Guillermo A. Herrera. *Pathology, LSU Health, Shreveport, LA.*

Background: It has been shown that MSCs play a crucial role in repairing the damaged mesangium. Using an ex-vivo kidney platform, it has been observed that in a model of mesangial injury by glomerulopathic light chains (GLCs), rat MSCs perfused through the renal artery migrate to the sites of mesangial injury where either amyloid deposition or increased extracellular matrix was present. MSCs engage in the disposal of altered mesangial constituents, as they clean the damaged areas and create a new mesangium.

Methods: Two platforms were used: 1- Ex-vivo kidney perfusion model and 2- 6D live cell imaging platform. In the first platform, mesangial damage was created by delivering GLCs for 2 days via renal artery followed by perfusion with rat MSCs; the process was monitored for up to 96 hours by sequential sampling of the perfused kidneys using light and TEM. In the second model, rat MCs grown on a matrix were made quiescent for 2 days and incubated with GLCs for 4 days and after mesangial damage was confirmed, RMSCs marked with PKH2 and Lysotracker / CD68 to monitor for phagocytic capabilities were introduced. The entire process was monitored for up to 5 weeks using sequential photography. Immunofluorescence/histochemical stains for MSCs (CD 44, 56 and 117) were also performed.

Results: After the MCs were treated with GLCs and damage occurred, MSCs migrated to the sites of injury. MSCs which show an undifferentiated appearance acquired a macrophage phenotype and proceeded to phagocytose the damaged mesangium, including apoptotic mesangial cells. In the early phases of the process, MSCs acquired prominent Lysotracker and CD68 cytoplasmic staining. After the cleaning process was completed, MSCs progressively acquired more cytoplasm, developed cytoplasmic processes with myofibrils and attachment plaques (TEM) and concomitantly expressed smooth muscle actin and smoothelin.

Conclusions: MSCs manifest marked plasticity as they engage in the process of mesangial remodeling. First, they acquire a macrophage phenotype endowing them to phagocytose apoptotic MCs, amyloid fibrils, and other debris. As they proceed to rebuild the damaged mesangium, they develop morphologic and immunohistochemical features typical of mature MCs.

TH-PO272

Wnt6 Regulates Epithelial Cell Fate Specification during Kidney Development and in Adult Renal Cells Hayley Beaton, Andrew Gaffney, Catherine Godson, Debra F. Higgins, John Crean. *Conway Inst of Biomolecular and Biomedical Research, Univ College Dublin, Dublin, Ireland.*

Background: Diabetic nephropathy (DN) is the leading cause of chronic kidney disease. Recent studies from our group and others identified a role for Wnt signalling in the pathogenesis of DN. Gene expression analysis of Wnt family members on human renal biopsies from DN patients identified differential expression of the novel ligand, Wnt6, correlating with severity of the disease.

Methods: Mouse embryonic whole mounts at Theiler stage 17.5 were analysed by in *situ* hybridisation. Wnt6 expression was determined in the unilateral ureteral obstruction (UUO) mouse model of tubulinterstitial fibrosis. Wnt6 was overexpressed in renal epithelial cell lines (HKC8s and MDCKs) and bone marrow derived mesenchymal stem cells. Signalling networks were assessed by Western blot.

Results: Wnt6 and FzD7 expression are prominent in the pronephros of the developing mouse kidney. TCF/Lef reporter activity is also prominent in the developing mouse pronephros. In the UUO mouse model, Wnt6 was down-regulated suggesting that loss of Wnt6 may have pathogenic significance. *In vitro* Wnt6 expression leads to *de novo* tubulogenesis in MDCK cells grown in 3D culture and increased expression of epithelial cell specific markers. Overexpression of Wnt6 in mesenchymal stem cells led to commitment to adipogenic/epithelial phenotypes. Wnt6 rescued epithelial to mesenchymal transition in

response to TGFβ. Wnt6 overexpression in renal epithelial cells inhibited TGFβ-mediated p65-NFκB nuclear translocation highlighting possible crosstalk pathways between Wnt and NFkB signalling.

Conclusions: We propose that Wnt6 is involved in determining cell fate specification and as such its increased expression activates transcriptional programmes that determine phenotypic transition. If these mechanisms can be established, they may be of pharmacological and clinical relevance in terms of developing new therapeutic strategies to slow or reverse the progression of DN.

TH-PO273

The Effects of High Glucose on Kidney Stem Cells and Its Injury Mechanism
Qingli Cheng, Guang Yang, Yang Liu, Qinglin Li. *Dept of Geriatric Nephrology, Chinese PLA General Hospital, Beijing, China.*

Background: To explore the effects of high glucose on the biological characteristics and paracrine action of kidney stem cells (KSC).

Methods: The KSC were isolated from the renal papilla in SD rats. The phenotye characteristics of KSC were identified. The ability of adipogenic and osteogenic differentiation of KSC was evaluated. The differences of gene expression between KSC and rat renal tubular epithelial cell (RTEC) were compared using qRT-PCR. The changes of the cell morphology, proliferation, phenotypic markers, chemokine expression and anti-hypoxia ability of SKC were investigated after cultured with high glucose (30mmol/L) media. The effects of KSC conditional media (pre-treated with high glucose) on the hypoxia/reoxygenation (H/R) RTEC were investigated.

Results: The positive staining of CD29, CD90, CD73 and CD45 in the KSC were 99%, 95.8%, 99.9% and 3.4% respectively. The positive stainings of CD133 and Nestin were 33.2% and 70.2%, their double staining rate was 31.4%. The differentiation to adipogenic and osteogenic were induced successfully in the KSC. Compared with RTEC, the expression of Nanog, Oct4/pou5f1, Sox2/sry-box-2 andα-SMA,Vimentin were higher, and the expression of E-Cadherin, CK18 were lower in the KSC.The KSC grew slowly in the high glucose media. However, the synthesis of Fibronectin, Collagean I and Collagean IV were increased in the KSC which cultured with high glucose media. Meanwhile, the gene expression of a-SMA, Vimentin, TGF-β, CTGF and PAI-1 were higher. After cultured in hypoxia environment for 24 hrs, the cell proliferation index, the gene expression of SDF-1 and CXCR4 of KSC were lower in the KSC which pre-treated with high glucose.The cell apoptosis rate, the level of LDH and MDA were lower, and the level of SOD were higher in the H/R RTEC after co-cultured with KSC conditional media. However, the renovated ability of the KSC was damaged by high glucose.

Conclusions: The KSC were isolated successfully from the rat renal papilla. The ability of proliferation, differentiation, anti-hypoxia and renovated of the KSC may injure in the high glucose media. These effects may via the changes of cell apoptosis and the oxidative stress in the KSC.

Erythropoietin Ameliorates Renal Damage in 5/6 Nephrectomized Rats via Endothelial Progemtor Cells
Jian-Xin Wan. *Dept of Nephrology, The First Affiliated Hospital of Fujian Medical Univ, Fuzhou, Fujian, China.*

Background: To investigate the effects of erythropoietin (EPO) on renal protection in rats with chronic renal failure (CRF) and its mechanism.

Methods: The CRF model was established by a two stage 5/6 nephrectomy procedure in rats. Experimental rats were randomly divided into four groups: sham operation group (control group), CRF group, CRF rats treated with 30 U/kg EPO (low-dosage group) and with 50 U/kg EPO (high-dosage group). CRF rats received EPO by hypodermic injection for 6 weeks and then were sacrificed. Serum creatinine (Scr), blood urea nitrogen (BUN), urine protein, haematoglobin (Hb) and blood pressure were measured. The CD34 and CD31 expressions in glomerulus were detected by immunohistochemistry method. The mRNA of ET-1, eNOS and VEGF were detected by RT-PCR. Peripheral blood endothelial progenitor cells (EPCs) were isolated by density gradient centrifugation from peripheral blood mononuclear cells. The ability of cell proliferation, adhesion and vasculogenesis in vitro was further observed.

Results: The expressions of CD34 and CD31 protein in glomerulus, and the expressions of eNOS and VEGF mRNA in renal tissue were higher in EPO treatment group than those in CRF model group (all $P<0.05$). The expression of ET-1 mRNA in renal tissue was lower in EPO treatment group than that in CRF model group. In addition, the Scr, BUN, urine protein and blood pressure in EPO treatment group were significantly lower than those in CRF model group (all $P<0.05$). Haematoglobin in EPO treatment group was higher than that in CRF model group ($P<0.05$). Reanl pathological injury was improved by EPO treatment in dose-dependent manner. Compared to sham operation group, the ability of cell proliferation, adhesion and vasculogenesis vitro in CRF rats was remarkably decreased ($P<0.05$, respectively). Such ability was promoted significantly in dose-dependent manner by EPO treatment ($P<0.05$, respectively).

Conclusions: EPO can ameliorate renal pathological injury and renal function in rats with chronic renal failure, maybe through improving the number and ability of endothelial progenitor cells and then promoting the renovation of glomerular capillary endothelium.

Funding: Government Support - Non-U.S.

The Secretome of Hydrogel Co-Embedded EPC and MSC Instructs Macrophage Polarization
Joseph A. Zullo, Ellen Nadel, May M. Rabadi, Matthew J. Baskind, Maharshi Rajdev, Cameron M. Demaree, Radovan Vasko, Savneek S. Chugh, Michael S. Goligorsky, Brian B. Ratliff. *New York Medical College, NY.*

Background: We previously reported delivery of endothelial progenitor cells (EPC) embedded in HA-hydrogels protects renal function during acute kidney injury (AKI) and promotes angiogenesis. We attempted to further ameliorate renal dysfunction by co-embedding EPC with renal mesenchymal stem cells (MSC), while examining their paracrine mechanisms that affect proinflammatory macrophages.

Methods: A live/dead assay determined if EPC-MSC co-embedding in HA-hydrogels improved viability during LPS treatment, while embedded delivery of cells to LPS-induced AKI mice was assessed for effects on mean arterial pressure (MAP), renal blood flow (RBF), serum creatinine, proteinuria and angiogenesis (femoral ligation). The cyto-/chemokine release from embedded stem cells was examined including effects on modulating the polarization and release of proinflammatory molecules from macrophages.

Results: EPC-MSC co-culturing improved stem cell viability during LPS exposure, an effect augmented by MSC hypoxic preconditioning. Delivery of co-embedded EPC with hypoxic preconditioned MSC to AKI mice demonstrated additive improvement (as compared to EPC delivery alone) in medullary RBF and proteinuria, with no differences observed for serum creatinine, MAP or angiogenesis. Exposure of proinflammatory M1 macrophages to EPC-MSC conditioned culture medium changed their polarization to anti-inflammatory M2 macrophages, while EPC-MSC delivery to endotoxemic mice elevated levels of circulating M2 macrophages. Incubation of co-embedded EPC-MSC with macrophages altered their release of cyto-/chemokines including enhanced release of anti-inflammatory IL-10 from macrophages.

Conclusions: Co-embedding EPC-MSC 1) improved their resistance to stress, 2) impelled macrophage polarization from M1 to M2, 3) altered macrophage release of cyto-/chemokines, and 4) improved renal and vascular function when MSC were preconditioned by hypoxia.

Creating Filtration Structure From a Suspension of Embryonic Kidney Cells
Christodoulos Xinaris,[1] Valentina Benedetti,[1] Mauro Abbate,[1] Sara Conti,[1] Paola Rizzo,[1] Rubina Novelli,[1] Daniela Corna,[1] Daniela Cavallotti,[1] Marina Morigi,[1] Ariela Benigni,[1] Giuseppe Remuzzi.[1,2] *[1]IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Bergamo, Italy; [2]Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy.*

Background: Worldwide, the lack of donor kidneys available for transplantation has driven a strong interest in developing methods for engineering new kidney tissue. Recently, we have shown that organoids constructed *in vitro* from embryonic kidney cells can integrate into living recipients, and perform kidney functions.

Methods: Here, we examined whether engineered organoids could provide the adequate environment to obtain *i)* mature 3D ultrastructural organization of filtration slits, and *ii)* selective transglomerular filtration and tubular uptake of fluorescent probes. Organoids made from suspensions of E11.5 mouse kidney cells were cultured *in vitro* for 5 days, then implanted under the renal capsule of a rat host, and allowed to grow for 2 weeks.

Results: Electron microscopy (EM) analysis of implanted organoids showed glomeruli in various developmental stages, with glomerular capillary walls covered by podocytes. The foot processes were regularly spaced and bridged by slit diaphragms, displaying differentiated ultastructure. A closer analysis of slit diaphragms ultrastructure by scanning EM in-lens detector revealed the presence of heterogeneous pores within the junction, similar to those of adult kidney. To test the physiological permselectivity of the filtration barrier, fluorescent dextrans of various molecular weights (MW) (10, 70 or 155 kDa) were systemically injected into the host rat. Analysis of implanted organoids showed that all dextrans were localized in α-actinin 4-positive glomeruli, while only those of low MW (10 and 70 kDa) were found in proximal tubuli where they colocalized apically with megalin-receptor, indicating transglomerular passage and tubular uptake of selectively ultrafiltered probes.

Conclusions: Thus, the proposed technology allows indeed to create nephrons with essential functional properties starting from cell suspensions. The present approach may open future perspectives for cell-based therapeutics and offers a methodological basis for developmental or disease-modeling studies.

Renal Tissue Decellularization and Regeneration: Therapeutic/Curative intervention Paradigm for Polycystic Kidney Disease
Sanjeev Puri,[1,2] Baldeep Channi,[2] Veena Puri,[3] Ranbir Chander Sobti.[4] *[1]Biotechnology, Panjab Univ (PU), Chandigarh, India; [2]Stem Cell & Tissue Engineering, PU; [3]Systems Biology & Bioinformatics, PU, Chandigarh; [4]Biotechnology, PU, Chandigarh, India.*

Background: Tissue regeneration through use of stem cell is a novel way of meeting the challenges both at the level of cure as well as understanding the molecular mechanisms involved in tissue regeneration process. The Chemical base decellularization followed by recellularization with stem cells is opening newer vistas for understanding both the renal tissue functioning as well as pathology, with special focus onPKD.

Methods: Two different experimental approaches were used. One of the approaches exploited chemical based decellularization of an adult kidney followed by recellularization with stem cells.The characterization for the decellularization/ recellularization was analysed employing histologic, Scanning Electron Microscopic analysis while the stem cell characterization was followed through flowcytometry.

Results: The de-cellularization produced renal scaffold devoid of any cells, confirmed by light microscopy followed by SEM. 3D porous structures along with Nanofibrous structures of ECM were found to be well maintained. The Masson's trichrome staining demonstrated well maintained collagen protein and decellularization did not show any adverse effect on ECM. The recellularization using mesenchymal stem cells isolated from bone marrow demonstrated their relocation to emptied scaffolds as seen by nuclear staining. Mass spectrometry allowed to determine the novel proteins important to development of the recelluarized structures. The similar approach was used to generate decellularized structures of *in vitro* renal cyst model system (metanephric system) and its recullularization using stem cells to find out the potentially common chemico-molecular components important for tissue regeneration both under normal and polycystic kidney disease condition.

Conclusions: The present work thus would delineate the importance of different chemico-molecular entities in understanding the disease patho-physiology, treatment and organ regeneration, specifically the one associated with polycystic kidney disease.

TH-PO278

Strategies for Proximal Tubule Differentiation of Human Induced Pluripotent Stem Cells

Anja Wilmes, Paul Jennings, Gerhard Gstraunthaler. *Div of Physiology, Innsbruck Medical Univ, Innsbruck, Austria.*

Background: The ability to generate human induced pluripotent stem cells (hiPSCs) from any individual has huge potential for several branches of clinical research, from disease elucidation to drug development. However, the development and optimization of differentiation protocols for target cells is not trivial. Successful differentiation protocols have been developed for several target cell types including neurons, cardiomyocytes and hepatocytes. However, there is currently no successful differentiation strategy to direct iPS cells into proximal tubular cells.

Methods: To this end we tested different combinations of growth factors, including bone morphogenetic proteins (BMPs), activin A, retinoic acid, and fibroblast growth factors (FGFs) in an attempt to differentiate hiPSC into proximal tubular like cells. hiPSC were grown on matrigel under feeder-free conditions in mTeSR1 medium. To induce differentiation, factors for maintenance of pluripotency were withdrawn and cells were cultured in DMEM/F12 supplemented with above mentioned growth factors, in different combinations for different times.

Results: In all cases, after 24 h cells had exhibited a radical change in gross morphology from small compact stem cell morphology to larger cobblestone shaped colonies. At day 4 in culture the pluripotent marker Oct4 was undetectable indicating a loss of pluripotency. The majority of cells could be maintained for up to 28 days in culture. Two of the combinations tested looked promising as cells expressed proximal tubule markers including aquaporin 1, claudin 2 and the renal epithelial marker cadherin 16. In addition solute and water transport could be observed by dome formation.

Conclusions: These results represent the first report of successful proximal tubule orientated iPSC differentiation. However, more characterization work is needed and further optimization will be required to improve proximal tubule differentiation status and purity.

TH-PO279

Epigenetic Induction of Kidney Lineages in Human Kidney Derived iPS Cells

Osamu Takase, Masaomi Nangaku, Keiichi Hishikawa. *Dept of Advanced Nephrology and ReGenerative Medicine, Div of Nephrology and Endocrinology, Graduate School of Medicine, Univ of Tokyo, Tokyo, Japan.*

Background: OSR1 is one of the earliest intermediate mesoderm markers, and OSR1+ cells induced from human iPS cells (201B7: established from human fibroblast) were reported to be able to differentiate into multiple cell types of intermediate mesoderm-derived organs in vitro and in vivo (Nature Commun. 4, 1367, 2013). However, OSR1+ cells were reported to fail to induce metanephric progenitors (Cell Stem Cell 14, 53, 2014). Recently epigenetic memory such as DNA methylation signature of iPS cells derived from parental cells were reported to determine the differentiation fate of the iPS cells (Nature 2012), and this discrepancy could be explained by epigenetic memory in fibroblast derived iPS cells. In this study, we tried to confirm the kidney specific induction protocol (Nature Commun, 2013) by using two different kinds of human iPS cells established from fibroblast (F-iPS) and kidney epithelial cells (K-iPS), and also tried to establish efficient induction of kidney lineages by epigenetic induction.

Methods: According to the kidney specific induction protocol, we treated F-iPS and K-iPS with Activin A, GSK-3β inhibitor, BMP-7 and combination of HDAC inhibitor (TSA). We examined expression of markers of kidney development (WT-1, Pax-1, Sall-1) and differentiation (AQP-1, Nephrin) by Western blot, RT-PCR, and real time-PCR.

Results: Our results confirmed induction of these markers both in F-iPS and K-iPS. Interestingly, we found more efficient induction of these markers in K-iPS treated with kidney specific induction protocol in a time-dependent manner as compared with F-iPS cells. Moreover combination of kidney specific induction protocol and TSA significantly augmented induction of these markers.

Conclusions: These results demonstrate that epigenetic induction with kidney specific induction protocol can augment epigenetic memory-determined differentiation of human iPS cells towards kidney lineages, and additional *in vivo* date using K-iPS and epigenetic induction will be discussed.

TH-PO280

Transposon Mediated Long-Term Kidney-Specific Transgene Expression after Gene Transfer In Vivo

Lauren Elizabeth Woodard,[1] Jizhong Cheng,[2] Matthew H. Wilson.[1] *[1]Dept of Medicine, Div of Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; [2]Dept of Medicine, Div of Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Dialysis has a ten-year survival rate of 10% and there is currently a shortage of donor organs for transplantation. Therefore, alternative breakthrough methods to treat patients with kidney disease are needed.

Methods: We have developed a procedure to efficiently and specifically deliver plasmid DNA to the kidneys of mice that is based on the principles of hydrodynamic tail vein injection: a high volume of injection and a rapid delivery of the DNA solution. We found that a fast injection of the renal pelvis with a DNA solution of sufficient volume was effective for delivery of plasmid DNA to the kidney.

Results: Mice given renal pelvis hydrodynamic injections had high levels of luciferase transgene expression that was localized specifically to the injected kidney and no other organs by IVIS imaging. The volume and amount of DNA injected were not as important as the speed of the injection. When we injected a plasmid containing the CMV promoter to drive the luciferase transgene, the majority of the gene expression was lost within the first month after the injection. For long-term expression, we co-injected a plasmid to produce a hyperactive piggyBac transposase in order to permanently integrate the luciferase transgene carried by the transposon plasmid into the genome. We tested several promoters (CMV, EF1alpha, gamma-GT, and podocin). EF1alpha produced the highest levels of long-term gene expression. Steady-state levels of long-term expression were seen from 35 days to 89 days following injection in mice injected with the transposon and transposase plasmids, significantly higher than the group of mice that did not receive transposase. Staining suggested EF1alpha-luciferase expression is mainly localized to the renal tubules, whereas the CMV promoter expressed mainly in the fibroblast population.

Conclusions: We have developed a method of kidney-specific gene expression that may be employed to introduce exogenous transgenes to study kidney function in mice with the potential to be translated to the clinic for renal gene therapy.

Population-Based Screening for Monogenic FSGS: Feasibility and Challenges

C. Gillies,[1] C. Robertson,[1] E. Otto,[1] Matthias Kretzler,[1] HM Kang,[1] M. Sampson.[1] *[1]U of Michigan; [2]Nephrotic Syndrome Study Network.*

Background: Sequencing Mendelian focal segmental glomerulosclerosis (FSGS) genes can identify causal mutations in familial cases. But it is more challenging to diagnose monogenic FSGS in sporadic cases. Using sequence data of 9 FSGS genes from population-based cases and controls, we sought to create a filter that can distinguish causal mutations from harmless rare or novel variants.

Methods: We sequenced *NPHS1, NPHS2, PLCE1, LAMB2, INF2, WT1, LMX1B, TRPC6, and ACTN4* in 94 Nephrotic Syndrome Study Network (NEPTUNE) subjects with FSGS and 60 ancestry-matched controls from the 1000Genomes Project Phase3 (1KG). We verified a high concordance of called variants for the 60 control subjects sequenced both by our lab and 1KG. We thus used the genotypes of all 1KG subjects as controls (n=2535). Our **gene-level filter** required variants to be *nonsense* and at <0.1% minor allele frequency (MAF) in Exome Sequencing Project (ESP). Or if *missense*; absent in ESP (or in the Human Gene Mutation Database and ESP MAF <0.1%) and predicted "damaging" in 2 of 3 of PolyPhen2, SIFT, and MutationTaster. We removed novel ESP variants that were common in any continental population. Our **isoform-level filter** classified *INF2 and LAMB2* variants as causal if they met the above requirements and were in isoforms under much stronger negative selection. We then calculated the prevalence and odds ratio of putative monogenic FSGS in NEPTUNE versus 1KG.

Results: With a prevalence of 5.3% versus 1.5% in 1KG, FSGS cases had 3.7 higher odds of putative monogenic FSGS (CI 1.4-9.6; p<0.01). Removing the isoform filter or relaxing the missense MAF filter to 0.1% did not change monogenic case prevalence. But prevalence increased in controls by 65% and 15%, respectively.

Conclusions: Our method used very stringent filters and isoform level data to reduce false positives. And we see significantly higher odds of causal mutations in cases versus controls, with 5.3% putative monogenic FSGS in NEPTUNE. Yet a 1.5% prevalence in controls is much higher than expected. Incomplete penetrance may contribute, but we aim to further reduce false positives by refining our method. Thus, when sequencing sporadic patients for FSGS, classifying them as monogenic should be done cautiously.

TH-PO282

Exome Sequencing of > 30 Genes Associated with Steroid Resistant Nephrotic Syndrome

Agnieszka Bierzynska,[1] Katrina Soderquest,[2] Hugh J. McCarthy,[1] Denis Andrew Baird,[1] Michael A. Simpson,[2] Graham M. Lord,[2] Ian N. Day,[1] Ania B. Koziell,[2] Gavin Iain Welsh,[1] Moin Saleem.[1] *[1]Bristol Renal, Univ of Bristol, United Kingdom; [2]King's College London, United Kingdom.*

Background: Steroid Resistant Nephrotic Syndrome (SRNS) is a glomerular disorder characterised by proteinuria, hypoalbuminemia, oedema and lack of response to immunosuppression. In unselected Paediatric SRNS, the incidence of disease causing gene mutations is around 20%. So far over 30 genes have been associated with this disease.

We followed up our previous findings that the increasing reliability of Next Generation Sequencing (NGS) provides the potential for revolutionising genetic investigation of this and similar patient groups.

Methods: We used whole exome sequencing to screen 196 paediatric SRNS patients for genes known to be associated with hereditary SRNS as well as to look for novel variants in other potential disease causing genes. Patients were collected via a national UK Renal Registry with comprehensive detail of phenotype. Significant variants detected by NGS were confirmed by Sanger sequencing.

Results: 21% of the sequenced patients had either a previously described mutation or a variant likely to be disease causing. Analysis revealed known as well as novel disease associated variations in the four commonest Nephrotic genes: *NPHS1, NPHS2, LAMB2* and *WT1* and also in other, more rare genes such as *LMX1B, MYO1E, ADCK4* and the recently identified *CRB2*. One of the tested patients was found to have 4 mutations in 2 genes. Phenotypically unexpected mutations were a hemizygous missense mutation in *COL4A5* in a patient without hearing loss and a *TRPC6 mutation* in a patient who presented at age of 8 years. Increased burden of certain common polymorphisms were noted in the known SRNS genes in cases versus controls.

Conclusions: Our results demonstrate the obvious clinical need for sequencing multiple genes in SRNS where genetic heterogeneity is a defining feature. We identified mutations and potentially pathogenic variants in genes that would not routinely be screened under current testing practice. Our detailed phenotypic information also enabled us to identify potential modifier variants from this cohort.

TH-PO283

CKD-Y: Next Generation Sequencing in Search of Primary Renal Disease Diagnoses in Young CKD/ESRD Patients Albertien M. van Eerde,[1] Edith Peters,[1] Kirsten Y. Renkema,[1] Bert van der Zwaag,[1] Marc Lilien,[2] Martin H. De Borst,[3] Rachel H. Giles,[4] Gerjan Navis,[3] Nine V. Knoers.[1] *[1]Dept of Medical Genetics, UMC Utrecht, Utrecht, Netherlands; [2]Paediatric Nephrology, Wilhelmina Children's Hospital, UMC Utrecht, Utrecht, Netherlands; [3]Dept of Nephrology, UMC Groningen, Groningen, Netherlands; [4]Dept of Nephrology, UMC Utrecht, Utrecht, Netherlands.*

Background: In the Netherlands, 25% of patients with early onset (<30 years) renal replacement therapy (RRT) have not been diagnosed with a primary renal disease (PRD) according to the ERA-EDTA registry classification. An additional 20% are registered with a CAKUT phenotype (congenital anomalies of the kidney and urinary tract) and approximately 10% have other congenital or hereditary disorders registered. These numbers are similar to other national registry data of similar renal disease patients. It is likely that in these young patients, part of the unknown PRD diagnoses represent CAKUT and other congenital/inherited diseases. If the PRD diagnosis is unknown, this hampers the classification and genetic counseling. Project CKD-Y aims to improve genetic diagnostics in and diagnostic classification of Young CKD/ESRD patients.

Methods: We have designed the "RENome" using SureSelect, Agilent technology to include 408 genes involved in hereditary renal disease and/or urinary tract development. The regions are captured and subsequently sequenced (SOLiD™ 5500XL platform; Applied Biosystems, Inc). The ~200 samples of all early onset (<30 years) RRT patients from the REGaTTA cohort are being sequenced. Variants detected by RENome sequencing will be validated by Sanger sequencing and for selected variants the pathogenicity will be functionally studied.

Results: RENome Next Generation Sequencing results will be presented, and applicability in diagnostic infrastructure and genetic counselling will be discussed.

Conclusions: RENome sequencing will for the first time show in how many young RRT patients rare variants in known renal disease genes are likely to have contributed to their renal disease. This will improve the possibilities for genetic counseling and diagnostic classification. *AMvE is supported by the Dutch Kidney Foundation (as are NK, RG, MdB) and Fonds NutsOhr*a.

TH-PO284

Rationalizing the Genetic Diagnosis of SRNS/FSGS Using Next Generation Sequencing Kits Olivia Boyer,[1,2,3] Beata S. Lipska-Zietkiewicz,[4,6] Olivier Gribouval,[1,2] Patrick Nitschke,[2] Christine Bole-Feysot,[1] Annelies Rotthier,[7] Jurgen Del Favero,[7] Franz S. Schaefer,[5,6] Corinne Antignac.[1,2,3,8] *[1]Inserm U1163, Imagine Inst, Paris, France; [2]Paris Descartes Univ; [3]Pediatric Nephrology, Necker Hospital, APHP; [4]Biology and Genetics, Medical Univ of Gdansk, Gdansk, Poland; [5]Pediatric Nephrology, Center for Pediatrics and Adolescent Medicine, Heidelberg, Germany; [6]Podonet Consortium; [7]Multiplicom NV, Niel, Belgium; [8]Medical Genetics, Necker Hospital, APHP.*

Background: Steroid-resistant nephrotic syndrome (SRNS) and idiopathic FSGS are genetically heterogeneous with > 25 causative genes identified to date. The stepwise genetic analysis through classical Sanger sequencing has become rather long and expensive. Conversely, exome sequencing analyses millions of genes in parallel but accumulates large amounts of data and may lead to ethically challenging incidental findings.

Methods: Through the EurenOmics consortium, our group designed a custom multiplex PCR kit (Multiplicom) that analyses 31 known or plausible SRNS/FSGS genes. This kit was validated on 23 mutated patients (97% sensitivity) then used to perform genetic testing in 71 patients without any identified mutation by classical screening, and 56 new patients (127 families). The median age at diagnosis was 4 yrs (0-48), and 39% had reached ESKD at a median age of 12 yrs (0-67). 54% had a positive family history and 21% extra-renal features.

Results: Mutations were identified in 15% of families previously tested negative with conventional screening and 20% of newly diagnosed patients. This translated into a mutation rate of 13% in autosomal dominant families, 50% in autosomal recessive or consanguineous families and 14% in sporadic cases. The mutated genes were: *NPHS1* (3 families), *NPHS2* (4), *PLCE1* (2), *WT1* (1), *INF2* (2), *LMX1B* (2), *MYO1E* (1) and *COQ2* (1), *COQ6* (1), *ADCK4* (2), *LAMB2* (1) and *SMARCAL1* (2). Interestingly, we identified a homozygous *MYO1E* missense mutation in 2 siblings with late onset autosomal recessive FSGS and ESKD around 35 years of age.

Conclusions: Targeted Next Generation Sequencing kits are powerful and cost-effective techniques that will allow the rationalization of genetic diagnosis of SRNS/FSGS.

Sequence Kernel Association Test to Discover Associated Regions in a Large National Pediatric Steroid Resistant Nephrotic Syndrome Cohort Denis Andrew Baird,[1] Agnieszka Bierzynska,[2] Ania B. Koziell,[3] Gavin Iain Welsh,[2] Ian N. Day,[1] Moin Saleem.[2] *[1]School of Social and Community Medicine, Univ of Bristol, Bristol, United Kingdom; [2]Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom; [3]Dept of Immunobiology, King's College London, London, United Kingdom.*

Background: Steroid Resistant Nephrotic Syndrome (SRNS) is a genetically and phenotypically heterogeneous, with a wide mutation spectrum, ranging from rare highly penetrant mutations to common risk contributing variants. In this sense, SRNS behaves more like a complex trait. Genome Wide Association Studies (GWAS) techniques have associated common variants underpinning many complex traits. However, for most diseases a large proportion of heritability still remains to be explained, directing GWAS research efforts towards detecting the contribution of rare variants. Collapsing methods, based on grouping rare variants across a region to increase power, have been developed to facilitate this. SKAT, a variance component collapsing method, was run on a cohort of 64 childhood SRNS cases, collected from the UK RADAR Registry, in order to determine specific regions of the exome associated with SRNS.

Methods: SKAT combined common and rare [1] was run on NPHS1. Multiple controls obtained from UK10K were used. The analysis is currently being repeated on a larger sample of 97 additional patients to confirm the NPHS1 association, and will be extended to incorporate all genes across the genome. In addition, collapsing over protein domains will be carried to reduce noise and localise signals within genes, and separate SKAT iterations will be performed for all, rare and common point mutations. 1. Sequence Kernel Association Tests for the Combined Effect of Rare and Common Variants. *Am. J. Hum. Genet.* **92,** 841–853 (2013).

Results: NPHS1 showed a strong association with SRNS overall.

Conclusions: SKAT is a commonly applied tool to elucidate rare variants in common, complex disease. However, often rare variant signals are not detected by collapsing methods. The association with NPHS1 indicates that SKAT could be a powerful tool for detecting regions which harbor functional mutations in rare, polygenetic diseases such as SRNS.

TH-PO286

Collagen Mutations Identified by Targeted Next Generation Sequencing Are the Most Frequent Mutations Underlying Adult Focal Segmental Glomerulosclerosis Christine Gast,[1,2] Reuben J. Pengelly,[2] Gopalakrishnan Venkat-Raman,[1,2] Sarah Ennis.[2] *[1]Wessex Renal and Transplant Service, Queen Alexandra Hospital, Portsmouth, Portsmouth, Hampshire, United Kingdom; [2]Human Genetics and Genomic Medicine, Univ of Southampton, Southampton, Hampshire, United Kingdom.*

Background: Multiple genes underlying focal segmental glomerulosclerosis (FSGS) and/or steroid resistant nephrotic syndrome (SRNS) have been identified, with the recent inclusion of collagen mutations. We aimed to investigate the distribution of gene mutations in adult patients with FSGS/SRNS by targeted next generation sequencing.

Methods: 91 adults from 86 families with familial or sporadic FSGS/SRNS were recruited as part of a study on familial kidney diseases. All individuals were ascertained through a single renal unit in the South of England. All but 2 were of Caucasian ethnicity, 34 had a family history of renal disease. DNA was extracted from whole blood or saliva using standard protocols. An Illumina Truseq Custom Amplicon Targeted Next Generation sequencing (NGS) panel was designed covering 39 genes for FSGS/SRNS including *COL4A3-5*. NGS sequencing was performed on the MiSeq system. Data were analysed using our standard Mendelian disease pipeline.

Results: Confirmed pathogenic mutations were identified in 14 patients, 11 with positive family history. Pathogenic *COL4A5* mutations were found in 4 patients from 3 families, all with a diagnosis of familial FSGS. Two siblings were compound heterozygous for different pathogenic *COL4A3* mutations. A single pathogenic *COL4A3* and *COL4A4* mutation were found in two individuals with sporadic FSGS, one had a family history of haematuria. Before NGS, Alports had only been suspected in two of 91 probands. Other pathogenic mutations included *LAMA5* (2), *INF2* (1), *CD2AP* (1), *NFX5* (1) and *NPHS2* (1). In other probands, novel mutations predicted to be pathogenic were found in *COL4A3*, *COL4A4*, *COL4A5*, *COQ2*, *INF2*, *TRPC6*, *WT1* and *SYNPO*.

Conclusions: We have shown that collagen mutations frequently underlie FSGS/SRNS and should be considered, particularly with a positive family history. Targeted NGS allows identification of these gene mutations.

TH-PO287

Whole Exome Sequencing Identifies Mutation of the *Exportin-5* as a Novel Single-Gene Cause of Nephrotic Syndrome Shazia Ashraf,[1] Carolin Sadowski,[1] Stefan Kohl,[1] Svjetlana Lovric,[1] Werner Pabst,[1] Heon Yung Gee,[1] Friedhelm Hildebrandt.[1,2] *[1]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Howard Hughes Medical Inst, Chevy Chase, MD.*

Background: Identification of single-gene causes of nephrotic syndrome (NS) has furthered the understanding of its pathogenesis. However, many genes and disease mechanisms remain unknown. To identify new genes, that if mutated cause NS, we combined homozygosity mapping (HM) and whole human exome sequencing (WES) in consanguineous families with NS.

Methods: An individual of consanguineous parents from Turkey with NS was cyclosporinA responsive and histologically showed minimal change NS. HM yielded >15 segments of homozygosity by descent with a cumulative homozygous segments of ~300 Mb. We performed WES in this individual to identify the underlying single-gene disease-causing mutation.

Results: By WES in this consanguineous family, we identified a homozygous missense mutation (p.Val552Ile) in the *Exportin-5* (*XPO5*) gene in an amino acid residue conserved since *Ciona intestinalis*. The mutation segregated with the affected status in this family and was absent from >6,500 European controls in the Exome Variant Server. XPO5 is a scaffold protein that belongs to a large family of karyopherins and thus mediates the transport of proteins between the nuclear and cytoplasmic compartments. XPO5 is known to bind the nucleoporins NUP214 and NUP153 in a Ran-GTP-independent manner and also to RAN in its GTP-bound conformation. Immunoflorescence microscopy showed that XPO5 is highly expressed in rat glomerular podocytes. XPO5 also co-localizes with SYNPO (synaptopodin) at the slit membrane in mature rat glomeruli.

Conclusions: We, thus, identified mutation of XPO5 as a potential novel single-gene cause of NS. Further genetic and functional studies will shed light on the involvement of nuclear pore proteins in the pathogenesis of NS and will provide a further step in understanding the disease mechanism.

Funding: Other NIH Support - DK076683, DK086542

TH-PO288

Exome Capture Identifies Mutation of NUP107 as a Novel Cause of Nephrotic Syndrome Svjetlana Lovric, Shazia Ashraf, Carolin Sadowski, Heon Yung Gee, Daniela A. Braun, Werner Pabst, Friedhelm Hildebrandt. *Nephrology, Boston Children's Hospital, Boston, MA.*

Background: Nephrotic syndrome is characterized by proteinuria, hypoalbuminemia, edema and hypertriglyceridemia. 20% of childhood NS is steroid resistant (SRNS). Whereas over 30 single-gene causes of SRNS are known, a large proportion of SRNS remains genetically unsolved.

Methods: To identify novel single-gene causes of SRNS we applied homozygosity mapping with whole exome sequencing (WES) to 100 families with SRNS. We than screened a worldwide cohort of ~800 families with NS with a barcoded array based multiplex PCR (48x48 Fluidigm Access Array™) and next generation re-sequencing.

Results: In a consanguineous family with 3 affected individuals we identified a homozygous missense mutation (p.Met101Ile) in the gene NUP107 (nucleoporin 107 kDa) by WES. NUP107 is a scaffold protein of the nuclear pore complex, which is responsible for the transportation of small molecules between the nucleus and the cytoplasm, e.g. mRNA export by small Ran GTPases. The identified amino acid substitution is located in an N-terminal phosphorylation site and in addition may result in loss of function by skipping exon 4. The mutation in NUP107 leads to a very distinct phenotype of nephrotic syndrome, with focal segmental glomerulosclerosis and microcephaly.

Conclusions: We here identified a mutation in NUP107 as a novel disease-causing gene of SRNS, revealing the nuclear core complex as a new pathomechanism of SRNS.

Funding: Other NIH Support - DK086542 and DK076683

TH-PO289

Functional Analysis of New Steroid-Resistant Nephrotic Syndrome Candidate Genes Sara Gonçalves,[1,2,3] Christelle Arrondel,[1,2] Martin Helmstädter,[4] Olivia Boyer,[1,2,5] Olivier Gribouval,[1,2] Christine Bole-Feysot,[1,2] Patrick Nitschke,[1,2] Marie-Claire Gubler,[1,2] Tobias B. Huber,[4,6] Matias Simons,[1,4,7] Geraldine Mollet,[1,2] Corinne Antignac.[1,2,8] *[1]Inserm U1163, Paris, France; [2]Paris Descartes – Sorbonne Paris Cité Univ, Imagine Inst, Paris, France; [3]Nephrology, Santa Maria Univ Hospital, Lisbon, Portugal; [4]Renal Div, Univ Hospital Freiburg, Freiburg, Germany; [5]Pediatrics Nephrology, Necker Hospital, Paris, France; [6]BIOSS, Albert-Ludwigs Univ, Freiburg, Germany; [7]ZBSA, Univ of Freiburg, Freiburg, Germany; [8]Genetics, Necker Hospital, Paris, France.*

Background: Inherited forms of steroid-resistant nephrotic syndrome (SRNS) are genetically heterogeneous and the disease-causing mutations remain unknown in approximately half of familial cases and the majority of sporadic cases. We sought to identify new genes implicated in SRNS.

Results: Exome sequencing was performed on 2 affected members of a consanguineous family, presenting SRNS, cardiomyopathy and neurologic impairment. We identified two homozygous missense variants in two candidate genes, ADD3 and KAT2B, both expressed in podocytes. Segregation analysis in non-affected family members did not exclude any mutation. The first gene encodes adducin γ, an important regulator of the actin cytoskeleton, and the second gene encodes the lysine acetyl transferase2B (KAT2B), which is involved in acetylation of histones. Using xCELLigence technology we found that adducin γ knock-down (KD) in a human podocyte cell line led to decreased adhesion and migration, whereas KAT2B KD led to decreased adhesion only. Additionally, validation experiments using the GAL4-UAS expression system were performed in Drosophila nephrocytes: KD of the ADD3 orthologue in garland nephrocytes disrupted the actin cytoskeleton, decreased the expression of the NEPH1 orthologue, kirre, and led to decreased endocytosis in adult nephrocytes.

Conclusions: Our results point to a major effect of ADD3 in podocyte biology. Transgenic fly lines carrying the human mutations will help to define the precise role of each mutation.

Funding: Government Support - Non-U.S.

TH-PO290

Exome Sequencing Identified Novel Mutations of *FKRP* in Familial Atypical Hemolytic Uremic Syndrome Hirofumi Watanabe,[1] Shin Goto,[1] Hajime Yamazaki,[2] Tadashi Yamamoto,[3] Ichiei Narita.[1] *[1]Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Dept of Internal Medicine, Nagaoka Red Cross Hospital, Nagaoka, Japan; [3]Dept of Structural Pathology, Inst of Nephrology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare renal thrombotic microangiopathy. Previously, disease-causing mutations of aHUS have been identified in the complement-related genes. However, with the advancement of sequencing technology, novel causative genes not related to complement regulation were recently reported. To dissect causative genes for aHUS thoroughly, we performed comprehensive genetic analysis in a family with aHUS harboring no mutations in complement-related gene.

Methods: We studied a Japanese multiplex family composed of three patients diagnosed with aHUS in infancy, clustered in a dominant transmission mode. Unequal crossing over at the *CFH* and *CFHR* loci was screened with multiplex ligation-dependent probe amplification (MLPA). Moreover, we conducted whole exome sequencing of three affected and three unaffected individuals using Ion Proton Sequencer. Variants identified by exome sequencing were filtered on the basis of variant annotation, functional expectation, and allele frequency. Genome-wide linkage analysis was also carried out using exome sequencing data.

Results: In this family, copy number abnormalities in *CFH/CFHR* co-segregating with the disease were not detected by MLPA analysis. Exome sequencing detected a total of 130 heterozygous and non-synonymous variants shared only by the affected individuals. Filtering against several variant databases and excluding variants harbored by additional unaffected members of the family, we identified five variants located in the region with maximum LOD scores. The mutation of two consecutive amino acids in *FKRP* (p.R167S and p.C168R) was predicted to have substantial effect on the protein structure or function.

Conclusions: We identified novel mutations of *FKRP* in a family with aHUS, and functional analyses of these mutations are in progress to reveal their roles in the development of aHUS.

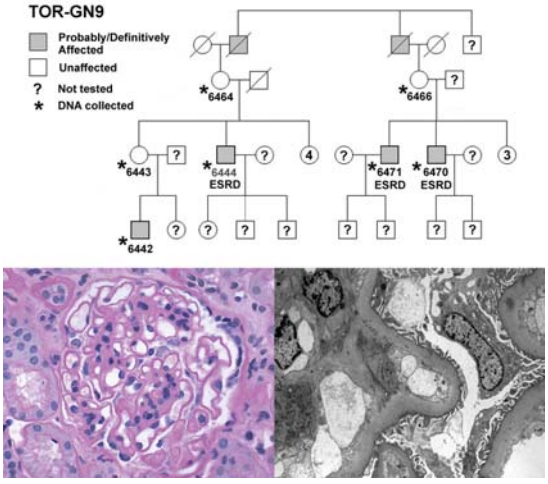
TH-PO291

A Familial Syndrome Associated with an Unusual Glomerular Pathology and Putative X-Linked Recessive Inheritance Moumita Barua,[1] Ginette Starkell,[2] Rohan John,[3] Daniel C. Cattran,[1] York P. Pei.[1] *[1]Div of Nephrology, Univ Health Network, Toronto, ON, Canada; [2]Dept of Pathology, Brampton Civic Hospital, Mississauga, ON, Canada; [3]Dept of Pathology, Univ Health Network, Toronto, ON, Canada.*

Background: The identification of Mendelian genes underlying rare familial disorders have yielded important insights in glomerular pathobiology.

Methods: We clinically ascertained the proband (6442) and other key or affected members of TOR-GN9. Whole exome sequencing (WES) of two affected members (6442 and 6471) is in progress.

Results: The pedigree of TOR-GN9 is shown in the upper panel of Figure.



The clinical course of our proband (6442) is characterized by recurrent tonsillitis and nephrotic range proteinuria up to 10 g/day. A renal biopsy revealed diffuse glomerular basement membrane thickening and mesangial expansion with focal global and segmental glomerulosclerosis by light microscopy (LM) and intramembranous immune complex deposition by electron microscopy (EM) (lower panel). Linear staining of IgG, IgA, kappa and lambda as well as IgM staining in the mesangium and capillary wall by immunofluorescence (IF) microscopy was also noted. He was treated with a course of steroids with partial remission of his proteinuria (~2 g/day) at the last follow-up. Review of the renal biopsy report from 6444 described similar findings on LM but no EM/IF was available. He was given a diagnosis of membranous nephropathy.

Conclusions: The absence of disease in three putative obligate female carriers (i.e. 6464, 6466, and 6443) in this family suggest an X-linked recessive inheritance. WES is in process and has the potential to identify the disease-causing genetic defect of this unusual syndrome.

Funding: Government Support - Non-U.S.

Autosomal Dominant Alport Syndrome: Molecular Analysis of the COL4A3/COL4A4 Genes and Clinical Outcome

Naohiro Kamiyoshi,[1] Kandai Nozu,[1] Natsuki Matsunoshita,[1] Hiromi Ohtsubo,[1] Takeshi Ninchoji,[1] Hiroshi Kaito,[1] Koichi Nakanishi,[2] Norishige Yoshikawa,[2] Kazumoto Iijima.[1]
[1]Dept of Pediatrics, Kobe Univ Graduate School of Medicine, Kobe, Japan; [2]Dept of Pediatrics, Wakayama Medical Univ, Wakayama, Japan.

Background: Alport syndrome encompasses a group of inherited, heterogeneous disorders involving chronic kidney disease progressing to end-stage renal disease (ESRD), sensorineural hearing loss and ocular abnormalities. Autosomal dominant Alport syndrome (ADAS) caused by heterozygous mutations in either *COL4A3* or C*OL4A4* gene is a rare mode of inheritance. Until now, only about 30 families with ADAS have been reported and the phenotype/genotype correlation is not well known.

Methods: A retrospective analysis of 24 genetically diagnosed patients with ADAS in 11 unrelated families was conducted. The analysis of *COL4A3/COL4A4* genes was performed by PCR and direct sequencing of genomic DNA for all exons and exon-intron boundaries.

Results: In our study, the mean age at first detection of proteinuria was 15.8 years. Five patients(20.8%) reached ESRD at the mean age of 60.6 years. No patient had hearing loss or ocular lesion. Molecular analysis revealed six novel mutations including four missenses, one splicing-site mutation and one in-frame mutation. Four mutations were reported as causative mutations for autosomal recessive Alport syndrome in the previous studies. Interestingly, heterozygous carrier parents of these mutations in those reports were asymptomatic or only presented microhematuria.

Conclusions: The present study showed the renal phenotypes in ADAS patients were much milder than X-linked or autosomal recessive Alport syndrome patients. Hearing loss and ocular abnormalities were quite rare in our cohort. Thus, it is difficult to make a diagnosis in the early phase of the disease. The correlation between mutation and phenotype was unclear. Especially, we detected four mutations previously reported as pathogenic mutations for ARAS in five ADAS families. These results indicate the existence of modifier genes to affect the phenotype of kidney disease in ADAS. Additional research is needed to confirm the predictive indicator for phenotypic variation of ADAS.

TH-PO293

Drug Repurposing for the Treatment of Experimental Alport Syndrome

Ana Konvalinka,[1] Xuewen Song,[1] Eun Hui Bae,[2] Fei Fang,[3] Vanessa R. Williams,[3] Rohan John,[4] James W. Scholey,[1,3] York P. Pei.[1] *[1]Div of Nephrology, Univ of Toronto, Toronto, Canada; [2]Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea; [3]Inst of Medical Science, Univ of Toronto, Toronto, Canada; [4]Pathology, Univ of Toronto, Toronto, Canada.*

Background: Alport syndrome (AS) is a hereditary disorder due to mutations in any of the genes encoding collagen-IV-a3a4a5 chains in the glomerular basement membrane, leading to ESRD. There are few treatment options for AS. Accordingly, we sought to identify existing drugs for the repurposed treatment of AS by studying gene expression in the kidneys of Col4a3-/-mice.

Methods: We performed gene profiling of renal cortices from male 129/Svj Col4a3-/-mice (KO) and wild type (WT) mice at 4 and 7 weeks of age (N=8/group). Gene expression was analyzed with Affymetrix_Mouse_Gene2.0_ST array. We used Significance Analysis of Microarrays (SAM) and 2-way ANOVA to identify differentially expressed genes. These genes were utilized for drug repurposing by Connectivity Map (CMAP) and Drug Pair Seeker (DPS) to find drugs that reverse AS gene expression changes.

Results: We used SAM to identify the "disease signature", composed of 769 significantly up-regulated and 113 significantly down-regulated genes in 7-week-old KO versus WT mice (FDR<1%). The top drug combination that reversed this disease signature in DPS included vorinostat and genistein. We next identified the "progression signature", composed of 426 differentially up-regulated and 501 down-regulated genes in 7-week-old compared to 4-week-old KO mice, when adjusted for age. The top drug that reversed the AS progression signature in CMAP was vorinostat (p=0.00032). Data reanalysis with 2-way ANOVA, accounting for the interaction between age and genotype, revealed that vorinostat and genistein were among the top drug combinations that reversed the AS progression signature. Both vorinostat and genistein inhibit tyrosine kinases.

Conclusions: Gene expression profiling and *in silico* analysis in a murine model of AS identified a novel drug combination that may reverse gene expression profile associated with renal disease progression. *In vivo* studies of this drug combination will determine if it impacts disease progression.

TH-PO294

Fourteen Different Monogenic Genes Account for 15% of Nephrolithiasis/ Nephrocalcinosis in a Mixed Pediatric and Adult Cohort

Jan Halbritter,[1] Michelle Baum,[1] Ann Marie Hynes,[2] Sarah Rice,[2] David T. Thwaites,[3] Zoran Gucev,[4] Jonathan Porath,[1] Ari Wassner,[5] Caleb Nelson,[6] Velibor Tasic,[4] John Andrew Sayer,[2] Friedhelm Hildebrandt.[1] *[1]Dept of Internal Medicine, Div of Nephrology, Boston Children's Hospital, Boston, MA; [2]Inst of Genetic Medicine, Univ of Newcastle, Newcastle, United Kingdom; [3]Inst of Cell & Molecular Biosciences, Univ of Newcastle, Newcastle, United Kingdom; [4]Medical Faculty Skopje, Univ Children's Hospital Skopje, Skopje, Macedonia, The Former Yugoslav Republic of; [5]Dept of Internal Medicine, Div of Endocrinology, Boston Children's Hospital, Boston, MA; [6]Dept of Urology, Boston Children's Hospital, Boston, MA.*

Background: Nephrolithiasis is a prevalent condition with a high morbidity. Although dozens of monogenic causes have been identified, the fraction of single-gene disease has never been studied.

Methods: To determine the percentage of cases that can be molecularly explained by mutations in one of 30 known monogenic causes of nephrolithiasis, we conducted a high-throughput mutation analysis in a cohort of 272 genetically unresolved individuals (106 children, 166 adults) from 268 families with one of the following diagnoses: nephrolithiasis (n=256), or isolated nephrocalcinosis (n=16).

Results: We detected 52 likely causative mutations in 14 of 30 genes analyzed, leading to a molecular diagnosis in 15.3% (41/268) of all cases. Twenty out of 52 detected mutations were novel (38.5%). The cystinuria gene *SLC7A9* (n=19) was most frequently mutated. The percentage of monogenic cases was surprisingly high, both in the adult (11.4%) and the pediatric cohorts (21.7%). Recessive causes were more frequent among children, while dominant disease occurred more abundantly in adults.

Conclusions: Our data represents one of the most in-depth studies of monogenic causes of kidney stone disease. We outline how knowledge of the molecular cause of nephrolithiasis and nephrocalcinosis has prognostic implications and will facilitate personalized treatment.

PAX2, a Key Molecule for Embryonic Kidney Development, Participates Progression of Kidney Dysfunction and Interstitial Fibrosis After Birth

Kengo Furuichi,[1] Yuta Yamamura,[2] Yasuyuki Shinozaki,[2] Yasunori Iwata,[2] Takashi Wada.[3] *[1]Div of Blood Purification, Kanazawa Univ Hospital, Kanazawa, Japan; [2]Dept of Disease Control and Homeostasis, Inst of Medical, Pharmaceutical and Health Sciences, Kanazawa, Japan; [3]Dept of Laboratory Medicine, Inst of Medical, Pharmaceutical and Health Sciences, Kanazawa, Japan.*

Background: The PAX2 gene, which encodes a developmental transcription factors, plays critical roles in development of the urogenital tract, eyes, ears, and central nervous system. Renal coloboma syndrome is a very rare condition that affects kidney and eye development. It was reported that around half cases of renal coloboma syndrome had PAX2 gene mutations. Here, we provide the evidence of PAX2 gene in kidney dysfunction after birth.

Methods: Twenty-six cases were clinically diagnosed as renal coloboma syndrome, and four cases had coloboma without any kidney abnormality (disease control). DNA of all cases was analyzed for PAX2 gene mutations by direct sequencing.

Results: Eleven out of 26 renal coloboma syndrome cases had PAX2 gene mutations. Four cases had novel mutations. Six cases (54.5% 6/11) were end stage kidney disease (ESKD) in PAX2 gene mutation group, and only two cases (13.3% 2/15) were ESKD in non-PAX2 gene mutation group. There was no ESAD case in coloboma only group. Proteinuria of renal coloboma syndrome with PAX2 mutations was tend to higher than that of renal coloboma syndrome without PAX2 mutations or coloboma only group (mena±SEM; 1.61±0.45, 0.64±0.32 g/gCr). Kidney biopsy of 6 cases with PAX2 gene mutation revealed that three were focal segmental glomerulonephritis and one was glomerulomegaly. Other two cases were non-IgA mesangial proliferative glomerulonephritis, and tubular interstitial nephritis, respectively.

Conclusions: Thus, our human data of renal coloboma syndrome indicate that PAX2 is not only a key molecule in embryonic kidney development, but also a key molecule in progression of kidney disease after birth.

TH-PO296

Renal Biopsies after 6-11 Years of Enzyme Replacement Therapy in 9 Young Classic Fabry Disease Patients

Camilla Tøndel,[1,4] Kristin Kampevold Larsen,[2,4] Rannveig Skrunes,[3,4] Sabine Leh,[2,4] Einar Svarstad.[3,4] *[1]Dep. of Pediatrics, Haukeland Univ Hospital, Bergen, Norway; [2]Dep. of Pathology, Haukeland Univ Hospital, Bergen, Norway; [3]Dep. of Nephrology, Haukeland Univ Hospital, Bergen, Norway; [4]Renal Research Group, Dep. of Clinical Medicine, Univ of Bergen, Bergen, Norway.*

Background: Data on renal morphologic effects of long-term ERT is limited. Previous studies have shown correlation between dose of Enzyme Replacement Therapy (ERT) and GL3-clearing from baseline biopsy to 5 years (y) biopsy (Tøndel et al., JASN, 2013). The purpose of this study was to evaluate the effect of ERT in patients treated up to 11 years.

Methods: 9 classic Fabry patients (8 male/1 female) with median age of 17 y (range 7-30 y) at start of ERT had their last kidney biopsies performed after a median duration of ERT of 8 y (range 6-11 y). 6 patients had a baseline biopsy before start of ERT, and 3 patients had their first renal biopsy 2-3 y after initiation of ERT. The patients were divided into a high dose group (cumulative dose > 75 mg/kg, 5 patients) and a low dose group (cumulative dose < 75 mg/kg, 4 patients). Various dosing regimen were given. The podocyte-GL3 was scored in toluidine blue sections using the scoring system of the International Scoring Group of Fabry Nephropathy (Fogo et al., NDT, 2010). All patients had full podocyte score at baseline.

Results: Glomerular endothelial and mesangial cells were cleared in all patients. There was a significantly higher clearance of the podocyte GL3 score in the high dose group than in the low dose group; median change -1.9 (range -0.50 to -3.33) and -0.20 (range 0 to -0.42), respectively, p-value =0.016. A small increase in podocyte scores was observed at 8 years in all patients (no=3) who were switched from agalsidase beta 1.0 mg/kg/eow to agalsidase alpha 0.2 mg/kg/eow after 5 y of ERT; + 0.57, + 0.81 and + 0.92.

Conclusions: Reduction of podocyte GL3 deposits may be achieved with long-term ERT across all dosing regimen, and the clearing is dose-dependent. Switch from high dose to low dose regimen after 5 y ERT may result in reaccumulation of GL3 in the podocytes. Serial kidney biopsies after long-term ERT are valuable in evaluating treatment response.

TH-PO297

Enzyme Replacement Therapy (ERT) in Fabry Disease (FD) Reduces Podocyte (PC) Globotriaosylceramide (GL3) Content within a Year (yr)

Behzad Najafian,[1] Michael Mauer,[2] Einar Svarstad,[3] Camilla Tøndel.[3] *[1]Univ of Washington; [2]Univ of Minnesota; [3]Haukeland Univ Hospital, Norway.*

Background: CKD is a common FD complication. Recent studies support a role for PC injury in FD nephropathy. Previous studies using flawed methodologies failed to show PC GL3 clearance after 1yr of ERT. We aimed to re-evaluate PC response to ERT using unbiased electron microscopic morphometry.

Methods: Paired biopsies (Bx) at baseline (BL) (ERT naïve) and after ~1yr of ERT (1 mg/kg Fabrazyme every 2 weeks) from 6 males with FD (age 31[18-46], median [range]) were studied. Fractional volume of GL3 inclusions per PC [Vv(Inc/PC)], mesangial [Vv(Inc/Mes)] and endothelial cells [Vv(Inc/Endo)] were estimated using point counting. Average PC volume [V(PC)] and volume of GL3 inclusions per PC [V(Inc/PC)] were estimated using the point sampled intercept method.

Results: V(Inc/PC) decreased in all cases from BL (3126±2091 μm^3) to 1yr (797±291 μm^3) (p=0.03). This reduction paralleled reduction in PC size from BL to 1yr (p=0.03). Vv(Inc/PC) was not statistically different between BL and 1yr. There was a strong relationship between V(Inc/P) or V(PC) at BL and % V(Inc/PC) reduction at 1yr (r=0.90, p=0.01), indicating that Bx with larger PC with more abundant GL3 at BL showed the most prominent GL3 loss at 1yr. While 0[0-10]% of PC at BL contained no GL3 inclusions, this increased to 15[4-25]% at 1yr. This increase did not correlate with change in Vv(Inc/PC), arguing that this phenomenon was likely not due to random sectioning. Vv(Inc/Endo) and Vv(Inc/Mes) approached to 0 at 1yr ERT.

Conclusions: These data, for the first time, document reduced GL3 in PC after 1yr ERT in male FD patients. The unchanged Vv(Inc/PC) explains why scoring methods failed to detect this in previous studies as our finding depended on reductions in PC size, a parameter very difficult to detect by subjective methods. Although further studies are needed to determine if this response is maintained with longer ERT duration, these results suggest that shorter studies may be adequate to detect important early treatment effects in FD. Increased PC with no GL3 following ERT is also novel and may suggest PC regeneration.

TH-PO298

Mosaicism of Podocyte Involvement Is Related to Podocyte Injury in Females with Fabry Disease

Behzad Najafian,[1] Michael Mauer,[2] Einar Svarstad,[4] Marie-Claire Gubler,[3] Camilla Tøndel.[4] *[1]Univ of Washington; [2]Univ of Minnesota; [3]Univ René Descartes, France; [4]Haukeland Univ Hospital, Norway.*

Background: Fabry disease (FD). an X-linked deficiency of α-galactosidase A,leads to intracellular globotriaosylceramide (GL-3) accumulation. Although less common than in males, CKD occurs in ~15% of females. Recent studies highlight the importance of podocyte (PC) injury in the development and progression of FD nephropathy. We hypothesized that the greater the % of PC with active wild-type GLA gene (due to X-inactivation of the mutant copy) the less is the overall PC injury.

Methods: Kidney biopsies from 11 treatment-naive females with FD, ages 14 [8-39] (median [range]) years were studied by electron microscopy and compared with 4 treatment-naive males. PC profiles with GL-3 inclusions, consistent with Fabry PC phenotype (FPC) and those without GL-3 inclusions, consistent with non-Fabry PC phenotype (NFPC) were counted in glomeruli. Volume fraction of GL-3 inclusions per PC [Vv(Inc/PC)], mesangial cells [Vv(Inc/Mes)], endothelial cells [Vv(Inc/Endo)] and foot process width (FPW) were estimated using unbiased stereology.

Results: In females, 50 [13-100]% of PC were NFPC. Vv(Inc/PC) in FPC was not different between females and males, consistent with little or no cross-correction between FPC and NFPC. However, Vv(Inc/Mes) and Vv(Inc/Endo) were ~20 times less in females compared to males. % NFPC per glomerulus (%NFPC/glom) correlated with age in females (r=0.69, p=0.04), suggesting a survival disadvantage for FPC over time. Age-adjusted %NFPC/glom was inversely related to FPW (r=-0.80, p=0.02), an indicator of PC injury. Vv(Inc/PC) in FPC in females correlated directly with FPW.

Conclusions: These findings support important relationships between PC mosaicism and PC injury in female FD patients. FPC may have discernable survival disadvantages in females. More rapid cell replication rates may provide more marked survival advantages to non-Fabry endothelial and mesangial cells in FD females. Kidney biopsy, by providing information about PC mosaicism, may help to stratify females with FD for kidney disease risk and to guide treatment decisions.

TH-PO299

Lyso-Gb3 Activates Fibrogenic Signaling in Human Podocytes

Maria D. Sanchez-Niño,[1] Ana Belen Sanz,[2] Sergio A. Mezzano,[3] Alberto Ortiz.[2] *[1]Nephrology, IdiPAZ, Madrid, Spain; [2]Nephrology, IIS-Fundacion Jimenez Diaz, Madrid, Spain; [3]Nephrology, School Medicine, Univ Austral, Valdivia, Chile.*

Background: Fabry disease leads to progressive proteinuric chronic kidney disease leading to glomerular sclerosis and interstitial fibrosis. However, the link between the metabolic abnormality and kidney fibrosis is poorly characterized. TGFbeta-1 and Notch1 are known mediators of kidney fibrosis, while chronic inflammation frequently leads to fibrosis. Globotriaosylsphingosine (lyso-Gb3) was recently identified as a bioactive molecule accumulating in Fabry disease. We hypothesized that lyso-Gb3 could modulate fibrogenic signaling in glomerular podocytes.

Methods: Notch1, Jagged and Hes1 expression was determined by immunohistochemistry in human renal biopsies from Fabry patients. The effects of Lyso-Gb3 in cultured human podocytes was assessed by qRT-PCR and Western blot. The regulation of Notch1 patchway was studied in cultured human podocytes exposed to Lyso-Gb3 and Notch1 function was explored by siRNA knock-down of Notch1. Using Electrophoretic mobility shift assay we studied NFkappaB activation.

Results: In human podocytes lyso-Gb3, at concentrations found in serum of Fabry patients: a) increased production of type IV collagen and fibronectin, b) increased TGFbeta-1 expression, c) promoted activation of the transcription factor NFkappaB, d) increased expression of Notch1 and its target Hes. Studies with inhibitors or antagonists of TGFbeta-1 (receptor antagonists, neutralizing antibodies), Notch1 (gamma-secretase inhibitor, Notch1 siRNA) and NFkappaB (parthenolide) illustrated the functional consequences of the activation of these pathways in response to lyso-Gb3 and unraveled the relationships between them.

Conclusions: Lyso-Gb3, a molecule accumulated in Fabry disease, promotes fibrogenic signaling even in podocytes expressing alpha-galactosidase. These data identify novel potential therapeutic targets to prevent progression of fibrosis in Fabry disease.

Funding: Government Support - Non-U.S.

TH-PO300

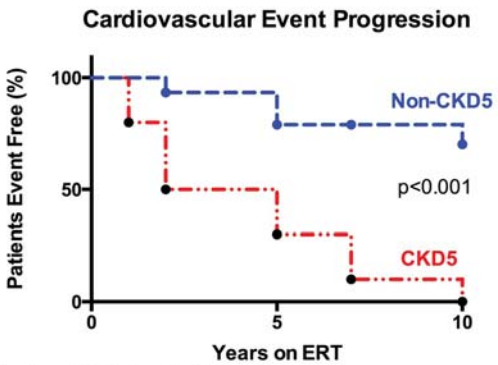
Severity of Fabry Nephropathy as a Marker of Cardiovascular Outcome: 10-Year Data from an Australian Cohort on Enzyme Replacement Therapy

Andrew S. Talbot,[1] Kathleen M. Nicholls.[1,2] *[1]Dept of Nephrology, Royal Melbourne Hospital, Victoria, Australia; [2]Dept of Medicine, Univ of Melbourne, Victoria, Australia.*

Background: Fabry Disease (FD) is an X-linked lysosomal storage disease caused by deficiency in the enzyme α–galactosidase A. Renal involvement results from progressive glomerular podocyte injury causing proteinuria, leading to focal segmental glomerulosclerosis and ultimately end-stage kidney disease (CKD5). Renal disease is a risk factor for cardiovascular (CVS) disease.

Methods: We performed a retrospective analysis of long-term outcomes of male FD (n=25) patients, from a single Australian centre, after 10-years on enzyme replacement therapy (ERT). Clinical outcomes were separated into patients with CKD5 (n=10) and those without (non-CKD5, n=15). Fabry nephropathy was monitored by proteinuria and nuclear ^{Cr}-51 EDTA glomerular filtration rate (GFR). Fabry cardiomyopathy was assessed by echocardiography and frequency of CVS events (death, arrhythmia, pacing device insertion, systolic dysfunction).

Results: GFR, in the non-CKD5 cohort, was unchanged from baseline to 10 years (86.9 ± 16.6 versus 82.2 ± 25.4 ml/min/1.73m^2, p=0.57). Proteinuria was stable to 10 years (baseline 0.37 ± 0.33 g/day versus 0.46 ± 0.42 g/day, p=0.42). CVS events were higher in patients with CKD5 over 10 years follow-up (100% versus 33%, p<0.001).



Number of Patients at Risk

Time (yr)	0	1	2	5	7	10
Non-CKD5	15	15	15	14	12	12
CKD5	10	10	10	9	7	6

Left ventricular mass index in CKD5 patients increased by 89.4 ± 78.3 g/m² versus 18.6 ± 29.1 g/m²p=0.014, in non-CKD5, driven by changes in interventricular wall thickness (7.7 ± 5.5mm versus 1.5 ± 2.0mm, p=0.004).

Conclusions: Severity of Fabry Nephropathy at commencement of ERT is a marker of CVS involvement and outcome. CKD5 is associated with worse baseline CVS parameters and significant progression despite ERT. Mild renal disease at commencement of ERT is associated with stable long-term renal function and reduced cardiac progression.

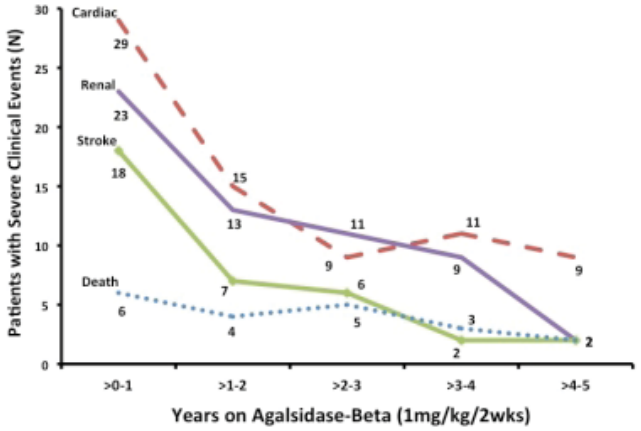
TH-PO301

Occurrence of Severe Clinical Events by Time on Enzyme Replacement Therapy with Agalsidase Beta among Patients with Fabry Disease David G. Warnock,[1] Sonia S. Maruti,[2] Gustavo Horacio Cabrera,[3] Joel Charrow,[4] Christoph Wanner,[5] Alberto Ortiz.[6] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Genzyme a Sanofi Company, Cambridge, MA; [3]Grupo Medico Del Viso, Buenos Aires, Argentina; [4]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL; [5]Univ of Würzburg, Würzburg, Germany; [6]Fundacion Jiménez Díaz, Madrid, Spain.*

Background: Fabry disease is an X-linked disorder that has been treated with enzyme replacement therapy (ERT) for nearly 15 years, but there is uncertainty about its effects on severe clinical events. We hypothesized that there is a "lag time" to benefit or reduction of severe clinical events after the first year of ERT, like the time needed for clearance of vascular endothelial globotriaosylceramide deposits by agalsidase beta.

Methods: Patients in the Fabry Registry (sponsored by Genzyme, a Sanofi company) were followed from the time they started ERT to the time they had a severe clinical event, or they stopped receiving agalsidase beta, or June 25, 2009 (start of the shortage of agalsidase beta). Severe clinical events included death, cardiac intervention, arrhythmia, heart failure, ESRD, or stroke. Patients were excluded if they had late-onset genetic variants or had ESRD before starting ERT.

Results: There were 186 severe clinical events among 1,298 patients treated with ERT (average dose 1 mg/kg/2 weeks) for up to 5 years. The number of events decreased after the first year of ERT. The incidence rate was 67 (95% CI:52-84) events per 1,000 patient-years during year 1, and 39 (95% CI:22-64) events per 1,000 patient-years after year 1 with 5 years follow-up.



Conclusions: Longer time on agalsidase beta appears to be associated with lower rates for severe clinical events, consistent with a lag time to benefit after starting agalsidase beta at 1 mg/kg/2 weeks.

TH-PO302

Identification of Urate Transporter 1 Gene Mutations in Spanish Patients with Idiopathic Renal Hypouricemia Felix Claverie-Martin,[1] Elizabeth Cordoba-Lanus,[1] Hilaria Gonzalez-Acosta,[1] Ricardo Enriquez,[2] Cesar Loris,[3] Cristina Aparicio Lopez.[4] *[1]Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife; [2]Hospital General de Elche, Elche; [3]Hospital Infantil Miguel Servet, Zaragoza; [4]Hospital de Getafe, Madrid, Spain.*

Background: Renal hypouricemia is an inherited and heterogeneous disorder characterized by impaired uric acid (UA) reabsorption in the proximal tubule. Patients present low serum levels of UA associated with excessive urinary wasting of UA, and some have severe complications like exercise-induced acute renal failure or nephrolithiasis. Mutations in the *SLC22A12* gene, encoding the renal tubular uric acid transporter 1 (URAT1), are the major cause of renal hypouricemia. Most mutations have been identified in Japanese patients, and only a few have been detected in Europeans. Here, we report clinical and molecular data of five Spanish patients diagnosed with idiopathic renal hypouricemia.

Methods: Blood and urinary samples were collected for measurement of UA and creatinine levels, and for genetic analysis. Patients were evaluated for renal stones or other renal diseases. Genomic DNA was isolated using a commercial kit. *SLC22A12* exons were amplified by PCR and the products were sequenced. Mutation prediction software was used to score the pathogenicity of genetic variants.

Results: The patients had persistently low serum UA levels ranging from 0.8 to 1.3 mg/ml and elevated fractional excretion of UA (27%-60%). One of the patients had nephrolithiasis and was also diagnosed with polycystic kidney disease. The other patients were asymptomatic. Sequence analysis revealed mutations in each patient. A new missense mutation, p.A476D, affecting transmembrane domain 11 of URAT1 was identified. Analysis with informatics tools predicted this change to be pathogenic. Two previously reported mutations, missense mutation p.T467M and deletion p.L415_G417del, associated with renal hypouricemia in families from the Czech Republic were also detected.

Conclusions: This is the first report of genetically diagnosed cases of renal hypouricemia in Spain. Although this disorder has been described mainly in Asian patients it should also be contemplated in other regions.

Funding: Government Support - Non-U.S.

TH-PO303

Comparison of Allopurinol and Febuxostat in Adenine Phosphoribosyltransferase Deficiency: Effect on Urinary 2,8-Dihydroxyadenine Excretion Vidar O. Edvardsson,[1,2] Hrafnhildur L. Runolfsdottir,[2] Steinunn Oddsdottir,[1] Inger Maria Agustsdottir,[1] Finnur Freyr Eiriksson,[3] Margret Thorsteinsdottir,[2,3] Runolfur Palsson.[1,2] *[1]Landspitali - The National Univ Hospital of Iceland, Reykjavik, Iceland; [2]Univ of Iceland, Reykjavik, Iceland; [3]ArcticMass, Reykjavik, Iceland.*

Background: The xanthine dehydrogenase (XDH) inhibitor allopurinol is known to prevent nephrolithiasis and chronic kidney disease in patients with adenine phosphoribosyltransferase (APRT) deficiency by decreasing the synthesis of 2,8-dihydroxyadenine (DHA). The aim of this exploratory pilot study was to compare the efficacy of allopurinol and the non-purine XDH inhibitor febuxostat in reducing urinary DHA excretion.

Methods: Patients with eGFR >60 mL/min/1.73 m² who are listed in the APRT Deficiency Registry of the Rare Kidney Stone Consortium and currently receiving allopurinol therapy, were enrolled in a 42-day pilot study. After 7-day washout period, the subjects were prescribed 400 mg of allopurinol in a single daily dose for 14 days. After a second 7-day washout period, all subjects were prescribed 80 mg febuxostat in a single daily dose for another 14 days. Twenty-four hour urinary DHA excretion was evaluated at the end of the first washout period and at the end of allopurinol and febuxostat treatment periods (days 7, 21 and 42). Urinary DHA was measured using UPLC-MS/MS and expressed as DHA-to-creatinine ratio (ng/mmol).

Results: To date, 6 of 10 patients have completed their participation in the study. The median (range) urinary DHA-to-creatinine ratio was 3207 (1620-5374) ng/mmol off therapy, 2105 (813-4014) ng/mmol on allopurinol and 422 (141-446) ng/mmol on febuxostat treatment. Statistical significance was not calculated due to the small number of subjects.

Conclusions: A marked decrease in the DHA-to-creatinine ratio was observed with both allopurinol and febuxostat therapy. In the prescribed doses, febuxostat appears to be more efficacious than allopurinol in reducing DHA excretion in patients with APRT deficiency. These results need to be confirmed in a larger patient sample.

TH-PO304

Dysfunctional Autophagy-Lysosome Pathway Triggers Apical Dedifferentiation in Nephropathic Cystinosis Alessandro Luciani, Jenny A. Kuerth, Olivier Devuyst. *Physiology UZH, Zurich, Switzerland.*

Background: Nephropathic cystinosis, a lysosomal storage disease caused by mutations in the *CTNS* gene encoding the lysosomal cystine transporter cystinosin, is characterized by generalized proximal tubule (PT) dysfunction that progresses, if untreated, to end-stage renal disease. The mechanisms linking lysosomal accumulation of cystine to PT cell dysfunction and the transition to renal failure remain largely unknown.

Methods: Using a combination of techniques, including electron microscopy and three dimensional tomography reconstruction, as well as functional lysosomal degradative assays, we analyzed endocytic uptake, lysosome function, and differentiation and proliferation markers in primary cultures of PT cells derived from micro-dissected kidneys of age- and gender-matched *Ctns*$^{-/-}$ and *Ctns*$^{+/+}$ mice.

Results: Studies in *Ctns*$^{-/-}$ PT cells demonstrated that the loss of cystinosin leads to perinuclear positioning of enlarged and dysfunctional lysosomes, with impaired clearance of autophagosomes containing ubiquitinated proteins and damaged mitochondria, compared to *Ctns*$^{+/+}$ cells. The defective mitochondrial clearance of *Ctns*$^{-/-}$ cells was associated with excessive production of reactive oxygen species (ROS) and increased tyrosine phosphorylation of ZO-1, loss of tight junction integrity, and abnormal nuclear translocation of ZONAB, a transcription factor that promotes cell proliferation but directly represses differentiation markers such as the megalin/cubilin receptors. Similar changes were observed in *Ctns*$^{-/-}$ kidneys *in vivo*. Scavenging of ROS with either mitochondria-targeted antioxidant mito-TEMPO or antioxidant synthetic SOD mimetic EUK-134 prevented the disruption of ZO-1 and restored the expression of megalin/cubilin in *Ctns*$^{-/-}$ PT cells.

Conclusions: These data reveal that the absence of cystinosin in *Ctns*$^{-/-}$ PT cells impairs the autophagy/lysosome pathway, which in turn induces oxidative stress, loss of tight junction integrity, abnormal ZONAB signaling and dedifferentiation and dysfunction of the cells. This chain of events can be rescued by anti-oxidants, opening new therapeutic perspectives to prevent the progression of nephropathic cystinosis.

TH-PO305

Long-Term Outcome of Renal Transplantation in Adult Cystinosis Patients
Camille Cohen,[1] Bernadette Chadefaux-Vekemans,[4] Renaud Snanoudj,[1] Henri A. Kreis,[1] Christophe M. Legendre,[1] Aude Servais.[1] *[1]Nephrology and Transplantation, Necker, Paris, France; [2]Kidney Transplantation, CHU, Nantes, France; [3]Nephrology, CHU, Vandoeuvre les Nancy, France; [4]Biochemistry B, Necker, Paris, France.*

Background: Cystinosis is a rare lysosomal disorder leading to end stage renal disease (ESRD) in more than 90% of patients before 20 years of age. We report outcome of renal transplantation in 30 adult cystinosis patients.

Methods: data of 30 adult patients were retrospectively analysed in 5 French university centers. A control cohort of 93 patients was constituted, matching with a 3/1 ratio to age, graft date, living/deceased donor and center to cystinosis patients.

Results: 31 transplantations in 30 patients were performed between1980 and 2013. Median age at transplantation was 20.4 years (7-36.5). At transplantation (D0), all patients had corneal cystine deposits, 3 diabetes and 7 hypothyroidism. All patients except one were treated by oral and ocular cysteamine at D0. Median leucocyte cystin level was 1.4 nmol ½ cystin/mg protein (0.4-4.7) at D0, and 1.9 (0.5-10) during follow up. Cystinosis complications occurred during follow up: diabetes mellitus (n=4), hypothyroidism (n=1), liver involvement (n=1), neurologic involvement (n=2). At 10 years, patient survival was respectively 97% and 99% in cystinosis and control group, and graft survival was not different between the two groups (86.5 and 72% respectively). After a median follow up of 144 months (6-340), six cystinosis patients (19%) reached ESRD (graft survival 53%). Number of graft rejections or infections was not different between cystinosis and control. Diabetes after transplantation occurred as frequently in cystinosis as in control patients (13% and 5% respectively, not significant), without difference for calcineurin inhibitors treatment.

Conclusions: Renal transplantation appears to be safe and efficient in adult cystinosis patient, with as good outcomes as aan age-matched population of kidney recipients. Diabetes risk after transplantation is not increased in patients with cystinosis.

TH-PO306

The Swan-Neck Lesion: Proximal Tubular Adaptation to Oxidative Stress in Nephropathic Cystinosis
Robert L. Chevalier,[1] Michael S. Forbes,[1] Barbara A. Thornhill,[1] Carolina I. Galarreta,[1] Corinne Antignac,[2] Marie-Claire Gubler,[2] Nathalie Nevo,[2] Michael P. Murphy.[3] *[1]Univ of Virginia, Charlottesville; [2]Hopital Necker, Paris, France; [3]Wellcome Trust, Cambridge, United Kingdom.*

Background: Cystinosis is a congenital metabolic disorder resulting from a mutation in cystinosin (*CTNS*), causing progressive proximal tubular cell flattening and the "swan-neck lesion" (SNL). Therapy with cysteamine can delay, but does not prevent, eventual renal failure.

Methods: To determine the role of oxidative stress in cystinosis, histologic sections of kidneys from C57BL/6 *Ctns*$^{-/-}$ mice were examined from 1 week to 9 months of age. This mutant strain develops Fanconi syndrome by 2 months (mo), and decreased GFR by 12 mo. Additional mice were treated with mitoquinone (MitoQ), an antioxidant targeted to mitochondria, or vehicle (dTTP) from 3-6 mo. Oxidative stress was revealed by staining with 4-hydroxynonenal (4HNE), and superoxide (formed by functioning mitochondria) was localized by nitroblue tetrazolium. Onset of SNL and proximal tubular volume fraction were determined by *Lotus tetragonolobus*, and tubular remodeling was revealed by transgelin immunostaining.

Results: 4HNE staining localized to the junction of the SNL and columnar tubular cells in 1-3 mo *Ctns*$^{-/-}$ mice, as well as to collapsing proximal tubules and interstitial cells at 9 m. Superoxide persisted around columnar cells distal to SNL, but was no longer generated by cells of the SNL, which expressed transgelin and lost *Lotus*-staining as well as most mitochondria. Treatment with MitoQ increased the fraction of Lotus-stained glomeruli in 6 mo mice from 28±1% to 38±4% ($p<0.05$), but did not significantly enhance proximal tubular volume fraction (54±1% versus 57±1%, $p=0.22$).

Conclusions: We conclude that oxidative stress is present at the "leading edge" of the early SNL, and in atrophied tubules and interstitial cells in advanced disease. Cells of the SNL adapt to oxidative stress by flattening with loss of apical cystine binding and mitochondrial loss, temporarily preventing ongoing cystine uptake and oxidative injury. Antioxidant treatment delays initiation of the SNL, and may provide therapeutic benefit in cystinotic children.

Intermediate Phenotypes of Dent-2 Disease and Lowe Syndrome in Patients with OCRL Mutations
Ken-Ichiro Miura,[1] Takashi Sekine,[2] Yutaka Harita,[1] Haruko Tsurumi,[1] Masataka Hisano,[4] Hyogo Nkakura,[3] Akira Ashida,[3] Takashi Igarashi.[5] *[1]Pediatrics, The Univ of Tokyo, Tokyo, Japan; [2]Pediatrics, Toho Univ Graduate School of Medicine, Ohashi Hospital, Tokyo, Japan; [3]Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan; [4]Pediatric Nephrology, Chiba Children's Hospital, Chiba, Japan; [5]National Center for Child Health and Development, Tokyo, Japan.*

Background: Mutations in the *OCRL* gene cause Lowe syndrome and Dent disease-2, which are generally discriminated by presence or absence of congenital cataract and mental retardation. Here, we report five patients with intermediate phenotypes of Dent-2 disease and Lowe syndrome, who carry novel mutations in the *OCRL* gene.

Methods: Direct DNA sequencing was performed in five patients from three unrelated families who were clinically diagnosed with Lowe syndrome or Dent disease. Clinical manifestations were also reviewed.

Results: Prominent low molecular weight proteinuria and cataract were noted in all patients. Patients 1-1 and 1-2 are brothers with mild developmental delay (IQ >70). Patient 1-3, their uncle, can fully care for himself. No treatment has been required for cataract in patients 1-2 and 1-3. Mental retardation in patient 2 was also mild (IQ 83). Of note, mental development in patient 3 was apparently normal. No patients needed alkali therapy for metabolic acidosis. Analyses in the *OCRL* gene revealed that families 1 and 2 carried the same missense mutation I271T in exon 9, and patient 3 carried a missense mutation V636E in exon 18.

Conclusions: We reported five patients with novel missense mutations in the *OCRL* gene who presented with cataract and mild or no mental retardation. To our knowledge, patient 3 is the first case with a mutation in the *OCRL* gene who presented with cataract requiring surgery but without mental retardation, which is an intermediate phenotype of Dent-2 disease and Lowe syndrome. These findings confirm phenotypic heterogeneity in patients with *OCRL* mutations.

TH-PO308

Clinical and Genetic Spectrum of Type 3 Bartter Syndrome
Rosa Vargas-Poussou,[1] Lamisse Mansour,[1] Isabelle Roncelin,[1] Anne Blanchard,[2] Xavier Jeunemaitre.[1] *[1]Genetics, APHP - Hôpital Européen Georges Pompidou, Paris, France; [2]Clinical Research Unit, APHP - Hôpital Européen Georges Pompidou, Paris, France.*

Background: Type 3 Bartter syndrome (BS) is a rare salt losing tubulopathy caused by mutations in the *CLCNKB* gene, coding for the basolateral chloride channel ClCkb. Patients with type 3 BS may have variable phenotype: antenatal/neonatal (A/N) BS, classical (C) BS or Gitelman syndrome (GS). The aim of this study was to analyze the phenotype/genotype correlation in a large cohort.

Methods: We retrospectively analyzed results of 106 patients belonging to 102 families with Type 3 BS addressed to our department during last 13 years (29 A/NBS, 50 CBS and 27 GS). The *CLCNKB* gene was analyzed by sequencing and MLPA.

Results: Clinically, 27% patients presented as A/NBS 47% as CBS and 26% as GS. Median [IQR] ages at diagnosis were 0.4[0.7-11.4] months, 1 [0.41-11.25] and 26 [16.5-42.5] years for A/NBS CBS and GS respectively. Polyhydramnios and prematurity were present in 93 and 36% cases of A/NBS. Main symptoms at diagnosis for CBS were failure to thrive and polyuria; for GS asthenia, cramps and fortuitous discovery of hypokalemia. Plasma Na and Cl were significant lower in A/NBS (p 0.0008 and 0.007) or CBS (p 0.001) compared with GS; GS had significantly lower Ca and Mg as compared to A/NBS (p 0.006, 0.004) or CBS (p 0.03, 0.02). Renin was significantly higher in A/NBS compared with CBS (p 0.004) or GS (p 0.002). Genetics: 56 different mutations were detected (5 splicing, 6 large del, 7 nonsense, 8 frameshift and 30 missense). 51 patients were homozygous (18 A/NBS, 20 CBS and 13 GS), 42 were compound heterozygous (10 A/NBS, 26 CBS and 6 GS) and only one heterozygous mutation was detected in 12 patients (1 A/NBS, 4 CBS and 7 GS). Percentages of mutated alleles by phenotype and mutation type were:

	Large deletions	Splicing	Frameshift/Nonsense	Missense
A/NBS	56	12	7	24
CBS	38	5	24	32
GS	21	0	17	62

Conclusions: 2/4 cases of type 3 BS correspond to CBS and ¼ either to A/NBS or GS. Large deletions and severe mutations are more frequently associated with A/NBS and CBS and missense mutations with GS. Biochemical data are similar in A/NBS and CB, in contrast a mild biochemical phenotype was observed in GS patients.

From Bench to Bed: T60M-the Most Frequent Mutation in Chinese Patients with Gitelman Syndrome
Lanping Jiang,[1] Hongbin Tu,[2] Chen Chen,[1] Xiaoyan Peng,[1] Min Nie,[1] Xuemei Li,[1] Xuewang Lee,[1] Limeng Chen.[1] *[1]Dept of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China; [2]NIH, NIDDK, Bethesda, MD.*

Background: To investigate the function of the most frequent mutation of Na-Cl cotransporter (NCC) in Chinese Gitelman Syndrome (GS) patients in vivo and in vitro.

Methods: Peripheral blood DNA samples of 63 patients with a clinical suspicion of GS were tested by direct sequencing of slc12a3 gene. Then we summarized the slc12a3 gene mutations of Chinese GS patients reported previously to figure out the most frequent mutations. In vitro, wild type human NCC cDNA-pGEM T vector and 6 missense mutations were generated by site-directed mutagenesis. $^{22}Na^{+}$ uptake experiment was carried out in xenopus laevis oocyte expression system. In vivo, hydrochlorothiazide test was carried out in 13 GS patients and 20 healthy controls.

Results: 47 patients were diagnosed GS genetically, 43 different mutations were identified, including 14 novel mutations, T60M was carried by 6 patients. Totally, 107 Chinese families were diagnosed GS genetically, 74 mutations and 196 mutated alleles were detected in these families. T60M, D486N, R913Q and c.2877_2878delAG were frequent mutants (≥5%), and T60M is the most frequent one (16.3%). Compared with wild-type NCC, mutants present different extent sodium uptake dysfunction, and T60M only remain

20% activity. Compared with health volunteers, Fractional excretion maximal/ baseline (FEmax/b) of potassium, sodium and chloride were observed significantly lower in 2 T60M homozygous mutation patients and other 11 GS patients.

Conclusions: T60M is the most frequent SLC12A3 gene mutation in Chinese GS patients. In vitro, $^{22}Na^{+}$ uptake experiment in xenopus laevis oocyte expression system indicate the dysfunction of it; in vivo, HCT test confirmed the impairment in GS patients.

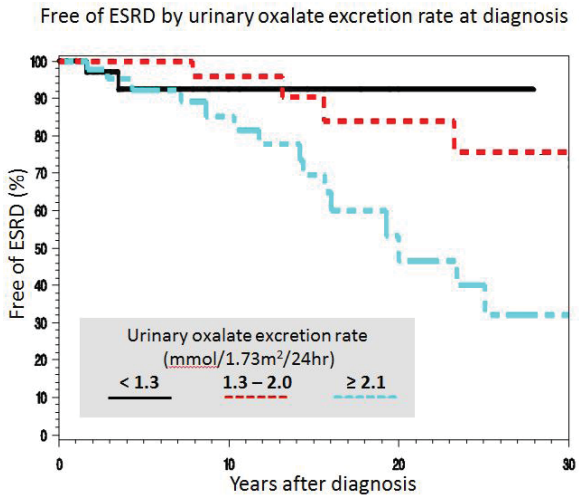
TH-PO310

Analysis of Urinary Risk Factors for ESRD among Patients with Primary Hyperoxaluria Fang Zhao, Eric J. Bergstralh, Ramila A. Mehta, Barbara M. Seide, Andrea G. Cogal, John C. Lieske, Dawn S. Milliner. *Mayo Clinic, Rochester, MN.*

Background: Clinical manifestations of primary hyperoxaluria (PH) are heterogenous, including time from diagnosis to end stage renal disease (ESRD). Factors that influence the rate of renal function decline are poorly understood. Thus urinary parameters at PH diagnosis were examined as potential predictors of kidney outcome.

Methods: Clinical data, including urinary chemistries, were analyzed among patients in the Rare Kidney Stone Consortium (RKSC) PH Registry without ESRD at diagnosis. The modified Schwarz (children) and MDRD (adults) equations were used to calculate eGFR. Data are expressed as median (25^{th}, 75^{th}). Renal survival was estimated using the Kaplan-Meier method and factors associated with renal survival determined by a Cox's proportional hazard model.

Results: Among 298 patients without ESRD at diagnosis, 192 (64.4%) had PH1, 35 (11.7%) had PH2, 38 (12.8%) had PH3 and 33 (11.1%) were of unclassified type. Median age at diagnosis was 7.9 (3.8, 18.2) years with a median eGFR of 73 (56.4, 97.5) ml/min/1.73m^2. Baseline urinary oxalate was 1.6 (1.1, 2.4) mmol/1.73m^2/24hr, while citrate was 398.0 (196.9, 697.5), calcium was 72.9 (43.4, 134.2), and phosphorus was 823.9 (551.5, 1044.1)mg/1.73m^2/24hr. ESRD developed in 59 (20%) patients during follow-up at a median of 13.2 (4.5, 20.3) years. Urinary oxalate excretion stratified by tertile at diagnosis significantly associated with renal survival [HR 2.3, 95%CI (1.1, 4.9), P=0.02], while excretion rates of citrate, calcium and phosphorous did not (P=0.16, 0.19 and 0.68, respectively). ESRD-free rate at 20 years was 92% for those with a urinary oxalate excretion rate <1.3, 84% for those 1.3 - 2, and 47% for those ≥ 2.1mmol/1.73m^2/24hr.



Conclusions: A higher urinary oxalate excretion rate at diagnosis predicts earlier progression to ESRD in PH.

TH-PO311

Clinical and Biochemical Features in Primary Hyperoxaluria Type 3 Prince Singh, Linda Hasadsri, Ramila A. Mehta, Andrea G. Cogal, Katharina Hopp, Peter C. Harris, John C. Lieske, Dawn S. Milliner. *Mayo Clinic, Rochester, MN.*

Background: Primary hyperoxaluria (PH) types 1 and 2 result in repeated stone episodes and kidney failure due to hepatic overproduction of oxalate. Recently identified PH3 is caused by mutations of *HOGA1*. Due to its rarity, the clinical course of affected individuals is uncertain.

Methods: The Rare Kidney Stone Consortium PH registry (n=420) was queried. PH3 diagnosis had been established in 39 hyperoxaluric individuals via bidirectional sequencing. Urine 4-hydroxy-2-oxoglutarate (HOG) excretion was measured in 16 patients (pts), 6 first-degree relatives genetically confirmed as carriers, and 252 controls. eGFR was calculated from modified Schwarz (children) and MDRD (adults) equations.

Results: Among 39 PH3 pts, median age at symptom onset was 2.9 years (0.9, 6.0) mean 25^{th}, 75^{th} %ile. Initial findings included urolithiasis (85%), hematuria (28%) and nephrocalcinosis (5%). Median eGFR was 95 ml/min/1.73m^2 (68,117).

Table 1. UHOG and Uox in PH3 patients, carriers, and control subjects

	PH3, n=16	Carriers, n=6	Controls, n=252
U_{ox}, µg/mg creat (mean, range)	188.6 (44.9-541.2)	57.6 (20.6-137.9)	45.9 (0-481)
UHOG, µg/mg creat (mean, range)	116.3 (25.8-582.1)	21.3 (11.2-53.9)	0.61 (0-3.8)
UHOG PH3 vs carriers p=0.01, PH3 vs control p<0.0001. UHOG carriers vs controls p=0.59			

Pts <2 years old had higher HOG excretion (298.5±180.3 µg/mg Cr, p<0.0001)) which declined with age (73.3±21.8 for pts >10 years old, p<0.0001). No gender association was observed for HOG excretion in pts even after age-adjustment. Patient follow-up was 6.9±9.2 years. Most (36/39) maintained stable eGFR (99.7 ml/min/1.73m^2/24h). In 3 pts eGFR was lower at last followup: 60 (age 19 yrs), 34 (age 71 yrs), and one progressed to ESRD (age 8 yrs).

Conclusions: Urolithiasis and hematuria, often starting in infancy, were common presenting features in this PH3 cohort. Renal function remained excellent in 36/39 during followup. HOG levels were higher in PH3 pts compared to carriers and carriers versus controls. Thus urine HOG may prove useful in diagnosis. PH3 appears to have a less severe phenotype than PH1, although a larger clinical experience is needed to confirm this observation.

Inactivation of Dstyk in Mice Causes Congenital Obstructive Uropathy Katarina Vukojevic, Miguel Verbitsky, Esther Lopez Rivera, Vivette D. D'Agati, Jonathan M. Barasch, Cathy Mendelsohn, Ali G. Gharavi, Simone Sanna-Cherchi. *Columbia Univ.*

Background: Congenital anomalies of the kidney and urinary tract account for most cases of pediatric end-stage kidney disease. We identified mutations in *DSTYK* (encoding a dual serine/threonine and tyrosine protein kinase) in 2.3% of patients with dominantly inherited urinary tract malformations. To gain insight into the mechanism linking mutations in *DSTYK* to human urinary tract malformations, we characterized a *Dstyk* knock-out mouse model.

Methods: Inactivation of *Dstyk* was performed in C57BL/6 mice by introducing an insertional gene-trapping vector designed to abrogate translation after exon 1. Mice and tissues were analysed at different time-points during development (E13.5, E15.5, E18.5) and postnatally (P1, P3, P7, 3 months).Morphological analysis was conducted on paraffin sections stained with hematoxylin and eosin. Because gene-trap models have been associated with incomplete gene inactivation, we conducted qPCR on cDNA from brain or kidney tissue to assess for residual expression.

Results: A total of 162 mice (34 embryos and 128 postnatal) were obtained by intercross between *Dstyk*$^{+/-}$ mice. Both embryos and mice were generated at expected proportions indicating absence of embryonic lethality. While all *Dstyk*$^{+/+}$ and *Dstyk*$^{+/-}$ mice survived, we observed high perinatal lethality in *Dstyk*$^{-/-}$ (8/26, 30.7%).Analysis of null embryos at different time-points showed no abnormalities in nephrogenesis at E13.5 and E15.5, while high penetrance of isolated bilateral hydronephrosis was observed at E18.5 (5/5, 100%) and P1-3 (12/17, 71%). No other overt extra-urinary phenotypes were observed in Dstyk$^{-/-}$ mice. The incomplete penetrance of the lethality and obstructive uropathy phenotypes can be explained at least in part by residual expression of Dstyk in Dstyk$^{-/-}$ mice. All mice surviving after P3 and 3/17 null mice between P1 and P3 without ureteric phenotype showed significant Dstyk cDNA espression (>15%).

Conclusions: Our results indicate that global inactivation of *Dstyk* in mice results in high-penetrance of isolated bilateral obstructive uropathy and perinatal lethality, identifying a novel player in ureteric development and function.

TH-PO313

Uretero-Pelvic Junction Obstruction and *TBX18* Mutations Asaf Vivante,[1] Stefan Kohl,[1] Daw-Yang Hwang,[1] Julian Jakob Schulz,[1] Shirlee Shril,[1] Amita Sharma,[2] Andreas Kispert,[4] Harald Jüppner,[2,3] Friedhelm Hildebrandt.[1,5] *[1]Div of Nephrology, Dept of Medicine, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Pediatric Nephrology Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA; [3]Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA; [4]Institut für Molekularbiologie, Medizinische Hochschule Hannover, Hannover, Germany; [5]Howard Hughes Medical Inst, Chevy Chase, MD.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) are the leading causes of chronic kidney disease in children (50%). Uretero-pelvic junction obstruction (UPJO) comprises about 10% of CAKUT and its pathogenesis is poorly understood. We had previously shown that a causative gene can be identified in about 10% of CAKUT cases.

Methods: To identify a causative gene for UPJO we investigated a four-generation Hispanic-White family with isolated dominant UPJO by whole exome sequencing followed by targeted sequencing in seven affected members. We also performed exon sequencing in 100 unrelated UPJO patients.

Results: We detected a protein truncating heterozygous mutation in *TBX18,* which encodes a transcription factor known to be involved in ureteral smooth muscle development.

This p.Gly337Valfs*19 mutation was present in all affected family members and absent from unaffecteds. An additional *TBX18* missense mutation, affecting a highly conserved residue at the T-box domain, was detected in 1 of 100 unrelated patients.

Conclusions: We identified *TBX18* mutations as the first genetic cause of UPJO suggesting that UPJO in humans may result from lack of ureteral smooth muscle differentiation.

Funding: NIDDK Support

TH-PO314

Porphyria-Associated Chronic Kidney Disease Nicolas Pallet, Iadh Mami, Eric Thervet, Alexandre Karras. *Hopital Europeen Georges Pompidou.*

Background: Acute Intermittent Porphyria (AIP) is a genetic disorder of the synthesis of heme caused by a deficiency in hydroxymethylbilane synthase (HMBS), leading to the overproduction porphyrin precursors in the blood and urine. Rare reports have associated AIP with chronic kidney disease. The aim of this study is to describe the clinical and biological characteristics, the renal pathology, and the cellular mechanisms of kidney disease associated with AIP.

Methods: All individuals (415) with HMBS deficiency who were followed-up in the French Porphyria Center were enrolled in 2003 in a population-based study. A follow-up study was performed in 2013 assessing patients for clinical, biological and histological parameters. In vitro and in vivo models were used to determine the mechanisms of the nephrotoxicity of porphyrin precursors.

Results: Chronic kidney disease occurred in up to 59% of the symptomatic AIP patients, with a decline in the glomerular filtration rate of approximately 1 ml/min/1.73 m^2 annually. Proteinuria was absent in the majority of the cases. The renal pathology was a chronic tubulointerstitial nephropathy, which was associated with fibrous intimal hyperplasia and focal cortical atrophy that is reminiscent of antiphospholipid syndrome-associated arteriopathy. Our experimental data provide evidence that porphyrin precursors promote apoptosis and epithelial phenotypic changes in the proximal tubular cells and might cause an active fibrogenic process.

Conclusions: Chronic kidney disease is a highly prevalent complication of AIP. Taking into account that HMBS mutations are frequent in the general population, the diagnosis of chronic kidney disease associated with AIP should be considered in cases of chronic tubulointerstitial nephropathy and/or focal cortical atrophy with severe proliferative arteriosclerosis.

TH-PO315

Targeted Sequencing of 208 Candidate Genes in 460 Patients with Congenital Anomalies of the Kidney and the Urinary Tract Improves Genetic Testing Nayia Nicolaou,[1] Isaac J. Nijman,[1] Albertien M. van Eerde,[1] Ernie M.H.F. Bongers,[2] Kirsten Y. Renkema,[1] Nine V. Knoers.[1] *[1]Medical Genetics, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]Human Genetics, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) comprise a spectrum of renal structural malformations that form the most common cause of end-stage renal failure in children. Familial cases implicate genetic factors, although genetic testing for human CAKUT is currently insufficient due to inadequate knowledge of the possible genes involved. Therefore, we aim to identify rare mutations in candidate genes and elucidate their involvement in disease aetiology to improve DNA diagnostics for CAKUT.

Methods: The coding regions of 208 candidate genes were sequenced in 460 CAKUT patients using a targeted next-generation sequencing approach. The genes selected were known to either play a role in human CAKUT or be involved in disrupted nephrogenesis in animal models. Average depth of sequencing coverage was 130X. Filtering and prioritization of variants, based on population frequency and in silico predictions on the effects of the mutations on protein function, resulted in the selection of 200 potentially pathogenic variants that were confirmed by Sanger sequencing.

Results: Validated variants were found in 94/208 genes in 236/460 patients, underlining the heterogeneity of CAKUT. 27/460 (6%) probands were diagnosed with a known disease-causing mutation. Of note, the identification of variants in DCHS2, FAT1 and FAT4 in multiple patients, implicates the planar cell polarity pathway in CAKUT. Furthermore, de novo variants included a well-known causal truncating variant in PAX2 and deleterious variants in the LGR4 and GNB3 genes.

Conclusions: To conclude, we identified novel mutations in a large candidate gene panel in a cohort of 460 CAKUT patients. Our method allows sequencing of 192 patients in a single sequencing run in a high-throughput and cost-effective manner. We detected clinically relevant variants, which facilitates genetic counselling for these patients, demonstrating the clinical implications of our gene panel.

TH-PO316

Microvascular Disease and BP Control in Males and Females with X-linked Alport Syndrome James Durham Smith,[1] Deb J. Colville,[1] Ecosse L. Lamoureux,[3] Tien Yin Wong,[2] Andrew Catran,[1] Judith A. Savige.[1] *[1]Medicine (Northern Health and Melbourne Health), The Univ of Melbourne, Melbourne, VIC, Australia; [2]Singapore Eye Research Inst, Univ of Singapore, Singapore, Singapore; [3]Dept of Ophthalmology, The Univ of Melbourne, Melbourne, VIC, Australia.*

Background: Poorly-controlled hypertension and secondary microvascular disease contribute to declining renal function. The aim of this study was to determine the prevalence and severity of microvascular disease in Alport syndrome from retinal images.

Methods: Individuals were diagnosed with X-linked Alport syndrome on the basis of a lamellated glomerular membrane, and gene studies. Retinal images from 17 males pre- and 11 post-transplantation and 28 females, all pre-transplantation, were examined for microvascular retinopathy (Wong and Mitchell classification), and for arteriole and venular calibre using a semiautomated system (University of Wisconsin).

Results: The males had an average age pre-transplant of 30 ± 19 years, and mean eGFR of 68 ± 28 ml/min/1.73 m^2. Fifteen (88%) had a mild or moderate retinopathy,11 (65%) had focal arteriole narrowing and 6 (35%) had haemorrhages. Their mean arteriole calibre was 142.8 ± 19.9 µm and mean venular calibre was 207.5 ± 29.7 µm. (Normal age-matched values were 148.4 ± 4.7 and 228.6 ± 11.6 µm respectively.) The post-transplantation males were older with a mean age of 38.2 ± 14.9 with eGFR of 42 ± 26 ml/min/1.73 m^2. Eight (72%) had a mild or moderate retinopathy, 5 (45%) had focal arteriole narrowing and 3 (27%) had haemorrhages. Arteriole and venular calibre were not different post transplantation (141.9 ± 17.6 and 208.3 ± 15.9 µm respectively). The females had an average age of 40.3 ± 16 year, and eGFR of 79 ± 16 ml/min/1.73 m^2. Twenty-one (75%) had a mild or moderate retinopathy, 17 had focal arteriole narrowing (61%) and 6 (21%) had haemorrhages. Their arteriole and venular calibre were 151.5 ± 19.8 and 217.7 ± 31.2 µm. (Normals were 163.9 ± 8.1 and 239.4 ± 15.8 µm respectively.)

Conclusions: Systemic microvascular disease is common in males and females with X-linked Alport syndrome and is not reversed by renal transplantation. Blood pressure control is not optimal in these individuals.

TH-PO317

Missense Mutations in the COL4A5 Gene, and the Effect of a Chemical Chaperone on ER Size and the Transport of the Collagen a5 Chain Extracellularly Judith A. Savige. *Medicine (Northern and Melbourne Health), The Univ of Melbourne, Melbourne, VIC, Australia.*

Background: Forty % of mutations in X-linked Alport syndrome are caused by missense variants in the COL4A5gene. This study examined the effects of COL4A5 missense mutations on the cell, and the consequences of treatment with a chemical chaperone, PBA.

Methods: Cell lines were produced from skin fibroblasts from two male and four female subjects with X-linked Alport syndrome caused by missense mutations, and from 4 non-hematuric normals. Growth curves were examined over five days. Levels of mRNA corresponding to ER stress (BiP, CHOP and ATF6), autophagy (ATG5, BECN1 and ATG7) and the pro- and antiapoptotic pathways (caspase 3, BAD and Bcl_2) were quantitated using RT-PCR (Applied Biosystems 7500). Levels of intra- and extracellular collagen IV alpha 5 chains were measured using an inhibition ELISA, before and after 10 mM PBA treatment. ER size was also estimated from electron micrographs, and mRNA levels for ER stress, autophagy and apoptosis compared before and after PBA treatment.

Results: Cell growth rates were reduced in the affected male but not female cell lines. Affected male and female cell lines had larger ER than unaffected individuals ($p<0.05$, $p<0.05$), and increased mRNA corresponding to ER stress, autophagy and apoptosis. Treatment with PBA reduced the size of the ER, reduced the amount of intracellular collagen a5(IV) chain, increased the amount of extracellular collagen IV a5 chain, but also increased apoptosis and autophagy activity.

Conclusions: Missense *COL4A5* mutations result in the ER accumulation of the mutant collagen IV a5 chain, and increased ER stress. They have an adverse effect on cell growth. Treatment with the chemical chaperone, PBA, increases the transport of the mutant collagen IV a5 chain extracellularly but also has adverse cellular effects.

Drosophila, a Highly Efficient and Relevant System for Validating Genetic Variants Causing Kidney Diseases Zhe Han,[1] Fujian Zhang.[2] *[1]Children's National Medical Center, Washington, DC; [2]301 Hospital, Beijing, China.*

Background: Large numbers of genetic variants are being identified from exome sequencing of kidney disease patients worldwide, but how to validate the causal factors remains a central question to be addressed. Mammalian models are cost-prohibitive to be used in large-scale. A low-cost, high-efficient and relevant *in vivo* model to test the effects of genetic variants on renal function is highly desirable.

Methods: We found that the fruit fly Drosophila has a specialized cell type called nephrocyte, which combines the function of mammalian glomerular podocytes and renal proximal tubules. We generated a transgenic fly line carrying a renal functional readout, and performed a genetic screen to discover hundreds of renal genes conserved from flies to humans. Moreover, we developed a novel genetic approach to test human genetic variants in the background of nephrocyte-specific removal of the corresponding fly gene products.

Results: We showed that the genes essential for filtration and protein reabsorption are highly conserved from Drosophila to humans. Using specific mutations identified from kidney patient exome sequencing, we generated Drosophila models in which the fly genes are replaced by the corresponding human genes (with or without variants) specifically in the nephrocytes. In two specific examples with the ADCK4 (COQ8) and ARHGDIA (RhoGDI) genes, we showed that nephrocyte function defects caused by knocking down of the corresponding fly genes can be rescued by targeted expression of these human wild-type genes in the nephrocytes but not by their disease-causing variants. Furthermore, Coenzyme Q10 treatment can rescue the renal function of COQ8 knockdown in nephrocytes, providing an example for feasible and relevant drug treatment testing in fly models of kidney diseases.

Conclusions: We have established an inexpensive, quick and relevant *in vivo* system for validating genetic variants identified from exome sequencing of kidney disease patients. This new model system also has the potential of testing potential drugs.

A High Frequency of Rare COL4A3/COL4A4 Variants in a Familial FSGS Cohort Andrew F. Malone,[1] Paul J. Phelan,[1] Gentzon Hall,[1] Alison Homstad,[1] Guanghong Wu,[1] Thomas Lindsey,[1] Matthew A. Sparks,[1] Stephen R. Smith,[1] Nicholas J. Webb,[5] Philip A. Kalra,[7] Andrey S. Shaw,[2] Peter J. Conlon,[3] J. Charles Jennette,[4] David Howell,[6] Michelle P. Winn,[1] Rasheed A. Gbadegesin.[1] *[1]Depts of Pediatrics and Medicine, Duke Univ Medical Center, NC; [2]Dept of Pathology and Immunology, Washington Univ, MO; [3]Beaumont Kidney Centre, Beaumont Hospital, Ireland; [4]Dept of Pathology and Laboratory Medicine, Univ of North Carolina at Chapel Hill, NC; [5]Royal Manchester Childrens Hospital, United Kingdom; [6]Dept of Pahology, Duke Univ Medical Center; [7]Hope Hospital, Salford, United Kingdom.*

Background: FSGS has many causes including inherited genetic defects. Proteinuria is the predominant clinical finding at presentation. Mutations in COL4A3 and COL4A4 are known to cause Alport syndrome and result in pathognomonic glomerular basement membrane findings on electron microscopy. There is phenotypic overlap of FSGS and Alport nephritis, yet the approach to treatment is very different for these distinct clinical entities.

Methods: To determine the prevalence of novel COL4A3 and COL4A4 variants in a cohort of families enrolled in a familial FSGS study, we performed next generation sequencing or direct sequencing on 70 families with a diagnosis of familial FSGS.

Results: We excluded mutations in known FSGS genes in all the families. Seven families (10%) from the cohort have rare or novel variants in COL4A3 or COL4A4. In all seven families, nephrotic range proteinuria and hematuria was present. Light microscopy showed classical FSGS histology. Glomerular basement membrane histology was variable but with no features typical of Alport nephritis. There was no recurrence of disease after kidney transplantation. In this study, families with COL4A3 and COL4A4 variants that segregate with disease represent 10% of our cohort of familial FSGS.

Conclusions: We propose that COL4A3 and COL4A4 variants be considered in the interpretation of next-generation sequencing data from such patients. This study illustrates the power of molecular genetic diagnostics in the clarification of renal phenotypes.

Intercalated Cells Are Critical to Kidney Innate Immunity Andrew L. Schwaderer,[2] Xi Chen,[2] Vijay Saxena,[2] Evan Barr-Beare,[2] David S. Hains.[1] *[1]Le Bonheur Children's Hospital, Memphis, TN; [2]The Research Inst at Nationwide Children's Hospital, Columbus, OH.*

Background: Intercalated cells regulate acid-base homeostasis, but recent findings indicate a role in the innate defense of the kidney. Mice deficient in Carbonic anhydrase 2 (*Car2*$^{-/-}$) are deficient in normal intercalated cells. The objective of this study is to evaluate the biological consequences of intercalated cell disruption in a murine UTI model.

Methods: *Car2*$^{-/-}$mice were compared to wild-type littermate controls. Mice were transurethrally challenged with uropathogenic *Escherichia coli.* Bladder and kidney bacterial burden was measured at 24 and 48 hours. The 24-hour experiment was repeated on mice with and without base supplementation. The RT^2 profiler antibacterial response array (Qiagen) was used to determine innate immune differences between genotypes at baseline and in response to infection.

Results: Mean kidney 24 hour post inoculation CFUs were higher in *Car2*$^{-/-}$compared to *Car2*$^{+/+}$mice at 301,357 ± 749,330 and 19,987 ± 53,965 respectively, p = 0.04. Kidney clearance of bacteria was achieved in 47% of *Car2*$^{+/+}$versus 16% of *Car2*$^{-/-}$ kidneys at 24 hours and 50% of Car2$^{+/+}$ versus 6% of *Car2*$^{-/-}$kidneys at 48 hours, p values of 0.014 and 0.012 respectively. Oral alkali supplementation to standardize the urine pH and serum bicarbonate levels did not rescue Car2$^{-/-}$ from increased kidney infection susceptibility. *Car2*$^{-/-}$mice have significantly increased neutrophil-gelatinase-associated lipocalin (Ngal) mRNA and protein and expression at baseline and a marked decrease ability to upregulate key bacterial response gene expression during kidney infection.

Conclusions: Our findings provide in vivo evidence that supports a role for carbonic anhydrase 2 and intercalated cells in promoting renal bacterial clearance. Decreased and/or deficient intercalated cells result in increased antimicrobial peptide production by other cells, which is not sufficient to prevent increased bacterial burden. Ngal has anti-inflammatory properties, thus its increased expression likely contributes to the decreased ability of *Car2*$^{-/-}$ kidneys to upregulate bacterial response genes following experimental UTI.

RNase6 Is an Up-Regulated Antimicrobial Peptide with Pyelonephritis Robert Easterling, Tad Eichler, Brian Becknell, John David Spencer. *The Research Inst at Nationwide Children's, Columbus, OH.*

Background: Pyelonephritis (pyelo) is marked by infiltrating leukocytes that secrete bactericidal molecules like antimicrobial peptides (AMP). Ribonuclease 6 (RNase6) is a potent AMP expressed by myeloid cells and rapidly kills uropathogenic *E.coli* (UPEC). The factors that regulate RNase6 expression are not characterized. We hypothesize that RNase6 production by monocyte/macrophages is regulated by UPEC and inflammatory cytokines associated with pyelo.

Methods: Primary peripheral blood mononuclear cells (PBMC) were isolated from healthy humans. CD14+ monocytes were selected and challenged with UPEC. THP-1 monocytic cells were differentiated with phorbol myristate acetate (PMA) or IFNγ+lipopolysaccharide (LPS). Fully differentiated THP-1 cells were stimulated with UPEC and inflammatory cytokines. RNA, protein lysates, and media were collected. qRT-PCR, ELISA, and immunoblot measured RNase6 expression. UPEC growth in stimulated and unstimulated media aliquots was assessed.

Results: Unstimulated CD14+ monocytes did not express RNase6 protein by ELISA or immunoblot *ex vivo*. *RNASE6* expression increased 3.5fold after 30 minute UPEC stimulation in CD14+ monocytes. RNase6 protein was detected within 30 minutes of UPEC exposure and secreted RNase6 concentrations reached 521.85±31.71ng/mL two hours after UPEC treatment (p=0.041). To evaluate the mechanisms of UPEC induced RNase6 secretion, we utilized THP-1 monocytic cells. Undifferentiated THP-1 cells express low levels of RNase6 mRNA and protein. When THP-1 cells were activated with PMA or IFNγ+LPS, *RNASE6* expression increased 25fold (p<0.001). RNase6 protein secretion increased from 8.16±2.1ng/mL to 221.27±48.78ng/mL (p=0.021). Stimulation of activated THP-1 cells with UPEC or inflammatory cytokines (IFN-γ, IL-1β, TNF-α) did not affect *RNASE6* expression. When UPEC was added to media samples with increased RNase6 concentrations, UPEC growth was suppressed (p=0.007).

Conclusions: RNase6 is a myeloid derived AMP that is induced by UPEC in primary human monocytes and up-regulated during macrophage differentiation. Elucidation of the factors that regulate RNase6 production may lend novel insight into the pathogenesis and prevention of pyelo.

Molecular Characterization of Serum IgA1 *O*-Glycosylation from Patients with IgA Nephropathy Kazuo Takahashi,[1] Stacy D. Hall,[2] Zina Moldoveanu,[2] Knud Poulsen,[3] Mogens Kilian,[3] Yoshiyuki Hiki,[3] Yukio Yuzawa,[1] Bruce A. Julian,[2] Jan Novak,[2] Matthew B. Renfrow.[2] *[1]Fujita Health Univ School of Medicine, Toyoake, Japan; [2]Univ of Alabama at Birmingham, Birmingham, AL; [3]Fujita Health Univ School of Health Sciences, Toyoake, Japan.*

Background: IgA1 with galactose (Gal)-deficient hinge-region *O*-glycans (Gd-IgA1) plays a key role in IgA nephropathy (IgAN). Serum level of Gd-IgA1 is elevated in most IgAN patients. To characterize IgA1 involved with IgAN, *O*-glycan microheterogeneity and attachment sites should be analyzed, as each hinge region has nine potential sites for *O*-glycosylation.

Methods: We developed a high-resolution mass spectrometry (MS) protocol and individually analyzed IgA1 from sera of 2 IgAN patients (IgAN-IgA1) and 2 healthy controls (HC-IgA1). Serum IgA1 was purified by affinity chromatography using anti-human IgA antibody. Neuraminidase-treated IgA1 proteins were digested with bacterial IgA-specific proteases and trypsin; hinge-region glycopeptides were analyzed by on-line liquid chromatography (LC) LTQ Orbitrap Velos Pro. Relative abundance of each glycopeptide was determined using a label-free quantitation method. Glycosylation sites in the hinge-region were determined by activated ion-electron capture dissociation (AI-ECD) Fourier transform ion-cyclotron resonance (FT-ICR) tandem MS.

Results: The combined LC-MS profiling using IgA-specific proteases and AI-ECD tandem MS data provided a comprehensive analysis of all sites of *O*-glycans and overall *O*-glycan microheterogeneity distribution of IgA1 hinge-region *O*-glycoforms. The total amount of *O*-glycans in IgAN-IgA1 was higher than that in HC-IgA1. Moreover, the amount of Gal-deficient *O*-glycans in IgAN-IgA1 was greater than that in IgA1 from HC-IgA1. AI-ECD FT-ICR tandem MS revealed that specific sites with Gal-deficient *O*-glycans or nonglycosylated sites.

Conclusions: Identification of *O*-glycosylation patterns of serum IgA1 provides useful information relevant to pathogenesis of IgAN. Glycoforms predominating in IgAN-IgA1 may be candidates for biomarkers specific for IgAN.

TGF-β1 Release from Human Proximal Tubular Epithelial Cells Is Stimulated by Galactose-Deficient Polymeric IgA1 Chee Kay Cheung,[1,2] Saarah Bashir,[1] Karen Molyneux,[1] Nigel J. Brunskill,[1,2] Jonathan Barratt.[1,2] *[1]Infection, Immunity and Inflammation, Univ of Leicester, Leicester, Leicestershire, United Kingdom; [2]John Walls Renal Unit, Univ Hospitals of Leicester, Leicester, Leicestershire, United Kingdom.*

Background: Progression in IgA nephropathy (IgAN) is dependent upon tubulointerstitial injury and not on severity of mesangial IgA1 deposition. Our previous data indicated that IgA1 is able to stimulate pro-fibrotic cytokine release from human proximal tubular epithelial cells (PTEC) to a far greater extent than albumin, IgG or IgM. We aimed to ascertain the structural properties of IgA1 required to elicit this response.

Methods: Total IgA1 was isolated from serum from 5 healthy subjects and 5 patients with IgAN by ammonium sulphate precipitation followed by Jacalin-agarose affinity chromatography. IgA1 was further separated into monomeric and high molecular weight/ polymeric IgA1 (mIgA1 and pIgA1) by size exclusion chromatography. An identical process was carried out in a patient with IgA deficiency as a control. Human HK2 PTEC were incubated with 100μg/mL mIgA1 and pIgA1 for 48h. TGF-β1 and IL-6 were measured in the supernatants by ELISA and mRNA in the cell lysates by qPCR. The galactosylation profile of individual IgA1 preparations was tested by their ability to bind to the GalNac specific lectin *Helix Aspersa (HA).*

Results: Both pIgA1 and mIgA1 significantly upregulated TGF-β1 release from PTEC, with pIgA1 having the strongest effect. pIgA1 also produced a significant upregulation in TGF-β1 mRNA expression. No significant increase in IL-6 release was observed. No significant increase in TGF-β1 or IL-6 release was observed after incubation with the IgA deficient control. pIgA1 showed lower HA-lectin binding versus mIgA1, and the level of IgA1 galactosylation inversely correlated with TGF-β1 release. No significant difference in cytokine release was seen between IgA1 prepared from patients with IgAN versus healthy subjects.

Conclusions: PTEC TGF-β1 production is significantly upregulated by IgA1, with a stronger effect observed with galactose-deficient polymeric IgA1. Leakage of this form of IgA into the urinary space through the damaged glomerulus may drive tubulointerstitial fibrosis in IgAN.

Abnormal Signaling in IgA1-Producing Cells from Patients with IgA Nephropathy Alters Glycosylation of Autoantigen, Galactose-Deficient IgA1 Colin Reily,[1] Koshi Yamada,[1,5] Zhi Qiang Huang,[1] Milan Raska,[1,4] Joshua Charles Anderson,[1] Hitoshi Suzuki,[1,5] Bruce A. Julian,[1] Christopher D. Willey,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Palacky Univ, Olomouc, Czech Republic; [3]Faculty of Medicine, Juntendo Univ, Tokyo, Japan.*

Background: IgA nephropathy (IgAN) is an autoimmune disease characterized by elevated production of autoantigen, IgA1 with galactose-deficient *O*-glycans (Gd-IgA1). Gd-IgA1, recognized by autoantibodies, forms immune complexes, some of which deposit in the kidneys and induce glomerular injury. Very limited information is available about signaling pathways involved in Gd-IgA1 production by IgA1-secreting cells from patients with IgAN.

Methods: IgA1-secreting cells from IgAN patients and healthy controls were stimulated with IL-6 or mock-stimulated and IgA1 production and glycosylation were assessed. Kinome profiling using PamStation 12 PTK (tyrosine kinome PamChip) and Western blotting were used for assessment of signaling using cell lysates from IgA1-secreting cells with or without IL-6 stimulation. RealTime RT-PCR was used to assess expression of specific genes.

Results: IL-6 enhanced production of Gd-IgA1 in IgA1-secreting cells from IgAN patients but not healthy controls. Kinome profiling and Western blotting revealed that IL-6 signaling was mediated by STAT3 and that IgA1-secreting cells from IgAN patients compared to the cells from healthy controls had enhanced and longer lasting phosphorylation of STAT3. siRNA knock-down confirmed the key role of STAT3 in IL-6-induced enhancement of Gd-IgA1 production. Moreover, differences in several other signaling pathways in IgA1-secreting cells from IgAN patients *versus* healthy controls were identified.

Conclusions: Studies of cytokine signaling revealed aberrancies in IgA1-secreting cells from IgAN patients centered around STAT3 signaling. The exaggerated and prolonged STAT3 activation was linked to increased Gd-IgA1 production. We postulate that abnormal signaling mechanisms in IgA1-producing cells may offer potential targets for future disease-specific therapy of IgAN.

TH-PO325

Pathogenic Role of Aberrantly-Glycosylated IgA1 and Corresponding Autoantibodies in Patients with Henoch-Schoenlein Purpura Nephritis Hitoshi Suzuki,[1,2] Zina Moldoveanu,[2] Bruce A. Julian,[2] Yusuke Suzuki,[2] Yasuhiko Tomino,[1] Robert J. Wyatt,[3] Jan Novak.[2] *[1]Juntendo Univ Faculty of Medicine, Tokyo, Japan; [2]Univ of Alabama at Birmingham, Birmingham, AL; [3]Univ of Tennessee Health Sciences Center, Memphis, TN.*

Background: Patients with Henoch-Schoenlein purpura with nephritis (HSPN) and IgA nephropathy (IgAN), but not with Henoch-Schoenlein purpura without nephritis (HSP) have elevated serum levels of galactose-deficient IgA1 (Gd-IgA1). Gd-IgA1 bound by Gd-IgA1-specific autoantibodies forms pathogenic immune complexes. Mucosal infections are often associated with clinical presentation and exacerbation of HSPN and IgAN. In IgAN, some Gd-IgA1 and autoantibodies originate from tonsillar Ig-secreting cells and some cytokines enhanceproduction of Gd-IgA1. Here, we assessed common pathogenic features of HSPN and IgAN.

Methods: Serum and Ig-secreting cells from patients with HSPN and HSP and healthy controls were used for analysis of IgA1 glycosylation and Gd-IgA1-specific IgG. Serum Gd-IgA1 and Gd-IgA1-specific IgG were measured before and after tonsillectomy in adult HSPN patients.

Results: IgA1 secreted by cells from HSPN patients had Gal-deficient *O*-glycans, whereas IgA1 from HSP patients and healthy controls was normally galactosylated. Levels of Gd-IgA1-specific IgG in sera and culture supernatants of Ig-secreting cells were higher in HSPN than in HSP patients or healthy controls ($P<0.01$). We subcloned IgA1-producing cells from 5 HSPN patients and determined that the secreted IgA1 had Gal-deficient *O*-glycans. This finding was consistent with decreased expression of ß1,3-galactosyltransferase observed in cells from HSPN patients compared to cells from HSP patients. Serum levels of Gd-IgA1 and Gd-IgA1-specific IgG were elevated in HSPN patients with active disease, as manifested by hematuria/proteinuria ($P<0.01$). Tonsillectomy in HSPN patients that reduced proteinuria and hematuria was accompanied by reduction of serum levels of Gd-IgA1 and Gd-IgA1-specific IgG ($P<0.001$).

Conclusions: Gd-IgA1 and Gd-IgA1-specific autoantibodies are elevated in patients with HSPN, supporting the hypothesis that HSPN and IgAN have common pathogenetic components.

TH-PO326

Expression of microRNAs in Kidney Biopsy, Plasma and Urine From Patients with IgA Nephropathy Zhangsuo Liu,[1] Lu Wen,[2] Junjun Zhang,[3] Guo Jia.[4] *[1]The First Affiliated Hospital of Zhengzhou Univ; [2]The First Affiliated Hospital of Zhengzhou Univ; [3]The First Affiliated Hospital of Zhengzhou Univ; [4]The First Affiliated Hospital of Zhengzhou Univ.*

Background: MicroRNAs(miRNA) are demonstrated to play important roles in the pathophysiology of IgA nephropathy (IgAN). In the present study, the expression of the four miRNA species (miR-148b, miR-194, miR-200a and miR-382) in patients with IgAN were evaluated,investigating whether these miRNAs can be used as non-invasive biomarkers in IgAN.

Methods: The expression of miRNAs in plasma and urine of 34 patients with biopsy-proven IgAN and kidney specimens of 7 patients was quantified by Real-time PCR technology. The results were compared to 13 healthy volunteers. The correlation between the miRNA levels and clinical parameters and Hass classification were analysed.

Results: We found that the levels of intra-renal miR-148b, miR-194 and miR-200a were down-regulated in patients with IgAN, while miR-382 was up-regulated ($P<0.05$); the IgAN group had significantly lower plasma miR-148b, miR-194 and miR-382, but higher miR-200a levels than controls($P<0.05$); patients with IgAN had lower urinary miR-194 and miR-200a, but higher miR-148b and miR-382 levels than controls ($P<0.05$). Plasma expression of miR-148b and miR-194 inversely correlated with Hass classification($P<0.017$). Urinary expression of miR-148b was significantly higher in Hass grade IV-V than those in grade III($P<0.017$) while miR-194 expression was significantly higher in Hass grade I-II and grade III than those in grade IV-V($P<0.017$). Urinary level of miR-148b negatively significantly correlated with complement 4(C4) ($P<0.05$), while miR-382 levels positively correlated with urine red blood cell counts ($P<0.05$).

Conclusions: MiRNAs may be involved in the pathogenesis of IgAN. Plasma and urinary expression of miRNAs has the potential of further development as non-invasive biomarkers of IgAN.

TH-PO327

Salivary Microbiota Associated with Immunoglobulin A Nephropathy (IgAN) Maria De Angelis,[1] Maria Piccolo,[1] Eustacchio Montemurno,[2] Gabriella Lauriero,[2] Carmela Cosola,[2] Marco Gobbetti,[1] Loreto Gesualdo.[2] *[1]DiSSPA, Univ of Bari, Italy; [2]DETO - Nephr Unit, Univ of Bari, Italy.*

Background: Immunoglobulin A nephropathy (IgAN) is one of the most common forms of primary glomerular disease. Along structural IgA abnormalities, hyperproduction of poorly galactosylated IgA1 is thought to play a role in the pathogenesis of primary IgAN. The downstream effector mechanisms triggered by mesangial IgA1 deposition and its etiology are poorly understood. Recently, a probable role of the enteric microbiota in educating the immune system and disease development was shown.

Methods: Aim of our study was to compare the composition of the salivary microbiota between IgAN pts and Healthy Controls (HC). Based on clinical data, IgAN pts were grouped into "non-progressors" (NP) and "progressors' (P). Each group was composed by 14 volunteers. The total salivary microbiota was characterized through an integrated approach of culture-dependent and -independent methods. Bacterial tag-encoded FLX-titanium amplicon pyrosequencing (bTEFAP) of 16S rRNA genewas carried out for genomic.

Results: The abundance of some OTUs belonging to Firmicutes phylum significantly ($P<0.05$) differed between NP, P and/or HC. *Gemella haemolysins*, *Granulicatella adiacens*, *Veillonella parvula* were positively associated ($P<0.05$) with HC. Within the phylum Bacteroidetes, *Prevotella* species were the highest in HC. The only exception was for *P. aurantiaca*. Compared to HC, the percentage of abundance of some OTUs belonging to Pasteurellaceae family (e.g., *Haemophylus parainfluenzae*) increased in P and even more in NP. Fusobacteriaceae with the genera Fusobacterium were the lowest in P while no statistically significant ($P>0.05$) differences were found between HC and NP samples.

Conclusions: Our results indicate significant differences in microbiota distribution among NP, P and HC, with interesting potential outputs for the development of specific diagnostic tests, and/or for treatment and prevention.

TH-PO328

GWAS Follow-Up Studies Identify Abnormal Signaling in B Cells from Patients with IgA Nephropathy, an Autoimmune Disease with Aberrantly *O*-Glycosylated Autoantigen

Koshi Yamada,[1,2] Zhi Qiang Huang,[1] Milan Raska,[1,3] Colin Reily,[1] Hitoshi Suzuki,[2,1] Zina Moldoveanu,[1] Krzysztof Kiryluk,[4] Yusuke Suzuki,[2] Yasuhiko Tomino,[2] Ali G. Gharavi,[4] Christopher D. Willey,[1] Bruce A. Julian,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Juntendo Univ Faculty of Medicine, Tokyo, Japan; [3]Palacky Univ, Olomouc, Czech Republic; [4]Columbia Univ, New York, NY.*

Background: IgA nephropathy (IgAN) is an autoimmune glomerulonephritis wherein immune complexes consist of IgA1 with galactose-deficient *O*-glycans (Gd-IgA1) and anti-Gd-IgA1 autoantibodies. Our GWAS identified a locus on chromosome 22q12.2 that contains genes encoding leukemia inhibitory factor (LIF) and oncostatin M (OSM), IL-6-related cytokines using gp130 for signal transduction and implicated in mucosal immunity and inflammation. Recently, we observed that abnormal IL-6/gp130/STAT3 signaling enhances production of Gd-IgA1 in IgAN. In this study, we characterized signaling mechanisms involved in Gd-IgA1 production induced by LIF, using immortalized IgA1-secreting cells derived from the circulation and tonsils of IgAN patients and controls.

Methods: IgA1-secreting cells derived from the circulation and tonsils of IgAN patients and controls were stimulated with LIF. Levels of secreted IgA1 and Gd-IgA1 were determined by ELISA. LIF/gp130 signaling pathways were analyzed by Western blotting, and the role of signaling pathways induced by LIF in Gd-IgA1 production was confirmed by using siRNA knock-down.

Results: LIF increased production of Gd-IgA1 in cells from the circulation and tonsils of IgAN patients but not in those from controls. STAT1 phosphorylation (Y705) induced by LIF was enhanced in cells from the circulation and tonsils of IgAN patients compared to those from controls. siRNA knock-down confirmed the central role of LIF/gp130/STAT1 signaling pathway in the enhanced production of Gd-IgA1 ($p<0.05$).

Conclusions: IgA1-secreting cells from IgAN patients responded abnormally to stimulation by LIF, a cytokine encoded in an IgAN-associated locus identified by GWAS. This abnormal signaling enhanced production of Gd-IgA1, the key autoantigen in IgAN.

TH-PO329

The Level of IgA Antibodies to Endothelial Cells Correlate with Histological Evidence of Disease Activities in Patients with Lupus Nephritis

Ayako Kondo,[1] Kazuo Takahashi,[1] Tomohiro Mizuno,[2] Daisuke Hirano,[1] Shin'ichi Akiyama,[3] Hiroki Hayashi,[1] Shigehisa Koide,[1] Hiroshi Takahashi,[1] Midori Hasegawa,[1] Yoshiyuki Hiki,[4] Shunji Yoshida,[1] Keiji Miura,[5] Yukio Yuzawa.[1] *[1]Fujita Health Univ School of Medicine, Toyoake, Japan; [2]Meijo Univ, Nagoya, Japan; [3]Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [4]Fujita Health Univ School of Health Sciences, Toyoake, Japan; [5]Fujita Health Univ Inst of Comprehensive Medical Science, Toyoake, Japan.*

Background: Although anti-endothelial cell antibodies (AECA) have been frequently detected in patients with systemic lupus erythematosus (SLE), their pathological role remains unclear. Because antigens expressed on the endothelial cell (EC) surface are pivotal for autoimmune reactions, methods that detect antibodies only to EC surface molecules are required. Therefore, we developed a solubilized cell surface protein capture enzyme-linked immunosorbent assay (CSP-ELISA) that is able to detect antibodies against membrane proteins.

Methods: Sera from 51 patients with biopsy-proven lupus nephritis (LN), 25 with SLE without renal involvement (non-LN SLE), 10 disease controls (DC) and 80 healthy controls (HC) were tested for IgG- and IgA-AECA to human umbilical vein EC (HUVEC) or human glomerular EC (HGEC) by CSP-ELISA.

Results: Titers of IgG- and IgA- AECA were significantly higher in LN and non-LN SLE patients than in the combined DC and HC ($P < 0.001$) groups. The significant correlation of titer of AECA to both HGEC and HUVEC indicated AECA in LN patients recognize membrane proteins expressed on HGEC and HUVEC. The level of IgG-AECA did not correlate with active lesions defined by ISN/RPS classification, but the level of IgA-AECA did correlate with histological evidence of active lesions in LN patients ($P < 0.001$). The level of IgA-AECA correlate with the presence of endocapillary hypercellularity and fibrinoid necrosis ($p < 0.001$). The sensitivity as diagnostic test of IgA-AECA for histological evidence of active lesions in LN patients was 0.92, with specificity 0.72.

Conclusions: The significant correlation of IgA-AECA to endocapillary hypercellularity indicate IgA-AECA is observed to be associated with endothelial damages in LN.

Novel Nephritogenic Goodpasture Autoantibodies Target Accessible Quaternary Epitopes of α345(IV) Collagen in Patient Kidneys

Dorin-Bogdan Borza,[1] Florina Olaru,[2] Wentian Luo,[2] Charles E. Alpers.[3] *[1]Meharry Medical College, Nashville, TN; [2]Vanderbilt Univ, Nashville, TN; [3]Univ of Washington, Seattle, WA.*

Background: Goodpasture (GP) disease is a severe autoimmune glomerulonephritis mediated by IgG autoAbs that bind to the GBM. Serum GP autoAbs mainly target two epitopes on α3NC1 monomers which are relatively inaccessible in cross-linked α345NC1 hexamers, the native form of the GP autoantigen in the GBM. Though anti-α3NC1 autoAbs are found in patient kidneys, whether they alone are sufficient to cause nephritis is not clear. In a classic study, GP autoAbs eluted from patient kidneys induced severe nephritis and death in monkeys, while serum autoAbs caused mild transient nephritis, despite linear fixation to the GBM. We tested the hypothesis that some GP autoAbs that bind in the kidney and cause nephritis are different from circulating autoAbs.

Methods: We analyzed the specificity of kidney-eluted autoAbs from three GP patients who developed fatal glomerulonephritis. Transgenic mice expressing human α3(IV) collagen were used for in vitro binding studies and passive immunization experiments.

Results: In one GP patient, kidney-eluted autoAbs bound to native α345NC1 hexamers, with minimal binding to α3-α5NC1 monomers, though anti-α3NC1 autoAbs were found in serum. In other two patients, kidney-eluted autoAbs bound both α3NC1 monomers and α345NC1 hexamers. Further analyses of eluted autoAbs identified two subsets with distinct properties. One bound to α3NC1 monomers but not to cross-linked α345NC1 hexamers nor to the native GBM, similar to classical serum GP autoAbs. Another bound to cross-linked α345NC1 hexamers and the native GBM, but not to α3NC1 monomers.

Conclusions: A novel type of anti-GBM autoAbs, recognizing quaternary epitopes present in α345NC1 hexamers but not NC1 monomers, was identified in the kidneys of GP patients. The hallmark feature of these autoAbs was the accessibility of their epitopes in the native GBM, in contrast to classical GP anti-a3NC1 autoAbs. GP autoAbs to quaternary a345NC1 epitopes can mediate nephritis in the absence of anti-a3NC1 autoAbs, though the severity of nephritis is likely exacerbated when both types of autoAbs are present in the GBM.

Moesin Is a Target of Autoantibodies in Proliferative Lupus Nephritis

Dawn J. Caster,[1] Erik Korte,[1] Ryan M. Sheehan,[1] Rachel Therese G'Sell,[1] Jon B. Klein,[1,2] Michael Merchant,[1] Michelle T. Barati,[1] Brad H. Rovin,[3] Daniel J. Birmingham,[3] Bahram Namjou,[4] Kenneth R. McLeish,[1,2] David W. Powell.[1] *[1]Medicine, Univ of Louisville, Louisville, KY; [2]VAMC, Louisville, KY; [3]Medicine, Ohio State Univ, Columbus, OH; [4]Pediatrics, Cincinnati Children's Hospital, Cincinnati, OH.*

Background: The mechanisms by which nephritogenic antibodies are generated in SLE and the basis for their deposition in the glomerulus are unclear. The present study tests the hypothesis that autoantibodies to native glomerular antigens contribute to the development of lupus nephritis (LN).

Methods: Human podocyte membrane extracts and human glomerular extracts were separated by SDS-PAGE and immunoblotted with sera from patients with proliferative LN (Class III and IV), membranous LN (Class V), SLE without nephritis, and normal individuals. Proteins in the MW regions corresponding to bands reactive with the LN samples were characterized by LC-MS/MS.

Results: Patients with LN demonstrated a reactive band at approximately 50 kDa in the podocyte membrane extracts and between 43-46 kDa in the glomerular extracts. LC-MS/MS of those bands identified 296 proteins from podocytes and 351 proteins from glomeruli. Bioinformatic analysis of those proteins determined that 68 podocyte proteins and 94 glomerular proteins were plasma membrane-associated. Of those plasma membrane-associated proteins, 14 were common to both the podocytes and glomeruli, including proteins previously implicated in autoimmune diseases: annexin A2, heat shock protein 60, alpha enolase, and moesin. Sera from patients with proliferative LN contained significantly increased anti-moesin IgG by ELISA, compared to the other groups ($p < 0.01$). IHC of kidney biopsies from patients with proliferative LN showed increased moesin expression along glomerular capillaries, compared to normal controls.

Conclusions: We conclude that moesin may be a target for glomerular autoantibody deposition in proliferative LN. Quantitative serum anti-moesin levels may be a useful biomarker for proliferative LN.

TH-PO332

The CKD Biomarkers Consortium Differentiating Treatment Responders from Non-Responders Using Biomarkers Identified from the Molecular Analysis of Lupus Nephritis Kidney Biopsies Samir Parikh,[1] Huijuan Song,[1] Paul L. Kimmel,[3] John W. Kusek,[3] Jianying Zhang,[1] Lianbo Yu,[1] Ana Malvar,[2] Brad H. Rovin.[1] *[1]Nephrology and Biostatistics, Ohio State Univ Medical Center, Columbus, OH; [2]Nephrology and Pathology, Hospital Fernandez, Buenos Aires, Argentina; [3]NIDDK, NIDDK, Bethesda, MD.*

Background: The molecular events occurring within the kidney during treatment of lupus nephritis (LN) are unknown. This work evaluated whether complete treatment responders (CR) and non-responders (NR) could be distinguished by differences in renal gene expression at diagnostic (Bx1) and repeat kidney biopsy (Bx2).

Methods: The expression of 511 immune-response genes was determined in kidney biopsies from 19 patients with proliferative LN and 4 normal controls using Nanostring technology. Biopsies were done at LN flare, and after completion of induction therapy. The median interval between biopsies was 8 (6-28) months. Using clinical criteria, 5 patients achieved CR, 10 achieved partial remission (PR) and 4 had NR. After normalization, a linear mixed model and paired t-test was used to compare transcript expression at baseline and between biopsies respectively. A 2-fold difference between transcript levels and p-value < 0.01 was required for differential expression. RT-PCR was used to validate selected transcripts.

Results: At Bx1, principal components analysis demonstrated complete segregation of CR from NR and normal controls from all LN. Interferon alpha, T and B cell signaling, and interleukin 10 pathways were activated in NR while apoptotic and T-cell regulatory pathways were activated in CR. A three gene signature differentiated CR from NR over the course of induction therapy. Neural cell adhesion molecule 1 (NCAM-1) and interleukin 28 (IL-28) increased 3-fold in CR compared to NR between Bx1 and Bx2 ($P<0.007$), whereas interleukin 17 (IL-17) decreased 65% in CR compared to NR ($P<0.004$).

Conclusions: These data suggest that the molecular profile of a responder is different than a non-responder at flare. The molecular analysis of the kidney biopsy at LN flare may be useful in predicting treatment response. For non-responders, response rates may improve through therapies that decrease IL-17 or increase NCAM-1 and/or IL-28.

Circulating Apoptotic Cell-Derived Microparticles Drive the Activation of Blood Dendritic Cell Subsets in Systemic Lupus Erythematosus Patients Jurgen Dieker,[1] Jurjen Tel,[2] Elmar Pieterse,[1] Astrid Thielen,[1] Marinka Bakker-van Bebber,[1] Jo H.M. Berden,[1] Jolanda De Vries,[2] Luuk Hilbrands,[1] Johan Van der Vlag.[1] *[1]Dept of Nephrology, Radboud UMC, Nijmegen, Netherlands; [2]Dept of Tumor Immunology, Radboud UMC, Nijmegen, Netherlands.*

Background: Persistent circulation of chromatin-containing apoptotic material and/or neutrophil extra cellular traps (NETs) has been proposed as an important driving force of the anti-chromatin autoimmune response in patients with systemic lupus erythematosus (SLE).

Methods: We analyzed microparticles isolated from plasma of SLE patients or healthy subjects, and assessed their effect on human blood-derived dendritic cells (DCs) and neutrophils.

Results: In SLE patients, we identified microparticles highly positive for annexin V and apoptosis-modified chromatin, not present in healthy subjects. These were mostly $CD31^+$/$CD45^-$ (endothelial), partially $CD45^+$/$CD66b^+$ (granulocyte), and negative for B and T cell markers. Microparticles isolated from plasma of SLE patients increased the expression of co-stimulatory surface molecules and production of pro-inflammatory cytokines in blood-derived plasmacytoid DC (pDCs) and myeloid DCs (mDCs). SLE microparticles also enhanced NETosis in blood-derived neutrophils. Microparticles from healthy subjects exhibited no significant effects on mDCs, pDCs and NETosis.

Conclusions: Concluding, circulating microparticles in SLE patients include a population of apoptotic cell-derived microparticles, not present in healthy subjects, which has pro-inflammatory effects on pDCs and mDCs, and enhance NETosis. These results underline the important role of apoptotic microparticles in driving the autoimmune response in SLE patients.

Treg17 Cells Are Programmed by Stat3 to Mediate Lupus Nephritis Malte A. Kluger, Simon Melderis, Matthias C. Meyer, Michael Luig, Boeren Goerke, Rolf A. Stahl, Ulf Panzer, Oliver M. Steinmetz. *III. Med. Klinik, Univ Hospital Eppendorf, Hamburg, Germany.*

Background: Th17 cells are central mediators of glomerulonephritis. The mechanisms underlying their counter regulation are largely unknown. We recently showed that Th17 specific regulatory T cells (Treg17) which depend on activation of Stat3 are mediators of acute crescentic GN. It is unknown to date whether they also play a role in chronically developing forms of nephritis. We therefore studied the function of Treg17 in the pristane model of lupus nephritis (LN).

Methods: Specific deletion of Stat3 was achieved using Foxp3Cre and CD4Cre x Stat3fl/fl mice. LN was induced by i.p. injection of pristane and peritoneal immunity was assessed at 1 week. Renal histology and function as well as systemic immunity were studied at 9 months.

Results: Foxp3Cre x Stat3fl/fl mice lacking Treg17 cells showed selectively enhanced peritoneal Th17 inflammation one week after induction of LN. In line, after 9 months, systemic immune responses were skewed towards Th17. Importantly, Foxp3Cre x Stat3fl/fl mice showed much greater mortality, as well as aggravated nephritis in terms of histology and inflammatory cell infiltration. Aggravation of disease was independent of humoral immune responses as shown by unchanged systemic autoantibody production as well as renal antibody and complement deposition. However, while analyses of systemic Tregs revealed unchanged numbers and percentages, renal Treg infiltration was strikingly reduced. FACS analyzes of renal Tregs from nephritic Foxp3Cre x Stat3fl/fl mice revealed near abscence of the trafficking receptor CCR6 which was abundantly expressed on wildtype Tregs. Importantly, the observed aggravation of disease was completely reversible in the absence of Th17 responses as shown at 9 months after LN induction in CD4Cre x Stat3fl/fl mice which lack not only Treg17 but also Th17 cells.

Conclusions: Our data indicate a protective role of Stat3 induced Treg17 cells in chronic lupus nephritis. Treg17 cells specifically target nephritogenic Th17 responses by using the chemokine receptor CCR6.

Deficiency for TNF Receptor 2 and TNF Receptor 1 and 2 Accelerates Autoimmunity and Lupus Nephritis in Lupus-Prone MRL-Fas/lpr Mice John M. Hoppe, Anela Taubitz, Nuru Eltrich, Volker Vielhauer. *Nephrologisches Zentrum, Medizinische Klinik und Poliklinik IV, Ludwig-Maximilians-Univ, Munich, Germany.*

Background: Tumor necrosis factor (TNF) contributes to organ damage in systemic lupus erythematosus (SLE). However, experimental data from SLE-prone mice and clinical experience in humans demonstrate that TNF is both a potent proinflammatory mediator, and an immune regulator limiting autoimmunity. This has prevented the successful implementation of TNF blocking therapies in SLE. The pleiotropic functions of TNF may be differentially mediated by the two TNF receptors TNFR1 and TNFR2. We therefore investigated the role of these receptors in lupus-prone MRL-*Fas*^{lpr} mice, in which inflammatory organ disease correlates with induced levels of TNF.

Methods: We generated MRL-*FAS*^{lpr} mice genetically deficient in TNFR1, TNFR2, or both receptors and phenotypically characterized these mice until 24 weeks of age.

Results: TNFR1-deficiency in MRL-*FAS*^{lpr} mice did not alter systemic autoimmunity or renal injury compared to wild-type littermates, despite a significantly increased formation of intrarenal extranodular lymphoid tissue with increased expression of cytokines and chemokines. In contrast, TNFR2- and particularly TNFR1,2 double-deficient MRL-*FAS*^{lpr} mice were characterized by accelerated autoimmunity, as revealed by increased mortality, more severe lymphoproliferation, higher anti-Sm autoantbody titers, increased renal accumulation of autoimmune CD4-CD8- T lymphocytes, and a reduced apoptotic rate in intrarenal lymphoid tissue. Proteinuria was more severe in TNFR1,2 double-deficient mice. Renal histology revealed exacerbated glomerular injury in TNFR2- and TNFR1,2-deficient MRL-*FAS*^{lpr} mice, and increased glomerular and tubulointerstitial infiltration of T cells in TNFR1,2-deficient mice. Renal expression of the proinflammatory cytokines IL-6 and IL-17A was increased in TNFR2- and TNFR1,2-deficient mice.

Conclusions: Our data demonstrate that selective deficiency of TNFR1 or 2 is not protective in lupus of MRL-*FAS*^{lpr} mice, but that TNFR2 and TNFR1 and 2 deficiency accelerates autoimmunity and organ damage.

Anti-Perlecan Antibodies in Murine Lupus Nephritis Luc Pomerleau, Melanie Dieude, Katia Hamelin, Julie Turgeon, Marie-Josee Hebert, Guillaume Bollee. *Centre de Recherche du Centre Hospitalier de l'Univ de Montreal, Montreal, QC, Canada.*

Background: LG3 is a proteolytic fragment of perlecan released by apoptotic endothelial cells. Autoantibodies reactive to LG3 were identified in renal transplant recipients with acute vascular rejection. In a mouse model, passive transfer of anti-LG3 antibodies enhanced vascular rejection. Lupus nephritis is closely associated with endothelial injury and immune-mediated injury to the glomerular capillaries. Here, we sought to explore the association between anti-LG3 antibodies and the progression of murine lupus nephritis.

Methods: Serum anti-LG3 titers and urinary excretion of LG3 were monitored from early to advanced stages of glomerular injury (21, 27 and 32 weeks) in NZB/W F1 mice, a common model of lupus nephritis. C57Bl6 mice were used as controls. Urinary excretion of LG3 was measured by Western blot and normalized to urine creatinine. Anti-LG3 titers were measured by ELISA. Urine albumin to creatinine ratios was also measured at 21, 27 and 32 weeks. At 32 weeks, mice were sacrified and renal histology was analyzed.

Results: At 21 weeks of age, NZB/W F1 mice showed no increase in albuminuria, LG3 was not detected in urine and anti-LG3 titers were similar in NZB/W F1 and controls. At 27 weeks, albuminuria was significantly higher in NZB/W F1 than controls. At 32 weeks, NZB/W F1 mice showed increased blood urea nitrogen, high-grade albuminuria and glomerular crescents. Serum anti-LG3 titers gradually increased in parallel with progression of glomerular injury and were significantly increased in NZB/W F1 mice compared to controls at 27 and 32 weeks ($n=5$-8 per group, $p<0.05$). At 32 weeks, LG3 was detected in the urine of NZB/W F1 mice but not in controls ($n=5$ per group, $p<0.05$).

Conclusions: We observed a progressive increase in serum anti-LG3 titers that parallels development of murine lupus nephritis. This suggests that LG3 released secondary to immune-mediated vascular injury induces the production of anti-LG3 antibodies, which

may aggravate glomerular microvascular injury, therebyleading to a vicious circle. Further studies are warranted to characterize the significance of urinary LG3 excretion and anti-LG3 antibodies in lupus nephritis.

TH-PO337

Different Glycosylation Patterns Influence the Physiological and Pathological Functions of Myeloperoxidase Jia Wang, Zhao Cui, Jian-Nan Li, Ming Hui Zhao. *Renal Div, Dept of Medicine, Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.*

Background: Myeloperoxidase (MPO) has been proven to be pathogenic in anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis. It also acts as bactericidal agent by catalyzing the production of hypochlorous acid, and hence reactive oxygen species, from hydrogen to peroxide and chloride ions. MPO has five N-linked glycosylation sites on its two heavy chains, which are occupied by either complex or high mannose structures. The effect of glycosylation pattern to the functions of MPO is barely known.

Methods: We used different glycosidases to remove different glycans on MPO molecule separately, including the innermost GlcNAc, alpha 2,3, alpha 2,6 and alpha 2,8-linked sialic acid, branched terminal fucose, β-D-galactopyranoside, β-linked mannose, α1-2 and α1-3 linked D-mannopyranosyl, unbranched α1-6 linked D-mannopyranosyl, and chitobiose core.

Results: Compared to MPO treated in the absence of glycosidases, there was a significant decrease in chlorination activity of MPO treated with glycosidases, in which the removal of D-galactopyranoside (0.35±0.02 versus 0.50±0.04, P<0.001) and alpha-linked sialic acid (0.35±0.02 versus 0.50±0.04, P<0.001) presented the most remarkable decline. Deglycosylation could reduce the binding between MPO and its physiological inhibitor-ceruloplasmin, with the most significance on the removal of innermost GlcNAc at the asparagine residues of MPO (0.37±0.04 versus 1.06±0.11, P<0.001). The binding between MPO and ceruloplasmin was hardly reversed by MPO-ANCA after deglycosylation to MPO, especially the removal of innermost GlcNAc at the asparagine residues (0.38±0.03 versus 0.12±0.04, P=0.002) and alpha-linked sialic acid (0.28±0.03 versus 0.12±0.04, P=0.009).

Conclusions: Different glycosylation patterns might influence the physiological and pathological functions of MPO, which deserved consideration in the investigations of ANCA-associated vasculitis pathogenesis.

Longitudinal Measurement of PR3 and MPO mRNA Levels in a Large Cohort of Patients with ANCA Disease Reveals That Increased Expression Per Neutrophil Correlates with Disease Activity Jia Jin Yang,[1] Caroline J. Poulton,[1] Candace Henderson,[1] Elizabeth J. Brant,[1] Britta E. Jones,[1] Elizabeth Alderman McInnis,[1] J. Charles Jennette,[2,1] William Franklin Pendergraft,[1] Ronald J. Falk,[1,2] Dominic J. Ciavatta.[3,1] *[1]Medicine, UNC-CH; [2]Pathology, UNC-CH; [3]Genetics, UNC-CH, Chapel Hill, NC.*

Background: We have demonstrated up-regulation of autoantigen genes in mature neutrophils and monocytes from patients with ANCA disease (J Am Soc Nephrol 2004, 15:2103-14). Here, we investigated levels of autoantigen gene expression in ANCA-patients during the disease course.

Methods: A total of 1270 samples were collected from 318 ANCA-patients during various stages of disease activity from 1999 to 2014. Levels of PR3 and MPO gene transcripts were determined by quantitative PCR, compared to calibrator samples and expressed as number of positive cells in 10^4 total cells.

Results: PR3 (n=1270, 158±515, p<0.0001) and MPO (387±937, p<0.0001) mRNA levels were significantly up-regulated in leukocytes from ANCA patients compared to healthy donors (n=135, PR3:16±36; MPO:56±56). Levels of PR3 and MPO gene transcription were closely correlated with disease activity during the disease course. PR3 (n=511, 246±648, p<0.0001) and MPO (556±1151, p<0.0001) mRNA levels were statistically elevated during active disease and reduced during remission (PR3: 96±394; MPO: 258±702). The mRNA test had a higher specificity than ANCA titer because ANCA titer was not decreased in some patients when remission was achieved. PR3 and MPO gene expression was affected by treatment (e.g. temporarily decreased with pulse corticosteroids; increased with rituximab). Higher absolute neutrophil counts, seen in 62% of active patients, did not explain increased PR3 and MPO gene expression, as expression per neutrophil was significantly higher in patients with increased expression (n=210, PR3:86±250, p<0.0001; MPO:163±306, p<0.0001) than that in patients with normal expression (n=236, PR3:3±3; MPO:15±8).

Conclusions: Active ANCA patients have significantly increased PR3 and MPO gene transcription per neutrophil that correlates with activity status during the course of disease and suggests that this aberrant expression is involved in the pathogenesis of ANCA disease.

TH-PO339

Serum Antibodies against Linear Peptides of Myeloperoxidase Were Identified in over Half Patients with Anti-Glomerular Basement Membrane Disease and Were Associated with Disease Severity Jian-Nan Li,[1] Zhao Cui,[1] Ming Hui Zhao.[1,2] *[1]Renal Div, Dept of Medicine, Peking Univ First Hospital; [2]Peking-Tsinghua Center for Life Sciences.*

Background: Some patients with anti-glomerular basement membrane (GBM) disease had coexisting anti-neutrophil cytoplasmic antibodies (ANCA), especially anti-myeloperoxidase (MPO) antibodies. Our previous study indicated that most sera from double positive patients recognized c-terminus of MPO heavy chain (H1, $MPO_{279-409}$). This study investigated the frequency of antibodies against overlapping linear peptides derived from H1 and intact MPO, in sera from patients with anti-GBM disease.

Methods: Sera from 76 patients with anti-GBM disease were collected on diagnosis. Thirteen overlapping linear peptides (H1-1~H1-13) covering $MPO_{279-409}$ were synthesized. IgG antibodies were screened from the 76 sera by ELISA using intact human MPO and the overlapping pepetides as solid phase ligands, respectively. Their clinical significance was further investigated.

Results: Of the 76 patients with anti-GBM disease, sera from 17 (22.4%) patients recognized intact human MPO, while, sera from 48 (64%) patients recognized linear peptides of $MPO_{279-409}$. No cross-reaction was detected among antibodies against α3(IV) NC1, linear peptides and intact MPO. Of the thirteen linear peptides, H1-4 (40.8%) and H1-12 (42.1%) had the highest recognition frequencies. Patients with antibodies against linear peptides presented with older age than those without the antibodies (58.4±15.1 versus 35.9±15.9 years; P=0.008). In comparison with the patients without antibody against H1-11~12, patients with antibodies against H1-11~12 showed significantly higher serum creatinine at the time of diagnosis [645.0 (378.5-1037.0) versus 464.5 (200.8-645.3) μmol/L, P=0.02], had significantly higher probability for progressing to ESRD (HR 2.22; 95% CI 1.08-4.58; P=0.031), and recognized significantly more types of linear peptides [0 (0-1) versus 4 (2.0-8.5), P<0.001].

Conclusions: Antibodies against linear peptides of MPO can be detected in majority of patients with anti-GBM disease and some were associated with disease severity, implying a common pathogenic mechanism of anti-GBM antibody and MPO-ANCA.

TH-PO340

The High Binding Affinity of HLA-DRB1*0405 and MPO Epitope aa 447–459 Determines the Poor Prognosis of ANCA Disease Yali Cao. *Nephrology, China-Japan Friendship Hospital, Beijing.*

Background: The HLA system plays a central role in the distinction between self antigens and non-self antigens. It has been demonstrated that DRB1*0405 is an independent risk factor for the poor response to treatment and the deterioration of renal function in Chinese patients with ANCA disease. MPO-ANCA reactive with MPO epitope aa 447–459 (RKIVGAMVQIITY) are exclusively associated with active disease.We asked if DRB1*0405 could be involved in antigen presentation and predict the prognosis.

Methods: Capture ELISAs were used to detect the bind affinity of MPO447–459 and DRB1*0405. Flow cytometry and immunofluorescence staining were used to identify the bind of MPO447–459 and DRB1*0405 on the surface of neutrophil.

Results: Capture ELISAs demonstrated MPO447–459 bound DRB1*0405 with high affinity. Neutrophils of healthy individuals are reported to contain cytoplasmic reservoirs of MHC II (DR) antigen. MHC II surface expression is detected on neutrophils of patients with active ANCA disease but not on neutrophils of patients with inactive disease.We asked if surface-expressed DRB1*0405 would bind MPO447–459 peptides. Surface expression of DRB1*0405 was detected in patients with activie disease who were genotyped as DRB1*0405,*0405. Surface-expressed DRB1*0405 protein bound MPO447–459, consistent with in vitro binding studies. With the remmission of ANCA disease, DRB1*0405 was undetectable and the surface binding was decreased. In contrast, neutrophils from a patient expressing DRB1*01,*14 and one expressing DRB1*03,*15 molecules were found not to bind MPO447–459. Specificity of MPO447–459 binding was verified by a competition study. Biotinylated MPO447–459 binding was decreased with increasing concentrations of nonbiotinylated peptide (54 to 12%). Flow cytometry data were validated by immunofluorescence staining.

Conclusions: These data indicate that DRB1*0405 molecules expressed on the surface of neutrophils are capable of binding certain pathogenic antigenic-MPO peptide that results in presentation to and activation of T cells. Taken together, the study suggest HLA-DRB1*0405 alleles might contribute to the pathogenesis of MPO-ANCA disease and determine the poor disease prognosis.

TH-PO341

Proteinase-3 T Cell Epitope Mapping in Systemic Vasculitis Vincent P. O'Reilly,[1] Simone A. Scollard,[2] Alice M. Coughlan,[1] Conleth F. Feighery,[2] Mark Alan Little.[1] *[1]Trinity Health Kidney Centre, Dublin, Ireland; [2]Dept of Immunology, Trinity College Dublin, Dublin, Ireland.*

Background: Granulomatosis with polyangiitis (GPA) is a severe autoimmune vasculitis that affects multiple organ systems and is characterised by antibodies against proteinase-3 (PR3). T cells are required for antibody class switching and secretion by plasma cells, suggesting a role for autoreactive T cells specific for PR3. Autoreactive T cells are present in healthy individuals where they are tightly supressed by regulatory T cells. Although much is known about the PR3 B cell epitope, specific T cell responses have not been defined.

Methods: We performed *in silico* analysis in an attempt to predict which PR3 peptide sequence best fitted the HLA-DP binding groove. Then, control and patient PBMCs or T-reg depleted CD4+ sorted T cells were stimulated with whole PR3 protein or 8 pools of linear 20-mer PR3 peptides. Proliferation was measured by tritiated thymidine incorporation or CellTrace loss. Cytokine responses (IL-6 secretion) were assessed with ELISA.

Results: In silico analysis predicted binding of amino acids 222-242 to HLA-DP. 44% and 0% of GPA patients and controls respectively showed reactivity to whole heat inactivated PR3 (p<0.05); only patients that were ANCA positive at the time of the assay showed proliferation. Monocytes pulsed with pool 7 peptides (AA 193-236) stimulated most CD4+ T cell proliferation (1.7X increase over vehicle). Pool 7 also stimulated secretion of IL-6

from the T cell monocyte co-cultures (2.6X increase over vehicle). An even stronger IL-6 signal (6.5-fold increase over vehicle) was observed in GPA patient co-cultures stimulated with pool 7, which included the predicted peptide sequence adjacent to the catalytic triad.

Conclusions: PBMCs from GPA patients proliferate in response to PR3 stimulation. T-reg depleted CD4+ cells from healthy controls respond to linear peptides of PR3, with a peptide binding sequence adjacent to the catalytic triad being the most likely candidate for key T cell epitope.

TH-PO342

Monocyte Subsets and Their Role in ANCA Vasculitis Eóin O'Brien, Mark Harrington, Mark Alan Little, Fionnuala B. Hickey. *Clinical Medicine, Trinity College Dublin, Dublin, Ireland.*

Background: Anti-neutrophil cytoplasm autoantibody (ANCA)-associated vasculitis (AAV) is an autoimmune condition affecting the microvasculature. It is the leading cause of rapid, progressive glomerulonephritis which leads to loss of kidney function. The autoantibodies are primarily directed against myeloperoxidase (MPO) or proteinase-3 (PR3), proteins expressed mainly in neutrophils and monocytes. Much of the research to date has been directed on the role of neutrophils with little research into the role monocytes play in disease. Similar to other immune cells, monocytes can be divided into subsets based on their inflammatory phenotype. These are categorised as Classical, Intermediate and Non-Classical, with non-classical being the most pro-inflammatory. The purpose of this study was to investigate the role of specific monocyte subsets in AAV.

Methods: Blood was obtained from AAV patients (active disease and remission), healthy donors and control individuals with other forms of kidney disease. Flow cytometry was used to evaluate the proportions of each subtype of monocyte (based on cell-surface expression of CD14 and CD16) and the amount of MPO or PR3 expressed on their surface. In order to investigate the effect of ANCA on monocytes, sorted monocytes were treated with patient ANCA, or with monoclonal antibodies (mAb) directed against MPO or PR3 and IL-1β production was measured by ELISA and Western blot. IL-1β in serum from patients and control individuals was measured by ELISA.

Results: This study indicates that in patients with active AAV, MPO and PR3 antigens are expressed on the cell surface of a higher proportion of monocytes compared to patients in remission. In addition we demonstrate that in these patients, MPO and PR3 are preferentially expressed on the more pro-inflammatory cells, (intermediate and non-classical). We also report that incubation of monocytes from control individuals with patient ANCA or mAb against MPO results in increased IL-1β production indicating inflammasome activation by ANCA. IL-1β was also detected in the serum of patients.

Conclusions: In summary, these data implicate a key role for monocytes as targets of autoantibodies in the pathogenesis of ANCA vasculitis.

TH-PO343

Soluble CD163 Level as a Biomaker of Active Disease in Systemic Vasculitis Limy Wong,[1] Claire Kennedy,[1] Vincent P. O'Reilly,[1] Louise Ann Elliott,[2] Alice M. Coughlan,[1] Paul O'Hara,[1] Fionnuala B. Hickey,[1] Emma Connolly,[1] Conleth F. Feighery,[1] Anthony M. Dorman,[4] Sarah Margaret Moran,[3] Michael Clarkson,[3] George S. Mellotte,[1] Mark Alan Little.[1] *[1]Trinity Health Kidney Centre; [2]Immunology, Trinity College Dublin; [3]Cork Univ Hospital; [4]Pathology, Beaumont Hospital.*

Background: A sensitive and specific biomarker to distinguish small vessel vasculitis (SVV) from mimics and infection, and to identify those at risk of relapse is lacking. We hypothesised that urinary and serum sCD163, which is upregulated in inflammation, mirror disease activity in SVV.

Methods: Using the Rare Kidney Diseases (RKD) Biobank, 323 urine and 420 serum samples from patients with SVV, disease controls (DC) and healthy controls (HC) were assayed for sCD163 by ELISA. Clinical data were derived from the linked RKD registry. Immunohistochemistry and rtPCR were performed on renal tissue from patients with SVV and from rats with MPO-ANCA vasculitis.

Results: Urinary sCD163 levels were significantly higher in those with active SVV (3.7±0.5ng/mL) than DC (1.4±0.4ng/mL), HC (0.6±0.02ng/mL) and SVV in remission (0.9±0.1ng/mL). The level was highest in active anti-GBM disease (17.6±9.4ng/mL). In SVV, only those with active renal disease displayed elevated levels (6.7±1.6); those with active extra-renal disease were indistinguishable from all control groups (0.7±0.1). Serum sCD163 levels were not significantly different in patients with SVV (332± IQR 240 to 528ng/mL) and DC (298,IQR 236 to 475ng/mL) or HC (287, IQR 226 to 463ng/mL); the highest serum sCD163 levels were observed in those with active anti-MPO disease (482, IQR 335 to 745ng/mL) and untreated SVV (518,IQR 324 to 1039ng/mL). There was no correlation between serum and urinary sCD163. CD163 was not detectable in rodent MPO-ANCA vasculitis kidney lesions, but was heavily expressed in the vascular adventitia of renal vessels. In human renal tissue, the degree of glomerular CD163 expression was tightly correlated with urine but not serum levels.

Conclusions: Urinary sCD163 associates very tightly with active renal vasculitis and provides a non-invasive measure of active vasculitic GN.

TH-PO344

Epigenetic Control of CD177 – A Receptor Presenting the ANCA Antigen Proteinase 3 Claudia Eulenberg, Sylvia Bähring, Friedrich C. Luft, Ralph Kettritz. *Experimental and Clinical Research Center, Charité Medical Faculty and the Max-Delbrück Center for Molecular Medicine, Berlin, Germany.*

Background: Proteinase 3 is the major ANCA antigen in granulomatosis with polyangitis (GPA). PR3-ANCA binding to membrane-expressed PR3 (mPR3) is a key event for neutrophil activation and subsequent necrotizing vasculitis. The neutrophil-specific CD177 receptor enables $mPR3^{high}$ expression on a neutrophil subset ($CD177^{pos}/mPR3^{high}$). ANCA patients show a higher percentage of $CD177^{pos}/mPR3^{high}$ neutrophils compared to healthies and the higher the percentage the worse the clinical disease course. We reported previously that CD177 protein and mRNA expression is restricted to $CD177^{pos}/mPR3^{high}$ neutrophils with a random monoallelic mRNA expression pattern. We hypothesized that epigenetic mechanisms control CD177 gene expression.

Results: Using the Infinium HumanMethylation450 BeadChip (Illumina) and cell sorting we found three CpGs in the potential CD177 promotor that were methylated in $CD177^{neg}$, but not in $CD177^{pos}$ cells ($p<0.001$; n=6). We next performed chromatin immunoprecipitation (ChIP) analysis to assess chromatin conformation in the two CD177 subsets. We identified a 75bp region upstream of the ATG that showed H3K4me3 mark (euchromatin) enrichment in $CD177^{pos}$ neutrophils ($p<0.05$; n=4). This putative promotor region contains a TATA box and binding sites for several transcription factors (TF). Finally, we established a $CD34^{+}$ hematopoietic stem cells (HSC) model system that is more suitable than terminally differentiated neutrophils for further studies, such as reporter assays. By haplotype analysis, undifferentiated HSC showed biallelic CD177 mRNA expression with one allele being silenced during neutrophilic differentiation. The resulting monoallelic expression reflected the status observed in neonatal neutrophils from the same cord blood donor.

Conclusions: Together, our data strongly implicate epigenetic mechanisms that are responsible for the generation of distinct CD177/mPR3 neutrophil subsets. Further studies need to identify the transcription factor(s) that control this process.

Drug Bioactivation by Myeloperoxidase and Covalent Binding to Target Proteins: Implications for Drug-Induced Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis Olivier Lardinois,[1] Leesa Deterding,[2] Jacob Hess,[1] Candace Henderson,[1] Ronald J. Falk,[1] William Franklin Pendergraft.[1] *[1]UNC Kidney Center, Dept of Medicine, Univ of North Carolina, Chapel Hill, NC; [2]Mass Spectrometry Group, National Inst of Environmental Health Sciences, Research Triangle Park, NC.*

Background: Drug-induced vasculitis is a serious side effect of certain medications and there is a strong association between drug-induced vasculitis and the formation of anti-neutrophil cytoplasmic autoantibodies (ANCA). The most often implicated drugs are hydralazine, propylthiouracil, and levamisole-adulterated cocaine. The precise mechanism by which these drugs cause vasculitis is still unknown. ANCA in drug-induced vasculitis are most frequently directed against the neutrophil granule enzyme MPO, which generates hypochlorous acid (HOCl). Most drugs that cause vasculitis are low molecular weight substances that can potentially be metabolized by MPO to reactive free radical compounds. We hypothesized that these electrophilic compounds react with MPO or with other target proteins to form hapten adducts that stimulate autoantibody formation. To our knowledge, the presence and specific location of any such drug-adducts on proteins has never been determined.

Methods: Drug-protein adducts were detected and quantified using immunochemical and liquid chromatography-mass spectrometry techniques.

Results: Our analysis revealed that all causal drugs investigated, except for hydralazine, form drug-protein adducts after in vitro exposure to HOCl and are bioactivated to reactive metabolites by MPO. We also detected intense adduct trapping in proteins exposed first to acrolein, an aldehyde product of endogenous lipid peroxidation, and then to hydralazine. Hydralazone derivatives formed during these reactions are sufficiently stable to unequivocally identify sites of adduction on proteins by liquid chromatography-tandem mass spectrometry.

Conclusions: All offending drugs investigated here have a high propensity to form adducts with proteins. Some derivatives formed during these reactions show strong structural similarities to that of other chemicals found in the environment, including pesticides.

Reduced $IL\text{-}10^{+}$ Regulatory B Cells in Patients with Active ANCA-Assoiated Vasculitis (AAV) Permit Increased Circulating Autoantibodies Lydia Aybar, JulieAnne G. McGregor, Susan L. Hogan, Yichun Hu, Carmen E. Mendoza, Elizabeth J. Brant, Caroline J. Poulton, Candace Henderson, Ronald J. Falk, Donna O. Bunch. *Nephrology and Hypertension, UNC, Chapel Hill, NC.*

Background: AAV Pathogenesis is B cell dependent, yet how B cell subsets modulate immunopathogenesis is unknown. Although their phenotype remains controversial, regulatory B cells (Bregs) play a role in immunological tolerance via IL-10.

Methods: We investigated putative $CD24^{hi}CD38^{hi}$ and $CD24^{hi}CD27^{+}$ Bregs, in addition to their $CD5^{+}$ subsets, in 69 patients with AAV. IL-10 production was determined following culture of peripheral blood mononuclear cells with CD40 ligand and CpG DNA.

Results: The $CD5^+$ subset of$CD24^{hi}CD38^{hi}$ B cells, but not $CD24^{hi}CD38^{hi}$ or $CD24^{hi}CD27^+$ B cells, was decreased in patients with active disease relative to patients in remission ($p\leq0.001$) and healthy individuals ($p\leq0.0001$). IL-10^+ B cells were reduced during active disease compared to patients in remission ($p=0.005$) and healthy controls ($p=0.001$). $CD5^+$ B cells produce more IL-10 than $CD5^{neg}$ cells (18% versus 11%). In paired analysis of 9 patients, as IL-10^+, $CD5^+CD24^{hi}CD38^{hi}$ and $CD24^{hi}CD38^{hi}$ B cells increased in disease remission, ANCA titers decreased.

Conclusions: $CD5^+$ $CD24^{hi}CD38^{hi}$ and IL-10-producing B cells similarly decrease in active disease and rebound during remission; $CD5^+$ B cells were enriched in IL-10 production. These data suggest that CD5 may identify IL-10-producing Bregs that malfunction during active disease, resulting in increased ANCA production.

Changing Mast Cell Phenotype with Cromogycate Provides a Novel Therapeutic Strategy to Treat Autoimmune Myeloperoxidase Anti-Neutrophil Cytoplasmic Antibody Associated Glomerulonephritis

Stephen R. Holdsworth, Kim M. O'Sullivan, A. Richard Kitching, Poh-Yi Gan. *Medicine, Monash Univ, Melbourne, Victoria, Australia.*

Background: The aim of the study was to test the hypothesis that cromoglycate can inhibit proinflammatory mast cell (MC) degranulation and enhance modulatory IL-10 synthesis resulting in therapeutic treatment of anti-MPO autoimmunity and glomerulonephritis (GN).

Methods: We compared MC frequency and degranulation status in 48 renal biopsies from patients with MPO-ANCA GN and 10 thin membrane disease (controls). Experimental anti-MPO GN was induced by immunization with MPO and GN triggered by a subnephritogenic dose of anti-GBM globulin. Cromoglycate (or saline control) was administered daily commencing either 2 days before or 10 days after (established disease) immunization.

Results: MCs were prominent in the interstitium of MPO-ANCA GN kidney biopsies (5±0.9 versus 1±0.2 cells/high power field [c/hpf] $p<0.05$) and were mainly degranulated (57±8 versus 0±0% $p<0.0001$) compared with controls. In experimental anti-MPO GN, cromoglycate treatment reduced MC degranulation (5±1 versus 15±4c/hpf $p=0.05$) at the immunization site and significantly reduced DC activation (CD40 and MHC-II expression) in draining lymph nodes. This was associated with significant reduction in anti-MPO autoimmunity (DTH, MPO stimulated T cell proliferation, IFNγ production; 3.6±1.3 versus 13.5±3.7ng/ml $p<0.05$) but increased IL-10 (198±16 versus 124±10pg/ml $p<0.05$). Glomerular injury was significantly reduced (albuminuria and segmental glomerular necrosis; 34±4 versus 62±6% of glomeruli affected $p<0.01$). Cromoglycate treatment of established disease also similarly attenuated GN (segmental glomerular necrosis; 32±4 versus 55±5% $p=0.01$). Cromoglycate effects were MC specific as administration to MC deficient mice developing GN had no effect on autoimmunity or GN. In vitro MPO stimulated proliferation of CD4+ Teffector cells (Teff) from MPO immunized mice was enhanced in the presence of MCs. Addition of cromoglycate to CD4+ Teff and MCs enhanced MC IL-10 production and inhibited Teff proliferation.

Conclusions: Cromoglycate specifically alters MC phenotype from injurious to immunomodulatory in anti-MPO GN and may offer new therapeutic opportunities.

Treatment of Experimental Autoimmune Vasculitis with a SYK Inhibitor

Stephen Paul McAdoo,[1] Anisha Tanna,[1] John P. McDaid,[1] Gurjeet Bhangal,[1] Esteban S. Masuda,[2] H. Terence Cook,[1] Frederick W.K. Tam,[1] Charles D. Pusey.[1] *[1]Imperial College London; [2]Rigel Pharmaceuticals.*

Background: Spleen tyrosine kinase (SYK) is phosphorylated during ANCA-induced neutrophil activation, and thus it represents a potential therapeutic target in AAV. We have shown previously that SYK inhibition with fostamatinib, a selective tyrosine kinase inhibitor, is an effective treatment in experimental models of anti-GBM disease, and that SYK is expressed and activated in human ANCA-GN. We have now studied the effects of SYK inhibition with fostamatinib in a rat model of anti-MPO vasculitis.

Methods: Disease was induced by immunising Wistar Kyoto rats (n=8/group) with the ANCA target antigen, myeloperoxidase (MPO). Disease onset was confirmed by development of haematuria and proteinuria 4 weeks after immunisation, Animals were then treated with vehicle, fostamatinib 20 mg/kg, or fostamatinib 30 mg/kg by twice daily oral gavage from week 4 to 6 and then assessed for disease severity at the end of week 6.

Results: Are shown in the Table below. Reported as median±IQR per group. Comparison by Kruskall Wallis test.

	Vehicle	Fostamatinib 20mg/kg	Fostamatinib 30mg/kg	p value
Proteinuria (mg/day)	2.88 (1.8-6.3)	0.13 (0.0-0.8)	0.23 (0-0.6)	0.0004
Haematuria (au)	3 (2-3)	0 (0-0.4)	0 (0-0.1)	0.0018
Abnormal Glomeruli (%)	12 (3-29)	5 (2-9)	0 (0-6)	0.0262
Macrophages/Glomerulus	1.77 (1.2-2.6)	0.25 (0.2-0.4)	0.2 (0.0-0.4)	0.0004
Serum Creatinine (μmol/l)	54 (52-58)	48 (47-52)	46 (43-47)	0.047
Lung Haemorrhage Score (au)	3 (2-3.8)	1 (0.3-1.8)	0 (0.1-0.4)	0.0001
Lung Haemosiderin Score (au)	3.0 (0.9-4.1)	0.5 (0.2-0.7)	0.2 (0.1-0.4)	0.0087
MPO-ANCA titre (au)	115 (95-160)	95 (75-120)	100 (70-120)	ns

Conclusions: In a preclinical model, SYK inhibition with fostamatinib is an effective treatment for crescentic glomerulonephritis and lung haemorrhage, the life-threatening manifestations of AAV, even after onset of disease. This therapeutic effect was seen at a low dose range of fostamatinib, estimated to be consistent with doses achieved in clinical studies using fostamatinib in non-renal disease. These observations support the potential investigation of targeting SYK in clinical studies of AAV.

TH-PO349

Human PTEC Modulate Autologous B Cell Function

Helen G. Healy,[1] Sandeep Sampangi,[1,2] Andrew J. Kassianos,[1] Xiangju Wang,[1] Sadia Afrin,[1,2] Ray Wilkinson.[1,2] *[1]Renal Medicine Dept, Royal Brisbane and Women's Hospital, Brisbane, Qld, Australia; [2]Inst of Health and Biomedical Innovation, Queensland Univ of Technology, Brisbane, QLD, Australia.*

Background: Research on infiltrating inflammatory cells in the kidney interstitium have, until fairly recently, not examined B cells other than in the specific environment of transplantation. In these reports, B cells, like dendritic cells, are localised almost exclusively within the kidney tubulointerstitium where they would be ideally placed to interact with proximal tubular epithelial cells (PTEC). We have previously reported that activated PTEC are able to down-modulate autologous lymphocyte and dendritic cell function.

Methods: B cells were cultured with autologous PTEC and readouts included proliferation, Ab/cytokine secretion and Ag expression.

Results: PTEC decreased B cell proliferative responses to the mitogen PWM and the TLR agonist R848. Interestingly, autologous PTEC also significantly decreased the number of B cells secreting both IgG and IgM Ab in response to these stimuli and overall levels of Ab production were also decreased. Transwell studies demonstrated that this modulation was primarily contact-dependant and blocking studies with anti-PD-L1 led to partial restoration in Ab production. Further blocking studies against soluble HLA-G and IDO, two other immuno-inhibitory molecules also up-regulated in our activated PTEC, demonstrated minor restoration of Ab responses. B cells cultured in the presence of PTEC displayed increased levels of CD38 but decreased levels of CD27, a marker of B cell blasts and memory cells. Cytokine analysis demonstrated increased levels of B cell-derived immuno-regulatory IL-10 in 75% of donors stimulated with R848 in the presence of PTEC.

Conclusions: We report that PTEC are able to modulate autologous B cell phenotype and function. This modulation is complex as our results demonstrate a contact-dependant component operating though PD-L1 but with other soluble and intra-cellular factors such as sHLA-G and IDO also playing a role. We hypothesize that such mechanisms may have evolved to maintain peripheral immune-homeostasis, especially within the inflammatory milieu that exists within many kidney diseases.

Coronin 1a Deficiency Protects Mice against Anti-Glomerular Basement Membrane Induced Humoral Immune Response

Charlotte Starke, Markus Latk, Bernd Hohenstein, Vladimir T. Todorov, Christian Hugo. *Div of Nephrology, Dept of Internal Medicine III, Univ Hospital Carl Gustav Carus at the Technische Univ Dresden, Dresden, Germany.*

Background: The family of Coronin's consists of cytoskeletal, actin binding proteins involved in regulation of actin-based motility-related processes. Furthermore, leukocyte-specific protein Coronin 1a (Cor1a) is essential for macrophage, T and B cell signaling. Previously, using microarray analyses we observed an upregulation of Cor1a during the time course of experimental glomerular injury. To date, nothing is known about the role of Cor1a in cytoskeleton-dependent processes such as cell migration, trafficking and cytokinesis during renal disease.

Methods: To investigate the role of Cor1a in glomerular injury, crescentic nephrotoxic glomerulonephritis was induced in Cor1a deficient (-/-) mice and wild-type (wt) littermates. Disease progression was analyzed by collecting serum and urine samples throughout the experiment weekly. To examine morphological changes a renal survival biopsy was taken on day 10 before mice were sacrificed for histological and flow cytometric analyses on day 21 after disease onset.

Results: In response to anti-glomerular basement membrane (GBM) glomerulonephritis we detected significantly reduced titers of IgG antibodies generated against the induction antibody in Cor1a-/- compared to wt mice. Since, Cor1a is essential for T cell homing and activation Cor1a-/- mice had strongly reduced numbers of renal CD4+ and CD8+ T cells during GBM-nephritis on day 21. Intriguingly, flow cytometric analyses of renal granulocytes and more precisely the neutrophils revealed a significant increase in Cor1a deficient mice compared with wt littermates whereas renal macrophages were not affected. However, histologic evaluation showed that GBM-nephritis in Cor1a-/- mice causes only minor changes on renal damage compared to wt mice and that these mice were not protected from crescentic glomerular injury.

Conclusions: Cor1a deficient mice fail to induce a humoral immune response during GBM-nephritis which is accompanied by reduced renal T cell numbers but an enhanced recruitment of neutrophils during crescentic nephrotoxic glomerulonephritis.

IL-17F Drives Renal Tissue Injury in Crescentic GN
Jan-Hendrik Riedel, Hans-Joachim Paust, Christian Franz Krebs, Jan-Eric Turner, Oliver M. Steinmetz, Rolf A. Stahl, Ulf Panzer. *III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: The T_H17 immune response is associated with the pathogenesis of autoimmune diseases, implicating the T_H17 "master cytokine" IL-17A as the critical mediator of autoimmune diseases such as human and experimental crescentic glomerulonephritis (GN). However, the relative importance of additional T_H17 effector cytokines such as IL-17F in renal tissue injury is unknown.

Methods: To study the impact of IL-17F on renal inflammation, we induced experimental crescentic glomerulonephritis (NTN) in wild-type, IL-17F, IL-17A, and IL-17 A/F gene-deficient mice.

Results: In line to recent data by us and others IL17A-deficiency leads to an attenuated course of disease after induction of glomerulonephritis when compared to wild-type animals. Interestingly, after induction of NTN, IL17A/F double knockout mice showed an even greater reduction of renal tissue injury and a conservation of renal function compared to IL17A gene-deficient mice indicating a unique role of IL-17F. Next we were able to identify significant production of IL17F by $CD4^+$ T cells and γΔ T cells in the kidneys of nephritic mice. To specifically analyze the role of IL17F we analyzed the course of NTN in IL17F gene-deficient mice. Intriguingly, these animals showed a highly significant reduction of renal tissue injury (glomerular crescent formation 24% versus 34% and tubulointerstitial damage score 20% versus 28%; $p<0.05$ and $p<0.001$, respectively) and preserved renal function (BUN 35mg/dL versus 82 mg/dL; $p<0.001$) when compared to wild-type mice.

Conclusions: We therefore conclude that both IL-17A and IL-17F, each of them prominently expressed by renal $CD4^+$ T_H17 cells and gamma delta T cells, significantly contribute to the development of renal tissue injury in experimental GN. This finding might be of great importance for the development of anti-IL-17-cytokine therapies in crescentic GN.

TH-PO352

Leptin Deficiency Inhibits IL-23/Th-17 Axis and Monocyte Chemoattractant Protein-1 Production in a Murine Model of Nephrotoxic Serum Nephritis
Kei Goto,[1] Yoshikatsu Kaneko,[1] Shin Goto,[1] Michael P. Madaio,[2] Ichiei Narita.[1] *[1]Niigata Univ Graduate School of Medical and Dental Sciences; [2]Dept of Medicine, Georgia Health Sciences Univ.*

Background: Recent studies have demonstrated that leptin promotes Th17 cell responses and enhances the production of proinflammatory cytokines. To clarify the effect of leptin in the regulation of IL-23/Th-17 axis and the activation of macrophages, we used a murine model of nephrotoxic serum nephritis (NSN).

Methods: Nephrotoxic serum was administered in C57BL/6J mice (WT) and food restricted C57BL/6J-ob/ob (FR-ob/ob) mice after preimmunization with sheep IgG in Complete Freund's adjuvant. Kidneys and blood were collected at sacrifice 7 days after nephrotoxic serum injection. Cytokine or chemokine expressions and Th17 cell proliferation in the kidneys were analyzed by quantitative real-time PCR. Murine macrophage RAW264.7 cell line or murine peritoneal exudate macrophages (PEMs) were used to investigate the direct effect of leptin by real-time PCR and ELISA.

Results: Following the induction of NSN, blood urea nitrogen was remarkably elevated in WT mice ($n=8$; $p<0.001$). Glomerulosclerosis were significantly inhibited in FR-ob/ob mice, and 75% of WT mice died until day 14, while all FR-ob/ob mice survived ($n=8$). Serum levels of murine IgG1 and IgG2b against sheep IgG were significantly reduced in FR-ob/ob mice, followed by decreased deposition of murine anti-sheep IgG in glomeruli. Expression levels of mRNA for Th17 related cytokines such as IL-17A, IL-22, IL-23p19, IL-6, TGF-β1, which were related with anti-sheep IgG antibody production, and that for F4/80 and monocyte chemoattractant protein (MCP)-1 were significantly reduced in FR-ob/ob mice kidneys, whereas those for Th1 and Th2 related cytokine were not different. Leptin directly upregulated IL-23p19 mRNA expression in RAW264.7 cells, and also induced MCP-1 secretion and mRNA expression in PEMs from db/db mice, which lack long form of the leptin receptor OB-Rb followed by phosphorylation of STAT3.

Conclusions: Leptin deficiency suppresses IL-23/Th-17 axis and secondary antibody production. Furthermore, leptin induced MCP-1 expression in macrophages in OB-Rb/STAT3-independent signaling pathways.

TH-PO353

Regulatory Macrophages Derived From Peritoneal Dialysate Reduce Renal Injury in Adriamycin Nephropathy
Qi Cao,[1] Yiping Wang,[1] Xin M. Wang,[2] Vincent W.S. Lee,[1] Hanh Nguyen,[1] Guoping Zheng,[1] Ye Zhao,[1] Stephen I. Alexander,[3] David C. Harris.[1] *[1]Centre for Transplant and Renal Research, Westmead Millennium Inst, The Univ of Sydney, Sydney, NSW, Australia; [2]Flow Cytometry Facility, Westmead Millennium Inst, The Univ of Sydney, Sydney, NSW, Australia; [3]Centre for Kidney Research, Children's Hospital at Westmead, Univ of Sydney, Sydney, NSW, Australia.*

Background: Patients undergoing peritoneal dialysis (PD) discard huge numbers of peritoneal macrophages in dialysate daily. Macrophages (MΦ) have shown great promise in cell therapy of different types of experimental kidney disease and human kidney transplantation. This study aimed to examine the potential of using peritoneal macrophages (PMs) from peritoneal dialysate to treat renal disease.

Methods: Peritoneal macrophages derived from PD patients were examined. Peritoneal dialysate was collected also from mice undergoing PD dailyfor 7 days via a silicon catheter in the peritoneal cavity. Murine adriamycin nephropathy (AN) was induced by 10 mg/kg adriamycin in BALB/c mice. Adoptive transfer of modulated macrophages derived from PD mice into mice with AN was used to assess their *in vivo* functions.

Results: PMs from PD patients and mice accounted for more than 40% of total peritoneal leukocytes. PMs from PD patients and mice expressed low levels of CCR2, but high levels of CD86 and MHC-II. Ninety % of PMs from PD patients maintained their viability after storage in liquid nitrogen for at least one year. PMs from PD patients and mice displayed normal macrophage function and could be modulated into an M1 or M2 phenotype. *In vivo*, adoptive transfer of M2 PMs from PD mice protected against renal injury in mice with AN.

Conclusions: M2 macrophages derived from PD mice are able to reduce renal injury in AN, suggesting that peritoneal macrophages from PD patients may have the potential for clinical therapeutic application.

Funding: Government Support - Non-U.S.

TH-PO354

Blocking Myeloid Growth Factors to Protect against Ischemia/Reperfusion Injury
Timothy M. Williams,[1] Andrea F. Wise,[1] Jade Barbuto,[1] Chrishan S. Samuel,[2] Daniel Stuart Layton,[3] John A. Hamilton,[4] Sharon D. Ricardo.[1] *[1]Anatomy and Developmental Biology, Monash Univ, Melbourne, VIC, Australia; [2]Pharmacology, Monash Univ, Melbourne, VIC, Australia; [3]Australian Animal Health Laboratory, CSIRO, Geelong, VIC, Australia; [4]Medicine, Royal Melbourne Hospital, The Univ of Melbourne, Melbourne, VIC, Australia.*

Background: Inflammation is a hallmark of ischemia/reperfusion injury (IRI), involving inflammatory cell infiltration. A subsequent remodeling phase is in part mediated by M2 macrophages. GM-CSF and CSF-1 are two growth factors that mediate myeloid cell function. This study aimed to protect mice from IRI by blocking GM-CSF or CSF-1R.

Methods: Mice received 40min unilateral IRI (25min bilateral IRI for renal function) and were administered αGM-CSF or αCSF-1R antibodies under two regimes: short-term (day -2, 0, 2 post-IR) and prolonged (day -2, 0, 2, 4, 7, 10 post-IR). Infiltrating myeloid cells were analyzed by flow cytometry, serum cytokines were assessed with a multiplex array and picrosirius red staining was used to measure collagen. Serum creatinine and urea were assessed at day 14.

Results: Short-term CSF-1R blocking, but not GM-CSF, delayed the infiltration of $Ly6C^+$ monocytes and reduced $F4/80^+$ macrophage numbers. With prolonged CSF-1R blocking, macrophages, including a $CD206^+$ M2 subset, were reduced at day 7. This also increased circulating CSF-1 levels and the M2 associated cytokines IL-4, IL-10, CCL2 and CXCL2. Levels of the pro-inflammatory cytokines IL-1β, IL-12 and IL-17 were also elevated. Neither antibody treatment altered collagen accumulation at days 7 or 14 post-IR compared to the IR control group. Increased creatinine and urea concentrations, reflecting reduced renal function, were observed at day 14 compared to the sham-IR control. Prolonged GM-CSF blockade did not improve renal function. Urea and creatinine concentrations appeared lower with CSF-1R blockade compared to the IR control group but assessment at different time-points is required to identify a true protective effect.

Conclusions: $Ly6C^+$ monocyte infiltration and $CD206^+$ M2 macrophage numbers can be altered with αCSF-1R antibody administration. These effects were not observed with GM-CSF blockade.

TH-PO355

Mitochondrial Dysfunction Confers Albumin-Induced NLRP3 Inflammasome Activation and Renal Tubular Injury
Aihua Zhang, Songming Huang, Guixia Ding, Zhanjun Jia. *Dept of Nephrology, Nanjing Children's Hospital, Nanjing Medical Univ, China.*

Background: Proteinuria is involved in the development of tubular lesions and in the progressive loss of renal function in chronic kidney diseases (CKDs) via uncertain mechanisms. The present study aims to define the roles of mitochondria in proteinuria-induced renal tubular injury and their underlying mechanisms.

Methods: Eight-week-old 129/Sv male mice were subjected to an intraperitoneal injection with low-endotoxin albumin for 11 days to produce albumin-overload model. Mitochondial function including ROS production, mitochondrial membrane poteintial (MMP), and ATP content was detected.

Results: Employing the albumin-overload mouse model, we observed severe tubular structure damage and striking tubular cell apoptosis. Furthermore, the tubular epithelial cells displayed a loss of E-cadherin expression and gained expression of α-SMA and vimentin, indicating a cellular phenotypic alteration. Strikingly, these albumin overload-induced abnormalities were robustly blocked by a mitochondrial superoxide dismutase-2 mimic, MnTBAP. In agreement with these results, we observed a marked change in mitochondrial morphology accompanied by mitochondrial Cytochrome c release and mtDNA copy number reduction. These alterations were largely reversed by MnTBAP, suggesting a key role for mitochondria-derived oxidative stress in mediating the albumin effect on mitochondrial dysfunction and subsequent tubular injury. Moreover, the NLRP3/caspase-1/cytokine cascade was activated in the kidney by albumin-overload and was entirely abolished by MnTBAP. In albumin-treated mouse proximal tubular cells, albumin directly induced, mitochondrial dysfunction, NLRP3/caspase-1/cytokine cascade activation, cell apoptosis, and cellular phenotypic transition. Similar to our in vivo results, treatment with either MnTBAP or cyclosporin A, a mitochondrial permeability transition pore inhibitor, remarkably attenuated these abnormalities in cells.

Conclusions: These novel findings demonstrate a potential role for mitochondrial dysfunction/NLRP3 inflammasome axis in the pathogenesis of proteinuria-induced renal tubular injury.

TH-PO356

VEGF Derived From Dendritic Cells Affects Their Maturation and Is Protective in Unilateral Ureteral Obstruction Joanna Kalucka,[1] Susanne Olbrich,[1] Daniel Engel,[2] Christian Kurts,[2] Kai-Uwe Eckardt,[1] Alexander Weidemann.[1] *[1]Medical Clinic Nephrology & Hypertension 4, Univ of Erlangen-Nuremberg, Erlangen, Germany; [2]Inst of Experimental Immunology, Univ Clinic of Bonn, Bonn, Germany.*

Background: Progression of chronic kidney injury is correlated with an increase of inflammation. Dendritic cells (DCs) constitute one of the major leukocyte populations in fibrotic kidney.Vascular Endothelial Growth Factor (VEGF) has been shown to be expressed and secreted by DCs in inflamed tissues; however its pathophysiologic role in DCs during renal inflammation and fibrosis is unknown. Thus, we investigate the role of VEGF in DCs during chronic kidney injury.

Methods: We generated a conditional knock-out mouse strain using the Cre-loxP technology (CD11c:cre/VEGFf/f). Conditional knock-out (cKO) VEGF mice and their wild-type (WT) littermates were subjected to unilateral ureteral obstruction (UUO) for 7 days and kidneys were analyzed for biochemical, histological, RNA and FACS parameters.

Results: VEGF cKO mice are born at normal Mendelian ratios without any obvious pathological changes, renal dysfunction, or changes in immune cell composition within the kidneys. However, 7 days after UUO, VEGF cKO mice exhibit significantly worse renal function than WT animals, suggesting that DC-derived VEGF affects immune responses which in turn affect the function of the contralateral, unobstructed kidney. Irrespective of the genotype, UUO kidneys display significantly less VEGF mRNA than control kidneys indicating that DCs do not contribute to overall VEGF expression in the kidneys. FACS analysis confirmed that DCs in the UUO kidney become functionally activated. Moreover, we noticed a significant reduction of $CD11c^{hi}$ MHCII+ DCs in VEGF cKO UUO kidneys, suggesting that VEGF plays a role in DC maturation.

Conclusions: Our results suggest that VEGF in DCs is necessary for their maturation and has a protective function in a model of chronic kidney injury. Further analysis is needed to investigate the downstream effectors of VEGF-dependent DC function, also on the healthy kidney. To our knowledge these intriguing data are the first to establish a significant function of VEGF in DCs in an in vivo model of kidney fibrosis.

TH-PO357

Natural Killer Cells Regulate Renal Fibrosis after Acute Kidney Injury Isaah Vincent,[1] Sun-Sang J. Sung,[1] Liping Huang,[1] Diane L. Rosin,[2] Mark D. Okusa.[1] *[1]Div of Nephrology, Univ of Virginia, Charlottesville, VA; [2]Dept of Pharmacology, Univ of Virginia, Charlottesville, VA.*

Background: Acute kidney injury (AKI) may lead to progressive renal disease and in some cases ESRD. Fibrosis is a key feature in the pathogenesis of progressive kidney disease yet the mechanisms that regulate fibrosis is unknown. Certain immune cells contribute to fibrosis while others attenuate fibrosis. Natural killer (NK) and Natural Killer T (NKT) cells have been linked to regulation of fibrosis in several different organ systems thus these studies were done to determine the role of these cells in renal fibrosis following AKI.

Methods: Kidney injury was induced by using either 24 minutes of unilateral renal ischemia followed by reperfusion (IRI) or an ip injection of 250 mg/kg folic acid (FA) in sodium bicarbonate. To determine the role of NK and NK T cells during fibrosis in the period after the initial inflammatory injury in AKI, we treated C57BL/6 mice with 200 µg PK136 monoclonal antibody against NK1.1, which depletes both NK and NK T cells, on days 5, 10, and 15 after inducing injury. Nineteen days after injury, mice were euthanized and kidneys collected and processed for histology (Masson's Trichrome), mRNA, and flow cytometry.

Results: In both IRI and FA models, compared to IgG-treated mice, PK136 treatment increased the fibrotic area within the kidney (by Masson's Trichrome), mRNA message of ECM component collagen 1, and the presence of myofibroblasts (indicated by a-SMA immunoreactivity). This may be due to changes in inflammatory environment, as PK136 depleted mice have decreased IFN-γ expression and increased IL-10 expression compared to IgG-treated mice. To determine whether NK or NK T cells play a role in fibrosis, AKI was induced in $Ja18^{-/-}$ and $CD1d^{-/-}$ mice, which lack NK T cells. Compared to WT mice, $Ja18^{-/-}$ and $CD1d^{-/-}$ mice had no increase in fibrotic area or collagen message, indicating that the enhanced fibrosis after PK136 depletion is due to the absence of NK cells.

Conclusions: NK cells, not NK T cells, aid in the suppression of fibrosis after AKI. Further investigation will focus on determining the mechanism by which NK cells regulate fibrosis within the kidney.

Funding: NIDDK Support

TH-PO358

Pericytes as Critical Innate Immune Sentinels following Ischemic Acute Kidney Injury Ivan G. Gomez,[1,2] Jeremy Stuart Duffield.[1,2] *[1]Depts of Medicine & Pathology, Univ of Washington, Seattle, WA; [2]Biogen Idec, Cambridge, MA.*

Background: Following kidney ischemia reperfusion injury (IRI), the innate immune system is activated, initiating inflammatory process and pericyte/myofibroblast activation. Previous studies have demonstrated that Toll-like receptor (TLR2 and TLR4) and Myd88 signaling is important in this process, but myeloid lineage TLRs and Myd88 are dispensable. However, the role of mesenchymal cells (pericytes [PCs]) in the innate immune response has not been explored in detail, but their function and known roles implicate them as sensors of injury and guardians of leukocyte recruitment to the interstitium.

Methods: Murine model of Unilateral-IRI was used for sterile kidney injury. Crude Danger Associate Molecular Patterns (DAMPs) were purified and characterized from IRI kidneys 24h after injury. PCs isolated from normal kidney of wild-type, *Tlr2-4-/-* and *Myd88-/-*, *Nalp3-/-* and *Caspase 1-/-* mice were cultured with stimulation of TLR ligands, DAMPs and LPS. For in vivo experiment, *Coll1a1-GFP (Coll-GFP)* and *FoxD1-Cre* crossed with *Myd88fl/fl* transgenic mice were used.

Results: Stimulation of PCs by TLR ligands resulted in secretion of a broad array of pro-inflammatory cytokines and chemokines including IL-6 and MCP-1, responses attenuated by Myd88 deficiency. DAMPs activated TLR-2/-4, Myd88 signaling pathways inkidney PCs, but not primary tubular epithelial cells or vascular endothelial cells. DAMP-mediated PC activation resulted in secretion of IL-6, MCP-1 but also IL-1b and IL-18, indicative of activation of inflammasome signaling. These responses were dependent on TLR-2/-4, Myd88 pathway, and the inflammasome receptor NLRP3. In vivo, Myd88 depletion in Foxd1 lineage mesenchymal cells, resulted in reduced inflammation and fibrosis, implicating that transition of pericytes to myofibroblasts requires active MyD88 signaling.

Conclusions: Our findings suggest that kidney PCs act as sentinel cells that actively modulate signaling through activation of innate receptors and contribute to inflammatory responses in sterile IRI.

TH-PO359

Bone Marrow Precursor Cells Produce Soluble Urokinase Receptor That Causes Focal Segmental Glomerulosclerosis Eunsil Hahm, Changli Wei, Andrew Zloza, Jevgenijs Lusciks, Jing Li, Isabel Fernandez, Jochen Reiser. *Internal Medicine, Rush Univ Medical Center, Chicago, IL.*

Background: Soluble urokinase receptor (suPAR) has been considered a circulating factor that causes focal segmental glomerulosclerosis (FSGS), yet the origin of pathological suPAR in FSGS remains unclear. Given there are variations in the biochemical forms by which suPAR can occur in FSGS, we analyzed suPAR expression in stem-like cell niches.

Methods: Adoptive transfer, humanization techniques, ELISA, and flow cytometry were performed.

Results: We observed that urokinase receptor (uPAR) expression is increased in bone marrow (BM) cells, but not circulating blood cells in the LPS proteinuric mouse model. Interestingly, LPS treatment increased uPAR expression in BM $Gr\text{-}1^{+}$ cells with a massive expansion of $Gr\text{-}1^{low}$ populations. Despite depletion of circulating $Gr\text{-}1^{+}$ cells, proteinuria was potentiated in LPS-challenged mice. In addition, granulocyte colony-stimulating factor (G-CSF) further elevated albumin-creatinine ratio (ACR) and plasma suPAR levels, compared to LPS alone. These data suggest that increased demand for BM cell production facilitates proteinuria. Stem-like $c\text{-}kit^{-}/Gr\text{-}1^{low}/sca\text{-}1^{+}$ BM cells were required for suPAR production and proteinuia induction. Ablation of BM cells by gamma irradiation significantly ameliorated proteinuria and reduced suPAR production in both balb/c and B6 mice in response to LPS, while transfer of BM cells restored proteinuria with an enhanced plasma suPAR levels upon LPS administration. However, uPAR null mice failed to restore LPS-induced proteinuria in irradiated WT mice. Moreover, NOD-*scid IL2rg*^{null} (NSG) immunocompromised mice given BM cells from LPS-challenged WT, but not uPAR null mice, exhibited increased ACR with augmented circulating and urinary suPAR levels. This indicated BM-derived uPAR is required for development of proteinuria. Humanized mice that engrafted with peripheral blood mononuclear cells (PBMC) of patients with FSGS developed proteinuria and elevated mouse suPAR in both plasma and urine.

Conclusions: These results suggest that stem-like $c\text{-}kit^{-}/Gr\text{-}1^{low}/sca\text{-}1^{+}$ BM cells are responsible for pathological suPAR causing FSGS.

Role of Apol1 in HIV-1 Internalization in Human Podocytes Pravin C. Singhal,[1] Manuela Valsecchi,[2] Massimo Aureli,[2] Xiqian Lan,[1] Karl Leon Skorecki,[3] Domenico Mavilio,[4] Joanna Mikulak.[4] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Dept of Medical Biotechnologies and Translational Medicine, Univ of Milan, Milan, Italy; [3]Medicine, Rambam Health Care Campus, Haifa, Israel; [4]Clinical and Experimental Immunology, Humanitas Clinical and Research Center, Milan, Italy.*

Background: Genetic variants of Apolipoprotein-1 (Apol1) are associated with FSGS and HIV-associated nephropathy (HIVAN). Apol1 is a serum trypanolytic factor linked to high density lipid particles. Intracellular Apol1 expressed by several cell types, including podocytes, appeared to be a lipid-binding protein relevant for the maintenance of cellular homeostasis through regulation of lysosomal activity as well as inhibition of HIV-1 replication. However, the molecular mechanisms involved in Apol1-mediated preservation of physiological conditions as well as in the onset of FSGS and HIVAN are still unresolved. We explore the role of Apol1 in HIV entry and accumulation in human podocytes in relation to membrane traffic and sphingolipid metabolism.

Methods: Expression of Apol1 in human podocytes was assessed by Western blot, qPCR and immunoflourescence analysis. Human podocytes were transfected with either wild type Apol1 (WT) or Apol1 G1 genetic variant and analyzed for glycohydrolases (α-mannosidase,ß-galactosidase,ß-hexosaminidase,ß-glucocerebrosidase, glucocerebrosidase-1 and glucocerebrosidase-2) activity or for HIV-1 accumulation of the specific strong-stop HIV-1 DNA by qPCR analysis. Trans-infection of HIV-1 to T cells was detected by qPCR.

Results: WT Apol1 in human podocytes co-localizes with Rab5 expressing early endosomes, and regulates lysosomal activity through inhibition of enzymatic activity of several lysosomal and membrane-associated glycohydrolytic enzymes. Expression of Apol1 G1 genetic variant resulted in the further decline in the activity of glycohydrolases and correlated with increased HIV-1 entry and accumulation compared to WT. Moreover, both WT and G1 were able to increase HIV infectivity after recovery by $CD4^+$ T cells from HIV-1 harboring podocytes.

Conclusions: Apol1 regulates the activity of glycohydrolases that is relevant for HIV-1 entry and accumulation in human podocytes.

Renin Enhances HIV Replication through Protease Activity and Activation of Pro (P)-Renin Receptor (RR) Nirupama Chandel, Xiqian Lan, Kamesh R. Ayasolla, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Blockade or inhibition of Ang II production are currently used to slow down the progression of HIV-associated nephropathy. HIV is known to subvert cellular machinery to enhance its replication. Recently, HIV has been reported to enhance T cell renin expression. We hypothesized that HIV induces a high renin state to promote its own replication in T cells (TCs). Since Ang II blockade enhances renin production, use of AT1 receptor blockers may enhance HIV replication and thus renin inhibition may be a better alternative to block production of Ang II in patients with HIV infection. However, if a patient with HIV infection is being treated effectively with antiviral therapy, the effect of AT1R blockade-induced HIV replication would not be of any consequence.

Methods: Freshly isolated human T cells (TCs) were pulsed with primary strain of HIV ($HIV\text{-}1_{92HT599,}$ HTC)for 2 h followed by treatment with different concentrations of renin. To establish a causal relationship, HTCs were treated with either buffer or renin with/without aliskiren (a renin inhibitor). To determine the role of (P)-RR and renin, control TCs and TCs silenced for (P)-RR/renin were pulsed with HIV. After 24 hours, HIV replication was assayed by mRNA expression for HIV-1LTR and protein expression by p24 ELISA. Additionally, renin-induced down stream molecular mechanisms were evaluated. Proteolytic activity of renin and HIV protease (Hpr) on angiotensinogen (Agt, renin substrate) and Gag polyproteins (Hpr substrate) was evaluated.

Results: Renin enhanced HIV replication in TCs in a dose dependent manner. (P)-RR deficient TCs as well as those lacking renin displayed attenuation of both NF-κB activity and HIV replication. TCs treated with Hpr and renin displayed binding of (P)-RR to promyelocytic zinc finger protein (PLZF). Renin, HIV, and Hpr activated PI3K pathway. Both renin and Hpr cleaved Agt to Ang I and also cleaved Gag polyproteins to p24. Furthermore, aliskiren inhibited renin- and Hpr-induced cleavage of Agt and Gag polyproteins.

Conclusions: Renin contributes to HIV replication in TCs via (P)-RR and through cleavage of Gag polyproteins.

HIV-1-Induced Trimethylation of Histone H3K49[me]^3 in Kidney Cells Is Associated with Enhanced Snail Expression but Down Regulation of E-cadherin and Vitamin D Receptor (VDR) Nirupama Chandel, Rivka Lederman, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: HIV infection of kidney cells plays a key role in the development of HIV-associated nephropathy (HIVAN). We previously reported that kindey cell phenotype in HIVAN is a consequence of epthelial mesenchymal transition (EMT). We hypothesized that HIV infection may be modulating kidney cell phenotype though the induction of epigenetic factors. Since epigenetic factors-induced alterations are reversible, identification of their role in the development of HIVAN may be used as a therapeutic strategy. In the present study, we evaluated the effect of HIV on trimethylation of Histone H3K49[me]^3 in kidney cells both *in vivo* and *in vitro*.

Methods: Renal tissues were harvested from four week old control (FVB/N) and HIV-transgenic (Tg26) mice (n=3 for each group). *In vitro* studies, human renal proximal tubular cells (HPTCs) were transduced with either empty vector (EV) or NL4-3 without *gag* and *pol* (HIV). Protein blots of renal tissues, EV/HPTCs and HIV/HPTCs were probed for trimethylation (H3K49 [me]^3). To explore a causal relationship between Snail expression and down regulation of E-cadherin and VDR, 293T cells were transfected with Snail plasmid. Control 293T and Snail/293T cells were probed for Snail. The same blots were stripped and reprobed for E-cadherin, VDR, and actin (n=3).

Results: Renal tissues from Tg26 mice (n=3) displayed enhanced triemethylation (H3K49 [me]^3) as well as enhanced expression of Snail, but down regulation of E-cadherin and VDR. Similarly, HIV/HPTCs (n=3) displayed enhanced trimethylation (H3K49 [me]^3) and Snaill expression but down regulation of E-cadherin and VDR. Since enhanced expression of Snail in 293T cells, led to down regulation of E-cadherin and VDR, HIV-induced down regulation of tubular cell E-cadherin and VDRappears to be mediated through enhanced expression of Snail.

Conclusions: HIV-1 down regulates tubular cell E-cadherin and VDR expression through upregulation of Snail via trimethylation of Histone H3K49[me]^3. Since loss of E-cadherin is a marker of loss of epthelial phenotype, HIV likely enhances kidney cell EMT via epigenetic factors.

Complement Activation in the Kidney during Preeclampsia Jamie S. Chua,[1] Maria Elisabeth Penning,[1] Cees van Kooten,[2] Aletta Buurma,[1] Jan A. Bruijn,[1] Ingeborg M. Bajema,[1] Eliyahu V. Khankin,[4] Kitty Bloemenkamp,[3] S. Ananth Karumanchi,[4] Hans J. Baelde.[1] *[1]Pathology, LUMC, Leiden, South Holland, Netherlands; [2]Nephrology, LUMC, South Holland, Netherlands; [3]Obstetrics, LUMC, Leiden, Netherlands; [4]Howard Hughes Medical Inst and Dept of Medicine, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA.*

Background: A growing body of evidence suggests that complement dysregulation plays a role in the pathogenesis of preeclampsia. The kidney is one of the major organs affected in preeclampsia. Because the kidney is highly susceptible to complement deposits, we hypothesized that preeclampsia is associated with renal complement activation.

Methods: We performed a nationwide search for renal autopsy material in the Netherlands using a computerized database (PALGA). Renal tissue was obtained from 11 women with preeclampsia, 25 pregnant controls, and 14 non-pregnant controls with hypertension. The samples were immunostained for C4d, C1q, MBL, properdin, C3d, C5b-9, IgA, IgG and IgM. Our findings in human samples were validated using a soluble fms-like tyrosine kinase 1 (sFlt-1) mouse model of preeclampsia.

Results: Preeclampsia was significantly associated with renal C4d —a stable marker of complement activation— and the classical pathway marker C1q. In addition, the prevalence of IgM was significantly higher in the kidneys of the preeclamptic women. No other complement markers studied differed between the groups. In the preeclampsia mouse model, the kidneys in the sFlt-1-injected mice had significantly more C4 deposits than the control mice.

Conclusions: The strong association between preeclampsia and renal C4d, C1q, and IgM levels suggests that the classical complement pathway plays a role in the pathogenesis of renal injury in preeclampsia. Moreover, our finding that sFlt-1-injected mice develop excess C4 deposits indicates that angiogenic dysregulation may play an important role in complement activation within the kidney. We suggest that inhibiting complement activation may be beneficial for preventing the renal manifestations of preeclampsia.

Podocytes Produce Complement Proteins which Contribute to Local Glomerular Complement Activity Lindsay S. Keir,[1,2] Anne Katrin Dettmar,[3] Gavin Iain Welsh,[1] Christoph Licht,[4] Anna Richards,[5] Jun Oh,[3] Moin Saleem.[1] *[1]Univ of Bristol, United Kingdom; [2]Scripps Research Inst, CA; [3]Univ Medical Center, Hamburg, Germany; [4]The Hospital for Sick Children, Toronto, Canada; [5]Univ of Edinburgh, United Kingdom.*

Background: Disordered complement activation is implicated in the pathogenesis of many glomerular diseases. The reason the glomerulus is vulnerable to complement dysregulation is unknown. Local production of complement components has been reported but remains controversial. The contribution of podocytes to this is unclear but podocyte damage occurs in complement related glomerulopathies. We hypothesised that podocytes produce complement proteins that are involved in local complement activation and regulation. This may explain the susceptibility of the glomerulus to defective complement control.

Methods: Complement protein expression of human conditionally immortalized podocytes was determined before and after interferon gamma (IFNg), interleukin 6 (IL-6) or vascular endothelial growth factor (VEGF) treatment. C3 convertase and complement challenge assays detected activity of secreted proteins. Murine kidneys (C57BL/6) were analysed for complement protein expression using immunohistochemistry and in situ hybridization. Complement activation was studied in primary rat podocytes treated with anti Fx1a antibodies and exposed to normal, C2 and C3 deficient sera.

Results: Human podocytes express mRNA and protein for both activatory and regulatory complement proteins. Some proteins were secreted, notably C3 and CFH which were functionally active. IFNg upregulated production of C3 and CFH. VEGF increased CFH and CD46 while IL-6 reduced them. Murine glomeruli expressed C3 and CFH mRNA and CFH, crry and CD59a proteins. Podocyte derived C2 and C3 contributed to complement activation in a model of membranous nephropathy.

Conclusions: Podocytes synthesize functional complement proteins which contribute to local glomerular complement activation and regulation. This may explain why podocytes are targeted in complement mediated diseases. Defining the role of podocyte derived complement proteins may advance our understanding of glomerular diseases and identify new treatment strategies.

TH-PO365

Effect of Interleukin-2 in Murine Podocytes Diego H. Aviles,[1] Jeannine Ory Ascani,[2] Arnold H. Zea,[1] William E. Smoyer,[3] Beatriz E. Finkel-Jimenez,[4] David Tate,[1] Anna Magdalena Wilk,[1] Krzysztof Reiss,[1] Tyrus Stewart.[1] *[1]LSU Health Sciences Center, New Orleans, LA; [2]Children's Hospital Research Inst, New Orleans, LA; [3]Nationwide Children's Hospital, Columbus, OH; [4]American Univ of the Caribbean School of Medicine, Coral Gables, FL.*

Background: The podocyte is a highly differentiated cell that serves as a key component of the glomerular filtration barrier. Injury to these cells can result in proteinuria. Evidence suggests that cytokines may play a role in the development of proteinuria. Previous studies have shown that patients with nephrotic syndrome have increased levels of IL-2. The purpose of this study was to investigate the effects of IL-2 on kidney podocytes.

Methods: A conditionally immortalized mouse podocyte cell line was used for all experiments. Expression of IL-2 receptor subunits was measured by real-time PCR, flow cytometry, and western blot. The activity of the Jak/Stat pathway was measured by real-time PCR and western blot. Markers of autophagy and apoptosis were measured by western blot. Mitochondrial depolarization and apoptosis were measured by flow cytometry.

Results: Murine podocytes express IL-2 receptor subunits, as shown by flow cytometry, real-time PCR, and western blot. Stimulation of murine podocytes with IL-2 resulted in significant increases in mRNA levels of STAT5a and STAT5b, in addition to significant increases in cytosolic STAT5a and JAK3 protein expression. The autophagy marker LC3II had significantly decreased protein expression following stimulation. The pro-apoptotic protein Bax and Caspase-8 inhibitor $cFlip_L$ also had significantly increased protein expression after stimulation. Mitochondrial depolarization and apoptosis were both significantly increased following stimulation.

Conclusions: The results of this study showed that murine podocytes express a functional IL-2 receptor and that IL-2 induces podocyte injury. This effect is mediated by JAK/STAT signaling. Furthermore, IL-2 causes a decrease in autophagy, which may contribute to the observed apoptosis. This study offers insight to cytokine induced podocyte injury.

TH-PO366

Live Imaging of Immune Complex Formation In Vivo Lai Guan Ng. *Singapore Immunology Network (A*STAR), Singapore.*

Background: Compelling evidence shows that immune complexes (IC) play a pathogenic role in various immune-related diseases. The hallmarks of IC-induced acute inflammatory responses are characterized by massive neutrophil infiltration, edema and tissue injury. While it is well established that neutrophils have a central role in IC-mediated inflammation, the dynamics of neutrophil-IC interactions are still poorly defined.

Methods: Here, using a combination of in vitro, in vivo genomic and functional assays together with multiphoton intravital microscopy in a mouse ear skin model of the reverse Arthus reaction, we investigated the mechanisms underlying neutrophil responses in IC-mediated inflammation.

Results: We found that, following the initial IC deposition, neutrophils started to accumulate in close proximity to the perivascular areas with deposited IC. This was followed by the interaction between neutrophils and IC, which eventually led to the subsequent extravasation of these cells and vascular leakage. Interestingly, we observed that neutrophil-IC interactions appeared to amplify the rate of IC deposition and neutrophils were able to internalize IC while transmigrating from the blood into the tissue. In addition, we discovered that neutrophils coordinate their accumulation and recruitment in response to IC-activation via a CXCR2 ligand-dependent quorum-sensing system.

Conclusions: We thus elucidate previously unknown mechanisms for IC-mediated inflammation, which may have significant implications for designing clinical therapies.

TH-PO367

The Influence of Renal Compartments on Dendritic Cell Signature Under Homeostatic Conditions and During Allograft Rejection Federica Chessa, Shijun Wang, Daniel Mathow, Zoran Popovic, Hermann-Josef Groene. *Cellular and Molecular Pathology, German Cancer Research Center, Heidelberg, Germany.*

Background: Renal dendritic cells (rDCs), a component of the renal mononuclear phagocytic system (rMoPh), play major roles in renal homeostasis and disease. A predominant distribution of rDCs in homeostatic renal cortex has been described. The functional relevance of the compartment-specific distribution and reactivity of rDCs remains unknown. Allograft biopsy studies have shown that the histopathological features of kidney allograft rejection mainly develop in renal cortex.

Methods: The aim of this study is 1) to comprehensively describe the renal leukocyte population of cortex and medulla with a focus on rDCs and 2) to investigate the gene expression profile of cortical and medullary rDCs, under homeostatic conditions and during transplant rejection.

Results: Our results confirm that the leukocyte density in renal cortex (2800 cells/mg of tissue) is significantly higher than in medulla (1680 cells/mg of tissue). Expression profile of rDCs in homeostasis shows upregulation of CD36 in cortex in comparison to medulla, indicating compartmental regulation of antigen uptake capacity of rDCs independent from inflammation. Upon allogeneic stimuli, a compartment-specific signature, including genes involved in antigen uptake, processing and presentation, occurs preferentially in cortical DCs of donor and host origin. Flow cytometry analysis of host leukocytes during rejection reveals a remarkable tendency of host alloreactive DCs to infiltrate cortex, where they reach a cell density of 7000 cells/mg of tissue, 7-times higher than in medulla. In addition, we observe a progressive loss of donor-derived rDCs, which is complete at 7 days post-transplantation, likely due to either cell death or migration towards host lymphoid tissues.

Conclusions: We conclude that, inspite of discrete differences of cortical and medullary rDCs under homeostatic conditions, upon allogeneic stimuli both resident donor rDCs and infiltrating host DCs in cortex acquire an activated profile with regard to alloantigen uptake, processing and presentation, thereby contributing to compartment-specific post-transplant kidney damage.

TH-PO368

Human Antibody-Drug Conjugate Target Glomeruli to Resolve Nephritis Nino Kvirkvelia,[1] Maggie McMenamin,[1] Besarion Lasareishvili,[2] Vanessa Iris Gutierrez,[1] Michael P. Madaio.[1] *[1]Medicine, Georgia Regents Univ, Augusta, GA; [2]Agricultural Univ of Georgia, Tbilisi, Georgia.*

Background: Current therapies to limit kidney disease progression, lack specificity, have suboptimal efficacy and often have systemic toxicity. To approach this problem, we postulated that human monoclonal (m) anti-α3 (IV) antibodies (Ab) that localize in glomeruli could serve as vehicles for targeted drug delivery for glomerular diseases. Given enhanced glomerular expression of α3 (IV), with very limited epitope exposure in other organs, it provides an ideal target for delivery of glomerular disease modifying agents. As a potential disease-modifying agent, we took advantage of recent observations that PGE_2 enhanced renal cellular recovery and regeneration after established immunologic injury during the course of nephrotoxic serum nephritis (NTN).

Methods: To enhance efficacy, limit systemic effects and specifically target the kidney, PGE_2 was chemically coupled to a human m anti-α3 (IV) Ab using the zero length crosslinker 1-Ethyl-3-[3-dimethylamino-propyl]carbodiimide HCL (EDC) and the conjugates (10-15μg/g of body weight) were injected in NTN mice.

Results: Chemical composition of conjugates was confirmed by western blotting, and anti-α3 (IV) activity was assessed by two site ELISA. Glomerular localization of the anti-α3 (IV) Ab–PGE_2 conjugates was visualized in NTN mice by IF and live animal in vivo imaging. Thereafter, the capacity of the conjugates to modify disease was determined during established NTN. Glomerulonephritis resolved, and BUN levels were reduced in the conjugate treated mice (66.6 ± 2.12mg/dL), as compared to mice treated with only NTS (99.3±13.7mg/dL, $p<0.005$). Podocyte injury, assessed by alterations in synaptopodin staining, was also limited in anti-α3 (IV) Ab–PGE_2 conjugate treated mice.

Conclusions: The results provide a novel means of targeting glomeruli with human reagents by providing efficient drug delivery to the site of injury. The approach has potential application for treatment of human glomerular diseases, independent of etiology.

Funding: NIDDK Support

TH-PO369

A Transgenic Model of Randall-Type Heavy Chain Deposition Disease Amélie Bonaud,[1] Sébastien Bender,[1,3] Michel Cogné,[1,3] Frank Bridoux,[2] Christophe Sirac,[1] Guy Touchard.[2] *[1]CRIBL, CNRS, Limoges, France; [2]Nephrology, Hospital, Poitiers, France; [3]Immunology, Hospital, Limoges, France.*

Background: Randall-type heavy chain deposition disease (HCDD) is a rare disorder characterized by glomerular and peritubular amorphous deposits of a truncated monoclonal immunoglobulin (Ig) heavy chain (HC) bearing a deletion of the first constant domain (CH1).However, the natural history and pathophysiological mechanisms of HCDD remain poorly described. If deletion of CH1 seems to be required for secretion of an isolated HC, mutations in the variable region probably account for tissue deposition.

Methods: To better understand the mechanisms of HC deposition in kidney, we have created a transgenic mouse model of HCDD. Using gene-targeted insertion into the Ig kappa locus, we have introduced a truncated human γ1 HC extracted from a patient with HCDD and added a CH1 domain flanked by two loxP sites. This KI design allowed the expression in plasma cells of a complete human γ1 HC that can be deleted of the CH1 domain upon CRE-mediated recombination.

Results: The complete HC is well produced in mice in association with murine light chains (LC) (6g/L). By contrast, the germline deletion of the CH1 domain induces a dramatic decrease of the human HC in sera (0.3g/L). Despite this low level of truncated HC, histological studies reveal significant peritubular and glomerular basement membrane depositions that are absent in mice expressing the complete human HC. These results demonstrate that the glomerular damages in HCDD rely on the production of an isolated truncated HC which, in absence of a LC partner, display a high propensity to aggregate even at very low concentration. Treatment of mice with proteasome inhibitors results in a strong decrease of renal deposits.

Conclusions: Further studies carried out on this model, including the conditional CRE-mediated deletion of the CH1 domain and a precise follow-up of renal function during the evolution of the pathology, will certainly shed lights on the physiopathological mechanisms of HCDD and provide new therapeutic perspectives.

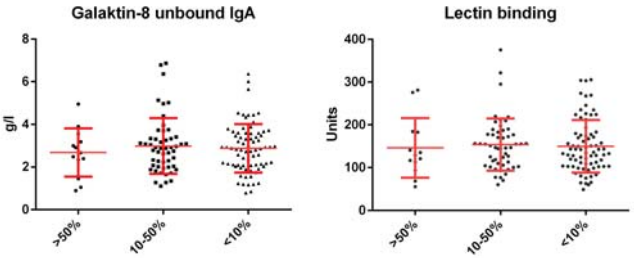
TH-PO370

Several Different Glycosylation Variants of IgA Are Elevated in Plasma of Patients with IgA Nephropathy But No One Seems to Correlate with Severity or Outcome Marten Segelmark,[4] Sigrid Lundberg,[1] Michael C. Carlsson,[2] Hakon Leffler,[2] Peter Pahlsson.[3] *[1]Clinical Science Intervention and Technology, Karolinska Inst, Stockholm, Sweden; [2]Laboratory Sciences, Lund Univ, Lund, Sweden; [3]Clinical and Experimental Medicine, Linköping Univ, Linköping, Sweden; [4]Medical and Health Sciences, Linköping Univ, Linköping, Sweden.*

Background: There are several glycosylation sites in the hinge region of IgA1 and plasma cells secrete a mixture of IgA1 O-glycoforms. The predictive value of plasma levels of such glycoforms remains unclear.

Methods: We analyzed IgA1 O-glycoforms in a cohort of 141 patients with IgAN and correlated the results with urinary albumin excretion at baseline and decline in GFR during follow-up (median 92.6 months; IQR 63.8-125.0). IgA1 O-glycoforms were measured by binding to human galactin-8 (Gal8) and a Helix aspersa (HA) lectin binding assay. Gal8 binds 2-3 sialyated galactosides while HA binds terminal GalNac.

Results: The two assays enabled us to separate four glycosylation variants (HA-binding, non-HA-binding, Gal8-binding, Gal8-non-binding). All variants were elevated but none correlated with proteinuria at inclusion or GFR slope during follow-up.



The figure show the plasma levels of two variants in patients with rapid progression, slow progression and in stable patients. When the relative binding to HA was compared with the relative binding to Gal8 we found no significant correlation (r=-0.06, p=0.49). A total of 80 follow-up samples from 25 patients were analyzed with the HA assay (range 0.5-16 years). Patients with stable GFR had a median change in the HA assay of 0.017 units per year compared to 0.015 units/year for patients with rapid progression (NS).

Conclusions: The glycosylation pattern of IgA1 is heterogenous but does not seem to be linked to severity and outcome. Glycosylation patterns are stable over time in both progessors and non-progressors.

TH-PO371

Reactivity of Tn-Specific Antibodies with Galactose-Deficient IgA1 from Patients with IgA Nephropathy Qi Bian,[1,2] Zina Moldoveanu,[1] Colin Reily,[1] Stacy D. Hall,[1] Audra A. Hargett,[1] Matthew B. Renfrow,[1] Bruce A. Julian,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Div of Nephrology, Changhai Hospital, Shanghai, China.*

Background: Most patients with IgA nephropathy (IgAN) have elevated levels of IgA1 with galactose-deficient hinge-region *O*-glycans (Gd-IgA1); Gd-IgA1 plays a key role in the disease pathogenesis. Gd-IgA1 *O*-glycans with terminal *N*-acetylgalactosamine (GalNAc) are also termed Tn antigen. Detection of Tn antigen can be accomplished either with GalNAc-specific lectin from *Helix aspersa* (HAA) or with antibodies. In this study, we assessed the reactivity of a panel of monoclonal Tn-specific antibodies with serum IgA1 and with IgA1 produced by cells from IgAN patients and healthy controls.

Methods: Mouse monoclonal Tn-specific antibodies 4G5, 3E8, 5F6 and 6E5 were obtained from Drs. Schjoldager, Mandel, and Clausen (Center for Glycomics, University of Copenhagen, Copenhagen, Denmark). Antibody reactivity with IgA1secreted by cells from IgAN patients and healthy controls was assessed by immunofluorescence microscopy. Standard Gd-IgA1 proteins were analyzed by high-resolution mass spectrometry and relative abundance of hinge-region glycopeptides was determined using a label-free quantitation method. IgA1 was purified from sera by affinity chromatography and polymeric and monomeric molecular forms were isolated by size-exclusion chromatography. Binding of HAA and Tn antibodies to IgA1 preparations was determined by ELISA.

Results: Of the four tested Tn antibodies, 6E5 bound to standard Gd-IgA1 proteins in ELISA. The binding was enhanced by enzymatically removing sialic acid. Using purified serum IgA1, 6E5 bound preferentially to polymeric forms. There was a direct correlation between binding of HAA lectin and 6E5 antibody ($R^2 = 0.772$). Moreover, 6E5 antibody bound to IgA1 produced in cells from IgAN patients but not from healthy controls.

Conclusions: A Tn-specific antibody 6E5 bound a glycoform(s) of standard Gd-IgA1 proteins as well as serum polymeric IgA1. Moreover, this antibody reacted with IgA1-secreting cells from IgAN patients but not healthy controls. Thus, glycoform-specific antibodies may provide a new tool for future testing of Gd-IgA1 in IgAN.

Serum Galactose-Deficient IgA1 Detected by Specific Monoclonal Antibody KM55 Is Increased in IgA Nephropathy Patients Yusuke Suzuki,[1] Hitoshi Suzuki,[1] Junichi Yasutake,[1,2] Yasuhiko Tomino.[1] *[1]Nephrology, Juntendo Univ Faculty of Medicine, Tokyo, Japan; [2]Nephrology Research Labs, Kyowa Hakko Kirin Co., Ltd., Tokyo, Japan.*

Background: Galactose-deficient IgA1 (Gd-IgA1) has been revealed to be an important factor for the onset and progression of IgA nephropathy. When measuring serum Gd-IgA1, lectin-based assay is known to be the only available method, but has some critical problems in stability and convenience. Thus we aimed to obtain Gd-IgA1 specific monoclonal antibody and establish more robust and reliable measurement method.

Methods: Rats were immunized with human Gd-IgA1 hinge region peptide to obtain Gd-IgA1 specific monoclonal antibody KM55. Enzyme linked immunosorbent assay with KM55 (KM55 ELISA) for specifically detecting serum Gd-IgA1 was consequently constructed. Serum Gd-IgA1 concentrations in human subjects were measured using KM55 ELISA assay.

Results: The measurement of serum Gd-IgA1 by KM55 ELISA revealed increased serum Gd-IgA1 concentration in IgA nephropathy compared to that in other renal diseases and non-renal diseases. In addition, the results obtained from KM55 ELISA and lectin-based assay positively correlated within the same serum samples.

Conclusions: KM55 ELISA, which provides a simple and robust measurement system, is an alternative method for determination of serum Gd-IgA1 levels in patients and is helpful for better understanding of IgA nephropathy.

TH-PO373

Specificity of Monoclonal Antibodies against a Synthetic Glycopeptide, an Analogue to the Hypo-Galactosylated IgA1 Hinge Region in IgA Nephropathy Yoshiyuki Hiki,[1] Hideo Hori,[1] Koichiro Yamamoto,[2] Yoshihiro Yamamoto,[2] Nobuya Kitaguchi,[1] Yukio Yuzawa,[2] Kazuo Takahashi.[2] *[1]Dept of Health Sciences, Fujita Health Univ, Toyoake, Aichi, Japan; [2]Dept of Medicine, Fujita Health Univ, Toyoake, Aichi, Japan.*

Background: Increased levels of hypo-galactosylated IgA1 (HypoGal-IgA1) in IgA nephropathy (IgAN) have been detected using a *Helix aspersa* agglutinin (HAA) lectin ELISA. In this study, we developed monoclonal antibodies to evaluate the HypoGal-IgA1 in IgAN, aiming to gain a more consistent and reproducible assay.

Methods: As an analogue to the HypoGal-IgA1 hinge region, a 19 mer synthetic peptide with five N-acetylgalactosamine (GalNAc) residues at positions 4, 7, 9, 11 and 15 (sHGP) [VPST(GalNAc)PPT(GalNAc)PS(GalNAc)PS(GalNAc)TPPT(GalNAc) PSPS-NH2] was synthesized. Two monoclonal antibodies against sHGP (35A12(IgG3 k) and 44H8 (IgG1 k)) that reacted with human IgA and sHGP but not with synthesized hinge peptide without GalNAc were developed.Their reactivities to serum IgA from IgAN patients (n=49), patients with other forms of kidney diseases (OKD, n =48), and healthy controls (HC, n = 41) were evaluated using ELISA assays. Each of monoclonal antibodies was coated on plates and HRP labelled anti-human IgA was used as a detector. All sera were treated with neuraminidase beforehand to remove neuraminic acid on GalNAc residues in IgA1 hinge region.

Results: The binding levels of the two antibodies against serum IgA were significantly higher (all, $p < 0.0001$, Steel-Dwass non-parametric test) in IgAN patients compared to HC and OKD patients. There were no significant differences between HC and OKD groups in both antibodies.There was close correlation of IgA binding levels between 35A12 and 44H8 ($R^2 = 0.734$). The areas under the curve (AUC) calculated from the receiver operating characteristic (ROC) curves of the IgAN patients against HC and OKD of 35A12 were 0.861 and 0.741, respectively. Those of 44H8 were 0.854 (versus HC) and 0.760 (versus OKD).

Conclusions: These results indicated that the monoclonal antibodies recognized similar epitopes in HypoGal-IgA1, which is found predominantly in IgAN patients. The developed antibodies are proposed to be a clinically useful tool for IgAN screening.

Urine Sediment Specific miRNAs as Biomarkers for IgA Nephropathy Derived Mainly from Urinary Erythrocyte Guangyan Cai,[1,2,3] ZhiYu Duan,[1,2,3] Ru Bu,[1,2,3] Yang Lu,[1,2,3] Kai Hou,[1,2,3] Xiang-Mei Chen.[1,2,3] *[1]Dept of Nephrology, Chinese PLA General Hospital, Beijing, China; [2]State Key Laboratory of Kidney Diseases, Beijing, China; [3]National Clinical Research Center of Kidney Diseases, Beijing, China.*

Background: IgA nephropathy (IgAN) is a kind of slowly progressive disease and biomarkers are required to reflect disease severity and progression. miRNAs in urine sediment seems to be promising candidate biomarkers.

Methods: Urine sediments from IgAN patients, primary glomerulonephritis (non-IgAN) patients and healthy controls were collected. Total miRNAs were extracted and analyzed by miRNA microarray. Urine erythrocytes in urine sediment were separated by CD235a magnetic bead and microvesicles were collected by ultracentrifugation to detect differential miRNAs sources.

Results: 214 differential miRNAs in urine sediment were screened out by miRNA microarray. Compared with normal control and disease control groups, miR-25, miR-144 and miR-486 levels were increased in IgAN. miR-486 showed a positive correlation with serum creatinine level. miR-144 and miR-486 levels were highest in Lee's grade III. miR-144 had a positive correlation with segmental sclerosis. miR-25, miR-144 and miR-486

levels were significantly higher in patients with glomerular hematuria. miRNAs levels of urinary sediment were greatly increased in the erythrocyte group (positive sorting group) compared with erythrocyte-free group (negative sorting group) by magnetic bead separation. The baseline levels of miR-25, miR-144 and miR-486 were significantly higher in erythrocytes than in tubular epithelial cells and polymorphonuclear leukocytes (major cell components in urine sediment). However, the levels of miR-144 and miR-486 in red blood cells had no difference between IgAN and control groups. The levels of miR-144 and miR-486 in microvesicles extracted from urine supernatant were higher in IgAN than control group.

Conclusions: Urine sediment miRNAs can be used as promising non-invasive biomarkers of IgAN. miR-25, miR-144 and miR-486 in urine sediment mainly comes from urine erythrocytes. Urine erythrocytes may play a biological role through releasing microvesicles.

Morphological and Qualitative Alterations of Glomerular Basement Membrane in IgA Nephropathy Yukinari Masuda, Kiyotaka Nagahama, Akira Shimizu. *Analytic Human Pathology, Nippon Medical School, Tokyo, Japan.*

Background: The glomerulus contains well-developed capillaries, which are at risk of injury due to high hydrostatic pressure, hyperfiltration, hypertension and inflammation. However, the pathological alterations of the injured glomerular basement membrane (GBM), are still uncertain in cases of glomerulonephritis. In the present study, we examined the morphological and qualitative alterations of the injured GBM in IgA nephropathy, in addition to the routine observation by transmission electron microscopy (TEM).

Methods: We examined the alterations of the GBM in 50 renal biopsy cases with IgA nephropathy using double immunostaining for the α2(IV) and α5(IV) chains of type IV collagen, and examining the ultrastructural alterations by TEM, and a new technique, low-vacuum scanning electron microscopy (LV-SEM), which can evaluate three dimensional surface of GBM. GBM alterations in IgA nephropathy were compared with cases with normal control.

Results: In normal control cases, an intact morphology of GBM was recognized with linear strong expression of α5(IV), but almost no expression of α2(IV), and smooth and regular appearance of their surface. By contrast, the GBM of IgA nephropathy cases showed various morphological and qualitative alterations. In the TEM findings, thinning, gaps, rupture, thickening with a lamellar and reticular structure and double contours were detected in the GBM. Double immunostaining for α5(IV) and α2(IV) showed thickening of the GBM with reduced α5(IV) and increased α2(IV), or mosaic images of α5(IV) and α2(IV), and multiple holes, fractures, spiny projections and rupture of α5(IV) in the GBM. In addition, LV-SEM showed an etched image and multiple holes in a widening and wavy GBM. These findings might be associated with the development of a brittle GBM in IgA nephropathy.

Conclusions: GBM alterations were frequently noted in IgA nephropathy, and were easily evaluated by double immunostaining for α2(IV) and α5(IV) of type IV collagen and LV-SEM. The evaluation of GBM alterations may enhance our understanding of the pathophysiology of the progression of glomerular diseases.

Expression of Prorenin Receptor in Renal Biopsies from Patients with IgA Nephropathy Nagisa Miyazaki, Ichijiro Murata, Genzou Takemura, Jun Matsumoto-Miyazaki, Gakuro Yoshida, Kaori Niimi, Ayuko Nishiwaki, Shinya Minatoguchi. *Second Dept of Internal Medicine, Gifu Univ Graduate School of Medicine, Gifu, Japan.*

Background: Prorenin receptor (PRR) is critically involved in the tissue renin-angiotensin system, and plays a key role in the development of organ damage in various renal disease. In Asia, immunoglobulin A (IgA) nephropathy is the most common form of primary glomerulonephropathy, but information is entirely lacking on the possible involvement of PRR in IgA nephropathy. In the present study, we assessed PRR levels in renal biopsy specimens from patients with IgA nephropathy and evaluated its relevance to the clinical and pathological features of the disease. We also examined the relevance of PRR expression to autophagy, as PRR is known to be an integral component of vacuolar-type H^+-ATPase which is essential for activation of the autophagic process.

Methods: We retrospectively reviewed the medical records of 48 patients with biopsy-proven IgA nephropathy diagnosed between February 2010 and January 2013. Paraffin sections stained with hematoxylin-eosin, PAS, Masson's trichrome, PAM and Sirius red were examined using a light microscope. Immunohistochemistry and immunofluorescence with a primary antibody against PRR and LC3, and immunoelectron microscopy for PRR were also performed. We assessed PRR levels in those specimens and evaluated its relevance to the clinical and pathological features of the disease.

Results: PRR was immunohistochemically localized on proximal tubular cells. The PRR positive area (%PRR area) correlated with daily urinary protein, which is known to reflect disease severity (r=0.286, p=0.049). PRR levels were weaker in tubular cells bordering areas of severe interstitial fibrosis. We also noted a positive correlation between autophagy activation and PRR levels in the same proximal tubular cells under a confocal microscope.

Conclusions: Our findings suggest renal expression of PRR in IgA nephropathy may be a compensatory response slowing disease progression by preventing tubular cell death and subsequent fibrosis through activation of cytoprotective autophagic machinery.

Association of Serum C3 and Mesangial C3 Deposition with IgA Nephropathy Xiaoyan Zhang, Jingyuan Xie, Weiming Wang, Xiaoxia Pan, Zhaohui Wang, Jing Xu, Pingyan Shen, Nan Chen. *Dept of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ, School of Medicine, Shanghai, China.*

Background: Recent studies indicated that complement activation is involved in the pathogenesis of IgA nephropathy(IgAN).The aim of this study is to investigate association between complement activation and severity and progression of IgAN.

Methods: 528 biopsy-proven IgAN patients were retrospectively recruited. Clinical,histological and progression data were recorded.Serum levels and renal depositions of factors related to alternative complement pathway were measured.Low C3 level was defined as serum C3 less than 85mg/dl.

Results: Severe mesangial C3 deposition was detected in 245 (46.4%) patients and low C3 level was found in 93 (21.7%) patients.When renal biopsy was taken,patients with more severe C3 deposition in kidney had higher serum levels of Cr,uric acid and IgA,lower levels of eGFR and BMI,more severe endocapillary hypercellularity,tubular atrophy and interstitial fibrosis.Patients with lower serum C3 level had lower white blood cell count (WBC),hemoglobin,triglyceride, cholesterol,eGFR and higher serum Cr.Negative correlation was found between mesangial C3 deposition and serum C3.Patients with lower serum C3 had a higher risk to develop to ESRD. Multivariate Cox regression analysis showed low C3 level was an independent risk factor for ESRD(HR=1.03,95%CI 1.04-1.01,p<0.001)after adjusted by sex,age and clinical indicators.By ELISA, we found IgAN patients with lower serum C3 had higher serum levels of C3a,SC5b-9 and lower levels of C4,CFH,CFI,CFB.Interestingly, patients with lower serum CFH had higher serum levels of C3a and SC5b-9 and stronger C3 deposition in mesangial area.Serum CFH was negatively correlated with complement activation products such as serum C5b-9(r=0.-254,P<0.05) and C3a(r=-0.239,P=0.05) in addition to positively correlated with CFB(r=0.375,P<0.01).

Conclusions: Complement activation is associated with clinical and histological severities and renal progression in IgAN patients.Alternative pathway activation with CFH as a key regulator is demonstrated in IgAN patients with low serum C3 level.

Validation of the Japanese Histologic Classification 2013 of Immunoglobulin A Nephropathy for Prediction of Long-Term Prognosis in a Japanese Single-Center Cohort Ryuta Sato,[1] Hideki Wakui,[1] Kensuke Joh,[2] Atsushi Komatsuda.[1] *[1]Hematology, Nephrology, and Rheumatology, Akita Univ Graduate School of Medicine, Akita, Japan; [2]Pathology, Tohoku Univ Graduate School of Medicine, Sendai, Japan.*

Background: The Japanese histologic classification (JHC) 2013 of immunoglobulin A nephropathy (IgAN) for prediction of long-term prognosis was newly proposed by Kawamura T et al (J Nephrol 2013). The glomerular lesion percentage score (GLPS) [number of glomeruli with cellular crescents, fibrocellular crescents, global sclerosis, segmental sclerosis, or fibrous crescents / number of total obtained glomeruli × 100 (%)] was assessed in the patients with IgAN and categorized into histologic grades (HGs) of HG1 (<25%), HG2 (25-49%), HG3 (50-74%), and HG4 (≥75%) in the JHC 2013. The aim of our study was to validate the correlation between the JHC 2013 system based on GLPS (HGs) and long-term prognosis in a Japanese single-center retrospective cohort.

Methods: 198 adult patients with IgAN were collected from 1980 to 2001 in Akita University Hospital. Renal biopsy specimens and clinical findings such as blood pressure, urinary protein, estimated glomerular filtration rate (eGFR), and steroid therapy were obtained. GLPS was assessed and categorized into HG1, HG2, and HG3/4 (≥50%) because only 9 patients had a HG4 (≥75%). Disease progression (50% eGFR decline or introduction of dialysis) was defined as a first endpoint. The risk of disease progression among three HGs and The association of GLPS (per 10%) with disease progression within 10 years after biopsy were examined by logistic regression analysis adjusted by clinical findings.

Results: Median follow up period was 12 years. Median age was 42 y/o (18-73). Disease progression occurred in 12.8% (12/94) of HG1 patients, 32.3% (21/65) of HG2 patients, and 46.2% (18/39) of HG3/4 patients. The risk of disease progression was significantly higher in the HG2 and HG3/4 groups than in the HG1 group (OR 3.3, P=0.004, and OR 5.9, P=0.0001 versus 1). A higher GLPS was significantly associated with disease progression (OR 1.3, P=0.004 in GLPS per 10%).

Conclusions: The JHC 2013 system was well correlated with long-term prognosis in our cohort of Japanese adult patients with IgAN.

Oxford and Electron Microscopy Based Classifications in IgA Nephropathy Byoung Geun Han, Youngsub Kim, Jae Seok Kim, Jae Won Yang, Seung-Ok Choi. *Div of Nephrology, Dept of Internal Medicine, Yonsei Univ Wonju College of Medicine, Wonju, Republic of Korea.*

Background: The oxford classification that was recently introduced is believed to improve the prediction of prognosis in IgA nephropathy. This study aims to investigate the relationship of the oxford classification and clinical prognostic factors (age, sex, proteinuria, creatinine) and whether this classification could predict renal survival. In addition, we developed a new classification that is based on electron microscopic findings and investigated the usefulness of it.

Methods: The subjects included 259 patients with IgA nephropathy which was proven by renal biopsy. We reclassified tissue samples by oxford classification. We applied the new

classification based on the electron microscopic findings (foot process fusion, glomerular basement membrane thickness and electron dense deposit site). We investigated the relationships of two classifications and clinical prognostic factors.

Results: The results showed that M variable of oxford classification was related to serum creatinine (M0 / M1, 0.9±0.5 / 1.1±0.6 mg/dL, p=0.007), S variable to urinary protein creatinine ratio (S0 / S1, 1.1±2.1 / 1.9±1.8 mg/g, p=0.012), T variable to age (T0 / T1 / T2, 31±14 / 44±16 / 29±10 years, p<0.001), sex (T0 / T1 / T2, 110 / 20 / 2 males, p=0.015), and serum creatinine (T0 / T1 / T2, 0.6±0.3 / 1.5±0.8 / 1.9±1.4 mg/dL, p<0.001). In electron microscopy, glomerular basement membrane thickness only was related with sex (p=0.023), and others showed no significant relationship. In addition, both oxford and electron microscopy based classifications could not predict renal survival.

Conclusions: This study indicates that oxford classification can be used to predict the prognosis of IgA nephropathy. However, we believe that this classification needs a representative variable which integrates the individual variables (M,S,E,T) to predict of prognosis more easily. Electron microscopy based classification did not show any significant relationship with prognostic factors. Therefore, we believe that the light microscopy based classifications including oxford classification are superior than the electron microscopy based classification in IgA nephropathy.

Does Expression of B7-1 mRNA Correlate with Proteinuria in Patients with IgA Nephropathy? Jennie Lönnbro-Widgren,[1] Peidi Liu,[2] Kerstin Ebefors,[2] Jenny C. Nystrom,[2] Borje Haraldsson.[1] *[1]Medicine, Univ of Gothenburg, Gothenburg, Sweden; [2]Neuroscience and Physiology, Univ of Gothenburg, Gothenburg, Sweden.*

Background: The glomerular filtration barrier is a highly specialized structure that allows high filtration of water but a total restriction of large molecules. Co-stimulatory protein B7-1 is normally not expressed on podocytes but when it is expressed it reduces the capacity of the podocyte to attach to surrounding matrix through β1-integrin. This leads to morphological changes of the podocytes and development of proteinuria. Expression of B7-1 has now been reported in patients with proteinuric kidney diseases but has been found difficult to stain for morphological analysis. Therefore, we investigated if expression of B7-1 mRNA is up regulated in patients with IgA Nephropathy (IgAN) and if this correlates with the degree of proteinuria.

Methods: We collected 24 IgAN patient biopsies and 47 controls from kidney donors and extracted the mRNA from the glomeruli. Microarrays were performed using Affymetrix GeneChip human genome U133 2.0+. Gene expression raw data was normalized using the Robust Multi-array Average (RMA) method. Fold-changes and p-values were processed using moderated T-Test statistics for both up and down regulated genes. The p-values were adjusted using FDR (False Discovery Rate). The analysis was performed in R. The expression of B7-1 was adjusted based on the average expression value of each sample and later compared with clinical data including U-albumin/creatinine, eGFR, s-creatinine, and disease progression rate.

Results: B7-1 mRNA was significantly up regulated compared to the control group, p<0.001. Plotting the value for B7-1 against the clinical data did not show any correlation between B7-1 mRNA expression and U-albumin/creatinine, s-creatinine, eGFR and disease progression rate.

Conclusions: Even if B7-1 mRNA expression was significantly up regulated in patients with IgAN the expression did not correlate with the degree of proteinuria. However, only three patients in this pilot study had proteinuria > 3.5 gram/24 hours. B7-1 mRNA expression in patients with heavy proteinuria needs to be further investigated, as well as the role of B7-1 in the pathogenesis of proteinuria.

TH-PO381

Primary IgA Nephropathy in Elderly Patients Wisit Cheungpasitporn,[1] Samih H. Nasr,[2] Charat Thongprayoon,[1] Michael A. Mao,[1] Qi Qian.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Anatomic Pathology, Mayo Clinic, Rochester, MN.*

Background: The objective of this study is to investigate and compare the clinicopathological features, treatment and outcomes of IgA nephropathy (IgAN) between elderly and younger adults, on which there has been no previously published data from the United States.

Methods: All native kidney biopsies with a pathological diagnosis of IgAN (n=1084) from Mayo Clinic Rochester between January 1, 1994 and December 31, 2013 were screened; relevant clinical data reviewed. Patients with secondary IgAN and Henoch-Schönlein purpura were excluded from analysis. All biopsies were classified based on the Oxford classification.

Results: A total of 45 elderly patients (age ≥65 years) with primary IgAN were identified and enrolled. 162 younger adults (age: 18-64 years) with primary IgAN were randomly selected from the same specimen collection for comparison. Elderly patients were in poorer general health as reflected by a higher Charlson Comorbidity Index (2.0 versus 0.9, p=0.007), higher pulse pressures (67 versus 47 mmHg, p<0.001), greater number of BP medications (2.3 versus 1.4, p<0.001) and more severe anemia (HGB: 10.6 versus 12.9 g/dL, p<0.001) at time of kidney biopsy. Pathologically, kidney specimens from elderly showed a higher degree of tubular atrophy and interstitial fibrosis, p=0.04, and vascular sclerosis, p<0.001, compared to the younger cohort. Treatments for IgAN (including ACE inhibitor, ARB and immunosuppressants) were similar between the two groups. Elderly IgAN patients had significantly worse renal and overall survival with more end-stage renal failure at 6 months (HR 5.1, 95% CI: 1.02-28.1, p=0.04) and lower percentage of 5-year survival (67.5 versus 91.8%, log-rank p<0.001). After adjusting for age and comorbidity differences, the harmful effects of IgAN on elderly patients' renal and overall survival remain significant, p<0.05.

Conclusions: Compare to younger adult IgAN patients, elderly IgAN patients show (1) a higher degree of baseline comorbidity, (2) higher degree of cortical scarring and vascular disease on biopsy, and (3) faster progression to ESRD and mortality (independent of age and comorbidity) despite receiving similar treatments for IgAN.

TH-PO382

IgA Nephropathy Clinical-Morphological Study Revealed Gender-Related Differences Mai Ots-Rosenberg,[1] Zivile Riispere.[2] *[1]Internal Medicine, Univ of Tartu, Tartu, Estonia; [2]Dept of Pathological Anatomy and Forensic Medicine, Univ of Tartu, Tartu, Estonia.*

Background: The Oxford classification of IgA nephropathy (IgAN) based on the MEST score (mesangial hypercellularity, segmental glomerulosclerosis, endocapillary hypercellularity, and tubular atrophy/interstitial fibrosis). The study aimed to investigate IgAN clinical-morphological correlations using MEST score and to find gender-related peculiarities in IgAN progression.

Methods: All native kidney biopsies (n=578) performed during 2001–2010 at the Tartu University Hospital were retrospectively reviewed. IgAN formed the main part (35.5%) of primary glomerulopathies (Riispere et al. Scand J Urol Nephrol, 2012). A total of 88 cases of IgAN during the 11 years were registered. To compose the patient cohort, we followed the recommendations of the International Consensus of IgAN study – the Oxford's classification of IgAN – and, thus, 73 IgAN cases were selected for the study. Baseline clinical data were collected within 3 months of the biopsy and at the end of a follow-up.

Results: Pathology findings for each biopsy were registered: 73% had diffuse mesangial hypercellularity (M1) and 32% had endocapillary hypercellularity (E1); segmental glomerulosclerosis/adhesion was found in 52% of the cases; tubular atrophy/interstitial fibrosis (T1) was present in few cases (10%); arteriosclerosis (A1 and A2) was registered in 35% of cases. The frequency of the findings was similar in males and females, except arteriosclerosis which was more frequent in male patients (P=0.004). M1, E1, S1, T1 and A2 scores were associated with the levels of MAP, eGFR and proteinuria. Patients were followed for an average of 4.1 years.

Conclusions: The main findings of the study revealed, similarly to the Oxford study, our cohort's pattern of MEST confirmed having a predictive value independent of clinical data as their higher score was linked to a worse outcome; second, contrary to the results of the whole cohort, we found gender-related differences in the mesangial hypercellularity category as one predictive value of disease progression, which was correlated to eGFR and measured as a mean rate of renal function decline.

T Cell Regulation in Children with Primary IgA Nephropathy and Henoch Schoenlein Purpura Licia Peruzzi,[1] Roberta Camilla,[1] Elisa Loiacono,[1] Alessandro Amore,[1] Luca Vergano,[1] Carla Guidi,[1] Giulio Mengozzi,[2] Rosanna Coppo,[1] Paola Puccinelli.[3] *[1]Nephrology Dialysis Transplantation, Citta della Salute e della Scienza. Regina Margherita Children's Hospital, Turin, Italy; [2]Laboratory Medicine, Citta della Salute e della Scienza, Turin, Italy.*

Background: Indoleamine 2,3-dioxygenase (IDO) catabolizes tryptophan to kynurenine (Kyn), a metabolite with immunoregulatory activity. IDO-expressing dendritic cells possess potent T cell regulatory properties. Primary IgA Nephropathy (pIgAN) and Henoch Schoenlein Purpura (HSP) are immune-mediated glomerular diseases with similarities but also differences in presentation and outcome.
